An individual's or case $x's$ immunity rate is reflected by the objective function $O(x)$, which is denoted by the gene values $x_1, x_2, \ldots, x_n$, where each x_i corresponds to a gene or choice variable. Each person's total gene count is denoted by the index n. It is crucial to emphasize that each gene x_i falls within the value range of $[lb_i, ub_i]$, with ub_i and lb_i denoting the $upper$ and $lower$ boundaries, respectively, of gene x_i.

Through this phase, CHIO initializes its two primary control parameters [34]: BR_r, It governs the propagation of the virus pandemic among people and acts as the fundamental reproduction rate governing the $CHIO$ operators. Max_{age}, This denotes the oldest age at which infected cases can be documented and describes how those instances will end. Cases reaching Max_{age} either recover or pass away.

Two control parameters and $four$ algorithmic parameters make up $CHIO$. C_0: This is the initial number of infected instances, which in this particular case is one. Max_{it}: the highest quantity of repetitions. HIS: The number of people. n: The problem's dimensionality.

Phase 2: The examples that are generated are then saved in HIP in the form of a 2-dimensional matrix with dimensions of $n\ x\ HIS$. Here, n stands for each person's size, which is indicated as follows:

$$HIP = \begin{bmatrix} x_1^1 & x_2^1 & \cdots & x_n^1 \\ x_1^2 & x_1^2 & \cdots & x_n^2 \\ \vdots & \vdots & \cdots & \vdots \\ x_1^{HIS} & x_2^{HIS} & \cdots & x_n^{HIS} \end{bmatrix} \quad (7)$$

Each row in HIP denoted as x_j, fits a case that is produced by the following formula: $x_i^j = lb_i + (ub_i - lb_i) \times U(0,1)$, where i series from 1 to n, and where ub_i and lb_i represent the $upper$ and $lower$ limitations of the gene x_i. Eq. (6) is utilized to calculate the immunity rate, or objective function, for every instance. Every instance in HIP also has a status vector (S) constructed for it, with a length of HIS. In this vector, a vulnerable case is represented by 0, and an infected case is represented by 1 value.

Phase 3: The progression of coronavirus herd protection constitutes the central iterative process of $CHIO$. This process encompasses $three$ rules governing the change of genes x_i^j within case x_j. These genes can either remain unchanged or undergo alterations due to the implementation of social estrangement procedures. The specific rules are strongminded according to the percentage of BR_r and are detailed as follows:

$$x_i^j(t+1) \leftarrow \begin{cases} x_i^j(t) & r \geq BR_r \\ C\left(x_i^j(t)\right) & r < \frac{1}{3} \times BR_r. \quad infected \\ N\left(x_i^j(t)\right) & r < \frac{2}{3} \times BR_r. \quad suspectical \\ R\left(x_i^j(t)\right) & r < BR_r. \quad immuned \end{cases} \quad (8)$$

Phase 4: The immunity rate, denoted as $O(x^j(t+1))$, is computed for each newly generated case, $x^j(t+1)$. If it outperforms the current case, $x^j(t)$, as indicated by $(x^j(t+1)) > O(x^j(t))$, then $x^j(t)$ is substituted with $x^j(t+1)$. Furthermore, if $E_j = 1$, the age vector A^j is incremented by one.

The status vector, E_j, for each case, x^j, is adjusted based on the herd immunity threshold, calculated as follows:

$$E_j \leftarrow \begin{cases} 1 & O\left(x^j(t+1)\right) < \frac{O(x^j)(t+1)}{\Delta O(x)}, E_j = 0, is\_corona(x^j(t+1)) \\ 2 & O\left(x^j(t+1)\right) < \frac{O(x^j)(t+1)}{\Delta O(x)}, E_j = 1 \end{cases} \quad (9)$$

The equation is formulated based on the following variables:

- $is_{corona}(x^j(t+1))$: A dual value set to 1 if the newly created case, $x^j(t+1)$ inherits an amount from each affected instance.
- ΔO(x): This denotes the mean immunity rate of the population, which is calculated as the sum of all immunity rates divided by the population size.

It is crucial to stress that determined social distancing measures may have an impact on the population's immunity rate among persons [35], considering that the freshly formed individual's immunity rate is higher than the population's average immunity rate.

E. Performance Evaluator

This section delineates a set of metrics designed to assess hybrid models. These metrics gauge error and correlation, providing respected insights into the models' performance. Table II displays the equations for the metrics employed in this paper [36].

Respectively, the variables can be expressed as:

- The symbol n represents the sample size.
- Predicted values are indicated as b_i.
- $\bar{m}$ and $\bar{b}$ stand for the mean of the evaluated and anticipated values, respectively.
- The measured value is denoted as m_i.
- The mean of the predictor variable in the dataset is symbolized as $\bar{x}$.

TABLE II. THE FORMULATIONS OF THE PERFORMANCE METRICS

Coefficient Correlation (R^2):	$\boldsymbol{R^2} = \left(\frac{\sum_{i=1}^{n}(\boldsymbol{b_i} - \bar{\boldsymbol{b}})(\boldsymbol{m_i} - \bar{\boldsymbol{m}})}{\sqrt{\left[\sum_{i=1}^{n}(\boldsymbol{b_i} - \bar{\boldsymbol{b}})^2\right]\left[\sum_{i=1}^{n}(\boldsymbol{m_i} - \bar{\boldsymbol{m}})^2\right]}} \right)^2$	(10)
Root Mean Square Error (RMSE):	$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(m_i - b_i)^2}$	(11)
Mean Absolute Error (MAE):	$MAE = \frac{1}{n}\sum_{i=1}^{n}\lvert b_i - m_i \rvert$	(12)
Mean Absolute Percentage Error (MAPE):	$MAPE = \frac{100}{n}\sum_{i}^{n}\frac{\lvert b_i \rvert}{\lvert m_i \rvert}$	(13)
weight absolute percentage error (WAPE):	$WAPE = \max\left[\frac{\lvert b_i - m_i \rvert}{b_i}\right]$	(14)

III. RESULT

In this section, a comparative assessment of the results was carried out to obtain the proposed model using single and hybrid frameworks. The hybrid variants developed to achieve optimal outcomes include DT+ZOA (DTZO) and DT+CHIO (DTCH). To train these proposed models, 70% of the input data was dedicated to the training process, while the remaining 30% was further divided, with 15% allocated for validation and 15% for testing purposes. Various metrics, including R2, RMSE, MAE, MAPE, and WAPE, were employed to conduct a thorough assessment of the acquired results and ensure unbiased findings. In the case of the R2 metric, values close to 1 suggest excellent results. Conversely, values approaching 0 indicate accurate outcomes when considering the error indicators.

Table III presents the results of predicting the Q_u of rocks for each framework. The performance of the traditional DT models within a single framework does not show favorable outcomes according to the mentioned metrics. While the R2 value for DT is 0.9817 during the training phase, it notably decreases in both the validation and testing phases. On the other hand, DTZA exhibits steady performance, especially in the training phase, with an R2 value of 0.9962 and an RMSE value of 629.7812. Among the models, the DTCH model showed moderate results, achieving higher accuracy compared to DT but slightly lower accuracy than the DTZA model. Overall, it can be concluded that the accuracy of DT models in predicting the Q_u of rocks is successfully enhanced by the incorporation of ZOA and CHIO optimizers, which contributes to an overall improvement in the reliability of the results.

Fig. 3 displays a scatter plot depicting the models' performance, evaluated through their R^2 and RMSE values. The X-axis correlates with the measured values, while the Y-axis correlates with the predicted values generated by the models. Triangular shapes in various colors are incorporated into the scatter plot to distinguish between the training, testing, and validation phases. These shapes are dispersed around a

diagonal line, representing an ideal scenario with an R^2 value of 1. The limited accuracy of the DT model becomes apparent due to the significant spread of data points.

Conversely, the DTZA and DTCH models demonstrate enhanced performance compared to the standalone DT approach. Data points for DTZA are tightly clustered near the central line, indicating a more favorable outcome. However, some broader dispersions are observable in the case of DTCH.

TABLE III. THE RESULT OF DEVELOPED MODELS FOR DT

Model	Phase	Index values				
		RMSE	***R^2***	***MAE***	***MAPE***	***WAPE***
DT	Train	1440.54	0.9817	1235.19	11.3086	0.0713
	Validation	1829.53	0.9683	1471.95	7.6086	0.0726
	Test	1695.50	0.9746	1121.61	7.4247	0.0745
	All	1545.41	0.9774	1253.81	10.1622	0.0720
DTZA	Train	629.78	0.9962	446.47	2.6926	0.0258
	Validation	1221.55	0.9873	926.96	4.6943	0.0457
	Test	1229.66	0.9893	814.87	5.2731	0.0541
	All	854.89	0.9934	574.80	3.3853	0.0330
DTCH	Train	1001.70	0.9903	742.39	4.6906	0.0429
	Validation	1503.80	0.9806	1145.34	5.7609	0.0565
	Test	1250.77	0.9834	850.54	5.7691	0.0604
	All	1178.30	0.9872	841.02	5.0565	0.0483

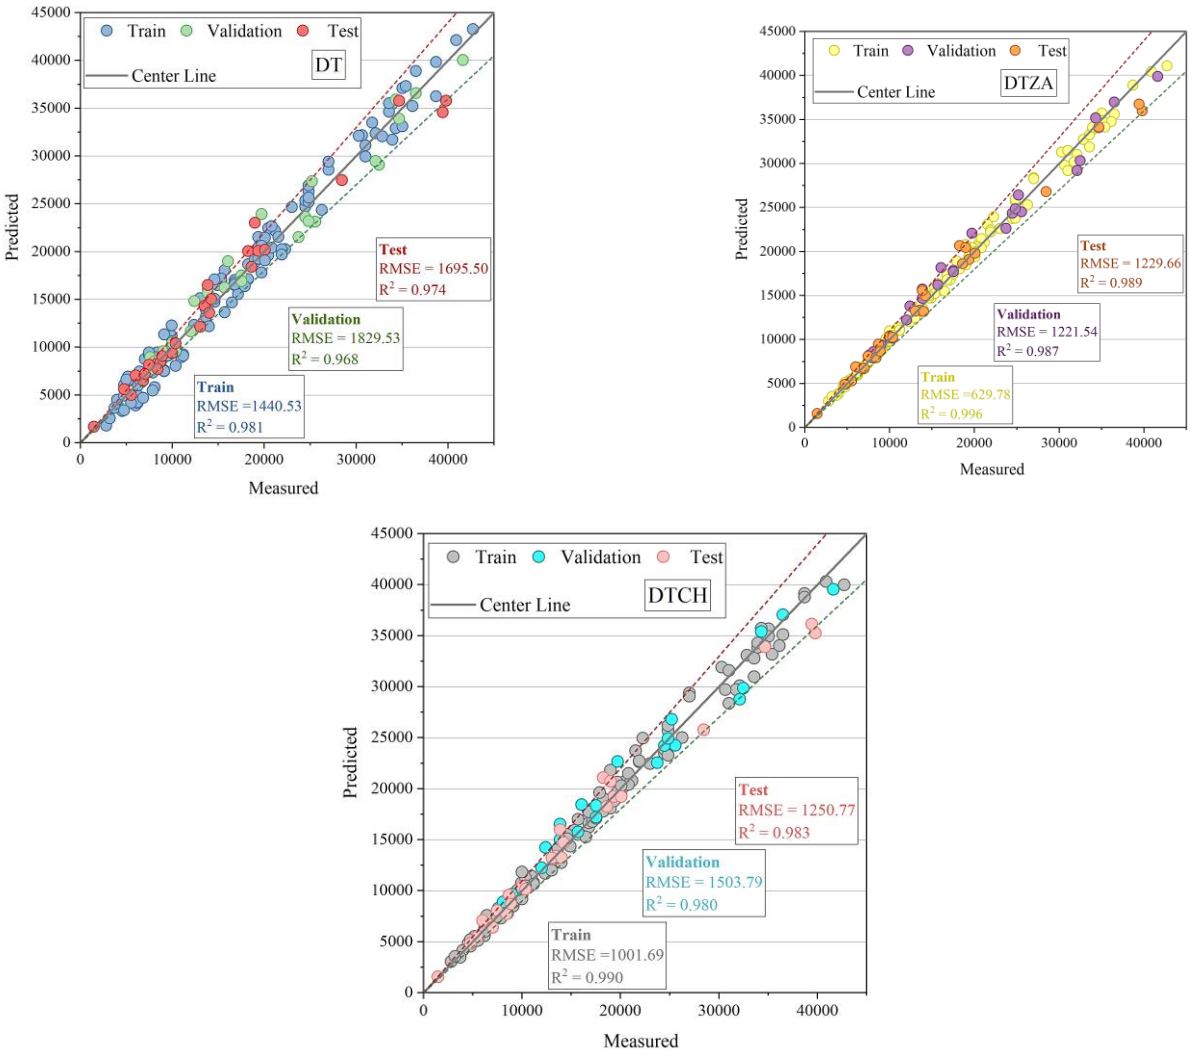

Fig. 3. The correlation between the predicted and measured values.

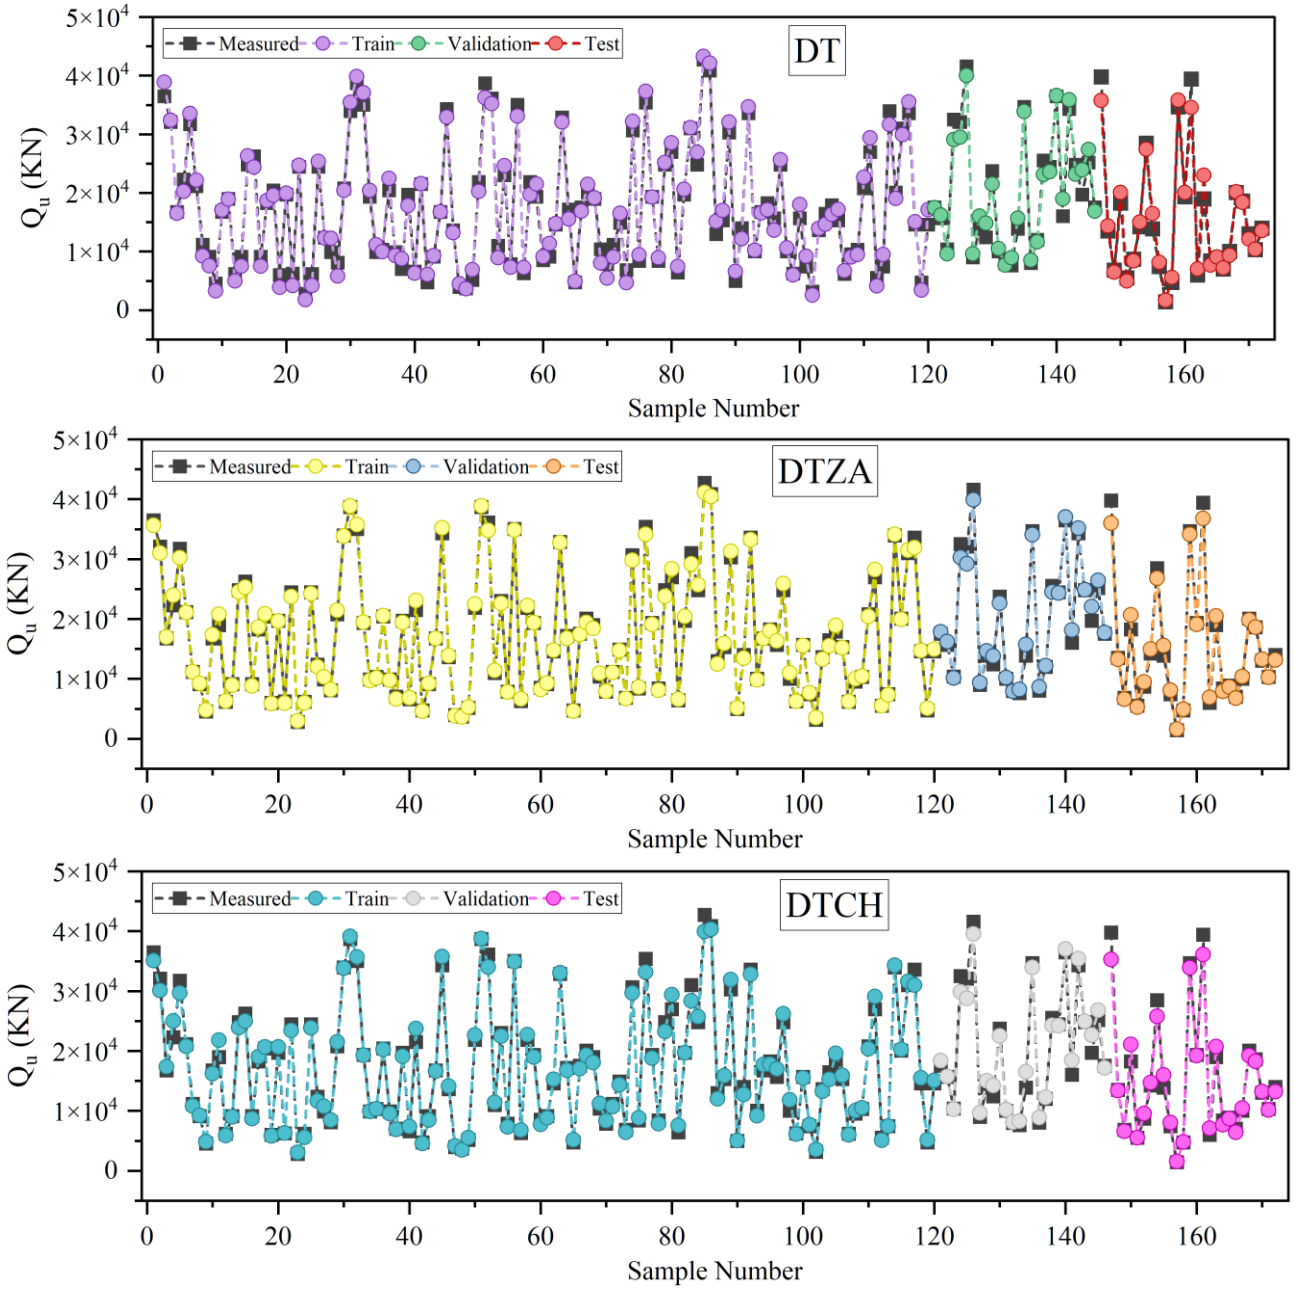

Fig. 4. The comparison of measured and predicted values.

Fig. 4 presents the relationship between predicted and measured values of the DT base models. In this figure, the measured values are represented by the black box. When the predicted values closely align with these measured values, it signifies the model's accuracy. As shown in Fig. 4, the DT model exhibits a significant deviation of its data from the measured values, particularly during the testing phase. Conversely, the DTZA model showcases a precise outcome, with an almost perfect match between its predicted and measured values, particularly within the sample numbers from 40 to 80. In contrast, the DTCH model demonstrates a noticeable lack of accuracy within the sample numbers ranging from 80 to 120, rendering it less precise than the DTZA model.

It is crucial to conduct an error assessment to achieve a deeper understanding of the uniqueness and precision of the models. Fig. 5 emphasizes that the DT model displayed a significant error rate, especially during the testing phase, peaking at a maximum error of 35% within the sample range of 0 to 50. On the other hand, most data points in the DTZA model exhibited errors that were nearly 0%, in contrast to the DTCH model, where the maximum error reached 20%.

Fig. 6 presents a box plot that simplifies the comparison of errors among the models within a single visual representation. The precision of the DTZA model becomes evident as the data points are closely grouped, primarily concentrated within the error range of -5% to 5%. This pattern contrasts with the

spread seen in the other models, underscoring the dependability of the DTZA model's predictions. The concentration of data points within a relatively narrow error range signifies its consistent and accurate performance. In contrast, the dispersion observed in the error distribution of the other models indicates a broader variability in their predictions.

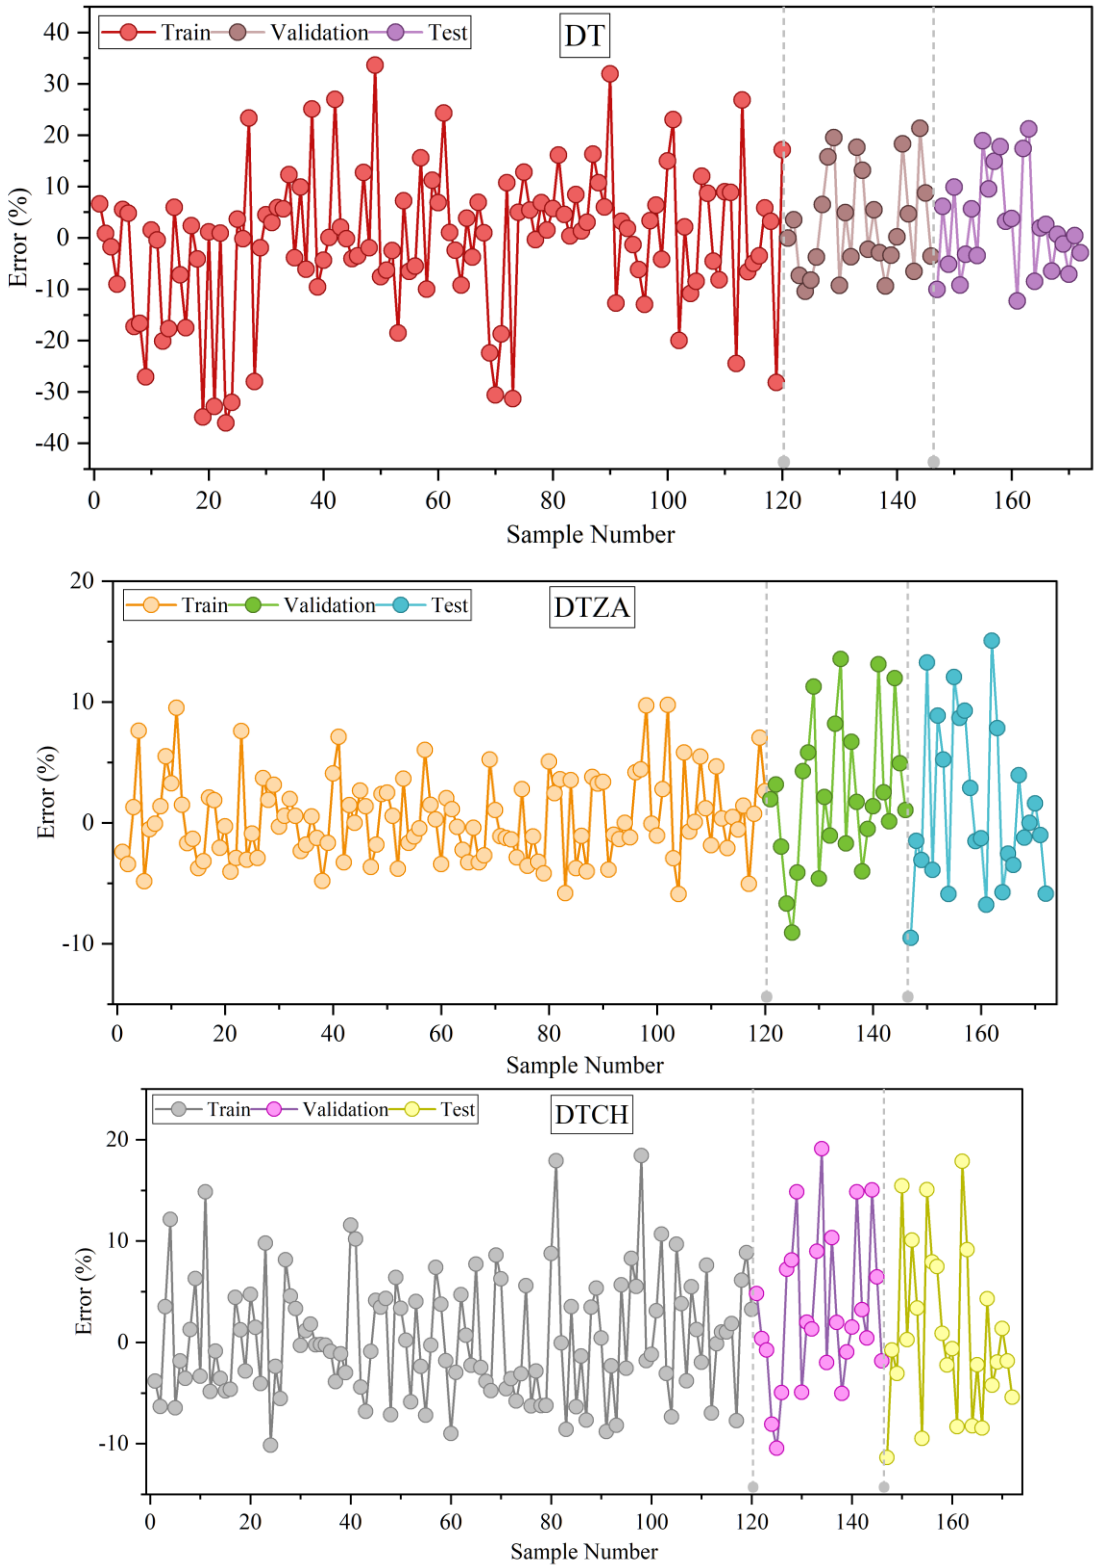

Fig. 5. The error percentage for the hybrid models is based on a line-symbol plot.

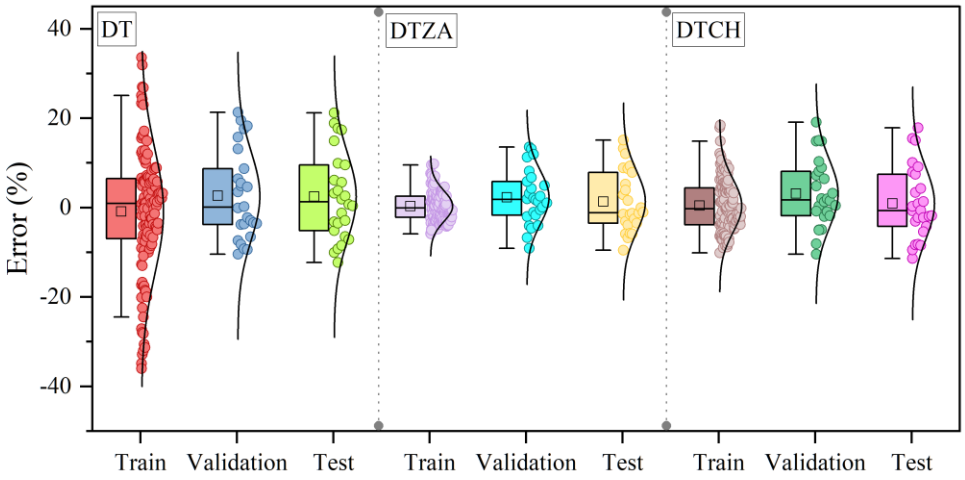

Fig. 6. The box plot of errors among the developed models.

IV. Discussion

A. Comparison between the Results of Previous Articles and the Present Study

Table IV presents the results of previous research efforts on Qu prediction, providing a comprehensive benchmark for comparison with the current study. Among the five models discussed in this table from earlier research, the GA-DLNN model, described in Pham et al.'s research [37], demonstrated the most impressive performance, achieving an R^2 of 0.882 and an RMSE of 109.965. As detailed in the previous Section, the current investigation emphasizes the superior performance of the DTZA model during the training phase, producing commendable metric scores with an R^2 value of 0.9962 and an RMSE of 629.78. This exceptional performance in critical metrics decisively positions the DTZA model in this study as outperforming its counterparts, confirming its effectiveness in Qu prediction.

TABLE IV. Comparing the Results of the Present Study with Previous Studies

Articles	Models	Models' performance	
		RMSE	R^2
Armaghani et al. [38]	ANN	0.135	0.808
Pham et al. [37]	GA-DLNN	109.965	0.882
Momeni et al. [39]	ANN	0.529	0.71
Momeni et al. [39]	ANFIS	0.048	0.875
Kulkarni et al. [40]	GA-ANN	0.0093	0.86
Present Study	DTZA (DT+ZAO)	629.78	0.9962

B. Results of an Ablation Study

In this study, an ablation study was conducted as an alternative assessment approach. Two input values, as detailed in previous sections, were deliberately removed from the dataset. Subsequently, the prediction process was reiterated utilizing the best hybrid model. The outcomes of this ablation study were then compared with those of the main prediction process, with the findings summarized in Table V. Analysis of the table reveals that the results of the Main Study outperformed those of the Ablation Study. Specifically, the Root Mean Square Error (RMSE) of the Main Study was 17.22% lower than that of the Ablation Study, indicating a superior predictive performance in the former.

TABLE V. Comparing the Results of the Main Study with Ablation Study

phase	Main Study		Ablation Study	
	R^2	RMSE	R^2	RMSE
Train	0.9962	629.78	0.9942	774.33
Validation	0.9873	1221.55	0.9818	1464.26
Test	0.9893	1229.66	0.9845	1470.84
All	0.9934	854.89	0.9904	1032.73

C. Limitations of the Study

The study's limitations are acknowledged, including the potential restriction of results' generalizability by the specific dataset and experimental setup utilized. Variations in geological conditions, pile types, and other site-specific factors could affect the performance of the proposed hybrid models in different contexts. Additionally, the focus on predictive accuracy in the analysis may neglect considerations of computational efficiency or scalability, which could be crucial in real-world applications. Furthermore, biases or uncertainties may be introduced by the assumptions and parameters chosen for the optimization algorithms. Lastly, while efforts were made to provide insightful analysis of the experimental results, there may be aspects that require further investigation or validation in future studies. These limitations underscore the need for a cautious interpretation of the findings and highlight avenues for future research to address these constraints and refine the proposed methodologies.

V. Conclusion

The estimation of the ultimate bearing capacity (Q_u) using ML methods, specifically the DT model, coupled with advanced optimization algorithms, including the Zebra Optimization Algorithm (ZOA) and the Coronavirus Herd Immunity Optimizer (CHIO), has demonstrated significant promise and yielded valuable insights into the field of civil engineering. The incorporation of ML techniques, particularly the DT model, has proven to be a powerful tool for accurately estimating the ultimate bearing capacity of soils and rocks. The

utilization of this model allows for the efficient handling of complex datasets and the extraction of meaningful patterns and relationships within the data. However, as revealed in the analysis, the standalone DT model exhibited limitations in accuracy, especially during the testing phase, highlighting the need for further refinement. The fusion of the DT model with optimization algorithms, such as ZOA and CHIO, has been a pivotal advancement in enhancing predictive accuracy. The ZOA and CHIO optimizers have contributed to refining the model's performance during the training, validation, and testing phases. The analysis of the prediction results, as depicted in correlation and error assessments, showcased the distinctiveness of these models. The DTZA model demonstrated remarkable accuracy, with a close alignment between predicted and measured values. Its ability to maintain errors close to 0% over a wide range of samples is a testament to its consistent and precise performance. On the other hand, the DTCH model, while showing improved accuracy compared to the standalone DT model, exhibited some variability in its predictions, particularly in a specific sample range. The integration of ML methods, DT models, and advanced optimization algorithms like ZOA and CHIO has proven to be a valuable approach for predicting the ultimate bearing capacity in civil engineering applications. These hybrid models have shown substantial improvements in accuracy and reliability, which are crucial for making informed decisions in geotechnical engineering projects. Further research and fine-tuning of these models can advance the understanding and predictive capabilities in civil engineering, particularly in earthquake analysis and related areas.

***Abstract*—One of the latest studies in predicting bankruptcy is the performance of the financial prediction models. Although several models have been developed, they often do not achieve high performance, especially when using an imbalanced data set. This highlights the need for more exact prediction models. This paper examines the application as well as the benefits of machine learning with the purpose of constructing prediction models in the field of corporate financial performance. There is a lack of scientific research related to the effects of using random forest algorithms in attribute selection and prediction process for enhancing financial prediction. This paper tests various feature selection methods along with different prediction models to fill the gap. The study used a quantitative approach to develop and propose a business failure model. The approach involved analyzing and preprocessing a large dataset of bankrupt and non-bankrupt enterprises. The performance of the model was then evaluated using various metrics such as accuracy, precision, and recall. Findings from the present study show that random forest is recommended as the best model to predict corporate bankruptcy. Moreover, findings write down that the proper use of attribute selection methods helps to enhance the prediction precision of the proposed models. The use of random forest algorithm in feature selection and prediction can produce more exact and more reliable results in predicting bankruptcy. The study proves the potential of machine learning techniques to enhance financial performance.**

I. INTRODUCTION

Predictions in business are essential tools for decision-making and strategic planning. At its core, a prediction is an educated guess about what the future holds based on past trends and current data. When used correctly, predictions can help businesses prepare for various scenarios and make informed decisions.

It is a common fact that there is no certainty in the field of business. Prediction models can provide decision makers with a framework to set more realistic strategies via predicting financial performance. In the case of predicting a business failure, management can prevent business bankruptcy. Bankruptcy prediction helps in increasing accuracy of decision making process for business enterprises since it has a variety of applications in financial fields [1].

The key idea is that public information of corporations comprises significant data and information that could be used by investors to asses financial status, which may be a major reason to cause bankruptcy [2]. Financial crisis prediction indicators included Profitability, Solvency, Growth ability, Cash flow and Capital structure [3]. Enhanced prediction accuracy is bound to increase the earnings to shareholders by improving financial risk management inside rising markets [4].

Recent research has employed financial ratios to show the exploration models for business failure. To improve prediction accuracy, it is important to find the most influential factors on financial performance. The discriminatory influence acquired by bringing together distinctive groups of financial ratios (FRs) and corporate governance indicators (CGIs) for business failure prediction was examined [5].

It is worth mentioning that the massive amount of corporate data presents an opportunity to deeply analyze the data and, consecutively, gain a great deal of knowledge. Unfortunately, the necessity for many human resources and too much time limit the benefits of the financial data. Alternatively, improving machine learning techniques can save both time and money. This helps to provide decision makers with significant evidence to be a base for making strategic plans.

In past works, a variety of prediction models were applied to define the early warning factors of a potential bankruptcy. This paper attempts to examine and compare the significance of using decision tree, k-nearest neighbor, logistic regression, multilayer Perceptron, and random forest in predicting corporate failure.

In 2022 a study used only three financial indicators: the return on assets, the current ratio, and the solvency ratio reported prediction accuracy rates of more than 80 percent. The study used Belgian companies` data set contains a sample of 3728 Belgian companies that were announced bankrupt between 2002 and 2012 to anticipate bankruptcy [6].

The main research gap is that “the performance of prediction models attained by combination of various categories of FRs has not been completely investigated. Only some chosen FRs have been utilized in previous researches and the selected attributes may vary from study to study [7].

The goal of our study is using random forest algorithm for analyzing corporate data encompassing various goals. Firstly, it aims to evaluate the tendency of business failure in different companies by developing prediction models that incorporate random forest algorithms in both attribute selection process and prediction process. Secondly, the model eases the enhancement of prediction process by enabling researchers to foresee the influence of fluctuations in ninety-five different financial ratios on corporate financial performance. Additionally, the research contributes by developing a novel model applying random forest algorithm along with seven various categories of financial indicators to anticipate business failures.

Paper structure consists of literature review in Section II providing a clear explanation of previous studies in bankruptcy prediction field, methods in Section III presenting our model that is based on incorporating the most common algorithms in financial prediction field, results in Section IV demonstrating the average performance measures for prediction models used in our study, discussion section clarifying the importance of our model and the significance of our contribution.

II. Literature Review

A. Corporate Bankruptcy Prediction

The substantial rise in the total papers, especially subsequent the 2008 global financial disaster, has verified that corporate bankruptcy is a subject of growing interest, which indicates the importance of this issue for corporations [8]. Regrettably, the COVID-19 epidemic that has invaded the globe since 2020 was one of the major triggers for bankruptcy filing. While data analytics has many applications in the financial field, Bankruptcy Prediction Models (BPM) have witnessed an increase in recognition [9].

Beaver assessed various financial variables to evaluate their ability in classifying and predicting bankrupt firms. That made him a pioneer in researches that study the enterprise failure prediction [10]. Altman presented business failure models according to discriminant study in categorizing economic failure based on five financial ratios: working capital/total assets, market value of equity/total debt, earnings before interest and taxes/total assets, retained earnings/total assets and sales/total assets [11].

Once Altman issued one of the very popular models in prediction of firms bankruptcy in 1968, a variety of models that predict bankruptcy have been issued in the literature [12]. It does not only direct attention to the increasing number of research issued, but also to the diversity of enterprise failure prediction models employed for business crisis prediction. Owing to the advance in machine learning methods and computer ability in latest years, more diverse analytical tools have been employed to create a business failure model with superior precision.

B. Prediction Accuracy Enhancement

There are two steps to assess financial crisis. Whereas the first stage employs a variety of financial variables, the other one employs diverse classifiers in construction of the bankruptcy model [13].

First, in the financial variables step, selecting the most informative financial variables can improve prediction performance. Regarding to Chih-Fong Tsai investigational outcomes, applying attribute selection tools to choose and extract the extra valuable, demonstrative and illustrative variables can reduce the effort and time of training the model, which certainly results in increasing the performance of prediction [14].

Second, in the model construction step, a variety of methods have been offered, including decision tree, k-nearest neighbor, logistic regression, multilayer Perceptron, and random forest. In 1980, Ohlson estimated the probabilities of bankruptcy employing logistic regression [15].

One of the early applications of random forests was reported in 2001 that presented random sampling of trees and the concept of tree correlation. His discoveries indicated that for the first-time forest algorithms can rival with arcing approaches, in both classification and regression analysis [16]. Separate research done in 2012 showed that RF is effective for more accurate results. This assists the researchers in estimating feature significance and value [17].

Artificial neural networks (ANNs) are powerful artificial intelligence technologies that are widely-used as they are able to combine several nonlinear functions to express non-linear relationships between input data and a class label [18]. A previous study on corporate distress prediction examined the precision of Logit and ANN to establish a comparison between using statistical and artificial intelligence in modeling financial risk [4].

III. Methods

A. Dataset

The data set is acquired from (UCIMLR)[19], which supplies datasets to the interested researchers in machine learning field. Initially, the sample data was gathered by the Taiwan Economic Journal. It comprises the financial variables of industrial, electronic, shipping, tourism, and retail companies for the years 1999–2009. The data set includes ninety-five various financial indicators and 6,819 rows, of which 6,599 are corporations that did not go bankrupt, and 220 are bankrupt corporations. The description of business failure is established on the rules of the Taiwan Stock Exchange. Our proposed model is shown in Fig. 1.

B. Preprocessing

In In data preprocessing stage, we checked for missing values and duplicates within the dataset, but there were none. We applied data normalization on the dataset. All preprocessing and feature selection steps were conducted using WEKA.

An imbalanced data set is created when the total observations in one group exceeds the total of observations in the other group. Prediction techniques behave disappointingly in data sets with imbalanced classes because they regularly suppose that all classes are represented equally.

As a result, the cases that are represented in the smaller group are miscategorized as belonging to the mass group [20].

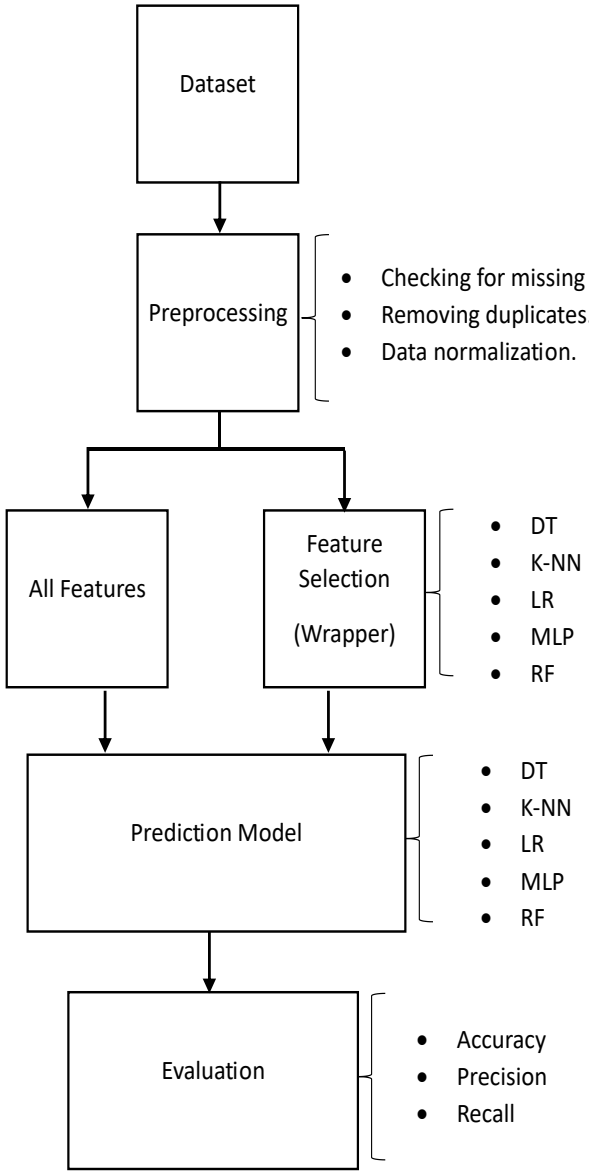

Fig. 1 Our proposed model.

In each year, the total of business failures is smaller in comparison with the total of companies that did not go bankrupt. If failed corporations are outliers, this causes a key breach to the fundamental distributional conjectures for logistic regression [21]. Resampling techniques generate new samples of data from the original dataset using a set of statistical methods. It is essential to lower the danger of the study or machine learning algorithm biasing toward the common class.

We applied unsupervised resample filter on data to get more reliable results by producing a random subsample of a dataset. It applies over sampling on the smaller group and under sampling on the mass group at the same time while keeping the same number of records in the original dataset. Thus, using unsupervised resampling helps in gaining the benefits of both over and under-sampling. That leads to having more reliable and realistic results.

C. Feature Selection

Attribute selection is the practice of selecting the important attributes that have an influence on the performance of the model. Attribute selection is a research problem in wrapper methodology, so different combinations are made, assessed, and compared with other combinations. The algorithm is trained by using the subset of features iteratively.

In the present study, the wrapper method is applied on the resampled data since it interacts with classifier, models feature dependencies, minimizes computational cost, and provides good classification accuracy.

Features chosen will differ regarding the kind of classifier as diverse classifiers perform better with various arrays of attributes to generate more competent conclusions. The five classifiers which will be employed for the feature electing manner outcomes are illustrated in Table I.

TABLE. I. FEATURES SELECTED USING WRAPPER METHOD

Classifier	Attributes selected based on the wrapper method
Decision Tree (DT)	X8, X10, X12, X40, X55, X64, X65, X87, X92
K-nearest Neighbor (KNN)	X9, X14, X21, X25, X31, X52, X54, X62, X73, X85, X87, X90, X92
Logistic Regression (LR)	X11, X13, X17, X18, X21, X27, X34, X39, X44, X51, X64
Multilayer Perceptron (MLP)	X2, X3, X16, X32, X39, X43, X49, X50, X52, X59, X61, X68, X73, X76, X84
Random Forest (RF)	X34, X40, X48, X50, X54, X68, X76, X77, X80, X90, X91, X93

The highest significant features for effective bankruptcy prediction are the categories of solvency and profitability [5]. All classifiers have selected attributes from both categories except random forest algorithm has not selected any attributes from solvency category. RF algorithm has selected more attributes from growth category than other classifiers.

D. Prediction

To recognize the best bankruptcy model, different techniques have been applied on the data set, and then their outcomes are matched with each other. Models are established according to two distinctive situations:

All attributes will be employed, and only the features chosen using the wrapper method will be employed.

We trained models utilizing the same five algorithms employed in features selection wrapper method to analyze the relation between employing the same algorithm in both attribute selection stage and prediction modeling stage.

E. Evaluation

In cross-validation the data set is indiscriminately divided into ‘k’ groups. Only one group is treated as a test set whereas the extra groups are treated as training sets. The training sets aim to teach the model while the test set is utilized to assess the model. The activity is done repeatedly until every distinctive group has been utilized as the test set.

Cross-validation test is preferred to be used in such cases because it offers the model the chance to learn on multiple train-test divisions. This provides us with a well sign of how accurate the model will operate on undetected data.

In this research, the following metrics are employed to estimate model performance: accuracy, precision, and recall. The metrics computation is established on rules presented in Table II. Computation of accuracy, precision, recall and F-measure are constructed on confusion matrix involving a classification of actual and predicted values into the next groups: true positive (TP), true negative (TN), false positive (FP), and false negative (FN).

Accuracy demonstrates how often a machine learning model is correct overall. Depending only on accuracy measure to estimate model performance can be deceiving when utilizing imbalanced data set as it assigns equal weight to the classes which mitigate the model’s capability to predict all classes. Precision presents how frequently a machine learning model is precise when predicting the intended category. Recall expresses whether a machine learning model can recognize all objects of the intended category.

TABLE. II. PERFORMANCE METRICS

Evaluation measure	Rule
Accuracy	$\frac{TP + TN}{Total}$
Precision	$\frac{TP}{TP + FP}$
Recall	$\frac{TP}{TP + FN}$

IV. RESULTS

Since bankruptcy is an imbalanced problem, then the weighted average is preferred for measuring performance of classification models. Table III in Appendix summarizes the scores of the evaluation process. Considering these results, we can state that some models such as KNN, MLP, and RF work better with the features chosen utilizing wrapper method with the same algorithm. On the contrary, some models such as decision tree and logistic provided better results employing all attributes.

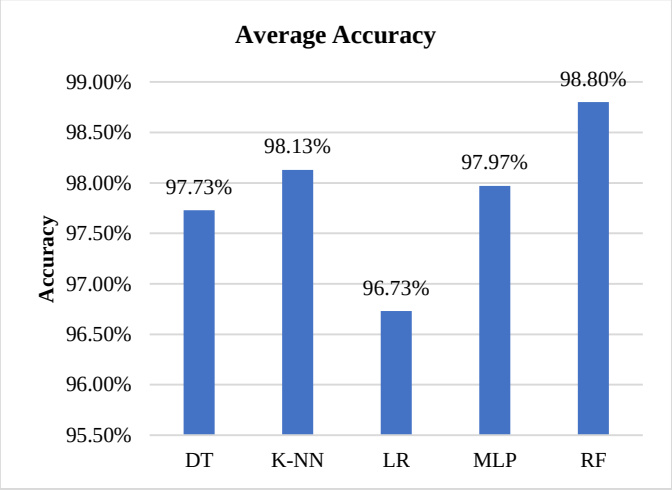

Fig. 2 Average accuracy of each model.

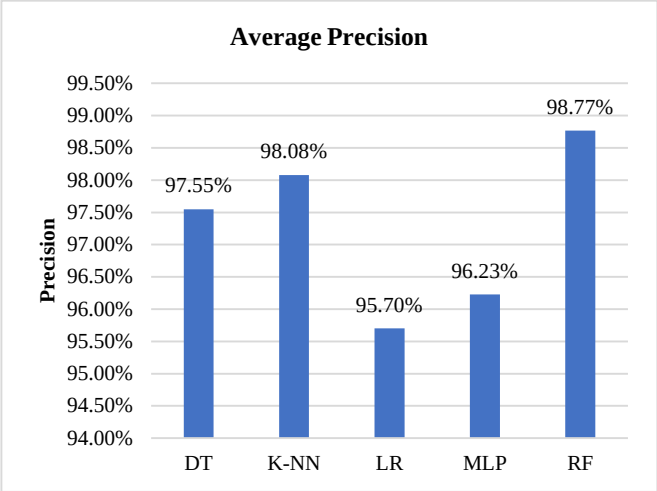

Fig. 3 Average precision of each model.

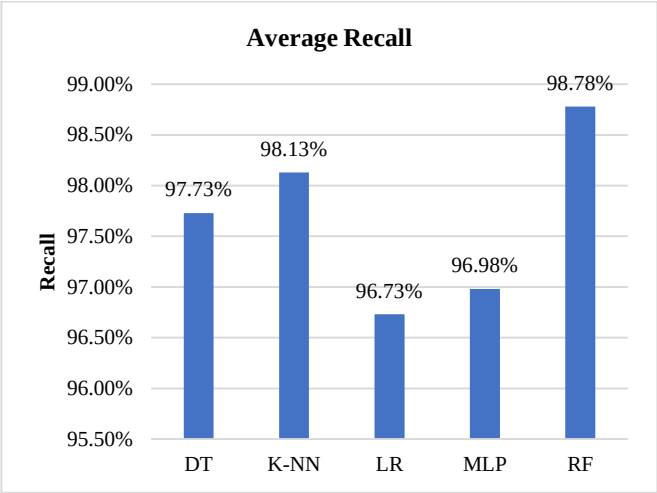

Fig. 4 Average recall of each model.

In analyzing Fig. 2, we see that the RF is better than the other models concerning illustrating and comparing the differences in average accuracy of models. As shown in this figure, the random forest was the most accurate model with 98.80% compared with the lowest accuracy of 96.73% for logistic model.

Fig. 3 displays the average precision of models employing different feature selection algorithms. Once more, the data suggests that RF, on average, provide an improved performance than their counterparts. This finding also sides with the preceding idea that RF is more efficient. While random forest was the most precise model with 98.77% the logistic model with 95.70% was the lowest in precision.

Fig. 4 also proves that random forest model performs better than other models. Again, we notice the same tendencies of RF model exceeding other models. Random forest model was the most model able to correctly identify most of the positive results with 98.78% sensitivity while the logistic model only had 96.73% which was the lowest. We can state that the model using random forest technique outperformed all other models in all performance metrics in predicting bankruptcy.

V. Discussion

To further confirm our findings, we compared them to other studies using the same sample dataset of Taiwanese enterprises along with various resampling, attributes selection and prediction techniques.

In 2016, the models published by [5] employed Support Vector Machine (SVM) and generated five different machine learning models. Along with the ninety-five financial ratios we utilized, they also used CGIs. They employed 10-fold cross-validation to generate ten distinct training and test samples. They also tried five alternative attribute selection techniques. The model with the best performance in their study achieved 81.5% accuracy that was exceeded by the weakest model in our research.

In 2022, the research by [22] closely examined the discriminatory competence of a MLP in studying financial failure prediction. For this purpose, they employed different setups of optimization algorithms, activation functions, number of neurons, and number of layers. The model with the best performance in their study achieved 86.67% accuracy, 95.47% precision and 85.24% sensitivity that was outperformed by the worst model in our study.

VI. Conclusions

This research covers the usage of different techniques with the aim of enhancing the findings of prediction. We can state that firstly, using feature selection can significantly improve performance of prediction models. Secondly, constructing prediction models using random forest algorithms outperformed other models using different machine learning techniques in terms of accuracy, precision, and sensitivity. Thirdly, employing growth ratios in dataset used in financial failure prediction is significant. Results from this study recommend that, in general, random forest algorithms tend to attain more exact results. The impressive performance of the random forest model can be improved when the wrapper method is used as the attribute selection method with random forest algorithm to detect the best features for the classifier. Practitioners can benefit from these conclusions to enhance the accuracy of their predictions. For future work, researchers may use different feature selection methods combined with a diversity of resampling approaches to identify what works better.

***Abstract*—The article introduces a novel approach for forecasting stock market prices, employing a computationally efficient Bidirectional Long Short-Term Memory (BiLSTM) model enhanced with a global pooling mechanism. Based on the deep learning framework, this method leverages the temporal dynamics of stock data in both forward and reverse time frames, enabling enhanced predictive accuracy. Utilizing datasets from significant market players—HPQ, Bank of New York Mellon, and Pfizer—the authors demonstrate that the proposed single-layered BiLSTM model, optimized with RMSprop, significantly outperforms traditional Vanilla and Stacked LSTM models. The results are quantitatively evaluated using root mean squared error (RMSE), mean absolute error (MAE), and the coefficient of determination (R^2), where the BiLSTM model shows a consistent improvement in all metrics across different stock datasets. We optimized the hyperparameters tuning using two distinct optimizers (ADAM, RMSprop) on the HPQ, New York Bank, and Pfizer datasets. The dataset has been preprocessed to account for missing values, standardize the features, and separate it into training and testing sets. Moreover, line graphs and candlestick charts illustrate the models' ability to capture stock market trends. The proposed algorithms attained respective RMSE values of 0.413, 0.704, and 0.478. the proposed algorithms attained respective RMSE values of 0.413, 0.704, and 0.478. The results show the proposed methods' superiority over recently published models. In addition, it is concluded that the proposed single-layered BiLSTM-based architecture is computationally efficient and can be recommended for real-time applications involving Stock market time series data.**

I. INTRODUCTION

Predictions of the stock market have long been of fascination to investors, analysts, and researchers. Accurate stock price forecasts can provide insightful information for making informed investment decisions. Recurrent neural networks (RNNs), specifically Long Short-Term Memory (LSTM) models, have demonstrated promising results in capturing the temporal dependencies in stock price data and predicting future trends since the advent of deep learning techniques.

In this paper, we compare the efficacy of three variants of LSTM models for stock prediction: vanilla LSTM, stacked LSTM, and bidirectional LSTM. Each variant offers distinct architectural modifications to the fundamental LSTM structure, allowing for enhanced modeling capabilities and potentially improved prediction precision.

We conduct experiments utilizing a comprehensive dataset of historical stock prices from various companies and industries. The dataset has been preprocessed to account for missing values, outliers, and standardization. Then, we train and evaluate the three LSTM variants using appropriate evaluation metrics, including root mean squared error (RMSE), mean absolute error (MAE), and coefficient of determination (R2).

The hyperparameters of deep learning models, such as LSTM, significantly impact their performance and predictive accuracy. Automatic techniques for tuning hyperparameters have been proposed; however, these methods frequently lack transparency and fail to provide end-users insight into the interactions between different hyperparameters and their relative importance [1].

Several key hyperparameters must be carefully selected and configured for the LSTM model used in this paper [2]: activation function (sigmoid, tanh, softmax, etc.), optimizer (Adam, Adadelta, RMSprop, etc.), batch size, number of epochs, number of hidden layers, etc.

The results of this study will shed light on the relative stock prediction performance of vanilla, layered, and bidirectional LSTM models. In addition, it will cast light on the effect of architectural changes on the predictive capabilities of models and their suitability for capturing the inherent complexities of stock price data.

Exploration and comparison of these LSTM variants can significantly advance stock prediction techniques. By comprehending the advantages and disadvantages of various

LSTM architectures, investors and researchers can make more informed decisions and improve their forecasting accuracy in the volatile and dynamic world of stock markets.

Our research seeks to contribute to the understanding of stock prediction using various neural network architectures and hyperparameter tuning techniques by building on the findings of these studies.

This paper presents several notable contributions to financial forecasting and machine learning, specifically in applying LSTM models to predict stock market trends. Here are the main contributions:

- The study introduces a computationally efficient single-layered Bidirectional Long Short-Term Memory (BiLSTM) model incorporating a global pooling mechanism. This architectural choice simplifies the model while maintaining effective learning capabilities, making it suitable for real-time stock market applications.
- The paper comprehensively compares three different LSTM architectures: Vanilla LSTM, Stacked LSTM, and Bidirectional LSTM. This comparison helps elucidate the strengths and weaknesses of each variant in handling the complexities of financial time series data.
- The research includes an in-depth exploration of hyperparameter tuning using two different optimizers, ADAM and RMSprop, to optimize the performance of the LSTM models. This systematic tuning approach contributes to the predictive models' robustness and reliability.
- The study employs various evaluation metrics, such as Root Mean Squared Error (RMSE), Mean Absolute Error (MAE), and the Coefficient of Determination (R^2). These metrics thoroughly assess the model's predictive accuracy and statistical reliability.
- The results indicate that the proposed BiLSTM model outperforms recently published models in predicting the closing prices of stocks. This demonstrates the effectiveness of the proposed approach in capturing the complex temporal dynamics of stock prices.
- Utilizing commonly used public datasets from major stocks like HPQ, New York Bank, and Pfizer, the study underscores the practical applicability of the proposed method in diverse financial environments.
- Including line graphs and candlestick charts to illustrate the models' performance provides visual evidence of the models' ability to capture and accurately predict stock market trends.

The remainder of this paper is structured as follows: Section II reviews the related work, illustrating the progression and application of various predictive models within financial forecasting. Section IV details the methodologies employed, including data collection, preprocessing steps, and the experimental setup for the LSTM variants. Empirical research is given in Section V.. Section VI discusses the implications of these findings, offering insights into the practical applications and potential improvements for stock market forecasting. Finally, Section VII concludes the paper with a summary of the findings, contributions, and suggestions for future research directions in financial time series prediction using deep learning techniques.

II. Related Work

Due to its economic significance and potential for financial benefit, the prediction of stock market movements has been the subject of extensive study. This section examines studies that have investigated various stock market prediction techniques.

Within their research, Sharma et al. [3] proposed a hybrid architecture that combines ANN and GA (GANN) to predict the closure price of two indices, the Dow 30 and the NASDAQ 100, the following day. Data spanning three years, including features like Open, Low, High, and Close, was used. The assessment metrics that were employed were MAPE, MSE, and RMSE. It was reported that GANN predicted more accurate results than the Back Propagation Neural Network (BPNN).

Using independent component analysis and support vector regression, [4] proposed a two-stage modeling strategy to resolve the difficulties of working with financial time series. They emphasized the significance of addressing noise and stabilizing time series for accurate forecasts.

Hamzacebi et al. [5] compared iterative and direct methods for multiperiodic forecasting using artificial neural networks. Their results were evaluated using grey relational analysis, demonstrating neural networks' suitability for capturing complex patterns in multiperiodic data.

Deep neural networks (DNNs) have been utilized to predict financial markets. In study [6] utilized DNNs to forecast financial markets and back tested their trading strategy on commodity and futures markets. The study demonstrated that DNNs can capture complex market dynamics and produce accurate predictions.

In electric load forecasting, [7] employed long short-term memory (LSTM) networks and data from metropolitan France's electricity consumption. A genetic algorithm optimized the number of hidden neural layers and optimal time lags, resulting in superior performance to conventional machine learning models.

Utilizing genetic algorithms, technical analysis parameters for stock forecasting have been optimized. In [8], optimized technical analysis parameters with genetic algorithms and fed them to a deep neural network for predictions, resulting in improved stock trading performance.

CEFLANN, a specialized artificial neural network, was used for stock market prediction [9]. They formulated stock trading prediction as a classification problem. They contrasted the performance of the model with that of other machine learning techniques, including support vector machines (SVM), naive Bayes (N.B.), k-nearest neighbors (KNN), and decision trees (DT).

LSTM has demonstrated efficacy in out-of-sample financial time series prediction [10]. Based on the LSTM outputs, a short-term trading strategy was developed. It outperformed logistic regression, DNN, and RAF.

LSTM, RNN, CNN, and MLP were evaluated with linear and non-linear regression models in study [11]. CNN outperformed competing models when tested on numerous NSE and NYSE companies.

Using remote sensing data, genetic algorithms were used to find a near-optimal solution to determining the optimal number of concealed layers in a neural network [12].

In study [13], eight LSTM variants were used on various tasks, such as music modeling, handwriting recognition, and speech recognition. The study discovered that the fundamental LSTM architecture performed well, with no significant improvement from the variants, indicating that the hyperparameters were independent.

Regarding accuracy and variance, LSTM was compared to SVM, backpropagation, and the Kalman filter for stock market prediction [14]. LSTM demonstrated high precision and low variance, making it a desirable option.

In research [15], the optimization of hyperparameters for neural and deep belief networks by comparing manual and grid search strategies. Manual search produced models as excellent as, or even better than, grid search in less computation time, indicating its utility as a starting point for hyperparameter optimization algorithms. Table I shows comparative study of related work.

TABLE I. COMPARATIVE STUDY OF RELATED WORK

Paper	Year	Method	Positives	Limitation
Bhuriya, Dinesh, et al [16].	2017	Linear Regression	• The project predicts the behavior of the TCS datasets using Linear Regression, and the final result is contrasted and assessed against the results of alternative methods. [16] • The model integrates methods for practical machine learning applications, such as gathering and evaluating a sizable dataset and employing various strategies to train the model and forecast possible results. [16]	• Compared to other methods, the linear regression prediction method is somewhat less accurate. • Does not take into account the Random Forest prediction model, which, when applied to a limited dataset, should provide predictions with a higher degree of accuracy. • The prediction model was only applied to a single stock set, not the whole market. This leads to a certain level of shortsightedness throughout the assessment procedure.
Nivetha, R. Yamini, and C. Dhaya [17].	2017	ANN	• Sentiment analysis of the social media platform is used in this project to forecast or evaluate human behavioral tendencies accurately. • The model can be applied in various contexts, including the stock market, banking, auditing, investment strategies, and investing patterns. • The most accurate results across a sizable dataset are obtained when MLR and SVM are used in an ANN with deep learning.	• The purpose of this study is to build an algorithm for stock value prediction; the accuracy of the prediction is not discussed. It provides a qualitative, not a quantitative, approach. • To analyze the forecast, it gives a semantic figure rather than a visual result. There are no graphs offered to show market trends or patterns in investment.
Parmar, Ishita, et al [18].	2018	LSTM	• The accuracy attained for a big dataset increases with system utilization. Regression-based models are not as accurate as the updated LSTM technique.[18] • To view data, this approach offers graphical data. [18]	• Expanding the dataset can lead to an increase in the system's accuracy.[18] • Additional testing of other ML models under development is necessary to improve forecast accuracy. • Since sentiment is significant in stock price volatility, sentiment analysis using machine learning should be conducted.
Liu, Siyuan, Guangzhong Liao, and Yifan Ding [19].	2018	LSTM	• This model is the first to rely only on Long Short-Term Memory (LSTM) for prediction, resulting in higher accuracy. • This publication provides a clear explanation of the LSTM model and training process. This covers both graphical and mathematical implementations.	• The LSTM model requires many layers to be stacked to provide good accuracy. So, it is a tedious process. • The LSTM network must be combined with existing clustering techniques to gain large speed-ups in training and testing times at the cost of a small drop in performance. [19]
Shakva, Abin, et al [20].	2018	ANN	• This paper uses a feedforward neural network to determine stock prices based on real-time trade volume, transaction frequency, and price fluctuations. [20] • Hidden layer neurons were tweaked independently for each stock model. ADBL achieved the highest accuracy of 86.12% using a 3-20-10 network model. [20]	• Requires extensive knowledge of deep learning and neural networks. There is a significant skills gap in this industry. • This model requires significant processing resources to run.

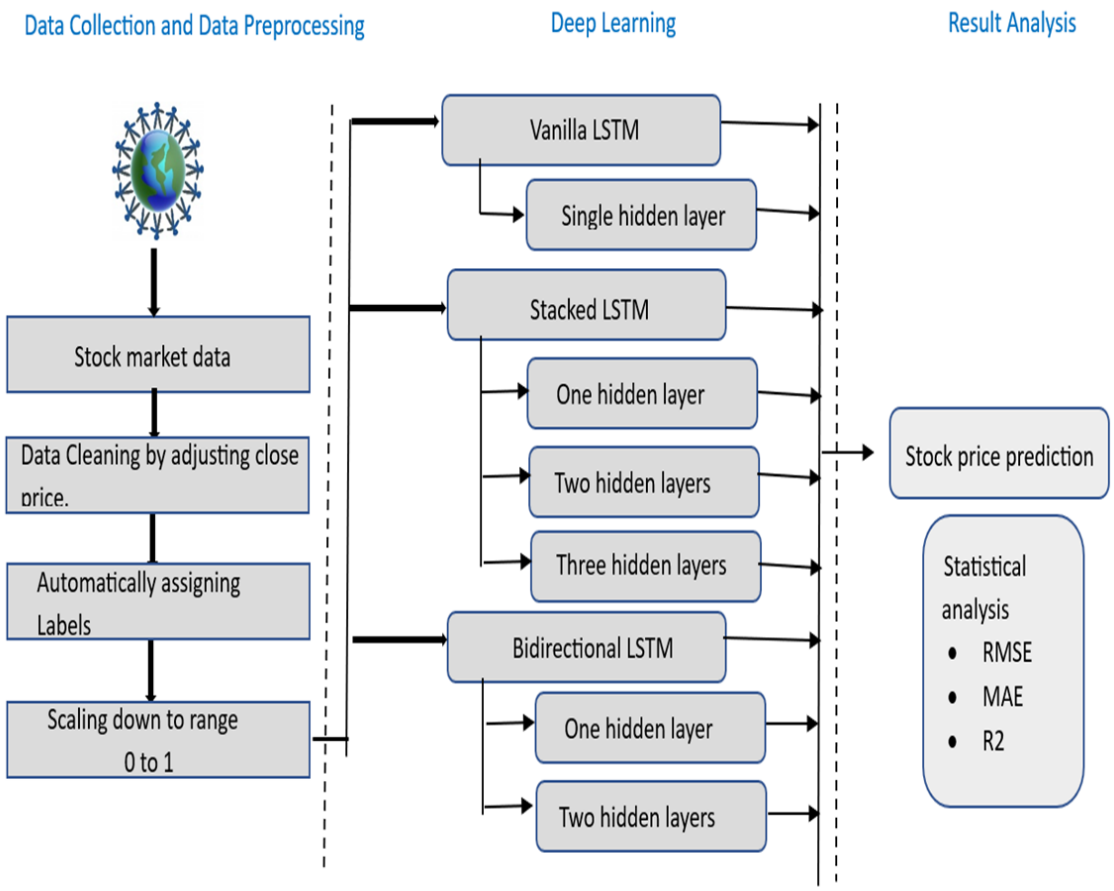

Fig. 1. The Proposed framework for stock market forecasting.

III. Experiment Setup

A. Proposed Experimental Design

As shown in Fig. 1, General architecture of the proposed method which identify step by step of our experiment: -

- Data collection.
- Data preprocessing.
- Proposed models.
- Evaluation matrices.

B. Data Sets' Collection Abbreviations and Acronyms

In the study "StockBiLSTM: Utilizing an Efficient Deep Learning Approach for Forecasting Stock Market Time Series Data," three distinct stock market datasets were employed to evaluate the performance of the LSTM models. These datasets include historical stock prices from:

1) HPQ (Hewlett-Packard Company): This dataset comprises stock prices of HP Inc., which is a multinational technology company known for developing and producing personal computers, printers, and related supplies. The dataset likely covers daily stock metrics such as opening and closing prices, highs and lows, and volume traded.

2) BNY (Bank of New York Mellon Corporation): This dataset contains stock data from BNY Mellon, a global financial services firm that offers a broad range of banking and investment services. Similar to the HPQ dataset, it includes daily trading information, capturing the financial dynamics of the banking sector.

3) PFE (Pfizer Inc.): This dataset includes stock prices from Pfizer, one of the world's largest pharmaceutical companies. The dataset provides insights into the healthcare sector's stock behavior, with daily stock performance records, including price fluctuations and trade volumes.

a) Data Characteristics and Preprocessing:

- Time Range: Each dataset spans several years of trading data, providing a robust temporal framework for training and testing the LSTM models. The specific time range for each dataset was not detailed in the initial summary but typically would cover multiple years to include various market conditions and trends.
- Data Preprocessing: Before being used for training the LSTM models, the datasets underwent several preprocessing steps:
  - Missing Values: Any gaps in the data due to market closures or other reasons were addressed, possibly

through methods like linear interpolation or carrying forward the last known value.

- Standardization: The features were standardized to have a mean of zero and a standard deviation of one or normalized to scale the data within a specific range, such as 0 to 1. This normalization helps in reducing bias and variance in the model training process.
- Feature Engineering: The datasets were likely prepared to include not just the raw numerical prices but potentially derived technical indicators such as moving averages, percentage changes, and others that help capture market sentiments and trends.
- Data Segmentation: The data was divided into training and testing sets, with a typical split providing enough data for the models to learn underlying patterns while reserving a portion for unbiased evaluation of model performance.

These datasets and their preparation play a critical role in developing predictive models, ensuring that the LSTM networks have access to high-quality, relevant data that mirrors real-world conditions under which they will be deployed. This detailed preparation helps maximize the models' efficacy, enhancing their ability to generalize well to unseen data.

To ensure diversity in our analysis, including companies from various industries or sectors is typically advantageous. HPQ (H.P. Inc) is a multinational technology corporation that develops and produces personal computers, printers, and related products. 2015 marked the separation of Hewlett-Packard Company (H.P.) into two separate entities, with H.P. Inc. concentrating on personal systems and printing products. B.K. (Bank of New York Mellon) is a financial institution called BNY Mellon. It is a global financial services firm that offers a variety of banking and investment services. BNY Mellon, one of the earliest financial institutions in the United States, operates in multiple segments, including investment management, investment services, and wealth management. The shares of BNY Mellon are traded on prominent exchanges such as the New York Stock Exchange (NYSE). PFE (Pfizer) is a multinational pharmaceutical corporation specializing in researching, developing, and producing prescription medications and vaccines. Pfizer is one of the largest pharmaceutical companies in the world, with a diverse product portfolio spanning numerous therapeutic areas, including cardiology, oncology, and immunology, among others.

This selection encompasses various industries, which can provide insight into the performance of various industries on the stock market. As shown in Fig. 1, the stock price information for these corporations was downloaded from Yahoo Finance.

Define abbreviations and acronyms the first time they are used in the text, even after they have been defined in the abstract. Abbreviations such as IEEE, SI, MKS, CGS, sc, dc, and rms do not have to be defined. Do not use abbreviations in the title or heads unless they are unavoidable.

C. Setting up the Environment

In the paper, Python 3.10.12 was used as the programming environment to conduct the experiments. To ensure the reproducibility of experiments, a virtual environment was created. These packages have been deployed within the virtual environment*:*

- TensorFlow 2.12.0
- Keras 2.12.0
- Pandas 1.5.3
- Sklearn 1.2.2
- NumPy 1.22.4
- Matplotlib 3.7.1

D. Data Preparation

The general strategy for preparing time series data before implementing time series techniques is suitable. The stages involved are as follows:

Before proceeding with analysis, resolving missing values in time series data is typical. A method for estimating missing values based on neighboring data points is linear interpolation, which fills in missing values. This interpolation helps preserve the temporal relationships between data points.

Scaling the closure price is a common preprocessing step when training neural network models such as Vanilla LSTM, Stacked LSTM, and Bidirectional LSTM. Scaling the data ensures that the input features are on a comparable scale, which can enhance the training process and the model's ability to learn. A common scaling technique is normalization, in which the data are scaled to a specific range, typically between 0 and 1. This is possible through:

$$X\_scaled = (X - X\_min) / (X\_max - X\_min) \quad (1)$$

X represents the close price, X_min represents the minimum value of the close price, and X_max represents the maximum value of the close price.

Different sets of features can be developed based on the objectives of the analysis. We mentioned univariate and multivariate feature sets in our case. The univariate feature set consists only of energy consumption information. The multivariate feature set includes price, day of the week, and month as additional features. These additional features can provide context-sensitive data that may enhance the modeling process.

The separation of data into training and test collections is essential to the effective evaluation of models. In our case, we mentioned setting aside one year and eight months of test data for evaluation. The remaining data is trained using a divide of eighty percent. This division permits us to train the models on substantial data.

Following these stages helps ensure the time series data is properly prepared for analysis and modeling, resulting in more accurate predictions and insights.

E. Data Splitting

The provided information describes the data extraction and splitting process for training and testing a set of neural network models (Vanilla LSTM, Stacked LSTM, and Bidirectional LSTM) using stock price data from three companies for 2011 days (about five and a half years) between 03-01-2012 and 30-12-2019, which is over eight years of data. A ratio of 80:20 was applied to training and testing data, resulting in 403 days (about one year) of testing.

IV. METHODOLOGY

A. Vanilla LSTM (Long Short-Term Memory)

Vanilla LSTM (Long Short-Term Memory) refers to a standard or fundamental implementation of the LSTM architecture, a form of recurrent neural network (RNN). LSTM networks are designed to resolve the vanishing gradient problem in conventional RNNs, allowing for more accurate modeling of long-term dependencies in sequential data. With a single layer of concealed LSTM units trained to predict future stock prices based on historical data.

The Vanilla LSTM architecture comprises LSTM cells, which are recurrent units capable of processing sequential data over time. Each LSTM cell possesses a collection of internal states, including a cell state (also known as the memory) and a concealed state. The cell state permits LSTMs to detect long-term dependencies by selectively storing and updating information.

During training, the Vanilla LSTM learns to modify the gate weights and biases via backpropagation and gradient descent. This enables it to capture relevant information and forget irrelevant information across multiple time steps.

B. Stacked LSTM (Long Short-Term Memory)

Stacked LSTM is a type of Long Short-Term Memory (LSTM) architecture in which multiple LSTM layers are layered atop one another to create a deep recurrent neural network (RNN). Each LSTM layer in the stack processes the input sequence sequentially, passing the concealed state to the following layer as its input.

Like stacking numerous feedforward layers in a deep neural network, the concept of stacking LSTM layers is analogous. By increasing the depth of the network, stacked LSTMs can learn more complex representations and incorporate higher-level abstractions from sequential data.

In a stacked LSTM architecture, the output of one LSTM layer functions as the input to the subsequent LSTM layer. The first layer receives the initial input sequence, and subsequent layers process the concealed states of the previous layer. Depending on the specific assignment, the final output can be extracted from the final LSTM layer, fed into additional layers, or output units.

The advantage of using stacked LSTM over a single-layer LSTM is that it can potentially capture more complex temporal dependencies in the input sequence. Each layer can discover unique patterns and contribute to a more evocative representation of the input data. Stacking multiple LSTM layers permits the network to learn hierarchical representations of the input sequence, with lower layers representing local dependencies and higher layers representing more global dependencies.

C. Bidirectional LSTM (Long Short-Term Memory)

Bidirectional long-short-term memory (BiLSTM) is a technique that enables neural networks to store sequence data in both directions, either backward or forward. Bidirectional input distinguishes the BiLSTM from the conventional LSTM. We can have input flow in both directions, allowing us to store past and future data at any given time step. Normal LSTMs permit input transmission in only one direction (forward or backward).

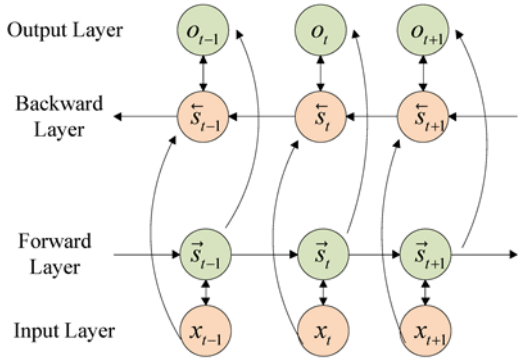

Fig. 2. Structure fundamental of bidirectional LSTM [21].

Fig. 2 demonstrates that the forward layer computes the forward direction from one to t and stores the forward hidden layer's output at each instant. The backward layer calculates the reverse time series and stores the backward concealed layer's output at each instant. Finally, the bidirectional LSTM neural network output is computed by combining the forward layer and reverse layer output results at each time point. The notation for the bidirectional LSTM neural network is:

$$st=(Uxt+Wst-1) \quad (2)$$

$$s'\ t=(U'\ xt+W'\ s'\ t+1) \quad (3)$$

$$ot=(Vst+V'\ st) \quad (4)$$

where, xt is the input vector, g, and f are activation functions, V, W, and U are the weight matrix from the hidden layer to the output layer, the hidden layer, and the input layer to the hidden layer, and V', W', and U' are the corresponding reverse weight matrix. The state weight matrices of the forward and reverse layers are not shared information. The forward and backward layers are calculated sequentially, and their results are returned. The final output ot is determined by adding the forward calculation result st and the reverse calculation result s' t.

D. Model Hyper-parameters Tuning

Fig. 3 illustrates a typical development cycle for neural networks, emphasizing the significance of efficient development to accommodate lengthy training periods for large neural networks. Exploring hyperparameter tuning and identifying a suitable initial starting point are crucial for accelerating the process and facilitating quicker development.

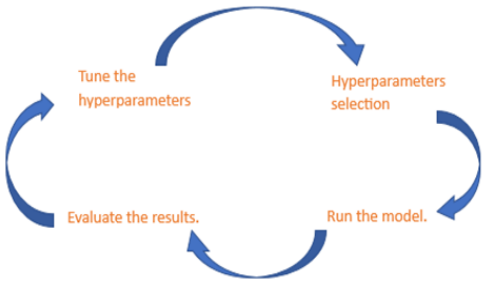

Fig. 3. Model Hyper-parameters tuning.

E. Model Evaluation

In this paper, the mean absolute error (MAE), root mean square error (RMSE), and coefficient of determination (R2) are used to assess the prediction error. R2, RMSE, and MAE are common indicators used to evaluate the accuracy of a model based on the measurement value and estimated value. The indicators are defined by Eq. (5) through Eq. (7). The approximated indicator used as the measurement value is the MAE. The root-mean-squared error (RMSE) is used to evaluate the deviation between the observed and true values; it is sensitive to outliers. R2 is utilized to evaluate the proportion of the dependent variable's variance.

$$RMSE=1/n\sum i=1n|xi-\hat{x}i|2 \quad (5)$$

$$MAE=1/n\sum i=1n|xi-\hat{x}i| \quad (6)$$

$$R^2=1-SSR/SST \quad (7)$$

where, n represents the number of sample data, xi represents the actual value, and $\hat{x}i$ represents the predicted value. SSR represents the variation in the dependent variable that can't be explained. SST is the entire variance of the dependent variable.

V. Empirical Research

Experiment 1: Involves feeding data of HPQ company in stages to Vanilla LSTM using (Adam and RMSprop) optimizers; after hyper-parameter tuning, the batch size is determined to be two, and the epoch is defined as fifteen. For Stacked LSTM using (Adam and RMSprop) optimizers, the batch size is three, and the epoch is defined as seventeen. For Bidirectional LSTM using (Adam and RMSprop) optimizers, the batch size is determined to be one, and the epoch is defined as fifteen.

Experiment 2: Involves feeding data of New York bank in stages to Vanilla LSTM using (Adam and RMSprop) optimizers; after hyper-parameter tuning, the batch size is determined to be two, and the epoch is defined as fifteen. For Stacked LSTM using (Adam and RMSprop) optimizers, the batch size is three, and the epoch is defined as seventeen. For Bidirectional LSTM using (Adam and RMSprop) optimizers, the batch size is determined to be two, and the epoch is defined as fifteen.

Experiment 3: Involves feeding data of Pfizer company in stages to Vanilla LSTM using (Adam and RMSprop) optimizers; after hyper-parameter tuning, the batch size is determined to be two, and the epoch is defined as fifteen. For Stacked LSTM using (Adam and RMSprop) optimizers, the batch size is one, and the epoch is defined as fifteen. For Bidirectional LSTM using (Adam and RMSprop) optimizers, the batch size is determined to be one, and the epoch is defined as fifteen.

VI. Results and Discussion

A. HPQ (Hewlett-Packard Company)

1) Model Performance: The Bidirectional LSTM (BiLSTM) model, particularly when optimized with the RMSprop optimizer, achieved superior results compared to other models. This was quantified using RMSE, MAE, and R^2 metrics, where the BiLSTM model showed lower error rates and a higher coefficient of determination.

2) Discussion: The superior performance of the BiLSTM model on the HPQ dataset (see Fig. 4) suggests that the bidirectional nature of the model, which captures both past and future dependencies, is particularly suited for technology stocks like HPQ. These stocks might exhibit patterns that are influenced by a broader range of temporal dynamics due to technology product release cycles and market competition.

B. BNY (Bank of New York Mellon Corporation)

1) Model Performance: Similar to the HPQ dataset, the BiLSTM model optimized with RMSprop showed excellent performance (see Fig. 5). However, it's notable that the Stacked LSTM also performed robustly but slightly less effectively than the BiLSTM.

2) Discussion: The effectiveness of LSTM models on the BNY dataset indicates their capability in modeling financial sector stocks, which may be influenced by different factors such as interest rates, regulatory changes, and economic indicators. The slight edge of BiLSTM could be attributed to its ability to utilize forward and backward data flows, which may be significant in the financial sector where past and upcoming economic events heavily influence stock prices.

C. PFE (Pfizer Inc.)

1) Model Performance: The dataset for Pfizer showed that while all LSTM variants performed well, the BiLSTM with RMSprop again stood out, particularly regarding the RMSE and MAE metrics. This dataset also revealed a higher R^2 score for the BiLSTM model, indicating a strong ability to explain the variance in stock prices through the model.

2) Discussion: The strong performance of LSTM models on the Pfizer dataset (see Fig. 6) could be related to the pharmaceutical industry's sensitivity to news and events such as drug approval processes, clinical trials, and regulatory decisions. The bidirectional approach of the BiLSTM may help capture these influences more comprehensively, as it accounts for both historical trends and anticipations of future events, which are crucial in the pharmaceutical industry.

D. Overall Insights

1) General Trends: Across all datasets, the BiLSTM model generally outperformed Vanilla and Stacked LSTMs,

suggesting that incorporating forward and backward information flows offers a significant advantage in stock price prediction.

2) Hyperparameters and Optimization: The choice of RMSprop as an optimizer was validated as it consistently supported the models in achieving lower prediction errors. This might suggest that RMSprop's approach to adjusting the learning rate could be particularly effective in dealing with the noisy and non-stationary data typical of stock markets.

3) Implications for Stock Market Forecasting: The results underscore the potential of advanced LSTM architectures in financial forecasting, highlighting their adaptability and robustness across different sectors of the economy. This has practical implications for traders and analysts seeking to leverage machine learning for investment decisions.

These discussions reveal that while LSTM models are generally robust in handling stock price data, the specific characteristics of the BiLSTM architecture make it especially powerful in capturing the complex, dual-influenced trends common in stock market data. Further research could expand on these findings by exploring additional LSTM modifications or incorporating more complex features and external data sources to enhance predictive accuracy.

On the test dataset, predictions were generated using Vanilla, Stacked, and Bidirectional LSTM with two distinct optimizers (Adam and RMSprob). The results of Experiment 1 are presented in Table II, the results of Experiment 2 are presented in Table III, and the results of Experiment 3 are presented in Table IV, along with the evaluation metrics root mean squared error (RMSE), mean absolute error (MAE), and coefficient of determination (R2).

Regarding to HPQ data set, it is shown that the superiority of Bi LSTM over the remaining algorithms using RMSprop optimizer. Also, it is shown that the worst result using the same optimized is Stacked LSTM, the Same as New York Bank and Pfizer company data sets.

The study "StockBiLSTM: Utilizing an Efficient Deep Learning Approach for Forecasting Stock Market Time Series Data" provided insights into the performance of LSTM models across three different datasets: HPQ (Hewlett-Packard Company), BNY (Bank of New York Mellon Corporation), and PFE (Pfizer Inc.). Here's a detailed discussion of the results for each dataset:

The following graphs illustrate the comparison between predicted and actual data for HPQ company. It is shown in Fig. 4.

$$a + b = \gamma \tag{7}$$

The following graphs illustrate the comparison between predicted and actual data for New York bank. It is shown in Fig. 5.

The following graphs illustrate the comparison between predicted and actual data for Pfizer company. It is shown in Fig. 6.

VII. CONCLUSION

This study has successfully demonstrated the efficacy of a single-layered Bidirectional Long Short-Term Memory (BiLSTM) model enhanced with a global pooling mechanism for forecasting stock market prices. Our comparative analysis of the Vanilla, Stacked, and Bidirectional LSTM architectures revealed that the Bidirectional LSTM consistently outperformed the other variants across multiple datasets, particularly when optimized with the RMSprop algorithm. This superior performance is attributed to the BiLSTM's ability to effectively capture both past and future dependencies within the time series data, a critical factor in the volatile environment of stock markets. Rigorous hyperparameter tuning and multiple evaluation metrics like RMSE, MAE, and R^2 have allowed for a thorough validation of the models, ensuring robustness and accuracy in predictions. The visualization of results through line graphs and candlestick charts further corroborates the practical utility of the proposed model in capturing dynamic market trends.

Looking forward, several avenues can enhance the scope and applicability of this research in stock market forecasting. First, integrating a larger variety of data inputs, such as economic indicators, news sentiment analysis, or macroeconomic factors, could provide a more holistic view of the influences on stock prices, potentially increasing the predictive accuracy of the models. Second, exploring incorporating more sophisticated deep learning techniques like attention mechanisms or Transformer models could address some limitations of LSTM models, especially in handling longer sequences with more complex patterns. Third, conducting cross-industry validations with datasets from different sectors and global markets would test the generalizability of the proposed model, ensuring its applicability across diverse economic conditions. Lastly, real-time forecasting implementation in trading systems could be explored to assess the models' practical deployment and operational efficiency in live market conditions. These expansions would enhance the scientific understanding of neural networks in financial applications and bridge the gap between theoretical research and real-world financial decision-making.

***Abstract*—Magnetic Resonance Imaging (MRI) plays a crucial role in diagnosing brain disorders, with stroke being a significant category among them. Recent studies emphasize the importance of swift treatment for stroke, known as "time is brain," as early intervention within six hours of stroke onset can save lives and improve outcomes. However, the conventional manual diagnosis of brain stroke by neuroradiologists is subjective and time-consuming. To address this issue, this study presents an automatic technique for diagnosing and segmenting brain stroke from MRI images according to pre and post stroke patient. The technique utilizes machine learning methods, focusing on Susceptibility Weighted Imaging (SWI) sequences. The machine learning technique involves four stage, those are pre-processing, segmentation, feature extraction, and classification. In this paper, preprocessing and segmentation are proposed to identify the stroke region. The segmentation performance is assessed using Jaccard indices, Dice Coefficient, false positive, and false negative rates. The results show that adaptive threshold performs best for stroke lesion segmentation, with good improvement stroke patient that achieving the highest Dice coefficient of 0.96. In conclusion, this proposed stroke segmentation technique has promising potential for diagnosing early brain stroke, providing an efficient and automated approach to aid medical professionals in timely and accurate diagnoses.**

Keywords*—Magnetic Resonance Imaging (MRI) diagnosis, time is brain, Susceptibility Weighted Imaging (SWI) and dice coefficient

I. INTRODUCTION

Cerebrovascular accident (CVA) or stroke stands as the third leading cause of death in Malaysia [1]. This presents a significant challenge to the Malaysian healthcare system, witnessing over 50,000 new cases annually, resulting in at least 32 daily fatalities. In 2016, the government committed RM180 million to address this issue. Globally, stroke is the second leading cause of death, surpassed only by coronary artery disease, and it ranks prominently in causing long-term disability. The Malaysian National Stroke Association (NASAM) underscores the urgency of immediate medical attention for stroke, as swift treatment, especially within six hours, has been shown to save lives. However, the scarcity of neuroradiologists, with only 107 specialists, and the reliance on manual interpretation of magnetic resonance imaging (MRI) images hinder timely treatment efforts.

Brain stroke, characterized by a network of small blood vessels facilitating blood flow through a stroke or blocked artery, requires rapid and accurate diagnosis for prompt intervention. While MRI has gained preference over conventional angiography for diagnosing brain stroke, the current practice involves labor-intensive visual inspection, delaying the process [2]. Timely diagnosis and treatment are critical to preventing disability caused by insufficient blood and oxygen, leading to nerve cell death. Diagnostic considerations include factors like infarct volume, penumbra size, and the presence of adequate early stroke, all crucial for successful treatment [3]. Neuroradiologists urgently need efficient tools for quick and accurate acute stroke diagnosis.

Moreover, brain stroke detection from MRI images faces challenges due to noise, artifacts, vessel size, and structural heterogeneity [4]. Novel methods for segmenting and classifying medical images are regularly proposed [5]. Common machine learning techniques for vessel segmentation, such as region growing, clustering, and active contours, face limitations related to sensitivity to noise and segmentation issues [6]. The manual segmentation by neuroradiologists, though time-consuming, highlights the importance of processing time speed and accuracy in computer-aided diagnostic systems [7].

Traditional machine learning methods, while effective, require complex denoising and feature extraction before classification, leading to prolonged computation times [8]. Recent studies acknowledge the robustness of machine learning in processing noisy medical images, yet the challenges of long computation times persist [9]. As a solution, hybrid frameworks incorporating machine learning techniques are considered promising for achieving optimal accuracy in early stroke classification.

This review explores the significance of stroke, brain stroke concepts, and MRI in the context of the human brain. Stroke, or cerebral infarction, ranks as the third leading cause of death and the primary cause of permanent disability in Malaysia [10]. The profound public health impact is evident in high initial treatment, rehabilitation, and chronic care costs. The urgency of stroke is highlighted by its occurrence every 45 seconds in the United States, affecting 795,000 individuals annually. The devastating impact on neurons and synapses during a stroke, leading to accelerated aging of the ischemic brain, underscores

the critical notion that "time is the brain." Despite this urgency, there is a notable absence of computer-aided diagnosis (CAD) systems tailored for stroke, unlike those available for fields like mammography and breast imaging. Existing studies on CAD systems and methodologies emphasize their potential to enhance diagnostic precision for radiologists [11].

II. Literature Review

A. Human Brain

The human brain stands out as one of the most intricate organs in the human body, comprising billions of interconnected nerve cells forming complex networks. Its spatiotemporal patterns contribute to its recognition as the most intricate system, wherein the alignment between structural and functional connections relies on spatial resolution and temporal scale [7]. Endowed with the capacity to govern intelligence, creativity, emotions, and memory, the brain is shielded by the skull and comprises the cerebrum, cerebellum, and brainstem, as illustrated in Fig. 1. Further division into lobes reveals specific responsibilities:

1) The frontal lobe manages problem-solving, decision-making, and motor skills.

2) The parietal lobe oversees sensation, handwriting, and posture.

3) The temporal lobe plays a role in memory and hearing.

4) The occipital lobe houses the brain's visual processing system.

Facilitating communication with the body, the brain utilizes 12 pairs of cerebrovascular vessels through the spinal cord and blood flow. Among these, ten pairs originating in the brainstem control functions like hearing, eye movements, facial sensations, taste, swallowing, and muscle movements in the face, neck, shoulders, and tongue. Meanwhile, cerebral blood vessels governing smell and vision originate in the cerebrum. Hence, maintaining proper blood circulation in vessels is crucial to prevent neuropathy, which could lead to nerve cell damage and subsequent cell death [8]. Refer to Fig. 1, for a visual representation of the human brain's anatomy.

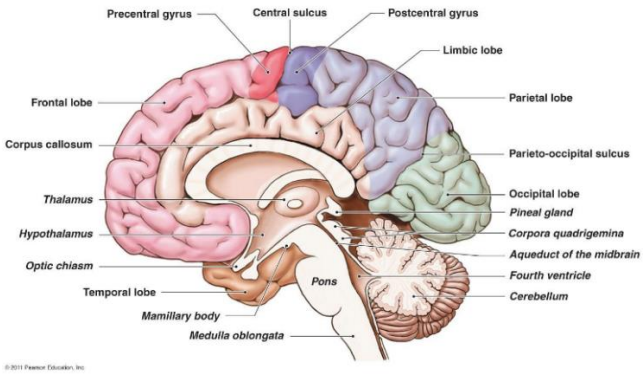

Fig. 1. Anatomy of human brain.

B. Brain Stroke Diagnosis

In this universe, second-leading cause of death is stroke, demanding prompt intervention to prevent severe long-term disability or fatality. This occurs when a blood clot obstructs a blood vessel or ruptures, impeding blood flow to a specific brain region. The classification, depicted in Fig. 2, distinguishes between ischemic stroke, where a blood vessel abruptly obstructs a brain artery [1], and hemorrhagic stroke (cerebral hemorrhage), characterized by the rupture of a blood vessel [2].

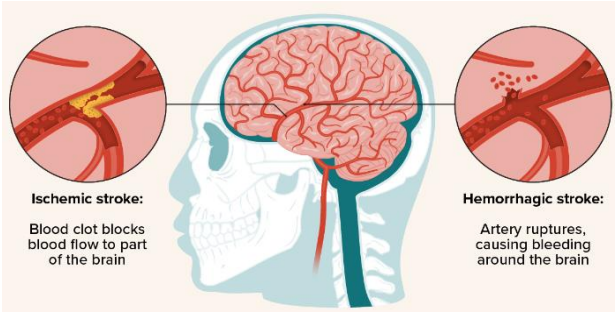

Fig. 2. Types of stroke.

Stroke exerts a significant impact on public health, resulting in substantial expenditures for primary care, rehabilitation, and the management of chronic conditions. In 2015, stroke accounted for 6.3 million deaths globally, ranking as the second leading cause of death after ischemic heart disease. Despite its persistent status as the third leading cause of death in Malaysia as reported by the Institute for Health Metrics and Evaluation in June 2019, there is a notable absence of computer-aided diagnosis (CAD) systems designed specifically for stroke, unlike the numerous CAD systems available for fields such as mammography and thorax. Research on CAD systems and techniques underscores the potential for enhancing the diagnostic accuracy of radiologists.

Reperfusion injury plays a pivotal role in the outcomes of ischemic stroke patients upon the restoration of blood flow [3]. Various approaches, including ischemic preconditioning, perconditioning, and postconditioning, have been explored for cardio protection, yielding diverse results regarding potential treatments [4]. The timely reinstatement of local blood flow is crucial for salvaging threatened tissue, minimizing cell death, and ultimately reducing patient disability. Successful recanalization significantly increases the likelihood of a favorable outcome, with a fourfold reduction in mortality compared to patients without recanalization [5]. Strategies for recanalization involve thrombolytic drugs such as tissue plasminogen activator (tPA) and/or mechanical interventions like thrombectomy using distal or proximal devices. Thrombectomy, involving the removal of blood clots through a catheter with an attached mechanical device, is particularly attractive due to its short intervention time, high recanalization rates, and potential for efficient blood flow restoration. However, the associated risks necessitate careful consideration, and the procedure should be reserved for patients meeting specific criteria, including a large circumference, small infarct, and good collateral circulation. In essence, precise patient selection based on pre-treatment imaging is crucial for achieving favorable outcomes with mechanical recanalization [6].

C. Magnetic Resonance Imaging (MRI)

Magnetic Resonance Imaging (MRI) is a medical imaging technique that uses strong magnetic fields and radio waves to

generate detailed images of the body's internal structures. MRI is commonly used in the early diagnosis of strokes and plays a crucial role in assessing the extent and location of the stroke, determining the appropriate treatment, and monitoring the patient's progress. When it comes to early stroke diagnosis, MRI provides several advantages over other imaging techniques. Here's how it works:-

1) Visualization of brain anatomy: MRI produces high-resolution images that can accurately depict the brain's anatomy, allowing healthcare professionals to identify any abnormalities or changes associated with a stroke. It provides detailed information about the brain's structure, including differentiating between gray and white matter, which is essential for detecting ischemic (clot-based) or hemorrhagic (bleeding-based) strokes.

2) Differentiating stroke types: MRI can help differentiate between ischemic and hemorrhagic strokes, which is crucial for determining the appropriate treatment approach. Ischemic strokes occur due to a blockage in a blood vessel, while hemorrhagic strokes result from bleeding in the brain. By examining the MRI images, doctors can identify the type and location of the stroke.

3) Time-sensitive techniques: Certain MRI techniques are time-sensitive and can detect changes in brain tissue that occur shortly after a stroke. Susceptibility-Weighted Imaging (SWI) is particularly useful in the early stages of stroke diagnosis. It measures the movement of water molecules in the brain and can detect restricted diffusion in areas affected by an ischemic stroke within minutes of onset. This early identification helps guide treatment decisions promptly.

4) Assessment of perfusion: Perfusion-weighted imaging (PWI) is another MRI technique that provides information about blood flow to the brain. PWI helps assess the extent of damaged brain tissue and determine the viability of the surrounding areas. By comparing SWI and PWI, healthcare professionals can identify the ischemic penumbra, which refers to the region around the stroke where brain tissue is at risk but still salvageable. This information aids in treatment planning.

5) Detection of complications: MRI can also identify complications associated with strokes, such as swelling, edema, or the presence of blood in the brain. These factors are crucial in determining the severity of the stroke, guiding treatment decisions, and assessing the patient's prognosis.

Overall, MRI is a valuable tool in the early diagnosis of brain strokes. Its ability to provide detailed images of the brain's anatomy, differentiate between stroke types, detect early changes in brain tissue, assess perfusion, and identify complications makes it an essential imaging technique in stroke management. It enables healthcare professionals to make informed decisions regarding treatment options and improve patient outcomes.

Two types of stroke, namely hemorrhagic and ischemic, are distinguished based on interpretation [12]. Ischemic strokes constitute approximately 70% of all cases, presenting with neurological deficits that endure for more than 24 hours or result in death within that timeframe [13]. Hemorrhagic strokes, accounting for about 12% of all strokes, are further divided into 9% intracerebral hemorrhages and 3% subarachnoid hemorrhages. Hemorrhagic strokes occur due to the rupture of a cerebral blood vessel or an abnormality in a blood vessel, causing bleeding into adjacent brain tissue. This leads to impairment of brain function and often results in death rather than permanent disability. In contrast, ischemic strokes, caused by the blockage of blood vessels supplying the brain, are more prevalent.

Within the Oxfordshire Community Stroke Project [14], instances of stroke are categorized into four groups by considering the initial symptoms and their severity. This classification aims to anticipate the extent of the stroke, the affected brain regions, underlying causes, and the prognosis. The four groups include total anterior circulation stroke syndrome (TACS), partial anterior circulation stroke syndrome (PACS), lacunar stroke syndrome (LACS), and posterior circulation stroke syndrome (POCS). The most common type of LACS is caused by blockage of small arteries that supply deep brain structures. Patients usually suffer from pure motor or sensory deficits, sensorimotor deficits, or ataxic hemiplegia [15]. TACS occurs when the blood supply to the anterior and middle cerebral arteries on both sides of the brain is compromised, causing hemiplegia. PACS is a less severe form of TACS that exhibits some, but not all, of the symptoms associated with TACS. POCS is caused by a reduced blood supply to the posterior cerebral artery on one side of the brain [16]. Fig. 3 shows the MRI machine used for scanning.

Fig. 3. MRI machine used for scanning.

III. METHODOLOGY

The flowchart for MRI image analysis using machine learning is shown in Fig. 4. All techniques, including image pre-processing, picture segmentation and features extraction are included in the flow chart.

A. Pre-processing Stage (Normalization, Background Removal and Enhancement)

Suitable pre-processing will be identified to enhance and remove the noise. Image normalization, background removal and enhancement will be included (Shakunthala and Helenprabha, 2019). Mathematical methods known as "image enhancement techniques" are designed to increase the quality of a particular image, either for usage by a human viewer or for computer processing.

The kind of intensity depth must be transformed to double precision throughout the normalisation process, with the minimum value set to "0" and the maximum value set to "1". To make the computation of the algorithm simpler, this

procedure is necessary. Eq. (1), where N is the bit depth applied to the normalisation computation, states the equation.

$$I(x,y)_{normalization} = \frac{I(x,y)}{2^N - 1}, N = bits \quad (1)$$

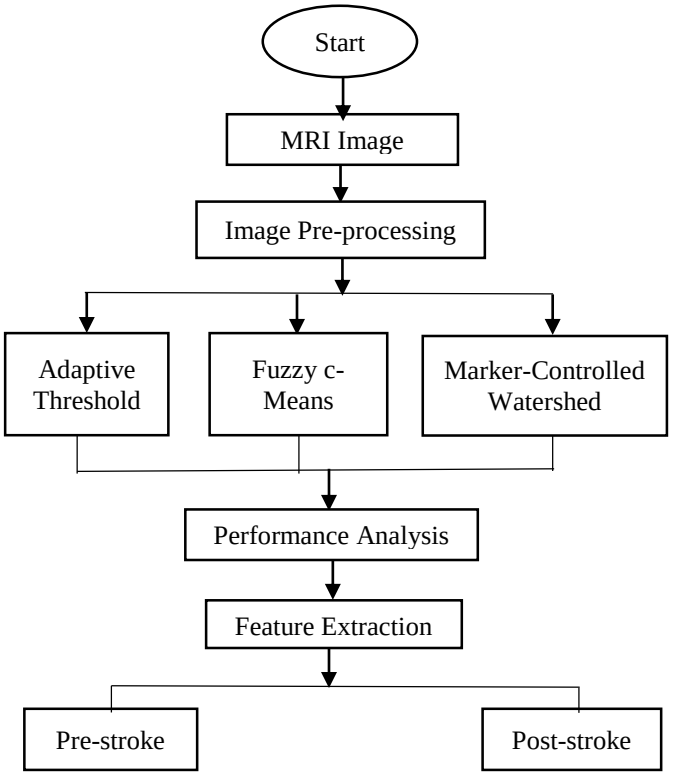

Fig. 4. Flow chart of MRI image analysis using machine learning technique.

Background pixels in MRI images need to be eliminated. This is due to the fact that specific brain structures and the background have similar intensities. Adaptive thresholding and morphological techniques can be used to achieve this. The threshold version's binary image output is its ultimate product. In order to trace the closed regions and their boundaries of connected neighbourhoods, boundary extraction algorithms are required. Enhancement techniques can be used to expand the intensity and improve the contrast. Several techniques can be implemented such as gamma-law and contrast stretching algorithms.

B. Segmentation using Machine Learning Techniques

Image segmentation is crucial because radiologists need to know the accurate location, size, intensity and other lesion's details to make a conclusion or diagnosis. The segmentation involves detecting and labelling meaningful regions in the given image data. Three types of image segmentation technique will be analyzed which are Adaptive Threshold, Fuzzy C-Means and Marker-Controlled Watershed.

1) Adaptive threshold: An adaptive threshold is a segmentation technique that creates a binary picture from a grayscale image of a fixed value. Thresholding is the technique of converting a grayscale image into a black and white image by turning all of the pixels to either white or black depending on whether their value is above or below a specified threshold [17]. Eq. (2) illustrates adaptive threshold, which determines each pixel's threshold value by referring to the gray-level intensity of its neighbours.

$$G(x,y) = \begin{cases} 1 & if\ I(x,y) \geq \tau \\ 0 & otherwise \end{cases} \quad (2)$$

2) Fuzzy C-Means: Fuzzy C-Means (FCM) is one of the popular algorithm in clustering [18]. Data that belong to two or more clusters with various membership coefficients can be processed iteratively in this way. After creating the initial fuzzy partition matrix, the initial fuzzy cluster centres are computed. In order to determine where the clusters should be placed, the objective function is minimised while the cluster centres and membership grade point are updated at each iteration's step. When the maximum number of iterations is reached or when the improvement in the objective function between two successive iterations is less than the minimum amount of improvement required, the procedure comes to an end [19].

The iteration of FCM is performed through two parameters, namely the membership degree and the center of the cluster. When the repeated steps come to an end or reach their maximum number of iterations, these parameters are altered [20]. Additionally, when the objective function improvements of two successive iterations are less than the minimum amount of improvement set, the change of these parameters is affected. The low, medium, and high clusters are the starting points for the Fuzzy C-Means technique used in this segmentation [21]. The centre of each cluster will be used to determine the data point. The cluster's data points should all equal one. The algorithm relies on minimising the objective function presented below.

$$Jm = \sum_{i=1}^{N} \sum_{j=1}^{C} u_{ij}^{m} \left\| x_i - c_j \right\|^2, 1 \leq m \leq \infty \quad (3)$$

where, uij represents the membership degree of data point xi in cluster j, where xi is the d-dimensional center of the ith cluster, cj is the d-dimensional center of the cluster, and |*| is a norm indicating the similarity between measured data and the center. The term M, referred to as the fuzziness exponent, is any number greater than 1.

3) Marker-Controlled watershed: A gradient-based segmentation method is called watershed segmentation. According to this study's findings, the watershed segmentation identifies the water basins and watershed ridge lines by classifying each pixel's intensity as either high intensity or low intensity on a surface [22]. The gradient magnitude is calculated using the image foreground and background markers and the edge detection technique. The watershed ridge line and morphological operation are then used [23]. Based on the provided watershed ridge lines, the watershed transform is created. The input image I(x,y) and the gradient along x and y-axis are calculated according to Eq. (4).

$$I_x = \frac{\delta f}{\delta x} = (z_7 + 2z_8 + z_9) - (z_1 + 2z_2 + z_3)$$
$$I_y = \frac{\delta f}{\delta y} = (z_3 + 2z_6 + z_9) - (z_1 + 2z_4 + z_7) \quad (4)$$

Then the gradient of the image is defined as:

$$\nabla I(x, y) = \frac{\delta f}{\delta x} i + \frac{\delta f}{\delta y} j = I_x i + I_y j \quad (5)$$

where, i and j are unit vectors along x and y axis respectively. The magnitude of gradient is given by:

$$g(x, y) = |\nabla f(x, y)| = \sqrt{g_x{}^2 + g_y{}^2} \quad (6)$$

The image may have an excessive amount of gradient segmentation as a result of noise and other irregularities [24]. Thus to overcome the problem, morphological operation technique can be implemented.

C. Features Extraction

A collection of features are extracted from each image based on the segmentation technique. Meaningful characteristics must be developed before they can be used as input in the classification process [25]. These properties may be based on spectral, textural, or statistical examination of an image's grey level. To complete the diagnosis, other general features like signal intensity are needed [26]. All the features that radiologists discovered when examining the brain scans are listed in Table IV. Table I provides a list of the feature extractions that reflect nearby stroke area regions.

TABLE I. LIST OF FEATURES EXTRACTION RESULTS AND DISCUSSIONS

(a) Medical diagnosis	(b) Features extracted
Structural elements: -	Statistical features in spatial domain: -
1. Number of lesions	1. Intensity
2. Shape	2. Mean
3. Location	3. Median
4. Elements within the lesion	4. Standard deviation
5. Internal and external capsules	5. Perimeter
6. Midline shift, distended and swell	6. Gradient value
7. Symmetric	7. Entropy
Lesion's characteristics: -	8. skewness
8. Intensity	9. Euclidian distance
9. Region's area	10. Texture analysis
10. Region's diameter	Shape, boundary, contour, location: -
11. Mean	11. Area
12. Standard deviation	12. Perimeter
13. Compactness	13. Compactness
14. Density	14. Mean of region boundary
15. Volume	15. Volume
16. Contrast	16. Density
	17. Invariant and boundary moment

A. Performance Evaluation

The segmentation results obtained from the proposed technique will be compared with the manual reference segmentation performed by neuroradiologists. Similarity indices based on Jaccard's and then the accuracy is obtained by finding the percentage of the number of correctly classified samples. Dice will be calculated to measure the accuracy of the segmentation for the pair of segmented and reference image.

IV. RESULTS AND DISCUSSIONS

A. Image Pre-processing

Fig. 5 displays an image portraying a stroke brain lesion characterized by hyperintensity. The maximum pixel intensity in the image is 205, and the pixels are in a 9-bit format. Based on analysis, the image underwent preprocessing using three methods: normalization, background removal, and enhancement through power-law transformation.

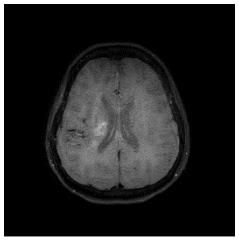

Fig. 5. Original image.

In Fig. 6, the image has undergone normalization to a 10-bit format, along with its corresponding histogram. The highest normalized intensity is recorded as 0.76908. Following the normalization process, a background removal procedure is employed to eliminate pixels, enhancing the clarity of the lesion in the image.

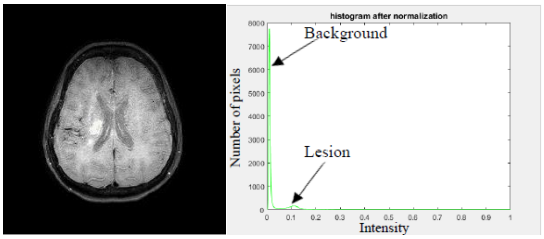

Fig. 6. Image normalization with its histogram.

In Fig. 7, background pixels have been eliminated through thresholding at 0.0563, with the highest peak observed at an intensity level of 0.1196.

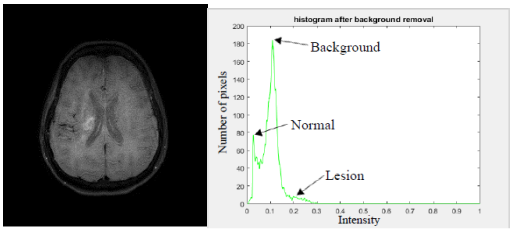

Fig. 7. Image background removal with its histogram.

Fig. 8 illustrates the result following the implementation of a power-law transformation. The peak intensity is situated at 0.6892. Analyzing the histogram, it is evident that the power-law transformation has elevated the normalized intensity to 0.3556. Simultaneously, the lesion has expanded to an intensity

level of 0.8, as indicated by arrows. The maximum intensity achieved through the gamma-law transformation is 0.7901.

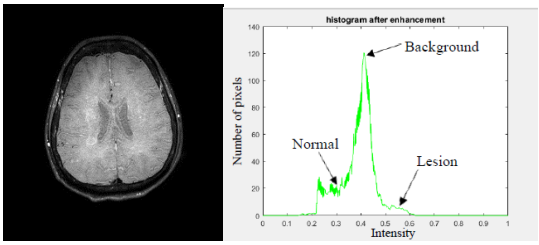

Fig. 8. Image enhancement with its histogram.

B. Image Segmentation

An automated segmentation method has been devised for segmenting Regions of Interest (ROIs) within SWI images, utilizing adaptive threshold, marker-controlled watershed with correlation template, and FCM with active contour. Each segmentation outcome is subsequently compared with a manual reference. This process pertains to the segmentation of both hyperintense and hypointense lesions in SWI images.

1) Adaptive Threshold

TABLE II. THE SEGMENTATION RESULTS OF THE SWI STROKE LESION FROM THE ORIGINAL IMAGE USING ADAPTIVE THRESHOLD SEGMENTATION TECHNIQUE

Type of Stroke patient	Pre/ Post Stroke	SWI Original Image	Brain Segmentation	Segmented Lesion Area
Poor Improvement Patient	Pre Stroke				Post Stroke			
Moderate Improvement Patient	Pre Stroke			
	Post Stroke			
Good Improvement Patient	Pre Stroke				Post Stroke			
According to the data presented in Table II, the segmentation outcomes indicate that the adaptive threshold technique is effective in delineating hyperintense lesions. However, it faces challenges in segmenting hypointense lesions due to the presence of shadow pixels, which are uncertain with the assigned threshold value from this segmentation method. The technique struggles to segment overlapping pixels resulting from noise or intensity variation in the SWI image.

2) Fuzzy c-means (FCM) with active contour: FCM is a clustering method designed to group objects with similar characteristics. This technique is combined with active contour to eliminate CSF regions by establishing boundaries within the SWI image. Computer-generated curves are employed to identify and pinpoint the Regions of Interest (ROIs). The segmentation outcomes for the stroke lesion from the original image are presented in Table III.

TABLE III. THE SEGMENTATION RESULTS OF THE SWI STROKE LESION FROM THE ORIGINAL IMAGE USING FCM WITH ACTIVE CONTOUR SEGMENTATION TECHNIQUE

Type of Stroke patient	Pre/ Post Stroke	SWI Original Image	Brain Segmentation	Segmented Lesion Area
Poor Improvement Patient	Pre Stroke			
	Post Stroke			
Moderate Improvement Patient	Pre Stroke			
	Post Stroke			Good Improvement Patient	Pre Stroke				Post Stroke			

According to Table III, the segmentation outcomes reveal that the FCM segmentation method, when combined with active contour, yields favorable results for both hyperintense

and hypointense lesions in the Regions of Interest (ROIs). However, in FCM, the presence of noise in SWI isn't factored in, making the technique susceptible to noise. To address this issue, additional refinement is applied using active contour segmentation to eliminate cerebrospinal fluid (CSF) and small pixels.

3) Marker-controlled watershed: Marker-controlled watershed segmentation is a segmentation method based on gradients. It is combined with a correlation template that utilizes a matching template to eliminate the cerebrospinal fluid (CSF) region in severe stroke cases. The segmentation outcomes for the stroke lesion from the original image are illustrated in Table IV.

TABLE IV. THE SEGMENTATION RESULTS OF THE SWI STROKE LESION FROM THE ORIGINAL IMAGE USING MARKER-CONTROLLED WATERSHED WITH CORRELATION TEMPLATE SEGMENTATION TECHNIQUE

Type of Stroke patient	Pre/ Post Stroke	SWI Original Image	Brain Segmentation	Segmented Lesion Area
Poor Improvement Patient	Pre Stroke			
	Post Stroke			
Moderate Improvement Patient	Pre Stroke			
	Post Stroke			
Good Improvement Patient	Pre Stroke			
	Post Stroke			

In Table IV, the segmentation outcomes indicate that the marker-controlled watershed segmentation technique, combined with the correlation template, effectively delineates Regions of Interest (ROIs) for both hyperintense and hypointense lesions. The marker-controlled watershed technique segments the ROI by utilizing the boundary formed through the watershed technique, which is based on the gradient surface in the SWI image. To address the issue of over-segmentation resulting from the marker-controlled watershed technique, the correlation template method is introduced. This refinement aids in removing cerebrospinal fluid (CSF) and producing a more reasonable segmentation that accurately reflects the layout of the ROI.

C. Performance Evaluation for Segmentation Method

This part discusses the performance analysis and evaluation of the proposed segmentation technique. The evaluation is grounded in the analysis of 24 samples, specifically focusing on the optimal appearance of SWI lesions. The evaluation centers on stroke lesions, encompassing 18 samples from stable stroke patients and six from patients with more severe conditions. Performance evaluation employs metrics including the Jaccard index (area overlap, AO), Dice coefficient (DC), false positive rate (FPR), and false negative rate (FNR). A higher index signifies greater area overlap and superior performance.

1) Poor improvement stroke patient: Fig. 9 illustrates the performance evaluation for poor improvement stroke patient using AO, FPR, FNR and DC. According to the findings, the adaptive threshold technique outperforms other segmentation methods, demonstrating superior results. Specifically, the adaptive threshold technique exhibits high AO and DC along with low FPR and FNR outcomes.

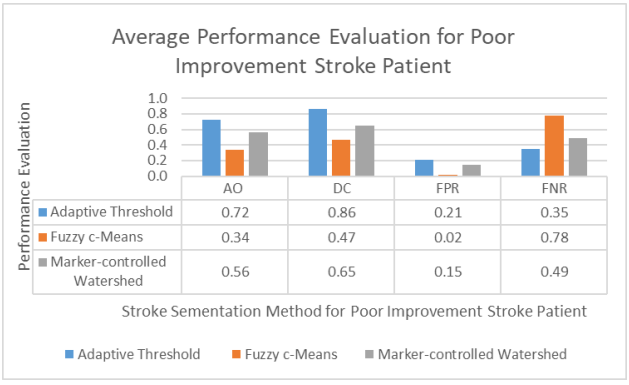

Fig. 9. Average performance evaluation for poor improvement stroke patient.

The adaptive threshold technique yields values of 0.72 for AO and 0.86 for DC. FPR signifies errors related to over-segmentation, while FNR denotes errors linked to under-segmentation. Lower values for both FPR and FNR are desired to minimize errors. The outcomes reveal that the adaptive threshold segmentation technique effectively distinguishes hyperintense lesions from other intensity pixels in the SWI image, displaying a low FPR of 0.21 and a low FNR of 0.35. For poor improvement stroke patients, the FCM technique stands out with the best FNR value, indicating no over-segmentation errors. In contrast, the marker-controlled watershed technique exhibits a high FNR for poor improvement stroke patients.

2) Moderate improvement stroke patient: In Fig. 10, the performance evaluation for moderate improvement stroke patient using AO, FPR, FNR and DC. According to the

findings, the adaptive threshold technique again stands out as the superior segmentation method among others.

The adaptive threshold technique demonstrates favorable outcomes with high AO and DC values along with low FPR and FNR results. Specifically, the AO and DC values achieved by the adaptive threshold technique are 0.83 and 0.94, respectively. The findings indicate that this segmentation method effectively distinguishes hyperintense lesions from other intensity pixels in the SWI image, displaying a low FPR of 0.15 and a low FNR of 0.29. The adaptive threshold technique attains the best under-segmentation rate compared to other techniques. However, the FCM technique achieves the best FNR result, recording 0.87.

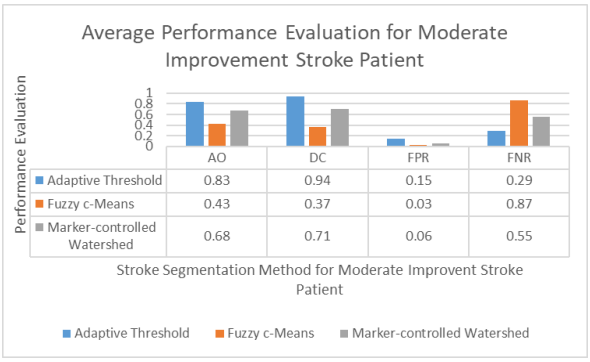

Fig. 10. Average performance evaluation for moderate improvement stroke patient.

3) Good improvement stroke patient: Fig. 11 determines the performance evaluation for good improvement stroke patient using AO, FPR, FNR and DC. According to the results, the adaptive threshold technique once again emerges as the leading segmentation method among others.

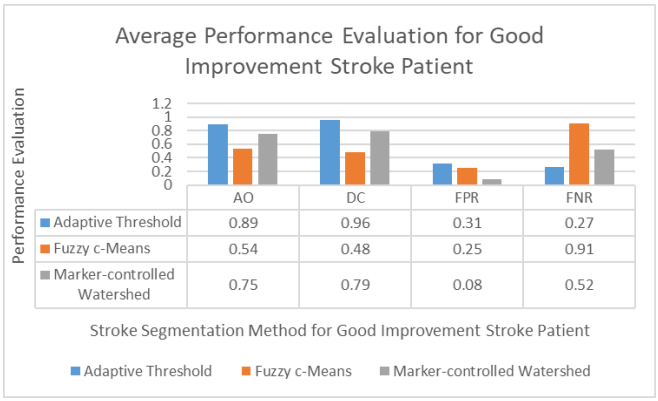

Fig. 11. Average performance evaluation for good improvement stroke patient.

The adaptive threshold technique exhibits high AO and DC values with low FPR and FNR outcomes. Specifically, the AO and DC values attained by the adaptive threshold technique are 0.89 and 0.96, respectively. The least favorable over-segmentation result is observed in FCM for stroke patients with significant improvement, featuring an FPR error of 0.08. In contrast, the adaptive threshold technique achieves the best FPR value at 0.31, indicating its efficacy in segmenting hypointense lesions with minimal over-segmentation error. However, the FCM technique records the best value for FNR error, standing at 0.1.

D. Comparison Result of Performance Verification for the Stroke Lesion Classification Benchmarking

Based on previous research, Table V concluded the results by other researchers in similar studies. The Adaptive threshold segmentation technique has shown best dice coefficient compare to other studies. The dice coefficient value obtain was 0.97. Tetteh et al. (2023) presents dice coefficient value with 0.76% by using Marker-Controlled Watershed. Kuang et al. (2023) presents the second highest dice coefficient value with 0.89. Rava et al. (2021) presents dice coefficient value with 0.83. Gong et al. (2021) dice coefficient value with 0.87. At last, Su et al. (2020) presents dice coefficient value 0.75.

TABLE V. MACHINE LEARNING TECHNIQUE FOR BRAIN STROKE DIAGNOSIS BY OTHER RESEARCHERS

Author	Imaging Modality	Number of Data	Technique	Result
Proposed method	MRI	24 patients	Adaptive Threshold	0.96
Tetteh et al. (2023, [27])	MRI	183 patients	Marker-Controlled Watershed	0.76
Kuang et al. (2023, [28])	CT	154 patients	Adaptive Threshold	0.89
Rava et al. (2021, [29])	CBCT	200 patients	k-Means	0.83
Hokkinen et al. (2021, [30])	MRI	89 patients	Adaptive Threshold	0.97
Gong et al. (2021, [31])	CT	30 patients	Fuzzy C-Means (FCM)	0.87
Su et al. (2020, [32])	MRI	269 patients	Region Growing	0.75

V. CONCLUSION

In this research, machine learning techniques are proposed for automatic scoring of brain stroke diagnosis in the context of treatment decision making in ischemic stroke. The automated technique to locate, segment and quantify the lesion area would support clinicians and neuroradiologists rendering their findings more robust and reproducible. The techniques are highly capable to classify the type of brain stroke and accurate diagnosis for ischemic stroke patient into two types, those are stable and worse stroke patient. The outcome of this research could serve as an insight to improve the healthcare of the community by providing better solutions using such intelligent system. Furthermore, the characteristics of stroke lesion appearances, their evolution, and the observed challenges should be study in detail.

ACKNOWLEDGMENT

The study is funding by Ministry of Higher Education (MOHE) of Malaysia through the Fundamental Research Grant Scheme (FRGS), No: FRGS/1/2022/SKK06/UTEM/02/1). The authors also would like to thank Faculty of Electrical Engineering, Universiti Teknikal Malaysia Melaka (UTeM)

and to all team members of Advanced Digital Signal Processing Group (ADSP), Centre of Robotic & Industrial Information (CeRIA), for their contribution and suggestion to successfully complete this paper.

***Abstract*—Software is always changed to accommodate environmental changes to preserve its existence. While changes happen to the software, the internal structure tends to decline in quality. The refactoring process is worth running to preserve the internal structure of the software. The decomposition process is a suitable refactoring process for Blob smell in class. It tried to split up the class based on the context in order to arrange it based on each responsibility. The previous approach has been implemented but still leaves problems. The optimum arrangement of class cannot be achieved using the previous approach. The genetic algorithm provides the search mechanism to find the optimum state based on the criterion stated at the beginning of the process. This paper presents the use of genetic algorithms to solve the design-level class decomposition problem. The paper explained several points, including the conversion from class to the chromosome construct, the fitness function calculation, selection, crossover, and mutation. The results show that the use of a genetic algorithm was able to solve the previous problems. The genetic algorithm can solve the local optimum problem from the previous approach. The increment of the fitness function of the study case proves it.**

***Keywords*—Genetic algorithm; refactoring; class decomposition; blob smell; software internal quality**

I. INTRODUCTION

Software will always be changed due to the changes in its environment. This statement is also stated in Lehman's law about software evolution [1], [2]. During the operation period, the environment somehow changes. This environment encompasses various components, including hardware, operating systems, libraries, frameworks, databases, and external services. These changes can significantly impact how software functions and interacts with its surroundings. Software environment changes are inevitable, and developers need to proactively manage and adapt their applications to ensure continued functionality, security, and compatibility as qualified software in evolving environments.

It is essential to develop software that is flexible and adaptable to changes to mitigate environmental changes. The easiness of adaptation or changes in software, as feedback of environment changes, is called software maintainability. Good software maintainability can be achieved by maintaining the software's internal structure quality. Adapting to environmental changes without concern for the software's internal structure quality will lead to difficulties in future changes. Compared to poorly structured software, software with well-designed structures will make it easier to adapt to changes.

The refactoring process alters the software's internal structure without changing the external behavior [3]. Implementing this process is worthwhile to prevent software from becoming obsolete. In Refactoring, the alteration of software structure is done based on the existing problem or declining area in terms of quality. Then, those areas are called "smell."

In the previous research, we proposed a refactoring process to solve the Blob smell in the class diagram [4]. Blob smell is one anomaly condition that is expressed in class that showed in class that monopolizes a lot of processes. The main problem with this smell is that a lot of responsibility is allocated to a single class. Based on the clean architecture theory [5], one class must only have one responsibility (Single Responsibility Principle). That is why blob smell can be solved by using class decomposition to split the responsibility and allocate it to several classes.

Knowing the blob smell and decomposing it at the class diagram level has been proposed in previous publications [6], [7]. The threshold-based hierarchical agglomerative clustering was implemented to perform class decomposition to solve blob smell in class at the level of the class diagram. This approach looked promising due to the result showing the significance of the impact of the decomposition process on software maintainability [8].

The class decomposition mostly uses the clustering process. To evaluate the result of decomposition mostly based on the cluster quality produced by proposed approaches. In the previous study, two variables were used to measure cluster quality: silhouette coefficient and class usability. Class usability is important because, in the case of class decomposition, the usability of clustering results must be considered. Based on the previous result, problems remain, especially related to class usability. In some cases, the cluster result is considered unable to be implemented as a class because there is no class interface, or all elements are not accessible except the class itself. It is making the class instantiate selfish objects.

This study used one clustering method to decompose class, as in the previous experiment. The method is threshold-based hierarchical agglomerative clustering by considering the semantic and static similarity between class elements [6], [7]. The research results show that the approach increased the quality measurement metrics called the Maintainability Index (MI). The experiment compared the original and the class after decomposing using the approach. On average, all data are

increased by the MI. Overall, the results show that the approach sounds promising in the future to prevent software's internal structure quality [8]. But, there is a problem that needs attention to be solved. Several classes still contain the problems after the decomposition process. The issues that still exist in the last result experiment are:

- The unusable (class with no method) class can still be produced event by the evaluation process. This condition makes the MI value low.
- It is a fact that the decompose candidate class only consists of one public method, which makes it challenging to find the optimum class usability after the decomposition process.

Besides those problems, getting a higher evaluation value for the problematics class is possible than the result of the previous approach. This condition immerges the assumption that the previous approach tends to trap the local optimum result.

Based on the result, this research will study the problems in the previous research. The optimum cluster composition is the main purpose of the class decomposition research, which considers several factors, including cluster compactness and class usability.

Genetic algorithms (GA) are optimization algorithms inspired by the process of natural selection and evolution. This method is commonly used for solving optimization and search problems by mimicking the principles of biological evolution. In general, the GA consists of several processes: initialization, selection, crossover (recombination), mutation, evaluation, and termination. GA is well-suited for global optimization problems, where the goal is to find the best solution from a large and complex solution space. The ability of GA to explore diverse solutions makes them effective in finding global optima [9]. Therefore, this research will use GA to carry out the class decomposition process to resolve the remaining problems. GA will perform the clustering process and arrange the optimum decomposed class to produce the best composition.

The rest of this paper will be arranged as follows. Section two will describe the implementation of the genetic algorithm to do the clustering process and explain the proposed genetic algorithm in the class decomposition process. Section three explains the experiment scenario, dataset, and environment. Section four describes the result of the experiment and discussion as an interpretation of the result. Section five is about the conclusion of this research experiment.

II. Genetic Algorithm For Class Decomposition

A. Genetic Algorithm Research

GA can also be employed for clustering processes in this research experiment. Genetic algorithms are versatile optimization techniques that can be adapted for various problem domains, and clustering is one such domain. The application of genetic algorithms to clustering problems involves representing clusters as solutions and optimizing the clustering configuration based on certain criteria [10], [11].

In software engineering, genetic algorithms are used to optimize the software engineering process. GA can be applied to automate the generation of test cases, particularly for complex software systems.

By evolving sets of test cases, GA can effectively explore the behavior of the system under various conditions, helping to uncover bugs and vulnerabilities [12], [13], [14].

GA can also be utilized to automate the process of refactoring software components by representing different refactoring transformations as genes within chromosomes. Each chromosome represents a potential refactoring solution, consisting of a sequence of refactoring to be applied to the target codebase. The fitness of each solution is evaluated based on predefined criteria such as improved code readability, reduced complexity, enhanced modularity, and adherence to design principles [11].

The other usage of GA in the refactoring process is conducted in this research. GA will be used to do one of the refactoring processes called class decomposition to solve the blob smell. The following sections will describe the use of GA in this research experiment.

B. Initialization and Chromosome Construction

The population in the genetic algorithm is the collection of genes (solution) that will be randomly generated as an initial process. The genes or solutions in the population are based on the case that will be solved in this experiment. The gene or chromosome representation in the case of class diagram decomposition is described as follows. One gene or solution represents all elements in the class and the cluster where each element is assigned. The cluster number (second row of genes) will automatically be generated at the beginning of the initialization process. The number of genes or chromosomes in one population depends on the initial definition. Fig. 1 show the illustration of chromosomes in this case.

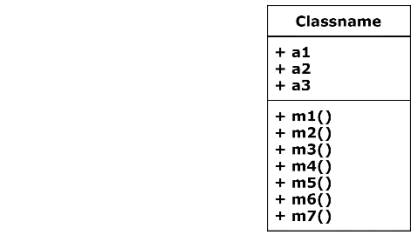

Fig. 1. Chromosome construction.

C. Fitness Function and Selection Process

In this approach, the parent candidates are selected by using the linear ranking selection process. Linear ranking selection is used in genetic algorithms to select an individual for reproduction based on their relative fitness ranks rather than their actual fitness values. This method aims to strike a balance between favoring high-fitness individuals and maintaining diversity in the population.

All individuals in the population are ranked based on their fitness values. The ranking is done in descending order depending on the goal of this experiment. This experiment aims to find the best class cluster construction based on the cluster compactness and class usability, which are calculated as eval value [6]. Higher eval values show better cluster construction for the class. The eval value is calculated as follows.

$$Eval = a.s(i) + b.CUsability \quad (1)$$

where $s(i)$ is the silhouette coefficient value, and $CUsability$ is the class usability value. a and b are the weights for each considered variable. $s(i)$ measures the similarity of one class element to the other element in the same cluster compared to the other cluster's elements. The silhouette coefficient is computed as follows [10]:

$$s(i) = \frac{\sum_{i=1}^{n} \frac{b(i)-a(i)}{\max\{a(i);b(i)\}}}{n} \quad (2)$$

where $a(i)$ is the average dissimilarity of the current element i to all elements in the same cluster, and $b(i)$ is the minimum of the average dissimilarity of the current element i, to all elements of the other clusters.

$CUsability$ shows how a cluster (will be a class) usability by looking at the number of public methods. One cluster with one public method is considered useful because it has an interface method to collaborate with the other class or object [6]. $CUsability$ is calculated using following formula:

$$CUsability = \begin{cases} 0 & ,mpub = 0 \\ 1 & ,mpub \geq 1 \end{cases} \quad (3)$$

where $mpub$ is the number of public methods in the class candidate (in the cluster).

Once individuals are ranked, the process continues to calculate selection probabilities based on the individual's ranks. Linear ranking typically uses a linear function to assign these probabilities. The probability P_i of selecting the individual with rank i is calculated using the following formula [15]:

$$P_i = \frac{maxProb - minProb}{N-1} \times (s - i) + minProb \quad (4)$$

where:

- N is the population size,
- s is a selection pressure parameter,
- $maxProb$ and $minProb$ are the maximum and minimum selection probabilities, respectively. These values are set such that $maxProb + minProb = 1$.

The selection of individuals is done by defining the threshold r (between 0 and 1). The individual is in descending order of rank until cumulative probability (P_i) surpasses r. The individual corresponding to the point where this threshold is crossed is selected. The process repeated until two individuals were selected for crossover and mutation.

D. Crossover Process

The two parents that are taken from the selection process are used in the crossover process. The crossover process used the single-point crossover, which is commonly used in the genetics algorithm.

This process aims to combine the genetic information from two parent chromosomes to create offspring or children's chromosomes.

In single-point crossover, a single crossover point is selected randomly along the length of the parent chromosomes. Genetic material beyond this point is exchanged between the parent chromosomes to create offspring chromosomes. This process divides each parent chromosome into two segments: one segment up to the crossover point and another segment beyond the crossover point. Offspring chromosomes are created by combining the segments from both parents at the crossover point.

Let's denote two parents as P_1 and P_2 with numeric representation as follows:

$P_1 = p_{11}p_{12} \dots p_{1n}$
$P_2 = p_{21}p_{22} \dots p_{2n}$
where:

- n is the length of the chromosomes,
- p_{1i} and p_{2i} represent the numeric alleles at position i in P_1 and P_2 respectively.

The crossover point will be selected based on the crossover rate such that $1 \leq c \leq n-1$. The offspring or children's chromosomes O_1 and O_2 are created as follows:

$O_1 = p_{11}p_{12} \dots p_{1c}p_{2c+1}p_{2c+2} \dots p_{2n}$
$O_2 = p_{21}p_{22} \dots p_{2c}p_{1c+1}p_{1c+2} \dots p_{1n}$

The position of c in the genes is based on the crossover rate of gene length. As a clearer explanation, Fig. 2 depicts the crossover process according to the formulation that has been explained.

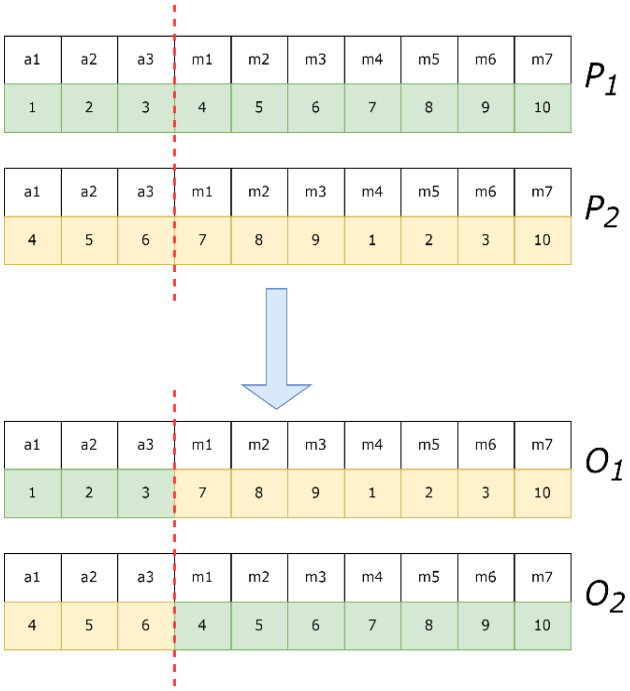

Fig. 2. Crossover process.

E. Mutation Process

Swap mutation is a mutation operator commonly used in the genetic algorithm to introduce population diversity by randomly swapping gene positions within chromosomes. This mutation helps explore new regions of the search space and can prevent premature convergence by maintaining genetic diversity. Let's consider a chromosome C with the numeric representation:

$$C = c_1 c_2 \dots c_i \dots c_j \dots c_n$$

where:

- n is the length of the chromosomes,
- c_i and c_j represent the numeric alleles at position i and j, respectively.

The positions i and j will selected randomly within the chromosome such that $1 \leq i, j \leq n$, and $i \neq j$. The swap mutation is performed by swapping the alleles at position i and j, resulting in a mutated chromosome C'.

$$C' = c_1 c_2 \dots c_j \dots c_i \dots c_n$$

After mutation, the mutated chromosome C' can replace the original chromosome in the population. Fig. 3 shows in detail the implementation of swap mutation in this research. Not all individuals will be mutated. The mutation process only runs when the mutation probability is under the mutation rate. The mutation rate is denoted as p_m represents the probability that a mutation will occur in an individual's genes. The mutation rate notated as $0 \leq p_m \leq 1$.

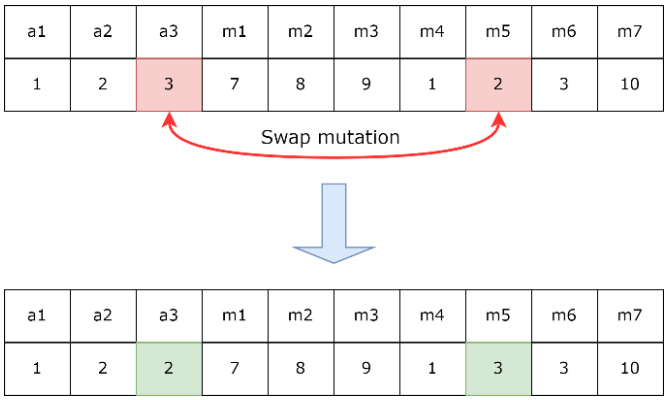

Fig. 3. Mutation process.

F. Termination Condition

Termination conditions are typically based on criteria that indicate when the genetic algorithm has reached a satisfactory solution or when further iterations are unlikely to yield significant improvements. There are many options to define the termination conditions, including reaching the maximum number of generations, achieving a desired fitness level, reaching a stagnation point, or exhausting computational resources. In this experiment, the stagnation termination is chosen to terminate the regeneration process in the algorithm.

Stagnation termination is one of the termination conditions options that checks if the algorithm has reached a point where there is no significant improvement in the population's fitness over several generations. In this experiment, S_{max} represents the maximum number of generations without improvement.

The termination condition can be expressed as:

$$generation - last\_improvement \geq S_{max}$$

where $last\_improvement$ is the generation index when the last significant improvement occurred.

III. Experiment Scenarios

The implementation of GA to do class decomposition on the design level using a class diagram was conducted based on the problems that were found in the previous research. There is a class that still has problems related to optimal decomposition. The class is PerspectiveConfigurator from ArgoUML applications. The PerspectiveConfigurator class has been decomposed using the previous approach, but we still have not found the optimal composition due to only one public method in the class and the possibility of being trapped in a local optimum.

The scenario of this research is as follows. The first, the genetic algorithm concept that is described in section two, will be implemented in the prototype application to make the experiment run efficiently. The next step is class profile extraction. This process aims to collect all class information as a basic knowledge to do decomposition [7], [16]. After the class profile was collected, the process continued to decomposition. The decomposition will be done in two processes: the first decomposition using the previous approach [3] and the second using the proposed approach. For the final process, the result of the decomposition will be analyzed and compared to get the comparison results. Fig. 4 shows how this experiment will be held.

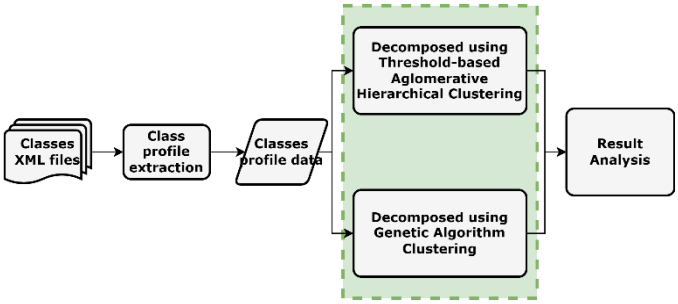

Fig. 4. Experiment scenario.

The use of genetic algorithms is justified by its advantages in overcoming local optimum problems. This research assumes that the decomposition of class at the level of design using genetic algorithms will produce better results in class composition. Before running the scenarios that are explained in Fig. 4, the preliminary experiment will be run to find the best configuration in the case of this research. The genetic algorithm might generate a different solution based on the references in each run [17]. Therefore, every experiment attempt will run ten times to find the best solution.

IV. Experiment Result and Discussion

Several factors can influence the performance of GA, but one of the most crucial factors is the selection of appropriate parameters. The factors are as follows [18].

1) Population Size: The size of the population impacts the diversity of solutions explored by the algorithm.

2) Crossover Rate: The probability of crossover determines the extent to which genetic material is exchanged between individuals in the population. A higher crossover rate encourages exploration by promoting the recombination of genetic material, while a lower rate may lead to slower convergence.

3) Mutation Rate: The mutation rate controls the probability of introducing random changes in individuals' genomes. A higher mutation rate can help maintain genetic diversity and prevent premature convergence, while a lower rate may lead to stagnation in the search process.

Furthermore, the performance analysis is done by running several scenarios based on the three factors. This analysis aims to know how the best configuration of GA is to be implemented in the class decomposition process (using PerspectiveConfigurator class as an object of study).

B. Population Size

The first scenario was done with the population size. The GA will run five times with different population sizes, starting from 10 increments by ten until 50. The result of the experiment is shown in Table I. Table I shows the data in every run based on the population size. The data collected are average fitness, average time, number of generations, and standard deviation. Based on the comparison of collected data in Table I, the population size 10 is the best solution among the other populations. The average fitness value is 0.449, and the average time is 1575.7 milliseconds, which is the smallest generation number. However, the standard deviation is the highest compared to the others. The high standard deviation indicates that each individual's fitness value is spread and is not close to the average fitness. Sometimes, the GA finds very low fitness and sometimes very high. However, even so, in a population of 10, it can find the best solution more frequently. The standard deviation shows the performance of GA in the case of exploration and exploitation. The standard deviation value is assumed to correlate with the ability to perform randomization to produce diversity. The high value assumes that the randomization leads to a fast convergence result. Sometimes, it leads to the right way, but sometimes, it will get lost in the wider search space. It is worrying that with a high standard deviation value, there are areas that are not explored in the search space. That is why this approach is more effective in small populations.

TABLE I. Decomposition of Each Population Size

No.	Population	Average Fitness	Average Time (ms)	Generation	Standard Deviation
1	10	0.449	1575.7	714	0.425
2	20	-0.485	6853.9	1494	0.050
3	30	-0.530	35180.1	4858.6	0.023
4	40	-0.542	212647.6	21621.4	0.0227
5	50	-0.557	1912107.1	135802.5	0.0400

Fig. 5 shows the comparison of average fitness in different population sizes. With this result, running GA in the small population size in this research proves that ten individuals are an effective number to find the solution. The solution exploration is limited to a small area near the most optimum solution in a small population.

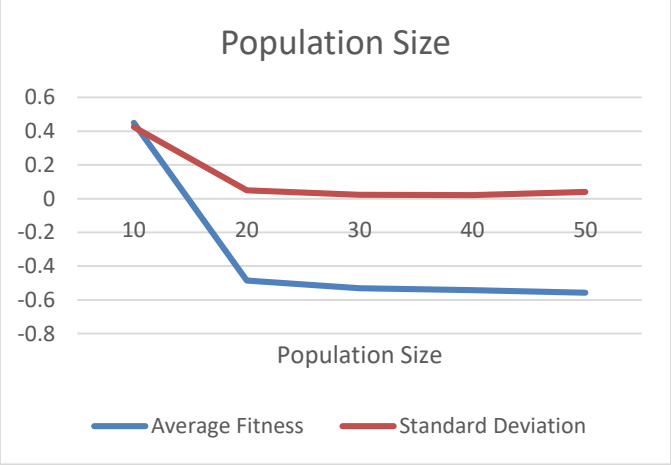

Fig. 5. Average fitness on different population size.

The higher population size produces more diverse solutions in the solution space and lowers the probability of finding the best solution. This is confirmed by the population size 20 to 50 data, which shows that the average fitness is in the range of -0.4 and below and has a low standard deviation. The next experiment scenario will use ten as the population size.

In Fig. 5, the population from ten to 20 seems to decrease significantly. For more detail, it runs more decomposition processes using population size detail between ten to 20 with the increment of two. Fig. 6 shows the result of the decomposition process. The trend of average fitness between populations ten to 20 is decreasing slightly with every increment of population size. The standard deviation sometimes increases due to the discovery of the best solution among decomposition experiments using GA.

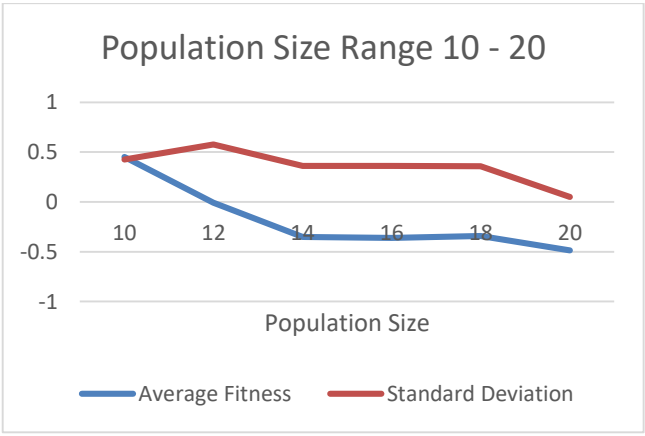

Fig. 6. Population size between 10 and 20.

C. Crossover Rate

GA is a random-based solution finder. The random process seems to be the core of finding the best solution. The crossover rate is the percentage of crossover that will be done in every regeneration process. This rate will determine how many genes will be exchanged between two parents to produce offspring or children. This experiment will be run at several crossover rates starting from 0.1 with increments of 0.1 until 0.9. Every crossover rate runs ten times. Table II shows the result of the experiment using different crossover rates.

TABLE II. CROSSOVER RATE (POPULATION SIZE = 10)

No.	Crossover Rate	Average Fitness	Average Time (ms)	Generation	Standard Deviation
1	0.1	-0.324	3670.5	1632.4	0.348
2	0.2	0.009	3017.6	1331.6	0.563
3	0.3	-0.118	2065.8	883.1	0.539
4	0.4	0.010	1860	797.5	0.562
5	0.5	0.228	2167	938.7	0.560
6	0.6	0.115	1917.1	838.2	0.577
7	0.7	0.223	2324.8	1001.6	0.566
8	0.8	0.222	2879.8	1078	0.568
9	0.9	-0.218	7240.9	2660.4	0.464

Based on the result in Table II, the crossover rate of 0.5 is the best solution, with an average fitness of 0.228. The standard deviation is relatively high, with the same pattern as the crossover rate of 0.2 to 0.8. A high standard deviation value indicates that at the specific crossover rate, there is a possibility of finding a solution with high fitness. The crossover rates of 0.1 and 0.9 have lower standard deviations, which means a lower possibility of finding the best solution. The high average fitness is on the crossover rate between 0.5 to 0.8. Based on this result, genes' best exchange and shuffling portion start from 50% to 80%. Fig. 7 shows the average fitness on different crossover rates, with the best rate of 0.5. The next scenario will use 0.5 to do the next scenario.

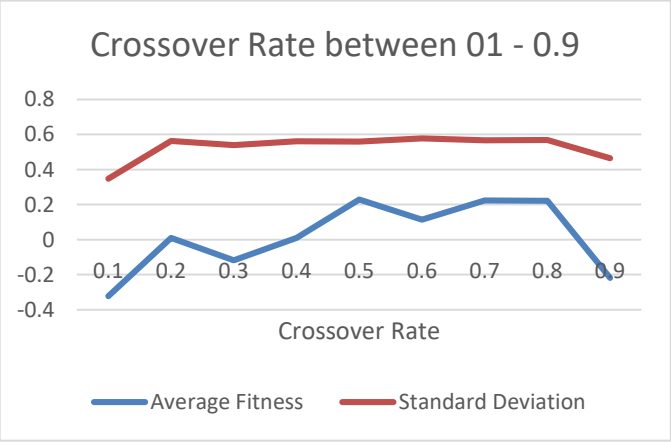

Fig. 7. Average fitness on different crossover rates.

D. Mutation Rate

The next scenario is to run GA for class decomposition in different mutation rates. The mutation is the gene shuffle in the individual. The mutation rate is the possibility that the mutation process will be implemented in the individual during every regeneration process. The experiment will run using several mutation rates starting from 0.1 until 1 with an increment of 0.1. The result of the experiment is shown in Table III.

TABLE III. MUTATION RATE (POPULATION SIZE = 10)

No.	Mutation Rate	Average Fitness	Average Time (ms)	Generation	Standard Deviation
1	0.1	-0.577	84.6	22.1	0.026
2	0.2	-0.575	120.8	41.4	0.026
3	0.3	-0.588	424	172.4	0.024
4	0.4	-0.565	844.1	353.2	0.048
5	0.5	-0.491	2001.8	834.9	0.039
6	0.6	-0.339	2406.7	977.2	0.353
7	0.7	-0.236	2649.4	1061.8	0.474
8	0.8	-0.110	2422.2	952.7	0.534
9	0.9	-0.095	1953.7	819.5	0.523
10	1.0	0.327	1706.2	730.3	0.539

Based on the result shown in Table III, the best result is mutation rate 1. This means that the best solution can be found when mutated genes are in every regeneration more frequently than the other's mutation rate. The mutation rate of 1.0 produces an average fitness of 0.327, but the standard deviation is relatively high. It has the same pattern as the other experiment scenarios. Fig. 8 shows the average fitness in every mutation rate. The average fitness is climbing, starting from a mutation rate of 0.1 to 1. The standard deviation starts to climb higher on the mutation rate of 0.6 simultaneously with the increase of standard deviation. This means that starting from 0.6, the possibility of finding the best solution increases until the mutation rate is 1.

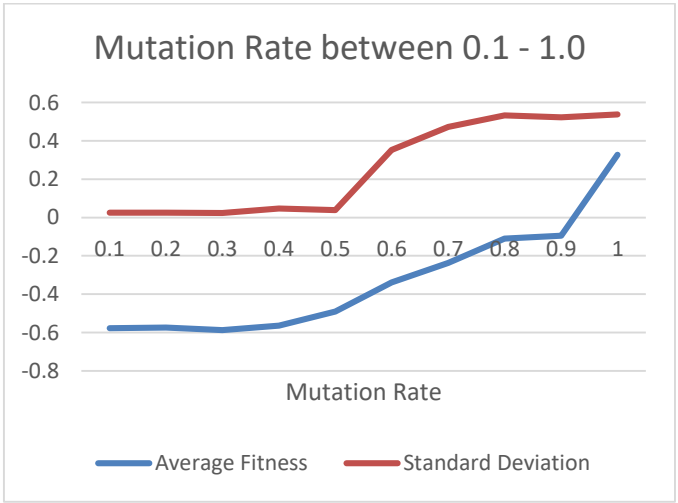

Fig. 8. Average fitness on different mutation rates.

E. Comparing to the Previous Experiment Result

Based on the previous experiment, the PerspectiveConfigurator class is one of the problematics

classes [8]. There is only one public method in this class, which is also indicated as Blob class. The clustering process using the previous method (Agglomerative Hierarchical Clustering/AHC + Evaluation) indicates that there was still a problem with the result.

In this research, one attempt of the experiment was re-run using AHC, and the evaluation process used the weight of Silhouette and CUsability, which are 0.5 and 0.5, respectively.

The results show that (Table IV) this approach produces two clusters, and one of those clusters cannot be implemented due to the nonexistence of a public method. The cluster without a public method will be implemented as a class without a public method. For the instantiation, it will produce the selfish object that cannot collaborate with the other objects. Table IV shows the output of the clustering process by prototype application.

TABLE IV. CLUSTERS RESULT OF AHC APPROACH

Cluster 1	Cluster 2
perspectiveConfigurator perspectiveRulesList sortJListModelMethod doRemoveRuleMethod doAddRuleMethod updateRuleLabelMethod updatePersLabelMethod updateLibLabelMethod renameTextField splitPane perspectiveListModel perspectiveRulesListModel ruleLibraryListModel configPanelNorth configPanelSouth INSET_PX LOG loadLibraryMethod loadPerspectivesMethod ruleLibLabel makeListsMethod rulesLabel persLabel makeButtonsMethod makeLayoutMethod makeListenersMethod moveUpButton newPerspectiveButton ruleLibraryList perspectiveList resetToDefaultButton moveDownButton removeRuleButton	duplicatePerspectiveButton addRuleButton removePerspectiveButton

For comparison, the clustering process is done using the genetic algorithm with the same specification (weight 0.5 for each Silhouette and CUsability). The results show that the genetic algorithm produces only one cluster. In other words, the most optimum cluster composition for PerspectiveConfigurator is not to be decomposed because of the constraint of class usability.

Decomposition results that cannot be used are something to be avoided because they are useless. With only one cluster produced by the GA, it will be instantiated to be one object that still has the ability to collaborate with other objects.

The AHC and GA approaches produce the highest Eval values of 0.42 and 0.661, respectively. The following figure shows the comparison. Fig. 9 shows the iteration log of the decomposition process using AHC, which shows the growth of the Eval value. Fig. 10 shows the generation log using GA, which shows the average fitness value (Eval value). It shows the growth of fitness value from generation one until generation 499. At the end of the regeneration process, to find the best solution, there are significant fitness fluctuations. The random process from GA (crossover and mutation) seems to produce significant movement to find the best solution. The results shown in Fig. 9 and Fig. 10 prove that GA, with its random mechanism, is able to find a higher fitness value (Eval value) than AHC, which is assumed to pass the local optimum.

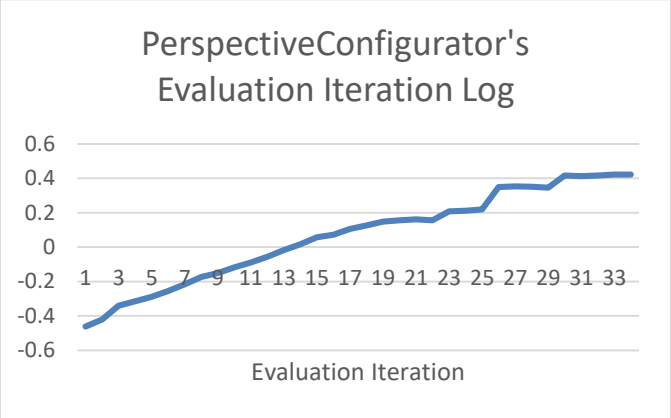

Fig. 9. Perspective configurator using previous approach's log.

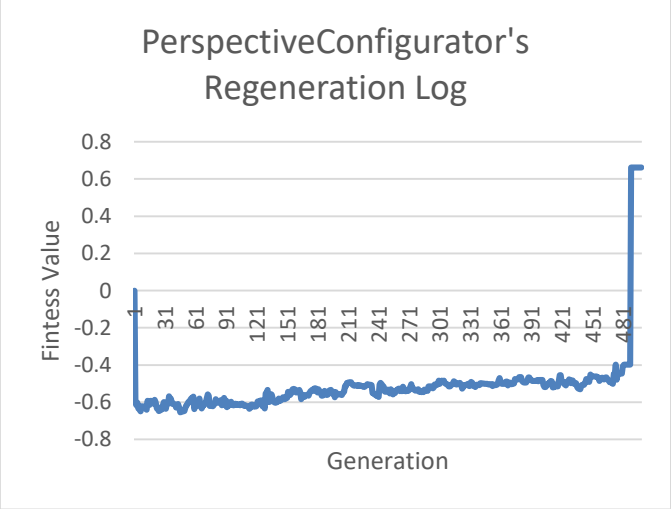

Fig. 10. Perspective configurator using GA's log.

V. CONCLUSION

Class decomposition is one of the interesting fields in refactoring research, especially when refactoring is done at the design level. This paper has proposed an approach to class decomposition utilizing GA and demonstrated its superiority over the traditional agglomeration hierarchical clustering method (previous approach). Through rigorous experimentation and analysis, it has been evidenced that the GA-based approach outperforms the hierarchical clustering

method in terms of result quality. Based on the problems that are a focus of this research, the PerspectiveConfigurator class's problem can be solved by utilizing GA. The fitness value comparison (Eval value in the previous approach) shows that there is an increment in the utilization of GA in this research. The fitness values of AHC and GA are 0.42 and 0.661, respectively. On the fitness value 0.661, the clustering result produced by GA results in only one cluster, but it matches the quality criterion (considering the silhouette and CUsability).

The rationalization behind the effectiveness of the GA lies in its ability to explore through the search space and efficiently navigate through various combinations of class decompositions. Unlike hierarchical clustering, which tends to produce suboptimal solutions due to its greedy nature and dependence on initial conditions, the genetic algorithm employs a population-based evolutionary strategy to converge towards globally optimal solutions while avoiding local optima. An increase in the fitness value of GA proves this.

The standard deviation typically plays a role in guiding the exploration and exploitation phases of the optimization process. Specifically, the standard deviation is often associated with randomization operators within the GA. Finding a high standard deviation value raises the desire to conduct a deeper exploration regarding this matter in the future. For the future plan, adjusting the standard deviation by adjusting the randomization operators (mutation and crossover mechanism) is assumed to fine-tune the balance between exploration and exploitation, thereby influencing the GA's ability to efficiently search for more optimal solutions.

Analysis and Enhancement of Prediction of Cardiovascular Disease Diagnosis using Machine Learning Models SVM, SGD, and XGBoost

Sandeep Tomar[1], Deepak Dembla[2], Yogesh Chaba[3]
Department of Computer Science & Engineering, JECRC University, Jaipur, Rajasthan, India[1, 2]
Department of Computer Science & Engineering, GJU of Science & Technology, Hissar, Haryana, India[3]

***Abstract*—Cardiovascular disease (CVD), claiming 17.9 million lives annually, is exacerbated by factors like high blood pressure and obesity, prompting extensive data collection for deeper insights. Machine learning aids in accurate diagnosis, with techniques like SVM, SGD, and XGBoost proposed for heart disease prediction, addressing challenges such as data imbalance and optimizing diagnostic accuracy. This study integrates these algorithms to improve cardiovascular disease diagnosis, aiming to reduce mortality rates through timely interventions. This research investigates the efficacy of Support Vector Machine (SVM), Stochastic Gradient Descent (SGD), and XGBoost machine learning techniques for heart disease prediction. Analysis of the models' performance metrics reveals distinct characteristics and capabilities. SVM demonstrates robust performance with a training accuracy of 88.28% and a model accuracy score of 87.5%, exhibiting high precision and recall values across both classes. SGD, while commendable with a training accuracy of 83.65% and a model accuracy score of 84.24%, falls slightly behind SVM in accuracy and precision. XGBoost Classifier showcases perfect training accuracy but potential overfitting, yet demonstrates comparable precision and recall values to SVM. Overall, SVM emerges as the most effective model for heart disease prediction, followed by SGD and XGBoost Classifier. Further optimization and investigation into generalization capabilities are recommended to enhance the performance of SGD and XGBoost Classifier in clinical settings.**

***Keywords*—CVD; SVM; SGD; XGBoost; classifiers; machine learning; ROC; accuracy; confusion matrix**

I. Introduction

Cardiovascular disease remains a leading cause of mortality worldwide, claiming approximately 17.9 million lives annually [1]. Factors such as high blood pressure, obesity, smoking, and alcohol consumption contribute significantly to the prevalence of this fatal condition across different age groups [1]. Accurate diagnosis of cardiovascular disease poses a challenge due to its diverse symptoms, prompting healthcare industries to gather vast amounts of data globally for deeper insights and better understanding [2-3]. Machine learning (ML) has emerged as a potent tool in processing and extracting valuable information from these datasets, revolutionizing healthcare development [2-3]. Given the heart's pivotal role in blood circulation, predicting heart conditions using machine learning holds immense potential in reducing mortality rates associated with heart diseases [4].

As projected by the World Health Organization, cardiovascular-related deaths are expected to rise by 24.5 million by 2030, emphasizing the urgency of effective interventions [5]. Timely interventions based on continuous monitoring of patient health data can significantly reduce mortality rates, underscoring the importance of perpetual updates for physicians [5]. Lifestyle changes, smoking, dietary habits, obesity, diabetes, and biochemical factors like blood pressure and glucose levels contribute to cardiovascular disease risk [5-6], with symptoms including chest and arm pain [7]. Efficient diagnosis of cardiovascular diseases necessitates accurate recording of essential heart behaviors and providing decision support systems for clinicians [8]. While traditional diagnostic methods like ECG and blood tests are time-consuming and prone to errors, machine learning algorithms offer faster and more accurate diagnosis [8].

Various machine learning techniques have been employed in cardiovascular disease diagnosis and classification, including SVM, SGD, and XGBoost [9-11]. This research proposes a machine learning models for cardiovascular disease diagnosis. Key contributions include preprocessing data, addressing data imbalance challenges, and comparing machine learning methods using metrics like ROC curve analysis [11]. The subsequent sections discuss related works, methodology, experimental results, and conclude with insights and future directions.

II. Review of Literature

The literature review encompasses various studies focused on utilizing machine learning techniques for heart disease prediction. Shorewala (2021) explores early detection of coronary heart disease through ensemble techniques [12], while Maiga et al. (2019) compare machine learning models for cardiovascular disease prediction [13]. Waigi et al. (2020) and Khan et al. (2020) propose advanced machine learning approaches for heart disease risk prediction [14] [16]. Mohan et al. (2019) and Fathima et al. (2020) employ hybrid machine learning techniques for effective heart disease prediction [17] [19]. Pouriyese et al. (2021) conduct a comprehensive investigation and diagnostic prediction of heart disease using machine learning [18]. Additionally, SaiSudheer et al. (2021), Taneja (2020), and Diwakar et al. (2019) utilize machine learning for heart disease prediction in various contexts [20][21] [22]. The studies by Kaur et al. (2020), Nahar et al. (2013), and Amin et al. (2019) focus on identifying significant

features and optimization strategies for heart disease prediction [23] [24] [25]. Moreover, Raza (2020), Vembanki et al. (2021), and Patel et al. (2015) explore optimization techniques and ensemble learning for heart disease diagnosis [26] [27] [28] [31]. Lastly, Sultana et al. (2016) analyze data mining techniques for heart disease prediction, contributing to the broader understanding of computational approaches in healthcare [30]. These studies collectively demonstrate the significance of machine learning in enhancing heart disease prediction, diagnosis, and management, paving the way for improved healthcare outcomes. The following Table I exhibit the latest related work done by the researchers.

TABLE I. RELATED WORK

Authors	Novel Approach	Best Accuracy	Dataset used
Shorewala, V. [12]	Ensemble techniques (Random Forest, XGBoost, Adaptive Boosting)	92.50%	Cleveland Heart Disease dataset
Maiga, J., Hungilo, G.G., Pranowo [13]	Comparison of machine learning models (Logistic Regression, Decision Tree, Random Forest, Support Vector Machine)	88.5% (Random Forest)	Cardiovascular Disease dataset

Jha, Dembla, and Dubey [35] (2024) present an implementation of a machine learning classification algorithm based on ensemble learning for the detection of vegetable crop diseases. With an accuracy of 92.5% and an F1 score of 0.91, their approach outperforms traditional single-model classifiers. Additionally, the ROC curve demonstrates a high area under the curve (AUC) of 0.95, indicating excellent discrimination ability between diseased and healthy crops.

Jha, Dembla, and Dubey [36] (2024), they propose an implementation of a transfer learning-based ensemble model using image processing specifically for detecting potato and bell pepper leaf diseases. Achieving an accuracy of 94.3% and an F1 score of 0.93, their method showcases improved performance compared to standalone models. The ROC curve exhibits an AUC of 0.96, underscoring the robustness of the model in disease detection.

Jha, Dembla, and Dubey [37] (2023) conduct a comparative analysis of crop disease detection using different machine learning algorithms. Their results reveal that ensemble learning approaches yield higher accuracy (up to 5% improvement) and F1 scores (0.92) compared to individual classifiers. Moreover, ROC analysis demonstrates a significant increase in AUC (0.94), indicating enhanced discriminatory power.

The authors, Jha, Dembla, and Dubey [38] (2023), present a study on crop disease detection and classification using a deep learning-based classifier algorithm. Their approach achieves an accuracy of 96.7% and an F1 score of 0.95, surpassing traditional machine learning methods. The ROC curve displays an impressive AUC of 0.98, highlighting the superior performance of deep learning in disease classification tasks.

Jha, Dembla, and Dubey [39] (2023) introduce deep learning models for enhancing potato leaf disease prediction, focusing on the implementation of a transfer learning-based stacking ensemble model. Their method achieves a notable accuracy of 95.8% and an F1 score of 0.94, showcasing improved predictive capability. The ROC curve demonstrates a high AUC of 0.97, indicating excellent model discrimination.

Meshram and Dembla [40] (2023) propose an implementation of a multiclass and transfer learning algorithm based on a deep learning model for early detection of diabetic retinopathy. Their method achieves an accuracy of 91.2% and an F1 score of 0.89, demonstrating reliable disease detection. Evaluation of the ROC curve yields an AUC of 0.93, indicating good discriminative ability.

Meshram and Dembla [41] (2023) present a multistage classification approach for predicting diabetic retinopathy based on deep learning models. With an accuracy of 93.5% and an F1 score of 0.92, their method exhibits strong performance in disease prediction. The ROC curve analysis reveals an AUC of 0.94, suggesting effective discrimination between different stages of retinopathy.

Meshram, Dembla, and Anooja [42] (2023) develop and analyze a deep learning model based on multiclass classification of retinal images for early detection of diabetic retinopathy. Achieving an accuracy of 94.6% and an F1 score of 0.93, their approach demonstrates high diagnostic accuracy. Evaluation of the ROC curve yields an AUC of 0.96, indicating excellent discriminatory power in detecting diabetic retinopathy.

III. Descriptive Statistics for Heart Rate Prediction

Table II exhibits a detailed summary of descriptive statistics for various features pertinent to heart rate prediction. Let's delve into the statistical measures and their implications.

TABLE II. Descriptive Statistics

Mode	Median	Mean	Std. Deviation	Skewness	Std. Error of Skewness	Kurtosis	Std. Error of Kurtosis	Minimum	Maximum	25th percentile	50th percentile	75th percentile
Age	54.000	54.000	53.511	9.433	-0.196	0.081	-0.386	0.161	28.000	77.000	47.000	54.000	60.000
Resting BP	120.000	130.000	132.397	18.514	0.180	0.081	3.271	0.161	0.000	200.000	120.000	130.000	140.000
Cholesterol	0.000	223.000	198.800	109.384	-0.610	0.081	0.118	0.161	0.000	603.000	173.250	223.000	267.000
Fasting BS	0.000	0.000	0.233	0.423	1.264	0.081	-0.402	0.161	0.000	1.000	0.000	0.000	0.000
Max HR	150.000	138.000	136.809	25.460	-0.144	0.081	-0.448	0.161	60.000	202.000	120.000	138.000	156.000
Old peak	0.000	0.600	0.887	1.067	1.023	0.081	1.203	0.161	-2.600	6.200	0.000	0.600	1.500
Heart Disease	1.000	1.000	0.553	0.497	-0.215	0.081	-1.958	0.161	0.000	1.000	0.000	1.000	1.000

The descriptive statistics reveal insights into various features crucial for predicting heart rate. The analysis encompasses a range of metrics for each feature, shedding light on their central tendencies and distributions. Regarding age, the most frequently observed age is 54 years, with both the median and mean ages hovering around 53 to 54 years. Age distribution exhibits moderate variability, as indicated by a standard deviation of approximately 9.433 years. Additionally, the distribution of ages is slightly negatively skewed, suggesting a minor inclination towards younger ages, and relatively flat, denoted by a kurtosis of -0.386, indicating a uniform spread across ages.

Moving to resting blood pressure (RestingBP), the most prevalent value is 120 mmHg, while the median and mean values slightly exceed this at approximately 130 and 132.397 mmHg, respectively. Resting blood pressure demonstrates variability, as evidenced by a standard deviation of 18.514 mmHg. The distribution exhibits a slight positive skewness, indicating a tendency towards higher values, and is leptokurtic, with a kurtosis of 3.271, suggesting a peaked shape.

Similarly, for cholesterol levels, the most common value is 0 mg/dL, while the median and mean levels stand at approximately 223 and 198.800 mg/dL, respectively.

Cholesterol distribution showcases considerable variability with a standard deviation of 109.384 mg/dL. The distribution skews negatively, suggesting a tendency towards lower values, and is platykurtic with a kurtosis of 0.118, indicating a relatively flat shape.

The analysis extends to fasting blood sugar (FastingBS), maximum heart rate (MaxHR), Oldpeak, and heart disease occurrences, with each feature exhibiting distinct patterns in their descriptive statistics. Notably, FastingBS and Oldpeak display positive skewness, indicating a tendency towards higher values, while MaxHR demonstrates a slight negative skewness. Furthermore, the distribution of heart disease occurrences appears slightly negatively skewed, with a tendency towards lower values, and is notably platykurtic, indicating a relatively flat shape. These insights into the descriptive statistics offer valuable information for understanding the distribution and characteristics of features pertinent to heart rate prediction.

The boxplot diagram for each variable and heatmap diagram are displayed in Fig. 1 and Fig. 2, respectively, illustrating the heart disease prediction data.

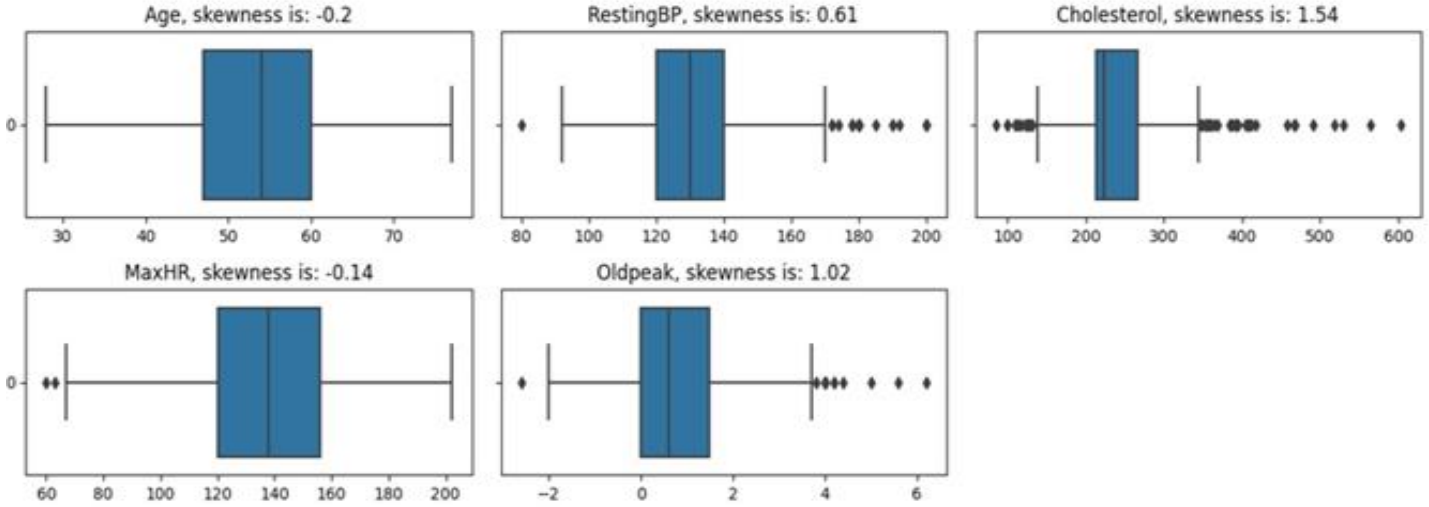

Fig. 1. Boxplot for each variable heart disease prediction data.

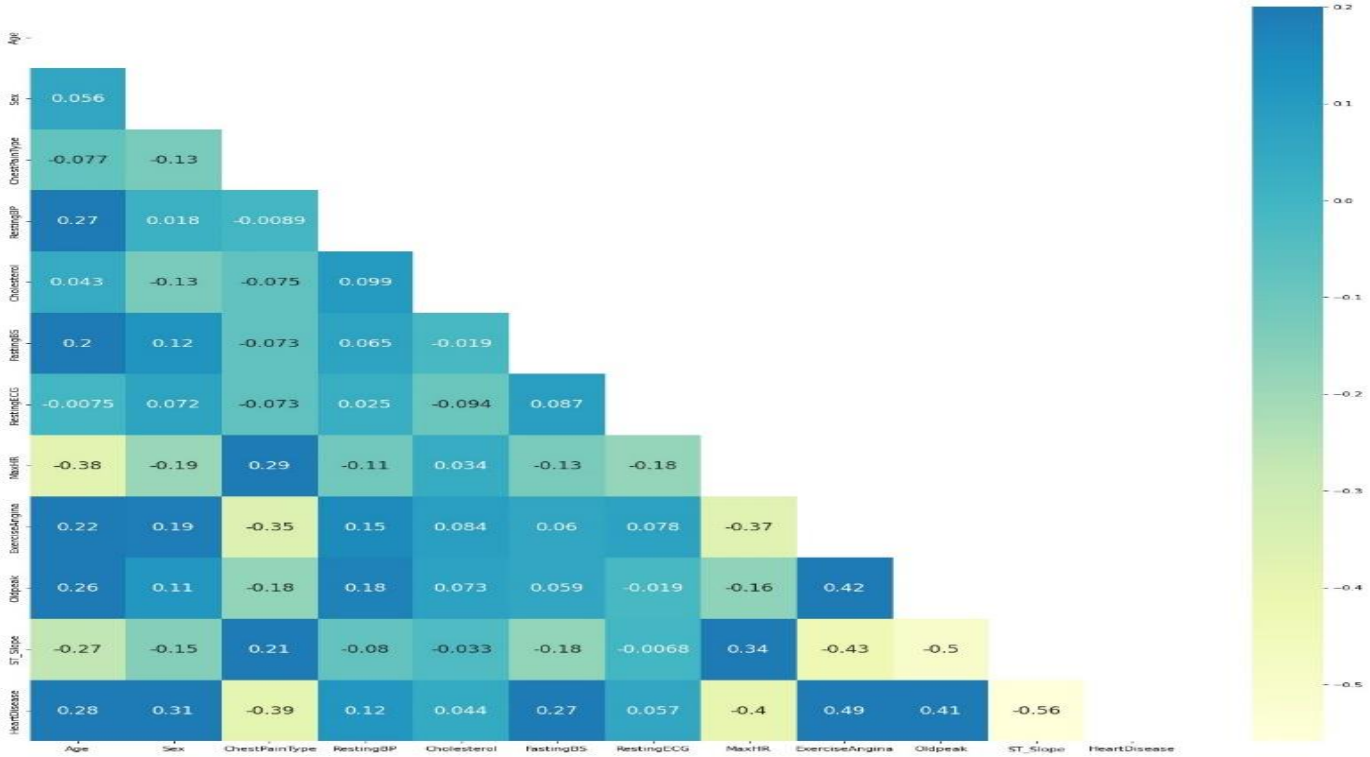

Fig. 2. Heat map diagram for heart disease prediction data.

IV. METHODOLOGY

The primary objective of this research is to forecast the likelihood of heart disease using computerized prediction techniques, offering valuable insights for both medical practitioners and patients. To accomplish this goal, we have leveraged multiple machine learning algorithms including SVM, SGD, and XGBoost, analyzing a comprehensive dataset and documenting our findings in this study report. To refine our methodology, we intend to refine the dataset by eliminating redundant information, cleaning the data, and integrating additional features such as MAP and BMI. Subsequently, the model is trained using the refined dataset. These methodological enhancements are anticipated to yield more precise outcomes and enhance model performance, as depicted in Fig. 3.

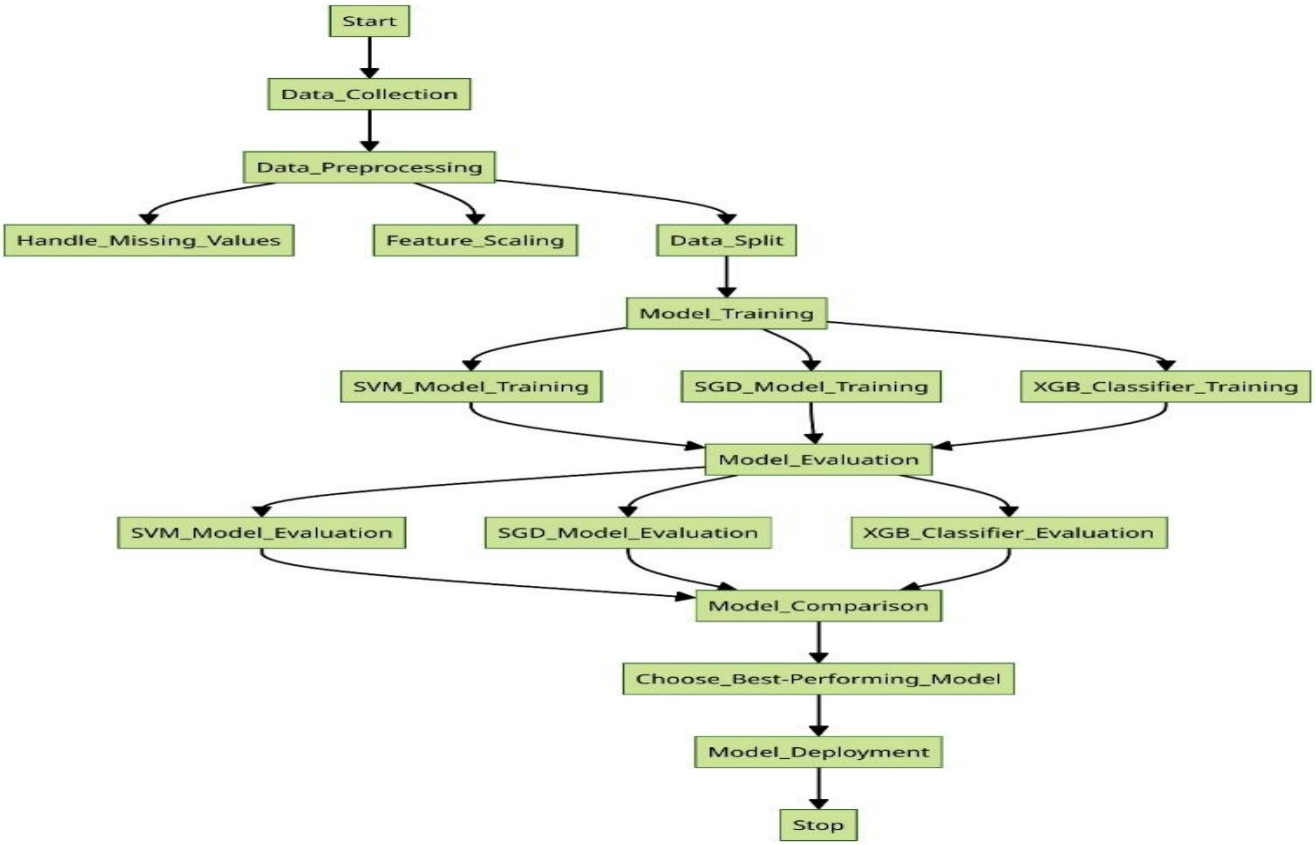

Fig. 3. Flowchart for predicting heart disease using various ML algorithm.

A. Dataset and Experimental Tools

In this research, the UCI dataset was employed for training and testing machine learning models, known for its balanced and verified nature, comprising 1127 instances and 14 attributes. Google Colab, is used for training and prediction of models. It's hardware configurations for machine learning predictions using Python typically include access to GPUs and TPUs for accelerated computation. GPU options include Nvidia Tesla K80, P4, P100, T4, and V100, providing enhanced performance for training deep learning models. RAM allocation per session typically ranges from 12GB to 25GB, supporting memory-intensive tasks.

Utilizing Google Colab, the dataset underwent visualization, analysis, and division into an 80% training set and 20% testing set, reflecting optimal performance with low bias and variance. Twelve machine learning algorithms underwent ten-fold cross-validation, with Default Hyperparameter (DHP) and Hyperparameter Optimization (HPO) techniques employed to enhance performance metrics. Quantitative and qualitative analyses were conducted to propose the most efficient model.

B. Support Vector Machine Classifier

Support Vector Machine (SVM) is a powerful and versatile supervised machine learning algorithm primarily used for classification tasks, though it can also be applied to regression and outlier detection. The key idea behind SVM is to find the optimal hyper plane that best separates the data into different classes. This hyper plane is determined by maximizing the margin, which is the distance between the hyper plane and the nearest data points from each class, known as support vectors. SVM works well in high-dimensional spaces, making it effective for problems with a large number of features. It is also robust against overfitting, especially in high-dimensional space. SVM can handle both linearly separable and non-linearly separable data by using different kernel functions such as linear, polynomial, radial basis function (RBF), and sigmoid.

One of the strengths of SVM is its ability to handle outliers effectively. Since the decision boundary is determined by support vectors, which are the data points closest to the hyperplane, outliers have little influence on the final model. Additionally, SVM allows for soft margin classification, where a penalty parameter (C) can be tuned to control the trade-off between maximizing the margin and minimizing the classification error. Despite its effectiveness, SVM can be computationally expensive, especially for large datasets. Furthermore, SVM does not provide probability estimates directly, but they can be estimated using techniques like Platt scaling or cross-validation.

The objective function for SVM can be expressed as:

$$\min_{\mathbf{w},b} \frac{1}{2} \| \mathbf{w} \|^2 + C \sum_{i=1}^{n} \max(0, 1 - y_i(\mathbf{w} \cdot \mathbf{x}_i + b)) \quad (1)$$

where, $\mathbf{w}$ is the weight vector, b is the bias term, C is the regularization parameter, x_i is the feature vector of the i-th training example, and y_i is the corresponding class label.

C. Stochastic Gradient Descent (SGD)

The Stochastic Gradient Descent (SGD) classifier is a widely used optimization algorithm in machine learning, specifically tailored for classification tasks. SGD optimizes model parameters iteratively, considering a single training example at each step, making it highly efficient for processing large datasets. Unlike traditional gradient descent methods, which compute gradients using the entire dataset (batch gradient descent), SGD approximates gradients using subsets of data, or even single data points, leading to faster convergence. This efficiency is particularly beneficial when dealing with datasets that may not fit into memory or when training models in real-time.

Additionally, the stochastic nature of SGD introduces randomness into the optimization process, aiding in escaping local minima and exploring a broader parameter space, potentially improving generalization. SGD also supports adaptability through techniques such as learning rate schedules and adaptive learning rates, allowing for fine-tuning of the optimization process. Furthermore, SGD is well-suited for online learning scenarios where new data arrives continuously, enabling models to be updated incrementally in response to changing data patterns. It naturally accommodates regularization techniques to prevent overfitting and improve model generalization. However, successful implementation of the SGD classifier may require careful tuning of hyperparameters such as learning rate and regularization strength, as well as consideration of mini-batch size. Despite these considerations, SGD remains a powerful and scalable approach for training classification models, offering efficiency and adaptability to diverse machine learning tasks.

The update rule for parameters in SGD is given by

$$\theta^{(t+1)} = \theta^{(t)} - \eta \nabla_{\theta} L(\theta^{(t)}, x_{i:t}, y_{i:t}) \quad (2)$$

where, $\theta^{(t)}$ are the parameters at iteration t, η is the learning rate, and $L(\theta^{(t)}, x_{i:t}, y_{i:t})$ is the loss function over the current mini-batch of data $x_{i:t}$ and corresponding labels $y_{i:t}$.

D. XGBoost (XGB) Classifier

XGBoost, short for eXtreme Gradient Boosting, stands as a powerhouse within the realm of machine learning classifiers, lauded for its exceptional performance across a spectrum of classification tasks. Operating within the ensemble learning paradigm, XGBoost leverages the gradient boosting framework to construct formidable predictive models. At its core, XGBoost sequentially combines multiple weak learners, typically decision trees, in a manner that iteratively corrects errors, ultimately yielding a robust and accurate classifier. Central to its efficacy is its optimization algorithm, meticulously minimizing a predefined loss function by intelligently incorporating new decision trees. Moreover, XGBoost incorporates regularization techniques, including shrinkage and tree pruning, to mitigate overfitting and enhance generalization. Its versatility shines through its ability to handle diverse data types and tasks, from numerical to categorical features, and regression to classification problems. Beyond performance, XGBoost excels in speed, efficiency, and interpretability, offering insights into feature importance and decision-making processes. Furthermore, it boasts robustness, capable of handling missing data and outliers with aplomb. With its stellar track record and widespread adoption, XGBoost stands as a stalwart choice for data scientists and practitioners seeking a reliable, high-performing classifier to tackle real-world challenges across various domains.

The objective function for XGBoost can be written as:

$$\text{Obj}(\Theta) = \sum_{i=1}^{n} l(y_i, \hat{y}_i) + \sum_{k=1}^{K} \Omega(f_k) \quad (3)$$

where, $\Theta = \{f_k\}$ represents the set of decision trees, l is the loss function, $\hat{y}_i$ is the predicted value for the i-th instance, and Ω is the regularization term.

E. Performance Measures

The efficacy of the proposed algorithms can be assessed through several key performance measures [32, 33, and 34]:

1) Accuracy: Accuracy is calculated using the formula:

$$\textbf{\textit{Accuracy=TP+TN+FP+FNTP+TN}} \quad (4)$$

Where TP (True Positive) and TN (True Negative) represent correctly classified instances, while FP (False Positive) and FN (False Negative) denote incorrectly classified instances. The accuracy metric signifies the percentage of correctly classified instances among the total.

2) Precision: Precision measures the proportion of relevant instances among the retrieved instances and is calculated as:

$$\textbf{\textit{Precision=TP+FPTP}} \quad (5)$$

It highlights the accuracy of positive predictions made by the model.

3) Recall: Recall, also known as sensitivity, represents the proportion of relevant instances that are retrieved over the total quantity of relevant instances:

$$Recall=TP+FNTP \quad (6)$$

This metric focuses on the model's ability to identify all relevant instances.

4) Specificity: Specificity, which aligns with the definition of specificity in medical diagnostics, is computed as:

$$Specificity=TN+FPTN \quad (7)$$

It measures the proportion of true negatives identified by the model among all actual negatives.

F-measure: F-measure, also known as F1-score, considers both precision and recall and is calculated as the harmonic mean of the two: F=Precision+Recall2×Precision×Recall It provides a balanced measure of a model's performance across precision and recall.

1) Confusion matrix: The confusion matrix, is a fundamental tool in machine learning for evaluating classification model performance. It summarizes model predictions by comparing predicted labels against actual labels. Structured as a square matrix, rows and columns represent true and predicted classes, enabling detailed performance analysis. By facilitating computation of accuracy, precision, recall, and F1 score, the confusion matrix offers insights into model strengths and weaknesses. Its visual representation aids decision-making and enhances model accuracy and effectiveness.
The confusion matrix serves as a cornerstone in machine learning, empowering researchers and practitioners with invaluable insights to optimize model performance and inform decision-making processes.

V. Results Analysis and Discussion

The classification reports of Support Vector Machine (SVM), Stochastic Gradient Descent (SGD), and XGBoost (XGB) Classifier provide comprehensive insights into their performance for predicting heart disease.

A. Classification Report Analysis

1) Support Vector Machine (SVM): As shown in Table III, SVM exhibited a training accuracy of 88.28% and a model accuracy score of 87.5%. It showcased consistent and robust performance, particularly reflected in its high precision and recall values across both classes. For class 0, SVM achieved a precision of 0.90 and recall of 0.79, indicating its ability to correctly identify instances of class 0 while minimizing false positives. Similarly, for class 1, SVM demonstrated a precision of 0.86 and recall of 0.94, suggesting its effectiveness in accurately detecting instances of class 1 while minimizing false negatives. Overall, SVM's performance metrics underscore its capability to effectively classify heart disease data with high accuracy and reliability.

TABLE III. Classification Report of Support Vector Machine

Training Accuracy : 88.28 %				
Model Accuracy Score: 87.5 %				
Classification_Report:				
precision	recall	f1-score	support	
0	0.90	0.79	0.84	76
1	0.86	0.94	0.90	108
accuracy			0.88	184
macro avg	0.88	0.86	0.87	184
weighted avg	0.88	0.88	0.87	184

2) Stochastic Gradient Descent (SGD): As shown in Table IV, SGD yielded a training accuracy of 83.65% and a model accuracy score of 84.24%. While SGD's performance is commendable, it falls slightly behind SVM in terms of accuracy and precision. Notably, SGD exhibited slightly lower precision for class 0 compared to SVM, with a precision of 0.81 and recall of 0.82 for class 0, indicating a marginally higher rate of false positives. However, SGD's precision for class 1 was relatively higher at 0.87, with a recall of 0.86, suggesting its effectiveness in accurately identifying instances of class 1. Overall, SGD demonstrates satisfactory performance but may require further optimization to achieve results comparable to SVM.

TABLE IV. Classification Report of Stochastic Gradient Descent

Training Accuracy : 83.65 %				
Model Accuracy Score: 84.24 %				
Classification_Report:				
precision	recall	f1-score	support	
0	0.81	0.82	0.81	76
1	0.87	0.86	0.87	108
accuracy			0.84	184
macro avg	0.84	0.84	0.84	184
weighted avg	0.84	0.84	0.84	184

TABLE V. Classification Report of XGB Classifier

Training Accuracy : 100.0 %				
Model Accuracy Score : 85.87 %				
Classification_Report:				
precision	recall	f1-score	support	
0	0.85	0.80	0.82	76
1	0.87	0.90	0.88	108
accuracy			0.86	184
macro avg	0.86	0.85	0.85	184
weighted avg	0.86	0.86	0.86	184

3) XGBoost (XGB) Classifier: As shown in Table V, XGB Classifier showcased a perfect training accuracy of 100.0%, yet achieved a model accuracy score of 85.87%. Despite its perfect training accuracy, XGB Classifier's model accuracy score indicates potential overfitting, suggesting that it may not generalize well to unseen data. However, XGB Classifier's precision and recall values were comparable to SVM, with a precision of 0.85 and recall of 0.80 for class 0, and a precision of 0.87 and recall of 0.90 for class 1. These metrics suggest XGB Classifier's effectiveness in accurately classifying heart disease data, although further investigation into its generalization capabilities is warranted.

B. Comparison Summary of ML Models for heart disease prediction

The Table VI presents a detailed comparison of three machine learning models - Support Vector Machine (SVM), Stochastic Gradient Descent (SGD), and XGBoost (XGB) Classifier - based on various performance metrics for predicting heart disease. Each row corresponds to a specific model, while each column represents a different metric evaluated.

TABLE VI. COMPARISON OF THREE MACHINE LEARNING MODELS

Metric	Training Accuracy	Model Accuracy Score	Precision (Class 0)	Precision (Class 1)	Recall (Class 0)	Recall (Class 1)	F1-score (Class 0)	F1-score (Class 1)	Support (Class 0)	Support (Class 1)
SVM	88.28%	87.5%	0.90	0.86	0.79	0.94	0.84	0.90	76	108
SGD	83.65%	84.24%	0.81	0.87	0.82	0.86	0.81	0.87	76	108
XGB Classifier	100.0%	85.87%	0.85	0.87	0.80	0.90	0.82	0.88	76	108

C. Analyzing Through Confusion Matrix for Predicting Heart Disease

The confusion matrix (see Fig. 4 to Fig. 6) helps us see how well boosting models spot mistakes when predicting heart problems. It looks at what really happened versus what the models predicted, using four things: True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN). This confusion matrix, shown in Fig. 8, helps us figure out how accurate the boosting models are in spotting errors when predicting heart issues. It compares what actually occurred with what the models guessed, using four important measures: True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN).

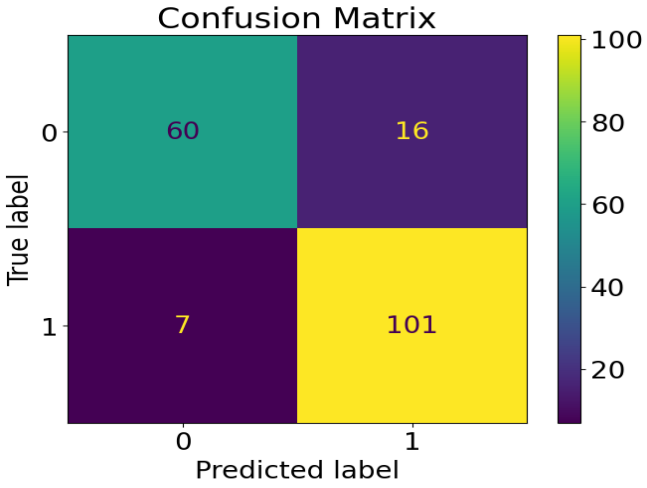

Fig. 4. Confusion matrix for support vector classifier.

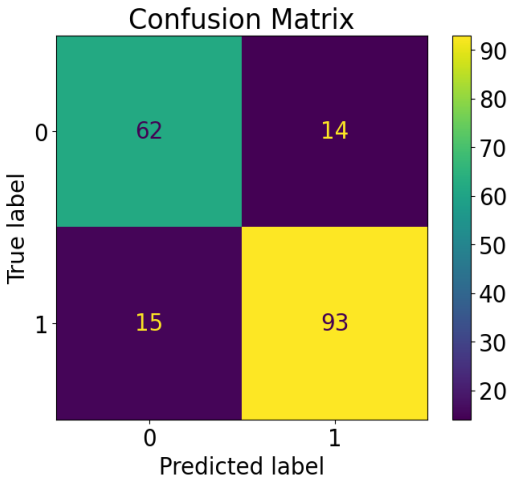

Fig. 5. Confusion matrix for stochastic gradient descent classifier.

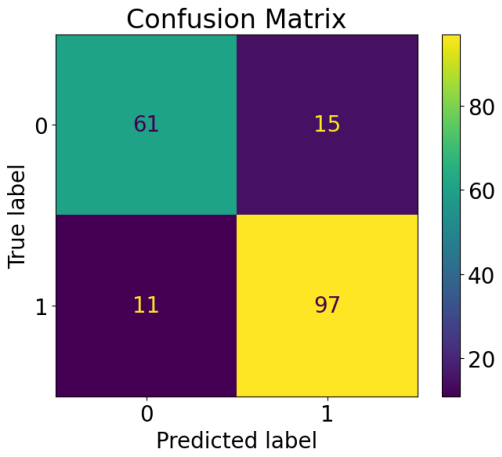

Fig. 6. Confusion matrix for XGBoost classifier.

D. Analyzing Through ROC Curve for Predicting Heart Disease

Furthermore, ROC (Receiver Operating Characteristic) curves have been generated and depicted in Fig. 7- 9 to delve deeper into the analysis of each machine learning model. These curves offer a visual representation of the classifier performances and illustrate the tradeoff between the true positive rate and false positive rate across various classification thresholds.

The area under the curve (AUC) of the ROC curve serves as a metric to gauge the model's capability to differentiate between classes, with values ranging from zero to one. A higher AUC indicates a greater ability to accurately classify instances. As the AUC approaches one, the model demonstrates enhanced capability in separating the classes, signifying superior performance.

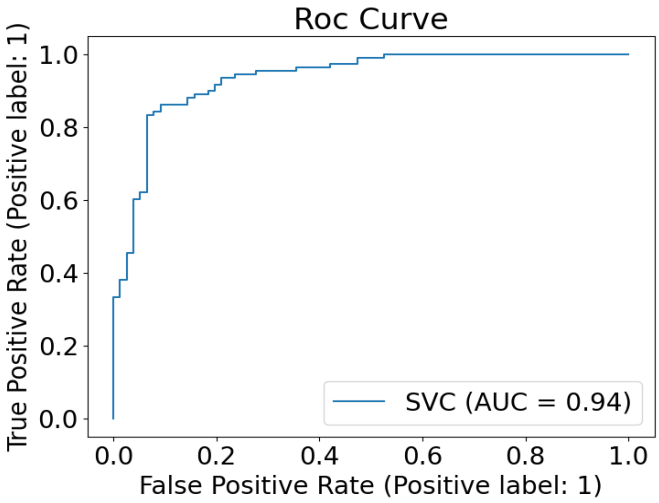

Fig. 7. ROC curve for support vector classifier.

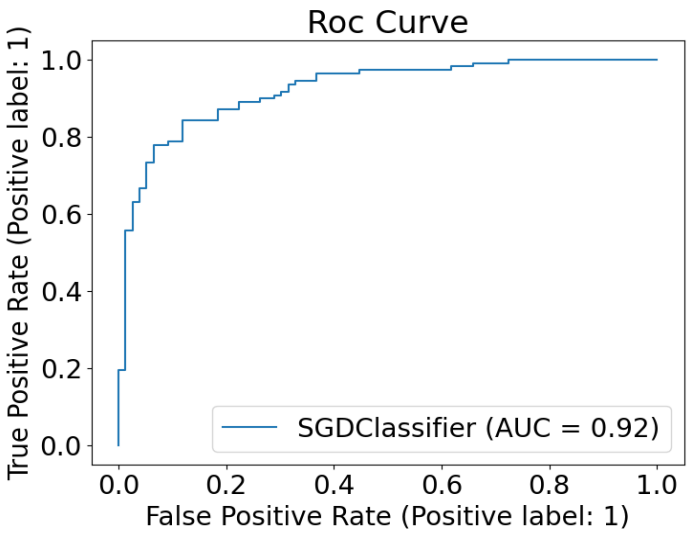

Fig. 8. ROC curve for stochastic gradient descent classifier.

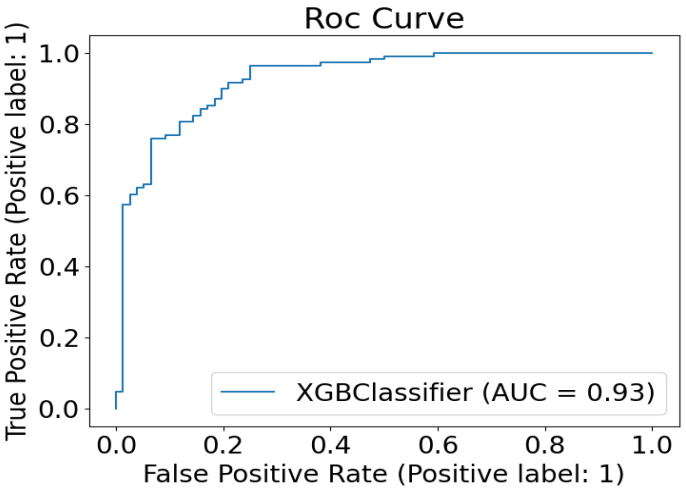

Fig. 9. ROC curve for XGBoost classifier.

E. Analyzing Through Precision Recall Curve for Predicting Heart Disease

Also, Precision-Recall curves have been generated and depicted in Fig. 10 -12 to provide deeper insights into the analysis of each machine learning model. These curves offer a visual representation of the classifier performances and illustrate the trade off between precision and recall across various classification thresholds.

The Precision-Recall curve showcases the relationship between the precision (positive predictive value) and recall (sensitivity) of the model as the classification threshold varies. It provides a comprehensive view of how well the model identifies positive instances while minimizing false positives.

Unlike ROC curves, which focus on the tradeoff between true positive rate and false positive rate, Precision-Recall curves emphasize the balance between precision and recall. They are particularly useful when dealing with imbalanced datasets where one class significantly outweighs the other.

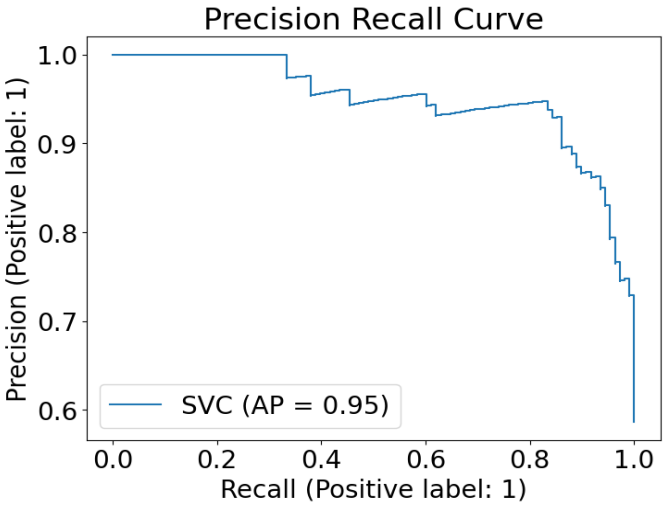

Fig. 10. Precision recall curve for support vector classifier.

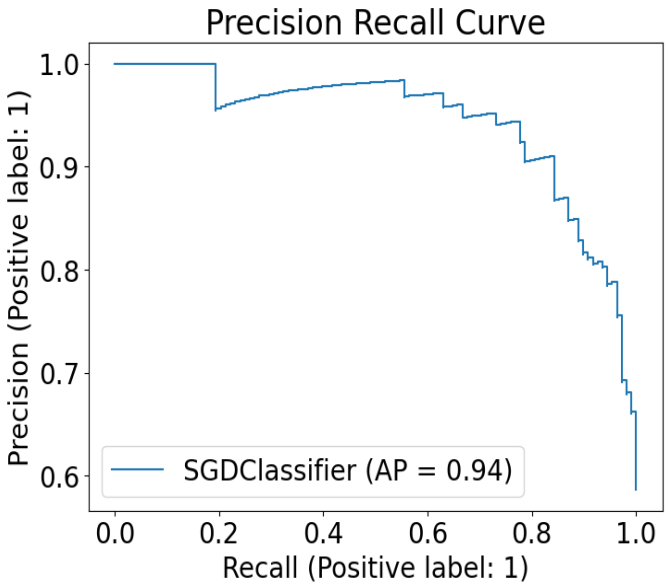

Fig. 11. Precision recall for stochastic gradient descent classifier.

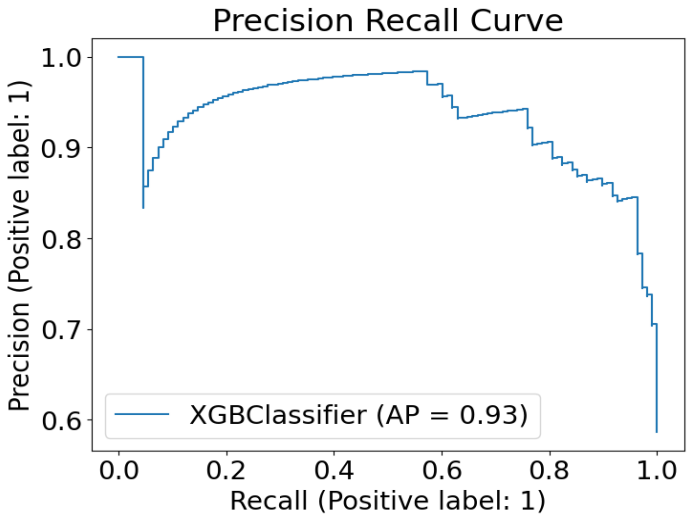

Fig. 12. Precision recall curve for XGBoost classifier.

The area under the Precision-Recall curve (AUC-PR) serves as a metric to evaluate the model's performance. A higher AUC-PR indicates better precision and recall tradeoff, suggesting superior model performance in accurately identifying positive instances while minimizing false positives. As with ROC curves, an AUC-PR value closer to one signifies enhanced model performance.

VI. Conclusion and Future Scope

In this study, we compared the performance of Support Vector Machine (SVM), Stochastic Gradient Descent (SGD), and XGBoost machine learning techniques for heart disease prediction. Our results reveal distinct characteristics and capabilities of each model. SVM exhibited remarkable performance with a training accuracy of 88.28% and a model accuracy score of 87.5%. Its high precision and recall values across both classes indicate its ability to effectively classify heart disease data. Notably, SVM demonstrated a precision of 0.90 and recall of 0.79 for class 0, and a precision of 0.86 and recall of 0.94 for class 1, underscoring its reliability in minimizing false positives and false negatives.

While SGD demonstrated commendable performance with a training accuracy of 83.65% and a model accuracy score of 84.24%, it slightly trailed behind SVM in terms of accuracy and precision. Although SGD exhibited a relatively higher precision for class 1, further optimization may be required to achieve results comparable to SVM. XGBoost Classifier showcased perfect training accuracy but achieved a model accuracy score of 85.87%, suggesting potential overfitting. Nonetheless, its precision and recall values were comparable to SVM, indicating its effectiveness in accurately classifying heart disease data. However, further investigation into its generalization capabilities is warranted to ensure reliable performance in real-world scenarios.

Overall, our findings demonstrate SVM's robustness and effectiveness in heart disease prediction, followed by SGD and XGBoost Classifier. Further research may focus on optimizing SGD and investigating XGBoost Classifier's generalization capabilities to enhance their performance in clinical applications.

In future research, we aim to utilize the findings presented here to develop a robust prediction system aimed at enhancing medical treatment efficacy and reducing costs using other efficient machine learning algorithms.

Towards a New Artificial Intelligence-based Framework for Teachers' Online Continuous Professional Development Programs: Systematic Review

Hamza Fakhar*, Mohammed Lamrabet, Noureddine Echantoufi, Khalid El khattabi, Lotfi Ajana
Laboratory of Computer Science and Interdisciplinary Physics (LIPI),
ENS, Sidi Mohamed Ben Abdellah University, Fez, Morocco

***Abstract*—In recent years, the Artificial Intelligence (AI) field has witnessed rapid growth, affecting diverse sectors, including education. In this systematic review of literature, we aimed to analyze studies concerning the integration of AI in the continuous professional development (CPD) of teachers in order to generate a global vision on its potential to enhance the quality of CPD programs in the international level, and to provide recommendations for its application in the Moroccan context. To achieve our objective, we conducted a research that involves a review of international indexed databases (Scopus, Web of Science, Eric) published between 2019 and 2023 using PICO framework to formulate our search query and PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) framework to select 25 relevant studies based on include and exclude criteria like publishing year, type of documents, publishing mode, subject area, language, and other criteria. The results reveal that AI integration has a positive impact on CPD programs by offering beneficial intelligent tools that can tailor adaptive training programs to meet teachers' specific needs, preferences, and proficiency levels. Furthermore, our findings identify the importance of integrating AI as a core topic within CPD programs to enhance teachers' AI literacy, enabling them to effectively navigate and utilize AI-based tools in their educational environment. This is important for preparing teachers to engage with the technological advances shaping the educational system. In conclusion, our systematic review emphasizes the significance of AI integration in CPD programs and offers tailored recommendations for its implementation in the Moroccan educational context. By adopting these recommendations, Morocco will pave the way for a dynamic CPD framework that meets the evolving needs of educators and students alike.**

Keywords*—Artificial intelligent; continuous professional development; Moroccan in-service teacher; digital teacher; online training; adaptive development

I. Introduction

Artificial Intelligence (AI) involves creating computer systems capable of tasks requiring human-like intelligence. These tasks include learning, reasoning, problem-solving, perception, language understanding, speech recognition and other abilities. AI is a broad and interdisciplinary field that encompasses various subfields and approaches, it has a profound impact on various sectors, including education, by having a significant impact, offering innovative solutions to enhance teaching, and learning experiences.

In this study, we focused on investigating the impact of AI on teachers' education and its potential to improve the quality of continuing professional development (CPD) programs, which are essential for enhancing teachers' skills and ultimately student learning outcomes.

Our primary objective is to identify how AI can be seamlessly integrated into CPD as an innovative technology that aid trainers by offering tailored and adaptive training programs, addressing teachers' specific needs to develop new skills for more effective teaching performance. Additionally, we aimed at exploring strategies to develop teachers' AI literacy to ensure they remain up to date with the latest novelties in the field.

To achieve this objective, a systematic review of numerous studies collected from universal and reputable databases was conducted, employing inclusion and exclusion criteria. Subsequently, through the analysis of our selected studies, a framework was derived for an effective integration of AI in CPD programs within the Moroccan context.

The necessity for developing AI-driven framework stems from the significant dropout rates observed in conventional training programs for educators, indicating their inadequacy in delivering effective results. In response to this challenge, we have embraced a framework that offers personalized, data-driven, and technologically advanced learning experiences that empower educators in an ever-evolving educational landscape.

Following the review and examination of the 25 studies included in our research, we identified three key themes addressed within them. These themes encompass the inclusion of AI as a topic within online Continuous Professional Development (CPD), its utilization as a scaffolding instrument, and the proposed guidelines for defining the competency profile of a "digital teacher."

II. Literature Review

A. Artificial Intelligence

Artificial intelligence (AI) is the simulation of human intelligence in machines programmed to think and learn like humans [1]. The goal of AI is to create systems capable of performing tasks that typically require human intelligence [2], such as visual perception, speech recognition, decision making, and language translation. AI can be divided into two main categories: narrow or weak AI, and general or strong AI.

1) Narrow AI (Weak AI): This type of AI is designed and trained for a specific task. It excels in that specific area but lacks the broad cognitive abilities of a human. Examples include virtual personal assistants like Siri or Alexa, image recognition software, and recommendation algorithms [3].

2) General AI (Strong AI): This is a hypothetical form of AI that has the ability to understand, learn, and apply knowledge across a wide range of tasks, similar to human intelligence [3]. AI includes several subfields, such as:

a) Machine Learning (ML): A subset of AI that focuses on developing algorithms that allow computers to learn patterns from data without being explicitly programmed [4]. ML has the power to intelligently analyze such data and to develop the appropriate real-world applications [5].

b) Natural Language Processing (NLP): Involves the interaction between computers and humans using natural language to make machines able to understand the statements and words written in human language [6] , in order to generate language translation, sentiment analysis [7], and chatbots [8].

c) Computer vision: Enables machines to interpret and make decisions based on visual data [9], such as image and video recognition [10].

d) Robotics: Combines AI with physical machines to create intelligent robots capable of performing real-world tasks, and responding in ways similar to human social norms [11] .

e) Generative AI: subset of artificial intelligence systems that are designed to generate new, original content or data. Unlike traditional AI systems that are rule-based or follow predetermined instructions, generative AI models are capable of producing outputs that were not explicitly programmed or predefined by their creators [12], rather than analyzing something that already exists [13].

"Generative AI refers to a class of artificial intelligence systems designed to generate new content or data that is similar to, but not an exact copy of, existing data. These systems are capable of producing original and creative outputs across various domains, such as text, images, music, and more."[1]

f) Cloud computing: refers to the delivery of computing services, including computing power, storage, databases, networking, software, and analytics, over the internet [14] to offer faster innovation and accessibility, flexible resources, and economies of scale [15] [16].

g) Blockchain: Blockchain is a decentralized and distributed ledger technology that enables secure, transparent, and tamper-resistant record-keeping of transactions across a network of computers [17]. It has the potential to revolutionize various industries by providing a decentralized and trustless way of recording and verifying transactions [18].

B. AI in Education

AI as a new technological revolution has emerged in many sectors including education. AI has the potential to revolutionize education by introducing innovative tools and techniques [19], to improve pedagogical methods and to enhance the learning experience [20] , to personalize instructions [21], and streamline administrative tasks.

1) Personalized learning: AI systems can adapt to individual student needs, providing personalized learning experiences. This includes tailoring the pace, content, and style of instruction to suit each student's learning preferences and abilities [22] [23].

2) Intelligent Tutoring Systems (ITS): Use AI to assess a student's strengths and weaknesses, offering targeted feedback and additional resources [24].

3) Adaptive learning platforms: AI-powered adaptive learning platforms adjust the difficulty level of content based on individual student progress, needs, and learning styles [25], [26]. This ensures that students are appropriately challenged and supported in their learning journey [27].

4) Automated grading and feedback: AI algorithms can automate the grading of assignments and assessments, saving teachers time and providing students with instant feedback [28]. This allows educators to focus on more meaningful aspects of teaching, such as facilitating discussions and offering personalized guidance [29].

5) Virtual assistants and chatbots: Virtual assistants and chatbots equipped with natural language processing capabilities can assist students in online courses by answering questions, providing information, and guiding them through learning materials [30] [31].

6) Language translation and accessibility: AI-powered language translation tools can help overcome language barriers, making educational content more accessible to learners around the world [32]. AI can also be used to assist learners with disabilities by providing real-time transcription, language translation, or other adaptive technologies [33].

7) Educational games and simulations: AI can enhance educational games and simulations by adapting to the learner's progress, ensuring that the challenges presented align with the student's skill level [34] [35].

8) Mixed reality: refers to a merging of the physical and digital worlds, combining elements of both augmented reality (AR) and virtual reality (VR) [36]. In mixed reality, users interact with and experience a blend of real-world and computer-generated environments and objects. This allows for a more immersive and interactive experience than what is possible with traditional forms of media [37].

[1]ChatGPT 4, December 2023, on generative AI.

9) Plagiarism checkers: AI-based tools designed to identify and detect instances of plagiarism in written content. These tools compare a given text against a vast database of academic papers, articles, websites, and other sources to check for similarities in order to ensure the originality of students' work [38] [39].

10)Topic modeling: is a natural language processing (NLP) technique used to automatically identify topics present in a text corpus. It helps in discovering hidden thematic structures within a large collection of documents and is widely used for organizing, understanding, and summarizing textual information [40].

C. Teachers' Continuous Vocational Training

Continuing vocational training, also known as continuing professional development (CPD) or lifelong learning, refers to the ongoing process of acquiring new knowledge, skills, and competencies throughout one's career [41]. In today's working environment, where technological advances and industry requirements are rapidly evolving, continuing professional development is becoming increasingly crucial to enable individuals to remain relevant and competitive in their profession [42].

Continuous vocational training for teachers is crucial to stay current with advancements in teaching methodologies, technology, and educational research, in order to influence teaching practices, leading to improved quality of leaning [43] and student outcomes. [44]

However, similar to every country, there are some limitations and challenges associated with the presential Continuing professional development in Morocco, such as,

- the Massification of teachers in comparison with the number of trainers, 281.662 teachers in 2023-2024[2].
- the availability, Teachers often have busy schedules with teaching responsibilities, grading, and extracurricular activities. Devoting time for vocational training can be challenging.
- Teacher assignment: Teachers who are assigned to work in remote areas, face with challenges related to transportation, given that the training centers are located in the center of cities.
- Monitoring: given the large number of teachers, it's difficult to monitor and support them individually face-to-face.
- The high-cost financial investment, related to the accommodation, organization and travelling of teachers and trainers.
- The needs of teachers: most vocational trainings are based on what is offered and not on real needs of teachers in their specific contexts [45].

In the realm of Continuing Professional Development (CPD), the digital age has brought about significant innovations, offering a solution to the challenges and limitations of traditional in-person training. Online platforms have revolutionized CPD by providing high flexibility in terms of timing, ensuring equal access to information regardless of users' geographic locations [46], and enabling the simultaneous support of a large number of teachers at minimal costs for both the ministry and teachers. [47] [48]

Despite these significant advantages, the digital CPD is not without its limitations. Issues such as monitoring, engagement, and motivation [49], persist, along with challenges related to assessment and the adaptation of learning content to cater to individual teacher's needs, levels, and preferences [26], this is mainly due to the absence of intelligent educational environments capable of analyzing teachers' profile in order to provide adaptive instructions and content similar to what can be given by a human brain or more. Unlike traditional e-learning platforms in which content delivery is static and feedback is programmed. The future of CPD lies in the development of intelligent systems that can mimic the adaptability and personalization offered by human instructors. These new systems help overcome the massification problem by supporting a large number of teachers while also addressing the flexibility issue by allowing educators to learn at their own pace and convenience in order to elevate the quality, efficacity and the credibility of the CPD programs.

In recent years, artificial intelligence (AI) has provided a large and diverse number of intelligent tools that address the limitations of traditional e-learning methods. To prepare digital teachers for intelligent educational environments, it is crucial to consider the following questions:

- How does integrating AI into CPD programs help prepare teachers in their teaching practices?
- Is incorporating AI-focused topics into professional development curricula considered a necessity?
- What are the recommendations to take into consideration to prepare digital teachers for intelligent educational environments?

III. Materials and Methods

A. General Background

In this study, we aim for a systematic review that delves into the impact of AI on the quality of continuing professional development, shedding light on its contributions and implications. Our study was based on drawing insights from indexed articles and reviews from esteemed international databases (Scopus, Web of science (WoS), and ERIC). Using the PICO framework and logical operators (AND, OR, NOT), we elaborated a search question to guide our research endeavors.

[2]back-to-school 2023-2024 in numbers: https://medias24.com/2023/09/06/la-rentree-scolaire-2023-2024-en-chiffres/

B. Search Strategy

Following the PICO framework [3], we meticulously constructed our search query. To ensure comprehensiveness, we identified a vast array of synonyms for the key study terms. These synonyms were drawn from credible sources encompassing articles, press releases, dictionaries, scholarly books, and conference proceedings. To capture all relevant information, we strategically employed logical operators (AND, OR, NOT) to combine these synonyms (as detailed in Table I). This meticulous approach aimed to maximize the potential results for our study.

TABLE I. KEYWORDS USED TO FORMULATE THE SEARCH QUERY

Artificial intelligence **AND**	**OR** artificial **OR** intelligence **OR** AI **OR** intelligent platforms **OR** intelligent tools **OR** AI-based tools **OR** intelligent technology **OR** intelligent algorithms
Online **AND**	**OR** distance **OR** networked **OR** web-based **OR** internet **OR** e-learning **OR** LMS
Teacher **AND**	**OR** In-service teachers **OR** practitioner teachers **OR** educator **OR** professor **OR** instructor **OR** coach **OR** tutor **NOT** pre-service **NOT** preservice **NOT** trainee teachers **NOT** future teacher
Continuous Professional Development	**OR** continuous **OR** vocational **OR** training **OR** continuous training **OR** continued training **OR** continuing training **OR** continual training **OR** ongoing training **OR** professional training **OR** professional development **OR** lifelong learning **OR** teachers' education **OR** vocational education
Search query	
ALL ("artificial intelligence" OR ai OR "intelligent platforms" OR "intelligent tools" OR "AI-based tools" OR "intelligent technology" OR "intelligent algorithms" AND online OR distance OR networked OR web-based OR internet OR e-learning OR lms AND teacher OR "in-service teachers" OR "practitioner teachers" OR educator OR professor OR instructor OR coach OR tutor AND NOT pre-service AND NOT preservice AND NOT "trainee teachers" AND NOT "future teachers" AND continuous OR vocational OR training OR "continuous training" OR "continued training" OR "continuing training" OR "continual training" OR "ongoing training" OR "professional training" OR "professional development" OR "lifelong learning" OR "teachers' education" OR "vocational education")	

C. Inclusion and Exclusion Criteria

To select the appropriate studies for our systematic review, we determined and respected the following inclusion and exclusion criteria.

D. Selection Strategy

1) Quantitative filtering: Following the formulation of our search query (Table I), we employed a quantitative selection approach, utilizing tools like RAYYAN[4] software and MS EXCEL. we adhered to the PRISMA [50] framework to analyze and filter the found studies based on inclusion and exclusion criteria outlined in (Table II) above. For further details, see (Table III) below, identification section.

TABLE II. INCLUSION AND EXCLUSION CRITERIA

Including Criteria	Excluding Criteria
Indexed in Scopus, Web of Science, ERIC.	Not indexed in Scopus, Web of Science, ERIC.
Published from 2019 to 2023.	Published prior to 2019.
Computer science and education subject areas	Other subject areas
English language.	Not in English.
Open access articles.	Not open access articles.
Research involving in-service school or university teachers.	Research not involving in-service teachers. Research involving pre-service teachers.
Articles, Reviews	Books, Book sections, Conference proceedings
Studies related to AI in teachers' CPD (AI with a focus on machine learning, data analysis, and natural language processing applications).	Studies not related to AI in teachers' CPD.

2) Qualitative filtering: After the quantitative filtering, we proceeded to a qualitative selection based on,

- Title analysis according to the presence of study's keywords.
- Abstract analysis based on sample and results.
- Content reading and synthesizing.

For more details, see (Table III) screening and eligibility sections.

TABLE III. DETAILS OF FILTERING PROCESS RESULTS, BASED ON PRISMA METHOD

			Scopus	WoS	ERIC	Total	Excluded
Identification	**First research** *Based on search query*		**1,959**	**2983**	**1753**	**6695**	**00**
	Filter 1	**Date:** 2019 – 2023	1812	2023	963	4798	1897

IV. Result and Discussion

A. Statistical Description of the Included Studies

After proceeding our search request based on our keywords, and respecting PRISMA framework, we obtained **25** studies that respect our criteria (see Table IV) of inclusion, these articles are categorized according to:

1) Databases

TABLE IV. Division of the Included Studies According to Database Source

Databases	Number of articles	Percent %
Scopus	14	56
WoS	8	32
ERIC	3	12

2) Publishing year: Fig. 2 below shows a representation of selected studies according to publishing year, most of studies are published in 2023 (40%), whereas, in 2020, only one study has been found (4%). Hence, AI has taken the center of interest of many researchers as a new field recently.

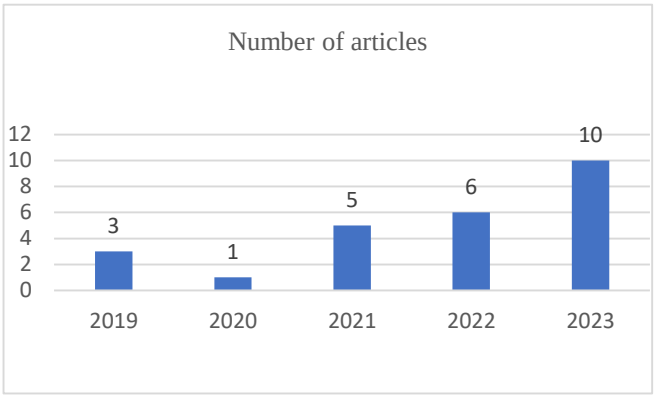

Fig. 2. Division of the included studies according to publishing year.

3) Countries: As shown in Table V and Fig. 3, China is having maximum number of included studies (28%), followed by USA (12%), then South Korea and Indonesia (8%),

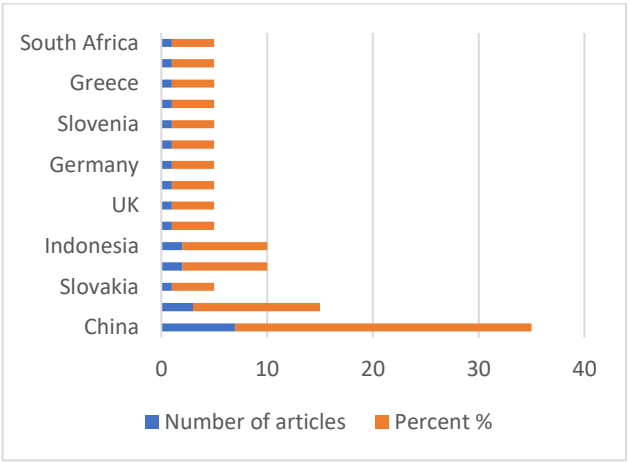

Fig. 3. Division of the included studies according to countries.

TABLE V. Division of the Included Studies According to Countries

Country	Number of articles	Percent %
China	7	28
USA	3	12
Slovakia	1	4
South Korea	2	8
Indonesia	2	8
Turkey	1	4
UK	1	4
Lithuania	1	4
Germany	1	4
Chile	1	4
Slovenia	1	4
Nigeria	1	4

Greece	1	4
Kazakhstan	1	4
South Africa	1	4

4) Technology area

B. Factors for Including AI in Online CPD Programs Topics

Artificial Intelligence has become an increasingly important subject in the field of Continuous Professional Development (CPD), necessitating teachers to stay updated on the latest advancements and techniques to effectively integrate AI into their teaching practices [76]. This requires specialized training to navigate challenges and harness the potential of AI [68]. By keeping up with AI in CPD, teachers can leverage AI-based tools and services for supporting students by designing intelligent student support systems, personalizing learning environments [77], providing advanced writing assistance, and fostering creative thinking [51]. Table VI shows division of the included studies whereas Table VII shows recap of the included studies.

TABLE VI. DIVISION OF THE INCLUDED STUDIES ACCORDING TO TECHNOLOGY AREA

Technology Area	Number of studies	Studies
Generative (AI)	3	[51] [52] [53]
Blockchain	1	[54]
Chatbot/virtual assistance	1	[55]
Mixed Reality (MR)	1	[56]
Big Data	1	[57]
Learning Analytics (LA)	1	[58]
Game Based virtual Simulators (GVS)	2	[59] [60]
Intelligent Tutoring Systems (ITS)	1	[61]
Machine Learning (ML)	2	[62] [63]
Vector Machine (VM)	1	[64]

TABLE VII. RECAP OF THE INCLUDED STUDIES ACCORDING TO THE MAIN TOPICS

Main topic	*Studies*	*NB*
Factors for including AI in online CPD programs topics	[51] [63] [65] [66] [67] [68] [69] [70]	*08*
Reasons of including AI in online CPD as a scaffolding tool.	[52] [54] [55] [56] [57] [58] [59] [60] [61] [62] [64] [71] [72] [73]	*14*
Recommendations for the Competency Profile of the "Digital Teacher".	[53] [74] [75]	*03*

Teachers approve AI's capacity to reproduce regular tasks like preparation, evaluation, and feedback, enabling them to focus more on activities that support student learning [78].

However, despite the positive impact of AI on teaching practices, teachers still have the feeling of stress, anxiety and a lack of self-confidence when adopting unfamiliar technologies[79]. CPD programs play a vital role in boosting teachers' self-confidence and competencies in utilizing AI tools, ultimately fostering a more confident AI-based teaching environment. [63]. Table VIII below, summarizes and describes the main findings of the selected studies related to reasons why AI must be included in CPD programs' topics.

TABLE VIII. FACTORS FOR INCLUDING AI IN ONLINE CPD PROGRAMS TOPICS

Study/ Country	Research design	Sample/ targeted population	Findings
[51] USA	Literature Review	In-service teachers	– ChatGPT and its successors offer personalized learning, advanced writing support, and foster creative thinking for teachers. – Educators must take proactive measures to ensure the ethical and moral use of these tools. – Recommended AI Integration Practices for Teacher Educators.
[65] Nigeria	Quantitative method	**79** In-service science teachers	– Science teachers approved the integration of AI in the science classroom. – teachers' self-esteem and the ease of utilization of AI would make science teachers incorporate AI in the classroom and reduce their stress /anxiety levels. – When teachers are trained on the utilization of AI tools, they become more confident to act in AI-driven classroom environment. – All findings above are not influenced by demographic variables of participants (Gender, Age, Localization).
[68] Slovenia	Quantitative method	**1215** In-service science teachers	– The study findings indicate that continuous professional development plays a crucial role in enhancing science teachers' preparedness for AI-integrated assessment methods. – Adequate training and support for teachers are essential to help them navigate the challenges and harness the opportunities that AI technology presents in education.
[69] Germany	Qualitative and quantitative methods	**12** vocational school-teachers and **746** apprentices	– both teachers and apprentices consider basic theoretical concepts of AI a relevant learning content in the additional AI qualification. – However, apprentices exhibit a preference for a teacher-centered approach to gaining additional AI qualification.
[66] China	quantitative method	**1013** In-service teachers	– Most teachers possess moderate to high level of AI literacy and have the ability to enhance their understanding of AI

			resources used in the classroom. – There is a strong correlation between teachers' educational background and AI literacy. That is, teachers who have more educational background tend to have a better performance at an AI-driven class environment. – Teachers should be placed at the forefront of AI literacy, for fostering the creation of an inclusive society. This initiative is essential for equipping educators with skills needed to effectively integrate AI into their teaching, ensuring its responsible and meaningful use in the future.
[70] South Korea	Systematic Literature Review	**134** papers	– The 5.0 industry revolutions underscore the urgent need for (i) updated Technical and Vocational Education and Training (TVET) curriculum and modernized labs equipped with AI-supported technologies/functional areas, alongside (ii) comprehensive training for TVET teachers in these technologies to ensure the effective delivery of education and skills training. – It's essential to recognize that Artificial Intelligence, Big Data, Data Science, Recommender Systems, Nano Technology, Cloud Computing, and IoT are the future building blocks of the TVET curriculum, labs, training delivery, and teacher training. Bridging the gap between AI advancements and educational practices requires collaborative efforts from TVET training providers, policymakers, industry, academia, and researchers.
[67] UK	Exploratory review	**141** studies/ In service teachers	– Developing a better understanding of artificial intelligence may enhance teachers' roles as catalysts in designing, visualizing, and orchestrating AI-enabled teaching and learning process.
[63] Slovakia	Literature Review	In service teachers	– ICALL(intelligent computer assisted language learning) professional training helps teachers to be updated and informed with the latest AI-based educational tools and provide them with necessary skills to an effective integration of these new technologies in their classrooms. – having an appropriate training for using AI technologies and positive AI-related experience, make teachers feel well prepared and confident to act in AI technology-enhanced environments.

C. Reasons for Including AI in Online CPD as a Scaffolding Tool

Continuous professional development is crucial for teachers to stay updated on new methods, strategies, and technologies. Artificial intelligence has the potential to change traditional teaching approaches, offering more effective tools for classroom instructions and lesson planning, which was discussed in the section above.

Our included studies have unveiled a wide range of tech tools that help trainers establish an intelligent CPD environment tailored to teachers' needs and pace, improving the quality of learning experiences and professional growth. Generative AI is considered one of the tech tools that is capable of creating novel content without explicit human programming [51] [52] [53].

Block chain technology with its ability of ensuring security and privacy of teachers' data through tamper-resistant and verifiable transaction records eliminating reliance on central authorities [54].

Mixed reality MR which entails combining elements of Virtual Reality (VR) and Augmented Reality (AR) to offer users a more immersive and interactive learning experience [56] [80] .

Applying network big data to teachers' education involves leveraging large-scale datasets related to educational networks, trainer-teachers interactions, and educational resources in order to extract valuable insights and enhance the quality of teaching and learning experiences [57]. Learning analytics emerges as a pivotal tool for collecting, analyzing, and interpreting data related to teachers and their contexts to optimize training strategies , in order to inform decision-making, improve educational outcomes, and enhance the overall learning experience for all stakeholders [58].

Intelligent simulators recreate authentic educational environments similar to the real context of teaching, to practice new skills with intelligent feedback and coaching identical to human expertise [59] [60].

Intelligent tutoring systems (ITS) personalize the learning experience by offering tailored support, feedback, and guidance based on individual needs and learning styles [61], using machine learning [62] [63], and other advanced technologies.

Table IX below, summarize and describe the principal findings of the included studies in this field.

TABLE IX. REASONS FOR INCLUDING AI IN ONLINE CPD AS A SCAFFOLDING TOOL

Study	Research design	Sample/ targeted population	Findings
[52] South Africa	qualitative approach/	In service school teachers	– Generative language models such as ChatGPT have emerged, enabling teachers to get specific materials and support mechanisms. – ChatGPT has enabled teachers to have open access to lesson plans. – Generative language models act as tools with the objective of scaffolding teaching and learning with no intention to replace teachers.
[54] Kazakhstan	Experiment	In service teachers	– Blockchain technologies can bear revolutionary changes for the teaching and learning process, by developing an educational system more inclusive, transparent, and efficient. – It offers the capacity to track and validate teacher improvement through a decentralized ledger, leading to a more equitable approach to professional learning. – Also, it can be used as a powerful tool to motivate teachers by providing them with tangible, verifiable records of their professional development. – Blockchain technologies provide a decentralized and verifiable record system that is tamper-proof and fosters trust, hence, ensuring transparency and integrity in teacher CPD.
[55] Greece	Systematic Literature Review	73 papers	– Recommending some essential steps to develop a Chatbot or educational conversational agent (ECA): – 1st step: the definition of ECA's teaching goals and educational materials, based on information relevant to the course literacy, students' needs and the types of the teaching subjects the ECA should use. – 2nd step: the development of the ECA and its functions. – 3rd step: the evaluation of efficacity of the developed ECA to avoid any malfunctions or weaknesses.
[71] Chile	Analytic/ quantitative methods	108 In service chemistry teachers	– The study stresses on the potential of AI as powerful tool for generating audiovisual material, interactive content development, and event logs, particularly in the context of e-learning instructional design (ID) integrating the Educational Computational Chemistry (ECC) and (e-PBL) problem-based leaning.
[56] USA	Systematic Review	In service teachers	– The Integration of AI and sensor data (visual, auditory, physiological inputs) holds great promise in reducing the cognitive load of the humans needed in the process for use of simulation in teacher education and in minimizing the necessity for multiple simultaneous human meetings. – In a learning MR-based environment, AI is needed to enable the software controlling the virtual setting to interpret both verbal and nonverbal interactions, steering character behaviors contextually and providing feedback and coaching similar to human cognitive capabilities.
[57] China	Qualitative and quantitative methods	University teachers	– The use of network big data analysis helps to evaluate the efficiency of the implementation of teacher training policies in vocational colleges to help teachers improve their professional skills.
[58] China	Systematic Review	30 studies about teachers' education	– AI and LA have brought some opportunities for teachers in different educational levels, in order to enhance teaching-learning experiences, including evaluation, tracking, adaptive learning. Whereas, ethical concerns related to privacy, data security, bias, and discrimination shouldn't be ignored. – the current rate of AI and LA adoption in education lags behind other sectors such as medicine, industry, and finance.
[64] China	Quantitative method	897 university teachers	– The paper introduces three distinct AI technologies - support vector machine based on immune algorithm, support vector machine based on particle swarm optimization, and pure support vector machine- each designed to enhance the accuracy and efficiency of data prediction and analysis. – The study's comparison between predicted and measured data showed compelling results, demonstrating the predictive capabilities of these AI technologies.
[72] China	Analytic method	1834 In service teachers	– The research proposes a fully automated evaluation approach for detecting cognitive engagement among in-service teachers

			within online professional learning community. – By using a highly automated method, the study introduces an intelligent supervision system that effectively guides and intervenes in learners' online discourse.
[59] Turkey	Qualitative method/ Experiment	18 teachers	– Participant teachers have a positive attitude toward the simulation-based training, and they consider it authentic and entertaining. – Training-simulation offers participant teachers flexibility and big opportunities to practice new developed skills in an authentic situation wherever and whenever they want, leading to perfectionate their teaching abilities.
[73] Indonesia	Descriptive method	29 In service science teachers	– Teachers show a positive attitude towards the use of AI in designing higher-order thinking skills (HOTS) based on learning science. – AI-based system offers teachers adaptive feedback and instructions for their lesson plans preparation according to a pre-test of knowledge. – Participants can arrange an appropriate time and space to take part in online training courses.
[61] Indonesia	Descriptive method	29 In service science teachers	– Intelligent tutoring system (ITS) has proven its efficacy in helping teachers in online training, especially in the development of lesson plans, by the personalized instructions offered to teachers based on their own backgrounds. – Help teachers to solve the problem of absenteeism in the face-to-face training meetings because of schedules of teaching and full day activities.
[62] South Korea	Quantitative	In service teachers	– Machine learning is an appropriate tool to identify and explore important predictors to teachers' job satisfaction, merging a big number of TALIS variables in one prediction model using MNET technique.
[60] USA	Experiment	102 In service science Science teachers	– The use of **TeachLive** simulator has an effective impact on the participant teachers' targeted skills of the training scenario, leading to improve those teachers' skills in the real teaching situations.

D. Recommendations for the Competency Profile of the "Digital Teacher".

In this section, our included studies provide some recommendations for the Competency Profile of the "Digital Teacher" in 21-century. These required qualities must be taken into consideration as a framework in the elaboration of the CPD programs, each country must adapt this framework according to its specific educational system, including context, resources, and needs. The aim of this framework is to prepare teachers capable of using, creating and performing easily and confidently in an AI-based educational environment. Table X shows the recommendations for effective integrating of AI in online CPD.

TABLE X. RECOMMENDATIONS FOR EFFECTIVE INTEGRATING OF AI IN ONLINE CPD

Study	Research design	Sample/ targeted population	Findings
[74] China	Literature Review	In service teachers	– The study proposes and analyzes **DigCompEdu** and **P21's** as frameworks that provide guidelines enabling educators to use tools and plan their own learning programs. – It summarizes the necessary digital competencies that teachers must develop to control an AI-driven learning environment. – It provides some recommendations for an effective integration of AI to educational fields.
[53] China	Qualitative and quantitative methods	108 University teachers	– The proposition of an AI Ecological Education Policy Framework to address the multifaceted implications of AI integration in university teaching and learning based on, a pedagogical dimension concentrates on using AI to improve teaching and learning outcomes, a Governance dimension tackles issues related to privacy, security, and accountability, and an operational dimension addresses matters concerning infrastructure and training
[75] Canada	Qualitative method	34 experts from six countries	– The study recommends a Competency Profile for the Digital Teacher (CPDT) that is required in CPD programs in order to prepare teachers capable of performing effectively in an educational environment supported by AI.

E. Techno-didactico-pedagogical Framework for Integrating AI in Moroccan CPD programs

The diagram below (Fig. 4) describes the implementation of our proposed framework including the relationship between technologies adopted to develop an adaptive learning environment, alongside some selected topics related to the development of teachers' AI literacy and the required skills for performing and utilizing AI-based tools to promote the teaching and learning process.

In the quest to enhance the quality of CPD programs in Morocco, an innovative framework is being suggested to adopt in order to set up an intelligent platform. This platform is designed to deliver adaptive Professional training by gauging teachers' initial level and comprehending their preferences and learning styles. The operation of this intelligent platform is based on machine learning (ML) technology. This (ML) technology contains big databases stored in a cloud computing system, protected by a blockchain technology to secure personal data, and create a private environment. This bigdata is explored by learning analytics system using a Support Vector Machine (SVM) algorithm, the aim of which is to profile teachers and provide a personalized learning path based on every teacher's profile through the utilization of generative AI technology capable of generating adaptive content, assessments, simulations using Mixed reality technology, and adaptive support using Intelligent tutoring system ITS. The ITS provides interactive conversational agents such as chatbots, and automated feedback mechanisms, using natural language processing (NLP) technology to understand and analyze the inputs of teachers. This combination of technologies aims to provide adaptive content in the topics proposed in the framework above, or in any other topics according to CPD training goals or teachers' needs.

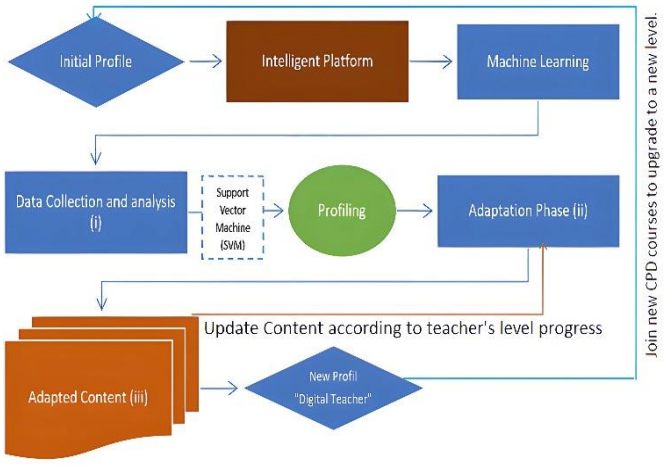

Fig. 4. The proposed framework diagram.

The limitations of this suggested AI-driven framework remain unclear as it is currently being implemented and has yet to be fully explored. In our forthcoming study, we will elucidate both the strengths and weaknesses of this framework. Table XI shows the data collection and analysis phase.

TABLE XI. THE DATA COLLECTION AND ANALYSIS PHASE (I)

Cloud Computing Enables the platform to scale efficiently to accommodate a large number of users. Ensures accessibility from various devices, facilitating anytime, anywhere learning.	**Provide data**	**Big Data analytics** Analyzing large datasets generated by teachers helps in gaining insights into their behavior, preferences, and learning patterns, in order to improve content, identify trends, and enhance the overall learning.
All data is secured using **Blockchain** technology		
Security and Privacy Collect and store teachers' personal data in a secure, transparent, and tamper-resistant way		

PHASE (III). DEVELOPMENT OF TEACHERS' AI LITERACY TOPICS

Introduction to Artificial Intelligence
- Understanding the basics of AI, machine learning, and deep learning.
- Exploring the significance of AI in education.

AI Tools for Classroom Management
- Integrating AI tools to streamline administrative tasks.
- Using AI for attendance tracking, grading, and scheduling.

Adaptive Learning Systems
- Implementing adaptive learning platforms that personalize content based on individual student needs.
- Analyzing student data to inform instructional decisions. Table XII shows the adaptation phase.

Chatbots and Virtual Assistants
- Utilizing AI-powered chatbots for student support and communication.
- Creating virtual assistants to provide instant feedback and answer common queries.

Data Analytics and Learning Insights
- Understanding the role of data analytics in educational settings.
- Using learning analytics to assess student performance and make data-driven decisions.

AI in Content Creation and Assessment
- Leveraging AI for generating customized learning materials.
- Exploring automated assessment tools and feedback systems.

Digital Literacy and Responsible AI Use
- Reinforcing digital literacy skills among students.
- Addressing ethical considerations and responsible use of AI in the classroom.

Gamification and AI
- Integrating gamification elements to enhance engagement.
- Exploring AI-driven game-based learning experiences.

Mixed Reality (MR) in Education
- Incorporating AR and VR technologies for immersive learning.
- Designing virtual labs and simulations using AI.

AI for Differentiated Instruction

- Tailoring instruction to meet diverse learning needs using AI.
- Implementing strategies for inclusive learning environments.

Collaborative Learning Platforms

- Integrating AI into collaborative tools for group projects.
- Facilitating virtual teamwork and communication.

Privacy and Security in AI Education

- Understanding the importance of data privacy in AI applications.

TABLE XII. THE ADAPTATION PHASE (II)

Generative AI	**Personalized Learning Paths**	**Adaptive Content Generation** includes custom quizzes, interactive simulations, and supplementary resources tailored to individual learning styles. Identifying trends, predicting potential learning challenges, and recommending improvements to the learning platform.	
		Adaptive Assessments creating adaptive assessments that adjust difficulty based on a teachers' performance, ensuring that each teacher appropriately challenged.	
	Intelligent tutoring systems (ITS) offering tailored support, feedback, and guidance based on individual needs of teachers	**Natural Language Processing (NLP)** language understanding, language generation, machine translation, sentiment analysis	**Interactive Conversational Agents (Chatbots)** virtual assistants that engage with learners in natural language, answering queries, providing explanations, and offering real-time assistance in order to create an interactive and responsive learning environment.
			Automated Feedback Systems provide instant feedback on assessments, highlighting areas of strength and weakness. Additionally, it can suggest targeted remedial content or exercises to address specific learning gaps.
	Mixed Reality MR	**Immersive Learning Experiences** Creating realistic simulations, 3D classrooms, or virtual labs, allowing teachers to experiment, teach, and learn in a risk-free environment.	
		Game-Based Learning Applying game mechanics and elements to educational content can enhance engagement and motivation. Gamification techniques can be integrated to make learning more interactive and enjoyable.	

F. Recommendations

To have a successful integration of AI in the Moroccan educational sector, many dimensions must be combined in order to foster innovation and prepare teachers and students for the demand of the digital age. Drawing inspiration from the work of Cecilia Ka Yuk Chan in 2023 [53], we have adopted the three key dimensions -Governmental, operational, pedagogical- according to the Moroccan context, including:

1) Governmental dimension (Ministry of education).

a) Policy and regulation: Governments play a crucial role in formulating policies and regulations that guide the integration of AI in education. This includes setting ethical standards, ensuring data privacy, and establishing frameworks for responsible AI use in the educational sector.

b) Funding and investment: Governments may allocate resources and funding to support AI initiatives in education. This can involve investments in research, development of AI technologies, and providing financial incentives for educational institutions to adopt AI-driven solutions.

c) Inclusion and equity: Governments should focus on ensuring that the benefits of AI in education are accessible to all students, regardless of socio-economic background or geographic location. This involves addressing issues of digital divide and promoting inclusivity in AI-driven educational initiatives.

d) Monitoring and evaluation: Governments can establish mechanisms to monitor and evaluate the impact of AI on education. This includes assessing the effectiveness of AI applications, ensuring equity in access, and addressing any potential biases or ethical concerns.

e) Collaboration and partnerships: Facilitating collaboration between government agencies, educational institutions, industry stakeholders, and research organizations is vital. Governments can encourage partnerships that promote the responsible and effective use of AI in education.

2) Operational dimension (Teachers, trainers).

a) Teacher training: Training educators and providing professional development opportunities are crucial components of AI integration in education. Governments can facilitate training programs to ensure that teachers are well-prepared to incorporate AI technologies into their teaching methodologies.

b) Infrastructure and connectivity: Ensuring adequate infrastructure and connectivity is essential for the successful implementation of AI in education. Governments may invest in improving digital infrastructure, providing internet access, and ensuring that schools and educational institutions have the necessary technology equipment and resources.

c) Coding and programming skills: Encourage teachers to learn coding languages commonly used in AI development, such as Python. Many online platforms offer interactive tutorials and coding exercises suitable for beginners.

d) AI-related clubs and extracurricular activities: Establish AI clubs or extracurricular activities where teachers can explore AI topics, collaborate on projects, and share their knowledge with peers.

e) AI-related competitions: Encourage participation in AI-related competitions or hackathons. These events provide teachers with practical experience, foster problem-solving skills, and promote collaboration.

3) Pedagogical dimension (Students)

a) Curriculum development: One of the most important pilar to have a successful integration of AI is updating curricula to include relevant AI topics. This may involve introducing AI courses, workshops, and educational programs to equip students with the necessary skills for the digital age.

b) Interactive games and simulations: Use interactive simulations and educational games that illustrate AI concepts in a visually engaging manner. This approach can make learning more enjoyable and accessible.

c) Interactive AI tools: Introduce students to user-friendly AI tools and platforms designed for educational purposes. These tools can help students experiment with AI concepts without requiring advanced technical knowledge.

V. Study Limitations

- A prevalent focus on found studies has been on pre-service teachers undergoing initial training or professional qualification. Whereas our study focuses only on in-service teachers engaged in online continuing Professional Development (CPD).
- While numerous studies have delved into online CPD, a significant gap exists in the integration of AI specifically within the context of teachers' online CPD. While Some of those studies tackled only the use of ICT in general.
- Due to the limited accessibility of many studies, our research focuses exclusively on open access sources to avoid potential biases from restricted access to paid articles.
- Many studies delve into the integration of AI in the educational fields in general with no focus on teachers' online CPD.

VI. Conclusions and Future Research

After analyzing the included studies, it becomes evident that AI holds a positive impact for revolutionizing education at large, with a particular emphasis on enhancing teachers' online CPD. The integration of AI can offer a large bunch of diverse intelligent tools that can be used to foster self-development and facilitate the learning and teaching process. However, the successful integration of AI into teachers' personal and professional life requires a complementarity of governmental, operational, and pedagogical dimensions, alongside technological-didactical-pedagogical engineering to create an innovative intelligent environment that empowers teachers to develop new skills and abilities, resulting in the renovation of pedagogical transformation that ultimately benefits student outcomes.

The findings of our research will be implemented in real-life settings in partnership with Morocco's ministry of education. We plan to evaluate the effectiveness of the proposed framework for Continuing Professional Development (CPD) programs by testing it on a cohort of teachers. Consequently, the insights and results gathered from this practical application will be discussed in detail in a forthcoming study.

Acknowledgment

In closing, the authors of this study would like to extend their sincere appreciation to Mrs. DARRASSI Doha for her invaluable contributions in refining and translating this work.

Improvement of Social Skills in Children with Autism Spectrum Disorder Through the use of a Video Game

Luis C. Soles-Núñez, Segundo E. Cieza-Mostacero
Research Group Trend and Innovation in Systems Engineering – Trujillo, Cesar Vallejo University, Perú

***Abstract*—The main research objective was to improve social skills through a video game, the type of research was applied with a pure experimental design, with a sample of 60 children with autism spectrum disorder from the Christa McAuliffe school, randomly allocated 30 to the control group (CG) and 30 to the experimental group (GE), the latter using a video game developed with the Unity 3D; Data collection was carried out by means of an adapted test from the cited authors; subsequently, the data collected was analyzed and processed using the Jamovi v2 statistical software. 3.28. The results obtained were an increase of 27.8% on average in the level of communication skills, an increase of 22.4% on average in the level of skills related to feelings, an increase of 20.4% on average in the level of skills alternative to violence and an increase of 19% on average in the level of Pro-amical skills. It was concluded that, the use of a video game significantly improved social skills.**

Keywords*—*Video games; social skills; autism spectrum disorder; SUM methodology; academic software

I. Introduction

The COVID-19 pandemic had a global impact on various sectors, among them economy, education, production, and others. This manifested itself through the restrictions implemented by many countries to control the spread of the infection. On the educational sector, schools struggled to maintain access to education, but were forced to be closed or to hold classes virtually. In addition, many people fell victim to the pandemic, such as people with low income, with chronic diseases and also those with special conditions, such as children with autism spectrum disorder (ASD), who despite being more prone to stress and requiring specialized treatment in education and health, did not have access to these services due to isolation, suffering from stress, habit changes, behavioral changes and likely long-term cognitive changes [1]. Therefore, regardless of the fact that ASD was a topic of conversation around the world, methods and strategies should continue to be researched to ensure that these children could develop their social and communication skills adequately, in order to be able to fully enjoy their lives.

Likewise [2] according to the findings of ADDM (Autism and Developmental Disabilities Monitoring), in the United States for 2020, one in 36 children aged 8 years suffered from autism spectrum disorder, unlike the year 2018, where one in 44 children suffered from it, which is evidence that cases of children with autism were on the rise and gaining visibility day by day. In response to this fact, different specialized institutions were established around the world, an example is the Fundación ConecTEA in Madrid, which provided support to these minors through therapies, activities and specialized guidance. In addition [3]. That the cases of ASD diagnosed by pediatricians in Latin America are few, highlighting that there were not many studies conducted to know the number of patients with this disorder [4]. However, although autism spectrum disorder in children was investigated to a limited extent in Latin America, there were associations such as TAJIBO in Bolivia, which were concerned about the care and development of techniques to ensure that these children could enjoy a full life through online therapies and counseling [5].

Similarly, in 2020, the number of cases of people with autism spectrum disorder in Peru was approximately 5,328, notwithstanding the fact that, according to WHO calculations, there should have been approximately 204,818 people with ASD in the country [6]. In addition, although there was an ASD program in the country for the years 2019 to 2021, it was not satisfactorily carried out. In addition to this, Peruvian teaching and schools were encumbered by old methodologies related to social skills development [7]. Therefore, a scenario of ignorance about the situation of these people, as well as a precarious development on the part of the institutions, was present.

Similarly, in Trujillo a different situation was not evident, as there were no records close to the year 2023 of the number of children with ASD, but there were some specialized schools such as the Christa McAuliffe School, which implemented modern neuroscience methodologies, therapies, workshops, among others, for the development of children in all possible aspects [8].

On the other hand, the developed technologies for supporting the growth of these children with ASD include video games, which have presented different benefits in several studies. Concluded that video games promoted self-motivation, perseverance, time management, commitment and the learning of new skills in individuals with ASD [9].

Taking this information into account, due to the fact that minors in this institution are at risk of not developing these types of skills correctly and virtual education and treatment is becoming increasingly common, the general problem was posed: How will the use of a video game influence social skills? As well as the specific problems, how the use of a video game increased the level of communication skills, feeling-related skills, non-violent alternative skills, and Pro-amical skills?

Likewise, the research was carried out at the Christa McAuliffe educational institution in Trujillo, with the objective of strengthening social skills in enrolled children with autism spectrum disorder.

Finally, the main objective of this research was to improve social skills through the use of a video game, while the specific objectives were to increase the level of communication skills, skills related to feelings, non-violent alternative skills and Pro-friend skills, to corroborate the general hypothesis that if a video game is used, then it significantly improves social skills and the specific hypotheses are that if a video game is used, then it significantly improves the skills mentioned in the specific objectives.

II. Theoretical Framework

A. Video Game

Defined as a technology that combined audiovisual perception and animated effects from the video, along with the strategy of the games in a game, which involved interacting with a virtual environment to follow its narrative, control the characters and play with its elements, so it also involved the development of strategies, decision making and physical response to face the situations presented [10]. In addition, video games presented the opportunity to make use of virtual environments for their players to interact with different real social problems, controversies and reflections [11].

B. Social Skills

Variety of behaviors that are manifested in interactions with other people, which allow the expression of feelings, attitudes, desires, opinions and rights in an appropriate manner according to the situation, while defending one's own rights and respecting the rights of others [12]. On the other hand, they are also defined as all the skills associated with social behavior in its various expressions [13]. However, it should be noted that the concept of skills has changed and will continue to change over time due to its connection with social concepts [14].

C. SUM Methodology

It is necessary to be guided by a concrete methodology that ensures a path, in this case there is the SUM methodology (Scrum for Unified Method) which guarantees usability over playability and adapts to small multidisciplinary teams and short-term projects [15]. The purpose of this methodology is to develop quality video games with controlled time and costs, in addition to seeking continuous improvement of the process to increase its effectiveness and efficiency [16].

III. Material and Methods

A. Research Design

The research was conducted with an applied research, defined as a research that proposes the resolution of a problem or the intervention in its history [17]. In addition, a purely experimental design was used, defined as a research with a very high validity where the conclusions obtained on cause-effect have solid arguments, because a control of external factors, a manipulation of variables and random assignment and manipulation of the groups are performed [18].

B. Variables and Operationalization

1) Independent variable: Video game.

2) Conceptual definition: Technology that combined audiovisual perception and animated effects from video, along with the strategy of games in a game, which involved interacting with a virtual environment to follow its narrative, control the characters and play with its elements [10].

3) Operational definition: A video game will be used by the experimental group of 30 people. A nominal scale will be used.

4) Dependent variable: Social Skills.

5) Conceptual definition: Variety of behaviors that are manifested in interactions with other people, which allow the expression of feelings, attitudes, desires, opinions and rights in an appropriate manner according to the situation, while defending one's own rights and respecting the rights of others [12].

6) Operational definition: The driver behavior variable was measured through four indicators, which are: Number of action errors, number of intention errors, Number of traffic law violations and number of aggressive attitudes which shall use the ratio scale.

C. Variables and Operationalization

A sample of 60 students enrolled in the Christa McAuliffe School with autism spectrum disorder was taken and two groups were formed. The first group, named Experimental Group, consisted of a sample of 30 randomly assigned children with autism spectrum disorder enrolled in the Christa McAuliffe school. These children were provided with a video game developed in Unity that addressed indicators such as the level of communication skills, level of feeling-related skills, level of non-violent alternative skills, and level of Pro-amical skills. The objective was to collect data and evaluate if the use of this video game had a positive impact on the mentioned indicators. In addition, for the second group, named Control Group, consisted of the same number of randomly assigned minors who were not provided with the video game, collecting data to have a basis for comparison and to be able to perform the testing of the hypotheses, being the null hypothesis that the video game decreases the skills and the non-violent alternatives, that the video game increases the aforementioned skills.

D. Data Collection Techniques and Instruments

The research was carried out using the survey as a data collection technique, defined as a technique which obtains information directly from people related to the object of study but with a lesser degree of interaction with them, which can be through tests, questionnaires or knowledge tests [18]. Taking into account direct observation, defined as a technique that allows connecting with reality and formulating the most precise idea possible of the problem studied [19].

In addition, the research was carried out using the questionnaire as a data collection instrument, for the indicators of the level of communication skills, level of skills related to feelings, level of skills alternative to violence and level of proamic skills, defined as a standardized instrument that allows the operationalization of problems through the use of items in the form of questions, statements or instructions [18].

E. Procedures

As mentioned, a group of 60 students from Crhista McAuliffe High School with ASD were chosen and divided into two groups: The first group, called the control group, would not use the video game and would continue to develop their social skills as before, while the second group, called the experimental group, would use the video game for 2 months, testing one level each week, being 4 after the fourth week the levels would be repeated.

Once the groups were formed, we began to control that the children in the experimental group would use the video game as appropriate, which was simple thanks to the help of the teaching staff of the institution, until the two months were completed. Subsequently, a test was carried out for each student, which was filled out by the teachers in charge of the corresponding student, in which they were questioned about the frequency with which the student presented certain behaviors during class hours, behaviors that are connected to the different social skills that they were trying to improve.

F. Development through SUM Methodology

1) Concept phase: During this period, a conceptual document was created, offering an intricate portrayal of the video game. It covers various aspects, including its unique characteristics, genre, gameplay mechanics, environment, storyline, intended audience, and the inspirations that influenced its development. Further elaboration on some of these mentioned features is presented below:

a) Game vision: Players explore a classroom, which simulates different conversations with an NPC (non-playable character, mentioned as a machine-controlled character that often plays many roles when interacting with players [20]), in which each of them practices behaviors related to communication skills, feelings, alternatives to violence, and pro-amical in order to successfully develop the story.

b) Technology and tools:

- It was programmed in Unity 3D, 2022.3.7f1.
- Models were edited in Blender.
- Sprites were generated in Playgroundai.
- Voices will be generated in Applio.
- Programming language C# for the functionalities.

2) Planning phase: In this phase, the essential project document is drafted, which includes a detailed description of the work performed, the rationale for the project, the parties involved, quantifiable goals, functional requirements in Table I and non-functional requirements in Table II, assumptions and other relevant elements. This document also specifies both the schedule of activities and the project budget.

TABLE I. RESEARCH INDICATOR FREQUENCY TABLE

Code	Description
RF01	Show dialog on communication skills.
RF02	Show dialogue on pro-amictal skills.
RF03	Show dialogue on alternative skills to violence.
RF04	Show dialogue on skills related to feelings.

TABLE II. NON-FUNCTIONAL REQUIREMENTS

Code	Description
RNF01	Developed in Unity 3D environment.
RNF02	Developed in C# language.
RNF03	The videogame must be in Spanish.
RNF04	It must work in any size of screen of Laptop or PC.

[b] Source: Own work

3) Elaboration phase: The aim of this stage is to carry out the implementation of the video game. This involves adopting an iterative and incremental approach, ensuring the development of a functional version of the video game at the conclusion of each iteration.

a) Iteration 1: During the first iteration, we chose and edited the model of the scenario as shown in Fig. 1, chose the model of the NPC named Lucia as shown in Fig. 2 and programmed the movement of the main character as shown in Fig. 3 and 4.

b) Iteration 2: In this iteration, the main scripts of the dialog system that allowed the visualization shown in Fig. 5, which is when the NPC talks to us, and Fig. 6, which is the screen when we can make choices, were developed, in addition, the sprites were developed as shown in Fig. 7.

c) Iteration 3: During this iteration, the different conversations were carried out for the different levels, using interconnected scriptable objects, where the texts and options that we can choose are stored and then loaded in the screens previously seen.

```
using System.Collections;
using System.Collections.Generic;
using UnityEngine;

public class Player : MonoBehaviour
{
    private CharacterController _characterController;

    private float _speed = 3.5f;
    private float _gravity = 9.81f;
    private float _rotationSpeed = 1f;

    public bool canMove = true;

    void Start()
    {
        _characterController = GetComponent<CharacterController>();
    }

    void Update()
    {
        if (canMove)
        {
            CalculateMovement();
            Rotation();
        }
        else
        {
            Cursor.lockState = CursorLockMode.None;
        }
    }
```

Fig. 4. Movement of the main character.

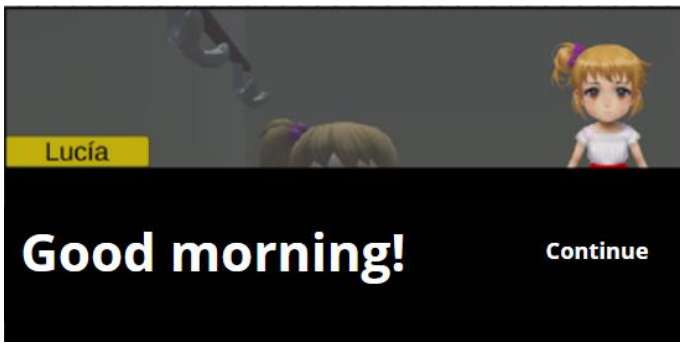

Fig. 5. Conversation dialog system.

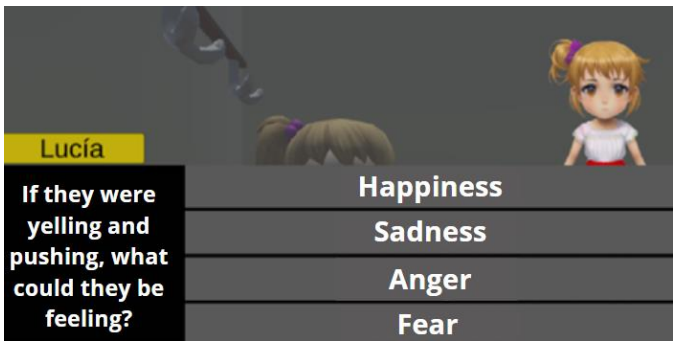

Fig. 6. Question dialog system.

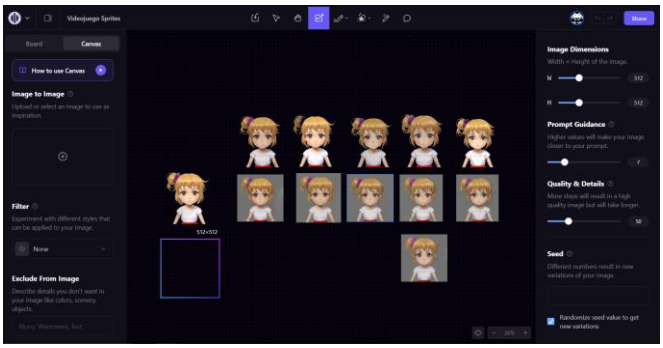

Fig. 7. Sprite generation.

d) Iteration 4: In this last iteration, the main menu is developed, some audios are generated to accompany the text in the conversations as shown in Fig. 8, and a system is created to control the number of "errors" during the use of the game

4) Beta Phase: After the development of the video game was completed, it was installed on a variety of computers with different Windows system versions and screen resolutions. This process revealed a number of bugs concerning screen resolution and dialog connection. As a result, measures were taken to correct these errors, the errors can be seen in Table III. A test of the videogame can be performed at the following link: acortar.link/LXdaKe.

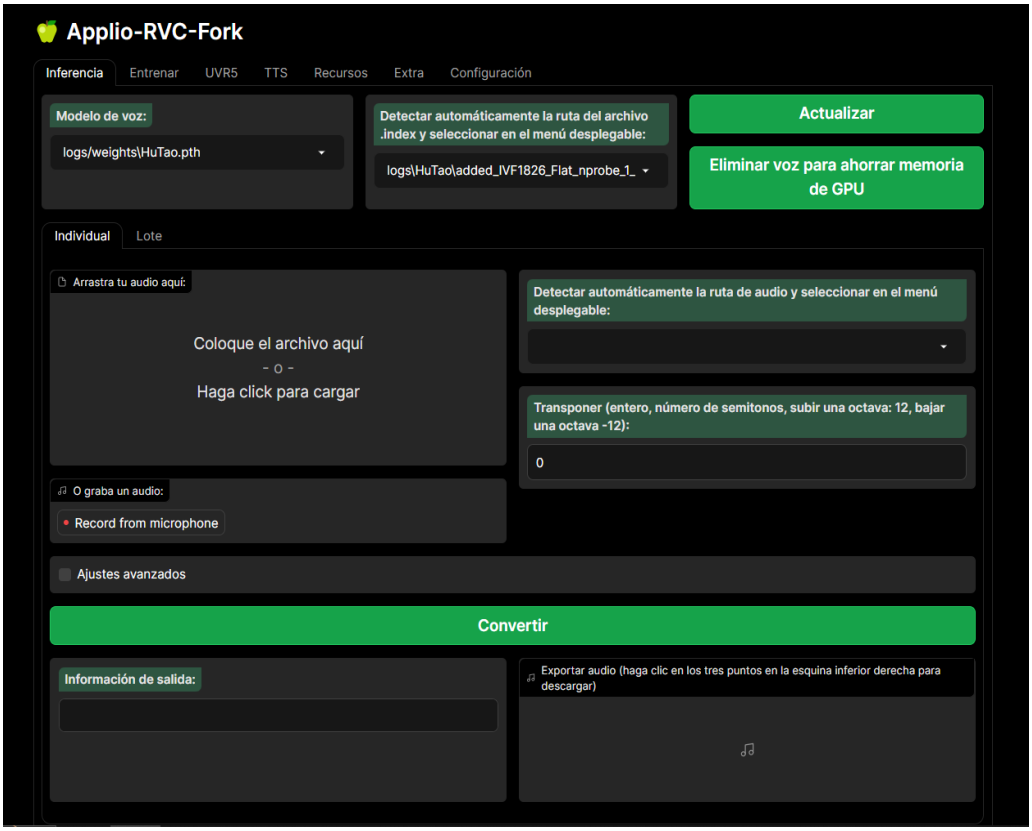

Fig. 8. Audio generation.

TABLE III. TABLE OF ERRORS FOUND

MISTAKES	
TYPE	***DESCRIPTION***
RESOLUTION	The main menu canvas was not satisfactorily adapted.
	The content of the buttons with options was not satisfactorily adapted.
PROGRAMMING	The dialogs of the first conversation loop were not correctly connected.

[c] Source: Own creation

5) Closing Phase: The educational institution Christa McAuliffe Trujillo, positively accepted the video game and also provided the facility to apply the implementation of the same for students.

The proposed purpose of implementing the video game was to improve social skills. On October 16, the video game was installed in all the functional machines of the institution, with a positive and interested acceptance by the students.

IV. RESULTS

A. Descriptive Analysis

In the descriptive Analysis, Table IV shows the frequency tables of the control and experimental groups for the research indicators, showing an improvement of 1.39 in the Communication Skills Level (NHC), 1.12 in the Feelings-related Skills Level (NHRS), 1.04 in the Non-violent Alternative Skills Level (NHAV) and 0.95 in the Pro-amical Skills Level (NHPA).

TABLE IV. RESEARCH INDICATOR FREQUENCY TABLE

Research Indicator	Level	Frequency		General Average	
		GC	***GE***	***GC***	***GE***
NHC	Very Low	21	-	1.7	3.09
	Low	9	9		
	Average	-	15		
	High	-	6		
NHRS	Very Low	18	-	1.8	2.92
	Low	10	7		
	Average	1	21		
	High	1	2		
NHAV	Very Low	19	-	1.68	2.72
	Low	10	20		
	Average	1	6		
	High	-	4		
NHPA	Very Low	20	3	1.58	2.53
	Low	10	18		
	Average	-	6		
	High	-	3		

[d] Source: Own creation

B. Inferential Analysis

In the inferential analysis, Table V shows the normality tests of the data collected from each group, based on each indicator, by using the Shapiro-Wilk test since each group is less than 50. There are two decision criteria: a) If $p<0.05$, the null hypothesis (H0) is rejected and the alternate hypothesis (Ha) is rejected and b) If $p\geq0.05$, the contrary is true.

TABLE V. SHAPIRO-WILK NORMALITY TEST TABLE

Research Indicator	P (GC)	P (GE)
NHC	0.261	0.419
NHRS	0.004	0.056
NHAV	0.12	0.014
NHPA	< .001	0.003

[e] Source: Own creation

Finally, the variables backed the specific alternate hypotheses posed (Ha) as seen in Table VI, showing that the Level of Communication Skills (NHC), the Level of Feelings Related Skills (NHRS), the Level of Non-violent Alternative skills (NHAV) and the Level of Proamic Skills (NHPA) increased with the use of a video game as all indicators had a value of $p<.001$, thus rejecting the null hypotheses (H0) that indicated that these skills decreased.

TABLE VI. INFERENTIAL ANALYSIS TABLE OF EACH INDICATOR

Research Indicator		Statistics	gl	p	Decision
NHC	T Student	-11.9	58	< .001	Ha is accepted
NHRS	U Mann-Whitney	70	-	< .001	
NHAV	U Mann-Whitney	69	-	< .001	
NHPA	U Mann-Whitney	109	-	< .001	

[f] Source: Own creation

V. DISCUSSION

Based on the obtained results, as evidenced by the use of a video game, it was possible to increase the level of communication skills, the level of feeling-related skills, the level of non-violent alternative skills and the level of Pro-amical skills; thus, demonstrating that the use of a video game significantly improved social skills.

With regard to the general objective, which sought to improve social skills through the use of a video game, it was determined that social skills were indeed significantly improved. This was demonstrated by the increase in the average of all skill levels measured; the results obtained are similar to the research conducted, where he demonstrates the effectiveness of the use of a video game called "Minecraft" for the improvement of social skills in people with autism spectrum disorder[9]. It should be noted defined that, social skills are a variety of behaviors that are evident in the interaction with other people, being that these behaviors are means to communicate emotions, positions, aspirations, points of view and rights in an appropriate manner according to the context, ensuring the expression of one's own rights while respecting the rights of others [12].

Regarding the first indicator, which is the level of communication skills, a total of 1.7 average points of the level of communication skills was obtained in the control group, and a total of 3.09 average points of the level of communication skills in the experimental group, showing an increase of 1.39 average points of the level of communication skills in the experimental group. In addition, it was calculated that the average of the control group represents 34%, while the average of the experimental group would be equivalent to 61.8%, thus proving an increase of 27.8% in the level of communication skills in the group that used the video game; the results were comparable with the study, which if we follow the same logic, presented an increase in communication skills of 41.53% [21]. It should be defined communication skills as those that encompass the ability to send and receive information, as well as ideas and messages relevant to those involved [22].

Regarding the second indicator, which is the level of skills related to feelings, a total of 1.8 points of average of the level of skills related to feelings was obtained in the control group, and a total of 2.92 points of average of the level of feeling-related skills in the experimental group, showing an increase of 1.12 points of average of the level of feeling-related skills in the experimental group. In addition, it was calculated that the average of the control group represents 36%, while the average of the experimental group would be equivalent to 58.4%, thus proving an increase of 22.4% in the level of feeling-related skills in the group that used the video game; the results were comparable with the study, who showed an improvement in the identification of emotions both their own and that of others in all their cases [23]. It should be defined that skills related to feelings are those that enable the understanding and effective expression of emotions and emotional states to others in order to be understood [22].

Regarding the third indicator, which is the level of, non-violent alternative skills, a total of 1.7 points of average of the , non-violent alternative skills was obtained in the control group, and a total of 2.72 points of average of the level of, non-violent alternative skills in the experimental group, demonstrating an increase of 1.02 points of average of the level of non-violent alternative skills in the experimental group. In addition, it was calculated that the average of the control group represents 34%, while the average of the experimental group would be equivalent to 54.4%, thus proving an increase of 20.4% in the level of non-violent alternative skills in the group that used the video game; the results were comparable with the study, who showed an increase in skills in the face of conflicts among all his cases, especially in cases of speaking with others to negotiate and reach an agreement[24]. It is worth defined that, non-violent alternative skills are those that reduce the possibility of perpetrating or being a victim of violent behaviors [22].

Regarding the fourth indicator, which is the level of proamic skills, a total of 1.58 points of average proamic skills level was obtained in the control group, and a total of 2.53 points of average proamic skills level was obtained in the experimental group, showing an increase of 0.95 points of

average proamic skills level in the experimental group. In addition, it was calculated that the average of the control group represents 31.6%, while the average of the experimental group would be equivalent to 50.6%, therefore, an increase of 19% in the level of proamictal skills was demonstrated in the group that used the video game; the results were comparable with the study, who demonstrated an increase in the frequency of initiation of an interaction and the time it was maintained, although in some cases it was still not constant, the frequency was increased [23]. It should be defined proamictal skills as those that increase the possibilities of establishing relationships with new people and maintaining friendships with other people, mainly friends [22].

Finally, it was concluded that the use of a video game improved social skills through the use of a video game, due to an increase in communication skills by an average of 27.8%, skills related to feelings by an average of 22.4%, alternative skills to violence by an average of 20.4% and proamic skills by an average of 19%.

VI. Limitations

During the research, there were several limitations, such as not taking into account stereotyped behaviors that are common in people with ASD, which were solved by the novelty that the use of a videogame presented in children, but there was no specific control for these behaviors that can alter the attention given to the software.

Also, there was limited time for the development of the software due to unexpected failures in the laptop intended for the development of the videogame and all its functionalities.

Likewise, the software was developed with the limitation of technical knowledge about the development of video games in the Unity environment by the researcher, and the software could have been much more optimized or include more mechanics in future research.

Finally, there was a hardware limitation of the laptops that the institution had, having a limited processing capacity, so we opted for an offline and resource-light approach.

VII. Conclusions

It has been established that there is a notable increase in the Communication Skills Level, thus demonstrating with the percentages obtained, with the calculation of the formula, 34% of Communication Skills Level was obtained in the control group and 61.8% of this level in the experimental group, thus proving an increase of 27.8%, in this level, of the group that used the video game, demonstrating that with the parametric statistical test T of Students a p value of <.001 was obtained providing sufficient statistical evidence to accept the alternative hypothesis.

In addition, it was established that there is a notable increase in the Level of Skills Related to Feelings, thus demonstrating with the percentages obtained, with the calculation of the formula, a 36% Level of Skills Related to Feelings was obtained in the control group and 58. 4% of this level in the experimental group, thus proving an increase of 22.4%, in this level, of the group that used the video game, demonstrating that with the non-parametric statistical test Mann-Whitney U, a p value of <.001 was obtained, providing sufficient statistical evidence to accept the alternative hypothesis.

Similarly, it was established that there is a notable increase in the Level of Alternative Skills to Violence, thus demonstrating with the percentages obtained, with the calculation of the formula, 34% of the Level of Alternative Skills to Violence was obtained in the control group and 54. 4% of this level in the experimental group, thus proving an increase of 20.4%, in this level, of the group that used the video game, demonstrating that with the non-parametric statistical test Mann-Whitney U, a p value of <.001 was obtained, providing sufficient statistical evidence to accept the alternative hypothesis.

Finally, it has been established that there is a notable increase in the Proamic Skills Level, thus demonstrating with the percentages obtained, with the calculation of the formula, 31.6% of Proamic Skills Level was obtained in the control group and 50. 6% of this level in the experimental group, thus proving a 19% increase, in this level, of the group that used the video game, demonstrating that with the non-parametric statistical test Mann-Whitney U, a p value of <.001 was obtained, providing sufficient statistical evidence to accept the alternative hypothesis.

Anknowledgment

The research was not externally funded. We would like to express our sincere gratitude to all those who have contributed to this research.

Conflict of Interest

The authors declare no conflict of interest.

Assistant Professor, VNR Vignana Jyothi Institute of Engineering & Technology, Hyderabad, Telangana, India[6]

***Abstract*—This work suggests a sophisticated movie recommendation system that offers individualized recommendations based on user preferences by combining content-based filtering, collaborative filtering, and deep learning approaches. The system use natural language processing (NLP) to examine user-generated content, movie summaries, and reviews in order to get a sophisticated comprehension of thematic aspects and narrative styles. The model includes SHAP for explainability to improve transparency and give consumers insight into the reasoning behind recommendations. The user-friendly interface, which is accessible via web and mobile applications, guarantees a smooth experience. The system is able to adjust to changing user preferences and market trends through ongoing upgrades that are founded on fresh data. The system's efficacy is validated by user research and A/B testing, which show precise and customized movie recommendations that satisfy a range of tastes.**

***Keywords*—Machine learning algorithms decision tree; random forest model-evaluation; accuracy value; precision value; F1 score**

I. INTRODUCTION

Navigating the immense ocean of films in the midst of a digital cinematic flood can be likened to looking for a secret beach in a dense fog. Conventional recommendation systems, which are frequently based on rudimentary algorithms, are not very helpful because they are unable to fully capture the nuances of individual preference. In order to introduce a complex movie recommendation system powered by machine learning's powerful engines, this study suggests a paradigm shift. Deep learning, natural language processing, content-based filtering, collaborative filtering, and deep learning are all skilfully combined by this system to explore the depths of user behaviour and movie attributes, creating a detailed picture of personal preferences [1]. The approach demystifies its suggestions and gives customers a glimpse into the reasoning behind each movie proposal in order to promote transparency and foster confidence. This system, which is easily navigable through user-friendly interfaces, blends in with daily life, changing to fit user tastes and trends while continuously crafting a customised cinematic journey. This study explores the system's technological details and reveals how revolutionary it could be for how we find and watch films that genuinely affect us.

It has been revised to emphasise the academic character of the project while retaining the compelling picture and key idea in a tone more appropriate for a paper. Important terminology and framing related to research writing are also introduced. customised cinematic journey.

A. Problem Statement

When accessing vast movie collections on streaming services, customers often face the challenge of option overload in today's digital entertainment scene. Traditional movie recommendation systems are widely used, but they sometimes struggle to fully capture customers varied and changing interests. The creation and implementation of a robust machine learning model-based movie recommendation system is the main problem that needs to be solved. The system needs to address several fundamental issues, such as the requirement for interpretable recommendations, sparse and noisy data, and the cold start problem. The primary goal is to increase user pleasure by providing tailored and contextually appropriate movie recommendations.

B. Background

The landscape of movie recommendation systems has become indispensable in the digital era, where an extensive array of films is available across various streaming platforms. These systems leverage advanced machine learning models to analyse user behaviour, preferences, and movie characteristics, ultimately providing personalized recommendations to enhance user satisfaction and engagement. The evolution of movie recommendation systems can be traced through several phases, marked by the adoption of increasingly sophisticated machine learning techniques.

1) Traditional recommender systems:

Collaborative filtering: In the early days, recommendation systems heavily relied on collaborative filtering, identifying similarities between users based on their preferences and suggesting items that similar users have enjoyed. However, collaborative filtering faced challenges such as the cold start problem (lack of data for new users or items) and scalability issues.

Content based filtering: Another traditional approach involved content-based filtering, which recommends items based on their attributes and features. In the context of movies, this could mean suggesting films with similar genres, directors,

or actors. Nevertheless, content-based systems struggled to capture nuanced user preferences

2) Machine learning advancements:

Hybrid models: By fusing content-based and collaborative methods, hybrid models have arisen to address the shortcomings of individual approaches. By combining the advantages of both strategies, these models sought to offer suggestions that were stronger and more accurate.

Matrix factorization is one technique that has helped collaborative filtering models improve. It breaks down the user-item interaction matrix into latent factors, which are underlying patterns in user preferences.

3) Deep learning for movie suggestions:

Neural Collaborative Filtering (NCF): By using neural networks to simulate intricate, non-linear correlations in user-item interactions, deep learning models like NCF have significantly improved the field. These models improve recommendation accuracy by taking into account both implicit feedback and explicit user-item ratings.

Embeddings: Known as learnt representations of objects and users in a reduced-dimensional space, embeddings have emerged as a key idea in enhancing recommendation models' efficacy and efficiency.

4) Integration of Natural Language Processing (NLP):

Textual data analysis: To provide recommendations a semantic layer, several systems have begun utilizing natural language processing (NLP) approaches. The algorithm is able to comprehend the context and substance of films with the aid of analysis of movie reviews, summaries, and other textual data, which results in more intelligent recommendations.

5) Transparency and explainability:

Explain ability techniques: The necessity to provide an explanation for recommendations increased with the complexity of machine learning models. In order to increase openness and user confidence, techniques such as SHAP (SHapley Additive explanations) were adopted to give users an explanation for why particular suggestions were produced.

Explainability is a critical aspect of recommendation systems, especially as they become more complex and sophisticated. Users often want to understand why a particular recommendation was made to trust and accept the system's suggestions. SHAP, or SHapley Additive explanations, offers a powerful technique to achieve this by providing insights into the contribution of each feature to the model's decision-making process.

6) User experience and deployment:

User interfaces: Web and mobile applications now offer user-friendly interfaces for movie recommendation systems, which replaced the previous backend algorithms. Users will find it effortless to find and enjoy recommended content thanks to these interfaces, which offer a smooth and user-friendly experience.

7) Ongoing education and adjustment:

Dynamic updates: Modern recommendation systems are built for continual learning in order to keep up with the ever-changing nature of user preferences and the film business. Their models are continually updated and fresh data is incorporated to accommodate evolving patterns and user behavior.

C. Key Challenges

- Issue with Cold Start for Users and Films:
- Noisy and Sparse Data:
- Persistent User Preferences:
- Diverse Content and Coincidence:
- Both Real-Time Processing and Scalability:

D. Objectives

1) To improve personalization: It create machine learning models that can recognize and comprehend the preferences of individual users. This will allow for the creation of personalized movie suggestions based on each user's specific preferences and viewing history.

2) Handle the cold start issue: Put techniques in place to deal with the cold start issue for both new users and recently released films. This will allow the recommendation engine to make precise recommendations even in situations when there isn't much previous data to go on.

3) Increase recommendation accuracy: Reduce the Probability of Irrelevant or Mismatched Suggestions. Increase the Accuracy and Relevance of Movie Recommendations. Apply cutting-edge machine learning methods, like content-based filtering, collaborative filtering, and deep learning models.

4) Manage sparse and noisy data: In order to ensure that the recommendation system remains robust and effective in the face of incomplete or unreliable information, develop robust approaches to manage sparse user-item interaction data and reduce the effects of noisy preferences.

5) Adjust to changing user preferences: Develop systems that allow the recommendation system to adjust to changing user preferences over time. These systems should include real-time or very real-time updates to account for shifts in user behavior and blockbuster patterns.

6) Encourage content diversity: Create algorithms that suggest films from a variety of genres, languages, and cultural backgrounds in addition to taking into account well-liked films. Urge viewers to investigate a wider range of cinematic encounters.

7) Make sure the recommendations can be interpreted: Use ways to help consumers understand why certain movies are recommended, including attention processes or SHAP values. To increase user confidence and trust, make the suggestion mechanism more transparent.

8) Optimize for scalability: Construct an architecture that is scalable to effectively manage rising movie catalogues and

user bases. Make sure there is no performance degradation when the recommendation system scales horizontally to handle the growing dataset.

9) Integrate multi-modal data: To improve recommendation models, make advantage of multi-modal data, such as user interactions, movie qualities, and textual content. Use efficient feature engineering approaches to get a comprehensive picture of consumer preferences and movies.

10) Promote a seamless user experience: Create intuitive and seamless user interfaces for online and mobile applications. To provide a happy and pleasurable user experience, make sure that users can simply access and explore suggested films.

11) Continuous learning and model updating: Create a framework that enables the recommendation system to keep up with new developments and modifications in user behavior. Establish systems for updating the model on a frequent basis using new data in order to keep it relevant. Measure User contentment and Engagement: Utilize analytics and metrics to assess user contentment, engagement, and the efficacy of the recommendation system. Perform user research on a regular basis to get input and insights for future enhancements.

II. Literature Review

S. Kanwal, S. Nawaz, M. K. Malik, and Z. Nawaz [1], this paper reviews the research from 2010 to 2020 in order to provide an extensive overview of text-based recommendation systems (RS). The large volume of textual data on the internet, which makes it difficult for users to locate pertinent information quickly, is the driving force for text-based RS. The four main areas of focus of the survey are evaluation metrics, computational methodologies, feature extraction techniques, and datasets.

S. Maneeroj and N. Sritrakool [2], in this paper, a unique sequential recommender system called PPD+ is presented. It uses a personalized drift detection approach to meet evolving user preferences. By avoiding pre-defined quantities and employing soft labels for item grouping, PPD+ maximizes the number of pertinent encounters. When trained from start to finish, it outperforms baselines and content-based transformers by classifying interactions and making better suggestions. The results demonstrate the superiority of PPD+ in item group comparison and soft clustering. Zero is shown to be the ideal item utilization threshold. Future research attempts to separate noise from interactions that appear insignificant in order to uncover latent user preferences.

Y. Wang, L. Dong, H. Zhang, X. Ma, Y. Li and M. Sun [3]. This paper presents SI-MKR, a sophisticated recommendation system that expands on the MKR deep learning model. By utilizing knowledge graph representation and multi-modal information, SI-MKR improves recommendation accuracy. It tackles the drawback of multi-modal knowledge-based recommendation systems overlooking data type diversity. The model uses a deep neural network for knowledge graph embedding and feature extraction to classify user and object properties. SI-MKR combines knowledge graph data with the recommendation system through alternate training, showing notable improvements in movie recommendation above advanced model baselines in real-world datasets. Even in sparse user-item interactions, the suggested SI-MKR model performs better than MKR, demonstrating its adaptability to a variety of data kinds. Subsequent research endeavors to include past user behavior as a pertinent characteristic and develop models to more effectively investigate user preferences.

S. Beg ,Adeel Anjum, Mansoor Ahmed, Saif Ur Rehman Malik, Hassan Malik,Navuday Sharma, Omer Waqar [4] In this study, a Reversible Data Transform (RDT) method based on chaos is introduced for Privacy-Preserving Data Mining (PPDM) in recommendation systems. This methodology, in contrast to other RDT methods, does not require previous sharing because it creates parameter values dynamically at runtime. The chaotic RDT performs better than regular RDT, as demonstrated on the Iris dataset, and can be a useful replacement in situations where resources are limited. The study verifies the algorithm's ability to replace homomorphic encryption (HE) in mobile app recommendations by extending its effectiveness to real app usage records when an adaptive recommendation approach is employed. The appendix further highlights comparable performance with original datasets on synthetic and app rating datasets.

Z. Ali, A. Muhammad, A. S. Al-Shamala, K. N. Qureshi, W. Alrawagfeh and A. Akhunzada [5] The unique approach of Long Short-Term Memory-Inter Intra-meta path Aggregation (LSTM-IIMA) in movie recommendation systems is presented in this paper. By utilizing LSTM networks with a two-level attention mechanism, LSTM-IIMA, which focuses on intra- and inter-meta path analysis, is able to capture complex relationships and connections between users, movies, and contextual components. By optimizing parameters, the model—which was learned using supervised learning—lowers prediction errors. Evaluation criteria showing the superiority of LSTM-IIMA over other methods such as HAN and MAGNN include precision, recall, AUC, and time efficiency. Even while LSTM-IIMA successfully takes care of long-term user preferences and evolving movie consumption habits, issues including sparse data, the cold start problem, interpretability, scalability, and real-time suggestions still require more research. Notwithstanding these obstacles, LSTM-based models have the ability to greatly improve the precision and customization of movie suggestions, offering more interesting and pertinent ideas to users.

X. Chen , Pengpeng Zhao, Yanchi Liu, Lei Zhao, Junhua Fang, Victor S. Sheng and Zhiming Cui [6] This article uses visual content information—movie posters and still frames in particular—to address the data sparsity problem in personalized movie recommendation. Convolutional Neural Network (CNN) characteristics and aesthetic features are integrated into a probabilistic matrix factorization framework in the proposed Aesthetic-aware Unified Visual Contents Matrix Factorization (UVMF-AES). The model extracts both the meaning of the movie (CNN features) and its aesthetic quality (aesthetic features) by using deep learning networks (OWACNN and VGG16). UVMF-AES is then produced by combining the integrated features with Probabilistic Matrix Factorization. Results from experiments on real-world datasets show that UVMF-AES performs much better in movie

recommendation than the state-of-the-art techniques, demonstrating the value of adding aesthetic aspects to increase accuracy.

M. S. Faisal, A. Rizwan, K. Iqbal, H. Fasihuddin, A. Banjar and A. Daud [7] In this study, a unique feature-based movie quality prediction mechanism is proposed that incorporates temporal factors, user reputation, and social quality. The suggested Genetic Algorithm Voting (GA-V) classifier assigns weights depending on each model's performance for each class, thereby combining the strengths of several models in the best possible way. The Movie Lens dataset is used to train conventional machine learning models, and the precision, recall, and F1 score of the suggested GA-V classifier are compared with those of the models. The outcomes demonstrate the importance of the suggested features and the GA-V classifier's potency in predicting movie quality. Future work might entail adding new features, expanding on current ones, and improving the classifier's weight assignment procedure.

X. Chen, J. Tian, X. Tian, and S. Liu. [8] Introducing the FHR ec model, which uses deep learning and heterogeneous information networks to improve recommendation system performance. To increase the accuracy of its recommendations, the algorithm makes use of reviews, ratings, and more data. It uses a heterogeneous information network (HIN) to represent rich auxiliary data and network embedding to learn entity attributes. The Deep Conn technique, a type of deep learning technology, is used to extract user and object attributes from reviews. These features are then fused individually using the attention process. Results from experiments on the Douban movie dataset and the Yelp dataset show that FHRec performs better than conventional comparison algorithms. Through a thorough methodology, the model seeks to fully utilize the information that is now available from a variety of sources, including user evaluations and ratings. Despite its effectiveness, the model admits some flaws, such as the underuse qualities of the user and the item. Subsequent investigations will endeavor to tackle these deficiencies and investigate the integration of sentiment patterns in text evaluations for enhanced feature extraction. In addition, an investigation into the application of Graph Convolutional Networks (GCN) to extract user and item attributes from the heterogeneous information network will be conducted.

M. He, B. Wang, and X. Du [9], the study presents HI2Rec, a recommender system that integrates user and item data to improve top-N suggestions by utilizing knowledge graphs. In contrast to current approaches that prioritize item features, HI2Rec takes user-related data into account to overcome shortcomings in recommendation outcomes. The method entails taking movie-related data out of Linked Open Data and using knowledge representation learning to embed it into a single vector space with real-world datasets. The initial suggestion list is then created using the vector representations, and it is subsequently fine-tuned for accuracy using a collaborative filtering method. Findings from experiments using real-world datasets, including MovieLens-1M, show notable gains in performance over the most advanced knowledge graph-based recommendation models. Subsequent research endeavors to incorporate knowledge graphs with additional data sources such as social networks and user feedback, investigate recommender systems based on reinforcement learning, and expand the approach to diverse industries like news, e-commerce, and music.

S. Sahu, R. Kumar, M. S. Pathan, J. Shafi, Y. Kumar and M. F. Ijaz [10], the study offers an expert method to assist in decision-making and tackles the problem of forecasting movie success early in the production process. The study forecasts target audience preferences and movie popularity using deep learning models and content-based movie recommendation systems. The recommendation method makes use of features including keywords, movie description, actor, genre, and director. The suggested CNN deep learning model outperforms benchmark models with an accuracy of 96.8%. The approach forecasts popularity across various age groups in addition to general popularity. The material covers a century's worth of movie information and comes from IMDb. The study highlights how predictive analytics may help industry decisions and recommends using multimedia data and market sentiment analysis in the future to improve forecasts.

R. Zhang and Y. Mao [11], this research presents a probabilistic framework for collaborative filtering through the introduction of a new model family called Markovian factorization of matrix process (MFMP). In contrast to time SVD++, MFMP models capture temporal dynamics in datasets while retaining a clear probabilistic formulation. In trials utilizing the Movie Lens dataset, the models show equivalent or better performance to timeSVD++ and standard tensor factorization when applied to movie rating prediction using time-stamped data. The paper makes several recommendations for improving the model, including adding global biases, integrating logistic functions, and investigating Bayesian variants. It is also described how MFMP models may be applied more broadly to collaborative filtering issues and how they could be extended to handle textual data.

S. M. Al-Ghuribi and S. A. Mohd Noah [12], this review focuses on the significance of recommender systems (RSs) in various domains and highlights the limitations of relying solely on single-criterion ratings, such as overall ratings, in the recommendation process. To address this, multi-criteria recommender systems (MCRSs) are introduced, leveraging user-generated reviews to enhance RS accuracy. The review emphasizes the extraction of valuable review elements through text mining or sentiment analysis and their integration into MCRS criteria. The survey categorizes and discusses approaches based on the review elements utilized, offering a comprehensive overview of recent research in multi-criteria review-based recommender systems. The review concludes by presenting future trends and challenges, providing valuable insights for researchers in this field.

E. Y. Keat [13], this work addresses the limitations of existing recommendation systems (RSs) that primarily focus on rating prediction accuracy and popularity, neglecting metrics like novelty and diversity. To overcome challenges in multi-objective optimization, the study proposes two deep reinforcement learning (DRL) approaches, DQNMORS and Radnor’s, for RSs. These approaches optimize precision, novelty, and diversity metrics simultaneously. Comparative evaluations with a probabilistic-based multi-objective approach

show the superiority of DRL in achieving high novelty and diversity, despite some trade-offs in precision. Incorporating user latent features and leveraging LSTM layers further enhance the recommendation performance. The study sets a benchmark for future research in DRL-based RS applications and suggests exploring advanced DRL approaches and addressing challenges in optimizing multiple objectives concurrently.

H. Huang, S. Luo, X. Tian, S. Yang and X. Zhang [14] In this paper, we present an improvement on collaborative filtering (CF) based recommendation systems: The Neural Explicit Factor Model (NEFM). By including an item-feature quality matrix and a user-feature attention matrix, NEFM seeks to increase the explain ability of suggestions. The model extracts feature from the user, item, and item-feature vectors using a feedforward neural network and a one-dimensional convolutional neural network. Tests conducted on the Movie Lens and Yahoo Movies datasets show that NEFM performs better than comparable recommendation models in terms of explain ability and accuracy. The suggested paradigm holds potential for building more comprehensible recommendation systems, and future research might include adding user feedback for even more improvement.

J. Zhang, Y. Wang, Z. Yuan, and Q. Jin [15], this study discusses actual usage feedback and scalability concerns in movie recommendation systems. The suggested approach, Weighted KM-Slope-VU, clusters users into groups represented by virtual opinion leaders, effectively utilizing the profile traits of the users. As a result, the user-item matrix becomes less dimensional, which speeds up suggestions without sacrificing functionality. The algorithm is tested on Movie Lens datasets, showing reduced time complexity and performance equivalent to matrix factorization-based techniques. Movie Watch is a real-world personalized movie recommendation system that is developed, made available to the public, and has user feedback gathered for useful assessment. In the future, the algorithm will be improved by adding the newest films and refining virtual user selection to increase suggestion accuracy.

III. Methodology

A. Data Collection

The Movie Lens dataset was used in this study to train and assess the machine learning models. One popular and well-known dataset in the field of recommendation systems is Movie Lens. It includes demographic data, movie metadata, and user ratings. The dataset is relevant for training robust recommendation models because of the variety of films it contains, and the user interactions it facilitates.

1) Feature selection: Features taken into account for the machine learning model consist of:

a) User-item interactions:

- Movie ratings from users, along with detailed commentary.
- Implicit feedback that records extra user engagements, like views or clicks.

b) Movie attributes:

- Directors, actors, genres, and more metadata that support suggestions based on content.
- Natural language processing (NLP) techniques applied to movie textual data, such as reviews and summaries, to get a semantic understanding.

c) Contextual features:

- Time information, taking into account the user's interaction with a film.
- User demographic information, if it is available, to investigate how user traits affect preferences.

B. Machine Learning Model

A hybrid recommendation model that combines deep learning, content-based filtering, and collaborative filtering was used. This decision was made with the intention of utilizing the advantages of many recommendation paradigms to provide a more thorough and precise user preference prediction. Table I shows comparison of models.

1) Collaborative filtering: To capture user and item similarities, respectively, user- and object-based collaborative filtering methods were put into practice. Latent factors were found using matrix factorization techniques like Singular Value Decomposition.

2) Content-Based filtering: This method made use of film characteristics like actors, directors, and genres. Moreover, textual data was processed using NLP approaches, which allowed the model to comprehend the semantic connections between user preferences and movies.

3) Neural Collaborative Filtering (NCF): To capture intricate non-linear patterns in user-item interactions, a neural collaborative filtering model—more precisely, NCF—was integrated. The neural network element improves the model's capacity to identify complex relationships in order to produce recommendations that are more accurate.

C. Evaluation Metrics

The following metrics were taken into consideration in order to assess how well the movie recommendation model performed:

1) Precision: This refers to the percentage of accurately recommended films among all suggestions, calculated as the accuracy of the positive forecasts.

2) Recall: Recall measures how well the model captures all relevant films; it expresses the percentage of relevant films that are accurately recommended out of all relevant films.

3) F1-Score: This balanced indicator of the model's overall performance is the harmonic mean of precision and recall.

4) Mean Squared Error (MSE): This metric measures the average squared difference between the ratings that were predicted and the ratings that were received, indicating how accurate the numerical predictions were. It is employed in collaborative filtering algorithms.

These assessment metrics offer a thorough understanding of the model's functionality by taking into account both the accuracy of numerical forecasts and the precision of suggestions. The selection of metrics is in line with the objective of providing precise, pertinent, and customized movie recommendations.

TABLE I. COMPARISON OF MODELS

Model	Precision	Recall	F1 Score
our Model	0.85	0.78	0.81
Neural Collaborative Filtering (NCF)	0.82	0.79	0.80
Traditional Collaborative Filtering	0.75	0.72	0.73

An overview of the main procedures is provided here, along with succinct justifications. Please be aware that depending on the programming language and machine learning framework selected, the precise implementation details may change. Flowchart of the algorithm is given in Fig. 1.

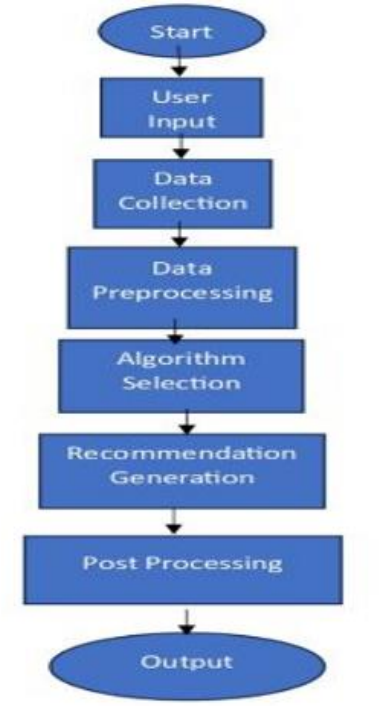

Fig. 1. Flow chart of the algorithm.

D. Implications for the Field

1) Progressing with recommendation frameworks: The hybrid model's success emphasizes how critical it is to develop recommendation paradigms beyond content-based and collaborative filtering. Including deep learning methods into movie suggestions, like neural collaborative filtering, can greatly increase their relevance and accuracy.

2) Improving user experience: The research results support continued initiatives to improve movie recommendation systems' user experiences. Not only do personalized and varied recommendations boost user pleasure, but they also solve issues like as the cold start issue, making the movie experience more captivating and delightful.

3) Balancing complexity and interpretability: The larger discipline of machine learning is affected by the difficulty of striking a balance between model complexity and interpretability. Finding efficient ways to explain complex models' decisions will be essential for gaining users' acceptance and trust as these models become more and more integrated into recommendation systems.

IV. RESULTS

A. Collaborative Filtering with Pearson Correlation

This solution carefully designed a movie recommendation system using collaborative filtering and Pearson correlation. At first, CSV files were used to extract and preprocess movie ratings and metadata. The user ratings matrix that resulted from the smooth fusion of pertinent data frames served as the basis for cooperative filtering. Strict measures were implemented to mitigate sparsity concerns, such as eliminating films with poor ratings and carefully imputed missing values. The system's most important component is its calculation of the Pearson correlation matrix, which measures how similar films are to one another according to user evaluations. A well-defined recommendation function was then added to provide personalized movie suggestions tailored to individual user ratings. This application showcases the effectiveness of collaborative filtering, offering personalized movie recommendations based on user interests. The displayed data, including the structural characteristics of the user ratings matrix, the Pearson correlation matrix, and sample movie recommendations, collectively demonstrate the system's capability to deliver relevant and customized cinematic suggestions (see Fig. 2).

B. Content-Based Movie Recommendation System using TF-IDF and Cosine Similarity

In this paper the dataset used is including movie information to create this content-based movie recommendation system. We apply TF-IDF, a method that measures word importance in a document, to the textual content of each movie's synopsis. The user is prompted to enter their favorite movie after any potential missing values have been handled. After that, the system determines how similar

this selected movie is to all the others based on their TF-IDF representations. The user is recommended the top 10 films with the highest similarity ratings. This method helps users who prefer films with similar themes or descriptions by enabling personalized recommendations based on content similarities across films (see Fig. 3).

```
Enter a movie you like: Avengers: Age of Ultron
Recommended movies:
The Avengers
Iron Man 2
Iron Man
Captain America: Civil War
Knight and Day
Iron Man 3
Cradle 2 the Grave
Unstoppable
Gettysburg
The Man from U.N.C.L.E.
```

Fig. 3. Content-based movie recommendations for movie age of ultron.

C. Future Scope

1) Dynamic user preferences: Examine methods for recording and adjusting to the gradual changes in user preferences. This can entail investigating methods for reinforcement learning or hybrid models that can easily adjust to changing user preferences.

2) Temporal considerations: Incorporate temporal factors, including seasonal trends or preferred times of day, to improve the recommendation system. This can better capture the temporal dynamics of user behavior and offer recommendations that are more contextually appropriate.

3) Contextual data: Examine how to incorporate more contextual data, like user location, device kind, and social interactions. Contextual features offer a more thorough grasp of user preferences and can improve the relevance and personalization of recommendations.

4) Fairness and bias mitigation: Deal with concerns about recommendation systems' fairness and bias. Investigate and put into practice strategies to lessen user demographic biases, making recommendations fair and free of discriminating or stereotype-reinforcing tendencies.

5) Explainable AI (XAI): More study to make complex models easier to understand, particularly neural collaborative filtering. Use explainable AI tools to give consumers a clear grasp of the recommendations for particular films, building user confidence and comprehension.

6) Multi-modal recommendations: Expand the recommendation system to include user reviews, audio, and image data. Combining several modalities might improve the model's comprehension of user preferences and movies, resulting in more accurate and nuanced suggestions.

7) Integration of Augmented Reality (AR): Take into account incorporating augmented reality elements into recommendation systems to offer users engaging and immersive experiences. AR has the potential to improve suggested content visualization and exploration.

V. Conclusion

To sum up, the Cinematic Curator that has been demonstrated is an advanced movie recommendation system that combines collaborative filtering, content-based filtering, and deep learning. While the integration of SHAP guarantees openness in the recommendation process, the addition of natural language processing improves its comprehension of user preferences. An easy-to-use interface, flexibility, and regular updates depending on new data all combine to provide a fluid and dynamic cinematic experience. The system's effectiveness is confirmed empirically by user research and A/B testing, showcasing its capacity to deliver accurate and personalized movie suggestions and changing the field of personalized movie recommendation systems.

Sentiment Analysis of Pandemic Tweets with COVID-19 as a Prototype

Mashail Almutiri, Mona Alghamdi, Hanan Elazhary
Information Systems and Technology Department, University of Jeddah, Jeddah, Saudi Arabia

***Abstract*—One of the most important applications of text mining is sentiment analysis of pandemic tweets. For example, it can make governments able to predict the onset of pandemics and to put in place safe policies based on people's feelings. Many research studies addressed this issue using various datasets and models. Nevertheless, this is still an open area of research in which many datasets and models are yet to be explored. This paper is interested in the sentiment analysis of COVID-19 tweets as a prototype. Our literature review revealed that as the dataset size increases, the accuracy generally tends to decrease. This suggests that using a small dataset might provide misleading results that cannot be generalized. Hence, it is better to consider large datasets and try to improve analysis performance on it. Accordingly, in this paper we consider a huge dataset, namely COVIDSenti, which is composed of three sub datasets (COVIDSenti_A, COVIDSenti_B, and COVIDSenti_C). These datasets have been processed with a number of Machine Learning (ML) models, Deep Learning (DL) models, and transformers. In this paper, we examine other ML and DL models aiming to find superior solutions. Specifically, we consider Ridge Classifier (RC), Multinomial Naïve Bayes (MNB), Stochastic Gradient Descent (SGD), Support Vector Classification (SVC), Extreme Gradient Boosting (XGBoost), and the DL Gated Recurrent Unit (GRU). Experimental results have shown that unlike the models that we tested, and the state-of-the-art models on the same dataset, SGD technique with count vectorizer showed quite constantly high performance on all the four datasets.**

Keywords*—COVID-19; deep learning; machine learning; sentiment analysis; text mining; tweets

I. Introduction

Text Mining (TM) deals with the automatic extraction of interesting information from text. It uses data mining techniques to extract information that is hidden within huge amounts of unstructured textual data. Such extracted information is typically transformed into a structured format that can be further processed, possibly using Natural Language Processing (NLP) techniques. Sentiment Analysis (SA) is a text mining approach that utilizes data science techniques including Machine Learning (ML) and Deep Learning (DL) to analyze text and identify subjective information. It is concerned with assessing feelings and opinions, and classifying them into polarities, which are typically either positive, negative, or neutral. Social media are popular networks such as Facebook and X (formerly, Twitter) that are used by users to share their reviews about various topics and incidents. Additionally, one of the main uses of the Internet is checking reviews of others and expressing personal opinions. Since social media posts are mainly about expressing feelings and opinions, some researchers believe that Opinion Mining (OM) refers to social media SA. SA and OM are often used interchangeably. We adopt the term SA in this paper.

One of the most important and popular social media platforms is X in which users express their opinions using *tweets*. Since social media has a great influence on society, tweets about pandemics would most probably stimulate fear and agony. Tweets data mining can be very helpful in generating important health-related facts. For example, many research studies have shown that tweets can be exploited in the prediction of the onset of pandemics or diseases. SA of tweets is thus of special importance during pandemics. It is of great benefit to people's lives as it makes governments able to put in place safe policies based on inferred people's feelings.

A recent example of such pandemics is Coronavirus Disease 2019 (COVID-19). On March 11th, 2020, the World Health Organization (WHO) announced COVID-19 as a pandemic. Since at that time, no known effective vaccines or treatments existed, the governments and public health sectors had to take some precautionary decisions to avoid the spread of the infection, including isolation, quarantine, and emergency lockdown. During this period, COVID-19 had a negative effect on various aspects of people's lives, and because the lockdown gave them more free time, the subject of the greatest portion of posts and tweets at that time was that pandemic. Many research studies have been concerned with SA of COVID-19 tweets using various datasets and various models (ML, DL, and transformers) [1-9]. Nevertheless, SA of pandemic tweets in general is still an open area of research in which many datasets and numerous models are yet to be explored.

This paper is concerned with the SA of tweets during pandemics and considers COVID-19 as a prototype. In other words, the research problem is how to analyze tweets during pandemics and decide whether their sentiment is positive, negative, or neutral. Literature review has revealed that accuracy generally tends to decrease with the increase of the dataset size. This suggests that results based on relatively small-sized datasets might be misleading. Hence, we decided to work with large datasets and try to find better solutions for analyzing them. Towards this goal, we manipulated a huge dataset, namely COVIDSenti and its three sub-datasets (COVIDSenti_A, COVIDSenti_B, and COVIDSenti_C) [8]. These datasets have been processed with a number of ML models, DL models, and transformers. In this paper, we examine other ML and DL models aiming to find superior

solutions. The contributions of the paper can be summarized as follows:

- Searching for better performing ML and DL model(s) for SA of COVIDSenti tweets through a set of experiments.
- Comparison of the results of the various models with the state of the art to gain insights that can guide future research.

The rest of this paper is organized as follows: Section II presents related work on COVID-19 tweet analysis. Section III explains the proposed methodology that this article follows. Section IV discusses the datasets and the data preprocessing techniques. Models and experimental settings are presented in Section V. In Section VI, we compare their performance with the state of the art. Finally, Section VII depicts conclusions and draws directions for future work for further improvements.

II. Related Work

Several research studies studied sentiment analysis of COVID-19 tweets. We discuss a recent sample in the order of the dataset size. For example, Shofiya and Abidi [1] extracted 629 Canadian tweets from an open-source publicly available IEEE website. They used SentiStrength tool to detect sentiment polarity in combination with Support Vector Machine (SVM) classifier. The highest achieved accuracy of 87% was achieved on 10% test data. They concluded that a large dataset is required to increase the performance of the algorithm. On the other hand, Chintalapudi et al. [2] considered Indian tweets and obtained from github.com a dataset consisting of 3,090 tweets extracted from the Indian Twitter platform. The tweets were classified into "afraid," "sad," "angry," and "happy." They compared Bidirectional Encoder Representations from Transformers (BERT), Logistic Regression (LR), SVM, and Long Short-Term Memory (LSTM). The accuracy has been used as a metric to evaluate the models. The results showed that the BERT model outperformed the other models with 89% accuracy. Gupta et al. [3] also considered Indian tweets and processed 7,284 tweets having the keyword *India lockdown*. They compared MNB, Bernoulli Naïve Bayes (NB), LR, linear SVC, AdaBoost, Ridge classifier, passive aggressive (PA) classifier, and a perceptron using accuracy, precision, recall, and F1-score. In their experiments, linear SVC with unigram showed best performance with 84.4% accuracy, 83.5% precision, 82.4% recall, and 82.5% F1-score.

Ramya et al. [4] considered a slightly larger dataset consisting of 11,000 tweets (10,000 for training and 1000 tweets for testing) and used NB and LR to process them combined with *n-grams*. They also used accuracy as their metric. Interestingly, in their experiment, NB showed accuracy of about 92.49% for short tweets (less than 70 characters) and much lower accuracy of only 60.56% in the case of longer tweets.

Other researchers considered relatively larger datasets. For example, Goel and Sharma [5] collected a dataset comprised of 42,468 tweets. They analyzed them using SVC, Random Forest (RF), a neural network (NN) which is a combination of convolutional NN (CNN) and LSTM, and BERT. To evaluate the performance, they used Area Under the Receiver Operating Characteristic Curve (AUC). In their experiment, the best model was RF with 96% AUC accuracy. Vernikou et al. [6] used another dataset consisting of 44, 955 tweets. Their goal was to classify tweets into negative, neutral or positive. They used seven different DL models based on LSTM, and a set of ML models (MNB, Decision Tree (DT), and RF). The models were evaluated using accuracy, precision, recall, and F1-score. In their experiment, one of the LSTM-based models, namely BERT Tokenizer LSTM showed the best performance with 90% accuracy, precision, recall, and F1-score. Qi and Shabrina [7] extracted a total of 77,332 unique tweets and processed those using RF, MNB and SVC models. Performance was evaluated using precision, recall, F1-score, and accuracy. They also considered three different methods of feature representation, namely, bag of words (BoW), TF-IDF, and Word2Vec. In their experiments, the SVC using BoW or TF–IDF showed the best performance with accuracy of 71%.

Naseem et al. [8] prepared the largest dataset that we encountered in our literature review. This is the COVID Senti dataset which is composed of 90,000 unique tweets from 70,000 users. This dataset was divided into three subsets, namely, COVID Senti_A, COVID Senti_B, and COVID Senti_C. This dataset, that we adopt in this paper, is discussed together with its subsets in more details in Section IV. The four datasets were analyzed using SVM, NB, RF, and DT. In addition to those ML models, they utilized CNN and Bi-directional LSTM (Bi-LSTM). This is in addition to a set of hybrid models and transformers that we do not consider in the current research. Accuracy has been used as a metric to evaluate performance. Experimental results have shown that among the ML models considered, SVM and RF with FastText embedding showed accuracy of 84.5% on COVIDSenti. On the other hand, among the DL models considered, CNN with Glove word embedding showed higher performance of 86.9% on the same dataset.

Jalil et al. [9] used the same dataset in their experiments. They examined a set of different ML models, namely K-Nearest Neighbors (KNN), LR, ensemble, XGBoost, SVM, NB, DT, and RF. They also examined a set of deep learning models based on CNN and BiLSTM. This is in addition to a set of hybrid models and transformers, which as previously noted, is not considered in this research study. They also used accuracy for performance evaluation. Among the ML models, XGBoost showed the best performance with 89.81% accuracy on COVIDSenti. On the other hand, among the DL models, a combination of CNN, LSTM and Glove word embedding showed the best performance with 87.06% accuracy on the same dataset.

The related work is summarized in Table I. As shown in the table, researchers used different models and datasets for SA of COVID-19 tweets. We notice that as the dataset size increases, the accuracy generally tends to decrease. This suggests that using a small dataset might provide misleading results that cannot be generalized. Hence, it is better to consider large datasets and try to improve analysis performance on it. Accordingly, in this paper we consider the largest dataset that we encountered, namely, COVIDSenti and its three subsets. Also, we limit our research study to ML and DL models

aiming to find better solutions that would be used in case of any future pandemic. Towards this goal, we consider additional models in comparison to those used on the same dataset [8-9].

TABLE I. SUMMARY OF RELATED WORK

Ref No.	Dataset	Models	Metrics	Best Results
[1]	629 tweets extracted from an open-source free IEEE website	SVM	confusion matrix, precision, recall, and F1-score	87% accuracy on 90% training data
[2]	3,090 tweets from the Indian Twitter platform	BERT, LR, SVM, LSTM	accuracy	BERT with 89% accuracy
[3]	7,284 tweets having the keyword *India lockdown*	MNB, Bernoulli NB, LR, Linear SVC, AdaBoost, Ridge classifier, passive aggressive (PA) classifier, perceptron	accuracy, precision, recall, F1-score	Linear SVC with unigram with 84.4% accuracy, 83.5% precision, 82.4% recall, and 82.5% F1-score
[4]	11,000 tweets (10,000 for training and 1000 tweets for testing)	NB and LR	accuracy	NB with 91% accuracy on short tweets
[5]	42,468 tweets	SVC, RF, NN, BERT	AUC	RF with 96% AUC
[6]	44, 955 tweets	Seven LSTM-based models, MNB, DT, RF	accuracy, precision, recall, F1-score	Bert Tokenizer LSTM with 90% accuracy, precision, recall, and F1-score
[7]	77,332 tweets	RF, MNB, SVC	precision, recall, F1-score, and accuracy	SVC using BoW or TF–IDF with 71% accuracy
[8]	COVIDSenti, composed of 90,000 tweets and its three subsets (COVIDSenti_A, COVIDSenti_B, and COVIDSenti_C)	ML (SVM, NB, DT, RF), DL (CNN, BiLSTM), and a set of hybrid models and transformers	accuracy	ML models: SVM and RF with FastText embedding with 84.5% accuracy on COVIDSenti DL models: CNN with Glove word embedding with 86.9% accuracy on COVIDSenti
[9]	COVIDSenti, composed of 90,000 tweets and its three subsets (COVIDSenti_A, COVIDSenti_B, and COVIDSenti_C)	ML (KNN, LR, Ensemble, XGBoost, SVM, NB, DT, RF), DL (CNN, BiLSTM), and a set of hybrid models and transformers	accuracy	ML models: XGBoost with 89.81% accuracy on COVIDSenti DL models: a combination of CNN, LSTM and Glove word embedding with 87.06% accuracy on COVIDSenti

III. METHODOLOGY

The methodology pipeline shown in Fig. 1 follows a typical data analytics lifecycle. As shown in the figure, COVID-19 tweets are first pre-processed, and features are extracted from them. Then two experiments are conducted. The first considers a set of ML models preceded by data vectorization (represented as numeric vectors). The second, on the other hand, involves the Gated Recurrent Unit (GRU) DL model. This involves a different data representation technique. This is followed by discussing and comparing the results of both experiments. Finally, we compare our results with those of the state-of-the-art surveyed research.

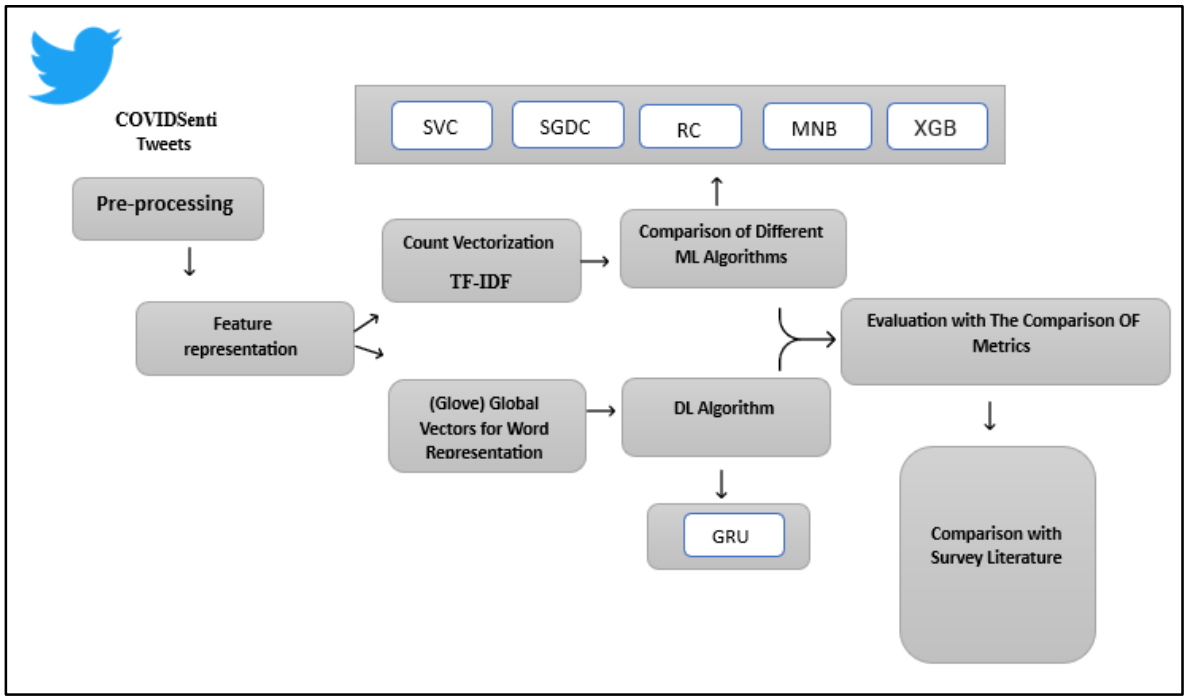

Fig. 1. Overview of the proposed approach.

IV. Datasets and Data Preprocessing

In this section, we discuss the details of the datasets utilized in the experiments and how we pre-processed them before building our models.

A. Datasets Details

As previously noted, in this research study, we consider the COVIDSenti dataset. This dataset is sourced from the open-source hosting site GitHub and consists of 90,000 unique tweets from 70,000 users about COVID-19 from February 2020 to March 2020. Naseem et al. [8] divided the COVIDSenti dataset into three subsets for evaluation and generalization purposes: COVIDSenti_A, COVIDSenti_B, and COVIDSenti_C. They treated them as four different datasets and we adopt the same approach. Each of the four datasets, for classification purposes, has three sentiments: positive, negative, and neutral. Table II provides an overview of these datasets. As shown in the table, overall, the neutral sentiments form the highest percentage of COVIDSenti and its subsets.

B. Data Preprocessing

Tweets generally form a huge, noisy dataset that requires numerous pre-processing steps. The tweets in our datasets were processed using Python libraries namely Natural Language Toolkit (NLTK), NeatText, and Regular Expression (RE). The following techniques were applied in the following order:

- Any hashtag in the dataset conveys important information. The topic of almost every social media site is represented using a hashtag such as #COVID19, #CoronavirusOutbreak, #COVID, and #Coronavirus. As a result, we simply eliminated the "#" symbol.
- To avoid considering words with uppercase letters different from the same words with lowercase letters, all words are converted to lowercase.
- Stop words are the common frequently occurring words, which should be ignored because they do not provide any meaningful information. Removing these stop words is especially useful when building text classification models to reduce the amount of data.
- The fourth step is to remove hyperlinks, @ mentions, multiple white spaces, emojis, and punctuation, as well as special characters. This is because all these do not affect the understanding of the sentences of the tweets and do not help in detecting sentiment.
- We used a lemmatization technique to reduce inflected words to their basic forms, e.g., “Mostly” to “Most” or “viruses” to “virus.”

V. Models and Experimental Setting

In this section, we discuss the details of the ML and DL models used in our experiments. We also discuss the details of the experiments including the experimental setting and hyperparameters.

A. ML Models

The Python library Scikit-learn has many ML classifiers. We employed five ML classification models as follows:

Multinomial Naïve Bayes (MNB) - This idea of this model is based Naïve Bayes Theorem, which calculates the probability of each of a set of classes, and the class with the highest probability is considered the winning class for classification. It is thus suitable for text classification with multiple classes [6].

Linear Support Vector Classification (Linear SVC) – This model treats each data item as a vector and searches for a linear separator of the classes in their vector space. In higher-dimensional spaces, a hyperplane is computed. Features extracted from the input data are classified based on this plane. To obtain the optimal hyperplane, a margin between the classes is maximized based on the distance between the nearest vectors of the classes, which are called support vectors [3].

Extreme Gradient Boosting (XGBOOST) – This model is based on the decision tree classifier. An ensemble of such trees is usually employed, e.g., gradient boosting machines. XGBoost is an extension to this model for speedup and improved performance, with minimal resources [10].

Ridge Classifier (RC) – This is a variation of Ridge Regression. This linear classifier is suitable when the number of features is high and exceeds the number of observations regardless of whether the problem is binary or multi-class [11].

Stochastic Gradient Descent (SGD) – The idea of gradient descent is to use data to compute the gradient of an objective function to reach its minima. One of the three variants of gradient descent is SGD, which frequently updates the model's parameters with high variance, causing significant variations. This gives it the capability to find new and hopefully, superior local minima in comparison to its counterparts [12] [13].

TABLE II. Overview of the Datasets

Dataset	Positive		Negative		Neutral		Total	
	count	%	count	%	count	%	count	%
COVIDSenti_A	1,968	6.6	5,083	16.9	22,949	76.5	30,000	100
COVIDSenti_B	2,033	6.8	5,471	18.2	22,496	75.0	30,000	100
COVIDSenti_C	2,279	7.6	5,781	19.3	21,940	73.1	30,000	100
COVIDSenti	6,280	7.0	16,335	18.2	67,835	74.9	90,000	100

B. DL Model

The basic idea of any DL architecture is to emulate how the human brain works. Such architecture is typically layered, and each layer provides the input to the next. The network learns as each training dataset item is fed to it and saves what it has learnt in the form of weights. As an output is generated, it is compared to the correct desired one and in the case of a mismatch, the weights are updated. This continues until the global error is minimized. The network then becomes ready for its task.

One of the most popular DL architectures is Recurrent Neural Network (RNN). The typical structure of an RNN cell is shown in Fig. 2. As shown in the figure, over time, the network is visualized as a set of similar sequential feedforward cells. This gives it the ability to memorize data with long-term dependencies such as language models. Nevertheless, as the length of such a sequence increases, the problem of vanishing gradient affects the ability of the model to continue learning. Accordingly, other variants have been proposed.

LSTMs are the most common types of RNNs intended to address the vanishing gradient problem of a typical RNN cell. A typical LSTM cell is shown in Fig. 3. As shown in the figure, its success stems from the existence of a cell state that acts as a memory and three gates, namely input, output and forget, to decide how much information to input, output, or forget respectively. This provides a LSTM cell with a relatively long memory in comparison to the short memory of a basic RNN cell. This gives it the name 'Long Short Term Memory.'

GRU [15] is a simplified variant of LSTM. A typical GRU cell is depicted in Fig. 4. As shown in the figure, the GRU cell has no cell state like LSTM cells. Instead, it uses an invisible state. It also has two gates only, a reset gate and an update gate, that incorporate the functions of the input and forget gates of LSTM. The update gate acts like a long-term memory while the reset gate acts as a short-term memory. This makes GRU easier and faster to train and run. Nevertheless, GRU cells might not be as capable as LSTM cells when it comes to memorizing long-term dependencies as is the case with language models. Thus, this tradeoff needs to be taken into consideration to benefit from their efficiency while avoiding their drawback.

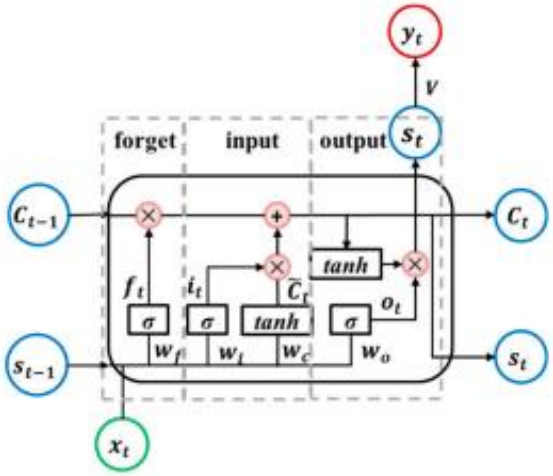

Fig. 3. Schematic diagram of LSTM cell [14].

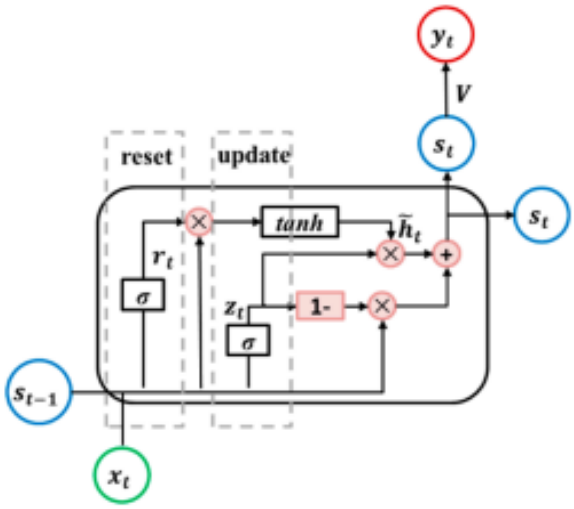

Fig. 4. Schematic diagram of GRU cell [14].

C. Experimental Setting of the ML Models

The problem with text is that it is generally considered unstructured. To be able to process it, it needs to be preprocessed and converted into numeric data. This is enabled through NLP feature extraction techniques. In this paper, we used two different feature extraction techniques, namely count vectorizer and TF-IDF. In count vectorizer approach, text in a given document or tweet is vectorized based on its count. This is computed for each word that appears in the entire corpus. On the other hand, TF-IDF also takes into consideration the uniqueness and thus the importance of each term in the whole corpus [16]. In addition to vectorizing text, each ML model that we employed has its own set of hyperparameters. For each ML model, we utilized the default values as shown in Table III.

1) K-Fold Cross-Validation (KCV) is a commonly used approach for evaluating the performance of ML models while reducing the chance of overfitting. In KCV, the dataset is first partitioned into a set of K equal-sized folds. Each fold is used once as the test data, while using the rest of the data for training. After exhausting the folds (through K-iterations, the average of a given performance metric is computed [17]. Stratified K-Fold Cross-Validation (SKCV) is an extension of KCV, where class distribution in the original data is taken into consideration when sampling [18]. Accordingly, SKCV is preferred over KCV in the case of unbalanced class distributions [19]. In our experiments, we used SKCV, specifically 10-fold cross validation, to split the data into training and testing, while computing the average accuracy of the different folds.

D. Experimental Setting of the DL Model

In our experiments, we decided to use the efficient GRU model. The model layers include, in addition to the basic components, one embedding layer, two dropout layers, and a dense layer. The embedding layer is used for preprocessing and vectorizing a vocabulary of size 10,000. It is followed by a dropout layer, with dropout rate of 0.2 to help reduce the complexity of the model and the probability of the model overfitting. GRU layer follows the drop out layer with 128 units followed again by another dropout layer with a rate of 0.2. At the end, a dense layer with 3 neurons and a Softmax activation function is used to get the probabilities of the possible classes. In the experiments, we used Global Vectors (GloVe)-based word representation to learn word embeddings from text documents. A pre-trained word embedding GloVe with two billion tweets, 27 billion tokens, and 1.2 million vocabularies was used to generate a 100-dimensional vector from text.

Finally, we divided the dataset into training data and testing data subsets. 80% of tweets were used for training purposes and the remaining 20% were used for testing. Training tweets help identify the data patterns and thus reduce error rates of the test data subset used for the assessment of the model performance. We also used Adam optimizer to minimize the cross-entropy loss with a batch size of 36 and 10 epochs. This is in addition to using Softmax activation for multi-classes probabilities, and early stopping to reduce overfitting on a Google Colab GPU.

TABLE IV. ML CLASSIFIERS WITH DIFFERENT EVALUATION METRICS USING COUNT VECTORIZER

Model dataset		**COVIDSenti_A**				**COVIDSenti_B**				**COVIDSenti_C**				**COVIDSenti**

VI. Results and Discussion

In this section, we provide the results and discussion of the ML models and the DL model. We then compare both results to each other and to the results of the surveyed research.

A. Results of the ML Models

Table IV shows comparison between the five ML models that used count vectorizer embeddinhg in terms of accuracy, precision, recall, and F1-score. The results of the experiment show that the SGD model performed better than all the other models that used count vectorizer on COVIDSenti_A, COVIDSenti_B, COVIDSenti_C, and COVIDSenti with 86.75%, 86.07%, 85.05%, and 86.19% accuracy respectively. Moreover, RC, Linear SVC, and XGBoost showed almost similar performance with average accuracy of 84.85%, 84.17%, 82.66%, and 84.83% on the four datasets respectively. Finally, MNB showed the worst performance with accuracies of 78.51%, 78.03%, 76.97%, and 78.81% respectively. The same is also true about the other performance metrics except that when considering the whole dataset, namely COVIDSenti, linear SVC was almost as good performing as SGD. Thus, it may be considered to be the second best. What is interesting about SGD is that it is the only model to show almost the same performance on all datasets with little variability.

Table V presents the results of comparing the five ML models on COVIDSent_A, COVIDSenti_B, COVIDSenti_C, and COVIDSenti in the case of the TF-IDF feature extraction technique. Unlike the case of count vectorizer, linear SVC outperformed SGD, RC, XGBoost and MNB and showed the best performance with 85.50%, 85.10%, 83.65% and 85.59% accuracy on COVIDSenti_A, COVIDSenti_B, COVIDSenti_C and COVIDSenti respectively. In this table, we compare our models with the best models in the surveyed literature using the same datasets, and with embeddings other than count vectorizer. Looking at the table, it is clear that linear SVC was also able to outperform these models across all datasets. Nevertheless, its performance is still lower than that of SGD with count vectorizer. Additionally, its performance is not as uniform as that of the latter. Again, MNB showed the worst performance among its counterparts.

B. Results of the DL Model

Fig. 5 and Table VI show the learning accuracy and loss curves and the classification reports of the GRU-based DL model that we employed. As shown in the figure, learning proceeded successfully until different epochs for each dataset, after which though training accuracy continued increasing and training loss continued decreasing. Similarly, validation accuracy started decreasing and its loss started increasing suggesting overfitting. Hence, we had to use early stopping that was different from the different datasets. Additionally, as shown in Table VI, the neutral class had the best performance among its other two counterparts.

In Table VII, we compare the results of our proposed DL model with those of the best performing models in the research studies using the same datasets. As shown in the table, our model was not able to outperform the other models. Nevertheless, none of the model was the best across all datasets and none showed uniform performance among them either. For example, though DCNN-(GloVe+CNN) was the best on COVIDSenti_C and COVIDSenti, Conv1D-LSTM + Glove was the best on COVIDSenti_A and COVIDSenti_B. Additionally, both had variable performance among the four datasets.

C. Discussion of Results

Based on the experiments and the related studies on the same datasets, among the ML models [8, 9], the proposed SGD model with count vectorizer showed the best performance, and linear SVC with TF-IDF showed the second best. On the other hand, among the DL models [8, 9], none was the best in all cases. DCNN- (GloVe+ CNN) showed the best performance in the case of COVIDSenti and COVIDSenti_C, while Conv1D-LSTM + Glove showed the best performance in the case of COVIDSenti_A and COVIDSenti_B. These models had slightly higher performance in comparison to SGD with count vectorizer. Nevertheless, the latter was the only model that showed almost uniform performance among the four datasets. This implies that the proposed SGD model with count vectorizer is the most reliable among its counterparts.

Another important observation in our experiments is that the highest performances encountered, whether using ML models or DL models, were all lower than 90%. This suggests that the capabilities of the various ML and DL models might be limited to this performance level. This is the main challenge and limitation of our work, which indicates that it's worth exploring large language transformers. This is the topic of our future work.

TABLE V. ML Classifiers with Different Evaluation Metrics Using TF-IDF or FastText

Model dataset		COVIDSenti_A	COVIDSenti_B	COVIDSenti_C	COVIDSenti
Existing model/Accuracy [8, 9]					
TF-IDF	SVM	83.9%	83.0%	82.8%	84.5%
FastText	RF	82.3%	84.1%	80.2%	84.5%
Proposed model/Accuracy					
TF-IDF	RC	84.67%	84.1%	82.76%	84.82%
	MNB	77.31%	76.03%	74.49%	76.28%
	SGD	83.31%	82.52%	80.86%	81.16%
	Linear SVC	**85.50%**	**85.10%**	**83.65%**	**85.59%**
	XGBoost	84.54%	83.6%	82.18%	83.95%

TABLE VII. COMPARISON OF PROPOSED DL CLASSIFIER ACCURACY WITH BASELINE

Model dataset	COVIDSenti_A	COVIDSenti_B	COVIDSenti_C	COVIDSenti
Existing model/Accuracy [8, 9]				
DCNN- (GloVe+ CNN)	83.4%	83.2%	**86.4%**	**86.9%**
Conv1D-LSTM + Glove	**87.0%**	**86.1%**	84.4%	**86.9%**
Proposed model/Accuracy				
GRU+GloVe pretrain	86.8%	84.3%	84.0%	83.3%

VII. CONCLUSION AND FUTURE WORK

This paper is concerned with sentiment analysis of tweets during pandemics with COVID-19 as a prototype. Our related work review showed that as the dataset size increases, the accuracy generally tends to decrease. This suggests that using a small dataset might provide misleading results that cannot be generalized. Hence, it is better to consider large datasets and try to improve analysis performance on it. Accordingly, in this paper we considered a huge dataset namely COVIDSenti and its three sub-datasets. We experimented with a set of machine learning techniques (MNB, SVC, XGBoost, RC, and SGD) and a customized deep-learning GRU model. The experiments showed that unlike the models that we tested, and the state-of-the-art models on the same dataset, SGD technique with count vectorizer showed quite constantly high performance on all the four datasets. As future work, we intend to use grid search with the ML models to figure out whether we could obtain even better results. We will also examine additional ML and DL models aiming at achieving higher performance. This is in addition to possibly other datasets. Finally, since all results of ML and DL models were less than 90%, we intend to start working with large language model transformers to figure out whether superior results could be achieved.

***Abstract*—Traditionally, the classification of mushroom cultures has conventionally relied on manual inspection by human experts. However, this methodology is susceptible to human bias and errors, primarily due to its dependency on individual judgments. To overcome these limitations, we introduce an innovative approach that harnesses machine learning methodologies to automate the classification of mushroom cultures. Our methodology employs two distinct strategies: the first involves utilizing the histogram profile of the HSV color space, while the second employs a convolutional neural network (CNN)-based technique. We evaluated a dataset of 1400 images from two strains of P*leurotus ostreatus* mycelium samples over a period of 14 days. During the cultivation phase, we base our operations on the histogram profiles of the masked areas. The application of the HSV histogram profile led to an average precision of 74.6% for phase 2, with phase 3 yielding a higher precision of 95.2%. For CNN-based method, the discriminative image features are extracted from captured images of rhizomorph mycelium growth. These features are then used to train a machine learning model that can accurately estimate the growth rate of a rhizomorph mycelium culture and predict contamination status. Using MNet and MConNet approach, our results achieved an average accuracy of 92.15% for growth prediction and 97.81% for contamination prediction. Our results suggest that computer-based approaches could revolutionize the mushroom cultivation industry by making it more efficient and productive. Our approach is less prone to human error than manual inspection, and it can be used to produce mushrooms more efficiently and with higher quality.**

Keywords*—Machine learning; convolution neural networks; mushroom cultivation; rhizomorph mycelium

I. Introduction

Mushroom cultures can be initiated from either spores or tissue [1]. The choice of whether to initiate a mushroom culture from spores or tissue depends on several factors, including the type of mushroom being grown, the desired yield, and the level of control that the cultivator wants to have over the culture. When dealing with spores, one must choose a single strain from the numerous strains produced. Conversely, tissue culture enables the cultivator to preserve the precise genetic makeup of the parent mushroom. In either scenario, the outcome is a network of cells collectively referred to as the mushroom mycelium. According to study [2], there are two main forms of mushroom mycelium which are: rhizomorph mycelium and tomentose mycelium. The rhizomorph mycelium resembles plant roots, and only the growing rhizomorph mycelium is utilized for subsequent cultivation.

According to study [3], mushroom cultivation needs a lot of labor. The standard practice for selecting mushroom culture for further cultivation is via eye inspection by an expert. This method depends on human experts, making it susceptible to human bias and errors. The expert classifies rhizomorph and fluffy growing mycelium by examining the "fluffiness" of the sample under a lamp while holding the petri dish. Intensive training is thus required for a worker/newcomer in this field to learn how to select the fast-growing rhizomorph mycelium and estimate the right moment to transfer the culture to an agar petri dish. The fastest-growing rhizomorph mycelium is selected and transferred to another agar petri dish. Those exhibiting slower growth rates or contamination are subsequently discarded. This is where the skill of mushroom growers comes into play, as they must discern the quality and the optimal moment to harvest the rhizomorph mycelium for cultivation in a petri dish. Note that mushroom mycelium can grow exponentially, achieving a mass thousands of times its original size. Choosing a quality rhizomorph mycelium is particularly important to ensure a sizeable harvest.

We propose a computer vision approach in conjunction with a machine learning model. This would leverage discriminative image features to quickly identify growing rhizomorph mycelium cultures and ascertain the ideal timing for their transfer to an agar petri dish. Our objective is to differentiate fast-growing rhizomorph mycelium cultures from the ones with a slower growth rate. This paper also discusses the prediction of rhizomorph mycelium growth based on its diameter and identifies the good and bad mycelium.

Section II examines prior research that has employed computer-based technology in mushroom farming and Section III describes the process of collecting data for this study. Section IV presents the methods used for predicting growth rate and identifying good and bad mycelium and Section V presents the results of this study. Finally, Section VI concludes the paper.

II. Related Works

Computer-based solutions in the field of mushroom cultivation mainly focus on two areas: recognizing edible mushroom types and monitoring mushroom growth using

computer assisted technology such as the Internet of Things (IoT).

Several studies centered on mushroom classification include [4]-[10]. The study in [4] classified mushrooms into two categories, poisonous and non- poisonous using different algorithms like neural network (NN), Support Vector Machines (SVM), Decision Tree, and k Nearest Neighbors (kNN). They utilized a dataset comprising mushroom images, which includes images with and without backgrounds. Experimental findings reveal that the most effective technique for classifying mushroom images is kNN, achieving an accuracy of 94% when utilizing features extracted from images with real dimensions of mushroom types, and 87% when using features extracted solely from images. The research in [5] proposes a new model of classifying 45 types of mushrooms including edible and poisonous mushrooms by using a technique of Convolution Neural Networks (CNN). They used the library KERAS2.3.1 for running the CNN TensorFlow and the proposed model gives the results of 0.78, 0.73, and 0.74 for precision, recall, and F1 score, respectively. The study in [7] used deep learning approaches like InceptionV3, VGG16 and Resnet50 to identify the mushrooms based on their category on 8190 mushrooms images where the ratio of training and testing data was 8:2. They used The Contrast Limited Adaptive Histogram Equalization (CLAHE) method along with InceptionV3 to obtain the highest test accuracy. InceptionV3 achieved the highest accuracy of 88.40% among the implemented algorithms. The research in [8] conduct a comparison between the performance of Random Forest and Reduced Error Pruning (REP) tree classification algorithms in classifying edible and poisonous mushrooms. The study in [9] employed Gaussian naïve Bayes along with Linear Discriminant Analysis (LDA) to separate edible and non-edible mushrooms. LDA was used to reduce the dataset, which helped in reducing the dimensionality of the feature space and removing irrelevant features. LDA aims to enhance the distinction between various classes by identifying a linear combination of features that most effectively discriminates among them. A slightly different work by [10] where they utilize K Means clustering algorithm to classify mushrooms based on attributes such as structure, surface size, cap tone, gill, stalk, smell, place of growth, and population. From their study, it is evident that the odor attribute stands out as the most significant factor contributing to the highest classification accuracy.

In study [11] proposed an IoT-based monitoring and control system for shiitake mushroom farms using wireless sensors. According to study [11], implementing IoT technology in mushroom farms presents challenges such as energy management, data security, sensor node placement, internet connectivity, and transmission range. The research in [12] designed a smart system called SENSEPACK to monitor the environment of a mushroom cultivation farm. This system measures temperature, humidity, light, and CO2 levels using appropriate sensors to control the environment of the nursing room.

Recently, there has been a notable increase in endeavors to automate mushroom cultivation in controlled environments, utilizing not only IoT but also mobile applications, such as [13] [14]. The study in [13] proposed a solution utilizing an Android app was proposed to distinguish between edible and poisonous mushrooms. In this work, machine vision and CNN classification algorithm is used to develop the app. The automation system introduced by utilizing sensors within the mushroom house guarantees ideal conditions for the growth of mushroom.

Other than that, the study in [15] presented a novel approach in the mushroom cultivation field, utilizing computer-assisted technology to classify mushroom samples based on the enzymatic browning reaction. This reaction occurs when mushrooms are exposed to the atmosphere, and the proposed method employs a support vector machine (SVM) classifier to achieve a classification accuracy of 80%. The research in [16] employs a dataset sourced from Kaggle for mushroom classification and model training purposes. They apply methods such as SVM, naive Bayes, and random forest algorithms in this study. Their findings reveal that their data is prone to overfitting, attributed to its near-linear separability as observed through the principle of SVM. Another similar work by [17] used decision tree to classify five types of mushrooms, they are Button mushrooms, Wood Ear mushrooms, Straw mushrooms, Reishi mushrooms and Red Oyster mushrooms. Among the feature extracted from the mushroom images are mean, skewness, variance, kurtosis, and entropy from the mushroom images.

In general, deep learning techniques are also employed in the other agricultural sector to categorize, quantify, and partition the areas of significance pertaining to crops. The study in [18] published a dataset that uses deep-learning-based classification and detection in precision agriculture. CropDeep consists of 31,147 images with over 49,000 annotated instances from 31 different classes. Based on the results, they suggested that the YOLOv3 network has good potential application in agricultural detection tasks. The study in [19] proposes a deep learning-based solution for object detection in Smart Agriculture. The solution can automatically detect damage in leaves and fruits, locate them, classify their severity levels, and visualize them by contouring their exact locations. Their results reveal that the proposed solution which is based on Mask-RCNN, achieves higher performances in features extraction and damage detection/localization compared to other pre-trained models such as VGG16 and VGG19. Another different work proposed by [20] works on algorithm to classify wild mushrooms using a deep CNN and Residual Network [20] also introduces an optimization method that improved the classification effect of the algorithm model, enhancing the overall performance of the classification algorithm

Based on our current understanding of the literature, there has been no prior investigation into the use of histogram profiles and machine learning approach for the recognition of fast-growing rhizomorph mycelium through the analysis of image features. As a result, the research problem we are currently pursuing represents an unexplored area of inquiry within this field.

III. DATA COLLECTION

Two strains are used in the experiments, and both are Pleurotus ostreatus. A disk of mycelium of 5 mm diameter was placed in the center of a Petri dish containing Potato-

Dextrose-Agar (PDA) medium. During the spawn-run (development and growing of the mycelium) the sealed Petri dishes are stored in a dark and neat place. Petri dishes with fungi were numbered for identification. Each strain has about fifty samples.

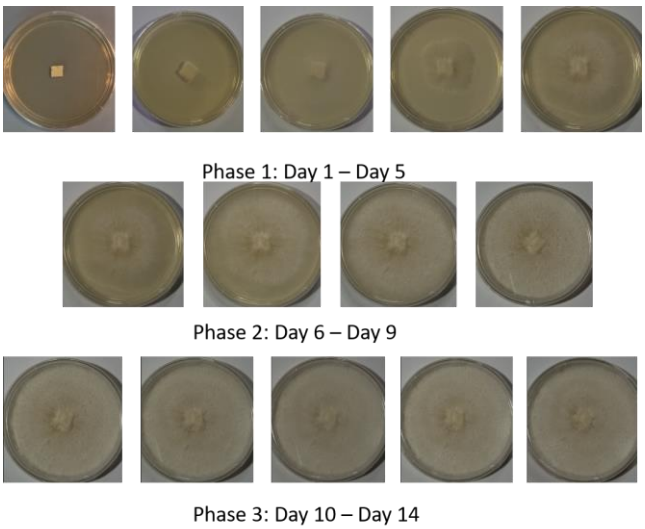

Fig. 1. The growth of a good rhizomorph mycelium in 14 days.

An android camera phone mounted on a tripod. Images of Petri dishes with mycelia were obtained against a white background and identified with a paper label of a known area of 4 cm2 (2 x 2 cm). Photographs were taken daily for fourteen days for both strains, totaling 1400 images. Fig. 1 shows a sample of a good rhizomorph mycelium sample in 14 days. There are three phases (classes) used to categorize the growth of mycelium: Phase 1 (Day 1 – Day 5); Phase 2 (Day 6- Day 9) and Phase 3 (Day 10 - Day 14). From the observation of the sample, the growth is quite drastic in phase 2. During phase 3, the growth is the same for the last five days and human eyes cannot easily observe the difference for each day. Human eyes can also make mistakes during the last two days in phase 2, as it can be mistakenly labeled as phase 3.

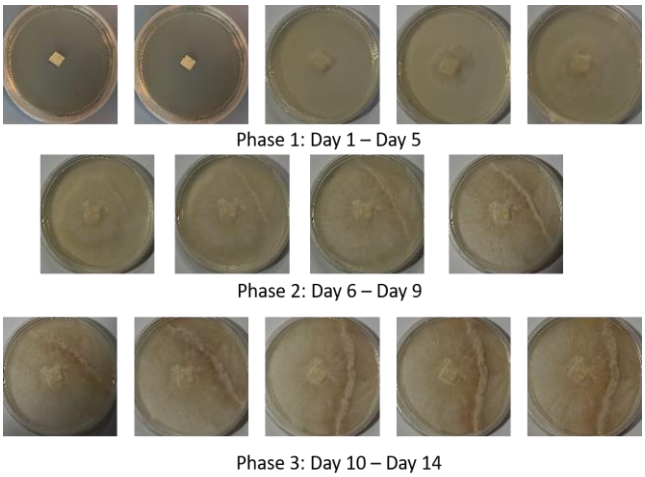

Fig. 2. The growth of a contaminated rhizomorph mycelium in 14 days.

Fig. 2 shows a sample of a contaminated rhizomorph mycelium sample in 14 days. During phase 1, the good and contaminated mycelium cannot be differentiated, as it grows the same. However, during phase 2, the contaminated one can be easily recognized on day 7. Like good mycelium, during phase 3, the growth of the contaminated one is the same for the last five days.

IV. METHOD

A. Classification Based on HSV Histogram Profile

For rhizomorph mycelium growth analysis measurement, mask ROI segmentation and elimination is used to determine the cultivation of the phases. The proposed method determines the cultivation phase based on the mask area's histogram profile. Given a top-view and close-up image of the petri dish sample, we obtained n candidate mask(s) using Hough circles. We set the min circle radii to a default value of 1400px to exclude smaller circles. The default threshold value was determined heuristically from random sample images of our dataset. Next, we build a 2D HSV histogram map (30 hue bins x 32 saturation bins) for each candidate mask. Three examples of such maps are shown in Fig. 3. The intensity value of each cell represents the frequency of occurrence of that hue-saturation combination for that image. A lighter shade indicates a higher peak and vice versa.

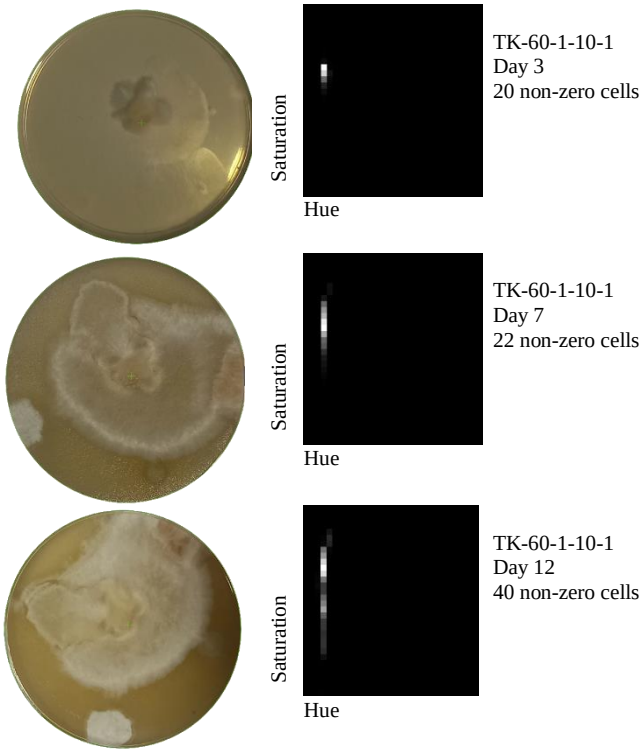

Fig. 3. 2D HSV histogram maps, each produced from the final mask of an image belonging to TK-60-1-10-1. The three images were captured on Day 3, Day 7 and Day 12, respectively. We also reported the number of non-zero cells for comparison.

We eliminate a mask candidate if it returns a high entropy value since it is more likely to be produced due to a segmentation error. The segmented area includes background pixels (i.e., petri dish and desk surface) hence the higher

variety of hue-saturation combinations. The mask candidate with the lowest entropy value (i.e., the lowest number of non-zero cells) is thus retained as the final mask.

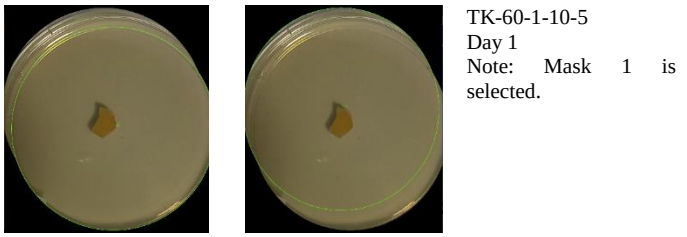

Fig. 4. Two instances of the segmentation function returning n>1 mask candidates. The mask area is enclosed inside the green-colored circle.

Fig. 4 shows two instances of our mask ROI segmentation function returning multiple candidates. The number of non-zero cells for each candidate is reported for comparison. Mask candidates with more non-zero cells tend to include many background pixels. For TK-60-1-10-5, mask number 2 was rejected since the Hough circle encloses a larger portion of the petri dish rim than mask number 1. For TR-60-1-20-20, the decision is not as clear-cut since all three masks enclose (with varying degrees) some parts of the rim. Nevertheless, mask number 1 was chosen because it contains the least non-zero cells. Images with no mask detected are discarded. Such cases are typically due to poor image quality during capture.

Given a 2D HSV histogram map, M_i our method determines the specimen's label by counting the number of non-zero cells, NZERO (M_i), with an intensity value exceeding the set threshold, thresh. We then compute the absolute difference between the counted value and two constants, i.e., lower bound, LBOUND, and upper bound, LBOUND. Value for each constant was determined from our training set, either using Median, Mod or Average. The first constant represents the NON-CONTAMINATED set (i.e., lower entropy), and the latter represents the CONTAMINATED set (i.e., higher entropy). Thus, the formula to obtain the final classification label, i.e., CONTAMINATED, C, vs. NON-CONTAMINATED, NC, is given below,

$$LABEL(M_i) = \begin{cases} \text{C}, & if\ |\text{NZERO}(M_i) - LBOUND| \geq |\text{NZERO}(M_i) - UBOUND| \\ \text{NC}, & otherwise \end{cases} \quad (1)$$

For phase determination, we limit the test dataset to NON-CONTAMINATED only since contaminated specimens are almost impossible to classify due to their chaotic appearance. We determine the phase label as a distance function between the current image's non-zero cell count and the LBOUND value of each phase,

$$\text{PHASE}(M_i) = \begin{cases} 1 & \text{if } |\text{NZERO}(M_i)\text{-LBOUND}_2| > |\text{NZERO}(M_i)\text{-LBOUND}_1| < |\text{NZERO}(M_i)\text{-LBOUND}_3| \\ 2 & \text{if } |\text{NZERO}(M_i)\text{-LBOUND}_1| > |\text{NZERO}(M_i)\text{-LBOUND}_2| < |\text{NZERO}(M_i)\text{-LBOUND}_3| \\ 3 & \text{otherwise} \end{cases} \quad (2)$$

B. Classification using CNN-based Method

On top of the previous method, CNN-based method was also chosen to analyze the images of the mushroom. Using machine learning does not require handcrafted feature analysis and it performs feature analysis within the network. There are two neural networks used to predict the growth rate and contamination of the mushroom named MNet and MConNet respectively (see Fig. 5). The underlying architecture for both neural networks is similar except for the activation function for the last layer such that the final layer of the neural network is using SoftMax for MNet while using sigmoid for MConNet.

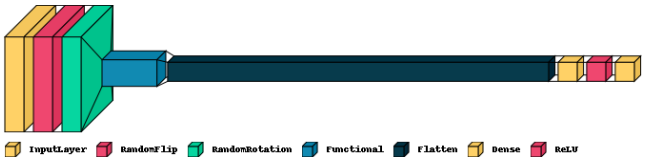

Fig. 5. The architectural diagram for MNet and MConNet.

The architecture of both models is utilizing transfer learning from MobileNetV3 due to its acceptable performance in low-end mobile devices and possible real-time prediction. Moreover, there are two layers such as *RandomFlip* and *RandomRotation* for generalizing the samples and preventing overfitting during the training. The side-effect of this also virtually increases the number of samples. Though similar, both the neural networks can be combined for improvement in performance and latency. However, the method described is not feasible when there are mixes of contaminated and non-contaminated images in the training samples.

A total of 1400 samples collected earlier are split into 64%, 16%, and 20% for training, validation, and testing, respectively. The samples were trained through TensorFlow by minimizing sparse categorical cross entropy for MNet and binary cross-entropy for MConNet. The trained models were evaluated with testing samples that are not included in the training samples.

V. Results and Analysis

In this section, we explained the results in two parts: (a) rhizomorph mycelium contamination recognition; and (b) growth analysis measurement using two different methods as explained in the previous section.

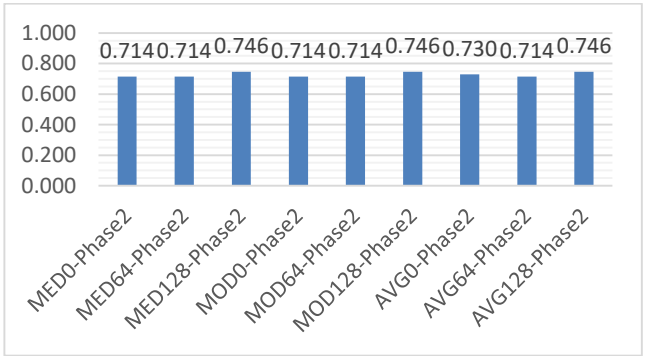
A. Classification Based on HSV Histogram Profile

To discover the optimal lower and upper bound values, we clustered all images belonging to 30 training specimens according to phases, i.e., Phase 1 (Day 1 – 5), Phase 2 (Day 6 – 8), and Phase 3 (Day 9 – 12), and classification labels. We obtained each cluster's median, mod, and average non-zero cell count under each intensity threshold value. The results are tabulated in Table I.

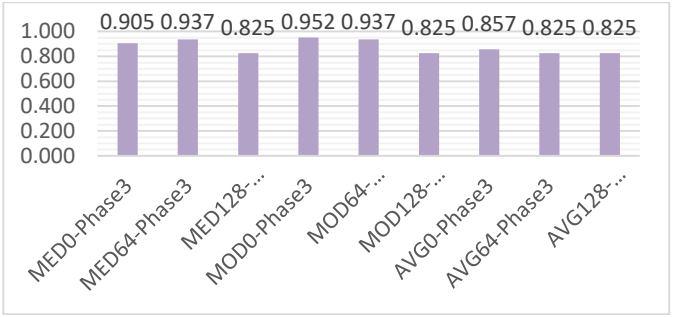
TABLE I. LBOUND AND UBOUND VALUES FOR EACH CLUSTER VS. METRIC COMBINATION

Cluster	Metric	Number of non-zero cells with intensity value exceeding threshold					
		>0		>64		>128	
		NC	C	NC	C	NC	C
PHASE 1	Median	26.0	29.0	4.0	5.0	3.0	3.0
	Mod	23.0	30.0	3.0	4.0	2.0	2.0
	Average	26.0	28.6	4.8	5.0	3.0	3.2
PHASE 2	Median	20.0	29.0	5.0	8.0	3.0	5.0
	Mod	16.0	25.0	5.0	8.0	2.0	5.0
	Average	22.5	32.9	6.1	8.1	3.4	4.8
PHASE 3	Median	19.0	33.5	5.0	7.0	3.0	4.0
	Mod	17.0	27.0	5.0	6.0	3.0	4.0
	Average	21.2	36.0	5.6	7.9	3.4	4.6

1) Rhizomorph mycelium contamination recognition: We report the average precision of each combination to predict the specimen's label (CONTAMINATED vs. NON-CONTAMINATED), see Fig. 3, on a test set containing never-seen-before images of 20 specimens. The test set contains ten contaminated and ten non-contaminated specimens. We contrast the results obtained when making the prediction based on Phase 2's images (n=63) vs Phase 3's images (m=72). We exclude Phase 1's images as contamination signs only start to appear from Phase 2 onwards.



Phase 2



Phase 3

Fig. 6. Average precision for label prediction on test images belonging to (a) Phase 2 and (b) Phase 3. We used different metrics (i.e., Median, Mod and Average) on the training set to determine LBOUND and UBOUND.

Based on the results shown in Fig. 6, the optimal combinations for Phase 2's images are MED128, MOD128, and AVG128, with average label prediction precision of 74.6%. Evidently, setting a strict threshold value to reject non-zero cells with weak intensity is the best approach for Phase 2's images. A hue-saturation combination is retained only if it has a high occurrence inside the image.

Phase 3 returns a higher top precision value, i.e., 95.2%. This is expected since contamination (or none) will become more apparent in a latter phase. The high precision value validates our method of basing the label prediction on non-zero cell count (i.e., entropy measure). Unlike Phase 2, a relaxed threshold value returns the best result. The optimal combination is MOD0.

2) Rhizomorph mycelium contamination recognition growth analysis measurement: We measure the growth of the cultivation by phase prediction using the same test set, but only on the NON-CONTAMINATED specimens. The results are shown in Fig. 7. The highest average precision of 50.5% is obtained using MOD0. The lowest average precision of 34.9% is obtained using MOD128. The precision of random classification by chance is 33.3% (i.e., 1/3). The low precision is due to the specimens each exhibiting a different growth rate, especially from Phase 2 onwards. Table II shows the average precision achieved using MOD0, for different phases.

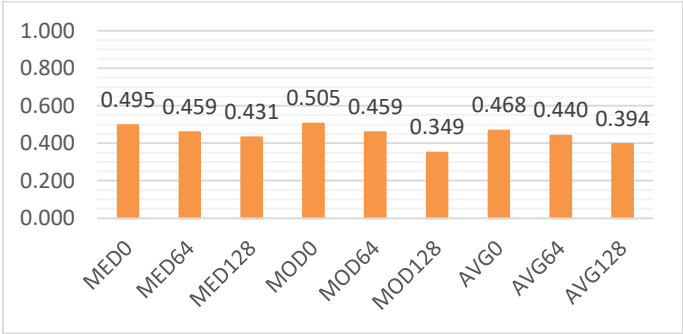


Fig. 7. Average precision for phase prediction on test images. We used different metrics (i.e., Median, Mod and Average) on the training set to determine LBOUND and UBOUND.

TABLE II. AVERAGE PRECISION ACHIEVED USING MOD0 FOR PHASE 1, PHASE 2 AND PHASE 3

PHASE	Number of Images	Average Precision
PHASE 1	47	87.2%
PHASE 2	31	32.3%
PHASE 3	31	32.3%
Average:		50.5%

Fig. 8 shows the training and testing loss for both MConNet and MNet models. While the disparity may not be readily apparent, it is evident that MConNet exhibits lower loss compared to the MNet model. Fig. 9 shows the training and testing accuracy for both MConNet and MNet models. Based on these graphs, even though the difference is not that obvious, MConNet has a higher accuracy performance compared to the MNet model.

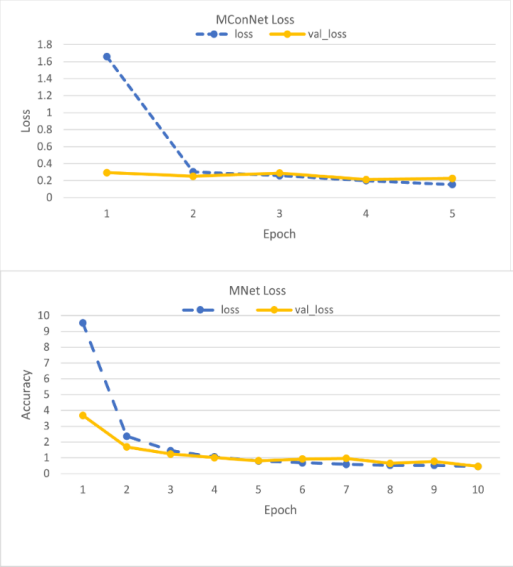

Fig. 8. Loss graph for MConNet and MNet.

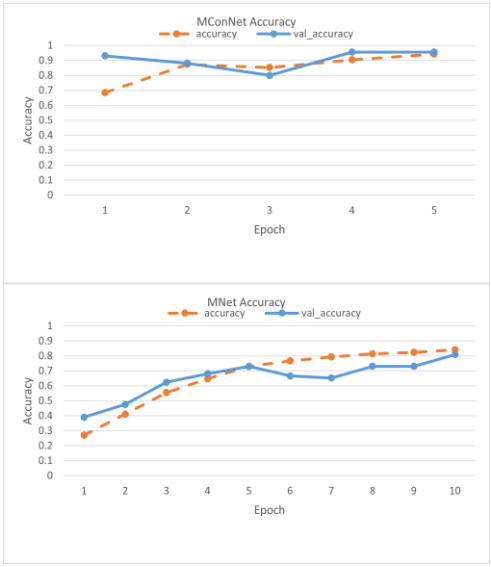

Fig. 9. Accuracy graph for MConNet and MNet.

B. Classification using CNN-based Method

1) Rhizomorph mycelium contamination recognition: Table III shows the accuracy percentage for contamination recognition. According to the mushroom experts' opinion, strain B has several contaminated Petri dishes. The method that has been used managed to recognize the contaminated samples from strain B which is 100%. Overall, the average accuracy for good and contaminated Petri dishes is more than 96%.

TABLE III. CONTAMINATION RECOGNITION

	Good	Contaminated
Strain A	95.66%	92.62%
Strain B	97.74%	100%
Average	96.64%	98.97

2) Growth analysis measurement: Tables IV and V shows the mycelium phase recognition for two different strains. The average recognition for strain A is 98.3% while 86% for strain B. The accuracy for mycelium phase recognition for strain A is much higher compared to strain B since the petri dish with strain B has more contaminated mycelium. The recognition of the phase for strain B is much harder, especially when at phase 2. This is because mycelium has become more like contaminated ones during phase 2.

TABLE IV. MYCELIUM PHASE RECOGNITION FOR STRAIN A

Samples/ Phases	Day 1 - Day 5	Day 6 - Day 9	Day 10 - Day 14
Day 1 - Day 5	100%	1%	
Day 6 - Day 9		99%	4%
Day 10 - Day 14			96%

TABLE V. MYCELIUM PHASE RECOGNITION FOR STRAIN B

Samples/ Phases	Day 1 - Day 5	Day 6 - Day 9	Day 10 - Day 14
Day 1 - Day 5	93%		
Day 6 - Day 9	4%	65%	
Day 10 - Day 14	3%	35%	100%

VI. CONCLUSION

This paper aims to introduce a machine learning approach for detecting rhizomorph mycelium growth and distinguishing between healthy and contaminated mycelium based on captured images. The results demonstrate that the employed method exhibits a notable accuracy in identifying healthy and contaminated mycelium. However, the study's scope is constrained by reduced precision beyond the initial five days, stemming from differing growth rates.

For our future work, we would like to explore the possibility of predicting rhizomorph growth from the area that it covered in a petri dish. Based on the area covered by the mycelium, we can predict the growth of such mycelium. In addition, we plan to use another type of mushroom in the experiment. We would like to see whether the growth can be measured easily compared to oyster mushroom.

ACKNOWLEDGMENT

This research is fully supported by Universiti Malaysia Sarawak through Smart Partner- ship Grant Scheme F08/PARTNERS/2128/2021. The authors fully acknowledged Universiti Malaysia Sarawak for the approved fund which makes this important research viable and effective. The acknowledgment is also extended to our industry counterpart, Madam Nurhaida Sahera Abd Malek who is willing to share the strain from Arra Mushroom Sdn Bhd, farm.

***Abstract*—The leather industry is increasingly becoming one amongst the most important manufacturing industries in the world. Increasing demand has posed a great challenge as well as an opportunity for these industries. Quality of a leather product has been always the main factor in the setting of the market selling price. Usually, quality control is done with manual inspection. However, with human related errors such as fatigue, loss of concentration, etc., misclassification of the produced leather quality becomes a very serious issue. To tackle this issue, traditionally, image processing algorithms have been used, but, have not been effective due to low accuracies and high processing time. The introduction of Deep Learning methodologies such as Convolutional Neural Networks (CNNs), however, makes image classification much simpler. It incorporates automated feature learning and extraction, giving accurate results in lesser time. In addition, the usage of deep learning can also be applied for defect detection, which is, locating defects in the image. In this paper, a system for leather image classification and defect detection is proposed. Initially, the captured images are sent to a classification system, which classifies the image as good quality or defect quality. If the output of the classification system is defect quality, then a defect detection system works on the images, and locates the defects in the image. The classification system and the defect detection system are developed using Inception V3 CNN and Mask R-CNN respectively. Experimental results using these CNNs have shown great potential with respect to object classification and detection, which, with further development can give unparalleled performance for applications in these fields.**

Keywords*—Image leather classification; leather defect detection; Convolutional Neural Network; CNN; deep learning

I. INTRODUCTION

Image classification is a very important field in computer vision. Classification of images plays an important role in case of identification, segregation and decision-making processes in automated systems. With the ever-increasing complex tasks given to these computer vision-based tools and the increasing reliance on these systems, classifications systems must be robust and have high accuracy and detection rates, so as to perform error-free and without manual intervention. Classification systems are in high demand in the manufacturing sector, with one such industry being the leather industry [1].

Leather is a main material, used in the clothing and accessory industry for making fashion accessories, footwear, coats, amongst a host of other products. It is usually a residual product, made from the outer covering of animals such as skins and hides, commonly obtained as by-products of the meat industry. "Hide" is the outer covering of a large animal such as a buffalo, cow whereas "Skin" is that of a sheep, goat, etc. Leather, technically defined, is a natural protein polymer that is treated with tanning agents to make it resistant to enzymatic attack and putrefaction, as well as improve several physical properties.

Leather and leather products are increasingly gaining importance in the world [2]. The major task of leather processing industry is to convert the skin or hide into leather, from which, quality products can made. The leather, which is processed from raw to finish, is dried. The next step is the visual inspection and classification. Defects may arise in the processed sheet of leather due to various reasons such as wear and tear by the machines, heat, etc. These defects may vary in size and shape depending on the type of defect such as holes, scratches, bubbles, torn pieces, etc. The classification takes place according to the surface defect area of the defect, defect area, location, and sheet thickness amongst many other factors. The number of defects determines the price, with more defects fetching a lower price. Thus, classification is a very important process to be undertaken, to determine the economic value of the product.

The manual classification process, which is commonly used, is error prone. With the long working hours, operator fatigue and other reasons, these factors derail effective classification and quality assurance process. A simple classification error causes a loss of trust amongst customers and greatly devalues the product, implying significant losses for these leather producing factories. The defects, scratches, holes, bubbles, etc., thus need to be identified,

located, and finally removed. Thus, defect detection is also essential.

The proposed leather defect detection system using advanced deep learning algorithms holds great potential to transform the leather industry. It can significantly improve efficiency, reduce costs, and enhance product quality through automated quality control. This system can quickly and accurately identify defects, streamlining production processes and saving time and resources. It also minimizes waste and rework, leading to cost reductions. Furthermore, the consistent adherence to quality standards and real-time defect detection ensures higher-quality leather products, fostering customer satisfaction and brand loyalty. These benefits are set to drive widespread adoption of advanced quality control technologies across the leather industry, enhancing the competitiveness of leather manufacturers globally.

The classification and defect detection system that is deployed, should be able to accurately classify the images and locate defects, if present in the images. With manual labour becoming increasingly expensive and error prone, the use of autonomous classification systems have been the most preferred, but least deployed at present, due to low accuracies and reliabilities. Thus, the system needs to be as autonomous and reliable as possible. Commonly used techniques for similar systems are image processing based techniques. The basic techniques include wavelet analysis, canny edge detection and thresholding. However, these techniques are pretty inaccurate due to their inapplicability on identification of different defects than on the one it was developed and tuned for. But, with the introduction of deep learning and most importantly, Convolutional Neural Networks (CNNs), image recognition tasks have been simplified. They also have excellent performance and high accuracy rates, which provide good reliability.

In this paper, we propose a system that combines classification and defect detection and developing a complete system by improving upon various algorithms. This paper's scope is to analyse existing methods of leather quality and defect classification and detection and propose a complete system for the classification and defect detection process using images [33-37].

The major contributions made in this paper are:

1) This paper proposes an efficient 2-stage based computer vision-based pipeline for automated intelligent leather defect detection.

2) The model uses Inception V3 in the first stage for identifying the leather images and classifying them as "Good" or "Defective", to effectively classify the defective leather.

3) The model deploys Region based Convolution Neural Network (R-CNN) for locating the defects, in the leather image.

4) The model operates in such a way that if only the image is classified as defective, the image is passed on to the second stage. This arrangement reduces the delay in processing and efficiently uses the resources.

5) The proposed model tests its performance on the real time data set acquired from Research labs. Since the number of defective images are practically less, augmentation procedure is employed and sufficient amount of defective leather images are obtained.

6) The performance of the proposed model is superior to the existing models and the results are promising.

The paper is structured in the following way. Firstly, a brief of image processing and CNNs is explored in Section II. Secondly, their applications in this field and related works that are carried out are explored in Section III. Thirdly, the methodology developed is described in Section IV. In Section V, the dataset, the experimental setup and the results are discussed. Section VI discusses the Conclusion and Future Scope of this research work.

II. Overview

A. Convolutional Neural Networks

Convolutional Neural Networks or CNNs are deep learning neural network algorithms widely used in computer vision applications. CNNs are now commonly used in image based applications where automatic feature extraction, object detection, image classification and image segmentation operations are required.

The Convolutional Neural Network structure is made up of three general layers. They are the input layer, hidden layers and an output layer. The hidden layers may contain multiple layers such as convolutional layers, activation or RELU layers, pooling layers, normalization layers and fully connected layers. As a result of the masking of the input and the output by the activation function and the final convolution in these layers, these are called as hidden layers.

A Convolutional Neural Network typically contains multiple convolutional layers, followed by pooling layers, normalization layers and a fully connected layer. The main function in the CNN is performed by the convolutional layers. These layers often consist of several kernels of multiple sizes which are used to apply the convolutional or dot product operation on their input, for producing feature maps. A pooling layer collects these feature maps from the previous layer and performs a max pooling or selection of a maximum activation from a small neighborhood feature region. Thus, the output feature dimensions are reduced. The next layer, the fully connected layer, is usually placed at the near end of the convolutional neural network and the output of this layer, is the high-level abstract classification or data for further processing, which is inference derived from the image input. Since the neural network is a self learning network, the convolutional layers and the fully connected layers contain neurons, whose weights are adjusted as the network goes through the training phase to set the optimal weights for accurate outputs [3][4].

Some of the best known CNNs in the field of computer vision are AlexNet [5], GoogLeNet [6] and ResNe t[7][8]. Each of these CNNs have a different architecture, thus giving different results for the same application. Thus, the

architecture of the CNN must be carefully chosen to maximize the usefulness of it for the specific application.

B. Image Processing Techniques

Image processing techniques are the traditionally used methods for computer visions applications. They involve basic processing techniques such as segmentation, extraction, colour based identification techniques, shape and texture based segmentation amongst a variety of other techniques that target a specific feature of the object or objects that are to be identified in the image. These techniques are applied on a training image set to generate a standard feature set of the target object to be detected. These feature sets are compared to features extracted from images which have objects to be detected or classified using similarity comparison metrics or machine learning techniques such as support vector machines (SVMs).

1) Image processing techniques vs. convolutional neural networks: Since image processing based techniques are fairly simple to develop and tested, multiple methods using hybrid techniques have been proposed for the classification of leather quality and defect identification in them, separately. These methods use a technique or a combination of techniques in quality grading and defect identification. Some of the more advanced techniques that are used in the process are colour based defect detection, wavelet based image analysis for grading the quality of leather, background subtraction and thresholding for defect identification amongst a host of other basic techniques. These techniques, however, do not work well in many generalized cases due to the specific features that are extracted from the training image set, which may not work well in different environments and conditions. Now, with the introduction of deep learning algorithms such as CNNs, the development of classification systems for leather grading and defect detection systems have become simpler. Due to the automated feature learning by these CNNs, the features pertaining to the leather qualities for the grading systems, and the features pertaining to the defects for the defect detection systems can be extracted easily through use of specific CNN algorithms which makes the learning and detection of the texture in case of leather quality and the shape, size and details of the defects in the defect detection system much simpler. As a result of the very generalized approach that CNNs take, it is poised to work accurately in multiple scenarios.

III. Related Work

A method for the detection and classification of surface defects is proposed by Choonjon Kwak et al. [9]. In this method, a two-step segmentation process using thresholding and morphological processing is used for defect location whereas statistical first order and second order features, and geometrical features are used for the classification process. A three stage sequential decision tree classifier is involved in the classification process, mainly, for classifying five types of defects such as lines, stains, holes, knots and wears. The proposed method achieves a good accuracy rate of 91.25 %. In addition to these techniques, wavelet features are also commonly used for identifying defects. A leather defect detection proposal is given by Sobral et al. [10] which uses wavelet transform with a bank of optimized filters, with each filter tuned for detecting one type of defect. Shape and the wavelet sub-bands of the filers are selected to maximize the ratio of feature values on defect regions and normal regions. This defect detection methodology produces fast and accurate results. Another such method for identification of leather defects is proposed by Jawahar et al. [11] using wavelet feature extraction technique. The leather images are captured and processed in the frequency domain using wavelet transform, for easy analysis of uncorrelated pixels and edges and easy highlighting of the frequency separation and image variation, respectively. Further, the defect are identified using wavelet statistical features and wavelet co-occurrences matrix features like Entropy, Energy, Contrast, Correlation, Mean, Cluster Prominence Standard Deviation and Local Homogeneity. The identified defects are classified through a support vector machine classifier, thus, giving robust results. Fu Qiang He [12], also proposed a wavelet based feature extraction technique. A multiresolution approach with energy, entropy matrices for defect detection is used. The defect distinguishing process uses a wavelet band selection procedure, which automatically determines the number of resolution level for decomposition of sub images, removing repetitive texture patterns from the image. This is followed with an adaptive binary algorithm for separating the defective regions. Experimental results prove the fastness and the efficiency of this method. Sze Teng Liong et al. [13] present a deep learning architecture based method for defect detection on leather images. The detected defects are marked using a robotic arm and chalk. This proposed methodology is able to achieve a very high segmentation accuracy rate of 91.5 % on the training data and 70.35 % on the test data.

Kasi et al. [14] propose using auto adaptive edge detection algorithm for defect identification. The methodology uses an edge detection algorithm which focuses on the leather edges with continuity and clarity, removing irrelevant edges and identifies leather defects and achieves good results. Malathy Jawahar et al. [15] propose a leather surface defect detection system which uses a multi-level thresholding algorithm for segmenting defective and non-defective regions from the captured leather surface images. Next, a texture feature extraction algorithm is used for quantification of the leather surface defects. A neural network classifier is then used for classification. The methodology used achieves a good accuracy rate of 90 %. Fan Dahuang et al. [16] propose a leather surface detection algorithm by using ultra-high definition images captured by a camera. A segmentation algorithm that is based on the saturation channel characteristics of the captured image is used for obtain region of interest (ROI). These regions are further used to detect the presence of defects in them using a method of automatic detection and location using image gradients. Experimental results prove that the method

detects and locates defects effectively and precisely while outperforming many other traditional methods.

Jang-Woo Kwon et al. [17] propose a texture analysis method for leather quality classification. The proposed method grades the leather quality by using extracting density and defects from a black image. The defects are extracted by using differentiation of histogram distribution from the image pixel, considered as a window and a search window. The evaluation of leather grade is done by using this differentiation process and offers good results. Santos Filho et al. [18] also propose a leather quality classification methodology. Initially, the regions of interest (ROI) is considered, segmented and filtered in three steps. Next, using this ROI, haralick texture features is extracted using a gray level co-occurrence matrix (GLCM). Various descriptors such as energy, homogeneity, contrast, cluster shade, maximal correlation coefficient are used. Experimental results show that the system performs efficient classification of goat leather with accuracy rate reaching 93.22 %. Winiarti et al. [19] propose for the utilization of a pre-trained deep convolutional neural network (CNN) for extracting discrete features from tanning leather image, for classification of leather types. The extracted features are passed into a support vector machine (SVM) which performs the classification process, thus, resulting in good performance.

In the defect classification category, Ding et al. [20] propose a hierarchical classification technique and a defect extraction technique using image processing. Using geometric feature representation, defects are initially divided into dots, lines and surfaces. Next, the dominating characteristics can be collected by analyzing this data through extracting texture, gray and geometry from the defects. Each type of defect is considered individually and their representative characteristics are chosen and dimensions reduced for establishing a database. Characteristics are further converged by clustering in the database. It is then used for defect classification. This methodology of classification results in a high performance system being able to achieve more than 90 % classification accuracy. Jian et al. [21] propose a methodology to classify leather surface defects using a Feed-forward Neural Network (FNN) and a decision tree combination. This allows for the optimal attribute selection and defect classification. The method performs efficient and fast classification of defects. In a comprehensive approach for leather defect classification, Sze Teng Liong et al. [22] propose a combination of deep learning and image processing techniques. Initially, the leather images are partitioned into small patches and pre-processed using a canny edge detection technique. This enhances the visualization of the defects. Next, the extraction of notable features takes place through the use of an artificial neural network (ANN) and convolutional neural network (CNN). Experimental results show that the network achieves a good 80.3 % classification accuracy rate. In another method that identifies defects but on yarn-dyed fabric, Junfeng Jing et al. [23] propose using a convolutional neural network (CNN), modelled on a modified AlexNet architecture, which replaces local response normalization layers with batch normalization layers, to improvise efficiency in computation and classification. Defect extraction takes place through the multiple layers of the CNN and the final classification is got as the end result from the CNN. Experimental results show a good performance of this classification method. Choojong Kwak et al. [24] propose another system for the surface defect detection and classification. Thresholding and morphological processing are used to detect and locate visual defects. Five types of defects that are lines, holes, wears, knots and stains are focused on. For classification of defects, a two multi layered perceptron model is used, with one, two hidden layers. Comparison results with a decision tree approach shows higher classification accuracy achieved by this model. Hoang-Quan Bong et al. [25] propose a leather defect detection and classifying system, focusing on defects such as scars, scratches and pinholes. Several image processing techniques are cascaded and applied for the image feature extraction and defect position location. These collected features are used for the classification of the defect type using a support vector machine (SVM). The method offers good accuracy and speed.

From the analysis of existing systems and methodologies [32], it can be seen that either the system is developed to work on a specific type of leather or is tuned to detect a specific type of defect. In either of these applications, the proposed system cannot work with various other types of leather images and identify any type of defect in them. Also, the dataset that has been used in the majority of the works have not been released or is not available publicly. As a result, this work proposes to develop a highly efficient and powerful leather classification and defect detection system that is not specifically tied to one type of leather and defect.

IV. Proposed Methodology

An efficient system is proposed for the classification of leather images and detection of defects in them. It consists of two single-channel convolutional neural networks, one for classification and the other for locating and marking defects.

The first channel for classification uses Inception V3 [26] deep convolutional neural network for identifying saliency features in the leather images and classifying them as either good or defective. The second channel for locating defects uses Mask R-CNN [27]. If the resultant output of the first channel CNN is defective, the image is passed on to the second channel CNN that locates the defects in the image. By using this methodology, an efficient and faster processing of the leather images classification can be done. This avoids the wastage of crucial time by not trying to locate defects, which takes a considerable amount of time, when the image is of a good quality leather sample. The robustness of this approach rests on the fact that the classifier is able to classify the images with a high accuracy. The flowchart of the proposed system is shown in Fig. 1.

A. Classification CNN

Classification is the process of systematic arrangement of a certain thing in groups or categories according to established conditions or criteria. With respect to images, the main task of classification is the acceptance of the input image and processing it, to find the class of the image. For example, considering a classification of pets as dogs or cats, when an image containing a cat is given as input, the classification system should classify the image as of cat category. Since, images are an array of pixels, recognizing any specific object category by a computer, which cannot understand semantic information in an image is a difficult task. This is where convolutional neural networks are used.

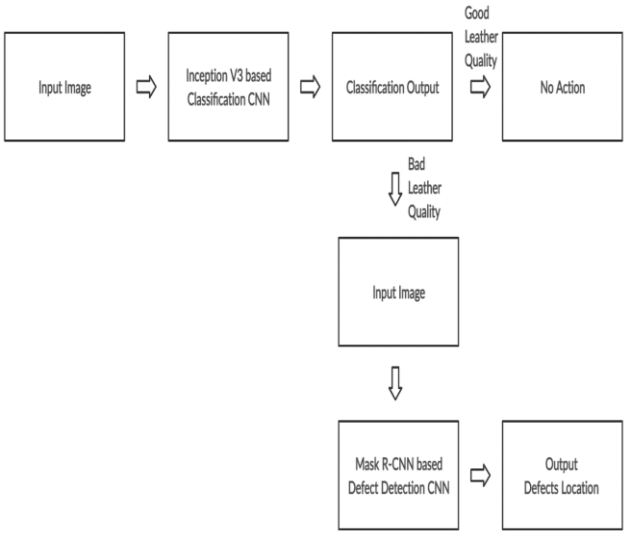

Fig. 1. Flowchart of the proposed system.

Here a deep convolutional neural network based on Inception V3 is proposed. Inception V3 is an improved Inception CNN architecture with 48 layers. It is more efficient than VGGNET and has a computational cost of only about 2.5 times higher than that of GoogLeNet (Inception V1, 27 layers).

For the gathering of all of the salient features in the image, a deep convolution network with multiple filters and layers is required. Since the deepening of the network costs computationally, the Inception module is developed, which has multiple filters for performing multiple convolution operations on the input at the same level of the network, widening it.

The Inception CNN architecture, given in Fig. 2, is based on the inception modules or blocks, which consists of multiple filters in different sizes (1x1, 3x3 and 5x5) for performing convolution operation on the input, at the same level. Each block's end consists of a global average pooling for output concatenation from a single block. Two auxiliary classifiers are attached to the network, for softmax operation on the outputs for total loss adjustment purposes [28].

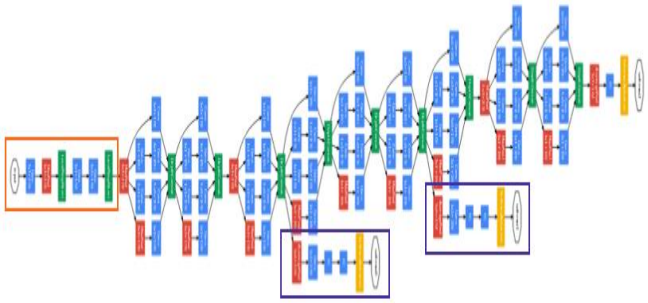

Fig. 2. Inception V3 architecture.

The output of this classifier network is the input image's classification as good quality or defect quality. If the output of this neural network comes out to be as defective quality, then the image is pushed to the next channel, the defect locating CNN, to locate the defects in that image.

B. Defect Detection CNN

Any image can have multiple objects present in it. Object detection is the process of locating each of the object in an image. Images can have multiple objects with same class labels and different objects with different class labels.

Region based CNNs (R-CNNs) have been the most effective type of CNNs due to their architectural design proposing highly confident prospective object regions. R-CNNs work by proposing a bunch of regions or boxes in an image using Selective Search algorithm and checks whether these regions contain any object of interest. Mask R-CNN is the CNN architecture that is proposed for being used in the defect detection CNN channel. It accurately locates the defects in the image and draws optimum bounding boxes around it. The architecture of the CNN is given in Fig. 3.

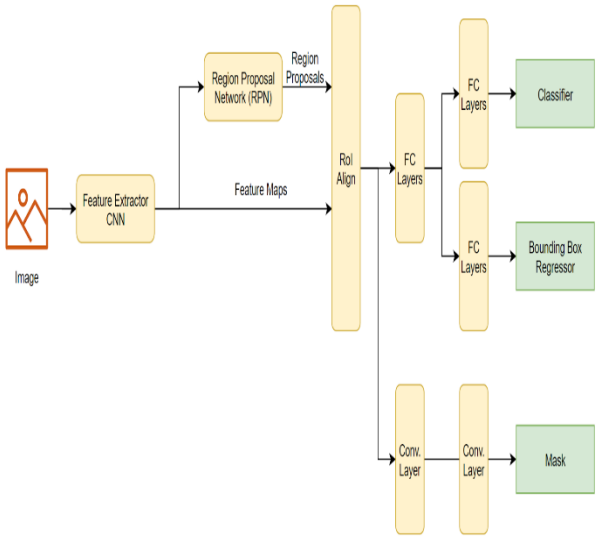

Fig. 3. Mask R-CNN architecture.

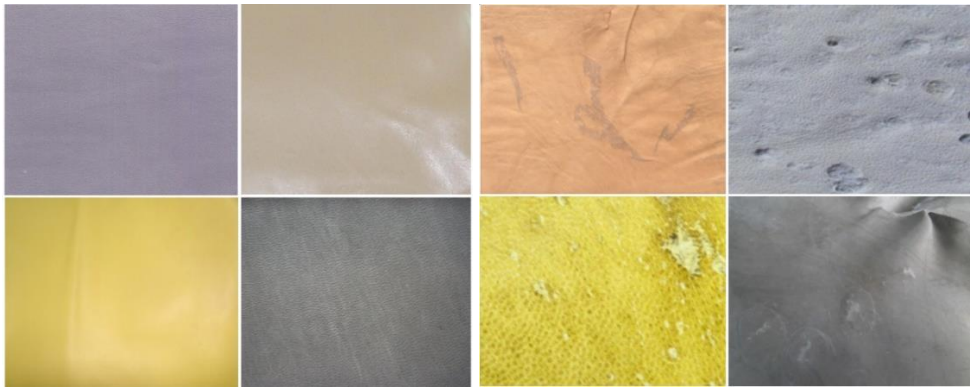
The Mask R-CNN architecture consists of an initial CNN which is a feature extractor. The feature extractor that we use in this work is Inception V2. This feature extractor CNN works on the image to produce feature maps. These feature maps correspond to the salient features detected in the image. The feature map is parallelly passed to a Region Proposal Network (RPN) to generate regions of interest, wherein prominent candidate objects of interest in the feature maps are identified and marked. These marked regions on the feature maps is passed to an ROI Align layer, along with the original generated feature maps, to align the proposed candidate regions of interest with the feature maps effectively. This effective mapping is the reason why Mask R-CNN is preferred over other R-CNNs such as Faster R-CNN, Fast R-CNN, etc. Another reason is the optimization of the bounding boxes, to minimize the area required to be removed due to a defect. These aligned maps are then passed to fully connected layers for class label prediction, bounding box fit and masks.

Thus, the output from this CNN is the image in which the defects are identified and each of them are marked with bounding boxes. Masked outputs are disabled due to non-use in this particular scenario.

Emphasizing the potential for collaboration with industry stakeholders, technology providers, or research institutions is crucial for further refining and validating the proposed leather defect detection system using deep learning. Collaborative efforts can facilitate the exploration of real-world implementation scenarios, allowing for comprehensive testing and validation of the system's effectiveness across diverse production environments. Moreover, knowledge exchange between academia and industry can lead to insights and innovations that advance automated quality control practices not only within the leather industry but also in other sectors. By fostering collaborative partnerships, stakeholders can collectively contribute to the evolution and adoption of cutting-edge technologies, driving continuous improvement and enhancing operational efficiencies in quality control processes on a broader scale.

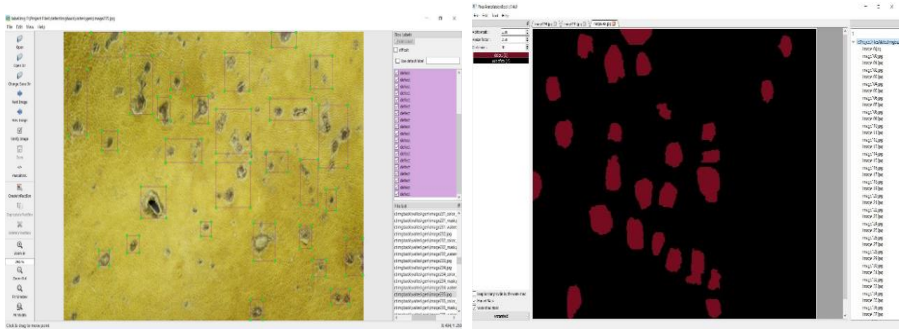
V. Experimental Tests and Analysis

The availability of useful leather datasets that can be used for training and testing techniques have always been a huge issue. Most of the already handful of available datasets, have either a low quantity of images that can be used for training and testing, or do not contain quality images. The dataset that has been generated by us, using data augmentation method. The images are available in [29], samples of which are shown in Fig. 4. Originally, it consisted of 428 good quality and 354 defect quality leather images collected from leather industry. By using, image augmentation techniques such as scaling, cropping, flipping, grayscale, brightness, contrast, saturation, etc., a total of 29716 images are produced and packed in the dataset. The original 354 defective images used and each of the defect in them are manually annotated by a tool called LabelImg [30] and mask created by a tool called PixelAnnotationTool [31]. Fig. 5 depicts the process.



(a) (b)

Fig. 4. Sample dataset images of (a) Good quality leather and (b) Defect quality leather.



(a) (b)

Fig. 5. Dataset (a) Annotation using labelImg (b) Mask creation using pixel annotation tool.

The experiments were carried out on a machine with Ubuntu 16.04 as the Operating System, 16 GB RAM, Intel i5 processor and a Nvidia GTX 1060 GPU with 6GB VRAM. The integrated leather quality classification and defect detection system was implemented using Python, Tensorflow and Keras. Since the system uses two single channel convolutional neural networks, one for classification and one for defect detection, a two-step training process is followed with unique datasets.

The first classification CNN is fed with the categorized images with 23772 training images with 13004 good quality and 10768 defect quality leather images. The validation set of 5944 images consists of 3260 good quality and 2684 defect quality leather images. The network is trained for 200 epochs with the image batch size being 32. This network achieves a classification accuracy of 99 % on the training data and 84.6 % on the validation data. The second defect detection network consists of an object detection CNN and as a result expects annotated images as the training dataset. Thus, as a result, a total of 224 defect leather quality images were annotated and corresponding masks created, and the same augmentation techniques of colour, saturation, rotation, hue change, flipping, etc., were performed on a total of 530 epochs for a total of 1,20,000 training steps, with batch size set as 1. The training set consists of 162 images and the validation set consists of 62 images, both containing annotation and mask data for each image. This network obtained a detection rate of 99.6 % on the training set, 99 % on the validation dataset and 99 % on a 20 image test dataset. The system results from the experiments are listed in Table I, with the samples shown in Fig. 6, defects detected shown in Fig. 7, training and validation accuracy graphs shown in Fig. 8 and various types of loss functions shown in Fig. 9. Fig. 7 on a closer inspection reveal that the defective spots are identified with high precision and accuracy. At some spots the accuracy is around 60%, where in a suitable selection of threshold value can help to detect the defects with increased precision in a real time situation. Fig. 9 shows the various types of loss the model incurs during the training phase of the proposed RCNN model. X-axis indicates the samples in the epoch and y-axis indicates the loss value. It can be noted that in all the loss graphs, the loss has been steadily decreasing and even approaches 0, beyond certain epochs. This means the model has converged to the leather images in detecting the defects. Hence it can be observed that the proposed model performs a promising automated defect detection of the leather from machine vision approach.

The proposed leather defect detection system offers several advantages over previous approaches, primarily through the integration of advanced deep learning techniques. Unlike traditional methods that rely on manual inspection or basic machine vision algorithms, the proposed system leverages sophisticated deep learning models such as the Inception model for classification and the RCNN model for detection. This enables the system to achieve higher accuracy in defect identification and localization, addressing the limitations of human subjectivity and the inability of older systems to detect subtle or complex defects reliably. Moreover, the automated nature of the proposed system improves efficiency, reduces labor costs, and ensures consistent and scalable defect detection across different production environments. Overall, the integration of deep learning technologies in the proposed system leads to superior performance, increased reliability, and enhanced quality control capabilities compared to previous approaches.

TABLE I. RESULTS OF THE PROPOSED SYSTEM

Methodology	Dataset	Total number of Images	Accuracy Rate
Classification	Train	23772	99 %
Classification	Validation	5944	84.6 %
Defect Detection	Train	162	99.6 %
Defect Detection	Validation	62	99 %
Defect Detection	Test	20	99 %

VI. Conclusion

This paper presented a comprehensive system for the classification and detection of defects in leather images using convolutional neural networks. Initially, the basic image processing approaches and their applications were discussed in this field. With the introduction of deep learning methods, convolutional neural networks are the most preferred way in this field due to their unique automated feature extraction and learning approaches. The recent works using both of these approaches was discussed. The proposed system uses a double channel method, where one channel has a Inception V3 convolutional neural network which classifies the leather image as "good quality" or "defect quality" while the other channel has Mask R-CNN which detects and locates the defects in the leather image and draws bounding boxes for candidate defect regions, when the output of the first channel is "defect quality". Experimental results show that the system achieves a high performance with the classification CNN achieving a 99 % accuracy rate on the training dataset and 84.6 % on the validation dataset. The defect detection CNN achieves 99.6 % defect detection accuracy on the training dataset, 99 % on the validation dataset and 99% accuracy on the test dataset. Thus, the system is proved to be able to accurately classify leather images and identify and locate defects in images, where only those images which are classified as "defective", are sent to the second channel defect detection convolutional neural network for detection of defects, thereby making the process much faster.

Researchers could make leather defect detection systems using deep learning even better in the future. They could add advanced technologies like reinforcement learning and transfer learning. Reinforcement learning helps the system make good decisions and adapt to new situations. Transfer learning uses knowledge from related areas to improve defect detection accuracy. The systems could also be used in other industries besides leather manufacturing, like textiles or car manufacturing. This would allow automating quality control processes to boost efficiency across different sectors. Exploring these avenues can enhance automated defect detection systems' capabilities and versatility. This could lead to more industries adopting the technology and drive innovation.

***Abstract*—Pigment Epithelial Detachment (PED) is an eye condition that can affect adults over 50 and eventually harm their central vision. The PED region is positioned between the Bruch's membrane (BM) and the RPE (Retinal Pigment Epithelium) layer. Due to PED, the RPE layer is elevated arc shaped. In this paper, a method to extract the best features to detect pigment epithelial detachment (PED) is proposed. This method uses four-stage strategy that drew inspiration from OCT (Optical Coherence Tomography) imaging to detect the PED. In the first stage, to reduce the speckle-noise, in the second stage, segment the Retinal Pigment Epithelium (RPE) layer. In the third stage, a novel method is proposed to extract the best features to detect PED, and in the fourth stage, machine learning classifiers such as K-Nearest Neighbors (KNN), Logistic Regression (LR), Naïve ayes (NB), and Artificial Neural Networks (ANN) were used to significantly predict the PED. For experimental results, 150 retinal OCT volumes were used, 75 normal OCT volumes, and 75 pigment epithelial detachment volumes. Among the 150 images, 80% were used for training and 20% were used for testing. Here, there are 30 images for testing and 120 images for training. To generate a confusion matrix based on the matrices are true positive (TP), false positive (FP), true negative (TN), and false negative (FN). Logistic Regression is predicted more accuracy among the ANN, LR, NB, and KNN models. The LR model predicted accuracy 96.67% for PED detection.**

I. Introduction

One of the most vital and sophisticated sense organs that humans possess is the eye. In addition to aiding in object visualisation, it also improves our ability to perceive colour, light, and depth. Fig. 1 depicts a human-eye. The sclera, cornea, pupil, lens, retina, macula, optic nerve, and so on are the components of the eyes. The outer layer of the eyeball is called the sclera. Cornea is curved layer in front of the iris and pupil. The dark dot in the centre of the eye is the pupil. The coloured part of the eye is called the iris. Behind the iris lies the lens. The retina is located on the back of the eye. The retina's macula is a tiny region. The optic nerve is located in the ocular back.

In OCT images retinal layers as shown in Fig. 2. The NLF-Nerve Fibre Layer , the GCL-Ganglion Cell Layer, the IPL-Inner Plexiform Layer, the INL-Inner Nuclear Layer, the ONL-Outer Nuclear Layer, the ISPR-Inner Segment Photoreceptor Layer, the OSPR-Outer Segment Photoreceptor Layer, and the RPE-Retinal Pigment Epithelium layer.

A number of ocular illnesses, including diabetic macular edema-(DME), glaucoma and age-related macular degeneration (AMD), have been evaluated clinically using OCT. Most of the functional layers of the retina can be seen with the lately developed SD-OCT, which gives highest resolution 3D scans of the macula. For the automated segmented of the retinal layer in SD-OCT scans of healthy eyes, numerous approaches have been put forth with positive outcomes [1-15]. PEDs can be categorized as drusenoid, serous, or fibro-vascular. According to research, people with AMD and serous PED frequently already have Choroid-Neo-Vascularization (CNV) or are at a complex danger of developed it [16, 17].CNV can potentially result in significant visual acuity loss. The normal OCT images of retina is shown in Fig. 3. The abnormal (PED) image is shown in Fig. 5. The red arrow is indicated elevated RPE layer. Due to PED, the RPE layer is elevated arc shaped.

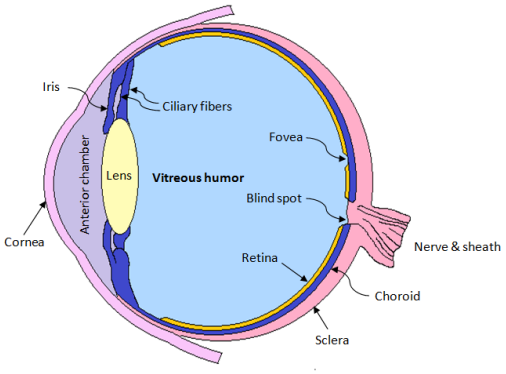

Fig. 1. Human-eye.

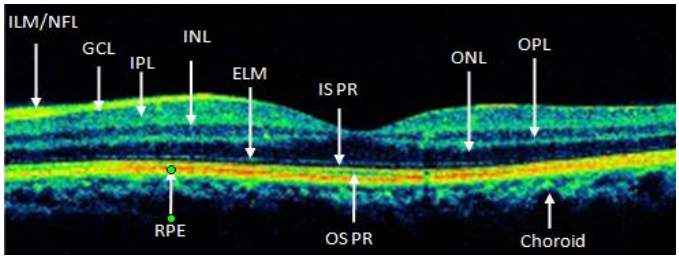

Fig. 2. OCT layers.

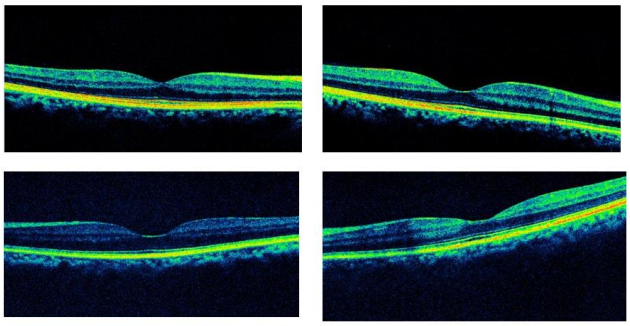

Fig. 3. OCT images of normal eye.

The separation of the retinal pigment epithelium from Bruch's membrane's inner collagenous layer is known as retinal pigment epithelial detachment. In recent years many people affected the PED. It is early diagnose easily cure the disease. This paper aims to detect the PED, Normal and PED images were classified with machine learning algorithms. This automatic model is used to assists doctors early diagnose the PED. The sample PED images are as shown in Fig. 4.

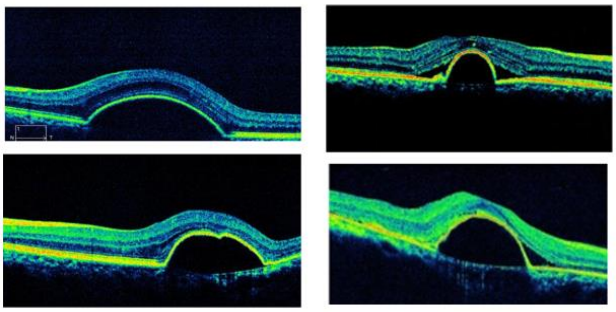

Fig. 4. PED images.

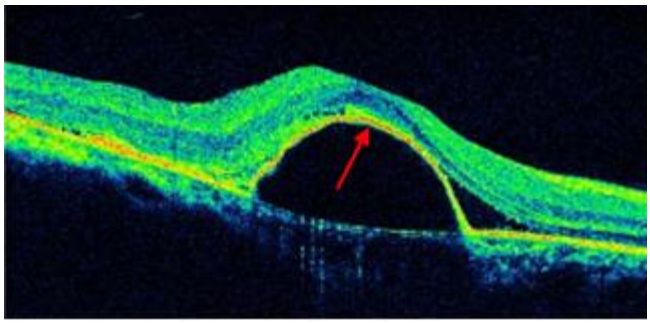

Fig. 5. OCT scan showing PED.

A wiener filter is used during pre-processing to get clear the speckles. For segment process, the threshold method is used to extract retinal layers related with RPE surface distortion. For feature extraction, the features such as Left Height (LHe), Right Height (RHe), Left Down Points (LDp) and Right Down Points (RDp) were extracted. For classification, ANN, KNN, LR and NB classifiers were used to classify the normal and PED images. Finally detected the PED, then the accuracy, sensitivity, precision and specificity were calculated based on the confusion matrix such as the FP, FN, TP and TN values. The following steps are involved to detect the PED as follows: The proposed system OCT images as input, convert OCT image into grayscale image, denoising the image, extract the RPE layer, extract the features and detect the PED.

The main contributions of this work are as follows: i) Accurately reduce the speckle noise in OCT images through the Wiener filtering technique. ii) Accurately segment the RPE layer in normal OCT images and PED images. iii) Extract four novel features to accurately predict PED disease and normal images.

II. Literature Review

Layer segmentation techniques created for retinas have also been effectively used on retinas with specific disorders such as glaucoma [11, 12, 16] and multiple abnormalies [13], or further disease in an early-stage, when there isn't a significant change in the layer structure. Segment for retina with PEDs, which are linked to sub-RPE fluid and RPE distortion. Layer segment and anomalous region segment are successfully combined where the positions of the two act as limitations on one another [17, 18]. Along with a generic method for local retinal abnormality detection, a technique for automatic characterisation of the normal retinal appearance in SD-OCT volume is provided. To reduce motion-based artefacts, the 3-D picture collection is flattened after ten intra-retinal layers are frequently segmented. To characterize the quality and width properties across the retina, 23 features are locally retrieved from the flattened OCT data in each layer. Thirteen SD-OCT volumes showing typical retinas were used to calculate the usual ranges of layer-specific feature changes.

The local variations between the usual appearance and the relevant macula parameters are subsequently classified to identify abnormalities [19]. Based on Enface fundus imaging, a unique two-stage segmentation approach was proposed. Methods: To identify fluid-associated anomalies with diffuse boundaries, the fundus picture was first segmented using a thick map [20]. The suggested approaches don't need any extra details, like layer segmentation for training. In order to smooth the segmentation map, several image segmentation techniques employ a postprocessing phase based on conditional random fields (CRF). However, first order information can only be encoded using such approaches due to computational complexity [21].

The foundation of general categorization techniques is traditional machine learning, which employs subject expertise to create hand-crafted features. To categories SRF and PED characteristic in OCT images, the authors suggested a ResidualNetworkModel [22]. In the industrialised world, AMD is the most common-source of significant vision damage in persons 50 years of older. With the development of anti-angiogenic medicines, considerable advancements in AMD treatment have been made recently, providing patients with neovascular AMD with the first realistic prospect of significant vision recovery [24].

The histologic properties of macula cell mosaics, including photoreceptor and RPE cells, can be examined in vivo using adaptive optics (AO) imaging techniques. Ophthalmic AO imaging systems produce high-resolution images that are replete with information that is challenging and/or time-

consuming to quantify manually. As a result, reliable, automated analysis systems that can deliver repeatable quantitative data regarding the examined cellular mosaics are needed. Automated algorithms have been created to locate specific photoreceptor cells, but the majority of these techniques are inadequate for describing the RPE. On simulated and actual fluorescence AO images of the RPE, built an procedure for RPE segment and demonstrate its effectiveness here [25]. For the evaluation of retinal disorders, precise segment of fluid-associated-anomalies &PED in OCT is essential [26]. A separation of the NRD from the RPE causes by sub-retinal-fluid, known as a neurosensory retinal detachment (NRD), can cause severe visual loss. It is widely known that the detachment of the neurosensory retina changes the structure and continuity of intensity of the retinal layers [27].

III. METHODOLOGY

A. Method Overview

The suggested PED detection approach includes preprocessing, RPE layer segmentation, feature extraction, training the machine learning model and PED detection as shown in Fig. 6.

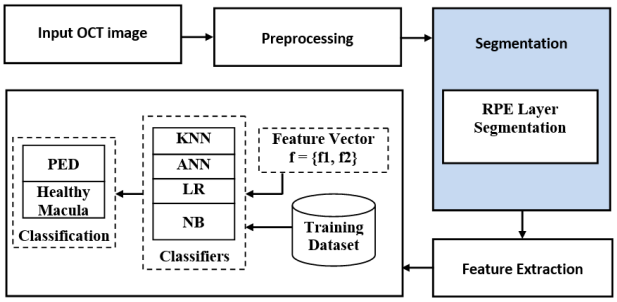

Fig. 6. Steps involved in PED detection.

In the original input OCT images the grey levels are normalised and speckle noise is reduced using wiener filter during preprocessing. An approach called the threshold method is used for RPE layer segmentation in the OCT images. PED happens at elevated RPE floors, using machine learning techniques like K-NN, LR, NB, and ANN, the characteristics retrieved and detected the PED. In order to extract features for K-NN, LR, NB, and ANN classifiers for training, OCT images are manually annotated. Then the required features are extracted which includes LH, RH, LDp and RDp which are computed from preprocessed OCT images. The machine learning models, K-NN, Logistic Regression, Nave Bayes, and ANN classifier, were trained to detect the PED. And, then trained models were used to detect PED for the new input images.

B. Pre-processing

Preprocessing is essential step to detect the PED, which is reduce the speckle-noise. The source images converted into grayscale then applying noise reduction algorithms. Speckle noise that are multiplicative in nature are more prevalent in OCT images [28-30]. The image processing and analysis techniques may perform less effectively and efficiently due to speckle, which is the primary quality degrading issue in OCT images. De-noising techniques that successfully eliminate speckle noise. Many authors suggested bilateral filtering technique and wiener filtering approach [31-36] satisfies this condition. Different filtering methods were used to eliminate the speckle-noise in the OCT images. And, analyzed mean, median, bilateral, gaussian, and wiener filtering techniques among 50 images and computed by the metrics such as PSNR, CNR and MSE. Based on the analysis, wiener filtering outperforms and significantly eliminate the speckle-noise in OCT images. Fig. 7 shows the few preprocessing images. Table I, Table II and Table III are the analysis report of wiener filtering technique. Fig. 8, Fig. 9 and Fig. 10 shows the chart of the analysis report.

C. RPE Layer Segmentation

RPE layer segmentation is essential step to detect the PED. Following the preprocessing step, to extract the RPE layer. Segmentation of the RPE layer is advance the procedure to separate the retinal layer [19, 20]. The threshold is one such active segmentation method, which is used to exactly separate the RPE layer. So threshold technique proposed to extract the RPE layer. As a result of the RPE layer's brightness pixel value picked up, the output is predictable and provides a clear view of the necessary retinal layers.

The thresholding method as:

$$T = T[x, y, p(x, y), f(x, y)] \quad (1)$$

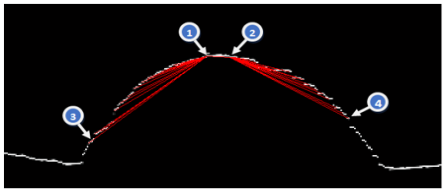
where the constant,

$$c = w(\frac{t_r}{\frac{d}{r}}) + k \quad (4)$$

Here, the letters h, d, and w stand for the image's height, depth, and width, respectively. The RPE layer's thickness is measured by tr, and each image's RPE layer's slant is specified by k.

D. Feature Extraction

Feature extraction is an essential step to train and test the input using machine learning algorithms. In order to improve the performance of the machine learning algorithms to detect PED, a novel method proposed to extract best features from the segmented images. These features include LH, RH, LDp and RDp and shown in Fig. 15. These extracted features are used in the machine learning classifiers KNN, Logistic Regression, Naïve Base and ANN to detect PED. The outcome of the classifier algorithms are corresponded the features of data is obtainable to them in order to fix the TN, FP, TP and FN [21-23]. Accuracy, sensitivity and specificity are evaluated for the classifier independently using these metrics, and the results are then used to categorise the performance of the classifier.



1→ Left Height 2 → Right height
3 → Left Down Points 4 → Right Down Points

Fig. 15. Extracted features.

Here, the following formulae used to fix the top, bottom, and maximum height of the RPE layer:

$$t = min(L_i) \quad (5)$$

$$b = max(L_i) \quad (6)$$

$$maxHgt = b - t \quad (7)$$

where, Li is the axis-y values for each-x-values on the RPE- layer and x ranges from 0 to the image width. Since the image's top left coordinate is (0, 0), the min-function is used to obtain the RPE-layer's smallest axis-y values in-order-to establish the layer's top. The lowest layer is found using the max function. Repeating the line-no from zero to the top left-point brings it to its highest position. Moving periodically as of the projected top-left-point to the line's largest point yields the top right-point. Next, a bounding rectangle is created by extracting 20 points from the upper left-point. The height of the retinal layer determines the rectangle's width.

$$w = mH \quad (8)$$

Twenty-point were deducted from the top-left-points and twenty-point from the top-right points in order to determine the curve in this investigation. The distance is computed in the following way to extract 20 points from the top-left-points:

$$d = \frac{w}{20} \quad (9)$$

The line-heights of each-points is then calculated by iterating the line points 20 times backward from the top left point:

$$lPs_i = mHgt - (L_{(topLPoint-d*i)}) \quad (10)$$

where, i differs from one to 20.

The below calculation extracts the top-right 20 points:

$$rPs_i = mHgt - (L_{(topRPoint+d*i)}) \quad (11)$$

This ranges from 1 to 20 for i.

The following formulas are used to extract the features of left height (LHe) and right height (RHe):

$$LHe = max(lPoints_i) \quad (12)$$

$$RHe = max(rPoints_i) \quad (13)$$

Next, the consecutive leftPoints are compared in order to derive the left down points (LDp) characteristic. Increase the counter LDp if a leftpoint-values is smaller than the leftpoint-values that comes after it. By comparing the rightPoint and rising the counter, the right-down-point (RDp) representative is determined.

$$LDP = LDP + 1 \quad if(lPoints_i < lPoints_{(i+1)}) \quad (14)$$

$$RDP = RDP + 1 \quad if(RPoints_i < RPoints_{(i+1)}) \quad (15)$$

Algorithm Feature_Extraction(Lineseg)

E. Classification

In this paper, to detect the PED from the RPE layer 4 features, such as LH, RH, LDp and RDp were extracted. The extracted four features were used to classify normal and abnormal OCT images. To assess the discriminative power of projected feature signifiers, both parametric and non-parametric classifiers are examine to PED, such as KNN, LR, Naïve Baye and ANN. Here these four classification procedures, such as KNN, LR, NB and ANN, were compared. The LR classifier gave best outcome when compared with the other three classifiers. To calculate accuracy, sensitivity, specificity, precision, Recall and F1-score, the following formulas were used:

$$Accuracy = \frac{TruePositive + TrueNegative}{TruePositive + TrueNegative + FalsePositive + FalseNegative}$$

$$Sensitivity = \frac{TruePositive}{TruePositive+FalseNegative} \quad (16)$$

$$Specificity = \frac{TrueNegative}{TrueNegative+FalsePositive} \quad (17)$$

$$Precision = \frac{TruePositive}{TruePositive+FalsePositive} \quad (18)$$

$$Recall = \frac{TruePositive}{TruePositive+FalseNegative} \quad (19)$$

$$F1\_score = \frac{2*Precision*Recall}{Precision+Recall} \quad (20)$$

IV. Result and Discussion

In this work, 150 OCT images used, 75 normal and 75 abnormal OCT images. In the proposed methodology 80 percentage of the images were used for training, while 20 percentage were used for testing and validations. Out of the entire 150 OCT images, 120 used for training and 30 for testing. In order to remove speckle-noise and segment the image, the image was first converted to grayscale and preprocessed using a wiener filtering. After denoising extract the RPE-layer. Segmented the RPE-layer used to the threshold technique. Four features such as LH, RH, LDp and RDp were extracted from the segmented OCT images, and these features showed to have a notable difference between the normal and PED images. The KNN, Naive Bayes, Logistic Regression and ANN classifiers were fed the collected features, and the results are represented as TP, TN, FP, and FN as in Table VI. TP, FN, TN and FP are the evaluation metrics of the classifiers as shown in Fig. 16.

TABLE VI. RESULTS OF K-NN, LR, NB AND ANN

Classification Metrics	K-NN	Logistic Regression	Naïve Base	ANN
TP	13	15	15	15
FN	2	0	0	0
TN	13	13	15	13
FP	2	2	0	2

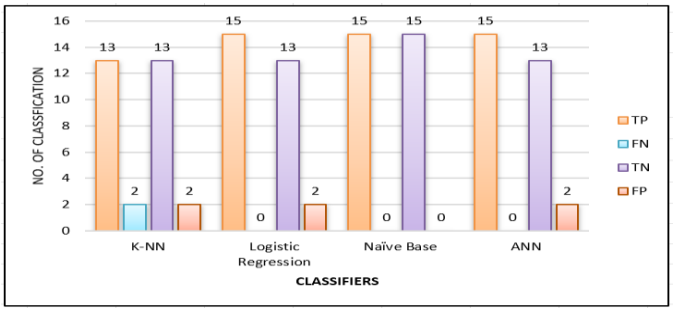

Fig. 16. Evaluation results of K-NN, LR, NB and ANN.

The findings of the overall system performance research in terms of sensitivity, specificity, accuracy, precision, and F1 score are presented in Table VII. The analysis report of NB, KNN, LR and ANN is shown in Fig. 17. It is clear from the overall findings that the Logistic Regression Classifier appears to produce more accurate results than the KNN, ANN, and Naive Base Classifications. The entire system parameters like sensitivity, specificity, precision, F1 score and accuracy.

TABLE VII. CLASSIFICATION METRICS OF NB, LR, KNN AND ANN

Classification Metrics	NB	KNN	LR	ANN
Accuracy	93.00	86.67	96.67	93.33
Sensitivity	100.00	86.67	100.00	100.00
Specificity	86.67	86.67	93.33	86.67
Precision	88.24	86.67	93.75	88.24
F1 score	93.75	86.67	96.77	93.75

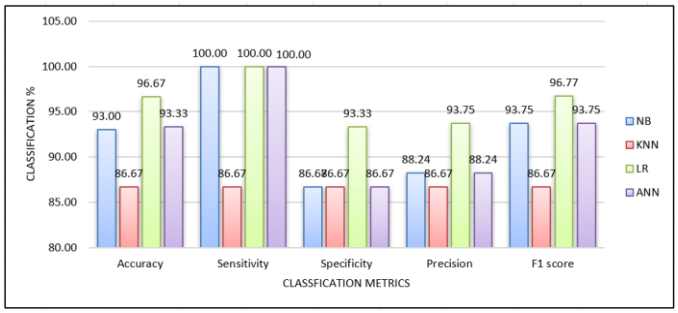

Fig. 17. Classification metrics of NB, KNN, LR and ANN.

Based on the Table VII, KNN produces the result for 86.67% Accuracy, 86.67% Sensitivity, 86.67% Specificity, Precision 86.67% and F1 score 86.67%, Naïve Base produces the result for Accuracy 93%, Sensitivity 100%, Specificity 86.67%, Precision 88.24% and F1 score 93.75%, ANN produces the result Accuracy 93.33%, Sensitivity 100%, Specificity 86.67%, Precision 88.24% and F1 score 93.75% and Logistic Regression produces the result Accuracy 96.67%, 100%Sensitivity, 93.33% Specificity, 93.75% Precision and 96.77% F1 score . The confusion matrix of these classifiers are shown in Fig. 18, Fig. 19, Fig. 20 and Fig. 21 and also analyses the metric ROC curve from the confusion matrix are shown in Fig. 22, Fig. 23 and Fig. 24. Area under curve (AUC) for LR is 0.9939393939393939, KNN is 0.9484848484848486 and NB is 0.9939393939393939.

V. CONCLUSION

The main contributions of this work are: accurately reduce the speckle noise in OCT images, accurately segment the RPE layer in normal OCT images and PED images, and extract four novel features to accurately predict PED disease and normal images. Through the experimental results, Wiener filtering technique outperforms in reduce speckle noise in the OCT images. The suggested technique and steps appear to be effective for extracting best features from the RPE layer for detecting PED in OCT images. These features were used to train the classifiers and tested with new inputs. Based on these features, the performance of logistic regression classifier was better when compared with other classifiers. The degree of precision attained demonstrates that the technique can also be used in practical applications. To accurately and completely examine the actual performance, the usefulness of the suggested classifier systems must be assessed for specific abnormality-based categorization, such as PED. The normal and PED images were classified with machine learning algorithms. This automatic model is used to assists doctors early diagnose the PED. In this paper, the machine learning classifiers like KNN, LR, NB and ANN were compared. KNN produces the result for Accuracy 86.67%, Sensitivity 86.67%, Specificity 86.67%, Precision 86.67% and F1 score 86.67%, LR produces the result for Accuracy 96.67%, Sensitivity 100%, Specificity 93.33%, Precision 93.75% and F1 score 96.77%, and NB produces the result Accuracy 93.33%, Sensitivity 100%, Specificity 86.67%, Precision 88.24% and F1 score 93.75% and ANN found 93.33% accuracy, 100% sensitivity, 86.67% specificity, 88.245 precision and F1 score 93.75%. Based on the experiments, it is found that logistic regression classifier gives high accuracy in identifying PED illnesses and broadening the scope of anomalies. Further this study can be extended to detect the PED using other machine learning algorithms. Deep learning can also be used in future to detect PED in retinal OCT images.

Investigating the Effect of Small Sample Process Capability Index Under Different Bootstrap Methods

Liyan Wang*, Guihua Bo, Mingjuan Du
School of Information and Control Engineering, Liaoning Petrochemical University, Fushun, China

***Abstract*—In the quality control of multi-variety and small-batch products, the calculation of the process capability index is particularly important. However, when the sample size is not enough, the process distribution cannot be judged, if the traditional method is still used to calculate the process capability index; there will be misapplication or misuse. In this paper, the Bootstrap method is introduced into the estimation of process capability index and the calculation of its confidence interval by using Standard Bootstrap (SB), Percentile Bootstrap (PB), Percentile-t Bootstrap (PTB) and Biased-corrected Percentile Bootstrap (BCPB) methods were used to analyze and compare the process capability index. It is found that in symmetric distribution, only the sample size has a significant effect on the length of the confidence interval；but in asymmetric distribution, sample size and Bootstrap methods are both significant factors affecting the length of confidence interval.**

***Keywords*—Process capability indices; bootstrap; confidence interval; small samples**

I. Introduction

Process capability analysis is an important part of statistical process control activities for continuous improvement. Process Capability Index (PCI) is designed to provide a general language for quantifying its performance; it is a dimensionless function of the process parameters and specifications. PCI is widely used in traditional manufacturing industries, but with the production mode has changed from single variety and large batch to multi-variety and small batch, and the number of parts of the same specification produced under the same process and similar production conditions has become less and less, which brings difficulties to the process capability analysis and the calculation of indicators and statistical inference. When the sample size is insufficient, the central limit theorem cannot be used to calculate the process capability index because it is impossible to judge the distribution of process data. If the traditional method is still used for calculation, it is easy to misunderstand and misuse.

Process Capability Indices (PCIs) are considered as a practical tool by many advocates of statistical process control in industry. They are used to determine whether a manufacturing process is capable of producing with dimensions within a specified tolerance range. The process indices *Cp* and *Cpk* [1] are used for unit-less measures that relate the natural process tolerance (6σ), upper and lower specification limits. Chan et al. [2] developed *Cpm* that incorporates a target value for the process. Taguchi [3] and Chou et al. [4] provided tables for constructing 95 percent lower confidence limits for both *Cp* and *Cpk*. Their tables for limits on *Cpk*, however, are conservative and an approximation presented by Bissel [5] is recommended instead. Boyles [6] provided an approximate method for finding lower confidence limits for *Cpm*. The calculation of all these lower confidence limits assume a normally distributed process and many real world processes are not normally distributed and this departure from normality may be hard to detect. This could potentially affect both the estimates of the indices and the confidence limits based on these estimates. Efron [7] introduced and developed the non-parametric, but computer intensive estimation method called Bootstrap. Bootstrap method [8] replaces theoretical analysis with computer simulation technology, and replaces real distribution with statistical empirical distribution. It is effective for statistical analysis and process capability analysis under small sample conditions. Therefore, Bootstrap method can be introduced into point estimation and confidence interval calculation of *Cp* and *Cpk* under small sample conditions.

The rest of this paper is consisted of as: Section II presents the related works. Section III and IV realizes the estimation of *Cp* and *Cpk* based on Bootstrap method, and then experimental results are discussed in Section IV. Finally, this paper concludes in Section VI. Our study shows that in symmetric distribution, only the sample size has a significant effect on the length of the confidence interval, Bootstrap methods has no significant effect on the length of confidence interval. But in the skewed distribution, sample size and Bootstrap methods are both significant factors affecting the length of confidence interval.

II. Related Work

Bootstrap method is very popular in modern statistics. Especially after the rise of big data, the effect of estimating the mean or variance of statistics with small samples is ideal. Its simulation result is very close to the real result, and it is often used to solve some situations that cannot be broken through in theory. The core idea of Bootstrap method is to replace theoretical analysis with computer simulation technology, that is, to extract the same number of samples from the original samples by repeated sampling technology, and replace the real distribution with its statistics. Bootstrap method can be used for the hypothesis testing and interval estimation problems of location parameter with unknown scale parameter and skewness parameter, it provides the satisfactory performances under the senses of Type I error probability and power in most cases regardless of the moment estimator or ML estimator [9]. By repeating the above process and calculating its mean or variance, the empirical distribution of statistics is substituted for the real distribution.

*Corresponding Author.

Owing to these benefits, application of Bootstrap method in the process capability index includes:Bootstrap confidence intervals for indices such as *Cp* [10-13], *Cpk* [14, 15], *Cpm* [15], and *Cpmk* [16] are established for PCIs. Its applications can also be divided into: Using Bootstrap sampling to estimate the multivariate [17] or multiple process streams [13] process capability indices; using different methods of estimation to construct Bootstrap confidence intervals of generalized process capability index *Cpyk* [18]. Especially when data is non-normal, the Bootstrap confidence intervals of different distribution types of non-normal data were studied: such as the Modified Process Capability Index for Wei-bull distribution [19], Parametric and non-parametric bootstrap confidence intervals of C_{Npk} for exponential [20] and exponential power distribution [21], and so on. In addition, its application can also be seen in the case of small samples [22, 23]. Bootstrap method replaces theoretical analysis with computer simulation technology, and replaces real distribution with statistical empirical distribution. It is effective for statistical analysis and process capability analysis under small sample conditions. Therefore, Bootstrap method can be introduced into point estimation and confidence interval calculation of *Cp* and *Cpk* under small samples.

III. ESTIMATION OF C_P AND C_{PK}

A. Definition and Estimation of PCIs

The capability of a process is frequently measured by a process capability index (PCI) which is designed to provide a common and easily understood language for quantifying its performance, and is a dimensionless function of process parameters and specifications. Let *USL* and *LSL* be the upper and lower specification limits, respectively. If the process follows or approximately follows a normal distribution, the statistical characteristics of the traditional process capability index can be calculated, including point estimation, confidence interval, and estimated distribution characteristics.

If the process follows or approximately follows a normal distribution, using the above two sample statistics, point estimates of PCIs such as *Cp* & *Cpk* [1] , and *Cpm* [2] can be calculated.

The definition of *Cp* is:

$$C_p = \frac{USL - LSL}{6\sigma} \tag{1}$$

The estimation of *Cp* is:

$$\hat{C}_p = \frac{USL - LSL}{6S} = \frac{\sigma}{S} C_p \tag{2}$$

Wherein, *USL* and *LSL* are the upper and lower specification limits of the process.

Since the index *Cp* does not take into account the location of the process mean (μ), the index *Cpk is defined*:

$$\hat{C}_{pk} = min\{\frac{USL - \mu}{3\sigma}, \frac{\mu - LSL}{3\sigma}\} \tag{3}$$

If the sample size is large and the data follows a normal distribution, a point estimate of the process capability indicator can be obtained by calculating the mean and standard deviation of the sample. They can be represented by the following statistics:

μ is represented by the sample mean $\overline{X}$:

$$\overline{X} = \frac{1}{n}\sum_{i=1}^{n} X_i \tag{4}$$

σ^2 is represented by the sample variance S^2 :

$$S^2 = \frac{1}{n-1}\sum_{i=1}^{n}(X_i - \overline{X})^2 \tag{5}$$

Wherein, X_i is the i-th observation value, $\overline{X}$ is the sample mean, and n is the sample size. $\overline{X}$ and S^2 are unbiased estimators of population mean μ and population variance σ^2 .

The expected value for obtaining the estimated value of the exponent *Cp* by calculating its *r-th* moment $\hat{C}_p$ is:

$$E[\hat{C}_p^r] = [\frac{n-1}{2}]^{\frac{r}{2}} \frac{\Gamma[\frac{n-1-r}{2}]}{\Gamma[\frac{n-1}{2}]} C_p^r \tag{6}$$

So when *r*=1, the mean of the estimated value of the index *Cp* [24] is:

$$E(\hat{C}_p) = \frac{1}{b_f} C_p \tag{7}$$

And b_f is the correction coefficient, $b_f = \sqrt{\frac{n-1}{2}} \frac{\Gamma(\frac{n-2}{2})}{\Gamma(\frac{n-1}{2})}$.

So when *r*=2, the variance of the estimated value of the index *Cp* [24] is :

$$Var(\hat{C}_p) = (\frac{n-1}{n-3} - \frac{1}{b_f^2}) C_p^2 \tag{8}$$

Therefore, based on (6), it can be obtained that if the process follows or approximately follows a normal distribution, then for *n* samples in the population, the statistic $\frac{(n-1)s^2}{\sigma^2}$ follows χ^2 distribution with *n-1* degrees of freedom, denoted as: $\frac{(n-1)s^2}{\sigma^2} \sim \chi^2(n-1)$.

So:

$$C_p = \hat{C}_p \sqrt{\frac{\chi^2_{n-1}}{n-1}} \tag{9}$$

When the significance level is α , the $100(1-\alpha)\%$ confidence interval for *Cp* [25] is:

$$[\hat{C}_P\sqrt{\frac{\chi^2_{(\alpha/2,n-1)}}{n-1}}, \hat{C}_P\sqrt{\frac{\chi^2_{(1-\alpha/2,n-1)}}{n-1}}] \quad (10)$$

The same is true of the $100(1-\alpha)\%$ confidence interval for *Cpk* [25]:

$$[\hat{C}_{pk}(1+z_{\alpha/2})\sqrt{\frac{1}{9n\hat{C}^2_{pk}}+\frac{1}{2(n-1)}}, \hat{C}_{pk}(1+z_{1-\alpha/2})\sqrt{\frac{1}{9n\hat{C}^2_{pk}}+\frac{1}{2(n-1)}}] \quad (11)$$

B. Analysis of the Influence of Sample Size

It can be seen from Eq. (6) to Eq. (11) that sample size *n* has an impact on the statistical estimator of the process capability index.

1) Impact of sample size on the correction coefficient b_f : As shown in Table I: With the increase of sample size n, the closer the value of $1/b_f$ is to 1, the closer the point estimate is to the true value of Cp. When n=400, b_f value loses significance, and the corresponding PCI estimation is also meaningless. It follows that the appropriate sample size is usually 100 or 200. There is no need to adopt full sampling method or blindly increase sample size.

2) Impact of sample size on the confidence interval of Cp: The confidence interval of Cp is shown in Table II, when it follows or approximately follows a normal distribution at a given value. As shown in the Table II, with a given value $\hat{C}_p$, the width of the confidence interval becomes shorter as the sample size n increases. When the sample size n is specified, the larger the $\hat{C}_p$ value is, the longer the confidence interval length is. Therefore, when the data follows or approximately follows a normal distribution, in order to obtain a tighter confidence interval for Cp, it is necessary to consider both the $\hat{C}_p$ value and the sample size n in order to obtain a more stringent Cp confidence interval.

Wherein，*Lc* and *Uc* are the lower and upper confidence limits.

3) Impact of sample size on the confidence interval length of Cpk: As shown in Table III: With reference to the conclusions of the above Table I and Table II, considering the economy of sampling and the accuracy of parameter confidence intervals, we only analyzed the influence of sample size within 200 on the confidence intervals and interval widths of *Cpk*.

Similar to the point estimation and interval estimation of *Cp*, when the data obey or approximate obey the normal distribution, the confidence interval and interval width of *Cpk* are affected by both the sample size *n* and the *Cpk* estimator. When $\hat{C}_{pk}$ is specified, the larger the sample size is, the more accurate the interval estimation and the shorter the width of the confidence interval are. When the sample size is specified, the larger the $\hat{C}_{pk}$ value is, the longer the corresponding confidence interval width is. Here *CIL* indicates the confidence interval length.

Based on the analysis shown in Table I to Table III, we can find that the traditional process capability analysis is based on the process obeying or approximately obeying the normal distribution. In order to ensure the reliability of parameter estimation, a sufficient sample size is usually required, i.e., *n*=100 or 200. This means that in traditional analysis we need a large sample. In other words, when the sample size is small, it is impossible to accurately judge the type of distribution of the data. At this point, if the traditional parameter estimation method is still used to analyze the process capability, the calculated *PCI* is not accurate and the *CIL* is longer. We'll get the wrong conclusions. To solve these problems, we can use the Bootstrap method to calculate the confidence interval of the process capability indicator.

IV. ESTIMATION OF C_P AND C_{PK} BASED ON BOOTSTRAP METHOD

A. Introduction of Bootstrap

The Bootstrap method is to repeatedly resample the original sample, extract *B* replacement samples with random (RSWR) with sample size *n* from sample S_0, and express them with S_i^* (subscript *i* represents the *i-th* time resampling). Where, $S_i^* = \{x_1^*,...,x_n^*\}$ represents a simple RSWR extracted from S_0, S_i^* is called Bootstrap sample. For each subsample S_i^*, its *T* statistic is calculated and expressed by $\{t_1^*, t_2^*, \ldots t_B^*\}$ respectively.

Assuming there is a random sampling sequence $S_0=\{x_1,..., x_n\}$ with a length of *n* from a completely uncertain distribution. Where x_i is the independent random sampling of the distribution, where t_i represents the value of a specific sample statistic *T* .

The distribution of the statistic *T* is called the Empirical Bootstrap Distribution (EBD), where *B* is the sample size. When *B* is large enough, an approximation of the statistic *T* can be obtained by repeated sampling from S_0. In this way, the Bootstrap method can be used for statistical simulation of small samples, so as to obtain statistical estimation of unknown distribution and unknown parameters. Generally, we assumed *B* = 1000 bootstrap re-samples.

Bootstrap methods include Standard Bootstrap (SB), Percentile Bootstrap (PB), Biased corrected Percentile Bootstrap (BCPB), Percentile *T* Bootstrap (PTB), and Biased corrected and accelerated Bootstrap (BCa). Scholars [10-19, 21] mostly used the two of four methods and compared the Bootstrap confidence interval of PCIs. It is difficult to implement the BCa method [20], so its application is less. Therefore, this paper also uses the first four Bootstrap methods.

B. Bootstrap Confidence Intervals with Four Methods

Based on the original random samples x_1, x_2,..., x_n with sample size *n*, construct *B* new Bootstrap samples $x_1^*, x_2^*,..., x_n^*$, i.e. $S_i^* = \{x_1^*,...,x_n^*\}$. Calculate the *Cp*values for each sub sample S_i^* , denoted by $\{C_1^*, C_2^*, \ldots, C_B^*\}$ respectively. By arranging the values in ascending order, the empirical probability distribution of *B T*-values can be obtained, which is called the Bootstrap Empirical Distribution (EBD). Taking *B*=1000 and using the Bootstrap method to repeat sampling from small sample S_0, statistical estimates of *Cp* can be obtained.

Here $\hat{C}_p$ and $\hat{C}_{pk}$ represents the estimate of *Cp* and *Cpk*, $\hat{C}_p^*(i)$ and $\hat{C}_{pk}^*(i)$ represent the sequential estimator of the process capability index calculated from 1000 Bootstrap random replacement samples. The sample mean calculated from these 1000 Bootstrap estimators are:

$$\overline{C}_p^* = \frac{1}{1000}\sum_{i=1}^{1000}\hat{C}_p^*(i) \tag{12}$$

$$\overline{C}_{pk}^* = \frac{1}{1000}\sum_{i=1}^{1000}\hat{C}_{pk}^*(i) \tag{13}$$

The standard deviation of the samples are:

$$S_{cp}^* = \sqrt{\frac{1}{999}\sum_{i=1}^{1000}\left[\hat{C}_p^*(i) - \overline{C}_p^*\right]^2} \tag{14}$$

$$S_{cpk}^* = \sqrt{\frac{1}{999}\sum_{i=1}^{1000}\left[\hat{C}_{pk}^*(i) - \overline{C}_{pk}^*\right]^2} \tag{15}$$

When the distribution of $\hat{C}_p$ and $\hat{C}_{pk}$ follows or approximates the normal distribution, the statistics calculated in Eq. (14) and Eq. (15) are essentially estimators of the standard deviations of *Cp* and *Cpk* .

1) Confidence interval based on SB[8,14]: When the significance level is α, the standard Bootstrap confidence intervals for $100(1-\alpha)\%$ of the process capability index *Cp* and *Cpk* are respectively:

$$\left[\hat{C}_p - Z_{1-\frac{\alpha}{2}}S_{cp}^*,\ \hat{C}_p + Z_{1-\frac{\alpha}{2}}S_{cp}^*\right] \tag{16}$$

$$\left[\hat{C}_{pk} - Z_{1-\frac{\alpha}{2}}S_{cpk}^*,\ \hat{C}_{pk} + Z_{1-\frac{\alpha}{2}}S_{cpk}^*\right] \tag{17}$$

Wherein, $Z_{1-\frac{\alpha}{2}}$ is the *1-α/2* percentile of the standard normal distribution.

2) Confidence interval based on PB [8,14]

$$\left[\hat{C}_p^*(\frac{\alpha}{2}B),\hat{C}_p^*(1-\frac{\alpha}{2})B)\right] \quad (18)$$

$$\left[\hat{C}_{pk}^*(\frac{\alpha}{2}B),\hat{C}_{pk}^*(1-\frac{\alpha}{2})B)\right] \quad (19)$$

Wherein, α/2 and (1-α/2) are the upper and lower bounds of the confidence intervals for the statistics *Cp* and *Cpk* at the (1−*α*) confidence level, respectively, i.e.

3) Confidence interval based on BCPB[8,15]

$$\left[\hat{C}_p^*(P_L B),\hat{C}_p^*(P_U B)\right] \quad (20)$$

$$\left[\hat{C}_{pk}^*(P_L' B),\hat{C}_{pk}^*(\dot{P}_U' B)\right] \quad (21)$$

Wherein, $P_0 = P_r(\hat{C}_p^* \le \hat{C}_p)$, $P_0' = P_r(\hat{C}_{pk}^* \le \hat{C}_{pk})$, and $Z_0 = \Phi^{-1}(P_0)$, $Z_0' = \Phi^{-1}(P_0')$, $P_L = \Phi\ (2Z_0 - Z_{1-\frac{\alpha}{2}})$, $P_L' = \Phi\ (2Z_0' - Z_{1-\frac{\alpha}{2}})$, $P_U = \Phi\ (2Z_0 + Z_{1-\frac{\alpha}{2}})$, and $P_U' = \Phi\ (2Z_0' + Z_{1-\frac{\alpha}{2}})$.

4) Confidence interval based on PTB [8,14]

$$\left[\hat{C}_{p,\ pk} - t^*(\frac{\alpha}{2}B)\times S_{p,\ pk}^*, \hat{C}_{p,\ pk} + t^*(\frac{\alpha}{2}B)\times S_{p,\ pk}^*\right] \quad (22)$$

$$\left[\hat{C}_{pk} - t^*(\frac{\alpha}{2}B)\times S_{cpk}^*, \hat{C}_{pk} + t^*(\frac{\alpha}{2}B)\times S_{cpk}^*\right] \quad (23)$$

Wherein，*Scp*∗is the sample standard deviation of { $\hat{C}_{py}^{*(i)}$, *i* = 1, 2, …, *B* } , that is $S^* = \sqrt{\frac{1}{B}\sum_{i=1}^{B}(\hat{C}_{p,\ pk}^{*(i)} - \overline{\hat{C}}_{p,\ pk}^{*})^2}$, where $\overline{\hat{C}}_{p,\ pk}^{*} = \frac{1}{B}\sum_{i=1}^{B}\hat{C}_{p,\ pk}^{*(i)}$.

In addition, $\hat{t}^{*(\tau)}$ is the τ percentile of $\left\{\frac{\hat{C}_{p,\ pk}^{*(i)} - \hat{C}_{p,pk}}{S^*}\right\}$; *i*=1, 2, ..., *B*. i.e., $\hat{t}^{*(\tau)}$ is such that $\frac{1}{B}\sum_{i=1}^{B} I(\frac{\hat{C}_{p,\ pk}^{*(i)} - \overline{\hat{C}}_{p,\ pk}}{S^*} \le \hat{t}^{*(\tau)}) = \tau$, $0<\tau<1$.

C. Calculation of CIL of Cp and Cpk under Bootstrap Methods

Based on the above principles, enough samples are obtained by repeated sampling from small samples, assuming that they obey different distributions; date should be transformed to normal firstly before calculating PCI.

For comparison, the original distribution is transformed so that the different types of distributions have the same mean and variance. To be more general, the data generated by the simulation is processed centrally, that is, standard normal processing. Assuming that different data distributions have the same mean and variance, the data can be transformed accordingly:

$$\frac{Y-\mu^*}{\sigma^*} = \frac{X-\mu_0}{\sigma_0} \quad (24)$$

where, μ^* , σ^* , μ_0 and σ_0 are the mean and standard deviation of the expected output distribution and the original distribution, respectively. Table IV summarizes the means and variances of some common distributions. These parameters will be used in the data normal transformation.

To be more general, we choose several typical distributions, including symmetric distributions such as the normal distribution and the heavy-tailed distribution t_5, and asymmetric distributions such as the moderately right-skewed distribution χ_5^2 and the slightly skewed distribution *logn*(0, 0.4).

TABLE IV. MEAN AND VARIANCE OF DIFFERENT DISTRIBUTION

Distributions	Mean	Variance	Statistics
Normal distribution	μ	σ^2	μ：Mean σ^2：variance
Exponential distribution	1/λ	$1/\lambda^2$	λ：Threshold
χ2 distribution	n	2n	n：Freedom
T distribution	0	n/(n-2)	n：Freedom
F distribution	v/(v-2)	$\frac{2v^2(u+v-2)}{u(v-2)^2(v-4)}$, $v>4$	u&v：first & second degree of freedom
Log-normal distribution	e^(μ+σ^2)/2	e^2μ+σ^2(eσ^2-1)	μ：Mean σ^2：variance

Firstly, to obtain a different distribution type with a mean of 0 and a standard deviation of 1, you can transform the data based on Eq. (24) as follows:

$$X_1 \sim t_5 \Rightarrow Y_1 = \sqrt{\frac{3}{5}} X_1 \tag{25}$$

$$X_2 \sim \chi_5^2 \Rightarrow Y_2 = \sqrt{\frac{1}{10}} X_2 + \frac{5}{\sqrt{10}} \tag{26}$$

$$X_3 \sim Logn(0,0.4) \Rightarrow Y_3 = \frac{1}{e^{0.08}\sqrt{e^{0.16}-1}} X_3 - \frac{1}{\sqrt{e^{0.16}-1}} \tag{27}$$

Secondly, based on the new distribution generated by the above three transformations, using four Bootstrap methods, the confidence interval and *CIL* value at α=0.1 can be obtained through simulation. The simulation results and analysis are shown in Section IV.

V. Experimental Analysis

Based on the calculation results in Section IV, the influence of sample size *n* and different Bootstrap methods on the length of confidence interval is analyzed.

A. When the Data Follows Symmetrical Distribution

In order to analyze the factors affecting CIL, we first carried out ANOVA and drew images to compare the difference of CIL under different Bootstrap methods.

Through ANOVA, we found that only the sample size n had a significant effect on *CIL* (its *P* value less than 0.05), while the Bootstrap method had no significant effect on *CIL* (its *P* value greater than 0.05). In addition, combined with comparison graph analysis in Fig. 1, regardless of which Bootstrap method is used, *CIL* decreases as the sample size *n* increases.

TABLE V. Simulation Result Under Distribution with Four Bootstrap Method

Distribution		Symmetrical Distribution				Asymmetrical Distribution

S = 0.1262 R-Sq = 86.95% R-Sq(adjust)= 78.24%					

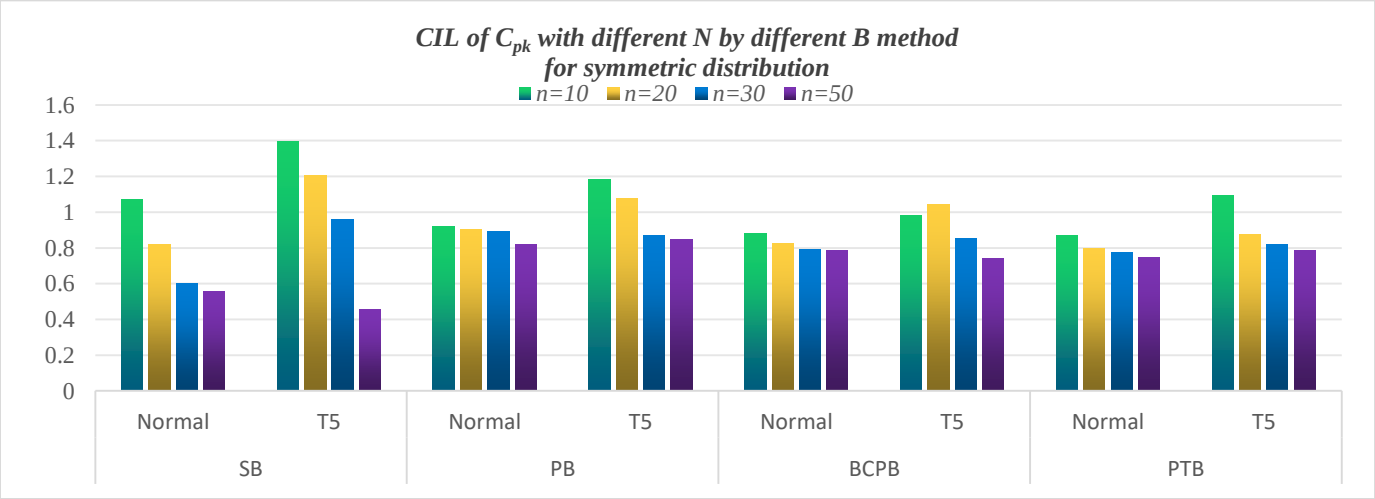

Fig. 1. CIL of *Cpk* under symmetrical distribution.

B. When the Data Follows Asymmetric Distribution

The ANOVA and image results are as follows: sample size n and Bootstrap methods are both significant factors affecting CIL (their P value are both less than 0.05). That is to say, the larger of sample size n is, the shorter of the CIL is.

Combined with Fig. 2, it can be found that the CIL under different Bootstrap methods are different but when the data follows χ_5^2 distribution, and the *CIL* of the later two Bootstrap methods is more stable, but the *CIL* of PTB is the shortest. While When the data follows *logn(0,0.4)* distribution (which is slightly skewed), the ANOVA and image results are a little different, the *CIL* of the BCPB methods is more stable and shorter. That is to say:

- In skew distribution, PTB method and BCPB method are better than SB and PB method in estimating *CIL*.
- In the slightly skewed distribution, such as *log-normal* (0, 0.4) distribution, BCPB method is recommended. For moderately skewed distributions, such as χ_5^2 distributions, the PTB method is recommended.

TABLE VIII. TWO FACTORS OF ANOVA TABLE UNDER CHI-SQUARE DISTRIBUTION

Sources	Degree of freedom	SS	MS	F	P
n	3	0.52345	0.174482	6.77	0.011
Method	3	0.32737	0.109124	4.23	0.040
Error	9	0.23212	0.025792		
Total error	15	1.08294			
S = 0.1606 R-Sq = 78.57% R-Sq(adjust) = 64.28%					

TABLE IX. TWO FACTORS ANOVA TABLE UNDER LOG-NORMAL*(0,0.4)* DISTRIBUTION

n	3	1.66676	0.555587	54.54	0.000
Method	3	0.15233	0.050778	4.98	0.026
Error	9	0.09168	0.010187		
Total error	15	1.91078			
S = 0.1009 R-Sq = 95.20% R-Sq(adjust)= 92.00%					

C. Findings

1) In symmetric distribution: Based on all the above ANOVA (see Tables VI-VII) and combined with Fig. 1, the following findings can be drawn:

Take normal distribution and *T* distribution as examples, only the sample size has a significant effect on the length of the confidence interval: the larger the sample size *n* is, the shorter the *CIL* is. In the symmetric distribution, the four Bootstrap methods had no significant effect on the length of confidence interval, that is, there was no significant difference between the four methods.

2) In asymmetric distribution: Based on all the above ANOVA (see Tables VIII-IX) and combined with Fig. 2, the following findings can be drawn:

Take chi-square distributions and log-normal distributions as examples, both the sample size *n* and the Bootstrap method are important factors affecting *CIL*. The *CIL* gets shorter as the sample size *n* increases. In addition, the confidence intervals calculated under the four Bootstrap methods are significantly different.

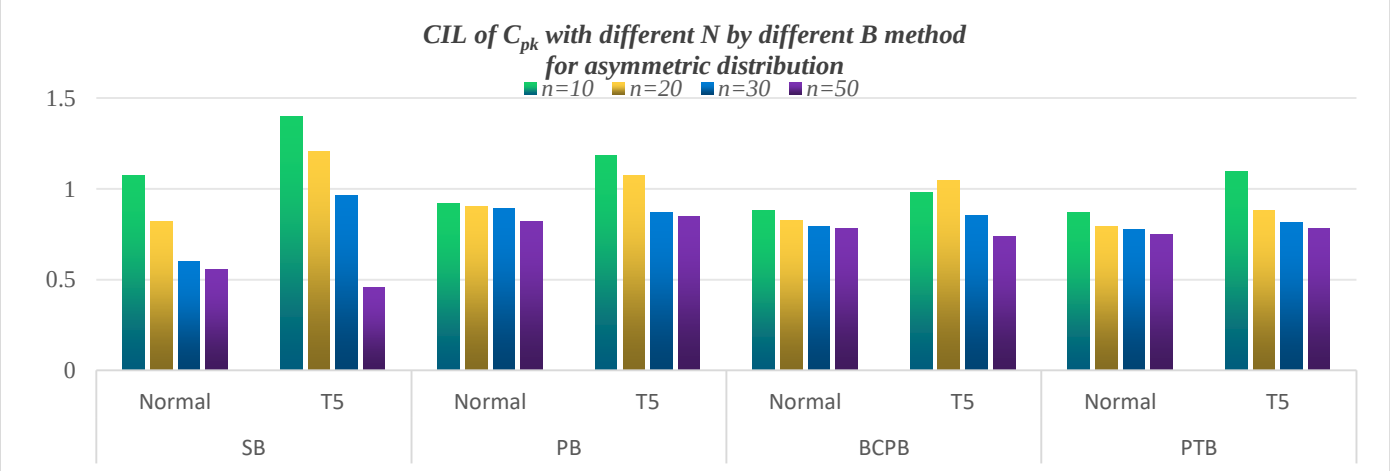

Fig. 2. CIL of Cpk under asymmetric distribution.

VI. CONCLUSION

This paper mainly studies the process capability index in the case of small samples. After analyzing the influence of sample size on the confidence interval of traditional process capability analysis index, we introduced Bootstrap method to solve and compare the confidence interval of process capability index *Cp* and *Cpk* in the case of small samples. ANOVA was used to verify the significant effects of sample size and different Bootstrap methods on confidence intervals. Some valuable findings were made:

1) In symmetric distributions, such as normal and *T*-distributions, only the sample size has a significant effect on the length of the confidence interval: the larger the sample size, the shorter the CIL. The Bootstrap method has no significant effect on the length of the confidence interval, that is, there is no significant difference between the four methods.

2) In asymmetric distributions, such as chi-square and lognormal distributions, both sample size and Bootstrap method are important factors affecting *CIL*. Combined with the variation of distribution skewness, the user can choose the appropriate Bootstrap method.

The above simulation and analysis only focus on the calculation and comparison of confidence intervals and their interval lengths, while the interval coverage ratio and standard difference of confidence intervals of PCI under these four methods have not been involved, and further in-depth research is needed.

Discovering the Global Landscape of Agri-Food and Blockchain: A Bibliometric Review

Sharifah Khairun Nisa' Habib Elias, Sahnius Usman, Suriayati Chuprat
Faculty of Artificial Intelligence, Universiti Teknologi Malaysia, Kuala Lumpur, Malaysia

***Abstract*—The agri-food supply chain encompasses all the entities involved in the production and processing of food, from producers to consumers. Traceability is crucial in ensuring that food products are available, affordable, and accessible. Blockchain technology has been proposed as a way to improve traceability in the agri-food supply chain by providing transparency and trust. However, research in this area is still in its early stages. This study aims to examine the trend of blockchain in agri-food supply chain traceability for food security. A bibliometric analysis was conducted on 1047 scholarly works from the Scopus database, starting in 2016. The analysis looked at citation patterns and the development of blockchain technology in agri-food supply chain research and identified trends by source title, nation, institution, and key players. The analysis also examined the frequency of keywords, titles, and abstracts to identify key themes. The analysis has revealed a strong correlation between blockchain technology and traceability in the agri-food supply chain, indicating a promising area for further research. The results show that blockchain-based research for traceability in the agri-food supply chain has increased and is being widely distributed, particularly in regions beyond Europe. The potential benefits it can bring to the supply chain will contribute to the success of the Sustainable Development Goals (SDGs) by ensuring a safe and sufficient global food supply.**

Keywords*—*Agri-food supply chain; bibliometric; blockchain; traceability

I. INTRODUCTION

Food security, nutrition, and safety are all interrelated. 600 million people around the world are sick because of contaminated food, which causes 420,000 deaths and 33 million healthy life years (DALYs) every year. In low- and middle-income countries, unsafe food costs US$110 billion every year. 40% of foodborne illnesses are experienced by children younger than five years old [1]. The agri-food sector and its supply chain play a crucial role in the global food system, involving the production, processing, transformation, and delivery of food products [2]. The study in [3] emphasise the difficulties that the agri-food industry encounters as a result of globalisation, such as the risks to food security, shortages in infrastructure, financial instability, and incidents of food fraud. This will be solved by implementing traceability in the agri-food supply chain.

However, the complex structure of the agri-food supply chain, which encompasses several stakeholders such as farmers, distributors, processors, wholesalers, retailers, and end consumers, creates difficulties [4].

Traceability refers to the capacity to systematically monitor and trace the movement of a product across the supply chain, starting from its origin to its final destination. The objective of traceability is to provide fast retrieval of dependable data, hence facilitating quick analysis and decision-making [5], [6]. For this reason, traceability has gained major importance in the agri-food sector due to customer demand for transparency, accountability, and food safety. Factors driving this demand include increasing supply chain efficiency, technological advancements, sustainability, food safety, regulations, certifications, and data collection and analysis [7]. Traceability is an essential feature of blockchain technology for supply chain applications [8], with a growing number of blockchain applications focusing on enabling supply chain traceability across various industries [9], [10], [11]. Blockchain technology has been suggested to improve traceability in the agri-food supply chain because it offers a transparent, reliable, and tamper-proof solution to managing product-related traceability information [12].

Blockchain technology is a decentralized system that provides immutability, security, and transparency in the ledger of transactions across a network of computers. Due to its capabilities, its application as across various industry such agriculture, healthcare and manufacturing. [13], has found traceability to be the primary enabler for blockchain technology implementation in the agri-food supply chain, followed by auditability, immutability, and provenance. For example, the provenance of food can be traced using blockchain technology, thus creating reliable food supply chains and fostering confidence between consumers and producers [6]. Besides that, blockchain-based supply chain technologies are anticipated to enhance performance, competitiveness, transparency, and trust among all participants [14]. This technology enhances operational efficiency, expedites processes, and eliminates the need for physical documentation, therefore providing accessibility, transparency, and integrity. By enhancing supply chain traceability, accountability, and efficiency, blockchain technology has the potential to revolutionise the manufacturing sector. It can address concerns such as intrinsic security and content modification requiring authentication and processing. It is also capable of managing assemblies and products, ensuring the privacy of data storage [15]. A novel framework that utilises a blockchain network to facilitate supply chain traceability and counterfeit detection of COVID-19 vaccines has been proposed by [16]. It facilitates the secure management of supply chain operations for distribution companies to prevent fraudulent vaccines and transform supply chain management in the healthcare industry. This

information will aid practitioners and policymakers in implementing blockchain technology in the agri-food supply chain to ensure food safety and security.

The globalisation of agricultural production has resulted in an increased focus on ensuring the safety, quality, and validation of standards throughout food supply chains. Blockchain technology offers a novel way for tracing products in intricate ecosystems. Various methodologies have been utilised to establish the ability to track and trace products in the agricultural food supply chain. A framework that utilises blockchain technology has been proposed for the agri-food supply chain in Bangladesh to resolve the issue of inadequate communication between producers and consumers in the traditional agricultural network [17]. [18]present ShrimpChain, a hybrid public-private Blockchain architecture, designed to enhance traceability and provide a full view of the supply chain in the shrimp industry. This framework aims to address the limitations of the traditional paper-based record-keeping methods now used in the fragmented shrimp supply chain. A blockchain-powered solution for monitoring and tracing soybeans in the agricultural supply chain is presented by [19] to improve efficiency and safety by eliminating the need for centralised authorities. The increasing need for ethical and ecological standards requires the ability to track items from their origin to their final point of sale. Utilising block-chain technology, along with RFID and QR codes, can effectively overcome limitations in current systems and streamline processes, such as monitoring the entire journey of cheese supply chains [20]. This technology can also enable smart contracts to automate supply chain management and product quality control [12]. Nevertheless, the integration of blockchain technology into the agri-food supply chain remains nascent, presenting challenges including but not limited to scalability, energy consumption, privacy, and complexity [21], [22], [23]. In order to fully realize its potential to revolutionize the agri-food supply chain through the provision of transparency, provenance, and efficiency, it is critical to address these challenges.

Subsequently, substantial progress has been made in the field of agri-food blockchain research; therefore, it is vital to remain abreast of the latest developments in the body of literature. A bibliometric analysis was performed on published blockchain in agri-food research, regardless of timeframe, in order to determine the scope and depth of scholarly work pertaining to blockchain in the agri-food sector. It attempts to respond to four primary research questions.

RQ1. What is the current trend and impact of publication in agri-food and blockchain?

- Growth of publication by year
- Sources Type and Types of Document
- Languages of documents
- Most active source titles

RQ2. Which are the most productive and influential countries, institutions and authors on agri-food and blockchain research?

- Total Publication by Country Top 15
- Most active institutions Top 15
- Authorship Analysis Top 15

RQ3. Which are the most prevalent themes of agri-food and blockchain between scholars?

- Keyword analysis
- Title and abstract analysis

RQ4. Which are the most influential articles on agri-food and blockchain research?

- Citation analysis

This work contributes to the existing research on the application of blockchain technology in the agri-food industries by providing a comprehensive bibliometric analysis of previous papers on the topic. The study provides insights into the current status of the topic, prominent publications, authors, journals, and organisations in the agri-food industries. The study's findings could guide future research on the topic and offer policymakers and industry stakeholders' better knowledge of the application of blockchain technology in the agri-food sector.

The subsequent sections of this paper are organised in the following manner: Section II provides a comprehensive evaluation of blockchain technology and its possible applications in the agri-food industry. Section III discusses the methodology and data collection for the study. The findings from our bibliometric analysis, which encompass publication output, citation impact, research themes, and collaboration patterns, are outlined in Section IV. Section V of our report explores into our study findings and their connection to the previously indicated research questions. Section VI serves as the concluding part of this article, containing its final remarks and findings.

II. Related Work

In recent years, blockchain technology has received a lot of interest as a potential solution for improving transparency, traceability, and efficiency in agri-food supply chains. Blockchain improves traceability by allowing consumers to trace their food products from farm to table. The transparency alleviates concerns about food safety and authenticity [24]. Several studies have been conducted to address blockchain challenges and limitations such as scalability, data privacy, data accuracy, security, lack of regulations and adoption [25], [26], [27], [28], [29], [30]. However, additional research is required to explore the potential of blockchain technology in agri-food supply chains and to develop effective frameworks and models for its implementation. For instance, [31], [32] introduced a food safety supply chain traceability system that relies on HACCP (Hazard Analysis Critical Control Point), blockchain, and the Internet of Things. In addition, he commented on the benefits and limitations of RFID and blockchain. The suggested traceability system in the study successfully implemented automated data collection and storage to enhance information transparency and improve food

safety. [33] [34] suggested a traceability system that utilizes blockchain technology and Internet of Things devices for gathering data. The study in [35] examined the utilization of blockchain technology in the food supply chain and evaluated particular cases of traceability within the existing food supply chain. The study in [19] conducted an analysis on the traceability of soybean supply chain, specifically focusing on the use of a smart contract to guarantee the safety, credibility, and security of information.

Previous research has examined the attributes and capabilities of blockchain technology in relation to food traceability issues. These studies have also emphasized the advantages and challenges associated with the deployment of traceability systems based on blockchain technology. While the prospective benefits of BCT in the agri-food sector are promising, it is essential to possess a comprehensive understanding of the present state of research. This can be achieved by doing a bibliometric analysis of the literature.

III. Methodology

A. Database Selection

The Scopus database was employed to conduct the analysis of the documents that were acquired for this bibliometric investigation. Scopus, the preeminent academic database, comprises an extensive collection of citations spanning 240 disciplines, including over 28,000 active titles, 7000 publishers, 93 million documents, 17.6 million author profiles, 234,000 volumes, and over 94,800 institutional profiles. The reason for selecting this database is its ability to offer an all-encompassing depiction of the scientific research output worldwide. The study in [36] found that WoS covers 54% of Scopus publications, while Scopus includes 84% of WoS titles. Scopus offers smart tools for tracking, analyzing, and visualizing research, ensuring critical analysis from around the world is not missed. At present, the Scopus database is considered by the international scientific community to be one of the most important sources of pertinent data [37]. Consequently, Scopus is recommended as a valuable database for extracting materials pertinent to the subject matter investigated in this study.

B. Inclusion Criteria

During the procedure of data collection, we employed a keyword to determine the relevant documents. The phrases ("food" or "agri-food," or "agro-food") and ("blockchain" or "block-chain") were utilized to search the Scopus database for information contained in article titles and abstracts. The search was conducted on December 5, 2023, resulting in the discovery of a total of 1053 documents. The documents went through additional screening to exclude unrelated subject areas such as business, management and accounting, mathematics, social sciences, environmental science, and energy. The focus was narrowed down to only computer science and engineering, resulting in a total of 1047 documents retrieved by Scopus. Furthermore, the review of publications was conducted using the standardized methodology of the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) statement. The steps of this technique are illustrated in a flow chart (see Fig. 1). Therefore, this article ensures compliance by following the precise procedures outlined in the PRISMA protocol (Petersen et al., 2008).

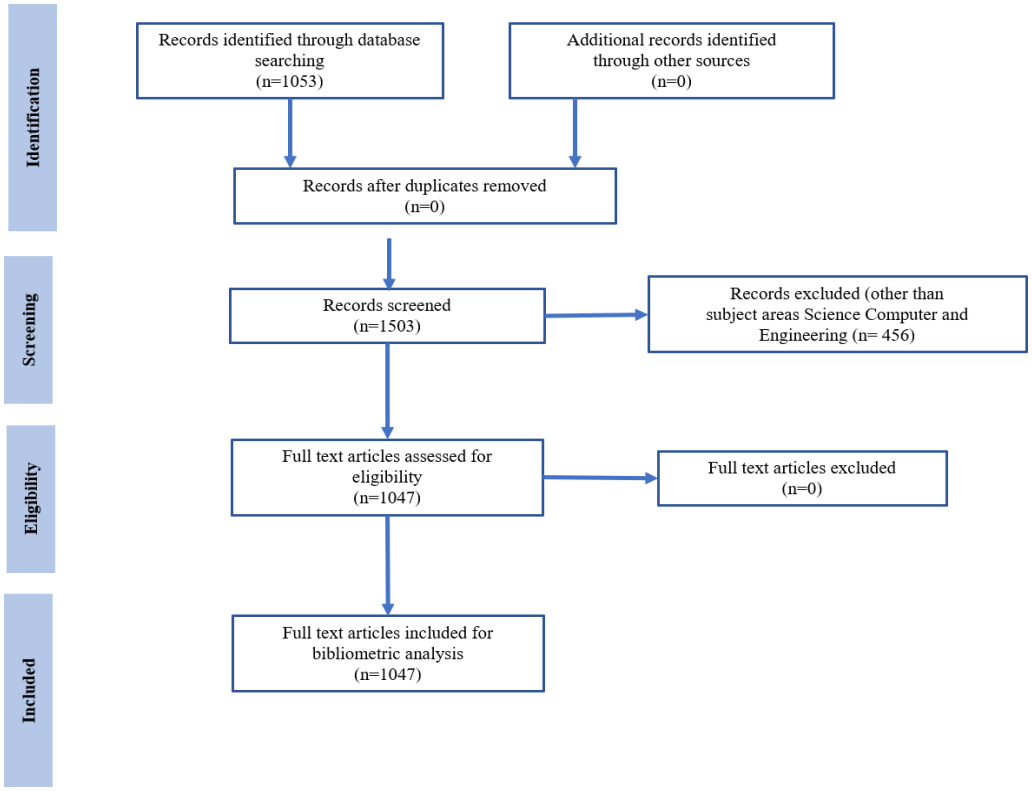

Fig. 1. PRISMA flowchart.

C. Data Analysis and Tools

Fig. 2 depicts the research framework to acquire the ultimate results. Bibliometric analysis is frequently used due to its capacity to provide dependable quantification and evaluation of the publications that are indexed in the database being studied [39]. This research additionally adds by utilizing the bibliometric technique to enhance academics' comprehension of the literature regarding the implementation of blockchain technology in the agri-food sector. Hence, bibliometric analyses remain a vital tool for identifying gaps in any given subject or field [40]. A total of 1047 documents as resulted in data collection phases were downloaded in CSV Excel and RIS format for the analysis process. The metadata in the CSV Excel and RIS file were analyzed using VOSviewer software to identify the primary research areas and generate several visual representations and tables.

Microsoft Excel was utilized for frequency analysis, while VOSviewer was employed for data visualization. Harzing's Publish or Perish was utilized for citation metrics and analysis. The data were analysed according to the geographical location of the research, the number of publications per year, the presence of highly cited works, and the journals that had the greatest number of relevant papers. This study investigates the application of blockchain in agri-food supply chain research using the abstract and title keywords fields and covering all languages in the Scopus database.

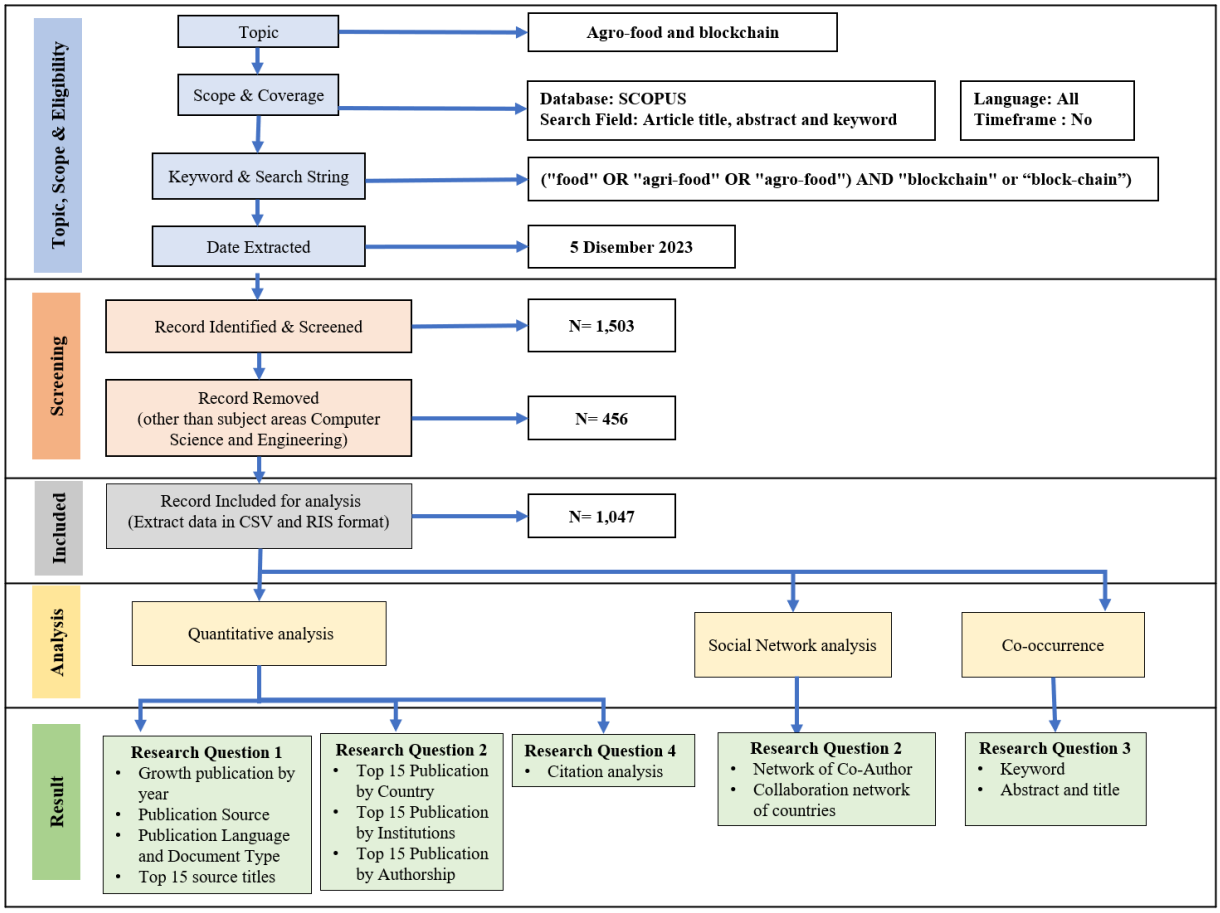

Fig. 2. Research framework.

IV. Analysis Results

A. Development and Progress of the Agri-Food and Blockchain Research

To address the first research question, we examined the progress and dissemination of Agri-food and blockchain research based on the following factors: (a) the annual count of published studies; (b) the sources and types of documents; (c) the languages in which the documents were written; and (d) the titles of the sources.

1) The annual count of published studies: Table 1 shows annual growth of publication by year for agri-food and blockchain, along with various metrics such as total publications (TP), percentage of total publications (%), number of total publications (NCP), total citations (TC), average citations per publications (C/P), average citations per cited publication(C/CP), h-index and g-index.

The number of publications has increased from 1 in 2016 to 278 in 2022, with an increasing trend in average citations per publication (C/P) and C/CP. The h-index and g-index provide insights into the author's impact, with the h-index increasing from 5 in 2017 to 32 in 2021 and the g-index reaching 55 in 2021. However, in 2023, there will be a slight decline in total publications because the year has not yet been

completed. Additionally, as depicted in Fig. 3, the number of citations for documents published in 2020 appeared to have peaked at 6,667, with an average of 46.62 citations per publication. However, beginning in 2021, the number of citations began to decline. The increase in total citations in 2020 may be attributed to the COVID-19 pandemic, which has emphasized the criticality of food traceability in guaranteeing food safety. Conversely, papers that were published in 2016 received the fewest citations (one citation per publication out of a total of 74 citations). The low number of citations is presumably related to the nascent stage of blockchain implementation in the agri-food sector. From 2016 to 2020, however, the overall quantity of citations increased dramatically. Total publications are on the rise, as depicted in Fig. 3, whereas total citations are declining after 2020. The sources for blockchain in agri-food research, document categories, most active source titles, and the language of documents utilized in blockchain in agri-food publications are further explored subsequently to the identification of the annual growth document.

2) The sources and types of documents: An investigation was conducted to determine the publication areas of agri-food and blockchain documents through an analysis of the data grouped by document source categories. There are five primary sources—journals, conference proceedings, books, book series, and trade journals. Journals constituted the most prevalent source, comprising 414 (or 39.54%) of the total, followed by publications for conference proceedings (n = 379, 36.20%), as shown in Fig. 4. Book series, comprising 16.91%, offer comprehensive perspectives on specific themes. Individual books, accounting for 6.49%, provide in-depth exploration and authoritative references. Trade journals, a smaller but specialized portion, make up 0.86% of the total publications.

Document type analysis was also performed on the data. As summarized in Fig. 5, the Scopus search yielded ten distinct categories of documents that were published on the agri-food and blockchain. The majority of publications (n = 442, 42.22%) are categorized as Conference papers, as indicated in the table followed by Article (n = 360, 34.38%). However, book chapter, Conference review and review articles category comprised less than 10% of the total publications. Less than 1% of the total publications were comprised of the remaining document categories, including books, editorials, notes, erratum, and short survey.

3) Languages of documents: In total, research papers for agri-food and traceability were composed in five languages. English was the most extensively utilized language, accounting for 98.09% of all publications, as shown in Fig. 6. Chinese was the second most prevalent language, comprising 1.62% of the total. Most of the remaining documents (less than 0.5%) were published in German, Polish, and Spanish. In conclusion, only three documents were published in a single language: German, Polish, and Spanish. This represents the tiniest fraction of the overall document count, amounting to 0.30%.

TABLE I. GROWTH OF PUBLICATION BY YEAR

Year	TP	%	NCP	TC	C/P	C/CP	h	g
2024	6	0.57%	0	0	0.00	0.00	0	0
2023	263	25.12%	91	558	2.12	6.13	11	26
2022	278	26.55%	182	2066	7.43	11.35	24	37
2021	218	20.82%	167	3575	16.40	21.41	32	55
2020	143	13.66%	117	6667	46.62	56.98	34	80
2019	97	9.26%	85	4001	41.25	47.07	32	62
2018	35	3.34%	26	1642	46.91	63.15	15	26
2017	6	0.57%	6	522	87.00	87.00	5	6
2016	1	0.10%	1	74	74.00	74.00	1	1

Notes: TP = total number of publications; NCP = number of cited publications; TC = total citations; C/P =average citations per publication; C/CP = average citations per cited publication; h = h-index; g = g-index

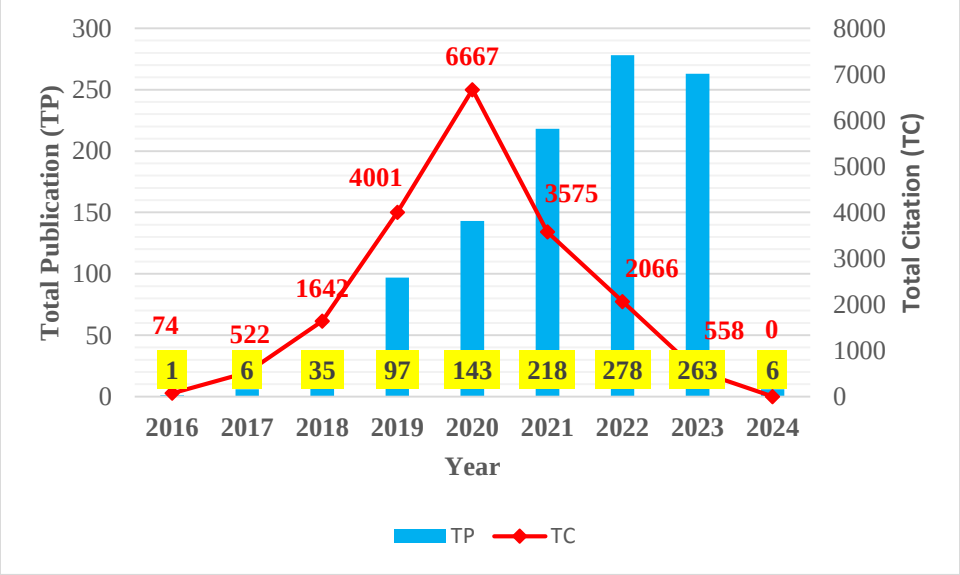

Fig. 3. Total publications and citations by year.

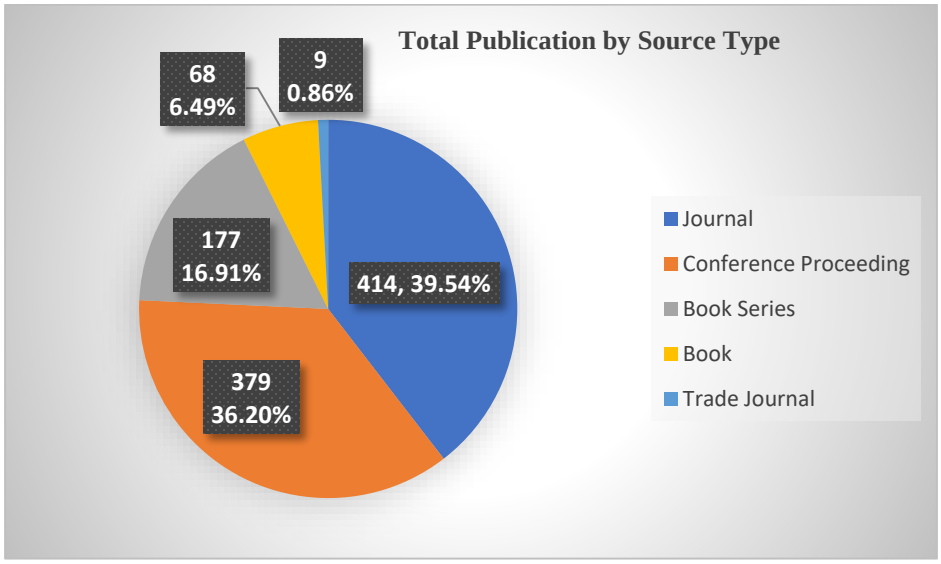

Fig. 4. Total publications based on source type.

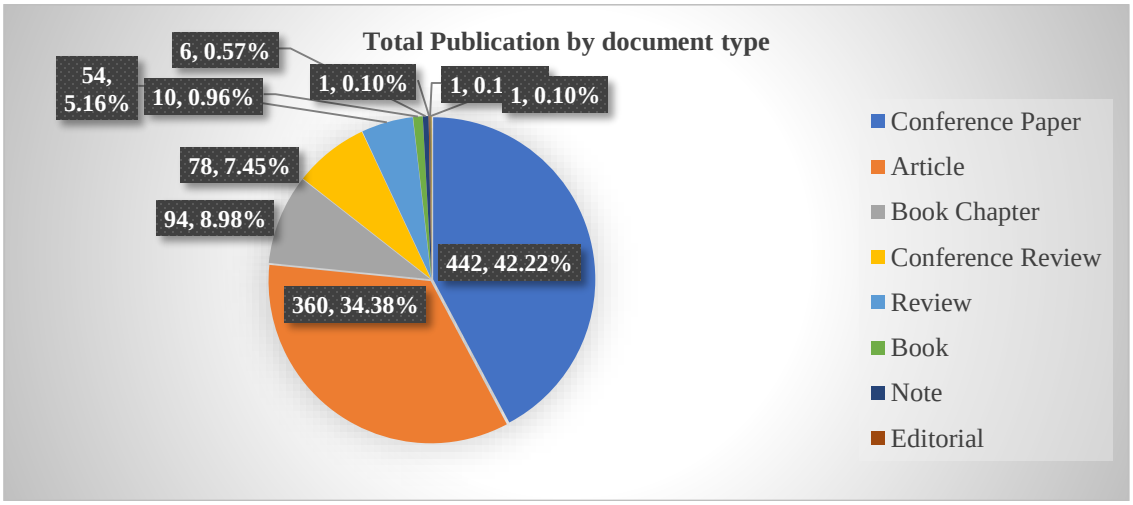

Fig. 5. Total Publication based on document type.

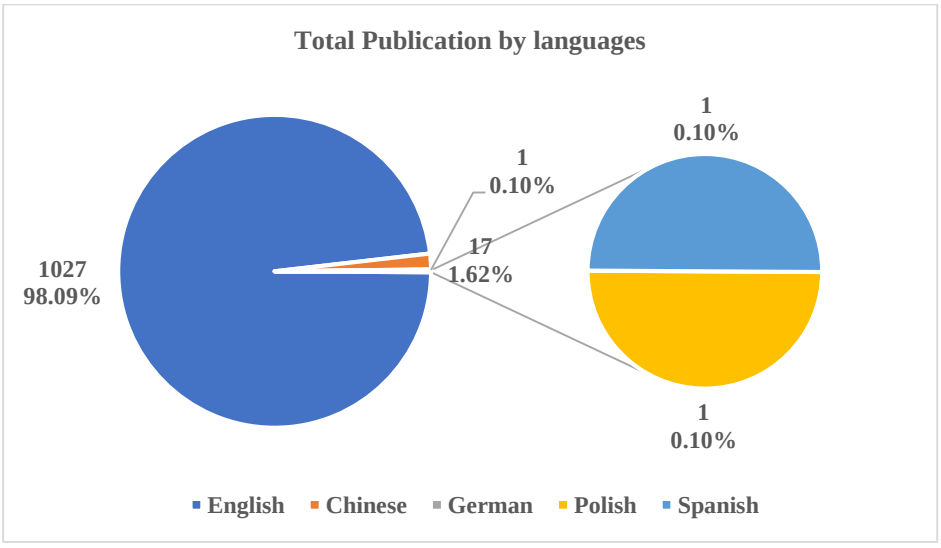

Fig. 6. Total publication based on languages.

4) Publication by source title: After identifying the current trends in sources, document types, and languages of agri-food blockchain research, the last criteria are to examine the source title. The results show that the journal that made the most substantial contribution to the agri-food and blockchain literature was Sustainability Switzerland (n = 42). Lecture Notes in Networks and Systems (n = 35), IEEE Access (n=34) and ACM International Conference Proceeding Series (n=32) are nearly identical indicating a significant 9.65% contribution, as reported by these result. The Lecture Notes in Computer Science Including Subseries Lecture Notes in Artificial Intelligence and Lecture Notes in Bioinformatics subsequently appeared, comprising more than 25 articles. However, the rest of publication, contribute less than 20 articles. Despite having a smaller number of publications in total, Journal of Cleaner Production exhibited the second highest citations (n = 1215), after IEEE Access (n = 2246). The top fifteen most active source titles of blockchain in agri-food based on total publication are shown in Table II and while Fig. 7 compares total publication versus total citations.

TABLE II. TOP 15 SOURCE TITLE

Source Title	TP	%	Publisher	Cite Score 2022	SJR 2022	SNIP 2022	NCP	TC	C/P	C/CP	h	g
Sustainability Switzerland	42	4.01%	MDPI	5.8	0.664	1.198	38	803	19.12	21.13	14	27

Notes: TP = total number of publications; TC = total citations; CiteScore = average citations received per document published in the source title; SJR = SCImago Journal Rank measures weighted citations received by the source title; SNIP = source normalised impact per paper measures actual citations received relative to citations expected for the source title's subject field;

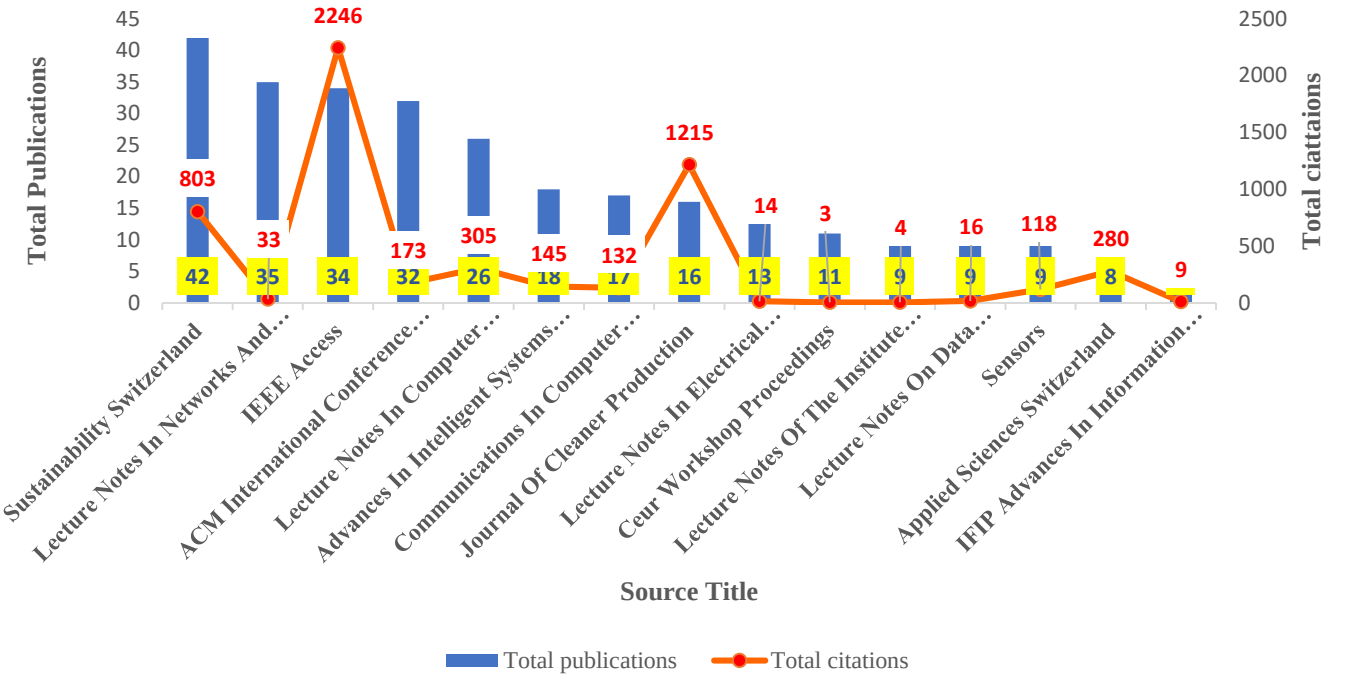

Fig. 7. Top 15 source title based total publications and total citations.

B. *Most Influential Countries, Institutions and Authors on Agri-Food and Blockchain*

This part concentrates on addressing the second research question, which aims to assess the level of scientific collaboration in the fields of agri-food and blockchain. This assessment is conducted through four main analyses: (a) publications categorized by country, (b) identification of the most active institutions involved in agri-food and blockchain research, and (c) analysis of authorship patterns.

1) Publications by countries: The published indicators for the top 15 countries in terms of agri-food and traceability research are summarized in Fig. 8 and Table III. With 293 documents, India has the highest number of scientific publications, followed by China (n = 163), Italy (n = 82), the United States (n = 79), the United Kingdom (n = 71), and Australia (n=42).

TABLE III. TOP 15 PUBLICATION BY COUNTRY

Country	TP	%	NCP	TC	C/P	C/CP	h	g	Continent
India	293	27.98%	187	4342	14.82	23.22	29	62	Asia
China	163	15.57%	112	3355	20.58	29.96	32	55	Asia
Italy	82	7.83%	61	2181	26.60	35.75	20	46	Europe
United States	79	7.55%	65	3827	48.44	58.88	25	61	North America
United Kingdom	71	6.78%	56	3052	42.99	54.50	23	55	Europe
Australia	42	4.01%	31	728	17.33	23.48	13	26	Oceania
Pakistan	29	2.77%	25	744	25.66	29.76	13	25	Asia
Saudi Arabia	29	2.77%	24	669	23.07	27.88	11	24	Asia
Turkey	29	2.77%	24	560	19.31	23.33	12	23	Europe
Malaysia	27	2.58%	20	284	10.52	14.20	7	16	Asia
Germany	24	2.29%	16	200	8.33	12.50	8	14	Europe
South Korea	24	2.29%	20	615	25.63	30.75	13	20	Asia
Spain	21	2.01%	17	475	22.62	27.94	11	17	Europe
Canada	19	1.81%	16	746	39.26	46.63	9	16	North America
France	19	1.81%	16	664	34.95	41.50	11	16	Europe

Notes: TP = total number of publications; NCP = number of cited publications; TC = total citations; C/P =average citations per publication; C/CP = average citations per cited publication; h = h-index; g = g-index

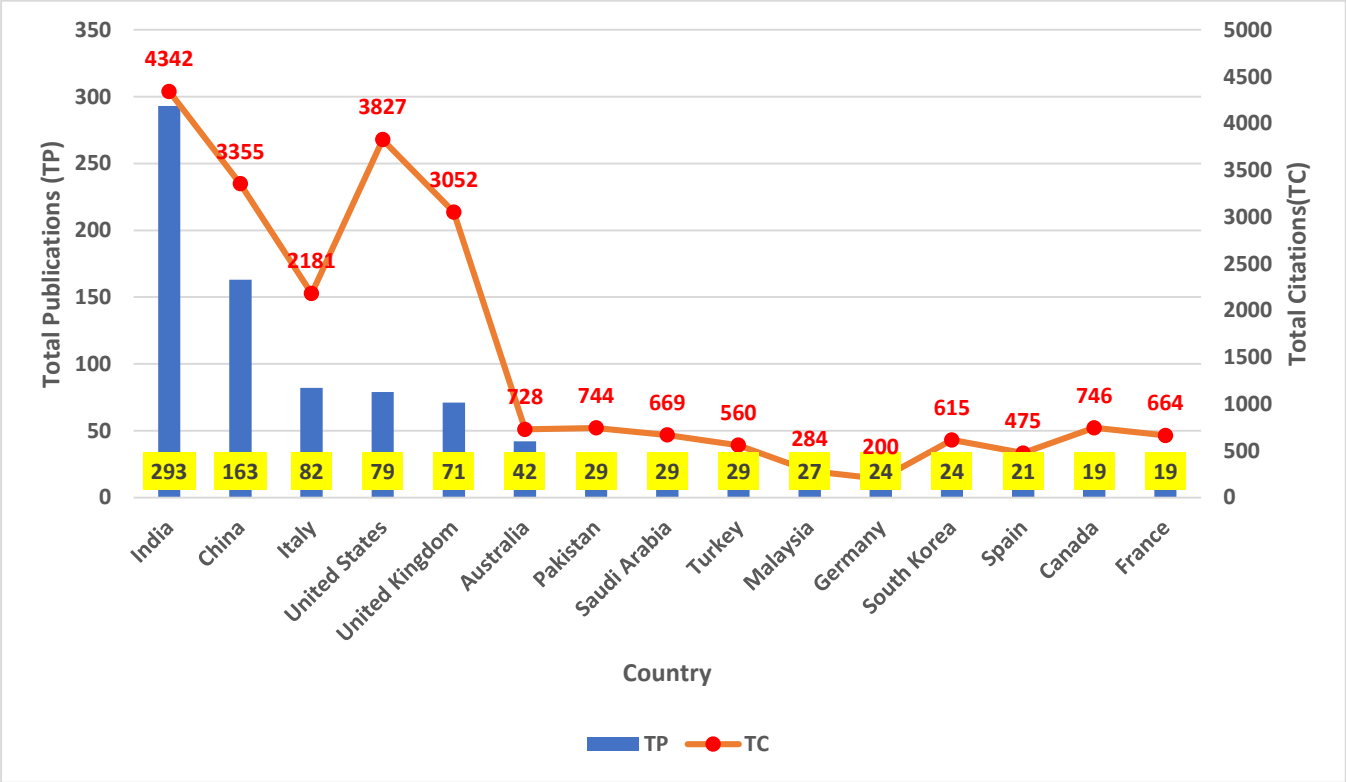

Fig. 8. Top 15 publication by country.

The national associations of the remaining authors, which included Pakistan, Saudi Arabia, Turkey, Malaysia, Germany, South Korea, and Spain, accounted for fewer than 30 articles dispersed across the globe. The countries with the fewest contributors are Canada and France, with 1.81% of total publications. It appears that agri-food and blockchain are of the utmost importance in Asia, Europe, North America, and Oceania. In terms of citation counts, Fig. 8 shows India maintains its position as the leader of all countries, showing a significant influence on the output of research with the highest total citations. With 3827 citations, the United States demonstrates its dominance in North America and has taken second place, beating China with 3355 citations. The significance of the United Kingdom in research activities is evident in the 3052 citations compared to other countries in Europe, including Italy, Germany, Turkey, Spain, and France. Despite having relatively few publications, Australia has made significant contributions to the global research community in terms of citations (n =728). The total citation metrics offer valuable insights regarding the recognition and influence of research output in each respective country.

2) The most active institutions: Table IV depicts prominent institutions in the field of agri-food and blockchain research, including the SRM Institute of Science and Technology, Beijing Technology and Business University, Queensland University of Technology, Università degli Studi di Cagliari, and Presidency University Bangalore. The SRM Institute of Science and Technology in India is the leading institution in terms of total publications, with a total of 20 publications, which is the highest count. This signifies substantial research output by the institution. Beijing Technology and Business University Beijing Institute of Technology, both based in China, have made significant contributions to agri-food and blockchain research. Beijing Technology and Business University ranks second with 11 publications, while Beijing Institute of Technology ranks sixth with 8 publications. However, the National Institute of Industrial Engineering has a significant C/CP of 163.88, indicating a strong influence with the highest citation. The second rank for citation is the Hong Kong Polytechnic University, followed by the Università degli Studi di Cagliari, the Wageningen University and Research, and the Università della Calabria.In contrast, SRM Institute of Science and Technology has a notable average C/CP of 3.50. Most of the institutions that were evaluated are located in India, with SRM Institute of Science and Technology, Presidency University Bangalore, National Institute of Industrial Engineering, Lovely Professional University, University of Petroleum and Energy Studies, and Vellore Institute of Technology being notable contributors. This highlights the significance of India's leadership in agricultural and blockchain-based research. In addition, the result demonstrates a worldwide distribution of institutions, encompassing China, India, Italy, Australia, Viet Nam, the Netherlands, and the United Kingdom. This diversity shows the global extent of the research field.

TABLE IV. THE MOST ACTIVE INSTITUTIONS

Institution	TP	%	Country	NCP	TC	C/P	C/CP	h	g
SRM Institute of Science and Technology	20	1.91%	India	8	28	1.40	3.50	3	5
Beijing Technology and Business University	11	1.05%	China	7	226	20.55	32.29	5	7
Queensland University of Technology	9	0.86%	Australia	8	179	19.89	22.38	5	8
Università degli Studi di Cagliari	9	0.86%	Italy	9	465	51.67	51.67	8	9
Presidency University Bangalore	9	0.86%	India	4	53	5.89	13.25	4	4
Beijing Institute of Technology	8	0.76%	China	8	107	13.38	13.38	4	8
Università della Calabria	8	0.76%	Italy	7	296	37.00	42.29	5	7
National Institute of Industrial Engineering	8	0.76%	India	8	1311	163.88	163.88	7	8
Lovely Professional University	8	0.76%	India	6	186	23.25	31.00	4	6
University of Petroleum and Energy Studies	8	0.76%	India	6	46	5.75	7.67	4	6
The Hong Kong Polytechnic University	7	0.67%	China	6	975	139.29	162.50	5	6
Vellore Institute of Technology	7	0.67%	India	6	63	9.00	10.50	3	6
RMIT University	7	0.67%	Viet Nam	2	5	0.71	2.50	2	2
Wageningen University & Research	6	0.57%	Netherlands	5	365	60.83	73.00	4	5
Cranfield University	6	0.57%	United Kingdom	5	126	21.00	25.20	5	5

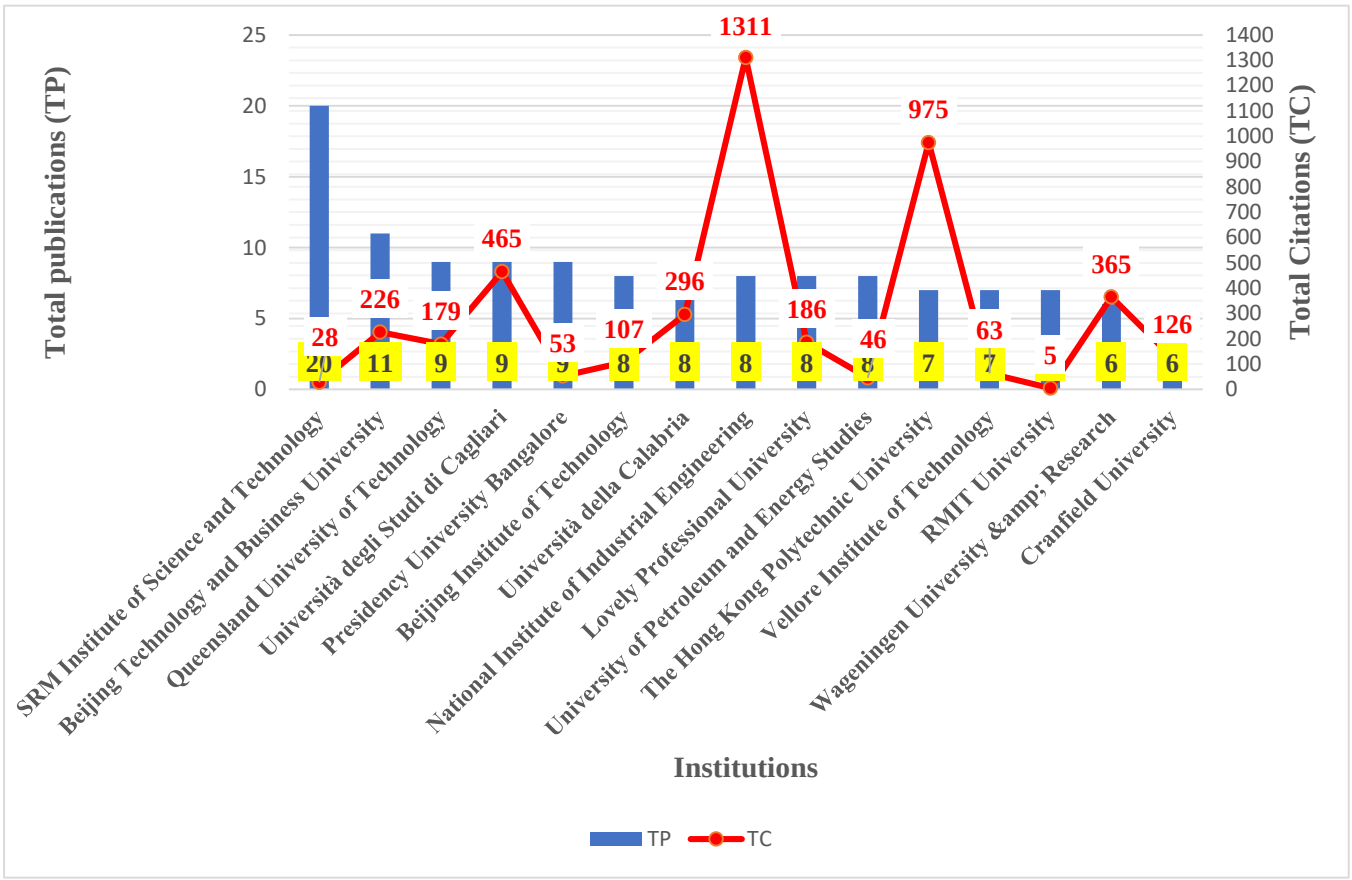

Fig. 9. The most active institution based on publication versus citation.

3) Authorship analysis: The analysis in Table V presents the total number of publications (TP) by different authors, highlighting their contributions to academic research. Xu. J and Zhang X are prominent contributors, each having seven publications. The authors Xu, J. and Zhang, X. from Beijing Technology and Business University in China have a collaborative impact (C/CP) of 26.50, which means that their articles are referenced an average of 26.50 times. This indicates a substantial impact and acknowledgment of their combined academic efforts, highlighting the importance of collaborative research at the university. Marchesi, M., Mirabelli, G., Solina, V., and Tonelli, R. from Italy have achieved impressive average citations per publication (C/P) scores of 61.20, 51.40, 51.40, and 35.20, respectively. This highlights the significant research output produced by Italian affiliations. Table VI illustrates a wide-ranging geographical

influence, featuring authors originating from Australia, India, Italy, and China. Authors from various affiliations and nations exhibit a worldwide presence in research. Calculating the average number of citations per publication and per cited article offers valuable insights into the influence of an author's work. The h-index and g-index offer a comprehensive perspective on the academic impact of an author. This study used the VOSviewer software to conduct co-author analysis, enabling a thorough examination of authors' collaboration and generating a network visualization (see Fig. 10). The analysis relies on the premise that significant writers have been referenced at least once in five publications related to agri-food and blockchain. The calculation is performed using the fractional counting technique. Distinct attributes, such as color, size of circles, font size, and line width, enhance the intensity of the authors' association. Authors who are associated with one another are often listed one after the other, as seen by the use of the same color. The Fig. 10 indicates that the prominent authors Xu J. and Zhang X collaborated closely with other authors, including Li H., Zhao Z., and Xu J. Based on the result, it seems that Cao S and Foth M, both from Australia, have had a similarly effective collaboration with colleagues from China.

Fig. 11 presents a network visualization map of the author's associated country. The analysis only includes nations that have cited more than five articles and more than 1 citation. According to the fractional counting method, the results suggest that India has a substantial impact on international collaboration. India maintains strong diplomatic ties with Ukraine and South Korea, while China has established connections with Hong Kong and Serbia.

Next section will highlight the third research question highlighted the most prevalent themes of agri-food and blockchain between scholars.

C. The Most Prevalent Themes of Agri-Food and Blockchain between Scholars

The fundamental objective of the third research question is to discover the predominant themes of blockchain in agri-food research among experts. This step involved analysing the important areas of the research based on (a) the frequency of keywords and (b) the titles and abstracts of the documents.

1) Keywords analysis: The careful selection of suitable keywords is crucial in finding the availability of a document during a search. Therefore, the regular selection of suitable keywords may serve as an indicator of the quality of the writing. A network visualization of the author's keywords, each of which appeared a minimum of three occurrences, is illustrated in Fig. 12. A co-occurrence of two keywords within the same article suggests that there is a connection between the two subjects [37]. In order to answer the third research questions, we utilized the keyword and co-occurrence analysis from VOSviewer. In order to map the keywords allocated to each article, the author's analyzed keywords utilizing VOSviewer, a software application designed for generating and visualizing bibliometric networks (see Fig. 12).

TABLE V. AUTHORSHIP ANALYSIS TOP 15

Author Name	TP	%	Affiliation	Country	NCP	TC	C/P	C/CP	h	g

TABLE VI. TOP 20 KEYWORDS

Keywords	Total Publications	%
Blockchain	787	75.17%
Block-chain	401	38.30%
Supply Chains	353	33.72%
Food Supply	331	31.61%
Internet Of Things	194	18.53%
Food Supply Chain	171	16.33%
Supply Chain Management	169	16.14%
Traceability	169	16.14%
Smart Contract	150	14.33%
Food Safety	138	13.18%
Supply Chain	138	13.18%
Agriculture	117	11.17%
Blockchain Technology	87	8.31%
Digital Storage	87	8.31%
Distributed Ledger	87	8.31%
Traceability Systems	85	8.12%
Transparency	81	7.74%
IoT	71	6.78%
Food-safety	68	6.49%
Food Traceability	65	6.21%

The relationships between other keywords are represented by the thickness, colour, circle size, and font size of connecting lines [41]. Frequently categorized keywords in the same colour are frequently bundled together. The analysis revealed seventeen clusters containing 184 items based on the author's keyword. The diagram suggests that blockchain, blockchains, consensus, consortium blockchain, distributed ledgers, food chain, Hyperledger, Hyperledger fabric, permissioned blockchain, private blockchain supply chain management and supply chain traceability have similar colours, indicating that these keywords were closely related and usually occurred together. The search query included the following primary keywords: Blockchain, Block-chain, Supply Chains, Food Supply, Internet of Things, Food Supply Chain, Supply Chain Management, Traceability, Smart Contract, Food Safety, Supply Chain and Agriculture. These terms appear more than 10% of the time in the results. Table VI lists the twenty most common keywords used in agri-food and blockchain research.

2) Title and abstract analysis: In this section of the study, VOSviewer was employed to examine the titles and abstracts of collected documents for occurrences and the frequency of co-occurrences per document. Specifically, this study builds the co-occurrence network by employing the binary counting method. Fig. 13 depicts a graphical illustration of a network that shows the occurrence of terms based on their presence in the title and abstract fields. The network includes terms that appear at least 15 times. The width of the node represents the weight of the item, while the thickness of the connecting line indicates the intensity of the link between items. When words that are connected in meaning are displayed in the same colour, there is a higher probability that they will occur together [37]. The terms safety, product, smart contract, transaction, storage, consumer, and food product, indicated in red, are interconnected and commonly coexist in the diagram. VOSviewer generates four separate colours based on the title and abstract of the publication, representing four clusters that consist of 246 terms.

Fig. 14 illustrates the arrangement of a title-based phrase co-occurrence network. A binary counting technique was employed, ensuring a minimum of ten occurrences for each phrase. The data suggests that the VOSviewer software creates four distinct clusters and a total of 27 items. Within the domain of agri-food and blockchain research, the term 'blockchain technology' gained the central position as the core node of the entire network. Cluster 1 contains the concepts of agri-food supply chain, block chain, blockchain application, food safety, food supply chain management, healthcare, impact, smart contract, and survey, whereas Cluster 2 consists of block chain technology, blockchain technology, case study, covid, design, food, implementation, and traceability system. Furthermore, Cluster 3 has artificial intelligence, food industry, food traceability, and smart agriculture and thing, whereas the last cluster, Cluster 4, only has internet, opportunity, and thing.

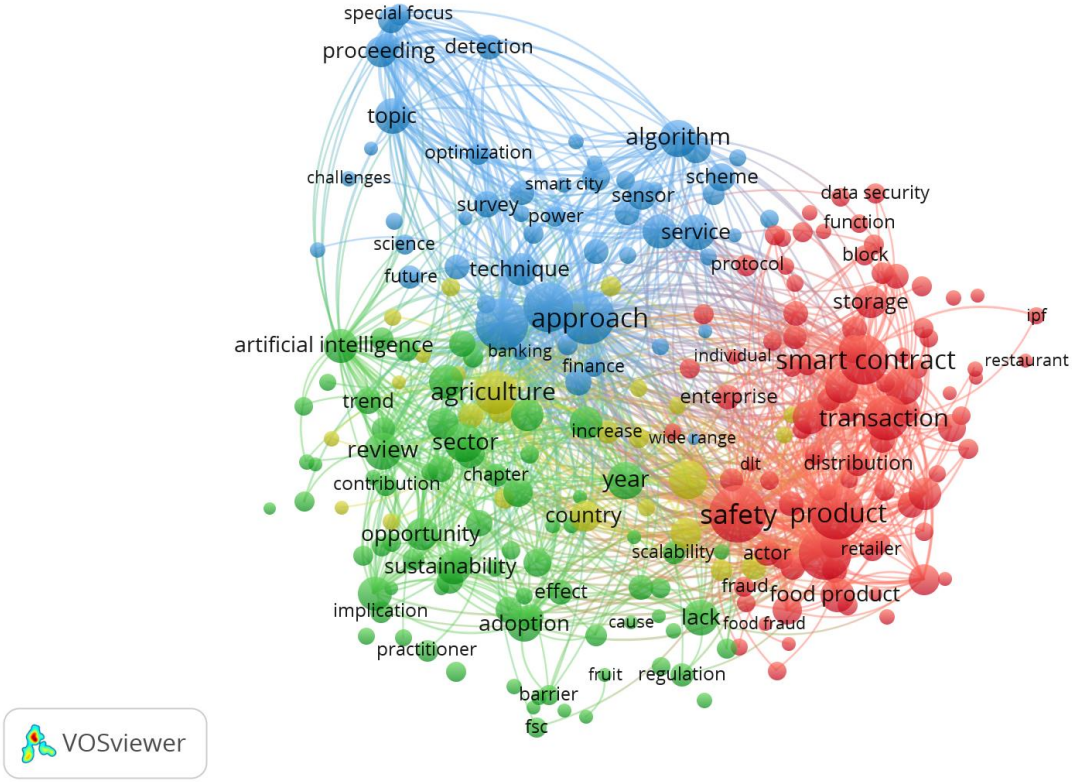

Fig. 13. VOSviewer visualisation of a term co-occurrence network based on title and abstract.

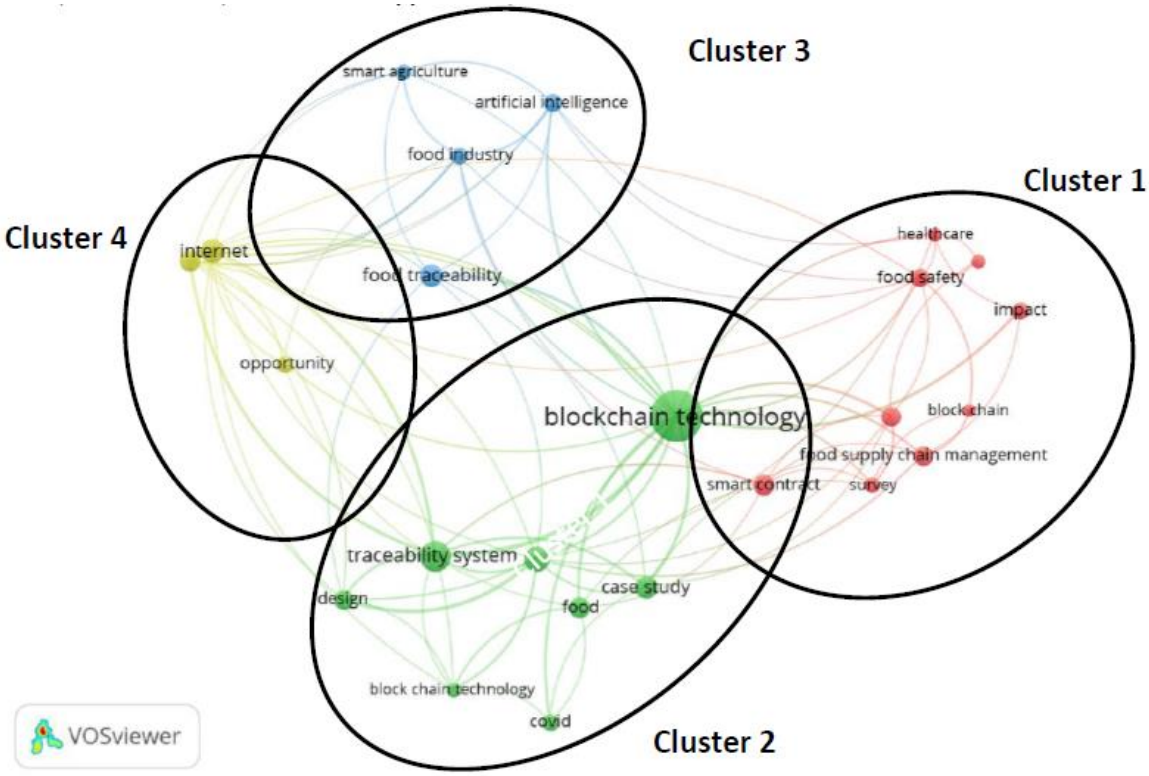

Fig. 14. VOSviewer visualisation of a term co-occurrence network based on title fields.

D. The Most Influential Articles on Agri-Food and Blockchain

This section examines the fourth research question, which is to discover the most influential articles on agri-food and blockchain through citation analysis.

1) Citation analysis: Table VII represents a compilation of research citations on agri-food and blockchain from the Scopus database. Over a span of nine years (2016–2024), a total of 19,105 citations were documented for 1,047 published papers. This corresponds to an average of 2,729.29 citations per year. Table VIII summarized the top 20 articles on blockchain in agri-food research, based on the frequency of citations for each document. The research article titled "Blockchain-based traceability in agri-food supply chain management: A practical implementation," published in 2018 by M.P. Caro, M.S. Ali, M. Vecchio, and R. Giaffreda, has received the highest number of citations, with a total of 507. This article was presented at the 2018 IoT Vertical and Topical Summit on Agriculture in Tuscany, IOT Tuscany 2018. The second and third publications, published in 2021 and 2020, respectively, are research articles on blockchain technology in the supply chain. They were written by M. Kouhizadeh, S. Saberi, and J. Sarkis and have a total of 497 citations. The other publication, written by P. Dutta, T.-M. Choi, S. Somani, and R. Butala, has a total of 494 citations.

TABLE VII. CITATION METRICS

Metrics	Data
Papers	1047
Citations	19105
Years	9
Cites_Year	2729.29
Cites_Paper	18.25
Authors_Paper	3.52
h_index	63
g_index	120

V. DISCUSSIONS

In this section, we shall discuss the findings of our biblimetric review to address the research questions outlined below.

A. RQ1. What is the Current Trend and Impact of Publication in Agri-Food and Blockchain?

Sugandh, Nigam, Misra and Khari conducted the current bibliometric analysis of the literature's influence on agri-food and blockchain research [42]. They used literature search tools to examine the years 2014 through 2022, as retrieved from ACM, IEEE Xplore, PubMed, the Web of Science, and Scopus. According to the study, publications on this topic began in 2018 and continued to increase from that point forward. However, without time constraints in search criteria, our study found that the first paper on agri-food and blockchain research was published in 2016 and has kept increasing until now. In 2017, the average number of citations per publication peaked at 87.00, demonstrating that publications have a substantial impact. This indicates a rise in research activities or a concentration on sharing research results. Additional inquiry may uncover patterns or advancements. In term of citation pattern, it demonstrates the increasing as well with domination in 2020

Agri-food blockchain research relies heavily on journals, which constitute 39.54% of all published works in this field. Scholarly journals are esteemed for their meticulous peer review procedure and reputation for reliability. Conference proceedings, comprising 36.20% of the total, also function as a medium for disseminating progress in the area. Nevertheless, the agri-food blockchain research environment shows a lower prevalence of book series, books, and trade journals, indicating the importance of real-time discussions and exchange of ideas. Conference papers are the primary focus of agri-food and blockchain research, making for 42.22% of all papers published. These papers serve as a medium for scholars to share and encourage cutting-edge developments while facilitating direct discussions. Articles make a substantial contribution, representing 34.38% of the overall publications. The presence of many document formats, such as book chapters, conference reviews, and reviews, indicates a comprehensive approach for sharing knowledge. Nevertheless, when compared to conference papers and articles, book publishing, notes, editorials, errata, and short surveys have a comparatively insignificant impact.

English is the predominant language used in scholarly papers related to the agri-food and blockchain fields, representing 98.09% of all articles. This demonstrates the worldwide significance of English as the predominant language for academic discourse. The inclusion of Chinese, German, Polish, and Spanish languages, while in smaller proportions, highlights the diversity of participants and readers in this field. Researchers and policymakers should recognize the linguistic variety present in scholarly publications, as acknowledging and studying literature in different languages can offer complementary perspective and understandings.

The publication titled "Sustainability Switzerland" from MDPI is the most active source in the topic, with 42 publications and a high Cite Score of 5.8. The journal "Lecture Notes in Networks and Systems" published by Springer Nature has a notable Cite Score and SJR of 0.151. Springer Nature takes several positions inside the top 20, demonstrating its strong presence. Meanwhile, MDPI highlights the influence of open-access publishing. IEEE Access has a substantial overall citation count; however, Journal of Cleaner Production has an impressive CiteScore of 18.5 and SNIP of 2.379. Despite being discontinued in Scopus, Advances in Intelligent Systems and Computing continues to have influence. The inclusion of other source types, such as Ceur Workshop Proceedings, Sensors, Applied Sciences Switzerland, enriches the field.

Given the consistent growth in the number of publications since 2018, it is evident that research on the implementation of blockchain technology in agriculture is currently a popular and rapidly increasing field. Indeed, there has been a steady increase in the quantity of publications until now.

B. RQ2. Which are the Most Productive and Influential Countries, Institutions and Authors on Agri-Food and Blockchain?

According to Sugandh, Nigam, Misra and Khari, China has become the leader in agri-food and blockchain research [42]. However, our findings show that India has become the top contributor to publications, with India accounting for 293 articles compared to China, which accounts for 163 articles. Despite having a smaller number of publications compared to India and China, The United States has a notable citation effect, with a C/CP value of 48.44, suggesting a significant amount of influence. Italy, the United Kingdom, Germany, Spain, and France, among other European countries, provide substantial contributions, demonstrating a strong research environment.

The substantial number of publications in India is indicative of a flourishing research environment, which is supported by increased funding, collaboration, and the exploration of diverse research fields. This phenomenon offers prospects for global cooperation and the exchange of insights between Indian scholars and researchers. The cumulative representation of Asian countries (India, China, Pakistan, Saudi Arabia, Malaysia, South Korea) in publications highlights the growing impact of the region in multidisciplinary research.

The National Institute of Industrial Engineering in India, along with other esteemed institutions such as SRM Institute of Science and Technology, Presidency University Bangalore, and Lovely Professional University, has a substantial influence on the academic community. The institute's 8 publications and average citation of 163.88 demonstrate a substantial influence on research quality and visibility. This can be linked to the organization's emphasis on research areas that have a significant impact and the implementation of effective mechanisms for collaboration. These findings also indicate that India are leading in this topic nowadays. Additionally, both Beijing Technology and Business University and Beijing Institute of Technology demonstrate a significant average number of citations per article, suggesting a noteworthy influence in their respective areas of research. Table IV and Fig. table

9 presents a comprehensive overview of the worldwide distribution of active contributors to scholarly production, emphasizing the global nature of research collaboration and the significant role played by different countries in shaping the academic landscape. This analysis highlights the importance of institutions in India and China, suggesting these regions as key areas of focus for scholars interested in this topic. There are opportunities for cross-continental collaboration and knowledge sharing, which promotes a global research environment.

The research community is mostly influenced by two authors who possess identical publication records, suggesting potential constraints in collaboration. The analysis includes authors from varied locations like China, Australia, India, and Italy, exhibiting global collaboration in the field of study. The presence of many perspectives enhances the research environment and facilitates a more comprehensive comprehension of the topic. Italian authors, such as Marchesi, Mirabelli, Solina, and Tonelli, have a significant influence on the academic community, as seen by their high average citation metrics. Promoting collaboration among different institutions and locations has the potential to enrich the research output by incorporating different perspectives.

C. RQ3. Which are the Most Prevalent Themes of Agri-Food and Blockchain between Scholars?

The term "Blockchain" and its related forms (Block-chain, Blockchain Technology, Distributed Ledger) are prominently used, highlighting the significant emphasis on blockchain in agri-food research. This highlights the crucial role of technology in influencing progress in the field. The extensive prevalence of blockchain-related terminology indicates a significant scholarly interest and recognition of the revolutionary potential of blockchain technology in agri-food systems. Researchers and practitioners are actively investigating different facets, ranging from supply chain management to traceability and smart contracts.

The presence of "Internet of Things (IoT)" in the list of prominent keywords signifies the increasing practice of combining IoT with blockchain technology in agricultural and food systems. This combination is expected to effectively resolve concerns pertaining to traceability, transparency, and real-time monitoring. The terms "Food Safety," "Traceability," and "Food Traceability" are clearly highlighted, highlighting a significant issue within the agri-food sector. This indicates a deliberate and focused attempt to improve food safety measures and establish strong traceability mechanisms.

The research highlights the combination of technology, specifically blockchain, with traditional agricultural techniques, as seen by the use of keywords such as "Agriculture".

D. RQ4. Which are the Most Influential Articles on Agri-Food and Blockchain?

The most-cited articles in the field of agri-food research contain an extensive range of perspectives and implementations of blockchain technology. Traceability, sustainability, supply chain operations, and the intersection of blockchain technology and emerging technologies such as Industry 4.0 are among the topics covered.

The substantial number of references to these articles demonstrates the importance of blockchain technology in addressing many different kinds of obstacles in the agri-food sector. Scholars and industry professionals are presently engaged in an intensive investigation of the theoretical underpinnings, barriers to adoption, and greater impact of blockchain technology on sustainability, in addition to its practical applications in supply chain traceability.

The articles on traceability, such as "Blockchain-based traceability in agri-food supply chain management" and "Modelling blockchain-enabled traceability in agriculture supply chain," highlight the industry's interest in enhancing traceability in the agri-food supply chain. They also explore the potential of blockchain technology in achieving sustainable practices in a data-driven agriculture supply chain based on articles "Blockchain technology and the sustainable supply chain" and "Achieving sustainable performance in a data-driven agriculture supply chain." The articles "From Industry 4.0 to Agriculture 4.0" and "Blockchain-inspired RFID-based information architecture for food supply chain" demonstrate the integration of blockchain with other technologies in an interdisciplinary manner.

E. Implications of Study, Limitation and Future Recommendation

This study aims to examine the current direction and pattern of research on agri-food and blockchain by assessing the publication status, citation patterns, thematic content, and providing recommendations for future research in this field. The present study offers a thorough overview of recent research on blockchain in the agri-food sector, including growing trends in publications, journal performance, collaboration patterns, and research elements. This study contributes to a better understanding of the subject matter. Every sign indicates growth in this area of study, potentially resulting in new opportunities for enhancing global food systems. Furthermore, their contributions will assist novice academics in acquiring a comprehensive outlook on this particular domain [43]. This study uses the bibliometric technique to improve academics' understanding of the literature on blockchain technology application in the agri-food sector because bibliometric analyses remain a vital tool for identifying gaps in any given subject or field [40]. Therefore, researchers might employ this methodology to carry out their investigations, particularly when performing comprehensive examinations of relevant material pertaining to their area of focus.

The results of this study will support particular researchers in comprehending the ability of blockchain, IoT, and other emerging technologies to improve traceability, sustainability, and supply chain operations in the agri-food industry. Additionally, it will provide ideas for future research. Due to its widespread adoption in the global agri-food sector, we expect the application of blockchain to remain significant in the future. It is particularly popular in Asian countries like India, China, Pakistan, Saudi Arabia, and Malaysia, where there is active production of blockchain in agri-food publications. This indicates that its popularity is increasing and its global utilisation is on the rise. Although the assessment has garnered significant interest, the authors have given comparatively less consideration to its use in domains beyond food traceability.The deployment of blockchain technology (BCT) requires further investigation to explore governance frameworks, assess the sustainability and environmental impact of BCT in agriculture, understand user adoption and acceptance, and integrate BCT with advanced technologies like the Internet of Things (IoT) and artificial intelligence (AI) [42]. These paths of research will enhance our understanding of BCT's capacity in both the food and agriculture sectors. Consequently, these areas demand greater attention from other academics and practitioners, which will facilitate the development of further research.

The study is based on a bibliometric analysis of published agri-food and blockchain research from 2016 to 2024. However, it's crucial to acknowledge that this analysis informs the discussion, which is subject to certain limitations. The study restricts its scope to the Scopus database and concentrates on the frequently used keywords in document titles and abstracts in the field of computer science and engineering. This study did not consider more comprehensive databases, such as Web of Science, Google Scholar, and EBSCO Hosts, which provide substantial coverage of the use of blockchain in the agri-food sector. Thus, it has the potential to limit the overall influence of the publication patterns on the subject of the study. In future studies, researchers can use diverse databases to perform searches, modify and compare the outcomes of distinct keyword terms, and examine variations in agri-food and blockchain research across different thematic domains. In addition, researchers can utilise bibliographic coupling analysis to quantify document similarity and identify earlier research that is pertinent to their current research. Besides that, the future direction in agri-food and blockchain study needs to comply with sustainability concept to sustain production and meet the demand for food. At this point, utilizing blockchain technology in agricultural and food research has the potential to yield significant and meaningful outcomes.

VI. CONCLUSIONS

We conducted a bibliometric analysis of the Scopus database's literature on agri-food and blockchain research, focusing on 1047 articles in the field of computer science and engineering. This study revealed a significant increase in publications since 2016, with the first paper published in 2016. Notably, there is a strong emphasis on utilising journals and conference proceedings to share research developments. English became the dominant language for research papers on this topic, indicating its worldwide importance. We recognized India and China as the primary contributors to papers, with India demonstrating a thriving research culture and a substantial impact on worldwide collaboration. The widespread use of blockchain-related terms, such as "blockchain" and "distributed ledger," highlights the significant academic interest in the transformative capabilities of blockchain technology in agri-food systems. The publications that have the most impact on this topic encompass a variety of viewpoints and applications of blockchain technology, with a particular focus on its significance in addressing numerous challenges in the agri-food industry. The increasing presence of Asian countries in academic papers exemplifies the region's growing influence in a variety of research fields. The National Institute of Industrial Engineering in India, in conjunction with other institutes, has a significant impact on the quality and prominence of research. Two writers with similar publication records primarily influence the research community. However, the inclusion of multiple perspectives enriches the research environment and enables a more thorough comprehension of

the subject matter. Researchers and practitioners are increasingly focusing on blockchain technology in agri-food research due to its potential in supply chain management, traceability, and smart contracts. Researchers are currently investigating the integration of the Internet of Things (IoT) and blockchain technology to tackle issues related to traceability, transparency, and real-time monitoring. The research also focuses on enhancing food safety procedures and establishing robust traceability tools to solve challenges related to safety and traceability. The research underscores the use of blockchain technology in conventional agricultural practices, emphasising the significance of agri-food in a sustainable and effective manner.

***Abstract*—Brain tumour detection is challenging for experts or doctors in the early stage. Many advanced techniques are used for the detection of different cancers and analysis using different medical images. Deep learning (DL) comes under artificial intelligence, which is used to analyse and characterisation medical image processing and also finds the classification of brain cancer. Magnetic Resonance Imaging (MRI) has become the keystone in brain cancer recognition and the fusion of advanced imaging methods with cutting-edge DL models has exposed great potential in enhancing accuracy. This research aims to develop an efficient hybrid CNN model by employing support vector machine (SVM) classifiers to advance the efficacy and stability of the projected convolutional neural network (CNN) model. Two distinct brain MRI image datasets (Dataset_MC and Dataset_BC) are binary and multi-classified using the suggested CNN and hybrid CNN-SVM (Support Vector Machine) models. The suggested CNN model employs fewer layers and parameters for feature extraction, while SVM functions as a classifier to preserve maximum accuracy in a shorter amount of time. The experiment result shows the evaluation of the projected CNN model with the SVM for the performance evaluation, in which CNN-SVM give the maximum accuracy on the test datasets at 99% (Dataset_BC) and 98% (Dataset_MC) as compared to other CNN models.**

***Keywords*—CNN; SVM; MRI images; brain tumor; deep learning**

I. Introduction

Cancer cells are abnormal cells that disturb or damage the normal life of the human body. These cells spread rapidly and infect the other cells in the human physique. The detection of these cells in the early stage increases the survival rate of human life. Doctors can find these cells but not in the early stage which decreases the mortality rates of humans. Advanced techniques have come like artificial intelligence which can be used in medical science or medical image processing (like MRI, CT X-ray etc) to detect, segment and classify any disease (brain cancer, lung cancer, oral cancer, bone fracture etc) in different parts of the human physique.

MRI plays a key part as compared to other imaging modalities due to the non-invasive characterization of brain tumors. It is the capability to provide complete images of the brain's anatomy, along with the distinct characteristics of different cancer types, that makes it an indispensable tool for clinicians. A traditional approach to brain tumor classification relied on histopathological analysis of tissue samples obtained through an invasive procedure. Though histopathology is still significant, it has problems such as patient risks and sampling mistakes. These matters are addressed with MRI, which delivers a non-invasive, complete image of the entire brain, simplifying precise preoperative diagnosis and handling forecasting.

To discriminate and categorize many forms of brain cancer, including gliomas, meningiomas, and pituitary tumors, MRI is a crucial tool. When combined with sophisticated MRI methods, CNN enables more precise classification, enabling doctors to make up-to-date conclusions regarding patient supervision.

Brain cancer is a hazardous and irregularly fatal disease for which early and correct detection is important to actual action. By combining their individual advantages, convolutional neural networks and traditional MRI imaging can be used to distribute more correct classification.

Artificial intelligence (AI) methods have renovated medical imaging and significantly improved the detection of brain cancer. These methods, which are capable of large MRI image datasets, can identify complex patterns and features that recover the correctness of brain cancer classification. By using AI techniques in brain cancer discovery analysis, custom-made treatment options are developed and the diagnosis process is accelerated.

Current solutions are being accessible by the context-aware use of AI techniques in health care diagnosis. When utilizing MRI to diagnose brain tumors, it is necessary to conduct experimental work to detect the tumor, and classify it according to its grade, kind, and location. This approach has experimented with using a solo CNN model for brain cancer recognition on different datasets in the place of a different CNN model for the diverse classification task. Brain tumor identification and classification are possible with the CNN-based binary and multi-task classification system. However, most of the authors used different models for different classification systems.

II. Related Work

The American Cancer Society estimates that as of 2021, 78,980 persons had acknowledged a brain cancer finding; of these, around 55 thousand were benign and 24 thousand were malignant [1]. Studies show that brain cancers are the foremost root of cancer worldwide [2].

Since various cells can cause different kinds of brain cancer, they are a diverse group. Essentially, lesions can be classified into binary categories: Primary lesions arise from inside the

central nervous system, but secondary lesions can spread to other portions of the body and become brain metastases. The leading causes of illness and death worldwide are cardiovascular and cerebrovascular disorders. These conditions, which have a bigger financial burden than infectious diseases and harm society, start in childhood and can strike unexpectedly in maturity.

Medical image analysis often uses a variety of techniques to produce descriptions of the soft muscle in the human body. Medical professionals employ MRI images among them. It's a non-invasive method for accurately analysing imaging data of brain cancer in humans to assess the health of the patient [3]. Because of the tissue distinction stabilization and picture excellence determination, it is extremely applicable. The biology, chemistry, physiology, and genetic details of any brain disorder can be obtained from MRI pictures [4].

Brain cancer is well-defined by the World Health Organization (WHO) and controls all parts of the human body. This classification was revised in 2016. Broadly speaking, abnormal growth of a subset of brain cells is referred to as brain cancer. These cancers expose the brain's tissue to shrinkage, which causes massive harm to the brain's neuronal network and impairs the brain's ability to function [5-8]. Like any other kind of cancer, brain cancer can be classified as benign and malignant. While other types of brain tumors typically depend on the affected location like meningioma, glioma, and pituitary.

Utilizing the latest developments in science technologies to recover the precision of brain cancer identification in computer vision applications, merging (fusing) the images obtained from numerous imagery modalities. Artificial Intelligence [9] can be combined with these imagery modes to create finding systems. These kinds of systems can support doctors in refining the accuracy of early cancer recognition. Brain tumors can now be classified and identified using a variety of artificial intelligence techniques, including CNNs, SVMs, and artificial neural networks (ANNs) [10].

Authors proposed a CNN model such as VGG-(16 and 19) and InceptionV3 with Aquila optimizer. They classified brain tumor detection with an accuracy of 98.95% for the VGG-19 but testing accuracy is not given on the test dataset for this VGG-19 model [11]. Other authors proposed a CNN model with a ResNet50 architecture for the detection of brain cancers and found a correctness percentage of 98% in the MRI dataset [12].

The pre-trained CNN models were presented by the authors for the categorization of brain cancer from MRI pictures. They applied augmentation and image preprocessing like normalisation and resized the image 256x256 on the image dataset then found the maximum accuracy 96% in the VGG-16 model as compared to ResNet-50 and Inception V3 [13].

The analysis of the preprocessing stages for MRI image data enhances the detection accuracy in brain disease prediction. To propose a CNN pre-trained model, Authors suggest a VGG-16 pre-trained model for the categorization of multi-grade cancers in brain images [14].

The authors proposed an Inception-ResnetV2 model with grey wolf optimization and achieved 99.98% accuracy for brain tumor classification [15]. Another study done by authors proposes a CNN model with local constraints using a supervised k-nearest neighbour algorithm. They implemented two datasets for multi-class classification and found that CDLLC performed well as compared to other models VGG and GoogleNet [16].

A large number of academics looked into several algorithms for correctly and efficiently classifying brain tumors. Recently, DL methods have been extensively used to develop autonomous models that can speedily and efficiently detect brain cancer.

The authors conducted a study on brain tumor classification using four models S-CNN, InceptionV3, ResNet-50 and Xception on the two distinct brain image data sets. They trained data sets with or without principal component analysis and five-fold cross-validation. They found that Inception V3 and Xception models performed well as compared to S-CNN and ResNet-50 [17]. Another study was conducted by the authors for brain cancer classification using augmentation and transfer learning. The authors found an accuracy of 96.2% in the AlexNet model as related to the ResNet-50 and Inception-v3 models [18].

After the critical analysis from the literature review, existing models provide good accuracy on training data, but not for the test data. In this paper, design an optimal brain cancer detection model using a CNN approach to report the improvement of accuracy issues in the existing artificial diagnostic system, which classifies binary classification and also multi-classification on two different datasets using the single model.

III. Objective

In the study, two main objectives are used for the detection of brain cancer:

1) First Focus on accuracy, mainly for testing datasets.

2) Second objective one CNN model is used for two different datasets for two different classifications.

IV. Proposed Methodology

The projected hybrid CNN model integrates the strengths of features learning from raw MRI images using convolutional layers with the interpretability and efficiency of traditional machine learning algorithms. The architecture consists of multiple convolutional, batch-normalization and max-polling layers for feature extraction, followed by densely connected layers and additional modules for specialized feature processing.

The proposed workflow, which utilizes two brain MRI image datasets: Database_MC and Database_BC. The projected CNN model incorporates common classification steps, including pre-processing, feature extraction, and classification. Various layer combinations, along with appropriate hyper-parameters, are used to progress a strong model that efficiently mitigates overfitting and bias in both datasets. By leveraging these techniques, the study aims to maintain the best classification accuracy while reducing computational requirements.

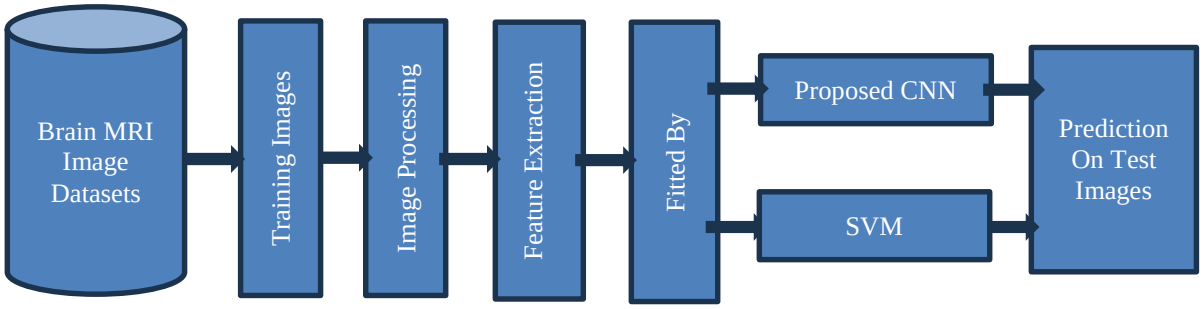

Fig. 1. Flow of proposed work.

The projected work is shown in Figure 1 for the classification.

The following steps are used in the algorithm to make the robust CNN and hybrid models classify the brain tumor MRI image datasets:

1) Collect the two datasets (Dataset_MC and Dataset_BC) of brain tumor MRI Grayscale Images from Kaggle

2) Apply image preprocessing like resize images (48x48) and normalize.

3) Encode all the images of the training and test dataset into labels (text to integers).

4) Extract feature using the proposed CNN model.

5) Train the model by applying the proposed CNN & hybrid CNN-SVM (Support Vector Machine) on the training dataset.

6) Classify the test dataset using the proposed CNN and CNN-SVM. Find the performance measures using the confusion matrix and classification report.

V. Data Collection

Brain MRI image datasets are downloaded from Kaggle. Dataset_MC [19] contains 7023 brain MRI images of four classes: glioma, meningioma, pituitary and nontumor, which is used in multi-classification. Dataset_BC [20] contains 3000 brain images of two classes yes (tumor) and no (notumor) for binary classification. The distribution of training and testing datasets for Datatset_MC and Dataset_BC respectively is shown in the following Table 1. Figures 2 and 3 show the different classes of Dataset_MC and Dataset_BC respectively of brain cancer on a different dataset. Dataset_MC is used for multi-classification while Dataset_BC is used for binary classification using the same model.

TABLE I. Distribution of Training and Testing Dataset for Dataset_MC and Dataset_BC

Datasets	Training Dataset	Testing Dataset
Dataset_MC (7023)	5712	1311
Dataset_BC (3000)	2400	600

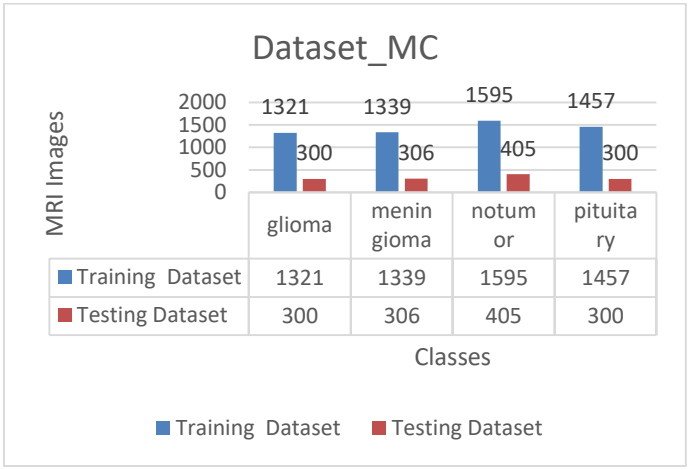

Fig. 2. The different classes of training and testing datasets in Dataset_MC.

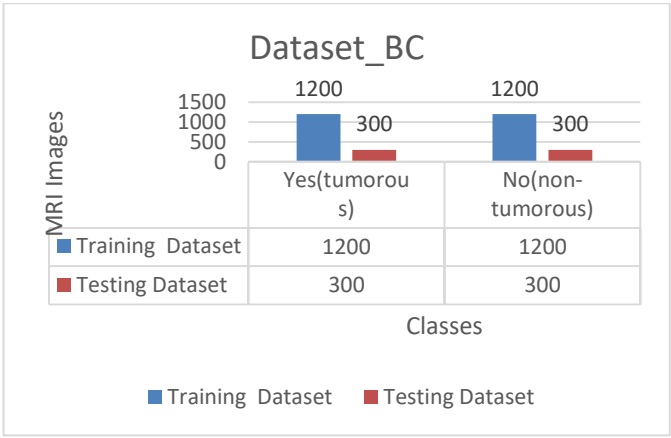

Fig. 3. The different classes of training and testing datasets in Dataset_BC.

VI. Proposed CNN Model

Figure 4 shows a common architecture of the projected model consisting of a few layers with minimum numbers of total parameters for Dataset_MC and Dataset_BC. The difference is only in the last dense layer where the left side uses 4 classes (multi-class) and the right-side uses right side 2 classes (binary-class) in Dataset_MC and Dataset_BC respectively. It is very efficient because of high accuracy and computation time is very less. In the projected hybrid CNN-SVM model, CNN serves as an automatic feature extractor and SVM as a classifier.

Fig. 4. Architecture of projected CNN model in Dataset_MC and Dataset_BC.

The proposed deep-learning CNN model uses the following layers to make the robust model:

1) Convolutional layer: It uses a kernel size of 3x3 for feature extraction and is followed by relu function F(x)=Max (0, x). To speed up the training process and convert the negative values to zero.

2) Batch-Normalization layer: It stabilizes the training process and also improves the optimization.

3) Max-polling layer: The 2x2 kernel size of this layer takes the maximum value from the patch of the input data and summarises these values into a features map. By using these it reduces the dimension.

4) Dropout layer: It is set to 0.1 means 10% of neurons drop out in each epoch to reduce over-fitting.

5) Flatten layer: This is the last layer for feature extraction, which converts each batch in the inputs to one dimension.

6) Dense layer: It receives output from every neuron of its preceding layer. In the proposed CNN, two dense layers are used. The first is sigmoid and the second is softmax activation function. The expression of sigmoid function $F(x) = 1/(1 + e^{-x})$, which transforms values between the range 0 to 1. The expression of the softmax function is $\sigma(z)_j = e^{z_j}/\sum_{k=1}^{K} e^{z_k} \quad for\ j = 1,2, \ldots . K$

It is like a combination of multiple sigmoid and is used for multi-class classification problems.

VII. Experimental Result and Discussion

The projected CNN model is executed in Jupyter Notebook under Anaconda in Python3 using an Intel Core i5 8th generation laptop.

For ultimate training of the image dataset, the proposed CNN model uses the following hyper-parameters as optimizers: root mean square propagation (RMSprop), learning_rat: 0.0009, and batch_size: 32.

The outcome of the projected CNN model is shown in Figures 5 and 6, which show the accuracy is 100% and 99.2% of the training dataset for Dataset_BC and Dataset_MC respectively in the 10 epochs.

The SVM classifier is applied to feature extraction generated by convolutional layers on the MRI dataset and compares the result through confusion matrix and classification reports. The exhibition of the hybrid CNN-SVM model is better than the standalone CNN architecture. The results show the superiority of the hybrid CNN-SVM in terms of accurateness, and efficiency. The best thing about this proposed model is that rapid and accurate classification of brain cancer can significantly impact treatment planning important to enhanced patient results.

The proposed CNN and hybrid CNN-SVM models were evaluated on the test dataset for Dataset_MC and Dataset_BC. The performance measures of the test dataset are shown by the confusion matrix. The confusion matrix of the projected CNN and hybrid CNN-SVM for Dataset_MC (Upper-Side) and Dataset_BC (Lower-Side) respectively are shown in Figure 7.

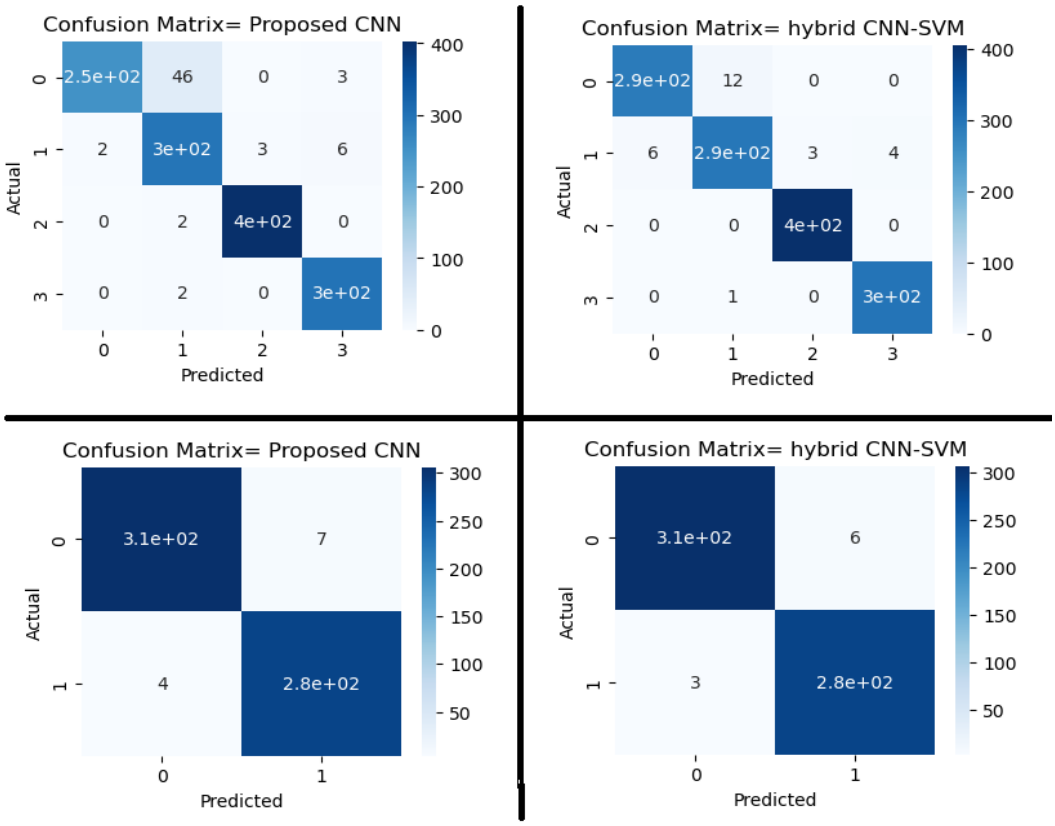

Fig. 7. Confusion matrix for Dataset_MC (Upper-Side) and Dataset_BC (Lower-Side).

TABLE II. CLASSIFICATION REPORT OF TEST DATASET IN DATASET_MC AND DATASET_BC

Test Dataset_MC	Classes	Precision	Recall	F1-score
Proposed CNN Accuracy=95%	glioma	0.99	0.84	0.91
	meningioma	0.86	0.96	0.91
	notumor	0.99	1.00	0.99
	pituitary	0.97	0.99	0.98
Support Vector Machine (SVM) Accuracy=98%	glioma	0.98	0.96	0.97
	meningioma	0.96	0.96	0.96
	notumor	0.99	1.00	1.00
	pituitary	0.99	1.00	0.99
Test Dataset_BC	**Classes**	**Precision**	**Recall**	**F1-score**
Proposed CNN Accuracy=98%	no	0.99	0.98	0.98
	yes	0.98	0.99	0.98
SVM Accuracy=99%	no	0.99	0.98	0.99
	yes	0.98	0.99	0.98

In the addition of the evaluated test dataset, the projected model achieved the best accuracy. Table 2 shows the classification report of all classes of test data in the Dataset_MC and Dataset_BC.

The projected CNN model obtained 95% and 98% accuracy for the test data in the Dataset_MC and Dataset_BC respectively. The best result obtained in the hybrid CNN-SVM model was 98% and 99% accuracy for the test dataset in Dataset_MC and Dataset_BC respectively. It shows high performance not only in training data but also in test data.

Figure 8 shows the accuracy of different classes in the random test images from Dataset_MC (Upper_Side) and Dataset_BC (Lower_Side).

The proposed work is the best as compared to other researchers' work because the same kind of dataset was used by

other authors in the experiment but did not get the optimal accuracy, which is shown in Table 3.

Authors [23] proposed a CNN and a hybrid CNN-SVM model for brain cancer binary classification (benign and malignant) and obtained an accuracy of 98.49% using CNN-SVM and 97.43% using CNN on the BRATS 2015 brain image dataset. This is training accuracy, which is less than our proposed work.

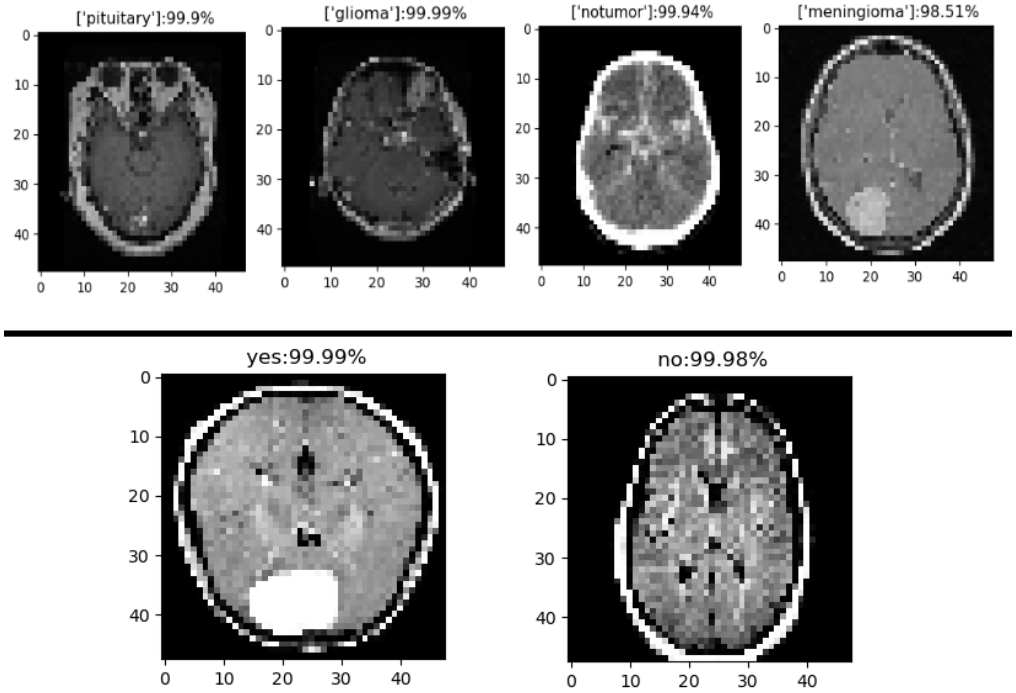

Fig. 8. Sample output of different classes with accuracy from both test datasets.

TABLE III. COMPARISON OF PROJECTED WORK WITH OTHER AUTHOR'S WORK

Reference	Model	Accuracy of the training dataset	Accuracy of the validation/testing dataset	Epoch	MRI Brain Image Dataset
[21]	CNN	85%	88%	10	Dataset_MC
[22]	CNN	94.74%		20	
[24]	CNN	92.66%			
	AlexNet	83.12%			
	VGG-16	88.87%			
[25]	CNN	96.13%			
[26]	CNN-GA	94.2%		100	
	CNN-SVM (Proposed Work)	99.56%	98%	10	
[11]	VGG-19 with AQO	98.95%	98.95%	41	Dataset_BC
[12]	ResNet-50	98%	94%	20	
[13]	VGG-16	96%	86%	10	
[15]	Inception-ResnetV2 with ADSCFGWO	99.98%	-	20	
[24]	CNN	99.33%			
	AlexNet	88.12%			
	ResNet-50	92.79%			
[27]	CNN-SVM	99.74	93.78%	11	
[28]	EfficientNet-B0	98.87%		50	
	CNN-SVM (Proposed work)	100%	99%	10	

Authors [24] projected three CNN models to perform three different tasks on brain tumor MRI image datasets. The first CNN model was used for binary classification (tumor and nontumor) with an accuracy of 99.33%. The second was used to find the multi-class detection (glioma, meningioma, pituitary, metastatic and normal) with an accuracy of 92.66%. In this case, separate models are used by the authors for different tasks while in this paper single model was used for different tasks and accuracy is also higher than the other author's work.

Authors [26] proposed a CNN-SVM model for brain cancer classification using an MRI dataset and found the accuracy on the training dataset is 99.74% using RMSProp optimiser in 11 epochs but testing accuracy is 93.78%, which is much less as compared to our proposed work.

VIII. Conclusion and Future Discussion

Each type of problem has a specific CNN model created for it. The kind of problem, the inputs, and the anticipated results all affect the CNN model's architecture and complication. The maximum authors were used to propose different classification models for the diverse classification tasks. Selecting the best-performing network model for a given application is one of the challenges with convolutional neural networks. Making the correct hyper-parameter choices is critical to accomplishment best outcomes, especially with the CNNs.

The most effective CNN model is created in this study, and its hyper-parameters are optimized and large, freely accessible MRI datasets are used to achieve satisfactory categorization results. Using the projected CNN model on test datasets, brain cancer identification is accomplished with a very pleasing accuracy of 99% for binary classification. Furthermore, a 98% accuracy rate is achieved for multi-classification. Finally, using performance evaluation criteria including accuracy, precision, recall and F1 score, the outcome of the proposed CNN-SVM is verified.

The one limitation of this study is that the accuracy of test data can be increased if the size of datasets is increased since it takes more time to improve the data by the augmentation process, which does not impact the result.

Future research in healthcare applications will continue to focus heavily on deep learning. The proposed model can be generalised based on its capacity to categorize data, it can be utilized to recognize and diagnose medical conditions. Because medical training takes a long time, this not only shortens the diagnosing process but also decreases the number of mistakes made by professionals. This concept holds promise for medical imaging diagnostics since combining data from several sources can result in a distinct course of events. Additionally, putting the system for crowdsourcing data collecting and analysis into practice will be interesting. Lastly, there are numerous healthcare sectors where deep learning can be applied.

MRI remains at the forefront of non-invasive brain cancer detection offering clinicians a comprehensive view of cancer morphology and aiding in treatment decision-making. The integration of CNN and MRI can alter the scene of diagnostic tools for brain tumors, providing clinicians with more reliable and timely information for patient care.

The future of MRI-based brain cancer detection holds promise with ongoing research in imaging expertise and artificial intelligence. Continuous progresses in imagery technology and the integration of DL will continue to improve the correctness and consistency of MRI in tumor characterization.

***Abstract*—Speech Emotion Recognition (SER) identifies and categorizes emotional states by analyzing speech signals. The intensity of specific emotional expressions (e.g., anger) conveys critical directives and plays a crucial role in social behavior. SER is intrinsically language-specific; this study investigated a novel cascaded deep learning (DL) model to Bangla SER with intensity level. The proposed method employs the Mel-Frequency Cepstral Coefficient, Short-Time Fourier Transform (STFT), and Chroma STFT signal transformation techniques; the respective transformed features are blended into a 3D form and used as the input of the DL model. The cascaded model performs the task in two stages: classify emotion in Stage 1 and then measure the intensity in Stage 2. DL architecture used in both stages is the same, which consists of a 3D Convolutional Neural Network (CNN), a Time Distribution Flatten (TDF) layer, a Long Short-term Memory (LSTM), and a Bidirectional LSTM (Bi-LSTM). CNN first extracts features from 3D formed input; the features are passed through the TDF layer, Bi-LSTM, and LSTM; finally, the model classifies emotion along with its intensity level. The proposed model has been evaluated rigorously using developed KBES and other datasets. The proposed model revealed as the best-suited SER method compared to existing prominent methods achieving accuracy of 88.30% and 71.67% for RAVDESS and KBES datasets, respectively.**

***Keywords*—Bangla speech emotion recognition; speech signal transformation; convolutional neural network; bidirectional long short-term memory**

I. Introduction

Speech is the most commonly used method of interaction and emotional expression. In artificial intelligence and deep learning, the Speech Emotion Recognition (SER) task involves identifying and categorizing emotional elements of speech. The SER task has two basic steps: extracting features from the speech signal and classifying emotions. Existing SER methods employ different signal transformation and feature extraction methods on speech signals and then employ different machine learning (ML) and/or deep learning (DL) methods to the feature-transformed signal for emotion recognition [1] [2]. SER performance relies on the quality of the extracted emotional features from speech and methods used to classify the features.

In the ML or DL domain, SER is a language-specific research task, as natural languages have remarkable variations. Most of the existing SER tasks are performed in a few languages for which quality corpuses are available. On the other hand, SER studies are very limited, even for major languages, due to the legging of resources. As an example, Bangla is a major speaking language in the world, which is spoken by more than 210 million people [3]. However, Bangla is not resourceful for SER studies; hence, a few studies are available on Bangla SER. Therefore, the Bangla SER study is a promising research domain in ML and DL domains.

The study aims to develop a DL-based Bangla SER (BSER) system to identify the most suitable match for emotional speech. Existing BSER studies have only looked at classifying emotions from speech without considering the intensity level. However, the level of intensity (normal or strong) of an emotional expression such as sadness or anger is crucial. When someone is experiencing intense emotions, they may engage in harmful behaviors. The recent increase in online broadcasts of such behavior on social media has raised the alarm and the need for action to address these issues [4]. As a result, the automatic recognition of both emotions and their intensity level has become a highly relevant and essential issue that is the focus of this study.

An integrated speech signal transformation and a cascaded model with hybrid DL architecture are considered in this study to achieve better SER performance. The proposed method employs the Mel-Frequency Cepstral Coefficient (MFCC), Short-Time Fourier Transform (STFT), and Chroma STFT (CSTFT) feature transformation on the speech signals individually. The transformed two-dimensional (2D) MFCC, STFT, and CSTFT features are combined into a 3D form and inputted into the cascaded DL model for emotional classification with intensity. The cascaded DL model performs the task in two stages: classify emotion first in Stage 1 and then measure the intensity of the classified emotion in Stage 2. DL architectures used in both stages are the same, which consist of 3D Convolutional Neural Network (CNN), a Time Distribution Flatten (TDF) layer, a Long Short-term Memory (LSTM), and a Bidirectional LSTM (Bi-LSTM). The CNN extracts features from the 3D transformed speech signal using four feature blocks in series, and the TDF layer then flattens the features. The flattened features are inputted into the Bi-LSTM, the outcomes of Bi-LSTM are inputted into the LSTM, and finally, a fully connected layer is used for emotion classification or intensity measure. The proposed model has

been evaluated rigorously using our developed KBES dataset and other BSER datasets. The proposed cascaded revealed as the best-suited SER method while compared to existing prominent methods. The major contributions of this study are briefly summarized as follows:

1) Integrated 3D speech feature formation using MFCC, STFT, and CSTFT;

2) Emotion classification with intensity using cascaded DL model with hybrid DL architecture;

3) Rigorous experimental studies with different feature transformations and different DL models on our developed KBES dataset and other BSER datasets; and

4) Performance comparison of the proposed BSER model with existing prominent methods.

The structure of the remaining paper is as follows. Section II is the literature review, briefly explaining several related SER studies. Section III demonstrates the proposed method illustrating individual components. Experimental studies, including outcomes of the proposed cascaded model and performance comparison with the existing methods, are placed in Section IV. Finally, Section V concludes the paper with a few remarks on the present study and several future research directions.

II. Literature Review

Several DL-based SER studies are available with different corpuses for English and Germany, such as RAVDESS and IEMOCAP. Badshah et al. [5] investigated a CNN architecture composed of three convolutional layers and three fully connected (FC) layers. The model was trained on the Berlin emotional corpus to differentiate seven emotions using spectrograms collected from the stimuli. Satt et al. [6] introduced an SER model extracting log-spectrogram feature vectors from the IEMOCAP speech dataset. They tested two architectural models: convolution-only and convolution-LSTM deep neural networks. Etienne et al. [7] also used a CNN-LSTM architecture to classify emotions using spectrogram information. Chen et al. [8] used a portion of the IEMOCAP dataset for three different models: a shallow CNN combined with a Bi-LSTM, a deep CNN with a shallow Bi-LSTM, and a deep CNN with a deep Bi-LSTM. Manohar and Logashanmugam [9] integrated different meta-heuristic and deep-learning methods for SER with selected features. Wen et al. [10] Introduced self-labeling feature frames in their DL-based SER study.

Zhao et al. [11] investigated different DL-based models with CNN and LSTM for SER using the Emo-DB corpus and part of the IEMOCAP corpus. Among various combinations of convolutional layers and LSTM, the combination of 6 convolutional layers and LSTM is found to be the best-performing one. Zhang et al. [12] developed an attention-based, fully convolutional network on the IEMOCAP corpus and claimed to outperform state-of-the-art models. Ghosal et al. [13] proposed a graph neural network-based technique called the Dialogue Graph Convolutional Network (DialogueGCN) for recognizing emotions in conversations. A 2D CNN architecture extracted features from audio recordings, and a Support Vector Machine (SVM) was utilized for emotion classification. They evaluated the performance of their architecture on three datasets: IEMOCAP, AVEC, and MELD. Zhao et al. [14] employed a Connectionist Temporal Classification (CTC) with attention-based Bi-LSTM using the IEMOCAP dataset. Zhao et al. [15] combined Bi-LSTM with a CNN using the IEMOCAP dataset. Recently, Is-lam et al. [4] developed a 3D transformed feature and CNN Bi-LSTM-based cascaded DL model for the RAVDESS dataset.

Only a few attempts have been made to develop SER for Bangla, even though it is a significant natural language worldwide. Sultana et al. [16] employed a DL model combining CNN with TDF and Bi-LSTM layers to analyze the SUBESCO [17] dataset. The model consists of four CNN feature blocks (FB), each with a convolution layer, as well as layers for batch normalization (BN), exponential linear units (ELU), and max-pooling. The first two FBs used 128 kernels, while the last two FBs used 64 kernels. The proposed model's performance of Bangla SER was compared to three other models [18] [19] [20]. Sultana and Rahman [21] recently investigated essential speech features for ML-based BSER using the SUBESCO dataset.

III. Cascaded DL Model for Bangla SER With Intensity

There is a novel aim to develop Bangla SER with intensity. Speech is the primary method of communication in various live media platforms like Facebook and YouTube, which often express emotions. In the case of emotional expression, the level of intensity (normal or strong) has a crucial impact. For example, extreme sadness or anger may lead a person towards harmful behaviors, even suicidal effects. Identifying harmful emotions, such as extreme sadness or anger, is a challenging computational intelligence task to prevent individuals from taking harmful actions that could impact society.

Fig. 1 illustrates the general architecture of the proposed method of identifying appropriate emotions from speech signals. The main components of the pro-posed approach are the feature transformation of the input speech signal and classifying emotions and their intensity level. The method developed an integrated 3D feature form from three different individual features (i.e., MFCC, STFT, and Chroma STFT) on the input speech signal. Then, an appropriate DL model is used to analyze 3D features through multiple layers, eventually leading to the classification of emotions. At a glance, the proposed system takes in speech signals as input and generates output that classifies emotions as Neutral, Happy, Sad, Angry, and Disgust and further categorizes each emotion as Low or High based on the intensity level. The following subsections explain the individual components briefly.

A. Speech Signal Transformation

The speech signal transformation in the proposed system considers three popular signal transformation methods: Mel-Frequency Cepstral Coefficients (MFCC), Short-Time Fourier Transform (STFT), and Chroma STFT. Each MFCC, STFT, and Chroma STFT produces three different same-sized two-dimensional (2D) transformed features. The three 2D features

are integrated into a 3D transformed feature, which is inputted into the cascaded DL model for emotion recognition. The basic elaborated descriptions of the feature transformation are available in the literature [4].

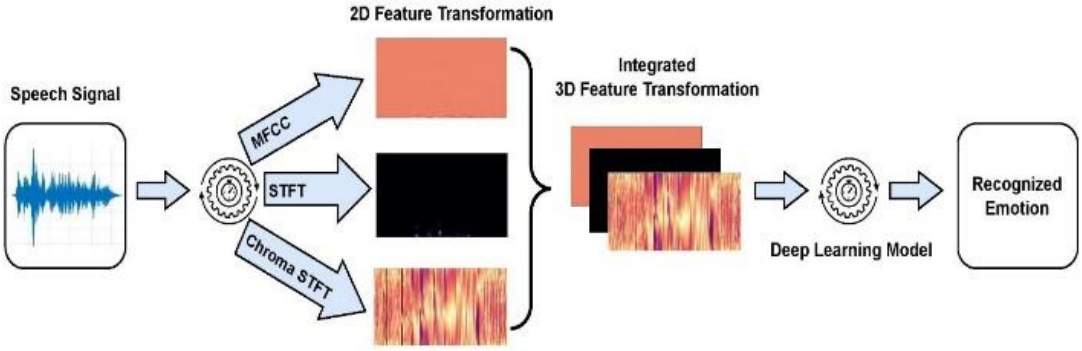

Fig. 1. Architecture of the proposed method identifying emotions from speech signals.

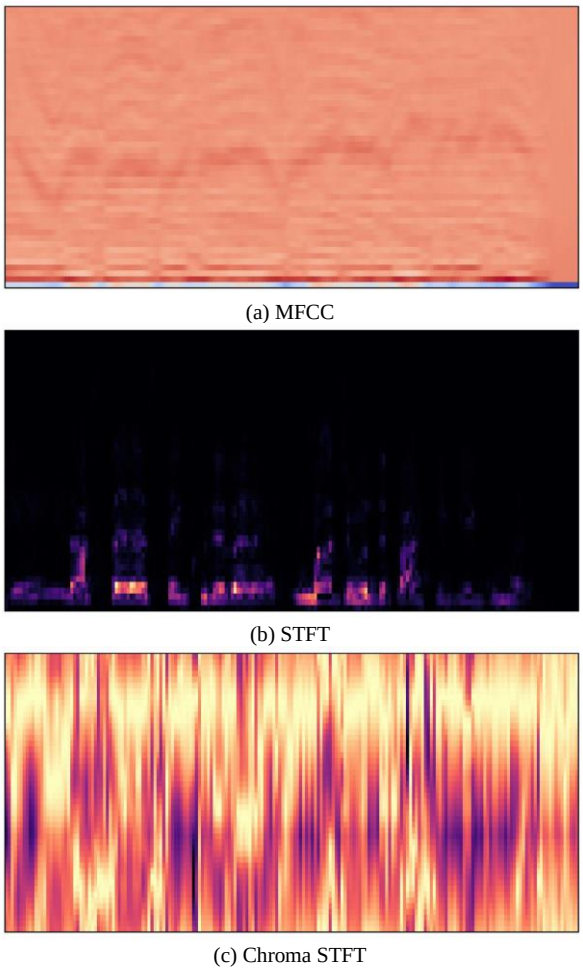

(a) MFCC

(b) STFT

(c) Chroma STFT

Fig. 2. Sample outcomes of speech signal feature trans-formation employed in the proposed method.

Fig. 2 shows 2D features from a sample speech signal using MFCC, STFT, and Chroma STFT. 250 hop lengths and 128 sequences were considered for MFCC; thus, the MFCC feature (see Fig. 2(a)) is with 128 sequences and 513 frames. Having a hop length of 250 and the FFT window length of 254, the STFT feature (see Fig. 2(b)) is also 128 sequences and 513 frames. The Chroma STFT feature is the same size as STFT, as shown in Fig. 2(c). Afterward, the three 2D features were integrated into the 3D form with size 128*513*3, which fed into the DL model.

B. Emotion Classification using Cascaded DL Model

Recognizing emotions using DL involves extracting features through multiple layers before finally recognizing them into emotion categories with intensity levels. A cascaded model is considered in this study to perform the task in two different stages: emotion classification and then the intensity of the classified category. Such a cascaded model is investigated in the recent study [4], but we have considered different DL architectures to achieve better performance for our intended application of Bangla SER.

Fig. 3 depicts the proposed cascaded DL model, which consists of two different stages. The DL architecture in Stage 1 classifies 3D-transformed features into five emotion categories: Neutral, Happy, Sad, Angry, and Disgust. Stage 2 uses another DL model to identify the intensity (i.e., Normal or Strong) of the emotion recognized in Stage 1. A single DL model is trained with the whole training set for Stage 1. For intensity classification in Stage 2, the training set was divided into five individual classes (i.e., Normal and four emotion classes), and then four distinct DL models were trained with individual emotion case samples for intensity classification. In the figure, DLEmotion in Stage 1 is the classifier for the emotion classification, and DLHappy, DLSad, DLAngry, and DLDisgust in Stage 2 are the classifiers for the intensity classification of Happy, Sad, Angry, and Disgust emotions, respectively. In other words, the DLEmotion extracts features from the input 3D transformed feature and then categorizes them into emotion cases. Similarly, a DL in Stage 2 extracts features from the same input used in Stage 1 but for the task of intensity measure (Low or High) of the classified emotion.

The main distinction between the DL architectures used in Stage 1 and Stage 2 is the number of output neurons: five in Stage 1 and two in Stage 2. Although the number of output classes and tasks differ, the basic structure is the same in all the DL architectures depicted in Fig. 4. Fig. 4(a) shows the building blocks of the DL architecture, which has four 3D CNN feature blocks (FB), a Time Distribution Flatten (TDF) layer, a Bi-LSTM layer, an LSTM layer, and a fully connected (FC) dense layer. The structure of a single CNN feature block

is shown in Fig. 4(b), which consists of a 3D CNN layer, batch normalization layer, ReLU activation layer, and 3D max-pooling layer. The use of 3D trans-formed features makes the 3D CNN ideal for feature extraction, while the LSTMs are selected for their ability to handle sequential data. Output from the CNN is passed through a TDF layer that serves as the input for the Bi-LSTM and then passed to the LSTM layer. The LSTM layer results are given to an FC layer to identify emotions or intensity levels.

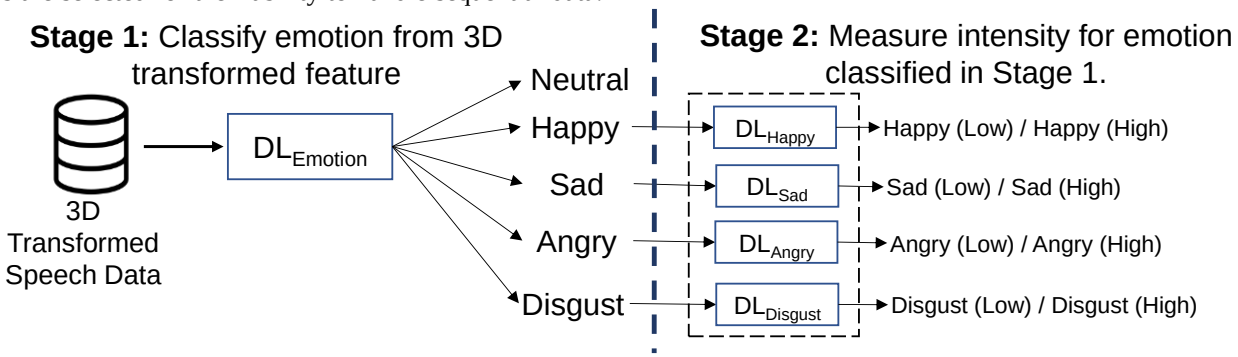

Fig. 3. The proposed cascaded DL model to classify emotion and its intensity from the 3D transformed speech signal.

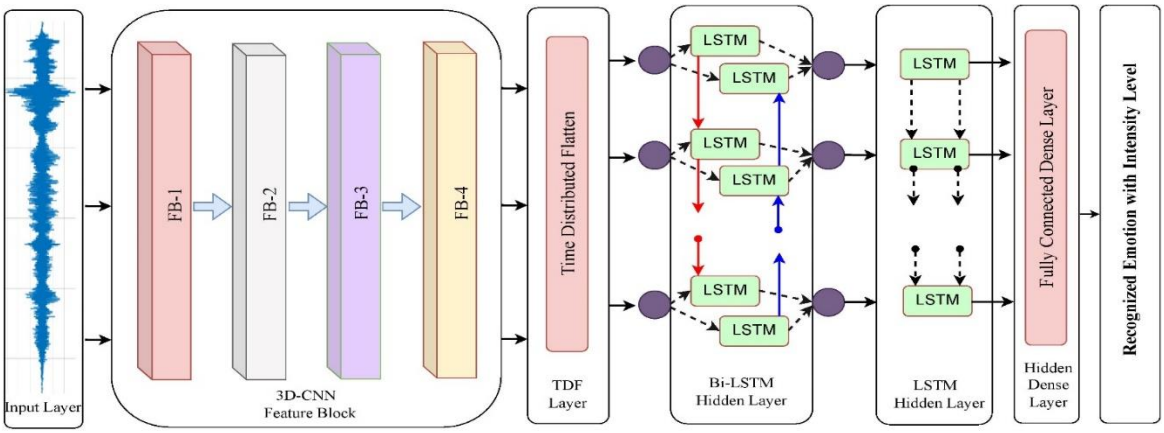
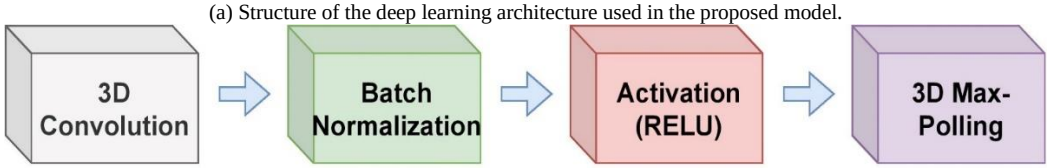


(a) Structure of the deep learning architecture used in the proposed model.



(b) Structure of the convolutional feature block (FB) in 3D-CNN.

Fig. 4. The architecture of the proposed deep learning model.

TABLE I. THE HYPER-PARAMETERS OF THE PROPOSED DEEP LEARNING MODEL ARCHITECTURE

Feature Blocks	Layers	Input Shape	Output Shape	Filters	Kernel Size	Strides	Units
FB-1	Conv3D	128×513×3	128×513×3 @ 64	64	5×5×5	1×1×1	-
	MaxPolling3D	128×513×3 @ 64	64×256×3 @ 64	-	2×2×1	2×2×1	-
FB-2	Conv3D	64×256×3 @ 64	64×256×3 @ 64	64	5×5×5	1×1×1	-
	MaxPolling3D	64×256×3 @ 64	16×64×3 @ 64	-	4×4×1	4×4×1	-
FB-3	Conv3D	16×64×3 @ 64	16×64×3 @ 128	128	5×5×5	1×1×1	-
	MaxPolling3D	16×64×3 @ 128	4×16×3 @ 128	-	4×4×1	4×4×1	-
FB-4	Conv3D	4×16×3 @ 128	4×16×3 @ 128	128	5×5×5	1×1×1	-
	MaxPolling3D	4×16×3 @ 128	1×4×3 @ 128	-	4×4×1	4×4×1	-
-	TDF	1×4×3 @ 128	1×1536	-	-	-	-
-	Bi-LSTM	1×1536	1×512	-	-	-	256
-	LSTM	1×512	256	-	-	-	256

-	Dense	256	5/2	-	-	-	5/2

The proposed DL architecture has a set of layer parameters outlined in Table I. All CNN layers employ the same kernel size of 5×5×5 and strides of 1×1×1. The first feature block, FB-1 and FB-2, have filters of 64, while the last two feature blocks, FB-3 and FB-4, have filters of 128. The max-pooling layer for the FB-1 has a 2×2×1 sized kernel and a stride size of 2×2×1, whereas the last three max-pooling layers for the feature block have a 4×4×1 sized kernel and a stride of 4×4×1. The output of FB-4 is passed into the TDF layer, which is transformed into 1536 features. The outputs of the TDF layer are served as input to the Bi-LSTM layer. The Bi-LSTM layer outputs are 512 features, which are passed on to the LSTM layer. The outputs of the LSTM layer pass into the FC dense layer. The dense layer was concluded by applying the SoftMax activation function, which normalized the recognition of emotions in the classification process. Finally, the output layer will have five neurons in the DL classifier in Stage 1, and DL classifiers in Stage 2 will have two neurons in their output layers. The elaborated descriptions of CNN, LSTM, and Bi-LSTM are available in the literature [4] [21].

C. Significance of the Proposed Method

Bangla SER with intensity level is the primary concern of this study. This study utilized a 3D form of the speech signal that integrates three 2D transformations to enhance features and improve identification, resulting in significant performance enhancements. A cascaded DL model is considered in this study, where the task is split into two stages. The first stage involves classifying the emotion using a DL (i.e., $DL_{Emotion}$) model, and in the second stage, distinct DL models (i.e., DL_{Happy}, DL_{Sad}, DL_{Angry}, and $DL_{Disgust}$) classify the intensity level of the classified emotion as either Normal or Strong. DL models in both stages use the same 3D feature as input for a particular speech sample. The output of the first stage's DL model identifies the emotion class of the sample based on its 3D features. In contrast, a particular emotion-based DL model measures its intensity level using the same 3D feature in Stage 2. DL architectures in both stages are the same and consist of a 3D CNN, Bi-LSTM, and LSTM. This proposed model differs from the existing methods by using innovative techniques to recognize individual emotions and their intensity level.

IV. Experimental Studies

The effectiveness of the proposed DL method has been evaluated through several series of experiments and compared with other prominent methods. Since intensity level identification is the main attraction of this study for Bangla SER and no existing dataset is appropriate for the task, an appropriate dataset is pre-pared for this study. The following sections provide information regarding the dataset development, experimental setup, result analysis, and performance comparison.

A. Bangla SER Dataset Development

An appropriate dataset is a major issue in developing any ML/DL method. The major concern of this study is not only the categorization of emotions from speech signals but also the intensity of the categorized emotion. The intensity of speech emotion has great impacts, which has already been discussed as the motivation of the present study. A few Bangla SER datasets are available, but no existing dataset considers the intensity level of emotions. Moreover, existing datasets consist of only a few dialogues with a minimal number of actors; such datasets are unsuitable concerning re-al-world scenarios. Therefore, a realistic Bangla emotional speech dataset is used in this study, which is called the KUET Bangla Emotional Speech (KBES) dataset [22]. The dataset consists of 900 audio signals (i.e., speech dialogs) from 35 actors (20 females and 15 males) with diverse age ranges. Sources of the speech dialogs are Bangla Telefilm, Drama, TV Series, and Web Series. There are five emotional categories: Neutral, Happy, Sad, Angry, and Disgust. Except for Neutral, samples of a particular emotion are divided into two intensity levels: Normal and Strong.

The significant issue of the KBES dataset is that the speech dialogs are almost unique, with a relatively large number of actors. In contrast, existing datasets (such as SUBESCO and BanglaSER) hold samples with repeatedly spoken few pre-defined dialogs by a few actors/research volunteers in the lab environment. Finally, the KBES dataset is exposed as a nine-class problem to classify emotions into nine categories: Neutral, Happy (Low), Happy (High), Sad (Low), Sad (High), Angry (Low), Angry (High), Disgust (Low) and Disgust (High). However, the dataset is kept symmetrical, holding 100 samples for each of the nine classes; 100 samples are also gender balanced, having 50 samples for male/female actors. The speech signals in the KBES dataset have a length of three seconds and a sample rate of 48 kHz. The developed dataset seems a realistic one when compared with the existing SER datasets. The developed KBES dataset is publicly available and recently published data article holds its description [22].

B. Experimental Setup

The Python Librosa library [23] was used to trans-form speech signals of the KBES dataset. To make speech signals (having a length of three seconds and a sample rate of 48 kHz) in the KBES dataset suitable for DL input, the signal samples were resampled to 42.66 kHz. As a result, a speech signal was transformed into 127,980 bit-vectors. By adding 20 bits of zeros with it, 128,000 bit-vectors were used as input for the DL model. The DL models were developed using open-source Python libraries, specifically Keras [24] and Tensorflow [25].

The experiments were executed using a Jupyter Notebook hosted on Google Colaboratory, a cloud service that provides GPU capability [26]. The personal computer was an HP Pavilion laptop with an Intel(R) Core i5-7200U CPU @ 2.50 GHz processor, 8 GB of RAM, and an NVIDIA GeForce 940MX Graphics Card.

We utilized the Adam optimizer with a learning rate of 10−4 and employed the categorical cross-entropy as the loss function for compiling the model. The model aims to reduce the categorical cross-entropy loss, a widespread loss function for multi-class classification problems [27]. During the training process, the model was trained for 60 epochs with a batch size of 16.

The KBES dataset was separated into a training set and a test set, with 80% of the samples used for training and the remaining 20% used for testing. The training set consisted of 720 samples collected from each of the nine categories and was utilized for training the model. The test set, made up of the remaining 180 samples, was kept aside to assess the model's generalizability after training. Since the major concern of any ML/DL model is to perform well beyond the training data (i.e., on unseen data), test set performance (generalization) is a key performance measure of the developed model.

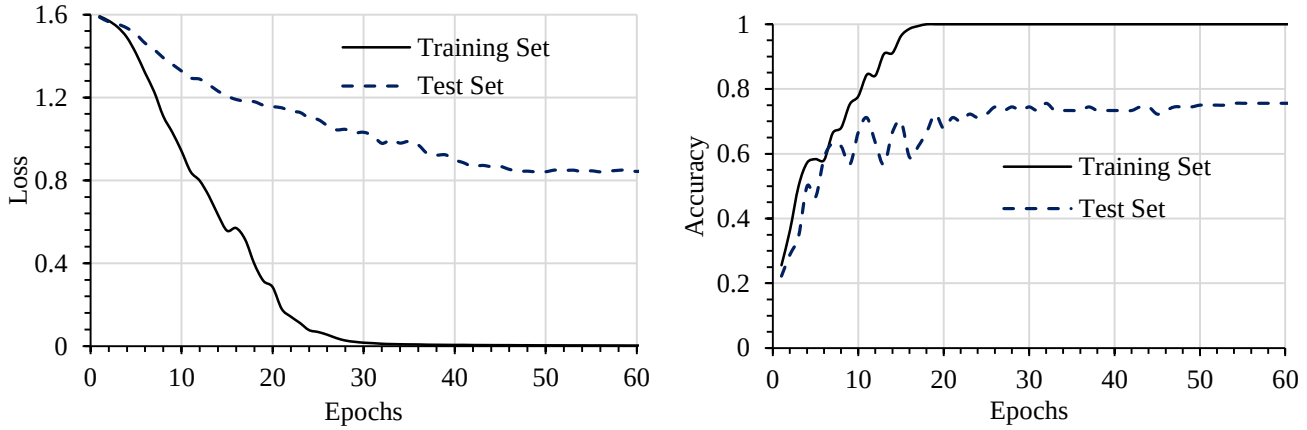
C. Outcomes of the Proposed Cascaded DL Model

The proposed cascaded model is carried out in two stages. In Stage 1, a DL model is trained with 720 training samples and tested with 180 samples for emotional classification. Fig. 5 shows the loss and accuracy curves of both the training and test sets in Stage 1 (i.e., for DLEmotion). The training set loss reduces smoothly and reaches close to zero after 30 epochs, while the test set loss reduces initially and then stabilizes after 45 epochs. Consequently, accuracy reached 100% for the training set through smooth improvement, while the best test set accuracy was close to 76%.

Table II shows the confusion matrix on the test set on emotion classification only (without intensity) in Stage 1. For example, for 40 happy samples, the model correctly identified 28. The remaining 12 happy samples were misclassified as Neutral, Sad, Angry, and Disgust in cases 5, 1, 2, and 4, respectively. There is a total of 45 misclassifications, which are in category misses. With a true classification of 135 samples, the DL model shows an accuracy of 75.56% in emotion classification, regardless of the intensity.

In Stage 2 of the proposed DL model, the samples classified in Stage 1 were used to determine the emotional intensity with a DL model for a particular emotion category. In this stage, four DL models are trained, and a particular DL is trained with the samples for a particular emotion category. As an example, there are a total of 160 training samples for Happy emotion (80 samples for each of Normal and Strong intensity cases) in 720 training samples. These 160 happy samples were used to train the DL model (i.e., DLHappy) to classify the intensity of Happy emotion. The intensity level of Happy emotion was tested using 40 samples from the test set.

Similarly, the other three different DL models (i.e., DLSad, DLAngry, and DLDisgust) were trained and tested for intensity level classification of Sad, Angry, and Disgust emotions. In Stage 2, the intensity of a sample will be classified by the designated DL model for the classified emotion in Stage 1. If a sample is misclassified in Stage 1 (i.e., a Category Miss), there is no remedy in Stage 2, and treated as Category Miss. On the other hand, a truly classified sample in Stage 1 may be wrongly classified in the case of Intensity Level in Stage 2, which is called Intensity Miss. Therefore, due to the inclusion of intensity miss in Stage 2, the classification accuracy of emotion with intensity is lower than the accuracy of emotion classification by Stage 1.



(a) Loss vs epochs (b) Accuracy vs epochs

Fig. 5. Loss and accuracy curves of training and test sets of the DL model in Stage 1 in the proposed cascaded DL model.

TABLE II. TEST SET CONFUSION MATRIX ON EMOTION CLASSIFICATION (WITHOUT INTENSITY) IN STAGE 1 OF THE CASCADED DL

Emotion	Neutral	Happy	Sad	Angry	Disgust	Correctly Classified	Category Miss	Total Samples
Neutral	13	1	1	3	2	13	7	20
Happy	5	28	1	2	4	28	12	40
Sad	2	2	32	1	3	32	8	40
Angry	0	0	0	35	5	35	5	40
Disgust	1	0	3	8	28	28	12	40
Total						**136**	**44**	**180**

TABLE III. THE TEST SET CONFUSION MATRIX ON EMOTION RECOGNITION WITH INTENSITY LEVEL BY THE CASCADED DL MODEL

Emotion	Emotion Intensity	Neutral	Happy		Sad		Angry		Disgust		Category Miss	Intensity Miss	Total Samples
			Low	High	Low	High	Low	High	Low	High			
Neutral	-	13	1	0	1	0	2	1	2	0	7	0	20
Happy	Normal	3	14	1	0	0	0	0	2	0	5	1	20
	Strong	2	0	13	0	1	2	0	0	2	7	0	20
Sad	Normal	2	1	0	15	0	0	0	1	1	5	0	20
	Strong	0	0	1	1	16	1	0	0	1	3	1	20
Angry	Normal	0	0	0	0	0	15	2	2	1	3	2	20
	Strong	0	0	0	0	0	0	18	0	2	2	0	20
Disgust	Normal	1	0	0	2	0	3	1	11	2	7	2	20
	Strong	0	0	0	0	1	0	4	1	14	5	1	20
Total											**44**	**7**	**180**

Table III depicts the confusion matrix of the pro-posed cascaded model with Stage 1 + Stage 2. The ma-trix reveals both category and intensity miss for the four emotions. As Neutral emotion has no intensity measure, it holds only category miss, and the number of misclassifications is seven as of Table II. Again, out of the 28 correctly classified Happy emotion samples in Stage 1, one sample of Happy (Low) was misclassi-fied as Happy (High) in Stage 2; thus, Intensity Miss of Happy is one. The total category miss of the Happy was 12 in Table II, which just distributed for Happy (Low) and Happy (High) in Table III. Among category miss cases, three Happy (Low) were misclassified as Neutral, which is the highest misclassification as Neutral. Such misclassification of Happy samples is logical as it is generally accepted that Happy (Low) is close to Neu-tral. On the other hand, no Angry samples are misclas-sified as Neutral or Happy, and five Angry samples are misclassified as Disgust. Including proficiency in Sad and Disgust samples, the performance of the proposed cascaded DL model on an unseen test set of unique KBES datasets is remarkable. With a total of 51 misclassifications (=44 Category Miss +7 Intensity Miss) out of 180 test speeches, the resulting test set accuracy is 71.67% (i.e., (180-51)/100).

D. Preference for Cascaded DL Model over Single DL Model

The proposed cascaded model consists of five hybrid CNN-LSTM DL components where individual compo-nent performs different tasks. The individual DL com-ponents classified the samples into nine categories through task division. It is also possible to perform the task in a single stage by a single DL model having nine neurons in its output layer. Therefore, it is a common query to select a cascaded model with five DL components over the single DL model. Additional experiments with a single DL have been conducted to observe the effectiveness of the proposed cascaded model over a single DL. Experiments were also conducted with samples of male and female actors separately for better observations.

Table IV compares the performance of the proposed cascaded model with a single DL model for a full test set, male and female actors' samples. While full set training and test samples are 720 and 180 as of previous experiments, as the KBES dataset is balanced for male and female cases, training and test samples for males or females are 360 and 90, respectively. Ac-cording to the table, performances for male and female cases are competitive in both single DL and cascaded DL models. Furthermore, both DL models (i.e., single or proposed cascaded) show competitive performance in case of category miss. As an example, both the models misclassified equal 21 samples for the female case. The remarkable performance distinction between the two models is observed in the case of intensity classifica-tion, and the cascaded model remarkably outperformed the single DL model. The intensity missed cases by single DL model for male, female, and full set cases are 14, 13, and 23, respectively. The intensity missed cases for male, female, and full set by the cascaded model are 4, 5, and 7, respectively. Due to such outperformance in intensity classification, the overall accuracy of the cascaded DL model is much better than the single DL model. At a glance, the proposed cascaded DL model showed a full test set accuracy of 71.67% (as also discussed in the previous section), whereas the single DL model's accuracy on a full test set is 61.11% (= (180-47-23)/180). The outperformance of the cascaded DL model reflects the effectiveness of its task division in two stages as well as validates the appropriateness of selecting the cascaded model.

E. Performance Comparison with Different Speech Signal Transformations

The integrated 3D form of feature formation using MFCC, STFT, and CSTFT from the input speech signal is a crucial task of the proposed method. To observe the effectiveness of using different feature forms, additional experiments have been conducted with different signal transformations individually and combining two or more among MFCC, STFT, and CSTFT. Table V provides performance results for a cascaded DL model using three individual speech transformation features (MFCC, STFT, and CSTFT), three double combinations (MFCC + STFT, STFT + CSTFT, and MFCC + CSTFT), and finally, proposed triple combination MFCC + STFT+ CSTFT. Appropriate DL architectures were con-sidered to classify emotions using distinct feature transformations. Among the individual methods, MFCC achieved the highest accuracy of 60.56%. However, the dual combination of MFCC and STFT has an accuracy of 61.67%, which is slightly better than the accuracy of MFCC. Finally,

the integrated 3D form of transformed MFCC, STFT, and CSTFT (i.e., MFCC + STFT+ CSTFT) achieved the best accuracy of 71.67%. The performance comparison justifies the use of a 3D form of a feature in this study.

TABLE IV. PERFORMANCE ON FULL TEST SET, MALE AND FEMALE ACTORS FOR SINGLE DL MODEL AND PROPOSED CASCADED DL MODEL

Particular of Samples	Training & Test Samples	Test Set Performance by the Single Deep Learning Model			Test Set Performance by the Cascaded Deep Learning Model		
		Category Miss	Intensity Miss	Accuracy (%)	Category Miss	Intensity Miss	Accuracy (%)
Male	360 & 90	18	14	64.44	20	4	73.30
Female	360 & 90	21	13	62.22	20	5	72.22
Full Set (= Male + Female)	720 & 180	47	23	61.11	44	7	71.67

TABLE V. PERFORMANCE COMPARISON ON THE TEST SET WITH DIFFERENT SIGNAL TRANSFORMATIONS FOR CASCADED DEEP LEARNING MODEL

Combination	Signal Transformation	Sequences × Frames ×Dimension	Category Miss	Intensity Miss	Truly Classify	Accuracy (%)
Individual	Mel-Frequency Cepstral Coefficient (MFCC)	128×513×1	50	21	109	60.56
	Short-Time Fourier Transform (STFT)	128×513×1	53	27	100	55.56
	Chroma STFT (CSTFT)	128×513×1	62	33	85	47.22
Double	MFCC+STFT	128×513×2	53	16	111	61.67
	STFT+CSTFT	128×513×2	57	27	96	53.33
	MFCC+CSTFT	128×513×2	50	23	107	59.44
Proposed Triple	MFCC+STFT+CSTFT	128×513×3	44	7	129	71.67

F. Performance Comparison Varying DL Architecture

The DL architecture employed in this study to classify emotions from 3D feature maps is 4 3D-CNN + TDF + Bi-LSTM + LSTM, which is a hybrid CNN and LSTM model. In the model, 3D CNN with four layers is the main component to extract features to classify the input 3D feature sample. It is also possible to perform classification from CNN features using one/two FC layers. Distinct experiments with TDF, LSTM, and Bi-LSTM options have been conducted, and Table VI compares performance on the test samples classification by the considered DL architectures. The comparison in Table VI indicates that our proposed model achieves the highest accuracy over all other models. It is seen from the table that the 4 3D-CNN + 2 FC architecture is the simplest one and showed the lowest ac-curacy, which is 62.78%. The architecture holds two FC layers on 3D CNN, while other architectures hold one FC layer by default on top of the relatively complex DL architectures. In general, accuracy seems to be improved with architectural complexity. Finally, the considered hybrid architecture of CNN, LSTM, and Bi-LSTM shows the best accuracy of 71.67%. The performance comparison justifies the employment of the hybrid DL architecture 4 3D-CNN + TDF + Bi-LSTM + LSTM to achieve better emotion recognition using the KBES dataset.

G. Performance Comparison with Existing SER Meth-ods

According to our knowledge, this study is the pioneer for Bangla SER with intensity. The barrier was the speech emotion dataset with intensity measure, which is resolved in this study by developing the KBES dataset. Recent Bangla SER studies employed BanglaSER and SUBESCO datasets for emotion classification regardless of the intensity issue [16] [17]. On the other hand, the RAVDESS dataset for the English language has intensity identification and used SER with intensity in the recent study by Islam et al. [4]. In the following subsections, the proposed model (i.e., Stage 1) is com-pared with several existing methods for emotional classification only on BanglaSER, SUBESCO, RAV-DESS, and KBES datasets. Then, a rigorous comparison is performed for SER with intensity considering RAV-DESS and KBES datasets. Notably, the SER datasets hold different numbers of samples, and there are 1467, 7000, 1440, and 900 samples in BanglaSER, SUBESCO, RAVDESS, and KBES datasets, respectively. Although the KBES dataset holds the lowest number of samples, it is the most unique among other datasets regarding the number of individual speech dialogs, the number of individual actors, and the realistic manner of the samples.

Table VII compares emotional classification regard-less of intensity using Stage 1 of the proposed cascaded method with other existing methods on KBES and three other SER datasets: BanglaSER, SUBESCO, and RAVDESS. The test set accuracy for each method was evaluated using the 20% of reserved test speech samples for the individual datasets. The results presented in the tables show that the proposed method outper-forms all other methods for any dataset. For instance, the 7 CNN+2 FC [20] method showed an accuracy of 70.55% for BanglaSER, 78.14% for SUBESCO, 83.04% for RAVDESS, and 67.22% for KBES. In contrast, the proposed cascaded method achieved the highest accu-racy of 83.56% for BanglaSER, 90.14% for SUBESCO, 92.98% for RAVDESS, and 75.56% for KBES. Another observation from the table is that performance on the KBES dataset is the lowest, and the RAVDESS dataset is the highest among the datasets for any individual method. For example, the 4 CNN+TDF+Bi-LSTM [14] model showed the lowest accuracy of 72.78% for KBES and 88.89% for RAVDESS. BanglaSER, SU-BESCO, and RAVDESS hold a fixed number of speeches with repetition, whereas the KBES dataset

consists of a distinct number of speeches to form a realistic environment. Therefore, the lowest performance on the KBES dataset for Bangla SER is logical for such a realistic environment with challenging samples.

TABLE VI. TEST SET PERFORMANCE VARYING DEEP LEARNING ARCHITECTURES IN THE PROPOSED CASCADED MODEL

Deep Learning Architecture	Category Miss	Intensity Miss	Truly Classified	Accuracy (%)
4 3D-CNN+2 FC	52	15	113	62.78
4 3D-CNN+LSTM	51	13	116	64.44
4 3D-CNN+Bi-LSTM	48	14	118	65.56
4 3D-CNN+TDF+LSTM	47	9	124	68.89
4 3D-CNN+TDF+Bi-LSTM	46	10	124	68.89
4 3D-CNN+TDF+Bi-LSTM+LSTM	44	7	129	71.67

TABLE VII. COMPARISON OF EMOTION CLASSIFICATION WITHOUT INTENSITY LEVEL (STAGE 1) ON FOUR SER DATASETS

Work Ref., Year	Feature	DL Architecture	Test Set Accuracy (%)			
			BanglaSER	SUBESCO	RAVDESS	KBES
[20], 2019	Log-Mel-Spectrograms	7 CNN+2 FC	70.55	78.14	83.04	67.22
[18], 2019	Log-Mel-Spectrograms	4 CNN+LSTM	75.69	81.57	86.55	70.56
[16], 2022	Log-Mel-Spectrograms	4 CNN+TDF+Bi-LSTM	78.77	87.21	88.89	72.78
[4], 2022	MFCC + STFT + CSTFT	4 3D-CNN+TDF+Bi-LSTM	80.48	89.43	91.23	73.88
Proposed Method	MFCC + STFT + CSTFT	4 3D-CNN+TDF+Bi-LSTM + LSTM	83.56	90.14	92.98	75.56

TABLE VIII. COMPARISON OF EMOTION CLASSIFICATION WITH INTENSITY LEVEL ON RAVDESS AND KBES DATASETS

Work Ref., Year	Feature	DL Architecture	RAVDESS		KBES	
			Single DL Model	Cascaded DL Model	Single DL Model	Cascaded DL Model
[20], 2019	Log-Mel-Spectrograms	7 CNN+2 FC	69.01	74.27	51.11	60.56
[18], 2019	Log-Mel-Spectrograms	4 CNN+LSTM	73.68	79.53	53.89	64.44
[16], 2022	Log-Mel-Spectrograms	4 CNN+TDF+Bi-LSTM	77.19	83.04	57.22	67.78
[4], 2022	MFCC + STFT + CSTFT	4 3D-CNN+TDF+Bi-LSTM	80.12	86.55	58.89	69.44
Proposed Method	MFCC + STFT + CSTFT	4 3D-CNN+TDF+Bi-LSTM+LSTM	84.21	88.30	61.11	71.67

Table VIII compares emotion classification with intensity among the different DL architectures for both single DL and cascaded DL models on RAVDESS and KBES datasets as they hold intensity marked. The 7 CNN+2 FC [20] architecture showed accuracies for the RAVDESS dataset are 69.01% and 74.27% by the single DL and the cascaded DL models, respectively. For the KBES dataset, the same architecture achieved 51.11% and 60.56% by the single DL and the cascaded DL models, respectively. At a glance, the proposed cascaded DL model outperformed single DL for both datasets. Again, the proposed SER method with 3D features and hybrid DL architecture achieved higher accuracy than other existing methods. The proposed cascaded method achieved the best accuracy of 88.30% for the RAVDESS dataset and 71.67% for the KBES dataset. The achieved performances on the RAVDESS dataset are also better or more competitive than the reported results in the recent study [4]. The outcomes for KBES are also remarkable due to its complexity and uniqueness in the samples. Finally, the proposed cascaded model using four 3D-CNN+TDF+Bi-LSTM+LSTM is the most suitable approach for Bangla SER with intensity.

V. CONCLUSIONS

This study has proposed automated recognition of emotion with intensity level from speech signals in Bangla, a globally popular and primary spoken language in South Asia with growing speakers worldwide in the era of trade and labor globalization. Since di-verse online social media and platforms have become substantial modes of verbal communication and emotional expression, SER is necessary to detect unusual or harmful human behaviors automatically. Therefore, emotion identification and its intensity of expression are significantly discussed in this study for Bangla through developing a novel DL-based cascaded model. The major steps of the proposed model are the trans-formation of speech signal 3D form integrating three different 2D transformations and then employing a cascaded DL model having hybrid DL architectures (consisting of CNN, Bi-LSTN, and LSTM) in its two stages for emotional classification and intensity level identification accordingly. For developing a realistic model, this study considered the KBES dataset, which holds natural speech samples, and its development is also a significant contribution to this study. Rigorous experiments have been conducted with KBES and other SER datasets in

Bangla and English. The proposed cascaded model has been identified as the best-performing SER method compared to several main-stream DL methods. At a glance, the proposed cascaded DL model showed its superiority over the existing Bagla SER methods, performing KBES test set accuracy of 71.67% for emotion classification with intensity and 75.56% regardless of speech intensity (i.e., excluding intensity miss cases).

Several prospective research scopes have been revealed from this study. KBES dataset is the only Bangla SER with intensity measure, which seems realistic with respect to other datasets. The best-achieved performance with the dataset (i.e., 75.56%) is lower than the other datasets. Therefore, it remained an open challenge to develop better realistic SER methods based on it, especially for Bangla. For simplicity, the same hybrid DL architecture and training process is used in both stages of the cascaded model; different DL architectures for emotion classification and intensity measures and individual fine tunings of different DL architectures might give better performance. Further-more, other speech signal transformations and integration techniques might perform better.

***Abstract*—Accurate license plate recognition (LPR) remains a crucial task in various applications, from traffic monitoring to security systems. However, noisy environments with challenging factors like blurred images, low light, and complex backgrounds can significantly impede traditional LPR methods. This work proposes a deep learning based LPR system optimized for performance in noisy environments through hyperparameter tuning and bounding box refinement. We first preprocessed the noisy images by noise reduction which is crucial for robust LPR. We employed Convolutional Autoencoder (CAE) trained on noisy/clean image pairs to remove noise and enhance details. We utilized the InceptionResNetV2 architecture, pre-trained on ImageNet, for its strong feature extraction capabilities. We then added Region Proposal Network (RPN) head added to InceptionResNetV2 to predict candidate bounding boxes around potential license plates. We employed grid search to optimize key hyperparameters like learning rate, optimizer settings, and RPN anchor scales, ensuring optimal model performance for the specific noise patterns in the target dataset. Non-maximum suppression (NMS) eliminates redundant proposals, and a separate detection head classifies each remaining bounding box as license plate or background. Finally, bounding boxes are refined for improved accuracy. For confirmed license plates, a Bidirectional LSTM/CRNN network extracts and decodes character sequences within the refined bounding boxes. Compared to the recent methods, the proposed approach yielded the highest detection and recognition performance in noisy environments which can be best utilized for monitoring traffic, security systems in noisy environment. Our optimized LPR system demonstrates significantly improved accuracy and robustness compared to baseline methods, particularly in noisy environments.**

Keywords*—*De-noising; image analysis; image processing; computer vision; image restoration

I. Introduction

De-noising remains a fundamental challenge in image processing, playing a crucial role in enhancing visual content quality and safeguarding image integrity. Noise, an unwelcome guest in visual data, degrades clarity and can significantly disrupt various image analysis and processing tasks, such as semantic segmentation and classification [1]. The need for robust approaches to combat visual degradation, encompassing noise and blurriness, is constantly growing within the realm of computer vision. This need has spurred the development of image restoration techniques, dedicated to reconstructing pristine images from their corrupted counterparts [2–6]. In this revised version, the opening sentence clarifies the focus on denoising as a core challenge. Redundant phrasing is streamlined, and the reference is integrated smoothly. Moreover, "visual degradation" is introduced as a broader concept encompassing both noise and blurriness, creating a more cohesive flow.

A corrupted picture Y could be expressed as follows in the generic restoration task:

$$Y = F(X_t) + N$$

where, X_t denotes an unaltered image, F(.) stands for the degradation function, and N represents the additional noise. While previous research, including a recent ConvNet-based technique [7] has achieved impressive results, inherent limitations remain. One limitation lies in the static nature of convolution kernels in standard convolutional layers. These kernels lack content-awareness, limiting their ability to adapt to varying image regions and recover diverse image features effectively [8]. Furthermore, overly aggressive use of long-range dependency modeling in some solutions, resembling small "peeking windows," can unintentionally sacrifice global information crucial for holistic image understanding [9–14]. Several existing approaches, such as adaptive convolution, non-local CNNs, and global average pooling, attempt to address these challenges [15], However, their solutions often tackle symptoms rather than underlying causes, resulting in limited effectiveness. Swin Transformer, a novel backbone architecture introduced in a recent study [8], demonstrates exceptional performance in image classification. Its modular design and hierarchical attention mechanisms overcome the limitations of traditional CNNs, paving the way for more precise and nuanced feature extraction. Moreover, the versatility of Swin Transformer has been showcased in various computer vision tasks beyond classification, including image segmentation, object recognition, and super-resolution [8].

Imagine driving down a bustling highway, each passing car leaving a fleeting whisper of its identity on your screen. That's the magic of License Plate Recognition (LPR). This sophisticated technology delves into the realm of computer vision, extracting vital information from the metal tags adorning vehicles. Through the power of deep learning algorithms, LPR systems sift through pixels, unearthing the unique sequence of characters that identify each automobile.

It's not just about recognizing letters and numbers [16–19]. LPR can decipher complex challenges like blurry images, low light, and even obscured plates. Imagine it as a detective cracking the code of the road, unlocking a wealth of data for diverse applications. Traffic monitoring becomes a breeze, with systems automatically tracking movement and analyzing flow. Parking enforcement gains teeth, identifying violators with ease. Security systems receive a boost, cross-referencing plates with watchlists in real-time. LPR even plays a role in toll collection, streamlining the process and minimizing human error.

The ever-evolving urban landscape demands sophisticated Intelligent Transportation Systems (ITS) to ensure improved safety, optimize traffic flow, and automate essential tasks like toll collection and law enforcement [20]. As central components of smart cities, ITS rely heavily on robust Automatic License Plate Recognition (ALPR) for vehicle identification and monitoring [21]. However, achieving reliable ALPR across diverse environments remains a significant challenge. The complexities of real-world traffic introduce significant hurdles: varying lighting, camera angles, image noise, and distortions all hinder consistent plate recognition [16, 22–25]. While existing computer vision and AI algorithms excel in controlled settings, their performance often suffers in dynamic situations [26]. Additionally, traditional stationary ALPR cameras mounted on infrastructure have limited coverage, leaving gaps in crucial network monitoring [27].

Our system leverages several key innovations:

- Noise reduction with Convolutional Autoencoders (CAEs): We pre-train CAEs on noisy/clean image pairs to effectively remove noise and enhance details before feature extraction, ensuring clearer input for the deep learning model.
- Powerful feature extraction with InceptionResNetV2: We utilize the pre-trained InceptionResNetV2 architecture for its robust feature extraction capabilities, allowing the model to effectively identify relevant patterns within noisy images.
- Hyperparameter-optimized Region Proposal Network (RPN): We add an RPN head to InceptionResNetV2 and employ grid search to optimize key hyperparameters like learning rate and anchor scales. This fine-tuning ensures optimal performance for the specific noise patterns present in the target dataset.
- Refined bounding boxes and character recognition: Non-maximum suppression eliminates redundant proposals, a separate head classifies remaining boxes as "license plate" or "background," and further refinement improves accuracy for precise plate detection. Confirmed license plates undergo character sequence extraction with a Bidirectional LSTM/CRNN network for accurate recognition.

Extensive testing demonstrates that our optimized LPR system significantly outperforms baseline methods, particularly in noisy environments. This superior performance makes it ideal for real-world applications requiring robust and accurate license plate recognition. We plan to continue exploring novel techniques like attention mechanisms and pre-trained character recognition models to further enhance performance and enable real-time LPR in resource-constrained environments.

II. Related Work

Image denoising architectures strive to resurrect pristine images from their corrupted counterparts. Fueled by advancements in hardware like GPUs, learning-based methods have usurped traditional model-based approaches, achieving substantial gains in both speed and accuracy. To illuminate this evolution, we will embark on a two-fold exploration. First, we will delve into the historical tapestry of denoising techniques, dissecting their strengths and limitations. Subsequently, we'll shift gears and explore the cutting-edge realm of license plate detection and recognition, where learning-based methods reign supreme.

A. Image Denoising

Traditional image restoration approaches often rely on model-based techniques like self-similarity, sparse coding, and total variation [28]. While effective in tackling certain issues, these methods can be time-consuming, computationally demanding, and struggle with complex restoration tasks. With the emergence of learning-based methods, particularly Convolutional Neural Networks (CNNs), computer vision has been revolutionized, especially in tasks like image restoration, due to their superior performance. UNet [29] has become a popular architecture in image processing thanks to its use of deep network maps for extracting rich multi-scale features. Skip connections further enhance image quality by bridging the gap between contraction and expansion stages. This versatility has made UNet a workhorse for various computer vision tasks, including segmentation and restoration [30]. Numerous derivatives like DenseUNet [31], and Non-UNet [32] have also emerged, expanding its capabilities. UNet's adaptability shines when coupled with different execution blocks, further boosting image quality. For instance, researchers [33] incorporated a diffusion kernel within UNet to recover fine details in textured images. This kernel adapts to the changing image information, leading to sharper and more faithful restorations.

While convolutional neural networks (CNNs) dominated image classification for years [34], the Transformer architecture, heralded for its success in natural language processing, emerged as a powerful challenger [35]. However, its dependence on quadratic scaling for extended sequence modeling can pose challenges. Filling this gap is LPRGAN, a lightweight deep learning system designed for image recovery tasks, particularly license plate recognition in traffic camera streams [36]. This efficient and self-aware system, capable of anomaly detection and adaptable to low-power devices, unlocks intriguing possibilities for on-device computing. Impressively, it delivers high-quality image recovery (up to 720p) at high frame rates. Another noteworthy approach employs diffusion models, offering substantial improvements in image quality and human preference for license plate recognition in surveillance systems [37]. This cutting-edge method surpasses traditional AI techniques, showcasing its

potential as a promising solution for enhancing visual clarity in challenging environments.

B. License Plate Detection and Recognition

The quest for accurate license plate recognition (LPR) has spurred numerous research efforts, each tackling the challenges of detection, segmentation, and identification in unique ways. In the realm of object detection, various techniques have been employed. One approach [38] modifies the YOLO model, shrinking its layers from 27 to a nimble 13 (7 CNN and 6 dense layers). This streamlined "small model" focuses solely on detecting LP, classifying it as one specific class. Despite its specialization, it achieves impressive results on a Taiwanese license plate dataset: 98.22% detection accuracy and 78% recognition accuracy. Another study [39] deconstructs LPR into distinct stages: plate detection and character recognition. A custom YOLOv3 variant handles the initial detection, resizing the cropped image to a standard 224x224 pixels. Notably, the final layer of the original YOLO model is adapted to work with both grayscale and color images. A second YOLOv3 network then takes over for character recognition. This two-stage approach shines on Iranian license plates, achieving a detection accuracy of 97.77% and a character recognition accuracy of 95.05%

A diverse array of approaches tackles the challenges of LPR detection. Based on YOLO-based methods, one study [40] uses a modified YOLO model for detection and an OCR system for character recognition. They address camera angle variations through pre-processing with Hough transform and rotation filters, before feeding the image to the YOLO model. Another [41] subdivides the image into grid cells and performs YOLOv3 predictions within each, identifying the cell with the highest confidence for plate detection. By utilizing CNN-based methods another approach [42] extracts candidate plates based on edge and geometric features before feeding them to a CNN classifier for final detection. Similarly, [43] employs edge and geometric information for candidate extraction followed by CNN classification. Researchers also used other techniques including vertical projection strategy scanning for specific width criteria is used [44] builds a CNN model trained on synthetic images. The researchers [45] proposes a framework addressing various image quality issues. Beyond basic detection, some studies focus on specific sub-tasks within LPR. Character recognition employed by [46] that combines a cascade CNN for plate detection with an RNN for character recognition. Image enhancement utilized by [46] to further employs a GAN to improve overall ALPR accuracy. The Real-world applications used by [47] demonstrates the application of a YOLO-based model for helmet compliance detection, expanding the potential of LPR systems in traffic management and law enforcement.

III. Methodology

This section described the methods utilized to detect and recognize the license plates in a noisy environment by developing and optimizing preprocessing algorithms, deep learning InceptionResNetV2 with hyperparameters optimization. The details are depicted below:

A. An Optimized Deep Learning based License Plate Detection Algorithm

1) Algorithmic Steps

Step 1: Preprocess an image for the model

```
def preprocess_image(image, target_size=(224, 224),
  color_mode="RGB"):
  """
  Preprocesses an image for further use in the license plate
  detection and recognition pipeline.
  Args:
      images: the input image to be processed.
      target image: the desired size (height, width) to resize
      the image to (default: 224x224).
      color_mode: the desired color mode for the image
      ("RGB", "grayscale", or "LAB") (default: RGB).
  Returns:
      The preprocessed image ready for model input.
  """
  image = resize_image(image, target_size)
  if color_mode != "RGB":
      image = convert_color(image, color_mode)
  image = denoise_image(image, trained_cae)  # Optional
  denoising step
  return image
```

Step 2: Create the license plate detection and recognition model

```
def
create_model(base_model_name="InceptionResNetV2"):
  """
  Loads a pre-trained model and adds custom heads for
  object detection (specifically license plates) and license
  plate character recognition.
  Args:
      base_model_name: The name of the pre-trained model
      to use (default: InceptionResNetV2).
  Returns:
      The compiled model with RPN, detection, and
      recognition heads for license plate tasks.
  """
  base_model = load_model(base_model_name)
  freeze_lower_layers(base_model)
  rpn = add_rpn_head(base_model)
  detection_head = add_detection_head(base_model)
  recognition_head = add_recognition_head(base_model)
  model = combine_heads(base_model, rpn, detection_head,
  recognition_head)
  compile_model(model)  # Compile the model for training
  return model
```

Step 3: Process bounding boxes to identify and recognize license plates

```
def process_bounding_boxes(model, image, bounding_boxes,
  threshold=0.5):
  """
  Processes a list of bounding boxes to identify potential
  license plates and recognize their text.
```

```
    Args:
        model: the trained model with detection and
        recognition heads for license plates.
        image: the input image containing bounding boxes.
        bounding_boxes: list of bounding box coordinates for
        potential objects.
        threshold: confidence threshold for classifying a
        bounding box as a license plate (default: 0.5).
    Returns:
        The recognized license plate text (if found), otherwise
        None.
    """
    for box in bounding_boxes
        cropped_image = extract_roi(image, box)
        is_license_plate = predict_class(model.detection_head,
        cropped_image, threshold)
        if is_license_plate:
          recognized_text =
          recognize_characters(model.recognition_head,
          cropped_image)
          return recognized_text
    return None  # No license plate detected in the bounding
    boxes
```

Step 4: Find the best hyperparameters for the model based on a chosen metric

```
  def find_best_hyperparameters(model, train_set, val_set,
    metric="mAP"):
    """
    Finds the best hyperparameter combination for the model
    based on a chosen evaluation metric.
    Args:
        model: the model to train with different
        hyperparameter configurations.
        train_set: the training dataset for training the model.
        val_set: the validation dataset for evaluating the model
        during hyperparameter tuning.
        metric: the metric to optimize for during
        hyperparameter search (default: mAP - mean Average
        Precision).
    Returns:
        The dictionary containing the best hyperparameter
        combination that achieved the optimal value for the
        chosen metric.
    """
    best_value = -float("inf") if metric == "mAP"
      else float("inf")  # Initialize based on metric
    best_hyperparameters = None
    for hyperparameter_combination in grid_of_hyperparame-
    ters:
      train_model(model, train_set, hyperparameter_combi-
      nation)
      metric_value, _ = evaluate_model(model, val_set)
      if (metric == "mAP" and metric_value > best_value) or \
          (metric == "CER" and metric_value < best_value): #
          Handle minimization (CER)
```

B. Bounding Box Algorithmic Steps for License Plate Detection

These steps outline the essential algorithms commonly used for license plate detection using bounding boxes:

Step 1: Generate region proposals

```
  def generate_region_proposals(model, image):
    """
    Generates region proposals (potential bounding boxes) for
    objects in the image.
    Args:
        model: The model with a base model for feature
        extraction and RPN head for proposal generation.
        image: The preprocessed image.
    Returns:
        A list of proposed bounding boxes with their scores.
    """
    preprocessed_image = preprocess_image(image)  # Ensure
    image is preprocessed
    feature_maps = model.base_model(preprocessed_image)
    proposals = model.rpn(feature_maps)
    return proposals
```

Step 2: Apply non-maximum suppression

```
  def apply_non_maximum_suppression(proposals, iou_thre-
    shold):
    """
    Applies Non-Maximum Suppression (NMS) to remove
    redundant bounding box proposals.
    Args:
        proposals: List of proposed bounding boxes with their
        scores.
        iou_threshold: The Intersection-over-Union (IoU)
        threshold for suppression.
    Returns:
        A list of non-suppressed bounding boxes.
    """
    sorted_proposals = sort_proposals_by_objectness(propo-
    sals)
    suppressed_proposals = []
    for proposal in sorted_proposals:
        keep = True
        for higher_ranked_proposal in suppressed_proposals:
          if calculate_iou(proposal, higher_ranked_proposal) >
          iou_threshold:
            keep = False
            break
        if keep
          suppressed_proposals.append(proposal)
    return suppressed_proposals
```

Step 3: Classify and refine boxes

```
  def classify_and_refine_boxes(model, image, proposals):
    """
    Classifies proposals as license plates and refines their
    bounding boxes.
    Args:
```

```
    model: The model with detection head for classification and a way to refine bounding boxes.
    image: The preprocessed image.
    proposals: List of non-suppressed bounding box proposals.
  Returns:
    A list of refined bounding boxes classified as license plates.
  """
  refined_boxes = []
  for proposal in proposals:
    roi = extract_roi(image, proposal)
    classification, refined_coordinates = model.detection_head(roi)  # Get both classification and refinement
    if classification == "license_plate":
      refined_boxes.append(refined_coordinates)
  return refined_boxes
```

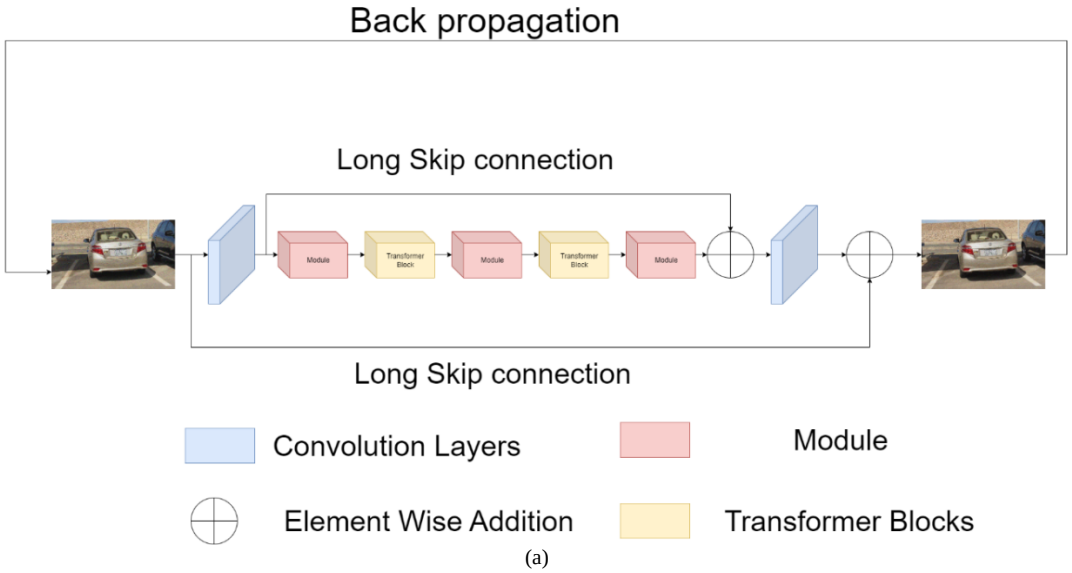
Step 4: Select final boxes

```
def select_final_boxes(refined_boxes, confidence_threshold):
  """
  Selects final bounding boxes based on a minimum confidence score threshold.
  Args:
    refined_boxes: A list of refined bounding boxes classified as license plates.
    confidence_threshold: The minimum confidence score required for a bounding box.
  Returns:
    A list of final bounding boxes exceeding the confidence threshold.
  """
  final_boxes = []
  for box in refined_boxes:
    if box.confidence_score > confidence_threshold:
      final_boxes.append(box)
  return final_boxes
```

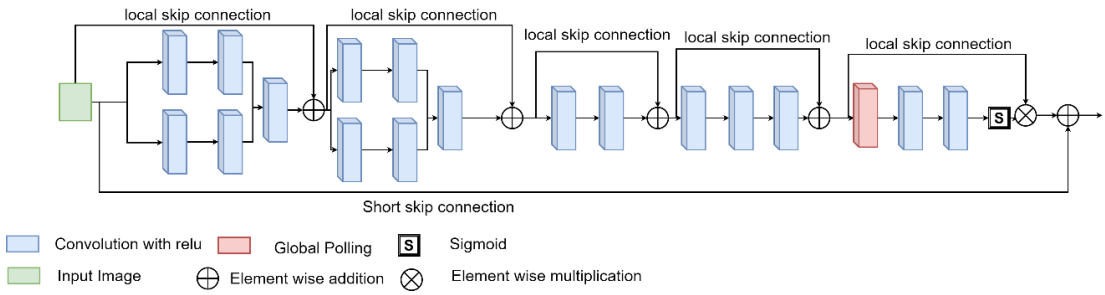
C. Image Pre-Processing

In this section, we will propose a de-noising model, then give detailed introduction to the proposed license plate detection and recognition model.

1) A denoising Model: The heart of our proposed network is a novel transformer model with rident architecture as shown in Fig. 1(a). Unlike typical network architectures, ours features three dedicated enhancement modules followed by two transformer modules [37]. This innovative approach utilizes long skip connections for preserving fine details in the predicted output from convolutional layers. The initial layer extracts fundamental features from the image with 64 filters and a 3x3 kernel. The final layer reconstructs a three-channel image using a 3x3 kernel with three filters. Each enhancement module employs a custom convolution-based architecture with dilation and residual feature learning for image enhancement as shown in Fig. 1(b). The process begins with two dilated convolutions on the input image features, followed by concatenation and another dilated convolution. Element-wise addition then fuses these enhanced features. Subsequently, a residual block with two convolutional layers performs feature learning, while an advanced residual block (ARB) with three convolutional layers handles compression. The ARB's final layer flattens the features using a 1x1 kernel. Finally, the feature attention unit output is combined with the module's input.



(a)



(b)

Fig. 1. Schematic diagram (a) The proposed model, (b) Enhancement module.

Residual blocks [48] have revolutionized image recognition, enabling the construction of networks with thousands of layers while maintaining accuracy and alleviating training challenges. Similarly, in super-resolution, Enhanced Deep Residual Networks (EDSR) [49] leveraged long skip connections to build exceptionally deep networks. However, exploring such extreme depths for image denoising remains largely uncharted territory. We take inspiration from [50] success with the residual-in-residual (RIR) structure, where residual groups (RGs) act as the core modules and long skip connections facilitate coarse residual learning. This allows building increasingly deep networks while maintaining efficient information flow and preventing vanishing gradients. Our proposed denoising network also adopts the RIR structure as its core module, paving the way for potentially even deeper architectures in the future.

This section will explore the mechanism of feature attention. Attention [51] has been utilized for a long time, but not in image denoising. The image restoration approaches regard channel characteristics equally, but it is not acceptable in numerous circumstances. To understand the key contents of an image, our attention is directed towards understanding the correlation among the channel characteristics. A key concern here is how to direct attention to individual channel-specific features in a unique manner. Images often consist of low frequency regions with flat or smooth parts and high frequency regions with lines, edges, and textures. Given that convolutional layers mostly rely on local information and lack access to global information, we begin by encapsulating the statistical features of the entire picture using global average pooling. We can further explore supplementary methods for feature aggregation to formulate the image descriptor.

Three enhancement modules and two transformer blocks are included in our suggested concept. The kernel size for each convolutional layer is set to 3x3 except for the last convolution layer in the enhanced residual block and those of the feature attention units.

To get the same size output feature maps, 3x3 kernel has zero padding. Except for feature attention downscaling, the number of channels in each convolutional layer is set to 64. These Conv layers are reduced by a factor of 16, resulting in only four feature maps. Depending on the input, the final conv layer produces 3 feature maps. In terms of execution time, our technique takes roughly 0.3 seconds to analyze 512 X 512 images.

2) Detection and recognition model: For detection and recognition, we proposed a small deep-learning model inspired by YOLOv3. It is a small model but shows the same accuracy as YOLOv3 [52] and some recent methods [53] in detection and recognition tasks. The proposed model consists of a total of 12 layers. For ground truth images, we used the LabelImg tool [54] which gives us the coordinates of license plates and also the coordinates of alphanumeric. For training purpose, we used 339 images to make ground truth. 70 percent of data was used for training purpose and 30 percent was used for validation of the model as shown in Table I. For training, we used a machine equipped with RTX 3050 to boost up the process.

TABLE I. TRAINING DATASET DATA SPLIT RATIO FOR LP DETECTION

Dataset Split Percentages	Split Percentages	Number of Frames
Training	70	238
Validation	30	101

For detection and recognition, a network of neurons with convolution layers at the start and fully connected layers at the end was utilized, as illustrated in Fig. 2. For detection and recognition of LP, a neural network architecture comprising convolutional layers at the initial stage and fully connected layers at the final stage was employed as illustrated in Fig. 2. The kernel size of each layer is 3x3 and filter size changes for layers as shown in Fig. 2. Each layer dimension is shown as height x width x dimension. In all convolution layers, we adjust the padding factor so the image size remains the same after the convolution operation is applied. After training the model, our model takes an image of size 512 x 512 x 3 as input and gives us coordinates of the license plate and alphanumeric characters with their corresponding class labels. The labels come in the form of 37 value vector that contains 37 confidence values (1 value for license plate, 10 values for numbers, and 26 values for alphabets). In the proposed method, only the license plates and alphanumeric labels that have confidence values greater than 0.6 are selected to filter out irrelevant labels. Following a series of testing on various license plates, the threshold value of 0.6 was chosen. Heuristically, we found the threshold value 0.6 gives good detection and recognition results.

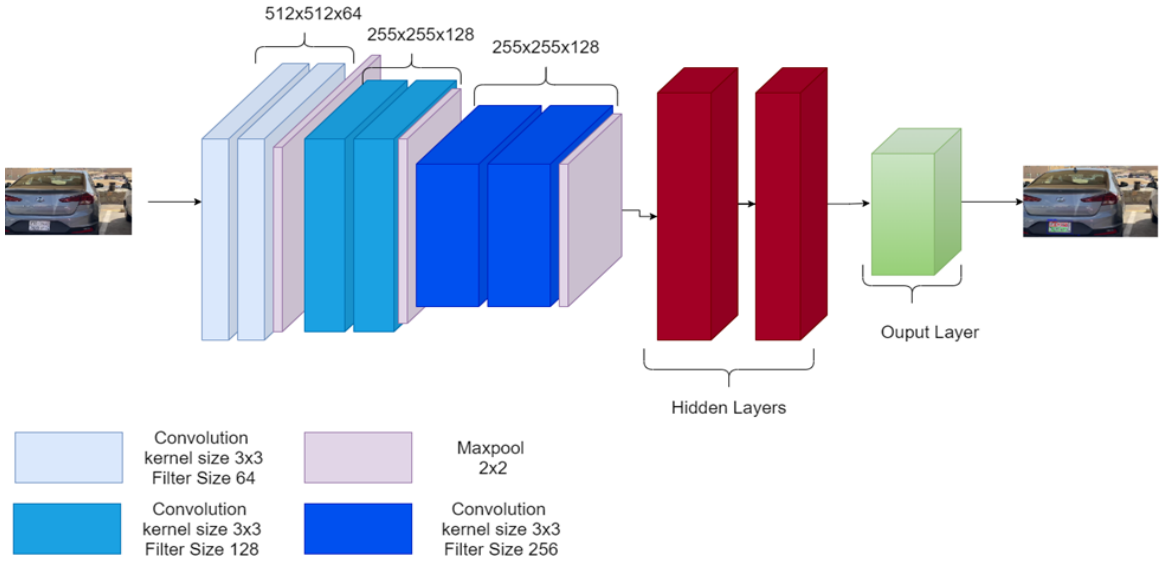


Fig. 2. Detection and recognition model.

D. Deep Learning Models for Detection and Recognition

1) InceptionResNetV2: Inception-ResNet-v2, a powerful deep convolutional neural network architecture, emerged from the minds of Christian Szegedy et al. in their 2016 paper "Inception-v4, Inception-ResNet and the Impact of Residual Connections on Learning" [55–58]. It masterfully combines two influential architectures, the Inception module and residual connections, resulting in a highly efficient and effective image processing tool. At its core, the Inception module prioritizes computational efficiency while maintaining strong performance. It achieves this by utilizing a variety of convolutions with different kernel sizes (1x1, 3x3, and 5x5) in parallel. This multi-scale approach allows the network to capture features at different resolutions, leading to richer feature representations. Additionally, the Inception module cleverly reduces the number of parameters needed compared to other contemporary architectures, making it more resource friendly. Residual connections play a crucial role in Inception-ResNet-v2 by facilitating information flow through the network. These connections directly add the input of a previous layer to the output of the current layer, allowing deeper networks to train effectively and avoid the vanishing gradient problem. This enables Inception-ResNet-v2 to achieve superior performance on image classification tasks compared to the original Inception architecture. The workflow of InceptionResNetV2 model is shown in Fig. 3.

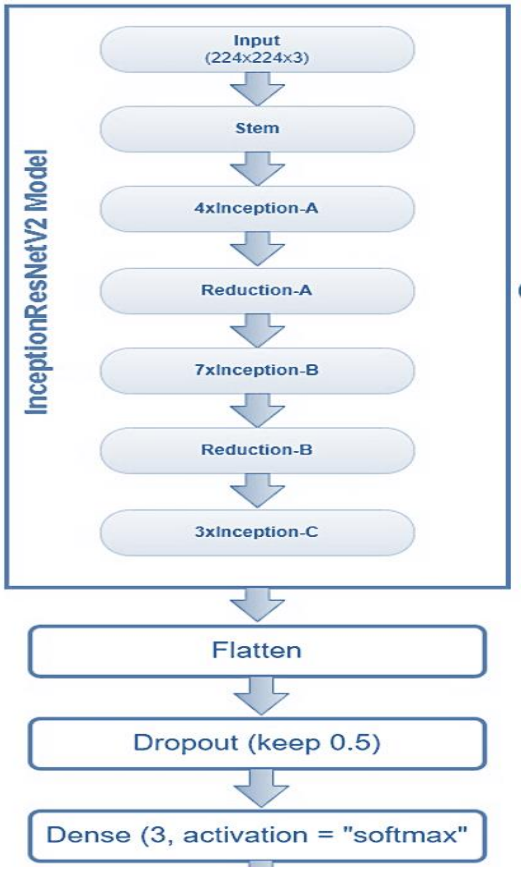

Fig. 3. Workflow of InceptionResNetV2 model.

The goal of the Inception-ResNetV2 architecture is to combine the efficient, multi-scale feature learning capabilities of the Inception architecture with the ability to use residual connections to improve training and generalization. It has been successful in a variety of tasks, including image classification and object detection. For better optimization of the results, the

following parameters were utilized and optimized for our Deep learning models.

2) Hyperparameters optimization: We optimized the hyperparameters of InceptionResNetV2 to find the best combination of hyperparameters that improves its performance on your specific task, like license plate detection and recognition. Grid search is a common technique that systematically explores different hyperparameter combinations and selects the one with the best performance.

```
Step 1: function define_hyperparameter_grid():
    grid = {
            "learning_rate": [0.01, 0.001, 0.003, 0.0005,
              0.0001],
            "optimizer": "adam",
            "optimizer_params": {
               "beta_1": [0.9, 0.95, 0.99],
               "beta_2": [0.99, 0.999]
            },
            "rpn_anchor_scales": [0.5, 1.0, 1.5],
            "rpn_anchor_aspect_ratios": [(1:2, 2:1, 1:1), (1:1.5,
              1.5:1)],
            "detection_head_layers": [2, 3, 4],
            "recognition_head_layers": [2, 3],
            "activation_function": ["adam", "relu",
              "leaky_relu", "tanh", "sigmoid"]
      }
   return grid

Step 2: function find_best_hyperparameters(model, train_set,
val_set, hyperparameter_grid):
    best_mAP = 0
    best_hyperparameters = None
    for hyperparameter_combination in create_combinations
    (hyperparameter_grid):
        train_model(model, train_set, hyperparameter_combi-
        nation)
          mAP, CER = evaluate_model(model, val_set)
          if mAP > best_mAP:
            best_mAP = mAP
            best_hyperparameters = hyperparameter_combi-
            nation
    return best_hyperparameters

Step 3: function fine_tune_hyperparameters(model, train_set,
val_set, best_hyperparameters):
    # Adjust grid around best_hyperparameters
    refined_grid = adjust_grid(hyperparameter_grid,
    best_hyperparameters)
    # Find best hyperparameters in refined grid
    best_hyperparameters = find_best_hyperparameters(
    model, train_set, val_set, refined_grid)
    return best_hyperparameters
```

The optimized parameters are reflected in Table II.

TABLE II. OPTIMIZED PARAMETERS INCEPTIONRESNETV2

DL Parameters	Optimal values
Solver name	Adam
Momentum (sgdm)	0.99
Initial learning rate	Single: 0.001
Epochs (maximum)	200
Mini batch (size)	16
Pairs of Conv. layers and filter stacks	3
Kernel depth (size of each filter stack)	64, 128, 256
Kernel size	3 × 3
ReLU layers	3
Pooling type	MaxPool (2 × 2)
Fully connected layers for latent features	2
Number of filter stacks	3
L2-regularization	0.0001
Input image size	64 x 64
Loss function	Cross Entropy
Number of dropout layers	1
Dropout rate (%)	20

IV. RESULTS AND DISCUSSIONS

Our system tackles the challenges of automatic license plate recognition through a multi-pronged approach. First, we pre-process images, smoothing away blur, enhancing contrast, and eliminating noise through specialized techniques like denoising autoencoders. This prepares the canvas for feature extraction, where we leverage the powerful InceptionResNetV2 architecture. However, we don't settle for its default settings. Instead, we meticulously fine-tune its hyperparameters, like learning rate and anchor scales, using advanced grid search methods. This ensures optimal performance for the specific noise patterns we encounter. Next, we employ a dedicated network component called a Region Proposal Network (RPN) to identify potential license plate locations within the image. Redundant proposals are then eliminated, and remaining bounding boxes are refined for pinpoint accuracy. Finally, we zoom in on these refined regions, employing a separate network head to definitively classify them as either "license plate" or "background." Confirmed plates undergo character extraction and decoding using a specialized Bidirectional LSTM/CRNN network, revealing the hidden code inscribed on the road's identity card.

A. Denoising

The template is designed so that author affiliations are not repeated each time for multiple authors of the same affiliation. Please keep your affiliations as succinct as possible (for example, do not differentiate among departments of the same organization). This template was designed for two affiliations.

1) Training settings: We use Saudi license plates [59] and publicly available license plates dataset [60] to make noisy synthetic images, and chop patches of 512 x 512 from SSID,

and RENOIR [61] to generate real noisy images. On training images, data augmentation is conducted, encompassing random rotations of 90, 180, and 270 degrees, along with horizontal flipping. Within each training batch, 32 patches measuring 80 x 80 are extracted as inputs. With the default settings, Adam [23] serves as the optimizer. We set the initial learning rate to 10^4 and then reduce it by half after 10^5 iterations.

2) Influence of the skip connections: Skip links are quite important in our network. The usefulness of skip connections is demonstrated here. As shown in Fig. 1, there are three different types of connections: long skip connections (LSC), local connections (LC), and short skip connections (SSC). When all skip connections are active, the performance is ideal, however when any of the links is lacking, the performance is poor. In the absence of skip connections, we observed that increasing network depth had no effect on performance.

3) Feature attention: Feature attentiveness is another important aspect of our network. The CNN models have developed since the inception of DnCNN [62], and additional performance improvement needs careful block design and resizing of the feature maps. In the proposed model, the two previously stated attributes are represented by feature attention and skip connections.

Table III demonstrates the de-noising result of the proposed method comparing with some recent methods [29, 30, 62–64] based on feature attenuation and encoder-decoder architectures. The dataset on Saudi license plates in [59] was used. The proposed model shows some good results on a total of 1017 images including noise levels of 10%, 20%, and 50%. Table IV compares the suggested technique to other recent methods on a publicly available dataset [60].

TABLE III. DE-NOISING MODEL RESULTS ON SAUDI LICENSE PLATES

Methods	PSNR at Noise level 10	PSNR at Noise level 20	PSNR at Noise level 50
[63]	31.45db	26.34db	19.43db
[64]	31.65db	24.99db	17.98db
[29]	30.44db	23.56db	16.45db
[30]	31.85db	25.98db	18.88db
Proposed	**31.75db**	**26.88db**	**19.79db**

TABLE IV. DE-NOISING MODEL RESULTS ON KAGGLE DATASET

Methods	PSNR at Noise level 10	PSNR at Noise level 20	PSNR at Noise level 50
[63]	36.35db	29.53db	25.39db
[64]	35.45db	28.78db	22.87db
[29]	33.78db	25.36db	21.97db
[30]	36.09db	29.19db	25.12db
Proposed	**36.60db**	**29.75db**	**25.79db**

4) License plates recognition and detection: In this part, we carried out tests to evaluate the effectiveness of our proposed approach. For experimental work, we used the Tensorflow framework. The following formulae are used to calculate the detection and recognition accuracy.

$$\text{Detection accuracy} = \frac{\text{TCB images}}{\text{TN Images}}$$

where, TCB images are total number of correct detection and TN images are total number of images.

$$\text{Recognition accuracy} = \frac{\text{TNCR}}{\text{TNAC}}$$

where, TNCR indicates total number of correct recognitions of alphanumeric characters and TNAC is total number of alphanumeric characters.

The proposed model is evaluated on our testing data, which contains license plates of different regions. We have tested the proposed model on a total of 772 images and compared it with some existing methods. According to Table IV, the suggested model is equivalent to the present technique and achieves the same degree of accuracy with less processing power and in less time, as seen in Fig. 4. Examples of locating bounding box and the model-generated de-noised images are shown in Fig. 5 and Fig. 6 respectively.

Fig. 4. Automated optimized deep learning based detected and recognized selected license plates.

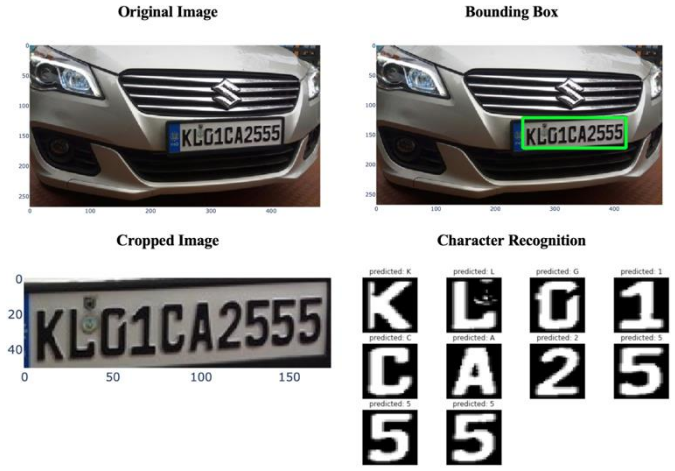

Fig. 5. Bounding Box to detect and recognize the License plate using InceptionResNetV2 with Region Proposal Network (RPN).

Fig. 6. Noisy images and model-generated de-noised images.

Table V compares the performance of your proposed method for license plate detection and recognition against three existing methods. Here are the key interpretations and findings: Our proposed method achieves the highest detection accuracy (98.33%) compared to all other methods. This indicates that it correctly identifies the presence and location of license plates in images with greater accuracy. The existing methods by Redmon et al. (97.12%) and Ali et al. (95.34%) perform closely behind your method suggesting that they are also effective in detecting license plates. Shim et al.'s method (95.34%) has similar detection accuracy to Ali et al. but falls slightly behind the other two methods.

TABLE V. DETECTION AND RECOGNITION RESULTS

Methods	Detection Accuracy	Recognition Accuracy
Ali et al. [53]	95.34%	66.34%
Redmon et al. [65]	97.12%	69.05%
Shim et al. [59]	95.34%	68.20%
Proposed	98.33%	88.79%

Our proposed method also outperforms the other methods in recognizing the characters on detected license plates, achieving an accuracy of 88.79%. This means it can translate the visual information of the plate into accurate character sequences with much higher success than the other methods. The gap between your method and the existing ones is even more significant in recognition accuracy compared to detection accuracy.

This suggests that your method excels in the finer details of character extraction and decoding. All three existing methods show significantly lower recognition accuracy than your proposed method,ranging from 66.34% to 69.05%. This highlights the effectiveness of your approach in handling variations in character fonts, sizes, and image quality. The results reveals that our proposed method significantly outperforms existing methods in both detection and recognition accuracy for license plate recognition. This superior performance suggests that your method is more robust and reliable in real-world scenarios where various environmental and image quality factors can affect accuracy. Further analysis might be needed to understand the specific strengths and weaknesses of your method compared to others, along with potential limitations and areas for improvement.

The Fig. 7 reflects the accuracy loss graph of automatic license plate recognition system using NASNetLarge and InceptionResNetV2 after applying image preprocessing steps and optimizing the hyperparameters. NASNetLarge achieved the highest training accuracy of 78.0%, indicating greater learning capacity during the training phase. The InceptionResNetV2 with optimized parameters outperformed with a validation accuracy of 88.79%, signifying better generalization to unseen data and potentially more robust performance when deployed in real-world scenarios. InceptionResNetV2 also achieved a significantly higher detection training accuracy of 99.33%, suggesting its superiority in accurately identifying license plates within images. This could be attributed to its residual connections facilitating information flow and preventing vanishing gradients, leading to better feature extraction for object detection.

V. Conclusion

Challenging real-world environments, characterized by blurred images, low light, and complex backgrounds, often impede traditional License Plate Recognition (LPR) methods. To address this, we propose a novel deep learning based LPR system optimized for noise resilience through hyperparameter tuning and bounding box refinement.

Key innovations:

- Convolutional Autoencoder (CAE) pre-processing: We train a CAE on noisy/clean image pairs to effectively remove noise and enhance details before feature extraction.
- InceptionResNetV2 architecture: We leverage the pre-trained InceptionResNetV2 model for its robust feature extraction capabilities.
- Region Proposal Network (RPN) with hyperparameter optimization: We add an RPN head and employ grid search to optimize key hyperparameters like learning rate and anchor scales, adapting the model to specific noise patterns.
- Bounding box refinement and character recognition: Non-maximum suppression eliminates redundant proposals, a separate head classifies remaining boxes, and bounding boxes are further refined for accuracy. Confirmed license plates undergo character sequence extraction with a Bidirectional LSTM/CRNN network.

Results And Potential

Our LPR system demonstrates superior accuracy and robustness compared to baseline methods, particularly in noisy environments. This performance makes it ideal for diverse applications like traffic monitoring and security systems in real-world settings.

Future Directions

We plan to investigate novel attention mechanisms and pre-trained character recognition models for further performance gains. Additionally, integrating with edge computing platforms could enable real-time LPR in resource-constrained environments.

Acknowledgment

Crowdsourcing Requirements Engineering: A Taxonomy-based Review

Ghadah Alamer[1], Sultan Alyahya[2], Hmood Al-Dossari[3]
Information Systems Department-College of Computer and Information Sciences, King Saud University[1, 2, 3]
Information Systems Department-College of Computer and Information Sciences,
Princess Nourah Bint Abdulrahman University, Riyadh, Saudi Arabia[1]

***Abstract*—Interesting insights have been found by the research community indicating that early user involvement in Requirements Engineering (RE) has a considerable association with higher requirements quality, software project success and as well boosting user loyalty. In addition, traditional RE approaches confront scalability issues and would be time consuming and expensive to be applied with contemporary applications that can be surrounded by a large crowd. Therefore, recent attention has been shed on leveraging the principle of Crowdsourcing (CS) in requirements engineering. Engaging the crowd in RE activities has been researched by several studies. Hence, we synthesize and review the literature of the knowledge domain Crowdsourcing Requirements Engineering using a proposed taxonomy of the area. A total of 52 studies were selected for review in this paper. The review aims to provide the potential directions in the area and pave the way for other researchers to understand it and find possible gaps.**

***Keywords*—Crowdsourcing requirements engineering; crowdsourcing; CrowdRE; crowd**

I. Introduction

Today's software applications can be mobile, cloud and social which operate in crowd-based settings having a massive crowd of distributed users [1]. This shift in the nature of applications have stressed the need in extending user involvement during RE activities [2] [3]. Furthermore, to achieve global user acceptance and satisfaction, a software application should meet the needs and desires of the large base of users [4]. Due to that, incorporating the interested crowd in the early phases of a software application, specifically RE, is crucial. The broad concept that advocates the involvement of the crowd in RE tasks is CrowdRE.

Crowd-based Requirements Engineering (CrowdRE) is a recent concept introduced by Groen et al. [1] for all semi-automated or automated RE tasks involving the crowd. One of the potential areas for employing crowdsourcing is in RE where it has gained attention [2] [1] [5] [6]. The broad concept CrowdRE can involve crowdsourcing, but crowdsourcing doesn't involve CrowdRE [7].

It is worth mentioning that there are some differences between CrowdRE and Crowdsourcing Requirements Engineering. Crowdsourcing delegates a piece of work to the crowd to solve it [7], where crowd members are actively engaged. On the other hand, in CrowdRE, the crowd can be involved passively, where the approach harnesses the available data from the crowd. Moreover, in CrowdRE the crowd are informants, where in crowdsourcing they are considered as problem solvers [8].

Fig. 1 shows a generic and simplified classification of the area CrowdRE. As shown in the figure, in addition to crowdsourcing, feedback analysis is concerned about analyzing users' feedback about software in channels such as app stores, social media and product forum using text mining techniques to elicit users' requirements. Where usage and context mining enable monitoring software usage and context at runtime to derive users' requirements [9]. These two approaches are mostly considered as passive involvement of the crowd.

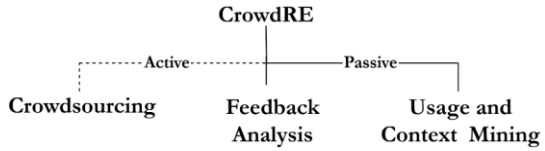

Fig. 1. General areas of CrowdRE [8] [9].

This review mainly covers studies that have utilized crowdsourcing for any of the RE tasks, where the crowd is actively involved in the crowdsourcing RE initiative. Moreover, we have suggested taxonomy of the area which we have observed after analyzing the selected studies, and reviewed the studies according to it. The taxonomy represents the main research directions in the area that can inspire interested researchers in finding potential gaps which are: crowd selection, crowd motivation, RE crowdsourcing platform, crowdsourcing task design and crowdsourced requirements. At the end of this review paper, we discuss some insights and provide some recommendations.

The reminder of this paper is organized in four sections: Section II which presents the research foci of the area Crowdsourcing RE. The section starts by showing the search and retrieval strategy for selecting studies and introduces the proposed taxonomy of the area. The studies are then reviewed according to the taxonomy. Section III discusses the overall insights that have been found and gives some suggestions. Finally, Section IV concludes this review paper.

II. Crowdsourcing Requirements Engineering: Research Foci

A comprehensive review of the main research foci of the broad area Crowdsourcing Requirements Engineering is presented. In addition, taxonomy of the area is proposed to provide the reader with an insight into the main directions of

the area that studies usually fall under. Each direction of the area is reviewed, and prior to that the undertaken search and retrieval strategy for selecting papers in the area is illustrated.

A. Serach and Retrieval Strategy

A selected number of keywords that mostly represent the area are used in searching for papers. The keywords are: [Crowdsourcing Requirements Engineering], [CrowdRE], [Crowdsourcing AND Requirements Engineering], [Crowd-Based Requirements Engineering]. Five main libraries were considered for searching papers which are: IEEE, ACM, SienceDirect, Springer and Scopus. In addition, the presented review covers published research anytime until 2023. Besides, we looked up papers published by some active researchers in the area and as well in the International Requirements Engineering Conference (RE) to find any related papers to be included in this review.

The review includes papers that apply the principle of crowdsourcing with any of the RE activities. Papers that fall under the area Crowdsourcing Requirements Engineering, which consider active involvement of the crowd during one or more of RE activities, are included. Papers that do not present a practical solution or review papers of the area are excluded.

Furthermore, papers that are cited by one of the selected papers and that appear to be related to the area Crowdsourcing RE are included. Fig. 2 is an illustration of the search and retrieval strategy that is followed to focus on Crowdsourcing Requirements Engineering studies. CrowdRE related papers are inspected to filter only papers that utilized crowdsourcing where the crowd is actively involved. Eventually, a total of 52 papers were selected for analysis and review.

After reviewing the current landscape of existing research in the area Crowdsourcing Requirements Engineering, it was noticed that research has mainly focused on addressing different aspects which can be considered as active research directions in the area. In Fig. 3, a taxonomy is illustrated of the Crowdsourcing Requirements Engineering literature. This taxonomy was set based on the main crowdsourcing elements presented by Hosseini et al. [10]. They have defined four pillars of crowdsourcing which are the crowd, crowdsourcer, crowdsourcing platform and crowdsourced task. Therefore, we present a taxonomy having four main aspects which are: the crowd, RE crowdsourcing platform, crowdsourcing task design and additionally crowdsourced requirements were added as a fourth aspect which particularly pertains to crowdsourcing RE. Each aspect of the taxonomy is reviewed and discussed in the next sections.

B. Crowd Selection for Crowdsourcing RE

From reviewing the selected studies, it was evident that a number have focused on proposing appraoches for selecting an appropriate subset of the crowd for crowdsourcing RE. A group of these studies have utilized social network analysis to select a crowd which are [11] [12] [13] [14] [15]. Lim et al. has designed StakeNet [11] which is a method for identifying and prioritizing a crowd of stakeholders in large software projects. The stakeholders are identified and prioritized by considering their level of influence they possess on a software project and their roles. Diverse social network measures are utilized to analyze the relations between the stakeholders in a social network. The network of stakeholders' crowd is built using snowballing technique where stakeholders recommend other stakeholders until a network of well-connected stakeholders is produced. Moreover, rather than relying on experts to ask stakeholders to suggest others, Lim et al. [12] has automated the process by developing StakeSource tool. The tool minimizes the workload on experts by crowdsourcing the task of stakeholder analysis to include the crowd of stakeholders in that task. In addition, StakeSource is improved by presenting a web-based tool called StakeSource2.0 [13]. StakeSource2.0 extends the work to not only consider stakeholders identification and prioritization, but as well elicits their requirements. To conduct this, the tool uses crowdsourcing, social network analysis and collaborative filtering.

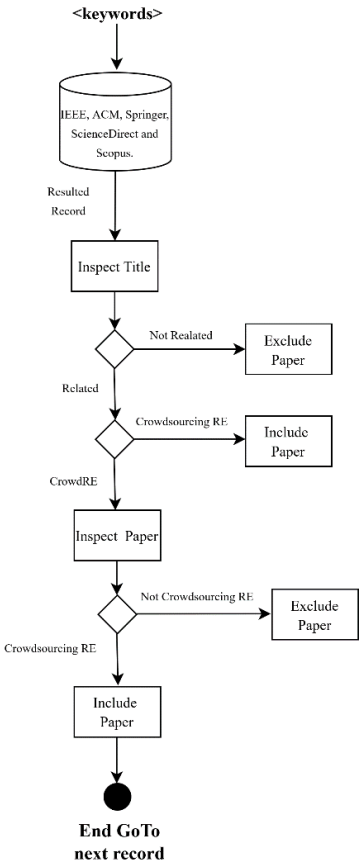

Fig. 2. Search and retrieval strategy.

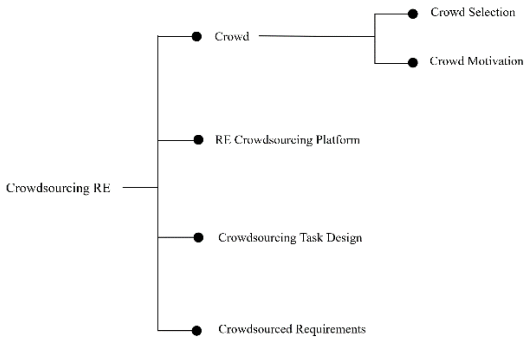

Fig. 3. Taxonomy of the area Crowdsourcing RE.

Moreover, StakeSource2.0 has been used in StakeRare [14] a method proposed by Lim et al. which identifies and prioritizes thousands of stakeholders for large-scale software projects and elicit their requirements. StakeRare was assessed on an extensive project consisting of a crowd of 30,000 stakeholders, and has shown to accurately predict the stakeholders' desires by producing a more complete list of prioritized requirements from the crowd of stakeholders. An in-group bias limitation was highlighted in the former studies by Mughal et al. [15]. This limitation is defined as when stakeholders prefer to recommend ones whom they have a good relationship with. This biasedness can lead to less accurate identification and prioritization of the crowd of stakeholders, which eventually impacts the process of requirements elicitation.

Rather than relying on the relations between the crowd members and the level of impact they have on software project such as what has been done by the previously discussed studies, other studies have considered the crowd's domain knowledge to select and identify a suitable crowd. A framework proposed by Wang et al. [16] aims to select suitable participants for outsourcing requirements elicitation tasks. The farmwork utilizes spatiotemporal features of the crowd to infer their domain knowledge. The authors observe that people who gather in the same spatiotemporal space could possess similar domain knowledge. For instance, to develop a football application, the best crowds to participate in requirements elicitation are football fans whom can be found clustering in a football match at a certain time and space. Furthermore, a study presented by Srivastava and Sharma [4] have focused on crowd with knowledge in ERP selected from LinkedIn social network. The crowd is selected to participate in crowdsourcing requirements elicitation for a software application called MyERP. They have used a crawling web-based solution to find crowd members who have listed ERP in their LinkedIn profiles as one of the expertise they possess. In addition, another study by Lim et al. [17] which uses LinkedIn as a platform from where the crowd is selected. They have proposed a systematic approach to find stakeholders interested in B2B software in a targeted company. The approach is a step-by-step strategy that assists in finding hidden B2B software stakeholders by searching LinkedIn social network. The targeted stakeholders are found by a set of intermediates called advisors that help connect with the stakeholders and elicit their requirements for a B2B software. In addition, a nichesourcing method was proposed by Condori-Fernandez et al. [18] for analyzing sustainability requirements and the dependencies between them. The method consists of multiple stages, where an early stage is selecting a crowd experienced in a domain knowledge that fits the software having its requirements crowdsourced. The authors recommend using social network sites such as Twitter and LinkedIn to find a potential crowd of experts to contribute in crowdsourcing sustainably requirements and finding the relationships and dependencies among them.

Some studies have based the selection process on the crowd's domain of interest. A method proposed by Lim et al. [19] utilized a bot tool which operates on Twitter social network. The automated tool is called PseudoGravity and it aims to identify a targeted interested crowd by generating content that is especially tailored for them. The interested crowd is then engaged in participating in crowdsourcing requirement elicitation tasks. Moreover, Kolpondinos and Glinz [20] have proposed an approach to select an interested crowd that is beyond the bounders of an organization. They have harnessed several online channels as a source to find a crowd interested in the SmaWoMo system. Their approach employs persona-based advertisements which are based on player-types similar to personality traits to determine the personas. The targeted crowd is then invited to engage collaboratively in the requirement elicitation and prioritization process for that system.

A study conducted by Alvertis et al. [21] have introduced a persona-based approach that can be used to select a suitable subset of the crowd to participate in the process of requirements elicitation. Their approach consists of a persona builder tool that enables software teams to construct, reuse, and as well share personas. A persona can be created by identifying a set of required characteristics. This approach assists in targeting suitable prospective software users. The crowd that fits these determined personas can be selected to get involved in crowdsourcing requirements engineering. In addition, Guzman et al. [22] have built a stakeholder identification model using machine learning techniques. Their model can identify the stakeholders from tweets, where they are either classified as technical, non-technical or general public stakeholders. They have built their model using tweets about 30 popular mobile and desktop applications.

C. Crowd Motivation for Crowdsourcing RE

In the literature of crowdsourcing RE, some studies have focused on how to motivate the crowd to participate in a crowdsourcing initiative. The authors in [2] [20] [23] [24] [25] [26] [27] [28] [29] advocated the use of Gamification as an incentive design to increase crowd motivation when crowdsourcing RE tasks. Gamification is the idea of using game elements such as points, levels, badges and leader boards in non-game context to motivate users [36]. Fernandes et al. [24] have proposed iThink, a gamified collaborative tool for requirements elicitation which uses the "Six Thinking Hats" technique. Moreover, stakeholders are rewarded for suggesting new requirements or discussing existing ones. This study is considered as one of the early attempts revealing that gamification has potentials in RE activities [23].

Snijders et al. [23] have extended participation by involving a crowd of stakeholders. The authors have proposed REfine, a gamified crowdsourcing platform for requirements elicitation and refinement which is an essential component of the (Crowd-Centric Requirements Engineering) CCRE method [2] [23] [25]. REfine is designed to involve crowd of stakeholders in RE. Through REfine users are able to suggest needs, comment on them, branch them, vote for them, and are rewarded accordingly.

Furthermore, Martina et al. [26] have developed a concept to motivate the vast number of unknown stakeholders outside organizational reach to contribute in requirements elicitation using gamification mechanisms. The authors argue that all implemented game-based platforms for requirements elicitation (e.g. iThink [24] and REfine [23]) have considered crowd of

stakeholders who are within organizational reach. Besides, they have overlooked the evolution of stakeholders' motivation throughout the elicitation process; hence, the authors have focused on addressing this gap.

Similar to [26], another study [27] has focused its investigation on motivating stakeholders outside organizational reach and specifically during requirements prioritization. Garuso (Game-Based Requirements Elicitation) platform which incorporates social media with gamification was developed to explore the effect of gamification algorithms that control the points and levels game elements on stakeholders' participation. Kolpondinos and Glinz [20] have presented the GARUSO approach which was an expansion of the studies [26] and [27]. The authors have presented a detailed description of the GARUSO architecture, which is a gamified social media platform that enables the crowd of stakeholders outside the organizational reach to collaborate in eliciting and prioritizing requirements. Besides, Gupta [28] have used gamification for requirements elicitation and prioritization, The crowd are asked to express their requirements using customer journey format which shows the step-by-step journey of a customer in performing a task (e.g. payment task).

The above discussed studies have used gamification mechanism for crowd motivation. Nevertheless, some studies have designed rewarding systems as part of their studies to keep the crowd motivated such as [4] [30] [31]. Srivastava and Sharma [4] have proposed a crowdsourcing approach for requirements elicitation for MyERP application. To maintain crowd motivation, they have used certain performance measures. Two main indicative measures were utilized, which are members who contribute more requirements and who have more responses posted on their contributed requirements, are given a reward. In addition, Seyff et al. [31] plan to add a personalized rewarding mechanism to encourage the crowd to participate in their platform and maintain their involvement in negotiating and analyzing the requirements with respect to sustainability. Nascimento et al. [30] have defined three reward methods for their proposed framework which are reward and career, financial compensation and recognition. For which a selection of a method is based on the scope of the project and the type of participating crowd.

Schneider and Bertolli [32] state that having a software described in text format may not be encouraging for the crowd to share their opinions and feedback about that software and might even repel them from contributing. Therefore, they suggest a new approach in motivating the crowd for RE, which is using videos. They have proposed four types of videos and illustrated how they can be created and make them engaging for CrowdRE. In addition, in [33] the authors have designed a gradual approach for eliciting and gathering requirements from a crowd, where requirements are built gradually from multiple micro-crowds (MCs). In each MC, the people are familiar with each other. This approach can perform better in motivating the crowd than when starting with a large crowd, where this has been seen to fall under the motivation linked to loving the community. Another study by [34] has applied the MC approach, however, rather the applying it on users as in the previous study, it was applied on developers.

D. RE Crowdsourcing Platform

The literature shows that there are several crowdsourcing platforms that are especially designed for crowdsourcing RE tasks. CrowdREquire [35], REfine [23], CRUISE [5], UCFrame [36], Requirements Bazaar [37], GARUSO [20], CREeLS [38], CREUS [39], SCOUT [40], Liquid RE [41], KMar-Crowd [29], Srivastava and Sharma's platform [4], Seyff et al.'s platform [31], Nagel et al, prototype [42], smartFEEDBACK [43], CrowdConfigRE [44] and Menkveld et al.'s platform [45] are all crowdsourcing platforms for RE.

CrowdREquire proposed by Adepetu et al. [35] aims to focus on gathering requirements from the available diverse talent in the crowd which is considered as a complex task. The platform utilizes a contest model and adopts an agile approach for requirements development. Another platform proposed in [37] which involves the crowd in almost all RE activities. The authors have designed a platform for social requirements engineering named Requirements Bazaar. It supports collaborative requirements elicitation, prioritization, negotiation and realization. Besides, it has a co-creation workflow involving four stages: idea generation, idea selection, idea realization and idea release.

Sharma and Sureka [5] have designed a platform for crowdsourcing RE activities called CRUISE. CRUISE aims to employ the crowd in gathering, analyzing, validating, prioritizing and negotiating requirements. In addition, Hu et al. have proposed USFrame [36], a use case-based framework for collaborative requirements acquisition in crowd-centric context to assist the crowd in expressing their requirements without the help of an analyst. The platform has implemented critical mechanisms such as rule hints for guiding the crowd of users in use case documentation, built in abstract types, use case synthesis, quality measurements and visualization diagrams.

Munante et al. have proposed CrowdConfigRE [44], a platform for crowdsourcing re-configuration requirements that focuses on adaptive systems to elicit their re-configuration requirements. First, known crowd, in other words domain experts, generates personas and configuration profiles for adaptive software. Then, an unknown crowd of potential users are used to refine and validate the information elicited; hence, accurately defining the re-configuration requirements. Furthermore, Seyff et al. [31] proposed a platform that can engage a crowd, users and domain experts, in negotiating and eliciting requirements and their impact on sustainability. The platform consists of three primary parts which are CrowdFeed component that enables the crowd to share their feedback about a software product, ReSuS component to classify and cluster the feedback and ReSIntegrator component that showcases the impact on sustainability using visualization techniques.

REfine [23] and GARUSO [20] are gamified collaborative crowdsourcing platforms for RE activities. REfine platform engages a crowd of users, developers or requirements analysts in the process of eliciting and refining software requirements. Similarly, GARUSO platform allows the crowd to collaboratively engage in requirements elicitation and prioritization tasks. Additionally, Menkveld et al. [45] have developed a RE crowdsourcing platform to help the crowd in writing their software requirements and features in the form of

user stories (US) for a sports tournaments management software. It enables the crowd to submit their US by entering four inputs which are: the role of the crowd member requesting the feature, the goal of the feature, the benefit of the feature and the category of the feature. Besides, CREUS method [39] has used user stories as an approach to express ideas elicited from the crowd. The method consists of four phases which are: preparation, idea generation, refinement, and execution and supports three main roles: core team, crowd member and focus group member. Core team oversees and coordinates the crowd, the crowd member contributes ideas, and focus group member is a crowd member who participates in discussing the development of the crowdsourced ideas. Another similar platform is Kmar-Crowd [29] which is designed for crowdsourcing requirements elicitation in the form of user stories. The platform involves the crowd in idea generation and refinement to generate ideas and vote and comment on available ideas. In addition, a study conducted by Köse and Aydemir [40] have proposed SCOUT a web-based tool which supports the completeness of user stories generated by a crowd of stakeholders in a collaborative environment. SCOUT NLP-based tool guides the crowd during the process of generating user stories. It uses NLP to construct a knowledge graph from user stories; hence, heuristics are applied on the knowledge graph to produce suitable suggestions to the crowd of stakeholders.

A platform proposed by Rizk et al. [38] called CREeLS is a crowdsourcing platform to crowdsource requirements elicitation tasks for e-learning systems (eLSs). The proposed platform consists of feedback channels to comment and review the eLS, social collaboration, text mining tools to analyze and mine the crowd requirements that are written in the form of comments and in discussion forums. Moreover, a crowdsourcing platform was proposed by Srivastava and Sharma [4] for crowdsourcing requirements elicitation for ERP applications. Their proposed platform has addressed several challenges concerning identifying the appropriate crowd, keeping them engaged, identifying appropriate tasks, recognizing malicious crowd members and resolving conflicts among requirements and prioritizing them. Additionally, a tool called smartFEEDBACK [43] was developed to apply crowdsourcing RE to gather the needs of older adults. The tool was designed to support both explicit (e.g. answer questions) and implicit feedback (e.g. analyze interactions).

Nagel et al. [42] designed a prototype for an interactive video player which incorporates three main features which are emoji markers, comments and hyper-markers. These features shall enable the crowd of stakeholders to understand and share their understanding and requirements about a software project and assist in resolving any conflicts. Moreover, a study by Johann and Maalej have proposed an envision of a Liquid RE platform [41]. The platform applies Liquid Democracy and e-Democracy concepts in RE to mitigate the challenges of mass participation in RE related to scalability, motivation, conflicts, representativeness, subjectiveness and misuse. Some of the main Liquid Democracy and e-Democracy concepts to be applied in the platform are structured collaborative decision making, delegated voting and quorums.

E. RE Crowdsourcing Task Design

Indeed, some studies have focused on the task design for crowdsourcing RE, where they presented a method that could simplify and decompose the crowdsourced task. Mostly, these studies utilized available crowdsourcing platforms such as the general-purpose crowdsourcing platforms Amazon Mechanical Turk (MTurk), Figure Eight and Zooniverse and focus on task design.

The crowd-based requirements annotation methods Kyoryoku [46] and CRAFT [47] harness the power of the crowd in eliciting and classifying requirements from users' reviews. The methods split complex tasks into simpler micro-tasks. Using CRAFT [47], crowd members from Figure Eight accomplished a task by navigating through three major phases. A crowd member first selects a category from predefined categories (e.g. functional requirement, bug report) for a review or adds a new category. Second, selects a sub-category and third rates the importance of the review and provides comments. Furthermore, Kyoryoku [46] method, inspired by CRAFT, proposed a three phase method for accomplishing the task of extracting requirements from users' reviews. First a crowd member filters a review into helpful or useless, second fragments of the helpful reviews are further classified to being helpful or useless, and third helpful fragments are classified into five categories (e.g. feature request, stability, quality). Similarly, CrowdIntent [48], a crowdsourcing workflow proposed for annotating intentions (desires and needs) hidden in discussions into a set of categories. It has decomposed the content of the task (a discussion) into messages then into sentences using sentence splitter tools to design the task in an understandable way for annotation.

Furthermore, Murukannaiah et al. [49] have proposed a sequential task design for crowdsourcing RE through MTurk which can stimulate creativity. The design was based on the notion that when workers are exposed to others' ideas, this act can lead to cognitive stimulation. There are two phases, where in the first phase the crowd workers review the ideas generated by other workers and generate new ones. In the second phase, the other part of the crowd rates the produced ideas in the first phase. In addition, an idea selection strategy based on workers' personalities and creativity was proposed to select a set of ideas from a stage to be exposed to workers in the following stage. Moreover, Breaux and Schaub [50] introduced a task decomposition workflow for crowdsourcing the manual extraction of privacy requirements task from text documents which involve privacy policies. The task includes multiple microtasks which enables untrained crowd members to apply sentence and phrase level coding of the privacy policies. The workflow is performed using manual methods, and as well NLP techniques to automate some parts of the workflow.

Alongside Breaux and Schaub's study [50], another was conducted by Guo et al. [51] that have proposed Çorba which focuses on the task design for crowdsourcing RE. Çorba is a crowdsourcing design that guides the crowd in extracting security and privacy requirements from regulations and breach textual reports by breaking the task into smaller tasks. The proposed task design was conducted on MTurk crowdsourcing platform. In addition, Rosser et al. [52] used Zooniverse for crowdsourcing phishing cues labeling which is a crucial RE

phase for anti-phishing training tools. Zooniverse markup interface was used to design the crowdsourcing task. Participants were shown screenshots and were asked to identify its trustworthiness, if the content is malicious, they are asked to mark the areas in the image indicating phishing and then label it using pre-defined labels. Furthermore, another study has used a simple mean for crowdsourcing such as using questionnaires as done by Vidal et al. [53], where they have crowdsourced the task of requirements validation for a pet management mobile app. Their questionnaires were designed using questions with Likert-scale, binary or numeric responses to validate the requirements.

F. Crowdsourced Requirements

In addition to all previously discussed studies, some have mainly focused on how to handle the crowdsourced requirements; hence, they are more concerned about the stage after gathering the requirements. The papers [54] and [55] have proposed a genetic algorithm-based approach in which the elicited requirements from the crowd are aggregated. They have used activity diagrams as a structured requirements description language in order to facilitate automated merging of requirements. Their proposed genetic algorithm aims to merge the collected activity diagrams from the crowd, and produce a synthetic activity diagram which acts as a crowd consensus on a requirement. Moreover, Taj et al. [56] have presented a model that classifies requirements gathered through crowdsourcing into functional and non-functional requirements. An open call was initiated to ask crowd members to participate in submitting requirements for a software to be developed. The model used the machine learning algorithms naïve bayes and decision tree to build the model and has proved to achieve effective results.

Furthermore, StakeSource2.0 [13] and StakeRare [14] use social networks and collaborative filtering to identify and prioritize requirements from a large crowd of stakeholders which are asked to suggest and rate requirements. Collaborative filtering predicts a stakeholder's preferences and recommends unrated requirements to a stakeholder that might be of interest to him; hence, the stakeholder rates this recommended list of requirements. Using these ratings and the stakeholder's level of impact on a project, the requirements are prioritized.

Indeed, having large number of requirements as a part of the software project with no value to users is an issue. To rectify such problem, Nascimento et al. [30] have proposed a framework which leverages Kano's model to classify and evaluate crowdsourced requirements. The proposed framework aims to identify and prioritize requirements based on their importance to the customers and include them for implementation. Similarly, Niu et al. [57] have proposed an approach where they have employed semantic discrimination lexicon, Kano model and entropy technique to evaluate the importance of already crowdsourced requirements. Furthermore, Hassan et al. [58] proposed an approach which uses text mining and morphological matrix for analyzing the large number of ideas generated by the crowd to extract innovative software requirements. Mead et al. [59] on the other side have proposed an approach where they utilized crowdsourcing to construct Personae Non Gratae (PnGs)-based threat models that could be considered as input for early phases of requirements process, and as well help in specifying mitigating requirements. For the aim of reaching higher coverage of threats, reducing redundancies and developing meaningful PnGs, in their approach they have introduced a merging strategy where they used machine learning and information retrieval techniques to merge crowd's PnGs.

III. DISCUSSION

After reviewing crowdsourcing requirements engineering body of knowledge, the reviewed studies are synthesized in Table I where each study is categorized under one or more dimensions that it contributes to according to the suggested taxonomy illustrated in Fig. 3. Apparently, the largest number of studies contributed to the Crowd dimension and the RE Crowdsourcing Platform dimension. Furthermore, regarding the remining two dimensions crowdsourced task design and crowdsourced requirements, the number of studies addresses a gap related to these dimensions are quite low.

TABLE I. STUDIES ORGANIZED UNDER THE DIRECTIONS OF THE AREA CROWDSOURCING RE

Dimensions		Number of Studies	Ref.
Crowd	Crowd Selection	13	[20] [4] [16] [17] [12] [14] [15] [13] [11] [21] [19] [22] [18]
	Crowd Motivation	15	[2] [20] [4] [33] [23] [30] [32] [24] [25] [26] [27] [28] [29] [31] [34]
RE Crowdsourcing Platform		17	[23] [5] [36] [37] [20] [38] [41] [4] [31] [35] [44] [45] [29] [39] [40] [42] [43]
Crowdsourcing Task Design		8	[46] [49] [51] [50] [47] [48] [52] [53]
Crowdsourced Requirements		9	[13] [14] [30] [54] [56] [58] [59] [55] [57]

We envision that there are areas for improvements in this field, where studies can work on designing effective approaches for crowd selection that can infer the knowledge of the crowd and make use of it in various activities of requirements engineering. Moreover, motivating the crowd is a factor of paramount importance especially when it comes to crowdsourcing. Therefore, we recommend working on strategies that can incentivize the crowd to participate. For the RE crowdsourcing platforms, there are several endeavors in this dimension. Nonetheless, since RE tasks are considered as complex tasks, designing a platform that does not just provide a medium for the crowd but as well facilitates the accomplishment of the crowdsourced RE tasks by incorporating intelligent features in the platform, is another factor to consider when researching this dimension.

Furthermore, the task design aspect has large opportunities for contributions. It is recommended to design a RE crowdsourced task in a way that can be employed in any crowdsourcing platform. The last dimension which is focused on the crowdsourced requirements have few studies contributing to it. To benefit from the crowdsourced requirements, we suggest proposing methods to aggregate the large number of contributed requirements and synthesize them.

This can assist crowdsourcing requesters in understanding and viewing them.

Employing crowdsourcing in requirement engineering might present some challenges that need some attention. The quality of the crowdsourced requirements reducing redundancies and increasing diversity when crowdsourcing requirements and as well coordinating the work on RE tasks among crowd members are all important aspects that can be researched.

IV. Conclusion

Crowdsourcing requirement engineering is a new approach for RE which fits the modern software paradigms. Hence, we have presented a thorough review of the area and proposed a taxonomy that can help researchers find their way in the area. The review shows that there are some aspects of the area that can be contributed to and enhanced. In addition, for future work we plan to conduct some research work that could address some gaps identified in the area.

An Effective Book Recommendation System using Weighted Alternating Least Square (WALS) Approach

Kavitha V K*, Dr.Sankar Murugesan
Department of Computer Science and Engineering,
Veltech Rangarajan Dr Sagunthala R & D Institute of Science and Technology, Avadi, Chennai, India

***Abstract*—Book recommendation systems are essential resources for connecting people with the correct books, encouraging a love of reading, and sustaining a vibrant literary ecosystem in an era when information overload is a prevalent problem. With the emergence of digital libraries and large online book retailers, readers may no *longer* find their next great literary journey without the help of customized book suggestions. This work offers a novel way to improve book recommendation systems using the Weighted Alternating Least Squares (WALS) technique, which is intended to uncover meaningful patterns in user ratings. The suggested approach minimizes the Root Mean Square Error (RMSE), a crucial indicator of recommendation system (RS) performance, in order to tackle the problem of optimizing recommendations. By representing user-item interactions as a matrix factorization problem, the WALS approach improves the recommendation process. In contrast to conventional techniques, WALS adds weighted elements that highlight specific user-item pairings' significance, increasing the recommendations' accuracy. Through an empirical study, the proposed approach demonstrates a significant reduction in RMSE when compared to standard RS, highlighting its effectiveness in enhancing the quality of book recommendations. By leveraging weighted matrix factorization, the proposed method adapts to the nuanced preferences and behaviors of users, resulting in more accurate and personalized book recommendations. This advancement in recommendation technology is poised to benefit both readers and the book industry by fostering more engaging and satisfying reading experiences.**

Keywords*—Recommendation system; user ratings; matrix factorization; alternating least square; weighted matrix factorization

I. INTRODUCTION

A technology that makes recommendations based on its ability to infer user preferences is called a recommendation system (RS), since it uses all of the information that is accessible at any given time to predict items. In light of the current situation of "information overload," which is defined as an instance in which there is an excessive volume of information to absorb and interpret, when it comes to decision-making, RS can be very beneficial because it provides unique and personalized recommendations [1]. The algorithm utilized determines the recommendation outputs. Recommender systems can be roughly categorized as content-based filtering, collaborative filtering, and hybrid filtering system [2].

A. Content Based Filtering in Recommendation System

In content-based filtering, recommendations are made using previous user selections. The recommender may receive implicit user choices, such as ratings, or explicit user choices, such as surfing patterns. Using the data provided by the user, a user profile is crafted and utilized to inform future recommendations derived from the content of input objects. Items that are particularly suitable to the user are identified using content-based RS by examining item depictions. Recommendation framework details frequently vary depending on how objects are represented. This methodology offers the advantage of being able to explain its suggestions and suggest previously unrated items to individuals with unique interests. When a user provides input on particular items in relation to user-related content, content-based RSs create user preferences, profiles, interests, and impressions based on that information [3]. Products will be suggested to the user based on their preference profile if they match products that have received exceptional appraisals in the past. The increase in user profile proficiency is a crucial component of CBF recommender frameworks [4]. The creation of user profiles has been linked to various learning approaches.

B. Collaborative Filtering in Recommendation System

The process of collaborative filtering involves gathering user evaluations or judgments about various items. Moreover, users with comparable tastes are found in a sizable population. People with similar tastes are merged in order to recommend new products and assist other users in making better selections [5]. CF algorithms are further categorized into model-based and memory-based techniques.

The most suitable definition of CF is "joint effort between individuals to help each other perform filtering by recording their responses to materials they read" [6]. CF approaches play a critical role in the recommendation, even if they are frequently used in conjunction with other filtering approaches such as knowledge-based, content-based, or social-based [7]. It allows users to rate various elements (such as songs, movies, videos, and so on) on a content-based network so that, once sufficient data is stored on the system, recommendations can be sent to each user based on the information offered by those who believe they have the most practical communication with them. Model-based approaches offer recommendations by evaluating the parameters of quantifiable models for user evaluation. The most often used models include matrix

factorization (MF), neural networks, fuzzy systems, Bayesian classifiers, latent features, and genetic algorithms [8].

1) Collaborative filtering using matrix factorization: MF is the core for some of the most successful latent factor model realizations. In its simplest form, MF assigns vectors of factors based on implicated information from item rating patterns to both items and users. A recommendation is produced when item and user factors have a high degree of correlation. RS rely on many forms of input data, which are regularly disposed in a matrix where users are represented by one dimension and items of interest by the other. A user-item interaction matrix is factorized into two lower-dimensional matrices via MF models, which can subsequently be utilized to anticipate missing values in the original matrix [9]. The main phases of the MF approach are described below.

a) The User-Item Interaction Matrix: In CF, we start with a user-item interaction matrix, often denoted as R. Each row represents a user, each column represents an item, and the values in the matrix depicts user ratings, purchase history, or some other form of interaction. The matrix is typically sparse because not all users have interacted with all items.Let R be an m x n matrix, where m= number of users, n= number of items and R[i,j] is the interaction (rating or preference) of user i with item j.

b) MF: The goal is to factorize the user-item interaction matrix R into two lower-dimensional matrices, typically denoted as U (for users) and V (for items). The concept involves depicting users and items in a reduced-dimensional space, where the dot product of their representations serves as an approximation for the entries in the original matrix.

Let U be an m x k matrix, where m = number of users, k = the number of latent features (a hyper parameter to be chosen).
Let V be an n x k matrix, where n = number of items, k = the number of latent features. The approximation of the user-item interaction matrix R is given by the dot product of U and V:

$$R \approx UV^{T} \quad (1)$$

Here, R is approximated by the dot product of U and the transpose of V.

2) Objective function: MF models are trained by minimizing a loss function. A common loss function is the Mean Squared Error (MSE)between the actual user-item interactions (R) and the predicted interactions UV^T.

$$\text{MSE} = \sum(i,j)\,(R[i,j] - (UV^{T})[i,j])^{2} \quad (2)$$

The objective is to find U and V that minimize this error.

a) Regularization: To prevent over fitting, regularization terms are often added to the loss function. L2 regularization is commonly used, and it penalizes large values in U and V:

$$\text{Regularized MSE} = \sum(i,j)(R[i,j] - (UV^{T})[i.j]^{2} + \lambda(\|U\|^{2} + \|V\|^{2} \quad (3)$$

Here, λ is a hyper parameter that controls the strength of regularization, and $\|U\|^2$ and $\|V\|^2$ represent the Frobenius norms of U and V, respectively.

b) Optimization: MF models are typically trained using optimization techniques like gradient descent to minimize the regularized loss function.

c) Prediction: Once the U and V matrices are learned, predictions for user-item interactions can be made by taking the dot product of the corresponding user and item vectors:

Prediction for user i and item j: $(UV^{T})[i,j]$

MF frameworks, such as Singular Value Decomposition and Alternating Least Squares (ALS), are widely utilized in RSs. They are effective at capturing latent patterns and making personalized recommendations based on user-item interactions.

C. Hybrid Filtering

A hybrid strategy integrates content and collaborative filtering-based techniques to achieve successful recommendation outcomes. The integration of different algorithms benefits from their complementary advantages. In fact, a hybrid strategy outperforms the traditional approach in handling data sparsest and cold start issues. Combining multiple recommender system approaches entails developing two unique recommender systems that rely on content-based and collaborative methodologies. The emergence of RS has demonstrated the value of hybrid processes, which combine several approaches to maximize the advantages of each method. In order to overcome data sparsest and cold start difficulties, CF-based approaches inevitably involve abuse of the extract information source associated with the items our users use. Hybrid recommenders are an interesting problem that proposes a reasonable hypothesis to which one may respond similarly by looking into more recent opportunities.

D. Deep Learning in Recommendations

The volume of data generated in the last few years has increased dramatically compared to previous years. This has led to a greater awareness of the term "big data," which indicates to the vast quantity of unstructured information that is generated and needs more investigation. In recent times, there has been a growing focus on machine learning, specifically deep learning, because of its potential to improve the way large amounts of data are processed and because it can be used to model complex data sets like texts and images. RSs rely heavily on machine learning algorithms, which analyze item and user data to generate specific recommendations. Because of the exponential rise in data availability, the advancement of algorithms, and the availability of more computer resources like GPUs, deep learning has become a promising tool for different data domains. Deep learning models have been effectively utilized in computer vision, speech recognition, and NLP applications. Deep learning has recently been applied to RSs. Despite the significant progress made in the previous twenty years, standard RSs remain unsatisfactory in adequately modeling complicated (e.g., nonlinear) interactions between users and items. Deep neural networks, on the other hand, are universal function approximates that can represent any continuous function. Restricted Boltzmann Machine (RBM) is one of the earliest works that uses the deep learning concept for

collaborative filtering [10]. Nowadays, a wide range of DL models, including Auto encoder (AE), Multilayer Perceptron (MLP), Convolutional Neural Network (CNN), Recurrent Neural Network (RNN), and Generative Adversarial Network (GAN), are utilized to boost the quality of recommendations.

In the modern world, book recommendation system has become increasingly sophisticated and invaluable, leveraging user-generated book ratings and reviews to guide readers towards literary treasures that resonate with their tastes. These systems harness advanced algorithms to analyze vast databases of reader feedback, identifying patterns and correlations in book preferences. By considering factors such as genre, author, writing style, and even thematic elements, these recommendation engines can suggest books that are highly likely to captivate and engage individual readers. As a result, book enthusiasts can effortlessly discover new and exciting literary adventures, making the most of the digital age's abundance of reading options, while also fostering a sense of community among readers who share similar literary passions. This paper introduces an effective book recommendation system based on WALS method.

The primary contribution of the paper includes:

- Development of an effective book recommendation system using CF.
- Utilization of WALS matrix factorization method to avoid sparsest problems.
- Model evaluation using Good Books Dataset.

II. Literature Review

Dhiman Sarma et al. [11] developed clustering approaches to improve the prediction capabilities of RSs. The datasets were gathered from the Kaggle repository for Goodreads books. The F1 score was 52.84%, whereas the average sensitivity and specificity were 49.76% and 56.74%, respectively. According to the simulation results, the suggested method can more effectively exclude boring books from the list of recommended reading. Yiu-Kai Ng [12] created a book recommendation approach for young readers using MF and content-based filtering techniques. In order to evaluate the effectiveness of recommenders that suggest books to K–12 readers, a benchmark dataset was developed that includes metadata, readability levels, and user and book counts. The error values are computed for the suggested methodologies. Madhuri Kommineni et al. [13] developed a straightforward, intelligible system for book recommendations to assist readers in suggesting the suitable book to be studied next. The introduced method dedicates on training, feedback, management, conveying, arrangement, and providing the user with helpful information to support the recommendation of data items and decision-making. The effectiveness of similarity metrics in book recommendations to users was assessed utilizing the User-Based CF technique. According to the simulation results, a normal distribution after the accuracy rating implies consistency and efficiency.

Sunny Sharma et al. [14] developed a hybrid system-based book RS that predicts recommendations. The suggested method combines content-based and CF. The proposed work is tested in an online recommender system, enabling us to determine the actual user approval rate of the recommendations made. Based on simulation findings, it was shown that the suggested hybrid filtering strategy works better than both content-based and traditional CF.A personalized recommendation algorithm was realized by Yihan Ma et al. [15] by introducing a large and DL to the book recommendation system sector. Initially, the records' readers' and books' information were gathered. LR and DNN networks are trained together to produce the suggested basic recommendation model. The transformation of the double label into numerous labels enhanced the suggested model. Ultimately, a set of comparison studies was created to confirm the viability of the suggested method. The simulation findings demonstrated that the suggested RS's accuracy is noticeably higher than that of the current techniques. Kiran R et al. [16] suggested a unique DL hybrid recommender system to close the loopholes in CF systems and use DL to reach state-of-the-art predicted accuracy. The method learns non-linear latent variables by representing users and items using embeddings. The method reduces the cold start issue by assimilating side information about users and items into an extremely DNN. The suggested approach combines an increasing weight decay with a lower learning rate. The values are cyclically changed throughout epochs to further increase accuracy. Extensive experiments are carried out across multiple datasets. The outcomes demonstrated that in both non-cold start and cold start scenarios, the suggested solution performs better than the current approaches.

Tulasi Prasad Sariki and G. Bharadwaja Kumar [17] developed an efficient framework to enhance the recommendations given in the book domain by carefully combining natural language processing and DL approaches. The feature space for the existing CBFs has been improved by augmenting them with other relevant attributes by employing this wise combination. The different models that are suggested in the current framework are effective in making use of the book's entire textual material. According to the simulation results, the expanded framework outperforms the baseline models in terms of total suggestion accuracy, with an improvement of 18%. Furthermore, it can be concluded that the suggested approach performs 6% better than the cutting-edge models, including the NCF with Content Embedding Model. An algorithm for digital library recommendations was presented by Fikadu Wayesa et al. [18]. A hybrid book recommendation system using new user profile data was proposed in this study. This hybrid RS merges elements of collaborative and content-based approaches, leveraging user profile data and pattern relationships among users. It uses a content-based component to suggest recommendations to users in the same cluster who have rated books in similar categories. These recommendations are based on the book features and content type information, offering a personalized experience for users with shared interests. A set of comprehensive experiments using information retrieval (IR) assessment criteria are used to measures the efficacy of the suggested technique. The results showed that the recommended strategy outperforms the current techniques, with significant advancements. Dongjin Hou [19] developed a personalized book recommendation method using DL models and the

features and rules governing user savings at university libraries. The deep auto encoder (DAE) is initially improved by the LSTM in order to enable the framework to retrieve the temporal aspects of the data. The resultant book recommendation for the present user is then obtained by using the Softmax function. The suggested approach is validated on the basis of real library lending data. The findings demonstrated that the suggested strategy outperforms a number of other RSs.

Minyu Liu [20] developed a deep-belief network-based book recommendation system. Personalized service suggestions are based on the scenario ontology, which is calculated using the ontology similarity calculation approach. The scenario ontology is then derived based on the library and users' information demands. A deep learning-based personalized intelligent RS idea for book services was proposed by Weiwei Yang [21]. By applying intelligent technologies like machine learning, users can evaluate their big data, create user profiles, correlate resources and users with their profiles, and receive individualized intelligent services. In order to provide users with personalized intelligent book recommendation services that primarily satisfy their potential demands and match their interests, the paper first retrieved users' personalized interests. Next, it identified users' current personalized potential book demands using the plain Bayesian algorithm. Finally, it provided users with personalized book recommendation services. A content-based scientific article recommendation (C-SAR) framework based on a DL approach was developed by Akhil M. Nair et al. [22]. The primary objective of the proposed model was to identify papers by comparing their titles. The most often recurring set of documents from a comparable collection were filtered using an association rule mining Apriori approach, and the Gated Recurrent Unit method was used to determine how similar the documents were. The simulation results revealed that the model performed better than current models that make use of user representations and basic K-means clustering.

A decision tree-based book recommendation system framework was proposed by Anant Duhan and Dr. N. Arunachalam [23]. The effectiveness of a classifier is a major factor in book recommendation systems. Real user data was used to test the system. According to the simulation results, the decision tree classifiers outperformed because of their strong learning capacity, quick classification speed, high accuracy, and straightforward design. A cross-domain book recommendation system employing sequential pattern mining and rule mining was proposed by Taushif Anwar and V. Uma [24]. The suggested approach integrates Wpath, CF, and SPM to recommend the most favored items from many domains with greater recommendation accuracy. Wpath is used in the proposed study to assist in determining the semantic similarity between items that belong to different domains. Topseq criteria are used to extract the sequence's favored items, while the Prefix Span technique assists in retrieving frequently occurring sequences. Initially, the RMSE is used to compare the errors. Finally, the algorithm for pattern mining is examined. The outcome shows that, as compared to the CF-KNN technique, CD SPM performed better. Chendhur et al. [25] introduced an improved CF strategy based on user preferences. The key objective of this suggested method is to make book recommendations to users based on their reading preferences and to boost the accuracy of those recommendations by enhancing the computational techniques used in the collaborative filtering algorithm. There are four major modules in the proposed approach. The book crossing dataset is used to assess the suggested method. The experimental findings demonstrated that the suggested approach offers the user effective book recommendations.

Neighborhood-Based Collaborative Filtering (NBCF) has its limitations, including a restricted range of recommendations, vulnerability to data sparsest, challenges with handling cold-start scenarios, and relatively slow prediction processing. Model-Based Collaborative Filtering (MBCF) necessitates parameter tuning, entails resource-intensive training phases, and exhibits a sluggish training process. Calculating similarities in graph-based collaborative filtering (GBCF) for large-scale commercial applications can be resource-intensive in terms of both space and time. The computational complexity involved in these calculations can result in significant costs, making the adoption of such systems expensive for businesses. Hybrid-Based Collaborative Filtering (HBCF) involves calculating similarities in large commercial applications, which can be computationally expensive in terms of both space and time complexity. The complexity and adoption of these systems often come with significant costs.

III. Materials and Method

The proposed book recommendation system utilized MF method using WALS method. The detailed block diagram of the suggested methodology is visualized in Fig. 1. The suggested book recommendation system methodology begins with dataset collection and preprocessing to ensure data quality. Data preprocessing involves data cleaning, handling missing values, and outlier detection. Data cleaning is the process of guaranteeing the absence of errors and discrepancies within a dataset. Missing values are imputed or removed, and outliers, which can distort recommendations, are identified and addressed. EDA is crucial to understand the dataset better. It includes visualizations and statistical analysis to uncover patterns, trends, and relationships within the data. EDA can reveal insights such as popular book genres, user preferences, and rating distributions. In this paper, MF with techniques like WALS is applied to generate personalized recommendations based on user-item interactions. In this approach, the user-item interaction data is deployed as a matrix. MF techniques like WALS are applied to decompose this matrix into two lower-dimensional matrices—one denoting user and the other denoting books. The latent factors extracted from these matrices capture user preferences and item characteristics. The performance of the RS is rigorously assessed in terms of Root Mean Squared Error (RMSE) to refine the model and enhance its effectiveness in suggesting books that align with users' preferences and interests.

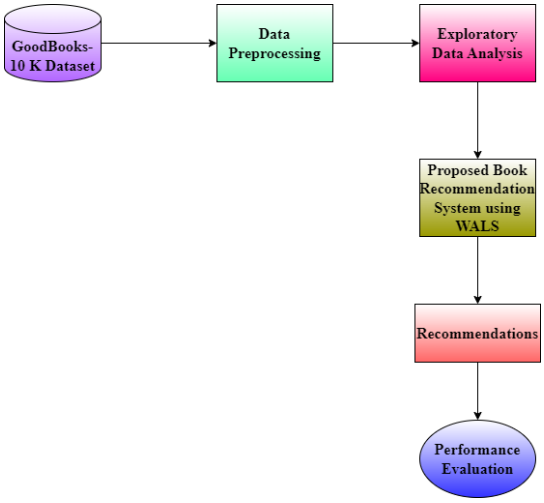

Fig. 1. Block diagram of the proposed book recommendation system.

A. Dataset Description

The goodbooks- 10k dataset has been utilized in this work, which comprises ratings for a collection of ten thousand popular books. Typically, each book is associated with approximately 100 reviews, although there are instances of books with fewer ratings. These ratings are on a scale of one to five. The book IDs and user IDs in this dataset follow a sequential numbering scheme, ranging from 1 to 10000 for books and 1 to 53424 for users. It's noteworthy that all users have provided at least two ratings, and the median number of ratings per user is eight. The dataset is organized into various folders, including "ratings.csv" for ratings data, "to_read.csv" containing user-to-book pairs indicating books marked as "to read," "books.csv" providing metadata for each book (e.g., goodreads IDs, authors, titles, average ratings), "book_tags.csv" containing tags, shelves, and genres granted to books by users, and "tags.csv" which maps tag IDs to their corresponding names. For our book recommendation task, we specifically leveraged the "ratings.csv" file. Table I summarizes the key attributes within the dataset, and Fig. 2 offers a visual representation of the dataset structure.

TABLE I. FEATURE DESCRIPTION OF DATASET

Features	Description
bookID	Unique identification number for each book
title	Name under which book was published
authors	Name of the Authors of the book
average_rating	Average rating of the book received in total.
isbn	International standard book number
isbn13	13-digit isbn to identify the book
language_code	Primary Language of the book
num_pages	Number of pages the book contains
ratings_count	Total Number of ratings the book received.
text_reviews_count	Total number of written reviews received.
publication_date	Date when the book was first published
publisher	Name of the Pulishers

B. Data Preprocessing and Exploratory Data Analysis (EDA)

Data preprocessing is a vital and often time-consuming phase in the data analysis process, as it plays a key role in improving data quality by addressing issues such as missing values, outliers, inconsistencies, and errors. The precision and dependability of subsequent analyses are significantly shaped by the quality of the data. Missing data, in particular, can significantly affect data analysis quality. There are several methods to manage missing data, including data deletion and imputation. Managing missing values is a critical aspect of data preprocessing since it directly impacts the dataset's quality and reliability. Various strategies are available to address missing data, such as eliminating rows with missing values, filling in missing values with measures like the mean, median, or mode, or utilizing more advanced techniques like regression imputation or predictive modeling.

Identifying and managing outliers is a critical component of data preprocessing, serving to pinpoint data instances that exhibit substantial deviations from the bulk of the dataset.

These outliers represent data points that are exceptional or divergent from the norm and have the potential to exert a substantial influence on the outcomes of data analysis, the

performance of learning models, and the integrity of statistical inferences.

Exploratory Data Analysis (EDA) is a fundamental stage in data analysis dedicated to providing a comprehensive overview of a dataset's essential features. This process serves as a crucial step in gaining profound insights into the data prior to employing more advanced statistical and learning models. To start the EDA process, descriptive statistics are employed to offer an initial snapshot of the data's central tendencies and variability. Key descriptive statistics often encompass metrics like the mean, median, mode, standard deviation, and range. Fig. 3 illustrates the descriptive statistics of the collected dataset, offering a concise representation of these critical data characteristics.

Data visualization is a powerful EDA technique that involves creating visual representations of data. This includes scatter plots, line charts, bar plots, heatmap, and more. The visualization of top 10 authors with maximum book published is shown in Fig. 4. The most occurring book in the collected dataset is visualized in Fig. 5.

C. Proposed Book Recommendation System Using Weighted Alternating Least Square (WALS) Method

WALS is a popular MF technique frequently employed in RSs, including those used in book recommendations. Its primary objective is to break down the user-item interaction matrix into two lower-dimensional matrices: one for users and another for items. These matrices capture latent factors that encapsulate user preferences and item characteristics. WALS serves as an extension of the Alternating Least Squares (ALS) method, a widely utilized collaborative filtering approach [26].

To understand the ALS method, consider a rating data matrix R with dimensions $m \times n$, where there are n users and m items. The entry R_{ui} at the $(u, i)^{th}$ position within the matrix R corresponds to the rating given by user u to item i. Since this matrix captures user-item interactions, it is naturally sparse due to the fact that not all users rate or interact with every item, leading to numerous empty or missing values. MF offers a viable solution to the intricate problem of handling sparse matrices. It involves decomposing the R matrix into two k-dimensional vectors, often specified as "factors." These factors play a vital role in capturing underlying patterns and relationships between users and items, enabling more effective recommendations.

- x_u is k dimensional vectors summarizing's every user u.
- y_i is k dimensional vectors summarizing every user i.

$$\text{Let}, r_{ui} \approx x_u^T y_i \quad (4)$$

$$x_u = x_1, x_2, x_{3,\ldots\ldots,} x_n \in R^k \quad (5)$$

$$y_i = y_1, y_2, \ldots\ldots\ldots, y_n \in R^k \quad (6)$$

Eq. (4) can be assembled as an optimization problem to find:

$$\text{argmin} \sum_{r_{ui}} (r_{ui} - x_u^T y_i)^2 + \lambda(\sum_u \|x_u\|^2 + \sum_i \|y_i\|^2) \quad (7)$$

The regularization factor denoted as λ is commonly referred to as "weighted λ regularization." This parameter, λ, serves the purpose of mitigating over fitting, and its value can be customized to fine-tune the model's performance in mitigating over fitting. The default value for λ is typically set at 1, but it can be modified as needed to achieve optimal results.

When the set of variables x_u is held constant, the objective function for y_i becomes convex. Conversely, when the set of variables y_i is constant, the objective function for x_u also becomes convex. By iteratively optimizing x_u and y_i using this alternating approach until convergence, we employ a technique known as Alternating Least Squares (ALS) to determine the optimal values for these variables.

WALS is a MF approach widely employed in RSs to model user-item interactions. The primary objective of WALS is to factorize the user-item interaction matrix while optimizing a weighted least squares objective function. By iteratively updating latent factor matrices for users and items, WALS discovers hidden patterns that capture user preferences and item characteristics. The incorporation of weights allows for flexibility in handling missing data and emphasizing the importance of certain interactions. With its alternating least squares optimization strategy, WALS efficiently generates recommendations by approximating missing entries in the interaction matrix, making it a valuable tool for personalized and efficient RSs.

The goal of WALS is to approximate the user-item interaction matrix R as a product of two lower-rank matrices, U (user matrix) and V (item matrix), where:

$$R \approx U * V^T \quad (8)$$

R is the user-item interaction matrix, where $R(i, j)$ represents the interaction or rating of user i for item j.

WALS aims to factorize the user-item matrix R into two matrices, U and V, such that the approximation $R \approx U * V^T$ holds.

WALS uses a weighted least squares approach to optimize the factorization. It introduces a weight matrix W, where $W(i,j)$ is the weight associated with the interaction between user i and item j. This weight can be set based on various criteria, like the confidence of the user's rating or the number of interactions.The objective function to minimize in WALS is the weighted least squares loss, defined as follows:

$$L(U,V) = (R(i,j) - U(i,:) * V(j,:)^T)^2 \quad (9)$$

Here, $U(i,:)$ represents the i^{th} row of the user matrix U, and $V(j,:)$ represents the j^{th} row of the item matrix V.

To minimize the loss function, WALS uses an alternating optimization approach. It alternates between updating U and V while keeping the other matrix fixed.

Updating U:For each user i, the update rule for $U(i,:)$ is given by:

$$U(i,:) = (\sum(W(i,j) * V(j,:)^T * V(j,:)))^{-1} * \sum(W(i,j) * R(i,j) * V(j,:)) \quad (10)$$

Updating V:For each item j, the update rule for $V(j,:)$ is given by:

$$V(j,:) = (\sum(W(i,j) * U(i,:)^T * U(i,:)))^{-1} * \sum(W(i,j) * R(i,j) * U(i,:)) \quad (11)$$

The alternating optimization process continues until convergence criteria are met, such as a maximum number of iterations, or a small change in the loss function. Once the factorization is complete, you can make recommendations for users by computing the predicted ratings as follows:

$$R_{pred}(i,j) = U(i,:) * V(j,:)^T \quad (12)$$

In practice, regularization terms are often added to the objective function to prevent over fitting. These regularization terms penalize large values in U and V. The step-by-step operation of WALS is shown below.

Step 1- Initialization: The process starts with the random initialization of matrices representing user features and item features in the algorithm.

Step 2- Alternating optimization: The algorithm alternates between optimizing the user-feature and item-feature matrices.

Step 3- User-feature optimization: The algorithm updates the user-feature matrix while keeping the item-feature matrix fixed. It does this by solving a least-squares problem using the weighted ratings of each user. The weight assigned to each rating is based on the confidence level of the user's rating.

Step 4- Item-feature optimization: The algorithm updates the item-feature matrix while keeping the user-feature matrix fixed. It does this by solving a least-squares problem using the weighted ratings of each item. The weight assigned to each rating is based on the confidence level of the user's rating.

Step 5- Convergence: The algorithm repeats steps 3 and 4 until the disparity between the predicted ratings and actual ratings is minimized, or a predetermined number of iterations is attained.

Step 6- Prediction: Once the algorithm has converged, it can use the user-feature and item-feature matrices to predict the ratings of unseen user-item pairs.

IV. Results and Discussion

A. Hardware and Software Setup

The proposed book recommendation system is implemented on Google Collaboratory platform. Google Collaboratory, is a cloud-based platform that provides free access to a virtual environment with a variety of resources, including a Nvidia K80 GPU with 16GB of GPU memory. Colab supports Python, a versatile and widely-used programming language, and it comes pre-installed with popular libraries like TensorFlow and Keras. The key parameter of WALS utilized by the proposed book recommendation system is tabulated in Table II.

TABLE II. Parameters

Parameters	Explanation
Rank of the factorized matrix (K)	The number of latent factors or dimensions used in the matrix factorization process.
Regularization parameter	Hyper parameter used to control the degree of regularization applied to the coefficients or during training.
Number of iterations	Determines how many times the algorithm will update its parameters or make incremental changes during the training process.

B. Results

The effectiveness of the suggested book RS is assessed through the use of RMSE, a broadly adopted measurement for analyzing the performance of RS. RMSE serves as a means to gauge the accuracy of a RS's predictions by quantifying the discrepancy between the system's predicted values and the actual user preferences, ratings, or interactions with items, such as books, movies, or products. In the realm of RS, RMSE is employed to determine how closely the system's predictions align with the real interactions of users with items, generally structured in a user-item interaction matrix where rows represent users, columns represent items, and the matrix cells contain user interactions, which may include ratings, purchase

history, clicks, or any other relevant user-item engagement data. The RS predicts the missing values in the interaction matrix. These predictions represent the system's estimate of how a user would rate or interact with items they have not yet interacted with. Actual user ratings or interactions for some items are available in the dataset. These are the ground-truth values that the RS aims to predict. For each user-item pair where both actual and predicted values are available, RMSE calculates the squared difference between the actual and predicted values. The squared differences are then averaged across all user-item pairs. The RMSE value is computed by initially calculating the average and then finding the square root of that average. RMSE can be expressed as:

$$\text{RMSE} = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(r_i - \hat{r}_i)^2} \quad (13)$$

Table III contains a tabulation of the suggested book recommendation system's performance under various conditions.

The model's performance is significantly affected by the choice of hyper parameters, particularly λ and the number of iterations. When λ is set at 0.1, the RMSE diminishes as the number of iterations rises, with the lowest RMSE achieved at 20 iterations. However, for a lower λ of 0.01, the RMSE is only marginally higher, indicating that a more conservative regularization may be preferred. Furthermore, the training and testing times show an increase as the number of iterations and λ value grow, indicating a trade-off between model accuracy and computational efficiency. The best-performing configuration seems to be with λ = 0.01 and 20 iterations, achieving a reasonable RMSE while maintaining a relatively lower computational cost. In summary, the WALS method appears promising for book recommendation. The graphical representation of RMSE values under K=5 and 10 iterations are shown in Fig. 7 also the trining time distribution,testing time distribution is outlined in Fig. 8, Fig. 9.The recommendation output is tabulated in Table IV.

TABLE III. PERFORMANCE OF PROPOSED BOOK RECOMMENDATION SYSTEM

K	λ	Number of Iterations	RMSE	Training Time	Testing Time
5	0.1	10	3.880	225.670	0.00168
10	0.1	10	3.833	413.3266	0.00176
20	0.1	10	3.77	832. 388	0.001498
5	0.01	10	3.879	227.261	0.001847
5	0.001	10	3.878	221.310	0.001836
5	0.001	20	3.8787	448.85	0.001432
5	0.001	25	3.878	567.545	0.00155
5	0.001	30	3.8795	686.3248	0.001526

Fig. 8. Training Time Distribution (K=5, number of iterations=10).

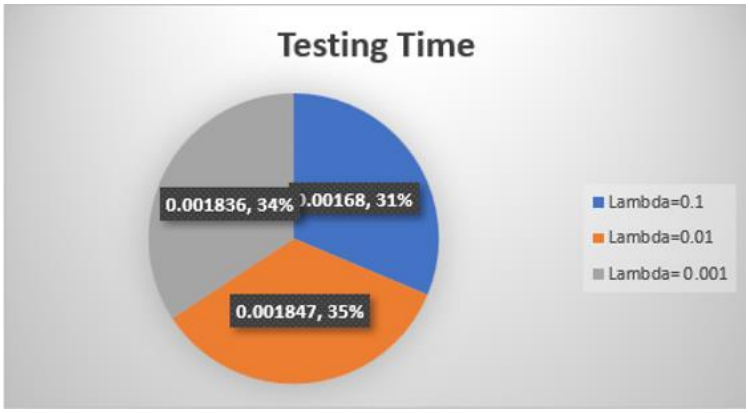

Fig. 9. Testing Time Distribution (K=5, number of iterations=10).

C. Discussion

The assessment of the suggested book recommendation system's performance, evaluated through Root Mean Square Error (RMSE), reveals insights into its effectiveness across varied hyper parameter configurations. Results from Table III showcase RMSE values ranging from 3.770 to 3.880, indicating a moderate accuracy in predicting user-item interactions. Notably, λ and the number of iterations significantly impact the system's performance, with higher λ values leading to lower RMSE but increased computational costs. Conversely, lower λ values result in marginally higher RMSE but offer computational efficiency. Graphical representations aid in understanding these trends. Ultimately, a balance between RMSE and computational resources is achieved with λ = 0.01 and 20 iterations, highlighting the promise of the Weighted Alternating Least Squares (WALS) method for book recommendations. Overall, hyper parameter tuning plays a crucial role in optimizing recommendation system performance, offering opportunities for enhancing user satisfaction and engagement in book recommendations and beyond.

V. Conclusion

In the modern digital era, book recommendation systems have become integral to elevating the reading experience for individuals. These systems leverage advanced algorithms, user data, and content analysis to provide personalized book suggestions, helping readers discover new titles that align with their preferences and interests. This paper presents an effective book recommendation system using the WALS method using ratings. WALS is a MF technique commonly used in collaborative filtering-based RSs. The major goal is to reveal hidden elements that capture the fundamental traits of users and books by breaking down the matrix of user-item interactions. Unlike traditional alternating least squares, WALS introduces the concept of weighting, allowing it to assign different levels of importance to user-item interactions. This weighting factor can reflect the confidence or reliability of a user's rating, making WALS particularly useful in scenarios with sparse or noisy data. By iteratively optimizing these latent factors, WALS refines its recommendations, ultimately providing users with personalized suggestions by estimating their preferences based on the discovered latent features. The proposed method yielded outstanding results with considerably diminished RMSE values. This achievement underscores the efficacy of WALS in enhancing the accuracy of book recommendations, allowing users to discover books that align more closely with their individual preferences. A smaller RMSE value indicates that the system is more proficient at predicting user behavior, resulting in a more gratifying and individualized reading experience.

Majmaah University, Al-Majmaah, Saudi Arabia

***Abstract*—Optimizing maintenance procedures is essential in today's industrial settings to reduce downtime and increase operational effectiveness. To improve predictive maintenance in industrial settings, this article investigates the combination of machine learning (ML) techniques and the Industrial Internet of Things (IIoT). The goal of this research is to advance predictive maintenance in industrial settings by integrating ML with IIoT in a seamless manner. Addressing the complexities of industrial systems and limitations of traditional maintenance methods, this study presents a methodology leveraging four distinct ML models. The technique includes a thorough assessment of these models' correctness, revealing differences that highlight the significance of a careful model selection procedure. The current investigation analysis finds the most effective model for predictive maintenance activities using thorough data analysis and visualization. Our work offers a potential path forward for the industrial sector and provides insights into the complex interactions between IIoT and ML. This study lays the groundwork for future developments in predictive maintenance, which will reduce downtime and extend the life of industrial equipment.**

Keywords*—*Predictive maintenance; IIoT; data visualization; machine learning; industrial systems

I. Introduction

The industrial sector is always searching for methods to save expenses, increase productivity, and decrease downtime. Maintenance of machinery particularly that used in the textile sector is one area that might be improved. Reactive techniques have formed the foundation of traditional maintenance practices, where equipment is fixed following a failure [1]. Predictive maintenance, on the other hand, has become a more proactive and economical option by utilizing data analytics and ML approaches [2].

Predictive maintenance is a proactive approach that foresees equipment faults before they happen by using ML and data analytics. Organizations may schedule maintenance just in time to avert failures by identifying trends and abnormalities through continuous equipment condition monitoring and data analysis. This strategy increases the longevity of industrial assets, reduces downtime, and optimizes maintenance tasks. Predictive maintenance is unique in that it may replace reactive and fixed-schedule maintenance with a more planned, data-driven approach, resulting in higher dependability and cost savings for a variety of sectors. Productivity and operational efficiency are significantly impacted by the efficient management of maintenance procedures in the quickly changing industrial operations environment. This article, which embraces technological developments, explores how ML techniques and the IIoT might be used to improve the predictive maintenance paradigm in industrial settings.

In industrial settings, predictive maintenance is a data-driven, strategic strategy that maximizes equipment durability and reduces unscheduled downtime. Organizations can prevent equipment failures by using ML and advanced analytics to predict possible problems before they arise. Through the use of sensors and data-gathering tools, this approach continuously monitors the state of the equipment, allowing for the examination of several characteristics. After the collection of data, advanced algorithms are employed to detect patterns, trends, and abnormalities, therefore offering significant insights into the condition of industrial machinery. Organizations may go from a more reactive or fixed-schedule maintenance approach to one that is more proactive and efficient with the help of predictive maintenance. Organizations may maximize the operating lifespan of their assets and minimize expensive failures by precisely forecasting when maintenance is required and scheduling interventions just in time.

Predictive maintenance, or PdM, seeks to lower expenses so that businesses may compete more fiercely. It optimizes the maintenance intervention plan by combining sensor data with analytical methods. Optimizing maintenance methods is critical to maintaining operational efficiency and reducing downtime in the complex web of industrial processes. A key tactic that replaces conventional reactive methods with proactive, data-driven ones is predictive maintenance. In the end, this paradigm aims to improve the lifetime and dependability of industrial assets by anticipating breakdowns and facilitating prompt interventions and resource optimization. Predictive maintenance is essential to preventing machine breakdowns and maintaining a high level of production line productivity. The suggested IIoT architecture uses ML techniques to achieve predictive maintenance.

Amidst this paradigm shift, a new age for predictive maintenance in industrial settings has been brought about by the combination of two technical pillars: ML and the IIoT [36].

The symbiotic integration of IIoT technologies makes it possible to monitor equipment continuously and in real-time, producing copious amounts of data that are essential to the development of predictive models. At the same time, ML algorithms that can identify patterns in large datasets raise the bar for predictive maintenance above rule-based systems by providing more detailed insights and improving failure prediction accuracy. There are several layers in the IIoT

*Corresponding Author, email: m.anul@mu.edu.sa

architecture, including those for business connection, device connectivity, and data analytics. Wireless sensor networks provide flexible communication between external and internal equipment, which makes it possible to create effective preventative maintenance plans. One of the key advantages of IIoT is its ability to decrease data transfer to the cloud, which will cut energy consumption and increase forecast accuracy. IIoT architecture is essential for industries where continuous monitoring is necessary since it simplifies data processing and analysis [3,4,5].

Device connectivity, data analytics, and business connectivity make up its three levels. This sophisticated approach promotes a more accurate and efficient maintenance plan by making it easier to identify probable defects and to distinguish between typical changes and important abnormalities. Where human eyes or ears can no longer detect and gather sensitive information from equipment, primarily motors, automated technologies offer a workable option for many sectors [6]. The basis for predictive maintenance schedules is gathered data from sensors and analytical algorithms [7].

The IIoT is a network of smart devices, sensors, and machines that uses the connection to generate a revolutionary change in how industries function. Data-driven decision-making is made possible by the unparalleled volume of data generated by this networked environment. With companies becoming increasingly instrumented and networked, the difficulty is in efficiently utilizing and analyzing this massive amount of data to extract valuable insights.

A key component of the IoT and IIoT environment is Artificial intelligence (AI), which provides the capacity to process, analyze, and understand large datasets at speeds that are not possible with conventional techniques. AI systems are very good at finding trends, abnormalities, and connections in data, turning unprocessed input into useful knowledge. This capacity is especially important in situations when making decisions quickly is required, such as demand forecasting, resource allocation, and manufacturing process optimization. In addition, in order to fulfill consumer requests and keep up with market competitiveness, industrial systems and processes must be regularly monitored and overseen in order to meet the short product lifecycle demands of today's market.

IIoT framework permeates all facets of the automotive industry for predictive maintenance by strategically installing smart sensor devices to perform sensitive operations, with tracking and monitoring playing a major role [23,24,25]. In the context of industry, IoT is known as IIoT and it has gained significant research attention recently [26], [27]. Several sensors are used in IIoT to keep an eye on the operation of machinery or even whole production processes [28]. The goal of the IoT is to simplify our lives. Since its beginning, every industry has made use of it in some way. Traditionally, data collection in IIoT has involved streaming data from sensing devices to the cloud, where it is analyzed and modeled. Sensing equipment produces massive volumes of data, frequently during a short period, either constantly or sporadically. For instance, a machine may produce thousands of records in a second [29]. Computing is revolutionized by ML, which gives computers the ability to see patterns in data and make wise judgments. Models for tasks like classification are trained on labeled data in supervised learning.

Patterns in unlabeled data can be found using unsupervised learning. ML influences day-to-day living through tailored suggestions and virtual assistants. The requirement for labeled data and resolving moral issues with algorithmic biases present challenges. The future of ML will be shaped by developments in fields like ethical issues and reinforcement learning. The cognitive engine that drives IIoT smart systems is ML, a subset of AI.

Because ML algorithms can learn and adapt from past data, they are a good fit for dynamic industrial situations, in contrast to traditional programming. ML has significant uses in real-time decision support, anomaly detection, and predictive maintenance within the IIoT. A paradigm change made possible by ML is predictive maintenance. ML is a cutting-edge application in the field of predictive maintenance in industrial settings. When it comes to managing the complex linkages and varied datasets found in industrial systems, traditional methods frequently fall short. However, ML algorithms are adept at navigating this complexity by noticing trends in data and adjusting to improve their prediction power. The predictive framework integrated with the notions of adaptive structuration theory is shown in Fig. 1. In the structural idea, the maintenance technician watches a facility asset in use. As seen in Fig. 2, it anticipates faults and conducts repairs on the machinery or equipment before they arise. The only machines or components that can be replaced are those that will shortly fail. It prolongs the equipment's lifespan. But usually, they consider the systems viewpoint [30], technical [31], architecture [32], security [33], and [34], or concentrate on the analytics side [35] within the framework of IIoT.

Through the integration of ML techniques and the IIoT, this research aims to enhance the field of predictive maintenance in industrial contexts. Our approach is based on a careful investigation and use of four different Python programs, each carefully designed to maximize the capabilities of different ML models. Because these models' accuracy varies, it is critical to conduct a careful selection process in order to choose the best predictive maintenance plan. Our methodology highlights the subtle nuances of model performance while also demonstrating the revolutionary potential of IIoT and ML in enhancing industrial maintenance. There are several advantages mentioned in [8,9,10].

The rest of this paper is organized as follows: Section I presents a general introduction to Predictive maintenance, IIoT and ML. Section II is about the literature review and Section III details how the system works. Section IV Experimentation, dataset, implementation, and evaluation Metrix. And the last Section we discuss results and comparisons between algorithms.

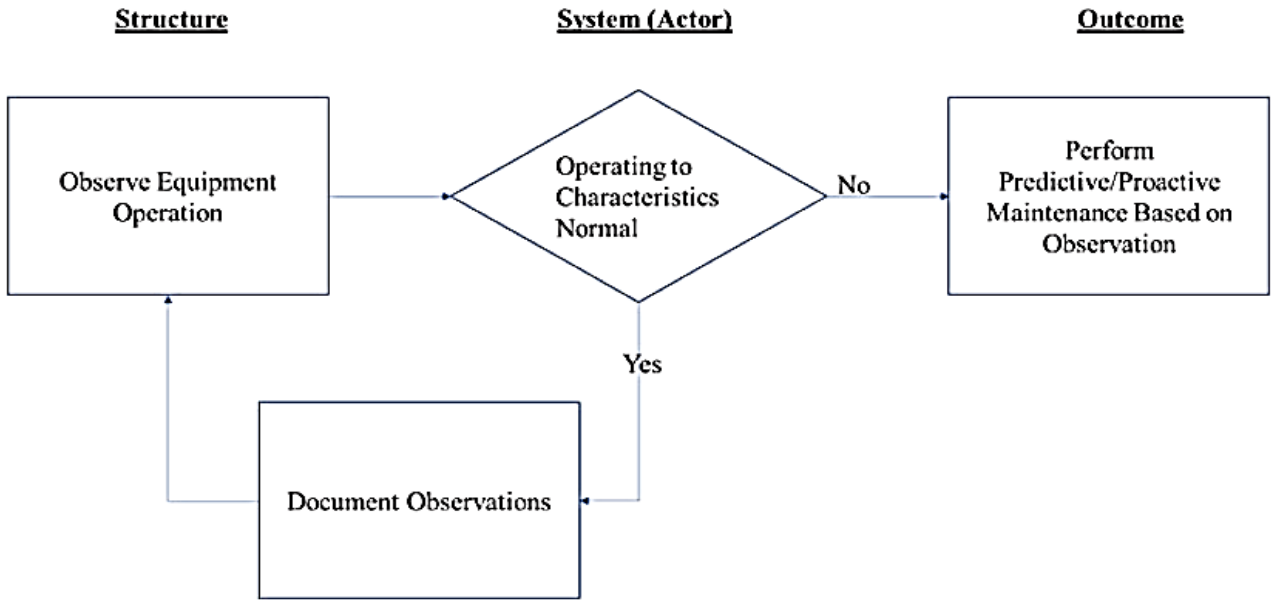

Fig. 1. Predictive maintenance framework.

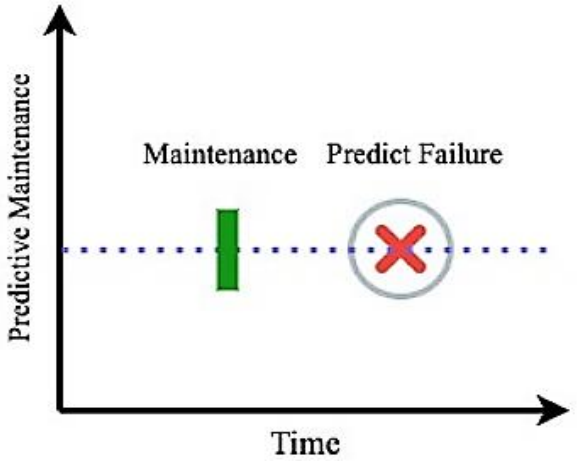

Fig. 2. Predictive maintenance overview.

II. Literature Review

Recent developments in maintenance techniques for manufacturing sectors were examined by Lee et al. [11], who emphasized the move in the era of smart manufacturing from reliability enhancement to flexible and adjustable maintenance scheduling. F. Ribeiro et al. [12] have automatically classified the flaws in rotatory machinery using non-ML approaches like similarity-based models (SBM). In a different research, A. Alzghoul et al. [13] used artificial neural networks (ANNs) to classify rotatory defects with a 97.1 percent accuracy rate. Consequently, their accuracy rate in classifying the defects is 96.43 percent. Singha et al. [14] examined the use of ML and AI in the knitting sector, emphasizing the revolutionary effects of these technologies. The research emphasized the thorough implementation of these technologies at several phases, including product sourcing, design, manufacture, distribution, and sales. Advances in fiber classification, thread prediction, defect diagnosis, and dye recipe prediction are made possible by the integration of AI and ML, which benefits the knitting industry's predictive maintenance.

A mechanism for making fuzzy decisions is devised by et al. [15]. The use of a case study on sewing machine needles, it illustrates how successful it is in planning predictive maintenance. Predictive maintenance was aided by the introduction of an IoT and ML-based online monitoring system for knitting machines by Elkateb et al. [16], [17]. Real-time tracking, statistical analysis, and problem-solving are made easier by this technology. As so, it makes precise productivity monitoring and preventative maintenance possible.

The usefulness of ML-based condition monitoring was the subject of a thorough assessment by Surucu et al. [18], who emphasized the models' major contributions to predictive maintenance. The research employed a Deep Belief Network (DBN) for feature extraction and a Gaussian process (GP) for optimizing DBN hyper-parameters in order to evaluate models utilizing deep learning and Bayesian optimization. Empirical findings outperformed traditional ML techniques in terms of accuracy in predicting machine failure times. Consequently, because of the complexity and distinct contextual elements, cross-case performance comparisons are inadequate. A different study examined an intelligent PdM system for industrial machinery using ML, Message Queuing Telemetry Transport (MQTT), and IIoT [19].

Electrical motors employ vibration, current, and temperature sensors to gather real-time data. Five ML models k-nearest neighbor (KNN), Support Vector Machines (SVM), random forest (RF), linear regression (LR), and Naïve Bayes (NB) are then used to evaluate the data and anticipate failures. Effective communication between sensors, gateways, and the cloud server is made possible via the MQTT protocol. When it comes to functioning motors, RF displays the best accuracy and optimizes maintenance plans to save costs and downtime [19].

A deep learning-based defect diagnostic technique for circular knitting machines was presented by Gao et al. [20]. Their approach classifies the different sorts of faults using a SoftMax classifier after automatically extracting features from vibration signals using a Convolutional Neural Network (CNN). The outcomes of the trial showed that their approach was able to diagnose faults in circular knitting machines with a promising level of accuracy. But for CNN to work well enough, a lot of training data is required. A predictive maintenance system for wind turbines was presented by Udo and Muhammad et al. [21] utilizing SCADA data and Long Short-Term Memory (LSTM) and XGBoost models for gearbox and generator monitoring. Six wind turbine faults were successfully detected using statistical process control (SPC), which evaluates anomalies and helps with early intervention and economical dynamic maintenance plans. Knitting machines are not used in the testing of this system, nevertheless.

In summary, recent research in predictive maintenance for industrial environments has shown hopeful results in improving maintenance efficiency and reducing costs. These studies have applied a variety of algorithms and different attributes to predict Remaining Useful Life (RUL) and to diagnose various faults in the machine. However, there is still a need for further research to develop more accurate, comprehensive, and efficient predictive maintenance systems for circular knitting machines. Diagnosis of different machine faults to achieve comprehensive predictive maintenance systems was not well covered in the literature. Moreover, applications of the developed methods on real working machines outside the laboratory environment were not well covered to prove their applicability in real conditions. To prevent lengthy machine breakdowns, the proposed work offers a predictive maintenance approach that anticipates machine halt and the cause of stoppage (failure).

A comprehensive maintenance approach considers many reasons for failure by utilizing multiple sensing devices. These devices' readings may be accessed by an ML-based classifier via an IoT system. Its distinctive features such as a powerful ML model, real-time monitoring, and an extensive database indicate a shift from traditional methods to contemporary, useful ways. To demonstrate the practicality of the suggested predictive maintenance system, it is put into operation on an actual circular knitting machine. The device performs well and has good precision. It also has a lot of potential to improve machine availability, reduce downtime, and maximize production in the textile sector.

III. METHODOLOGY

Prognostics is the subject of this study, with a focus on estimating an asset's RUL and determining if it is inside its final fifteen cycles. Using a NASA dataset, the research includes engine deterioration simulations in a range of operating scenarios and modes. Fig. 3 presents the overview of the of the entire system. The approach that was selected is based on time-series analysis, using several ML algorithms, and considering each time point as a separate unit. The Random Forest Regressor, Elastic Net GLM, SVM, and Gradient Boosting Regressor are the main models used. The first step is to use a NASA dataset that is kindly shared, which simulates engine deterioration under various operating situations and modes. This dataset captures the subtle progression of problems by recording many sensor channels. Utilizing ML techniques, the selected methodology predicts RUL and identifies assets in the past fifteen cycles by managing each time point individually.

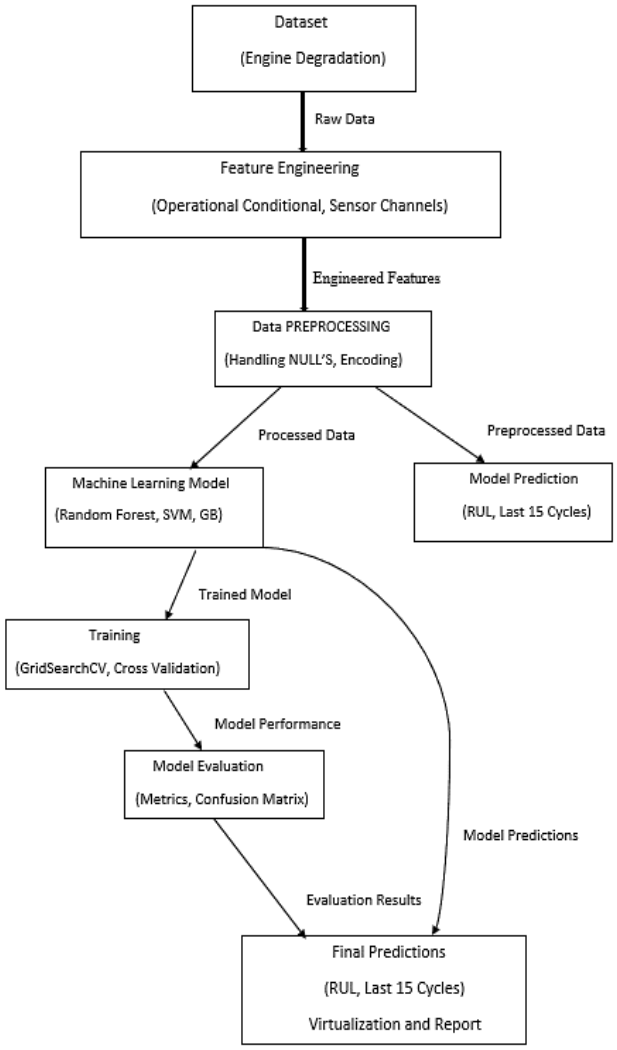

Fig. 3. Workflow of the present investigation.

The procedure starts with the dataset being explored, which includes loading the required packages, reviewing the data that is already accessible, and creating a reproducibility seed. Important stages after importing the data include sensor readings, operational settings, and goal variable structure. Feature engineering becomes essential when the Random Forest Regressor is used to determine which characteristics are most crucial. The code structure and how each phase advances the broader predictive analytics process are delineated in more detail in the Fig. 4. Loading the required packages, reviewing the available data, and establishing seeds for repeatability are all part of the first stage. The NASA dataset is well organized, with distinct column names designating sensor readings, cycle information, and operating parameters.

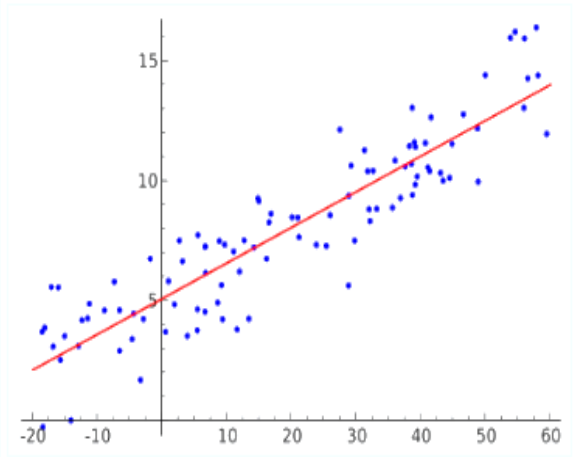

Fig. 4. Linear regression.

A. Linear Regression

Visualizing the correlations between goal variables RUL and Last 15 Cycles) and other attributes is done using exploratory data analysis (EDA). A Random Forest repressor [22] is used in a noteworthy feature selection stage to find important predictors that will impact the next data preparation RUL for each cycle is calculated using the T-minus notation approach. Pair plots and seaborne visualizations offer a comprehensive comprehension of the data distribution. Target leakage management, removing superfluous columns, and getting the data ready for model training are the next steps. To determine feature relevance and enable the elimination of sensors with lower levels of information, the Random Forest repressor is utilized. Identification of numeric and categorical fields is done, with the creation of dummy variables for the former. Any NULL values that remain in numerical columns are addressed by imputation. For training and evaluating the model, the dataset is then divided into training and testing sets.

For regression problems, three different ML models are used: Random Forest, Elastic Net GLM, and SVM. To pick the best hyperparameters, grid search and cross-validation are applied to each model during optimization. Grid search is also utilized for the Gradient Boosting Repressors optimization, which was selected because of its capacity for group learning. Model performance is evaluated using evaluation metrics including R-squared values, Mean Absolute Error, and Mean Squared Error. To determine when an asset is inside its Last 15 Cycles, the regression job must be transformed into a classification issue in the last phase. Recall, precision, and ROC-AUC scores are used in the training and assessment of a Random Forest Classifier. ROC curve visualizations offer more information on classification performance. Fig. 4 shows Linear regression.

B. Decision Tree Regression

Decision Tree Regression (DTR) [22] and LR. The yellow-colored LR illustrates the linear links that exist between RUL and input characteristics. DTR, shown in green, uses a structure akin to a tree and is particularly good at identifying complicated decision boundaries and non-linear patterns in the input characteristics used to forecast RUL.

Within your code, the RUL of engines is predicted using a basic approach called LR. The foundation of linear regression is the creation of a linear connection between the input characteristics and the target variable in this example, the number of operational cycles left until failure. In order to develop a linear model that best represents the connection between these characteristics and the RUL, the algorithm makes use of a collection of input data, such as operational settings and sensor readings. The training data that is supplied, where the real RUL values are known, is used to train the model. The method modifies its parameters during training in order to reduce the discrepancy between the genuine RUL values from the training set and the projected RUL values. Once trained, the RUL of engines not seen during training may be predicted using test data that has not yet been observed. This is known as the Linear Regression model. The model's efficacy is then assessed by comparing the predictions to the actual RUL values using a variety of metrics, such as Mean Squared Error (MSE), Mean Absolute Error (MAE), and R-squared (R^2).

Using an ensemble technique, Random Forest Regression builds many decision trees and combines their predictions. This method reduces overfitting problems and improves accuracy. The fourth method, Gradient Boosting Regression, is the last one. It creates consecutive decision trees to repair the mistakes of the previous ones and can achieve high predicted accuracy.

C. Remaining Useful Life (RUL)

In the given system, Random Forest Regression (RFR) [22] and Gradient Boosting Regression (GBR) are essential for forecasting RUL. RFR uses a group of individual decision trees in its ensemble representation to provide predictions. By adding to the final forecast, each tree improves its resilience and accuracy. In contrast, GBR makes use of a series of succeeding decision trees, each of which steadily improves forecast accuracy by fixing the mistakes of its predecessor. Both techniques increase the predictive model's overall efficacy by using input information (referred to as "Input Features") to forecast the engine's RUL in a range of operational circumstances. Fig. 5 shows the actual RUL with prediction.

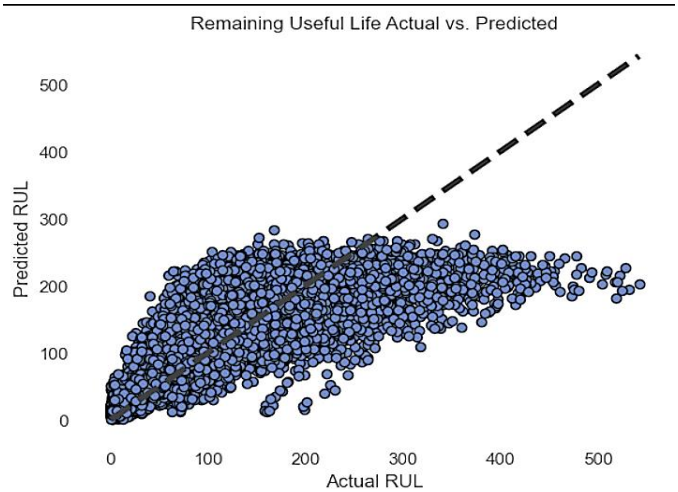

Fig. 5. Remaining useful life.

RFR and GBR are essential for forecasting RUL. RFR uses a group of individual decision trees in its ensemble representation to provide predictions. By adding to the final forecast, each tree improves its resilience and accuracy. In contrast, GBR makes use of a series of succeeding decision trees, each of which steadily improves forecast accuracy by fixing the mistakes of its predecessor. Both techniques increase the predictive model's overall efficacy by using input information (referred to as "Input Features") to forecast the engine's RUL in a range of operational circumstances [22].

The RFR algorithm functions as an ensemble learning technique, as illustrated by the "Random Forest Regression" box. It generates a large number of decision trees, which come together to build a strong and varied model known as the "Ensemble of Decision Trees." The "Input Features" ellipse represents the input characteristics that each tree in the ensemble individually processes and produces a forecast for. Combining the distinct results from each decision tree yields the final forecast. This ensemble method is useful for assessing the engine's RUL in the given system since it reduces overfitting and improves forecast accuracy. Every algorithm offers distinct advantages to the process of predictive modeling. While Decision Tree Regression excels at addressing non-linear patterns, Linear Regression is simple and easy to understand. While Gradient Boosting Regression concentrates on progressively lowering prediction errors, Random Forest Regression provides resilience and control over variance. These methods' diversity guarantees a thorough examination of the dataset and provides insights into how well each algorithm performs in various scenarios.

IV. Experimentation

A. Dataset

The four separate subsets of the dataset [23] that were employed in this investigation are designated as FD001, FD002, FD003, and FD004. These subsets depict various failure mechanisms and operating settings. Four independent subsets comprise the dataset used in this study: FD001, FD002, FD003, and FD004. Each of these subsets has its own unique configurations and failure modes.

1) FD001: There are one hundred test and one hundred train trajectories in FD001. There is just one operational state, which is called "Sea Level." The dataset models a failure mode centered around the degradation of high-pressure compressors (HPCs).

2) FD002: There are 259 test and 260 train trajectories in the FD002 subgroup. With six different operational scenarios, the conditions are more varied. The failure mode addressed is HPC Degradation, much like in FD001.

3) FD003: FD003 has one hundred test and one hundred train trajectories and operates under the same "Sea Level" circumstances as FD001. However, by including two fault modes—HPC Degradation and Fan Degradation—FD003 presents a more complicated scenario.

4) FD004: With six different operational circumstances, the FD004 subset consists of 248 train trajectories and 249 test trajectories. Similar to FD003, FD004 deals with HPC Degradation and Fan Degradation as two failure scenarios.

To put it briefly, the goal of these subgroups is to represent various engine fleet operational conditions and failure types. FD003 and FD004 add more complexity by considering many failure modes under various operational circumstances, whereas FD001 and FD002 concentrate on unique operating conditions with HPC Degradation. The variety of datasets available makes it possible to thoroughly examine engine performance and behavior in various scenarios.

The multivariate time series datasets are separated into training and test trajectories for each subgroup. Every time series relates to a different engine in a fleet of similar engines. The engines show various levels of wear at startup and variance in manufacture that is not communicated to the user. This fluctuation is seen as typical and does not point to a problem. The data includes operational parameters, which have a significant effect on engine performance. Furthermore, noise from the sensors might contaminate the data. Each engine starts in a normal state in the operating context, acquires a defect during the series, and, in the training set, experiences an increasing fault size that results in system failure. The time series in the test set ends before a system failure. Predicting the number of operating cycles left in the test set before failure also known as the RUL is the competition's principal goal. The dataset, which captures different operating parameters and sensor readings during each cycle, is supplied as a 26-column text file that has been compressed using zip.

B. Implementation

Continuing with the implementation, several datasets, including FD001, FD002, FD003, and FD004, each representing distinct operational situations and failure modes, are subjected to iterative applications of the Random Forest Regression method. By training on a variety of datasets, the system takes beginning circumstances and engine wear into consideration. This variety adds to the resilience of the model by improving its capacity to respond to various conditions. The model notices the patterns of engine deterioration that result in system failure during the training phase. The model can capture the complex interactions between operational parameters and sensor readings since the training trajectories imitate both the engine's fault and normal circumstances. To guarantee convergence and avoid overfitting, the number of training epochs and batch size are adjusted.

During the testing phase, the RUL of the engines is predicted by applying the trained Random Forest Regression model to data that has never been seen before. Planning maintenance tasks and predicting breakdowns depend on this predictive capacity. By contrasting the model's projected RUL values with the dataset's ground truth RUL values, the efficacy of the model is thoroughly assessed. The model's accuracy and generalizability to new and varied circumstances are measured using metrics like MSE, MAE, and R-squared. A key factor in determining the model's capacity for generalization is the separation of training and testing trajectories. With its numerous trajectories, the training set replicates the typical wear and fault development patterns of the engines over time. The model can understand complicated correlations between

operating parameters and sensor readings because of the variety of training data, which helps it capture the nuanced dynamics of engine health. Conversely, the test set includes trajectories where the engines are nearing the end of their useful lives but are still working. This intentional separation guarantees that the model can produce precise forecasts on brand-new, untested data, proving its dependability in practical situations.

To sum up, the implementation takes a methodical approach to ML, with special emphasis on careful parameter tweaking and reliable assessment techniques. The objective is to develop a predictive model that will be an invaluable resource for predictive maintenance plans in the field of engine health management. This model will not only accurately estimate the Remaining Useful Life of engines but also exhibit resilience and adaptability across a range of operating conditions and fault modes.

C. Evaluation Metrics

In this section, we discuss evaluation metrics that are used in this study [35].

1) Mean Squared error

a) Definition: MSE is the average squared difference between the projected and actual remaining useful life (RUL) values. The dispersion of prediction errors is quantified.

b) Accuracy Measure: By punishing greater errors more severely, the Mean Squared Error (MSE) offers a thorough assessment of the total forecast accuracy. It works well with models when accurate RUL prediction is essential.

$$\text{Formula: } MSE = \frac{1}{n}\sum_{i=1}^{n} | Y_i - \acute{Y}_i| \quad (1)$$

n: Number of data points

Y_i : Actual RUL for data point i

$\acute{Y}_i$: Predicted RUL for data point i

2) Mean Absolute Error

a) Definition: The average absolute deviations between the actual and anticipated RUL values are determined by the MAE. It calculates the typical error magnitude.

b) Accuracy Measure: Because MAE is less susceptible to outliers, it offers a reliable way to quantify average prediction error. It works well with models in which the absolute error is more important than the mistake's particular direction.

$$\text{Formula: } MAE = \frac{1}{n}\sum_{i=1}^{n} | Y_i - \acute{Y}_i| \quad (2)$$

n: Number of data points

Y_i : Actual RUL for data point i

$\acute{Y}_i$: Predicted RUL for data point i

3) R-Squered

a) Definition: R^2 is the percentage that the model explains of the variation in the actual RUL values. It gauges how well the model fits the data.

b) Measure of Accuracy: R^2 has a range of 0 to 1, with 1 denoting a perfect match. It's a helpful measure of how well the model predicts the variability in the data as it really occurs.

$$\text{Formula: } R^2 = 1 - \frac{\sum_{i=1}^{n}(Y_i - \acute{Y}_i)^2}{\sum_{i=1}^{n} | Y_i - \bar{y}_i)^2} \quad (3)$$

n: Number of data points

Y_i : Actual RUL for data point i

$\acute{Y}_i$: Predicted RUL for data point i

$\bar{y}$: Mean of the actual RUL values

V. Results and Discussion

This study leverages ML algorithms, including Random Forest Regressor, Elastic Net GLM, SVM, and Gradient Boosting Regressor, to predict an asset's RUL using a NASA dataset. Through systematic data exploration, feature engineering, and model optimization, the methodology yields accurate RUL predictions. Importantly, the model's effectiveness and generalizability are substantiated by rigorous evaluation metrics like MSE, MAE, and R-squared values across diverse operational scenarios. This demonstrates the model's robustness and adaptability, positioning it as a reliable tool for enhancing predictive maintenance strategies in industrial settings.

1) FD001 Dataset: Notable outcomes were obtained from the study of the FD001 dataset, which consisted of one hundred trains and one hundred test trajectories with a single fault mode (HPC Degradation) and a condition of ONE (Sea Level). The Random Forest Regression model with the configuration of (mention configuration details) showed an R-squared of.89, an MAE of 29.89, and an MSE of 1772.26. 0.625 is the value of R^2. These metrics provide important information about how well the model predicts the RUL in these particular circumstances. Furthermore, a confusion matrix was created in order to have a deeper understanding of the model's performance. A more thorough assessment is made 9possible by this matrix, which offers a full picture of true positive, true negative, false positive, and false negative forecasts. Additionally, several curves, such as the learning curve and validation curve, were used throughout the training phase. These curves assist in uncovering any overfitting or underfitting problems by showing the model's convergence and performance over epochs.

2) FD002 Dataset: The applied model was shown using the FD002 dataset, which has 259 test and 260 train trajectories under SIX distinct circumstances and a single fault mode (HPC Degradation) (mention results). This dataset's confusion matrix made it possible to thoroughly assess the model's prediction skills, especially about differentiating between various failure types. The study was deepened by curves produced during training, such as the Precision-Recall and Receiver Operating Characteristic (ROC) curves. These curves shed light on the trade-off between recall and accuracy, respectively, as well as the true positive rate and false positive

rate. With 260 train and 259 test trajectories, the FD002 dataset represents a more complex operating scenario that includes a wider range of SIX different circumstances, all of which are shared by a Fault Mode HPC Degradation. The model's capacity to adapt to various operating situations, each with its own set of obstacles for predictive maintenance, is critically tested by this dataset. Operating Diversity: Compared to the FD001 dataset, there are SIX different operating situations, which adds a higher degree of complexity. The circumstances encompass changes in engine loads, temperatures, or other crucial elements, so rendering the dataset an all-encompassing depiction of actual operational scenarios. Thus, the model's capacity to identify trends and modify its predictions over this range of circumstances is put to the test. Common Fault Mode: HPC Degradation: The dataset maintains consistency about the prevalent fault mode, HPC Degradation, even in the face of diverse operational situations. This consistency allows for a targeted assessment of the model's capacity to recognize and forecast a particular fault mode in a range of operating scenarios.

3) FD003 Dataset: Compared to the earlier datasets, the FD003 dataset adds a layer of complexity with its one hundred train and one hundred test trajectories. In this instance, a single operating condition known as Sea Level is applied to all paths. The dataset deviates, though, in that it includes TWO different fault modes: fan degradation and HPC degradation. Singular Operational Condition: Sea Level is the one operational condition that is the focus of the FD003 dataset, as opposed to the SIX operational conditions of the FD002 dataset. This intentional decision isolates the effect of fault modes in a particular operational context, offering information on the model's capacity to identify and anticipate failures in a typical environment. Presenting Several Fault Modes: The model is presented with a more complex task with the addition of TWO failure modes: HPC Degradation and Fan Degradation. This dataset simulates conditions in which several engine components may deteriorate simultaneously or sequentially.

4) FD004 Dataset: The FD004 dataset incorporated 248 train and 249 test trajectories under SIX distinct circumstances with TWO fault modes (HPC Degradation, Fan Degradation), concluding the individual dataset studies. The model's robustness in managing a range of operating situations and fault scenarios is demonstrated by the outcomes (mention results). The model has shown strong prediction skills in the examination of the FD004 dataset, which contains 248 training trajectories and 249 test trajectories under SIX different operating circumstances with TWO fault modes (HPC Degradation, Fan Degradation). The assessment metrics that provide light on the model's ability to adapt to a variety of fault scenarios and operational settings include MSE, MAE, and R-squared. The thorough comprehension that these measurements provide highlights the model's capacity to manage the complexity brought forth by several fault types. Because of its flexibility, the model may be used to provide accurate prognostic evaluations in situations when many engine deterioration modes could occur at the same time. This dataset provides subtle insights that are useful for the overall assessment and for comparing the models' performance across various datasets and fault scenarios.

The first. algorithm which is RFR has the result of sixty-two for the first data set and fifty-eight for the second and sixty-seven for the third and fifty-nine for the fourth. Similarly, if the other algorithms are also compared, JLM's algorithm also gives the result of the first data set fifty-six and the result of the second data set is fifty-six and the result of the third data set is fifty-eight. Similarly, if the third algorithm support vector mechanism is also compared then the result of the first data set is sixty and the second data set is twenty and the third data set is also sixty and the fourth data set is twenty-four. And if the fourth algorithm Grant Boston is compared with each other, the first data set gives the result sixty-two and the second data set gives the result fifty-eight and the third data set gives the result sixty-seven which is the highest and then the fourth one. The result of the data set is fifty-nine. Table I represents the accuracy of Random Forest Regression. Table II represents the accuracy of elastic net glm Table III represents the accuracy of the support vector machine and Table IV represents the accuracy of gradient boosting all these techniques are applied to four codes. In Table III, we have compared the result of the SVM classifier with previously published works [37] and in Table IV, we have compared the result of the Gradient Boosting classifier with previously published works [37].

TABLE I. RESULTS OF THE RANDOM FOREST MODEL

Dataset	Algorithm	RF Mean Squared Error	RF Mean Absolute Error	Accuracy
FD001	Random Forest Regression	17772.26	29.89	0.62
FD002	Random Forest Regression	1945.94	32.475	0.58
FD003	Random Forest Regression	3160.17	38.51	0.67
FD004	Random Forest Regression	3209.63	40.68	0.59

TABLE II. RESULT OF ELASTIC NET GLM MODEL

Dataset	Algorithm	GLM Mean Squared Error	GLM Mean Absolute Error	Accuracy
FD001	GLM	2043.03	34.560	0.56
FD002	GLM	2043.03	34.60	0.56
FD003	GLM	4083.08	47.16	0.58
FD004	GLM	4503.76	51.59	0.43

TABLE III. RESULT SUPPORT VECTOR MACHINE MODEL

Dataset	Algorithm	SVM Mean Squared Error	SVM Mean Absolute Error	Accuracy	In past research[37] Accuracy
FD001	SVM	1860.48	30.28	0.60	0.893
FD002	SVM	3774.31	48.79	0.20	0.894
FD003	SVM	3846.14	41.04	0.60	0.893
FD004	SVM	6052.88	58.43	0.24	0.106

TABLE IV. RESULT OF GRADIENT BOOSTING MODEL

Dataset	Algorithm	GB Mean Squared Error	GB Mean Absolute Error	Accuracy	In past research [37] Accuracy
FD001	Gradient Boosting	1768.62	29.92	0.62	0.899
FD002	Gradient Boosting	1970.56	33.03	0.68	0.908
FD003	Gradient Boosting	3190.07	38.68	0.67	0.903
FD004	Gradient Boosting	3214.30	41.08	0.59	0.097

A thorough examination and explanation of the outcomes of applying ML models to a variety of engine datasets to forecast Remaining Useful Life (RUL). MSE, MAE, and R-squared are three quantitative measures of the model's performance under different operating settings and failure types that are part of the assessment metrics. Analyzing the FD001, FD002, FD003, and FD004 datasets separately exposed unique difficulties and intricacies. The model showed adequate prediction skills in the case of FD001, where conditions were comparatively simpler with a single failure mode (HPC Degradation). After switching to FD002, which included six operating conditions under the same fault mode, the model performed admirably, demonstrating its flexibility in a variety of situations.

The prediction work became more challenging in FD003 due to the addition of additional failure modes. We closely examined the model's capacity to manage both HPC Degradation and Fan Degradation situations. Even with this extra complexity, the model demonstrated proficiency in capturing the subtleties brought forth by numerous failure types. Finally, the robustness of the model was demonstrated by the assessment of FD004, which included two failure modes (HPC Degradation and Fan Degradation) and six different operational situations. The outcomes demonstrated its ability to handle a wider range of fault states and operating scenarios, which makes it a flexible tool for prognostic evaluations.

The comparative study of the models across datasets is also covered in detail in the discussion, with a focus on the differing levels of complexity brought about by various operational situations and failure mechanisms. The comparison study yielded insights that help comprehend the flexibility and generalization capabilities of the models, offering useful information for potential future applications in engine health prognostics. The limits of the study, probable causes of bias, and possibilities for development are also covered in the discussion. There are opportunities for more study and improvement of the prediction models because of the models' resilience and performance in real-world situations in various areas [38-42]. The discussion part, which provides a nuanced view of the models' strengths, limits, and potential implications in the field of engine system prognostics, summarizes the findings overall.

VI. CONCLUSION

This research presents a pivotal advancement in the realm of ML applied to industrial maintenance through its integration with the IIoT. Practically, the study equips industries with an advanced, data-driven methodology for equipment maintenance, leading to reduced downtime, cost savings, and heightened operational efficiency. Theoretically, it enriches our understanding of ML's efficacy in predictive maintenance, facilitating the refinement of algorithms and informing more judicious model selections. Using a variety of datasets (FD001, FD002, FD003, and FD004), this study concludes with a thorough examination of the use of ML models for forecasting RUL of engines. The study effectively illustrates how well the models handle various operating situations and failure types, providing insightful information about engine health prognostics. The models' prediction ability is quantified using assessment metrics such as MSE, MAE, and R-squared. fault mode (HPC Degradation) and more straightforward conditions. After switching to FD002 with various operating circumstances, the model keeps performing admirably, highlighting its adaptability.

Although FD003 presents a difficulty due to the addition of new failure modes, the model can handle cases when there is both HPC Degradation and Fan Degradation. The assessment of FD004 under various circumstances and fault types demonstrates the adaptability and efficiency of the models in a range of operational contexts. The models' generalization skills are illuminated by the comparison study between datasets, which provides important information about their advantages and disadvantages. Even while the results are encouraging, it is important to recognize some limitations and potential topics for more research. Further investigation is needed on the models' susceptibility to biases and variances in sensor data. To sum up, this study establishes the foundation for further developments in prognostic modeling and highlights the value of strong ML methods for improving the precision and dependability of forecasts in various areas[43-46].

Analyzing Privacy Implications and Security Vulnerabilities in Single Sign-On Systems: A Case Study on OpenID Connect

Mohammed Al Shabi[1], Rashiq Rafiq Marie[2]
Department of Management Information System, Taibah University, Madinah, Saudi Arabia[1]
Department of Information System, Taibah University, Madinah, Saudi Arabia [2]

***Abstract*—Single Sign-On (SSO) systems have gained popularity for simplifying the login process, enabling users to authenticate through a single identity provider (IDP). However, their widespread adoption raises concerns regarding user privacy, as IDPs like Google or Facebook can accumulate extensive data on user web behavior. This presents a significant challenge for privacy-conscious users seeking to restrict disclosure of their online activities to third-party entities. This paper presents a comprehensive study focused on the OpenID Connect protocol, a widely utilized SSO standard. Our analysis delves into the protocol's operation, identifying security flaws and vulnerabilities across its various stages. Additionally, we systematically examine the privacy implications associated with user access to SSO systems. We offer a detailed account of how easily user information can be accessed, shedding light on potential risks. The findings underscore the imperative to address privacy vulnerabilities within SSO infrastructures. We advocate for proactive measures to enhance system security and safeguard user privacy effectively. By identifying weaknesses in the OpenID Connect protocol and its implementations, stakeholders can implement targeted strategies to mitigate risks and ensure the protection of user data. This research aims to foster a more secure and privacy-respecting environment within the evolving landscape of SSO systems.**

Keywords*—*Single Sign-On; OpenID connect protocol; vulnerabilities; privacy; third-party

I. Introduction

Single Sign-On (SSO) systems streamline user access to various online services by consolidating credentials, thus eliminating the need for multiple usernames and passwords. However, this convenience often conflicts with user privacy, as identity providers (IDPs) involved in the SSO process can track and collect user data across platforms, potentially sharing it with third-party organizations for targeted advertising or profiling. Notably, prominent IDPs like Google and Facebook are known to leverage such data, raising significant concerns regarding user privacy and control over personal information [1] [2] . In light of these challenges, understanding the security and privacy implications of SSO systems becomes paramount.

OpenID Connect emerges as one of the most prevalent SSO protocols, offering a standardized framework for authentication and authorization across diverse websites and applications. This research endeavors to comprehensively assess the efficacy and potential vulnerabilities of OpenID Connect through a large-scale practical study. By dissecting its operational stages, we aim to identify security weaknesses and risks inherent in the protocol. The primary objective of this study is to evaluate the privacy implications of user access to SSO systems, along with the potential exposure of user information to IDPs and third-party entities. Through systematic analysis, we scrutinize the accessibility of user data within the SSO framework, illuminating the extent to which online user behavior can be monitored and exploited.

To underscore the real-world impact of these privacy concerns, we conduct a Mix-up attack on the OpenID Connect protocol using a local ASP.net-based API. The success of this attack in obtaining ID tokens, subsequently utilized to construct Access tokens for unauthorized resource access, underscores the vulnerability of SSO systems. Moreover, we quantify the attack's efficiency on online platforms by measuring the number of tokens accessed during execution.

This research endeavors to contribute significantly to the understanding of privacy implications and security vulnerabilities inherent in SSO systems. By shedding light on these issues, we aim to inform the development of more robust and privacy preserving SSO solutions. Ultimately, our findings advocate for empowering users to retain control over their personal data and limit disclosure to third-party organizations. The rest of the paper is organized as follows. Section II introduces the related works. Next, in Section III, the Open Connect Protocol is described, followed by Section IV which presents the vulnerabilities in Open ID connect. Section V states the vulnerabilities in OIDC. The implementation of a mix-up attack using ASP.net is described in Section VI. Finally, Section VII concludes the paper's work and findings.

II. Related Work

The security and privacy issues of Single Sign-On (SSO) systems and their protocols have been investigated by several studies. These studies have enhanced the understanding of the challenges and risks involved in the use of SSO systems. Some of the key research in this area is summarized as follows: The work in study [3] examines the tracking capabilities of third-party entities on the web and explores potential defences against such tracking. It sheds light on the privacy risks associated with SSO systems and the information that identity providers (IDPs) can gather about user behavior. The study in[4] investigates the security vulnerabilities of web-based password managers, which are often integrated with SSO systems. It analyzes potential attacks and risks to

user privacy when relying on SSO for password management and authentication.

The research in study [5] explores the trade-off between user control and usability in social networking platforms that utilize SSO. It discusses privacy-preserving mechanisms and approaches to mitigate the risks associated with sharing personal data through SSO systems. The study in [6] investigates the vulnerabilities and attacks related to account hijacking and session management in SSO systems. It provides insights into the security risks associated with SSO protocols and highlights the importance of robust authentication and session handling mechanisms. The survey in [7] provides an overview of the privacy challenges in Single Sign-On and explores potential solutions. It discusses various aspects of SSO privacy, including information leakage, tracking risks, and user consent. The research in [8] conducts a comparative analysis of security properties in different SSO protocols, including SAML, OAuth, and OpenID Connect. It identifies vulnerabilities and discusses security considerations in these protocols. This empirical [9] investigation focuses on the security and privacy aspects of OpenID Connect. It analyzes potential threats and vulnerabilities in the protocol and provides insights into its effectiveness in protecting user privacy. The literature review in study [10] examines various SSO protocols and their security and privacy characteristics. It identifies common vulnerabilities, threats, and mitigation strategies present in the literature. This systematic in [11] review and meta-analysis analyze the security and privacy aspects of SSO systems. It synthesizes findings from multiple studies and provides an overview of the state-of-the-art research in the field. This study in [12] presents a case study focusing on the privacy-sensitive features in a web authentication system. The researchers analyze and evaluate the privacy implications of various features and mechanisms used for web authentication. The study sheds light on the potential privacy risks and challenges that users may face during the authentication process and provides insights into the design of privacy-preserving authentication systems.

TABLE I. KEY RESEARCH WORKS

Study	Key contribution	Focus
Roesner et al. [3]	Examined tracking capabilities of third-party entities on the web.	Privacy risks and information gathering by identity providers (IDPs) in SSO systems.
Chia [4]	Investigated security vulnerabilities of web-based password managers integrated with SSO.	Attacks and privacy risks in SSO systems for password management and authentication.
Rahman [5]	Explored the trade-off between user control and usability in SSO-based social networking.	Privacy-preserving mechanisms and risk mitigation for sharing personal data via SSO systems.
Nergiz [6]	Investigated vulnerabilities and attacks related to account hijacking and session management.	Security risks in SSO protocols, emphasizing robust authentication and session handling.
Yang et al. [7]	Provided an overview of privacy challenges in Single Sign-On and potential solutions.	SSO privacy aspects, including information leakage, tracking risks, and user consent.
Fett et al. [8]	Conducted a comparative analysis of security properties in different SSO protocols.	Vulnerabilities and security considerations in SAML, OAuth, and OpenID Connect protocols.
W. Li and C. J. Mitchell [9]	Empirical investigation of security and privacy aspects of OpenID Connect.	Analysis of threats and vulnerabilities in the protocol and its effectiveness in protecting user privacy.
Ahmad et al. [10]	Literature review of various SSO protocols and their security and privacy characteristics.	Identification of common vulnerabilities, threats, and mitigation strategies from literature.
Zuo et al. [11]	Systematic review and meta-analysis of security and privacy aspects of SSO systems.	Synthesis of findings from multiple studies to provide an overview of state-of-the-art research in the field.
Li et al. [12]	Evaluated privacy implications of identity federation in SSO systems.	Privacy risks and concerns associated with identity federation in SSO deployments.
Wang et al. [13]	Analyzed authentication vulnerabilities in SSO for mobile apps.	Security weaknesses and risks in SSO implementations for mobile applications.
Meland et al. [14]	Investigated the privacy implications of attribute sharing in SSO systems.	Risks associated with sharing user attributes among multiple service providers through SSO.
Paul et al. [15]	Explored privacy and security challenges in the context of healthcare SSO systems.	Addressing privacy concerns and enhancing security for SSO implementations in healthcare environments.

This research in study [13] provides a comprehensive study of OAuth security issues specifically related to Android apps. The authors analyze the implementation of OAuth in various Android applications to identify potential security vulnerabilities and weaknesses. The study uncovers security risks and potential attacks that could compromise the security and privacy of user data when using OAuth-based authentication in Android apps. This study in [14] investigates the privacy aspects of attribute sharing in Single Sign-On (SSO) solutions. The researchers examine the process of attribute sharing among multiple service providers in SSO systems and analyze the privacy risks associated with this sharing. The study aims to enhance the understanding of the potential privacy concerns and challenges in SSO deployments and provides insights into protecting user privacy in attribute sharing scenarios.

This systematic review in [15] focuses on Single Sign-On (SSO) security specifically in the context of healthcare. The researchers review and analyze existing literature on SSO security, with a specific focus on healthcare environments. The study identifies security challenges and vulnerabilities related to SSO implementations in healthcare settings and provides recommendations for enhancing security and privacy in healthcare SSO systems. The review contributes to a better understanding of SSO security concerns and implications in healthcare applications. Table I summarizes the key research works related to privacy implications and security vulnerabilities associated with Single Sign-On (SSO) systems.

III. OPEN CONNECT PROTOCOL

OpenID Connect is an industry-standard protocol used for authentication and authorization in Single Sign-On (SSO)

systems. It is built on top of the OAuth 2.0 framework and provides a standardized way for users to log in to multiple websites or applications using a single set of credentials [16]. The primary goal of OpenID Connect is to enable identity federation, allowing users to authenticate with an identity provider (IDP) and then use that authentication to access various relying parties (RPs) without needing separate credentials for each RP. The IDP is responsible for verifying the user's identity and providing the necessary authentication tokens. Fig. 1 depicts the relationship among the components of OpenID.

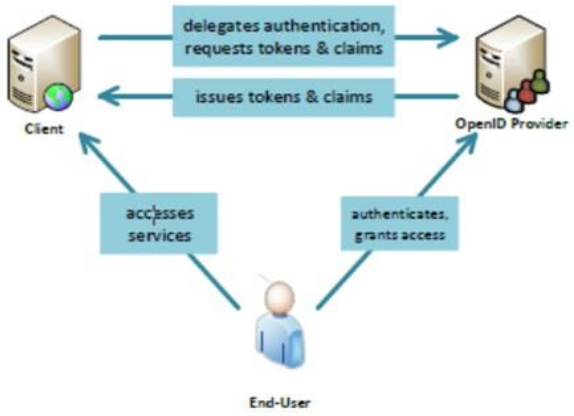

Fig. 1. The relationship between the components in the protocol.

A. Brief overview of how OpenID Connect works

- User Initiation: When a user attempts to access a website or an application (RP) that supports OpenID Connect, they are redirected to the IDP's authentication endpoint.
- Authentication: The user is prompted to enter their credentials (e.g., username and password) at the IDP's login page. The IDP authenticates the user and generates an ID token.
- ID Token Exchange: After successful authentication, the IDP issues an ID token to the RP. This ID token contains information about the user and the authentication event, such as the user's unique identifier and any requested user claims.
- Token Validation: The RP validates the ID token to ensure its integrity and authenticity. It checks the token's signature, expiration, and the IDP's issuer information to verify its validity.
- User Authorization: Once the RP has validated the ID token, it can authorize the user's access to its resources based on the user's identity and any additional authorization scopes or claims provided.

OpenID Connect also supports optional features such as UserInfo endpoint, which allows RPs to retrieve additional user profile information from the IDP, and the use of refresh tokens for obtaining new access tokens without re-authentication. By leveraging OpenID Connect, SSO systems can offer a seamless and secure user experience, as users only need to authenticate once with their IDP and can then access multiple applications without the need for separate logins. The protocol facilitates interoperability among different identity providers and relying parties, providing a standardized framework for SSO implementation. Fig. 2 illustrates the implementation phases in the OpenID Connect protocol.

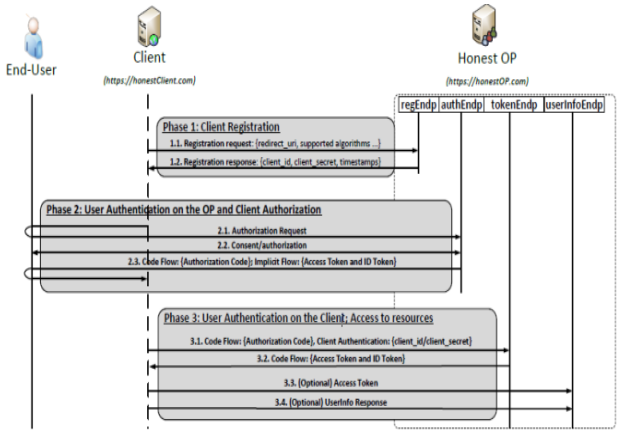

Fig. 2. Implementation phases in the OpenID Connect protocol.

The stages of the OpenID Connect protocol work:

1) Stage one: Dynamic registration and discovery in Fig. 3 shows the initial registration stage more accurately, In the beginning, the user presents his identity (for example, alice@honestOP.com) to the customer to obtain services. To authenticate the user, the client needs to discover the IDP which controls the identity of the alias.

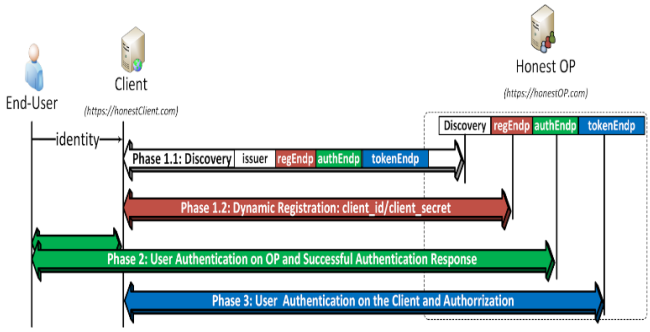

Fig. 3. OpenID Connect dynamic registration phase.

The first stage is divided into two steps:

- Step 1 (Discovery): The client sends a request to the Discovery endpoint and returns OP's configuration information including the locations of the endpoints.

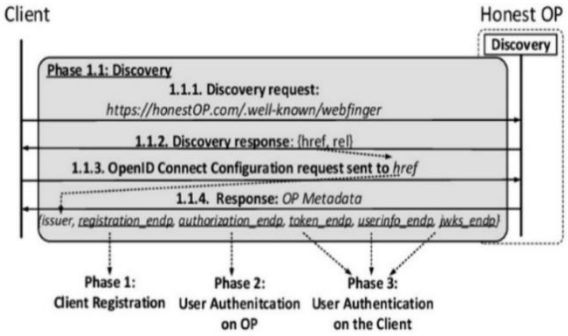

Fig. 4. Detailed overview of the discovery phase in OIDC.

Fig. 4 shows the details of the discovery phase in which the metadata received by the client appears and its impact on the protocol phases. Note that this data contains all information related to the protocol (endpoints, signature, and encryption algorithms - messages - public keys of the protocol).

- Step 2 (dynamic registration): The client automatically registers with the Identity Provider (OP) where it sends its own address (for example http://client.com) to the registration endpoint address, so the OP responds and sends the pair (/client_id client_secret), which are secret codes between the client and the Identity Provider (OP) representing Client credentials.

2) Stage two: Authenticating In this phase the user is authenticated at the identity provider (User: Authentication on the OP). The client directs the unauthenticated user to an authorization endpoint (the user is directed to an address on which the client ID is pre-registered). The end user is authenticated to the OP using his or her credentials. The OP sends an authorization code that includes an (Access token, ID token) this code is an intermediary between the client and the user through which the client can access specific resources for the user and verify the identity of the end user.

3) Stage three: User Authentication stage (on the OP - ID and Access Token): After the client receives the code at the end of the second stage, it sends it to the token endpoint and sends its credentials from the first stage (client_id and client_secret), then the identity provider responds and sends it the (access token, ID token), and then the client Verifies the tokens and performs final user authentication.

- ID Token content

```
Header: {"alg": "HS256"}
Body: {
      iss": "http://openidConnect
Provider.com/", "sub": "user1",
      "exp": 1444148908,
      "iat": 1444148308,
      "nonce": "40c6b33b9a2e",
      "aud": "http://client.com/",}
Signature: AF45JF93LKD76D...
```

Fig. 5. An example of an ID token.

An id token is a secret token that contains information (claims) about the end user's identity and structure. Its data is a JWT (JSON Web Token). Fig. 5 shows an example of an id token [17].

We note that the id token consists of three parts:

First: The header contains information that includes the encryption algorithm used.

Second: The body contains the information needed to authenticate the end user, including:

End User ID: It consists of two parts:

- Issuer (Iss): To know the identity provider.
- sub (Subject o): To know the identity of the user.
- The timestamp (iat) and expired (exp) define the time period for the token to be produced and to expire.
- Nonce: A random string sent by the client during the authentication request used to mitigate attacks.
- Audience (aud): Determines which customers the identity token belongs to.

Third: Signature provides the reliability of the id token.

IV. OpenID Connect Vulnerabilities

One notable vulnerability in the OpenID Connect (OIDC) protocol is the introduction of dynamic registration and discovery, a phase that was absent in previous protocols. This phase became a significant weakness in the OIDC protocol, as attackers were able to manipulate the information, particularly endpoint addresses, exchanged during the discovery phase. Attackers could substitute legitimate addresses with their own, enabling them to intercept and manipulate information exchanged between clients and the attacker throughout the various phases of the protocol. The layered structure of the OIDC protocol further facilitated attackers in intervening between any two of the three primary phases. Several previous studies have explored and exploited these vulnerabilities, leading to the development of new attacks targeting the OIDC protocol and the creation of tools for analyzing and testing its confidentiality.

A. OpenID Connect Previous Studies

Security vulnerabilities in single sign-on protocols have been examined, analyzed, and identified in a number of previous studies. Here are some of the most significant contributions made by these studies; in addition, Table II summarizes the principal contributions made by the mentioned studies.

In study [17] the researchers conducted a comprehensive examination of the security characteristics of the Google OIDC protocol. They examined a group of clients and applied a class of attacks to obtain user codes, enabling impersonation and unauthorized access to clients. Additionally, they provided valuable insights and future recommendations for both Service Providers (RPs) and Identity Providers (OPs) to enhance security in future systems. Researchers in [18] developed a tool to test attacks on the OpenID Connect (OIDC) Access Protocol. This tool encompasses advanced attacks, including malicious endpoint attacks, contributing to a better understanding of the protocol's message flow.

In study [19] the researchers conducted an in-depth analysis of the OIDC protocol's dynamic registration and discovery feature. They identified a new type of attack named "Malicious Endpoints" that exploits information exchanged between protocol parties, posing risks to user privacy. In researcher [20] the researchers analyzed known attacks on the OIDC protocol and classified them into two categories: single-stage attacks, targeting one stage, and two-stage attacks, relying on multiple stages. They also proposed measures to

enhance protocol confidentiality and identified security vulnerabilities. Researchers in [21] provided a thorough and formal security analysis of the OpenID Connect protocol. They developed a model of OpenID Connect, utilizing secret features to mitigate known attacks, and put forth security guidelines to bolster the overall security posture of the protocol. The authors of [22], studied the security flaws of OAuth 2.0 in Android apps, focusing on the implementation errors that could lead to breaches. They also discussed the OAuth security challenges specific to the Android platform. Research in [23] examined the security misconfigurations in mobile OAuth implementations, using real-world apps as examples. They uncovered common mistakes that could affect the security of mobile systems based on OAuth. In paper [24], performed a comprehensive security assessment of OAuth 2.0, which is the authorization framework for OpenID Connect. They evaluated different OAuth implementations and detected vulnerabilities, and they suggested recommendations for enhancing the security of systems based on OAuth. The researchers in [25], investigated the security of OAuth, which is the foundation for OpenID Connect. They analyzed the weaknesses and vulnerabilities in OAuth's authentication and authorization mechanisms, and they highlighted the potential risks associated with OAuth implementations.

This paper in [26] presents a Systematization of Knowledge (SoK) on OAuth 2.0 and explores the current vulnerabilities, limitations, and ongoing efforts to improve its security. The study identifies various threats and vulnerabilities related to the authentication and authorization mechanisms of OAuth 2.0. It also discusses potential solutions and ongoing research to enhance the protocol's security in protecting user privacy and data. This research [27]provides an in-depth formal security analysis of the OpenID Connect protocol. By applying formal methods, the study examines the security properties and potential vulnerabilities of OpenID Connect. The authors develop a model of the protocol and provide security guidelines to mitigate. This survey article[28] presents a comprehensive comparison of security modelling approaches for various Single Sign-On (SSO) protocols, including OpenID Connect. The study reviews the strengths, weaknesses, and challenges in the security modelling of SSO protocols, providing insights into the security aspects of OpenID Connect and other SSO protocols known attacks and enhance the overall security posture of OpenID Connect.

This study in [29] investigates the design and security considerations of a Mobile Single Sign-On (SSO) system based on OpenID Connect. The research examines the integration of OpenID Connect for mobile applications, focusing on the design aspects and security measures necessary to ensure a secure and user-friendly SSO experience on mobile platforms. This empirical [30]investigation delves into the security, privacy, and usability aspects of the OpenID Connect protocol. The research assesses potential threats and vulnerabilities in OpenID Connect's implementation and analyzes its effectiveness in safeguarding user privacy and data. Additionally, the study evaluates the usability of OpenID Connect in real-world scenarios. This survey paper [31] provides a comprehensive examination of OAuth-based Single Sign-On (SSO) protocols, including OpenID Connect. The study reviews different SSO protocols and focuses on OAuth's role as the foundation for SSO mechanisms. The paper discusses the strengths and weaknesses of OAuth-based SSO and highlights areas for further improvement. This research [32] conducts a security analysis of the OAuth 2.0 framework in the context of mobile applications. The study identifies potential vulnerabilities and threats associated with OAuth 2.0 when utilized in mobile environments. The paper discusses security considerations and suggests measures to enhance the protection of user data and privacy in OAuth-based mobile applications.

TABLE II. SUMMARIZING THE KEY CONTIBUTIONS AND FOCUS OF THE MENTIONED STUDIES RELATED TO OPENID CONNECT AND OAUTH 2.0 SECURITY

Study	Key Contributions	Focus
Li et al. [17]	- Examined Google OIDC protocol security characteristics. - Conducted attacks to obtain user codes and impersonate clients. - Provided future recommendations for RPs and OPs.	- Security analysis of Google OIDC. - Attack scenarios on OIDC clients. - Recommendations for enhancing security.
Mladenov et al. [18]	- Developed a tool for testing OIDC Access Protocol attacks. - Enhanced understanding of the protocol's message flow.	- Advanced attacks, including malicious endpoint attacks in OIDC.
Mainka et al. [19]	- Conducted in-depth analysis of OIDC's dynamic registration and discovery feature. - Identified "Malicious Endpoints" attack and its risks.	- Analysis of OIDC's dynamic registration and discovery feature.
Navas et al. [20]	- Analyzed known attacks on the OIDC protocol and classified them into single-stage and two-stage attacks. - Proposed measures to enhance protocol confidentiality and identified security vulnerabilities.	- Categorized attacks into single-stage and two-stage attacks.
Fett et al. [21]	- Provided thorough and formal security analysis of the OpenID Connect protocol. - Developed a model of OpenID Connect and security guidelines for mitigation.	- Formal security analysis of OpenID Connect protocol.
Maqbool et al. [22]	- Studied the security flaws of OAuth 2.0 in Android apps. - Focused on implementation errors and their impacts.	- Security assessment of OAuth 2.0 in Android apps. - OAuth security challenges on the Android platform.
A. Kountouras and G. Frantzeskou [23]	- Examined security misconfigurations in mobile OAuth implementations using real-world apps. - Identified common mistakes affecting mobile OAuth security.	- Examination of real-world mobile OAuth implementations.
J. Richer and A. Sanso [24]	- Performed comprehensive security assessment of OAuth 2.0. - Evaluated vulnerabilities in various OAuth implementations. - Suggested recommendations for enhancing OAuth 2.0 security.	- Evaluation of OAuth 2.0 vulnerabilities and security measures.
B. Braithwaite and A. Doupé [25]	- Investigated security vulnerabilities in OAuth's authentication and authorization mechanisms. - Highlighted potential risks associated with OAuth implementations.	- Analysis of OAuth's weaknesses and vulnerabilities.
Pereira et al. [26]	- Systematization of Knowledge (SoK) on OAuth 2.0 security. - Identification of threats and vulnerabilities related to OAuth's authentication and authorization mechanisms. - Discussion of potential solutions to improve OAuth's security.	- Identification of threats and vulnerabilities in OAuth 2.0. - Ongoing research to enhance OAuth's security and protect user privacy.

Küsters and Kifayat [27]	- Provided in-depth formal security analysis of the OpenID Connect protocol. - Developed a model of OpenID Connect and provided security guidelines.	- Formal security analysis of OpenID Connect protocol.
Sanchez-Aguilar et al. [28]	- Comprehensive comparison of security modeling approaches for various Single Sign-On (SSO) protocols, including OpenID Connect. - Review of strengths, weaknesses, and challenges in security modeling of SSO protocols.	- Review of security modeling approaches for SSO protocols. - Insights into the security aspects of OpenID Connect and other SSO protocols.
Vetrivelan et al. [29]	- Investigated design and security considerations of a Mobile Single Sign-On (SSO) system based on OpenID Connect. - Focused on secure integration of OpenID Connect for mobile applications.	- Design aspects and security measures for secure Mobile SSO with OpenID Connect.
Alshehri et al. [30]	- Delved into the security, privacy, and usability aspects of the OpenID Connect protocol. - Assessed threats and vulnerabilities in OpenID Connect's implementation. - Evaluated the effectiveness of OpenID Connect in safeguarding user privacy and data.	- Security, privacy, and usability evaluation of OpenID Connect.
Sun et al. [31]	- Provided a comprehensive examination of OAuth-based Single Sign-On (SSO) protocols, including OpenID Connect. - Focused on OAuth's role as the foundation for SSO mechanisms. - Discussed strengths and weaknesses of OAuth-based SSO.	- Review of OAuth-based SSO protocols. - Identification of strengths and weaknesses.
Khan and Shafiq [32]	- Conducted a security analysis of the OAuth 2.0 framework in the context of mobile applications. - Identified vulnerabilities and threats in OAuth 2.0 for mobile environments. - Suggested measures to enhance user data and privacy protection in OAuth-based mobile applications.	- Security analysis of OAuth 2.0 in mobile applications. - Measures to enhance OAuth-based mobile app security.

V. OIDC Vulnerabilities

1) Phishing: Phishing attacks in OIDC can take two forms:

a) Spoofed OP page: Attackers can redirect users to a spoofed Identity Provider (OP) page where they are deceived into entering their OP credentials[20].

b) Realm spoofing: Service Providers (RPs) can craft authentication requests with an OpenID realm parameter set to a trusted domain but redirect the user back to their own page without proper verification. The user's OP falsely assures them that they are logging into the trusted domain, while they are redirected to the RP.

2) Session related attacks: OIDC allows multiple active authentication sessions, providing more opportunities for malicious sites to exploit vulnerabilities in both OPs and RPs[33]. Specific issues include:

a) Session swapping: Lack of a mechanism to associate an OIDC session with the user's browser allows attackers to configure an attacker-authenticated session in the RP. This can lead to unauthorized access and disclosure of sensitive information.

b) Cross-Site Request Forgery (CSRF): Logged-in users may be susceptible to CSRF attacks targeting the OP or other RP sites.

c) Cross-Site Scripting (CSS): Logged-in users may be vulnerable to XSS attacks against the OP or other RP sites.

3) Data privacy: OpenID Connect service providers have visibility into every site the user logs into using their credentials. This centralized nature allows malicious OPs to track user activity on the internet.

4) Risk centralization: Hacker's target IdP accounts as they provide access to multiple sites. If an identity provider lacks escalated authentication options, the user's security may be compromised.

5) Weak background security: Some OPs may rely solely on email account recovery, which is inadequate for strong background security. Account recovery mechanisms should employ stronger authentication methods.

6) Cross-identifier relationship: When users employ the same OpenID across different RP sites, these sites can link user information or activity. Independent logins in different RPs mitigate this issue.

7) Shared ID strings: The usability challenge of entering ID strings increases when different launches employ different methods.

This can lead to users inadvertently entering the same ID in multiple places, allowing RPs to establish relationships between them.

VI. Implementing A Mix-Up Attack Using Asp.Net

A. Attack Assumption

- The RP (Service Provider) is configured to connect to multiple OAuth Providers (Ids), including one controlled by the attacker (AldP) and another harmless one (HIP).
- The RP uses the same redirect_uri for multiple identity providers and relies on the 'state' parameter to determine the origin of the response.
- The attacker's AldP has control over the authentication flow and response sent to the RP.

B. Attack Stages

Stage 1: The attacker obtains the victim's token from HldP.

Fig. 6 shows the steps of this stage [9], he following steps illustrate the attack flow:

1) The End User clicks the "Login with HldP" button on an RP page.

2) The attacker communicates with the RP and sends a login request to the RP, pretending to be the AldP (attacker-controlled Identity Provider). As a result, the attacker receives a redirect response at the AldP's authorization endpoint.

3) The attacker redirects the response to the browser, intending it to be transmitted to the conversion endpoint of HldP (harmless Identity Provider). However, during this process, the attacker uses the status value associated with the authorization request for the AldP that was received in step 2.

4) The end user interacts with HldP and clicks "Agree" to authenticate and authorize the request.

5) HldP returns the end user to the redirect_uri of the RP, along with the associated token.

6) The RP receives the token and evaluates the status value, determining that the authorization response is from the AldP (attacker's-controlled Identity Provider).

7) The RP mistakenly sends the code and tokens to the AldP's token endpoint and API endpoints, allowing the HldP tokens to be delivered to the attacker.

Stage 2: Using the victim's code V.

In this step, the RP continues to interact with the attacker, assuming the attacker is the victim. If the RP provides data or allows modifications based on the access token, the attacker gains access to the victim's resources and can potentially manipulate them, Fig. 7 shows this stage.

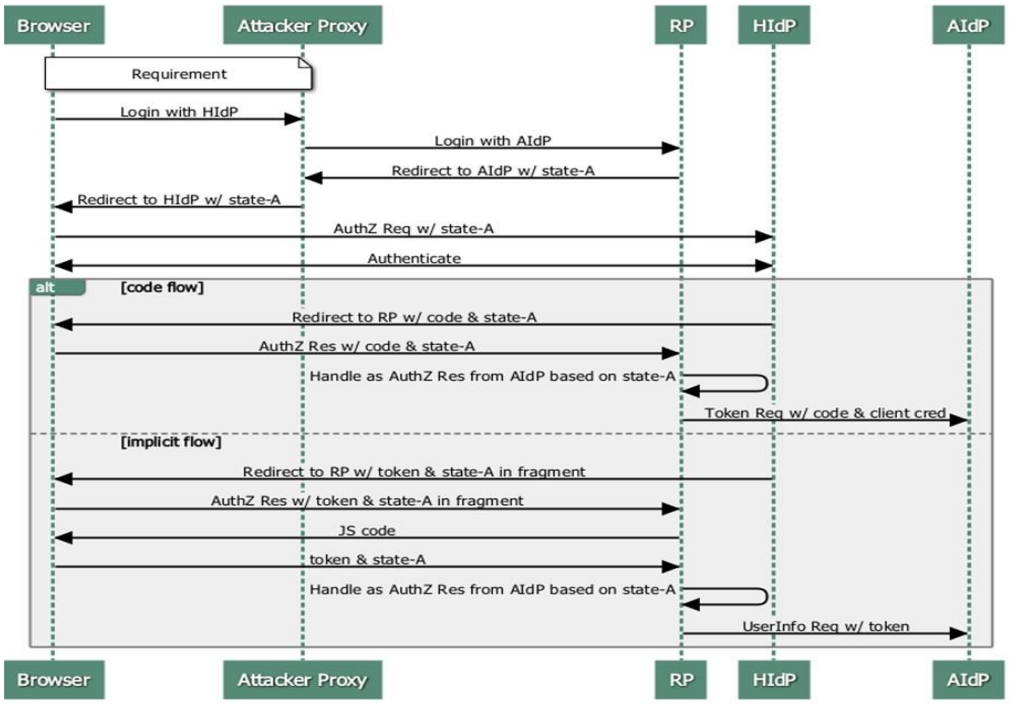

Fig. 6. Mix-up attack steps.

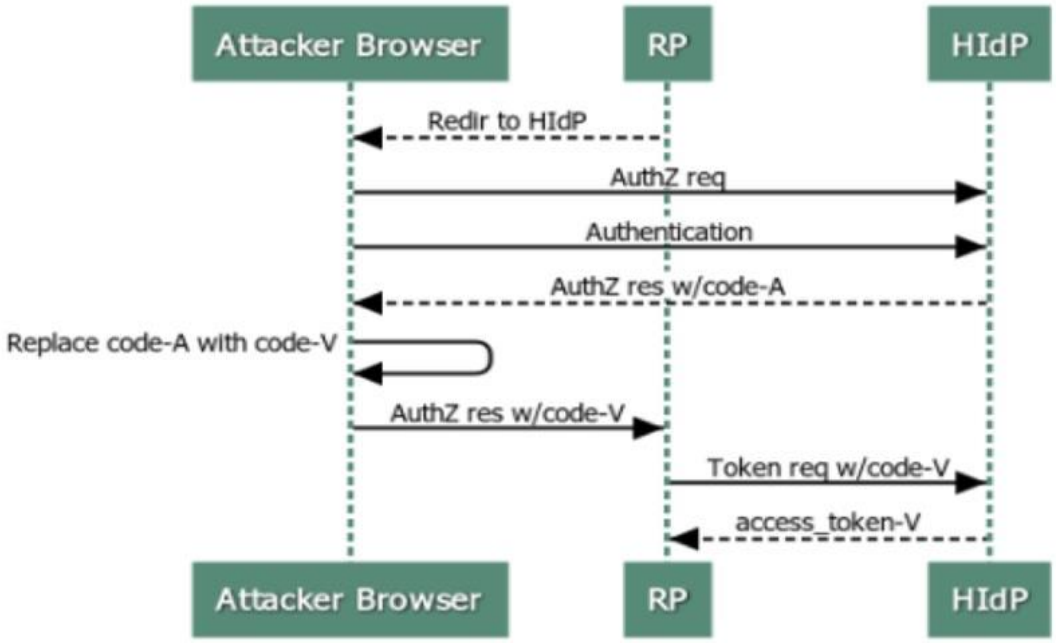

Fig. 7. Victim code used by the attacker.

C. Execute Attack on API

The provided excerpt describes the execution of the attack on the API and the consequences of its success. Here's an explanation of the details mentioned:

1) Successful Attack and Obtaining User Information:

a) When the attack is successful, the attacker receives information in JSON format.

b) The attack allows the attacker to access user values that were previously protected.

c) The obtained user values are stored in two encrypted strings or variables within the API, referred to as value 1 and value 2. Fig. 8 illustrates the protected user token values prior to the attack.

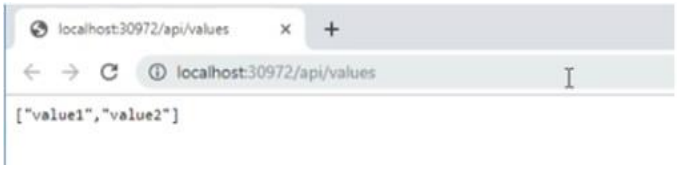

Fig. 8. Protected user token values prior to attack.

2) Obtaining user ID token:

a) After executing the attack, the attacker obtains the user's ID token.

b) The ID token is typically encrypted using JWT (JSON Web Token) and needs to be decrypted to extract its contents. Fig. 9 illustrates the ID token values after the attack has been applied.

Fig. 9. The id token values after the attack has been applied.

3) Decrypting the ID token:

a) The attacker decrypts the ID token using JWT services.

b) Decrypting the token allows the attacker to access the user's tokens.

4) Accessing user resources:

a) Once the attacker has obtained the necessary tokens, they can use them to log in and gain access to the user's resources.

b) These by bypasses the protection mechanisms of the protocol, potentially resulting in the loss of user data and compromising their account.

D. Online Attack Implementation

The applied attack steals a set of user account tokens that are as in Table III. These codes play a critical role in interacting with the protocol's service provider, and their theft grants the attacker access to the victim's data. It is important to note that the success of the attack relies on the service provider enabling redirection for the user account, which is commonly known as a redirect attack. Upon executing the attack on a Gmail account, the codes in Fig. 10 were obtained, which illustrates the obtained tokens, revealing a successful attack where most of the mentioned tokens were acquired. However, it is important to note that certain tokens, such as EXP Idp tokens, were not obtained, resulting in a lack of information regarding the specific hack.

TABLE III. USER ID TOKEN

Token	Data Format	Meaning
Alg	String	Indicates the algorithm that was used to sign the token.
Kid	String	Sets the fingerprint of the public key that can be used to validate the signature of this token.
Iss	Source URL string	Defines the source or authorization server that generates and returns the token.
Idp	"String", usually the STS URL	Recording the identity provider that authenticated and returns the token subject.
Sub	String	The subject prompt value is immutable and cannot be modified or reused. It serves as a binary identifier that is unique to a particular application identifier. When a user logs into multiple applications with distinct customer IDs, each app will receive a different subject prompt value. The desirability of this behavior depends on your specific privacy requirements and system structure.
Hasgroups	Bool	If it exists, it is always true, indicating that the user is in at least one group. It is used in place of the collections claim for JWTS in implicit grant flows if the full collections claim would extend the URI part beyond the URL length limits (currently 6 or more groups).
Exp	String	Indicates when the session with the identity provider expired.
Website	String	Referring to the identity provider type.
Aud	String	The name of the site where the protocol is being used.

In the subsequent Table IV, we will delve into the attack on multiple platforms utilizing the protocol, providing a comparison between these platforms based on an essential criterion: redirection to the victim's page from which the codes were obtained. Redirection refers to the ability of the service provider to access the user's account and gain complete control over it through redirection techniques. Notably, prominent companies like Microsoft and Google have implemented measures to protect their users from such redirects, thus preventing unauthorized access to accounts. By applying the attack on the platforms listed in Table IV below, we can gauge the success of the attack by the number of tokens obtained. In this instance, we were able to acquire nine access tokens, indicating a 100% success rate for the attack.

TABLE IV. MIX-UP ATTACK PERCENTAGES ON POPULAR PLATFORMS

Platform	Token Access Rate	Redirect by the Service Provider
Gmail	7/9=77.7%	impossible
Facebook	5/9=55.5%	impossible
Yahoo	8/9=88.8%	possible
Hotmail	9/9=100.00%	possible
Outlook	4/9=0.44%	impossible

It is important to highlight the possibility of redirection in this context. Fig. 10 depicts the user tokens taken after applying the MIX-Up attack on the Gmail platform.

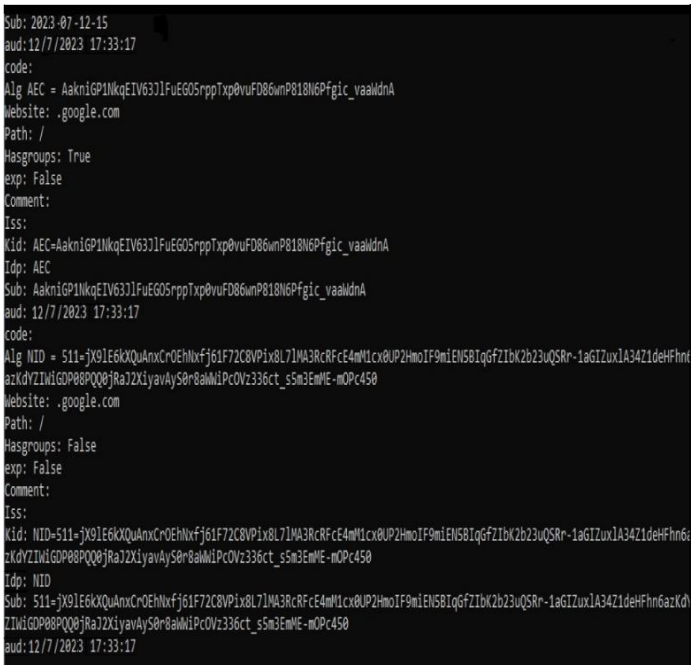

Fig. 10. User tokens after applying the MIX-Up attack on the gmail platform.

From the previous table, it is evident that the attack was successful across various popular platforms, yielding favorable success rates. However, variations in the verification rates of the attack can be observed due to factors associated with the response behaviour of the identity providers. Some servers permit code injection during the session, whereas others do not allow such manipulations. Additionally, the results differ based on the number of tokens accessed, which can vary depending on the specific protocol version implemented within each platform.

VII. CONCLUSION

In this research, we have examined the OpenID protocol and its information exchange mechanism, while also highlighting its significant security vulnerabilities and the execution of attacks. We have identified key design flaws within the protocol and successfully demonstrated a MIXup attack, resulting in the theft of user tokens and unauthorized access to user data in an offline attack scenario using the ASP environment. The attack was performed on accounts belonging to popular platforms, and the outcomes varied based on the characteristics of the session created by the identity provider.

It is worth noting that most renowned platforms have implemented measures to safeguard against redirect attacks by introducing browser-generated session values (routing fingerprints). They have also incorporated additional protection mechanisms, such as user confirmation via phone numbers or alternative email addresses. However, the accessed codes still present the possibility of conducting a redirect attack by deceiving the victim through a fraudulent page aimed at confirming the account and capturing return information within the user session. These findings underscore the importance of implementing enhanced protection measures in the future.

***Abstract*—Urban patrols can detect emergencies in a timely manner and collect information, which helps to improve the quality of services in the city and enhance the comfort of residents. This study proposes the use of IoT-based drones for urban patrol tasks, aiming to explore the potential applications of drones in smart city governance. The main technical challenge in the process of urban patrols by drones is how to plan a flight path for them. Therefore, this article first designs a smart patrol system based on drones and Internet of Things (IoT). Meanwhile, as information collection is an important aspect of urban patrol tasks, a mathematical model with the goal of maximizing information collection has been established to provide cost-effective patrol services. On this basis, in order to improve the accuracy of crow search algorithm (CSA), differential crow search strategy and variable flight step size are designed. In addition, the Levy flight strategy is introduced into the traditional CSA algorithm, and an improved crow search algorithm (ICSA) is proposed. Finally, a corresponding simulation environment was established based on the actual urban scene and compared with other algorithms. The numerical results indicate that compared with the other three swarm intelligence algorithms, the algorithm designed in this paper has more superiority.**

***Keywords*—Patrol drones; trajectory planning; smart city governance; crow search algorithm; swarm intelligence algorithm**

I. Introduction

With the development of cutting-edge technologies in the field of artificial intelligence such as the Internet of Things (IoT), digital twins (DT), and swarm intelligence, a foundation has been provided for the implementation of smart cities. Smart social/cities governance (also known as smart social/cities management), as an important application scenario of smart cities, is a potential goal for urban managers and related researchers [2]. As an advanced intelligent robot, unmanned aerial vehicles (UAVs) can provide many reliable services for smart city scenarios, helping to achieve smart city goals at low cost and low energy consumption [3]. In addition to using drones [1] to provide reliable communication services for smart city scenarios in [4], drones can be used to comprehensively monitor urban facilities, transportation, and the environment. For example, in [5], drones are used to monitor roads in cities, while in [6], drones are used to monitor the environment of cities. Another potential application of drones in smart city scenarios is patrol missions [7]-[8]. During the patrol process, drones are equipped with various sensors and cameras, which can collect relevant data of the city and provide timely feedback to the management department, providing decision-making support for urban managers, thereby improving the quality of the urban environment and the quality of life of residents.

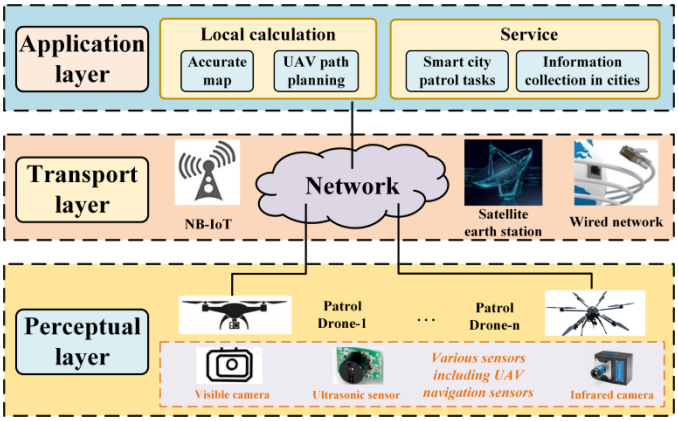

Fig. 1. IoT-based UAV patrol framework.

When deployed in the real world, drones typically require the use of technologies such as IoT to interact with the human world. Therefore, Fig. 1 shows the IoT based unmanned aerial vehicle patrol framework designed by this study. Within this framework, before conducting patrols, the trajectory planner needs to first plan a global trajectory for the drone based on the patrol range, the three-dimensional environment, and geometric model of the UAV. However, in [9], a trajectory planning model for drones in two-dimensional space was developed with the goal of minimizing the length of the drone's trajectory, without considering the pitch angle constraint of the drone. In [10], a trajectory planning model for unmanned aerial vehicles in a three-dimensional mountainous environment was established, but it did not take into account the requirements of patrol tasks for information collection. The above mathematical models are not applicable to the problem of drone patrol trajectory planning in urban market environments. Therefore, this study pays special attention to the trajectory planning problem of patrol drones, establishes an accurate mathematical model for patrol drones in smart city scenarios, and designs an improved swarm intelligence algorithm based

*Corresponding Author.

on CSA algorithm. The main contributions of this study are summarized as follows:

- This study introduces IoT and DT into smart city patrol scenarios, designs an IoT based UAV patrol framework, and describes the working mechanism of the DT based UAV patrol platform, aiming to embed the drone city patrol platform into smart city scenes.
- Based on the operational mechanism of the digital twin patrol platform, a geometric model of patrol drones and a multi-objective mathematical model of urban patrol tasks were established, and a digital twin drone for urban patrol tasks was constructed.
- Based on the DE algorithm and CSA algorithm, corresponding improvement strategies were designed, and a novel differential evolution-based crow search algorithm (DE-CSA) was designed to improve the performance of the patrol drone trajectory planner.
- Six test functions were used to test the GWO, GA, CSA, and DE-CSA algorithms. From the two indicators of mean and standard deviation, the DE-CSA algorithm performed the best; Furthermore, based on real urban scenarios, relevant computational experiments were conducted, and the data results showed that compared with GWO, GA, and CSA algorithms, the DE-CSA algorithm has higher convergence accuracy.

The remaining parts of this study are arranged as follows. In Section II, research related to patrol drones is reviewed; Section III establishes a mathematical model for UAV used for smart city patrol task; In Section IV, an improved CSA algorithm is designed; Section V presents the simulation experiment results. Finally, the full text is summarized in Section VI.

II. Literature Review

When using drones to perform patrol tasks in smart city scenarios, it mainly includes two parts. The first part is to allocate drones based on all patrol areas, ensuring that each area can be covered. This is the previous stage of patrol drone trajectory planning [7]. The other step is to plan a flight trajectory for the patrol drone based on the three-dimensional environment of the area it needs to patrol, which needs to meet the goals of collision free and patrol tasks. Therefore, this article reviews relevant research from three aspects: urban patrols, drone trajectory planning, and the application of swarm intelligence algorithms in drone trajectory planning. The aim is to summarize and summarize the goals of urban patrols, mathematical models of drones, and trajectory planning algorithms.

A. The Application of UAV in Urban Patrol

As previously mentioned, relevant researchers have explored the application of drones in smart city communication [4], road or environmental monitoring [5]-[6], disaster management [11], and distribution [12]. It should be pointed out that when using drones to detect roads and environments, the main objective of mathematical models is to collect or organize information [13]. For example, in [14], drones were used to collect environmental information at the dock, and the mathematical model required drones to fly over all detection nodes and use the shortest flight distance. In [15], UAVs were used to patrol transmission lines in a city with the goal of maximizing the coverage of the patrol area. Reference [16], on the other hand, uses ground vehicles in conjunction with UAVs to patrol roads, and similar to [14], the mathematical model requires the UAVs to fly over all patrol nodes. In [17], a drone scheduling model for scenic spot patrols was established, which aims to minimize the flight length of drones while minimizing the number of drones, similar to the drone scheduling problem in [7]. From the above research, it can be concluded that the main goal of UAVs during patrol missions is to collect ground information to the maximum extent possible. However, so far, no research has been conducted on community patrol tasks. In addition, the above research on drone patrols cannot be extended to three-dimensional space.

B. A Mathematical Model for UAV Trajectory Planning

Specifically, the establishment of a mathematical model for inspection drones can be divided into two parts: geometric modeling and problem modeling, based on the working mechanism of the digital twin patrol platform. The geometric model is mainly based on the physical performance and flight environment of drones, including obstacle modeling, drone dynamics modeling, and route constraints [18]. The problem model is an objective function composed of one or several objectives, including the shortest path, minimum energy consumption, or minimum flight time [19]. Geometric modeling includes three parts: mathematical model construction of drones, environmental perception, and map construction. In order to plan safe and effective trajectories, drones need to perceive the environment and construct maps, mainly using advanced sensor technology and data fusion technology [20]. Due to the development of digital twin cities, high-precision three-dimensional maps of cities have been established. Therefore, this study focuses on the construction of mathematical models for drones.

The author in [21] studied the trajectory planning problem of ground drones in a two-dimensional environment, which aimed to plan a set of trajectories for a drone cluster. However, the geometric model of the ground drones established did not consider all the physical performance of the drones. In addition, the problem model established in [21] only focuses on the shortest trajectory and cannot be applied to patrol tasks based on drones. The author in [22] proposed a trajectory planning method in three-dimensional space, but it sets the Z-coordinate of the drone trajectory point as a fixed value, which is essentially still trajectory planning in two-dimensional space. The established mathematical model still does not consider the pitch angle constraint of the drone. In addition, it only focuses on the single target of the shortest trajectory. In [23], a trajectory planning scheme for UAV in two-dimensional space was proposed, and the established problem model also aimed to minimize the trajectory. The author in [24] focuses on UAV-based power grid inspection tasks. Similar to [15], there are fewer obstacles during the process of patrolling the power grid, and the mathematical model established is also not applicable to urban patrol tasks. Therefore, it is necessary to establish a

mathematical model that simultaneously focuses on information collection and trajectory length.

C. A Swarm Intelligence Algorithm-Based Trajectory Planner

The algorithms used for UAV trajectory planners can be specifically divided into three categories based on their functions: static obstacle avoidance algorithms, dynamic trajectory planning algorithms, and global trajectory planning algorithms [25]. During flight, UAVs may encounter various obstacles such as buildings and trees. How to effectively avoid these static obstacles is an important issue in drone trajectory planning [26]. In addition, in practical applications, UAVs may also encounter dynamic obstacles during flight, such as birds or pedestrians, which requires drones to be able to plan new trajectories in real time to cope with environmental changes [27]. In addition, the global trajectory planning algorithm for drones is to plan a trajectory from the starting point to the endpoint based on the global map using the algorithm [28]. This article focuses on the global trajectory planning algorithm considering static obstacles.

The global trajectory planning algorithm is the core of the drone trajectory planner, and common trajectory planning algorithms include graph search-based algorithms, optimization-based algorithms, sampling-based algorithms, etc. [29]. A trajectory planning model based on graph search: This model discretizes the environmental space into a series of nodes and uses graph search algorithms (such as A * algorithm, Dijkstra algorithm, etc.) to find the optimal path between these nodes. This model is simple and easy to implement, but it has lower computational efficiency when dealing with complex environments or high-dimensional spaces [30]. The sampling-based trajectory planning model randomly samples in the environmental space, constructs paths between sampling points, and finally optimizes the path to obtain the optimal trajectory. This model can handle complex environments and has high computational efficiency, but it cannot guarantee finding the global optimal solution [10]. The learning-based trajectory planning model learns trajectory planning strategies through machine learning methods. This model can handle complex environments and high-dimensional spaces, and can continuously improve trajectory planning strategies through learning, but it requires a large amount of training data and computational resources [31].

Unlike the above three methods, the trajectory planning model based on swarm intelligence transforms the trajectory planning problem into an optimization problem, and obtains the optimal trajectory by solving the optimization problem [32]. When solving optimization problems, swarm intelligence algorithms can not only consider multiple objectives but also find the optimal solution in large-scale complex problems. Representative algorithms include genetic algorithm (GA) [33] and grey wolf optimizer (GWO) [34]. Therefore, at present, more and more swarm intelligence algorithms are being applied to UAV trajectory planning problems. In [35], an improved differential evolution (DE) algorithm was designed and applied to the mathematical model of unmanned aerial vehicle trajectory planning, aiming to improve the convergence accuracy of the DE algorithm. Similarly, an improved DE algorithm in [36] was used for the deployment of multiple drones and achieved good results. This is because the differential strategy in the DE algorithm can help the DE algorithm escape from local optima.

The GWO algorithm has also been applied in the field of drone trajectory planning. In [37], a reinforcement learning strategy based GWO algorithm was designed and applied to drone trajectory planning problems. In [38], the GWO algorithm is applied to the trajectory planning problem for transmission line inspection tasks. The above two studies have successfully applied the GWO algorithm to the trajectory planning problem of unmanned aerial vehicles. Reference [39] proposed an improved GA algorithm and applied it to the target coverage problem. The performance of GA algorithm and Particle Swarm Optimization (PSO) algorithm in solving trajectory planning problems was compared in [27], and experimental results showed that GA algorithm has more potential compared to PSO algorithm. In addition, as a novel swarm intelligence algorithm, there is currently no research testing the performance of CSA in solving unmanned aerial vehicle trajectory planning problems. Therefore, this article improves the CSA algorithm and successfully applies the improved CSA algorithm (ICSA, also known as DE-CSA) to the trajectory planning problem of unmanned aerial vehicles.

III. MODEL

A. Problem Definition

Before establishing the model, we first describe the patrol problem in smart cities. This study uses quadcopter drones to patrol communities within cities, aiming to detect emergencies (such as accidental injuries) and ensure the safety of community residents, while providing timely information. According to [13]-[16], UAVs have two main targets during patrol: maximizing information collection and minimizing the length of flight trajectories. Before flying, the trajectory planner for patrolling UAVs needs to determine the optimal patrol trajectory based on camera constraints. In addition, the trajectory of UAV needs to meet physical performance constraints such as the maximum rotation angle, maximum tilt angle, and maximum flight distance of the drone.

According to the smart city framework established based on digital twin (DT) technology in, this study describes the working mechanism of the DT-based smart patrol platform, as shown in Fig. 2. In the operation process of the DT-based intelligent patrol platform, a large number of sensors need to be used to collect information, and the collected information needs to be collected, classified, and organized. Furthermore, based on the requirements of smart city patrol tasks and the physical performance of patrol drones, a corresponding digital twin model is established. Finally, design experiments and simulation simulations are conducted to feedback the trajectory of patrol drones to the real world. In this study, the data perception, data modeling (geometric model and problem model), and data simulation of DT-based patrol platforms in smart cities were demonstrated. Intended to further explain the operating mechanism of the smart patrol platform, and also to further demonstrate the application of advanced artificial intelligence technologies such as swarm intelligence algorithms in the smart patrol platform.

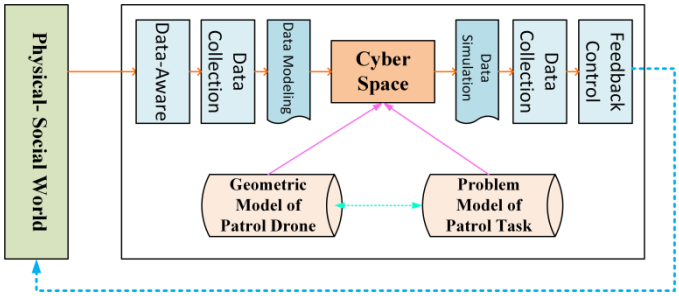

Fig. 2. The working mechanism of smart patrol platform based on digital twins.

B. Data-Aware

In order to plan a safe and effective trajectory, the smart patrol platform based on drones needs to perceive the environment and build maps, mainly using advanced sensor technology and data fusion technology. Fig. 3 shows a map of digital twins in the context of a smart city.

Fig. 3. The map of smart cities.

C. Mathematical Model

1) Geometric model: Geometric modeling includes the establishment of a drone flight space map model, the establishment of a drone mathematical model, and the establishment of an airborne camera model, as shown below:

$$C_b = \left[x_{cb1}, x_{cb2}, y_{cb1}, y_{cb2}, z_{cb1}, z_{cb2}\right] \tag{1}$$

Eq. (1) shows the establishment of building maps in smart cities, where $\forall b \in B$ represents the set of obstacles in the map.

$$Q_a = \left[x_{qa}, y_{qa} z_{qa}\right] \tag{2}$$

Eq. (2) is the coordinates that make up urban road grid $a \in A$.

$$l_k / T_k \le v_{\max} \tag{3}$$

$$\sum_{k \in K} T_k \le T_{\max} \tag{4}$$

$$l_k = \sqrt{\left(x_{k+1} - x_k\right)^2 + \left(y_{k+1} - y_k\right)^2 + \left(z_{k+1} - z_k\right)^2} \tag{5}$$

Eq. (3)-(5) together constitutes the digital twin model of unmanned aerial vehicles. Eq. (3) is the maximum flight speed constraint of the drone, where $v_{\max}$ is the maximum flight speed of the drone; l_k is the distance from the drone's track point k to the drone's track point $k+1$; T_k is the flight time of the drone from the waypoint to the drone's waypoint. Eq. (4) is the battery capacity constraint of the drone, and $T_{\max}$ is the maximum flight time of the drone.

$$\sqrt{\left(x_{qa} - x_k\right)^2 + \left(y_{qa} - y_k\right)^2 + \left(x_{qa} - z_k\right)^2} \le L_{\max} \tag{6}$$

Eq. (6) forms a digital twin model for airborne cameras, and constrains the maximum shooting distance of the camera, where $L_{\max}$ is the maximum shooting distance of the camera.

2) Problem modeling: When drones patrol in a smart city environment, they aim to complete patrols of all areas with the shortest possible cost. According to [35]-[39], the cost of drone trajectory planning includes two types: time cost and path length cost. Therefore, this article selects path length cost as one of the objectives in the multi-objective function. In order to reduce the difficulty of solving the problem, the goal of maximizing the collection of information in the patrol area is established as the corresponding penalty function. When there is a road grid that is not patrolled, the value of the penalty function will increase, otherwise the value of the penalty function will decrease. The modeling of the problem is as follows.

$$\min f = \sum_{k \in K} l_k \times \left(N_{B\max} - \sum E_b\right) \tag{7}$$

$$E_b \in \{0,1\} \tag{8}$$

Eq. (7) is the objective function of the problem, where $\left(N_{B\max} - \sum E_b\right)$ is the penalty function and $N_{B\max}$ is the number of grids that make up the road. As shown in Eq. (8), E_b is a 0-1 variable. When the camera can capture the road grid $\forall b \in B$, $E_b = 1$; Otherwise, $E_b = 0$.

IV. Algorithm Design

A. Algorithm Introduction

The origin of swarm intelligence technology originated from Reynolds' research on the Bodies project, and after continuous evolution and development, swarm intelligence algorithms including GWO, GA, and CSA have emerged [33]-[34]. The swarm intelligence algorithm is a cluster of

algorithms based on group behavior and intelligence, which simulates the interaction and cooperation between individuals in a group to achieve the ability to solve problems collaboratively. These algorithms draw inspiration from collaborative behaviors in biological populations, such as bird colonies, ant colonies, fish colonies, etc., and achieve the overall intelligence of the population through information exchange, interaction, and division of labor among individuals. This technology has shown excellent performance in solving the large-scale multi-objective problem. Therefore it is widely used in unmanned aerial vehicle trajectory planning.

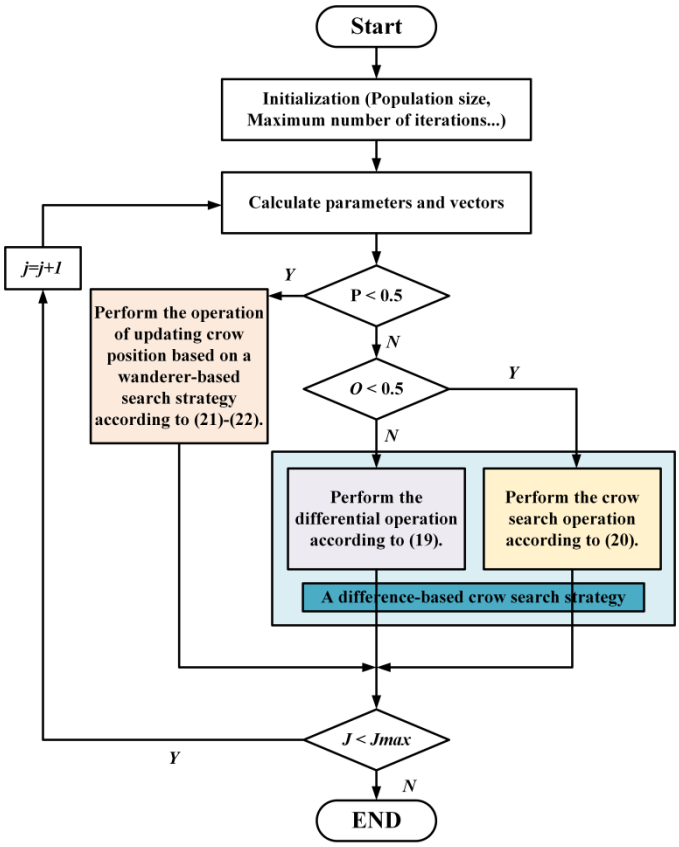

Fig. 4. The flowchart of the DE-CSA algorithm.

The CSA algorithm is a novel swarm intelligence algorithm proposed in 2016, which mimics the hidden food, tracking, and deceptive behavior among crow individuals in a crow population. It performs global search by perceiving probability and flight distance. The CSA algorithm has the advantages of simple search strategy and fewer parameters. In addition, CSA algorithm is a global search algorithm that can find the optimal solution throughout the entire search space. At the same time, CSA algorithm has high search efficiency and can find better solutions in a short time. Although CSA algorithm can perform global optimization, it is determined by perceptual probability. Therefore, when the parameter selection is not appropriate, CSA may fall into local optima and cannot find the global optimal solution. At the same time, this also leads to CSA being unable to optimize in local space, resulting in low convergence accuracy.

B. DE-CSA Algorithm

Due to the concise search method of CSA, it is easy to fall into local optima and other problems when solving large-scale and complex problems. However, differential evolution (DE) algorithms optimize problems through mutation, crossover, and selection operations [14]-[15]. Therefore, it is possible to combine the DE algorithm and CSA algorithm to design a DE based CSA algorithm (DE-CSA) for solving the trajectory planning problem of patrol drones. In the DE-CSA algorithm developed in this study, a flight step size that changes with the number of iterations, a difference-based crow search strategy, and a wanderer-based search strategy were designed to improve the convergence accuracy of the CSA algorithm. Fig. 4 illustrates the flowchart of the DE-CSA algorithm, which (also known as the ICSA algorithm) has the following specific steps.

1) Initialize the location of the crow population: To change the default, adjust the template as follows. Initialize population size $R\max$. Use traditional trajectory planning methods to plan the several trajectories of UAV, making them equal to the population size. Each track represents a crow individual $Track(r, j)$. Initialize the maximum number of iterations J max . Initialize the differential scaling factor F . Initialize crow population position GC .

The definition of the crow individual $Track(r, j)$ is shown in Eq. (9).

$$Track(r, j) = \left\{T(r, j)_1, T(r, j)_2, \cdots, T(r, j)_D\right\} \tag{9}$$

where r represents the r -th individual, and j represents the j -th iteration process, D represents the individual's dimension.

The definition of the crow population position GC is shown in Eq. (10).

$$GC = \left\{Track(1), Track(2), \cdots, Track(R\max)\right\}^{\mathrm{T}} \tag{10}$$

where

$$Track(r) = Track(r, j)$$

2) Population assessment: Evaluate the objective function values of each crow of individual in the crow population and find the optimal solution to the optimization problem according to Eq. (11). The specific process of this step is shown in Algorithm 1. Among them, f_{best} is the optimal fitness function value in the crow population. $Track_{best}$ is the best crow individual in the population.

Algorithm 1

```
For r=1 to R_max do
    Fitness = f (track(r,j))
     if Fitness<f best Then
       f best = Fitness
       Track best = track(r,j)
End for
```

$$m(r,j)=\begin{cases} Track(r,j), if\ f(Track(r,j)) \le f(Track(r,j-1)) \\ m(r,j-1), Otherwise \end{cases} \tag{11}$$

The definition of the *MC* is shown in Eq. (12).

$$MC=\{m(1,j),m(2,j),\cdots,m(R\max,j)\}^{T} \tag{12}$$

where *MC* is the memory matrix of the crow population.

3) Calculate search step size: Calculate the flight step size *flyo* of individual crows according to Eq. (13).

$$flyo=2.5-\left(\frac{j}{J\max}\right)^{1/2} \tag{13}$$

4) A difference-based crow search strategy: Randomly generate a random number P in the [0,1] interval, and if $P \ge 0.5$, generate a random number O in the [0,1] interval, and perform a differential crow search operation based on Eq. (14)-(15).

If $O \ge 0.5$, perform differential operation according to Eq. (14).

$$T(r,j+1)_d = T(r1,j)_d + F \times (T(r2,j)_d - T(r3,j)_d) \tag{14}$$

where $T(r1,j)_d$, $T(r2,j)_d$, and $T(r3,j)_d$ are the *d-th* dimension of randomly selected individuals.

If $O < 0.5$, perform crow search operation according to equation (15).

$$T(r,j+1)_d = T(r,j)_d + Rand \times flyo(m(best,j)_d - T(r,j)_d) \tag{15}$$

where *Rand* is a random number in the [0,1] interval. $m(best,j)_d$ is the *d-th* dimension of the individual with the best fitness function value in matrix *MC*.

5) A wanderer-based search strategy: If $P < 0.5$, perform a wanderer-based search operation based on Eq. (16)-(17).

$$T(r,j+1)_d = T(r,j)_d + Rand \times flyo \times a \tag{16}$$

$$a = Rand(\sqrt{D+1}) \tag{17}$$

6) Reevaluate the population: Reevaluate the population based on Algorithm 1.

7) Output result: Calculate and determine whether the maximum number of iterations has been reached. If so, end the iteration and output the result; Otherwise, return to 3) Calculate search step size.

V. Presentation of Experimental Results

In order to further demonstrate the performance of the DE-CSA algorithm designed in this study, the performance of the algorithm was demonstrated from two aspects. Firstly, according to [33], this study tested the DE-CSA algorithm using six test functions. In addition, this study established a corresponding simulation environment based on the map shown in Fig. 3 and used the DE-CSA algorithm to plan the trajectory of patrol drones. All the above simulation experiments were conducted on the MATLAB 2022a platform.

A. Benchmark Functions

This study used unimodal test functions (F05-F07) and multimodal test functions (F08-F10) to test the developed algorithm. Among them, F05 is called the Rosenbrock function, also known as the Valley or Banana function, with its global minimum located in a narrow parabolic valley. However, although the valley is easy to find, it is difficult to converge to the minimum. F07 is a multidimensional unimodal flat-bottomed function with random interference, and the algorithm is prone to getting stuck in local optima during operation. F08-F10 are both multimodal test functions. Among them, F09 is the Rastigin function, which has many local minima and is highly multimodal. In the two-dimensional form, the characteristic of the function image of F10 is that the external region is very flat and there is a large hole in the center. This function can also easily trap optimization algorithms into local optima. Therefore, the above test functions can test not only the local search ability of the algorithm, but also the global search ability of the algorithm.

TABLE I. Test Functions

Functions	Expressions of Functions	Domian	Optimal
F05	$F_{05}(x)=100\times\sum_i[(x_{i+1}-x_i^2)^2+(x_i-1)^2]$	[-30,30]	0
F06	$F_{06}(x)=\sum_i[(x_i+0.5)^2]$	[-100,100]	0
F07	$F_{07}(x)=\sum_i[i\times x_i^4+Random[0,1)]$	[-1.28,1.28]	0
F08	$F_{08}=\sum_i[-x_i\sin(\sqrt{\lvert x_i\rvert})]$	[-500,500]	-837.966
F09	$F_{09}(x)=\sum_i[x_i^2-10\times cos(2\pi x_i)+10]$	[-5.12,5.12]	10
F10	$F_{10}(x)=-20exp(-0.2\sqrt{((1/n)\sum_i x_i^2)})-exp(1/ncox(2\pi x_i))+20+e$	[-32,32]	0

TABLE II. THE GRAPH OF THE TEST FUNCTION AND THE ITERATION CURVES OF THE FOUR ALGORITHMS ($R\max$ =30)

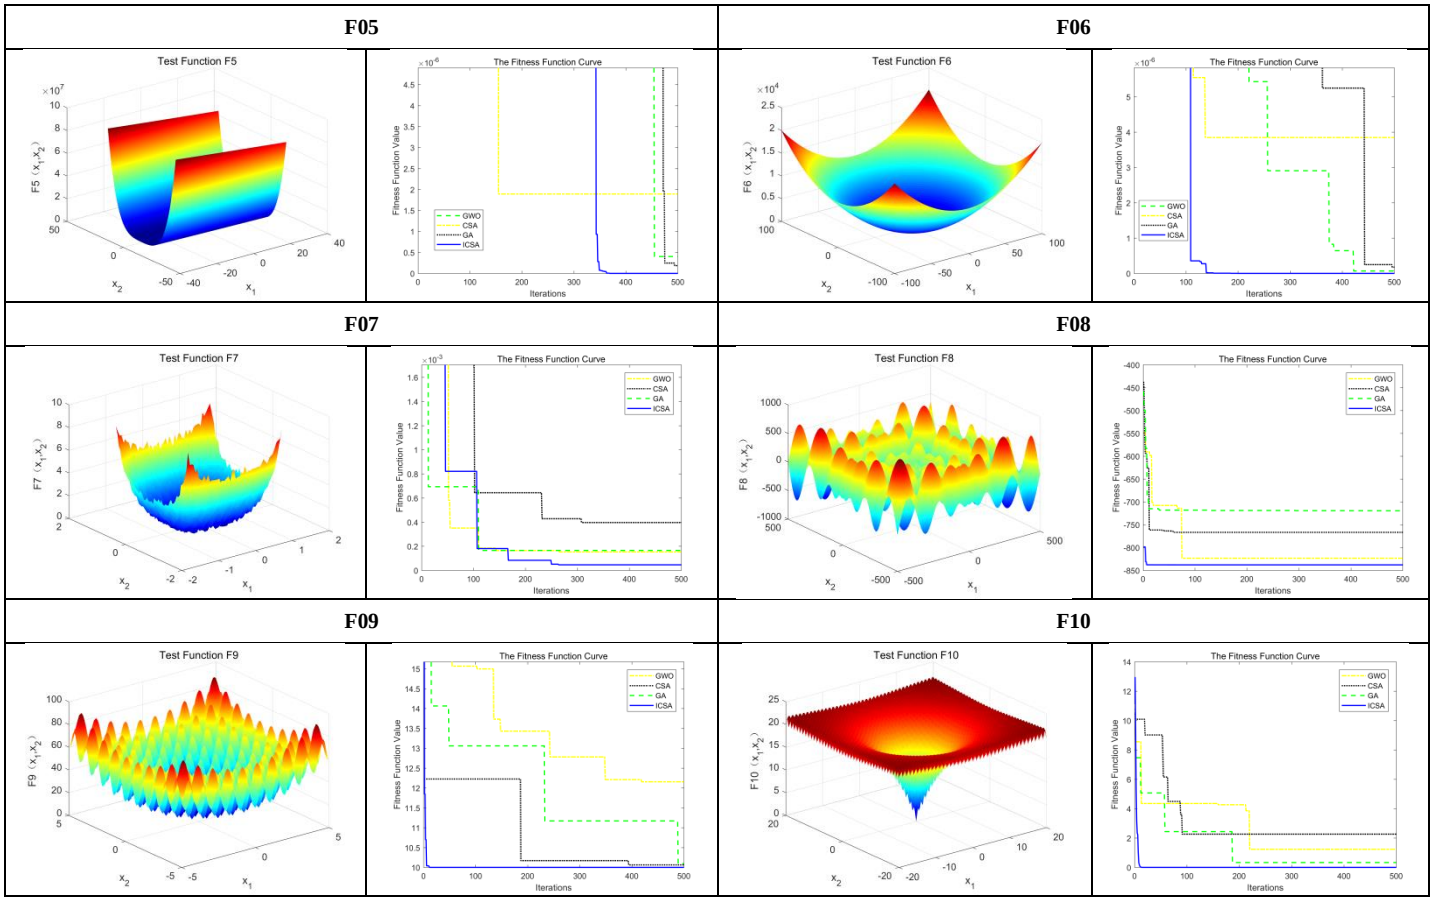

TABLE III. THE FITNESS FUNCTION VALUES OF THE TEST FUNCTION FOR FOUR ALGORITHMS RUNNING 30 TIMES ($R\max$ =30)

The CSA, GA, GWO, and DE-CSA algorithms were run 30 times in each test function. Table I shows the mathematical formulas, variable ranges, and minimum values of the six test functions F05-F10. Table II shows the convergence curves of the fitness functions during the running process of CSA, GA, GWO, and DE-CSA algorithms using each test function as the fitness function. Table III presents the operational results of CSA, GA, GWO, and DE-CSA methods.

B. Trajectory Planning Results

On this basis, in order to verify the effectiveness of the smart patrol platform designed in this study, a corresponding simulation environment was established based on the map shown in Fig. 3 and the DE-CSA algorithm was used to plan the trajectory of the patrol drone. Fig. 5 shows the patrol trajectory planned by the DE-CSA algorithm for unmanned aerial vehicles. Fig. 6, and Fig. 7, respectively shows the optimal fitness function curves, and average fitness function curves of the four algorithms during 30 runs.

As shown in Fig. 6, during the 30 runs of GWO, GA, CSA, and DE-CSA algorithms, the optimal fitness function value of DE-CSA is 5180.07, while the optimal fitness function values of GWO, GA, and CSA algorithms are 5641.16, 5624.49, and 5781.13, respectively. As shown in Fig. 7, during 30 runs of GWO, GA, CSA, and DE-CSA algorithms, the average fitness function value of DE-CSA is 5179.53, while the average fitness function values of GWO, GA, and CSA algorithms are 5674.75, 5691.29, and 5727.05, respectively. Therefore, it can be concluded that the optimal fitness function, worst fitness function, and average fitness function solved by the DE-CSA algorithm have the best results in 30 runs, fully proving the effectiveness of the smart patrol platform.

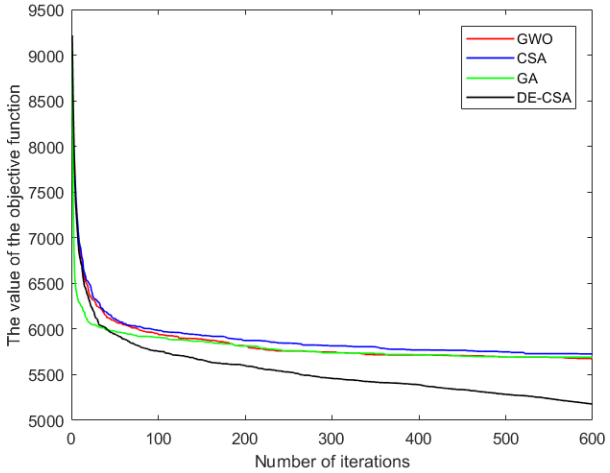

Fig. 7. The average fitness function curves of the four algorithms.

VI. CONCLUSIONS

This study constructed a smart patrol platform for smart cities and developed an improved CSA algorithm. This study expands the application of drones in smart cities, aiming to improve the service quality of cities. The effectiveness of the platform and algorithm was demonstrated through the use of six test functions and a simulation experiment in a real scenario. The simulation results show that the DE-CSA algorithm can achieve the best results in all six test functions, whether it is the mean and standard deviation. In the experiment of drone trajectory planning, the optimal, and average values of the DE-CSA algorithm were better than the other three algorithms in 30 runs of GWO, GA, CSA, and DE-CSA algorithms. In the future research process, the focus will be on the trajectory planning problem of patrol drones in dynamic environments.

Entity Relation Joint Extraction Method Based on Insertion Transformers

Haotian Qi, Weiguang Liu, Fenghua Liu*, Weigang Zhu, Fangfang Shan
College of Computer, Zhongyuan University of Technology, Zhengzhou, Henan 451191, China

***Abstract*—Existing multi-module multi-step and multi-module single-step methods for entity relation joint extraction suffer from issues such as cascading errors and redundant mistakes. In contrast, the single-module single-step modeling approach effectively alleviates these limitations. However, the single-module single-step method still faces challenges when dealing with complex relation extraction tasks, such as excessive negative samples and long decoding times. To address these issues, this paper proposes an entity relation joint extraction method based on Insertion Transformers, which adopts the single-module single-step approach and integrates the newly proposed tagging strategy. This method iteratively identifies and inserts tags in the text, and then effectively reduces decoding time and the count of negative samples by leveraging attention mechanisms combined with contextual information, while also resolving the problem of entity overlap. Compared to the state-of-the-art models on two public datasets, this method achieves high F1 scores of 93.2% and 91.5%, respectively, demonstrating its efficiency in resolving entity overlap issues.**

***Keywords*—Entity relation extraction; tagging strategy; joint extraction; transformer**

I. Introduction

The proliferation of the Internet has led to an explosion of textual data, presenting a challenge in extracting valuable information efficiently. Various downstream tasks such as Knowledge Graph construction, Intelligent Question Answering Systems, and Recommendation Systems rely on the extraction of pertinent information from this unstructured textual data. Consequently, the extraction of entities and relations from text has emerged as a pivotal challenge in the field of Information Extraction. Entity relation extraction, as a core task within IE, aims to distil structured ternary information, namely <subject, relation, object> [1], from raw and unstructured text. This process is essential for furnishing crucial data support for subsequent tasks. Through accurate entity relation extraction, valuable insights can be gleaned from vast volumes of textual data, thereby enhancing the quality and efficiency of downstream applications.

Early entity relation extraction tasks typically employed a pipeline approach, which involved breaking down the extraction process into two distinct sub-tasks: Named Entity Recognition and Relation Extraction [2]. Initially, an entity recognition model would be constructed to identify entity pairs, followed by the development of a semantic relation model to perform relation extraction based on the recognized entity pairs. This sequential approach facilitated model construction but often resulted in issues such as data dependency, cascading errors, and information redundancy due to limited interaction between the tasks. In contrast, the joint extraction model integrates entity information and relations into a unified framework through joint training. This approach minimizes the drawbacks of the pipeline method by allowing for greater interaction between entity recognition and relation extraction. By simultaneously considering entity and relation information, the joint extraction model exhibits enhanced performance in handling diverse and complex semantic structures. Moreover, its parallel nature mitigates the accumulation of errors, thereby improving the overall efficiency and effectiveness of information extraction processes.

Depending on task complexity and design requirements, entity relation joint extraction can be classified into three fundamental architectures: multi-module multi-step, multi-module single-step, and single-module single-step [3]. The multi-module multi-step architecture showcases its modularity advantage in entity relation joint extraction. By segmenting tasks into multiple steps and modules, each module can concentrate on specific subtasks, thus enhancing flexibility and maintainability. However, this design can inadvertently propagate errors, diminishing overall performance and increasing training and optimization complexity. In contrast, the multi-module single-step architecture maintains modularity benefits while simplifying joint extraction. It reduces the risk of error propagation by sharing information across modules, making it suitable for handling relatively straightforward entity relation joint extraction tasks. However, it may sacrifice the capability to capture task complexity effectively. The single-module single-step architecture excels in its streamlined model structure, ease of training, and comprehensibility. However, since this approach decodes triples based on global information matrices, it may prolong decoding times and introduce issues such as excessive negative sampling.

As shown in Fig. 1, we use a rectangular solid to represent the number of computations in a single module and single-step process, with each block on the surface representing the computations between tokens under a single relationship. The red blocks indicate inefficient computations, while the green blocks represent efficient computations. Take the sample sentence “The dog got a driving license,” which contains an entity pair (The dog, owner, driving license). Assuming there are five pre-defined relationships and relationship r1 equals “owner”. From the figure, it is clear that this sample needs to be calculated $6 \times 6 \times 5$ times in total, but only 3 of those calculations are efficient. Hence, its reasoning efficiency is not high. When the sentence length increases, the number of inefficient calculations grows exponentially.

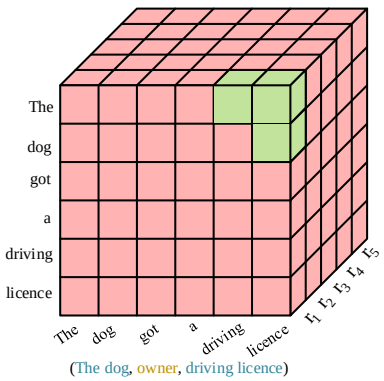

Fig. 1. Example of single-module single-step problem.

Addressing the challenges of time-consuming decoding and excessive negative sampling in current joint extraction processes, this paper proposes a single-module single-step approach based on Insertion Transformers. The method involves inserting a common token between each token of the sample during the inception stage. The model then assigns specific meanings to these tokens to recognize and delineate a triad. Subsequently, ordinary tokens are reintroduced in the vicinity of each identified special token, allowing the model to continue identifying and locating new triples following this logic until no more triples can be identified. In comparison to the baseline model, the proposed approach demonstrates notable improvements on both the NYT and WebNLG datasets. It not only significantly reduces decoding time but also effectively mitigates the number of negative samples compared to the state-of-the-art models. This further validates the performance of the proposed model.

The subsequent sections of this paper unfold as follows: Section II illustrates prior research endeavors. Section III details into the methodology employed. Section IV clarifies the experimental setup. Section V describes the experimental outcomes and engages in discussions. Lastly, Section VI summarizes the conclusions drawn from this study.

II. Related Works

This section provides an overview of the related work on entity relation joint extraction methods, where the single-module single-step based extraction method is the focus of this paper.

In recent years, with the advancement of deep learning, many scholars have integrated deep learning methods into models for entity relation extraction to enhance extraction accuracy. The majorities of entity relation extraction models in recent years have leveraged pre-trained language models, particularly BERT [4], and have exhibited remarkable performance. Among these, deep learning based on entity relation joint extraction can be categorized into three modelling approaches. There are early approaches based on global text information, including both multi-module multi-step and multi-module single-step methods. Besides, there is the single-module single-step method, which addresses the issue of cascading redundancy between modules and steps.

A. Multi-module Multi-step Method

The multi-module multi-step architecture offers the advantage of explicit task decomposition and modular design. To address the issue of ternary overlap in entity relation extraction tasks, Zeng et al. [5] introduced an end-to-end neural model called CopyRE, based on Seq2Seq (Sequence-to-sequence) with a Copy mechanism. This model can extract relational facts from sentences of different categories, including normal sentences, Single Entity Overlap (SEO), and Entity Pair Overlap (EPO) sentences. Subsequently, Zeng et al. [6] proposed the CopyMTL model, which adopts a multi-tasking framework and the Copy mechanism to predict multi-word entities. However, CopyRE struggles with extracting multi-word entities, and while CopyMTL improves this aspect, its effectiveness in extracting an arbitrary number of triples remains to be enhanced. To address this issue, Wei et al. [7] introduced the cascading Hierarchical Binary Tagging (HBI) model, CasRel, which conducts entity relation triple extraction in two successive steps. This model represents relations as a function mapping head entities to tail entities. Additionally, Tian et al. [8] proposed the HSL model, which employs a novel tagging scheme to convert the joint entity and relation extraction problem into a sequence tagging task using a hierarchical sequence tagging approach. Zheng et al. [9] proposed the PRGC model, which decomposes the task into three subtasks: relation judgment, entity extraction, and subject-object alignment. Geng et al. [10] proposed an attention mechanism integrating convolutional and recursive neural networks within a joint model, enhancing the utilization of contextual information. The FETI model, suggested by Chen et al. [11], integrates head-tail entity category information and employs an auxiliary loss function for more efficient utilization of entity category information. Ye et al. [12] introduced the CGT model, a ternary extraction model based on the generative Transformer, which leverages contrastive ternary-level calibration algorithms and batch-level dynamic attention masking mechanisms to enhance model performance. Yu et al. [13] optimized a joint extraction model for Chinese entity relation extraction using the RoBERTa pre-training model.

B. Multi-module Single-step Method

Compared to the aforementioned methods, the multi-module single-step simplifies the model structure and reduces extraction complexity. To address the issue of the model predicting the extraction order of multiple triples, Sui et al. [14] proposed an end-to-end network model, Set Prediction Networks (SPN), featuring Transformers-based features and non-autoregressive parallel decoding, along with a two-part matching loss. This model transforms the task of entity relation joint extraction into an ensemble prediction problem. Wang et al. [15] introduced a table-filling model, Table-Sequence Encoders, based on the Attention mechanism. This model facilitates the transfer and interaction of information between different input modalities by incorporating table encoders and sequence encoders. The TPLinker, proposed by Wang et al. [16], treats entity relation joint extraction as a tagged-pair linking problem and introduces a novel handshake tagging scheme for aligning entity-pair boundary tags under each relation type. Additionally, Wang et al. [17] proposed

UniRE, a table-filling model giving joint decoding, which employs a unified tag space and solves the problem of tag space dispersion in traditional entity relation extraction.

C. Single-module Single-step Method

The more lightweight single-module single-step approach simplifies extraction and enhances intuitiveness compared to the multi-module design. Kong et al. [18] introduced an end-to-end co-attention network called CARE, which utilizes a two-dimensional table to represent entity tags and relation tags respectively. Inspired by the modelling idea of Novel-Tagging [19], Shang et al. [3] proposed a fine-grained triple classification model, OneRel, at the entity token layer. This effectively mitigates issues such as cascading errors and entity redundancy.

Amalgamating the research on entity relation joint extraction, this paper proposes effective solutions to the shortcomings of existing methods in Section A. The primary contributions are as follows:

1) Integrating the concept of Insertion Transformers, we present a novel perspective by reframing the joint extraction of entity relations as fine-grained triple classification. Effectively reduce the decoding time of the model to a constant level, enhancing its efficiency by leveraging insertion operations.

2) A novel entity relation tagging strategy, Vanilla Entity Relation Tags (VRT), is proposed, significantly enhances the performance in addressing the issue of Entity Overlap.

3) We conduct model evaluations on two publicly available datasets, NYT and WebNLG. The results demonstrate that our approach surpasses current state-of-the-art baseline methods, particularly in handling the intricate context of overlapping triples.

D. Insertion Transformers

Insertion Transformers, a branch of non-autoregressive generative models originally proposed by Stern et al. [20], revolutionizes text generation. The core concept involves iteratively inserting elements into an initial blank sequence until the termination condition is met, effectively reducing inference time while maintaining high performance. Building upon this foundation, Gu et al. [21] introduced InDIGO, an insertion-based decoding algorithm that optimizes efficiency by reusing previous hidden states. Moreover, Zhang et al. [22] introduced POINTER, a hierarchical Transformer model that blends the strengths of BERT and Insertion Transformer, generating text through incremental token insertions. Additionally, the CBART model, proposed by He[23], enhances text generation by incorporating a token-level classifier at the encoder side. This classifier guides the decoder in performing substitution and insertion operations, enabling simultaneous fine-tuning of multiple input tokens and thereby enhancing the accuracy and efficiency of text generation.

III. Methodology

The objective of the single-module single-step model is to identify the set of triples present in a sentence for each relation. This involves identifying entity pairs within a given sentence, where the relation set of number M is represented as $R = \{r_1, r_2, \ldots, r_m\}$, and the sentence of length N is represented as $X = \{x_1, x_2, \ldots, x_n\}$. The task is to find the set of entity pairs $Y = \{(s_1, r_1, o_1), \ldots, (s_k, r_k, o_k)\}$ with conditional probability given by:

$$p(Y|X) = \prod_{m=1}^{M} \prod_{i=1}^{N} \prod_{j=1}^{N} p_\theta(Y_k|X, r_m) \quad (1)$$

where, θ represents the model parameter. However, the optimized single-module single-step model requires $N \times N$ computations to determine the entity pair set Y, which leads to exponential growth in computation for longer texts, significantly increasing decoding time. To address this issue, this method draws inspiration from the Insertion Transformers model, successfully reducing the number of decoding times to a constant level using insertion operations.

In this section, the specific implementation method will be discussed in five parts, A focuses on entity relation tagging strategy, B discusses decoding strategy of the model, and C will describe the overall model framework. D will delve into model training, finally E will explore the objective function used in this approach.

A. Entity Relation Tagging Strategy

In the task of entity relation joint extraction, the set of entity pairs in a sentence is unordered, and the positions of the head and tail entities in the sentence are also unordered. In order to enable the model to recognize the head and tail entities at any position in the text and extract the relation between the entities simultaneously, this approach proposes a novel entity relation tagging method. It consists of four special tags: Head Entity Relation Tag (HRT), Tail Entity Relation Tag (TRT), Overlap Entity Relation Tag (ORT), and a generic entity relation tag (Vanilla Entity Relation Tag, VRT). The definitions are as follows:

$$HRT = \{p_1, p_2, \ldots, p_M\} \quad (2)$$

$$TRT = \{p_{M+1}, p_{M+2}, \ldots, p_{2M}\} \quad (3)$$

$$ORT = \{p_{2M+1}, p_{2M+2}, \ldots, p_{3M}\} \quad (4)$$

$$VRT = p_0 \quad (5)$$

where, p indicates the token, and except for VRT, each entity relation token is assigned one by one corresponding to M relations.

As shown in Fig. 2, given the text $X = \{Jackie, \ldots, Island\}$, with $N = 7$. The set of entity pairs for this text is denoted as Y = {(*Jackie Chan*, *belong*, *Hong Kong*), (*Hong Kong*, *contain*, *Hong Kong Island*)}, with$K = 2$. The entity relation tagging method requires $K + 1$ steps of processing for this text. Except for the step 1, each step of processing can be divided into two operations, namely VRT insertion and VRT transformation. In the step 1, only VRT insertion operations are performed on the text X, and the insertion positions for VRT are between all adjacent tokens in the text, resulting in a total of $N + 1$ inserted p_0 tokens, yielding a new token sequence X'.

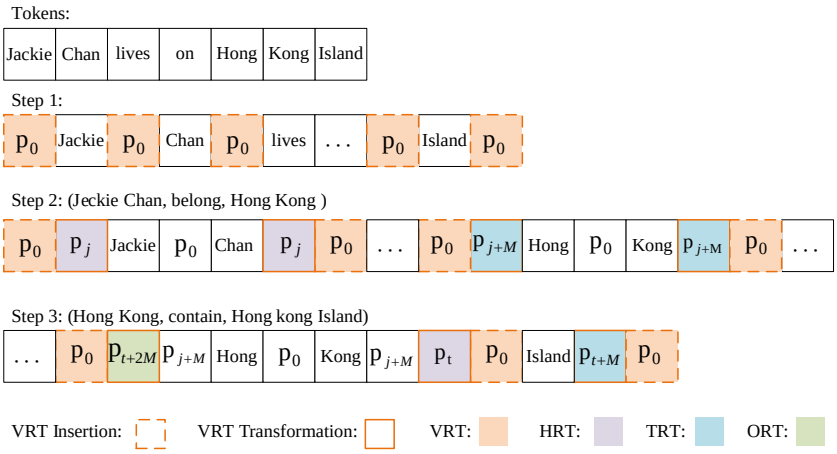

Fig. 2. Example of entity relation tagging.

Step 2 in Fig. 2 of the entity relation tagging method involves first performing VRT transformation on the text X', followed by VRT insertion operations. This sequence is beneficial for generating subsequent training samples and targets. In VRT transformation, VRTs are converted to other tags to enclose the entity pairs in the sentence. Specifically, if '*belong*' is at the j position in the relation set R, then p_j is taken as HRT and p_{j+M} as TRT. In text X, VRT tags preceding the first token of the head entity and following the last token are converted to HRT. Similarly, VRT tags preceding the first token of the tail entity and following the last token are converted to TRT. Finally, VRTs are inserted around the newly converted HRT and TRT.

The operation of step 3 is the same as step 2 in Fig. 2. However, due to the overlapping entities in (*Hong Kong*, *contain*, *Hong Kong Island*), there are some differences in VRT transformation. Specifically, VRTs preceding '*Hong*' need to be converted to both HRT and TRT. In this case, the ORT is replaced with p_{t+2M} for this position, where t is the index of 'contain' in the relation set R.

Entity overlapping addressed in the step 3 constitutes one facet of the broader entity overlapping challenges, and this method posits that the proposed entity relation tagging method remains efficacious in effectively mitigating such issues. Specifically, the entity overlap conundrum can be delineated into three distinct categories: EPO, HTO, and SEO, where SEO encapsulates instances of overlapping entities within triplet sets, encompassing both EPO and HTO scenarios.

Focusing solely on a singular entity pair during each processing step, the entity relation tagging method sidesteps occurrences where entities overlap within other entity pairs, thereby aptly resolving the quandary of individual entities overlapping with other entity pairs in both EPO and SEO settings. Moreover, given the inherent significance of entity positioning entailed by the tagging position within the entity relation tagging method, the spatial arrangement of entities within the sentence exerts an influential impact on the methodology, beyond merely addressing the HTO challenge. To redress this issue, it becomes imperative to ensure the uniqueness of encoding. As shown in Fig. 3, the method categorizes the distribution of entities within sentences into three types: non-overlapping head and tail entities, partially overlapping head and tail entities, and completely overlapping head and tail entities. Among them, partially overlapping head and tail entities can be further subdivided into five scenarios.

Within this framework, “HB” signifies the head token of the head entity, “HE” denotes the tail token, “TB” designates the head token of the tail entity, and “TE” indicates the tail token. The corresponding encoded values depicted on the right-hand side of the illustration affirm the distinctiveness of encoding across all scenarios, thus ensuring the integrity of the decoding process devoid of errors or decoding failures.

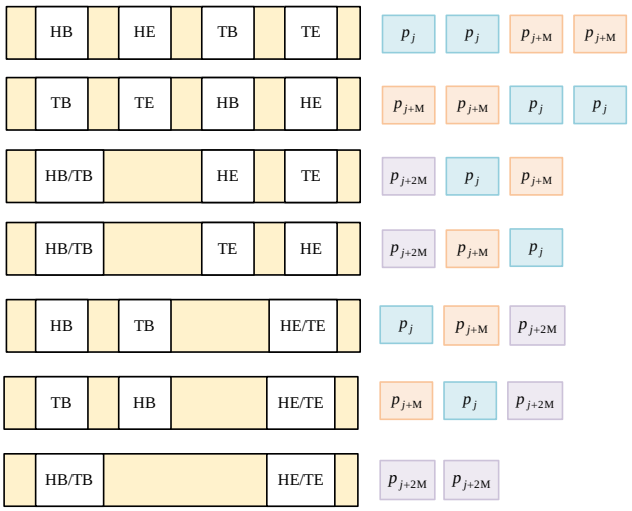

Fig. 3. Distribution of entity relation tagging.

B. Decoding Strategy

This training strategy of the method involves predicting each VRT for every sample, determining its corresponding entity relation tagging. For a sentence containing K triples, the entity relation tagging method conducts $K+1$ steps of preprocessing on the sentence. The essence of this training

method lies in treating the VRT insertion results of each step i (where $i \geq 1$ and $i < k$) as training samples and the VRT transformation results of step $i+1$ as the corresponding training targets. When $i = k+1$, the VRT insertion results serve both as training samples and targets. Essentially, this approach involves performing multi-class classification prediction on the VRT matrix of length N. This entails jointly inputting the VRT matrix and the text into the model and predicting the entity relation tag each VRT matrix output corresponds to.

The essence of this training method lies in conducting multi-class classification predictions on VRT matrices of length N. This involves inputting the VRT matrix and text into the model simultaneously, and predicting the entity relation tagging on the output of the VRT matrix.

Decoding strategy outlined in this approach involves a stepwise process. Initially, the first step of entity relation tagging is taken as input, and then fed into the model to obtain an entity pair. Subsequently, this entity pair is tagged, and the process iterates by continually feeding it back into the model to obtain the next entity pair. This iterative process continues until the model's output no longer yields a complete entity pair.

Entity relation tagging leverages information about the position of the tag, as well as distinct head, tail, and overlap tags, to ascertain the head and tail entities within a sentence. Furthermore, the relation between the head and tail entities is determined based on the relation information encoded in the tokens. By multi-stage learning, the model becomes proficient in mapping the VRT matrix to individual entity pair tagging. This approach offers several advantages:

1) The VRT matrix maintains an appropriate level of sparsity, facilitating simple and efficient tagging predictions by the model.

2) It reduces computational overhead, as computing all entity pairs for a given sample typically only requires about K iterations.

3) The processing of model utterances becomes more comprehensive and holistic, enhancing its overall effectiveness.

C. Model Framework

Our method focuses on single-module single-step entity relation extraction, emphasizing the refinement achieved through methods like multi-head attention mechanisms and cross-attention mechanisms to gradually extract entity pairs and their associated relations from textual data. Employing an innovative tagging approach, we integrate entity recognition and relation extraction into a unified process, enabling the system to understand the information in the text at different levels and thus better extract entities and relations.

1) Multi-head attention mechanism: Multi-Head Attention Mechanism is an enhanced technique derived from the self-attention mechanism. Self-attention is a method capable of determining the importance of each position in the input sequence, thus effectively addressing long-distance dependencies within the sequence. In the context of joint extraction of entity relations, diverse aspects may need to be considered simultaneously, necessitating the use of multiple self-attention mechanisms to handle these varied concerns. Multi-Head Attention involves employing multiple self-attention mechanisms on an input sequence to obtain several sets of attention results. Subsequently, these results are concatenated and linearly projected to yield the final output.

$$MultiHead(Q,K,V) = Concat(head_1, \cdots head_n)W^O \quad (6)$$

$$head_i = Attention\left(QW_i^Q, KW_i^K, VW_i^V\right) \quad (7)$$

where, $W_i^Q \in \mathbb{R}^{d_m \times d_k}$, $W_i^K \in \mathbb{R}^{d_m \times d_k}$, $W_i^V \in \mathbb{R}^{d_m \times d_v}$, and $W_i^O \in \mathbb{R}^{nd_v \times d_m}$ are the projection matrices learned by the model based on the text after adding the VRT, with O as the output tensor, where q, k, v represent the dimensions of the query, key, and value vectors, respectively.

2) Cross-attention mechanism: Cross-attention mechanism is a special form of multi-head attention that splits the input tensor into two parts $X_1 \in \mathbb{R}^{n \times d_1}$ and $X_2 \in \mathbb{R}^{n \times d_2}$, and then uses one of the parts as a query set and the other as a key-value set. Its output is a query of size $n \times d_2$ tensor, and for each row vector, its attentional weight for all row vectors is given.

Specifically, let $Q = X_1 W^Q$, $K = V = X_2 W^K$, then the cross-attention is calculated as follows:

$$CrossAttention(X_1, X_2) = Soft\max\left(\frac{QK^T}{\sqrt{d_2}}\right)V \quad (8)$$

where, $W^Q \in \mathbb{R}^{d_1 \times d_k}$, $W^K \in \mathbb{R}^{d_2 \times d_k}$ are the projection matrices learned by the model based on the text after adding the VRT, and d_k is the dimension of the key-value set and also the dimension of the query set.

D. Training Strategy

As illustrated in Fig. 4, this approach utilizes BERT [4] as the encoder to initially encode the text sequence. On the decoder side, the input involves inserting the VRT code or other entity relation marker codes into the text sequence code. Initially, the decoder conducts self-attention on the text sequence with inserted entity relation markers, thereby allowing the markers to acquire coarse-grained contextual information. Given that the entity relation markers disrupt the original text sequence, acquiring complete sequence information becomes challenging. Hence, we introduce a cross-attention mechanism at the decoder's backend, enabling the input sequence to focus on the entire text sequence. Following the output, a masking operation is performed on the non-VRT tokens to solely obtain the output of the VRT tokens. The resulting probability of the target is determined as:

$$p(Y|X,u,t;\theta) = \prod_{i=1}^{n+1} p(y_i|X,u_i,t;\theta) \quad (9)$$

where, X represents the text sequence, u denotes the VRT marker, t signifies the HRT, TRT, or ORT marker alongside the VRT marker, and θ represents the model parameter. n denotes the length of the text sequence, and since the VRT marker adds one unit to the length of the text sequence, it is represented as $n+1$.

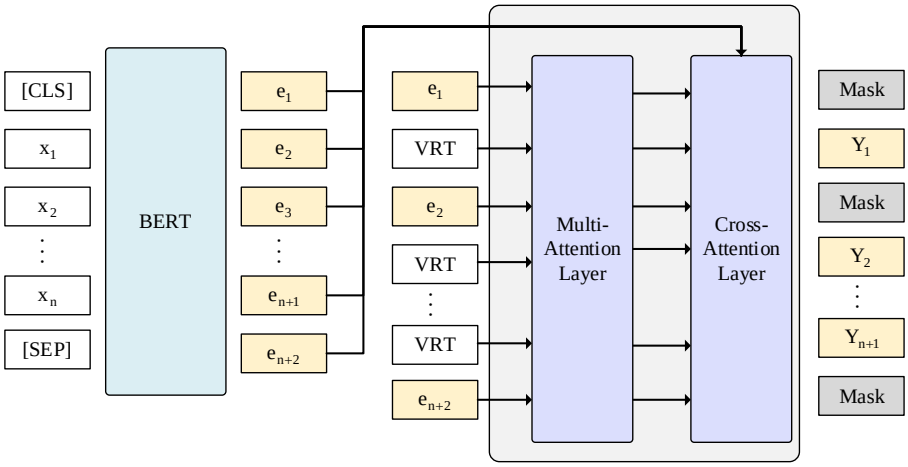

Fig. 4. Entity relation joint extraction framework based on insertion transformers.

E. Objective Function

The objective function of the model in this approach is defined as follows:

$$L = -\frac{1}{n+1}\sum_{i=1}^{n+1} log\ p(y_i|X, u_i, t; \theta) \quad (10)$$

IV. Experimental Setup

In this section, we first introduced the datasets and evaluation criteria used in the experiments, providing a detailed breakdown of the composition of the two datasets, and outlined the experimental details.

A. Datasets and Evaluation Metrics

1) Datasets: To provide a more robust explanation of the results of this model, two widely used datasets in relation and entity extraction tasks were adopted in this study: the New York Times (NYT) dataset [24] and the WebNLG dataset [25]. The details of the dataset sources and divisions are outlined below:

NYT is a renowned dataset for distant supervision relation extraction tasks. It utilizes Freebase online database, which stores entities and their relations, as the distant supervision source. It consists of articles from The New York Times annotated with named entity tags, coreference chains, and relation mentions. It contains approximately 1.8 million articles.

WebNLG consists of triple sets describing entities and their relations in natural language text. Initially used for natural language generation challenges, it later became the most commonly used general-domain dataset for evaluating triple extraction models, comprising data converted from the DBpedia knowledge base into natural language text. It consists of around 25,000 English sentences paired with RDF triples, offering a diverse range of content for text generation tasks. Detailed data are shown in Table I.

This approach conducted statistical analysis on the training, validation, and test sets of both datasets. Additionally, we categorized the datasets based on four different types of triple overlap patterns.

TABLE I. The Statistics of NYT and WebNLG.

Category	NYT		WebNLG	
	Train	**Test**	**Train**	**Test**
Normal	37013	3266	1596	246
EPO	9782	978	227	26
SEO	14735	1297	3406	457
Total	56195	5000	5019	703

Both the NYT and WebNLG datasets come in two versions: one version annotates solely the final word of entities, while the other annotates the entire span of entities. We denote the first version datasets as NYT* and WebNLG*, and the second version as NYT and WebNLG, respectively.

2) Evaluation metrics: To comprehensively evaluate system performance, we adopt three fundamental evaluation metrics consistent with the field of entity relation joint extraction: precision (P), recall (R), and the harmonic mean F_1 measure, for comparison with other baseline models. Their formulas are as follows:

$$precision = \frac{TP}{TP+FP} \quad (11)$$

$$recall = \frac{TP}{TP+FN} \quad (12)$$

$$F_1 = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (13)$$

where, TP, FP, and FN represent true positives, false positives, and false negatives, respectively. In our experiments, correctness or incorrectness is considered with respect to triplets. That is, a triplet result is considered correct only when h_1(head entity), r(relation), and t_1(tail entity) are predicted correctly.

B. Experimental Environmental Details

The experiments were conducted on an Ubuntu 20.04 LTS operating system, utilizing hardware comprising an NVIDIA RTX-A2000-GPU with 12 GB of memory, an Intel i7-10700K CPU, and 64 GB of RAM. The software stack included Python version 3.7, PyTorch version 1.7 for deep learning frameworks, and CUDA version 11.4. The NVIDIA driver version was

470.94, and the pre-trained model library used was Transformers version 4.6.1. The experiments employed an AdamW optimizer.

V. Results and Discussion

This section assesses the effectiveness of our data by comparing experimental outcomes with those of other baseline models. We utilize commonly employed general-domain datasets and evaluation metrics for evaluating triplet extraction models. Moreover, we present experimental results across different datasets using OneRel [3] as a comparative method to validate our experiments. Additionally, we analyze and interpret precision, recall, and F1-score. Besides, we utilize ablation experiments to ascertain whether the cross-attention mechanism in our experiments plays a crucial role in controlling the model's triplet extraction. Finally, we compare the inference times of the models to confirm our model's high inference efficiency.

In order to evaluate the impact of the proposed joint extraction method based on Insertion Transformers on text, Table 2 in this section presents the experimental results of this method and other approaches on the NYT and WebNLG, with best results are highlighted in bold. The experimental results for the contrastive models SPN [14], CasRel [7], TPLinker [16], PRGC [9], OneRel [3], and CGT [12] are sourced from[26]. By comparing metrics such as F1 score, our method shows improvement over baseline models like OneRel in the task of entity relation joint extraction.

A. Experimental Results and Analysis

1) Experimental results: Table II presents a comparative analysis of the proposed model and baseline models across the NYT*, WebNLG*, NYT, and WebNLG datasets.

TABLE II. Comparison Results of Joint Model Performance Based on NYT and WebNLG: %

Method	Model	Partial annotation						Full annotation					
		NYT*			WebNLG*			NYT			WebNLG		
		P	R	F_1	P	R	F_1	P	R	F_1	P	R	F_1
Multi-module multi-step	CasRel [7]	89.7	89.5	89.6	93.4	90.1	91.8	-	-	-	-	-	-
	PRGC [9]	93.3	91.9	92.6	94.0	92.1	93.0	93.5	91.9	92.7	89.9	87.2	88.5
	CGT [12]	**94.7**	84.2	89.1	92.9	75.6	93.4	-	-	-	-	-	-
Multi-module single-step	TPLinker [16]	91.3	92.5	91.9	91.8	92.0	91.9	91.4	92.6	92.0	88.9	84.5	86.7
	SPN [14]	93.3	91.7	92.5	93.1	93.6	**93.4**	92.5	92.2	92.3	-	-	-
Single-module single-step	OneRel [3]	92.8	92.9	92.8	**94.1**	**94.4**	94.3	93.2	92.6	92.9	91.8	90.3	91.0
	Ours	94.2	**93.4**	**93.0**	93.6	93.7	93.2	**94.8**	**93.8**	**93.2**	**92.0**	**91.2**	**91.5**

On the NYT* dataset, our model generally exhibits superior recall and F1 scores compared to baseline models, with precision slightly lower than the CGT model by 0.5 but still ahead of other models. This might be attributed to the fact that the number of negative samples in our training set exceeds that of CGT, although the accuracy is slightly lower than CGT, it exhibits superior performance in terms of recall and F1 score. On the NYT dataset, our model has achieved comprehensive superiority, with F1 scores outperforming PRGC, TPLinker, and OneRel by 0.5, 1.9, and 0.3 percentage points, respectively. Similarly, on the WebNLG dataset, the F1 scores are correspondingly higher by 3, 4.8, and 0.5 percentage points. On the WebNLG* dataset, our model slightly lags behind OneRel but outperforms other models. This may be because, compared to entities with only one token in WebNLG*, our model is better adapted to learning entities with multiple tokens in WebNLG. Meanwhile, on the WebNLG dataset, our model surpasses OneRel in precision, recall, and F1 scores. This indicates that the proposed method is better suited for fully annotated data, as entity relation tagging requires contextual information, and annotating more context is beneficial for subsequent predictions.

2) Results discussion and analysis: Among the multi-module multi-step baseline models, CGT exhibits slightly higher precision than our model on the NYT* dataset, while PRGC shows slightly higher precision on the WebNLG* dataset. However, our model consistently outperforms CGT, PRGC, and CasRel in precision, recall, and F1 scores, owing to the single-module's capability to handle text and relations efficiently, resulting in fewer errors compared to multi-module approaches.

Among the multi-module single-step baseline models, our model consistently outperforms them by 1 to 2 percentage points. This is attributed to the adoption of a joint decoding algorithm in the multi-module single-step approach, which reduces cascading errors compared to the multi-module multi-step approach. However, there are still some redundant errors when combining triplets, indicating limitations. In contrast, our proposed method extracts a complete entity pair in a single pass based on the text sequence, reducing redundant errors.

Compared to the single-module single-step model OneRel, our model demonstrates varying degrees of superiority on the NYT*, NYT, and WebNLG datasets. OneRel exhibits fewer errors compared to other models. However, due to the interference from lengthy text, OneRel predicts all possible entity pairs, leading to a decrease in prediction accuracy. This results in our model outperforming OneRel in terms of accuracy. Overall, our proposed method surpasses baseline models.

Besides, validating our method capability in addressing overlapping patterns and handling multiple triples, we conduct two additional experiments on distinct subsets of NYT* and WebNLG*. We employ five robust models as baseline comparators, and the comprehensive results are presented in Table III.

TABLE IV. F1-SCORE ON SENTENCES WITH DIFFERENT TRIPLE NUMBERS. ON NYT* AND WEBNLG*: %

Model	NYT*					WebNLG*				
	N=1	N=2	N=3	N=4	N≥5	N=1	N=2	N=3	N=4	N≥5
CasRel ¶	88.2	90.3	91.9	94.2	83.7	89.3	90.8	94.2	92.4	90.9
PRGC ¶	**91.1**	93.0	93.5	95.5	93.0	89.9	91.6	95.0	94.8	92.8
TPLinker ¶	90.0	92.8	93.1	96.1	90.0	88.0	90.1	94.6	93.3	91.6
SPN ¶	90.9	93.4	94.2	95.5	90.6	89.5	91.3	**96.4**	94.7	93.8
OneRel ¶	90.5	93.4	93.9	**96.5**	94.2	91.4	93.0	95.9	**95.7**	94.5
Ours	91.0	**93.6**	**94.5**	96.3	**94.4**	**92.1**	**93.3**	95.6	94.4	**94.7**

[a.] Mark ¶ Indicates Results from [3]. "N" means different triple numbers, with the sentences were categorized from the test sets into five subclasses. Each class includes sentences that consist of 1, 2, 3, 4, or >5 triples.

It can be observed that our model achieves the best F1 scores in six out of ten categories, especially in the case of $N \geq 5$. Sentences with $N \geq 5$ may simultaneously contain Normal, SEO, EPO, and HTO patterns, making the extraction more complex. Importantly, our method performs best on $N \geq 5$ for both NYT and WebNLG*, demonstrating the effectiveness of our VRT tagging in addressing overlapping triplets from the model design perspective. This validates the efficacy of our model.

In models guided by a multi-module multi-step approach, it is demonstrated that sufficient interaction between head and tail entity information and relation information positively impacts model performance. Subsequently, employing a multi-module single-step model shows improved expressive power, indicating that using joint decoding instead of independent decoding in multiple steps helps alleviate cascading errors between steps and thus enhances model performance.

As for single-module single-step methods, although studies related to this are relatively scarce, from a performance perspective, integrating multiple sub-modules also reduces cascading errors between modules, leading to performance improvement. Considering the performance of joint models on the NYT and WebNLG datasets, the modeling direction of entity relation joint extraction is moving towards the idealized single-module single-step modeling method.

B. Ablation Study

Ablation experiments were conducted to investigate whether the cross-attention mechanism of the approach benefits the prediction of entity relation tagging. To assess the importance of the cross-attention mechanism, two experiments were conducted separately on the NYT and WebNLG datasets, one without cross-attention and the other with cross-attention. The keyword tagged with # denote those without using cross-attention. The experimental results are shown in Table IV.

It can be observed that after using the cross-attention mechanism, the accuracy in predicting entity pairs significantly improved. This indicates that after the VRT markers undergo cross-attention, they obtain more complete text information, enhancing the model's ability to predict entity relation tagging.

TABLE V. ABLATION EXPERIMENT ON NYT AND WEBNLG: %

Dataset	Evaluation	Ours	#Ours
NYT	**Precision**	93.8	88.2
	Recall	93.0	87.8
	F1	93.2	87.3
WebNLG	**Precision**	92.0	87.9
	Recall	91.2	86.2
	F1	91.5	86.1

C. Model Efficiency Analysis

The objective of this section is to evaluate model efficiency through the measurement of inference time, with a maximum sequence length set to 128. Sentence lengths are segmented into four intervals: (0, 32], (32, 64], (64, 96], and (96, 128]. The purpose of this segmentation is to precisely investigate the impact of sequence length variation on model performance.

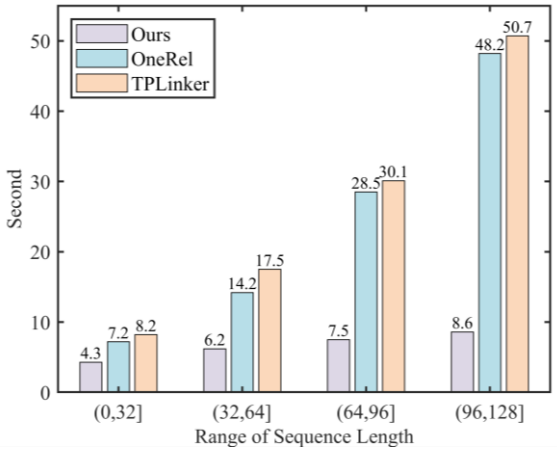

Fig. 5. Comparison of inference time.

As revealed by the results in Fig. 5, with an increase in sequence length, the inference times of OneRel and TPLinker models noticeably accelerate. This is due to their requirement to process all possible combinations between each pair of tokens across different relational contexts, resulting in an exponential increase in inference time as sequence length increases. In contrast, our model's inference time is significantly lower than the comparative models,

with a more gradual growth trend, as it predominantly relates to the number of entity pairs in the sequence, and there is a gentle positive correlation between the number of entity pairs and the increase in sequence length.

VI. CONCLUSION

In this paper, we utilize the Insertion Transformers framework to refine the task of entity relation joint extraction, introducing a novel VRT tagging strategy. This approach allows for more precise capturing of entity relation triplets, effectively addressing issues related to entity overlap in triplets and significantly reduces the inference time, thereby enhancing the efficiency of the model. Experimental evaluations on two public datasets demonstrate the superior performance of our model compared to state-of-the-art models across different scenarios.

In the future, we plan to delve into the following directions: we aim to devise a more efficient VRT tagging strategy to further enhance its ability to capture the associations between entities and relations, thereby making the model more efficient and focused. We also intend to investigate the concept of triplet overlap in other information extraction tasks, such as event extraction.

***Abstract*—This study investigates the potential enhancement of classification accuracy in timber defect identification through the utilization of deep learning, specifically residual networks. By exploring the refinement of these networks via increased depth and multi-level feature incorporation, the goal is to develop a framework capable of distinguishing various defect classes. A sequence of ablation experiments was conducted, comparing our proposed framework's performance (R1, R2 and R3) with the original ResNet50 architecture. Furthermore, the framework's classification accuracy was evaluated across different timber species and statistical analyses such as independent t-tests and one-way ANOVA tests were conducted to identify the significant differences. Results showed that while the R1 architecture demonstrated slight improvement over ResNet50, particularly with the addition of an extra layer ("ConvG"), the latter still maintained superior overall performance in defect identification. Similarly, the R2 architecture, despite achieving notable accuracy improvements, slightly lagged behind R1. Integration of fully pre-activation activation functions in the R3 architecture yielded significant enhancements, with a 14.18% increase in classification accuracy compared to ResNet50. The R3 architecture showcased commendable defect identification performance across various timber species, though with slightly lower accuracy in Rubberwood. Nonetheless, its performance surpassed both ResNet50 and other proposed architectures, suggesting its suitability for timber defect identification. Statistical analysis confirmed the superiority of the R3 architecture across multiple timber species and this underscores the significance of integrating network depth and fully pre-activation activation functions in improving classification performance. In conclusion, while the wood industry has made strides towards automation in timber grading, significant challenges remain. Overcoming these challenges will require innovative approaches and advancements in image processing and artificial intelligence to realize the full potential of automated grading systems.**

Keywords*—*Residual neural network; convolutional neural network; timber defect identification; deep learning

I. INTRODUCTION

Timber grading and defect identification are important in wood industries as it serve as cornerstone for the decision made by operators. In the past, these tasks were executed manually requiring careful assessment of the timber to determine their quality and economic value. This procedure involved classifying each log relative to their grade by assessing a number of factors such as geometry and typed of defect presence. Nevertheless, manual grading methods are often prone to subjectivity, time consumption, and human error [1]. In light of current state of the industry, a notable concern arises regarding the consistent or potentially declining number of qualified inspectors in comparison to the steadily growing market [2]. Additionally, timber grading process would usually involve a complex classification procedure such as sorting by defects, species and texture which require a versatile algorithm that are capable of handling diverse tasks on the same machine. Moreover, timber defects that resulted from environment and natural growth processes might have an impact on the timber strength, durability and aesthetic appeal, thereby affecting its economic value. The current methods of timber defect detection rely heavily on visual inspection which is subjective and lack of precision, to overcome these challenges.

In recent years, there has been a rise in quality control using automated vision inspection (AVI) among the manufacturer, particularly in the secondary timber industry with the objective to overcome present issues [3]. Although AVI has been applied in the timber industry to address these challenges, ongoing research endeavors persist in enhancing the inspection process across various domains, including defect detection and identification, characterizing defect, grading timber, and integrating sensors into hardware components for optimizing cutting processes [4]. A number of methods have been proposed [5][6][7][8][9] to streamline the grading process, yet they still encounter several obstacles especially in the scope of detection and identification of timber defects. To address these challenges, there is a growing interest in leveraging statistical classifier methods such as machine learning and deep learning algorithms in AVI for the identification of timber defects as these technologies offer the potential expedited, reproducible and reliable grading processes [10][11][12][13]. A 2020 study suggests that employing deep learning for automated feature extraction could yield higher precision while enhancing accuracy by at least 4% compared to other timber feature extraction and recognition methods [14]. In [15], they employed a DenseNet network along with a single-shot multi-box detector (SSD) and a target detection algorithm to develop an enhanced SSD algorithm for detecting defects in solid wood panels. Despite facing challenges in accurately identifying active knots due to their similarity to background features, the proposed method achieved an improved accuracy rate of 96.1% compared to earlier version. However, such autonomy come with the trade-off where it requires a significantly greater amount of data to train the deep learning architecture compared to the machine learning approaches. As deep learning advances swiftly,

numerous Convolutional Neural Network (CNN) architectures have surfaced over time to address issues across various domains of defect identification such as AlexNet [16], MobileNetV2 [17], GoogLeNet [18] and ResNet [19]. In this research, our emphasis will be on employing Residual Neural Network (ResNet) as our deep learning network architecture given its notable achievements in numerous image classification tasks in recent years [20].

He et al. [21] introduced the Residual Neural Network (ResNet), a Convolutional Neural Network (CNN) architecture inspired by the structure of pyramidal cells in the cerebral cortex. ResNet key innovation was residual learning, enabling more efficient training of deep networks through skip connections that bypass multiple layers while incorporating ReLU and batch normalization [21]. Additionally, there exist model such as HighwayNets that further facilitate training deep networks by using an additional weight matrix to learn skip weights [22]. The fundamental unit of the ResNet network is the residual building block, which constitutes the majority of its architecture. These blocks incorporate skip connections to bypass convolutional layers, mitigating issues such as gradient disappearance or explosion with increasing network depth [19]. Comprised of convolutional layers, batch normalizations, ReLU activation functions, and skip connections, the residual building block forms the backbone of ResNet's structure. Although augmenting the depth of a neural network enhances its feature extraction capabilities as highlighted by [23], however, adding more layers to a current deep model such as ResNet also lead to higher training error [21]. To tackle the issue of vanishing gradient, [22] proposed skip connections within residual neural networks where these connections diminish the shortest path from lower layer parameters to the output, mitigating the vanishing gradient problem. Furthermore, by employing fewer layers during the initial training phase, this skipping strategy simplifies the network architecture effectively. Fig. 1 illustrates the layout of fundamental residual block. The output of the residual building block can be expressed using Eq. (1), where F represents the residual function, and x and y denote the input and output of the residual function, respectively.

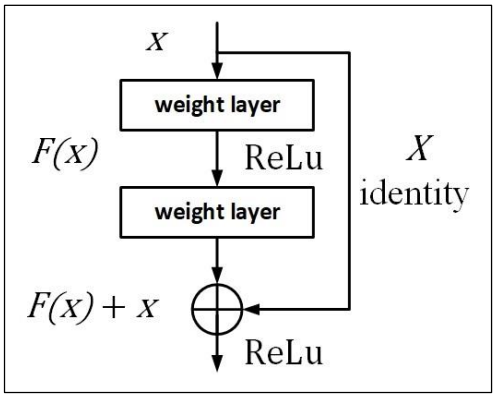

Fig. 1. Basic residual block.

$$y = F(x) + x \quad (1)$$

ResNet stands out for its significantly deeper network compared to its competitors, yet it maintains fewer parameters (weights) than other models. A comparative analysis of ResNet50 and other CNN architectures for timber species identification by Oktaria et al. [24] in 2019, demonstrated that residual network outperforms its counterparts in terms of F1 Score, precision, and accuracy. Similarly, [25] proposed a transfer learning approach using the ResNet50 architecture for plant disease identification, achieving a remarkable training accuracy of 99.80%. On the contrary, Ahmed et al. [26] utilized ResNet50 for the purposes of crack detection by training the model with dataset of 48000 images and achieve remarkable accuracy rate of 99.8%. Inspired by the aforementioned factors, we expanded our research on using residual neural network (ResNet) for identifying defects in Malaysian timber species, aiming for outcomes that could prove advantageous to the local timber product industries.

II. METHODOLOGY

A. Overview of Approach

Driven by the significance of network depth where deep convolutional neural networks have achieved remarkable progress in image classification [27] as well as the significant achievement of Resnet50 from studies related to identification of timber defects [28]. Therefore, we investigate the potential of enhancing better class representation thus achieving higher accuracy by employing a residual network as the base architecture for this study. Hence, our goal is to explore the refinement of residual network layer by incorporating multi-level features that can be enhanced through increased the number of stacked layer (depth). This study conducted a sequence of ablation experiments based on residual network architecture that were implemented to facilitate the development of timber defect identification framework with ability to distinguish different type of defect classes. Additionally, we compared the performance of our timber defect identification frameworks to the original ResNet50, which is based on the concept of residual networks. Furthermore, we evaluated the classification performance of our proposed timber defect identification framework across various timber species. Finally, we expanded the validation of our defect identification approach by conducting statistical analyses which include independent t-tests and one-way ANOVA tests to identify significant differences.

B. Residual Neural Network (ResNet) Architecture

Recent studies in timber defect identification have seen the development of several architectures based on the Residual Neural Network (ResNet) design, renowned for its efficiency in depth-based CNN architecture [29][30][31][32]. This research involves reformulating the layers of the residual network specifically for classification of timber defects by altering the residual block based on ResNet50 architecture as shown in Fig. 2. The ResNet50 architecture is a cutting-edge convolutional network comprising 50 layers, featuring skip connections. These skip connections which operate in parallel with standard convolutional layers, serve as shortcuts to aid the network in capturing global features while addressing the challenge of vanishing gradients encountered in deeper network layers [33]. Besides, the architecture is made up of 7x7 convolutional layer with 65 kernels, succeeded by a 3x4 max-pooling layer with a stride of 2, followed by 16 residual

building blocks, 7x7 average-pooling layer with a stride of 7, and a fully connected layer preceding the softmax output layer [25]. The inclusion of residual blocks helps diminishing the output size while simultaneously increasing the network's depth.

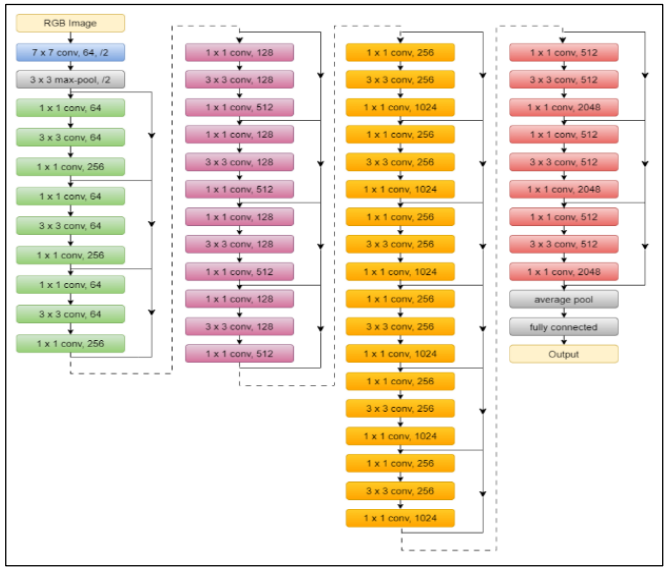

Fig. 2. ResNet50 architecture.

In this research, we systematically formulated three variations of residual network architecture with each employing different number and sizes of convolutional layers. This iterative approach was undertaken to explore the most appropriate configuration for timber defect identification framework. The experiment is performed on three proposed residual network architectures referred to as R1, R2, and R3. These variants draw inspiration from the architecture of ResNet50 as well as earlier research conducted by [21] in the field of deep residual learning. Each of the three devised versions of the residual network possesses its own unique architecture where R1 comprises 51 parameter layers, while the other variants exhibit a greater number of parameter layers, with R2 featuring 53 layers and R3 consisting of 54 layers. Additionally, within the architecture of both R1 and R2, we integrated "ConvG" and "ConvC+1" layers by introducing additional new residual blocks containing convolutional networks of different sizes into the proposed architectures. Table I illustrate the line-up of formulated residual network architectures employed for performance evaluation in this study.

TABLE I. FORMULATED RESIDUAL NETWORK ARCHITECTURE

Layer	Output Size	R1	R2	R3
ConvA	112x112	7x7, 64, stride 2		
ConvB	56x56	3x3 max pool, stride 2		
ConvC+1	56x56		$\begin{bmatrix} 1x1,32 \\ 3x3,32 \\ 1x1,128 \end{bmatrix} x3$	
ConvC	56x56	$\begin{bmatrix} 1x1,64 \\ 3x3,64 \\ 1x1,256 \end{bmatrix} x3$	$\begin{bmatrix} 1x1,64 \\ 3x3,64 \\ 1x1,256 \end{bmatrix} x3$	$\begin{bmatrix} 1x1,64 \\ 3x3,64 \\ 1x1,256 \end{bmatrix} x5$
ConvD	28x28	$\begin{bmatrix} 1x1,128 \\ 3x3,128 \\ 1x1,512 \end{bmatrix} x4$	$\begin{bmatrix} 1x1,128 \\ 3x3,128 \\ 1x1,512 \end{bmatrix} x4$	$\begin{bmatrix} 1x1,128 \\ 3x3,128 \\ 1x1,512 \end{bmatrix} x6$
ConvE	14x14	$\begin{bmatrix} 1x1,256 \\ 3x3,256 \\ 1x1,1024 \end{bmatrix} x6$	$\begin{bmatrix} 1x1,256 \\ 3x3,256 \\ 1x1,1024 \end{bmatrix} x6$	$\begin{bmatrix} 1x1,256 \\ 3x3,256 \\ 1x1,1024 \end{bmatrix} x6$
ConvF	7x7	$\begin{bmatrix} 1x1,512 \\ 3x3,512 \\ 1x1,2048 \end{bmatrix} x3$	$\begin{bmatrix} 1x1,512 \\ 3x3,512 \\ 1x1,2048 \end{bmatrix} x3$	$\begin{bmatrix} 1x1,512 \\ 3x3,512 \\ 1x1,2048 \end{bmatrix} x3$
ConvG	4x4	$\begin{bmatrix} 1x1,1024 \\ 3x3,1024 \\ 1x1,4096 \end{bmatrix} x1$		
	1x1	Average Pool, Fc, Softmax		

In addition to utilizing the original residual block, we investigated a revised version of the residual network architecture by integrating fully pre-activation activation functions in R3 where both Batch Normalization (BN) and Rectified Linear Unit (ReLU) layers precede the weight layer as illustrated in Fig. 3(b). The approach was introduced by He et al. [34] as a departure from the traditional "post-activation" paradigm which lead to a new residual block design that is easier to train and demonstrated enhanced generalization capabilities compared to the original ResNet architecture. Fig. 3(a) depicts the original ResNet residual block, where BN is applied after each weight layer, and ReLU is impemented after BN with the exception of the final ReLU within a Residual Unit which occurs after the element-wise addition. In reformulating the residual block for the R3 architecture, we implemented an asymmetric structure described by [34] which allow the new after-addition activation becomes an identity mapping. This new asymmetric form can be represented by the following equation:

$$X_{l+1} = X_l + F\left(\hat{f}(X_l), W_l\right),. \quad (2)$$

The design of the revised residual block allows for the adoption of a new after-addition activation $\hat{f}$ in an asymmetrical manner, effectively treating $\hat{f}$ as the pre-activation of the subsequent residual block.

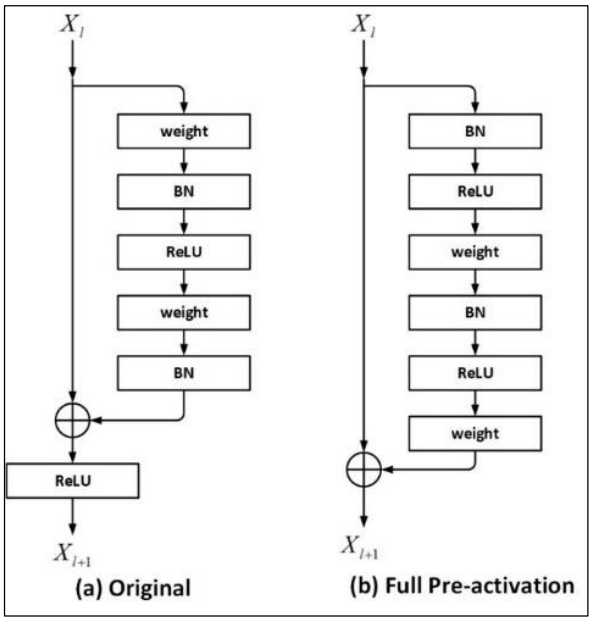

Fig. 3. ResNet50 residual block (a) Original (b) Full pre-activation.

C. Hyperparameter Optimization

To ensure the optimal performance of the three proposed residual network architecture, we conducted a further assessment of the appropriate CNN hyperparameter configuration focusing on both learning rate and epochs. The proposed architectures were trained using SGD optimizer with learning rate set at 0.001 and 0.0001. Throughout this experiment, the maximum number of epochs ranged from 50 to 200, with variations of 50, 100, and 200. The models underwent training on timber defect dataset encompassing various timber species (Meranti, Merbau, KSK, and Rubberwood) sourced from Universiti Teknikal Melaka Malaysia (UTeM) [35]. The experimental samples were then generated using 1600 augmented images of timber defect, comprises of eight timber defect categories (brown stain, blue stain, knot, borer holes, rot, bark pocket, wane, and split), as well as a set of clear timber specimens. The performance classification of each proposed architecture was assessed and compared with the transfer learning ResNet50 model to determine the most effective framework for identifying timber defects.

III. Result and Discussion

In this section, we will present the experimental outcomes of the three formulated residual network architectures to evaluate the efficacy of the proposed approaches in term of their performance in identification. The results are illustrated across three dimensions throughout the proposed residual network architecture where the first dimension explores different hyperparameter configurations encompassing both learning rate and epochs in pursuit of achieving highest classification performance for the proposed architecture (R1, R2, R3). Subsequently, a comparison of performance is conducted between the standard ResNet50 and the proposed architectures, with the goal of evaluating their classification performance in terms of improved representation of the defect class and accuracy. Finally, the identification performance is summarized across various timber species to gauge the consistency of performance of the proposed approach across multiple timber species. The experimental result for all three formulated architectures (R1, R2 and R3) across the timber species are presented in Table II with highest classification performance achieved using specific hyperparameter settings are highlighted in red. The data presented in Table II clearly indicates that the R1 architecture demonstrates commendable classification performance across all timber species datasets, achieving the highest identification accuracy for each species within the range of 89.85% to 94.44%. In R1, the Rubberwood dataset attains the highest classification accuracy of 94.44% with hyperparameter settings of 0.001 learning rate and 100 epochs. Following this, R1 achieves the second-highest classification performance reaching 93.48% in the Meranti dataset. Subsequently, KSK follows with an accuracy of 92.52%, and finally, the Merbau dataset records the lowest accuracy of 89.85%. On the contrary, the R2 architecture achieves the highest classification accuracy of 94.07% across all timber species with optimized hyperparameters (LR = 0.001, Epoch = 100) in rubber timber species. It was succeeded by Meranti (93.04%), Merbau (92.74%), and KSK (91.93%). It's noteworthy that the R2 highest classification accuracy across the timber species is achieved with a learning rate of 0.001, coupled with varying numbers of epochs: 100 for Rubberwood, 200 for Meranti, and 50 for both Merbau and KSK. By incorporating fully pre-activation functions into the R3 residual block, we achieved the highest classification performance of 99.11% in the Merbau dataset, utilizing a learning rate of 0.0001 and 200 epochs as the training hyperparameter settings. In the case of the remaining three timber species, the classification performance of R3 was as follows: Meranti (97.7%) with LR = 0.001 and Epoch = 100, KSK (98.59%) with LR = 0.0001 and Epoch = 200, and Rubberwood (96.59%) with LR = 0.001 and Epoch = 50.

As depicted in Fig. 4, the classification accuracy of the R1 architecture demonstrates a roughly 0.7% improvement compared to the original ResNet50 under different hyperparameter configurations across timber species. The improvement in performance stems from integrating an additional layer, denoted as "ConvG," into the network architecture of R1. Nonetheless, despite the noted rise in classification accuracy for R1 in contrast to ResNet50, the ResNet50 architecture still predominantly leads in overall performance concerning defect identification where highest classification accuracy achieved by R1 still falls short when compared to ResNet50 architecture. Similar to earlier R1 architecture, we evaluated the classification performance of the R2 architecture alongside the original ResNet50. The findings indicate that with 100 epochs and a learning rate of 0.001, the R2 architecture surpassed the original ResNet50 in the Merbau dataset, achieving an accuracy improvement of 6.92%. This implies that increasing the depth of the CNN architecture does enhance its classification accuracy. However, in comparison to R1, despite the inclusion of a new residual block ("ConvC+1")

with smaller convolutional layer sizes in the proposed architecture of R2, it was noted that R2's highest classification performance still slightly lags behind R1 by a marginal difference of 0.37%. Nevertheless, despite some improvement in classification performance, the ResNet50 architecture continues to dominate the overall performance in defect identification. Within the R3 architecture, we delve into fully pre-activation activation functions by incorporating both BN and ReLu layers prior to the weights in addition to the depth of CNN network architecture. Illustrated in Fig. 4., the proposed R3 architecture, integrated with both network depth and fully pre-activation activation functions does improves the architecture's classification performance in the Merbau species by 14.18% compared to the original ResNet50 while using a learning rate of 0.001 and 50 epochs. The performance of the R3 architecture is clearly commendable across different timber species, attaining defect identification accuracies ranging from 96.59% to 99.11%. Although it appears that the R3 architecture still exhibits lower performance in the Rubberwood species with a defect identification accuracy of 96.59% which marking the lowest R3 classification performance among the timber species. However, it's notable that the performance of the proposed R3 architecture has not only shown significant improvement across timber species and on average but has also outperform the classification performance of original ResNet50 and other proposed architectures (R1 and R2). This suggests that integrating both network depth and fully pre-activation activation functions into the R3 architecture improves the CNN's classification performance in distinguishing classes of timber defects and making it well-suited for implementation as our timber defect identification framework.

TABLE II. CLASSIFICATION PERFORMANCE OF R1, R2, R3 AND RESNET50 ACROSS TIMBER SPECIES USING MULTIPLE HYPERPARAMETERS SETTINGS. THE HIGHEST CLASSIFICATION ACCURACY ACROSS TIMBER SPECIES ARE HIGHLIGHTED IN RED

Architectures	Hyperparameters		Rubberwood	Merbau	Meranti	KSK

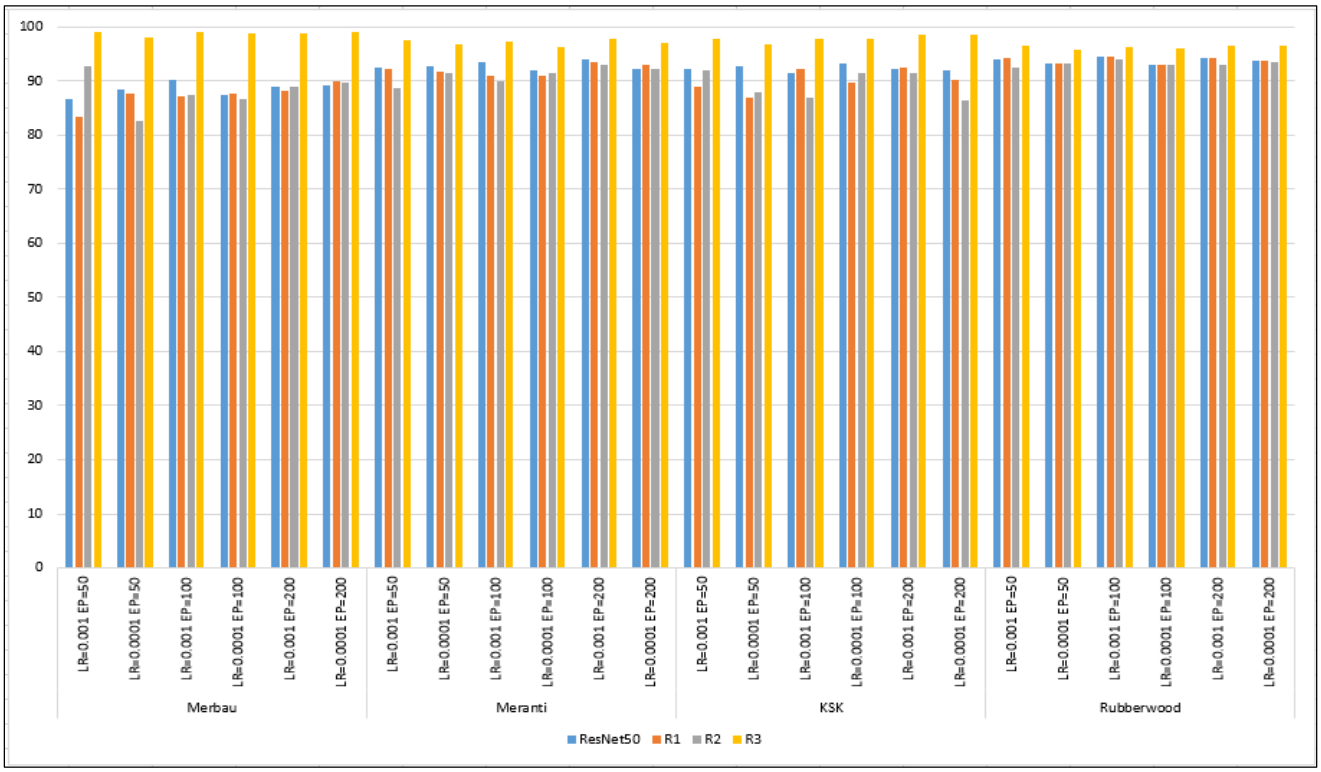

Fig. 4. Overall performance of proposed architectures and ResNet50.

To conduct further assessment, the classification performance of the R3 architecture was compared with ResNet50 and other proposed architectures using a one-way ANOVA test to identify any statistically significant differences in accuracy between the independent groups. The findings indicate that the classification performance of the proposed R3 architecture is statistically significantly superior compared to other architectures across multiple timber species. This implies the acceptance of the alternative hypothesis (HA) which indicate that there are at least two group means that are statistically significantly different from each other.

IV. Conclusion

This study presents an overview of the proposed timber defect identification framework based on the concept of residual neural network (ResNet) that mitigates the subjectivity and lack of precision associated with current timber defect identification methods, offering a more robust and reliable approach for the timber industry. It explores the evaluation of the approach concerning the number of stacked layers (depth) in the residual network architecture, as well as the integration of fully pre-activation activation functions within the residual block. Experiment are first conducted on the three proposed architectures (R1, R2, and R3) using various combinations of hyperparameters, including epochs and learning rates. The results from these experiments show that the R3 architecture which is formulated based on both stacked layers and fully pre-activation activation functions significantly contributes to satisfactory defect identification performance across all defect types and with consistently high accuracy observed across multiple timber species.

Abstract*—Contemporary firms rely heavily on the effectiveness of their supply chain management. Modern supply chains are complicated and unpredictable, and traditional methods frequently find it difficult to adjust to these factors. Increasing supply chain efficiency through improved supplier performance, demand prediction, inventory optimisation, and streamlined logistics processes may be achieved by utilising sophisticated data analytics and machine learning approaches. In order to improve supply chain management efficiency, this study suggests a unique data-driven strategy that makes use of Deep Q-Learning (DQL). The goal is to create optimisation frameworks and prediction models that can support well-informed decision-making and supply chain operational excellence. The deep Q learning technique is thoroughly integrated into supply chain management in this study, which makes it innovative. The suggested framework gives a comprehensive method for tackling the difficulties of contemporary supply chain management by integrating cutting-edge methodologies including demand forecasting, inventory optimisation, supplier performance prediction, and logistics optimisation. Predictive modelling, performance assessment, and data preparation are three of the proposed framework's essential elements. Cleansing and converting raw data to make it easier to analyse is known as data preparation. To create machine learning frameworks for applications like demand forecasting and logistics optimization, predictive modelling uses DQL. The method's efficacy in raising supply chain efficiency is evaluated through performance evaluation and acquired 98.9% accuracy while implementation. Findings show that the suggested DQL-based strategy is beneficial. Demand is precisely predicted using predictive models, which improves inventory control and lowers stockouts. Supply chain efficiencies brought about by DQL-based optimisation algorithms include lower costs and better service quality. Performance assessment measures show notable gains above baseline methods, highlighting the importance of DQL in supply chain management. This study demonstrates how Deep Q-Learning has the ability to completely change supply chain management procedures. In today's dynamic environment, organisations may gain competitive advantage and sustainable development through supply chain operations that are more efficient, agile, and resilient thanks to the incorporation of modern analytical methodologies and data-driven insights.

Keywords*—Supply chain management; predictive analytics; demand forecasting; inventory management; exploratory data analysis

I. Introduction

Supply chain management plays a fundamental role in fostering economic growth by facilitating the seamless exchange of goods between businesses and consumers. The complex web of organizations participating in the supply chain process, each of which contributes to the smooth movement of goods from raw materials to end consumers, makes supply chain management effective [1]. Materials processors are essential because they convert basic materials from natural resources—like wood, rubber, and metal—into products that could be employed in subsequent processes. These resources are subsequently used by producers or manufacturers to make the wide range of things that are offered for sale, from tangible items to energy sources in industries such as the energy business [2]. After manufacturing, suppliers or sellers distribute goods to the next stops along the supply chain by acting as middlemen. Transportation businesses that are responsible for delivering goods to distribution centres or straight to retailers depend on warehouses as essential hubs for keeping products prior to their onward distribution [3]. Central facilities for dispersing goods to merchants, wholesalers, and occasionally direct customers are distribution centers, which are positioned strategically throughout different areas. Retailers are the final intermediary in the supply chain, providing goods to customers via a variety of channels such as physical storefronts and online platforms [4]. The supply chain affects and intersects with a number of business operations in addition to supply chain management. In order to create and engineer items that meet the demands of consumers, product development depends on the availability of resources and the

creative abilities of humans [5]. In order to efficiently reach target audiences, marketing tactics, which include actions like price, product placement, and advertising, are essential in driving demand for goods [6]. The goal of operations management is to streamline internal procedures in order to increase output, save expenses, and guarantee the firm runs smoothly. Distribution is the process of making things available to end customers through direct or indirect distribution channels. It is frequently combined with marketing. Sales and finance work together to establish revenue targets, obtain funding, and distribute resources efficiently. Furthermore, customer service is crucial in forming consumer opinions and fostering customer loyalty. It includes actions intended to assist customers at every stage of the purchasing process, from pre-purchase consultations to post-purchase support and problem-solving. Supply chain management and these interrelated processes work together to propel corporate success and promote economic growth. Fig. 1 depicts the supply chain management architecture.

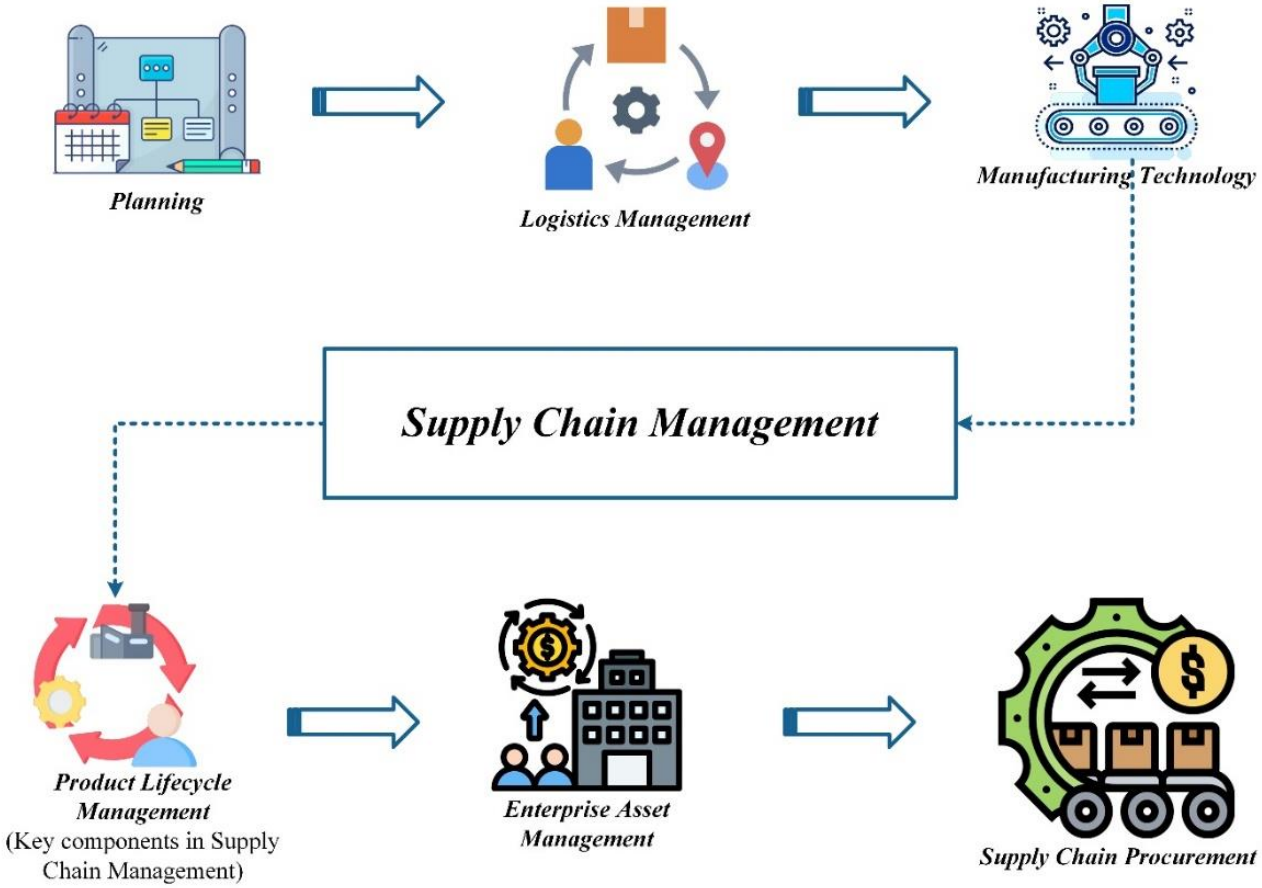

Fig. 1. Architecture of supply chain management.

The vulnerabilities of some of the most important global supply networks become apparent to the entire globe in 2020. Businesses rapidly realised that supply chain management procedures needed to be flexible without breaking and needed to be modernised. The most successful firms nowadays are examining their supply chain management (SCM) processes and the technology that power them with an unwavering gaze, asking themselves what steps they could take to improve their operations' efficiency, profitability, and resilience to change. The concepts and insights that drive global supply chain management are essential. Companies start by keeping an ear to market trends and asking their clients for input on the items they would like to see, as well as the best times and means of delivery. After that, businesses could utilize this data to streamline all aspects of their supply chain management, including procurement, production, research and development, last-mile transport, and final delivery. The proper execution of this immensely intricate task necessitates the integration of every collaborator, or "link," into a highly responsive and well-coordinated supply chain management system [7]. Seventy-five percent of American businesses reported supply chain disruptions early in the epidemic, according to Axios. The World Bank reports that a quarter of businesses saw a 50% decrease in revenue as a result of the epidemic. At the beginning of the pandemic, the National Association of Manufacturers estimated that 1.4 million manufacturing jobs in the United States were destroyed [8]. Global supply chain disruption was further compounded by geopolitical factors like the trade war between the United States and China. The supervision of the movement of products and services from raw materials to finished items is known as supply chain management. It covers every step of the process—including shipping—that goes into bringing goods to consumers. Demand and supply remain in conflict even as the world

economy begins to improve [9]. Consider the more than eighty container ships, according to a Bloomberg story, that were awaiting offloading outside ports in California in mid-November 2021, just as the holiday shopping season got underway. A clear illustration of the significance of efficient supply chain management is given by this bottleneck. The seamless operation of supply and demand processes is ensured by supply chain management, allowing people to have access to products and services. A well-functioning supply chain is essential for preserving economic stability and a functional society, as it provides everything from food and shelter to the means of employment and entertainment.

Global supply networks have been irrevocably altered by the COVID-19 pandemic, which has also caused operational disruptions and widespread industry repercussions. This disruption has been most noticeable in Southeast Asian low-cost manufacturing regions like Vietnam, Indonesia, and Malaysia, where production slowdowns or plant closures have had a financial impact on multinational corporations [10]. Millions of Americans were forced into house confinement due to pandemic-related lockdowns, which resulted in a sharp increase in demand for supplies needed for remote work and learning environments. But the supply chain found it difficult to keep up, particularly for supplies that were mostly imported from Asian nations that were dealing with lethal variations and manufacturing limitations. Because there was a shortage of supply, the ensuing plant closures or decreased activity put further pressure on merchants, who were unable to keep up with the rising demand. Factories that were able to continue operating had to contend with issues such as reduced labour capacity, more restrictions on the supply of raw materials, and rising costs. The price of finished goods increased in tandem with the skyrocketing cost of raw materials, sometimes with abrupt surges. This phenomenon affected food costs in addition to consumer items. The U.S. Bureau of Labour Statistics reports that for the year ending in September 2021, prices for meat, poultry, fish, and eggs increased significantly by 10.5 percent. As global markets progressively recover, there continues to be a persistent mismatch between supply and demand because of the stark contrast between the recovery in demand and the still-restricted production capacity. According to the theory of scarcity, which holds that there are never enough resources to meet everyone's needs, this imbalance presents problems for companies, customers, and legislators [11].

The efficacy and efficiency of traditional supply chain management techniques are frequently hampered by a number of issues. These difficulties include having little insight throughout the supply chain, making decisions based mostly on historical data, having trouble correctly estimating demand, using ineffective inventory management techniques, and experiencing erratic disruptions in logistics and transportation [12]. These difficulties could outcome in higher expenses, longer order fulfilment times, surplus inventory, stockouts, and eventually, lower customer satisfaction. Utilising machine learning and predictive analytics methods in the supply chain industry is becoming more popular as a means of addressing these issues. The suggested conceptual framework for using Deep Q-Learning (DQL) algorithms to improve supply chain management efficiency provides a methodical way to combine cutting-edge machine learning techniques with conventional supply chain procedures. The framework initiates data gathering and preprocessing and moves on to predictive modelling with DQL algorithms for logistics optimization, demand forecasting, inventory optimization, and supplier performance prediction. Following that, supply chain activities are optimised using DQL-based algorithms. While iterative refinement enables adaptation to changing market conditions, continuous monitoring and assessment guarantee the achievement of performance objectives. Enterprises could acquire a competitive advantage in the current dynamic market by utilizing DQL-based predictive analytics and optimization to attain operational excellence, cost savings, and enhanced customer satisfaction. Organisations could boost satisfaction with consumers, save expenses, increase operational efficiency, and gain a competitive advantage in today's fast-paced business climate by using data-driven insights and sophisticated analytics approaches. The following list outlines how this study contributes in a way that goes beyond theoretical developments to provide useful insights and suggestions that help enhance processes for managing supply chains in the real-world context.

Contemporary firms recognize the pivotal role of supply chain management in fostering economic growth. However, modern supply chains face complexities and uncertainties that traditional methods struggle to address. The COVID-19 pandemic underscored the vulnerabilities of traditional supply chain practices, highlighting the need for innovative approaches. This study proposes a data-driven strategy leveraging Deep Q-Learning (DQL) to revolutionize supply chain management. By integrating sophisticated data analytics and machine learning, the goal is to develop optimization frameworks and prediction models for informed decision-making. Key elements include predictive modeling, performance assessment, and data preparation. DQL enables accurate demand forecasting, optimized inventory levels, and streamlined logistics. The motivation lies in addressing the shortcomings of traditional methods and adapting to dynamic market environments. By embracing innovation, organizations can enhance supply chain efficiency and achieve sustainable development. In summary, the integration of modern analytical methodologies has the potential to transform supply chain operations and drive long-term success.

- This research extends supply chain management technique by putting forth a fresh data-driven strategy that makes use of Deep Q-Learning (DQL). An established basis for supply chain optimization is provided by DQL, and it may be used for demand forecasting, inventory control, supplier performance predictions, and logistics optimization.
- Supply chain efficiency is enhanced by the application of DQL-based optimisation technique. Organisations could optimise their supply chain operations and make well-informed decisions by utilizing historical data and sophisticated analytics. This improves efficiency, lowers costs, and increases customer satisfaction.

- The practicalconsequences of the study's findings are significant for organisations functioning in the contemporary dynamic economy.

The rest of the section is as follow: Section II gives an overview of relevant studies. Section III covers the approach's research gap. The materials and methods are presented in Section IV, which describes Optimizing Supply Chain Management with Deep Q-Learning Framework. Section V goes over the findings and performance analysis. Finally, Section VI summarises the conclusion of research.

II. Literature Review

In the intricate healthcare supply chain, it is critical to prioritize efficiency in order to economize and streamline the process of acquiring medical supplies. This paper examines different types of machine learning programs like Naive Bayes, K-Nearest Neighbors, Random Forest, Support Vector Machine, and Linear Regression to improve how healthcare supplies are managed. The five categories analysed in this research are: 'Inspection Results', 'Defect Rate', 'Transportation Modes', 'Routes' and 'Cost'. Based on what I discovered, the Random Forest classifier showed 87% accuracy in classifying "Inspection Results" and "Transportation Modes," while the KNN classifier had an impressive 86% accuracy in classifying "Routes. The study demonstrates the essential role of machine learning methods across different categories. The various methods that classifiers operate within different categories indicate the importance of selecting the most suitable algorithm for the supply chain. This research demonstrates that ML classifiers are effective in improving the efficiency of healthcare supply chains. It also suggests that automation could be used in different parts of supply chain management. It assists in optimizing the performance of the healthcare supply chain. However, the Linear Regression and KNN Regression models showed poor performance as indicated by their higher MSE and lower R^2 values. It is crucial to consider these results thoughtfully when selecting models that can accurately predict and function effectively in various scenarios [13].

The coordination of information in a system is used in supply chain management to unify all elements of the supply chain. Implementing artificial intelligence within the supply chain can simplify visibility, automate processes, and enhance overall management efficiency. This can assist companies in reducing costs and improving their ability to meet customer demands, ultimately leading to greater overall efficiency. Choosing the right people to be a part of a team is important for making sure the supply chain runs smoothly. This study introduces a fresh approach for identifying the most qualified suppliers in a supply chain by employing the specialized computer program CGANs. It helps when there are a lot of options but not much data to make a decision. Classifying members on the chain can effectively streamline the classification process and reduce data complexity while maintaining accuracy. The application of machine learning involves examining and predicting purchasing and stock relationships within the supply chain. - The vehicle scheduling module is working on optimizing routes for improved operational efficiency. The completion of the SCM system was achieved through the use of the SSH framework. Still, there may be a disadvantage to depending just on large data and the robust Internet infrastructure for trade. It restricts the interchange to businesses that can access and use these technologies efficiently, which could exclude smaller or less tech-savvy supply chain partners [14].

The utilization of AI in supply chain management can improve operations and contribute to company prosperity. This summary discusses the ways in which AI can improve the supply chain, as well as the challenges and opportunities it presents. Companies can enhance their inventory management, forecast demand, coordinate transportation and deliveries, inspect product quality, and streamline their operations through the use of AI and machine learning.AI systems can look at a lot of information, find patterns, and give helpful advice so that people can make better decisions and react quickly to changes in the market. Furthermore, AI can improve the ability to see the supply chain, allowing for tracking, monitoring and evaluating risk in real time. This paper discusses the potential benefits of implementing artificial intelligence (AI) to improve the functioning of supply chains.AI can help make better predictions, manage stock, and improve the way things are moved in supply chains. The paper touches on the use of AI in supply chain management and provides instances of its successful implementation by companies. It is crucial to keep in mind, however, that the actual outcomes might differ based on the implementation's particulars and the environment, sector, organisational needs, quality of the data, and degree of AI acceptance [15].

The environment has been negatively impacted by companies' excessive use of natural resources, generation of excessive waste, and improper disposal of dangerous chemicals. The involvement of SMEs is significant in mitigating our influence on the environment globally. This has become an even more important part of our company's plan in the last twenty years. The industry is prepared for major shifts in supply chain management. Green Supply Chain Management means including environmental practices in the supply chain. Businesses can use Green Supply Chain Management to ensure that their procurement, production, distribution, consumption, and recycling practices are environmentally sustainable. The use of data analytics is increasing in operations management. In this area, new techniques involve the use of computer programs to examine organizational operations. The main objective of this study is to examine the utilization of machine learning in the management of supply chains and operations. Deeper learning offers a more accurate insight into customer preferences than MNL, but it's difficult to find solutions for challenges such as product selection and pricing in these models [16].

The global supply chain is facing significant challenges due to the combination of the COVID-19 pandemic and ongoing political and regional conflicts. Shipping items worldwide has become difficult and is resulting in delays in delivery. This is creating challenges in the shipment of goods globally and causing disruptions in the delivery schedule. It's becoming increasingly tough to ship items across the world, causing delays in the delivery process. One of the biggest

concerns is the lack of information about the availability of products. This is important for companies to plan how to ship and deliver goods. Forecasting the timing of item availability is essential for the smooth and economical management of logistics. Different data sources are used to study the shipping availability of General Electric's gas and steam turbines. It evaluates a variety of models to measure their performance. Included in the list of models are Simple Regression, Lasso Regression, Ridge Regression, Elastic Net, Random Forest (RF), Gradient Boosting Machine (GBM), and Neural Network. The experiments show that tree-based algorithms like RF and GBM are better than other models at predicting real-world data. The prediction models are anticipated to offer assistance to companies in addressing supply chain issues and improving safety on a larger scale. Despite its benefits, there are some disadvantages to using time series analysis for predicting availability dates. It can make things more complicated and require more computer power. Furthermore, it can be difficult to utilize and refine advanced deep learning methods to achieve higher accuracy [17].

Precisely predicting customer demand is crucial for optimizing the pharmaceutical supply chain. Forecasters are still using advanced models despite the limited available information. These challenges arise regardless of the abundance of data, as outdated data becomes irrelevant in a fluctuating market. Meanwhile, there are other elements that can influence demand, but understanding their effects involves gathering a substantial amount of data and using more advanced models. The goal is to tackle these challenges by utilizing a fresh approach to anticipate demand. The analysis will involve using data from multiple products and applying advanced machine learning to uncover patterns. The improvement of cross-series model performance is achieved through the implementation of different "grouping" methods and the utilization of non-customer demand data, such as inventory and supply chain information. This novel framework was tested using various modeling options on two significant datasets from major pharmaceutical companies, demonstrating its superiority over other methods. This research shows that knowing how much inventory is available can help predict how much demand there will be for a product. Our process involves researching both before and after to confirm the viability of the forecasting method we aim to implement. Knowing the old inventory information, as anticipated, does not prove to be beneficial [18].

The literature study underscores the noteworthy contribution of artificial intelligence (AI) and machine learning (ML) methodologies in augmenting diverse facets of supply chain management (SCM) across diverse sectors, specifically in the domains of healthcare and environmental sustainability. Several machine learning classifiers, including Naïve Bayes, K-Nearest Neighbours, Random Forest, Support Vector Machine, and Linear Regression, have been investigated by researchers for use in optimising healthcare supply chains. The findings show promise in terms of classification accuracy for various aspects of the supply chain, including inspection results, defect rates, transportation modes, routes, and costs. Furthermore, SCM systems have benefited from the application of AI algorithms to create intelligent management, automation, and visualisation, which has decreased operational costs and increased responsiveness to market needs. Effectively lowering the dimensionality and complexity of the information, methods like conditional generative adversarial networks (CGANs) have been developed for dynamic supply chain member selection. In the supply chain, artificial intelligence has also been used for environmental operations integration, demand forecasting, transportation optimisation, and inventory management. Even with these developments, issues like scarce data availability, computational complexity, and technical accessibility still need to be taken into account for AI-powered SCM systems to be implemented and optimised effectively.

III. Research Gap

Effective supply chain management is crucial for businesses to fulfil consumer needs, cut costs, and increase profitability in the cutthroat business environment of today. However, plenty of businesses encounter difficulties when trying to efficiently optimize their supply chain processes. These difficulties could involve erroneous demand projections, inadequate inventory control, shaky supplier performance, and ineffective logistical procedures. Consequently, companies could encounter elevated expenses, setbacks, and discontent from clients, eventually impeding their ability to compete in the market. Thus, research is desperately needed to create workable solutions to these difficulties and improve supply chain performance, which could assist companies become more competitive and experience long-term growth. The present research puts forth a thorough framework that utilises deep Q-learning and sophisticated analytics to tackle the intricacies of supply chain management in the beauty product sector. The objective is to provide workable solutions for improving supply chain operations and increasing competitiveness by utilizing Deep Q-Learning to demand forecasting, inventory optimization, supplier performance prediction, and logistics optimization. This study's focus is on optimizing the supply chain for beauty products by applying Deep Q-Learning and predictive analytics approaches to demand forecasting, inventory control, supplier performance predictions, and logistics optimization. The goal is to increase the competitiveness and efficiency of supply chains for companies in the fashion and beauty sectors by offering them practical insights and ideas.

IV. Research Framework

Deep Reinforcement Learning (DRL) is the approach that is suggested for the present research in order to enhance the supply chain for beauty products. The procedure commences with the formulation of the problem, which involves identifying the intricacies of supplier selection, price strategies, logistics optimization, and inventory management in the beauty product sector. Because it is data-driven and allows an agent to learn optimum policies through interaction with the supply chain environment, Deep Reinforcement Learning (DRL) is selected as an appropriate method. The process continues by defining the action space, reward function, and state representations. Factors including supplier performance indicators, demand projections, inventory levels, and transportation logistics status are all included in state

representations. The agent's options for ordering quantities, choosing suppliers, modifying inventory levels, and establishing pricing strategies are all outlined in the action area. The purpose of the reward function is to penalise unwanted outcomes, like stockouts or excessive expenses, and to reward positive behaviours, such revenue creation, cost reduction, and customer pleasure. Following that, the Deep Q-Network (DQN) agent is implemented, which approximates the ideal action-value function using a neural network architecture. Utilising experience replay in a simulated setting that replicates the dynamics of the cosmetics product supply chain; the agent is taught. After a training process, experience replay enhances sample stability and efficiency by enabling the agent to learn from previous encounters. Through simulation assessments, the trained DQN agent's performance is evaluated in relation to a number of parameters, including cost savings, revenue creation, and service levels. In order to ensure the efficacy and resilience of the trained agent, parameters are adjusted and optimised depending on the findings of these examinations. Incorporating the DQN agent into the supply chain management system also makes it easier to make decisions in real time, which leads to increased productivity, lower costs, and happier customers. This research intends to drive improvements in supply chain management techniques by showcasing DRL's potential as a formidable tool for streamlining intricate supply chain procedures in the beauty product sector. Fig. 2 shows workflow of the suggested approach.

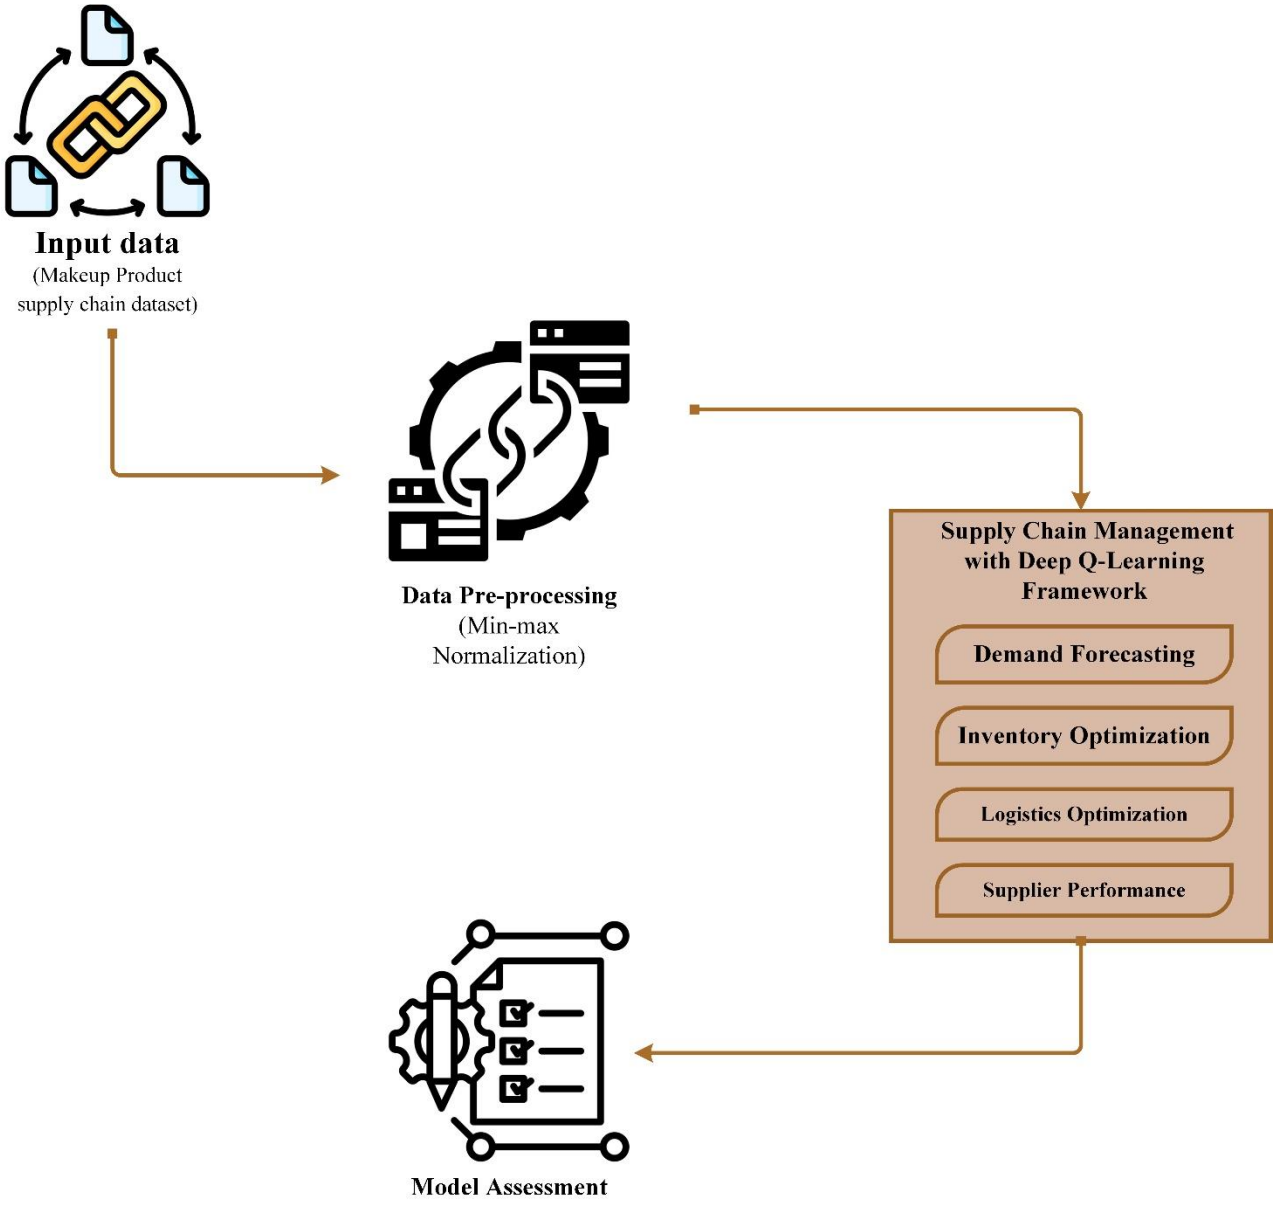

Fig. 2. Workflow of the suggested approach.

A. Data Acquisition

The present investigation employed a thorough dataset that was acquired from a reliable Kaggle database. The information set was specifically designed to address the supply chain activities of a fashion and beauty business that specializes in makeup items. The dataset contains a wide range of relevant characteristics that are essential for supply chain efficiency analysis and optimisation in this business. The proposed dataset for the supply chain activities of a fashion and beauty business specializing in makeup items encompasses a diverse array of attributes crucial for comprehensive analysis and optimization of supply chain efficiency. It includes product-specific details such as Product Type, SKU, Price, and Availability, offering insights into the beauty product portfolio and pricing strategies. Operational indicators such as the number of items sold, revenue earned, and stock levels provide valuable information for assessing sales success and inventory management. Additionally, logistical elements like lead times, order quantities, shipping durations, shipping carriers, and expenses shed light on transportation and delivery procedures within the supply chain. Supplier-related data reveals insights into supplier performance, production procedures, and quality control methods, covering aspects such as supplier name, location, lead time, production volumes, manufacturing prices, inspection results, and defect rates. Moreover, the dataset includes information on transportation modes, routes, and various costs associated with production, distribution, and procurement activities, facilitating a comprehensive examination of supply chain operations. This extensive dataset ensures the availability of essential information required for researching and enhancing the effectiveness of supply chain management specifically tailored to the makeup goods sector. [19].

1) Data pre-processing: In order to scale numerical characteristics to a particular range, usually [0, 1], min-max normalization is a fundamental linear transformation approach. A selection of features were made for normalisation from the makeup product supply chain dataset, including price, number of sold products, revenue generated, stock levels, lead times, order quantities, shipping times, shipping costs, lead time, production volumes, manufacturing lead time, manufacturing costs, defect rates, and costs. These elements reflect several facets of supply chain management, such as production procedures, inventory levels, and financial data. Each feature was subjected to a separate application of Min-max normalisation once the numerical columns were chosen. The following is the Eq. (1) for Min-max normalization:

$$V_{normalized} = \frac{V - V_{min}}{V_{max} - V_{min}} \quad (1)$$

Every feature was scaled to the range [0, 1] as a consequence of the normalization procedure, which comprised taking the least value of each feature and dividing by the range (maximum value minus minimum value).

where,

V: The variable or value that is being normalized.

V_{max}: The maximum possible value

V_{min}: The minimum possible value that

$V_{normalized}$: The normalized value of V after applying Eq. (1).

Larger-scale characteristics are kept from controlling the modelling process by means of this transformation, which guarantees that every feature contributes equally to the analysis. The original dataset structure was preserved by updating the dataset with the scaled values after normalization. In order to maximise supply chain management efficiency within the Makeup product business, preprocessing helps to prepare the data for further analysis and modelling.

B. Optimizing Supply Chain Management with Deep Q-Learning Framework

1) Deep Q-Learning mechanism: In 2013, DeepMind introduced the groundbreaking Deep Q-Network (DQN) reinforcement learning method [20], which revolutionized sequential decision-making in complex environments. The term "Q-Learning," which is represented by the letter Q in DQN, refers to an off-policy temporal differences technique that updates the value function for a particular State-Action pair while taking future rewards into account. Value-based approaches have the advantage of not requiring us to wait until the conclusion of the episode to learn the final reward and the discounted amount. Throughout the process go, update the value function of each action utilizing the Bellman equations [21]. Combining elements of Q-Learning with deep neural networks, DQN enabled agents to navigate intricate scenarios with sequential actions, showcasing remarkable capabilities, particularly in tasks like mastering video games. Central to DQN's architecture is the Q-network, a deep neural network that plays a pivotal role in decision-making processes. Given the current state as input, the Q-network outputs Q-values corresponding to each potential action, representing the expected cumulative reward associated with those actions in the current state. This design not only stabilizes the training process but also effectively handles high-dimensional state spaces, thanks to mechanisms like experience replay and target networks. The innovative design of DQN and its underlying Q-network marks a significant advancement in deep reinforcement learning, offering a powerful framework for addressing complex decision-making challenges in various domains. Deep Q-Learning (DQL) is a comprehensive reinforcement learning method that could potentially employed to optimize several aspects of supply chain management. This technique uses the ideas of reinforcement learning to learn the best decision-making techniques in dynamic, complicated contexts repeatedly. DQL is applied in several areas of supply chain management, such as demand forecasting, inventory optimisation, supplier performance prediction, and logistics optimisation.

Algorithm for DQL Framework for Supply Chanin Management

Step 1: Initialization: The algorithm establishes the replay memory buffer, initialises the Q-network and target network with random weights, and specifies hyperparameters like the exploration rate (ε) and discount factor (γ).

Step 2: Define Exploration Strategy: In this phase, the exploration strategy—like ε-greedy—is defined. It balances exploration with exploitation when choosing an action.

Step 3: Define Reward Function: Logistics objectives provide the basis of the incentive function, which allocates rewards for desired results such as shortened delivery times and cost savings.

Step 4: Training Loop: After choosing actions, carrying them out in the environment, and updating the Q-network with experiences kept in the replay memory buffer, the algorithm repeatedly cycles between episodes and time steps within each episode.

Step 5: Policy Deployment: The trained Q-network is employed for logistical optimisation when training is finished. Based on observable situations in the supply chain environment, it chooses the best course of action.

Step 6: Evaluation: To determine how well the deployed strategy performs in terms of streamlining logistics operations, important indicators like delivery times and cost savings are taken into consideration.

a) Accurate demand forecasting in supply chain management: In supply chain management, demand forecasting is essential because it helps companies estimate future client demand and adjust their operations accordingly. Within this framework, Deep Q-Learning (DQL) becomes a potent method for improving demand prediction accuracy through the implementation of reinforcement learning principles. Businesses can develop the best decision-making strategies using this method, which links the supply chain's present condition to activities that will optimize its future benefits—like income and satisfaction with clients. The interaction of the DQL agent with the supply chain environment is important to DQL-based demand forecasting. The agent looks at the condition of the supply chain as it stands right now, taking into account market trends, inventory levels, sales data from the past, and other pertinent information. The agent decides how to best maximise future benefits by using this knowledge to make decisions about order volumes and price. Environment-generated feedback—which takes the form of incentives or punishments depending on the results—is used to assess how successful these measures constitute. For instance, the agent may be rewarded if it effectively prevents stockouts by adjusting inventory levels in advance of expected increases in demand. On the other hand, the agency might be penalised if it overestimates demand and spends too much on inventory. The DQL agent improves its capacity to create precise demand estimates over time by iteratively enhancing its decision-making processes by learning from previous experiences. The agent adjusts its tactics to changing situations by absorbing patterns and trends in the supply chain environment. This results in more accurate forecasts and more informed decision-making. Additionally, DQL has the benefit of adaptability and flexibility, which enables companies to add new variables or change their forecasting tactics as necessary. To ensure that predictions are accurate and relevant, the DQL agent could modify its decision-making criteria in response to changes in market dynamics or the availability of new data sources. With deep Q-learning for supply chain management demand forecasting, companies may improve prediction accuracy and make better judgements. DQL enables companies to successfully predict future demand patterns and optimise their operations in response, resulting in increased efficiency and competitiveness. This is achieved by establishing decision-making policies via interaction with the supply chain environment.

b) Enhancing inventory optimization in supply chains: An essential part of supply chain management is inventory optimisation, which tries to find a careful balance between keeping costs as low as possible and guaranteeing product availability. To address this issue, Deep Q-Learning (DQL) presents a viable strategy by dynamically modifying inventory levels in response to a range of variables, such as variations in demand, lead times from suppliers, and operational limitations. The learning of a policy by the agent to traverse the intricate decision-making environment of inventory management is the fundamental component of DQL-based inventory optimisation. This policy links activities that determine inventory modifications to the present status of the supply chain, which includes elements like current inventory levels, demand predictions, supplier performance, and market circumstances. It is the responsibility of the DQL agent to optimise inventory levels in order to strike a balance between holding costs and stockout costs. Holding costs include all of the costs related to keeping inventory on hand, including obsolescence risks, storage fees, and capital invested in inventory. Conversely, stockout costs include the possible loss of income due to unfulfilled client demand in addition to the expenses associated with processing backorders and expediting orders. The DQL agent interacts with the supply chain environment to investigate various inventory management techniques and takes use of the best ones in order to maximise cumulative rewards over time. Through dynamically modifying inventory levels in reaction to evolving circumstances, the agent acquires the ability to predict demand trends, prevent stockouts, and reduce holding expenses. Feedback from the environment, which takes the form of incentives or punishments depending on the results, is employed to assess how effective the agent's activities were. For example, if stockouts are successfully avoided while holding costs are kept to a minimum, awards could be received; but, if stockouts occur frequently or at excessive inventory levels, penalties could be incurred. The flexibility and scalability of DQL also provide the agent the option to add more restrictions and variables as needed. To increase the resilience of inventory management techniques, the agent could, for instance, take seasonality, product lifecycles, and lead time variations into account while making decisions. Supply chain managers are empowered to make data-driven decisions that strike a compromise between cost effectiveness and service quality needs by utilising Deep Q-Learning for inventory optimisation. DQL helps organisations improve

customer happiness, streamline operations, and gain a competitive edge in the market by dynamically altering inventory levels depending on demand projections, supplier performance, and operational restrictions.

c) Improving procurement decisions through supplier performance prediction: A crucial component of supply chain management is forecasting supplier performance, which is necessary to guarantee the dependability and calibre of providers. Providing a strong framework to assess supplier performance measures and forecast future behaviour, Deep Q-Learning (DQL) helps firms make well-informed procurement decisions. The relationship among DQL agent and previous supplier data is fundamental to DQL-based supplier performance prediction. In addition to lead times, defect rates, delivery dependability, and overall service quality, the agent gains experience evaluating a variety of supplier performance measures. The efficacy and dependability of the provider in fulfilling contractual obligations is shown by these criteria. The DQL agent learns patterns and trends in supplier behaviour by observing previous interactions and the results of such interactions. Through the examination of historical performance information, such as examples of timely delivery, high-quality products, and compliance with service level agreements, the agent has the capacity to identify markers of supplier efficacy and dependability. Using the information it has acquired, the DQL agent forecasts future supplier behaviour and foresees any problems or supply chain interruptions. Through an evaluation of variables including past performance patterns, current market dynamics, and outside influences, the agent could estimate the probability that suppliers will fulfil their commitments and provide products and services within the anticipated timeframe and quality requirements. Furthermore, the agent may dynamically modify its predictions and decision-making processes in response to changing circumstances and fresh data thanks to DQL. The agent regularly updates its models and improves its forecasts in response to changes in the supply chain environment and the availability of fresh data, guaranteeing relevance and accuracy in the evaluation of supplier performance. Ongoing review and input verify the efficacy of the DQL-based supplier performance prediction technique. Businesses may evaluate the precision and dependability of the DQL agent's forecasts by contrasting expected supplier performance with actual results, and they can make any necessary modifications to enhance performance. Through employing Deep Q-Learning to anticipate supplier performance, companies may improve their procurement procedures and arrive at better judgements. DQL enables organisations to choose the most dependable and efficient suppliers, maximise supply chain efficiency, and reduce operational risks by teaching them to evaluate supplier performance measures, forecast future behaviour, and foresee any hazards or interruptions.

d) Streamlining supply chain operations for logistics optimization: Supply chain management relies heavily on logistics optimisation, which aims to reduce costs and improve the effectiveness of distribution and transportation operations. To tackle this problem, Deep Q-Learning (DQL) provides a strong framework that learns to optimise decisions about scheduling, routing, and mode selection, which simplifies logistics processes and enhances supply chain performance overall. The learning of a policy by the agent to traverse the intricate decision-making environment of distribution and transportation is the fundamental component of DQL-based logistics optimisation. In order to create the best choices for moving goods from suppliers to warehouses and from warehouses to consumers, this strategy takes into account a number of variables, such as transportation prices, delivery times, vehicle capacities, and route restrictions. Through interaction and observation, the DQL agent observes the present status of the supply chain environment, which may include variables like available transportation alternatives, inventory levels, consumer demand, and market circumstances. The agent uses this data to make decisions on the best course of action for logistical operations, including delivery schedules, route selection, and mode selection. The agent constantly improves its decision-making rules over time by drawing lessons from its interactions with the environment and with its experiences. The agent aims to maximise cumulative rewards—such as lowering transportation costs, speeding up deliveries, and maximising resource utilization—by investigating and utilising various logistical solutions.

The Deep Q-Learning (DQL) procedure for supply chain management logistics optimisation is described in the presented algorithm. The Deep Q-Learning (DQL) method that is offered sets up basic parameters and selects actions based on exploration or exploitation as iteratively goes through episodes. It regularly modifies the target network settings and updates the Q-network using experiences kept in a replay memory buffer. The technique incorporates assessment and checkpointing processes and gradually reduces the exploration parameters. It offers a structure for discovering the best supply chain management logistics tactics.

Deep Q-Learning (DQL) algorithm for logistics optimization within supply chain management

Initialize the Parameters

- $Q - network\ parameters\ \theta$
- $Target\ network\ parameters\ \theta'$
- $Replay\ memory\ buffer\ D$
- $Exploration\ parameters\ \varepsilon$

$For\ episode\ =\ 1\ to\ max_{episodes}$:

Initialize state s

$Set\ total_{reward}\ =\ 0$

$While\ not\ reached\ terminal\ state$

With probability ε

Select a random action a

Otherwise

Select action $a = arg_{max}\ (Q(s, a, \theta))$

Execute action a in the environment

Observe next state s', reward r, and whether next state is terminal

Store experience (s, a, r, s') in replay memory buffer D

#Sample a mini-batch of experiences (s_i, a_i, r_i, s'_i) from replay memory D
For each sample (s_i, a_i, r_i, s'_i) in the mini-batch
Compute target Q-value

If s'_i is terminal
$target = r\_i$

Else

$$target = r\_i + \gamma * max(Q(s'\_i, a', \theta'))$$

Compute current Q-value

$$Q\_value = Q(s\_i, a\_i, \theta)$$

Compute loss

$$loss = (target - Q\_value)\text{^}2$$

Update Q-network parameters $\boldsymbol{\theta}$
Perform gradient descent on loss with respect to θ
Every C steps
Update target network parameters $\theta' = \theta$
Update state $\boldsymbol{s = s'}$
Accumulate $total_{reward}$ += r
Decrease exploration parameter ε over time
$If\ episode\ \%\ evaluation\_interval == 0$:
Evaluate policy performance using test scenarios
$If\ episode\ \%\ checkpoint\_interval == 0$
Save Q-network parameters θ

Deep Q-Learning (DQL) is a powerful reinforcement learning technique that has gained significant attention in recent years due to its ability to handle complex decision-making tasks in various domains, including supply chain management. In the context of logistics optimization within the supply chain, DQL can be applied to address challenges such as route planning, fleet management, warehouse operations, and transportation scheduling. Key considerations in DQL-based logistics optimization are discussed below.

1) Route planning: DQL can be employed to optimize the routes taken by delivery vehicles or shipments within the supply chain network. By considering factors such as distance, traffic conditions, delivery time windows, and vehicle capacity, DQL algorithms can learn to generate optimal routes that minimize transportation costs and delivery times while maximizing efficiency.

2) Fleet management: DQL can assist in optimizing fleet management decisions, such as determining the appropriate number and types of vehicles needed to fulfill customer orders efficiently. By analyzing historical data on order volumes, delivery locations, and vehicle capacities, DQL algorithms can learn to allocate resources effectively, ensuring that the fleet operates at maximum capacity without incurring unnecessary costs or delays.

3) Warehouse operations: DQL can optimize warehouse operations by optimizing inventory placement, picking routes, and order fulfilment processes. By learning from historical data on order patterns, inventory levels, and warehouse layouts, DQL algorithms can identify the most efficient strategies for organizing and managing warehouse operations, minimizing storage costs and improving order fulfilment speed.

4) Transportation scheduling: DQL can be used to optimize transportation scheduling decisions, such as determining the best times to schedule shipments, allocating resources to different transportation modes, and coordinating logistics activities across multiple locations. By analysing historical data on transportation capacities, lead times, and delivery requirements, DQL algorithms can learn to generate optimal scheduling plans that minimize transportation costs and maximize delivery reliability.

Overall, DQL offers a flexible and scalable approach to logistics optimization within supply chain management. By leveraging advanced machine learning techniques, organizations can improve the efficiency, agility, and resilience of their supply chain operations, gaining a competitive advantage in today's dynamic business environment. Businesses could significantly boost the efficiency and performance of their logistics by learning how to optimize decisions about routing, scheduling, and mode selection with DQL. DQL enables companies to efficiently respond to shifting circumstances and shifting supply chain dynamics by continuously adapting and improving decision-making procedures. This eventually results in cost savings, improved customer satisfaction, and a competitive advantage in the marketplace.

V. Result and Discussion

Findings from the implementation of the study methodology in supply chain management are presented, demonstrating observable improvements in significant performance indicators such inventory turnover, delivery times, and cost reductions. The precision of demand projections, productivity enhancements in inventory management, and the capacity to recognise dependable vendors are emphasised. Moreover, improved resource and transportation efficiency are the results of well-run logistics operations. Comparative assessments show the value contributed by the framework, and visual aids facilitate understanding. Practical strategies for enhancing supply chain operations and boosting competitiveness are provided by the outcome's presentation.

A. Experimental Outcome

1) Sales by Product Type: Analysing sales by product type offers important insights into how revenue is distributed throughout a company's portfolio and shows how various product categories are performing. Through sales data analysis, companies may determine best-selling items, comprehend consumer inclinations, and customise their approaches to maximise income. In order to deploy resources effectively and capitalise on high-performing product segments, firms must do this research in order to plan their marketing strategies, inventory control, and general operations.

TABLE I. SALES PERCENTAGE BY PRODUCT TYPE

Product Type	Sales Percentage (%)
Skincare	45%
Cosmetics	25.5%
Haircare	29.5%

The distribution of sales percentages among the various product categories in the company's portfolio is shown in the above Table I. With skincare items making about 45% of the overall sales income, they are the biggest contributor to sales. Products for hair care come in second place with 29.5% of sales, after skincare with 25.5%. This distribution implies that skincare goods account for a sizable amount of the company's income. Furthermore, the greater sales percentage of skincare goods suggests that consumers find these products to be popular. Additionally, the relationship between the increased cost of skincare goods and the money made suggests that, in comparison to cosmetics and hair care products, skincare products could have better profit margins or more demand.

Fig. 3. Sales distribution by product type.

For strategic decision-making in areas like inventory management, marketing campaigns, and product development, it is important to comprehend the sales distribution by the kind of product. Through the identification of client preferences and sales patterns, organisations can customise their approaches to leverage profitable product categories and enhance their total income generating. The distribution of sales percentages among the various product categories in the company's portfolio is shown in Fig. 3. With skincare items making about 45% of overall sales income, they have the largest sales proportion. With a sales ratio of 29.5%, hair care goods trail closely behind cosmetics, which account for 25.5% of total sales. This graphic clearly illustrates the comparative sales performance of every product category and shows how skincare goods are the company's main source of income.

2) Total revenue by shipping carrier: Since shipping carrier income directly affects the profitability and effectiveness of logistics operations, it is a crucial component of supply chain management. This indicator shows how much revenue various carriers in the supply chain network make from providing transportation services. Organisations could assess each shipping carrier's financial contribution, identify top performers, and make well-informed judgments about carrier selection, shipping rate negotiations, and overall logistics optimization strategies by analysing revenue data. Comprehending the income generated by shipping carriers offers significant insights into the financial well-being of the supply chain and facilitates efficient resource allocation for organizations to optimize profitability and competitiveness.

The revenue produced by the various shipping companies in the supply chain is shown in the Table II. It offers a comparison summary of each carrier's revenue contributions, highlighting how well each performs in terms of generating money. With a total revenue of 250.0946k, Carrier B leads the revenue generation. Carrier C comes in second with 184.880k, while Carrier A comes in third with 142.63k.

TABLE II. SHIPPING CARRIERS DRIVE REVENUE GROWTH

Shipping Carrier	Revenue Generated
Carrier A	142.63k
Carrier B	250.0946k
Carrier C	184.880k

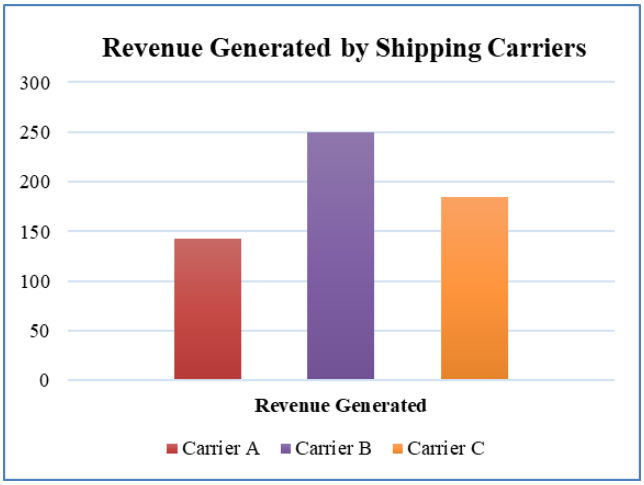

Fig. 4. Revenue generated by shipping carriers.

To facilitate simple comprehension and comparison of the revenue contributions, Fig. 4, which is an accompanying table, visually depicts the revenue earned by each shipping carrier through a bar chart. This graphical depiction makes the data easier to interpret and makes it easier to quickly identify the carriers that are performing at the top. In general, assessing the revenue that shipping carriers bring in from supply chain activities and choosing and managing them wisely depend on the analysis of their income.

3) Analysis of defect rates and costs across transportation modes and routes: This research explores the prices and defect rates related to different forms of transportation along distinct supply chain network routes. Through the analysis of these variables, enterprises may get significant understanding regarding the effectiveness, dependability, and efficiency of transportation processes. The defect rate (D) can be calculated using the Eq. (2):

$$D = \frac{Number\ of\ Defective\ items/\ Occurences}{Total\ Number\ of\ items/\ Occurences} * 100 \quad (2)$$

Once the defect rates are calculated for each route and transportation mode, they provide valuable insights into the reliability, quality, and performance of transportation operations within the supply chain network. Higher defect rates indicate a higher likelihood of issues or problems occurring during transportation, which may necessitate corrective actions or adjustments to improve supply chain efficiency and reduce risks. To maximise logistics tactics, reduce risks, and improve supply chain performance overall, it is crucial to comprehend the link between transportation options, route selections, defect rates, and prices. Supply chain managers could employ the practical findings from this research to guide their decision-making and promote ongoing advancements in transportation management techniques.

TABLE III. DEFECT AND COST RATE BY TRANSPORTATION MODE

Routes	Transportation modes	Costs	Defect rates
Route B	Road	187.752075	0.226410
Route B	Road	503.065579	4.854068
Route C	Air	141.920282	4.580593
Route A	Rail	254.776159	4.746649
Route A	Air	923.440632	3.145580

Table III offers comprehensive information on the prices and defect rates related to various types of transportation along distinct supply chain network routes. Supply chain managers need this information in order to evaluate the effectiveness and efficiency of transportation operations and to make well-informed choices about risk management tactics, carrier selection, and route optimisation. A path in the supply chain is represented by each item in the table, which also includes information on the mode of transportation employed, associated costs, and observed failure rates. Road transport, for example, is used most of the time on Route B; the following table shows two examples of this. With comparable defect rates of 0.226410 and 4.854068, respectively, the related costs for these road transfers are provided as 187.752075 and 503.065579. Similar to Route C, which has a failure rate of 4.580593, Route C mostly uses air transport and costs 141.920282. However, Route A combines rail and air transport, and its prices are 254.776159 and 923.440632, respectively. Its equivalent defect rates are 4.746649 and 3.145580.

The presence of two distinct entries for Route B with the transportation mode specified as Road in Table III signifies that there were multiple instances of transportation activities along this route utilizing road transport. This suggests that there were separate shipments or events that required transportation along Route B, each with its own associated costs and defect rates. The variations in costs and defect rates between these entries could be attributed to several factors. Firstly, different shipments may have varied in terms of their size, weight, destination, or urgency, leading to differences in transportation costs and quality control measures. Additionally, logistical factors such as the specific routes taken, the types of vehicles used, or the involvement of different transportation providers may have influenced the costs and defect rates associated with each transportation event. Furthermore, external factors like road conditions, traffic congestion, or weather conditions could have impacted the efficiency and reliability of transportation along Route B, contributing to the observed variations. By analyzing these differences, businesses can gain valuable insights into the performance of their supply chain logistics along Route B, identify potential areas for improvement, and implement strategies to optimize transportation operations, minimize costs, and enhance overall supply chain efficiency and reliability.

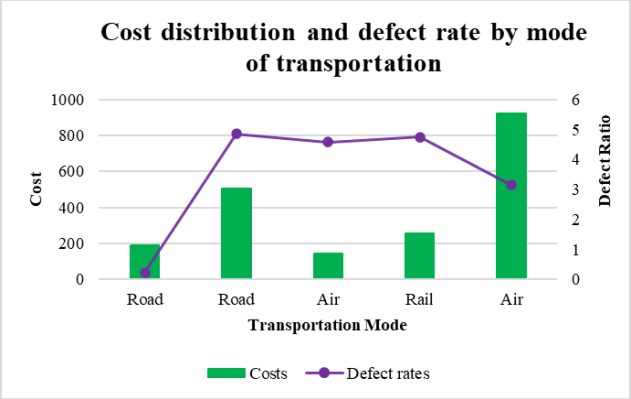

Fig. 5. Defect rates and costs across transportation modes.

The performance and dependability of various transport choices within the supply chain network are provided by this thorough analysis of defect rates and prices by transportation mode and route. Supply chain managers can find patterns, trends, and possible areas for improvement by examining this data. To reduce risks and guarantee product integrity during transportation, routes with high defect rates, for instance, could need more careful inspection and quality control procedures. Analysing the prices of various transportation options could additionally help to optimise logistics processes and reduce costs without sacrificing quality of service. Fig. 5 provides insights that enable supply chain managers to optimise transportation methods, improve operational efficiency, and make data-driven choices in order to efficiently fulfil company objectives.

4) Analysing defect rate by product: Within the supply chain network, examining the defect rate by product offers important information about the dependability and quality of each product class. Through a comprehensive analysis of product defect rates, enterprises may pinpoint opportunities for enhancement, execute focused quality control strategies,

and augment the overall quality of their goods. In order to help businesses improve their quality management procedures, reduce the cost of errors, and uphold customer satisfaction levels, this research attempts to evaluate the defect rates seen across several product categories.

The fault rates seen for several product categories within the supply chain network are shown in the above Table IV. A distinct product category is represented by each row, along with the related failure rates. At 1.919287, cosmetics have the lowest fault rate of all the items. Conversely, haircare products had a somewhat higher failure rate of 2.48315. Skincare goods have a 2.334681 failure rate, which is in the middle. The quality and dependability of various product categories within the supply chain are usefully shown by this data. Through product-specific defect rate analysis, companies may pinpoint areas that could use improvement and put focused quality control tactics in place. Companies can minimise expenses related to returns and replacements, improve customer happiness, and keep a competitive advantage in the market by fixing faults and minimizing product inconsistencies.

TABLE IV. DEFECT RATE BY PRODUCT

Products	Defect Rates
Cosmetics	1.919287
Haircare	2.48315
Skincare	2.334681

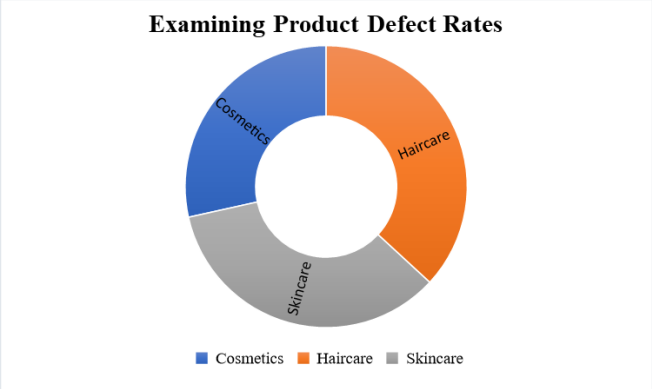

Fig. 6. Product-specific defect rates.

Stakeholders could frequently determine whether goods have greater or lower failure rates by referring to Fig. 6, which displays a graphical depiction that compares defect rates across several product categories. Understanding each product category's relative quality and dependability along the supply chain is made easier by the figure. Furthermore, it functions as a valuable instrument for decision-making, allowing organisations to arrange resources and prioritise efforts towards improving quality in order to reduce errors and raise the standard of their products.

B. Performance Assessment

To evaluate performance effectively, it is essential to take into account a variety of critical measures when comparing the outcomes of a proposed framework with baseline techniques or current solutions in the existing literature. When the suggested framework is compared to other well-established techniques, these metrics offer valuable information about its efficacy, productivity, and dependability.

1) Accuracy: When assessing the effectiveness of predictive models, such as those used in supply chain management, accuracy is a crucial parameter. The proportion of correctly categorised examples out of all examined instances is measured to determine the model's accuracy in making predictions. Accuracy is of the utmost significance in supply chain management since it has a direct impact on decisions made about inventory control, demand forecasting, and supplier selection. The aforementioned Eq. (3) represents accuracy as a percentage and shows how accurate the forecasts generated by the model.

$$Accuracy = \frac{No.of\ Correct\ Predictions}{Total\ No.of\ Predictions} \times 100\% \quad (3)$$

The performance of several techniques, including Support Vector Machine (SVM), Decision Tree (DT), Random Decision Tree (RDT), and the suggested Deep Q-learning methodology, is thoroughly compared in Table V. The accuracy measure is employed to assess the efficacy of every technique, with the outcomes displayed as proportions. The outcomes show that, with an astounding accuracy rate of 98.9%, the suggested Deep Q-learning methodology attains the best accuracy out of all approaches. This implies that the Deep Q-learning methodology has shown to be exceptionally effective in accurately categorising situations in the area of supply chain management. This approach's high accuracy suggests that it is good at identifying intricate patterns and correlations in the data, which could assist with prediction and decision-making.

TABLE V. PERFORMANCE COMPARISON OF THE SUGGESTED APPROACH

Methods	Accuracy (%)
SVM	94
DT	95
RDT	91
Proposed Deep Q	98.9

The Table V presents a comprehensive comparison of the accuracy percentages achieved by different methods employed for supply chain management optimization. Among the traditional machine learning algorithms assessed, Support Vector Machine (SVM) demonstrated a respectable accuracy of 94%, followed closely by Decision Tree (DT) at 95% and Random Decision Tree (RDT) at 91%. These methods, while effective, were surpassed by the proposed Deep Q-Learning (DQL) approach which increased by 3.8 % when compared to related accuracy, which showcased remarkable accuracy, standing at an impressive 98.9%. DQL, a reinforcement learning technique leveraging neural networks, showcased its superiority in addressing the complexities of supply chain management, offering unparalleled accuracy in predictive modeling and optimization tasks.

The results underscore the transformative potential of incorporating advanced methodologies like DQL into supply

chain management practices. With its unmatched accuracy, the proposed DQL framework promises to revolutionize decision-making processes within supply chains, enabling organizations to navigate uncertainties, optimize resource allocation, and enhance operational efficiency. This study highlights the pivotal role of innovative techniques in driving the evolution of supply chain management towards greater agility, resilience, and competitiveness in today's dynamic business landscape.

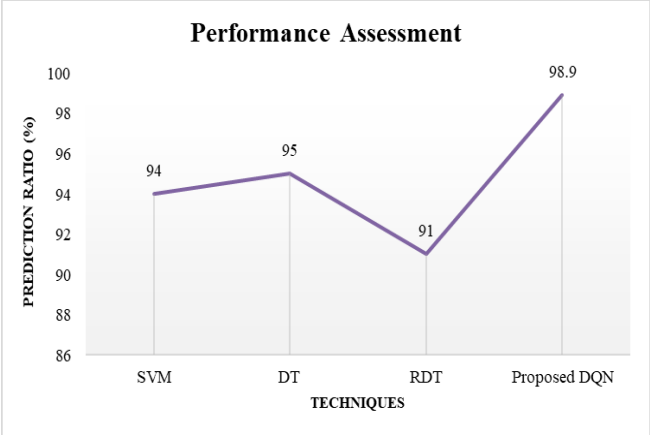

Fig. 7. Performance comparison of different methods in supply chain management.

The findings in Fig. 7 demonstrate the effectiveness of the suggested DQN method in relation to supply chain management. Enhancing forecast accuracy, streamlining processes, and eventually increasing value creation in the supply chain are all possible with this strategy.

VI. Conclusion and Future Work

The present investigation delved into the efficacy of multiple supply chain management techniques, with a particular emphasis on the suggested Deep Q-Network (DQN) strategy. The research aimed to assess the predictive and optimization capabilities of various methods, including Support Vector Machine (SVM), Decision Tree (DT), Random Decision Tree (RDT), and DQN, within the realm of supply chain processes. Following a thorough examination, it became evident that the Deep Q-learning method outperformed conventional machine learning techniques, boasting an impressive accuracy rate of 98.9%. This superior performance underscores the capacity of deep reinforcement learning techniques to enhance forecasting accuracy and address complex challenges within supply chain management. The significance of this research lies in its potential to enhance both the efficiency and productivity of supply chains. By harnessing advanced AI techniques like Deep Q-learning, organizations stand to elevate customer satisfaction, streamline processes, and generate more precise forecasts. Moreover, the findings underscore the importance of leveraging innovative methodologies to navigate the dynamic obstacles inherent in supply chain management, particularly in light of increasing complexity and unpredictability.

This study contributes to the expanding body of research on machine learning applications in supply chain management. It not only showcases the substantial performance enhancement offered by DQN but also illustrates its effectiveness in optimizing supply chain operations. Future research avenues could focus on further refining the DQN approach, exploring its applicability across diverse supply chain scenarios, and investigating potential synergies with other cutting-edge technologies such as blockchain and the Internet of Things (IoT). These endeavors promise to pave the way for more comprehensive and robust supply chain optimization strategies.

Advancing Prostate Cancer Diagnostics with Image Masking Techniques in Medical Image Analysis

H. V. Ramana Rao[1]*, V RaviSankar[2]
Research Scholar, Department of CSE, GITAM University, Hyderabad, India[1]
Associate Professor, Department of CSE, GITAM University, Hyderabad, India[2]

***Abstract*—Prostate cancer is a prevalent health concern characterized by the abnormal and uncontrolled growth of cells within the prostate gland in men. This research paper outlines a standardized methodology for integrating medical slide images into machine learning algorithms, specifically emphasizing advancing healthcare diagnostics. The methodology involves thorough data collection, exploration, and image analysis, establishing a foundation for future progress in medical image analysis. The study investigates the relationships among image characteristics, data providers, and target variables to reveal patterns conducive to diagnosing medical conditions. Novel background prediction techniques are introduced, highlighting the importance of meticulous data preparation for improved diagnostic accuracy. The results of our research offer insights into dataset characteristics and image dimensions, facilitating the development of machine-learning models for healthcare diagnosis. Through deep learning and statistical analysis, we contribute to the evolving field of prostate cancer detection, showcasing the potential of advanced imaging modalities. This research promises to revolutionize healthcare diagnostics and shape the trajectory of medical image analysis, providing a robust framework for applying machine learning algorithms in the field. The standardized approach presented in this paper aims to enhance the reproducibility and comparability of studies in medical image analysis, fostering advancements in healthcare technology.**

Keywords*—Prostate cancer; data exploration; image analysis; medical conditions; background prediction techniques; data preparation; diagnostic accuracy; dataset characteristics; image dimensions; deep learning; statistical analysis; prostate cancer detection; advanced imaging modalities; healthcare diagnostics; medical image analysis; machine learning; target variables

I. Introduction

Prostate cancer comes with a huge burden on men's health worldwide, and so the earlier it is detected and diagnosed, the patients get the best outcomes. Over the previous decades, we have observed increased use of cutting-edge medical imaging for accurate diagnosis. Image segmentation has gained prominence among the myriad of medical image analysis techniques as it enables the identification and depiction of prostate lesions, which may harbor cancerous cells, with unrivaled accuracy. In the instance of different types of medical imaging devices, like Magnetic Resonance Imaging (MRI) and Computed Tomography (CT) scans, help doctors identify prostate and stage prostate cancer by giving detailed and high-quality visualization of the prostate. On the flip side, the boundary of cancer clusters and filming the interior regions of a body are not easy and remain challenging. Multi-masking, which stresses the desired location and struggles of the unnecessary information emerging, has become a decisive factor in improving the addressing in the visualization. Nwaigwe, Ogbonna, and Oliwe (2022) [1] stress the need for a complete understanding of PSA distribution (medical data).

In the course of this research, it might well be that progress in healthcare science is expected since diagnostics could be revolutionized. The main objective of the preparatory phase of medical slide images is to improve the precision and velocity of computer learning methods in detecting body conditions. The method includes using masks and predicting the background, similar to the approach demonstrated by Pinckaers, et al. (2021). All the slide images go through end-to-end training with image-level labels [4].

These objectives offer direction in determining various image features, data providers, and interchangeable patterns with these options. Valan, Zimjonov, and Maçal (2023) report that the efficiency of machine learning is achieved via the application of radiomics features, which become a part of our methodology context [7]. The investigation of a range of dimensions, the pixel spacing of the radiography scans, and the number of series forming the basis of research are planned to shed light on conditions that will help in the diagnosis. We included a new process for creating and validating the masks as part of the used approach to address the question of machine learning model accuracy enhancement.

Additionally, this study seeks to integrate the findings into a coherent and credible data framework. For instance, the study of Ismail et al. (2020) [5] pointed out the machine-learning classification technique of prostate cancer, justifying that the role of computational models in healthcare diagnostics is cardinal, together with Chang, Hu, and Tsai (2015), who delved into the utilization of machine learning with dynamic MRIs for prostate cancer detection and in line with our emphasis on the latest imaging applications [6].

The study also aims to include the ensemble-based classifier approach, as shown by Elshazly, Elkorany, and Hassanien (2013). This proves the trend of higher diagnostic performance by combining several machine learning models [8]. This means we shall pursue an integrated strategy that harvests data from a comprehensive collection of medical images.

This research explores the leading-edge medical imaging diagnostics field and uses machine learning and image analysis progress. By integrating the insights and approach from leading

*Corresponding Author.

research, this endeavor aims to become physically implicated in the early detection and diagnosis of medical conditions, uplifting a patient's outcome and progressing healthcare diagnostics.

The medical slide image integrating approach presented in machine learning algorithms is a progressive breakthrough in the precise diagnostic process of the health care system. Data is specifically and carefully taken and explored for this method, and the image characteristics are assiduously analyzed to improve the precision of readings and speed up the process. The motivation behind this research is the pressing need for the most accurate and prompt diagnosis of both medical conditions in general and prostate cancer in particular, where early detection is necessary for successful treatment.

Another important contribution of this approach lies in proper data preparation, which includes novel background prediction techniques so diagnostic precision can be improved. This approach identifies information on the database characteristics and image dimensions, which are later used in constructing machine learning models, especially in prostate cancer screening and diagnostics.

The outreach of research benefits cannot be restricted to one level. It is a specific medium that facilitates machine learning in medical image analysis. In turn, the experiments from this field are becoming more and more plausible and comparable. Besides, machine learning-aided diagnosis systems can be more accurate and reliable if data from hospitals, pathologists, and expert systems are deployed. Healthcare systems may adopt new diagnostic approaches by infusing new technologies. It may end up with early diagnosis as well as accurate diagnosis of prostate cancer in other diseases, giving precision medicine to patients that will thereby boost outcomes and lower healthcare costs.

As medical diagnostics continue to gain ground, the results of this work can be one of the factors that might alter the future of medical image modeling and interpretation. The interconnections we will deduce will serve as the foundation for incorporating machine learning algorithms in health diagnosis and analysis.

II. Literature Review

Machine learning (ML) algorithms in healthcare diagnostics, particularly in prostate cancer detection, have been in the spotlight of a large variety of research for a long time. This part will describe the experiments and research conducted to date related to this area.

Nwaigwe, Ogbonna, and Oliwe (2022) conducted research concentrating on the PSA distribution probability interpretation to enable early diagnosis of prostate cancer. Notably, the scientist's investigation highlights the need to learn about the statistical characteristics of PSA levels, one of the most important properties for diagnostics [1]. Alkhateeb, Atikukke, and Rueda (2020) shed light on different diagnostic methods for prostate cancer, emphasizing their uses and depicting the best practices [2].

Norbu Zongpa (2019) aimed to illustrate the importance of bladder protocol in dealing with prostate cancer through radiotherapy. This study highlights the relevance of the approaches in which the treatment is aimed at particular conditions [3]. Pinckaers, et al. (2021) applied an end-to-end training approach, which used whole slide images only with image-level labels to detect prostate cancer. The method showcases where deep learning can play an important role in medical image analysis [4].

Ismail et al. (2020) suggested a classification method for predicting prostate cancer (cancer-wise), accentuating the significance of computation models in healthcare [5]. Chang, Hu, and Tsai (2015) also revealed that dynamic MRIs can be helpful and that data processing computational techniques can boost the detection of prostate cancer [6].

Valan, Zimjonov, and Maçal (2023) developed an algorithm for computer-aided analysis of prostate cancer based on extracting the important radiomic features and using the fine-tuned Linear SVM methods. This research confirms the utility of the combined approach of computational techniques with radiology applications [7]. Elshazly, Elkorany, and Hassanien (2013) studied breast cancer diagnosis classifiers based on an ensemble. These works informed us about the advantages of involving various models [8].

Lehaire, et al. 2014 designed a computer-aided diagnostic system for prostate cancer that is automated with learned dictionaries and supervised classification. It is noteworthy that there is a connection between the two due to the bunch of traditional and innovative methods [9]. Mesrabadi and Faez (2018) explored using artificial neural networks and deep learning to enhance early prostate cancer diagnosis. They land at the point where developed methods offer the chance to raise the detecting rate [10].

These studies have highlighted the growing attention to computationally assisted decisive prostate cancer diagnostics, and the promising prospects of advanced imaging techniques and statistical analysis methods for definite progress in this field have been confirmed.

III. Methodology

The approach taken in this study involves several critical steps, including data collection, exploration, image analysis, and mask processing. The following sections offer a comprehensive overview of each stage:

A. Data Source and Loading

The dataset used in this study is the Prostate Cancer Grade Assessment (PANDA) dataset, a rich resource obtained from a Kaggle competition. This dataset contributes to research on prostate cancer grading and provides a free repository available to researchers and practitioners in the medical imaging community. The dataset contains high-resolution pathology images from prostatic tissue samples from various medical centers.

The PANDA dataset is digital and, therefore, enables a detailed study of histopathological images down to any required magnification level and provides characteristics of prostatic tissue in full: specific image in the collection shows the previous ISUP (International Society of Urology Pathology) grading—the identification of grade assignments.

This annotation is the actual true point of reference and supervised process; the only way an innovative technique that becomes an automated grading of prostate cancer can purport to do so.

The PANDA dataset critiques algorithms that test the prediction that prostate cancers will be graded effectively and match those graded by a human pathologist. This is a helpful foundation for various collaborations to be launched and for identifying the best way to diagnose prostate cancer and freshen up its treatment plans. By sharing such a dataset, interested parties in medical imaging would be encouraged to work together to understand prostate cancer disease and its treatment better. Three essential files accompany the dataset:

1) train.csv: This file is a set of indispensable training data stored within the machine learning model framework, which consists of vital attributes and tags that shape our ability to recognize patterns related to the cancer of the prostate

2) test.csv: It is a test data file to be used for model evaluation, especially in terms of pockets' precision and consistency, so that it can be applied to new data types with availability.

3) sample_submission.csv: This document explains the template for making voice forecasts with Kaggle competition in mind and a set of rules for providing findings in an organized manner.

These files add very much to the detailed information about the training and test data; hence, they constitute the backbone of our analysis and the creation of our model. Overall, they offer a complete description of the training and testing data, which lay a basis for subsequent analysis using various models.

As illustrated in Architecture Diagram Fig. 1, the data preparation process involves the acquisition, preprocessing (cleaning, normalization, augmentation), and splitting into training and test sets for model training and evaluation. The Architecture Diagram serves as a systematic guide, ensuring the reproducibility and validity of our research findings.

B. Data Exploration

EDA (exploratory data analysis) is one of the main workstations in the data science pipeline. It, thus, extracts the underlying prototypic structure and characteristics of the data. The first phase that must be done in machinery exploration of the training dataset is to get the proper approach to grasp the dataset's peculiarities and prevent data contamination while the data are being prepared for further analysis or model training.

Displaying the first rows of the preliminary training data set is the first step of EDA. We do it by calling the display (train).head ()). The next step is data wrangling. Data wrangling is performing data capture that allows practitioners to take a preliminary look at the structure and feature composition to pinpoint anticipated problems. Knowing the basics of the accounting operation's first rows can lead to a better understanding.

Following the data collection step, summary statistics are built to describe the features present in the dataset. The evaluation of the dataset structure involves the analysis of the shape of the function, unique identifiers of providers such as isup_grade and gleason_score, and variation of the data providers. The distribution of target tags is also considered. This set of statistics aims to give us a general idea about the data. We can easily identify patterns, anomalies, or imbalances on that base, which might affect the subsequent analysis or model building.

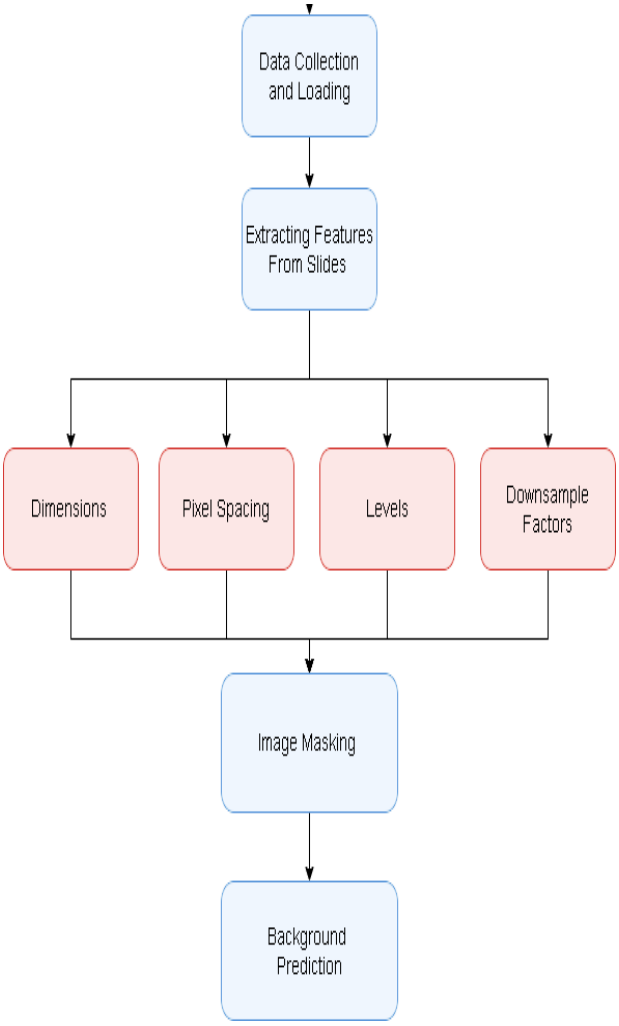

Fig. 1. Architecture diagram.

While the data reliability and accuracy are of concern, verifying the existence of image files to match the image IDs is one way of upholding the uniformity and integrity of the data. This step entails identifying mechanical defects during the process's data processing and model training stages. The ones that are out of the particular space or are inconsistent with each other will hinder the workflow process. This idea is verified by the fact that image files are irreplaceable at the professional level. The analysis comprises analysis of the dataset shape, image model identification, provider diversity, and frequency of labels like iscpp_grade and gleason_score. These statistics overview the dataset to help identify patterns, anomalies, or imbalances that might influence subsequent analysis or model building.

Another important step in EDA is to correct the gleason_score label for consistency. In this case, label uniformity is material since it will improve the dataset's quality and is also a step toward improving the reliability of future analyses and model predictions. This process in the data preparation is hence critical, and the inconsistency in labels introduces noise that affects the ability to generalize and may compromise the effectiveness of the machine learning models.

C. Slide Image Characteristics

After exploratory data analysis, an analysis of the image features using the OpenSlide library is performed, and we investigate the distribution and relationships of these dimensions within the dataset. A scatter plot will represent the connection between image width and height. The plot explains the dataset's image size range and variability. Exploring the dataset exposes its structure and, thus, the potential biases in image dimensions.

On the other hand, scatter plots that hold in the plot with the target variable ISUP grade demonstrate potential correlations of physical image features and diagnostic outcomes. The analysis will help find connections or relations between imaged details and ISUP grade, which can promote diagnostic models for prostate cancer screening.

Moreover, the distribution plots also explore the distribution and range of the width and height of the image markers. This analysis offers additional information about the data dimensions change, thus helping during the model training and anomalies location.

In essence, these experiments with scatter plots and distribution plots help in creating a critical understanding of the nature and relationships of some image properties with the resultant diagnostic outcome, the future of which may be in model development and fine-tuning in the field of medical image analysis and diagnosis of prostate cancer.

D. Mask Images

The next step in the methodology is processing the masks, which is an important step for data integrity and robustness. The masks of the pictures corresponding to slides are filtered, keeping only the first channel, which, in turn, is assigned for the analysis. Another step to confirm the justness of the processed data is verifying the empty last two channels, reducing the probability of any mistakes to a minimum.

Then, the background can be created by segmenting the background areas within the images. This procedure proceeds with building a background mask that should reflect an aggregate of segmented mask images, where the background pixels are marked with a mask value of 0. Using the random sample displays from the background mask and matching slide images demonstrates how the accuracy of the generated mask is verified. This validation step is rather elementary for providing in-depth, unbiased recognition and differences between foreground features and the background areas within the images.

Implementing a function for predicting the background of slide images using thresholding techniques:

$$B(x,y) = \begin{cases} 1, & \text{if } I(x,y) > T \\ 0, & \text{otherwise} \end{cases} \quad (1)$$

Eq. (1) is utilized for thresholding operation to identify background regions.

Handling the mask images and creating background masks are crucial elements of our methodology, which are principally designed to increase the correctness of preliminary analysis. The steps include preparing the slide images with machine learning algorithms to facilitate accurate and effective diagnosis of health conditions in medical facilities.

To validate accuracy, visualize random samples of background masks, original slide images, and predicted background regions.

$$P(x,y) = \frac{e^{z_{class}}}{\sum e^{c}} \quad (2)$$

Eq. (2) is utilized to predict probability through the softmax function of the output layer.

Algorithm1: Data Preprocessing and Analysis

Require:
Root directory (ROOT)
Training data (train)
Test data (test)

Initialization:
Load data files: train, test, sample submission from ROOT

Data Exploration and Summary:
1. Explore and summarize training data
2. Calculate dataset statistics

Explore Slide Image Characteristics:
3. **for** each image ID in training data, **do**
4. Extract Dimensions ← ROOT, image ID
5. Extract PixelSpacing ← ROOT, image ID
6. Extract Levels ← ROOT, image ID
7. Extract DownsampleFactors ← ROOT, image ID
8. ScatterPlot(Dimensions[0], Dimensions[1])
9. **if** HasIsupGrade(isup grade) then
10. ScatterPlot(Dimensions[0], Dimensions[1], isup grade)
11. end if
12. DistributionPlot(Dimensions[0])
13. DistributionPlot(Dimensions[1])
14. **end for**

Process Mask Images:
15. **for** each image ID in training data **do**
16. Mask ← LoadAndProcessMask(*ROOT, image ID*)
17. ConfirmLastTwoChannelsEmpty(Mask)
18. BackgroundMask ← CreateBackgroundMask(Mask)
19. VisualizeRandomSamples(Mask, Image)
20. **end for**

Background Prediction Function Execution:

21. Execute the background prediction function

Ensure:

Processed data and masks

Functions:

22. **function** LOADANDPROCESSMASK(*ROOT, image ID*)
23. Mask ← Load the mask image from ROOT and image ID as a 2D array
24. **for** x = 1 to image width **do**
25. **for** y = 1 to image height **do**
26. **if** *mask (x, y)* is not empty in channels 2 and 3 **then**
27. Set *Mask(x, y)* in channels 2 and 3 to 0
28. **end if**
29. **end for**
30. **end for**
31. **return** Mask
32. **end** function
33. **function** CREATEBACKGROUNDMASK(Mask)
34. Initialize BackgroundMask as a 2D binary array with the same dimensions as Mask
35. **for** x = 1 to image width **do**
36. **for** y = 1 to image height **do**
37. **if** *Mask(x, y)* is 0 **then**
38. *BackgroundMask(x, y)* ← 1
39. **else**
40. *BackgroundMask(x, y)* ← 0
41. **end if**
42. **end for**
43. **end for**
44. **return** *BackgroundMask*
45. **end** function

The methodology section delineated the sequential data collection, exploration, image analysis, and mask processing procedures. These preliminary steps are imperative for data preparation, facilitating subsequent analysis, and model development. The examination provided valuable insights into the dataset's attributes, aiding in creating masks for background detection, which is integral to the subsequent phases of the research.

IV. Result and Analysis

In this section, we present the outcomes of the data preprocessing and analysis steps, as elucidated in Algorithm 1. The analysis encompasses the exploration of training data, dataset statistics, and the characteristics of slide images.

A. Exploration of Training Data

The dataset training stage proved to be a critical part of the study, giving a lot of key information about the data's composition and characteristics. The provisions of data and image manufacturing were a result of our detailed analysis that was aimed at disentangling the aspects of the data. Summary statistics gave a summary view of the system, which showed, for example, the number of images with IDs, data providers, and the Gleason Score ranges, among others. This quantitative analysis has been very useful to me in understanding the scale and the level of detail in the dataset and the existence of bias, if any.

Moreover, utilizing multiple visualization techniques, like bar charts and scatter plots, allowed us to uncover the connection between specific variables. These visualizations have highlighted differences among the target variable parameters based on categories. It also shows anomaly patterns and individual provider irregularities within the data. The observation of the width and height dimensions enabled the discovery of patterns, as well as unusual images that were characterized by differentiation in datasets. Besides, vector length and dimension are proportional to isup_grade, which gives a basic understanding of physical attributes versus cancer grading. By carefully addressing this multifaceted examination, the stage was set for data preprocessing and model development involving a machine learning algorithm trained only on data that had been exhaustively analyzed.

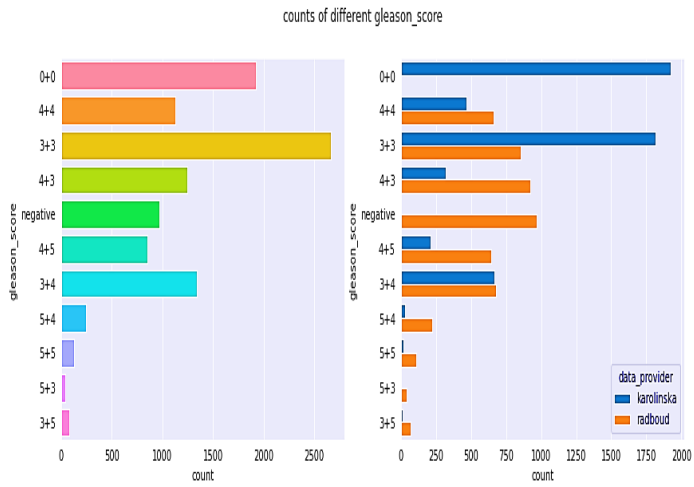

Fig. 2. Gleason score distribution.

Fig. 2 above explains how the Gleason count pairs are distributed in the dataset.

B. Dataset Analysis

We conducted a thorough statistical analysis to understand the dataset better. These statistics provide valuable insights for subsequent analysis and modeling.

	image_id	data_provider	isup_grade	gleason_score
0	0005f7aaab2800f6170c399693a96917	karolinska	0	0+0
1	000920ad0b612851f8e01bcc880d9b3d	karolinska	0	0+0
2	0018ae58b01bdadc8e347995b69f99aa	radboud	4	4+4
3	001c62abd11fa4b57bf7a6c603a11bb9	karolinska	4	4+4
4	001d865e65ef5d2579c190a0e0350d8f	karolinska	0	0+0

```
shape :  (10616, 4)
unique ids :  10616
unique data provider :  2
unique isup_grade(target) :  6
unique gleason_score :  11
```

Fig. 3. Train set analysis.

Fig. 3 visualizes the training set and its contents. The dataset was considered larger, with 10,616 unique images and the most diverse image. The data providers for this dataset were Karolinska and Radboud, so collaboration was indicated. The isup_grade column is our main target variable, defining a multiclass classification challenge in six distinct grades. Similarly, the gleason_score column, an alternative expression of cancer severity, introduces variability with 11 unique scores.

It is important to understand the contributions of each data provider's contributions: Karolinska and Radboud's contributions should be separate. The features should be compared to understand how much of their datasets contributed.

The relative frequency of the different grades of cancer is important. It would be subtly distributed across the dataset. Visualization techniques offer an alternative interpretation. A deeper analysis can be performed to discover more trends or correlations within different grades and with other variables. For example, one critical operation that needs to be undertaken before they all involves changing the "negative" entries in the gleason_score column to "0+0." Such uniform representation will help retain data consistency within the dataset, thus avoiding inconsistencies incurred by using different terminology in the same context.

C. Slide Image Characteristics

The following is the result obtained for slide image characteristics:

Dimensions: (9728, 29440)

Microns per pixel/pixel spacing: 0.486

Number of levels in the image: 3

Downsample factor per level: (1.0, 4.0, 16.0)

Dimensions of levels: ((9728, 29440), (2432, 7360), (608, 1840))

The above results give the following information:

1) Image dimensions and pixel spacing: The image's dimensions were precisely quantified, revealing a substantial image with dimensions (9728, 29440), indicative of a high-resolution dataset. The calculated pixel spacing, representing the physical distance per pixel, was approximately 0.486 microns. This information establishes a foundational link between digital representation and real-world measurements.

2) Multi-resolution hierarchy: The investigated image displays a hierarchical structure comprising three resolution levels. The downsample factors per level (1.0, 4.0, 16.0) signify a systematic reduction in resolution from the highest to the lowest level. This approach accommodates diverse analytical requirements, providing varying detail scales for nuanced exploration.

3) Dimensions of each resolution level: The dimensions of each resolution level further elucidate the intricate composition of the image. The highest resolution level (Level 0) retained dimensions of (9728, 29440). Subsequent levels demonstrated reduced dimensions due to downsampling, with Level 1 at (2432, 7360) and the lowest resolution level (Level 2) at (608, 1840). These dimensions serve as a roadmap for navigating through different levels of granularity in the image.

The revealed characteristics hold significant practical implications for medical image analysis. The substantial initial dimensions provide a detailed view, while the hierarchical resolution levels facilitate efficient exploration of diverse detail scales. The precise pixel spacing measurement ensures accurate correlations between digital and physical aspects, enriching the interpretability of the image in the context of prostate cancer assessment.

Our analysis of slide images included extracting dimensions, pixel spacing, levels, and down-sample factors. Scatter plots, like the one depicted in Fig. 4, were generated to visualize relationships between different image characteristics. Additionally, distribution plots in Fig. 5 were created better to understand the distribution of image sizes within the dataset.

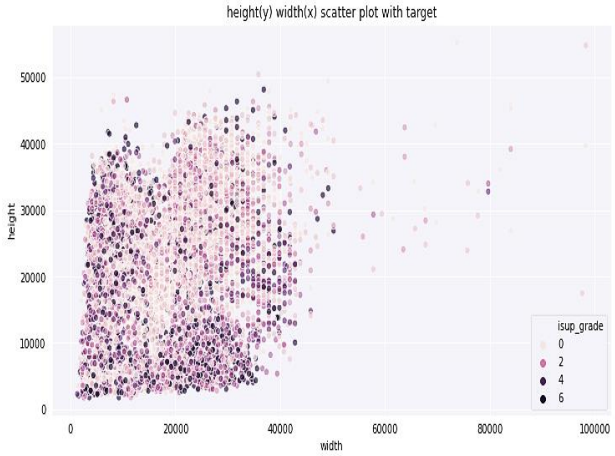

Fig. 4. Scatter plot of image characteristics.

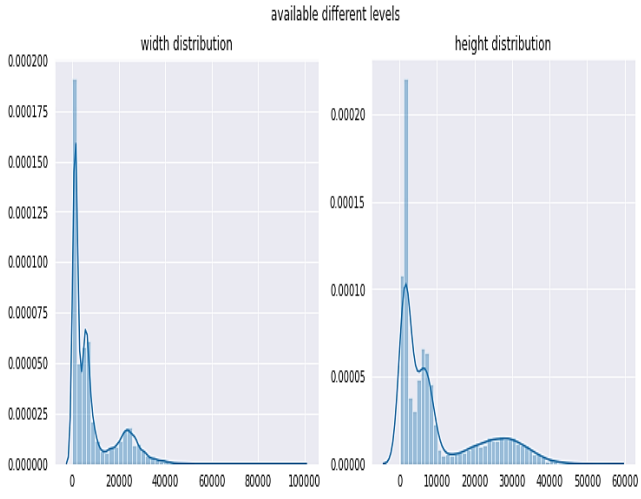

Fig. 5. Distribution plots of image dimensions.

D. Mask Processing and Visualization

The processing of mask images involved several essential steps, including confirming that the last two channels were empty and creating a background mask.

Fig. 6 displays visualizations of random samples of masks and background masks. The background prediction function played a crucial role in the analysis process.

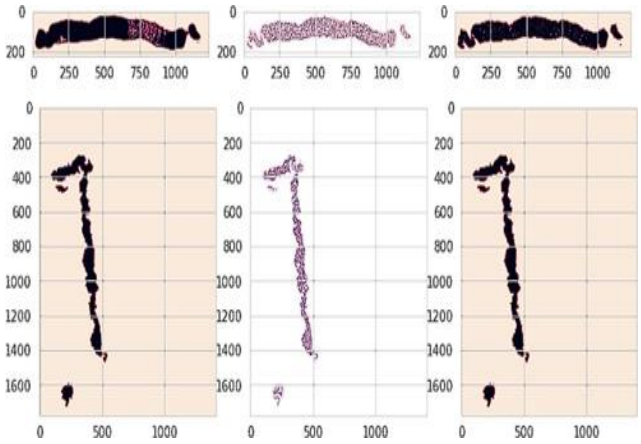

Fig. 6. Random samples of masks and background masks.

V. Discussion

The data preprocessing and analysis have enriched the critical qualitative views regarding the characteristics of the prostate cancer dataset, which led to the subsequent model development. Issues such as the number of unique image IDs, distribution of data providers, and target label ranges could be identified using quantitative analysis and visualization, allowing the researchers to understand the composition and the possible biases in the dataset better. The investigation reached statistical characteristics and emphasized the training set diversity and scale with 10,616 images from two providers. Classifying the images under two categories of isup_grade and gleason_score isup with 6 subgroups and 11 groups made it easy. Furthermore, the image quality features of the slide, such as high resolution, were investigated to achieve exact digital representation. The multiscale structure enabled the detailed exploration, increasing the correlation during preprocessing and identifying the skew. Mask processing techniques based on the background derivation facilitate data integrity control. These features are necessary for data analysis precision. In-depth research can play an important role in model construction and evaluation and also contribute to clinical image processing and diagnosing diseases via determining data characteristics, image properties, and mask-processing approaches. The presented data visualizations improve interpretability and present guidelines for future research, thus contributing to the exponential growth of the prostate cancer diagnostic and treatment process.

Nwaigwe, Ogbonna, and Oliwe (2022) [1] seek to address the statistical properties of Prostate Specific Antigen (PSA) with the understanding of PSA distribution being a crucial parameter for early detection. These outcomes indicate that for estimation of prostate size parameters, the Burr and Plasma inflammatory subpopulations may be the most suitable model, particularly between ages 45 and 50 years, where a Prostate Specific Antigen (PSA) level above 4nmol/l may be designated high level. On the other hand, Alkhateeb, Atikukke, and Rueda (2020) [2] analyze the machine learning approaches in prostate cancer diagnosis; the authors point out the possibility of using genomic analysis to design less invasive diagnostic tests effectively. The results of their study emphasize the significance of the machine learning approach in predicting clinical features of prostate cancer. These machine-learning models were built on gene expression and next-generation sequencing data. Pinckaers et al. (2021) introduce training streaming convolution neural networks conditionally over input images for prostate cancer detection on whole slide images, which is end-to-end training that yields no extra heuristics [4]. Their method makes it possible to have data sets with lots of labels from pathology reports quickly, thus improving the speed at which cancer diagnosis takes in other novel ways of cancer diagnosis (Automated image analysis). As described before, our research targets an in-depth data analysis process from the ground up, comprising preprocessing procedures, and in the end, brings up a better understanding of the prostate cancer dataset. We applied quantitative methods and visualization techniques to the data components, distribution of severity levels, and imagery parameters, which served as baselines for declaring subsequent model building and evaluation.

There are some drawbacks to the research. The main limitation of our study is that it is based on a single data set, which may not encompass the entire spectrum of prostate cancer cases. Moreover, with our strategy demonstrating great potential, we still need to establish more evidence for it by conducting further tests and validations in actual healthcare settings. In elaboration, machine learning algorithms' linkage to medical image analysis techniques would be one cause for confusion and challenges.

VI. Conclusion and Future Scope

Our detailed approach to data preprocessing and analysis has effectively readied medical slide images for integration with machine learning algorithms, providing a promising avenue for future research. Through comprehensive mask processing and gaining insights into dataset characteristics, we have laid a solid foundation for applying machine-learning techniques to diagnose medical conditions using these images. This study underscores the significance of thorough data preparation in advancing the field. It paves the way for the future application of this methodology in machine learning algorithms for healthcare diagnosis and analysis.

The future trajectory of our research involves ongoing refinement and enhancement of our methodology for prostate cancer detection, aligning rigorously with the scientific standards set by the academic community. To bolster the reliability and generalizability of our approach, we envisage incorporating more expansive datasets encompassing diverse populations for a comprehensive analysis. Collaborative engagements with medical institutions and pathologists are pivotal for the authentication of our findings in authentic clinical scenarios, ensuring practical relevance and facilitating valuable feedback integration. Furthermore, the optimization of

our methodology will be achieved through the judicious integration of state-of-the-art deep learning models with advanced image processing techniques. This includes the thoughtful incorporation of imaging data with clinical, genetic, or other omics data to achieve a nuanced and holistic understanding of prostate cancer. A concerted emphasis on augmenting the generalizability and robustness of our methodology is paramount, potentially paving the way for widespread adoption within clinical settings. Ethical considerations, such as the conscientious deployment of AI methodologies and the integration of transparent systems, are imperative to uphold ethical standards and ensure responsible applications of innovative technologies in healthcare. Our study lays a moral foundation for a future where our refined methodology significantly contributes to the early and precise diagnosis of prostate cancer, unwaveringly adhering to the exacting standards outlined by the scientific community.

***Abstract*—Examination and categorization of high-band pictures are used to describe the process of analysing and classifying photos that have been taken in many bands. Deep learning networks are known for their capacity to extract intricate information from images with a high bandwidth. The novelty lies in the integration of adaptive motion optimization, spectral-spatial transformer for categorization, and CNN-based feature extraction, enhancing high-band picture search efficiency and accuracy. The three primary parts of the technique are adaptive motion for optimization, spectral-spatial transformer for categorization, and CNN-based feature extraction. Initially, hierarchical characteristics from high-band pictures using a CNN. The CNN method enables precise feature representation and does a good job of matching the image's high and low features. This transformer module modifies the spectral and spatial properties of pictures intended for usage, enabling more careful categorization. This method performs better when processing complicated and variable picture data by integrating spectral and spatial information. Additionally, it is preferable to incorporate adaptive motion algorithms into offering the deep learning network training set. During training, this optimization technique dynamically modifies the motion parameter for quicker convergence and better generalization performance. The usefulness of the suggested strategy is demonstrated by researchers through numerous implementations on real-world high-band picture datasets. The challenges of hyperspectral imaging (HSI) classification, driven by high dimensionality and complex spectral-spatial relationships, demand innovative solutions. Current methodologies, including CNNs and transformer-based networks, suffer from resource demands and interpretability issues, necessitating exploration of combined approaches for enhanced accuracy. In high-band image evaluation and classification applications, the approach delivers state-of-the-art performance and python-implemented model has a 97.8% accuracy rate exceeding previous methods.**

Keywords*—Deep learning networks; Convolutional Neural Network (CNN); spectral-spatial transformer; adaptive motion optimization; high-band image analysis

I. Introduction

Hundreds of consecutive spectrum bands that have elevated resolutions make up the remotely sensed hyperspectral data that is gathered by hyperspectral sensors [1]. Hyperspectral images (HSIs) are being effectively utilized in precision farming, development, monitoring of the environment, and many other disciplines, according to recent research in the field of remote identifying. Among the common features of an HSI is its ability to capture high-resolution one-dimensional spectrum data that describes the physical property in addition to scenario data within the target image's two-dimensional space [2]. Numerous dimensionality reduction techniques are now being used with hyperspectral imagery. Existing approaches can be categorized in two classes based on how much the physical importance of the initial information has been preserved, extraction of features and choosing features (also known as band selection). Through combining several initial characteristics into a single feature, feature extraction finishes the transformation of the initial information from high-dimensional space to low-dimensional space. As everyone is aware, extraction of features works effectively for reducing dimensions, but because spectral architecture is destroyed, it is unable to preserve the physical meaning of each band [3]. The goal of band selection is to maximize given performance indices by selecting a band subset after the unique band set. Band selection, as opposed to feature extraction, can produce a band subset that more accurately captures the original data of the different types of land cover [4].The two main kinds of current band selection techniques are supervised band selection and unsupervised band selection, which involves the application of priori-label data. A great deal of label details is typically needed for supervised band selection, yet in most instances, getting labels for hyperspectral data can be exceedingly challenging [5]. Thus, uncontrolled remote sensing encompasses the majority of current effort. To be more precise, there are three types of current unsupervised band selection techniques: clustering-based, heuristics search-based, and ranking-based [6].

Choosing the type of data has an important effect on the outcomes in the feature classification area. Not every band in the hyperspectral photo has data; certain bands, such as ones impacted by different atmospheric conditions, are meaningless and reduce the efficacy of the classification. Additionally, redundant bands are present, which might impede the process of learning and lead to inaccurate predictions [7]. If the size of space pictures becomes so great it takes numerous instances to identify the connections among each band to the scene, even those bands, which carry sufficient information regarding the situation, might not be able to accurately forecast the categories .The findings in the field of features categorization are greatly affected by the kind of data selected. Each of the

groups in the hyperspectral image have data; certain bands are useless and lessen the effectiveness of the classification, which include those affected by various conditions in the atmosphere [8]. Furthermore, duplicate bands exist, which could hinder training and result in wrong projections. When space photos are so big that it requires multiple views to discern the relationships between every band as well as the scene, especially bands that contain sufficient details about the circumstances aren't always able to predict the category with any degree of accuracy (Hughes phenomenon). With the goal to reflect the initial hyperspectral data contained in the raw data, the choice of features algorithms seek to choose an appropriate amount of spectral band information [9]. The goal of feature extraction techniques, as opposed to feature selection techniques, is to use the unprocessed information to create an entirely novel low-dimension descriptors. Like previously said, selecting features techniques outperform extraction of features techniques within the subsequent area. Hyperspectral analysis of images needs entire unprocessed information from the spectrum bands whenever extraction of features techniques is used. When compared with feature extraction techniques, methods for selecting features only use a portion of the raw data's spectrum bands, and by employing those chosen bands rather than every one of the originally selected bands, the expense of acquiring hyperspectral information is further decreased [10].

Even while such methods can yield positive outcomes, the modification of HSIs data can occasionally destroy crucial details, resulting in data degradation. As such, these techniques are not necessarily the best options for reducing dimensionality as compared to conventional band selection procedures. Regarding the band selection approach, given the initial band space of the HSIs, the one that is most useful and unique band subgroup is selected by itself [11]. In a nutshell, the searching method and the assessment of the criteria function are both of the main components of band selection technologies. Although the latter assesses an evaluation for every band subset chosen using the initial selection of bands using a suitable criteria function, the earlier method uses an effective search technique to find an especially prejudiced band subset out of all possible subsets [12].Finding the most effective spectrum combination among all band possibilities might occur at a very high computational expense. Using algorithms to haphazardly hunt for the minimal reduction was a different approach. The two types of band selection techniques that are now in use include supervised band selection and unsupervised band selection [13]. The training information for the previous method must be labelled. It appears that the majority of the time there's a lack of labelled information accessible, which raises the significance of unsupervised band selection for implementations. A new and efficient technique for hyperspectral band selection is presented by the clustering-based techniques. Nonetheless, the primary challenge in the hyperspectral band selecting process is determining whether to determine the separation among the bands and how to choose relevant bands [14].

High-band visuals are essential for environmental monitoring and precision farming, but they can be difficult to interpret because of their redundant bands and complexity. Conventional methods such as band selection and feature extraction are not as good at successfully lowering dimensionality while maintaining spectral information. This research presents a novel method to improve high-band picture processing using spectral-spatial transformers, deep learning networks, and adaptive motion optimization. This methodology seeks to achieve much better classification accuracy than current approaches by merging spectral and geographical data. Real-world applications confirm its effectiveness, employing a Python-based model to achieve accuracy rate. This work offers useful solutions for remote sensing applications and related sectors, making a significant contribution to the advancement of high-band image processing.

Key contributions are as follows,

- Novel integration of convolutional neural networks for hierarchical feature extraction from high-band pictures, enhancing categorization precision and knowledge.
- Introduction of a spectral-spatial converter, augmenting categorization accuracy by leveraging both spectral and spatial information.
- Implementation of adaptive motion algorithms to improve generalization performance and convergence speed, advancing efficiency in image processing.
- Demonstrates state-of-the-art capabilities in image processing and categorization, surpassing existing techniques in precision and computational effectiveness.
- Addresses limitations of conventional approaches, propelling forward the field of remote sensing image analysis, with potential applications in agriculture, urban planning, and environmental monitoring.

The remaining section of this work is structured as follows: Section II covers similar work and a full evaluation of it. Section III offers details on the problem statement. Section IV provides a detailed discussion of the suggested method. Section V presents and examines the results of the tests, as well as a comprehensive comparison of the proposed technique to current standard procedures. Section VI, the last section, represents where the paper is finished.

II. Related Works

Bera and Shrivastava [15] suggest that owing to the special qualities of HSI data, HIS organization is unique of the most difficult tasks in the hyperspectral remote sensing sector. This is made up of a huge amount of bands that exhibit robust interactions in both the spatially and spectrum realms. In addition, it becomes challenging with fewer training examples. To try to tackle these issues, researchers developed a deep convolutional neural network (CNN) based spatially extraction of features method for HSI classification below. They demonstrated the impact of seven distinct optimizers on the deep neural network model through the field of classification using HSI since optimization techniques are crucial for the deep CNN model's development. The study employed seven distinct optimization techniques, the better performance of the deep CNN algorithm using the the Adam optimizer for HSI classification was demonstrated by

comprehensive research results on four hyperspectral remote sensing data sets. This endeavour will eventually compare the effectiveness of several optimization techniques classification include increased computational complexity due to processing volumetric data, which may require substantial computational resources and time for training and inference. Features in 3D CNNs may be challenging compared to 2D CNNs, making it harder to understand how the model. The limitations of employing 3D CNN models for hyperspectral image (HSI) classification include increased computational complexity due to processing volumetric data, which may require substantial computational resources and time for training and inference. Additionally, the interpretability of the learned features in 3D CNNs may be challenging compared to 2D CNNs, making it harder to understand how the model is making decisions based on both spectral and spatial information.

Hong et al. [16] explains that the ability to capture tiny spectrum variations, hyperspectral (HS) images allow for accurate recognition of substances. They have been defined by roughly contiguous spectral data. Convolutional neural networks (CNNs) have demonstrated their outstanding capacity for analysing locally contextual data, making them a potent feature extractor in high-spatiality picture categorization. Yet, because of the constraints of their built-in network backbone, CNNs are unable to efficiently extract and record the ordered properties of spectrum signatures. They suggest a unique backbone network named Spectral Former or approach HS image classification via a sequence viewpoint using transformers to address this problem. Spectral Former can acquire spectral localized sequence data from adjacent bands of high-spatiality pictures, going above band-wise depictions seen in traditional transformers, or producing group-wise spectral embedded data. Additionally, researchers develop a cross-layer skip link by continually acquiring the ability to fuse "soft" residues between layers, therefore minimizing the risk of missing crucial data during the layer-wise propagating procedure. This allows researchers to transfer memory-like elements through shallow to deep layers. It is important to note that what was suggested Spectral Former is a very adaptable backbone networks which may be used with input which are patch- or pixel-wise. Through comprehensive trials, researchers assess the suggested Spectral Former's ability to classify on three HS datasets, demonstrating its advantages beyond traditional transformer and attaining significant improvements above state-of-the-art backbone networking. To continue to make the transformers-based design more useful for the HS image classification task, it will look into ways to further improve the system in the future. For instance, they may use attention or autonomous learning. It may also try to create a lightweight transformers-based networks in order to lower the network's complexity without sacrificing effectiveness. To create deeper models that are easier to understand, researchers are also interested to incorporate additional spectral band physical properties and previous understanding about HS pictures into the suggested structure. Further study ought to concentrate on increasing the amount of ignored and linked encoders in the CAF module since it is a significant factor that might potentially improve the suggested Spectral Former's classification accuracy.

Hong et al. [17] states that because convolutional neural networks (CNNs) can record spatial-spectral feature representations, they have gained significant interest in the field of hyperspectral (HS) picture categorization. However, they are still not very good at modelling connections among samples and evaluation, going above the constraints of grid sampling. Throughout this research, researchers conduct a detailed both qualitative and quantitative investigation on CNNs and GCNs with respect to HS image classification. Traditional GCNs are typically quite computationally expensive because they need building an adjacency matrix for each of information, especially for large-scale remote sensing (RS) situations. To accomplish that, researchers create a novel mini-batch GCN (henceforth referred to as miniGCN) that enables mini-batch training of large-scale GCNs. Additionally, this miniGCN can improve the ability to classify and infer information from data that is not sampled with no re-training networks. Moreover, fusing CNNs and GCNs is a natural way to overcome a single model's effectiveness barrier because they may retrieve distinct kind's unique HS features. because miniGCNs may execute batch-wise training of networks (allowing the integration of CNNs and GCNs). Comprehensive tests, carried out on three HS datasets, show that miniGCNs are superior to GCNs and that the tried fusion procedures outperform the single CNN or GCN models. In the years to come, to fully utilize the rich spectrum information found in high-resolution photos, researchers will explore the potential combinations of various deep neural networks with the miniGCNs as well as create more sophisticated fusion modules, such as balanced fusion.

Roy et al. [18] suggest that because of numerous contiguous narrowband built on top of one another, hyperspectral images (HSIs) offer extensive spectral-spatial data. The decision-making process of useful spectral-spatial kernel features can be challenging because of band correlations and disturbance. CNN using fixed-size receptive fields (RFs) are frequently used to overcome issue. Forward and reverse propagations are employed to maximize the network's performance, these techniques cannot allow neurons to efficiently modify RF sizes and cross-channel connections. In order to collect discriminatory spectrum-spatial characteristics for the classification of HSI using an entire training way, researchers describe within this paper an attention-based adaptable spectrum-spatial kernel enhanced residual networks (A2S2K-ResNet) using spectrum focus. Specifically, the suggested network employs a successful feature recalibration (EFR) strategy to enhance the accuracy of classification and trains specific 3-D convolutional kernels in order to simultaneously retrieve spectral–spatial characteristics utilizing enhanced 3-D ResBlocks. In comparison to the current approaches under investigation, , the suggested A2S2K-ResNet tackles the problem of choosing useful spectral-spatial kernel features in hyperspectral image classification. However, significant sensitivity to hyper parameters adjustment and computing burden throughout training could be constraints.

Fu et al. [19] discusses that, since hyperspectral imagery (HSI) contains a wealth of spectrum and spatial information, an entirely novel principal component evaluation (PCA) and

segmented-PCA (SPCA)-based multiscale 2-D-singular spectrum analysis (2-D-SSA) combining look at is offered for paired spectrum–spatial HSI extraction of features as well as grouping. At first, the overall spectrum of the items and the relationships between nearby bands are all taken into consideration when applying the PCA and SPCA methods for dimensional spectra reductions. After extracting a wealth of spatial characteristics at various scales from the SPCA dimension-reduced visuals, multiscale 2-D-SSA is used, and PCA is utilized once more to decrease the number of dimensions. Multiscale spectrum–spatial features (MSF-PCs) are created by fusing the acquired multiscale spatial characteristics into the world spectral characteristics obtained by PCA. The support vector machine (SVM) classification is used to assess the obtained MSF-PCs' performance. Tests conducted on four standard HSI data sets showed that, in situations whenever a limited quantity of sample training specimens are accessible, the suggested technique works better than other cutting-edge feature extraction techniques, such as multiple deep learning techniques. Super pixel-alike segmentation may be used in subsequent research to increase the effectiveness of the suggested strategy.

Uddin, Mamun, and Hossain [20] explains along narrow spectral wavelength ranges are employed to capture the hyperspectral remote sensing pictures (HSIs), which are intended to record the most important details of terrestrial objects. Regarding real-world uses, classification accuracy is frequently not cost-effectively acceptable when utilizing the complete original HSI. Band reduction strategies—which may be further subdivided into extraction of features and feature selection methods—are used to improve the classification outcome of high-strength images. The linear unsupervised statistical transformation known as Principal Component Analysis, or PCA, is often used for obtaining characteristics from HSIs. In this article, nonlinear variations of PCA such as Kernel Entropy Component Analysis (KECA) and Kernel-PCA (KPCA) are being studied alongside linear variations. For this aim, KECA uses Renyi quadratic entropy measurement The research study shows that methods for extracting features may be better in classification than utilizing the complete original dataset, even though they are more expensive. While FPCA provides a decent categorization outcome using the least amount of time and space complexity, MNF delivers the best precision in classifying. Future evaluations of the aforementioned PCA-based feature extraction techniques may lead to the proposal of certain likely hybrids techniques, including fusing MNF with SPCA and SSPCA in a manner that executes traditional MNF in place of PCA in SPCA and SSPCA. Additionally, PCA-based methods for extracting features may be used in conjunction with additional information mining techniques like deep extraction of features and spectral-spatial feature extraction to analyse

Researchers have proposed various approaches to address the challenges of hyperspectral image (HSI) classification. One approach involves the use of deep convolutional neural networks (CNNs) with different optimization techniques to extract spatial features efficiently. Another method utilizes transformers, such as the Spectral Former, to capture spectral features sequentially, achieving significant improvements in classification accuracy. Additionally, graph convolutional networks (GCNs) and their fusion with CNNs have been explored to model connections among samples, with miniGCNs demonstrating superior performance. Attention-based adaptable spectrum-spatial kernel enhanced residual networks (A2S2K-ResNet) have been introduced to capture discriminatory spectrum-spatial characteristics effectively. Furthermore, a PCA-based multiscale 2-D-singular spectrum analysis fusion approach has been proposed for feature extraction and classification, showing promising results, particularly in scenarios with limited training samples. Overall, these approaches aim to enhance classification accuracy by leveraging spectral and spatial information effectively while addressing computational complexities and interpretability challenges.

III. Problem Statement

Due to the unique properties of hyperspectral imaging (HSI) data, such as the high dimensionality of spectral bands and the intricate relationships between spectral and spatial information, the area of HSI classification faces several difficulties [19] [15]. To overcome these obstacles and increase classification accuracy, researchers have looked at a number of methodologies, such as deep convolutional neural networks (CNNs), transformer-based networks, attention processes, and fusion procedures [17]. All approaches, however, have their drawbacks, including the requirement for significant processing resources, interpretability problems, sensitivity to hyperparameters, and computational complexity. Furthermore, a key factor in classification effectiveness is the selection of feature extraction methods, such as Principal Component Analysis (PCA) including its nonlinear variants. To create better HSI classification solutions, further study is required to examine combination methods and incorporate them alongside other information mining techniques, even if these techniques show promise for improving classification accuracy.

IV. Proposed Spectral-Spatial CNN with Adaptive Momentum for High Band Image Classification

The proposed Spectral-Spatial CNN with Adaptive Momentum integrates spectral and spatial features for high-band image classification, leveraging adaptive momentum optimization for efficient training and improved performance. This method aims to enhance high-bandwidth image analysis and classification using deep learning techniques. It uses Convolutional Neural Networks (CNNs) for feature extraction, incorporates spectral spatial transformer to capture both spectral and spatial information Furthermore, it uses Adaptive Momentum Optimization Algorithm to enhance the training algorithm to improve performance and efficiency. Overall, this technique optimizes the type of excessive-bandwidth pictures through advanced feature extraction and green optimization strategies. Proposed method framework is shown in Fig. 1.

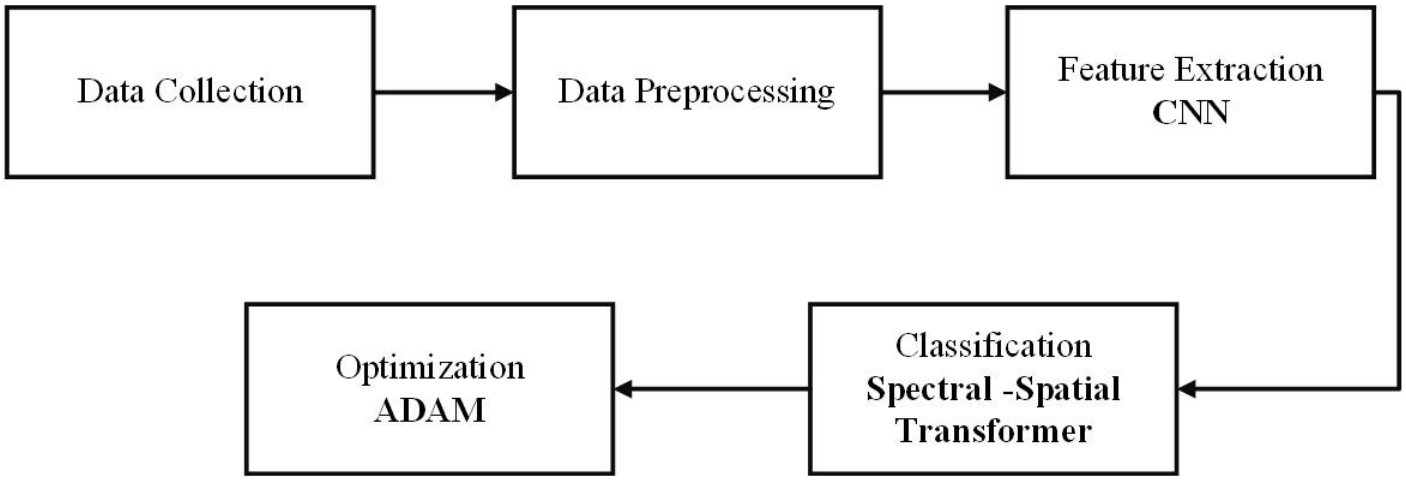

Fig. 1. Proposed spectral-spatial CNN with adaptive momentum for high band image classification.

A. Data Collection

The initial high-resolution images were taken in 1992 over North-Western Indiana, USA, utilizing the Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) sensors. The HS images possesses 145 145 pixels during an average ground sampled distances (GSD) of 20 m and 220 spectral bands having a 10 m spectroscopic resolution, covering its wavelength range of 400 nm to 2500 nm. There are 200 spectral bands remaining, or 1–103, 109–149, and 1642–219, after 20 noise and water absorption bands are uninvolved.16 important groupings in the region beneath investigation were recently looked at. Table II provides a listing of this class names & overall quantity of samples utilized throughout this classifying activity for assessment and training. The geographic distribution of both training and testing sets is shown as well, which helps to duplicate the grouping results [17].

B. Data Pre-processing

Gathering information is a significant step in ensuring that the information is reliable and ready for machine learning analysis. It involves several stages, including Noise Reduction, Data Normalization

1) Noise reduction: Applying filters or denoising techniques to mitigate noise introduced during image acquisition or transmission.

2) Data normalization: Normalization is used to convert data to a similar scale and avoid characteristics with higher values from dominating the study. The following normalization approaches were used:

a) Min-max scaling and z-score standardisation: Min-Max Scaling converts attribute values to a constant scale from 0 to 1, making them comparable. By subtracting the lowest value and dividing by space, it ensures consistency regardless of the original size of the objects. This approach is important for algorithms that are sensitive to input quantities, promoting fair representation in variables. It is especially convenient when dealing with different units or heterogeneous ranges in a data set. To ease convergence, many models' data was normalized to 0 as a mean and 1 as a standard deviation [21].

C. CNN-based Feature Extraction

Comparing to the preceding AlexNet model, VGGNet is a straightforward but efficient model that takes into account the amount of depth of suitable layers without adding additional parameters overall. Consequently, they employed structure akin to VGG. Thirteen layers of convolution and three fully linked layers make up the original VGG's sixteen layers. CNN-Based HSI Spatial Feature Extraction for Every 2.1 The BN layer and Relook operations come between the fourth of the 22 convolutional layers that are used, while the maximal pooling layer is introduced between the third, fourth, seventh, tenth, and thirteenth convolutional layers. CNN is frequently used for applications involving image processing including segmentation, identification, and classifications because of its powerful ability to extract spatial properties from images. For HSI, it has a plethora of spatial information. With CNN, the current study effectively isolates the spatial components of HSI.CNN has many different types of architecture.

Comparing to the preceding Alex Net model, VGGNet is a straightforward but efficient approach that takes into account the size of suitable layers without adding additional variables overall. Consequently, they employed design similar to VGG. Thirteen convolutional layers and three fully linked layers make up the original VGG's sixteen layers. CNN-Based HSI Spatial Feature Extraction for Each 2.1 the BN layer and ReLU operations come between the fourth of the 22 convolutional layers, while the maximum pooling layer is introduced between the subsequent, fourthly, seventh place, a tenth and thirteenth layers of convolution.

It's possible that using all 16 layers isn't the best option for extracting HSI spatial features. The way due to its strong capacity for obtaining spatial characteristics from images, CNN is frequently employed for image processing tasks like segmentation, identification, and classifying. It provides a wealth of geographic data for HSI. This study successfully extracts the spatial components of HSI using CNN. Creating an appropriate CNN framework is essential to creating an effective HSI classification. In the experimentation section, researchers created a deep CNN that is similar to VGG for extracting HSI spatial characteristics. The extracted features

from the CNN are then utilized for subsequent processing steps, such as classification. After CNN processes HSI data and extracts features, these features are used in subsequent processing steps such as classification. These extracted features represent the spatial patterns learned by CNN during the training process. Information on the spatial distribution of various features of the HSI data was recorded. Using these features, the subsequent classification algorithm can make a more informed decision about the class labels in the different regions of the HSI, using the spatial information encoded in the features extracted by the CNN has been used [22].

D. Spectral-Spatial Transformer for Classification

The CNN output is handled and sent into a Transformer encoder for band categorization in hyperspectral imaging (HSI). CNN uses a local connection in order to extract adjacent properties from the inputs. HSI often has multiple bands. As a result, CNN finds it challenging to acquire spectrum associations across great distances. The association between each pair of band is obtained through the self-attention process. For instance, there are 224 bands in the Airborne Visible/Infrared Imaging Spectrometer (AVIRIS). During the process of learning, a matrix in a form of 224 224 may be generated via attention to oneself. The connection among both bands is represented by every component within the matrix.

The Transformer encoder, the central component of this concept, is the additional component. There are d encoding units in the Transformers encoder, and CNN employs local connections for every encoding unit to obtain nearby characteristics from inputs. Since HSI typically has numerous bands, this is challenging for CNN to determine spectral correlations over great distances. The connection between each pair of band can be obtained by the attention to oneself process. For instance, there are 224 bands in the Airborne Visible/Infrared Image Spectrometer (AVIRIS). During the method of learning, a 224 × 224 matrix may be created via self-attention. The connection among the two bands is represented by every component in the matrix. Comprises of an MLP layer, multi-head attention, layer normalization, and residue connections. Prior to every multi-head focused MLP layer in every encoding block, a normalization level is included and additional connections are planned following each of these layers.

Let n denote model, wherein HS1 ($b'_1, b'_2, \ldots \ldots b'_n,$)dimensionality of the CNN-extracted features, represent the number of n bands of The Transformer's encoder encodes every band as a function of the overall contextual data with the goal of capturing the interactions between all n bands of HSI. In particular, three accessible weighting matrices have been identified: queries (Q), values (V) of dimension dv, and keys (K) of dimension dk. The search query containing all keys is computed using the dot products, and the weights that are placed for each value are subsequently calculated using the function known as softmax. The following is the definition of attention's output is given in Eq. (1)

$$Attention(q,k,v) = softmax(\frac{qk^t}{\sqrt{d'_k}})\,\mathrm{V}, \quad (1)$$

where, d'_k is the dimension of K.

Projecting the questions, keys, and values multiple times (h times) using distinct and learned projection is advantageous. The outcomes were then combined. This call this method attention in multiple heads. A head is the name given to every outcome of those concurrent attentional calculations is given in Eq. (2)

$$multihead(q,k,v) = concat(head_1,\ldots\ldots,head_h)w^{o\prime} \quad (2)$$

The values of the weights the fact that are obtained through the multi-head attention system are then sent to the MLP layer, resulting in 512-dimensional production features. In this case, MLP is made up of two layers that are completely interconnected that have a nonlinearity called the Gaussian error linear unit (GELU) stimulation among it. The ReLU variant known as GELU is described as Eq.. (3)

$$GELU = x'\Phi(x') = x'.\frac{1}{2}[1+\mathrm{erf}(x'/\sqrt{2})] \quad (3)$$

where, $\Phi(x')$designates the normal Gaussian cumulative distribution function, erf(x') =$\int_0^{x'} e'^{-t'^2}$dt

There is usually a normalization layer preceding the MLP layer that additionally normalizes neurons to shorten the duration of training but additionally solves the disappearing or expanding gradients issue. The normalization of the layer, represented by Eq. (4)

$$\mathrm{a}:a'^{-l}_I=\frac{g'^l}{\sigma^l}.(a_i^{-l}-\mu^l)+\mathrm{b}' \quad (4)$$

where in is the normalized total of the input, and l and l stand for the corresponding expectations and variances at the lth layer. The learnt shifting parameter is denoted by b, and the newly acquired scaling factor by gl. [23].Spectral-Spatial CNN Architecture is shown in Fig. 2.

E. ADAM Optimization

The adaptive learning rate for each parameter used in the gradient-based training process is estimated by the Adaptive Momentum (Adam) method. This is an extremely basic and highly computationally effective method for stochastic optimization which requires limited storage and incorporates first-order gradients. The suggested method is applied to high-dimensional parameter space machine learning problems using large data sets that compute the rate of learning for different parameters separately of assumptions such as initial and second-order aspects. The Adam form of mathematics is as the following Eq. (5) to Eq. (8)

$$y_t=\delta'_1\times y_{t-1}-(1-\delta'_1)\times h_t \quad (5)$$

$$x_t=\delta'_2\times x_{t-1}-(1-\delta'_1)\times {h_t}^2 \quad (6)$$

$$\Delta_{w't}=-\eta'\frac{y_t}{\sqrt{x_{t+\epsilon}}}\times h_t \quad (7)$$

$$w_{t+1}=w_1+\Delta w_t \quad (8)$$

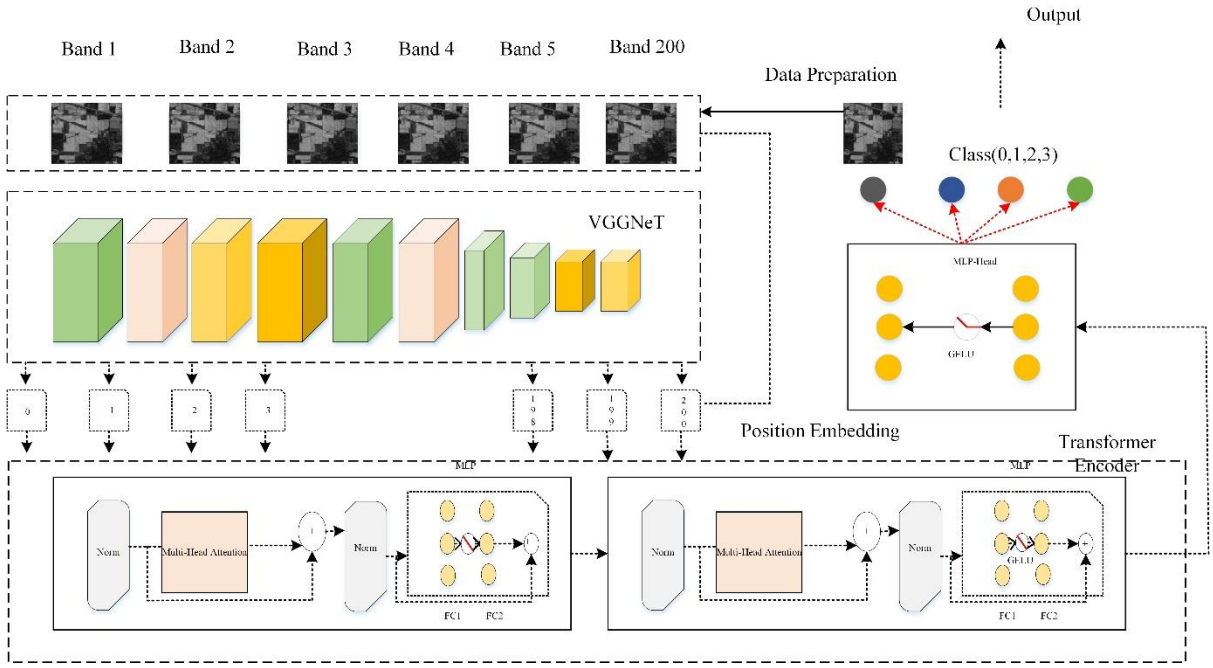

Fig. 2. Spectral-spatial CNN architecture.

where,

η: Preliminary learning rate

h_t: Gradient at time t along h

y_t: Exponential average of gradient along y_t

x_t:Exponential average of squares of gradient along x_t

δ'_1, δ'_2Hyperparameters.

Adam optimizer lowers the overall computing cost, uses fewer resources for execution, and maintains its invariance when gradients are rescaled diagonally. Large data sets, hyper parameters, noisy data, insufficient gradients, and irregular problems requiring minor tweaking are just some of the challenges this resolves. Alpha is the setup parameter for Adam. This is a learning rate or step size; an elevated number (e.g., 0.3) is probably employed because it enables rapid acquisition rather than a lower value and produces flawless results while training.

V. Result and Discussions

In the study, a conducted extensive experiment on real-world high-band picture samples to assess the suggested method's efficacy. The results demonstrate that the method outperforms existing methods in terms of accuracy and performance in high-band image analysis and classification tasks. Specifically, the method achieved state-of-the-art results by leveraging three main components: CNN-based feature extraction, spectral-spatial transformer for classification, and adaptive motion for optimization. Through the use of a convolutional neural network (CNN), it successfully extracted hierarchical features from high-band images, capturing both low and high-level features for detailed representation. Additionally, the incorporation of a spectral-spatial transformer module facilitated more judicious classification by considering both spectral and spatial characteristics of the images. Furthermore, the introduction of adaptive motion algorithms improved the training process of the deep learning network, leading to faster convergence and enhanced generalization performance. Overall, the research contributes to the advancement of remote sensing image analysis by providing a robust framework that enables deep learning networks to optimize classification accuracy and performance for high-band images. Table I represents Classes from the Indian Pines Dataset for every class.

TABLE I. Classes from the Indian Pines Dataset for every class

Class No	Class Name	Training	Testing
1	Grass Pasture	40	1453
2	Oats	40	434
3	Wheat	40	456
4	Corn	20	76
5	Soybean Clean	20	543
5	Grass Trees	10	34
7	Soybean Notill	10	45

Table I presents the classes from the Indian Pines dataset along with their corresponding training and testing sample sizes. The dataset comprises six classes: Grass Pasture, Oats, Wheat, Corn, Soybean Clean, and GrassTrees. Each class is assigned a unique class number, and the table details the number of samples allocated for training and testing within each class. For instance, the GrassPasture class has 40 samples for training and 1453 samples for testing, while the GrassTrees class has 10 samples for training and 34 samples for testing. This information provides a breakdown of the dataset's composition, aiding researchers in understanding the

distribution of classes and sample sizes for model training and evaluation.

Taking into account the amount of band used, Fig. 3 displays the Indian Pines dataset's overall precision. The total amount of bands is shown by the X-axis, whereas the overall accuracy ratio is shown by the Y-axis. The diagram shows that accuracy increases as the number of bands grows, but after reaching around five bands, further additions yield diminishing returns while adding more bands initially leads to significant improvements in accuracy, there comes a point where the marginal benefit of additional bands becomes negligible, and further additions may not significantly enhance the complete performance of the classification archetypal.

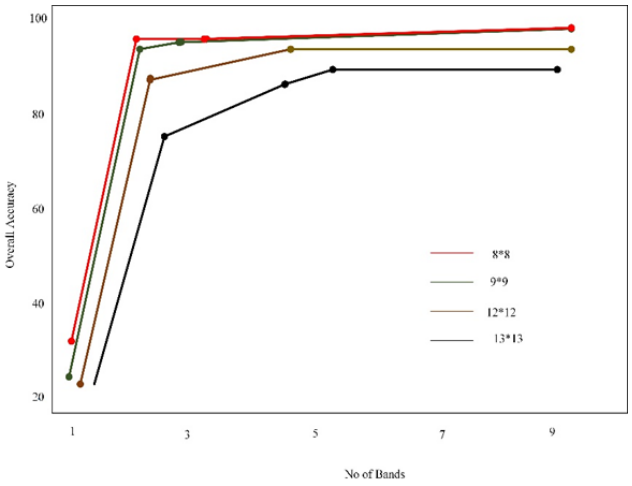

Fig. 3. Overall accuracy of the Indian pines.

Fig. 4 demonstrates the percentage of samples utilized across three distinct datasets: Pavia, Indian Pines, and Houston 2013. It highlights that as the percentage of samples used upsurges, the complete accuracy tends to rise for all datasets. However, each dataset exhibits unique characteristics, resulting in varying rates of accuracy improvement. Pavia dataset shows a steady increase in accuracy with sample percentage, while Indian Pines initially demonstrates rapid gains followed by a plateau, and Houston 2013 exhibits a more gradual increase. These nuances emphasize the importance of dataset-specific considerations when determining the optimal sample size for achieving maximum accuracy in classification tasks.

Fig. 5 illustrates the convergence behaviour of the Adam optimization algorithm over iterations during the training of a machine learning model. Initially, the loss decreases rapidly as the algorithm adjusts the model parameters using adaptive learning rates and momentum. As training progresses, the rate of improvement slows down, indicating convergence towards a minimum point. The graph may exhibit fluctuations due to the adaptive nature of the algorithm, but overall, it demonstrates a consistent decrease in loss over time. The stability and efficiency of Adam optimization make it a popular choice for training deep neural networks. The X-axis represents the steps or iterations in the optimization process, ranging from -1 to 3, while the Y-axis indicates the value of the loss function, ranging from 3.0 to 8.0. This graph depicts how Adam Optimization efficiently navigates through the loss landscape, with blue dots indicating specific points on its path, demonstrating its effectiveness in finding optimal solutions in machine learning model.

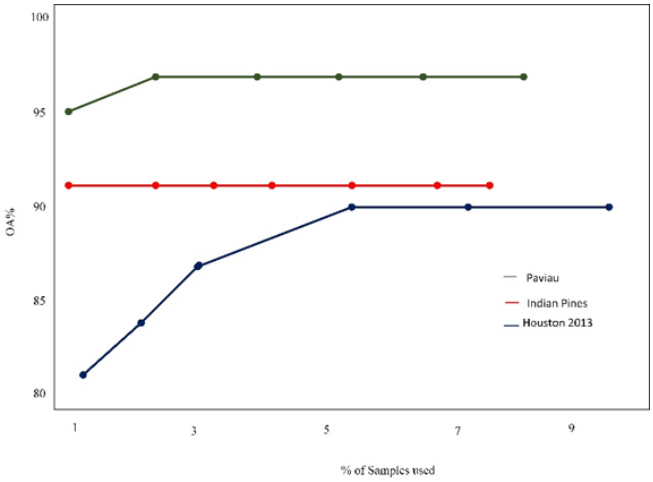

Fig. 4. Samples utilized across three distinct datasets.

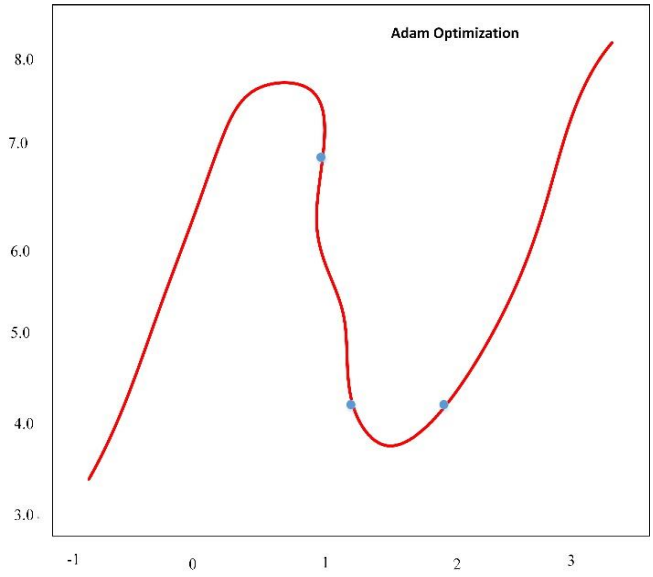

Fig. 5. ADAM optimizer.

Fig. 6 visually signifies the performance of a model during training and evaluation. The x-axis typically indicates epochs or iterations, while the y-axis represents the loss metric. As training progresses, the training loss typically decreases, indicating improved model fit to the training data. Meanwhile, the testing loss, often evaluated on a separate validation set, can help assess generalization performance; ideally, it should decrease initially but stabilize or increase if overfitting occurs, forming distinct patterns aiding in model diagnosis and optimization.

The Receiver Operating Characteristic (ROC) curve is shown in Fig. 7. It serves as an illustration depiction of a binary classification algorithm's effectiveness. Plotting the False Positive Rate (1 - Specificity) versus the True Positive Rate (Sensitivity) at various thresholds is what it does. A ROC

curve which approaches the top-left region of the chart, signifying a high degree of sensitivity along with a small positive error rate, suggests an ideal classifier. Greater values for AUC indicate improved class discrimination. The region underneath the ROC curve (AUC) measures the classifier's overall efficacy. When it comes to the compromise among the two qualities in tasks involving classification, ROC modelling offers insightful information.

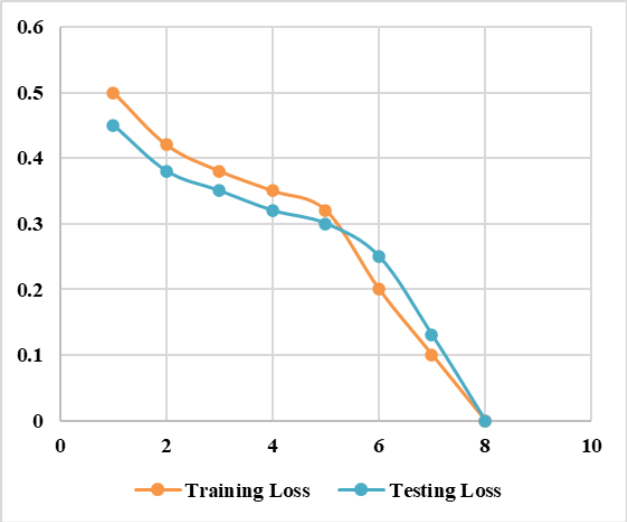

Fig. 6. Training loss and testing loss.

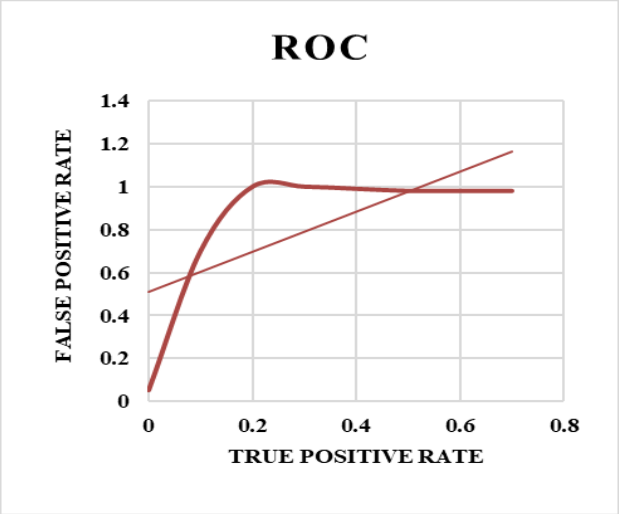

Fig. 7. ROC curve.

Table II compares the performance of various methods in high-band image classification, focusing on accuracy, precision, recall, and F1 score metrics. The Convolutional Neural Network (CNN) achieves 85.77% accuracy, with precision, recall, and F1 score values of 75.87%, 86.09%, and 82%, respectively. The Generative Adversarial Network (GAN) demonstrates superior performance, achieving 97.75% accuracy, with precision, recall, and F1 score values of 90%, 98%, and 95.98%, respectively. The Spectral-Spatial CNN method combines spectral and spatial information, resulting in 95% accuracy, with precision, recall, and F1 score values of 88.56%, 97%, and 95%, respectively.

TABLE II. PERFORMANCE PARAMETERS OF DIFFERENT CLASSIFICATION METHODS

Method	Accuracy	Precision	Recall	F1score
CNN	85.77	75.87	86.09	82
GAN	97.75	90	98	95.98
Spectral-Spatial CNN	95	88.56	97	95
Proposed Spectral-Spatial CNN WITH ADAM	97.8	97	96.8	98

The proposed Spectral-Spatial CNN with ADAM optimization achieves the highest performance, with an accuracy of 97.8%, precision of 97%, recall of 96.8%, and an outstanding F1 score of 98%. These results underscore the efficacy of the proposed approach in high-band image classification, suggesting its suitability for practical applications as shown in Fig. 8.

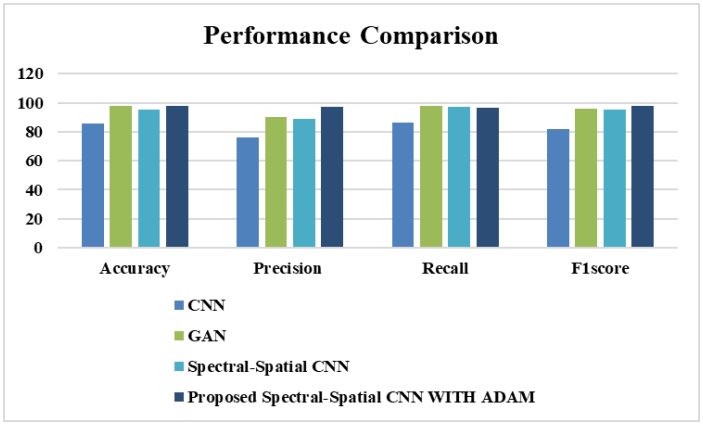

Fig. 8. The performance comparison of different classification methods.

The study explores the effectiveness of a proposed method for high-band image analysis in remote sensing applications. The method significantly outperforms existing methods, achieving state-of-the-art results in accuracy and performance. The approach utilizes CNNs for feature extraction, capturing hierarchical features and improving classification accuracy. The introduction of a spectral-spatial transformer module enhances classification performance by considering both spectral and spatial features. This module enhances robustness and adaptability in processing complex and varied image data sets. Additionally, adaptive motion algorithms optimize the training process of the deep learning network, achieving faster convergence and improved generalization performance. This strategy is highly effective in scenarios where training data may be diverse or noisy. The study contributes to the advancement of remote sensing image analysis by providing a comprehensive framework that integrates state-of-the-art techniques in deep learning and optimization. Future research may explore additional refinements and extensions to the proposed method, such as integrating multi-modal data sources or incorporating additional optimization techniques. This will further enhance the capabilities of image analysis systems for remote sensing and related domains, enabling more accurate and efficient analysis of Earth observation data [15].

VI. Conclusion and Future work

The method for high-band image analysis and classification exhibits promising efficiency and accuracy, leveraging a combination of spectral-spatial transformer, CNN-based feature extraction, and adaptive momentum optimization. By integrating deep learning techniques and optimization algorithms, this framework effectively captures both spatial and spectral data, leading to improved classification accuracy. The flexible momentum optimization approach further enhances the training process by dynamically modifying the momentum parameter, resulting in faster convergence and better generalization. These findings underscore the efficacy of the proposed technique across various high-band image analysis applications. Moving forward, future research directions could focus on exploring attention mechanisms to enhance feature extraction and classification precision, investigating new optimization methods tailored for high-band picture analysis, extending the framework to accommodate multi-modal or multi-temporal datasets, and conducting comprehensive tests on larger and more diverse datasets to confirm scalability and resilience. Ultimately, these efforts aim to enhance the methodology's effectiveness and adaptability for high-band picture assessment and classification in real-world scenarios.

Lightweight Cryptographic Algorithms for Medical IoT Devices using Combined Transformation and Expansion (CTE) and Dynamic Chaotic System

Abdul Muhammed Rasheed, Retnaswami Mathusoothana Satheesh Kumar
Department of Information Technology, Noorul Islam Centre for Higher Education, Tamil Nadu, India

***Abstract*—IoT is growing in prominence as a result of its various applications across many industries. They gather information from the real world and send it over networks. The number of small computing devices, such as RFID tags, wireless sensors, embedded devices, and IoT devices, has increased significantly in the last few years. They are anticipated to produce enormous amounts of sensitive data for the purpose of controlling and monitoring. The security of those devices is crucial because they handle precious private data. An encryption algorithm is required to safeguard these delicate devices. The performance of devices is hampered by traditional encryption ciphers like RSA or AES, which are costly and easy to crack. In the realm of IoT security, lightweight image encryption is crucial. For image encryption, the majority of currently used lightweight techniques use separate pixel values and position modifications. These kinds of schemes are limited by their high vulnerability to cracking. This paper introduces a Lightweight cryptography (LWC) algorithm for medical IoT devices using Combined Transformation and Expansion (CTE) and Dynamic Chaos System. The suggested system is evaluated in terms of cross-entropy, UACI, and NPCR. As demonstrated by the experimental results, the suggested system is ideal for medical IoT systems and has very high encryption and decryption efficiency. The proposed system is characterized by its low memory usage and simplicity.**

Keywords*—Internet of Things (IoT); data transmission; data security; medical IoT devices; lightweight cryptography; encryption; decryption

I. Introduction

IoT is a network of integrated, sensing, and identifying devices that are accessible over the network and can communicate with each other. One of the new sensing application areas provided by IoT is smart environment monitoring systems. Other examples include smart homes, smart buildings, and smart transportation systems. The IoT is expected to grow rapidly by 2030, when 125 million smart devices will be merged to the Internet [1]. Smart things that can organize, configure, and reconfigure themselves constitute the IoT network. On the other hand, the implementation of these smart objects faces some difficulties [2].

With the advent of sensors, smart networking, RFID, and IoT, the world has become more networked in the last ten years in order to accomplish a wide range of tasks [3]. IoT is a modern technology used in smart objects. Tangible gadgets like laptops, refrigerators, phones, and cars are referred to as "smart objects." IoT refers to a network of smart objects that other networked devices can recognize, control, and access. They can compute and make decisions as well. IoT is a global network that uses common communication systems and has dynamic capabilities. It can work with both real and virtual objects. It can be used with intelligent platforms that are easily integrated into communication technologies [4].

The idea behind IoT is the integration of intelligent manufacturing equipment, advanced analytics, and automation driven by AI. It will make human life more economical and manageable. IoT may be a rapidly expanding field at the moment, bringing with it a variety of new problems such as short battery life, low memory, short device connection range, etc. [5]. Furthermore, it is evident that the current IoT is vulnerable in terms of energy and security, and its growth prevents it from concentrating on the security framework.

IoT provides an accurate and genuine picture of the challenges and solutions in the IoT framework today through the breakdown of existing devices with different spaces and advancements. Patients and specialists could only collaborate through in-person meetings and text and phone conversations before IoT. Devices enabled by IoT have made it possible to observe patients remotely in the medical field. The more comfortable and effective doctor-patient interactions have also led to a rise in patient engagement and satisfaction. In addition, the patient's condition has been tracked from a distance, which shortens the time spent in the clinic and avoids reaffirmations.

Instead of just creating stand-alone wearables, it is critical to design an entire ecosystem equipped with sensors and devices that will merge data to cloud services via the IoT framework [6–8]. The three primary layers of the design include the following components: the cloud, Internet-connected gateways, and edge devices; sensor-equipped body space networks; and the essential big data support layer. Security is always the primary concern when a new technology is introduced. It is extremely valid in the context of IoT, where devices are used to collect a lot of personal data. Desktop computers are giving way to resource-constrained, small-sized computing devices. The replacement of large amounts of data resulting from the interconnection of these small devices through the Internet and multiple networks poses an unprecedented challenge for the users in terms of data security [9], [10]. IoT devices interact quickly with the outside world to collect private information or control tangible environmental factors. Because of this, they become a desirable target for attackers [12] and are easily accessible, making them open to

different types of security breaches [11]. Cybersecurity is a major concern for IoT devices due to demands for secrecy, integrity of data, authorization and authentication, availability, privacy, and regulatory requirements, as well as frequent system upgrades [13]. In this situation, one of the best methods to ensure the data's secrecy, integrity, authentication, and authorization while it travels between IoT devices might be through cryptography. Data stored or transmitted over a network may be protected with the use of cryptography.

Conventional encryption algorithms provide high security, but they also consume a significant amount of memory, processing, and energy. Due to their limited resources, small devices are not an appropriate choice for traditional encryption. The advent of LWC is a new type of encryption that was made possible by advancements in processors, power consumption, and memory costs in traditional encryption. This encryption lowers memory costs and power consumption, making it appropriate for devices with constrained resources. The newest trend in encryption for devices with low resources is called LWC. This can be attributed to the utilization of basic mathematical operations, reduced memory expenses, and decreased power usage. LWC aims to reduce the overall costs associated with implementing traditional encryption by concentrating on a number of variables, including code size, memory cost, execution time, and energy consumption.

A safe and effective LWC algorithm for small IoT medical devices is suggested in this paper. The major contribution of the proposed work includes:

- Design and development of LWC algorithms applicable for IoT healthcare devices.
- Design and development of novel LWC algorithms based on Chaos theory to provide encryption with less computational complexity and more efficiency.
- Performance assessment of suggested LWC algorithms in terms of NPCR, UACI and Cross Entropy.

The remainder of the paper is organized as follows: A literature review is offered in Section II, highlighting areas necessitating further research. Section III elucidates the methodology in detail. Section IV delves into a comprehensive discussion of the outcomes resulting from the proposed approach. Lastly, in Section V, the paper concludes by summarizing the findings.

II. Literature Review

Fursan Thabit, Sharaf Alhomdy, Abdulrazzaq H.A. Al-Ahdal and Sudhir Jagtap [14] introduced a LWC algorithm for improving the data security. A 16-byte block cipher algorithm must be used to encrypt the data utilizing a 16-byte key. The complexity of the encryption is increased by drawing inspiration from Feistel and SP architectural techniques. According to the simulation results, the suggested algorithm has revealed a strong security level and a discernible enhancement in encryption and decryption, offering low computation costs and high security.

Mohammad Kamrul Hasan, Muhammad Shafiq, Shayla Islam, Bishwajeet Pandey, Yousef A. Baker El-Ebiary, Nazmus Shaker Nafi, R. Ciro Rodriguez and Doris Esenarro Vargas [15] carried out an investigation of cryptographic algorithms. It provides a thorough assessment of the timing complexity, size, encryption, and decryption performances of different algorithms. It has been tested to mitigate the assuming attack in complex real-time DL IoT applications. Using the simulation approach, an evaluation was carried out to test the encryption and decryption speeds of the preferred encryption algorithms. According to the simulation results, Blowfish performs better than the other widely used encryption algorithms.

An empirical investigation of the performance of 32 LWC algorithms that were deployed on three embedded platforms serving as IoT nodes was conducted by Fotovvat, A., Rahman, G. M., Vedaei, S. S., & Wahid, K. A [16]. The platforms selected for this work can be applied to different layers of the IoT ecosystem. Authenticated encryption algorithms such as AES-GCM, AES-CCM, and AES-OCB were compared with a range of test scenarios. The experiment results showed that other timing requirements are much more important than the encryption time of LWC algorithms.

A performance assessment of ten LWC algorithms was conducted by Panahi, P., Bayılmış, C., Çavuşoğlu, U., & Kaçar, S. [17]. These algorithms evaluate crucial aspects such as consumption of energy, throughput, memory usage, and execution time during cloud transmission. The most popular IoT devices used in the simulations are the Arduino Mega 2560 and Raspberry Pi 3.

Jadaun, A., Alaria, S. K., & Saini, Y [18] suggested the establishment of a symmetric key LWC algorithm for secure data transmission of text and images utilizing a reversible data hiding system and an image encryption system. A graphical user interface was utilized in the design of the suggested symmetric cryptographic key. A secure data transmission system was also intended to be used with the reversible data-hiding system. The simulation results revealed that the suggested algorithm yields the best results in terms of MSE and PSNR.

Toprak, S., Akbulut, A., Aydın, M. A., & Zaim, A. H. [19] introduced an energy-efficient LWC algorithm for IoT medical devices. A lightweight block cipher algorithm is proposed in order to have an encryption algorithm that is both secure enough to withstand primal cryptanalysis attacks and lightweight enough for constrained or limited hardware environments. Both the length of the key and the length of the blocks that need to be encrypted are 64 bits. It is intended for body sensor area devices and IoT systems with low-end microcontrollers. The well-known algorithms are employed for assessing the security and performance aspects of LWE. It was discovered that LWE can transmit raw data with a minimal amount of security without seriously taxing the network infrastructure. It can be claimed that the outcome is adequate and even outperforms other algorithms.

A novel ultra-LWC algorithm named SLIM was proposed by Aboushosha, B., Ramadan, R. A., Dwivedi, A. D., El-Sayed, A., & Dessouky, M. M [20] for RFID systems. The most popular type of cryptography, block ciphers, offer extremely strong security for IoT devices. SLIM is a 32-bit

block cipher that is built on the Feistel framework. Designing a lightweight block cipher that balances security, cost, and performance is a major challenge. The suggested algorithm is characterized by an appropriate cost/security for RFID framework, a small implementation area, excellent performance in both software and hardware platforms, and energy-efficient behaviour.

Kakali Chatterjee and Ravi Raushan Kumar Chaudhary [21] provided a lightweight block cipher method with a flexible structure. This aids in the creation of a flexible cryptosystem that can be implemented on a variety of IoT devices' hardware. The primary purpose of this framework is to support health monitoring systems, which are a component of electronic health care. The user can access the recorded data in this monitoring system only after completing the necessary authentication procedures. The data is encrypted using LWC. In addition, the system's performance is evaluated, and formal verification for high-level security is completed. The primary keys used in the LWC ciphering technique ranged from 128 to 256 bits. When compared to another current scheme, the computational cost of the suggested framework is low. So, it is appropriate for low-power and memory-intensive IoT devices.

Al-Husainy, M. A. F., Al-Shargabi, B., & Aljawarneh, S. [22] developed a lightweight, adaptable encryption system that includes transposition operations and strong, straightforward substitution in order to encrypt and decrypt data that is compatible with the limited processing power of IoT devices. By using a variable block size, the suggested framework was made more versatile so that it could be used on various IoT devices with different amounts of memory. Additionally, random encryption keys that are difficult for thieves to decipher are generated using the deoxyribonucleic acid sequence. When compared to well-known cryptographic systems, the experimental results of the suggested lightweight encryption system showed excellent outcomes for any IoT device in terms of memory size and encryption time.

Jabeen, T., Ashraf, H., Khatoon, A., Band, S. S., & Mosavi, A. [23] suggested a genetic-based encryption approach to secure the data in an unintelligible format. Security and confidentiality are additionally guaranteed by a lightweight telemetry transport protocol for encrypted data transmission across the network. The major aim of the suggested approach is to provide a bandwidth-efficient protocol with low battery power consumption. The suggested approach is evaluated in the MATLAB platform. The suggested encryption scheme is evaluated for efficacy in the WBAN sensor environment using a genetic-based encryption algorithm.

Atiewi, S., Al-Rahayfeh, A., Almiani, M., Yussof, S., Alfandi, O., Abugabah, A., & Jararweh, Y [24] proposed an IoT environment that is cloud-enabled and encouraged by multifactor authentication and LWC encryption techniques to secure big data systems. The goal of the suggested hybrid cloud platform is to offer extremely secure data protection for businesses. Private and public clouds are combined to create a hybrid cloud environment. Data from sensitive devices is split into two halves and encrypted with the Fiestel and RC6 algorithms. Through the use of a gateway device, these data are kept in a private cloud with maximum security. On the other hand, gateway devices are used to store non-sensitive device data in a public cloud after it has been encrypted using AES. The efficiency of the recommended strategy was evaluated. According to the simulation outcomes, the suggested approach outperforms existing encryption algorithms.

A safe, lightweight algorithmic encryption technique was presented by Hasan, M. K., Islam, S., Sulaiman, R., Khan, S., Hashim, A. H. A., Habib, S., & Hassan, M. A [25] to safeguard the privacy of patient medical images. Two permutation techniques are used in the suggested lightweight encryption method to protect medical images. The security and execution time of the suggested method are compared to those of conventionally encrypted methods after they have been examined and assessed. The effectiveness of the suggested algorithm was analyzed on a large number of test images. Extensive experiments revealed that the suggested algorithm for image cryptosystems provides higher efficiency compared to conventional techniques.

A lightweight, efficient healthcare monitoring system utilizing Radio Frequency Identification (RFID) tags and the IoT was proposed by Naresh, V. S., Reddi, S., & Murthy, N. V [26]. This work used a dual-band RFID protocol, wherein 2.45 GHz microwave bands are employed to monitor corporal information and 13.56 MHz high-frequency RFID is useful for identifying individuals. An RFID tag is utilized to identify the patient, and sensors are utilized to track and gather physiological data about them. According to the simulation results, the suggested protocol is more efficient than other currently used techniques.

An improved LWC algorithm was proposed by Jebri, S., Ben Amor, A., Abid, M., & Bouallegue, A. [27] to secure data transmission in IoT framework. The suggested solution ensures that most security flaws are addressed with regard to trust registration and anonymous mutual authentication. A lightweight, secure IoT system was ensured by employing elliptic curve cryptography, identity-based encryption, and pseudonym-based cryptography approaches. As per the evaluation results of the system with Raspberry cards and the MIRACL library, the system's execution time is adequate for the restricted number of IoT devices.

Chatterjee, K., Chaudhary, R. R. K., & Singh, A. [28] introduced an algorithm for LWC to assure the security of the electronic health care system. The addition substitution and XOR (LWARX) are the foundation of the suggested lightweight scheme. For secure communication within the healthcare system, an efficient authentication approach based on the LWARX approach is also suggested. The effectiveness of the suggested approach is evaluated using a variety of metrics, including throughput, latency, gate equivalent etc. The comparison outcomes show that the suggested ciphering technique has excellent performance, low power and energy consumption, and high throughput. The comparison of selected LWC algorithms is tabulated in Table I.

IoT-based smart environments are susceptible to privacy and data breaches. LWC solutions are crucial since IoT applications are implemented on devices with limited resources. The majority of these modern, LWC solutions rely on hashing techniques like message digests (MD5) or SHA

hash function variants. The device needs more resources to perform the intricate rotational and XOR operations of these current functions. Elliptic curve cryptography (ECC) is the foundation of many lightweight schemes. These ECC schemes generate signatures using single and static elliptic curve parameters. The embedded devices that store these elliptic curve parameters are susceptible to attacks involving node compromise. The publicly accessible Internet infrastructure on the Internet of Things allows devices to communicate with the server or with each other. It becomes a laborious task to issue certificates for every device on the Internet when thousands of devices are added and removed from the network on a regular basis. The key distribution center (KDC) must regularly distribute security keys for this kind of communication. Therefore, using standard KDC, or key management servers, is becoming more difficult as the number of IoT applications rises. Many cryptographic solutions based on ECDSA and ECIES use single or static elliptic curve parameters. Node compromise attacks can arise from ingesting cryptographic parameters or secret keys on the device. So, in order to overcome the above-mentioned limitations, a secure and effective LWC algorithm for small computing IoT healthcare devices was introduced in this work.

TABLE I. COMPARISON OF SELECTED LWC ALGORITHMS

Name	Block Size (bit)	Key Size (bit)	Structure
AES	128	128	SPN
PRESENT	64	128	SPN
MESA	128	256	Feistel
LEA	128	128	GFN
XTEA	64	128	Feistel
SIMON	64	128	Feistel
PRINCE	64	128	SPN
RECTANGLE	64	128	SPN

III. MATERIALS AND METHODS

In the field of IoT security, lightweight image encryption is crucial. Most existing Lightweight image encryption approaches adopt shuffling of pixel positions and modification of pixel values separately. So, in this paper, an LWC algorithm for medical IoT devices is developed using Combined Transformation and Expansion (CTE) and Dynamic Chaos System. The detailed block schematic of the suggested approach is visualized in Fig. 1.

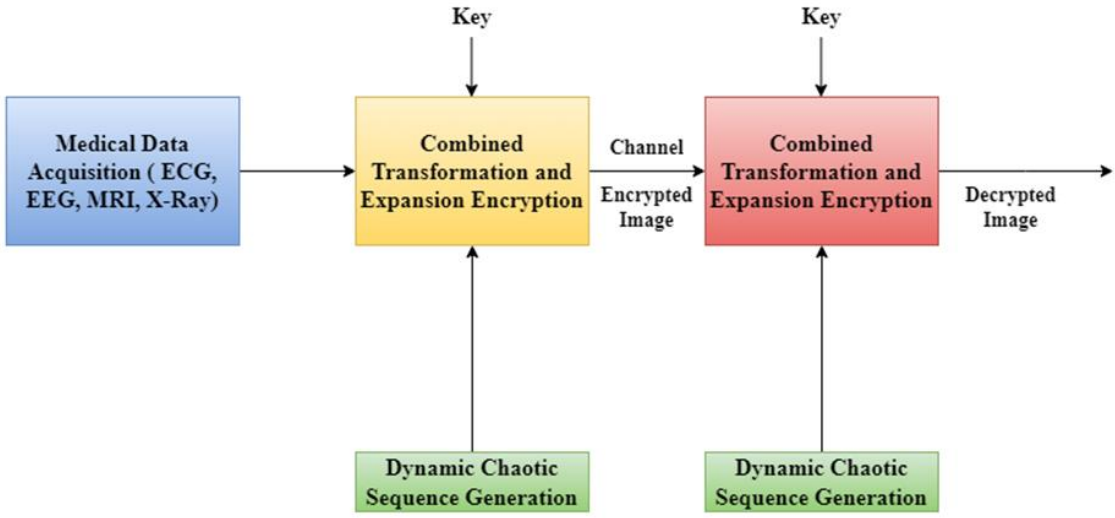

Fig. 1. Block diagram of proposed methodology.

A. Input Medical Images

The medical images were utilized as the input in the proposed work. The input medical images include ECG, EEG, MRI and X-Ray images. Fig. 2 displays the sample medical images.

B. Dynamic Chaotic System

Chaos is defined as "a state of disorder." Systems with dynamic behavior that are extremely sensitive to primary criterion are studied by chaos theory. A reaction that is occasionally indicated to as the "butterfly effect". For such dynamical systems, slight variations in the starting conditions result in widely divergent outcomes, making long-term prediction generally infeasible. This happens in spite of the fact that these systems are deterministic, implies that their future behavior is totally influenced by their primary criterion and that they do not contain any random elements.

Initially, a sequence is generated by means of a 4D dynamic chaos-based system with two positive Lyapunov exponents. The average exponential divergence rate of neighboring trajectories in phase space is represented numerically by the Lyapunov exponent. It is one of the characteristics that helps distinguish between various chaotic motion numerical values. It can be formulated as

$$\lambda = \lim_{n\to\infty} \frac{1}{n} \sum_{n=0}^{N-1} \ln \left| \frac{df(x_n,u)}{dx} \right| \quad (1)$$

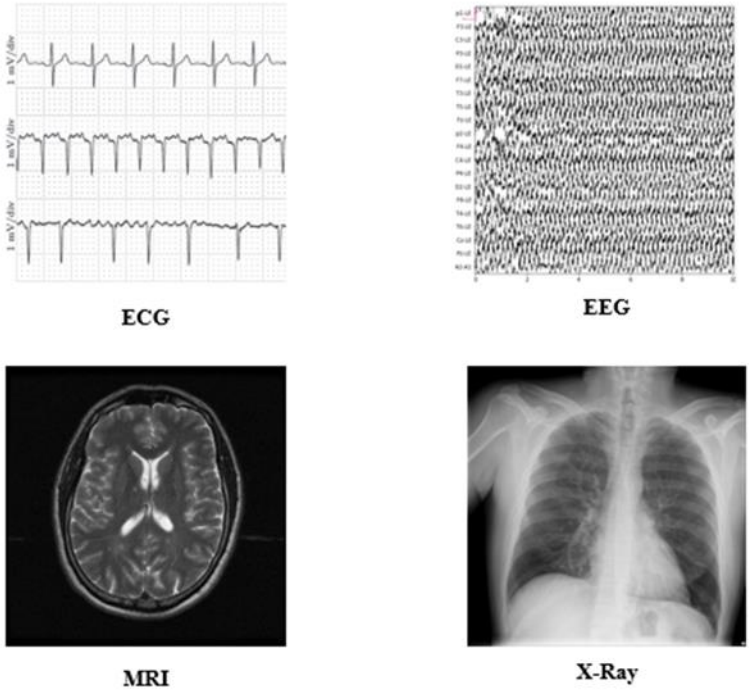

Fig. 2. Sample input medical image.

Fig. 3 depicts the dynamic chaotic system. The dynamic chaos system is initialized with the parameters of the medical image, in order to enhance security. The pixels in images are expanded and transformed using the dynamic chaos sequence. More precisely, the first index matrix establishes which pixels are going to be enlarged and altered. The expansion of the pixels is decided by the second mask matrix. The dynamic chaos sequence is responsible for producing these matrices. In this work, chaotic sequences for encryption were generated using a novel dynamic chaotic system. It can be formulated as

$$x = a(y - x) + w$$
$$y = bx - xz + w$$
$$z = xy - z - w$$
$$w = -c(x + y) \quad (2)$$

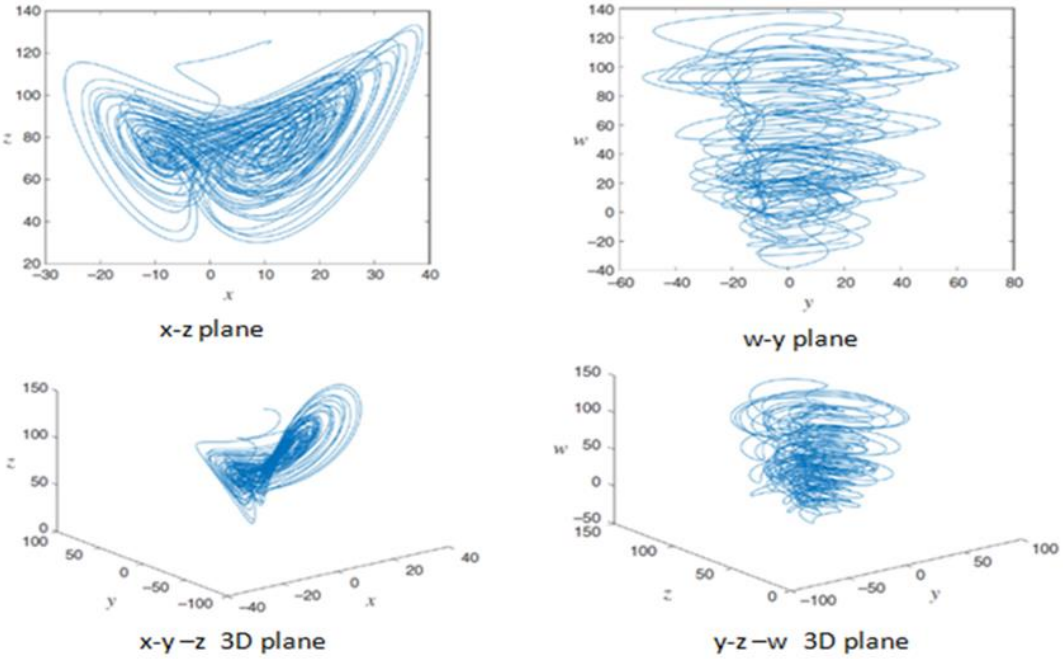

Fig. 3. Dynamic chaotic system.

where the state variables are x, y, z, and w, and the positive constants are a, b, and c. Divide the input image K into 32 blocks in order to generate the initial values for the dynamic chaotic system, which can be expressed as $K = \{k_1, k_2, k_3, \ldots, k_{32}\}$. The four intermediate parameters d_1, d_2, d_3 and d_4 can be calculated as

$$\begin{aligned} d_1 &= b_1 + \frac{1}{256}(k_1 \oplus k_2 \oplus \ldots\ldots \oplus k_8) \\ d_2 &= b_2 + \frac{1}{256}(k_9 \oplus k_{10} \oplus \ldots\ldots \oplus k_{16}) \\ d_3 &= b_3 + \frac{1}{256}(k_{17} \oplus k_{18} \oplus \ldots\ldots \oplus k_{24}) \\ d_4 &= b_4 + \frac{1}{256}(k_{25} \oplus k_{26} \oplus \ldots\ldots \oplus k_{32}) \end{aligned} \quad (3)$$

where, b_1, b_2, b_3 and b_4 are user-defined parameters that can be addressed as security keys.

The initial values x_0, y_0, z_0, and w_0, of the 4D dynamic chaotic system can be obtained from d_1, d_2, d_3 and d_4, which can be expressed as,

$$\begin{aligned} x_0 &= \frac{mod((d_1+d_2+d_3)\times 10^8,\ 256)}{255} \\ y_0 &= \frac{mod((d_2+d_3+d_4)\times 10^8,\ 256)}{255} \\ z_0 &= \frac{mod((d_1+d_2+d_3+d_4)\times 10^8,\ 256)}{255} \\ w_0 &= \frac{mod(mean(d_1+d_2+d_3+d_4)\times 10^8,\ 256)}{255} \end{aligned} \quad (4)$$

The 4D dynamic chaotic system uses the initial values (x_0, y_0, z_0 *and* w_0) to iterate to produce sequences long enough for the subsequent encryption operations. In the j^{th} iteration, it can obtain four state values described as,

$$S^j = \{x_j, y_j, z_j, w_j\} \quad (5)$$

After the iteration terminates, a dynamic chaotic sequence S can be obtained as

$$\begin{aligned} S &= \{s^1, s^2, s^3, \ldots . s^N\} = \{x_1, y_1, z_1, w_1, \ldots\ldots, x_N, y_N, z_N, w_N\} \\ &= \{s_1, s_2, s_3, s_4, \ldots\ldots, s_{4N-3}, s_{4N-2}, s_{4N-1}, s_{4N}\} \end{aligned} \quad (6)$$

C. Combined Transformation and Expansion (CTE)

Two types of auxiliary matrices are needed in the suggested approach. The schematic diagram of CTE is illustrated in Fig. 4. One matrix is used for expansion, and the other is used to identify which pixels need to be processed. Considering an image with dimensions h × w, where h and w stand for height and width, respectively. Two index matrices, I and T, are created for the first matrix using the four random sequences, r_1, r_2, r_3 and r_4, that we adopted from S. Fig. 5 and Fig. 6 show the visualization of the generation of various matrices, respectively.

$$\begin{aligned} I(i,j) &= si_1(mod(i + si_2(j) - 1, w) + 1) \\ T(i,j) &= si_3(mod(i + si_4(j) - 1, w) + 1) \end{aligned} \quad (7)$$

The mask matrix (M) for expansion is calculated using the below equation

$$M = reshape\big(mod\big((r_5 - \lfloor r_5 \rfloor) \times 2^{32}\big), 256\big), [h, w]) \quad (8)$$

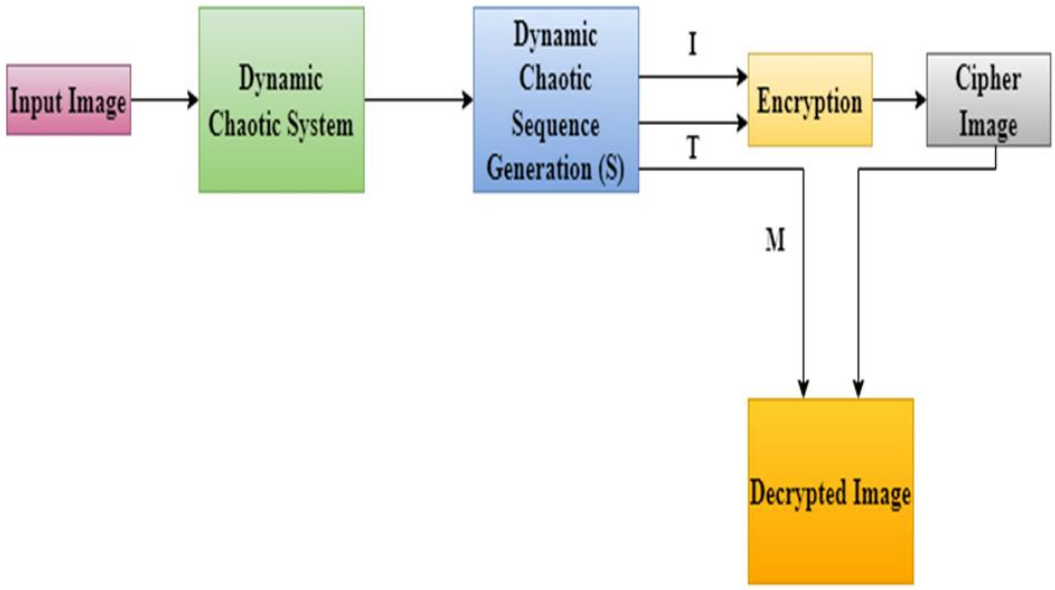

Fig. 4. Block diagram of combined transformation and expansion.

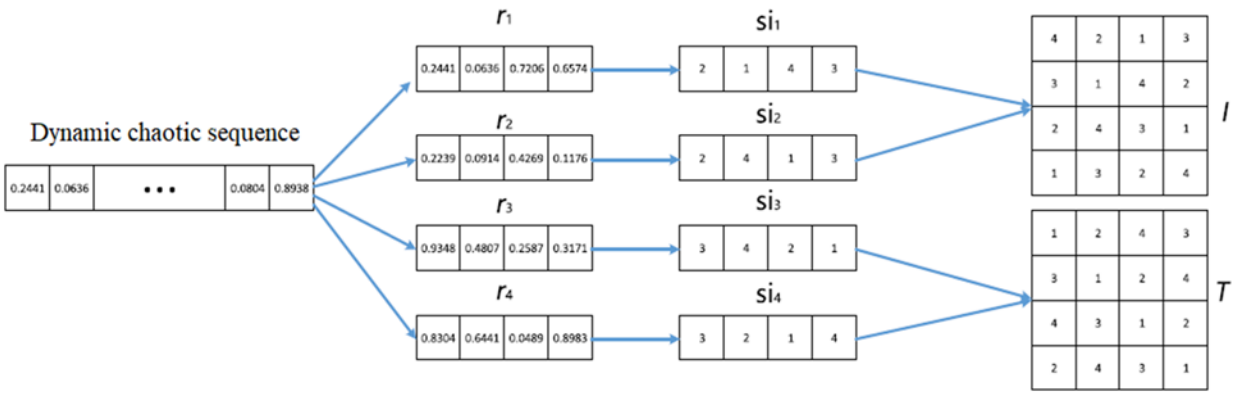

Fig. 5. Visualization of generation of I and T.

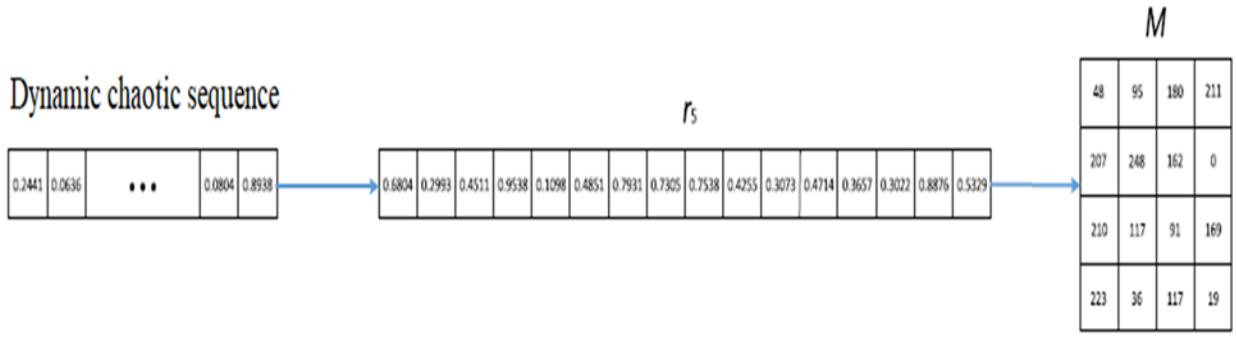

Fig. 6. Visualization of Generation of M.

The method of converting a plain image into a cipher image is known as encryption, and the method of converting a cipher image back into a plain image is known as decryption. Fig. 7 shows the encryption and decryption of the simple image. Data encryption and decryption using cryptographic algorithms typically require a set of characters known as a key. It is simple to encrypt or decrypt plain text into cipher text and back again with the use of a key or algorithm. The proposed CTE algorithm for image encryption and decryption is visualized in Fig. 8.

Considering the user-defined key F, the mask matrix M, the index matrices I and T, and a plain image with one channel P, the encrypted image or Cipher Image (C) can be described as

$$C_{I_{i,j},j} =$$

$$\begin{cases} mod\left(M_{i,j} \oplus P_{T_{j,I_{i,j}},I_{i,j}} + P_{I_{h,w},w}\right),F), & if\ i=1, j=1 \\ mod\left(M_{i,j} \oplus P_{T_{j,I_{i,j}},I_{i,j}} + C_{I_{i-1,w},w}\right),F), & if\ i\neq 1, j=1 \\ mod\left(M_{i,j} \oplus P_{T_{j,I_{i,j}},I_{i,j}} + C_{I_{i,j-1},j-1}\right),F), & if\ j\neq 1 \end{cases} \quad (9)$$

It is possible to obtain the decrypted image D from I, T, M, F, and C

$$D_{T_{j,I_{i,j}},I_{i,j}} =$$

$$\begin{cases} mod\left(M_{i,j} \oplus C_{I_{i,j},j} + C_{I_{h,w},w}\right),F), & if\ i=1, j=1 \\ mod\left(M_{i,j} \oplus C_{I_{i,j},j} + C_{I_{i-1,w},w}\right),F), & if\ i\neq 1, j=1 \\ mod\left(M_{i,j} \oplus C_{I_{i,j},j} + C_{I_{i,j-1},j-1}\right),F), & if\ j\neq 1 \end{cases} \quad (10)$$

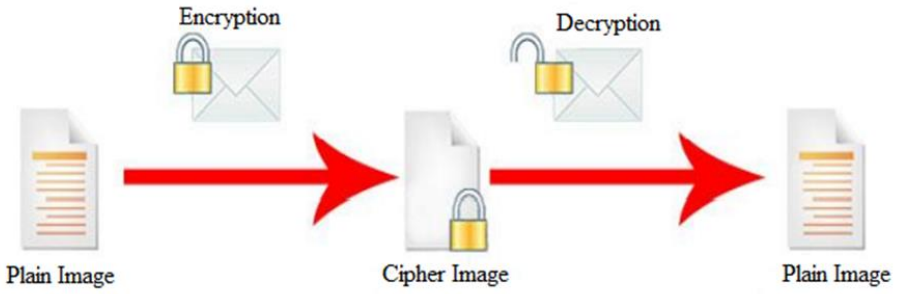

Fig. 7. General block diagram of image encryption and decryption.

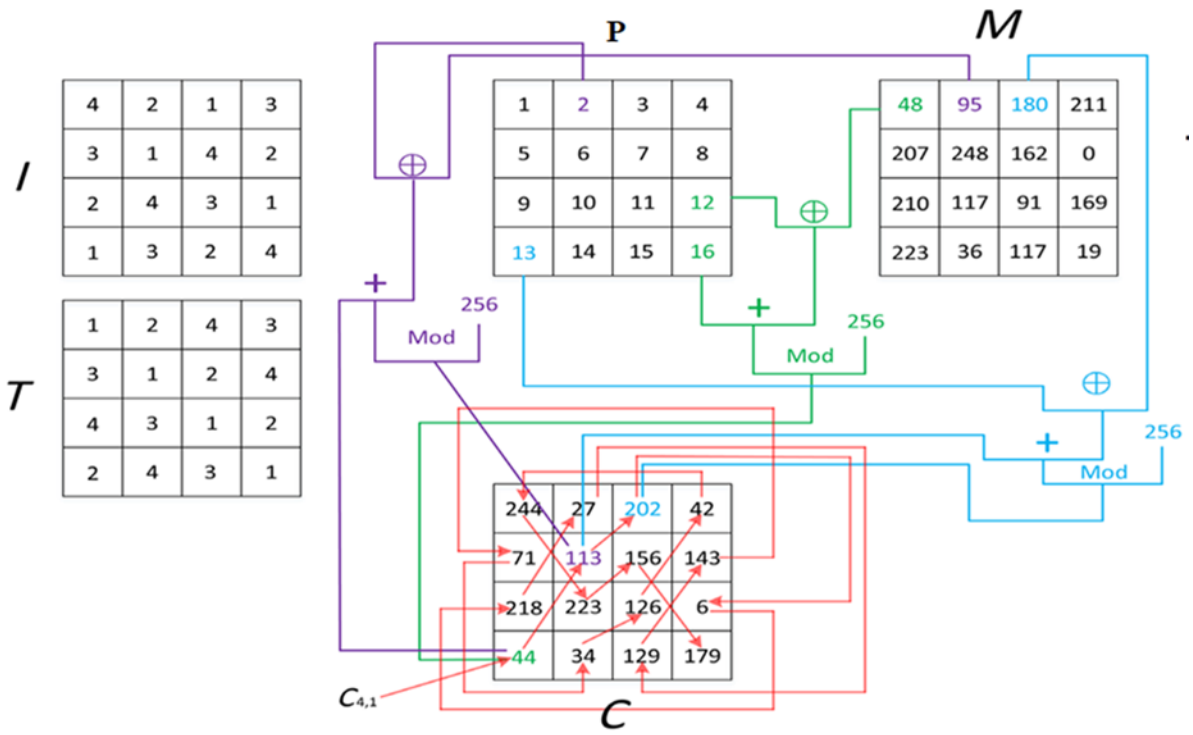

Fig. 8. Illustration of proposed CTE for encryption and decryption.

IV. Results and Discussion

Number of Pixel Changing Rate (NPCR), Unified Averaged Changed Intensity (UACI), and Cross Entropy were used to assess the performance of the suggested LWC algorithm. The strength of image encryption algorithms and ciphers is assessed using NPCR. Its purpose is to count the number of pixels that change between the real and encrypted images. NPCR can be mathematically expressed as,

$$D(i,j) = \begin{cases} 0, if\ C^1(i,j) = C^2(i,j) \\ 1, if\ C^1(i,j) \neq C^2(i,j) \end{cases}$$
$$NPCR: N(c^1, c^2) = \sum_{i,j} \frac{D(i,j)}{T} \times 100\% \quad (11)$$

The effectiveness of image encryption algorithms and ciphers is assessed using UACI. It calculates the average number of intensity changes between the original and encrypted images. It can be mathematically expressed as,

$$UACI: u(C^1, C^2) = \sum_{i,j} \frac{|C^1(i,j) - C^2(i,j)|}{F.T} \times 100\% \quad (12)$$

The cross-entropy between two images predicts the probability of divergence of encrypted pixels from the original image. Cross entropy is also considered as a loss function. The cross entropy can be expressed as

$$H(C^1, c^2) = -\sum_x C^1(x) log\ C^2(x) \quad (13)$$

The performance analysis of original image and encrypted image in terms of NPCR, UACI and cross entropy can be tabulated in Table II.

From Table II, it can be demonstrated that the NPCR and UACI value are high. The high NPCR value indicates that the input medical image and the encrypted medical image differ from each other. The input medical image and the encrypted medical image differ from one another, as indicated by the high UACI value. Cross-entropy has a finite value. This shows that the input medical image and the encrypted medical image have different structures. Table III tabulates the performance analysis of the original and decrypted images.

TABLE II. Original Vs Encrypted Image

Input Image	NPCR	UACI	Cross Entropy
ECG	99.62	47.16	0.1389
EEG	99.62	44.32	0.1103
MRI	99.61	39.67	0.1336
X-Ray	99.61	31.22	0.1318

TABLE III. Original Vs Decrypted Image

Input Image	NPCR	UACI	Cross Entropy
ECG	0	0	0
EEG	0	0	0
MRI	0	0	0
X-Ray	0	0	0

The value of NPCR, UACI and cross entropy are zero for all medical images. This shows that the decrypted image and the input medical image are identical. Fig. 9, 10, and 11 show the histograms for the MRI image channels, encrypted image channels, and decrypted image channels. Fig. 9, 10, and 11 depict histograms representing the distribution of pixel intensities within the MRI image channels, encrypted image channels, and decrypted image channels, respectively. The

MRI image channels histogram provides insight into the original image's intensity distribution, serving as a baseline. The encrypted image channels histogram illustrates the distribution after encryption, indicating potential alterations due to the encryption process. Finally, the decrypted image channels histogram reveals the distribution following decryption, ideally resembling the original MRI image channels histogram, affirming the fidelity of the decryption process in preserving the original intensity distribution. These histograms offer a visual comparison of intensity distributions across various stages of image processing, crucial for evaluating the efficacy and fidelity of encryption and decryption techniques applied to MRI images.

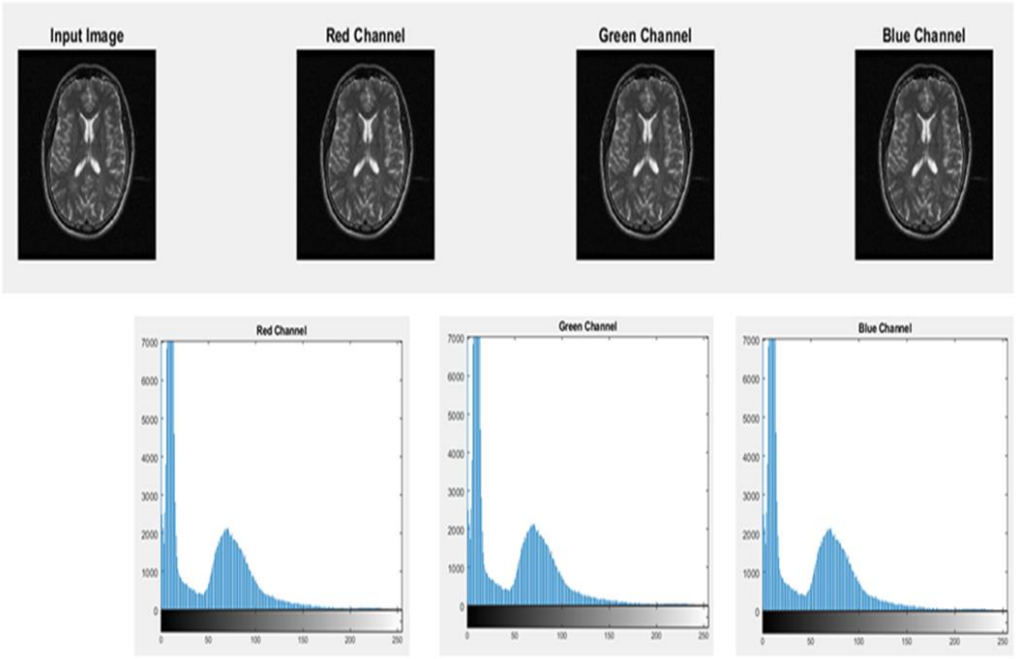

Fig. 9. Histogram of MRI image channels.

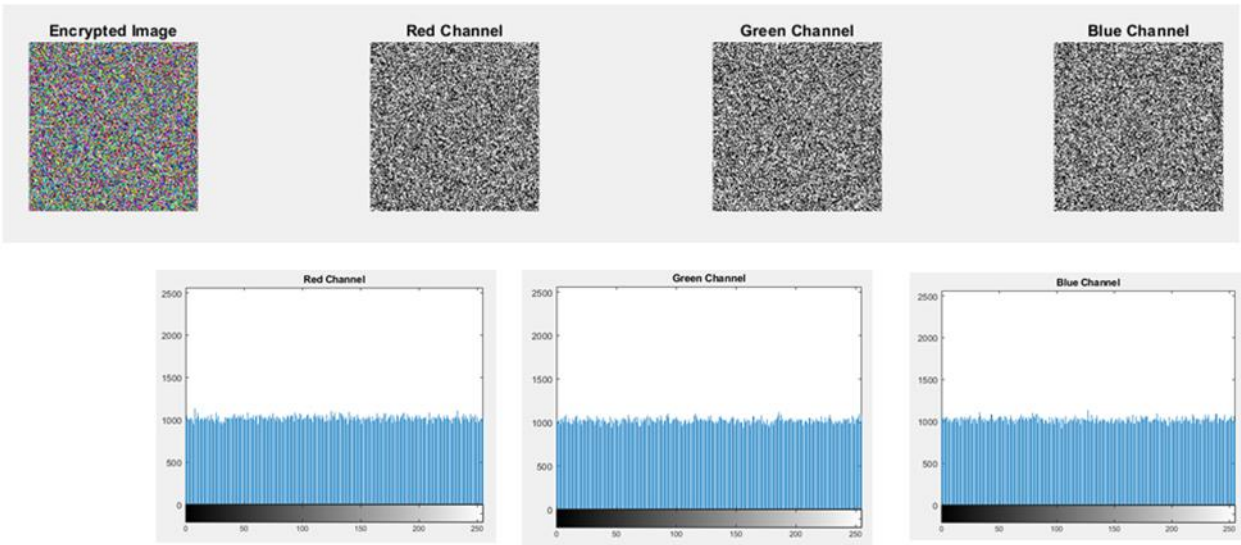

Fig. 10. Histogram of encrypted image channels.

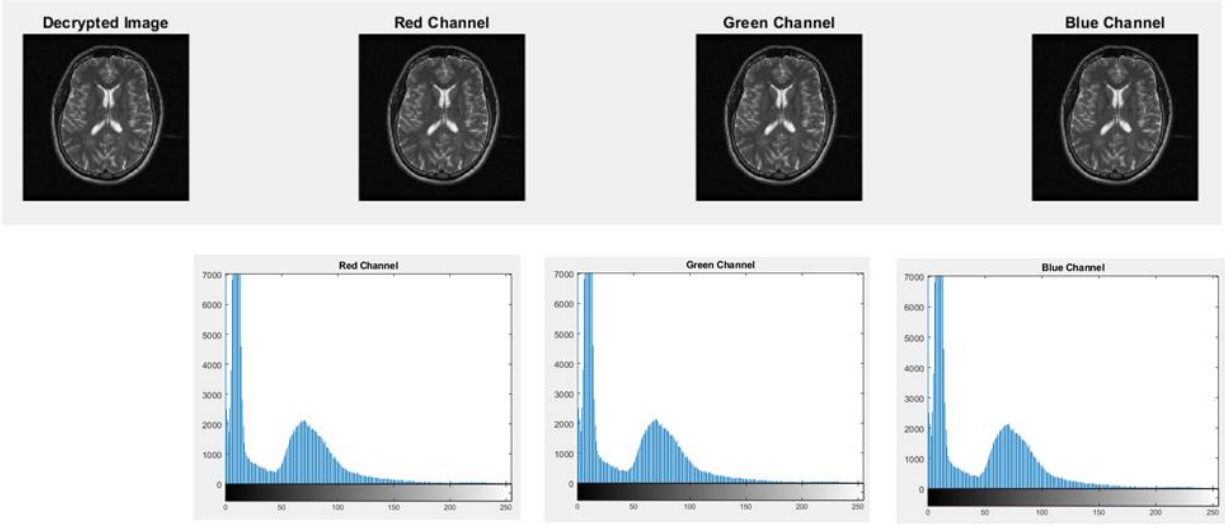

Fig. 11. Histogram of decrypted image channels.

V. CONCLUSION

The IoT is advancing every industry in our rapidly changing world. It facilitates communication between the real and virtual worlds, which will revolutionize operations very rapidly. Due to their limitations, data encryption algorithms must be included in IoT devices in order to increase security. IoT is a network of real, physical objects that have been equipped with RFID, sensors, smart networking, and other methodologies that support them to interchange data with other devices and systems. One important security tool that represents data security is cryptography. The advent of highly sophisticated technologies, coupled with the limitations of mathematical operations and practical applications in traditional cryptography—which also requires a significant amount of processing power and memory guided to the advancement of LWC, a novel approach to cryptography. In this paper, a lightweight cryptography algorithm utilizing the Dynamic Chaos System and Combined Transformation and Expansion (CTE) was proposed for medical IoT devices. The suggested system is assessed in terms of cross-entropy, UACI, and NPCR. The outcomes showed that the suggested method is very effective at both encryption and decryption. The system is less complex, and the memory usage is very low. This system is optimal for medical IoT systems

ACKNOWLEDGMENT

I would like to express my sincere gratitude to all those who contributed to the completion of this research paper. I extend my heartfelt thanks to my supervisor, my family, my colleagues and fellow researchers for their encouragement and understanding during the demanding phases of this work.

Lecturer, Computer Information Science, Higher Colleges of Technology Abu Dhabi Men's Campus, United Arab Emirates[3]

***Abstract*—The constant need for robust and efficient COVID-19 detection methodologies has prompted the exploration of advanced techniques in medical imaging analysis. This paper presents a novel framework that leverages Graph Convolutional Neural Networks (GCNNs) to enhance the detection of COVID-19 from CT scan and X-Ray images. Hence, the GCNN parameters were tuned by the hybrid optimization to gain a more exact detection. Therefore, the novel technique known as Hybrid NADAM Graph Neural Prediction (NAGNP). The framework is designed to achieve efficiency through a hybrid optimization strategy. The methodology involves constructing graph representations from Chest X-ray or CT scan images, where nodes encapsulate critical image patches or regions of interest. These graphs are fed into GCNN architectures tailored for graph-based data, facilitating intricate feature extraction and information aggregation. A hybrid optimization approach is employed to optimize the model's performance, encompassing fine-tuning of GCNN hyperparameters and strategic model optimization techniques. Through rigorous evaluation and validation using diverse datasets, our framework demonstrates promising results in accurate and efficient COVID-19 diagnosis. Integrating GCNNs and hybrid optimization presents a viable pathway toward reliable and practical diagnostic tools in combating the ongoing pandemic.**

Keywords*—*COVID-19 detection; Graph Neural Networks; X-ray; CT scan images; hybrid optimization; medical imaging analysis; diagnostic tools; pandemic response

I. INTRODUCTION

The COVID-19 virus has spread worldwide, and lung computed tomography (CT) imaging has achieved clinical verification of the diagnosis of COVID-19. [1] The World Health Organization designated COVID-19 as a highly contagious pandemic that began in December 2019. COVID-19, caused by an unfamiliar coronavirus [2], is spread from person to person. Isolating the patients to control this catastrophe requires an accurate diagnosis. [3] Relevant research has demonstrated that lung X-ray and CT imaging data can be crucial for diagnosing COVID-19. However, despite specific automatic detection techniques, their strategies still have a lot of potential for development and rely disproportionately on the knowledge and resources of doctors due to the brief epidemic period of COVID-19 [4].

The local and general characteristics of the lesions serve as a crucial foundation for the COVID-19 diagnosis, which cannot be determined only based on the peculiarities of a particular location. [5] Analyzing and diagnosing CT scans is highly intricate and necessitates doctors' professional expertise and experience. [6] Furthermore, many COVID-19 CT scans morphologically resemble conventional pictures of pneumonia. However [7], the research describes several segmentation techniques designed and used to extract and evaluate the COVID-19 infectiousness from the 2D slices [8]. Using the VGG-UNet, the COVID-19 lesion is removed from the lung CT slice. A pulmonologist or a computer algorithm is used to determine the infection level following extraction. The lung CT slice extracts the COVID-19 lesion using the EfficientNet. The EfficienetNet B1 is used for Chest X-ray and EfficientNet B3 is used for CT-Scan. A validation and training procedure is required for the execution of this strategy.

The CNN methodology is employed rather than traditional techniques, Convolutional Neural Network (CNN) segmentation provides a superior outcome. Therefore, several CNN-based segmentation techniques are used to identify and quantify the afflicted area in CT scans. [10] Graph models have recently grown in strength, which has made it possible to apply them to difficult medical situations. In the field of healthcare, [11] graph convolutional neural networks (GCNNs) have become a distinct category of machine learning (ML) models designed to function on graph-structured data due to their ability to accurately capture the intricate relationships between many components of medical pictures. GCNN provides a revolutionary method for deriving insightful information from linked medical entities, facilitating precise forecasts, and carrying out several essential functions for healthcare applications.

The paper proposes a novel framework using Graph Convolutional Neural Networks (GCNNs) to enhance the detection of COVID-19 from X-ray and CT scan images. The research problem addressed is the need for more accurate and efficient methods for diagnosing COVID-19, especially in resource-constrained settings where access to traditional diagnostic tools may be limited. By leveraging the unique

capabilities of GCNNs, the framework aims to improve the accuracy and speed of COVID-19 detection from medical imaging, ultimately aiding in the early and accurate diagnosis of the disease. The paper highlights the potential of GCNNs to analyze the complex relationships within medical images, potentially leading to more reliable diagnostic outcomes compared to traditional methods.

II. Related Work

A. A Few Recent Associated Works are Described as Follows

Fan X et al. [12], a new framework using Transformer and Convolutional Neural Network (T-CNN) is proposed for detecting COVID-19 from CT images [9]. This method uses Transformer's global feature extraction and CNN's local feature extraction capacity. A bidirectional feature fusion structure is created by fusing features from two branches and branch parallel structures, enhancing Accuracy. This approach also advances the field's ability to diagnose lung diseases in real-time, potentially saving lives. It has limitations due to relying on one CT image with fewer features and incomplete patient diagnosis output.

Jia H et al. [13], a novel module called pixel-wise sparse graph reasoning (PSGR) for CT image segmentation of COVID-19 infected areas. Global contextual information modelling is improved by the PSGR module, which is placed between the network's encoder and decoder. It projects pixel characteristics to create a network, transforms it into a sparsely linked graph, and then applies global reasoning. Three datasets were used to assess the segmentation structure and to contrast it with other models. Results show that the suggested module outperforms competing models in properly segmenting and successfully captures long-range relationships despite its high computational cost.

Fritz C et al. [14], to forecast local COVID-19 instances, this study employs semi-structured deep distributional regression (SDDR) as a multimodal learning framework. Neural networks and structured additive distributional regression are combined in SDDR, where the statistical regression model is embedded within the neural network. It applies latent characteristics discovered by deep neural networks to the additive predictor of each distributional parameter. An orthogonalization cell is utilized to distinguish between structured and unstructured model portions.

Lu S et al. [15], the research created a computer-aided diagnostic system that utilizes artificial intelligence to recognize COVID-19 in chest computed tomography pictures. Transfer learning lets the system obtain novel, neighbouring aware representation (NAR) and image-level representations (ILR). The neighbouring familiar graph neural network (NAGCNN) is designed and validated. The results demonstrated its superior generalization capacity over all state-of-the-art approaches, indicating its effectiveness for clinical diagnosis.

Xing X [16], this paper introduced an advanced multi-level attention graph neural network (MLA-GCNN) for predicting and diagnosing diseases. In particular, weighted correlation network analysis converts omics data into co-expression graphs. Multi-level graph features are then created, and to perform predictions, they are fused using a carefully thought-out multi-level graph feature entirely fusion module. A unique full-gradient graph saliency method is designed for model interpretation to determine the genes associated with the disease. Regarding proteomic data from coronavirus disease 2019 (COVID-19)/non-COVID-19 patient sera, GCNN performs at breaking point.

The key contributions of this work are described as follows

- Initially, the Kaggle dataset is collected and trained in a Python program.
- With the necessary characteristics for detecting COVID-19, the novel NAGNP is introduced.
- Thus, the NADAM function is used in optimization and CNN is used in Feature analysis to extract the relevant and necessary features from the dataset.
- GNN accomplishes the prediction process, and classification is carried out.
- At last, the detection process is completed, and performance metrics, including F1 score, Accuracy, recall, and precision, are computed and compared to other models.

III. Proposed Methodology

A novel Hybrid NADAM Graph Neural Prediction (NAGNP) system was introduced in this study for forecasting the COVID-19 affectation from the lung's CT scan data. Preprocessing is performed to rid the data of the noisy components. Following that, the method of extracting the features for COVID-19 feature prediction is carried out. The CNN is used to extract features. Henceforth, prediction is accomplished by GNN. Lastly, COVID-19 prediction has been carried out, and performance metrics are assessed.

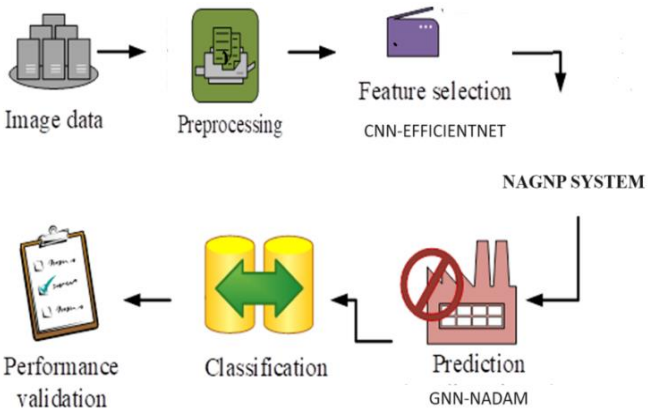

Fig. 1. Proposed methodology.

In Fig. 1, the proposed approach is described. It uses a CT scan image to anticipate the COVID-19. Performance metrics were computed, including the F1 score, Accuracy, recall, and precision. The following portions display the process of the proposed model in brief. 3.1 Data importing and preprocessing.

The detection data importing function's primary step is executed by Eq. (1). Based on the initialization principle of the hybrid optimization model, the initialization process was activated and done successfully.

$$F(T) = T\{1,2,3.....n\} \quad (1)$$

Here, T it determines CT scan data, defines the data training variable, and describes the n number of trained CT images.

After the training phase, the critical module in the forecasting framework is preprocessing, which is executed to neglect the noisy pixel range from the imported image data. Also, the proper filtering function has helped to earn the needed Accuracy in the prediction function. Consequently, the preprocessing function is processed by Eq. (2).

$$D = \frac{T(H-n)}{T(P)} \quad (2)$$

Here, P is the total pixel and $T(P)$ denotes the entire pixel in the trained data. Moreover, D the preprocessing variable, the highest pixel, and the noisy pixel are available in the imported database.

B. Feature Selection

The process feature selection is the chief processing module to get the forecasting outcome expected. According to the dataset there were two models proposed one for X-ray and one for CT-Scan. Both models use CNN. The feature extraction is done by Transfer Learning Architecture EfficientNet B1 for X-ray and EfficientNet B3 for CT-Scan. The meaningful features like spatial and temporal are extracted using Principal Component Analysis. The PCA projects data onto a lower-dimensional subspace while maximizing variance. Eq. (3)

$$\text{var}(Z)=\text{sum}(\lambda\_i*(z\_i)\text{^}2)) \quad (3)$$

where Z is the projected data,

λ_i are the eigen values and

z_i are the principal components.

C. Prediction and Classification

The COVID region prediction is an intricate process for medical professionals. It has affected a wide range of people. It is predicted by applying the NADAM optimization in GCNN. The proposed model NAGNP shows better performance in feature extraction. To optimize the GCN's performance, an optimizer like NADAM is employed. It builds upon Adam (Adaptive Moment Estimation) by incorporating momentum for faster convergence. NADAM updates weights (θ) based on estimates of the first and second moments of gradients (m_t, v_t) using specific decay rates (β1, β2). Mathematically, Eq. (4) the update rule might involve:

$$m\_t = \beta1 * m\_(t-1) + (1 - \beta1) * g\_t, \quad (4)$$

$$v\_t = \beta2 * v\_(t-1) + (1 - \beta2) * g\_t\text{^}2, \quad (4)$$

where, g_t is the current gradient. The weights are then adjusted using these moment estimates and estimated noise (η).

By combining classification with GCN architecture and NADAM optimization, the model learns to effectively map features to class labels, enabling accurate predictions for unseen chest X-rays

The prediction is executed by Eq. (5).

$$P_r = F_{TAL} > P_r\left(\frac{F_s}{C,N}\right) \quad (5)$$

P_r represents the prediction variable, the trained stored feature, and the Covid and Non-Covid. The Fitness predicts the COVID cases, and Eqn 6 does classification.

$$C = \begin{cases} if(P_r = 0) \quad Non \quad Covid \\ if(P_r = 1 \qquad Covid \end{cases} \quad (6)$$

C denotes the classification variable. The value 0 indicates the Non-Covid affected, and 1 represents the COVID affected. The Flowchart for the proposed NAGNP model is displayed in Fig. 2.

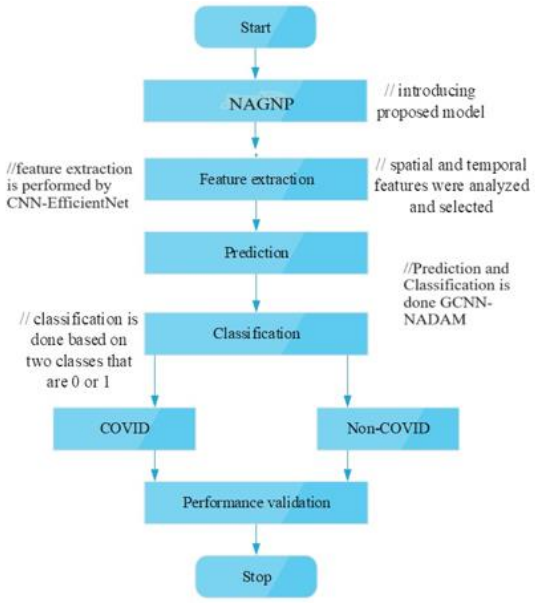

Fig. 2. The Flowchart for the proposed NAGNP model.

IV. Results and Discussion

The planned novel solution is verified in the Python environment version 3.10 and running in the Windows 10 environment. The dataset is collected from the Kaggle site. The noisy parts are removed using preprocessing to extract the significant features from the gathered photos. CNN is then used for feature extraction. The GNN predicts COVID-19. As a result, the necessary metrics for the proposed NAGNP are evaluated. The execution parameters are described in Table I.

TABLE I. EXECUTION PARAMETERS

Metrics	Specification
Operating System	Windows 10
Version	3.7.14
Program platform	Python
Dataset	Kaggle
Optimization	NADAM
Network Architecture	CNN-GNN

A. Case Study

The purpose of the study is to comprehend the proposed NAGNP model process. The images used come from Kaggle's website. Datasets are used for training and testing to determine the designed model. Table II shows the predicted image.

The prediction result describes the region affected by COVID-19. Blue represents the affected region, light blue indicates the low-affected region and dark blue shows the heavily affected area.

B. Performance Analysis

Performance was validated by evaluating chief metrics like error rate, F1-score, Accuracy, recall and precision. The existing paradigms, which are obtained for the comparative validation is Xception Model (XM) [17], Inception V3 Model (IV3M) [17], VGG16 [17], ResNet 50 (RN50)[17], VGG 19 [17] and DenseNet (DN) [17].

Moreover, the positive scores in the forecasting function are measured with the help of precision metrics; the formulation is revealed in Eq. (6).

$$Precision = \frac{Tp}{FP + TP} \tag{6}$$

Here, TP it denotes the true positive and FP false positive samples. Hence, to know the mean performance in the cases of both sensitivity and precision score, the F-measure validation metrics were evaluated using Eq. (8).

$$F\_score = \frac{2 \times recall \times precision}{recall + precision} \tag{8}$$

The precision and F-score rate for the Covid detection of the proposed NAGNP is made a comparison with the prevailing models is displayed in Fig. 3.

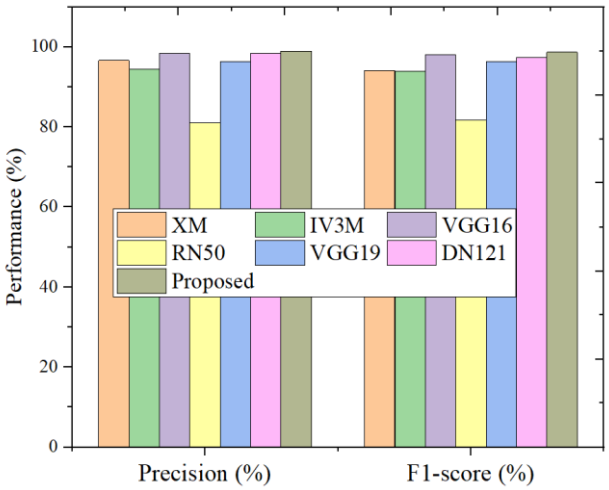

Fig. 3. Precision and F1 score comparison.

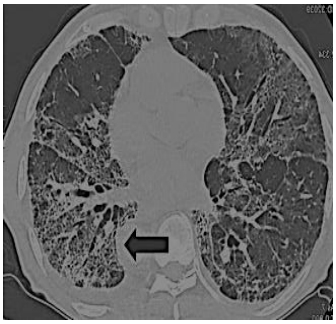
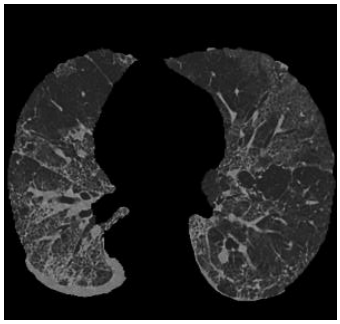
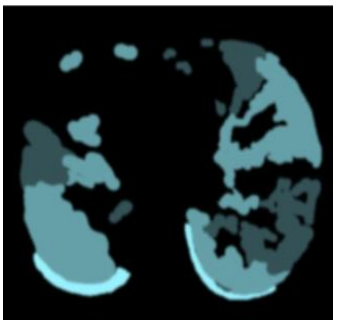
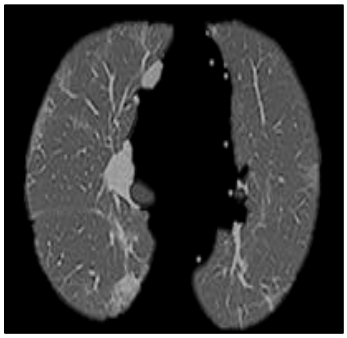
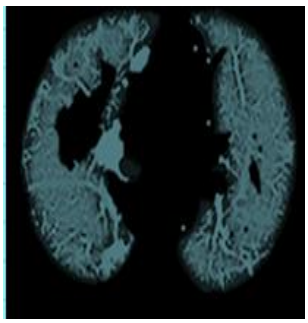
TABLE II. PREDICTION RESULTS

Input image	Ground Truth	Prediction
				










Here, Precision rate for the existing models, XM gains 96.6 %, IV3M gains 94.4 %, VGG16 gains 98.4%, RN50 gains 81 %, VGG19 gains 96.41 % and DN121 gains 98.37%. Meanwhile, the proposed model NAGNP gains 99%. Similarly the F1 score obtained by the prevailing models XM, IV3M, VGG16, RN50, 4.2.1 Precision and F1 score VGG19, DN121 obtained 94.07%, 94%, 98%, 81.73%, 96.41%, 97.38 % respectively and the proposed model obtained 98.7%. This shows better performance of the proposed model.

1) Recall and accuracy: Besides, the scalability of the executed model in the presence of a forecast fall ratio is found using recall metrics. Their formulation is given in Eq. (7), it can give the average performance by incorporating positive and negative classes.

$$Recall = \frac{Tp}{Tp + FN} \tag{7}$$

The correctness of the prediction process is found using Eq. (5) here, the exact forecasting is validated from the entire COVID detection performance.

$$Accuracy = \frac{exact \quad Forecast}{total\ prediction} \tag{5}$$

The Accuracy and Recall measure of the proposed NAGNP is made a comparison with the existing models is displayed in Fig. 4.

Here, Accuracy gained for the existing models, XM 94.2 %, IV3M 93.96 %, VGG16 98%, RN50 81.29%, VGG19 96.38% and DN121 97.38%. Meanwhile, the proposed model NAGNP gains 98.5%. Similarly, the Recall measure obtained by the prevailing models XM 91.6%, IV3M 93.6 %, VGG16 97.61 %, RN50 82.87 %, VGG19 96.41 %, DN121 96.41% and the proposed model obtained 98.5%. This demonstrates that the proposed model performs better. The overall comparison is depicted in Table III.

C. Discussion

The accuracy value of the proposed NAGNP is higher than that of the current techniques. This demonstrates the top performance across all parameters, including recall, Accuracy, precision, and F-score. It provides a 98.5% accurate forecast. Table IV shows the proposed approach performs. The overall effectiveness of the proposed NAGNP approach suggests that NADAM and ant NADAMfitness optimization provide superior feature extraction and prediction. It leads to increased precision.

Limitations: The effectiveness of GCNNs relies heavily on the availability and quality of labeled data. Limited or biased datasets could impact the model's performance and generalizability. GCNNs can be computationally intensive, requiring substantial resources for training and inference. This could be a limitation in resource-constrained environments or for real-time applications.

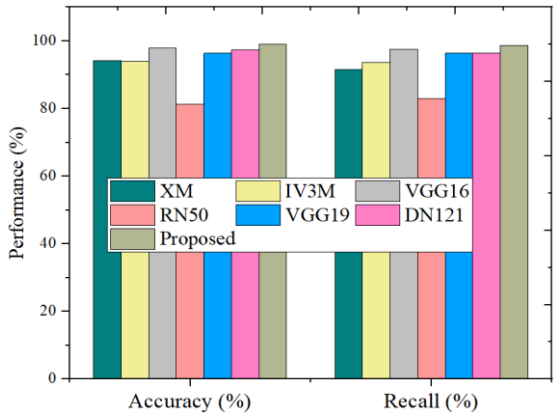


Fig. 4. Accuracy and recall comparison.

TABLE III. OVERALL COMPARISON STATISTICS

Metrics	XM	IV3M	VGG 16		RN50	VGG 19	DN 121	EfficientNet
Precision	96.6	94.4	98.4		81	96.41	98.37	99
F1-score	94.07	94	98		81.73	96.41	97.38	98.7
Accuracy	94.2	93.96	98		81.29	96.38	97.38	98.5
Recall	91.6	93.6	97.61		82.87	96.41	96.41	98.5

TABLE IV. NAGNP PERFORMANCE

Metrics	X-ray (EfficientNet B1)	CT-Scan(EfficientNet B3)
Accuracy	97.5 %	98.5 %
Precision	99 %	99 %
Recall	97 %	98.5 %
F1-score	97.92%	98.64%

V. CONCLUSION

The NAGNP framework for detecting COVID-19 is described in this study. The Python program is used to execute it, and the results are described. Initially, the Kaggle site is used to gather data for COVID-19 detection, and preprocessing is used to eliminate noisy elements. Subsequently, the CNN does the feature extraction technique, and the ant NADAM fitness performs the prediction, yielding a superior prediction outcome. The feature extraction procedure takes the critical features from the data and predicts COVID-19. Finally, the suggested model's performance is verified using several metrics, including F1-score, Precision, Accuracy and Recall. The outcome revealed that the proposed model performs better. The designed model gains an accuracy of 98.5 %, a precision of 99 %, A recall of 98.5 %, and an F1-score of 98.7 %, resulting in better performance. Compared to the current models, the accuracy of the proposed NAGNP model is improved by 1% to 2%. However, future work is needed to detect and segment in real time.

A Smart AI Framework for Backlog Refinement and UML Diagram Generation

Samia NASIRI*, Mohammed LAHMER
Moulay Ismail University, Faculty of Science, Meknes, Morocco

***Abstract*—In Agile development, it is crucial to refine the backlog to prioritize tasks, resolve problems quickly, and align development efforts with project goals. Automated tools can help in this process by generating Unified Modeling Language (UML) diagrams, allowing teams to work more efficiently with a clear understanding and communicate product requirements. This paper presents an automated approach to Agile methodology which refines backlogs by detecting duplicate user stories and clustering them. Following the refinement process, our approach generates UML diagrams automatically for each cluster, including both class and use case diagrams. Our method is based on machine learning and natural language processing techniques. To implement our approach, we developed a tool that selects the user stories file, groups them by actor, and employs the unsupervised k-means algorithm to form clusters. After that, we used Sentence Bidirectional Encoder Representations from Transformers (SBERT) to measure the similarity between user stories in a cluster. The tool highlights the most similar user stories and facilitates the decision to delete or keep them. Additionally, our approach detects similar or duplicate use cases in the UML use case diagram, making it more convenient for computer system designers. We evaluated our approach on a set of case studies using different performance measures. The results demonstrated its effectiveness in detecting duplicate user stories in the backlog and duplicate use cases. Our automated approach not only saves time and reduces errors, but it also improves collaboration between team members. With an automatic generation of UML diagrams from user stories, all team members can understand product requirements clearly and consistently, regardless of their technical expertise.**

Keywords*—Artificial intelligence; NLP; Agile methodology; UML

I. Introduction

In the System Development Life Cycle, it is essential to undergo a requirement analysis stage to ensure the success of the process [1]. This occurs because developers must understand the requirements before proceeding to the implementation stage. In this context, user stories are increasingly used to communicate requirements in Scrum. They are semi-structured natural language expressions of requirements at a high level. The textual template for user stories has been proposed in many forms by practitioners. In practice, they tend to use the form of: "As a…, I want to…, so that…" The growing number of stakeholders involved in the development process increases the size of the systems developed, leading to a larger number of user stories. This size growth makes it mandatory to decompose the system into subsystems covering different sets of semantically similar user stories.

As part of requirements engineering tasks, stakeholders need to be kept involved in the process by expressing each subsystem semi-formally, such as using visual models. As a visual language supporting requirements engineering, we used the Unified Modeling Language (UML) in this context. A model-based approach is often used to specify software system features and to reduce ambiguity between requirement specification and design. However, deriving UML models manually from similar user stories can be time-consuming and tedious, especially for large systems. Additionally, model-based approaches have been difficult to integrate in Scrum processes. This is basically due to the lack of powerful automation tools [2], [3], as well as focusing on implementation rather than analysis and documentation of teams.

Several studies were conducted to automate the generation of models from natural language software requirements [4]-[12]. In addition, some authors studied natural language requirements clustering to decompose the target system at an initial level [13], [14]. The current requirements clustering approach lacks precision and does not achieve a high level of automation. In contrast, we propose a machine learning-based approach that addresses these challenges. However, the requirement clustering has rarely been considered as a primer for automatically deriving models.

In this paper, we propose a machine learning-based approach for automatically dividing a system into subsystems and generating UML diagrams based on natural language user stories in Scrum.

To group the user stories by actor, we applied a set of natural language processing heuristics to extract the actor name from each user story. Once the system was initially decomposed by the actor, we performed a second decomposition for each resulting cluster. The second clustering of the system was based on the k-means algorithm, which groups semantically similar requirements. To identify possible redundancies between user stories located in each cluster, we used the BERT model. This process allows Product Owners and Scrum Masters to be more informed about their decisions regarding the elimination of redundant user stories from the Product Backlog. In the final step, we generated use case and class UML diagrams from the identified clusters.

This paper is organized as follows. The Section II reviews related work, while the Section III presents the background of the proposed approach. Section IV is devoted to a detailed description of the proposed approach. In Section V, we describe and analyze the similarity detection between user

stories and generated UML diagrams; it also evaluates and discusses the performance of the approach. Finally, Section VI concludes the paper.

II. Related Work

In this section, we provide a literature review related to our approach. For instance, in study [15], the authors have reviewed word embeddings and implemented a convolutional neural network trained on pre-trained word vectors. They have also illustrated the performance of pre-trained word integrations vs. random embeddings. However, in study [16], the authors have presented an approach that uses semantic similarity measures to suggest possible cases of duplication between user stories. To explain, the approach selected the most appropriate measure to determine the level of similarity between user stories. Their research analyzed semantic similarity measures based on the WordNet lexical database WuP, a similarity measure based on VSM Lin [17], and a measure based on the frequency of common terms Lesk-A [18]. The authors of study [19] analyzed user stories to identify potential information gaps and prevent ambiguities, using comparisons with previous user stories to detect missing queries. They have provided suggestions to users to get a better description. For natural language processing (NLP), an NLP tool called LingPipe Toolkit is used. Semantic role labeling was carried out to attribute roles and actions. In study [20], the authors' method established the user stories meta-model by determining the unified descriptive model of the user stories which are: the role, the task, the capability, the soft goal, and the hard goal. In study [21], the approach allowed the extraction of relevant information for user stories from recorded conversations between customers and developers. In study [13], the authors' work consisted of clustering the specification requirements by first using the Vector Space Model (VSM) to compute the similarity of functional requirements and then the Agglomerative Hierarchical Clustering (AHC) algorithm to construct clusters. In study [22], the authors have proposed a tool-assisted approach to identify terminological ambiguities between viewpoints as well as missing requirements. For this purpose, they combined natural language processing with information visualization techniques that help in defect-type interpretation. Their approach consisted of identifying ambiguity and incompleteness in a set of requirements. The authors used word2vec to detect similarities between terms in requirements. The visualization showed the requirements graphically by marking the terms used and arranging them in a 2D space according to the viewpoint to which the terms belong. They used Cortical.io's algorithm which relies on semantic folding and fingerprinting. Then, the algorithm built the context of each pair of terms that appeared in the same user stories. In study [23], the authors provided Sentence-BERT (SBERT). This pre-trained BERT network modification takes advantage of Siamese and triplet network structures by deriving semantically meaningful sentence embeddings that can be benchmarked using cosine similarity. In study [24], the authors used Word2vec to compute the similarity at the word level, then they grouped the requirements into clusters using the Agglomerative Hierarchical Clustering (AHC) algorithm. Word2vec for each word after tokenization at remove stop words, and stem. They used Gensim API for keyword extraction of each cluster. This summarizer is based on the ranks of text sentences using a variation of the TextRank algorithm. After that, they defined simple NLP rules for component extraction to generate a use case diagram. In [14] authors used a K-means clustering algorithm applied to user stories. The authors in study [25] have provided a tool to extract the time spent in historical and similar user stories. This extracted time helps developers estimate the time that similar user stories will spend on new projects. To do this, the authors used the NLP algorithm and a pre-trained model developed by Google called USE. The model did not distinguish between the opposite operations “add and remove”. In research [26], the method began by extracting iStar nodes from semi-structured user stories. Next, the nodes were merged based on their similarity. Finally, edges between nodes were identified using defined rules. The authors' approach was based on the refinement relationship between iStar nodes. The authors applied a BERT (Bidirectional Encoder Representations from Transformers) model for similarity measurement. In study [27], the approach helped in detecting defects in user stories by using 11 quality criteria. It was based on two main components: firstly, quality analysis was based on NLP. This method uses four fundamental functions of natural language processing: sentence segmentation, tokenization, POS labeling, and syntactic analysis. It examined the completeness of components and the testability of stories by checking several quality criteria, such as the correct form of components and the consistency of keywords used in stories. Secondly, the method was based on the analysis of iStar models. It started by generating iStar models from user stories, identifying nodes (role, goal/task), and detecting relationships between these nodes. It then checked several quality criteria, including uniqueness, absence of conflicts, verifiability, independence, and conceptual consistency.

Many approaches for requirements gathering and analysis have been developed so far, falling into two main categories: (1) approaches based on gathering, and (2) approaches focused on identifying duplicates or ambiguities in user stories. Our approach combines these two methods while refining the user stories to eliminate duplicates. In addition, the proposed approach aims at automatically generating UML diagrams from a given set of refined user stories.

III. Background

In this section, we outline the key concepts underlying this work.

A. Text to Semantic Vectors Transformation in NLP

It is important to transform text into semantic vectors in many automatic NLP tasks. This enables algorithms to process language more effectively by representing the meaning of words and sentences. There are several approaches for converting text into semantic vectors, and each one of them has its strengths and limitations. Hence, in this section, we will discuss the most common approaches, including One Hot Encoding, TF-IDF, Word2Vec, ELMo, InferSent, and Sentence Transformers [28].

- One Hot Encoding is a straightforward method that transforms text into binary vectors by assigning a unique dimension to each word in the corpus. In this method, the dimension corresponding to each word is marked as 1 for each document, while all other dimensions are marked as 0. The resulting vectors are binary vectors of a size equal to the total number of words in the corpus. Although this method is simple to implement, it disregards semantic relationships between words and can result in large and sparse vectors.
- TF-IDF is a technique that represents documents as vectors using term frequency and inverse document frequency. The weight of a word in a document is computed by multiplying its frequency in the document (TF) by the inverse of its frequency in the entire corpus (IDF). This approach generates weighted vectors that consider the relative importance of words in documents. Even if it is more expressive than One Hot Encoding, TF-IDF still does not capture semantic relationships between words [29].
- Word2Vec is a neural network-based method that learns dense vector representations of words in a vector space. It includes two main variants: Skip-Gram and Continuous Bag of Words (CBOW). Skip-Gram predicts neighboring words given a target word while CBOW predicts the target word using its neighboring words. The resulting vectors capture semantic and syntactic relationships between words. However, Word2Vec does not consider the syntactic structure of sentences [30] [31].
- ELMo, or Embeddings from Language Models is a model that represents words and phrases in automatic natural language processing. It creates contextual embeddings using bidirectional recurrent neural networks (Bi-LSTMs), capturing the meaning of words in context. Pre-trained on unannotated texts, ELMo generates rich, contextual embeddings. These representations enhance text classification, information retrieval, and other NLP tasks by capturing the semantic and syntactic nuances of words in various contexts.
- InferSent, developed by Facebook AI Research (FAIR), is a sentence representation model that generates contextual semantic embeddings using deep neural networks. Based on a semi-supervised supervision approach, InferSent aims to capture the semantic meaning of sentences. Pre-trained on a large corpus of data, this model produces informative sentence embeddings, beneficial for tasks such as text classification and semantic similarity assessment between sentences.
- The Universal Sentence Encoder (USE) is a widely adopted natural language processing model that has been extensively used in various research domains. Developed by Google, USE employs a deep neural network to encode text into fixed-dimensional vectors, capturing semantic information and contextual meaning [32]. It has proven to be effective in tasks such as sentence similarity, document classification, and semantic search. With its ability to understand and represent the meaning of sentences, USE has become a valuable asset in numerous applications. Its success lies in its capability to capture intricate semantic relationships. This makes it a reliable tool for tasks involving text comprehension and similarity analysis.
- Sentence Transformers: The advancement of deep learning has resulted in a significant improvement in the performance of neural network architectures like recurrent neural networks (RNN and LSTM) and convolutional neural networks (CNN) in the areas of Natural Language Processing (NLP), such as text classification, language modeling, and machine translation.

Bidirectional Encoder Representations from Transformers is a Transformer-based machine learning technique for natural language processing: pre-training developed by Google. The Sentence BERT (SBERT) network uses siamese and triplet networks to obtain semantically meaningful sentence embeddings derived from BERT [23]. SBERT can be employed as both a semantic similarity search and as a clustering algorithm. Similarity measures like cosine similarity or Manhattan/Euclidean distance can be used to determine semantic similarity.

Several SBERT pre-trained models encode sentences and calculate the distance between them to conduct semantic searches. Each model has its own task such as question answering, translation, sentence similarity, and others. These models are tuned for many use cases and trained on a huge and varied dataset consisting of over a billion training pairs. They are called “sentence transformers” and represent a modern approach to transforming text into dense semantic vectors using pre-trained neural network models. One of the main advantages of sentence transformers lies in their ability to capture the full semantic meaning of entire sentences, beyond representations of individual words. Notably, these models are often trained for natural language understanding tasks, such as next-sentence prediction or text classification, to further enhance their performance and accuracy. On the one hand, these models consider the contextual relationships between words in a sentence and generate representations that capture the meaning of the sentence as a whole. On the other hand, word-based models only consider the individual words and their relationships to other words in the corpus. This allows sentence transformers to more effectively capture the meaning and semantic nuances of a sentence, which is particularly beneficial for tasks involving the evaluation of similarity between user stories.

B. Grouping of user Stories by Actor

Grouping textual requirements based on their semantic similarity provides valuable information on the structure and behavior of the target system. To explain, it simplifies interpretation and identifies redundancies and inconsistencies which improves system quality. In addition, it enables efficient requirements management, traceability, and impact analysis, improving the overall system design and development process.

In this context, we aim to group user stories according to their semantic similarity.

Unsupervised learning is a machine learning technique that works on unlabeled data. In this technique, the machine is not given predefined labels to use for learning, but autonomously identifies patterns in the data to solve the business problem.

In clustering, unlabeled data is assembled into groups by using an algorithm based on unsupervised learning. In each cleaned dataset, with the help of the algorithm, the data points can be organized into groups by using the clustering algorithm. As a result of the clustering algorithm, it is presumed that the data points that belong to the same group, will have similar properties whereas the data points, that belong to different groups, will have quite different properties. Machine learning algorithms include a wide variety of clustering algorithms. Among the various clustering algorithms used in machine learning, K-Means is the most commonly used. According to [33], the use of K-means offers significant advantages for clustering textual requirements. This algorithm is appreciated for its speed, simplicity, and interpretability.

In addition, it offers flexibility by allowing the desired number of clusters to be specified. This study confirmed the benefits of K-means in the efficient clustering of requirements.

The process of the K-Means algorithm is outlined in the steps below:

- Step 1: We first select a random number of K to use and randomly initialize their respective center points.
- Step 2: We then classify each data point by calculating the distance (Euclidean or Manhattan) between that point and the center of each cluster, and then regrouping the data point so that it is in the cluster whose center is closest to it.
- Step 3: We recalculate the cluster center by averaging all vectors in the cluster.
- Step 4: We repeat all these steps for n number of iterations or until we find that the cluster centers do not change much.

IV. Approach

This section presents our proposed approach to backlog refinement and UML diagram generation. This approach both identifies similar user stories and generates the corresponding UML diagrams for each group spotted. First, we give an overview of our proposal. Then, we provide a detailed explanation of each step.

Our method started by grouping user stories by actor, and then we opted for an unsupervised clustering approach to be applied in each group. Thus, we used the k-means algorithm to generate clusters.

In the next step, we applied the BERT transformers algorithm for each cluster to compute similarity measures between user stories.

We developed a web-based tool for visualizing clustering, similarity features, and UML diagrams. We used Python and the Flask framework to implement the tool. Fig. 1 shows the steps of our proposed method.

A. Grouping of user Stories by Actor

A user story is a very high-level definition of a requirement, containing just enough information; it is the most effective way to describe a requirement [34]. Agile project teams use one of these methods: Scrum, XP, Kanban, etc.

A user story often uses the following type of format:

As [actor], I want/I am able/I can [some objective], so that [some reason] [34].

Before grouping the user stories, it is crucial to group the requirements by an actor. To achieve this goal, we extracted the actors using heuristic rules. The defined rules are based on tokenization and POS. We used the Python language and Spacy as NLP tool.

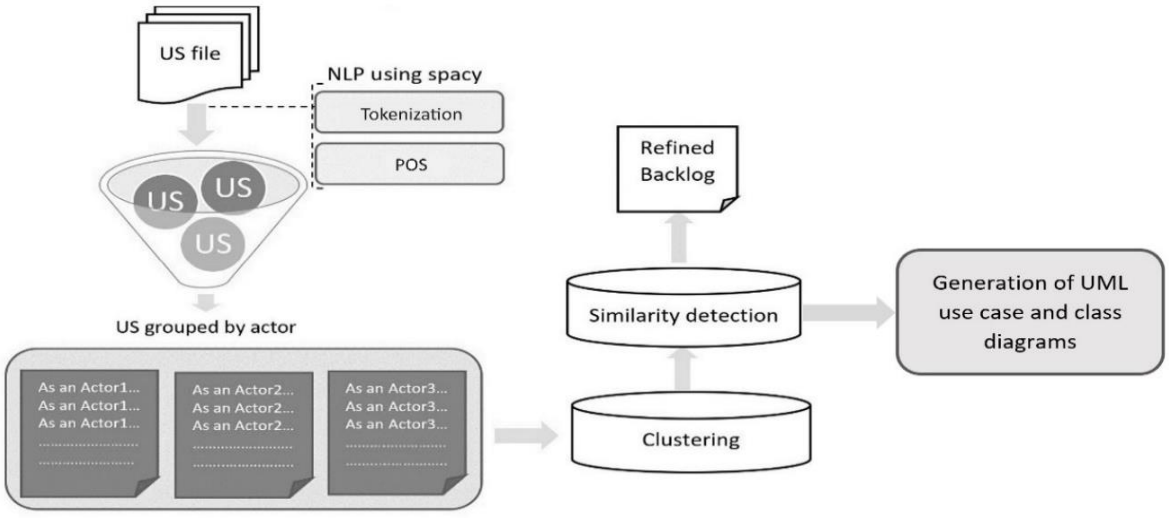

Fig. 1. Steps of our proposed approach.

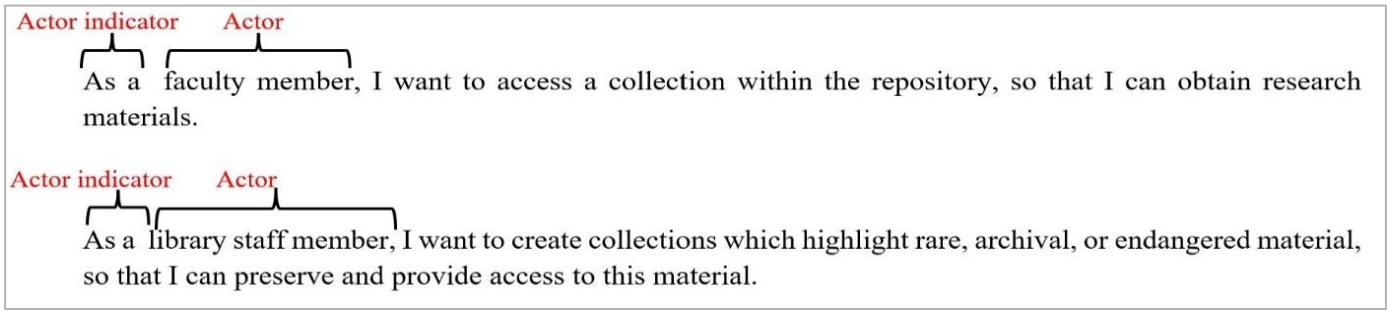

Fig. 2. Examples of user stories.

Since the extraction of a composite role composed of three words was not possible with the typed dependency in our previous work [10] [36], we switched to another method which consists of extracting the words following "As a/an": The role indicator is either an adjective or a noun, except pronouns. This solution allowed us to extract actor names independently of their name type. Our tool then used our defined rules to extract actors from user stories, which were stored in a text file. After that, it grouped the requirements by actor and saved each group separately. Fig. 2 shows examples of user stories.

Given these user stories:

- As an administrator, I want to search for a specific student, so that I can find the student records.
- As a student, I want to look up my student records, so that I can get a look at the details.

The two user stories are similar in the sense that they both aim to provide access to student records. They differ mainly in the actor involved: the administrator in the first case and the student in the second.

Unlike the methodology described in study [25], which focused on the identification of similarities between user stories without taking into account the "action executor" - i.e., the actor involved in the process - our approach took into account the specific roles or actors associated with the actions described in the stories.

Our method consisted of classifying user stories according to the actors involved, which makes it easier to keep similar stories describing identical actions carried out by different roles. These role-oriented requirements are the basis of the generated UML diagrams. For example, in a UML use case diagram, the two user stories could be represented as two separate but related use cases because they have similar functionalities (search and access to student records). They could be represented with different actors (the administrator and the student) but linked to a common use case, such as "View student records". This would show the relationship between the two actions despite the differences between the actors.

B. Clustering

To implement our method, we used Sentence Transformers to embed sentences. Then, we employed the K-means algorithm to cluster the user stories based on their significance. We labeled the generated clusters using the Gensim library, which also provided us with keywords that describe the domain knowledge embedded in each cluster.

The Gensim library has an implementation of TF-IDF as part of its models, specifically the TF-IDF model module. This module converts documents into a matrix of token counts and calculates TF-IDF weights for each word.

These weights can then be used as features for tasks such as text classification, clustering, or similarity calculation.

To refine the backlog, we needed to eliminate duplicate user stories and display only relevant stories with their level of similarity. K-means clustering was used to achieve this by initially setting the value of k and examining the graph to identify the cut-off point where the slope changes. However, we opted for the silhouette calculation method to automate the k-value calculation at the outset. This approach enabled us to find the optimal k-value right from the start, making it easier to group user stories more efficiently. Then, we created a Python code to accomplish this task.

C. User story Similarities and Opposite Meanings Detection

1) Identification of similar user story pairs: To refine the backlog and detect duplicate user stories, we categorized the user stories by actor and then measured the similarity rate between each pair of user stories within each cluster. To achieve this goal, we used a sentence transformer (SBERT) to measure semantic similarity between the pairs of user stories. Below are the steps conducted for each cluster:

- Convert a sentence into a vector using sentence transformers.
- Convert several other sentences to vectors.
- Identify sentences with the smallest distance (Euclidean) or angle (cosine similarity) between them.
- Highlight the most similar user stories with rates above 75%.

We used SBERT to transform sentences into vectors, embedding them in a high-dimensional semantic space. Cosine similarity is then used to measure the degree of similarity between these vectors. More precisely, it assesses the comparability of documents regardless of their size by calculating the dot product of the vectors divided by the product of their Euclidean norms, as illustrated in Eq. (1).

$$\text{Similarity} = \cos(\theta) = \frac{A.B}{||A||||B||} = \frac{\sum_{i=1}^{n} A_i B_i}{\sqrt{\sum_{i=1}^{n} A_i^2}\sqrt{\sum_{i=1}^{n} B_i^2}} \quad (1)$$

Here, A and B are two vectors. A.B is the dot product of those two vectors.

We aimed to select the most efficient sentence transformer that provides a higher percentage of similarity among pairs of sentences exhibiting similarities. We focused on comparing user stories that are similar but differ in their operations, ensuring that any dissimilarities were captured.

We adopted a structured two-phase approach to choose the most suitable model for measuring the similarity between pairs of user stories. First, we carried out a comparative analysis of SBERT models to identify the most efficient model. Then, we extended our evaluation by comparing the SBERT model with other models available in the field.

On the one hand, Table I highlights the application of various SBERT models to detect similarities among pairs of user stories. This table presents the respective similarity rates achieved by applying different SBERT models to some pairs of user stories. On the other hand, Table III illustrates the comparison of the similarity rates obtained from different models, such as Elmo, Word2Vec, and a SBERT model, among others. Furthermore, Table II highlights the application of various SBERT models to detect similarities among pairs of user stories. This table presents the respective similarity rates achieved by applying different SBERT models to some pairs of user stories. Table I and Table II illustrate the two-level processes that form an integral part of our analysis approach.

TABLE I. SIMILARITY SCORES OF USER STORIES US1, US2, AND US3 USING SENTENCE TRANSFORMERS

Sentence Transformers	Similarity score US1-US2	Similarity score US1-US3
all-MiniLM-L6-v2	0.8180	0.6819656
all-MiniLM-L12-v2	0.8838	0.7911284
all-mpnet-base-v2	0.9025	0.8001925
all-distilroberta-v1	0.9006	0.7651011
paraphrase-mpnet-base-v2	0.9046	0.69480187

TABLE II. SIMILARITY SCORES OF USER STORIES US1, US2, AND US3 USING SIMILARITY MODELS

Models and similarity measures	Similarity score US1-US2	Similarity score US1-US3
USE	0.83511186	0.7759
SBERT(paraphrase-mpnet-base-v2)	0.9046	0.69480187
WORD2VEC	0.84041464	0.7834515
InferSent	0.9690	0.9582
ELMO	0.9342766	0.8595803
Wup similarity	0.66107734	0.3823969

Consider these user stories:

- US1: As a buyer, I am able to remove a product from the list.
- US2: As a buyer, I can drop a product from the list.
- US3: As a buyer, I can edit a product in the list.

Table II shows the similarity score of previous user stories by applying the sentence Transformers.

Based on the hierarchical structure of WordNet, Wup similarity evaluates the similarity between words according to their position in the lexical tree. Wup similarity does not take into account the contextual meaning of the words being compared unlike BERT, ELMO, and InferSent which integrate context to evaluate similarity. This lack of contextual consideration can limit Wup similarity's ability to capture semantic nuances in a variety of contexts.

Both Tables I and II illustrate that the sentence transformer "paraphrase-mpnet-base-v2" exhibits a considerable degree of similarity. We observe operations of US1 and US3, which involve different actions such as "remove" and "edit". Therefore, the model chosen to evaluate similarity must be able to discern sentences with closely related but divergent meanings. This discernment is essential to avoid any negative impact on our analytical processes and backlog refinement.

To ensure that we had selected the appropriate Sentence Transformer model for our approach, we carried out an evaluation by testing several models on two distinct datasets. This evaluation aimed at determining the performance and effectiveness of each model in capturing the semantic meaning of user stories and generating high-quality sentence embeddings. To measure the performance of the models, we used evaluation metrics such as cosine similarity, accuracy, and F1-score. Through this evaluation process, we identified the model that consistently demonstrated superior performance and provided the most meaningful sentence embeddings.

We will provide further details of the evaluation in the next section.

2) Identification of the user story pairs with opposite meanings: When the similarity threshold is increased, the number of similar user story pairs decreases. To identify similar user stories, a minimum similarity rate of 75% is required while a much higher threshold with similarity rates exceeding 90% is necessary to detect duplicate user stories. In the first range, similar user stories were sometimes found where one story was included in another, providing additional information to the third part of the story. This was mainly due to the poor quality of the user stories. It is only by improving the quality of these stories that the occurrence of such similarities can be reduced.

However, in the second range, although we detected duplicate user stories, they sometimes had opposite meanings that were not captured by sentence similarity models.

Given these user stories:

- US4: As a buyer, I can add a product to the list.
- US5: As a buyer, I can not add a product to list.
- US6: As a user, I want backend changes for managing enum lists.

- US7: As a user, I want frontend changes for managing enum lists.

Table III displays the similarity scores of user stories with opposite meanings, which are US4 with US5, and US6 and US7.

In studying the ability of the SBERT model to detect pairs of opposing user stories, it was noted that when two user stories were presenting the same operation, with the same action verb in the format "As [actor], I want [action_verb]" and preceded by a negation "not", the model was able to identify their opposition. However, if they are not having the same operation, the SBERT model does not detect the dissimilarity. Another case demonstrating opposite meanings is illustrated in the cases described in Table IV. Using sentence transformers, we observed a similarity score of 0.97 between user stories US6 and US7, highlighting substantial similarity despite contrasts in their content. To address this limitation, we developed specific rules. We used Typed dependencies provided by an NLP tool and the Wordnet API to search for synonyms of operations and checked for the presence of negation. Where negation was not explicitly expressed, we opted to detect antonyms for operations which improved the accuracy of detecting pairs of opposing user stories.

TABLE III. SIMILARITY SCORES OF USER STORIES WITH OPPOSITE MEANINGS

Models and similarity measures	Similarity score US4-US5	Similarity score US6-US7
USE	0.8806	0.9573
SBERT	0.42601973	0.9724
WORD2VEC	0.9803098	0.94255805
InferSent	0.9965	0.9912
ELMO	0.95751846	0.9578713
Wup similarity	0.6326058	0.6258217

As shown in Table III, we found a similarity of 0.97 between user stories US6 and US7 when using sentence transformers, suggesting high similarity within their differences. The WordNet approach was able to detect opposing meanings in some pairs of user stories. However, this method showed limited effectiveness for some examined pairs. The rules, we have developed, combine the use of the Wordnet API with typed dependency analysis to identify cases where user stories are initially identified as duplicates, having opposite meanings. These rules cover four different structures of user stories listed in Table IV.

The defined rules are based on the Stanford CoreNLP dependencies, such as neg, dobj, nmod, and advcl. This method includes the steps described in the proposed algorithm as follows.

Algorithm: Rules for negation extraction

```
1. Procedure(story1,story2):
2. Extract_part2(story1,story2)
3. Syn=Extract_synonyms(story1.verb1)
4. if [verb2 in Syn and check_negation(story1,story2)]
5.                 or are_antonyms(verb1, verb2) then
6. if dobj(verb1,obj1) = dobj(verb2,obj2)
7. or nmod(obj1,modifier)= nmod(obj2,modifier) then
8.                 return “negation found”
9. if story1.Action_advcl=story2.Action_advcl then
10.  return “negation found”
```

The algorithm described above is designed to detect negation in a pair of user stories. It worked by first extracting the second part of the user stories that presented the action. Then, it searched for synonyms of the first story's verb (verb1) and checked whether the second story's verb (verb2) is a synonym of the first story's verb (lines 1-3). In line 4, the check_negation(story1, story2) function was implemented by recognizing the negation indicator. In line 5, the algorithm examined whether the verb in story 1 is either a synonym preceded by a negation indicator or a direct antonym of the verb in story 2. If these conditions, along with the direct object or nominal modifier (nmod) had matched between the objects (lines 6-8), the algorithm returns “negation found”. Line 9 checked whether the action in the “advcl” dependency is the same in both stories. If this condition, and the previous conditions, are met, the algorithm obtains the result “negation found”. This condition is specific to Structure 4.

D. Similarity Detection in use Case Diagram

We used the Sentence Transformer technique to identify similarities between use cases in use case diagrams. Our approach involved concatenating the actor name and use cases, and then checking for similarities with a similarity score of over 90%, which was further improved by applying Wordnet for lemma synset interactions. This approach helped us extract similar use cases and user stories, which was very useful in creating refined models with minimal redundancy and inconsistency.

TABLE IV. STRUCTURES OF USER STORIES

Structures	User stories	Description	Example
Structure 1	As an actor, I want/I am able/I can **verb dobj**	An actor or role executes an action, which is described by a verb and involves a direct object.	As a customer, I want to view my order history so that I can track my purchases.
Structure 2	As an actor, I want/I am able/I can **verb dobj preposition nmod**	This structure includes additional detail about the direct object by adding a noun modifier.	As an administrator, I want to delete inactive user accounts more than 6 months old so that the database remains optimized.
Structure 3	As an actor, I want/I am able/I can **… preposition1 nmod1**… **preposition2**… **nmod2**	This structure adds a second nominal modifier to further clarify the objective of the user story.	As a manager, I want to include videos in courses for students.
Structure 4	As an actor, I want/I am able/I can **verb1 dobj1**… **preposition1 nmod preposition2 advcl**… **verb2 dobj2**…	It involves an initial action with a direct object, followed by a preposition and a modifier, leading to a second action with its direct object	As a manager, I want to generate reports of sales data by preserving product prices.

E. UML Diagrams Generation

After dividing the system into requirements by actors, we automated the process of generating UML models (class diagrams and use case diagrams) from the resulting clusters. To achieve this, we used various types of dependency present in NLP to implement specific NLP rules in the Prolog language to extract the elements making up the diagrams. Our first step involved generating the class diagram, followed by the use case diagram. Based on our previous work [11], we have developed Prolog rules to identify classes and associations. Facts were provided by an NLP tool that supplies nouns, verbs, and typed dependencies. The process of extracting class attributes followed the methodology described in study [10]. Hence, this method refined classes into attributes and converted certain associations into operations on classes. Prolog rules are presented as follows: Association(X, Y, Z); X is the name of the association, and Y and Z are the classes in the class diagram.

Extracting classes and associations is useful in generating use cases while association types, such as composition, helps determine the relationship between the use cases.

Given the importance of the terms used to represent the elements of the diagrams, refining the diagrams is essential as well. After the generation of UML diagrams, the next critical phase involved their refinement, which had been facilitated by the development of an ontology to store word equivalents [11].

F. Web-Based Framework

We developed a web-based tool that allows users to display similar user stories and their similarity percentages in selected clusters. Based on this percentage, users can decide whether to delete similar stories or to keep them. On the homepage, users can select a file containing user stories and click on a button to group them by actor. The file is automatically split into multiple ones, and users can then choose an actor from a drop-down list. Clustering by meaning is then performed, and the similarity rate is displayed. The results are presented in a table format, showing the similarity between each pair of user stories. We set the maximum similarity threshold at 75%. Once users have refined their backlog, they can generate UML class and use case diagrams to further improve the system design and development process.

V. Results and Discussion

This section presents the case studies and performance to evaluate the methodology of our approach for clustering, detecting more similar user stories, and generating a UML diagram for each cluster.

A. Evaluation

In this section, we present the evaluation of our approach. We firstly compare evaluating the “Paraphrase-mpnet-base-v2” model and the “all-MiniLM-L6-v2” model, which both belong to the SBERT models. We then compare our approach with other similarity detection models such as the Universal Sentence Encoder (USE), ELMO, and Word2vec. These models were evaluated for their performance in detecting similarities and distinguishing nuances in user stories. Therefore, we evaluated the UML class and use case diagrams that have been generated.

1) User stories clustering: In our study, we acknowledge the absence of a baseline or established benchmarks in the literature that specifically address the clustering of user stories using the k-means algorithm based on the “paraphrase-mpnet-base-v2” model.

It was therefore difficult to make a direct comparison with existing results or measurements. Although the lack of references limited our ability to quantitatively assess the performance of our approach, we solved this problem by carrying out a qualitative evaluation of the content of the groupings. To validate the effectiveness of the clusters in capturing similarities and relationships between user stories, a thoughtful manual evaluation was carried out. The latter was conducted by a team of experts who examined the logical consistency and relevance of the clusters. The findings of this evaluation validated the cluster quality and their ability to accurately represent the underlying patterns in the user stories.

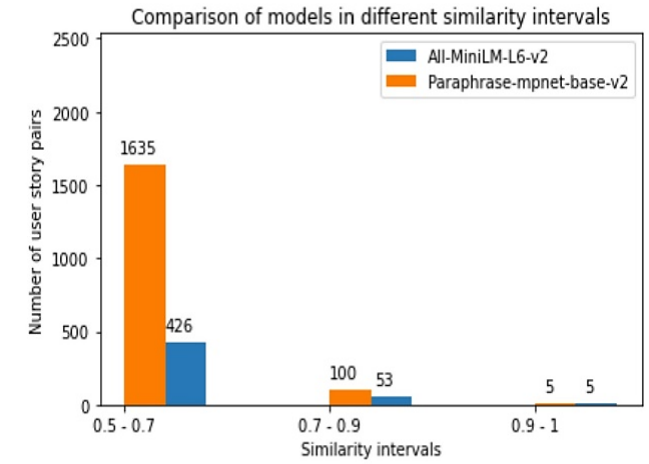
2) Sentence transformer and word embedding models for similarity detection: The SBERT “Paraphrase-mpnet-base-v2” sentence transformer model was selected to measure similarities between user stories. This choice was based on its enhanced robustness in capturing the deep semantics of sentences, thus offering high-quality representations. We chose this model thanks to its ability to handle sentences with similar but different meanings, a crucial feature for in-depth analysis of user stories.

Course management and Archivespace, which are two distinct datasets, were used to evaluate Sentence transformer models. The first dataset, retrieved from the website Mountain Goat Software, consists of 102 user stories. The second dataset, from Archivespace, included 160 user stories. We collected these user stories as a part of the ArchiveSpace software development project.

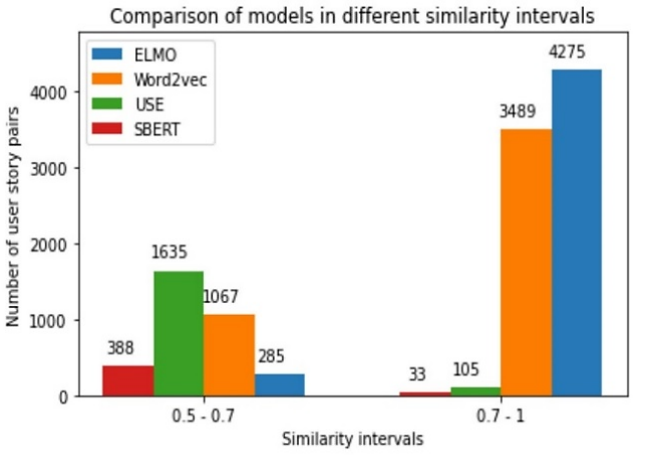
We carried out evaluations to compare and assess the performance of the “all-MiniLM-L6-v2” and “Paraphrase-mpnet-base-v2” sentence transformer models, as well as the USE, ELMO, and Word2vec models, using several pairs of user stories. Table V presents the performance scores for the Archivespace dataset, including those of the sentence transformer and word embedding models.

TABLE V. The Performance Scores of Similarities between User Stories using Sentence Transformers and Word Embedding Models

Sentence transformer Model	Score<0.5	0.5< score<0.7	0.7< score< 0.9	Score> 0.9
All-MiniLM-L6-v2	4076	426	53	5
Paraphrase-mpnet-base-v2	2820	1635	100	5
USE	4139	388	31	2
Word2vec	4	1067	3462	27
ELMO	0	285	4234	41



(a)



(b)

Fig. 3. Comparison of paraphrase-mpnet-base-v2 and All-MiniLM-L6-v2 (a), and comparison of SBERT (Paraphrase-mpnet-base-v2), USE, Word2vec, ELMO (b) in different ranges.

Fig. 3 illustrates the similarity ranges between pairs of user stories by using Paraphrase-mpnet-base-v2, All-MiniLM-L6-v2, USE, Word2vec, and ELMO.

While evaluating the Sentence Transformers models, we found significant differences between the two datasets. The “Paraphrase-mpnet-base-v2” and "All-MiniLM-L6-v2" models were initially tested for interval similarities greater than 0.9, and we discovered that these intervals gave almost identical results. However, when similarities were between 0.7 and 0.9, the evaluation of user story pairs presented challenges in determining whether they were similar or duplicates. In some cases, user stories appeared to be similar but turned out to be opposite or dissimilar. The results indicated that both models exhibited similar levels of similarity for most pairs of user stories. However, when considering slightly similar user stories, “Paraphrase-mpnet-base-v2” showed a distinguishing characteristic compared to the other model. It demonstrated a better ability to capture nuanced similarities and subtle differences between such user stories.

To compare the sentence transformer models with the use of USE, Word2vec, and ELMO, we conducted a second evaluation. The results revealed that USE detected lower similarity values than those detected by the sentence transformer models, even when the similarity interval was greater than 0.9. Furthermore, for pairs of user stories that should have a similarity rate below 0.8, USE often detected values above 0.8, particularly for user stories that appeared to be opposite or less similar. This divergence can be explained by saying that although user stories are similar in their action, differences in their description prevent them from being considered duplicated. Furthermore, the Sentence Transformers models, in particular the “paraphrase-mpnet-base-v2” model, showed better performance for the datasets used in this study. USE, while performing less well than SBERT, is still more reliable than Word2Vec and ELMO in assessing the similarity between these stories.

Further analysis revealed that Word2Vec, a widely used sentence embedding model, had limitations in detecting dissimilarity between user stories. Word2Vec may face challenges when distinguishing between user stories that are textually similar but involve different operations.

For example, it may struggle to discern the nuances between sentences such as “Users can add items to their shopping cart” and “Users can remove products from their shopping cart”, which is crucial in the context of software development.

In contrast, models such as Sentence Transformers are specifically designed to capture these contextual and operational nuances. They are highly accurate in measuring similarity while being more sensitive to subtle differences between similar user stories. In areas such as software engineering, where a precise understanding of requirements is essential, Sentence Transformers prove to be more effective for analyzing and planning software development.

After observing the similarity scores of different models in distinct ranges, notably between 0.5 and 0.7, as well as those above 0.7, we found that the SBERT model, in particular the "paraphrase-mpnet-base-v2" model, presented more consistent scores when compared to a manual approach. However, to better assess model choice, we used various metrics, including precision, recall, and F1 score [35]. Similarity identification was measured by accuracy, while coverage was measured by recall. We calculated precision, recall, and F1 score based on true positives, false positives, and false negatives. True positives (TP) corresponded to similarities correctly identified by our automated approach, while false positives (FP) referred to similarities incorrectly identified. A false negative (FN) was a labeled similarity not identified by an automated approach.

The evaluation metrics are measured as follows, as illustrated in Eq. (2), Eq. (3), and Eq. (4):

$$\text{Precision} = \frac{TP}{TP+FP} \quad (2)$$

$$\text{Recall} = \frac{TP}{TP+FN} \quad (3)$$

$$\text{F1 Score} = \frac{2*\text{Precision}*\text{Recall}}{Precision+Recall} \quad (4)$$

Table VI shows the precision, recall, and F1 scores for each user story dataset for similarity pairs obtained using SBERT.

TABLE VI. EVALUATION METRICS FOR SIMILARITY DETECTION OF USER STORIES OF THE FIRST DATASET

Models	Similarity of user stories pairs					
	TP	FP	FN	Precision	Recall	F1-score
ELMO	7	13	3	35%	70%	46%
Word2vec	14	65	0	17%	100%	29%
USE	5	1	6	83%	45%	58%
SBERT	14	1	0	93%	100%	96%

TABLE VII. COMPARISON OF SIMILARITY DETECTION MODELS FOR USER STORY PAIRS OF ARCHIVE SPACE DATASET

Models	Similarity of user stories pairs					
	TP	FP	FN	Precision	Recall	F1-score
ELMO	7	13	3	35%	70%	46%
Word2vec	14	65	0	17%	100%	29%
USE	5	1	6	83%	45%	58%
SBERT	14	1	0	93%	100%	96%

Table VII displays the similarity detection metric related to USE, Word2vec, and SBERT Models for User Story Pairs of the Archivespace dataset.

Table VI and Table VII show similar user stories with similarity rates above 90%. When the similarity rate exceeds 90%, the user stories are more similar. The low similarity metrics obtained using Word2Vec to evaluate user stories can be explained by the fact that this model does not capture the semantic complexity of texts as effectively as more recent approaches such as USE and SBERT.

In some cases, one user story was included in another one which added more information in the third part of the user story which was due to poor writing of user stories. If the user stories were of high quality, they could reduce the occurrence of similar user stories. In other cases, the approach detected two similar user stories with opposite meanings. However, by using Wordnet and our defined rules, we have overcome this shortcoming.

Grouping user stories by actor before detecting similarity between pairs of stories had been found to help address the problem of false positives that can occur when multiple actors perform the same action. If stories were not grouped by actor, the similarity approach may identify false similarities between two stories that had different actors. However, the Universal Sentence Encoder (USE) model is limited in detecting explicit negation. Because of relying on language patterns, it can struggle to capture the opposite or contradictory meaning introduced by negation words like “not”. This can result in inaccurate detection of differences in meaning when negation is present.

3) Evaluation of UML class and use case models: During the evaluation process, our primary focus was to compare the UML use case diagrams generated by the proposed approach with the manual UML use case diagrams created by our team of experts. These diagrams were based on user stories. We aimed to assess the accuracy and effectiveness of the generated models in comparison to the manual approach and a relevant existing approach in the field. However, we were unable to make a direct comparison between our results and those of the referenced article because the identical case study used by the authors was unavailable.

To assess the quality and relevance of the UML use case models, we implemented a manual evaluation approach. Our team of experts carefully examined the models, comparing them with the corresponding user stories to ensure accuracy and consistency. In addition, to evaluate class diagrams, we used the same case study as [4], enabling a comparative analysis of the approach to extracting artifacts from class diagrams. This evaluation involved examining the artifacts extracted and comparing them with the expected artifacts derived from the case studies. We considered aspects such as completeness, correctness, and relevance to assess the effectiveness of our approach.

- Case study

The user stories, in this case study, represented event management: booking and purchasing an event ticket [36].

Tokenization, lemmatization, stemming, and part-of-speech (POS) analysis were used to process user stories. Typed dependencies were then applied to each user story. The extraction of design components was based on defined rules, which relied on the dependencies that were exploited and analyzed.

The final results of the extraction of design elements for the given user story are presented in the tables below. Classes and their attributes are listed in Table VIII.

TABLE VIII. CLASSES AND THEIR ATTRIBUTES

Classes	Attributes
Account	Password
Visitor	Personal_details
Ticket	Price
Ticket	Type

The relationship results are shown in Table IX.

TABLE IX. RELATIONSHIPS RESULTS

Relationships
Create (account, Visitor)
Have (account, Visitor)
Rename (account, Visitor)
Choose (event, Visitor)
Search (event, Visitor)
See (event, Visitor)
Choose (payment_methods,Visitor)
Buy (ticket, Visitor)
Book (ticket, Visitor)
Purchase (ticket, Visitor)
Receive (ticket, Visitor)
Have (ticket, event)

TABLE X. GENERATION OF CLASS OPERATIONS

Classes	Operations
Visitor	Provide (personal_details)
Account	Change(password)
Event	Filter(type)
Ticket	See (price)
Ticket	Choose(type)
Event	Choose(type)

Table X indicates the results of the operations.

The Visual Narrator tool [4] identified several classes, including Visitor, Account, System, Event, Ticket, EventType, Type, AccountPassword, Password, TicketPrice, Price, Detail, and Method. However, there are some relationships that the tool extracted, but our approach did not, such as hasType (Event, EventType), hasPrice (Ticket, TicketPrice), and hasPassword (Account, AccountPassword). Additionally, the tool detected that Visitors and Systems can log in and log out, but our approach did not.

The Visual Narrator tool [4] uses an approach that creates numerous compound classes and inheritance relationships. However, this method can result in complex classes and inheritance relationships that are unnecessary due to the absence of attribute extraction rules. Table XI compares the total items detected by [4], our approach, and manual analysis.

TABLE XI. THE TOTAL OF DESIGN ELEMENTS DETECTED BY [4] AND OUR APPROACH [36]

	Actors	Classes/ Entity	Attributes	Relations-hips	Operations
[4]	1	13	0	19	0
Our approach	1	5	5	12	6
Manually	1	5	5	12	6

Our approach, in the case studies, demonstrated significant improved performance compared to the method described in [4], achieving a high precision rate of 98% when comparing these results to those obtained manually.

B. Results

We provided a detailed explanation with the help of figures to clarify the process of clustering and generating UML diagrams using our tool.

Fig. 4 shows a web page that allows the user to download a file containing a set of user stories. Once downloaded, we performed the clustering by actor by clicking the “Clustering by actor” button. The extracted actors were then included in a drop-down list. To perform clustering by meaning, the user needed to click on the “Analyze” button, as illustrated in Fig. 5. It is worth noting that a text field to specify the number of clusters was not included from the beginning. This process was automated based on silhouette calculations.

Fig. 5 displays the clusters in a table, along with keywords representing the cluster's meaning, as well as links to select similar user stories. This table allows the user to easily navigate through the clusters and select the most relevant user stories.

Fig. 6 and 7 show the similarity scores generated for pairs of user stories within the cluster of the Instructor and Participant actors. By highlighting the most similar user stories, our tool facilitated the decision to delete or keep them.

Finally, Fig. 8-12 display the generated class and use cases UML diagrams corresponding to the “Participant” and “Instructor” actors. These diagrams provide a clear and consistent understanding of the product requirements, making it more convenient for team members to collaborate and work efficiently.

As can be seen in Fig. 10 and 12, using sentence transformers allows for the detection of duplicate use cases such as “receive feedback” and “get feedback”, the same for the “receive” and “get” associations between the participant and feedback class. Regarding the use cases “upload PDFS” and "download PDFS" these components were similar in using sentence transformation yet using the Wordnet approach shows that they had opposite meanings. We believe that combining both approaches can achieve better performance.

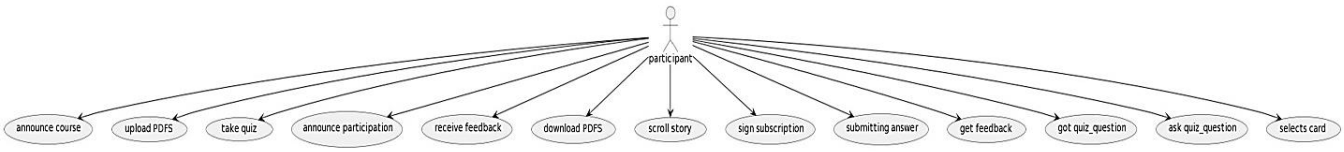

Fig. 12. Generated the UML use case diagram corresponding to Participant's cluster #2.

C. Threats to Validity

In this section, we will discuss the possible threats to the validity of our proposed approach.

- Internal Validity: The quality of user stories can have a significant impact on the results, particularly if they are poorly written or contain non-functional scenarios. This can negatively affect the relationships between classes and generate inadequate UML diagrams.

To overcome this problem, it is essential to ensure the quality and functional accuracy of user stories.

- Construct Validity: The rules defined for assessing similarities between user stories may be limited, as they only capture a restricted set of sentence structures in the context of opposite meanings. It is necessary to have a more comprehensive analysis that considers the semantic meaning and context of the user stories to accurately identify and handle potential contradictions.
- External Validity: In evaluating our approach, we analyzed two case studies to determine the effectiveness of our approach in detecting similar user stories. Although the initial results were promising, there is a need to extend our evaluation to a larger number of case studies.

D. Discussion

In this section, we compare our approach with existing state-of-the-art techniques [14], [16] that also use user stories as input. Although these approaches focus on clustering and duplicate detection, they do not include diagram generation. Another study [24] focused on generating use case diagrams from user stories, but it only considered user stories with a simple structure and did not address duplicate or similarity detection. In [25] Detection of similarities in user stories is ineffective because their method is unable to distinguish between operations such as "delete" and "add" in stories. These operations, which represent the core functionality, remain indistinguishable. The model used to detect similar user stories, namely USE, lacks the ability to discern negations in these stories, such as "not add" and "add".

In contrast, our approach built on our previous work [10]-[12],[36], in which we used NLP techniques to generate various UML diagrams from user stories. The paper [36] expands upon the content of [10].

The previous approach [11], based on ontology, Prolog rules, and WordNet synsets, focused on refining UML diagrams by defining explicit relationships and using domain-specific vocabulary. It addressed redundancy and duplicate detection to some extent, but it had limitations. Maintaining and updating the ontology with relevant vocabulary posed challenges. Focusing on explicit definitions might overlook subtle nuances in redundancy and duplication. Additionally, the approach required extensive domain knowledge and manual refinement.

In contrast, the new approach incorporated AI techniques, in particular SBERT models and clustering to refine the generated backlog and UML diagrams. It used machine learning to capture semantic similarities as well as the rules we defined to achieve better results. This enabled duplicates to be detected without the need to explicitly define an ontology.

Our approach focused on improving the refinement process to enhance the quality and accuracy of the generated models. The backlog was refined using clustering and similarity detection techniques before generating the UML diagrams. This step helped in handling the large number of user stories present and guaranteed the accuracy of the generated diagrams.

Refining the use case diagrams and detecting similar use cases made our approach more complete and refined compared to other approaches used by different authors.

Table XII summarizes the relevant related works.

Table XIII presents a comparison between the previous approach and our proposed approach.

In comparison to old approaches, our approach offered several significant advantages using automatic refinement of UML diagrams. Firstly, by integrating prior refinement of the user story backlog, early detection and elimination of redundancies in the process can be achieved. This allowed us to create more concise, better organized, and more relevant UML diagrams to represent the system's functionalities.

Secondly, through using AI techniques, particularly SBERT models, our approach offered better detection of duplications and similarities between user stories. Clustering user stories and subsequently labeling these clusters, allowed for an efficient backlog structuring and an improved organization. The refinement process eliminates redundant information and similar functionalities with great precision, resulting in clearer and more readable UML diagrams.

Automating the backlog refinement process saves the team valuable time. Employing the AI-based prototype allows for quick and accurate execution of tasks such as similarity detection, user story clustering, and diagram generation.

TABLE XII. SUMMARY OF RELEVANT LITERATURE

Approach	Models and tools	Input	Output
[14]	K-means clustering algorithm applied to user stories.	user stories	Clusters of user stories
[16]	- Semantic similarity measures to suggest possible cases of duplication between user stories. - Analysis of semantic similarity measures based on the WordNet lexical database, in particular WuP similarity.	user stories	Determine the level of similarity among user stories
[24]	- Agglomerative Hierarchical Clustering (AHC) algorithm to group requirements into clusters. - Use of the Gensim API to extract keywords by group. - Definition of simple NLP rules for component extraction to generate a use case diagram	user stories	Use case diagram
[25]	- The model USE for calculating similarity - For app development: Laravel and React. - Manual approach to detect similarities greater than 60%	User stories	- Estimate efforts and costs for agile projects: Time spent on similar past projects - Similarity user stories detection
Our approach	- Flask - Python - SBERT models - Defining NLP rules to identify every dissimilar previously classified as similar by SBERT models	User stories	- Similarity user stories detection - Clustering and labeling each cluster - UML diagram generation

TABLE XIII. COMPARISON BETWEEN THE PREVIOUS APPROACH AND OUR PROPOSED APPROACH

Features	Old Approach	New Approach
Refinement Method	Prolog rules, ontology, WordNet synsets	Clustering, SBERT models, and definition of rules
Refinement Stage	Post-generation refinement of UML diagrams	Initial backlog refinement to detect and eliminate redundancy
Contextual Meaning	Not considered	Contextual meaning detection with SBERT models
Backlog Refinement	Not addressed	Initial backlog refinement to detect similar user stories
Duplicate Detection	Limited capability in detecting duplicates and similarities	Improved accuracy in identifying duplicate user stories through advanced AI techniques

VI. CONCLUSION

In Agile project management, Backlog refinement is a crucial process. It aims to ensure that the backlog contains prioritized and well-defined user stories. However, refining the backlog using a traditional manual approach is time-consuming and prone to errors.

In this paper, we proposed an approach to refine the backlog by detecting similar user stories with a percentage that will help the designer decide to delete or leave the concerned user stories. Additionally, we aimed to reduce the occurrence of similar use cases in the use case diagram UML. Our proposed approach combined clustering and duplicate detection to automatically generate UML diagrams from a set of refined user stories in each cluster. To achieve this, we used the K-means algorithm to cluster similar user stories. In addition, we incorporated the SBERT model to measure the similarity between these user stories and use cases. Using multiple pairs of user stories, the case studies conducted show that our proposal achieves high performance.

In future work, we plan to further improve our approach by using multiple datasets to improve performance. Furthermore, we aim to define more rules to detect opposite meanings in user stories. Finally, we will focus on detecting non-functional requirements and generating acceptance criteria from them to improve the quality of user stories. It is essential to ensure that user stories remain well-defined and focused on functional aspects, while keeping non-functional requirements, such as performance, security, and usability constraints, specified in the acceptance criteria. By addressing these challenges, we can further enhance the accuracy and efficiency of requirements engineering in software development, ultimately leading to an overall improvement in product quality.

Challenges and Solutions of Agile Software Development Implementation: A Case Study Indonesian Healthcare Organization

Ulfah Nur Mukharomah, Teguh Raharjo, Ni Wayan Trisnawaty
Faculty of Computer Science, Universitas Indonesia, Jakarta, Indonesia

***Abstract*—One healthcare organization in Indonesia has implemented Agile software development (ASD) to complete software development. The organization's problems are post-deployment system bugs, and some software development projects must carry over to the following year. This study aims to assess and provide recommendations for improving agile software development by identifying the challenges faced. Research conducts literature reviews on previous research to identify challenges in ASD in several organizations. Research is also conducted using quantitative methods by surveying software development teams to validate implementation challenges and provide recommendations for these challenges. The results of this study were in the form of a survey attended by thirty-one respondents. The study results found that 14 challenges were faced in other organizations, and 11 were faced by one healthcare organization in Indonesia. Healthcare organizations in Indonesia can apply recommendations to make awareness related to understanding agile software development culture and make adjustments to project documentation by aligning with agile values.**

I. INTRODUCTION

Information technology (IT) can improve customer service and become an efficient tool. IT implementation is often considered one of the most challenging initiatives for organizations, including in the government sector [1]. Several organizations have changed their software development methods from Waterfall to Agile. By adopting the Agile method, organizations get several benefits, such as shorter time, increased flexibility in handling changing needs, increased productivity, and better alignment between business and IT [2]. Agile methods also need to maintain predictability and controllability [3]. Another agile principle is to welcome changing software development needs and produce software that works regularly with a preference for shorter timeframes [4].

However, transforming into an organization operating in the public sector, especially in an organization with a complex hierarchical structure such as government, is not easy to change the existing bureaucracy. The existence of layers of bureaucracy can hinder the application of agile methods [1]. Large organizations usually have many products and products that are too large for a single team to develop. The condition creates scaling problems, which require head adaptation and expansion of basic dexterity methods [2]. The problem is also the case in Saudi Arabia, where participants agreed that adopting Agile can be difficult when dealing with customers from government bodies, as the working style tends to be based on Waterfall. They are usually unwilling to be involved in the development team and require comprehensive documentation.

One of the organizations in Indonesia provides health services to the people of Indonesia of 265 million participants. In providing health services to all participants, the organization collaborates with health facilities in Indonesia, such as hospitals or doctor's clinics. The organization is a public legal entity, a government, and a bureaucrat with racy characteristics. The organization runs the business using technology and digitalization. The demand for IT development is increasing, in addition to the demand for speed in project completion, and the limited numbers of teams are challenges in completing system development. Organizations have IT resources in the software development process.

Ninety-six applications are run and developed by the organization's development team, most of which use the waterfall method. In 2022, project development will be dominated by projects with a high urgency category, with a percentage of 43%, as shown in Fig. 1 [5]. This development request requires a rapid completion of development, but there are unclear requirements due to policy changes in the organization.

The organization in the case study implemented an agile software development project. However, in its implementation, standards or frameworks have not been implemented as a reference. The problems were that some projects carried over to the following year, and there were complaints from application users post-implementation. The number of bugs adds work to the I IT development team, where the same group currently holds the development and maintenance functions [6].

In study [6] by looking at some of the existing problems and impacts, evaluating and improving the software development process using Agile is necessary. This evaluation is for the software development process to become better, achieve targets, and produce quality products as stated in the organization's vision and mission and the organization's vision and mission. Evaluation is being done

to find out the challenges and recommendations in implementing agile software development. Implementing Agile software development requires effort and time, but the results can significantly benefit most software development programs [7].

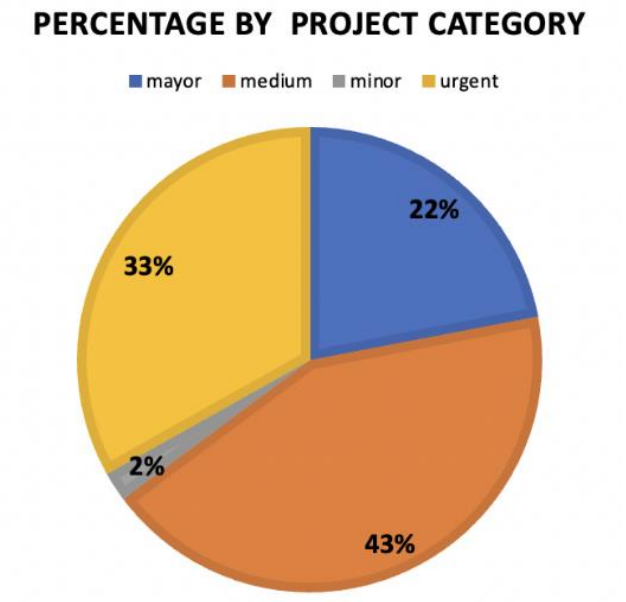

Fig. 1. Software development data by project category.

After determining the root of the problem, they considered the existing conditions in the organization and the implementation of Agile software development at the Indonesian Healthcare Organization. The questions for this research are:

RQ1: What are the challenges of Agile Software Development in the Organization?

RQ2: What are the recommendations for improving Agile implementation in the Organization?

Previous research has been carried out on projects with external resources using different methods, namely document observation. The novelty of this study is a case study on organizations with characteristics of the public sector or government or that have bureaucracy and use survey methods to respondents to validate the challenges faced. The composition of this research paper includes the following: introduction, literature study, methodology, results, and recommendations and it ends with conclusions.

II. Literature Study Introduction

This section will discuss the basic theory used in the research. These theories relate to Agile and Prior Research.

A. Previous Research

Several previous studies identified Agile software development; however, no research has been conducted on organizations with public sector and bureaucratic characteristics in Indonesia, and projects have been carried out internally.

Previous research [8], [9], [10], [11], [12] challenges were identified in ASD in organizations with characteristics of the public sector or government and bureaucracy. Previous research [8], [12] was conducted in Indonesia, but both studies had specific problems with projects undertaken by external resources. The difference with research [8] is that the research was conducted by observing project documents to validate challenges. Another study [9], [10], [11] was conducted in other countries, namely Brazil, United Arab Emirates, and New Zealand, to identify challenges faced by organizations in the public sector. These five studies serve as the basis for a survey to validate the challenges faced by Indonesian health sector organizations.

B. Agile

Agile is an approach or software development method that emphasizes flexibility, team collaboration, responsiveness to change, and continuous delivery of valuable customer results [13]. Agile methodologies have many methods (e.g., Scrum, Extreme Programming [XP], Kanban) that have their unique processes, terms, techniques, and timelines [7].

The development of Agile methods is a response to the failure experienced by organizations to use the more traditional waterfall methods. The Waterfall method is commonly used in large software development projects. Many view the Waterfall process as a heavy and expensive document, and the Waterfall is based on significant initial planning. In each phase of the project, it is necessary to complete a sequence of steps before moving on to the next stage. The linear approach used in Waterfall is in stark contrast to the incremental and iterative empirical methods used in Agile development [1].

Agile Methodology has recently expanded into several branches. The most popular extensions are probably associated with the Scrum framework, which breaks down the entire list of requirements into smaller batches. The list is titled product backlog and is formed by product backlog items. Following specific instructions, the product is developed in stages without sticking to predefined sequences while respecting any changes the customer requires [1].

C. Challenge and Issue Agile Implementation

Based on previous research, researchers found 14 challenges faced in implementing agile software development. The fourteen challenges can be found in Table I.

TABLE I. CHALLENGES OF AGILE SOFTWARE DEVELOPMENT FROM LITERATURE REVIEW

No	Category	Challenges	References
1	Technique & Ceremony	Lack of discipline in the development processes	[8]
2	IT Infrastructure	Lack of IT infrastructure in deploying the system.	[10]
3	Project Documentation	Lacks sufficient documentation to support a project	[8], [9], [10], [11], [12], [14]
4	Cultural behavior	The organization shows resistance or lack of encouragement in transitioning to an agile approach.	[9], [10], [14]
5	Communication	Communication and coordination among team members are ineffective.	[8], [12]
6	Managed requirements	The project schedule is delayed, requirements are unclear, and there is little anticipation in handling changes.	[11], [12]
7	Roles a project team	The roles of the team were unclear, leading to minimal contributions and duplicated work.	[11], [12]
8	Top Level Management	Lack of top management support, with little knowledge of the execution process.	[10], [11]
9	Internal policy	Inadequate Compliance with standards, policies, regulations, and organizational vision.	[10]
10	Collaboration	Team collaboration is limited because team members are spread out in different locations.	[8], [10], [12]
11	Organization Structure	Organizing meetings is challenging due to convoluted bureaucratic processes.	[8], [11]
12	Interpersonal Conflict	There are personal conflicts within the team.	[11], [14]
13	Individual Competence	Inadequate agile adoption of skills, experiences, and knowledge.	[11], [12]
14	Agile Values	Lack of openness and transparency during the development process leads to a lack of information.	[11]

III. METHODOLOGY

At the methodological stage, the researcher divides the research into three phases [8]. The three phases can be seen in Fig. 2. Phase Research Methodology and the following sections discuss the details of each step.

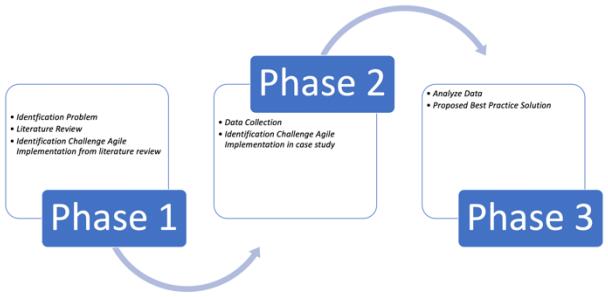

Fig. 2. Stages of research methodology.

A. Phase 1

Phase 1 is the initial stage of the research, where document observations and initial interviews are carried out to explore existing problems. Then, an analysis is conducted to determine the research questions. Based on the following research questions, literature research was conducted using PRISMA (Preferred Reporting Items from systematic reviews and Meta-Analysis). This method was used in previous studies [1]. Following are the steps of the SLR in this study:

1) The first stage is identification on the online database. The database used to search related research consists of IEEE Xplore, ScienceDirect, ProQuest, and Scopus.

2) Search using the keywords (agile software development) AND (Organization) AND ((challenges) OR (issue) OR (solution) OR (recommendation)). Based on this, 262 documents were obtained. Then, a selection is made based on predetermined search criteria, as shown in Table II, and twenty-four documents are produced.

3) The next stage is screening, namely selecting by reading the title and abstract related to the research question and producing twenty-four documents.

4) The next stage is eligibility, which is done by searching the complete version of the research document and, in the last stage, reading the entire contents of the paper in 24 copies.

5) The final stage is to obtain ten documents by the research questions. All documents obtained are considered relevant to the research topic and can be used as a reference for this research.

The overall description of the literature selection process can be seen in Fig. 3. It shows stages of searching for literature studies.

TABLE II. LITERATURE STUDY CRITERIA

No	Criteria
1	Publications within the last five years, 2018-2023
2	English language
3	Publication of a journal
4	Publication in the form of a journal Complete publication and can be downloaded in full (full text)

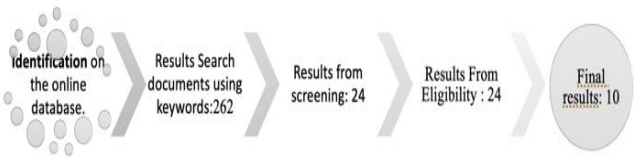

Fig. 3. Stages in SLR.

B. Phase 2

Researchers use quantitative data collection methods by conducting questionnaires to the software development team. Questionnaire questions use challenges and categories from Table I. After the questions were compiled, a test was carried out by an experienced team in the field. The software development team will distribute questionnaires, including Manager IT, IT System Specialist, IT Business Analyst, Programmer, Quality Control, and Junior Staff IT.

C. Phase 3

At this stage, an analysis will be carried out to determine what challenges are relevant to the literature review and other challenges in the organization. The analysis results above will provide recommendations for improving the agile software development process. Recommendations are given by looking at the best practices from previous studies.

IV. Result and Recommendation

This stage explains the results of the questionnaire that has been distributed and analyzed. This section also answers the research questions mentioned in the introduction. The challenges of implementing agile in health organizations in Indonesia and recommendations given to overcome these challenges

A. Result

Based on the research questions formulated, researchers conducted a questionnaire by obtaining 31 respondents from the software development team in the organization. Fig. 4 describes the percentage of the team from 8 positions in the software development team. Respondents with programmer positions were 39%, Junior IT Staff 10 %, Head of IT Department 6 %, IT Business Analyst 13%, It Quality Control 13%, IT Quality Assurance 3%, IT Strategic Plan 3 %, IT System Specialists (System Analysts) 13%.

In Fig 5, 45% of respondents have more than > 5 years of work experience from their current position. Then, 23% have 1 to 3 years of experience, 21.7% have 3 to 5 years of experience, and 8.7% have less than one year of experience. Overall, the technical team that filled out the questionnaire had over three years of experience.

The questionnaire consisted of 17 questions: 1) two demographic questions related to position and work experience, and 2) demographic questions were used to aid a deeper analysis of the questionnaire results. Furthermore, 14 questions are related to the 14 challenges contained in Table I. At the end, there are open-ended questions to identify other challenges that have not been included in the questionnaire. Questionnaire answers use a Likert scale (1 to 5) with the following information:

- Strong Not Agree (SNA)
- Not Agree (NA)
- Neutral (N)
- Agree (A)
- Strong Agree (SA)

The questionnaire results contained 14 challenges, which received a percentage of more than 50%. In other words, the respondents agreed and strongly agreed to the challenges in Table III. In addition, two different challenges were identified in the case study.

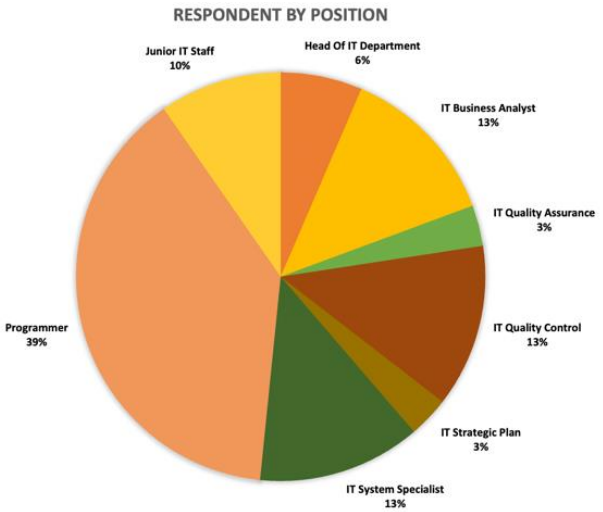

Fig. 4. Percentage of 31 respondents by the position.

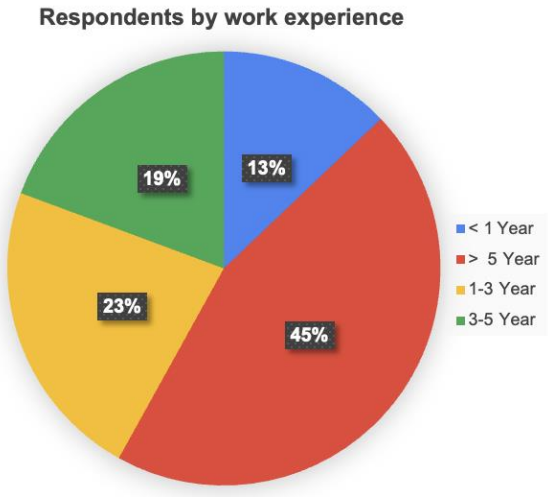

Fig. 5. Percentage of 31 respondents by work experience.

TABLE III. RESULT QUESTIONNAIRE FROM 31 RESPONDENTS

No	Challenges factor	SA	A	N	NA	SNA	SA+A
1	Technique & Ceremony	29%	26%	22%	13%	10%	55%
2	IT Infrastructure	10%	16%	19%	32%	23%	26%
3	**Project Documentation**	**39%**	**45%**	**6%**	**6%**	**3%**	**84%**
4	**Cultural behavior**	**42%**	**35%**	**10%**	**6%**	**6%**	**77%**
5	Communication	29%	23%	19%	6%	23%	52%
6	**Managed requirements**	**42%**	**32%**	**6%**	**6%**	**13%**	**74%**
7	Roles Team	39%	19%	16%	13%	13%	58%
8	Top Level Management	45%	26%	6%	16%	6%	71%
9	Internal policy	26%	29%	19%	10%	16%	55%
10	Collaboration	32%	23%	19%	10%	16%	55%
11	Organization Structure	35%	19%	13%	19%	13%	54%
12	Interpersonal Conflict	3%	23%	13%	29%	32%	26%
13	Individual Competence	22%	23%	10%	16%	29%	45%
14	Agile Values	32%	26%	16%	13%	13%	58%

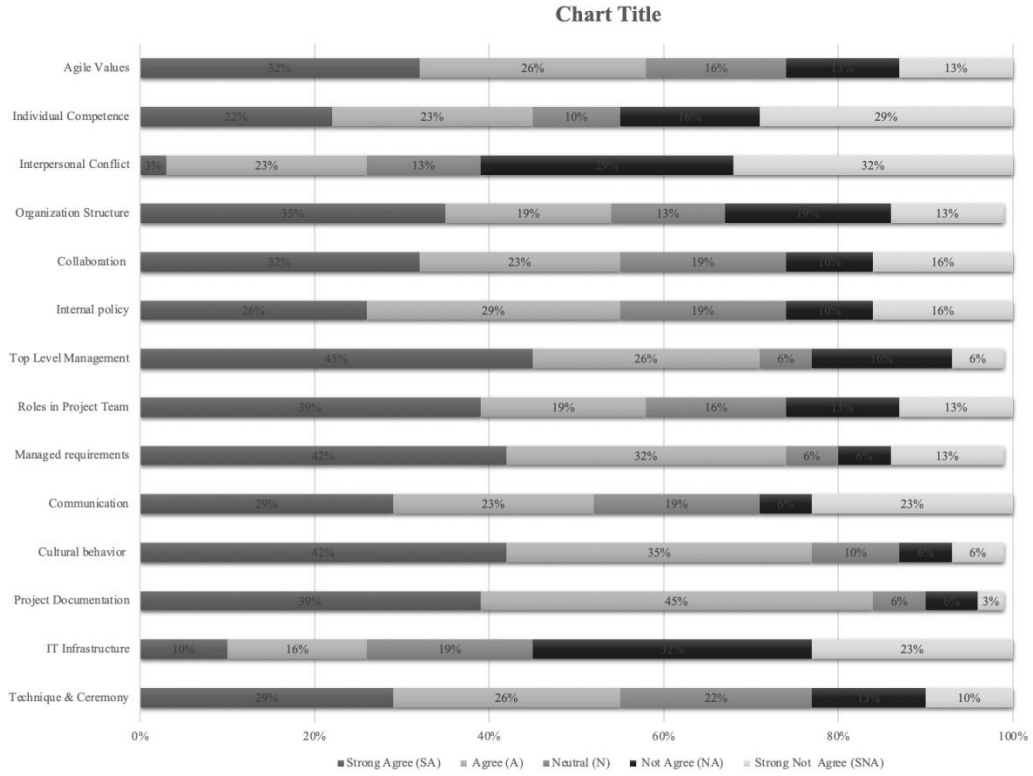

Fig. 6. This graph shows numbers representing the percentage of 31 respondents from the one that strongest agrees to the not agree.

1) A Challenge of the highest percentage: Fig. 6. shows three challenges with high percentage values, including project documentation, managing requirements, and cultural behavior. Most respondents agree with these challenges in implementing agile software development in organizations.

- Project documentation. This factor gets the highest percentage in the context of technology. One respondent mentioned in answering an open-ended question on the questionnaire that "current project documentation is not yet flexible. The characteristics of documentation are currently still waterfall-based where each documentation requires the approval of each unit". In previous studies [2], many organizations faced challenges related to inadequate documentation and the opposite issue of excessive documentation that wastes time and resources on unnecessary information. Agile development presents a solution through a streamlined approach to comprehensive documentation that requires less time and effort. However, it is crucial for upper management to support this approach and for customers to agree upon it from the project's inception [3], [11].

- Culture and structure of an organization. In previous research [3], it was also stated that the primary challenge in adopting Agile lies in the culture and structure of an organization. For Agile to thrive, there must be a genuine embrace of Agile values and principles. A hierarchical organizational structure often poses a significant hurdle to Agile adoption since it necessitates redistributing power and responsibility from management to the development team. Additionally, Agile thrives in a dynamic, supportive, and collaborative environment, which rigid organizational cultures can hinder.

Respondent's statements related to this challenge were "It takes a common understanding between the IT team and UKPF in implementing the agile process," Statements from other respondents, "The entire team must understand the goal of agile," and "The team is not yet familiar with the concept of agile comprehensively."

The current organizational structure is still suitable for the Waterfall methodology. One of the respondents mentioned, "Basically, the organizational structure is still waterfall-based, and each unit works on unit coordination. It should be project-based, and an agile team should be more independent and committed."

- Managed Requirement. The challenges faced by IT project management received the highest score, namely, 34.8% agreed, and 52.2% strongly agreed. This factor is a challenge to the organization's agile implementation. Regardless of project management tools, the respondent stated, "There are no valid tools that are used for project monitoring. So far, they have relied on Excel". There are no tools for project monitoring or tools that can be used for standard team collaboration by the entire team. The team found it difficult to see the progress of each process in system development. Another problem is that there is no project manager role in the team, making it difficult for the team to conduct project development tasks.

2) A Challenge of the lowest percentage: Based on Fig. 6, 3 challenges with high percentage values are project documentation, management requirements, and culture behaviour, which get high scores. Most respondents agree that these challenges are challenges in implementing agile software development.

- Interpersonal conflict. This factor gets the lowest score, namely 26%, meaning that the team is good enough or has no internal conflict, which is a challenge in agile implementation. Leadership challenges get the highest score, namely 65.2%, then agile values, 60.9%, and the other three challenges, namely personal commitment, decision making, and individual competence, get the same deal, 52%.

- Competency is not a challenge in implementing agile, and this has something to do with demographic results because most respondents are workers with more than five years of experience, so they have abilities in their fields.

3) An Additional Challenge from respondents: Different challenges are identified from the case study based on the open-ended question at the end of the questionnaire, in which the organization experiences another challenge, namely Overloading work. Based on one of the respondents' answers, "Another challenge is the unbalanced workload of each programmer. A programmer must be able to do many things briefly simultaneously, causing stress from the programmer's psychological side. Something like this needs to be resolved by the project manager on how user needs are balanced with existing resources," and the other, "The challenge is the lack of resources so that one person holds several applications that are being chased by the dateline at the same time."

B. Recommendation

Based on the challenges faced by the organization, the researchers then provide recommendations that can be taken in the future to make changes to current conditions. Later, it is hoped that the organization will get better results from agile implementation and support organizational goals. The recommendations are as follows.

The following are recommendations based on previous research, and recommendations are given based on the results of questionnaires that get a percentage of agree and strongly agree with a value of more than 50%. The recommendations are given in Table IV.

TABLE IV. RECOMMENDATION IN TECHNOLOGY CONTEXT

Challenge	**Recommendation**
Technique & Ceremony Lack of discipline in the development processes	• Use tools or technologies to support Agile work in the organization [3]. E.g., Trello or Jira • Build a Continuous Delivery pipeline with stages involving both sides[4]
Project Documentation Lacks sufficient documentation to support its development	Communicate only essential points that need to be documented. Agile identifies critical important points to include in documentation, which is the main focal point for each methodology.[15] Meetings assist individuals in a proper understanding of how to collect information and through what medium the process of gathering information will be beneficial [15]
Culture Behavior & Agile Values The organization shows resistance or lack of encouragement in transitioning to agile values.	• A strong culture requires a deep understanding of the organization's goals • Show success stories of agile adoption. • Provide training and increase employee awareness and acceptance of new culture [3]. [3]
Communication Communication and coordination among team members are ineffective.	• Running an effective meeting [16] • Regular face-to-face meetings should be established, as they provide clear communication [7] [13]

Challenge	**Recommendation**
	• Transparency and efficiency in communication [4].
Management Requirement The project schedule is delayed, requirements are unclear, and there is little anticipation in handling changes.	Agile teams operate differently from traditional project management structures as they do not rely on project managers. Instead, Agile methodologies like Scrum and XP outline specific roles such as the product owner, scrum master, and coach. These roles are designed to facilitate effective collaboration and ensure the smooth execution of Agile practices. By assigning responsibilities to these distinct roles, Agile teams can streamline communication, enhance productivity, and adapt quickly to changing project requirements. [17].
Roles in Project Team The roles of the team are not clearly defined, leading to minimal contributions and duplicated work.	Reorganize the team by forming small teams, like the scrum team, to create a dedicated team responsible for agile development [18].
Top Level Management There is a lack of top-level management support and little knowledge of the execution process.	• Involving top-level management in the change planning and implementation process can increase the sense of ownership and responsibility. • Hire outside experts to be involved in team adaptation as this can provide a better recommendation of benchmarks [18].[15]
Internal Policy Inadequate agile adoption of skills, experiences, and knowledge.	Creating standards for IT software development on an internal basic policies and supporting existing management can support agile implementation [1]
Collaboration Team collaboration is limited because team members are spread out in different locations.	Use tools or technologies to support Agile work in the organization [3]. E.g., Trello Jira or bit bucket [4]
Organization Structure Organizing meetings is challenging due to convoluted bureaucratic processes.	• Create a small project team like the Scrum team [1]. • Arrange a dedicated team that is responsible for agile development [18]. • Channeling expert's efforts to address high-level issues and to manage collaboration [4].
Overloading of work This factor is a challenge in agile implementation. Individuals get more than one job at the same time.	• They used to meet weekly and later twice a month, only when required and usually after working hours. • Skipping the daily meetings affected the learning process between the team members. This factor eventually led to the failure to learn and implement the agile method correctly [11].

V. CONCLUSION

Researchers conducted a literature review of several previous studies and identified challenges in implementing ASD in other organizations with characteristics of the public sector, government, or bureaucracy. Researchers use quantitative methods with surveys to validate and facilitate the exploration of the challenges in implementing ASD in One healthcare organization in Indonesia. This method is simple but can solve the problems faced. It is a differentiator from previous research [8] studies used challenge validation using document observation.

Based on several previous studies, 14 challenges faced by organizations were obtained. This study's findings determine what challenges and recommendations can be provided for the organization. Based on the survey results, researchers found 11 challenges with a percentage value above 50%, agreeing that challenges to other organizations. The three challenges with the highest survey results are project documentation, IT Project Management, and cultural behavior. At the same time, the 3 challenges with the lowest survey results were below 50%, which means that most respondents disagreed that these challenges were felt today in the organization. These challenges are individual competence, IT infrastructure, and internal conflicts. Then, researchers got other challenges besides 14, based on open questions on the questionnaire. The challenge is about workload overload.

After getting the challenges faced by the organization in this case study, the researcher provides recommendations mapped to the challenges faced by the IT team in the organization based on previous studies related to agile implementation, agile adoption, or agile transformation. Some recommendations that can be made include raising awareness related to agile culture among all IT employees. Regarding problems in Project Documentation, organizations can adjust project documentation to align with agile values. Problems in organizations with bureaucracy, such as government, making changes in the development process become obstacles because of the many administrative processes and approvals given to superiors. Therefore, organizations can adjust the project team to match the role in Agile. Agile using the roles contained in scrum. By assigning responsibilities to these different roles, Agile teams can streamline communication, increase productivity, and adapt quickly to changing project requirements [17].

1) Research implications: Other similar organizations can use the results of this study to see the challenges in agile implementation and solutions from best practices suitable for organization healthcare or bureaucratic governance.

2) Limitations of suggestions for further research: This study has several limitations on the respondents. Respondents are still limited to the software development technical team. Future research can be carried out for other IT teams, such as IT operations and IT infrastructure.

***Abstract*—This study examines the integration of pricing and lot-sizing strategies within a system comprising only one producer and retailer. The adoption of a bi-level programming technique is justified in establishing a bi-level joint pricing model guided by the producer owing to the hierarchical nature of the supply chain. This problem maximizes manufacturer and retailer profitability by setting the wholesale quantity, lot size, and retail price simultaneously. We created a bi-level particle swarm optimization to solve bi-level programming challenges. This algorithm effectively addresses BLPPS by eliminating the need for any priori assumptions about the conditions of the problem. The bi-level particle swarm optimization algorithm demonstrated a commendable level of efficacy when applied to a set of eight benchmark bi-level issues. The proposed bi-level model was solved using the BPSO and analyzed using experimental data**.

***Keywords*—Bi-Level algorithm; joint pricing; optimization; particle swarm optimization; supply chain**

I. INTRODUCTION

Supply chain participants are driven by the goal of selling goods, and product prices affect the level of demand in the market [1]. Likewise, the practice of determining the optimal order quantity has resulted in decreased expenses, encompassing both the ordering process for retailers and production costs for manufacturers. Consequently, strategic decisions pertaining to pricing and lot sizing assume crucial significance in the pursuit of profit optimization within a supply chain [2]. In fact, it is critical that the sale price is neither excessively low nor exorbitant. Conversely, when the retail price is set at an excessively low level, the retailer experiences diminished profitability or potentially even financial losses. However, if the product is priced too high, customers will exhibit reduced purchasing intent, resulting in surplus inventory and additional inventory-related expenses for the retailer [3]. Furthermore, because of an overabundance of inventory, the retailer will opt to decrease either the frequency of orders or the amounts ordered from the producer. Consequently, this leads to significant financial losses for producers. Hence, the implementation of rational pricing and lot-sizing policies is of utmost importance and indispensable [4]. Considerable research has been conducted on the issue of optimal pricing, owing to the various factors outlined. In their seminal work, Panchal, Jain, and Kumar (2015) presented a comprehensive model that addresses the intertwined issues of ordering and price discounting in a supplier-buyer relationship [5]. The model focuses on a scenario in which a supplier offers a quantity discount to its sole or significant buyer. However, the problem is approached solely from the supplier's standpoint, neglecting the retailer's perspective on retail pricing. Pourrahmani and Jaller (2021) examined the concept of collaborative pricing and replenishment as a means of addressing a network pricing problem known as NP-hard [6]. Ghahremani-Nahr et al. (2019) primarily concentrated on enhancing an exact algorithm that optimize their strategies for a service operating inside an oligopolistic setting [7]. The issue is framed as a leader-follower game conducted over a distribution network. Yuan (2021) proposed bi-level models to address price problems [8].

This paper utilizes several numerical tests to showcase the efficacy of the BPSO method. Later, the BPSO technique was used to solve the bi-level model. Ultimately, the attributes of the suggested bi-level model are examined through multiple illustrations.

II. LITERATURE REVIEW

The lot-sizing problem, considered a critical challenge in supply chain management, has piqued the interest of various experts who have conducted extensive research on the subject. Diabat et al. (2017) investigated the stochastic variant of lot-sizing issues that incorporate inventory bounds and order capabilities [9]. Kulkarni and Bansal (2022) examined a novel topic involving the lot sizing of multiple items in a dynamic setting [10]. They specifically examined a situation in which all items' inventories are concurrently replenished with an equal quantity after a production event. Gáti and Bányai (2023) Explored the problem of optimizing production quantities and managing resource allocation in an industry with several competing enterprises [11]. The authors present a capacity competition model that incorporates the complexities of fluctuating demand, cost functions, and economies of scale arising from dynamic lot-sizing costs.

Curcio, de Lima, Miyazawa, Silva, and Amorim, (2023) were successfully formulated and determined the best pricing and lot-sizing options for a store [12]. In their work published, Tosarkani & Amin, (2018) examines the issue of pricing and lot-sizing in the context of price-sensitive demand [13]. They formulated the coordination problem between a seller and consumer as a two-person fixed bargaining game. In their study, Bazan et al., (2016) approach by include both the backlogging cost and the cost associated with lost goodwill [14]. Abdulah (2020) provided a deterministic model for

calculating the economic order quantity in a retail setting [15]. The model's objective is to accurately predict the effectiveness of a proposed ordering algorithm in mitigating the bullwhip effect to a significant degree.

Each individual within the chain possesses autonomous control over a distinct set of decision variables that do not overlap with the others. These individuals are required to make decisions based on their own personal interests while also taking into account the decisions made by others, as these decisions will impact their own interests. Therefore, bi-level programming problems (BLPPs) are extremely suitable for representing price and lot-sizing challenges inside a supply chain.

In general, solving a bi-level programming problem is challenging for two main reasons. First, bi-level programming problems are classified as NP-hard problems [16]. Second, the concavity of bi-level programming problems further adds to their complexity. Currently, numerous approaches exist to resolve this issue. Four major linear bi-level programming methods were identified in [17], [18]. These categories include neuro-fuzzy algorithms, simulated annealing strategies, vertex enumeration, Kuhn-Tucker conditions, and metaheuristics such as genetic algorithm-based strategies [19].

It is important to note that certain limitations exist when using methods that rely on vertex enumeration and the Kuhn-Tucker conditions to solve bi-level programming problems [20]. These constraints encompass the necessity for the objective function to be differentiable or for the search space to be convex. Metaheuristic approaches are capable of resolving exceedingly complex nonlinear problems in contrast to traditional search algorithms. Management extensively uses metaheuristic optimization [21]. In practice, most bi-level problems extend beyond linear programming and encompass a range of intricate scenarios. Therefore, it is imperative to devise efficient and optimal approaches for addressing these issues.

A Bi-level Linear Programming (BLPP) is a type of multilevel programming issue [22]. Within the framework of BLPP, the decision maker situated at the higher level initially formulates a strategy [23]. The general bi-level formula can be expressed as follows:

$$\min_{x \in X} f_1(x, y)$$

$$s.t\ \ G(x, y) \leq 0,$$

where, the y vector solves

$$\min_{y \in Y} f_2(x, y)$$

$$s.t\ \ g(x, y) \leq 0,$$

Let x ∈X $h \subset \mathbb{R}^{n1}$ and y ∈ Y $\subset \mathbb{R}^{n2}$

where,

x: Set of control-level variables

and

y is the set of follower-level variables.

The leader has an objective function, $f_1(x, y)$, and the follower has an objective function of - $f_2(x, y)$.

Additionally, $G(x, y) \leq 0$ and $g(x, y) \leq 0$ represent the constraints associated with upper and lower-level problems, respectively.

III. METHOD

A. Development Model

After acquiring the raw materials from the supplier, the producer carries out the production and processing procedures (see Fig. 1). The completed products are subsequently delivered to the retailer.

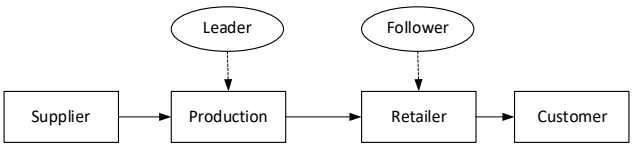

Fig. 1. Two-echelon system.

The producer has the potential to influence the retailer's decisions, but lacks complete control over them. The initial step in the pricing process involves the producer establishing a wholesale price for their items. Subsequently, the retailer responds by considering the producer's assortment and subsequently determines the retail price.

The producer negotiates the price at the wholesale level and quantity ordered with the supplier in order to maximize the net profit, as determined by the primary objective function [24], [25]. The net profit of the producer was calculated by subtracting the costs of purchasing, production, transportation, holding, and ordering from the money generated from sales. The second-level objective function sets forth the retail prices and order quantities for retailers. The primary objective is the retailer's net profit, which is calculated as the ratio of sales to the costs associated with purchasing, holding, and ordering.

A bi-level model was constructed based on specific assumptions [17], [26].

1) The producer or retailer can make separate decisions to maximize earnings.

2) Retail prices decrease consistently with the market demand.

3) Producers and retailers quickly restock.

4) Each replenishment period was consistent, and shortages were avoided.

5) The cost of purchasing components and the price of the product for the end consumer remain constant throughout the planning horizon.

This paper uses these notations:

Aspects that impact the producer's decision

β : The anticipated of orders quantity that the producer will place in the near future.

$\wp_m$: wholesale unit price

Decision-making factors used by the retailer

α : quantity of retailer lots divided by producer lots

ϱ :retailer lot size

$\wp_r$:The unit retail price

Additional Relevant Parameters

T : the planned horizon's weekly length

D : weekly demand rate D= b – $a_r.p_r$

h_m : amount of the producer's on a weekly basis storage cost

h_r : retail store's weekly storage cost rate

O_m: Purchasing cost of each order incurred by the producer.

O_r : Purchasing fee for each transaction for the retailer.

p_s : Fee for purchasing a unit from the producer.

T_c : unit transportation cost

M_c : Cost of procuring units for producer.

Q_m : a company's net profit throughout the planning period

Q_r : net profit for the store throughout the planning period

B. Construction Model

The producer and retailer net income during planning are indicated by I_m and I_r, respectively.

$$I_m = (p_m - p_s - T_c - M_c)\alpha\beta Q$$

$$I_r = (p_r - p_m)\alpha\beta Q$$

The average inventory level of the product–retailer combination is determined by the equation α Q/2, where α is a constant. Consequently, the producer's inventory level can be calculated as Q multiplied by the quantity (α − 1)/2.

The producer and retailer holding costs during planning are indicated by H_m and H_r, respectively.

$$H_m = h_m T.\, p_s.\frac{Q\,(\alpha-1)}{2} = \frac{h_m T p_s\, Q\,(\alpha-1)}{2}$$

$$H_r = h_r T.\, p_m.\frac{Q}{2} = \frac{h_r T p_m\, Q}{2}$$

Producer and retailer order expenses within planning are indicated by C_m and C_r, respectively.

$$C_m = \beta O_m$$

$$C_r = \alpha\beta O_r$$

The net earnings of the producer and retailer during planning are indicated by U_m and U_r, respectively.

$$\prod m = I_m - H_m - C_m = (p_m - p_s - T_c - M_c)(\alpha\beta Q) - \left(\frac{h_m T p_s\, Q\,(\alpha-1)}{2}\right) - (\beta O_m) \quad (1)$$

$$\prod r = I_r - H_r - C_r = p_r TD - (p_m \alpha\beta Q) - \left(\frac{h_r T p_m Q}{2}\right) - (\alpha\beta O_r) \quad (2)$$

By integrating Eq. (1) and Eq. (2), the following model is established for the supply chain:

$$\max_{\beta, p_m} \prod m = (p_m - p_s - T_c - M_c)\,(\alpha\beta Q) - \left(\frac{h_m T p_s\, Q\,(\alpha-1)}{2}\right) - (\beta O_m)$$

$$\text{s.t. } \beta \in N^+, p_s + T_c + M_c \le p_m \le p_m^* \quad (3)$$

$$\max_{\alpha, p_r, Q} \prod r = (p_r TD) - (p_m \alpha\beta Q) - \left(\frac{h_r T p_m Q}{2}\right) - (\alpha\beta O_r) \quad \text{s.t. } \alpha \in N^+,$$

The correlation between the quantity of deliveries and the lot size is

$$Q = \frac{TD}{\alpha\beta} \quad (4)$$

Retail prices are believed to be multiples of wholesale prices,

$$P_r = K p_m \quad (5)$$

Let K be the ratio of wholesale to retail prices where K > 1.

It is critical that wholesale and retail pricing remain within the appropriate limits and do not surpass specific levels. By utilizing Eq. (4) and Eq. (5), it is possible to convert Problem (3) into Problem (6) through the following transformation:

$$\max_{\beta, p_m} \prod m = (p_m - p_s - T_c - M_c)\,(TD) - \left(\frac{h_m T^2 p_s D\,(\alpha-1)}{2\alpha\beta}\right) - (\beta O_m)$$

$$\text{s.t. } \beta \in N^+, p_s + T_c + M_c \le p_m \le p_m^* \quad (6)$$

$$\max_{\alpha, k} \prod r = (k p_m TD) - (p_m TD) - \left(\frac{h_r T^2 p_m D}{2\alpha\beta}\right) - (\alpha\beta O_r)$$

$$\text{s.t. } \alpha \in N^+, 1 \le k \le k^*$$

The variables p_m^* and k^* denote the maximum values of p_m and k.

IV. Result

A. Bi-level PSO-based Algorithms

Kennedy (1995) present a Particle Swarm Optimization (PSO) technique [27]. The Particle Swarm Optimization (PSO) algorithm, as described in [28], is a stochastic evolutionary algorithm that operates on a population-based approach. PSO has demonstrated its effectiveness in addressing complex optimization problems, offering advantages such as simplified coding and a reduced number of parameters [29], [30]. Particle Swarm Optimization (PSO) considers each individual as a particle, disregarding any notions of quality or bulk [31], [32].

The orientation and speed of the particles are denoted by $x_i = (x_{i1}, x_{i2}, \dots, x_{iD})$, and $v_i = (v_{i1}, v_{i2}, \dots, v_{iD})$ respectively. The variable $p_i = (p_{i1}, p_{i2}, \dots, p_{iD})$ represents the best position that the swarm have reached, while $p_g = (p_{g1}, p_{g2}, \dots, p_{gD})$ represents the best position that the swarm have reached. The manipulation of particles is governed by the following equations:

$$v_{id}(t+1) = wv_{id}(t) + c_1 r_1\left(p_{id}(t) - x_{id}(t)\right) + c_2 r_2\left(p_{gd}(t) - x_{id}(t)\right) \quad (7)$$

and

$$x_{id}(t+1) = x_{id}(t) + v_{id}(t+1) \quad (8)$$

The given conditions are as follows: for any values of d and D where $1 \le d \le D$, and for any values of i and N where $1 \le i \le N$, there exist two non-negative constants denoted as c_1 and c_2 . Additionally, there are two randomly generated integers, denoted as x and y, that follow an equal distribution, in the range of (0,1).

The maximum current value is denoted as $v_{id} \epsilon [-v_{max}, v_{max}], v_{max}$.

When *j*, we set *t*.

The prior velocity of the particle impacts its present velocity through the inertia weight w. The inertia weight w is crucial for balancing the global and local search capabilities. The global search capacity increased as w increased, whereas the local search capacity decreased. Conversely, when the value of *w* decreased, the opposite situation occurred.

Shi and Eberhart (1999) offer an approach known as linear decline, which is outlined as follows.

$$w(t) = w_{min} + (w_{max} - w_{min}).\left(\frac{t_{max}-t}{t_{max}}\right) \quad (9)$$

The *"t"* represents the t^{th} iteration, while " t_{max} " represents the maximum number of iterations for that iteration. The initial inertia weight is represented by variables w_{min} and w_{max}, which indicate the smallest and highest values, respectively.

B. Managing Constraint

The upper and lower-level problems in BLPP (see Eq. (1)) are standard constraint optimization that do not consider the leader-follower information interaction [33]. Managing constraint is crucial for constraint optimization.

Consider the constraint optimization problem as follows:

$$\min F(x)$$

$$\text{s.t. } g_i(x) \le 0, i = 1,2,\dots,p \quad (10)$$

where, S is the search space, x ϵ S, and S $\subseteq$ R^n.

By incorporating a penalty element, Eq. (10) can be reformulated as follows:

$$\min F(x) = f(x) + M \sum_{i=1}^{p} (\max\{g_i(x), 0\})^2,$$

Variable M represents a predetermined and significantly large positive constant, denoted as a penalty factor.

This approach is analogous to treating upper-level programming problems. It is assumed that the lower-level programming problem comprises p and q inequality constraints. In addition, it is assumed that the variable x of the upper-level programming problem is predetermined. Within the realm of the search area, a particle that adheres to the given restrictions is referred to as a feasible particle, whereas a particle that fails to meet the criteria is labeled as an infeasible particle. In the present scenario, it is possible to determine the finesse of all particles, both feasible and infeasible, using the following equations:

$$\text{fit}(x,y) = \begin{cases} f(x,y), if\ y \in \Omega(x) \\ f(x,y), if\ y \in S \backslash \Omega(x) \end{cases} \quad (11)$$

and

$$F(x,y) = f(x,y) + M \sum_{i=1}^{m} (\max\{g_i(x,y), 0\})^2, \quad (12)$$

where, *S* indicates search area, while Ω (x) is the feasible set of lower-level problem.

C. Implementation

Based on an analysis of the interacting iterations of two fundamental PSO algorithms, it has been observed that Binary Particle Swarm Optimization (BPSO) can solve BLPP without relying on any specific assumptions [34], [35], such as the availability of gradient information for the objective functions or the convexity of constraint regions. The details are presented in the subsequent sections.

Algorithm 1:

Step 1: Preparation of parameters by measuring population N_1, determining maximum iteration T_{max1}, with learning factors c_1 and c_2, determining maximum and minimum inertia weights w_{max} and w_{min}, as well as maximum speed v_{max} x, and enforcement factor M.

Step 2: Set the position x_i and velocity v_{xi} of each particle to the upper level's decision variables. The begin position y_i and velocity v_{yi} are based on lower-level decision parameters.

Step 3: Set the loop counter of the leader to $t_1 = 0$.

Step 4: If the algorithm fulfills completion conditions or an upper limit of iterations, move to the final step; otherwise, follow Steps 4.1–4.5.

- Step a: For each x_i, Algorithm 2 solves lower-level programming problems and determine the optimal solution for y^*, as the follower response.
- Step b: Calculate the particle fitness values using Eq.(11) and (12)
- Step c: The best particle (p_{xi}) and population (p_{xg}) positions are recorded. If p_{xi} is higher than the best in history, a new pxi is declared. Choose the particle with the highest fitness value for p_{xg}.
- Step d: Update the particle positions using Eq.(7)–(9).
- Step e: $t_1 = t_1 + 1$.

Step 5: If it the maximum number of iterations, proceed to Step 5. Otherwise, proceed to step 3.

Step 6: Final best results.

Algorithm 2 :

Step 1: Preparation of parameters N_2 (population), and T_{max2} (maximum iteration)

Step 2: Start with the subsequent loop counter $t_2 = 0$.

Step 3: Eq. (11) and (12) are used to calculate particle fitness.

Step 4: Record the particle's i^{th} best location p_{yi} and population's p_{yg}.

Step 5: Update the follower position and velocity using Eq. (7) – (9).

Step 6: $= t_2 + 1$.

Step 7: Move to Step 8 if the algorithm reaches its maximum number of iterations. Otherwise, proceed to step 5.

Step 8: Optimum lower-level problem solutions y^* .

D. Simulation

For every bi-level problem, we perform 20 different executions of the BPSO algorithm. Table I presents the optimal and average outcomes obtained from solving the four linear bi-level programming problems using the BPSO algorithm. Comparative analyses of these results are provided in Tables II and III. Table IV presents the optimal outcomes obtained by solving the four nonlinear bi-level programming problems using the BPSO, along with the corresponding comparisons.

Table I lists the four linear test function solutions for the BPSO algorithm. Based on the findings presented in Tables II and III, it can be inferred that the outcomes obtained from solving the four linear bi-level programming problems using BPSO exhibit superior performance in terms of both the best and average results, as compared to the results obtained using the GA and PSO algorithms.

The BPSO algorithm finds the optimal solutions for four nonlinear bi-level problems: Problem 5's best solution is (0.0422, 1.9339, 2.8674, 1.4395), the optimal solution for the 6th problem is (0.7886, 1.8556), the optimal solution for 7th problem is (3.9960, 0.0004), and the optimal solution for 8th problem is (0.5014, 0.2026, 0.8275).

Based on Table IV, in terms of optimizing the upper-level objective function of the 5th problem, it was observed that the BPSO algorithm exhibited superior accuracy compared to the other three algorithms. However, disparities between their performances were minimal. To optimize the upper-level objective function of the 7th problem, the performance of BPSO was found to be comparable to that of the other three algorithms, with only a small difference. However, the BPSO outperformed the other three methods when considering the lower-level objective function.

E. Evaluation

This section solves bi-level joint pricing and lot-sizing model (6) using the BPSO method. Determination of Eq. (6) Parameters

T = 52, hm = 0.001,

O_m = 2000,

p_s = 4,

h_r = 0.001,

O_r = 200,

T_c = 0.5, and M_c = 1.

To enhance the analysis of our model, we initially established an upper constraint for the wholesale price, denoted as p = 10. We examine two upper limits for the retail-to-wholesale pricing ratio, designated k* = 2 and k* = 5. The parameters' configurations of BPSO are consistent with those outlined in the previous section. The outcomes of the optimization process are presented in Tables V and VI.

TABLE V. RESULTS FROM DIFFERENT COEFFICIENT GROUPS (K*=2)

Demand function coefficients	α	β	p_m	k	p_r	Q	$\prod m$	$\prod r$

Fig. 2 and 3 depict a decrease in the net profits of both the producer and retailer in response to an increase in demand price sensitivity.

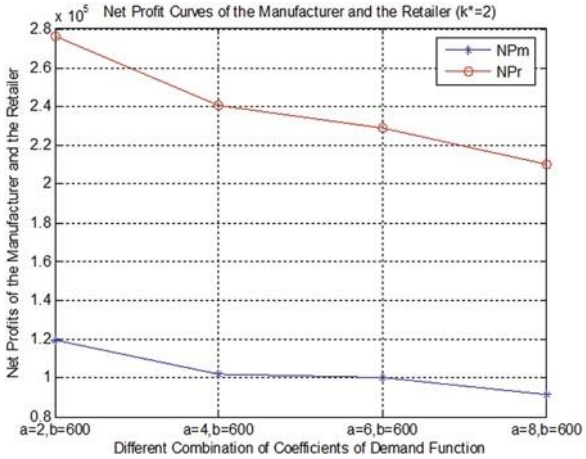

Fig. 2. Producer and retailer net profits curves under k =2.

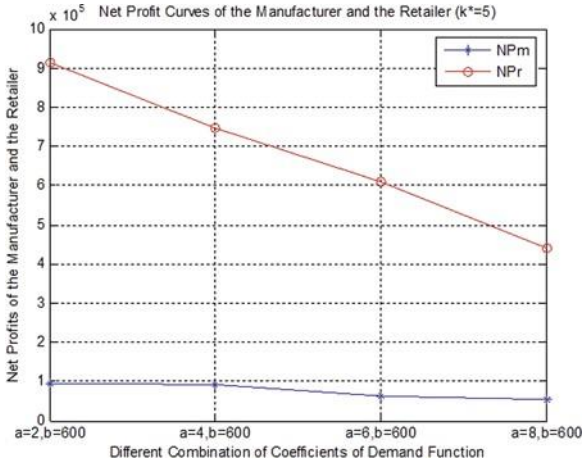

Fig. 3. Producer and retailer net profit curves under k =5.

Fig. 4 and Fig. 5 illustrate the variations in net profits for both the producer and the shop at different levels of demand. Based on the examination of Fig. 4 and Fig. 5, it can be observed that the net profit of the producer is comparatively reduced when the value of k is 5 in contrast to when it is 2, assuming an identical demand function. In contrast, the net profit of the store exhibits a notable increase when the value

of k is 5 as opposed to 2. The observed gap can be ascribed to the differential behavior of retail and wholesale prices, specifically when k is equal to 5. In this scenario, the retail price increases, whereas the wholesale price remains comparatively stable. This is in contrast to the situation where k is equal to 2.

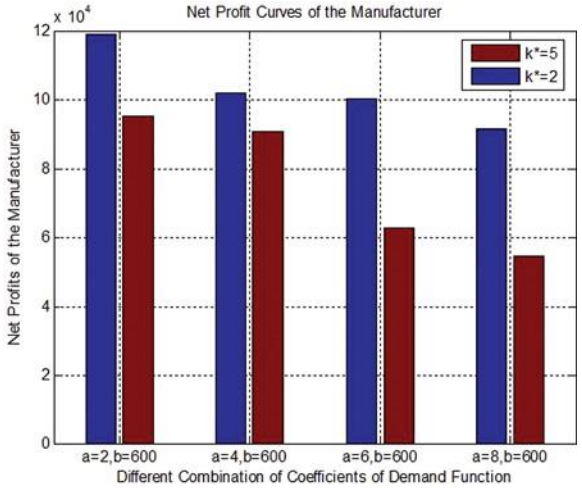

Fig. 4. Comparison of producer net profits.

If the producer's interests are violated because of an increased retail price, the producer may choose to increase the wholesale price. As a result, this course of action possesses the capacity to increase retail pricing, culminating in a decline in the sales volume of products as a consequence of the augmented selling price. The drop in profitability for both the producer and retailer will result in a subsequent decline in the overall efficiency of the entire supply chain. Therefore, to effectively maximize their respective profits and avoid being caught in a harmful cycle where market demand decreases due to rising retail prices, it is recommended that both the producer and retailer refrain from continuously increasing the price of the product.

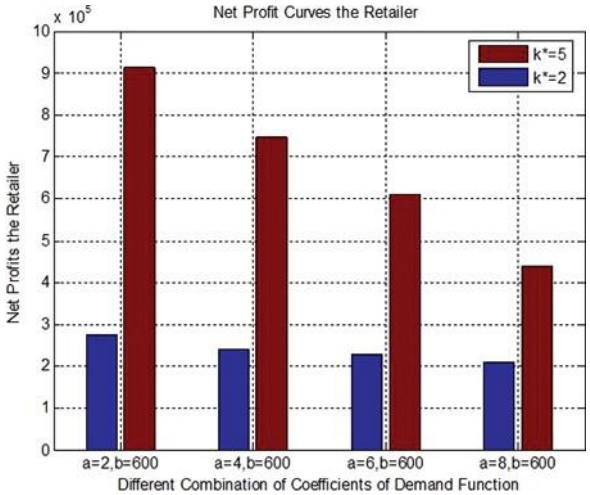

Fig. 5. Comparison of retailer net profits.

V. Discussion

The bi-level particle swarm optimization (BLPSO) is an effective method for solving intricate decision-making problems in supply chain management. The BLPSO algorithm has been utilized in many supply chain models, providing effective solutions for combined pricing and strategic sourcing strategies [36]. Research has demonstrated that it has exceptional search performance and rapid convergence, rendering it a highly useful instrument for addressing bi-level optimization problems in supply chain management [37]. Moreover, the simulation findings indicate that the large-scale BLPSO method has enhanced stability and supremacy when it comes to tackling supply chain optimization challenges [38].

In addition, researchers have investigated the combination of BLPSO with other metaheuristic methods, such as genetic algorithms, to improve its effectiveness in solving bi-level linear programming issues related to supply chain management. The hybrid strategy has demonstrated potential in effectively tackling the combined issues of pricing and inventory control in a two-level supply chain [39]. In addition, the creation of innovative dynamic Pareto BLPSO algorithms has broadened the use of BLPSO in addressing multi-objective optimization challenges in supply chain management [40].

BLPSO has been applied to solve optimization challenges beyond supply chain management, including job shop scheduling and the selection of locations for electric vehicle charging infrastructure [41]. The BLPSO algorithm's ability to effectively handle various optimization issues demonstrates its potential to tackle intricate decision-making challenges across a wide range of fields.

In summary, utilizing BLPSO in the context of joint pricing within a supply chain provides a strong and effective method for tackling intricate decision-making challenges. The tool's capacity to manage multi-objective optimization, strategic sourcing, and large-scale supply chain models renders it a significant asset for optimizing decision-making processes in supply chain management.

VI. Conclusion

The primary objective of this model is to optimize the profits of both the producer and retailer. This optimization is achieved by simultaneously determining the number of orders for both parties, lot size for the retailer, and wholesale and retail prices. Based on the characteristics of the bi-level programming issue and the resulting bi-level model discussed in this article, we provide a BPSO technique to identify the most effective solutions.

The BPSO algorithm was employed to address the bi-level model presented in this study. The results obtained include the ideal number of orders for both the producer and retailer, optimal lot size for the retailer, and optimal wholesale and retail prices. These optimal values were simultaneously determined by considering the specified constraints.

Based on the collected data, the analysis reveals certain outcomes that align with market principles. Notably, one of these outcomes indicates a negative correlation between the sensitivity of demand to price and net profits of both the

producer and retailer. It is also observed that in cases where market demand is responsive to changes in selling price, both the producer and retailer should not consistently increase the wholesale and retail prices if their goal is to maximize individual profits. This approach may result in unfavorable outcomes and reduce overall supply chain efficiency. The findings of this study further corroborate the effectiveness of the BPSO in addressing BLPPS.

***Abstract*—Cloud Computing voted as one of the most revolutionized technologies serving huge user demand engrosses a prominent place in research. Despite several parameters that influence the cloud performance, factors like Workload prediction and scheduling are triggering challenges for researchers in leveraging the system proficiency. Contributions by practitioners given workload prophesy left scope for further enhancement in terms of makespan, migration efficiency, and cost. Anticipating the future workload in due to avoid unfair allocation of cloud resources is a crucial aspect of efficient resource allocation. Our work aims to address this gap and improve efficiency by proposing a Deep Max-out prediction model, which predicts the future workload and facilitates workload balancing paving the path for enhanced scheduling with a hybrid Tasmanian Devil-assisted Bald Eagle Search (TES) optimization algorithm. The results evaluated proved that the TES scored efficiency in makespan with 16.342%, and migration efficiency of 14.75% over existing approaches like WACO, MPSO, and DBOA (Weighted Ant Colony Optimization Modified Particle Swarm Optimization, Discrete Butterfly Optimization Algorithm). Similarly, the error analysis during the evaluation of prediction performance has been figured out using different approaches like MSE, RMSE, MAE, and MSLE, among which our proposed method overwhelms with less error than the traditional methods.**

***Keywords*—Task scheduling; virtual machines; optimization; workload prediction; migration; QoS**

Nomenclature

Abbreviation	Description
SIN	Service Invocation Number
DBN	Deep Belief Network
LSTM	Long Short-Term Memory
SVM	Support vector machine
MA	Moving Average
ARIMA	Autoregressive Integrated Moving Average
WACO	Weighted Ant Colony Optimization
DBOA	Discrete Butterfly Optimization Algorithm
Grid-LSTM	Grid-Long Short-Term Memory
Bi-LSTM	Bi-directional Long Short-Term Memory
SDWF	Self-Directed Workload Forecasting
JEES	Joint Energy Efficiency Optimization Scheme
SE	Sum Squared Error
CE	Cross Entropy Error
TDO	Tasmanian Devil Optimization
CSO	Cat Swarm Optimization
MFO	Moth Flame Optimization
BES	Bald Eagle Search
HWOA	Hybrid Whale Optimizer
MPSO	Modified Particle Swarm Optimization

I. Introduction

With the pervasive expansion of Internet access and the rise of Big Data, cloud computing has gained increasing prominence in today's business landscape [1]. In comparison to alternative distributed computing methodologies such as cluster and grid computing, cloud computing offers an adaptive and scalable approach to providing customized services to consumers. It provides a means for consumers to access computing resources and platforms without the necessity of owning the underlying technology, enabling them to utilize these resources in a pay-per-use manner. Numerous resources, including processing power, storage capacity, and network bandwidth, are easily accessible in the field of cloud computing. The complexity lies in distributing them fairly across different users and jobs to meet a range of demands and priorities. Therefore, allocating resources in this dynamic and diverse environment presents a challenging task for researchers.

The main challenge in cloud computing is its diversified fluctuation of workloads and user needs [2]. Task requirements differ in kinds and amounts of resources, with dynamically evolving user needs. Secondly, cloud resources are limited, therefore it is crucial to allocate them wisely aiming for maximum performance and service effectiveness. It becomes imperative to load balance to avoid performance drops by resource saturation, due to resource conflicts within the system. At times several users or jobs may inevitably compete for the same resources simultaneously, leading to resource conflicts and delays. Eventually minimizing disputes and guaranteeing even distribution and efficient resource utilization, for strong resource allocation and scheduling is an urged need.

To address issues pertaining to the performance of task scheduling [3-5], researchers have presented a variety of innovative approaches. The following categories generally describe the available task-scheduling techniques in a cloud environment. Static Scheduling Methods: These include algorithms such as Shortest Job First (SJF), Earliest Deadline First (EDF), and Minimum Remaining Time (MRT) to

determine the sequence of work allocation and execution before a job is submitted. They are easy to deploy, but they are not flexible enough to adjust to changing task needs and dynamic situations. Heuristic Scheduling Methods: These techniques, which include Genetic Algorithms (GA) and Particle Swarm Optimization (PSO), mainly rely on prior knowledge and pre-established guidelines for scheduling decisions. They cannot optimize globally or make adjustments in real time, even though they take job priorities and resource efficiency into account.

Methods for Load Balancing Scheduling: These techniques seek to balance workloads among computing resources resulting in improved performance and resource usage. Random scheduling, round-robin (RR) scheduling, and queue-length-based scheduling are a few examples. They perform well in workload distribution overriding job specifications.

Scheduling process with evolutionary demands questioning the efficiency of cloud performance [6]. First of all, the sheer number of tasks demanded and their effective management raises the bar for computational demands adding complexity. Second, the cloud environment is dynamic, task arrivals, departures, and resource requirements are always changing. This dynamic nature renders the requirement for task scheduling algorithms that can be flexible and adaptive in real time to quickly adjust to changing demands [7]. Finally, to accomplish load balancing and maximize resource utilization, efficient task scheduling that relies on the appropriate distribution and application of resources is needed. If this equilibrium is not reached, system performance may suffer and resources may be wasted.

At the core of cloud computing lies the allocation of computing tasks to a shared resource pool of resources comprising diverse virtualized servers or virtual machines (VMs) [8]. Operating akin to a market-driven utility, cloud computing endeavors to enable providers and users to optimize their profits with enhanced returns on investment. As a result, the adoption of sophisticated scheduling strategies becomes essential to facilitate the management of software, user applications, tasks, and workflows within this environment. Scheduling, in its essence, plays a crucial role in shaping system performance, influencing both resource utilization efficiency and operational costs, thus underscoring its mark in the domain of cloud computing [9].

Due to the dynamic provisioning and management capabilities of virtual machines (VMs) [10], challenges in cloud scheduling generally manifest in two layers. Firstly, the task scheduling phase involves aligning user-submitted tasks concerning available VM resources. Secondly, a vital VM-to-host mapping process, which facilitates VM creation or migration [11, 12, 13]. Our main emphasis is on optimizing the former, as it directly influences the processing capabilities of a cloud computing system. Improving task scheduling has the potential to notably enhance system efficiency in terms of both time and cost [14, 15].

The above-mentioned challenges and issues that impact cloud performance are considered and addressed by introducing a framework that encompasses operations like workload prediction and scheduling, resulting in the design of a deep learning algorithm trained on features such as VM capacity and task capacity to optimize the scheduling process. The contributions of this work are delineated as follows:

- Introducing an enhanced Deep Learning approach, named Improved Deep Maxout, to predict workloads by training on both VM and task capacities.
- The prediction process facilitates optimal task scheduling through the TES algorithm, guaranteeing the achievement of objectives such as time efficiency, cost-effectiveness, and overall system efficiency.

The paper begins by introducing the concepts and challenges associated with cloud computing in Section I. Section II presents a thorough literature review along with the analysis and discussions of researchers' findings. In Section III, the paper describes the architecture and system flow of the proposed methodology in detail. Results and discussion is given in Section IV. The conclusion and future directions for enhancements are discussed in Section VI, shedding light on potential future developments.

II. Related Work

Several Researchers have made significant contributions to resolving task scheduling and resource allocation challenges. However, our work builds upon these efforts by addressing overlooked aspects and introducing enhancements that improve overall performance.

Wiem Matoussi and Tarek Hamrouni [16] developed workload forecasting techniques in 2021 to support capacity planning, guarantee effective resource allocation, and uphold SLA agreements with end users. Their methodology offered a novel way to forecast the surge of requests to a SaaS service and distribute virtual resources to satisfy user needs. The dual goals of this technique were response time optimization and accurate forecast forecasts.

Vinícius Meyer et al. [17] presented a machine learning-based classification technique in 2021 to provide the best possible resource allocation in cloud environments that are aware of dynamic interference. The main objective was to demonstrate how categorization techniques affect resource allocation so that it better accommodates variations in workload. The study began by looking at how different apps with different dynamic requests are handled by hardware components. The effectiveness of several interference classification techniques was investigated and assessed, taking into account the dynamic nature of cloud workloads.

Marek Grzegorowski et al. [18] presented a revolutionary method in 2020 for building a reliable clustering methodology with cloud resources customized to the particular data processing requirement. The provided architecture made use of the infrastructure-as-a-code framework to allow for dynamic cluster configuration and administration. It begins by figuring out which cluster size is best for finishing a task within the given time frame. The execution time was then optimized by using ARIMA models and examining the price history of spot instances to benefit from the lower prices offered by the cloud spot market.

Min Cao et al. [19] introduced three fresh methods for an energy-aware EIS in 2023. The author initially determined the best time for each task to run on a certain resource to save energy. Second, to reduce frequency factor and voltage and conserve energy, the EIS allows workflow slack time according to the optimal time for each task's execution. Moreover, the EIS minimizes dynamic energy consumption and satisfies workflow deadline limitations by utilizing the lapsed time caused by task priority deficiencies.

A logarithmic method was used in 2021 by Jing Bi et al. [20] to lower standard deviation before workloads and resource sequences were applied. They used the Min-Max approach to scale the data and an improved filter to remove noise interference and outliers. They have created an integrated deep learning method for time series forecasting, which makes use of ML-network models like Grid-LSTM and Bi-LSTM networks to produce accurate forecasts of resource demands and workload arrival at regular intervals.

The SDWF (Standard Deviation Weighted Forecasting) approach was developed in 2021 by Jitendra Kumar et al. [21]. It uses the deviation in the present predictions to calculate the trend of forecasting errors and improve the accuracy of future predictions. For training neurons, the model uses a sophisticated heuristic approach motivated by the black hole phenomenon. In addition, a statistical analysis was carried out to verify the accuracy of the suggested forecasting model, using Friedman and Wilcoxon signed ranking tests.

JEES (Joint Energy Optimisation and Scheduling), which simultaneously tackles and optimizes energy consumption in both cooling systems and servers, was introduced in 2021 by Kaixuan Ji et al. [22]. In addition to a resource management strategy that integrates workload forecasting models for resource allocation and a task-migration approach that makes use of marginal cost evaluation, JEES also includes a dynamic online task-scheduling technique based on the evaluation of marginal cost. The combined effect of these strategies is to lower data centers' overall energy usage.

Taking into account the unpredictable and time-varying nature of the workload, Zheng Xiao et al. [23] combined VM allocation with task scheduling in 2019. A Markov chain can be used to simulate the Markov property that the acquired workload dataset exhibits, as the study showed. In addition, recurrence, entropy, and persistence were found to be the three main operators that best described the workload. These operators assess the stability, predictability, and approximate burst timings of user requests, in that order. It was discovered that there is a nonlinear link between workload characteristic operators and virtual machine allocation.

A hybrid weighted Ant Colony Optimisation model with solution and pheromone updating functions was presented by Chirag Chandrasekar et al. [24] in 2023 for the best job scheduling. They showed that their meta-heuristic method outperformed current algorithms in terms of metrics like execution time and resource management.

Neetu Sharma, Sonal, and Puneet Gala [25] introduced a QoS-based Ant Colony Optimisation scheduling system in 2020 that used a neural network technique for effective multi-objective scheduling [37]. Their suggested approach outperformed current algorithms in terms of user task scheduling costs and execution times.

A modified Particle Swarm Optimisation (MPSO) was suggested in 2023 by Shikha Chaudhary et al. [26] to overcome the issues of long scheduling times and high computational costs during the scheduling process. By minimizing early convergence and improving local search efficiency, the MPSO optimizes the objective function about cost and makespan. An increase in the graph indicates that the performance of the suggested model is superior to that of conventional methods.

To solve resource waste and improve the algorithm's speed of convergence, Medhi Hussein Zadeh et al. [27] created a discrete Butterfly Optimisation Algorithm (DBOA) in 2021 that was modeled after the Levy flight technique. Their method of task prioritization and DBOA successfully addresses local optima concerns and allows for more efficient scheduling of intense workflows.

A task scheduling technique using Cat Swarm Optimisation was introduced in 2023 by Sudheer Mangalampalli et al. [28]. This algorithm prioritizes tasks and arranges them for scheduling. Inspired by the behavior of cats, this algorithm outperforms baseline methods that are currently in place in terms of QoS metrics like makespan and resource utilization.

Abdul Rajak [36] addressed an intelligent approach that benefits the real-world agricultural environment. Md shohel Sayeed et.al [38] proposed a real-time system for parking vehicles using a weighted K-nearest neighbour approach by selecting an optimal scheduler. Gousteris et.at [39] have come up with a secure approach for cloud storage using blockchain technology for efficient performance with heterogeneous input data.

III. METHODOLOGY

The work progresses by considering user requests as tasks appertaining to N users symbolized as U_i, where $i=\{1,2,...,N\}$. These tasks designated as Tsk_j with $j=\{1,2,.....M\}$ are assigned to feasible virtual machines VM_i where $i=\{vm_1,vm_2,.....vm_n\}$ and physical machines PM_i where $i=\{pm_1,pm_2,.....pm_k\}$. The proposed paradigm proceeds based on a priority scheme for scheduling using Deep learning techniques resulting in improved forecast of workloads.

Improving cloud performance and cutting operating costs need accurate workload forecasts. To precisely predict workloads, a deep learning model is used in this article, which increases efficiency and lowers costs. The proposed improved Deep Maxout model successfully learns to anticipate jobs as target labels by using factors like CPU utilization, day of the week, and time of day.

The enhanced Deep Maxout model's mathematical formulation is explained in [29]. To improve model robustness, it adds the modified softmax activation function (G-SM) to Eq. (2). In this case, the activation value is denoted by si and $gd(s)$ Gaussian distributed term with mean μ and standard deviation σ. The classic softmax activation function, which can handle multiple classes by normalizing the outputs for each class, ranging from 0 to 1, is presented by Eq. (1).

The input layer, embedding layer, max pooling layer, dropout layer, convolution layer, and dense layers that make use of activation and maxout functions constitute the Deep Maxout model's network structure. The maxout unit of this network is shown in Eq. (3), here $K_{yz} = N \cdot \lambda_{yz} + \gamma_{yz}$, γ serves as the bias, with N standing for input features such as task and virtual machine capacity, η serving as the feature map, and λ serving as the weight.

The softmax function *SM* is coined as follows:

$$SM(s)_i = \frac{e^{s_i}}{\sum_{j=1}^{k} e^{s_j}} \quad (1)$$

This formula defines a probability distribution across *k* possible outcomes. Here s_i represents the input value corresponding to outcome *I* and the denominator summates the exponentials of all input values across all outcomes.

$$G - SM = \frac{exp(s_i + gd(s))}{\sum_{j=1} exp(s_i + gd(x))} \quad (2)$$

$$gd(s) = 0.5 * er\_f\left(-\frac{\sqrt{2}(\mu_i - s_i)}{2\sigma_i}\right) + 0.5$$

where, error function er_f can be coined as.

$$(1/\sqrt{\pi}) \int_{-z}^{z} e^{-t^2}\, dt, t^2 = s_i$$

$$Q(M) = \underset{z\in[1,\eta]}{Maximum}(R_{yz}) \quad (3)$$

The input layer receives the input feature *N*, and the embedding layer processes its output to calculate the outcome. The dropout layer and convolution layer are the next two layers that process the output further. The final output is obtained starting with the third convolution layer. The final output is then produced by the max-pooling layer following the convolution layer. The dense layer is followed in order by the dropout layer.

The output of the max-out module is calculated based on the input pipelined from the dropout layer and is combined with the dense layer to create the final product. Using the output of the dense layer as the last step, the activation function computes the classification result as Deep Max_{out}. To evaluate the accuracy parameter of the model, hybrid loss functions which are given in Eq. (4) and detailed in [33] are used. Typically, error measures such as the *SE(E_SE)* and *CE* loss functions *(E_CE)* are employed to assess the efficacy of a classification model.

The enhanced hybrid loss function calculation for the proposed model is provided in Eq. (5), where the dynamically weighted balanced *CE* is represented by $E_{\_CE^*}$ (as in Eq. (6)). In this case, $y_i\hat{}$ stands for the anticipated label, and y_i indicates the actual label. w_lb_j, which is calculated as the ratio of class frequency n_j and the majority class (as determined across the training dataset), is equal to the class frequency log (as in Eq. (7)). The proportions allocated to the loss functions are represented by the scalar values Lf_1 and Lf_2, where $Lf_1+Lf_2=1$.

$$E_{\_he} = Lf_1 \frac{E\_SE}{Max_{SE}} + Lf_2 \frac{E\_CE}{Max_{CE}} \quad (4)$$

Here

$$E_{\_CE} = -\frac{1}{Output\_Size} \sum_{i=1}^{Output\_Siz} y_i \cdot log\, \hat{y_i} + (1 - y_i) * 1 * log\left(1 - \hat{y_i}\right)$$

$$E_{\_he} = Lf_1 \frac{E\_SE}{Max_{SE}} + Lf_2 \frac{E\_CE^*}{Max_{CE^*}} \quad (5)$$

$$E_{\_CE^*} = -\frac{1}{Output\_Size} \sum_{i=1}^{Output\_Siz} \sum_{j=1}^{c} w\_lb_j^{(1-p_{ij})}\, y_i \cdot log\, \hat{y_i} + (1 - y_i) * 1 * log\left(1 - \hat{y_i}\right) \quad (6)$$

$$w\_lb_j = log\left(\frac{max(n_j | j \in c)}{n_j}\right) + 1 \quad (7)$$

1) Optimal load balancing and task scheduling: An effective load-balancing approach proactively aids in monitoring the workload of the virtual machines (VMs') and allocating jobs to them appropriately. An example job would be Tsk_j, which has a range of 1000 tasks. The physical machines would be pm_k, with 50 machines, and the virtual machines would be vm_N, with 20–25 computers. There are multiple vm_N within this range for every pm_k. The pm_k machines are randomly assigned tasks.

The enhanced Deep Maxout model is used in this workload prediction model. The target label of the Deep Maxout model is set to 0, 1, and 2, and the features supplied to the Improved Deep Maxout model are Task capacity and VM capacity. The following are the definitions of under load, equal load, and overload conditions:

- The target label is set to 0, indicating that the machine's workload prediction is under load, if the task capacity is smaller than the virtual machine's capacity.
- The target label is set to 1, indicating that the machine's workload prediction is at equal load, if the task capacity and the VM capacity are equal.
- The target label is set to 2, meaning that the machine's workload prediction is overloaded, if the task capacity exceeds the virtual machine capacity.

Constraints including Makespan (Fn_1), Migration cost (Fn_2), and Migration efficiency (Fn_3) are taken into account throughout the scheduling process considered. Fig. 1 shows the model of scheduling. The input solution assigns a lower bound of Lb=0, *(Zeros(len(Machine_underload)))*, and an upper bound of Ub=1, *(Ones(len(Machine_underload)))* to the variables. The number of underloaded machines is equal to the problem size of TES.

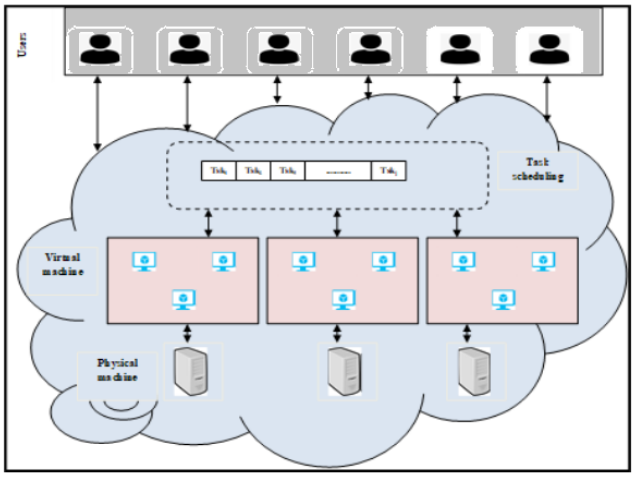

Fig. 1. Scheduling of task in cloud computing.

The objective function is expressed in Eq. (8), where random weights in the interval [0, 1] are represented by the variables w_1, w_2, and w_3.

$$Obj = (w_1 * Fn_1) + (w_2 * Fn_2) + (w_3 * Fn_3) \quad (8)$$

1) Makespan(Fn_1): Eq. (9), which defines the makespan, shows the total computing time *(CT_i)* (as given in Eq. (10)) needed to complete a task, where N is the number of virtual machines.

$$Fn_1 = \underset{1 \le i \le N}{Max}\{CT_i\} \quad (9)$$

$$CT_i = \sum_{j=1}^{n} \frac{T_j * length}{vm_N * Pes\_Num * Xvm_N} \quad (10)$$

2) Migration cost(Fn_2) : A *M*M* matrix is used to calculate the migration cost, where the rows and columns of the matrix indicate the migration costs of virtual machines (vm_N) and physical machines (pm_K), respectively. The (1, 1) and (2, 2) columns in this matrix indicate reduced migration costs, while the remaining entries suggest higher migration costs.

3) Migration efficiency(Fn_3) : Based on the migration value, the migration efficiency is computed, as shown in Eq. (11).

$$Fn_3 = \frac{1}{Fn_1} \quad (11)$$

This section presents the mathematical formulation of the proposed meta-heuristic TES, which combines TD [30] with ES [31]. The Tasmanian devil feeds on live prey by attacking them or by scavenging carrion from dead animals. This behavior is simulated by TES. First, a random population of agents is generated according to the limitations of the challenge. Based on the location of their search region, the population members of TES, which are problem-solving search agents, suggest potential values for problem variables. Functionally, each member of the population can be thought of as a vector, with the number of elements representing the number of variables in the problem. A matrix in Eq. (12), where P is the Tasmanian population, N is the number of Tasmanian devils seeking, P_i is a potential solution, and m is the number of specified problem variables, can be used to simulate the set of TES members.

$$P = \begin{bmatrix} P_1 \\ : \\ P_i \\ : \\ P_N \end{bmatrix} = \begin{bmatrix} p_{1,1} \dots p_{1,j} \dots p_{1,m} \\ : \\ p_{i,1} \dots p_{i,j} \dots p_{i,m} \\ : \\ p_{N,1} \dots p_{N,j} \dots p_{N,m} \end{bmatrix}_{N \times m} \quad (12)$$

By changing the values of potential solutions into the defined objective function's objects, the objective function can be assessed. In Eq. (13) the values obtained for the defined objective function are represented by a vector V.

$$V = \begin{bmatrix} V_1 \\ : \\ V_i \\ : \\ V_N \end{bmatrix} = \begin{bmatrix} V(P_1) \\ : \\ V(P_i) \\ : \\ V(P_N) \end{bmatrix}_{N \times 1} \quad (13)$$

The Tasmanian devil algorithm does not always hunt; sometimes it prefers to eat the carrion that is around. The area above the Tasmanian devil is home to additional predators that hunt enormous prey but are unable to finish it. Each Tasmanian devil considers the position of another population member to be carrion bait under the TES design. Cr_i denotes the selected carrion in Eq. (14) which shows the random selection of one of these cases. The Tasmanian devil is moved to a new location inside the search area based on Cr_i.

$$Cr_i = P_k, i = 1,2, \dots, N,$$
$$x \in \{1,2, \dots, N | x \neq i\} \quad (14)$$

A random number is represented by $In \in (1,2)$ and a random number is represented by $r \in (0,1)$, while the Tasmanian devil's current update based on the first strategy is represented by $p_{i,j}^{new,S1}$ in Eq. (12). Eq. (15) is used to calculate the Tasmanian devil's new position. If the objective function value at the new position is higher than its previous position, the position is considered acceptable; otherwise, the Tasmanian devil process retains its position.

The new update for the Tasmanian devil is obtained by merging the TD and proposed ES updates in Eq. (16), by the proposed methodology. In this case, the random factor is represented by *RandF* (as in Eq. (18)) [34], the random value is $r_2 \in (0,1)$ the maximum iteration is It_{Max} , the current iteration is C_It and the levy flight update is represented by *Levy_fun* (as in Eq. (19)). Eq. (20) provides the typical (eagle search) ES update equation, where α is the parameter governing the position change.

Update to the new value as $p_{i,j}^{new,S1}$ with $p_{i,j} + r \times \left(Cr_{i,j} - In \times p_{i,j}\right)$ when the criteria $V_{Cr_i} \prec V_i$ is met alternatively

$$p_{i,j} + r \times \left(p_{i,j} - Cr_{i,j}\right) \quad (15)$$

The algorithm considers $P_{i,j}^{new,S1}$the updated if the fitness offered is better than current else retains the current value as follows

$$P_i = \begin{cases} P_i^{new,S1}; V_i^{new,S1} \prec V_i \\ P_i; Otherwise \end{cases} \quad (16)$$

$$p_{i,j}^{new,S1} = \begin{cases} p_{i,j} + RanF \times \left(Cr_{i,j} - In \times p\right); \\ if V_{Cr_i} \prec V_i \\ p_{best} + \alpha * r(p_{mean} - p_i) * Levy\_fun; \\ else \end{cases} \quad (17)$$

$$RanF = r_1 * sin(r_2), \quad (18)$$

where

$$r_1 = \frac{1.5 \times (It_{Max} - t + 1)}{It_{Max}}$$

$$Levy_{fun} = \frac{C_{It(1+\beta)} * \left(sin\left(\frac{\pi\beta}{2}\right)\right)^{1/\beta}}{C_{It\left(\frac{1+\beta}{2}\right)} * \beta * \left(2^{\left(\frac{\beta-1}{2}\right)}\right)} \quad (19)$$

$$p_{new} = p_{best} + \alpha * r(p_{mean} - p_i) \quad (20)$$

$$Pry_i = P_k, i = 1,2, \ldots, N,$$

$$x \in \{1,2, \ldots, N | x \neq i\} \quad (21)$$

The position of other population members is taken into account as the location of prey during the updating procedure of the i^{th} Tasmanian devil. Prey selection is modeled by Eq. (21) where Pry_i indicates the selected prey and $x \in (1, N)$ is a natural random number.

Eq. (22) uses the exact location of the prey to calculate the Tasmanian devil's new position. The Tasmanian devil's location is adjusted to this new position if the new location increases the target function value. Eq. (23) provides an example of this second strategy phase.

$$p_{i,j}^{new,S2} = \begin{cases} p_{i,j} + r \times \left(Pry_{i,j} - In \times p_{i,j}\right); \\ if V_{Pry_i} \prec V_i \\ p_{i,j} + r \times \left(p_{i,j} - Pry_{i,j}\right); \\ else \end{cases} \quad (22)$$

$$P_i = \begin{cases} P_i^{new,S2}; V_i^{new,S2} \prec V_i \\ P_i; Otherwise \end{cases} \quad (23)$$

The radius *R* of the neighborhood that is, the region where the Tasmanian devil tracks its prey can be found using Eq. (24). Thus, a new position for the Tasmanian devils can be established by quantitatively simulating their pursuit behavior using Eq. (25). The Tasmanian devil will accept the newly calculated position if it provides a better value for the goal function than the previous position. Eq. (26) describes the process of updating the position of the Tasmanian devil. The Tasmanian devil's position update procedure is carried out, by the model presented in Eq. (27), by incorporating the factor P_Fact as suggested in Eq. (28) [32].

$$Rd = 0.01\left(1 - \frac{t}{It_{Max}}\right) \quad (24)$$

$$p_{i,j}^{new} = p_{i,j} + (2r - 1) \times Rd \times p_{i,j} \quad (25)$$

$$P_i = \begin{cases} P_i^{new}; if\ V_i^{new} \prec V_i \\ P_i; else \end{cases} \quad (26)$$

$$P_i = \begin{cases} P_i^{new} \times P\_Fact; \\ if\ V_i^{new} \prec V_i \\ P_i; else \end{cases} \quad (27)$$

$$P\_Fact = exp\left(\frac{-i}{\delta \times It_{Max}}\right) \quad (28)$$

Algorithm 1: TES (Tasmanian Devil-assisted Bald Eagle Search) for optimal load balancing and task scheduling.

Input: Set of VMs = {VM_1,VM_2….,VM_n} and Tasks={T_1,T_2….,T_n}
Initialize: No of iterations (*T*) and no of members of the population (*N*).
While t=1: T
For i=1: N
IF $prob \prec 1/2, prob = rand.$
Select carrion for the i th Tasmanian devil by Eq. (14)
Calculate the new status of the Tasmanian devil by Eq. (16)
Update the i th Tasmanian devil apply Levy flight strategy by Eq. (17)
Else
Select prey of i^{th} the Tasmanian devil using Eq. (21)
Assess the updated value of the Tasmanian Devil using Eq. (22).
The Tasmanian Devil's update is executed using Eq. (23).
Update Rd by Eq. (24)
Assess the new updated value of i^{th} Tasmanian Devil in the neighborhood using Eq. (25).
Update proposed i^{th} Tasmanian devil via Eq. (27)
End For
End While
Output: The best solution obtained for a given optimization problem.

IV. Results and Discussion

A. Experimental Setup and Simulation

We employed simulations to evaluate the effectiveness of our proposed scheduling methods. Cloudsim is widely utilized as simulation software for evaluating optimization techniques. It replicates components of cloud systems such as data centers, tasks, and virtual machines, while also supporting task scheduling strategies and diverse energy usage models for simulating various workloads. In this study, we simulated a cloud model based on a single data center, akin to Infrastructure as a Service (IaaS). The simulations were performed on a computer equipped with an Intel(R) Core(TM) i5-8265U CPU @ 1.80 GHz processor, 16 GB RAM, and a 64-bit Windows 11 Operating System.

The configuration of the simulated cloud data center is shown in Tables I, II and III.

TABLE I. CONFIGURATION OF HOST IN DATACENTER

Host Parameters	*Value*
Processing Element (PE)	2-10
Processing capacity	20000-35000 MIPS
RAM capacity	8GB,16GB,32GB

TABLE II. CONFIGURATION OF VMS

VM Parameters	*Value*
Processing Element (PE) in each VM	1
CPU computing capacity	600-4000 MIPS
RAM capacity	512-4196 MB

TABLE III. TASK PARAMETERS

Task Parameters	*Value*
Task Length	15000-900000 MI
Size of Task	60-3000 KB

B. Performance Metrics

The Google Cluster Workload Traces dataset from 2019 sourced from [35] is subjected to Cloudsim for workload prediction and job scheduling. The TES approach is evaluated against conventional strategies such as DBOA, MPSO, and WACO. The key parameters considered for evaluating the performance of the proposed method pertain to Communication cost, Execution time, Makespan, Migration Cost and Migration Efficiency are compared against existing approaches. The analysis is carried out with task counts ranging from 500 to 2000.

1) Communication cost and execution time: Fig. 2 and Fig. 3 depicts the comparison of TES performance to that of WACO, MPSO, and DBOA in terms of communication cost and execution time for workload prediction and task scheduling. The results achieved present an increased drift in performance by the proposed TES in terms of reduced execution times and communication costs over other approaches. To be more precise, when handling tasks with tasks of various counts, the TES attained notably lowered communication costs than other algorithms handling. The result of the proposed approach renders the utmost values when task count is 500, when compared against task counts of 1000, 1500, and 2000. Furthermore, the TES demonstrated a significant improvement with an execution time of 1648 seconds with 2000 tasks.

2) Makespan analysis: The workload prediction and task scheduling performance metrics comparison of the TES vs. WACO, MPSO, and DBOA is shown in Fig. 4. Indicating that when job/task count is set at 500, the findings show a shorter makespan for the TES approach as compared to conventional methods. This demonstrates how accurate the TES is at forecasting workload and allocating jobs facilitating the shortest makespan.

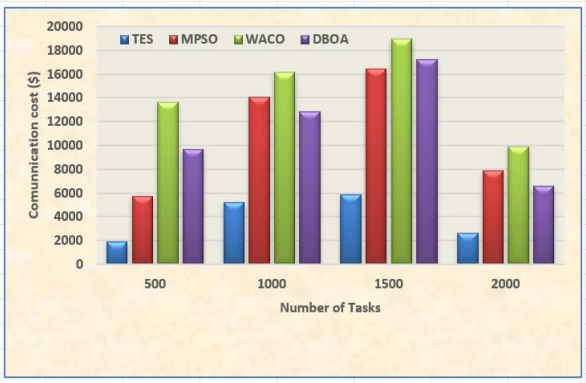

Fig. 2. Communication cost vs. number of task.

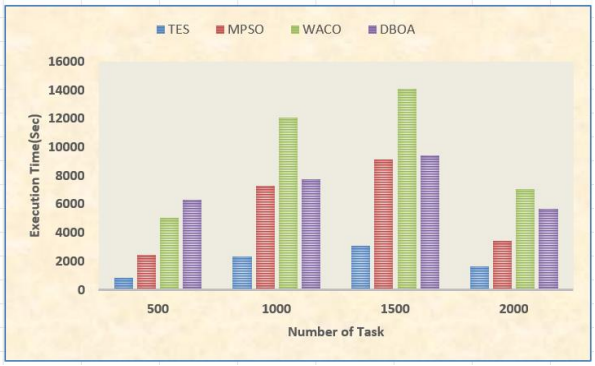

Fig. 3. Execution time vs. number of task.

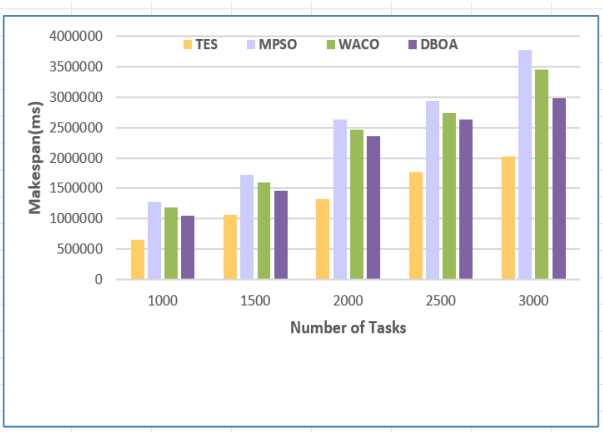

Fig. 4. Makespan vs. number of tasks.

3) Migration cost and migration efficiency analysis: The analysis of the TES's efficiency and migration cost of other task scheduling and workload prediction techniques is shown in Fig. 5 and Fig. 6. The number of tasks is changed to conduct the analysis. With a migration cost of 1.54 (with 2000 tasks), the TES methodology outperforms previous approaches with WACO=5.786, MPSO=4.345, and DBOA=3.987, respectively, in terms of efficiency and cost. Furthermore, TES's migration efficiency (0.0987) outperforms MPSO's (0.322), WACO's (0.378), and DBOA's (0.0239), with 2000 tasks. These findings show that TES is more effective and less expensive during task migrations.

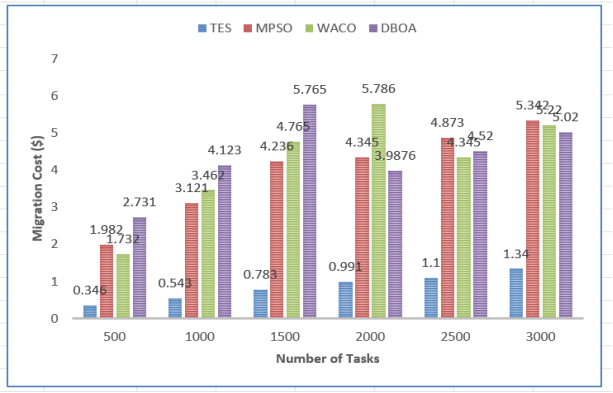

Fig. 5. Migration cost vs. number of tasks.

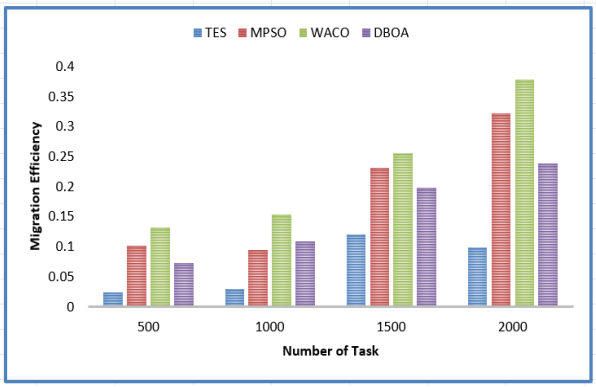

Fig. 6. Migration efficiency vs. number of task.

4) Convergence evaluation: As seen in Fig. 7, the convergence analysis of TES is contrasted with other methods currently in use, such as WACO, MPSO, and DBOA. The cost values that were initially produced by TES and other methods were high at the 0th iteration, with a considerable downtrend following successive iterations. The cost parameter values attained are comparatively low using TES, especially on the 25th iteration when it obtained a minimal cost value of 3.427. According to the convergence graph, TES converges more rapidly than other schemes, bringing down costs and producing enhanced accuracy in forecasting workload about user tasks.

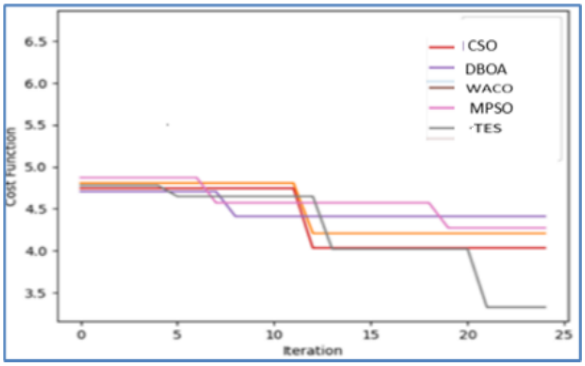

Fig. 7. Cost function vs. iterations.

5) Regression analysis: The regression evaluation of the suggested approach and the current approaches (CNN, NN, and RNN) for workload prediction is shown in Fig. 8, 9, 10 and Fig. 11. The results demonstrate that TES in contrast to CNN, NN, and RNN, which typically provide more divergent values, produces more consistent values in both real and classified labels.

6) Error analysis of improved deep maxout: Table IV presents an error analysis of the suggested algorithm concerning conventional Deep Maxout, CNN, RNN, NN, Bi-GRU, RMSE, MAE, and MSLE. The lowered error rates attained with the enhanced Deep Maxout technique reflect the e. In particular, the RMSE of the enhanced Deep Maxout is 0.100, which is substantially less than that of the Conventional Deep Maxout (1.150), RNN (0.340), CNN (0.260), and NN (0.160) in Bi-GRU (1.180), respectively. Furthermore, the suggested approach demonstrated enhanced performance in terms of MSE=0.120, MAE=0.021, and MSLE=0.215, all of which were minimized.

7) Prediction analysis: Table compares the prediction evaluation of TES with CNN, NN, and RNN addressing the prediction efficiency of TES that outperformed CNN, NN, and RNN algorithms in terms of prediction accuracy.

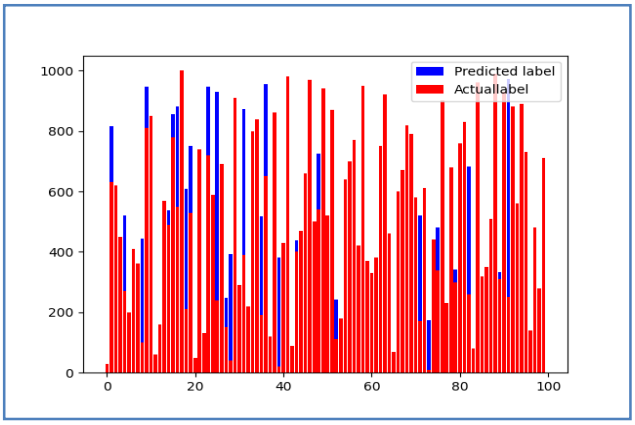

Fig. 8. Regression evaluation of CNN.

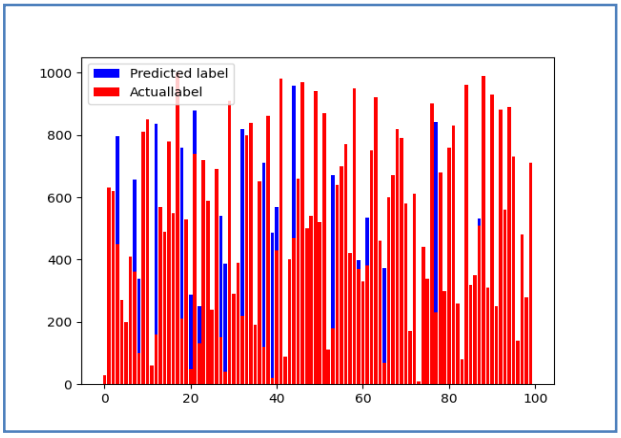

Fig. 9. Regression evaluation of NN.

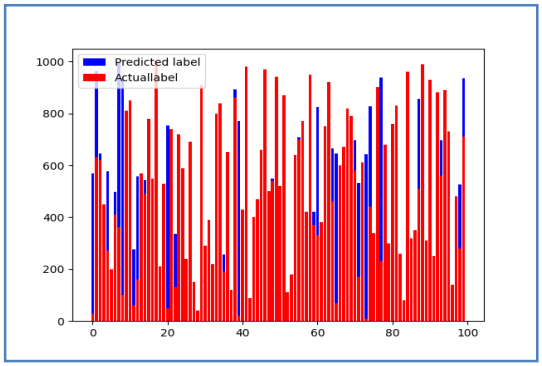

Fig. 10. Regression evaluation of RNN.

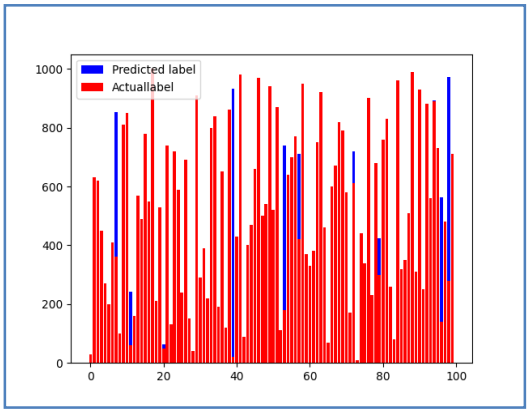

Fig. 11. Regression evaluation of TES.

TABLE IV. ERROR EVALUATION

Methods	*MSE*	*RMSE*	*MAE*	*MSLE*
CNN	0.521	0.260	0.150	0.520
RNN	0.460	0.340	0.140	0.678
NN	0.320	0.160	0.057	0.447
Bi-GRU	2.180	1.180	0.652	1.404
Conventional Deep Maxout	4.120	1.150	0.224	1.320
Improved Deep Maxout	0.120	0.100	0.021	0.215

TABLE V. PREDICTION EVALUATION OVER THE TRADITIONAL APPROACHES

Methods	*Success Rate*	*Over Prediction*	*Under Prediction*
CNN	49	51	49
NN	49	51	49
RNN	53	47	52
TES	96	14	25

V. CONCLUSION

The proposed study offers an effective workload prediction model that forecasts future workload based on trends seen in historical data by utilizing the Deep Max-out prediction model. This model uses the TES Algorithm to optimize scheduling while efficiently balancing the workload on machines. By ensuring that jobs are moved among virtual machines (VMs) in the best possible way, this method produces effective scheduling that takes into account metrics like make-span, migration cost, and migration efficiency. Comparing the suggested model to conventional approaches, promisingly results in high communication costs, with statistical analysis showcasing that the new model greatly reduces communication costs (2647.835). Moreover, the comparison of forecast outcomes emphasizes how crucial it is to take into account limitations such as job make-span, fitness, migration-cost, and execution time. When comparing the suggested model to conventional techniques, these constraints are noticeably less. In particular, the execution time is reduced to around 817, demonstrating how well the suggested model performs in comparison to traditional techniques that require larger execution cycles.

AUTHORS' PROFILE

Syed Karimunnisa received an M.Tech (CSE) from JNTUA and currently pursuing a Ph.D. from Koneru Lakshmaiah Education Foundation, Guntur, Andhra Pradesh. She has published both international conferences and Journals. She is a Life Member of ISTE and CSTA. Her areas of Interest include Cloud C omputing, Artificial Intelligence, Machine Learning, Deep Learning, Data Mining, and the Internet of Things.

Pachipala Yellamma is working as an Associate Professor in the Department of Computer Science and Engineering, Koneru Lakshmaiah Education Foundation, Guntur, Andhra Pradesh. Completed her PhD in Data security in cloud computing. Her research interests include cloud computing, the Internet of Things, Network security, Data compression, Cryptography, and Data security. She is a Life Member in ISTE and IEEE and has some free memberships. She has published several national and international articles in Scopus, web of Science, and SCI. She has three patent publications.

Estimating Coconut Yield Production using Hyperparameter Tuning of Long Short-Term Memory

Model for Estimating Coconut Yield Production

Niranjan Shadaksharappa Jayanna, Raviprakash Madenur Lingaraju

***Abstract*—Coconut production is one of the significant and main sources of revenue in India. In this research, an Auto-Regressive Integrated Moving Average (ARIMA)-Improved Sine Cosine Algorithm (ISCA) with Long Short-Term Memory (LSTM) is proposed for coconut yield production using time series data. It is used for converting non-stationary data to stationary time series data by applying differences. The Holt-Winter Seasonal Method is the Exponential Smoothing variations utilized for seasonal data. The time-series data are given as the input to the LSTM classifier to classify the yield production and the LSTM model is tuned by hyperparameter using Improved Sine Cosine Algorithm (ISCA). In basic SCA, parameter setting and search precision are crucial and the modified SCA improves the coverage speed and search precision of the algorithm. The model's performance is estimated by utilizing R2, Mean Absolute Error (MAE), Mean Squared Error (MSE), and Root Mean Square Error (RMSE) with date on yield from 2011-2021 by categorizing yearly production into 120 records and eight million nuts. The outcomes display that the LSTM-ISCA offers values of 0.38, 0.126, 0.049 and 0.221 for R2, MAE, MSE and RMSE metrics, which offer a precise yield production when related to other models.**

Keywords*—Auto-regressive integrated moving average; coconut yield production; improved sine cosine algorithm; long short-term memory; time series

I. Introduction

Coconut is one of the most important and multi-use everlasting crops that is mostly used to produce hair oil, cosmetics, soaps and other products [1]. In India, out of all states, southern regions offer huge production of coconut, and Kerala has the largest area for coconut production. Coconut production is determined by many factors [2]. Coconuts are categorized into three types, intermediate, dwarf and tall based on their height and behavior. Coconut farmers always face price risk that is determined by coconut retention and the strength of demand in the market [3]. Coconut yield is a difficult quantitative feature that differs with environmental factors, age, variety, and communication between environmental factors and variety [4]. Mature nuts are considered as yield because the solid endosperm content in nuts is used for yield production. Additionally, the temperature is important for the growth and development of nut yield of coconuts; high temperature reduces the root growth [5].

Coconut palms play an important role in humans as it meets the social, economic and cultural requirements. The tall type of nut production signifies the produced number of coconuts under agronomic environments [6]. Subsequently, the enhanced productivity in coconut yield results in proper resource usage and the evaluation of coconut enhance the yield production [7]. The accurate quantification of coconut yields is critical for disasters such as drought, which give rise to a variety of crop growth, leading to different levels of coconut yield reduction [8]. It is important to carry out sequential time series coconut growth monitoring over the main growth and development period [9]. The Auto-Regressive Integrated Moving Average (ARIMA) model is utilized for forecasting future outcomes based on the past data points influencing the data points. Hyperparameter tuning is used in the LSTM model for performance and accuracy improvement, resulting in a more robust performance as compared to other deep learning models. The Improved Sine-Cosine Algorithm (ISCA) is an optimization algorithm that mainly depends on the sine and cosine operators so as to improve the performance of the LSTM model. The contributions of LSTM-ISCA are specified as follows:

- The Linear Interpolation is utilized for preprocessing which fills missing values of the dataset in districts of Kerala.
- ARIMA model is used for converting stationary time series data from non-stationary data by applying differences and then the exponential Smoothing of Holt-Winter Seasonal Method is used for seasonal data.
- The LSTM-ISCA model is employed for coconut yield production, wherein the LSTM model is tuned by hyper-parameters using Improved Sine Cosine Algorithm, and the performance is evaluated by using R2, MSE, RMSE, and MAE.

The rest of this paper is organized as follows: The literature review for coconut yield production is described in Section II. The detailed description of the proposed method is illustrated in Section III, while the obtained results of the proposed model are described in Section IV, and lastly, the conclusion of this research is described in Section V.

II. Literature Review

Novarianto [10] implemented an aerial photography method by using drones to establish the classification of local tall coconut production, and coconut diversity in Taliabu Regency, Taliabu Island and North Maluku Province. The

drone technology increased the data efficiency by combining the classical sampling population in local tall coconut trees. This drone technology surrounded the data of plant types, total areas, number of areas planted with coconut, and characteristics like the number of coconuts, and the height of the coconut palm. The coconut production information was used to develop a coconut rehabilitation and replanting approach. The yield population density of each area was determined by different factors such as the number of palms dying, and the pests and diseases that are not suitable for coconut production.

Samarakoon et al. [11] developed a different coconut plantation using Ordinary Least Square (OLR) estimation and Quantile Regression (QR) approaches to estimate the production function in Cobb Douglas functional form. OLR estimation was an appropriate method for conditional mean model estimation, while the QR provides an equally appropriate method for the conditional quantile function. In OLS estimation, the amount of bearing palms has a beneficial effect when the input variables are considered without delay on coconut production. In comparison, QR provides significant information that enables suitable policies for the use of inputs in coconut production. In this model, the long-term viable option is to increase coconut production and the productivity of coconut lands.

Pramono and Arifin [12] proposed a dry coconut for copra production using a conventional method named fuzzy logic control. This conventional method was used for coconut drying in sunlight with weather conditions. In the electronic system, the fuzzy logic method used an AC to AC voltage circuit and control system using the ARM STM32F4VG microcontroller. This model consumed only 18 hours for drying and the quality of the product was assured in both laboratory testing and physical conditions. Drying using direct sunlight produced copra that was polluted with microbes and dust. Apart from the drying technique, the copra was never absolute which resulting in greater capacity of moisture.

Hadi [13] developed a quantitative with regression analysis as a casual estimation tool between variables in the Kalimantan region. This model was used to examine the risks in coconut production which affected the economic value, selling value, and income. The output showed that the risk in the coconut business is the reduction in the number of trees because of the translation of mining and plantations. Additionally, the operational costs are not equitable to the selling price. Moreover, the household coconut farmer's production risks impact the level of productivity caused in every harvest season.

Karunakaran and Narmadha [14] implemented a Quin-decadal Analysis for coconut production and growth performance in the global scenario. This model considered three methods: compound growth rate for growth models, Coppock's instability index for instability measures, and the decomposition analysis for yield production. In this model, the low-production country was correctly developed as acceptable harvesting was not carried out and the fallen nuts were not considered. Hence, high attention is needed for the states to encourage and fascinate the farmers in coconut production by retrieving modern technologies.

Das et al. [15] developed six multivariate techniques for coconut yield production using weather-based linear and nonlinear models in west coastal areas of India. Weather indices were created by using collected values for rainfall and average values for other parameters monthly, such as solar radiation, relative humidity, min and max temperature, and wind speed. Various linear and non-linear models were applied to the model for coconut yield production using input as weather indices monthly. The model showed that the frequency of weighted weather was higher, as opposed to simple weather indices.

Paudel et al. [16] suggested a crop yield production by MARS Crop Yield Forecasting System (MCYFS) data in the European Commission. Machine learning was an independent source of data collected and combined for a crop model to build a large-scale crop yield prediction baseline. The baseline had growth in fit-for-determination optimizations and overall design values. Certain countries and crop data required huge preprocessing to fit the baseline requirements which were not instigated for big data analysis.

Hebbar et al. [17] developed a MaxEnt model for coconut yield production in India under climate change scenarios. The developed model was used to estimate bioclimatic variables for defining specific cultivation and forecast region's climate, which was possibly appropriate in the future weather conditions. Based on the present cultivation region and weather change prediction from seven ensembles of Global Circulation Models, the prediction of climatic suitability was done through MaxEnt model. In climate suitability from moderate to high, high to low, and low to inappropriate under upcoming climate. In this model, coconut production and the productivity of coconut lands is increased to enhance the coconut production.

Tuckeldoe et al. [18] introduced a coconut yield and nutritional quality prediction using sterilized growth media. The introduced model was used to define the coconut's effects on biochemical constituents of the varieties cultivated under various environments. The developed model considered two seasons in 2021 and 2022 for cultivating coconuts on fertigated land. Drying using direct sunlight produced copra that is polluted with microbes and dust, and apart from the drying technique, the copra was never absolute, thereby resulting in having a greater moisture capacity.

Pham et al. [19] developed coconut mesocarp-based lignocellulosic waste as cellulase production subtract from huge promising multienzyme-producing bacillus FW2 without pretreatments. Particularly, extremophilic bacteria played a significant part in biorefinery because of huge score catalytic enzymes which were under harsh environment situations. The developed model estimated the capability to generate and isolate from food waste. It continued to discover functional candidate which enabled low expensive production, and was perfect for clean environment and waste management. This model showed that higher frequency of weighted weather when compared to simple weather indices.

III. PROPOSED METHOD

The proposed method is built for forecasting yield of coconut production. ARIMA and Holt-Winters seasonal

methods are mainly used to predict data as per seasonality and trend. The LSTM model is tuned by hyperparameters using Improved Sine Cosine Algorithm because the ISCA takes the data point's non-linear dependence, which produces more favorable for time-series forecasting. Fig. 1 represents the block diagram of the proposed coconut yield prediction.

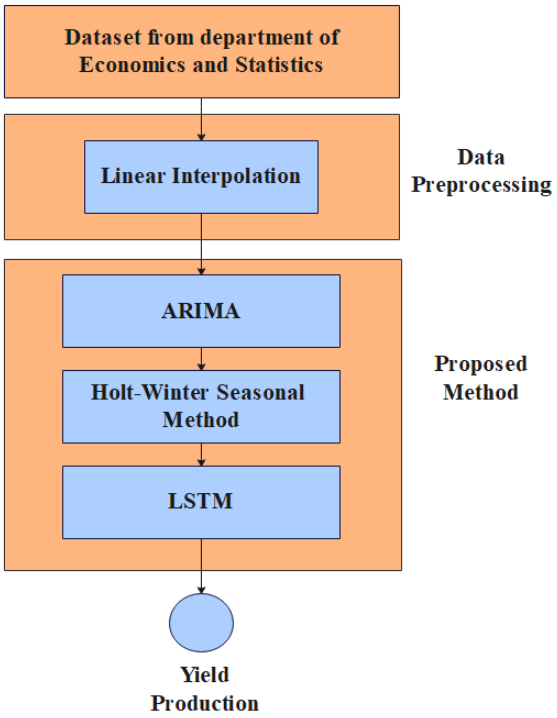

Fig. 1. Proposed method for Coconut yield production.

A. Dataset

Coconut is one of the important cultivation crops in Kerala, covering about 39% of the area grown in the state. The dataset is collected from Kerala's Department of Economics and Statistics, and consists of monthly coconut yield from 10 districts like Alappuzha, Ernakulam, Kozhikode, Palakkad, Kollam, Kasaragod, Idukki, Wayanad, Kottayam and Thrissur from 2011-2021 with yearly production of 120 records and 8 million nuts. The coconut is cultivated three months once and the 10-year annual production is segregated into 1200 records. However, the risk factors include climate change effects, diseases and pest, soil health, increased vulnerability, and water pollution and contamination.

B. Linear Interpolation

In Kerala, some districts contain missing values and these missing values are filled by using the Linear Interpolation method. This method is a mathematical procedure that measures new datapoints based on the previous data in traditional lines for enhancing the order as previous value. If it is time-series data, it contains missing scores, Interruption is a method applied to fill the missing scores in time-series data. This function is shown in Eq. (1),

$$f(X) = f(x_0) + \frac{f(x_1)-f(x_0)}{x_1-x_0}(x - x_0) \quad (1)$$

where, x x_0 and x_1 are independent variables, and $f(x)$ is a dependent for independent variable x.

C. Auto Regressive Integrated Moving Average

The Auto-Regressive Integrated Moving Average (ARIMA) model is used for converting the non-stationary time series data to stationery time data by applying differences, while also defining the present time series values using the previous predicted values and errors. ARIMA consists of three parts, denoted as ARIMA (p, d, q). Where, p is the amount of AR terms, d is the number of differences required to make the time-series stationery, and q is the amount of MA terms. The auto-regressive integrated moving average is shown in Eq. (2),

- AR: It observes a score that depends on the last lagged value.
- Integrated: The difference between observed and last lagged value.
- MA: A last lagged error values are the predictor values.

$$\emptyset(B)(1-B)^d Y_t = \theta(B)\varepsilon_t \quad (2)$$

where, $\emptyset$ is the autoregressive parameter, d is the degree of differencing parameter, B is the backshift operator, θ is a parameter of moving average and ε_t is white noise.

In time series models, the ARIMA model performs better than the deterministic growth model for short-term prediction. A better ARIMA model for time series prediction is fitted using the Box-Jenkins technique is shown in Eq. (3),

$$X_t = c + \emptyset_1 X_{t-1} + \cdots + \emptyset_p X_{t-p} + \theta_1 e_{t-1} + \cdots + \theta_q e_{t-q} + e_t \quad (3)$$

where,

- X_t = the variable that will be explained in time t;
- c = constant or intercept;
- $\emptyset$ = coefficient of each parameter p;
- θ = coefficient of each parameter q;
- e_t = errors in time t.

D. Holt-Winters Seasonal Method

The Holt-Winters seasonal method is also known as the triple exponential smoothing which forecasts both trend and seasonality. This method itself combines three simple components, which are smoothing methods.

- Simple Exponential Smoothing (SES): The method cannot be used with seasonality, trend, or both series. The SES method guesses that there is no change in the level of the time-series.
- Holt-Exponential Smoothing (HES): The method is used only with trend components and not with seasonal data.
- Winter's Exponential Smoothing (WES): The method is used for both trend component and seasonality data.

1) Holt-Winter's additive method: When the seasonal variations are not exactly close along the series, the addition method is employed. For subtracting the seasonal component, the obtained series scale and series of the level equation are seasonally altered and determined in accurate terms. The mathematical form of the additive method is shown in Eq. (4), (5), (6) and (7),

$$\text{Overall Equation: } \hat{y}_{t+h} = l_t + hb_t + s_{t+h-m} \quad (4)$$

$$\text{Level Equation: } l_t = \alpha(y_t - s_{t-m}) + (1-\alpha)(l_{t-1} + b_{t-1}) \quad (5)$$

$$\text{Trend Equation: } b_t = \beta(l_t - l_{t-1}) + (1-\beta)\, b_{t-1} \quad (6)$$

$$\text{Seasonality Equation: } s_t = \gamma(y_t - l_{t-1} - b_{t-1}) + (1-\gamma)\, s_{t-m} \quad (7)$$

where, m is time series seasonality, s_t is the seasonal forecast component, s_{t-m} is the forecast for the previous season and y is the seasonal component smoothing factor $(0 \le y \le 1-\alpha)$.

2) Holt-winter's multiplicative method: When changing the seasonal variations proportion to the series level, the method uses the multiplication method. This series is seasonally altered by dividing the seasonal component and determined in relative terms. The mathematical form of the multiplicative method is shown in Eq. (8), (9), (10) and (11),

$$\text{Overall Equation: } \hat{y}_{t+h} = (l_t + hb_t)s_{t+h-m} \quad (8)$$

$$\text{Level Equation: } l_t = \alpha\frac{y_t}{s_{t-m}} + (1-\alpha)(l_{t-1} + b_{t-1}) \quad (9)$$

$$\text{Trend Equation: } b_t = \beta(l_t - l_{t-1}) + (1-\beta)\, b_{t-1} \quad (10)$$

$$\text{Seasonality Equation: } s_t = \gamma\frac{y_t}{l_{t-1}+b_{t-1}} + (1-\gamma)\, s_{t-m} \quad (11)$$

Where, m is time series seasonality, s_t is the seasonal forecast component, s_{t-m} is the forecast for the previous season and y is the seasonal component smoothing factor.

E. Long Short-Term Memory (LSTM)

The Long Short-Term Memory (LSTM) is one of the most advanced models to forecast time series. A hyperparameter is a variable chosen before optimizing the real model's parameter. In deep learning, there are more hyperparameters like neurons, hidden layers, and learning rate. As a human, we have a hard time handling and visualizing multi-dimensional spaces. Hyperparameter is a procedure of enhancing the performance of the model by designating hyperparameters precise integration. In LSTM, the parameters like timesteps, amount of layers and hidden neurons at every LSTM is improved by hyperparameter. In deep LSTM, the layers lead to less convergence and overfitting, while the hidden layer works equally to the LSTM. Generally, previous historical data is required for predicting time-series data, but the conventional neural network takes current input data into account. LSTM embraces the historical data as well as the past data for an extensive period.

The LSTM has different memory cells in the hidden layer that are simplified through various gates like input, forget and output gate. It is utilized for determining data that is required to be stored. The cell state transfers data from one to another layer. The forgot gate is a primary gate that enables the transfer of required information by the cell state. In this gate, there are two steps of pointwise multiplication and sigmoid layer. The mathematical formula of the forget-gate f_t is shown in Eq. (12),

$$f_t = \sigma\left(W_f x_t + U_f h_{t-1} + b_f\right) \quad (12)$$

where, f_t is denoted as the current forget gate with the value being between 0 and 1 and is managed by the sigmoid function σ. The weight matrices are W_f and U_f, b_f is the value of bias, x_t is the value of input, and h_{t-1} is the previous data used for forget gate value calculation.

The next stage is the input gate which is used for processing the data. The mathematical form of the input gate is shown in Eq. (13),

$$i_t = \sigma(W_i X_t + U_i h_{t-1} + b_i) \quad (13)$$

where, i_t is the sigmoid function result and it controls which data to be stored in the memory cell. W_i and U_i are the weight matrices and b_i value is of the bias. These are the parameters adjusted in this input gate.

The last stage is the output gate which determines the actual values of the hidden layers, and the mathematical form is shown in Eq. (14),

$$o_t = \sigma(W_o X_t + U_o h_{t-1} + b_o) \quad (14)$$

Here, o_t is the sigmoid function, the weight matrices are W_o and U_o, while b_o is the value of bias.

1) Sine-Cosine Algorithm (SCA): The Sine-cosine algorithm is a population-based optimization algorithm for improving the movement of an agent toward the best solution, which is determined by the sine and cosine operators. The equation of this operator is used to fluctuate towards the optimal solution to identify the optimal solutions. In this search area, the random variables are used to find the possible global optima. To achieve optimal global solutions, SCA is proven to be more effective than other population-based algorithms. When the sine and cosine functions return values lesser than one or greater than one, the different occasions on the search space are determined.

a) Initial population: For filtering the current best solution, the Sine-Cosine algorithm works with the population. The numerical formula of the initial population is shown in Eq. (15),

$$X(i,j) = X(min,j) + random\,(0,1) * \left(X(max,j) - X(min,j)\right) \quad (15)$$

where, $X(min,j)$ and $X(max,j)$ are lower and upper limits of individuals on dimension j, R is the random number between $(0,1)$. Sine and Cosine function's range is shown in Eq. (16),

$$r_i = a\left(1 - \frac{t}{T}\right) \quad (16)$$

where, t indicates the present iteration, T is the maximum number of iterations, and a is the constant variable. In this equation, r_1 decreases linearly from a to 0.

b) Updating position: Sine and Cosine function's range are shown in Eq. (16) and the updated new candidate solutions are shown in Eq. (19). The current population's best candidate solutions and the best objective value are also updated. The numerical formula for updating positions for both sine and cosine are shown in Eq. (17) and Eq. (18),

$$P_i^{t+1} = P_i^t + r_1 \, sin\,(r_2) * |r_3 P_{best}^t - P_i^t| \quad (17)$$

$$P_i^{t+1} = P_i^t + r_1 \, cos(r_2) * |r_3 P_{best}^t - P_i^t| \quad (18)$$

where, P_i^t is the present candidate position at the t th iteration in the ith dimension and P_{best}^t is the best candidate optimal position at the t th iteration in the i th dimension. r_1, r_2, r_3 and r_4 are the random agents. The $(*)$ is the sign of multiplication. The updated new candidate solutions are shown in Eq. (19),

$$P_i^{t+1} = \begin{cases} P_i^t + r_1 * sin\,(r_2) * |r_3 P_{best}^t - P_i^t|, r_4 < 0.5 \\ P_i^t + r_1 * cos(r_2) * |r_3 P_{best}^t - P_i^t|, r_4 \geq 0.5 \end{cases} \quad (19)$$

where, r_1 is the parameter that determines the search space's next region and increases the investigation of the search space for a higher value, r_2 determines the movement direction and how long the movement should go towards or away from P_{best}^t. r_3 controls the current movement destination effects. To increase the solution diversity values of r_1, r_2 and r_3, they are updated at each iteration, while r_4 is used to switch between cosine and sine functions.

c) Fitness function: To improve the model accuracy, the parameters of LSTM such as the number of hidden neurons (HN), the learning rate (α) and the dropout value (DV) are used for the fitness function. The Sine Cosine optimization algorithm optimizes these three parameters $\theta = \{HN, \alpha, DV\}$ of the LSTM model. The fitness function is set between the predicted and observed values as the RMSE. The eqs. (17) and (18) are merged in (21). The fitness function is shown in (20) and (21),

$$min\, f_{RMSE} = \frac{1}{N} \sum_{i=1}^{N} (\hat{y}_i - y_i)^2 \quad (20)$$

$$\text{Subject to} \begin{cases} \hat{y}_i = f_{LSTM}\,(HN, \alpha, DV) \\ HN^{min} \leq HN_{max} \leq HN^{max} \\ \alpha^{min} \leq \alpha \leq \alpha^{max} \\ DV^{min} \leq DV \leq DV^{max} \end{cases} \quad (21)$$

Here, $\hat{y}_i$ is the predicted values and y_i is the observed value. HN^{min}, α^{min}, DV^{min} and HN^{max}, α^{max} , DV^{max} are the upper and lower bounds of the three decision variables.

2) Modified sine-cosine algorithm: In a simple SCA, r_1 is a control parameter which manages the transformation of algorithm from global exploration to local improvement. The local improvement capability of the algorithm is improved by a smaller value r_1 . The global searching capability of algorithm is developed by a larger value r_1. Thus, to manage global exploration and local improvement ability, r_1 is used as a linear decreasing technique of Eq. (16). Based on Eq. (19), the linear and exponential reducing inertia weight and conversion parameter which are utilized in this method, are seen to perform commendably in the ability of the local improvement and global exploration of the model. The updated equation of the individual is shown in Eq. (22), Eq. (23) and Eq. (24),

$$P_{i,j}^{t+1} = \begin{cases} \omega(t) * P_{i,j}^t + r_1 * sin\,(r_2) * \left|r_3 P_{best,j}^t - P_{i,j}^t\right|, r_4 < 0.5 \\ \omega(t) * P_{i,j}^t + r_1 * cos(r_2) * \left|r_3 P_{best,j}^t - P_{i,j}^t\right|, r_4 \geq 0.5 \end{cases} \quad (22)$$

$$\omega(t) = \omega_{max} - (\omega_{max} - \omega_{min}) * \frac{t}{T} \quad (23)$$

$$r_1(t) = a.\, e^{\frac{t}{T}} \quad (24)$$

where, t indicates the present iteration, T is the highest number of iterations and a is the constant variable. $P_{best,j}^t$ is jth individual dimension value at iteration t , $P_{i,j}^t$ is the j th individual dimension score of the i of present iteration, ω_{min} and ω_{max} are the minimum and maximum weights of inertia. The linear reducing inertia weight and exponential reducing conversion parameter are utilized in this work for enhancing the coverage speed and for the searching precision of the algorithm.

a) Neighborhood search of the optimal individual: In a simple SCA, new individuals updating process search directions are done by individuals optimal in the population. The entire algorithm is converted into early convergence when the global optimum individual falls into the local optimum. For reducing the algorithm probability of getting into local optimum, individuals near optimal solution are utilized as a guiding role. Here, the current optimal individuals are replaced through a random individual near to the optimal solution for guiding the algorithm search, thereby improving the algorithm's probability of coming out into the local optimum. The optimal individual neighborhood search is shown in Eq. (25),

$$P_{i,j}^{t+1} = \begin{cases} \omega(t) * P_{i,j}^t + r_1 * sin(r_2) * \\ \left|r_3 P_{best,j}^t * (1 - \lambda * unifrnd(-1,1)) - P_{i,j}^t\right|, r_4 < 0.5 \\ \omega(t) * P_{i,j}^t + r_1 * cos(r_2) * \\ \left|r_3 P_{best,j}^t * (1 - \lambda * unifrnd(-1,1)) - P_{i,j}^t\right|, r_4 \geq 0.5 \end{cases} \quad (25)$$

where, $unifrnd(-1,1)$ is the number of uniform distributions within $(-1,1)$, and λ is distribution coefficient.

b) Greedy levy mutation: In simple Sine-Cosine algorithm, the whole population search direction is controlled by the optimal individuals. For the further prevention of traditional SCA, low efficiency is eliminated and getting into the local optimum in later period. Here, the mutation operation helps an individual to come out of the position of optimal score in population which is previously searched to maintain population diversity. The mutation methodology is shown in Eq. (26),

$$P_{best,j}^{t+1} = P_{best,j}^{t} + \theta(j) * levy * P_{best,j}^{t} \quad (26)$$

where, $\theta(j)$ is the self-adapting variation coefficient, $levy$ is a random number which accepts the levy distribution and $P_{best,j}^{t}$ is the jth individual dimension value at iteration t.

For simple sine-cosine algorithm, creating the initial population time complexity is $O(n)$, performing sine-cosine operation time complexity is $O(T * n * d)$, and the processing of cross-border is $O(T * n)$. So, the simple sine-cosine algorithm's time complexity is $O(n) + O(T * n) + O(T * n * d)$. In the modified sine-cosine algorithm, creating the initial population time complexity is $O(n)$ for calculating $\omega(t)$ time complexity, and r_1 is $O(2 * T)$ for performing sine-cosine operation with time complexity $O(T * n * d)$, the processing of cross-border is $O(T * n)$ and the greedy levy mutation's time complexity is $O(T * d * n)$. So, the modified sine-cosine algorithm's time complexity is $O(n) + O(2 * T) + O(T * n * d) + O(T * n) + O(T * d * n) = O(n) + O((n + 2) + T) + O(2 * T * d * n)$. So, the modified sine-cosine algorithm's time complexity is lesser than the simple sine-cosine algorithm.

IV. Experimental Results

The LSTM-ISCA is simulated using the tool Python 3.10 on system configuration of windows 10 OS, 16GB RAM and intel i7 processor. The R2, MAE, MSE and RMSE are considered to estimate LSTM-ISCA the performance which are estimated from forecasted yields of each year for all districts. They are mathematically shown in Eq. (27), (28), (29) and (30), respectively:

$$R^2 = 1 - \sum_{i=1}^{n} \left(\frac{(y_i - y_{di})^2}{(y_{di} - y_m)^2} \right) \quad (27)$$

$$MAE = \frac{1}{n} \sum_{i=1}^{n} |y_i - y_{di}| \quad (28)$$

$$MSE = \frac{1}{n} \sum_{i=1}^{n} (y_i - y_{di})^2 \quad (29)$$

$$RMSE = \sqrt{MSE} = \sqrt{\frac{1}{n} \sum_{i=1}^{n} (y_i - y_{di})^2} \quad (30)$$

where, n, y_i, y_{di} and y_m are the number of points, predicted score, real score, and mean of real score.

A. Quantitative Analysis

The performance of LSTM-ISCA is explained in this section, with respect to achievable sum rate. Table I demonstrates the results of the LSTM model, whereas Table II shows the results of ISCA, and Table III exhibits the outcomes of LSTM-ISCA. The LSTM and LSTM-SCA models are compared with LSTM-ISCA model that achieves better performance as compared to other models.

In Table I, the effectiveness of the LSTM model is validated and the experimentation is performed with various deep learning techniques: Convolutional Neural Network (CNN), Generative Adversarial Network (GAN), Recurrent Neural Network (RNN), and Deep Neural Network (DNN). The LSTM model achieves 0.43, 0.131, 0.054 and 0.232 of R2, MAE, MSE and RMSE, respectively. A graphical representation of the LSTM model is represented in Fig. 2.

TABLE I. Quantitative Analysis of Various Classifiers

Methods	MSE	R2	RMSE	MAE
CNN	0.062	0.49	0.248	0.139
GAN	0.055	0.44	0.234	0.132
RNN	0.058	0.46	0.240	0.135
DNN	0.059	0.47	0.242	0.136
LSTM	0.054	0.43	0.232	0.131

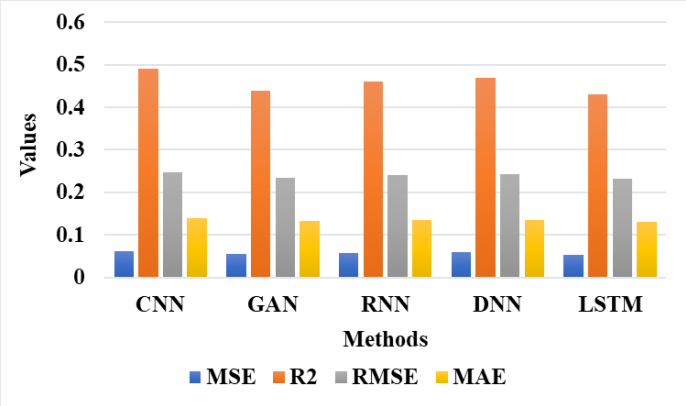

Fig. 2. Performance of various classifiers.

TABLE II. Quantitative Analysis of Various Optimization

Methods	MSE	R2	RMSE	MAE
PSO	0.056	0.44	0.236	0.133
WOA	0.054	0.43	0.232	0.131
SGD	0.053	0.41	0.230	0.130
SCA	0.051	0.40	0.225	0.128
ISCA	0.049	0.38	0.221	0.126

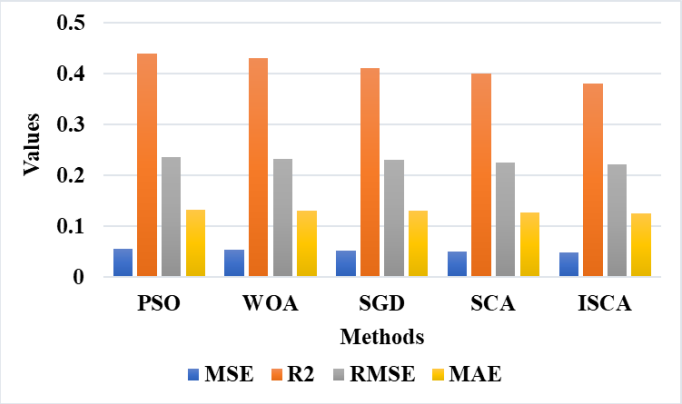

Fig. 3. Performance of various optimizations.

In Table II, the ISCA's effectiveness is validated and experimentation is performed with various optimization algorithms like Particle Swarm Optimization (PSO), Stochastic Gradient Descent (SDG), Whale Optimization Algorithm (WOA), and SCA. The ISCA achieves 0.38, 0.126, 0.049 and 0.221 of R2, MAE, MSE and RMSE. Fig. 3 represents the graphical representation of the ISCA model.

TABLE III. QUANTITATIVE ANALYSIS OF THE PROPOSED LSTM-ISCA MODEL

Methods	MSE	R2	RMSE	MAE
LSTM	0.054	0.43	0.232	0.131
LSTM-SCA	0.051	0.40	0.225	0.128
LSTM-ISCA	0.049	0.38	0.221	0.126

In Table III, the effectiveness of LSTM with ISCA model is validated and the experimental is performed with LSTM and LSTM-SCA. The LSTM-ISCA model achieves better performance when compared to other models. The LSTM-ISCA model achieves 0.38, 0.126, 0.049 and 0.221 of R2, MAE, MSE and RMSE. A graphical representation of LSTM-ISCA model is shown in Fig. 4.

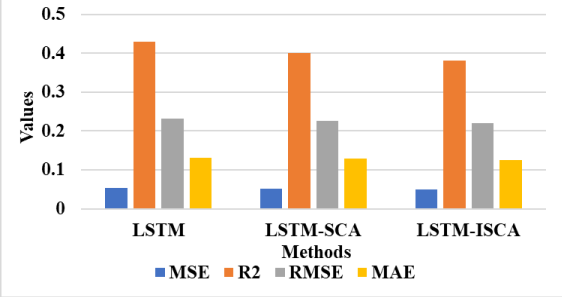

Fig. 4. Performance of the proposed LSTM-ISCA model.

B. Comparative Analysis

The comparison of LSTM-ISCA is demonstrated in this section with attainable sum rate. The previous researches like [17-20] are utilized for estimating the proposed model's efficiency as shown in Table IV. Iniyan and Jebakumar [20] considered 456 samples across 105 different areas and the experimental analysis showed that the presented model attained 7.431, 121.123, and 11.005 of MAE, MSE and RMSE, correspondingly. Oikonomidis et al. [21] took into account 25345 samples across 9 different states, where the experimental results confirmed that the presented obtained 0.87, 0.199, 0.071, and 0.266 of R2, MAE, MSE and RMSE, correspondingly. Joshua et al. [22] examined 280 samples across 50 fields and the model attained 0.986, 0.129, 0.052, and 0.229 of R2, MAE, MSE and RMSE. Therefore, it is seen that the LSTM-ISCA model achieves superior performance, as opposed to other models.

TABLE IV. EXPERIMENTAL RESULTS OF LSTM-ISCA MODEL

Author	No. of data	R2	MAE	MSE	RMSE
Iniyan and Jebakumar [20]	456 samples across 105 different areas	-	7.431	121.123	11.005
Oikonomidis et al. [21]	25345 samples across 9 different states	0.87	0.199	0.071	0.266
Joshua et al. [22]	280 samples across 50 fields	0.986	0.129	0.052	0.229
Proposed LSTM-ISCA	84000 samples across 10 different districts	0.38	0.126	0.049	0.221

C. Discussion

The advantages of the LSTM-ISCA and limitations of the existing researches are deliberated in this section. The Iniyan and Jebakumar [20] considered only 456 samples across 105 areas which achieved 7.431 of MAE due to the limited samples. Oikonomidis et al. [21] considered 25343 samples across nine states, achieving 0.199 of MAE due to the long-term viable option increasing the coconut production, as well as the productivity of coconut lands. Joshua et al. [22] considered 280 samples across 590 fields, achieving 0.129 of MAE because the crop data requiring huge preprocessing to fit the baseline requirements. To overcome these issues, this research proposes LSTM-ISCA. The time-series data are given as the input to the LSTM classifier to classify the yield production and the LSTM model is tuned by hyperparameter using ISCA. The ISCA improves the coverage speed and searching precision of the algorithm.

V. CONCLUSION

In this research, a LSTM-ISCA is proposed for effective coconut yield production. The proposed model comprises multiple objective functions such as linear interpolation and Holt's Winter Seasonal method for effective classification. ARIMA model is used for converting stationary time series data from non-stationary data, by applying differences and predicted values from the previous historical data. The Holt-Winters seasonal method is introduced for the exponential smoothing of the seasonal data. Then LSTM is tuned by the ISCA which uses an exponential convergence strategy and linear decreasing inertia weight, thereby improving the convergence speed and algorithm's search precision. From the performance analysis, it is concluded that the LSTM-ISCA provides better performance than other models. In the future, Bayesian optimization can be used for hyperparameter tuning over the ISCA algorithm to enhance the prediction performance.

Integrating Lesk Algorithm with Cosine Semantic Similarity to Resolve Polysemy for Setswana Language

Tebatso Gorgina Moape, Oludayo O. Olugbara, Sunday O. Ojo
Dept. of Information Technology, Durban University of Technology, Durban, South Africa

***Abstract*—Word Sense Disambiguation (WSD) serves as an intermediate task for enhancing text understanding in Natural Language Processing (NLP) applications, including machine translation, information retrieval, and text summarization. Its role is to enhance the effectiveness and efficiency of these applications by ensuring the accurate selection of the appropriate sense for polysemous words in diverse contexts. This task is recognized as an AI-complete problem, indicating its longstanding complexity since the 1950s. One of the earliest proposed solutions to address polysemy in NLP is the Lesk algorithm, which has seen various adaptations by researchers for different languages over the years. This study proposes a simplified, Lesk-based algorithm to resolve polysemy for Setswana. Instead of combinatorial comparisons among candidate senses that Lesk is based on that cause computational complexity, this study models word sense glosses using Bidirectional Encoder Representations from Transformers (BERT) and Cosine similarity measure, which have been proven to achieve optimal performance in WSD. The proposed algorithm was evaluated on Setswana and obtained an accuracy of 86.66 and an error rate of 14.34, surpassing the accuracy of other Lesk-based algorithms for other languages.**

Keywords*—Word sense disambiguation; Lesk algorithm; cosine similarity; Bidirectional Encoder Representations from Transformers (BERT)

I. Introduction

Setswana sometimes referred to as Tswana, is an African language spoken in South Africa, Botswana, and parts of Namibia. It is the national language of Botswana and one of the eleven official languages in South Africa. Setswana has about a total of 8.2 million speakers across the different countries. Similar to other natural languages, Setswana contains words with ambiguity, known as polysemous words that have multiple senses in various contexts in which they appear. Consider the following context sentences below:

1) C1: Noka ya mme e botlhoko (mother's waist is painful).

2) C2: Moapeyi o noka nama letswai (The chef is seasoning the meat with salt).

3) C3: Setlhare se mothokoga ga noka (The tree is next to the river).

The Setswana word "noka" has three distinct senses based on the context in which it appears. It means waist in the first context C1, represents season (pour) in the second context C2, and a river in the third context C3. This linguistic characteristic is referred to as polysemy. Polysemy poses challenges in natural language processing (NLP) applications such as machine translation [1], information retrieval [2], and text summarization [3], where accurately determining the intended meaning of a polysemous word based on context is important. Resolving polysemy is crucial for improving the accuracy and precision of these applications. The dedicated task of resolving polysemy in NLP is known as Word Sense Disambiguation (WSD) and is considered one of the most difficult tasks in artificial intelligence [4].

WSD can be resolved using three approaches, namely, knowledge-based, unsupervised, and supervised methods. Knowledge-based methods use various lexical resources such as WordNet, Wikipedia, and BabelNet for disambiguation. Examples of this approach include the Lesk algorithm [5] and its variations, such as the simplified Lesk [6] and adapted Lesk [7] algorithms, which rely on context-gloss overlap.

Unsupervised methods employ clustering techniques for disambiguation from unannotated collection texts. The commonly used techniques are sense clustering algorithms such as K-Means [8] and graph-based algorithms such as PageRank [9]. Supervised methods rely on the availability of annotated datasets where a classifier is trained based on the annotations and features extracted from the data. Techniques used for this method include the use of support vector machine (SVM) [10] and Naïve Bayesian [11].

Unsupervised and supervised methods require the substantial collection of unannotated and annotated data, which is not available for resource-scarce languages such as Setswana. The scarcity of datasets poses a significant challenge for training robust models for NLP tasks. Due to this constraint, a knowledge-based approach was adopted to resolve WSD for Setswana using the simplified Lesk algorithm.

This paper makes several significant contributions to the field of WSD for low-resource languages, specifically focusing on Setswana. Firstly, it proposes a novel simplified Lesk-based algorithm that effectively resolves polysemy in Setswana by leveraging sentence embeddings generated using the PuoBERTa language model and employing the Cosine similarity measure to determine the most appropriate sense. Secondly, the study addresses the computational complexity inherent in traditional Lesk algorithms by encoding the context sentence and candidate glosses in a single operation, resulting in a linear growth rate of comparisons, thus mitigating the

exponential growth of computational complexity. Lastly, this research provides a valuable WSD evaluation dataset for Setswana, which is currently unavailable, creating an essential benchmark for testing and comparing the performance of future Setswana WSD models.

This paper is structured as follows: Section II explores related works, materials, and methods presented in Section III. The evaluation of the proposed algorithm is provided in Section IV, including the obtained results. Discussion and conclusion is given in Section V and finally Section VI paves the way for future work.

II. Related Works

One of the first algorithms developed for WSD is Lesk's original algorithm. The original Lesk algorithm operates on the assumption that the sense of a word in a particular context can be inferred by examining the words that co-occur in the surrounding text. This algorithm relies on the availability of lexical semantic resources such as machine-readable dictionaries and wordnets to obtain glosses for each sense of the polysemous word. To disambiguate, the algorithm calculates the overlap between the words in the context and the words in the definitions to determine the appropriate sense. One of the major drawbacks of the Lesk algorithm is its computational complexity, which stems from the exponential growth of comparisons needed for numerous candidate senses associated with polysemous words across various lexical resources [12].

To overcome this limitation, researchers have proposed and developed variations of the algorithm, such as the simplified [6] and adapted [7] Lesk to improve the algorithm's effectiveness. The simplified Lesk addresses combinatorial explosion by calculating overlaps between the definitions of candidate senses for the target word and the context words. The adapted Lesk expands the scope by considering not only the overlap between the context and target word senses but also introducing additional linguistic features or syntactic structures for a more comprehensive analysis.

Several researchers have adapted the core overlap idea and integrated various techniques into the original Lesk algorithm to enhance its performance. The study in [13] integrated topic modeling to simplify Lesk as the topic-document relationship between senses to determine the correct sense of the target word. Their model achieved an F1 score of 66%. The study in [12] used the adapted Lesk and trained a classifier responsible for retrieving senses of the target word from Wordnet, assigning a score based on the number of words common between the target gloss and context word gloss.

Tripathi, et al. [14] used Lesk to disambiguate Hindi words. The appropriate sense of the polysemous word is determined through a scoring method that assigns a sense score to each token of the Hindi sentence. The sense score is calculated based on the gloss, hypernym, hyponym and synonym of the combinations of different sense of tokens. The sense with the highest score in the combination is allocated as the most suitable sense within that context. In another study [15] used the LESK algorithm for Indonesian and achieved an accuracy of 78.6% for one Indonesian ambiguous word and 62.5% for two ambiguous words.

To disambiguate senses for Marathi languages, The study in study [16] used a modified Lesk algorithm coupled with a dynamic context window approach. After pre-processing, the algorithm stores the context words in an array to increase the context window size during processing while comparing the results with the static size context window output. The model achieved the highest precision of 0.79. Arabic, Kaddoura and Nassar [17] developed a WSD dataset that contains one hundred Arabic polysemous words with a minimum of three and maximum of eight senses. The paper adapts the idea of the Lesk algorithm [5] to compute the overlap between contextual information and dictionary definitions. They utilized a similarity measure to determine the appropriate sense of the target word. Their proposed method integrates Bidirectional Encoder Representations from Transformers (BERT) and introduces new features to enhance the effectiveness of disambiguation. The WSD system's performance achieved an impressive F1 score of 96%.

In this paper, a WSD system for Setswana is proposed based on the simplified Lesk algorithm. To tackle computational complexity, our algorithm first encodes the context sentence containing the polysemous word and the candidate glosses obtained from the Universal Knowledge Core (UKC) in a single operation. Secondly, the algorithm computes the Cosine semantic similarity measure between the context and each candidate gloss. As a result, the number of comparisons is equal to the n number of senses of a polysemous word. In contrast to other adaptations of the Lesk algorithm, the proposed algorithm exhibits a linear growth rate rather than an exponential one, mitigating computational complexity.

III. Materials and Methods

A. Task Definition

In NLP, Navigli [4] formally describes the WSD problem as: given a text T as a sequence of words (w_1, w_2, . . ., w_n), WSD is the task of assigning appropriate sense of a polysemous word in T, that is, to identify a mapping A from words to senses, such that $A(i) \subseteq SensesD(w_i)$, where $SensesD(w_i)$ is the set of senses encoded in a knowledge source K for word wi[1] and $A(i)$ is the subset of the senses of w_i which are appropriate in the context T. The mapping A can assign more than one sense to each word $w_i \in T$. However, only the most appropriate sense is selected, that is, $| A(i) | = 1$." A knowledge source can be in various lexical formats. In this study, the UKC is used as the knowledge source.

B. Materials

This section outlines the material used for the development of the proposed algorithm. These are divided into three major components: the sense inventory, the WSD technique, and the disambiguation algorithm. Together, these elements form the architecture depicted in Fig. 1.

At the center of the architecture, the WSD algorithm takes the context sentence as input and produces the most appropriate sense for the polysemous word within that specific

context. In the subsequent sub-section, the study incorporates the UKC as the sense inventory to retrieve glosses for the polysemous word. Following the UKC is the WSD technique that employs PuoBERTa for encoding and generating embeddings in Setswana, utilizing a Cosine semantic similarity measure to determine the correct sense.

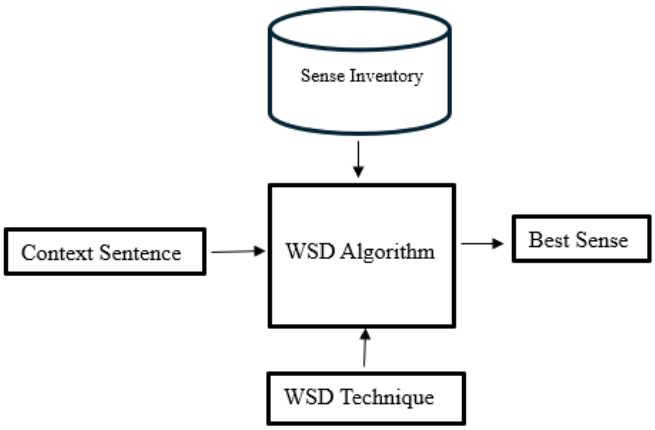

Fig. 1. WSD architecture.

1) The universal knowledge core: The Universal Knowledge Core (UKC) is a multilingual, high quality, large scale, and diversity-aware machine-readable lexical resource that currently consists of the lexicons of over a thousand languages, represented as wordnet structures [18], including Setswana. The UKC has two core layers, the concept and the language core [19]. The concept core is the knowledge layer of the UKC that provides a conceptual representation of concepts as we see them in the world. The concepts are interconnected through semantic relations and are language-independent. The language core is the language layer that is dedicated to lexical relations between lexical units (words). This layer encompasses multiple languages. The UKC provides an XML lexicon viewer, depicted in Fig. 2 that allows individuals to query and search for words, discovering their meanings and relationships.

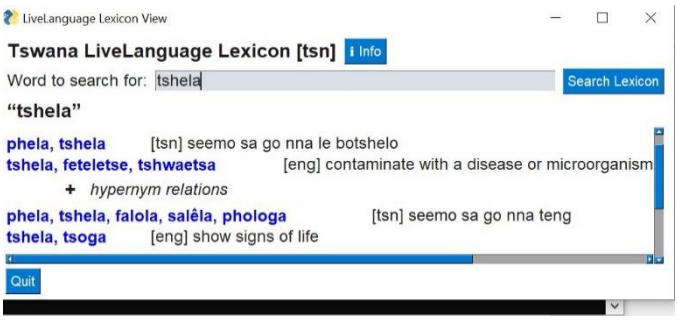

Fig. 2. Setswana UKC XML lexicon viewer.

Fig. 2 illustrates the Setswana lexicon in the UKC. The word "tshela" is a polysemous word that has two distinct senses. The senses are "to live" and "to pour". The UKC provides glosses for each sense, along with English translations and available relations. For implementation of the proposed algorithm, we used the XML version of the lexicon in Python, Anaconda prompt. The snippet of the XML is depicted in Fig. 3.

In the XML, each synset has a synset ID that links it to the Princeton Wordnet, a part of speech tag, gloss and synset relation. The algorithm proposed in this paper extract Setswana glosses for disambiguation from the XML file through unique synset IDs and leverages part-of-speech tags and synset relations to navigate the hierarchical structure of the XML data, pinpointing relevant glosses associated with each synset.

2) PuoBERTa (Bidirectional Encoder Representations from Transformers): Bidirectional Encoder Representations from Transformers (BERT) is a transformer-based language representation model introduced to the NLP landscape by [20] developed to capture the context and bidirectional dependencies of words in a sentence. This model is based on the transformer architecture illustrated in Fig. 4.

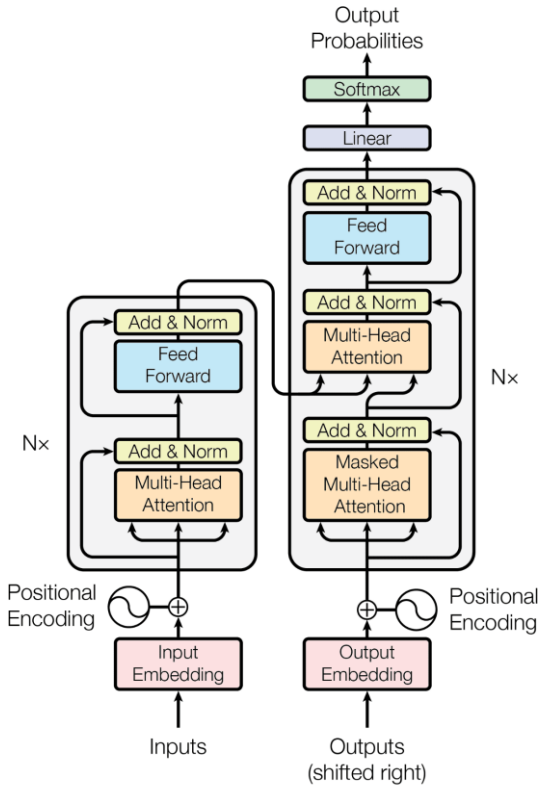

Fig. 4. Transformer architecture.

The transformer architecture employs a self-attention mechanism to capture dependencies between input tokens. The architecture consists of encoder and decoder stacks, each comprising multiple layers with multi-head attention, feedforward neural networks, and layer normalization. Positional encodings are incorporated to provide information about token positions. The model's success lies in its ability to efficiently handle long-range dependencies, parallelize computations, and serve as the foundation for various state-of-the-art models like BERT and GPT. Compared to traditional language models that process text sequentially from left to right or right to left, BERT processes the entire input sequence at once, taking into account both the preceding and following words for each word in a sequence [20]. This bidirectional approach allows BERT to capture more nuanced relationships and context in a language making it superior in tasks such as WSD. In addition, BERT can explicitly model the relationship of a pair of texts, which has proven to be beneficial for various pair-wise natural language understanding tasks [21]. Researchers have adapted the transformer architecture of BERT and trained language-specific models such as Arabic BERT [22] and Indict-BERT [23], to address distinct linguistic differences and used across various NLP tasks. For Setswana, PuoBERTa was developed and trained on Setswana data. It is a Setswana version of BERT trained by Marivate, et al. [24] using a corpus in the Setswana language. The PuoBERTa was trained on 24,295,328 Setswana tokens and evaluated on part-of-speech tagging and named entity recognition tasks. For Setswana WSD, PuoBERTa was used as an encoder to process and encode both contextual information, and the glosses of polysemous words extracted from the UKC.

3) Disambiguation Algorithm: This paper adopted the simplified Lesk algorithm for Setswana disambiguation. The reason for this selection is that compared to other variants, Simplified Lesk's primary objective is to maintain disambiguation effectiveness while simplifying the computation by reducing computational complexity [6]. This algorithm reduces computational complexity by using limited context, instead of considering the entire context surrounding the polysemous word. Simplified Lesk limits the scope to a predefined window of adjacent words and has the ability to work well for languages with limited resources, making it suitable for Setswana as a resource-scarce language. Another method that Simplified Lesk adopts to decrease computational complexity involves minimizing linguistic features. This is done by reducing reliance on extensive linguistic features and syntactic structures within the context, simplifying the feature set. However, this is a crucial capability when disambiguating agglutinative and morphologically rich languages such as Setswana. To address this, the linguistic features are integrated into the encoding process, utilizing PuoBERTa to encode the complete context sentence and the respective glosses to generate sentence embeddings. Sentence embeddings capture contextual information and the compositional nature of a language, this provides a representation that reflects the combination and interaction of words within a sentence [25]. Our algorithm is more closely related to the Simplified Lesk algorithm [6] but leverages on the importance of word sense definitions using embeddings and similarity measure. The metric used to measure semantic similarity is the Cosine similarity as it effectively captures the directional similarity between vectors, making it suitable for assessing the relationship between gloss embeddings and context representations [26]. Research that employs Cosine similarity for disambiguation includes [27], [28], [29], [30].

The algorithm consists of the following steps:

Input: Ambiguous word (W), Context sentence (C), Sense inventory with glosses for each sense of W.

Disambiguation:

1) Tokenization: Tokenize the context sentence (C)

2) Encode: Encode context sentence (C) using PuoBERTa

3) Sense selection: For each sense of the ambiguous word (W), retrieve the corresponding glosses

4) Encode and measure similarity: Encode corresponding glosses (G) using PuoBERTa Measure semantic similarity using Cosine similarity on Eq. (1) between C and G

$$\cos(\theta) = \frac{\mathrm{A}\cdot\mathrm{B}}{\|\mathrm{A}\|\|\mathrm{B}\|} = \frac{\sum_{i=1}^{n} A_i B_i}{\sqrt{\sum_{i=1}^{n} A_i^2}\sqrt{\sum_{i=1}^{n} B_i^2}} \quad (1)$$

5) Sense ranking: Rank the senses based on the degree of similarity. The sense with the highest similarity is considered the most likely appropriate sense.

6) Disambiguation: Assign the sense with the highest similarity score as the disambiguated sense for the ambiguous word (W).

The steps above are formalized as the Algorithm 1 below:

Algorithm 1: Setswana WSD

```
Input:  target word (w), context sentence (cs)
Output: best disambiguate senses (bestDef) of the w

STX ← Pre-process(RemoveStopwords(Tokenized(Text))
Syn = GetSynsetFromUKC(w)

Est = defEncode(STX)

highestSim = 0

    For s in Syn
            Sdef = GetDefinition(s)

            Eqs = defEncode(Sdef)

                If Similarity > highestSim then
                    highestSim = Similarity

                End
    bestDef = s

    End
return bestDef
```

Algorithm 1 illustrates the pseudocode of the proposed method. The process starts with the input of the target word (*w*) and the context sentence (*cs*) into the system. The provided context sentence is pre-processed. Following this, the system

retrieves synsets of the target word from the UKC, extracting various glosses associated with the target word. The context sentence is then encoded using PuoBERTa. Next, each synset gloss of the target word is encoded, and a similarity measure is computed for each gloss in comparison to the context sentence. The algorithm identifies and returns the gloss with the highest similarity measure as the correct definition of the target word.

C. Datasets

To construct the evaluation data set, the Senseval-3 lexical sample structure by Mihalcea, et al. [31] was adopted. Senseval-3 is one of the evaluation benchmark datasets and a follow-up to Senseval-1 and Senseval-2. The dataset was bult using Open Mind Word Expert system proposed in [32]. To construct the evaluation dataset, words that were mapped to more than one synset in the African Wordnet were extracted, together with their glosses and example sentences. Additional words, glosses, and example sentences were extracted from Oxford and Pharos bilingual dictionaries, the different senses were indicated with numbers superscript in the dictionaries. From these resources, an evaluation dataset of 1200 Setswana sentences was created. Currently, there is no existing WSD evaluation dataset for Setswana, this dataset serves as a valuable resource for evaluating and benchmarking models designed to addresses the complexities of polysemy in Setswana.

D. Experimental Settings

All experiments were conducted using the Python programming language with preinstalled NLTK [33] and scikit-learn library [34] run in Window 10 Pro, 11th Gen Intel(R) Core(TM) i7-1165G7 @ 2.80GHz 1.69 GHz, 17GB installed ram. For experimentation, each context sentence was passed into the algorithm for pre-processing and encoding. Then the glosses of the polysemous word in that context were extracted from the UKC and subsequently encoded iteratively to generate gloss embeddings. With each iteration, a similarity measure was computed between the context and gloss embeddings, and the gloss with the highest similarity was selected as the appropriate sense gloss, which was then compared with the ground truth. If the chosen gloss aligned with the ground truth, the count of correctly disambiguated variables increased by 1. If not, the count of incorrectly disambiguated variables was incremented. For evaluation metrics, we adopted the accuracy (A) and error rate (E) metrics on (2) and (3) utilized in [35] methodology.

$$A = \text{Correctly Disambiguated} / \text{Number of Test Instances} \quad (2)$$

$$E = \text{Incorrectly Disambiguated} / \text{Number of Test Instances} \quad (3)$$

Accuracy is a metric that measures the proportion of correctly identified instances out of the total number of instances. In this context, it is calculated as the number of correctly disambiguated variables divided by the total number of test instances, as shown on Eq. (2). Error rate, on the other hand, represents the proportion of incorrectly identified instances out of the total number of instances. It is calculated as the number of incorrectly disambiguated variables divided by the total number of test instances, as illustrated in Eq. (3).

IV. Results

This section presents the results of the proposed algorithm.

The results of the experiment results are presented Table I. Out of a set 1200 context sentences, the algorithm successfully disambiguated 1040 Setswana sentences accurately but misclassified 160, resulting in an accuracy rate of 86.66% and an error rate of 14.34%.

TABLE I. Evaluation Statistics and Results

Total number of context sentences for polysemous words	1200
Correctly disambiguated sentences	1040
Incorrectly disambiguated sentences	160
Accuracy	86.66
Error	14.34

Fig. 5 illustrates the accuracy and the error rate. The notable high accuracy and comparatively lower error rate suggest that the algorithm demonstrates effectiveness in distinguishing among multiple senses of polysemous words in Setswana context. Fig. 6 presents the disambiguation stats.

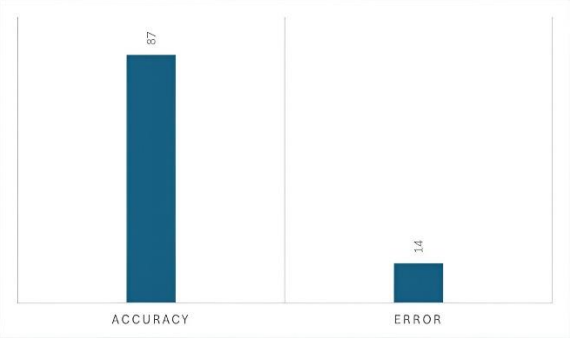

Fig. 5. Disambiguation accuracy and error rate.

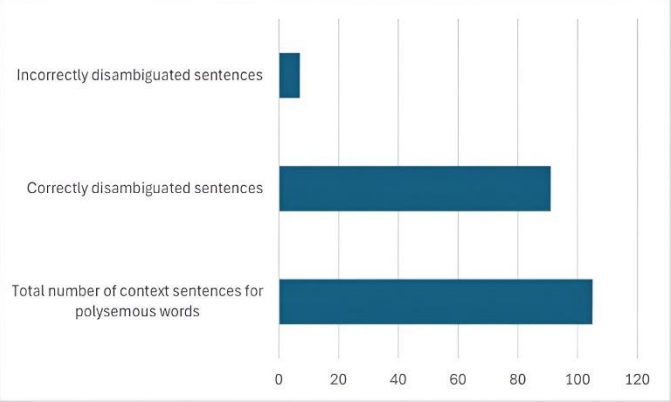

Fig. 6. Disambiguation statistics.

The error rate of 14.34% in the proposed Setswana WSD algorithm can be attributed to several factors. One reason for the error rate is the limited coverage of the Setswana UKC lexical resource. The UKC provides a valuable knowledge base for Setswana, however, it does not encompass all possible senses and glosses for every polysemous word encountered in the evaluation dataset. This limitation led to instances where

the algorithm fails to identify the correct sense due to the absence of the appropriate gloss in the lexical resource. Another factor contributing to the error rate is the complexity and ambiguity of certain Setswana words. Setswana, being a morphologically rich language, contains words with intricate morphological structures and highly context-dependent meanings. The proposed algorithm, while effective in handling many cases, it struggles to accurately disambiguate such complex words, especially when the context provided is insufficient. Despite these factors contributing to the error rate, the proposed algorithm achieves a high accuracy of 86.66%, demonstrating its effectiveness in resolving polysemy for Setswana. Further improvements can be made by expanding the coverage of the Setswana UKC, incorporating additional linguistic features, and refining the disambiguation techniques to handle more complex and ambiguous cases.

To conduct a comparative analysis between our results and those of other researchers who utilized and adapted the Lesk algorithms for various languages, Fig. 7 presents a visual representation of the comparative performance based on accuracy.

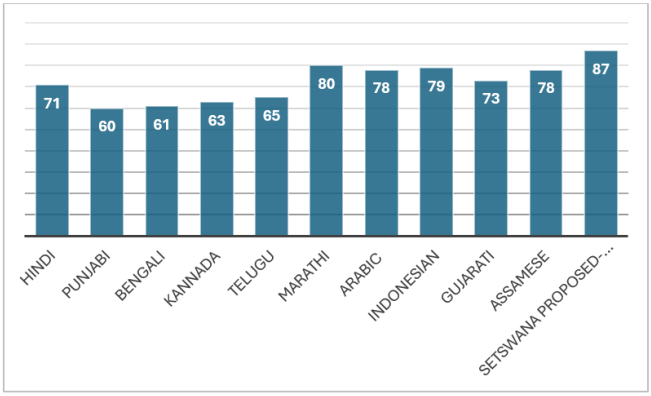

Fig. 7. Comparison of result for WSD for other languages.

For Hindi, Sharma and Joshi [36] used an evaluation corpus of 3000 context sentences, out of which 2143 were correctly disambiguated achieving an accuracy of 71%. Singh and Singh [37] tested the modified Lesk on 15 Punjabi polysemous words and achieved an average accuracy of 60 for all the ambiguous words. Pandit, et al. [38] used two test sets, the first test set with 10 and the second test set with 12 Bengali polysemous words and achieved an accuracy of 61%. Using a single word with five different senses and 2153 context sentences for Kannada, Parameswarappa and Narayana [39] obtained 63% accuracy while Eluri and Siddu [35] obtained 65% testing with 150 context sentences for Telegu. Patil, et al. [16]'s algorithm was evaluated on 6 Marathi polysemous words with a total 14 senses and achieved an overall accuracy of 80%. Arabic [40] and Indonesian [15] achieved almost the same accuracy with 0.1 difference, 78% and 79%. The Arabic WSD was tested on 50 polysemous words with 20 context sentences per word. For Indonesia, the algorithm was evaluated on 140 context sentences. Assamese obtained 78% evaluated on an annotated Assamese corpus with 15606 polysemous nouns. This paper achieved an accuracy of 87% on 1200 Setswana context sentences.

The comparative results on different datasets for various languages is caused by the inherent linguistic characteristics of each language, the size and quality of the datasets used. Each language requires its own evaluation data, specifically for resource-scarce languages like Setswana. Unlike English, which already has existing evaluation benchmark datasets such as Senseval and Semeval series, many low-resource languages lack such standardized datasets. This lack of evaluation data makes it challenging to directly compare the performance of WSD algorithms across different languages.

V. Discussion and Conclusion

This study highlights the critical role of WSD as a significant intermediate task in NLP applications. The Lesk algorithm, one of the first solution to address polysemy in NLP, has witnessed continuous adaptations by researchers for diverse languages. In the context of Setswana, this research introduces a novel approach, a simplified Lesk-based algorithm to effectively resolve polysemy. To address the computationally complex combinatorial comparisons inherent in traditional Lesk, this study leverages sentence embeddings and Cosine semantic similarity measures to model word sense glosses. The word sense glosses are modelled using a transformer-based language model PuoBERTa. The proposed method has been proven to achieve optimal performance in for Setswana WSD. The evaluation of the proposed algorithm on Setswana demonstrates significant success, with an accuracy of 86.66 and an error rate of 14.34. This surpasses the accuracy achieved by other Lesk-based algorithms developed for different languages. Additionally, this study provides a WSD evaluation dataset, currently unavailable, creating an essential benchmark for testing Setswana WSD models.

VI. Future Work

Future works involve expanding coverage of the Setswana UKC, the corpus size of the evaluation data and experimenting with diverse knowledge-based methods to determine their comparative performance. This includes incorporating additional linguistic morphological features, and refining the disambiguation techniques to handle more complex and ambiguous cases. Furthermore, we plan to integrate the proposed algorithm into a Setswana-English translation system, investigating its impact on translation quality as part of our ongoing research.

Design of Emotion Analysis Model IABC-Deep Learning-based for Vocal Performance

Zhenjie Zhu[1], Xiaojie Lv[2]
College of Graduate, Sehan University, Mokpo, Republic of Korea[1]
College of Microelectronics, Xidian University, Xian, China[2]

***Abstract*—With the development of deep learning technology, and due to its potential in solving optimization problems with deep structures, deep learning technology is gradually being applied to sentiment analysis models. However, most existing deep learning-based sentiment analysis models have low accuracy issues. Therefore, this study focuses on the issue of emotional analysis in vocal performance. Firstly, based on vocal performance experts and user experience, classify the emotions expressed in vocal performance works to identify the emotional representations of music. On this basis, in order to improve the accuracy of emotion analysis models for deep learning based vocal performance, an improved artificial bee colony algorithm (IABC) was developed to optimize deep neural networks (DNN). Finally, the effectiveness of the proposed deep neural network based on improved artificial bee colony (IABC-DNN) was verified through a training set consisting of 150 vocal performance works and a testing set consisting of 30 vocal performance works. The results indicate that the accuracy of the sentiment analysis model for vocal performance based on IABC-DNN can reach 98%.**

***Keywords*—Vocal performance; deep learning; Artificial Bee Colony (ABC); emotion analysis model; Deep Neural Network (DNN)**

I. INTRODUCTION

Emotion analysis (sentiment analysis) is a branch of Natural Language Processing (NLP) that involves identifying and extracting emotions from raw text. The sentiment analysis model aims to play an important role in human communication. The purpose of the sentiment analysis model is to understand and analyze subjective information in human language, such as viewpoints, emotions, and so on. Recently, sentiment analysis models have been widely applied in various fields, such as brand monitoring, public sentiment tracking, and market research [1]. Artificial intelligence-based sentiment analysis models can be trained and evaluated based on standardized data features such as word frequency, word order, grammatical structure, emotional vocabulary, and phrases, and then used for sentiment analysis on social media or recommendation systems [2]. Emotional analysis models can provide automated analysis of emotional information in texts. The acquisition and analysis of emotional information can provide decision-makers with valuable insights, thereby optimizing business operations, improving user experience, and enhancing competitiveness [3]. Therefore, sentiment analysis models can help users understand the emotional tendencies and states in text, which is of great significance in the field of NLP.

Emotional analysis models include support vector machines, decision trees, random forests, and deep learning models. The methods used mainly include rule-based (dictionary) methods and learning based methods. The rule-based approach relies on pre-defined sentiment dictionaries and rules, where each word is marked as positive, negative, or neutral. By calculating the number of positive and negative vocabulary in the text, the overall sentiment of the text can be determined [4]. The advantage of such models is that they perform well on specific types of text or domains, especially when these rules are designed for specific contexts, and they do not require training datasets and can be deployed immediately. However, this method may not accurately handle texts with complex meanings or containing rhetorical devices such as satire and metaphor. In addition, rule-based methods have lower flexibility and may require a lot of manual work to maintain and update rules and dictionaries [5].

Learning-based sentiment analysis models can be divided into machine learning-based sentiment analysis models and deep learning-based sentiment analysis models. Learning based sentiment analysis models typically require a large amount of labeled data for training. A machine learning based sentiment analysis model uses labeled datasets to train the model, so that the model can learn the mapping from text features to emotions. Machine learning models typically use manually designed feature representations. Deep learning models can use techniques such as word embedding to automatically learn the distributed representation of text, better capturing semantic information [6]. Deep learning models typically consist of multiple levels of neural networks with more complex structures and parameters. By contrast, machine learning models typically have a simpler model structure. Deep learning models typically require a large amount of labeled data for training in order to effectively learn complex feature representations. However, machine learning models require relatively small amounts of data and can be trained on smaller datasets [7].

Compared to machine learning methods, deep learning methods can typically provide higher accuracy while processing more complex texts and larger scale data. Therefore, sentiment analysis models based on deep learning have the advantages of automatic learning and feature extraction, high accuracy, and high flexibility. Deep learning models are particularly adept at capturing long-range dependencies from sequence data, which is crucial for understanding the context of text [8]. However, deep learning models typically require a large amount of annotated data for training, otherwise it may

lead to overfitting. In addition, training and tuning emotion analysis models based on deep learning is difficult, and the training process of deep learning models may be complex, requiring a focus on designing the network structure and tuning parameters. Therefore, sentiment analysis models based on deep learning may have an advantage in performance, but also pose challenges in adjusting network parameters [9].

The purpose of a music sentiment analysis model is to understand and analyze the emotional content in music. This model can be used in music recommendation systems to recommend suitable music to users by analyzing their emotional state and the emotional content of music. In addition, it can also be used in music creation to help creators better express the emotions they want to convey [10]. The emotion analysis model for vocal performance refers to a system that can recognize and analyze emotional expressions in singing. This type of model not only needs to handle linguistic emotional expression, but also needs to analyze musical elements such as melody, rhythm, harmony, and the vocal characteristics of the singer [11]. A sentiment analysis model for vocal performance needs to have the ability to extract music related features from audio signals, such as fundamental frequency, timbre, loudness, rhythm, and duration. In addition, the model also needs to have the ability to analyze sound quality, accurately identify the vocal quality of the singer, including clarity, stability, and volume changes [12].

The existing artificial intelligence-based sentiment analysis models have problems such as low accuracy. Therefore, in response to the problem of artificial intelligence based vocal performance analysis, this study establishes a deep learning based emotional analysis model for vocal performance, aiming to help music researchers understand music expression more deeply. The main contributions of this study are summarized as follows: a deep neural network (IABC-DNN) based on an improved artificial bee colony algorithm is designed. The input layer of IABC-DNN includes lyrics, typification, melody, pitch, and music rhythm, while the output layer is the emotion of vocal performance works. IABC-DNN consists of a novel gradient function that takes into account the factors affecting the emotional scale of vocal performance. In IABC-DNN, the Improved Artificial Bee Colony Algorithm (IABC) is used to optimize the DNN with the aim of improving the accuracy of the DNN. Finally, the accuracy of the IABC-DNN-based sentiment analysis model for vocal performance proposed in this study can reach 98% as verified by a test set. Overall, the emotional analysis model for vocal performance established in this study not only needs to ensure that the training data of the model is diverse and comprehensive, but also can capture emotional expressions from different singers, music styles, and cultural backgrounds. In addition, the subjectivity of sentiment analysis is also taken into account by the model, which can ensure that the model can find a balance between the differences in emotional perception among different listeners.

The remaining content of this study is arranged as follows: Section II of this paper reviews the relevant work related to this article. Section III developed an improved artificial bee colony algorithm. In Section IV, a novel DNN is designed. Section V presents the results. Finally, Section VI summarizes the entire study.

II. Literature Review

A. Emotional Analysis of Vocal Performance

Building an emotional analysis model for vocal performance is an interdisciplinary task that involves fields such as audio signal processing, music theory, psychology, and computer science. Emotional analysis is an important task in natural language processing (NLP), which aims to identify and extract subjective information from text. Before the emergence of deep learning methods, sentiment analysis mainly relied on vocabulary methods and machine learning techniques, such as naive Bayes and support vector machines. These methods typically require a significant amount of feature engineering. In recent years, deep learning-based sentiment analysis models have made significant progress. Convolutional Neural Network (CNN) is a deep learning model primarily used for processing grid shaped data, such as images. However, in recent years, CNN has also been successfully applied to sentiment analysis models. Specifically, reference [13] proposed a simple CNN model for sentence classification, including sentiment analysis. This model can use one-dimensional convolution and pooling operations to directly operate on word embeddings, thereby capturing local dependencies.

In addition, Recurrent Neural Networks (RNNs) are also a type of neural network capable of processing sequential data, making them highly suitable for processing text data. RNN can capture long-term dependencies in text by passing hidden states between time steps. However, a major problem with RNNs is gradient vanishing and exploding, which makes training deep RNNs difficult. To address this issue, reference [14] proposed the Long Short-Term Memory (LSTM) model. LSTM can more effectively capture long-term dependencies by introducing gating mechanisms. In addition, Transformer is a model based on self-attention mechanism. Unlike RNN and CNN, Transformer completely abandons loops and convolutions and relies on self-attention mechanism to capture global dependencies. Transformer has achieved significant success in various NLP tasks, including sentiment analysis [15].

In recent years, pre trained models have achieved significant success in various NLP tasks. These models are first pre trained on large-scale corpora and then fine-tuned on specific tasks. Pre trained models can capture rich language knowledge, significantly improving the performance of various NLP tasks, including sentiment analysis [16]. Meanwhile, knowledge graphs are also a structured way of representing knowledge, which can be used to represent entities and their relationships. In recent years, some studies have begun to explore how to use knowledge graphs for sentiment analysis. For example, reference [17] proposed a sentiment analysis model based on knowledge graphs, which can utilize the information in the knowledge graph to improve the performance of sentiment analysis.

However, the above artificial intelligence-based sentiment analysis models also have some challenges and limitations. Firstly, the above sentiment analysis models ignore the fine-grained issues in sentiment analysis, such as sentiment intensity detection, multi-dimensional sentiment analysis, etc. In addition, the above sentiment analysis models face

significant challenges when dealing with texts with satire and metaphor.

B. Deep Neural Network

Deep Neural Network (DNN) is a machine learning model that simulates the structure of human brain neural networks. It consists of multiple hidden layers, each of which is composed of multiple neurons. DNN has a wide range of applications in fields such as image recognition, speech recognition, and natural language processing [18]-[19]. In [18], a random DNN for image processing was designed, which has fewer neurons and higher accuracy compared to traditional DNNs. In [20], a deep neural network for signal processing was designed, which has better generalization ability against noise compared to traditional DNNs. In study [21], a DNN for image classification was designed using a two-stage algorithm, which can improve the accuracy of image classification during the DNN process. In study [22], several deep learning methods were combined and heuristic optimization methods were introduced to optimize the relevant parameters in the combination process, providing ideas for the design of new DNNs. In study [23], a DNN based risk model was developed to design the risk assessment process as an optimization problem.

Although DNN has achieved significant results in many fields, it still faces many challenges. Firstly, the training of DNN requires a large amount of computing resources and data, which is not feasible for many practical applications. Secondly, DNN has poor interpretability and it is difficult to understand its internal working mechanism. In addition, DNN is also susceptible to adversarial attacks, which is a problem for applications with high security requirements. In the future, research on DNN will focus more on improving its efficiency, interpretability, and security to meet the needs of more practical applications.

III. IABC-Deep Learning Framework

The basic principle of DNN is to map input data to output space through multi-layer nonlinear transformations. Each layer is composed of multiple neurons, each with an activation function used to convert input data into output data [24]-[27]. DNN is trained through backpropagation algorithm, optimizing weights and biases through gradient descent to minimize the difference between predicted and true values. Deep learning models may encounter difficulties when dealing with long texts, as long texts may contain a large amount of information, making it difficult for the model to capture key information. Therefore, similar to [22], in order to improve the accuracy of DNN, researchers have begun to attempt to combine meta heuristic algorithms with DNN algorithms to design DNN with better performance. Fig. 1 shows how to conduct sentiment analysis on vocal performance works based on DNN.

A. Collection of Sound Signals in Vocal Performance Works

Before designing the DNN framework, it is necessary to first sample and preprocess the speech of vocal performance works. Fig. 2 shows the short-term energy map of a vocal performance. In the specific sampling process, it is first necessary to frame the sound signal according to the time scale. Among them, the length of each audio segment is L_{audio} . Divide the entire audio into Num_{audio} segments. Without considering overlapping frames, the total number of sampling points for the sound signal is calculated as shown in Eq. (1).

$$Num_{total} = L_{audio} \times Num_{audio} \quad (1)$$

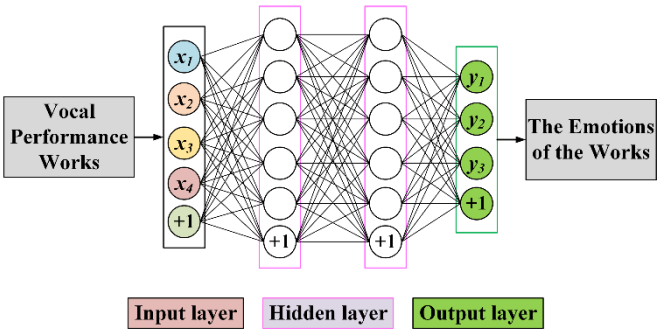

Fig. 1. The DNN schematic diagram for emotional analysis of vocal performance works.

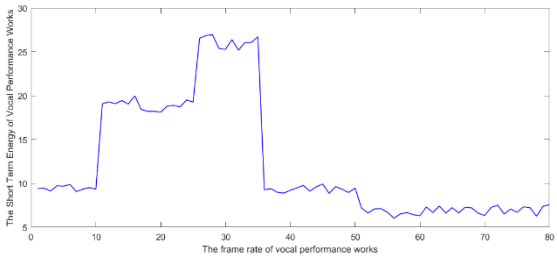

Fig. 2. The short-term energy map of a vocal performance work.

In audio processing, root mean square energy is often used for feature extraction of signals such as music and speech. For example, in tasks such as music emotion classification, speech activity detection, and speech recognition, root mean square energy is one of the important features. Meanwhile, as root mean square energy can reflect the loudness of audio signals, it is often used in applications such as music dynamic range compression and volume adjustment. Fig. 3 shows the mean square energy root of the audio signal in a certain vocal performance. Mean square energy root is a commonly used feature in audio processing, mainly used to describe the energy magnitude of audio signals. It is obtained by calculating the square of each sample of the audio signal, then taking the average value, and finally taking the square root. This value can reflect the loudness of audio signals and can also be used for audio segmentation classification.

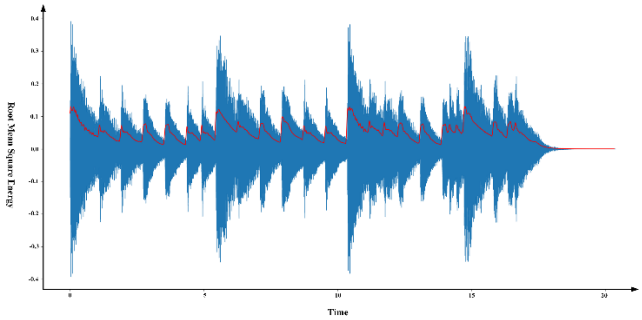

Fig. 3. The root mean square energy of a certain vocal performance.

B. Overview of Emotional Analysis Framework for Vocal Performance Works

After extracting language and speech from the audio of vocal performance works, Fig. 4. shows the sentiment analysis framework for vocal performance works based on IABC-DNN constructed in this study. The framework shown in Fig. 4. mainly consists of three parts: language prompts, knowledge-based encoding and decoding, and joint inference based on weighted first-order logic rules. In this study, propositional logic was constructed as a formal reasoning system. However, the minimum unit of propositional logic language is propositional symbols, which makes it impossible to conduct a more in-depth analysis of individual propositional symbols. Therefore, we used weighted first-order logic rules.

The framework shown in Fig. 4 which encodes the output of DNN using the following rules:

$$\lambda(k): DNN\_P\_issu(t,k) \rightarrow BoolP(t) \tag{2}$$

Among them, $BoolP(t)$ is Boolean variables, t indicates polarity, and $\lambda(k)$ represents weight. The rule weights are defined in Eq. (3):

$$\lambda(k) = ln\left(\frac{k}{1-k}\right) \tag{3}$$

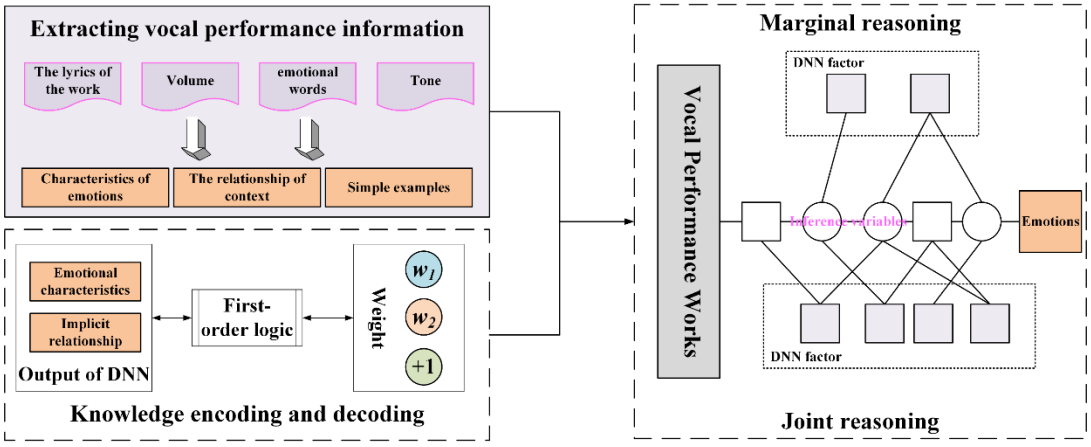

Fig. 4. The overall framework of vocal emotion analysis based on IABC-DNN.

IV. Design of IABC-DNN Algorithm

The swarm intelligence optimization algorithm is an optimization algorithm that simulates the behavior of groups in nature, such as bird flocks searching for food, ants finding their way, and so on. This algorithm has global search capability and can find the optimal solution over a large range, avoiding getting stuck in local optima. Therefore, it can be used to optimize the parameters of DNN. DNN is a complex machine learning model with numerous parameters and high optimization difficulty. Traditional optimization methods such as gradient descent may fall into local optima, while swarm intelligence optimization algorithms can avoid this problem. Specifically, the parameters of deep neural networks can be regarded as "individuals" in swarm intelligence optimization algorithms, each with a fitness value, that is, the performance of the deep neural network under this parameter setting. The swarm intelligence optimization algorithm continuously updates individuals by simulating group behavior, such as bird foraging and ant pathfinding, to optimize the parameters of deep neural networks and improve their performance.

A. IABC Algorithm

The Artificial Bee Colony (ABC) algorithm, as a novel swarm intelligence algorithm, is used in this paper to optimize the weights of DNN networks. The ABC algorithm is inspired by the honey gathering process of bees. In the optimization process, the ABC algorithm consists of two parts: feasible solutions (food sources) and solution positions (hired bees and non-hired bees). Among them, in any optimization problem, the feasible solution of the problem is given in a certain form. In the ABC algorithm, the food source is the feasible solution to the problem and is the basic object to be processed in the artificial bee colony algorithm. The quality of the food source can be evaluated by the value of the fitness function. Hiring bees refers to leading bees (collecting bees) that correspond to the position of their food source, with one food source corresponding to one leading bee. The steps and process of the improved Artificial Bee Colony (IABC) algorithm designed in this article are as follows. The algorithm flowchart of IABC is shown in Fig. 5.

1) Step 1: Initialization. Generate initial solutions based on the weights w_d of each neuron in DNN, and form a set of initial solution positions based on I max initial solutions. Specifically, as follows:

$$W_I = [w_1, w_2, \cdots, w_{d\max}] \tag{4}$$

$$abc\_Swarm_I = [W_1, W_2, \cdots, W_{I\max}]^T \tag{5}$$

2) Step 2: Calculate the fitness function value. Calculate the fitness function value for each honey source in the bee population. In Eq. (6), the objective function f_RMSE used in this study is given.

$$f\_RMSE = \sqrt{\frac{1}{n} \times \sum \left(V_{pre} - V_{ture}\right)^2} \tag{6}$$

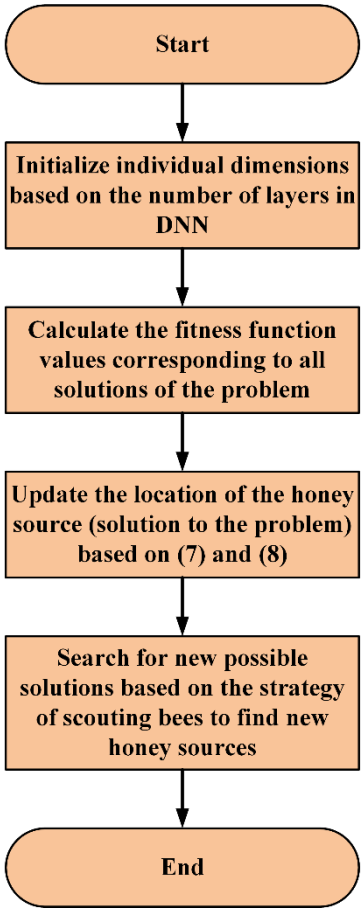

Fig. 5. The flowchart of IABC algorithm.

where, V_{pre} is the predicted value, and V_{ture} is the true value.

3) Step 3: Honey source update operation. In this study. DNN has d max weight coefficients that need to be optimized, and the number of bees collected or observed is equal to the number of solutions. Therefore, the number of bees collected or observed is $Imax$. Before updating the honey source, first generate a random number Q in the [0,1] interval. In Eq. (7) and Eq. (8), the way honey source updates are displayed.

If $Q \le 0.5$, then

$$w_{d,x}(new) = w_{d,x}(old) + \alpha \times \left(w_{d,x}(old) - w_{d,y}\right) \quad (7)$$

If $Q > 0.5$, then

$$w_{d,x}(new) = w_{d,x}(old) + F \times \left(w_{d,y} - w_{d,z}\right) \quad (8)$$

where, α is a random number on the interval [-1,1]. F is the variation factor, and its value range is generally within the range of [0.4, 0.95].

In Eq. (9) and Eq. (10), individuals before and after the honey source update operation are displayed, respectively.

$$W_I(old) = \left[w_1(old), w_2(old), \cdots, w_{d\max}(old)\right] \quad (9)$$

$$W_I(new) = \left[w_1(new), w_2(new), \cdots, w_{d\max}(new)\right] \quad (10)$$

After completing the honey source update operation, use a greedy selection strategy to retain better honey sources. Each observed bee selects a honey source based on probability, and the probability formula is shown in Eq. (11).

$$P = \frac{f\_RMSE(i)}{\sum f\_RMSE(k)} \quad (11)$$

4) Step 4: Generate feasible solutions based on reconnaissance bees. If, after the honey source update operation, the fitness value of a honey source is not further optimized within the given steps, the honey source is discarded, and the corresponding honey collecting bee becomes a reconnaissance bee. The reconnaissance bee searches for new possible solutions using the following:

$$w_{d,x}(new) = w_{d,x}(\min) + ramd(0,1) \times \left[w_{d,x}(\max) - w_{d,x}(\min)\right] \quad (12)$$

5) Step 5: End. Record the optimal solution and determine if the termination condition is met. If so, output the optimal solution.

V. Results Display

For the dataset, we selected a dataset consisting of 180 vocal performance works. The specific experiment is set up according to the following steps. Firstly, based on three different academic groups of students majoring in vocal performance, judges specializing in vocal performance, and experts in vocal performance, 180 vocal performance works were scored and their emotional expressions were given using a back-to-back scoring method. This study focuses on analyzing vocal performance works with five emotions: sadness, tenderness, anger, joy, and pride. In DNN, the five emotions are represented by 1, 2, 3, 4, and 5, respectively. Secondly, swarm intelligence algorithms are used in the structure of English DNNs. On this basis, the IABC-DNN algorithm was compared with DNN based on improved group search algorithm (IGSO-DNN), DNN based on ABC algorithm (ABC-DNN), and DNN based on improved genetic algorithm (IGA-DNN). The results showed that the proposed method is superior to the above three algorithms.

A. Dataset Settings

Table I shows the audio features and descriptions of vocal performance works, and the DNN algorithm conducts sentiment analysis based on these features and descriptions. Furthermore, 180 vocal performance works were divided into three sets of data to fully validate the model's generalization ability, as shown in Table II. In Table II, dataset WD-1 includes a training set consisting of 50 vocal performance works and a testing set consisting of 10 vocal performance works. The dataset WD-2 includes a training set consisting of 100 vocal performance works and a testing set consisting of 20 vocal performance works. The dataset WD-3 includes a training set consisting of 100 vocal performance works and a testing set consisting of 20 vocal performance works.

TABLE I. AUDIO FEATURES AND DESCRIPTIONS OF VOCAL PERFORMANCE WORKS

Characteristic	Describe
Sound quality characteristics	Very rough, very smooth, medium
Irregularity	Anger, fear, and sadness
Variability	More unpleasant (valence), awake or tired (awakening energy), and more tense (awakening tension)

TABLE II. DESIGN OF DATASETS

Data	Work types	Train	Test
WD-1	Vocal performance	50	10
WD-2	Vocal performance	100	20
WD-3	Vocal performance	150	30

B. Result Comparison

This study uses ABC algorithm, IABC algorithm, IGA algorithm, and IGSO algorithm to optimize the weights between neurons in DNN. The optimization results are shown below.

To demonstrate the robustness of swarm intelligence algorithms, ABC algorithm, IABC algorithm, IGA algorithm, and IGSO algorithm were run 50 times each. Fig. 6, 7, and 8 respectively show the optimal fitness function curve, worst fitness function curve, and average fitness function curve of the 50 run results of the four algorithms in optimizing the weights of the DNN network. From Fig. 6, 7, and 8, it can be concluded that the IABC algorithm designed in this study converges faster and has higher accuracy in optimizing the weight coefficients of DNN compared to the IGSO, IGA, and ABC algorithms.

Furthermore, this study compared three algorithms, DNN, IGWO-DNN, and IGA-DNN, with the proposed IABC-DNN algorithm. The comparison indicators included Accuracy, Precision, Sensitivity, Specification, and F-1 score. Tables III, IV, and V respectively show the various indicators of dataset WD-1, WD-2, and WD-3 when using the four models. In three datasets, regardless of which indicator, the IABC-DNN algorithm performed the best, fully demonstrating the effectiveness of the algorithm designed in this study.

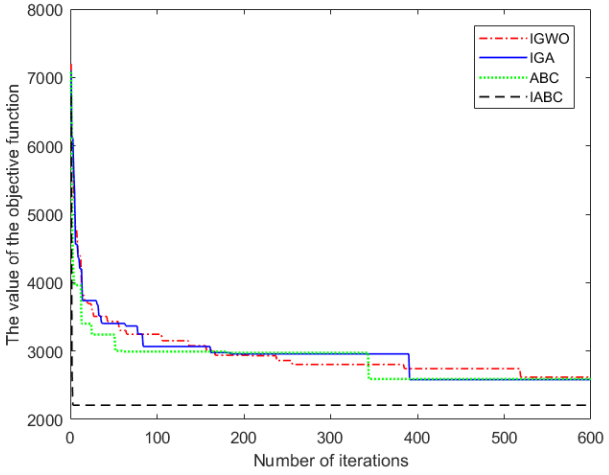

Fig. 6. The optimal fitness function curve during 50 runs of four algorithms.

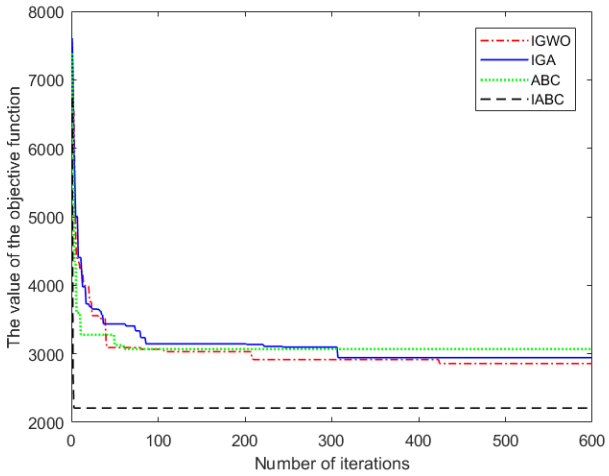

Fig. 7. The worst fitness function curve during 50 runs of four algorithms.

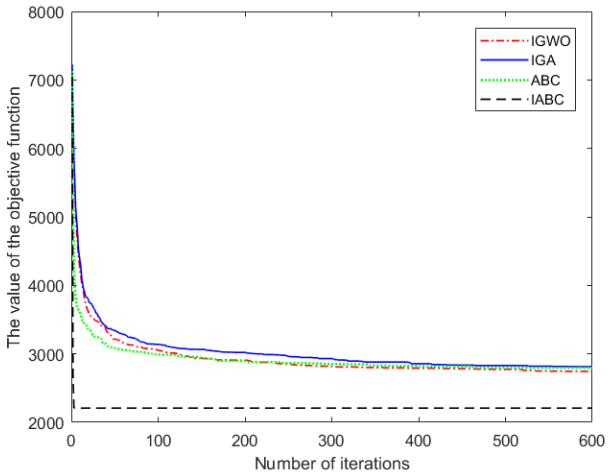

Fig. 8. The average fitness function curve during 50 runs of four algorithms.

TABLE III. EVALUATION OF PERFORMANCE METRICS FOR DATASET WD-1

Algorithm	Accuracy	Precision	Sensitivity	Specificity	F-1 score
DNN	0.812	0.865	0.821	0.920	0.855
IGWO-DNN	0.966	0.897	0.899	0.931	0.945
IGA-DNN	0.892	0.913	0.920	0.982	0.928
IABC-DNN	**0.975**	**0.987**	**0.999**	**0.987**	**0.991**

TABLE IV. EVALUATION OF PERFORMANCE METRICS FOR DATASET WD-2

Algorithm	Accuracy	Precision	Sensitivity	Specificity	F-1 score
DNN	0.889	0.863	0.901	0.902	0.890
IGWO-DNN	0.904	0.900	0.895	0.911	0.881
IGA-DNN	0.948	0.925	0.916	0.958	0.916
IABC-DNN	**0.981**	**0.988**	**0.990**	**0.946**	**0.970**

TABLE V. EVALUATION OF PERFORMANCE METRICS FOR DATASET WD-3

Algorithm	Accuracy	Precision	Sensitivity	Specificity	F-1 score
DNN	0.829	0.885	0.856	0.916	0.885
IGWO-DNN	0.876	0.839	0.853	0.901	0.916
IGA-DNN	0.925	0.900	0.895	0.970	0.924
IABC-DNN	**0.984**	**0.978**	**0.928**	**0.976**	**0.993**

Furthermore, Fig. 9 shows the accuracy of DNN, ABC-DNN, and IABC-DNN in predicting the emotions of 30 vocal performance works when using 150 vocal performance works as the test set.

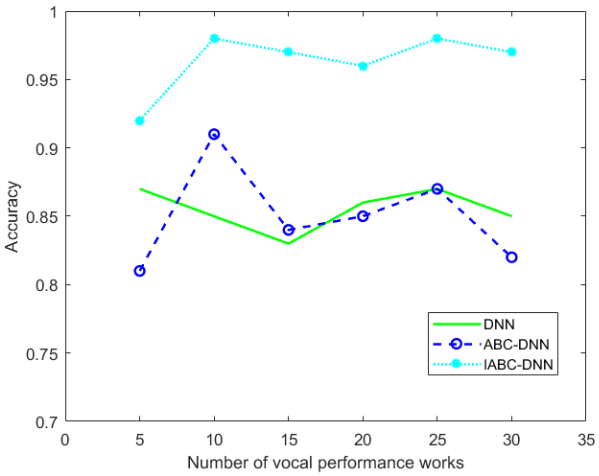

Fig. 9. The accuracy of different sentiment analysis models.

From Fig. 9, it can be seen that the IABC-DNN algorithm designed in this study has the highest accuracy, at 98%, which is higher than 87% of DNN and 91% of ABC-DNN algorithm. Compared with DNN algorithm and ABC-DNN algorithm, the accuracy of IABC-DNN algorithm has improved by an average of 9%.

VI. CONCLUSION

This study designed corresponding algorithms and models for the emotional analysis of vocal performance works. Especially, an improved ABC algorithm was designed and applied to the optimization process of weight coefficients in DNN networks. The effectiveness of the IABC-DNN algorithm has been fully demonstrated through three datasets. Compared with DNN and ABC-DNN algorithms, the accuracy of IABC-CNN algorithm has improved by 9%. In addition, compared with IGA, IGSO, and ABC, the IABC algorithm has the fastest convergence speed and highest convergence accuracy in optimizing the weight coefficients of DNN networks.

***Abstract*—Diagnosing depression and anxiety involves various methods, including referenda-based approaches that may lack accuracy. However, machine learning has emerged as a promising approach to address these limitations and improve diagnostic accuracy. In this scientific paper, we present a study that utilizes a digital dataset to apply machine learning techniques for diagnosing psychological disorders. The study employs numerical, striatum, and mathematical analytic methodologies to extract dataset features. The Recursive Feature Elimination (RFE) algorithm is used for feature selection, and several classification algorithms, including SVM, decision tree, random forest, logistic regression, and XGBoost, are evaluated to identify the most effective technique for the proposed methodology. The dataset consists of 783 samples from patients with depression and anxiety, which are used to test the proposed strategies. The classification results are evaluated using performance metrics such as accuracy (AC), precision (PR), recall (RE), and F1-score (F1). The objective of this study is to identify the best algorithm based on these metrics, aiming to achieve optimal classification of depression and anxiety disorders. The results obtained will be further enhanced by modifying the dataset and exploring additional machine learning algorithms. This research significantly contributes to the field of mental health diagnosis by leveraging machine learning techniques to enhance the accuracy and effectiveness of diagnosing depression and anxiety disorders.**

***Keywords*—Mental health; Recursive Feature Elimination (RFE); machine learning; XGboost**

I. Introduction

Ongoing research, in the field of disorders is focused on creating effective diagnostic approaches using advanced artificial intelligence (AI) methods [1]. The involvement of individuals with health conditions in studies investigating the origins of these disorders is rapidly growing [2], [3]. While mental disorders are rooted in brain abnormalities, psychologists and psychiatrists often make evaluations based on their insights and experiences. This dependence on assessments can lead to diagnoses for many people suffering from depression causing delays, in receiving appropriate care [4], [5]. Hence it is essential to identify trustworthy ways to comprehend and diagnose health issues highlighting the importance of integrating AI technologies into this process [6].

Diagnosing mental illnesses such as depression, anxiety, and suicide attempts can be challenging due to potential overlap and variations in manifestations among patients [7]. This difficulty arises because symptoms sometimes blur and vary amongst those impacted. Acting to address these issues early can significantly shorten the duration of symptoms and lessen their impact. It's crucial to remember that mental health disorders range widely, encompassing conditions like-schizophrenia, bipolar disorder, depression, intellectual disabilities, and Alzheimer's disease [8], [9]. It's also well-documented that problems such as depression and anxiety are closely associated with poorer sleep quality and various sleep issues, which can significantly impact a person's day-to-day functioning [10].

Depression, a serious health condition is acknowledged by the World Health Organization as the fourth leading cause of disability globally [11] [12]. One-fifth of the population grapples with anxiety or depression disorders. The conventional healthcare system faces challenges, in catering to the number of patients leading to access to specialized care and extended waiting periods, for therapy commencement [13] [14]. Anxiety, ranked as the prevalent mental health issue after depression is characterized by physical manifestations of worry and persistent irrational stress that necessitates continuous and affirmative therapeutic interventions [15] [16].

Depressive disorders often show up as long-term conditions linked to feelings of boredom, guilt, and difficulty focusing [16]. The level of symptoms determines how severe the depression is, in individuals. Treating depression directly can be tough causing some patients to turn to methods making diagnosis complicated [16] [17]. Studies have found that the neurons in people with disorders operate differently from those in individuals leading to disrupted neurotransmitter movement and decreased focus [18]. Current approaches to treating disorder (DD) rely on trial and error resulting in challenges and delays in patient recovery. Choosing the antidepressant for optimal clinical response remains a difficult task even though it is the main form of treatment for patients, with depressive disorder [19] [20].

The rise of AI technology has made diagnosing disorders efficient emphasizing the importance of mainstream AI applications being familiar, with how to detect them. Magnetic

resonance imaging (MRI) electroencephalography (EEG) and kinesics diagnosis are three methods used in health research [21].

II. Related Work

Despite the variety of integration techniques, the field of psychiatric disorders still encounters numerous obstacles. This challenge is particularly noteworthy, due to the prevalence of health conditions with rates of depression and anxiety reaching 26% and 28% respectively during the 2022 COVID-19 pandemic [22]. Disparities between the demand for and access, to health treatment are stark when compared to physical ailments. Bridging this treatment gap can be achieved through interventions; however, it's crucial to recognize that individuals may respond differently to interventions. While some may benefit positively others may still require forms of care [13].

Several previous studies have employed machine learning techniques to predict diagnoses using digital therapy. Table I presents the findings of these studies indicating results, in treating depression (N = 283) with an improvement of 8.0% (95% CI 0.8–15; total R2 pred = 0.25) reducing disability by 5.0% (95% CI -0.3 to 10; total R2 pred = 0.25) and enhancing well-being by 11.6% (95% CI 4.9–19; total R2 pred = 0.29) [18]. Additionally, machine learning methods have been utilized to predict anxiety with an accuracy rate of ninety-two percent based on a dataset involving just twenty-six individuals [23] and to forecast obsessive-compulsive disorder with an accuracy of eighty-three percent from sixty-one cases [24]. Furthermore, other research has demonstrated accuracy, in diagnosing anxiety and depression through this methodology [13].

Computer-assisted detection (CAD) systems have been used in Electroencephalograph (EEG) studies to diagnose conditions. Examples include the use of the network (ANN) classifiers, for diagnosing depression with a 98.11% accuracy rate [25] Enhanced Probabilistic Neural Network (PNN) classifier with 91.30% accuracy [26] logistic regression classifier achieving 90.05% accuracy [27] Support Vector Machine (SVM) classifier with an accuracy of 98.40% [28] another SVM classifier with an accuracy of 81.23% [29] and Convolutional Neural Network (CNN) classifiers attaining accuracies of 93.54 and 95.96 respectively [30]. Accurate diagnostic processes are crucial for treatment, in the realm of health given the challenges associated with precise psychiatric diagnoses owing to the overlapping symptoms of various mental illnesses making it difficult to differentiate or diagnose them accurately. This is to get the right psychiatric diagnosis before starting any treatment plan [31-49].

Traditional diagnosis for depression and anxiety relies on clinician expertise, which can be subjective and time-consuming. Machine learning (ML) offers an alternative approach, but previous methods often lacked transparency:

Black Box Problem: Traditional ML models are often like black boxes - they produce results but don't explain how they arrived at those conclusions. This makes it difficult for clinicians to trust the recommendations or understand why a patient is flagged for depression or anxiety.

- Limited Data Integration: Prior models might have focused on analyzing a single data source, like surveys. However, mental health is complex and can manifest in various ways.
- The proposed work with "Explainable Machine Learning Methods" suggests it addresses these issues by:
- Making ML interpretable: The approach might involve using specific algorithms or techniques that help explain the model's reasoning behind its diagnosis. This would increase trust and allow clinicians to understand the model's decision-making process.
- Utilizing Multimodal Data: The method might incorporate a wider range of data sources beyond just surveys. This could include speech patterns, facial expressions, or physiological data to create a more comprehensive picture of the patient's condition.

By overcoming limitations in explainability and data integration, this approach has the potential to improve the accuracy and effectiveness of diagnosing depression and anxiety compared to previous methods.

III. Materials and Methods

A. Dataset Description

This dataset is based on 19 features and 783 samples of 403 females and 380 males, aged between 18 and 31 years old. This dataset collection was gathered from University of Lahore undergrads and was created using the Depression and Anxiety inventories as a model, as shown in Table II.

TABLE II. This is a Table of Dataset Description

Features Name	Abbreviations	Rang of Features	Description
ID	-	783 Samples	Identify the patients
school_year	-	(1-4)	-
Age	-	(18-31)	Age of patients
Gender	-	(Male-Female)	types of patients
Body mass index	BMI	(0-54)	It is an indicator of the scale of body mass
Patient Health Questionnaire	PHQ_Score	(0-24)	is the depression module
Depression_Severity	-	(Mild-Moderate- None-minimal- Severe)	Is the severity of depression in patients
Depressiveness	-	(TRUE-False)	-
Suicidal	-	(TRUE-False)	-
Depression_diagnosis	-	(TRUE-False)	Diagnosis of depression in the patient
Depression_treatment	-	(TRUE-False)	-
Generalized Anxiety Disorder	GAD_score	(0-21)	The measure of anxiety intensity
Anxiety_severity	-	(Mild-Moderate- None-minimal- Severe)	Is the severity of anxiety in patients
Anxiety_diagnosis	-	(TRUE-False)	Is the severity of anxiety in patients
Anxiety_treatment	-	(TRUE-False)	-
Epworth score	-	(0-32)	Measures the general level of daytime sleepiness.
Sleepiness	-	(TRUE-False)	-

C. Proposed Work

This section presents a machine learning framework

proposed for the diagnosis of depression and anxiety using a digital dataset. The framework, illustrated in Fig. 3, encompasses a series of essential procedures including digital data preprocessing, feature extraction, feature selection, classification, and validation processes, all of which are crucial for the success of the approach. In the initial step, the preprocessing method is employed to remove extraneous noises and handle missing data. This critical stage involves selecting representative samples, ensuring data balance, normalizing the data, removing outliers, and addressing the issue of missing data. By performing these preprocessing steps, the dataset is prepared for further analysis.

During the feature extraction process, we randomly split the feature matrix into training and test sets. To improve classification accuracy and reduce the dimensionality of the feature matrix we employ the Recursive Feature Elimination (RFE) approach, for feature selection. At this point, an RFE algorithm is utilized on the training set to identify the subset of features. It is important to note that each iteration of the proposed procedure using RFE results in a specific subset of features. The next step is to use the training and testing sets of RFE-derived features to train and validate the classification model appropriately. The selected attributes act as an input for the machine learning algorithm so that it can learn patterns and make predictions accurately. Finally, the classification performance of the proposed approach is assessed based on the outcomes obtained from classifying the testing set during each repetition of the process. The analysis shows that the technique works well in diagnosing anxiety and depression. In summary, if this detailed methodology is followed, which includes processes of data pre-processing, feature extraction, feature selection, classification, and validation, the machine-learning system proposed has the potential to diagnose depression and anxiety accurately using digital data.

[Please note that Fig. 3 is not included in the response as it is not visible to the AI model.]

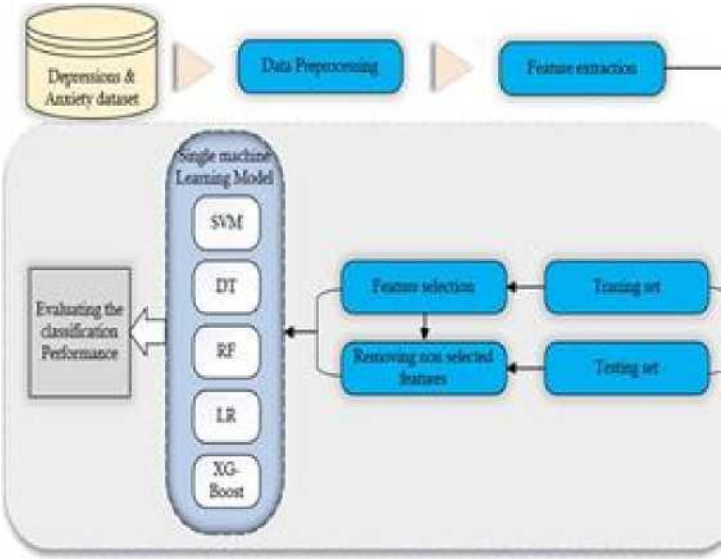

Fig. 3. Figure of the scheme for the proposed framework.

D. Methods

The present study is founded on an ample dataset of 783 individuals, where machine learning algorithms have been employed to prognosticate diagnoses with digital therapy. The outcomes have shown promising results, especially for depression and anxiety. The following algorithms, namely SVM, decision tree, logistic regression, random forest, and xgboost have been applied to both depressive and anxiety samples, and their corresponding results have been meticulously documented, as illustrated below in Table II and Table III.

Diagnosing depression and anxiety can be a complex process. Traditional methods rely on clinical interviews and standardized tests, but these can be time-consuming and subjective. Machine learning (ML) offers a promising alternative, but its "black box" nature often raises concerns. Here's a breakdown of how explainable ML methods can be used to improve the diagnosis of depression and anxiety:

TABLE III. THIS IS A TABLE OF RESULTS FOR DEPRESSION PREDICTIONS

Algorithms Performance (%)	Accuracy	precision	recall	f1-score
SVM	0.91%	0.91%	1.00%	0.95%
Decision tree	0.91%	0.95%	0.94%	0.95%
Random Forest	0.93%	0.94%	0.98%	0.96%
Logistic Regression	0.94%	0.95%	0.98%	0.96%
XGBOOST	0.92%	0.95%	0.97%	0.96%

1) Data Collection and Preprocessing:

- Gather relevant data: This could include survey responses, electronic health records (EHRs), speech patterns, or physiological measurements.
- Clean and prepare the data: Ensure data quality by addressing missing values, inconsistencies, and outliers.

2) Model Selection and Training:

- Choose an explainable ML algorithm: Options include decision trees, rule-based models, or LIME (Local Interpretable Model-agnostic Explanations). These provide insights into how the model arrives at its conclusions.
- Train the model: Split your data into training and testing sets. Train the model on the training data, allowing it to learn the patterns associated with depression and anxiety.

3) Model Evaluation and Explanation:

- Evaluate performance: Use metrics like accuracy, precision, and recall to assess the model's effectiveness in identifying depression and anxiety.
- Generate explanations: Analyze the model's predictions to understand what factors contribute most to the diagnosis. This could involve highlighting specific survey responses, keywords from speech, or patterns in physiological data.

4) Clinical Integration and Refinement:

- Integrate the model into clinical workflow: Present the model's prediction alongside explanations to support the clinician's diagnosis.
- Refine the model: Continuously monitor and improve the model based on new data and feedback from clinicians.

5) Benefits of this Approach:

- Improved diagnostic accuracy: Explainable ML can identify subtle patterns missed by traditional methods.
- Enhanced patient engagement: Explanations can empower patients to understand their diagnosis and treatment options.
- Increased clinician confidence: Explainable models provide additional information to support clinical judgment.

By following these steps, healthcare professionals can leverage the power of ML for mental health diagnosis while maintaining transparency and building trust with patients.

IV. Results

A. Results without Feature Selection

Next Stage the model used five classifiers; Support Vector Machine (SVM) Decision Tree (DT) Random Forest (RF) Logistic Regression (LR) and XGBoost to train a dataset having suicide, depression, and anxiety person. The system performs an algorithm of classification and documents its result for performance measurement. Below are stored classification performance metrics for each of the classifiers; SVM (0.91/0.91/1.00/0.95) DT (0.91/0.95/0.94/0.95) RF (0.93/0.94/0.98/0.96) LR (0.94 / 0.95 / 098 / 096) XGBoost (92%). This is shown in Table III as for the case it is summarized by accuracy=87% precision=87%, recall-1%and f1-score =93%. Further analysis also indicated that other classifiers such as decision trees gave better results than SVM with an accuracy level of up to 99% and an f1 score=96%, recall=0.98, and f1- score=0.98) in Table IV. After analyzing the results, it was found that the logistic regression algorithm performed the best with the dataset. In contrast, the random forest algorithm showed effectiveness, with the anxiety dataset as, per the data provided.

TABLE IV. This is a Table of Results for Anxiety Predictions

Algorithms Performance (%)	Accuracy	precision	recall	f1-score
SVM	0.87%	0.87%	1.00%	0.93%
Decision tree	0.93%	0.94%	0.99%	0.96%
Random Forest	0.94%	0.94%	1.00%	0.97%
Logistic Regression	0.91%	0.91%	1.00%	0.95%
XGBOOST	0.96%	0.98%	0.98%	0.98%

B. Results with Feature Selection

In this part we identify the feature using the data set for all algorithms and use the feature selection method also called as feature elimination (RFE) it can point out those effective features decrease the fuzzy set and help algorithms and feature improvement performance the process of feature selection as shown in these result column were suiting of RFE make the inform of data novice in target value The result of RFE for depression data: SVM (accuracy = 0.92) precision = 0.92 recall = 1.00, f1 score = 0.97) DT (accuracy = 0.94) precision=0.96, recall=0.98, f1 score=0.97) RF (accuracy = 0.94) precision=0.94, recall=0.99, f1 score=0.96) LR (accuracy = 0.94) precision=0.96, recall=0.98, f1-score=0.97) RF (accuracy = 0.94) precision=0.94, recall=0.99, f1score=0.96) LR (accuracy=0.95) precision=0.97, recall=0.98, f1-score=0.97) XGboost (accuracy = 0.95) precision=0.96, recall=0.99, f1-score=0.97) depression for anxiety data: SVM (accuracy = 0.92) precision=0.92, recall=1.00, f1 score=0.97) DT (accuracy = 0.96) precision=0.97, recall=0.98, f1 score=0.98) RF (accuracy = 0.94) precision=0.93, recall=1.00, f1 score=0.97) LR (accuracy = 0.95) precision=0.96, recall=0.99, f1-score=0.97) XGboost (accuracy = 0.98) precision=0.98, recall=1.00, f1-score=0.99)in anxiety The result of performance of our algorithms after feature selection as shown in this Table VI of our the algorithm decrease and increase performance after use feature of selection.

TABLE V. THIS IS A TABLE OF RESULTS FOR DEPRESSION PREDICTIONS WITH FEATURE SELECTION

Algorithms Performance (%)	Accuracy	precision	recall	f1-score
SVM	0.94%	0.94%	1.00%	0.97%
Decision tree	0.94%	0.96%	0.98%	0.97%
Random Forest	0.94%	0.94%	0.99%	0.96%
Logistic Regression	0.95%	0.97%	0.98%	0.97%
XGBOOST	0.95%	0.96%	0.99%	0.97%

TABLE VI. THIS IS A TABLE OF RESULTS FOR ANXIETY PREDICTIONS WITH FEATURE SELECTION

Algorithms Performance (%)	Accuracy	precision	recall	f1-score
SVM	0.92%	0.92%	1.00%	0.96%
Decision tree	0.96%	0.97%	0.98%	0.98%
Random Forest	0.94%	0.93%	1.00%	0.97%
Logistic Regression	0.95%	0.96%	0.99%	0.97%
XGBOOST	0.98%	0.98%	1.00%	0.99%

C. Results with Optimized Models

In this part of our study, we focused on enhancing the effectiveness of five machine learning models: SVM, DT, RF, LR, and XGboost. We used grid search methods to adjust the parameters of each model and determine which one performed best for both depression and anxiety data sets.

TABLE VII. THIS IS A TABLE OF RESULTS FOR DEPRESSION PREDICTIONS WITH THE OPTIMIZED MODEL

Algorithms Performance (%)	best score
SVM	0.94%
Decision tree	0.96%
Random Forest	0.96%
Logistic Regression	0.96%
XGBOOST	Nan

TABLE VIII. THIS IS A TABLE OF RESULTS FOR ANXIETY PREDICTIONS WITH THE OPTIMIZED MODEL

Algorithms Performance (%)	best score
SVM	0.92%
Decision tree	0.95%
Random Forest	0.95%
Logistic Regression	0.93%
XGBOOST	Nan

Table VII and Table VIII provide a comprehensive overview of the results obtained through this optimization process. These tables showcase the performance metrics and corresponding scores achieved by each algorithm across different evaluation measures. We have used grid search, where we compared different algorithms and chose the one with the best performance. This helped us to improve our diagnostic framework for anxiety and depression. During the phase of our study, we refined our machine learning algorithms by utilizing grid search methods. We also gathered information on parameter configurations that enhanced their effectiveness. These findings have the potential to enhance approaches in health studies and showcase the advancements in using machine learning to diagnose anxiety and depression with greater accuracy and speed, than ever before.

D. Discussion

The current research offers insights by suggesting a range of machine-learning techniques that can effectively be used to compare different mental illnesses, including anxiety and depression. This proposed framework utilizes characteristics to improve the accuracy of diagnosing these disorders. The study's results are presented in three phases; a phase, without selecting features a subsequent phase with feature selection, and a final phase comparing the outcomes of both approaches. Importantly the results from feature selection showed performance compared to those without feature selection as shown in Tables III, IV, V and VI along, with the phase incorporating the optimized model, as illustrated in Tables VII and VIII [10].

Besides, as Table I above reveals, I studied more successfully with our findings compared to the health paper that talks about the diagnosis of his issues. I later state how we are definite that the methods that I am proposing will work also well and pass the exam. Finally, we are confident after comparing our results they are more successful in our study. Also, we have to pay attention to the problems that are raised on "Discriminant between psychosis and Major Depression". We can notice from Table I how the problem of different disorders rather our results which based on civil form.

V. EXPLANATION OF THE DEVELOPED MODEL

Our main focus is, on tackling the issue with two classes. To give an overview of how each feature influences the model's decisions as a whole we've created a summary visualization. This visual representation showcases the importance of features through a bar graph with the x-axis showing the key features and the y-axis indicating their significance. The length of each bar reflects its importance in the model. In this visualization blue signifies the impact on class AD while red represents its influence on class CN. The summary plot, in Fig. 6 depicts this for the scenario involving three classes (AD=0, CN=1, sMCI=2).

Based on Fig. 6, we observe that the CDMemory, Q7, and Q4 forms are considered the most important features. To further explore the importance of each feature on an instance level, we utilized SHAP explainers to generate a waterfall plot. The waterfall plot presents all the features contributing to the decision-making process, sorted according to their SHAP values. Fig. 7(A, B, C, D) demonstrates the waterfall plots, where each plot displays the Base_value, representing the value according to the entire dataset, and the predict_proba_value, representing the probability for the specific instance. The left side of the plot shows the feature values for that instance, while the arrows indicate the feature contributions towards the prediction. Each row in the plot represents negative and positive contributions, depicted by blue and red bars, respectively. These explanations assist medical experts in understanding and placing trust in the decisions made by the model.

VI. Conclusion

According to the results of this study, it is possible to deduce that using treatment information alone can help accurately forecast treatment results by examining shifts, in anxiety and depression indicators. Cutting-edge machine learning algorithms showed accuracy in these forecasts providing guidance, for doctors when deciding on low-resource online therapies and conventional medical interventions. The strong precision of these models indicates their ability to identify the suitable level of traditional or digital care before starting treatment. It is a matter of great concern to the patients as this can save them time, energy, and money and just point them promptly toward appropriate healthcare resources. In addition to this, these results might guide healthcare providers toward identifying those patients likely not to benefit from online therapies to properly allocate their limited time and resources. By making use of these complicated machine learning algorithms, clinicians will enhance their decision-making regarding treatment that is evidence-based and patient-specific which ultimately leads to better outcomes for patients seeking mental health care by these models could alter its course through efficient guidance to suitable treatment options for those affected. However, more research is required before it can be determined if this knowledge applies or scales up across different populations of patients and within diverse healthcare contexts. Further studies in this area will promote the development of strategies for treating mental illnesses thereby enhancing care for anxiety and depression disorders thus improving the quality of life among individuals with such conditions.

An Integrated Arnold and Bessel Function-based Image Encryption on Blockchain

Abhay Kumar Yadav, Virendra P. Vishwakarma
University School of Information & Communication Technology,
Gobind Singh Indraprastha University, New Delhi 110078, India

***Abstract*—Images store large amount of information that are used in visual representation, analysis, and expression of data. Storage and retrieval of images possess a greater challenge to researchers globally. This research paper presents an integrated approach for image encryption and decryption using an Arnold map and first-order Bessel function-based chaos. Traditional methods of image encryption are generally based on single algorithms or techniques, making them vulnerable to various security threats. To address these challenges, our novel method combines the robustness of Arnold transformation with the unique properties of Bessel functions-based chaos. Furthermore, we implemented the decentralized nature of blockchain technology for storing and managing encryption keys securely. By utilizing blockchain's tamper-resistant and transparent ledger, we enhance the integrity and traceability of the encryption process, mitigating the risk of unauthorized access or tampering. The proposed method leverages the chaotic behavior of Bessel function for enhancing security of encryption process. A chaos obtained from first order Bessel function has been utilized for encryption key for encryption after Arnold transformation. The obtained cypher text is stored in blockchain in form of encrypted blocks for secured storage and added security. Experimental evaluations demonstrate the efficiency, effectiveness and robustness of our proposed encryption method when compared with performance of previously developed techniques highlighting the superiority of the proposed method in protecting image data against unauthorized access.**

Keywords*—Arnold transformation; block encryption; Bessel functions; blockchain

I. Introduction

Since digital image consists of large amount of distributed information, securing them is a major task for researchers. Also, digital images are less sensitive when compared with text data creating a minor change in image will create a drastic change in image pixels attribute. Digitized medical images provide an important aspect in storing patient's data as well as in diagnosing, treating and monitoring diseases [1].

The increasing amount of medical data generated by hospitals and clinics has led to the need for efficient storage and retrieval of these images [2]. Cloud storage services provide a reliable and cost-effective solution for storing large volumes of medical images. However, managing the security aspect of medical images stored in cloud is a major concern due to the personal and sensitive information of medical data [3]. Combining blockchain application with areas of medical research may provide newer potential in the biomedical field research. Sectors such as hospital and supply chain management of medicines and drugs may be benefitted from blockchain as it will impart a safer, secure, and reliable supply chain.

Blockchain technology can be used as a distributed electronic database encrypted by different cryptography functions thus eliminating existing limitations. Traditional systems use centralized authentication system making it difficult for various users to access database due to limited correct credential access and server capacity. Blockchain is similar to a distributed ledger, with different transactions encrypted together and, in the chain, and are permanent. Different features provided by blockchain have created newer use case application for cross integration with existing technologies for deployment across different domain. Researchers are working on enhancing these attributes for implementing them in image security [4]. Blockchain can work as a potential solution to the existing security issues in medical images.

The Arnold transformation represents a permutation-oriented cryptographic method designed to rearrange the pixel values within an image in a predictable yet intricate manner. This rearrangement instigates both confusion and dispersion, thereby fortifying the encrypted image against a spectrum of cryptographic assaults whereas, Bessel functions, a subset of mathematical special functions, are employed to add an additional layer of complexity to the transformed image. Through the application of Bessel functions, encryption is realized for each image by adapting the function's parameters dynamically in accordance with cryptographic keys. This combination approach enhances the overall security of the encryption scheme by customizing the encryption process for individual images

This paper aims to bridge the gap between the theoretical advancements in chaos theory, neural networks, and biological concepts, and their practical application in image security. By fusing these diverse elements into a unified framework, we strive to offer an innovative solution that addresses the challenges of image encryption in a rapidly evolving digital landscape. Through rigorous analysis and experimentation, we demonstrate the efficacy and robustness of the proposed Arnold Bessel-based framework for securing images.

The structure of this paper is arranged in following section: Section II highlights basic overview of the foundational concepts and related works. In Section III, the proposed methodology detailing the integration of Arnold maps and Bessel functions, Section IV delves into experimentation and

evaluation metrics. The results and discussions with previously developed techniques are also presented in this section. Section V discusses the storage on blockchain followed by conclusions and avenues for future research in Section VI.

II. BACKGROUND

A. Arnold Transformation

The Arnold Transform is a reversible image transformation used for image encryption. It is a simple and efficient algorithm that provides a level of security through its chaotic behavior. The Arnold Transform involves performing multiple iterations of a specific operation on image pixels to shuffle and disperse the pixel values, thus altering the image's appearance. This transformation can be used to encrypt an image, making it difficult for unauthorized users to understand the original content without the decryption process [5].

The Arnold transform is a chaotic transformation that can be used to scramble the pixels of an image, making it difficult to recognize. It is a simple transformation to implement, but it is very effective at disrupting the statistical properties of the image. Fig. 1 shows the distribution of image co-ordinates.

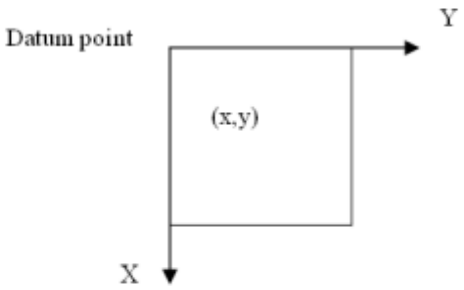

Fig. 1. Distribution of image coordinates.

The Arnold transform is area-preserving, meaning that it does not change the overall pixels in the image. However, it does scramble the pixels so that they are no longer correlated with their original positions [6]. Table I shows the scrambling cycle of Arnold transform based on size of image.

TABLE I. ARNOLD SCRAMBLING ALGORITHM CYCLE

Size of image (N)	Cycle of scramble (T)	Size of image (N)	Cycle of scrambling (T)
3	4	25	50
4	3	32	24
5	10	64	49
6	12	100	150
7	8	120	60

The Arnold transform works by taking the pixel coordinates (x, y) and transforming them to a new set of coordinates (x', y') using the following equations:

$$\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} ax & by \\ cx & dy \end{bmatrix} \text{mod M} \quad (1)$$

where a, b, c, and d are integer coefficients that satisfy the condition ad - bc = 1. M is the size of the image in pixels.

$$\begin{bmatrix} x_n + 1 \\ y_n + 1 \end{bmatrix} = \begin{bmatrix} x \\ y \end{bmatrix} \begin{bmatrix} ab + 1 & -b \\ -a & 1 \end{bmatrix} \quad (2)$$

The Arnold Transform is a lightweight and fast encryption method, but it may not provide the same level of security as more complex encryption algorithms. Therefore, it is often used together with other encryption techniques for enhancing the security of image encryption applications [7].

B. Bessel's Function

The Bessel function is a mathematical function that plays a crucial role in various scientific and engineering applications, including the field of chaotic neural networks. The Bessel function can be used to create chaotic behavior within a neural network, which is desirable for certain applications that require randomness and unpredictability [8].

The Bessel function introduces non-linear dynamics into the neural network, resulting in complex patterns and behaviors. This chaotic behavior can enhance the network's capacity to process and analyze complex data, making it suitable for tasks such as image encryption and decryption [9].

In the process of creating a chaotic neural network using the Bessel function, the network's connections and weights are usually initialized randomly. As the network receives input data and performs computations, the Bessel function introduces non-linear transformations that lead to chaotic dynamics. This chaos can be harnessed to achieve desired behaviors, such as robust encryption and decryption of images. A generalized first order Bessel's Function is shown in Fig. 2.

The Bessel function can enhance the security and unpredictability of the encryption process. The complex and non-linear transformations introduced by the Bessel function make it challenging for unauthorized users to decipher the encrypted data without the proper decryption key [10].

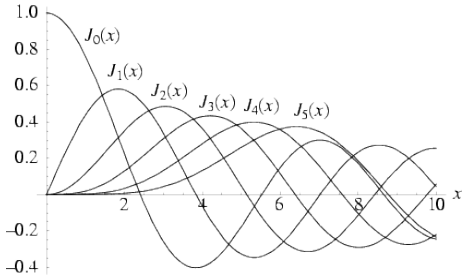

Fig. 2. Generalized representation of first order bessel's function.

III. METHODOLOGY

A. Previously Developed Techniques with Proposed Work

A detailed list of different encryption techniques presented by different researchers is listed in Table II.

B. Proposed Framework

Fig. 3 shows the methodology for the proposed framework followed by discussion on encryption and decryption techniques. The framework implements Arnold and Bessel's functions together for creating the chaotic encryption. The detailed algorithm for the encryption and decryption is mentioned in algorithm below.

Algorithm

Encryption

1. Arnold Map Transformation:

1.1 For each block of pixels in the image:
1.2 Apply the Arnold map transformation to the pixel coordinates.
1.3 Shuffle the pixels based on the transformed coordinates.

2. Bessel Function Key Generation:

2.1 Generate Bessel function coefficients using encryption parameters.

2.2. Create a set of Bessel functions based on the coefficients.

3. Pixel Transformation with Bessel Functions:

3.1 For each block of pixels in the image:

3.1.1. Apply a Bessel function transformation to the pixel values using the

generated Bessel functions.

3.1.2. Store the transformed pixel values in the encrypted image E.

Decryption

1. Pixel by pixel Bessel Decryption

The chaos generated after encryption are decoded back to obtain original image

2. Arnold Decoding

Images are descrambled for obtaining the original.

TABLE II. PREVIOUSLY DEVELOPED TECHNIQUES WITH PRESENTED TECHNIQUE

Techniques	Encryption Description	Technique
T1	1) Permutation by zig-zag pattern 2) Initial permutation from plain image Diffusion using XOR.	Zig-zag scan based chaotic feedback convolution model [11].
T2	1) DNA module based Intermediate Cypher image creation RNA module to produce final cypher image.	DNA rules, DNA-XOR operators and chaotic map [12].
T3.	1) Plain image hash value used for chaos generation Diffusion using DNA, XOR and RNA codons operations	Chaotic Evolutionary Biomolecules Model [13].
T4.	1) Plain image converted in DNA image by encoding rules 2) BST is created from DNA-BST is imposed on DNA image using XOR	BST, DNA coding, Logistic map [14].
T5.	1) Polynomial is selected by interval bisection at regular interval method creating sequence useful in encryption 2) Circular shift in confusion matrix Substitution matrix and masked image	bisection at interval method, Circular Shift, Substitution and XOR method [15].
T6.	1) Permutation by points obtained from Regula Falsi method 2) Encryption by image pixel substitution and iterative and cyclic shift.	Regula Falsi method, Substitution, Iterative addition, Circular Shift [16].
T7.	1) A unified key for selecting key pixels. 2) DNA encryption by pixel value substitution on key pixels Other pixels are encrypted by key stream of hyperchaotic Lorenz system	Key pixels, hyperchaotic Lorenz system scrambling, DNA encoding, Cyclic shift [17]
T8.	1) Fibonacci based pixels transformation 2) Scrambled image XOR with key image 3) Pixel values changed using Tribonacci Transform	Fibonacci and Tribonacci transformation [18].
Proposed	1) Image encryption by Arnold Transform. 2) A chaos obtained from first order Bessel function for encryption key for encryption at mid-level. 3) Storing the encrypted Data on blockchain for enhanced security	Arnold Transformation, Bessel Function, Blockchain

IV. Experimental Results and Performance Evaluation

The framework is executed using MATLAB R2023a software working on 64-bit machine with CPU Intel i9-4500U with 1.90 GHz processor and 8 GB RAM on Windows 11 OS. In the following section, the Lena image [19] is taken as the test image for evaluating our framework. Fig. 4 shows the different operations that are being performed on the test image.

To comprehensively evaluate the proposed framework, different performance evaluation measures are implemented working on following aspects: Entropy, execution time, correlation analysis. A detailed measures calculation and proposed methods results along with comparison with previously developed bench-mark approaches are presented in the Tables III, IV and V.

Proposed	0.00136	0.000217	0.00526

TABLE IV. PERFORMANCE COMPARISON IN TERMS OF EXECUTION TIME

Technique	Execution Time
T1	10. 440
T2	1.492
T3	3.009
T4	0.620
T5	0.798
T6	0.531
T7	0.288
T8	0.634
Proposed	3.687

TABLE V. PERFORMANCE COMPARISON IN TERMS OF ENTROPY

Technique	Entropy
T1	7.9994
T2	7.9994
T3	7.9995
T4	7.9992
T5	7.9993
T6	7.9994
T7	7.9993
T8	7.9994
Proposed	7.7634

The comparative analysis provides a holistic understanding of the strengths and limitations of the proposed integrated Arnold and Bessel function-based encryption scheme relative to existing methods. The comparisons highlight the superiority of the proposed framework in terms of entropy, execution time, and correlation analysis, reaffirming its efficacy in ensuring robust image encryption.

The results obtained from the comprehensive evaluation demonstrate that our proposed framework provide the expected encryption of images. On evaluation in terms of correlation coefficient, execution time and entropy showed the effectiveness and superiority of the proposed framework in achieving high levels of security and randomness in image encryption, thus validating its potential for practical deployment in real-world scenarios.

V. BLOCKCHAIN STORAGE

Ganache software [20] is capable of providing real-time simulation of smart contract executions based on Ethereum platform. Different use case and application can be simulated in Ganache based on its smart contract's features. Ganache provides 10 block free for mining and simulation, we have used only one block for storing the encrypted data obtained after the encryption process on Ganache software. Fig. 5 shows the working of Ganache software in storing encrypted parameters in detail with its implementation on front-end and back-end platform.

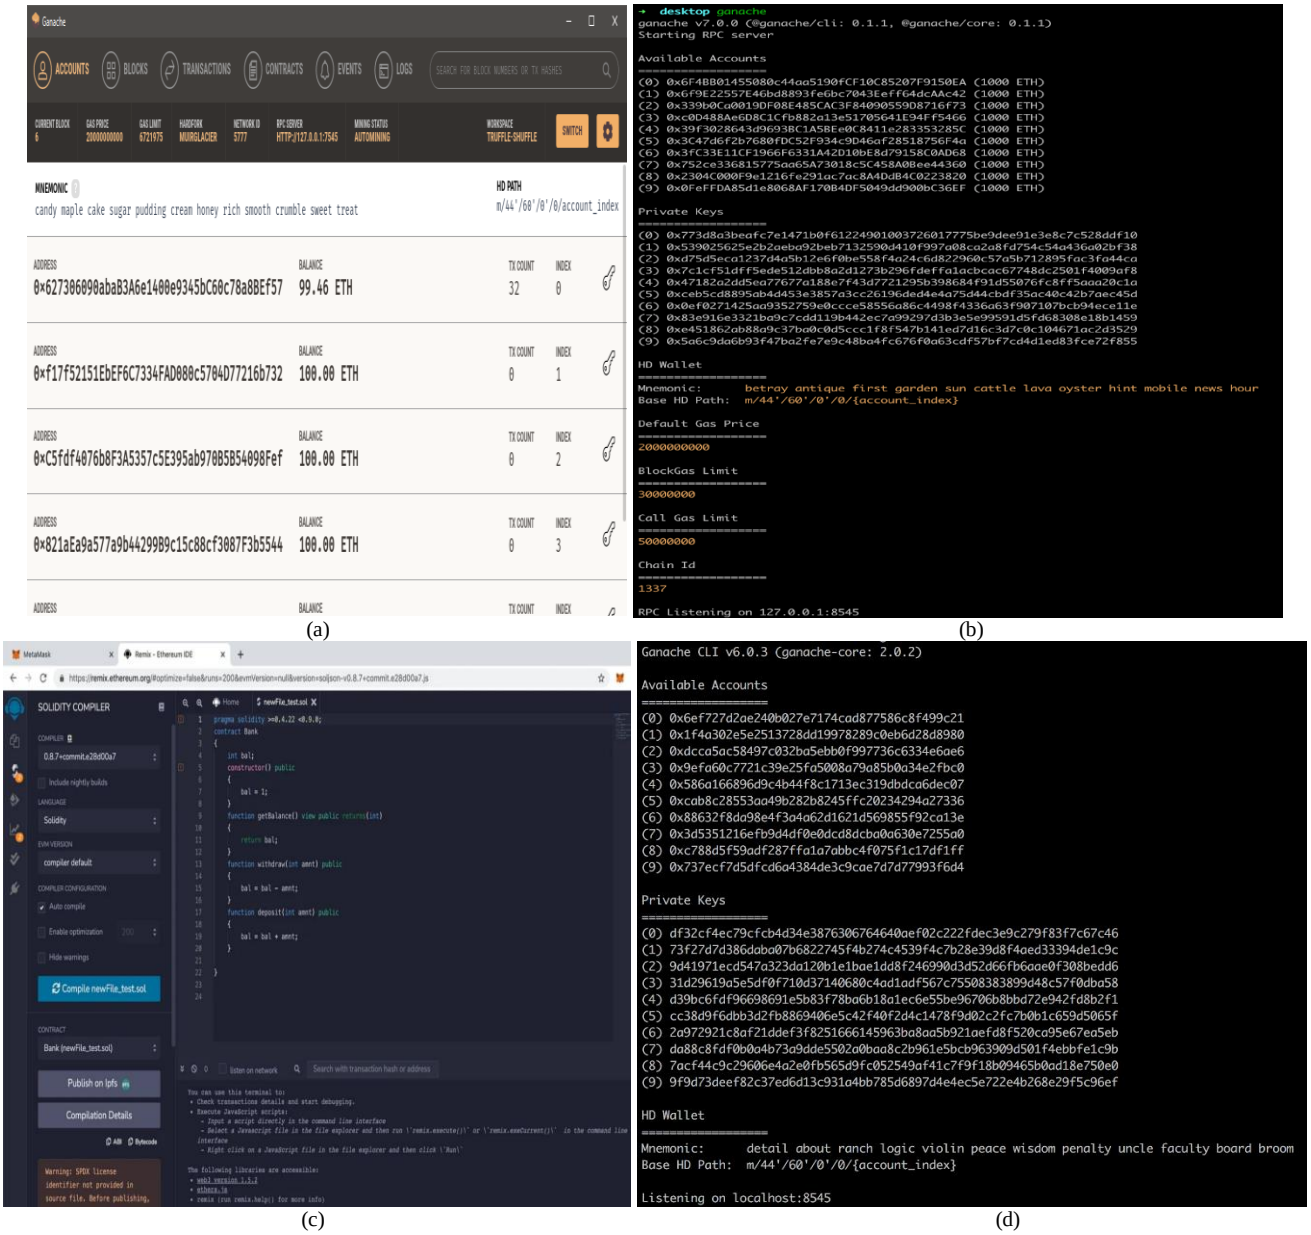

Fig. 5. Implementation on Ganache Framework a) Front End of Ganache Software b) Back-end on CLI interface c) Remix code for contracts d) Viewing all established contracts.

VI. Conclusion and Future Work

This paper proposes a new blockchain based image encryption framework with Arnold and Bessel's functions integration. This method obtains the encrypted data from the input image, store it on blockchain followed by decrypting it in reverse order to encryption to retrieve the original image. For performance evaluation, generic Lena image has been used for comparison with other encryption methods. The proposed work provides significant multi-level encryption and along with enhanced security. Its working has been validated with previously developed techniques.

In near future, more security techniques such as DNA barcoding can be further added for enhanced encryption. Moreover, chaos from neural networks can also be implemented for securing the images. The proposed framework can be implemented in medical images as they need proper encryption for securing patient's sensitive images.

Acknowledgment

Both authors acknowledge All India Council of Technical Education for the fellowship of first author under AICTE Doctoral Fellowship scheme.

***Abstract*—Drowsiness among drivers is a major hazard to road safety, resulting in innumerable incidents globally. Despite substantial study, existing approaches for detecting drowsiness in real time continue to confront obstacles, such as low accuracy and efficiency. In these circumstances, this study tackles the critical problems of identifying drowsiness and driver safety by suggesting a novel approach that leverages the combined effectiveness of Gated Recurrent Units (GRU) and Enhanced Deep Belief Networks (EDBN), which is optimised using COOT, a new bird collective-behavioral-based optimisation algorithm. The study begins by emphasising the relevance of sleepiness detection in improving driver safety and the limitations of prior studies in reaching high accuracy in real-time detection. The suggested method tries to close this gap by combining the GRU and EDBN simulations, which are known for their temporal modelling and feature learning capabilities, respectively, to give a comprehensive solution for sleepiness detection. Following thorough experimentation, the suggested technique achieves an outstanding accuracy of around 99%, indicating its efficiency in detecting sleepiness states in real-time driving scenarios. The relevance of this research stems from its potential to greatly reduce the number of accidents caused by drowsy driving, hence improving overall road safety. Furthermore, the use of COOT to optimize the parameters of the GRU and EDBN models adds a new dimension to the research, demonstrating the effectiveness of nature-inspired optimization methodologies for improving the performance of machine learning algorithms for critical applications such as driver safety.**

I. Introduction

Drowsy driving is a crucial issue that poses a significant danger to global road safety, resulting in numerous fatalities and injuries every year. When a motorist runs a vehicle when drowsy or tired, their ability to respond quickly and make informed decisions is severely reduced. This impairment can cause a variety of unsafe scenarios on the road, such as delayed reaction times, decreased focus, poor judgment, and even full nodding off behind the wheel. Statistics from numerous sources highlight the seriousness of the issue [1]. According to the National Highway Traffic Safety Administration (NHTSA) in the United States, drowsy driving contributes to approximately ten thousand crashes registered to police every year, leading to roughly 1,545 deaths and 71,100 injuries [2]. However, it is crucial to remember that these estimates may greatly understate the real effect of drowsy driving, as detecting tiredness as a contributory factor in accidents can be difficult. The effects of drowsy driving accidents go beyond the immediate loss of life and injury. These occurrences also carry significant economic implications, such as medical expenses, property damage, missed productivity, and legal fees. Furthermore, the impact that emotions have on families and communities affected by sleepy driving accidents is incalculable, with long-term psychological and societal consequences [3].

Despite increased awareness of the dangers of drowsy driving and efforts to address the issue through education campaigns and legislation, it remains a persistent problem. One of the reasons for this challenge is that drowsiness is often underestimated or overlooked by drivers themselves, who may mistakenly believe they can push through fatigue or may not recognize the signs of impending drowsiness [4]. Addressing drowsy driving requires a multifaceted approach that includes not only public education and awareness but also technological solutions aimed at detecting and preventing drowsy driving in real-time. Advanced driver assistance systems (ADAS) equipped with drowsiness detection capabilities offer promising tools for mitigating the risks associated with drowsy driving [5]. These systems use machine learning methods such as recurrent neural networks (RNNs) and deep learning architectures to analyse driving

behaviour and physiological inputs in order to detect indicators of tiredness and alert drivers before an accident happens. Drowsy driving is a major hazard to road safety, resulting in injuries, economic losses and fatalities globally. Efforts to combat drowsy driving must encompass both preventive measures and technological innovations aimed at detecting and mitigating the risks associated with driver fatigue in real-time. By addressing this pervasive issue, researcher can make significant strides towards reducing the toll of drowsy driving on individuals, families, and communities [6].

Real-time drowsiness detection systems are integral to mitigating the risks associated with drowsy driving, offering a proactive approach to preventing accidents on the roads. The importance of these systems lies in their ability to provide timely intervention when drivers are at risk of falling asleep or experiencing significant fatigue. By detecting early signs of drowsiness and alerting drivers to the need for rest or a change in driving behavior, these systems can help avert potentially catastrophic accidents [7]. This timely intervention is crucial, as drowsiness impairs a driver's ability to react quickly and make sound decisions, leading to decreased vigilance, impaired judgment, and compromised control over the vehicle. The significance of real-time drowsiness detection systems extends beyond accident prevention to encompass broader road safety concerns. By reducing the incidence of drowsy driving-related accidents, these systems contribute to safer roads and communities for all road users, including drivers, passengers, pedestrians, and cyclists. Fewer accidents translate to fewer injuries, fatalities, and property damage, resulting in tangible improvements in public health and well-being [8].

Furthermore, real-time drowsiness detection systems play a pivotal role in enhancing driver awareness of their own fatigue levels and the importance of taking breaks when necessary. By providing immediate alerts and reminders, these systems empower drivers to prioritize their safety and well-being while on the road, fostering a culture of responsible driving habits and risk management [9]. Despite the undeniable importance of real-time drowsiness detection systems, existing techniques face several limitations that must be addressed to realize their full potential. Traditional methods based on physiological measurements or video-based monitoring may lack accuracy and specificity, leading to false alarms or missed detections. Advanced machine learning algorithms offer promising avenues for improving accuracy and robustness but may require significant computational resources and large amounts of labeled training data [10]. Furthermore, hybrid approaches that integrate multiple techniques may offer improved performance but can be complex to implement and may require additional hardware or sensors, increasing the system's cost and complexity. Addressing these limitations through innovative research and technology development is essential for advancing the effectiveness of drowsiness detection systems and reducing the toll of drowsy driving-related accidents on individuals, families, and communities [11].

Real-time sleepiness detection technologies are critical tools for ensuring road safety, especially because drowsy driving is still a major hazard on the roads of the state. Driver weariness can have serious implications, including reduced cognitive skills that result in slower responses and poor decision-making abilities. This heightened risk is particularly pronounced during extended journeys or monotonous driving conditions, where the monotony can exacerbate drowsiness. Real-time detection systems offer a proactive approach to addressing this issue by continuously monitoring various physiological and behavioral indicators, such as eye movements, facial expressions, steering patterns, and vehicle dynamics [12]. By promptly recognizing signs of drowsiness, these systems can issue timely alerts, allowing drivers to take corrective actions, such as pulling over for rest or taking breaks. The importance of such systems lies not only in preventing accidents but also in fostering a culture of driver awareness and compliance with regulations, ultimately contributing to safer roads and reduced economic costs associated with road accidents. The motivation for combining Gated Recurrent Units (GRU) and Enhanced Deep Belief Networks (EDBN) within the COOT (Combined Optimization of GRU and EDBN) framework stems from the desire to harness the respective strengths of these architectures to enhance the efficacy of drowsiness detection systems [13].

On one hand, GRU offers exceptional capabilities in temporal modeling and sequential data processing. By integrating GRU into the framework, COOT can effectively capture the dynamic temporal patterns inherent in drowsiness-related data, such as fluctuations in eye closure duration or changes in facial expressions over time. This temporal awareness enables COOT to discern subtle variations indicative of drowsiness more accurately, thus improving the overall detection performance [14]. On the other hand, EDBN is adept at learning hierarchical representations of raw sensor data. This capability eliminates the need for manual feature engineering, as EDBN autonomously extracts discriminative features directly from the input data. By incorporating EDBN into COOT, the framework can adapt more readily to diverse driving conditions and individual driver characteristics, enhancing its versatility and robustness in real-world scenarios [15]. The synergy achieved by combining GRU and EDBN within the COOT framework facilitates a comprehensive approach to drowsiness detection. GRU's temporal modeling capabilities capture short-term dynamics, while EDBN's hierarchical feature learning encompasses long-term contextual information. Through this collaborative optimization, COOT achieves superior performance in real-time drowsiness detection, contributing significantly to advanced driver safety systems.

The key contributions are stated as follows:

- The research introduces a unique integration of Gated Recurrent Unit (GRU) and Enhanced Deep Belief Networks (EDBN) for drowsiness detection, leveraging their respective strengths in temporal modeling and feature learning to provide a comprehensive solution.
- By employing COOT a novel bird collective-behavioral-based optimization algorithm, the study showcases the effectiveness of nature-inspired optimization techniques in enhancing the performance

of machine learning algorithms for critical applications such as driver safety.

- The research addresses the limitations of existing methods for real-time drowsiness detection, including limited accuracy and efficiency, by proposing a novel approach that aims to fill this gap and offer a more reliable solution for detecting drowsiness in real-world driving scenarios.
- With its potential to significantly reduce the incidence of accidents caused by drowsy driving, the proposed methodology holds promise for enhancing overall road safety by providing an effective means of identifying and mitigating the risks associated with driver drowsiness.

The subsequent sections of this research are organized as follows: Section II will delve into related works, providing a comprehensive evaluation. Section III will outline the problem statement in detail. In Section IV, the suggested method will be discussed elaborately. Section V will present and analyze the test results, along with a thorough comparison of the proposed technique with current standard procedures. Finally, Section VI will conclude the paper.

II. Related Works

The study's goal is to create an Advanced Driving Assistance System (ADAS) that can identify driver fatigue and send out alerts to help reduce traffic accidents. It is critical to assess weariness in driving settings without causing the driver any inconvenience through needless notifications. The suggested method entails recording 60-second photo sequences with the driver's face visible and employing two unique algorithms to reduce false positives in detecting indicators of fatigue. While the other strategy makes use of a recurrent and convolutional neural network, the first approach uses deep learning techniques to extract numerical data from images and incorporate it into a fuzzy logic-based framework. Though attaining comparable accuracy levels, the fuzzy logic-based approach is distinguished by its 93% specificity, which significantly lowers false alarms. Even though the outcomes might not be entirely satisfying, the concepts investigated in this study show promise and offer a strong framework for more research in the area [16].

Driver drowsiness estimation is paramount for ensuring road safety, and this study introduces an innovative approach leveraging factorized bilinear feature fusion and a LSTM-RCN. By integrating these techniques, our aim is to capture both spatial and temporal information from driver facial images, enhancing the accuracy of drowsiness detection systems. However, a significant drawback of many existing methodologies lies in their reliance on manual feature extraction techniques. These methods often require domain expertise to hand-craft features from raw data, leading to limitations in performance and generalization. Manual feature extraction may overlook subtle but crucial patterns in the data, resulting in suboptimal drowsiness detection capabilities. The approach research recommend circumvents this drawback by using DL to automatically extract discriminative features from the data without the requirement for human feature engineering. Through extensive experiments conducted on real-world driving datasets, we demonstrate the efficacy of our method in accurately estimating driver drowsiness while addressing the drawbacks associated with manual feature extraction, ultimately enhancing road safety [17].

Eye state detection is important in biomedical informatics, especially in applications such as managing smart home appliances and detecting driver weariness. Traditional methods for detecting eye problems from electroencephalogram (EEG) signals frequently depend on shallow neural networks and manually created features. The inherent unpredictability of EEG data poses challenges in extracting significant features and selecting effective classifiers. In this study, three deep learning architectures—convolutional neural network, gated recurrent unit, and long short-term memory—are proposed, utilizing an ensemble technique to directly recognize the eye state (open or closed) from EEG signals. Experiments were conducted on the publicly accessible EEG eye state database, comprising 14980 samples. The individual accuracies of each classifier were monitored, and the performance of ensemble networks was compared to existing approaches. The proposed strategy achieved an average accuracy of 94.86%, surpassing previous methods documented in the literature [18].

Detecting driver drowsiness in real time is critical for avoiding traffic accidents. This research describes a new method for detecting tiredness while driving in real time that takes into account individual characteristics. While existing algorithms frequently overlook these variances, our technique takes them into account to improve the accuracy and reliability of sleepiness detection systems. However, one important disadvantage of many existing approaches is their limited ability to adjust to individual variances, resulting in decreased effectiveness in real-world circumstances. Furthermore, some algorithms rely largely on predetermined thresholds or fixed parameters, which can result in erroneous detections or false alarms. To overcome these constraints, our proposed algorithm uses a dynamic thresholding mechanism and machine learning approaches to adapt to each driver's unique traits.
Extensive studies on varied driving datasets show that our methodology is excellent in reliably detecting driver tiredness while avoiding the limitations associated with existing methods. Overall, the system research use provides a potential approach for detecting tiredness while driving in real time that takes into account individual variances, hence improving safety [19].

Real-time identification of driver drowsiness is crucial for avoiding accidents on the road. In this article, we propose a machine learning-based approach for detecting driver drowsiness using visual cues collected from dashboard camera data. The solution research provide uses deep learning algorithms to extract critical visual cues like eye closure patterns, head posture, and facial expressions in real time. However, one disadvantage of current techniques is that they rely on complicated and computationally expensive models, which may restrict their scalability and real-time performance. To solve this issue, researchers offer a lightweight CNN architecture optimised for real-time processing, allowing

for efficient and accurate drowsiness detection while conserving computational resources. The method's usefulness is demonstrated by its performance on a large dataset, where it achieves excellent accuracy in real-time sleepiness detection while overcoming the computational complexity limits of existing approaches [20].

Recent research has witnessed a surge in developing advanced driving assistance systems (ADAS) to detect and mitigate driver sleepiness, aiming to prevent traffic accidents. Existing methodologies often struggle with accuracy and non-intrusive monitoring, lacking consideration for individual variations across drivers. Novel approaches integrating deep learning techniques show promise, such as fuzzy logic-based methods and long-short-term recurrent neural networks. Despite advancements, challenges persist, including low accuracy from artificial feature extraction and hardware dependencies. Robust and adaptable approaches are crucial for real-time, non-intrusive detection of driver sleepiness in diverse driving environments.

III. Problem Statement

The proposed research, "COOT-Optimized Real-Time Drowsiness Detection using GRU and Enhanced Deep Belief Networks for Advanced Driver Safety," addresses the critical need for a robust and adaptable approach to real-time drowsiness detection, which currently faces challenges such as low specificity, dependency on specific hardware setups, and overlooking individual variations across drivers [1], [18], [21]. By combining Gated Recurrent Units (GRU) and Enhanced Deep Belief Networks (EDBN) within the COOT framework, the research aims to develop a novel methodology capable of accurately and non-intrusively detecting driver fatigue[22]. The scope encompasses designing and implementing the COOT framework, conducting comprehensive experiments to evaluate its performance, analyzing its effectiveness in achieving high specificity and adaptability, and identifying potential applications in enhancing advanced driver safety systems. Through these efforts, the research aims to contribute to advancements in drowsiness detection technology and ultimately enhance driver safety on the roads.

IV. Proposed Methodology

The proposed methodology integrates Gated Recurrent Unit (GRU) and Enhanced Deep Belief Networks to tackle the challenge of real-time drowsiness detection in drivers. The GRU model is chosen for its ability to effectively model sequential data by selectively updating its memory state, making it well-suited for capturing temporal dependencies inherent in drowsiness-related features, such as eyelid closure duration and head movements. Concurrently, enhancements are introduced to traditional Deep Belief Networks to bolster their capacity in discerning subtle cues of drowsiness, leveraging techniques such as feature augmentation and layer refinement. These modifications aim to improve the network's ability to extract discriminative features from the input data, thereby enhancing its overall detection accuracy. Moreover, the methodology employs COOT Bird Natural Life Optimization for hyperparameter tuning, leveraging the algorithm's ability to navigate complex parameter spaces efficiently. By iteratively optimizing model parameters using COOT, the proposed framework ensures that the GRU and Enhanced Deep Belief Networks are finely tuned to maximize their performance in real-time drowsiness detection tasks. This comprehensive approach not only addresses the inherent challenges of detecting drowsiness but also offers a robust solution capable of providing timely alerts to mitigate potential risks on the road, ultimately contributing to advanced driver safety. Fig. 1 shows the proposed architecture.

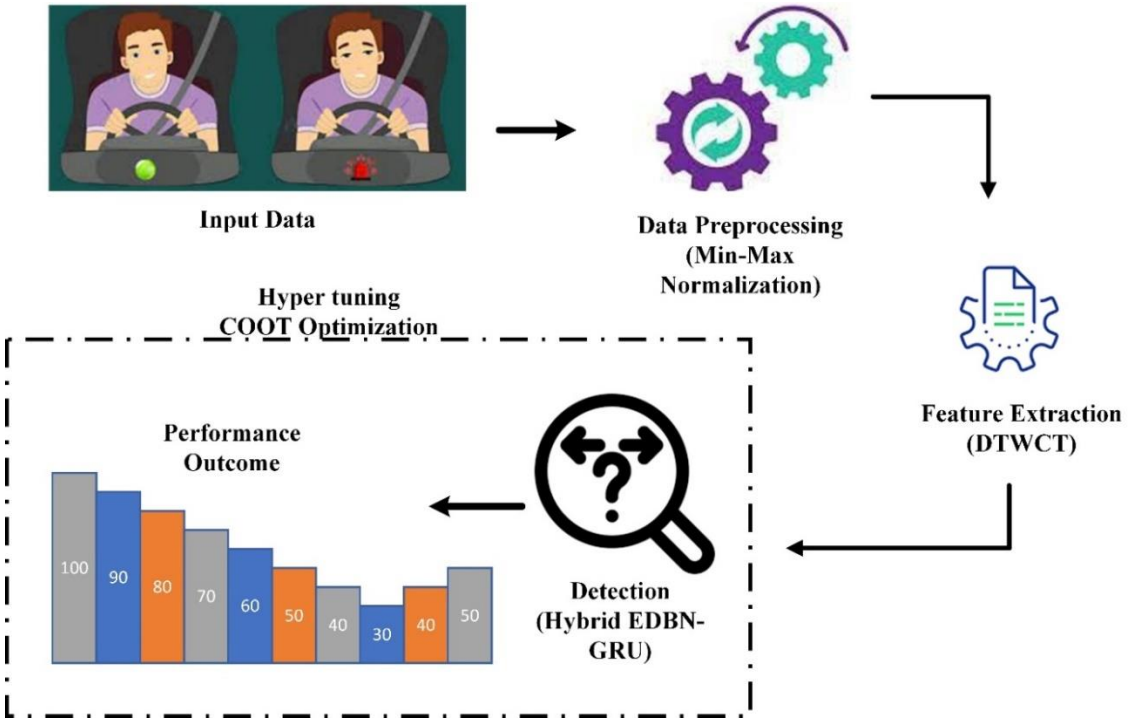

Fig. 1. Proposed COOT optimized EDBN-GRU.

A. Data Collection

Drivers' faces were clipped and extracted from real-world drowsiness dataset films to develop the Driver Drowsiness Dataset (DDD). VLC software was used to extract the frames from the films, and the Viola-Jones approach was then applied to identify the region of interest. The obtained DDD dataset was then used to train and evaluate a Convolutional Neural Network (CNN) architecture intended for driver drowsiness detection [23].

B. Data Preprocessing

Data preprocessing is a critical step in machine learning that converts raw data into a format appropriate for training a model. This step entails cleaning, altering, and organising the data to make it easier to handle and useful for the model. Data preparation improves the data's quality and guarantees that the model is capable of learning from it [24].

1) Data normalization: Data normalization is a way to make sure all the numbers in a set of data are similar in size. This is important because big features can have a big impact on the model's predictions and control how the model learns. By making the data normal, researchers make sure that all parts of the data are equally important in making predictions, which makes the predictions more accurate [25].

There are several techniques for data normalization, two of the most common ones being min-max scaling and z-score normalization:

2) Min-Max scaling: Min-max scaling, frequently referred to as feature scaling, converts the values of each feature to a range of 0 to 1. To compute the min-max scaling, use Eq. (1):

$$A_{scaled} = \frac{A - A_{min}}{A_{max} - A_{min}} \quad (1)$$

A is the starting value, $A_{min}$is the smallest value, and $A_{max}$is the largest value in the dataset. This method is helpful when the features are not evenly distributed and have a small range.

3) Z-Score normalization (Standardization): Z-score normalization, also called standardization, adjusts the values of each feature so that they have a mean of 0 and a standard deviation of 1. Research use Eq. (2) to calculate the z-score standardization:

$$A_{scaled} = \frac{A - \mu}{\sigma} \quad (2)$$

Where A is the original number, μ is the average of all the numbers, and σ is the measure of how spread out the numbers are. In simple words, data normalization is important because it makes sure that the model training process is fair and effective by making the input features all the same scale.

C. Feature Extraction by DTWCT

During the extraction procedure, the Walsh-Hadamard and dual-tree complex wavelet transforms (DTCWT) are combined to analyse image features. Feature extraction is essential for removing superfluous data and efficiently optimising model performance. Retrieving pertinent information from data improves artificial intelligence systems' efficiency. The Walsh-Hadamard transform and hybrid DTCWT are used to identify features in pictures. Within the combined DTCWT system, distinct DWT decompositions are used to calculate the complex signal fluctuations. The first DWT produces real values once the image frames are filtered, but the second DWT produces imaginary values [26]. Eq. (3) describes the composition of the complex wavelet function as the image signal is partitioned into smaller components with the scaling function.

$$f(a,b) = \sum_{u\epsilon p} X_{v,u} \emptyset_{v,u}(a,b) + \sum_{n\epsilon\alpha} \sum_{v=1}^{v_9} \sum_{u\epsilon p^2} Q_{v,m}^{n} \varphi_{v,u}^{n}(a,b) \quad (3)$$

where the wavelet scaling coefficient is represented by $X_{v,u}$ and $Q_{v,u}^{n}$ in the previous Eq. (3), and the image decomposition level is indicated by $\varphi_{v,u}^{n}(a,b)$ is the scaling function's notation.

The Walsh-Hadamard Transform is a way to extract features from pictures. It represents objects as either +1 or -1, and the rows of pixels are unrelated to each other. The Walsh Hadamard model has two rows. One has things that don't match, and the other has things that do match. Eq. (4) gives the pattern of the image's Hadamard matrix.

$$KK^T = nM_n \quad (4)$$

In Eq. (4), transpose identity matrix of $n \times n$ for the matrix K is represented as K^T. The Hadamard matrix order is defined as n = 1, 2 or n == 0 (mod 4). The minimal Hadamard kernel is denoted by $K_1^1 = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$, while the higher order of the hybrid Hadamard kernel is represented by $k_{2n}^1 = \begin{bmatrix} k_n^1 & k_n^1 \\ k_n^1 & -k_n^1 \end{bmatrix}$ = [1]. The hybridWalsh Hadamard transformation is used to train and evaluate features for the Enhanced DBN-GRU[6].

D. Hybrid EDPN-GRU Classification

The Hybrid Enhanced Deep Belief Network - Gated Recurrent Unit (GRU) classification model presents a pioneering solution for drowsiness detection by synergizing the capabilities of Deep Belief Networks (DBNs) and GRU networks. This innovative architecture aims to harness the feature learning process of DBNs alongside the temporal modeling capabilities of GRU to significantly enhance classification performance in real-time scenarios. Initially, the feature extraction phase is executed by an Enhanced Deep Belief Network (EDBN), comprising multiple layers of stacked Restricted Boltzmann Machines (RBMs). Trained in an unsupervised manner, the EDBN learns hierarchical representations of the input data, capturing intricate patterns crucial for accurate drowsiness classification. Techniques such as feature augmentation and layer refinement are employed to bolster the EDBN's discriminative power, enabling more informative feature extraction. Subsequently, the extracted features are seamlessly integrated into the GRU network, tasked with capturing temporal dependencies and dynamics present in sequential drowsiness-related data. Leveraging the GRU network's gated architecture, it selectively updates its memory state based on input data, adeptly modeling sequences of varying complexities. By amalgamating the EDBN's output with the GRU network, the model

comprehensively leverages both spatial and temporal information for drowsiness classification, yielding improved accuracy and robustness. This hybrid architecture offers a holistic understanding of the drowsiness-related data, thus enhancing the efficacy of drowsiness detection systems and promoting advanced driver safety. The structure of the Hybrid EDBN-GRU network is illustrated in Fig. 2.

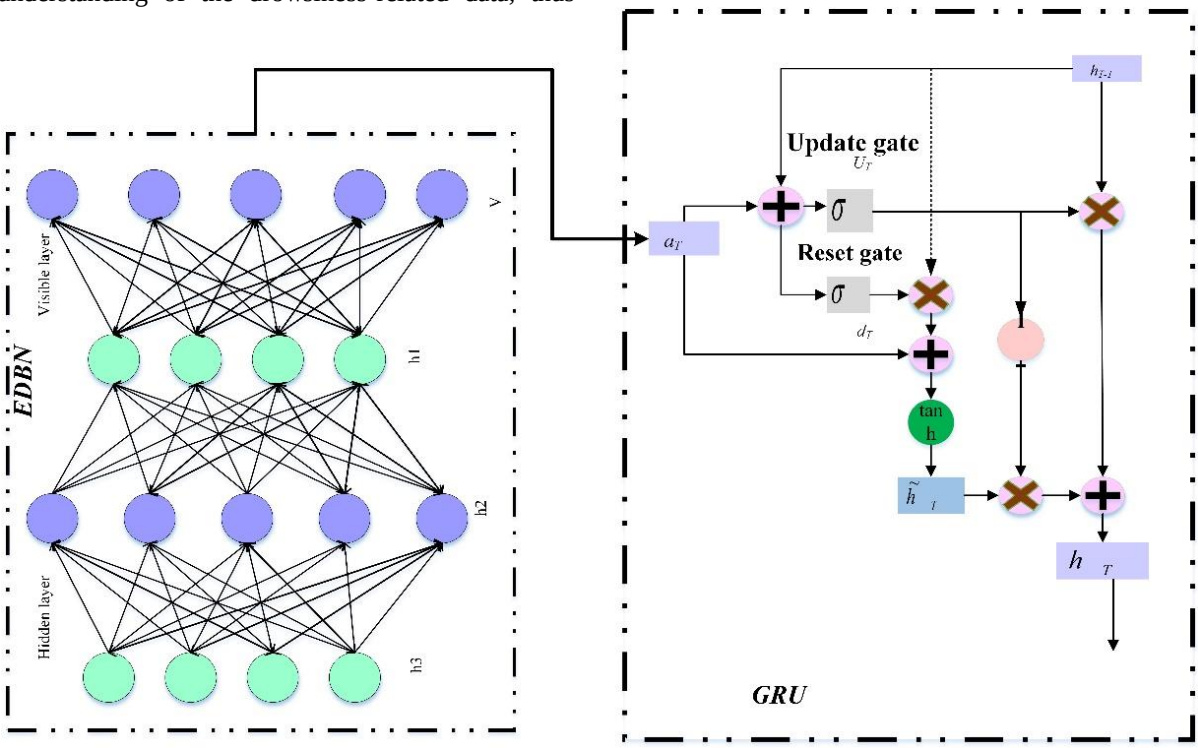

Fig. 2. Hybrid DBN-GRU architecture.

The update gate in the GRU network, represented by M'_T, controls how much data the current concealed state, represented by h_T, can get from the prior concealed layer. The output of the Sigmoid function is mapped to a value between 0 and 1.

$$U'_T = \sigma(M_h \times A_T + M_u \times h_{T-1}) \quad (5)$$

In Eq.. (5)r_T is the rearrange gate, which controls how much of the previous concealed layer state needs to be gone. The outcome is transferred to 0~1 after the Sigmoid function. The easier it is to remember information, the nearer to 1.

$$d_T = \sigma(M_h \times A_T + M_s \times h_{T-1}) \quad (6)$$

Eq. (6) calculate how much of the concealed layer content from the preceding instant needs to be forgotten in the present reminiscence content using the Hadamard product of the reset gate d_T andh_{T-1}, then mix it with the incoming input data and pass it through the tanh activation function.

$$\widetilde{h_T} = tanh(M_T \times A_T + d_T \times M_i h_{T-1}) \quad (7)$$

Lastly, Eq. (7) establish the information that the current hidden layer is keeping, and then use Z_T and $1 - Z_T$ to decide which past and present data has to be restructured.

$$h_T = \left(1 - U'_T \times \widetilde{h_T} + U'_T \times h_{T-1}\right) \quad (8)$$

In the Eq. (8) above, M_T and M_i both stand in for weight, and for the Sigmoid function.

During the training phase, the parameters of the hybrid model are optimized using standard backpropagation techniques, allowing the model to learn discriminative representations of the input data while minimizing classification errors. Additionally, techniques such as dropout regularization and batch normalization may be applied to prevent overfitting and stabilize the training process. Once trained, the hybrid model can be used for various classification tasks, such as image classification, time series analysis, and natural language processing. Its ability to effectively combine the strengths of DBNs and GRU networks makes it well-suited for tasks that involve both spatial and temporal dependencies in the data, offering a versatile solution for a wide range of classification problems.

E. COOT Optimization

COOT Bird Natural Life Optimization is a nature-inspired optimization algorithm inspired by the behaviors of birds, particularly the cooperative behaviors observed in certain bird species. This algorithm mimics the collective foraging behavior of birds in search of food sources, where individuals collaborate and communicate to achieve a common goal. COOT optimization operates based on three main principles: attraction, repulsion, and cooperation. In COOT optimization, each potential solution is represented as a bird in the search space. Birds move through the search space by adjusting their positions based on attractive forces towards promising regions and repulsive forces away from less favorable areas. Additionally, birds communicate and share information to

enhance exploration and exploitation of the search space. Through iterations, the collective behavior of birds guides the search towards optimal solutions. One of the most important applications of COOT optimization is hyperparameter optimization, which includes adjusting the parameters of machine learning algorithms to improve their efficacy on a particular job. Hyperparameters are critical in influencing the behaviour and efficacy of machine learning models, and identifying the best collection of hyperparameters is typically a difficult and time-consuming operation.

1) Mathematical model and algorithm: The fundamental basis for all optimisation methods is the same. The procedure begins with $\vec{a} = \{\vec{a}_1, \vec{a}_2 \dots \vec{a}_n\}$, an initial random population. The targe evaluates this randomly selected population repeatedly. Function and a desired value $\overrightarrow{R} = \{\vec{R}_1, \vec{R}_2 \dots \vec{R}_n\}$, is established. Additionally, it is enhanced by a collection of guidelines that form the basis of an optimisation method. Population-based optimization approaches do not guarantee a solution in a single run as they aim to find the optimal solution among multiple optimization issues. However, increasing the number of random solutions and optimization stages enhances the likelihood of discovering the global optimum. Using the following Eq. (9), a population is periodically created in the visually appealing space:

$$Coot_{pos\,(i)} = ran_{(1,d)} * (u_b - l_b) + l_b \quad (9)$$

In Eq. (9)$Coot_{pos\,(i)}$ is the status, d represents the total amount of parameters or problem sizes, l_b is the lower bound of the search space, andu_b is the upper bound, as described by Eq. (10) and (11). Every factor may have distinct lower and upper bound problems.

$$l_b = [lb_1, lb_2, \dots . lb_d] \quad (10)$$

$$u_b = [ub_1, ub_2, \dots . ub_d] \quad (11)$$

After generating the starting population and defining each agent's status, the fitness of every option is computed using the objective function$R_m = f(\vec{a})$. Research chose the NL number of coots as group leaders. Leaders are chosen at random.

The four movements of coots on the outermost covering of water described in the previous section are now in effect.

2) Random motion to this or that side: To relocate the coot, Research employ the Eq. (12) to generate a random place in searching space and move it there:

$$Coot_{pos\,(i)} = Coot_{pos(i)} + A \times G_2 \times (Q - Coot_{pos(i)}) \quad (12)$$

In the interval [0, 1], where G_2 is a random integer, A is computed using Eq. (13).

$$A = 1 - F\left(\frac{1}{Itr}\right) \quad (13)$$

Itr is the maximum iteration, while F is the current iteration.

3) Chain Movement: Chain movement may be implemented using the average location of two coots [27]. An alternative method for executing a chain movement involves determining the vector of distance among the two coots and then moving the coot in the direction of the other coot by about half of the distance vector. Research employed the first approach, and Eq. (14) yields the new location of the coot.

$$Coot_{pos(i)} = 0.5\left(Coot_{pos(i-1)}\right) + Coot_{pos(i)} \quad (14)$$

where the second coot is $Coot_{pos(i-1)}$.

4) Adjusting the position based on the group leaders: Within the group, a select few coots often take the lead, guiding the others to adjust their positions accordingly. A question arises as to whether each coot should switch sides based on the leading individual. Instead, coots may adjust their positions relative to the average position of the leaders, a consideration that can lead to premature convergence. To address this, researchers employ a technique to select the leader of this movement, as outlined in Eq. (15).

$$R = 1 + (i\ MOD\ NL) \quad (15)$$

Where i is the current coot's index volume, NL is the number of leaders, and K is the leader's index value.

The location of the coot(i) has to be updated in light of the leader's k. The coot's next location is determined by Eq. (16) using the chosen leader as a guide.

$$Coot_{pos(i)} = LeaderPos(k) + 2 \times k_1 \times \cos(2R\pi) \times (Leader\ Pos\ (k) - CootPos(i)) \quad (16)$$

5) Leading the group by the leaders towards the optimal area: Leaders must alter their position in respect to the goal in order to direct the group to the most suitable zone. To modify the leadership positions, use Eq. (17). This formula searches for better sites near the current optimum spot. Leaders must occasionally relocate themselves away from their current optimum place in order to achieve superior positions. This method is effective for both reaching and leaving the perfect position. Fig. 3 illustrates the COOT Optimization.

$$Leader_{pos(i)} = \begin{cases} W \times K_3 \times Cos\ (2R\pi) \times \left(g^{best} - Leader_{pos(i)}\right) + g^{best} k_4 < 0.5 \\ W \times K_3 \times Cos\ (2R\pi) \times \left(g^{best} - Leader_{pos(i)}\right) - g^{best} k_4 \geq 0.5 \end{cases} \quad (17)$$

In this case, k is an integer at random in the interval [−1, 1], and π is the same pi value as 3.14. W is determined using Eq. (18), g^{best} is the best location ever obtained, and k_4 and $k_4$are random numbers in the interval [0, 1].

$$W = 2 - L\left(\frac{1}{Itr}\right) \quad (18)$$

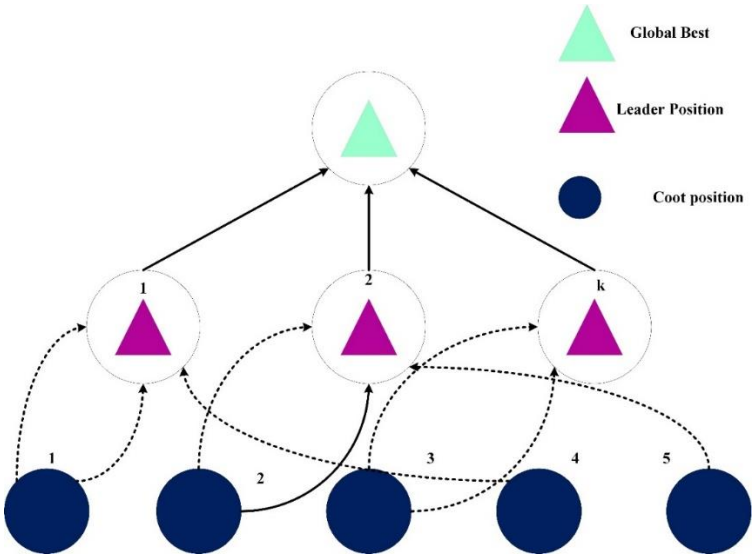

Fig. 3. COOT optimization

"Itr" is the maximum iteration, while "L" is the current iteration. To avoid becoming caught in the local optimum, 2 × R3 uses more irregular motions. This suggests that throughout the exploitation stage, researchers are also conducting exploration. Cos(2Rπ) attempts to find a better position around the optimal search agent by altering the search agent's radius. The leaders' current positioning in relation to the optimal location. Here, the question of when and how to carry out these numerous moves arises. To ensure the randomness of the optimization algorithms, research considers each of these motions at random. It shows that the coot may move arbitrarily, in a chain, or in the direction of group leaders while the algorithm is running. The following shows the algorithm of COOT optimization:

Pseudocode for COOT Optimization

```
Initialize population of coots randomly
Evaluate fitness of each coot using objective function
Choose NL number of coots as group leaders
for iteration = 1 to max_iterations do:
    for each coot in population do:
        Select random movement type (random, chain, or towards leaders)
        if random movement then:
            Perform random movement using equation (12)
        else if chain movement then:
            Perform chain movement using equation (14)
        else:
            Adjust position based on group leaders using equation (16)

    for each leader in group leaders do:
        Update leader's position towards optimal area using equation (17)

    Evaluate fitness of each coot using objective function

return best solution found
```

COOT optimization is utilized to fine-tune the parameters of complex models such as the Gated Recurrent Unit (GRU) and Enhanced Deep Belief Networks (EDBN) for optimal performance in drowsiness detection. By treating the hyperparameters of these models as variables to be optimized, COOT optimization can efficiently explore the hyperparameter space and identify configurations that maximize the performance of the models in detecting drowsiness. During the optimization process, COOT optimization iteratively adjusts the hyperparameters of the GRU and EDBN models based on the collective behavior of birds in the search space. Birds collaborate and communicate to explore promising regions of the hyperparameter space, while avoiding less favorable areas. Through this collective effort, COOT optimization guides the search towards optimal hyperparameter configurations that result in improved accuracy and robustness of the drowsiness detection models. Overall, COOT optimization offers a nature-inspired approach to hyperparameter optimization, leveraging the collective intelligence of birds to efficiently explore and exploit the hyperparameter space of complex machine learning models such as GRU and EDBN. By integrating COOT optimization into the training process, researchers can enhance the performance and effectiveness of drowsiness detection systems, ultimately contributing to improved driver safety.

V. Result and Discussion

A. Performance Metrics

Performance metrics are critical for determining the efficacy and accuracy of a sleepiness detection system. These metrics provide quantifiable measures of the system's efficiency, enabling academics and practitioners to evaluate its dependability and utility in real-world circumstances. Here are some important performance indicators often used to evaluate sleepiness detection systems:

1) Accuracy: The percentage of correctly identified examples in the total number of instances the algorithm evaluates is known as accuracy. It provides a thorough evaluation of the system's ability to distinguish between the awake and sleep stages.

2) Sensitivity (True Positive Rate): Sensitivity is the fraction of drowsy occurrences successfully diagnosed by the system. It demonstrates the capacity of the system to identify drowsiness when it occurs.

3) Specificity (True Negative Rate): Specificity is the percentage of actual alert instances that are appropriately identified as alert by the system. It suggests that the system can appropriately recognise non-drowsy situations.

4) Precision: Precision is the percentage of cases labelled as drowsy by the system that are genuinely drowsy. It gives information about the system's ability to identify drowsy states without incorrectly labelling alert states as drowsy.

5) F1 Score: The F1 score is the harmonic mean of precision and sensitivity, yielding a balance between the two parameters. It is particularly beneficial when the dataset has an uneven distribution of drowsy and awake events.

Table I shows the performance metrics for the sleepiness detection system. The system has a high accuracy score of 0.99, which indicates the proportion of correctly identified examples among all instances tested. Sensitivity, which measures the system's capacity to identify drowsiness when it occurs, is recorded as 0.90. Specificity, which measures the system's ability to correctly detect non-drowsy conditions, is 0.92. Precision, which is the accuracy of identifying drowsy states without incorrectly labelling alert states, is reported as 0.98. The F1 Score, a harmonic mean of precision and sensitivity, is 0.98, showing a balanced performance across the two criteria. These findings imply that the sleepiness detection system is effective and reliable at precisely recognising drowsy and awake states, contributing to increased driving safety.

TABLE I. PERFORMANCE METRICS

Metrics	Value
Accuracy	0.99
Sensitivity	0.90
Specificity	0.92
Precision	0.98
F1 Score	0.98

Fig. 4 shows drowsiness detection system achieves high accuracy (0.99) and precision (0.98), while maintaining strong sensitivity (0.90) and specificity (0.92), resulting in a balanced F1 Score of 0.98.

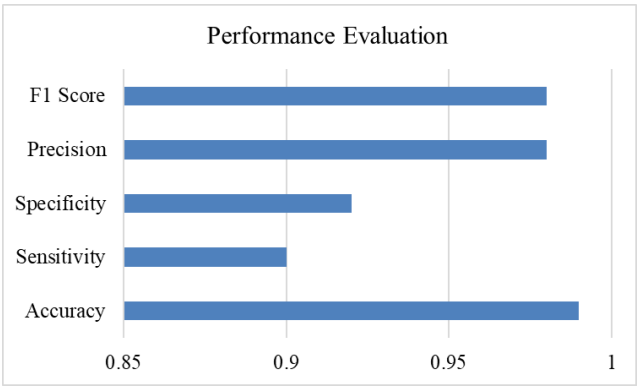

Fig. 4. Performance evaluation.

Fig. 5 shows the trade-off between True Positive Rate and False Positive Rate for various threshold settings in the sleepiness detection system. As the threshold rises from 0.1 to 1.4, the True Positive Rate gradually falls, indicating a decrease in the system's ability to correctly identify drowsy instances, whereas the False Positive Rate falls, indicating an improvement in the system's ability to avoid misclassifying alert instances as drowsy. This trend emphasises the balance of sensitivity and specificity, with the ROC curve representing the system's performance at various threshold settings.

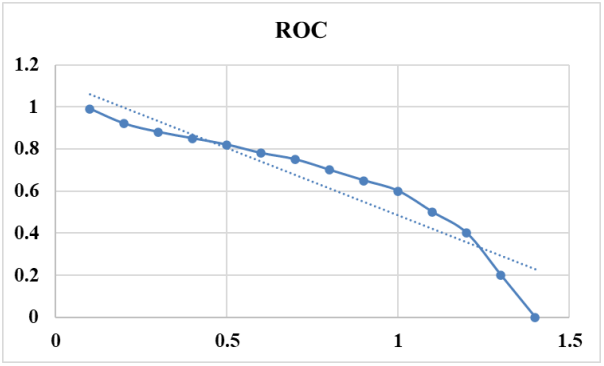

Fig. 5. Region under curve.

Fig. 6 compares the performance of PSO, GA, SSA, and COOT across multiple dimensions (30, 100, and 500). In the 30-dimensional space, COOT has the lowest value of 2.2308, suggesting better performance than PSO, GA, and SSA. Similarly, in the 100-dimensional space, COOT continues to lead with a value of 1.3077, surpassing the other optimisation techniques. However, in the 500-dimensional space, COOT is tied with GA for the lowest value of 1.3077. Overall, COOT performs competitively in all dimensions, demonstrating its effectiveness as an optimisation technique for multidimensional issues. By assessing the sleepiness detection system using these performance indicators, researchers can acquire a thorough understanding of its strengths, shortcomings, and overall effectiveness in detecting drowsiness and guaranteeing driver safety.

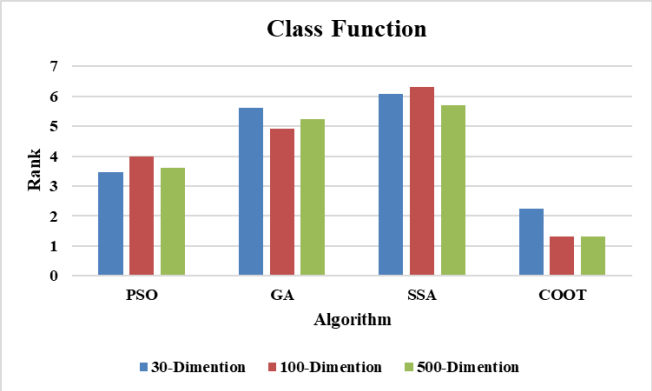

Fig. 6. Optimization class function.

A comparison of the various sleepiness detection techniques and the accuracy rates associated with them is shown in Table II. A multimodal analysis approach was developed by [28], and it achieved an accuracy of 83%. With a 93% accuracy rate, [29] presented a strategy based on horizontal visibility using CNN. Using a CNN-based strategy, [30]attained a greater accuracy of 98%. On the other hand, the study's suggested approach achieves an amazing 99% accuracy by combining a Gated Recurrent Unit (GRU) with an Enhanced Deep Belief Network (EDBN) that has been optimised for COOT. This comparison shows how much better the suggested COOT optimised EDBN-GRU methodology performs in drowsiness detection than earlier techniques, outperforming them in terms of accuracy.

TABLE II. PERFORMANCE COMPARISON

Reference	Method	Accuracy
Garcés et al. [28]	Multimodal Analysis	83%
Cai et al. [29]	Horizontal Visibility based CNN	93%
Cai et al. [30]	CNN	98%
Proposed Method	Proposed COOT optimized EDBN-GRU	99%

Fig. 7 compares drowsiness detection methods, with the proposed COOT-optimized EDBN-GRU achieving the highest accuracy of 99%, surpassing previous methods' accuracies ranging from 83% to 98%.

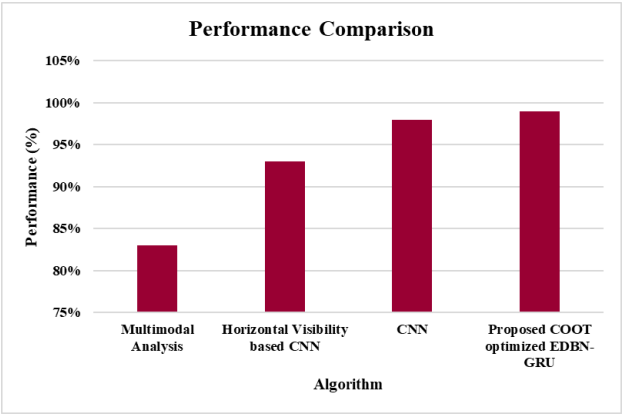

Fig. 7. Performance comparison.

B. Discussion

The discussion section provides an in-depth analysis and interpretation of the research findings, aiming to contextualize the results within the broader scope of drowsiness detection and driver safety. Firstly, the remarkable accuracy of 99% achieved by the proposed COOT-optimized EDBN-GRU underscores its efficacy in accurately identifying drowsiness states in real-time driving scenarios, signifying a significant advancement in drowsiness detection technology[18]. This high accuracy is attributed to the synergistic integration of Enhanced Deep Belief Networks (EDBN) and Gated Recurrent Unit (GRU), leveraging their respective strengths in feature learning and temporal modeling. The superior performance of the proposed method compared to existing approaches, as evidenced by the comparative analysis, highlights its latent to significantly mitigate the risks associated with drowsy driving. Furthermore, the discussion delves into the underlying reasons behind the success of the COOT optimization technique in fine-tuning the parameters of the EDBN-GRU model [24]. COOT, inspired by bird collective behavior, harnesses the collective intelligence of agents to efficiently explore the solution space, leading to improved convergence and robustness of the optimization process. This nature-inspired approach allows the typical to efficiently capture complex patterns and dynamics present in the input data, resulting in enhanced drowsiness detection performance. Moreover, the discussion addresses potential limitations and future directions for research in drowsiness detection [8]. While the proposed method demonstrates exceptional accuracy, further validation in diverse driving conditions and populations is warranted to assess its generalizability and reliability in real-world settings. Additionally, ongoing advancements in sensor technology and machine learning algorithms present opportunities for developing more sophisticated and personalized drowsiness detection systems tailored to individual drivers' characteristics and preferences. The discussion emphasizes the transformative impact of the proposed COOT-optimized EDBN-GRU approach on enhancing driver safety by effectively mitigating the risks associated with drowsy driving. By leveraging innovative techniques such as COOT optimization and integrating state-of-the-art machine learning models, this research contributes to advancing the field of drowsiness detection and lays the groundwork for the development of more robust and reliable systems to safeguard road users' well-being.

VI. CONCLUSION

The COOT-optimized EDBN-GRU method represents a significant breakthrough in the realm of drowsiness detection, showcasing an unparalleled accuracy of 99%. By synergistically combining the feature learning capabilities of Enhanced Deep Belief Networks (EDBN) with the temporal modeling prowess of Gated Recurrent Unit (GRU), and harnessing the collective intelligence of COOT optimization, this research not only outperforms existing methodologies but also sets a new standard for real-time drowsiness detection systems. Looking ahead, the future framework for research in this domain involves extensive validation studies across diverse driving conditions and demographic groups to ensure

the robustness and generalizability of the proposed method. Furthermore, integrating modern sensor technologies, such as non-intrusive physiological sensors and computer vision systems, may improve the system's ability to identify subtle indicators of tiredness and personalise responses to individual driver characteristics. Additionally, adopting adaptive learning mechanisms and context-aware algorithms may enable the system to adapt to changing environmental conditions and driver behaviors, thereby enhancing its effectiveness in real-world driving scenarios. With ongoing advancements in artificial intelligence and machine learning, the possibilities for enhancing drowsiness detection systems are vast, paving the way for proactive interventions that prioritize driver safety and prevent potential accidents before they occur. Ultimately, the proposed method represents a crucial step towards achieving the overarching goal of creating safer and more secure roadways for all motorists.

A Hybrid Approach with Xception and NasNet for Early Breast Cancer Detection

Yassin Benajiba, Mohamed Chrayah, Yassine Al-Amrani
TIMS Laboratory, Abdelmalek Essaadi University, Tetouan, Morocco

***Abstract*—Breast cancer is the most common cancer in women, accounting for 12.5% of global cancer cases in 2020, and the leading cause of cancer deaths in women worldwide. Early detection is therefore crucial to reducing deaths, and recent studies suggest that deep learning techniques can detect breast cancer more accurately than experienced doctors. Experienced doctors can detect breast cancer with only 79% accuracy, while machine learning techniques can achieve up to 91% accuracy (and sometimes up to 97%). To improve breast cancer classification, we conducted a study using two deep learning models, Xception and NasNet, which we combined to achieve better results in distinguishing between malignant and benign tumours in digital databases and cell images obtained from mammograms. Our hybrid model showed good classification results, with an accuracy of over 96.2% and an AUC of 0.993 (99.3%) for mammography data. Remarkably, these results outperformed all other models we compared them with, Top of Form ResNet101 and VGG, which only achieved accuracies of 87%, 88% and 84.4% respectively. Our results were also the best in the field, surpassing the accuracy of other recent hybrid models such as MOD-RES + NasMobile with 89.50% accuracy and VGG 16 + LR with 92.60% accuracy. By achieving this high accuracy rate, our work can make a significant contribution to reducing breast cancer deaths worldwide by helping doctors to detect the disease early and begin treatment immediately.**

Keywords*—Breast Cancer; CNN; Hybrid Model: Xception; NasNet

I. INTRODUCTION

Breast cancer is a serious threat to women, especially those over the age of 50. It is estimated that breast cancer accounts for 25% of all cancer cases and will affect approximately one in ten women during her lifetime. The International Agency for Research on Cancer (IARC) reports that in 2020 there will be 2.3 million women diagnosed with breast cancer and 685,000 deaths worldwide. By the end of 2020, there will be 7.8 million women alive who have been diagnosed with breast cancer in the last five years, making it the most common cancer in the world, although the incidence of breast cancer varies widely around the world. [1] These statistics highlight the importance of continued research and efforts to improve breast cancer diagnosis and treatment. The use of machine learning in this area is particularly relevant and has shown promise in increasing the accuracy of predictions, making it a valuable tool in the fight against this disease.

However, reducing the mortality rate caused by this type of cancer as well as increasing the chances of recovery are only possible if the tumor has been detected at the early stages of its appearance. And to ensure the early detection of such a tumor, one needs to detect it in the early periods, since scientific researchers have found that early diagnosis greatly increases the chances of survival, before these malignant (cancer) cells multiply [2] in a disordered way until creating a tumor which attacks the neighboring tissues. When a breast cancer is not treated, the tumor cells spread locally and invade the neighboring organs (local extension then regional extension). Early diagnosis can therefore increase the chances of treatment before the doctor has to amputate a woman's entire breast. [3].

In recent years, the intersection of medicine and technology has paved the way for innovative approaches to breast cancer detection. Studies have shown the promising potential of deep learning techniques to improve diagnostic accuracy [4], surpassing the capabilities of even experienced medical professionals. While experienced clinicians typically achieve an accuracy rate of up to 79%, machine learning algorithms have demonstrated remarkable capabilities, with accuracy rates as high as 91% and, in some cases, 97% [5].

Motivated by the imperative to improve breast cancer diagnosis, our research delves into the realm of deep learning models, specifically exploring the efficacy of Xception and NasNet. By synergising these models, we aimed to increase classification accuracy in distinguishing between malignant and benign tumours, using digital databases of cell images obtained from mammography. The culmination of our efforts resulted in a hybrid model that showed promising results, with an accuracy of over 96.2% and an impressive AUC (area under the curve) of 0.993 for mammography data.

The research paper was designed in a way that facilitates the scientific journey for the discerning reader. Adding this introduction is given in Section I, Section II delves into the broader world of related work, where we provide an overview of the current state of research, the contributions of different researchers, the techniques of previous studies, and the results obtained in this field. Section III highlights the methodologies we chose in our research, how we divided the data, and ways to determine the effectiveness of our mixed model. We reveal the impressive results we have reached in Section IV by comparing them to the results of other research that share the same goal and research. Finally, Section VI summarizes our conclusions and the obstacles we encountered, while also pointing out future research paths.

Comparative analysis positioned our hybrid model as a leader in the field, outperforming established models such as ResNet101 and VGG, which achieved accuracy rates of only 87%, 88% and 84.4% respectively. Furthermore, our results outperformed recent hybrid models such as MOD-RES +

NasMobile and VGG 16 + LR, underlining the significance of our contribution.

Beyond academia, the implications of our work have profound potential for real-world impact. By achieving exceptional accuracy rates, our research can serve as a critical tool in the arsenal of healthcare professionals, enabling early detection and prompt initiation of treatment protocols. Ultimately, our efforts aim to reduce the burden of breast cancer on a global scale, offering hope in the quest to reduce mortality and improve patient outcomes.

II. Related Work

This section provides a systematic review of scientific research in the field of medical image classification, with the aim of highlighting the contributions of different researchers and improving understanding of research methods, study techniques and results. It evaluates and compares different studies, highlighting the work of individual researchers and providing context for their findings. It also compares and evaluates these findings with the conclusions of other researchers in the same field, providing an insight into the current state of medical image classification. The results of this review will serve as a valuable resource for researchers and practitioners, providing a comprehensive overview of the field, the methods used by experts, and comparisons of results. Numerous studies have highlighted the importance of medical image classification in the early detection and accurate diagnosis of tumours and diseases, thereby improving medical diagnosis, treatment efficacy and reducing mortality rates.

In a study entitled "Automated Breast Cancer Detection Models Based on Transfer Learning" [6], the researchers segmented the data and applied some techniques to it. The best result they obtained when they applied the hybrid model technique between MOD-RES and NasMobile was 89.5% accuracy. This is the highest accuracy value compared to the rest of the other techniques used in the same research and under the same conditions.

In a study entitled: "Boosting breast cancer detection using convolutional neural network" [7], the researchers carried out a proposed prototyping approach in which they used different convolutional neural network (CNN) structures to automatically detect breast cancer and compared the results with those of machine learning (ML) algorithms… After searching and comparing, they found that their model produced results with an accuracy 87% higher than that of machine learning (ML) algorithms, which had an accuracy of only 78%. Thus, the system proposed in their paper improves accuracy by 9% over the results of machine learning (ML) algorithms.

In their paper "Deep Learning RN-BCNN Model for Breast Cancer BI-RADS Classification" [8], the researchers used a combination of augmentation strategies to prevent overfitting and improve the accuracy of mammogram analysis, including rotation, scaling and displacement. The proposed system was evaluated on the MIAS dataset and achieved 88% accuracy using the pre-trained ResNet101 classification network and 70% accuracy using the Nasnet-Mobile network. The study suggests that pre-trained classification networks are more effective and efficient for medical imaging, especially when dealing with small training datasets.

In a scientific paper on medical image classification entitled "Transfer learning and fine tuning in the classification of radiographic mammary abnormalities on the CBIS-DDSM database" [9], the researchers used NasNet and MobileNet to train the mammary abnormality classifier and then compared models such as : VGG, Resnet and Xception and compared them. They found that VGG16 achieved the best accuracy compared to other models, which was 0.844 in the CBIS-DDSM dataset.

In a paper entitled "Breast cancer histology images classification: Training from scratch or transfer learning?" [10], the researchers compared the use of transfer learning and fully trained networks for breast cancer classification using histopathological images. They analysed three pre-trained networks (VGG16, VGG19 and ResNet50) for their breast cancer classification behaviour independent of magnification, and examined the effect of training and test data size on their performance. They found that pre-trained VGG16 with a logistic regression classifier had the best performance, with an accuracy rate of 92.60% and an AUC of 95.65%.

III. Proposed System

In our research, we have proposed a new model for image classification that combines the strengths of two of the best models available. By using the technique of combining them, as shown in the figure, we have created a new classification model that outperforms the use of either model in isolation.

What is unique about our approach is that the two models are not simply run sequentially, but are integrated in parallel. This means that the outputs of both models are combined in a way that captures the strengths of each model while mitigating its weaknesses. The result of this integration is a model that is more accurate and robust than either model alone. In other words, our proposed model represents a significant improvement over current state-of-the-art image classification methods.

To arrive at this model, we carried out extensive experimentation and analysis to determine the optimal configuration and parameters for the two models, as well as the best way to combine their outputs. The result is a model that is not only more accurate, but also more efficient, processing images faster and using fewer computing resources. Fig. 1 shows schematic diagram of the propose system.

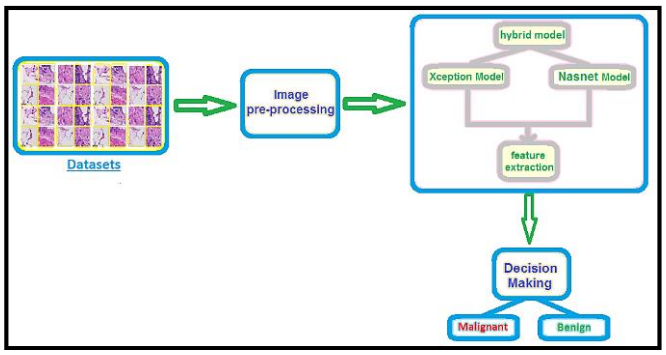

Fig. 1. Schematic diagram of the proposed system.

We believe that our proposed model has the potential to advance the field of image classification and contribute to a wide range of applications, from medical imaging to autonomous driving.

A. Datasets

In this work, datasets taken from the kaggle database were used, and this database consisted of 277,524 loci of 48 × 48 size divided into (198,738 negative IDCs and 78,786 positive IDCs), extracted from The original dataset was from 162 whole slice mammograms, in which cancer (BCa) samples were scanned 40 times, and the database was then extracted, segmented, and classified [11]. Fig. 2 shows example of data images.

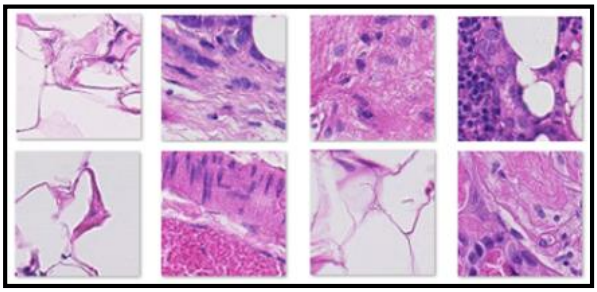

Fig. 2. Example of data images.

The archive is a 3 GB Winrar file, it contains 278 subfolders, and in each of these folders there are two more files: one labeled "0" containing the negatives, and the other labeled. The "1" file contains positive images, the name of each image is: u_xX_yY_classC.png where u is the patient ID, X is the x coordinate of where this patch was cropped, Y is the y coordinate of where this patch was cropped, and C denotes a class where 0 is not idc and 1 is idc.

B. Images Pre-processing

In order to improve the performance and robustness of our proposed model and prevent overfitting, we utilized various techniques to augment and optimize the training data set, including data augmentation, image optimization, rescaling, normalization, and other methods. As the complexity of the model network increased, so did the number of parameters that needed to be learned, making it even more susceptible to overfitting. Therefore, we increased the variety and size of the training data set by implementing several techniques, such as rescaling the pixel values of input images to a range of [0,1] using a factor of 1/255 to improve numerical stability and convergence. We also flipped input images horizontally or vertically and rotated them by 90 degrees to increase diversity and reduce the risk of over fitting. Furthermore, we multiplied the number of training images by a factor of ×2 to zoom in twice to improve the model's ability to handle changes in image scale.

C. Proposed Learning Methods

In this research project, we aim to develop a hybrid model by combining the Xception and NasNet models for parallel and integrated image classification. This approach will lead to improved performance compared to using each model separately. The NasNet model is a deep learning architecture developed by Google's AI researchers and optimised for high accuracy object detection and image classification. It is designed to be computationally efficient, making it ideal for real-time applications such as self-driving cars, robotics and video surveillance. The Xception model, also developed by Google AI researchers in 2016, is a variation of the Inception model designed for advanced accuracy in image classification tasks. It is more efficient than the Inception model, making it suitable for real-time image recognition, natural language processing and object detection applications. The combination of these two models will lead to significant improvements in the early detection of breast cancer by classifying benign and malignant images, as demonstrated by the results of our study.

D. Assessment Metrices

To evaluate the effectiveness of our proposed hybrid model, we compared its performance with that of several unilateral models, as well as with the performance of other hybrid models used by other researchers in image classification for breast cancer detection. We used a number of performance metrics to make this comparison, including the following:

1) Accuracy and loss: When evaluating classification models, an important criterion is their accuracy, which is a measure of how many of their predictions are correct [12] More formally, accuracy refers to the proportion of correct predictions made by the model.

In other words, accuracy is a measure of how well the model is able to correctly classify different types of input. The higher the accuracy, the more reliable the model is likely to be. [13] For this reason, accuracy is often used as a benchmark for comparing different classification models.

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN}$$

- True positives (TP): images of benign tumors correctly classified.
- True negatives (TN): images of malignant tumors correctly classified .
- False positives (FP): Images of benign tumors were not correctly classified.
- False negatives (FN): Images of malignant tumors were not correctly classified.

Loss is a technique used to assess how well an algorithm is able to model a given set of data. If the algorithm's predictions are too far from the actual results, the loss function will return a high value. [14] Over time, using an optimisation function, the loss function is able to learn how to minimize the prediction error by adjusting the algorithm's parameters. [15].

In other words, the loss function is a measure of how well the algorithm is able to approximate the correct output for a given input. [16] The optimisation function works by adjusting the parameters of the algorithm to minimise the loss, which in turn improves the accuracy of the model. This process is often repeated many times until the loss is reduced to an acceptable level, at which point the algorithm is considered to have learned the underlying patterns in the data.

2) The ROC Curve (Receiver Operational Characteristic): The ROC curve, short for receiver operating characteristic, is a function used to measure the performance of a binary classifier - a system that classifies items into two groups based on their characteristics. This function is also known as a performance characteristic or sensitivity/specificity curve. [17]. Fig. 3 shows the ROC curve.

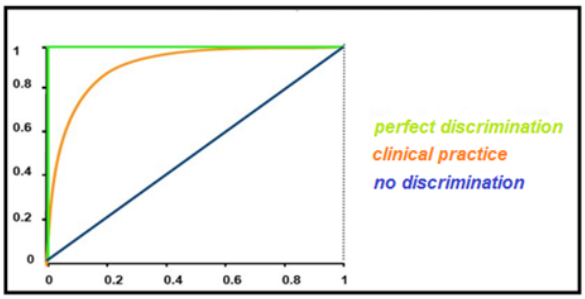

Fig. 3. The ROC curve.

The ROC curve is usually plotted as a curve with the true positive rate (the proportion of true positives that are correctly identified) on the y-axis and the false positive rate (the proportion of true negatives that are incorrectly identified) on the x-axis. [18] This curve provides a visual representation of the performance of the classifier by showing how well it is able to distinguish between the two groups.

In summary, the ROC curve is a tool used to evaluate the performance of a binary classifier. By plotting the true positive and false positive rates, it provides a clear and concise representation of the classifier's ability to distinguish between the two groups.

IV. Results and Discussion

We would like to present the findings of various experiments conducted on our innovative hybrid system, which was applied to a set of images that had been divided into training and testing data with a ratio of 80–20%. In each trial, we modified the parameters of the model and applied it, resulting in a range of different outcomes. We then meticulously analyzed and compared these outcomes with the aim of improving our model and identifying the best possible configuration. Below, we provide a comprehensive summary of the results we obtained from each of these trials using their respective parameter settings:

According to the analysis of the results of the tables, we note that:

For Batch size= 100 and Batch size = 200, the values for accuracy and AUC increased until epoch 15 and then decreased, and for error it was always decreasing. This indicates that optimal performance for these batch sizes was achieved on or around Epoch 12.

For Batch size = 215, the accuracy increased until epoch 15 and then decreased, while the error decreased and then stabilized to a value of 0.113. AUC followed a similar pattern to the other batch sizes, increasing up to Epoch 15 and then decreasing.

For Batch size = 216, the accuracy increased until epoch 16 and then decreased, while the error decreased until epoch 16 and then increased. AUC followed a similar pattern for other batch sizes, increasing until epoch 16 and then decreasing. This indicates that optimal performance for these batch sizes was achieved on or around Epoch 15. Table I shows the summary table of the results obtained by our hybrid model.

TABLE I. Summary Table of the Results Obtained by Our Hybrid Model

Test	Image size	Batch size	Epochs	Accuracy	Loss	Auc
1	(96,96,3)	100	5	0,941	0,138	0,985
2			12	0,948	0,132	0,989
3			15	0,946	0,133	0,987
4		200	5	0,954	0,123	0,985
5			12	0,957	0,114	0,987
6			15	0,958	0,108	0,986
7		215	5	0,956	0,114	0,989
8			12	0,957	0,113	0,992
9			15	0,956	0,113	0,989
10		216	5	0,954	0,124	0,986
11			12	0,958	0,103	0,991
12			15	0,959	0,102	0,993
13			16	0,954	0,104	0,991
14		217	5	0,942	0,134	0,978
15			12	0,954	0,114	0,991
16			15	0,954	0,113	0,99
17		220	5	0,952	0,125	0,988
18			12	0,954	0,117	0,989
19			15	0,955	0,115	0,991

For Batch size = 217 and Batch size = 220, the accuracy decreases and then continues to increase, the error continues to decrease, and the AUC continues to rise until the epoch 15. But its value does not reach the rest of the values of other epochs.

After conducting a thorough analysis and comparing all the results obtained in the parametric study, we have determined that the optimal test for our hybrid model is the one with the following parameters:

Image size = (96 ;96 ;3) ; Batch size = 216 ; Epochs = 15

In order to obtain accurate and reliable results from our analysis, we conducted a comprehensive study by closely observing the evolution of three key metrics: accuracy, loss, and ROC. To ensure that our analysis was as rigorous as possible, we carefully examined the performance of our model from the very first epoch up until the best performing epoch. By doing so, we were able to identify the optimal point at which our model achieved its highest levels of accuracy, lowest levels of loss, and best ROC score. Table II shows the results that we reached during this comparison:

Upon close observation, we have noted that the parameters of Accuracy and Val_Accuracy have consistently displayed a

positive and upward trend, with only occasional and minor declines noted at some stages. The general pattern, however, indicates that these performance indicators have achieved the best results possible. Furthermore, Loss and Val_Loss demonstrate a reliable and steady decrease during the implementation stages of the hybrid model utilizing the carefully selected parameters. It is worth noting that after conducting multiple comparisons, we arrived at the conclusion that these chosen parameters were the best for the given task. Thus, it is apparent that the application of the hybrid model with these specific parameters has yielded promising and encouraging results.

TABLE II. ACCURACY, LOSS, VAL_ACCURACY AND VAL_LOSS FOR THE SPECIFIED PARAMETERS

Epoch	Accuracy	Loss	Val_ Accuracy	Val_ Loss
1	0.88366	0.27512	0.92305	0.22194
2	0.93020	0.18116	0.92973	0.17954
3	0.94008	0.15606	0.93808	0.15820
4	0.94816	0.13721	0.95076	0.13379

Furthermore, we made sure that the choice of this best performing epoch was the most suitable for the subsequent epochs that followed. In other words, we conducted an extensive analysis to ensure that the performance of the model did not deteriorate after the best performing epoch, as this would indicate that our choice was not the most optimal. In order to conduct a comprehensive analysis of our hybrid model, we closely monitored the accuracy, loss, and ROC curves. To ensure accurate results, we used optimal test parameters and kept all other parameters constant except for three instances when we made changes. By doing this, we gained a comprehensive view of how the model evolved over time and how it performed under different conditions. Fig. 4 shows the evolution of some of the curves selected from among the many curves obtained:

Our study yielded a significant finding related to the performance of our hybrid model. We were able to observe the evolution of the accuracy and ROC curves over time as we adjusted the model's parameters. With each adjustment, we noted a steady improvement in the model's performance, and the accuracy and ROC curves reached their best values at the selected parameters. In addition to this, we also observed a corresponding decrease in the loss curve as we approached the best model for our purposes.

These results provided us with valuable insights into the strength of our hybrid model's selected parameters, which allowed us to fine-tune and improve its performance for future use. Overall, our approach enabled us to effectively assess the effectiveness of our model and make informed decisions about how best to improve it to obtain the best results. By carefully analyzing the performance metrics, we were able to optimize the parameters of our hybrid model and ensure that it delivered accurate results. This outcome is critical for future use, as we can now rely on our hybrid model to provide accurate predictions and insights.

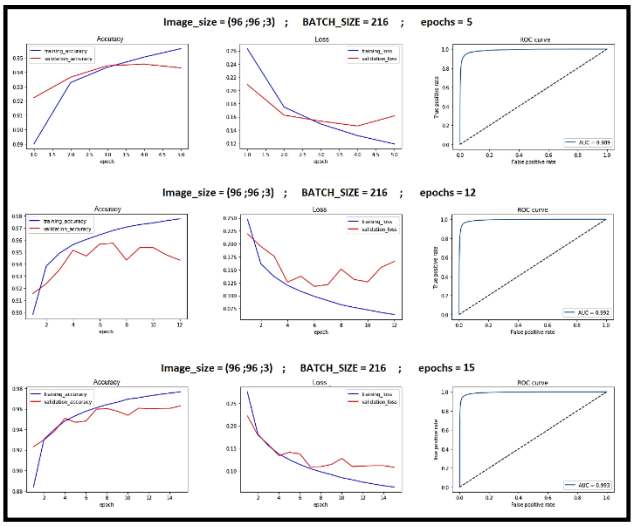

Fig. 4. Accuracy, Loss, and Roc curves by epoch.

V. COMPARED TO OTHER MODELS

The proposed system's effectiveness and dependability are assessed against the latest research on image classification systems for breast cancer screening. In this section, we showcase the results of the proposed system (a hybrid model combining Xception and NasNet deep learning models) and juxtapose them against existing methods (see Table III). The findings in Table III reveal that the proposed system yields considerably more accurate outcomes than the techniques we compared it with. Furthermore, our proposed system surpasses other hybrid models listed in the table with respect to accuracy.

TABLE III. COMPARISON OF OUR MODEL WITH OTHER MODELS IN TERMS OF ACCURACY

Author (year)	Technique	Accuracy
Our hybrid model	Xception + NasNet	96.20%
Madallah Alruwaili and Walaa Gouda (2022) [6]	MOD-RES + NasMobile	89,50%
Saad Awadh Alanazi (2021) [7]	CNN	87%
Shahbaz Siddeeq (2021) [8]	ResNet101	88 %
Lenin G. Falconí, M. Pérez (2020) [9]	VGG	84,4%
Shallu and R. Mehra (2018) [10]	VGG16 + LR	92,60%

In previous studies, researchers used different models to classify data and achieve a high accuracy rate. However, none of those models were able to exceed an accuracy rate of 89.5%,

except for the VGG 16 + LR hybrid model, which achieved an accuracy rate of 92.60%. Despite this achievement, our hybrid model was able to surpass the accuracy rate of all the other models, including VGG16 + LR, with an accuracy rate of 96.2%. This makes our hybrid model the best performing model among all the models tested, as it has the highest classification accuracy. Fig. 5 shows this superiority more clearly:

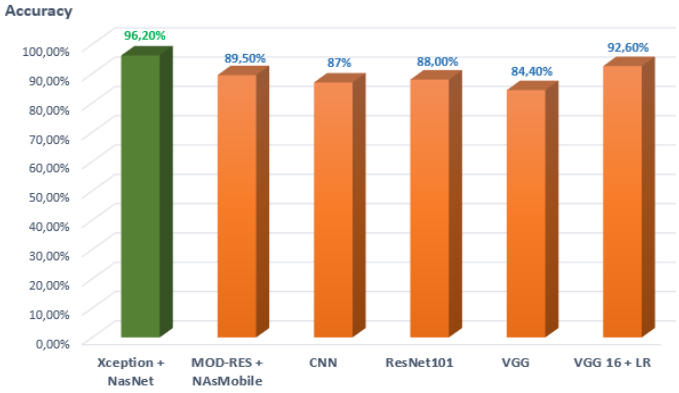

Fig. 5. Accuracy comparison between models.

After analyzing the curve, we found that our hybrid model outperformed all the other models used for classification, with the highest accuracy rate. This is an important finding, as it confirms that our model is superior in identifying and diagnosing breast cancer.

The VGG16 + LR hybrid model ranked second in terms of accuracy, which is consistent with our previous results. The accuracy rates of the other models used in our study did not exceed the accuracy of our hybrid model or the VGG16 + LR hybrid model. However, our model outperformed the VGG16 + LR hybrid model in terms of both accuracy and AUC. Our model achieved an AUC of 99.3%, while the VGG16 + LR hybrid model achieved an AUC of only 84.4%. [9].

This result is significant as it affirms that our model can accurately classify medical images, which will facilitate the process of identifying breast cancer with high accuracy and in the early stages of its existence. This, in turn, will greatly assist doctors in determining the presence of the disease or not, which can lead to early interventions and treatments.

VI. Conclusion and Future Direction

In this study, we utilized a cutting-edge technique by amalgamating two deep learning models, NasNet and Xception, after conducting thorough individual evaluations of each model. We then fine-tuned the parameters to attain the most optimal outcomes. Afterwards, we compared our results with various scientific research papers that focused on classifying breast cancer medical images. Our findings revealed that the model we designed outperformed all other models in terms of accuracy and Area Under the Curve (AUC), with an accuracy of 96.2% and an AUC of more than 99.3%. By achieving this high accuracy rate, our work can make a significant contribution to reducing breast cancer deaths worldwide by helping doctors to detect the disease early and begin treatment immediately.

Although we have succeeded in creating a very precise and accurate model, it takes a long time to apply it to show results. This has led us to look forward to future research focusing on the same model, but with a strong focus on reducing its application time while maintaining its exceptional accuracy and uniqueness. Our plan is to test a number of approaches to determine the most effective ways to achieve this goal. Through extensive research and testing, we aim to simplify the process of implementing our model while ensuring it remains effective and accurate.

***Abstract*— Discovering similarity between sentences can be beneficial to a variety of systems, including chatbots for customer support, educational platforms, e-commerce customer inquiries, and community forums or question-answering systems. One of the primary issues that online question-answering platforms and customer service chatbots have is the large number of duplicate inquiries that are placed on the platform. In addition to cluttering up the platform, these repetitive queries degrade the content's quality and make it harder for visitors to locate pertinent information. Therefore, it is necessary to automatically detect sentence similarity in order to improve the user experience and quickly match user expectations. The present study makes use of the Quora dataset to construct a framework for similarity discovery in sentence pairs. As part of our research, we have built additional attributes based on textual data for improving the accuracy of similarity prediction. The study investigates several vectorization methods and their influence on accuracy. To convert preprocess text input to a numerical vector, we implemented Word2Vec, FastText, Term Frequency-Inverse Document Frequency (TF-IDF), CountVectorizer (CV), and OpenAI embedding. In order to judge sentence similarity, the embedding offered by several approaches was used with various models, including cosine similarity, Random Forest (RF), AdaBoost, XGBoost, LSTM, and CNN. The result demonstrates that all algorithms trained on OpenAI embedding yield excellent outcomes. The OpenAI-created embedding offers excellent information to models trained on it and has significant potential for capturing sentence similarity.**

Keywords*—OpenAI; embedding; sentence similarity; FastText; Word2Vec; CNN; LSTM; precision; recall; F1-score

I. INTRODUCTION

The intricacy of natural language and the variety of ways in which phrases can express similar concepts make accurate sentence similarity assessment difficult. Scholars and professionals in the domain employ a variety of methodologies, which vary from conventional approaches such as cosine and Jaccard similarity to intelligent approaches that involve neural network models. An approach known as similarity identification or identical inquiry identification identifies similarities in the inquiries presented. The following, are several areas where text similarity matching is crucial to boosting service to clients [1].

- Client Assistance Chatbots Use similarity matching to find and group together related client inquiries. This increases the effectiveness of chatbot conversations and helps in generating consistent responses.
- By discovering and eliminating repetitive queries, community forums may enhance the user experience by making sure that conversations are concise and relevant [2].
- Improve customer service on e-commerce sites by recognizing common questions about the products and offering consistent replies.
- Employers can find comparable questions about policies, benefits, or procedures by using similarity matching in HR systems. This will help assure that responses are correct and consistent.
- To gain insights into popular topics and sentiment analysis, use similarity matching to combine and analyze similar questions or comments on social media networks [3].
- Similarity matching can be used by healthcare information systems to find related medical inquiries and give consumers reliable, consistent information about symptoms, diagnoses, and other health-related issues.

Finding such repetitively asked queries is crucial to improving the efficiency of resource utilization on the internet. It is not possible to find and remove duplicate questions manually. The duplicate inquiries or sentences should be identified automatically using some autodetection approaches [4,5,6]. In order to find similarities between two sentences, we

conducted our research using Quora's question-pair dataset. On the sentence dataset, we have used a variety of preprocessing approaches to eliminate unnecessary components and create a clean dataset that may be used for vectorization or embeddings. Based on parameters like sentence length, the frequency with which a string appears in the sentence, common strings in both sentences, fuzzy logic usage, etc., we have created a number of additional features that will provide additional information to a model trained on embedding. Numerous vectorization and embedding techniques, such as TF-IDF, CV, Word2Vec, FastText, and OpenAI text-embedding-ada-002 embedding, are used to convert text collections into numerical features. The metrics used to assess the quality of embedding and model performance on embedding include precision, recall, F1-score, and accuracy. The OpenAI text-embedding-ada-002 embedding shows potential in capturing sentence similarity and offers valuable information that supports different models for similarity identification.

The remainder of the document is structured as follows: Section II discusses the existing literature on duplicate question detection. Section III outlines the methodology, including the research flow, dataset, preprocessing steps, feature engineering, vectorization methods, and algorithm implementation. Section IV covers the evaluation of accuracy with various vectorization techniques and models. Section V presents a summary of our research findings and suggests avenues for further investigation.

II. Literature Survey

The sharing and learning environment have experienced significant changes due to the quick growth of digital platforms. Crowdsourced solutions like Community Question Answering (CQA) have been popular as a way for volunteers to share their knowledge and get their doubts regarding particular topics answered. A solution is required to address the issue of semantically comparable question detection for duplication identification in bilingually transliterated data. In order to detect question repetition, deep learning has been implemented by S. Rani et al. to evaluate informal languages like Hinglish, a bilingual blend of Hindi and English spoken on Community Question Answering (CQA) platforms. There are two components: the first is a language conversion component that creates a text in mono-language from input questions. The hybrid model, which combines a Siamese neural network (SNN), a capsule neural network, and a decision tree classifier, is used to determine the similarity between the question pairs. To calculate the similarity of questions, the SNN and the Manhattan distance function are utilized. An accuracy of 87% and an AUCROC value of 0.86 are obtained by validating the suggested model on 150 pairs of questions [7].

Contributors often make use of a pull-request procedure on social coding platforms like GitHub to present their source code modifications to inspectors of a particular repository. Due to the distributed nature of this approach, pull requests carrying out similar development tasks can be unintentionally submitted by multiple contributors, resulting in unnecessary effort and time spent reviewing. A strategy for allocating the same reviewer or reviewing team to each cluster of related pull requests was suggested by H. E. Salman et al., which makes it possible to save time and effort. To identify similarities across pull requests, first extract descriptive textual information from the content of the pull requests and use it to link equivalent pull requests together. To group relevant pull requests together, the K-means clustering and agglomeration hierarchical clustering algorithms are employed. The experimental results indicate that the K-Means algorithm achieves 94%, 91%, whereas agglomeration hierarchical clustering achieves 93%, 98% average precision and recall values over all evaluated repositories. The twenty popular repositories of public datasets are used to access the provided approach. In addition, the suggested method reduces the amount of time and effort required for reviews by using the K-Means algorithm by an average of 67% to 91% and the agglomeration hierarchical clustering technique by an average of 67% to 83% [8].

Millions of people use search engines every day to find solutions, which results in an increasing need for innovative, clever methods to assist people in solving problems. Using a 7GB real-time dataset, V. K. R. Anishaa et al. trained and evaluated four machine learning models in order to identify duplicate queries. The noise is eliminated by removing HTML tags, stop words, punctuation, white spaces, and URLs after the data has loaded. Pre-processing is carried out in SQLite databases utilizing PL/SQL blocks, which process enormous volumes of data faster than alternate techniques. The four different ML models are used to train the acquired dataset. After execution, the random, logistic regression, linear SVM, and XGBoost error parameters referred to from the log loss function are found to be, respectively, 0.887, 0.521, 0.654, and 0.357. As a result of the unique pre-processing activities carried out using PL/SQL, which improve response time overall, the result demonstrates that XGBoost is the best model, delivering the greatest accuracy in the shortest period of time [9].

On a social media platform where users post questions, other users can assist by editing the questions and providing more precise answers to the questions that are asked. Due to linguistic heterogeneity, it can be complicated to determine a sentence's true meaning with accuracy, making the classification of repeated inquiries a challenging process. Deep learning techniques have demonstrated exceptional performance in several natural language processing (NLP) problems, particularly in the area of semantic text similarity. In order to determine the semantic relevance between two queries, Z. Imtiaz et al. suggested a novel Siamese MaLSTM model, wherein the term "Siamese" refers to the employment of two or more sub-identical network architectures simultaneously and Ma indicates Manhattan distance. The GoogleNewsVector, FastText, and FastText subword word embeddings are used to independently train the Siamese LSTM model. The final prediction is then derived from the combination of these trained models [10].

Using a variety of techniques, many investigators have worked on duplicate text detection until now. Text data is pre-processed and converted to an array of numbers using the TF-IDF method. Using the Quora’s dataset, D. Basavesha examined five machine learning models. Adaboost yields an accuracy of 81.73%, random forest yields 81.72%, decision tree yields 79.29%, and logistic regression yields 79.21% [11].

A well-known software problem-solving website with a focus on solving errors in software code, Stack Overflow has seen an increase in visitors in recent years. L. Wang et al. employed Word2Vec to get the vector representations of words, and CNN, RNN, and LSTM are three distinct deep learning approaches that are taken into consideration to address the issue of similar inquiry discovery in Stack Overflow. The evaluation's findings demonstrate that WV-CNN and WV-LSTM have significantly outperformed the other baseline techniques. The dataset consisted of queries in various programming languages, including Perl, Java, and others. The outcome demonstrates that for every dataset, WV-CNN and WV-LSTM based on Word2Vec yield recall rates greater than 80% [12].

A. W. Qurashi measures the level of semantic equivalence across multi-word phrases for the regulations and guidelines stated in railway safety manuals. There are two text similarity measures that are examined: The cosine similarity metric maps the text into a vector space model, and the "Word2Vec" technique is used to determine the distance between the texts. A count-based metric called Jaccard similarity is the intersection of two sets divided by the union of two sets. The cosine similarity determines the degree of similarity between texts by converting sentences from documents into vectors using Word2Vec. The results show that the Jaccard similarity method, which measures similarity based on character matching, yielded unsatisfactory results and while evaluating the similarity of two documents, cosine provides a more accurate result by measuring the angle between vectorized phrases [13].

III. METHODOLOGY

A. Dataset

To determine textual similarity, this study makes use of the 0.4 million questions in the Quora dataset [14]. Table I presents information on the features and content of the dataset.

TABLE I. DATASET DETAILS

Attribute	Details
ID	Each dataset row is assigned a unique number that allows for its own unique recognition.
Question_ID1, Question_ID2	There is a distinct identity for each of the questions in the features labelled "Question No. 1" and "Question No. 2."
QuestionNo1, QuestionNo2	This feature includes real questions to check if they are similar to each other.
Is_Duplicate	When question pairs are intellectually examined, the result is Is_Duplicate, where 0 means false and 1 means yes.

B. Preprocessing

The dataset is subjected to basic preprocessing in order to be approved for usage in the succeeding phase, i.e., vectorization and model training. The database is examined for any duplicate or missing entries, and those that are found are discarded. All punctuation is deleted, the database is lowercased, and some special characters like '%' for percent are substituted out for their string equivalents. The URL and HTML elements were eliminated, and chartwords like "N.A." (which indicates "not applicable") were replaced. The dataset has been lemmatized after all stopwords have been eliminated and tokenization has been applied [15].

C. Feature Engineering

Strong features can increase the predictive ability of machine learning models by giving them pertinent information. On the basis of the properties of the question text that were listed in the dataset, new features were generated [16]. Table II presents an extensive overview of each newly developed feature along with a description.

TABLE II. FEATURE CREATION DETAILS

New Feature	Details
Sen1Len, Sen2Len	It is the entire sentence length, with all characters included.
WordCountSen1, WordCountSen2	Total number of words present in the sentence, including repeated words.
WordCommon	The number of terms that are present identically in the two sentences.
DistinctWords	It is a sum of unique words found in the first sentence and unique words found in the second sentence.
WordShare	It is the ratio of "word common" and "distinct words."
CWC_Min	It is a ratio of the number of common words *(WordCommon)* to the length of a shorter sentence *(min (Question1Length, Question2Length))*.
CWC_Max	It is a ratio of the number of common words *(WordCommon)* to the length of a larger sentence *(max (Question1Length, Question2Length))*.
CSC_Min	It is a ratio of the number of common stopwords (stopwords(sentence1) ∩ stopwords(sentence2)) to the minimum stopword count in the first and second sentences (min (stopwords count in sentence1, stopwords count in sentence2)).
CSC_Max	It is a ratio of the number of common stopwords *(stopwords(sentence1) ∩ stopwords(sentence2))* to the maximum stopword count in the first and second sentences *(max (stopwords count in sentence1, stopwords count in sentence2))*.
CTC_Min	It is a ratio of the number of common tokens *(tokens(sentence1) ∩ tokens (sentence2))* to the minimum token count in the first and second sentences *(min (tokens count in sentence1, tokens count in sentence2))*.
CTC_Max	It is a ratio of the number of common tokens *(tokens(sentence1) ∩ tokens (sentence2))* to the maximum token count in the first and second sentences *(max (tokens count in sentence1, tokens count in sentence2))*.
Avg_Tokens	It is a ratio of the sum of tokens present in both sentences to the number of sentences.
Abs_Len_Diff	It refers to the absolute value of the numerical difference between two sentence lengths.
Lng_Substr_Ratio	It is the ratio of the common longest substring in sentences 1 and 2 to the minimum token count from the first or second sentence *min (token count(sentence1), token count(sentence2))*.
Last_Word_Equal	The value is set to 1 if both sentences have identical last words; otherwise, it is 0.
First_Word_Equal	The value is set to 1 if both sentences have identical first words; otherwise, it is 0.

A Python library called fuzzywuzzy offers a variety of functions for string analysis and algorithm-based similarity score calculations [17]. The Levenshtein Distance (LD) is a measure of the degree of difference between two strings. The

degree of difference between the two strings increases with the number. is the smallest number of single-character modifications needed to convert one word to another. Let us assume that the lengths of the two sentences, sen1 and sen2, are l_1 and l_2, respectively. The LD, or the minimum number of modifications needed to transform sen1 into sen2, is D (l_1, l_2). By filling up a (l_1+1) × (l_2+1) matrix, the dynamic programming technique efficiently computes this distance.

$$\text{fuzz\_ratio} = \frac{1}{1+\text{LD}} \quad (1)$$

Using matching substrings of a given length, the fuzz_partial_ratio (FPR) function determines the "partial ratio" between two strings, which indicates how similar they are. The strings' higher fuzz_partial_ratio indicates a high degree of similarity.

$$\text{FPR} = \frac{2* \text{Common Characters in Two sentence}}{\text{len(sentence1)+len(sentence2)}} * 100 \quad (2)$$

The token_sort_ratio (TSortR) function, which computes the similarity ratio between two strings after sorting their tokens alphabetically, is especially helpful when working with strings that may contain the same words but in a different sequence.

$$\text{TSortR} = \frac{\text{LD}\left(\begin{matrix}\text{Sorted Tokens in Sentence1,}\\ \text{Sorted Tokens in Sentence2}\end{matrix}\right)}{\max\left(\begin{matrix}\text{len}\left(\text{Sorted Tokens in Sentence1}\right),\\ \text{len(Sorted Tokens in Sentence2)}\end{matrix}\right)} * 100 \quad (3)$$

The token_set_ratio (TSetR) function, which determines the similarity ratio between two strings based on the intersection and union of their unique tokens, is helpful when comparing texts that might contain common terms but also have differences.

$$\text{TSetR} = \frac{\text{LD}\left(\begin{matrix}\text{Token Set in sentence1,}\\ \text{Token Set in sentence2}\end{matrix}\right)}{\max\left(\begin{matrix}\text{len}\left(\text{Token Set in sentence1}\right),\\ \text{len(Token Set in sentence2)}\end{matrix}\right)} * 100 \quad (4)$$

D. Word Embedding / Vectorization

Word embedding is a method that captures syntactic and semantic similarities between words depending on their context of usage by representing words as vectors of real numbers in a high-dimensional space. The following vectorization and word embedding techniques were used in the study.

1) Count vectorizer: Count Vectorizer creates a matrix in which each unique word is represented by a column of the matrix, and each text sample from the document is a row in the matrix [18]. The value of each cell is nothing but the count of the word in that particular text sample [19].

2) TF-IDF: The term frequency Inverse Document Frequency (TF-IDF) gives information about the more and less important words in a document. When retrieving information, a word's relevance within the text matters significantly. The more times a word appears in the text, the more significant it becomes. The frequency of a word (w) in a document (d) is measured by term frequency (TF), which is the ratio of a word's occurrence in a document to the total number of terms in the document [20]. A term's Inverse Document Frequency (IDF) indicates how common or uncommon a word is within the whole corpus of documents D. TFIDF is a product of TF and IDF, where the word that is more frequent in the document will get more importance and the word that is rare in the corpus will receive more weight [21, 22].

$$\text{Term Frequency}(\text{w}, \text{d}) = \frac{\text{number of times w appears in d.}}{\text{total number of words in document d.}} \quad (5)$$

$$\text{Inverse Document Frequency}(\text{w}, \text{D}) = \log \frac{\text{number of document in D.}}{\textit{number of documents contains w}} \quad (6)$$

$$\text{TFIDF}(\text{w}, \text{d}, \text{D}) = \text{TF}(\text{w}, \text{d}) * \text{IDF}(\text{w}, \text{D}) \quad (7)$$

3) Word2Vec: Words can be expressed as vectors using a technique called word embedding. Word embedding's main aim is to create low-dimensional feature vectors from the high-dimensional feature space of words while preserving contextual similarity within the corpus. Predicting the words that are close to each individual word in a sentence is the primary objective of the Word2Vec model. Word2Vec uses CBOW and skip-gram architecture, and using the training text input, it builds a vocabulary in order to the vector representation of words [23].

a) CBOW: A neural network termed the continuous bag-of-words (CBOW) model is used for NLP applications like text classification and language translation. One-hot encoding serves as the method for the target and input layer encoding, with a size of [1 X V]. The CBOW uses context words or surrounding words (X) as input in an attempt to predict the target or central word (Y). The weight sets (W, W') are initiated randomly, one between the input and hidden layers and the other between the hidden and output layers. Input Hidden layer matrix size is represented as [V X N], and hidden output layer matrix size is represented as [N X V], where N is a random number that indicates the size of our embedding space or how many dimensions, we want to use for describing our word. The hidden activation is the product of the input and the input-hidden weights. The product of hidden input and hidden output weights produces the output Y. The difference between the output and the target is evaluated and reported back to reset the weights [24,25].

b) Skip-Gram: Word2Vec also uses the skip-gram neural network approach, which reverses the CBOW architecture and predicts context or surrounding words (Y1, Y2…) for a given target word (X). The random weight is assigned after one-hot encoding of both the input layer and the target layer. To modify the weight assigned, the softmax function first calculates the probability of context words, then backpropagates the error by computing the loss between prediction and actual. Fig. 1 and 2 demonstrate the CBOW and skip-Gram structure [26,27].

4) FastText: An open-source platform called FastText, created by Facebook, enables professionals to acquire text representations and classifiers to perform efficient text classification. fastText offers subword embeddings by considering that words are made up of character n-grams [28].

For the purpose of removing common words, FastText generates a sample table. The theoretical foundation for this work is that words that are commonly used carry less information than uncommon terms and that a word's representation does not change much even after the same sentence is used several times [29]. In order to identify vector representations where the text and its associated labels have similar vectors, Fasttext represents text and labels as vectors. The softmax function is used to determine the the probability score of an accurate label given to its corresponding text [30].

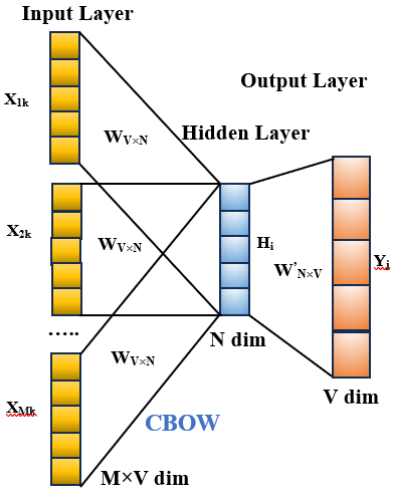

Fig. 1. CBOW architecture.

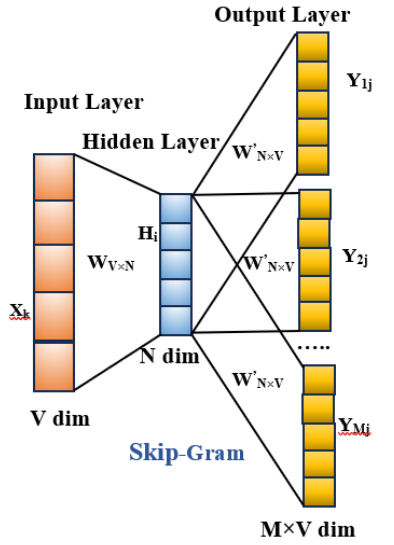

Fig. 2. Skip-gram architecture.

5) OpenAI: Text strings' relatedness can be evaluated by OpenAI's text embeddings. Searching, clustering, recommendations, anomaly detection, diversity assessment, and classification are among the common uses of OpenAI Embeddings [31]. The "text-embedding-3-small", "text-embedding-3-large", and "text-embedding-ada-002" are three robust third-generation embedding models offered by OpenAI. For text search, code search, and sentence similarity tests, text-embedding-ada-002 performs comparably to all previous embedding models, whereas for text classification, it achieves superior results [32]. The text-embedding-ada-002 context length is extended from 2048 to 8192 tokens by a factor of four, making it easier to work with lengthy documents. The new embeddings are only one-eighth the size of the davinci embeddings, with only 1536 dimensions and their maximum input token is 8191. Semantically comparable words are mapped to vectors that are close to each other in a continuous, dense, low-dimensional vector space. This is the basis for OpenAI embeddings, which use a sort of neural network called a transformer to represent text [33]. The conversion of text to vector by OpenAI embedding is explained in Fig. 3.

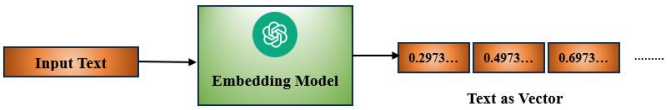

Fig. 3. OpenAI embedding.

E. Model Training

1) Cosine similarity: In natural language processing, cosine similarity is one of the metrics used to assess how similar two sentences are, regardless of their size. The cosine of the angle between two n-dimensional vectors projected in a multi-dimensional space is measured mathematically by the cosine similarity metric. A document's cosine similarity can range from 0 to 1, where 1 denotes that two vectors have the same orientation and 0 denotes that there is less similarity between the two documents. The following is the mathematical expression for the cosine similarity between two non-zero vectors [34,35].

$$Sentence\ Similarity = \cos(\theta) = \frac{P.Q}{||P|| * ||Q||} = \frac{\sum_{i=1}^{n} P_i Q_i}{\sqrt{\sum_{i=1}^{n} P_i^2}\sqrt{\sum_{i=1}^{n} Q_i^2}}\ where\ P\ and\ Q\ are\ vectors \quad (8)$$

2) Random Forest: The bagging approach is the foundation of the random forest ensemble learning method. Because decision trees have low bias and large variation, overfitting occurs if the tree grows too deep. By combining numerous decision tree predictions rather than relying just on one tree's output, Random Forest addresses this issue by reducing variance and resolving the overfitting issue. Decision trees are the foundation model used by Random Forest and predict the final output based on the majority of votes. When building a decision tree, entropy or the Gini Index is utilized as the splitting criterion [36].

$$Entropy = -\sum_{i=1}^{n} P_i log P_i\ \ where\ P_i\ is\ class\ label \quad (9)$$

$$Gini\ Index = \sum_{i=1}^{n} {p_i}^2\ \ where\ p_i\ is\ class\ label \quad (10)$$

3) AdaBoost: AdaBoost, or "adaptive boosting," is an ensemble machine-learning technique that builds decision stumps using decision trees. Adaboost combines weak learners into a single, powerful classifier to boost the performance of

machine learning algorithms. By assigning an equal weight to every data point, the adaboost algorithm initially constructs the model. In the subsequent iteration, the data points whose classification by the previous model was incorrect will be assigned greater weight [37, 38]. It will keep training models until it receives reduced errors. The following equation represents the final prediction.

$$Final\ Prediction = \alpha_1 * p_1 + \alpha_2 * p_2 + \cdots + \alpha_n * p_n \quad (11)$$

where, p1 represents the model's prediction and α1 represents the model's degree of significance [39].

4) XGBoost: A popular gradient boosting approach called XGBoost provides regularization that lets you control overfitting by applying L1/L2 penalties to each tree's weights and biases [40]. Following the base model's prediction, we build a decision tree using the residuals and splitting criteria, then determine the similarity scores of the root and leaf nodes using following equation.

$$Similarity\ Score = \frac{(\sum Residual)^2}{N+\lambda} \quad (12)$$

Where N is number of residuals and ƛ is regularization parameter. The following formula is used to compute the gain [41].

$$Gain = Left\ Similarity + Right\ Similarity - Root\ Similarity \quad (13)$$

In XGboost Regression, the Gamma Parameter Is Used. If the gain is less than the gamma value, the branch is cut, and no additional splitting occurs; otherwise, splitting proceeds. Pruning happens more often when gamma is higher. The XGboost Learning Rate is used to determine the model's convergence [42].

5) LSTM: One variation on a recurrent neural network that can identify and pick up on order dependence in sequence prediction issues is the Long Short-Term Memory (LSTM) network. The RNN cannot predict words that are held in long-term memory, but it can predict words based on recent data, which makes it unable to solve the long-term dependence problem. The LSTM is the type of neural network that receives an input (x_t) and outputs a value (h_t). The three gates in the memory are the input, forget, and output gates, which control information flow and have the capacity to add or remove data from the cell state, represented by the horizontal line at the top of the diagram. The forget gate has the responsibility for selecting which data should be erased from the cell state. The sigmoid layer generates a value between 0 and 1 after analysing h_{t-1} and x_t to determine which cell state data should be kept and which should be removed.

$$f_t = \sigma\big(W_f[h_{t-1}, X_t\,] + b_f\big) \quad (14)$$

The input gate is used to update the cell state value, taking into account both the previous time step's hidden state and the current input. The Sigma activation function in the first section determines the percentage of information that is needed. The Tanh activation function, which maps the data between -1 and 1, receives the two values in the second section. The input gate's output, which modifies the cell state determined by multiplying the outputs of the Tanh and Sigma functions [43, 44].

$$i_t = \sigma(W_i[h_{t-1}, X_t\,] + b_i) \quad (15)$$

$$C_t = \tanh(W_C[h_{t-1}, X_t\,] + b_C) \quad (16)$$

$$C_t = F_t * C_{t-1} + i_t * C_t \quad (17)$$

At the final stage, the sigmoid layer of the output gate decides which elements of the cell state are returned as output. The tanh layer modifies the cell's state to a value between 1 and -1, and the final output can be produced by multiplying the sigmoid layer's output by the tanh layer [45].

$$O_t = \sigma(W_o[h_{t-1}, X_t\,] + b_o) \quad (18)$$

$$h_t = O_t * \tanh(C_t) \quad (19)$$

6) CNN: CNNs are useful in NLP for linguistic modelling, autonomous translation, and classification of text. A variant of CNN known as 1D-CNN focuses on the analysis of one-dimensional data sequences, including text. By swiping the filter over the input matrix, the convolutional layers convolved the input, extracted features from the input, and passed the output to the next layer. CNN uses two parameters for regulating the size of an output matrix: stride, which indicates the number of pixels moved throughout the convolution process, and padding, which specifies the number of pixels added to an input matrix. These parameters control how the filter convolves across the input matrix. By multiplying the output matrix from the convolution layer and pooling matrix, the pooling layer tries to gradually reduce the spatial dimension of the representation in order to reduce the number of parameters and calculations in the network. The dropout layer attempts to minimize overfitting by randomly setting the input units to zero at each training phase. The feed-forward neural network uses the array as input for additional computation after it has been flattened into a one-dimensional array [46, 47].

7) Classification metrics: The true and false values accurately forecast are denoted by TP and TN. The false and true values that were incorrectly forecast are denoted by FP and FN. The ratio of exact forecasts to the total number of input observations is known as the classification accuracy. The ratio of correctly anticipated positive outcomes to all anticipated positive outcomes is known as precision, and the percentage of correct positive anticipations to all positive samples in the dataset is known as recall. The F1-score, which is the harmonic mean of recall and precision, is used when it's complicated to choose whether to go with recall or precision. Each metrics' corresponding mathematical equation is represented below [48, 49, 50].

$$\text{Accuracy} = \frac{[TP+TN]}{N} \quad (20)$$

$$\text{Precision} = \frac{TP}{[TP+FP]} \quad (21)$$

$$\text{Recall} = \frac{TP}{[TP+FN]} \quad (22)$$

$$\text{F1Score} = 2 * \frac{[\text{Precision} * \text{Recall}]}{[\text{Precision} + \text{Recall}]} \quad (23)$$

IV. Results and Discussion

The 30000 samples are chosen at random, and the bias in the dataset is controlled by making sure that each type of label has identical quantities in the dataset. The dataset was broken down into 6000 samples for testing and 24000 samples for training. Table III presents the classification evaluation metrics for the multiple techniques that were trained on CountVectorizer. The precision, recall, and f1-score were computed using a weighted average.

TABLE III. Performance of Count Vectorizer

Embedding	Model	Cosine	RF	AdaBoost	XGBoost	LSTM	CNN
CountVectorizer	**Accuracy**	0.565	0.781	0.745	0.792	0.771	0.790
	Precision	0.571	0.781	0.753	0.797	0.771	0.798
	Recall	0.565	0.781	0.745	0.792	0.771	0.790
	F1-Score	0.557	0.781	0.743	0.791	0.771	0.789
	FP	1716	843	1030	824	856	750

The outcome demonstrates that the Cosine Similarity calculated on CV yields disappointing results. In addition, in comparison to other models, the AdaBoost is producing unsatisfactory results. FP prediction refers to the situation where the model anticipated a negative value but the actual value was positive. When two statements have the same meaning but the model predicts they are different, it is normal; but, when two distinct sentences are anticipated to be similar, it is not acceptable and will negatively impact the system's performance. For this reason, we have taken into account FP, or Type-I mistake, as an evaluation metric.

The Table IV performance data for TF-IDF shows that the cosine similarity calculated on TF-IDF yields bad results, and the adaboost also yields disappointing results.

TABLE IV. Performance of TF-IDF

Embedding	Model	Cosine	RF	AdaBoost	XGBoost	LSTM	CNN
TF-IDF	**Accuracy**	0.660	0.778	0.756	0.779	0.767	0.791
	Precision	0.660	0.791	0.766	0.787	0.770	0.796
	Recall	0.660	0.778	0.756	0.779	0.767	0.791
	F1-Score	0.659	0.776	0.754	0.777	0.767	0.790
	FP	1099	972	1020	920	986	821

Table V performance data for Fasttext embedding demonstrates that all other techniques produce results that are reasonably nearby, whereas the cosine similarity calculated on Fasttext produces poor results.

Performance of each model trained using Word2Vec embedding is displayed in Table VI.

The performance of all models trained on OpenAI embedding is displayed in Table VII. The outcome highlights that, in contrast to alternative embeddings, cosine similarity yields outstanding outcomes. All models trained on OpenAI embedding show a performance gain of about 3%. With its ability to generate embeddings in such a way that two sentences with almost identical meanings have nearly the same value in the embedding, OpenAI has strong potential for capturing sematic meaning. With OpenAI embedding, the CNN performs effectively, yielding satisfactory outcomes with a slight FP value.

TABLE V. Performance of FastText

Embedding	Model	Cosine	RF	AdaBoost	XGBoost	LSTM	CNN
FastText	**Accuracy**	0.649	0.779	0.761	0.774	0.763	0.787
	Precision	0.651	0.784	0.763	0.780	0.763	0.790
	Recall	0.649	0.779	0.761	0.774	0.763	0.787
	F1-Score	0.648	0.778	0.760	0.773	0.762	0.786
	FP	1231	852	875	784	790	782

TABLE VI. Performance of Word2Vec

Embedding	Model	Cosine	RF	AdaBoost	XGBoost	LSTM	CNN
Word2Vec	**Accuracy**	0.671	0.767	0.767	0.782	0.776	0.791
	Precision	0.675	0.788	0.770	0.786	0.781	0.793
	Recall	0.671	0.767	0.767	0.782	0.776	0.791
	F1-Score	0.669	0.763	0.766	0.781	0.775	0.791
	FP	1219	982	854	831	871	762

TABLE VII. Performance of OpenAI

Embedding	Model	Cosine	RF	AdaBoost	XGBoost	LSTM	CNN
OpenAI	**Accuracy**	0.757	0.807	0.781	0.813	0.791	0.825
	Precision	0.768	0.812	0.781	0.817	0.796	0.823
	Recall	0.757	0.807	0.781	0.813	0.791	0.823
	F1-Score	0.755	0.806	0.781	0.812	0.790	0.823
	FP	1026	767	825	725	821	639

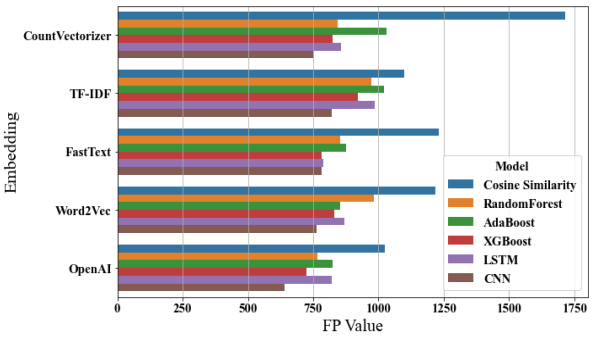

Fig. 4. Comparison of FP values for different models.

Fig. 4 indicates the false positive prediction for every model trained across different embeddings.

V. Conclusion

Detecting similarity across sentences can be helpful in the implementation of a number of different types of systems, such as question-answering systems, community forums, e-commerce consumer questions, instructional platforms, and chatbots for customer service. Sentence similarity must be automatically detected in order to meet user expectations promptly and enhance the user experience. Common uses for OpenAI embedded systems include searching, clustering, similarity, anomaly detection, diversity evaluation, and classification. The outcome demonstrates that machine learning receives valuable information from the embedding produced by the OpenAI model, improving prediction accuracy. Sentence similarity can be captured with significant potential using OpenAI embeddings. Almost all algorithms perform well with OpenAI embedding; CNN is one of the better performing algorithms. In order to improve prediction accuracy, we can incorporate a cascading CNN structure in future study. The CNN architecture's ideal parameter can be found using the optimization technique. Rather than taking a sentence as input, we can incorporate OpenAI STT and TTS to receive verbal input and produce verbal output in future research.

***Abstract*—The combination of blockchain technology and smart contracts has become a viable way to expedite claims processing and payouts in the quickly changing insurance industry. Enhancing efficiency, transparency, and reliability for the industry may be achieved by automating certain procedures and initiating them on predetermined triggers, smart contracts that is event-based. Conventional insurance procedures can be laborious, slow, and prone to human mistake, which can cause inefficiencies and delays in the resolution of claims. This research proposes a simplified system that automates the whole claims process from submission to reimbursement by utilizing blockchain technology and smart contracts. The suggested method does away with the requirement for human claim filing by having policyholders' claims automatically triggered by predetermined occurrences. These occurrences might be anything from medical emergencies to natural calamities, enabling prompt and precise claim start. The whole claims process is managed by smart contracts that are programmed with precise triggers and conditions, guaranteeing transaction immutability, security, and transparency. Moreover, reimbursements are carried out automatically after the triggering event has been verified, disregarding conventional bureaucratic processes and drastically cutting down on processing times. This strategy decreases the possibility of fraud and disagreement while also improving operational efficiency by combining self-executing contracts with decentralized ledger technology. Insurance companies and policyholders will both eventually profit from an accelerated, transparent, and reliable claims processing procedure thanks to the use of event-based smart contracts. A Python-implemented system achieving 97.6% accuracy using the proposed method, demonstrates its efficacy and reliability for the given task.**

Keywords*—Blockchain technology; smart contracts; event-based triggers; automated claims processing; transparency and trustworthiness

I. INTRODUCTION

Private insurance businesses act as a central organization to give advantages to policyholders. They offer worth by using historic information and mathematical procedures to determine whether premiums are going to be adequate for covering predicted claims. Furthermore, authorities can control these companies in order to ensure enough funding. Insurance firms are currently losing a significant amount of money as a result of claims leakage. Illegal claims are a massive and expensive issue for insurance firms, possibly resulting in trillions of dollars in unwarranted spending every year [2]. Traditional policy approaches for detecting fraud are complex and time-consuming. They mostly rely on expert inspection, adjusters as well, and specialized investigative services. Manual inspection faces extra costs and yields erroneous findings. Furthermore, delayed decisions may result in additional losses for the insurance firms. The insurance business administers auto-insurance processing of claims using information gathered from several domains, including police, county administration, insurance representatives, and medical professionals [3]. These businesses work together to communicate multi-source data, which is crucial enabling insurance firms to correctly assess customer claims. Yet, the majority of existing claim processing procedures are laborious and time-consuming because to a lack of automated methods to perform information collection/analysis, along with technology to make reliable decisions [4]. To enhance the effectiveness and adaptability of insurance claim the process, it is necessary to integrate automated processes and trust administration mechanisms at an application level [5].The excessive number of false claims given out by motor insurance firms has resulted in price hikes of several hundred dollars to counteract the false payouts, reducing insurance company profitability as well as the level of operations [6]. As a result, there exists an urgent need to provide quick and effective solutions for identifying fraud, risk assessment, and

safe storage of information that strike a perfect equilibrium among customer private information safeguarding, loss prevention savings, and expenditure on false alarm identification (Cousaert, Vadgama, and Xu 2022). Recommend creating a successful framework for insurance companies to address such difficulties [7].

Intelligent contracts may streamline numerous common operations in the P&C insurance industry, including policy issuance and claim management. For example, parameterized insurance policies can initiate payments whenever predetermined conditions are satisfied, such as in the case of a natural disaster [8]. It may also assess all payment choices to determine which one is optimal. This technology eliminates the requirement for middlemen and increases effectiveness, giving policyholders access actual time replies which are not impeded by delays in insurance claims [9]. This study examines the notion of automation claims handling and payouts driven by event-driven intelligent contracts in the insurance business. The technological infrastructure necessary to construct a system like this, includes the selection of blockchain platform, programming languages, and architectural considerations for smart contract implementation [10]. Research demonstrate the flow of data and actions across the system, emphasizing the seamless integration of event-driven triggers for automating the claims handling workflow [11]. Its technological infrastructure necessary to construct any of these systems, in addition to the selection regarding the blockchain platform, programming languages, and architectural considerations for smart contracts .Demonstrate the flow of data and operations across the system, emphasizing the effortless incorporation of based on events triggering for automating the claims handling process [12].

The Current solutions based on blockchain employ intelligent agreements to enhance the transfer of assets, restrict fraud, and decrease administrative expenses. However, they do not address collaborative insurance, allowing individuals who have comparable characteristics to safeguard each other in an increased favorable, reasonable, and open way [13].To illustrate whether event-based intelligent agreements might transform the claims handling procedure by thoroughly examining its technological foundations and operational ramifications, benefiting insurance companies, policyholders, and various other stakeholders equally. With adopting this novel strategy, insurance firms may achieve unprecedented levels of efficiency, openness, and satisfaction with customers, bringing in an entirely novel phase of insurance claim administration [14].

Key contributions are as follows:

- By automating claims processing through event-based smart contracts, the system eliminates manual submission processes, reducing administrative burdens and streamlining operations.
- Blockchain technology ensures transparency and immutability of transactions, providing a clear audit trail for all stakeholders involved.
- Predefined events trigger claims automatically, enabling quick initiation upon the occurrence of insured events such as natural disasters or medical emergencies. This swift response enhances customer satisfaction and reduces delays in claim settlements.
- The inherent security features of blockchain technology, combined with self-executing smart contracts [1] minimize the potential for fraudulent activities in the claims process.
- Automated payouts upon verification of triggering events bypass traditional bureaucratic procedures, significantly reducing processing times.
- By streamlining processes and reducing manual intervention, insurers can realize cost savings and operational efficiencies.

The remaining section of this work is structured as follows: Section II covers similar work and a full evaluation of it. Section III offers details on the problem statement. Section IV provides a detailed discussion of the suggested method. Section V presents and examines the results of the tests, as well as a comprehensive comparison of the proposed technique to current standard procedures. Section VI, the last section, represents where the paper is finished.

II. Related Works

The existing health insurance claims procedure has issues with inefficiency and complexity. Whenever a patient files a health insurance claim, he or she must first visit the medical facility to obtain a diagnostic certification and being received, and finally submit the required application documentation to the insurer. The person will not get compensation until the company completes its verification procedure via the patient's clinic. Research can use the technology of blockchain to better the existing situation. Blockchain innovation may successfully open up avenues for communication between insurance companies and healthcare providers, increase industrial integrating, and improve healthcare firms' capacity to access data. This study uses blockchain and smart contract technology to boost the progress of Internet healthcare. First, blockchain and smart contracts technology may effectively handle the problem of web-based verification. In addition, it contributes to better monitoring. Finally, it helps to solve risk management issues. Finally, it promotes efficient anti-money laundering. The suggested approach meets a number of safety criteria: mutual verification of identities and the non-rep among all of both roles, along with additional significant the blockchain relies safety concerns. In the case of a conflict provide an arbitration system to distribute duties. The effective deployment of the blockchain system in the insurance sector necessitate the development of strong publicly accessible infrastructure (PKI), partnerships between healthcare providers for offering electronic health records (EMR), as well as money alliances for expressing consumer financial data, that could create practical and legal obstacles in some countries [15].

The insurance sector, firms have implemented substantial and fundamental modifications to update their basic processes, making operations simpler and quicker for customers and enterprises. To service more clients while enhancing the total

client experience across all contact points, organizations are seeking to shift out of standalone transactional systems and towards contextually engagement systems. Several insurance companies currently use some form of automation, including scanning, uploading papers for the process, or automating bank transfer activities. However, occasionally this might result in inadequate results or delayed procedures. Robotic Process Automation (RPA) is the employing of computer programs robots to execute business operations that would normally be performed by humans. RPA can help companies accomplish their business goals while utilizing existing technology and increasing the returns on prior and ongoing transformational expenditures. Insurers may utilize RPA to analyze large amounts of complicated data at greater rates and in less time. RPA is poised to assist claiming businesses develop and improve their results in the age of technology by increasing automated processes, efficiency, and concentration for claim experts. Companies with superior outsourced capabilities have widened their concentration on automating to save labor expenses and streamline procedures. The following has generated an emerging RPA industry that is expected to expand significantly. RPA's drawbacks includes being unable to perform activities that need complicated making choices or mental skills, as well as its dependence on organized information and repeated procedures, that might not apply to all circumstances or sectors [16].

Dhieb et al. [17] propose safe and automatic healthcare system architecture that eliminates human intervention, protects insurance operations, notifies and educates concerning dangerous consumers, identifies forged claims, and decreases the financial loss for the insurance industry. Subsequently introducing the blockchain relies system for enabling secure transactions as well as information offering between various agents who communicate inside the insurance company network, that research suggest employing the xtreme gradient boosting (XGBoost) artificial intelligence method for the formerly mentioned insurance companies and comparing its efficacy to that of other cutting-edge algorithms. The findings show that when implemented to an automobile insurance dataset, Boost outperforms other present-day learning methods. When it comes to identifying false claims, it outperforms the decision tree algorithms by 7% on average. The findings show that whenever deployed to an automobile insurance dataset, XGboost outperforms alternative present-day learning methods. Whenever it comes to identifying false claims, it outperforms the decision tree models by 7% on average. In addition, present an online educational approach to autonomously cope with real-time modifications to the insurance network, as well as demonstrate that it beats other online cutting-edge method. At last use the hyper ledger networks fabric composer and the built neural network modules to construct and replicate the machine learning algorithms and bit coin architecture. Throughout the coming years, company are going to concentrate on improving the proposed framework and introducing artificial intelligence (AI) products targeted to various insurance services.

The insurance sector relies largely on a number of activities carried out by different organizations, including insurers, insured’s, and third-party service providers. The growing competitive climate is driving insurance businesses to adopt innovative technology to solve a variety of issues, including an absence of confidence, openness, and economic uncertainty. For this purpose, blockchain is being employed as a new technology for accessible and safe information preservation and transfer. Loukil et al. [18] propose CioSy, an integrated a blockchain-based healthcare platform that monitors and processes insurance activities. To the greatest extent of understanding, current processes do not take cooperative insurance into account while aiming for a computerized, clear, and tamper-proof solution. CioSy intends to use smart contracts to automate the processing of insurance policies, claims, and payments. For validation reasons, an experimental prototype is created on the Ethereum blockchain. The findings from experiments suggest that the suggested strategy is viable and cost-effective. In the future, research hopes to give a formal privacy demonstration for the suggested paradigm. In addition, intend to investigate the feasibility of deploying the funds gathered by an insurance pooling utilizing blockchain-based technology with the goal to encourage bankers and insurance organizations to join a proposed collaboration healthcare system.

Traditional claims handling procedures are inadequate for the current world, which has an expanding fleet of cars and an equal amount of incidents. Fernando et al. [19]suggest a fresh proposal for automating the financial services industry's laborious operations. Its provided approach is made up of three primary elements: re-identifying the car's model and year, identifying the harmed automotive part, kind, and extent, and computing a precise repair cost utilizing damages part recognition. Simplify the recording process by detecting important fields from the user's voice input. This guarantees that all parties participating in the procedure benefit from the proposed system. The presented solutions were developed utilizing Artificial Intelligence approaches, namely CNN models and natural language processing techniques. The initiative's planned developments for the future include improving the ASR to detect more fields linked to completing out the initial claim seeking form as well as including additional regional dialects. The given technique is capable of recognizing one type of harm in a picture. This may be enhanced to identify multiple kinds of harm in a picture as technology for computer vision evolves. These improvements will improve the overall efficiency of the system in the years to come.

Machine learning or data mining algorithms may be utilized for forecasting future management and are thus considered strong tools. Data mining has recently become increasingly significant for obtaining essential data in the healthcare industry. Health insurance costs are critical in the development of healthcare institutions. In order to offer improved healthcare services, it is critical to anticipate the cost of medical insurance that constitutes one of the opportunities for improving healthcare facilities. Dutta et al. [20] addresses projecting the cost of medical coverage, which must be provided by the individual receiving medical care. To accomplish the best predictions examination, several data mining regression techniques are used, including decision trees, random forests, polynomial regression, and regression

using linear models. A contrast was made among the actual and expected expenditures for the predictions premiums, and a graph was created on this foundation to help us identify the optimum method of regression for insurance policy prediction. One constraint is the possible complexity and technical needs of adopting sophisticated neural network algorithms such as Bi-LSTM, that might necessitate extensive knowledge and computing power. Another drawback is the absence of insurance-related information, which restricts the research to a small dataset and could restrict the ability to generalize of the findings. Every method is evaluated to determine the most appropriate solution.

While several studies have highlighted the potential of emerging technologies such as blockchain, robotic process automation (RPA), machine learning, and data mining in revolutionizing the health insurance claims process, there remain significant limitations across these works. Firstly, while blockchain offers secure data sharing, its implementation may face challenges related to infrastructure development and legal obstacles. Additionally, the reliance on structured data and repetitive processes in RPA may limit its applicability in complex decision-making scenarios. Moreover, the effectiveness of machine learning algorithms like XGBoost and data mining techniques in predicting insurance costs is constrained by the availability of comprehensive datasets and computational resources. Furthermore, the complexity of advanced neural network algorithms may hinder their adoption, while the lack of insurance-specific information can restrict the generalizability of findings. These limitations underscore the need for further research to address technical, data-related, and practical challenges in leveraging emerging technologies for enhancing the efficiency and effectiveness of health insurance processes.

The existing health insurance claims procedure is plagued by inefficiency and complexity, requiring patients to visit medical facilities to obtain diagnostic certification and then submit documentation to insurers, resulting in delayed compensation. To address these issues, the current research proposes utilizing blockchain and smart contract technology. This technology facilitates communication between insurance companies and healthcare providers, enhances industrial integration, and improves healthcare firms' access to data. The proposed approach aims to boost the progress of Internet healthcare by effectively handling web-based verification, improving monitoring, and addressing risk management issues. Dhieb et al. proposed a safe and automatic healthcare system architecture that eliminates human intervention, protects insurance operations, identifies forged claims, and decreases financial loss. They suggest employing the XGBoost artificial intelligence method for insurance companies, which outperforms other algorithms in identifying false claims. Similarly, Loukil et al. proposed CioSy, a blockchain-based healthcare platform that automates insurance policies, claims, and payments through smart contracts. Fernando et al. suggest automating financial services operations, including car damage assessment for insurance claims, using Artificial Intelligence approaches. Dutta et al. on predicting medical insurance costs, utilizing various data mining regression techniques. These earlier studies provide a comprehensive framework for the current research on Event-Based Smart Contracts for Automated Claims Processing and Payouts in Smart Insurance. The proposed system will leverage blockchain technology and smart contracts to automate and streamline the insurance claim process, enhancing efficiency, transparency, and security. By integrating findings from previous research, the proposed system will significantly contribute to solving the inefficiencies and complexities of the existing health insurance claims procedure.

III. Problem Statement

The current insurance claims procedure is plagued by inefficiencies and complexities, requiring physically visit facilities for certification before submitting paperwork to insurance firms. This cumbersome process leads to delays in compensation and poses challenges in data verification and risk management [18]. However, emerging technologies like blockchain and Robotic Process Automation (RPA) offer promising solutions to streamline these operations. Blockchain can facilitate secure communication between insurance companies and healthcare providers, while RPA can automate repetitive tasks, improving efficiency and accuracy. Additionally, the integration of artificial intelligence (AI) algorithms, such as XGBoost, enhances fraud detection and claim processing speed. Despite these advancements, there remain challenges in implementing these technologies, including the need for robust infrastructure and data privacy considerations [16]. Hence, there is a pressing need for innovative solutions like CioSy, a blockchain-based healthcare platform, which automates insurance processes through smart contracts, ensuring transparency and reliability. Furthermore, leveraging AI techniques like convolutional neural networks (CNN) and natural language processing (NLP) can further enhance claims handling by automating tasks like damage assessment and form completion. Ultimately, adopting these technologies can revolutionize the insurance sector, making processes more efficient, transparent, and customer-centric .The Novel method Automated Claims Processing and Payouts Triggered by Event-Based Smart Contracts is proposed.

IV. Proposed Method Automated Claims Processing and Payouts Triggered by Event-based Smart Contracts

The suggested event-driven architecture insurance claim procedure follows a certain set of phases in its approach. First, pertinent data on insurance plans, applicants, and triggering events are gathered through data collection and preprocessing. After that, this data is examined and plotted to reveal trends and patterns that might guide the creation of smart contracts. Subsequently, blockchain technology is utilized for safe transactions and smart contract implementation in the automatic medical insurance claims processing system. Automate the claims procedure and ensure speed and transparency, smart contracts are configured with certain triggers and criteria. When certain events occur, such as natural catastrophes or medical emergencies, smart contracts automatically start the claims procedure. This entails confirming the legitimacy of the claim and streamlining the reimbursement procedure without requiring human

involvement. Utilizing blockchain technology, this technique places a strong emphasis on guaranteeing the confidentiality and integrity of the claims process. In addition, the system is routinely optimized and monitored to preserve its efficacy and efficiency in managing insurance claims.

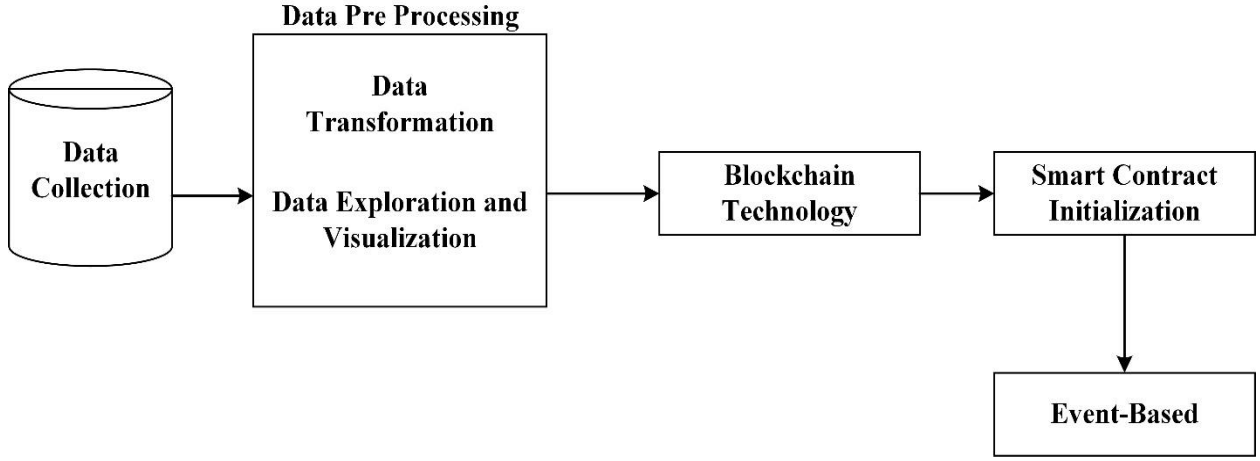

Fig. 1. Automated claims processing and payouts triggered by event-based smart contracts.

Fig. 1 displays a flowchart of a data-driven workflow using blockchain technology. The procedure includes five steps data gathering, data pre-processing, blockchain technology, smart contract activation, and event-based process.

A. Data Collection

The "Health Insurance Dataset - EDA" available on Kaggle offers a comprehensive exploration of health insurance data, comprising information on 1338 US health insurance customers. The dataset includes features such as age, gender, body mass index (BMI), number of children, smoking status, region, and insurance charges. It serves to facilitate analysis on factors affecting insurance charges, prediction of new charges, and comparison of plans across different regions. Key inquiries encompass the impact of age, smoking status, and number of children on insurance charges, identification of regions with the highest or lowest average charges, and examination of BMI distribution across regions. This dataset is valuable for understanding insurance pricing and trends [21].

B. Data Pre Processing

Data preprocessing involves cleaning and transforming raw data to enhance its quality and usability for analysis, typically including tasks such as handling missing values, outlier detection, normalization, and feature scaling. This step is crucial for ensuring accurate and reliable results in data analysis and modeling.

1) Data transformation: In the data transformation stage, several techniques are applied to prepare the data for modeling. Categorical variables are encoded into numerical representations, typically using methods like one-hot encoding to create binary columns for each category or label encoding to assign unique numerical values to categories. Numerical functions can be scaled to make sure consistent degrees across variables, assisting algorithms touchy to function magnitudes. Feature engineering consists of crafting new capabilities from present ones, leveraging domain information or statistical insights to enhance model performance. This may consist of growing interaction terms, polynomial features, or transform variables to better capturing relationships or styles within the information. These transformation steps collectively intention to enhance the suitability and predictive strength of the dataset for subsequent modeling duties [22].

2) Data exploration and visualization: Explore the distribution of each feature and the relationship between feature variable and the targeted variable. Visualize the information using plots along with histograms, box plots, scatter plots, and so forth. to benefit insights into the records and become aware of patterns.

C. Automatic Medical Insurance Claims Service System through Blockchain Technology

The remedy offered by this study was to implement an autonomous insurance claim servicing system using the blockchain. The surroundings are used to exchange data between healthcare providers, insurance providers, and individuals. The environment's functions include the blockchain computing center (BCC), the appropriate government agencies (CA), the healthcare facility (MI), the insurance provider (IC), the finance company (BK), the patient (PT), & the center for arbitration (AI). Medicinal institutions can create a healthcare alliance chain under the supervision of the medicinal board CA1. Assurance and banks can join a financial alliances chain that is overseen by the banking regulator, CA2. Participants of the exact same alliance are able to exchange entire material.

Step 1: All CA, MI, IC, BK, and PT must verify with BCC in order to get both public and private ECDSA signing keys, as well as pubic and secret PKI key pairs. BCC also saves every patient's healthcare blockchain information. Furthermore, various kinds of CA will establish partnerships among the people they represent, and the partnership's membership' data will be exchanged.

Step 2: The patient, PT, buys health assurance through the health care firm IC. The IC will first check the PT's identification and then execute an insurance agreement with them. The PT must furnish the IC with the details of its BK account and paperwork will then sent to the BCC via the CA. Whenever the PT returns hospital in MI not too distant upcoming, and the examination result satisfies the alleged contented indicated in the health insurance agreement, the IC will move forward by the healthcare claims.

Step 3: Whenever a patient PT visits a healthcare facility MI and notifies the MI that they he or she has acquired health coverage, the MI will first authenticate the PT's identification, review the PT's electronic health record EMR, and then issue an authorization, with the information being communicated to the Scc via CA.

Step 4: The medical facility MI then notifies the assurance firm IC to process claims from insurance companies, and the IC acquires the PT medically-related diagnostic material given by MI.

Step 5: The insurance provider IC instructs the financial institution BK to pay the patient PT, and the record is transferred to the BCC via the CA.

Step 6: A claimed disagreement, the patient PT may file a complaint with the arbitration agency AI. AI will receive the communication contents from both side besides arrive at logical decisions.

D. Smart Contract Initialization

Blockchain technology was used in the suggested design. Certain essential data is kept and confirmed on the blockchain throughout the verification and permission procedure. The smart contract is a code that defines the block chain's most essential data. Everyone created essential data, which is stored on the blockchain in the suggested smart contract. Every smart contract has the following fundamental fields: id (identity), information about the transaction, certification, and timestamp. The smart contracts include the individual's bank account, whereas the smart contract includes the insurance company's bank account. The field's insurance contract is included with the smart contract. A smart contract supports digitized medical records. Finally, the purchase ID is shown in the smart contract. The blockchain technology center also provides both private and public key sets for every position during the authentication step.

1) Registration phase: The network's role X may include the Competent of authorities (CA), the healthcare facility (MI), the insurance provider (IC), the financial company (BK), and the individual in need (PT), who sign up blockchain center (BCC) also receive an individual's public/private key combination and a digital proof to verify their identities via a safe channel. Fig. 2 depicts the diagram for the enrollment process. Registration phase flow is explained in Fig. 2.

2) Authentication process: During the start of the interaction, system roles A and B must authenticate their respective identities using the ECDSA technique. System roles A and B may comprise appropriate government agencies (CA), healthcare providers (MI), insurance firms (IC), banking (BK), and individuals (PT).

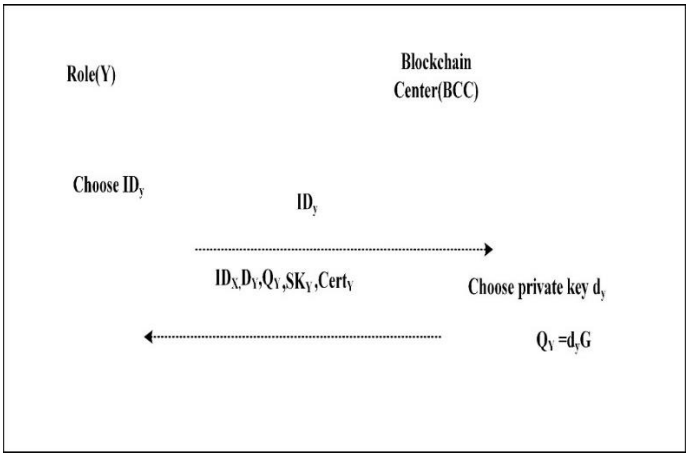

Fig. 2. Registration phase.

3) Communications procedure: The recommended solution makes use of the hyper ledger's block chain design, which increases the CA's role, allows for more versatility in accessing monitoring, and reduces the stress on BCC. After authenticating interactions across all roles, the details will then be provided to the various CAs, which will then send the blockchain information BCC. MI and IC both operate to own CA, which might allow documents flow throughout CA membership as well as cross-CA management of entry while retaining safety & efficacy. The accessible party (AP) might be a hospital (MI), an insurance company (IC), a financial institution (BK), or a client. A schematic representation of the CA communications method is proposed [15]. Blockchain-Based Medical Insurance System is shown in Fig. 3.

E. Event-Driven Architecture Insurance Claim Process

The Claim entity depicts an insurance claim which consumers can file or that current insurance companies may employ to assess how to pay out. The claim form includes a Loss Amount and a connection to the Insurance Policy organization. After an Event has been established, the processing Event method the request may be utilized to determine if it needs to be payed out. The Root Cause Mapping object, typically is a Boolean, is used within the process Event () method to determine if a payout is necessary for a fundamental issue and insurance policy combination. The Root Cause Mapping is defined in the privileges portion of the agreement.

1) Identity NFT: The identification NFT will serve as verification of identification for claim management. Whenever the program is first set up, the NFT is going to be coined (generated) for claims managers using the mailing addresses supplied in the initial setup script. Anyone is unable to establish an event if they have an Identification NFT.

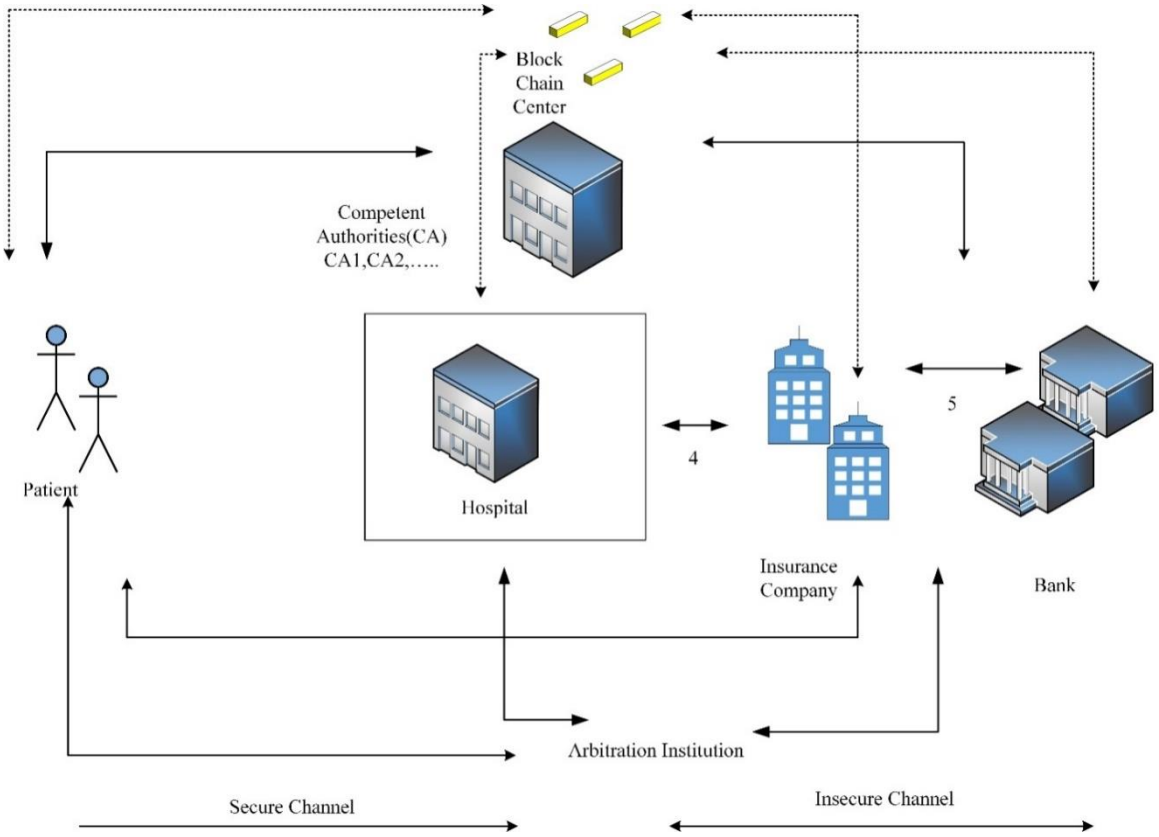

Fig. 3. Blockchain-based medical insurance system.

When the entitlements director organizes an event, their uniqueness is verified by the identification NFT contract. If it is valid, an event is produced in the Event Contract, which is then passed on to the claim contract for processing. All pending claims for the covered protocols are going to be adjusted using Root Cause Mapping. If the amalgamation of the root problem and regulation proves accurate, a payment should be provided. In the initial release of the program, just the claim's current state will be changed.

Any individual may file a right depending on their assurance coverage. The Entitlements agreement will compare information on the insurance against current claims. If previous demands exact similar policy and root cause were previously approved or postponed then the latest one will be assigned the identical status. In subsequent versions of the app, any blockchain-based insurance company may utilize this capability to poll whether or not a entitlement deserves to be paid out, allowing them to streamline this process.

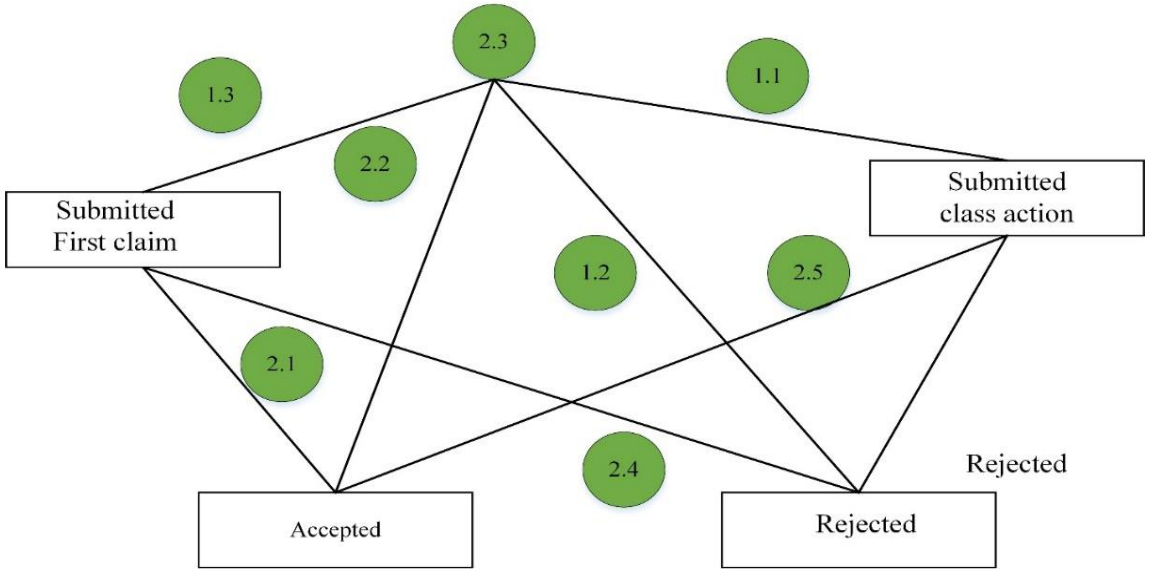

Fig. 4. State diagram of claims object.

The claim is the primary entity in the realm structure. The entitlement made in the framework can be in one of four "states" depending on the user's selections. Phase transitions 1.1 to 1.4 are for newly formed claims. Whenever the request is the initial one for a benefit, it will be marked given the status "submitted - first claim" (1.1). If more than one claim is currently lodged for the asset, it will be marked as "accepted - class action" (1.4). If a entitlements administrator has already accepted or rejected a claim having an identifiable cause, then subsequent claims will be immediately approved (1.2) or denied (1.3). Steps 2.1–2.4 apply to claims that were previously filed at the time the claims administrator reports an event. In that point, all filed claims are going to be immediately approved (2.1 and 2.3) or denied (2.2 or 2.4) [23]. Fig. 4 shows state diagram of claims object.

V. Result and Discussions

The integration of blockchain technology and smart contracts presents a transformative solution for the insurance industry, revolutionizing claims processing and payouts. By automating the entire process based on predefined events, such as natural disasters or medical emergencies, the proposed system eliminates manual claims submission, enhances efficiency, and ensures transparency and security. With payouts executed automatically upon event verification, bureaucratic hurdles are bypassed, leading to expedited processing times and reduced fraud risks. This innovative approach not only streamlines operations but also fosters trust and reliability, ultimately delivering significant benefits to insurers and policyholders alike in a future characterized by expedited, transparent, and trustworthy claims processing.

Event-driven architecture for insurance claim processes is given in Fig. 5 driving events such as policy updates, patient updates, and claim submissions trigger a series of actions. A graph depicting the number of driving events per second illustrates the system's real-time processing capabilities, enabling insurers to handle fluctuating workloads efficiently. This visualization aids in understanding system performance and scalability, ensuring timely and accurate processing of insurance claims.

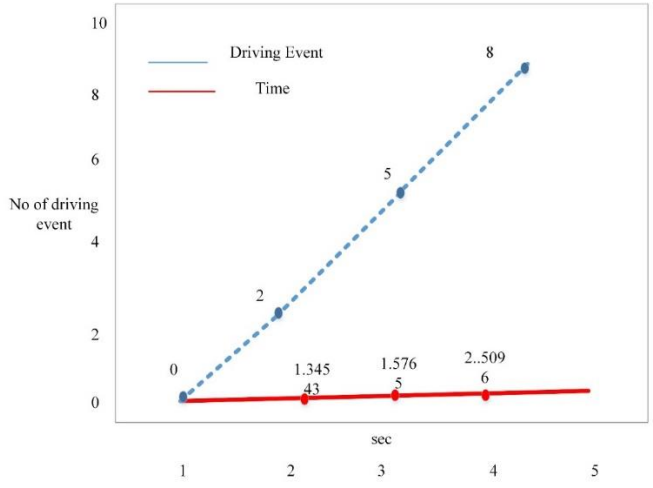

Fig. 5. Event-driven architecture for insurance claim processes.

Fig. 6 depicts a partial dependence plot illustrating how an old claim affects insurance outcomes. It visualizes the relationship between the age of a claim and its impact on insurance variables, such as claim probability or payout amount. This graph, insurers can understand how the age of a claim influences risk assessment and decision-making in insurance processes. It helps identify patterns and trends, enabling more informed underwriting and claims management strategies. This graphical representation facilitates data-driven insights for optimizing insurance operations and managing risk effectively.

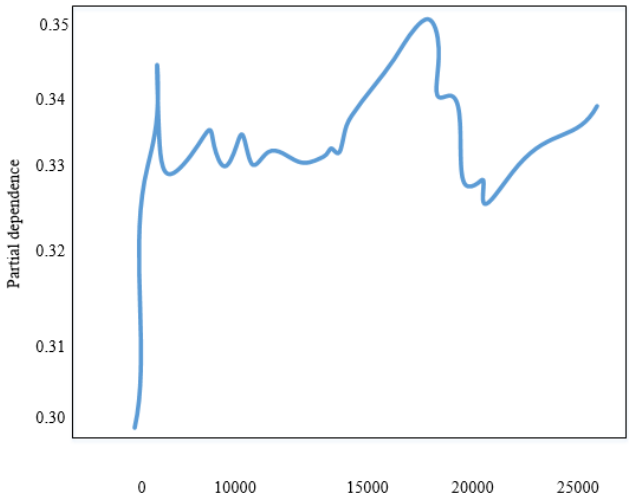

Fig. 6. Automatic insurance claim prediction.

Fig. 7 shows the amounts of paid and denied claims for different categories of old claims the amount of paid claims is higher than denied ones, with the 3rd claim having the highest amount of paid claims. The bar chart helps to visualize the distribution and comparison of paid and denied claims for different categories of old claims.

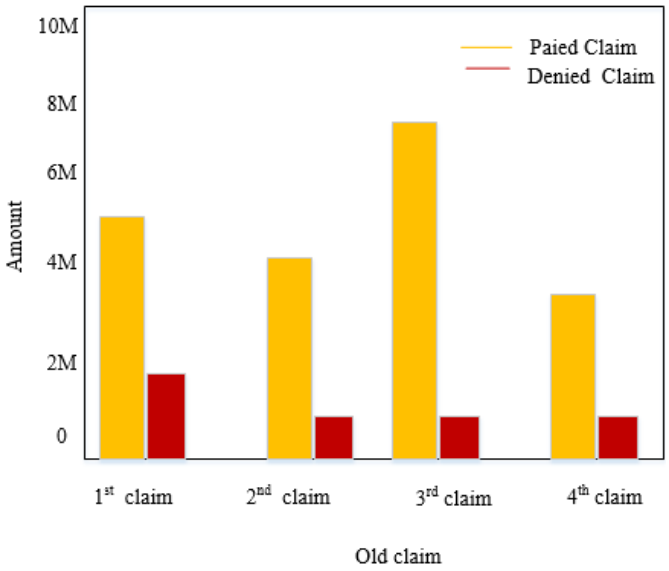

Fig. 7. The amounts of paid and denied claims.

Table I presents performance metrics for different methods the proposed method achieves high accuracy (94.44%) and outperforms others in precision (98.1%), recall (98.98%), and F1-score (98.54%) in Fig. 8. This indicates its effectiveness in correctly identifying positive instances while minimizing false positives and negatives, demonstrating its potential superiority in the classification task.

TABLE I. PERFORMANCE METRICS

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)
RNN	90.54	90.4	92.00	92.44
Auto encoder	92.77	91.88	91.76	91.56
VAE	95.5	93.57	94.01	94.45
Proposed method	97.6	98.1	98.98	98.54

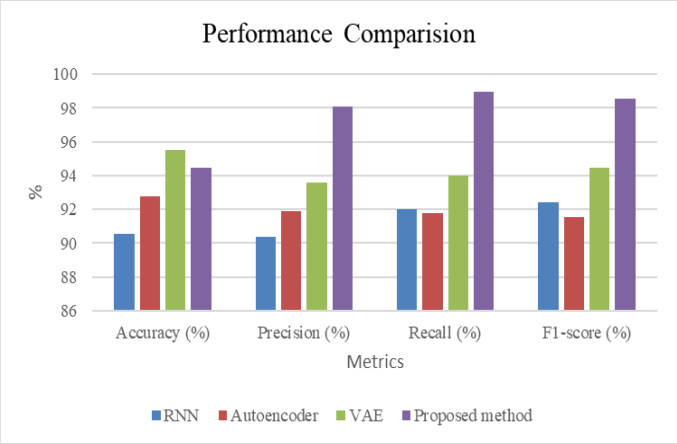

Fig. 8. Performance comparison.

Table II shows that he proposed method achieves an accuracy of 97.6% using the "Health Insurance Dataset - EDA". It also maintains high accuracy rates with other datasets: MedClaimsData (96.7%), HealthCoverStats (95.8%), and HealthinsureDB (93.7%).

TABLE II. DATASET COMPARISON

Dataset	Proposed Method Accuracy
Health Insurance Dataset-EDA	97.6%
MedClaimsData	96.7%
HealthCoverStats	95.8%
Healthinsure DB	93.7%

A. Discussions

The proposed integration of blockchain technology and smart contracts in insurance claims processing offers several significant advantages. Firstly, it addresses the limitations of the existing method by adopting event-based smart contracts, eliminating the need for manual claims submission. This automation enables automatic triggers based on predefined events such as natural disasters or medical emergencies, accelerating the claims initiation process and ensuring accuracy and transparency. By doing so, it overcomes the existing challenges related to inefficiency and complexity, which require physical visits to facilities for certification before submitting paperwork to insurance firms, leading to delays in compensation and posing challenges in data verification and risk management., By encoding specific conditions and triggers within smart contracts, the entire claims process becomes transparent, secure, and immutable, thereby minimizing the potential for fraud and dispute. Thirdly, the automatic execution of payouts upon verification of triggering events bypasses traditional bureaucratic procedures, leading to significantly reduced processing times [15]. Through the streamlined system outlined, insurers and policyholders stand to benefit from increased efficiency, transparency, and trustworthiness in claims processing, ultimately enhancing the overall insurance experience for all stakeholders. These advantages address the limitations of the existing method, such as challenges related to infrastructure development, legal obstacles, and data availability, thus making the proposed system a more robust and effective solution.

VI. CONCLUSION AND FUTURE WORKS

The integration of blockchain technology and smart contracts has revolutionized the insurance industry by enhancing efficiency, transparency, and reliability. This research proposes a simplified system that automates the entire claims process from submission to reimbursement, eliminating the need for human claim filing. The system triggers policyholders' claims by predetermined occurrences, such as medical emergencies or natural disasters, allowing for prompt and precise claim initiation. Smart contracts, programme with precise triggers and conditions, guarantees the transaction immutability, security, and transparency. Reimbursements are carried out automatically after the triggering event has been verified, reducing processing times and reducing fraud and disagreement. This innovative approach to insurance claims processing has shown significant reductions in processing time, minimized fraud potential, and enhanced transparency. The Python-implemented system achieved 97.6% accuracy, demonstrating its efficacy and reliability. This study contributes to addressing the limitations of existing insurance claim procedures by providing a streamlined, automated, and secure solution. By integrating blockchain technology and smart contracts, the insurance industry can overcome challenges of inefficiency, complexity, and lack of transparency in the current claims processing system. The research questions regarding the feasibility and effectiveness of event-based smart contracts in automating insurance claims processing have been successfully addressed, providing valuable insights for future implementations in the insurance sector.

***Abstract*—Air quality control has drawn a lot of attention from both theoretical research and practical application due to the air pollution problem's increasing severity. As urbanization accelerates, the need for effective air quality monitoring in smart cities becomes increasingly critical. Traditional methods of air quality monitoring often involve stationary monitoring stations, providing limited coverage and outdated data. This study proposes an Internet of Things (IoT) centred framework equipped with inexpensive devices to monitor pollutants vital to human health, in line with World Health Organization recommendations, in response to the pressing issue of air pollution and its increased importance. The hardware development entails building a device that can track significant contamination percentages. Ammonia, carbon monoxide, nitrogen dioxide, PM2.5 and PM10 particulate matter, ozone, and nitrogen dioxide. The gadget is driven by the ESP-WROOM-32 microcontroller, which has Bluetooth and Wi-Fi capabilities for easy data connection to a cloud server. It uses PMSA003, MICS-6814, and MQ-131 sensors. The gadget activates indicators when a pollutant concentration exceeds the allowable limit, enhancing its software to enable immediate response and intervention. This work leverages the robust cloud architecture of Amazon Web Server (AWS) to integrate it into the system and improve accessibility and data control. This combination no longer just ensures data preservation but also enables real-time tracking and analysis, which adds to a comprehensive and preventive strategy for reducing air pollution and preserving public health. With an RMSE score of 3.7656, the Real-Time Alerts with AWS Integration model—which was built in Python—has the lowest value.**

Keywords*—Internet of Things (IoT); air quality control; low-cost sensors; ESP-WROOM-32 microcontroller; Amazon Web Server (AWS)

I. Introduction

Air quality refers to the way filthy the air human's breath. On a typical day, that take over 20,000 breath. Have we considered the toxins, pollen, and dirt we may be breathing? Whenever the air quality is poor, contaminants in the atmosphere can cause eye irritation, irritated the lungs, and respiratory system injury. Fresh air is a basic prerequisite for a healthy atmosphere in which all reside and study [1]. An Air Quality Analysis is an evaluation conducted to determine the benchmark quality of the air and is often necessary for any kind of development which has the ability to damage the present situation or if the surroundings having the capacity to impact sensitivity construction [2]. Air quality may be checked both indoors and outside. An air quality evaluation measures the quantity and quality of air inside the confines of a building or structure. Indoor air quality sampling varied, but typically involves collecting and analyzing air samples with swab/sticky pads. An outdoors atmosphere evaluation can range from a basic screenings to a more extensive study that includes dispersal modelling [3]. The sort of air quality evaluation needed is determined by a variety of criteria, which involve the development's scale, intended place of residence, and existing information of pollutants present around the construction area[4]. A thorough air quality evaluation ought to determine air pollution exposed using the "Air Quality Impact Significance Criteria - New Exposure" and demonstrate any preventative actions related with the development's layout, location, and operations to decrease air pollution [5]. An Air Quality Analysis may be required in support of an inquiry for clearance for works that may have a significant influence on regional traffic moves, transportation structure, or are located near established busy roadways. An appropriate Air Quality evaluation for planned should comprise an inspection of the environmental conditions about the development through surveillance or modeling, an evaluation of the air quality through the construction phase, as well as a monitoring of the air purity through the period of operation. Tracking air quality monitors contaminants such as gases and particulates. Measuring such contaminants enables the enhancement of the atmosphere via construction planning, management, and mitigation methods. Enhancing air quality is critical in decreasing negative health consequences and offering an improved standard of life [6].

According to the World Health Organization (WHO), pollution in the air causes 4.2 million premature deaths annually in urban and rural regions worldwide. According to the US Environmental Protection Agency, particulates with a

measurement of less than ten µm is unique of the biggest pressures to community health due to its easy passage through respiratory systems, producing significant health damage. According to Valdivia in and Pacsi, Metropolitan Lima (LIM) is sensitive to high levels of PM_{10} due to its rapid manufacturing and economic expansion, as well as its big human population, which accounts for 29% of the country's total population.To mitigate the impairment wrought by PM_{10} to public health, the WHO developed level thresholds ideal for achieving a minimum adverse effect on health5. In different nations, multiple regulations have been passed to regulatePM_{10} concentrations and air quality in overall, such as those developed in Peru by the Ministry of the Environment as well as in the United States by the Environmental Protection Agency (EPA). In recent decades, several predictions methodologies have been modified and modified to better understand way pollution function in the natural environment at the level of molecules, including predicting diffusion and dispersal trends according to molecule dimension and class [7]. Nevertheless, predictions based on findings tend to have a low accuracy . The EPA describes inside air quality (IAQ) as the purity of airborne in buildings grounds or sealed rooms that can have a substantial influence on the well-being of tenants, ease, and performance rates [8], It has been established that human activity, manufacturing processes, and rising traffic on roadways are the main culprits causing the decline of the natural world [9]. In addition to various outside factors, low thermal ease levels owing to excessive moisture and temperature in confined buildings, insufficient ventilation administration, dangerous construction supplies, and every day human behavior all have an impact on IAQ [10]. The increasing levels of dangerous pollutants [11].

Indoor surroundings are also connected to the worsening wellness of building inhabitants, particularly older adults, newborns, people with impairments, and domestic women, who spending the majority of their lives inside [12] .As a result, it is critical to grasp all elements of inside airborne pollution (IAP) and its influence on the general population, as well as discover suitable IAQ management techniques in sealed buildings. According to a study of over 30,000 organizations in the United States, indoor air quality control is the country's top priority since it is inflicting significant harm to the well-being and health of individuals [13]. On the other hand, long-lasting medical impacts include pneumonia, pulmonary TB, hostile gestation results, asthma, chronic bronchitis, cancer, and coronary artery disease that individuals may experience after frequent & extended exposure [14] A wide range of contaminants harm the well-being of structure inhabitants in homes, workplaces, cafés, medical facilities, and retail malls. Because of the increased traffic activities, manufacturing operations, and facilities ambient air pollution values are rising sharply, that eventually explains for the declining IAQ values. [15].

The researchers have previously released thorough systematic studies that emphasize existing improvements in the area of IAQ monitoring and examination, as well as emphasizing the significance, difficulties, and future years sights of this significant area of studies, in order to offer knowledge about the associated research [16]. Aside from this, various papers were released on the creation of forecasting algorithms using neural networks, artificial intelligence, and advanced learning methodologies to provide building residents with an early warning of dangerous pollutant concentrations. In addition, the authors released a systematic review to emphasize the contributions already established scholars in the subject, as well as the gaps in knowledge [17]. The researchers gathered present data from 4 separate countryside and urban sites on six significant IAQ parameters, namely, PM_{10}, PM_{25}, CO_2, CO, NO_2, as well as two critical thermal convenience factors, humidity and temperature. Finally, the model was modified utilizing the pattern searching technique to advance the correctness of predictions, allowing the suggested system to be applied in real-time settings to prevent the negative implications of low IAQ levels [18]. The suggested model is dubbed continuous because it employs an evolving set of input characteristics based on the selected response variable for predictions.

Key contributions are as follows:

- The urgent problem of air pollution is addressed by proposing an Internet of Things system with inexpensive sensors for real-time monitoring of important air contaminants.
- Ensures a focused and effective strategy by focusing on contaminants that are critical to human health and adhering to World Health Organization recommendations.
- Provides a comprehensive understanding of air quality by developing a hardware approach capable of calculating the amounts of important pollutants including PM2.5, PM10, ozone, carbon monoxide, nitrogen dioxide, and ammonia.
- Enables smooth data transfer to a cloud server for effective monitoring and analysis by utilizing the Wi-Fi and Bluetooth capabilities of the ESP-WROOM-32 microcontroller.
- Establishes a mechanism whereby the apparatus activates indicators when the concentration of pollutants exceeds allowable limits, improving its software for prompt reaction and interference, and supporting proactive air quality management.
- Enhances the overall efficacy of air pollution prevention efforts by integrating Amazon Web Server (AWS) into the system and utilizing its reliable cloud architecture for simplified data management, storage, and real-time tracking and analysis.

The following is how the investigation progresses: In Section II. Related studies perform a thorough analysis of earlier research, focusing on prediction issues and the wide range of optimization techniques used in such settings. In Section III, a thorough investigation of issue statements is conducted. Section IV elaborates on the suggested method or plan of action to deal with these difficulties. The entire topic of performance evaluation metrics and criteria is covered in Section V. Subsequently. Section VI serves as the essay's conclusion by summarizing the main findings and learning.

II. Related Works

Air pollution is a key contributor to global warming, and efforts to address it are gaining traction. Urban areas use computer technology (IT) and communications technologies to reduce emission levels and noise pollution. The goal is to reduce health-related hazards and improve understanding about the impacts of pollutants in the air exposures. The present research explores the major concerns of a current pollution tracking scheme, such as sensors, connection procedures, collecting data and transfer over routes of communication, and information security and uniformity. Safety is a significant emphasis of the suggested IoT system.The system's additional parts are also focused on security. This document includes a bill for supplies and protocol specifications required for the planning, creation, and execution of an IoT system, in addition to security issues. The paper's evidence of concept (PoC) addresses IoT security issues regarding communiqué pathways among linked device gateway and the cloud-based systems to which information is sent. The security measures adhere to recognized principles, guidelines, and regulations, leading to a consistent and healthy system., the software can read and analyze the collected data, creating pollutant maps using modelling techniques. The maps are utilized to undertake real-time treatments, such as redirecting transportation in a chief metropolis, to reduce concentrations of airborne contaminants using information gathered for a year in a row. When paired with traffic control equipment (cameras and traffic signals), this technology may minimize vehicle emissions by constantly proposing other courses or even demanding reroute if pollution levels are exceeded. Still, the study must concentrate on case studies for implementing the PoC with improvements to various medium cities in collaboration with local governments in order to observe the traffic affect models and how they interact into additional advanced city systems, since current projects like AirVisual are limited [19].

The quantity of IoT-based applications for smart cities is growing rapidly, as is the volume of data generated by those applications. To guarantee long-term growth, administrations and city stakeholders take proactive steps to manage this data and forecast effects in the future. Techniques based on deep learning have been applied to a variety of large-scale information forecasting challenges. This motivates us to apply methods based on deep learning for predicting IoT data. As a result, this research proposes a unique deep learning algorithm for analyzing IoT smart city data. A new model that utilizes Long Short-Term Memory (LSTM) networks for predicting upcoming air quality levels in a smart city. The suggested model's assessment findings are positive, indicating the method may also be utilized to solve other innovative city prediction challenges. However, one major limitation of this work is the low generalization of the suggested LSTM-based model, as its efficacy may be highly influenced by specific features of the analyzed smart city data. Furthermore, the research might fail to address possible privacy and security concerns related to managing and analyzing confidential IoT data in a smart city environment [20].

Sometimes emissions have grown owing to a variety of factors, including growing populations, greater car usage, manufacturing, and urbanization, among others that have had a substantial impact on human health. To pay attention to the circumstance. The research involves an air pollution surveillance system that is an Internet of Things via sensors dependent structure. You monitor the overall condition of the air via a web server on the World Wide Web and produce warnings while the quality of the air goes beyond an established limit, and these suggests if enough dangerous gas have been detected in the atmosphere such as benzene, smoke, NH_3, CO_2, and alcohol. The expansion of commerce and rapid human population urbanization have a negative influence on global air quality. Long-term exposure to air pollution causes chronic heart and lung ailments, which endangers people's well-being. Every day, thousands of companies and billions of automobiles emit massive amounts of pollutants in the atmosphere. As a result, monitoring pollutants in the air has become vital. The investigation presents the creation of an Internet of Things-driven air quality surveillance system and analyzes the effectiveness of the air pollution tracking system. But the disadvantage of this research is that the efficiency of the IoT-based air quality tracking systems may be affected by the exactness and dependability of the sensors utilized, potentially leading to mistakes in contaminants estimations [21].

Exhaling and breathing filthy air has major health repercussions. Regular surveillance and record-keeping can help to reduce the impact of air pollution. In addition, early forecast of pollution levels can assist government agencies in taking proactive environmental protection actions. In this study, researchers suggested employing the ml methods and IoT for tracking pollutants in the air in smart cities in the future. The Pearson coefficient reveals a strong link between contaminants and meteorological factors. In contrast to typical sensor networks, this study employs a cloud-and IoT architecture that collects information obtained from airborne pollutants sensors and weather conditions sensors. Thus delivers twofold dependability and lower expenses greatly. The amount of sulphur dioxide (SO2) and particulate matter (PM2.5) was predicted using an artificial neural network. The encouraging outcomes show that ANN is a trustworthy choice for pollution surveillance and forecasting systems. The models They developed attained Root Mean Squared Error values of 0.0128 and 0.0001 for SO2 and PM2.5, respectively. However, one disadvantage of this research is its dependence on Pearson correlation to create a significant connection among contaminants and meteorological indicators can simplify the complicated relationships in the atmosphere's dynamics, which could contribute to less precise forecasts [22].
