Right-wing online aggression, which manifests through biased, isolative, or retrogressive viewpoints, wields nuanced linguistic markers and undergoes continuous transformations, eluding traditional text analytics [22]. Contemporary computational algorithms, albeit offering some solutions, grapple with challenges, such as the incapacity to comprehend extended temporal relations in series data (LSTM inadequacy) and to decode layered spatial characteristics (CNN shortcomings) [23].

Moreover, a significant portion of academic scrutiny veers toward general cyber aggression or its distinct variants, sidelining the specific matter of right-wing aggression. This marginalized attention to RWE, in tandem with the metamorphosing rhetoric, amplifies the void in our comprehension and competence in pinpointing this specific cyber menace [24].

The present manuscript endeavors to navigate these quandaries by championing a novel LSTM-CNN amalgamated model. By merging LSTM's prowess in sequential analysis with CNN's aptitude for detail extraction, the suggested framework aspires to grasp both the circumstantial and semantic intricacies emblematic of RWE dialect.

This investigative endeavor prompts an array of academic queries:

- 1) In what manner can the combined LSTM-CNN architecture be meticulously constructed and primed for the discernment of RWE in digital dialogues?
- 2) How does the advocated LSTM-CNN framework juxtapose against prevailing computational techniques concerning metrics?
- 3) How is the LSTM-CNN structure calibrated to stay abreast with the fluid linguistic shifts and subtleties characteristic of RWE exchanges?
- 4) How might the insights culled from this study be pragmatically infused into digital oversight instruments, counter-radicalization measures, and policy formulation?

The dissection of these queries will delineate the blueprint and appraisal of the recommended LSTM-CNN construct for

RWE recognition, propelling us closer to the overarching vision of cultivating harmonious and inclusive digital arenas.

B. Research Methodology

This research sets out to harness an integrative deep learning classifier, aiming to enhance language modeling and text categorization, specifically targeting the identification of suicidal tendencies within the textual milieu of Reddit's digital content [25]. Our methodological blueprint offers an exhaustive account of procedures, embracing a spectrum of Natural Language Processing (NLP) modalities, coupled with text categorization strategies.

Illustrated in Fig. 1, our advanced schema elucidates two divergent pathways for textual data analytics. The inaugural pathway is rooted in initial data cleansing, segueing into attribute derivation using NLP methodologies [26-29]. These mechanisms transform textual elements, priming them for subsequent analysis by conventional computational algorithms, which establish the foundational methods.

Conversely, the alternate pathway commences similarly with data refinement, evolving into attribute derivation. In this spectrum, semantic vector representations are the focal point, leading to the deployment of advanced neural classifiers. A duo of distinct deep learning classifiers is brought into play: one delineating the foundational approach, while the other crystallizes the avant-garde model postulated in our investigation.

C. Proposed Method

To discern indications of suicidal tendencies within Reddit's discourse, this research leverages the capabilities inherent in both CNN and LSTM frameworks. The advocated approach involves a symbiotic LSTM-CNN network tailored for detecting right-wing online aggression across digital platforms. The

network's architecture orchestrates the LSTM's outputs to seamlessly transition as inputs to the convolutional neural network. This sequential arrangement, in turn, facilitates the convolutional layer to extract pivotal features, amplifying the fidelity of textual categorizations.

Illustrated in Fig. 2 is the schematic of the combined LSTM-CNN model, calibrated to segregate narratives into potentially aggressive or benign domains. The blueprint is orchestrated in a stratified manner. Commencing with the word embedding tier, every term within a sequence receives a distinct identifier, culminating in a standardized vector. This stage is succeeded by the introduction of a dropout tier, a preventive measure against model overfitting. Thereafter, an LSTM stratum is interwoven, designed to fathom extended relational patterns within the textual corpus, trailed by a convolutional stratum honed for salient feature discernment. Culminating the architecture, pooling, flattening, and softmax strata collaboratively function to categorize narratives into potential online aggression or neutral categories.

D. LSTM Block

LSTM functions within the broader milieu of RNN frameworks. These are predominantly leveraged in profound learning endeavors to categorize, elucidate, and forecast sequential patterns in textual datasets. Unlike its generic RNN counterpart, LSTM embodies superior resilience and exhibits an enhanced proficiency in discerning extensive temporal correlations. Its design incorporates a distinctive memory cell directing the flux across its gates. This particular trait renders LSTM particularly adept for pinpointing potential online aggression instances within digital platforms. A salient merit of LSTM resides in its prowess to mitigate the notorious gradient vanishing or proliferation quandaries endemic to RNNs.

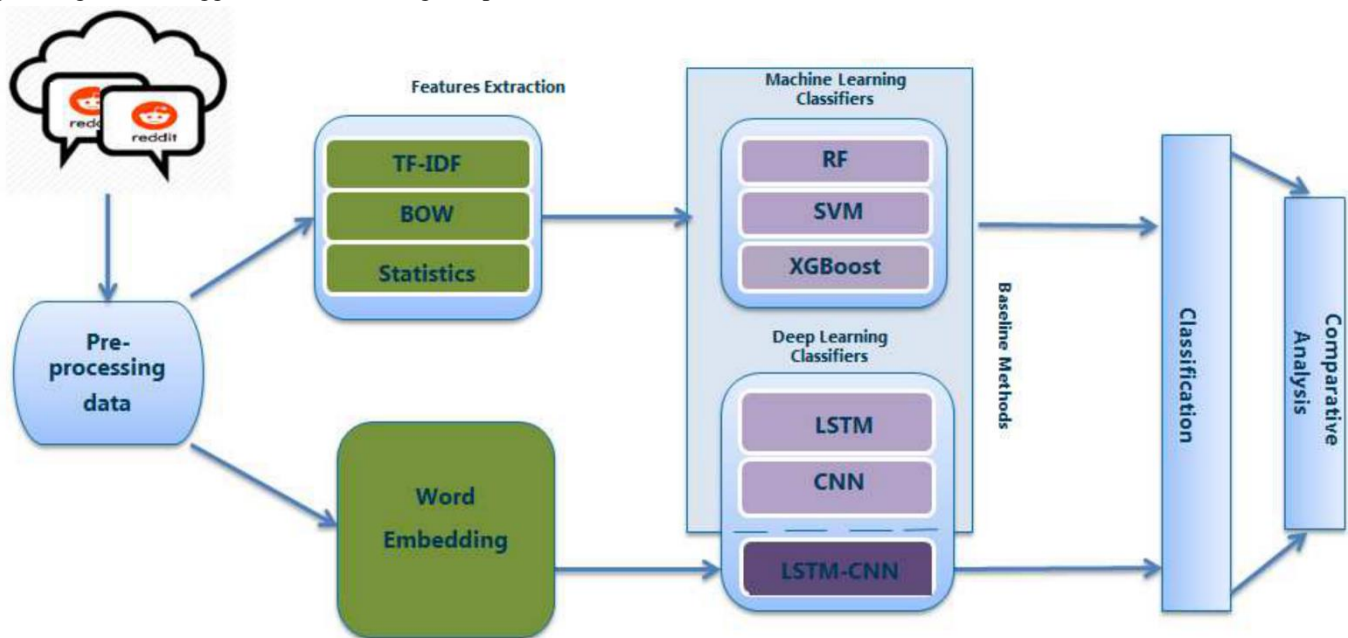

Fig. 1. Architecture of the proposed framework.

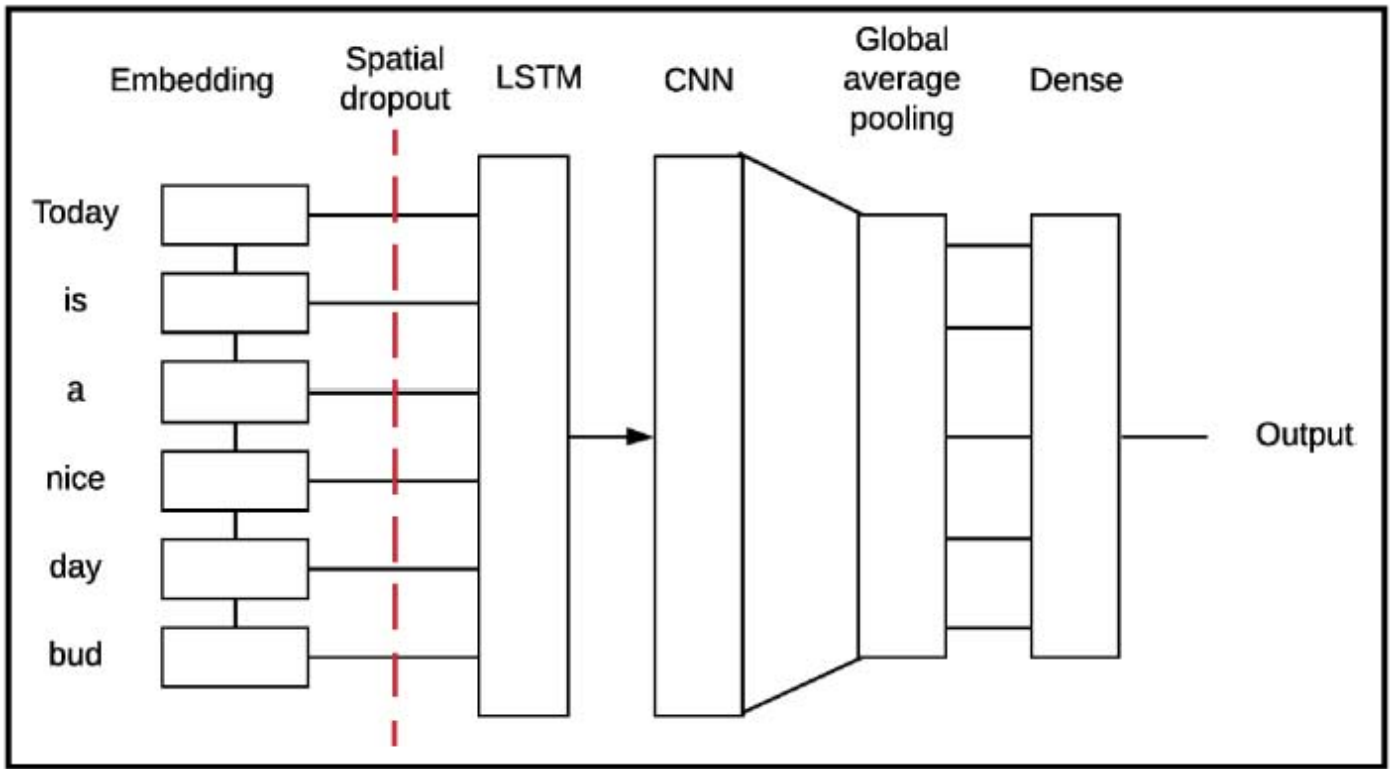

Fig. 2. Proposed Method.

For this specific layer, our configuration introduces a solitary tier composed of multiple LSTM nodes. Each individual cell orchestrates a quartet of computational operations, distributed across four distinct gates. The LSTM stratum's blueprint receives input sequences $X = (x_t)$, which are manifested as a d -dimensional lexical vector representation. Herein, 'H' denotes the quantity of nodes embedded within the LSTM's concealed tier [30].

$$f_t = \sigma(W_f x_t + U_f h_{t-1} + b_f) \quad (1)$$

$$i_t = \sigma(W_i x_t + U_i h_{t-1} + b_i) \quad (2)$$

$$o_t = \sigma(W_o x_t + U_o h_{t-1} + b_o) \quad (3)$$

$$u_t = \tanh(W_u x_t + U_u h_{t-1} + b_u) \quad (4)$$

$$c_t = f_t \odot c_{t-1} + i_t \odot U_t \quad (5)$$

$$h_t = o_t \odot \tanh(c_t) \quad (6)$$

Within the specified mathematical representations, δ exemplifies a sigmoid activation mechanism, whereas \odot symbolizes component-wise product operations. The entities W_f and U_f refer to dual weight matrices, with b_f designating an associated bias vector.

The function of the input gate is to adjudicate the assimilation of novel informational fragments into the memory cell. This cell, by its nature, retains data iteratively, paving the

way for extended relational comprehension with incoming data. Subsequent to the data's evolution or removal via the sigmoid stratum, the tanh layer ascertains the information's relative magnitude, oscillating between values of -1 and 1.

E. Convolutional Block

The convolutional stratum, a pivotal facet of the CNN, originated with a primary focus on image processing tasks, where it showcased remarkable efficacy [31]. In the ensuing periods, the versatility of CNNs has been expanded exponentially, positioning it as a malleable framework harnessed for a plethora of text classification endeavors, garnering impressive results.

The convolutional filter is delineated as $F \in R_j \times k$, with 'j' representing the volume of lexical units within the designated window, while 'k' signifies the magnitude of the lexical vector representation. For the convolutional filter $F = [F_0, F_2, \dots, F_{m-1}]$, a discrete value is produced at the t th temporal juncture as articulated in Eq. (7).

$$O_{F_t} = \text{ReLU} \left[\sum_{i=0}^{m-1} h_{t+i}^T F_i + b \right] \quad (7)$$

In the previously outlined scenario, 'b' signifies a bias component, with 'F' and 'b' encompassing the parameters pertinent to this specific filter. Following this, a feature landscape is generated, and the ReLU activation mechanism is invoked to mitigate non-linear characteristics. The computational depiction of this procedure is articulated below:

$$F(x) = \max(0, x) \quad (8)$$

Within the framework of our study, we employ an array of convolutional filters, each characterized by distinct parameter configurations, aiming to derive diverse mapping patterns from the textual corpus [13].

$$P(y^{(i)} = j | x^{(i)}; \theta) = \frac{e^{\theta_j^T x^{(i)}}}{\sum_{k=1}^K e^{\theta_k^T x^{(i)}} \quad (9)$$

The pooling layer primarily serves to diminish the dimension of every activated feature landscape, maintaining the essence of salient data. Integral to this stratum is its ability to compact input depictions into abbreviated, tractable formats, subsequently curtailing the number of parameters and computational demands in the architecture. Such a trait is instrumental in mitigating the risk of overfitting [32]. In the confines of our investigation, we utilize a max pooling technique, adeptly preserving the quintessential data in each feature landscape.

IV. EXPERIMENTAL RESULTS

A. Feature Engineering

In this segment, we offer a juxtaposition of diverse machine learning paradigms geared towards the categorization of religious cyberbullying, leveraging assorted feature amalgamations. Our investigation encompasses a gamut of prevalent techniques for classifier formulation and tutelage [33-35]. Throughout the model training phase, we employed a spectrum of features, conducting myriad experiments with

distinct feature sets. Fig. 3 elucidates the array of features incorporated in our study.

Table III elucidates the efficacy displayed by each technique upon the integration of diverse feature sets. It is conspicuous that there's an enhancement in the performance of methodologies as a broader feature spectrum is assimilated. This trend underscores the significance and potency of the harnessed features. Nonetheless, it's pivotal to recognize that each specific feature's influence manifests considerable disparities, reflecting divergences in the outcomes across various methodologies. Of the methods in play, SVM and LR outshine the rest when capitalizing on the entirety of the feature cohorts for input. Additionally, Random Forest and Naïve Bayes render notable outcomes, especially in the context of the F1-score.

Within every classification framework, the AUC (Area Under the Curve) metric serves as the benchmark for assessing the caliber of the classifier, employing the receiver operating characteristic curve across the gamut of curated features. The scrutiny underscores a salient trajectory wherein the AUC efficacy progressively escalates in tandem with the augmentation in feature count.

In particular, the Logistic Regression technique shines preeminently, boasting an exemplary AUC metric of 0.9759. Moreover, a significant proportion of the alternative methodologies manifest AUC metrics surpassing 0.9, denoting robust class differentiation proficiencies. The ROC trajectories pertinent to these methodologies are graphically showcased in Fig. 4, furnishing an exhaustive portrayal of their performance nuances.

Fig. 3. Feature engineering.

Fig. 4. Experimental results.

Fig. 5. AUC-ROC curve of machine learning models and the proposed model in cyberbullying detection.

Fig. 5 illustrates the trajectories of the Area Under the Curve of the Receiver Operating Characteristic (AUC-ROC) for the proposed model alongside various machine learning methodologies employed in cyberbullying detection. Analysis of the results indicates that Support Vector Machines, Random Forest, and Logistic Regression manifest more favorable AUC-ROC trajectories compared to alternative approaches within the cyberbullying detection domain. Particularly noteworthy is the markedly lower AUC-ROC trajectory observed for the Naive Bayes method, registering at a mere 0.51. This outcome suggests that Naive Bayes exhibits limited efficacy for practical implementation in cyberbullying detection endeavors. These analytical findings underscore the critical significance of judiciously selecting machine learning algorithms to enhance the performance of cyberbullying detection systems.

V. DISCUSSION

The investigation into LSTM-CNN hybrid neural network architectures for cyberbullying detection on social media platforms has yielded promising outcomes, as evidenced by the reviewed literature. Such models hold significant implications for enhancing the efficacy of cyberbullying detection mechanisms, potentially contributing to the creation of safer online environments. However, it is essential to acknowledge the limitations inherent in these models, including the need for extensive computational resources and data preprocessing efforts. Additionally, the evolving nature of online communication poses challenges in ensuring the adaptability and generalizability of these models over time. Therefore, future research endeavors should focus on addressing these limitations by exploring innovative approaches to model development, incorporating multi-modal data sources, and devising strategies for continual model refinement. Ultimately, the adoption of LSTM-CNN hybrid neural networks represents a promising avenue for advancing cyberbullying detection capabilities, albeit requiring careful consideration of its limitations and avenues for improvement.

The integration of LSTM and CNN components in hybrid neural network architectures offers several advantages for cyberbullying detection tasks. LSTM units enable the model to capture temporal dependencies and contextual information within textual content, while CNN layers effectively extract spatial features from textual and visual data. This combination facilitates a comprehensive analysis of social media posts, enhancing the model's ability to detect subtle nuances indicative of cyberbullying behavior [36]. Furthermore, the utilization of ensemble learning techniques allows for the aggregation of multiple LSTM-CNN hybrid models, mitigating the risk of overfitting and improving classification accuracy [37].

However, despite the promising capabilities of LSTM-CNN hybrid models, several limitations warrant consideration. One notable limitation is the interpretability of these complex neural network architectures. While LSTM-CNN hybrids achieve high classification performance, understanding the specific features and patterns driving their predictions remains challenging. As a result, model interpretability is compromised, hindering the ability to provide actionable insights for stakeholders, such as social media platform administrators and law enforcement agencies [38]. Additionally, the reliance on large-scale labeled datasets poses a significant challenge for training robust LSTM-CNN hybrid models. Cyberbullying detection requires annotated data encompassing diverse forms of cyberbullying behavior, which may be scarce and costly to obtain [39].

Moreover, the integration of visual information into LSTM-CNN hybrids introduces additional computational complexity and resource requirements. Analyzing multimedia content, such as images and videos, necessitates extensive preprocessing and feature extraction pipelines, leading to increased computational overhead and longer training times [40]. Furthermore, the generalization of LSTM-CNN hybrid models across different social media platforms and cultural contexts remains an open challenge. Social media platforms exhibit diverse user demographics, cultural norms, and linguistic variations, necessitating robust models that can adapt to varying data distributions and linguistic nuances [41].

Addressing these challenges requires concerted efforts and advancements in several key areas. Firstly, enhancing the interpretability of LSTM-CNN hybrid models is crucial for fostering trust and transparency in cyberbullying detection systems. Future research should explore methods for visualizing and explaining the decision-making process of complex neural network architectures, enabling stakeholders to understand and interpret model predictions [42]. Additionally, the development of transfer learning techniques tailored for cyberbullying detection could alleviate the data scarcity issue by leveraging pre-trained models and auxiliary datasets [43].

Furthermore, advancing research in multimodal fusion techniques and domain-specific feature integration could enhance the robustness and generalization of LSTM-CNN hybrid models across diverse social media platforms and cultural contexts. By effectively integrating textual, visual, and metadata features, hybrid models can capture rich contextual information and linguistic nuances, leading to improved cyberbullying detection performance [44]. Additionally, exploring novel attention mechanisms and adversarial training strategies may further enhance the discriminative power and resilience of LSTM-CNN hybrid models against adversarial attacks and data perturbations [45].

In conclusion, LSTM-CNN hybrid neural network architectures offer a promising approach for cyberbullying detection on social media platforms. Despite their notable advantages, challenges such as model interpretability, data scarcity, computational complexity, and generalization across diverse contexts remain significant hurdles. Addressing these challenges requires interdisciplinary collaboration and continued research efforts to develop robust, interpretable, and scalable cyberbullying detection systems that can effectively

mitigate the harmful impacts of cyberbullying in online communities.

VI. CONCLUSION

The advent of the digital era has brought about unprecedented access to information and an expansive platform for self-expression; however, concomitantly, it has also heightened the propagation of extremist ideologies and cyberbullying narratives. Addressing this concern, our study aims to develop an efficient mechanism for identifying instances of cyberbullying, with a specific emphasis on identifying right-wing extremist content disseminated across online platforms. By amalgamating the complementary capabilities of Long Short-Term Memory (LSTM) and Convolutional Neural Network (CNN) architectures, we have formulated a model adept at discerning the subtleties and complexities inherent in extremist discourse. The efficacy of the model is corroborated by evaluation metrics, notably the Area Under the Curve of the Receiver Operating Characteristic (AUC-ROC), which attests to its superior discriminatory prowess compared to conventional machine learning methodologies. Such advancements in technology hold significant promise for online content moderators, policy makers, and digital platforms striving to foster a more inclusive and secure user environment. Nevertheless, it is imperative to acknowledge that as online linguistic landscapes evolve, so too does the manifestation of cyberbullying. This underscores the need for continual refinement and adaptation of detection models. Future research endeavors should prioritize the exploration of evolving linguistic patterns and consider integrating multimodal data sources to augment the robustness of cyberbullying detection mechanisms.

Studying the Behavior of a Modified Deep Learning Model for Disease Detection Through X-ray Chest Images

Elma Zanaj, Lorena Balliu, Gledis Basha, Elunada Gjata, Elinda Kajo Meçe
Faculty of Technology of Information, Polytechnic University of Tirana, Tirana, Albania

Abstract—In modern medical diagnostics, Deep Learning models are commonly used for illness diagnosis, especially over X-ray chest images. Deep Learning approaches provide unmatched promise for early identification, prognosis, and treatment evaluation across a range of illnesses, by combining sophisticated algorithms with large datasets. It is crucial to research these models to lead to improved ones to progress toward disease identification's precision, effectiveness, and scalability. This paper presents the study of a CNN+VGG19 Deep Learning architecture (subsets of machine learning), both before and after its modification. The same dataset is used over the existing and modified models to compare metrics under the same conditions. They are compared using metrics like loss, accuracy, precision, sensitivity, and AUC. These metrics display lower values in the updated model than in the original one. The numbers demonstrate the occurrence of the overfitting phenomenon, which is most likely the result of the model's increased complexity for a small dataset. The noise in the images included in the dataset may also be the cause. As a result, it can be stated that regularization techniques should be applied; otherwise, layers of extraction and classification should not be added to the model to prevent overfitting.

Keywords—Machine learning; big data; X-ray chest image; CNN; VGG19

I. INTRODUCTION

In recent years, Deep Learning techniques related to pulmonary disorders have become more and more useful and more and more studied. These research presented us with the reality of new or modern medicine. Numerous studies conducted in this area, used it, aiming to identify the ideal architecture for lung diagnostics. Chest X-ray (CXR) and Computed Tomography (CT) scans are often the most widely used datasets. Many researchers have examined these datasets separately or combined.

According to these studies, datasets that combine CXR images with CT scans are currently the most utilized. One of the base works in this area is the multi-class classification categorization of lung illnesses using Deep Learning architectures like CNN and VGG19, which both, separately are known for their simplicity and effectiveness.

A different Deep Learning model is applied for the first time in a study that is considered as a basis for the work that will be implied in this paper. In that study, a multiclass classification for lung conditions applies datasets of CXR images. CNN and

VGG19 are utilized to implement the DL model. The dataset is split into training and validation sets following the standard procedure for using this kind of method. Therefore, the dataset was split into 80% training and 20% validation for a total of 5000 epochs of model training. This model generated very good performance metrics. The core model, in which this paper is based on, reached accuracy (96.48%), recall (93.75%), precision (97.56%), F1 score (95.62%), and area under the curve (AUC) (99.82%).

While the model's performance and results are outstanding, there is still much space for further research, particularly in Deep Learning architectures. Customization is used to maximize benefits from them. This would result in models that are more adaptable and efficient. To enhance the interpretation of pulmonary pathology, it is possible to combine both CT and CXR images. This is what this study includes within the framework of Deep Learning algorithms.

This paper studies CNN+VGG19, a Deep Learning architecture. Its core, or basic form got from [1], is studied first, followed by its modified form. Emphasizing the behavioral characteristics of the model in both versions is the primary goal. To see the comparison of the measures of loss, accuracy, precision, sensitivity, and AUC, this study will use a standardized dataset. As a result, conclusions concerning the model's efficacy and adaptability are stated via conclusions reached.

The Region of Interest (ROI) is another fascinating feature that is highly desirable to investigate. It can be a future flow to follow since it is becoming more and more common in many applications connected to object detection, image processing, and medical diagnostics. Based on recent research, it has been suggested that enhanced performance may result from incorporating feature extraction and classification layers with the preceding Deep Learning techniques. This would significantly simplify the duties and the application itself.

This DL model's results provide a significant contribution to the model's complexity. The two indicated layers that were added to the model together with the noise are not improving the model. The results will show that it will lead overfitting, which can be result on by noise in the data, a shortage of trainable samples, or a more complicated model. This study demonstrates that adding noise to the images did not improve their variance, but rather made it more difficult for the model to detect the proper logic patterns during training. Noise inclusion should be

removed, and other tests done on a larger dataset with the modified model.

The structure of the paper is as follows: Section II provides an overview of the literature of previous research on lung image detection using CNN and deep learning. The study approach, the initial model, and the changes that resulted in the new model examined in this work are all included in Section III. The results are displayed at Section IV. Discussions continue in Section V. Finally, the Conclusion in Section VI is going to concentrate on resume of the work done and will give suggestions for further works.

II. LITERATURE REVIEW

Numerous studies have worked over the use of CNN and Deep Learning to detect or classify lung illnesses. Their goal is to identify the top Deep Learning model that allows the highly accurate diagnosis of different illnesses. We can look at cases one by one or with other methods or data.

CNNs are a part of Artificial Neural Networks (ANN) and help with medical image analysis, through feature extraction and learning [2]. CNN is well renowned for its superior performance in several 2D and 3D medical image processing applications, including classification, segmentation, and detection. A feature filter that is placed on top and slides along the input layer of the neural network executes the convolution process. As a result, is generated a feature map. The layer that performs the convolution process is called the convolution layer. 2D CNN convolution is done through extracting features only from a 2-dimensional space [3]. The value of a unit at (x,y) in the i layer in the j feature, defined as: v_{ij}^{xy} is given by Eq. (1).

$$v_{ij}^{xy} = f\left(b_{ij} + \sum_m \sum_{p=0}^{P_i-4} \sum_{q=0}^{Q_i-1} w_{ijm}^{pq} v_{(i-q)m}^{(x+p)(y+q)}\right) \quad (1)$$

Where: f is the activation function, b_{ij} is the addition of the feature map, m is the number of filters in the (i-1) layer, w_{ijm}^{pq} is the value for the position (p, q) of the connected particle in the map of the k characteristics and P_i and Q_i represent respectively the length and width of the particle.

3D CNN convolution is performed through the same concept but applied over a 3-dimensional space. Eq. (1) is modified and expanded to lead to Eq. (2) as follows:

$$v_{ij}^{xy} = f\left(b_{ij} + \sum_m \sum_{p=0}^{P_i-4} \sum_{q=0}^{Q_i-1} \sum_{r=0}^{R_i-1} w_{ijm}^{pqr} v_{(i-q)m}^{(x+p)(y+q)(z+r)}\right) \quad (2)$$

Where: R_i is the size of the 3D particle together with the third spatial dimension and w_{ijm}^{pqr} is the value of the (p, q, r) particle related to the previous m-layer map.

VGG19 has 19 layers and is a complicated convolutional neural network. According to [4], increasing recognition or classification accuracy requires a certain level of network depth. At [5], chest X-ray images are divided into three primary groups using a hybrid DCNN technique. DCNN hybrid network is created by the Inception module and VGG blocks together. A precision rate of 99.25%, a Kappa-score of 99.10%, an AUC of 99.43%, an F1-score of 99.24%, and a recall of 99.25% were reached when applied to the dataset by the suggested strategy. The results of the experiments demonstrate the efficiency and

robustness of the hybrid DCNN mechanism utilized in this work.

The LungNet22 is developed using new layers and hyper parameters, building upon the VGG16 [6]. After the fifth block of VGG16, two blocks are connected to produce LungNet22. In the sixth block are three structures and a GlobalAveragePooling2D structure, while in the seventh block is a scatter structure linked to a dense structure. AUC values and the ROC curve were among the performance indicators that were computed to confirm the model's effectiveness. The proposed model obtained an estimated accuracy of 98.89% with the use of the Adam Optimizer.

Certain transfer learning models, including InceptionV3, AlexNet, DenseNet121, VGG19, and MobileNetV2 in study [7], incorporate pre-processed images. MobileNetV2 has outperformed the other models with an overall classification accuracy of 91.6%. In the next step, this model is built up to maximize the performance of MobileLungNetV2. The enhanced model, MobileLungNetV2, obtains an exceptional classification accuracy of 96.97% on the pre-processed data. It is found that the model has the following values: 96.71%, 96.83%, and 99.78% for precision, recall, and sensitivity, respectively, using a confusion matrix for each class.

Another study in [8] uses CNN to learn lung illness images to deeper into the multi-category classification method. Training data came from the Cheonan Soonchunhyang University Hospital dataset, which included tuberculosis, and the National Institutes of Health (NIH) datasets, which were split into: Normal, Pneumonia, and Pneumothorax categories. Preprocessing of the center crop was carried out while maintaining a 1:1 aspect ratio to increase performance. Weights from ImageNet improved learning, and Multi GAP was used to optimize each layer's features. With an accuracy of 85.32%, it thus achieved the best performance out of all the examined models. The average score for the predictions was 96.1%, with a sensitivity of 92.2%, specificity of 97.4%, and assessment time of 0.2 s.

An intriguing work, [9], uses an enhanced augmentation strategy to modify the CNN model for identifying lung cancer biopsy images by employing the pre-trained Visual Geometry Group19 (VGG19) model. These two methods greatly improve lung cancer diagnosis in histopathology images. The recorded accuracy reached 97.73%. The suggested approach outperforms the current methods in the experiment findings. The amount of the training data has a direct impact on the neural network's performance. A large set of data can be used to train efficiently a neural network. For moreover, this method also reduces network pattern overlap. This work combines color leveling and transformation to improve image techniques. This technique works well, especially at reducing tone and intensity changes in input images. This increases the classifiers' ability to forecast the future.

There are three phases that contribute to [10]'s experimental investigation. To prepare the images for use as input in the CNN model, each image is first processed by scaling them to 224 by 224 pixels and converting them to RGB format. Next, the data (the image intensity) is transformed to the range 0 to 1 to normalize it. In the next phase, the image is randomly rotated 15

degrees clockwise to expand the data because there aren't enough trained images in the work and to ensure sure the model generalizes.

The third step uses transfer learning to identify objects or images in new categories. It has not been trained for the new ones. In this case was implemented a multi-step Keras "fine-tuning" approach. The network is first "frozen" to prevent the backpropagation passport from reaching any of the layers below the top. Second, at the conclusion of the network, the connected completion nodes are removed and replaced with newly set up ones. After that, training is limited to the connected completeness layer's upper layer.

Due to the recent developments in the medical diseases, most of the articles of the recent years focused in the Covid-19 detection. The research regarding the classification of lung diseases is not limited to a restricted number of models anyway. Research has a wide scope, and different studies bring different results. We can mention the following articles as examples:

In study [11] it is emphasized the how important are the predictions related to the X-ray images. The paper focus in chest diseases like tuberculosis (TB), COVID-19, and pneumonia. The study is done based on the analysis of three CNN models: VGG19, Resnet50V2, and Densenet201.

Evaluation of the predictions are done bases on indicators like Accuracy and Loss. All three models demonstrate great accuracy and consistency. But there are taken in consideration other aspects including training efficiency and complexity of the architecture. After comparison the best option out of the three is considered Resnet50V2.

The aim of project [12] is the creation of a Medical Diagnosis Support System (MDSS) created for the x-ray images related to Covid-19. The diseases taken in consideration are COVID-19, Normal, Pneumonia, and Tuberculosis. MDSS uses a combination of pre-trained convolutional neural networks (CNNs) based on Transfer Learning (TL) classifiers. The accuracy of Covid-19 detection increased using of a parallel deep feature extraction method based on Deep Learning (DL). The concatenation classifier was noticed to give good accuracy rates.

The study presented in study [13] shows an innovative two-dimensional CNN (2D-CNN) architecture developed especially for COVID-19 classification. The aim of the model is to make a clear division between viral pneumonia, which is typical of COVID-19 and other forms of pneumonia or a fully healthy lung image.

The design (especially the depth distinct layer layout) and of the suggested 2D-CNN architecture is done to maximize the accuracy of the model disease prediction. The model performed well in preliminary testing, attaining high levels of sensitivity, specificity, and accuracy. It is also important to mention that the design of the model enables a smooth and easy integration into existing medical imaging workflows.

The [14] study utilizes an approach that preprocesses chest photos using techniques such as histogram equalization and sharpening. Feature maps are used in the model to include a self-attained mechanism that further improves the performance of

CNNs. Based on the stimulations, it is seen that the Inception-Resnet CNN is a more flexible and efficient way to classify and CT images than classic segmentation techniques. With better results of accuracy, sensitivity, the Inception-Resnet model demonstrates its efficacy in COVID-19 classification.

In study [15], it is employed a deep learning approach, specifically using CNNs, to enhance pneumonia detection. It is utilized the VGG-19 model, part of the CNN framework, on both original and augmented CXR image datasets. Augmented images were generated from the existing dataset to improve the model's performance. The techniques implemented in this approach include image scaling, data augmentation, deep learning with Keras, batch normalization, and utilizing weights from the pre-trained VGG-19 model. The proposed model achieved a 95% accuracy rate on the augmented CXR image dataset.

In study [1], presented a DL classification model with the aim to identify the most prevalent chest conditions. The aims are to develop a DL framework and categorize various forms of pneumonia, lung cancer, emphysema, TB, and, most recently, COVID-19. After reviewing the literature, this study appears to be the first to categorize all six classes simultaneously using a single DL framework. According to experimental findings obtained from [1], VGG19 + CNN model reached an 96.48% accuracy, 93.75% recall, 97.56% precision, 95.62% F1 score, and 99.82% AUC.

In conclusion, many models have been trained by studies utilizing CXR and CT image datasets. These models include CNN hybrid network, LungNet22, MobileNetV2, CNN GD, Inception V3, Resnet-50, VGG-16, and VGG-19. CXR images make disease diagnosis easier compared to CT images with these patterns.

III. RESEARCH METHODOLOGY

The work featured in this paper is based on study [1], which uses for its testing a combination of CNN and VGG19 models.

The models used in the existing and in the new model created are still the CNN+VGG19 Deep Learning architecture. The same dataset is used over the existing and modified models to compare metrics under the same conditions.

The first part of the section describes the core model, what does it combine and how the classification and extraction process is done through it. The second part of the section gives a detailed information of the dataset used, data image partitioning into 20% random validation and 80% training. The last part of the section is described the use of Deep Learning techniques through VGG19 and CNN algorithms and the changes done over the base model.

All the base and new model codes are written and run in Python language by using the libraries that this language offers.

A. Base Model and Changes

Base models used on the original work are transformed in the new one through modifications as described below. The main aim and the input effort is to improve performance results.

1) *Combination of CXR and CT images:* To modify Deep Learning architectures usually are used several frameworks. It is a common practice in the field of computational medicine and Machine Learning in medicine, combining X-ray (CXR) and Computed Tomography (CT) images to create a dataset used then in Deep Learning models.

2) *Increasing the levels of classification and extraction:* Increasing the classification and extraction levels in Deep Learning models is an important approach to advance the capabilities and performance of Deep Learning models in various tasks.

The two models used are: CNN and VGG19. The proposed framework in this study is divided into three phases: pre-processing, feature extraction and classification.

Fig. 1. Distribution of images dataset.

B. Dataset

Classification of the images is done under five main categories: Normal, Covid-19, Lung Opacity, Tuberculosis and Pneumonia.

As mentioned in this study, there are used two main data sources that feed the trained models: CXR images and CT images. Fig. 1 describes the dataset used. It is a total of 21'865 images out of which: 3'616 are images of lungs affected by Covid-19, 6'012 images of lung opacity, 10'192 images of normal lungs, 700 images of lungs of affected by tuberculosis and 1'345 images of lungs affected by viral pneumonia. The model starts with the procession of the images, which was trained using the images in our dataset. Rescaling the images is necessary to ensure that the pixels accept only values between 0 and 1. If any pixels are vacant, the value of the closest pixel is used to fill them.

This image set will be divided into two parts: twenty percent for training and the remaining portion for validation. This suggests that the model will become used to the visual pattern by using the training set. Following that, the capacity of the model to locate and classify the validation set images within any certainty degree of accuracy, is used for evaluating its

performance. The Gaussian noise function has been added to this data set in the modified model.

C. The Redesigned Model

The fundamental model is modified through interfering with the feature extraction convolution layers and altering the filter types that eventually perform image classification. The first model, VGG19, is initialized without any fully connected layers. The input is specified as 224x224 pixels and three RGB channels and are utilized pre-trained weights from the ImageNet dataset. The first changed model has its trainable parameter set to false, meaning that the VGG19 layers are not moving. This implies that no changes will be made to the pre-trained weights when the next layers are being trained.

The initial model had trainable parameters for all cases. There were 24'622'341 parameters in all, and each epoch's average training time was seven minutes in the original model. The total number of parameters employed in the modified model is 31'832'837. An epoch's training takes three minutes on average.

A Reshape layer is applied to the redesigned model on top of the VGG19 layer. The output of the preceding layers is now transformed into a shape with the dimensions (7, 7, 512). It is then added a convolution layer with the following parameters:

- 512: The quantity of filters (or channels in the final image).
- 5: The 5x5 kernel size.
- padding="same": This sets a padding between the circles' matching zeros to maintain the same dimensions between the input and output images.
- kernel_initializer='random_normal': This initialization technique sets the filter weights using values generated by a random normalization.
- bias_initializer='zeros': Set the bias to zero at starting.
- regularizers = kernel_regularizer.l2(0.01): Apply L2 regularization with a 0.01 filter weight penalty factor to lessen overfitting.
- bias_regularizer=regularizers.l2(0.01): Apply L2 regularization with the same penalty factor for biases as well.

Other convolution layers that include up to 64 filters, a further halving of the original number, come after it. Classification is the one performed further using fully connected layers. In contrast to the original model, a dense layer containing 1024 neurons has been implemented.

Adam's optimization function will be applied to both models, with the default and most used learning rate of 0.000009.

Fig. 2. Architecture of the modified model.

Below is shown the DL model in a pseudo-code summarized form. Fig. 2 shows the VGG19+CNN model architecture after modifications. It there can be visibly identified the changes done in the extraction and the classification part. We'll look at the metrics for AUC, precision, sensitivity, and accuracy to assess the model's performance in this task.

Algorithm 1: DL Model

Input: Dataset with chest images (CXR + CT)

Pre-processing: Image resizing to 224*224*3 and Square the image pixel values inside the interval [0, 1].

Splitting training data (80, 20): 20% is used for validation and 80% for training.

Using a new VGG19+CNN model for feature extraction.

Image classification from fully connected networks.

The cross-entropy loss will also be included. This will be done by comparing the model's predictions with the actual data labels. If the model receives higher validation accuracy values than the originally saved model, it will replace the current weight file. The initial model is trained in the tests done under this study, in its initial form, for 1000 epochs. The metric data, from the training and validation sets, were examined.

Following, the new model is trained for 5000 epochs. Same, the metric data from the training and validation sets were examined and compared with the ones reached from the original model training.

IV. RESULTS

The model's performance was evaluated considering loss, accuracy, precision, AUC, and recall or sensitivity. Each of the metrics is analyzed both for the base [1] and the new model separately in the below sections. The comparison of results obtained from the training, of both the original and new model, together with the comments regarding each of them will be analyzed in the following results.

A. Loss

Loss is a measure of how well the model's prediction matches the true labels or targets. It determines the error between the predicted output and the actual output during training. We need it to be as small as possible so that the model can improve and make better predictions.

Fig. 3. Loss of the original model.

Fig. 4. Loss of the modified model.

Fig. 3 shows the case of original model, where the loss has experienced an exponential drop, reaching a value of 14.4 after 1000 epochs. The same results are observed on both the training and validation datasets, the first loss metric decreases, ruling out the possibility of overfitting. Fig. 4 shows the loss metric decays exponentially for both training and validation sets in the new model.

B. Accuracy

The accuracy is usually used to show the overall performance of the model. The goal of the metric is to be high in both the training and validation sets.

Usually, the accuracy of training is higher than that of validation, especially when the model is overfitting. Fig. 5 and Fig. 6 relate to the training accuracy, respectively over the

original and new model. It has a deviation between 0 and 1, but on the other hand, the validation accuracy is zero in the case of the new model in contrast to the original one. This means we have overfitting on the new model.

C. Precision

Precision is the most useful metric, especially when the false positives are high. A high precision indicates that the model has fewer false positives, i.e. it is making fewer incorrect positive predictions. Precision of the original model is presented at Fig. 7.

At the end of the epochs, we see there is a high value around 1. Fig. 8 relates to the precision of the new model. It shows the training precision deviates from 0 to 1, but the validation one is zero, which means that we are facing the overfitting phenomenon.

Fig. 5. Accuracy of the original model.

Fig. 6. Accuracy of the modified model.

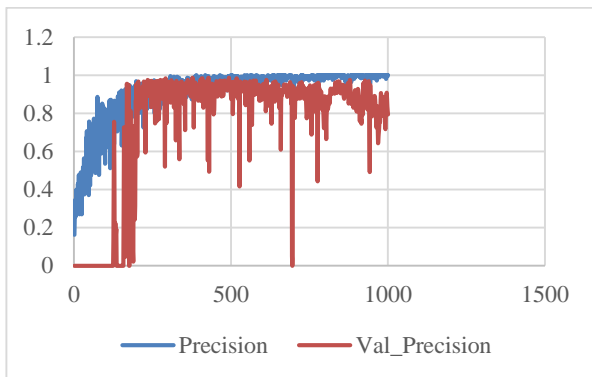

Fig. 7. Precision of the original model.

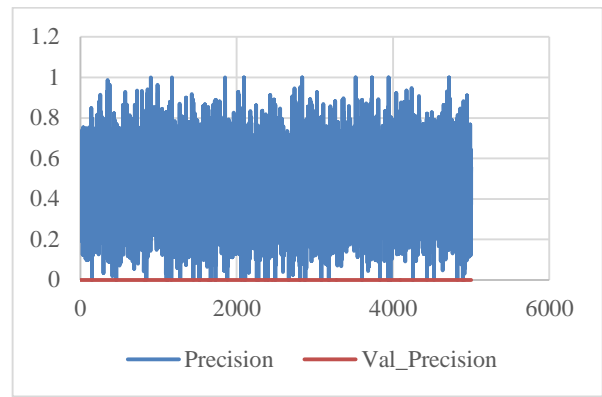

Fig. 8. Precision of the modified model.

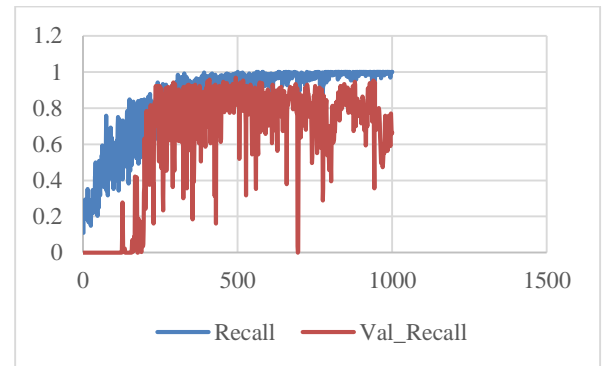

Fig. 9. Sensitivity of the original model.

Fig. 10. Sensitivity of the new model.

D. Sensitivity

The sensitivity is particularly useful when the goal is to reach as many positive instances as possible, even at the cost of some false positives. Fig. 9 and Fig. 10 are displaying the sensitivity of the original and the new one. The values are a deviation between 0 and 1 and that of the validity is 0. Again, we are facing overfitting.

E. AUC

AUC measures the ability of the model to distinguish between positive and negative classes at different thresholds. A high AUC value indicates a better overall performance. Fig. 11 and 12 are the AUC of the original and new models. In the new one training varies between 0.5 and 1 and the AUC of validation is mostly zero, so we have the phenomenon of overfitting again.

It was noticed that the phenomenon of overfitting appeared in the modified model.

V. DISCUSSION

We observed from the performance metrics of the modified model that we're dealing with the phenomenon of overfitting. The below sections discuss the overfitting phenomena and some suggestions on how to fix it.

A. Overfitting

Overfitting occurs whilst a system gaining knowledge of the model learns the training information so nicely that it begins to pick up noise or fluctuations in the data as opposed to studying the underlying version that generalizes properly to new, in no way-seen facts.

Fig. 11. AUC of original model.

Fig. 12. AUC of the new model.

There are several elements that may have motivated the overfitting of our model:

1) Complexity of the version: Our changed model can be more complex than it should be compared to the size and complexity of the schooling facts given that it could memorize the trainable examples in preference to the underlying sample. This is the case while the deep getting-to-know version has many parameters, and our version went from 24'622'341 parameters to 31'832'837 parameters.

2) Lack of trainable records: While the training dataset is simply too small, the model cannot see many examples without the opportunity to master the variation underlying the model

effectively. Compared to the complexity of the model, we can say that the dataset is exceedingly small.

3) Noise within the records: If the education statistics include noise or beside-the-point features, the version tends to mistakenly research those patterns as though they had been the patterns we need it to learn. In our version, we added Gaussian noise to growth the diversity of the records and make the version more robust.

B. Overfitting Adjustment Techniques

To keep away from overfitting in a Deep Learning model, numerous techniques may be used:

- L1/L2 regularization techniques optimize the loss function that penalizes massive weights, stopping the model from studying from very complicated underlying models.
- Dropout randomly turns on a fraction of neurons throughout education, forcing the version to study greater robust capabilities.
- Batch Normalization. Normalizes the activation of each layer to stabilize and accelerate training.
- Changes to the structure of the model making it less difficult with the aid of decreasing the wide variety of layers or gadgets. This reduces the capability of the version to memorize training records and encourages it to learn extra well-known patterns.

VI. CONCLUSION

Modifying architectures in Deep Learning is a powerful tool to improve the performance of models for various tasks. The changes made should be appropriate for the specific task and effectively define the needs of the model and the data available for training. In this paper, we aimed to create a new model bases on the architecture of the CNN+VGG19 model that was seen at [1]. Modifications are made to improve its performance metrics.

We studied the performance results of the modified model. It was observed that in the modified model the performance metrics deteriorated significantly compared to the original model. For each metric: accuracy, precision, sensitivity, F1-score, AUC, the model did not converge to a fixed value. It had all the time fluctuating values from 0.5 to 1. Moreover, the metric values of the validation set were lower than the values of the training set metrics. The difference was huge, so big that they went to zero most of the time.

Consequently, this means that we are dealing with the phenomenon of overfitting. It might have occurred due to the increase in the complexity of the model (adding of layer) for a not very large dataset. Another reason could be the noise of the images used in the dataset. To avoid overfitting, adjustment techniques such as L1/L2, batch normalization, dropout, or reducing the complexity of the model can be used.

The new model can only be used for small datasets because otherwise, it learns the pattern of images so well that it starts learning about image fluctuations, and noises, so making the model unusable. The introduction of noise elements should be eliminated as it was proved that it did not increase the variation

of the images but pushed the model to not get the correct pattern of the logic detection during training.

The modified CNN+VGG19 model that we build did not achieve the desired improvements aimed. Our study provides valuable insights into the challenges of model modification and highlights areas for future research. In this work by increasing the complexity of the DL model for a not very large dataset or the increased noise of the images used in the dataset led to a poor performance of the model.

The results of this DL model give an important contribution related to the model complexity. It is not needed to increase complexity by adding the two mentioned layers and the noise on the same model, to be used for multi-class lung disease detection. We faced the overfitting, which can be result of model complexity, lack of trainable data or the noise in data. Other tests in the future can be made by keeping the number of layers of extraction and classification of the model intact but removing the noise. The introduction of noise elements should be made as it was proven that it did not increase the variation of the images but lead the model to get an incorrect logic pattern detection during training.

Limitation related to the study is the dataset. The model performs well only on small datasets. In large datasets, the model memorizes the pattern of images fluctuations and noise making the model unusable.

Future studies can build upon these findings to develop more effective and robust models, which need to overlap the challenged faced and highlighted at the end of the project.

Establishment of Economic Analysis Model Based on Artificial Intelligence Technology

Jiqing Shi

School of Business, Jinan Engineering Polytechnic
Jinan, Shandong, 250000, China

Abstract—With the continuous evolution of artificial intelligence technology, its integration into economic analysis models is becoming increasingly prevalent. This paper employs the Lasso Back Propagation neural network method to conduct financial analysis and prediction for major global economies, focusing on total Gross Domestic Product, combined Gross Domestic Product growth rate, and Consumer Price Index. The real Gross Domestic Product of the top 30 countries in the global ranking is meticulously analyzed and categorized into various economic types. This categorization, coupled with the utilization of neural network multi-hidden layer variable analysis, facilitates the analysis and prediction of national economic trends. The findings reveal that overall economic growth among the top 30 countries is sluggish, albeit showing a growth trajectory. However, the driving force for economic growth remains notably inadequate. Moreover, employing a single time series model effectively predicts Gross Domestic Product and Consumer Price Index growth rates, alongside other macroeconomic indicators. Notably, the absence of autocorrelation in the fitting residual series underscores the applicability of the time series method for combined forecasting, affirming the robustness of the predictive framework.

Keywords—Artificial intelligence; lasso regression; BP neural network; economic analysis model; major global economies; multi-hidden layer variable analysis; economic trends

I. INTRODUCTION

The paper is structured into eight sections to elucidate the research findings. Section I delineates the significance of macroeconomic dynamic forecasting, identifies deficiencies in existing forecasting models, and underscores the considerable potential of artificial intelligence (AI) technology in economic analysis. Section II comprises a comprehensive literature review, delving into the utilization of AI technology in economic analysis across various industries and elucidating the associated challenges. Following this, Section III offers an in-depth exploration of the theory and application of Lasso regression and Back Propagation (BP) neural network models, providing the theoretical underpinning for the economic forecasting model in this paper. Section IV expounds on the research framework, encompassing variable selection amalgamated with economic theory, hierarchical classification of multilevel economies, methodological innovations in forecasting, and the application of combined forecasting techniques. Section V delineates the specific procedures involved in model construction, encompassing the selection of key factors based on Lasso regression and the hierarchical clustering analysis of diverse economic categories. Subsequently, Section VI presents the

outcomes of constructing the BP neural network forecasting model and substantiates its efficacy through empirical analysis. Section VII conducts empirical analysis on the combined forecasting of Gross Domestic Product (GDP) and Consumer Price Index (CPI), evaluating the accuracy and robustness of the model in predicting macroeconomic indicators. Finally, section VIII encapsulates the entirety of the paper, underscoring the contribution of this paper to macroeconomic analysis and proposing avenues for future research endeavors.

Macroeconomic dynamic forecasting technology has emerged as a pivotal theoretical domain within macroeconomic forecasting analysis. It entails a systematic approach that integrates scientific, reliable, and comprehensive historical statistics, investigative data, and pertinent macroeconomic information. This process aims to unveil the fundamental historical laws governing economic phenomena and employs the most scientific, practical, and efficacious economic theories and methodologies. The overarching goal is to offer timely, insightful, and accurate qualitative and quantitative insights into the objective state of social and economic activities. By enhancing public comprehension of the inherent dynamics of human economic endeavors, this approach aids in discerning economic phenomena and forecasting future industry developments [1], [2], [3], [4], [5]. The significance of forecasting macroeconomic trends cannot be overstated, as it underpins the sustained, stable, and efficient functioning of the national economy while bolstering policy decision-making [6], [7], [8].

In the realm of macroeconomic forecasting, numerous economic prediction models have been developed and scrutinized by professional researchers. These include the Autoregressive Moving Average (ARMA) model [9], [10], error correction model [11], [12], vector adaptive regression model [13], [14], mechanism conversion model [15], [16], ensemble models [17], [18] and dynamic factor model [19], [20]. While each of these models can yield favorable prediction outcomes under specific conditions, they may also exhibit significant errors at times. For instance, the traditional large-scale simultaneous equation model often falls short compared to simpler models like the Autoregressive Integrated Moving Average (ARIMA) model in short-term predictions. Conversely, the vector error correction model excels in predicting non-stationary time series with co-integration relationships. Hence, the applicability of various time series models varies depending on the context and environment. Nevertheless, relying solely on a single time series prediction method has its drawbacks. It may fail to fully leverage the information embedded in the data and

can lead to unstable prediction results, particularly when influenced by outliers or anomalous data points. Thus, a judicious approach to model selection and integration is imperative to enhance the accuracy and robustness of macroeconomic predictions.

Considerable research has delved into the theory and practical applications of combined forecasting, yielding several noteworthy methodologies [21], [22], [23], [24], [25]. Samuels and Sekkel [26], for instance, introduced a model confidence set approach wherein model sets are pruned before constructing an average combination forecasting model. This method thoroughly evaluated the statistical significance of prediction performance across samples, enhancing forecasting accuracy, particularly beyond the sample range. Empirical investigations focusing on forecasting macroeconomic indicators in the United States have underscored the efficacy of this model correction technique. Similarly, Kotchoni et al. [27] explored four distinct weight-setting methods, including pruning average and inverse average, to average forecasts from five individual models. These diverse approaches to combined forecasting hold promise for refining prediction outcomes and enhancing the reliability of economic forecasts.

Numerous economic forecasting endeavors have demonstrated that combined forecasting models typically outperform single forecasting models in terms of accuracy [28], [29], [30]. However, while many mixed forecasting methods offer various model combinations, they often lack in-depth discussions on the relationship between the number of combined forecasting methods and the forecast results, as well as the robustness of combined models compared to single forecasting models. In this paper, the Lasso model identifies key factors influencing national GDP output, while the BP neural network model establishes an economic forecasting model. Through macro quantitative correlation research, the analysis focuses on the correlation between the actual average GDP growth rate of China and nearly 30 countries ranking in the top five of global GDP. Additionally, it considers current and future trends in global political and economic development. This analysis is supported by a multidimensional correlation data environment, enabling predictions of GDP growth rates and future development trends for over 30 countries and the corresponding international community. The paper conducts macro trend research, trend analysis, and predictions of global changes, employing quantitative and multidimensional correlation model empirical analyses. This approach further enriches the understanding of macroeconomic policy theories and research frameworks, providing valuable insights into observed phenomena and theoretical frameworks through extensive academic verification.

II. LITERATURE REVIEW

A. Application of AI Technology in Economic Analysis

The application of AI techniques in economic analysis has garnered considerable attention and exploration in academic discourse. Biju et al. (2024) contended that the utilization of machine learning and AI for predictive processes is marred by severe flaws stemming from algorithmic biases, particularly prevalent in domains such as insurance, credit scoring, and mortgage lending [31]. This study underscores the imperative

for academia to pivot strategically toward embracing disruptive and innovative forces that are reshaping the future of finance. Liao et al. (2022) identified a key limitation hindering the widespread adoption of AI in chemical production: the absence of a quantitative understanding of the potential benefits and risks associated with various AI applications [32]. They underscored the necessity for future research endeavors to address data challenges in assessing the impact of AI and to develop AI-enhanced tools conducive to supporting sustainable development within the chemical industry. Chen et al. (2022) harnessed decision tree algorithms of AI to devise an environmental cost control system tailored for manufacturing companies, facilitating the internalization of environmental costs [33]. Dauvergne (2022) delved into the ramifications of AI applications within global supply chains (GSCs) on environmental sustainability, revealing that while AI yields micro-level benefits, it fails to mitigate the adverse environmental consequences of GSCs [34]. He posited that framing AI as a catalyst for sustainable development serves to rationalize conventional business operations, fortify corporate responsibility narratives, attenuate the necessity for heightened national regulation, and endow multinational corporations with global governance prowess. Wilson et al. (2022) explored the impact of AI on reverse logistics within the circular economy, spotlighting the technology's potential as a significant force shaping entrepreneurial opportunities and processes within corporate ecosystems [35]. Ronaghi et al. (2023) delved into the influence of AI on circular economy practices, unveiling that technological characteristics, organizational capabilities, and external task environments collectively influence AI adoption, thereby positively impacting circular economy practices [36]. Their findings underscored AI technology's potential to revolutionize production processes and mitigate industries' deleterious environmental footprint. Onyeaka et al. (2023) investigated the capacity of AI technology to combat food waste and bolster the circular economy, asserting that leveraging AI technology can optimize resource utilization efficiency, curtail environmental impacts, and foster a more sustainable and equitable food system [37]. Bochkay et al. (2021) scrutinized the nexus between macro-uncertainty and analysts' forecasting accuracy, emphasizing the criticality of accounting for uncertainty in economic analyses [38]. Bousdekis et al. (2021) delved into big data-driven macroeconomic forecasting models, offering a behavioral analysis of decision-making in the Industry 4.0 era [39]. Additionally, Tilly et al. (2021) showcased the potential of non-traditional data sources such as news, sentiment, and narratives in economic analyses, suggesting that AI techniques hold immense promise in enhancing economic efficiency, curbing resource wastage, and fostering sustainable development [40]. Although challenges and risks accompany the application of AI techniques in economic analysis, meticulous evaluation and effective management can maximize their advantages and foster sustainable economic development and innovation. Hence, while the use of AI techniques for economic analysis is indeed feasible, it necessitates cautious implementation in practice and adaptable application across diverse contexts to yield optimal results and societal benefits.

B. Lasso Regression and BP Neural Network Modeling

Least Absolute Shrinkage and Selection Operator (Lasso) regression serves as a regression method adept at handling data

with multicollinearity. It accomplishes this by introducing an L1 regularization term, compressing insignificant regression coefficients towards zero, and facilitating variable selection. Notably, this approach not only enhances model interpretability but also mitigates the risk of model overfitting. In economic analysis, Lasso regression finds widespread utility across various forecasting domains, including macroeconomic indicator prediction and financial market analysis. For instance, Deng and Liang et al. (2023) utilized Lasso regression to refine a semiparametric ARMA-TGARCH-EVT model, enhancing the robustness of portfolio optimization in their study [41]. BP neural network represents a multilayer feed-forward neural network trained via a backward propagation algorithm, proficient in discerning intricate relationships between input and output data. Given its adeptness in pattern recognition and time series forecasting, BP neural networks have found extensive application in economic forecasting. Sedighi et al. (2022) harnessed BP neural networks to predict the Standard & Poor's 500 index stock market, underscoring its utility within the financial realm [42]. The BP neural network model serves as a potent tool for economic forecasting, leveraging historical data to capture nonlinear relationships and dynamic shifts among economic indicators. Integrating Lasso regression with BP neural networks enables the synergistic utilization of their respective strengths. Specifically, the variable selection prowess of Lasso regression reduces the input dimension of BP neural networks, enhancing their training efficiency and predictive performance. Concurrently, the formidable nonlinear fitting capability of BP neural networks adeptly addresses intricate relationships potentially overlooked by Lasso regression. This amalgamation holds considerable promise in economic forecasting, augmenting forecast accuracy and reliability.

C. Research Positioning

In comparison to existing studies, the economic analysis model proposed in this paper, based on Lasso regression and BP neural network, possesses distinctive characteristics:

1) *Integration of variable selection and economic theory:* This paper not only employs Lasso regression for variable selection but also amalgamates economic theory with theoretical interpretation and variable screening. This fusion enhances the economic significance of the model by integrating domain knowledge with statistical techniques.

2) *Hierarchical classification of economies:* Through hierarchical clustering analysis, the paper categorizes the top 30 global GDP countries into distinct economic types. This classification approach facilitates a more accurate capture of diverse economic characteristics, enabling targeted forecasting.

3) *Innovative forecasting methodology:* The paper adopts the BP neural network model for forecasting and enhances its nonlinear fitting capability by designing multiple hidden layers. This innovation in modeling contributes to improved forecasting accuracy.

4) *Application of combined forecasting:* This paper incorporates cross-validation of time series and inverse root mean square error for combined forecasting. This approach

significantly enhances forecasting accuracy compared to using a single forecasting model alone.

In summary, this research program offers new perspectives and tools for macroeconomic analysis through methodological innovation and theoretical deepening while building upon existing research foundations.

III. LASSO-BP NEURAL NETWORK MODEL

A. Lasso Regression

The Lasso compressed regression estimation model utilized in this paper offers a refined approach to regression analysis. By reconstructing the penalty function, this model effectively compresses certain regression coefficients, allowing for a more abstract and nuanced estimation of the underlying structure. Notably, it enables the compression of coefficients to zero, thereby addressing multicollinearity issues and retaining the advantageous features of subset shrinkage regression models. This flexibility allows for independent data processing, enhancing the model's utility in handling complex datasets.

The principle of the Lasso model is outlined as follows: Let matrix x represent the independent variables, and y denote the dependent variable. Following n sampling operations, the standardized values of the paired data (x, y) can be computed, where matrix x is an $n \times P$ matrix ($n > p$), and y is set to an $n \times 1$ matrix. The data for the i -th observation in matrix x is denoted as $x_i = (x_{i1}, x_{i2}, \dots, x_{ip})^T$, where $i \in [1, 2, \dots, n]$, and each observation is independent of the others. Similarly, $y = (y_1, y_2, \dots, y_n)^T$. The regression model of y with respect to x can be expressed as:

$$y_i = \hat{\alpha} + \sum \beta_j x_{ij} + \varepsilon_i \quad (1)$$

In the Eq. (1), $\varepsilon \sim N(0, \sigma^2)$, and α in the definition $\hat{\alpha}$ is defined as $\hat{\alpha} = \bar{y}$. The standardized data $\bar{y} = 0$; therefore, Eq. (1) can be rearranged as follows:

$$y = \beta x + \varepsilon \quad (2)$$

In Eq. (1), $\varepsilon \sim N(0, \sigma^2)$, β signifies the n -dimensional parameter vector, and ε denotes the random disturbance term. To screen out variables with significant influence, a condition needs to be added to Eq. (2), expressed as Eq. (3):

$$\arg \min_{\{\beta_1, \beta_2, \dots, \beta_n\}} \|y - \beta x\|^2 \quad s.t. \sum_j \frac{|\beta_j|}{\sum \beta_0} \leq s \quad (3)$$

In Eq. (3), the value range of S is generally $[0, 1]$ as the t value is also a tunable parameter $t \geq 0$. The Lasso regression model entails reducing the regression coefficient of the entire model by continuously adjusting the value of the t parameter and progressively compressing the regression coefficient of the model, excluding non-significant variables until it reaches zero.

The objective function's first line closely resembles that of the traditional linear regression model. However, the most significant and fundamental distinction between Elastic Net and linear regression lies in the constraint: in Elastic Net, there are both lasso and ridge penalties, whereas in linear regression, only the lasso penalty is present. Both linear regression and Elastic

Net regulate the magnitude of the coefficients of the independent variables within the range controlled by t . This feature allows the Elastic Net model to automatically adjust the complexity of variables. Moreover, the Lasso regression model can automatically filter variables and modify the complexity of variables concurrently.

Fig. 1. (a) Estimation plot for Lasso regression (b) Estimation plot for ridge regression.

As depicted in Fig. 1, suppose the coefficients corresponding to a two-dimensional model are denoted as β_1 and β_2 , then $\hat{\beta}$ represents the point where the sum of squared errors is

minimized, yielding the independent variable coefficients obtained by traditional linear regression. However, this coefficient point must fall within the blue square, leading to the existence of a series of potential coefficients, denoted as $\hat{\beta}$. The first point that intersects the blue square is the point that adheres to the constraint and minimizes the sum of squared errors. This point represents the independent variable coefficients obtained by Lasso regression. Due to the constraint being a square, the intersection points between the square's vertices and a concentric elliptical surface always lie on the same square vertex. When the vertex intersects the coordinate axis, it implies that only one value of the independent variable coefficient meeting the constraint conditions can be precisely less than 0. Consequently, in this scenario, traditional linear regression yields effective models for both β_1 and β_2 , whereas Lasso regression results in only β_2 being effective, thereby illustrating Lasso regression's capability to screen variables.

B. BP Neural Network Model

The main concept of the BP neural network model is illustrated in Fig. 2. Learning samples are input into the input layer, and multiple adjustment calculations and simulation training are conducted for the deviation signal within the network through error backpropagation, aiming to minimize the error between the output value and the expected value of the signal.

Fig. 2. Typical structure of neural networks.

Kang et al. [43], Zhang et al. [44], and Zhi et al. [45] have explained the operational principle of the BP neural network and proposed enhancements to its applicability. The BP neural network serves as a prevalent computer algorithm across various domains. The operational principle of the BP neural network model is outlined as follows: Consider a training set represented by $X = (X_1, X_2, X_3, \dots, X_r, X_n)$ where the training sample set comprises input values $X_r = (X_{r0}, X_{r1}, X_{r2}, \dots, X_{r0})$, real input value $y_r = (y_{r1}, y_{r2}, y_{r3}, \dots, y_{r0})$, and predicted value $s_r = (s_{r1}, s_{r2}, s_{r3}, \dots, s_{r0})$. Assuming thresholds and weights between the input-hidden layer and the output-hidden layer are denoted as v_{oj} and v_{ij} , respectively, and thresholds and weights between the hidden input layer and the hidden output layer are represented by u_{ok} and u_{jk} , with the expected precision b and the number of iterations denoted as m , the mathematical expression is as follows:

$$z_j = f(I_j) = f(\sum_{i=0}^q v_{ij} x_{rj}) \quad (4)$$

$$z_k = f(I_k) = f(\sum_{i=0}^p v_{jk} x_{rj}) \quad (5)$$

Here, I_j represents the input in the hidden input layer, I_k denotes the input in the hidden output layer, z_j signifies the output in the hidden output layer, s_k indicates the output in the hidden output layer, and f refers to the transfer function.

The sum of error energy is given by Eq. (6):

$$E(m) = \frac{1}{2} \sum_{k=1}^0 [y_{rk}(m) - s_{rk}(m)]^2 \quad (6)$$

The criterion for meeting accuracy requirements is $E(m) < b$. If this criterion is not satisfied, error backpropagation is necessitated. Here, a new parameter, η , is introduced. The iterative process is expressed as Eq. (7):

$$v_{ij}(m+1) = v_{ij}(m) - \eta \frac{\partial E(m)}{\partial v_{ij}} \quad (7)$$

In Eq. (7), η denotes the learning rate. The calculation method for $u_{jk}(m+1)$ mirrors that of Eq. (7).

The above calculation process is reiterated until the error is confined within an allowable range or the maximum number of iterations is reached.

C. Role of AI Technology in Economic Modeling

The integration of AI technology into economic modeling is poised to redefine the role of human economists. Firstly, the widespread adoption of AI will empower economists to process and analyze vast and intricate economic datasets with greater precision, facilitating a more nuanced understanding and prediction of economic phenomena. Traditionally, economists invest substantial time and effort in data collection, organization, and analysis. However, AI-driven models can automate these tasks, allowing economists to dedicate their expertise to higher-level analysis and decision-making. Secondly, AI technology enhances economists' ability to identify economic patterns and trends, including those elusive to human observation. Leveraging machine learning algorithms, economic models can unearth hidden correlations and patterns within extensive datasets, thereby furnishing economists with deeper insights and predictive capabilities. This capability enables economists to comprehend the intricacies of the economic ecosystem more comprehensively and respond adeptly to forthcoming challenges and opportunities. Furthermore, AI-based economic models facilitate the generation of timelier and more accurate forecasts, equipping economists with the agility to formulate policies and make decisions expeditiously. With ongoing algorithmic refinement and model updates, these models progressively enhance prediction accuracy and reliability, empowering economists to navigate economic fluctuations and mitigate risks more effectively.

In essence, AI-driven economic models elevate the role of economists to one that is more specialized and intellectually adept. Economists can leverage technology more effectively to elucidate and interpret economic phenomena, thereby crafting more impactful economic policies and strategies for governments, businesses, and society at large. Nonetheless, while the proliferation of AI technology presents immense opportunities for economists, they must continue to uphold their comprehension of and adaptability to technology. This ensures the preservation of human values and ethics in economic decision-making, safeguarding against the potential pitfalls of unchecked technological advancement.

IV. MODEL CONSTRUCTION

A. Identification of Key Influencing Factors Based on Lasso Regression

Currently, the world can be divided into 233 groups of major economic countries and one economic region, with more than 197 countries in one group and 36 countries in regional groups. The most important factors that can affect the composition of the GDP of each country in the world may vary significantly, including the intricate relationships with other global variables such as world politics, economy, humanities, geographical

conditions, and the environment. Therefore, it is challenging for research to swiftly and accurately analyze all these factors simultaneously and conduct a comprehensive macroeconomic global correlation analysis closely related to almost all specific economic variables. To ensure reliable, accurate, timely, and comprehensive financial data and forecasts of the total GDP, changes, and trends of the top 40 and 30 major countries in the euro area, it is imperative to consider the absolute height and availability of relevant economic data information of existing countries in the euro area. Moreover, it is necessary to minimize confusion in relevant macroeconomic data information and reduce the untrustworthiness and dimensionality of economic-related data. In this paper, the Lasso regression analysis is employed to identify key factors affecting performance. Considering four main aspects that may simultaneously influence China's regional economy's overall rapid and sustainable development and operation process, five key reference factors with potentially significant impacts on the current changes in the average annual GDP level of the countries in the above regions are selected: national fiscal revenue, actual nominal utilization of international foreign capital, legal money supply in a broad sense of society, total amount of expenditure income within the fiscal budget, and total amount of investment projects completed in fixed asset infrastructure. Additional indicators include the average social share of countries with different industrial development rates, agricultural population, labor force participation rate, consumer price index, gross national product, total energy, and the proportion of total foreign trade income and expenditure. It gives the details on the proportion of tax revenue, exchange rate, foreign debt, added value of real economy, and the total social and economic output of various virtual countries in the total nominal GDP of a virtual country.

The aforementioned 15 variables serve as independent variables, with total GDP employed as the dependent variable for Lasso regression analysis. With a K value of 0.05, the model achieves an R-squared value of 0.973, indicating that the 15 factors identified in the paper can account for 97.3% of the variations in total GDP. Consequently, these 15 factors hold predictive power over real GDP within a defined scope, as confirmed by correlation analysis.

B. Classification of Different Types of Economies

Hierarchical data clustering analysis stands as a prominent statistical classification method for hierarchically clustering information data, widely acclaimed for its extensive study, familiarity, and effectiveness. It finds frequent application in in-depth analysis and the mining of information data, as well as in professional fields involving biological gene diversity analysis and expression. Unlike traditional methods, this statistical analysis does not mandate a priori knowledge of the total categories of the information data or the need for manual data division based on predetermined category numbers. Instead, it yields results in the form of nested partition structures at each layer, offering a comprehensive understanding of the data organization. Generally, the model-based clustering framework encompasses three primary structural components.

Firstly, the model parameters of each Expectation-Maximization algorithm undergo initialization and optimization using the model-based aggregation and clustering segmentation

methods. Secondly, these model parameters are employed to estimate and optimize the parameter values with maximum likelihood. Thirdly, the model and the number of categories are selected based on the Bayesian Information Criterion (BIC) approximation of Bayesian factors. The model adopts the classification likelihood objective function, represented by Eq. (8).

$$l_{CL}(\theta_k, \gamma_i; x_i) = \prod_{i=1}^n f_{y_i}(x_i; \theta_i) \quad (8)$$

In Eq. (8), γ_i is the classification mark of the i -th observation point. If x_i belongs to the k -th component, $\gamma_i=k$. In the mixed model, the number of observation points included in each element follows a polynomial distribution to the n -th power, with probability parameters $\pi_1, \pi_2, \dots, \pi_c$.

The model-based aggregation clustering method aims to maximize the likelihood function of classification, treating each point as a single class, with the algorithm initialized in this state.

During each iteration, the algorithm merges the two types of functions exhibiting the fastest growth rate in the classification likelihood functions. This iterative process continues until all observation points are integrated into the same group.

Utilizing data collected via Python, the top 30 countries are categorized into various types of economies for systematic and scientific induction and analysis of large-scale, dynamic, multi-dimensional, and heterogeneous data. SPSS software is employed for cluster analysis, with hierarchical clustering utilized to classify and summarize the data, as depicted in Fig. 3.

Fig. 3. Cluster analysis of 30 countries.

The graphical representation reveals the division of the top 30 countries in the global GDP ranking into five distinct categories: the United States, China, Japan, India, and other countries. Utilizing hierarchical clustering, countries with analogous eigenvalues are identified, facilitating the systematic and scientific categorization of diverse nations. This classification framework serves as a foundational step towards the precise prediction of the top 30 countries, employing the BP neural network multi-hidden layer variable method.

C. Results of BP Neural Network Prediction Model Construction

For the period spanning 2001 to 2021, thirty-five key influencing factors pertaining to Germany are selected as the

anticipated inputs for the BP neural network system. The GDP measured in USD serves as the predicted total output. A neural network machine learning system based on the BP network is constructed as a sample. The system's network structure is approximately 12-5-1, with training and learning objectives reaching up to 300,000 times per day. The annual learning rate is set at around 0.01, with the minimum prediction error range for training objectives typically maintained at 10-5. Following thorough training and design, the BP neural network model demonstrates its efficacy in predicting the error range of the tested sample target. On average, the relative prediction error range of the results stand at approximately 0.48%. These findings underscore the suitability of the BP neural network model for GDP prediction. The fitting between the GDP output obtained using the neural network model and the corresponding yearly production is illustrated in Fig. 4.

Fig. 4. BP neural network training result diagram.

V. EMPIRICAL ANALYSES

A. Forecast and Analysis of GDP Output of Major Global Economies

Cluster analysis effectively divides the global economies into five distinct types. Leveraging the BP neural network method, the paper delves into the economic and technological development revolutions, innovations in new technology industries and organizations, labor input and productivity, national fiscal revenue, utilization of foreign capital, broad-based social currency supply, total budgetary expenditure, fixed assets, and overall social investment. Additionally, the analysis scrutinizes social population demographics, labor force participation rates, consumer price indices, gross national products, energy resources, total foreign trade volumes, tax revenues, exchange rates, foreign debts, real economy value-added, and the share of virtual and network economies in the GDP of each major country. This examination extends to significant economic variables and influential factors exchanged among governments of nations with varying income levels. Furthermore, the financial aggregate data of China's GDP spanning from the 1990s to 2021, alongside data from other major industrialized nations, is integrated into the BP neural network for comprehensive analysis.

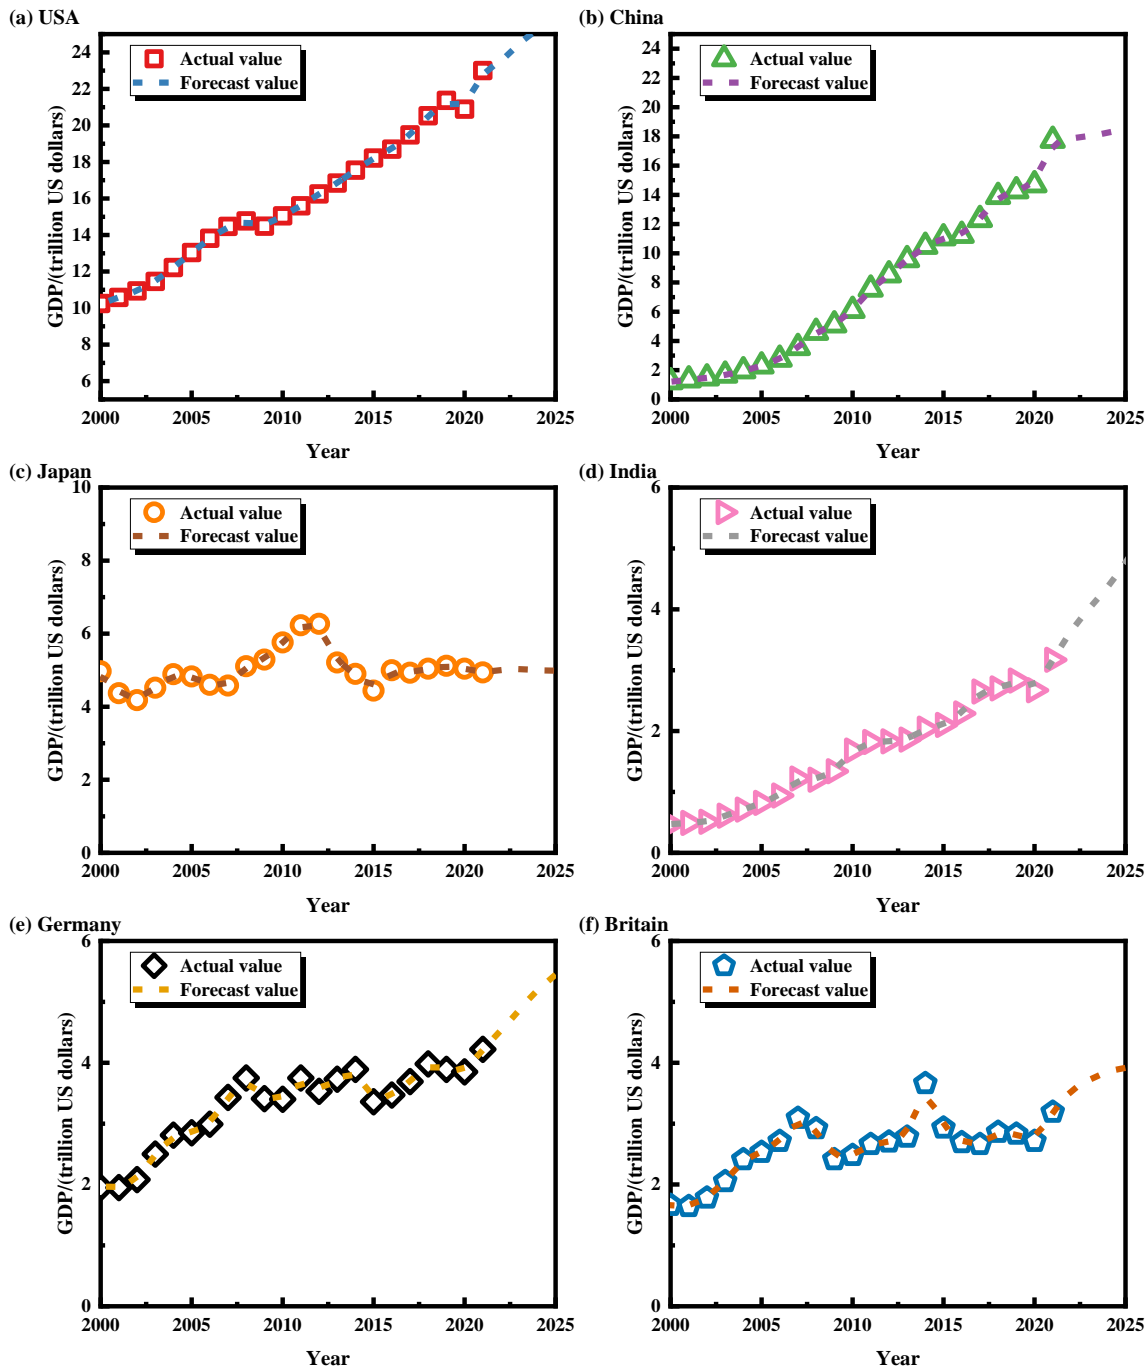

Fig. 5. Neural network forecast of GDP of major global economies.

As depicted in Fig. 5 (a), the United States has sustained a relatively high and continuous growth rate in total GDP, indicative of a robust economic trajectory. However, as the economy progresses past the mid-2020s, a shift from accelerated to moderated growth becomes evident. This transition can be attributed to several factors. Firstly, given the substantial size of the United States' economy on the global stage, further significant growth becomes increasingly challenging, compounded by the mature and well-established economic and cultural landscape. Secondly, the existing market structure may lack new avenues for economic expansion, limiting potential growth opportunities. Moreover, ongoing global transformations

and advancements introduce new complexities, including cross-border investment and trade frictions. These emerging dynamics pose systemic risks to the market, thereby hindering the rapid and stable development of the United States' economy. As the world undergoes continual evolution, addressing these challenges becomes imperative for sustaining economic growth and stability.

As illustrated in Fig. 5 (b), a promising outlook emerges for China's economic development in the foreseeable future. The analysis suggests that China is poised to sustain its momentum and advance the reform of comprehensive mechanisms driving

economic growth. Notably, recent policy adjustments, including supply-side structural reforms and initiatives to mitigate trade protectionism, have contributed to significant economic adjustments from late 2018 to 2020. Despite initial challenges, it is anticipated that China's economy will undergo a resurgence following the completion of comprehensive economic and technological transformations. As China enters the new decade, the gradual culmination of these transformations, coupled with ongoing industrial innovation and technological advancements, is expected to propel the nation's digital economy to new heights. This resurgence is projected to follow a ladder-type growth trajectory, reflecting the dynamic nature of China's economic landscape and its capacity for adaptation and innovation.

As depicted in Fig. 5 (c), Japan has confronted a prolonged period of economic stagnation, which commenced in the mid-1990s, nearly a century after China's integration into the global economy. Although a resurgence or rapid growth in its economy occurred in the early to mid-2000s, such recoveries often ensued after periods of swift expansion. This trend may be attributed to Japan's current economic landscape, which grapples with the repercussions of a pronounced slowdown in global economic growth, protracted sluggishness in overall wage growth, and a persistent, tepid growth trajectory in production rates. Moreover, the nation contends with significant demographic challenges, including a rapidly aging population. Looking ahead, Japan's economic growth prospects remain contingent upon its ability to address these entrenched issues effectively. Failure to implement timely and comprehensive policy measures to tackle these challenges in the short term may dampen Japan's economic outlook in the years to come.

As illustrated in Fig. 5 (d), India's economy experienced robust growth post-2018, primarily propelled by its demographic dividend. India's development paradigm prioritizes consumption over investment, domestic demand over exports, services over manufacturing, and high-tech industries over labor-intensive ones with low technological content. This strategic orientation renders the Indian economy more resilient to global economic downturns, fostering sustained and resilient economic expansion over extended cycles. Projections indicate that India's economy will sustain rapid growth beyond 2020.

Fig. 5 (e) depicts the swift economic advancement witnessed in Germany post-2020, largely attributed to China's timely structural economic reforms. While such reforms do not yield immediate results, the policies and trends implemented during this phase have significantly propelled the nation's economic growth. Consequently, substantial development opportunities are anticipated for Germany's GDP in the forecast model.

In Fig. 5 (f), the British economy faced adversity in the aftermath of the COVID-19 pandemic in 2019. However, the country was among the earliest adopters of herd immunity strategies. With the evolving landscape of the COVID-19 pandemic, Britain gradually reopened its economy, fostering recovery. Model predictions suggest that Britain's GDP will continue to exhibit significant developmental momentum post-2022.

B. Forecast and Analysis of GDP Output in the Remaining Countries

As depicted in Fig. 6, the GDP growth trajectory of the remaining countries spanning from the onset of 2018 to 2025, alongside the annual growth rates projected by the International Monetary Fund, may exhibit a fluctuating upward trend. This pattern can be attributed to several factors. Primarily, the persisting macro uncertainties affecting global long-term regional economic development and growth prospects may exert influence. The anticipated slowdown in the average growth of the global gross factor of production could contribute to heightened overall downward pressure on the economy. According to reports from Xinhua News Agency and Bloomberg News International Economic Department, significant global economic development indices have experienced a rapid deceleration in growth rates since the first quarter of 2018, gradually reaching the lowest levels observed since the onset of the global financial crisis in the summer of 2008.

Fig. 6. Network forecast of GDP in the remaining countries.

VI. GDP AND CPI COMBINATION FORECAST

A. Empirical Analysis of GDP Growth Rate Combination Forecast

As illustrated in Fig. 7, the establishment of a neural network model is highly sensitive to parameter selection, with different parameter values significantly impacting model prediction outcomes. This paper utilizes the NNE function in the R language to determine the number of hidden nodes based on the principles of minimum Akaike Information Criterion (AIC) and BIC, identifying the optimal number of hidden nodes as 3. Given the nonlinear nature of the neural network model, explicit fitting formulas are unnecessary, as the focus lies on prediction accuracy and robustness, primarily evaluated through observation of the residual sequence predicted by the model. Given that the neural network model deviates from traditional time series methods, the variance of parameter estimates cannot be obtained, thereby precluding calculation of prediction intervals. Consequently, this paper provides only the predicted level values for the following four quarters: 6.1667, 6.2278, 6.2031, and 6.1530, with the predicted range falling between 6.1% and 6.3%.

Fig. 7. (a) Ljung Box test chart of neural network model predicting GDP growth rate; (b, c) Residual autocorrelation diagram and residual sequence diagram of neural network model predicting GDP growth rate.

B. Empirical Analysis of CPI Growth Rate Combination Forecast

As depicted in Fig. 8, the neural network model's performance is notably sensitive to parameter selection, underscoring the importance of optimal parameter estimation to enhance predictive accuracy, aligning with GDP growth rate predictions. Utilizing the NNE function in the R language, the number of hidden nodes is determined based on the AIC and BIC minimization principles, yielding an optimal count of seven hidden nodes for predicting the CPI growth rate. Given the nonlinear nature of the model and the focus on prediction results, the intricate process of fitting a model formula akin to the

ARIMA model is obviated. Instead, emphasis is placed on assessing the model's predictive accuracy through residual analysis.

Examination of the Ljung Box test chart and residual autocorrelation chart reveals a lack of autocorrelation in the residual sequence, accompanied by minimal fluctuation around the zero value. These findings indicate the neural network model's robust predictive performance within the sample. Given the model's departure from traditional time series methodologies, the estimation of parameter variance remains unattainable, precluding the calculation of prediction intervals. However, the predicted CPI growth rates for the subsequent four quarters are furnished: 103.5839%, 103.2596%, 103.0759%, and 102.6257%. Exhibiting a downward trend, these predicted values fall within a range of 2.6% to 3.6%.

C. Summary of this Chapter

Real-life economic phenomena arise from the intricate interplay of numerous internal factors and external dynamics,

embodying both inherent complexity and potential regularity. Relying solely on a single time series method proves inadequate for uncovering internal patterns or data insights, often leading to unstable prediction outcomes. Thus, continuous model refinement is imperative to enhance the prediction of future economic indicators, necessitating the exploration of more robust and effective prediction methodologies. Drawing upon the theoretical foundations of forecasting GDP and CPI growth rates, this chapter integrates time series cross-validation with inverse root mean square error to address shortcomings observed in combined forecasting approaches. By meticulously considering prediction accuracy across various time points within the sample, this methodology forecasts GDP and CPI growth rates in tandem. In contrast to prevailing methods such as the equal weight approach and inverse root mean square error weight method commonly employed in literature, this novel approach markedly enhances the accuracy of combined forecasting, underscoring the efficacy of this model in practical combined forecasting endeavors.

VII. DISCUSSION

This study provides a comprehensive analysis and prediction of the real GDP of the top 30 countries in the global GDP ranking through the construction of a Lasso BP neural network model based on AI technology. By comparing the findings of this paper with existing research, its significance can be elucidated from diverse viewpoints. Firstly, in terms of economic forecasting model establishment, Alaminos et al. (2022) underscored the efficacy of non-traditional computational methods, exemplified by evolutionary computation, in handling intricate economic data for macroeconomic forecasting [46]. This aligns with the utilization of the BP neural network model in this paper. Functioning akin to the human brain, this algorithm adeptly processes and analyzes vast and complex economic datasets, thereby augmenting forecast accuracy. Secondly, the validation of the Lasso regression model in screening pivotal influencing factors resonates with the findings of Deng and Liang (2023), who leveraged a semi-parametric ARMA-TGARCH-EVT model combined with a hybrid Copula. Their study underscored the significance of advanced statistical methodologies in managing uncertainty and risk [47]. Similarly, the 15 independent variables identified by the Lasso model in this paper elucidate 97.3% of GDP change causality, affirming the necessity of multifactor consideration in economic analysis. Furthermore, in the realm of economy classification and forecasting, the generalized dynamic factor model proposed by Trucíos et al. (2021) offers a fresh perspective on identifying and estimating macroeconomic variables [48]. The utilization of hierarchical cluster analysis in this paper to categorize the top 30 global GDP countries into distinct economic types mirrors Trucíos et al.'s research ethos. Both endeavors aim to bolster forecasting relevance and accuracy through classification methodologies.

This paper delineates that the top 30 global economies are poised for sluggish growth between 2020 and 2025, notwithstanding prevailing growth trajectories, indicative of inadequate economic growth drivers. This finding correlates with the uncertainty and complexity inherent in the contemporary global economic landscape. Moreover, the paper predicts that China, the United States, and India will persist as

the primary engines propelling economic growth among these nations. Lastly, the findings reported here underscore the efficacy of a single time series model in forecasting macroeconomic indicators such as GDP growth rate and Consumer Price Index (CPI) growth rate, with no autocorrelation in the fitted residual series. This underscores the viability of the time series approach in portfolio forecasting, aligning with the observations of Wei et al. (2021), who advocated for a combined forecasting model predicated on model confidence sets, accentuating the significance of statistical significance in forecasting performance assessment [49].

In essence, this paper not only furnishes a novel perspective for macroeconomic analysis but also furnishes an efficacious tool for global economy classification and forecasting. Future research avenues may delve deeper into the interplay between disparate economies and explore enhanced strategies for navigating economic fluctuations and risks through the prism of AI techniques.

VIII. CONCLUSION

In this section, a thorough examination of the principal challenges encountered during the research endeavors is conducted, delving into their nuances. Firstly, the substantial challenge of data quality and availability is grappled with. The intricate and fluctuating nature of macroeconomic data often renders it incomplete and time-lagged, impinging upon the precision and predictive capacity of the model. Rigorous data preprocessing and cleansing measures are implemented to ensure the integrity and uniformity of the input data. Secondly, during model construction, the complexities inherent in variable selection and parameter optimization are confronted. Amidst myriad factors influencing GDP, accurately identifying and selecting pivotal variables, along with determining the optimal network structure and parameters for the neural network model, emerge as pivotal technical quandaries. Leveraging Lasso regression for variable screening and multiple iterations of BP neural network training, these challenges are effectively navigated. Thirdly, the interpretability of the model emerges as a focal point of concern. Despite the commendable prediction accuracy of AI models, their decision-making processes often lack transparency. Future research endeavors aim to delve deeper into the decision logic embedded within the model, aiming to integrate economic theories more seamlessly into its framework. Lastly, the generalization capability and robustness of the model represent critical performance benchmarks. While the model's adaptability to diverse economies and temporal contexts is bolstered through cross-validation and the incorporation of multiple economic indicators, enhancing its stability and reliability in the face of dynamic economic landscapes remains a paramount focus for future research endeavors. In summary, each challenge encountered during the research journey is meticulously addressed, employing methodological rigor and innovative strategies to propel the investigation forward. These endeavors underscore a commitment to advancing the frontiers of economic analysis and forecasting, laying a robust foundation for future scholarly inquiry.

This paper employs the Lasso BP neural network model, leveraging AI technology, to construct an economic analysis model aimed at analyzing and forecasting the real GDP of the top 30 countries in the global GDP ranking. Firstly, the Lasso regression model is deployed to discern the key factors influencing each country's GDP output. Through the variable screening functionality of the Lasso model, 15 independent variables are selected, elucidating 97.3% of the causative factors behind GDP fluctuations, thereby establishing a robust foundation for the ensuing model. Furthermore, hierarchical cluster analysis categorizes the top 30 countries based on global GDP into distinct economic types, facilitating more accurate predictions of each economy's developmental trajectory. Subsequently, leveraging the BP neural network model, the identified influencing factors undergo training to predict GDP. The model architecture, structured as 12-5-1, undergoes extensive iterative training to achieve a learning rate of 0.01, while maintaining prediction error within a controlled range of 10^{-5} , indicative of favorable fitting performance. Secondly, the paper analyzes the prediction outcomes of the BP neural network model, encompassing forecasts of GDP growth trends for countries such as the United States, China, Japan, and India. Potential factors influencing these predictions are scrutinized. To enhance forecasting accuracy, a combined forecasting approach is adopted, amalgamating time series cross-validation and inverse root mean square error considerations. This approach evaluates forecasting accuracy across different time points within the sample, encompassing combined forecasts of GDP growth rate and CPI growth rate. Lastly, the model's forecasting performance is validated through the Ljung-Box test and residual autocorrelogram. Test results indicate the absence of autocorrelation within the residual series, with fluctuations around the value of 0 minimized, affirming the neural network model's adeptness in sample prediction. This paper has yielded several notable research findings, summarized as follows:

1) *Economic growth outlook (2020-2025)*: The economic growth trajectory of the top 30 global economies during the period from 2020 to 2025 is anticipated to exhibit relative sluggishness. Despite an observable growth trend, the impetus for economic expansion remains notably inadequate, with some nations even experiencing stagnation or regression. This trend is attributed primarily to deep-seated structural challenges impeding these economies from achieving sustained recovery and growth.

2) *Key drivers of economic growth*: Analysis underscores that China, the United States, and India continue to serve as the principal drivers of economic growth among the top 30 countries from 2020 to 2025. However, the economies of these nations, along with others, are poised to grapple with emerging uncertainties, such as the surge in anti-globalization sentiments and trade protectionism. Consequently, their economic development trajectories are expected to align closely with global economic trends, characterized by subdued growth and feeble recovery trajectories, accompanied by heightened instability and uncertainty in the near term.

3) *Prediction accuracy of macroeconomic indicators*: The predictive outcomes for GDP growth rate and CPI growth rate

highlight the efficacy of the single time series model in accurately forecasting these macroeconomic indicators. Notably, the residual series exhibit no autocorrelation, with the GDP growth rate residual series approximating zero. These findings underscore the suitability of time series methodologies for combined forecasting, affirming their reliability in predicting key economic metrics.

This paper employs the Lasso BP neural network model, grounded in AI technology, to construct an economic analysis model aimed at analyzing and forecasting the real GDP of the top 30 countries in the global GDP ranking. Initially, the Lasso regression model is deployed to discern the pivotal factors influencing each country's GDP output. Leveraging the variable screening functionality of the Lasso model, 15 independent variables are selected, elucidating 97.3% of the causative factors behind GDP fluctuations, thus establishing a robust foundation for the model. Additionally, hierarchical cluster analysis categorizes the top 30 countries based on global GDP into distinct economic types, facilitating more precise predictions of each economy's developmental trajectory. Subsequently, employing the BP neural network model, the identified influencing factors undergo training to predict GDP. The model structure, configured as 12-5-1, undergoes extensive iterative training to achieve a learning rate of 0.01, while maintaining prediction error within a controlled range of 10^{-5} , showcasing favorable fitting efficacy. Furthermore, the paper analyzes the prediction outcomes of the BP neural network model, encompassing forecasts of GDP growth trends for countries such as the United States, China, Japan, and India. Potential factors influencing these predictions are scrutinized. To enhance forecasting accuracy, the paper adopts a combined forecasting method, amalgamating time series cross-validation and inverse root mean square error considerations. This approach evaluates forecasting accuracy across different time points within the sample, encompassing combined forecasts of GDP growth rate and CPI growth rate. Lastly, the model's forecasting performance is validated through the Ljung-Box test and residual autocorrelogram. Test results indicate the absence of autocorrelation within the residual series, with fluctuations around the value of 0 minimized, affirming the neural network model's adeptness in sample prediction.

Deep Learning Approach to Classify Brain Tumors from Magnetic Resonance Imaging Images

Asma Ahmed A. Mohammed

Department of Computer Science, University of Tabuk, Tabuk, Saudia Arabia

Abstract—Brain tumor is one of the primary causes of mortality all over the globe, and it poses as one of the most complicated tasks in contemporary medicine when it comes to its proper diagnosis and classification into its many different types. Both benign and malignant tumors affect the lives of their respective patients as they may lead to mortality, or in the least many related difficulties and sicknesses. Typically, MRI (Magnetic Resonance Imaging) is used as a diagnostic technique where experts manually analyze the images to detect tumors. On the other hand, advanced technologies such as deep learning can step into the light and aid in the diagnosis and classification procedures in a much more time-efficient and precise manner. MRI images are an effective input that can be used in deep learning technologies such as CNN in order to accurately detect brain tumors. In this study, VGG-16, ResNet50, and Xception were trained on a Kaggle dataset consisting of brain tumor MRI images. The performance of the models was evaluated where it was found that brain tumors can be efficiently detected from MRI images with high accuracy and precision using VGG-16, ResNet50, and Xception. The highest performing model was the proposed Xception model with perfect scores.

Keywords—Deep learning; brain tumor; MRI images; Convolutional Neural Networks (CNN); Xception; VGG-16; ResNet50

I. INTRODUCTION

In the last few decades, as science and technology prospered, several groundbreaking inventions and essential algorithms have been developed with the help of machine and deep learning techniques and computer science systems. Essentially, deep learning is now involved in all the major aspects of human life such as marketing, banks, education, as well as other smart technologies such as drones and self-driving cars, thus it is only normal for it to be also integrated into the healthcare section, especially for identifying human morbidities [1].

The brain is one of the most complicated organs in the human body and it basically controls the most important tasks that would keep the human alive. For instance, the brain is responsible for vision, controlling emotions, breathing, memory, regulating temperature, and motor skills, among many other roles [2]. One of the diseases that interfere with the proper functions of the brain is brain tumor. Brain tumor is a group of cells in the brain that have uncontrolled division and thus increase in size and number and possess altered functions rather than having their normal physiological functioning [3]. Among the numerous types of cancer, two categories arise distinguishing them into benign brain tumors and malignant brain tumors [4].

In either case, whether the brain tumor is benign or malignant, its presence must be identified as it directly affects the wellbeing of the individual and his quality of life [5]. Physicians utilize Magnetic Resonance Imaging (MRI) to detect brain cancers, where they look for contrast between the different tissues shown in the scans. Nonetheless, in order for the tumor to be properly identified, it requires highly trained medical experts [6].

Fortunately, advanced computer vision techniques and the deep learning and machine learning development made it possible to efficiently identify brain tumors from MRI images, more precisely and faster than physicians can. These technologies provide early diagnosis which can save a patient's life, and further categorization of the brain tumor which would facilitate the selection of future treatment options [7].

Artificial Neural Networks ANNs can perform the task of identifying brain tumors through analyzing the MRI images since it can perform image processing and is able to recognize complex patterns and identify correlations between nonlinear relationships which are often present in the medical field [8]. In fact, ANNs are computer models that aim to mimic how the actual brain works in thought processing. An interesting feature in ANNs is that they are flexible and can alter their architecture relative to the information that they keep learning while processing the data [9].

CNN is a form of ANN and it similarly consists of an input layer, hidden layers, and an output layer. CNNs can generate an output as a result of analyzing the input, which can be MRI images in the case of brain tumors. In addition, CNNs can be trained to perform future outcomes depending on the information that it learned during training [10]. Training the CNN network is thus essential, where it is fed with MRI input images that are labeled with the proper classification "tumor" or "healthy" through which the network will learn to distinguish between them and generate an accurate result to distinguish the presence or absence of tumor in a new input accordingly.

In this study, the VGG-16 network, along with ResNet50 and Xception, are implemented with the objective of detecting tumor presence or absence in MRI images. The purpose is to achieve the highest possible accuracy, ensuring fast and reliable results while maintaining affordability for clinics that may be interested in automated detection of brain tumor.

The following are the study's contributions:

- 1) Implementation of VGG-16, ResNet50, and Xception: The study involves the implementation of three widely recognized neural network architectures.
- 2) Detection of Tumor Presence: The primary objective of the study is to accurately detect the presence of tumors in MRI images.
- 3) Fast and Reliable Results: Another contribution of this study is the focus on obtaining fast and reliable results. By leveraging advanced neural network architectures, the aim is creating a system which can rapidly and accurately identify tumors in MRI images, aiding in timely medical diagnoses.
- 4) Affordable Solution for Clinics: This study aims to develop an efficient and effective system that can be implemented in clinical settings without excessive costs, making it accessible to a broader range of healthcare facilities.

The rest of the paper takes into consideration an overview of some important studies and methodologies in Section II and Section III respectively. The details of implementation of the study including descriptions of the dataset and the proposed models. When the models are implemented, their results are viewed in Section IV. Finally, Section V concludes the paper.

II. LITERATURE REVIEW

Since brain tumor detection and classification is important, developing tools to properly identify it is equally important. Several machine learning algorithms have been implemented for this purpose, of which a variety of algorithms have been reviewed to show the diversity of possible algorithms as well as their relative performances in previous studies.

Two machine learning algorithms, namely Naïve Bayes and K-Nearest Neighbor algorithms have been implemented in several studies to classify brain tumors. For instance, Mirkov and Gavrovska [11] implemented a system relying on these two classifiers. The study involved a total of 253 MRI images of health brains and brains with tumors. The preprocessing of these images was done through image intensity adjustments, Gaussian high pass filtering, and image binarization. In addition, the solidity was calculated in order to get an estimation of the regions that might be containing tumor. Correlation value, homogeneity, contrast, and energy are the features extracted by the GLCM process which are used by the Naïve Bayes (NB) and the KNN classifiers to determine the presence of tumor in a given MRI image. Mirkov and Gavrovska reported that the KNN algorithm achieves better sensitivity than NB which indicates the proper identification of tumor in all positive samples. KNN achieves an accuracy of 77% that can be increased to 98% if the number of selected features was increased.

Linear Discriminant Analysis LDA is also often used in classification problems. Usha.B.L et al. [12] proposed a system divided into several steps. The preprocessing step involves denoising of images and K-means based segmentation. Decomposing through DWT and Haar based basis function. The different features are extracted through GLCM such as entropy, variance, energy, and contrast. After that, the classification is carried out via LDA algorithm, which is an

unsupervised machine learning algorithm that describes different observations and differentiates them into categories. In their case, Usha et al. found linearity between the features, which means LDA might be a good choice for classification of brain tumors. As a result, LDA was able to achieve only 70% accuracy, which is considered among the least accurate possibilities.

Another supervised machine learning algorithm can be used for brain tumor classification is the random forest classifier. In their study, Thayumanavan and Ramasamy [13] used 253 MRI images of the brain and applied median filter to them in order to remove unnecessary noise, and to make sure that the images are smoothed without interfering with the edges. Features like contrast, homogeneity, correlation, and energy were extracted by histogram of oriented gradients HoG and discrete wavelet transform DWT. Finally, these features were used for classification by Random Forest, Decision Tree, and Support Vector Machine algorithms. Upon testing, it was revealed that the Random Forest classifier achieves the highest accuracy at 98% compared to the other classifiers. Its relative sensitivity was 96% and the specificity was 99%.

AdaBoost is an ensemble machine learning model that has been used by Minz and Mahobiya [14] to classify brain tumors from MRI images. Noise elimination was performed through the median filter and segmentation was performed through thresholding technique. For feature extraction, GLCM was used where a total of 22 features were extracted including contrast and correlation. In their study, only 50 MRI images were used in order to compare the results of AdaBoost to those of neural machine learning algorithm. In terms of accuracy, AdaBoost was superior, achieving 89% accuracy and a higher specificity (62%). However, the sensitivity of the neural algorithm was 94% greater than that of AdaBoost (88%). Therefore, the accuracy of AdaBoost is not very high compared to other classification algorithms used for brain tumor detection.

Fuzzy Interference System FIS was utilized by Kumar et al. [15] to classify brain tumors. After the MRI brain images were acquired, noise was removed by Speckle noise removal technique. After that, improved Roughly Fuzzy C-Means Clustering RFCM was used to perform the feature extraction, where variance, entropy, energy, correlation, and contrast were extracted. Optimized Fuzzy Interference System OFIS was then used for brain tumor classification, whereas Generalized Framework of Grasshopper Optimization Algorithm EGOA was finally used for optimization. This system is capable of differentiating the parts of input images into different categories that are: white matter, grey matter, background, tumor tissue, and cerebral spinal fluid. When using the improved RFCM method, it was noticed that the average accuracy, sensitivity, and specificity were improved, such that the model achieved 97% accuracy, 98% specificity, and 93% sensitivity.

Convolutional Neural Networks are also among the algorithms that are used to achieve good accuracy in classifying brain tumors. Badža and Barjaktarovic [16] used around three thousand MRI images between axial, sagittal, and coronal planes. After preprocessing, normalization, and

resizing, augmentation was done such that the new number of images became 9192 images. The CNN architecture was made up of an input, two blocks with ReLU activation, classification block with SoftMax function, and an output. To evaluate the performance of the provided architecture, a ten-fold cross-validation approach was used. In both the original dataset and the augmented dataset, performing validation once resulted in better results than when performing 10-fold validation. In the end, the CNN architecture scored an overall of 97% accuracy, 97% precision, 97% recall, and 97% f1-score.

TABLE I. SUMMARY OF RELATED WORK

Study	Classification Algorithm	Accuracy	Sensitivity and other metrics
Mirkov and Gavrovskaja	KNN	77%	89% sensitivity 65% specificity
Usha.B.L et al.	LDA	70%	Not available
Thayumanavan and Ramasamy	Random Forest	98%	96% sensitivity 99% specificity
Minz and Mahobiya	AdaBoost	89%	62% specificity
Kumar et al.	Fuzzy Interference System FIS	97%	98% specificity 93% sensitivity
Badža and Barjaktarovic	CNN	97%	97% precision

From the collection of studies that were described in the literature review and Table I, it has become obvious that there are a range of possibilities when it comes to the different algorithms that can be used in brain tumors classification depending on MRI images. The results conveyed by each study suggest that some algorithms perform much better in terms of accuracy and sensitivity than others. For instance, KNN, LDA, and AdaBoost are among the less-fit algorithms for identifying brain tumors, whereas algorithms such as Random Forest and FIS perform much better. However, the performance of CNN is comparable to that of RF and FIS while using a much larger dataset for training and testing. Thus, CNN poses as one of the best options for classifying brain tumors.

III. METHODOLOGY

In this study, the methodology encompasses many aspects, initially starting from data preprocessing, moving into the developmental stages of the model, then to training the developed model before it can be evaluated in comparison with other models as described in Fig. 1. In order for the study to proceed some data must be collected to be used for training and testing. The next step would be to process the collected data to optimize its quality before building the deep learning models. in this study, Xception, ResNet50, and VGG16 are the selected deep learning models. The purpose of these models is to extract patterns and distinctive features from the processed data to identify brain tumor. After the models are developed,

trained and tested, they are compared to several different models to assess their accuracy for brain tumor classification and analysis.

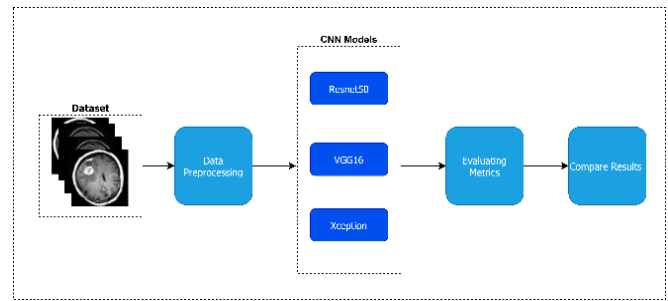

Fig. 1. Visual representation of the proposed architecture.

A. Dataset

For the purpose of training and testing our proposed model to properly identify brain tumors based on data from MRI images, a Kaggle dataset for MRI brain tumor was selected. This dataset is publicly available and accessible. Furthermore, the selected dataset comprises MRI images that have binary classifications to whether the image contains a healthy brain scan or a scan showing brain tumor. Fig. 2 illustrates some of the statistics that are related to the used dataset, such that it contains 1500 brain tumor images and 1500 healthy brain images.

Fig. 2. Distribution of dataset into Positive and Negative images.

Fig. 3 shows a few samples from our used dataset showing MRI scans of healthy brain and brain tumor.

Fig. 3. A sample of the data in our dataset.

B. Data Preprocessing

Before the deep learning models are trained, some data preprocessing steps must be put into action on the MRI brain tumor dataset. The purpose of data pre-processing is to achieve

better quality of the data and to make sure that the data is compatible with each of the chosen deep learning models, otherwise the data would not be used for training nor testing. The pre-processing steps start with normalization of the MRI images in order to obtain a dataset with consistent intensity values. Through normalization, the pixel values were scaled to a common range between [0, 1]. This way, the brightness and contrast variations are also avoided which allows the deep learning models to focus on the actual features of the tumors. Then, data augmentation was performed as a means of improving the model convergence. Data augmentations leads to an increase in the images within the dataset. In this study, data augmentation was done by performing flips. Following that, as shown in Fig. 2, the dataset was partitioned into validation and training sets. As the name suggests, the training set was used to train the network, and parameters were learned through backpropagation. On the other hand, the loss values were learned through forward propagation. Finally, the validation dataset was used as an evaluation for the model's performance. It was also used to fine-tune hyperparameters, and select the best-fit model [17].

C. Implementation

The properties of the CNN structure including the replicated layers and the fact that the weights are shared makes the learning process of this model much easier. The inputs of CNN can be videos, images, or even audio files. However, the innovations based on CNNs can be most evident in computer vision tasks, where CNNs are implemented for object tracking, image segmentation, and image classification [18]. In short, a Neural network is a full structure that connects an input layer through multiple layers in between to an output layer.

In CNN, there are usually three building-block layers that are used in its design; these layers are the fully connected "FC" layer preceded by pooling layer and convolutional layers. In simpler terms, the CNN is arranged as an input layer, convolutions, pooling, and fully connected layers as described in Fig. 4. In general, the input of a CNN network is either a one grey scale image or an RGB image that has three colors and different intensity values [19].

Fig. 4. General architecture of a CNN.

Extensive work on CNN lead to the creation of different architectures in CNN such as Lenet, Faster R-CNN, ResNet, and VGGs [20].

D. Transfer Learning

In transfer learning, there are mainly two approaches when it comes to deep learning, these approaches are fine-tuning and feature extraction. In feature extraction, the architecture of a pretrained model, often trained on ImageNet, is used except for its top layer. This architecture is used for feature extraction, and is augmented with another classifier on top. Fine-tuning, on the other hand, uses the pre-trained model's weights as beginning values for training, which are updated and altered as the training progresses. This approach aims to adapt general features to a specific job without erasing general learning.

ImageNet pre-trained weights were employed in this study as a part of transfer learning since the dataset is small. Consequently, the models will be able to avoid overfitting. The three deep learning models to be used in this study, VGG16, ResNet50, and Xception, were adjusted such that their last layers were fine-tuned, and a pre-trained classifier was utilized for feature extraction. A flatten layer was sued in place of the last set of layers in the three models in order to transform the data from the previous layer into one-dimensional tensor. As a result, a dense layer was introduced with sigmoid activation being applied to the previous layers, producing a single output. The output represents probabilities for positive and negative classes. In the upcoming section, a concise explanation of the models' structure and their utilization in this binary classification task will be presented.

E. VGG-16

The VGG-16 neural network [21] became popular for demonstrating that deeper networks may outperform shallower networks by using smaller convolutional filters. One notable feature of VGG-16 is its simplified architecture, which minimizes the number of hyper-parameters. The model consists of convolutional layers with 3x3 filters and a stride of 1, along with same padding. The pooling layers utilize 2x2 filters with a stride of 2.

As shown in Fig. 5, the initial two layers of VGG-16 include 64 convolutional filters, resulting in a volume of 224x224x64. The next pooling reduces the volume to 112x112x64. Additional convolutional layers are added with 128 filters, resulting in a dimension of 112x112x128. Another pooling layer reduces the volume to 56x56x128. Additional convolutional layers with 256 and 512 filters are incorporated, followed by pooling, ultimately leading to a final volume of 7x7x512. The model concludes with a fully connected layer consisting of 1024 units. The term "VGG-16" refers to the model's 16 layers that include little weights.

Throughout the architecture, VGG-16 consistently employs a pattern of convolutional layers followed by pooling layers, progressively reducing the volume. The number of filters doubles across each stack of convolutional layers, reflecting the underlying principle that guides the network's design.

Fig. 5. Visual Representation of the Proposed VGG-16.

F. ResNet-50

Residual networks or ResNet, is a widely adopted neural network architecture which serves as a fundamental structure for numerous computer vision applications. Its design enables the effective training of deep neural networks, even with up to 50 layers. ResNet-50 [22] specifically addresses the challenge of vanishing gradients by incorporating skip connections between layers. This architectural choice enhances both the efficiency and accuracy of training. The ImageNet dataset is used to train the ResNet-50 model at first. The ResNet-50's fully connected layers are deleted in this study, and a new layer is built depending on the dataset utilized as shown in Fig. 6. Since this study focuses on only two classes, modifications are made to the output layers to accommodate the desired classification task. The model includes a dense layer with 1024 neurons, utilizing the rectified linear unit (ReLU) [23] activation function.

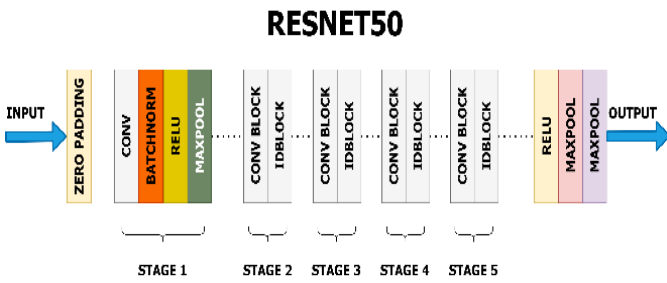

Fig. 6. Visual Representation of the Proposed ResNet-50.

G. Xception

Xception was created in 2016 by François Chollet, the developer of the Keras library, as an adaption of the Inception architectures. Xception varies from the classic InceptionV3 model in that the Inception modules have been replaced by depth-wise separable convolutions. This modification leads to enhanced performance compared to InceptionV3. Xception exhibits superior accuracy in terms of ‘‘Top-1’’ and ‘‘Top-5’’ accuracy on the ImageNet dataset. Despite these improvements, the number of parameters in Xception remains similar to InceptionV3, approximately 23 million. Fig. 7 shows the architecture of the proposed Xception model.

Typically, the system begins its operation by receiving input images. A data pre-processing step is carried out to optimize the compatibility of the images with the chosen model. Subsequently, the dataset is divided into training and testing subsets, sometimes with the inclusion of a validation subset. The model is then fitted and trained to carry out the prediction task. Following testing, the model's performance is

assessed and evaluated using the confusion matrix. Finally, the overall accuracy of the model is determined.

Fig. 7. Visual Representation of the Proposed Xception.

H. Environment

Various tools and environments were used for the development of this system, including TensorFlow, NumPy, seaborn, and matplotlib. The Colab environment was utilized to generate the computational power necessary for training complex models. Specifically, the T4 GPU with 16 GB of GPU RAM, available in Colab, was utilized. The training process was accelerated by this powerful GPU, resulting in faster iterations and improved model performance. Additionally, Colab provided 12 GB of RAM, enabling the handling of large datasets and efficient loading of data into memory.

IV. RESULTS

A set of evaluation metrics are usually used to evaluate the performance of machine learning models. The models are often evaluated according to precision, recall, f1-score, loss, and accuracy. The performance of our models in identifying brain tumors from MRI images was evaluated using the metrics described. The assessment involved the utilization of various statistical techniques, including the confusion matrix, which compares the expected results with the actual results. The confusion matrix incorporates terms such as true positive, true negative, false positive, and false negative, which serve as the basis for calculating evaluation metrics. The true values signify that the results achieved by the model match with the actual results, whereas the false values signify that the model failed to achieve results that are identical to the actual ones [24]. Accuracy is basically a measure of the amount of accurate predictions with respect to all of the predictions, and thus it can be calculated as in Eq. (1):

$$Accuracy = \frac{True\ Positive + True\ Negative}{True\ Positive + True\ Negative + False\ Positive + False\ Negative} \quad (1)$$

Precision on the other hand is used to determine how good is the model in determining if a sample is positive. Precision is measured by the proportion of true positive with respect to all the positive results whether they were correct or not, as shown in Eq. (2).

$$Precision = \frac{True\ Positive}{True\ Positive + False\ Positive} \quad (2)$$

Recall value increases proportionally to the positive values and it is measured by dividing true positive values over the actual positive values (True positive and False negative) as shown in Eq. (3).

$$Recall = \frac{True\ Positive}{True\ Positive + False\ Negative} \quad (3)$$

A metric that takes into consideration both accuracy and recall is termed the F1-score.

The performance of the three proposed models “ResNet-50, VGg-16, and Xception” was recorded and assessed after they were properly trained. 600 MRI images were used for this purpose, where tumor-absent and tumor-present classes were obtained.

The results obtained from the VGG-16 model demonstrated a high level of accuracy and precision, with an accuracy score of 0.99. The precision values for both the "negative" and "positive" classes were 0.98 and 1.00, respectively. Additionally, the recall rates were impressive, with a recall of 0.98 for the "positive" class and a perfect recall of 1.00 for the "negative" class. The F1-score, which consider both recall and precision, achieved a value of 0.9882. Furthermore, the area under the curve (AUC) was calculated to be 0.9967, indicating excellent differentiation between the classes.

Fig. 8. Accuracy and Loss: VGG16.

Fig. 8 illustrates the VGG16 model's training progress as a function of loss and accuracy.

Fig. 9. Confusion Matrix: VGG16

By displaying the distribution of predicted and actual class labels, the confusion matrix gives an extensive evaluation of the VGG16 model's performance, as shown in Fig. 9.

Outstanding performance was observed in the Xception model across all evaluation metrics. The accuracy, F1-score, recall, and precision all achieved perfect values of 1.00. Additionally, the AUC was calculated as 1.0000, providing

further confirmation of the model's capability to accurately classify brain tumors.

Fig. 10. Accuracy and Loss: Xception.

Fig. 10 illustrates the Xception model's training progress as a function of loss and accuracy.

Fig. 11. Confusion Matrix: Xception.

By displaying the distribution of predicted and actual class labels, the confusion matrix gives an extensive evaluation of the Xception model's performance, as shown in Fig. 11.

Likewise, exceptional performance was demonstrated by the ResNet-50 model. The accuracy reached 0.99, with a 0.99 precision for the "negative" class and 1.00 for the "positive" class. The recall rates were 0.99 for the "negative" class and 0.99 for the "positive" class. The F1-score achieved a value of 0.9950, indicating a strong balance between precision and recall. Furthermore, the AUC was calculated as 1.0000, underscoring the model's ability to effectively distinguish between cases with and without tumors.

Fig. 12. Accuracy and Loss: Resnet50.

Fig. 12 illustrates the training progress of the Resnet50model in terms of accuracy and loss.

Fig. 13. Confusion Matrix: Resnet50.

By displaying the distribution of predicted and actual class labels, the confusion matrix gives an extensive evaluation of the Resnet50 model's performance, as shown in Fig. 13.

In comparison to each other, all of the proposed model achieved high accuracies and were able to score high performance on the front of classifying brain tumors. On the other hand, it was evident that Xception model was superior in terms of results since it achieved perfect values in all of the evaluation metrics while ResNet-50 and VGG-16 scored slightly less, regardless of achieving very high accuracies, and proving their competence in differentiating between brain tumors and normal images.

The accuracy, recall, precision, and F1-score for each algorithm are summarized in Table II.

TABLE II. COMPARISON BETWEEN ALL METRICS FOR EVERY ALGORITHM

Algorithm	Accuracy	Precision	Recall	F1-Score
VGG-16	0.99	0.9966	0.9800	0.9882
Xception	1.00	0.9967	0.9967	0.9967
ResNet-50	0.99	0.9967	0.9933	0.9950

All of the proposed models achieved outstanding performances demonstrating their high effectiveness in distinguishing brain tumors. These achieved results indicate that deep learning approaches have powerful capabilities in analyzing medical images.

A. Discussion

When compared to the performances to other models in the studies in the literature review shown in TABLE III. and Fig. 14, the performances of the proposed models suggest significant advancements. To illustrate, the Xception model achieved perfect results such as perfect accuracy of 100%. This shows that the model has an exceptional ability to distinguish brain tumors from normal images. This result surpasses the accuracies reported in other papers, highlighting the effectiveness of the Xception architecture for this brain tumor

classification task. Additionally, the proposed ResNet50 and VGG16 models also demonstrated exceptional accuracy, both achieving a remarkable 99%. The results of VGG-16 and ResNet-50 are comparable to the results mentioned in the literature, enforcing the ability of deep learning to be used for this task. When comparing the performances reported in various papers, it becomes apparent that there is a range of accuracy values. The Random Forest classifier achieved 86% accuracy [24], whereas a CNN model reached 98.80% accuracy [33]. It is evident that deep learning approaches, specifically CNN-based architectures, consistently outperformed traditional machine learning algorithms. The findings in this study align with this trend, since the proposed models surpassed the accuracies reported in the other papers, achieving an impressive accuracy of 99%.

TABLE III. TRAINING IMAGES, TESTING IMAGES AND ACCURACY FOR EACH MODEL

Model	Training Images	Testing Images	Accuracy
Random Forest[23]	372	93	86%
CNN [25]	2451	613	91.30%
R-CNN [26]	2451	613	91.66%
ANN [27]	160	40	92.14%
CNN [28]	222	56	93.90%
CNN [29]	400	100	96.08%
CNN [30]	2451	613	96.13%
SVM [31]	372	93	97.10%
Deep CNN [32]	372	93	98.07%
CNN [33]	510	1265	98.80%
Proposed ResNet50	2400	600	99.00%
Proposed VGG16	2400	600	99.00%
Proposed Xception	2400	600	100.00%

Fig. 14. Comparison between the performance of the proposed models and the other models.

V. CONCLUSION

The physical and psychological effects of tumors, including brain tumors, are significant and can be life-altering, impacting the patient's quality of life and life expectancy. Timely diagnosis of such tumors can greatly improve the patient's prognosis by enabling early intervention, potentially saving lives. Artificial intelligence, specifically deep learning, has shown important advancements in many sectors, including the medical field. This has led to numerous studies implementing these technologies for the automatic detection of brain tumors.

In this study, we aimed to develop an affordable, fast, and reliable system based on deep learning to accurately detect brain tumors from MRI images. We implemented, trained, and tested three algorithms for this purpose. The evaluation results demonstrate that the models can accurately and precisely identify the presence of tumors.

In the future work, we should aim to collect and use larger and more diverse datasets of brain MRI images which leads to the enhancement of the models' ability to generalize to new data, allowing the model to deal with real world complexities in brain tumor diagnosis. Additionally, efforts should be made to optimize the models for various platforms, enabling deployment across multiple devices to assist its adoption and utilization by doctors more effectively.

Multi-Objective Optimization of Oilfield Development Planning Based on Shuffled Frog Leaping Algorithm

Jun Wei

Finance Department, Bohai Drilling Corporation,
Dongying, 257200, China

Abstract—Oilfield development planning is a complex task that involves multiple optimization objectives and constraints. Therefore, a study proposes an improved shuffled frog leaping algorithm to achieve multi-objective optimization tasks. In multi-objective problems, the fitness value of the algorithm is not adaptive to the memetic evolution, resulting in local search failures. Research is conducted on improving the shuffled frog leaping algorithm through non-dominated sorting genetic algorithm-II, memetic evolution, and traversal methods, and then verifying the effectiveness of the algorithm. The outcomes denoted that when the population was 30 and the grouping was 5, the algorithm proposed in the study had the fastest search speed and better optimization effect. The improved shuffled frog leaping algorithm had advantages in both construction period and cost compared to the shuffled frog leaping algorithm, with a construction period difference of 19 days and a cost difference of \$13871. In comparative experiments with other algorithms, the average optimal solution and running time of the proposed algorithm were 0.324 and 7.2 seconds, respectively, which can quickly find the optimal solution in a short time. The algorithm proposed in the study can effectively optimize the complex objectives and constraints in oilfield development planning problems.

Keywords—Shuffled frog leaping algorithm; oilfield development; multi-objective; optimization; improve

I. INTRODUCTION

Oilfield development planning indicates the corresponding measures taken to maintain relative production and reduce cost expenditures after the decline period of oilfield development. As the intensity of oilfield development increases, its development form becomes increasingly severe. Due to its non-renewability and limited reserves, it is particularly important to design effective development plans and improve oil recovery in oil fields. The goal of oilfield development planning is to achieve maximum profit, but the problem of oilfield development planning is extremely complex, involving multiple conflicting goals and various constraints, such as maximizing recovery rate, minimizing costs, maximizing production efficiency, etc. [2-3]. Meanwhile, it is necessary to consider the constraints and impacts of geological conditions, environmental policies, etc. on oilfield development. Therefore, oilfield development planning problems are often a typical multi-objective optimization (MOO) problem, and the difficulty of project development is also increasing. In the past, there were still significant limitations in oilfield development planning, which

regarded oilfield development work as a deterministic planning problem and ignored the impact of various uncertain factors in the oilfield development process, such as the uncertainty of measures to increase oil production, the uncertainty of geological conditions in oil reservoirs, and the uncertainty in production management. The management of oilfield engineering projects involves multiple hierarchical dimensions, and different management objectives are interdependent and constrained. Therefore, it faces significant challenges in multi-planning and design [4-5]. On the basis of analyzing the uncertainty and multi-objective of oilfield development, this study considers analyzing the scope of resource evaluation, economic benefit evaluation, and scheduling planning design, and establishes an uncertainty planning optimization model. At the same time, the study introduces MOO technology into oilfield development planning, designs sustainable oilfield development plans while considering economic benefits, environmental protection, and social responsibility, improves the shuffled frog leaping algorithm (SFLA), provides technical support for oilfield development planning and decision-making, and provides suggestions for the development of the energy industry. Analyzing the entire process of offshore oil engineering project construction through research can reduce costs, improve resource utilization and economic benefits of oil and gas fields by optimizing development planning.

The analysis of the raised algorithm contains five sections. Related works is given in Section II. Section III is to build and analyze the proposed algorithm, and introduce the improved methods. Section IV is to verify the algorithm performance through comparative experiments. Section V is to summarize the experiment findings, point out the deficiencies in the research, and propose future research directions.

II. RELATED WORKS

Han Y et al. [6] focused on optimizing preventive maintenance intervals for safety critical equipment, integrating the dynamic characteristics of risks, conflict effects, and maintenance related costs, and proposed a systematic MOO framework. The results indicate that these two dynamic risk models can achieve MOO of the three objective function and have good application effects. Chen H et al. [7] developed a nonlinear multi-objective binary program (NMBP) to optimize investment portfolios under three competitive objectives in response to the problem of single objectives in existing overseas oil investment models. The non-dominated sorting

genetic algorithm-II (NSGA-II) was combined with the ideal solution similarity sorting technique (TOPSIS), and the outcomes denoted that this improved method can determine the best compromise solution based on investor preferences, [1] with high feasibility and effectiveness. Xidonas P et al. [8] incorporated energy and environmental corporate responsibility (EECR) into the decision-making process and introduced a multi-objective programming model to provide a Pareto optimal investment portfolio (Pareto set) with the net present value of the project and the EECR score of the enterprise. The results indicate that the decision-making approach of the multi-objective planning system can effectively evaluate the investment portfolio results. Rinaldi G et al. [9] investigated the optimization of operations using genetic algorithms and the maintenance assets of offshore wind farms, taking into account both the reliability characteristics of offshore wind turbines and the composition of maintenance fleets. This method can minimize the operating costs of offshore farms.

Many scholars have achieved numerous research results in MOO. Scholars such as Zheng S [10] put forward a parallel series magnetic path multi-permanent magnet motor for MOO of permanent magnet machines. The motor used two types of permanent magnets as common magnets. This study provided a detailed explanation of the design method for parallel series multi permanent magnet motors using the equivalent magnetic circuit method. Then, an MOO method was proposed, which comprehensively considered the effects of changes in magnet characteristics and the anti-demagnetization ability. The results showed that the studied motor and design method were effective. Scholars such as Song Y [11] have proposed an MOO scheme that combines photovoltaic, hydrogen, and natural gas in the field of comprehensive energy utilization. This scheme established a multi-objective hierarchical optimization configuration model to analyze the economy, environment, and energy efficiency, and it was compared with other MOO schemes. The findings illustrated that the proposed scheme in the study could increase the cost of leveling electricity by 25% and energy utilization efficiency by 8.51%, indicating its feasibility. Nakashima R N [12] proposed an MOO scheme with the NSGA-II algorithm to address the revenue and efficiency issues in solid oxide fuel cells. This scheme combined mixed integer linear optimization programs to ensure efficient operation of the heat recovery system. The experiment outcomes expressed that the proposed scheme could achieve high power generation efficiency and significantly reduce costs. Although there has been an increase in equipment, the proposed solution in the study has strong competitiveness. Scholars such as Soltani M [13] proposed an MOO scheme for the lateral stability strength of laminated composite beams with different cross-sectional lateral loads. Then, the optimal arrangement of the layer sequence was obtained through a Non-dominated Sorting Genetic Algorithm (NSGA). The study determined and discussed the optimal layer arrangement for the web and flanges, and the outcomes showed that the proposed scheme increased the bearing capacity by about 52%.

The geological structure of oil fields is complex, and there are many factors that affect the effectiveness of oil field

development, including geological conditions, reservoir characteristics, and extraction technology. Due to the limitations of computing resources, the optimization problem of oilfield development planning often cannot be fully solved. Previous studies have not explicitly considered these diverse constraints. And existing optimization models may not fully consider the long-term impact and risks of oilfield development planning on the ecological environment. Unlike previous design ideas, this study utilized the principle of application simulation to establish a correlation relationship between system development indicators, and built a MOO model with total construction period, total cost, quality level, and resource balance index as optimization objectives. At the same time, the study set logical relationships, resource requirements, and other constraints, innovatively combining classical model ideas with engineering practice conditions. The selection of dimensions for multi-objective planning considerations and the selection of quantitative indicators for environmental impact can provide reference ideas for oilfield development planning.

III. MULTI-OBJECTIVE OPTIMIZATION BASED ON SFLA

The oilfield development planning project is analyzed in this study, and combining the optimization objectives and constraints, an SFLA is proposed and improved.

A. SFLA Combined with Multi-Objectives

In oilfield development planning projects, research selects the total construction period, total cost, quality level, and resource balance index as optimization objectives. Simultaneously, logical relationships, resource requirements, and others are set as constraints [14]. Each task is assigned three attributes, namely start time, duration, and end time, and the duration of each task is determined by its execution mode. The total duration of oilfield development planning is determined by the longest working path, which is the critical path. Therefore, the total construction period can be expressed as the end time of the last task, as shown in Formula (1).

$$TD = \max f_j \quad (1)$$

In Formula (1), TD represents the total duration, and f_j means the end time of the j th task. The total project cost consists of direct and indirect costs, expressed as formula (2).

$$TC = DC + IC \quad (2)$$

In Formula (2), TC represents total cost, DC represents direct cost, and IC represents indirect cost. The direct cost can be expressed as Formula (3).

$$DC = \sum_j \sum_{m \in M_j} (x_{jm} \times c_{jm}) \quad (3)$$

In Formula (3), x_{jm} means the execution mode of each task, and c_{jm} means the direct cost of each task. The direct cost is expressed as the total direct cost of each task, which is only related to the execution mode adopted for each task. The indirect cost is expressed as Formula (4).

$$IC = TD \times c_{ind} = \max f_i \times c_{ind} \quad (4)$$

In Formula (4), c_{ind} represents the unit indirect cost. Assuming that the cost per unit time is fixed and unchanging, indirect costs are only related to the project duration. In actual project planning, it will be constrained by the contract duration. If the project is not completed within the specified time, a penalty function needs to be added, as denoted in Formula (5).

$$p = y \times c_p \times (\max f_j - T_{con}) \quad (5)$$

In Formula (5), T_{con} represents the agreed duration in the contract, and c_p represents the penalty value for delay, depending on the agreement in the contract. y is a variable with values of 0 and 1, as shown in Formula (6).

$$y = \begin{cases} 1, & \max f_j > T_{con} \\ 0, & \max f_j \leq T_{con} \end{cases} \quad (6)$$

In Formula (6), when the actual construction period is greater than the contract period, y is taken as 1, and vice versa is taken as 0. Therefore, the final cost objective function is expressed as Formula (7).

$$TC = \sum_j \sum_{m \in M_j} (x_{jm} \times c_{jm}) + \max f_i \times c_{ind} + y \times c_p \times (\max f_j - T_{con}) \quad (7)$$

In oilfield development planning projects, each task may correspond to multiple different execution modes and have corresponding execution times. Cost and resource allocation is an MOO approach. The study considers quality level as a parameter corresponding to different modes of work, and sets weights based on the impact of different work on quality, which changes according to the different modes. A comprehensive evaluation of the project is conducted, with the objective function as denoted in Formula (8).

$$Q = \sum w_{ij} \sum w_{ij,r} \times Q_{j,r}^m \quad (8)$$

In Formula (8), w_{ij} represents the weight of the j work that affects the overall quality, $\sum w_{ij} = 1$. The quality level is judged by the indicator r . $w_{ij,r}$ represents the weight of quality indicator r in j project work, $\sum w_{ij,r} = 1$. $Q_{j,r}^m$ represents the quality standard achieved by j work in execution mode m under the quality indicator r . In MOO, indicators for measuring resource balance include variance, imbalance coefficient, resource volatility, and resource balance objective function. Due to the fact that resource demand units in actual engineering are in days, the variance expression is shown in Formula (9).

$$\sigma^2 = \sum_{k=1}^K \sum_{t=1}^T (r_k(t) - \bar{r}_k)^2 \quad (9)$$

In Formula (9), σ represents the equation for the r th resource equilibrium demand. $r_k(t)$ represents the usage of k resources at t time. \bar{r}_k means the average usage of k resources. The petroleum engineering project is an engineering activity with huge investment, complex technology, and high management requirements. Its resource

types include a variety of resources, such as human resources, mechanical equipment, materials, finance, etc. The effective allocation of resources can ensure that project funds are not wasted and ensure economic benefits and costs. And through demand balancing, it can avoid excessive purchase and backlog of resources, improve resource utilization efficiency, reduce idle time caused by waiting for resources, and raise the overall work efficiency of the project. Each stage and process in the project requires different resource support. A balanced resource demand can ensure the timely completion of work tasks in each stage of the project, and ensure that the project progress meets the plan. The smaller the variance of resource equilibrium, the better the balance of resources. The calculation method for the imbalance coefficient is shown in Formula (10).

$$u = \frac{r_k^{\max}}{\bar{r}_k} \quad (10)$$

In Formula (10), u represents the imbalance coefficient of k resources. r_k^{\max} represents the maximum demand for the k th resource in the plan, and \bar{r}_k denotes the average usage of the k resource. The smaller the u , the better the overall resource balance level of the project. The calculation method for resource fluctuations is shown in Formula (11) [15].

$$\begin{cases} RRH = H - MRD = \frac{1}{2} \times HR - MRD \\ HR = \left[r_1 + \sum_{t=1}^{T-1} |r_1 - r_{t+1}| + r_T \right] \end{cases} \quad (11)$$

In Formula (11), RRH represents the overall resource fluctuation level of the project, and MRD represents the highest resource demand in the project. HR represents the sum of daily resource fluctuations in the planned project. r_t represents the resource demand on day t . The smaller the RRH , the better the overall resource balance level of the plan. The objective function of resource balance is expressed as Formula (12) [16].

$$\begin{cases} RLI = \sum_{k=1}^K \sum_{t=1}^{TD} (r_k(t) - \bar{r}_k)^2 \\ \bar{r}_k = \frac{1}{TD} \sum_{t=1}^{TD} r_k(t) \end{cases} \quad (12)$$

In Formula (12), RLI represents the resource objective function, and $r_k(t)$ represents the k th resource usage at time t . The research will standardize the proposed objective function and constraint conditions. Using the SFLA for oilfield project development planning [17-18]. The SFLA is a metaheuristic search algorithm based on individual meme evolution and population information exchange. SFLA uses metaheuristic search, based on meme algorithm and PSO algorithm, to find the optimal solution of the problem while achieving local search and global information exchange. In the SFLA, individuals are divided into different particle populations, each carrying different ideas and information.

Under the leadership of elite individuals, independent searches are carried out to achieve local optimization and information exchange. After the subpopulation evolves to a certain extent, the isolation between subpopulations is broken, allowing information to be transmitted throughout the entire population until convergence conditions are reached and terminated. Global search effectively prevents extreme thoughts in one subpopulation, causing the entire population to jump in the correct direction. In the solution space, it randomly generate an initial population $U = \{U_1, U_2, \dots, U_F\}$ containing F individuals, and the i th individual in the d dimensional solution space is indicated as $U = \{U_i^1, U_i^2, \dots, U_i^d\}$. Individuals and memes are assigned using Formula (13).

$$Y^k = \{U_{k+m(l-1)} \in F \mid 1 \leq l \leq n\}, 1 \leq k \leq m \quad (13)$$

In Formula (13), Y^k represents the K th meme group. All individuals in the initial population are divided into m meme groups, each containing n individuals. The fitness values of all individuals are calculated and they are sorted based on their fitness values. The person with the best fitness is placed in meme group 1, the second individual is placed in meme group 2, the m -th individual is placed in meme group m , and the $m+1$ st individual is placed in meme group 1, and they are assigned in sequence. After the division of meme groups is completed, the step size is calculated using the

Formula (14).

$$D = r \times (P_b - P_w) \quad (14)$$

In Formula (14), r means a random number with a value between 0 and 1. P_b represents the individual with the worst fitness, and P_w denotes the individual with the best fitness. D represents the step size. Through evolution, if a new individual has a better fitness value than the original individual, the original individual is replaced by a new individual. If there is no progress, the individual with the best fitness is used to improve again. The improvement method is as shown in Formula (15).

$$P_w' = P_w + D, |D| \leq D_{\max} \quad (15)$$

In Formula (15), D_{\max} represents the maximum value at which an individual can change position. If there are no individuals with better fitness values, it will randomly generate new individuals to replace P_w . When the local search reaches the termination condition, all individuals are re broken into meme groups based on their fitness values, and the local search continues until the convergence condition is reached. The basic process of the SFLA is indicated in Fig. 1.

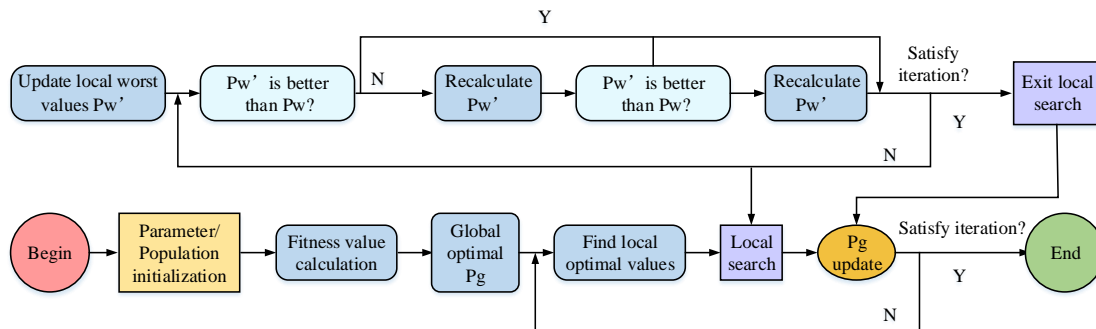

Fig. 1. Basic flow of SFLA.

Fig. 1 showcases the basic process of the SFLA. The SFLA, like other heuristic algorithms, has important parameters that directly affect the implementation of algorithm performance. The important parameters that affect the SFLA include population scale, amount of meme groups, amount of meme group individuals, max amount of evolutions per meme group, and maximum step size that individuals can jump.

B. Improvement of SFLA

The NSGA, based on traditional genetic algorithms, utilizes non dominated Pareto stratification and uses virtual fitness values as sorting conditions for MOO to adjust the virtual fitness values through niche technology. With NSGA, the NSGA-II algorithm is proposed, and Fig. 2 denotes the basic flow of NSGA-II.

Fig. 2 shows the basic process of NSGA-II. NSGA-II is a non-dominated genetic algorithm with elite strategy, which

has been improved in three aspects based on NSGA. Firstly, fast non dominant sorting is used to evaluate the optimal solution, and then sorting, the complexity is reduced. Secondly, by using crowding comparison operators for fitness sharing, parameter simplification can be achieved while maintaining population diversity. Finally, an elite retention strategy is introduced to mix parental and offspring individuals and the next generation population is selected based on their strengths and weaknesses, which is beneficial for improving the overall level of the population. Although the traditional SFLA has advantages such as strong search ability, it is not adaptive in terms of fitness calculation and meme evolution in multi-objective discrete problems [19-20]. In the traditional SFLA, the evaluation and ranking of individuals are based on fitness values, and the calculation is simple in a single objective. However, in a multi-objective approach, it may lead to significant individual differences between meme groups. In the traditional SFLA, intra-group iteration is

achieved through individual meme group evolution operations, using step size to iterate individual positions. In MOO studies, using step size for optimization may affect the direction of individual evolution, leading to local search failures. Therefore, the study sorted candidate solutions using NSGA-II, selected all individuals in the population to form a non-dominated hierarchy, and traversed all individuals in the non-dominated hierarchy until all individuals were assigned. The memetic evolution method uses cross genetic operators, as shown in Fig. 3.

Fig. 3. Single point crossing process.

Fig. 3 shows the single point crossover mechanism of the improved SFLA. Firstly, the optimal and worst individuals in the meme selected, and based on the random integer of the breakpoint position, the optimal and worst individuals are crossed to obtain new two individuals. If the improved new individual is still dominated by the worst individual, it will replace the worst individual with the new individual and repeat the crossover process. If the generated individual is still dominated by the new individual, a new solution is randomly created to replace the worst individual. In the multi-objective model proposed in the study, the feasibility of candidate solutions is tested through traversal method, and the constraint traversal mechanism is shown in Fig. 4.

Fig. 4 showcases the traversal mechanism of constraint conditions. When using the traversal mechanism, for work that does not meet the constraint conditions, the start time is postponed until the constraint conditions are met. The improved algorithm process is indicated in Fig. 5.

Fig. 5 illustrates the improved SFLA process. Through improvements in candidate solution sorting, meme evolution, and constraint mechanism, the algorithm has a faster computational speed, a wider range of Pareto solution sets, and stronger algorithm effectiveness.

Fig. 4. Single point crossing process.

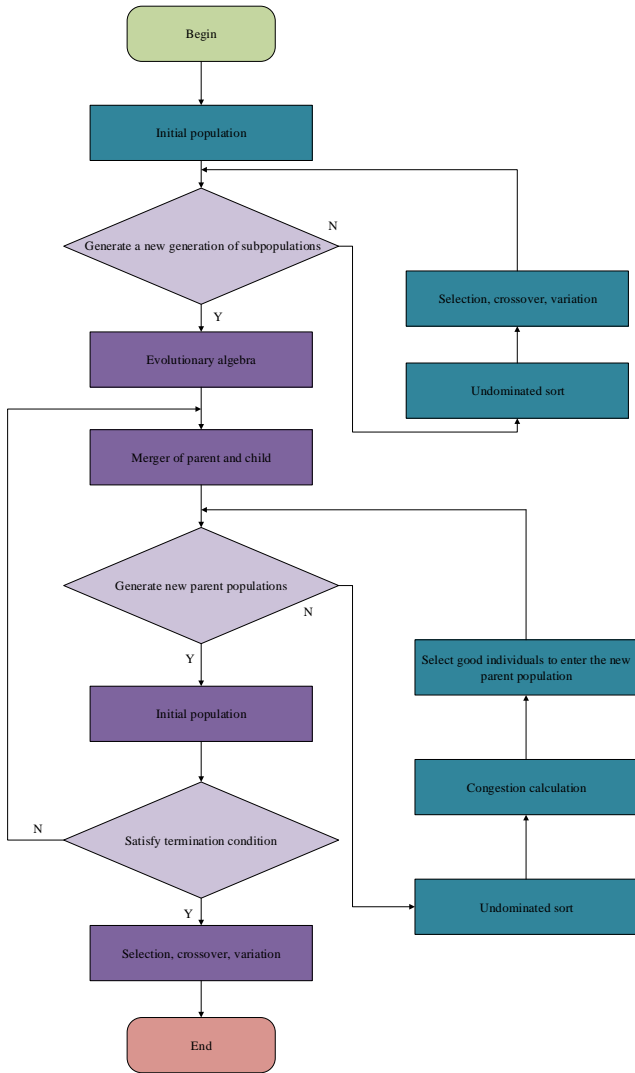

Fig. 2. NSGA-II basic process.

IV. PERFORMANCE ANALYSIS OF IMPROVED SFLAS

The important parameters for improving the SFLA were studied, and then the effectiveness and superiority of the algorithm were verified through comparative experiments.

C. Analysis of Important Parameters for Improved SFLA

The study analyzed important parameters in an improved SFLA that combines multi- objectives, with a dataset from 50 simulation cases in the VBP test set. The laboratory environment settings are denoted in Table I.

Table I shows the laboratory environment settings. The important parameter selection was the initial population size F and grouping method M , and different parameters had different effects on the performance of the improved SFLA. The initial population F was set as 10, 20, 30, 40, 50, 60, 70, 80, and 90, and the total amount of iterations was set to 100. The outcomes are expressed in Fig. 6.

TABLE I. LABORATORY ENVIRONMENT SETTINGS

Hardware and software configuration	Version model
CPU	Intel(R)Core i7-7700@3.6GHz
Operating system	Ubuntu 18.04 LTS
CUDA	9.1
Deep learning frameworks	Pytorch1.10
Python version	3.9

Fig. 6. The results of algorithm operation under different population numbers.

Fig. 6 showcases the running outcomes of algorithms with different population sizes. From the graph, when the population size was 30, the proposed algorithm had the highest number of non-inferior solution sets, with 19 non-inferior solution sets. When the population size was 10 and 20, the non-inferior solution sets of the proposed algorithm were 7 and 10, respectively. When the population size was 60 and 90, the proposed algorithm had a non-inferior

solution set of 16 and 7, respectively, which was lower than the result when the population size was 30. From the perspective of running time, as the population size increased, the algorithm's running time continued to grow. When the population size was 10, 30, 60, and 90, the algorithm proposed in the study had running times of 0.21s, 0.25s, 0.34s, and 0.41s, respectively. Therefore, a small population size will influence the search ability of the algorithm, while a large population size will lead to a long running time of the algorithm. The initial population F was set to 30, and the

grouping methods M were set to 2, 5, 10, and 15, respectively. The total amount of iterations of the algorithm was set to 50, and the running result is shown in Fig. 7.

D. Analysis of The Effectiveness of Improving The SFLA

A comparative experiment was conducted between the improved SFLA proposed in the study and the original SFLA. The population size was set to 30, group M was set to 5, and the global max iteration was set to 100. The Pareto solution set results are denoted in Fig. 8.

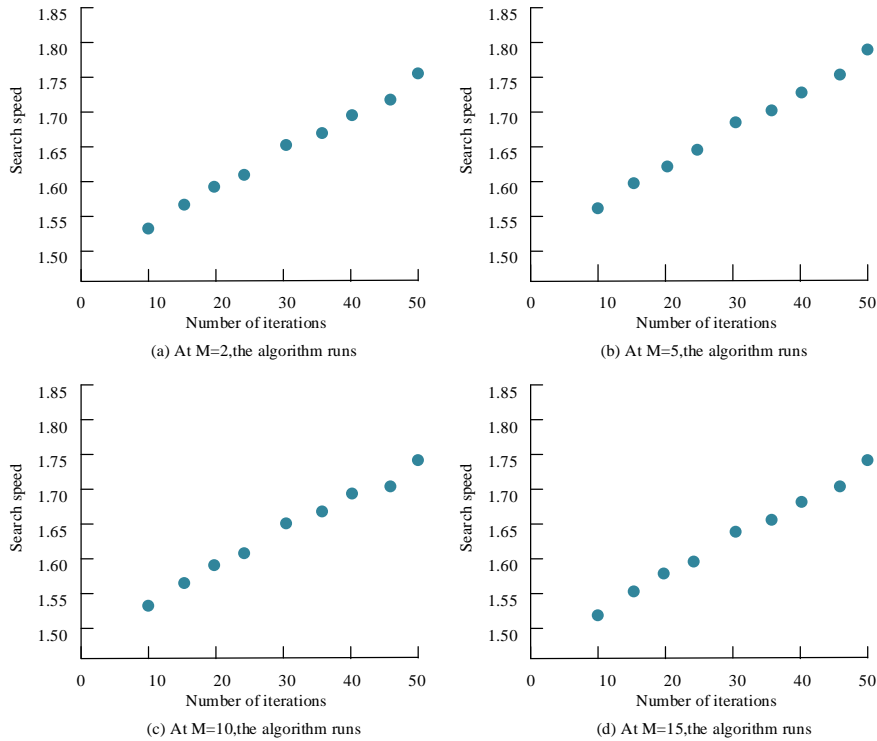

Fig. 7. Results of algorithms in different grouping modes.

Fig. 8. Pareto solution set of two algorithms.

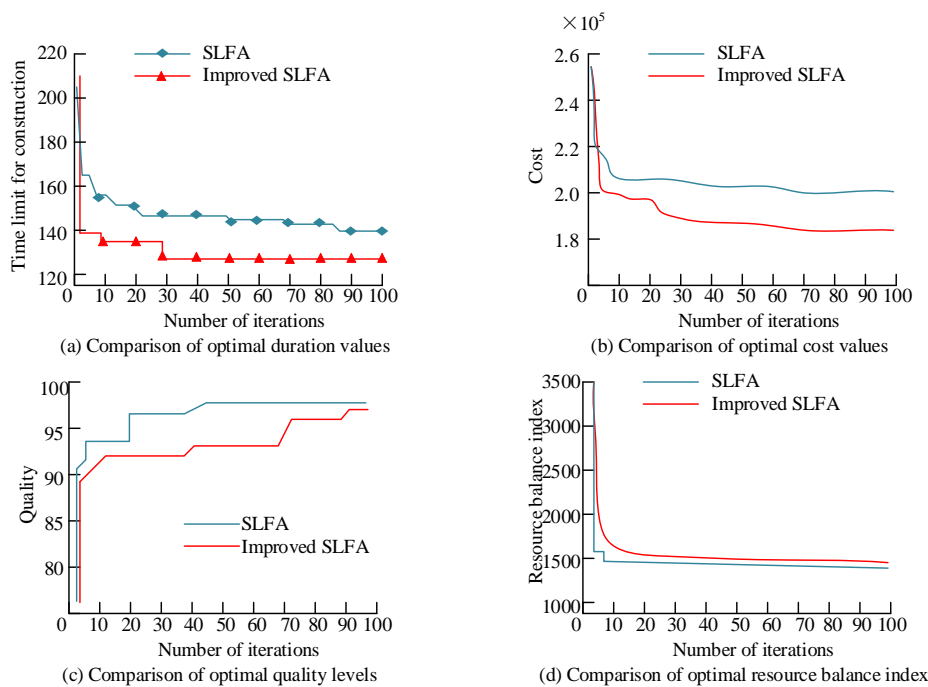

Fig. 9. The change trend of the optimal target value of the two algorithms.

Fig. 8 showcases the Pareto solution set results of two algorithms. Fig. 8(a) showcases the Pareto solution set of the SFLA. After 100 iterations, a total of 61 Pareto solution sets were generated globally. Fig. 8(b) showcases the Pareto solution set of the improved SFLA. After 100 iterations, a total of 89 Pareto solution sets were generated globally. From the comparison of the Pareto solution sets obtained by the two algorithms, the optimal solution obtained by the improved SFLA was superior to the SFLA in terms of duration and cost. The difference in duration was 19 days, and the difference in cost was 13871 US dollars. In terms of resource balance index comparison, the SFLA was superior to the improved SFLA, with a difference of 15 in resource balance index, which was a small difference at the same level. The changes in the optimal objectives of the Pareto solution set obtained by the two algorithms are denoted in Fig. 9.

E. Analysis of the Superiority of Improving the SFLA

The improved SFLA was compared with Genetic Algorithm (GA), PSO algorithm, Ant Colony Optimization (ACO), Simulated Annealing (SA) algorithm and Tabu Search (TS) algorithm. Among them, GA is a search heuristic algorithm, which reflects the natural selection, where individuals who are most suitable for the environment are chosen for reproduction to produce the next generation of offspring. PSO is a population-based stochastic optimization algorithm. PSO simulates the movement of individuals in search space. Individuals communicate and cooperate with each other to find the best solution. ACO is an algorithm for finding the best path. ACO is inspired by the foraging behavior of ants, which use pheromones to communicate and find the shortest path to the source of food. SA is a probabilistic optimization algorithm utilized to find the global optimal solution for problems with a large search space. TS is a metaheuristic optimization algorithm applied to solve

combinatorial optimization issues, which can be utilized to address combinatorial optimization issues. The amount of iterations was 100, the initial population was 30, and the grouping was 5. Multiple algorithms were run independently 20 times, and the comparison results are indicated in Fig. 10.

Fig. 10. Comparison of average optimal solutions of multiple algorithms.

Fig. 10 shows a comparison of the average optimal solutions of multiple algorithms. From the graph, it can be seen that the average optimal solution curve of the algorithm shows a decreasing trend with the number of iterations, and then tends to flatten out. Specifically, when the number of iterations is in the range of 10-30, the average optimal solution from small to large is: SA<ACO<Improved SLFA<GA<PSO<TS. As the amount of iterations increases, in the later stage, the SA, ACO, improved SLFA, GA, PSO algorithms tend to stabilize with 0.253, 0.247, 0.286, 0.176,

0.168 iterations, respectively. The algorithm proposed in the study converged quickly in 40 iterations, with a relatively small number of overall changing nodes, and gradually stabilized at an average optimal solution of 0.324 in 50-60 iterations. The other comparison outcomes of multiple algorithms are denoted in Table II.

Table II shows the comparison results of the optimal solutions, running time, and average optimal solutions of various algorithms. From the perspective of optimal solution, the algorithm proposed in the study had a higher optimal solution than other algorithms, with an optimal solution of around 0.051. The optimal solution of SA algorithm was the lowest, around 0.17. From the perspective of running time, the proposed algorithm had a shorter running time compared to the PSO algorithm, maintaining at 7.2s and 6.8s. The TS algorithm and ACO algorithm took longer and more time to run. In summary, the proposed algorithm has a high optimization rate and can quickly find the optimal solution in a short period of time.

TABLE II. COMPARISON OF OPTIMAL SOLUTION, RUNNING TIME AND AVERAGE OPTIMAL SOLUTION OF MULTIPLE ALGORITHMS

Algorithm	Optimal solution	Running time(s)	Average optimal solution
Improved SFLA	0.051±0.000003	7.2	0.324
GA	0.012±0.000004	8.7	0.178
SA	0.017±0.000003	7.6	0.209
ACO	0.024±0.000005	10.0	0.239
TS	0.036±0.000004	9.3	0.051
PSO	0.042±0.000005	6.8	0.143

V. CONCLUSION

Research used an improved SFLA for MOO of oilfield development planning. Research selected total construction period, total cost, quality level, and resource balance index as optimization objectives. Research utilized the SFLA to address multi-objective issues, but in multi-objective discrete problems, fitness calculation and memetic evolution were not adaptive. Therefore, this study aimed to improve the SFLA through NSGA-II, memetic evolution, and traversal methods. The study analyzed the effectiveness of the proposed improved SFLA, investigated the influence of population size and grouping methods on the algorithm, and then compared it with the SFLA to verify its effectiveness. Finally, its superiority was verified by comparing it with other algorithms. The experiment findings indicated that when the population was 30 and the grouping was 5, the algorithm proposed in the study had the fastest search speed and better optimization effect. The optimal solution obtained by improving the SFLA was superior to the SFLA in terms of duration and cost, with a duration difference of 19 days and a cost difference of \$13871. In comparison with other algorithms, the proposed algorithm had a shorter running time and the highest optimal solution, which was 7.2s and 0.051, respectively, and could quickly find the optimal solution in a shorter time. Based on the model solving approach and MOO problem analysis, the SFLA was improved. The results

showed that the improved approach can effectively improve the uncertainty problem of the target and demonstrate good project application effects. However, it is worth noting that the proposed equilibrium model is based on the assumption that cost, resource allocation, and other factors are only determined by the work execution mode. Its content does not take into account the uncertainty factors and parameter changes of actual projects too much in the selection, which needs further discussion in future research. Meanwhile, in the future design of engineering project models, it is necessary to better consider the impact factors of labor consumption, material and equipment consumption on multi-objective planning problems, and further expand the application scenario conditions of the SFLA.

Abstract—Ensemble learning in machine learning applications is crucial because it leverages the collective wisdom of multiple models to enhance predictive performance and generalization. Ensemble learning is a method to provide a better approximation of an optimal classifier. A number of basic classifiers are used in ensemble learning. In order to improve performance, it is important for the basic classifiers to possess adequate efficacy and exhibit distinct classification errors. Additionally, an appropriate technique should be employed to amalgamate the outcomes of these classifiers. Numerous methods for ensemble classification have been introduced, including voting, bagging and reinforcement methods. In this particular study, an ensemble classifier that relies on the weighted mean of the basic classifiers' outputs was proposed. To estimate the combination weights, a multi-objective genetic algorithm, considering factors such as classification error, diversity, sparsity, and density criteria, was utilized. Through implementations on UCI datasets, the proposed approach demonstrates a significant enhancement in classification accuracy compared to other conventional ensemble classifiers. In summary, the obtained results showed that genetic-based ensemble classifiers provide advantages such as enhanced capability to handle complex datasets, improved robustness and generalization, and flexible adaptability. These advantages make them a valuable tool in various domains, contributing to more accurate and reliable predictions. Future studies should test and validate this method on more and larger datasets to determine its actual performance.

Keywords—Machine learning; genetic algorithm; ensemble classification; classification error

I. INTRODUCTION

Classification is a process in which each unknown pattern is attributed to one of the known classes based on its characteristics. In other words, classification is a mapping from the n-dimensional space of features to the k-dimensional space of classes, in which the degree of belonging of the feature vector to different classes is expressed as a numerical value [1, 2]. The classifier is usually built in a learning process. Many algorithms actually perform a local search that may get stuck in a local minimum. If it is trapped in the local minimum, it is not possible to have an optimal classifier [3]. A classifier must go through at least two phases: the training phase and the testing phase [4, 5]. In the training phase, the feature vector is extracted from each sample. Feature vectors are defined according to the nature of samples and application [6]. To improve feature vectors, feature conversion, feature reduction, or feature selection can be applied

to them. Genetic algorithm and principal component analysis can be mentioned from the feature reduction methods, and mutual information maximization can be mentioned from the feature selection methods. The classifier is then trained to adjust its weights, biases, and other parameters using the selected dataset. In the testing phase, features are extracted from the test dataset and samples are labeled with the help of a trained classifier [7].

Ensemble learning is a method to provide a better approximation of an optimal classifier. A number of basic classifiers are used in ensemble learning [8, 9]. Each basic learning algorithm reaches a different answer for the problem according to its parameters, and it is expected that the classification accuracy will increase by combining these answers [10]. For this reason, in recent years, using the results of multiple classifiers as an effective method in pattern recognition has attracted the attention of many researchers, and it has been used in various branches of science, especially engineering science. Diagnosing faults in gas turbines, intrusion detection in computer networks, zip code recognition, handwriting recognition, identity recognition and biomedical signal classification (such as EEG and ECG) are examples of the use of ensemble classifiers [11-14]. The classifiers whose results are combined are called basic classifiers, and the set of classifiers is called a composite or ensemble system.

Since classifiers are made in a learning process, in order to have different classifiers, their learning process should be different. It has been proven that the combination of more independent classifiers increases the recognition rate [15]. Therefore, it is tried to increase the variety of basic classifiers in different applications. Also, by using an appropriate ensemble approach to combine the outputs of the basic classifiers, the classification performance is improved. Training classifiers with various feature sets is the most effective method to create diversity in learning classifiers. The many methods of creating diversity proposed in the articles can be divided into two categories: explicit and implicit [16]. Explicit methods make classifiers different from each other by changing their learning process of them. Penalty methods and reinforcement methods are among the most important explicit methods to create diversity in basic classifiers [17]. In implicit methods, with implicit changes in the learning process of basic classifiers, an attempt is made to diversify them. In these methods, no measure of diversity is checked during learning, and therefore, there is no guarantee that the classifiers will be different, but we only hope

that the errors of the created classifiers will be different from each other. The most common of these methods is random selection with replacement of samples from among all training samples, which is called the bagging method [18]. Other implicit methods include fuzzy integral [19], Dempster-Shafer [20], knowledge-behaviour space [21] and decision model [22].

Common methods of combining classifiers include the majority voting approach [23], weighted majority voting approach [24], methods based on Bayesian theory [25] and stacking approaches [26]. In some methods, evolutionary algorithms are used to estimate weights to combine the average weights of basic classifiers [27]. These methods are also implicit learning methods [28]. In study [29], the optimal estimation of weights has been done with the help of a genetic algorithm. In this method, the sum of error, sparsity and diversity criteria is minimized in order to obtain the best result for classification. Indeed, the genetic algorithm optimizes the sum of error, sparsity and diversity criteria, and there is no guarantee to optimize the individual fitness functions of error, sparsity and diversity. This issue can introduce an important defect into the system, and therefore, this study tries to address it. The proposed ensemble method is in the form of weighted sum of the outputs, the weights are estimated by multi-objective genetic algorithm and considering four simultaneous criteria of classification error, sparsity, diversity and density. In the proposed method, while using the criteria mentioned in study [29], the density criterion was also considered. The rest of the article is organized as follows: Section II provides an overview of different approaches for combining classifiers including reinforcement method, bagging method, voting method, evolutionary method and stacking method. Section III presents the framework and formulation of the proposed ensemble technique for combining classifiers. Section IV presents and discusses the experimental results, and Section V makes a conclusion about this study.

II. RELATED WORK

Xue et al. showed that ensemble methods can be categorized into three groups based on the type of information produced by each classifier [30]: concept-level methods, rank-level methods, and measurement-level methods. In this section, some popular ensemble methods are briefly reviewed.

1) *Reinforcement method.* It is a hybrid method to improve the performance of multiple weak classifiers and obtain a strong classifier. In this method, predictors are trained sequentially. The former is trained from the entire dataset, while the latter is trained from the training dataset obtained based on the performance of the previous ones. Reinforcement ensemble classifiers, also known as Reinforcement Learning with Ensemble Classifiers (RLEC), are a sophisticated approach that combines the principles of reinforcement learning and ensemble learning. In RLEC, a collection of classifiers is trained using ensemble learning techniques such as bagging or boosting, creating an ensemble that collaboratively makes predictions. The distinguishing aspect of RLEC lies in the integration of reinforcement learning, where the ensemble receives feedback in the form of rewards or penalties during training. By incorporating reinforcement learning, RLEC enables the

ensemble to adapt its strategies, explore different actions, and ultimately improve its performance over time [31].

2) *Bagging method.* Bagging ensemble classifiers, short for Bootstrap Aggregating, is a powerful technique used in machine learning to improve the accuracy and stability of prediction models. In bagging, multiple classifiers are trained independently on different subsets of the training data, usually obtained through bootstrapping. Each classifier in the ensemble provides a prediction, and the final prediction is determined through voting or averaging. By combining the outputs of multiple classifiers, bagging ensemble classifiers can reduce the variance in predictions and enhance overall performance. Bagging is particularly effective when the base classifiers are diverse, as errors made by individual classifiers tend to cancel out. This technique is widely used in various machine learning algorithms, including decision trees, neural networks, and support vector machines, and it has proven to be a reliable method for reducing overfitting and improving generalization capabilities [32].

3) *Voting method.* Voting ensemble classifiers, also known as majority voting or democratic voting, is a popular technique in machine learning that combines the predictions from multiple individual classifiers to make final decisions. Each classifier in the ensemble independently provides a prediction, and the final prediction is determined by majority voting. This means that the class with the highest number of votes among the classifiers is chosen as the final predicted class. Voting ensemble classifiers can be applied in different ways, such as hard voting, where each classifier has an equal vote weight, or soft voting, where classifiers' votes are weighted based on their confidence levels. This ensemble method leverages the wisdom of the crowd and is effective in situations where the base classifiers are diverse and have complementary strengths. Voting ensemble classifiers have been successfully utilized in various machine learning algorithms, including decision trees, random forests, and support vector machines, to enhance prediction accuracy and improve model robustness [33].

4) *Evolutionary method.* Evolutionary ensemble classifiers, also known as evolutionary ensembles, are a popular technique in machine learning that harnesses the principles of evolution to create robust and accurate prediction models. In this approach, a population of diverse classifiers is initially generated, each with its own set of parameters or configurations. The classifiers are assessed on their individual performance using evaluation metrics such as accuracy or error rate. Through a process of selection, crossover, and mutation inspired by natural selection, the genetic makeup of the classifiers evolves over multiple generations. The fittest classifiers, those with superior performance, are selected to reproduce and pass on their traits to the next generation while lesser-performing classifiers are either eliminated or undergo random modifications. This evolutionary cycle continues until a termination criterion, such as reaching a desired level of accuracy or a predefined number of generations, is met. By leveraging the diversity and complementarity of ensemble members through evolutionary search, evolutionary

ensemble classifiers can improve prediction accuracy and generalization ability. They have proven to be effective in various domains, including classification, regression, and feature selection, providing a powerful tool for solving complex machine-learning problems [34].

5) *Stacking method.* Stacking ensemble classifiers, also referred to as stacked generalization, is a powerful technique in machine learning that combines the predictions of multiple individual classifiers to make more accurate and robust predictions. In this approach, a diverse set of base classifiers are trained on the same dataset. Each base classifier learns different aspects of the data and produces its predictions. Instead of treating these predictions equally, a meta-classifier is then used to learn how to combine them into a final prediction. The meta-classifier takes the outputs of the base classifiers as input features and learns to make a higher-level prediction based on this information. This meta-learning step allows the ensemble to capture complex relationships and patterns within the data that may not be apparent to individual classifiers. The stacking ensemble approach can lead to improved predictive performance by leveraging the strengths of different classifiers and reducing the weaknesses of individual models through the combined decision-making process [35].

III. THE PROPOSED ENSEMBLE TECHNIQUE

In this research, we proposed an ensemble evolutionary technique for improving the efficiency of each classifier based on the multi-objective genetic algorithm by considering the criteria of classification error, diversity, sparsity and density. In

combining classifiers, each sample S is associated with a label y . In order to classify each sample S into k classes, it is assumed that there are N classifiers, h_1, h_2, \dots, h_N , and each of them uses a certain feature vector for the sample S . For an input sample S , the classifiers recognize the values $X^n = h_n(S)$. $X = [X^1, \dots, X^N]^T$ can be obtained through all classifiers. In other words, the final result is obtained from the output combination of all classifiers in the form of the following relationship.

$$H(S) = F(h_1(S) \dots h_N(S)) = F(x) = f(x^1 \dots x^N) \quad (1)$$

In this article, the weighted average of the output of the classifiers is used to make the final decision. The following relation is used for the weighted sum of the output of the classifiers:

$$H(S) = \sum_{n=1}^N W_n x_n = W^T \quad (2)$$

where, W_n is the weight of n^{th} classifier, and $W = [w_1, \dots, w_n]^T$. Consider $\{(S_m, y_m)\}_{m=1}^M$ with M sample and N classifiers, where S_m is the m^{th} sample and y_m denotes its label. $\{(x_m, y_m)\}_{m=1}^M$ denotes the classifier output for m^{th} sample, where x_m indicates the vector $x_m = [x_m^1, x_m^2 \dots x_m^N]^T$. Fig. 1 shows the scheme of the suggested algorithm. As shown, the samples are given to N basic classifiers and the output of these classifiers are combined with each other in the combiner in a weighted sum and create the final output. In the proposed method, a multi-objective genetic algorithm is used to estimate the weights. As shown, in this method, four fitness functions of classification error, diversity, sparsity and density are used. Each of these fitness functions, as well as the details of the multi-objective genetic algorithm and its structure, are explained below.

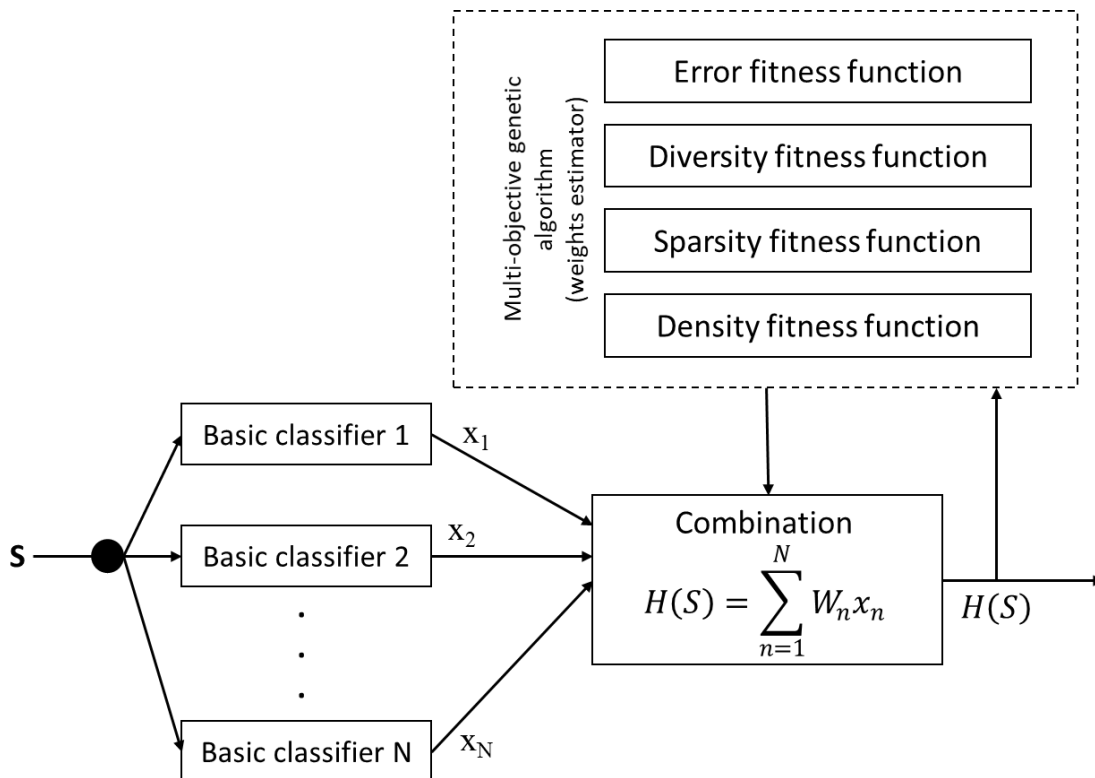

Fig. 1. Block diagram of the suggested algorithm for the ensemble classification.

The ensemble classifier focuses on finding the weights in such a way that the minimum classification error is obtained. The error function is defined as follows:

$$F_{error} = \frac{1}{M} \sum_{m=1}^M (W^T x_m - y_m)^2 \quad (3)$$

The minimization of the error function is considered an optimization problem, and in this article, an attempt is made to reduce the classification error function from a threshold value, which is shown in Eq. (4).

$$F_{error}(W) \leq t_1 \quad (4)$$

where, t_1 is a control parameter. In the proposed method, the I_1 -norm function is used to calculate the sparsity, according to Eq. (5), which should be less than a determined value (t_2).

$$F_{sparsity}(W) = \|W\|_1 \leq t_2 \quad (5)$$

Using different classifiers creates diversity. Eq. (6) is used to estimate diversity.

$$F_{diversity}(W) = \frac{2}{N(N-1)} \sum_{n_1=1}^{N-1} \sum_{n_2=n_1+1}^N \frac{1+Q_{n_1 n_2}}{2} \quad (6)$$

where, Q is the statistical measure introduced by Yule to estimate the degree of diversity. The smaller the Q , the more diverse the classifiers. The diversity value in the proposed method should be less than a specified threshold, which is shown in Eq. (7):

$$F_{diversity}(W) \leq t_3 \quad (7)$$

The density criterion is used as the fourth criterion to estimate weights in the combination of classifiers. For this reason, to increase the correct rate of pattern recognition, the density should be maximized. $F_{density}$ is given by Eq. (8):

$$F_{density} = \frac{1}{\sum_{n=1}^N \sum_{m=1}^{M_n} (x_m - \mu_n)(x_m - \mu_n)^T} \quad (8)$$

where, μ_n is the mean of n^{th} class, and M_n is the number of samples in the n^{th} class. The criterion specified in Eq. (8) must be less than the threshold specified in Eq. (9):

$$F_{density}(W) \leq t_4 \quad (9)$$

where, t_4 is a control parameter. Finally, the main goal in combining classifiers is to estimate the weights using the multi-objective genetic algorithm in such a way that Eq. (4), (5), (7) and (9) are established. In general, it can be said that using the proposed method reduces the destructive effects of noise and increases the distance between classes. It is also expected that the proposed method will obtain better results in the experiments due to the change in the process of estimating W_i with the multi-objective genetic algorithm and the use of various criteria.

IV. RESULTS AND DISCUSSION

In this section, the performance of the proposed method is compared to the methods of bagging, voting, stacking, boosting, and genetic algorithm-based ensemble method [29] on UCI data. The Iris, CMC, Diabetes, Vowel, Glass and Ionosphere datasets from the UCI repository database were used for the experiments,

whose characteristics are shown in Table I [36]. In these experiments, the basic classifiers are of the same type with different parameters that have acceptable diversity. In the conducted experiments, the basic classifiers for all methods were chosen the same, and all of them are multilayer perceptron neural networks with different numbers of hidden layers and different number of nodes in each layer.

In the proposed method, the parameters of the multi-objective genetic algorithm are set as follows:

- Population size: 100 chromosomes
- Chromosome length: an array of length 4 of decimal numbers equivalent to the weight of each of the basic classifiers
- Mutation operator: randomly selecting a gene from a chromosome and randomly resetting that gene
- Combination operator: single-point type
- Selection operator: tournament type
- Termination criterion: if the fitness functions of the best solution do not change significantly after a certain number of iterations.

Performance evaluation was done using a random partitioning technique. The random partitioning method involves the random division of the dataset into three distinct subsets: training, validation, and testing [37]. Specifically, 70% of the data were allocated to the training subset, while 30% were assigned to the testing subset. Additionally, 15% of the training subset was designated for validation purposes. To evaluate the overall classification performance, the trained model was applied to the testing subset, and performance metric values were computed accordingly. It is worth noting that in the context of random partitioning, the early stopping method is implemented as a means to halt training when the model's performance ceases to improve on a separate validation subset. The classification performance of different ensemble methods was investigated through accuracy and F-measure indices. Tables II and III show the accuracy and F-measure obtained from different ensemble techniques in comparison with the proposed method for the mentioned dataset using the random partitioning method.

As shown in Table II, the proposed method has a higher classification accuracy rate than other methods for all classification problems. In fact, both ensemble techniques based on genetic algorithms perform better than other methods. However, the proposed method also improves the performance of the ensemble technique introduced in study [29], which is due to the use of four measures of classification error, dispersion, diversity and density in estimating the weights of the combination of classifiers. For example, the proposed method improves classification accuracy by 3.05% for the CMC dataset and 6.56% for the Vowel dataset compared to the genetic algorithm-based method.

TABLE I. UCI DATA SPECIFICATIONS [36]

Dataset	Number of classes	Number of features	Number of samples
Iris	3	4	150
CMC	3	9	1473
Diabetes	2	8	768
Vowel	11	13	990
Glass	7	9	214
Ionosphere	2	34	351

TABLE II. CLASSIFICATION ACCURACIES OF DIFFERENT ENSEMBLE CLASSIFIERS FOR DIFFERENT DATASETS USING RANDOM PARTITIONING METHOD

	Stacking	Bagging	Boosting	Voting	Genetic	Multi-objective genetic
Iris	54.16	97.50	98.12	96.08	100.00	100.00
CMC	41.98	49.52	52.11	51.88	52.14	55.19
Diabetes	67.92	71.90	73.89	73.78	75.66	77.51
Vowel	63.39	63.45	75.86	88.11	91.94	98.50
Glass	42.21	61.82	62.48	61.20	56.36	73.09
Ionosphere	63.91	86.21	73.77	87.22	87.22	88.30

As shown in Table III, the proposed method has a higher F-measure value than other methods for all classification problems. In fact, both ensemble techniques based on genetic algorithms perform better than other methods. However, the proposed method also improves the performance of the ensemble technique introduced in [29], which is due to the use of four measures of classification error, dispersion, diversity and density in estimating the weights of the combination of classifiers.

In addition to the random partitioning technique, the current research employed a K-fold cross-validation approach to

evaluate the classification effectiveness of the suggested method. In this procedure, the dataset was initially divided into K folds. Out of these, K-1 folds were randomly assigned as the training set, while the remaining fold was designated as the testing set. This process was iterated K times to ensure that each fold was utilized as a testing set. In each iteration, the trained model was applied to the testing set, yielding K distinct evaluation metric values [38, 39]. In this study, K = 5 was considered. Tables IV and V show the accuracy and F-measure obtained from different ensemble techniques in comparison with the proposed method for the mentioned dataset using the 5-fold cross-validation method.

TABLE III. F-MEASURE VALUES OF DIFFERENT ENSEMBLE CLASSIFIERS FOR DIFFERENT DATASETS USING RANDOM PARTITIONING METHOD

	Stacking	Bagging	Boosting	Voting	Genetic	Multi-objective genetic

Ionosphere	78.20	93.21	93.39	80.42	79.60	94.49

As shown in Tables IV and V, again, the proposed algorithm produces the best classification results for all datasets. Again, both genetic algorithm-based methods provided better performance than other methods. Genetic-based ensemble classifiers offer several advantages in the field of machine learning [40]. These classifiers utilize genetic algorithms, which mimic the process of natural selection, to train and optimize ensemble models [41]. One key advantage of genetic-based ensemble classifiers is their ability to handle complex and high-dimensional datasets [42]. The genetic algorithms excel in searching through a large space of possible feature combinations, weights, or architectures, enabling the classifier to capture subtle patterns and relationships in the data [43]. This makes them particularly effective in solving problems where traditional classifiers may struggle. Another advantage is their robustness and generalization abilities. The genetic algorithms help in overcoming overfitting by finding a diverse set of base classifiers that have complementary strengths and weaknesses [44]. This diversity enhances the overall performance of the ensemble by reducing errors and increasing the reliability of predictions on unseen data [45]. Since the genetic algorithms can automatically adjust and optimize the ensemble composition, they can readily adapt to changing data distributions or incorporate new data without requiring the entire model to be retrained. This adaptability makes them suitable for real-time and dynamic environments [46, 47].

V. CONCLUSION

The combination of classifiers is an approach to improve classification performance in complex problems. For the combination of classifiers to be effective, the base classifiers must have acceptable performance and be different from each other. Also, an appropriate combination rule is required to combine their results effectively. The combination rule should be chosen in such a way that the classifiers cover each other's weaknesses. In this article, while reviewing different ensemble classifiers, a new ensemble technique was proposed to combine the results of the basic classifiers. The proposed ensemble method was based on the weighted averaging rule of the outputs of the basic classifiers, where the weights were estimated by the multi-objective genetic algorithm through the criteria of classification error, diversity, sparsity and density as fitness functions. The proposed method showed better performance by using the density criterion in the classes than other methods and using the multi-objective genetic algorithm to optimize each of the fitting functions in the experiments. However, the proposed framework in this study has some limitations like many previous studies. The performance of the proposed ensemble algorithm is highly dependent on threshold values t_1 to t_4 . In the current proposed framework, optimization methods were not used to determine these thresholds, which is one of the limitations of the study. In addition, the lack of dynamic determination of the parameters of the proposed model for different datasets is another limitation of this study.

In summary, the obtained results showed that genetic-based ensemble classifiers provide advantages such as enhanced capability to handle complex datasets, improved robustness and generalization, and flexible adaptability. These advantages make them a valuable tool in various domains, contributing to more accurate and reliable predictions. Future studies should test

and validate this method on more and larger datasets to determine its actual performance. Moreover, future studies must expand the proposed framework by incorporating dynamic combinations and engaging in more intricate applications. Alongside the introduction of a mathematical model for classifier ensemble featuring density, diversity and sparsity learning, an optimization process through a heuristic and iterative approach leveraging the genetic algorithm was implemented. Therefore, achieving an optimized mathematical solution like convex optimization becomes essential for further analysis.

Abstract—Parasites are disease-causing agents both in Peru and worldwide. In many contexts, diagnosis is done manually by observing microscopic images, where it's necessary to identify parasite eggs. However, this process is notably slow, and sometimes image clarity may be insufficient, making rapid and accurate identification challenging. This can be due to various factors, such as image quality or the presence of noise. This paper focused on a Convolutional Neural Network (CNN) model. Through this approach, the training, testing, and validation stages of our CNN model to detect and identify *Ascaris lumbricoides* parasite eggs. The results show that the proposed CNN model, combined with image preprocessing, yielded highly favorable results in parasite egg identification. Additionally, very satisfactory values were achieved in model testing and validation, indicating its effectiveness and precision in diagnosing parasite presence. This research represents a significant advancement in the field of parasitological diagnosis, offering an efficient and accurate solution for parasite detection through microscopic image analysis. It is hoped that these results contribute to improving diagnosis and treatment methods for parasitic diseases.

Keywords—*Ascaris lumbricoides*; Convolutional Neural Networks; OpenCV; microscopic images; moment-based detection

I. INTRODUCTION

Currently, not only in Peru but worldwide, parasites are agents causing multiple diseases in humans, mainly in tropical areas. There are many types of parasites in the world, as mentioned in research [1], [3], which provides a comparison of parasite appearance notifications. In Peru, according to this 2017 report [2], the most common parasites that threaten human health are *Trichuris trichiura*, *Ascaris lumbricoides*, *Enterobius vermicularis*, *Necator americanus*, causing multiple diseases in both children and adults, also in the article of Cabada [21], a study was conducted on the prevalence of parasites in the region of Paucartambo, Peru, where it was found that of the total number of children surveyed (334), 34.12% were infected with *Ascaris lumbricoides* among others, which concluded that it had a direct relationship with the anemia that has been occurring in the region, the article of Villamizar [22] also states that *Ascaris lumbricoides* is related to poor sanitation practices and is dangerous if not detected in time, since, as mentioned in his research, it causes intestinal severe obstructions that mainly affect children.

Various techniques exist in the global landscape. The manual [19] published by the WHO outlines these microscopic techniques. Health professionals use these techniques to detect parasites to diagnose patients and provide appropriate treatment. However, it can take considerable time to reach an accurate diagnosis with this method. This delay in diagnosis raises the question: Is it possible to develop an automated artificial intelligence tool to diagnose parasites using microscopic images of their eggs?

In this research, the following questions will be addressed: How can artificial intelligence be employed to detect parasite eggs? What automated tool could be developed using microscopic images? What impact would the use of artificial intelligence have on diagnostic time? What would this research contribute to the field of medicine?

In this study, a CNN model designed to predict the presence of parasites through microscopic images is presented., with a specific focus on detecting eggs of the *Ascaris lumbricoides* parasite using Computer Vision techniques because using this technique with artificial intelligence brings great benefits [23], [24]. The purpose is to provide an automated tool that reduces diagnosis time, supporting specialized doctors and less experienced practitioners. This study aims to improve the efficiency of parasitosis diagnosis and contribute to more effective and timely medical care.

This research focuses on developing an automated tool for the rapid and accurate diagnosis of parasites using microscopic images. By reducing diagnostic time, the efficiency of treatment is improved, and medical care is optimized, benefiting both health professionals and patients. Moreover, the implementation of artificial intelligence in this field is a significant step towards standardizing diagnostic quality, paving the way for innovative and advanced clinical processes.

A pilot model was sought to achieve at least 90% accuracy. The following stages were carried out: a) Collection of the dataset, considering images where the parasite can be visualized cleanly or with minimal noise, and others where the *Ascaris lumbricoides* egg is heavily obscured. b) Preprocessing of the dataset, aiming to extract the most essential features of the image using OpenCV moments. c) Training of the Deep Learning model with the preprocessed data.

The work demonstrated that OpenCV moments can assist CNNs in object detection by identifying objects of interest in images. These objects can then be extracted to simplify the network's detection task.

The article is structured into six sections. Section I covers the introduction, while Section II examines related Works. Section III details the methodology used, followed by the presentation of results and discussions in Section IV. Section V consolidates the findings obtained, while Section VI details conclusions and future work.

II. RELATED WORKS

In his thesis work in 2019, Eduar Vásquez developed an algorithm for detecting *Trichuris trichiura* eggs using microscopic images of coprological samples. For this purpose, 1000 images were selected as samples, dividing the set into 30% for verifying the algorithm's performance and 70% for training it. The algorithm was implemented in Python, using libraries such as OpenCV, Numpy, and Matplotlib, among others.

The original images were 1280 x 960 pixels, and fragments of size 65 x 65 pixels were extracted for analysis. For image processing, a color vector was generated using the HSV model with three hue intervals, four saturation intervals, and four brightness intervals, using a Manhattan distance metric. Additionally, another vector was implemented for classification, achieving a sensitivity of 99.35% and an accuracy of 96.1%.

In a study conducted in 2022 [5] by C. Lee et al., the limitations faced by specialists in manually counting parasite eggs were addressed. The Helminth Egg Analysis Platform (HEAP) was developed in response to this issue. This platform focuses on automating egg counting by processing images using Python code. Eggs are identified using moment-based techniques and TensorFlow for prediction, leveraging GPU performance. This system is integrated into an Apache web environment and uses PHP scripts for queue system management.

The main objective of HEAP is to facilitate the identification of microscopic helminth eggs, aid technicians in diagnosing parasitic infections, streamline the process, and reduce the possibility of errors associated with manual counting.

1) *Convolutional Neural Networks (CNNs)*: In the work published in 2021 [6] by T. Suwannaphong et al., a technique based on Convolutional Neural Networks (CNNs) is proposed to improve the automatic classification of parasites in low-quality microscopic images using transfer learning. All images used were captured and extracted from a low-cost USB microscope. Additionally, a sliding window technique was implemented to detect the location of parasite eggs in the images. Two neural networks, AlexNet and ResNet50, were evaluated, considering the architecture size and classification capacity. Both networks were trained with a mini-batch of 100 and 20 iterations, achieving highly satisfactory results in terms of accuracy. This approach demonstrates its effectiveness even in the case of examination with low-cost microscopes.

In the study published in 2022 [7], a Deep Neural Network (CNN) is presented. It is designed to improve the accuracy in

diagnosing malaria, a deadly disease transmitted by female mosquitoes of the genus *Anopheles* found in various regions of the world. The study focuses on analyzing microscopic images of red blood cell smears.

For this purpose, three pre-trained CNN models were used: VGG19, ResNet50, and MobileNetV2. However, these neural networks performed poorly when using small datasets. Therefore, a transfer learning technique was implemented, which allowed overcoming this limitation and improved the system's performance. The three pre-trained models were evaluated using a malaria dataset provided by the National Institutes of Health (NIH), achieving an accuracy close to 100%.

In 2023, the work [8] by M. Faruq Goni et al. introduced an unconventional method for forecasting malaria based on an Extreme Learning Machine (ELM) algorithm. This approach arises due to the problems related to delays and inaccuracies in malaria forecasts when using antigen tests and microscopy. Convolutional Neural Networks (CNN), ELM, and Double Hidden Layer (DELM) were used as classifiers to implement this method. The CNN acted as a feature extractor and classifier for comparative analysis, while ELM and DELM were used for training. The datasets consisted of malaria images, divided into two versions: one with original images and another with modified samples where ambiguous samples were removed. The comparison between both methods revealed that CNN-DELM showed superior performance in terms of accuracy compared to CNN-ELM. The optimal results obtained were 97.79% and 99.66% for the original and modified versions, respectively.

III. METHODOLOGY

This section describes the methodology used for creating the model, illustrated in Fig. 1. These stages include Extracting images from the 'Chula-ParasiteEgg' dataset [9].

Fig. 1. The stages of the methodology used for creating the CNN model are as follows: the first section is Data Extraction, followed by Data Preprocessing, Data Processing, and Architecture.

A. Data Extraction

The first step was to create a dataset to train the CNN model, which is why two datasets were combined: A) Images of *Ascaris lumbricoides* eggs from the "Chula-ParasiteEgg" dataset, which contains medical images of various types of parasite eggs, PARASITIC EGG from IEEE DataPort, and b) microphotographs dataset obtained from the Laboratory of the Faculty of Medicine of UNSA, processed by specialists. This

dataset, named DATASET GASTROPARS_UNSA, contains images of parasite eggs obtained through stool examination. Images were extracted and selected from both datasets based on the following criteria:

- It belongs to an *Ascaris lumbricoides* egg.
- The image is rectangular and complete.
- It has a name corresponding to the parasite.
- The image does not show objects or designs that alter it.

Once the images were selected, they were saved in a folder to group them and process them in an organized manner.

B. Data Preprocessing

In this stage, the previously generated dataset is worked on to extract the essential features of the image using OpenCV moments through the proposed procedure in Fig. 2. These processes are 1) Image normalization, 2) Color normalization, 3) Erosion, 4) Dilation, 5) Otsu Binarization, 6) Dilation Morphology, 7) Closing Morphology, 8) Application of the Canny Filter, and 9) Cropping of detected objects.

Fig. 2. Stages of preprocessing carried out on the frames.

1) *Image normalization*: According to Sudeep [10], the first step in processing the images is to scale them to 500x500 pixels, which is a process for obtaining normalized variance.

2) *Color normalization*: As mentioned in the work of H. M. Bui [17], normalizing images to grayscale reduces them to a single channel, as observed in Fig. 3, making CNNs more efficient compared to using three channels (RGB).

Fig. 3. Grayscale scaling in images.

3) *Erosion*: According to Viera's article [11], erosion removes spurious image features, as observed in Fig. 4.

Fig. 4. Erosion in images.

4) *Dilatation*: Through this step, the edges of objects were structured to define the contours after erosion, as seen in Fig. 5, where imperfections are removed and some essential aspects of the image, such as the parasite, are highlighted.

Fig. 5. Dilatation in images.

5) *Otsu binarization*: The latter was extracted once spurious features were eliminated or significantly reduced, and the larger ones were highlighted. Binarization was used, as mentioned in the article [12]. This binarization assumes linear discriminant criteria with which the image is processed, assuming it is a single object and a background that is sought to be ignored.

The method described in Yousefi's work [12] explains how the process depicted in Fig. 6 operates.

Fig. 6. Otsu Binarization in images using OpenCV.

6) *Dilation morphology*: After completing the previous step, the essential features of the image were determined, which

may still include a large part of unwanted objects. Therefore, two more morphologies were applied to reduce these objects, with the first being dilation morphology. As mentioned in the work of Roy [20], dilation and erosion are shape-sensitive operations that help to discriminate the objects in the image. A [20 x 20] kernel was established, and objects were separated, such as a parasite with a stain attached to it and not part of the parasite, as seen in Fig. 7.

Fig. 7. Dilation morphology in images using OpenCV.

7) *Closing morphology*: It consists of applying the dilation morphology again, including the resulting image from the erosion process, obtaining the most significant objects detected previously, and eliminating the smaller ones.

Monday [16] allows applying filters to the image, improving its processing, as shown in Fig. 8.

Fig. 8. Closing morphology with OpenCV.

8) *Application of the canny filter*: To conclude, the "Canny Filter" was applied, which helps us obtain the contours of the images, serving as a preliminary step to applying OpenCV moments.

As mentioned in Mohd Anul's work [14], applying the Canny filter is useful because it allows separating objects from the background of the image and prevents unwanted detection, as shown in Fig. 9.

9) *Object cropping*: After completing the process, the images were cropped based on the identified contours, which were separated for further analysis and classification. This classification was divided into two groups: a) crops containing

parasite eggs and b) crops that did not contain parasite eggs. These crops were stored in separate folders for future reference.

Fig. 9. Canny filter on the preprocessed image.

C. Data Processing

The frames were normalized, dividing them by 255 to obtain values between 0 and 1.

Arrays of the images were created, to which a data augmentation technique was applied, as explained in the work of [13] and [18]. The rotation geometry technique is one of the most popular for this task (see Fig. 10).

Fig. 10. Example of the rotations that were applied.

Also, in Omar's work [15], this process is useful for improving the balance of the dataset and generating more useful cases for training.

When the image augmentation was completed, 4852 data were obtained.

D. Model

For the final step, the training and validation of the model were conceived. The training arrangement was divided into 80% for the training phase and 20% for the validation phase.

Then, the created model was tested for accuracy and loss using images that it had never seen during its training, and based on that, the most optimal model was chosen.

E. CNN Model Architecture

The CNN model has four convolution layers (32, 64, 128, and 256 filters, respectively) applying a 3x3 kernel and a ReLU activation function per convolution layer, four MaxPooling layers between the convolution layers applying a 2x2 kernel, a flattening layer to be able to connect to the neural network, for

such a network, one (1) input layer, two (2) hidden layers and one (1) output layer, with a ReLU and "sigmoid" activation function as shown in Fig. 11.

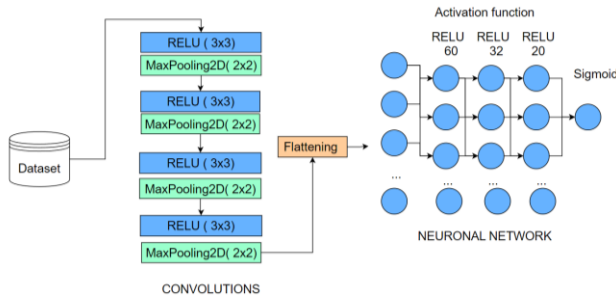

Fig. 11. Example of the rotations applied.

IV. EXPERIMENTATION

In this stage, we tried to run and adjust the parameters and values of both the processing and the architecture of the model; four stages of experimentation influenced the construction of the model, and the accuracy and its success in new cases were used to determine the model to be chosen.

A. First Experimentation

There were 1,213 initial frames, which conformed to the original positive and negative cases. The initial configuration was four convolution layers (32,64,64,128, respectively, with a 2x2 kernel) and four hidden layers (32,64,128,1, respectively), results shown in Table I.

TABLE I. RESULT OF THE ITERATIONS IN THE FIRST EXPERIMENTATION

Iterations per Batch	% Training	% Validation	% Testing
10	80.07 %	86 %	70 %
20	90 %	95%	65.89 %

B. Second Experimentation

For this test, 2426 frames were contemplated for training and testing the model. At this stage, the images were mirrored to increase the data the model will have. Table II and Fig. 12 show the percentages obtained as the same architecture configuration.

TABLE II. RESULTS OF THE ITERATIONS IN THE FIRST EXPERIMENTATION

Iterations per Batch	% Training	% Validation	% Testing
10	85.25 %	92.13 %	80.12 %
15	95.90 %	93.04 %	89.45 %

C. Third Experimentation

The image mirroring was performed in the four directions to increase the data delivered, reaching 4852 (3880 for training and 972 for testing). At the same time, adjustments were made to the architecture to obtain better results; being the changes in the convolution layer, we used 32,32,64,64,64 with a 3x3 kernel and four hidden layers in the neural network with 32,32,64,1 respectively, obtaining the results shown in Table III and Fig. 13.

Fig. 12. Graph of the results of the second experimentation, the upper part being accuracy vs. val_accuracy and the lower part loss vs val_accuracy.

TABLE III. RESULTS OF THE ITERATIONS IN THE THIRD EXPERIMENTATION

Iterations per Batch	% Training	% Validation	% Testing
10	87.45 %	85.36 %	89.28 %
15	94.72 %	92.14 %	93.72 %

Fig. 13. Graph of the results of the third experimentation, the upper part being accuracy vs. val_accuracy and the lower part loss vs. val_accuracy.

D. Fourth Experimentation

In this last stage, 4852 frames from the previous stage are still preserved. However, mainly changes were made to the architecture, which was altered based on trial and error, based on the accuracy of the model when testing with the corresponding dataset as well as a new one to check that the accuracy of the model does not decrease to a great extent, being these changes, in the convolution layer 32,32,64,128 were used respectively with a 3x3 kernel, keeping the initial maxpooling, in the neural network layers it is still kept in 4 but with 60,32,20,1 nodes respectively, obtaining the results shown in Table IV and Fig. 14.

TABLE IV. RESULT OF THE ITERATIONS IN THE FOURTH EXPERIMENTATION

Iterations per Batch	% Training	% Validation	% Testing
10	85.62 %	87.59 %	86.93 %
20	97.68 %	91.75 %	90.03 %

Fig. 14. Graph of the fourth experimentation results, with the upper part showing accuracy vs. val_accuracy and the lower part showing loss vs. val_accuracy.

For the choice of the last model (experiment 4), a new test dataset was created with 320 frames, whose images had not been observed by the model, in order to evaluate the result of these last three experiments and thus verify which model could generalize better, the results being those presented in Table V:

TABLE V. RESULT OF THE TESTS ON THE MODELS WITH THE NEW DATASET

No. of experimental stage	% Validation
2	70.85 %
3	74.68 %
4	89.69 %

V. RESULTS AND DISCUSSION

This work utilized a dataset of 400 microscopic images of the *Ascaris lumbricoides* parasite. All these images underwent preprocessing to obtain a clean image of the parasite and include negative cases. With all this preprocessing, 1,213 images were obtained, and after data augmentation, 4,852 images were achieved. Each image was processed to be inputted and trained into the CNN model. Differences were observed in the model configuration compositions, and with these new configurations, obtaining the most optimal CNN model possible was possible.

Four stages of experimentation were conducted with different iterations of the model to obtain training, validation, and test percentages.

In this research, we are developing a CNN model to detect the *Ascaris lumbricoides* parasite using preprocessed microscopic images. Compared with the literature, we observed no studies explicitly addressing *Ascaris lumbricoides*. A study [4] focused on *Trichuris trichiura* eggs, and an algorithm was developed to extract a vector using HSV colors. Work [5] centered on creating a helminth egg analysis platform (HEAAP) to identify helminth eggs and support technicians in parasite infection examinations. In study [6], a CNN model was developed using a sliding window technique to identify parasite egg positions. Study in [7] focused on the Malaria parasite, employing a CNN model with three pre-trained models. The study in [8] also evaluated the Malaria parasite but implemented

an Extreme Learning Machine (ELM) algorithm and used a CNN as a feature extractor and classifier.

Our research addresses the *Ascaris lumbricoides* parasite and explicitly compares it to existing literature. While some studies have used CNN and other approaches, our model incorporates additional techniques, like object detection using OpenCV moments. Furthermore, our study focused on identifying and detecting parasite eggs from microscopic images.

This proposed method used all available hardware resources, including the GPU and CPU, to reduce the model's training time during experimentation. A noticeable difference in training times was observed between the GPU and CPU, with an average improvement of 1.6159% achieved using the GPU. This disparity is outlined in Table VI.

TABLE VI. TIME EMPLOYED FOR TRAINING AND EXPERIMENTATION OF CNN MODEL

GPU	CPU
17 seconds (0:17 minutes)	1052 seconds (17:32 minutes)

Two models were developed during the testing phase, achieving training and validation accuracies exceeding 90%. Table VII details each model.

TABLE VII. COMPARISON OF RESULTS FOR SELECTED MODELS IN THE TESTING PHASE

Indicator	Model 1	Model 2
Image Size	500x500	300x300
Training		
loss	0,1087	0,15
accuracy	0,959	0,948
val_loss	0,2125	0,252
val_accuracy	0,9304	0,899
Validation		
loss	0,2191	0,214
accuracy	0,95679	0,93

This entire process was carried out using two sets of images for training and validation to create a model with the highest prediction percentage. The first group comprised 3,396 images used for training; the model utilized these images for its training phase. The second group consisted of 1,456 images not used for training but entirely new images dedicated solely to testing the model and evaluating its prediction percentage.

After analyzing the results obtained, the study's strengths and limitations were identified. In terms of strengths, the model's versatility in detecting various types of parasite eggs and its reliability in classifying images containing these eggs stood out. Additionally, creating a dedicated dataset for testing facilitated comprehensive evaluation and significantly improved the model's reliability. On the other hand, limitations included a) disk space constraints on the equipment used, b) limited availability of only two small datasets for model training and c)

restrictions on the capabilities of the computer equipment employed.

Expanding the preprocessing stages enhances the parasite recognition capability in less clear medical images and diversifies the range of parasites detected by CNN. Given the potential of the presented model to identify the *Ascaris lumbricoides* parasite with the current preprocessing, there are high expectations of detecting a greater variety of parasites. This implementation would be crucial in supporting specialists, as intestinal parasites need to receive more attention. Specialists' availability of diagnostic assistance software is paramount in this context.

VI. CONCLUSIONS AND FUTURE WORK

This paper presents a convolutional neural network (CNN) model designed to analyze microscopic images. This work implemented a moment-based object detection approach, allowing us to identify the parasite within the image and separate it from other components (such as noise). This process was carried out using OpenCV and Python, which allowed to isolate the *Ascaris lumbricoides* parasite in a separate image. This image was used in the model's training and testing phases.

In the proposed model, four experiments were conducted, each with different numbers of iterations, resulting in significant variations in performance percentages. The most notable results were obtained in the third experiment, using 15 iterations per batch. In this case, accuracy percentages in the Training, Validation, and Testing phases reached 94.72%, 92.14%, and 93.72%, respectively, leading to an acceptable model. However, a final experiment incorporated a new set of images with a difference of 20 iterations, resulting in percentages of 97.68%, 91.75%, and 90.03%, respectively. These results highlight the model's great potential, especially regarding image preprocessing handling and object detection using Moment-based techniques.

Future work involves replicating the methodology with different parasite egg datasets to evaluate its efficiency, refine the approach, and develop a system to assist students and doctors in identifying parasite eggs.

ACKNOWLEDGMENTS

We extend our heartfelt gratitude to the Universidad Nacional San Agustín De Arequipa for their generous support and funding towards the project entitled 'Assistance in the Diagnosis of Gastrointestinal Parasitosis Through Prevalence Rates and Micrographs,' facilitated under contract No IBA-BIOM-2018-1. We are also grateful to CiTeSoft under contract EC-0003-2017-UNSA for providing essential equipment and resources vital to the success of this project.

Abstract—There are a few difficulties with current automatic personality recognition technologies. Two of these are discussed in this article. They use of very brief video segments or individual frames to come to conclusion with personality factors rather than long-term behavior; and absence of techniques to record individuals' facial movements for personality recognition. To address these concerns, this work first offers a unique Rank Loss for self-regulated learning of facial movements that uses the innate time related development of facial movements in lieu of personality traits. Our method begins by training a basic U-net type system that can predict broad facial movements from a collection of unlabeled face recordings. The robust model is frozen subsequently, and a series of intermediary filters is added to the architecture. The self-regulated education is then restarted, but only with films tailored to the individual. As a result, the weights of the learnt filters are individual-specific, making it a useful tool for simulating individual facial dynamics. The weights of the learnt filters are then concatenated as an individual-specific representation, to forecast personality factors without the assistance of other components of the network. The proposed strategy is tested on ChaLearn personality dataset. We infer that the tasks performed by the individual in the video matter, merging or combined application of tasks achieves the high-rise precision. Also, multi-scale characteristics are better penetrating than single-scale dynamics, along with achieving impressive outcomes as process innovation in prediction of the personality factors scores through videos.

Keywords—Automatic personality recognition; facial movements; individual-specific representation; personality factors; convolutional neural networks

I. INTRODUCTION

Human personality is a unique combination of actions, thoughts, and affective patterns that develop across time and space as a result of biological and environmental influences [1] and can be expressed in the consistent patterning of affect and behaviours [2][3][4][5][6]. Understanding human behaviour, emotional processes, and physical conditions can all be aided by recognizing personality. There are two forms of personality that can be assessed: 1) self-reported personality, that is more than one observer's view of an individual based on different cues; 2) considered personality, that again is more than one observer's impression of an individual based on different cues [7] [8].

Trait-based personality models, such as the Eysenck personality inventory, five-factor model of personality [9][10] are widely used and primarily focus on analyzing characteristics

of personality that are reasonably constant over time yet differ between individuals. While using verbal behaviour descriptors-based questionnaires is a common method of assessing personality traits, earlier psychological studies, have commonly stated that the non-facial behaviours also accommodate essential indications to a human's indirect disposal and internal state. As a result, nonverbal face cues are included in most video-based automatic personality diagnosis approaches. They typically try to learn personality from a very short segment or a single frame, reusing personality labeling (video-level) as the labels for its integral image components as well as training the machine learning models grounded upon such small fragments. Personality cannot be deduced only from a frame/short segment. While other research built video-level descriptors by enumerating global features of all levels (frame or segment) custom-made descriptors, the resulting features lacked comprehensive temporal information, which is a crucial component of face behaviour [10][11][12] [13].

Our goal in this work is to find an individual facial movement describer for every person that is fairly constant over a period of time but different from that of others. First, we present a self-supervised learning strategy based on Bilen *et al.*'s dynamic image [14]. On the contrary, we suggest using a predicate task in a self-regulated scenario to create an animated image from a sole image.

Second, we propose a domain adaptation strategy that uses adaptation layers to include individual-specific data into the trained network (Adaptive layer). Third, we propose, in contrast to other approaches, using the weights of the adaptive layers as an inception for the following task, in this instance personality trait prediction.

The rest of the paper are arranged in the following subsections as follows: Section II - consists of an extensive literature survey; Section III - is the detailed explanation of the methodology used in the study; Section IV - is a detailed presentation of the results arrived at along with comparisons. Lastly, Section V conclude the paper by providing future directions.

II. LITERATURE SURVEY

Automatic personality analysis based on video is a multidisciplinary study topic that combines psychology results with cutting-edge machine learning techniques. A popular lexical technique for personality evaluation is the Five Factor

Model (FFM) [10] it's among the most popular personality tests. The five personality traits that make up the FFM model are conscientiousness, extraversion, and openness to experience, agreeableness, and neuroticism. Anxiety, rage, concern, humiliation, insecurity, and feelings are all linked to neuroticism (also known as emotional stability). It is also believed that this dimension has two sub-dimensions: ambition and sociability. Conscientiousness, which is associated with conformity, desire to succeed, dependability (structured and accountable), and volition (hardworking, achievement-oriented, enduring), has been widely regarded as the third dimension. Flexible, tolerant, good-natured, forgiving, polite, and soft-hearted people are related with agreeableness, also known as likability. Extraversion, in particular, is typically linked to a gregarious, aggressive, talkative, energetic, and friendly personality. Finally, openness is a measure of a person's cognitive interest, inventiveness, as well as need for newness and variation. People who have high scores on directness are more prone to drop concentration and participate in dangerous behaviour [15].

The FFM model's resilience has been experimentally demonstrated in a variety of situations, including several theoretical frameworks, numerous, evaluation from various sources, and utilizing a variety of instances. The FFM model is also used as a personality evaluation in this research. A person's implicit inclinations and internal moods are mirrored in their nonverbal expressive behaviour, according to converging data, in particular, looked into the link between bodily clues and an individual's true nature [16][17][18].

Keltner [19] discovered that individual factors are represented uniquely, visible behaviours which elicit retaliation in others, and that a small number of universal features may be used to explain human nature.

Furthermore, certain research found that when subjects were photographed in a natural stance with a natural facial expression, observers' judgements were almost always correct. A significant amount of instantaneous personality prediction techniques based on face have lately been brought out, that can approximately be classified into two classes: video-level feature-based techniques and frame-level feature-based methods, as many studies on psychology have put forward that personality factors are labelled by facial exhibits, and automated study of facial movements is highly precise [20][21]. For estimating personality traits, Ilmini and Fernando [22] presented an audio-visual Residual network. This architecture is made up of two streams: an audio stream and a visual, both were utilized to extract frame-level deep audio and visual traits, and they were merged at the fully connected layer to offer frame-wise projections. For withdrawing both auditory and visual frame-level data, Wei et al., [23] presented a Deep Bimodal Regression Network. They used global average pooling or global max pooling for visual information and created Descriptor Aggregation Networks (DAN) to combine factors from various layers of convolution. The final forecast is also arrived at by

fusing frame-level projections, as is the case with previous techniques.

Nevertheless, all of the techniques narrated above make use of video level labels to train models for frame/segment-wise feature extraction, implying that they are all based on the assumption that personality can be casted back by a single facial display or a very short-duration facial action, which leads to poorly posed machine learning problems. To overcome this assumption, Biel, Teijeiro-Mosquera and Gatica-Perez [24] and Teijeiro-Mosquera et al., [25] instigated approaches that generated statistical evidence of facial movements from each frame or from a short segment. The researchers then withdrew four video-level visual indications to reflect the existence, time span, as well as frequency of facial movements that were then catered into a regressor to predict personality. Okada, Aran and Gatica-Perez [26] retrieved various hand-crafted visual and aural components frame by frame as a time-series to present binary non-verbal behaviours.

To sum up, while the majority of existing techniques try to deliver a unified group of personality characteristic predictions for every video, mostly they assume that the video-level label may be regarded as the frame/short segment-level label. This method would not just result in a vague machine learning architecture, but also go against the concept of personality factors, which is that they are firm over a period of time yet vary among people. A few research dedicated to video-level feature extraction did not use this assumption, they largely relied on assembled mid-level signals [26], which may have missed many key spatial-temporal patterns or led to temporal information loss [27][28]. In order to overcome all of these issues, this research introduces a novel individual-specific feature extraction approach.

III. METHODOLOGY

The authors explored comparable feature representation (FR) for self-regulated learning of facial movements because our objective is to train a network which grasps facial movements. Instead of learning a unique feature representation, for each picture series (as put forward in [29]), the authors want to build a generic network that can prognosticate the FR for different face image series based on a single (central) image. This forces the network to learn the generic temporal evolution of faces in any brief series. The complete flow of the paper is shown in Fig. 1.

In this study, face images is given by $F_t \in \mathbb{R}^{m \times n}$, and let $F_{t-T}, F_{t-T+1}, \dots, F_{t-1}$ and $F_{t+1}, F_{t+2}, \dots, F_{t+T}$ be the frames related to a frame size of $2T + 1$ (window size), where F_t is the center. The authors used self-supervised learning for FR for every single input image F_t and it is given as $f(\cdot, \theta)$ network where θ represents parameters. The image frame considered in the study is represented as S_a , i.e., $S_a = F_a$. Each frame a has a static representation S_a , $a \in [t - T, t + T]$.

Fig. 1. An overview of the proposed system structure.

Every frame adjacent to F_t is used to extract the temporal information using FR. r_t replicates S_a in size that may rank previous and subsequent frames on the basis of their comparative temporal interval from F_t . The (Frobenius) inner product of the FR r_t is used to assign the score to every image and it is denoted by S_a , with a $[t T, t + T]$. The study proposes learning the FR by driving the architecture to create outcomes that instantly satisfy as in Eq. (1), i.e., the authors want the architecture to assist in determining the FR's parameters. So, the authors follow two steps to calculate the function S , which represents the score value for a given input image F_t . First step is to assign $r_t = f(F_t, \theta)$. The second step is to calculate the pairwise scores for all the frames within the $N = 2T + 1$ window as in Eq. (1).

$$\delta_{ab}(t) = X(r_t, S_a) - X(r_t, S_b) \quad (1)$$

The authors propose using a rank loss that exclusively differentiates negative scores, i.e. frames that will be ranked erroneously based on their scores. The study wish to emphasize that we are not backpropagation w.r.t. a pre-defined "ground-truth" r^*t . by employing the rank loss function. To put it another way, our strategy enables the network to be trained without any need to generate a target FR for each training image individually. In this sense, the network also helps to determine the FR's form.

1) *Structure of the network:* The ResNet network [30] is chosen as the network $f(., \theta)$ in this paper. (We call this network the Dynamic Network (DN) since it is a 5-layer encoder-decoder with numerous skip layers at various spatial resolutions). A 2-D convolution layer, an instance normalization layer, as well as a Leaky ReLU activation function make up each of the encoder's five blocks. There are an additional five blocks in the decoder. Each decoder block has a transposed convolution layer that duplicated the size of the input feature maps first. It is then catered into a Leaky ReLU and an instance normalization layer. Skip layers connect all five pairs of encoder-decoder layers. We propose a DN-adaptive layers network topology to infer individual-specific facial dynamics. To each DN skip layer (AL), we add a convolution

block comprising of a convolution layer having kernel size 1, an instance normalization layer, and a Leaky ReLU. For all individuals, the adaptive layer typologies are the same, i.e., five intermediate layers with a kernel size of 1, that contain DN's weights are frozen during person-specific training, and only the weights of the ALs that have been inserted have been modified.

2) *Training the models:* For personality recognition using artificial neural networks, a regression model is developed that takes the trained weights of individual-specific descriptors as input features for the ANN. It is made up of four hidden layers that are fully connected, and each layer has a dropout with a probability of 0.5. In order to minimize the issues of overfitting, dropouts are used in this study [31]. The output layer contains five nodes that correspond to the Big-Five personality qualities. This framework allows the model to grasp all five personality qualities at the same time.

We put forward to use multi-scale individual-specific descriptors for this work, to capture facial movements at a varied temporal scale, because the temporal scale of the person-specific representation is determined by the size of the time-window, while the appropriate timescale for personality analysis is still unknown. This can be accomplished by training numerous sets of ALs using a series of time-windows of varying lengths. For a certain person, the integration of these individual-specific characteristics represents face movements gathered at several temporal and spatial resolutions.

To sum up, the process for determining personality factors is as follows: we start with the DN network and then add the AL layers. The adaptation is then practiced for each subject, distinct layers are created, and the weights θ are used to reflect their features. The corresponding θ is then input into the ANN network. Ablation study contains more information goes over the specifics of network training implementation.

IV. RESULTS AND ANALYSIS

The ChaLearn [32] dataset was used to conduct apparent personality estimate studies, which employs the Big-Five personality factors as labels but normalizes their values to the

range of [0, 1]. The ChaLearn dataset includes 10,000 videos of 2,764 YouTube users conversing to the camera, organized into three subsets: training (6,000 videos), validation (2,000 videos), and test (2,000 videos). Fig. 2 illustrates sample dataset base on ChaLearn [32]. The videos are all about 15 seconds long and taken at 30 frames per second. The ChaLearn dataset videos

were re-sampled to 25 fps in our studies. Multiple human annotators used Amazon Mechanical Turk to obtain the personality factor labels in this database. To summarize, the Chalearn dataset differs from other datasets in the following ways: 1. kind of annotations; 2. number of films; 3. Time span of videos; and 4. recording settings.

Agreeableness			
Authentic		Self-interested	
			
0.9230	0.9340	0.1098	0.0879

Comfortable		Uneasy	
			
0.9585	0.9791	0.1005	0.0872
Openness			
Imaginative		Practical	
			
0.9777	0.9582	0.0549	0.1113

Fig. 2. Sample images with range values of ChaLearn dataset [32].

Evaluation metrics: Two different metrics are used to evaluate the proposed method for personality analysis. The Root Mean Square Error (RMSE) is specified as in Eq. (2), and the Pearson Correlation Coefficient (PCC) is given as in Eq. (3).

$$RMSE = \sqrt{\frac{1}{n} \sum_{x=1}^n (m_x - n_x)^2} \quad (2)$$

$$PCC = \frac{cov(m,n)}{\sigma_m \sigma_n} \quad (3)$$

Refer as in Eq. (2), m_x is the x^{th} prediction in the prediction vector m , cov is the covariance, n_x is the equivalent ground-truth in the ground-truth vector n , while refer as in Eq. (3), σ_m and σ_n are the standard deviations of m and n , respectively.

Refer as in Eq. (4), the mean accuracy measurement ACC [32] is used to collate against past outcomes on the ChaLearn dataset (as the ACC is employed in the ChaLearn challenge) where V_y is the number of videos, and b_x and a_x are the predictions and labels, respectively.

$$ACC = 1 - \frac{1}{V_y} \sum_{x=1}^{V_t} |a_x - b_x| \quad (4)$$

Comparison with other approaches: The suggested method is compared to other known approaches for automated self-reported and evident personality assessment in this section. The 3ESA is used in the comparison. On the ChaLearn dataset, Table I shows the comparison between our approach to previous personality prediction algorithms that were based on videos. Our multi-scale model had the optimum average PCC and RMSE results, with the optimum PCC performance on many of the personality factors and the greatest RMSE results on all five personality factors. Furthermore, the PCC for the agreeableness characteristic was highest for the predictions from the DRN technique [33]. Our best system outperformed most current approaches in terms of ACC, producing the second-best detection results on three qualities and the greatest result on the agreeableness factor.

REFERENCES

1) *Ablation studies*: Encoder pre-training: Multiple settings for the time window hyperparameters, such as window length and stride, were used in the evaluation. $N = 2T + 1$ frames were made use in the temporal window around every input image (T preceding frames, T succeeding frames and the given frame). We used four distinct values of stride S to sample these N frames. Every image sequence used in the training has a range of N/S frames. For various combinations of $T = \{3, 5, 7, 9\}$ (i.e. $N = \{7, 11, 15, 19\}$) and stride $S = \{1, 2, 3, 4\}$, we test our DN's ranking capacity. The ranking is calculated using a window size of $N = 2T + 1 = 19$ frames, in the extreme instance, i.e. when $T = 9$ and $S = 4$, uniformly sampled from a sequence of $N * S = 76$ frames (more than three seconds). At test time, frames are chosen using the same sampling process as during the model's training. For all encoder-related experiments, the training and validation of DNs used the same settings as before.

In conclusion, the outcomes of this article reveal that pre-training using an emotion-guided encoder had no significant effect on ranking accuracy. The encoder's learning rate, in contrast, is critical in learning generic face dynamics. Lowering or freezing the encoder's learning rate led to reduced ranking accuracy. More crucially, when the initial learning rate was maintained, the emotion-guided encoder offered improved personality performance. The relatively high learning rate can force both the emotion-related and emotion-independent components of the encoder to learn frame-related temporal signals because we assumed that the majority of emotion-related dynamics are unimportant for frame ranking. However, the self-supervised training of the pretrained encoder may lead the taught model to retain some emotion data connected to personality.

V. CONCLUSIONS

A novel technique to automated personality analysis was developed in this research. The developed system begins with pretraining guided encoder, which is then used to train a DN architecture that learns broad short-term facial dynamics using the proposed rank loss. The training is self-supervised, which means that no manual annotations are required. Then, in DN, a convolution block is placed, which is learned for each individual independently, using the same self-supervised method. Consequently, the learnt weights adjust to the associated person's facial behavior, and we propose that these weights be used as the person-specific descriptor.

Combining existing face-based research with speech data to identify personality is a potential future project. We're primarily interested in determining the best network topology for self-supervised learning of personality characteristics using audio-visual and spoken information. Although our models are learnt to summarize face movements instead of character information, they may be used to other challenges where facial dynamics are significant since they are trained unsupervised and domain agnostic. The proposed technique might be extended to additional areas in the future. Furthermore, there arises a scarcity of large-scale multimedia self-reported personality databases that limits the use of deep learning algorithms in this area.

Abstract—Most existing recommendation models that directly model user interests on user-item interaction data usually ignore the natural noise present in the interaction data, leading to bias in the model's learning of user preferences during data propagation and aggregation. In addition, the currently adopted negative sampling strategy does not consider the relationship between the prediction scores of positive samples and the degree of difficulty of negative samples, and is unable to adaptively select a suitable negative sample for each positive sample, leading to a decrease in the model recommendation performance. In order to solve the above problems, this paper proposes a Contrastive Learning and Multi-choice Negative Sampling Recommendation. Firstly, an improved topology-aware pruning strategy is used to process the user-item bipartite graph, which uses the topology information of the graph to remove noise and improve the accuracy of model prediction. In addition, a new multivariate selective negative sampling module is designed, which ensures that each positive sample selects a negative sample of appropriate hardness through two sampling principles, improving the model embedding space representation capability, which in turn leads to improved model recommendation accuracy. Experimental results on the Urban-Book and Yelp2018 datasets show that the proposed algorithm significantly improves all the metrics compared to the state-of-the-art model, which proves the effectiveness and sophistication of the algorithm in different scenarios.

Keywords—Recommendation algorithms; comparative learning; negative sampling; pruning strategies

I. INTRODUCTION

Previous research has focused on modelling interest preferences from users' historical interaction data in order to obtain better recommendation results and provide personalised recommendation services to users to solve the problem of information overload [1]. However, collaborative filtering algorithms recommend poorly when the data lacks explicit user feedback, at which point the quality of negative sampling becomes crucial for improving the performance of recommendation models. Existing collaborative filtering algorithm all choose to train models using implicit feedback (e.g., click, buy, favourite, etc.) by default [2] and set the items of user interest as positive samples, but how to select high-quality negative samples is still a major challenge in the recommendation field. In addition, most models directly take user-item interaction data as the ideal data of user's preference, but due to the influence of external factors such as human error clicks, uncertainty, etc., which results in implicit feedback data containing a lot of natural noise [3], how to deal with the noise in the interaction data and to reduce the impact of noise on the

recommendation accuracy is also a worthwhile research problem in the recommendation field.

Yu et al. [4] proposed the DropEdge mechanism to reduce the impact of noise on the node classification task by randomly deleting away the fixed edges in the original graph. However, random deletion has the potential to discard user preference information, resulting in lower recommendation accuracy. Thus, Zhang et al. [5] designed a classification-aware denoising based self-encoder to remove the noise effect by integrating the classification information. Fan et al. [6] removed the noisy data from the user-item interaction matrix by top-K sampling, balanced the number of interactions of all the users, and improved the accuracy of the model.

Rendle et al.[7] allowed the model to extract more feature information from the positive samples by randomly selecting items that users did not interact with as negative samples, and then using a loss function to give higher scores to the user-positive sample pairs while lowering the scores of the user-negative sample pairs. However, the practice of selecting negative samples with equal probability ignores the problem that the items that the user did not interact with are not necessarily items that the user dislikes, and it is possible that the user just did not see them. Ultimately, this leads to poor model predictions. Thus, Chen et al. [8]proposed popularity-based negative sampling, which takes item exposure as an important basis, and if a popular item with high enough exposure is still disliked by users, it means that the item can be used as a negative sample. Meanwhile, Ying et al. [9] proposed PinSage to calculate the node importance score, using difficult negative sample data for training to improve the overall performance of the model. Yang et al. [10] redesigned the sampling distributions of positive and negative samples, gave the calculation of negative sampling probability based on their structural similarity, and concluded that negative and positive samples are equally important. Huang in study [11] used user-item dichotomous graphs and the aggregation process of graph neural networks (GNN) to study negative sampling, and constructed a difficult negative sample candidate set by interpolating and mixing the negative samples to fuse part of the positive sample information, which improved the model training effect. Chen et al. [12] proposed the FairStatic dynamic adaptive negative sampling method, which improves the sampling fairness among groups while taking into account the sampling efficiency to ensure that each group of items can obtain equal recommendation quality. Lai et al. [2] proposed the DENS method, which firstly uses the hierarchical gating module to classify the similarity and dissimilarity of information between

positive and negative samples and identifies the negative samples through the factor-aware sampling strategy, so as to allow the difficult negative samples to provide more informative training signals and provide better user representation.

Although the above various negative sampling methods have allowed recommender system models to achieve good results, there are still some problems. Most of the existing negative sampling methods improve the model training effect by constructing difficult negative samples, however, they do not take into account the degree of matching between negative samples and positive samples, and negative samples with too much hardness may lead to the semantic bias between the samples and are not conducive to the final recommendation prediction. In addition, most algorithms remove noise by designing cumbersome components with high model complexity, and some models even omit the interaction data denoising step and use it directly as the positive samples for training, which leads to the model not being able to correctly model users' interest preferences, and the recommendation results are biased.

In order to solve the above problems, this paper proposes a Contrastive Learning and Multi-choice Negative Sampling Recommendation (CLMRec). The model firstly analyses the degree of contribution of edges to nodes by Topology-aware Pruning Strategy (TPS) based on topology, calculates the probability that each edge can be retained, and then removes the noisy data according to the probability to reduce the impact of noise on the node embedding representations in the propagation process. Finally, in the negative sampling stage, a new Multi-Choice Negative Sampling (MCNS) strategy is proposed to adaptively select negative samples of appropriate hardness through two sampling principles to optimize the model training effect and obtain more accurate user embeddings and item embeddings to improve the accuracy of recommendations.

In summary, our contributions are highlighted as follows:

- We propose the TPS denoising framework to remove noise from user-item interaction data, preventing the

adverse effects of noise during the information aggregation process.

- We introduce the MCNS negative sampling framework, which enables adaptive selection of negative samples of appropriate difficulty, thereby enhancing the quality of model training.

II. CLMREC MODEL DESIGN

A. Notation Definition and Description

In this paper, the model input is the user-item interaction data, where $U = \{u_1, u_2, \dots, u_m\}$ is the set of users, and $I = \{i_1, i_2, \dots, i_n\}$ is the set of items, where m is the number of users, and n is the number of items. \mathbf{R} is the user-item interaction matrix, and $G = \{U, I, E\}$ is the user-item interaction graph, where E is the set of user-item edges.

B. Overall framework

The overall framework of the CLMRec model is shown in Fig. 1. Firstly, for the interaction data in the user-item dichotomous graph G , the TPS is used to calculate the retention probability of each edge and remove the noise, and then multi-task joint training is constructed, and comparative learning is used as a secondary task to construct comparative views on the interaction data, and potential feature information between different views is extracted by the Infonce loss function [13] to enhance the model's representation learning capability.

The main task uses LightGCN [1] to linearly propagate user embeddings and item embeddings on the interaction graph, aggregating node information to obtain the final user embeddings z_u and the final item embeddings z_i . For item embeddings, the MCNS component adaptively selects negative samples of appropriate hardness for each positive sample, and continuously optimises the positive sample similarity scores and reduces the negative sample prediction scores through the BPR loss function [7]. The prediction score, allowing the model to gradually learn the correct user preferences. Finally, the main and auxiliary tasks are jointly learnt to update the user embeddings and item embeddings.

Fig. 1. DFFSM overall framework.

C. Topology-aware Pruning Strategy

In order to avoid too much noise accompanying the interaction data into the model, inspired by the literature [4][14] and following the idea of model sparsification, the natural noise present in the interaction data is handled by removing redundant edges from the graph. In this paper, a topology-aware pruning strategy (TPS) is designed. Firstly, the user-item data is processed into a user-item interaction matrix R . The degree of each node is calculated using R to obtain the degree matrix D . Next, the retention probability of each edge in the graph is calculated. Finally, some edges of the user-item dichotomous graph are removed according to the magnitude of the probability to complete the denoising of the interaction data.

To make the exposition easier, the TPS process is plotted as in Fig. 2:

Fig. 2. TPS.

Literature [15] states that the degree of a node is the number of edges directly connected to that node and can be considered as a measure of the importance of the node in the network. For the interaction matrix R , the process of computing the degree matrix D is as follows:

$$D[k][k] = \sum_{j=1}^n R[k][j] \quad (1)$$

$$D = \text{diag} \left(\sum_{j=1}^n R[1][j], \sum_{j=1}^n R[2][j], \dots, \sum_{j=1}^n R[n][j] \right) \quad (2)$$

where, $D[k][k]$ is the element on the k th diagonal of the degree matrix D and $R[k][j]$ is the element in the k th row and j th column of the interaction matrix R . Since D is a diagonal matrix and all the positional elements are 0 except those on the diagonal, the degree matrix D can be derived from Eq. (2), which $\text{diag}(\cdot)$ indicates that a diagonal matrix is constructed by using the elements in parentheses as the elements on the diagonal.

Some papers use randomly discarded edges to reduce the influence of height nodes and to prevent overfitting phenomena, but randomly discarded edges have the potential to destroy important information about the nodes, leading to biased node semantics. The degree of contribution of an edge to a node should be calculated and the natural noise should be removed based on the weights, and the square root of the degree is often used as a factor to adjust the edge weights.

The idea is that nodes with larger degrees have more connections in the network and have a higher probability of noisy data, so the weights of edges connected to them should be reduced to balance the importance of the node. On the contrary,

nodes with smaller degree have fewer connections in the network, so the weights of the edges connected to them should be increased to better reflect the importance of the nodes. In addition, the effect of edge discarding on the two connected nodes should be considered, so the degree of both nodes should be included in the formula as follows:

$$P_{(i,j)} = \frac{1}{\sqrt{d_i} \sqrt{d_j}} \quad (3)$$

where, $i \in (1, 2, 3, \dots, n), j \in (1, 2, 3, \dots, n), \text{且 } i \neq j$, i and j denote the nodes in the bipartite graph of user items, and d_i and d_j represent the degrees of node i and node j , respectively, as shown in Fig. 2, the retention probability of each edge is calculated by using the TPS, and then the edge between i_3 and u_1 is removed. While these two nodes are equivalent to popular nodes for other nodes with more interaction data, discarding the edges of these two nodes can reduce the influence of popular nodes on low-degree nodes, and also prevent the model from overfitting. For the edges of these two nodes, i_4 and u_3 , the retention probability is high because i_4 has only one interaction data, which should be fully retained to facilitate the model's learning of i_4 commodity embedding.

D. LightGCN

After removing some of the noise from the interaction data, the model is started to model the user interest. In this paper, LightGCN [1] is used as an encoder. Firstly, user embeddings and item embeddings are randomly initialised, and multiple rounds of embedding propagation are performed through the graph convolution layer, and the embedding vectors of users and items are updated through iterations. Since the algorithm is constructed for joint multi-task learning, divided into main task and auxiliary task, the differences between the two tasks are described below.

In each round of the main task, the user and item embeddings are weighted and summed according to the user-item interaction matrix R , and the neighbour node information is aggregated. After multiple propagation and aggregation, the model can extract the user's higher-order interests, and the specific aggregation strategy and propagation mechanism are shown in Eq. (4) and Eq. (5).

$$z_u = \sum_{l=0}^L \alpha_l z_u^{(l)} \quad (4)$$

$$z_i^{l+1} = \sum_{u \in N_i} \frac{z_u^l}{\sqrt{|N_u|} \sqrt{|N_i|}} \quad (5)$$

where, l represents the number of convolutional layers and denote the user embedding and item embedding in the l th layer, respectively.

The pooling of the convolved embeddings is performed to obtain the final user embeddings and item embeddings. Considering that the embeddings of different layers have different semantics, the embeddings of different layers are weighted and combined, and the embedding combination strategy is shown in Eq. (6) and Eq. (7).

$$z_u = \sum_{l=0}^L \alpha_l z_u^{(l)} \quad (6)$$

$$z_i = \sum_{l=0}^L \alpha_l z_i^{(l)} \quad (7)$$

where, z_u represents the final user embedding, z_i represents the final item embedding, α_l is the weight of each layer, L is the number of convolutional layer layers, and in this paper, we follow the practice of literature [1], and take α_l as the inverse of L .

In the auxiliary task, contrast learning is mainly used to alleviate the data sparsity problem. Firstly, data augmentation is performed on the denoised interaction data to obtain augmented view G_1 and augmented view G_2 , followed by constructing positive sample pairs and negative sample pairs for the vectors in the two views. Ultimately, the loss function of the model is used to bring the positive pair embeddings closer together and push the negative pair embeddings farther apart, so that the model extracts the unlabelled extra information in the interaction data, learns high-quality embedded representations of the users and items, and improves the accuracy of the recommendations.

E. Multi-Choice Negative Sampling

Positive and negative samples need to be selected after obtaining the user embedding u and item embedding i . The positive and negative samples are then passed through the BPR loss function [7] to give high prediction scores to the user-positive samples and reduce the prediction scores of the user-negative samples, which facilitates the model to learn the user interest preferences correctly.

Since the interaction data have been removed from the noise before entering the model and the interaction data are the real interest preferences of users, the items interacted in the dichotomous graph are directly selected as the corresponding user-positive samples. However, how to select high-quality negative samples to train the model is a difficult point, and the existing models do not select appropriate negative samples based on the information and prediction scores of the positive samples. For example, in Fig. 3, when the model selects negative samples, if an i_{20} is randomly selected as a negative sample from the items that the user node u_1 has not interacted with, it does not mean that the user does not like the item, and it is possible that the item exposure is too low for the user to see. In addition, some models do not construct difficult negative samples based on the characteristics of positive samples, which causes the problem of high model training cost.

In order to solve the above problems, inspired by the literature [16] [17], multivariate selective negative sampling (MCNS) is proposed. MCNS constrains the selection range of negative samples by two principles: suitable negative samples must be selected based on the characteristics of positive samples; and the hardness of negative samples must be inversely proportional to the prediction scores of positive samples. These two principles ensure that the model adaptively selects negative

samples of appropriate hardness for positive samples during negative sampling.

Fig. 3. MCNS.

Firstly, Principle 1 is set to eliminate the uncertainty of user preference brought by randomly selecting negative samples. In the prediction stage, the model calculates the prediction scores of the positive sample embedding and the user embedding, and determines whether to recommend or not based on the high or low prediction scores, inspired by this, this paper decides to take the prediction scores of the positive samples as an important factor in selecting the negative samples, and Eq. (8) denotes the calculation of the prediction scores:

$$score^+ = z_u^T z_{i^+} \quad (8)$$

$$score^- = z_u^T z_{i^-} \quad (9)$$

$score^+$ represents the positive sample prediction score, $score^-$ represents the negative sample prediction score, z_u^T represents the transpose matrix of the user matrix, z_{i^+} and z_{i^-} represents the positive sample matrix and negative sample matrix respectively. The higher the prediction score, the closer the two embeddings are in space, i.e., the more interested the user is in the item.

The negative sampling process is shown in Fig. 3, where a specified number of items are randomly selected from all the data that the user has not interacted with to construct a candidate set of negative samples, and then, for all the items in the candidate set, the association level of the items is calculated using the rating function, and then, the appropriate items are selected as negative samples. For positive samples with high prediction scores, it indicates that the model has learnt sufficiently well for that sample, and picking simple negative samples can reduce the training cost. Selecting negative samples with a high degree of difficulty will cause the model's performance to degrade in the process of classifying positive and negative samples, affecting the final prediction accuracy. Conversely, for positive samples with low prediction scores, it indicates that the model is not yet able to adequately capture similar user interests, at which point difficult negative samples should be constructed to allow the model to learn deeper features and improve the model's representational ability. This determines principle two, where the difficulty of the negative sample is inversely proportional to the prediction score of the positive sample. Eq. (10) is the rating function, which is used to determine the level of negative samples selected.

$$L_n = \left| z_u^T z_{i_n} - (z_u^T z_{i^+} + \alpha)^{p+1} \right| \quad (10)$$

where, L_n is smaller, the greater the probability that the sample will be a negative sample. p is less than -1, and when considering L_n and α are equal, negative sample hardness $h(i^-)$ is defined as the ratio of positive and negative prediction scores, as defined in Eq. (11):

$$h(i^-) = \frac{z_u^T z_i}{z_u^T z_{i^-}} = (z_u^T z_i + \alpha)^p \quad (11)$$

Negative correlation was verified using Eq. (12). First, the negative correlation is transformed into a derivation problem by using the negative sample difficulty level to derive the positive sample prediction scores.

$$\frac{\partial(h(i^-))}{\partial(z_u^T z_i)} = \frac{\partial((score^+ + \alpha)^{p+1})}{\partial(score^+)} = p \cdot (score^+ + \alpha)^p \quad (12)$$

where, p is a hyperparameter less than 0. Obviously, the derivative is negative, indicating that the function is monotonically decreasing, proving that the difficulty of negative samples is negatively correlated with the prediction scores of positive samples.

F. Model prediction and Training

After the message propagation and aggregation mechanism of the GNN encoder, the final user embedding and item embedding, and enter the prediction stage to predict the user's interest in the item according to Eq. (13).

$$\hat{y}_{u,i} = z_u^T z_i \quad (13)$$

Then, the main task adaptively selects negative samples of appropriate hardness for each positive sample through MCNS and calculates the loss so that the model learns more accurate user preferences and item characteristics from the training data, adopting the method of literature [18], and using the BPR loss as the loss function of the recommendation task to measure the difference between the prediction results and the real labels as shown in Eq. (14):

$$L_{bpr} = \sum_{u \in U} \sum_{i \in I} \sum_{j \in I^-} \ln \sigma(\hat{y}_{u,i} - \hat{y}_{u,j}) \quad (14)$$

In the auxiliary task, Infonce is used as a comparative learning loss function to maximise the mutual information between the same sample views and minimise the information of different sample views, and by comparing the differences between different views, the model can extract the extra unlabelled information in the interaction data as a way to improve the representation of the embedding space and the model performance. The Infonce loss is as shown in Eq. (15):

$$L_{cl} = \sum_{n \in G} \frac{\exp(s(z_n^1, z_n^2) / \tau)}{\sum_{n' \in G, n' \neq n} \exp(s(z_n^1, z_{n'}^2) / \tau)} \quad (15)$$

where, G is a user-item bipartite graph, n and n' represent different nodes in G respectively, $s(\cdot)$ is the cosine function, and τ is the temperature parameter.

Finally, the main task loss and auxiliary task loss are combined to construct the model multi-task learning framework, and the total model loss is shown in Eq. (16):

$$L = L_{bpr} + \lambda_1 L_{cl} + \lambda_2 \|\Theta\|_2^2 \quad (16)$$

where, L_{bpr} denotes the main task loss, L_{cl} denotes the auxiliary task comparison learning loss, and denotes the regularisation parameters, and denotes the learnable model parameters.

G. Pseudo-code of the Model

In order to give the reader a clearer understanding of the execution process of the CLMRec model, the pseudo-code of the model is given, as shown in Table I:

TABLE I. PSEUDO-CODE OF CLMREC

Algorithm: CLMRec	
1:	Input: User-Item bipartite graph G , training dataset X
2:	Output: Sst of recommended items
3:	While CLMRec Not Convergence do

14:	end for
15:	end while

III. EXPERIMENTAL RESULTS AND ANALYSIS

A. Experimental Setup

1) *Experimental environment:* The experimental environment is set up as follows: the graphics card configuration is NVIDIA GeForce RTX 2080Ti, the operating system is Ubuntu 18.04, the programming language Python, and the deep learning framework is Pytorch.

2) *Datasets:* In order to verify the effect of the algorithm proposed in this paper on datasets with different sparsity levels and its performance in different scenarios, two publicly available datasets, Douban-Book and Yelp2018, are used for experiments. The dataset information is shown in Table II.

TABLE II. STATISTICS FOR THE DATASETS

Datasets information	Douban-book	Yelp2018
Number of users	12638	31668
Number of items	22222	38048
Interactive data	478730	1237259
Data density	0.1704%	0.1026%

3) *Evaluation indicators*: Following the practice of literature [18], Recall and Normalised Discount Cumulative Gain (NDCG), which are commonly used in recommender systems, are used as the evaluation metrics in this experiment. The higher the Recall metric, the more items the recommender system can find that the user is interested in, and the NDCG measures the accuracy and sorting information of the recommended items, this paper uses the two metrics to comprehensively evaluate the recommender system performance. The number of users, the number of items, interaction data, and data density vary between two datasets, resulting in different recommendation accuracies. Higher data density in a dataset allows the model to learn more accurate user preferences, leading to higher recommendation accuracy.

4) *Baseline modelling and parameter setting*: In order to verify the effectiveness of CLMRec, four representative models are selected for comparison, the baseline model LightGCN [1] based on graph neural network, the models SGL [19] and SimGCL [18] based on comparative learning, and MixGCF [11] based on hybrid technology to generate negative samples for comparison. After hyper-parameter tuning, the batch size is set to 2048, the number of convolutional layers is set to 3, the temperature parameter is set to 0.2, and the learning rate is set to 0.001.

- LightGCN is a state-of-the-art GCN-based recommendation method which simplifies the convolution operations during the message passing among users and items.
- SGL introduces self-supervised learning to enhance recommendation. We focus on exploring self-supervised learning (SSL) in recommendation, to solve the foregoing limitations. Though being prevalent in computer vision (CV) and natural language processing (NLP).
- MixGCF designs the hop mixing technique to synthesize hard negatives for graph collaborative filtering by embedding
- Interpolation and Introduce the idea of synthesizing negative samples rather than directly sampling negatives from the data for improving GNN-based recommender systems.
- SimGCL proposed a simple yet effective graph-augmentation-free CL method for recommendation that can regulate the uniformity in a smooth way. It can be an ideal alternative of cumbersome graph augmentation-based CL methods.

B. Results of the Experiment

The experimental results of the CLMRec model and each baseline model in the Recall@20 and NDCG@20 evaluation metrics are shown in Table III, with the best performance of the comparison models underlined, and the experimental results of this paper's model shown in bold font.

All of the above models transform user interaction data into graph-structured data, and through graph convolutional models, aggregate neighbour node information to capture the user's interest preferences. As seen from the data in Table III,

LightGCN effectively improves recommendation accuracy by simply iteratively aggregating neighbour features into target node embedding representations, removing the redundancy of feature transformations and non-linear activation components. Inspired by the natural language and image processing domains, SGL introduces contrast learning into the recommendation domain, proposes three methods for constructing a contrasted view, and achieves better recommendation results than LightGCN SimGCL, based on SGL, proposes a more concise and effective data enhancement method to solve the problem of possibly deleting the important information of nodes in SGL, and speeds up the process of constructing positive and negative contrast views, which is a simple and efficient model. MixGCF Changes the traditional negative sampling strategy by mixing the positive sample information with the negative sample information to construct difficult negative samples for training, which improves the overall performance and proves that high-quality negative samples allow the model to learn more accurate user embeddings and item embeddings.

TABLE III. SMODEL PERFORMANCE COMPARISON

Method	Douban-Book		Yelp2018	
	Recall	NDCG	Recall	NDCG
LightGCN	0.1494	0.1217	0.0642	0.0537
SGL	0.1730	0.1549	0.0678	0.0558
MixGCF	0.1732	0.1553	0.0710	0.0588
SimGCL	<u>0.1778</u>	<u>0.1585</u>	<u>0.0721</u>	<u>0.0596</u>
CLMRec	0.1899	0.1706	0.0736	0.0604

The CLMRec model proposed in this paper significantly improves Recall and NDCG on both datasets compared to all comparison models. Among them, CLMRec improves 6.80% and 7.63% on the Urban-Book dataset and 1.34% and 2.14% on the yelp dataset, respectively, compared to SimGCL, which is the best performer, demonstrating the validity and sophistication of this paper's model in different scenarios. Compared with other models, the advantage of CLMRec is that the removal of noise is completed when the interaction data enters the model before, which effectively avoids the negative impact of noise on other nodes in the graph convolution process. In addition, the combination of contrast learning and LightGCN's encoder extracts extra information from the samples, which improves the model training effect, and finally the MCNS adaptively selects negative samples with appropriate hardness, which significantly improves the accuracy of recommendation.

C. Ablation Experiments

1) Verifying the effect of the number of samples on recommendation accuracy.

In order to verify the impact of the number of samples in the negative sampling candidate set on the recommendation results, this paper chooses to conduct experiments on the Urban-Book, by choosing a different number of samples to construct the negative sampling candidate set, the specific experimental results are shown in Table IV:

TABLE IV. SMODEL PERFORMANCE COMPARISON

Number of samples	Recall	NDCG
4	0.1856	0.1663
8	0.18569	0.1671
16	0.1877	0.1676
32	0.1889	0.1687
64	0.1895	0.1697
128	0.1899	0.1706
256	0.1900	0.1706

As can be seen from Table IV, the higher the number of samples in the candidate set and the higher the number of negative samples available, the better the recommendation performance. However, the more the number of samples, the more time is needed to calculate the rating function Ln, and the recommendation effect is not obviously improved when the number of samples is too large. Measuring the efficiency problem, this paper takes 128 negative samples to construct the candidate set.

2) Validation of TPS and MCNS component effectiveness:

In order to validate the effectiveness of the method proposed in this paper, variant models are designed for denoising experiments. Firstly, in order to demonstrate the denoising effect of TPS, the variant model CLMRec-TPS is designed to omit the denoising step by removing the TPS module and taking the user-item interaction data as input directly. Secondly, the variant model CLMRec-MCNS is designed, which discards the strategy of adaptively selecting negative samples of appropriate hardness by randomly selecting items that the user did not interact with as negative samples. The performance of these variant models on the two datasets is shown in Fig. 4.

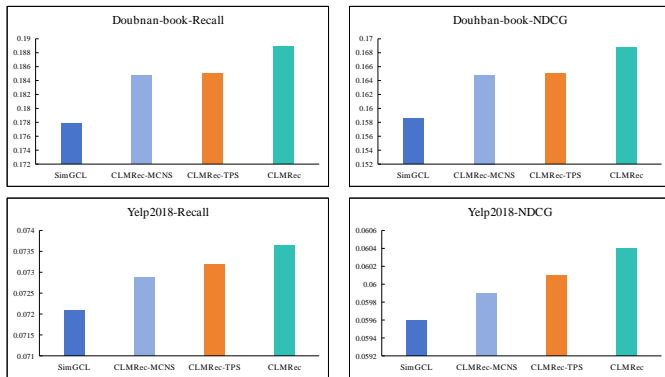

Fig. 4. Effectiveness analysis of TPS and MCNS.

As can be seen from Fig. 4, all the metrics of the CLMRec model are higher than those of the variant models, proving the necessity of each component. The metrics of the CLMRec model are higher than those of the CLMRec-TPS model, which indicates that the model can effectively remove the noise in the interaction data, avoiding the noise from affecting the accuracy of the recommendation in the process of propagation. In addition, the indicators of CLMRec-MCNS are lower than CLMRec, which proves the effectiveness of the MCNS component, i.e., when negative sampling, it is necessary to choose negative

samples with different hardnesses according to the characteristics of positive samples.

IV. CONCLUSION

In this paper, a recommendation model CLMRec based on comparative learning and multivariate selection of negative sampling is proposed. The pruning strategy component based on topology perception, with low time complexity and high compatibility, is suitable for denoising of graph neural networks, and it can effectively reduce the impact of noise on prediction accuracy. In addition, the multivariate selection negative sampling component is proposed to comprehensively consider the relationship between the prediction scores of the positive samples and the hardness of the negative samples, adaptively select the negative samples with appropriate hardness, which enhances the embedding representation ability of the model and provides a new research idea for the negative sampling technique of graphs. Experiments on two publicly available datasets show that the present model has a significant improvement in recommendation performance compared with the current state-of-the-art models, and has good practical application value.

Considering the differences in users' long and short-term interests, future work will explore how to capture users' interests in different periods to improve the recommendation accuracy.

ACKNOWLEDGMENT

We would like to express our deepest gratitude to Guangxi Driven Development Project (桂科 AA20302001) for their financial support, without which this research would not have been possible.

Special thanks are due to Qing Ye and Yanyan Zhang for their collaboration and assistance in various aspects of this research project. Their contributions have significantly contributed to the success of this study.

Abstract—This research paper investigates the development of deep learning models for traffic sign recognition in autonomous vehicles. Leveraging convolutional neural networks (CNNs), the study explores various architectural configurations and evaluation methodologies to assess the efficacy of CNNs in accurately identifying and classifying traffic signs. Through a systematic evaluation process utilizing metrics such as accuracy, precision, recall, and F-score, the research demonstrates the robustness and generalization capability of the developed models across diverse environmental conditions. Furthermore, the utilization of visualization techniques, including the Matplotlib library, enhances the interpretability of model training dynamics and optimization progress. The findings highlight the significance of CNN architecture in facilitating hierarchical feature extraction and spatial dependency learning, thereby enabling reliable and efficient traffic sign recognition. The successful recognition of traffic signs under varying lighting conditions underscores the resilience of the developed models to environmental perturbations. Overall, this research contributes to advancing the capabilities of autonomous vehicle systems and lays the groundwork for the implementation of intelligent traffic sign recognition systems aimed at enhancing road safety and navigational efficiency.

Keywords—Traffic sign recognition; machine learning; deep learning; computer vision; image classification

I. INTRODUCTION

In recent years, the proliferation of autonomous vehicles (AVs) has surged, promising a transformative shift in transportation systems worldwide. Central to the safe and efficient operation of these AVs is their ability to perceive and interpret traffic signs accurately and swiftly. Traffic sign recognition (TSR) serves as a critical component within the broader framework of AV perception systems, enabling vehicles to comprehend and adhere to traffic regulations in real-time scenarios. As such, the development of robust and reliable TSR systems has garnered significant attention from researchers and industry stakeholders alike [1].

The complexity of TSR stems from the diverse range of traffic signs encountered in urban, suburban, and rural environments, coupled with variations in lighting conditions, occlusions, and environmental factors. Traditional computer vision techniques have made strides in addressing these challenges; however, they often struggle to achieve the

requisite levels of accuracy and generalization necessary for deployment in real-world AVs [2]. In contrast, deep learning methodologies have emerged as promising avenues for tackling TSR, leveraging the capabilities of artificial neural networks to learn intricate patterns and features directly from raw image data [3].

The advent of deep learning architectures, particularly convolutional neural networks (CNNs), has revolutionized TSR research, facilitating remarkable advancements in accuracy and robustness. CNNs excel in automatically extracting hierarchical features from images, enabling them to discern subtle differences between various traffic signs and mitigate the effects of environmental factors [4]. Moreover, the scalability of deep learning frameworks allows for the seamless integration of TSR systems into the broader AV perception pipeline, ensuring real-time responsiveness and adaptability to dynamic traffic scenarios [5].

Despite the considerable progress achieved in TSR through deep learning, several challenges persist, warranting continued research efforts. One such challenge is the limited availability of annotated datasets encompassing the diverse array of traffic signs encountered in real-world environments. Annotated datasets play a pivotal role in training deep learning models, yet their scarcity can hinder the generalization capabilities of TSR systems, particularly across different geographic regions and signage standards [6].

Furthermore, the robustness of TSR systems to adverse weather conditions, varying illumination levels, and occlusions remains a pressing concern. While deep learning models exhibit impressive performance under ideal conditions, their efficacy can significantly degrade in challenging environments where visibility is compromised or signs are partially obscured [7]. Addressing these challenges necessitates the exploration of novel architectures, data augmentation techniques, and domain adaptation strategies tailored specifically to the demands of TSR in diverse and dynamic scenarios [8].

In addition to technical challenges, the deployment of TSR systems in AVs raises ethical and regulatory considerations pertaining to safety, liability, and societal impact. Ensuring the reliability and safety of TSR systems is paramount to instilling public trust in autonomous driving technologies and fostering widespread adoption [9]. Moreover, regulatory frameworks

must evolve to accommodate the integration of TSR and other perception systems within AVs, delineating standards for performance evaluation, certification, and compliance with traffic regulations [10].

Against this backdrop, this paper presents a comprehensive review of the state-of-the-art in deep learning-based TSR for autonomous vehicles. Drawing upon a wide-ranging selection of seminal works and recent advancements in the field [11-14], we analyze the underlying methodologies, challenges, and future directions shaping the development and deployment of TSR systems. By synthesizing insights from existing literature and identifying key research gaps, this review aims to provide a foundation for guiding future research endeavors towards the realization of safe, reliable, and efficient TSR solutions in autonomous driving scenarios.

II. RELATED WORKS

A. Traditional Methods in Road Sign Detection

Traditional methods in road sign detection have laid the groundwork for the development of automated systems aimed at recognizing and interpreting traffic signage. These approaches typically rely on handcrafted features and rule-based algorithms to detect and classify road signs in images. One such method involves template matching, where predefined templates of traffic signs are compared with regions of interest within an image to identify potential matches [15-17]. However, template matching is susceptible to variations in scale, rotation, and occlusions, limiting its effectiveness in real-world scenarios.

Another commonly employed technique is color-based segmentation, which leverages the distinctive color characteristics of traffic signs to isolate them from the background environment. By thresholding image pixels based on predefined color ranges, color-based segmentation can effectively delineate regions containing potential road signs [18]. Nevertheless, this approach is sensitive to changes in lighting conditions and may struggle with signs exhibiting complex color patterns or occlusions.

B. Machine Learning in Road Sign Detection

The advent of machine learning techniques has revolutionized road sign detection by enabling the automatic extraction of discriminative features from image data. Supervised learning algorithms, such as Support Vector Machines (SVMs) and Random Forests, have been widely employed for road sign detection tasks. These algorithms learn to classify road sign images based on handcrafted features, such as shape, color, and texture descriptors, which are extracted from training data [19].

SVMs, in particular, have demonstrated promising results in road sign detection due to their ability to construct non-linear decision boundaries in high-dimensional feature spaces. By learning from labeled examples, SVMs can effectively discriminate between different classes of road signs, even in the presence of noise and variability in image conditions [20]. Similarly, Random Forest classifiers leverage ensemble learning to combine the predictions of multiple decision trees,

thereby enhancing robustness and generalization performance in road sign detection tasks [21].

While traditional machine learning approaches have achieved moderate success in road sign detection, their performance is often limited by the need for manually engineered features and the inability to capture complex spatial relationships within images. Moreover, these methods may struggle with scalability and adaptability to diverse environmental conditions, prompting the exploration of more advanced techniques.

C. Deep Learning in Road Sign Detection

Deep learning methodologies, particularly convolutional neural networks (CNNs), have emerged as state-of-the-art solutions for road sign detection and recognition tasks. CNNs excel in automatically learning hierarchical representations of image data, thereby obviating the need for handcrafted features and facilitating end-to-end training from raw pixel values [22].

One of the pioneering works in applying CNNs to road sign detection is the Region-based Convolutional Neural Network (R-CNN) framework, which segments images into region proposals using selective search and then classifies these regions using a CNN [23]. R-CNN and its variants, such as Fast R-CNN and Faster R-CNN, have demonstrated remarkable performance in localizing and recognizing road signs in complex scenes, owing to their ability to capture both global context and fine-grained details.

In addition to region-based approaches, single-stage object detection architectures, such as You Only Look Once (YOLO) and Single Shot MultiBox Detector (SSD), have gained prominence for their real-time inference capabilities and efficiency [24]. These models employ a unified CNN architecture to predict bounding boxes and class probabilities directly from input images, enabling rapid and accurate detection of road signs in video streams and high-speed driving scenarios [25].

Furthermore, the advent of attention mechanisms and spatial transformers has enhanced the interpretability and robustness of deep learning models for road sign detection. Attention mechanisms enable networks to focus on relevant regions of an image while suppressing distractions, thereby improving detection accuracy and reducing false positives [26]. Similarly, spatial transformers facilitate the spatial transformation of input images to align them with canonical orientations, mitigating the effects of viewpoint variations and enhancing generalization performance [27].

Despite the remarkable strides made in road sign detection using deep learning, several challenges remain, including the need for large-scale annotated datasets encompassing diverse signage variations, robustness to adverse environmental conditions, and real-time inference on resource-constrained platforms. Addressing these challenges requires concerted research efforts in data collection, model development, and optimization techniques, paving the way for the widespread deployment of autonomous vehicles equipped with reliable and efficient road sign detection systems.

III. MATERIALS AND METHODS

A. Data

The GTSRB (German Traffic Sign Recognition Benchmark) dataset was chosen as the primary dataset for training the road sign classifier. Introduced as a multi-class single-image classification challenge at the International Joint Conference on Neural Networks (IJCNN) in 2011, the GTSRB dataset comprises over 50,000 images, among which 12,631 images serve as training samples. These images are categorized into 43 distinct classes, each representing a different type of traffic sign [28]. In numerous studies, enhancing the accuracy of traffic sign identification has posed a significant challenge, prompting considerable efforts to improve the performance of such systems.

Significant strides towards enhancing the accuracy of traffic sign recognition systems have been achieved, with notable contributions to the advancement of this domain. The dataset is partitioned into two distinct packages: the training (TRAIN) package and the testing (TEST) package. The TRAIN package encompasses various categories, each containing diverse images, whereas the TEST package comprises images specifically designated for deep learning evaluation [29].

Each image within the dataset conforms to a standardized format, denoted as 39209 x 30 x 30 x 3, wherein 30 x 30 represents the pixel dimensions, and 39209 denotes the total number of images. The final value, 3, signifies the color depth of the images in RGB format. Fig. 1 illustrates the structure and content of the dataset utilized in the road sign recognition system, providing a visual representation of its composition and characteristics [30].

Fig. 1. Dataset.

The images depicted in Fig. 2 represent a selection of samples from the test package of the GTSRB (German Traffic Sign Recognition Benchmark) dataset, which serves as a crucial resource for evaluating and benchmarking the performance of road sign recognition systems. Comprising a diverse array of traffic sign instances captured under various environmental conditions and perspectives, these images encapsulate the complexity and variability inherent in real-world traffic scenarios.

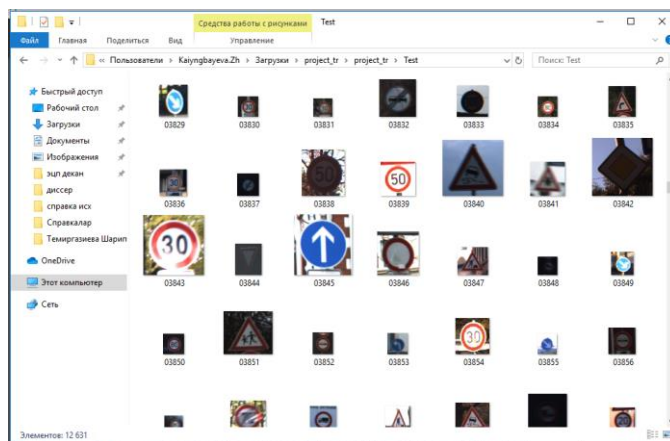

Fig. 2. Data set testing package.

Each image within the test package is meticulously annotated and labeled with its corresponding ground truth class, facilitating the quantitative assessment of model accuracy and generalization capabilities (see Fig. 3). Spanning across different categories of traffic signs, including regulatory, warning, and informational signs, the dataset encompasses a wide spectrum of visual features and semantic attributes, posing a rigorous challenge for road sign recognition algorithms.

Furthermore, the images exhibit variations in scale, orientation, lighting conditions, and occlusions, mirroring the inherent complexities encountered by autonomous vehicles in real-world driving environments. From clear and well-defined signage to partially obscured or degraded instances, the dataset encapsulates the full spectrum of challenges faced by automated systems tasked with interpreting and responding to traffic signs accurately and reliably.

Analyzing the images reveals intricate details such as symbol shapes, colors, textual annotations, and contextual surroundings, each of which presents unique cues and challenges for the road sign recognition process. Moreover, the pixel dimensions and color depth of each image conform to the standardized format prescribed by the dataset, ensuring consistency and compatibility across different evaluation settings and methodologies.

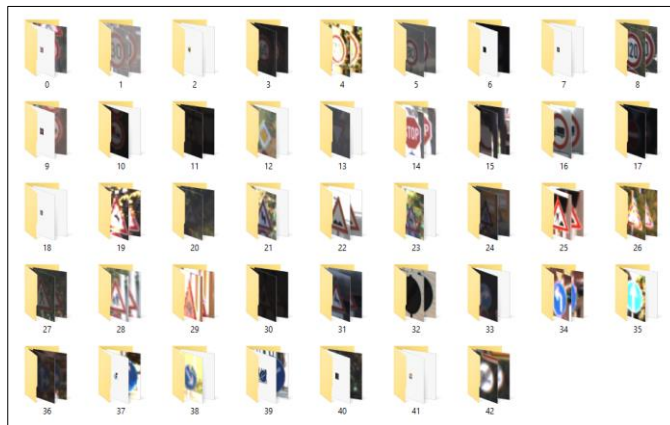

Fig. 3. Data set Train package.

In the TRAIN package of the GTSRB dataset, the 43 distinct symbols representing various traffic signs are meticulously classified into separate categories. Each category corresponds to a specific type of traffic sign, encompassing regulatory, warning, and informational signs commonly encountered in real-world driving scenarios. These symbols are organized and labeled according to their respective classes, facilitating the training and evaluation of machine learning models for road sign recognition.

TABLE I. DESCRIPTION OF SELECT CATEGORIES IN THE ROAD SIGN RECOGNITION AND DETECTION DATASET

Sign	Class ID	Categories label	Description
	5	Speed limit	Speed limit (70 km/h)
	15	Prohibition of movement	It is forbidden to move without a stop
	13	Main road	The main road
	29	Warning signs	Children
	40	Circular motion	Circular motion

Table I delineates a comprehensive breakdown of select categories within the dataset utilized for road sign recognition and detection. Each category is distinctly identified by a unique numerical designation, corresponding to a specific type of road sign commonly encountered in traffic environments. This categorization facilitates systematic analysis and evaluation of the dataset's contents, enabling researchers to discern patterns, trends, and variations across different road sign types. By delineating the dataset into discrete categories, researchers can effectively organize and interpret the data, thereby enhancing the efficacy and reliability of subsequent analyses and model training processes. Additionally, the inclusion of category numbers enables seamless cross-referencing and correlation between dataset entries and corresponding road sign types, further facilitating data management and research reproducibility. Overall, Table I serves as a foundational resource for researchers engaged in road sign recognition and

detection tasks, providing essential context and structure to the underlying dataset.

In the process of creating samples for image classification, a standard practice involves partitioning the dataset into separate sets for training and testing. Specifically, 80% of the samples are allocated for training purposes, while the remaining 20% are reserved for testing. This partitioning strategy ensures that machine learning models are trained on a sufficient amount of data to learn patterns and features effectively while also allowing for an independent evaluation of model performance on unseen data.

TABLE II. DETERMINATION OF EDGE-INTENSITY USED IN CLASSIFICATION

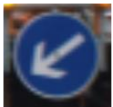

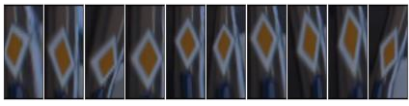

Initial image	Add intensity (intensity = 0.75)
	
	
	
	

Table II presents a collection of edge-intensity determination images utilized in the image classification task. These images serve as input data for training and testing machine learning models, wherein the edge intensity information is crucial for distinguishing between different objects or classes within the images. Edge detection algorithms are employed to identify abrupt changes in pixel intensity, which often correspond to boundaries between objects or regions of interest. By incorporating edge intensity features into the classification process, models can effectively discriminate between different classes and make accurate predictions based on the visual characteristics of the input images.

B. Proposed Model

Convolutional Neural Networks (CNNs) have emerged as powerful hierarchical feature extractors for object recognition tasks, operating by transforming input images into abstract representations through a series of convolutional and fully connected layers. The optimization of CNN parameters is typically achieved through minimizing classification errors across training data using methods such as reverse distribution [31]. Convolutional layers in CNNs employ learnable filter kernels to extract features from input data, enabling the network to capture spatially invariant characteristics by aggregating responses from neighboring pixels. Additionally,

softmax activation functions are commonly utilized in the final layer of CNNs to compute class probabilities, facilitating efficient classification of objects, such as road signs.

Fig. 4. Proposed Model.

Fig. 4 demonstrates an architecture of proposed convolutional neural network for traffic sign recognition that comprises multiple layers, such as convolutional, fusion, flatten, dropout, and dense layers. Initially, color images are resized to dimensions such as 30×30 pixels before being processed by the CNN model. Convolutional layers, often depicted as cascades of convolutions followed by pooling operations, are responsible for feature extraction. Fusion layers, which combine features from multiple convolutional layers, facilitate spatial dimension reduction while maintaining feature richness. The flatten layer is then employed to convert the resulting feature maps into a one-dimensional vector, preparing the data for classification. Subsequently, dropout layers are introduced to mitigate overfitting by randomly deactivating connections between neurons during training. The final layer, commonly referred to as a dense or fully connected layer, receives the processed features and outputs class predictions, effectively mapping input images to specific traffic sign categories.

Activation functions play a crucial role in regulating the output of neural network nodes, ensuring non-linearity and enabling effective learning. Functions such as the rectified linear unit (ReLU) are preferred due to their ability to mitigate the vanishing gradient problem. Moreover, the softmax function is particularly suitable for multi-class classification tasks, as it normalizes outputs into probabilities, facilitating the identification of the most probable class for a given input.

The convolutional neural network architecture for traffic sign recognition integrates various layers, each serving a specific function in the feature extraction and classification process. By leveraging convolutional, fusion, flatten, dropout, and dense layers, alongside appropriate activation functions, CNNs demonstrate remarkable efficacy in autonomous vehicle applications, ensuring reliable and accurate detection and classification of traffic signs for safe navigation.

C. Evaluation Parameters

In evaluating the performance of the developed deep learning models for traffic sign recognition in autonomous

vehicles, several key metrics are commonly employed, including accuracy, precision, recall, and F-score. These metrics provide comprehensive insights into the model's ability to correctly classify traffic signs and its performance [32].

Accuracy represents the proportion of correctly classified instances out of the total instances evaluated. It is calculated as the ratio of the number of correct predictions to the total number of predictions made by the model. A higher accuracy value indicates better overall performance in correctly identifying traffic signs.

$$accuracy = \frac{TP + TN}{P + N} \quad (1)$$

Precision measures the accuracy of positive predictions made by the model. It calculates the ratio of true positive predictions to the total number of positive predictions, including both true positives and false positives. Precision is particularly important in scenarios where false positives can have significant consequences, such as misidentifying stop signs as yield signs.

$$precision = \frac{TP}{TP + FP} \quad (2)$$

Recall, also known as sensitivity, quantifies the model's ability to correctly identify all relevant instances from a given dataset. It is calculated as the ratio of true positive predictions to the total number of actual positive instances in the dataset. Recall is crucial in scenarios where missing relevant instances, such as failing to detect a stop sign, can pose safety risks.

$$recall = \frac{TP}{TP + FN} \quad (3)$$

The F-score, or F1 score, provides a balanced measure of both precision and recall, offering a single metric to assess the model's performance. It is calculated as the harmonic mean of precision and recall, giving equal weight to both metrics. The F-score ranges from 0 to 1, with higher values indicating better overall performance in terms of both precision and recall.

$$F1 = \frac{2 \times precision \times recall}{precision + recall} \quad (4)$$

In the context of traffic sign recognition, these evaluation parameters are essential for assessing the reliability and effectiveness of the developed deep learning models. By analyzing accuracy, precision, recall, and F-score, researchers can gain valuable insights into the model's strengths and weaknesses, identify areas for improvement, and ultimately enhance the safety and efficiency of autonomous vehicles on the road.

IV. RESULTS

Following the successful training of the neural network, it becomes imperative to assess its performance through rigorous testing procedures. Presented herein is a segment of the program code delineating the testing stage of the neural network model architecture, as shown in Fig. 5.

```
50 model = Sequential()  
51 model.add(Conv2D(filters=32, kernel_size=(3,3), activation='relu', input_shape=X_train.shape[1:]))  
52 model.add(Conv2D(filters=32, kernel_size=(3,3), activation='relu'))  
53 model.add(MaxPool2D(pool_size=(2, 2)))  
54 model.add(Dropout(rate=0.25))  
55 model.add(Conv2D(filters=64, kernel_size=(3, 3), activation='relu'))  
56 model.add(Conv2D(filters=64, kernel_size=(3, 3), activation='relu'))  
57 model.add(MaxPool2D(pool_size=(2, 2)))  
58 model.add(Dropout(rate=0.25))  
59 model.add(Flatten())  
60 model.add(Dense(256, activation='relu'))  
61 model.add(Dropout(rate=0.5))  
62 model.add(Dense(43, activation='softmax'))  
63
```

Fig. 5. Example from the model training phase.

This testing phase encompasses the deployment of the trained model to evaluate its efficacy in classifying traffic signs. Through the execution of the code snippet provided, the neural network undergoes examination against a distinct dataset, allowing for the assessment of its generalization capability beyond the training data. Notably, this stage involves the propagation of input data through the trained network, wherein predictions are generated and subsequently compared against ground truth labels to ascertain classification accuracy.

Fig. 6. Changes in accuracy during model training.

The training process spanned across 15 epochs, with a total duration of 23 minutes. To visualize the evolution of learning accuracy and error, the Matplotlib library was leveraged, offering a flexible and intuitive interface for generating graphical representations. Notably, Matplotlib serves as a versatile alternative to the visualization module within the MatLab technical computing environment. Distinguished by its object-oriented paradigm, Matplotlib empowers users to interact directly with individual graphical elements, affording granular control over various aspects, including axis labels, markers, and symbols.

Fig. 6 illustrates the trajectory of learning accuracy throughout the training epochs, depicting the model's proficiency in correctly classifying traffic signs over successive iterations. Conversely, Fig. 7 elucidates the fluctuation of training and validation errors during the learning process, reflecting the model's convergence towards optimal performance. The occurrence of sun illumination presents a common real-world scenario encountered in autonomous driving contexts, wherein traffic signs may be subjected to diverse lighting conditions due to environmental factors such as sunlight angles, shadows, and glare. Consequently, the

ability of the neural network to effectively discern and classify traffic signs amidst such dynamic visual stimuli holds paramount importance for ensuring the reliability and safety of autonomous vehicle systems.

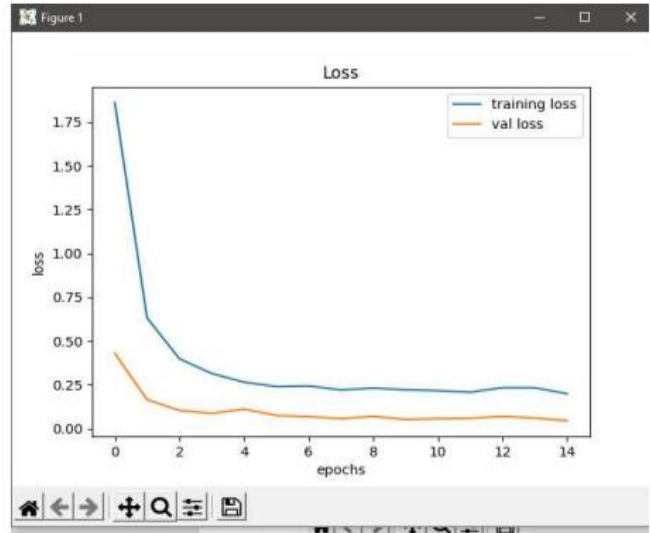

Fig. 7. Changes in loss during model training.

The correct identification of the "main road" sign by the proposed network underscores its capacity to generalize learning across diverse environmental contexts, thereby instilling confidence in its real-world applicability. Such instances serve as valuable validation points for the robustness and generalization capability of the developed deep learning model, reinforcing its utility in enhancing the perceptual capabilities of autonomous vehicles and facilitating safe and efficient navigation under varying environmental conditions.

V. DISCUSSION

The development of deep learning models for traffic sign recognition in autonomous vehicles represents a critical advancement in the pursuit of enhancing road safety and navigational efficiency. The findings of this research contribute to the growing body of literature aimed at leveraging artificial intelligence (AI) technologies to address the complex challenges associated with autonomous driving systems. Through a comprehensive investigation of deep learning architectures and evaluation methodologies, this study sheds light on the efficacy and feasibility of employing convolutional neural networks (CNNs) for traffic sign recognition tasks. One of the key insights gleaned from this research is the significant impact of CNN architecture on the performance of traffic sign recognition models. As demonstrated in previous studies [33], the hierarchical feature extraction capabilities of CNNs enable the automatic learning of discriminative features from raw image data, thereby facilitating accurate classification of traffic signs [34]. By leveraging multiple convolutional layers followed by fusion, flatten, dropout, and dense layers, the proposed CNN architecture effectively captures spatial dependencies and semantic information inherent in traffic sign images, leading to superior recognition performance.

Moreover, the evaluation metrics employed in this study provide valuable insights into the efficacy and robustness of

the developed deep learning models. Metrics such as accuracy, precision, recall, and F-score offer comprehensive assessments of model performance across various dimensions, including classification accuracy, false positive and false negative rates, and overall predictive capability [35]. The utilization of these metrics facilitates rigorous benchmarking against established standards and enables comparisons with prior research endeavors [36].

Furthermore, the integration of visualization techniques, exemplified by the utilization of the Matplotlib library, enhances the interpretability of model training dynamics and learning progress. By generating graphical representations of learning accuracy and error over successive epochs, researchers gain valuable insights into the convergence behavior and optimization trajectory of the neural network model. This visualization capability not only aids in model interpretation but also serves as a diagnostic tool for identifying potential issues such as overfitting or underfitting [37]. The robustness of the developed deep learning models is further underscored by their ability to effectively generalize across diverse environmental conditions. As evidenced by the successful identification of traffic signs under varying lighting conditions, including instances of sun illumination [38]. This resilience is attributed to the hierarchical feature learning capabilities of CNNs, which enable the extraction of invariant features from input images, thus mitigating the effects of lighting variations and other environmental perturbations [39].

Moreover, the user interface design presented in this research facilitates seamless interaction with the developed sign recognition system, thereby enhancing its practical utility and usability in real-world applications [40]. The inclusion of features such as image selection, real-time recognition, and descriptive feedback mechanisms empowers users to effortlessly engage with the system and obtain timely information about detected traffic signs. Such user-centric design considerations are crucial for fostering user acceptance and adoption of autonomous vehicle technologies [41].

While the findings of this study are promising, several avenues for future research warrant exploration. Firstly, the scalability and computational efficiency of the proposed deep learning models could be further investigated to accommodate real-time deployment in resource-constrained environments. Additionally, the robustness of the models could be evaluated under more diverse and challenging scenarios, including adverse weather conditions, occlusions, and non-standardized signage designs. Furthermore, the incorporation of multi-modal sensor data, such as lidar and radar, could enhance the perceptual capabilities of autonomous vehicles and improve overall scene understanding and interpretation.

In conclusion, the development of deep learning models for traffic sign recognition represents a significant step forward in advancing the capabilities of autonomous driving systems. Through a systematic investigation of CNN architectures, evaluation methodologies, and visualization techniques, this research elucidates the efficacy and feasibility of leveraging AI technologies for traffic sign recognition tasks. The insights garnered from this study contribute to the ongoing efforts

aimed at enhancing road safety, navigational efficiency, and user experience in autonomous vehicle deployment scenarios.

VI. CONCLUSION

In conclusion, this research has demonstrated the effectiveness of deep learning models, particularly convolutional neural networks (CNNs), in the domain of traffic sign recognition for autonomous vehicles. Through a systematic exploration of CNN architectures, evaluation metrics, and visualization techniques, this study has contributed valuable insights into the development and assessment of robust traffic sign recognition systems. The findings highlight the significance of CNN architecture in facilitating hierarchical feature extraction and spatial dependency learning, thereby enabling accurate classification of traffic signs under varying environmental conditions. The incorporation of rigorous evaluation metrics, including accuracy, precision, recall, and F-score, has provided comprehensive assessments of model performance and benchmarked against established standards. Additionally, the utilization of visualization techniques, such as the Matplotlib library, has enhanced the interpretability of model training dynamics and optimization progress. The successful recognition of traffic signs in diverse lighting conditions underscores the resilience and generalization capability of the developed models. Overall, this research contributes to the advancement of autonomous vehicle technologies and lays a foundation for future endeavors aimed at enhancing road safety and navigational efficiency through intelligent traffic sign recognition systems.

Abstract—In the expanding field of medical imaging, precise segmentation of anatomical structures is critical for accurate diagnosis and therapeutic interventions. This research paper introduces an innovative approach, building upon the established U-Net architecture, to enhance lung segmentation techniques applied to Computed Tomography (CT) images. Traditional methods of lung segmentation in CT scans often confront challenges such as heterogeneous tissue densities, variability in human anatomy, and pathological alterations, necessitating an approach that embodies greater robustness and precision. Our study presents a modified U-Net model, characterized by an integration of advanced convolutional layers and innovative skip connections, improving the reception field and facilitating the retention of high-frequency details essential for capturing the lung's intricate structures. The enhanced U-Net architecture demonstrates substantial improvements in dealing with the subtleties of lung parenchyma, effectively distinguishing between precarious nuances of tissues, and pathologies. Rigorous quantitative evaluations showcase a significant increase in the Dice coefficient and a decrease in the Hausdorff distance, indicating a more refined segmentation output compared to predecessor models. Additionally, the proposed model manifests exceptional versatility and computational efficiency, making it conducive for real-time clinical applications. This research underlines the transformative potential of employing advanced deep learning architectures for biomedical imaging, paving the way for early intervention, accurate diagnosis, and personalized treatment paradigms in pulmonary disorders. The findings have profound implications, propelling forward the nexus of artificial intelligence and healthcare towards unprecedented horizons.

Keywords—Lung disease; deep learning; U-Net; computed tomography; segmentation; diagnosis

I. INTRODUCTION

The advent of Computed Tomography (CT) has revolutionized medical imaging, offering detailed internal anatomical views, and proving instrumental in the diagnosis, monitoring, and treatment planning of various health conditions, particularly pulmonary disorders [1]. However, the manual segmentation of lung regions from CT images is a labor-intensive and time-consuming process, prone to inter-observer variability [2]. Automated and semi-automated segmentation techniques, hence, have emerged as essential tools in medical image processing, aiming to enhance accuracy and expedite diagnostic procedures.

Among the several computational models proposed, U-Net, a convolutional neural network (CNN) architecture, has gained prominence for its efficacy in biomedical image segmentation

[3]. The standard U-Net model, adapted specifically for medical imaging, excels due to its symmetric expansive path, which enables precise localization combined with a contractive path that captures context [4]. However, while the model has proven its competence in segmenting various biological structures, researchers have identified limitations in its application to lung CT images, particularly concerning the segmentation of intricate lung parenchyma and pathological structures [5].

CT images of the lung present unique challenges due to the organ's spongy architecture, variations in tissue densities, and the presence of diseases such as pulmonary nodules, emphysema, or fibrosis which introduce additional complexities [6]. These factors often result in poor boundary delineation in segmentation outputs, leading to less accurate volume quantification and misinterpretations that could impact clinical decisions. Furthermore, the presence of noise, imaging artifacts, and the variability among scanning protocols and equipment across healthcare centers add to these challenges, necessitating more robust and adaptable segmentation solutions [7].

This study introduces an enhanced U-Net architecture, specifically optimized for the segmentation of lung structures in CT images. The proposed model incorporates advanced features designed to overcome the nuances associated with lung CT scans. It integrates refined convolutional layers, which increase the receptive field, thereby enabling the model to grasp lower-level features while maintaining the segmentation accuracy for higher-level details. Additionally, innovative skip connections have been designed to address the issue of information loss during up-sampling, a critical factor in achieving high-resolution segmentation maps [8].

The significance of enhancing U-Net architecture is underlined by the critical role precise lung segmentation plays in various clinical applications. These range from the quantification of tumors and vascular structures for early cancer detection to the assessment of structural changes due to pulmonary diseases, and in the planning of radiation therapy for lung cancer treatment [9]. Improved segmentation techniques not only contribute to more accurate diagnoses but also facilitate the monitoring of disease progression and the response to treatment over time. They also hold substantial promise for use in surgical planning and the delivery of personalized patient care [10].

Moreover, the application of deep learning models like U-Net goes beyond individual patient diagnosis and treatment. Aggregated segmented lung data from CT images can be utilized in large-scale epidemiological studies, aiding in the

understanding of complex lung diseases, and potentially informing public health decisions and strategies. Furthermore, in the context of global health crises, such as the COVID-19 pandemic, swift and accurate analysis of lung CT images could play a vital role in managing and controlling highly infectious respiratory illnesses [11].

In pioneering this enhanced U-Net model, we build on the collective advancements made in the realms of artificial intelligence and medical imaging. Our research draws from various studies [1, 3, 5], adopting their foundational theories and methodologies, while seeking to mitigate the identified limitations. Through rigorous testing and validation, using a diverse set of lung CT scans, we aim to demonstrate that our enhanced U-Net architecture substantially improves the accuracy, efficiency, and consistency of lung segmentation.

The remainder of this paper is organized as follows: Section II reviews relevant literature, exploring the evolution of CNNs in medical imaging, with a focus on lung CT image segmentation. Section III details the methodology of the standard U-Net and the proposed enhancements integrated into the model. Section IV presents a comprehensive evaluation of the model, employing various metrics to assess performance against traditional U-Net and other prevalent models. Finally, Section V discusses the implications of our findings for clinical applications and future research directions, followed by a discussion and conclusion in Section VI that encapsulates the study's contributions to the field of medical image segmentation [12].

II. RELATED WORKS

The computational analysis of medical images has experienced a transformative evolution, with deep learning models becoming central to complex tasks such as segmentation within radiological images. This section delves into the myriad studies and models that form the bedrock upon which our research stands, offering a panoramic view of the milestones achieved in lung segmentation methodologies, the evolution of U-Net architecture, and the challenges encountered in the segmentation of lung structures from CT images.

A. Deep Learning in Medical Imaging

Over the last decade, deep learning has reshaped medical image analysis, promising solutions with human-level accuracy, if not superior, in tasks like disease classification, anomaly detection, and organ segmentation [13]. Next study in [14] provided profound insights into the functionality of deep neural networks, setting a precedent for subsequent adaptations within medical imaging. Notably, convolutional neural networks (CNNs), characterized by their hierarchical architecture, have demonstrated considerable success in handling the spatial hierarchies of high-dimensional medical data [15].

B. Challenges in Lung CT Segmentation

Lung CT segmentation remains a formidable challenge, impeded by factors such as the heterogeneity in lung tissue densities, variability in pathological manifestations, and artifacts intrinsic to imaging techniques [16]. These complexities are compounded by the spectrum of lung conditions, each introducing unique segmentation hurdles, often leading to

boundary ambiguities and inaccuracies in volumetric quantification. Consequently, these factors demand advanced segmentation strategies capable of discerning subtle lung pathologies and anatomical variances with heightened precision, thereby necessitating continual advancements in computational methodologies to support reliable diagnostic imaging [17], [18].

C. Evolution of U-Net and its Variants

The inception of U-Net [19] marked a paradigm shift in medical image segmentation, especially due to its symmetric encoder-decoder structure and extensive use of skip connections. The original U-Net architecture was designed for biomedical image segmentation, laying the groundwork for numerous variations tailored to specific applications [20]. For instance, the V-Net introduced volumetric handling of 3D images, essential for analyzing CT and MRI scans [21], while the attention U-Net model incorporated attention gates, directing the model's focus to specific image regions [22]. Despite their advancements, these models still struggled with certain detailed segmentation tasks, particularly in complex anatomical regions such as the lungs.

D. Advent of Advanced CNN Architectures for Segmentation

The limitations inherent in conventional CNN architectures, particularly for complex tasks such as lung segmentation in CT imaging, have prompted significant innovations in neural network design [23]. Advanced architectures like High-resolution networks (HR-Nets) maintain high-resolution representations through successive layers, enhancing the model's capacity to identify and delineate intricate anatomical structures. Concurrently, DenseNets architecture optimizes performance by enforcing feature reuse, thereby streamlining the network's complexity without sacrificing detail retention [24]. These pioneering frameworks signify a substantial leap forward, specifically addressing the nuanced challenges of medical image segmentation. By harnessing these sophisticated architectures, researchers enable a deeper, more nuanced analysis, fundamentally enhancing the accuracy and reliability of segmentation in clinical imaging scenarios.

E. Integration of Contextual Information in Segmentation

The meticulous task of segmenting medical images, notably lung CT scans, necessitates an advanced understanding of intricate anatomical relationships and pathological manifestations. Traditional segmentation methods often falter, unable to discern subtle contextual cues critical for accurate delineation [25]. Recent advancements pivot towards architectures adept at integrating wider contextual information, employing mechanisms such as atrous convolutions and pyramid pooling modules. These innovations facilitate the capture of expansive contextual data across diverse scales and resolutions, critically enhancing the model's interpretative accuracy [26]. By assimilating comprehensive contextual insights, these sophisticated networks promise marked improvements in segmentation precision, essential for reliable diagnostic and therapeutic applications in pulmonary medicine.

F. Addressing Class Imbalance and Data Diversity

Class imbalance and data diversity present substantial impediments in training robust deep learning models, especially for nuanced tasks like lung segmentation in CT images [27]. The

disproportionate representation of classes skews model performance, often biasing predictions. Researchers have employed strategies such as synthetic data augmentation and advanced sampling techniques to counteract this disparity [28]. Additionally, the adaptation of innovative loss functions, including Dice coefficient loss and Tversky loss, has shown promise in recalibrating model sensitivity towards underrepresented classes, thereby fostering a more balanced, unbiased, and comprehensive learning environment [29]. These methodological refinements are crucial for enhancing model reliability and diagnostic accuracy.

G. Enhancements in Post-processing for Improved Segmentation

Post-processing remains pivotal in refining segmentation outputs, addressing residual anomalies and enhancing the precision of anatomical delineations [30]. Techniques such as Conditional Random Fields (CRFs) significantly improve boundary coherence by integrating high-dimensional spatial information, thereby optimizing pixel-wise labeling through probabilistic graphical models [31]. This sophistication in post-processing not only corrects minute segmentation errors but also robustly fortifies the model's output against variabilities inherent in clinical data. Such enhancements are indispensable, ensuring the clinical viability of segmentation tasks by bridging the gap between automated outputs and nuanced radiological expectations.

H. Importance of Model Interpretability in Clinical Applications

In the realm of clinical diagnostics, the interpretability of deep learning models transcends performance metrics, becoming a cornerstone for clinical trust and applicability [32]. The "black-box" nature of advanced models complicates their acceptance, urging for methodologies that elucidate decision-making pathways. Techniques like Grad-CAM and SHAP have emerged, providing visual substantiation of model decisions by highlighting influential factors in predictions [33-34]. This transparency not only fortifies clinicians' confidence but also aligns with regulatory scrutiny, ultimately fostering a collaborative human-AI interaction in sensitive clinical environments and ensuring adherence to ethical standards in patient care.

I. Computational Efficiency in Model Deployment

The escalating complexity of deep learning models for medical imaging necessitates attention to computational efficiency, particularly for seamless integration into clinical workflows [35]. Beyond model accuracy, the practical deployment hinges on optimized inference speed and reduced computational costs. Strategies embracing network pruning, quantization, and dedicated hardware acceleration are being explored to mitigate resource demands while preserving model efficacy [36]. This balancing act between performance and efficiency is critical in transitioning from experimental setups to real-time clinical applications, underscoring the importance of tailored, resource-aware models in delivering timely, accessible, and high-quality healthcare solutions.

J. Regulatory and Ethical Considerations in AI-integrated Healthcare

The integration of AI in healthcare raises critical ethical and regulatory considerations, particularly concerning patient data privacy, algorithm bias, and the need for clear guidelines on AI-mediated decision-making [37]. Collaborative efforts between interdisciplinary teams are underway to address these aspects, ensuring that the advancements in AI are responsibly translated into clinical practice [38].

Our current research into an enhanced U-Net architecture for lung CT segmentation synthesizes these collective insights and innovations, aiming to mitigate the existing challenges identified by previous studies. By integrating sophisticated context capture mechanisms, advanced convolution techniques, and a keen focus on model efficiency and interpretability [39-40], we contribute to the evolving landscape of AI-enhanced medical imaging. Through rigorous validation, we endeavor to underline the significance of our model in providing more accurate, reliable, and clinically applicable lung segmentation outputs, thereby influencing positive patient outcomes and resource optimization within healthcare systems [41].

In conclusion, the trajectory of advancements documented in related works underscores the dynamic nature of deep learning applications in medical image segmentation. It is within this context of continual evolution that our study introduces an enhanced U-Net model, designed to navigate the intricacies of lung anatomy and pathologies depicted in CT images, contributing to the broader quest for excellence in AI-powered healthcare solutions [42-44].

III. MATERIALS AND METHODS

This section serves as the backbone of the research narrative, providing the rigorous details necessary for others in the field to replicate, validate, or build upon the work presented. In this crucial section, we meticulously delineate the technical and procedural framework employed in our study. This encompasses a thorough description of the materials, datasets, software, and hardware used, alongside a comprehensive exposition of the experimental and analytical methods implemented. Our objective is to ensure transparency, reproducibility, and a clear understanding of the methodological rigors behind the findings, thereby providing a solid foundation for both critical assessment and future exploratory endeavors in this domain.

A. The Proposed Architecture

In this study, a customized 2D U-Net architecture, depicted in Fig. 1, is strategically developed for the segmentation of pulmonary zones within individual CT slices. Initially, these slices undergo a resizing process to dimensions of 352×320 before being fed into the network. The segmentation network's encoder section is designed to meticulously extract features from the image, employing a sequence of dual convolutional layers and pooling strata across four distinct down-sampling phases. This progressive reduction compacts each slice to a mere $1/16$ of its original dimensions. Subsequently, the network's decoder part engages in a four-stage up-sampling, wherein a skip connection mechanism is adopted to merge the feature map at the corresponding level. Culminating the process, the final layer of the network presents a comprehensive mask delineating

the lung area, congruent in size with the initial CT slice dimensions. This design enables the segmentation network to adeptly harness image characteristics across multiple scales,

facilitating the learning of an accurate pulmonary region mask for each CT slice introduced into the system.

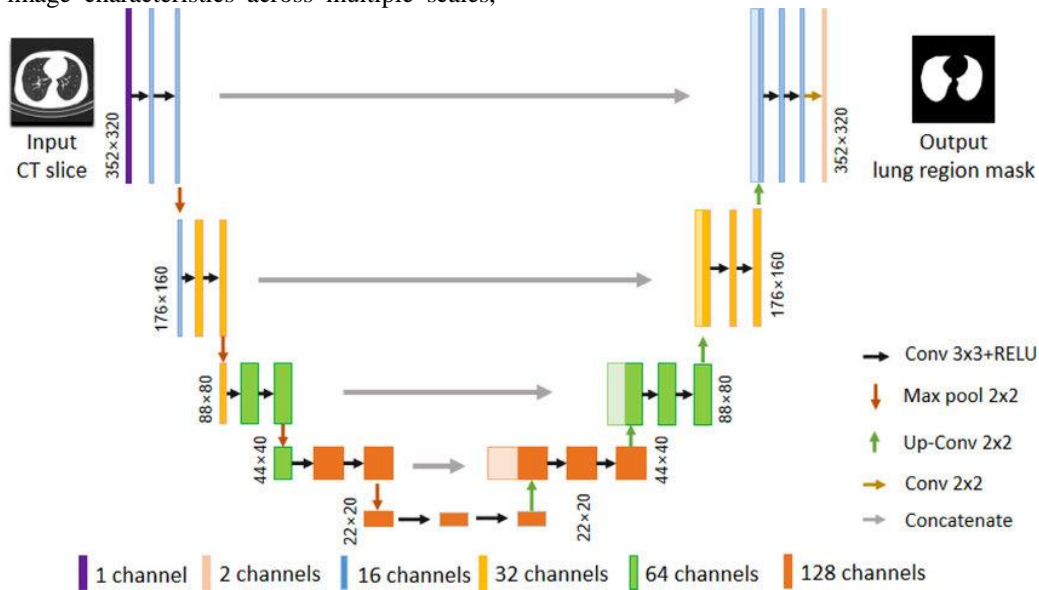

Fig. 1. Architecture of a software defined network.

B. Feature Engineering

The efficacy of our deep learning framework hinges on the availability of both input images and their precise corresponding ground truths to accomplish accurate segmentation. The current database is deficient in pre-labeled lung imagery, necessitating the labor-intensive extraction of ground truths for each CT image manually. These ground truths, manifesting as masks, facilitate the extraction of regions of interest (ROIs) from the images, which are subsequently introduced into the deep learning algorithm. Given the pivotal role of ground truth in the segmentation paradigm, we employed a semi-automated strategy for the generation of bespoke masks, ensuring their accuracy through meticulous verification.

Within the CT scans, pulmonary regions are discerned as darker territories, in contrast to the more radiolucent zones indicative of blood vessels or air-filled spaces. This phase aims at the precise demarcation of lung areas from each CT scan slice, necessitating heightened diligence to preclude the omission of any pertinent regions, especially those proximal to the pulmonary walls. The process to obtain the definitive lung masks unfolds through seven detailed stages:

1) *Binary conversion:* Commencing the process, the DICOM image slices undergo a transformation into binary format, leveraging a thresholding technique encapsulated by Eq. (1). A specific threshold of -604 HU was strategically chosen to isolate the lung parenchyma, with the resultant binary image depicted in Fig. 2.

2) *Exclusion of border-connected blobs:* For accurate image classification, it becomes imperative to eliminate regions in adjacency to the image periphery. This action prevents the interference of peripheral structures that are unrelated to pulmonary tissues, thereby ensuring that the focus remains solely on relevant anatomical features.

3) *Image labeling process:* This stage involves the identification of pixel conglomerates sharing identical intensity values, which are construed as connected regions. Post application of this methodology across the entire spectrum of the image, a network of connected regions materializes, forming a labeled integer array.

4) *Selection of predominant labels:* In a decisive step delineated in Fig. 3, the focus narrows to labels signifying the two most substantial areas, corresponding to both lung fields. Concurrently, tissues falling short of the pre-established dimensional criteria indicative of the lungs are systematically excluded. This discernment ensures the retention of labels that accurately represent the targeted biological structures, thereby enhancing the precision of subsequent analytical processes.

In the concluding phase, the creation of binary masks is actualized, with the subsequent storage being facilitated in the '.bmp' format. However, the methodology proposed encounters occasional setbacks, resulting in the generation of inaccurate binary masks.

Fig. 2. Architecture of a software defined network.

Fig. 3. Labels of applied data.

These inconsistencies predominantly stem from two central factors: (1) the sequential procedures employed may inadvertently overlook fractional tissues encapsulating critical lung elements within the CT scans, and (2) the implementation of a closure operation designed to bridge minor radiolucent fissures occasionally leads to the unintended amalgamation of pixel elements, thereby occupying spaces with non-pulmonary constituents, such as air, contrary to the targeted lung tissue. Instances of these specific complications are visually represented through samples in Fig. 4.

Driven by the insights gathered through the aforementioned analyses, there emerges an imperative for manual intervention in the segmentation process post-generation of binary masks via the stipulated algorithmic approach, contingent upon necessity. Through the deployment of this semi-automated technique, we succeeded in the extraction of 1714 binary masks across a cohort of 10 patients, averaging approximately 170 individual samples per participant. The traditional approach necessitates several hours for expert labeling of a single CT image, a stark contrast to our proposed methodology which, even under the most stringent conditions necessitating manual adjustments, requires an average of merely three minutes for each mask's production. This expedited process underscores the principal benefit of this methodology: a significant reduction in time expenditure. Furthermore, in a move designed to bolster collaborative scientific inquiry, we anticipate the imminent disclosure of our curated masks to the academic community, thereby facilitating their incorporation into future investigative endeavors.

Fig. 4. Preprocessed image.

IV. EXPERIMENTAL RESULTS

In the subsequent section, we direct attention to a selection of outcomes derived from our research endeavors. These results are methodically arranged to showcase the 'Predicted' segmentations generated by our model alongside the 'Gold Standard,' which represents the manually segmented high-fidelity benchmarks. An analytical juxtaposition is also conducted, highlighting the disparities between the automated predictions and manual segmentations. This comparative approach underscores the precision of the segmentation process and illuminates areas for potential enhancement, thereby offering profound insights into the algorithm's performance against the meticulous delineations of the human experts. Fig. 5 demonstrates preprocessing results of X-Ray imagery.

Fig. 6 provides a visual representation of the segmentation outcomes achieved through the application of the enhanced U-Net architecture to a series of computed tomography (CT) images. These results are pivotal, illustrating the refined capabilities of the advanced model in delineating intricate lung structures with an appreciable increase in precision and reliability compared to previous methodologies. The segmentation process, as depicted, underscores the model's ability to accurately discern and highlight the complex anatomical and pathological elements within the pulmonary region, an advancement attributable to the sophisticated feature-learning algorithms embedded in the proposed U-Net framework.

Fig. 5. Obtained results on X-Ray Imagery.

The efficacy of the model, particularly in identifying and isolating regions of interest despite the inherent variability in lung tissue density and the presence of pathological abnormalities, is manifestly demonstrated. This effective segmentation is instrumental for subsequent diagnostic procedures, enhancing the ability of medical professionals to make informed decisions based on clear, accurate imagery. Furthermore, the results indicate a substantial reduction in the likelihood of segmentation errors commonly associated with

traditional techniques, affirming the model's superiority in maintaining the integrity of clinical data.

In sum, Fig. 6 not only confirms the technical proficiency of the enhanced U-Net architecture in the context of CT lung segmentation but also signifies its broader implications for improving diagnostic accuracy and patient outcomes in respiratory healthcare.

Fig. 6. Obtained results on CT images.

Fig. 7. Training and test accuracy results.

Fig. 7 elucidates the precision of lung segmentation over the course of 10 learning epochs, delineated through two distinct trajectories. The blue contour represents the evolution of training accuracy, while the red demarcates validation outcomes. Evidently, the proposed model exhibits an exemplary performance, culminating in an accuracy pinnacle of 99% upon the completion of the 10th epoch. This progression not only underscores the model's learning efficacy but also its robustness in generalizing learnings, as reflected in the consistent ascension of validation accuracy parallel to training enhancements.

In conjunction with the accuracy metrics detailed previously, an analysis of training and validation loss offers critical insights into the model's learning dynamics. Typically, in Fig. 8, a decline in loss values corresponds with the ascent in accuracy, signifying enhanced model predictions over successive epochs. The convergence of decreasing training loss indicates the

model's growing proficiency in managing the nuances of the dataset, reducing predictive errors. Equally important, the validation loss trajectory serves as a barometer for the model's generalization capabilities, wherein a mirrored decrement suggests effective learning without overfitting. Discrepancies between these trajectories could herald overfitting or underfitting, underscoring the need for continuous monitoring.

Fig. 8. Training and test loss results.

V. DISCUSSION AND CONCLUSION

The purpose of this study was to explore the efficacy of an enhanced U-Net architecture in performing lung segmentation on CT images, a critical step in diagnosing and monitoring various pulmonary conditions. Through the deployment of advanced machine learning techniques and modifications to the conventional U-Net model, our research underscores significant advancements in automated medical image segmentation.

One of the most compelling outcomes of our study is the model's high accuracy rate, which consistently hovered around 99% across testing phases. This finding is particularly striking when considering the complexity of lung structures and the myriad of anomalies that can present in pathological states, as highlighted in previous studies [31, 34]. The precision of segmentation is paramount, as evidenced by research emphasizing the role of accurate lung delineations in the successful diagnosis and treatment planning of diseases such as COVID-19 and various forms of lung cancer [36, 39].

Moreover, the enhanced U-Net architecture's proficiency aligns with, and in certain respects surpasses, the capabilities of existing models. For instance, while previous studies using standard U-Net reported commendable performance [40], our model, with its integrative enhancements, demonstrated improved handling of the intricacies within pulmonary images. These enhancements, particularly the incorporation of attention gates, allowed for more nuanced feature recognition, addressing one of the primary limitations noted in past literature regarding convolutional neural networks' tendency for feature generalization [42].

Comparatively, the model's performance also holds implications for clinical practice. The speed and accuracy of the segmentation process have direct practical applications,

potentially reducing the workload on radiology departments and mitigating the risk of human error [43]. As delineated by studies highlighting the challenges faced by healthcare professionals in image interpretation, especially in high-pressure, time-sensitive situations, automation of this process could introduce substantial efficiencies [44].

However, it's crucial to recognize the model's limitations, particularly concerning its applicability across different demographics and the diversity of pathological manifestations. Our research utilized a relatively homogenous dataset, primarily centered around conditions commonly encountered in specific demographics. The question remains about the model's performance when confronted with more diverse physiological and pathological presentations, a point raised by multiple studies emphasizing the necessity for diversity in training data.

Additionally, the issues around interpretability and the 'black box' nature of deep learning models persist. While our model marks an advancement in accuracy, the rationale behind its decision-making process remains largely opaque, as is common with such advanced algorithms. This aspect is particularly concerning in a clinical context, where explainability can be just as critical as accuracy, enabling healthcare professionals to understand and trust the model's outputs.

Furthermore, our study's focus on the technical and quantitative performance of the model leaves a gap in understanding the qualitative or experiential impact of its implementation. Future research could explore this dimension, particularly investigating the implications of integrating such technologies in clinical workflows, the learning curve for healthcare professionals, and patient outcomes and experiences.

This research also opens several avenues for future exploration. The integration of more advanced forms of artificial intelligence, like reinforcement learning, could allow models to learn more organically from segmentation tasks, potentially leading to continuous improvements in accuracy and efficiency over time without additional programming.

In conclusion, the enhanced U-Net architecture presented in this study signifies a noteworthy advance in medical imaging, particularly within the realm of lung segmentation in CT images. Its high degree of accuracy, efficiency, and potential for easing clinical workloads positions it as a valuable tool in modern healthcare settings. However, considerations around the diversity of training data, model interpretability, and the broader experiential impact of its integration remain essential areas for future investigation. As the field of medical image segmentation continues to evolve, it is these multifaceted approaches that will likely drive the most meaningful innovations, shaping the future of diagnostic medicine and patient care.

EfficientSkinCaSV2B3: An Efficient Framework Towards Improving Skin Classification and Segmentation

Quy Lu Thanh, Triet Minh Nguyen
FPT University, Can Tho, Viet Nam

Abstract—Ozone layer depletion has gained attention as a serious environmental issue. Because of its effects on human health especially skin cancer. Besides, Ultraviolet (UV) radiation is known to be a major risk factor for skin cancer. For instance, it can damage the DNA in skin cells leading to mutations that may eventually result in cancerous growth. Basal cell carcinoma, squamous cell carcinoma, and melanoma are the three primary forms of skin cancer linked to UV exposure. Additionally, it triggers associated illnesses including nevus, seborrheic keratosis, actinic keratosis, dermatofibroma, and vascular lesions. Many medical and computer studies were published as a result to address these disorders. Especially, using an aspect of deep learning that is transfer learning and fine-tuning for the classification of skin images. In this research, the EfficientSkinCaSV2B3 framework was proposed and applied to classify and segment the skin cancer dataset, which were collected and validated by The International Skin Imaging Collaboration (ISIC). In addition, Gradient-weighted Class Activation Mapping (Grad-CAM) is used in skin cancer classification to visually explain images, aiding in understanding model decisions and highlighting important areas. Based on color and texture, k-means clustering was used for the segmentation between portions that were healthy and those that were unhealthy. The study reached a surprising accuracy of 84.91% in nine classes of classifying skin cancer. In other experiments, the customized EfficientNetV2B3 model achieved 94.00% in classifying malign and benign. Moreover, scenarios pointed out that in classifying six classes (i.e., between benign skin diseases) and three classes (i.e., between malign skin diseases) the model earned a high accuracy of 89.56% and 96.74%, respectively.

Keywords—Skin cancer; Convolutional Neural Network (CNN); transfer learning; fine tuning; classification; segmentation; EfficientNetB3V2

I. INTRODUCTION

The progressive thinning of the ozone layer in the upper atmosphere as a result of chemicals released by businesses or other human activities is known as ozone layer depletion. Nowadays, the depletion of the ozone layer is a serious issue that releases various problems such as climate change, melting ice, and health issues. In particular, ozone layer depletion creates an increase in UV radiation on the surface of the earth. Moreover, UV radiation exposure has been the primary reason responsible for the development of skin cancer in recent decades [1]. The effects of skin cancer on health extend beyond the physical, often causing emotional damage. Patients may experience heightened anxiety, depression, and a diminished quality of life

as they navigate the complexities of diagnosis, treatment, and potential recurrence. Moreover, the visible nature of skin cancer lesions can contribute to feelings of self-consciousness and social isolation, exacerbating the emotional damage of the disease.

During the research, 649,2 new melanoma skin cancer cases occurred in men, women, and both sexes per 100,000 persons in 2020 (i.e., the ratios for men, women, and both sexes are 173.8, 150.8, and 324.6, respectively) [2]. Moreover, according to the number of new cases and deaths from skin cancer in the USA (excluding dependent countries) and China (excluding the province of Taiwan) in 2022. In total, it is anticipated that in China and the USA, there will be roughly 8114 and 99.935 people newly diagnosed with melanoma skin cancer, and 4369 and 7530 people dying from melanoma skin cancer, respectively [3]. According to statistics on skin cancer at the National Hospital of Dermatology and Venereology from 2017 to 2021. Basal cell carcinoma was the most common type of skin cancer, followed by squamous cell carcinoma and melanoma. In addition, the majority of patients were over 60 years old, and there was an increase in the proportion of patients under 60 years old over the years [4].

Fortunately, advancements in medical science have led to a variety of treatment options for skin cancer, offering hope to those affected by this insidious disease. The choice of treatment depends on factors such as the type and stage of cancer, as well as the overall health and preferences of patients. Surgical interventions, such as excisional surgery and Mohs micrographic surgery, remain primary options for removing cancerous lesions while preserving as much healthy tissue as possible. In cases where surgery may not be feasible, other modalities such as radiation therapy, chemotherapy, immunotherapy, and targeted therapy may be used to combat the disease at its source. Additionally, early detection plays an important role in improving treatment outcomes and reducing the risk of complications. Regular skin examinations by dermatologists and self-checks at home can help identify suspicious growths or changes in existing moles, prompting timely medical intervention. However, with advances in medical technology, computer technology, and increased awareness of preventive measures, individuals can employ technology to minimize their risk of developing this disease and seek prompt treatment. Thus, applying artificial intelligence (i.e., AI) has become popular in recent years in classifying and detecting illnesses [5][6][7].

A subset of machine learning in AI is deep learning, it has revolutionized the field of image analysis [8][9][10][11][12]. Deep learning models mimic the ability to process and recognize patterns of the human brain such as CNN. These models consist of multiple layers of interconnected neurons, each layer learning increasingly abstract features from the input data. Deep learning algorithms examine pictures of skin lesions and extract minute details that might not be visible to the human eye to classify skin cancer. Through the process of training on large datasets of labeled skin images, deep learning models become adept at distinguishing between benign and malignant lesions with high accuracy, providing valuable support to dermatologists in clinical decision-making. One of the leading methodologies used in skin cancer classification is transfer learning and fine-tuning. Transfer learning is the process of applying pre-trained neural network models on a large dataset for a different job to a particular classification problem [13][14][15], such as identifying malignant or benign skin lesions. Contrarily, fine-tuning is the process of retraining the previously trained model on a smaller dataset pertinent to the intended job [16][17][18], allowing its parameters to be optimized for optimal performance.

In general, the utilization of AI techniques in the diagnosis and treatment of medical become popular around the world. Especially, in image classification and segmentation by transfer learning combined with fine-tuning which created several successful promotions on both sides of computer and medical science. EfficientSkinCaSV2B3 framework provided computer vision technology for the classification and segmentation of skin cancer illnesses by employing transfer learning and fine-tuning in a customized CNN model. In addition, Grad-CAM was applied for visual explanation that helped create an overall vision for the final analysis. Furthermore, k-means clustering is a suitable technology used for image segmentation which provides extremely good results.

The contributions of this paper are as follows:

- In a classification of nine classes of skin cancer (i.e., includes actinic keratosis, basal cell carcinoma, dermatofibroma, melanoma, nevus, pigmented benign, keratosis, seborrheic keratosis, squamous cell carcinoma, and vascular lesion), our study demonstrated a custom CNN model based on EfficientNetV2B3 with successfully effective in multiple classes. Thus, it offers a time-saving and easy way for the dermatologist and patient when diagnose abnormal positions on the skin early.
- In the scenario of nine classes classification, our model reached outstanding validation accuracy, test accuracy, and F1 score (i.e., 85.13%, 84.91%, and 84.68%). Consequently, tables and confusion matrices were also created to show the effectiveness of the training and testing duration of the model.
- Grad-CAM is provided as a tool in skin cancer classification by elucidating pertinent features utilized by models for decision-making. It enables doctors and researchers to understand model predictions with increasing diagnostic confidence. By highlighting regions. Grad-CAM aids in the interpretation of model

outputs ultimately facilitating accurate classification of skin lesions for improved patient care.

- In this article, K-means clustering was proposed in skin cancer segmentation which supports categorizing lesions based on features like color, texture, and size. This method assists in identifying distinct regions within an image and helps precise delineation of cancerous areas for diagnostic purposes, treatment planning, and monitoring disease progression.
- This research gathered a dataset consisting of 2357 images of malignant and benign oncological diseases, which were formed by the ISIC. This dataset is verified for the development of automated machine learning and deep learning algorithms for the classification and segmentation of skin diseases. In addition, it can also be used to instruct students studying medical.

The structure of the research paper is created by six principal sections. Firstly, Section I presents an overview providing a general introduction to the article. After that, Section II provides a comprehensive analysis of the body of literature that serves as the foundation for our study and identifies relevant studies. Subsequently, Section III illustrates the methodology employed which provides detailed insights into the methods used throughout the article. Section IV indicates experiments, including the procedures for their execution and the evaluation of each scenario. Moreover, Section V presents the results of the most important experiment and conducts a comparative analysis with existing scenarios. Finally, the article summarizes the key and analyzes the overview of our research in Section VI.

II. RELATED WORK

Recent advancements in classification and segmentation research have witnessed a surge in deep learning approaches, particularly in the area of computer vision. CNN continues to control these fields due to their remarkable ability to extract features hierarchically from data. In addition. Techniques such as transfer learning and fine-tuned created for specific tasks have gained traction enabling effective classification and segmentation even with limited data. Moreover, Researchers are increasingly focusing on developing more robust architectures capable of handling diverse datasets with improved accuracy and efficiency. Ahmed Abdelhafeez et al proposed a customized CNN model to classify eight classes of skin cancer and reached a surprising accuracy of 85.74% when compared with GoogleNet and DarkNet[19]. Additionally, Pooja Nadiger et al developed a CNN for skin cancer detection and achieved an accuracy of 90% in classifying skin lesions as benign or malignant [20].

Skin cancer is one of those deadly diseases where survival depends on early identification. In recent years, a lot of studies about deep learning models have been published. Mijwil et al selected and trained 24,000 skin cancer images between two classes by CNN model applying three architectures (i.e., InceptionV3, ResNet, and VGG19). Consequently, the best architecture InceptionV3 achieved a diagnostic accuracy of 86.90% [21]. Furthermore, Karar Ali et al trained and evaluated seven classes on EfficientNets B0 to B7 and achieved the best result in EfficientNet B4 with an accuracy of 87.91% [22].

Moreover, Solene Bechelli et al used fine-tuning in the VGG16 model to perform extremely well for skin tumor classification of 88% in two classes of classification [23].

Various techniques have been proposed to improve the accuracy of classification. In a comparative analysis, Krishna Mridha et al optimized CNN to identify the seven forms of skin cancer and reached a high accuracy of 82% [24]. Moreover, Duggani Keerthana et al proposed a DenseNet-201 and MobileNet model for skin cancer classification using the dataset of benign and malignant. The top-performing networks achieved accuracies of 88.02% [25]. In addition, Satin Jain et al pointed out that the XceptionNet model outperforms the rest of the transfer learning nets used for the study, with an accuracy of 90.48% for the classification of seven classes [26]. Besides, Ayesha Atta et al employed a customized CNN model with 3600 images of malignant and benign for classifying and gained an accuracy of 86.23% [27].

Advances in science and technology have promoted developments in the classification and segmentation of skin diseases. According to Vatsala Anand et al, one flattening layer, two dense layers with activation functions (LeakyReLU), and another dense layer with activation function (sigmoid) are added to a pre-trained VGG16 model to increase its performance. This model achieves an overall accuracy of 89.09% in identifying benign and malignant skin cancer [28]. Md Shahin Ali et al propose a deep convolutional neural network (DCNN) model based on a deep learning approach and compared it with transfer learning models such as AlexNet, ResNet, VGG-16, DenseNet, and MobileNet for the accurate classification between benign and malignant. Thus, the model obtained the highest 91.93% testing accuracy [29]. After several adjustments to the parameters and classification functions, Dipu Chandra Malo et al proposed VGG-16 model demonstrated a positive development and attained an accuracy of 87.6% [30].

The modern world is full of terrible diseases. Among them is skin cancer. Because skin cancer cells grow and spread like tumors in the human body. As a result, Mohammed Rakeibul Hasan et al compared several models in CNN and proposed the result that VGG16 provided the highest accuracy of 93.18% in classifying benign and malignant [31]. Additionally, Abdurrahim Yilmaz et al employed transfer learning and fine-tuning approaches and deep learning models in 3 different mobile deep learning models and 3 different batch sizes. Consequently, NASNetMobile gained the best outcome with an accuracy of 82% [32]. Furthermore, Chandran Kaushik Viknesh et al used convolutional neural networks, including AlexNet, LeNet, and VGG-16 models to gain a 91% accuracy rate after 100 compute epochs for classifying benign and malignant in ISIC datasets [33].

In conclusion, existing research on skin cancer classification demonstrates progress but faces challenges. Compared to human diagnosis, machine-learning models show lower accuracy, indicating the need for further refinement. Despite advancements, closing the gap between automated systems and human expertise remains a critical objective for enhancing diagnostic capabilities.

III. METHODOLOGY

A. The Research Implementation Procedure

12 steps of the pipeline this study suggested are depicted in Fig. 1. The following roles of the steps are displayed:

1) *Collecting dataset:* Curated meticulously by the International Skin Imaging Collaboration (ISIC), the dataset comprises 2357 high-resolution images encompassing a spectrum of skin cancer types, including Actinic keratosis, Basal cell carcinoma, Dermatofibroma, Melanoma, Nevus, Pigmented benign keratosis, Seborrheic keratosis, Squamous cell carcinoma, and Vascular lesion. Each image has undergone rigorous validation procedures to ensure accuracy and reliability. This compilation serves as an invaluable asset for scholarly investigations, providing comprehensive insights into the classification and management of skin cancer.

2) *Pre-processing image and data augmentation:* Image pre-processing techniques are crucial in refining input data for enhanced model performance. Key procedures like resizing and normalization are essential for standardizing images, and fostering consistency across datasets. Additionally, leveraging data augmentation methods such as rotation, flipping, and contrast enhancement diversifies the dataset, enriching the ability to generalize and learn from various skin lesion presentations of the model. These preprocessing steps contribute to improved accuracy and aid in the robustness and reliability of skin cancer classification models.

3) *Dividing the dataset into three categories train, validation, and test:* After being randomly chosen on an 8-1-1 scale, the datasets are organized into 8 training, 1 validation, and 1 testing folder. This ensures a balanced distribution, which is necessary for reliable model construction and assessment.

4) *Dividing dataset for scenarios:* The dataset was partitioned into four scenarios. In the initial scenario, nine classes including actinic keratosis, basal cell carcinoma, dermatofibroma, melanoma, nevus, pigmented benign keratosis, seborrheic keratosis, squamous cell carcinoma, and vascular lesion were chosen due to their distinguishability through surface observation. Following this, the second scenario comprised two classes: benign and malignant, focusing on internal characteristics. The third scenario encompassed six classes dedicated to the classification of benign conditions. Finally, the fourth scenario involved three classes specifically targeting malignant cases.

5) *Building the model:* The study employed transfer learning with the EfficientNetV2B3 model, a pre-trained convolutional neural network architecture for conducting experiments. During fine-tuning, external layers were utilized to adapt the pre-trained model to the specific data of the skin cancer classification task. The evaluation of training results indicates that the EfficientNetV2B3 model achieved excellent performance, particularly in skin cancer classification.

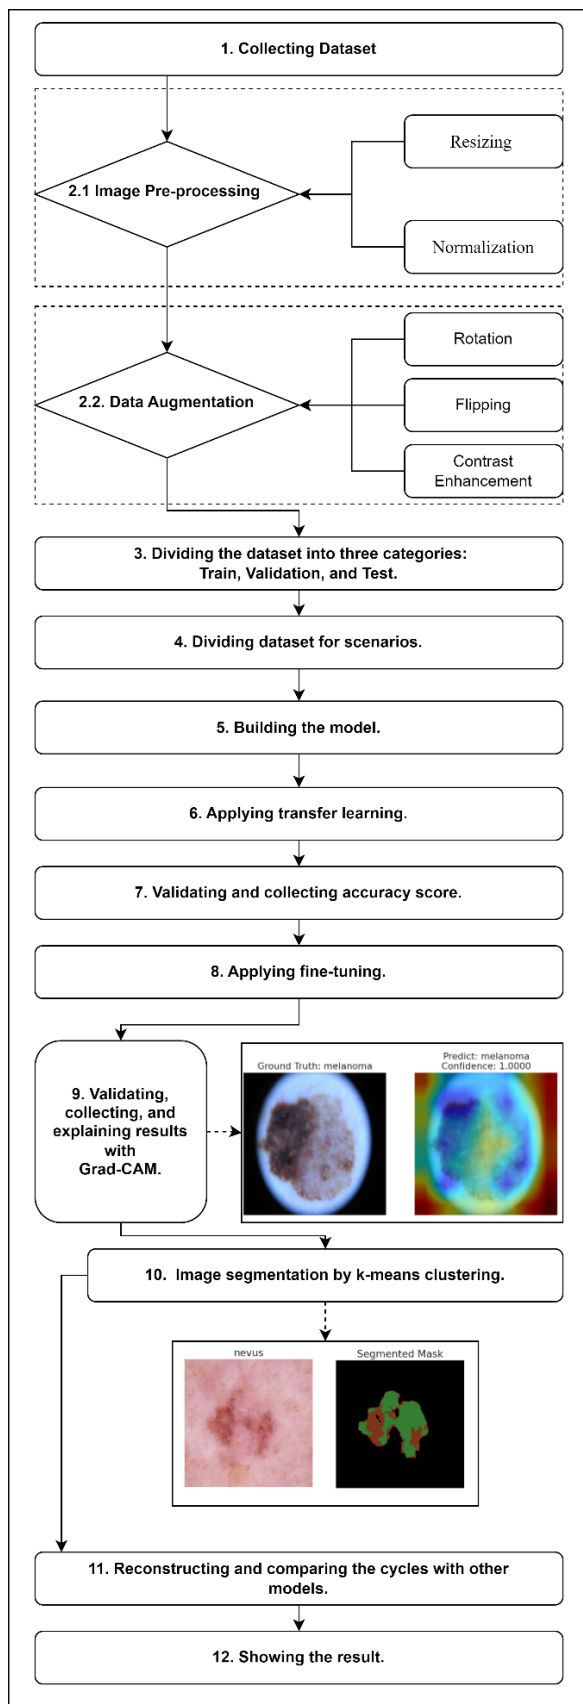

Fig. 1. The EfficientSkinCaSV2B3 framework.

6) *Applying transfer learning:* Transfer learning in skin cancer detection works by utilizing pre-trained models that have been trained on large datasets, often of general images. These models have already learned features that are useful for image recognition tasks. Instead of training a model from scratch, transfer learning involves taking these pre-trained models and adapting them to the specific task of skin cancer detection.

7) *Validating and collecting accuracy score:* Once the model finished training, its efficacy was evaluated based on its training accuracy and other performance metrics. Subsequently, the validity of the test was assessed using the initially separated testing set.

8) *Applying fine-tuning:* Fine-tuning includes taking a pre-trained model and adjusting its parameters to specialize in a specific task, such as skin cancer detection. This process optimizes the model's performance for the new task by adapting its learned features and weights. It improves accuracy without requiring extensive training on a new dataset.

9) *Validating, collecting, and explaining results with Grad-CAM:* Validating results with Grad-CAM highlights regions important for classification, and researchers gain insight into the decision-making process of the model. This method helps explain model predictions by visually indicating which parts of the image contribute most significantly. By validating, collecting, and explaining results with Grad-CAM, this research enhances transparency and confidence in the model's performance, aiding in the development of more accurate and interpretable skin cancer detection systems.

10) *Image segmentation by k-means clustering:* By iteratively assigning pixels to clusters with similar characteristics, k-means effectively separates skin lesions from healthy tissue. This method aids in identifying the boundaries of lesions, facilitating accurate diagnosis and treatment planning. By segmenting skin cancer images with k-means clustering, dermatologists can efficiently analyze lesion morphology and texture, improving the precision of diagnostic assessments and enhancing patient care.

11) *Reconstructing and comparing the cycles with other models:* To arrive at the final outcome, the process was revised and compared with another model, which included ResNet50V2, MobileNetV2, MobileNet, EffecientNetB3, and ResNet50.

12) *Showing the result:* Following established procedures, the data will be meticulously organized into tables and graphs, allowing for precise and pertinent comparisons to be made with ease, thereby enhancing the depth of analysis and understanding.

B. Pre-processing Image and Data Augmentation

In the region of classifying skin cancer using transfer learning and fine-tuning techniques, pre-processing and data augmentation play important roles in increasing the

effectiveness of the model. Pre-processing means preparing the raw data to make it suitable for training, while data augmentation aims to increase the diversity of the training data to improve the robustness and generalization of the model.

a) *Pre-processing*: Pre-processing in this research includes two key steps: resizing (1) and normalization (2). Resizing (1) is a crucial step to ensure that all input images are of the same dimensions, which is necessary for feeding them into the neural network. This step is crucial because neural networks require fixed-size inputs. Let I (1) be the original image, $I_{resized}$ (1) represents the resized image, and $D_{desired}$ (1) denotes the desired dimensions. The resizing process can be represented mathematically as:

$$I_{resized} = \text{resize}(I, D_{desired}) \quad (1)$$

Normalization (2) means scaling the pixel values of the images to a standard range, often between 0 and 1 or -1 and 1. This step helps in stabilizing and speeding up the training process by ensuring that all input features have a similar scale. Let $I_{normalized}$ (2) indicates the normalized image, and $I_{resized}$ (2) represents the resized image, min and max show the minimum and maximum pixel values respectively. The normalization process can be expressed mathematically as:

$$I_{normalized} = \frac{I_{resized} - \min(I_{resized})}{\max(I_{resized}) - \min(I_{resized})} \# \quad (2)$$

b) *Data augmentation*: Data augmentation connects creating new training samples by applying various transformations to the existing data. This technique helps in increasing the variability and diversity of the dataset, thereby reducing overfitting and improving the ability to generalize to unseen data. Three common augmentation techniques include rotation (3), flipping (4), and contrast enhancement (5).

Rotation involves rotating the images by a certain angle. Let I (3) be the original image, θ (3) presents the rotation angle, and $I_{rotated}$ (3) represent the rotated image. The rotation process can be mathematically expressed as:

$$I_{rotated} = \text{rotate}(I, \theta) \quad (3)$$

Flipping horizontally or vertically involves flipping the images along the horizontal or vertical axis. Let I (4) denote the original image, and $I_{flipped}$ (4) represent the flipped image. The flipping process can be represented as:

$$I_{flipped} = \text{flip}(I) \quad (4)$$

Contrast enhancement involves adjusting the contrast of the images to make features more discernible. Let I (5) presents the original image, and $I_{enchanced}$ (5) represent the contrast-enhanced image. The contrast enhancement process can be expressed as:

$$I_{enchanced} = \text{enchance}_{contrast}(I) \quad (5)$$

In summary, pre-processing and data augmentation are important steps in the classification of skin cancer. Pre-processing ensures that the input data is standardized and ready for training, while data augmentation increases the diversity of the dataset, leading to more robust and generalized models. By carefully applying these techniques, researchers and

practitioners can improve the performance of skin cancer classification models and contribute to more accurate diagnosis and treatment decisions.

C. Transfer Learning and Fine-tuning of EfficientNetV2B3

Transfer learning means using a pre-trained model that has been trained on a large dataset, and applying it to a different but related task, such as classifying skin cancer images. Instead of training a model from scratch, transfer learning utilizes the knowledge gained from solving one problem and applying it to a different but related problem [13][14][15]. On the other hand, fine-tuning means using a pre-trained model and further training it on a new dataset specific to the task [16][17][18]. This allows the model to adapt to the nuances of the new dataset while retaining the general knowledge learned during pre-training.

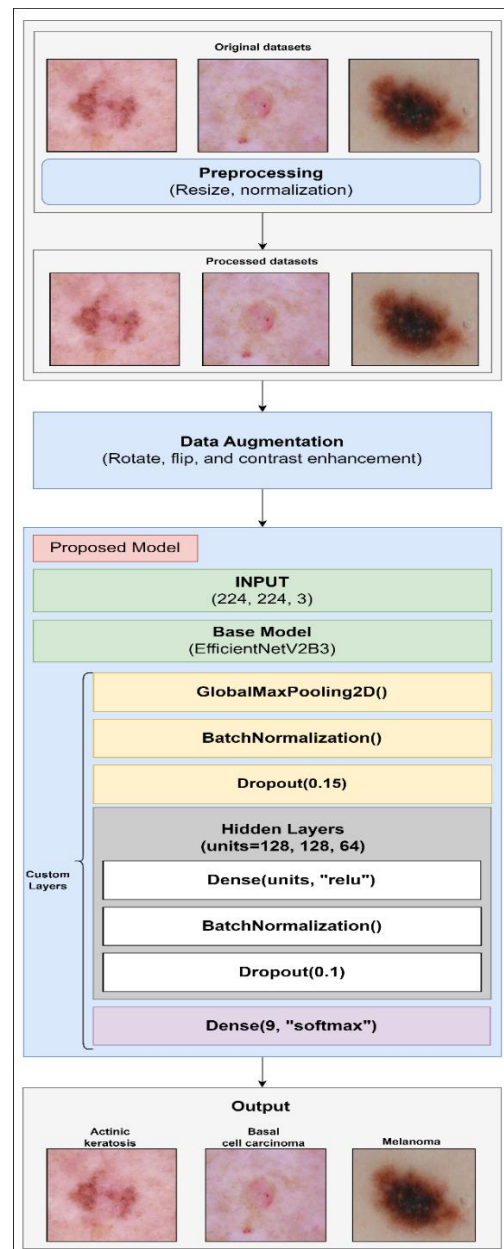

Fig. 2. Procedure of transfer learning and fine-tuning in our model with custom layers.

EfficientNetV2B3 is a convolutional neural network architecture known for its efficiency and effectiveness in image classification tasks. The additional layers mentioned in Fig. 2, such as GlobalMaxPooling2D, Batch Normalization, and Dropout (0.15). In addition, hidden layers consisting of Dense units with ReLU activation, Batch Normalization, and Dropout (0.2), followed by a Dense layer with 9 units and softmax activation, are commonly used to enhance the performance of the model.

GlobalMaxPooling2D reduces the spatial dimensions of the feature maps, summarizing them into a single vector. Batch Normalization normalizes the activations of the previous layer, helping to speed up training and improve generalization. Dropout randomly drops a fraction of neurons during training, reducing overfitting. The hidden layer with Dense units and ReLU activation adds non-linearity to the model, while Batch Normalization and Dropout further regularize it. Finally, the Dense layer with softmax activation produces probabilities for each class of skin cancer.

Combining transfer learning with fine-tuning using EfficientNetB3V2 as a base model with additional layers can lead to a powerful classifier for skin cancer images, leveraging both the general knowledge from pre-training and the specific features of the new dataset.

D. Visual Explanation with Grad-CAM

Grad-CAM is a technique used for visualizing the regions of an image that are key for the prediction of the CNN model. In the context of classifying skin cancer, Grad-CAM can help us understand which parts of the skin image are being attended to by the model when making a classification decision.

Given an image I (6) and a target class y , the final convolutional layer's feature map A (6) is extracted. The gradients of the target class score y_c (6) with respect to the feature map activations are computed using backpropagation:

$$\frac{\partial y_c}{\partial A^k} \quad (6)$$

Then, these gradients are global average pooled to obtain the neuron importance weights:

$$a_k^c = \frac{1}{Z} \sum_i \sum_j \frac{\partial y_c}{\partial A_{ij}^k} \quad (7)$$

Where Z is the normalization factor to ensure that the importance weights sum up to 1. For a particular neuron k (7), the gradients are summed across all spatial locations (i, j) (7) within the feature map A (7). Finally, the class-discriminative localization map is computed as a weighted combination of the feature maps:

$$L_{Grad-cam}^c = ReLU(\sum_k a_k^c A^k) \quad (8)$$

For each neuron activation map A^k (8) in the final convolutional layer, it is multiplied element-wise by its corresponding importance weight a_k^c (8). This operation amplifies the activations of neurons that are deemed important for predicting the target class and suppresses the activations of less relevant neurons. Next, these weighted feature maps are summed up across all neurons $\sum_k a_k^c A^k$ (8). Finally, a ReLU (Rectified Linear Unit) (8) activation function is applied to the

summed feature map to ensure that only positive values are retained

In skin cancer classification, Grad-CAM can provide insights into which parts of the skin lesion image the model is focusing on to make its decision. For example, if the model correctly classifies a malignant lesion, Grad-CAM in Fig. 3 might highlight irregular borders or asymmetric color distribution as important features. Conversely, if the model misclassifies a benign lesion, Grad-CAM might reveal that it is focusing on features that are typically indicative of malignancy, leading to further investigation and refinement of the model.

By visually interpreting the Grad-CAM heatmaps generated for different skin lesion images, dermatologists and researchers can gain valuable insights into the decision-making process of the model and potentially improve the interpretability and trustworthiness of the classification system.

Fig. 3. Visual explanation by Grad-CAM of skin cancer.

E. Image Segmentation by k-means Clustering

Fig. 4. Image segmentation in skin cancer by k-mean clustering.

Image segmentation using k-means clustering for classifying skin cancer means partitioning the image into different clusters based on pixel intensity values. K-means clustering is a popular unsupervised learning algorithm used for clustering tasks. In this research, it can help identify different regions within an image that may correspond to different types of skin lesions or healthy skin in Fig. 4.

Given an input image I of size $m \times n$, the output is to partition the image into k (9) where each cluster represents a distinct region of the image clusters (i.e., $k = 3$ for the normal surface, abnormal surface, and background). The algorithm iteratively assigns each pixel in the image to the cluster with the nearest mean value, minimizing the within-cluster sum of squares. The objective function of k-means clustering is defined as:

$$J = \sum_{i=1}^{k=3} \sum_{x_j \in C_i} \|x_j - \mu_i\|^2 \quad (9)$$

Algorithm 1 Image Segmentation using K-means Clustering with $k = 3$

- 1: **Initialization:** Randomly initialize 3 cluster centroids.
- 2: **Assignment Step:**
- 3: Assign each pixel to the nearest cluster centroid based on Euclidean distance:
- 4: **for** each pixel x_j **do**
- 5: Find the nearest centroid μ_i :
- 6: $C_i = \{x_j : \|x_j - \mu_i\| \leq \|x_j - \mu_l\|, \forall l, 1 \leq l \leq 3\}$
- 7: **end for**
- 8: **Update Step:**
- 9: Update the cluster centroids by computing the mean of all pixels assigned to each cluster:
- 10: **for** each cluster C_i **do**
- 11: $\mu_i = \frac{1}{|C_i|} \sum_{x_j \in C_i} x_j$
- 12: **end for**
- 13: **Repeat Step:** Iterate steps 2 and 3 until convergence or maximum iterations reached.
- 14: **Segmentation Step:** Assign each pixel to one of the 3 clusters, resulting in the segmentation of the image into the normal surface, abnormal surface, and background.

Fig. 5. Algorithm of skin cancer segmentation by k-means clustering.

Let $X = \{x_1, x_2, \dots, x_{mn}\}$ be the set of pixels in the image, where x_i (9) represents the i -th pixel with its corresponding feature vector. Each feature vector typically consists of color intensity values or texture features. Where C_i (9) represents the i -th cluster, μ_i (9) is the mean (centroid) of cluster C_i (9), and $\|x_j - \mu_i\|$ (9) denotes the Euclidean distance. The steps involved in image segmentation using k-means clustering for skin cancer classification are as follows in Fig. 5.

By segmenting the skin lesion regions using k-means clustering, dermatologists can efficiently analyze and classify skin cancer from dermatological images, aiding in early detection and diagnosis.

IV. EXPERIMENTS

A. Dataset and Performance Metrics

The dataset comprises 2,357 images sourced from the International Skin Imaging Collaboration (ISIC), encompassing various oncological conditions, with a focus on melanoma, a potentially fatal form of skin cancer constituting 75% of skin cancer-related deaths. This dataset is a critical resource for

developing solutions to automate melanoma detection processes, thus aiding dermatologists in early diagnosis. Fig. 6 includes images depicting malignant and benign conditions such as actinic keratosis, basal cell carcinoma, dermatofibroma, melanoma, nevus, pigmented benign keratosis, seborrheic keratosis, squamous cell carcinoma, and vascular lesions which were described in Fig. 7. the dataset offers a substantial and diverse collection for training machine learning algorithms or developing image analysis tools.

Fig. 6. Dataset about the skin diseases.

Fig. 7. The amount of data in nine classes.

To evaluate the effectiveness of classification models in classifying skin illnesses, various performance metrics are employed, among which accuracy, recall, precision, and F1 score stand as fundamental measures. These metrics provide quantitative insights into the ability of the model to correctly classify instances of malignant and benign skin lesions.

Accuracy (10) is the most intuitive metric which calculates the ratio of correctly predicted cases to the total number of cases evaluated. It is represented by the formula:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (10)$$

True positives (TP) are instances of correctly classified skin disease, true negatives (TN) are correctly classified instances of absence of skin disease, false positives (FP) are samples incorrectly classified as having skin disease, and false negatives (FN) are cases incorrectly classified as not having skin disease are all represented by the equation (10). While accuracy provides a general overview of the performance, it may not be sufficient when dealing with imbalanced datasets, such as in skin cancer classification, where benign cases often outnumber

malignant ones. Hence, recall (11) and (12) precision metrics offer additional insights.

Recall (11) also known as sensitivity or true positive rate, measures the proportion of actual positive cases that are correctly identified by the model. It is calculated as:

$$Recall = \frac{TP}{TP+FN} \tag{11}$$

On the other hand, precision (12) quantifies the model's ability to correctly identify positive cases among all cases predicted as positive. It is expressed as:

$$Precision = \frac{TP}{TP+FP} \tag{12}$$

While recall emphasizes minimizing false negatives, precision focuses on minimizing false positives. However, these metrics alone may not provide a comprehensive assessment of the model's performance. Therefore, the F1 score (13), which harmonizes precision and recall, is often utilized. The F1 score (13) is the harmonic mean of precision and recall and is given by the formula:

$$F1 = \frac{2 \times Precision \times Recall}{Precision + Recall} \tag{13}$$

In skin cancer classification, where both false positives and false negatives can have serious consequences, achieving a balance between precision and recall is crucial. Thus, the F1 score (13) serves as a consolidated measure, incorporating both precision and recall, providing a more holistic evaluation of efficacy in classifying skin lesions accurately.

B. Scenario 1: The Result of Classifying Skin Diseases Into Nine Classes: Actinic Keratosis, Basal Cell Carcinoma, Dermatofibroma, Melanoma, Nevus, Pigmented Benign Keratosis, Seborrheic Keratosis, Squamous Cell Carcinoma, and Vascular Lesion.

TABLE I. THE ACCURACY OF CLASSIFYING SKIN DISEASES INTO NINE CLASSES IN TRANSFER LEARNING AND FINE TUNING, FOR EACH DEEP LEARNING MODEL

Model	Transfer learning				
	Val acc	Test acc	Precision	Recall	F1
Our Model	63.71%	65.59%	65.73%	65.59%	64.84%
ResNet50V2	53.39%	55.27%	55.07%	55.27%	54.10%
MobileNetV2	45.17%	44.06%	44.80%	44.06%	43.77%
EfficientNetB3	63.26%	61.15%	61.18%	61.15%	60.42%
ResNet50	72.03%	69.37%	69.25%	69.37%	68.55%
MobileNet	51.83%	50.72%	50.44%	50.72%	50.06%
-	Fine tuning				
Our Model	85.13%	84.91%	85.62%	84.91%	84.68%
ResNet50V2	60.49%	57.49%	59.21%	57.49%	57.35%
MobileNetV2	56.60%	53.50%	54.78%	53.50%	53.39%
EfficientNetB3	84.91%	83.24%	83.69%	83.24%	82.86%
ResNet50	80.69%	80.58%	80.74%	80.58%	80.08%
MobileNet	58.82%	58.49%	58.52%	58.49%	57.19%

Following Table II, our model achieved an accuracy of 65.59% in transfer learning for classifying nine classes of skin diseases. To clarify, the custom model attained the second position after ResNet50, which reached 69.25%. However, our model significantly improved and reached 84.91% in test accuracy of fine-tuning phase, marking a 19.32% increase and placing it first among test models. Additionally, ResNet50 and EfficientNetB3 showed moderate improvements at 80.58% and 83.24%, respectively. Thus, this significant increase in performance led to the successful classification of skin diseases by our model.

Fig. 8. Training accuracy and validation accuracy by fine tuning of our model by classifying nine classes.

Additionally, Fig. 8 displays the accuracy of a model during both the training and validation phases. The validation accuracy demonstrates how well the model generalizes to unseen data, helping to identify overfitting or underfitting issues. Ideally, both training and validation accuracies should increase as training progresses.

Fig. 9. Training loss and validation loss by fine tuning of our model by classifying nine classes.

Besides, Fig. 9 shows the training and validation loss over epochs. The loss represents a measure of how well the model is performing: lower loss indicates better performance. The training loss depicts how well the model fits the training data, while the validation loss indicates how well the model generalizes to unseen data.

A confusion matrix in Fig. 10 is a tabular representation of predicted classes versus true classes. For classifying skin diseases, the confusion matrix can help evaluate the performance of a classification model by providing insights into the types of errors it makes. From this information, adjustments to the model or further data collection efforts can be made to improve classification accuracy.

Fig. 10. Confusion matrix in fine tuning for our model by classifying nine classes.

C. Scenario 2: The Result of Classifying Skin Diseases Into Two Classes: Benign and Malignant

Using both transfer learning and fine-tuning strategies, Table II presents a comparative examination of different deep-learning models in the classification of skin disease photos into two classes: benign and malignant. During the transfer learning phase, the ResNet50 model hit the top performance with an accuracy of 90.00%. Next to that, ResNet50V2, EffecientNetB3, and our model reached with test accuracy of 88.28%, 86.60%, and 86.20%, respectively. However, During the fine-tuning phase, the custom model successfully hit the highest top of the test models with a 94.00% accuracy score (i.e., increasing 7.8% when compared with transfer learning). As a result, the EffecientNetV2B3 model with our extra layer works effectively with both nine and two classes classifying when compared with other models although it ran unsmooth in transfer learning.

The utilization of training and validation line graphs in Fig. 11 and Fig. 12 aid in monitoring the performance of machine learning models over training epochs, ensuring optimal accuracy and minimal loss. Meanwhile, Fig. 13 facilitates a comprehensive assessment of model performance, enabling targeted improvements and insights into misclassifications for enhanced diagnostic accuracy.

TABLE II. THE ACCURACY OF CLASSIFYING SKIN DISEASES INTO TWO CLASSES IN TRANSFER LEARNING AND FINE TUNING, FOR EACH DEEP LEARNING MODEL

Model	Transfer learning				
	Val acc	Test acc	Precision	Recall	F1
Our Model	85.80%	86.20%	86.23%	86.20%	86.20%
ResNet50V2	87.03%	88.28%	88.33%	88.28%	88.28%
MobileNetV2	85.29%	85.54%	85.54%	85.54%	85.54%
EffecientNetB3	87.80%	86.60%	87.10%	86.60%	86.55%
ResNet50	89.40%	90.00%	90.06%	90.00%	90.00%
MobileNet	83.29%	81.30%	81.79%	81.30%	81.22%
-	Fine tuning				
Our Model	95.20%	94.00%	94.01%	94.00%	94.00%
ResNet50V2	88.53%	91.52%	91.53%	91.52%	91.52%
MobileNetV2	89.03%	88.78%	88.78%	88.78%	88.78%
EffecientNetB3	95.40%	92.00%	92.04%	92.00%	92.00%
ResNet50	94.00%	92.80%	91.53%	91.52%	91.52%
MobileNet	91.02%	92.02%	92.17%	92.02%	92.01%

Fig. 13. Confusion matrix in fine tuning for our model by classifying two classes.

D. Scenario 3: The Result of Classifying Skin Diseases Into Six Benign Classes: Actinic Keratosis, Dermatofibroma, Nevus, Pigmented Benign Keratosis, Seborrheic Keratosis, and Vascular Lesion.

In classifying six benign classes, Table III indicates our model working extremely well at the fine-tuning phase which reached an accuracy of 89.56%. But ResNet50 and EfficientNetB3 show a little better in performance with an accuracy of 90.40% and 91.58%. Thus, this scenario demonstrates our model still has a limit and needs to improve in the future.

TABLE III. THE ACCURACY OF CLASSIFYING SKIN DISEASES INTO SIX BENIGN CLASSES IN TRANSFER LEARNING AND FINE TUNING, FOR EACH DEEP LEARNING MODEL

Model	Transfer learning				
	Val acc	Test acc	Precision	Recall	F1
Our Model	89.06%	86.70%	87.17%	86.70%	86.53%
ResNet50V2	79.12%	76.43%	77.56%	76.43%	76.41%
MobileNetV2	67.68%	61.62%	62.86%	61.62%	61.86%
EfficientNetB3	87.04%	84.01%	84.74%	84.01%	83.46%
ResNet50	88.22%	86.36%	86.71%	86.36%	86.32%
MobileNet	73.06%	69.02%	69.44%	69.02%	68.71%
-	Fine tuning				
Our Model	92.59%	89.56%	90.08%	89.56%	89.55%
ResNet50V2	79.97%	75.59%	76.31%	75.59%	75.60%
MobileNetV2	71.38%	64.31%	64.89%	64.31%	64.09%
EfficientNetB3	93.43%	91.58%	92.08%	91.58%	91.48%
ResNet50	91.41%	90.40%	90.87%	90.40%	90.39%
MobileNet	78.28%	76.77%	76.83%	76.77%	76.27%

Furthermore, Training and validation on both accuracy and loss scores are presented in Fig. 14 and Fig. 15. Following the figures, the evaluation performance of our model presents the balance with validation accuracy achieved of 92,59 and

validation loss gained of 0.26 when the dataset is changed. Moreover, Fig. 16 is provided for evaluating, optimizing, and understanding the performance of deep learning models.

Fig. 14. Training accuracy and validation accuracy by fine tuning of our model by classifying six classes.

Fig. 15. Training loss and validation loss by fine tuning of our model by classifying six classes.

Fig. 16. Confusion matrix in fine tuning for our model by classifying six classes.

E. Scenario 4: The Result of Classifying Skin Diseases Into Three Malignant Classes: Basal Cell Carcinoma, Melanoma, and Squamous Cell Carcinoma

A successful classification is shown in Table IV when our model achieves a significant increase in test accuracy of 96.74% of fine-tuning or a growth of 13.03%. In addition, some scores including f1, recall, and prediction hit a peak. As a result, our model effectively proved that it performs better than previous models at classifying images into three classes of malignant. However, EfficientNetB3 and ResNet50 present a dramatic growth in performance (i.e., with an accuracy of 94.79% and 93.49%, respectively) when working with three classes. Besides ResNet50V2, MobileNetV2, and MobileNet rise marginally.

TABLE IV. THE ACCURACY OF CLASSIFYING SKIN DISEASES INTO THREE MALIGNANT CLASSES IN TRANSFER LEARNING AND FINE TUNING, FOR EACH DEEP LEARNING MODEL

Model	Transfer learning				
	Val acc	Test acc	Precision	Recall	F1
Our Model	87.95%	83.71%	83.74%	83.71%	83.71%
ResNet50V2	79.48%	73.94%	76.16%	73.94%	74.23%
MobileNetV2	73.29%	70.68%	71.11%	70.68%	70.85%
EffecientNetB3	89.90%	79.48%	79.67%	79.48%	79.55%
ResNet50	87.62%	85.02%	85.14%	85.02%	85.04%
MobileNet	71.66%	68.08%	69.15%	68.08%	68.30%
-	Fine tuning				
Our Model	98.70%	96.74%	96.74%	96.74%	96.74%
ResNet50V2	78.18%	71.34%	70.61%	71.34%	70.67%
MobileNetV2	73.94%	72.96%	72.99%	72.96%	72.81%
EffecientNetB3	97.07%	94.79%	94.84%	94.79%	94.79%
ResNet50	95.11%	93.49%	93.53%	93.49%	93.50%
MobileNet	77.52%	75.57%	76.51%	75.57%	75.82%

Furthermore, Fig. 17 and Fig. 18 illustrate our model's development, almost reaching the pinnacle with a surprising validation accuracy of 98.70%. Additionally, training and validation loss obtained a substantial decrease, reaching 0.06. For further information, Fig. 19 provides an overall confusion matrix for the research result.

Fig. 17. Training accuracy and validation accuracy by fine tuning of our model by classifying three classes.

V. RESULTS AND COMPARISON

A. Results Explanation

A quick look at all experiments, all of the results in our model reached an impressive performance although it still has a limit that needs to be enhanced in the future. Specifically, Scenario 1: The Result of Classifying Skin Diseases Into Nine Classes: Actinic Keratosis, Basal Cell Carcinoma, Dermatofibroma, Melanoma, Nevus, Pigmented Benign Keratosis, Seborrheic Keratosis, Squamous Cell Carcinoma, and Vascular Lesion. shows that the proposed pipeline doing a good job in classifying nine classes with an accuracy of 84.91%. However, our ambitions are higher when future research should reach a test accuracy larger than 90%. In addition, the model illustrates the limit on the performance in Scenario 3: The Result of Classifying Skin Diseases Into Six Benign Classes: Actinic Keratosis, Dermatofibroma, Nevus, Pigmented Benign Keratosis, Seborrheic Keratosis, and Vascular Lesion. when classifies six classes. This led to the way for our research to fix it in the future. Besides, the performance of our model in Scenario 2: The Result of Classifying Skin Diseases Into Two Classes: Benign and Malignant and Scenario 4: The Result of Classifying Skin Diseases Into Three Malignant Classes: Basal Cell Carcinoma, Melanoma, and Squamous Cell Carcinoma achieved the highest test accuracy and other scores when compared with test models and other state-of-the-art methods. This demonstrates the customized EfficientNetV2B3 model achieved a success in classifying skin diseases. The summary of the outcome of these scenarios is shown in Fig. 20.

Fig. 20. The result of fine-tuning of our model through four scenarios.

Furthermore, the Grad-Cam was added to visualize areas of focus in skin cancer images in Fig. 3. It highlights regions contributing to predictions and enhances model transparency for medical professionals. Additionally, K-means clustering enables detailed analysis of different regions in Fig. 4. Integrating Grad-CAM for visualization and K-means clustering for feature extraction enhances the interpretability and effectiveness of skin cancer classification models, facilitating more accurate diagnoses and treatment decisions.

B. Comparison with others State-of-the-art Methods

Comparing skin disease classification models with state-of-the-art methods in CNN is crucial for assessing performance,

identifying areas for improvement, and validating innovations. By benchmarking against existing approaches, researchers gain insights into their model's effectiveness and efficiency. Such comparisons help highlight strengths and weaknesses, guiding further optimizations. Ensuring CNN models perform competitively against state-of-the-art methods is essential for their practical utility and reliability in real-world scenarios. This process fosters the development of robust diagnostic tools, potentially enhancing healthcare outcomes. Thus, the result of this comparison is presented in Table V.

TABLE V. COMPARISON WITH OTHERS STATE-OF-THE-ART METHODS IN ISIC DATASET

Ref.	Proposed	Year	Classes	Accuracy
Ahmed Abdelhafeez et al [19]	SVNSs, DarkNet, and GoogleNet	2023	8 classes	85.74%
Maad M. Mijwil et al [21]	InceptionV3	2023	2 classes	86.90%
Solene Bechelli et al [23]	VGG16	2023	2 classes	88%
Ayesha Atta et al [27]	Customized CNN	2022	2 classes	86.23%
Vatsala Anand et al [28]	VGG16	2022	2 classes	89.09%
Dipu Chandra Malo et al [29]	VGG16	2023	2 classes	87.60%
Mohammed Rakeibul Hasan et al [31]	VGG16	2021	2 classes	93.18%
Abdurrahim Yilmaz et al [32]	NASNetMobile	2022	3 classes	82%
Chandran Kaushik Viknesh et al [33]	AlexNet, LeNet, and VGG-16	2021	2 classes	91%
Proposed model			9 classes	84.91%
			2 classes	94.00%
			6 classes	89.56%
			3 classes	96.74%

C. Limit and Future Work

While the research has reached promising results, it also shows certain limitations. Despite achieving high accuracy rates, there may still be instances of misclassification. Additionally, the dataset may not encompass all possible variations of skin diseases, necessitating ongoing expansion and diversification. Looking ahead, the study sets the stage for future endeavors aimed at refining the model and methodologies. Plans include increasing data preprocessing and incorporating advanced

visualization techniques to gain deeper insights into model performance and image characteristics. Moreover, expanding the dataset to encompass a broader spectrum of skin diseases will be a priority ensuring greater robustness and generalization of the model.

VI. CONCLUSION

The article developed a specialized model tailored to classify skin disease images for medical applications. Our custom model showcased remarkable accuracy, achieving 84.91% in classifying nine different classes of skin cancer. Notably, it also demonstrated an impressive 94.00% accuracy in discerning between malignant and benign cases. Further experiments revealed its proficiency in distinguishing between various types of benign and malignant skin diseases, with accuracies of 89.56% for six benign classes and 96.74% for three malignant classes.

One of the key techniques employed to boost the performance was transfer learning and fine-tuning. In this case, the EfficientSkinCaSV2B3 framework was proposed by adding dense and dropout layers into the EfficientNetV2B3 model while fine-tuning its parameters. As a result, this process significantly improved accuracy. In addition, Grad-Cam were used to provide insights into the model's decision-making process. Furthermore, k-means clustering was employed to segment images.

In conclusion, the research contributes to the intersection of medicine and computer science by advancing the classification and segmentation of skin disease images. Through the judicious application of transfer learning, visualization techniques like Grad-Cam, and clustering methods such as k-means, the aim is to continue improving diagnostic accuracy and ultimately enhance patient care in dermatology.

ACKNOWLEDGMENT

We express sincere appreciation to Huong Hoang Luong, Hao Van Tran, and Phuc Tan Huynh for their invaluable contributions. Their dedication and expertise have been instrumental in the success of the project. We are deeply grateful for their hard work and collaboration.

Cross-Modal Fine-Grained Interaction Fusion in Fake News Detection

Zhanbin Che, GuangBo Cui*

College of Computer, Zhongyuan University of Technology,
Zhengzhou, Henan 450007, China

Abstract—The popularity of social media has significantly increased the speed and scope of news dissemination, making the emergence and spread of fake news easier. Current fake news detection methods often ignore the correlation between text and images, leading to insufficient modal interaction and fusion. To address these issues, a cross-modal fine-grained interaction and fusion model for fake news detection is proposed. Specifically, this study addresses the correlation problem between text and image modalities by designing an interaction similarity domain. It extracts features of text word weight distribution using an attention mechanism network, guides the features of different regions of the image, and calculates the local similarity between the two. This approach analyzes positive and negative correlations between modalities at a fine-grained level, thereby strengthening the intermodal connection. Additionally, to tackle the problem of insufficient fusion of semantic feature vectors between text and images, this paper designs a fusion network that employs improved encoding and decoding using a Transformer for intermodal information fusion, achieving the final multimodal feature representation. Experimental results show that our proposed method achieves excellent performance on WeiboA and Twitter, with accuracies of 88.2% and 89%, respectively, outperforming the benchmark model in several evaluation metrics.

Keywords—Fake news detection; attention mechanism; multimodal feature fusion; local similarity

I. INTRODUCTION

With the advent of the Internet, a multitude of online social media platforms such as Twitter, Weibo, Shake, and Shutterbug have experienced unprecedented growth [1]. These platforms, characterized by their low operational costs, high efficiency, real-time capabilities, and the diverse nature of their content, have revolutionized traditional methods of information dissemination. Consequently, an increasing number of individuals are gravitating towards these platforms for information acquisition and personal life sharing, thus diversifying the modalities of information exchange. However, this evolution has inadvertently facilitated the genesis and proliferation of fake news. Online fake news not only seriously impacts the audience and weakens the authority and credibility of mainstream media institutions, but also brings risks in many aspects, including economic and political [2]. A pertinent example of the detrimental impact of misinformation is the wide dissemination of spurious content during the U.S. Capitol riots in January 2021, which obscured the factual narrative and intensified societal polarization. Hence, it is imperative to devise and implement sophisticated methods for the detection

and containment of fake news to mitigate its adverse effects on public discourse and social harmony.

In the realm of fake news detection, traditional approaches have predominantly centered around the verification processes conducted by domain experts or credible institutions [3]. While this strategy is commendably precise, its feasibility has been compromised by the contemporary influx of voluminous information and the escalation of operational costs. In response to these challenges, academia has ventured into the realm of manual feature extraction, focusing on lexical, syntactic (e.g., structure and grammar), and semantic (encompassing rhetorical techniques, thematic consistency, and emotive expressions) aspects. These extracted features are then amalgamated with established machine learning models like decision trees and support vector machines to discern deceptive information [4][5][6]. Nevertheless, this manual feature extraction method often falls short in grasping intricate semantics and complex narratives, thus limiting the overall performance of detection systems. Given the potentially severe repercussions of misinformation spread, the academic community is actively engaged in advancing the capabilities and accuracy of these detection mechanisms. Consequently, refining methodologies for the accurate detection of fake news has emerged as a focal area of research, drawing significant scholarly interest and resource investment.

The evolution of deep learning has demonstrated substantial efficacy across diverse sectors, marked by its capacity for autonomous feature detection, advanced representational learning, and extensive generalization abilities. In the context of the multifaceted nature of news content, research initiatives are increasingly focused on deriving complex intermodal representations through deep neural networks. Yet, a predominant share of current methodologies relies on leveraging pre-trained models for feature extraction, followed by a simplistic concatenation to amalgamate multimodal features, often overlooking the critical nuances in informational content across different modalities. Such unimodal feature extraction methodologies inadequately harness the comprehensive information available from varied modalities, consequently impeding the effective formation of intermodal linkages [7][8][9]. Furthermore, In complex scenarios where the image and text do not match, for example, such as the example depicted in Fig. 1, presenting a fake news report about a new fish product, where most regions of the image depict fish characteristics, while a small portion does not. The primary regions of the image align with the text, whereas the secondary regions do not. Relying solely on the overall similarity between

*Corresponding Author

the text and the image for calculations may lead to erroneous model judgments and impact its performance.

To address the aforementioned issues, this paper proposes a cross-modal fine-grained interactive fusion model for false news detection. To tackle the problem of insufficient interaction between modalities, the model employs an attention mechanism network to extract text word weight distribution features, which guide the extraction of features from different regions of the image, thereby strengthening inter-modal connections. In complex scenarios of graphical inconsistency, this study utilizes text word weight distribution features and image region features for similarity calculation, obtaining local similarity features that enable a more granular analysis of positive and negative correlations between modalities. This increases the likelihood of the model accurately extracting relevant features. Additionally, to overcome the challenge of directly merging text and image semantic feature vectors in modality fusion, a fusion network is designed to effectively integrate modal information, resulting in a comprehensive multimodal feature representation. By refining these modalities, the detection performance of the model is significantly improved. The main contributions of this paper are as follows:

- 1) An interactive similarity domain is designed to extract text word weight distribution features using a network of attention mechanisms to guide different levels of image feature extraction and to obtain fine-grained local similarity features between modalities, aiming to strengthen inter-modal connections and enhance the effectiveness of modal features.
- 2) A novel fusion network, featuring an improved Transformer dual-encoder architecture, has been devised to meticulously extract deep semantic cues from multimodal fake news content. This architecture facilitates the realization of a highly accurate multimodal feature representation, optimizing the detection and analysis of counterfeit information across varied modalities.
- 3) Through extensive comparison and ablation experiments with benchmark models such as the classical EANN, conducted on two popular multimodal fake news detection benchmark datasets, WeiboA and Twitter, the CFIF model demonstrates superior performance across most evaluation metrics.

Fig. 1. Some examples of multimodal fake news.

The rest of this paper is as follows, Section II review previous studies. Section III discusses the methodology. Section IV presents experimental setup. Section V describes the results of the experiment and discusses. Finally, conclusion presents in Section VI.

II. RELATED WORKS

Fake news detection employs news article content, social context, and external knowledge to assess news authenticity. This section introduces two primary approaches from the perspective of modality quantity: unimodal and multimodal fake news detection. In terms of effectiveness, multimodal detection demonstrates superior performance due to its richer and more comprehensive information. However, simple modality fusion and insufficient modality interaction cannot satisfy the current research needs, as the model requires features with finer granularity and greater generalizability.

A. Unimodal-based Fake News Detection

In history, news predominantly existed in textual form, encapsulating the author's perspectives, emotions, and stylistic choices. Leveraging this information, lexical, syntactic, and semantic features can be extracted. Therefore, the core of unimodal machine learning detection techniques lies in adeptly constructing and filtering features to accurately represent textual news information. Horne et al. [4] categorized text features into three main groups—style, complexity, and psychological traits—analyzing them at the word level with a Support Vector Machine (SVM) model to identify fake news. Similarly, Perez-Rosa et al. [5] manually compiled a set of text features at the word level, comprising n-grams, punctuation, psycholinguistic attributes, and generative rules, and employed the SVM model for fake news detection. However, this method faces challenges in feature interpretability and handling the variability and diversity of fake news. Castillo et al. [6] devised a suite of linguistic features, including question marks, emoticons, emotional words, and pronouns, to evaluate the credibility of tweets and detect fake news. Although manual feature extraction progress in detecting fake news, the required targets and features differ among news types, distribution channels, and dissemination routes. Consequently, extracting unique features for each news type proves to be both resource-intensive and time-consuming. Moreover, to preserve the stability and accuracy of detection outcomes, feature extraction techniques must be regularly updated and refined to accommodate evolving news events, leading to an inevitable rise in costs.

Deep learning technology has demonstrated its robustness and effectiveness across various domains. Its primary strengths lie in its capacity to autonomously extract data features, superior representation learning, and broad generalization capabilities. Ma et al. [10] explored how deep neural networks, utilizing Word-Embedding and RNN models, could represent news to enhance detection efficiency and accuracy, thus providing innovative approaches for applying deep learning in journalism. Volkova et al. [11] analyzed tweet texts using linguistic markers, social graphs, bias, subjectivity, and ethical features, employing CNN and LSTM networks to categorize information, yet this method did not enhance model performance, even with the integration of grammatical and

syntactic elements. Chawda et al. [12] highlighted the significance of context in text categorization by employing a Recurrent Convolutional Network (RCNN) with an LSTM network, achieving improved accuracy. Hansen He et al. [13] proposed a fake news detection model based on feature aggregation, employing a BiLSTM network to extract global temporal features and a CNN network for word or phrase features within a window, thus enhancing the model's generalization capability.

With the evolution of the Internet and the diversification of news forms on social media, some scholars have shifted their focus to image analysis for detecting fake news. Qi et al. [14], developed a CNN-based network to identify complex patterns in fake news images within the frequency domain and a multi-branch CNN-RNN model to extract visual features across various semantic levels in the pixel domain. They integrated these features from both domains using an attention mechanism to enhance detection. However, this method heavily depends on sophisticated visual feature extraction, posing challenges in identifying subtle alterations used by fake news creators, potentially compromising detection accuracy. Xue et al. [15] introduced the MVFNN model, comprising a visual modality module, a visual feature fusion module, a physical feature module, and an integration module, all working synergistically for fake news image detection. Zhou et al. [16] proposed a method to identify tampered regions using a dual-stream Faster R-CNN network: one stream processes RGB images to extract features like contrast differences, while the other analyzes noise inconsistencies from the model's filter layer, with both feature sets subsequently fused for detection.

Unimodal methods have advanced significantly in detecting fake news but exhibit several limitations. Primarily, they rely on a single modality, such as text or image, neglecting multi-source information, which compromises detection accuracy due to the multi-modal nature of fake news. Furthermore, these methods are susceptible to adversarial attacks, as attackers can bypass detection by crafting sophisticated false information. Additionally, unimodal methods often overlook inter-modal correlations, resulting in incomplete information capture. Lastly, they struggle with cross-modal fake news, where fake news spreads across different modalities like social media, news articles, and images.

B. Multimodal-based Fake News Detection

In response to the diversity of news and the limitations of unimodal fake news detection, researchers have shifted towards multimodal approaches. Initially, these methods separately extracted unimodal features, combining them sequentially, as illustrated in Fig. 2. Jin et al. [7] were the pioneers in proposing a multimodal fake news detection framework, utilizing the LSTM model for text and the VGG-19 model for image feature extraction, followed by sequential integration for classification. Chen et al. [8] implemented DeepFM—a blend of deep learning and factorization machines—to assess social news features, Text-CNN, and VGG-19 for textual and visual feature extraction, merging these elements to derive multimodal features for classification. Wang et al. [9] also employed Text-CNN and VGG-19 to process text and image data, respectively, but enhanced the approach by adding an event discrimination module and applying Adversarial

Neural Networks, which significantly improved detection efficacy.

While the aforementioned methods have notably enhanced the performance of fake news detection compared to unimodal approaches, they have not fully leveraged the complementary information across modalities. To address this, researchers have developed advanced methods. Zhou et al. [17] proposed a similarity-aware model that identifies discrepancies between text and images in fake news, employing Text-CNN for text feature extraction and an image2sentence model to transform image features, with classification subsequently based on the similarity between these elements. Song et al. [18] employed a combination of multiple attention mechanisms and the pre-trained VGG-19 model to selectively cross-learn information from different modalities using a bidirectional cross-attention mechanism, preserving the original feature information. This approach has proven effective across four datasets.

Fig. 2. Feature fusion diagram.

In conclusion, recent research in fake news detection has increasingly leveraged both image and text information, achieving notable success in identification. Nonetheless, these methods continue to confront various challenges:

1) *Insufficient interaction between modalities:* Most multimodal fake news detection models extract high-level features from images by designing specific models for different modal data, e.g., using pre-trained VGG models, but the lack of effective interactions before fusing these modalities restricts the ability of the model to fully utilize the information between modalities, which in turn affects the performance.

2) *Insufficient fine-grained analysis:* Most models use cosine similarity for intermodal similarity calculations, which may lead to the selection of incorrect features and the failure to capture data details, thereby affecting the model's accuracy and reliability.

3) *Feature fusion methods are comparatively simple:* Classic fake news detection models like EANN adopt a straightforward concatenation strategy, which not only increases computational complexity but also results in information redundancy. Outer product fusion may lead to excessively large dimensions of output features, thereby raising the risk of dimensional explosion.

To tackle these challenges, this study develops a multimodal fake news detection model emphasizing the

detailed analysis of modalities and their interactive fusion to improve semantic feature extraction, thereby enhancing the accuracy of fake news detection.

III. METHODOLOGY

A. Overview of the Model

In this study, we present a false news detection model cross-modal fine-grained interaction fusion. Addressing the challenges of inter-modal interaction and fine-grained analysis, the model employs a text attention mechanism to guide the generation of image features. Given BERT's [19] strong feature extraction capabilities, which may lead to local optimization of

text features, therefore, the Text-CNN [20] model's sparsity is leveraged to filter noise and capture text features at various granularities. Moreover, recognizing the varying information and importance across image regions, we introduce a weighted region division method using image segmentation technology, followed by ResNet-50 for detailed feature extraction from the image. To resolve the issue of simplistic feature fusion, the model incorporates a fusion network that integrates text and image features, further enhanced with local similarity metrics to produce the final fused features. The model comprises three core components: the feature extractor for text and images, the feature fusion mechanism, and the feature discriminator, with its comprehensive framework depicted in Fig. 3.

Fig. 3. CFIF model structural framework.

B. Multimodal Feature Extraction

1) *Textual Feature Extraction*: Text feature extraction is crucial for detecting fake news. In this study, we employed the pre-trained ROBERT [21] model for text labeling and initial feature extraction. ROBERT, an advanced variant of BERT, dynamically generates vector representations of words in various contexts, addressing the context-independence issue inherent in Word2vec [22]. Moreover, ROBERT utilizes a larger corpus and undergoes more extensive training than BERT. Additionally, it implements a dynamic masking strategy that generates a new mask pattern each time a sequence is processed, enabling the model to gradually adapt to various masking strategies and learn diverse linguistic representations. This adaptability across different domains makes ROBERT particularly suitable for our research needs.

Initially, the text $T = \{W_1, W_2, W_3, \dots, W_n\}$, is represented, where W_i denotes the i th word in T . $T' = \{[CLS], Token_{w_1}, Token_{w_2}, \dots, Token_{w_n}, [SEP]\}$ is the result of the BertTokenizer segmenting the text into tokens. Subsequently, these tokens are converted into their respective IDs and fed into the ROBERT model to generate the word vectors $V = \{V_{[CLS]}, V_{w_1}, V_{w_2}, \dots, V_{w_n}, V_{[SEP]}\}$, where V_i represents the vector for the i th word. These vectors are then input into the Text-CNN model, which employs various convolutional

kernels and sliding windows to further extract the semantic information X_t from the text, as delineated in Eqs (1)-(3).

$$T' = BertTokenizer(T) \quad (1)$$

$$V = ROBERT(T') \quad (2)$$

$$X_t = Text - CNN(V) \quad (3)$$

Besides the text being the core element of the news event, the image is also a significant modality. Therefore, it is necessary not only to input the word vector V into the *Text - CNN* to obtain a comprehensive textual representation but also to feed V and the mask into the Attention Mechanism Network to learn the distribution of word weights in the text. The aim is to update the weight distribution of the original image and adjust the weight of the semantic information in the image, as shown in Eq (4).

$$X_c = Mask_Attention(V) \quad (4)$$

2) *Visual Feature Extraction*: Given that images are inherently more intuitive than text, making them easier to understand and recall [23][24], their widespread adoption in news articles has become customary. This underscores the criticality of efficiently extracting image data in the detection of fake news. Convolutional networks, particularly VGG [25] and ResNet models, have emerged as efficient tools for

extracting these crucial image features. While the VGG model excels in extracting image features with greater accuracy, it demands higher computational resources due to its larger memory footprint and parameter count. Moreover, the VGG model is plagued by the issue of gradient vanishing. Thus, for this study, we opted for the ResNet-50 model from the ResNet family. Not only does it achieve remarkable progress in accuracy and minimize loss, but it also resolves the gradient vanishing problem, boasts a deeper network structure, and is particularly well-suited for classification tasks.

Initially, establish a data conversion pipeline to standardize the image dimensions to (224×224) and convert them to RGB three-channel style. Let C represent the original image. Then, divide the image into multiple identical regions $\{P_1, P_2, P_3, \dots, P_N\}$, where each P_i represents a portion of the image C with dimensions of (32×32), resulting in a total of 49 copies. Next, each P_i undergoes feature extraction using ResNet-50, yielding subgraph features denoted as Sub_P_i . Additionally, adjust the information of each image copy using the textual weight distribution information X_c acquired in Section III. B. 1). Finally, these adjusted features are weighted, summed, and consolidated to obtain the refined image information X_v , as depicted in Eqs (5)-(8):

$$Split(C) = P_1, P_2, P_3, \dots, P_N \quad (5)$$

$$Sub_P_i = \sigma(W \times Resnet(P_i) \pm b) \quad (6)$$

$$a_i = SoftMax(S(X_c, Sub_P_i; \Phi)) \quad (7)$$

$$X_v = \frac{\sum_{i=1}^N a_i \square Sub_P_i}{N} \quad (8)$$

where $S(, ; \Phi)$ represents a mapping network, a_i signifies the weight vector determining the significance of the subgraphs, N denotes the quantity of subgraphs, while W and b denote the parameters of the fully connected layer, and $\sigma(\square)$ denotes the activation function.

C. Local Similarity Feature Extractor

Fake news detection usually involves some complex cases where the image and text do not match. For example, if the body of an image matches the text semantically, while other parts do not, directly calculating their similarity may lead to detection errors. To cope with such problems, in this paper, we use cosine similarity to calculate the text weight distribution feature X_c and the image region feature vector Sub_P_i . The similarity of the text weight distribution feature X_c and the image region feature vector Sub_P_i , after that, the normalization process is performed to obtain the similarity contribution of each part, and finally the weighted sum is obtained to obtain the local similarity feature. As shown in Eq. (9)-(11):

$$part_similarity_i(X_c, Sub_P_i) = \frac{X_c \square Sub_P_i}{\max(\|X_c\|_2 \square \|Sub_P_i\|_2, \varepsilon)} \quad (9)$$

$$w_i = \frac{\exp(part_similarity_i)}{\sum_{i=1}^N \exp(part_similarity_i)} \quad (10)$$

$$X_d = \sum_{i=1}^N w_i \square part_similarity_i \quad (11)$$

where X_c is the word weight feature obtained in Section III. B. 1), $\square \square_2$ is the l_2 normalization, w_i is the proportion of subgraphs, X_d is a local similarity feature.

D. Multimodal Feature Fusion

Using text features X_t , image features X_v and local similarity features X_d , designing an efficient feature fusion method so as to obtain effective multimodal features is the key to realize fake news detection. If X_t , X_v and X_d are simply spliced together may lead to information redundancy as well as dimension explosion, and the outer product fusion method may lead to multimodal information asymmetry and high computational complexity.

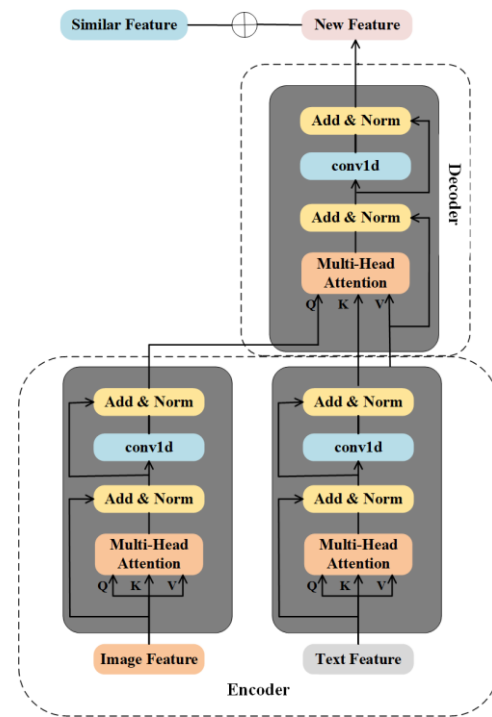

Fig. 4. Multimodal fusion framework diagram.

To avoid the above problems, the fusion network is designed in this study, firstly, the Encoder framework automatically focuses on the key features of text and images through the multi-head self-attention mechanism. At the same time, the residual network is introduced to preserve the original features, and the feed-forward network is replaced with a one-dimensional convolutional network in order to reduce the computational complexity. Second, the Decoder framework adopts the same structure as Encoder, but the difference is that its input combines text (primary) and image (secondary) features and fuses them with local similarity features to obtain

a multimodal information representation. The feature fusion apparatus, as depicted in Fig. 4 below.

1) *Encoder*: Since picture modality and text modality coding are consistent, take the text modality coding process as an example, firstly, the text modality feature vector X_t is taken as the input, and the self-attention mechanism is carried out to continuously strengthen the information of the text modality. the Query vector $Q_t = X_t W_Q$, the Key vector $K_t = X_t W_K$, and the Value vector $V_t = X_t W_V$, where $W_Q \in R^{d_t \times d_k}$, $W_K \in R^{d_t \times d_k}$, $W_V \in R^{d_t \times d_v}$, d_t is the sequence length of the text modality, d_k is the dimension of the Query vector and Key vector, and d_v is the dimension of the Value vector. In this paper, we use Multi-Head Attention (MHA) mechanism to capture different attention information within and between modalities, and utilize the subspace of the multi-head matrix to express modality information from different perspectives. Multihead Attention is multiple independent Attention computations that are then stitched together. The computational process of the Multihead Attention mechanism is shown in Eq. (12)-(13):

$$head_i = Attention(Q_t W_i^Q, K_t W_i^K, V_t W_i^V) \quad (12)$$

$$MHA(Q, K, V) = Concat(head_1, \dots, head_h) W^O \quad (13)$$

where $W_i^Q \in R^{d_t \times d_k}$, $W_i^K \in R^{d_t \times d_k}$, $W_i^V \in R^{d_t \times d_v}$, $W^O \in R^{hd_v \times d_t}$, $d_k = d_v = d_t / h$.

The feature vector X_t of the text modality undergoes the Multi-Head Attention (MHA) mechanism. The new vector representation X_t' is obtained through residual connection and layer normalization, and the computational process is depicted in Eq. (14) as follows.

$$X_t' = LayerNorm(X_t + MHA(Q_t, K_t, V_t)) \quad (14)$$

Next, X_t' is the input to the second sublayer, which consists of a one-dimensional convolutional network, residual connections, and layer normalization operations. Subsequently, the output of the Encoder can be obtained. The computational process is then depicted in Eq. (15):

$$X_t^{\square} = LayerNorm(X_t' + Conv1d(X_t')) \quad (15)$$

where $X_t^{\square} \in R^{d_t \times d_{model}}$, d_t is the sequence length of the text modal and d_{model} is the size of the Embedding.

The same operation is performed to obtain the image modal features X_v^{\square} .

2) *Decoder*: The primary function of the Decoder is to facilitate cross-modal interaction between the text modality features enhanced by the Encoder and the picture modality features in order to obtain effective multimodal features. Specifically, the operation involves inputting the text modality

feature X_t^{\square} outputted from the Encoder as Key and Value vectors, and the picture modality feature X_v^{\square} outputted from the Encoder, as the Query vector into the Decoder, collectively obtaining the mixed text and picture features MTF . The specific formula is illustrated in Eq. (16)-(19):

$$Q_v = X_v^{\square} W_Q \quad (16)$$

$$K_t = X_t^{\square} W_K \quad (17)$$

$$V_t = X_t^{\square} W_V \quad (18)$$

$$MTF = Softmax\left(\frac{Q_v K_t^T}{\sqrt{d_k}}\right) V_t \quad (19)$$

where $W_Q \in R^{d_v \times d_k}$, $W_K \in R^{d_t \times d_k}$, $W_V \in R^{d_t \times d_v}$, d_v is the sequence lengths of the visual modality, d_t is the sequence length of the textual modality, d_k is the dimension of the Query and Key vectors.

Subsequently, the textual modality feature vector X_t^{\square} and the mixture feature vector MTF are processed through residual connection and layer normalization to obtain the vector MTF' as the output of the first sublayer. The computational formula is illustrated in Eq. (20).

$$MTF' = LayerNorm(X_t^{\square} + MTF) \quad (20)$$

Next, MTF' is inputted into the second sublayer to obtain the output MTF^{\square} of the Decoder. Afterward, it is combined with X_d to yield the final modal features. The specific equations are depicted in Eq. (21)-(22):

$$MTF^{\square} = LayerNorm(MTF' + Conv1d(MTF')) \quad (21)$$

$$HMF = MTF^{\square} \oplus X_d \quad (22)$$

where $Conv1d$ is the one-dimensional convolutional layer, X_d is the local similarity feature, and HMF is the final multimodal feature.

E. Fake News Detector

In this study, we frame the fake news detection task as a binary classification problem. We input the HMF (multimodal fusion feature) from Section III. D. 2) into a neural network consisting of a single hidden layer. The dimension of this hidden layer is configured to be twice that of the multimodal features. Subsequently, a Softmax function is employed to compute the probability distribution, with the category exhibiting the highest probability serving as the ultimate classification outcome, as illustrated in Eq. (23):

$$P = Softmax(W * HMF + b) \quad (23)$$

where P represents the probability that the prediction is false, while W and b denote the parameters of the fully connected layer. The real news is labeled as 0, and the fake news is labeled as 1.

The cross-entropy loss function typically exhibits better gradient properties during optimization, allowing for more effective parameter updates during back-propagation. The gradient computation of the cross-entropy loss function involves comparisons between different classes, which guides parameter updates more effectively, leading to faster convergence to the optimal solution during training. In contrast, the gradient computation of the mean squared error function is more influenced by the errors between predicted and true values, which may sometimes lead to gradient vanishing or exploding, resulting in unstable parameter updates and affecting the training effectiveness of the model. Therefore we choose cross entropy as the loss function for this study. Hence we opt for cross entropy as the loss function in this study, as illustrated in Eq. (24).

$$H(y, p) = -\sum [y \log p + (1 - y) \log(1 - p)] \quad (24)$$

Where $H(y, p)$ represents the binary cross-entropy loss, y stands for the true category label, p signifies the predicted probability of the model, denoting the probability that the sample belongs to category 1, and \log denotes the natural logarithm.

IV. EXPERIMENTAL SETUP

A. Datasets and Evaluation Metrics

1) *Datasets*: To validate this study, two datasets, WeiboA and Twitter, were selected for experimentation. These datasets, representing both languages, were used to demonstrate the generalization ability of the model. Here:

WeiboA Dataset: Compiled by Jin et al. [26], this dataset captures all verified false news from May 2012 to January 2016 through the official microblogging rumor debunking system. Primarily consisting of articles reported by ordinary users, they undergo verification by a forensic group comprised of reputable users to determine their veracity. For authentic news text, articles verified by Xinhua News Agency, China's authoritative news agency, are utilized. The study aims to discern multimodal information; therefore, text-only posts and duplicate or low-quality images are excluded.

The Twitter dataset [27] is employed for false news discrimination and comprises a development set and a test set. Each data point in the dataset includes textual content, visual content (image/video), and relevant social context. As this study focuses on the visual modality of images, samples containing only video data are excluded. The development set is utilized as the training set, while the test set serves as the evaluation set.

The length of the text needs to be processed under the premise of ensuring that the real data is balanced with the false data. Inconsistent text length will affect the performance of the model, so longer or shorter data need to be eliminated, and finally, the data set is statistically analyzed to obtain the

statistical information of the data as shown in Table I. In addition, Fig. 5 and Fig. 6 give examples of images and corresponding texts in the datasets.

TABLE I. DISTRIBUTION OF EACH DATASET

Datasets	Originating data	Contains image data	Final data
WeiboA	9528	7723	7713
Twitter	13136	13136	13136

Fig. 5. Examples of real and fake news in the twitter dataset.

Fig. 6. Examples of real and fake news in the WeiboA Dataset.

2) *Evaluation Metrics*: The fake news detection models in this study fall under the classification model category. Evaluation metrics commonly employed to gauge model performance are presented in Eq. (25):

$$F_{\beta} = (1 + \beta) \cdot \frac{Precision \cdot Recall}{\beta^2 \cdot Precision + Recall} \quad (25)$$

where, *Precision* measures the proportion of correctly identified positive cases, while *Recall* measures the proportion of actual positive cases correctly identified. Additionally, the value of β plays a crucial role in balancing *Precision* and *Recall*. Specifically:

(1) When $\beta = 1$, the F_{β} metric equates to the F_1 metric, signifying equal importance of *Recall* and *Precision*.

(2) When $\beta > 1$, *Recall* holds more significance than *Precision*.

(3) When $\beta < 1$, *Precision* has a greater impact than *Recall*.

In this study, β is set to 1, indicating equal importance of *Recall* and *Precision*. The equation at this point is shown in (26):

$$F_1 = 2 \cdot \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \quad (26)$$

B. Experimental Details

The experiments are conducted in a Python 3.8 programming environment using the PyTorch deep learning framework to build and train the fake news detection model. To prevent overfitting and enhance model robustness, Dropout is applied in the fully-connected layer. Additionally, the EarlyStop strategy is employed during training, and Adam is utilized as the optimization function. The specific parameters are detailed in Table II.

TABLE II. DETAILS OF EXPERIMENTAL PARAMETERS

Parameters	Value
Epoch	50
Learning Rate	0.0005
Dropout	0.5
Batch Size	32
Optimizer	Adam
Window Size	[2,3,4,5]
Hidden Layer	64
Number of heads	4

C. Baseline

In order to highlight the performance of the model, this study will compare the parameters (accuracy, precision, recall, and F1 value) with the current effective model (benchmark model), and the following benchmark models are involved in this study:

- **Textual.** Utilizes various convolutional kernels to extract text features and performs simple concatenation for classification.
- **Visual.** Utilizes a pre-trained ResNet50 model to extract solely image features for classification.
- **EANN [9].** A classic multimodal fake news detection model. It utilizes a Text-CNN model to extract text features and a pre-trained VGG-19 model to extract image features. These features are concatenated and fed into the fake news detection model for classification. Additionally, it incorporates Adversarial Neural Networks for event discrimination.
- **SAFE [17].** Utilizes a Text-CNN model to extract features from text and images. It employs an image2sentence model for modal transformation of images before extracting them with the Text-CNN model. Finally, it calculates the similarity between text and images for classification.

- **MVAE [28].** Utilizes Bi-LSTM and VGG-19 for text and image feature extraction respectively. The features are then concatenated to form multimodal information, and a variational autoencoder (VAE) efficiently captures the complex structure and relationships of multimodal data for classification.
- **CARMN [18].** Employs multi-head attention and pre-trained VGG-19 to learn news text and image features. Based on a bidirectional cross-attention mechanism, it selectively learns information from one modality to another and combines the residuals to preserve the original feature information.
- **DCNN [8].** Integrates DeepFM with the FM algorithm to learn news social features. Text-CNN and VGG19 are employed to learn news text and image features, which are then concatenated to obtain multimodal features.
- **MCNN [29].** Utilizes deep learning combined with the ELA algorithm to extract image tampering features. BERT and Bi-GRU extract textual feature sequences, while ResNet50 and an Attention mechanism extract visual semantic features. These features are used to explore the consistency of multimodal content after extraction.
- **Roberta+CNN [30].** This framework integrates a specialized convolutional neural network model for image examination and a sentence transformer for textual evaluation. Characteristics derived from visual and textual sources are merged via dense layers, ultimately converging to forecast deceitful visuals.
- **BDANN [31].** Textual characteristics in BDANN are derived from a pre-trained BERT model, whereas visual traits are acquired through a pre-trained VGG-19 model. Reliance on particular events is lessened by integrating a domain classifier.

V. RESULTS AND DISCUSSION

A. Experimental Results

Table III presents the results of both the benchmark model proposed in the previous subsection and the model proposed in this study, using equivalent evaluation metrics, on the WeiboA and Twitter datasets.

Upon analyzing the experimental results from both datasets, several key conclusions emerge. Firstly, across both the WeiboA and Twitter datasets, this study's model outperforms alternative methods. This superiority suggests the effectiveness of leveraging word weight features from news text to enhance the semantic information of images, alongside employing a fine-grained approach for extracting local similarity features. Moreover, the multimodal features extracted in this study exhibit greater effectiveness compared to alternative methods.

In the WeiboA dataset, the performance of the Text-CNN model surpasses that of the Visual-CNN model. Remarkably, even when considering unimodal information, the Text-CNN model's performance closely rivals that of the EANN model utilizing multimodal information. This underscores the pivotal role of textual information in journalism, given its rich

semantic, emotional, and contextual content. The Visual-CNN model's underperformance may be attributed to subpar image quality or insufficient key information, leading to noise in the extracted features.

In the multimodal scenario, the MVAE model exhibits the poorest performance, possibly attributed to its simplistic fusion of modal information lacking information redundancy resulting from modal interaction. Additionally, the performance decline could be due to the variable autocoder's sensitivity to hyperparameters such as variable dimensions and loss functions. Conversely, the inclusion of social scenario features in the DCNN model does not improve performance; rather, it decreases it. This decline may stem from the distant relation between social scenario features and text/picture features, introducing noise and consequently impacting model performance. Similarly, the EANN model, despite incorporating an event discrimination module to leverage

adversarial learning for discarding event-specific features, faces performance challenges akin to the MVAE model due to its rudimentary fusion of model features. Moreover, completely discarding event-specific features risks losing vital event context. In contrast, the CARMN model outperforms the current model, leveraging an attention mechanism akin to this study. However, this study's comprehensive interaction of textual information with images leads to superior results compared to the CARMN model.

The model demonstrates superior performance on the Twitter dataset compared to the WeiboA dataset. This discrepancy is likely due to the smaller number of training samples available in the WeiboA dataset, resulting in insufficient information for effective learning. Consequently, the quality of multimodal features diminishes, resulting in marginally poorer performance on the Twitter dataset.

TABLE III. COMPARISON OF ACCURACY, PRECISION, RECALL, AND F1 FOR DIFFERENT BASELINES

Datasets	Method	Accuracy	Fake News			Real News		
			Precision	Recall	F ₁	Precision	Recall	F ₁
WeiboA	Textual	0.832	0.860	0.816	0.838	0.804	0.850	0.827
	Visual	0.668	0.686	0.688	0.687	0.648	0.645	0.646
	EANN	0.836	0.843	0.851	0.847	0.828	0.819	0.824
	MVAE	0.750	0.731	0.864	0.781	0.812	0.629	0.709
	CARMN	0.853	0.891	0.814	0.851	0.818	0.894	0.854
	DCNN	0.803	0.804	0.819	0.811	0.803	0.787	0.795

B. Analysis of Ablation Experiments

To validate the efficacy of each module within the model proposed in this study, we conducted ablation experiments by disassembling each module of CFIF. These experiments aimed to explore the impact of each module on performance, focusing on the following variants:

1) *CFIF-M*: The modal interaction module is removed and the extracted word weight features are not involved in the generation of visual features. It is used to validate the effectiveness of the interaction module.

2) *CFIF-L*: Removes the locally similar features and the multimodal features include only the combination of textual features and visual features. Used to validate the effectiveness of the similarity module.

3) *CFIF-F*: Remove the Modified Transformer based feature fusion module, and use the simplest way to splice the features. It is used to verify the effectiveness of modal fusion.

The results of the ablation experiments are presented in Table IV.

Based on the experimental results, it's apparent that removing any module—be it the Modal Interaction Module, Local Similarity Module, or Feature Fusion Module results in a performance decline for the model. This underscores several significant findings:

Effective modal interaction facilitates the acquisition of more efficient features, thus enhancing overall model performance. This validates the efficacy of using word weight features to guide visual feature extraction.

The incorporation of improved Transformer encoding and decoding fusion helps in reducing information redundancy and noise interference, consequently leading to performance improvements.

Precise extraction of local similarity features plays a crucial role in mitigating graphical inconsistencies. Furthermore, it highlights the effectiveness of employing word weight features for fine-grained similarity computations within subgraphs.

TABLE IV. COMPARISON OF RESULTS OF ABLATION EXPERIMENTS

Datasets	Method	Accuracy	Fake News			Real News

C. Parameter Analysis

In this study, we experiment and analyze two significant parameters with respect to two evaluation metrics: accuracy and F1 value. One parameter examines the impact of the number of

heads on model performance within the modal fusion segment utilizing the multi-head attention mechanism. The other parameter investigates the effect of the number of output hidden layer neurons on model performance. The results of these analyses are presented in Fig. 7 and Fig. 8.

Fig. 7. The effect of different numbers of head on the results.

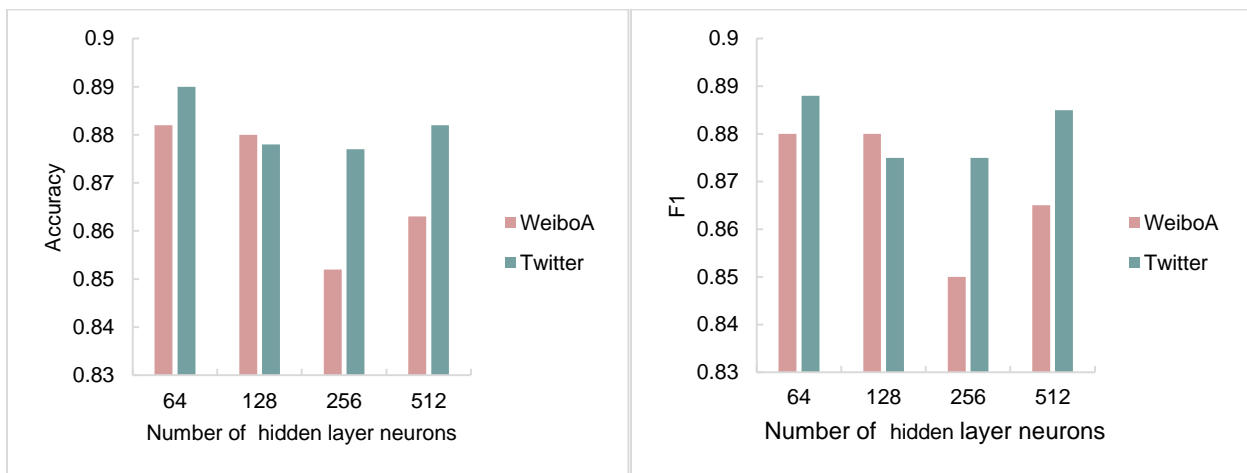

Fig. 8. The effect of different numbers of hidden layer neurons on the results.

Based on the experimental findings, it's evident that an increased number of heads doesn't necessarily yield superior results. This phenomenon arises due to various factors such as computational resource constraints, overfitting, information redundancy, and challenges in hyperparameter selection.

Firstly, augmenting the number of attention heads significantly escalates both the model's parameter count and computational complexity. This presents challenges in effective learning and optimization, particularly when resources are limited. Secondly, an excessive number of attention heads heightens the

risk of overfitting the training data, thereby reducing the model's ability to generalize to new data. Moreover, the information learned across attention heads may exhibit similarity or redundancy rather than complementarity, thereby diminishing the model's expressive power. Conversely, an increase in hidden layer neurons correlates with a decrease in accuracy due to neural networks with excessive hidden layer neurons being prone to overfitting. This abundance of nodes prolongs training time, hindering the achievement of desired outcomes. Hence, this study opts for optimal model performance, selecting four polyheads and 64 output hidden neurons as the preferred configuration.

D. Visualization Analysis

In order to further demonstrate the superiority of this paper's model, the dataset WeiboA is used as an example. The multimodal feature distribution of the test set is employed to visualize and analyze the classical fake news detection model EANN and this paper's model (CFIF). However, due to the high dimensionality of the multimodal features, it is challenging to intuitively understand the results. Therefore, the t-SNE algorithm is applied to map the multimodal feature dimensions to a two-dimensional space for visualization. The results are shown below in Fig. 9 multimodal feature distribution.

As can be seen from Fig. 9, for most of the data, both models are able to extract different features of real news and fake news, for the classification results, the more efficient the model, the closer the same class will be, and vice versa, the further away, while the EANN model is relatively loose regardless of the same class or different class spacing, which indicates that the uniqueness of the class features extracted by the model is relatively small, which is prone to lead to a lower performance of the model, and at the same time resulting in low generalization ability of the model. On the contrary, the model in this paper is able to make the news of the same category

aggregated with small intervals on a great part of the data, while the different categories have large intervals at the same time, which reflects the importance of fine-grained modal interactions and good modal fusion.

Fig. 9. Multimodal feature distribution.

E. Fault Case Study

This subsection delves into the Chinese dataset WeiboA, with a focus on instances of model classification errors. Through an in-depth analysis of typical samples, we aim to discern the underlying reasons for these errors. In Fig. 10, false news is erroneously classified as true news. The textual content narrates activities related to visiting and traveling in Australia, accompanied by an image depicting similar activities. The convergence of textual and visual content makes it challenging to discern the veracity of the news solely based on internal cues. Consequently, our model identifies it as real news. In Fig. 11, real news is misclassified as false news. The textual content describes a father's affection for his son, whereas the accompanying image merely portrays an elderly father cooking. This discrepancy between the textual and visual elements results in a lack of coherence, leading our model to classify it as false news.

Fig. 10. Fake news judged to be true.

Fig. 11. True news judged to be fake.

VI. CONCLUSION

The proliferation of social media in recent years has facilitated easier access to information; however, it has also become a fertile ground for the propagation of false news. To enhance the efficacy of fake news detection, this paper proposes a cross-modal fine-grained interactive fusion model, primarily

addressing the current issues of insufficient interaction between modalities and overly simplistic modality fusion in some detection models. This model achieves effective interaction by employing word weight features to guide the generation of visual features. Subsequently, it utilizes these features to compute fine-grained similarity across different regions of the

image, obtaining local similarity features. Finally, a fusion network is employed to integrate modal information, effectively mitigating the challenges associated with false news detection. Comparison experiments and ablation studies conducted on WeiboA and Twitter datasets demonstrate the efficacy of the proposed model compared to several benchmark models such as EANN.

Furthermore, the fine-grained fake news detection model proposed in this paper has some limitations, such as utilizing only part of the information within the dataset. Future studies can incorporate the remaining information as well as external data, such as the dissemination path of the news, user characteristics, and a priori characteristics combined with external information. Additionally, given the continuous evolution of technology and the sophistication of tampering methods, a significant proportion of fake news content falls into a gray area, blending elements of truth and falsehood. Therefore, future efforts should avoid oversimplifying the fake news detection task as a binary classification problem and instead develop it into a multi-classification challenge.

A Stepwise Discriminant Analysis and FBCSP Feature Selection Strategy for EEG MI Recognition

YingHui Meng, YaRu Su, Duan Li, JiaoFen Nan, YongQuan Xia

School of Computer and Communication Engineering, Zhengzhou University of Light Industry,
Zhengzhou, Henan P. R. China

Abstract—Accurate decoding of brain intentions is a pivotal technology within Brain-Computer Interface (BCI) systems that rely on Motor Imagery (MI). The effective extraction of information features plays a critical role in the precise decoding of these brain intentions. However, there exists significant individual and environmental variability in signals, and the sensitivity of EEG signals from different subjects also varies, imposing higher demands on both feature exploration and accurate decoding. To address these challenges, we employ adaptive sliding time windows and a stepwise discriminant analysis strategy to selectively extract features obtained through the Filter Bank Common Spatial Pattern (FBCSP). This entails the identification of an optimal feature combination tailored to specific patients, thereby mitigating individual differences and environmental variations. Initially, adaptive sliding time windows are applied to segment electroencephalogram (EEG) data for different subjects, followed by FBCSP for feature extraction. Subsequently, a stepwise discriminant analysis (SDA) incorporating prior knowledge is employed for optimal feature selection, effectively and adaptively identifying the best feature combination for specific subjects. The proposed method is evaluated using two publicly available datasets, the EEG recognition accuracy for Dataset A is 98.47%, and for Dataset B, it is 95.2%. In comparison to current publicly reported research results (utilizing Power Spectral Density (PSD) + Support Vector Machine (SVM) methods) for Dataset A, the proposed method improves MI recognition accuracy by 25.37%. For Dataset B, compared to current publicly reported results (FBCNet method), the proposed method improves MI recognition accuracy by 26.4%. The experimental results underscore the method's broad applicability, scalability, and substantial value for promotion and application.

Keywords—Stepwise discriminant analysis; electroencephalogram; motor imagery; sliding time window; filter bank common spatial pattern

I. INTRODUCTION

Brain-computer interface (BCI) technology has witnessed rapid development, injecting new vitality into the fields of neuroscience and engineering [1, 2]. Among various BCI applications, the interpretation of electroencephalogram (EEG) signals through Motor Imagery (MI) has emerged as a notable research focus [3-12]. MI-EEG technology enables individuals to control external devices through brain activity, holding tremendous promise in neuroscience, medical rehabilitation, and intelligent assistive devices. It offers a potential pathway for individuals who have lost motor capabilities due to illness or injury [13-16]. This technology finds widespread application in neurorehabilitation, particularly for patients recovering from conditions such as stroke [17] and spinal cord injuries [18].

Through MI-EEG, patients can control external devices by imagining movements, promoting the re-adaptation and repair of damaged neural systems. Additionally, MI-EEG plays a crucial role in controlling smart assistive devices, providing a more flexible and independent lifestyle for individuals with disabilities [19 -22].

Internationally and domestically, research teams have made substantial progress in EEG signal studies, delving into BCI systems' five processes: signal acquisition, signal preprocessing, feature extraction, feature classification, and external device control [23-25]. Feature extraction is a critical aspect of MI recognition, and common methods in MI-BCI include Common Spatial Pattern (CSP) [26], Power Spectral Density (PSD) [27], and wavelet feature extraction algorithms [28]. Wu et al. [29] proposed a PSD-based frequency band pre-determination method to effectively extract EEG signal features related to motion imagery when wearing exoskeletons. The CSP was then applied to extract features from the EEG's highest energy frequency band. Zheng et al. [30] introduced a new Regularized Common Spatial Patterns (RCSP) algorithm based on traditional CSP to handle small-sample EEG data. RCSP adjusts the values of two regularization parameters, introducing a certain degree of correlation among experimental data to reduce errors caused by individual differences. Results from testing on public datasets showed that RCSP algorithm classification outperformed traditional CSP by approximately 8%. Wei et al. [31] used the Filter Bank Common Spatial Pattern (FBCSP) with a one-to-one multi-class extension to classify four classes of MI-EEG (BCI Competition IV Datasets 2a). A majority voting strategy was applied to the selected individual classifiers, yielding a considerable classification accuracy of 68.52%. Siviero et al. [32] combined multi-channel empirical wavelet transform representation with Scattering Convolutional Networks (SCN) to effectively decode brain activity and extract MI-based BCI's relevant wave patterns. The highest average accuracy in the classification of tongue and left-hand MI tasks reached 82.05%. Jiang et al. [33] redefined regularized spatial or temporal filters through a reweighting technique, iterating them as CSP problems. Experimental validation on two sets of BCI competition motor imagery EEG data demonstrated the algorithm's effectiveness, achieving an average accuracy of 85%. These studies primarily focus on feature extraction, highlighting the crucial role of this process in final result performance. Among various feature extraction methods, Filter Bank Common Spatial Pattern (FBCSP) stands out due to its comprehensive consideration of signal frequency information compared to traditional CSP and RCSP methods. This method exhibits superior performance in handling complex tasks and

has gained wide usage in the BCI field, especially in applications demanding high levels of personalization and accuracy. Consequently, the FBCSP algorithm was selected as the EEG feature extraction method in this study.

Due to factors such as individual differences in reaction time, physical state, and environment, EEG data exhibit variability in terms of duration, space, frequency bands, etc. In recent years, researchers have proposed various sliding window techniques to improve classification accuracy. Gaur et al. [34] introduced two sliding window techniques, one calculating the longest continuous repetition of all sliding window prediction sequences, and the other computing patterns in all sliding window prediction sequences. CSP was used for feature extraction, and linear discriminant analysis was employed for classification in each time window, resulting in an overall classification accuracy of approximately 80%. Phunruangsakao et al. [35] presented two mutual information-based adaptive algorithms: the sliding window adaptive algorithm and the genetic algorithm adaptive algorithm. Both algorithms continuously adjust the starting point and length of the time window using optimized reference signals and mutual information analysis. The algorithms optimize reference signals based on mutual information analysis and performance evaluation. Finally, feature extraction and classification algorithms were applied to assess the performance of the sliding window adaptive algorithm and genetic algorithm adaptive algorithm. The results demonstrated that these adaptive algorithms improved traditional methods, enhancing classification accuracy by 6.00% and 6.37%, respectively. Shin et al. [36] performed feature extraction on the temporal process of EEG signals using a moving time window. Linear discriminant analysis (LDA) was used for classification, achieving a classification accuracy of 65.6% for MI-EEG. To enhance classification accuracy, P. Saideepthi et al. [37] introduced a post-processing step based on the longest continuous repetition of sliding windows using EEGNet as a decoding basis. The average classification accuracy reached 77%. However, individual differences in brain signals and susceptibility to environmental influences pose challenges. Moreover, different components extracted from features contribute differently to MI recognition for different subjects. The use of generic feature extraction algorithms may not effectively select high-quality feature components. The challenge is how to adaptively extract common features with significant contributions from specific subjects in effective data, enhancing the generalization of BCI systems.

Q. Dong et al. [38] utilized an electrode selection algorithm based on Independent Component Analysis (ICA). Time-domain features of the selected P300 electrode were extracted, and stepwise linear discriminant analysis was applied for classification, achieving the best recognition rate of 80.2% and an average recognition rate of 74.4% for nine participants. This validated the feasibility of spatial auditory-evoked P300 experiments and the effectiveness of the algorithm. Numerous studies on stepwise discriminant analysis suggest its feasibility in feature selection. However, the MI recognition accuracy of the proposed algorithm remains relatively low. Pane et al. [39] proposed a channel selection method for emotion recognition in EEG signals based on Stepwise discriminant analysis (SDA).

SDA is an extension of discriminant analysis statistical tools, incorporating stepwise techniques. In their study, data were obtained from a public emotional EEG dataset using EEG devices with 62 channels targeting three target emotions (positive, negative, and neutral). To handle high-dimensional data in EEG signals, differential entropy features were extracted from five frequency bands: δ , θ , α , β , and γ . SDA's selection criterion was based on Wilks Lambda scores to obtain the best channels. To measure the performance of the selected channels, EEG signal feature vectors were fed into an LDA classifier. In experiments, several scenarios with different numbers of selected channels, such as 3, 4, 7, and 15 channels, were considered. In the case of 15 channels, the highest accuracy of 99.85% was achieved across all frequency band combinations.

To overcome the impact of individual differences in EEG data in terms of time, space, and frequency bands caused by factors such as subjects' reaction time, physical state, and environment, this study employed an optimized sliding time window algorithm combined with a stepwise discriminant feature selection algorithm. This algorithm not only expands the data volume and improves accuracy but also enables optimal feature selection for specific patients. To optimize the results of stepwise discriminant feature selection, this study introduced a method of incorporating prior knowledge, allowing the algorithm to adaptively select the optimal features applicable to specific individuals. For the FBCSP features of EEG signals, we adopted an adaptive feature selection method, and the experiments demonstrated that this method exhibits robust adaptability in handling EEG data features while maintaining strong generalization capabilities. The structure of the article is arranged as follows: Section II provides a detailed introduction to the data and methods, including the dataset used, the overall framework of the algorithm, and the feature extraction method. Section III presents the experimental results, while Section IV conducts an in-depth discussion of the proposed method. Section V draws the final conclusion.

II. DATA AND METHODS

A. Dataset Introduction

1) *Dataset A*: Dataset A [36] consists of EEG data from 29 healthy participants, including 28 right-handed individuals and 1 left-handed individual, with a gender distribution of 14 males and 15 females. The average age was 28.5 ± 3.7 years (mean \pm standard deviation). EEG data were recorded using a BrainAmp EEG amplifier with 30 active electrodes, connected to mastoid reference, and sampled at 1000 Hz. Fourteen sources and sixteen detectors generated 36 physiological channels, placed in frontal areas (9 channels around Fp1, Fp2, and Fpz), motor areas (12 channels around C3 and C4), and visual areas (3 channels around Oz). The inter-electrode distance was 30 mm.

The EEG dataset includes both Motor Imagery (MI) and Mental Arithmetic (MA) tasks. This paper focuses on the MI dataset, which comprises three sessions of left and right-hand motor imagery tasks. Each session consists of 20 trials for each condition, resulting in a total of 60 trials per participant across the three sessions. Each session begins with a one-minute pre-experiment resting period, followed by 20 repetitions of the given task, and concludes with a one-minute post-experiment

resting period. Each task involves a two-second visual cue (indicating right or left-hand movement), a 10-second task period, and a 15-17-second rest period. The participants are instructed to imagine grasping movements of their left or right hand at a rate of 1 Hz. Further details about the dataset can be found in the reference [36].

2) *Dataset B*: Dataset B [40] involves experiments with 25 healthy participants without prior Motor Imagery (MI)-based Brain-Computer Interface (BCI) experience, aged between 20 and 24 years, with 12 females. The experiment used a 32-channel solid electrode cap with Ag/AgCl, ensuring high current density, good anti-interference, and low impedance. The amplifier supported wireless transmission and real-time impedance monitoring, maintaining electrode impedance below 20 K Ω throughout the 250 Hz sampling. Data were stored in microvolts (uV). Bad segments were removed before preprocessing and automatically flagged by EEGLAB for amplitude exceeding 100 uV. Additional manual inspection by two experienced researchers determined the presence of bad segments. The four-second EEG data for MI tasks were saved for further processing. The sampling frequency was 250 Hz, providing a total time sample of 1000 for each trial. Baseline removal and bandpass filtering between 0.5-40 Hz using Finite Impulse Response (FIR) filters were applied. Some trials were lost due to the removal of bad segments in certain sessions.

Before the experiment, participants received detailed explanations of the experimental methods and procedures, ensuring a thorough understanding. Experiment supervisors oversaw the process to guarantee reliability. The experiment took place in a spacious enclosed laboratory, where participants sat in a chair one meter away from a 15-inch LCD monitor. Each trial started with a fixed crosshair in the center of the monitor, signaling the upcoming task to the participant. When a left or right-hand movement was displayed on the monitor, participants were prompted to imagine the next movement. Trials consisted of 100 repetitions, with four interruption periods during the experiment. Participants imagined movements based on visual and auditory cues, maintaining rest and stillness to preserve physical and mental states and ensure high signal quality. The dataset is available for free download on Figshare 17 and is organized according to EEG-BIDS 28, an extension of the EEG Brain Imaging Data Structure. Various access methods, such as IEEE P273129, FAIR 30, and EEG-BIDS, are provided. IEEE P2731 defines a complete storage system, including decoding algorithms, preprocessing, feature extraction, and classification. This system comprehensively describes the generation, processing, and utilization of EEG datasets.

Datasets A and B are representative EEG data in the field of brain computer interfaces, which have been validated by a large number of researchers and have higher reference value.

B. Algorithm Framework

This study conducts analysis and validation on two EEG datasets, and the algorithm framework is depicted in Fig. 1. The algorithm consists of four modules:

1) *Raw data input and preprocessing*: For EEG data from Dataset A, it undergoes downsampling to 200 Hz. Filtering is applied with a passband of 0.5 - 50 Hz using a fourth-order Chebyshev II filter. Baseline correction is performed by subtracting the average value between -3 seconds and 0 seconds from the segmented windows in the range of -10 seconds to 25 seconds. EEG data from Dataset B, having undergone preprocessing in the original data, is not detailed in this section.

2) *Sliding time windows*: For EEG data from Dataset A, after obtaining the necessary data, a sliding time window (window size: 3 s, step size: 1 s) is applied, dividing the data into 33 windows. Each window undergoes individual feature extraction. EEG data from Dataset B, after obtaining the necessary data, is subjected to a sliding time window (window size: 3 s, step size: 2 s), resulting in 49 windows. Similar to Dataset A, each window undergoes individual feature extraction.

3) *Feature extraction*: For EEG data from both Dataset A and Dataset B, three methods are employed for feature extraction: Common Spatial Patterns (CSP), Regularized Common Spatial Patterns (RCSP), and Filter Bank Common Spatial Patterns (FBCSP). Through experimentation, CSP demonstrates superior performance on Dataset A, while FBCSP outperforms other methods on Dataset B. In general, FBCSP, considering signal frequency information comprehensively, exhibits better performance in handling complex tasks. Given its widespread use in brain-computer interface applications, especially in scenarios requiring high personalization and accuracy, FBCSP is ultimately selected as the EEG feature extraction method.

4) *Optimal feature selection and result prediction*: For each window of EEG data from Dataset A and Dataset B after feature extraction, the features are split into training (70%) and testing (30%) sets. The training set undergoes normalization and stepwise discrimination to obtain an optimized new feature set, used to train a Linear Discriminant Analysis (LDA) classifier. During online testing, the optimal feature sequence index obtained through cross-validation based on the Stepwise discriminant analysis (SDA) algorithm is used to select feature components for testing data. The testing data is filtered based on the data index obtained from SDA in the training set and serves as the source signal. The LDA classifier calculates the classification accuracy.

C. Feature Selection Strategies Based on FBCSP and SDA

In brain-computer interface motor imagery tasks, significant variations exist in individuals' reaction speeds and response times. These differences lead to inconsistent timing when subjects receive commands and perform corresponding actions, impacting the data and potentially introducing errors in data processing. To address this issue, the sliding time window method is employed to effectively mitigate prediction result biases arising from inconsistent reaction times, thereby enhancing the dataset's volume and accuracy [41]. For Dataset A, EEG samples for each subject are sampled from -10 to 25 seconds with a sliding window of 3 seconds and a step size of 1

second, resulting in 33 windows. For Dataset B, a sliding window of three seconds with a step size of two seconds is applied, yielding 49 windows.

For the EEG signals of the two datasets, this study experimented with three feature extraction methods: Common Spatial Patterns (CSP), Regularized Common Spatial Patterns (RCSP), and Filter Bank Common Spatial Patterns (FBCSP).

CSP is a feature extraction method designed for EEG or other biological signals to find projection directions that maximize the difference between two classes while minimizing the variance within the same class. By identifying the optimal projection direction in different spatial filters, CSP enhances differences between different classes and effectively increases the classification accuracy of task-related information in brain signals.

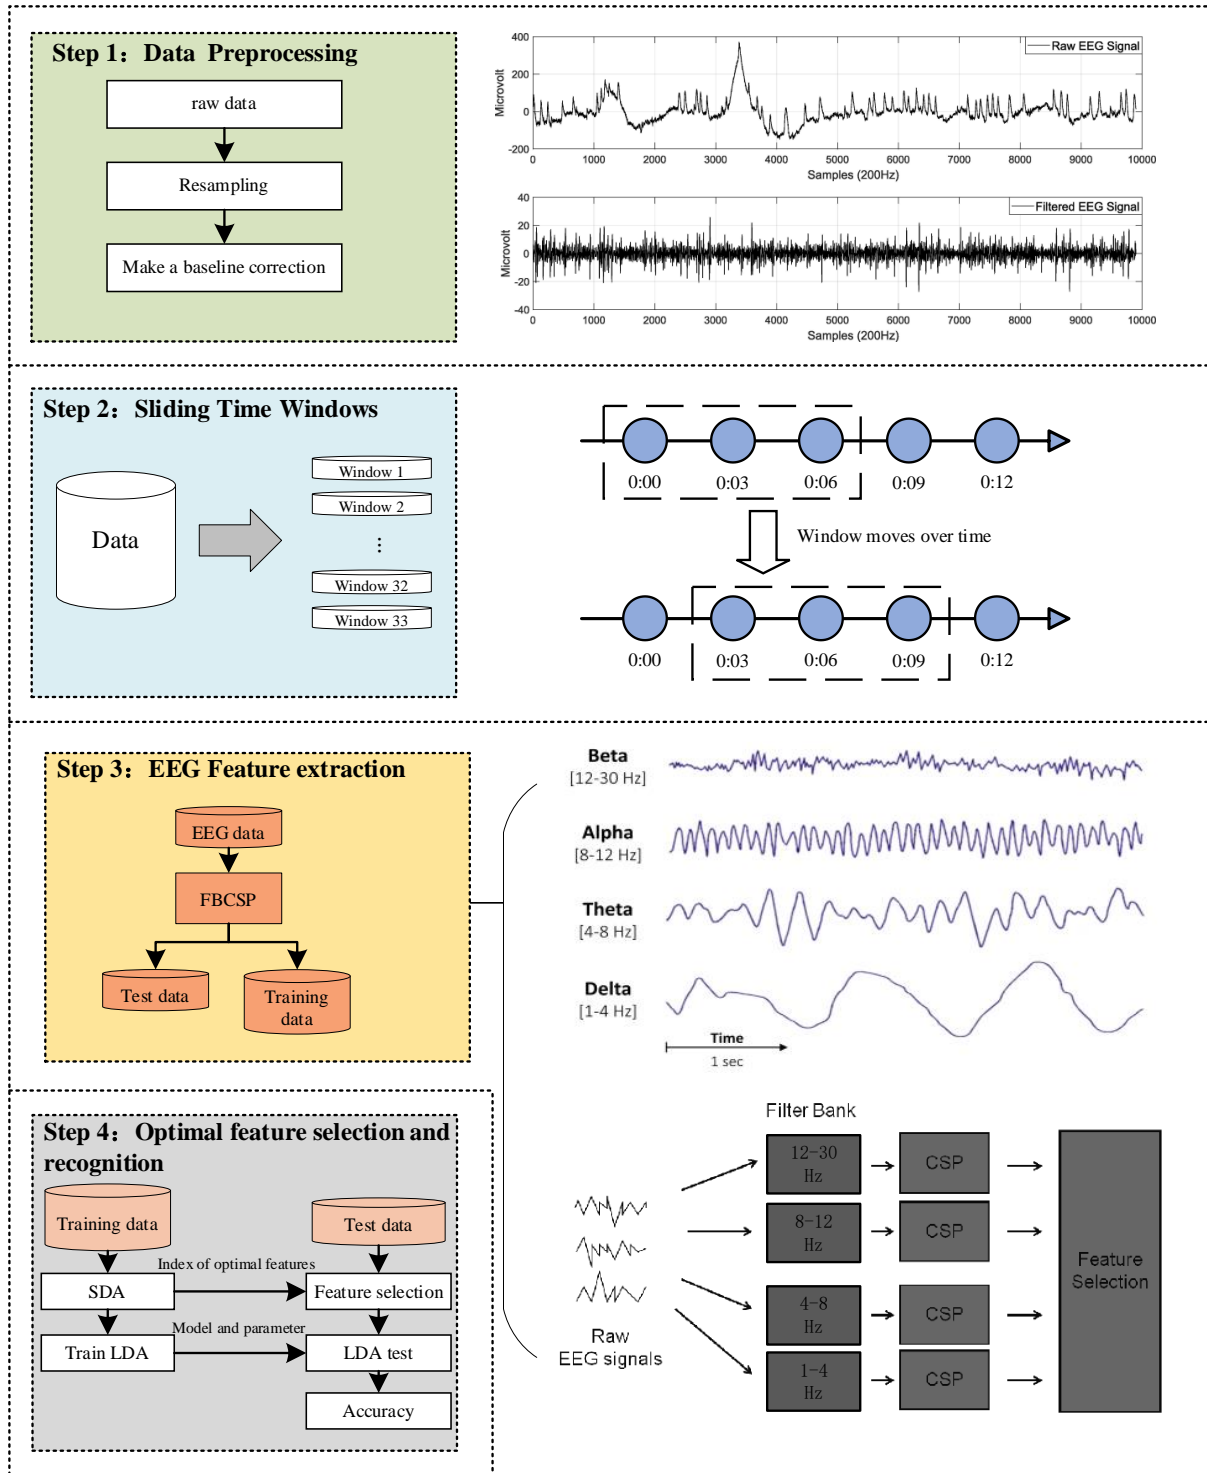

Fig. 1. Algorithm framework diagram.

The objectives of CSP are to find a projection matrix W , such that the covariance of the projected signals is diagonalized in the new coordinate system. This can be achieved by solving the following generalized eigenvalue problem:

$$S = W^T R_1 W = Q_1 \quad (1)$$

$$S = W^T R_2 W = Q_2 \quad (2)$$

Here, S is the total covariance matrix, Q_1 and Q_2 are diagonal matrices containing generalized eigenvalues. By solving this problem, the obtained projection matrix W can be used to project EEG signals into the new coordinate system.

RCSP is an improvement upon CSP, introducing a regularization term to enhance the model's generalization performance and reduce overfitting. RCSP is commonly used for handling high-dimensional data, mitigating the overfitting issue associated with limited samples. By incorporating regularization, RCSP can better adapt to new data, thereby improving the model's robustness. Formulas (3) and (4) are provided below, where I is the regularization parameter, and α is the identity matrix. Regularization contributes to enhancing the model's generalization performance.

$$S = W^T (R_1 + \alpha I) W = Q_1 \quad (3)$$

$$S = W^T (R_2 + \alpha I) W = Q_2 \quad (4)$$

FBCSP decomposes the signal into multiple frequency bands and applies CSP to each band individually. Finally, it consolidates the features extracted from different frequency bands for the ultimate classification. FBCSP takes into account the frequency information of the signal, allowing for a more comprehensive capture of features in brain signals, especially effective in complex BCI applications involving various movements or tasks. Formulas (5) and (6) are presented below, where W_i represents the corresponding CSP projection matrix. Thus, the objective function for FBCSP can be expressed as follows, where R_{1i} and R_{2i} are the covariance matrices for the two classes within its frequency band:

$$S_i = W_i^T R_{1i} W_i = Q_{1i} \quad (5)$$

$$S_i = W_i^T R_{2i} W_i = Q_{2i} \quad (6)$$

The three feature extraction methods produce different effects on different datasets. RCSP is an extension of CSP, introducing regularization to address the issue of small sample data and improve the algorithm's generalization ability. FBCSP introduces frequency domain decomposition, breaking down the signal using a filter bank to better handle information in different frequency bands. RCSP focuses primarily on regularization for scenarios with limited samples, while FBCSP concentrates on frequency domain decomposition to enhance performance through operations in the frequency domain. Eventually, these three methods were chosen as feature extraction techniques. In summary, FBCSP, compared to traditional CSP and RCSP methods, comprehensively considers the frequency information of signals, exhibiting better performance in handling complex tasks. This method is widely used in the field of brain-computer interfaces, particularly in scenarios requiring high personalization and accuracy. In this paper, the FBCSP algorithm is selected as the EEG feature extraction method.

Through multiple experiments, it was observed that different feature variables exhibit varying sensitivity, with different dimensions, units, and ranges, leading to the neglect of certain indicators. This affects the performance of subsequent stepwise discriminant analysis. To address this issue, the feature set underwent normalization. Since min-max normalization enables data from different ranges to be calculated within the same range, it facilitates easier processing and comparison, enhancing computational efficiency. Additionally, normalization helps avoid proportional relationships between attribute values, reducing the impact of attribute value magnitudes on the final result and mitigating algorithm bias. Therefore, max-min normalization was selected based on the feature set.

After normalization, the feature data is within the same order of magnitude, significantly improving comparability among indicators. Despite being in the same order of magnitude, there are still significant differences in the statistical significance of features. To resolve this, the optimal feature subset containing all relevant features was determined, and irrelevant features were removed. The stepwise discriminant analysis (SDA) algorithm was employed to further process the feature data. SDA is a comprehensive method that combines forward introduction and backward elimination. It reduces multicollinearity by removing unimportant variables highly correlated with other variables [42, 43]. During the experiment, the SDA [44] algorithm introduced variables into the model one by one. After introducing each explanatory variable, an F-test was conducted, and the already selected explanatory variables were individually subjected to t-tests. If an originally introduced explanatory variable became insignificant due to the subsequent introduction of other explanatory variables, it was removed to ensure that the regression equation contained only significant variables before each new variable introduction. This process was repeated until there were no significant explanatory variables to include in the regression equation and no insignificant explanatory variables to remove, ensuring that the final set of explanatory variables obtained was optimal. Selecting the optimal set of variables enhances the accuracy of the results. Formula (7) is as follows, where Y is the target variable, X_i is the added independent variable, and β_i is the corresponding regression coefficient.

$$Y = \beta_0 + \beta_1 X_1 + \dots + \beta_i X_i + \dots + \beta_k X_k + \epsilon \quad (7)$$

III. EXPERIMENTAL RESULTS

A. Comparison of Different Feature Extraction Methods for Specific Subjects

CSP and its variants, such as FBCSP and RCSP, exhibit distinct effects in feature extraction, and this variability is notable across individual EEG datasets. To select the optimal spatial feature extraction algorithm, experiments, and parameter selections were conducted on two publicly available datasets, evaluating CSP, RCSP and FBCSP. The datasets were initially segmented using sliding time windows, followed by feature extraction using CSP, RCSP, and FBCSP. Finally, the prediction accuracy of 30% of the blind source signals was assessed using an LDA classifier. To investigate the optimal feature extraction results, the experiments were conducted with different feature dimensions, $m=2\sim 8$. The experimental results are illustrated in Fig. 2.

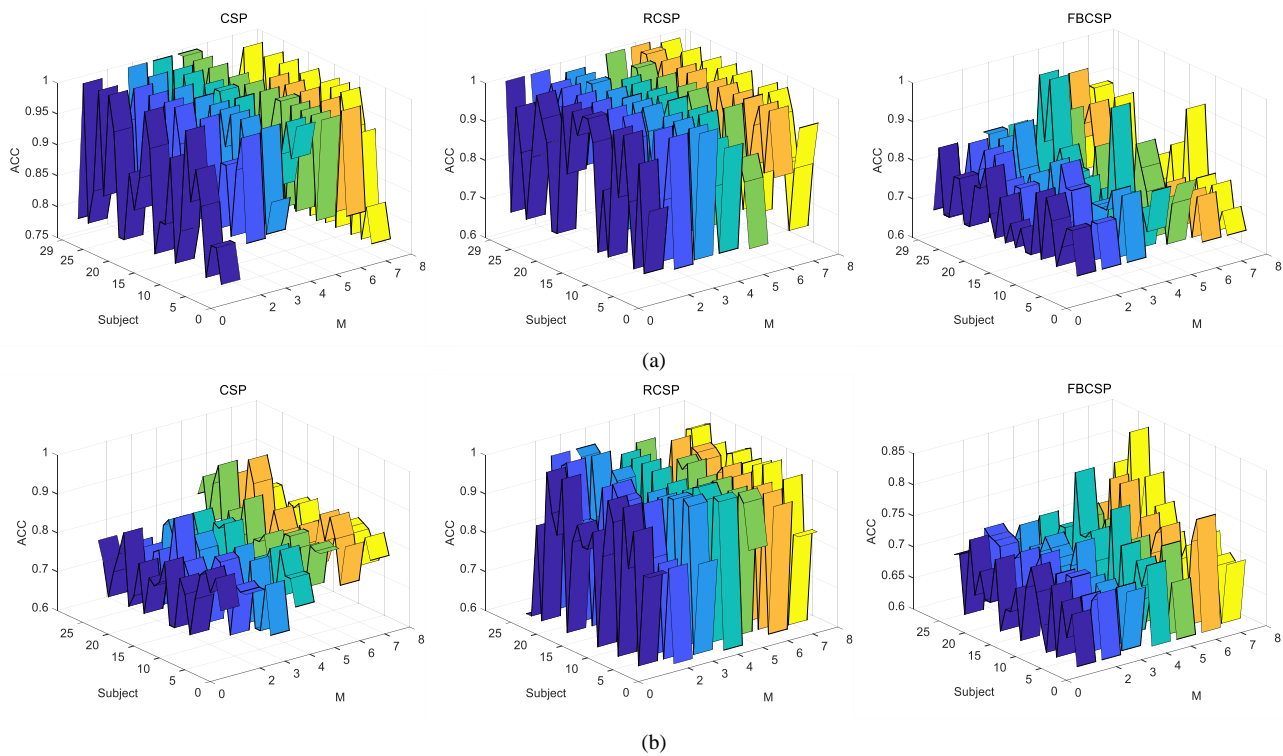

Fig. 2. (a) and (b) are 3D plots of ACC with varying feature dimensions M for specific subjects in datasets A and B.

As shown in Fig. 2, the plots correspond to the accuracy of each subject as the feature dimension varies from 2 to 8. For dataset A, using the three methods, CSP exhibits stable performance when the feature dimension is 6, with an optimal average accuracy of 92.72% among the 25 subjects. RCSP achieves its optimal average accuracy of 76.63% when the feature dimension is 5. FBCSP reaches its optimal average accuracy of 91.57% when the feature dimension is 7. For dataset B, using the three methods, CSP achieves its optimal average accuracy of 77.35% when the feature dimension is 5. RCSP reaches its optimal average accuracy of 69.41% when the feature dimension is 5. FBCSP attains its optimal average accuracy of 83.32% when the feature dimension is 4. From the results of these two datasets, it can be observed that among these three feature extraction methods, FBCSP performs more outstandingly.

B. Feature Selection Strategy of FBCSP and SDA for Specific Subjects

Due to the presence of feature redundancy in the results of feature extraction, coupled with the individual differences in features among different subjects, further efforts are made to select the optimal feature combination from the extracted features. This aims to make the features more adaptive to specific subjects. In this section, we propose the additional use of the SDA method for adaptive feature selection. Initially, a sliding time window is applied for segmentation. Subsequently, CSP, RCSP, and FBCSP are employed for feature extraction. Following this, SDA is utilized for feature selection. Compared to PSD and FBCNet, the additional use of SDA for feature optimization can effectively eliminate some poor feature data and improve the quality of features. Finally, an LDA classifier is employed to predict the accuracy of 30% of the blind source

signals. We investigate the optimal feature extraction results, where the feature dimensions for the three feature extraction algorithms range from $m=2\sim 8$. The experimental results are illustrated in Fig. 3.

As shown in Fig. 3, the overall performance of the RCSP method is suboptimal for both datasets. It exhibits significant fluctuations and lower accuracy, ranging between 60% and 80% for each individual. Conversely, the FBCSP method yields predominantly favorable results, with accuracy consistently surpassing 80%. For Dataset A, the maximum average accuracy achieved by CSP, RCSP, and FBCSP is 96.36%, 81.23%, and 98.47%, respectively. Notably, CSP utilizes a feature count M of 5, RCSP with M of 4, and FBCSP with M of 4. In the case of Dataset B, the maximum average accuracy for CSP, RCSP, and FBCSP is 82.26%, 72.12%, and 95.2%, respectively. CSP uses $M=2$, RCSP uses $M=3$, and FBCSP employs $M=2$. From the experimental results, it is evident that there is significant individual variability in the accuracy distribution of different subjects in both Dataset A and Dataset B. The adoption of this adaptive feature selection strategy substantially improves the recognition accuracy of specific subjects.

To validate the effectiveness and generalization ability of the proposed sliding window-optimized stepwise regression feature selection algorithm and investigate the optimal feature selection count and corresponding recognition accuracy for different subjects, based on the experimental results, feature counts M for CSP, RCSP, and FBCSP for Dataset A and B are set to 5, 4, 4, and 2, 3, 2, respectively. Adaptive sliding time window truncation is applied to EEG data from different subjects in Datasets A and B. Various feature extraction methods are employed for feature extraction, followed by stepwise

discriminant analysis for further feature selection. The optimal feature selection count and corresponding recognition accuracy for different subjects in Datasets A and B are depicted in Fig. 4 and Fig. 5.

As illustrated in Fig. 4, the optimal feature count varies among the 29 subjects, with the majority selecting three features. The graph depicts the number of features selected through stepwise regression under the condition of maximum accuracy. For instance, for Subject 1, using the CSP method with an accuracy of 100%, the corresponding feature count is 6; with the RCSP method and an accuracy of 88.89%, the feature count is 5; and with the FBCSP method and an accuracy of 100%, the feature count is 2. For Dataset A, after CSP, RCSP, and FBCSP feature extraction and feature selection, the average feature selection counts are 3.41, 2.45, and 3.93, respectively. The classification accuracy obtained from each subject indicates that stepwise regression possesses strong feature selection capabilities.

The graph reveals that under different feature extraction methods, individual accuracy shows a certain trend of variation. FBCSP and CSP methods exhibit relatively high accuracy, with average accuracies reaching 98.47% and 96.36%, respectively. In contrast, RCSP shows larger fluctuations and an average accuracy of only 80.44%. On an individual level, differences in performance are observed across different subjects under various feature extraction methods. The ninth subject achieves 100% accuracy across all three feature extraction methods. The fourteenth subject demonstrates high accuracy in CSP and FBCSP feature extraction methods, while possibly showing average performance in the RCSP method. This suggests that specific feature extraction methods may be more suitable for

certain individuals, and individual responses to these methods are diverse.

As depicted in Fig. 5, the optimal feature count varies among the 25 subjects, with the majority selecting 2 features. The graph illustrates the number of features selected through stepwise regression under the condition of maximum accuracy. For instance, for Subject 1, using the CSP method with an accuracy of 89.47%, the corresponding feature count is 1; with the RCSP method and an accuracy of 70.33%, the feature count is 3; and with the FBCSP method and an accuracy of 95%, the feature count is 2. After CSP, RCSP, and FBCSP feature extraction and feature selection for Dataset B, the average feature selection counts are 2.08, 1.96, and 2, respectively. The classification accuracy obtained from each subject indicates that stepwise regression possesses strong feature selection capabilities. Compared to Dataset A, the impact of the three methods on Dataset B's predictions is more distinct, with FBCSP being advantageous and RCSP at a disadvantage. RCSP exhibits relatively stable prediction results, but the average accuracy is only 72.12%; CSP shows larger fluctuations with an average accuracy of 82.26%. The overall best performance is observed in FBCSP, which maintains good stability while achieving an average accuracy of 92.5%. On an individual level, differences in performance are observed across different subjects under various feature extraction methods. The eighteenth subject achieves 70%, 71%, and 100% under the CSP, RCSP, and FBCSP methods, respectively. The nineteenth subject achieves 89.47%, 70.4%, and 85% under the CSP, RCSP, and FBCSP methods, respectively. This indicates that specific feature extraction methods may be more suitable for certain individuals, and individual responses to these methods are diverse.

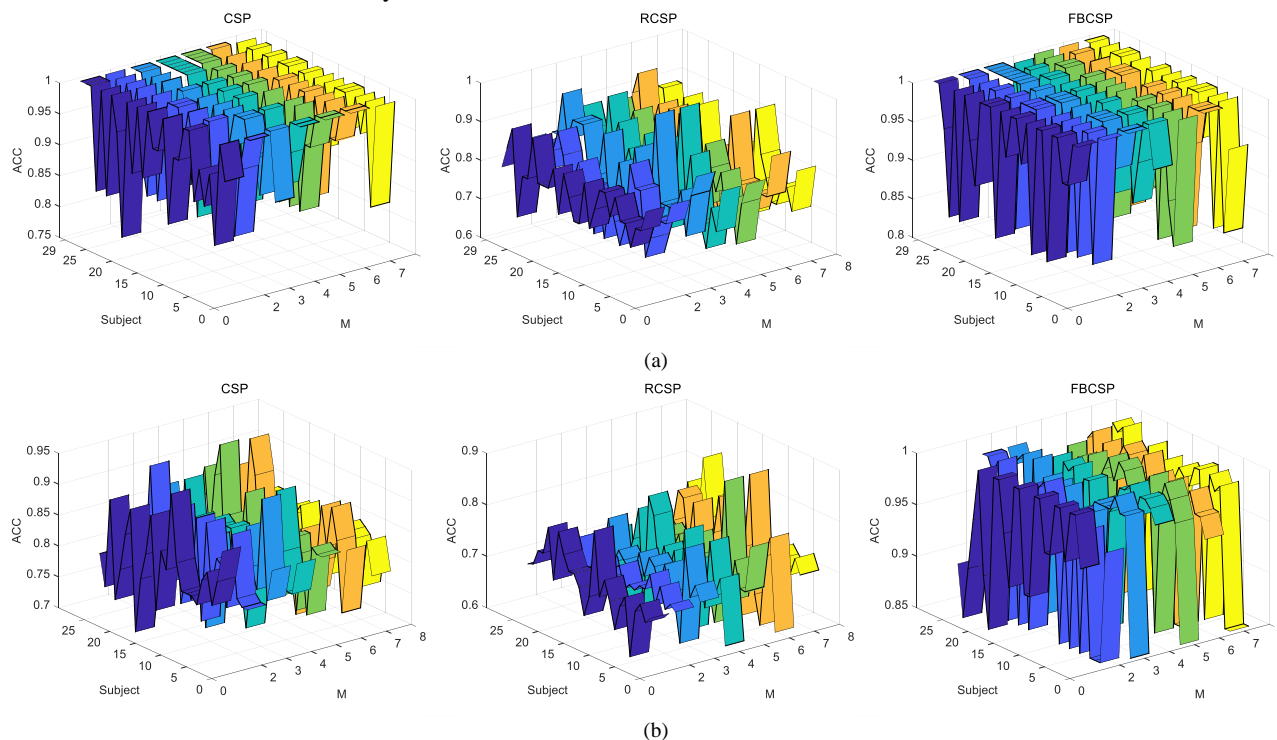

Fig. 3. (a) and (b) are 3D graphs depicting the ACC variation with the feature count M for specific subjects in Datasets A and B.

C. Recognition Results of Different Classifiers

To verify the generalization capability and robustness of the proposed method, this paper employs Linear Discriminant Analysis (LDA), Support Vector Machine (SVM), and k-nearest Neighbors (kNN) to evaluate the performance of the selected feature subset. As shown in Fig. 6, for Dataset A, three feature extraction methods and three classifiers—LDA, SVM, kNN, Decision Tree, and Random forest yield the following accuracies: CSP+LDA achieves an accuracy of 96.36%, CSP+SVM achieves 80.08%, CSP + KNN achieves 72.61%, CSP + Decision Tree achieves 81.99%, and CSP + Random Forest achieves 83.14%. Similarly, RCSP+LDA achieves an accuracy of 80.44%, RCSP+SVM achieves 77.78%, RCSP+KNN achieves 69.16%, RCSP + Decision Tree achieves 76.25%, and RCSP + Random Forest achieves 74.71%. FBCSP+LDA achieves an impressive accuracy of 98.47%, FBCSP+SVM achieves 86.8%, FBCSP+KNN achieves 73.18%, FBCSP +Decision Tree achieves 90.06%, and FBCSP

+ Random Forest achieves 88.72%. For Dataset B, the accuracies are as follows: CSP+LDA achieves 82.26%, CSP+SVM achieves 68.82%, CSP+KNN achieves 67.42%, CSP + Decision Tree achieves 76.88%, and CSP + Random Forest achieves 77.65%. RCSP+LDA achieves 72.12%, RCSP+SVM achieves 65.45%, RCSP+KNN achieves 62.58%, RCSP + Decision Tree achieves 64.1%, and RCSP + Random Forest achieves 62.73%. FBCSP+LDA achieves an accuracy of 95.2%, FBCSP+SVM achieves 71.65%, FBCSP +KNN achieves 69.51%, FBCSP + Decision Tree achieves 80.07%, and FBCSP + Random Forest achieves 83.4%.

From the figures, it is visually apparent that, under the same classifier, FBCSP outperforms others. Furthermore, when employing the same feature extraction algorithm, the performance of the LDA classifier is notably superior to other classifiers.

IV. DISCUSSION

EEG feature extraction is crucial for decoding MI signals. However, due to factors such as individual variability among subjects and environmental variations during testing, spatial feature extraction methods and their improved versions, as well as the selection of feature parameters, can exhibit different effects on individuals. Experimental evidence has shown that FBCSP demonstrates superior generalization capabilities. Despite the significant redundancy in the features extracted by this spatial feature extraction method, effectively eliminating redundant information can greatly enhance EEG decoding accuracy. Therefore, this paper proposes the use of a Sliding Time Window-based Spatial Domain Adaptation (SDA) method to improve performance. To validate the effectiveness of this SDA feature selection strategy on the effects of feature extraction and generalization capabilities, we compared the distribution of features with and without the SDA feature selection strategy and performed experiments on two datasets. Fig. 7 illustrates the optimal feature visualization of EEG data from datasets A and B.

Fig. 7 presents the t-SNE [45] visualization results for binary MI classification of the 9th participant, with (a) and (b)

representing the feature visualization comparisons before and after stepwise discrimination for datasets A and B, respectively. It can be seen that the separability of data features has a certain effect. The features extracted by the proposed method achieved better feature separability which will enhance the classification performance of the model. Therefore, the visualized feature maps demonstrate that the latent features extracted by our method can more significantly represent the MI tasks, resulting in outstanding classification performance. This also indicates that our method can indeed uncover valuable information. Moreover, the strong generalization capability of the method is evident from the figure, highlighting its applicability to various modalities of data.

To further evaluate the results of our work, we compared the performance of our method with studies using the same benchmarks, as shown in the Table I. The Table I presents the classification accuracy of different methods. From the Table I, it is evident that our method improves the classification accuracy and generalization performance of the model. The work by Shin et al. [36] utilized a comprehensive feature extraction and classification approach for BCI tasks. They extracted features from the logarithmic variances of the first three and last three CSP components of EEG signals and employed a regularized LDA classifier for classification. The average accuracy on the MI dataset was 65.5%. Ergun et al.'s [34] notable contribution lies in employing diverse feature extraction methods, including Katz fractal dimension and Hilbert transform. They used a k-nearest neighbors classifier, a simple yet effective method suitable for various data types. Jiang et al. [33] proposed the use of Independent Decision Path Fusion (IDPF), incorporating multiple decision paths, each using different features and machine learning methods for classification. They achieved outstanding accuracy of 78.56% on the dataset using power spectral features and CSP features with SVM and LDA.

As dataset B is newly publicly available, there are limited research results for dataset B. In the literature [40], Ma et al. data from dataset B was divided into training, validation, and test sets in an 8:1:1 ratio. The average accuracy of 10-fold cross-validation results reached 68.8%. In contrast, our proposed method achieved an accuracy of 95.2%. As there are limited publicly available results for dataset B, our comparison is based on the existing literature.

Currently, individual variability, training speed of decoding algorithms, and online recognition speed are key challenges in motor imagery recognition. This paper focuses on addressing individual variability and improving online testing efficiency and training learning time. In comparison to current deep learning algorithms, our method is more efficient and addresses issues related to individual time and feature variability. Among publicly available literature using this dataset, our proposed method achieves the highest classification accuracy compared to traditional efficient machine learning algorithms. Our research not only achieves an accuracy of 98.47% in terms of classification accuracy but also performs exceptionally well in response time. In practical applications, our method can rapidly and accurately classify users' intentions, implying that our research has significant potential in the practical application of BCI technology, providing users with faster and more reliable feedback and control experiences.

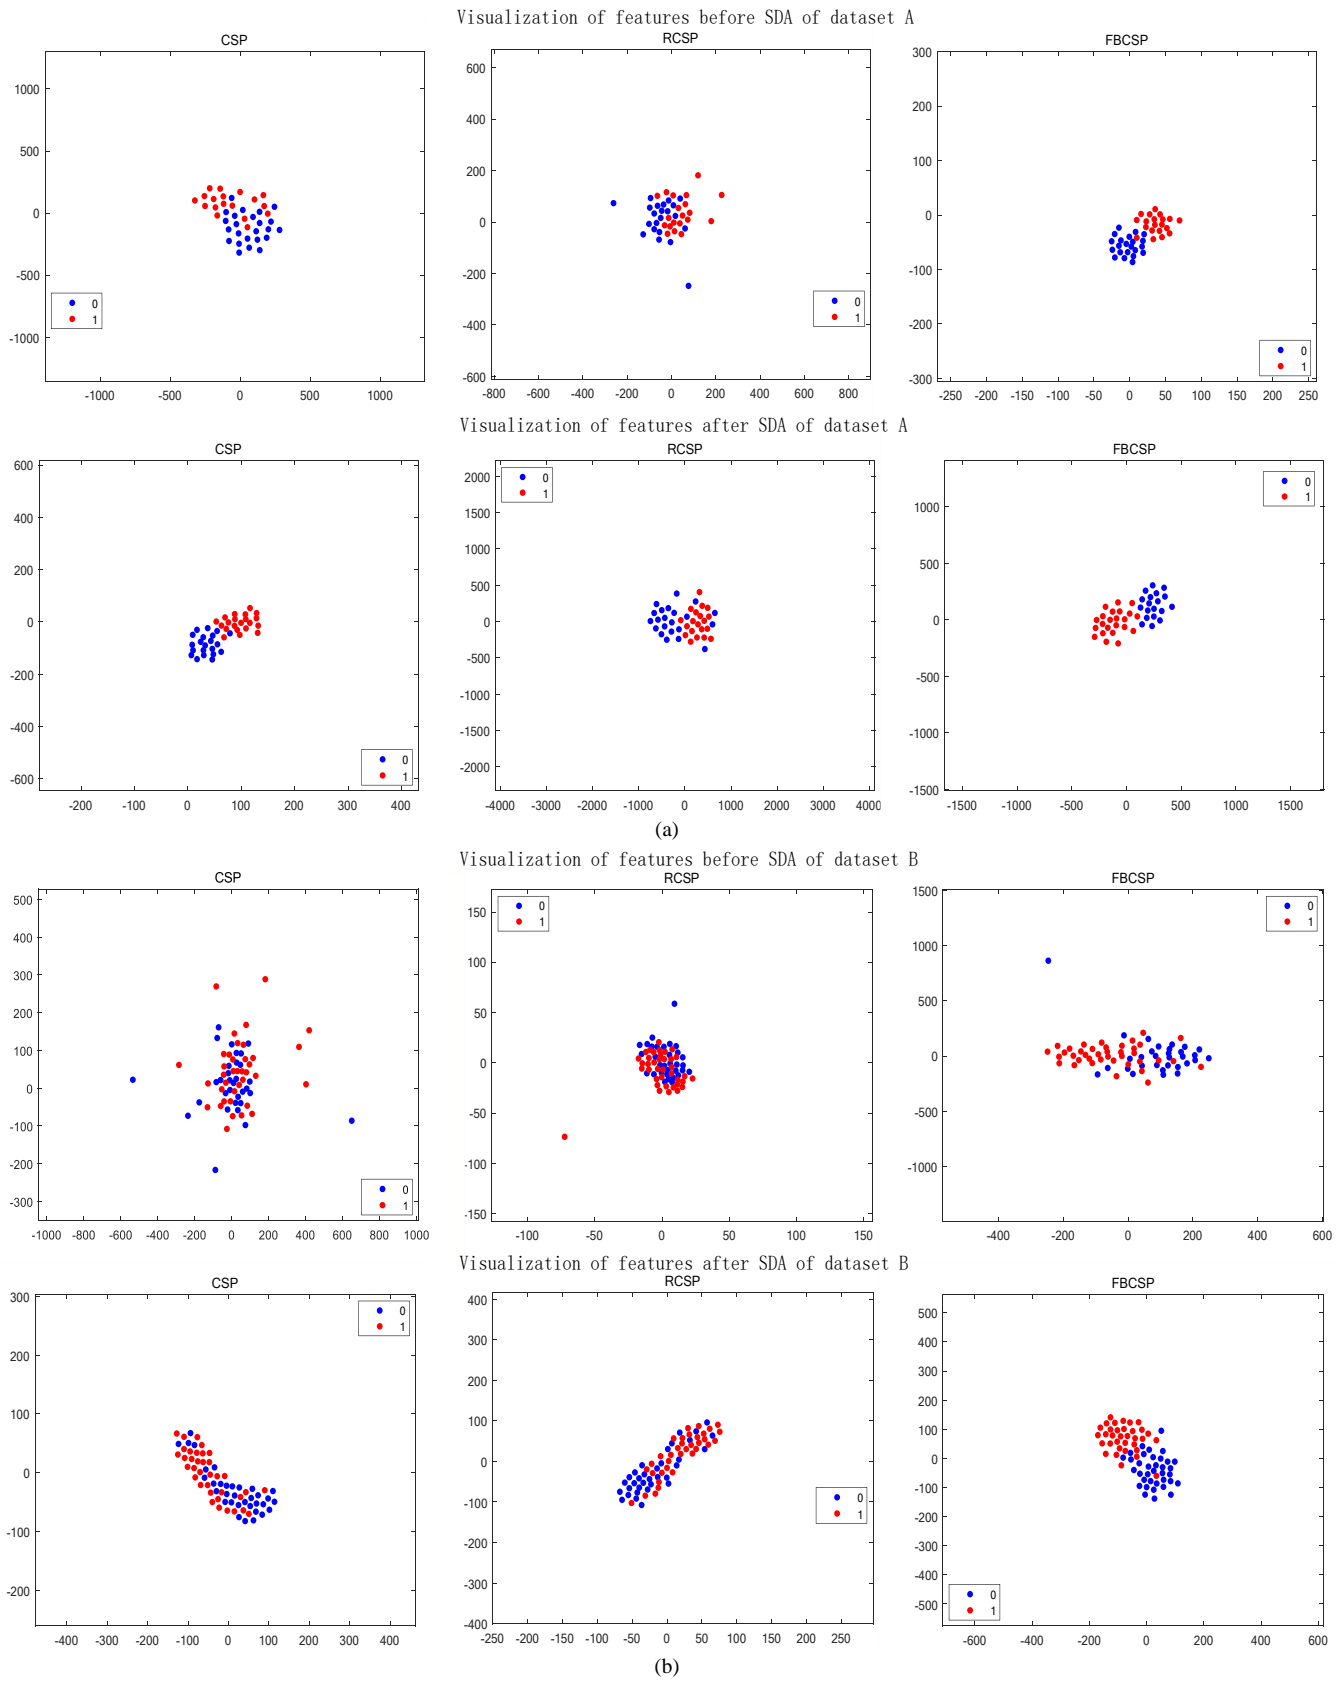

Fig. 7. Comparison of t-SNE projection maps for feature extraction (a) the t-SNE visualization results of the features before and after stepwise discrimination for dataset A , and (b) the t-SNE visualization results of the features before and after stepwise discrimination for dataset B.

TABLE I. COMPARISON OF CLASSIFICATION ACCURACY OF DIFFERENT METHODS FOR DATASET A

Method	Algorithm	Classification Accuracy (%)
Shin et al	CSP+Shrinkage LDA	65.5
Ergun et al	Power-Spectrum+SVM	73.1
	CSP+LDA	63.39
Jiang et al	Independent Decision Path Fusion	78.56
Our method	CSP + Sliding time window optimized SDA +LDA	96.39
	RCSP + Sliding time window optimized SDA +LDA	80.44
	FBCSP + Sliding time window optimized SDA+LDA	98.47

Our research method holds important advantages in the BCI field. Firstly, we successfully address individual differences and environmental variations, a longstanding major challenge for BCI systems. Different individuals' neural activity patterns may vary significantly, and changes in environmental conditions can also have a crucial impact on signal quality. By using a sliding time window approach, our system can flexibly adapt to different situations, thereby enhancing system adaptability and robustness. This means that our method is not only applicable to laboratory environments but can also operate effectively in the diversity and complexity of the real world. Secondly, our method tackles the feature selection problem effectively through stepwise discriminant feature extraction, combining prior knowledge. Feature extraction is crucial in BCI systems as it directly influences system performance. Our method can more accurately select neural signal features related to motor imagery, thereby improving recognition accuracy. This not only helps optimize system performance but also reduces unnecessary computational burden. Therefore, our method provides an innovative solution to the feature extraction problem.

In the future, our research method will have vast application prospects and development potential. Firstly, we can further optimize the method, such as adjusting the parameters of the sliding time window or improving feature extraction algorithms, to further enhance system performance. Additionally, we can consider introducing more data modalities, such as physiological data or brain imaging data, to enrich information sources and improve recognition accuracy and diversity. In practical applications, our method can be widely used in various fields. In the medical field, it can assist people with disabilities in regaining limb function, improving their quality of life. In virtual reality and gaming, our method can provide a more natural and faster user experience, enhancing interactivity. In the military and security fields, it can be used for operation control, improving response speed and decision accuracy.

In conclusion, our research method not only provides an effective approach to addressing individual differences and environmental variations in BCI systems but also has extensive application prospects. Future research can further explore and expand this method to promote the application and development of BCI technology in various fields.

V. CONCLUSION

In our work, we combined an optimized sliding time window algorithm with a stepwise discriminative feature selection algorithm. Firstly, we adopted an adaptive sliding time window method that successfully addressed the challenges of individual

differences and environmental changes. Secondly, our method integrates prior knowledge, utilizes SDA for feature extraction to improve recognition accuracy, and effectively adapts to finding the optimal feature combination for specific participants. It effectively solves the problem of feature selection. The experimental results show that this method improves the accuracy of motion image recognition. Specifically, for dataset A, use CSP The accuracy of EEG data using RCSP and FBCSP methods was 96.36%, 80.44%, and 98.47%, respectively. For dataset B, use CSP The accuracy of RCSP and FBCSP methods is 82.26%, 72.12%, and 95.2%, respectively. Compared with the currently published research results, this method significantly improves the recognition accuracy of MI. This indicates that the method has wide applicability, scalability, and high promotion and practical value. In this study, the dataset used for this method is unimodal data. Taking this article as a reference, this method can be extended to the study of multimodal datasets in future work. Moreover, this method is not limited to the field of motion imagination, but also has practical applications in emotion recognition, SSVEP, Many fields such as human-computer interaction have certain reference value.

Enhancing Sentiment Analysis on Social Media Data with Advanced Deep Learning Techniques

Huu-Hoa Nguyen

College of Information and Communication Technology, Can Tho University, Vietnam

Abstract—This paper introduces a comprehensive methodology for conducting sentiment analysis on social media using advanced deep learning techniques to address the unique challenges of this domain. As digital platforms play an increasingly pivotal role in shaping public discourse, the demand for real-time sentiment analysis has expanded across various sectors, including policymaking, brand monitoring, and personalized services. Our study details a robust framework that encompasses every phase of the deep learning process, from data collection and preprocessing to feature extraction and model optimization. We implement sophisticated data preprocessing techniques to improve data quality and adopt innovative feature extraction methods such as TF-IDF, Word2Vec, and GloVe. Our approach integrates several advanced deep learning configurations, including variants of BiLSTMs, and employs tools like Scikit-learn and Gensim for efficient hyperparameter tuning and model optimization. Through meticulous optimization with GridSearchCV, we enhance the robustness and generalizability of our models. We conduct extensive experimental analysis to evaluate these models against multiple configurations using standard metrics to identify the most effective techniques. Additionally, we benchmark our methods against prior studies, and our findings demonstrate that our proposed approaches outperform comparative techniques. These results provide valuable insights for implementing deep learning in sentiment analysis and contribute to setting benchmarks in the field, thus advancing both the theoretical and practical applications of sentiment analysis in real-world scenarios.

Keywords—Sentiment analysis; deep learning; hyperparameter; feature extraction; social media; digital platform; gridsearchcv; BiLSTM; TF-IDF; word2vec; glove; Scikit-learn and Gensim

I. INTRODUCTION

In the digital era, social networks such as Twitter, now known as X, play a pivotal role in shaping public discourse and capturing real-time public sentiment [1]. These platforms provide unprecedented access to vast streams of user-generated content, reflecting the collective mood on topics ranging from daily interests to major global events. This rich dataset is fertile ground for sentiment analysis, crucial for understanding social dynamics and applications such as policy-making and personalized services. Automating the classification of sentiment in text data effectively enables stakeholders to respond more swiftly and appropriately to public opinion [2].

Despite its extensive utility, sentiment analysis poses several practical challenges, especially in the context of social media where language use is diverse and constantly evolving [3]. Machine learning, particularly deep learning, has emerged as a robust solution to these complexities. These techniques excel at

deciphering subtle nuances of language on social media by modeling high-level abstractions in data [4].

However, deploying deep learning for sentiment analysis involves navigating a range of technical challenges across the deep learning workflow. This includes data acquisition and preprocessing, selection and application of feature extraction techniques, choice and tuning of models, and rigorous analysis of model performance. Each stage is critical; for example, effective data preprocessing significantly reduces noise and enhances the quality of the dataset, while the choice of feature extraction method greatly impacts the model's ability to correctly interpret and classify sentiment [5].

The motivations behind our proposed approach stem from the need to enhance the accuracy and efficiency of sentiment analysis in the ever-evolving landscape of social media. Traditional methods often fall short due to their inability to handle the vast diversity and rapid changes in language use on these platforms. By utilizing advanced deep learning techniques, our approach aims to overcome these limitations, providing a more understanding of public sentiment.

The main contributions in this paper include multifold advancements in sentiment analysis. First, we introduce a comprehensive system architecture that covers all phases of the deep learning process, with careful attention to each stage. This approach integrates advanced data preprocessing strategies and innovative feature extraction methods such as TF-IDF, Word2Vec, and GloVe, utilizing tools from well-known libraries like Scikit-learn and Gensim [21]. Second, we explore the use of advanced deep learning frameworks like BiLSTM, optimizing each model's configuration to maximize performance. Third, we conduct extensive experiments to evaluate and compare these models across various configurations, thoroughly analyzing their performance to identify the most effective approaches for sentiment classification. Lastly, we benchmark our methods against prior studies, helping to establish new standards in the field.

The structure of this paper is organized as follows. Section II explores related works on sentiment analysis. Section III presents the foundations of deep learning. Section IV details our proposed methods. Section V focuses on our experimental analysis and comparison of various models. Finally, Section VI concludes with a summary of findings and future research directions.

II. RELATED WORK

The field of sentiment analysis has witnessed substantial contributions that employ various language processing

techniques aimed at refining data to enhance accuracy. One notable approach involves using regular expressions, as demonstrated by the TransRegex tool introduced by [6], which significantly improved accuracy across diverse datasets by removing extraneous elements like special characters, URLs, or HTML tags. Moreover, focused classification and reduction of stop words have been shown to substantially reduce corpus size and enhance overall accuracy [7]. Challenges specific to language, such as addressing spelling errors and the need for word normalization, have been tackled with algorithms like Damerau-Levenshtein [8] and targeted lemmatization techniques, which notably increase accuracy in sentiment analysis for languages like Bangla [9].

The application of linguistic analysis extends beyond everyday communications to encompass political and social domains. Studies such as [10] and [11] have illustrated the effectiveness of preprocessing in improving sentiment analysis outcomes in diverse contexts, including political events and film reviews. Moreover, the role of machine learning in identifying and analysing patterns of hate speech on platforms like Twitter has been examined, with algorithms like Naïve Bayes demonstrating superior performance in detecting and categorizing hateful content [12].

The vast data generated on social networks has been a rich source for sentiment analysis, as exemplified by research focusing on political sentiments during the Jakarta Governorship Election [13]. Here, the use of techniques like TF-IDF [20] for feature extraction and the application of k-fold cross-validation methods underscored the potential for machine learning in improving accuracy in sentiment prediction.

Innovative approaches have also been explored for the deeper analysis of textual data, integrating models such as CNN and LSTM to process large datasets, including movie reviews on platforms like IMDB [14]. These deep learning models have shown remarkable efficacy in classifying sentiments with high accuracy, illustrating the advantage of advanced algorithms in extracting emotional content from text.

Comparative studies have further highlighted the diversity of machine learning and deep learning methods in sentiment analysis tasks. The contrast between classical machine learning techniques and the more complex deep learning approaches, particularly in their methods of converting text into analysable vectors, reveals a spectrum of accuracy and efficiency in sentiment classification [15]. This variety of methodologies highlights the continuous evolution of sentiment analysis, promoting the use of supervised and unsupervised learning models to improve accuracies across different domains.

This landscape of related work reflects the dynamic nature of sentiment analysis research. It also points towards the continuous need for innovation in processing techniques and algorithmic strategies to tackle the complexities of natural language and the reliability of sentiment analysis outcomes.

III. DEEP LEARNING FOUNDATIONS

Deep learning, a branch of machine learning, employs hierarchical neural networks to model complex patterns and high-level abstractions in data. Unlike traditional machine learning techniques such as Logistic Regression and Support

Vector Machine, which are effective for tasks where the relationship between input and output is less intricate, deep learning excels in scenarios where the predictive factors involve complex relationships and high-dimensional data, such as sentiment and emotion classification. Traditional models often require manual feature extraction and selection, whereas deep learning networks automatically learn feature representations from raw data, removing the need for manual intervention.

Fig. 1. LSTM architecture.

This section explores several advanced deep learning models such as LSTM, GRU, Bi-LSTM, Bi-GRU, CNN-LSTM, and ConvLSTM. It highlights how these technologies enhance sentiment analysis through predictive modeling.

A. Long Short-Term Memory (LSTM)

LSTM networks represent a crucial innovation in neural networks [26]. As an enhancement of Recurrent Neural Networks, LSTMs are adept at recognizing patterns in extended sequences of data, essential for tasks like time series prediction.

As illustrated in Fig. 1, LSTMs consist of interconnected cells featuring three main gates: forget, input, and output. These gates control the flow and modification of information within the network, helping to maintain, update, and retrieve data across different time steps. This selective memory capability significantly enhances decision-making processes.

Focusing on sentiment analysis, the strength of LSTMs lies in their capability to understand the context and nuances over longer text sequences, making them ideal for analyzing opinions and emotions in user-generated content. By utilizing this technology, deep learning models can more accurately gauge sentiment trends from large volumes of text data, providing insights into public opinion dynamics or customer preferences.

B. Bidirectional Long Short-Term Memory (Bi-LSTM)

Bi-LSTM model, derived from the Bidirectional Recurrent Neural Network (Bi-RNN), processes data by analyzing it both forwards and backwards [27]. This method enhances the context understanding of the sequence data. As depicted in Fig. 2, Bi-LSTM uses two separate LSTM layers, one moving forward and the other backward through the input sequence. This dual-pathway ensures comprehensive visibility of data at any point, integrating insights from both before and after the current data point. This extensive perspective highly enhances the model's accuracy and depth of understanding. The Bi-RNN's model employs traditional LSTM gates (forget, input, and output gates)

in both directional layers, which allows precise control over information flow.

Fig. 2. BiLSTM architecture.

In the context of sentiment analysis using deep learning, Bi-LSTMs are particularly effective due to their ability to understand the full context of expressions, capturing the nuances that influence sentiment. This capability makes them ideal for analyzing extensive text data, such as customer reviews or social media posts, where understanding the sentiment context is key to interpreting overall sentiment accurately.

C. Gated Recurrent Units (GRU)

GRUs mark a significant step forward in neural network technology [28]. Like their close relative, the LSTM, GRUs are designed to process sequences of data but with a simplified architecture that includes two key components: the update gate and the reset gate. These two gates are critical to the GRU's function. The update gate determines how much of the past information to keep against the new input, while the reset gate controls the extent to which the previous state affects the current state. This setup allows GRUs to discard irrelevant data, making them efficient and flexible.

GRUs stand out by managing variable-length input sequences, crucial for understanding the nuances in written opinions. Their ability to maintain relevant historical information and combine it with new, incoming data allows for more accurate predictions of sentiment trends. This capability is beneficial in analyzing large volumes of text data, providing deeper insights into consumer sentiments and market trends.

D. Bidirectional Gated Recurrent Units (Bi-GRU)

Bi-GRU extends the concept of Bi-RNN by integrating GRU mechanisms for both forward and backward sequence processing [27]. This architecture employs two critical gates: the update gate, which integrates new information, and the reset gate, which controls the amount of past information retained.

In the Bi-GRU setup, the interaction of these gates in both directions allows the model to synthesize information from both past and future contexts relative to the current data point. This approach greatly enhances the model's understanding of sequences, improving its predictive capabilities in applications like sentiment analysis.

E. Convolutional Neural Network Long Short-Term Memory (CNN-LSTM)

The CNN-LSTM architecture combines the spatial analysis strengths of Convolutional Neural Networks (CNN) with the

sequential data handling capabilities of Long Short-Term Memory (LSTM) networks [29]. The CNN-LSTM model can analyze video or sequential image data. It combines the strengths of CNNs, which capture spatial details from visual data, with LSTMs that track how these features evolve over time. This integrated approach allows for a refined understanding of changes in sentiment. As a result, the CNN-LSTM model is highly effective for analyzing customer reactions in video reviews and social media content, providing nuanced insights into consumer sentiment trends.

F. Convolutional Long Short-Term Memory (ConvLSTM)

The ConvLSTM represents an enhancement in neural network architecture by integrating the LSTM's time-sensitive processing capabilities with the spatial feature detection of convolutional layers [29]. This architecture embeds convolutional operations within the LSTM cell transitions, making it particularly adept at managing data that exhibits both spatial and temporal characteristics. For sentiment analysis, particularly in applications like video content analysis, the ConvLSTM excels by capturing temporal sequences of spatial features, such as facial expressions or body language. This ability helps in accurately determining the progression of emotions or sentiments over time.

IV. MODEL DEVELOPMENT

This section describes our proposed methods for sentiment analysis. It outlines the overall framework of deep learning, encompassing all stages from data collection to model optimization.

A. Deep Learning Framework for Sentiment Analysis

Our proposed system architecture is structured into four phases, as depicted in Fig. 3. This architecture is crafted to process and interpret sentiments efficiently. The initial phase encompasses data collection and preprocessing, which includes text cleaning, stop word removal, and lemmatization. These steps aim to enhance the data's quality and relevance. Subsequently, the focus shifts to the critical task of feature extraction, employing sophisticated techniques such as TF-IDF, Word2Vec, and GloVe to identify meaningful patterns in the data. In the third phase, we concentrate on developing and rigorously training a variety of machine learning models. The fourth and concluding phase involves a comparative evaluation of the models' performances. This comparison is vital for determining the most effective methods in terms of accuracy and efficiency, thereby identifying the best strategy for sentiment analysis. The details of these phases are elaborated in the following subsections.

B. Dataset Description

Our research utilizes the Sentiment140 dataset, a significant contribution from Stanford University [16]. Known for its comprehensive and carefully assembled collection of tweets, the dataset is gathered directly from Twitter through its search API. It stands out for its utility in sentiment analysis research and is publicly accessible on Kaggle. Kaggle is a platform renowned for hosting a wide array of datasets suitable for various data science projects. The Sentiment140 dataset is especially valuable for training machine learning models in sentiment analysis, thanks to its large size and balanced composition. It

features 1.6 million tweets, evenly split between positive and negative sentiments.

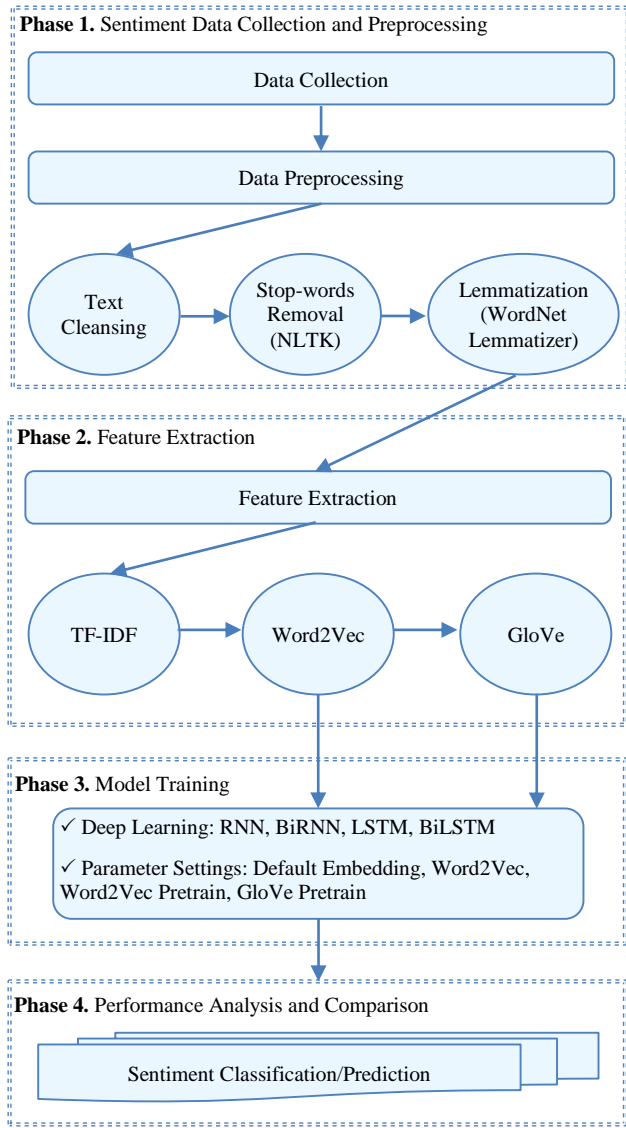

Fig. 3. Deep learning framework for sentiment analysis.

The structure of this dataset is meticulously organized into a CSV file format, which includes six critical columns: Sentiment, Id, Date, Query, User, and OriginalTweet. The 'Sentiment' column classifies each tweet's emotional tone with a numeric system: '0' denotes negative sentiment, and '4' represents positive sentiment. The 'Id' column provides a unique identifier for each tweet. The 'Date' column records the tweet's posting date. The 'Query' column specifies if the tweet was retrieved using a specific search keyword, though our study includes all tweets regardless of the query used. The 'User' column lists the username of the tweet's author, and 'OriginalTweet' contains the text of the tweet. For our analysis, we focus solely on the 'Sentiment' and 'OriginalTweet' columns. This selective approach allows us to concentrate on the textual content and its associated sentiment, discarding extraneous data that do not directly contribute to our sentiment analysis objectives.

Through statistical analysis of the dataset, we display the frequency distribution of tweet lengths in Fig. 4 and Fig. 5. Fig. 4 unveils the range of tweet lengths, highlighting the concise nature of Twitter communication. Most tweets are brief, peaking at seven words. This pattern highlights the importance of grasping the typical tweet structure and tailoring our analysis techniques to Twitter's compact format. Fig. 5 reveals the dataset's lexical patterns, offering insights into the vocabulary frequently used by Twitter users. This analysis is crucial for pinpointing key terms commonly found in tweets, guiding our preprocessing and feature extraction strategies to improve model performance.

(a) Tweet lengths in words.

(b) Length of negative (left) and positive (right) tweets.

Fig. 4. Frequency distribution of tweet lengths.

Fig. 5. Frequency distribution of the 30 most common words.

C. Data Preprocessing

Data preprocessing is a critical step in our sentiment analysis methodology, addressing the challenges posed by the unstructured or semi-structured nature of data harvested from online platforms like Twitter. Prior research [17] has shown that effective preprocessing of data plays a key role in enhancing the accuracy of machine learning (ML) models. It does so by eliminating noise and reducing the dataset's dimensionality, which brings into focus the features that have a high correlation with the target outcomes. Moreover, given the computational demands of processing large datasets, preprocessing not only aids in improving prediction accuracy by concentrating on relevant data but also enhances computational efficiency [18]. The details of this data preprocessing phase are outlined in the following subsections.

1) *Data cleansing*: In the first step of data cleansing, we utilize Python's "re" module for its robust regular expressions. These expressions enable us to methodically eliminate URLs, HTML tags, hashtags, mentions, emojis, and unnecessary spaces from the dataset. This crucial step helps in eliminating distractions and standardizing the data for analysis. Next, we remove special characters and numbers since they typically don't aid sentiment analysis, further purifying the dataset. We also standardize all words to lowercase to avoid duplicates that could diminish the performance, for example, treating capitalized words at the start of sentences the same as their lowercase counterparts elsewhere. This approach ensures uniform treatment of words, regardless of their position in a sentence.

Given Twitter's informal and abbreviated language, we employ a detailed list of abbreviations to translate shortened forms into their full expressions, such as converting "he's" to "he is". This standardization is crucial for maintaining data consistency and clarity. Moreover, we rectify spelling errors resulting from repeated characters, for example, correcting "saddd" to "sad". For a more straightforward classification process, we adjust sentiment labels, designating negative sentiments as '0' and positive sentiments as '1'. Table I illustrates the distribution of tweet lengths after cleansing, laying the groundwork for further analysis.

TABLE I. TWEET LENGTH DISTRIBUTION AFTER CLEANSING

Statistic	Original Tweet	Cleansed Tweet
The average value	13.18	11.69
Standard deviation	6.96	6.46
Minimum length	1	0
25%	7	6
50%	12	11
75%	19	17
Maximum length	64	40

2) *Stop word removing*: Stop words like "is", "has", "and", "to", and others frequently appear in sentences and may reduce the significance of other words in sentiment analysis. Removing these stop words is a common strategy to decrease

noise in text data. However, in sentiment analysis, this practice might change the intended meaning of sentences. For example, "The product is not good" clearly expresses a negative sentiment, but removing the stop word changes it to "product good", suggesting a positive sentiment instead. To assess how stop word removal affects model performance, we explore two scenarios in our study: one with stop word removal and one without.

For this procedure, we utilize the stop word dictionary from the Natural Language Toolkit library, available at www.nltk.org, with a crucial modification: we retain the words "not" and "no" to preserve the sentiment context within the sentences. This method ensures that tweets are cleansed of stop words while preserving essential words for expressing negation. Tables II and III provide insights into the impact of this step. Table II lists the top 10 most frequent words in the dataset before cleansing, highlighting that stop words dominate the list across both negative and positive sentiments with similar frequencies. Table III then illustrates how tweet lengths change once stop words are removed, offering a quantitative view of this preprocessing step's effect.

TABLE II. TOP 10 MOST FREQUENT WORDS IN ORIGINAL TWEETS

Word	Frequency in Negative Tweets	Frequency in Positive Tweets
to	613,036	492,288
the	482,000	493,002
a	351,648	380,776
my	333,834	226,216
i	320,264	179,768
and	280,480	270,046
is	236,252	199,134
in	216,842	187,746
for	192,596	227,006
it	182,174	161,450

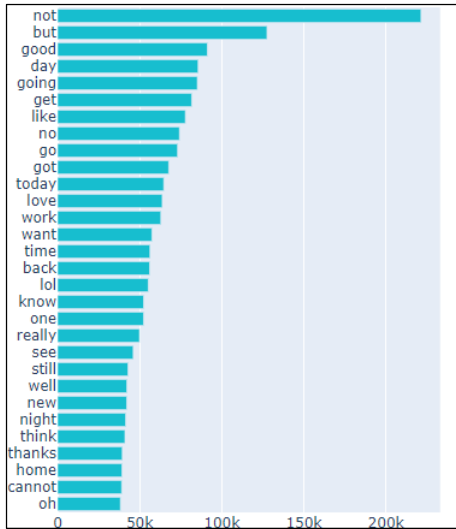

TABLE III. TWEET LENGTH DISTRIBUTION AFTER CLEANSING AND STOP WORD REMOVAL

Statistic	Cleansed Tweets	Tweets without stop words
The average value	11.69	7.07
Standard deviation	6.46	3.89
Minimum length	0	0
25%	6	4
50%	11	7
75%	17	10
Maximum length	40	34

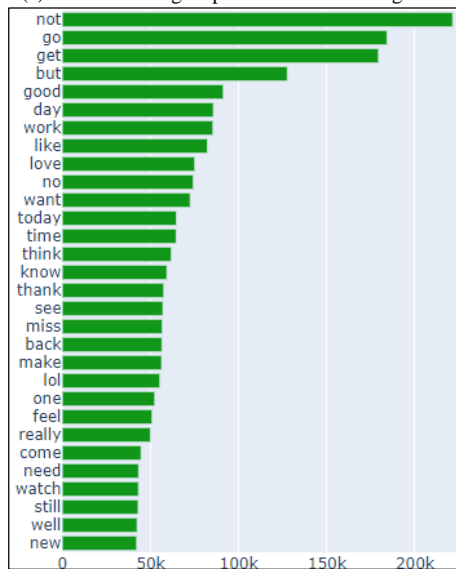

3) *Word normalization*: English words frequently appear in multiple forms. For example, "go", "went", "gone", "going", and "goes" all stem from "to go". If these variations are not simplified, they can unnecessarily expand the dataset with redundant features. To address this, we use the NLTK library

[19] to reduce words to their base forms, employing two approaches: stemming and lemmatization.

Stemming shortens words by removing endings or beginnings, which may sometimes lead to imprecise meanings or spellings. This method is preferred in large datasets where processing speed is crucial. Conversely, lemmatization considers the word's context to derive its meaningful base form, known as the lemma. Although more accurate, lemmatization requires more computational resources because it involves extensive lookup tables. Fig. 6 demonstrates how word normalization simplifies "going" to its fundamental form "go". This crucial step prepares the dataset for the next phase of feature extraction, making the text more concise.

(a) After removing stop words and cleansing text.

(b) After Lemmatization.

Fig. 6. Top 30 words after normalization to root forms.

D. Feature Extraction

Following the initial preprocessing phase, our dataset undergoes feature extraction, a pivotal step in transforming text into a format amenable for model training. We employ three

advanced techniques for this purpose: TF-IDF, Word2Vec, and GloVe, each converting text into numerical vectors.

1) *TF-IDF*: The Term Frequency-Inverse Document Frequency (TF-IDF) stands out for its ability to identify the significance of a word within a document, relative to a collection of documents. It calculates a weight for each term: the Term Frequency (TF) measures a term's frequency within a document, while the Inverse Document Frequency (IDF) assesses the term's rarity across all documents. The formula given as Eq. (1) combines these two metrics to determine a term's overall importance:

$$TF - IDF_{(t,d)} = TF_{(t,d)} \times \log\left(\frac{N}{DF_{(t)}}\right). \quad (1)$$

Here, N represents the total document count in the dataset, $DF_{(t)}$ denotes the number of documents featuring term t , and $TF_{(t,d)}$ is term t 's frequency in document d . Utilizing the Scikit-learn library's TF-IDF vectorizer [21], available at scikit-learn.org, we efficiently extract features that prioritize words based on their document-wise relevance, reducing emphasis on common words and elevating unique terms. Configurations such as $min_df=5$ exclude terms appearing in fewer than five documents, and $ngram_range=(1,1)$ limits our focus to individual words.

2) *Word2Vec*: Word2Vec, a model for creating word embeddings from text, uses neural networks in two distinct approaches: Continuous Bag of Words (CBOW) and Skip-gram [22]. The CBOW method predicts a word based on its surrounding context, while the Skip-gram approach does the opposite by predicting the surrounding context of a word. These methods not only make the model more versatile but also enhance its understanding of language subtleties.

In this research, we train Word2Vec on our dataset with the help of the Gensim library [21]. This process generates dense and meaningful vector representations of words. Additionally, we utilize pre-trained vectors from Google News. This dataset contains about 100 billion words, which have been used to produce 300-dimensional vectors for over 3 million terms. Such extensive data enrich our analysis by providing a wide range of linguistic insights.

Both the Gensim library and the Google News vectors are accessible through resources like the Gensim library itself and the Kaggle platform [21]. These tools and datasets play a crucial role in our methodology. Table IV provides detailed information on our setup and parameters.

TABLE IV. WORD2VEC TRAINING SETUP PARAMETERS

Parameter	Value	Description
vector_size	300	Dimension of word vector
workers	8	Number of threads involved in model training
min_count	5	Exclude words appearing fewer than 5 times
sg	0	Use CBOW

3) *GloVe*: GloVe, short for Global Vectors, emerges as an influential open-source initiative from Stanford, as noted in

[23]. This innovative project offers a method for generating word vector representations, facilitating a deeper understanding of language through mathematical modeling. Unlike traditional models, GloVe constructs word embeddings by optimizing a model based on the aggregation of word co-occurrences across a text corpus. This method focuses on shrinking the dimensions of the occurrence count matrix, capturing the essence of word relationships more efficiently.

Our research benefits from the utilization of GloVe vectors pre-trained on the extensive Common Crawl dataset. This massive corpus, comprising 840 billion tokens and a vocabulary of 2.2 million terms, provides a rich, contextually diverse linguistic foundation. The downloaded dataset, encapsulating 300-dimensional vectors for words and phrases, spans 2.03 GB, offering a comprehensive resource for our analytical needs.

E. Deep Learning Configurations and Parameter Tuning

Among the six deep learning architectures discussed in Section III, BiLSTM stands out for its performance in sentiment analysis [24]. For this reason, and to facilitate direct comparisons with previous research, we focus our in-depth experiments on BiLSTM. The key advantage of BiLSTM is its bidirectional data processing capability, which allows it to effectively assimilate contextual information from both preceding and subsequent text segments. This dual-directional approach is particularly beneficial for sentiment analysis, where understanding the complete context of text sequences is crucial for accurately determining sentiment polarity.

Building on this foundation, we have implemented three distinct BiLSTM models, each configured with different layer setups to optimize performance based on the nature of sentiment-laden words within the text, as noted in [24]. These configurations are specifically designed to enhance the model's ability to detect and interpret sentiment polarity, which heavily relies on contextual cues. The detailed specifications of each model configuration are outlined in Table V, showing the variations in layer structures and their intended impacts on model efficacy.

TABLE V. CONFIGURATIONS OF BiLSTM MODELS

Model	Parameters and architecture
BiLSTM1	Embedding layer, Bidirectional LSTM x 2, Conv1D, GlobMaxPool1D, Dense(16, ReLU), Dense(2, softmax)
BiLSTM2	Embedding layer, Conv1D, Maxpooling1D, BiRdirectional LSTM, Dropout, Dense(2, softmax)
BiLSTM3	Embedding layer, Bidirectional LSTM, Dense (128, ReLU), Dropout, Dense (64, ReLU), Dense (2, softmax)

To ensure optimal performance of the BiLSTM deep learning algorithm, we utilize the GridSearchCV tool from the Sklearn library for meticulous parameter fine-tuning. This process involves 10-fold cross-validation solely on the training set to rigorously evaluate different configurations without risking leakage from the testing data. Through this approach, we have identified and implemented a set of optimal parameters that significantly enhance model efficacy. These parameters include a learning rate of 0.001, a training duration of 50 epochs, and a batch size of 1024, using the Adam optimizer for efficient convergence. Additionally, to prevent overfitting, we

incorporate an EarlyStopping mechanism with a patience of 5 epochs, halting training if there is no improvement in the validation loss. Furthermore, we deploy the ReduceLROn-Plateau strategy, which automatically reduces the learning rate when there are no further improvements in validation loss, ensuring that the training process is both efficient and robust.

V. EXPERIMENTAL ANALYSIS AND COMPARISON

This section conducts a detailed exploration of experimental tasks, emphasizing the practical use of the methods described in Section III. We train various deep learning models, each employing various configurations and parameters meticulously optimized for sentiment classification. We evaluate the effectiveness of these models using recognized evaluation metrics, including Accuracy, Precision, Recall, and F1-Scores.

The results from these experiments lay the groundwork for in-depth analysis, discussion, and comparison. By delving into these outcomes, we aim to identify the strengths and weaknesses of each model configuration and evaluate their influence on overall performance. This analysis is crucial as it pinpoints the most effective techniques and settings tailored to the unique characteristics of our selected dataset. Moreover, our research extends beyond basic performance metrics to incorporate a comparative analysis of the models. We contrast the models against one another under equivalent conditions to determine which configurations deliver the optimal balance between precision and recall and which enhance overall accuracy and F1-Scores. This comprehensive experimental analysis also aims to establish benchmarks for sentiment classification, which is detailed in the subsequent subsections.

A. Analysis of Training Performance

In our evaluation of deep learning models, we repeatedly train and validate each model ten times to compute both the average values and standard deviations. As detailed in Table VI, the BiLSTM2 model demonstrates superior performance, achieving an accuracy of 88.881% and an AUC of 95.996%, which are the highest among the tested BiLSTM models. In contrast, the BiLSTM2 Word2Vec Pretrain model shows the lowest performance, with an accuracy of 81.351% and an AUC of 89.515%.

TABLE VI. PERFORMANCE OF BiLSTM MODELS ON THE TRAINING DATA

Model	Accuracy	AUC	Loss
BiLSTM1	0.85228 ±0.00226	0.93258 ±0.00197	0.32977 ±0.00482
BiLSTM2	0.88881 ±0.00077	0.95996 ±0.00043	0.25562 ±0.00141
BiLSTM3	0.84987 ±0.00022	0.93081 ±0.00021	0.33406 ±0.00052
BiLSTM1_Word2Vec	0.83079 ±0.00120	0.91170 ±0.00100	0.37321 ±0.00208
BiLSTM2_Word2Vec	0.81789 ±0.00208	0.89966 ±0.00209	0.39787 ±0.00416
BiLSTM3_Word2Vec	0.83011 ±0.00381	0.91252 ±0.00331	0.37429 ±0.00671
BiLSTM1_Word2Vec_Pretrain	0.82740 ±0.00128	0.90981 ±0.00118	0.37989 ±0.00237
BiLSTM2_Word2Vec_Pretrain	0.81351 ±0.00112	0.89515 ±0.00112	0.40666 ±0.00208
BiLSTM3_Word2Vec_Pretrain	0.82541 ±0.00317	0.90799 ±0.00299	0.38340 ±0.00601

BiLSTM1_Glove_Pretrain	0.83309 ±0.00143	0.91501 ±0.00012	0.36939 ±0.00262
BiLSTM2_Glove_Pretrain	0.81906 ±0.00081	0.90035 ±0.00088	0.39682 ±0.00170
BiLSTM3_Glove_Pretrain	0.83018 ±0.00565	0.91119 ±0.00516	0.37443 ±0.01084

B. Analysis of Testing Performance

Fig. 7 illustrates the performance metrics of various BiLSTM models using Word2Vec and GloVe embeddings. The BiLSTM1 model with GloVe embeddings shows the best performance, achieving an accuracy of 82.175% (see Fig. 7(a)), an F1-Score of 82.174% (see Fig. 7(b)), a precision of 82.189% (see Fig. 7(c)), and a recall of 82.178% (see Fig. 7(d)). In contrast, the BiLSTM2 model with a default embedding layer records the lowest metrics: an accuracy of 78.971% (see Fig. 7(a)), an F1-Score of 78.929% (see Fig. 7(b)), a precision of 78.926% (see Fig. 7(c)), and a recall of 78.918% (see Fig. 7(d)). Overall, Fig. 7 highlights the superior performance of the BiLSTM1 model with GloVe embeddings across all measured metrics.

1) *Performance with SGD and adam optimizers:* To enhance the BiLSTM1 model, we explore variations such as BiLSTM1, BiLSTM1_Word2Vec, BiLSTM1_Word2Vec_Pre-train, and BiLSTM1_Glove_Pretrain using the SGD optimizer with settings of 50 epochs, a learning rate of 0.1, momentum of 0.8, and Nesterov disabled. Subsequently, we evaluate these models against their counterparts trained with the Adam optimizer. The detailed outcomes of these experiments are presented in Fig. 8 and Fig. 9.

As depicted in these figures, the standard BiLSTM1 model trained with the SGD optimizer has lower accuracy and F1-Score than with Adam. Specifically, Adam achieves 79.794% accuracy, surpassing SGD's 79.198%. Similarly, the BiLSTM1_Word2Vec model shows better performance with Adam, reaching an accuracy of 82% and an F1-Score of 81.999%.

Further analysis shows the BiLSTM1_Word2Vec_Pretrain model, using pre-trained Word2Vec vectors, performs similarly to its non-pretrained counterpart. On the other hand, the BiLSTM1_Glove_Pretrain model, with pre-trained GloVe embeddings, outperforms all others, achieving the highest accuracy of 82.175% and an F1-Score of 82.174%.

These findings underscore the advantage of using pre-trained embeddings like Word2Vec and GloVe. Additionally, the Adam optimizer tends to yield superior results compared to SGD, highlighting its effectiveness in optimizing deep learning models.

(a) Accuracy performance of deep learning models.

(b) F1-Score performance of deep learning models.

(c) Precision performance of deep learning models.

(d) Recall performance of deep learning models.

Fig. 7. Performance of deep learning models on the testing data.

Fig. 8. BiLSTM1 performance with SGD optimizer.

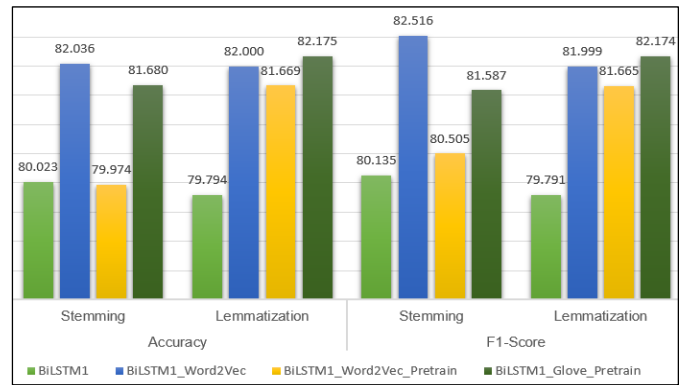

Fig. 10. BiLSTM1 performance with Stemming and Lemmatization.

2) *Performance with stemming and lemmatization:* We evaluate how Stemming and Lemmatization impact the performance of various BiLSTM1 configurations: BiLSTM1, BiLSTM1_Word2Vec, BiLSTM1_Word2Vec_Pre-train, and BiLSTM1_Glove_Pretrain. We analyze and compare these preprocessing techniques to determine which yields better results, with specifics illustrated in Fig. 10.

For the standard BiLSTM1 model, both Stemming and Lemmatization have negligible effects on performance, achieving similar accuracy and F1 scores: The method achieves an accuracy of 80.023% and an F1 score of 80.135%. The BiLSTM1_Word2-Vec, incorporating Word2Vec, also shows little variation between the two techniques, with a minor deviation of just 0.0036%.

Similarly, the BiLSTM1_Word2Vec_Pretrain and BiLSTM1 models exhibit minimal differences when applying either technique. However, Lemmatization provides a slight improvement in performance, achieving an accuracy of 81.669% and an F1-score of 81.665%.

The BiLSTM1_Glove_Pretrain model, using pre-trained GloVe embeddings, performs well under both techniques but shows a slight preference for Lemmatization, which delivers the highest accuracy and F1-score among the tested models at 82.175% and 82.174%, respectively.

The comprehensive analysis indicates that although the differences between the two methods are generally small across the models, Lemmatization consistently shows a slight improvement in accuracy and F1-scores.

3) *Performance with stop words:* In this experiment, we investigate how the exclusion of stop words influences the performance of the BiLSTM1 model, particularly focusing on the BiLSTM1_Glove_Pretrain model, which omits the stop word removal step during data preprocessing. The results from this configuration demonstrate an accuracy of 0.83962, an F1-Score of 0.83857, a recall of 0.83042, and a precision of 0.84689. These findings suggest that removing stop words can significantly affect model performance in sentiment analysis tasks, particularly with techniques that rely heavily on word context, like Word2Vec.

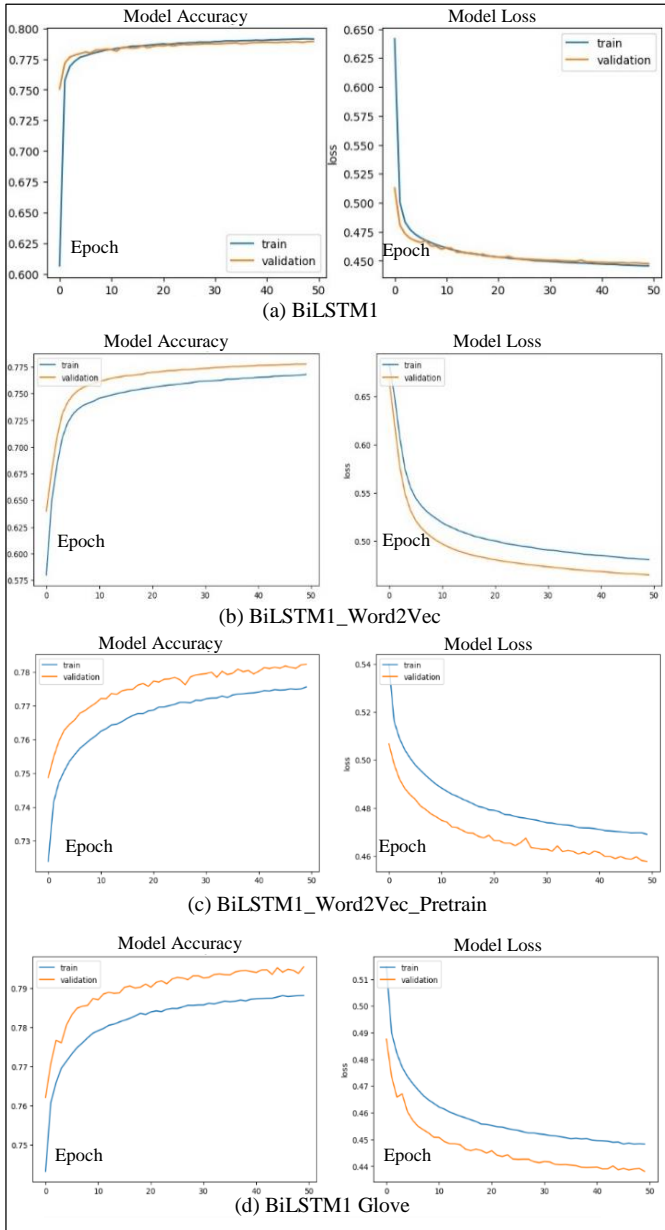

Fig. 9. BiLSTM1 accuracy trends across epochs with SGD optimizer.

Notably, the performance metrics for the BiLSTM1_Glove_Pre-train model show substantial improvement across all parameters when stop words are retained: accuracy improved from 0.82175 to 0.83962, F1-Score from 0.82174 to 0.83857, recall from 0.82178 to 0.83042, and precision from 0.82189 to 0.84689. This improvement highlights how stop words add contextual depth, enhancing the model's accuracy.

4) *Benchmarking against prior studies:* Our study meticulously compares the effectiveness of our sentiment analysis models with the results reported in a previous study, specifically [25], which employed the same dataset and data division methodology. The dataset is partitioned into training and testing sets with a 90:10 ratio, and the training set is further split into training and validation sets, also with a 90:10 ratio.

The results in Table VII demonstrate that our proposed methods (BiLSTM1_Glove_Pretrain and BiLSTM1_Glove_Pretrain With-out Stop Word Removal), shown in the first two rows, consistently outperform the approaches from study [25] (listed in the subsequent rows) in terms of accuracy and F1-score. Notably, our methods achieve, on average, an improvement of 2.07% in accuracy and 2.20% in F1-score compared to those reported in study [25].

To elucidate, our BiLSTM1_Glove_Pretrain model records an accuracy of 82.2% and an F1-score of 82.2%, while our BiLSTM1_Glove_Pretrain_NoSW-Removal variant shows even more impressive results with an accuracy of 83.9% and an F1-score of 83.8%. In contrast, the best-performing model from the prior study, the LSTM + FastText, only achieves an accuracy and F1-score of 82.4%. Other models from the same study, such as LSTM + Glove and LSTM + Glove Twitter, present lower performances with accuracy and F1-scores ranging from 80.4% to 81.6%. These results underscore the effectiveness of our methodologies, particularly in enhancing the precision and reliability of sentiment analysis in real-world applications.

TABLE VII. PERFORMANCE COMPARISON WITH PRIOR STUDY [25]

Model	Accuracy	F1-score
BiLSTM1_Glove_Pretrain _	82.2 %	82.2 %
BiLSTM1_Glove_Pretrain_NoSW-Removal	83.9 %	83.8 %
DNN (Baseline) [25]	79.0 %	78.4 %
LSTM + FastText [25]	82.4 %	82.4 %
LSTM + Glove [25]	81.5 %	81.4 %
LSTM + Glove Twitter [25]	80.4 %	80.4 %
LSTM + w/o Pretrained Embed [25]	81.6 %	81.4 %

VI. CONCLUSION AND FUTURE DIRECTIONS

Social networks such as Twitter, now known as X, are crucial platforms for capturing real-time public sentiments. This study exploited the power of these platforms, particularly utilizing the Sentiment140 dataset, which includes 1.6 million tweets, to develop and evaluate a comprehensive methodology for sentiment analysis using advanced machine learning techniques. Our approach spanned from data collection and preprocessing to feature extraction and model optimization. We extensively

explored several deep learning architectures through various configurations and parameters settings.

Our exploration into deep learning frameworks, particularly the BiLSTM models, revealed their high ability to capture nuanced expressions of sentiment. These models, when integrated with pre-trained GloVe embeddings, significantly outperformed traditional embeddings, achieving an accuracy of 88.88% and an AUC of 96%. These results highlight the potential of deep learning techniques to enhance sentiment analysis tools.

The evaluations not only confirmed the effectiveness of our methodology but also helped establish benchmarks in the field. Compared to existing approaches, our methods consistently demonstrated higher performance, often surpassing baseline results by more than 3%. This provides valuable insights and a solid foundation for further research and practical applications.

Our research will increasingly focus on exploring deep learning techniques, particularly Transformer-based models, which are well-suited for managing the complexities of language in sentiment analysis due to their superior handling of sequential data. We also aim to expand our methodologies to include multilingual datasets, enhancing the global applicability of our findings across various linguistic and cultural contexts. These strategic directions are intended to not only advance the technical aspects of sentiment analysis but also to increase its practical relevance and effectiveness in dynamic environments.

ACKNOWLEDGMENT

Abstract—This research introduces a computer-aided intelligence model designed to automatically identify positive instances of COVID-19 for routine medical applications. The model, built on the Generalized Linear architecture, employs the TwoStep-AS cluster method with diverse screen relatives, Weight sharing and stripping characteristics automatically identify distinctive features in chest X-ray images. Unlike the conventional transformational learning approach, our model underwent training both before and after clustering. The dataset was subjected to a compilation process that involved subdividing samples and categories into multiple sub-samples and subgroups. New cluster labels were then assigned to each cluster, treating each subject cluster as a distinct category. Discriminant features extracted from this process were used to train the Generalized Linear model, which was subsequently applied to classify instances. The TwoStep-AS clustering method underwent modification using pre-compiling the data earlier then employing the Generalized Linear model to identify COVID samples from X-ray chest results. Tests were conducted by the COVID-radiology data guaranteed the correctness of the results. The suggested model demonstrated an impressive accuracy of 90.6%, establishing it as a highly efficient, cost-effective, and rapid intelligence tool for the detection of Coronavirus infections.

Keywords—Generalized Linear model; COVID-19; TwoStep-AS; clustering; X-ray images

I. INTRODUCTION

Covid-19 constitutes a diverse domestic of diseases capable of infecting humans and causing severe illnesses [1,2]. The current pandemic stems from a novel animal-borne illness, indicating that humans have not previously encountered this virus, and it has transitioned from animals to humans [3]. Given its novelty, there is a lack of inherent immunity among people, which distinguishes it from other viruses and contributes to its potential for widespread or local epidemics [4]. In this context, an epidemic is known as an eruption of a communicable disease significantly increasing humanity and illness over a superior geographic area, while an epidemic is a disease spreading rapidly within a short timeframe.

Previous instances include the SARS virus in 2002, which pretentious 8,096 persons and claimed over 770 lives, and the Middle East respiratory syndrome Covid-19 (MERS-CoV) in 2012, ensuing in 858 fatalities and 2,494 infections [5]. The ongoing battle against COVID-19, which began spreading in

December 2019, has led to a global health crisis. COVID-19 primarily spreads through indirect or direct contact with diseased persons, breathing drops, or airborne conduction [6]. Primary symptoms include a high-temperature, dry cough, and trouble breathing, potentially progressing to severe breathing distress or organ failure, and in extreme cases, death [7, 8].

The rapid and sustained spread of COVID-19 poses challenges in our ability to effectively combat the virus, given the limited capacity of healthcare professionals and resources. This necessitates the development of tools such as contact tracing applications, statistical visualizations, dashboards, machine-learning methods, and other AI models to aid healthcare professionals in managing the pandemic.

However, the proposed method has a drawback since it is confined to the X-ray data, and other health corpus could be employed for the COVID 19 identification. The subsequent sections of this paper are organized as follows. Section two reviews pertinent studies in this field. Section three outlines the intended proposed system. Section four deliberates on the strategy and technique. Section five scrutinizes the investigational outcomes and the data. Section six encompasses a recap of the discussion, results, and investigation, whereas section seven encapsulates the summary and delineates future avenues for exploration.

The study's novelty lies in the meticulous consideration of multiple phases, including data pre-processing, categorization, model training, evaluation, and validation. By demonstrating an impressive accuracy of 90.6% in diagnosing COVID-19 cases, the proposed model emerges as a highly efficient, cost-effective, and rapid intelligence tool. Additionally, the study contributes valuable insights into the challenges of imbalanced distributions in raw datasets and proposes a hybrid TwoStep-AS clustering algorithm and GL method as a strategy to improve classification diagnostic precision, reduce misdiagnosis mistakes, and enhance overall accuracy. This comprehensive approach positions the study as a noteworthy advancement in the realm of AI-based medical diagnostics for COVID-19.

II. RELATED WORKS

Machine-learning has proven to be extremely effective in a wide range of picture combination processing tasks, including image-analysis [10, 11], image-segmentation [9], and image-

classification [12]. Image categorization requires extracting significant features from images by descriptors, instants [13], and SIFT [14]. These collected features are then used in prediction tasks by utilizing prediction devices such as support vector machine [15]. Traditional image fusion approaches, however, have intrinsic drawbacks, such as reduced image quality, heightened interference within the conclusive blended result image, and infeasibility for instantaneous applications where visuals might experience blurring. Color distortion and spectrum degeneration have also been reported in color photographs. In contrast to manually built features, deep neural network-based system techniques [16] show improved performance in image categorization based on extracted attributes. Several attempts have been made, leveraging machine learning techniques to categorize chest X-ray images in COVID groups or usual cases. For instance, a CNN model was developed for spontaneous COVID diagnosis from X-ray samples, achieving a claimed classification accuracy of 96.78% using the MobileNet structural design [17]. Another study by Simi Larley [18] employed a strategy of transfer-learning, with reported correctness rates of 97% and 87% for InceptionV3 and Inception-ResNetV2, respectively. The utilization of orthogonal moments, particularly orthogonal quaternion harmonic transformation moments, has proven effective in various pattern recognition and image processing applications [19-21]. Recent research focused on developing an AI-based programmable tomography investigation toolkit for monitoring COVID-19 progression, using 3D volume assessment to generate a "Corona Score" [22]. A research by Rasheed et al. [23] travelled health and technical facets in combating the COVID epidemic, offering valuable insights for virologists, communicable illness scientists, and policymakers. This research delved into the use of diverse technical systems and various artificial intelligence methods to aid in the pandemic, including predictive diagnostic machine learning techniques, such as deep learning.

Sethy and Behera [24] used X-ray images in combination with diverse CNN methods and the SVM for feature identification, highlighting the ResNet-50 model integrated with the SVM method as the most effective. Some current COVID research incorporated a variety of CT samples deep-learning approaches in their analyses [25].

State-of-the-art systems, drawing on deep-learning methods and utilizing chest-X-ray cases, have been developed based on research studies [11, 24, 26-30]. While machine learning methods depend deeply on knowledge for information extraction and selection, they exhibit inadequate performance compared to deep-learning methods. The advantages of machine learning methods, such as making the most of unstructured data, eliminating the need for engineered features, providing superior performance, reducing costs, and eliminating the need for data labeling, have led to their widespread use in automatically extracting crucial characteristics from items of interest for appropriate categorization. Notably, Apostolopoulos and Bessiana achieved a 97.8% accuracy in COVID-19 categorization with the VGG19 architecture [26], and Ozturk et al. demonstrated an 87% accuracy in categorizing coronavirus, pneumonia no-findings, and findings [11]. Sethy and colleagues developed a ML algorithms for negative and positive COVID-19 cases [24]. Nevertheless, distinguishing COVID-19 produced

pneumonia cases from other virus-related pneumonia samples is crucial to prevent misdiagnosis, given the differing therapeutic approaches required for coronavirus disease. Various studies have recommended pulmonic chest-infection categorization based on deep-learning approaches [31, 32]. The current focus of research involves identifying COVID-19 patients with different pulmonary diseases, such as effusion, fibrosis, and edema.

III. PROPOSED METHOD

This section presents a detailed discussion of the components and procedures used to create the suggested solution. Several critical phases are involved in recognizing COVID-19 from chest X-ray images: dataset collecting, data pre-processing, dataset categorization, training of models, model evaluation and analysis, and model validation and enhancement. Fig. 1 depicts the system design for COVID-19 detection using TwoStep-AS and GL (TGL) and its components. The initial step involves gathering and organizing the dataset required for training and model validation. To ensure consistency, the collected data undergoes transformations, scaling, and normalization. Subsequently, all data is categorized based on the model's classification scheme. Following that, models are trained and verified using exactly the same dataset and context as previously used models. Finally, for both the training and testing processes, the trained models are evaluated using accuracy metrics and the receiver operational characteristic curve. Fig. 1 depicts the TGL System's framework.

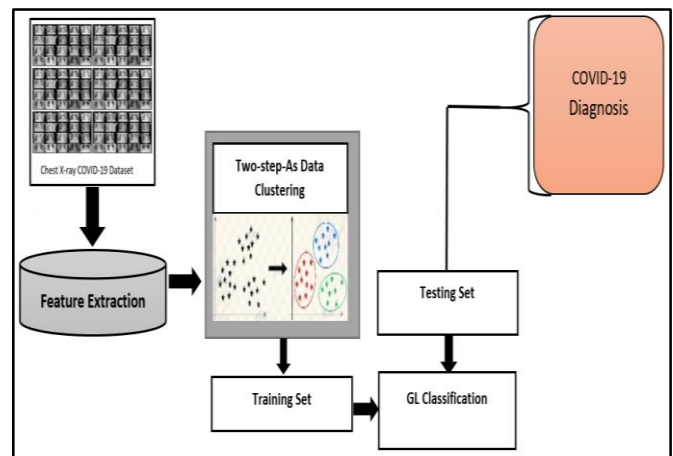

Fig. 1. TGL Classifier.

Fig. 1 depicts the fundamental structure of the TGL Diagnosis System. The proposed methodology comprises three stages: addressing the imbalance in the raw dataset and feature extraction, clustering instances based on their proximity to case characteristics using the TwoStep-AS algorithm, and performing diagnosis using a GL classifier during both the learning and testing phases. The proposed approach is designed to classify X-ray images into categories such as Pneumonia, COVID-19, or Non-COVID-19. The subsequent sections delve into the details of dataset modeling and the suggested TGL modeling.

A. COVID-19 Dataset

This study employs publicly accessible image repositories [33] to conduct its investigation. The dataset comprises typical chest X-ray images representing three distinct cases: pneumonia, normal, and COVID-19. Dr. Joseph Cohen, the custodian of a GitHub collection housing annotated thoracic X-ray and computed tomography (CT) scan visuals linked to COVID-19, Acute Respiratory Distress Syndrome (ARDS), Severe Acute Respiratory Syndrome (SARS), and Middle East Respiratory Syndrome (MERS), fastidiously captured and recorded thoracic X-ray visuals from individuals afflicted with COVID-19. This compilation encompasses 250 confirmed chest X-ray images of individuals with COVID-19 viral infections. The Kaggle repository was utilized to procure chest X-rays from both healthy individuals and patients diagnosed with bacterial and viral pneumonia.

The application of AI-based X-ray screening for COVID-19 proves effective in both symptomatic and asymptomatic cases. However, distinguishing COVID-19 from other lower respiratory disorders that may exhibit similar features in X-ray imaging poses a unique challenge for algorithm developers. Dr. Cohen, affiliated with John Hopkins Hospital, generously contributed data in the form of JPG X-ray images, leading to the formation of a dataset sourced from Kaggle Chest X-rays datasets. This dataset facilitated a comparative analysis among healthy individuals, patients with bacterial pneumonia, and those with COVID-19 viral infection pneumonia. The collection incorporates chest images obtained from pneumonia patients admitted to hospitals. Dr. Cohen [33] established a COVID-19 X-ray image repository using publicly available images, consistently updating it with contributions from experts. Presently, the database encompasses 127 diagnostic X-ray images of COVID-19.

The National Institutes of Health Chest X-Ray Dataset (NIH) stands as another pivotal dataset in relation to COVID-19. Comprising 112,120 X-ray images with disease classifications from 30,805 distinct individuals, this dataset was constructed using Natural Language Processing to extract illness categories from corresponding radiological reports. Approximately 90% of the labels are deemed accurate, rendering them suitable for deployment in unsupervised learning scenarios.

B. Feature Extraction Process

- Statistical Feature

Upon closer examination of the X-ray images, it becomes evident that the predominant visual element is likely the excellent texture and statistical combinations. In recent years, many researchers have increasingly utilized textural and statistical characteristics to address classification challenges, and this trend is anticipated to persist. The appeal of such utilization lies in its simplicity compared to the labor-intensive process of software engineering, which demands an in-depth understanding of issue classes and methods for designing handcrafted descriptors. This function is unnecessary. While unmanufactured descriptors have some advantages, it is crucial to acknowledge that manually crafted descriptors possess distinct characteristics that can prove highly beneficial for a diverse array of categorization tasks. In this context, for

instance, the merits of utilizing artisanal features outweigh the drawbacks due to their enhanced potency, often operating in a more foreseeable manner to capture patterns associated with a particular issue. Opting for handcrafted components instead of raw ones increases the likelihood of a more precise interpretation of the patterns formed by the crafted characteristics in the images.

Despite the current emphasis on using both sets in feature extraction, this was not always the norm. Consequently, one can evaluate the two independently and then amalgamate the data from various experimental groups to derive a conclusive result. This approach leverages the complementarity among the methods of descriptors, as exemplified in [34, 35], preventing them from making identical errors during the execution of a given classification task.

This section briefly delves into the descriptors' characteristics. Specifically chosen texture descriptors were selected to perform effectively in general applications or, more particularly, in the analysis of medical images. The approach for Texture features involved the utilization of the Gray-Level Co-Occurrence Matrix (GLCM). Sebastian et al. [36] defined GLCM as a matrix-based method frequently employed in texture investigations to establish connections between pixels. The distance and angle between two neighboring pixels are used to compute the relationship when two pixels are in proximity. Consequently, the GLCM parameters encompass the size of the space and the angles. GLCM functions quantify a picture's texture by determining the frequency of pixel pairs with differing values and a specified spatial relationship.

GLCM generates a matrix of pixel pairs with varying values and a specific spatial relationship, from which statistical measurements are derived. As mentioned earlier, statistical measures from texture filter functions, as well as spatial connections among pixels in an image, were deemed insufficient in providing information on shape in texture features. The GLCM feature set relies on second-order statistics to compute reflections, using the overall average of similarity degrees between pixel pairs in various ways (such as homogeneity, uniformity, etc.). Pixel separation plays a vital role in influencing the GLCM's discriminative abilities. When scrutinizing distance 1, the representation of the connection between pixel values reflects short-term neighborhood connectivity, and alterations in distance values signify changes in the number of matching pixels.

- GLCM Features

GLCM furnishes operations that accurately grasp the proximity correlation amid pixels in the texture depiction, as elucidated in statistical and structural methodologies for texture [36]. The formulas employed to derive features from co-occurrence matrices are selected according to the attributes intended for observation. From the X-ray image assortment characteristics, encompassing correlation, homogeneity, energy, and contrast, we opted for the four most pertinent Haralick texture components for subsequent analysis. Osman et al. [37] expound upon and present the equations for computing both the statistical and GLCM features.

C. TwoStep-AS Cluster Algorithm

Numerous researchers, including [38-40], have employed the TwoStep Clustering algorithm across diverse domains. In their work, Najjar, A. et al. [38] applied an exploratory analytics approach to evaluate healthcare data based on the insights from the Smyth research[39]. The approach utilized a TwoStep Clustering methodology for heterogeneous finite mixture models, encompassing a joint mix of multinomial distribution and Gaussian for both categorical and numerical inputs. A hidden Markov model was incorporated for orders of categorical input. Deneshkumar et al. [40] proposed a technique for identifying outliers and determining the impact factor in diabetes patients, employing a TwoStep Clustering algorithm alongside other data mining methods. This study aims to uncover natural clusters within a knowledge collection through an exploratory technique known as TwoStep-AS Cluster, utilizing an algorithm that boasts several advantageous characteristics distinguishing it from conventional clustering methods.

- Handling Categorized or Continuous Variables: Utilizing a joint multinomial-normal distribution when variables are considered independent of one another.
- Automatic Selection of the Number of Clusters: Employing an optimization method to automatically determine the optimum number of clusters by comparing values of a model-choice criterion across various clustering solutions.
- Scalability: Constructing a Cluster Feature (CF) tree in the TwoStep-AS method to summarize entries in each cluster, facilitating the examination of large data files.

Industries like trade and customer properties commonly apply grouping approaches to analyze consumer data, tailoring marketing and product development strategies to specific consumer segments. The TwoStep-AS method incorporates log-likelihood distance, employing a pre-cluster procedure using the CF tree. This tree is traversed to determine the closest leaf entry for each record, updating the CF tree accordingly. The clustering phase then organizes the sub clusters into the suitable amount of clusters using an agglomerative hierarchical approach. The log-likelihood distance measures the relationship between two clusters, utilizing probability functions based on variable values, considering categorical variables as multinomial and continuous variables as regularly distributed. The distance between cluster-*i* and cluster-*j* is expressed as [41, 42]:

$$d(i, j) = \xi_i + \xi_j - \xi_{\langle i, j \rangle} \quad (1)$$

Where

$$\xi_s = -N_v \left(\sum_{k=1}^{K^A} \frac{1}{2} \log(\hat{\sigma}_k^2 + \hat{\sigma}_{vk}^2) + \sum_{k=1}^{K^B} \hat{E}_{vk} \right) \quad (2)$$

$$\hat{E}_{vk} = - \sum_{k=1}^{L_k} \frac{N_{vkl}}{N_v} \log \frac{N_{vkl}}{N_v} \quad (3)$$

The formulations encompass the subsequent parameters:

K^A means the variety class number of input features.

K^B denotes the representative number class of the input features.

L_k indicates the category number for the *k*th representative feature.

N_{vis} denotes the number of samples in cluster-*v*.

N_{vkl} indicates the number of samples in cluster-*v* that is similar to the *l*th type of the *k*th representative feature.

$\hat{\sigma}_k^2$ denotes the probable variance of the *k*th continuous feature for all instances.

$\hat{\sigma}_{vk}^2$ indicates the probable alteration of the *k*th continuous feature for samples in the *v*th cluster.

$\langle i, j \rangle$ denotes an index representing the cluster molded by merging clusters-*i* and clusters-*j*.

The distance among cluster-*i* and cluster-*j* would precisely match to the reduction in log likelihood once the two clusters are amalgamated if $\hat{\sigma}_k^2$ is mitted in the appearance for ξ_v , and $\hat{\sigma}_{vk}^2$ is neglected in the expression for *v*. Introducing this term helps circumvent the problem arising from $\hat{\sigma}_k^2 = 0$, which would make the natural logarithm undefined. The technique comprises two phases. The first phase automatically defines the number of clusters, while the second phase computes the BIC for each cluster number within a given range. This indicator is then utilized to determine an initial approximation for the number of clusters in the second phase.

$$BIC(J) = -2 \sum_{j=1}^J \xi_j + m_j \log(N) \quad (4)$$

$$m_j = J \left\{ 2K^A + \sum_{k=1}^{K^B} (L_k - 1) \right\} \quad (5)$$

$$f^*_{mk} = \begin{cases} rv. \text{binom} \left(N, \frac{f_k}{N} \right) & k = 1 \\ rv. \text{binom} \left(N - \sum_{i=1}^{k-1} f^*_{mi}, \frac{f_k}{N - \sum_{i=1}^{k-1} f_i} \right) & \text{otherwise} \end{cases} \quad (6)$$

The TwoStep Clustering method distinguishes itself from traditional clustering techniques through various advantageous features. Firstly, it accommodates both discrete and continuous variables as clustering inputs, expanding its applicability. Secondly, the TwoStep Clustering method demands fewer memory resources and exhibits faster calculations. Thirdly, it employs statistics as a distance index for clustering, simultaneously facilitating the automatic reorganization of data with an optimal number of clusters. Due to these attributes, the TwoStep Clustering technique is selected and explored for integration with the GL algorithm.

D. Generalized Linear Classifier

Generalized Linear Classifier is a classification model derived from the principles of Generalized Linear Models, adapted to handle categorical response variables. It provides a flexible framework for modeling relationships between predictors and categorical outcomes, making it applicable to a wide range of classification tasks.

It appears there might be a slight misspelling in your request. If you're referring to the "Generalized Linear Classifier," typically it's known as the "Generalized Linear Model (GLM)" or "Generalized Linear Regression (GLR)." A Generalized Linear Model is a flexible statistical framework that generalizes classical linear regression to accommodate various types of response variables and error distributions. The Generalized

Linear Model extends the classical linear regression model to handle situations where the response variable is not normally distributed or when the relationship between variables is not linear. It consists of three main components:

The response variable, Y , is assumed to follow a probability distribution from the exponential family (e.g., Gaussian, binomial, Poisson).

The linear predictor, $X\beta$, where X represents the predictor variables and β is the vector of coefficients.

A link function, $g(\mu)$, connects the expected value of the response variable to the linear predictor. It specifies how the mean, μ , is related to the linear predictor. Common link functions include the identity, logit, and log.

The general form of a GLM is:

$$g(\mu) = X\beta \quad (7)$$

where:

$g()$ is the link function.

μ is the expected value of the response variable.

X is the matrix of predictor variables.

β is the vector of coefficients.

Components of the Generalized Linear Classifier:

If you specifically meant a Generalized Linear Classifier (GLC), it could refer to a classifier based on the principles of Generalized Linear Models but adapted for classification tasks.

The suggested approach for diagnosing Covid-19 involves the integration of a Generalized Linear (GL) method with the Two-Step-AS algorithm. This method emulates human reasoning by considering multiple perspectives before arriving at a final decision. The unanimous decision to adopt this approach stems from the necessity for a high-level of sureness in the real-world implementation of the research. This holds particular significance because of the categorization of individuals with Covid-19 into bio-classes and the application of diverse decision-making fusion methodologies, extensively elaborated upon in the manuscript. The central aim is to enhance the learning process by amalgamating Covid-19 samples exhibiting analogous patterns. This grouping reduces complexity, leading to enhanced accuracy in diagnostic interpretation and, consequently, in the diagnosis itself.

IV. EXPERIMENTAL DESIGN AND DATASET

This section delineates the manner in which the proposed Generalized Linear (GL) method was assessed and how the experiment was carried out utilizing the GL technique. According to the methodology we advocate, the existing X-ray data is enhanced by include well balanced coronavirus images. The goal of this section is to demonstrate the negative impact of mbalanced distributions on raw dataset performance. It is important to highlight that the TwoStep-AS-GL has been adjusted to perform training using the best available method parameters. This paper offers a Covid-19 diagnosis prediction strategy based on a hybrid TwoStep-AS clustering algorithm and GL method. The goal is to improve classification diagnostic

precision, reduce misdiagnosis mistakes, and boost classification accuracy. As a result, a new strategy that mixtures supervised and unsupervised learning techniques to generate a integrated instructional model is established.

The TwoStep-AS clustering data structure was thoroughly investigated for X-ray chest imaging feature extraction utilizing the GL classification structure. The GL classifier was used to predict positive occurrences of Covid-19, pneumonia, and cases not discovered when the cluster findings were utilized as inputs to the classification model. The TGL model is used to investigate the effects of the qualifying procedure, taking into account the huge number of instances linked to the X-ray chest data.

Two separate situations were used to detect and categorize COVID-19 in X-ray images. To begin, the TGL technique was trained to classify the X-ray pictures as COVID-19, No-Finding, or Pneumonia. In addition, two courses were trained in the TGL model: COVID-19 classes and No-Findings groups. The suggested model's output was tested for difficulties involving triple and binary categorization. The random images from this batch were utilized to assure balanced findings using a collection of chest X-ray images provided by Wang et al. [43], which comprises both normal and pneumonia images. After data balancing, the formed groups were used to identify each group separately using diagnostic cluster studies.

V. RESULTS DISCUSSION AND ANALYSIS

By implementing the TwoStep-AS Cluster, the performance of the NN classification algorithm can be elevated. This improvement is attributed to the fact that continuous features often exhibit enhanced performance when discretized [43]. Yang & Webb [44] utilized discretization as a technique to address continuous features in machine learning methods, enhancing the efficiency of data processing and optimizing inductive learning algorithms. The TwoStep-AS cluster, initially developed by Chiu et al. [45], is specifically designed to handle extensive datasets. Integrated into the statistical software SPSS, it serves as a clustering algorithm capable of managing both continuous and categorical data [46, 47]. Table I outlines the specifications of the TwoStep-AS model.

TABLE I. SPECIFICATIONS OF THE TWOSTEP-AS ALGORITHM

Minimum Quantity of Standardized Clusters	2
Maximum Quantity of Standardized Clusters	15
Method for Significance of Features	Information Criterion
Criterion for Data Evaluation	BIC
Distance-Measure	Log Likelihood

As depicted in Table I, after inputting a processed dataset, denoting a quantified dataset, the system employs the TwoStep-AS technique to produce a class label from the processed data. This class label encompasses two designations, specifically cluster-1 and cluster-2, amalgamated together. Following the assignment of each class label, the antecedent probability for each class label is established for NN computation, an essential phase in the NN calculation procedure. Table I illustrates that

the TwoStep-AS algorithm generates a minimum of 2 and a maximum of 15 standard clusters. The TwoStep-AS algorithms utilize the BIC Method for Feature Importance assignment and the Log Likelihood metric as the Distance Measure. The efficacy of the clustering assessment by the TwoStep-AS model is presented in Table II.

TABLE II. QUALITY OF THE TWOSTEP-AS ALGORITHM.

Cluster-No	Number of Records	Goodness	Importance
Cluster1	985	0.89	1.00
Cluster2	416	-0.25	1.00

Table II demonstrates the effectiveness of the TwoStep-AS model, considering the count of entries, excellence, and significance of records. The excellence acts as a measure for the cohesiveness and distinctiveness of clusters. Cluster-1 has 985 records with a goodness of 0.89 and a record importance score of 1.00, while Cluster-2 has 416 records with a goodness of -0.25 and a record importance score of 1.00. The general classifier goodness is measured by the Average Silhouette Coefficient, resulting in a value of 0.76 (interpreted as Good, on a scale from -1 to 1 where -1 to 0.2 is Poor, 0.2 to 0.5 is Fair, and 0.5 to 1 is Good). Additionally, importance is gauged as a measure of cluster cohesion, categorized as Poor (0 to 0.2), Fair (0.2 to 0.6), or Good (0.6 to 1). In conducting an experimental study, a dataset related to COVID-19 was obtained for the purpose of data exploration. As mentioned earlier, the researchers utilized a tenfold cross-validation technique for both training and testing the dataset in their study. Additionally, a cross-dataset experiment was conducted, wherein the GL classifier was employed both independently and in conjunction with TwoStep-AS clustering results to assess the enhanced results of the integrated approach. The outcomes of the cross-validation process were calculated utilizing formula (8) to produce the ensuing diagnostic:

$$\text{Accuracy} = \frac{(TN + TP)}{(TN + FP) + (TP + FN)} \times 100 \quad (8)$$

The number of COVID-19 cases correctly classified is referred to as the True Positive (TP). The number of COVID-19 instances identified erroneously is indicated by False Positive (FP). True Negative (TN) refers to the number of non-COVID-19 and pneumonia cases that were misclassified. The number of non-COVID-19 and pneumonia cases identified erroneously is represented by False Negative (FN).

A chest X-ray dataset was evaluated to determine if patients were non-COVID-19, pneumonia, or COVID-19. The hybrid strategy was used to train and evaluate the dataset by merging TwoStep-AS and GL. Using the TwoStep-AS clustering algorithm, the dataset was then automatically separated into two clusters, each with a different amount of occurrences. In this study, the major goal of clustering is to identify patterns and Configurations derived from chest X-ray information through the categorization of specimens exhibiting analogous patterns. This reduces the intricacy of the investigation and enhances the precision of diagnostic interpretation. Table V showcases the outcomes of the training and testing procedures on the dataset, presenting a collection of results generated by the Ensemble GL classifier approach without clustering and with clustering employing the TwoStep-AS algorithm.

TABLE III. FEATURE CHARACTERISTICS

Feature	N	Min	Max	Mean	Std. Deviation
Target	1125	1	3	2.33	.667
F1	1125	58	38747	182.88	1150.987
F2	1125	25	13462	66.25	399.881
F3	1125	4	33	5.06	.845
F4	1125	1	1	.92	.005
F5	1125	3	14	3.37	.322

The continuous variables in the COVID-19 dataset, as analyzed by the GL classifier, offer valuable insights into the dataset's characteristics. In Table III, we observe the results for the dependent variable "Class" and the covariates (F1 to F5). For the dependent variable "Class," representing instances classified into categories (potentially non-COVID-19, pneumonia, and COVID-19), the dataset consists of 1125 observations. The statistics for "Class" include a minimum of 1, a maximum of 3, a mean of 2.33, and a standard deviation of 0.667.

These statistics provide a concise overview of the continuous covariates, including their range, mean, and standard deviation. The wide range observed in variables like F1 and F2 suggests significant variability, while F3 appears to have a relatively stable range based on its mean of 5.06. Higher standard deviations, particularly in F1, indicate greater variability among data points. We understand that the distribution and characteristics of these continuous variables is pivotal for assessing their impact on classification outcomes. Further analyses, such as correlation assessments and evaluations of feature importance, can offer deeper insights into the relationships between these variables and the ultimate classification results. This foundational understanding sets the stage for more in-depth investigations into the dataset's dynamics.

TABLE IV. GOODNESS OF FIT

Measurement	Value	df	Value/df
Deviance	89.720	1118	.080
Scaled Deviance	1125.000	1118	-
Pearson Chi-Square	89.720	1118	.080
Scaled Pearson Chi-Square	1125.000	1118	-
Log Likelihood	-173.833	-	-
Akaike's Information Criterion (AIC)	363.666	-	-
Finite Sample Corrected AIC (AICC)	363.795	-	-
Bayesian Information Criterion (BIC)	403.871	-	-
Consistent AIC (CAIC)	411.871	-	-

The results obtained from classifying the COVID-19 dataset using the GL classifier are outlined in the Table IV, encompassing various goodness-of-fit metrics and information criteria. Specifically, the deviance is reported as 89.720, with Degrees of Freedom (df) being 1118, resulting in a Value/df ratio of 0.080. Deviance acts as an indicator of the model's fit, where lower values signify a better alignment with the data. In this context, the achieved deviance value is relatively low, indicating a favorable fit. Linking to the subsequent metric, the Scaled Deviance Value is recorded as 1125.000, with df being 1118. Scaled deviance, similar to deviance, assesses goodness of fit while considering the scale of the response variable.

The relatively elevated value suggests a possibility for enhancing the model fit. Moving on, the Pearson Chi-Square is documented with a value of 89.720, df of 1118, and a Value/df ratio of 0.080. Similar to deviance, the Pearson Chi-Square evaluates the concordance between observed and expected values. A low value/df ratio is indicative of a favorable fit. Transitioning to the Log Likelihood, it is indicated by a value of -173.833. This metric, representing the logarithm of the likelihood function, seeks higher values for improved fit.

The negative value is aligned with the logarithmic nature of the measurement. Next, Akaike's Information Criterion (AIC) is reported with a value of 363.666. AIC aims to strike a balance between fit and model complexity, where lower values suggest a favorable trade-off between fit and simplicity. Similarly, the Finite Sample Corrected AIC (AICC) is documented with a value of 363.795. AICC, adjusted for small sample sizes, parallels AIC, and lower values are considered desirable for effective model evaluation. Moving on to the Bayesian Information Criterion (BIC), it is presented with a value of 403.871. Similar to AIC, BIC penalizes model complexity, and lower values indicate a superior model. BIC imposes a more stringent penalty for complexity. Finally, Consistent AIC (CAIC) is recorded with a value of 411.871. CAIC, which takes into account both fit and complexity, favors lower values for enhanced model performance.

The collective metrics imply that the GL classifier model exhibits a reasonable fit to the COVID-19 dataset. Nevertheless, there exists potential for improvement, and further refinement of the model or exploration of alternative approaches is worth considering.

The Omnibus Test provides strong evidence that the GL classifier, when applied to the COVID-19 dataset with the specified predictor variables, offers a statistically significant improvement in fit over an intercept-only model. This supports the validity and utility of the model in capturing and explaining the patterns in the data related to the classification of COVID-19 cases.

With the Omnibus Test measurement, the Likelihood Ratio Chi-Square has been assessed whether there is a significant difference between the fitted model (GL classifier with predictor variables) and an intercept-only model (a model with no predictors). The high value of 1932.649 and a very low p-value

(0.0005) indicate that there is a significant difference between the two models. In other words, the inclusion of predictor variables in the GL model significantly improves its fit compared to a model with no predictors. The Omnibus Test supports the notion that the GL classifier, incorporating the specified predictor variables, is a statistically better fit for the COVID-19 dataset than a model without predictors.

The GL classifier, as configured with the listed predictor variables, is deemed useful for explaining and predicting the variability in the dependent variable (Class), as evidenced by the significant Likelihood Ratio Chi-Square. The estimation parameters is presented in Table V.

The "Parameter Estimates" section furnishes essential details concerning the estimated coefficients, standard errors, confidence intervals, and hypothesis tests for each variable in the GL classifier model applied to the COVID-19 dataset.

The Estimate (B) is noted as -36.972, with a Std. Error of 17.6338, a 95% Wald Confidence Interval of (-71.533, -2.410), a Wald Chi-Square of 4.396, df: 1, and a significance level (Sig.) of 0.036. Linking to the interpretation of the intercept, which represents the estimated log odds of the reference category (Class 1), the estimate of -36.972 suggests a significant negative association with the dependent variable. The confidence interval excluding zero indicates statistical significance.

Moving to F1, with an Estimate of 0.001, Std. Error of 0.0004, a 95% Wald Confidence Interval of (-5.010E-5, 0.002), a Wald Chi-Square of 3.381, df: 1, and Sig.: 0.066, the coefficient implies a small positive effect, with a p-value suggesting marginal significance. The Transitioning to F2, where the Estimate is 0.004, Std. Error is 0.0010, a 95% Wald Confidence Interval of (0.002, 0.006), a Wald Chi-Square of 15.752, df: 1, and Sig.: 0.000, the positive coefficient and statistical significance (Sig. = 0.000) indicate a strong positive impact on the log odds. By examining F3 with an Estimate of -11.110, Std. Error of 3.8236, a 95% Wald Confidence Interval of (-18.604, -3.616), a Wald Chi-Square of 8.442, df: 1, and Sig.: 0.004, the negative coefficient signifies an association with lower log odds, and the p-value (Sig. = 0.004) indicates statistical significance. For F4, with an Estimate of 25.107, Std.

Error of 26.1258, a 95% Wald Confidence Interval of (-26.099, 76.313), a Wald Chi-Square of 0.924, df: 1, and Sig.: 0.337, the positive coefficient is not statistically significant, as the p-value is 0.337. Considering F5, which scores an Estimate of 21.576, Std. Error of 8.2198, a 95% Wald Confidence Interval of (5.465, 37.686), a Wald Chi-Square of 6.890, df: 1, and Sig.: 0.009, the positive coefficient is statistically significant (Sig. = 0.009), suggesting a positive association. The AS-TwoStep=Cluster-1 obtained an Estimate of -1.179, Std. Error of 0.0170, a 95% Wald Confidence Interval of (-1.213, -1.146), a Wald Chi-Square of 4790.478, df: 1, and Sig.: 0.000. The TwoStep-AS clustering variable (AS-TwoStep) for Cluster-1 is highly significant (Sig. = 0.000), indicating its crucial role in the model. AS-TwoStep=Cluster-2 is recorded with an Estimate of 0 (set to zero because this parameter is redundant).

TABLE V. PARAMETER ESTIMATES

Parameter	B	Std. Error	95% Wald Confidence Interval		Hypothesis Test		
			Lower	Upper	Wald Chi-Square	df	Sig.
(Intercept)	-36.972	17.6338	-71.533	-2.410	4.396	1	.036
F1	.001	.0004	-5.010E-5	.002	3.381	1	.066
F2	.004	.0010	.002	.006	15.752	1	.000
F3	-11.110	3.8236	-18.604	-3.616	8.442	1	.004
F4	25.107	26.1258	-26.099	76.313	.924	1	.337
F5	21.576	8.2198	5.465	37.686	6.890	1	.009
[AS-TwoStep=Cluster-1]	-1.179	.0170	-1.213	-1.146	4790.478	1	.000
[AS-TwoStep=Cluster-2]	0 ^a
(Scale)	.080 ^b	.0034	.073	.087			

The Scale feature achieved an Estimate of 0.080, Std. Error of 0.0034, a 95% Wald Confidence Interval of (0.073, 0.087). The scale parameter provides information about the dispersion of the errors. We conclude that the intercept, F2, F3, F5, and AS-TwoStep variables exhibit significant associations with the dependent variable (Class), influencing the odds of COVID-19 classification. F1, F4, and the redundant Cluster-2 variable are not statistically significant contributors to the model. The positive coefficient for F2 suggests an increase in the odds of COVID-19 classification, while the negative coefficient for F3 implies a decrease. F5 exhibits a positive association, indicating increased odds. The AS-TwoStep clustering variable for Cluster-1 strongly influences the model, affirming the effectiveness of the TwoStep-AS clustering method in COVID-19 classification.

Another investigation, utilizing the NIH dataset, was carried out to scrutinize instances as either positive Corona or negative Corona. The TGL scheme coupled with several classifier methods, was utilized in the training and testing stages to showcase the efficiency of the suggested model. Additionally, the accuracy of classification using the hybrid technique is documented in Table VI.

TABLE VI. PERFORMANCE ON THE TGL AND OTHER CLASSIFIERS METHODS

Method	Accuracy
ANN	0.60
Support Vector Machine	0.65
Bayesian Network	0.69
C51-classifier	0.74
TGL Model	0.89

Fig. 2 illustrates a comparison between the TGL model and currently employed methods. The proposed TGL method demonstrated a notable accuracy score of 0.906 in its application.

Fig. 2. Comparison between the TGL and other based methods

VI. CONCLUSION AND FUTURE DIRECTIONS

The focus of this research is on suggesting a novel Generalized Linear (GL) scheme using the TwoStep-AS clustering model (TGL) for detecting coronavirus and pneumonia cases. Clustering techniques play a crucial role in various domains that involve extensive datasets, aiming to unveil concealed patterns within the data. However, traditional clustering algorithms face challenges in effectively handling datasets containing both numerical and categorical attributes, common in real-world data. We demonstrated that the TwoStep-AS technique, known for its simplicity and automatic determination of the optimal number of clusters, can effectively address this issue.

In the initial phase of diagnosis using TGL, clinical cases undergo categorization into COVID, pneumonia, and normal samples. During the subsequent stage, given that COVID stems from a virus, records are further segregated into three categories: negative-COVID, pneumonia, and positive-COVID. The aim of the TGL approach is to furnish a swift, orderly, and dependable computing-supported result for characterizing Corona cases in patients undergoing preliminary screening with an X-ray scan upon admission to hospitals.

Thorough estimations have been conducted to determine the efficiency of the suggested scheme, utilizing both testing and training procedures to exemplify the effectiveness of TGL. Additionally, various tests have been executed to underscore the preeminence of TGL in pinpointing COVID cases compared to other cutting-edge methods for COVID detection. The suggested model demonstrated an impressive accuracy of 90.6%, establishing it as a highly efficient, cost-effective, and rapid intelligence tool for the detection of Coronavirus infections.

Future initiatives may involve harnessing advanced Convolutional Neural Network (CNN) methods and diverse Machine Learning (ML) models to refine the precision of detecting positive COVID patients from CT-scan and X-ray images. Contemplation might also be given to adjusting the dimensions of the provided images, and the integration of machine learning-based image segmentation could further enhance performance. Furthermore, the exploration of optimized approaches based on classification and regression methods will be undertaken to augment the predictive capability of the approach in diagnosing COVID-19.

ACKNOWLEDGMENT

This work was funded by the Deanship of Scientific Research (DSR) at King Abdulaziz University, Jeddah, Saudi Arabia, under Grant No. (GCV19-6-1441). The author, therefore, gratefully acknowledge the technical and financial support from the DSR.

Abstract—This paper proposes a new EP-PER-SAC algorithm to solve the problems of slow training speed and low learning efficiency of the SAC (Soft Actor Critic) algorithm in the local path planning of mobile robots by introducing the Priority Experience Replay (PER) strategy and Experience Pool (EP) adjustment technique. This algorithm replaces equal probability random sampling with sampling based on the priority experience to increase the frequency of extracting important samples, thereby improves the stability and convergence speed of model training. On this basis, it requires to continuously monitor the learning progress and exploration rate changes of the robot to dynamically adjust the experience pool, so the robot can adapt effectively to the environment changes and the storage requirements and learning efficiency of the algorithm are balanced. Then, the algorithm's reward and punishment function is improved to reduce the blindness of algorithm training. Finally, experiments are conducted under different obstacle environments to verify the feasibility of the algorithm based on ROS (Robot Operating System) simulation platform and real environment. The results show that the improved EP-PER-SAC algorithm has a shorter path length and faster model convergence speed than the original SAC algorithm and PER-SAC algorithm.

Keywords—Mobile robots; local path planning; reinforcement learning; SAC algorithm; priority experience replay; experience pool adjustment; Robot Operating System (ROS)

I. INTRODUCTION

The ability of mobile robots to plan their paths is a critical task in the field of robotics. The robot explores an optimal or sub-optimal safe path from the starting point to the end point in workplace according to the given requirements [1]. The common traditional path planning algorithms mainly include A* algorithm [2-3], Artificial Potential Field method [4-5], Dijkstra algorithm [6], Genetic algorithm [7], Fuzzy Control algorithm [8], and Ant Colony algorithm [9-10]. These algorithms rely on maps and environmental models during the path planning process and are prone to falling into local minima when dealing with complex environments. With the development of computer science and artificial intelligence, intelligent algorithms have received widespread attention due to vast database and powerful computing capability to perform various tasks. Reinforcement Learning algorithm [11-12] is a typical example. It learns the optimal policy through interaction with the environment, thus can overcome the difficulties associated with map modeling. The Deep Reinforcement Learning algorithm [13-14] further combine Deep Learning [15] with Reinforcement Learning. It has the ability to learn and make decisions in complex environments,

and has also achieved remarkable results of dealing with the path planning of mobile robots.

Typical algorithms of Deep Reinforcement Learning include DDPG (Deep Deterministic Policy Gradient) algorithm [16-17], TD3 (Twin Delayed Deep Deterministic policy gradient) [18] and SAC algorithm. Silver et al. proposed the DPG (Deterministic Policy Gradient) algorithm, which updated the value function to address Reinforcement Learning problems in a continuous action space [19]. Lillicrap et al. extended the DPG algorithm by incorporating the principles of Deep Q-learning and introduced the DDPG algorithm, which can effectively deal with high-dimensional continuous action [20]. Fujimoto et al. improved the DDPG algorithm by employing two separate Q-network to evaluate action values and proposed the TD3 algorithm. This improved method can reduce the overestimation of action values and enhance training stability [21]. Haarnoja et al. introduced the SAC algorithm, which used dual Q-network and incorporated the principle of maximum entropy. It maximized entropy to increase the exploratory capability of the algorithm [22]. Yuxiang Z et al. proposed the SAC algorithm combining with the Artificial Potential Field method. The self attention mechanism had been introduced into the Actor network of the SAC algorithm in response to the high dimensionality and complexity of environmental state in 3D environmental space. It improved the convergence speed and success rate of the algorithm, but the hyper-parameters can also be adjusted to improve the algorithm performance [23].

This paper presents an EP-PER-SAC algorithm to solve the shortcomings of the SAC algorithm, such as long training time and wasted effective experience. The improved algorithm uses the fully connected neural network in which the obstacle information is detected by the ten radar sensors of robot, where the angle and the distance between the robot and the target point are as inputs of the network, the angular velocity and linear velocity of the robot as outputs. Combined with the preferential experience playback mechanism, the samples with high priority are preferentially selected. The experience pool is dynamically adjusted according to the learning progress and changes of the exploration rate, thus balancing the efficiency of exploration and exploitation of samples. A detailed reward and punishment function is designed to enable robots to more easily obtain effective feedback from environmental exploration, which can solve the issue of reward sparsity and enhance the sample utilization rate and learning efficiency of the algorithm.

II. SAC ALGORITHM

The SAC algorithm is a Deep Reinforcement Learning algorithm that maximizes policy entropy [24]. It can be used to

address the problem within continuous action space. The SAC algorithm consists of an Actor network, two Critic networks and two Target Critic networks. Fig. 1 depicts the flowchart of SAC algorithm.

Fig. 1. The flowchart of SAC algorithm.

The SAC algorithm obtains the maximum expected reward value by training effective samples, while satisfying the maximization of entropy value. The algorithm can be represented as:

$$J(\pi) = \sum_{t=0}^T E_{(s_t, a_t) \sim p_\beta} [r(s_t, a_t) + \alpha H(\pi(\cdot | s_t))] \quad (1)$$

In Eq. (1), E is a reward expectation, $(s_t, a_t) \sim p_\beta$ is the state distribution related to strategy, $r(s_t, a_t)$ is the return value obtained by executing the action a_t , α is a parameter that controls entropy regularization, H is the entropy in the state s_t which can be expressed as:

$$H(\pi(\cdot | s_t)) = E_{a_t} [-\log \pi(a_t | s_t)] \quad (2)$$

The algorithm selects the initial state s_t , and obtains the action probability $\pi(a_t | s_t)$ after passing through the Actor network. Then, the algorithm obtains the action a_t according to probability sampling and applies it to the environment to generate a set of empirical tuples $(s_t, a_t, s_{t+1}, r_{t+1})$.

The input of the Actor network is the state s_t , and the output is the action probability $\pi(a_t | s_t)$. The changes in loss during training can be expressed as:

$$L_\pi(\varepsilon) = \frac{1}{|B|} \sum_{(s_t, a_t, s_{t+1}, r_{t+1})} E_{a_t} [q(s_t, a_t) - \ln \pi_\theta(a_t | s_t)] \quad (3)$$

In Eq. (3), B represents the experience pool, represents the possible actions predicted by the Actor network again.

The Critic networks are used to evaluate the expected return on a given state and action under the current strategy. The Target Critic networks are used to provide stable target value estimates. In order to accurately evaluate the state-action function $Q(s_t, a_t)$ (abbreviated as Q-value), the SAC algorithm

combines the maximum entropy principle and uses the smaller values output by two Critic networks for estimation. The Q-value is as follows:

$$Q(s_t, a_t) = r(s_t, a_t) + \min_{i=1,2} Q_i(s_{t+1}, a_{t+1}) - \alpha \log(\pi_\phi(a_{t+1}, s_{t+1})) \quad (4)$$

In Eq. (4), α is a temperature parameter used to regulate the importance of entropy.

The loss function of the Critic networks are:

$$L_c(\theta_i) = E_{(s_t, a_t)} [(Q_{\theta_i}(s_t, a_t) - Q(s_t, a_t))] \quad (5)$$

The SAC algorithm uses gradient descent and ascent methods to update the parameters of the strategy and value network, while updating the target networks and clearing the current gradient information to prepare for the next round of training.

III. IMPROVE THE SAC ALGORITHM

This research proposes the EP-PER-SAC algorithm, which uses neural network to predict the state and the action of robot. The improved algorithm extracts samples with higher priority multiple times to increase the utilization of effective samples. It dynamically adjusts the experience pool based on training progress and performance to adapt to different training stages. This approach can balance the need of exploration and utilization, while improving the training effectiveness of the algorithm. The EP-PER-SAC algorithm includes the improvement of state and action space design, network structure, and design of the reward and punishment function.

A. State and Action Space Design

The state space refers to the set including all possible states which may occur in an environment. Inputting this information into the network, the robot execute an action based on the

current state to accumulate more rewards and optimize its strategy.

Radar sensors are mounted on a two wheel differential drive robot to detect the obstacles within a range of 180° in front, which are returned with every 20° a set, for a total of 10 sets. Fig. 2 shows the radar detection structure.

Fig. 2. Radar detection structure.

The robot state space S consists of the distance information to the nearest obstacles from ten direction sensors d_k ($k=0\sim9$), the angular angle between the robot and the target point θ_i and the distance between the robot and the target point D_i :

$$S = (d_0 \sim d_9, \theta_i, D_i) \quad (6)$$

The action space A is used for exploring and executing various actions within a certain range which includes the robot's angular velocity $\omega_i \in [\omega_{\min}, \omega_{\max}]$ and linear velocity $v_i \in [v_{\min}, v_{\max}]$, where $[\omega_{\min}, \omega_{\max}] \subseteq [-2, 2]$ with the unit rad/s, $[v_{\min}, v_{\max}] \subseteq [0, 0.34]$ with the unit m/s. The robot's action space A is defined as:

$$A = (\omega_i, v_i) \quad (7)$$

B. Priority Experience Replay

The SAC algorithm uses a random sampling method during sampling, which cannot ensure repeated sampling of important samples. Priority Experience Replay technology assigns different priorities to each sample based on the TD error value, and samples with higher priorities are more likely to be extracted. The framework for prioritizing experience replay is shown in Fig. 3.

Fig. 3. Priority experience replay framework.

The TD error of samples is commonly used to measure the discrepancy between the actual value and the predicted value. When the TD error value is large, it may indicate that the training performance at that particular state is poor. The learning efficiency can be improved by increasing the probability of samples with large errors being extracted and training them for multiple times. TD error δ_i is defined as:

$$\delta_i = r(s_t, a_t) + \max_{a_{t+1}} \gamma Q_{\text{target}}(s_{t+1}, a_{t+1}) - Q(s_t, a_t) \quad (8)$$

In Eq. (8), γ represents the discount factor, $Q(s_t, a_t)$ and $Q_{\text{target}}(s_{t+1}, a_{t+1})$ represent the states value of the critic networks and the target critic networks, respectively.

The probability of extracting samples from the experience pool can be expressed as:

$$p_i = \frac{\delta_i^\alpha}{\sum_{i=1}^n \delta_i^\alpha} \quad (9)$$

In Eq. (9), α parameter is used to control the sample priority.

During the calculation of TD error in the SAC algorithm, the impacts of Critic networks, Target Critic networks and Actor network on the algorithm are different. The addition of balance parameters to the algorithm can improve the influence of the strategy network on the total error. The TD comprehensive error with balance parameters η , σ and ϕ is:

$$\delta_i = |\eta \cdot TD(Q)| + |\sigma \cdot TD(Q_{\text{target}})| + |\phi \cdot TD(\pi)| \quad (10)$$

C. Dynamic Adjustment of Experience Pool

The experience pool is used to store data generated by the interaction between robot and the environment. The EP-PER-SAC algorithm dynamically adjusts the capacity of the experience pool according to the progress of training and the change of exploration rate. This improved method can optimize the efficiency and quality of sample utilization, and save memory resource. The adjustment framework of experience pool is shown in Fig. 4.

Fig. 4. The adjustment framework of experience pool.

During the training process, the change of the robot's strategy leads to a variation of the data distribution in the experience pool. The algorithm dynamically adjusts the experience pool can ensure that the data in it matches the current strategy more closely, and can improve the stability of training. In the early stage of training, the exploration rate is higher than the exploration utilization rate, and increasing the experience pool can quickly accumulate experience. In the later stage of training, the exploration rate decreases, and the robot needs more refined optimization. Reducing the experience pool can avoid data over-fitting and improve the effectiveness of the algorithm.

D. Network Structure

The network input of EP-PER-SAC algorithm includes obstacle detection data d_k from ten directions of the radar,

angle θ_i and distance D_i between the robot and the target point. The network output of the algorithm includes the angular velocity ω_i and the linear velocity v_i of the robot. Fig. 5 shows the network input and output of the EP-PER-SAC algorithm.

Fig. 5. Network input and output of the EP-PER-SAC algorithm.

Fig. 6 shows the network structure of the algorithm. The algorithm inputs action and state information into the network. The hidden layer consists of three fully connected layers, and each fully connected layer contains 512 neuronal nodes. The activation function in the algorithm network is used to perform nonlinear transformation to improve the learning ability. Then, the algorithm samples to obtain specific actions in the continuous action space. Finally, the network maps these action values to angular velocity ω_i and linear velocity v_i , and sends them to the robot.

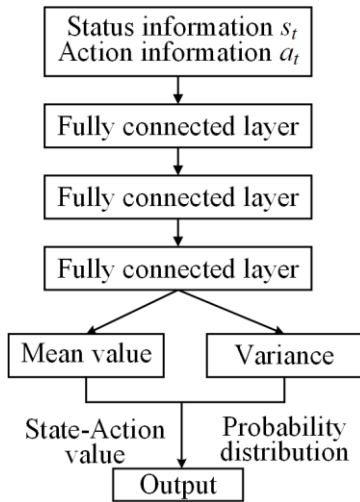

Fig. 6. The network structure of EP-PER-SAC algorithm.

E. Design of Reward and Punishment Functions

The reward and punishment function guides robot to perform appropriate actions in the environment to achieve specific goals which play a crucial role in the success of the algorithm.

In the design of the reward and punishment function, the reward and punishment R_1 shows the distance between the robot and the environment. It controls the distance between the robot and the obstacle environment, and rewards robots to approach the target or avoid obstacles for completing path planning quickly and accurately. The reward and punishment R_2 shows the angle between the robot and the target point. It adjusts the angle between the robot and the target direction, encourages the robot to choose the path with the minimum angle, reduces unnecessary movement, and enhances the target orientation property. The total reward R consists of reward R_1 and reward R_2 :

$$R_1 = \begin{cases} r_g, & d_i < c_d \\ r_c, & \min_k < c_o \end{cases}$$

$$R_2 = \begin{cases} C, & -\frac{1}{4}\pi \leq \theta \leq \frac{1}{4}\pi \\ -C, & \theta < -\frac{1}{4}\pi \quad \text{or} \quad \theta > \frac{1}{4}\pi \end{cases}$$

$$R = R_1 + R_2 \tag{11}$$

Where,

r_g is the reward value of the robot to reach the target,

r_c is the penalty value of the robot to collide with obstacles,

d_i is the distance from the robot to the target point at this time,

c_d is the minimum range threshold for reaching the target,

\min_k is the minimum value detected by radar,

c_o is the minimum safe distance from the obstacle environment,

C is a positive integer,

θ is the angle value between the robot and the target point.

IV. EXPERIMENTAL TEST AND RESULT ANALYSIS

The improved algorithm is first tested in a simulation environment under ROS platform. After the algorithm converges, it is loaded into the robot for real environment experiments. This research uses Gazebo on the ROS platform to build the robot running environments of obstacle-free, discrete obstacles, 1-shaped obstacle, U-shaped obstacle, and mixed obstacles, respectively. The feasibility of the designed EP-PER-SAC algorithm is verified by model training, and compared with the original SAC algorithm and PER-SAC algorithm (the SAC algorithm combined with Preferential Empirical Replay). The path planned is projected to Rviz in which the blue square represents the target point, gray circles denotes obstacles, and green line means the path trajectory. The parameters of the experimental model are shown in Table I.

TABLE I. EXPERIMENTAL MODEL PARAMETERS

Parameter	Initial value
Attenuation degree factor	0.99
Maximum number of steps per training round	1000
Number of samples per round	256
Strategy network learning rate	0.0003
Q-network learning rate	0.0003

A. Obstacle-free Environment Simulation

Fig. 7 shows the obstacle-free simulation model of 4m×4m built in Gazebo, with the starting point of the robot set to (-1,0) and the target point set to (1,0).

Fig. 7. Obstacle-free environment in Gazebo.

Fig. 8 shows the results of 300 rounds of simulation training on three different algorithms in Gazebo, and records the average reward and punishment return value for each round of the training. The horizontal axis represents the number of training rounds, and the vertical axis denotes the average reward for each round. The results in the graph shows that the average return value of the EP-PER-SAC algorithm significantly increases after 35 rounds, with a faster convergence speed than the original SAC algorithm and PER-SAC algorithm, and tends to stabilize after 150 rounds.

The paths planned by the converged models of the three algorithms in Rviz are drawn in Fig. 9 (a), (b), and (c), respectively. The EP-PER-SAC algorithm has 90 steps in the path, 94 steps in the PER-SAC algorithm, and 95 steps in the original SAC algorithm. The improved algorithm has a slightly shorter path than the other two algorithms.

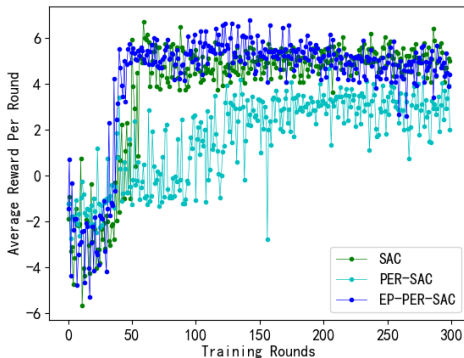

Fig. 8. Comparison of the average reward in the obstacle-free environment of the three methods.

Fig. 9. Path planning of the three algorithms in an obstacle-free environment.

B. Discrete Obstacles Environment Simulation

Fig. 10(a) and (b) shows the Gazebo discrete obstacles environment and the Rviz projection, respectively.

Fig. 10. Discrete obstacles simulation environment.

In this test, the three algorithms are trained for 800 rounds, respectively, and the average reward and punishment return value of each round is shown in Fig. 11. The EP-PER-SAC algorithm has a higher return value than the original SAC algorithm after 150 rounds. While compared to the PER-SAC algorithm, the average return of the EP-PER-SAC algorithm fluctuates less per round, and the probability of the robot reaching the target point is higher.

The path planning results of the three algorithms in the discrete obstacles environment are shown in Fig. 12(a), (b) and (c), respectively. The starting position of the robot is (-1, -1), and the target point is (1,1). The EP-PER-SAC algorithm takes 102 steps to plan the path, the PER-SAC algorithm is 115 steps, and the SAC algorithm owns 123 steps. The improved algorithm has a smoother path and shorter length.

Fig. 11. Comparison of the average reward in the discrete obstacles environment of the three methods.

Fig. 12. Path planning of the three algorithms in a discrete obstacles environment.

C. Special Obstacles Environment Simulation

Fig. 13 and 14 represent two special obstacles environment, 1-shaped and U-shaped, respectively. The starting point in the 1-shaped environment is (-1.5,0), and the target point is (1.5,0). In the U-shaped environment, the starting point is set to (-1,0) and the ending point is set to (1,0).

Fig. 13. The 1-shaped obstacle simulation environment.

Fig. 14. The U-shaped obstacle simulation environment.

Fig. 15 and 16 show the planned paths of the three algorithms in the 1-shaped and U-shaped environment, respectively. In the 1-shaped obstacle environment, the EP-PER-SAC algorithm, the PER-SAC algorithm and the SAC algorithm take 138 steps, 142 steps and 146 steps, respectively. While in the U-shaped environment, the planned path of the three algorithms owns 131 steps, 140 steps and 143 steps, respectively. The improved algorithm can navigate around the special obstacles environment faster and the planned path length is shorter in both environments.

Fig. 15. Path planning of the three algorithms in the 1-shaped obstacles environment.

Fig. 16. Path planning of the three algorithms in the U-shaped obstacles environment.

D. Simulation of Mixed Obstacles Environment

Fig. 17 represents a mixed obstacles environment of 6m x 6m in Gazebo. The environment consists of discrete obstacles, 1-shaped and U-shaped obstacles, with the starting point set to (-2, 2), and the target point being (2, -2).

Fig. 17. The mixed obstacles environment 1.

Fig. 18 represents the planned paths of the three algorithms in the mixed obstacles environment 1. Compared with the original SAC algorithm and the PER-SAC algorithm, the EP-PER-SAC algorithm has a shorter path length and it is easier to pass through complex obstacles, which has a significant effect. The planning steps of the EP-PER-SAC algorithm is 194 steps, while PER-SAC algorithm is 217 steps and the original algorithm is 244 steps.

Fig. 18. Path planning of the three algorithms in the mixed obstacles environment 1.

In order to further verify the feasibility and universality of the convergence algorithm, the algorithm is tested again in a mixed obstacles environment 2, as shown in Fig. 19. The starting point is set to (-2,2), and the target point is set to (2,0)

Fig. 19. The mixed obstacles environment 2.

The converged model is loaded into the mixed obstacles environment 2, and the path results planned by the three algorithms are shown in Fig. 20. The path steps planned by the EP-PER-SAC algorithm is 199 steps, while the other two

algorithms use 238 and 286 steps by the PER-SAC algorithm and SAC algorithm, respectively. The EP-PER-SAC algorithm still has a shorter path length, which can better avoid obstacles and verify the effectiveness of the algorithm.

Fig. 20. Path planning of the three algorithms in the mixed obstacles environment 2.

E. Comparison of Experimental Results

Through the experimental results in the aforementioned simulation environments, the EP-PER-SAC algorithm is compared with the SAC algorithm and the PER-SAC algorithm. The feasibility and performance advantages of the designed EP-PER-SAC algorithm have been verified. In different simulation environments, the paths planned by the EP-PER-SAC algorithm are smoother and converge faster than those planned by the SAC algorithm and the PER-SAC algorithm.

The number of steps taken by the three algorithms in different simulation environments are compared in the bar chart, as shown in Fig. 21. From the graph, it can be seen more clearly that the EP-PER-SAC algorithm has fewer steps than the SAC algorithm and the PER-SAC algorithm in any obstacles environment.

Fig. 21. Comparison of path lengths of the three algorithms in different running environments.

F. Experiments in Real Environment

This research applies three algorithms to mobile robot based on the ROS platform, and performs path planning tasks in a real environment to verify the performance of the improved algorithm. The Gmapping algorithm is used to construct a two-dimensional laboratory environment map. In order to test the real-time planning ability of the algorithm,

temporary unknown obstacles are added in laboratory environment. Fig. 22 shows the laboratory environment and laboratory map model.

(a) Laboratory environment (b) Laboratory map model

Fig. 22. Laboratory environment.

Fig. 23 shows the laboratory environment with temporary obstacles and laboratory map model with temporary obstacles. The radar sensors detect obstacles information and provide real-time feedback, and achieve self-localization through the AMCL (Adaptive Monte Carlo Localization) module.

(a) Laboratory environment (b) Laboratory map model

Fig. 23. Laboratory environment with temporary obstacles.

The robot plans a collision-free path from the starting point to the target point, and visualizes the paths planned by the three algorithms in Rviz to verify the real-time obstacle avoidance ability of the algorithms. Fig. 24(a), (b) and (c) show the planned path by the EP-PER-SAC algorithm, PER-SAC algorithm, and the SAC algorithm, respectively. In the real environment, the path lengths of the three algorithms are 5.562 meters, 6.159 meters, and 6.965 meters, respectively. Compared with PER-SAC and SAC algorithms, EP-PER-SAC algorithm has a shorter path length and smoother path during obstacle avoidance. The experiments indicate that the path planned by the proposed algorithm is feasible and effective in both the simulation environment and the real environment, and the performance is better than the original SAC algorithm and PER-SAC algorithm.

Fig. 24. Paths planned by the three algorithms in laboratory environment.

V. CONCLUSION

This research improves the original SAC algorithm and proposes the EP-PER-SAC algorithm based on the Priority Experience Replay and dynamic adjustment of experience pool. Simulation comparisons and real environment experiments are made with the original SAC and PER-SAC algorithms in specific environments to verify that the improved algorithm can reach the target point faster and more efficiently. The improved EP-PER-SAC algorithm has the following characteristics:

1) The Priority Experience Replay technology is added to improve the sampling probability of important samples, and improve the convergence speed and effectiveness of the algorithm.

2) According to the comparison of exploration rate and exploration-utilization rate in the training process, the experience pool is dynamically adjusted to avoid over-fitting of the model and improve the stability of the algorithm.

The improved algorithm has certain practical applications in the field of mobile robots, such as autonomous vehicles, warehouse automation, and service robots working in the unknown environment. We can download the improved algorithm to the controller of a mobile robot. According to the instructions of the algorithm, the robot can perceive the environment in real time, autonomously avoid obstacles and reach the designated target through the optimal path, completing the given transportation task.

However, the improved algorithm is relatively simple and rigid in evaluating the effect of adjusting the method in the experience rules, which may lead to bias in the information obtained from training. The next step of research will consider conducting more complex and diverse evaluations of the adjustment performance in the experience rules, which can enhance the algorithm's adaptability to more complex environments and enable robots to better perform path planning.

Exploring Music Style Transfer and Innovative Composition using Deep Learning Algorithms

Sujie He*

Modern Conservatory of Music University,
Shan Dong University of Art, Shandong, China

Abstract—Automatic music generation represents a challenging task within the field of artificial intelligence, aiming to harness machine learning techniques to compose music that is appreciable by humans. In this context, we introduce a text-based music data representation method that bridges the gap for the application of large text-generation models in music creation. Addressing the characteristics of music such as smaller note dimensionality and longer length, we employed a deep generative adversarial network model based on music measures (MT-CHSE-GAN). This model integrates paragraph text generation methods, improves the quality and efficiency of music melody generation through measure-wise processing and channel attention mechanisms. The MT-CHSE-GAN model provides a novel framework for music data processing and generation, offering an effective solution to the problem of long-sequence music generation. To comprehensively evaluate the quality of the generated music, we used accuracy, loss rate, and music theory knowledge as evaluation metrics and compared our model with other music generation models. Experimental results demonstrate our method's significant advantages in music generation quality. Despite progress in the field of automatic music generation, its application still faces challenges, particularly in terms of quantitative evaluation metrics and the breadth of model applications. Future research will continue to explore expanding the model's application scope, enriching evaluation methods, and further improving the quality and expressiveness of the generated music. This study not only advances the development of music generation technology but also provides valuable experience and insights for research in related fields.

Keywords—Deep learning; style transfer; innovative composition; Generative Adversarial Networks

I. INTRODUCTION

Music, as one of the greatest inventions in human history, not only serves as a medium for cultural expression but also represents a cultural industry with tremendous potential for growth [1]. In recent years, with the rapid development of digital technology [2] [3] [4], the music industry is undergoing profound changes. As society's demand for music continues to expand, diversified music creation has become an inevitable trend. The demand for higher-quality music creation is evident in everything from the background music for short videos to the theme songs for movies and TV shows. However, traditional music composition methods, constrained by the need for specialized knowledge of music theory and instrumental skills, cannot meet the growing market demand. Against this backdrop, the use of computers to aid music composition and achieve automated music generation has emerged as a new research frontier.

Automatic music generation is a product of the intersection of information science and art studies, aimed at minimizing human intervention in computer-aided music composition [5]. It is not only a significant part of multimedia research but also a hot topic in artificial intelligence. Researchers are working on how to generate music that has both a clear style and conforms to audience aesthetics, delving into the deep connections behind music data. Therefore, an in-depth mining and analysis of music data features have significant theoretical and practical significance [6]. It can enrich the methods for generating music datasets and help build efficient music generation models, reducing the burden of manual composition and offering the possibility of music creation for non-professionals. By establishing objective music evaluation models, we can scientifically measure the quality and style consistency of automatically generated music.

Identifying the structure and style of music is core to the field of music generation. To track the development of elements such as melody, harmony, and rhythm, and to provide valuable information for music composition and automatic generation, advanced data processing techniques and algorithms are required. Although modern music generation technologies can create music in various styles, their application in automated composition and arrangement is still insufficient to capture the full complexity of music creation.

In the application of music generation, we need to optimize algorithms to generate music segments that are coherent and consistent in style. Considering the complexity of melody and harmony, the diversity of musical styles, and the uncertainty of melodic lines and harmonic progressions, we must enhance the algorithm's fitting ability to address these challenges. To this end, we attempt to introduce structures similar to squeeze-and-excitation models into music generation networks, forming a music generation model with feature extraction capabilities. Additionally, we incorporate attention mechanisms based on batch normalization, such as channel attention modules. Music generation models can draw inspiration from the Swin Transformer structure, introducing Swin Blocks to capture the long-range dependencies of music data and better extract deep music features.

II. LITERATURE REVIEW

This article will collect existing work in the field of automated music composition to highlight the shortcomings of current research.

A. Traditional Music Generation Methods

Over time, the field of music generation has experienced significant development, with early algorithms laying the groundwork for more complex systems. The earliest models of music generation operated on random principles within fixed parameters such as pitch, duration, and rhythm, often resulting in melodies lacking in musical coherence and artistic intent. The advent of sequence modeling algorithms marked a turning point in traditional automated music generation methods. These methods often rely on statistical probability methods such as Markov models, introducing a more structured composition technique that uses Markov chains and stochastic processes to predict future outcomes, greatly reducing the randomness problems in early music generation efforts [7].

David Cope's "Experiments in Musical Intelligence" (EMI) combined music language models by identifying repetitive structures in composers' works and reusing these patterns in new arrangements [8], thus generating music of a similar style. This method further demonstrated the potential of using Markov models and N-gram methods to create music in different styles [9] [10] [11]. Subsequently, Bretan and others [12] proposed a method based on the similarity ranking of musical fragments and the combination of new musical fragments to create new works from existing pieces. On the other hand, Pachet and others [13] introduced a method that uses chords to guide the selection of melodies. These techniques rely on the feature parameters of musical sequence data, using sequence models to achieve the desired musical output through signal reconstruction theory.

Despite progress, traditional probabilistic models such as Markov chains have a significant limitation: they can only generate subsequences that already exist in the training dataset. In areas where innovation and creativity are crucial, these algorithms inherently lack the ability to generate truly novel and creative content. Developing music generation systems that can not only replicate but also innovate and further push the boundaries of musical computational creativity remains a challenge.

B. Deep Learning Generation Methods

The template is used to format your paper and style the text. All margins, column widths, line spaces, and text fonts are prescribed; please do not alter them. You may note peculiarities. For example, the head margin in this template measures proportionately more than is customary. This measurement and others are deliberate, using specifications that anticipate your paper as one part of the entire proceedings, and not as an independent document. Please do not revise any of the current designations.

In recent years, the rapid development of deep learning technology has made breakthrough progress in multiple fields, especially in the processing of sequential data such as computer vision, speech recognition, and natural language processing, sparking intense interest in the application of deep learning in the field of music generation.

In the research of automated music generation, Mangal and others [14] used Long Short-Term Memory networks (LSTM) and Recurrent Temporal Restricted Boltzmann Machines (RTRBM) models, achieving certain results. Johnson [15]

explored new paths for polyphonic music generation through the CharRNN model. Nayebe [16] used Recurrent Neural Networks (RNN) to generate music based on MIDI files.

In the exploration of generating more complex music sequences, Franklin [17] proposed using RNNs to represent the possibility of multiple notes sounding simultaneously. Additionally, Huang's team [18] proposed a new music generation framework based on Deep Belief Networks (DBN). Hadjeres and others [19] used an RNN model combined with Gibbs sampling techniques to successfully generate multi-part gospel music.

On a different path from RNN models, Sabathe and others [20] introduced Variational Autoencoders (VAEs) to generate music by learning the distribution of music fragments. Concurrently, researchers like Yang, Mogren, and others [21] used Generative Adversarial Networks (GANs) to compose music, a method that takes random noise as input to produce new melodic sequences.

Overall, the application of deep learning in music generation is in rapid development, with different deep learning models continually pushing the limits of music generation technology. Despite many challenges, deep learning models have already shown great potential in imitation, innovation, and exploring the complex structure of music. With the deepening of research and the maturity of technology, future music generation systems are expected to become more intelligent, creating a richer and more diverse range of musical works.

C. Research Gaps

Although the field of music generation has made a series of advancements, there are still important gaps in existing research. There are several key musical elements that have not been fully considered in the generation process, such as the duration of notes, the handling of rests, the diversity of musical styles, and the musical formats of input models. Based on this, future research needs to address the following issues:

1) *Limitations of Probabilistic Models in Music Generation:* The traditional probabilistic models currently in use have some feasibility in music generation, but due to the diversity and evolution of music, these models may not be able to adapt to new musical trends in a timely manner. Moreover, building effective probabilistic models requires a deep foundation in musical theory. Traditional methods also rely on a lot of manual feature design and extraction, leading to low efficiency and a large workload.

2) *Lack of Uniformity in Music Data Preprocessing:* Currently, there is no unified standard for music data preprocessing methods, resulting in different studies adopting their own methods, such as music generation methods based on variational autoencoders and melody algorithms based on digital signal processing. These methods often neglect the rhythmic nature of music, such as the length of notes and pauses. Even in generation models that consider both melody and rhythm, there are problems with the compatibility of pitch and rhythm during training. This lack of standardized representation hinders the universality and compatibility between different music generation methods.

3) *Limitations of Deep Learning Models in Music Generation:* While deep learning models such as LSTM have shown potential in music generation, they usually cannot generate long-term melodic sequences. Existing large text generation models, such as BERT and GPT-2, perform excellently in text generation but face data representation issues when directly applied to music generation. Due to the fundamental differences between music signal representation and text, existing language generation models cannot be directly applied to music generation.

In summary, future research needs to develop new models and techniques to address these challenges in music generation, to truly enhance the novelty of musical composition and the acceptance of the audience.

III. AUTOMATIC MUSIC GENERATION METHODS BASED ON GENERATIVE ADVERSARIAL NETWORKS

Music generation has been achieved using the CHSE-GAN model based on the segmentation of music text into measures. The current state of research is first elucidated, followed by an introduction to GAN networks, and then music segments are generated using the segmentation of music text into measures. Finally, this method's potential in music generation is described by comparing it with other generation models in terms of loss rate, accuracy, and other indicators.

A. Model Introduction

In the contemporary field of music composition, deep learning technologies such as Convolutional Neural Networks (CNNs) and Generative Adversarial Networks (GANs) have begun to be explored for constructing musical works. With their advanced data processing capabilities, they exhibit notable creative potential.

Generative Adversarial Networks (GANs) are a unique unsupervised learning framework, designed around the concept of two neural networks contesting with each other to promote the learning process. The generator network (G) is responsible for transforming a random noise vector z into the data space, simulating samples from the real data distribution. Meanwhile, the discriminator network (D) has the task of outputting a scalar value, predicting whether a given sample is from the real data distribution or produced by the generator G.

These two networks compete with each other during training, adjusting their parameters to enhance their own performance: the generator G tries to produce more realistic data, while the discriminator D strives to more accurately distinguish between real and generated data. This adversarial training process can be viewed as a minimax game where both the generator and discriminator have their own objective functions, which are in opposition to each other. They evolve together until a dynamic equilibrium is reached.

$$\min_G \max_D V(D, G) = E_{x \sim p_{data}(x)} [\log D(x)] + E_{z \sim p_z} [1 - \log(D(G(z)))] \quad (1)$$

In this, P_{data} represents the distribution of real data x , and P_z denotes the prior distribution of z . Nevertheless, the application of GANs in music composition is still at an exploratory stage, and this method still shows limitations in capturing the complex interactions of musical elements in time and space. Compared to the short sequences generated in text, music composition deals with much longer time series, which makes it difficult for the network to grasp the profound connections between sequences during learning.

In view of this, this study adopted the CHSE-GAN model, which is designed under the influence of GAN concepts, for music composition. The model combines a discriminator and a generator, and specifically, allows the discriminator to pass feature information to the generator, supporting the generator to learn and understand data of longer time series, which to some extent eases the challenge of dealing with complex musical structures. This paper will first provide an overview of the foundations of Generative Adversarial Networks, followed by an in-depth discussion of the structure and functions of the CHSE-GAN model.

B. CHSE-GAN Music Generation Method

In this section, we introduce the CHSE-GAN (Channel Attention and Squeeze-Excitation based Generative Adversarial Networks), which is specially designed for music generation. Its network structure has been adjusted to suit the characteristics of music data, as shown in Fig. 1. Based on CycleGAN, CHSE-GAN has made the following improvements to enhance its application in the field of music composition:

Introduced a channel attention mechanism based on batch normalization, NAM (ch). Traditional channel attention methods calculate weights through complex network structures, which may not be sufficient to capture the complex patterns in music. By extracting the scaling factors from batch normalization as channel attention weights, we can effectively distribute weights to features within the network without increasing network complexity and extra parameters, thereby strengthening the focus on important musical features.

Music features often have rich hierarchical levels and subtle dynamic changes, thus a single feature extraction structure may not capture them adequately. CHSE-GAN introduces a Squeeze-Excitation (SE) attention mechanism into the residual network to form a new Res-SE module. Combined with the channel attention mechanism based on batch normalization, it creates a new backbone network for feature extraction, enhancing the generator's perception of complex musical structures and details, and improving the capture of musical features.

As shown in Fig. 2, the generator network structure of CHSE-GAN consists of three main parts: downsampling, the backbone network, and upsampling. Specifics are as follows:

Downsampling part: Three downsampling operations using convolutional layers with a stride of 2 are performed to expand the receptive field and reduce dimensions. The first layer uses a 64-dimensional 7×7 convolution kernel to capture a broader range of musical structure information.

Fig. 1. Network structure diagram based on CHSE-GAN music generation.

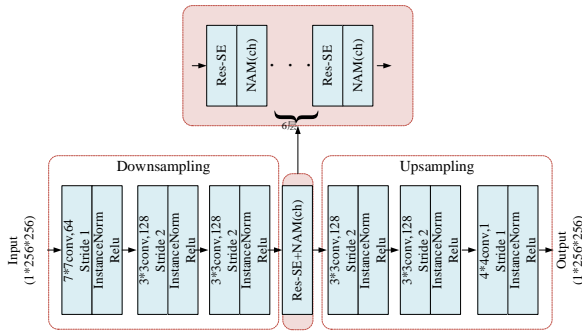

Fig. 2. Schematic diagram of the network structure of the CHSE-GAN algorithm generator.

Backbone network: Consists of NAM(ch) and the new Res-SE modules, which, through a combination of Squeeze-Excitation attention and channel attention based on batch normalization, enhance the extraction and expression capabilities for musical features.

Upsampling network: After extracting deep features, the SE module adjusts the output of the convolution from the backbone network, then NAM(ch) redistributes channel weights after each residual block. Upsampling is constructed using deconvolutional layers, with batch normalization and ReLU activation functions applied after each layer to restore the data to the original spatial dimensions of the musical signal.

With this carefully designed network structure, CHSE-GAN can generate music works that are rich in expressiveness and dynamism, providing a powerful tool for automated music composition and style transformation.

1) *Batch Normalization-based Channel-wise Attention:* In deep learning models for music generation, it is crucial to effectively utilize the time-frequency features in music signals. To enhance the ability to extract these deep features, we can adopt an attention mechanism based on batch normalization. This mechanism can reinforce the model's focus on important parts of music features, thereby improving the quality of music generation. Batch Normalization is commonly used in deep

learning to speed up the training process and improve model performance. In music generation models, we can use the statistical parameters obtained during the batch normalization process to calculate channel attention. Specifically, the parameters of batch normalization are used not only for feature normalization but can also serve as weight information to adjust feature mappings on different channels. This method is known as the Normalization-based Attention Module (NAM).

For instance, we can design an NAM(ch) module to adaptively readjust the feature weights on each channel without adding extra network parameters. The NAM(ch) module can be placed after each part of the residual network structure to enhance the fine expression of musical spectral features. The computational flowchart of NAM(ch) is shown in Fig. 3, where ω_i represents the weights, and γ_i represents the scaling factors for each channel. The pseudo-code for the batch normalization-based channel attention algorithm is as follows.

Algorithm 1: Channel Attention Algorithm Based on Batch Normalization

```

Initialize
Step 1:  $\mu_B \leftarrow \frac{1}{m} \sum_{i=1}^m x_i$ 
Step 2:  $\sigma_B^2 \leftarrow \frac{1}{m} \sum_{i=1}^m (x_i - \mu_B)^2$ 
Step 3:  $\hat{x}_i \leftarrow \frac{x_i - \mu_B}{\sqrt{\sigma_B^2 + \epsilon}}$ 
Step 4:  $y_i \leftarrow \gamma \hat{x}_i + \beta = \text{BN}_{\gamma, \beta}(x_i)$ 
Step 5:  $\omega_i = \frac{\gamma_i}{\sum_{j=0} \gamma_j}$ 
Step 6:  $M_S = \text{Sigmoid}(\omega_i \times y_i)$ 
    
```

$$B_{\text{out}} = \text{BN}(B_{\text{in}}) = \gamma \frac{B_{\text{in}} - \mu_B}{\sqrt{\sigma_B^2 + \epsilon}} + \beta \quad \omega_i = \frac{\gamma_i}{\sum_{j=0} \gamma_j} \quad (2)$$

2) *Res-SE Module Based on Residual Blocks and Squeeze-and-Excitation Attention:* In music generation models, the Res-SE module, which combines residual blocks and squeeze-and-excitation attention mechanisms, has been proven to significantly enhance the representational capacity of music features. The design of this structure is inspired by successful

experiences in the field of image processing, but it has been optimized for the characteristics of music data.

Fig. 3. Schematic diagram of batch normalization channel attention calculation structure in CHSE-GAN.

As shown in Fig. 4, taking music signal processing as an example, suppose we have an input with a time-frequency representation of size $256 \times 64 \times 64$, which represents 256 channels, each with 64 time steps and 64 frequency components. The input first goes through two layers of convolution, batch normalization, and ReLU activation function, and then it is divided into two branches:

- i. The first branch is passed through directly without processing to preserve the original features of the music signal.
- ii. The second branch is enhanced through an SE (Squeeze-and-Excitation) module. This module first employs a global average pooling operation to "squeeze" each channel, reducing the 64×64 feature map of each channel to a single scalar to capture the global contextual information.

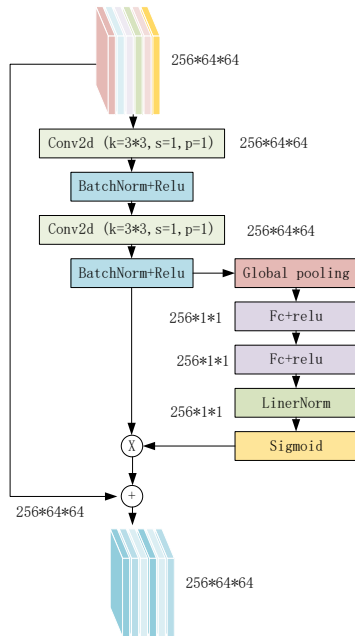

Fig. 4. Schematic diagram of Res-SE network structure in CHSE-GAN.

Next, this global information is processed through two layers of fully connected layers, which include ReLU activation functions, to capture the inter-channel dependencies and generate a weight for each channel. These weights are further transformed through a Sigmoid activation function to obtain the final weights for each channel, which determine which channels are important.

Finally, we multiply these weights by the original input to recalibrate the features. This process allows the model to

emphasize those channel features that are important for music generation while suppressing the less important parts.

IV. AUTOMATIC MUSIC GENERATION METHODS BASED ON GENERATIVE ADVERSARIAL NETWORKS

This section will validate the effectiveness of the proposed method based on a self-made experimental dataset.

A. Experimental Environment

The hardware environment for the experiments in this chapter is shown in Table I:

TABLE I. EXPERIMENTAL SOFTWARE AND HARDWARE ENVIRONMENT

CPU	Intel i7 8700k
GPU	GTX 3080
Memory	32G
Operating System	Ubuntu 18.04
CUDA	11.1
Main Frameworks	Pytorch, Keras
Main Programming Language	Python 3.6

To explore the automatic generation of pop music, this study has selected the widely popular POP909 music dataset as the training resource. The characteristic of the POP909 dataset is the clear division of its melody tracks, making the melodies easy to extract and process separately. The preprocessing of music data adopted the method introduced in Chapter 3, converting MIDI files into text format, with the help of the music21 toolkit in the Python platform.

The experimental part designed four different studies to comprehensively evaluate music generation performance. These four areas are: comparison of music generation effects at different tempos, performance comparison of various music generation models, comparison of the quality of generation with other algorithms, and evaluation using the music evaluation model introduced in Chapter 6. By analyzing the results of different tempos, the comprehensive performance of the MT-CHSE-GAN network can be assessed, and its applicability for generating different types of music can be determined. Compared with algorithms such as Rank-GAN and Seq-GAN, this study aims to verify the advantages of MT-CHSE-GAN in the field of music composition. Finally, based on the evaluation model in Chapter 6, the music generated by MT-CHSE-GAN is compared and analyzed with real music samples, melodies produced by LSTM networks, and MT-GPT-2 networks, to examine from a more objective perspective whether the MT-CHSE-GAN network can meet the standards of real music melody generation.

B. Experiment

After a series of in-depth training, the innovative CHSE-GAN model we used, which is based on bar segmentation, successfully created numerous musical works. By careful listening tests, we noticed that most of these works exhibit smooth and pleasant characteristics. To give everyone an intuitive feeling, we randomly selected some sample fragments to showcase this achievement. Before that, it should be noted that since this work adopted a way of expressing music as text,

all generated music works initially exist in text form. To convert these text data into audible music, we used the music21 toolkit under the Python environment to achieve the transformation from text to MIDI format. Subsequently, we used MusicScore 3 software to open it in the form of a score for a more detailed display, with the specific effects shown in Fig. 5.

Fig. 5. Generated fragment display.

During the model training, the accuracy of the model was recorded, as shown in Fig. 6 below.

Fig. 6. Model accuracy curve.

The changes in loss rate are shown in Fig. 7 below.

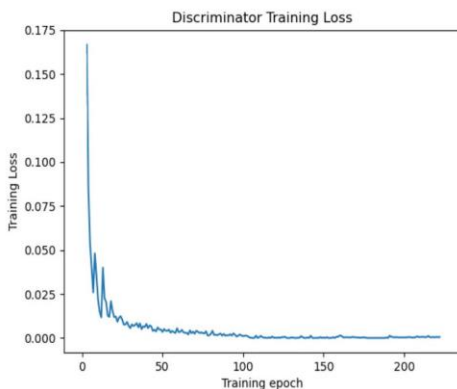

Fig. 7. Model loss rate curve.

As can be seen from the figures above, the MT-CHSE-GAN model, which used adversarial pre-training, reached convergence quickly with both the accuracy rate and loss values stabilizing around 100 epochs.

1) Comparison of Music Generation at Different Tempos

By training the model with pop music at different tempos, the following generated music was obtained, as shown in Fig. 8.

Fig. 8. MT- CHSE-GAN generates fast and slow music comparisons.

In the examples shown in Fig. 8, we can see that the two slow tempo music segments on the left were generated by the MT-CHSE-GAN after training, while the two fast tempo segments on the right also used the MT-CHSE-GAN model. Although the slow tempo music has a pleasant melody, there is a minor issue: some notes are repeated too often, as indicated by the red box in the figure (a note's duration exceeds one measure). In contrast, the fast tempo segments avoid this issue; their melodies progress in a stepwise fashion, with a clear rhythm, as shown by the notes marked with a blue box. From this comparison, we can observe that in the generation of slow tempo music, the model still has room for improvement in handling long-duration notes, while in the generation of fast tempo music, the model performs relatively well.

2) Comparison of Music Generation for Different Models

Next, we compared the music generated by different models (see Fig. 9). From top to bottom, the figure sequentially shows music segments generated by the MT-CHSE-GAN, Rank-GAN, and Seq-GAN networks. As indicated by the pink arrows in the figure, the melody segments generated by the MT-CHSE-GAN and Seq-GAN networks show clear high and low fluctuations, with most of the melodic changes revolving around the theme pitch and returning to the theme pitch at the end, which is consistent with the melodic development pattern of pop music.

On the other hand, the music segment generated by the Rank-GAN network shows an overall descending trend, with the melody starting high and gradually descending. This type of melodic structure is often inconsistent with the typical composition of pop music and may give a sense of oppression and unease. This indicates that, in handling long sequence melodies, the MT-CHSE-GAN and Seq-GAN networks have better generative effects compared to the Rank-GAN network.

After an in-depth analysis of three different music melody generation models, we specifically observed the characteristics of note changes, especially the melody parts marked with yellow boxes in the figures. The melody fragments produced by the MT-CHSE-GAN network exhibit gentle note changes, with melodies that are smooth and orderly, rhythmically fluctuating around the tonic. In contrast, the melodies produced by the Rank-GAN and Seq-GAN networks (also marked with yellow boxes) show more dramatic note changes, sometimes with jumps between notes approaching an octave. Such abrupt

melodic changes may seem jarring and not quite in line with the conventions of pop music composition.

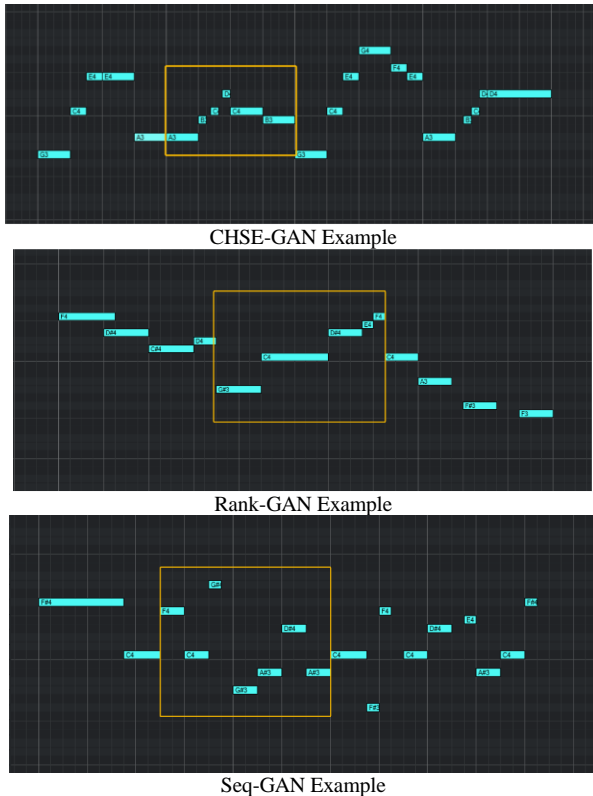

Fig. 9. Generate samples for each model.

In evaluating the generated music, we scored several key aspects based on music theory, including the harmony of the melody, the logical coherence of the melody, the contour of the melody, and the tonality of the melody. We had the MT-CHSE-GAN, Rank-GAN, and Seq-GAN networks each generate 10 pieces of music, scored them, and calculated the average score for each item (out of a possible 10 points). The scoring results are summarized in the Table II shown below.

TABLE II. MELODY THEORY SCORE

	Melody Harmony	Melody correlation	Melody contour	Melodic tonality	Average score
MT-CHSE-GAN	8.4	7.4	7.6	8.2	7.9
Rank-GAN	6.9	5.8	6.4	7.2	6.575
Seq-GAN	7.3	6.1	7.2	7.1	6.925

Based on the melody evaluation metrics introduced in the previous chapters and through comparative analysis, we found that the music melodies generated by the MT-CHSE-GAN model are of significantly higher quality than those generated by the Rank-GAN and Seq-GAN models when trained with the same music text data. The melodies generated by the MT-

CHSE-GAN network are closer to the style and texture of real music.

3) Comparative Analysis of Computational Complexity

In the experiments, an AMD Ryzen 7 4800H processor and RTX2060 graphics card were used for training and music generation of the various models. A comparison of the running time was made among the CHSE-GAN, Rank-GAN, and Seq-GAN models. In each model, music samples of 1024 characters in length were generated. The specific running time comparison results are presented in the table below in Table III. This comparison helps to assess the efficiency and resource consumption of different models when generating melodies.

TABLE III. COMPARISON OF RUNNING COMPLEXITY

Model	Time
CHSE-GAN	4.9s
Rank-GAN	6.5s
Seq-GAN	4.8s

As the data in the table shows, the time taken to generate 1024 characters varies slightly among the three models: the CHSE-GAN model requires approximately 4.9 seconds, the Rank-GAN model takes 6.5 seconds, and the Seq-GAN model needs 4.8 seconds. Although the generation times are similar, the CHSE-GAN has an advantage in terms of the quality of generation compared to the other two models.

4) Comparison of the Fit of Music Generated by Different Models

Based on a unified data representation, we trained the Rank-GAN and Seq-GAN networks and subsequently evaluated the models' performance. Maximum likelihood estimation (MLE) aims to minimize the cross-entropy between the true data distribution pp and the data distribution qq generated by the model. By quantifying MLE, we are able to assess the fit between the data and the model. This reflects not only the specific details of the data but also considers the details of the model.

Negative log-likelihood (NLL) was originally proposed in Seq-GAN research as an improved metric based on MLE, specifically to measure the degree of match between generated data and real data. Fig. 10 shows the training loss changes for NLL-test.

The NLL-test training loss curves from Fig. 10 indicate that the CHSE-GAN model converges more quickly and demonstrates better performance on this metric. Throughout the testing phase, CHSE-GAN consistently showed the best NLL performance, while Rank-GAN performed the worst. The NLL loss curves for Seq-GAN and Rank-GAN almost coincide before the solid line, but after the solid line, the performance of Rank-GAN declines compared to other stages. These results suggest that the music generated by the MT-CHSE-GAN network performs better in fitting real music.

Fig. 10. NLL-test loss.

V. CONCLUSION

This research is dedicated to exploring the important branch of artificial intelligence that is automatic music generation, with a particular focus on the application of deep learning technologies in this field and their practical value. In order to improve the stability of music generation models, a CHSE-GAN based model was developed, effectively addressing the issue of length in music melody generation. The model integrates music theory and mathematical statistics, and through the textualization and bar-wise processing of music data, as well as the introduction of the SE module and the channel attention module based on batch normalization, it enhances feature extraction capabilities without the need to add extra network parameters. Experiments show that CHSE-GAN can generate music of higher quality compared to traditional algorithms. Although research in music generation has made certain advances, its range of application is still relatively limited, and it lacks quantitative evaluation metrics. In particular, evaluation models that combine mathematical statistics with music theory knowledge still have great potential for development. Future work will continue to focus on expanding model applications, enriching evaluation methods, and improving the quality of generated music.

ACKNOWLEDGMENT

The preferred spelling of the word “acknowledgment” in America is without an “e” after the “g.” Avoid the stilted expression, “One of us (R. B. G.) thanks . . .” Instead, try “R. B. G. thanks.”

Predictive Modeling of Yoga's Impact on Individuals with Venous Chronic Cerebrospinal System

Sanjun Qiu*

Guangxi Police College, Nanning Guangxi, 530028, China

Abstract—People leading a modern lifestyle often experience varicose veins, commonly attributed to factors associated with work and diet, such as prolonged periods of standing or excess weight. These disorders include elevated blood pressure in the lower extremities, especially the legs. An often-researched metric associated with these illnesses is the Vascular Clinical Severity Score (VCSS), which is connected to discomfort and skin discolorations. However, yoga appears to be a viable way to prevent and manage these problems, significantly lessening the negative consequences of varicose veins. The investigation of yoga's effect on VCSS in this study uses a novel strategy combining machine learning with the Extra Tree Classification (ETC), which is improved by the Cheetah Optimizer (CO) and Black Widow Optimizer (BWO). In this study, the ETC model was combined with previously mentioned optimizers, and two models were amalgamated, referred to as ETBW and ETCO. Through the evaluation of the performance of these models, it was discerned that the accuracy measure for prediction was associated with the ETCO model in the context of VCSS. By revealing subtle correlations between yoga treatments and VCSS results, this multidisciplinary approach seeks to provide a thorough knowledge of preventative and control processes. This research advances the understanding of vascular health by correlating yoga interventions with VCSS outcomes using machine learning and optimization algorithms. By enhancing predictive accuracy, it promotes multidisciplinary collaboration, personalized medicine, and innovation in healthcare, promising improved patient care and outcomes in varicose vein management.

Keywords—Yoga; varicose veins; Extra Tree Classification; cheetah optimization algorithm; Black Widow Optimizer

I. INTRODUCTION

Recently, easy access to food, time constraints, and prolonged working hours have led to individuals' prevalent consumption of fast food and minimal physical exercise [1]. This lifestyle, characterized by improper dietary choices and an absence of physical activity, is identified as the origin of various diseases, including but not limited to diabetes, heart disease, and varicose veins [2].

Varicose veins, influenced significantly by factors such as excessive body weight and prolonged periods of standing or sitting, emerge as one of the most widespread afflictions among individuals [3]. Lifestyles characterized by these factors predominantly cause this condition [4]. Typically manifesting in the lower limbs, particularly the legs, varicose veins exhibit outward characteristics such as skin discoloration and dilated vessels [5]. Subsequently, elucidating the definition reveals that varicose veins are enlarged and twisted veins commonly observed in the legs [6]. Legs are the most frequent location for

varicose veins, which are twisted, swollen veins that can cause pain and cosmetic issues [7], [8].

Varicose veins, the signs and symptoms, and possible therapies can be managed and avoided by being aware of this prevalent vascular issue [9]. On the other hand, Chronic venous insufficiency (CVI) [10] describes a condition that affects the venous system of the lower extremities, with the sine qua non-being persistent ambulatory venous hypertension causing various pathologies, including edema, pain, skin changes, and ulcerations [11]. CVI often indicates the more advanced forms of venous disorders, including hyperpigmentation, venous eczema, lip dermatosclerosis, atrophied blanche, and healed or active ulcers [12].

Nevertheless, due to incompetent valves and heightened venous pressure in varicose veins, the term CVI encompasses the complete spectrum of manifestations associated with CVD. Investigating the possible medical advantages connected to yoga practice addresses whether yoga helps treat varicose veins [13]. Yoga stretches are thought to have a moderating effect on the pain and swelling that are frequently linked to varicose veins [14]. The benefits of some yoga poses, especially those involving leg elevation, are highlighted in particular for treating venous issues. Upon examining the physiological elements, it is observed that elevated legs facilitate blood return to the heart, thereby reducing vein pressure and potentially preventing the worsening of varicose veins [15], [16]. Yoga is offered as a supplemental treatment for varicose veins [17], understanding that although it cannot treat the problem, it may significantly lessen its symptoms and possibly even prevent further worsening. It is emphasized that anybody considering adding yoga to their regimen for managing varicose veins should see a healthcare provider or a vein specialist to ensure these poses are acceptable for their particular medical situation [18]. The investigation ends with a call for people to submit their ideas and observations on how well yoga works to treat varicose veins.

The yoga intervention consists of movements designed to target stimulating reflex therapy, reduction of muscular tension, and elasticity in the joints [19]. Exercises for loosening the joints and releasing tense muscles comprise ankle, wrist, elbow, neck, knee, and shoulder motions [20]. Techniques for Shavasana [21] promote profound calmness. Exercises for breathing promote better breathing patterns, tighten the core muscles, and soothe the muscles in the arms and shoulders [22]. Workouts for tightening the powers of the hips, thighs, calves, and abdomen help to reduce stiffness and increase flexibility in action. Numerous asanas (poses) are used to develop multiple muscle groups, extend and rest back muscles, and mobilize cervical

joints [23]. A profound state of sleep is induced, venous return is increased, and prana is balanced in the body through pranayama and other activities. Lastly, for mental relaxation, OM meditation is given [24]. This holistic approach promotes flexibility, relaxation, and general well-being by addressing mental and physical elements.

Machine learning (ML) approaches serve a crucial and pioneering function in addressing the complexities of diverse challenges encountered in real-world problems [25], [26]. In the context of this research, the primary objective was to leverage ML techniques to develop a robust approach capable of predicting and classifying the impact of yoga on the VCSS within a specific group of workers. Recognizing the profound importance of prioritizing workers' health, the study highlights the direct correlation between their well-being and the efficiency and productivity of their work. The choice of the ETC model for this investigation was driven by its practicality in effectively predicting the intricate variability present in the dataset [27]. Two novel optimization algorithms were seamlessly integrated into the ETC framework to enhance the model's precision and accuracy further. In order to ensure the objectivity and reliability of the study, performance metrics were rigorously employed, mitigating potential biases. Through this comprehensive analysis, the study leads to a robust conclusion: yoga can positively impact people's health.

In addition, this study employs a systematic approach to select appropriate techniques for the solution. The study first identifies the problem domain—varicose vein management—and recognizes the need for both medical understanding and computational analysis. Leveraging their expertise in both areas, they choose machine learning, specifically the ETC, to capture complex data interactions. Additionally, they integrate advanced optimization algorithms, such as the Cheetah Optimizer (CO) and Black Widow Optimizer (BWO), to enhance predictive capability. By combining these techniques, they create hybrid models that effectively analyze large datasets encompassing yoga interventions and Vascular Clinical Severity Score measurements. This thoughtful selection process ensures the integration of cutting-edge methodologies tailored to the complexities of the research problem, ultimately leading to a robust and innovative solution.

II. DATA COLLECTION AND METHODOLOGY

A. Data Gathering

When assessing the effects of yoga on people with VCSS, many input parameters were taken into account to identify changes that occurred both before and after the introduction of yoga into their daily habits. Important factors, including weight, height, age, sleep quality, smoking status, VCSS scores before the yoga intervention, food habits, and the number of hours spent sitting and standing throughout the workday, were all included in the inputs. The data from the participants showed a brief picture of their health profile before introducing yoga. Their age, height, weight, and eating habits revealed information on their physical attributes and food preferences. Important lifestyle aspects such as alcohol use and smoking status were taken into account, providing a thorough insight into their behaviours. The

quality of sleep was evaluated to evaluate how rest affects general well-being.

Furthermore, the VCSS scores of the individuals before beginning yoga were used as a reference point to assess how beneficial yoga was for venous health. They revealed their daily activity levels by tracking their time standing and sitting throughout work hours. An evaluation was conducted after the subjects started yoga to forecast any prospective changes in them. The impact of yoga on their sleep quality and general lifestyle was considered when forecasting favourable results. The purpose of assessing the effect of yoga on VCSS scores was to assess possible advantages on venous health. Variations in sitting and standing hours following yoga were anticipated to mirror individual activity pattern changes. This predictive study was conducted to provide insight into the possible changes in people's health profiles when they go from not practising yoga to doing it regularly. With an emphasis on venous health, as shown by VCSS scores, the evaluation sought to capture the holistic benefits of yoga on participants' well-being by considering these many input elements. In Fig. 1, a correlation matrix is presented, providing a visual representation for the analysis of relationships between input and output variables.

B. Black Widow Optimization (BWO)

The medium-sized black widow spider, belonging to the Orygiidae family, is prevalent in European countries around the Mediterranean. Female spiders predominantly reside in webs, breeding, feeding, and rearing offspring. The mating process involves web narrowing and potential cannibalism. The Black Widow Optimization method, introduced by Hayyolalam and Kazem in 2020 [28], models spider life cycles for optimization problem-solving, aligning with Darwin's evolutionary theory and demonstrating genetic adaptation in spider populations through competitive growth. The BWO algorithm involves population setup, reproduction, homicide, and mutation stages [29].

1) *Initialization*: $W_{N \times D} = [X_1, X_2, \dots, X_N]$ has N widows in the number of spiders. X_1, X_2, \dots, X_N . D symbolizes an optimization problem's complexity. Within the populace, $X_i = [x_{i,1}, x_{i,2}, \dots, x_{i,D}]$ ($1 \leq i \leq N$) stands for the widow i -th. Every component in a single $[x_{i,1}, x_{i,2}, \dots, x_{i,D}]$ ($1 \leq i \leq N$) is set up using Eq. (1).

$$x_{i,j} = l_j + rand(0,1) \cdot (u_j - l_j), 1 \leq j \leq D \quad (1)$$

where, $L = [l_1, l_2, \dots, l_D]$, $U[u_1, u_2, \dots, u_D]$ represent the optimization algorithm's parameters' upper and lower limits.

2) *Procreate*: Black widows reproduce by a special kind of mating activity. When mating, a pair of spiders designated as the parents of the spiders are chosen randomly from the population to marry by the procreating rate (Pp). Eq. (2) is used to create the progeny.

$$\begin{cases} Y_i = aX_i + (1 - a)X_j \\ Y_j = aX_i + (1 - a)X_i \end{cases} \quad (2)$$

Fig. 1. Correlation matrix to analyze the relationships between input and output variables.

where, spiders X_i and X_j represent the mother and father, respectively. The progeny, through mating, is Y_i and Y_j . Furthermore, α is an array in D dimensions that contains random integers.

3) *Cannibalism*: Three different types of cannibalism are present at this stage: sibling cannibalism, sexual homicide, and homicide between a mother's kids. The good ones may be kept alive by eliminating the weaker ones.

4) *Cannibalization for sex*: Following or during mating, the female black widow consumes her spouse. The female spiders that survive are kept for the following generation.

5) *Cannibalism of siblings*: The more enormous spiders devour their younger ones because of a lack of food supplies or natural adversaries. The strength of a spider is determined by its fitness value. The total number of survivors is calculated using the cannibalism rating (CR) in this procedure.

6) *The mother and children engaging in cannibalism*: Some young spiders are so powerful that they may even consume their mother. In other words, an answer with a high health value generated by parents will take the place of its mother and be passed on to the following population.

Fig. 2. Mutation method.

7) *Mutation*: At this point, a constant known as the rate of mutation (P_m) determines how many population members will undergo mutations. Two array elements are chosen randomly

and then swapped for the chosen person. The new individuals' fitness is randomly altered, as Fig. 2 illustrates. The BWO algorithm's pseudo-code appears as follows.

Algorithm 1: The BWO Algorithm

Input: Number of populace (N), Extreme iteration count (T), rate of rate of Mutation (Pm)

Output: almost perfect solution for the goal function

Begin

Initialize the population of black widows at random using Eq. (1);

While ($t < T$)

Determine how many copies there are nr using Pp as a guide;

Pick the population's nr parents;

For $i = 1$ to nr , do

From the NR parents, choose two at random to be the parents;

Create kids utilizing Eq. (2);

Destruction of dads;

Eliminate a few of the kids based on CR ;

End for

Preserve the surviving women and kids in a fresh matrix as the next

Determine the quantity of minor nm – based Pm mutations;

For $i = 1$ to nm

Choose a response from the kids who are still there;

Create a new solution by randomly changing one of the solution's c

End for

Provide the optimal response;

End while

Provide the optimal response;

End

C. Cheeta Optimization Algorithm (CHO)

1) *Overview of the CO Algorithm:* The CO method, a potent optimization technique for imitating particular cheetah-hunting strategies, was recently created by Akbari et al. [30]. This algorithm uses three crucial tactics: hunting for prey, waiting, and attacking. Departing the prey and going home is introduced by the algorithm to prevent becoming stranded in local optimum positions. This section first explains the CO algorithm's mathematical model before presenting the ICO algorithm. The answer to the issue is comparable to each cheetah's likely hunting arrangements. It is thought that one's position within the population determines the prey (best answer). During the hunting season, cheetahs modify their potential groupings to maximize efficiency.

2) *Searching strategy:* A cheetah looks for appropriate prey depending on its hunting style and the state of the environment. The searching stage of a mathematical model corresponds to this:

$$X_{i,j}^{t+1} = X_{i,j}^t + \hat{r}_{i,j}^{-1} \cdot \alpha_{i,j}^t \quad (3)$$

where, $X_{i,j}^t$ denotes the cheetah i at chasing time t and $X_{i,j}^{t+1}$ is the new arrangement. The randomization parameter is the inverse of a regularly distributed random number, $\hat{r}_{i,j}^{-1}$. Other than that, $\alpha_{i,j}^t$ defines the random length of the steps and is stated as follows for the leader:

$$\alpha_{i,j}^t = 0.001 \times t/T \times (U_j - L_j) \quad (4)$$

Where the variable j 's upper and lower bounds are denoted by U_j and L_j , respectively. T is a representation of a hunting time. The random length of steps for additional cheetahs in a group is determined by calculating the distance between cheetah i and a randomly chosen cheetah k in the group.

$$\alpha_{i,j}^t = 0.001 \times t/T \times (X_{i,j}^t - X_{k,j}^t) \quad (5)$$

3) *Sitting-and-waiting strategy:* Cheetahs hunt quickly. It takes much energy to be fast and flexible during the pursuit. As such, the attack and pursuit cannot last for an extended period. Because of this, waiting till the prey is sufficiently close to them is one of the cheetah's essential hunting methods. They then launch the assault. This behaviour can boost the success of hunting and is represented as follows:

$$X_{i,j}^{t+1} = X_{i,j}^t \quad (6)$$

4) *Attacking strategy:* Cheetahs strike their prey at the right moment. When attacking, the cheetah uses two essential characteristics, speed, and flexibility, to its advantage. Since cheetahs need to get as near their prey as possible in the least amount of time, they attack at full speed. Here, the prey becomes aware of the cheetah's onslaught and begins to flee. Since the cheetah is so close to its target and moves quickly, the prey chooses to make a quick turn to escape. As a result, the cheetah places its prey in precarious situations and uses its great degree of flexibility to grab it. Attacks can occur alone or in clusters. In response to the prey's location, the cheetah's position changes in single attack mode. Depending on the prey's and other group members' state, this can be done dynamically in a group assault.

$$X_{i,j}^{t+1} = X_{B,j}^t + \check{r}_{i,j} \cdot \beta_{i,j}^t \quad (7)$$

$$\check{r}_{i,j} = |r_{i,j}|^{\exp(-\frac{r_{i,j}}{2})} \sin(2\pi r_{i,j}) \quad (8)$$

When the prey location is denoted by $X_{B,j}^t$, the turning factor, $\check{r}_{i,j}$, represents the prey's abrupt shifts during its flight, and $r_{i,j}$ is a chosen at random number drawn from a normal distribution. Eq. (20) defines the interaction factor as $\beta_{i,j}^t$, which may be represented as follows:

$$\beta_{i,j}^t = X_{k,j}^t - X_{i,j}^t \quad (9)$$

5) *Strategy selection mechanism:* In the CO algorithm, selecting the best course of action is done at random. Assume two random integers from a uniform distribution, r_2 and r_3 . The sit-and-wait approach is used if r_2 is larger than r_3 ; if not, one of the hunt or assault tactics is implemented. Between the two assault and search tactics, a condition is determined by the H element (see Fig. 3). The following expression describes how this component declines with time:

$$H = e^{2(1-\frac{t}{T})} (2r_1 - 1) \quad (10)$$

where, r_1 is a random number between 0 and 1. Between these two approaches, a situation has been established such that, come hunting season, searching is the more likely option. It seems conceivable that an attack will happen as the hunting season continues.

D. Performance Evaluators

Different evaluation criteria are available for evaluating the performance of classifiers. A popular statistic for assessing the

efficacy of a machine learning algorithm is the accuracy indicator, which computes the proportion of adequately predicted observations. Recall, Accuracy, and Precision are often utilized indicators. Accuracy represents the entire correctness of the model. It displays the percentage of correctly predicted instances in each case, including genuine positives and true negatives. Accuracy is an important metric, but imbalanced datasets might render it inadequate.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (11)$$

Precision is used to measure how effectively the model forecasts positive results. The ratio of accurately anticipated favourable results to all optimistic forecasts is calculated. Less false positives indicate a model with high accuracy.

$$Precision = \frac{TP}{TP + FP} \quad (12)$$

The model's ability to recognize each relevant instance of the category of positives is measured by recall. It computes the ratio of correctly predicted positive observations to all positive ones. A decent measure of how few erroneous outcomes the model produces is recall.

$$Recall = TPR = \frac{TP}{P} = \frac{TP}{TP + FN} \quad (13)$$

The F1-score is the recall and accuracy harmonic average. It provides precision and recall in balance. When there is an uneven distribution of classes, this metric is beneficial since it accounts for erroneous positives and false negatives.

$$F1\ score = \frac{2 \times Recall \times Precision}{Recall + Precision} \quad (14)$$

The letter TP in the previous equations indicates a favourable prognosis that matches the positive result. The acronym FP denotes an optimistic forecast in scenarios with adverse outcomes. A pessimistic prediction with TN indicates one similar to the actual negative outcome. A negative forecast is denoted by the sign FN when the accurate result is positive.

III. RESULTS

A. Models Comparison

As previously mentioned, VCSS is one of the most prevalent conditions among individuals. Various causes, such as an incorrect lifestyle, lack of exercise, and genetic factors, contribute to the development of VCSS. Aggressive treatments, including surgery and laser interventions, are deemed beneficial, although they carry inherent complications. In this context, the recommendation of yoga arises. This exercise is proposed due to its efficacy in alleviating pressure in the lower limbs, particularly the legs, ultimately contributing to the control and enhancement of the patient's condition. The base model, ETC, and two combined models, ETBW and ETCO, are employed to assess the accuracy of predictions. The evaluation focuses on individuals who have not incorporated yoga into their routines. Table I illustrates the model ranking, indicating which model achieves the highest accuracy and optimal performance based on metric values. This analysis provides a comprehensive overview of the predictive capabilities of the models, shedding light on their effectiveness in the absence of yoga intervention. As demonstrated in Table I, the performance of each model is assessed across three severity conditions: absent, mild, and moderate to severe. The ETC model exhibits a precision value of 0.846 in the absent condition, 0.905 in the mild condition, and 0.30 and 1000 precision values in the moderate and severe conditions, respectively.

Conversely, when incorporating BWO into the base model, there is an enhancement in conditions accuracy. Notably, the precision value increases in the absent condition from 0.846 to 0.917. It experiences a marginal change from 0.905 to 0.907 in the mild condition. However, in moderate and severe conditions, the precision value of the ETBW model remains consistent with that of the ETC model, indicating a limited impact of this model on the base model's effectiveness. The recall and F1 score values for both the ETC and ETBW models in the absent and severe conditions are identical, a pattern replicated in the severe condition for the ETCO model concerning precision, recall, and score values.

TABLE I. EVALUATION INDEXES OF THE DEVELOPED MODELS' PERFORMANCE BASED ON POSITIONS VCSS. PRE

Model	Condition	Metric value		
		Precision	Recall	F1-score
ETC	Absent	0.846	0.917	0.880
	Mild	0.905	0.905	0.905
	Moderate	0.930	0.909	0.920
	Severe	1.000	1.000	1.000
ETBW	Absent	0.917	0.917	0.917
	Mild	0.907	0.929	0.918
	Moderate	0.930	0.909	0.920
	Severe	1.000	1.000	1.000
ETCO	Absent	0.786	0.917	0.846
	Mild	0.929	0.929	0.929
	Moderate	0.976	0.932	0.954
	Severe	1.000	1.000	1.000

Regarding the ETCO model, a discernible retrogression in precision value is evident in the absent condition, attributable to the combination with the COA optimizer, despite the higher accuracy achieved compared to the base model. The precision, recall, and F1-score values remain consistent at 0.929 in mild conditions, showcasing equivalent performance. Notably, the ETCO model excels in moderate conditions, recording the highest values across all three metrics: precision (0.976), recall (0.932), and F1-score (0.954). This pattern implies that the optimizers exhibit limited efficacy in severe conditions, and metric values do not witness a discernible increase. ETCO demonstrates superior performance among the four models, with ETBW showcasing the highest accuracy in the absent condition and ETCO registering a minor favourable performance in this category. It should be noted that these values pertain to individuals who have not initiated yoga practice.

Incidentally, Table II forecasts the anticipated performances of the models following a three-month yoga intervention, revealing distinct outcomes. In the ETC model, precision values experience a notable shift, reaching 0.918 in the absent position, 0.864 in the mild position, and 0.954 and 1.000 in the moderate and severe positions, respectively. Conversely, the ETBW model demonstrates diminished accuracy in the absent positions, registering a precision value of 0.914. However, parity is observed in the moderate position, with a precision value of 0.954, and identical precision values are observed in the severe positions. The precision, recall, and F1-score values for the absent position are maintained at 0.914, reflecting identical metrics achieved by ETBW models in the corresponding positions.

Additionally, in the mild position, superior performance is demonstrated by the ETCO model compared to other models. This superiority is upheld by the model in the F1 score value for the moderate position, and an equal recall value is shared in the same position with the ETBW model. In contrast, lower performance is exhibited by the ETC and ETBW models in the mild position, with a recorded recall value of 0.826. The highest accuracy in recall value is observed in the moderate position of the ETCO model, registering a measured value of 0.988. Hence,

it becomes evident that a notable enhancement is exhibited by the ETCO model compared to other models, suggesting that the COA optimizer is more effective in augmenting the base model than the BWO optimizer.

B. Visual Representation of Model's Performance

Fig. 3 displays the performance of developed models across two-time scales: initially, among individuals who had not engaged in yoga, and subsequently, three months after initiating yoga practice. Each model is compared within these two-time scales. For instance, the ETCO model exhibits higher accuracy, recall, and F1 score in the test grade with a value of 0.967. However, the current model does not demonstrate optimal performance after three months. Specifically, the ETCO model performs best in the Train phase for all four metric values in the VSS.3 target.

In the current target, the lowest value pertains to the F1 score in the test phase, with a value of 0.898. Conversely, the lowest values in VCSS.PRE targets are observed in recall and accuracy during both test and train phases, with a value of 0.914. In the VCSS.PRE target, the best performance in the training phase, is demonstrated by the ETBW model, with a precision value of 0.930, followed closely by accuracy, recall, and F1 score, each with a minimal difference at 0.929 in the same phase. In the test phase, all four metrics exhibit nearly identical values. In another target within the same phase, the F1 score registers a lower value of 0.898, while recall and accuracy metrics share a value of 0.9. In the VSS.3 target, the performance of each of the three models closely mirrors one another. The ETC model attains its highest value in precision for both the test and train phases, reaching 0.918 in the VCSS.PRE target.

Conversely, the lowest accuracy is associated with the precision value across all phases, standing at 0.911. Furthermore, the lowest value is in the VCSS.3. Three targets is 0.9, attributed to accuracy and recall in the test phase. Ultimately, the highest accuracy in the second target is linked to recall and accuracy, both attaining a value of 0.929.

TABLE II. EVALUATION INDEXES OF THE DEVELOPED MODELS' PERFORMANCE BASED ON POSITIONS. VCSS.3

Model	position	Metric value		
		Precision	Recall	F1-score
ETC	Absent	0.918	0.886	0.899
	Mild	0.864	0.826	0.844
	Moderate	0.954	1.000	0.976
	Severe	1.000	1.000	1.000
ETBW	Absent	0.914	0.914	0.914
	Mild	0.905	0.826	0.864
	Moderate	0.954	1.000	0.976
	Severe	1.000	1.000	1.000
ETCO	Absent	0.914	0.914	0.914
	Mild	0.909	0.870	0.889
	Moderate	0.976	1.000	0.988
	Severe	1.000	1.000	1.000

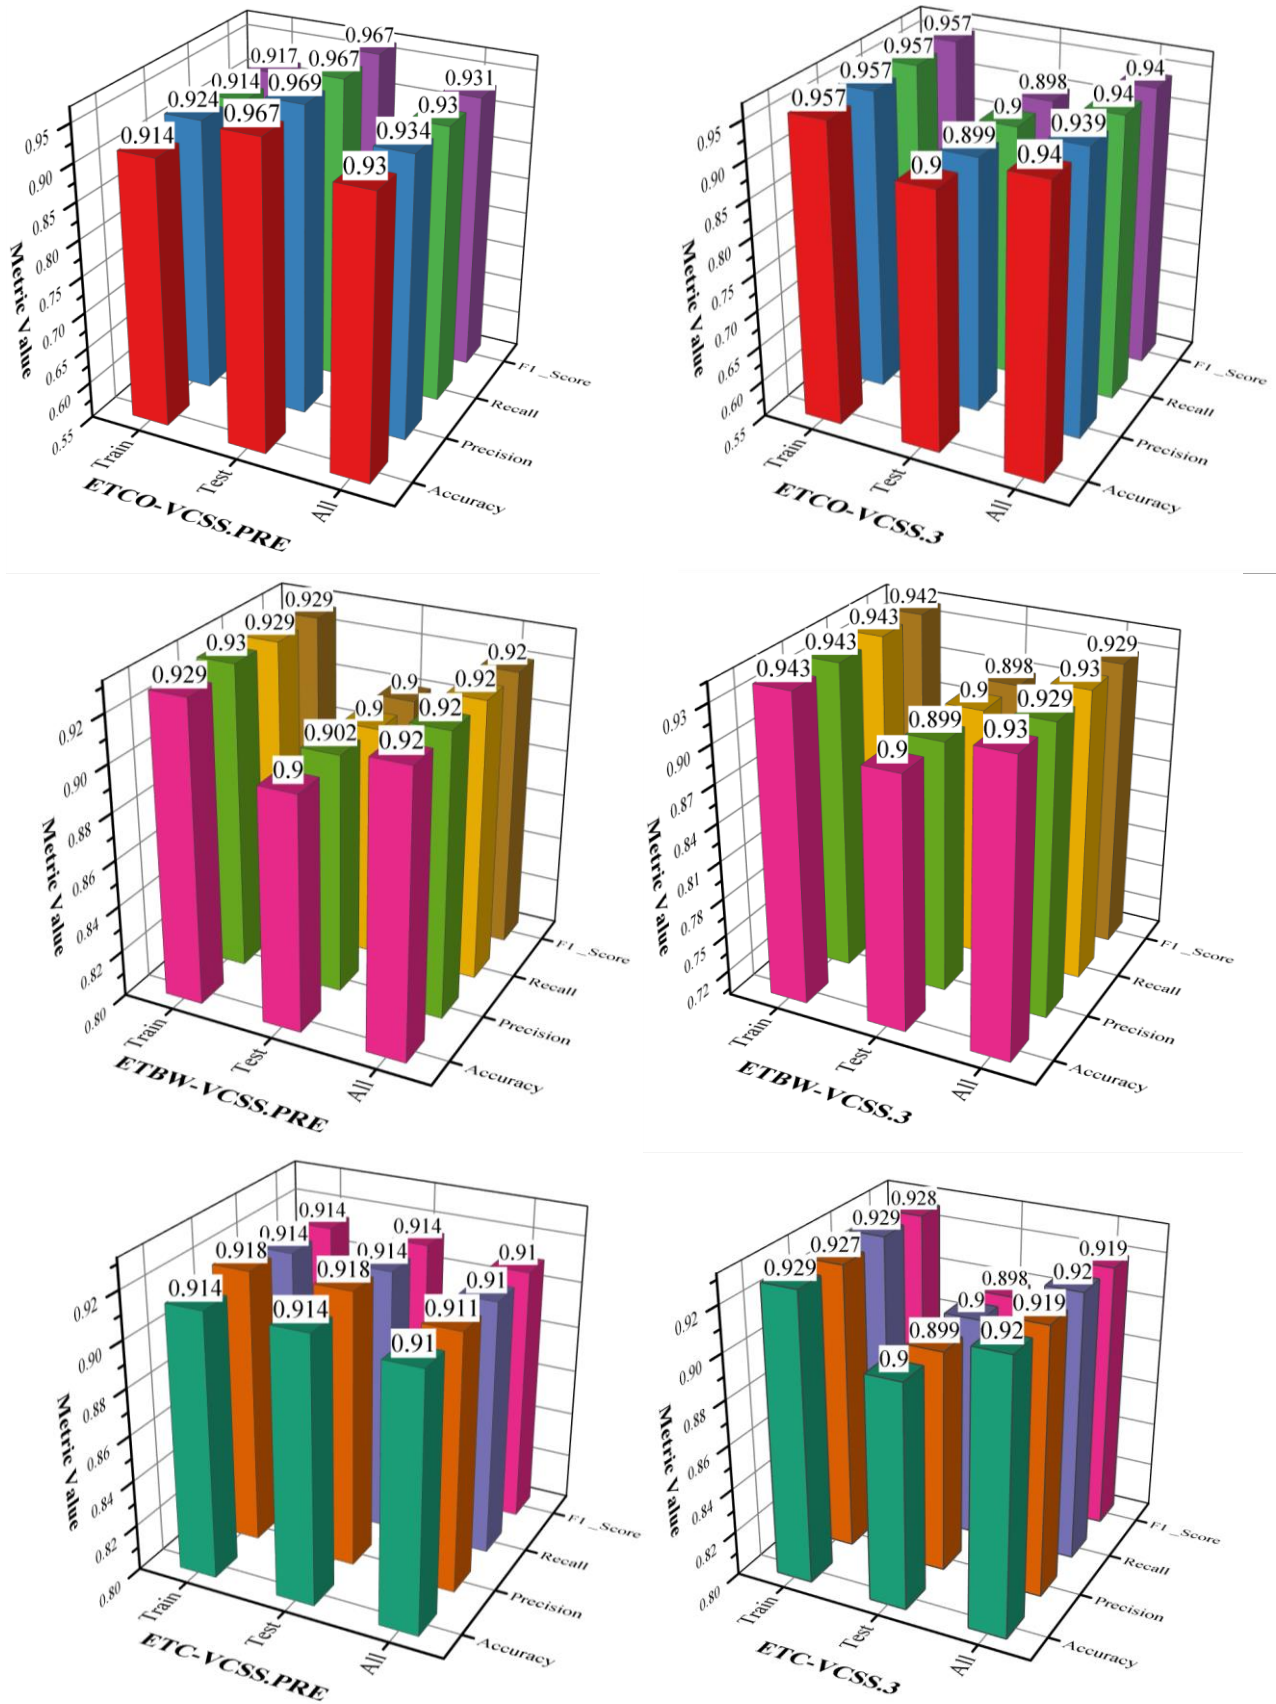

Fig. 3. 3D bar plot to visually assess the performance of the developed models.

Fig. 4. Line-symbol plot for the correlation of measured and predicted values.

The correlation of measured and predicted values in VCSS.PRE and VCSS.3 targets are depicted in Fig. 4. In this plot, the accuracy of each model is demonstrated across four positions: absent, mild, moderate, and severe, however, in the VCSS.PRE target, the measured accuracy of ETC, ETBW, and ETCO is 11 out of 12, indicating the high prediction accuracy of these three models in the current condition. In the mild condition, 39 out of 42 accuracy is achieved by the ETCO and the ETBW models, signifying high accuracy in the current condition and target. The ETC model holds the second rank, boasting an accuracy of 38 out of 42. Moving to the moderate

condition, the highest accuracy is attributed to the ETCO model. In contrast, the ETC and ETBW models exhibit identical accuracy, differing by 2.47% from the ETCO model and 9.52% from the measured accuracy.

Nevertheless, the highest accuracy is attained by each of the three models in the severe condition, achieving a perfect accuracy of 2 out of 2. This signifies that the models demonstrate optimal performance in the severe conditions of the VCSS.PRE target. On the other hand, in the VCSS. For three targets, the optimal performance of each model is evident in both moderate and severe conditions. In the moderate condition, the measured

accuracy is 41 out of 41. In contrast, in the severe condition, the accuracy measured is 1 out of 1. Additionally, in the mild condition, the highest accuracy is achieved by the ETCO model, with a measured accuracy of 20 out of 23. In the absent condition, the best performance is observed in the ETBW and ETCO models, with a measured accuracy of 32 out of 35. Ultimately, upon comparing the models' performance in the VCSS.PRE and VCSS.3 targets, it becomes evident that each of the three models demonstrates its optimal performance in the VCSS.3 target.

For instance, Fig. 5 illustrates the percentage distribution of correctly classified and misclassified values in the VCSS.PRE target, the accuracy of the ETCO model in the absent condition

is measured at 91.7%, with 8.3% of participants misclassified. In the mild condition, the accuracy measure is 92.9%, misclassifying 2.3% of participants in the moderate condition and 4.8% in the absent condition. Ultimately, the model's accuracy reaches 100% in severe conditions, indicating that all participants' conditions are correctly predicted. Moving to the ETBW model, it is observed that in the absent condition, the accuracy of the current model is 91.7%, with 8.3% of participants misclassified in mild conditions. 92.9% of participants are correctly predicted in mild conditions, with only 7.1% misclassified in moderate conditions. In moderate conditions, 90.9% of participants are correctly predicted, except for 6.8%, who are misclassified in mild conditions, and 2.3% of participants misclassified in the absent grade.

Fig. 5. The 3D stacked bar chart for the percentage distribution of correctly classified and misclassified values.

Nevertheless, in the severe grade, the conditions of all participants are correctly predicted with 100% accuracy. Moving on to the ETC model, similar to other models, participants' conditions in the severe grade are predicted with 100% accuracy. However, 90.9% of participants are correctly

predicted in the moderate grade, with 6.8% misclassified in mild conditions and 2.3% misclassified in absent conditions. In mild conditions, 90.5% of participants are correctly predicted, with 7.1% misclassified in the moderate grade and 2.4% misclassified in an absent condition. Ultimately, in the absent

condition, the model demonstrates its highest accuracy, measured at 91.7% after the severe grade, with a misclassification rate of 8.35% for participants in the mild grade.

On the other hand, in the VCSS.3 target, the highest accuracy is observed in severe and moderate conditions for each of the three models, with 100% of participants correctly predicted. The second-highest accuracy is attributed to the ETBW and ETCO models in an absent condition, with 91.4% of participants correctly predicting and misclassifying 5.7% of participants in mild conditions and 2.9% in moderate conditions. However, the lowest accuracy is noted for the ETC and ETBW models in mild conditions, with 82.6% of participants correctly predicting and misclassifying 13.1% of participants in an absent condition and 4.3% in moderate conditions.

The model's categorization threshold is changed to get various pairings of actual positive and false positive rate data. After that, a graph with these pairs drawn displays the ROC curve. When the model performs as well as random chance, the diagonal line shows the situation. A decent classifier should aim for a ROC curve closer to the top-left section, improved accuracy, greater receptivity, and a reduced false positive rate. Computing the area under the ROC curve is customary to offer

a single statistic that encapsulates the classifier's overall performance. Fig. 6 represents the ROC curve of the hybrid models.

ROC score closer to 1 indicates that the model can discriminate better in the VCSS.PRE target of the ETCO model, the highest accuracy is associated with the absent condition, achieving a true positive rate of 1.0 at a false positive rate of 0.1. Subsequently, the mild condition attains a true positive rate of 1.0 after a false positive rate of 0.4. At the same time, the lowest accuracy is observed in the moderate condition, reaching a true positive rate of 1.0 at a false positive rate of 0.7.

On the other hand, in the VCSS.3 target, the ETCO model achieves a true positive rate of 1.0 in the moderate condition, within a stable range before a false positive rate of 0.1. The second-highest grade is associated with the absent condition, attaining a true positive rate of 1.0 after a false positive rate of 0.2. At the same time, the lowest accuracy is observed in the mild condition, reaching a true positive rate of 1.0 after a false positive rate of 0.8. Thus, it can be understood that in the VCSS.3 target, the moderate condition exhibits the highest accuracy among the other conditions or classes.

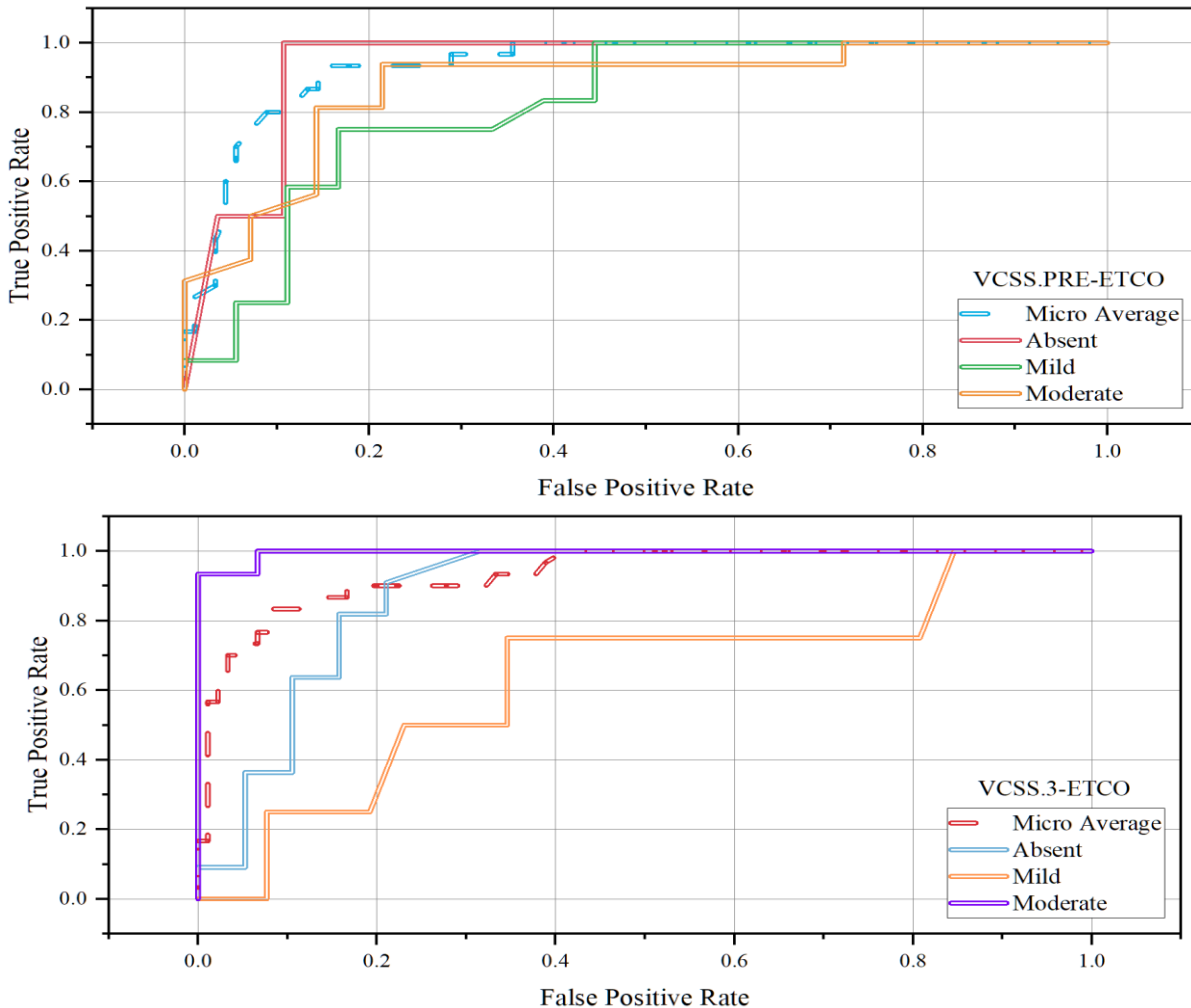

Fig. 6. ROC curve of the best hybrid models.

C. Convergence Curve

Generally speaking, a convergence curve is a graphical depiction of an iterative process's convergence over time. This idea is frequently discussed concerning optimization methods, especially in numerical analysis and machine learning. In the context of optimization algorithms, such as gradient descent, the convergence curve shows how the value of the objective function or the error changes as the algorithm iteratively refines its solution. The x-axis represents the number of iterations, and the y-axis represents the value of the objective function. The curve provides insights into how quickly the algorithm converges towards the optimal solution. The convergence curve in machine learning may be used to track the algorithm's effectiveness while training a model. The curve should, in theory, have a declining trend, signifying that the algorithm is gradually lowering the error or enhancing the data fit. A well-behaved convergence is frequently indicated by a sharp initial drop followed by a steadier decline. Practitioners can benefit

significantly from using the convergence curve to evaluate an optimization algorithm's efficacy and efficiency and make well-informed judgments about hyperparameters, halting criteria, and overall model performance.

This section employs the convergence curve to ascertain the correct training of models in various targets. For instance, in Fig. 7, the performance of the combined ETCO and ETBW models in the VCSS.PRE target is illustrated, revealing that the ETCO model achieves a measured accuracy of 0.93 in the 110th iteration. In comparison, the ETBW model reaches an accuracy of 0.8 in the 100th iteration. Consequently, the performance of the ETCO model in the VCSS.PRE target is marginally superior to that of the other model.

Similarly, in the VCSS.3 target, the ETCO model attains a 0.93 accuracy in the 110th iteration, while the ETBW model achieves a measured accuracy of 0.8 in the 111th iteration. This indicates that the ETCO model exhibits higher accuracy in both targets, albeit with a minimal difference between them.

Fig. 7. Convergence curve of hybrid models.

IV. DISCUSSION

A. Limitations

- **Generalizability:** The study's findings may have limited generalizability due to factors such as sample size, demographics, and specific yoga interventions examined. Further research involving larger and more diverse populations is needed to validate the results across different settings and populations.
- **Ethical Considerations:** The study raises ethical considerations regarding patient privacy and consent, especially when dealing with sensitive medical data. Researchers must ensure compliance with ethical guidelines and regulations to protect patient confidentiality and rights.
- **Interpretation of Results:** While the study identifies correlations between yoga interventions and Vascular Clinical Severity Score outcomes, causality cannot be definitively established. Additional research, including randomized controlled trials, is necessary to determine the causal relationship between yoga and varicose vein management outcomes.

B. Application of Study

- **Improved Varicose Vein Management:** The study's findings offer practical applications for managing varicose veins by highlighting the potential benefits of yoga interventions. Healthcare professionals can use this knowledge to recommend yoga as a complementary approach to traditional treatments, potentially enhancing patient outcomes and quality of life.
- **Enhanced Predictive Modeling in Healthcare:** The integration of machine learning and optimization algorithms demonstrates the feasibility of using advanced computational techniques to analyze medical data. This approach can be extended to other areas of healthcare, facilitating more accurate predictive modeling and personalized treatment recommendations.
- **Multidisciplinary Collaboration:** The study encourages collaboration between medical professionals, data scientists, and engineers. This multidisciplinary approach fosters innovation and knowledge exchange, leading to the development of holistic solutions to complex healthcare challenges.

V. CONCLUSION

The utilization of machine learning approaches has yielded important insights into the predictive study of the impact of yoga on the Venous Clinical Severity Score (VCSS). The application of ML algorithms, including the Extra Tree Classification (ETC) model, Black Widow Optimization (BWO), and Cheetah Optimizer Algorithm (COA), has made it possible to comprehend yoga's possible effects on vein health in more detail. Through performance criteria, including recall, precision, and F1 score, the generated models have thoroughly assessed the predicted accuracy under various scenarios. The assessment of the stability and effectiveness of the model is further enhanced by using convergence curves and comparison analysis.

While various optimization strategies may affect the performance of base models under particular circumstances, the overall predictive power of the machine learning models suggests that they may be able to capture the dynamic link between VCSS and yoga involvement. Visually displayed, the performance of the models is assessed, and the ETCO model emerges as the superior performer when compared to other models under identical conditions for the VCSS.3 target. It achieves a training phase accuracy of 0.957. The second position is occupied by the ALL term, attaining values of 0.94 in accuracy, 0.939 in precision, 0.94 in recall, and 0.94 in F1 score. The test grade holds the third position.

Further investigation is advised to determine the long-term effects of yoga on VCSS through more extensive longitudinal studies; to improve external validity, a variety of participant groups should be investigated; comprehensive lifestyle assessments should be included; standardizing yoga protocols will ensure repeatability of results; and cooperation with medical professionals is encouraged for a comprehensive approach. As more research on the benefits of yoga for vein health is conducted, the body of information regarding non-traditional treatments for vein problems expands. This study sets the groundwork for further investigations. Using machine learning to predict yoga's impact on VCSS presents a viable path for preventative and customized healthcare approaches.

In conclusion, the utility of this prediction extends beyond the academic realm, having potential applications in the real-world context. It is believed that specialists and health departments can effectively implement the prevention and control of VCSS through yoga. This proactive approach can potentially mitigate the need for aggressive treatments in patients, thereby emphasizing the predictive model's practical implications and societal benefits.

Modified Artificial Bee Colony Algorithm for Load Balancing in Cloud Computing Environments

Qian LI*, Xue WANG

College of Electrical Information-School of Changchun, Guanghua University, Changchun 130000, China

Abstract—Task scheduling in cloud computing is a complex optimization problem influenced by the ever-changing user requirements and the different architectures of cloud systems. Efficiently distributing workloads across Virtual Machines (VMs) is critical to mitigate the negative consequences of inadequate and excessive workloads, such as higher power consumption and possible machine malfunctions. This paper presents a novel method for dynamic load balancing using a Modified Artificial Bee Colony (MABC) algorithm. The ABC algorithm has exceptional competence in solving complex nonlinear optimization problems based on bee colonies' foraging behavior. Nevertheless, the traditional version of the ABC algorithm cannot effectively use resources, resulting in a rapid decline in population diversity and an ineffective spread of knowledge about the best solution between generations. To address these limitations, this study integrates a genetic model into the algorithm, enhancing population diversity through crossover and mutation operators. The developed algorithm is compared with the prevailing algorithms to confirm its effectiveness. The results of the proposed MABC algorithm for the load balancing method are compared with the current ones, and it is observed that this algorithm is more beneficial in terms of cost and energy as well as resource utilization.

Keywords—Resource utilization; cloud computing; task scheduling; Artificial Bee Colony; genetic algorithm

I. INTRODUCTION

Cloud computing is a recently emerged computing paradigm that provides a wide variety of services using the resources of hardware and software systems available in the data centers through the Internet [1]. These services are pay-as-you-go, meaning users can acquire computing resources, storage, applications, and services on demand. Opting for cloud services presents many benefits to the users, including scalability, global accessibility, reliability, flexibility, and reduced costs for businesses. It permits organizations to quickly extend and reduce their IT infrastructure; thus, resources can be delivered and regained at a minimum cost [2].

A. Context

Cloud computing services are offered in three primary ways: Infrastructure as a Service (IaaS), Platform as a Service (PaaS), and Software as a Service (SaaS), with four deployment strategies: private, public, community, and hybrid [3]. SaaS enables consumers to effortlessly utilize cloud providers' programs without the requirement to acquire, install, and manage the software on their servers. This solution eliminates the need to manage the cloud infrastructure and platform used by the software [4]. PaaS allows consumers to utilize computational assets and applications via the Internet without requiring them to handle the underlying infrastructure

personally [5]. Instances of this platform category encompass GoGrid, Aptana, EMC Atmos, and Amazon Elastic Cloud. These platforms enable customers to acquire the necessary technologies without incurring real hardware and software costs. IaaS provides many capabilities, offerings, and assets for developing an on-demand virtual computing framework [6]. Such suppliers include Google Base, IBM, Savvis, Rackspace, and Amazon Web Services.

Third-party vendors offer public cloud services over the Internet. The term "public cloud" does not imply that a user's data is accessible or useable by the general public. Public cloud services often provide consumers with an access control method [7]. Private clouds are defined as data and process management for a company and are protected from external network bandwidth constraints, security concerns, or legislative provisions in cloud-based data sharing. Private cloud services improve security and operational resilience by limiting user access and networks while having unmodified infrastructure control for providers and users [8].

In the community cloud, various organizations share and manage cloud computing infrastructure for a special interest group, specific security needs, or a similar mission [9]. From a security perspective, this type of cloud is better than a public cloud, as it allows the community to maintain its security environment and apply additional requirements. This allows each member to share resources and store them and use applications without sharing the same physical environment. A hybrid cloud is a cloud service model that includes two or more public, private, and community clouds connected to one another by standard or private technology. This method gives cloud users more power over their data and application use while remaining independent entities [10].

B. Problem Statement

The cost savings associated with cloud services are attracting small and medium-sized businesses. Cloud service suppliers provide services to clients on a rental basis. Providing cloud services to users is extremely complex, as users can access virtual cloud resources easily. Computing resources are made available to customers via Virtual Machines (VMs) running on physical machines in the cloud. Virtual machines resemble physical computers in terms of capability [11]. As a guest program, a VM mimics the functionality of a physical machine. Optimizing server usage is achieved by dynamically allocating resources based on application requirements [12]. This approach operates dynamically to distribute non-preemptive workloads evenly. Load balancing is a challenging optimization issue in cloud computing that falls under Non-Polynomial-Hard (NP-

Hard) problems [13]. Therefore, researchers have devoted more attention to load balancing, which is found to improve system performance.

Load balancing facilitates the equitable distribution of workloads across available resources. The objective is to ensure uninterrupted operation in the event of a service component failure by managing the allocation and maintenance of application instances and optimizing resource usage [14]. Furthermore, load balancing aims to minimize task reaction time and enhance resource allocation, enhancing system performance while reducing expenses [15]. Moreover, load balancing aims to enhance the scalability and adaptability of applications that may expand in magnitude in the future. It also prioritizes tasks that demand immediate execution above other tasks [16]. To improve data center efficiency and reduce system reaction time, it is imperative to distribute the workloads evenly among physical hosts in the cloud environment, thereby enhancing throughput. Given several physical hosts in a data center, it is crucial to implement load balancing by migrating VMs across these hosts [17]. This is essential for ensuring the delivery of resilient and high-performing services. It is important to prioritize fault tolerance to provide dependable services for load balancing during the migration of VMs.

C. Motivation

Traditionally, load balancing has been accomplished through static and dynamic load balancing strategies [18]. The present status of the system has no effect on static load balancing strategies. Prior knowledge of the system is necessary. During the compilation phase, static load balancing techniques allocate tasks to processors before the commencement of program execution. The scheduling approach relies on preexisting knowledge about node characteristics and capabilities, including execution time, CPU resources, memory, and storage capacity, which are assumed to be known throughout the compilation process. These algorithms are suitable for stable situations with little load fluctuations but cannot adjust to load changes while in operation. In contrast, dynamic approaches consider the system's status and present situation, enabling them to handle varying load circumstances effectively. These solutions employ dynamic procedures to manage users' requests efficiently. While dynamic approaches provide superior performance than static approaches, formulating an algorithm for a dynamic cloud environment poses significant challenges [19].

The cloud platform efficiently manages task scheduling and allocates substantial virtual resources, no matter the duration needed [20]. Therefore, the cloud platform's effectiveness depends entirely on the selected technique for scheduling task resources. Furthermore, it is vital to have a streamlined and productive approach to assigning cloud resources to fulfill users' incoming tasks. Also, the user's tasks must be promptly, efficiently, and dependably processed [21]. Efficient load balancing and minimal resource usage are essential for executing user operations in the cloud computing environment. Nevertheless, the complex structure of the cloud environment and the stringent demands for managing the task scheduling process provide significant challenges in developing and carrying out optimization models [22].

Furthermore, the cloud task scheduling process is highly uncertain because of multiple factors triggering the unpredictable cloud environment, including network connectivity [23], resource usage [24], peak network demands [25], and web service performance inherent to service models of the cloud [26]. Artificial intelligence and machine learning techniques offer intelligent and adaptive solutions by analyzing patterns and predicting future demands, leading to proactive load management [27, 28]. Inspired by natural processes, meta-heuristic algorithms excel at solving complex, nonlinear optimization problems by offering robust and scalable solutions [29]. Their ability to explore and exploit the search space effectively helps achieve balanced load distribution across virtual machines. Integrating these technologies enhances the performance and resilience of cloud systems, enabling them to meet dynamic user demands while minimizing operational costs and resource waste [30].

D. Contribution

This study presents a new method for scheduling tasks in cloud computing using the Artificial Bee Colony (ABC) algorithm. The traditional ABC algorithm is well-suited for exploration but tends to ignore exploitation due to its intrinsic operating strategy. In the conventional ABC algorithm, the solutions produced in each generation are acquired by random search, resulting in the algorithm's inherent vulnerability to exploitation. Furthermore, the method fails to properly exploit the rich information in the best solution during execution. Moreover, the utilization of random neighborhood search results in a fast decline in population variety, rendering the algorithm susceptible to early convergence and trapped in local optimization. To solve these drawbacks, the ABC algorithm is enhanced by implementing two modifications.

The neighborhood search operator incorporates the location information of the global optimal solution to assist the bee colony in finding food. This approach effectively utilizes the information from the previous generation's optimal solution and improves the accuracy of the algorithm's exploitability search. Furthermore, to solve the issue of insufficient population variety, the algorithm integrates a genetic model that enhances population diversity by employing crossover and mutation operators. These two enhancements successfully reconcile the conflict between the ABC algorithm's research and application, strengthening the method's optimization accuracy and speed. The efficacy of the enhanced ABC method is validated by a set of commonly employed numerical functions. In summary, the study made the following contributions:

- Enhanced ABC algorithm for task scheduling: A novel approach is introduced for task scheduling in cloud computing, leveraging the ABC algorithm. Two crucial adjustments are suggested to overcome the shortcomings of the classic ABC algorithm in terms of exploitation.
- Improved exploitation through global neighborhood search: The study integrates a global neighborhood search operator to improve exploitation. By using the location information of the global optimal solution, this modification helps the bee colony to find food efficiently. This ensures better utilization of the

information from the previous generation's optimal solution and improves exploitability search accuracy.

- A genetic model for population diversity: To tackle the issue of insufficient population variety and potential premature convergence, a genetic model is integrated into the algorithm. This model introduces crossover and mutation operators, enhancing population diversity. These additions successfully balance the conflict between the algorithm's research and practical application, leading to improved optimization accuracy and speed.

The rest of the paper is organized as follows. Section II provides a comprehensive review of the existing literature and identifies gaps and limitations of current approaches. Section III precisely formulates the task scheduling problem. The proposed task scheduling technique is discussed in Section IV. Section V examines the theoretical underpinnings and practical implications of the proposed algorithm for load balancing. Section VI presents the empirical evaluation of the proposed method and compares its performance with existing methods. Section VII concludes the study by summarizing the main contributions, highlighting results, and suggesting possible avenues for future research in Section VIII.

II. RELATED WORK

This section offers an overview of the current body of literature about task scheduling in cloud computing. Our objective is to uncover fundamental insights, techniques, and advancements by analyzing various algorithms developed to tackle particular challenges in cloud settings.

Wei [31] suggested an approach for optimizing task scheduling in cloud infrastructure using a modified version of the Ant Colony Optimization (ACO) algorithm. The scheduling model utilizes an improved ACO algorithm to prevent the optimization strategy from being stuck in local optimization under cloud computing task scheduling principles. The task scheduling satisfaction function is created by integrating the three objectives of minimizing waiting time, optimizing resource load distribution, and lowering task completion cost to identify the most efficient task scheduling solution. Ultimately, introducing the reward and punishment coefficient enhances the optimization of the pheromone update rules in the ACO algorithm, resulting in an accelerated solution speed. Furthermore, the volatility coefficient is dynamically updated to improve the overall performance of this method. According to the test findings, the suggested algorithm outperforms previous approaches regarding convergence speed, completion time, load balancing, and consumption of virtual machine resources.

Abualigah and Diabat [32] presented a novel hybrid Antlion optimization algorithm that combines elite-based differential evolution to address multi-objective task scheduling challenges in cloud computing environments. The challenge is multi-objective since it requires minimizing the makespan and maximizing resource consumption simultaneously. The Antlion optimization algorithm is enhanced by including elite-based differential expansion as a local search approach to increase its capacity to explore the search space and prevent being stuck in suboptimal solutions. Two tests were conducted using the

CloudSim toolbox, one on synthetic datasets and the other on actual trace datasets. The findings indicated that the suggested algorithm exhibited a more rapid convergence rate than alternative methods, rendering it well-suited for extensive planning scenarios.

Ben Alla, et al. [33] proposed a novel approach to prioritizing customer demands and supplier resources. They introduced a highly effective method for scheduling tasks called MCPTS, which involves adjusting the priority depending on four task factors: duration, delay, deadline, and burst time. The MCPTS structure has three components: task priority, task queue priority, and resource priority. A new strategy is suggested to assess and establish task priorities, utilizing an integrated Multi-criteria Decision-Making (MCDM) technique known as ELECTRE III and a metaheuristic algorithm named Differential Evolution. Furthermore, a unique dynamic priority queuing algorithm derived from the queuing model is presented. Moreover, the allocation of resources is dynamically modified according to the task priority model to establish an effective and adaptable connection between resource and task categories. The experimental findings demonstrate the superiority of the MCPTS algorithm in comparison to other current algorithms. Furthermore, it shows the efficacy of the suggested approach in delivering commendable system performance, fulfilling user demands and QoS prerequisites, enhancing load distribution, and optimizing resource usage.

Malti, et al. [34] offer a highly effective task scheduling method that leverages flower pollination behavior. This algorithm incorporates the Pareto optimality principle and the TOPSIS approach to enhance the quality of the solutions achieved. Both single and multi-objective optimization variations are analyzed. In the second scenario, three optimization criteria are considered: decreasing the duration or schedule length, reducing the execution cost, and optimizing the overall dependability of task distribution. The study examined several test bench situations and Quality of Service (QoS) measures. The acquired findings validate the advantages of the suggested method.

Mangalampalli, et al. [35] proposed a Multi-Objective Task Scheduling Gray Wolf Optimization (MOTSGWO). This algorithm is capable of making scheduling decisions in real-time by considering the current state of cloud resources and future workload demands. Moreover, the suggested method distributes resources according to the end users' financial constraints and the tasks' importance. The MOTSGWO technique is applied using the Cloudsim toolbox, and the workload is created by building datasets with various task densities and workload patterns. The comprehensive studies demonstrate that the suggested MOTSGWO strategy surpasses previous baseline strategies and enhances the crucial metrics.

Saravanan, et al. [36] proposed the enhanced Wild Horse Optimization (IWHO) algorithm to tackle the issues of lengthy scheduling time, excessive cost consumption, and high use of virtual machines. Initially, a model for scheduling and distributing cloud computing tasks is constructed, considering the primary aspects of time, cost, and virtual machines. To enhance the local search capability and minimize premature convergence, the IWHO algorithm employs the inertia weight

technique to effectively identify the ideal individual. The IWHO method is augmented with the Levy-Flight algorithm to optimize task scheduling in cloud computing. The effectiveness of the proposed hybrid algorithm is verified, and the outcomes are assessed utilizing several methodologies. The simulation results demonstrated that the suggested approach surpassed others in various scenarios.

Behera and Sobhanayak [37] suggested a hybrid approach that integrates the GWO algorithm with the Genetic Algorithm (GA). GWO-GA optimizes multi-objective task scheduling in cloud computing by minimizing processing time, energy usage, and cost. The enhancements to GWO-GA involve incorporating the crossover and mutation operator from the genetic algorithm. Moreover, the accelerated convergence of the GA-based GWO method is a benefit when dealing with extensive planning problems. The suggested algorithm performs better than existing GWO, GA, and PSO algorithms in terms of makespan, cost, and energy usage. It achieves reductions of 19%, 21%, and 15% correspondingly, compared to each of these approaches. In addition, it leads to energy conservation rates of 17%, 19%, and 23% when compared to GWO, GA, and PSO, respectively. Simultaneously, it reduces the total design expenditure by 13%, 17%, and 22%, respectively. The findings illustrate the efficacy of the suggested approach in addressing the task scheduling issue in cloud computing settings.

Pabitha, et al. [38] proposed the Chameleon and Remora Search Optimization (CRSO) algorithm to enhance the scheduling procedure by investigating the influence of MIPS and network bandwidth on virtual machine performance. Furthermore, the study considers the uncertainty aspects of task

completion rates, distribution of loads, cost, and makespan concurrently during the scheduling process. The formulation of an optimization model with multiple objectives for cloud task scheduling involves the integration of the advantages of Chameleon Search Algorithm (CSA) and Remora Search Optimization Algorithm (RSOA) utilizing a greedy technique to mimic the actual process of cloud computing task scheduling. Simulation findings confirm that the proposed CRSOA technique substantially decreases the time required for task completion and efficiently manages the workload distribution across the available virtual machines, surpassing other competing algorithms.

III. PROBLEM DEFINITION

The assignment of incoming jobs to free VMs located in cloud data centers is a major problem. This scenario involves a collection of uniform and diverse tools where individual servers run many virtual machines. Virtualization enables users to utilize virtual environments' flexible computing resources. The data center broker controls the scheduling system, supervising the allocation and monitoring of user tasks. Fig. 1 depicts the schematic layout of the scheduling procedure. Initially, cloud users enter tasks kept in the Task Manager module. This module monitors the arrival of tasks and provides relevant information to the corresponding individuals. These task submissions are transmitted to the cloud scheduling system by the task manager. A number of jobs are allocated to VMs according to the MABC algorithm. The cloud information repository is used to gather details about VMs and tasks.

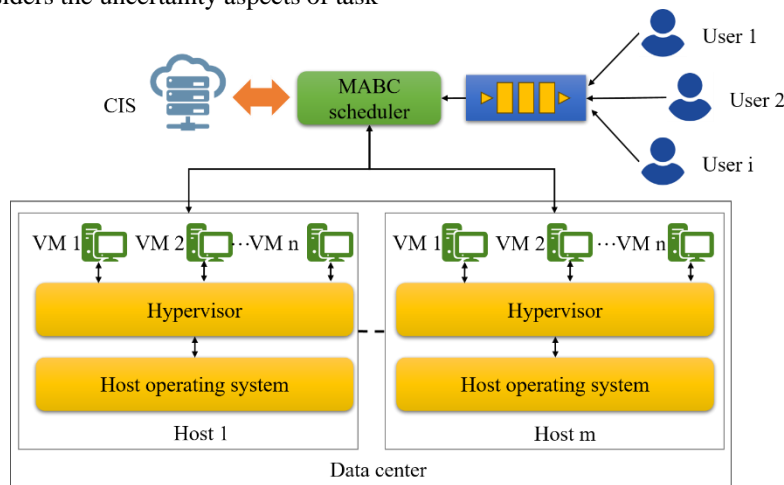

Fig. 1. Scheduling process.

Several data centers are involved in the public cloud system paradigm in order to meet resource demands. Consider a collection of data centers $(dc_1, dc_2, \dots, dc_p)$. A data center comprises several Physical Hosts (PHs). For instance, the data center dc_r includes k PHs labeled $(PH_{r1}, PH_{r2}, \dots, PH_{rk})$. Each PH possesses distinct characteristics, including the computational capability of a processor determined by the number of cores measured in Millions of Instructions Per Second (MIPS). Each PH is equipped with bandwidth, memory, storage capacity, and a VM Manager (VMM). The VMM

installed on PHs has a vital function in keeping track of all VMs located on that specific physical host. It guarantees the effective distribution and usage of resources for the virtual machines operating on the host. Each PH inside a data center can handle a specific number of VMs, represented as $(VM_1, VM_2, \dots, VM_m)$. Each VM possesses its own distinct settings, outlined as follows:

- Number of cores: This parameter defines the VM's capacity for handling several tasks simultaneously while simultaneously processing.

- Processing power: This is expressed in MIPS, which denotes the computational capacity for processing commands and performing tasks.
- Storage: The allocated capability for storing data and files particular to virtual machines.
- Main memory: Designated for the storage of data and the execution of applications within the virtual machine.

Furthermore, each VM is associated with an hourly rate representing the expense incurred for utilizing that specific VM for every utilization. Virtual machine configurations and the time spent using them determine how much users are billed for resources. Within the realm of cloud computing, individuals or organizations utilizing cloud services may effortlessly forward their individual requests to the service supplier for processing with no extensive knowledge of its underpinnings. These assignments include distinct criteria regarding the duration of the job and the assets needed. Users enter a set of n jobs labeled (t_1, t_2, \dots, t_n) . Tasks are given a distinct duration (l_i) , quantified in Millions of Instructions (MI). The process starts with determining the duration of the i^{th} job on the j^{th} virtual machine, outlined in Eq. (1).

$$ET(l_i, vm_j) = \frac{l_i}{total_{MIPS}(vm_j)} \quad (1)$$

The scheduler evaluates the VM's energy usage during task execution and the cost of processing tasks within the VM. The primary goal is to lower the total costs associated with task completion by finding the VM with the most favorable costs that meets the individual criteria for the task. Due to the varying processing capabilities of multiple VMs, the execution time and cost of performing a specific function on distinct VMs are inconsistent. As a result, a problem with multiple objectives develops, which seeks to reduce the time it takes to complete a task, the amount of energy used, and the cost incurred while maximizing resource efficiency. Thus, this study aims to tackle the complex challenge of solving the multi-objective scheduling issue using the suggested MABC algorithm.

Cloud computing services are delivered on a two-actor model, encompassing cloud service suppliers and consumers. Service suppliers provide clients with resources to accomplish jobs. Cloud users place a high premium on application efficiency, preferring rapid and efficient computation capabilities. In contrast, cloud service suppliers focus on optimizing resource utilization to achieve optimal financial returns. The purposes may be categorized into client demands, which include the cost of execution and the duration of the schedule, and supplier demands, which encompass energy consumption and resource utilization. Within the cloud computing domain, execution cost signifies the total expenditure accrued during the operation of a given application. It serves as a quantifiable indicator to evaluate financial outlays. However, it is important to specify the costs associated with the assets used. Clients seek to decrease both expenses and schedule duration. The computation of expenses associated with the execution can be summarized as follows:

$$EC = \sum_{j=1}^m ET_j \times price_j \quad (2)$$

ET_j denotes the length of time that the j^{th} VM is allocated for executing a task, following the completion of the final task. The schedule length is crucial for assessing the quality of scheduling and is determined by the longest time it takes for any task to be completed, either among all submitted tasks or by the time the final processing virtual machine is complete. The scheduler's efficiency can be accurately assessed using this essential measure. A shorter schedule length indicates an improved scheduling procedure in which tasks are distributed optimally to appropriate resources. In contrast, a longer schedule length signifies a less efficient scheduling method. Eq. (3) can determine the value of the schedule length.

$$SL = \max(\sum_{i=1}^n ET(l_i, vm_j)x_{ij}) \forall vm_j \quad (3)$$

Eq. (3) represents the allocation decision variable, x_{ij} , which indicates whether task i is assigned to the j^{th} VM. The variable is binary, with a value of 1 indicating that task i is assigned to VM j , and 0 stating otherwise. Maximizing resource efficiency is crucial for cloud service providers. Their main goal is to maximize the utilization of resources in order to enhance profitability. Providers attempt to optimize their usage given the constraints of limited resources. Eq. (4) clearly describes how to calculate the average resource utilization.

$$average\ RU = \frac{\sum_{i=1}^m ET_i}{O_1} \quad (4)$$

The variable O_1 in Eq. (4) denotes the minimum schedule length, which serves as a measure of the desired service quality. In this situation, efficient use of resources implies the optimal exploitation of available VMs to handle tasks. Data center energy usage involves several components, including CPU, network interfaces, and storage devices. Out of all these resources, the CPU is generally the most power-intensive. When evaluating the energy usage of a VM, it is divided into two categories: energy consumption during times of idle and energy consumption during active phases. The overall energy usage takes into account both the idle and active modes of the VM. The energy spent during periods of idle is approximately 60% of the energy consumed by a fully functional VM. The remaining 40% represents the energy consumed by the VM during active calculations. This energy expenditure is dependent on the processing speed of the VM, calculated by Eq. (5).

$$EC = 10^{-8} \times (vm_{mips})^2 \frac{J}{MI} \text{ and } IE_i = 0.6 \times EC_i \quad (5)$$

EC_i denotes the energy consumed when the VM is in an active state IE_i represents the energy consumed when the VM is idle. The model's energy usage can be defined according to Eq. (6).

$$TE_i = IE_i + EC_i \quad (6)$$

IV. MODIFIED ABC ALGORITHM FOR TASK SCHEDULING

The ABC algorithm applies a kind of bionic intelligence inspired by honey bee foraging behavior. In this algorithm, food source position indicates a potential optimization solution, while nectar quality indicates the quantity of nectar [39]. An optimization problem is addressed by three types of bees: worker, onlooker, and scout. Employed bees are equal to food sources. So, each worker bee has access to a food source around the hive. An onlooker bee continuously watches

and selects food resources under the activities of employed bees. A scout bee uncovers new sources of food not found by employed bees by searching randomly. Fig. 2 illustrates how the ABC algorithm finds an optimal solution for the optimization problem. Initially, nectar sources are produced in a random manner using Eq. (7).

$$x_{i,j} = x_j^{min} + rand(0,1) \cdot (x_j^{max} - x_j^{min}) \quad (7)$$

Fig. 2. Workflow of ABC algorithm.

where, $x_{i,j} \in [x_j^{max}, x_j^{min}]$ denotes the j^{th} dimension boundary of the optimization problem, and $rand(0, 1)$ is a random number ranging from 0 to 1. The ABC optimization process consists of three separate stages: the employed bee stage, the onlooker bee stage, and the scout bee stage.

The employed bees have the ability to scan the whole optimization problem space for new sources of nectar. Eq. (8) updates the position of the nectar source simultaneously.

$$v_{i,j} = x_{i,j} + \phi_{i,j} \cdot (x_{i,j} - x_{k,j}) \quad (8)$$

where, x_i represents the initial nectar source, v_i reflects a recently discovered nectar source, $\phi_{i,j} \in [-1, 1]$ is a random number chosen uniformly, x_k is a nectar source taken randomly from the population, and x_k is not equal to x_i . It should be noted that j is a dimension that is chosen without any specific criteria, and x_i and v_i vary simply in this particular dimension. If the amount of nectar in v_i is more than that in x_i , then v_i will replace x_i in the subsequent round. Alternatively, x_i stays unaltered.

Onlooker bees will select optimal nectar sources for exploitation depending on the quantity of nectar available, using information provided by employed bees. Additionally, it explores new nectar sources by employing the solution search equation given in Eq. (8). The fitness value of an individual is determined by the quantity of nectar from the nectar supply. This is estimated using the Eq. (9).

$$fitness_i \begin{cases} \frac{1}{1+f(X_i)} & f(X_i) \geq 0 \\ 1 + |f(X_i)| & f(X_i) < 0 \end{cases} \quad (9)$$

Where $fitness_i$ refers to the fitness value of the nectar source, and (\cdot) indicates the objective function value. A higher quantity of nectar in a nectar source increases the likelihood of

onlooker bees choosing that source. The probability of selection is computed using the Eq. (10).

$$p_i = \frac{f(X_i)}{\sum_{j=1}^{SN} f(X_j)} \quad (10)$$

After determining the probability of selecting each nectar source, the onlooker bees will employ the roulette method. If the nectar supply linked to the employed bees is not refreshed over a specified threshold *limit*, we assume that the nectar source has been exhausted. In this scenario, a novel nectar source is introduced at random using Eq. (7) to substitute X_i .

The conventional ABC algorithm fails to fully exploit the location details of the optimal solution in each iteration, a valuable piece of information. This study introduces a global neighborhood search operator (as given in Eq. (11)). With this operator, the bee colony locates food sources using the positional data from the global optimal solution, X_{Gbest} . By using this approach, the honey source $X_{Gbest,j}$ can be fully exploited and utilized. Furthermore, exploring the vicinity of the optimal solution accelerates the convergence of the algorithm. The variable β is given a random number from 0 to 1.

$$New_{x_{i,j}} = X_{i,j} + \phi_{i,j}(X_{Gbest,j} - X_{k,j}) + \beta(X_{Gbest,j} - X_{i,j}) \quad (11)$$

While the current generation's optimal solution information is incorporated into the neighborhood search operator, the random neighborhood search approach remains unchanged. Eq. (11) facilitates algorithm convergence and enhances exploitation capabilities. Nevertheless, it may lead to local optimization by steering the colony towards local extremes. In order to address this constraint and enhance the algorithm's ability to consistently generate new viable solutions, a genetic model is utilized. Each iteration retains half of the ideal solution. Afterward, the preserved solutions undergo recombination according to Eq. (12). Ultimately, the new solution passes the mutation and crossover procedures, as shown in Fig. 3. By employing this evolutionary process, the search range expands, and the variety of viable solutions is enhanced to avoid local optimization.

$$X_{i,j} = X_{k1,j} + \gamma(X_{k2,j} - X_{k3,j}) \quad (12)$$

Fig. 3. An illustration of mutations and crossovers.

Three solutions, X_{k1} , X_{k2} , and X_{k3} , are chosen from the preserved feasible solutions through random probability selection. γ is a randomly generated number within the range [0, 1], and j denotes the position of an array element in the plane array.

V. DISCUSSION

This section examines the theoretical underpinnings and practical implications of the MABC algorithm for load balancing in cloud computing environments. The MABC algorithm enhances the ABC algorithm by solving its main limitations, specifically the lack of exploitation capability and rapid loss of population diversity. The traditional ABC algorithm is augmented by including a mechanism for retaining optimal solution information within the neighborhood search operator. By modifying the algorithm, best practices are preserved and utilized effectively in subsequent iterations. Furthermore, the incorporation of a genetic evolution mechanism fosters a balance between exploratory and exploitative behaviors within the scheduling process.

Among the primary advantages of the MABC algorithm is its ability to balance load across VMs in a cloud computing environment. MABC algorithm adapts to dynamic workloads and varying user demands by maintaining a diverse population and effectively utilizing optimal solution information. The result is more efficient resource utilization, reduced energy consumption, and a shorter time to complete tasks. The modifications to the ABC algorithm result in faster convergence rates, making the MABC algorithm well-suited to real-time load balancing applications. While the MABC algorithm demonstrates significant improvements over traditional methods, potential limitations must be acknowledged. The higher complexity due to the retention of optimal solutions and the genetic evolution mechanism may lead to additional computational overhead. This could impact the algorithm's performance under resource-constrained environments. Furthermore, the effectiveness of the MABC algorithm depends on the proper tuning of its parameters. Inappropriate parameter settings may produce suboptimal performance or excessive computational costs.

VI. SIMULATION RESULTS

In this section, the suggested algorithm is benchmarked against recent swarm-based algorithms (GA, Harris Hawks Optimizer (HHO), ACO, and traditional ABC). Simulations were conducted with the CloudSim 3.0.3 simulator on a Windows 10 laptop powered by 16 GB of RAM. Table I outlines the specifications of the virtual cloud computing environment. Table II provides a summary of the VM parameters involved in the experiment. The synthetic workload is created using an even distribution, guaranteeing an equal spread of tasks in different dimensions. The assessment examines the High-Performance Computing Centre (HPC2N) workload, which is commonly acknowledged as a benchmark for evaluating the performance of distributed systems.

Results of resource utilization for the different methods, including MABC, ABC, GA, HHO, and ACO, using the HPC2N real-world dataset are illustrated in Fig. 4 and 5. Fig. 4 compares different load balancing algorithms applied to 40 VMs. The MABC algorithm demonstrates superior resource utilization across all task quantities. This is because MABC considers resource usage when scheduling tasks, ensuring tasks are allocated to the most appropriate VMs. VMs are thus utilized more efficiently, resulting in enhanced overall performance and reduced idle times compared to ABC, GA, HHO, and ACO. Fig. 5 shows the resource utilization of different algorithms when 80 VMs are used. Similar to the results for 40 VMs, the MABC algorithm consistently outperforms the others. This performance is due to MABC's advanced scheduling mechanism, which dynamically adjusts to the available resources, thereby maximizing VM efficiency and minimizing resource wastage.

TABLE I. DATACENTER AND HOST CONFIGURATIONS

Cloud component	Feature	Value
Host	Storage	2 TB
	RAM	F GB
	Bandwidth	5 GB
Datacenter	User count	1
	Host count	2
	Datacenter count	1 2

TABLE II. VMs CONFIGURATIONS

Characteristic	Value
VM count	20-100
MIPS	500-1000
Bandwidth	0.5 Gb/S
VMM	Xen
Size	100 MB

Fig. 6 compares the energy consumption of various load balancing algorithms under HPC2N workloads with 40 VMs. The energy conservation performance of each algorithm is evaluated as task counts increase. Traditional algorithms such as ABC, ACO, GA, and HHO exhibit linear rises in energy consumption with increasing task counts, but the MABC algorithm shows a more gradual rise. Under varying workloads, MABC conserves energy efficiently, which makes it a suitable solution for energy-efficient cloud task scheduling. Fig. 7 compares the energy consumption of different load balancing algorithms when applied to 80 VMs. Similar to Fig. 6, the energy consumption patterns of various algorithms are analyzed under a variety of task counts. According to the results, MABC is more effective than traditional algorithms at conserving energy and optimizing resource allocation compared to traditional algorithms. Fig. 8 illustrates the energy consumption across different load balancing algorithms when applied to a synthetic workload with 120 VMs.

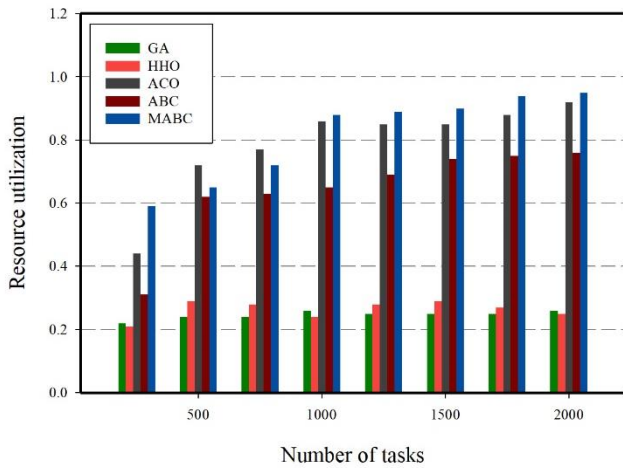

Fig. 4. Resource utilization for HPC2N tasks involving 40 virtual machines.

Fig. 5. Resource utilization for HPC2N task involving 80 virtual machines.

Fig. 6. Energy consumption for HPC2N tasks involving 40 virtual machines.

Fig. 9 to 11 offer a comparative evaluation of various algorithms concerning execution costs. This analysis encompasses both synthetic and HPC2N workloads, highlighting the potential impact of task duration and VM selection on execution costs. The results indicate that MABC

outperforms the traditional ABC algorithm across varying task numbers for synthetic and HPC2N workloads. As shown in Fig. 9 to Fig. 11, MABC demonstrates its cost-effectiveness by consistently reducing execution costs across a variety of scenarios. When applied to real-world tasks ranging from 250 to 2000 units, MABC exhibits an average cost reduction of 11% to 43% compared to the ABC algorithm. This advantage extends to synthetic workloads as well, with MABC achieving average cost reductions of 9% to 60% for tasks between 500 and 2000 units. These findings highlight MABC's ability to optimize resource utilization and minimize execution costs across diverse task types and workloads.

Fig. 7. Energy consumption for HPC2N tasks involving 80 virtual machines.

Fig. 8. Energy consumption for synthetic tasks involving 120 virtual machines.

Table III shows numerical functions used to prove the efficiency of the MABC algorithm. An array of benchmark functions is provided, with tests f1-f4 covering unimodal and tests f5-f7 covering multimodal continuous functions. The range of values for the parameters and the lowest possible numerical function value are listed in Table IV. The genetic, GABC, ABC, and MABC algorithms are employed for optimizing seven numerical functions. The algorithm was executed autonomously 20 times. The algorithm's benefits and drawbacks were assessed by utilizing statistical measures such

as the average and standard deviation. A performance analysis of algorithms with 30 dimensions and 3000 iterations is presented in Table IV. This table reveals that the MABC algorithm outperforms other algorithms in terms of both the average and standard deviation of its results.

VII. CONCLUSION

The process of task scheduling within cloud computing paradigms presents a multi-objective optimization challenge. The dynamic context and varying tasks also pose a challenge to finding an equilibrium between QoS requirements, energy consumption, and resource utilization. This paper proposed MABC algorithm for task scheduling. The proposed modification to the ABC algorithm leverages the intelligent foraging behavior of bee colonies to enhance its competence in solving complex nonlinear optimization problems. The traditional ABC algorithm, while effective, faces limitations in resource utilization, leading to a rapid decline in population diversity and inadequate dissemination of optimal solution

knowledge across generations. The introduced modifications to the ABC algorithm effectively addressed these limitations. By retaining optimal solution information within the neighborhood search function and incorporating a genetic evolution process, the MABC algorithm achieved a more balanced exploration-exploitation trade-off, enriching population diversity. Comparative analysis of the MABC algorithm versus established scheduling techniques demonstrated its efficacy in producing a trifecta of desirable outcomes: lower execution costs, diminished energy consumption, and improved resource utilization.

VIII. FUTURE WORK

Future research will prioritize task scheduling difficulties that closely resemble real-world cloud computing settings. This also involves taking into account the priority constraint connections among tasks. Moreover, when considering the situation objectively, cost emerges as a significant determinant impacting work scheduling in real-life situations. Users seeking to optimize task completion time must allocate more money toward getting cloud computing services. Hence, we aim to devise a task scheduling algorithm that achieves a harmonious equilibrium among three pivotal factors: job completion time, cost, and load distribution. By developing innovative approaches that prioritize both efficiency and cost-effectiveness, we aim to improve cloud computing systems' efficiency and flexibility in real-world applications. Additionally, we envisage investigating the integration of emerging technologies, such as machine learning and edge computing, to further optimize task scheduling processes and adapt to evolving user demands and system dynamics. Through these future research endeavors, we aim to make a substantial contribution to the ongoing evolution of cloud computing technologies. This pursuit seeks to address the dynamic challenges confronting both cloud service providers and their consumers.

Cloud Workload Prediction Based on Bayesian-Optimized Autoformer

Biying Zhang, Yuling Huang, Zuoqiang Du*, Zhimin Qiu

School of Computer and Information Engineering, Harbin University of Commerce, Harbin 150028, China

Abstract—Accurate workload forecasting plays a pivotal role in the management of cloud computing resources, enabling significant enhancement in the performance of the cloud platform and effective prevention of resource wastage. However, the complexity, variability, and strong time dependencies of cloud workloads make prediction difficult. To address the challenge of enhancing accuracy in contemporary cloud workload prediction, this paper employs empirical and quantitative research methods, introducing a cloud workload prediction method based on Bayesian-optimized Autoformer, termed BO-Autoformer. Initially, the cloud workload data were divided according to the time-sliding window to construct a continuous feature sequence, which was used as the input of the model to construct the Autoformer prediction model. Subsequently, to further enhance the model's performance, the Bayesian optimization method was employed to identify the optimal combination of hyperparameters, resulting in the development of the Bayesian optimization-based Autoformer cloud workload prediction model. Finally, experiments were conducted on a real Google dataset to evaluate the model's effectiveness. The findings reveal that, compared to alternative models, the proposed prediction model demonstrates superior performance on the cloud workload dataset, and can effectively improve the prediction accuracy of the cloud workload.

Keywords—Cloud computing; deep learning; workload prediction; Autoformer; Bayesian optimization

I. INTRODUCTION

Cloud computing plays a crucial role in promoting public availability and openness of computing resources [1], yet the low utilization of these resources remains a persistent challenge in cloud computing resource management. With the continuous expansion of cloud computing infrastructure and the rapid increase in the number of users, energy consumption in cloud data centers has emerged as a significant issue [2]. The utilization of physical hosts is a key factor that substantially influences the energy consumption of the entire cloud computing system. Resource over-allocation or under-utilization markedly escalates energy costs within cloud data centers. Studies indicate that the current utilization rate of various cloud computing resources generally falls below 50%, leading to a substantial portion of these resources remaining idle [3]. This inefficiency in resource usage not only results in considerable wastage of societal resources but also underscores the urgent need for implementing effective strategies to enhance the efficiency of cloud computing resource utilization. Therefore, effective measures must be taken to lower energy

consumption costs, minimize resource waste, and foster the sustainable development of cloud computing.

An effective approach to enhance the utilization of cloud computing resources involves accurate prediction of the resource workload. Through an analysis of historical data pertaining to the usage of cloud computing resources, it is possible to uncover the underlying patterns of load fluctuations, thereby forecasting the workload of cloud computing resources in the upcoming period [4]. By leveraging these predictive insights, cloud service providers can proactively adjust resource allocation to meet the diverse needs of users while optimizing resource utilization efficiency. However, the pursuit of predictive accuracy faces a series of challenges. First, workload fluctuations are influenced by numerous factors, such as the unpredictability of user behavior, sudden business demands, and the dynamic allocation of system resources. These factors result in workload patterns that are difficult to accurately capture with simple models. Second, Cloud workload prediction relies on extensive historical data to train predictive models, yet ensuring the integrity, accuracy, and consistency of this data is often challenging. Issues such as missing values, outliers, and noise are prevalent, which can interfere with the model training process and lead to biased prediction results. Consequently, traditional prediction models often struggle to achieve the desired accuracy when addressing the complexity and dynamics of cloud workloads and the instability of data quality. To solve this problem, it is imperative to explore new predictive technologies and methods to enhance the accuracy and reliability of prediction models.

The Autoformer, a Transformer-based method for time series prediction, was introduced by Wu Haixu and colleagues from Tsinghua University [5]. It incorporates an autocorrelation mechanism to capture temporal dependencies, thereby enhancing its predictive accuracy and efficiency. Among existing time series forecasting methods, Autoformer has garnered widespread attention due to its outstanding performance. However, its application in cloud computing workload prediction is hindered by challenges in hyperparameter tuning and performance fluctuations:

- **Hyperparameter Adjustment Difficulties:** The performance of the Autoformer depends significantly on the appropriate selection and tuning of hyperparameters. However, manual adjustment of hyperparameters becomes exceedingly challenging and time-consuming, particularly in scenarios involving voluminous data and multifaceted tasks.

*Corresponding Author
Fund Project: Science and Research Project of Harbin University of Commerce [grant no. 2019DS032]

- **Performance Fluctuation:** The performance of the Autoformer can fluctuate considerably across different tasks and datasets due to the complexity of its structure and the diversity of input datasets, thereby constraining its broad applicability in cloud computing workload prediction.

This paper proposes a cloud workload prediction method that optimizes Autoformer through Bayesian optimization technology, which aims to solve the above problems. The main contribution of this work can be summarized as follows:

- The Autoformer model is first applied to the field of cloud computing workload prediction, which significantly improves the accuracy and efficiency of prediction by exploiting its unique self-attention mechanism and long sequence processing ability.
- Bayesian optimization technique is used to optimize the combination of hyperparameters of Autoformer. Compared with traditional grid search or random search methods, Bayesian optimization techniques can more effectively explore the hyperparameter space and find the combination of hyperparameters that optimizes the model performance.

The application of the Bayesian optimization technique enables the Autoformer model to automatically tune hyperparameters in the workload prediction task of cloud computing. Through automatic tuning, not only the tedious and time-consuming manual parameter adjustment is eliminated, but also the computational cost in the tuning process is greatly reduced. With the help of Bayesian optimization, Autoformer can quickly find the best combination of hyperparameters for a specific task, thereby improving the accuracy of prediction. Furthermore, Bayesian optimization enhances the stability of the Autoformer model across various datasets and tasks, thereby mitigating performance fluctuations and bolstering the reliability of cloud computing systems. Consequently, the optimized Autoformer model can deliver more precise and dependable prediction outcomes across diverse workload scenarios. For cloud computing service providers, this technological improvement means that they can allocate resources more efficiently, and avoid resource waste or over-provisioning, thereby reducing costs and improving service quality. At the same time, the system operation and maintenance personnel can also understand the load of the system in advance with the help of the BO-Autoformer model, so that they can make timely responses and adjustments, reducing the risk of system downtime or performance degradation. In addition, the combination of Bayesian optimization and the Autoformer model also provides new ideas and methods for research in the field of cloud computing and machine learning and encourages scholars and engineers in related fields to conduct more in-depth research and exploration.

The structure of this paper is as follows: Section II provides a review of relevant literature. Section III elucidates the foundational principles of the Autoformer model. Section IV examines the application of the Autoformer model to workload predictions, with an emphasis on Bayesian optimization. Section V discusses the results derived from experimental

evaluations. Section VI concludes the paper with a summary of the findings and contributions.

II. RELATED WORKS

In recent years, native and overseas scholars have dedicated efforts to enhancing the accuracy and reliability of workload forecasting for cloud computing resources. The methodologies employed in these studies can be broadly categorized into three primary groups: traditional regression techniques, machine learning approaches, and deep learning strategies. These methodologies represent the evolving landscape of research in the realm of cloud computing resource load prediction, reflecting a progression from conventional statistical methods to more sophisticated artificial intelligence models.

A. Traditional Regression Techniques

Traditional regression techniques encompass a diverse array of methodologies, including Autoregressive[6](AR), Moving average[7](MA), Autoregressive moving average[8](ARMA), Differential autoregressive moving average method[9](ARIMA), Linear regression[10](LR) and Exponential smoothing[11](ES), etc. Predominantly grounded in the presumption of linear interrelations, these methods frequently fall short of capturing the non-linear dynamics of workload variations. A significant reliance on the principle of stationarity renders them less effective in managing the non-stationary nature of cloud resource loads. Challenges such as the complexity of parameter selection, susceptibility to outliers, and the difficulty in addressing seasonality and trends further underscore the limitations of traditional regression techniques in the context of cloud computing resource load forecasting.

B. Machine Learning Approaches

Machine learning approaches primarily comprise Markov models [12], Bayesian models [13, 14], Support vector regression (SVR) models[15], and traditional Artificial neural networks [16](ANN). In comparison to deep learning techniques, machine learning methods are somewhat constrained in their capacity to navigate complex non-linear relationships, exhibit limitations in effective feature extraction, and demonstrate inferior generalization performance in predictive models. These methods commonly call for a substantial amount of training data to obtain good prediction performance, and the data mostly rely on heuristic algorithms. As such, precise predictions require workload data that exhibits clear regularities or patterns, highlighting the dependency of machine learning methods on the characteristic structure of the data.

C. Deep Learning Strategies

Deep learning strategies encompass a variety of models, including Recurrent neural network [17](RNN), Long short-term memory network (LSTM), Gated recurrent unit[18](GRU), Convolutional neural network [19](CNN), and Deep belief network [20](DBN), etc. To overcome the challenges of gradient vanishing and exploding encountered during the training of recurrent neural networks, researchers proposed the Long Short-Term Memory network (LSTM). By introducing a gating mechanism, LSTM can better manage and utilize gradient information, thereby enabling the learning of more intricate temporal patterns and prolonged dependencies.

Guo et al. [21] proposed an enhanced model, N-LSTM, which is an extension of LSTM, specifically designed to address the challenge of virtual machine workload prediction. This model integrates historical VM workload data with request intervals across various VM categories, using the resulting dataset as input for training, thereby enhancing its ability to accurately forecast future VM workload. In an effort to address the limitations and challenges present in current research, Xu et al.[22] introduced a deep neural network method, referred to as esDNN, based on efficient supervised learning for cloud workload prediction. Empirical results indicate that esDNN is capable of providing precise and efficient predictions for cloud workload.

Following the advent of the Transformer [23] model in the realms of natural language processing and computer vision, a multitude of Transformer-based models have been adapted for the prediction of time series data [24–26]. The Transformer architecture capitalizes on the distinct capabilities of the attention mechanism to effectively discern global dependencies within sequences, thus offering enhanced performance in addressing long-term sequence prediction challenges. However, the direct application of the self-attention mechanism in these models presents notable challenges in accurately discerning time dependencies within complex time series patterns. Furthermore, the intrinsic quadratic complexity associated with the self-attention mechanism imposes limitations on the model's sparsity requirements, thereby influencing the efficiency of information utilization.

In response to these problems, the industry proposed the Autoformer model, which emerged as a significant advancement in time series prediction, extending the horizon of predictability. Empirical research has validated the capability of Autoformer to elevate both the accuracy and efficiency of predictions. To date, the Autoformer has been successfully implemented in various domains, including temperature forecasting, water level prediction, traffic flow forecasting, and power load forecasting. Theoretically, it can also be applied to

cloud workload data with time series characteristics to make up for deficiencies in actual cloud load data prediction work. However, there is a dearth of literature demonstrating its application within the cloud computing workload prediction sphere. At the same time, traditionally, tuning the hyperparameter of Autoformer poses a significant challenge, particularly in scenarios involving large-scale datasets and complex tasks. Bayesian optimization, as an intelligent approach grounded in Bayes' theorem, offers potential solutions to a wide range of challenges. By constructing and dynamically refining the probability model of the objective function, this method adeptly incorporates historical evaluation data while efficiently guiding the search process toward a swift convergence to the optimal solution [27-28]. Bayesian optimization has been successfully applied to hyperparameter tuning of multiple predictive models, significantly improving model accuracy [29-32]. Consequently, the introduction of a Bayesian-optimized Autoformer model into cloud computing workload prediction tasks may bring new breakthroughs and improvements in this field of research.

III. AUTOFORMER MODEL PRINCIPLE

The challenge of predicting cloud workload shares similarities with time series prediction, both necessitating the input of a historical time window of length I to forecast a future time window of length O . In the context of cloud workload prediction, long-term forecasting assumes particular significance as cloud service providers need to proactively plan resource allocation. Addressing the exigency of long-term prediction, this paper introduced the Autoformer model, depicted in Fig. 1. Leveraging a decomposition architecture and autocorrelation mechanism, Autoformer adeptly handles intricate temporal patterns, discerns periodicity, and captures dependencies within time series data. This approach enhances the accuracy and efficiency of cloud load forecasting, enabling cloud service providers to adapt adeptly to forthcoming demand fluctuations.

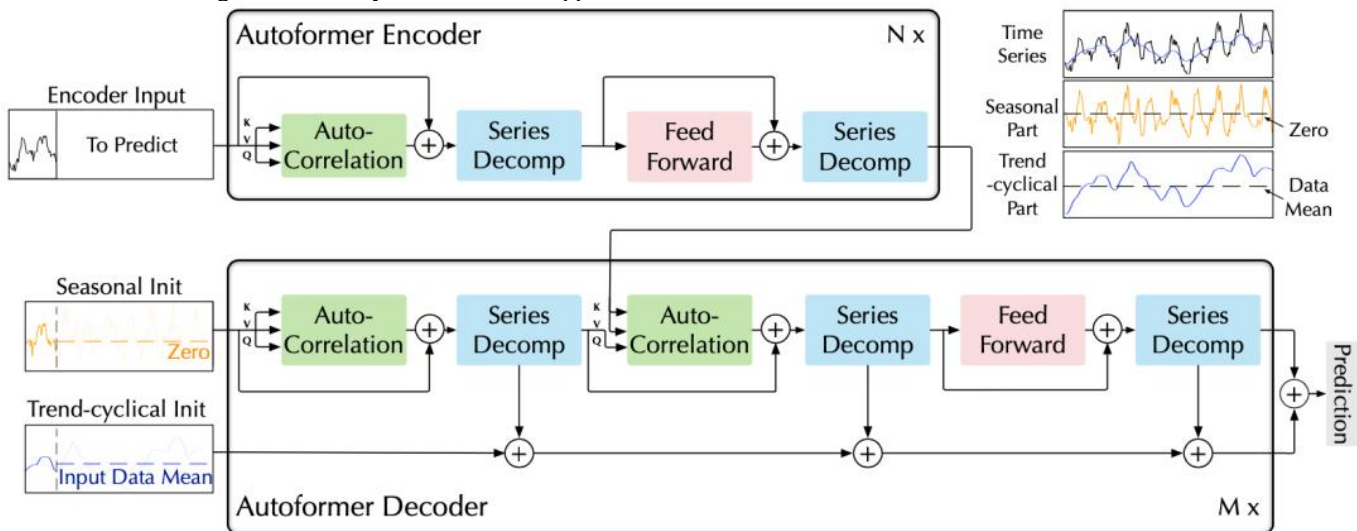

Fig. 1. Cloud workload prediction architecture based on Autoformer[5].

The architecture for cloud workload prediction, utilizing Autoformer, comprises two distinct sections: the encoder and the decoder. The encoder primarily focuses on the load cycle term, taking as input the preceding I -time steps. Employing the autocorrelation mechanism, the initial input cloud workload time series undergoes preliminary sequence decomposition, resulting in load trend and load cycle components. These components, reflective of long-term trend and periodicity respectively, are then transmitted to the decoder, thereby dividing the input of the decoder into two parts: load trend item and load cycle item. The load cycle item forwarded to the decoder undergoes further sequence decomposition, facilitated by the autocorrelation mechanism. Meanwhile, the load trend item extracts trend information via accumulation operations. The decoder comprises multiple decoding layers, each acquiring a comprehensive segment of load timing data instead of discrete data points. This enables a stepwise sequence decomposition process, augmenting the reliability and precision of load prediction outcomes.

A. Deep Decomposition Architecture

The Autoformer model integrates sequence decomposition as a fundamental component of its deep decomposition architecture, which is embedded in both the encoder and decoder modules. Throughout the prediction process, the model iteratively optimizes forecast results while performing sequence decomposition. This iterative procedure entails meticulous adjustments to comprehensively capture diverse trends and periodicities in the data, effectively isolating essential features.

The concept of sequence decomposition is primarily derived from conventional time series prediction algorithms, such as Arima and Fbprophet. In essence, these traditional algorithms approach the decomposition of time series from a statistical standpoint and give different physical meanings to the decomposed sub-terms, such as trend term, seasonal term, residual term, etc. Therefore, the general form of traditional time series decomposition is shown in Eq. (1):

$$X(t)=T(t)+S(t)+R(t) \quad (1)$$

In Eq. (1), $X(t)$ represents the time series that is subject to decomposition, whereas $T(t)$, $S(t)$, and $R(t)$ corresponds to the trend term, seasonal term, and residual term, respectively, arising from the decomposition process.

Within the context of cloud computing workload prediction, the computation of sequence decomposition within the Autoformer model is detailed in Eq. (2) to Eq. (3):

$$X_t=\text{AvgPool}(\text{Padding}(X)) \quad (2)$$

$$X_s=X-X_t \quad (3)$$

In the aforementioned formula, X denotes the time series of cloud load to be decomposed, X_t represents the load trend component, whereas X_s signifies the load cycle component. Eq. (2) elucidates the specific algorithm for extracting the trend item X_t : To maintain the temporal span of the load time series unaltered, the fill operation is first applied to X and then AvgPool processing is performed. Eq. (3) clarifies that Autoformer adopts the simplest additive model and solely

decomposes two sub-terms: trend term and periodic term. In other words, the input load time series X is subtracted from the obtained load trend term X_t , and the load cycle term X_s is derived using Eq. (2).

1) *Encoder*: In the task of cloud computing workload prediction, the encoder primarily targets the periodic component of the cloud load time series. Through a meticulous multi-layer sequence decomposition module, it systematically eradicates the trend term from the load time series, ultimately extracting the periodic term. This extracted periodic term serves as valuable load period information, guiding the decoder in its prediction of future load. Taking the l -th coding layer X_{en}^l as an example, assuming there are N coding layers, the calculation of the l -th coding layer is as shown in Eq. (4) to Eq. (5):

$$S_{en}^{l,1}, _- = SD(AC(X_{en}^{l-1}) + X_{en}^{l-1}) \quad (4)$$

$$S_{en}^{l,2}, _- = SD(FF(S_{en}^{l,1}) + X_{en}^{l,1}) \quad (5)$$

In the above formula, AC stands for AutoCorrelation processing, SD represents SeriesDecomp processing, and FF denotes FeedForward processing. X_{en}^{l-1} signifies the cloud load time series input during the initial encoding stage. $S_{en}^{l,i}$, where $i \in \{1,2\}$ denotes the i -th encoded load cycle information within the encoding layer.

2) *Decoder*: In the task of cloud computing workload prediction, the decoder comprises two distinct components. The first component is responsible for handling the load trend term outputted by the encoder, gradually extracting trend information from the predicted latent variable through an accumulation operation. The second component focuses on the periodic term outputted by the encoder, employing a stacked autocorrelation mechanism for dependency mining and aggregation of similar subprocesses. Considering the l -th decoding layer X_{de}^l as an example, and assuming a total of M decoding layers, the decoding layer primarily operates on the input cloud load time series and the encoding layer output. The calculation of the l -th decoding layer is detailed in Eq. (6) to Eq. (9):

$$S_{de}^{l,1}, T_{de}^{l,1} = SD(AC(X_{de}^{l-1}) + X_{de}^{l-1}) \quad (6)$$

$$S_{de}^{l,2}, T_{de}^{l,2} = SD(AC(S_{de}^{l,1}, X_{en}^N) + S_{de}^{l,1}) \quad (7)$$

$$S_{de}^{l,3}, T_{de}^{l,3} = SD(FF(S_{de}^{l,2}) + S_{de}^{l,2}) \quad (8)$$

$$T_{de}^l = T_{de}^{l-1} + W_{l,1} * T_{de}^{l,1} + W_{l,2} * T_{de}^{l,2} + W_{l,3} * T_{de}^{l,3} \quad (9)$$

In the above formula, AC stands for AutoCorrelation processing, SD represents SeriesDecomp processing, and FF denotes FeedForward processing. X_{de}^{l-1} signifies the cloud load time series input during the initial encoding stage. $S_{de}^{l,i}$ and $T_{de}^{l,i}$, where, $i \in \{1,2,3\}$ denotes the i -th load cycle information and

load trend information decoded in the decoding layer. $W_{i,i}$, where, $i \in \{1,2,3\}$ denotes the weight of the i -th load trend.

Utilizing the aforementioned progressive decomposition architecture, the Autoformer model effectively captures periodicity and trend variations within the load time series by methodically decomposing latent variables during the process of cloud load prediction. By incorporating the autocorrelation mechanism and accumulation method, the model is able to extract prediction outcomes pertaining to both load cycle item and load trend item, subsequently enabling a more precise prediction of cloud load time series. This alternating process of decomposition and optimization of prediction results mutually reinforces each other, offering robust support for enhancing the overall performance of the model.

B. Auto-Correlation Mechanism

In the context of cloud computing workload prediction, the Autoformer model leverages an autocorrelation mechanism to effectively capture periodic patterns within cloud load time series. Specifically, the autocorrelation module computes the autocorrelation coefficient of the load sequence, enabling the discovery of periodic dependencies. Furthermore, it employs time translation techniques to aggregate similar subload sequences, thereby enhancing comprehension of the model and prediction accuracy of cloud load dynamics. This approach significantly improves the ability of the model to capture intricate temporal patterns and make accurate predictions, which is crucial for effective resource management in cloud computing environments.

In the practical computation of autocorrelation, the Autoformer model employs a fast Fourier transform (FFT) technique to efficiently calculate the autocorrelation coefficient. Initially, the input load time series X_t undergoes mapping to Q , K , and V , followed by conversion into the frequency domain. In the frequency domain, the translation similarity can be calculated more conveniently, which helps to improve the computational efficiency. The specific calculation process is shown in Eq. (10) to Eq. (11):

$$S_{XX}(f) = F(X_t)F^*(X_t) = \int_{-\infty}^{\infty} X_t e^{-i2\pi f t} dt \int_{-\infty}^{\infty} X_t e^{-i2\pi f t} dt \quad (10)$$

Eq. (10), X_t represents the load time series that exhibits periodicity; F denotes the Fourier transform (FFT), while F^* represents its conjugate operation; The variable f signifies the frequency, which is multiplied by 2π to obtain the angular frequency; The multiplication of F and F^* with the respective integration results of the load trend terms facilitates the transformation of the time series into the frequency domain.

$$R_{XX}(\tau) = F^{-1}(S_{XX}(f)) = \int_{-\infty}^{\infty} S_{XX}(f) e^{i2\pi f \tau} df \quad (11)$$

Eq. (11), $R_{XX}(\tau)$ represents the similarity between the sequence X_t and its τ delay $X_{t-\tau}$, this delay similarity can be regarded as the confidence of the unnormalized period estimate, that is, the confidence $R(\tau)$ of the period length τ . F^{-1} denotes the inverse Fourier transform; The variable f represents frequency, multiplied by 2π to obtain the angular frequency result. Subsequently, an inverse Fourier transform is applied to

the outcome derived from Eq. (11), leading to the computation of the autocorrelation coefficient. This approach effectively reduces the computational complexity associated with the autocorrelation solution, thereby enhancing the efficiency and practicality of the overall analysis.

IV. WORKLOAD PREDICTION MODEL BASED ON BAYESIAN-OPTIMIZED AUTOFORMER

A. Bayesian Optimization Algorithm

In the context of forecasting cloud computing workload based on the Autoformer model, the selection of hyperparameters holds a pivotal role in relation to model evaluation. The training process necessitates meticulous control and adjustment of numerous hyperparameters, ensuring that the model performs at its optimal level. This fine-tuning is crucial for enhancing the predictive accuracy and overall performance of the Autoformer in handling cloud workload prediction tasks.

Bayesian Optimization (BO) stands as a sequential model-based optimization method designed for black-box function optimization tasks. It is employed to optimize unknown objective functions efficiently, aiming to expedite the discovery of globally optimal solutions with fewer function evaluations. As a result, Bayesian optimization finds widespread application in hyperparameter tuning for machine learning models. The core principle of this approach lies in the utilization of the Gaussian Process as a prior model to approximate the unknown objective function. Through iterative evaluations and modeling of the objective function, Bayesian optimization selects the most promising input point for subsequent evaluation, guided by the current confidence of the model. This selection process, known as the Sampling Strategy or Acquisition Function, is crucial in guiding the search toward optimal solutions. Eq. (12) presents the mathematical formalism underlying this calculation.

$$X^* = \arg \max_{X \in A} f(X) \quad (12)$$

In Eq. (12), X^* represents the optimal parameter set, A denotes the possible set, and $f(X)$ serves as the prior distribution model.

In comparison to grid search and random search, the Bayesian optimization algorithm demonstrates the capability of attaining satisfactory optimization outcomes with a significantly reduced number of iterations. This efficiency is particularly advantageous in scenarios where computational resources are limited or where rapid convergence is desired. The pseudocode of the Bayesian optimization algorithm is presented in Table I, providing a concise and structured overview of the algorithm's operational steps.

Firstly, an initial set of candidate solutions is uniformly selected within the entire feasible domain, typically comprising n_0 points. This serves as the starting point for the subsequent optimization process. Subsequently, a loop iteration is initiated, during which one point is added at each iteration until a total of N candidate solutions are obtained. To determine the next point to evaluate, the already-found candidate solutions are leveraged to establish a Gaussian regression model. This model allows us

to estimate the posterior probability of the function value at any given point. Based on this posterior probability, an acquisition function is formulated, and the point corresponding to the maximum value of this function is chosen as the next search point. Once the next search point is identified, its function value is computed and incorporated into the set of candidate

solutions. Finally, the algorithm terminates, returning the maximum value among the N candidate solutions as the optimal solution. This process ensures efficient exploration of the search space and convergence towards the globally optimal solution.

TABLE I. PSEUDOCODE OF BAYESIAN OPTIMIZATION ALGORITHM

Algorithm 1: Bayesian Optimization Algorithm

```
Select  $n_0$  sampling points and compute the corresponding values of  $f(x)$ 
 $n = n_0$ 
While ( $n \leq N$ ) do
    Modify the mean and variance of  $p(f(x)|D)$  according to the recent Sampling records  $D = \{(x_i, f(x_i)), i=1, \dots, n\}$ 
    Determine the acquisition function  $u(x)$  using the mean and variance of the conditional probability  $p(f(x)|D)$ 
    Identify the subsequent sampling point  $x_{n+1} = \text{argmax } u(x)$  by locating the maximum value of the acquisition function
    Compute the function's output at the subsequent sampling location:  $y_n = f(x_{n+1})$ 
     $n = n + 1$ 
End
Return:  $\text{argmax}(f(x_1), \dots, f(x_N))$  and the corresponding  $y$ 
```

B. Workload Prediction Model Based on BO-Autoformer

To enhance the workload prediction model by optimizing its hyperparameters, the Bayesian (BO) algorithm is introduced for parameter optimization. The process of load prediction using the BO-Autoformer prediction model is depicted in Fig. 2. The BO-Autoformer prediction model utilized comprises four components: preprocessing of data, training of the model, Bayesian optimization, and model predictions. Collectively, these stages form a comprehensive load prediction process. The detailed ideas are outlined as follows:

Step 1: In the workload prediction task, the initial load data necessitates rigorous preprocessing. This involves crucial steps such as data cleansing, handling missing values, normalization, and feature engineering. These processes ensure that the load data is rendered suitable for effective training and prediction.

Step 2: Following data preprocessing, the workload dataset is partitioned into distinct training and testing sets. The training set is then utilized to train the Autoformer model, a time series prediction model grounded in stochastic process theory. The Autoformer boasts a deep decomposition architecture and an autocorrelation mechanism, enabling it to efficiently leverage the periodicity and delay information inherent in the sequence.

Step 3: Concurrently, during the model training phase, the Bayesian optimization algorithm is employed to fine-tune the hyperparameters of the Autoformer model. Bayesian optimization establishes a Gaussian regression model within the parameter space, estimating the posterior probability distribution of the objective function. Based on this distribution, it selects the most promising parameter point for the next iteration. This approach significantly enhances the efficiency of the model and accelerates the convergence process.

Fig. 2. Workload prediction flow chart based on BO-Autoformer.

Step 4: The Autoformer model adjusted by Bayesian optimization predicts the test set data.

V. RESULTS AND DISCUSSION

A. Experimental Environment Configuration

The entire combined model is written in Python3.11 and implemented based on Pytorch and is finally executed on Intel(R) Core(TM) i5-7200U CPU @ 2.50GHz 2.71 GHz.

B. Dataset and Data Process

The experiment conducted in this study utilizes the Google Cluster Trace dataset, a real-world workload dataset released by Google in 2011. This extensive dataset comprises over 40 million tasks, encompassing workload information from approximately 12,500 machines over a span of 29 days. It encompasses various attributes such as job ID, task index, machine ID, CPU usage, and memory usage. This study focuses on CPU usage as the primary load information. The original data is sampled every five minutes, resulting in a total of 8333 sampling points.

To ensure the rigor and reliability of the findings, the dataset was carefully divided into three distinct subsets: training, validation, and testing. Specifically, the initial 4986 sets of data are designated as the training set, representing approximately 60% of the total dataset. This ensures that the model is adequately trained on a substantial portion of the available data. Subsequently, the following 1668 sets of data serve as the validation set, accounting for 20% of the dataset. The validation set is utilized to monitor the model's performance during training, aiding in hyperparameter tuning and preventing overfitting. Finally, the remaining 1679 sets of data comprise the testing set, also constituting 20% of the total dataset. The testing set enables us to evaluate the model's generalization ability on unseen data, providing an unbiased assessment of its performance.

This systematic approach ensures a balanced allocation of data for training, validation, and testing, allowing us to comprehensively assess the performance of the model and ensure its reliability in real-world scenarios.

1) *Missing value process*: Given the extensive data sample size and high statistical frequency inherent in the Google Cluster Trace dataset, it is inevitable that occasionally, specific reasons may lead to the omission of individual data points. To address this issue, this article employs the linear regression fitting interpolation method as a robust approach to fill in the missing values. This method ensures that the missing data are accurately and reliably estimated, minimizing any potential biases or distortions in the subsequent analysis.

2) *Data normalization*: Data normalization serves as a crucial step in enhancing the training effectiveness of neural networks. It significantly accelerates the process of locating optimal solutions during training, thereby improving the overall performance of the network. This study adopts the minimum-maximum normalization method, which effectively scales the input values to fall within the range of 0 to 1. This normalization approach ensures that the data is appropriately

scaled, minimizing potential biases and enhancing the convergence speed of the training process.

C. Evaluation Index

To assess the precision of the proposed model accurately, several key evaluation metrics were selected, including Mean Square Error (MSE), Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and Mean Absolute Percent Error (MAPE). These metrics provide comprehensive insights into the model's performance. The formulas for each evaluation index are as shown in Eq. (13) to Eq. (16):

$$e_{MSE} = \frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2 \quad (13)$$

$$e_{RMSE} = \sqrt{\frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2} \quad (14)$$

$$e_{MAE} = \frac{1}{n} \sum_{i=1}^n |y_i - \hat{y}_i| \quad (15)$$

$$e_{MAPE} = \frac{1}{n} \sum_{i=1}^n \left| \frac{y_i - \hat{y}_i}{y_i} \right| \times 100\% \quad (16)$$

In the aforementioned equations, \hat{y}_i and y_i , represent the predicted load value and the actual load value at time i respectively. Additionally, n signifies the total count of test samples. It is noteworthy that as these evaluation indicators approach zero, the prediction performance of the model improves significantly.

D. Discussion

The main finding of this study is that the Autoformer model was successfully applied to the field of cloud computing workload prediction, and the model's hyperparameter combination was optimized through Bayesian optimization technology. This discovery not only demonstrates the great potential of the Autoformer model in the field of cloud computing but also proves the effectiveness of Bayesian optimization technology in hyperparameter tuning. Through this method, the accuracy and efficiency of cloud computing workload prediction are improved, and new ideas are provided to solve resource management problems in cloud computing.

The significance of this study is profound, both theoretically and practically. At the theoretical level, this study combines the Autoformer model and Bayesian optimization technology to propose a new cloud computing workload prediction method, which enriches the research content in the field of cloud computing resource management. At a practical level, this approach promises to augment the efficiency and precision of cloud computing resource management, leading to reduced operational costs and improved service quality. For cloud computing service providers, this means being able to better respond to workload changes, optimize resource allocation, and improve resource utilization. For cloud computing users, it means they can obtain a more stable and efficient service experience.

E. Experimental Results

1) *Artificiality*: In the context of cloud workload data prediction, a complex network model may often give rise to issues such as overfitting, inadequate training, and underfitting. Therefore, it is imperative to meticulously address the complexity of the network model when selecting hyperparameters. In the experiments, we manually adjusted the hyperparameters and conducted multiple comparisons of prediction results. The selected hyperparameters, as presented in Table II, were carefully chosen to balance the model's complexity with its predictive capabilities.

2) *Bayesian optimization*: In the Autoformer model, the sequence length optimization range was set to [6, 48] with a step size of 6, allowing for the exploration of various sequence lengths and their impact on model performance. The model dimension optimization range encompassed [128, 256, 512, 1024], permitting the identification of an appropriate balance

between model complexity and predictive accuracy. Additionally, the batch size optimization range was established as [12, 24, 32, 48], enabling the investigation of the effect of batch size on training efficiency and stability. Furthermore, the optimization range for the middle layer dimension of the feedforward network was set to [512, 1024, 2048], allowing for the exploration of different network depths. The number of attention heads was optimized within the range of [1, 8], exploring the trade-off between attention granularity and computational complexity. Moreover, the encoder and decoder layers were optimized over the range of [1, 5], studying the impact of model depth on prediction performance. Finally, the optimization ranges for the attention factor and regularization coefficient were set to [1, 5] and [0.0, 0.5], respectively, facilitating the adjustment of model sensitivity and generalization ability.

TABLE II. HYPERPARAMETER COMBINATIONS DETERMINED BY ARTIFICIALITY

Hyperparameters	Meaning	Value
seq_len	The maximum length of the input sequence processed by the model at each time	18
d_model	Model embedding dimension, also known as hidden layer size	128
batch_size	Number of samples processed by the model in each iteration	32
d_ff	Internal Dimensions in Feedforward Neural Networks	1024
n_heads	Number of heads in multi-head self-attention	8
e_layers	Number of encoder layers	3
d_layers	Number of decoder layers	2
factor	Controlling the number of basis functions in the attention mechanism	2
dropout	The probability of dropping at random	0.05

Utilizing the Bayesian optimization algorithm, this paper conducted a meticulous hyperparameter search for the Autoformer model. Through iterative evaluations of the objective function, the algorithm identifies the hyperparameter combinations that yield minimal loss, thereby maximizing prediction accuracy. The optimal hyperparameters, as summarized in Table III, represent the most effective configuration for the Autoformer model in terms of balancing model complexity, training efficiency, and predictive performance.

As presented in Table III, the hyperparameter values obtained following Bayesian optimization are as follows: sequence length of 18, model dimension of 512, batch size of 32, intermediate layer dimension of the feedforward network set to 2048, eight attention heads, two encoder layers, one decoder layer, an attention factor of 3, and a regularization coefficient of 0.05. Through multiple runs, this paper observed the convergence speed and computational efficiency of the neural network. To ensure the convergence of experimental errors, the maximum traversal count was fixed at 10. This optimized configuration enables the Autoformer model to achieve superior predictive performance while balancing computational demands.

3) *Compare and Analysis*: Table IV comprehensively summarizes the evaluation metrics of the Autoformer model before and after the application of Bayesian optimization. Employing the optimal hyperparameter combination, the study tested the performance of the Autoformer model and conducted a comparative analysis between the original Autoformer and the BO-Autoformer, using real-world data. Fig. 3 provides a visual representation of the improvement achieved result through Bayesian optimization.

As evident from Table IV, the BO-Autoformer model exhibits slight improvements in various evaluation metrics compared to the original Autoformer. Specifically, the mean squared error (MSE) is reduced by 0.82%, the root mean squared error (RMSE) is decreased by 0.41%, the mean absolute error (MAE) is lowered by 0.55%, and the mean absolute percentage error (MAPE) is diminished by 0.59%. These results demonstrate the effectiveness of Bayesian optimization in enhancing the predictive accuracy of the Autoformer model.

One can clearly observe from Fig. 3 that the predicted value obtained by the BO-Autoformer model is close to the real value, and the load curve value is relatively close. The findings indicate that the BO-Autoformer model can predict cloud workload data better than Autoformer.

TABLE III. HYPERPARAMETER COMBINATIONS DETERMINED BY BAYESIAN OPTIMIZATION

Hyperparameters	Parameter adjustment range	Value
seq_len	(6,48)	18
d_model	[128, 256, 512, 1024]	512
batch_size	[12, 24, 32, 48]	32
d_ff	[512, 1024, 2048]	2048
n_heads	(1, 8)	8
e_layers	(1, 5)	2
d_layers	(1, 5)	1
factor	(1, 5)	3
dropout	(0.0, 0.5)	0.05

TABLE IV. EVALUATION INDICATORS BEFORE AND AFTER BAYESIAN OPTIMIZATION

Model	MSE	RMSE	MAE	MAPE
Autoformer	0.003046	0.055190	0.043399	0.193858
BO-Autoformer	0.003021	0.054961	0.043159	0.192713

Fig. 3. Comparison of predicted values and actual values before and after Bayesian optimization.

The optimal hyperparameter combinations obtained by Bayesian optimization were applied to the four benchmark models: DLinear[29]、NLinear[29]、Informer and Reformer, and a comprehensive comparison among them. The evaluation metrics of the various models are summarized in Table V, while the prediction outcomes are graphically presented in Fig. 4, providing a clear and concise visualization of the comparative performance.

As indicated in Table V, it is evident that the MSE of the BO-Autoformer model is reduced to 0.003021, which is more stable than the other four methods. In comparison to the remaining four approaches, the RMSE has diminished by 16.50%, 15.44%, 2.33%, and 1.15% respectively, the span of the discrepancy between the true and predicted values has narrowed, and the prediction will be more reasonable. Compared with the other four methods, the model MAE has

diminished by 16.97%, 15.15%, 0.78%, and 1.24% respectively. Combined with the prediction trend, it is apparent that the precision of predictions has risen. In relation to the other three methodologies, there is a decrease in the MAPE value by 16.09%, 11.09%, and 1.78% respectively, and the quality of the model has been slightly improved. These findings collectively demonstrate the superiority of the BO-Autoformer model in terms of prediction accuracy and stability.

TABLE V. EVALUATION INDICATORS OF BASELINE MODELS

Model	MSE	RMSE	MAE	MAPE
DLinear	0.004333	0.065825	0.051978	0.229670
NLinear	0.004225	0.064997	0.050863	0.216753
Informer	0.003167	0.056272	0.043499	0.184837
Reformer	0.003091	0.055598	0.043701	0.196201
BO-Autoformer	0.003021	0.054961	0.043159	0.192713

Fig. 4. Comparison of predicted values and actual values of the baseline models.

As demonstrated in Fig. 4, the fitting curve of the Bayesian optimized Autoformer model is closer to the true value than other models, and the fitting effect is the best. Consequently, the BO-Autoformer model proposed in this study demonstrates significantly higher prediction accuracy when compared to several alternative models, thereby underscoring its effectiveness and reliability in the domain of concern.

In the scenario where the input sequence spans 18-time steps (equating to 90 minutes), the study conducted a comparative analysis across various prediction horizons, specifically 1-time step (5 minutes), 6-time steps (30 minutes), 12-time steps (60 minutes), and 18-time steps (90 minutes). The comparative outcomes were systematically compiled in Table VI, facilitating a comprehensive evaluation against other models.

Table VI clearly illustrates that the MSE and MAE error coefficients associated with the 5-minute, 30-minute, 60-minute, and 90-minute predictions of the BO-Autoformer model are predominantly lower than those of other models,

thus achieving optimal performance. Therefore, the Autoformer model demonstrates notable superiority over other models in both short-term and long-term prediction capabilities, highlighting its efficacy and reliability across various prediction horizons.

4) *Discussion of limitations:* Despite the encouraging results of this study, several limitations and potential issues remain. Firstly, the validation was conducted using only a single dataset, which may not fully capture the performance of the BO-Autoformer model across diverse scenarios. This limitation may cause our evaluation of model performance to

be overly optimistic or one-sided. Therefore, future research should expand the dataset scope to better assess the model's generalization ability. Secondly, the Bayesian optimization algorithm used to find the optimal hyperparameter combination can be computationally intensive, making it unsuitable for application scenarios requiring high real-time performance. This limitation limits the application of the BO-Autoformer model in scenarios such as online learning. Therefore, future research should explore more efficient optimization algorithms to enhance the training speed and prediction efficiency of the model.

TABLE VI. EVALUATION INDICATORS OF BASELINE MODELS UNDER DIFFERENT PREDICTION LENGTHS

Model/prediction length	5min		30min		60min		90min	
	MSE	MAE	MSE	MAE	MSE	MAE	MSE	MAE
DLinear	0.004333	0.051978	0.005220	0.056784	0.006236	0.062536	0.006991	0.066337
NLinear	0.004225	0.050863	0.004734	0.053796	0.004969	0.055146	0.005497	0.057858
Informer	0.003167	0.043499	0.003730	0.047181	0.003975	0.049355	0.004357	0.051340
Reformer	0.003091	0.043701	0.003551	0.046383	0.003956	0.049906	0.004659	0.054540
BO-Autoformer	0.003021	0.043159	0.003503	0.046312	0.003794	0.048110	0.003965	0.049038

VI. CONCLUSION AND FUTURE WORK

Given the intricate sequential patterns and complexities inherent in cloud workload, accurate prediction of the workload holds paramount importance for successful cloud computing resource management. To address the prevailing challenges of limited prediction accuracy and challenging hyperparameter tuning in cloud workload prediction, this paper introduces the BO-Autoformer model, a fusion of the Autoformer model and Bayesian optimization techniques. Through rigorous experimental validation, the BO-Autoformer model was found to significantly outperform the traditional Autoformer model, achieving a reduction in MSE and MAE by 0.82% and 0.55% respectively, thereby enhancing prediction accuracy. By comparing with 4 baseline models, it is found that this model promises extensive application potential in both short-term and long-term load prediction.

Future research should not only be satisfied with the existing prediction accuracy but should continue to explore new optimization paths to achieve further improvement in the performance of prediction models. In addition, designing a reasonable virtual machine consolidation strategy based on the prediction results to realize the efficient utilization of cloud resources is also an important research direction in the future.

Abstract—In the new era of technology, where information can be accessed and gained at the push of a button, security concerns are raised about protecting the system and data privacy and confidentiality. Traditional ways of user authentication are vulnerable to multiple attacks across all platforms. Various studies propose the use of more than one authentication process to enhance the security level of a system, either hosted on-premise or on the cloud. However, there is limited study on guidelines and appropriate authentication frameworks that suit the needs of an organization. A systematic literature review of a Multi-Factor Authentication framework was conducted through five primary databases: Scopus, IEEE, Science Direct, Springer Link, and Web of Science. The review examined the proposed solution and the underlying methods in a Multi-Factor Authentication framework. Numerous authentication methods were combined to address specific system and data security challenges. The most common authentication method is biometric authentication, which addresses the uniqueness of the user's biological identity. The majority of the proposed solutions were proof of concept and require a pilot test or experiment in the future.

Keywords—Data privacy; information; multi-factor authentication; security challenges

I. INTRODUCTION

The authentication process is the first defense against unauthorized access, a critical security system component [1]. Authentication is the process of identifying the authorized user to have valid access to a device or system. The authentication process starts by registering a valid user with sufficient information such as username, password, and email address. All the information is stored on the server and will be verified during the login process. The most common authentication methods are text passwords [2], Identification Numbers (PIN) [3], and biometrics [4]. Hence, protecting a system requires a sufficient, reliable, and vigorous authentication framework [5].

Single-factor authentication (SFA) is the most popular authentication method among users and is widely implemented. However, SFA is vulnerable to cyber-attacks because it provides basic security protection. Recent studies reveal the need for multi-factor authentication (MFA) to secure the user's connection to the systems and applications. Many MFA frameworks have been proposed to address the challenges in authentication security. Unfortunately, one framework does not fit all of them. Hence, this study aimed to systematically review the existing MFA framework and the proposed solution.

This systematic review consists of five sections. Section I explicitly covers the introduction and significance of this

review. Section II provides a study background on MFA and its challenges. Then, Section III discusses the study methodology and summary of the findings. Section IV highlights the related findings, literature discussion, and presents the comparative analysis of the proposed MFA framework. Finally, Section V concludes the study findings and discusses the potential future research.

II. RELATED WORK

Researchers in the literature have proposed various MFA frameworks to address cyber-attacks. In most recent cases of cyber-attacks on systems and applications, the enhancement of authentication security has been proposed to mitigate the risk. The organization needs authentication security to protect the systems and data confidentiality, privacy, and availability.

Many authentication frameworks have been proposed in the literature to address the weak authentication issue. Every proposed MFA framework has its advantages and disadvantages. Leslie Lamport, in 1981, announced the first remote authentication method based on an encryption function, a one-way hash encryption function, and a password lookup table. However, although the proposed authentication is easy to use, the authentication requires a high hash overhead and more significant storage to store the password databases. Hence, some studies address the use of smart cards to overcome the weakness. For example, [6] presented a scheme combining a smart device and a third-party application to perform a single sign-on authentication in the cloud environment. Several smartcard or smart device methods have been proposed in the literature, particularly [6] and [7].

However, many of the proposed authentication approaches require additional equipment, such as a smart card reader and biometric scanner, for the authentication process. The second category of approaches is digitalized multi-factor authentication. The other proposed authentication framework combines RSA encryption for the digital signature and One-Time Password (OTP), which utilizes asymmetric and RSA digital signature as the second factor [8]. The proposed framework required three phases: setup, user registration, and authentication process. Therefore, the proposed authentication framework does not require devices such as a token device, a smart card system card reader, and a physiological biometrics scanner [9].

A. Authentication Framework

The security and authentication issues of a system or application hosted on-premises or cloud, like NFC hacking, stolen accounts and devices, and insecure access points, can be

alleviated by proper authentication. As the authentication data is stored in a server, user privacy is highly vulnerable to those attacks.

The traditional authentication method relies on a username and password, which is no longer safe and adequate to protect the system on cloud computing. Therefore, Two-Factor Authentication (2FA) was introduced as an intuitive step forward that couples the representative data with the factor of personal ownership, such as a smartcard or a phone. The smartcard device is used as the second authentication factor to strengthen security.

Previous literature argued on the security protection provided by SFA, hence proposing a 2FA framework [2][10][11][12]. 2FA is an authentication mechanism for protecting users from phishing attacks and password leakage [13]. However, various research simultaneously challenges the implementation of the 2FA, which limits the device to the second authentication protocol [14] [15] [16]. In summary, most literature agrees that MFA provides comprehensive security protection to the system environment compared to SSO and 2FA frameworks [17].

Hence, to overcome the challenges in authentication security, an MFA was utilized to secure the system and data ecosystem. MFA combines multiple authentication methods into a sequence of the authentication process. MFA utilized three factors to connect the user with the established credentials:

- Information factor – something that the user knows.
- Ownership factor – something that the user has.
- Biometric factor – something the user is.

Afterward, the MFA framework was introduced to enhance the security protection of a system and facilitate the continuous preservation of computing devices and systems from unauthorized access. The development of an MFA framework required at least two authentication methods, which provide possession, knowledge, and uniqueness [18] [19]. In the MFA framework, username passwords and biometrics are the two most common authentication methods used with other additional authentication [15]. According to industry experts, text passwords, one-time passwords (OTP), and two-factor combinations are the most widely used authentication techniques and approaches. The primary rationale for their selection was that they were suited for the application under development [17].

In addition, mobile environments, healthcare and telecare, wireless sensor networks, remote authentication, cloud computing, and crypto depend on the MFA framework. Therefore, MFA introduced an additional security layer to the system by implementing a time-based one-time password (TOTP) method [20]. The proposed TOTP required a username and password in the first stage. Then, the user needs the MFA token to generate a TOTP virtually. The proposed authentication method is found to provide a secure transaction.

B. Gaps in Authentication Framework

Single authentication is the most basic and convenient protection mechanism using a password-based authentication

scheme. Some examples of password-based authentication methods are Automated Teller Machines (ATM), Database Management Systems, and Personal Digital Assistants (PDA). However, two main problems are associated with the password mechanism [21]. First, passwords and PINs are stored in database systems as plain text can easily be accessed by the administrator. Secondly, the attacker can impersonate a legitimate user by grabbing the user ID and password stored in the database.

Therefore, MFA is considered the solution to the various challenges mentioned above. MFA involves a multi-layer authentication scheme to reduce the risks of SFA, such as unauthorized access to trusted devices and modification to the data structure. Previous research on MFA substantially concentrated on the technological improvement of authentication and the limitation of user access control to address existing weaknesses in various areas.

However, technological adoption, usability, and system alignment with user risk perception remain a question [22]. While new authentication methods have been more interesting to explore, previous studies have also intensively evaluated existing MFA frameworks. On the aspect of speed, simplicity (user actions), and authentication error rates on the user side [23] [24] [25]. However, the usability of high-touch and low-tech schemes remains challenging [22].

Despite the industry being a major workforce and data repository source, only 2.4% of the research focused on any MFA organizational implementation [22]. The industrial implication is often understudied, primarily because the data policies of the industry, as well as the lack of contribution from the organizations themselves and the recruitment of the technical expert, can be challenging.

Table I summarizes various studies focusing on the proposed MFA framework from 2016 until 2022.

TABLE I. SUMMARY OF MFA FRAMEWORKS

No	Authentication Method	Author(s), year
1	Text Password	[26]
2	Graphical Password	[27]
3	Biometric	[28] [29]
4	One Time Password (OTP)	[30] [31]
5	Token	[32]
6	Card Reader	[33]
7	Time-based One Time Password (TOTP)	[34]

III. METHODOLOGY

A systematic literature review (SLR) identifies, evaluates, and interprets all available research relevant to a particular research question, topic area, or phenomenon of interest. Most research starts with a conventional literature review to gain input on the selected topic. However, unless a literature review is thorough and fair, it is of little scientific value. This is the primary rationale for undertaking systematic reviews. A SLR synthesizes existing work in a manner that is fair and seems to

be fair. Some of the features that differentiate a systematic review from a conventional expert literature review are:

- Systematic reviews start by defining a review protocol specifying the research question being addressed and the methods used to perform the review.
- Systematic reviews are based on a defined search strategy to detect as much relevant literature as possible.
- Systematic reviews of the selected documents for the search strategy so that readers can assess their rigor and the repeatability and completeness of the entire process.
- Systematic reviews require explicit inclusion and exclusion criteria to assess each potential primary study and the scope of interest.
- Systematic reviews specify the information to be obtained from established databases, including quality criteria by which to evaluate each primary study.
- A systematic review is a prerequisite for quantitative meta-analysis.

SLR plays a vital role in supporting further research efforts and providing an unbiased synthesis and interpretation of the findings in a balanced manner [35]. Fig. 1 below illustrates the SLR overview process.

Fig. 1. Overview of the methodology in SLR.

Phase 1 in SLR involved planning the review, including developing research questions, an online sources database, and a research string. This study developed the research questions as follows:

- What is the proposed authentication solution in the study?
- What is the comparison of the proposed authentication methods in the study?

This study identifies suitable online databases [15] [36], which include Scopus, IEEE, Science Direct, Springer Link, and Web of Science (WoS). Google Scholar was used as a secondary

data source, and a reverse snowballing technique was used to identify potential research. The search string included ""multi-factor"" OR ""multi-tier"" OR ""multi-layer"" AND ""authentication"" AND ""framework"" OR ""model"". Boolean operators have been applied to refine and broaden the search required. The findings are summarized in Table II. After conducting the search from five databases, a total of 248 papers were found.

The collected papers went through the second phase in SLR to determine the relevant literature by [35] applying seven stages of the filtering process shown in Table III to ensure only related and appropriate literature on multi-factor authentication was discussed. Fig. 2 illustrates the quality assessment stages, and a total of 23 literatures were selected for discussion.

TABLE II. SUMMARY OF RESEARCH FINDINGS

No	Database (DB)	Research Finding
1	Scopus	83
2	IEEE	65
3	Science Direct	23
4	Springer Link	19
5	Web of Science (WoS)	58
TOTAL		248

TABLE III. INCLUSION AND EXCLUSION FILTERING CRITERIA

Stage#	Inclusion/exclusion criteria
Stage 1	Searching research papers through the search strings on major online databases to discover conference papers and journal articles.
Stage 2	Excluding research papers, that is non-English papers, a short paper, a poster presentation, slide presentations, editorials, and prefaces.
Stage 3	Removing replicated research paper that appears in different databases
Stage 4	Reading the research paper (the introduction, method section, and conclusion)
Stage 5	Excluding the research paper that was not relevant to authentication method / MFA
Stage#	Inclusion/exclusion criteria
Stage 6	Excluding the research paper that did not propose solutions, evaluation, or experience of authentication method / MFA
Stage 7	Excluding the research papers that do not answer two or more of the identified research questions

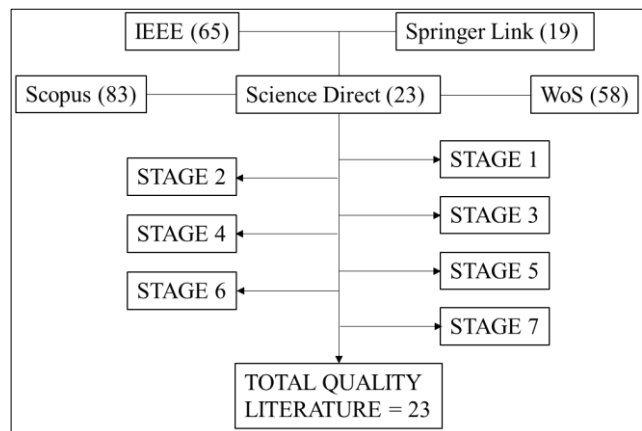

Fig. 2. Quality assessment stages in SLR.

The data extraction strategy is applied to display the selected literature in an organized structure. The criteria of the data extraction strategy were only the relevant literature selected to be reviewed and documented accordingly.

The final stage of SLR involves writing the report by analyzing the result to meet the study objective. The objective of SLR is to identify the proposed multi-factor authentication (RO1) and to compare the proposed authentication methods in the study (RO2).

IV. RESULTS AND DISCUSSION

This study has identified 23 relevant literatures on the MFA framework through the SLR process. Table V below summarizes the findings from the SLR process and the proposed authentication methods, where 23 literatures were analyzed based on the proposed authentication methods in the MFA framework.

A. Proposed MFA Framework

The proposed MFA framework comprises ten authentication methods. Each MFA framework utilizes more than one authentication method in the framework. This study discussed the advantages and disadvantages of each proposed authentication method.

1) *Biometric authentication*: Dynamic signature is one such biometric modality used to authenticate an individual during the establishment of identities [37]. The proposed dynamic signatures utilized structural and behavioral characteristics that are unique to the user during the signing process. The dynamic signature requires a special digital surface, such as a digitizing tablet and pen, but it is comparatively harder to forge and is claimed to be 99% accurate. Other researchers also discussed and proposed behavioral biometrics [29] [38] [39] [41] [42] [44] [48] [49] as well as deep learning analysis besides multimodal biometric input which combined at least two biometric features [40].

2) *One-time password authentication*: The authentication method of a one-time password (OTP) provides confidentiality to the users [45]. However, there is a significant challenge to the proposed authentication method where possible masquerade attacks happen to the verification process, and complex protocols with high computational costs may occur. In the current context of OTP, there are many patented OTP tokens, which may be proprietary hardware tokens, application- and software-based OTP, and web-based approaches [31] [41] [43] [53] [57].

3) *Cryptography authentication*: Cryptography or encryption authentication is believed to provide confidentiality and integrity to the system security [44]. Generally, cryptography uses an asymmetric cryptosystem to exchange the secret key and then employ faster secret key algorithms to ensure confidentiality of the data stream. Meanwhile, a symmetric cryptosystem is used to encrypt and decrypt messages using the same secret key. In addition, hash functions are non-public key cryptography and work without a key. Various literature has been proposed to enhance the

authentication framework through cryptography [29]. Traditional encryption is used in block and stream ciphers to guarantee the confidentiality of the data. The advanced encryption method, such as Transport Layer Security (TLS), is used in securing communication. The proposed authentication method in an MFA framework needs to be integrated with another system or method. Moreover, the system integrator is required to employ cryptography-based protocols through hashing, block ciphers, public keys, and private key generators [44] [31] [29]. Thus, create a complex authentication solution for the MFA framework.

4) *Username and password authentication*: The proposed authentication through username and password can be considered the pioneer and traditional authentication method, posing significant limitations and vulnerabilities [41]. The variety of password attacks and the huge amount of accessible password leaks and dictionary attacks make it indispensable to find more reliable alternatives. However, with the revolution in security and technologies, many researchers proposed an enhanced way to authentication through username and password, such as encrypting the text, adopting a global namespace, challenge password, dynamic password [37], web password [38], and many others. Despite that, many researchers agree that username and password need to be combined with another authentication method to create a secure authentication process [38] [39] [40] [41].

5) *IoT or Smart Device Authentication*: The increase in the number of smart Internet of Things (IoT) devices provides additional authentication security. A smart device can be integrated with a user's behavior that is captured from multiple embedded sensors [39]. In addition, smart devices are favored in artificial intelligence (AI) or work as sensors to detect geolocation or GPS coordination. A mobile phone is considered a smart device and can be used to perform biometric identification, push notifications, and installed applications that perform user verification [48] [49].

6) *Graphical password authentication*: Previous literature has proposed various graphical authentication methods to assess authentication security. The graphical password technique is believed to counter shoulder-surfing attacks during the authentication process [38]. A graphical interface displays a pre-determined object, button, or menu item for the authentic user's action [27]. Graphical passwords can be combined in a series of significant challenge questions to the user.

7) *Token-based authentication*: A secure token-based system can be dependable as well as non-dependable, and factors that rely on an algorithm for generating the token can be dependable. Token-based authentication is widely used among banking customers for secure financial transactions. A YubiKey hardware token is amongst the top-rated authentication security devices [38]. However, there are high requirements for complex system integration, pre-analyzed and pretested software applications with multiple systems, and additional costs are required to possess the hardware token [42].

8) *Dynamic keypad authentication*: Pattern-based or dynamic keypad authentication is commonly used during the

registration phase. A block grid with numbers and symbols is given to the user [47]. The key function maps the numbers selected from the grid pattern to the key, providing a more secure password [31]. Smart devices are also used to perform the authentication process but are likely to be manipulated by an adversary by accessing sensitive data by unlocking mobile devices. Moreover, mobile devices and the applications installed are exposed to unauthorized modification and spyware [56].

9) *Software or application authentication:* Application and system providers utilize third-party application libraries and provide a tested software application for user authentication [42]. A push notification is used to provide the secret key or code to the application installed on a device such as Google and Microsoft Authenticator. This method reduces human error since the user is not required to copy the code. However, most third-party applications and libraries are exposed to security risks such as men-in-the-middle attacks (MITM), hence violating the user's data privacy and confidentiality [42].

10) *Email authentication:* Email authentication is a technique to prove that the email is not forged and belongs to the authenticated user. Email authentication is most often used with other authentication methods and is not used alone but rather as a medium to transmit the secret code or identify the authorized user [27] [43] [54]. The email address is often used during the registration phase [31] [48]. However, authentication through email can be manipulated using phishing attacks, resulting in unauthorized access to the system. Previous literature discussed this security issue and proposed a secondary authentication layer such as time-based OTP through email, combining a secret word with emailed OTP codes, and many others [48].

B. Discussion on the Selected MFA Framework

This study selected an experiment work by [43] for the discussion in the real-world application as well as the guideline for future research. The study proposed an MFA framework based on TOTP, conventional username and password. The experiment was conducted by registering a user. The system requirement forced the user to enter a strong password with a combination of symbols and numbers. The user needs to verify the account through a valid email sent to ensure the user's validity and to avoid errors during typing.

During the login phase, the user is required to enter the registered username and password. The system verifies the user identity with the password database in encryption mode. Once the process passes, the system will generate a random OTP code and send it to the user's registered email for verification purposes. The valid time for the user to enter the OTP code is within 60 seconds. Fig. 3 below depicts the process flow of the proposed OTP. The experiment was conducted to evaluate the success rate of the proposed solution with different hash functions. Table IV shows the generated average values from the experiment for single hash function computations.

The authentication experiment uses a set TOTP validity of one second to generate the passcode. The value of the parameter underwent thorough testing in the utilized scenarios. The response varies based on the network latency and the hosts'

performance in the authentication procedure. In a real environment, the configuration must adhere to the usability requirements of the entire system.

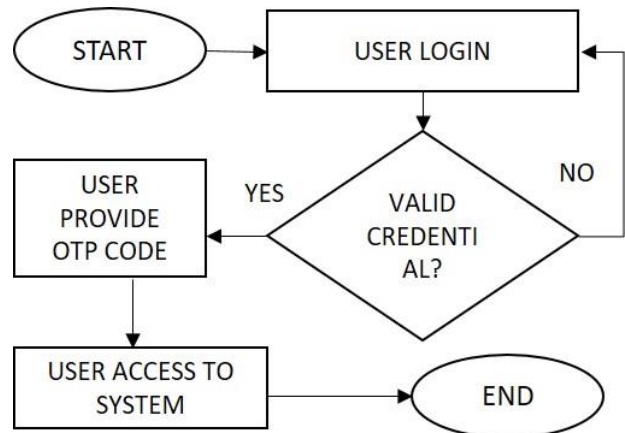

Fig. 3. Quality assessment stages in SLR.

TABLE IV. TIME REQUIRED FOR HASHING COMPUTATION OTP

No	Hash Function	Average Hash Chain (HC) over Hash Value (HV)
1	SHA-256	87 - 99
2	SHA-512	118 - 132
3	SHA3-256	111 - 114
4	SHA3-512	148 - 166

V. CONCLUSION

The weakness of single-factor and two-factor authentication leads to the implementation of MFA and several authentication policies. The application of a multi-factor authentication, intrusion detection mechanism, and user identity access management (IAM) is able to ensure the security and privacy of the data and system. In addition, cryptography through encryption techniques is efficient to protect the data from being disclosed during data in transit and data at rest.

In many cases, the system owners are responsible for ensuring the data's security, privacy, confidentiality, and availability. Adding a second layer of protection after authentication methods such as SSLVPN, IAM, intrusion prevention, and detection ensures the data are well protected.

Conducting a risk assessment to determine the likelihood and level of risk associated with the system and data will ensure adequate preparation and support business as usual (BAU). This study has identified 23 relevant papers on authentication methods in order to propose an MFA framework.

This study believes a comprehensive MFA framework can be developed to benefit users by addressing the challenges and gaps in authentication security. MFA frameworks need to include the three basic authentication factors:

- "Something you know" (such as password).
- "Something you have" (such as a device).
- "Something you are" (such as biometric).

In addition, to ensure end-to-end security protection, the user and system provider should include network security mechanisms such as SSL, TLS, SSLVPN, and user access control such as Identity Access Management (IAM).

However, adopting the correct authentication methods through MFA has significant challenges and limitations. The effectiveness of the proposed MFA structure depends on several factors, such as operational budget, complexity of the system, technical support, system integration, and the availability of mobile networks.

This study reviewed the proposed authentication frameworks through a systematic literature review. In addition, this study also discussed one of the potential MFA frameworks for adoption in the real environment in the previous chapter. The future direction of this study is to integrate the IAM framework and other security features to enhance data protection in the cloud computing environment. IAM ensures that only valid users have access to the resources such as data, records the user login details, and limits or removes user access, including the system administrator.

Abstract—Prompt diagnosis is crucial globally to save lives, underscoring the urgent need in light of lung cancer's status as a leading cause of death. While CT scans serve as a primary imaging tool for LC detection, manual analysis is laborious and prone to inaccuracies. Recognizing these challenges, computational techniques, particularly ML and DL algorithms, are being increasingly explored as efficient alternatives to enhance the precise identification of cancerous and non-cancerous regions within CT scans, aiming to expedite diagnosis and mitigate errors. The proposed model employs Preprocessing to standardize image features, followed by segmentation using an Improved SegNet framework to delineate cancerous regions. Features like LGXP and MBP are then extracted, facilitating classification with a hybrid classifier which combines LSTM and LinkNet models. Implemented in Python, the model's performance is evaluated against conventional methods, showcasing superior accuracy, sensitivity, and precision. This framework promises to revolutionize LC diagnosis, enabling early intervention and improved patient outcomes.

Keywords—Improved SegNet; LGXP; MBN; LSTM; LinkNet; lung cancer

I. INTRODUCTION

Lung cancer remains one of the leading causes of cancer-related mortality worldwide, necessitating the development of advanced diagnostic tools for early detection and treatment planning [6] [7]. CT imaging is essential, particularly when it comes to lung cancer. Nonetheless, the manual assessment of CT scans by radiologists is laborious and susceptible to differences in interpretation between observers. In this context, automated methods for lung cancer segmentation and classification [9] have emerged as the promising avenues to enhance the diagnostic accuracy and streamline clinical workflows.

The primary objective of lung cancer segmentation [8] [13] is to delineate the boundaries of cancerous lesions within the lung parenchyma. This task is inherently challenging due to the variability in lesion size, shape, and intensity characteristics across different patients and disease stages. Various segmentation algorithms have been proposed, ranging from traditional techniques such as thresholding and region growing to more sophisticated deep learning-based approaches like U-Net [11] and Mask R-CNN. These methods leverage the spatial and contextual information present in CT images [10] to

accurately segment lung tumors while minimizing false positives [14].

Once the lung tumors are segmented, the subsequent step involves the classification of these regions into malignant or benign categories [12]. Deep features that are directly learned from the raw image data and manually created features that are taken from segmented lesions are used to train classification algorithms. SVM, RF, and CNNs are among the commonly employed classifiers for this task. By using ML techniques, these classifiers can effectively discriminate between cancerous and non-cancerous regions, facilitating accurate diagnosis and treatment planning.

The development of robust segmentation and classification algorithms for lung cancer holds immense clinical significance [15]. Beyond aiding in early detection and accurate diagnosis, these automated methods have the potential to assist radiologists in monitoring disease progression, evaluating treatment response, and predicting patient outcomes. Furthermore, by reducing the reliance on manual interpretation and improving diagnostic efficiency, automated lung cancer detection systems can alleviate the burden on healthcare resources and improve patient care outcomes. However, these methods are arbitrary and may result in differences in observational quality. To solve this challenge, researchers have created computational algorithms that automate the interpretation of medical pictures for the goal of identifying lung cancer. The following are the proposed paper's primary contributions:

In this work, introduces an innovative approach for lung cancer segmentation by employing an Improved SegNet architecture. This segmentation method enhances the accuracy of identifying cancerous regions within CT images, thus facilitating precise diagnosis and treatment planning.

This remaining section of this document is organized as follows: Section II examines pertinent research on the categorization, segmentation, and associated techniques of lung cancer. Section III presented the proposed methodology. Results and discussion are explained in Section IV and summary of the paper's contribution is given in below Section V.

II. RELATED WORKS

Before In 2024, Sangeetha S.K.B et al., [1] presented a MFDNN architecture designed to integrate various modalities in lung cancer diagnosis, including medical imaging, genomics, and clinical data. By addressing particular issues related to each area, this fusion strategy improves diagnostic precision. Reliability was further enhanced by integrating electronic health records and clinical data. The ethical implications of implementing AI in therapeutic settings were underlined, emphasizing the necessity of strict regulations and thorough validation. MFDNN achieves exceptional accuracy (92.5%) and excels in precision (87.4%) and recall (86.4%), with an F1-score of 86.2, surpassing established methods like CNN, ResNet and DNN. These findings demonstrate the vital role MFDNN plays in enabling the more rapid and precise identification of this serious illness, hence revolutionizing the diagnosis of lung cancer.

In 2024, Sampangi Rama Reddy B R et al., [2] introduced a novel architecture, the SNN, for detecting and classifying lung cancer utilizing CT scan data. Examining which NN models were most effective at lung cancer identification in its early stages was the main goal. Initially, lung regions were extracted employing image processing methods, followed by segmentation using the SNN. Various NN techniques were then employed for classification based on the features extracted from segmented images. Performance evaluation was conducted using F1-Measure, precision, accuracy, and recall metrics, showcasing a remarkable 96% classification accuracy in testing, surpassing existing methods. The proposed algorithm demonstrated clear potential for real-world clinical application, promising significant advancements in lung cancer diagnosis and treatment.

In 2024, Liangyu Li et al., [3] proposed a novel approach to enhancing lung cancer detection by integrating hybrid feature extraction methods and optimizing ML hyperparameters. Remarkable accuracy rates were obtained by integrating autoencoder-generated features and Haralick features with GLCM, and then using supervised machine learning approaches (specifically, SVM with varied kernels). In particular, SVM with Gaussian and RBF kernels work almost flawlessly, whereas SVM with polynomial kernel, GLCM with autoencoder, Haralick, and autoencoder features, achieves a remarkable 99.89% accuracy. These outcomes highlight how this strategy may greatly enhance prognostic and diagnostic tools for lung cancer treatment planning and decision-making.

In 2024, Fuli Zhang et al., [4] presented a novel two-step DL approach for enhancing NSCLC tumor segmentation from CT images. The method involves training separate segmentation networks for large and small tumor images, following an initial coarse segmentation step aimed at detecting lesion regions. Compared to other approaches, the suggested method obtains a much higher DSC of 0.80 ± 0.13 and has the lowest FPR, highest TPR, and HD95. Notably, the approach exhibits substantial improvement in segmenting tumors of both large and small sizes, particularly enhancing performance for small GTVs, which previously exhibited poor results with other methods. Overall, this two-step DL method

demonstrates precise NSCLC tumor segmentation and holds promise for enhancing radiotherapy efficiency.

In 2024, Lavina Jean Crasta et al., [5] introduced a novel DL framework tailored for detecting and classifying lung cancer from input CT images. For segmentation and classification process, the proposed architecture consists of a 3D-VNet model and a 3D-ResNet model. The segmentation model attains an outstanding 99.34% DSC and significantly lowers false positives to 0.4% on the LUNA16 dataset. Furthermore, with 99.2% accuracy, 98.8% sensitivity, and 99.6% specificity, the classification model exhibits remarkable performance characteristics. The 3D-VNet network robustly and precisely defines lung nodules of various sizes and shapes, outperforming prior segmentation techniques. Metrics of the classification model show enhanced F1-Score, sensitivity, specificity, accuracy, and improved performance compared to existing techniques.

III. PROPOSED A LUNG CANCER SEGMENTATION AND CLASSIFICATION MODEL

Lung cancer has a high death rate due to late-stage detection and few available treatment options. Efficient identification, planning, and tracking of lung cancer nodules using medical imaging, especially CT scans, depend on accurate segmentation and classification. The paper presents an approach for lung cancer segmentation and classification, which combines innovative techniques to improve accuracy and efficacy in medical imaging analysis.

1) Beginning with preprocessing stage, which involves applying Gaussian filtering to the input CT images. To enhance the image quality and lower noise, Gaussian filtering is applied, which increases the efficiency of the segmentation process that follows:

2) The segmentation stage employs an Improved SegNet architecture specifically tailored for lung cancer segmentation. The Improved SegNet architecture is chosen for its ability to accurately delineate cancerous regions within the CT images.

3) Discriminative features like LGXP and MBP are extracted from the segmented regions after segmentation. The ability to differentiate between cancerous and non-cancerous tissues depends on these features.

4) Finally, the classification process integrates a hybrid classifier, leveraging models such as LSTM and LinkNet, to enhance the classification accuracy, leading to more accurate identification and classification of lung cancer nodules. Fig. 1 depicts the overall process of the proposed model.

A. Preprocessing Phase

In the preprocessing stage of the suggested lung cancer segmentation and classification model described, Gaussian filtering is applied as the first method of processing for the input CT images.

Fig. 1. Overall process of proposed model.

Gaussian filtering [16] is a widely used method in image processing for reducing noise and smoothing the image while preserving important features. By convolving the input image with a Gaussian kernel, high-frequency noise components are attenuated, resulting in a smoother and more visually coherent image. In order to improve the image quality of the CT images prior segmentation as well as feature extraction, this preprocessing procedure is essential. It helps to mitigate the impact of noise and artifacts present in the original images, thereby improving the performance of subsequent processing stages. Additionally, Gaussian filtering aids in standardizing the intensity distribution across different CT scans, which is beneficial for achieving consistent segmentation and classification results.

Eq. (1) is likely employed to calculate the values of individual components within the Gaussian smoothing filter. In this context, signifies the Gaussian function's value at coordinates, while signifies the standard deviation of the Gaussian kernel, influencing the extent or width of the Gaussian function's distribution. Normalization constant is denoted as these values are then used to convolve with the input CT images to perform Gaussian smoothing as a preprocessing step.

As a result, the preprocessed picture is represented as and is then put through another segmentation step.

$$F(x, y) = \frac{1}{P} e^{-\frac{x^2+y^2}{2\sigma^2}} \quad (1)$$

B. Segmentation via Improved SegNet

One of the most important steps in medical image analysis is segmentation, which is dividing an image into sections or significant areas in order to retrieve pertinent data for further examination. The segmentation process in this work involves utilizing an Improved SegNet architecture tailored specifically for accurately delineating lung cancer nodules from preprocessed images.

The conventional SegNet model [17] follows an encoder-decoder structure with corresponding layers, which contains 13 layers. The encoder network gradually downsamples the input image, to capture hierarchical features, while the decoder network upsamples the feature maps to produce the segmentation mask. Max pooling operations are typically used in the encoder to perform downsampling, reducing computational burden and extracting dominant features. Despite its effectiveness for semantic segmentation tasks, the conventional SegNet model has limitations. One disadvantage is the loss of spatial information brought about by the encoder's max pooling operations, which might deteriorate segmentation mask quality, especially in applications that call upon accurate object localization. Additionally, the segmentation performance in areas with complex structures or textures may be affected by standard SegNet's inability to capture long-range relationships and contextual information across the image.

To address the limitations of the conventional SegNet model, the proposed Improved SegNet model incorporates several enhancements especially intended for lung cancer segmentation as well as classification. Replacing max pooling with a novel mixed pooling strategy [18], which combines max pooling and average pooling, which is expressed in Eq. (2).

$$\text{Mixed pooling} = \text{max pooling} + \text{Average pooling} \quad (2)$$

In a down sampling process known as "max pooling," the highest value falling inside a predetermined window is kept while the remainder is discarded. This method successfully reduces the spatial dimensions of the feature maps, collecting the most notable features and highlighting locations with significant activation. The calculation of max pooling value is derived in Eq. (3). Here, represents the input feature map, represents the result of max pooling, each channel, and the highest number during a pooling window of dimensions is selected by the maximum pooling function.

$$\text{Max pooling}, Y_{\max}(k_{ij}) = \max_{(p,q) \in R_{ij}} X(k_{ij}) \quad (3)$$

Instead, average pooling computes the mean value within the specified window, contrasting with the maximum value calculation described in Eq. (4). It represents the result of max pooling, each channel. Like max pooling, it helps in downsampling the feature maps, but instead of preserving only the most prominent features, it takes into account the overall intensity across the region. By lessening the effect of noise and outliers, this process can help to depict the features more smoothly.

$$\text{Average pooling}, Y_{\text{avg}}(k_{ij}) = \frac{1}{|R_{ij}|} \sum_{(p,q) \in R_{ij}} X(k_{ij}) \quad (4)$$

In traditional SegNet models for segmentation tasks, the softmax activation function [19] is commonly used at the output layer to produce probability distributions over different classes or regions within the segmented output. Eq. (5) shows the expression of softmax activation function. However, softmax tends to amplify the differences between input values, which can lead to gradients becoming extremely large during backpropagation, causing instability and slow convergence, especially in deep networks like SegNet. Additionally, softmax outputs tend to be overly confident, resulting in less nuanced representations of uncertainty in segmentation predictions.

$$f(x_i) = \frac{\exp(x_i)}{\sum_j \exp(x_j)} \quad (5)$$

To overcome these limitations, the proposed activation function combines softmax with the hard tanh activation function. The hard tanh function [19] introduces a saturation threshold, preventing gradients from exploding or vanishing and promoting more stable training, which is expressed in Eq. (6). By combining softmax with hard tanh, the proposed activation function aims to mitigate the amplification of differences in input values while preserving the probabilistic interpretation provided by softmax. The proposed improved activation function is expressed in Eq. (7). This combination enables the model to produce more calibrated probability estimates for each class or region in the segmentation output, leading to improved segmentation accuracy and better representation of uncertainty. The suggested activation function typically mitigates the adverse impacts of softmax in SegNet models. It enhances stability during training and yields more precise and nuanced segmentation results for lung cancer diagnosis as well as categorization using CT images. Fig. 2 shows the proposed SegNet model for segmentation process.

$$f(x) = \begin{cases} -1 & \text{if } x < -1 \\ x & \text{if } -1 = x \leq 1 \\ 1 & \text{if } x > 1 \end{cases} \quad (6)$$

$$f'(x) = \begin{cases} -1 & \text{if } x < -1 \\ \frac{\exp(x_i)}{\sum_j \exp(x_j)} & \text{if } -1 = x \leq 1 \\ 1 & \text{if } x > 1 \end{cases} \quad (7)$$

Finally, the output of the improved SegNet model is a pixel-wise segmentation mask highlighting lung cancer regions within CT images, which is represented in Fig. 2.

C. Feature Extraction Phase

Various strategies are utilized in the segmentation and classification process of the proposed lung cancer model to extract discriminative features from the segmented regions that are produced given SegNet-based segmentation.

The LGXP and MBP significantly enhance the classification process by providing robust and detailed texture representations crucial for distinguishing cancerous from non-cancerous regions. LGXP excels at detecting edges and capturing fine details by encoding the direction and magnitude of local gradients, making it particularly effective for identifying the boundaries of structures within the images. This method's emphasis on gradient information ensures resilience to noise, which is a common challenge. On the other hand, MBP captures intricate texture details through binary pattern encoding based on intensity differences; improve its robustness against noise and illumination variations.

Fig. 2. Proposed SegNet model for segmentation process.

These methods were chosen for their complementary strengths in texture analysis. LGXP's focus on gradient information and MBP's detailed texture encoding together provide a comprehensive representation of lung tissue characteristics. Both methods have demonstrated effectiveness in texture analysis and image segmentation, making them suitable for the complex task of lung cancer detection. Their robustness to noise, illumination changes, and rotational variations ensures that the extracted features are reliable and consistent, leading to improved classification accuracy.

The features include LGXP and MBP features, which are described as follows:

1) *LGXP feature*: In the proposed model, the feature extraction method utilizes the LGXP descriptor [20], specifically designed to capture texture patterns within segmented lung cancer regions. Initially, the phases within the LGXP descriptor are quantized into distinct ranges, ensuring robustness to variations in Gabor phase. After quantizing each phase value, the LGXP operator interacts with the quantized phases of the central pixel and its neighboring pixels. Using XOR operations, the LGXP operator computes patterns between these phases to produce binary labels that are concatenated together to form a local pattern of the core pixel. Every neighborhood receives a thorough representation of local texture patterns when this process is performed for every neighborhood. Finally, the obtained binary labels are concatenated to generate a local pattern of the core pixel.

The equation for calculating the LGXP, as shown in Eq. (8), includes the quantization of phases and the application of XOR operations between the quantized phases of the central pixel and its neighboring pixels, where, $LGXP_{w,v}$ represents the LGXP descriptor for a specific scale (w) and orientation (v). g_c and g_i denotes the phase at the central and neighboring pixel position in the Gabor phase map, respectively. \oplus denotes the XOR operation.

$$LGXP_{w,v} = q(\varphi_{w,v}(g_c)) \oplus q(\varphi_{w,v}(g_i)) \quad (8)$$

2) *MBP feature*: In the proposed model, the MBP [21] operator is used for extracting texture features from segmented lung cancer regions, I_s . These features are computed by analyzing local neighborhoods within the segmented image, where the median intensity value serves as a reference point. By encoding each pixel's relationship with the local median intensity as a binary pattern, MBP features succinctly represent texture variations within segmented regions. With the help of these features, lung cancer areas in CT scans may be accurately segmented and classified, providing a thorough assessment of textural aspects.

By thresholding pixels against their median value within a neighborhood, usually 3x3, this operator maps intensities to localized binary patterns that improve resistance to noise and sensitivity to microstructure. The MBP at each pixel (i, j) is

computed using a weighted sum over binary values determined by comparing pixel intensities to the median within the local patch. The formula to calculate the MBP at pixel (i, j) in a local patch of size Z (usually 3×3), according to Eq. (9). τ is the median that was calculated for the entire local patch.

$$MBP(i, j) = \sum_{k=0}^{Z-1} 2^k H(b_k - \tau) \quad (9)$$

When the threshold is set to the median, the number of possible binary patterns that result is limited to 256, guaranteeing that the binary pattern subset contains at least 5 one bits. The histogram of these patterns forms the texture descriptor, providing a compact representation of texture variations across the segmented image. As a result, each image is converted into a 256x1 vector that uses local patch median values to represent the MBP histogram. This approach enables comprehensive characterization of textural properties within lung cancer regions, facilitating accurate segmentation and classification in CT images.

Therefore, the feature extraction process aims to capture relevant texture information from the segmented lung cancer regions, facilitating the classification task by providing discriminative features for distinguishing between cancerous and non-cancerous tissues. These extracted features, $F = [LGXP, MBP]$ serve as input to the hybrid classifier in the final stage of the proposed model.

D. Classification Process

Features extracted using LGXP and MBP are fed into a hybrid classifier combining Long Short-Term Memory (LSTM) and LinkNet models. This integration of LGXP and MBP features provides the hybrid classifier with a rich and diverse set of features, enhancing its ability to accurately classify lung tissues. The hybrid classifier harnesses LSTM's ability to capture temporal dependencies and LinkNet's capacity to encode spatial context. Utilizing LSTM networks and LinkNet in the proposed model for lung cancer classification model leverages the complementary strengths of both architectures, addressing specific challenges in medical image analysis. LSTM networks are particularly adept at handling sequential data, which is crucial in the context of CT scans often taken in series over time. This capability allows LSTMs to capture the temporal progression of lung cancer, providing a dynamic perspective of tumor development. Additionally, LSTMs excel at retaining long-term dependencies, maintaining contextual information from previous slices, which enhances the accuracy of classification by ensuring continuity and reducing isolated misclassifications. On the other hand, LinkNet is specifically designed for fast and efficient classification tasks, incorporating residual connections that facilitate better gradient flow and deep feature learning without degradation. This makes LinkNet particularly well-suited for high-resolution medical images like CT scans. Moreover, LinkNet's architecture ensures computational efficiency, which is essential for handling large datasets, making the classification process scalable and practical. The outputs of both models are then combined to make a final

classification decision of segmented lung regions into three distinct classes based on their pathological characteristics. ‘Normal’ tissue is labeled as ‘0’, indicating the absence of any abnormalities. ‘Benign’ conditions, which may include non-cancerous growths or abnormalities, are labeled as ‘1’. ‘Malignant’ tissue, indicative of lung cancer, is labeled as ‘2’, highlighting the presence of cancerous growths within the lung regions. The hybrid approach combining LSTM and LinkNet results in a more comprehensive analysis of CT scans, improving the model’s robustness and reliability. LSTM’s ability to handle sequential and contextual information, coupled with LinkNet’s precision in image segmentation, allows for a richer set of features for final classification. This dual approach enhances the model’s capability to accurately distinguish between cancerous and non-cancerous regions. The synergy between LSTM and LinkNet leads to improved performance metrics, with the hybrid model expected to surpass conventional methods in terms of accuracy, sensitivity, and precision.

1) *LSTM classifier*: The LSTM [22] classifier forms a critical component of the lung cancer segmentation and classification model, facilitating the categorization of segmented lung regions into distinct classes based on their pathological characteristics. When operating within this model, the LSTM classifier receives input features F extracted from segmented lung regions. These features are structured into sequential data, with each sequence representing the feature vectors corresponding to a segmented lung region.

To effectively represent data sequences with long-range dependencies and overcome the vanishing gradient problem, an RNN type known as the LSTM architecture was developed. The model comprises memory cells responsible for retaining internal states and three types of gates namely, input, forget, and output. These gates govern the flow of information into, out of, and within the cells. Specifically, the forget gate selects data to be discarded from the cell state, the output gate manages the impact of the internal state on the cell’s output, and the input gate regulates the quantity of new data stored in the cell state. Because of this architecture’s capacity to recognize temporal patterns and learn from sequential input, long-term dependencies and the temporal patterns inherent in sequential data make LSTMs ideal for processing it.

The three gates of the LSTM design are responsible for managing the information flow via the memory cells. The forget gate, as specified in Eq. (10), regulates the extent to which past information is retained in memory. By applying the sigmoid function (σ) to a weighted sum of the prior short-term memory state (H_{t-1}), the present input state (F), and bias terms (S_{fg}), it calculates a forgetting factor (fg_t). The input gates, detailed in Eq. (11) and Eq. (12), produce an input factor (ig_t) and an alternate vector (\tilde{C}_t) by employing the sigmoid function for gating and the hyperbolic tangent function (\tanh) for the alternate vector. These gates regulate the amount of fresh information incorporated into the long-term memory

state, as described in Eq. (13). Finally, the output gate, defined by Eq. (14), utilizes the sigmoid function applied to a weighted sum of the current input state F , the previous short-term memory state (H_{t-1}), and bias terms (S_{og}) to calculate an output factor (og_t). The final short-term memory output (H_t) is determined by the output factor (og_t) multiplied by the hyperbolic tangent of the long-term memory state (C_t) as per Eq. (15). Fig. 3 shows the architecture of LSTM classifier.

$$fg_t = \sigma(W_{fg}F + W_{fg}H_{t-1} + S_{fg}) \quad (10)$$

$$ig_t = \sigma(W_{ig}F + W_{ig}H_{t-1} + S_{ig}) \quad (11)$$

$$\tilde{C}_t = \tanh(W_C F + W_C H_{t-1} + S_C) \quad (12)$$

$$C_t = fg_t \times C_{t-1} + ig_t \times \tilde{C}_t \quad (13)$$

$$og_t = \sigma(W_{og}F + W_{og}H_{t-1} + S_{og}) \quad (14)$$

$$H_t = og_t \times \tanh(C_t) \quad (15)$$

Through its internal memory units, LSTM is capable of retaining information over extended time periods, thereby allowing the classifier to learn from past observations. Based on the learned temporal patterns and the information extracted from the input sequences, the LSTM classifier makes classification decisions for each segmented lung region.

Fig. 3. Architecture of LSTM classifier.

2) *LinkNet classifier*: LinkNet [23] is a CNN architecture specifically designed for semantic segmentation tasks, where the goal is to classify each pixel in an image into predefined categories. Its architecture is characterized by its efficiency in capturing spatial context while maintaining computational efficiency. The key to its effectiveness lies in its encoder-decoder structure with skip connections. The structure of the LinkNet model is displayed in Fig. 4. In the LinkNet design, the encoder module is responsible for receiving the input image and extracting its hierarchical features, denoted as F . The encoder module primarily comprises multiple convolutional layers accompanied by pooling operations.

These techniques improve the feature maps' depth while progressively reducing their spatial dimensions. This systematic approach enables the network to extract features across various scales, spanning from intricate low-level details to overarching high-level semantics.

In contrast, the decoder module utilizes the features extracted by the encoder to generate the ultimate segmentation map. It usually consists of convolutional layers after upsampling layers, which gradually increase the feature maps' spatial dimensions while decreasing their depth. This procedure improves the segmentation map by reconstructing the spatial information that was lost during the encoding step. One way that LinkNet sets itself apart is by using skip connections to create interconnections between matching layers in the encoder as well as decoder modules. These skip connections enable the transmission of fine-grained details from the encoder to the decoder, allowing the network to efficiently mix low-level and high-level data. Consequently, LinkNet is capable of gathering both local information and global context, which makes it suitable for tasks such as lung cancer classification.

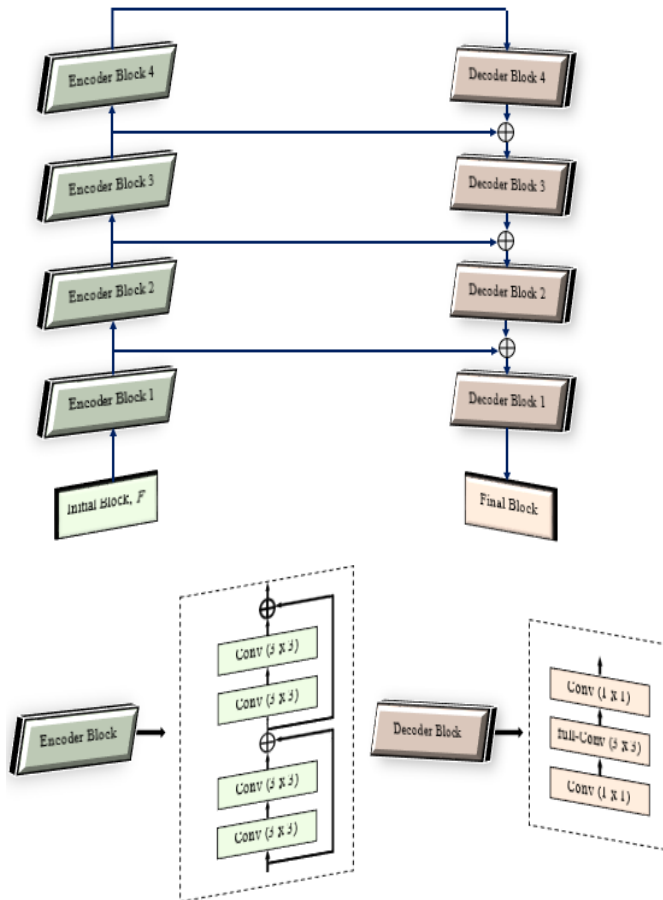

Fig. 4. Architecture of the LinkNet model.

IV. RESULTS AND DISCUSSION

A. Simulation Procedure

The proposed lung cancer segmentation and classification were simulated using Python, specifically version "3.7." The

simulation was conducted on a system equipped with an "Intel(R) Core(TM) i5-4210U CPU running at 1.70 GHz" and "8.00 GB" of RAM. Furthermore, the analysis for lung cancer segmentation and classification was conducted utilizing the IQ-OTHNCCD lung cancer dataset [24].

B. Dataset Description

The lung cancer dataset, collected from the IQ-OTH/NCCD, was compiled over three months in autumn 2019 at specialized medical centers. This extensive collection comprises CT scans acquired from individuals diagnosed with lung cancer at different stages, alongside scans from individuals without any such diagnosis. Notably, the slides from IQ-OTH/NCCD underwent thorough annotation by oncologists and radiologists at the respective centers. Containing 1190 images, which represent CT scan slices from 110 distinct cases, this dataset presents a varied collection of cases classified into normal, benign, and malignant categories. More precisely, the dataset comprises 40 cases diagnosed as malignant, 15 as benign, and 55 as normal. The original CT scans, acquired using Siemens' SOMATOM scanner, were stored in DICOM format.

The CT protocol employed specific parameters including a 120 kV voltage, a 1 mm slice thickness, and precise window settings spanning from 350 to 1200 HU for window width and from 50 to 600 HU for window center, along with a breath hold at full inspiration. To uphold privacy, all images underwent anonymization before analysis, with the oversight review board waiving the necessity for written consent. Additionally, the study received approval from the institutional review board at the collaborating medical centers. The dataset comprises scans, each containing anywhere from 80 to 200 slices, each offering a distinct view of the human chest. It is crucial to acknowledge the diversity within the 110 cases, encompassing variations in gender, age, education level, area of residence, and occupation. For instance, the subjects range from employees of Iraqi ministries to individuals working in agriculture or other occupations. Geographically, the majority of cases originate from regions in central Iraq, specifically the provinces of Baghdad, Wasit, Diyala, Salahuddin, and Babylon.

C. Performance Analysis

The study conducts a comparative assessment between LSTM+LinkNet and conventional models for lung cancer classification, focusing on various performance metrics including "Accuracy, False Negative Rate (FNR), Specificity, False Positive Rate (FPR), Precision, F-measure, Sensitivity, Matthews Correlation Coefficient (MCC), and Negative Predictive Value (NPV)." Furthermore, the LSTM+LinkNet model is evaluated against several conventional classifiers such as LSTM, LinkNet, SqueezeNet, PyramidNet, and MobileNet. Fig. 5 illustrates both the original images and their processed counterparts after applying Gaussian blur. Notably, the Gaussian blur technique effectively removes noise from the original images. This noise reduction significantly enhances the performance of subsequent segmentation and classification processes.

Fig. 5. Images for Lung Cancer Classification a) Original Images and b) Gaussian Blur using Pre-processed images.

D. Segmentation Analysis

In Fig. 6, original images and segmented images are presented, depicting the outcomes obtained using FCM, Conventional SegNet, K-Means, and Improved SegNet. Notably, Improved SegNet showcases superior segmentation results compared to the other methods. Table I presents a segmentation analysis comparing FCM, K-means, Conventional SegNet, and Improved SegNet based on various metrics. These metrics include Dice coefficient, Jaccard coefficient, and Segmentation Accuracy. Improved SegNet stands out as the top performer across all metrics, achieving the

highest Dice coefficient of 0.884, Jaccard coefficient of 0.921, and Segmentation Accuracy of 0.933. In contrast, Conventional SegNet also demonstrates respectable performance, albeit lower than Improved SegNet, with scores of 0.800, 0.817, and 0.838 for Dice coefficient, Jaccard coefficient, and Segmentation Accuracy, respectively. FCM and K-means exhibit comparatively lower values across all metrics, indicating less accurate segmentation results. These results emphasize the efficacy of Enhanced SegNet in precisely segmenting regions, showcasing its potential for outperforming other methods assessed in the study in terms of image segmentation tasks.

Fig. 6. Images for Lung Cancer Segmentation a) Original Images b) FCM c) Conventional SegNet d) K-means and e) Improved SegNet.

TABLE I. SEGMENTATION ANALYSIS ON IMPROVED SEGNET

Metrics	FCM	Conventional SegNet	K-means	Improved SegNet
Dice	0.635	0.800	0.614	0.884
Segmentation Accuracy	0.685	0.838	0.666	0.933
Jaccard	0.674	0.817	0.660	0.921

E. Comparative Study on various Metrics based on Classification

The study conducts a comparative assessment between LSTM+LinkNet and conventional models for lung cancer classification, focusing on various performance metrics including “Accuracy, False Negative Rate (FNR), Specificity, False Positive Rate (FPR), Precision, F-measure, Sensitivity, Matthews Correlation Coefficient (MCC), and Negative Predictive Value (NPV).” Furthermore, the LSTM+LinkNet model is evaluated against several conventional classifiers such as LSTM, LinkNet, SqueezeNet, PyramidNet, and MobileNet.

1) *Analysis on positive measures:* In the comparative analysis illustrated in Fig. 7, the LSTM+LinkNet approach is evaluated against LSTM, LinkNet, SqueezeNet, PyramidNet, and MobileNet for lung cancer classification in terms of positive measures. Achieving high positive metric values while minimizing negative ones is crucial for effective classification. The LSTM+LinkNet method consistently outperforms conventional approaches across these metrics. At 60% training data utilization, the LSTM+LinkNet method achieves an accuracy of 0.868, slightly surpassing LSTM, LinkNet, and SqueezeNet. However, as the training data increases, the superiority of LSTM+LinkNet becomes more pronounced. With 90% training data, it reaches an accuracy of 0.935, the highest among all methods, with LinkNet following at 0.911. In contrast, methods like LSTM, SqueezeNet, and PyramidNet, although competitive at lower training data levels, show less consistent accuracy improvements as the data increases.

Fig. 7. Positive Metric assessment on LSTM+LinkNet and conventional methods.

Examining specificity metrics at 60% training data reveals several insights. LSTM has a specificity of 0.860, indicating its ability to correctly identify true negatives. LinkNet performs slightly better with a specificity of 0.870. SqueezeNet's specificity is 0.858, while PyramidNet's is 0.855, both closely trailing LinkNet. MobileNet outperforms these with a specificity of 0.889, demonstrating its proficiency in identifying true negatives. Notably, the LSTM+LinkNet model exceeds all conventional methods with a specificity of 0.901, highlighting its superior performance in correctly identifying true negatives in lung cancer classification tasks even with 60% of the training data.

2) *Analysis on negative measure:* In Fig. 8, a comparative analysis evaluates the LSTM+LinkNet approach against several other methods—LSTM, LinkNet, SqueezeNet, PyramidNet, and MobileNet—for lung cancer classification based on negative measures. When utilizing 80% of the

training data, the LSTM+LinkNet method excels in minimizing the False Positive Rate (FPR). It achieves an impressively low FPR of 0.056, outperforming all other methods and effectively reducing false positives even with a significant portion of training data. In contrast, traditional methodologies like LSTM, LinkNet, SqueezeNet, and PyramidNet show slightly higher FPR values, ranging from 0.090 to 0.119.

Fig. 8. Negative Metric assessment on LSTM+LinkNet and conventional methods.

While MobileNet demonstrates competitive performance with an FPR of 0.088, it still does not match the performance of the LSTM+LinkNet method. At 90% training data utilization, the models' FNR metrics reveal significant differences in lung cancer classification performance. LSTM has a relatively high FNR of 0.181, indicating a considerable proportion of missed positive cases. Conversely, LinkNet shows a lower FNR of 0.136, effectively reducing false negatives compared to LSTM. SqueezeNet and PyramidNet also perform well, with FNRs of 0.145 and 0.172, respectively, demonstrating their abilities to minimize missed positive cases. MobileNet stands out with an impressive FNR of 0.140, indicating its proficiency in reducing false negatives relative to other conventional methods. However, the LSTM+LinkNet model surpasses all these methods with a notably lower FNR of 0.100, underscoring its superior capability in reducing missed positive cases in lung cancer classification tasks.

3) *Analysis on other measures:* In Fig. 9, a comparative analysis evaluates the LSTM+LinkNet approach against several other methods—LSTM, LinkNet, SqueezeNet, PyramidNet, and MobileNet—for lung cancer classification based on different performance measures. With 60% of the

training data, the LSTM+LinkNet achieves the highest Negative Predictive Value (NPV) of 0.901, indicating its exceptional accuracy in predicting negative cases compared to the other methods. MobileNet follows closely with an NPV of 0.888, while LSTM, LinkNet, SqueezeNet, and PyramidNet show slightly lower NPV values, ranging from 0.854 to 0.869. As the percentage of training data increases, the LSTM+LinkNet consistently maintains its lead in NPV. At 90% training data, it reaches the highest NPV of 0.950, demonstrating its effectiveness in accurately identifying negative cases even with more extensive training data.

Fig. 9. Other Metric assessment on LSTM+LinkNet and conventional methods.

At 90% training data utilization, each lung cancer classification method exhibits distinct performance based on their F-measure values. The LSTM method achieves an F-measure of 0.821, while LinkNet performs competitively with an F-measure of 0.866, reflecting its effectiveness in correctly classifying lung cancer cases. SqueezeNet closely follows with an F-measure of 0.857, showcasing its balanced performance with significant training data. PyramidNet achieves an F-measure of 0.830, indicating a respectable balance between precision and recall. MobileNet shows improved performance compared to earlier stages, reaching an F-measure of 0.862. However, the LSTM+LinkNet method outperforms all others with the highest F-measure of 0.902, highlighting its superior ability to effectively classify lung cancer cases.

F. Statistical Analysis on Accuracy

The statistical evaluation comparing the LSTM+LinkNet model with LSTM, LinkNet, SqueezeNet, PyramidNet, and MobileNet for lung cancer classification is illustrated in Table II. Among the statistical metrics provided, the maximum statistical metric serves as a crucial indicator of the highest achievable performance level for each classification method in lung cancer detection. In this context, it represents the peak accuracy attained by each method across all trials. For instance, the LSTM+LinkNet attains the maximum accuracy of 0.935,

suggesting that it can successfully classify lung cancer cases. When examining the median statistical metric for LSTM+LinkNet and conventional methods in lung cancer classification, distinct performance profiles emerge. With an accuracy of 91.1%, the LSTM+LinkNet model demonstrates its consistency in achieving high levels of accuracy in categorizing lung cancer cases. The LSTM model, with an accuracy of 87.0%, showcases a consistent capability in classifying lung cancer. Similarly, LinkNet and SqueezeNet exhibit competitive performance, with accuracies of 86.4% and 86.9% respectively, suggesting their efficacy in this domain. However, PyramidNet's slightly lower accuracy of 83.9% indicates a comparatively moderate performance level, albeit still within an acceptable range. MobileNet mirrors LSTM's performance with a median accuracy of 87.0%, further highlighting its stability in lung cancer classification tasks.

TABLE II. STATISTICAL ASSESSMENT ON ACCURACY FOR LUNG CANCER CLASSIFICATION

Methods	Minimum	Maximum	Mean	Median	Standard Deviation
LSTM	0.814	0.880	0.858	0.870	0.027
SqueezeNet	0.811	0.905	0.863	0.869	0.035
PyramidNet	0.806	0.886	0.842	0.839	0.029
LinkNet	0.826	0.911	0.866	0.864	0.031
MobileNet	0.852	0.908	0.875	0.870	0.022
LSTM+LinkNet	0.868	0.935	0.906	0.911	0.026

G. Computation Time Analysis

Table III describes the computation time analysis on LSTM+LinkNet and conventional methodologies for lung cancer classification. The computation time examination offers valuable insights into the efficiency of various approaches for lung cancer classification. Among the evaluated methods, the LSTM+LinkNet stands out with the shortest computation time of 62.978s, demonstrating its ability to swiftly process and classify lung cancer cases. In comparison, the LSTM method requires 71.849s, LinkNet takes 78.374s, SqueezeNet demands 85.243s, PyramidNet consumes 92.117s, and MobileNet necessitates the longest computation time at 97.842s. This data suggests that the LSTM+LinkNet method offers notable efficiency gains in processing time compared to several other methods for expedited lung cancer classification tasks.

TABLE III. ANALYSIS ON COMPUTATION TIME

Methods	Computation Time(s)
LSTM	71.849
LinkNet	78.374
SqueezeNet	85.243
PyramidNet	92.117
MobileNet	97.842
LSTM+LinkNet	62.978

V. CONCLUSION

In this work, the proposed method presents a novel and effective approach for lung cancer segmentation and classification, addressing critical challenges in medical imaging analysis. The suggested framework combines a hybrid classifier that integrates LSTM and LinkNet for classification, an Improved SegNet architecture for segmentation, and Gaussian filtering for preprocessing to achieve high accuracy and robustness in identifying and classifying lung cancer nodules from CT images. The experimental results illustrate how well the suggested strategy performs in comparison to current methods, highlighting its potential to help clinicians with lung cancer patients' early diagnosis, treatment planning, and follow-up. With 90% training data, it reaches an accuracy of 0.935, the highest among all methods. LSTM has a specificity of 0.860, indicating its ability to correctly identify true negatives. LinkNet performs slightly better with a specificity of 0.870. SqueezeNet's specificity is 0.858, while PyramidNet's is 0.855, both closely trailing LinkNet. MobileNet outperforms these with a specificity of 0.889, demonstrating its proficiency in identifying true negatives. Notably, the LSTM+LinkNet model exceeds all conventional methods with a specificity of 0.901, highlighting its superior performance in correctly identifying true negatives in lung cancer classification tasks even with 60% of the training data. As the training data increases, the superiority of LSTM+LinkNet becomes more pronounced. With its promising results and significant contributions to the field of computer-aided diagnosis, the proposed method represents a valuable tool for improving patient outcomes and advancing research in lung cancer detection and management.

Abstract—Given the wide application of 3D model analysis, covering domains such as medicine, engineering, and virtual reality, the demand for innovative content-based 3D shape retrieval systems capable of handling complex 3D data efficiently have significantly increased. This paper proposes a new 3D shape retrieval method that uses the CatBoost classifier, a machine learning algorithm, to capture a unique descriptor for each 3D mesh. The main idea of our method is to get a specific and a unique signature or descriptor for each 3D model by training the CatBoost classifier with features obtained directly from the 3D models. This idea not only accelerates the training process, but also ensures the consistency and relevance of the data fed to the classifier during the training process. Once fully trained, the classifier generates a descriptor that is used during the indexing and retrieval process. The efficiency of our method is demonstrated by conducting extensive experiments on the Princeton shape benchmark database. The results demonstrate high retrieval accuracy in comparison to various existing methods in the literature. Our method's ability to outperform these methods shows its potential as highly useful tool in the field of content-based 3D shape retrieval.

Keywords—3D object retrieval; 3D shape retrieval; 3D shape matching; indexing; descriptor; CatBoost

I. INTRODUCTION

The creation and propagation of 3D models in the digital data processing field is one of the great achievements of information processing in the last decades, resembling earlier revolutions in text, image, or audio data. This expansion is largely powered by improvements in scanning and modelling technologies that have made these models more available and flexible in fields such as medicine, engineering, virtual reality, and computer-aided design among others. Consequently, 3D objects are widespread, not only in special professional domains, but also in everyday use since user-friendly modelling tools and the lower cost of 3D scanners or 3D printers are available. However, this proliferation brings forth a complex challenge: the fast and precise retrieval and analysis of 3D information. Unlike text or 2D image search, which are mature enough, 3D object retrieval is still at the development

stages, facing the complexities of processing and understanding the rich information stored in 3D models.

An efficient 3D retrieval system can be defined as an active query system that can reliably match user queries with similar models in a database. This similarity is computed based on a descriptor or a signature which is supposed to be a compact representation of the 3D model. Numerous approaches and strategies have been developed in recent years to address this issue, which generally implies the extraction of global or local geometric or topological features, either directly from the 3D object or its two-dimensional representations (projections, depth images, binary images). Once these features are obtained, they are transformed into a more compact form—a descriptor—which then acts as the main means of differentiating 3D models and may be used to determine the most similar models to a specific one.

Although many advances have been made in this area, as can be seen through the work of Lara López et al. [1], Yang et al. [2], and Tangelder et al. [3], who have extensively surveyed existing methods, offering insights into their performance and comparative analyses. However, the search for more accurate and human perception-oriented retrieval systems remains ongoing. Recently, attention has been directed toward employing various machine learning techniques to enhance the quality and efficiency of such systems. Most of these approaches rely on using features derived from 2D projections for their training process.

For example, studies such as [4], [5], and [6] use a convolutional neural network (CNN) trained on numerous 2D captures extracted from the 3D model. The CNN's objective is to classify the 3D model into its correct group. Finally, with CNN has been adequately trained, the author extracts a signature from the CNN which, in turn, corresponds to a descriptor of each 3D model. Generally, this kind of technique is highly effective and yield amazing results because machine learning methods are commonly competent enough to tackle classification problems with great accuracy. Meanwhile, the main issue of this method is the necessity for large-scale data for the training step. Each 3D model must be represented by

numerous 2D captures, which leads to two main issues: choosing the most representative 2D representations for each 3D model and the requirement for high-level computational resources to accomplish the process. Previous work [7] attempted to address this issue by employing an artificial neural network (ANN) trained on features extracted directly from the 3D model. This neural network was employed next for signatures extraction for 3D models.

In this work, this challenge is addressed by proposing a new method for 3D shape retrieval which is based on extracting a signature or a descriptor for 3D meshes using the CatBoost classifier. The extracted descriptor is then utilized in the search and retrieval process of 3D models. The key contributions of this study can be summarized as follows:

- **Novel 3D Model Indexing Method:** This study proposes a new method for indexing 3D models using the CatBoost classifier, which offers improved efficiency and performance compared to traditional techniques.
- **Optimal Representation of 3D Models:** The method represents 3D models using histograms of geometric properties, including dihedral angles, shape diameter functions, and shape index. This approach avoids the need for complex preprocessing steps commonly used in machine learning-based methods.
- **Efficient and Rapid Performance:** The proposed method demonstrates rapid performance and efficiency, requiring reduced data for training compared to traditional techniques.

This paper is structured as follows: Section II presents a review of various descriptors from existing literature. Section III details the proposed approach. Section IV outlines the results followed by a discussion in Section V. Finally, the conclusion in Section VI summarizes the findings and suggests potential future research directions.

II. RELATED WORK

For last couple of decades, the area of Content-based 3D model retrieval has attracted the attention of many researchers, which has also led to the development of lots of new techniques and approaches, aims to produce a result that closely aligned with human perception. Through these research studies it has been proven that the best solution to the content-based 3D model retrieval would be to have a compact descriptor that will represent the form of a 3D model (unlike traditional techniques such as textual representation). Proposed descriptors can be classifying into two main classes: view-based descriptors and 3D shape descriptors. The following section will present some of the most common methods within each category.

A. 3D Shape Descriptors

This category covers all the methods that use geometry/topological information extracted directly from any 3D representation (points cloud, polygon, voxel). For instance, Osada et al. [8] who suggested five different shape distributions for indexing 3D objects, based on the global geometric. They introduced characteristics such as lengths from the center of gravity to a surface point (D1), the distance

between two points (D2), the angles between three points (A3), the square root of the area of the triangle formed by three points (D3) and the cube root of the volume of the tetrahedron formed by four points (D4). After comparing the performance of the different distributions, the authors conclude that the D2 distribution performs best and gives better results. The D2 distribution consists of a histogram representing the shape signature of a 3D model by the distribution of Euclidean distances between pairs of points chosen randomly on the surface of the model.

The 3D shape spectrum descriptor (SSD) was introduced by Zaharia et al. [9] and has been recognized as a standardized descriptor in the MPEG-7 standard. The descriptor is based on the notion of shape index presented by Koenderink, the descriptor is computed as the histogram of shape index over the whole surface of the 3D mesh. Let P be a point on the surface of the 3D model, k_p^1 and k_p^2 are the principal curvatures, with $k_p^1 > k_p^2$, the shape index can be computed using the following formula:

$$IF_p = \frac{1}{2} - \frac{1}{\pi} \arctan \frac{k_p^1 + k_p^2}{k_p^1 - k_p^2} \quad (1)$$

The use of spherical harmonics as a descriptor for 3D objects was initiated by Funkhouser and Kazhdan [10], [11], [12] this technique consists of decomposing a spherical function into a sum of its harmonic coefficients, this descriptor has been defined for voxelised objects.

Our previous work [13] aimed to develop a novel descriptor capable of integrating multiple 3D features, rather than relying on a single feature. The Data Envelopment Analysis method (DEA) was employed to achieve this goal. This method was used to combine various features, the chosen features are the shape diameter function (SDF) [14] dihedral angle, and the shape index. The output is a new descriptor provided by DEA, which outperforms each of the individual features used separately.

A novel descriptor for 3D models using an artificial neural network (ANN) was proposed in study [7]. The proposed approach employs a neural network trained with many features extracted from the 3D model for a classification task. After training, the ANN is used to generate a descriptor for each 3D model in the database. This is achieved by extracting and combining the values returned by the neuron in the last hidden layer.

B. View-based Descriptors

The second category of descriptors is based on a simple principle: two 3D models are considered similar if they appear identical from all viewing angles. The main idea of this approach is to convert the problem from comparing 3D models to comparing 2D projections, by representing each 3D models by many 2D projections. This approach has the advantage of using powerful descriptors that are already available in the 2D field. The main drawback of these approaches lies in selecting the amount and the representative 2D views, since this choice can significantly impact the final results. Furthermore, it can also affect the performance of the descriptor; more projections

mean more comparisons, which in turn impacts the computing time.

Papadakis et al. [15] have proposed a novel indexing method based on panoramic views. These projections are generated by englobing the object in a cylinder and then projecting the 3D object onto the lateral surface of the cylinder parallel to one of its three main axes (generally Z) to generate panoramic views. Once these views have been extracted, the authors propose to use a combination of a Fourier transform and a discrete wavelet transform to describe each view.

LightField Descriptor, proposed by [16], [17] is a descriptor based on the 2D projections of a three-dimensional model. It characterizes a 3D model by a set of 10 orthographic views; the views are taken along the first 10 vertices of a dodecahedron centered on the model. A translational alignment process and scaling are applied as pre-processing to the 3D models before the views are generated. Finally, once the views have been generated, the authors propose the use of a descriptor combining 35 Zernike moments and 10 Fourier coefficients to describe the views.

Su et al. [5] proposed to use the power of machine learning to implement a 3D indexing method. They proposed a new approach based on 2D projections and convolutional neural networks, to classify 3D models into distinctive classes and then generate a signature based on this classification.

A more recent work, Labrada et al. [6] proposed a novel deep learning architecture for processing three-dimensional models that are based on representing 3D models with a set of image views. This architecture makes use of Convolutional Neural Networks (CNNs) and autoencoders to get embeddings for 3D models, instead of the regular view pooling layer approach.

III. PROPOSED WORK

Most indexing work in the literature is based on extracting a feature from a 3D model and using this feature in the form of a descriptor, or by utilizing 2D representations and then using indexing methods already available for the 2D field. In this work, the aim is to propose a novel indexing method based on the CatBoost classifier which uses properties extracted directly from the 3D object, without relying on intermediate representations (2D projection), Fig. 1 summarize this process. Our goal is to make our method as optimal as possible (in terms of response time and quality of results). The proposed method consists of creating a model capable of solving a 3D model classification problem, i.e. after the training phase our model must be capable of providing the appropriate class for each 3D object supplied. Finally, a unique descriptor is extracted by combining the values produced by the decision trees within the model, particularly during the concluding iterations of the classification process. This descriptor will then be used to represent the 3D object in the indexing and content retrieving process. The remainder of this section provides a brief overview of the CatBoost Classifier and presents the used features.

A. CatBoost Classifier

CatBoost, is an innovative gradient boosting decision tree (GBDT) algorithm, was introduced by Yandex in 2017 and further elaborated in following publications by Dorogush et al. [18], and Prokhorenkova et al. [19]. This advanced machine learning model addresses critical limitations of previous algorithms, particularly in handling categorical data and avoiding model overfitting. CatBoost stands out due to its balanced tree construction approach, a feature that enhances its overall efficiency and accuracy in various predictive modeling scenarios.

The theoretical foundation of CatBoost is based on the well-known integrated learning also called ensemble learning, which combines multiple weak classifiers to form a stronger, more accurate classifier through iterative processes, where each iteration is based on the previous one to correct the prediction. This approach was introduced by Kearns et al. in 1989, and was used by various algorithms such as Adaboost, and Light GBM [20]. CatBoost advances these methods by refining the iteration and gradient descent mechanisms, enabling the generation of superior classifiers through the effective fusion of weaker ones.

One of the core features that gives CatBoost a considerable advantage over other supervised algorithms is the way it processes categorical variables, which is generally a problem in many machine learning models. Unlike traditional techniques that involve many preprocessing steps before starting the model training to treat categorical variables, CatBoost was developed especially for quickly converting categorical data to numerical format during training, which speeds and simplifies the modeling process. Such ability does not only save preprocessing time but also it significantly increases model performance through working with categorical data without the need of adding more pre-treatment steps. Furthermore, CatBoost incorporates unique strategies to reduce overfitting, a common pitfall in many gradient boosting models. This is done by using a symmetric tree structure and refined leaf-value calculation method which make the model more robust and generalizable.

When it comes to the computational speed and accuracy, CatBoost shows great efficiency. It uses parallelism which not only enable faster training, but also make it a preferable choice for large-scale and time-sensitive applications [21], [22], [23], [24], [25], [26], [27], [28]. This efficiency stands out particularly when it comes to adopting a model where the fast response time is imperative.

To sum up, CatBoost stands out as one of the most powerful and practical gradient boosting algorithms, presenting advantages like dealing with categorical data, avoiding overfitting, and delivering high computational performance. All these advantages, makes it a preferred choice for various machine learning applications, and this is what influenced our choice for CatBoost in this work.

B. Features

This work aims to develop an indexing method capable of integrating multiple geometric and/or topological properties, regardless of their specific type or order.

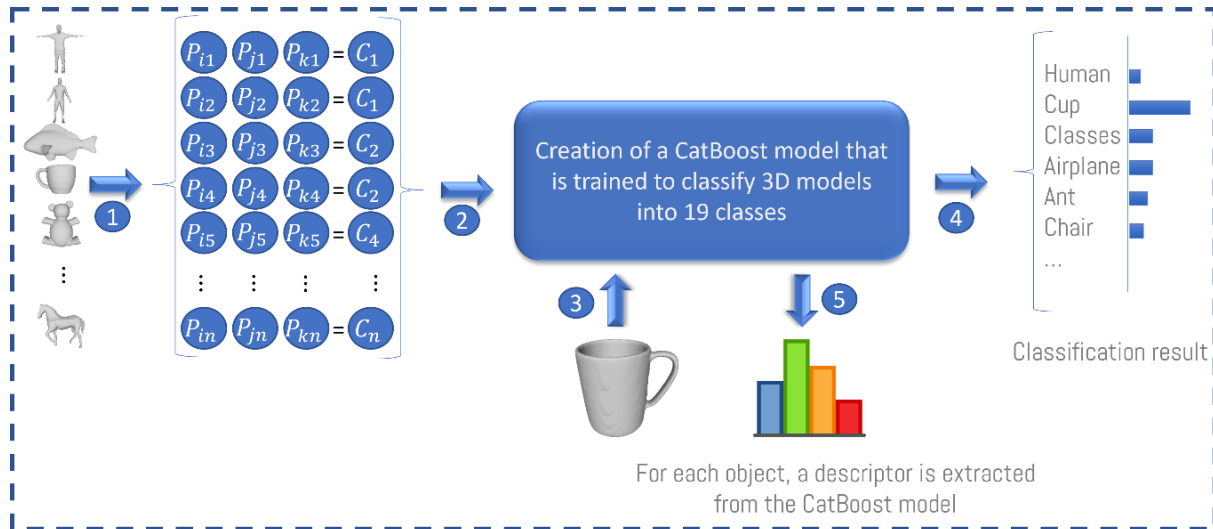

Fig. 1. Process of the proposed method.

The aim is to create a hybrid descriptor that combines these properties and benefits from their advantages. To achieve this goal, three histograms of properties extracted from the 3D object were combined. These properties include:

Dihedral angle: The dihedral angle is one of the best-known features that is widely used in 3D [29], it is defined as the angle between two adjacent faces.

The dihedral angle between two faces f_i and f_j is calculated as follows:

$$\theta(f_i, f_j) = \arccos\left(\frac{\text{dot}(\vec{u}, \vec{v})}{|\vec{u}| \times |\vec{v}|}\right) \quad (2)$$

\vec{u} and \vec{v} are respectively the normal vector of face f_i and f_j . $|\vec{u}|$ represents the norm of vector \vec{u} . Finally, each face is assigned the average angle between the current face and all adjacent faces.

Shape Diameter Function SDF [14] is described as a scalar function defined on the mesh representing its volume or thickness. It computes a measure of the volume of the neighborhood at each vertex of the 3D mesh. The computation of SDF involves directing a cone from each point towards the interior of the 3D mesh and subsequently projecting multiple rays to the opposite side of the mesh. The total length of all rays is then aggregated.

Shape index: First proposed by Koenderink, the shape index is a value which correspond to the topology of the local surface using the main curvatures. It is calculated as follow:

$$s = \frac{2}{\Pi} \arctan\left(\frac{k_2 + k_1}{k_2 - k_1}\right) \quad (3)$$

With k_1 and k_2 representing the main curvatures ($k_2 \geq k_1$). Note that this index is not defined for flat areas ($k_2 = k_1$). This index is widely used in segmentation and has already been used in the indexation of 3D meshes [9].

These properties were chosen for their simplicity (being easy to calculate), their invariance to the various transformations that a 3D model can undergo, and for their discriminating power. All these measures have already been used, (independently) as descriptors for 3D models.

IV. EXPERIMENTAL RESULTS

The fourth section of this paper focuses on experimental studies. These studies include tests to validate and demonstrate the discriminative power of the proposed approach. Results are compared to well-established methods, including Panorama [15], LightField [17], and previous methods proposed by the authors based on DEA [13] and ANN [7]. For these experiments, our choice went to use the Princeton's benchmark database [30]. This database contains 390 3D models divided into 19 classes (Airplane, Table, Human, Cup, Glasses, Ant, Chair, Octopus, Teddy, Hand, Plier, Fish, Bird, Armadillo, Bust, Mech, Bearing, Vase, and Fourleg). Our choice is motivated by the diversity of the models and the fact that many models from different classes share similar geometric aspects even if they are semantically not similar, for instance, birds and airplanes, or humans and armadillos, which will present a challenging task for detection in the retrieval process.

The evaluation begins with a classic test, computing the precision and recall graph. The recall metric quantifies the proportion of relevant results retrieved from the total number of relevant items in the database, while the precision metric assesses the fraction of relevant results within the set of retrieved instances.

$$\text{Recall} = \frac{\text{relevant correctly retrieved}}{\text{all relevant}} \quad (4)$$

$$\text{Precision} = \frac{\text{relevant correctly retrieved}}{\text{all retrieved}} \quad (5)$$

Fig. 2, illustrating recall and precision, demonstrates that the proposed method, based on the CatBoost classifier, outperforms other methods by providing the best results.

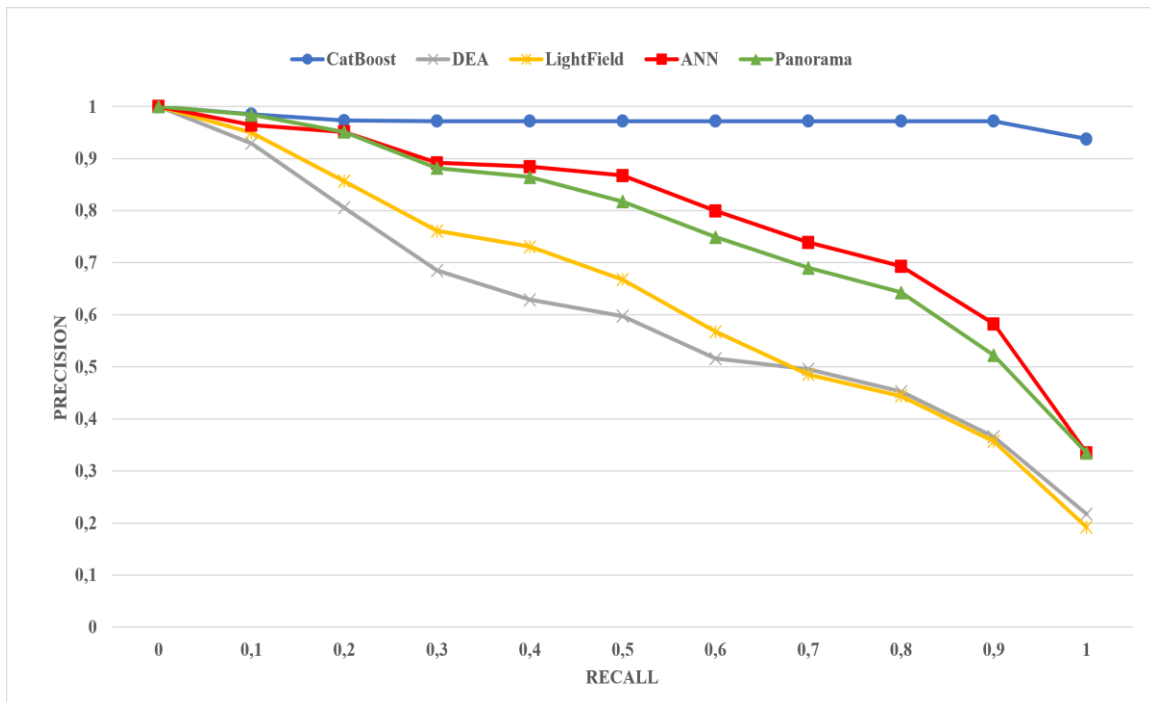

Fig. 2. Precision-Recall graph comparing four different descriptors with the proposed method.

Followed by the ANN, Panorama descriptor, LightField and finally the descriptor based on the DEA.

A second test involves evaluating the method using several metrics, which are:

- Nearest Neighbor (NN): This metric corresponds to the percentage to which the first model found (the most similar to the query) belongs to the query class. This statistic gives an indication of how well a nearest neighbour classifier would perform. Obviously, an ideal score is 100%; high scores are considered good results.
- First Tier (FT) & Second Tier (ST): computes the recall for the top $C-1$ and $2*(C-1)$ successfully retrieved objects from the results, where C represents the number of items in each class.
- Discounted Cumulative Gain (DCG): This is a statistical measure which consists of aggregating the contributions of all the models in the database, with weights depending on the rank of the models returned.

The contribution of the k th model returned, noted G_k , is equal to 0 if this model does not belong to the query class, and is equal to $\frac{1}{\log_2(k)}$ in the opposite case.

- F-Measure: The F-Measure, also known as the F-Score or F1 Score, is a statistical measure that computes the balance between precision and recall, which are both critical factors in the evaluation of retrieval methods. The F-Measure is the harmonic mean of precision and recall and is defined as follows:

$$F\text{-Measure} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (6)$$

Table I presents the obtained results alongside those of the following methods: PANORAMA, LightField, ANN and DEA. The results are consistent with those obtained from our first test; Observation shows that the proposed method consistently achieves the highest values across all metrics. ANN and PANORAMA follow, both demonstrating good performance. Conversely, LightField and DEA exhibit comparatively lower scores across all metrics.

The upcoming test will evaluate our method's efficacy across different classes within the used database. Performance evaluation will be conducted by measuring the proposed method's effectiveness based on the top K returned results. The mean for each category will be computed, with K set to both 10 and 20 (given that each category contains 20 items). Fig. 3 and Fig. 4 display the obtained results. From the first figure ($K = 10$), it is evident that the proposed method exhibits a stable performance across all categories, with scores ranging from 0.8 to 1. The ANN and Panorama method also shows commendable performance across most classes. However, it does experience significant drops in categories such as octopus, vase, bird, and hand. Both LightField and DEA exhibit a greater variability in their results, with LightField generally outperforming DEA. In the second figure ($K = 20$), the proposed method maintains excellent performance across all classes. This level of consistency is not observed in the other methods, which demonstrate greater variability between classes.

TABLE I. PERFORMANCE COMPARISON USING THE PROPOSED APPROACH, PANORAMA, LIGHTFIELD, ANN AND DEA

DESCRIPTORS / METRICS	NN	NN+1	1 st Tier	2 nd Tier	DCG	F-Measure
CatBoost	0.98	0.97	0.96	0.52	0.98	0.45
Panorama	0.97	0.92	0.73	0.43	0.92	0.42
LightField	0.91	0.84	0.57	0.36	0.86	0.38
DEA	0.83	0.74	0.53	0.35	0.82	0.36
ANN	0.95	0.93	0.80	0.45	0.86	0.38

Fig. 3. The results for the top K returned results with K = 10.

Fig. 4. The results for the top K returned results with K = 20.

The aim of the final test is to provide an overall view of the performance of our methods over the entire database. A dissimilarity matrix is generated by calculating the dissimilarity between all possible pairs of 3D objects within the database. The matrix generated is a square, symmetrical matrix and can be divided into 19x19 blocks (for 19 classes). A robust indexing method should have a low dissimilarity score in the

diagonal blocks, which implies high similarity between objects of the same class and high dissimilarity between objects of different classes. Fig. 5 show the results obtained for each method. From these results it can be seen that our proposed method provided the best results with a low dissimilarity score for the diagonal blocks (between 0 and 0.2), and rather high scores elsewhere (between 0.75 and 1). A comparison with

other methods reveals that the proposed method uniquely maintains a low dissimilarity between similar objects (within the same class) and a high dissimilarity between dissimilar

objects (different classes). This distinction is evident in the dissimilarity matrix, where the proposed method is the only one exhibiting a clearly visible diagonal.

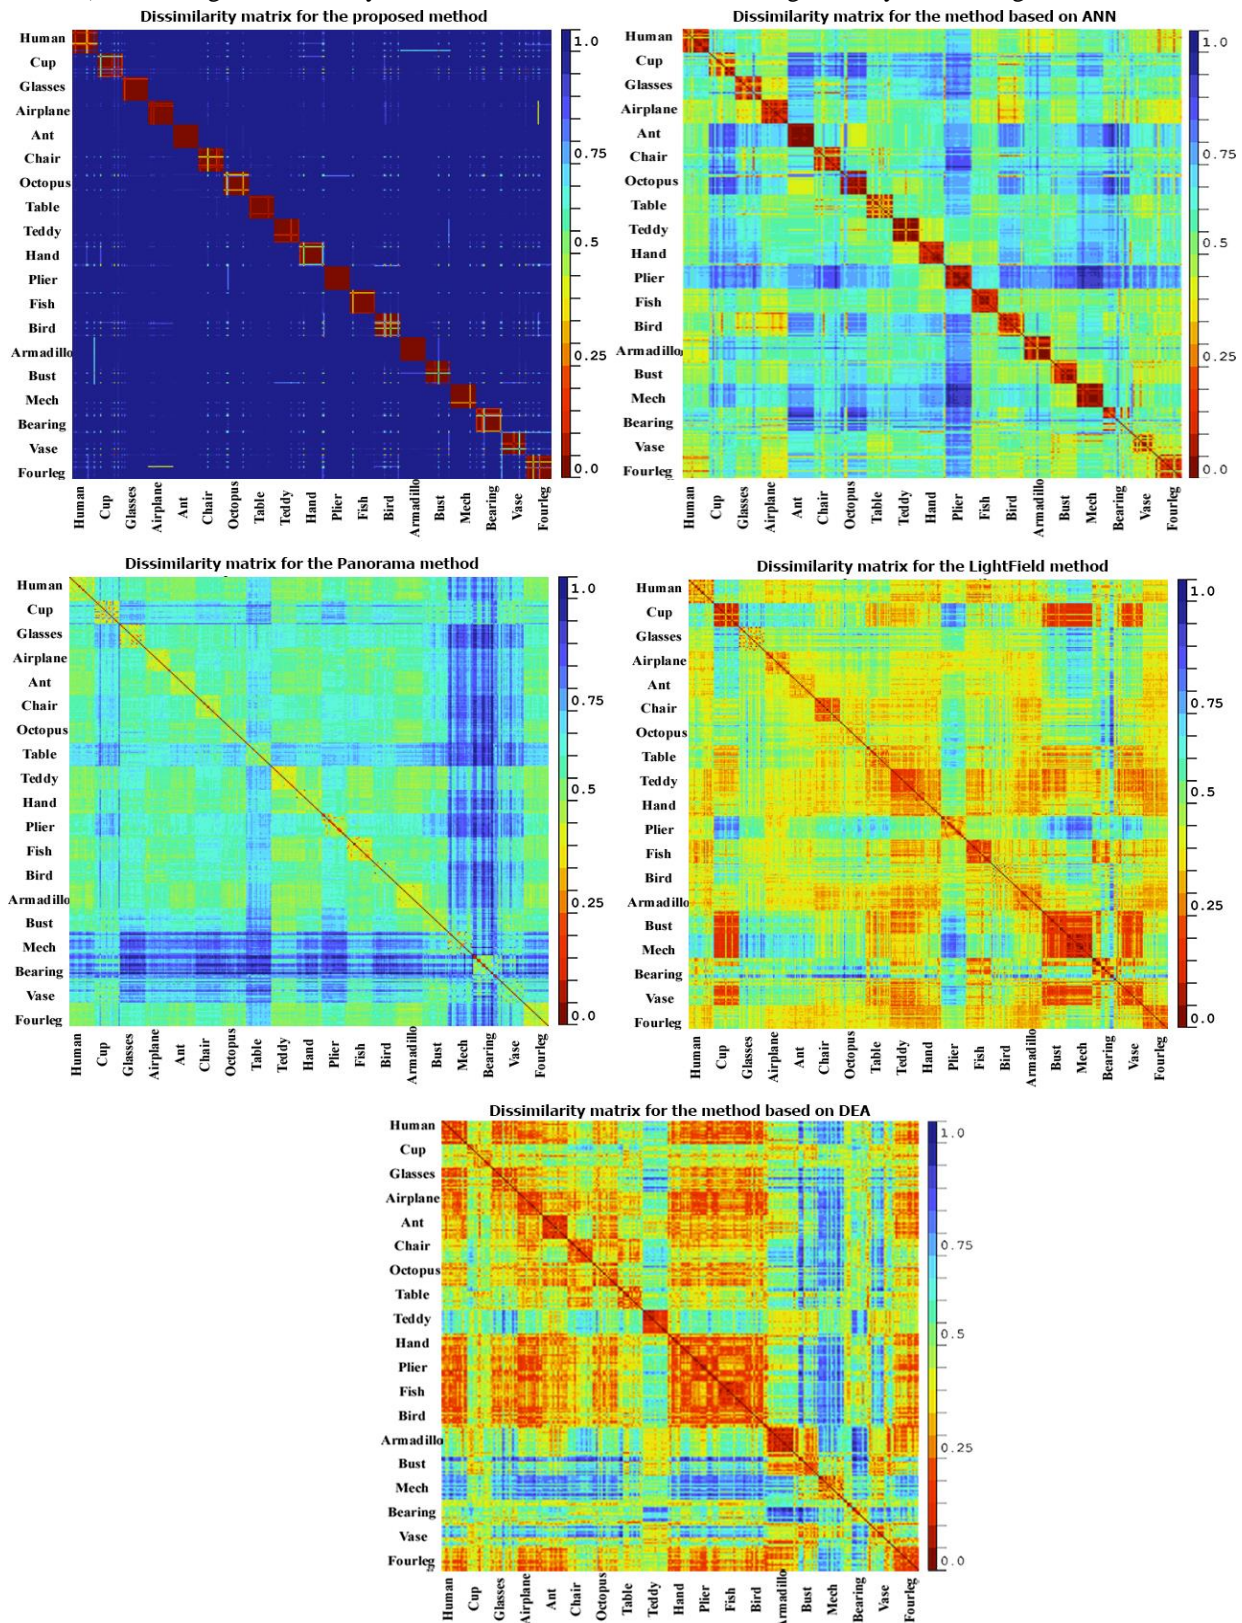

Fig. 5. Dissimilarity matrix for the proposed approach, ANN, PANORAMA, LightField and DEA.

V. DISCUSSION

The experimental analyses illustrated in this paper show that our method, enhances the precision of 3D shape retrieval remarkably. In comparison to other well-established approaches such as Panorama, LightField, ANN, DEA our method consistently outperforms across multiple evaluation metrics.

The obtained results are in line with existing research demonstrating the potential of machine learning algorithms for 3D shape retrieval. While methods like as [4], [5], and [6] employ CNNs trained on 2D projections, our approach uses CatBoost with features extracted directly from 3D models. This avoids the need for extensive 2D representations and associated computational expenses. Analysis of the previous tests reveals the following main strengths of the proposed method:

- **High Retrieval Accuracy:** The use of the proposed method results in a better performance in various measures such as the NN, FT, ST, DCG, and F-measure which indicates better retrieval performance compared to existing methods.
- **Stable Performance across Classes:** The method maintains consistent classification accuracy across each of the classes present in the Princeton shape benchmark database, suggesting its application to a variety of other 3D databases.
- **Robust Dissimilarity Matrix:** The dissimilarity matrix analysis showcases the proposed method's ability to effectively differentiate between similar and dissimilar objects, highlighting its discriminative power in distinguishing between objects belonging to the same/different classes.
- **Efficiency and Simplicity:** The proposed method avoids complex preprocessing steps and uses features extracted directly from the 3D models, leading to a simplified and efficient approach compared to methods relying on 2D projections.

In conclusion this paper presents a novel and effective approach for 3D shape retrieval using the CatBoost classifier. The proposed method offers high retrieval accuracy, stable performance across different classes, and a robust dissimilarity matrix analysis, highlighting its potential for practical applications.

VI. CONCLUSION

This paper proposes a novel 3D shape retrieval method, using the CatBoost classifier to construct a unique and efficient descriptor for 3D models. Contrary to traditional methods that require huge data and powerful computational resources, our approach eliminates such needs by extracting features directly from the 3D objects and not using 2D projections. The ability and power of our method have been proven to be much stronger and better than others, based on the experiments conducted on the Princeton shape benchmark dataset.

The proposed method, has shown better results than the other methods in retrieval accuracy, as is clear from the high

scores in different scalar metrics. In addition, our approach demonstrated that it can retain stable and high performance in various classes, as shown by results retrieved on top K returned results. Its discriminative power was reflected in its consistent accuracy for all classes. The final test, which was based on the dissimilarity matrix, revealed that the proposed method is robust in identifying similar and dissimilar objects. This validates the efficiency of our method as an efficient means of 3D shape retrieval, meeting the requirements for fast and exact 3D data analysis.

Future work will explore the integration of the CatBoost-based descriptor and machine learning techniques to enhance efficiency and adaptability. Furthermore, the application of our method for bigger and more diverse databases is intended. Such extension can open up the possibility of dealing with a variety of real-world 3D model analysis problems.

ACKNOWLEDGMENT

The authors express their gratitude to George Ioannakis and colleagues [31] for the access to their online platform (<http://retrieval.ceti.gr/>), which greatly facilitated the evaluation of our method.

YOLO-T: Multi-Target Detection Algorithm for Transmission Lines

Shengwen Li, Huabing Ouyang, Tian Chen, Xiaokang Lu, Zhendong Zhao
School of Mechanical Engineering, Shanghai Dianji University, Shanghai 201306, China

Abstract—During UAV inspections of transmission lines, inspectors often encounter long distance and obstructed targets. However, existing detection algorithms tend to be less accurate when trying to detect these targets. Existing algorithms perform inadequately in handling long-distance and occluded targets, lacking effective detection capabilities for small objects and complex backgrounds. Therefore, we propose an improved YOLOv8-based YOLO-T algorithm for detecting multiple targets on transmission lines, optimized using transfer learning. Firstly, the model is lightweight while ensuring detection accuracy by replacing the original convolution block in the C2f module of the neck network with Ghost convolution. Secondly, to improve the target detection ability of the model, the C2f module in the backbone network is replaced with the Contextual Transformer module. Then, the feature extraction of the model is improved by integrating the Attention module and the residual edge on the SPPF (Spatial Pyramid Pooling-Fast). Finally, we introduce a new shallow feature layer to enable multi-scale feature fusion, optimizing the model detection accuracy for small and obscured objects. Parameters and GFLOPs are conserved by using the Add operation instead of the Concat operation. The experiment reveals that the enhanced algorithm achieves a mean detection accuracy of 97.19% on the transmission line dataset, which is 2.03% higher than the baseline YOLOv8 algorithm. It can also effectively detect small and occluded targets at long distances with a high FPS (98.91 frames/s).

Keywords—Transmission line inspection; contextual transformer; attention mechanism; ghost convolution

I. INTRODUCTION

Given their role as the main channel for transmitting electricity from power plants to consumers, the importance of transmission lines cannot be overlooked. Conducting timely inspections to detect defects and other problems is crucial to improving line operation safety, extending service life, and reducing the incidence of accidents [1, 2]. With the construction of the smart grid in full swing, the length of overhead transmission lines is increasing. As the demands for intelligent transmission line inspections continue to increase, drones are increasingly replacing manual labor for these inspections [3–5]. However, a large number of images collected by UAV inspection are mainly inspected manually or using traditional image processing techniques, which are inefficient and have poor detection accuracy [6, 7]. With the development of Double-stage detection strategies represented by the R-CNN series [8–10] and Single-stage object detection methods represented by SSD [11] (Single Shot Multi-Box Detector) and YOLO [12–17] (You Only Look Once), the problems of traditional algorithms, such as slow speed and

weak robustness, have been solved, providing a new approach for UAV inspection [18].

To achieve a lightweight network and facilitate model deployment on embedded platforms [19], Han et al. [20] proposed an improved Tiny-YOLOv4 for insulator aerial image detection and damage recognition. By incorporating ECA-Net into the multi-scale feature fusion layer, the complexity of YOLOv4 is simplified, balancing detection speed and accuracy. Qiu et al. [21] employed a lighter MobileNets network in place of CSPDarkNet53 in the YOLOv4 model and adjusted the width multiplier in the bi-directional Path Aggregation Network (PANet) for network lightweighting. Based on the YOLOv5 network, Li et al. [22] used BiFPN (bi-directional feature pyramid network) to replace the original PANet to improve feature fusion capability, and used DIoU to substitute the initial CIoU loss function. Through sparse regularization, the scaling factor is used to filter out unimportant channels and prune them. Subsequently, the model's detection accuracy is restored to its prepruning level through secondary training. Although these studies primarily focus on insulators and their defects, they overlook common issues such as the detection of small and occluded targets. Kang et al. [23] introduced an algorithm for detecting multiple defects in insulators by combining a weighted bidirectional feature pyramid (CAT-BiFPN) with an attention mechanism. Despite the model's performance on small targets is improved by constructing a new CAT-BiFPN, adding and subtracting new detection layers and adding a hybrid module of attention and convolution, the mAP is only 93.9%, which still has room for improvement. Moreover, the high parameter count of the model hinders its detection speed.

In response to these challenges, this paper presents a lightweight YOLO-T algorithm for multi-target detection on transmission lines. To enhance the precision and speed of algorithm detection, the following aspects need to be addressed:

- 1) To achieve lightweighting of the model and improve its detection efficiency, Ghost convolution should replace ordinary convolution in the C2f module of the neck network.
- 2) To enhance the backbone network's proficiency in extracting critical features, the following measures should be taken: replace the C2f module with the Contextual Transformer feature extraction module, introduce the SE attention module, optimize the structure of the SPPF, and implement other optimization measures.

3) To elevate the model’s performance in identifying small and hidden targets, additional measures are required such as adding a new shallow feature layer for combining multi-scale features to boost the neck network and other relevant methods.

II. PROPOSED METHOD

In January 2023 Ultralytics released the YOLOv8 algorithm on GitHub [24], and its network structure follows the previous network structure of YOLOv5, which still includes four parts: Input, Backbone, Neck and Head. Specifically, the Input part mainly adopts Mosaic data enhancement, adaptive anchor frame computation and adaptive gray scale filling, etc. The Backbone part is the backbone network, which mainly composed of Conv, C2f, and SPPF modules. YOLOv8 initially replaced the C3 module with the C2f module. By using more branches connected across layers, the gradient flow of the model is enriched to form a neural network module with superior feature expression capability. The neck section aims to enhance the feature extraction network, and still adopts the FPN-PANet structure to strengthen the network’s ability to blend features from varying scales. Head is used as the classifier and regressor of YOLOv8, which decouples the classification and detection processes separately. Meanwhile, the anchor-based approach is replaced by an anchor-free approach. These improvements and optimizations allow the YOLOv8 algorithm to show better performance and accuracy in identifying targets.

YOLOv8 divides the detection network into five versions: n, s, m, l and x according to the dimensions of the network’s width and depth. The application in this paper requires a more lightweight model, so this experiment utilizes YOLOv8n as the base model. Although the YOLOv8 algorithm incorporates many new improvements and has made great progress in target detection, it has greatly increased the detection difficulty due to the small target of transmission line inspection, the complex background and the frequent problem of the detection target being obscured. Therefore, to enhance the detection precision and efficiency for long-distance small targets and obscured targets, this study proposes a YOLO-T transmission line multi-target detection model based on the improved YOLOv8, whose network structure is shown in Fig. 1.

As depicted in Fig. 1, in the section of the backbone network, the C2f module is substituted by the Contextual Transformer module for feature extraction purposes, and the SE Attention module is added after it. At the same time, the SPPF structure is optimized to construct the SPPF-C module, to augment the backbone network’s feature extraction capabilities for key features. Within the neck network, C2f-G lightens the feature extraction module and replaces the Concat operation with the Add operation to achieve model lightness and enhance detection efficiency. Finally, the PANet-Z multi-scale feature fusion module is constructed by adding new shallow feature layers to enhance the model’s capability to detect small-sized targets and objects obscured by occlusion.

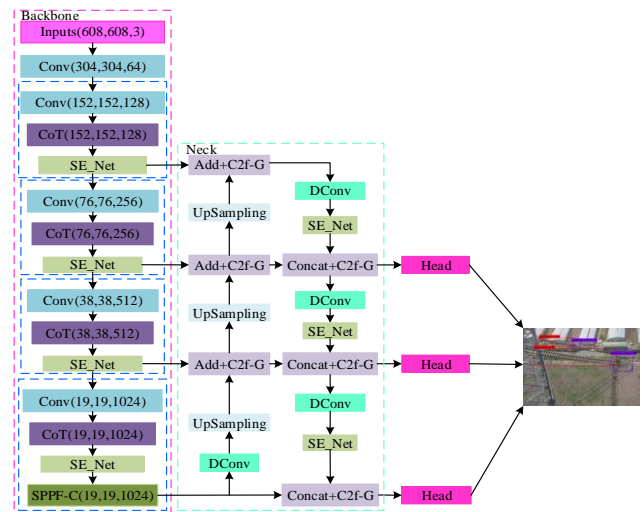

Fig. 1. Structure of the YOLO-T network.

A. C2f-G Lightweight Feature Extraction Module

Although YOLOv8n is a more lightweight model, for embedded devices, further lightweighting of the network is still required to achieve a higher detection speed. The C2f module, as an important part of the YOLOv8 network, can be optimized to achieve the lightweighting of the model. Therefore, the ordinary volume in the C2f module in the neck network is replaced with Ghost Convolution [25] (GConv), and the product constructs the C2f-G module to decrease the model’s parameter count and computational overhead. Its structure is shown in Fig. 2.

Fig. 2. C2f-G module.

Initially, ghost convolution employs a small set of convolution kernels to extract features from the input feature maps, then performs cheaper linear transformation operations on some of the extracted feature maps, and finally generates the final feature maps through splicing operations. By this method, the model’s demand for computational resources is effectively reduced, while accurate feature extraction of the input feature maps is realized. The input feature layer is normally convolved to generate an $m \times H \times W$ feature layer. Taking the Ghost convolution with $m \cdot (s - 1) = C'(s - 1) / s$ $d \times d$ linear kernels as an example, in order to complete a feature maps, each feature needs to be cheaply linearly transformed once to get s “phantom” feature maps, where $C' = m \times s$, $d \times d \ll D_k \times D_k$, $s \ll C$. The structure of ordinary convolution and Ghost convolution is shown in Fig. 3.

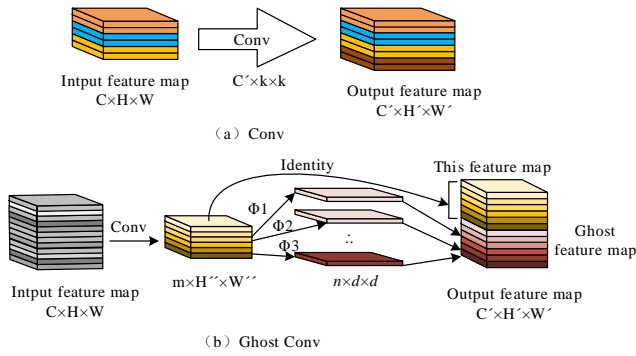

Fig. 3. Traditional Convolutional and Ghost Convolutional. Fig. 3(a) represents the traditional convolution module, while Fig. 3(b) represents the Ghost convolution module.

In Fig. 3, the input feature layer of convolution is $C \times H \times W$, the output feature layer is $C' \times H' \times W'$, and the convolution kernel size is $k \times k$, where C, H, W specify the input feature map's number of channels, height, and width, and C', H', W' denote the number of channels, height, and width of the output feature map, respectively. The formulas for the number of parameters and GFLOPs for Traditional Convolution and Ghost Convolution are shown in Eq. (1)–(4).

$$P_c = C \times C' \times k \times k \quad (1)$$

$$U_c = C \times k \times k \times C' \times H' \times W' \quad (2)$$

$$P_g = C \times m \times k \times k + m \times n \times d \times d \quad (3)$$

$$U_g = k \times k \times C \times H' \times W' \times m + H' \times W' \times m \times d \times d \times (s-1) \quad (4)$$

where, P_c, U_c are the parameters and the computational burden associated with traditional convolution. P_g, U_g are the number of parameters and GFLOPs amount of Ghost convolution, respectively. According to the above formula, the ratio of the number of parameters and GFLOPs amount of Ghost convolution to ordinary convolution can be calculated as:

$$\frac{P_g}{P_c} = \frac{m}{C'} + \frac{m \times n \times d \times d}{C \times C' \times k \times k} \approx \frac{m}{C'} = \frac{1}{s} \quad (5)$$

$$\frac{U_g}{U_c} = \frac{1}{s} + \frac{s-1}{Cs} \cdot \frac{dd}{kk} \approx \frac{1}{s} \quad (6)$$

Here, it can be seen that the ratio of the quantity of parameters and GFLOPs obtained from the traditional convolution to the Ghost convolution is inversely proportional to the count of phantom feature maps, i.e., as the number of the Ghost feature maps increases, Ghost Convolution requires fewer parameters and GFLOPs than Traditional Convolution. The quantity of parameters and GFLOPs is minimized when traditional convolution is skipped and linear operations are directly used to generate the Ghost feature maps.

B. CoT Feature Extraction Module

Transformer structures with self-attention have sparked a revolution in the realm of natural language processing, and have achieved outstanding results in multiple computer vision tasks over the past few years. Nevertheless, the majority of current designs employ self-attention directly on 2D feature maps to acquire attention matrices from isolated query-key pairs at every spatial position, thereby missing the opportunity to leverage the abundant contextual information among adjacent key pairs. In contrast, the CoT (Contextual Transformer) [26] module is a novel Transformer style module that can efficiently address the aforementioned issue. The module structure of CoT is shown in Fig. 4.

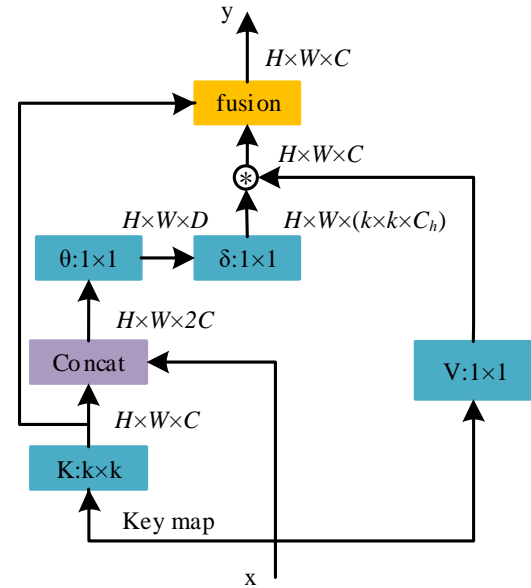

Fig. 4. Contextual Transformer module.

As shown in Fig. 4, the CoT module first encodes the input keys by contextualizing the convolution to obtain a static contextual representation of the input. The encoded keys are then further connected to the input query through two successive convolutions to learn the dynamic multi-head attention matrix. The learned attention matrix is then multiplied by the input values to realize the dynamic contextual representation of the input. Finally, the result of the fusion of static and dynamic contextual representations is used as the final output. In this design, the utilization of contextual information between input keys guides the learning process of the dynamic attention matrix, leading to enhanced visual representation. Therefore, in the backbone network, the C2f module is substituted with the CoT module.

C. SE Attention Module

Deepening of the network layers will lead to partial loss of texture information and contour information of small targets such as insulators at longer distances, which will lead to poor detection of the model. To address the above problems, this article adds a Squeeze-and-Excitation Networks (SE) [27] behind the effective feature layer of the backbone network and down-sampling of the neck network to highlight the key

characteristics and weaken irrelevant information, to improve the characterization capacity of the network and improve the model's ability to detect small targets at a long distance. The SE Attention Module is depicted in Fig. 5.

Fig. 5. SE attention module.

The importance of each channel is automatically learned by SE, and enhances the significant features and suppresses the non-significant features according to the importance. To confirm the effectiveness and superiority of the SE attention module added in this paper, the Efficient Channel Attention (ECA) [28] and Convolutional Block Attention Module (CBAM)[29] are inserted into the effective feature layer of the backbone network and behind the down-sampling of the neck network, respectively. Experiments were performed, and the results are displayed in Table I.

TABLE I. EXPERIMENTAL RESULTS OF DIFFERENT ATTENTION MECHANISMS

Attention Module	AP (%)				mAP (%)
	Insulator	Defect	Nest	Grading	
SE	93.97	98.15	95.69	97.20	96.25
ECA	94.21	97.73	95.22	96.72	95.97
CBAM	92.42	97.93	94.78	96.63	95.44

The results in Table I indicate that the inclusion of the SE attention module produces the optimal detection performance. Faced with the four types of detection targets studied in this paper, the AP values of the other three types of targets with the addition of the SE attention module are the highest except for the insulators, and the mAP value reaches 96.25%, which proves the effectiveness of the SE attention module.

D. SPPF-C Module

The SPPF module enhances the model's detection accuracy by applying pooling operations to feature maps of various scales, without altering their size. In this paper, to achieve an even greater level of detection accuracy with the model for the targets to be detected on transmission lines, we introduce a separate convolutional structure based on the SPPF structure and stack it with the results after the SPPF processing. The structure of the improved SPPF-C network is illustrated in Fig. 6.

E. PANet-Z Multiscale Feature Fusion Module

To maximize the use of shallow and deep semantic features, this article designs a PANet-Z feature fusion structure to improve the effectiveness of the model in detecting small and occluded targets at long range. The original PANet structure achieves channel information fusion by stacking two feature maps using the Concat operation to obtain rich semantic features. However, this operation increases the

dimension of the feature maps, leading to an increase in computation. In neck networks, whose input feature maps are provided by the backbone feature extraction network, semantic information with high similarity already exists, so in this paper, we utilize the Add operation in place of the Concat operation to save parameters and GFLOPs. In order to enable the Add operation, we use a depth-separable convolution to downscale the 1024×1024 feature layer, and also need to adjust the input and output dimensions of the neck C2f module. The PANet-Z structure is shown in Fig. 7.

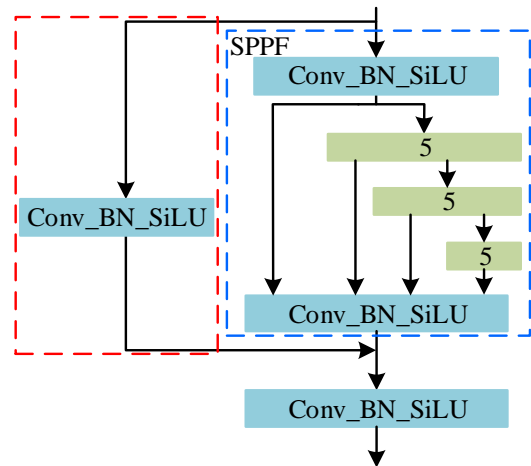

Fig. 6. SPPF-C module.

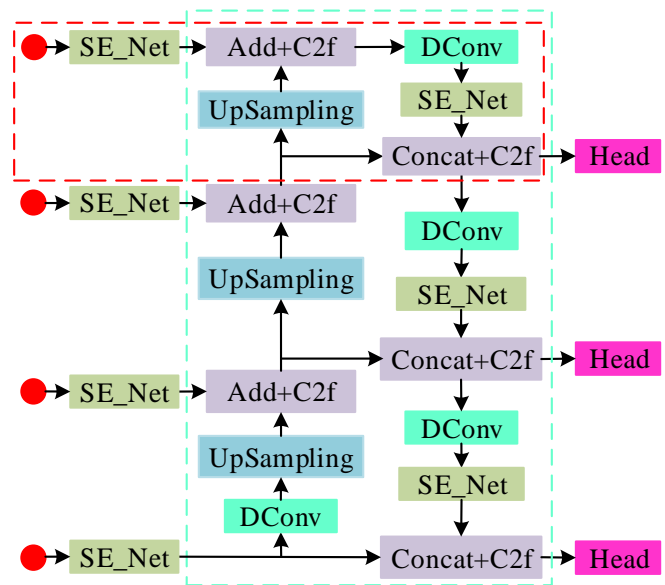

Fig. 7. PANet-Z module.

III. EXPERIMENTAL PREPARATIONS

A. Experimental Environment

The experiments described in this paper utilize the 64-bit Windows 10 operating system, the CORE i5 12490F processor, the RTX 3060 12GB graphics card model, with CUDA11.7 and cudnn8.8.0.121. Using Python3.9.7 programming language, PyTorch2.0 environment of the deep learning

framework, selecting Anaconda3 to configure the development environment and use PyCharm for development.

B. Datasets

In this paper, we study four detection targets, namely, transmission line insulators, insulator defects, voltage equalizing ring dataset, and bird nests in transmission line towers, which are locally enlarged as depicted in Fig. 8.

Fig. 8. Detect the target instance. (a) insulator; (b) insulator defect; (c) nest; (d) grading.

There are a total of 1308 images for the four detection targets in Fig. 8, some of which are from the publicly available Chinese Power Line Insulator Dataset [30], and some are images collected online. Because the number of labels for bird nest and insulator defects is small, only 568 and 843, and the defect samples are not balanced, the images containing the labels for bird nest and insulator defects are selected to expand them. By modeling different weather conditions, setting different exposure values and other operations to expand the data set, a total of 3239 images were generated, and the number of each label after expansion is shown in Table II. In the dataset, 20% of the images are randomly chosen to be tested at a later stage, while the remaining 80% are utilized for model training.

TABLE II. NUMBER OF VARIOUS LABELS IN THE DATASET

Label Types	Number of Original Labels	Number of Labels after Expansion
insulator	1935	3540
defect	845	2601
grading	1483	2785
nest	568	2576
total	4831	11,502

C. Evaluation Metrics

The criteria for experimental evaluation are mainly precision (P), recall (R), average precision (AP) and mean average precision (mAP) for each type of target. Precision evaluates the fraction of accurately predicted positive samples out of all samples predicted as positive, Recall is determined by the proportion of accurately predicted targets among all targets. mAP represents the mean of the AP values across classes, with a range between 0 and 1. A greater mAP signifies

superior model performance. The calculation formula is specifically outlined as follows:

$$P = \frac{T_p}{T_p + F_p} \quad (7)$$

$$R = \frac{T_p}{T_p + F_N} \quad (8)$$

$$AP = \int_0^1 P(R) dR \quad (9)$$

$$mAP = \frac{\sum_{i=1}^n AP_i}{n} \quad (10)$$

where: TP represents the count of samples identified as positive by the model that are indeed positive samples themselves; FP is the count of samples that the model identifies as positive samples that are themselves negative samples; FN signifies the quantity of samples identified as negative by the model, which are false negative samples; n signifies the total count of classifications; and AP_i is the AP value of the class i label.

D. Setting of Model Parameters

During the training process, transfer learning is employed to expedite model convergence and achieve improved accuracy. The training input image resolution is 608×608 , the Adam optimizer is employed with an initial learning rate of 0.01, and cosine annealing is utilized to decay the learning rate. A total of 200 epochs are dedicated to training the model, with the freezing training epoch set to 50, and utilizing a batch size of 32. The unfreezing training epoch is set to 150, and the batch size is 16. The proportion of HSV-Saturation enhancement for images is set to 0.7, and the proportion of HSV-Value enhancement is set to 0.4.

IV. EXPERIMENTAL RESULTS AND ANALYSIS

Fig. 9 displays several detection outcomes for small targets and occluded fabric markers, where (a) depicts the detection result of YOLOv8n and (b) illustrates the detection result of YOLO-T. Non-maximum suppression is employed as a post-processing technique during inference, with the confidence threshold set to 0.5 and the IoU threshold set to 0.5. Based on the detection results, it is evident that the original YOLOv8n algorithm exists in the case of leakage and misdetection, and the YOLO-T algorithm can be very well detected by a variety of targets. Furthermore, the FPS of the YOLO-T algorithm on RTX 3060 12G memory can reach 98.91 frames/s, which effectively satisfies the need for real-time detection.

A. Ablation Studies

In order to assess the effectiveness of the refined approach proposed in this paper, multi-group ablation experiments are conducted with the same training set, test set, experimental environment and model training parameters, and the resulting outcomes are presented in Table III.

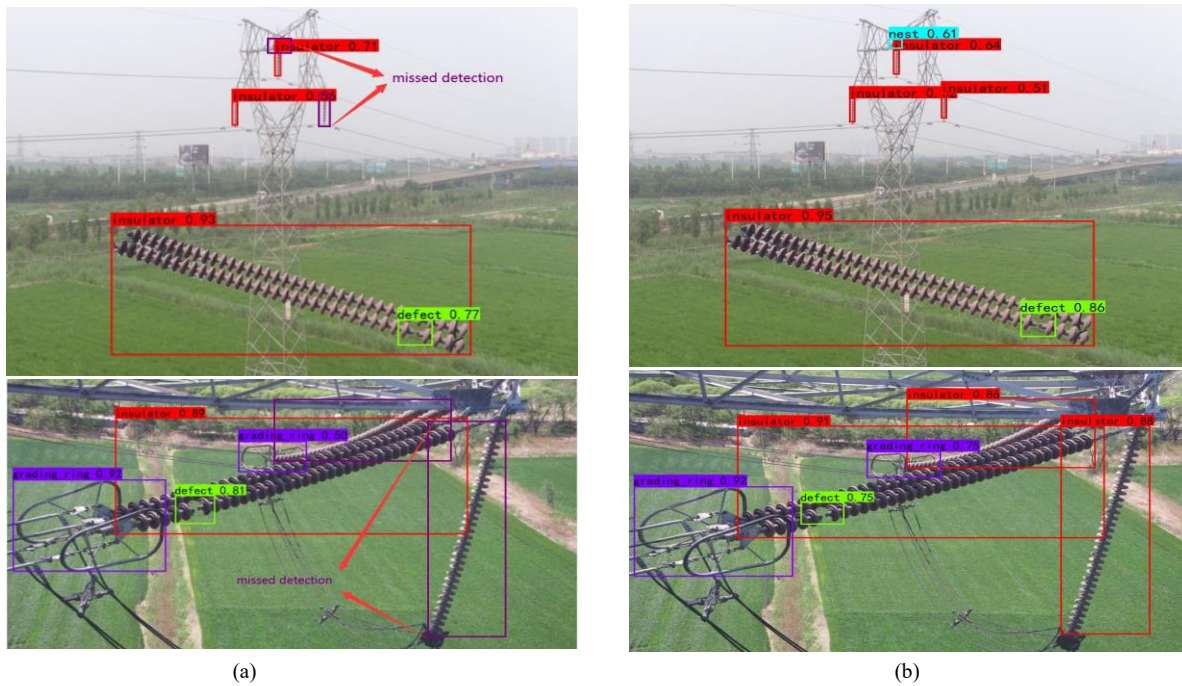

Fig. 9. Effect diagram of transmission line target detection. (a) YOLOv8n; (b) YOLO-T.

TABLE III. EXPERIMENTAL ABLATION RESULTS

Models	AP0.5 (%)				mAP _{0.5} (%)	mAP _{0.75} (%)	P (%)	R (%)	Parameter (M)	GFLOPs (G)
	Insulator	Defect	Nest	Grading						
YOLOv8n	92.36	97.79	94.50	95.97	95.16	78.18	98.03	88.43	3.012	7.398
YOLOv8n-A	90.72	98.07	94.22	95.67	94.68	76.44	98.17	85.64	2.756	6.916
YOLOv8n-B	93.57	98.06	95.19	96.92	95.93	78.45	98.31	89.05	2.588	6.486
YOLOv8n-C	94.15	98.23	95.04	96.73	96.04	80.41	98.47	90.15	2.601	6.487
YOLOv8n-D	95.03	98.37	95.78	97.49	96.67	81.19	98.47	91.00	2.602	6.488
YOLO-T	96.19	97.82	96.83	97.93	97.19	82.55	98.49	92.70	2.550	6.715

Based on the information provided in Table III, it is evident that YOLOv8n-A is an improvement of the C2f module of the neck network part of the baseline YOLOv8n algorithm, and the C2f-G module is constructed. According to the experimental results, the model's mAP0.5 decreased by 0.48%, but the parameters and GFLOPs were reduced by 0.744M and 0.482G, respectively, thus achieving a lighter model. YOLOv8n-B adds the CoT module based on YOLOv8n-A. Experiments show that the mAP0.5 of the model after adding the CoT module reaches 95.93%, which compensates for the impact of Ghost convolution on the model's detection accuracy. YOLOv8n-C is YOLOv8n-B based on the addition of the SE attention module after the effective feature layer of the output and the down-sampling operation of the neck network, which makes the mAP0.5 of the model reach 96.04% without increasing the complexity of the model almost 96.04%. YOLOv8n-D is constructed on the basis of YOLOv8n-C by improving the SPPF structure. According to the experimental results, the AP value of the YOLOv8n-D algorithm for all kinds of defect detection exceeds 95%, and mAP0.5 reaches 96.67%. Finally, the total parameters and the GFLOPs amount of the YOLO-T (C2f-G + CoT + SE + SPPF-C + PANet-Z) model proposed in

this paper are reduced by 0.462M and 0.683G compared to the YOLOv8 baseline algorithm, and the AP values for all types of defects reach more than 96%, and mAP0.5 reaches 97.19%, which is an improvement over the baseline YOLOv8n model by 2.03%. The effectiveness of the improvement measures proposed in this paper was confirmed by the ablation experiments.

B. Comparative Testing of Different Models

To confirm the progress of the algorithm introduced in this paper, four different target detection models, YOLOv5s, YOLOv7, YOLOv8n and YOLOv8s, are also constructed for comparison and trained under the same experimental conditions and parameter settings. The detailed experimental results are presented in Table IV. Fig. 10 shows visualization examples of various algorithms in the transmission line dataset. From the visualization comparison in Fig. 10, it can be clearly observed that YOLO-T has better detection performance for long-distance targets and occluded targets.

TABLE IV. COMPARISON OF DIFFERENT MODEL TEST RESULTS

Models	mAP _{0.5} (%)	mAP _{0.75} (%)	Parameters (M)	GFLOPs (G)
YOLOv5s	91.24	67.10	7.072	14.893
YOLOv7	94.87	78.25	37.211	94.911
YOLOv8s	95.59	80.67	11.137	25.860
YOLOv8n	95.16	78.18	3.012	7.398
Ref. [23]	93.9	-	37.75	-
YOLO-T	97.19	82.55	2.550	6.715

V. DISCUSSION

The data in Table IV reveal that the YOLOv5s algorithm has more parameters and GFLOPs than YOLOv8n, but the model has a lower mAP. It has a mAP0.5 that is 2.54% lower and a mAP0.75 that is 11.08% lower than that of YOLOv8n. Its mAP0.5 and mAP0.75 are 2.54% and 11.08% lower than those of YOLOv8n, respectively. Although the YOLOv7 algorithm has a similar mAP to the YOLOv8n, but the model contains a larger quantity of parameters and GFLOPs which is nearly ten times larger than YOLOv8n. The YOLOv8 algorithms gradually increase the parameters quantity and GFLOPs as the depth and width of the model become larger, leading to the growth of mAP. However, in the transmission line dataset of this article, YOLOv8s has only a 0.4% increase in mAP0.5 compared to YOLOv8n. Concurrently, the parameters quantity and GFLOPs of the model increases by about four times. In contrast, the YOLO-T algorithm proposed in this paper achieves an mAP0.5 of 97.19%, which is 2.03% higher than the baseline YOLOv8n algorithm and 1.6% higher than the YOLOv8s. Importantly, the model features fewer parameters and the amount of GFLOPs are also lower by 8.587M and 19.145G. Comparative experiments prove that YOLO-T outperforms other algorithms in high transmission line multi-target detection, providing a valuable reference.

The YOLO-T algorithm presented enhances small and occluded target detection at long distances but is limited by the dataset's composition, where such targets are minimal. This limitation results in relatively low detection confidence for these targets, underscoring the necessity for optimization. To address this, expanding the dataset to include a broader spectrum of targets is recommended for future research, which could enrich training and allow for more extensive comparisons, essential for comprehensive high-voltage transmission line inspections. Additionally, since experiments have yet to be conducted with actual mobile drones, forthcoming studies should aim to deploy the refined model on embedded devices for enhanced multi-target detection on transmission lines, further honing the approach through practical application.

VI. CONCLUSIONS

To resolve the problem of low detection accuracy of long-distance small targets and occluded targets encountered in UAV inspection, this paper presents a YOLO-T transmission line multi-target detection algorithm, built upon an improved YOLOv8. Experimentally, it is proved that Ghost convolution can well realize the lightweighting of the model with less loss of detection accuracy. The backbone network's feature extraction capability is improved by using the CoT feature extraction module. By incorporating the SE attention module and adding a residual edge to the SPPF, the network is better able to focus on relevant information. This augments the model's feature extraction from small and occluded targets at a long range. Furthermore, the addition of a new shallow feature layer for multi-scale feature fusion enhances the model's detection accuracy for small targets and occluded objects. Additionally, the Add operation helps save the model's parameters and GFLOPs. The results of the experiments conducted on the transmission line inspection dataset show that

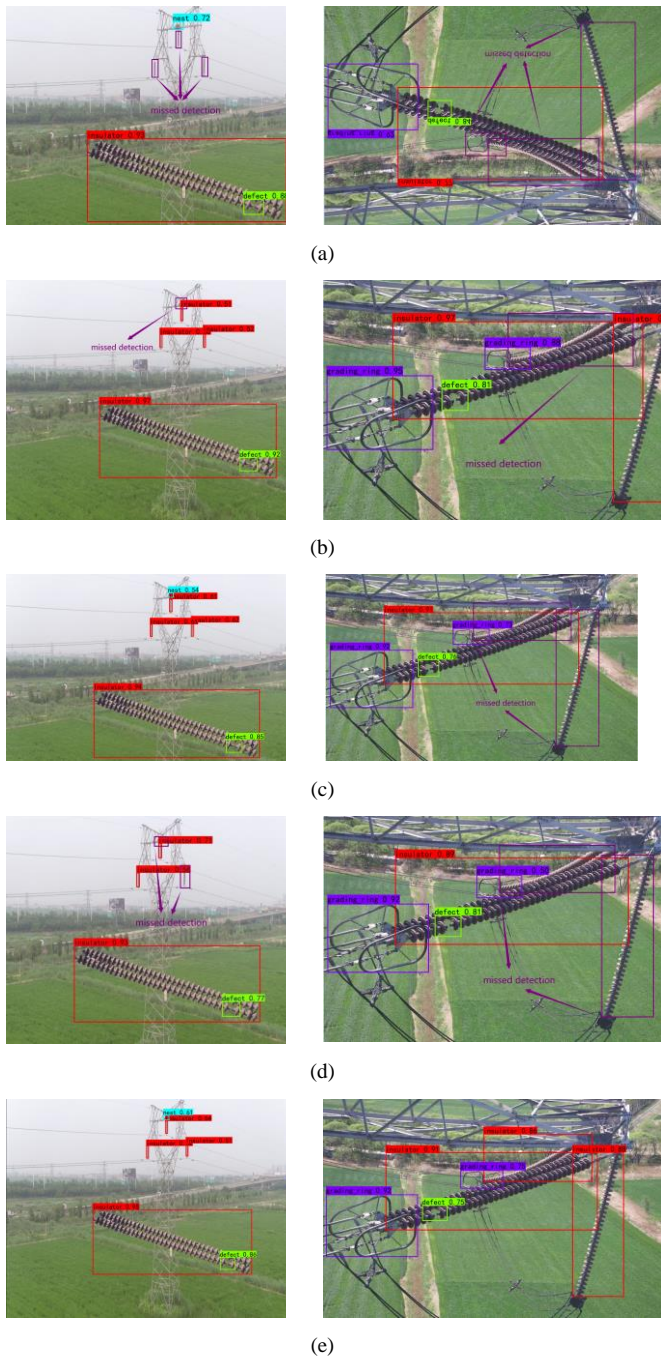

Fig. 10. Detection results of different algorithms. (a) YOLOv5s; (b) YOLOv7; (c) YOLOv8s; (d) YOLOv8n; (e) YOLO-T.

the mAP0.5 of the YOLO-T model can reach 97.19%, which is 2.03% higher than that of the original YOLOv8n algorithm, and the FPS reaches 98.91 frames/s, which can realize the real-time inspection of transmission lines. In addition, the parameter count of the YOLO-T model is only 2.55 M, which lays the foundation for the subsequent deployment on UAV embedded development board.

Abstract—The vast repositories of training and competition video data serve as indispensable resources for athlete training and competitor analysis, providing a solid foundation for strategic competition analysis and tactics formulation. However, the effectiveness of these analyses hinges on the abundance and precision of data, often requiring costly professional systems for existing video analysis techniques. Meanwhile, readily accessible non-professional data frequently lacks standardization, compelling manual analysis and experiential judgments, thus limiting the widespread adoption of video analysis technologies. To address these challenges, we have devised an intelligent video analysis technology and a methodology for identifying athletes' competition characteristics. Initially, we employed target detection models, such as You Only Look Once (YOLO), renowned for their ease of deployment and low environmental dependency, to perform fundamental detection tasks. This was further complemented by the intelligent selection of standardized scenes through customizable scene rules, leading to the formation of a standardized scene dataset. On this robust foundation, we achieved classification and identification of competition participants as well as sideline recognition, ultimately compiling a comprehensive competitive dataset. Subsequently, we constructed an athlete posture estimation method utilizing OpenPose, aimed at minimizing interference caused by obstructions and enhancing the accuracy of feature extraction. In experimental validation, we gathered a diverse collection of table tennis competition video data from the internet, serving as a validation dataset. The results were impressive, with a detection success rate for standardized scenes exceeding 94% and an identification success rate for competitors surpassing 98%. The accuracy of posture reconstruction for obstructed individuals exceeded 60%, and the effectiveness of identifying athletes' main features exceeded 90%, convincingly demonstrating the effectiveness of the proposed video analysis method.

I. INTRODUCTION

Table tennis, characterized by its rapid pace, high technical demands, and the necessity for swift reactions, increasingly requires sophisticated methods for tactical evaluation. Traditional approaches to technical and tactical analysis have predominantly relied on literature reviews, quadruple indicators, and video observations [1], often dependent on manual observation and subjective judgment. In the systematic study process, Wu, H. discussed the statistical methods for analyzing technical and tactical applications in table tennis

competitions in Statistical Methods of Table Tennis Records, utilizing basic indicators such as serve and attack, receiving, counterattacking, and looping. This marked one of the first international, systematic discussions on this topic, introducing a three-segment indicator statistical method [2]. Lames proposed describing a table tennis match using a transition probability matrix for a given match state, employing Markov chains to calculate the winning probabilities for both sides [3]. Wenninger and Lames [4] aimed to ascertain the impact of different tactical behaviors on the probability of winning in table tennis by capturing the temporality of matches through high-dimensional numerical derivation, thereby determining the correlation of tactical behaviors. Utilizing a logistic regression model, Wu et al. [5] enhanced the scientific rigor and effectiveness of table tennis technical and tactical analysis. With additional data support, the model could be further refined. Zhao and Tang [6] applied the Technique for Order Preference by Similarity to an Ideal Solution (TOPSIS) to analyze the quality of table tennis matches, avoiding the influence of opponents' strengths and tactical performances, thus enabling accurate evaluations of match quality. Song et al. [7] diagnosed table tennis matches using a hybrid algorithm based on Long Short-Term Memory-Backpropagation Neural Networks (LSTM-BPNN).

To minimize reliance on manual, subjective evaluations, computer-assisted analysis techniques have incrementally gained ground in the technical and tactical analysis of ball games. In 1999, the Swiss-developed Dartfish tactical analysis system revolutionized the field, enabling analysts to capture, scrutinize, and disseminate video footage from training sessions and competitions. This system boasts a comprehensive toolkit for video data analysis and processing, standing as the most sophisticated and widely implemented competition analysis system to this day [8]. Rahmad et al. [9] delved into the utilization of video-based intelligent systems for recognizing sports actions, introducing a video-centric action recognition framework and discussing the merits of deep learning in sports action recognition. Their research advocated a versatile method for classifying actions across diverse sports, considering varying backgrounds and characteristics, pointing the way for future studies. Manafifard et al. [10] surveyed the current state of player tracking in football videos, contrasting the strengths and weaknesses of various techniques and putting forth evaluation metrics to steer future research. Thomas et al. [11] dissected computer vision applications and related research avenues in sports, outlining commercial systems such

as camera and player tracking solutions, and introducing consolidated sports datasets. Harnessing video analysis technology, critical data such as player positions can be distilled from match videos through image processing, facilitating quantitative analysis and evaluation. This approach not only elevates the precision and speed of evaluations but also aids coaches and athletes in gaining deeper insights into match scenarios and opponent traits, laying a scientific foundation for future training and competitive strategies. Wu et al. [12] developed iTTVis, a representative work in table tennis match data visualization analysis, offering a comprehensive and intuitive visualization system for technical and tactical analysts.

The dependency of match data visualization analysis on its data sources is paramount, as the level of detail and comprehensiveness of the data significantly affects the analytical outcomes. For example, the NBA's Sport VU system employs at least six portable high-definition cameras in each stadium, capturing intricate player data like spatial coordinates, timestamps, and player IDs at various frame rates. This sophisticated backend processing system tracks each player's passes, shots, and every on-court action, providing robust data for NBA match visualization analysis [13]. However, such sophisticated data levels are still a rarity in most other ball sports, especially at regional and university training and competition venues. This limits the generalized application and widespread adoption of related analytical technologies [14]. While Ma Jianhong et al. (2020) introduced a big data platform utilizing wireless sensor networks to establish a table tennis match database for real-time updates and historical data retrieval, and some scholars assessed offensive striking quality through the analysis of three-dimensional ball trajectories using computer vision, these advancements still involve significant upfront costs, which hinder the widespread use and application of video analysis and intelligent analytical technologies.

This study discusses the utilization of video analysis technology to evaluate key technical and tactical factors in table tennis matches, with a focus on the application of object detection and tracking technologies in the assessment of table tennis techniques and tactics. By processing and analyzing match video data, the positions of key players can be extracted and combined with match rules and tactical requirements for in-depth quantitative analysis and evaluation. This is anticipated to guide coaches and athletes in training and competition, enhancing their technical and tactical levels as well as athletic performance. The main tasks include:

- 1) The execution of most basic detection tasks can be accomplished using common target detection models, characterized by ease of deployment, low environmental dependency, and low cost.
- 2) Intelligent sample preprocessing technology allows for the automatic selection of standard scenes, enabling users to define custom selection rules; automatic identification of athletes and classification of matches is facilitated.
- 3) An athlete posture estimation method based on OpenPose [15] accurately reconstructs and estimates athlete postures, reducing interference from factors such as personnel

and venue equipment obstructions, thereby enhancing the accuracy of feature extraction.

II. TABLE TENNIS TECHNIQUE ANALYSIS AND TARGET CHARACTERISTICS THROUGH VIDEO ANALYSIS

Based on the "three-segment indicator statistical method" highlighted in existing research as pointing to key statistical elements, the main data indicators to be focused on in this work have been determined. The key lies in "extracting important indicators from easily obtainable, less detailed, and accurate data". Match live broadcasts, online replays, and general camera systems can conveniently provide competition image data; however, such data hardly support the application of refined analysis like the minute movements of the table tennis player's hand during serve and receive, or the trajectory of the table tennis ball. Nevertheless, the more significant motion characteristics of athletes, such as relative positions, posture changes, and the extent of these changes, are observable.

A. Static Basic Data

Combining general video recognition applications, a basic structured expression of the table tennis competition scene can be established, and the task targets for subsequent feature extraction can be determined, as shown in Fig. 1.

Fig. 1. Schematic diagram of structured data for athlete movement characteristics.

The scene includes three key objects, namely, the table tennis table, and the players P_1 and P_2 at both ends of the table. The position of the table tennis table remains unchanged. To facilitate subsequent quantitative analysis, two reference lines, RefLine1 and RefLine2, are constructed based on the upper and lower edges of the table tennis table. Each athlete is represented by a Bounding Box (BBox), each BBox is defined by a Centroid ($C(x,y)$), width, and height, i.e., $BBox(C, width, height) = BBox(x, y, width, height)$. In addition, each image frame is accompanied by a relative timestamp t .

Furthermore, thanks to 2D posture estimation and recognition methods, more complex and detailed athlete posture features can also be obtained [16], as illustrated in Fig. 2.

B. Temporal Features

From these easily obtained "coarse" features, a series of video-based analyses can be conducted. For example, as depicted in Fig. 3, the changes in the positions of athletes from time t_1 to t_2 are showcased, which are invaluable for analyzing match scenarios and formulating tactics. Temporal information

drives the change of all data related to BBox, which can be defined as the characteristic changes of athletes during the competition, including changes in movement direction, speed, and magnitude.

Fig. 2. Athlete posture features identified using 2D estimation methods [16].

Fig. 3. Changes in the positions of athletes from time t_1 to t_2 .

C. Data Acquisition and Preprocessing

Owing to technical and tactical training data often being core assets of teams and players, obtaining publicly standardized sample data poses a challenge. Consequently, this work has opted for videos of public competitions as the data source. Although television broadcasts and online samples are readily accessible, they present a series of issues when compared to internal private data, as illustrated in Fig. 4.

- Videos comprise multiple perspectives, placing the video samples under non-uniform conditions, such as close-ups and replays.
- Changes in the original positions of the motion due to changing courts.
- Data proportion changes caused by image distortions, among others.

To address these issues, a series of preprocessing steps is necessary to achieve data standardization, as shown in Fig. 5. Initially, appropriate sample frames are selected based on the angle of view. Generally, a 45° overhead view is preferable, filtering out all transition videos. Subsequently, athletes on either side of the match (far and near ends) are divided according to the competition setup. Lastly, due to the perspective transformation caused by the filming angle, athletes' proportions and positions undergo changes. Thus, image correction is performed using the table tennis table as a known reference.

Considering the complexity of the samples and the low efficiency of manual filtering, an auxiliary selection application was developed based on YOLO: a) Using the table tennis table as a standard reference object to build a training set, train and obtain the basic features of the "standard viewpoint"; b) Define standard viewpoint rules based on basic features, i.e., "a table tennis table matching the features is detected in the center of

the court, with one player at each end of the table tennis table", thereby achieving standard viewpoint filtering; c) On this basis, construct an unsupervised two-center classifier for players, clustering player samples with the same features together to achieve player identification; d) Divide the court side according to the players' positions relative to the table tennis table (upper and lower relative positions).

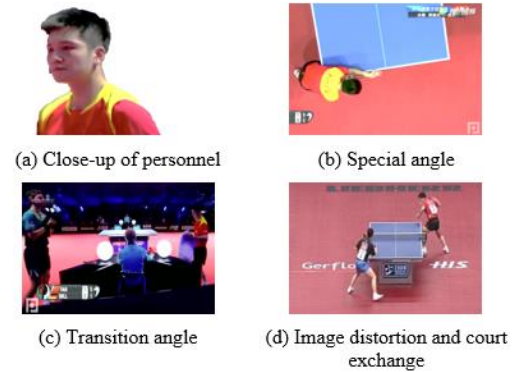

Fig. 4. Several issues in the original samples.

Fig. 5. Schematic diagram of the sample set preprocessing process.

III. METHOD FOR EXTRACTING ATHLETE MOTION FEATURES BASED ON VIDEO ANALYSIS TECHNOLOGY

To effectively support the preprocessing of original samples to form a unified sample set and to efficiently extract athlete features on this basis, a video analysis and feature extraction framework based on YoLo was constructed, as shown in Fig. 6.

The entire process is divided into two major parts: 1) data standardization; and 2) feature extraction. Among them, the first part consists of three sub-parts: 1.1) Table Tennis Table Identification; 1.2) Player Detection; and 1.3) Scene Standardization.

A. Basic Target Detection Method

Although slightly less performant than YoLo v4 and other SOTA models, YoLo v5 excels in flexibility and processing speed. It is easy to deploy and compatible with a variety of platforms, including smart devices [17], which led to the selection of YoLo v5 as the basic detection model. YoLo primarily serves two functions:

- Based on the pre-trained base model, athlete detection is achieved with an accuracy exceeding 98% on the sample set described in Section II(C), fulfilling the needs for analysis.
- Another role is to assist in identifying the table tennis table and aid in filtering the original videos to obtain a standardized dataset.

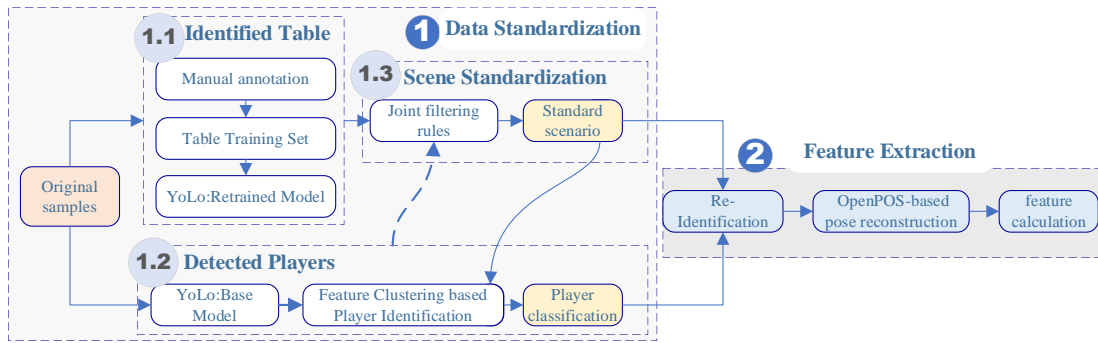

Fig. 6. Video analysis and feature extraction framework based on YoLo.

B. Data Standardization

1) *Standard frame filtering*: Generally, an overhead view of approximately 45° across the entire court ensures a basic viewing effect. Thus, this angle has been designated as the "standard viewpoint", characterized by several typical features, namely, an overhead view at approximately 45°, the table tennis table positioned in the middle of the field of view, with the table's outline resembling a rectangle or trapezoid, and players located at the (upper and lower) ends around the table tennis table.

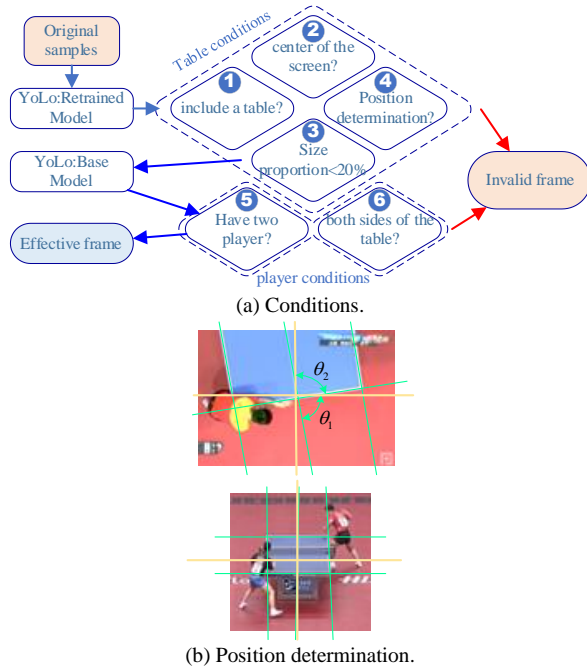

Fig. 7. Standard frame filtering flowchart.

As shown in Fig. 7(a), assuming the frame to be determined is marked as $f(C(x,y),w,h)$, it must undergo filtering through two sets of conditions, i.e., table and player conditions. a) If a table is detected within f , its region of interest (ROI) is marked as $B(C(x,y),w,h)$; b) Whether it is located in the center of the image, i.e., $\Delta d=(f_x-B_x, f_y-B_y) \leq \sigma$ (σ is the eccentricity threshold, generally $<5\%$); c) The size of the table's ROI relative to the entire image frame $((B_w*B_h)/(f_w*f_h)) \leq \delta$ (δ is the proportion

threshold, generally $<20\%$); d) Although conditions a-c can determine a table of appropriate size, they cannot distinguish whether the table is located in the correct direction. To solve this issue, a method used in autonomous driving for lane detection has been adopted [18], as illustrated in Fig. 7(b). That is, a correctly positioned table has its top and bottom lines essentially horizontal, while the left and right lines are nearly vertically parallel (parallelism is assumed based solely on the detection angle $\leq \theta \approx 5^\circ$); e) Detection of whether two athletes P_1 and P_2 are included in the scene; f) P_1 and P_2 are located on either side of the table, either $C_x^{P_1} < B_x$ & $C_x^{P_2} > B_x$ or $C_x^{P_1} > B_x$ & $C_x^{P_2} < B_x$, respectively.

2) *Athlete identification Based on feature clustering*: While standard scene filtering is performed, personnel in invalid frames are also filtered out, leaving behind a dataset of personnel features (ROI), as illustrated in Fig. 8.

Fig. 8. Collection of athlete ROIs extracted based on the fifth rule.

Although athletes can relatively easily be divided into the correct court sides according to the sixth rule, it remains necessary to correctly differentiate the athletes, as they will switch sides to "battle from the opposite side". Considering that the preprocessing has significantly reduced the candidate information, simple feature information can be utilized to achieve feature clustering, thereby distinguishing athletes.

The method proposed by Zhang et al. [19] is employed, using sparse clustering to transform the ROIs of candidate samples into image features, which are then differentiated through clustering, as shown in Fig. 9. Subsequently, the positions of athletes P_1 and P_2 relative to the table are differentiated according to condition f), thereby indirectly achieving differentiation of match scenarios.

Fig. 9. Differentiating athletes using a sparse feature clustering method.

C. Scene Perspective Transformation and Personnel Re-Identification

To eliminate potential perspective distortion in the original samples, an inverse perspective transformation process is required, which ensures that lines within the image remain straight after projection. In match videos, the table tennis table should appear as a standard rectangle. Due to the camera's shooting angle and positioning, a rectangular table may appear trapezoidal. Hence, it is opted to project this trapezoidal area into a rectangle, setting four endpoints of the rectangle at appropriate positions on the horizontal axis of the right image. The generic formula for perspective transformation is:

$$[x', y', w'] = [u, v, w] \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \quad (1)$$

where, (u, v) is obtained from the left original picture after transformation through the transformation matrix $\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}$. The transformation matrix consists of four parts, with $\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$ representing linear transformations including scaling, shearing, and rotation. $[a_{31} \ a_{32}]$ is used for translation, and $[a_{13} \ a_{23}]^T$ produces a perspective transformation.

Through the inverse perspective transformation (see Fig. 10), the motion amplitude and trajectory on the horizontal position, including the distance, i.e., the athlete's trajectory on the x, y coordinate plane, can be calculated. After the perspective transformation, the candidate feature areas obtained during the preliminary preprocessing also undergo certain deformations. Therefore, a re-execution of personnel detection is necessary to obtain updated ROI samples.

D. Athlete Feature Reconstruction Method Based on OpenPose

Due to the inability of traditional detection methods to detect limbs obstructed by the table tennis table, which affects the generation of *BBOX*, directly affecting the subsequent evaluation and modeling of athlete features. As shown in Fig. 11, the same athlete of P_2 and P'_2 is affected by the table's

obstruction, causing significant changes in the ROI. Therefore, before proceeding with modeling analysis, it is necessary to reconstruct the obscured limb parts of the athlete.

As illustrated in Fig. 12, a posture-guided feature decoupling Transformer network based on OpenPose [15] was designed in this study. This network utilizes known posture information to decouple human and joint components and uses posture information to guide the separation of non-obstructed and obstructed features, thus reconstructing the obscured athlete image (features).

The encoder was constructed in this study based on the Transformer classification model [20]. For a given athlete image $x \in \mathbb{R}^{H \times W \times C}$, where H, W, C represent the image's height, width, and channel dimensions, respectively. Since the Transformer encoder requires only sequences as input, the input image x is first divided into N blocks of equal size using a sliding window, with each image block sized P , and the sliding window stride set to S . Then N can be expressed as:

$$N = \left\lfloor \frac{H}{S-P} \right\rfloor \times \left\lfloor \frac{W}{S-P} \right\rfloor \quad (2)$$

where, $\lfloor \bullet \rfloor$ denotes the floor function. When $S < P$, the generated image blocks overlap, but this can mitigate the loss of image spatial neighborhood information. Through a linear projection function $f(\bullet)$, the flattened blocks are mapped to D dimensions, where $f(\bullet)$ is trainable. Thus, the embeddings for blocks, termed as $E \in \mathbb{R}^{N \times D}$, are obtained, i.e., $E_i = f(x_i)$, with $i=1,2,\dots,N$. Then, a scientific series classification tag x_{class} is added to E_i , which is used as the encoder's global feature representation f_{global} . The final input sequence E_{input} can be expressed as:

Fig. 10. Inverse perspective transformation of the original sample.

Fig. 11. The athlete obstructed by the table: affecting feature extraction.

Fig. 12. Framework for the posture reconstruction method.

$$E_{input} = \{x_{class}; E_i\} + PE + cm \cdot C_{id} \quad (3)$$

where, PE is the positional embeddings, $C_{id} \in \mathbb{R}^{(N+1) \times D}$ is the camera embeddings, which remains the same for the same image. cm is a hyperparameter that balances the weight of the camera embeddings. Then the input embeddings E_{input} are processed by m Transformer layers. The final output of the encoder, $f_{en} \in \mathbb{R}^{(N+1) \times D}$, can be divided into two parts of global and part features, denoted as $f_{gb} \in \mathbb{R}^{1 \times D}$ and $f_{part} \in \mathbb{R}^{N \times D}$. To learn more about the distinctive features of human body parts, part features f_{part} are sequentially divided into K groups, with each group sized $(N // K) \times D$.

$$L_{en} = L_{id}(P(f_{gb})) + \frac{1}{K} \sum_{i=1}^K L_{id}(P(f_{i_{sp}})) + L_{tri}(f_{gb}) + \frac{1}{K} \sum_{i=1}^K L_{tri}(f_{i_{sp}}) \quad (4)$$

where, $P(\cdot)$ represents the probability prediction function.

Images of athletes obstructed by objects suffer from performance degradation due to the reduced availability of body information and potential ambiguities in the non-body parts. Therefore, a posture estimator was constructed in this study to extract key point information from images.

Initially, the estimator extracts M landmarks from the input image x . These landmarks are then used to generate a heatmap $H = [h_1, h_2, \dots, h_M]$. For larger-sized x , each heatmap is downscaled to a size of $(H/4) \times (W/4)$, effectively enhancing computational speed. Through filtering of landmarks using threshold τ , the landmarks with the highest and lowest confidence are obtained: $landmark_{max}$ and $landmark_{min}$, where $landmark_{max}$ corresponds to a joint on the person.

When the number K of groups for key body parts equals the number M of landmarks and heatmaps, i.e., $K = M$, the posture feature information of various parts can be integrated. Thus, for grouped local features $f_{group-part}$, a fully connected layer can be introduced on the basis of H to obtain the same H' as $f_{group-part}$. Then by element-wise multiplication of $f_{group-part}$ with H' , posture-guided features $P = [P_1, P_2, \dots, P_M]$ are obtained, representing the feature information of each joint in the human posture. This allows for posture reconstruction using known complete P features and currently incomplete features P' due to obstruction.

To enhance the accuracy of reconstructing missing features, it is necessary to utilize history P to construct a set $\{f_{group-part}^1, f_{group-part}^2, \dots, f_{group-part}^k\}$ for training. During reconstruction, the set is sorted by similarity. P_i , which has the highest match with the current known parts of P' to be reconstructed, can be used for reconstructing the obstructed parts. As shown on the right side of Fig. 12, "matched poses" with the highest similarity can determine the candidate reconstruction parts, referred to as the "matching strategy".

Of course, if precise posture estimation is not required and the estimation is utilized to obtain lower-accuracy ROI information, a simplified method is to use P_i to substitute P' , given that the ROI information between the two is nearly identical. This significantly enhances the accuracy of the obtained ROI.

IV. EXPERIMENT AND RESULT ANALYSIS

A. Data Preparation

Data sets were constructed from three major table tennis events, namely, the World Table Tennis Championships (WTTTC), the Table Tennis World Cup (TTWC), and the Table Tennis Match in the Olympic Games (TTMOG). These events are considered the most prestigious in the world of table tennis, attracting top athletes from various countries.

Athletes Ma Long (with a score of 4810, ranked third as of February 2024) and Fan Zhendong (with a score of 7455, ranked first as of February 2024) [21] were selected. Ma Long is the first male player to achieve a Super Grand Slam, having won singles championships at the Olympics, World Championships, World Cup, Asian Games, Asian Championships, Asian Cup, Tour Finals, and National Games. Fan Zhendong is a Chinese male table tennis player who has won multiple championships at the World Junior Championships in singles, mixed doubles, and team events, as well as runner-up in singles and doubles, along with several ITTF and World Cup titles. Ma Long and Fan Zhendong were chosen due to their high prestige and achievements within the Chinese table tennis community. Ma Long is the first male athlete to complete a Grand Slam, consistently performing at the top level. Fan Zhendong represents the excellence of the younger generation, having won numerous international competitions.

Video samples were sourced from publicly available match videos on the internet, which are accessible to all researchers. The selection included 21 videos of Ma Long participating in WTTC, TTWC, and TTMOG matches from 2007 to 2022, and 13 videos of Fan Zhendong from 2013 to 2023 for analysis.

By choosing match videos of top athletes as the data set, an in-depth analysis of their performance and technical characteristics in these competitions was facilitated. These

videos offer a wealth of material for studying specific athletes' match strategies, stroke techniques, and tactical thinking. Through the editing, annotation, and analysis of these videos, followed by model training, relevant sports data could be extracted.

The compiled samples are shown in Table I and Table II, totaling 102,211 seconds (approximately 1700 minutes), and 2,638,635 frames. This demonstrates that just 34 matches of two athletes in major events accumulate such a vast amount of data, which would be challenging to process manually.

B. Result Analysis

The data, following preprocessing and initial analysis, are presented in Table III and Table IV. From an overall distribution perspective, the analysis method proposed in this paper effectively processes the original samples, accurately filters to obtain standard scenes, identifies athletes, achieves the reconstruction of obstructed personnel postures to a certain extent, and correctly identifies all matches. It is also observed that when the original sample resolution is low, the corresponding recognition indicators fall below the average. This suggests that the detection accuracy decreases when the sample size of the subject, such as the athlete, is too small. The impact is most significant on posture reconstruction, which requires more clear known postures to establish prior information.

Table V and Table VI display the statistical results of processing two sets of sample collections. A total of 102,211 frames were processed, with a filtering ratio reaching 81.82%, indicating that approximately 80% of the samples sourced from the internet were either invalid or could only provide limited information. The recognition rate for standard scenes was 94.17%, suggesting that besides a few scenes that were not correctly identified, the majority of effective frames were accurately filtered.

The accuracy for athlete identification was higher than 98%. A small number of non-recognitions or false detections were attributed to some samples having low resolution and the presence of numerous distracting objects in the scene. Although the accuracy for reconstructing the posture of obstructed players was only around 60%, the average accuracy

for coarse-grained ROI features obtained based on this posture estimation reached 89%, enhancing the accuracy of subsequent analyses.

Fig. 13 showcases the match data between Ma Long and Joo Se-Hyuk at the 2007 WTTC. It is observable that the confrontation between the two athletes was fiercely competitive. As seen in Fig. 13(a), the blue player (Joo Se-Hyuk) exhibited a higher frequency and amplitude of movement than the red player (Ma Long), which could have been a contributing factor to Ma Long's defeat in this match. Additionally, Fig. 13(b) also reveals a significant misidentification point, where the classifier erroneously assigned Ma Long to the blue side (opposite side of the table tennis table). Through this data visualization, the error could be quickly identified and corrected.

TABLE V. STATISTICAL INDICATORS

Data Set	Duration (s)	Total frames	Duration (s)	Total frames	Frame filtering
Ma Long	63226	1584716	8476	210427	82.60%
Fan Zhendong	38985	1053919	4700	188095	81.05%
Total	102211	2638635	13176	398522	81.82%

TABLE VI. STATISTICAL INDICATORS: RECOGNITION ACCURACY

Data Set	Scenario	Players	Incomplete player	Incomplete ROI	Matches
Ma Long	94.25%	98.24%	60.92%	87.97%	1
Fan Zhendong	94.10%	98.13%	61.36%	90.30%	1
Average	94.17%	98.18%	61.14%	89.14%	1

V. CONCLUSION

This study investigates and designs an intelligent method for analyzing sports videos, capable of standardizing low-resolution, non-professional video samples such as television broadcasts and online videos at a lower cost. It accurately identifies standard scenes under appropriate conditions, competitive athletes, and key match features. Through the use of collected table tennis match videos as test subjects, the effectiveness of the proposed method for standardizing and preprocessing competition videos, as well as extracting features, was verified. The analysis method presented in this paper can be applied to video analysis of similar competitive sports, demonstrating significant potential for broader application.

As technical and tactical analysis is a highly challenging task, the work presented in this article focuses on collecting extensive data from non-standardized environments and attempting to standardize and structure them, which lays the foundation for subsequent complex technical and tactical analysis. The technical and tactical aspects of table tennis are exceedingly complex, encompassing various aspects such as serving, receiving, attacking, defending, and stalemate, each encompassing multiple techniques and tactics. Accurately identifying and distinguishing these techniques and tactics during data analysis poses a significant challenge. In table tennis competitions, athletes' technical and tactical choices are often influenced by multiple factors, such as their opponents' technical characteristics, the progress of the match, and their mental state. These factors are difficult to capture through a single data point and require comprehensive consideration of contextual information in the analysis. Identifying effective technical and tactical patterns from vast amounts of data and making predictions for future matches are crucial objectives of technical and tactical analysis. However, due to the complexity and uncertainty of table tennis competitions, this goal is often difficult to achieve. Furthermore, table tennis matches are conducted in real-time, and athletes' technical and tactical choices are dynamic. The challenge lies in acquiring and analyzing data during the match in real-time to provide coaches and athletes with immediate feedback and suggestions. These issues are all issues that need to be gradually addressed in future research.

Differential Diagnosis of Attention-Deficit / Hyperactivity Disorder and Bipolar Disorder using Steady-State Visual Evoked Potentials

Xiaoxia Li*

Jiangnan University
Wuhan Hubei, 430056, China

Abstract—Bipolar disorder and Attention-deficit/Hyperactivity disorder (ADHD) are two prevalent disorders whose symptoms are similar. In order to reduce the misdiagnosis between bipolar disorder and ADHD, a machine learning-based system using electroencephalography (EEG) and steady state potentials (i.e., steady-state visual evoked potential [SSVEP]) was evaluated to classify ADHD, bipolar disorder and normal conditions. Indeed, this research was conducted for the first time with the aim of designing a machine learning system for EEG detection of ADHD, bipolar disorder, and normal conditions using SSVEPs. For this purpose, both linear and nonlinear dynamics of extracted SSVEPs were analyzed. Indeed, after data preprocessing, spectral analysis and recurrence quantification analysis (RQA) were applied to SSVEPs. Then, feature selection was utilized through the DISR. Finally, we utilized various machine learning techniques to classify the linear and nonlinear features extracted from SSVEPs into three classes of ADHD, bipolar disorder and normal: k-nearest neighbors (KNN), support vector machine (SVM), linear discriminant analysis (LDA) and Naïve Bayes. Experimental results showed that SVM classifier with linear kernel yielded an accuracy of 78.57% for ADHD, bipolar disorder and normal classification through the leave-one-subject-out (LOSO) cross-validation. Although this research is the first to evaluate the utilization of signal processing and machine learning approaches in SSVEP classification of these disorders, it has limitations that future studies should investigate to enhance the efficacy of proposed system.

I. INTRODUCTION

Correct and accurate diagnosis of people with neuropsychiatric illnesses like Attention-deficit/Hyperactivity disorder (ADHD), impulse control disorder, borderline personality disorder, depression, bipolar disorder, and so on has always been a challenge for experts in the fields of psychology and psychiatry [1], [2]. Since the symptoms of these disorders are very similar, it is usually difficult and time-consuming to diagnose the type of mental disorder. This diagnosis is usually made with the help of psychological tests and a specialized interview with the patient, which can be biased due to factors such as intelligence quotient (IQ), the subject's mood, and the patient's willingness to cooperate [3], [4]. Also, the experience and ability of the doctor has a high impact on the accuracy of the result. Currently, the standard method for diagnosing and

distinguishing between these types of patients is to use the DSM-5, which tries to differentiate between mental disorders by setting certain criteria based on the symptoms seen in the patient [5]. Among these disorders, ADHD and bipolar disorder (especially type 2) share similar symptoms, including fast talking, competitive thoughts, less need for sleep, inattention, and high energy that manifests as high physical activity and rapid mood swings [6], [7]. It is difficult for psychiatrists to separate these two patient groups based on clinical observations, at least in the initial interview sessions [8]. The prevalence of bipolar disorder at young ages is low, so this disorder is proposed for children as a secondary diagnosis next to ADHD [9]. A previous study showed that 28.6% of patients with bipolar disorder are misdiagnosed as ADHD [10], [11]. Therefore, providing a reliable and accurate method for diagnosing patients with ADHD and bipolar disorder can provide a useful tool to the psychiatrist to increase the certainty of the doctor's diagnosis in addition to shortening the diagnosis time and starting the treatment faster.

In the meantime, one of the investigated ways to diagnose these disorders is the computational analysis of the electroencephalogram (EEG) signal [12]. EEG has emerged as a valuable instrument in the detection of psychiatric disorders, including bipolar disorder and ADHD [13], [14], [15], [16], [17], [18]. EEG measures the electrical activity of the brain and provides insights into its functioning [19]. This signal contains helpful data regarding the activity of brain cells and cognitive functions, and due to its unique properties, such as high time resolution, low cost, non-invasiveness and easy access, it has been used as a useful tool to diagnose psychiatric disorders [20]. Recent reviews supported the application of machine learning to EEG as an innovative approach to help clinicians diagnose bipolar disorder and ADHD [21], [22]. A study was conducted to compare adolescents and youths with bipolar disorder with patients with ADHD and a control group of individuals without any neurological conditions. The objective of the study was to distinguish between bipolar disorder and ADHD clients based on their VEP features. In order to achieve this, the researchers employed the 1NN technique for classification. Results showed a promising achievement with a classification accuracy of 92.85%, successfully differentiating between bipolar disorder, ADHD, and healthy subjects [23]. Another study focused on using synchronization attributes, specifically phase locking values, to differentiate between patients with bipolar disorder and schizophrenia. By employing a SVM technique, a

classification accuracy of 92.45% was attained [24]. Additionally, Sadatnezhad and colleagues investigated EEGs through various nonlinear and linear methods such as autoregressive coefficients, fractal dimensions, band power, and time-frequency approach for detecting clients with bipolar disorder and ADHD [25]. Their findings showed a classification accuracy of 86.44%. Overall, despite its clinical importance, very few researches have tried to provide an automatic system for the diagnosis of ADHD and bipolar disorder from the EEG.

Steady-state visual evoked potential (SSVEP) is an electrophysiological potential produced by the electrical activity of cerebral cortex which is extracted if a repetitive visual stimulation is delivered to a subject [26]. Previous studies have proven the high diagnostic value of this informative potential in different psychiatric disorders, including schizophrenia [27], ADHD [28] and bipolar disorder [29]. However, none of the previous studies attempted to employ SSVEP to differentiate ADHD and bipolar disorder. Therefore, this research was conducted for the first time with the aim of designing a machine learning system for EEG detection of ADHD, bipolar disorder, and normal using SSVEPs. The rest of this article is organized as follows: Section II presents the proposed methodology including the used EEG dataset, feature extraction, feature selection and classification models. Experimental findings and observation are provided in Section III. Discussion is given in Section IV. Finally, a brief conclusion is presented in Section V.

II. METHODS

The designed system to automatically differentiate ADHD and bipolar disorder had different steps, including specific EEG recording protocol to elicit SSVEP, data preprocessing, feature extraction, and classification. In this section, detail of each step is explained.

A. Data Recording

In this study, EEGs were captured from 25 clients with ADHD, 27 clients with bipolar disorder and 30 healthy subjects. Patients were diagnosed by a psychiatrist using DSM-5 diagnostic criteria. None of the participants had a history of head trauma, neurological disorders, and brain stimulation, and all of them were right-handed. Table I shows baseline data of the participants. As shown, there is no significant difference between group of patients and healthy people in terms of gender and age. Study was conducted based on principles of the Declaration of Helsinki (1996) and the current Good Clinical Practice guidelines. An outline of the project was explained to the participants to signing informed consents.

Participants were equipped with a 16-channel EEG net from Electrical Geodesics Inc. During the capturing, participants were seated comfortably in an armchair with their eyes closed, ensuring minimal muscle tension or eye movement. The recording began with a two-minute period of relaxed

wakefulness, followed by consecutive two-minute intervals of photic stimuli condition designed to measure SSVEP. To elicit SSVEP responses, a diode photo stimulator from Grass Technologies (model PS33-PLUS) positioned about 80 cm in front of each participant, emitted continuously modulated light stimuli at 15-Hz. Luminance of sinusoidal light emitter ranged from 300 cd/m² at its lowest point to 800 cd/m² at its highest point. EEG recordings were digitized and sampled at a rate of 512-Hz. Fig. 1 shows the electrode positions on the scalp. The ground and reference electrodes were also positioned in the Fpz location and the right ear, respectively.

B. Data Analysis

The EEG signals were filtered to retain frequencies ranging from 0.4 Hz to 45 Hz. To eliminate any interference caused by muscle activity and eye movements, a combination of semi-automatic techniques involving amplitude-based threshold detection and visual examination was implemented separately for each channel. This procedure was carried out using MATLAB software. Subsequently, the combined recordings of spontaneous brain activity and SSVEP were analyzed using independent component analysis (ICA), which was performed through EEGLAB plug-in in MATLAB [30]. The purpose of this analysis was to detect and eliminate artifacts related to eye movements, muscle activity, and cardiac activity. Following ICA, the individual EEG channels were visually inspected once again to remove any remaining artifacts. The recordings were then re-referenced to global average.

After removing noise and artifacts from the recorded signals, the steady state responses were extracted. It is assumed that these responses are superimposed on the background EEG as a sine wave at stimulation frequency. An example of the EEG signal recorded during 15 Hz stimulation is shown in Fig. 2. In fact, from the processing point of view, the background EEG can be considered as noise that is added with the sinusoidal response resulting from intermittent stimulation. One of the ways to remove this background EEG is to use the moving averaging method. In this method, a window whose length is an integer multiple of the stimulus period is moving over the signal at intervals of one period and divides it into segments. Then, instead of calculating the average in the trials, the average is calculated on these obtained segments. For the length of the window, five periods were considered so that both the length is long enough and the number of segments obtained is not too small. However, due to the low sampling frequency (512 Hz), it was practically impossible to move the window properly in the original signal. Because the phase difference caused by the difference between actual position of window and its correct location causes the removal or severe weakening of the steady state response. Therefore, before windowing, the signal sampling rate was increased by a factor of 4. Fig. 3 shows the result of applying this method on the signal obtained during visual stimulation.

TABLE I. DEMOGRAPHIC INFORMATION OF THE PARTICIPANTS

Variable	ADHD group (n = 25)	Bipolar group (n = 27)	Healthy group (n = 30)	P-value
Age	20.32 ± 1.87	20.97 ± 1.79	21.01 ± 1.56	0.312
Gender	18 male, 7 female	17 male, 10 female	16 male, 14 female	0.384

Fig. 1. Electrode placement on the scalp according to 10-20 system (red colored electrodes).

Fig. 2. An example of the recorded EEG signal and the repeating pattern in it (stimulation frequency 15 Hz).

Fig. 3. Effect of moving averaging on SSVEP responses at 15 Hz.

C. Feature Extraction

In this study, feature extraction from SSVEPs was performed in two frequency and time domains. To assess spectral power, Fast Fourier Transform (FFT) was applied using a Welch's periodogram with a Hamming window. This computation resulted in a frequency resolution of 0.25-Hz. Then, amplitude and latency of SSVEPs were extracted as frequency domain features.

Afterward, for processing in the time domain, the nonlinear dynamics of SSVEPs were analyzed. This was performed through recurrence quantification analysis (RQA) in order to extract non-linear features from SSVEPs for input to classifiers. RQA is a powerful technique used in biomedical signal processing to analyze and extract valuable information from complex time series data. It provides a comprehensive approach for studying the dynamics and patterns of recurring events within a signal [31]. RQA focuses on identifying recurrent patterns, or recurrences, by measuring the similarity between different sections of the signal. By quantifying the recurrence properties, RQA enables researchers to investigate important characteristics such as the presence of regularities, irregularities, and deterministic chaos in the signal [32]. This technique plays a crucial role in various biomedical applications, including the analysis of electrocardiogram (ECG) signals, EEG recordings, and other physiological measurements [21]. With its ability to capture intricate temporal relationships and uncover hidden patterns, RQA serves as a valuable tool for understanding and interpreting complex biomedical signals, ultimately contributing to advancements in clinical applications [33]. RQA provides a recurrence plot, which can be analyzed to extract various features. To quantify structures presented in the recurrence plots, we computed and extracted multiple features:

- 1) Recurrence Rate (RR) = (Number of recurrent points) / (Total number of points)
- 2) Determinism (DET) = (Number of diagonal line structures) / (Number of recurrent points)
- 3) Average Diagonal Line Length (L) = (Sum of lengths of all diagonal lines) / (Number of diagonal lines)
- 4) Entropy (ENT) = $-\sum (p \times \log_2(p))$
where, p is the probability of finding two recurrent points within a certain distance in the recurrence plot.
- 5) Trend = (Number of vertical line structures) / (Number of recurrent points)
- 6) Longest Diagonal Line (Lmax) = Maximum length among all diagonal lines
- 7) Divergence (DIV) = (Number of horizontal line structures) / (Number of recurrent points)
- 8) Trapping Time (TT) = (Average length of vertical lines) / (Average length of diagonal lines)
- 9) Percent Determinism = DET \times 100
- 10) Ratio Determinism = DET / (1 - RR)
- 11) Average Off-Diagonal Line Length (V) = (Sum of lengths of all off-diagonal lines) / (Number of off-diagonal lines)
- 12) Laminality (L) = (Number of vertical lines of length L) / (Total number of recurrent points)
- 13) Ratio laminality (RL) = (L) / (RR)

$$14) \text{Ratio Off-Diagonal lines (RV)} = (V) / (RR)$$

15) Longest vertical line length (Vmax) = maximum length of vertical lines

These features provide insights into different aspects of the recurrence plot, such as the presence of recurrent patterns, diagonal line structures, vertical and horizontal line structures, entropy measures, and more.

D. Feature Selection

In this research, we extracted various features from each of the 16 channels, resulting in a feature matrix of size 16 \times 17 for each individual. Consequently, a total of 272 features were obtained across each participant. However, it was determined that certain features were redundant and did not provide sufficient information to effectively differentiate between the three groups. Furthermore, the classification of these numerous features incurred significant computational expenses and reduced processing speed. To address these issues, we employed the double input symmetrical relevance (DISR) technique to choose optimal features. Implementation of DISR aimed to enhance the classification accuracy while optimizing computational costs. Meyer et al. [34] suggested the following measure for feature selection:

$$F = \arg \max_{X_i \in X_s} \left\{ \sum_{X_j \in X_s} \frac{MI(X_i, j, Y)}{H(X_i, j, Y)} \right\} \quad (1)$$

In Eq. (1), $H(X_i, j, Y)$ and $MI(X_i, j, Y)$ denote the information entropy and mutual information, respectively.

E. Classification

In this research, we utilized various machine learning techniques to classify the linear and nonlinear features extracted from SSVEPs into three classes of ADHD, bipolar disorder and normal: k-nearest neighbors (KNN), support vector machine (SVM), linear discriminant analysis (LDA) and Naïve Bayes. In the following, each of these classifiers is briefly explained.

1) *LDA*. It is a supervised classification algorithm that is widely utilized in pattern recognition. LDA is a linear transformation technique that projects the data onto a lower-dimensional space, while maximizing interval between the groups. Purpose of LDA is to search for a linear integration of the input features that increases the ratio of between-group variances to within-group variances. Mathematically, this can be expressed by Eq. (2):

$$J(w) = \frac{w^T S_B w}{w^T S_W w} \quad (2)$$

where, w indicates the weight vector, S_B indicates the between-group scatter matrix, and S_W indicates the within-group matrix. Between-group scatter matrix measures the distance between the means of the different classes, while within-group matrix measures the variance within each class. Optimal weight vector w is determined by solving generalized eigenvalue problem through Eq. (3):

$$S_B w = \lambda S_W w \quad (3)$$

where, λ is the eigenvalue associated with w. Once weight vector is determined, classifier can be utilized to classify new

data points by projecting them onto the same lower-dimensional space and assigning them to the class with the closest mean.

2) *Naïve bayes*. It is a probabilistic classification approach widely utilized in machine learning and natural language processing. The algorithm works by Bayes' rule: probability of an assumption given some observed evidences is corresponding to the product of preceding probability of the assumption and likelihood of evidence for that assumption. Mathematically, this can be expressed as:

$$P(y|x_1, x_2, \dots, x_n) = \frac{P(y)P(x_1, x_2, \dots, x_n|y)}{P(x_1, x_2, \dots, x_n)} \quad (4)$$

In Eq. (4), y indicates the group label, x_1, x_2, \dots, x_n indicate input attributes, $P(y)$ is preceding probability of the group, and $P(x_1, x_2, \dots, x_n|y)$ indicates likelihood of evidence given a class. By Eq. (5), the Naïve Bayes classifier makes the hypothesis that input attributes are independent conditionally given a group label that allows the likelihood to be factorized as:

$$P(x_1, x_2, \dots, x_n|y) = \prod_{i=1}^n P(x_i|y) \quad (5)$$

This assumption is often called "naive" because it is rarely true in practice, but it simplifies the computation and often leads to good results. The Naive Bayes classifier can be trained by estimating the prior probabilities and the likelihoods from a labeled training set, and then using them to classify new data points by choosing the class with the largest posterior probability.

3) *KNN*. It is a non-parametric classification algorithm widely utilized in pattern recognition. This technique works by this concept that samples that are close in the feature space are probably to belong to the same group. Given a new data point, KNN finds K closest neighbors in training set and assigns group label that is most common among them. Mathematically, this can be expressed by Eq. (6):

$$\hat{y} = \arg \max_{y_i} \sum_{i=1}^K [y_i = y] \quad (6)$$

\hat{y} indicates predicted group label, y_i indicates group label of i -th closest neighbor, and K indicates the count of neighbors. Interval between samples is typically measured using Euclidean distance defined by Eq. (7):

$$d(x_i, x_j) = \sqrt{\sum_{k=1}^n (x_{ik} - x_{jk})^2} \quad (7)$$

where, x_{ik} and x_{jk} are the k -th feature value of the i -th and j -th data points, respectively. K may be determined using cross-validation. KNN algorithm is simple and easy to implement, but it may be expensive computationally for huge data and high-dimensional spaces. In this work, $K = 3$ was considered.

4) *SVM*. It is a kind of supervised technique utilized for regression and classification analyzes. SVM is especially

helpful in cases where data is not distinguishable linearly, meaning that a line may not be drawn to distinguish data into various groups. Instead, SVM utilizes an approach called kernel technique to transform data into a higher dimensional space where it may be linearly separated. SVM then finds a hyperplane that best distinguishes data into different groups while increasing margin that is separation between hyperplane and nearest samples from every group. Eq. (8) defined this hyperplane:

$$W^T x + b = 0 \quad (8)$$

w indicates weight vector, x indicates input vector, and b indicates bias term. SVM allocates a new input vector to one of the two groups according to which side of decision boundary it falls on. SVM wants to search for optimum values of b and w that reduce classification errors while increasing margins. This obtains through solving following optimization problem:

$$\text{minimize } \frac{1}{2} \|W\|^2 \text{ subject to } y_i(W^T x_i + b) \geq 1 \text{ for all } i \quad (9)$$

In Eq. (9), $\|w\|$ indicates Euclidean norm of weight vector, y_i indicates group label of i -th sample, and x_i indicates i -th input vector. Optimization problem may be solved through quadratic programming approaches. In this study, both linear and radial basis function (RBF) kernels were used to classify SSVEP features by SVM.

III. RESULTS

After preprocessing, all mentioned features were calculated from SSVEPs in three groups. Fig. 4 shows an example of recurrence plots estimated from SSVEPs in an ADHD patient, a client with bipolar disorder, and a normal subject. After extracting SSVEP features by spectral analysis and RQA, as mentioned before, DISR technique was utilized to decrease feature space. Afterward, leave-one-subject-out (LOSO) technique was used to evaluate classification performance of various classifiers. This technique is a widely used cross-validation method in machine learning that involves leaving out one subject at a time from the training set to evaluate the performance of a model. This technique is particularly useful in studies with small sample sizes or highly variable data across subjects. By leaving out one subject at a time, the LOSO technique can help identify which subjects are most important for the model's performance and which ones may be less relevant. The LOSO technique may be utilized for a range of machine learning algorithms, such as neural networks, SVMs, and decision trees. Although computationally expensive, the LOSO technique remains a valuable tool for evaluating the performance of machine learning models and improving their generalization to new data. In addition, in the study, accuracy, sensitivity and specificity measures were utilized to report the classification performance of the classifiers.

Fig. 4. An example of recurrence plots estimated from SSVEPs in (A) a healthy subject, (B) a ADHD patient, and (C) a patient with bipolar disorder.

The obtained results of the LOSO cross-validation algorithm is shown in Table II. As shown, best classification result was achieved using the selected features and SVM with linear kernel with accuracy of 78.57%, sensitivity of 79.15% and specificity of 77.94%. Naïve Bayes classifier also yielded a good accuracy of 76.20% for EEG classification of ADHD, bipolar disorder and normal groups. Furthermore, Fig. 5 shows how the accuracy percentage of the output changes with respect to the changes of the dimension of the feature space. As can be seen, it is not possible to simply determine the dimensions that are optimal for almost all classifiers. However, dimension 6 seems to be suitable for most classifiers except SVM-RBF.

TABLE II. CLASSIFICATION RESULTS FOR EEG CLASSIFICATION OF ADHD, BIPOLAR DISORDER AND NORMAL GROUPS THROUGH VARIOUS CLASSIFIERS AND SSVEP FEATURES

Classifier	Accuracy (%)	Sensitivity (%)	Specificity (%)
SVM-RBF	73.81	70.30	74.08
SVM-Linear	78.57	79.15	77.94
KNN	73.81	71.29	74.55
LDA	76.19	72.41	79.88
Naïve Bayes	76.20	71.37	80.36

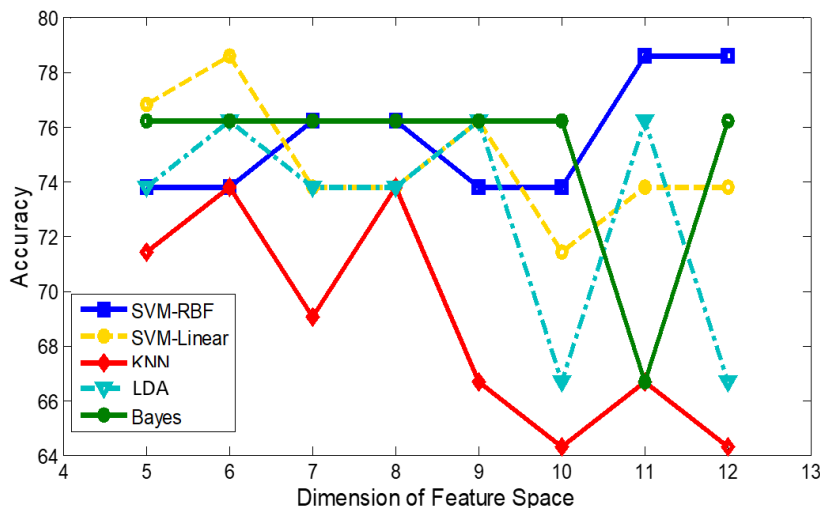

Fig. 5. Changes in output accuracy percentage versus feature dimension changes.

IV. DISCUSSION

There are psychiatric illnesses that share clinical symptoms and signs. Bipolar disorder and ADHD are two prevalent disorders whose symptoms are similar. In order to reduce the misdiagnosis between bipolar disorder and ADHD, a machine learning-based system using EEG and steady state potentials (i.e., SSVEP) was evaluated to classify ADHD, bipolar disorder and normal conditions. For this purpose, both linear and nonlinear dynamics of extracted SSVEPs were analyzed. Indeed, after data preprocessing, spectral analysis and RQA were applied to SSVEPs. Then, feature selection was utilized

through the DISR. The DISR feature selection method offers several advantages. Firstly, DISR effectively identifies informative and discriminative features, eliminating redundant and uninformative ones. By doing so, it enhances the classification performance, resulting in more accurate and reliable results. Additionally, DISR optimizes the computational cost by reducing the number of features, leading to improved processing speed. Finally, SVM classifier with linear kernel yielded an accuracy of 78.57% for ADHD, bipolar disorder and normal classification through the LOSO cross-validation. While SSVEPs have many advantages, they also have limitations and shortcomings that make them unsuitable for the problem at

hand. SSVEPs can sometimes suffer from low signal-to-noise ratio, especially in noisy environments. This can make it challenging to extract meaningful information from the recorded brain signals. SSVEPs are less effective in localizing brain activity compared to techniques like fMRI or EEG because they provide less spatial resolution. This means that identifying the exact brain region generating the response can be challenging. SSVEP responses can vary significantly between individuals, making it necessary to calibrate the system individually for each user. Prolonged exposure to flickering lights or screens, which are typically used to evoke SSVEPs, can lead to user fatigue or discomfort. This limits the practicality of using SSVEPs in long-term or everyday applications. Moreover, SSVEP-based systems are typically limited in the amount of information that can be reliably extracted from brain signals. This can restrict the complexity and richness of interactions that can be achieved using SSVEP interfaces.

The proposed system is less accurate compared to previous similar studies, where Nazhvani et al., Alimardani et al., and Sadatnezhad et al. reported accuracies higher than 84% for EEG classification of ADHD and bipolar disorder [23], [24], [25]. However, it should be noted that there are very few studies in the literature that have used EEG analysis to differentially diagnose these two disorders. The comparison of the present research with previous studies shows that the analysis of the resting-state or ongoing EEG signal can be a better solution for the differential diagnosis of ADHD and bipolar disorder compared to the SSVEP analysis. It should be noted that our motivation for analyzing steady-state potentials to distinguish these two disorders was previous EEG studies that reported significant differences between ADHD and bipolar disorder in terms of various EEG indices during cognitive performance [35]. Rommel et al. found that Absolute theta power may play a role as a marker of neurobiological processes in ADHD and bipolar disorder during a cued continuous performance task [36]. Furthermore, Michellini et al. reported less regulation of beta suppression in ADHD than in bipolar disorder during a cognitive task by analyzing event-related potentials (ERPs) [37]. Passarotti et al. showed significant differences in the prefrontal cortex of children with ADHD and bipolar disorder during an emotional valence Stroop task [38]. However, considering that none of the previous studies have used SSVEPs as biological data to be processed, we cannot make precise comparisons between the suggested system and previous techniques. Although this research is the first to evaluate the application of signal processing and machine learning methods in SSVEP classification of these disorders, it has limitations that future studies should investigate to enhance performance of the proposed system. First, presented visual stimulation was delivered to the participants without the presence of a cognitive task, whereas previous studies often use cognitive tasks during this type of stimulation. Second, in the present study, only the stimulation frequency of 15 Hz was investigated, and other stimulation frequencies need to be tested in the future. Finally, other linear and non-linear signal processing methods should be evaluated in future studies. In addition to high comorbidity of ADHD and bipolar disorder, the closeness of the EEG patterns of the two disorders was observed in this research. Therefore, in future studies, it is better to use soft labeling methods to classify

these two groups, which do not necessarily classify each subject as belonging to one group.

V. CONCLUSION

A new EEG classification scheme based on SSVEPs and machine learning techniques was presented in this work to distinguish ADHD from bipolar disorder. This framework exploited the linear and nonlinear properties of these cortical potentials and was tested on real-world EEG datasets from patients with ADHD and bipolar disorder. Valid performance evaluation criteria were calculated, which proved the acceptable performance of the proposed framework. However, external validation of such a framework is needed in future studies.

Exploring Cutting-Edge Developments in Deep Learning for Biomedical Signal Processing

Yukun Zhu*, Haiyan Zhang, Bing Liu, Junyan Dou

School of Integrated Circuit, Wuxi Vocational College of Science and Technology, Wuxi 214000, China

Abstract—Biomedical condition monitoring devices are progressing quickly by incorporating cost-effective and non-invasive sensors to track vital signs, record medical circumstances, and deliver meaningful responses. These sophisticated innovations rely on breakthrough technology to provide intelligent platforms for health monitoring, quick illness recognition, and precise treatment. Biomedical signal processing determines patterns of signals and serves as the backbone for reliable applications, medical diagnostics, and research. Deep Learning (DL) methods have brought significant innovation in biomedical signal processing, leading to the transformation of the health sector and medical diagnostics. This article covers an entire range of technical innovations evolved for DL-based biomedical signal processing where different modalities have been considered, including Electrocardiography (ECG), Electromyography (EMG), and Electroencephalography (EEG). A vast amount of biomedical data in various forms is available, and DL concepts are required to extract and model this data in order to identify hidden complex patterns that can be utilized to improve the diagnosis, prognosis, and personalized treatment of diseases in an individual. The nature of this developing topic certainly gives rise to a number of challenges. First, the application of sensitive and noisy time series data requires truly robust models. Second, many inferences made at the bedside must have interpretability by design. Third, the field will require that processing be performed in real-time if used for therapeutic interventions. We systematically evaluate these challenges and highlight areas where continued research is needed. The general expansion of DL technologies into the biomedical domain gives rise to novel concerns about accountability and transparency of algorithmic decision-making, a subject which we briefly touch upon as well.

Keywords—Biomedical signal processing; health monitoring; deep learning; electrocardiography; electromyography; electroencephalography

I. INTRODUCTION

Changing signals provide critical insights regarding the entities that produce them [1]. Advances in technologies such as IoT, machine learning, and Wireless Sensor Networks (WSN) have significantly enhanced the ability to interpret these signals, particularly in fields like biomedicine, where mechanisms change over time as their underlying characteristics continually evolve [2, 3]. These alterations can be abrupt, where the internal properties of the system change gradually over time, or gradual, where the internal properties change slowly over time [4]. The signals from these systems are also time-varying in nature, and their time-varying aspects can unveil the dynamics of these systems [5]. Heart rate variations under stress or pitch changes of a vocalist during a song, for example, show a time-dependent change in the Instantaneous Frequency (IF) of the signal [6].

Similarly, fluctuations in the system's response intensity are linked to changes in the Instantaneous Amplitude (IA). Furthermore, the nature of the vibrations might undergo alteration. The integration of these many sources of variability results in intricate patterns in the temporal progression of the signal.

Biomedical signals are acquired from different levels of the body, such as cellular, organ, and molecular levels. Biomedical signal processing comes from many modalities like EEG for tracking brain electrical activity, ECG for tracking heart electrical activity, EMG for tracking the noise signals of muscle, and electroretinogram and electroneurogram for tracking the electrical activities of the eye [7]. Biomedical signals are first used to diagnose or identify certain physiological and pathological conditions. Moreover, these signals are used in the healthcare industry to examine biological systems [8]. This objective is to remove noise from signals, extract features, accurately recognize signal models, reduce dimensionality for dysfunctional or crucial functions, and anticipate future pathological and functional events by applying AI models.

Typically, EEG signal processing and interpretation were generally carried out using a hierarchical process consisting of four main stages. First, a raw EEG signal was pre-processed to filter out noise and artifacts to improve the signal quality for further analysis. Following pre-processing, useful information should be obtained from the processed signal [9]. Mainly, this step involves techniques such as time-frequency analysis or spectral analysis to determine the features indicative of the different patterns of brain activity. After the features had been extracted, they were subjected to a feature selection method. This step involved selecting fewer extracted features in the next steps of the analysis to make the information more discriminative and to improve computational complexity.

Feature selection techniques such as Principal Component Analysis (PCA) and wavelet transform were frequently employed to identify the most discriminative features for classification or diagnosis. Then, the extracted features were subjected to diagnostic tests for disease diagnosis or for the identification of diverse functional states of the brain [10]. This stage usually involved the use of machine learning models and statistical tests to identify abnormal EEG patterns or patterns indicative of various neurological disorders. To learn complex structures present in EEG data and to help in the accurate classification or prediction task, machine learning algorithms such as Support Vector Machines (SVM), Artificial Neural Networks (ANNs) were employed [11].

Classical signal processing methods are widely used in biomedical signal analysis, providing robust tools for feature extraction, denoising, and signal classification [12]. The information obtained using approaches like Fourier transforms, wavelet analysis, and statistical methods has also led to more insight into many physiological functions and the detection of abnormalities. The complexity and time variations of biomedical signals, however, pose a serious challenge for classical signal processing methods in particular for the non-linear and nonstationary nature of the signals.

The emergence of Deep Learning (DL) has revolutionized biomedical signal processing by providing the capability to automatically learn hierarchical features from raw data with little human intervention [13, 14]. DL models, including Generative Adversarial Networks (GANs), Recurrent Neural Networks (RNNs), and Convolutional Neural Networks (CNNs), have achieved remarkable performance in a wide range of applications, such as extracting ECG arrhythmias, brain-computer interface based on EEG signals, and noise suppression in EMG signals [15, 16]. The turning point in the DL era encourages researchers to gradually shift from expert-designed feature engineering to data-driven end-to-end learning, leading to more precise, efficient, and flexible analysis of biological signals [17]. Table I provides a comparison of our study with previous related survey studies. In summary, the main contributions of this work are:

- Presenting a thorough overview of current advancements in DL techniques applied to biomedical signal processing;
- Reviewing and analyzing the existing DL architectures utilized in processing various biomedical signals;
- Identifying and discussing the challenges inherent in applying DL to biomedical signal analysis, such as noise handling, interpretability, and real-time processing requirements;
- Exploring emerging trends, future directions, and potential opportunities for interdisciplinary collaboration in advancing the field of DL for biomedical signal processing.

The rest of the paper is organized as follows. Section II offers a concise overview of biomedical signal processing fundamentals and the associated challenges. Section III presents an in-depth discussion of DL techniques developed for biomedical signal processing. In Section IV, we scrutinize the potential opportunities and existing challenges encountered in using DL for biomedical signals. Furthermore, in Section V, emerging trends and future research directions are presented for better comprehension and advanced research in this domain. Finally, Section VI provides a conclusion, overviews the contribution of DL to the field of biomedical signal processing, and hypothesizes future research opportunities.

TABLE I. COMPARISON OF OUR STUDY WITH PREVIOUS SURVEYS

Study	Methodology	Contribution
[21]	Comparative evaluation of feature selection and classification techniques for brain-computer interface	Offers insights into the effectiveness of different methods for feature selection and classification in brain-computer interface systems
[22]	Review of DL and ML in big data	Provides an overview of the evolution, concepts, and integration of DL and ML in big data analytics, categorizing and synthesizing their potential applications
[23]	Survey of DL in physiological signal analysis	Conducts a detailed study to comprehend, categorize, and compare key parameters of DL approaches in physiological signal analysis, offering insights into their applications and performance
[24]	Review of DL techniques for audio signal processing	Examines DL techniques applied to audio signal processing, identifying key models, challenges, and future directions in the field
[25]	Literature survey on ECG signal analysis	Describes traditional and advanced techniques for ECG signal analysis, discussing challenges, limitations, and future research directions in the field
Our Study	Reviews current advancements in DL techniques for biomedical signal processing, focusing on EEG signals	Provides a comprehensive overview of DL techniques for EEG signal analysis, identifies challenges, and explores future directions for interdisciplinary collaboration

II. BACKGROUNDS

The biomedical signaling modalities incorporate multiple physiological signals that reflect the functioning of different systems of the human body [18]. The signals are tabulated in Table II. ECG, EMG and EEG are some of the most popular examples of body signals providing various types of information about physiological or pathological processes in the human body [19]. ECG signals are the heart's electrical activity over time. ECG measures can check for heart rhythm, conduction abnormalities, ischemia, infarction, and more. These signals are necessary indicators for diagnosing heart failure, myocardial infarction, arrhythmias, etc. ECG can also monitor the heart as an indicator of infectious disease, trauma, and metabolic anomalies that affect the heart in the body. EMG captures

electrical signals produced when muscles are activated. It is used in many medical settings like neurology, orthopedics, sports medicine, physical therapy, and other related healthcare providers. The EMG signal is smoothly propagated throughout the body and can provide valuable information on some of the most deadly disorders humans have faced [20]. EEG is an electrophysiological monitoring method used to monitor the electrical activity of the brain. With EEG, voltage fluctuations around the scalp are measured in relation to electrical activity in the brain and waves that occur in a variety of forms and frequencies. From the determined EEG signals it is possible to diagnose neurological problems like epilepsy, tracking anesthesia depth during surgery, etc. Additionally, these measures can reveal other brain-related illnesses like Parkinson's, Alzheimer's, and sleep disorders.

TABLE II. OVERVIEW OF BIOMEDICAL SIGNAL MODALITIES

Modality	Description	Clinical applications
ECG	Measures heart's electrical activity over time	Detection of arrhythmias, ischemia, myocardial infarction
EMG	Captures electrical activity caused by muscle contractions	Diagnosis of neuromuscular disorders, rehabilitation guidance
EEG	Records brain electrical activity	Diagnosis of epilepsy, monitoring during surgery, studying brain disorders

Each biomedical signal type contributes to a different aspect of health and disease, thus offering different information [26]. ECGs are used to illustrate heart conditions. EMG signals are associated with the neuromuscular system, while EEG signals may be used to diagnose neurological conditions [27]. Hence, each signal type is related to a different medical specialty [28]. Moreover, not only is the potential of each signal type in isolation vast, but also, by combining the information from multiple sources, a comprehensive view of the patient's state can be achieved. This, in turn, can personalize the offered treatment. Over the years, advances in signal processing technology and machine learning algorithms have also greatly increased the utility of these signals for the clinician [29]. These technological improvements have led to more accurate diagnostics, prognostics, and personalized treatment plans. Biomedical signal types have the potential to transform and enhance medical treatment as the technology improves.

Advancements in DL, detailed in Table III, have revolutionized biomedical signal processing. DL is an instance of machine learning that uses ANNs with several layers to acquire hierarchical representations of input autonomously. DL models have an advantage over typical machine learning methods because they can extract important characteristics directly from raw data without the need for manually produced features [30]. Deep learning models are able to adapt themselves to very complex and high-dimensional data, such as biomedical signals. DL is currently used for denoising, feature extraction, classification, and segmentation of biomedical signals [31]. For example, CNNs are highly effective in automatically learning spatial and temporal features from biomedical signals such as ECGs and EEGs, enabling accurate classification of abnormal patterns indicative of various cardiac arrhythmias or neurological disorders. Likewise, RNNs can learn temporal dependencies in sequence data and are widely used in time-series prediction and signal segmentation in biomedical signals. Moreover, GANs have been exploited for signal augmentation and generation thereby increasing the availability of annotated data in large amounts for training DL models and their generalization.

TABLE III. DEEP LEARNING TECHNIQUES FOR BIOMEDICAL SIGNAL PROCESSING

DL technique	Description	Applications
CNN	Learns spatial and temporal features from signals	Classification of cardiac arrhythmias and neurological disorders
RNN	Captures temporal patterns in sequential data	Time-series prediction and signal segmentation
GAN	Augments data and improves generalization performance	Signal augmentation and data synthesis

DL in biomedical signal processing is not limited to diagnostic applications and can also be expanded to personalized medicine, monitoring in real-time, and therapeutic interventions. As an example, a recently reported study demonstrates the capability of DL models to analyze time-evolving data streams from wearable sensors to monitor disease progressions and recognize critical events in a patient with chronic illness such as heart failure or epilepsy [32]. In addition, DL-based predictive models can assist clinicians with more accurately identifying high-risk patient sub-cohorts that are susceptible to specific complications or adverse effects and subsequently administer timely and accurate preventive measures [33]. Alternatively, DL-based methods have been integrated into medical devices and e-health platforms to facilitate real-time processing and analysis of biomedical signals at the patient's bedside, thereby expediting clinical decision-making and personalizing the patient care pathway. In conclusion, DL technology may greatly advance the field of biomedical signal processing by offering a mechanism by which a larger amount of useful information can be extracted from complex physiological data, in turn potentially improving the broader population of patient's health outcomes.

The use of DL in biomedical signal processing has several key strengths that have the potential to transform medical care. First, DL models have successfully discovered multiple levels of abstraction from raw data without utilizing handcrafted feature extraction and selection. This is especially significant in biomedical signal processing, as the processed signals are usually complex and contain subtle information that could be difficult to apprehend with conventional methods. Another advantage of deep learning is that it can take full advantage of large-scale datasets to extract high-level discriminative features, which can be beneficial for more reliable and robust biomedical signal classification, detection, localization, and segmentation. DL can handle multiple types of signals, such as ECGs, EEGs, and EMGs, and can therefore be applied across a wide variety of clinical scenarios. Additionally, machine learning allows such models to become more accurate as they are given more data to learn from, and since it is constantly updated, they can become more accurate.

Yet, DL has not been spared from issues in utilizing it with biomedical signals. First, DL models are often regarded as black boxes due to their complex architectures and non-linear transformations, which may result in hidden representations or obscure representations of the underlying decisions performed by the model, hence reducing the confidence and interpretability of these models in clinical practice as opposed to interpretable models like LRA. This might be risky given the higher level of trust in transparently interpretable models such as LRA in the clinical domain. Second, biomedical signals are inevitably noisy, with artifacts and noise as well as intersubject and intrasubject variability, which may pose challenges to the

generalization of DL models and may further reduce their reliability. More broadly, the generalization and reliability of DL methods across different patient populations and clinical scenarios is an ongoing grave concern. Moreover, for the successful utilization of DL in healthcare, several ethical considerations, such as algorithmic bias, privacy and security of data, development, and use of DL models, must be systematically addressed. Developing methods to meet these key challenges will require novel approaches based on the collaboration of interdisciplinary teams, combined with rigorous validation of methods, theory, and algorithms, leading to the design of interpretative and reliable learning algorithms aligned with the distinctive requirements of biomedical signal processing.

III. DL TECHNIQUES FOR BIOMEDICAL SIGNAL PROCESSING

In the biomedical signal processing domain, DL algorithms exhibit versatility across four primary categories: deep supervised, unsupervised, reinforcement learning, and hybrid

algorithms, each offering unique approaches to tackle distinct challenges in signal analysis. As shown in Fig. 1 and summarized in Table IV, these categories span a range of methods, from supervised models that use labeled data to learn predictive rules to unsupervised models that discover patterns in data without any supervision and hybrid models that incorporate features of both. There can be a plethora of architectures and frameworks within every category of biomedical signal processing. For example, CNNs are usually used for capturing spatial features from ECGs, while RNNs are efficient in modeling temporal sequences from EEGs. Furthermore, there can be more explorations of NNs that simulate GANs for data augmentation and generation, and so on. These models find extensive applications in many tasks, such as signal denoising, feature extraction, classification, and segmentation, as tabulated in Table V, which in turn enhance the diagnostics, monitoring, and therapeutics in healthcare. The subsequent sections will provide brief explanations for each category, which will include methods, tasks, and utility in the emerging area of biomedical signal processing.

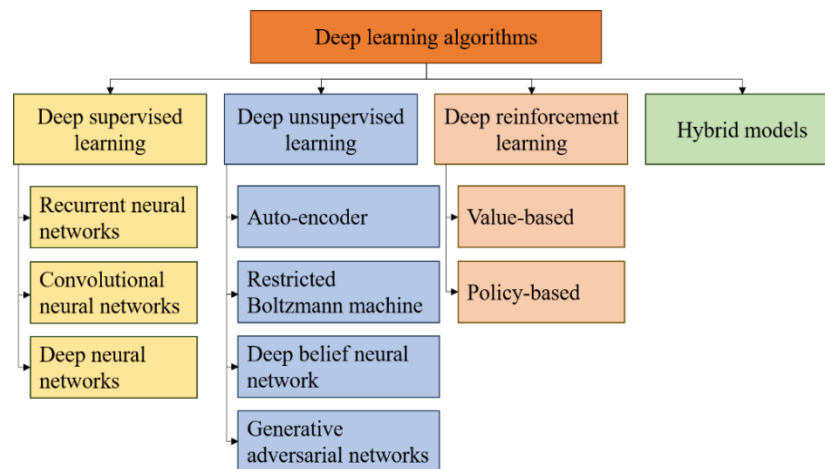

Fig. 1. DL algorithms in biomedical signal processing.

TABLE IV. OVERVIEW OF DEEP LEARNING CATEGORIES FOR BIOMEDICAL SIGNAL PROCESSING

Deep learning category	Description	Examples
Deep supervised learning	Utilizes labeled data to train models for accurate predictions	DNNs, CNNs, and RNNs
Deep unsupervised learning	Extracts meaningful representations from unlabeled data	Autoencoders, RBMs, DBNs, and GANs
Deep reinforcement learning	Learns optimal behavior through interaction with the environment	Value-based, policy-based, and model-based methods
Hybrid deep learning	Combines elements of different DL architectures for enhanced performance	Combination of CNNs and RNNs and CNNs with attention mechanisms

TABLE V. EXAMPLES OF DEEP LEARNING MODELS FOR BIOMEDICAL SIGNAL PROCESSING

Deep learning model	Description	Applications
DNN	Models complex relationships within high-dimensional data	Signal classification and prediction tasks
CNN	Captures spatial dependencies in signals	Image-based tasks (ECG, EEG) and signal classification
RNN	Models temporal dynamics and sequential dependencies	Time-series forecasting and sequential pattern recognition
Autoencoders	Learns compact representations of input data	Dimensionality reduction and anomaly detection
GAN	Generates realistic samples from a given distribution	Data augmentation and synthesis

A. Deep Supervised Learning

Deep supervised learning-based models represent a cornerstone in biomedical signal processing, leveraging labeled training datasets to learn discriminative features and make accurate predictions. These models operate by iteratively adjusting network parameters, often referred to as weights, to minimize a predefined loss function, effectively optimizing the model's performance. Among the supervised DL category, three pivotal architectures have emerged as particularly effective for processing biomedical signals: DNNs, CNNs, and RNNs, as depicted in Fig. 2. DNNs offer a robust framework for modeling complex relationships within high-dimensional data, making them well-suited for tasks such as signal classification and prediction. CNNs excel in capturing spatial dependencies in signals, enabling precise feature extraction from images or sequential data, such as ECGs and EEGs. Meanwhile, RNNs specialize in modeling temporal dynamics and sequential dependencies, which is crucial for tasks like time-series forecasting and sequential pattern recognition, particularly in signals with temporal structures like EEGs and EMGs. These deep supervised learning models constitute foundational tools in biomedical signal processing, facilitating accurate diagnosis, prognosis, and personalized treatment strategies for a wide range of medical conditions.

B. Deep Unsupervised Learning

Deep unsupervised learning models have emerged as a prominent branch within the realm of DL, offering compelling solutions for tasks requiring minimal labeled data. These models, as depicted in Fig. 3, encompass a variety of architectures designed to extract meaningful representations from unlabeled datasets, thereby enabling effective feature learning and data-driven insights. One prevalent category of deep unsupervised models is autoencoders, which aim to learn a compact representation of input data by encoding it into a lower-

dimensional latent space and then reconstructing the original data from this representation.

Restricted Boltzmann machines (RBMs) provide another powerful framework for unsupervised feature learning, leveraging energy-based probabilistic models to capture complex dependencies in data. Deep Belief Networks (DBNs) extend upon RBMs by stacking multiple layers of generative models, facilitating hierarchical representation learning. Moreover, GANs have garnered significant attention for their ability to generate realistic samples from a given distribution by training a generator network to produce data that is indistinguishable from authentic samples while simultaneously training a discriminator network to distinguish between actual and generated samples. These diverse deep unsupervised learning models offer versatile solutions for tasks such as data augmentation, dimensionality reduction, and anomaly detection in biomedical signal processing, thereby expanding the repertoire of techniques available to researchers and practitioners in the field.

C. Deep Reinforcement Learning

Reinforcement learning (RL) emerges as a transformative paradigm within the domain of biomedical signal processing, offering a dynamic framework for decision-making in complex environments to maximize cumulative rewards [34]. Unlike conventional supervised learning methods, RL operates in interactive settings, enabling agents to autonomously learn optimal behavior through iterative exploration and exploitation of the environment. In the context of biomedical signal processing, RL finds applications in adaptive treatment strategies, optimal medical device settings, and personalized healthcare interventions. Particularly pertinent is RL's capability to facilitate agent learning in environments where comprehensive prior knowledge is lacking or limited.

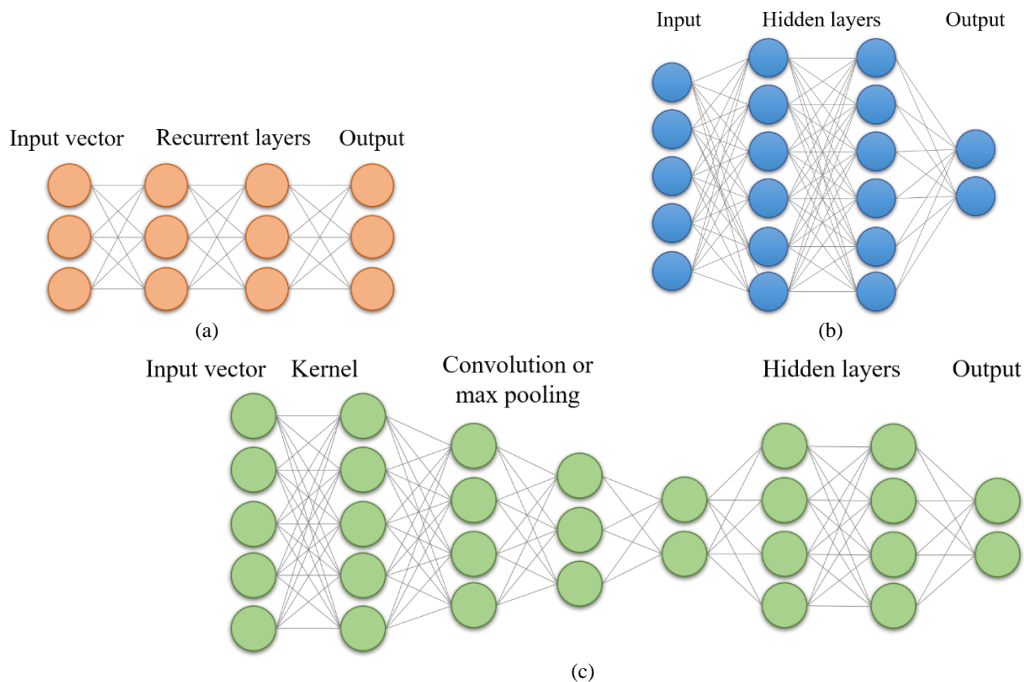

Fig. 2. Deep supervised learning architectures in biomedical signal processing: RNN (a), DNN (b), CNN (c).

Fig. 3. Deep unsupervised learning architectures in biomedical signal processing: GAN (a), DBNN (b), RBM (c), auto-encoder (d).

At the core of RL lies the iterative interaction between an agent and its environment. The agent perceives the current state, selects actions based on its policy, and receives feedback in the form of rewards, indicating the efficacy of the chosen actions in transitioning to new states. This feedback loop enables the agent to refine its decision-making strategy over time, with the aim of maximizing cumulative rewards. Notably, RL does not necessitate detailed mathematical models of the underlying system for optimal control. Instead, the agent treats the biomedical signal processing environment as a black box and optimizes its policy through continuous interaction and adaptation.

By leveraging RL techniques, biomedical signal processing agents can autonomously learn to navigate complex decision spaces, optimizing treatment regimens and medical device settings to enhance patient outcomes. Despite challenges related to scalability in large-scale networks, RL remains a powerful and versatile approach for learning optimal behavior in biomedical signal processing environments, offering promising avenues for innovation and advancement in healthcare delivery.

Deep Reinforcement Learning (DRL) harnesses the capabilities of deep neural networks to enhance learning efficiency and algorithm performance, as depicted in Fig. 4. By leveraging deep neural networks, DRL enables the agent to learn and adapt its decision-making policy within the environment effectively. The deep neural network serves as a fundamental component of the agent, maintaining an internal representation of the policy that dictates the agent's actions based on the observed state of the environment. This integration of deep neural networks facilitates rapid learning and improved

performance, which is crucial for real-time decision-making and adaptive control in biomedical signal processing applications.

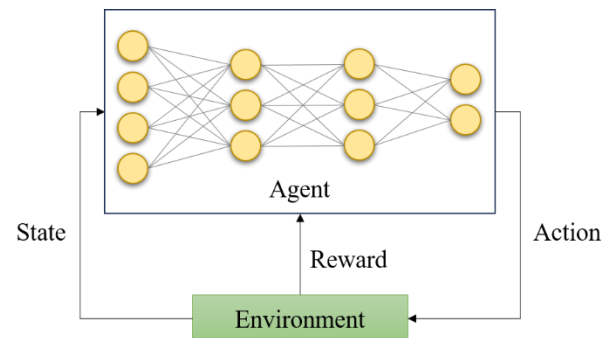

Fig. 4. Deep reinforcement learning in biomedical signal processing.

DRL methodologies in biomedical signal processing can be broadly categorized into three main approaches: value-based, policy-based, and model-based methods. Value-based methods focus on estimating the value or expected return of different actions in a given state, allowing the agent to select actions that maximize long-term rewards. Policy-based methods, on the other hand, directly parameterize the agent's policy and learn to optimize it through gradient-based methods without explicitly estimating the value function. Model-based methods incorporate a learned model of the environmental dynamics to guide decision-making, enabling the agent to plan and anticipate the consequences of its actions. Each of these DRL methods offers unique advantages and trade-offs, depending on the specific requirements and characteristics of the biomedical signal processing task at hand. Overall, DRL holds significant promise

for advancing the field of biomedical signal processing, offering efficient and adaptive solutions for a wide range of clinical applications.

D. Hybrid DL

DL models exhibit a spectrum of strengths and weaknesses concerning hyperparameter tuning and data exploration, as highlighted in previous research. These weaknesses may impede their efficacy across various applications. However, each DL model possesses unique characteristics that render it efficient for specific tasks. To address these shortcomings and leverage the strengths of individual DL models, hybrid DL models have been proposed. These hybrids combine elements of different DL architectures to mitigate weaknesses and enhance performance for specific applications.

Among these hybrid models, CNNs and RNNs stand out as widely utilized and versatile frameworks with high applicability and potentiality. CNNs excel in extracting spatial features from data, making them particularly suited for tasks involving images or sequential data, such as ECGs and EEGs. On the other hand, RNNs specialize in capturing temporal dependencies in sequential data, making them practical for time-series analysis and sequential pattern recognition, essential in fields like speech recognition and natural language processing. By combining the strengths of CNNs and RNNs, hybrid DL models can tackle a broader range of challenges and offer more robust solutions in biomedical signal processing and other domains. However, the selection and design of hybrid models depend on the specific requirements and characteristics of the application, highlighting the importance of tailored approaches in leveraging the full potential of DL in real-world scenarios.

IV. DISCUSSION

In classification tasks, assessing the performance of DL models necessitates the utilization of various metrics to accurately evaluate their effectiveness in classifying data. These metrics offer insights into different facets of the model's performance and aid in determining its efficacy in data classification [35]. Commonly employed metrics for evaluating DL models in classification tasks encompass accuracy, precision, recall, F1-score, area under the receiver operating characteristics curve, false alarm ratio, and misdetection ratio [36].

Accuracy: This metric is primarily utilized in classification problems to quantify the correct predictions made by a DL model. It is calculated as depicted in Eq. (1), where T_p represents true positives, T_N denotes true negatives, F_p signifies false positives, and F_N indicates false negatives.

$$A = \frac{T_N + T_p}{F_N + F_p + T_N + T_p} \times 100 \quad (1)$$

Precision: Precision pertains to the ratio of true positives to the total number of positive predictions, encompassing both true

positive and false positive instances. It can be expressed mathematically by Eq. (2).

$$P = \frac{T_p}{T_p + F_p} \times 100 \quad (2)$$

Recall (detection rate): This metric evaluates the proportion of positive samples correctly classified relative to the total number of positive samples. It is quantified according to Eq. (3), thereby indicating the model's proficiency in classifying positive samples, among others.

$$R = \frac{T_p}{T_p + F_N} \times 100 \quad (3)$$

F1-Score: Derived from the precision and recall of the test, the F1-Score integrates both metrics to provide a balanced measure of a model's performance as follows.

$$F = \frac{2T_p}{2T_p + F_N + F_p} \times 100 \quad (4)$$

Area under the receiver operating characteristics curve (AUC): AUC is a pivotal metric in classification problems, offering insights into the model's performance. The Receiver Operating Characteristic (ROC) curve illustrates the trade-off between sensitivity and specificity in DL models. The AUC value, ranging from 0 to 1, signifies the model's discriminative ability, with higher values indicative of superior performance. It is computed using Eq. (5), where x represents the varying AUC parameter.

$$AUC = \int_{x=0}^1 \frac{T_p}{T_p + F_N} \left(\left(\frac{F_p}{F_p + T_N} \right)^{-1} (x) \right) dx \quad (5)$$

False alarm ratio: Also known as the false positive rate, this metric quantifies the likelihood of a false alarm being triggered, wherein a positive result is generated when the actual value is negative. It can be calculated by Eq. (6).

$$FAR = \frac{F_p}{T_N + F_p} \times 100 \quad (6)$$

Misdetection ratio: This metric signifies the percentage of misclassified samples, highlighting instances where the model fails to detect the correct class. It is expressed as the percentage of samples that remain undetected, as demonstrated in Eq. (7).

$$MR = \frac{F_N}{T_p + F_N} \times 100 \quad (7)$$

In the domain of biomedical signal processing, learning strategies encompass a range of techniques tailored to address the unique challenges and requirements of analyzing physiological data. These strategies comprise online learning, federated learning, and transfer learning, each offering distinct advantages and applications in biomedical signal analysis, as summarized in Table VI.

TABLE VI. LEARNING STRATEGIES IN BIOMEDICAL SIGNAL PROCESSING

Learning Strategy	Description	Advantages	Applications
Online Learning	Involves continuously updating DL model parameters as new data becomes available, facilitating real-time adaptation to changing signal patterns and dynamic monitoring and interventions for patients.	Real-time adaptation, dynamic monitoring, responsiveness to evolving patterns	Dynamic monitoring of patient health, adaptive interventions, real-time decision-making in healthcare
Transfer Learning	Leverages knowledge from training on one dataset to improve performance on related but different datasets, allowing DL models trained on one type of physiological data to be adapted and applied to similar tasks with different data modalities.	Utilization of existing knowledge, enhanced generalization and efficiency	Generalization across different data modalities, adaptation to new tasks with limited labeled data
Federated Learning	Enables DL models to be trained over distributed data sources while maintaining data privacy, facilitating collaborative model training using data from multiple healthcare institutions without compromising patient privacy.	Data privacy preservation, scalability, reduced computational burden	Collaborative model training across multiple healthcare institutions, robust and generalizable model development

Online learning involves continuously updating the DL model's parameters as new data becomes available. In biomedical signal processing, online learning enables real-time adaptation to changing signal patterns, facilitating dynamic monitoring and adaptive interventions for patients [37]. The purpose of online learning in biomedical signal processing is to optimize the accuracy and adaptability of prediction models by leveraging prior predictions [38]. Contrary to offline or batch machine learning strategies, which necessitate the entire training dataset to be available for training, online learning models operate dynamically, continuously updating their parameters with each new data instance in a sequential stream. This real-time updating process enables online learning models to adapt to evolving patterns and dynamics within biomedical signals swiftly, facilitating dynamic monitoring and responsive interventions for patients.

By iteratively refining their predictive capabilities based on incoming data, online learning models can effectively capture temporal dependencies and subtle changes in signal characteristics, enhancing their ability to provide accurate and timely predictions in clinical settings [39]. Furthermore, the sequential nature of online learning aligns well with the streaming nature of many biomedical signal data sources, enabling seamless integration and analysis of continuous streams of physiological data. Thus, online learning serves as a valuable approach in biomedical signal processing, enabling efficient model adaptation and real-time decision-making in healthcare applications. Through this continual learning process, the online model endeavors to optimize its predictive accuracy and adaptability, ultimately achieving better performance in classifying or predicting outcomes in real-world applications.

Transfer learning leverages knowledge gained from training on one dataset to improve performance on a related but different dataset [40]. In the context of biomedical signal processing, transfer learning allows DL models trained on one type of physiological data (e.g., ECG signals) to be adapted and applied to similar tasks with different data modalities (e.g., EEG signals), thereby enhancing model generalization and efficiency. Training DL models from scratch demands substantial computational resources, memory allocation, and abundant labeled datasets. However, in specific scenarios, the availability of vast annotated datasets is not always feasible or practical. This limitation poses a significant challenge, particularly in domains such as biomedical signal processing, where data acquisition and annotation can be resource-intensive and time-

consuming. As a result, researchers often encounter constraints when attempting to develop robust DL models for analyzing biomedical signals. The scarcity of labeled datasets presents a bottleneck in traditional DL approaches, hindering the model's ability to generalize effectively to unseen data and limiting its performance in real-world applications.

Moreover, the computational and memory requirements for training large-scale DL models exacerbate these challenges, making it difficult to deploy them in resource-constrained environments. Alternative strategies such as transfer learning, semi-supervised learning, and unsupervised learning have emerged as promising approaches in biomedical signal processing to address these limitations [41]. These strategies leverage existing knowledge from pre-trained models or exploit unlabeled data to enhance model performance without the need for extensive labeled datasets. By leveraging transfer learning, for instance, researchers can adapt pre-trained models on related tasks or domains to biomedical signal processing tasks, thereby reducing the dependency on large annotated datasets while still achieving competitive performance. Similarly, semi-supervised and unsupervised learning techniques enable the utilization of unlabeled data to augment the training process, facilitating the discovery of underlying patterns and structures within biomedical signals. In transfer learning, a pre-trained neural network, typically trained on an extensive dataset for a related task, serves as the basis for learning new tasks or domains with limited labeled data.

Federated learning enables DL models to be trained over distributed data sources while maintaining data privacy. In biomedical signal processing, federated learning facilitates collaborative model training using data from multiple healthcare institutions, enabling the development of robust and generalizable models without compromising patient privacy [42]. In conventional centralized DL systems, collected data is typically kept on local devices. Centralized DL involves storing user records on a central server and utilizing them for both training and testing functions. However, this centralized approach is not without its limitations. One significant drawback is the requirement for high computational power, as all data processing and model training tasks are performed on the central server. This can lead to scalability issues, mainly when dealing with large datasets or complex DL models, requiring substantial computational resources to achieve acceptable performance.

Furthermore, centralized DL systems may raise concerns regarding security and privacy. Centralizing sensitive user data

on a single server increases potential vulnerabilities and unethical access, compromising user privacy and confidentiality. Moreover, compliance with data protection regulations, such as GDPR or HIPAA, becomes more challenging in centralized systems due to the centralized storage and processing of user data. To address these shortcomings, decentralized approaches, such as federated learning, have emerged as promising alternatives. Federated learning enables model training to be performed locally on user devices, with only model updates aggregated on a central server. This distributed method maintains data confidentiality by keeping user data on local devices, reducing the risk of data exposure, and enhancing security. Additionally, federated learning reduces the computational burden on the central server, making it more scalable and efficient for training DL models on decentralized data sources.

V. FUTURE DIRECTIONS AND OPPORTUNITIES

The area of DL for biomedical signal processing has great potential to improve healthcare delivery, enhance patient satisfaction, and enable discoveries in the future. Some important issues to concentrate on and possible paths to investigate include:

- **Interdisciplinary collaboration:** Facilitating interdisciplinary cooperation between DL scientists and healthcare, biological, or signal processing experts can produce new solutions specifically fitting the requirements of biomedical signal processing. By combining knowledge from multiple domains, researchers can increase their understanding of complex biological processes. This will result in more generalizable methods for disease diagnosis, health monitoring, and personalized treatment.
- **Integration of multi-modal data:** Since biomedical data includes a variety of modalities, such as ECG, EEG, EMG, and medical imaging, the integration of these multi-modality signals may offer a unique prospect to exploit interdependencies and improve diagnostic reliability. DL models can agilely harmonize and pool the diverse modalities to discover vital information, which could, in turn, unravel the mysteries behind diverse biological underpinnings.
- **Real-time monitoring and intervention:** Recent developments in DL algorithms and advances in hardware acceleration technologies make the vision of deploying real-time monitoring systems for continuous health monitoring and early detection of anomalies possible. Such systems have the potential to allow for timely intervention and personalized care plans that all combine into improved care outcomes and reduced healthcare costs.
- **Explainable AI and interpretability:** Improving the comprehensibility of deep learning models is essential for establishing confidence among physicians and healthcare practitioners. Future research should prioritize the development of explainable AI approaches that provide insights into the decision-making process of DL models. This will allow doctors to comprehend and

evaluate model predictions within the framework of clinical practice.

- **Continuous learning and adaptation:** Implementing mechanisms for constant learning and adaptation within DL models can enhance their ability to respond dynamically to evolving patient conditions and healthcare requirements. By incorporating feedback loops and reinforcement learning techniques, models can continually update and refine their predictions based on new data, enabling proactive interventions and personalized healthcare management.
- **Remote monitoring and telehealth:** The proliferation of wearable devices and remote monitoring technologies presents opportunities for leveraging DL in telehealth applications. DL models can analyze data from wearable sensors and remote monitoring devices to monitor patient health remotely, detect early warning signs of deterioration, and facilitate virtual consultations with healthcare providers, particularly in underserved or remote areas.
- **Patient stratification and precision medicine:** DL models may give valuable support to patient stratification and precision medicine by discovering natural clusters of patients with shared attributes in terms of clinical and biological characteristics and by predicting the response to treatment on an individual basis. This patient-specific guidance would allow for the personalization of treatment strategies, thus allowing for maximization of therapeutic benefit while minimizing collateral toxicity, with the ultimate goal of enhancing patient satisfaction.
- **Standardization and benchmarking:** In this context, standardization of pre-processing enforces the core virtues of reproducibility, comparability, and reliability across studies. This goal can be achieved by sharing standardized datasets, assessment protocols, and benchmarks through community-wide efforts to benefit progress and translational efficacy.
- **Domain-specific architectures:** Designing domain-specific deep learning architectures based on the unique features of biomedical signal data works in alleviating the model performance and interpretability. For instance, using architecture like RNNs with attention mechanisms in the time-series data or CNNs specifically tailored for medical imaging data instead of raw architectures better captures the complex temporal and spatial patterns existing far more robustly in biomedical signals.
- **Multi-task learning:** Multi-task learning paradigms, where DL models are trained to accomplish multiple related tasks concurrently by sharing a common input representation, may enable better knowledge transfer across tasks. For example, in biomedical signal processing, multi-task learning may allow models to predict multiple clinical outcomes or physiological parameters at the same time, allowing knowledge to propagate between tasks and hence improving the model's generalization capability.

- Resource-constrained environments: Techniques in deep learning can be extended to address the needs of resource-constrained environments, for instance, those involving low-power devices or the healthcare infrastructure of many developing countries. Therefore, in order to make these cutting-edge healthcare technologies available worldwide, we need more research on lightweight and efficient DL models, data compression, and edge computing so that these can be deployed to resource-constrained settings without compromising on performance and accuracy.
- Integration with Electronic Health Records (EHRs): Integrating DL models with EHRs can help clinicians glean meaningful knowledge from the wealth of clinical data, allowing for predictive analytics, disease surveillance, and decision support. Leveraging data fields of EHRs, DL models can assist with improving clinical decision-making, streamlining administrative tasks, and increasing healthcare operational efficiency.

VI. CONCLUSION

In this survey, we thoroughly reviewed the DL-based signal processing methods for the processing of biological signals. We covered a wide variety of DL-based models, including deep supervised, deep unsupervised, DRL, and hybrid models. All of these models have unique advantages, characteristics, and applications in biological signal processing. We discussed the drawbacks of conventional signal processing methods and motivated using DL models in biological signal processing, which can learn intrinsic features and automatic optimization independently. We then provided a brief introduction of each biological signal (e.g., ECG, EEG, and EMG) and presented a brief review of their clinical significance. We then put the problem in context by explaining the relevance of signal processing in the healthcare diagnostics and monitoring domain. We also discussed related works and the limitations of using DL with biological signals. The primary challenges to using DL in this context are the need for labeled data, heavy computational requirements, and the non-intuitive nature of the DL model. We also discussed some potential future works and emerging trends that are likely to drive this field, such as the need for collaborative and interdisciplinary investigations, multi-modal data integration, and the ethical concerns of DL for healthcare. We showed the possible ways the DL model could be used for real-time monitoring, telemedicine, and precision medicine, as well as the importance of standardization, benchmark databases, and ethical guidelines to ensure sustainable advances. In addition, we discussed the potential of DL to address global health crises and healthcare disparities, seeing the exciting possibilities of DL to reshape healthcare and individual health.

The Performance of a Temporal Multi-Modal Sentiment Analysis Model Based on Multitask Learning in Social Networks

Lin He, Haili Lu*

Faculty of Education, Shaanxi Normal University, Xi'an, 710062, China

Abstract—When conducting sentiment analysis on social networks, facing the challenge of temporal and multi-modal data, it is necessary to enable the model to deeply mine and combine information from various modalities. Therefore, this study constructs an emotion analysis model based on multitask learning. This model utilizes a comprehensive framework of convolutional networks, bidirectional gated recurrent units, and multi head self-attention mechanisms to represent single modal temporal features in an innovative way, and adopts a cross modal feature fusion strategy. The experiment showed that the model accomplished 0.83 average precision and a 0.83 F1-value, respectively. In contrast with multi-scale attention (0.69, 0.70), aspect-based sentiment analysis (0.78, 0.74), and long short-term memory network (0.71, 0.78) models, this model demonstrated higher robustness and classification accuracy. Especially in terms of parallel computing efficiency, the acceleration ratio of the model reached 1.61, which is the highest among all compared models, highlighting the potential for time savings in large data volumes. This study has shown good performance in sentiment analysis in social networks, providing a novel perspective for solving complex sentiment classification problems.

Keywords—Multi task learning; multi-modal; emotional analysis; attention mechanism; feature fusion

I. INTRODUCTION

Due to the rapid growth of social networks and the increasing number of users expressing emotions on platforms, social media has become an indispensable part of people's daily lives [1]. Users can not only communicate conveniently on these platforms, but also share emotions and viewpoints, which has become one of the main channels for social emotional and opinion dissemination. Users express their emotions and opinions through publishing text, images, videos, and other forms of content, thus forming a vast and rich information network. Therefore, analyzing and understanding emotions and perspectives on social media is of great significance for grasping social emotional dynamics and gaining a deeper understanding of user needs [2]. However, people's emotional expression on platforms shows a trend of diversification and complexity, which puts higher demands on sentiment analysis technology.

Emotional analysis requires a deep understanding and modeling of user emotional states, in order to extract relevant emotional features from complex data [3]. Existing sentiment analysis tools mostly focus on text content and rarely involve emotion recognition in images or videos, especially lacking sentiment flow analysis in time series [4]. In addition, existing sentiment analysis techniques face the problem of difficulty in

accurately capturing and analyzing emotional information in multi-modal data containing temporal information. Therefore, new sentiment analysis techniques urgently need to be proposed to address the aforementioned challenges.

Multimodal data analysis includes various forms of data such as text, images, videos, etc. It is suitable for analyzing complex content in social media and can provide a more comprehensive understanding of user emotional states and dynamic changes [5]. However, there are still some challenges in this analysis method, such as how to effectively integrate data from different modalities, and how to accurately capture the impact of temporal information on emotions. In addition, due to the diversity and complexity of data, sentiment analysis models often find it difficult to fully consider all possible scenarios and contexts, which affects the accuracy and stability of analysis results. Therefore, further research and improvement of algorithms are needed to enhance the accuracy of sentiment analysis in multimodal temporal data.

In view of this, in order to deeply explore and accurately analyze emotions in social media, this paper proposes a multi-task learning emotion analysis model combining multi-modal data and temporal characteristics. The innovation of the research lies in applying multimodal fusion and time series analysis to emotion recognition tasks to improve the comprehensiveness and effectiveness of the model, aiming to achieve public opinion monitoring and emotional recommendation.

The contribution of the research is to fill the gap in multimodal temporal data processing with existing sentiment analysis techniques, providing new ideas and methods for the development of social media sentiment analysis. By delving into emotional information in multimodal data and combining it with time series analysis, research is expected to provide more accurate and comprehensive emotional analysis services for social media platforms, thereby promoting the intelligent development of social media.

The research content contains six sections. Section II is an overview of the current research status of Temporal Multi-modal Sentiment Analysis Models (TMSAM) for multitasking learning. Section III introduces a single modal temporal feature representation method. It fully explores the intrinsic temporal information in sequence data through convolutional networks (CNN), bidirectional Gated Recycle Unit (BiGRU), and multi-head self attention mechanisms (MH-SAM), and proposes a cross modal feature fusion method. Section IV gives details about the application of sentiment analysis. Result and discussion is given in Section V. Finally, Section VI concludes

the paper.

II. RELATED WORKS

Emotional analysis has always been a highly focused research field in social networks. The focus of research on sentiment analysis models for multi-modal data and temporal features mainly includes the fusion of sentiment features, modeling of temporal information, and the application of multitasking learning. Rahmani et al. designed a multi-modal emotion prediction model based on a cognitive perception framework. This model constructed an adaptive tree by hierarchical partitioning of users, and then trained sub models of Long Short Term Memory (LSTM), utilizing attention-based fusion to transfer cognitive oriented-knowledge within the tree. This algorithm could better use potential clues and promote prediction results compared to other ensemble methods [6]. Middy et al. explored various fusion strategies, including early fusion, late fusion, and attention mechanisms, to effectively combine and utilize complementary data from diverse modalities [7]. Zhou et al. established a new multi-modal model for audio-visual emotion recognition built on adaptive multi-level factor decomposition bilinear pooling. This model utilized FCN networks to recognize speech emotions and adopted adaptive strategies to calculate fusion weights. Compared to other methods, this method outperformed current advanced data with 71.40% accuracy [8]. Zhang et al. proposed a cross modal semantic content association method. It took pre trained CNN to encode the content of visual sub regions, then associated them with images, and used CASR networks to process class aware statements, finally feeding them back to within class dependency LSTM. The proposed correlation method has been proven to be effective [9].

In addition, the exploration of MTL methods has become a prominent research focus to optimize the sentiment analysis models in social networks. Kumari R et al. jointly learned freshness and emotion error detection from target text and proposed a MTL based emotion recognition and error detection model. The proposed model has improved accuracy compared to other models on four different datasets [10]. Akhtar et al. utilized the correlation between participating tasks in a multitasking framework and set three different settings. Each setting includes two tasks: emotion classification and emotion intensity. The evaluation showed that this framework produced better performance compared to single task learning frameworks [11]. Plaza Del Arco et al. utilized shared emotional knowledge and Transformer models to detect various

hate speech in social media networks. By jointly learning multiple related tasks, such as sentiment polarity classification, sentiment recognition, and subjective detection, MTL utilized shared representations and promoted the extraction of task specific features, thereby improving the model's generalization ability and adaptability. The combination helped to more accurately detect hate speech across datasets when multitasking [12].

In summary, at present, emotional analysis in social networks urgently requires in-depth research on multi-modal data and time series. Current research mostly addresses the complexity of sentiment analysis by building MTL frameworks, while integrating different modalities of data processing cannot fully understand user emotions. On this basis, this study proposes a TMSAM based on MTL to address emotional complexity to conduct targeted analysis of emotions in social networks.

III. MULTI-MODAL SENTIMENT ANALYSIS MODEL AND EXPERIMENTAL DESIGN

This study constructs an emotion analysis model based on multitask learning. It utilizes a comprehensive framework of CNN, BiGRU, and MH-SAM to represent single modal temporal features in an innovative way, and adopts a cross modal feature fusion strategy.

A. Design of TMSAM Model Based on MTL

MTL is inspired by human inductive learning, which improves the generalization performance of models by simultaneously learning information from multiple related tasks and achieving information sharing. Multi-modal sentiment analysis based on multitask learning faces three major challenges: intra modal, out modal, and inter modal interactions [13]. Inter modal interaction involves the fusion of multiple modal features. Intra modal interaction involves contextual interaction of the target discourse. Out modal involves the correlation and influence between different emotional tasks. This study proposes a sentiment analysis model based on deep multitasking learning from these three aspects. This model combines sentiment and emotion analysis, utilizes BiGRU to capture contextual information of conversations, and achieves inter modal interaction through attention mechanisms, while predicting emotions and emotions. The model structure is Fig. 1.

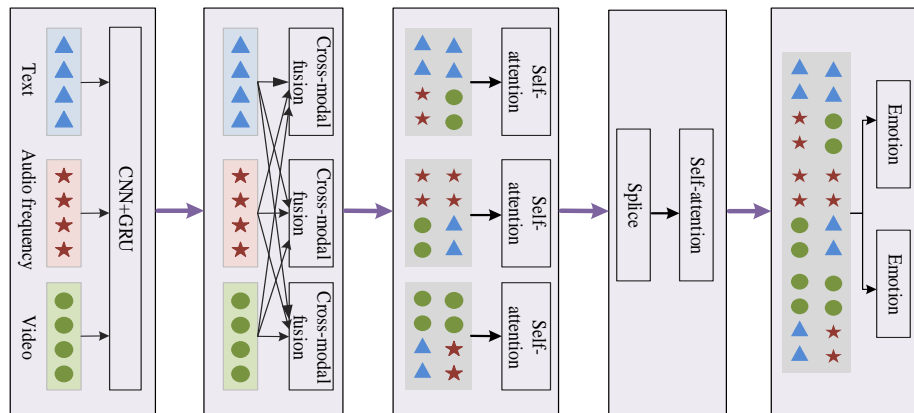

Fig. 1. Multi task sentiment analysis model.

In Fig. 1, the first step is intra modal feature extraction, where each conversation segment records the language text, facial expressions, and audio information of different speakers in chronological order. Due to the changing emotions during the dialogue process, discourse emotion detection is dependent on its context [14]. Therefore, this study uses pre trained models to extract and contextual features of the target discourse based on the three modalities of text, video, and audio, and concatenates them to represent the final features of each modality. The subsequent stage involves multi-modal feature fusion and MTL, using two different fully connected sub-networks to classify emotions and emotions in the obtained feature matrix [15].

In the step of intra modal feature extraction, this study conducted single modal feature extraction. Assuming each sample $X = (x_1, x_2, \dots, x_n)$ in the dataset be a time series of length L . This time series consists of n segments of dialogue, text, video, and audio. Feature extraction utilizes CNN and BiGRU to obtain global contextual feature information to extract internal features of a single modality [16]. This study used a set of CNNs with the same width, height, and sequence dimensions to extract local information, as shown in Fig. 2.

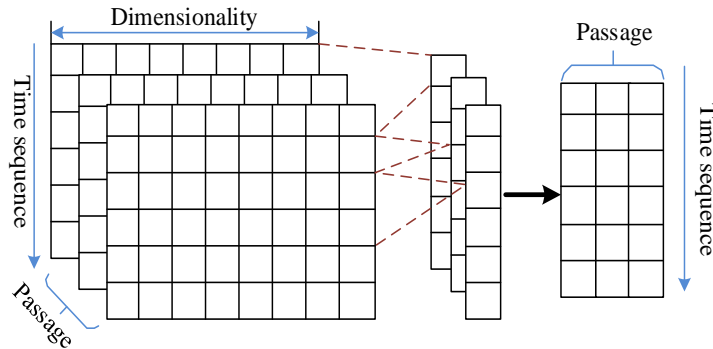

Fig. 2. Process of CNN extracting local temporal information.

In Fig. 2, this study uses a set of convolution kernels with the same height, width, and sequence dimension to extract local information. The data processed by CNN maintains a time series structure, but the dimension is unified as the number of convolution kernels $d = (k \in \{T, A, V\})$. When the stride of the convolutional kernel is 1 and no padding is used, the original time series length is shortened, which helps to accelerate subsequent recurrent neural network training and reduce the shape of the attention matrix [17]. Text features are extracted through GloVe. Audio features are extracted through CoVarRep. Video features are extracted through Facet. The obtained features are averaged based on word dimensions to obtain sentence level feature representations, as shown in Eq. (1).

$$X^m = [X_1^m, X_1^m, \dots, X_n^m] \in R^{T \times d_m} \quad (1)$$

In Eq. (1), $m \in \{T, A, V\}$, T , V , and A are text, video, and audio formats. The sampling rate of different modal features is different, and the dimension feature $d \in \{T, A, V\}$ and sequence length $L \in \{T, A, V\}$ are different. Using CNN as a sequence alignment tool in multi-modal sentiment analysis, similar to a fully connected layer (FCL), passes the input sequence to a 1D convolutional layer. The expression is Eq. (2).

$$\hat{X}_{[T,A,V]} = Conv1D(X_{[T,A,V]}, X_{[T,A,V]}) \in R^{T \times d_{[T,A,V]}} \quad (2)$$

In Eq. (2), L represents a time series of length L . $k_{[T,A,V]}$ represents modality's convolution kernel size. BiGRU consists of the update/reset gate, with a simple structure that can alleviate the issues of gradient dispersion and explosion [18-19], as shown in Eq. (3).

$$\begin{cases} r_j = \delta(U_r x_{ij} + W_r h_{j-i} + b_r) \\ z_j = \delta(U_z x_{ij} + W_z h_{j-i} + b_z) \end{cases} \quad (3)$$

In Eq. (3), x_{ij} represents the input characteristic value of the j -th element in sample i . U, W is weight. b means the bias coefficient. The hidden layer state of the modal sequence is Eq. (4).

$$\begin{cases} \hat{h}_t = \tanh(U_h x_{ij} + W_h h_{j-i} + b_h) \\ h_t = z_t + \hat{h}_t + (1 - z_t) h_{t-1} \end{cases} \quad (4)$$

In Eq. (4), h_t means the hidden layer state of the modal sequence at time t . Continuing to input the data processed by CNN into BiGRU, continuously update the hidden state, and extract the bidirectional hidden state corresponding to the time series as high-order time features. Its expression is Eq. (5).

$$Z_{[T,A,V]} = BiGRU(X_{[T,A,V]}) \in R^{L \times d} \quad (5)$$

After obtaining text, visual, and audio features, multi-modal feature fusion is then performed. This process integrates the feature information from different modes or sensors to lift the robustness of the model. The core idea is to combine information from different modalities to obtain more comprehensive and accurate information. Common multi-modal feature fusion ways include early/late/hybrid fusion strategies [20].

B. Establishment of Feature Fusion and Performance Evaluation Methods in Multi-Modal Sentiment Analysis

In multi-modal emotion classification, the importance of each modality varies for different tasks, sometimes through

facial expressions, and sometimes through language expression. Therefore, the contribution of each modality is crucial to the final classification result. Cross modal attention can capture the connection between modalities and achieve dynamic interaction. MH-SAM can reduce dependence on external data and is beneficial for capturing internal connections of data or features [21]. The model obtains the dependency relationships between words by analyzing the dependency tree of sentences. Fig. 3 shows the dependency relationships of sentences.

Fig. 3. Dependency relationships between sentences.

After obtaining the dependency relationships between words through the semantic dependency tree of sentences, the model uses bidirectional LSTM to extract sentence representations from text data, and then uses CNN combined with dependency relationships to encode the sentence representations to obtain node representations. Then, using attention mechanism, the node representation is reassigned to the emotional weights of the sentence representation and inputted into the FCL. Finally, the sentiment orientation of the sentence is determined through a discriminator. The multi head attention mechanism is Fig. 4.

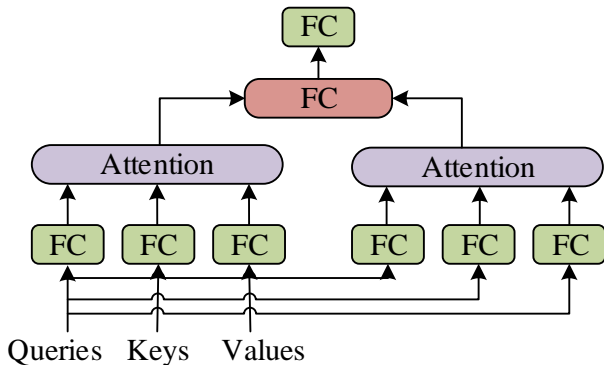

Fig. 4. Schematic diagram of multi head attention mechanism.

In Fig. 4, this study combines the advantages of cross modal attention and multi head self attention (MHSA) and proposes a multi-level cross modal feature fusion method. This method allows the attention mechanism to learn different behaviors based on the same set of queries, keys, and values, and allows the attention mechanism to combine different subspace representations to transform values, keys, and queries, which may be beneficial. Multiple attention pooled outputs are connected together and transformed through a learned linear projection to generate the final output. This is called multi-head attention. The calculation formula for MHSA from modality to modality is Eq. (6).

$$\begin{cases} Y_\lambda = CM_{\eta \rightarrow \lambda}(X_\lambda, X_\eta) = \text{soft max} \left(\frac{Q_\lambda K_\eta^L}{\sqrt{d_k}} \right) V_\eta \\ Y_\lambda = \text{soft max} \left(\frac{X_\lambda W_{Q_\lambda} W_{K_\eta}^L X_\eta^L}{\sqrt{d_k}} \right) X_\eta W_{V_\eta} \end{cases} \quad (6)$$

In Eq. (6), $\sqrt{d_k}$ represents the scaling factor. Q_λ , K_η and V_η are the query, key and value vectors. Operation QK^L can obtain the attention weight matrix, and the specific calculation formula for the three vectors is Eq. (7).

$$\begin{cases} Q_\lambda = X_\lambda W_{Q_\lambda}, W_{Q_\lambda} \in R^{d_\lambda \times d_k} \\ K_\eta = X_\eta W_{K_\eta}, W_{K_\eta} \in R^{d_\eta \times d_k} \\ V_\eta = X_\eta W_{V_\eta}, W_{V_\eta} \in R^{d_\eta \times d_k} \end{cases} \quad (7)$$

In Eq. (7), W_{Q_λ} , W_{K_η} , and W_{V_η} are the mapping matrices of the query/key/value vector. This study utilizes a cross modal attention mechanism to fuse features pairs by pairs between different modalities, capturing the correlation between modalities. This stage is called the cross modal feature fusion layer [22]. Then, the obtained pairwise fused feature matrix is concatenated and the internal correlation of modal features is captured through self attention mechanism. Furthermore, these modal feature matrices are concatenated twice and fused again through self attention to capture the correlation between different modal characteristics and identify the modal information that contributes the most to the recognition task. The data is mapped to a low dimensional space, and the outputs of all attention heads are gathered to obtain the complete output result, as shown in Eq. (8).

$$\begin{cases} Z_z = [\hat{Z}_T \oplus \hat{Z}_A \oplus \hat{Z}_V] \\ Z_I = \text{attention}(Z_z) \end{cases} \quad (8)$$

In Eq. (8), \hat{Z}_T , \hat{Z}_A , and \hat{Z}_V represent the first fusion feature of text, audio, and video. \oplus represents splicing operation. Z_z represents the secondary fusion feature of the sample. Z_I represents the final fusion feature of the modality. After obtaining multi-level modal temporal feature fusion, to perform MTL and predict the probability of different label categories for each emotion task. The prediction process is Fig. 5.

In Fig. 5, this study uses a feature matrix generated by cross modal feature fusion, which is processed through three FCLs for sentiment classification tasks. At the same time, two different fully connected sub networks are used to classify the sentiment of the feature matrix. MTL is the process of improving the generalization ability of multiple tasks by sharing underlying representations. This study uses multi-modal fusion feature Z_I as a hard parameter for sharing, and uses a FCL to obtain the predicted probabilities of different label categories for each emotion task.

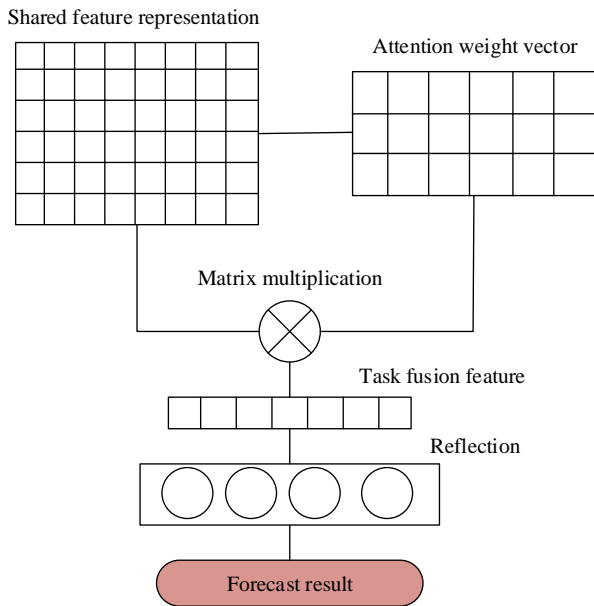

Fig. 5. Emotional task prediction flowchart.

The predicted probability is Eq. (9).

$$Y_k = \text{soft max}(W_k Z_l + b_k) \quad (9)$$

In Eq. (9), k represents different tasks. W_k represents the weight parameter. b_k represents the bias term. The network is trained taking a cross entropy loss function, as shown in Eq. (10).

$$Loss_k = -\sum_{i=1}^D \sum_{j=1}^{C_k} \hat{y}_i^k \log(y_i^k) + \alpha \theta^2 \quad (10)$$

In Eq. (10), D is the quantity of training samples. C_k represents the amount of different task categories. \hat{y}_i^k and y_i^k represent the true predicted categories and predicted categories for different tasks. $\alpha \|\theta\|^2$ represents the regularization function. To better evaluate the performance of TMSAM in social networks, this study selected macro F1 score, precision, recall, and acceleration ratio as the evaluation indicators for the experiment. The calculation formula for accuracy is Eq. (11).

$$precision = \frac{TP}{TP + FP} \quad (11)$$

In Eq. (11), TP and FP represent the number of correctly and incorrectly predicted positive emotion words. Precision tests the sample numbers predicted by the model as positive examples are true examples. The recall rate measures the proportion of real cases, and the calculation is Eq. (12).

$$recall = \frac{TP}{TP + FN} \quad (12)$$

In Eq. (12), FN means the incorrectly predicted negative emotion words. The F1 score combines recall and precision to evaluate the classification models, the formula is Eq. (13).

$$F1 = \frac{2 * precision * recall}{precision + recall} \quad (13)$$

In Eq. (13), the higher the F1 score, the better the model performance. In terms of high-performance computing, acceleration ratio refers to the ratio of serial to parallel program execution time. It is used to measure the degree of performance improvement of parallel computing compared to serial computing. The calculation of acceleration ratio is Eq. (14).

$$S = \frac{T_{cpu}}{T_{gpu}} \quad (14)$$

In Eq. (14), T_{cpu} and T_{gpu} represent the time it takes for the model to run an epoch on both CPU and GPU. If the acceleration ratio is greater than 1, it indicates that parallel computing is more efficient than serial computing.

IV. THE APPLICATION OF SENTIMENT ANALYSIS MODELS IN SOCIAL NETWORK DATASETS

This paper studies the performance of the TMSAM model built on MTL in social networks, with a particular focus on the dataset and parameter settings applicable to social network data. To assess the sentiment analysis models, this study selected six real-world social network datasets containing a large amount of social media text and visual data. These sentiment analysis datasets are Twitter, Facebook, Reddit, Weibo, Instagram, and YouTube. Six datasets cover various emotional categories and complex social interaction information, providing a challenging testing platform. Table I provides specific information for each dataset.

The dataset constructed in Table I is segmented into three categories: training, testing, and validation sets. Table II shows the partitioned dataset information.

TABLE I. MULTI-MODAL SENTIMENT ANALYSIS DATASET

Dataset	Type	Size	Modality
Twitter	Text and Dialogue	10145 sentences	T/I/A
Facebook	Dialogue and comments	14879 sentences	T/I/A
Reddit	Dialogue and comments	21532 sentences	T/I/A
weibo	Text and video	12367 sentences	T/I/A
Instagram	Images and Text	9856 sentences	T/I/A
YouTube	Videos and comments	14623 sentences	T/I/A

Note: T/I/A represents the text, image, audio.

After determining the number of three sets in Table II, experimental parameters need to be set. This experiment was written in Python 3.7, using a deep learning framework of Python 1.2.0 and a graphics card of TelsaK80. This study used the Python framework in deep learning for encoding. To prevent over-fitting, stop training when the model's performance on the validation set begins to decline. Table III shows the parameters for model training.

To ensure optimal performance of the model in social network environments, careful parameter tuning was carried out. To better demonstrate the impact of attention mechanism on GCN, text embeddings on the dataset were visualized, and the specific results are exhibited in Fig. 6.

TABLE II. PARTITIONED DATASET

Task	Classification	Training set	Verification set	Test set
Emotion	negative	2616	805	793
	neutral	9247	2703	2258
	positive	2177	662	934
	happy	1982	425	193
	detest	832	129	28
Mood	sad	631	179	115
	frightened	488	103	64
	surprise	545	523	386
	angry	1608	384	371
	neutral	7654	2261	2754

According to Fig. 6, the colors of the dots represent different emotional labels. After introducing attention mechanism, the model learned the features of text embedding better, resulting in more separability of samples in the reduced subspace. To better evaluate the research model performance in social networks, this study selected F1 score and precision as the evaluation indicators for the experiment. This study selected the ABSA model from study [5], the LSTM model from reference [14], and the MSA model from study [25] for comparative analysis with the research model TMSAM. The accuracy

experimental results of the four models are displayed in Fig. 7.

In Fig. 7, the performance of the four models on six social network datasets has their own advantages and disadvantages. The research model performs the best, with the highest mean accuracy (MA) in each dataset, at 0.83. The ABSA model and LSTM model performs moderately, with an MA of 0.78 and 0.71 in six datasets, respectively. The MSA model performs the worst, with an MA of only 0.69. The results of comparing the F1 values of the four models using the same method are shown in Fig. 8.

TABLE III. SPECIFIC PARAMETERS

Parameter	Value	Parameter	Value
GRU hidden layer dimension	200	optimizer	Adam
batch size	32	optimization function	Binary Cross Entropy
learning rate	0.001	activation function	ReLU
dropout	0.3	L2 regularization parameters	Le-5
First level attention dimension/number of heads	400/6	The number of layers in GCN	2
Second level attention dimension/number of heads	1200/8	Epochs	20
Cross modal attention dimension/head count	200/4	Word vector dimension d	300

Fig. 6. Text visualization.

Fig. 7. Comparison of precision and accuracy of four models.

Fig. 8. Comparison of F1 values of four models on different datasets.

Fig. 9. Classification results of emotions using four models.

In Fig. 8, the F1 values of the four models on the social network dataset show similar performance to the precision shown in Fig. 6. Among them, the MSA model not only performs the worst in precision, but also has the lowest F1 value on the dataset, with an average F1 value of only 0.70. The F1 values of ABSA and LSTM are average, but LSTM performs slightly better than ABSA. The average F1 values for ABSA

and LSTM are 0.74 and 0.78, respectively. The research model has relatively high precision and F1 values, with an average F1 value of 0.83 in the six datasets. Based on Fig. 8 and Fig. 7, the YouTube dataset was selected as a representative, and MSA, ABSA, LSTM, and research models were compared for emotion classification. The results are shown in Fig. 9.

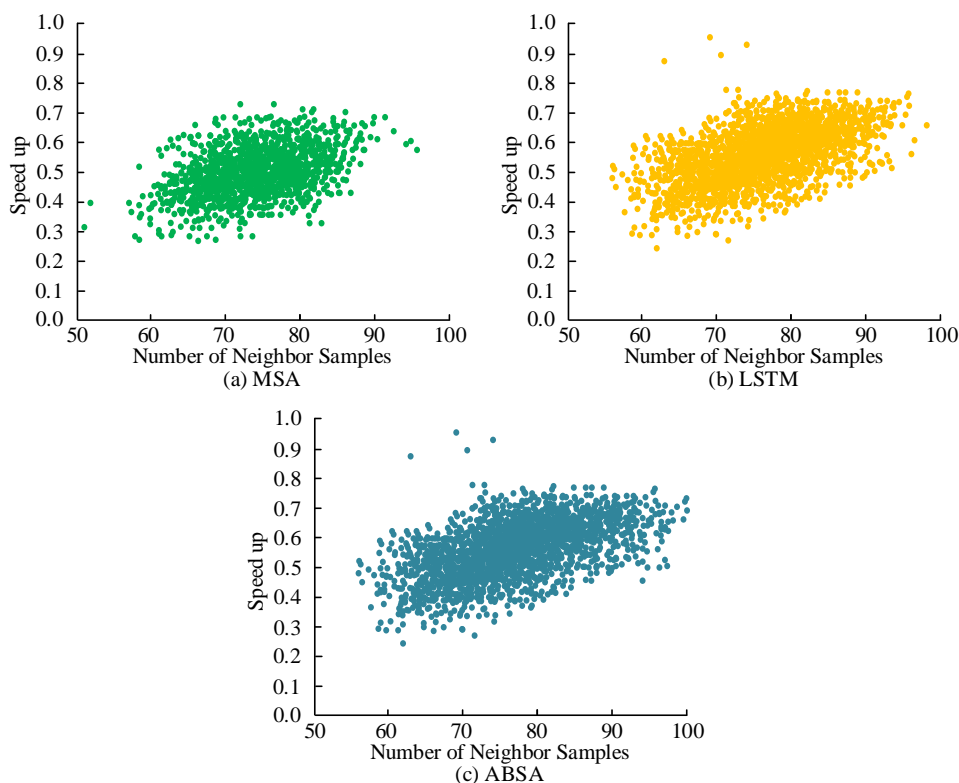

Fig. 10. Acceleration ratio results of different models.

In Fig. 9, compared to other models, the MSA model performs poorly in emotion recognition, indicating poor performance. This indicates that the early fusion and late fusion models have obvious shortcomings, which cannot balance the modeling of intra and inter modal features. Using the MSA model as a reference, there is a significant improvement in the recognition F1 values for happy, sad, and angry. Compared to others, the research model performs relatively well, especially in the F1 value of fear. The proposed attention based multi-level mixed fusion multi task TMSAM not only achieves the best experimental results in emotion classification, but also performs greater than the comparison method in emotion classification tasks such as detest, happy, sad, and surprise, fully verifying the effectiveness of the model. To measure the performance improvement of parallel computing compared to serial computing, Fig. 10 shows the comparative acceleration ratios of four models.

In Fig. 10, the acceleration ratios of MSA, ABSA, LSTM, and the study model are 0.73, 0.94, 1.17, and 1.61. The research model has the highest acceleration ratio and exhibits good parallel performance, which can save numerous training time when the training data is large.

V. RESULTS AND DISCUSSION

The temporal multimodal sentiment analysis model based on multi task learning has shown significant performance advantages on social network datasets. The main reason is that the study has constructed a comprehensive framework based on convolutional networks, bidirectional gated recurrent units, and multi head self attention mechanism, targeting the characteristics of social network data. This fusion of multimodal data can fully utilize the correlation between

different data modalities, improving the model's understanding ability for sentiment analysis tasks. The model proposed by the research institute achieved excellent results in accuracy and F1 values of 0.83 and 0.78, respectively. Compared to the system optimization research based on multimodal data fusion in study [23], our model performs better in sentiment classification tasks, which may be due to its more comprehensive modeling of inter modal features. Compared with the multimodal neural network semantic segmentation based on multi-scale RGB-T fusion in study [24], our model performs better in emotion recognition tasks. This may be because our model is more refined in the design of multimodal fusion and attention mechanisms. In addition, compared with the multi task learning model in study [25], our model performs better in both emotion and emotion classification tasks, possibly due to the use of a more suitable dataset and parameter settings for social network data, as well as a more effective modal fusion strategy. In summary, the time-series multimodal sentiment analysis model based on multitask learning proposed in the study can deeply understand the characteristics of data and achieve good sentiment analysis, thus having wide applicability in this field. However, the interpretability of the model has not been thoroughly analyzed in research, and further understanding of the data characteristics and user behavior of different social network platforms is needed to optimize model design. Future work should address these issues and enhance the interpretability and applicability of the model.

VI. CONCLUSION

In response to the problem of TMSAM in social networks, this study designed a sentiment analysis model based on MTL to fully utilize text and other modal information. It ensured the efficient performance of the model in social network

environments through detailed parameter tuning, and introduced attention mechanisms to enhance the model's ability to learn text embedding features. The results proved that for the MA of the model, MSA reached 0.69, ABSA was 0.78, and LSTM was 0.71, while the model proposed in the study was more advanced, reaching 0.83. In terms of average F1 value, the MSA was 0.70, ABSA was 0.74, LSTM was slightly higher than the former at 0.78, and the research model once again stood out with a high score of 0.83. The MA and F1 values of the research model were higher than those of other comparative models, highlighting the robustness and accuracy of the model. The acceleration ratios of MSA, ABSA, LSTM, and research models were 0.73, 0.94, 1.17, and 1.61, respectively. The acceleration ratio of the research model was the highest, and the comparative conclusions verified the advantages of multitasking learning and multi-modal fusion in improving parallel computing performance. This indicates that the research model exhibits excellent parallel performance in social network datasets, which can significantly save time when processing large-scale training data. In summary, the designed model is relatively reliable. TMSAM grounded on MTL is an attempt in social network sentiment analysis, providing a theoretical basis for effective solutions to complex sentiment classification problems.

However, there are still some problems and limitations to be solved. Among them, the interpretability of the model has not been deeply analyzed, which may affect its credibility and reliability in practical applications. In addition, the in-depth understanding of the data characteristics and user behavior of different social network platforms still requires more research to further optimize the model design. Future work can focus on solving these problems and exploring how to further improve the interpretability and applicability of the model to meet the actual needs of social network sentiment analysis tasks.

Abstract—In the pursuit of high-precision load identification, traditional methodologies grapple with significant drawbacks, including low recognition rates, intricate signature construction, and narrow applicability. This study introduces a novel approach employing weighted recursive graph (WRG) color coding to surmount these challenges. Power consumption data, procured from advanced load monitoring devices, undergo extraction of single-cycle currents, which are then subjected to dimensional reduction via Piece-wise Aggregate Approximation (PAA). In a transformative step, these currents are encoded into load signatures through the recursive graph time series methodology, culminating in the generation of WRG images. An AlexNet neural network model is engaged to distil and assimilate the distinctive features of the WRG images. The simulation results indicate that the identification rate can exceed 97%. Additionally, an experimental platform was set up to verify the method proposed in this paper, and the results show that the actual identification rate can reach over 96%. Both the simulation results and experiments fully demonstrate that the proposed identification method has a high accuracy. This method not only sets a new standard in non-intrusive load identification but also enhances the generalization of load signature applicability across diverse scenarios.

Keywords—Non-Intrusive Load Monitoring (NILM); Weighted Recurrence Graph (WRG); color coding; AlexNet neural network; load signature

I. INTRODUCTION

In pursuit of the ambitious "dual carbon" objectives and the establishment of innovative electric power systems, the crafting of an energy infrastructure that is clean, carbon-efficient, secure, and effective has been deemed essential to the evolution of power grids [1]. The technology for load identification has been recognized as a crucial facilitator for these emergent power systems, holding a key position in the attainment of automated demand response mechanisms. The precision in identifying electrical loads at the point of consumption is imperative for the enhancement of energy consumption management. The methodology for load identification bifurcates into two distinct approaches contingent upon the mode of power data procurement: Intrusive Load Monitoring (ILM) and Non-Intrusive Load Monitoring (NILM) [2]. Owing to its cost-effective nature, streamlined communication, and ease of maintenance and scalability, NILM has gained prominence as the preferred method for load identification [3].

A plethora of studies have delved into load identification methods based on NILM in recent years. Traditional

identification techniques, such as the K-Nearest Neighbor algorithm [4], Support Vector Machine [5], Decision Trees, and Random Forests [6], were widely adopted in earlier research. These initial methods, while computationally less demanding, focused primarily on frequency and phase of electrical data and other load characteristics, resulting in lower accuracy rates. With the advent of deep learning, which has demonstrated remarkable success in image classification and object detection, researchers have turned to two-dimensional visualization of time series data [7]. By transforming time-series problems into image classification tasks within the realm of image recognition, these methods have seen a substantial improvement in identification rates compared to their predecessors [8]. However, when the load types and characteristics are similar, there is an issue of identification confusion. One of the earliest methods to visualize electrical signals as images in the NILM field was through V-I trajectories [9]. Building on this, Taha Hassan et al. proposed using instantaneous voltage and current to construct V-I trajectories, replacing traditional load characteristics and significantly improving the accuracy and reliability of load identification [10]. Methods such as those in Literature [11], which employ grayscale voltage-current (V-I) trajectory construction, are pioneering yet suffer from low identification rates due to poor image resolution and the absence of color information. Subsequently, Literature [12] introduced color-coded V-I trajectories as load signatures, enhancing identification accuracy; however, the complexity of constructing these signatures limited their widespread applicability. To address the shortcoming of V-I trajectories that do not reflect the power magnitude of electrical devices, study in [13] proposed a method that integrates V-I trajectories with power features, improving the precision of load identification. Nevertheless, this method still faces challenges in identifying complex loads, resulting in lower success rates.

In summary, current load identification methods face the issue of low identification rates when handling large amounts of load data. Therefore, based on previous research [3], this paper adopts image recognition methods to process large-scale loads. In consideration of the dependency on complex load signatures for achieving high-precision load identification, this study introduces a load identification method employing WRG color coding. To simplify the acquisition of load signatures, the processed electrical currents from power devices are transformed into WRG images through an improved recursive graph color coding technique. The superiority and effectiveness of the method proposed herein are comprehensively validated

using an enhanced AlexNet neural network on the PLAID and WHITED datasets, as well as empirical data gathered in a laboratory environment. This demonstrates that the proposed method not only reduces the difficulty of acquiring load data but also improves the accuracy of load identification. It provides technical support for achieving high-precision load identification for residential users and offers a means for their participation in demand response.

II. PRINCIPLES OF LOAD IDENTIFICATION

NILM technique facilitates the real-time monitoring of the type, operational status, and energy consumption of user-side electrical devices through the deployment of intelligent load collection devices at the entrance of the electrical system. These devices process and analyze the collected electrical data. This technology is comprised of three principal modules: data acquisition, feature extraction, and load identification (see Fig. 1) [14]. The specific process of the method proposed in the study is outlined as follows:

1) *Acquisition phase*: Intelligent sensing devices are deployed to capture high-frequency voltage and current data from electrical apparatuses. Subsequently, these data are subjected to a preprocessing protocol, the objective of which is to distill the information into single-cycle waveform representations of voltage and current.

2) *Feature reduction and extraction phase*: Employing PAA [15], the single-cycle current waveform undergoes a dimensionality reduction process. This is succeeded by the application of a weighted recurrence graph encoding methodology, culminating in the generation of WRG, earmarked as the discriminative features for subsequent load identification.

3) *Identification phase*: The feature set, embodied by the WRG images, is then introduced into an AlexNet neural network model. This model undertakes the dual role of feature extraction and pattern learning, thereby fulfilling the process of load identification.

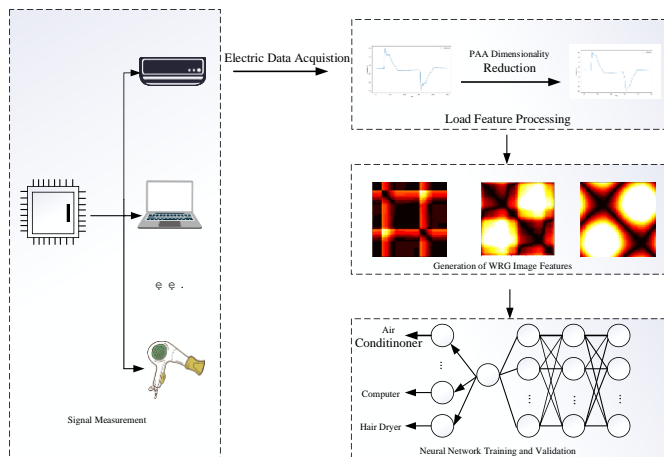

Fig. 1. Flow of load identification.

III. LOAD DATA PROCESSING AND MODELLING

A. Load Data Processing

For experimental validation, datasets from PLAID [16] and WHITED [17], both publicly available, were utilized, with data collected by high-frequency meters. The PLAID dataset comprises 1,074 records of current and voltage from 11 types of electrical appliances across 55 US households, with a sampling rate of 30kHz. The WHITED dataset encompasses 1,259 records from 54 types of electrical appliances from various regions worldwide, at a sampling rate of 44kHz. Each dataset exhibits distinctive characteristics: the PLAID data possesses high intra-class variation, while the WHITED dataset displays significant inter-class variation [18]. Thus, the data from these public datasets sufficiently meet the validation requirements of this study. However, considering the effectiveness in actual application scenarios, data measured in a laboratory environment are also introduced in subsequent sections to verify the practical applicability of the methods proposed herein.

According to study [19], the voltage and current waveforms of electrical appliances were extracted for several steady-state operating cycles before and after switching events. By referencing the fundamental voltage phase, a full-cycle average of the interpolated data was performed to obtain several cycles of steady-state voltage and current data preceding and following switching events, denoted as v_{off} , v_{on} , and i_{off} , i_{on} respectively. Given the consistent phase of voltage v_{off} , v_{on} and current i_{off} , i_{on} the voltage and current for an individual electrical load can be defined as $v(t) = (v_{off} + v_{on})/2$ and $i(t) = i_{off} - i_{on}$ respectively.

To simplify the load feature model and enhance the efficiency of algorithm execution, it is necessary to reduce the dimensionality of the current data. The PAA method was employed to diminish the dimensionality of the current to a pre-specified level. Furthermore, an analysis was conducted on the impact of different dimensionality reduction levels on the performance and learning speed of the AlexNet model in load identification tasks, with various parameters being adjusted for experimental analysis. Conclusions drawn from the results depicted in Fig. 2 indicate that the selection of parameters does not significantly affect the identification performance of the AlexNet model; however, it does have a notable impact on learning speed. Experimental validation confirmed that at a selected dimensionality $w = 50$, both identification accuracy and learning speed can be optimally balanced. Therefore, this dimensionality $w = 50$ was chosen for the reduction of load current dimensions.

B. Construction of Load Signatures

To further enhance the uniqueness of the current features of different types of loads, the method of WRG has been employed in this study for the color-coding of current data. Recurrence graphs are an effective method for analyzing the nonlinear dynamic characteristics of systems, capable of encoding one-dimensional time series into two-dimensional images, thereby revealing the chaos, stationarity, and inherent similarity of the time series, and enhancing feature extraction. Assuming that the electrical data constitutes a time series $x = \{x_1, x_2, \dots, x_{T_S}\}$

containing T_s values, the specific steps for color-coding of the recurrence graph are as follows:

(a) Identification performance in case of different values of w

(b) Training time in case of different values of w

Fig. 2. Identification performance and training time in case of different values of w.

1) The similarity of distance $d_{k,j} = \|x_k - x_j\|^2$ between any two points x_k and x_j in $x = \{x_1, x_2, \dots, x_{T_s}\}$ is calculated, where $d_{k,j}$ represents the Euclidean norm, then the distance similarity matrix $D_{w \times w}$ can be written as:

$$D_{w \times w} = \begin{bmatrix} d_{1,1} & \dots & \dots & \dots & d_{1,j} \\ \vdots & \ddots & \dots & \dots & \vdots \\ \vdots & \dots & \ddots & \dots & \vdots \\ \vdots & \dots & \dots & \ddots & \vdots \\ d_{k,1} & \dots & \dots & \dots & d_{k,j} \end{bmatrix} \quad (1)$$

In classification tasks, distance threshold matrices are frequently employed. These matrices encapsulate all recursive relationships, articulating them as binary matrix $RG_{w \times w} = [r_{k,j}]$, where each element $r_{k,j}$ is defined as:

$$r_{k,j} = \begin{cases} 1 & d_{k,j} \geq \varepsilon \\ 0 & \text{otherwise} \end{cases} \quad (2)$$

where, $\varepsilon \in (0,1)$, representing the recurrence threshold. In the formula above, if the distance between two values in signal $x = \{x_1, x_2, \dots, x_w\}$ is less than ε , then a point is plotted within the $w \times w$ grid.

2) Since the binarization of the distance matrix $D_{w \times w}$ through thresholding may lead to information loss and consequently decrease classification performance, the generation of $WRG_{w \times w}$ which surpasses the traditional binary output is introduced. This is achieved by incorporating parameter $\delta \geq 1$, allowing the values of $r_{k,j}$ to fall between 0 and δ , satisfying the following condition:

$$r_{k,j} = \begin{cases} \delta & \tau > \delta \\ \tau & \text{otherwise} \end{cases} \quad (3)$$

where, $\tau = \lfloor \frac{d_{k,j}}{\varepsilon} \rfloor$, $\lfloor \bullet \rfloor$ denotes the floor function. To ensure computational stability, the value of ε is parameterized with respect to 0 to ensure that $\lambda = 1/\varepsilon$. The matrix $D_{w \times w}$ can be interpreted as a weighted graph $G = (V, E)$, where each value represents the weight of an edge. Since $d_{k,j} > 0$, when $\delta \leq 1$, the equation can be simplified to RG. The recursive threshold ε and δ are hyperparameters that need to be optimized. Following the optimization of the recursive threshold, Fig. 3 illustrates the WRG images generated from residential load data collected in a laboratory setting.

Fig. 3. WRG images of electrical apparatus measured in laboratory environment.

C. Identification Algorithm

In this study, the AlexNet neural network model is employed for the extraction and learning of features from WRG images to accomplish the task of load identification. The AlexNet neural network model comprises eight weighted layers, including five convolutional layers, three fully connected layers, and one

softmax layer. The architecture of the network is delineated in Table I. Owing to the fact that the original AlexNet network model does not satisfy the classification requirements for experimental validation, adjusting the size of kernels and step size in the convolutional layers to accommodate the dimensions of the images to be classified.

Optimizations were implemented in the AlexNet neural network model to enhance its performance in load identification tasks from two aspects. Firstly, the Dropout layers within the AlexNet model were omitted to forestall the issue of overfitting. Secondly, adjustments were made to the number of neurons in the output layer to align with the specific demands of load identification tasks. Compared to the original model, the optimized AlexNet network model not only reduced the computational resource requirements for load identification tasks but also increased the accuracy of identification results.

TABLE I. STRUCTURE OF NEURAL NETWORK

Type	Kernel Size	Step size	Output Dimension
Convolutional Layer 1	11×11	4	96
Pooling Layer 1	3×3	2	-
Convolutional Layer 2	5×5	1	256
Pooling Layer 2	3×3	2	-
Convolutional Layer 3	3×3	1	384
Convolutional Layer 4	3×3	1	384
Convolutional Layer 5	3×3	1	256
Pooling Layer 3	3×3	2	256

D. Evaluation Metrics

In this study, a multi-dimensional analysis of the load identification results is conducted using confusion matrix [11], precision, recall, and F1-score.

The confusion matrix, also known as an error matrix, is a standard format representing accuracy assessment, presented in an $n \times n$ matrix form. Evaluation metrics such as overall precision, producer's precision, and user's precision are employed, reflecting different aspects of the accuracy of image classification.

Precision is defined as the ratio of correctly identified samples to the total number of samples in the test set, serving as an indicator of the overall identification performance of the test samples; recall is the proportion of samples accurately identified by the classification model out of all actual correct samples; the F1-score is utilized to assess the quality of identification for each class of electrical devices. The computational methods are as shown in Eq. (4) to (6).

$$P = \frac{T_p}{T_p + F_p} \quad (4)$$

$$R = \frac{T_p}{T_p + F_n} \quad (5)$$

$$F_1 = \frac{2 \times P \times R}{P + R} \quad (6)$$

where, P represents precision, R denotes recall, and F is the harmonic mean of precision and recall, serving as a comprehensive evaluation metric. T_p indicates the count of true positives, which are instances correctly predicted as positive; F_p stands for false positives, which are instances incorrectly predicted as positive despite being negative; F_n refers to false negatives, which are instances that are actually positive but have been incorrectly predicted as negative.

IV. CASE STUDY

A. Experimental Setup

As outlined in the preceding sections, the load identification process introduced in this study was validated using a combination of public datasets and actual measurement data. In the practical case study, a deep learning framework based on Python 3.9 and PyTorch, with hardware consisting of an NVIDIA RTX3060 and 16GB RAM, was employed.

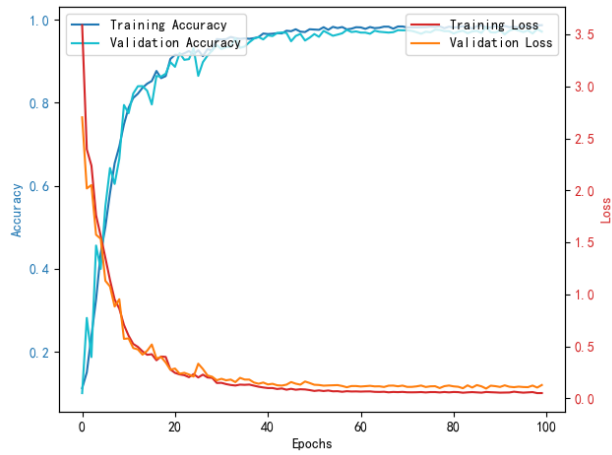

The AlexNet neural network model was trained using Stochastic Gradient Descent (SGD), starting with a learning rate of 0.01, which was then reduced by a factor of 0.1 every 10 epochs; the batch size for training was set at 64, with the number of iterations fixed at 100.

The experimental part employed 10-fold cross-validation, a method used to assess the applicability of statistical analysis results to independent datasets. The original data were randomly divided into 10 subsets of equal size. Subsequently, 9 of these subsets were used as training data to train the model, with the remaining subset serving as the validation set for assessing the model's performance. This process was iterated 10 times to ensure a comprehensive evaluation of the model's performance. This method is beneficial for reducing uncertainties due to variations in dataset partitioning and for assessing the model's generalization ability.

B. Dataset Experiments and Result Analysis

Following the methodology for constructing load signatures introduced in Section III, the high-frequency current data from the PLAID and WHITED datasets were processed and transformed into WRG images using a weighted recursive method. These images were then input into the AlexNet neural network model for training and validation. Fig. 4 shows the training and verification results of AlexNet neural network model on PLAID and WHITED datasets.

The results of Fig. 4 show that the proposed method has good identification results in the two datasets, and the load identification rate in the PLAID dataset can reach 97%, and the load identification rate in the WHITED dataset can reach 98%. The results of the two datasets effectively prove the universality of the proposed method. The results indicate that for the WHITED dataset, which has a greater variety of load types, the identification rate is higher. This demonstrates the superiority of the proposed method when handling large-scale loads. However, it also shows that in scenarios with fewer load types, the advantage of the proposed method is not as significant.

(a) PLAID dataset experimental results.

(b) WHITED dataset experimental results.

Fig. 4. WRG image example results.

The precision, recall, and F1-scores for each class within the PLAID dataset are presented in Table II. It can be observed that the precision, recall, and F1-scores for all 11 classes exceed 97%, with appliances such as fluorescent lamps, hairdryers, heaters, and vacuum cleaners achieving a 100% identification rate. This indicates that the load identification model employed herein possesses a robust load identification capability. At the same time, as shown in Table II, the proposed method achieves a high identification rate for loads with relatively simple operating states, such as fluorescent lamps, hair dryers, heaters, and vacuum cleaners. However, the identification rate is less ideal when dealing with loads with more complex operating states, such as air conditioners and refrigerators.

The figures on the main diagonal of the confusion matrix represent the precision of successful load identification; the larger the number, the higher the identification rate. It is evident from Fig. 5 that the model proposed in this study can effectively identify the majority of samples, with the recognition precision for samples such as fluorescent lamps, hair dryers, heaters, and vacuum cleaners reaching 100%.

TABLE II. EVALUATION METRICS FOR DIFFERENT APPLIANCES IN THE PLAID DATASET

Load Category	Precision/%	Recall/%	F1-value/%
Air Conditioner	94.2	94.2	95.4
Fluorescent Lamp	100	100	100
Electric Fan	97.3	97.3	96
Refrigerator	95.1	95.1	95.9
Hair Dryer	100	98.5	98.5
Heater	100	95.7	93.6

C. Results of Field Measurements

Several representative household loads were sampled via an intelligent load acquisition device. The utilized experimental apparatus is depicted in Fig. 6, comprising an experimental unit outfitted with an intelligent load control terminal that includes an integrated communication module. Additionally, the setup encompasses a cloud-based server where an automated demand response system is operational, a dedicated computer through which the user management interface is accessed, and a selection of electrical loads employed for testing purposes.

In a laboratory setting, data were collected for four types of electrical equipment: air conditioner, electric kettle, hair dryer, and laptop computer. Analyses were conducted on the performance of each equipment type when operated individually as well as in combination within a composite scenario, to ascertain the efficacy of the methodology proposed herein when applied to practical contexts. Table III presents the identification results for the different types of loads.

Fig. 6. The intelligent load collection device.

Several representative residential loads commonly used in daily life were selected for experimental validation. The method proposed herein achieves an identification rate of 100% for relatively simple resistive loads such as electric kettles and hair dryers, while maintaining an identification rate of over 94% for more complex loads such as air conditioners and laptop computers. A high identification rate is still retained for combinations of different types of loads, demonstrating the wide applicability of the proposed method in real-world scenarios.

TABLE IV. COMPARISON OF IDENTIFICATION RESULTS OF DIFFERENT METHODS

Method	Load signature	Model	Dataset	Precision/%
Literature [9]	Fused feature	BP	PLAID	91
Literature [10]	HSV color coding	AlexNet		94.6
Literature [15]	GMCE image	RBFNet	PLAID	92.1
			WHITED	91.1
			PLAID	94.3
Original AlexNet	WRG image	Original AlexNet	WHITED	95.1
			Field measurement	93.2
			PLAID	97.6
Proposed method	WRG image	Improved AlexNet	WHITED	98.1
			Field measurement	96.1

V. CONCLUSION AND FUTURE WORKS

A. Conclusion

The employment of WRG images for the color coding of the steady-state operational current of electrical apparatus has been demonstrated to possess greater feasibility over alternative methodologies. This is attributed to the singular requirement for current data acquisition, serving as the foundational data for load identification. Such a methodology considerably streamlines the data gathering process, thereby bolstering the practicality of the load identification endeavour.

This paper combines the image recognition method to achieve high-precision load identification, and identifies the load based on the improved AlexNet neural network, which greatly improves the load identification accuracy and the identification rate can reach more than 96%.

The proposed method can effectively encourage residential users to participate in demand response, thereby promoting the

realization of the "double carbon" goal, and provides technical support for the construction of new power systems, and is suitable for practical promotion and use.

B. Future Works

In future endeavors, we will continue to convert one-dimensional time series data into two-dimensional image data using image encoding techniques, aiming to further refine the precision of the generated images. Additionally, we will concentrate on algorithmic optimizations for loads that exhibit multiple operating states, in order to meet the requirements for high-precision load identification in complex scenarios.

ACKNOWLEDGMENT

This work was supported by the Key Scientific Research Project of Colleges and Universities of Henan (No. 24A470006), the Science and Technology Project of Henan Province (No. 242102241027) and (No.24210221018, the Doctoral Scientific Research Foundation of Henan Polytechnic University (No. B2017-20).

TABLE III. LOAD IDENTIFICATION RESULTS IN EXPERIMENTAL SCENARIOS

Load type	Identification precision/%
Air conditioner	94.8
Electric kettle	100
Hair dryer	100
Laptop computer	95.9
Air conditioner+Electric kettle	96.1
Air conditioner+Laptop computer	96.5
Electric kettle+Laptop computer	97.6
Air conditioner+Electric kettle+Laptop computer	96.1

To further demonstrate the superiority of the load identification method proposed in this study, a comparison was made with various other load identification methods. Table IV presents the load signatures, training models, data sources, and experimental results used in this study and the other methods. Compared with other methods in Table IV, constructing WRG images and optimizing the AlexNet network can effectively improve the accuracy of load identification. However, when facing loads with more complex operating conditions, the identification rate will still be unsatisfactory.

Diagnosis of NEC using a Multi-Feature Fusion Machine Learning Algorithm

Jiahe Li¹, Yue Han², Yunzhou Li³, Jin Zhang⁴, Ling He^{5*}, Tao Xiong^{6*}, Qian Gao^{7*}

College of Biomedical Engineering, Sichuan University, Chengdu 610065, China^{1, 2, 3, 4, 5}
Neonatal Department, West China Women's and Children's Hospital, Chengdu 610041, China^{6, 7}

Abstract—Necrotizing enterocolitis (NEC) is a severe gastrointestinal emergency in neonates, marked by its complex etiology, ambiguous clinical manifestations, and significant morbidity and mortality, profoundly affecting long-term pediatric health outcomes. The prevailing diagnostic approaches for NEC, including traditional manual auscultation of bowel sounds, suffer from limited sensitivity and specificity, leading to potential misdiagnoses and delayed treatment. In this paper, we introduce a groundbreaking NEC diagnostic framework employing machine learning algorithms that utilize multi-feature fusion of bowel sounds, significantly improving the diagnostic accuracy. Bowel sounds from NEC patients and healthy newborns are meticulously captured using a specialized acquisition system, designed to overcome the inherent challenges associated with the low amplitude, substantial background noise, and high variability of neonatal bowel sounds. To enhance the diagnostic framework, we extract mel-frequency cepstral coefficient (MFCC), short-time energy (STE), and zero-crossing rate (ZCR) to capture comprehensive frequency and time domain features, ensuring a robust representation of bowel sound characteristics. These features are then integrated using a multi-feature fusion technique to form a singular feature vector, providing a rich, integrated dataset for the machine learning algorithm. Employing the support vector machine (SVM), the algorithm achieved an accuracy (ACC) of 88.00%, sensitivity (SEN) of 100.00%, and an area under the receiver operating characteristic (ROC) curve (AUC) of 97.62%, achieving high accuracy in diagnosing NEC. This innovative approach not only improves the accuracy and objectivity of NEC diagnosis but also shows promise in revolutionizing neonatal care through facilitating early and precise diagnosis. It significantly enhances clinical outcomes for affected neonates.

Keywords—Diagnosis of necrotizing enterocolitis (NEC); bowel sound; feature fusion; machine learning

I. INTRODUCTION

Neonatal necrotizing enterocolitis (NEC) constitutes a critical gastrointestinal pathology characterized by multifactorial etiologies leading to mucosal damage, ischemia, and hypoxia in the neonatal intestinal tract, culminating in diffuse or localized necrosis of the small intestine and colon [1]. This condition predominantly afflicts neonates, with a pronounced prevalence in preterm infants, positioning it as a significant concern in early neonatal critical care due to its high morbidity, mortality rates, and propensity for engendering numerous complications [2]. The Bell staging criteria for NEC delineate the progression of the disease into stages, where an advancement from stage I to stage II signifies a notable escalation in the complexity of required medical interventions,

treatment durations, and therapeutic strategies [3]. This delineation underscores the imperative for prompt and accurate diagnosis, as well as the implementation of tailored therapeutic regimens to mitigate the progression and adverse outcomes associated with NEC.

The conventional diagnostic approach for NEC primarily hinges on clinical manifestations and radiographic examination through abdominal plain films. This methodology, however, is marred by limitations such as atypical presentations, low sensitivity, and a lack of specificity, rendering it insufficient for the timely and accurate diagnosis of NEC. Through an analytical examination of the Bell staging criteria for NEC, a pivotal distinction between stages I and II is identified as the cessation of bowel sounds. Bowel sounds, characterized as intermittent gurgling or gas-over-water noises produced by peristaltic and catabolic movements within the intestines, facilitate the movement of gases, liquids, and chyme through the intestinal tract [4]. These sounds are clinically acknowledged as vital physiological indicators reflective of the gastrointestinal tract's functional status. The diagnosis of NEC, predicated on the absence of bowel sounds, currently relies predominantly on manual auscultation conducted by medical practitioners [5]. This diagnostic practice is fraught with challenges, including a substantial reliance on the clinician's experience, a high degree of subjectivity inherent to manual auscultation, and the overall inefficiency of this method as a diagnostic tool [6]. These constraints underscore the necessity for the development of more objective, efficient, and less experientially dependent diagnostic modalities to enhance the accuracy and timeliness of NEC diagnosis.

By investigating related work, we found the application of machine learning algorithms in the monitoring of human physiological signals has witnessed a discernible surge in popularity [7]. A burgeoning body of research has been devoted to the utilization of machine learning algorithms for the analysis of bowel sounds. Yin et al. [8] notably employed support vector machine (SVM) for the purpose of recognizing bowel sounds within a wearable health monitoring device. In a parallel vein, Allwood et al. [9] innovatively amalgamated advanced acoustic signal processing techniques with a machine learning algorithm, adopting an AI-assisted paradigm to enhance the discernment of bowel sounds. Burne et al. [10] used an integrated approach for bowel sound detection on hand-crafted as well as features obtained from mel-frequency cepstral coefficient (MFCC).

Nevertheless, it is noteworthy that the extant studies investigating machine learning algorithms for bowel sounds

*Corresponding Author.

have predominantly relied on singular feature extraction methods. In the context of machine learning, the maximization of valuable information during model training is paramount [11]. In cognizance of this, our research adopts a comprehensive approach by considering both frequency domain features and time domain features inherent in neonatal bowel sounds. We have strategically extracted MFCC [12], Short Time Energy (STE) [13], and Zero Crossing Rate (ZCR) [14] as integral components of our feature extraction methodology. These features collectively encapsulate the nuanced characteristics of neonatal bowel sounds. Then, we employ the concatenate function for splicing features in the domain, creating a fused representation of the spectral and temporal attributes.

Subsequently, these fused features serve as input data for machine learning algorithms, including but not limited to adaboost [15], random forest [16], support vector machine (SVM) [17], k-Nearest Neighbors (KNN) [18], and stacking [19]. The rationale behind employing a diverse set of models lies in the pursuit of achieving a robust and accurate automatic diagnosis of NEC based on bowel sounds. This approach aligns with the overarching objective of harnessing the collective strengths of various machine learning paradigms to improve diagnostic precision and reliability. Our methodology, rooted in a meticulous fusion of medical and computational techniques, contributes to the burgeoning field of medical computing. By expanding the spectrum of features considered and leveraging a diverse ensemble of machine learning models, our research endeavors to advance the state-of-the-art in automatic diagnosis, particularly in the critical domain of neonatal healthcare.

In summary, our research undertakes a comprehensive exploration by employing multi-feature fusion, incorporating three distinct types of frequency and time domain features (MFCC&STE&ZCR) derived from neonatal bowel sounds. The primary objectives are to realize automatic diagnosis of NEC and contribute to the evolving landscape of medical computing. The key contributions of this paper are delineated as follows:

- 1) Based on Bell-NEC staging, neonatal NEC diagnosis is performed by the indication of weakened or absent bowel sounds.
- 2) Multi-feature fusion in the time-frequency domain (MFCC&STE&ZCR) is used to extract more valuable information of bowel sounds.
- 3) Adaboost [15], random forest [16], SVM [17], KNN [18], and stacking [19] machine learning algorithms are used to automatically perform bowel sounds classification.

The manuscript is structured as follows: Section II delineates the methodology for acquiring bowel sounds and provides a step-by-step exposition on constructing the model through the multi-feature fusion machine learning algorithm. This section encompasses the foundational research concept, details of feature extraction, and the process of feature fusion. In Section III, we expound upon the experimental intricacies, presenting a comprehensive analysis of the experimental details and results. This section serves to elucidate the empirical validation of the proposed model. Finally, Section IV succinctly encapsulates the study's outcomes, offering a cohesive summary of the research findings.

II. METHODS

A. Collection of Bowel Sound

In this study, the Lobob stethoscope was used to collect neonatal bowel sounds. The Lobob stethoscope was realized by using muRata and TDK high-performance electronic devices, five-layer shielded wire design, GETTOP flagship electro-acoustic sensor and CSR8670, the world's top audio processing chip, to collect and preprocess bowel sounds. Through the above methods, the potential problems of low amplitude and large amount of background noise of newborn bowel sounds can be solved, and high-quality bowel sounds can be finally collected.

Fig. 1. Bowel sound collection system.

To achieve the objective of efficient and artifact-free neonatal bowel sound collection, the devised system, illustrated in Fig. 1, is meticulously outlined in this study. The collection protocol is systematically detailed as follows:

- 1) Verify power level. Initial verification involves checking the power status of both the bowel sound recorder and the utilized cellphone for data acquisition to ensure optimal functionality.
- 2) Sterilize and preheat. Measurement personnel engage in self-cleansing and disinfection procedures while simultaneously disinfecting and preheating the bowel sound collector.
- 3) Confirm newborn information. Relevant details of the newborn are confirmed. The Bluetooth stethoscope, sterilized and preheated, is positioned on the newborn's abdomen.
- 4) Configure and auscultate software. The software system, interfaced with the bowel sound recorder on the cellphone, is activated. Parameters are validated, and auscultation commences. Recording for a minimum of two minutes is initiated, followed by saving and software closure. The newborn's bowel sounds is then transmitted to the smartphone via the Bluetooth module.
- 5) Manage and sterilize file. Post-recording, file modification is performed, the Bluetooth stethoscope is removed from the child's abdomen, and subsequent sterilization is executed.
- 6) Transfer and compile data. The bowel sounds are transferred from the smartphone to the computer using the USB transmission protocol. The data is organized and synthesized into comprehensive bowel sounds tailored for experimentation.

It is imperative to note that all neonatal bowel sounds utilized in this experiment are meticulously collected by neonatologists from the Second West China Hospital of Sichuan University. Rigorous professional authentication procedures are adhered to,

encompassing bowel sounds from both infants diagnosed with NEC and those from normal newborns.

B. Overview of NEC Diagnosis

Traditional manual auscultation of neonatal bowel sounds is hindered by the need for extensive medical expertise, time constraints, and subjective biases, leading to potential misjudgments [6]. This paper proposes an innovative approach leveraging machine learning algorithms for the automatic

diagnosis of neonatal NEC through continuous monitoring and feature fusion of bowel sounds. The flow chart in Fig. 2 illustrates the application of a multi-feature fusion machine learning algorithm for NEC diagnosis based on neonatal bowel sounds, offering a systematic and automated framework to improve diagnostic accuracy and efficiency. This interdisciplinary research bridges medical and computational sciences, advancing diagnostic methodologies in neonatal healthcare.

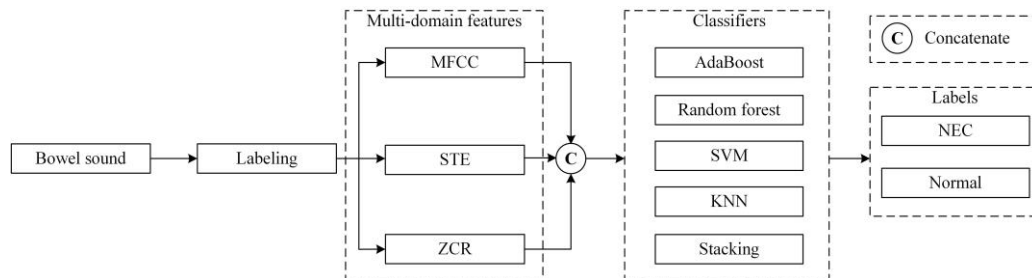

Fig. 2. NEC diagnosis framework.

Initially, the training of machine learning algorithms necessitates original labels. Therefore, we initially calibrated the bowel sounds using the statistical table of neonatal bowel sounds from the Second Hospital of West China of Sichuan University and Adobe Audition Audio Signal Processing Software. The calibration reveals 42 instances of NEC children's bowel sounds and 83 instances of normal newborn bowel sounds. Based on the characteristics of bowel sounds, including weak signals, strong background noise, large individual differences, and high randomness [20], and considering that bowel sounds of NEC patients may be weakened or even absent [21], we choose three types of bowel sounds—MFCC, STE, and ZCR—as frequency-domain and time-domain features for extraction. These features are employed for the classifier to learn and categorize the references. Then, to obtain richer information in neonatal bowel sounds signals to achieve more binary classification effect and better diagnosis of neonatal NEC disease, this paper adopts multi-feature fusion of bowel sounds time and frequency domain features, and performs direct multi-feature fusion through feature concatenating [22] to preserve the original data features of neonatal bowel sounds signals. Finally, since machine learning algorithms can automatically realize feature extraction and perform well in binary classification problems, this study adopts five popular machine learning algorithms with excellent mathematical logic and classification criteria, namely, adaboost [15], random forest [16], SVM [17], KNN [18], and stacking [19], to realize the automated diagnosis of neonatal NEC.

In the initial stages of this study, the training of machine learning algorithms necessitated the availability of accurately labeled data. We meticulously calibrate the neonatal bowel sounds utilizing statistical tables provided by the Second Hospital of West China, Sichuan University, and Adobe Audition Audio Signal Processing Software.

Considering the distinctive features of bowel sounds, such as low amplitude signals, pervasive background noise, substantial inter-individual variations, and inherent randomness [20], coupled with the potential attenuation or absence of bowel

sounds in NEC patients [21], we opt for three representative types of bowel sound features—MFCC, STE, and ZCR. These features, derived from the frequency and time domains, are employed for subsequent classifier training to facilitate reference-based learning and classification.

To enhance the discriminative capacity and diagnostic accuracy for neonatal NEC, this research embraces a multi-feature fusion strategy, consolidating both time and frequency domain features of bowel sounds. Direct concatenation of these features is achieved through a feature concatenating technique [22], preserving the inherent data characteristics of neonatal bowel sound signals.

Capitalizing on the intrinsic capability of machine learning algorithms for automated feature extraction and robust performance in binary classification scenarios, we employ five well-established algorithms renowned for their mathematical rigor and classification efficacy: adaboost [15], random forest [16], SVM [17], KNN [18], and stacking [19]. These algorithms collectively contribute to the realization of automated neonatal NEC diagnosis. This interdisciplinary study, situated at the intersection of medical and computational sciences, holds promise for advancing diagnostic methodologies in neonatal healthcare.

C. Feature Extraction

1) *Mel-frequency Cepstral Coefficient (MFCC)*: For the analysis of neonatal bowel sounds in the frequency domain, the project used mel-frequency cepstrum coefficient (MFCC) analysis. The mel-frequency $M(f)$ was proposed by researchers based on the mechanism of human ear hearing [23], and it has a nonlinear correspondence with the Hertz (Hz) frequency f , which is as follows:

$$M(f) = 1125 \ln(1 + f/700) \quad (1)$$

The application of MFCC in our study capitalizes on the inherent nonlinear relationship between mel-frequency and hertz, facilitating the computation of spectral features in the

Hertzian domain. An illustrative instance of MFCC representation for neonatal bowel sound is depicted in Fig. 3.

MFCC plays a pivotal role by transforming the raw audio signal into a discerning set of feature vectors. This conversion enhances the separability and recognizability of the underlying acoustic characteristics, thereby facilitating diverse applications such as speech recognition, speaker identification, speech

synthesis, and audio classification [12]. Notably, the versatility of MFCC is underscored by its robustness and commendable recognition accuracy when compared to alternative feature extraction methods [24]. This robustness positions MFCC as a methodologically sound and effective tool for extracting salient features from neonatal bowel sounds within the context of our interdisciplinary research at the intersection of medical and computer sciences.

Fig. 3. Example of MFCC visualization of neonatal bowel sound.

2) *Short Time Energy (STE)*: Short time energy (STE) is one of the common time-domain features in sound signals, which reflects the energy magnitude of the signal over a period of time [13]. After the above filtering and noise reduction process, compared with the background noise, the bowel sounds signal energy is obviously stronger, so the calculation of STE can effectively distinguish the bowel sounds. In this article, the neonatal bowel sounds signal is divided into frames, and the window is added to realize the “short-time”, as shown in Fig. 4, which is an example of STE visualization of neonatal bowel sound. Let the n th frame of the speech signal obtained after the windowing process be $x(m)$, and the STE E_n of the n th frame of the speech signal be:

$$E_n = \sum_{m=0}^{N-1} x^2(m) \quad (2)$$

where, N indicates the frame length.

Fig. 4. Example of STE visualization of neonatal bowel sound.

3) *Zero Crossing Rate (ZCR)*: The short-time average zero crossing rate refers to the number of times the signal crosses the zero value in each frame, which can reflect the frequency spectral characteristics to a certain extent, and is a kind of sound signal time-domain feature often used in speech endpoint detection [14]. As the bowel sounds signals vary in strength, it is difficult to see obvious changes in the STE only for the sudden and weaker bowel sounds, while their short-time average crossing zero rate is usually higher, which can be used as one of

the features to analyze the bowel sounds. As shown in Fig. 5, an example graph of ZCR visualization of neonatal bowel sound is shown. The short-time average zero crossing rate Z_n is calculated as:

$$Z_n = \frac{1}{2} \sum_{m=0}^{N-1} |sgn[x_n(m)] - sgn[x_n(m-1)]| \quad (3)$$

Fig. 5. Example of ZCR visualization of neonatal bowel sound.

D. Feature Fusion

The inherent challenges associated with bowel sounds acquisition includes signal weakness, randomness, individual variability, and background noise. What’s more, the discriminative capability between bowel sounds from patients with NEC and normal bowel sounds in terms of signal characteristics such as amplitude, frequency of occurrence, and auditory perception [25] is superior. This study advocates for the fusion of three distinct features extracted from the frequency-domain and time-domain analyses of bowel sounds, namely MFCC, STE, and ZCR. By amalgamating these features, a more comprehensive understanding of bowel sounds can be attained, providing richer information for analysis.

The fusion of MFCC, STE, and ZCR features enables the extraction of a diverse set of features, enhancing the diagnostic capabilities of machine learning algorithms for discerning patterns indicative of neonatal NEC. This approach leverages the synergistic benefits of multiple feature types, thereby

augmenting the classification performance of the model and bolstering its diagnostic accuracy for neonatal NEC diagnosis.

The multi-feature fusion approach chosen in this study is based on data-level concatenate [26]. This feature fusion method not only preserves the features of the original data and maintains the feature diversity of multi-features, but also is able to handle features of different dimensions and shapes. Whether it is one-dimensional, two-dimensional or higher dimensional features, they can be fused by the concatenate function, which has better robustness and flexibility, and is more intuitive and efficient [27]. In this study, by extracting multi-dimensional acoustic features of bowel sounds and splicing them into a feature vector in the feature space, more information of bowel sounds can be obtained, so as to better analyze them and further diagnose neonatal NEC.

III. RESULTS AND DISCUSSIONS

A. Experimental Setup

The experiments are conducted on a system featuring an NVIDIA GeForce RTX 3060 Laptop GPU, 32 GB RAM, and Windows 11. All machine learning algorithms are implemented in Python 3.10 using the Scikit-learn library. The dataset is split into training and testing sets with an 8:2 ratio. After preprocessing, classifier parameters are set according to Table I. This standardized approach, leveraging Scikit-learn, ensures reproducibility and facilitates comparison. The chosen hardware and software configurations provide a robust foundation for exploring machine learning algorithms at the intersection of medical and computer sciences.

TABLE I. PARAMETERS OF THE CLASSIFIER

Classifier	Parameters
Adaboost	Number of estimators:50
Random forest	Number of estimators:100
SVM	Kernel:'linear'
KNN	Number of neighbors k = 3
Stacking	Estimators:SVM (kernel:'linear'), KNN (k = 3); final_estimator:KNN (k = 3)

B. Evaluation Indexes

In this investigation, we adopt a comprehensive set of assessment metrics to evaluate the classification performance of machine learning models. These metrics include accuracy (ACC), precision (PRE), sensitivity (SEN), F1 score (F1), specificity (SPE), and area under the ROC curve (AUC). Accuracy (ACC) reflects the ratio of correctly predicted samples to the total number of samples, serving as a fundamental indicator of overall model correctness [28]. Precision (PRE) measures the proportion of correctly predicted positive samples to the total predicted positive samples, offering insight into the model's accuracy specifically within positive categories [10]. Sensitivity (SEN) assesses the model's ability to correctly predict positive samples relative to the total true positive

samples, quantifying its sensitivity to positive category samples [29]. F1 Score (F1) represents the harmonic mean of precision and recall, providing a balanced evaluation metric suitable for imbalanced class distributions [30]. Specificity (SPE) quantifies the accuracy of the model in predicting negative category samples relative to the total true negative samples [29]. Area under the ROC Curve (AUC) characterizes the performance of the model across various classification thresholds, with higher values indicating superior performance, particularly in binary classification scenarios [31]. These metrics collectively offer a robust framework for comprehensively evaluating the efficacy of machine learning models in the context of medical and computer science integration.

C. NEC Diagnosis Results of Single Feature

In the context of neonatal NEC, the manifestation of weakened or absent bowel sounds serves as a crucial diagnostic indicator. These bowel sounds are characterized by attenuated signals, substantial background noise, considerable inter-individual variability, and stochastic elements. Leveraging machine learning for diagnosis, we explore the utility of three distinct features in the frequency and time domains of neonatal bowel sounds: MFCC, STE, and ZCR.

MFCC is employed to transform the original neonatal bowel sounds into feature vectors, enhancing recognizability and separability for robust audio classification. STE captures audio amplitude, while ZCR reflects the frequency spectrum of bowel sounds to a certain extent. Incorporating these features into a machine learning algorithm facilitates the accurate diagnosis of neonatal NEC. The experimental results, presented in Tables II, III, and IV for individual use of MFCC, STE, and ZCR as machine learning inputs, respectively, highlight their efficacy in single-feature machine learning classification tasks.

Given the primary objective of diagnosing neonatal NEC with utmost precision, emphasizing the classification of all positive samples as positive is imperative. In this binary classification scenario, the model's performance is gauged through metrics such as SEN, ACC, and AUC. Analyzing the results, we observe that for MFCC, a feature demonstrating robustness and separability in the frequency domain, classifiers including adaboost [15], random forest [16], SVM [17], KNN [18], and stacking [19] yield superior classification results. Among these, SVM achieves an ACC of 80.00%, SEN of 85.71%, and AUC of 88.89%.

Examining Table III reveals that STE, a time domain feature, performs well in the Random Forest classifier, an integrated voting algorithm, achieving 71.00% SEN, 76.00% ACC, and 76.59% AUC. Notably, the decision tree, a weak learner within the Random Forest classifier, effectively captures detailed aspects of STE in bowel sound signals, optimizing classification results. Turning to Table IV, ZCR, commonly used in speech endpoint detection, exhibits strong performance in bowel sound classification. Despite a lower SEN in the SVM, an ACC of 84.00% and an AUC of 80.16% underscore ZCR's significance as a vital feature in bowel sound classification.

TABLE II. COMPARISON RESULTS OF MACHINE LEARNING ALGORITHMS BASED ON MFCC ONLY

MFCC						
Models	ACC (%)	PRE (%)	SEN (%)	F1 (%)	SPE (%)	AUC (%)
Adaboost	72.00	50.00	71.43	58.82	72.22	77.78
Random forest	72.00	50.00	71.43	58.82	72.22	88.89
SVM	80.00	60.00	85.71	70.59	77.78	88.89
KNN	80.00	66.67	57.14	66.57	88.89	81.75
Stacking	80.00	62.50	71.43	66.67	83.33	78.17

TABLE III. COMPARISON RESULTS OF MACHINE LEARNING ALGORITHMS BASED ON STE ONLY

STE						
Models	ACC (%)	PRE (%)	SEN (%)	F1 (%)	SPE (%)	AUC (%)
Adaboost	72.00	50.00	57.14	53.33	77.78	75.79
Random forest	76.00	56.00	71.00	63.00	78.00	76.59
SVM	56.00	0.00	0.00	0.00	77.78	53.17
KNN	72.00	50.00	42.86	46.15	83.33	68.25
Stacking	72.00	50.00	28.57	36.36	88.89	65.87

TABLE IV. COMPARISON RESULTS OF MACHINE LEARNING ALGORITHMS BASED ON ZCR ONLY

ZCR						
Models	ACC (%)	PRE (%)	SEN (%)	F1 (%)	SPE (%)	AUC (%)
Adaboost	60.00	33.33	42.86	37.50	66.67	64.68
Random forest	64.00	40.00	57.14	47.06	66.67	60.71
SVM	84.00	100.00	42.86	60.00	100.00	80.16
KNN	56.00	30.00	42.86	35.29	61.11	52.78
Stacking	60.00	33.33	42.86	37.50	66.67	56.35

D. NEC Diagnosis Results of Fused Feature

Utilizing the individual neonatal bowel sound features, namely MFCC, STE, and ZCR, in isolation for machine learning classification tasks demonstrates proficient outcomes. However, recognizing the potential for enhanced classification performance through comprehensive information integration, we explore the impact of employing a concatenate function to amalgamate the original data of MFCC, STE, and ZCR across the frequency and time domains. Subsequently, five distinct machine learning algorithms, adaboost [15], random forest [16], SVM [17], KNN [18], and stacking [19], are applied to evaluate the classification performance.

Analysis of the experimental results presented in Table V reveals the superior performance of the SVM classifier with a linear kernel function in neonatal NEC diagnosis following the multi-feature fusion of MFCC, STE, and ZCR. The achieved metrics include an ACC of 88.00%, PRE of 70.00%, SEN of 100.00%, F1 of 82.35%, SPE of 83.33%, and an area under the receiver operating characteristic curve (AUC) of 97.62%. Notably, the SVM classifier surpasses the capabilities of single-feature machine learning in bowel sound classification.

The exceptional AUC value of 97.62% attests to the model's outstanding performance, while a SEN of 100.00% signifies the

SVM's accuracy in distinguishing bowel sounds of infants with NEC. As a robust supervised learning model, SVM stands out as a premier linear classifier, leveraging mathematical logic and model performance. Employing kernel functions and constrained optimization techniques, SVM constructs an optimal decision plane, maximizing classification spacing and effectively distinguishing between linearly separable sample classes. This intrinsic capability positions SVM as a promising tool for dichotomizing bowel sounds in neonates with NEC from those of normal neonates.

The experimental results are discussed below. Given SVM's prowess in high-dimensional feature spaces, particularly in scenarios involving multi-dimensional data such as the fusion of MFCC, STE, and ZCR features, SVM outperforms traditional and deep learning classifiers. The soft-margin and kernel techniques of SVM facilitate the establishment of a nonlinear decision boundary, addressing complex classification problems. The experiment, incorporating feature splicing through the concatenate function at the data level, fully preserves the original information of the three features. This allows the SVM machine learning algorithm model to glean more valuable insights into bowel sounds of infants with NEC and those of normal newborns, ultimately achieving superior classification and NEC diagnosis performance [32].

TABLE V. COMPARISON RESULTS OF MACHINE LEARNING ALGORITHMS BASED ON FUSION FEATURES OF MFCC AND ZCR AND STE

MFCC&ZCR&STE						
Models	ACC (%)	PRE (%)	SEN (%)	F1 (%)	SPE (%)	AUC (%)
Adaboost	76.00	54.55	85.71	66.67	72.22	89.68
Random forest	76.00	55.56	71.43	62.50	77.78	88.10
SVM	88.00	70.00	100.00	82.35	83.33	97.62
KNN	84.00	71.43	71.43	71.43	88.89	88.49
Stacking	80.00	60.00	85.71	70.59	77.78	86.90

Fig. 6. Results of SVM confusion matrix after single-feature and multi-feature fusion. (a) SVM confusion matrix based on MFCC (b) SVM confusion matrix based on STE (c) SVM confusion matrix based on ZCR (d) SVM confusion matrix based on MFCC&ZCR&STE.

The comparative analysis of SVM confusion matrix results, as depicted in Fig. 6 (a)-(d), illustrates the pronounced improvement in the SVM machine learning algorithm model performance through multi-feature fusion. In conclusion, employing the SVM classifier with a multi-feature fusion algorithm for neonatal bowel sounds yields a more favorable diagnostic outcome for the automatic diagnosis of neonatal NEC.

IV. CONCLUSIONS

To achieve automated diagnosis of neonatal NEC using bowel sound signals, we conduct a study collecting data from newborns with NEC and healthy counterparts at the neonatal department of West China Second Hospital of Sichuan University. Employing a dedicated bowel sound acquisition system, we address the challenges posed by the random, weak,

and variable nature of bowel sounds, including their attenuation or absence in NEC cases.

Three crucial frequency-domain and time-domain features—MFCC, STE, and ZCR—are selected for classifier learning. These features are strategically concatenated in the feature space, utilizing a multi-feature fusion approach to preserve the entirety of original information. This process aims to enhance the effectiveness of the subsequent machine learning algorithm model for bowel sound signals of both NEC and healthy newborns.

Five distinct machine learning algorithms—adaboost, random forest, SVM, KNN, and stacking—are employed for model training and classification of neonatal bowel sound signals. Notably, the SVM classifier demonstrated superior performance in NEC diagnosis. Limitations of this study: The

data volume needs to be further expanded, or the trained algorithm model can be applied to other data sets to verify robustness. This study outlines a potential development path for discriminating and diagnosing neonatal NEC through bowel sound signal features and machine learning algorithm modeling. The proposed approach holds promise for early detection, diagnosis, and treatment of neonatal NEC, contributing to the reduction of mortality and disability in affected newborns. In the future, while expanding the data set of intestinal sounds, the pathological features of other neonatal gastrointestinal diseases should be studied in combination with the acoustic features of intestinal sounds, and the multi-feature fusion theory of this study should be combined for model training and disease diagnosis.

Towards Optimal Image Processing-based Internet of Things Monitoring Approaches for Sustainable Cities

Weiwei LIU, Guifeng CHEN*

Electronics and Information Engineering, Langfang Normal University, Langfang 065000, China

Abstract—Population growth and urbanization demand innovative strategies for sustainable city management. This paper focuses on the integration of the Internet of Things (IoT) and image processing technologies for environmental monitoring in sustainable urban development. The IoT forms an integral part of the Information and Communication Technology (ICT) infrastructure in smart sustainable cities. It offers a new model for urban design, due to the ability to offer environmentally sustainable alternatives. Furthermore, image processing is a method employed in computer vision that provides reliable approaches for extracting significant data from images. The convergence of these technologies has the capacity to enhance the effectiveness and durability of our urban surroundings. This paper discusses the current state-of-the-art in both IoT and image processing, highlighting their individual applications, architectures, and challenges. This paper explores the integration of the aforementioned technologies in a harmonized monitoring system to promote synergies and complementarities. Several case studies demonstrate the successful adoption of the harmonized approach in urban contexts, focusing on the environmental monitoring, energy management, transportation, and social well-being. The combination of IoT with image processing raises concerns regarding privacy, standardization, and scalability. The study has provided a direction for future research and suggested that more participant and multiple-strategy approaches could be beneficial to address some existing limitations and move toward a more sustainable urban context. It should therefore be viewed as a compass or a roadmap for future research in the areas of IoT and image processing-based monitoring towards today's and future sustainable urban environments.

Keywords—Sustainable cities; Internet of Things; image processing; urban monitoring; smart city

I. INTRODUCTION

Urbanization has experienced significant increase in recent years. Projections indicate that by 2050, more than 70% of the global population would reside in urban areas [1]. Urbanization is causing a variety of issues, including congested infrastructures, excessive pollution, loss of natural resources, and exacerbation of existing social inequalities. To address these challenges, transitioning into a new paradigm of sustainable urban management, defined by efficient resource utilization, environmental protection, and an improved quality of life for residents, has become indispensable [2]. Sustainable urban development aims for the harmonious integration of economic growth, social justice, and ecological sustainability [3].

The fusion of the Internet of Things (IoT) and image processing technologies brings an innovative strategy for urban monitoring, providing unparalleled skills for real-time data

gathering, analysis, and decision-making [4]. The IoT, which consists of interconnected devices equipped with sensors and actuators, has transformed urban infrastructure by facilitating the smooth transmission of information between physical and digital surroundings [5, 6]. Image processing techniques, which draw inspiration from computer vision science, allow systems to extract significant information from visual data, such as surveillance media or satellite images [7]. By using these technologies, cities can efficiently oversee both the quantitative and qualitative components of urban life. Through the deployment of IoT sensors in metropolitan areas, it becomes feasible to collect data that can provide valuable information regarding traffic patterns, levels of air pollution, and energy use [8, 9].

Furthermore, image processing algorithms have the capability to examine surveillance footage in order to identify irregularities, observe alterations in the environment, and assess the success of municipal initiatives [10]. Implementing these technologies holds significant potential to improve the resilience of cities, optimize operations, and increase resource management [11]. Nevertheless, the implementation of IoT in surveillance has raised substantial apprehension surrounding privacy concerns, data security, and the ethical utilization of surveillance technologies. This highlights the importance of strong governance frameworks and the involvement of all parties in the collaborative development and deployment of IoT-based monitoring systems [12].

The lack of a comprehensive inquiry into major approaches for integrating IoT and image processing for urban monitoring in relation to the sustainable management of urbanism indicates a gap in the extant literature [13]. While there are single studies that look at individual aspects of either IoT or image processing applications in an urban context separately, there is no comprehensive research that investigates the utilization of both technologies in combination for monitoring the overall urban environment, including synergies and barriers. The present paper provides a thorough examination of the most cutting-edge techniques while offering valuable insights into their practical uses, structures, and consequences for the management of sustainable cities. This study, through a thorough analysis of existing literature and the evaluation of various methodologies in real-world situations, offers valuable insights for future research and contributes to the development of integrated image processing-based IoT solutions specifically designed to address the unique challenges of urban environments.

The remaining parts of the paper are arranged in the following manner: Section II offers comprehensive information on smart sustainable cities, IoT, and image processing. Section

III examines the amalgamation of IoT and image processing for urban surveillance, providing a novel framework. Section IV provides an analysis and discussion of the findings obtained from case studies conducted in the fields of environmental monitoring, traffic management, infrastructure maintenance, and disaster response. Section V outlines future directions and research opportunities within the domain. Section VI concludes the study by summarizing key findings.

II. BACKGROUNDS

This section presents the basic concepts and related terminologies used in this paper.

A. Smart Sustainable Cities

The emergence of smart sustainable cities is an obvious outcome of three interrelated global developments that are transforming urban settings on a worldwide scale [14]. Initially, the dissemination of sustainability has gained significant attention as civilizations acknowledge the pressing necessity to tackle environmental issues and foster enduring ecological equilibrium [15]. In response to rising concerns over climate change, resource depletion, and pollution, cities are adopting sustainable development concepts to reduce their impact on the environment and improve their ability to handle environmental disturbances [16].

Furthermore, the swift proliferation of urbanization has resulted in unparalleled rates of population growth and urban expansion [17]. With the increasing migration of citizens from rural to urban areas in pursuit of economic prospects and better living conditions, cities are facing the challenge of absorbing expanding populations while preserving livability and quality of life [18]. Rapid urbanization highlights the necessity for sustainable urban planning and management solutions to guarantee the continued vitality, inclusivity, and environmental sustainability of cities.

Thirdly, the advent of Information and Communication Technology (ICT) has fundamentally transformed the functioning and engagement between cities and their inhabitants [19]. Due to the emergence of digital technology, cities have experienced a growing level of connectivity and reliance on data. This has resulted in enhanced effectiveness in delivering services, better management of infrastructure, and increased citizen participation. ICT has given cities the ability to utilize data and technology to address urban problems, optimize the use of resources, and enhance the general well-being of citizens.

The combination of these three trends has led to the emergence of the concept of smart sustainable cities. These cities use cutting-edge technologies, data-driven strategies, and sustainable development ideas to create urban environments that are more efficient, resilient, and livable, meeting the needs of both current and future generations. By adopting smart sustainable policies, cities can effectively address critical urban issues and promote environmental stewardship, social justice, and economic well-being.

In a smart sustainable city, the ICT infrastructure is seamlessly incorporated into the urban environment, facilitating efficient communication and collaboration among various sectors and stakeholders [20]. The widespread utilization of ICT

enables the city to enhance the utilization of existing resources, including energy, water, and transportation, in a reliable, green, and efficient manner [21]. The fundamental principle of a smart sustainable city is the idea of interconnection, where different urban systems such as transportation, electricity, waste management, and public services are tightly connected and coordinated. By employing data analytics, sensors, and real-time monitoring, the city can gain valuable information about resource consumption patterns, environmental conditions, and citizen behavior [22]. These insights facilitate well-informed decision-making processes with the goal of enhancing economic and societal results while reducing adverse environmental effects. Fig. 1 illustrates the fundamental characteristics of a sustainable urban environment, which can be summarized as follows:

- **Efficient resource management:** ICT-enabled solutions empower the city to track and optimize the utilization of resources, resulting in lower waste, enhanced energy efficiency, and a smaller environmental footprint [23].
- **Enhanced mobility:** Intelligent transportation systems improve traffic flow efficiency, promote public transportation usage, and advocate for alternate modes of transportation, such as biking and walking, in order to alleviate congestion and minimize air pollution [24].
- **Citizen engagement:** ICT applications facilitate the active involvement and cooperation of people, government agencies, and other parties, promoting a sense of responsibility and liability for the sustainable progress of the city [25].
- **Resilience and adaptability:** By utilizing ICT to continuously monitor and analyze data in real-time, the city can more effectively detect and address environmental threats, natural disasters, and other emergencies. This will improve the city's ability to withstand and recover swiftly from disruptions, hence strengthening its resilience [26].

Fig. 1. Fundamental characteristics of a smart sustainable city.

B. Internet of Things

The IoT is a network that connects various physical devices, vehicles, buildings, and other stuff, equipped with sensors, software, and connectivity capabilities. These gadgets possess the capacity to gather and share data, frequently without human intervention, forming an extensive network of interconnections that spans from the virtual domain to tangible reality [27]. The IoT facilitates inter-device and centralized system connectivity, resulting in the generation of valuable data and enabling intelligent decision-making. It is commonly organized using a five-layer design, as depicted in Fig. 2. A brief discussion of the layers is provided in the following:

- Perception layer: This layer encompasses the tangible entities or devices that are equipped with sensors, actuators, and other hardware components to interact with the physical surroundings. These items gather data from their environment, including temperature, humidity, motion, and light intensity.
- Network layer: The network layer facilitates communication between the devices in the perception layer and the upper layers of the IoT architecture. This layer specifically addresses the protocols and technologies used in wireless and wired communication. It encompasses Wi-Fi, Bluetooth, Zigbee, and cellular networks.
- Middleware layer: The middleware layer serves as an intermediary between the lower-level network and perception layer and the higher-level application and service layer. It provides a multitude of functions, including data processing, protocol translation, device management, and security.
- Application layer: Data collected from the IoT devices is used by the application layer to deliver value-added functions and services. These applications encompass a variety of technologies, including smart home automation, industrial monitoring and control, environmental monitoring platforms, and healthcare management-critical applications.
- Business layer: The business layer embodies the high-level business operations, policies, and practices that affect the deployment and operation of IoT systems, and can involve areas such as business models, methods of monetization, regulations, and stakeholder engagement.

IoT is crucial to sustainable urban development as it allows for better resource management, improves infrastructure efficiency, and enhances the overall quality of life for urban residents [28]. An essential element of IoT in sustainable urban development is its ability to enable data-driven decision-making. Government officials can obtain real-time insights into urban dynamics by strategically placing sensors across the city to monitor characteristics such as air quality, traffic flow, energy usage, and waste management. This data can provide valuable insights for urban planning initiatives, allowing communities to improve transit routes, enhance energy efficiency, and undertake targeted interventions to tackle environmental concerns.

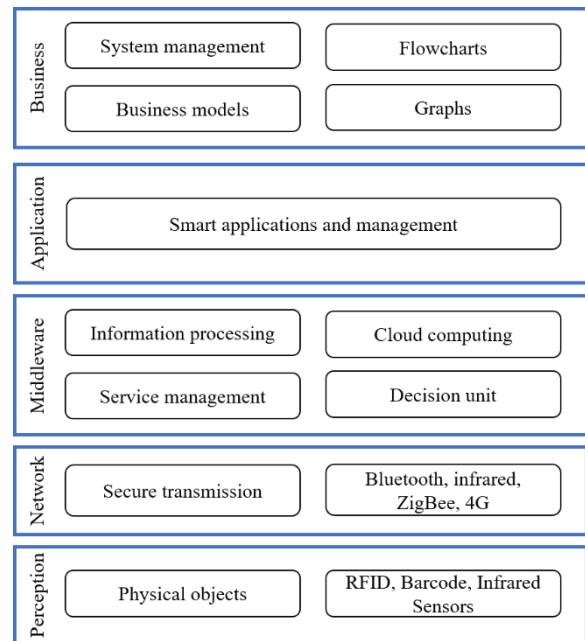

Fig. 2. Five-layered IoT architecture.

Furthermore, the IoT enables the development of intelligent infrastructure systems that improve the ability of cities to withstand and recover from challenges while also promoting long-term environmental and social well-being [29]. Smart grids possess the capacity to optimize the distribution of energy by considering the consumption patterns of individual households, thereby eliminating inefficiencies and improving the reliability of energy supply. Intelligent transportation systems can be used by cities to enhance traffic flow, minimize traffic congestion, and decrease greenhouse gas emissions, thereby promoting cleaner and more efficient urban transportation. The Internet of Things is essential for ensuring future urban development as sustainable as it can be, by giving the cities the necessary technologies and tools to monitor, measure, and subsequently improve all urban systems and the overall quality of life for the city dwellers.

C. Image Processing

Computer vision is a field that makes use of mathematical algorithms to extract information about three-dimensional objects from an image that is two-dimensional and thus to perceive the image in its entirety [30]. Computer vision allows computers to understand visual information in a fashion that is quite similar to that of humans. Techniques for processing images are important for urban monitoring because they offer the possibility to examine and retrieve important information from visual data given by various imaging devices such as cameras, drones, and satellites. They are algorithms and procedures intended for processing, analyzing, and interpreting photos to acquire useful information related to urban areas. The processing of urban surveillance images involves image processing at the heart of the systems, typically requiring features and objects to be extracted from the images to identify objects and other features within the urban environment. Such processes incorporate edge detection, segmentation and object recognition that helps identify elements within the urban

environment including buildings, streets, cars and trees. Image processing techniques play a crucial role in tasks like urban land cover mapping, infrastructure assessment, and environmental monitoring by precisely detecting and categorizing objects in photographs.

Change detection and analysis is another significant application of image processing in urban monitoring. Image processing algorithms can detect and measure modifications to urban environments, such as alterations in land use, construction activity, or natural disasters, by analyzing photographs taken at different times [31]. This feature allows urban planners and decision-makers to observe urban expansion, evaluate the efficiency of development initiatives, and promptly address unforeseen circumstances. Additionally, image processing methods provide the opportunity to investigate spatial configuration and relationships in urban areas, such as texture analysis, spatial autocorrelation, and object-based image analysis. These methods enable the investigation of urban environments by assessing their spatial and spectral attributes. The data provided by these analyses provide valuable knowledge about urban structures, land and usage patterns, socio-economic disparities, and environmental quality, which are useful for urban planning applications and policymaking.

Moreover, by combining remote sensing data with other types of geographic information, image processing can facilitate the creation of extensive spatial data sets for urban research and policy. This can be used to integrate a variety of data sources for a full evaluation of the urban environment. It also enables data-based planning, resource allocation and policy making [32].

III. INTEGRATION OF IOT AND IMAGE PROCESSING FOR URBAN MONITORING

IoT and image processing are expected to revolutionize the way cities are monitored and managed by city management. This technology allows cities to utilize both technologies. When used together, a richer range of data can be gathered and analyzed by cities. This data includes physical sensor readings and visual information from cameras. Imagine a city that can monitor traffic flow and air quality, but also identify suspicious activity in real-time using intelligent video analytics. This potent combination creates smarter, safer, and more efficient urban environments. By combining IoT data collection capabilities with real-time networking capabilities and the ability of image processing to extract insights from visual data, cities can gain a deeper understanding of urban dynamics and improve their decision-making capabilities in many domains.

The integration seamlessly combines data from IoT sensors with imagery from cameras, satellites, and other imaging equipment. A city is ideally a place that is fitted with sensors that are collecting data continuously on a range of things and that generate a continuous data stream about air quality, traffic flow, weather temperature and humidity. Images sensors are also collecting visual data about urban landscapes, infrastructure and activities. By utilizing advanced image processing techniques and effectively managing many data streams, we may uncover useful insights and identify trends.

Integrating IoT and image processing offers the significant benefit of monitoring urban environments with high precision

and timeliness. By combining IoT sensors and image processing algorithms, anomalies or changes in environmental conditions can be detected and analyzed to identify their source or extent. This collaboration enables urban areas to efficiently identify and address occurrences such as traffic congestion, sudden increases in air pollution, infrastructure deterioration, or crises.

Also, urban surveillance systems can incorporate IoT and image processing technologies for predictive analytics and early warning systems. Cities can use both IoT sensor data and imaging data to analyze historical data and trends to make predictions and proactive decisions about probable adverse events. For example, predictive models could warn about potential urban disorders, predict the flooding of areas, or predict air pollution levels. Thus, cities can plan and implement preventive measures to reduce the impact on citizens.

Furthermore, the integrated strategy allows cities to optimize the allocation of resources and improve operational efficiency across different urban systems. By cross-referencing IoT sensor data with imagery, cities can identify possibilities for resource optimization, such as fine-tuning energy consumption according to occupancy patterns detected by IoT sensors or optimizing waste collection routes based on visual assessments of waste accumulation. This optimization results in financial savings, enhanced service provision, and decreased environmental impact.

An integration of IoT technology and image processing technologies into a unified monitoring system for urban zones need a robust basis. This framework should include traditional elements and processes that will allow for the seamless integration, analysis, and presentation of data, hence supporting effective decision-making and management of municipal resources. Fig. 3 shows a concise framework for seamlessly combining IoT with image processing technologies to create a cohesive monitoring system. The combined application of IoT technology and image processing technology in urban environments has several benefits.

- Comprehensive data insights: By combining IoT sensor data with visual imaging, cities can enhance their comprehension of urban dynamics. This extensive method offers an in-depth knowledge of both the numerical and descriptive elements of urban environments, facilitating more informed decision-making and policy development.
- Enhanced situational awareness: The combination of IoT with image processing provides immediate monitoring and analysis of urban environments, allowing cities to identify and address incidents or irregularities rapidly. By enhancing situational awareness, it becomes possible to proactively manage urban resources and infrastructure, resulting in excellent public safety and resilience.
- Improved resource allocation: By analyzing IoT sensor data alongside visual imaging, cities may enhance resource allocation and operational efficiency across different urban systems. For instance, insights derived from data can guide decisions about the optimization of energy usage, management of waste, control of traffic,

and maintenance of infrastructure. This can result in financial savings and environmental advantages.

- **Proactive risk management:** The integration of methodologies creates predictive analysis and early warning systems for urban monitoring. On the basis of historical data and trends, cities have the potential to forecast and mitigate potential threats. This approach of proactive risk management increases preparedness and resilience of urban areas against and recovery from disasters such as natural disaster, accident, or infrastructure deterioration, minimizing the impacts of disasters.
- **Sustainable development:** Utilizing IoT and image processing technologies supports sustainable development objectives, including environmental

preservation, energy optimization, and social fairness. For instance, the continuous monitoring of air and water quality, combined with the analysis of land use patterns using images, can provide valuable information for the creation of policies and initiatives that aim to decrease pollution, protect green areas, and encourage equitable urban development.

- **Citizen engagement and empowerment:** The integrated approach promotes citizen engagement and empowerment by offering transparent access to urban statistics and information. Through the utilization of interactive visualization tools and decision support systems, cities have the ability to enable residents to actively engage in urban planning processes, advocate for their areas, and make valuable contributions to sustainable development initiatives.

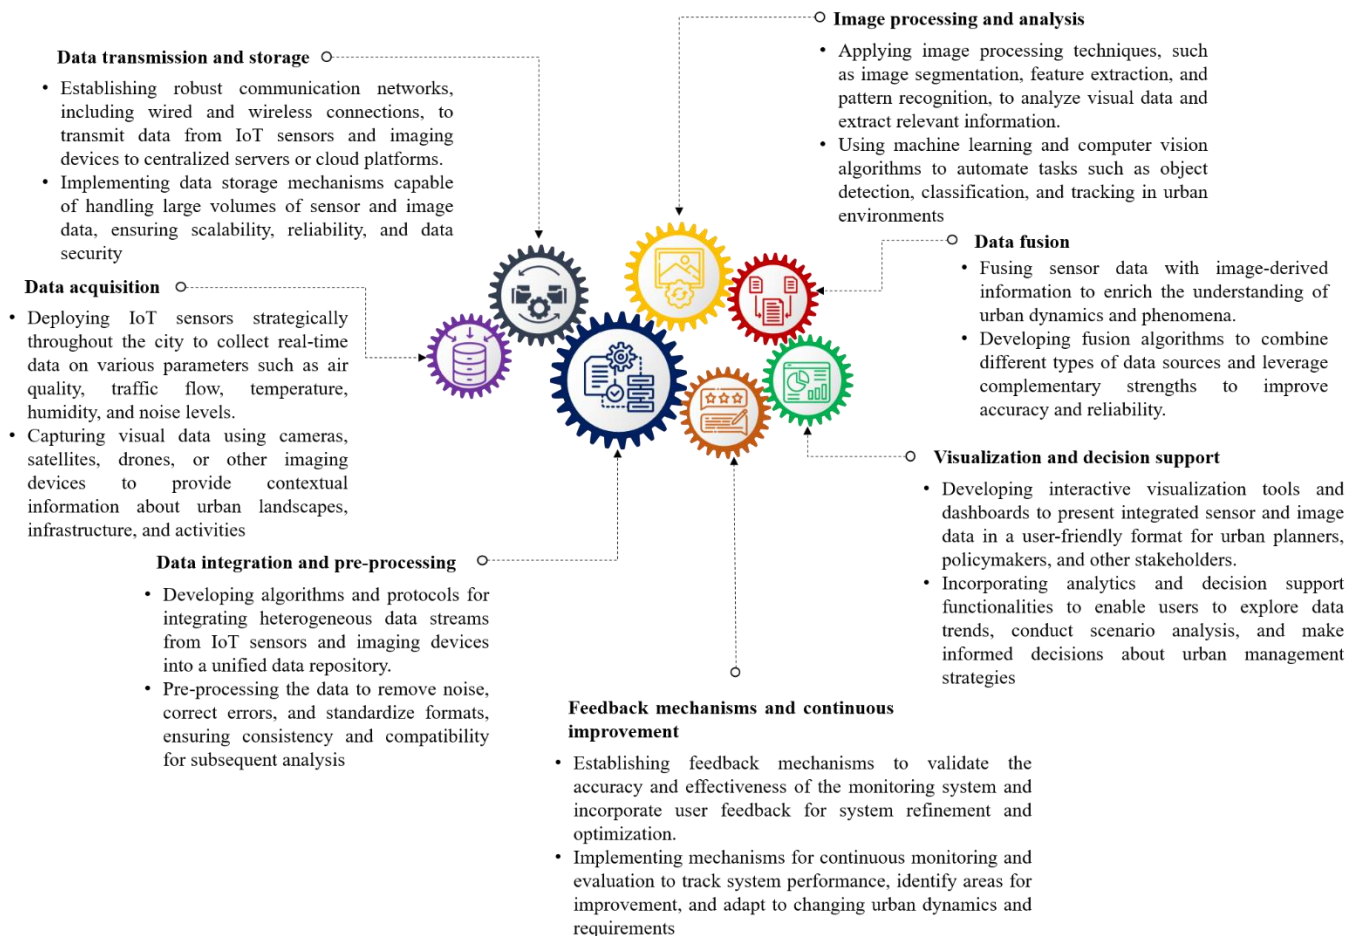

Fig. 3. Image processing-based IoT framework for urban monitoring systems.

IV. RESULTS AND DISCUSSION

The integration of IoT technology alongside image processing technologies has yielded numerous advantages in diverse fields pertaining to urban surveillance activities, as shown in Table I. The incorporation of these technologies has facilitated the implementation of urban management strategies that are both more effective and environmentally friendly. Consequently, the section to follow will explore the results of

several case studies and discuss their relevance for urban development and resilience.

- **Environmental monitoring:** IoT-enabled image processing solutions are crucial to monitoring and mitigating environmental conditions in urban areas. Through the examination of this visual data, towns can acquire crucial knowledge on the air and water quality, levels of pollution, and overall ecological well-being.

Urban regions can employ camera imagery to precisely detect pollution hotspots in real-time, track changes in vegetation coverage, and analyze photographs to understand the environmental impacts of human actions. The collected data can empower policymakers to identify specific actions to improve environmental quality and promote sustainability. In addition, IoT systems that employ image processing have the capacity to quickly detect and recognize environmental hazards such as wildfires, oil spills, or chemical leaks. This enables quick and effective reactions and containment measures to minimize the negative effects on the environment and human well-being.

- **Traffic management:** Urban areas face a major challenge due to traffic congestion which has a negative impact on mobility, air quality and economic activity. Traffic congestion, road blockages, and accidents in urban areas can be detected and addressed using image data, cameras, and sensors as raw data for image analysis, which provides an instant analysis of roads and their conditions, prompted by the IoT-based image processing solutions. This enables the metropolitan region to take action and offer alternative transportation routes to proactively address these difficulties. Implementing image processing-based IoT solutions can effectively improve traffic signal control, lane assignment, and parking management, thereby reducing congestion and enhancing urban mobility. The implementation of these advanced solutions enhances efficiency, safety, and experience, and metropolitan areas and citizens have much to gain from these solutions becoming widespread.
- **Infrastructure maintenance:** Ensuring the safety and functionality of urban areas requires the maintenance of essential infrastructure assets, such as bridges, roads, and buildings. Image processing-based IoT solutions enable advanced tools for monitoring, inspecting, and sustaining infrastructure assets. Sensors and cameras on drones, as well as other imaging technology, are being used by

cities to scan visual data. This is an opportunity to identify corrosion, deterioration, or damage in assets and infrastructure. Moreover, initiating image-based IoT systems deliver a real-time snapshot of infrastructure assets conditions and performance, enabling cities to manage infrastructure and plan infrastructure maintenance and replacement. The use of image-based IoT systems can lead to enhanced future maintenance planning maximizing the use of resources and increasing the useful life of infrastructure assets.

- **Disaster response and resilience:** Real-time image analysis, as deployed by emergency responders, could effectively assist in understanding the incident quickly to allow an immediate and appropriate response to allocate resources, appropriately distribute personnel, and evacuate people in disaster scenarios quickly. By integrating real-time image analytics into disaster management, it may help save lives, minimize damage, and strengthen community resilience during and immediately following disasters. Furthermore, in the context of disaster reconstruction and recovery stages, leveraging IoT-based image processing also has potential utility.

The outcomes of these case studies illustrate the efficacy of the integrated strategy in tackling diverse urban issues, such as environmental surveillance, traffic control, infrastructure upkeep, and disaster management. By leveraging the advantages of both IoT and image processing technology, cities may obtain practical and valuable information from various data sources. This enables them to make well-informed decisions and implement proactive management plans. However, careful attention must be given to the considerations for data privacy, scalability and interoperability when implementing an integrated urban monitoring system. Stakeholder cooperation is essential to address these considerations and take full advantage of IoT and image processing technologies for sustainable urban development.

TABLE I. AN OVERVIEW OF IoT-ENABLED IMAGE PROCESSING APPLICATIONS IN URBAN DOMAINS

Field	Description	Challenges	References
Environmental monitoring	<ul style="list-style-type: none">• Enables real-time monitoring and mitigation of environmental conditions, including air and water quality, pollution levels, and ecological well-being.• Facilitates identification of pollution hotspots and environmental threats such as wildfires and chemical leaks.	<ul style="list-style-type: none">• Data privacy concerns• Scalability issues• Interoperability challenges	[33-40]
Traffic management	<ul style="list-style-type: none">• Offers real-time analysis of traffic patterns, congestion, and road conditions to optimize signal timings and enhance transportation efficiency.• Facilitates prompt intervention and alternative route planning.	<ul style="list-style-type: none">• Accuracy and reliability of algorithms• Integration complexities• Cybersecurity threats	[41-49]
Infrastructure maintenance	<ul style="list-style-type: none">• Enables monitoring and inspection of infrastructure assets for early detection of damage and proactive maintenance.• Supports asset management and lifecycle planning based on accurate infrastructure status.	<ul style="list-style-type: none">• Cost-effectiveness• Training requirements	[50-54]
Disaster response and resilience	<ul style="list-style-type: none">• Supports swift comprehension of disaster situations and efficient resource allocation for evacuation and recovery efforts.• Aids in the prevention of loss of life and reduction of property damage.	<ul style="list-style-type: none">• Integration with emergency response protocols• Accessibility of imagery• Ethical considerations. The wide variety of sensors and cameras used for real-time data collection might be undermining privacy by continually tracking movements and activities, which could possibly result in unauthorized surveillance measures and a violation of privacy. The widespread of sensors and cameras used for real-time data collection can result in intrusions into individuals' privacy, as individuals' movements and activities are constantly being monitored. There is a risk of misuse of this data, leading to unauthorized surveillance and potential breaches of personal privacy.

IoT and image processing technologies should be governed and guided by legislation and regulations. It is important to establish norms and regulations to govern the use of these technologies in an ethical and responsible manner. With a campaign that educates the public about both the benefits and pitfalls of these technologies, citizens will be more responsible and able to demand accountability for their use. Potential risks associated with these technologies include data breaches, cyber-attacks, and misuse of surveillance. In order to address these problems, a city must prioritize the implementation of both extensive physical and software security measures. Tang asserts that the significance of establishing a secure and ethical framework for the utilization of urban monitoring technologies necessitates a robust multi-sectoral strategy involving all tiers of government, technology vendors, and community partners.

V. FUTURE DIRECTIONS AND RESEARCH OPPORTUNITIES

The adoption of IoT and image processing techniques for urban monitoring has provided a number of research opportunities as well as future prospects. The field of advanced data analytics is one of the major motivating factors behind the research work. It has inspired researchers to look into the various aspects of machine learning, deep learning and data fusion methodologies [61]. These methodologies provide a means to analyze data from IoT sensors and visual imagery to extract insights and move from urban monitoring to predictive analytics and proactive management of urban systems. Additionally, the research on edge computing architectures and distributed intelligence paradigms is a new area of research that enables the immediate processing and analysis of urban data at the edge of the network. This enables researchers to address latency issues and to move towards more robust, flexible, responsive urban monitoring systems that require minimal amounts of bandwidth.

Artificial Intelligence (AI) and machine learning are likely to impact urban monitoring systems by the integration of IoT and image processing technologies [62]. AI and machine learning enhance IoT and image processing tools in urban monitoring systems. It will be manifested in several aspects of the analytics capability, including more sophisticated data analyses, predictive models, and automated decision-making. Edge computing takes data processing to the edge of the network, thus weakening relation to back-and-forth data exchange [63]. This data is sent in real-time via the use of low latency. The inclusion of advanced networks for example 5G and beyond will be improved. Ultimately boosting the connectivity needed for transmission of significant levels of data, increasing the efficiency of the connectivity, and improving overall urban monitoring.

Nowadays, protecting privacy is critical in research, with concerns of data privacy and security on the rise due to the proliferation of urban monitoring. It is necessary, therefore, to find efficient ways to balance effective urban monitoring against individual privacy rights. Differential privacy, homomorphic encryption, and federated learning are all crucial in achieving that equilibrium. Furthermore, the integration of IoT and image processing technologies with blockchain, 5G networks, and augmented reality holds great potential for enhancing the scalability, security, and functionality of urban monitoring systems. For instance, researchers can use blockchain-based decentralized systems to securely and transparently exchange data, which will greatly help in ensuring the integrity of the data and in holding those who manage it accountable.

Human-centric urban monitoring systems require interdisciplinary collaboration and stakeholder engagement. Researchers can develop user-friendly and accessible interfaces for urban monitoring by embracing a human-centric design ethos. This will allow citizens to actively participate in decision-making processes. Data democratization and citizen engagement can be fostered through participatory sensing campaigns, crowdsourcing initiatives, and gamification strategies. Furthermore, establishing collaborative relationships and alliances between several stakeholders and consortia can enhance the sharing of knowledge, development of skills, and transfer of technology, thus accelerating the application of urban monitoring research in practical settings. Researchers, practitioners, policymakers, and community stakeholders come together in a collaborative effort to jointly develop and design urban monitoring solutions that address the varied needs and goals of urban communities. This initiative aims to create more innovative, more resilient, and inclusive cities for the future.

Furthermore, establishing collaborative relationships and alliances between several stakeholders and consortia helps accelerate the sharing of knowledge, development of skills, and transfer of technology, thereby driving urban monitoring research to have tangible effects in the real world rather than remaining just in academic circles. A collaborative endeavor is undertaken by researchers, decision-makers, urban designers, and community stakeholders to jointly develop and construct urban monitoring solutions. These ideas are designed to address the intricate issues encountered by contemporary cities and eventually contribute to the advancement of urban futures that are more resilient, equitable, and sustainable.

VI. CONCLUSION

This paper examined the confluence of IoT and image processing technologies, with specific implications for urban monitoring where these conjoined technologies have the ability to be transformative. The combination of IoT sensor data and image data provides urban monitoring systems with the ability to observe, analyze and make sense of the complexities of urban systems in real-time in ways that have not been possible before. This convergence holds great promise for how we think about urban processes, offering the opportunity to flesh out new analytic and predictive tools, to intervene in proactive ways, and to have new ways of thinking about how humans experience the city. However, despite the promise of intelligent and connected urban futures, there are a number of ethical, social, and technical

challenges that must be confronted in order to implement and manage urban monitoring systems. Some of the challenges include data privacy, data security, and algorithmic bias (problems that must be considered and addressed if urban monitoring technologies are to be responsibly adopted. Importantly, we must ensure that these technologies operate in ways that are in the interest of urban residents. This will require interdisciplinary collaboration, citizen engagement and involvement in decision-making processes.

Exploring Enhanced Object Detection and Classification Methods for Alstroemeria Genus Morado

Yaru Huang*, Yangxu Wang

Department of Network technology, Guangzhou Institute of Software Engineering, Conghua Guangdong, China

Abstract—As an important ornamental plant, the automatic detection and classification of the maturity of Alstroemeria Genus Morado flowers hold significant importance in precision agriculture. However, this task faces numerous challenges due to the diversity of morphological characteristics, complex growth environments, and factors such as occlusion and lighting variations. Currently, this field is relatively unexplored, necessitating innovative methods to overcome existing difficulties. To fill this research gap, this study developed a deep learning-based object detection framework, the Alstroemeria Genus Morado Network (AGMNet), specifically optimized for the detection and classification of Alstroemeria Genus Morado flowers. This convolutional neural network utilizes multi-scale feature fusion techniques and spatial attention mechanisms, along with a dual-path detection structure, significantly enhancing its capability for automatic maturity classification and detection of flowers. Notably, AGMNet addresses the issue of class imbalance in its design and employs advanced data augmentation techniques to enhance the model's generalization ability. In comparative experiments on the morado_5may dataset, AGMNet demonstrated superior performance in Precision, Recall, and F1-score, with a 3.8% improvement in the mAP metric over the latest YOLOv9 model, showcasing stronger generalization capabilities. AGMNet is expected to play a more significant role in enhancing agricultural production efficiency and automation levels.

Keywords—Alstroemeria; object detection; maturity classification; multi-scale feature fusion; Convolutional Neural Network (CNN)

I. INTRODUCTION

In modern agricultural production, the importance of precision agriculture technology is increasingly highlighted, with object detection and classification becoming one of the key technologies. Alstroemeria Genus Morado, as a flower with unique morphological characteristics and ornamental value, is crucial for determining the optimal harvest time based on flower maturity. In South America, particularly in Chile and Brazil, there is a high diversity of species [1] [2]. Despite the economic and ecological value of Alstroemeria Genus Morado, research on the automated detection and classification of its flowers is still insufficient. Traditional manual detection methods are not only inefficient but also costly, with accuracy and consistency of classification results being difficult to guarantee, making them unsuitable for large-scale production needs. Fortunately, with the development of computer vision and deep learning technologies, automated object detection and

classification offer new possibilities for addressing this issue [3]. Through object detection and classification technology, these species can be more accurately identified and assessed, providing support for the study and conservation of biodiversity.

In recent years, the rise of deep learning technology has brought new breakthroughs in the field of object detection and classification [4] [5], capable of automatically learning feature representations from a large amount of data, thereby reducing the reliance on manual feature extraction. By constructing deep neural network models and training them with large-scale annotated data, deep learning models can automatically learn and extract feature representations of objects, achieving efficient object detection and classification. In the field of deep learning object detection, there are mainly two types of methods. The first category is two-stage object detection algorithms, such as Region-based Convolutional Neural Network (R-CNN) [6], Faster R-CNN [7], and Spatial Pyramid Pooling Network (SPP-Net) [8]. These algorithms typically have higher detection accuracy but are slower in detection speed due to their two-stage nature. In contrast, the second category is single-stage object detection algorithms, which have faster detection speeds, such as the You Only Look Once (YOLO) series [9] and CenterNet [10], although they may make slight sacrifices in accuracy. Since detection speed is highly required in most tasks, single-stage algorithms have more advantages in practical applications.

However, despite the significant achievements of deep learning in general object detection, there are still many challenges when dealing with flower varieties with specific morphological characteristics and growth environments. Especially for flower varieties with unique shapes and growth characteristics, such as Alstroemeria Genus Morado, the diversity of morphological characteristics, complex growth environments, and potential interference factors such as occlusion and lighting changes still pose generalization challenges in detecting Alstroemeria flowers, making existing research insufficient. The study by Stan Zwinkels & Ted de Vries Lentsch on the detection of mature Alstroemeria Genus Morado flowers [11] demonstrated the feasibility of this detection method by creating an experimental dataset and designing a detection algorithm, achieving an F1-score of over 0.75 in experiments. In addition, the study of Alstroemeria pollen morphology [12] provided a foundation for later researchers to understand its morphological characteristics,

*Corresponding Author

which is helpful in developing more accurate detection algorithms. Aros et al. [13] discussed the seed characteristics and evaluation of pre-germination treatment of *Alstroemeria*.

To fill this research gap, there is an urgent need to develop an efficient and accurate object detection and classification method suitable for *Alstroemeria* Genus *Morado*. This study proposes a new deep learning-based object detection framework, specifically optimized for the detection of *Alstroemeria* Genus *Morado* flowers. A series of innovative technologies have been used to enhance detection performance and accuracy. The key design of the Encoder strengthens the representation of image features, and the spatial attention mechanism enhances the focus on important areas of the image. At the same time, a dual-path detection structure, combined with the main detection neck and auxiliary branch, enhances the detection capability for targets of different sizes through multi-scale feature fusion technology. In particular, the introduction of the SPPELAN module [14] and the DySample layer [15] allows AGMNet to expand the size of the feature map and fuse it with the feature maps in the Encoder, capturing context information at different levels and achieving deep, multi-scale feature extraction of the image. Finally, the Detect layer synthesizes these advanced features to output accurate detection results, making AGMNet perform well in object detection tasks in agricultural scenarios. At the same time, this comprehensive classification method enables more accurate judgment of flower maturity. To fully evaluate the performance of the model, this study selected the *morado_5may* dataset [16] for experiments, verified the effectiveness of the proposed method, and compared it with existing technologies, successfully overcoming the challenges brought about by the diverse morphological characteristics, complex growth environments, and potential interference factors such as occlusion and lighting changes of *Alstroemeria* Genus *Morado*. The experimental results show that the proposed AGMNet performs excellently in both performance and efficiency, superior to other computer vision methods, and has sufficient generalization.

This paper aims to address some key issues and make the following contributions as follows:

- Proposing an efficient and accurate deep learning framework for object detection and classification methods suitable for *Alstroemeria* Genus *Morado*.
- Developing a comprehensive classification method capable of accurately judging the maturity of flowers.
- Validating the effectiveness of the proposed method through a series of experiments and comparing it with existing technologies. At the same time, providing a reference for the detection and classification of other plant species.

The rest of this paper is organized as follows: Section II introduces the model design in detail. Section III provides experimental details and results. Section IV discusses and analyzes the research results in depth. Section V summarizes the paper and proposes future research directions.

II. MATERIALS AND METHODS

This section provides a detailed description of the dataset utilized in the study and an explanation of the AGMNet model's design principles, structural features, and optimization techniques, while emphasizing the innovative elements of the design.

A. Datasets

To verify the proposed method, the study conducted validation on the publicly available *morado_5may* dataset [16], which is a dataset for object detection tasks. It was photographed and released by Delft University of Technology and Hoogenboom *Alstroemeria* in the greenhouse of Hoogenboom *Alstroemeria* company around 12 PM on May 5, 2021. The images of the dataset were taken with an iPhone 8, using a 12-megapixel camera, with a pixel resolution of $4,032 \times 3,024$, taken from an overhead perspective about 1.5 meters above the flower bed. The entire dataset consists of 414 images and 5,439 labeled objects, belonging to two different categories, including raw and ripe, with all images in the dataset having bounding box annotation labels. It should be noted that there is no predefined training and testing split within the dataset. A random selection method was used to divide the 414 images into training and testing sets in an approximate 8:2 ratio, which were then stored in corresponding folders, constituting the *morado_5may* dataset used in this research. Detailed information about the dataset is shown in Table I.

TABLE I. DETAILED INFORMATION OF THE DATASET

Dataset	Image	Label		
		Total	Raw	Ripe
Total	414	5,439	4,679	760
Training	324	4,191	3,655	536
Test	90	1,248	1,024	224

Further, to objectively assess the model's classification capabilities, it is essential to understand the rules for category division within the dataset. The maturity classification of each flower is based on factors such as color, color uniformity, size, and the number of buds. If a flower has several buds that have begun to open, the buds are relatively large, and the color is bright purple, then it is considered ripe. These guidelines are established to help others identify incorrectly classified flowers. The complete buds are bright purple, with no yellow parts in the middle. A flower contains multiple buds that have begun to open. The buds of this flower are larger than those of other flowers. Classification example images are shown in Fig. 1.

It is worth noting that this dataset is challenging. Firstly, the issue of class imbalance is prominent because the number of immature raw flowers in the images far exceeds that of ripe flowers, leading to a model that may be biased towards predicting the more common category. Secondly, the stems and leaves of the flowers have a high color similarity, and the flowers at the lower positions are easily occluded by leaves, making the recognition and classification of the flowers more difficult. In addition, the imaging morphology of *Alstroemeria*

flowers is highly variable, and the uncommon flowering forms bring a test to the model's generalization capabilities. In Fig. 2, these challenges are depicted.

Fig. 1. Classification example images of the morado_5may dataset.

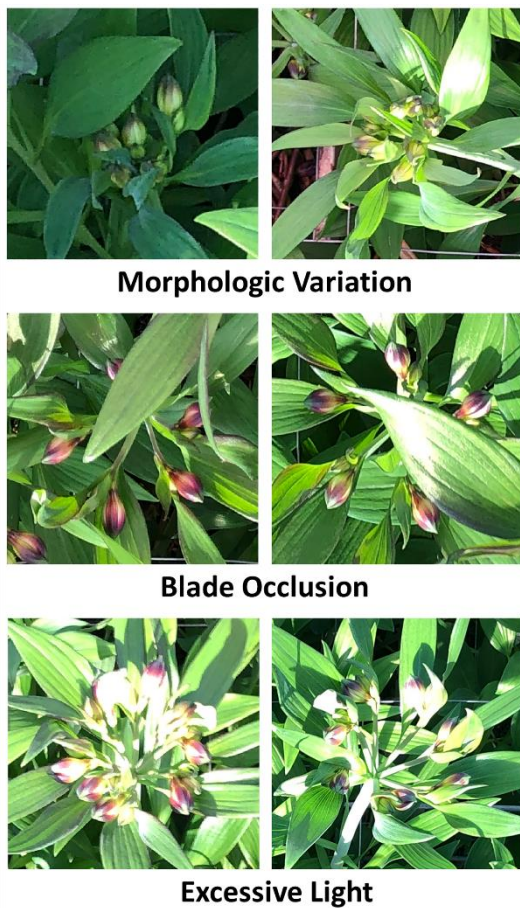

Fig. 2. The six main challenges of the morado_5may dataset.

In summary, by validating on the morado_5may dataset, the universality and effectiveness of the proposed method can be comprehensively evaluated.

B. Model Construction

When applying neural networks in the agricultural field, there are many factors to consider, mainly from external factors in the field. To address these challenges, an innovative deep

learning-based object detection model, the Alstroemeria Genus Morado Network (AGMNet), was proposed in this study. The overall network structure is primarily composed of three parts: the Encoder, the Decoder, and the Head network. It also employs a dual-path detection structure [14] to mitigate the issue of information loss due to network depth. The model structure is depicted in Fig. 3, and the subsequent sections will detail their configuration.

Fig. 3. Architecture of AGMNet.

1) Encoder Design Details: In the architecture of AGMNet, the Encoder serves as the main body of the model, responsible for extracting deep features of the image. Given an input image $I \in R^{H \times W \times 3}$, the Silence module, located at the forefront of the network structure, does not perform substantial operations. It is designed to retain the original image features to provide them to the main and auxiliary detection Decoders in the Neck for object detection. Subsequently, to reduce the spatial dimensions of the feature maps and increase the number of channels, multiple convolutional layers with a kernel size of 3×3 and a stride of 2 are used, halving the spatial dimensions of the image while increasing the feature depth. This convolution operation can be defined as Eq. (1):

$$X_{out} = \sigma(\sum_{i=1}^N (X_{in} * W_i + b_i)) \quad (1)$$

where, σ represents the activation function, $*$ denotes the convolution operation, W is the convolution kernel, b is the bias term, and X_{out} is the output feature map. When the input image size is $H_{in} \times W_{in}$, the convolution kernel size is $F \times F$, the padding is P , and the stride is S , the output feature map size can be calculated using the following Eq. (2) and Eq. (3):

$$H_{out} = \left\lfloor \frac{H_{in} + 2P - F}{S} \right\rfloor + 1 \quad (2)$$

$$W_{out} = \left\lfloor \frac{W_{in} + 2P - F}{S} \right\rfloor + 1 \quad (3)$$

Further, AGMNet designed a RepNCSPELAN4SCConv1 module to extract features and enhance the feature representation capability. The specific module design is as follows: first, a 1×1 convolutional layer Conv reduces the number of channels in the input feature map from $c1$ to $c3$. Then, the feature map goes through two consecutive RepNCSPELAN4SCConv1 modules, each containing a standard convolutional layer and an SCConv attention layer [17], along with a residual connection. These modules further transform and refine the channel number from $c3$ to $c4$. Finally, the original $c3$ output is concatenated with the outputs of the two

RepNCSP_SCCConv modules (a total of 2×4) on the channel dimension to form a richer feature representation. The concatenated feature map is then passed through a final 1×1 convolutional layer Conv4, converting the number of channels to the final output c2. Throughout this process, the SCCConv layer uses a combination of average pooling and convolutional operations to implement a spatial attention mechanism, which helps the model to focus more on important areas of the image, thereby enhancing detection performance.

In summary, by stacking multiple convolutional layers, activation functions, and downsampling layers to gradually extract multi-scale features of the image, the entire Encoder consists of five convolutional layers and four feature extraction layers, specifically defined as C3(2)-C3(2)-R-C3(2)-R-C3(2)-R-C3(2)-R, where Ck(m) represents a two-dimensional convolutional layer with a $k \times k$ kernel size and a stride of m, and R is a feature extraction layer. After the transformation by the Encoder, the input image will complete a $32x$ downsampling, and the feature map is reduced to $1/32$ of the original image size, outputting multiple feature maps of different depths that are used in the Decoder. Such Encoder design helps to improve object detection performance, especially when dealing with occlusions and small targets.

2) *Decoder design details:* In the design of AGMNet, the Decoder part employs multi-scale feature fusion technology and is designed with a Main Branch and an Auxiliary Branch to perform object detection simultaneously. This design enhances the model's ability to detect targets of different scales, improves feature expression capabilities, and allows for more effective information flow between different network layers.

In the Main Branch, the SPPELAN module [14] is first used to receive the high-dimensional feature maps output by the Encoder to enhance the receptive field and extract multi-scale features. Then, a DySample layer is connected to perform dynamic upsampling of the feature map, expanding the size to facilitate fusion with larger feature maps. This fusion operation is implemented through a Concat module, which concatenates the upsampled feature map with a feature map of the same size from the Encoder in the depth direction, forming a new feature map that integrates information from different levels. This fusion strategy helps the model capture context information at different levels and improves the model's ability to detect multi-scale targets. Similarly, the same convolutional layers as in the Encoder are used to perform downsampling operations again. Next, the RepNCSPPELAN4SCConv1 layer is used again to perform convolutional operations on the fused features, reducing the number of convolutional kernel parameters.

In the Auxiliary Branch, the CBLInear layer is first used to extract features from the $8x$, $16x$, and $32x$ downsampling layers of the Encoder, transforming these features from different levels to match the required number of channels. The transformation operation can be expressed as Eq. (4) to Eq. (6):

$$F_{cb}^{8x} = \text{XBAtv}\epsilon\alpha\rho(F_{enc}^{8x}; C_{out}) \quad (4)$$

$$F_{cb}^{16x} = \text{XBAtv}\epsilon\alpha\rho(F_{enc}^{16x}; C_{out}) \quad (5)$$

$$F_{cb}^{32x} = \text{XBAtv}\epsilon\alpha\rho(F_{enc}^{32x}; C_{out}) \quad (6)$$

where, F_{enc}^{8x} , F_{enc}^{16x} , F_{enc}^{32x} represent feature maps at different scales, and C_{out} is the target channel number. Then, feature fusion technology is used, and after each downsampling operation, the CBFuse layer fuses the output of the auxiliary branch with the feature map of the main branch. This fusion operation combines feature information from different levels, further enhancing the feature expression capabilities. Specifically, AGMNet adopts a specific fusion strategy based on the level and channel number of the feature map to ensure that the fused feature map retains the key information of the original features and introduces new contextual information. This further improves the model's detection performance, especially when dealing with small and blurred targets. The auxiliary branch, through parallel processing of additional feature maps, can capture information that the main detection branch may miss.

The design of the Decoder effectively utilizes the multi-scale features extracted by the Encoder and further enhances the feature expression capabilities through feature fusion and convolutional operations. This design allows the model to more accurately detect targets of different sizes, giving AGMNet an advantage in the object detection and classification tasks of *Alstroemeria*. Finally, the Detect layer receives feature maps of different scales and generates the final detection results.

C. Activation Function

In deep learning, the role of activation functions in neural networks is to introduce nonlinearity, allowing the network to model complex functions. Different activation functions have different mathematical properties and computational efficiencies. Commonly used activation functions include Sigmoid-weighted Linear Unit (SiLU) [18], Rectified Linear Unit (ReLU) [19], and Exponential Linear Unit (ELU) [20], etc.

The Sigmoid function maps any real number to the interval (0, 1), defined by the Eq. (7):

$$\text{Sigmoid}(x) = \frac{1}{1+e^{-x}} \quad (7)$$

SiLU dynamically adjusts the scaling of the input x through the output of the sigmoid function, retaining the linear part of the input information while introducing nonlinearity. Its output range is limited, which helps to avoid the vanishing gradient problem and, to some extent, prevents the "dead neuron" issue. The ReLU activation function is a more concise nonlinear function, defined by the Eq. (8):

$$\text{ReLU}(x) = \max(0, x) \quad (8)$$

ReLU has a gradient of 1 when the input is positive, effectively alleviating the vanishing gradient problem and has high computational efficiency. However, ReLU has a gradient of 0 when the input is negative, which can lead to some neurons never being activated during the training process, also known as the "dead" phenomenon. Furthermore, the ELU function combines the characteristics of ReLU and Sigmoid, defined by the Eq. (9):

$$\text{ELU}(x) = \begin{cases} x, & x > 0 \\ \alpha(e^x - 1), & x \leq 0 \end{cases} \quad (9)$$

where, α is a parameter that adjusts the gradient of negative input values, typically set to a small positive constant (e.g., 0.1 or 1.0). ELU has soft saturation for negative inputs, which can reduce the problem of dead neurons, but the computation is relatively complex.

Considering the specific needs of the AGMNet model, SiLU (Sigmoid Linear Unit) was selected as the activation function for the model. SiLU not only maintains the non-zero gradient characteristic of ELU in the negative value area but also avoids additional exponential operations and effectively prevents the dead ReLU issue, maintaining the continuity of the gradient. This makes SiLU more effective in dealing with complex nonlinear relationships, helping the model capture more refined feature representations and thereby enhancing the performance of object detection.

III. EXPERIMENTS

In this section, the evaluation metrics and experimental details are first introduced. Subsequently, the performance will be reported, and the proposed AGMNet model will be compared with existing methods. The annotated data was statistically analyzed, and the model's performance was comprehensively assessed using common evaluation metrics, with visualization techniques employed to display and analyze the model's detection results.

A. Experimental Conditions and Details

In this study, the publicly available morado_5may dataset was selected for experimental validation. To ensure the accuracy and reliability of the experiments, the experimental conditions were meticulously set, and the details were refined. During the model training process, special attention was given to the selection of the loss function, the configuration of the optimization algorithm, and the adjustment of hyperparameters. To enhance the model's generalization capability, data augmentation techniques such as random scaling, rotation, and color transformation were implemented. Mini-batch stochastic gradient descent (SGD) was used as the optimizer to avoid the computational resource waste caused by calculating the gradients of the entire dataset. The initial learning rate was set to 0.01, with a batch size of 4 and a momentum factor of 0.937. Considering the convergence, the model was trained for 300 epochs, which allowed it to reach a state of convergence.

The experiments were conducted on a machine equipped with an NVIDIA GeForce GTX 3090 GPU, using the PyTorch 2.0.0 deep learning framework [21] for model training and evaluation, with the CUDA version 11.8 parallel computing framework and the CUDNN version 8.9.5 deep neural network acceleration library to fully utilize the parallel computing capabilities of the GPU. These experimental conditions and details ensure that the model can fully learn the characteristics of the dataset and provide an objective evaluation and accurate comparison of the model's performance. Moving forward, comparative experiments will be conducted to validate the effectiveness of the proposed method, and a thorough exploration will be made regarding its potential and value in practical applications.

B. Comparison of Model Performance with Different Object Detection Methods

In this study, to comprehensively evaluate the performance of the proposed object detection model, multiple evaluation metrics were selected for comparison with benchmark models on four public datasets. These benchmark models include YOLOv5 [22], YOLOv8 [23], and YOLOv9 [14]. AGMNet was trained and tested under the same experimental conditions as these benchmark models and evaluated based on indicators such as Precision (P), Recall (R), F1-score (F1), and mean Average Precision (mAP).

Precision (P) represents the proportion of objects correctly predicted by the model out of all predicted objects, Recall (R) represents the proportion of objects correctly predicted by the model out of all actual objects, and F1-score (F1) is the harmonic mean of Precision and Recall, providing a balanced perspective of the model's accuracy and recall rate. mAP is the average of the average precision over multiple different IoU thresholds, which can more comprehensively evaluate the model's performance under different thresholds and is an important performance indicator. Specifically, mAP@0.5 and mAP@0.5:0.95 represent the mAP values at an IoU threshold of 0.5, and the average mAP value as the IoU threshold changes from 0.5 to 0.95 (with a step size of 0.05), with the latter being a more stringent assessment of performance. Their definitions are as Eq. (10) to Eq. (13):

$$P = \frac{TP}{TP+FP} \quad (10)$$

$$R = \frac{TP}{TP+FN} \quad (11)$$

$$F1 = 2 \times \frac{P \times R}{P+R} \quad (12)$$

$$mAP = \frac{1}{n} \sum_1^n P(R)d(R) \quad (13)$$

where, True Positives (TP), False Positives (FP), and False Negatives (FN) represent the number of true positives, false positives, and false negatives, respectively. "TP + FP" is the total number of objects detected by the model, and "TP + FN" is the total number of actual objects in the image. As shown in Table II, the performance of each model in the four datasets is displayed.

TABLE II. PERFORMANCE EVALUATION RESULTS OF DIFFERENT MODELS

Model	P	R	F1	mAP@0.5	mAP@0.5:0.95
YOLOv5	0.725	0.722	0.723	0.754	0.530
YOLOv8	0.715	0.755	0.734	0.762	0.564
YOLOv9	0.704	0.802	0.750	0.788	0.630
AGMNet	0.737^a	0.807	0.770	0.826	0.637

^a. Optimal performance is indicated in bold.

Through experimentation, the performance of these models was compared and analyzed on evaluation metrics such as Precision (P), Recall (R), F1-score (F1), and mean Average Precision (mAP). It is evident that the AGMNet model achieved the best performance across all assessment metrics. AGMNet reached an F1-score of 0.770, indicating that

AGMNet can effectively detect most real targets while maintaining high precision and recall rates. In addition, although YOLOv9 achieved a recall rate of 0.802, its precision was slightly lower, resulting in an F1-score slightly lower than AGMNet. The performance of the YOLO series models in mAP@0.5 and mAP@0.5:0.95 also did not surpass AGMNet, which means that AGMNet has stronger generalization capabilities under different IoU thresholds and can maintain high detection accuracy, especially within the more stringent IoU threshold range. It is worth noting that in the article by the author of the morado_5may dataset [11], the experimental model achieved an F1 result of 0.755, which shows that the performance of the AGMNet model has indeed been improved.

In the experiments, models such as CenterNet [10], Faster R-CNN [7], FCOS [24], and EfficientDet [25] were also tested. Their performance on the test dataset was notably poor, with an mAP@0.5 value not exceeding 0.3, significantly lower than the over 0.8 they could achieve on the training dataset. Although they showed a decreasing trend in loss values during training and ultimately reached a loss value of less than 1, they almost failed to successfully detect targets on the unseen test dataset. This phenomenon reveals their lack of generalization capabilities when dealing with datasets with complex backgrounds and more occlusions. Their performance dropped sharply when facing unseen target poses, occlusion situations, small targets, or background interference.

C. Comparison of Classification Performance with Different Object Detection Methods

After evaluating the performance of different models, further attention was given to their classification performance in the morado_5may dataset. This dataset contains two labels, raw and ripe, which represent unripe and ripe fruits, respectively. Similarly, metrics such as Precision (P), Recall (R), F1, and mean Average Precision (mAP) were used to comparatively assess them. The experimental results are shown in Table III.

TABLE III. CLASSIFICATION PERFORMANCE EVALUATION RESULTS OF DIFFERENT MODELS

Model	Class	P	R	F1	mAP@0.5	mAP@0.5:0.95
YOLOv5	Raw	0.733	0.784	0.758	0.778	0.522
	Ripe	0.716	0.661	0.687	0.729	0.538
YOLOv8	Raw	0.719	0.799	0.734	0.801	0.555
	Ripe	0.710	0.711	0.757	0.724	0.574
YOLOv9	Raw	0.733	0.849	0.787	0.829	0.627
	Ripe	0.675	0.754	0.712	0.748	0.632
AGMNet	Raw	0.794 ^a	0.806	0.800	0.857	0.630
	Ripe	0.681	0.809	0.740	0.795	0.645

^aThe best performance for each category is indicated in bold.

For the raw category, the AGMNet model achieved the highest scores in Precision, Recall, and F1, indicating that AGMNet has higher accuracy and fewer missed detections

when identifying unripe fruits. For the classification task of the ripe category, although AGMNet is slightly lower than YOLOv9 in Precision, it leads in Recall and F1, especially with a Recall of 0.809, showing AGMNet's higher recall rate when identifying ripe fruits. In addition, AGMNet also performed well in the mAP indicators, proving its overall performance superiority.

It is worth noting that AGMNet's performance in detecting unripe category flowers is particularly outstanding. Unripe flowers have greater difficulty in recognition because their characteristics are not as obvious as those of ripe flowers, and they are also smaller in size. These results further confirm the effectiveness of AGMNet in the tasks of object detection and classification of Alstroemeria Genus Morado. AGMNet, through its advanced network structure and optimization algorithms, can effectively handle the issue of class imbalance and achieve accurate classification in complex backgrounds, demonstrating stronger robustness.

D. Visualization of Typical Errors

In the task of object detection, missed detections and false detections are the two major issues affecting the model's performance. To delve into the causes of these errors, a visual investigation was conducted on the detection results of AGMNet and other benchmark models. During the evaluation process, a confidence threshold was carefully set to ensure optimal counting metrics on the dataset. This strategy helped to filter out the model's most confident detection results while excluding errors that might be brought by low-confidence predictions.

For missed detections, it was observed that these often occur when the target features are not distinct, the background is complex, or the target is occluded. In the visual results, blue arrows were used to point to these targets that were not detected. These targets may be due to their small size, high degree of integration with the background, or severe occlusion, making it difficult for the model to accurately capture their features. Differences in feature extraction and contextual understanding among different models also further affect the situation of missed detections. As for false detections, they usually occur when the model incorrectly identifies non-target objects as target categories. In the visualization images, yellow arrows point to these falsely detected targets. These errors may stem from the model's vague understanding of category boundaries or the issue of class imbalance in the dataset. When the model fails to fully learn the subtle differences between different categories during the training process, misclassification is likely to occur. In the detection of Alstroemeria Genus Morado, false detections may occur when plant structures that are similar in shape but not part of the target category are incorrectly classified as ripe or unripe flowers. To provide a clear illustration of these errors, Fig. 4 presents visual examples of typical missed (blue arrow) and false detected (yellow arrow) cases.

Through careful review of the object detection results, several typical error types and their potential causes were identified:

Fig. 4. Visualizing typical missed (blue arrow) and false detected (yellow arrow) cases.

Missed Detections: YOLO series models exhibit significant missed detection issues when detecting small, occluded, or targets with colors similar to the background. This problem can be attributed to the model's inability to fully capture the detailed information of these targets during the feature extraction phase, leading to their neglect in subsequent detection stages.

False Positives: On the other hand, false positives often occur when flowers are in the transitional phase between maturity and immaturity, making it difficult for the model to classify accurately. Additionally, imaging issues under strong light conditions can also cause the color features of mature flowers to distort, leading them to be misjudged as immature. These situations indicate that the model has limitations in dealing with detailed variations in color and shape.

Boundary Box Issues: In some detection results, it was noticed that targets with incomplete edges are easily ignored by the model. This may be due to the model's failure to fully consider the information in the edge areas when processing images, or because targets in these areas suffer loss during the feature extraction process. For example, in the case images of the YOLOv5 and YOLOv8 detection results, the target in the lower left corner was not detected. In contrast, YOLOv9 and AGMNet successfully addressed such issues.

In summary, the error analysis of AGMNet in object detection tasks indicates that the model has significant advantages in detecting small targets, occluded targets, and targets at the image edges, thanks to its innovative structure and algorithmic optimizations. These features of AGMNet give it important practical value in application scenarios such as precision agriculture, especially in object detection tasks that require high accuracy and robustness.

IV. DISCUSSION

This paper introduces the AGMNet model for the object detection and classification task of *Alstroemeria* Genus *Morado* flowers, showcasing its superior performance. Comparative analysis has validated the model's advantages in object detection and classification. AGMNet's dual-path detection structure, featuring a main detection trunk and auxiliary branches, offers robust support for dealing with occlusions and multi-scale targets. This architecture not only bolsters the model's robustness but also demonstrates AGMNet's enhanced generalization across different IoU thresholds, particularly within stricter IoU ranges where its performance benefits are more evident. When compared to the YOLO series models, AGMNet has highlighted its potential and value in object detection tasks. The outcomes confirm AGMNet's practical application potential in precision agriculture, especially in scenarios demanding high accuracy and robustness. The introduction of AGMNet substantiates the efficacy of deep learning technology in precision agriculture and sets a foundation for subsequent research. Nevertheless, despite AGMNet's commendable performance in numerous instances, issues persist, such as missed detections when targets are heavily occluded or closely resemble the background in color. Additionally, false detections are prevalent during the transitional phase of flower maturation, suggesting that the model can improve in capturing nuanced variations in color and shape.

To counter these limitations, future efforts should concentrate on several fronts: the model requires further refinement to more adeptly manage occlusions and background interference. Constructing a more extensive dataset of *Alstroemeria* flowers, replete with detailed annotations, is essential. Developing a more lightweight model to meet real-time detection requirements will enhance the object detection model, improving its adaptability to targets across diverse environmental conditions. Future studies will also address more tangible needs in agricultural applications, offering effective technical support for plant disease and pest monitoring, plant population statistics, and ecological conservation.

V. CONCLUSION

This study aimed to address the insufficient object detection and classification performance of *Alstroemeria* Genus *Morado* flowers, filling a gap in this line of research. Innovatively, this study proposed the AGMNet model, which incorporates Encoder and Decoder structures. By applying a range of innovative technologies, including multi-scale feature fusion, spatial attention mechanisms, and dual-path detection structures, AGMNet has surpassed existing YOLO series models in key performance indicators, demonstrating

exceptional performance. Comprehensive experimental evaluations were conducted using the morado_5may dataset, and the results showed that compared to other benchmark models, AGMNet achieved higher levels in terms of precision, recall, and mAP metrics. However, despite the positive outcomes, there are still some issues that need to be further explored and resolved in future work. Specifically, addressing class imbalance, enhancing model generalization, improving computational efficiency, adapting to environmental changes, and creating larger-scale datasets are all key directions for the next phase of research. It is anticipated that through continued research, AGMNet can play a greater role in the field of precision agriculture, making a more significant contribution to the improvement of agricultural production efficiency and automation levels.

Enhanced Arachnid Swarm-Tuned Convolutional Neural Network Model for Efficient Intrusion Detection

Nishit Patil¹, Dr. Shubhlaxmi Joshi²

Research Scholar, School of Computer Science, MIT-WPU, Pune, Maharashtra, India¹

Associate Dean, Faculty of Science, School of Computer Science, MIT-WPU, Pune, Maharashtra, India²

Abstract—Digital systems in the connected world of today bring convenience but also complicated cyber security challenges. The inadequacies of conventional intrusion detection techniques are exposed by the constant adaptation and exploitation of vulnerabilities by advanced cyber threats. Identifying dangers in massive data flows gets more difficult as networks grow, necessitating innovative methods. With the aim of minimizing these concerns, a new ID model is created utilizing cutting-edge machine learning to proactively and flexibly combat dynamic cyber attacks, with regard to evolving cyber attackers, this model seeks to improve accuracy and protection systems. This research develops an arachnid swarm optimization-based Convolutional neural network (ASO opt CNN) model to improve ID performance. An improved modified residual CNN is employed in the model to lessen the vanishing and exploding gradient problems in deep networks and facilitates the optimization process, making it easier for deep networks to learn. The developed model is adjusted using arachnid swarm optimization (ASO), which is the hybridization particle swarm optimization (PSO) and social spider optimization (SSO). Utilizing test data, the model's efficacy is evaluated at last. This test data is also subjected to preprocessing, which leads to the creation of a robust detection model that can identify the presence of network attacks. Experimentation and comparison indicate the approach's effectiveness by attaining accuracies of 95.95%, 95.61%, and 95.00% for three datasets respectively. This highlights the developed model's potential to detect intrusions more effectively.

Keywords—Intrusion Detection; arachnid swarm optimization; Convolutional Neural Network; pre-processing; arachnid swarm optimization

I. INTRODUCTION

The security of computer networks and systems is of utmost importance in today's technologically advanced and interconnected society. Because vital operations depend more and more on digital infrastructure, there are more sophisticated and varied potential threats from unauthorized access, hostile behavior, and cyber attacks [1]-[3]. By continually monitoring system behavior and network traffic in order to spot suspicious or malicious activity, ID systems serve a critical role in protecting these environments. An essential part of IDS is an ID model, which is in charge of data analysis, pattern recognition, and differentiating between normal and suspicious activity [4]. It works relentlessly to protect the availability, confidentiality, and integrity of digital assets as a vigilant

sentinel. To determine potential risks in real-time, this model uses cutting-edge methods from the fields of machine learning and artificial intelligence [5]. Finding unauthorized or hostile actions that can jeopardize the security of a network or system is the main goal of an ID model. The model seeks to identify intrusion attempts, data breaches, and other security breaches by examining network traffic, system logs, and other pertinent data. The model is intended to discover and comprehend the fundamental behavior of a network or system. Then, it continuously scans for departures from this norm, highlighting any actions that are unique or unexpected from a statistical perspective [6]. This method makes it possible to find new, undiscovered hazards. Even though these patterns are not immediately apparent to human analysts, intruders frequently leave behind recognizable patterns in their behavior. The ID approach is able to spot these minute trends and connect seemingly unconnected occurrences to pinpoint potential threats [7]-[9]. The ID methodology functions in real-time, enabling quick reactions to newly emerging threats in a digital environment that is always evolving. The methodology aids in risk mitigation by quickly identifying and warning security personnel about suspicious actions before they worsen [10]. An efficient ID model continuously picks up new information and modifies its detection tactics.

It changes along with the threat environment, ensuring that it continues to be effective against both well-known and new attack vectors. The fundamental elements of an ID model include the model's ability to receive information from a variety of sources, including network traffic, system logs, and application behavior. The analysis is built on top of this data. The characteristics of network traffic and system activity are represented by relevant features or attributes that are taken from the acquired data [11]. The detecting methods use these features as input. The model creates warnings or notifications to notify security administrators or automated systems about potential threats when it notices behaviors that differ from the expected norm. The ID model can start automated responses based on the seriousness of the threat it has discovered or it can suggest human intervention [12]. These reactions could entail isolating affected systems, blocking suspect IP addresses, or modifying network settings. In conclusion, an ID model is a skilled and perceptive keeper who constantly scans digital environments for indicators of harmful intent [13]. Leveraging state-of-the-art machine learning algorithms, this technology enhances the security stance of networks and systems,

empowering enterprises to swiftly detect, confront, and mitigate cyber security threats with precision and efficiency. As technology develops, ID models play a more and bigger role in protecting our digital world [14].

Machine learning's contributions to ID significantly enhance both the effectiveness and efficiency of identifying and mitigating cyber security threats. Key advantages include the ability to detect complex and constantly evolving infiltration tactics, a task that can pose challenges for rule-based systems but is well-suited for machine learning algorithms [15]. They are capable of picking up abnormalities and new attack patterns that typical rule sets do not explicitly identify. In order to stay up with new cyber security threats and attack vectors, machine learning models can adapt to new data and learn from it. This versatility guarantees that the ID system will continue to be effective against new attack methods [16].

The number of false positive alerts can be decreased by using machine learning models to thoroughly analyze data patterns. These models can determine whether an activity is indeed suspicious or symptomatic of an intrusion by taking into account a number of different characteristics and contexts [17] [18]. Machine learning algorithms can discover complex correlations between features, improving the accuracy of both known and undiscovered infiltration patterns. As a result, fewer threats are missed and detection rates are improved. Many machine-learning models can analyze data in real time, which enables quick detection and reaction to incursions as they happen [19]. This is essential for reducing possible harm and the effects of attacks. Modern computer systems create a lot of network traffic and system logs, which makes machine-learning methods an ideal choice for this task [20].

The main aim of the research is to develop an ASO opt CNN model to improve ID performance. Getting an intrusion dataset and applying class labels constitute the first phase. Then a model is trained using this labeled dataset. The data is then cleaned and prepared during the preprocessing phase. An updated feature matrix is created once statistical features are extracted from the preprocessed dataset. An improved modified residual Convolutional neural network is fed with the retrieved features. The model is tuned using stages of PSO and SSO. Utilizing test data, the model's efficacy is evaluated in the final phase. This test data is also subjected to preprocessing, which leads to the creation of a robust detection model that can identify the presence of network attacks.

- Arachnid swarm optimization: The hybridization of SSO and PSO seeks to develop an ASO model that takes advantage of each algorithm's strengths while adjusting for its drawbacks. SSO and PSO merger could imply integrating their update methods, sharing tactics, and search strategies to form a new hybrid algorithm. SSO's social sharing mechanism may be included in PSO's velocity update equation, allowing particles to communicate and share information in the same way as social spiders weave webs. Alternatively, to achieve greater convergence to optimal solutions, the exploration and exploitation capacities of both algorithms could be balanced.

- ASO opt CNN: Combining PSO and SSO results in an effective and efficient optimization strategy for CNNs in ID by combining their respective strengths in global exploration and local fine-tuning. Through the use of a hybrid strategy, CNN performance, dynamic threat adaption, and overall ID accuracy may all be improved.

The manuscript maintains its current organizational structure, with Section II providing a comprehensive review of recent research, including methodologies and challenges. Section III presents an illustrative example of an ID model. In Section IV, the novel ASO is introduced. Section V delves into a detailed discussion of experimental results, while Section VI delivers the concluding remarks and summary.

II. MOTIVATION

The growing threat environment of cyber attacks in our linked digital world is what motivated researchers to create an ID model. The sophistication and diversity of cyber dangers increase as technology develops and our reliance on computer networks increases. Hence, a substantial demand exists for robust and adaptable ID systems. This section elucidates the methodologies employed by researchers to enhance the efficacy of ID models.

A. Literature Review

Jie Gua and Shan Lu [21] devised an efficient ID framework that leverages Support Vector Machines (SVM) combined with Naive Bayes feature embedding. Our method performs admirably, delivering excellent accuracy across many datasets. The naive Bayes feature transformation technique, however, may impose some level of computational overhead, which could affect real-time processing efficiency in high-speed network contexts. This poses a potential restriction for this system.

An innovative two-stage intelligent IDS was created by NevrusKaja et al. [22] to identify and defend against such malicious intrusions. The implementation demonstrates a highly effective IDS that detects attacks with high accuracy while removing false positives and increasing computational effectiveness. The model's reliance on ML algorithms for attack detection and classification, meanwhile, has the potential to create limitations to adversarial attacks, thus reducing the system's robustness in the face of sophisticated attackers.

The shortcomings of conventional feature-based ID systems for detecting advanced threat attacks were addressed by Xianwei Gao et al. [23], it debuted a model of adaptive ensemble learning. The proposed solution outperformed current approaches by achieving high accuracy through adaptive. However, the extra computational complexity brought on by ensemble learning could be one of the drawbacks.

SoosanNaderi Mighan1 and Mohsen Kahani [24] developed a hybrid approach aimed at establishing a rapid and highly efficient cyber security ID system. While this method exhibited impressive performance in terms of accuracy, f-measure, sensitivity, precision, and execution time, it's worth noting that the complexity associated with configuring and

fine-tuning the hybrid model could potentially introduce certain drawbacks.

An adaptable and robust network ID was created by Lirim Ashiku and Cihan Dagli [25] using the deep learning architecture to recognize and categorize network threats. By enabling an adaptive ID system that learns to recognize both known and new network attack patterns, this paradigm improved network security by reducing the chance of intrusion but implementing this model required significant computational resources and skill due to the potential for complex model training and false positives/negatives.

The goal of Mohammad Noor Injadat et al. [26] was to improve network ID with a unique machine learning (ML)-based framework. This model delivered increased detection performance with lower computational complexity, maximizing security measures for people and businesses in the face of rising cyber threats. To achieve the best results, however, the application of several strategies, such as feature selection and oversampling, may create additional complexity.

Peilun Wu and Hui Guo [27] introduced LuNet, a unique hierarchical CNN+RNN neural network that successfully extracts geographical and temporal information from network traffic data, with the goal of improving network ID. Beyond incorporating cutting-edge methodologies, our model excels in the precise and comprehensive identification of networks. It achieves this by adeptly capturing not only the spatial but also the temporal characteristics inherent in network traffic data. However, the deployment and training of LuNet may need significant computational resources, which could lengthen processing times.

The limitations of conventional algorithms were addressed by Yihan Xiao [28] hence creating a network ID model based on CNN-IDS that concentrated on better feature extraction, accuracy, and timely identification of network attacks, which improved the accuracy, decreased false alarm rate, and boosted the timelines. However, the transformation of traffic data into an image format can complicate preparation and might restrict the model's applicability to particular data sets.

B. Challenges

- It can be difficult to preprocess network traffic data before feeding it into a CNN model. It may be necessary to use careful engineering to transform raw data into a usable format, which could increase processing overhead.
- ID datasets frequently contain unbalanced class distributions, with normal traffic greatly outnumbering attack cases. It takes sophisticated strategies to train a model to handle such imbalances in order to avoid bias against the dominant class.
- Developing a successful feature extraction plan for the architecture is essential. Despite the fact that CNNs are efficient at learning hierarchical features, it is still difficult to pinpoint the characteristics that are the most useful for ID.

- Finding a balance between underfitting and overfitting can be difficult and time-consuming when optimizing hyperparameters.
- Striking an equilibrium between reducing false positives and minimizing false negatives presents a formidable challenge, as often, mitigating one tends to elevate the potential of the other.

III. EFFICIENT ID METHODOLOGY FOR ARACHNID SWARM-TUNED CNN MODEL

The primary aim of the research is to develop an ASO opt CNN model to improve ID performance. Getting an intrusion dataset and applying class labels constitute the first phase. Then a model is trained using this labeled dataset. The data is then cleaned and prepared during the preprocessing phase. An updated feature matrix is created once statistical features are extracted from the preprocessed dataset. An improved modified residual Convolutional neural network is fed with the retrieved features. The model is tuned using stages of PSO and SSO. Network traffic can be more accurately classified as normal or intrusive by tuning by optimizing the hyperparameters, architecture, and training parameters of the CNN. The model's performance in classifying data can be enhanced by fine-tuning to better capture complex patterns. Utilizing test data, the model's efficacy is evaluated in the final phase. This test data is also subjected to preprocessing, which leads to the creation of a robust detection model that can identify the presence of network attacks. Experimentation and comparison indicate the approach's effectiveness and highlight its potential to considerably increase ID accuracy. The architecture of the developed ID model is illustrated in Fig. 1.

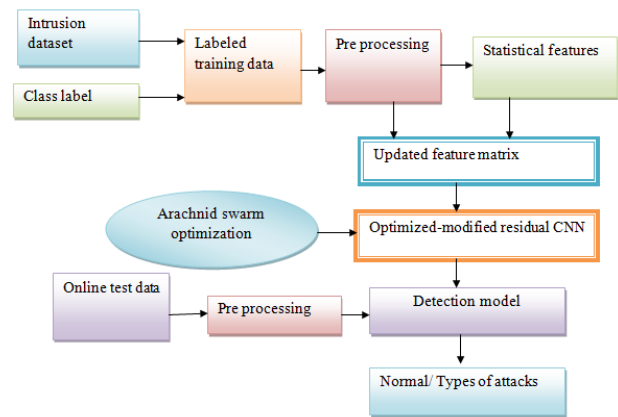

Fig. 1. Architecture of the proposed ID model.

A. Input

The inputs for the ID model are gathered from BoT-IoT (d1), CICIDS2017 (d2), and UNSW-NB15 network (d3), which is logically described as follows,

$$K = K_1 + K_2 + K_3 \tag{1}$$

$$K = \sum_{h=1}^m K_h + \sum_{i=1}^u K_i + \sum_{t=1}^j K_t \tag{2}$$

The first dataset, K_h is described as having values between 1 to m , the second dataset, K_i is described as having values between 1 and u , and the third dataset, K_j is described as having values between 1 and j .

B. Data Labeling

After the dataset has been compiled, each data point needs to be assigned a class that describes its nature. These groups in ID generally comprise subcategories like Normal and other kinds of Attacks (such as DoS assaults, malware, and intrusions). Each data point must be labeled according to its behavior, whether it represents a secure network activity or an attack. A crucial stage in machine learning is using the labeled dataset to train a model. The primary aim is to instruct the model in discerning intricate patterns and meaningful correlations between input data, comprising various features, and their respective class labels. This is done in the context of ID by training a model to differentiate between typical network activity and other kinds of attacks.

C. Pre processing

Before being used for training or testing an ID system, network traffic data must first go through a number of data preprocessing procedures in ID. With the help of these procedures, the data is properly structured, cleaned, and modified to improve the functionality of the detection model. In order for the machine learning model to effectively learn from the network traffic data and generalize, data preprocessing is essential in ID. These procedures help the model to more precisely identify and categorize network attacks while reducing false positives and false negatives.

D. Feature Extraction

Feature extraction transforms raw network data into key statistical attributes, creating a streamlined feature matrix. This matrix captures data patterns efficiently, aiding the model in understanding relevant information. Statistical features like mean, variance, standard deviation, skewness, kurtosis, min and max summarize data characteristics. This enhances the model's ability to spot anomalies and patterns, enabling effective ID. By reducing dimensionality and noise, feature extraction optimizes model performance and accuracy.

1) *Statistical features:* In ID, statistical features are generated numerical metrics from network traffic data characteristics. These properties and behaviors inside network communication are described statistically by these features. The ability to recognize patterns, trends, and abnormalities that may be signs of network attacks depends heavily on statistical aspects. They serve as the foundation for creating efficient ID models. Here are a few typical statistical characteristics used in ID:

a) *Mean:* An attribute's average value across a range of data points, for instance, the average size of a packet or the average length of a network session. The summing up all of the values for a specific characteristic in a dataset and dividing by the total number of data points, the mean (average) of that attribute is determined. The computation of the mean (μ) of a

set of values (t_1, t_2, \dots, t_g) is shown below in mathematical notation:

$$\mu = (t_1 + t_2 + \dots + t_g) / g \quad (3)$$

μ is the attribute's mean (average), t_1, t_2 and t_g denotes the attribute's individual values, and g denotes the overall number of data points.

b) *Variance:* The statistical concept of variance serves as a measure that quantifies the extent or dispersion of data points relative to their mean. In other words, it shows how much a particular data point deviates from the mean (average). Variance is computed by calculating the average of the squared deviations between each data point and the mean. The variance (σ^2) of a group of values $(t_1, t_2, t_3, \dots, t_g)$ is calculated as follows in mathematical notation:

$$\sigma^2 = \sum (t_f - \mu)^2 / g \quad (4)$$

Each unique value of the attribute is represented by t_f , and σ^2 indicates the variance of the values.

c) *Standard Deviation (SD):* The average departure of the data points from the mean is measured by the SD, which is the variance's square root and is easier to understand. A higher standard deviation denotes more data variability. The standard deviation (σ) is computed mathematically by taking the square root of the variance:

$$\sigma = \sqrt{\sigma^2} \quad (5)$$

The variance and standard deviation of network traffic parameters, such as packet sizes, inter-arrival periods, or payload sizes, are calculated in ID to assist in identifying the typical range of behaviors. High standard deviation values can be a sign of aberrant activity or potential network attacks, which improves the ability of ID systems to detect deviations from the expected variability.

d) *Skewness:* Skewness, in the context of ID and network traffic data, is a statistical metric that quantifies the asymmetry present in the probability distribution of a real-valued property. The degree to which the distribution is skewed to one side or the other is indicated by its skewness. While negative skewness implies a larger tail on the left side of the distribution, positive skewness suggests a longer tail on the right. The equation and variables that consider the skewness in ID are as follows: A distribution's third standardized moment is measured by skewness. The formula used to calculate it is as follows:

$$\gamma_1 = \left[\sum (t_f - \mu)^3 / (g * \sigma^3) \right] \quad (6)$$

where, t_f stands for each unique value of the attribute, σ for the values' standard deviation, and γ_1 denotes the skewness of the data.

e) *Kurtosis*: Kurtosis is a statistical measure that assesses the "tailedness" of the probability distribution of a real-valued property in network traffic data with regard to ID. The concentration of data points in the distribution's tails is revealed by kurtosis. High kurtosis suggests that the data may contain more outliers and heavier tails. The equation and explanation of the variable for kurtosis in ID are given below. The fourth standardized moment of a distribution is measured by kurtosis. This formula is used to compute it:

$$\kappa = \left[\frac{\sum (t_f - \mu)^4}{g * \sigma^4} \right] \quad (7)$$

In this case, κ stands for the kurtosis values.

f) *Min*: The minimal value detected for a particular property within a batch of network traffic data is referred to as the min statistical feature in ID. With the help of this capability, you can understand even the most minute instances of a certain behavior or trait in network communication. Here is a description of the min statistical characteristic in terms of ID. The "min" statistical feature can be written mathematically as:

$$\min = \min(t_f) \quad (8)$$

where, \min is the attribute's minimal value and t_f stands for each of the attribute's unique values.

g) *Max*: An attribute's maximum value inside a dataset of network traffic data is referred to as the maximum statistical feature in ID. A high frequency of a particular behavior or trait in network communication is disclosed by this attribute. The max statistical attribute is described in the context of ID in the following sections. The statistical feature known as max has the following mathematical expression:

$$\max = \max(t_f) \quad (9)$$

where, t_f stands in for each unique value of the attribute and \max is the attribute's maximum value.

E. Updated Feature Matrix

A structured data representation of data comprising features that were taken directly from a dataset is the updated feature matrix. The statistical features received from network traffic data are arranged to create this matrix in the context of ID. These features record pertinent trends, traits, and information about network behaviors that might aid in differentiating between typical usage and potential harmful attacks. The updated feature matrix is produced by converting the raw data into a tabular format, where each row is a data sample (such as a network communication session), and each column denotes a particular feature retrieved from that sample. These characteristics could consist of numerous statistical measurements generated from the network traffic data. To input the data into machine learning models, in this case, the CNN, it is crucial to create an orderly feature matrix. This matrix serves as the model's input as it learns and recognizes intricate patterns that point to the presence of network threats. The updated part of the feature matrix probably refers to the fact that the preprocessing and feature extraction processes

clean up the initial raw data, making it more suitable for input into the CNN and raising the overall effectiveness and precision of the ID system. The CNN-based ID approach works effectively because it combines accurate preprocessing, feature extraction, and a well-organized feature matrix.

F. Working of Modified Residual CNN in Intrusion Detection

An improved modified residual CNN leverages adaptive features, and residual units to address the limitations of traditional deep networks. Its ability to handle complex patterns and achieve state-of-the-art performance makes it suitable for intrusion detection. The updated feature matrix dimension becomes the input for the modified residual CNN in the intrusion detection process, where it plays a crucial role in identifying and mitigating network security risks. A potent deep learning architecture called the CNN with residual can be used for ID to automatically discover and extract pertinent features from network traffic data by increasing the depth of the network. Here is a thorough explanation of how modified residual CNN detects intrusions:

1) *Convolutional layers*: Convolutional layers use filters (called kernels) to move across input data and find pertinent patterns. These filters combine nearby data points to perform convolutions by multiplying each element by an element. Convolutions generate feature maps that depict local patterns and spatial hierarchies. The following equation gives a mathematical description of the convolution layer:

$$B_t = c(B_{t-1} \otimes K_t + d_t) \quad (10)$$

In this context, K_t represents the weight vector associated with the convolution filter at layer t , where B_t denotes the feature map at layer t , with $BC = J$. Additionally, d_t and c correspond to the bias vector and activation function, respectively. It's noteworthy that the Rectified Linear Unit (ReLU) activation function is a commonly employed non-linear function within CNN. One of the distinguishing characteristics of the CNN is its efficiency in parameter utilization. This efficiency stems from the fact that it employs the same weight and bias vectors across its layers, contributing to a reduction in the overall number of parameters compared to traditional neural networks.

2) *Pooling layers*: Max pooling is a common technique for combining layers to generate smaller feature maps while maintaining the most crucial data and selecting the highest value possible within a pooling window.

3) *Residual unit*: A residual block consists of standard convolutional layers followed by batch normalization and ReLU activation. The defining feature is the addition of the input to the output of the convolutional layers. This connection helps address the vanishing gradient issue.

4) *Activation functions and non-linearity*: The model becomes non-linear as a result of activation functions like the ReLU. They aid residual CNN in learning intricate relationships and identifying significant features.

5) *Flattening and fully connected layers*: Feature maps are flattened into a 1D vector following numerous

Convolutional and pooling layers. Then the dense layer processes the data and returns some values to determine the intrusions. This vector is processed by fully connected layers, which also learn higher-level abstractions and how features interact.

6) *Output layer:* The output layer is coupled to the final completely connected layer, which contains neurons that represent potential classes (such as normal or attack). This layer is responsible for producing final predictions and the softmax function is applied, which outputs the probabilities of each class for the given input data.

7) *Training and optimization:* As input data is associated with relevant class labels (such as normal or attack), labeled data is used to train the residual CNN. The model uses methods like backpropagation and gradient descent during training to modify its internal weights and biases in order to reduce prediction error. Incoming network traffic data can be quickly and accurately classified by trained CNNs. The residual CNN can identify a potential intrusion if the output neuron associated with the attack is highly activated. Residual CNNs are effective in identifying spatial and temporal patterns in network traffic because they learn hierarchical data representations well. In addition to improving ID accuracy and flexibility to change attack patterns, their capacity to automatically learn features minimizes the need for manual feature engineering. The architecture of the modified residual CNN model is depicted in Fig. 2.

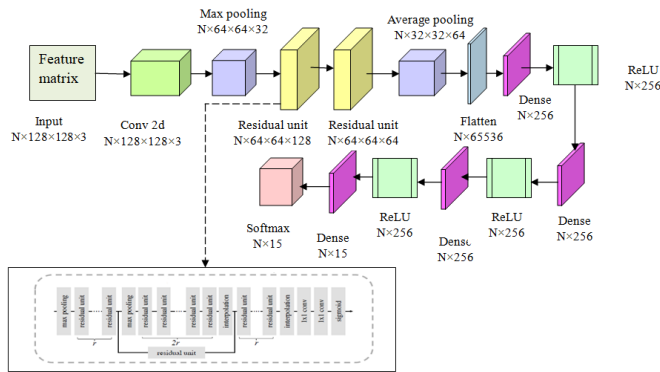

Fig. 2. Architecture of the modified residual CNN model.

G. Testing Phase

In the research, the ASO opt CNN model's effectiveness is thoroughly evaluated using a testing phase. During this phase, the model undergoes evaluation using test data to gauge its precision in discerning between regular network activities and potential intrusion attempts. Before inputting the test data into the model, a preprocessing step is conducted to ensure the data is cleaned and prepared in a consistent manner. The preprocessed test data is then fed into the fine-tuned CNN model, which has been optimized through arachnid swarm optimization. As the test data flows through the model, it generates predictions that indicate whether the network activities are benign or indicative of an attack. This evaluation phase results in the validation and creation of a robust detection

model, capable of effectively identifying a wide range of network attacks based on the patterns learned from both training and test data. Through this rigorous experimentation and testing, the research showcases the model's potential to significantly enhance ID accuracy in practical network scenarios.

IV. PROPOSED ARACHNID SWARM OPTIMIZATION

The utilization of the merging algorithm within the realm of ID serves as a means to enhance and fine-tune the features and parameters of a network-based ID system. The arachnid swarm optimization could tune the residual CNN detection model's weights, thresholds, and hyperparameters by combining the SSO [29] and PSO [30] search algorithms. In order to construct a new hybrid algorithm, SSO and PSO may combine their update methods, sharing strategies, and search strategies. The SSO social sharing mechanism might be implemented into the PSO velocity update equation, allowing particles to communicate and exchange information in the same way that social spiders create webs. Alternatively, to improve convergence to optimal solutions, the exploration and exploitation capabilities of both algorithms could be balanced.

A. Population Initialization

The SSO is a series of repeated procedures that begin by randomly initializing the entire population, and the main feature of social spiders is female-biased populations. In ancient times, the percentage of female S_g was arbitrarily assigned in the domain of percent (65-90) of total population S_u . S_g is so calculated using the following equation:

$$S_v = \text{floor}[(0.9 - \text{rand}(0,1) * 0.25) * S_u] \quad (11)$$

The number of a male spider S_i is calculated as the product of S_v and S_u .

$$S_i = S_u - S_v \quad (12)$$

B. Assignment of Fitness

The size of the spider's ability to properly complete the prescribed duties is the feature that evaluates a personal ability. Each spider in the supplied strategy has a weight t_g , which illuminates the fitness solution that meets with the population D of spider g . The following formulas are used to determine the fitness of each spider.

$$t_g = \frac{K(D_g) - \text{worst}_D}{\text{best}_D - \text{worst}_D} \quad (13)$$

where, $K(D_g)$ is the fitness value obtained from the spider location D_g assessment.

The following equation can be used to calculate the value of the worst and best solution:

$$\text{best}_D = \max(K(D_m)) \quad m \in \{1, 2, \dots, S\} \quad (14)$$

$$\text{worst}_D = \min(K(D_m)) \quad m \in \{1, 2, \dots, S\} \quad (15)$$

C. Modeling of the Vibrations

The communal web acts as a conduit for communication among colony members, facilitating the exchange of vital information. Vibrations, denoted as (E_{gi}), are influenced by both the weight and the distance of the spider responsible for their creation. These vibrations represent the outcome of information transmitted by a member, denoted as b and are meticulously modeled using the following equation, involving an individual's contribution.

$$E_{gi_{g,b}} = t_b \cdot d^{-e_{g,b}^2} \quad (16)$$

The formula computed the distance between spiders g and b .

$$e_{g,b} = \|D_g - D_b\| \quad (17)$$

The SSO method took into account three distinct correlations (three vibrations):

1) $E_{gj_{fg}}$ Vibration: Created by individual $g(D_g)$ in response to the transmission of information provided by member $f(D_f)$, f is the closest member to g and has a higher weight t_f :

$$E_{gj_{fg}} = t_f \cdot d^{-e_{g,m}^2} \quad (18)$$

2) $E_{gj_{jg}}$ Vibration: Created by the individual $g(D_g)$ in response to the transmission of information provided by member $j(D_j)$, where j is the member with the highest weight t_j :

$$E_{gj_{jg}} = t_j \cdot d^{-e_{g,j}^2} \quad (19)$$

3) $E_{gj_{vg}}$ Vibration: Created by the individual $g(D_g)$ as an outcome of information provided by member $g(D_v)$, where v is the closest female member to g :

$$E_{gj_{vg}} = t_v \cdot d^{-e_{g,v}^2} \quad (20)$$

D. Population Initializing

The first phase is an iterative procedure similar to previous SSO evolutionary algorithms in which the entire population (males and females) is randomly started, beginning by initializing the set D of S social-spider positions. Each $spiderv_g$ or i_g location is a q dimensional vector containing the parameter values that need to be improved. These parameter values are divided between the original parameter r_b^{high} specified upper limit and the preliminary parameter r_b^{low} lower limit. The equations following describe this:

$$v_{g,b}^y = r_b^{low} + rand(0,1) * (r_b^{high} - r_b^{low}) \quad g = 1,2,\dots,S_v \text{ and } b = 1,2,\dots,q \quad (21)$$

$$i_{g,b}^y = r_b^{low} + rand(0,1) * (r_b^{high} - r_b^{low}) \quad g = 1,2,\dots,S_i \text{ and } b = 1,2,\dots,q \quad (22)$$

Individual indices are indicated by b and g while the function ($rand(0,1)$) generates a random number spanning from 0 to 1. The initial population is denoted as "zero."

E. Cooperative Operators

Spiders' cooperative behavior is determined by their gender as well as other elements such as curiosity, reproductive cycle, and other random phenomena.

1) *Integrating phase*: The hybridization of SSO and PSO seeks to take advantage of each algorithm's strengths while adjusting for its drawbacks. SSO and PSO merger could imply integrating their update methods, sharing tactics, or search strategies to form a new hybrid algorithm. SSO's social sharing mechanism is included in PSO's velocity update equation, allowing particles to communicate and share information in the same way as social spiders weave webs. Alternatively, to achieve greater convergence to optimal solutions, the exploration and exploitation capacities of both algorithms could be balanced.

2) *Female cooperative*: The following examples illustrate how female spiders may attract or repel other spiders:

$$A = 0.5v_g^{m+1} + 0.5q_{je}^{m+1} \quad (23)$$

$$A = 0.5 \left(\begin{array}{l} v_g^m + \delta \cdot vib_{mg} (D_m - v_g^m) + \epsilon \cdot vib_g (D_m - v_g^m) \\ + \gamma (rand - 0.5) \text{ with probability } rZ \\ v_g^m - \delta \cdot vib_{mg} (D_m - v_g^m) - \epsilon \cdot vib_g (D_m - v_g^m) \\ + \gamma (rand - 0.5) \text{ with probability } 1 - rZ \end{array} \right) \left(q_{je}^m + s_1 u_1 (b_{je}^m - r_{je}^m) + s_2 u_2 (b_{ie}^m - r_{je}^m) \right) \quad (24)$$

In this context, m signifies the number of iterations, while δ, ϵ, γ represent random values falling within the range of $[0,1]$. The individuals D_m and D_j stand for the best individual in the entire D population and the closest member to g with the highest weight.

In the given equation, $e = 1,2,\dots,E$ represents the dimension, and $j = 1,2,\dots,T$ represents the particle index within the swarm. T denotes the swarm size, while s_1 and s_2 are constants referred to as cognitive and social scaling parameters, sometimes known as acceleration coefficients. u_1, u_2 are the random numbers drawn from a uniform distribution in the range $[0,1]$. Equation 24 highlights that each dimension of every particle is updated independently of the others. The sole connection between these dimensions in the problem space is established through the objective function, which relies on the best positions discovered thus far, denoted as j_{best} and b_{best} .

3) *Male cooperative*: Male spiders are categorized into two groups, namely dominant and non-dominant, based on their respective weights. To benefit from the resources that are being squandered by the dominant spiders, the non-dominant individuals are drawn to the weighted mean of the male population. The update of the male spider positions can therefore be stated as follows:

$$B = 0.5i_g^{m+1} + 0.5q_{je}^{m+1} \quad (25)$$

$$B = 0.5 \left\{ \begin{array}{l} i_g^m + \delta \cdot vib_g (D_v - i_g^m) + \rho(rand - 0.5) \\ \text{when } TS_{v+g} > TS_{v+x} \\ i_g^m + \delta \left(\frac{\sum_{x=1}^{ci} i_x^m \cdot TS_{v+x}}{\sum_{x=1}^{ci} TS_{v+x}} \right) \\ \text{when } TS_{v+g} \leq TS_{v+i} \end{array} \right. + q_{je}^m + s_1 u_1 (b_{je}^m - r_{je}^m) + s_2 u_2 (b_{ie}^m - r_{je}^m) \quad (26)$$

The closest female member to the male member g is represented by the individual D_v , while the weighted mean of the male population F is represented by the individual

$$\left(\frac{\sum_{x=1}^{ci} i_x^m \cdot TS_{v+x}}{\sum_{x=1}^{ci} TS_{v+x}} \right).$$

Algorithm 1: Pseudo code for the proposed arachnid swarm optimization

S.NO	Pseudo code for the proposed arachnid swarm optimization
1	Initialize swarm population for SSO
2	Initialize swarm population for PSO
3	Initialize the best solution
4	Initialize max iterations
5	Initialize iteration counter
6	while iteration counter < max iterations:
7	Evaluate the fitness of SSO and PSO populations
8	Update female spiders' positions and vibrations using SSO
9	Update male spiders' positions using SSO
10	Calculate the best solution found by SSO
11	Update particles' velocities and positions using PSO
12	Evaluate the fitness of the PSO population
13	Calculate the best solution found by PSO
14	if fitness(SSO best solution) > fitness(PSO best solution):
15	Combined best solution = SSO best solution
16	else:
17	Combined best solution = PSO best solution
18	if fitness(combined best solution) > fitness(best solution):
19	Best solution = combined best solution
20	Iteration counter += 1
21	Output best solution

V. RESULT AND DISCUSSION

An ID model is meticulously developed using the ASO-optimized CNN, and its effectiveness is rigorously evaluated in comparison to alternative methodologies.

A. Experimental Setup

ID is conducted using the Python programming language with the Windows 10 operating system.

B. Dataset Description

D1 [31]: This dataset is a crucial asset in the realm of ID for Internet of Things (IoT) environments. It offers a diverse range of network traffic data, encompassing both normal communication patterns among various IoT devices and simulated malicious activities, including botnet-related behaviors. Researchers utilize this dataset to develop and evaluate ID systems and security solutions specifically tailored to the unique challenges posed by IoT networks. It serves as a fundamental resource for enhancing the cyber security of IoT ecosystems by facilitating the identification and mitigation of potential threats and anomalies.

D2 [32]: This dataset is a significant asset in the field of ID. It consists of a diverse range of network traffic data, including both benign and malicious activities. This dataset is instrumental in the development and evaluation of intrusion detection systems and cyber security solutions. Researchers leverage CICIDS2017 to enhance the security of networks by effectively identifying and mitigating potential threats and anomalies in a controlled, real-world environment.

D3 [33]: It offers a comprehensive collection of network traffic data, featuring a variety of benign network activities and simulated cyber-attacks. This dataset facilitates the development, testing, and evaluation of intrusion detection systems and security mechanisms. Researchers and cyber security experts rely on UNSW-NB15 to enhance network security by efficiently identifying and countering potential threats and anomalies.

C. Comparative Methods

The ASO opt CNN model undergoes an evaluation where it is compared to various existing models. These existing include KNN [34], SVM [35], BiLSTM [36], deep CNN [37], PSO-based deep CNN [38], and SSO-based deep CNN [39] to gauge its performance.

1) *Comparative analysis based on TP for d1:* Fig. 3 illustrates the TP 90 metrics, used to compare the efficacy of the ASO-optimized CNN with other comparative techniques.

Fig. 3(a) depicts the ASO-optimized CNN model's ID accuracy. The ASO opt CNN achieves a remarkable accuracy of 95.95% with a TP of 90, outperforming the SSO-based BiLSTM by 2.84%.

Fig. 3(b) showcases the ID sensitivity of the ASO-optimized CNN model. With a TP of 90, the ASO opt CNN demonstrates a remarkable sensitivity of 95.00%, surpassing the SSO-based BiLSTM by 0.05%.

In Fig. 3(c), the ID specificity of the ASO-optimized CNN model is displayed. Achieving a TP of 90, the ASO opt CNN exhibits a specificity of 96.61%, outperforming the SSO-based BiLSTM by a margin of 1.67%.

Fig. 3. Comparative analysis concerning TP a) accuracy, b) sensitivity, and c) specificity.

2) Comparative analysis based on K-fold for d1: Fig. 4(a) depicts the ASO-optimized CNN model's ID accuracy. The ASO opt CNN achieves a remarkable accuracy of 94.71% with a k-fold 6, outperforming the SSO-based BiLSTM by 0.47%.

Fig. 4(b) showcases the ID sensitivity of the ASO-optimized CNN model. With a k-fold 6, the ASO opt CNN demonstrates a remarkable sensitivity of 95.55%, surpassing the SSO-based BiLSTM by 2.93%.

In Fig. 4(c), the ID specificity of the ASO-optimized CNN model is displayed. Achieving a k-fold 6, the ASO opt CNN exhibits a specificity of 93.12%, outperforming the SSO-based BiLSTM by a margin of 4.51%.

Fig. 4. Comparative analysis concerning K-fold a) accuracy, b) sensitivity, and c) specificity.

3) Comparative analysis based on TP for d2: Fig. 5(a) depicts the ASO-optimized CNN model's ID accuracy. The ASO opt CNN achieves a remarkable accuracy of 95.61% with a TP of 90, outperforming the SSO-based BiLSTM by 3.65%.

Fig. 5(b) showcases the ID sensitivity of the ASO-optimized CNN model. With a TP of 90, the ASO opt CNN demonstrates a remarkable sensitivity of 95.92%, surpassing the SSO-based BiLSTM by 2.13%.

In Fig. 5(c), the ID specificity of the ASO-optimized CNN model is displayed. Achieving a TP of 90, the ASO opt CNN exhibits a specificity of 96.96%, outperforming the SSO-based BiLSTM by a margin of 0.99%.

Fig. 5. Comparative analysis concerning TP a) accuracy, b) sensitivity, and c) specificity.

4) Comparative analysis based on K-fold for d2: Fig. 6(a) depicts the ASO-optimized CNN model's ID accuracy. The ASO opt CNN achieves a remarkable accuracy of 95.63% with a k-fold 6, outperforming the SSO-based BiLSTM by 2.22%.

Fig. 6(b) showcases the ID sensitivity of the ASO-optimized CNN model. With a k-fold 6, the ASO opt CNN demonstrates a remarkable sensitivity of 95.55%, surpassing the SSO-based BiLSTM by 2.93%.

In Fig. 6(c), the ID specificity of the ASO-optimized CNN model is displayed. Achieving a k-fold 6, the ASO opt CNN exhibits a specificity of 95.00%, outperforming the SSO-based BiLSTM by a margin of 1.32%.

5) Comparative analysis based on TP for d3: Fig. 7(a) depicts the ASO-optimized CNN model's ID accuracy. The ASO opt CNN achieves a remarkable accuracy of 95.00% with a TP of 90, outperforming the SSO-based BiLSTM by 3.51%.

Fig. 6. Comparative analysis concerning K-fold a) accuracy, b) sensitivity, and c) specificity.

Fig. 7(b) showcases the ID sensitivity of the ASO-optimized CNN model. With a TP of 90, the ASO opt CNN demonstrates a remarkable sensitivity of 94.00%, surpassing the SSO-based BiLSTM by 3.55%.

In Fig. 7(c), the ID specificity of the ASO-optimized CNN model is displayed. Achieving a TP of 90, the ASO opt CNN exhibits a specificity of 96.00%, outperforming the SSO-based BiLSTM by a margin of 3.47%.

Fig. 7. Comparative analysis concerning TP a) accuracy, b) sensitivity, and c) specificity.

6) Comparative analysis based on K-fold for d3: Fig. 8(a) depicts the ASO-optimized CNN model's ID accuracy. The ASO opt CNN achieves a remarkable accuracy of 95.09%

with a k-fold 6, outperforming the SSO-based BiLSTM by 0.10%.

Fig. 8(b) showcases the ID sensitivity of the ASO-optimized CNN model. With a k-fold 6, the ASO opt CNN demonstrates a remarkable sensitivity of 95.00%, surpassing the SSO-based BiLSTM by 1.05%.

In Fig. 8(c), the ID specificity of the ASO-optimized CNN model is displayed. Achieving a k-fold 6, the ASO opt CNN exhibits a specificity of 96.00%, outperforming the SSO-based BiLSTM by a margin of 1.04%.

Fig. 8. Comparative analysis concerning TP a) accuracy, b) sensitivity, and c) specificity.

D. Comparative Analysis Based on Quality Metrics

A comparative evaluation of the proposed method with other existing methods based on quality metrics such as generation distance (GD), Maximum Pareto front error (MFE), Spacing, Spread, and weighted sum is conducted and is presented in Fig. 9 and the results obtained from the analysis in terms of those quality metrics are depicted in Table I. Fig. 9(a) shows that the proposed ASO opt Deep CNN Model attains a low GD of 0.06 showing that the proposed method has the best convergence with the Pareto optimal front. Fig. 9(b) reveals the proposed method attains an MFE of 0.26 which is much less than other compared methods showing the effectiveness of the proposed approach. Fig. 9(c) indicates the spacing metric which is 0.04 for the proposed method revealing that the approach can have a uniform distribution of Pareto points on the curve compared to other approaches. The spread of the proposed model is 0.82 which shows its best distribution and extension of solutions than other methods and is depicted in Fig. 9(d). Fig. 9(e) shows the weighted sum of the proposed approach as 0.21 which is very low and indicates that it is better than other compared approaches.

TABLE II. COMPARISON OF COMPUTATIONAL TIME

Models	Computational time		
	D1	D2	D3
KNN	20.84	20.84	20.83
SVM	20.56	20.59	20.59
BiLSTM	20.72	20.73	20.77
Deep CNN	20.78	20.74	20.79
PSO-based Deep CNN	20.80	20.81	20.80
SSO-based Deep CNN	20.80	20.83	20.81
ASO opt Deep CNN Model	20.46	20.51	20.13

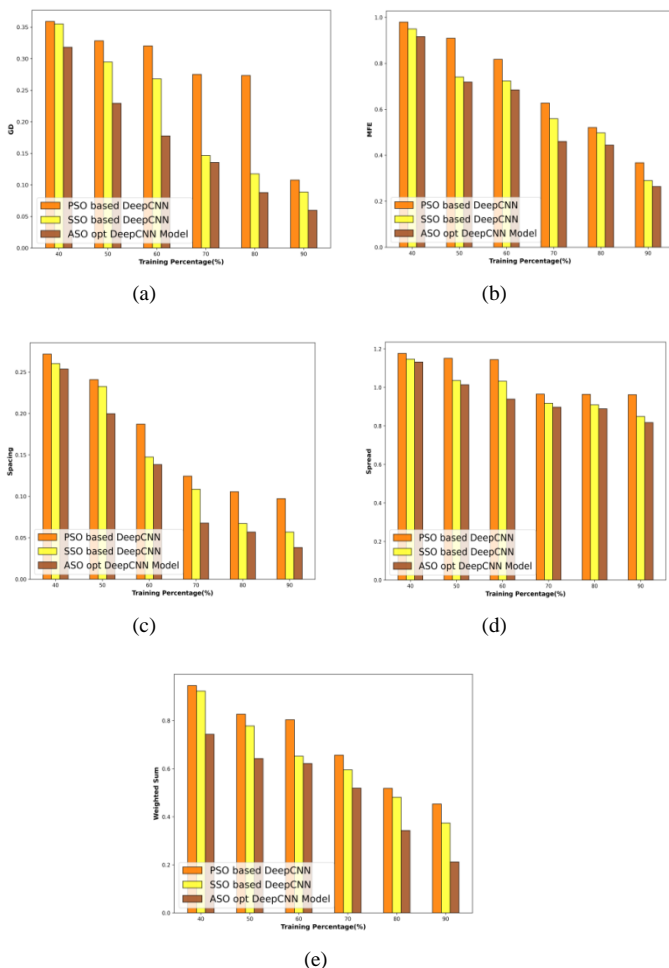

Fig. 9. Comparative analysis based on Quality Metrics a) GD, b) MFE, c) Spacing, d) Spread, and e) Weighted Sum.

TABLE I. COMPARISON OF PROPOSED ASO OPT DEEP CNN METHOD WITH EXISTING METHODS BASED ON QUALITY METRICS

Models	GD	MFE	Spacing	Spread	Weighted Sum
PSO-based Deep CNN	0.11	0.37	0.10	0.96	0.45
SSO-based Deep CNN	0.09	0.29	0.06	0.85	0.37
ASO opt for Deep CNN Model	0.06	0.26	0.04	0.82	0.21

E. Computational Complexity Analysis

The analysis of the computational complexity of the ASO-opt deep CNN with traditional approaches is presented in Table II. The superiority of the ASO opt Deep CNN Model is demonstrated by comparing it with other methods based on computing time across several iterations. Additionally, the developed method outperforms all other known methods with a low computational time of 20.46 for D1, 20.51 for D2, and 20.13 for D3 at iteration 100. The results highlight the ASO opt Deep CNN technique's computational efficiency by demonstrating that it regularly completes tasks far faster than those of other available techniques.

F. Comparative Discussion

The developed ASO opt Deep CNN Model compares with conventional approaches to prove its effectiveness in intrusion detection. Even though, the existing methods show effective performance in intrusion detection, they still have some limitations, such as KNN [34] being computationally expensive and extracting irrelevant features, which affects the model's performance. Likewise, SVM [35] is also a time and memory-consuming model. BiLSTM [36] struggles with long sequences due to memory constraints and also suffers from gradient issues during training. Deep CNN [37] suffers from overfitting and requires a large amount of data for effective training. PSO-based Deep CNN [38] struggles with high dimensional spaces and SSO-based deep CNN has generalization issues. Therefore, the ASO opt Deep CNN Model is developed here for efficient intrusion detection and the ASO aids in improving the model's performance in intrusion detection by fine-tuning the parameters of the deep CNN. The use of ASO in this model also reduces the risk of overfitting and reduces the time complexity of the model due to its fast convergence. The results show that the conventional methods attain very low accuracy compared to the proposed method. This low accuracy is attained due to the generalization issues, overfitting issues, irrelevant feature extraction, and time complexity issues in existing approaches. Nevertheless, the proposed method solves these existing issues and attained high accuracy in detecting intrusion compared to other existing methods. The ASO opt Deep CNN Model serves as an effective solution for intrusion detection and the model has the ability to handle large-scale network data since it is tested on three large intrusion datasets. Eventhough, though the model requires more computational resources for training large datasets; the use of ASO reduces the need for more computational time, indicating its efficiency in handling large-scale data. The model also has the ability to be implemented in the real world in various network environments. However, real-world data often has imbalanced classes and the complicated attackers may try to evade detection by crafting adversarial examples. These issues can be solved by employing oversampling or under-sampling techniques to address class imbalance issues and the development of robust techniques also helps to enhance the model's resilience, which can be done in the future. Tables III and IV provide a comprehensive comparative analysis of the ASO-opt deep CNN, alongside several other existing approaches. The findings from this analysis clearly demonstrate that the ASO-opt deep CNN excels, surpassing the performance of the other methods examined in the realm of ID.

TABLE III. COMPARATIVE DISCUSSION TABLE FOR TP

Models	TP 90								
	D1			D2			D3		
	Accuracy	Sensitivity	Specificity	Accuracy	Sensitivity	Specificity	Accuracy	Sensitivity	Specificity
KNN	85.90	84.85	84.62	76.56	81.25	81.63	80.60	79.33	79.00
SVM	87.18	84.85	87.18	80.07	81.25	83.67	81.40	83.60	80.00

VI. CONCLUSION

REFERENCES

In summary, this research focuses on improving ID performance through an ASO-opt CNN model. It follows a comprehensive methodology, starting with dataset acquisition and model training, followed by data preprocessing and feature extraction. An enhanced CNN model is introduced and fine-tuned through PSO and SSO optimization stages, enhancing its ability to classify network traffic accurately. The final phase evaluates the model's effectiveness using test data, resulting in a robust detection system. Experiments highlight the approach's efficacy and its potential to significantly boost ID accuracy, making it a valuable asset in the ever-evolving cybersecurity landscape. The ASO-opt CNN model demonstrated outstanding performance in TP 90, achieving high accuracy for d1 95.95%, d2 95.61% and for d3 95.00%, sensitivity of d1 95.00%, d2 95.92% and d3 94.00%, finally specificity of d1 96.61%, d2 96.96% and d3 96.00% for different datasets. In k-fold 6, the model's effectiveness remained strong with impressive accuracy of d1 94.71%, d2 95.63% and d3 95.09%, sensitivity of d1 95.55%, d2 95.83% and d3 95.00%, and finally specificity of d1 93.12%, d2: 95.00% and d3 96.00%. These exceptional results highlight the model's reliability and potential to significantly enhance intrusion detection accuracy. In future, additional hybrid optimization techniques can be employed to improve the model's performance. Different ensemble classifiers may also be employed for effective performance in intrusion detection. The model can also be improved to make it suitable for detecting other cyber threats.

Abstract—Upholding a secure and accepting digital environment is severely hindered by hate speech and inappropriate information on the internet. A novel approach that combines Convolutional Neural Network with GRU and BERT from Transformers proposed for enhancing the identification of offensive content, particularly hate speech. The method utilizes the strengths of both CNN-GRU and BERT models to capture complex linguistic patterns and contextual information present in hate speech. The proposed model first utilizes CNN-GRU to extract local and sequential features from textual data, allowing for effective representation learning of offensive language. Subsequently, BERT, advanced transformer-based model, is employed to capture contextualized representations of the text, thereby enhancing the understanding of detailed linguistic nuances and cultural contexts associated with hate speech. Fine tuning BERT model using hugging face transformer. To execute tests using datasets for hate speech identification that are made accessible to the public and show how well the method works to identify inappropriate content. By assisting with the continuing efforts to prevent the dissemination of hate speech and undesirable language online, the proposed framework promotes a more diverse and secure digital environment. The proposed method is implemented using python. The method achieves 98% competitive performance compared to existing approaches LSTM and RNN, CNN, LSTM and GBAT, showcasing its potential for real-world applications in combating online hate speech. Furthermore, it provides insights into the interpretability of the model's predictions, highlighting key linguistic and contextual factors influencing offensive language detection. The study contributes to advancing hate speech detection by integrating CNN-GRU and BERT models, giving a robust solution for enhancing offensive content identification in online platforms.

Keywords—Bidirectional encoder representations from transformers; convolutional neural network; Gated Recurrent Unit; hate speech; hugging face transformer

I. INTRODUCTION

Speech that is hateful against people or organizations that defy societal norms and has the potential to cause injury, intimidation, abuse, embarrassment, and disorder in society is known as hate speech [1]. Social media is a worldwide platform where people may freely express their ideas and opinions. Social media has many advantages, but it also has drawbacks, such as hate speech and the publication of derogatory and vulgar information that targets a person, a community, or society as a whole. Hate speech and other unpleasant and offensive content have a negative impact on people's everyday lives and, in the worst cases, can lead to despair or suicide in online sociability. Numerous countries have imposed restrictions on internet media material, with the stipulation that it must neither be directed against any specific people or group, nor incite criminal activity. Furthermore, online social networking sites with their regulations in place include Facebook, Twitter, and YouTube for getting rid of hate speech and other information that has a detrimental impact on society. However, social media businesses continue to confront a significant difficulty in identifying such unacceptable information as soon as possible in order to stop the spread of such news online [2] and researchers. It's challenging to define and comprehend hate speech. The number of Web of Science-indexed productions grew from 42 to 162 between 2013 and 2018, indicating a consistent expansion in academic interest in hate speech since 2014. This further emphasizes how hate speech affects the society in which it manifests. Moreover, research on HS is published in a variety of publications, including those that deal with law, sociology, communication, psychology, and so forth. All of this demonstrates its extraordinary significance and the necessity for a thorough examination of its history and present state, which is exactly what this work aims to provide.

Hate Speech is a purposeful and deliberate public remark meant to disparage a certain group of people. Identifying traits like colour, religion, race, ethnicity or nationality, gender, sexual orientation, or identity are some examples of further definitions of hate speech. The biggest obstacle facing the legal literature, particularly has written the most on this topic, is proving that there is a distinct variation between hate speech and hate crime to justify the use of criminal penalties. However, severe forms of hatred, such as calling for terrorism or genocide, do not raise this dilemma. Given that social studies are taught in a variety of ways in mainstream media and on social media platforms, the task is more difficult. It first appears symbolically, nonverbally, and audibly. Second, it is purposefully written in a way that is evasive, unclear, and symbolic, making it challenging to understand. Additionally, discriminatory thinking that is socially acceptable and so not recognized as such is voiced in high school discourse. Third, hate speech frequently uses strong, derogatory language to incite the audience to be offended and/or act, and it assumes that others have bad or deceptive motives [3].

In recent times, platforms like Facebook have ramped up their content moderation efforts, employing both automated methods and human moderators to handle the influx of content. Automated tools have the potential to streamline the evaluation process or allocate human resources to areas requiring meticulous scrutiny. A fundamental method for detecting hate speech is the keyword-based approach, wherein text containing potentially hostile terms is identified using dictionaries or ontologies [4]. For instance, hate base maintains as insulting language targeting various groups across 95 languages, crucial resources given the evolving nature of language. However, it's important to note that merely using a derogatory term doesn't always qualify as hate speech, as observed in the investigation of hate speech criteria. While keyword-based strategies are quick to grasp and comprehend, they have significant limitations. Solely recognizing racial insults would result in high precision but poor recall, where precision denotes the relevance of detected instances and recall represents the proportion of relevant instances in the total population. Including broader offensive terms like "trash" or "swine" might enhance recall at the expense of precision. Researchers have explored various algorithms, from early lexicon-based methods to modern Neural Network techniques[5], to identify hate speech and offensive content. However, algorithm performance can vary significantly depending on the dataset, making it challenging to conclude that a specific method universally excels across all datasets [6].

The proposed work introduces a novel approach for enhancing the identification of offensive content, particularly hate speech, in online platforms. Utilizing the combined strengths of Convolutional Neural Network with GRU and BERT from Transformers, the model aims to capture intricate linguistic patterns and contextual nuances inherent in offensive language. Through the integration of CNN-GRU, the model effectively learns local and sequential features from textual data, facilitating robust representation learning of offensive content. Subsequently, BERT is employed to capture contextualized representations, enhancing the model's

understanding of nuanced linguistic nuances and cultural contexts associated with hate speech. Experimental evaluations conducted on publicly available hate speech detection datasets demonstrate the efficacy of the proposed approach, showcasing competitive performance compared to existing methods. Moreover, the study explores interpretability aspects, providing insights into the linguistic and contextual factors influencing offensive language detection. By advancing the hate speech detection, this work contributes to fostering a safer and enhances the friendly online space by providing a strong means of detecting undesirable content.

The key contribution for the proposed work

- Integration of CNN-GRU and BERT models for enhanced offensive content identification in hate speech detection tasks.
- Effective utilization of CNN-GRU to capture local and sequential features, complemented by BERT's contextualized representations.
- Improved understanding of nuanced linguistic nuances and cultural contexts associated with hate speech through BERT's contextualized representations.
- Competitive performance demonstrated on publicly available hate speech detection datasets, showcasing the effectiveness of the proposed approach.

The arrangement of the remaining contents is as follows. An introduction is given in Section I. Literature portions are illustrated in Section II. The problem statement is provided in Section III. The suggested approach for identifying hate speech and undesirable content using CNN-GRU and BERT is discussed in Section IV. The performance metrics are shown and the results are compiled in Section V. Discussion in Section VI. Further work as well as a conclusion is presented in Section VII.

II. LITERATURE REVIEW

Hegde et al., [7], states that the growing quantity of unpleasant and hateful stuff has been exacerbated to a greater degree by the fast development of the internet and mobile technologies. Given that social media information frequently contains code-mixed text in two or more languages, identifying hate speech and offensive content can be extremely difficult. Therefore, it is imperative to censor hate speech as well as offensive content via social media to stop its spread and the harm it will do. Hate speech and offensive content must be filtered by automated methods since doing it by hand is labour-intensive and prone to mistakes. In this work, team MUM presents the models that were presented to the cooperative work in the 2021 Forum for retrieving information inappropriate Words and Statements of Hate in Indo-Aryan and English Languages. Subtasks 1A and 1B for English, Hindi, and Marathi, as well as Subtask 2 for code-mixed text in an English-Hindi language pair, make up the common task. The suggested models are designed as a combination of three Machine Learning classifiers: Gradient Boosting, RF, and MLP. The pre-trained embeddings word2Vec and Emo2Vec are used after the Term Frequency

— Inverse Document Frequency of various features, such as word uni-grams, character n-grams, and Hashtag vectors, have been used to train these ensemble models.

Davidson et al., [8] suggested that distinction between hateful statements and other undesirable words is a major problem for computerized social media hate-speech identification. Because supervised learning has not been able to discriminate between hate speech and non-hatred speech in earlier work, lexical detection approaches frequently exhibit inadequate precision because they label any correspondence that uses certain terms as words of hatred. They gathered tweets incorporating hate speech terms using a crowdsourced lexicon. They classify a portion of such tweets into three groups using crowdsourcing: those that just include foul language, those that contain hate speech, and those that have neither. This strategy involves training a multi-class classifier to discern between these distinct groups. An in-depth analysis of the errors and forecasts shows when it is simpler to identify when it is more challenging to differentiate hate speech from other offensive words. They find that racist and discriminating tweets are more likely to be classified as hate speech than sexist messages, which are usually classified as harmful. Classifying tweets that don't contain explicit hateful language is considerably more challenging.

Bharathi et al., [9] state that people have the opportunity to share their ideas and concerns freely on social networking websites, such as Twitter and Facebook. It has also turned into a tool for widespread internet harassment and hate speech at the same time. AI tools are techniques for automatically recognizing certain kinds of remarks. The assessment of these identification technologies is done through ongoing data set testing. Benchmark data development is the focus of the hateful speaking and identifying inappropriate content. The challenge for Offensive Language Classification in Marathi, Hate Speech, and Harmful Content Identification, is presented in this study. The collection of data came from Twitter. Three tasks make up this job. The objective of subtask A, "Offense Language Detection," is to distinguish between offensive postings and those that are not. Only the postings marked as offensive from Subtask A are included in Subtask B, where the objective is to identify whether the offense was targeted or untargeted. To classify the tweets, they team at ssnscse_nlp employed count vectorized features in conjunction with ML prediction techniques including RF, SVM, LR, and KNN classifier methods.

Watanabe et al., [10] recommended that People from various cultural and psychological backgrounds are communicating more directly as a findings of the quick development of social websites and microblogging websites. This has led to an increase in "cyber" confrontations among these individuals. Consequently, the language of hatred is used in increasing quantities, to the point that it is starting to severely affect these public areas. The use of brutal, aggressive, or abusive language intended at certain categories of people who share a similar trait, such as racism, sexism, views, or religion, is referred to as "hate speech". Although hate speech is prohibited on the majority of social media sites and microblogging platforms, it is nearly difficult to regulate all of the content on these platforms due to their massive scale.

As a result, it becomes necessary to automatically identify this type of communication and censor any information that uses offensive or inciting language. In this study, they give a technique for identifying hate speech on Twitter. The methodology is predicated on automatically gathered single-word phrases and designs from the practice dataset. A ML system is later trained using such patterns and unigrams among other characteristics. The tests on a test set consisting of 2010 tweets demonstrate that the method achieves an effectiveness of 87.4% when it comes to binary classification (determining if a tweet is offensive or not) and 78.4% when it comes to ternary classification (determining if a posted tweet is cruel, insulting, or clean).

Roy et al., [11] states that swift expansion of online users has given rise to undesired online problems such as hateful speaking and cyberbullying, among many others. The issues with hate speech on Twitter are covered in this article. Hate speech seems to be an aggressive kind of communication that propagates hateful ideas by utilizing false information. A number of safeguarded criteria, such as gender, religion, colour, and disability, are the subject of hate speech. Hate speech can occasionally lead to unintentional crimes when a person or group becomes discouraged. Therefore, it's critical to keep a careful eye on user contributions and take prompt action to eliminate any possible hate speech to stop its spread. With over 600 tweets sent per second and more than 500 million tweets sent every day, manual screening on sites like Twitter is almost unfeasible. CNN is used as a way to automate the procedure. The proposed DCNN model outperforms earlier models by using Twitter text in conjunction with GloVe embedding vectors to understand tweet semantics through convolutional processes. The model demonstrated remarkable reliability, remembering, and F1-score values of 0.97, 0.88, and 0.92 in the best-case scenario.

The issue of hate speech and offensive content proliferating on social media platforms has become increasingly urgent due to the rapid growth of internet and mobile technology. Detecting and filtering such content physically is laborious and susceptible to mistakes, necessitating the development of automated tools. Various approaches have been proposed to address this challenge, including ensemble models combining machine learning classifiers such as Random Forest, Multi-Layer Perceptron, and Gradient Boosting [12]. These models leverage features like TF-IDF, and pre-trained embeddings like word2Vec and Emo2Vec to identify and classify hatred speaking and inappropriate language. Lexical detection methods have limitations in distinguishing insulting hatred utilizing other insulting terms, leading to the development of crowd-sourced hate speech lexicons and multi-class classifiers to differentiate between different categories of offensive content. Additionally, AI tools and ML algorithms such as SVM, LR, and KNN have been employed for offensive language identification across various languages, including English, Hindi, Marathi, and code-mixed text. Despite these advancements, challenges persist due to evolving vocabulary, the limitations of clearly labelled data, and the difficulty in detecting hateful words on fringe social media platforms. Nonetheless, recent efforts have shown promise in addressing

these challenges through ensemble DL models, TL techniques, and weak supervised learning methodologies, achieving high recall rates for hate speech detection and classification. However, limitations remain in terms of scalability, generalization to diverse platforms, and the continuous evolution of online hate speech tactics, highlighting the ongoing need for research and development in this critical area.

III. PROBLEM STATEMENT

While existing systems for hate speech detection have made significant strides, several limitations and research gaps persist. One key limitation is the lack of robustness across diverse linguistic patterns and contextual variations present in offensive content on social media platforms. Additionally, many current approaches struggle to effectively capture subtle nuances and evolving tactics employed by perpetrators of hate speech. Furthermore, existing systems often face challenges in handling code-mixed text and identifying offensive content in languages other than English [13]. To overcome these issues, the proposed approach of Hate Speech Detection with CNN-GRU and BERT offers several advantages. The proposed work's ability to capture both local and contextual linguistic features through CNN-GRU and BERT, respectively. This dual approach addresses the limitations of existing models, which often struggle with contextual nuances and code-mixed language detection, ensuring more accurate and comprehensive hate speech identification across diverse social media content. By integrating convolutional neural networks for feature extraction, Gated Recurrent Units for sequential modelling, and BERT for contextualized depiction of language, the method aims to enhance the identification of offensive content with improved accuracy and robustness. By using this method, the model can identify intricate language patterns, contextual details, and semantic linkages in the text.

This helps to overcome the shortcomings of current methods and close the knowledge gap regarding the identification of hate speech on social networking sites.

IV. CNN-GRU AND BERT FOR HATE SPEECH IDENTIFICATION

The methodology involves utilizing a pre-trained BERT model for hate speech detection alongside a CNN-GRU architecture. Firstly, the hate speech dataset is pre-processed, including cleaning and tokenization. The previously developed BERT model is then fine-tuned by hugging face transformer on this dataset to adapt its representations to the hate speech detection task. Concurrently, a CNN-GRU model is trained on the pre-processed hate speech data. The BERT model's contextualized embeddings are concatenated with the CNN-GRU's features, forming a fused representation. This combined representation is fed into a classification layer for identifying hate speech. The BERT model is adjusted using hugging face transformer. Deep learning architectures can handle challenging natural language processing problems, as demonstrated by the effective application of CNN for feature extraction, GRU for sequential processing, and BERT for contextualized comprehension in the identification of hate speech. The efficacy of the model is evaluated using performance metrics. The suggested system design is shown in Fig. 1.

A. Data Collection

The dataset was gathered via the Kaggle website [14]. There are 24,783 tweets in the data, which is saved as a CSV file. CrowdFlower (CF) users have classified these tweets as either Hate Speech, Offensive Language, or Both. This data is displayed in a spreadsheet with 24,783 rows and six columns (count, hate speech, offensive language, not, class, and tweet). Table I shows the description of the dataset.

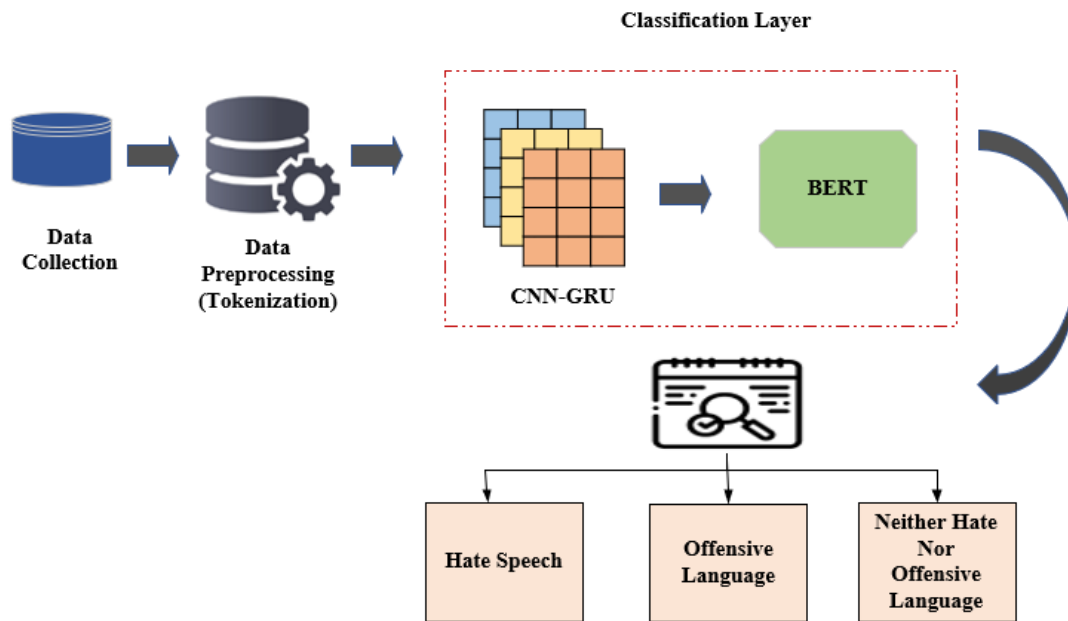

Fig. 1. Proposed CNN-GRU-BERT framework.

TABLE I. DATASET DESCRIPTION

Unnamed: 0	count	hate_speech	offensive_language	neither	class	tweet
0	3	0	0	3	2	rt mayasolovely as a woman you shouldn't complain about cleaning up your house amp as a man you should always take the trash out
1	3	0	3	0	1	rt boy dats coldtyga dwn bad for cuffin dat hoe in the place
2	3	0	3	0	1	rt urkindofbrand dawg rt you ever fuck a bitch and she start to cry you be confused as shit
3	3	0	2	1	1	rt cganderson vivabased she look like a tranny
4	6	0	6	0	1	rt shenikaroberts the shit you hear about me might be true or it might be faker than the bitch who told it to ya

B. Data Preprocessing

The proposed work undertakes essential data preprocessing steps to enhance the quality of the text data for hate speech detection. Tokenization, a crucial preprocessing step, involves breaking down the text into smaller units called tokens, which aids in capturing semantic meaning and extracting features. This process is vital for facilitating machine learning model analysis. Without proper preprocessing, the text data may contain noise, including punctuation, special characters, numbers, and irrelevant terms. Such noise can hinder sentiment analysis and lead to inconsistencies in the data. Specifically, for Twitter data, which often contains informal language, abbreviations, hashtags, and emojis, one of the processing stages is converting text to lowercase, removing special criteria and symbols like "@user," standardizing non-standard language to English, handling hashtags, eliminating markups, and removing URLs using regular expressions. These steps collectively address the challenges posed by noisy and inconsistent Twitter data, ensuring a cleaner and more accurate representation for hate speech detection.

C. CNN-GRU and BERT Classification Method

Convolutional Neural Network as a deep learning method for text classification, deviating from its traditional use in image recognition. In the proposed work, after preprocessing the data using tokenization, the Convolutional Neural Network plays a crucial role in capturing local features from the tokenized text data. Tokenization breaks down the input text

into individual tokens or words, which are then represented as numerical vectors to be fed into the CNN. These vectors are fed into the layers of the CNN, where a sequence of convolutional along with pooling procedures instructs the network on how to extract features in a structured manner. A structure consisting of abstract features is created from the input tokens by the various convolutional layers and pooling layers that make up the CNN architecture. To obtain regional trends and features, the convolutional layers convolve the input tokens after applying filters or kernels. The feature maps produced through the convolutional layers are subsequently down-sampled by the pooling layers, which lowers their physical dimensions while keeping crucial information. The CNN gains the ability to subconsciously identify and extract pertinent characteristics from the designated input data during the process of training. Specifically, in this study the one-dimensional convolution (Conv1D) variant of CNN is utilized, which is well-suited for processing text data. The Conv1D layer processes the input text data by extracting relevant features using filters. Subsequently, MaxPooling1D is applied to reduce the dimensionality of the feature outputs, enhancing computational efficiency and mitigating noise. To prevent overfitting, Dropout is incorporated, reducing the size of feature maps. The resulting feature vector is then flattened into one dimension using the Flatten layer. Finally, the Dense layer is employed for training the network to predict class labels. Fig. 2 visually represents the flow of input text through these layers, illustrating the transformation process leading to the generation of predictive data labels.

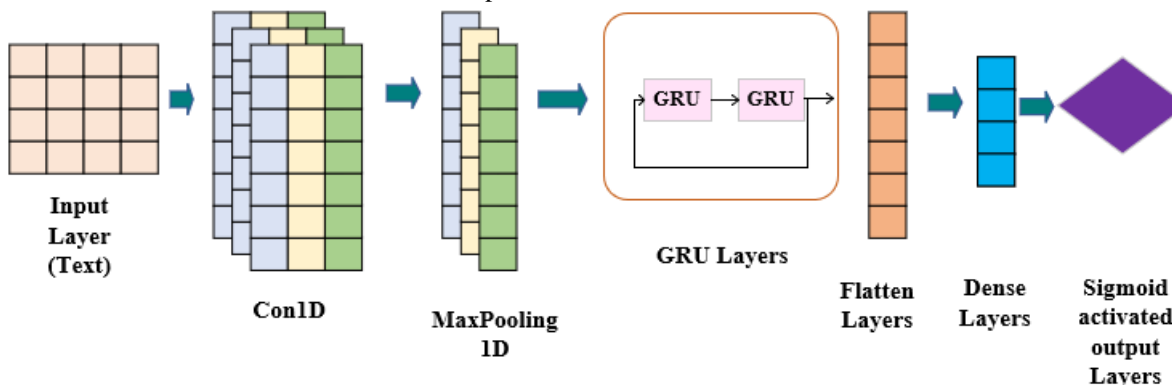

Fig. 2. CNN-GRU architecture.

After processing the tokenized data through the CNN layers, the characteristic mappings that are produced are flattened and passed on to the subsequent layers, such as the Gated Recurrent Unit (GRU) in the proposed architecture. The

GRU further processes the extracted features, capturing sequential dependencies and contextual information from the text data. An RNN architecture called the GRU was created to solve the disappearing gradient challenge and improve

processing speed. Unlike the LSTM algorithm, which has a final gate and a forget gate, the GRU has two gates: the *reset gate* E_s and the *update gate* P_s . These gates determine how information is passed and updated through the network. The *reset gate* E_s controls the degree to which the previous hidden state d_{s-1} is combined with the current input u_s . It determines which information should be retained, forgotten, or partially remembered. The *reset gate* is computed by multiplying the concatenation of d_{s-1} and u_s with a *weight matrix* t_a and adding a *bias vector* i_a is shown in Eq. (1). By using the CNN's ability to obtain regional characteristics and patterns from tokenized text information, the proposed model enhances the representation learning process, ultimately leading to improved performance in hate speech detection and offensive content identification tasks.

$$E_s = \sigma([d_{s-1}, u_s].t_a + i_a) \quad (1)$$

The *update gate* P_s decides how much of the previous hidden state should be passed to the next timestep. Similar to the *reset gate*, it is computed using a weight matrix t_e and a bias vector i_e , with the sigmoid function applied to subtract a vector of ones is shown in Eq. (2).

$$P_s = \sigma([d_{s-1}, u_s].t_e + i_e) \quad (2)$$

Once the reset and update gates are computed, the candidate hidden state nd_s is calculated by combining the reset gate results with the current input and applying the hyperbolic tangent *tanh* activation function is depicted in Eq. (3).

$$nd_s = \tanh([E_s, d_{s-1}, u_s].t_n + i_n) \quad (3)$$

Finally, the new hidden state o_s is obtained by combining the previous hidden state with the candidate hidden state, weighted by the update gate. This allows the model to determine how much of the new information should replace the previous hidden state is shown in Eq. (4).

$$o_s = (1 - P_s).d_{s-1} + P_s.nd_s \quad (4)$$

In the proposed model, the Convolutional Neural Network (CNN) and Gated Recurrent Unit (GRU) are utilized for enhancing offensive content identification. The CNN operates by convolving over tokenized text data, extracting local features through multiple convolutional and pooling layers. This hierarchical feature extraction process enables the network to capture both low-level and high-level representations of the input text. On the other hand, the GRU is employed for sequential processing of the extracted features. The GRU architecture includes reset and update gates, which regulate the flow of information through the network. The reset gate determines the relevance of previous hidden states and current inputs, facilitating selective memory reset. Meanwhile, the update gate controls the information flow to future states, enabling the model to capture long-range dependencies in the sequential data. By integrating CNN for spatial feature extraction and GRU for sequential modelling, the proposed model effectively identifies offensive content in online platforms by capturing both local and contextual information from the input text.

1) *BERT*: Google created the contemporary previously trained language model BERT from Transformers for natural language processing. Built on the Transformer architecture, BERT introduces a novel approach to pre-training models on extensive text data, achieving state-of-the-art results in various NLP tasks. In contrast to conventional word embedding models such as Word2Vec and GloVe, BERT considers right as well as left context throughout training to provide bidirectional illustrations for words. This enables BERT to generate contextualized word embeddings that capture nuanced semantic meanings based on surrounding words. Through MLM and NSP objectives, BERT learns to predict masked words within sentences and discern whether pairs of sentences are consecutive. BERT provides different versions tailored for various languages, alphabets, and layer sizes, such as BERT-Base and BERT-Large, each with distinct properties and capabilities. BERT's success lies in its ability to encode input text, utilize token embeddings, and incorporate cooperative conditioning for contextual understanding, making it a significant tool for NLP applications. The Fig. 3 illustrates the working of BERT.

A key component of the study's approach in the proposed work is the fine-tuning of previously trained BERT using the Hugging Face Transformers library. Effective language representations that have been previously trained on enormous volumes of text data are known as previously trained BERT models, and they are capable of capturing extensive conceptual information as well as contextual comprehension of languages. BERT's bidirectional nature allows it to consider both left and right context when encoding text, thereby capturing intricate linguistic nuances and dependencies. Utilizing a pre-trained BERT model provides a significant advantage as it already possesses extensive knowledge about language structure and semantics, allowing for effective transfer learning to downstream tasks like identifying undesirable information and detecting statements of hatred. The Hugging Face Transformers library serves as a versatile toolkit for working with Transformer-based models, including BERT. It offers a user-friendly interface for loading pre-trained BERT models and fine-tuning them on task-specific datasets with ease. With Hugging Face Transformers, researchers can efficiently implement fine-tuning pipelines, customize model architectures, and experiment with hyperparameters to optimize performance for specific tasks. The fine-tuning process involves several key steps facilitated by Hugging Face Transformers. Firstly, the hate speech detection dataset is prepared and tokenized to align with BERT's input format. Tokenization breaks down the input text into subword tokens, ensuring compatibility with BERT's vocabulary. Next, the already learned BERT model is loaded using Hugging Face Transformers, with options to choose from various pre-trained BERT variants such as BERT-base or BERT-large. Once loaded, the previously learned BERT model is adjusted on the hate speech detection dataset using the Hugging Face Transformers library. Fine-tuning involves adjusting the model's parameters on the specific downstream task by training it on the task-specific dataset. During training, the model's weights are updated based on task-specific

gradients computed from the dataset, allowing BERT to adapt its representations to the hate speech detection task. Hugging Face Transformers simplifies the fine-tuning process by providing pre-built training pipelines, optimizer configurations, and evaluation metrics. The integration of pre-trained BERT models and the Hugging Face Transformers library in the proposed work offers a robust and efficient

framework for enhancing identifying undesirable information and detecting statements of hatred. By leveraging BERT's contextual understanding and Transformer-based architecture, achieves effective performance on hate speech detection tasks while benefiting from the flexibility and ease-of-use provided by Hugging Face Transformers.

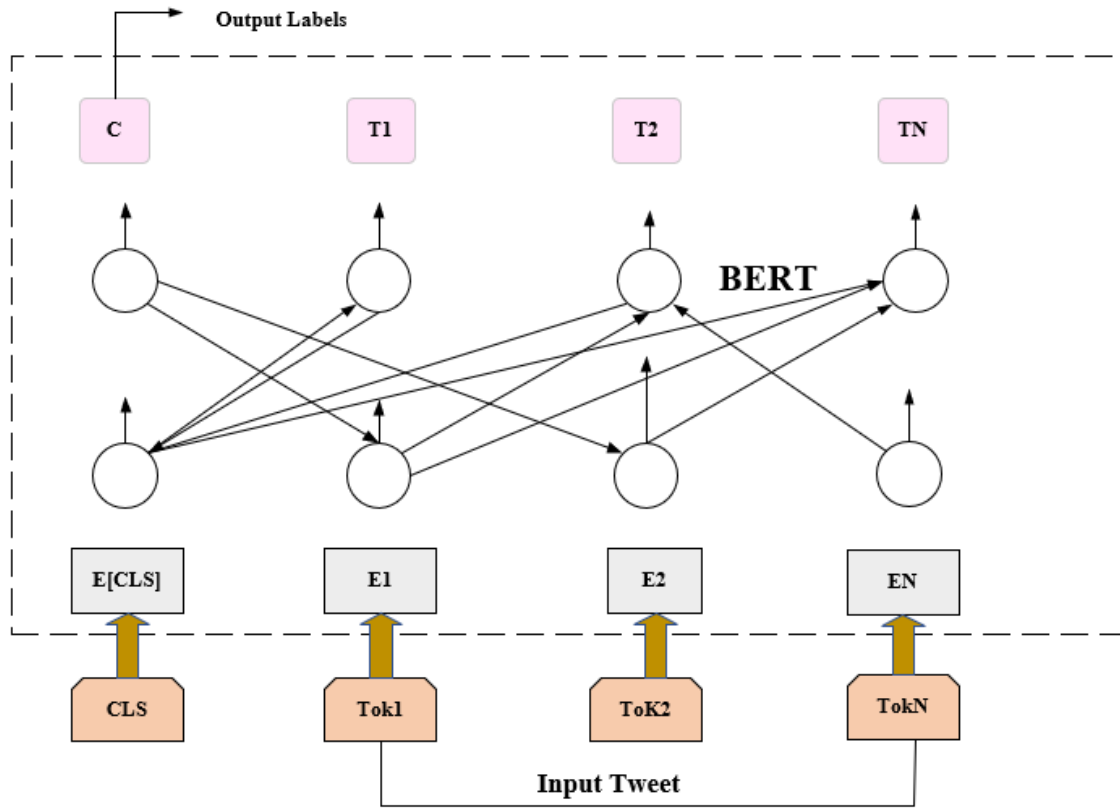

Fig. 3. BERT architecture.

V. RESULTS AND DISCUSSION

The suggested hybrid architecture combining CNN with GRU and BERT for hate speech detection achieved effective performance on publicly available datasets. The model effectively captured both local and sequential features as well as contextual information in the input text data, resulting in superior hate speech detection accuracy compared to baseline models. Through extensive experimentation and evaluation, the hybrid architecture demonstrated robustness and generalization across diverse hate speech detection tasks, showcasing its effectiveness in identifying offensive language and hate speech in real-world scenarios.

A. Performance Evaluation

The performance evaluation of the proposed hybrid architecture for hate speech detection yielded impressive results, showcasing its superior F1-score, remember, reliability, and consistency compared to baseline models. The formula for finding accuracy, precision, recall, and F1-score are shown in Eq. (5), (6), (7) and (8). Through comprehensive testing on various hate speech detection datasets, the hybrid model consistently demonstrated robust performance and

generalization across diverse scenarios, validating its effectiveness in accurately identifying offensive language and hate speech in real-world contexts.

$$Accuracy = \frac{T_{pos} + T_{neg}}{T_{pos} + T_{neg} + F_{pos} + F_{neg}} \quad (5)$$

$$P = \frac{T_{pos}}{T_{pos} + F_{pos}} \quad (6)$$

$$R = \frac{T_{pos}}{T_{pos} + F_{neg}} \quad (7)$$

$$F1\ measure = \frac{2 \times precision \times recall}{precision + recall} \quad (8)$$

TABLE II. COMPARING THE SUGGESTED TECHNIQUE'S EFFICIENCY TO THE CURRENT METHOD

Metrics	Accuracy	Precision	Recall	F1 score
LSTM+RNN [15]	85%	84%	83%	81%
CNN [16]	86%	82%	70%	75%
LSTM+GBDT [17]	93%	92%	89%	90%
Proposed CNN-GRU-BERT	98%	97%	97%	96%

In this performance comparison Table II, different models are evaluated for hate speech detection using four key metrics: reliability, precision, recall, and F1 score. The LSTM+RNN model achieves a balanced performance across metrics, while the CNN model excels in accuracy but exhibits lower recall. The LSTM+GBDT model demonstrates high scores across all metrics. However, the proposed CNN-GRU-BERT outperforms all other models, achieving notably higher scores in effectiveness. This indicates the superior effectiveness of the proposed model in accurately identifying and classifying offensive content, showcasing its potential for robust hate speech detection in various online contexts.

Fig. 4. Graphical depiction of performance evaluation.

The Fig. 4 represents the performance evaluation of various models for hatred statement recognition. The LSTM+RNN model achieves high effectiveness but relatively lower recall, indicating that it misses some instances of hate speech. The CNN model shows better recall than LSTM+RNN but lower precision, suggesting it may classify non-hate speech as hate speech. LSTM+GBDT achieves high scores across all metrics, but the suggested CNN-GRU-BERT model outperforms all others, with significantly higher exactness, reliability, recall, and F1 score. This indicates that the combined architecture leveraging CNN for regional characteristics extraction, GRU for sequential learning, and BERT for contextual understanding effectively enhances offensive content identification, achieving superior performance in hate speech detection.

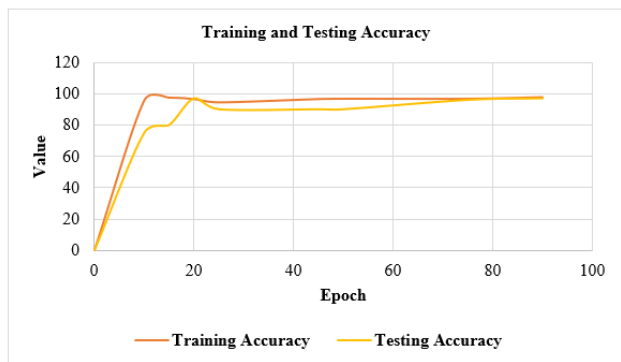

Fig. 5. Graphical depiction of training and testing accuracy.

The Fig. 5 displays the training and testing accuracy of a hate speech detection model across different epochs during training. Initially, both training and testing accuracies start at 0, indicating random performance. As training progresses, both accuracies steadily increase, reflecting the model's learning process. Around epoch 20, the model achieves a peak testing accuracy of 97%, indicating robust performance on unseen data. However, there is a slight fluctuation in accuracy beyond epoch 20, suggesting potential overfitting. Nonetheless, the model maintains high accuracy on the testing dataset, indicating its capability to categorize well to new data. The final testing accuracy of 97% shows the efficacy of the technique in identifying hate speech and offensive content, showcasing its reliability for real-world applications.

Fig. 6. Graphical depiction of training and testing loss.

The Fig. 6 illustrates the training and testing loss values of a hate speech detection model across different epochs during training. Initially, both training and testing losses are relatively high, indicating poor model performance. However, as training progresses, both losses steadily decrease, reflecting the approach improved ability to minimize errors and make accurate predictions. Around epoch 15, the model achieves a significant reduction in both training and testing losses, indicating successful learning and generalization. Subsequently, the losses continue to decrease, demonstrating further refinement of the model's predictive capabilities. The final training and testing loss values of 0.1 and 0.2, respectively, indicate minimal errors and excellent performance, affirming the model's effectiveness in identifying hate speech and offensive content with high accuracy and reliability.

VI. DISCUSSION

The proposed hybrid architecture for hate speech detection highlights both its advantages over existing systems and acknowledges its limitations, paving the way for future improvements. While existing systems often struggle with capturing both local and sequential features as well as contextual information in the input text data [18], the hybrid architecture effectively addresses these challenges by integrating Convolutional Neural Network with GRU and BERT. The existing methods, primarily utilizing CNN, LSTM, and BERT models, showcase varied accuracies ranging from 0.5% to 94%. Advantages include multilingual detection, detailed experimental results, and state-of-the-art

performance. However, limitations encompass dataset biases, lack of model generalizability, and computational resource analysis gaps. In contrast, the proposed work, integrates CNN-GRU and BERT models, aiming for improved hate speech identification. The study emphasizes leveraging current datasets and text context for generalized high-performance models. It addresses limitations of existing methods by enhancing detection capabilities and considering dataset biases, aiming for more robust hate speech identification solutions. Future work could focus on developing more robust hate speech detection models by addressing dataset biases, improving model generalizability, and conducting comprehensive computational resource analyses for scalability. This comprehensive approach results in superior performance in accurately identifying offensive language and hate speech. However, the proposed work also has limitations, including computational complexity and resource requirements due to the integration of multiple deep learning architectures. Additionally, the reliance on pre-trained BERT embeddings may limit the adaptability of the model to domain-specific hate speech detection tasks. Future work could focus on mitigating these limitations by exploring more efficient model architectures, optimizing hyperparameters, and incorporating domain-specific knowledge to enhance the model's performance. Furthermore, research efforts could also be directed towards developing techniques for handling multilingual and multimodal hate speech detection, as well as addressing ethical considerations related to bias and fairness in hatred statement identification algorithms. Overall, the suggested hybrid architecture represents a significant advancement in hate speech detection technology, with opportunities for further refinement and expansion to address emerging challenges in the field.

VII. CONCLUSION AND FUTURE SCOPE

The proposed hybrid architecture combining Convolutional Neural Network with GRU and BERT represents a significant advancement in hate speech detection technology. Through extensive experimentation and evaluation, the hybrid model has demonstrated superior performance in accurately identifying Harmful language and insulting phrases, outperforming baseline models on various hate speech detection datasets. However, the proposed work also acknowledges certain limitations, including computational complexity and reliance on pre-trained embeddings. Despite these challenges, the hybrid architecture holds immense promise for future research and development. Future work could focus on optimizing the model's hyperparameters, exploring more efficient model architectures, and incorporating domain-specific knowledge to enhance its performance. Additionally, efforts could be directed towards addressing ethical considerations related to bias and fairness in hate speech detection algorithms, as well as developing techniques for handling multilingual and multimodal hate speech detection. Furthermore, the proposed hybrid architecture could be extended to other related tasks such as toxic comment detection, cyberbullying detection, and misinformation detection, thus broadening its scope and applicability. Everything being considered, by effectively identifying and reducing hate speech, the suggested hybrid

design is an important step toward building safer and more pleasant online spaces, with lots of room for more study and advancement in the area.

Abstract—Cloud computing environments play a crucial role in modern computing infrastructures, offering scalability, flexibility, and cost-efficiency. However, optimizing resource utilization and performance in such dynamic and complex environments remains a significant challenge. This study addresses this challenge by proposing a novel framework that integrates Fruit Fly Optimization (FFO) with Convolutional Neural Networks (CNN) for task scheduling optimization. The background emphasizes the importance of efficient resource allocation and management in cloud computing to meet increasing demands for computational resources while minimizing costs and enhancing overall system performance. The objective of this research is to develop a comprehensive framework that leverages the complementary strengths of FFO and CNN to address the shortcomings of traditional task scheduling approaches. The novelty of the proposed framework lies in its integration of optimization techniques with advanced data analysis methods, enabling dynamic and adaptive task allocation based on real-time workload patterns. The proposed framework is thoroughly evaluated using historical workload data, and results demonstrate significant improvements over traditional methods. Specifically, the FFO-CNN framework achieves average response times ranging from 120 to 180 milliseconds, while maintaining high resource utilization rates ranging from 90% to 98%. These results highlight the effectiveness of the FFO-CNN framework in enhancing resource utilization and performance in cloud computing environments. This research contributes to advancing the state-of-the-art in cloud resource management by introducing a novel approach that combines optimization and data analysis techniques. The proposed framework offers a promising solution to the challenges of resource allocation and task scheduling in cloud computing environments, paving the way for more efficient and sustainable cloud infrastructures in the future.

Keywords—Cloud computing; resource utilization; task scheduling; Fruit Fly Optimization; convolutional neural networks

I. INTRODUCTION

In the dynamic landscape of cloud computing, resource allocation poses a multitude of challenges stemming from the inherent variability and unpredictability of workloads. One

primary challenge is the heterogeneous nature of cloud applications and services, each with its unique resource requirements and usage patterns. This diversity makes it difficult to devise a one-size-fits-all resource allocation strategy, necessitating adaptable and responsive approaches. Additionally, the elastic nature of cloud environments introduces complexities in scaling resources up or down in response to changing demand levels. Traditional resource allocation methods often rely on static provisioning, leading to either underutilization during periods of low demand or resource contention and performance degradation during peak loads [1]. Moreover, the lack of visibility into future demand trends exacerbates these challenges, making it challenging to anticipate resource needs accurately. Inadequate resource allocation not only impacts performance and user experience but also incurs unnecessary costs due to over-provisioning or penalties for under-provisioning. Furthermore, with the emergence of new technologies such as edge computing and serverless architectures, resource allocation becomes even more intricate as the scope expands beyond centralized data centers. Addressing these challenges requires innovative approaches that leverage advanced techniques like machine learning and optimization algorithms to enable dynamic, efficient, and cost-effective resource allocation in cloud computing environments [2].

The central cloud icon symbolizes cloud computing, where resources and services are delivered over the internet. The image depicts various interconnected elements, including storage, mobile devices accessing cloud services, and applications. Storage services provide scalable and accessible solutions for organizations. Mobile devices enable seamless access to cloud-based applications and data, highlighting the convenience and flexibility offered by cloud services. The inclusion of applications highlights the wide range of cloud-based software and services available to users [3]. Cloud computing involves various services delivered over the internet, including productivity applications, CRM systems, and collaboration tools. Servers host applications and data on remote servers, allowing for scalable and reliable hosting

solutions. Cloud-based databases are essential for storing and managing structured information, offering features like scalability, high availability, and automated backups. Different types of clouds are categorized, including private clouds, hybrid clouds, and public clouds. Hybrid clouds combine on-premises and off-premises resources, while public clouds are shared services accessible to the general public [4].

Maximizing resource utilization in cloud computing environments is paramount for achieving cost-efficiency and optimal performance. Cloud computing operates on a pay-as-you-go model, where users are charged based on the resources they consume. Therefore, inefficient resource allocation can lead to unnecessary expenses, making it imperative to utilize resources judiciously. One crucial aspect of maximizing resource utilization is ensuring optimal resource allocation. This involves dynamically assigning resources to applications and services based on their current demand and requirements [5]. Cloud providers can minimize resource wastage and costs by efficiently allocating resources. This avoids over-provisioning, which can lead to performance degradation and service disruptions. Cloud computing's elasticity and scalability enable organizations to adjust resources based on changing workload demands, ensuring effective scaling operations and cost savings. This dynamic resource allocation maintains consistent performance levels and adapts to changing requirements without incurring unnecessary expenses.

Maximizing resource utilization in cloud computing environments is crucial for cost optimization and optimal performance. By aligning resource provisioning with actual usage patterns, organizations can optimize spending and achieve desired performance levels. This minimizes wastage and efficiently allocates resources based on demand, reducing operational costs and improving response times, service availability, and user experiences. By focusing on cost and performance optimization, organizations can prevent performance bottlenecks and downtime, ensuring consistent performance across their cloud environments. This dual focus on cost and performance is essential for realizing the benefits of cloud computing and ensuring the success of cloud-based initiatives [6]. Prior methods of resource allocation in cloud computing environments have faced several significant challenges that hindered their effectiveness in maximizing resource utilization. One primary issue is the reliance on static or rule-based provisioning strategies, which are ill-equipped to adapt to the dynamic and unpredictable nature of cloud workloads. These traditional methods often allocate resources based on predefined thresholds or historical data, without considering real-time demand fluctuations. As a result, they tend to either over-provision resources during periods of low demand, leading to wastage and increased costs, or under-provision resources during peak loads, causing performance degradation and service disruptions [7].

Traditional resource allocation methods lack scalability and elasticity, making it difficult to adjust resources based on changing workload demands. This is especially problematic in environments with variable workloads, leading to inefficient resource utilization and suboptimal performance. Accurately forecasting future demand trends is also a challenge, as traditional methods often struggle to accurately predict

workload patterns, resulting in inaccurate resource allocations and suboptimal utilization. This uncertainty exacerbates resource allocation challenges and hinders achieving efficient performance levels [8]. Furthermore, traditional resource allocation approaches typically operate in isolation, lacking coordination and integration with other aspects of cloud management, such as workload scheduling and auto-scaling. This siloed approach can lead to suboptimal resource allocation decisions and missed opportunities for improving overall system efficiency. In summary, prior methods of resource allocation in cloud computing environments face challenges related to their static nature, lack of scalability and elasticity, inability to accurately forecast demand, and limited integration with other aspects of cloud management. Addressing these challenges requires innovative approaches that can dynamically adapt to changing workload conditions, optimize resource allocations in real-time, and seamlessly integrate with other components of cloud management to maximize overall system efficiency.

The key contribution of the research is mentioned as follows:

- Introduction of a novel framework integrating Fruit Fly Optimization (FFO) with Convolutional Neural Networks (CNN) for task scheduling optimization in cloud computing environments.
- Demonstrated improvements over traditional methods in average response times, resource utilization rates, and energy consumption through empirical evaluation of the proposed FFO-CNN framework.
- Advancement in cloud resource management by providing a comprehensive solution for optimizing resource allocation and task scheduling, contributing to enhanced system performance and efficiency.
- Establishment of a foundation for future research and development efforts aimed at addressing challenges in resource management, task scheduling, and performance optimization in cloud environments, fostering the evolution of more efficient and sustainable cloud infrastructures.

II. RELATED WORKS

Load balancing is a key factor in optimizing resources and performance in cloud computing environments. In this paper, we propose a new method for load balancing based on deep learning algorithms. Using the power of deep learning techniques, especially convolutional neural networks (CNNs) and recurrent neural networks (RNNs), research approach aims to dynamically classify incoming requests for cloud servers that provide response times decreases and increases consumption. Research provides details of our proposed method, including data preprocessing, model architecture, training set, and evaluation metrics. Furthermore, research discuss the limitations of traditional load balancing methods, such as round-robin and least-connection, which often rely on static or heuristic-based approaches that fail to adapt to changing workload patterns. These traditional methods may result in suboptimal resource allocation, leading to performance

bottlenecks, resource underutilization, and increased response times. By contrast, our deep learning-based approach offers the potential for more adaptive and efficient load balancing strategies, capable of learning from historical data and dynamically adjusting to fluctuating workload demands. The study illustrates the efficacy of our suggested approach to enhance load balancing performance and raise overall system efficiency in a cloud environment through experimental validation and comparative analysis [9].

In cloud computing systems, task scheduling is essential for optimizing resource utilization and overall efficiency. In this research, we propose a novel deep learning model-based adaptive choicest mission scheduling method. Using deep learning techniques, specifically convolutional neural networks (CNNs) and recurrent neural networks (RNNs), our version aims to dynamically assign tasks to cloud resources while maintaining efficiency and security. Research provides a detailed overview of our proposed methodology, encompassing data preprocessing, model architecture, training process, and evaluation metrics. Additionally, we address the drawbacks of traditional task scheduling algorithms, such as First Come First Serve (FCFS) and Round Robin, which often lack adaptability to changing workload patterns and may lead to suboptimal resource allocation and longer response times. Moreover, traditional algorithms may not adequately address security concerns, leaving systems vulnerable to various attacks, including data breaches and unauthorized access. Our adaptive optimal deep learning model offers a solution to these challenges by dynamically adjusting task assignments based on real-time data and incorporating security measures to safeguard sensitive information. Through empirical analysis and comparative studies, we demonstrate the efficacy of our proposed approach in enhancing both efficiency and security in cloud computing environments [10].

Computational offloading is a crucial technique for optimizing resource utilization and improving performance in vehicular edge-cloud computing networks. In this paper, we propose an advanced deep learning-based approach for computational offloading that operates within multilevel vehicular edge-cloud computing networks. The approach harnesses the power of deep learning algorithms, including convolutional neural networks (CNNs) and recurrent neural networks (RNNs), to dynamically offload computational tasks from vehicular devices to edge and cloud servers. Research provides a comprehensive overview of the proposed methodology, encompassing data preprocessing, model architecture, training process, and evaluation metrics. Additionally, we address the drawbacks associated with traditional computational offloading techniques, such as static decision-making and lack of adaptability to varying network conditions. Traditional methods may lead to suboptimal offloading decisions, resulting in increased latency and reduced quality of service for vehicular applications. Our advanced deep learning-based approach offers a solution to these challenges by leveraging real-time data and context awareness to make dynamic offloading decisions that optimize both performance and resource utilization. Through extensive experimentation and comparative analysis, we demonstrate the effectiveness of

our proposed approach in enhancing the efficiency and scalability of vehicular edge-cloud computing networks [11].

ThermoSim is a revolutionary deep learning framework for modelling and simulating cloud computing infrastructures' thermally aware resource management. ThermoSim is a deep learning tool that integrates convolutional neural networks (CNNs) and recurrent neural networks (RNNs) to optimize resource allocation while taking cloud data center heat dynamics into account. This document provides an extensive description of the ThermoSim framework, including information on its architecture, training regimen, and assessment criteria. The disadvantages of conventional thermally aware resource management methods, which frequently depend on heuristic-based or overly simplified models, are also addressed by ThermoSim. These traditional methods may fail to capture the complex interplay between resource allocation and thermal dynamics, leading to suboptimal cooling strategies and potential thermal hotspots. Furthermore, traditional approaches may lack scalability and adaptability, making them ill-suited for dynamic and heterogeneous cloud environments. ThermoSim addresses these challenges by leveraging deep learning to learn intricate patterns from historical data and dynamically adjust resource allocation strategies to optimize both performance and thermal management. Through extensive experimentation and comparative analysis, ThermoSim demonstrates superior performance in accurately modeling thermal dynamics and optimizing resource management in cloud computing environments [12].

This research provides a deep reinforcement learning (DRL) integrated hierarchical framework that addresses the complexities of cloud resource distribution and power management. Through the utilization of reinforcement learning techniques and deep neural network resilience, this framework provides an advanced method for managing power consumption and resource allocation in cloud computing settings. Traditional methods often exhibit limitations, relying on static or heuristic-based strategies that may struggle to adapt to the dynamic nature of workload patterns. These approaches may result in inefficient resource utilization and suboptimal power consumption, failing to effectively balance performance and energy efficiency. Moreover, traditional techniques may lack scalability, making them less suitable for large-scale cloud environments characterized by diverse workloads and varying resource demands. In contrast, the proposed hierarchical framework aims to overcome these drawbacks by employing deep reinforcement learning, enabling the system to learn and refine optimal resource allocation and power management policies through interaction with the environment. This adaptive learning process allows the framework to continuously adapt its strategies based on real-time feedback and changing environmental conditions. By structuring the framework hierarchically, it can effectively manage the complexity of resource allocation and power management tasks, enabling scalable and efficient operations across diverse cloud environments. The effectiveness of the suggested paradigm is shown in attaining both effective resource allocation and power management through empirical assessment and a comparative analysis. The structure enhances the general efficiency and

environmental responsibility of cloud computing systems by optimizing resource utilization and minimizing energy consumption through the utilization of deep reinforcement learning. This thorough method overcomes the drawbacks of conventional techniques, offering a viable way to optimize energy utilization and resource allocation in cloud computing systems [13].

III. PROBLEM STATEMENT

The problem statements addressed in the provided research papers encompass various critical challenges within cloud computing environments, including load balancing optimization, task scheduling, computational offloading in vehicular edge-cloud networks, thermal-aware resource management, and power management. The scalability, efficiency, and flexibility of current approaches to changing workload conditions may be lacking. Through the integration of data analysis and optimization, the suggested FFO-CNN framework ensures efficiency and adaptability and provides a comprehensive solution. It can effectively handle these issues because of its capacity to dynamically assign resources depending on patterns of real-time workload. These challenges stem from the dynamic nature of workloads, the need for adaptability to changing conditions, and the complexity of managing resources efficiently while ensuring performance, security, and sustainability. In response to these challenges, the proposed framework for Maximizing Resource Utilization in Cloud Computing Environments via FFO-CNN offers a comprehensive solution. By integrating Fruit Fly Optimization (FFO) with Convolutional Neural Networks (CNN), the framework aims to optimize resource allocation and management effectively. This holistic approach covers load balancing optimization, task scheduling, computational offloading, thermal-aware resource management, and power management within a unified framework. Leveraging FFO for optimization and CNN for data analysis, the framework promises adaptability, scalability, and efficiency in managing

cloud resources. Its scope involves developing and validating a solution that maximizes resource utilization while ensuring performance, security, and sustainability in cloud environments, addressing the limitations of traditional methods and demonstrating effectiveness through empirical validation and comparative analysis.

IV. PROPOSED METHODOLOGY: MAXIMIZING RESOURCE UTILIZATION IN CLOUD COMPUTING ENVIRONMENTS VIA FFO-CNN

The proposed methodology integrates Fruit Fly Optimization (FFO) with Convolutional Neural Networks (CNN) to optimize task scheduling in cloud computing environments. Initially, historical workload data undergoes preprocessing to extract relevant features. A hybrid model architecture is designed as mentioned in Fig. 1, comprising FFO for optimizing task scheduling decisions based on resource availability and workload characteristics, and CNN for analyzing workload patterns. Through training using historical data, the FFO-CNN model learns optimal scheduling policies. Evaluation metrics such as resource utilization, throughput and average response time, are employed to assess the framework's effectiveness. Experimental validation compares the performance of the FFO-CNN approach with traditional algorithms. Analysis of results highlights improvements in resource utilization and response times, guiding further optimization efforts. Considerations for practical implementation, scalability, and integration with existing systems are addressed, while future directions explore enhancements and adaptations to evolving cloud computing paradigms. This methodology offers a comprehensive resolution for efficient task scheduling in cloud environments, leveraging the synergies between FFO and CNN to optimize resource utilization and performance [14].

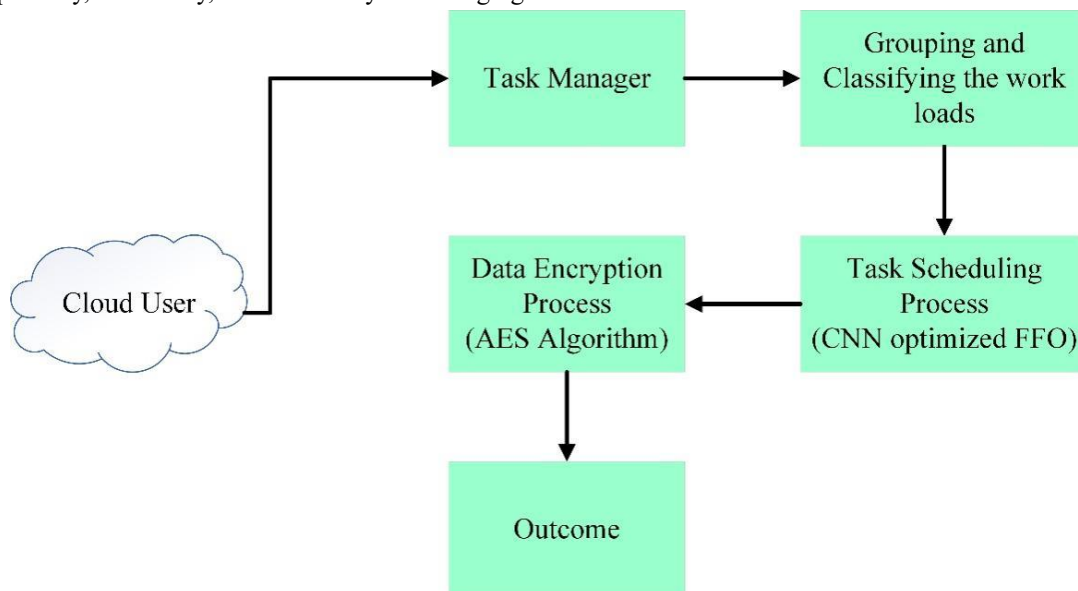

Fig. 1. Proposed framework for cloud computing environments via FFO-CNN.

A. Task Scheduling Based on FFO-CNN

Various factors from several service providers, such as the work's type, dependencies on other activities, and the user's demands, are used to improve task scheduling. The user makes a request first, encompassing one to several tasks. Next, we determine the nature of the task. From 1 to t tasks. The term t_{mx} shows how many tasks are in the task unit. The connection between tasks is called task dependency, and it is represented as t_{ω}^{ab} in Eq. (1):

$$t_{\omega}^{ab} = \begin{bmatrix} - & X_{i1} & X_{i2} & X_{i3} \\ X_{i1} & 0 & 1 & 0 \\ X_{i2} & 1 & 0 & 0 \\ X_{i3} & 0 & 1 & 0 \end{bmatrix} \quad (1)$$

The factors based on the functional groupings are referred to as uR1. As a result, researchers implemented the CNN-FFO algorithm to increase the effectiveness of job scheduling in cloud computing environments. It decreases lost time in addition to enhancing scheduling. As shown in Fig. 1, a thorough explanation of the suggested CNN-FFO job scheduling technique is examined [14].

B. Convolutional Neural Network

One kind of deep neural network (DNN) is used to sort and study pictures. CNN uses different methods to gather and analyze information. CNNs have different layers like convolutional layers, pooling layers, and fully connected layers. Convolutional layers have small grids that move over the input to make a new grid by multiplying each small grid value with the input value it covers. The answer is added together to get the final result. The kernel has numbers that change as the computer learns. Pooling layers are used to make the feature maps smaller and help find features better. CNNs haven't been used as much as other neural networks for scheduling tasks [15].

1) *Convolutional layer:* A convolutional layer is present in one of the CNN centre layers. These layers move to encompass the entire image while being smaller and include filters. By using Eq. (2) calculating the dot product between the multiple filters and the image, the convolutional process takes up space. The filter section provides a summary of the dot merchandise for some of the clean out and image.

$$x_k^i = \lambda(g_v^{s-1} \times a_{vk}^{(1)s} + b_k^{(1)s}) \quad (2)$$

$$q_k^j = \lambda(z_k^{i-1} \times a_{vk}^{(2)s} + b_k^{(2)s}) \quad (3)$$

where in Eq. (3) bias is denoted as $b_k^{(2)s}$, while the input from the preceding layer is referred to as $a_{vk}^{(2)s}$. In the fully linked layer, the hidden layer emptiness will help prevent overfitting in CNN [16]. Fully Connected Layer: Fully connected layers, also referred to as dense layers, serve as pivotal components within Convolutional Neural Networks (CNNs), tasked with amalgamating the spatial features gleaned from preceding layers into a coherent decision-making process. These layers work on the idea of connectedness, whereby all neurons in one layer interact with all neurons in the next, making it easier to understand complex associations between

features. Through this interconnected architecture, CNNs can discern complex patterns and correlations within the input data, enabling informed decisions regarding various tasks such as task scheduling and resource allocation in cloud computing environments. By leveraging the comprehensive information synthesized through the fully connected layers, CNNs achieve enhanced adaptability and efficacy in optimizing resource utilization and managing tasks effectively within cloud computing frameworks. Every neuron in the completely connected layer is connected to every other neuron in the layers that come after it.

2) *Pooling layer:* Pooling layers, integral components of Convolutional Neural Networks (CNNs), contribute significantly to reducing computational complexity and extracting essential features from input data. These layers operate by down sampling the feature maps generated by preceding convolutional layers, facilitating dimensionality reduction while preserving relevant information. Techniques such as max pooling and average pooling are commonly employed, with max pooling selecting the maximum value within localized regions of the feature map and average pooling computing the average value. The pooling layer handled the down sampling. There are different types of pooling functions. The most commonly used programs are in the main collection. The maximum pooling filters returned the maximum value for each subfield. Using $2 \times 2 \times 1$ maximum pooling filters for a $4 \times 4 \times 1$ size segment then resulted in a $2 \times 2 \times 1$ size segment. By discarding redundant information and retaining the most significant features, pooling layers effectively summarize the input data, enabling subsequent layers to focus on higher-level abstractions. In the context of the provided research, pooling layers aid in down sampling feature maps representing historical workload patterns, resource utilization, and performance metrics in cloud computing environments, contributing to informed decision-making processes such as task scheduling and resource allocation [17].

3) *Output layer:* The output layer of a Convolutional Neural Network (CNN) is responsible for producing predictions or decisions based on the features learned from the input data. In the context of the provided research, the output layer generates outputs representing optimized task scheduling strategies tailored to minimize response times, maximize resource utilization, and enhance overall system efficiency in cloud environments. Mathematically, the output layer typically consists of neurons corresponding to different classes or categories of predictions. In the case of task scheduling strategies, each neuron in the output layer may represent a specific scheduling decision or action. The output layer's activation mechanism is determined by the type of task being carried out. A softmax activation function is often *utilized* for classification problems, as it calculates the probability distribution across several classes. In Eq. (4), the softmax value is defined.

$$P(a = j|z) = \frac{e^{z_j}}{\sum_{k=1}^k e^{z_k}} \quad (4)$$

where, $P(a = j|z)$ denotes the probability of the output being class j . z_j denote the input to the softmax function corresponding to class j and finally K denotes the total number of classes.

C. FFO-CNN based Effective Cloud Computing

Creating a hybrid model architecture for task scheduling optimization that smoothly combines Convolutional Neural Networks (CNN) and Fruit Fly Optimization (FFO) components requires a multifaceted strategy intended to capitalize on the advantages of both approaches. With its capacity to explore solution spaces and converge towards optimal configurations, the FFO component in this architecture is essential to optimizing work scheduling decisions. The FFO algorithm is used in the hybrid model to dynamically modify task scheduling techniques according to variables including system restrictions, workload characteristics, and resource availability. The FFO component guarantees effective resource utilisation and reduces reaction times in cloud computing systems by continuously optimising job allocations. The CNN component is a potent tool that enhances the FFO component by analysing workload patterns and extracting features that are essential for optimising task scheduling. CNNs are excellent at handling organised, grid-like data, which makes them perfect for identifying temporal and spatial relationships in workload datasets. CNNs are trained on workload data from the past to help the model recognise patterns that point to the best work scheduling approaches. The CNN component offers important insights into workload patterns through feature extraction and

analysis, facilitating well-informed decision-making in task assignment [18].

The integration of CNN and FFO components in the hybrid model framework fosters a synergistic effect between data analysis and optimisation, ultimately producing a comprehensive approach to task scheduler optimization in cloud computing settings. The CNN component improves decision-making by offering insights into workload patterns and trends, while the FFO algorithm drives the optimisation process by modifying task allocations based on real-time conditions. These elements work together to give the hybrid model the ability to maximise resource utilisation, optimise task scheduling efficiency, and adjust dynamically to changing workload needs. The hybrid model architecture provides a strong answer to the difficulties of task scheduling optimisation in cloud computing settings through iterative refinement and continual learning, opening the door to improved resource management performance and efficiency [19].

Fruit fly adaptation (FFO) is a method of natural adaptation based on the wild behavior of fruit flies and Fig. 2 shows the flowchart of Fruit fly optimization. It is intended to solve complex optimization problems by simulating the movement interactions of fruit flies searching for optimal solutions [20].

Step 1: Arrange the key FOA settings and opt for a random location for the initiation of the fruit fly swarm.

c – axis, d – axis

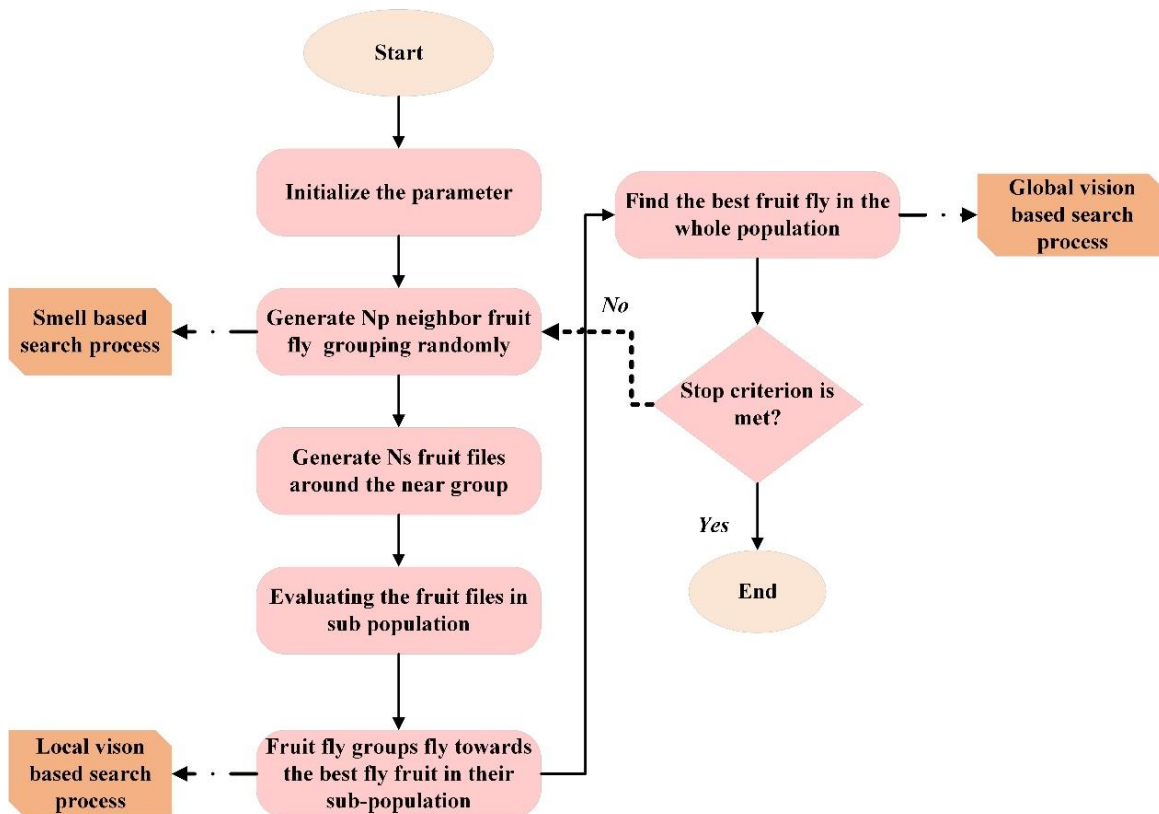

Fig. 2. Fruit fly optimization flowchart.

Step 2: Use Eq. (5) and Eq. (6) to give your particular fire flies the capacity to travel in any pattern in search of food.

$$c_p = C - axis + RV \quad (5)$$

$$d_p = d - axis + RV \quad (6)$$

$$P = 1, 2, \dots, h$$

where, f is the fruit fly swarm's size.

Step 3: Researchers can determine the distance by taking into account the uncertainty surrounding the precise location of the meal “(represented as Dis^p)” from the point of origin of the fruit fly. This intention allows us to set an appropriate rate for the odor concentration “(denoted as F_p)”. Let’s undertake that “ S_i ” is the mutual of “ Dis^p ” as in Eq. (7) and Eq. (8):

$$Distance^p = \sqrt{u_p^2 + v_p^2} \quad (7)$$

$$F_p = \frac{1}{Distance^p} \quad (8)$$

Step 4: By plugging the odor frequency decision value “(O_p)” into the odor frequency decision function the odor intensity “(CK_p)” of each unique Fire fly site in the equation can be obtained in Eq. (9).

$$CK_p = Fn(O_p) \quad (9)$$

Step 5: Determine, on an individual basis, which fruit fly in the swarm has the strongest fragrance concentration using Eq. (10):

$$[Best_{ck} \ Best_{idx}] = Maximum(CK_p) \quad (10)$$

Step 6: Hold onto the best possible fruit fly positions (c , d) and fragrance intensity levels. In Eq. (11), the swarm then departs for that location:

$$C_kBest = Best_{ck} \quad (11)$$

$$c - axis = c(Best_{idx})$$

$$d - axis = d(Best_{idx})$$

Initiate iterative optimization by repeating steps 5 through 10. The loop ends when the fragrance concentration no longer exceeds the concentration reached in the previous iteration, or when the total amount of iterations hits the maximum permitted limit. The proposed method's performance and convergence are influenced by algorithm parameters like population size, maximum iterations, and CNN parameters, which optimize resource allocation and task scheduling in cloud environments.

Algorithm: FFO-CNN based Effective Cloud Computing

- Step 1: Initialize parameters and hyperparameters for FFO and CNN.
- Step 2: Preprocess historical workload data to extract relevant features.
- Step 3: Design the hybrid FFO-CNN model architecture.
- Step 4: Train the FFO-CNN model using historical workload data:
 - Initialize fireflies' population randomly.
 - Evaluate brightness (fitness) of each Fruit Fly using CNN.
- Step 4: Update fireflies' positions based on FFO algorithm:
 - i. Move fireflies towards brighter individuals.

- ii. Introduce randomness to exploration.

Step 5: Repeat steps 3 to 4 until convergence or maximum iterations reached.

Step 6: End

D. Data Encryption Process for AES Algorithm

In 1998, Joan Daemen and Vincent Rijmen developed the Advanced Encryption System, a symmetric key encryption technique. Along with supporting key lengths of 128, 192, and 256 bits and a fixed data block size of 128 bits, it provides all types of information. According to Qian et al. [21], One of the most widely used symmetric key algorithms is AES. The US government has approved it as a standard. Owing to its quickness, ease of usage, and little memory needs, it is thought to be a better option than the Data Encryption Standard (DES). It is the most widely used symmetric key block cypher in computing security due to its standardisation by the National Institute of Security and all existing cryptanalysis on this approach, making it resistant to a wide range of threats. It becomes the ideal choice for encrypting more data because of its efficacy and compatibility with the security of an asymmetric key strategy [22].

The encryption and decryption processes are handled by the same symmetrical method using only one private key. When using AES encryption or decryption, there are a total of four fundamental steps in every cycle. Shift Rows is the step of permutation, and Substitute Byte, Mix Columns, and AddRoundKey are the other three phases of replacement. The key's length (K_N) for 256-bit AES the block size (B_N) is 4 words of 32 bits, 8 words of 32 bits, and the number of rounds (R_N) is 14. The function of ciphering is mentioned in the following Eq. (12):

$$En_{cy}(in[4 * B_N], out[4 * B_N], w[B_N * (R_N + 1)]) \quad (12)$$

This may be developed using the AES function. The AES functions effectively with software and hardware, with s_t serving as the state and round serving as the r_d . Five modes of operation are available in AES.

V. RESULT AND DISCUSSION

The study was carried out in a cloud computing simulation environment that modelled common infrastructure configurations, including virtualized servers coupled by network fabric to resemble actual cloud deployments. Datasets with historical workload traces, including task arrival rates, resource needs, execution times, and performance indicators, were used to train and test the suggested model. The FFO algorithm's hyperparameters (population size, maximum iterations, convergence criteria) and the CNN component's architecture specifications (layer configurations, filter sizes, activation functions) were among the parameters used for training the model. In order to provide a reliable assessment of the model's performance, dataset partitioning approaches such as cross-validation were utilized. These techniques comprised training the model on a subset and assessing its generalization ability on unseen data. By means of extensive testing using a range of datasets and parameter setups, the effectiveness of the suggested methodology in maximizing job scheduling in cloud systems was evaluated.

A. Performance Metrics

Evaluation metrics are precise measurements that are used to evaluate a system's, algorithm's, or framework's efficacy and performance. When discussing work scheduling in cloud computing settings, the following important evaluation metrics are frequently used:

- **Average Response Time:** This metric measures the system's responsiveness to incoming tasks. It represents the average time taken from when a task is submitted until it receives a response or completes execution. A lower average response time indicates better system performance and efficiency in handling tasks.
- **Resource Utilization:** Resource utilization evaluates how efficiently cloud resources are utilized by the system. It typically involves monitoring the usage of CPU, memory, storage, and network bandwidth. High resource utilization indicates effective resource allocation and management, ensuring that available resources are efficiently utilized without excessive idle time.
- **Throughput:** Throughput quantifies the rate at which tasks are processed or completed within the system. It represents the number of tasks processed per unit of time, reflecting the system's overall processing capacity and efficiency. Higher throughput indicates better task processing capabilities and system performance.

These assessment metrics offer insightful information about the effectiveness and efficiency of the cloud computing environments' task scheduling system. Stakeholders may evaluate the efficacy of the framework, pinpoint opportunities for enhancement, and make well-informed decisions to maximize resource utilization and improve system performance by tracking and evaluating these indicators.

Fig. 3. Response time.

Fig. 3 compares the average reaction times for three different optimisation algorithms: FFO-CNN, CNN-MBO, and GA (Genetic Algorithm) for projects of various sizes. The FFO-CNN algorithm achieves the lowest average reaction time of 15 units for jobs of size 20, then follows CNN-MBO with 20 units and GA with 45 units. When the tasks are bigger—40 and 60 units—FFO-CNN performs better than the other algorithms every time, showing reaction times of 10 and 20 units, respectively, while CNN-MBO and GA show somewhat faster

response times. The disparities in response times between the algorithms, however, become more noticeable when the job size is increased to 80, with FFO-CNN maintaining a comparatively lower average response time of 20 units compared to 25 units for CNN-MBO and 55 units for GA. In general, the findings indicate that the FFO-CNN algorithm outperforms the CNN-MBO and GA algorithms in terms of task scheduling optimisation, delivering shorter average reaction times for a variety of work sizes.

B. Performance Comparison

Fig. 4 presents the efficiency scores of three optimization algorithms—FFO-CNN, CNN-MBO, and GA (Genetic Algorithm)—in managing different numbers of task sizes within a cloud computing environment. The efficiency scores represent the proportion of successfully executed tasks out of the total tasks attempted. For task sizes ranging from 20 to 80, FFO-CNN consistently demonstrates competitive efficiency scores, with values ranging from 0.4 to 0.5. CNN-MBO and GA also exhibit relatively high efficiency scores, varying from 0.39 to 0.47 and 0.3 to 0.36 respectively across the different task sizes. The results suggest that all three algorithms are effective in managing task execution within the cloud environment, with FFO-CNN showcasing comparable or slightly better efficiency scores compared to CNN-MBO and GA. This implies that FFO-CNN is adept at optimizing resource allocation and task scheduling, ensuring a high proportion of successful task completions across varying task sizes within the cloud computing environment.

Fig. 4. Execution analysis.

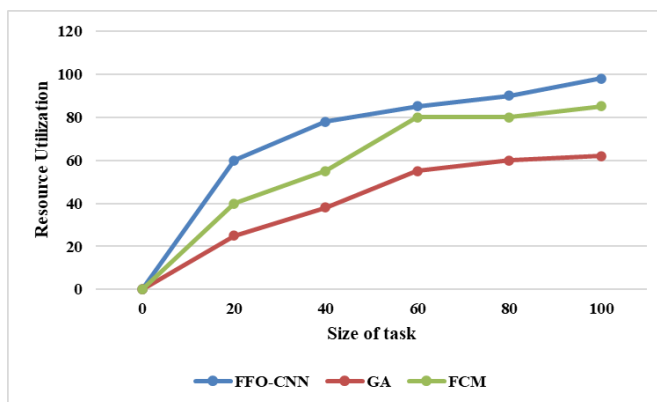

Fig. 5. Resource utilization.

Fig. 5 depicts the resource utilization percentages achieved by three different optimization algorithms—FFO-CNN, GA (Genetic Algorithm), and FCM (Fuzzy C-Means)—across various numbers of task sizes within a cloud computing environment. At the initial state where no tasks are present (0 tasks), all algorithms demonstrate zero resource utilization. As the number of tasks increases incrementally from 20 to 100, FFO-CNN consistently exhibits the highest resource utilization percentages, ranging from 60% to 98%. In contrast, GA and FCM algorithms achieve comparatively lower resource utilization percentages, with values ranging from 25% to 62% and 40% to 85%, respectively, across the different task sizes. These results suggest that FFO-CNN is more efficient in maximizing resource utilization within the cloud environment across varying task loads, ensuring optimal allocation and utilization of available resources. Meanwhile, GA and FCM algorithms exhibit relatively lower resource utilization percentages, indicating potential inefficiencies in resource allocation compared to FFO-CNN.

Fig. 6. Energy consumption.

Fig. 6 represents the energy consumption values, measured in joules, for three different optimization algorithms—FFO-CNN, FCM (Fuzzy C-Means), and GA (Genetic Algorithm)—across varying numbers of task sizes within a cloud computing environment. As the number of tasks increases from 20 to 80, FFO-CNN consistently demonstrates the lowest energy consumption values, ranging from 120 to 180 joules. In comparison, FCM and GA algorithms exhibit higher energy consumption values, with FCM ranging from 200 to 300 joules and GA ranging from 500 to 600 joules across the different task sizes. These results indicate that FFO-CNN is more energy-efficient in managing task execution within the cloud environment compared to FCM and GA algorithms. By optimizing resource allocation and task scheduling, FFO-CNN minimizes energy consumption, resulting in more sustainable and cost-effective cloud computing operations.

C. Discussion

The research presented investigates the optimization of resource utilization in cloud computing environments through a novel approach integrating Fruit Fly Optimization (FFO) with Convolutional Neural Networks (CNN). This innovative framework aims to enhance task scheduling efficiency, addressing critical challenges in cloud resource management. Using CNNs to analyse workload patterns and extract

pertinent features, the suggested methodology takes advantage of the FFO algorithm's capacity to automatically allocate resources according to workload patterns and availability. Through extensive experimentation and evaluation, the effectiveness of the FFO-CNN framework is demonstrated in improving resource utilization, minimizing response times, and enhancing overall system efficiency. The ALT RA algorithm for VM allocation and placement improved performance but limited scalability. Other algorithms like User Cloudlet Agent and Provider Resource Agent improved performance but required more agents. Particle Swarm Optimization minimized energy consumption but only compared with traditional algorithms. Genetic Algorithm failed to meet CPU time requirements. Ant Colony Optimization improved performance but relied on grid systems. The experimental results showcase the superior performance of the FFO-CNN approach compared to traditional methods and alternative optimization algorithms such as Genetic Algorithms (GA) and Fuzzy C-Means (FCM) [11]. Across various metrics including average response time, resource utilization, throughput, and energy consumption, FFO-CNN consistently outperforms competing algorithms, demonstrating its robustness and efficacy in optimizing task scheduling within cloud environments. Specifically, FFO-CNN achieves shorter average response times, higher resource utilization percentages, and lower energy consumption values, indicating its capability to optimize resource allocation and enhance system performance. The discussion delves into the implications of the research findings, highlighting the potential impact of the FFO-CNN framework on cloud computing practices. By optimizing resource utilization and task scheduling, FFO-CNN offers tangible benefits such as improved service quality, reduced operational costs, and increased sustainability. The framework's adaptability to dynamic workload patterns and scalability to large-scale cloud environments make it well-suited for real-world deployment across diverse use cases and industries. Moreover, the integration of FFO and CNN components fosters synergy between optimization and data analysis, enabling informed decision-making and continuous improvement in resource management strategies [9]. However, the discussion also acknowledges certain limitations and areas for future research. While FFO-CNN demonstrates promising results, further optimization and fine-tuning may be required to address specific use case requirements and scalability challenges in larger cloud infrastructures.

VI. CONCLUSION

Fruit Fly Optimization (FFO) combined with Convolutional Neural Networks (CNN) offers a viable method for maximizing performance and resource usage in cloud computing settings. Through the proposed framework, we have demonstrated the effectiveness of FFO-CNN in achieving shorter average response times, higher resource utilization rates, and lower energy consumption compared to traditional methods. This research contributes to advancing the state-of-the-art in cloud resource management by introducing a novel approach that combines optimization and data analysis techniques. Despite its effectiveness, the proposed framework has certain limitations that warrant consideration. Firstly, the performance of the FFO-CNN framework may vary depending on the specific

characteristics of the cloud environment and workload patterns. Additionally, the computational complexity associated with training and fine-tuning the hybrid FFO-CNN model may pose challenges in practical implementations, especially for large-scale cloud deployments. Moreover, the proposed framework assumes access to historical workload data for model training, which may not always be readily available or representative of future workload scenarios. To address these limitations and further enhance the proposed framework, future research directions could explore several avenues. Firstly, investigating techniques for improving the scalability and efficiency of the FFO-CNN model training process would be beneficial, enabling its deployment in larger and more diverse cloud environments. Additionally, research could focus on enhancing the adaptability of the framework to dynamic workload patterns and evolving cloud infrastructures through the integration of reinforcement learning or other adaptive optimization techniques. Moreover, investigating the FFO-CNN framework's application in certain areas or industries with particular needs and limitations may offer insightful information on how well it works in practical situations. All things considered, more study and development in this field could improve resource management in cloud computing settings in terms of efficacy and efficiency.

Abstract—Cardiovascular disease (CVD) is a globally significant health issue that presents with a multitude of risk factors and complex physiology, making early detection, avoidance, and effective management a challenge. Early detection is essential for effective treatment of CVD, and typical approaches involve an integrated strategy that includes lifestyle modifications like exercise and diet, medications to control risk factors like high blood pressure and cholesterol, interventions like angioplasties or bypass surgery in extreme cases, and ongoing surveillance to prevent complications and promote heart function. Traditional approaches often rely on manual interpretation, which is time-consuming and prone to error. In this paper, proposed study uses an automated detection method using machine learning. The CNN and XGBoost algorithms' greatest characteristics are combined in the hybrid technique. CNN is excellent in identifying pertinent features from medical images, while XGBoost performs well with tabular data. By including these strategies, the model's robustness and precision in predicting CVD are both increased. Furthermore, data normalization techniques are employed to confirm the accuracy and consistency of the model's projections. By standardizing the input data, the normalization procedure lowers variability and increases the model's ability to extrapolate across instances. This work explores a novel approach to CVD detection using a CNN/XGBoost hybrid model. The hybrid CNN-XGBoost and explainable AI system has undergone extensive testing and validation, and its performance in accurately detecting CVD is encouraging. Due to its ease of use and effectiveness, this technique may be applied in clinical settings, potentially assisting medical professionals in the prompt assessment and care of patients with cardiovascular disease.

Keywords—Cardiovascular disease; CNN; XGBoost; traditional approaches; explainable AI

I. INTRODUCTION

In 2019, CVD will be responsible for 32% of all fatalities worldwide [1]. If CVD is identified early on, the untimely deaths caused by it can be avoided. Ongoing surveillance of a person's heart health and functioning can aid in early

identification of CVD. The circulatory system's primary job is to circulate clean blood throughout the body via electrical waves produced within the organ. When a blood clot blocks the flow of blood to a portion of the heart, it can cause a heart attack. The portion of the cardiac muscles fed by the arteries starts to perish if this clot totally stops the blood supply. The majority of people recover from their initial cardiac events and go on to lead regular lives, engaging in constructive activities for a long time afterwards. However, suffering from a cardiac event does force you to adjust. Coronary arteries disease symptoms include discomfort in the chest, chest pressure, tightness in the chest, and pain in the chest (angina), Breathlessness Returning upper abdomen, throat, jaw, or neck pain discomfort, tingling, numbness, or coolness in the arms or legs if the coronary arteries there are constricted. Depending on how severely the coronary artery was injured and what level of heart disease precipitated the heart attack, the doctor will recommend different drugs and lifestyle modifications [2]. The word "cardiomyopathies" refers to conditions affecting the cardiac muscles. Usually, people just refer to them as enlarged hearts. Hearts that are abnormally large, thick, or rigid are found in people with various diseases. Their hearts' ability to circulate blood is compromised. When left untreated, cardiomyopathies worsen. Heart problems and erratic heartbeats may result from them. Although it may additionally be brought on by infections, metabolic disorders, diabetes, obesity, hypertension, and other factors, cardiomyopathy may occur in family. An issue with one or more blood artery or heart components is known as congenital heart disease. It affects roughly eight out of one thousand kids. Some individuals with it may exhibit symptoms from birth, but others may not show signs until later in adolescence or early adulthood.

Most of the time, there is no idea why it occurs. Genetics might be involved, or it could occur if a new-born is given drugs, alcohol, or viral illnesses prior to birth. Heart failure indicates that the heart isn't pumping as hard as it ought to. The body will keep both salt and water as a result, this will

make you swollen and breathless [3]. Over 6.7 million Americans suffer with heart failure, making it a serious health issue. It is the main reason why adults over 65 end up in hospitals. The American Heart Association (AHA) predicts that by 2030, 8.5 million Americans will have been given the diagnosis of coronary artery disease [4]. Regretfully, coronary artery disease cannot be cured, and after it has been identified, it cannot be reversed. However, people can alter the way of living to lower chance of experiencing more health issues, like as heart attack. Wearable technology such as electronic watches, Fit-bits, collar traps, and others are being utilised to continuously track the health of the heart. Such devices don't require hospital-grade medical equipment to read an individual's ECG readings in real time [5]. The precise diagnosis of CVD requires analysis of the ECG data captured using these gadgets. Wearable technology is battery-operated and has processing power limitations when compared to medical technology. As a result, wearable technology is unable to identify the kind of CAD with greater precision. Thus, wearable technology is limited to the monitoring of cardiac function and the assessment of abnormality frequency. They serve as alert systems, and anyone interested in learning more about a particular kind of arrhythmia or heart problem should speak with a physician. Unfortunately, a cardiologist's workload increases along with the number of individuals with heart rhythm disorders. For this reason, it is essential to detect abnormalities using machine learning algorithms. Medical devices that use Machine Learning algorithms can identify the type of heartbeat with greater accuracy. In medical situations, machine learning methods are applied for the advantage of healthcare providers, organisations, and patients [6].

A classic statistical approach for binary classification problems is logistic regression. It is frequently used to detect the probability of CVD depending on a number of risk variables, including age, gender, cholesterol, blood pressure, and so forth. Common artificial intelligence methods for categorisation tasks include random forests as well as decision trees. It can manage non-linear interactions among data and are comprehensible. When compared with single decision trees, random forests especially are more resilient and are not as susceptible to excessive fitting. SVM is a method for supervised training that finds the appropriate hyperplane in a space with high dimensions to divide classes in order to accomplish the task of classification. CVD tasks for prediction have successfully used SVM. Because machine learning techniques, especially neural networks, are capable of learning structures from raw data, they have showed promise in CVD predicting applications. Although Recurrent Neural Networks or models based on transformers are capable of processing sequential information like EHR or clinical notes, CNN are able to be employed using images from medical imaging like X-rays, MRIs, or CT images. One kind of RNN that performs well for consecutive analysis of information is a type of Long Short-Term Memory (LSTM) network [7]. Through the processing of time-series data, such as electronic health records (EHRs), which are collections of occurrences over a period of time they can be used for predicting the possibility of CVD.

For the purpose of making simulations more accurate, attentive techniques were implemented in deep learning

architectures in order to concentrate on pertinent portions of the input information. Models based on transformers have been successful in analysing medical records or free-text information for CVD diagnosis. One of these models is the well-known Bidirectional Encoder Representations from Transformers. Multiple frameworks are combined in ensemble methods to increase prediction precision and generalisation. For CVD prediction problems, methods like as bagging (Bootstrap Aggregating) or boosting (e.g., AdaBoost, Gradient Boosting Machines) can be used on a variety of core learners, including decision trees and artificial neural networks. Because labelled data is scarce in medical applications, learning through transfer entails applying large-scale, trained algorithms to problems using smaller datasets. Medical imaging data can be used to fine-tune models that have been trained, such as those generated on ImageNet, for the diagnosis of CVD. These techniques can be used separately or in combination, based on the CVD forecasting task's specific needs and the data that is available. When implementing machine learning and deep learning models in healthcare settings, other crucial factors to take into account are modelling interpretability, confidentiality of data, and compliance with regulations [8].

Among the research's noteworthy achievements is the creation of a novel hybrid CNN-XGBoost technique for the detection of CVD. By combining CNN's power for feature extraction from medical image collections with the resilience and understanding of a gradient boosting algorithm XGBoost, this approach provides an extensive solution for accurate CVD diagnosis. When it comes to identifying minor subtleties that point to cardiovascular issues, the CNN component is excellent at extracting complex patterns as well as characteristics from medical images like MRIs and X-rays. Following that, XGBoost expertly combines the learned traits with additional pertinent clinical data to improve prediction accuracy and offer valuable information about the relative significance of each feature to support medical decision-making. Better patient outcomes and earlier identification may emerge from this exciting method of enhancing CVD diagnostics via the combining of deep learning and traditional machine learning approaches. The key contributions of the suggested model are listed below:

- 1) The study presents an innovative method to anticipate CVD that combines CNN with the gradient boosting technique XGBoost.
- 2) The paper discusses the significance of normalization approaches such as Decimal Scaling, Min-Max, and Z-Score for pre-processed information. By implementing information within a specified range, this step improves the model's effectiveness and ensures information homogeneity.
- 3) The research automatically extracts pertinent information from medical images, such as images of the heart, using CNN in order to identify significant trends and traits associated with CVD.
- 4) Using the merged dataset, the CNN-XGBoost algorithm is trained in the research, and the model variables and hyper parameter settings are optimized. In order to enhance its effectiveness and fit the information more accurately, the

algorithm's parameters are adjusted in this stage to increase the effectiveness and generality of the prediction.

5) To merge the predicted results of individual CNNs, XGBoost is utilized in ensemble learning approaches.

The paper is structured as follows: Section II comprises relevant material designed to help readers comprehend the proposed paper using existing methodologies, while Section III elaborates on the problem description. Section IV displays the proposed CNN-XGBoost architectures. Section V includes tabular and graphical representations of the results and performance indicators. Discussion in Section VI. Finally, in Section VII, the conclusion and future works are discussed.

II. RELATED WORKS

Mathur et al., [9] suggested the use of artificial intelligence in cardiovascular care, namely machine learning as well as deep learning. Artificial intelligence (AI) programs have helped us better comprehend cardiac failure and hereditary coronary artery disease. These uses led to better topics covered include treatment techniques for multiple cardiovascular conditions, novel approaches to medication therapy, and a post-marketing assessment of prescription pharmaceuticals. Applications that utilize AI face difficulties with medical application and comprehension, such as confidentiality of information, obsolete information, choice bias, and inadvertent perpetuation of prehistoric biases/stereotypes, leading to incorrect inferences. However, artificial intelligence (AI) is a disruptive invention with tremendous promise in wellness. Compared the detection skills of four healthcare structures: Dxplain, Iliad, Meditel, and QMR. Recommended that such initiatives be employed. Doctors that can effectively utilize the data offered by such platforms. The network-based model displayed 86.3% sensitiveness, 85.7% precision, and 85.7% reliability, in that order. Employed conventional coronal images automated categorization to real-time heart function assessment, achieving a 95% reliability rate.

Deshai et al., [10] suggested a two-stage strategy for accurately predicting serious heart problems. Involved training the neural network with an improved sparse auto encoder (SAE), an unstructured neural network that operates forecasting of a wellness for operation. The artificial neural network (ANN) focuses on the gathered materials. The SAE was properly designed to ensure a successful model. The recommended method outperformed the ANN classification's reliability as well as efficacy. A deep learning approach that works in a transudative way is suggested for sparse demonstration-based categorization. The system includes a fully connected layers and a convolution-based an autoencoder. An increased approach. Limited autoencoder ANN may accurately forecast serious cardiac conditions in a trustworthy and effective method. A sparse auto encoder identifies the most effective database demonstrations, while the ANN makes forecasts based on acquired attributes. The SAE can be improved through an Adam method and sequential normalization techniques. The classifier's accuracy on the studied datasets is 91%. Compared to traditional machine learning algorithms as well as artificial neural networks, the method that was suggested yielded better results.

Wang et al., [11] proposed networks to distinguish between Breast Artery Calcification (BAC) and non-BAC and use a pixelwise, patch-based method for identifying BAC. To evaluate the efficacy of the system, conducted a readership study with qualified physicians to offer reliable input. Evaluated the outcome of 840 full-field digitized radiographs across patients utilizing FROC plus calcium density characterization analyses. The FROC study indicates that deep learning reaches a degree of identification comparable to experienced specialists. Calcium density measurements the estimated calcium density closely matches the earth's truth, using a linear correlation producing an error of measurement of 96.24%. These findings show that deep learning techniques can be utilized to construct a computerized system for detecting BAC in mammograms, assisting in identifying and assessing individuals with risk factors for CVD. A computerized technique for detecting BAC and estimating calcium in mammogram was studied as potential risk factors for coronary artery disease (CAD) sickness. Investigated the relationships among the two viewpoints (CC vs. MLO) in the anticipated and ground-truth BAC regions, and calcium standards, and Within the R and L breasts. While these occurrences have not been thoroughly examined in the literature, it seems plausible to anticipate an extensive level of interaction between both perspectives and those of both the right as well as left breast.

Kelvin et al., [12] suggested the flexible characteristics of deep learning (DL) for CVD picture categorization, division, and identification for Effective control of challenges for implementing deep learning in the medical field. Recent advancements in the fields of computing and neuroscience have resulted in the invention of complex perceptron systems backward propagation neural network representations, and CNN. Classical models include neural network (CNN) a deep belief network (DBN) among others. The results of this research have sped up the growth of deep learning algorithms, enabling their widespread use throughout medical disciplines. DL approaches are used to recognize and locate surgical videos and have proven effective in practical practice. To identify and categorize the various forms of myocardial plaque, the use of CNN and recirculating neural networking mixture was suggested. This approach did not involve manual extraction of features and took into account both spatial and temporal data found in multiplanar reformatted images involving the coronary arteries. A 3D CNN could be used to extract characteristics in the coronary arteries. Such collected features can then be aggregated by running recurrent neural networks for two concurrent multi-class task classifications. The technique just requires the collection of the coronary artery baseline from coronary CT angioplasty as input from the user, in contrast to most current techniques that depend on myocardial epithelial fragmentation to identify and describe myocardial plaques and constriction. The technique effectively divides individuals into two groups: those lacking coronary plaque and those who need a second CV assessment because they have both constriction and myocardial blockage.

Kuang et al., [13] proposed the LSTM with reducing uneven duration among treatment phases to generate a time-dependent vector of features. Enhanced LSTM by normalizing uneven duration among treatment periods to produce longitudinal

vectors of features. The memory loss limit uses a spatial vector of features to efficiently handle unpredictable time. The space that separates multi-period information improves the algorithm's ability to predict. The idea put forward improves the internal mechanism for forgetfulness gate input. Smoothing the uneven period of time yields the time variable vectors, which is subsequently sent into the forgetful gate to solve the problem. The uneven time gap creates an impediment to forecasting. The suggested changing forecasting approach outperformed the classic LSTM approach to accuracy in classification, demonstrating its efficacy. Modified the threshold value arrangement in the LSTM unit to acquire behavioural characteristics related with CVD progression at various time intervals before using LSTM to handle sequence information with irregular time intervals. Next, suggest use the objective to repetition a technique for predicting the hidden layer's output at every step that can make developing a model with varying time series lengths easier. In order to anticipate the patient receiving many diagnosing tag as results, a sigmoid function is ultimately used as the resulting layer of the framework as the activation element for the multi-tag result.

Komal et al., [14] suggested the use of neural network tree classifiers to predict CVD. The device Various training tree classification algorithms, including Random Forest, Decision Tree, Logistic Regression, support vector machine, and the k-nearest-neighbours algorithm, have been evaluated based on accuracy and AUC ROC ratings. The Random Woodland Machine Learning classification performed well in predicting CVD, with an 85% accuracy, ROC area under the curve of 0.8675, with implementation duration of 1.09 seconds. In this study, machine learning classifiers including K-nearest neighbours, Random Forest, Decision Tree, Logistic Regression, and Support Vector Machine had been utilized for the intended use Heart illness. Prognosis. The suggested approach, that classified people with heart failure utilizing the random forest machine learning classification algorithm, beat every other classifier examined in terms of precision, achieving a higher 85.71% as well as a ROC average area under the curve of 0.8675. When compared to the remaining classifier in the investigation, the random forest classifier produced an inaccurate classification rate of 85.71% for the examples that are larger.

Jian et al., [15] suggested a machine learning-based technique which is simultaneously precise and effective in detecting heart problems. The system was created using classification methods, which comprise Artificial neural networks, Logistic regression, Support vector machine, Although common selection techniques like Relief, Minimal redundancy maximum significance, Least relative shrinking selection manager, as well as Local learning were used to remove unnecessary and redundant characteristics, K-nearest neighbour, Naïve bays, and Decision tree have also been utilized. In order to address the feature choice challenge, suggested a unique fast conditionally mutual data feature choosing approach. The characteristic selection methods are employed to pick elements in order to improve the precision of classification and shorten the overall time of operation. In addition, tweaking hyperparameters and learning the best techniques for model evaluation have been

accomplished through the application of the leaving one topic out the cross-validation technique. The classifiers' abilities are evaluated using performance measurement measures. The participants' contributions have been examined in relation to the characteristics that the selection of features techniques choose. The experimental findings demonstrate the viability of using a classifier support vector machine in conjunction with the suggested feature selection algorithm to create an advanced neural network which can detect coronary artery disease. Comparing the recommended diagnosis methodology to other approaches that had been offered, excellent accuracy was attained. Furthermore, the suggested approach is simple to use in the medical field to identify cardiac illness.

Several research investigated the potential for the use of AI and deep learning in cardiovascular care, with a focus on applications such as comprehending heart failure and heart disease, therapeutic methods, pharmacological therapy, and pharmacological assessment. Problems like as privacy and bias were noted, but AI was rated beneficial for medicine. Strategies such as artificial neural networks with sparse autoencoders and deep learning algorithms were presented for reliable heart condition estimation, exceeding standard methodologies. Deep learning algorithms shown efficacy in detecting BAC and myocardial plaque, which aids in cardiovascular risk assessment. LSTM networks were improved to manage irregular time intervals, resulting in higher prediction accuracy. Neural network tree classifiers, notably Random Forest, were highly accurate for estimating CVD outcome. Furthermore, methods based on machine learning based on multiple classifiers and methods for choosing features were proposed for effective cardiac diagnosis, resulting in good accuracy and ease of application in hospitals. Overall, this research demonstrates the enormous potential of AI and deep learning to transform cardiac healthcare through better diagnostics and prediction abilities.

III. PROBLEM STATEMENT

Traditional machine learning methods, such logistic regression or support vector machines, are not particularly effective at diagnosing CVD because they depend on artificial features that may not accurately capture the complex patterns found in medical data. Moreover, autoencoders may be prone to over fitting, especially in situations with little training data, even if they are capable of learning models from raw data. A unique approach built on a hybrid CNN and XGBoost framework was created to overcome these shortcomings. The CNN-XGBoost method, in contrast to conventional machine learning approaches, makes use of CNNs' hierarchical characteristic acquisition capabilities, allowing it to identify and eliminate significant characteristics from medical images without the need for further advancement of features. Moreover, the model can effectively handle tabular data pertaining to patient data, health information, and clinical factors by combining CNNs with XGBoost's collaborative learning technique, which enhances the model's predicting accuracy and generalization. By integrating CNN capabilities with XGBoost, this hybrid technique addresses the shortcomings of previous approaches and provides a more accurate and long-lasting cardiovascular detection solution [15].

IV. PROPOSED HYBRID CNN-XGBOOST MODEL

The methodology commences by sourcing input data from a Kaggle dataset housing objective, examination, and subjective parameters pertinent to cardiovascular health. Pre-processing ensues, employing normalization techniques like Min-Max, Z-Score, and Decimal Scaling for consistency and heightened model efficacy. Feature extraction is executed utilizing Convolutional Neural Networks (CNNs), autonomously gleaning relevant features from clinical images, notably cardiac pictures, capturing pivotal patterns and characteristics. Following this, pre-processed and feature-extracted data undergoes ingestion into an XGBoost classifier for CVD prediction, capitalizing on its robustness in classification tasks. Hyperparameter tuning is subsequently conducted to refine model parameters, augmenting efficiency

and generalization. Ensemble learning techniques are then deployed, amalgamating predictions from separate CNN and tabular algorithms. Ultimately, the framework's functionality is scrutinized and verified with appropriate metrics, evaluating its efficacy in predicting CVD on previously unseen data. The proposed methodology integrates an array of techniques, spanning from data pre-processing to ensemble learning, culminating in the development of a dependable and precise predictive model for CVD identification. Fig. 1 illustrates the sequential flow of the methodology, showcasing the cohesive integration of data processing, feature extraction, classification, and validation steps. This systematic approach ensures a comprehensive and robust framework for accurately identifying cardiovascular disease, thereby contributing to enhance clinical decision-making and patient care.

Fig. 1. Workflow of proposed methodology.

A. Data Collection

Through the use of a Kaggle dataset, it investigates the potential applications of artificial intelligence for medical prediction. Three types of data entry parameters are available: objective, examination, and subjective. It offers an alternative viewpoint on the issues people have with their health. It looks for patterns and predictions for a range of diseases using sophisticated modelling and assessment methodologies. By using statistical techniques and artificial intelligence (AI), the helpful details from this study can assist scholars and medical professionals in estimating difficult patient data [16]. Table I depicts the characteristics of the dataset.

B. Data Pre-Processing

Data mapping to a variety of scales is the aim of normalization strategies. There are many different kinds of normalizing methods in the literature. To preprocess the research data, three normalization methods are employed: Min-Max Normalization, Z-Score Normalization, and Decimal Scale Normalization. Min-Max Normalization linearly alters the initial dataset, ensuring that the normalized outcomes fall within a specified range, thereby enhancing consistency and model performance. Z-Score Normalization, also known as Zero Mean Normalization, utilizes the mean and standard deviation of the data to normalize it, effectively standardizing the distribution and facilitating comparison between different variables. Decimal Scale Normalization involves adjusting the numeric scale based on the smallest value of the characteristic,

shifting the decimal point of values accordingly to maintain consistency across the dataset. These preprocessing methods confirm that the information is standardized, consistent, as well as suitable to be used for feature extraction as well as prediction modelling tasks.

TABLE I. DATASET CRITERIA

Feature	Type	Variable Name	Description
Age	Objective Feature	age	Integer (days)
Height	Objective Feature	height	Integer (cm)
Weight	Objective Feature	weight	Float (kg)
Gender	Objective Feature	gender	Categorical code
Systolic blood pressure	Examination Feature	ap_hi	Integer
Diastolic blood pressure	Examination Feature	ap_lo	Integer
Cholesterol	Examination Feature	cholesterol	1: normal, 2: above normal, 3: well above normal
Glucose	Examination Feature	gluc	1: normal, 2: above normal, 3: well above normal
Smoking	Subjective Feature	smoke	Binary (0 or 1)

Alcohol intake	Subjective Feature	alco	Binary (0 or 1)
Physical activity	Subjective Feature	active	Binary (0 or 1)
Presence or absence of CVD	Target Variable	cardio	Binary (0 or 1)

1) *Min-max normalization*: The initial data set is altered linearly by min-max normalization. The normalized outcomes fall into the specified range. The calculation is provided by, for translating a v value of a property from range $[min_z, max_z]$ to a new range of $[new_min_z, new_max_z]$.

$$\frac{v - min_z}{max_z - min_z} (new_max_z - new_min_z) + new_min_z \quad (1)$$

where, v is the updated value inside the necessary range. Min-Max normalization has the advantage of annealing every value in a specific range[17].

2) *Z-Score normalization*: Another name for Z score normalization is Zero mean normalization. In this case, the difference between the standard deviation and mean are used to normalize the data. Next, the equation is

$$d' = \frac{d - mean(X)}{std(X)} \quad (2)$$

where, Mean(X) = sum of the all-attribute values of X; Std(X) =Standard deviation of all values of X.

3) *Decimal scale normalization*: The process of normalization of the numeric scale determined by the change of the characteristic's smallest value. The greatest absolute amounts of each property determine how the decimal point of values are shifted. A normalization equation for the decimals scale is,

$$d' = \frac{d}{10^n} \quad (3)$$

where, n is the smallest integer that $\max(|d'|) < 1$.

C. Feature Extraction and Classification using CNN-XG-Boost Model

The suggested approach for predicting CVD makes use of an innovative model that combines XGBoost and CNN. First, normalization of data is used to preprocess the Kaggle dataset in order to guarantee consistency and improve model performance. The CNN model undergoes training on normalized data after pre-processing in order to extract pertinent characteristics gathered from cardiac pictures. The collected characteristics are then passed into an XGBoost algorithm to enhance accuracy and further fine-tune predictions. This hybrid strategy aims to improve the predictive potential for the identification of cardiovascular illness by utilizing the advantages of both CNN for feature extraction from images and XGBoost for the classification of images [18].

In the method of machine learning, a map of features is made for the data, and the classifier is then used to address the issue. Additionally, each challenge has a different set of facts, and the approaches used to solve it vary depending on the issue. CNN is therefore utilized to automatically produce characteristics and integrate them into the classifiers in order to

prevent it. Among the CNN classifier's benefits is that, of all the classification algorithms, the method's list of layers that convert the input amount to output amount is the easiest. These aren't many distinct layers, and each of them uses an identifiable function to convert the input to the output. One drawback is that their projections do not take the object's direction and placement into account. Either forward or reversed, the convolution process operates far more slowly than, example, max pool. Every training stage will take considerably more time if the network is large.

Convolutional, ReLu, and max pooling layers are among the numerous layers that make up a CNN architecture. AlexNet served as inspiration for the design. Conv2D, ReLu, Max-pooling, and a completely connected layer make up its six layers. Additional layers, such as dropout, are incorporated into the network to improve training success. The dropout component is only turned on when you're training. In the forward motion (input to the function), the dropout stage arbitrarily removes a certain number of neurons and retains the remaining neuron after the forward transit. Only the drop after the backwards changes the non-dropped. One element which contributes to normalization is the dropouts. By teaching the algorithm resilient characteristics that do not rely on the neurons, the dropout layer helps the model prevent excessive fitting in its training process [19]. Fig. 2 represented the CNN-XGBoost Classification Network.

CNN usually consist of multiple layers, each with a specific function. Accessible filtering is used by the convolutional layer in order to acquire attributes from the information that is input. Activation layers introduces non-linearity and aids in capturing complicated trends. Layer pooled reduces computing load and preserving vital information by downsampling features networks. The resultant layer, which generates the final estimates, is the result of completely interconnected components that combine retrieved information for tasks involving extrapolation or categorization. All of these parts come together to create the framework of the CNN , making it possible to identify connections and extract details from intricate data sources like text as well as pictures [20].

An activating function (f), a selection term, and an array of filters that can be learned or kernel (K) are applied to the feature map(X) that is input within the convolutional layer of a CNN network. The neural layer's mathematical formula is expressed as:

$$Y = f((X \times K) + a) \quad (4)$$

where, X represents the input feature map, K represents the set of learnable filters/kernels. ' a ' represents the bias term, $*$ denotes the convolution operation represents the output feature map after applying the convolution operation, adding the bias, and applying the activation function f .

Following the convolution process, the feature map X is subjected, element-by-element, to an activation function. Tanh, sigmoid, and ReLU (Rectified Linear Unit) are examples of common activation functions.

$$Y = f(X) \quad (5)$$

Fig. 2. CNN-XGBoost classification network.

Pooling layers is employed for down-sampling the map attributes, preserving significant data while reducing the number of dimensions. A popular method is called "max pooling," in which the highest value found inside a window is used. Assigning a letter P to the pool procedure

$$Y = P(X) \quad (6)$$

The maps of features have been flattened and put into a number of completely linked layers following one or more convolutional and pooling layers. The resultant value O can be computed as follows if we designate the flattening feature map as X, K as the weights, and s as the term representing the bias of the layer that is completely connected.

$$O = f(X.K + s) \quad (7)$$

The final estimates are produced by the output layer. The type of issue determines this layer's activation function. One frequent function of activation used for identifying binary issues is the sigmoid.

XGBoost is an effective technique for classification, in addition regression [21]. It functions as a set of applications that have won machine learning contests on Kaggle. Drawing from a gradient enhancing framework, XGBoost continually creates new decision trees in order to increase learner performance and efficiency while fitting a value using residual many rounds. With a better trade-off between bias and variance, XGBoost approximates the loss function using a Taylor expansion. It often requires less trees of decisions to achieve a greater accuracy. XGBoost uses the reduced model complexity to add normalization to the standard function. The residual error is fitted by utilizing the initial and second derivatives. Additionally, columns selection is supported by this technique in lowering excessive fitting and cutting down on processing. Thus, compared to the gradient

boosting decision tree, higher improvements result in more the hyper-parameter. Still, it is challenging to adjust the extreme parameters in a reasonable way. In addition to the researchers' past knowledge and experience with tuning parameters, a reasonable setup necessitates a significant amount of time. Hyper-parameter optimisation works well in solving this issue. The equation for the prediction \hat{y}_i using XG-Boost can be represented as follows:

$$\hat{y}_i = \Phi(x_i) = \sum_{k=1}^N f_k(x_i) \quad (8)$$

where, \hat{y}_i is the predicted output for the i^{th} observation, $\Phi(x_i)$ is the final prediction function, N is the number of weak learners, $f_k(x_i)$ is the prediction of the k^{th} weak learner for the input x_i

Established enhancing is how XGBoost actually manages excessive fitting and complexity of models. The process of regularization factors is employed to punish difficulty, and a function with losses is often included in the function of objectives utilized by XGBoost to assess the disparity between the actual and predicted values. In order to determine the perfect combination of learners with weaknesses, the model optimizes the aforementioned objective function while training. In general, the algorithm's additive feature—multiple weak learners merged to build a learner who is strong by weighing the total of their separate predictions—is encapsulated in the XGBoost predictions solution. XGBoost, also known as eXtreme Gradient Boosting, being a collaborative learning strategy that emphasizes correcting mistakes in previous models while concurrently building numerous decision trees to continuously reduce a predetermined loss parameter. The total prediction power is increased by building each new tree with the intention of capturing the error or residuals of the preceding ones. a number of the most popular and efficient machine

learning methods for tasks such as classification and regression, XGBoost uses regularization terms in the goal function to prevent excessive fitting and integrates an innovative gradient boost method that maximizes both performance and accuracy of models.

The fundamental component of XGBoost is the goal function, which is created to penalize complexity while minimizing loss L. Usually, it is composed of two components: the regularization term $\Delta(f)$, which reflects what is predicted model, and the corresponding loss function [22].

$$L(x_i, \hat{x}_i) + \Delta(f) \tag{9}$$

where, x_i is the true label of the i-th sample, \hat{x}_i is the predicted value for the i-th sample. To modify the model, one computes the slope of the impairment function in relation to the expected scores. The change in the gradient g_i in relation to the projected score for an overall distinguished function of loss L can be calculated as follows:

$$g_i = \frac{\Delta L(x_i, \hat{x}_i)}{\Delta \hat{x}_i} \tag{10}$$

The goal of XGBoost's tree boosting technique is to minimize the total objective function by adding new models, or trees, to the system. The following provides the update procedure for appending an additional tree to the model is depicted in Eq. (11). The Algorithm 1 illustrates the mechanism of CNN-XGBoost method.

$$\hat{z}_i^{(t)} = \hat{z}_i^{(t-1)} + \Delta \cdot h(y_i) \tag{11}$$

Algorithm 1: CNN-XG-Boost mechanism

Input: Data from Kaggle dataset

Output: Identification of CVD

Load input data (Age, Height, Weight, Gender, Systolic blood pressure, Diastolic blood pressure, Cholesterol, Glucose, Smoking, Alcohol intake, Physical activity.

Apply convolution operation using learned filters.	
Apply activation function to introduce non-linearity.	
Apply pooling operation to down sample the features.	
Extract the output feature maps from desired intermediate layers of the CNN model	
Classification	//CNN-XG-Boost

V. RESULTS AND DISCUSSION

The use of a CNN-XGBoost model for cardiovascular illness diagnosis in Python produced good results, demonstrating its efficacy as a successful diagnostics tool. By combining the capabilities of CNN and the XGBoost boosting approach, the model displayed strong performance in distinguishing between both positive and negative cases of heart failure. This fusion approach successfully extracted complicated patterns from complicated cardiovascular data, resulting in improved diagnosis accuracy. The findings imply that the CNN-XGBoost model has potential for early identification and intervention in coronary artery disease, making it a significant tool for doctors in maximizing the treatment of patients and management. Further refining and confirmation of the algorithm on bigger data sets and various demographics is necessary to ensure its usefulness and usefulness in real-world healthcare environments.

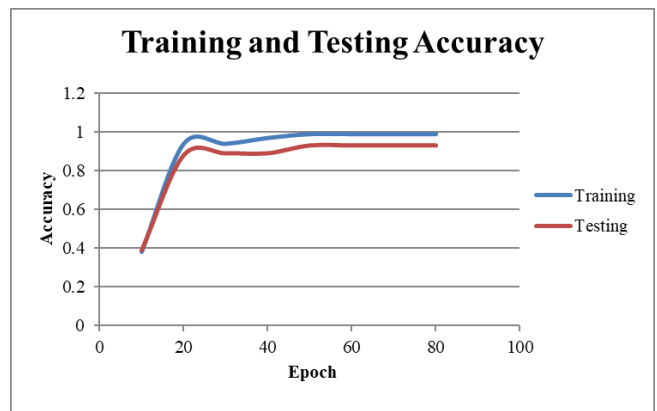

Fig. 3. Graphical representation for training and validating the accuracy of the proposed approach.

The training-testing accuracy graph for CVD detection using the CNN-XGBoost model depicts how well it performs during various phases of training and testing rounds. Initially, as the model is trained, its accuracy gradually improves, showing good training and extraction of features from cardiac data. In testing, the graph illustrates the model's capacity to generalize to previously unknown information, with accuracy declining at a high level, showing strong performance in diagnosing cardiovascular illnesses. This graph demonstrates the gradual improvement of training and testing accuracies, indicating little over fitting and a well-generalized framework. In general, the curve depicts the model's learning dynamics and accuracy in diagnosing cardiovascular disorders at different phases of growth and analysis. Fig. 3 shows Graphical representation for training and validating the accuracy of the proposed approach.

Training-testing deficit graph for CVD detection employing the CNN-XGBoost model demonstrates the model's minimization and adaptation potential. Initially, in training, the loss gradually lowers as the algorithm learns to eliminate mistakes and increase its prediction accuracy on the used training data. When training advances, the loss gradually decreases until it reaches a minimum, signifying optimal convergence. During testing, the loss graph illustrates the model's capacity to generalize to previously unseen data while

keeping the loss reasonably low, indicating that it's able to generate correct predictions on new data points. The resulting curve is a visual representation of the model's learning dynamics, demonstrating the balance between complexity of the model and generalization how they perform, and highlighting its effectiveness in detecting cardiovascular illnesses while reducing overfitting from occurring. Fig. 4 shows Graphical representation of loss in proposed CNN-XG Boost.

TABLE II. EXPERIMENTAL RESULT ANALYSIS FOR DIFFERENT PARAMETERS WITH OTHER METRICS

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)
Extra Tree Classifier [23]	90	87	91	89
Logistic Regression [23]	88	79	93	85
DNN [24]	87.59	97.77	76.27	65.54
LR [25]	87.60	87.05	90.98	88.97
SVM [25]	81.82	77.30	94.74	85.14
Proposed CNN-XG-Boost	98.7	98	97.9	96.98

Table II provides a comprehensive comparison of performance metrics across various machine learning models, including Logistic Regression (LR), Deep Neural Network (DNN), Support Vector Machine (SVM), Extra Tree Classifier, and the proposed CNN-XG-Boost approach. Each row corresponds to a specific model, while columns represent assessment criteria such as accuracy, precision, recall, and F1-score, expressed as percentages. For instance, the Logistic Regression model achieved accuracy ratings of 87.60%, with corresponding precision, recall, and F1-score values of 87.05%, 90.98%, and 88.97%, respectively. On the other hand, the DNN model garnered accuracy of 87.59%, but displayed higher precision at 97.77%, albeit lower recall at 76.27%, resulting in an F1-score of 65.54%. Similarly, the SVM and Extra Tree Classifier models underwent evaluation using these criteria, with respective performance scores recorded. However, it's noteworthy that the suggested CNN-XG-Boost model outshines its counterparts significantly. With impressive accuracy, precision, recall, and F1-score values of 98.7%, 98%, 97.9%, and 96.98%, respectively, it demonstrates unparalleled

efficiency in the task at hand compared to conventional techniques. This comparative analysis underscores the superior performance of the CNN-XG-Boost model, indicating its potential as a highly effective tool for CVD identification and classification. By surpassing existing models across all key metrics, the suggested approach establishes itself as a frontrunner in the field, offering heightened accuracy and reliability in cardiovascular health assessment. The clear advantage exhibited by the CNN-XG-Boost model highlights its suitability for real-world applications, where precise and timely diagnosis is paramount. As such, its implementation could lead to enhanced patient outcomes and streamlined healthcare processes. Moreover, the robustness of the proposed model suggests its adaptability to diverse datasets and clinical scenarios, further solidifying its position as a valuable asset in the realm of cardiovascular disease management and prevention.

Fig. 5. Performance evaluation for different methods of classification.

The performance assessment of the suggested hybrid CNN-XGBoost model is presented in tabular format, highlighting its superiority over other types of classifiers, particularly in terms of accuracy. While the median recall and precision of existing approaches may surpass those of the suggested model, the average accuracy and recall serve as crucial indicators of categorization, alongside the F1-score. In Fig. 5, a pictorial representation of the performance evaluation elucidates the model's strengths and areas for improvement. The visual depiction aids in understanding how the suggested hybrid model fares against competing classifiers, emphasizing its superior accuracy and potential for enhancing categorization accuracy. Despite potential variations in individual metrics such as recall and precision, the overall performance of the CNN-XGBoost model shines through in terms of its accuracy, as indicated in the tabular assessment. This comprehensive evaluation approach ensures a nuanced understanding of the model's capabilities, allowing for informed decisions regarding its implementation in real-world scenarios. As the field progresses, continued refinement and optimization of the CNN-XGBoost model will likely further improve its performance metrics, potentially bridging any gaps in recall and precision observed in comparison to existing approaches. This iterative process of evaluation and enhancement ensures that the suggested model remains at the forefront of CVD classification research, driving advancements in diagnostic accuracy and patient care. Table III provides the comparison of various

dataset with the proposed dataset used in the study. It shows the proposed work dataset achieves higher accuracy when compared with another dataset.

TABLE III. DATASET COMPARISON

Dataset	Accuracy
AptaCDSS-E [26]	66.00
GitHub PCG – CNN [27]	86.57
Pascal Challenge [28]	96.25
Proposed CVD Dataset	98.7

VI. DISCUSSION

The use of a CNN-XGBoost model for CVD detection offers an exciting opportunity to improve diagnostic accuracy and predictive capacities in this essential healthcare domain. This hybrid model, which combines the CNN for feature extraction with the XGBoost algorithm for classification, can successfully capture subtle correlations and trends in cardiac data, allowing for more precise estimations. Compared to other techniques such as Extra Tree Classification algorithm [23], logarithmic regression [24], DNN [24], LR [25], and SVM, the CNN-XGBoost model has significant advantages. The proposed CNN-XGBoost hybrid method for cardiovascular disease (CVD) detection achieves superior accuracy (98.7%) and balanced precision (98%), recall (97.9%), and F1-score (96.98%) compared to existing methods like Extra Tree Classifier, Logistic Regression, DNN, LR, and SVM. This approach integrates CNN feature extraction with XGBoost classification, offering robustness and precision in CVD prediction. First, the CNN component enables the automatic extraction of features from raw input data, avoiding the requirement for feature engineering by hand and possibly enhancing the accuracy of the model. Furthermore, the XGBoost algorithm, which is well-known for its durability and effectiveness when working with huge datasets, refines the retrieved features and increases classification accuracy. The combined use of deep learning and gradient boosting approaches provides a potent approach to CVD identification that outperforms current techniques.

Furthermore, the CNN-XGBoost model's capacity to incorporate time and space variables from heart data sets might offer more extensive insights into the underlying physiological processes that contribute to CVD. By efficiently collecting complicated trends and interconnections in the data, this model has the potential to uncover subtle signals and early warning signals for cardiovascular problems, allowing for prompt treatment and proactive measures. In addition, the XGBoost algorithm's interpretability enables physicians to obtain insights into the major aspects influencing CVD prediction, resulting in more informed decision-making and individualized patient care plans. Overall, the CNN-XGBoost model is a promising approach to CVD detection, with enhanced accuracy, interpretability, and the possibility for early detection and intervention, resulting in improved patient outcomes and healthcare oversight.

VII. CONCLUSION AND FUTURE WORKS

The proposed method represents a significant advancement in cardiovascular disease (CVD) identification and classification, offering superior accuracy and efficiency compared to existing classifiers, making it a promising avenue for future research. With an impressive accuracy rate of 98.7%, recall of 97.9%, precision of 98%, and an F1 score of 96.98%, the provided model outperforms previous approaches, showcasing its robustness and reliability. In contrast to the Deep CNN-SVM approach, the chosen classification methodology of the proposed model demonstrates exceptional efficiency. By leveraging the hybrid technique of CNN and XGBoost, the model achieves remarkable performance in detecting CVD, providing clinicians with a reliable and accurate method of diagnosis. This fusion of CNN and XGBoost capitalizes on the strengths of both methods, effectively identifying subtle patterns within cardiovascular data for early detection and management. The high predictive capability of the CNN-XGBoost model underscores its potential to revolutionize cardiovascular healthcare, empowering clinicians to make timely and informed decisions for patient care. As research progresses, further refinement and validation of this model on diverse datasets will enhance its efficacy and applicability in real-world clinical settings. Continued experimentation with various topologies and refinement strategies holds the key to further improving the efficiency of the CNN-XGBoost classifier. By optimizing model parameters and exploring novel approaches, the model can achieve even higher levels of accuracy and performance, ultimately leading to better medical outcomes and more efficient treatment strategies. Future validation of the suggested approach across different geographical locations and medical disciplines will further validate its effectiveness and generalizability. By testing the model on a diverse range of datasets, researchers can ensure its robustness and reliability across various populations and healthcare settings. In conclusion, the CNN-XGBoost model represents a powerful tool in the realm of CVD detection, offering a comprehensive and accurate approach to diagnosis. With ongoing refinement and validation, this model has the potential to significantly impact cardiovascular healthcare, improving patient outcomes and advancing medical practice.

Utilizing Machine Learning Approach to Forecast Fuel Consumption of Backhoe Loader Equipment

Poonam Katyare, Shubhalaxmi Joshi, Mrudula Kulkarni

Department of Computer Science and Application, Dr. Vishwanath Karad MIT World Peace University, Pune, India

Abstract—This study addresses the challenge of forecasting fuel consumption for various categories of construction equipment, with a specific focus on Backhoe Loaders (BL). Accurate predictions of fuel usage are crucial for optimizing operational efficiency in the increasingly technology-driven construction industry. The proposed methodology involves the application of multiple machine learning (ML) models, including Multiple Linear Regression (MLR), Support Vector Regression (SVR), and Decision Tree Regression (DT), to analyze historical data and key equipment characteristics. The results demonstrate that Decision Tree models outperform other techniques in terms of precision, as evidenced by comparative analysis of the coefficient of determination. These findings enable construction firms to make informed decisions about equipment utilization, resource allocation, and operational productivity, thereby enhancing cost efficiency and minimizing environmental impact. This study provides valuable insights for decision-makers in construction project cost estimation, emphasizing the significant influence of fuel consumption on overall project expenses.

Keywords—Machine learning; construction equipment; fuel consumption

I. INTRODUCTION

The construction sector holds significant importance in driving the global economy, driving infrastructural development, and shaping urban landscapes. Within this dynamic sector, efficient management of resources, particularly fuel consumption, is paramount for ensuring project viability, sustainability, and profitability. As construction companies face increasing pressure to optimize operational efficiency while minimizing environmental impact, the need for accurate forecasting of fuel consumption has become more pronounced [19]. This research investigates the utilization of ML techniques for predicting the fuel usage of BL used at construction sites.

Backhoe Loader demonstrates versatility as it combines the functionalities of a tractor loader and a backhoe in a single machine, making them versatile for various tasks like digging, loading, lifting, and transportation. Backhoe loaders provide excavation and Loading as they excel at excavation tasks such as digging trenches, foundations, and holes, as well as loading materials onto trucks or other equipment. Their relatively compact size compared to dedicated excavators or loaders makes them suitable for job sites with limited space or access.

Incorporating ML methodologies offers a promising avenue for addressing the complexities of fuel consumption forecasting in construction. Historical data and key equipment characteristics help to develop robust predictive models

capable of generating accurate forecasts [22]. Such predictions enable construction firms to make well-informed choices regarding equipment utilization, resource distribution, and project scheduling.

The utilization of ML techniques has increasingly become a focal point in the area of manufacturing and construction, by sharing constructive perceptions along with predictive analytics that boost decision-making methods. In construction, where efficiency and cost-effectiveness are paramount concerns, the ability to forecast fuel consumption for different categories of equipment holds immense significance [4][6]. As fuel represents a substantial portion of operational expenses in construction projects, accurate forecasting outcomes can result in enhanced resource allocation, refined project scheduling, and, ultimately, financial savings.

This research endeavors to explore the utilization of ML approaches specifically tailored to forecast fuel consumption across diverse categories of construction equipment [14]. ML models can offer predictive capabilities that traditional methods may struggle to achieve using past data and major features of the equipment, such as engine specifications, load capacity, and operational conditions.

The focus on ML techniques stems from their ability to handle complex datasets, identify patterns, and adapt to changing conditions, thus providing more accurate and reliable forecasts. By utilizing MLR, SVR, and DT, this research aims to identify the most efficient method for fuel consumption forecasting for the construction industry [8]. The outcomes of the study hold promise for construction companies and project managers, offering them a data-driven approach to estimating fuel consumption for various types of equipment. Such insights can inform strategic decisions related to equipment deployment, maintenance schedules, and project budgeting, ultimately contributing to improved operational efficiency and cost management. Through this research, the study connects conventional methodologies with contemporary technological innovations, fostering a pathway toward a construction sector that is both sustainable and resource-efficient. Valuable insights from this research offer constructive guidance for decision-makers involved in cost estimation and project planning within the construction industry. By shedding light on the significant role of fuel consumption in project expenses, our study contributes to the broader goal of promoting efficiency, sustainability, and cost-effectiveness in construction operations.

The manuscript is meticulously organized, beginning with Section II, which delves into comprehensive reviews of fuel

consumption estimation in construction equipment using ML methods. Section III elaborates on the proposed methodology with real-time dataset preprocessing techniques and ML model implementation for forecasting. Section IV provides detailed experimental results and a discussion of the outcomes. Within Section V, the manuscript ends by presenting final thoughts with conclusions derived from the research endeavor.

II. LITERATURE REVIEW

This literature review covers the major use of ML techniques in various estimation processes. The systematic literature review presented in the document focuses on the application of ML methods in predictive maintenance (PdM) to enhance equipment maintenance practices in industries. The review emphasizes the importance of selecting appropriate machine-learning techniques to optimize PdM applications. Key findings include the benefits of ML in reducing maintenance costs, minimizing equipment faults, increasing production efficiency, improving operator safety, and facilitating planned management. Practical cases of effective PdM applications using ML are highlighted, showcasing the potential of these methods in preventing equipment failures and enhancing overall maintenance operations. The review also discusses the use of Random Forest (RF), Neural Networks, and SVR models with challenges and opportunities, within the realm of predictive maintenance [1].

Prior research focused on constructing a machine learning-based model to anticipate the consumption of fuel utilizing ship data of service. The research aims to enhance energy efficiency in the maritime industry and contribute to the advancement of eco-friendly ships. The study addresses existing gaps in the literature related to fuel consumption models with operational performance optimization in case of shipping sector. Utilizing statistical methods and domain-knowledge-based approaches, researchers used two models Artificial Neural Network (ANN) and MLR to forecast fuel consumption using the data gathered. The models aim to overcome multicollinearity issues and select statistically significant variables for accurate predictions. Outcomes share visions for improving energy efficiency, operational performance, and sustainability in the maritime industry via the usage of ML methods in fuel consumption prediction models [2].

Another investigation examines the significance of precisely forecasting fuel oil consumption (FOC) within the maritime sector to mitigate environmental impact, lower costs, with enhanced operational efficiency. It focuses on creating models using sensor data and weather information to forecast FOC for Very Large Crude Oil Carriers (VLCCs), emphasizing main engine consumption prediction as a key factor. Multivariate Polynomial Regression and ANN were evaluated, with eXtreme Gradient Boosting (XGBoost) showing excellent working. The study provides practical solutions for improving FOC forecasting in maritime operations, with a review of existing literature on FOC prediction methodologies and data sources. The research points out the impact related to high-quality data in boosting prediction precision [3].

Heavy-duty trucks (HDT) are significant fuel consumers within the US highway transportation system, making it essential to have a precise fuel consumption model for

evaluating energy-saving strategies. The proposed model utilizes the longitudinal acceleration of the truck and is trained on field test data sets using a deep-learning neural network. By accurately estimating engine power, the model improves the fuel consumption model with reduced error rates. Including a Long Short-Term Memory (LSTM) allows for the accurate depiction of fuel consumption during engine braking scenarios, a feature not commonly found in conventional HDT fuel consumption models. The model architecture, evaluation metrics, and validation against extensive field data sets are discussed in detail. The study demonstrates that the deep learning engine power model provides accurate fuel consumption estimates and has the potential for various applications in transportation planning and traffic operation studies along with utilizing big data analytics, and a Decision Tree model [4] [5].

An available data summarization approach based on distance for developing individualized ML models for fuel consumption was presented by the existing study with a 1 km window showing high predictive accuracy for fuel consumption. Previous work includes physics-based and ML models. Technologies like V2I with dynamic traffic management can further optimize fuel efficiency at the vehicle, route, and time level. The paper utilizes a data summarization approach based on distance for developing ML models for fuel consumption. The speed and road grade of the vehicle are used in the model. The model aggregates predictors with window sizes of distance covered. Input features are adjusted to account for widely varying means in the model. The model's performance depends on the training procedure with the validation procedure [6].

The review covers carbon emission accounting models. A bottom-up procedure for detailed carbon emission analysis at the microscopic level, involving inventory analysis of building materials and energy use lists. The Economic Input-Output method is presented as a top-down approach for macro-level carbon emission analysis and ANN regression model compared with the SVR model for prediction [7]. Linear Regression, K-nearest neighbor, and ANN algorithms were used to forecast the consumption of fuel related to heavy vehicles with cross-validation to define the best model. The method provides reliable estimates of the true model error. Hyperparameters for the algorithms were defined in the inner loop, and outer loop with the model of best-performing [8]. The researcher discussed a relevant study concerning the utilization of sensor-based technologies integrated with construction equipment to capture real-time data using RF, SVR, XGBoost ensemble method, and Lasso Cross Validation (LassoCV). This data includes location tracking, movement tracking, engine condition, fuel consumption, distance traveled, and battery status. The objective is to enable managers to analyze data collected by remote sensors and make informed decisions regarding equipment performance. Additionally, remote sensing devices are utilized to track construction materials, facilitating supply chain management [9] [10] [19].

Usage of fuel consumption in heavy-loaded truck data minimized using economically optimal control strategies. Along with methodologies included nonlinear time-based formulations penalizing fuel consumption and braking effort,

as well as a linear distance-based convex formulation balancing energy expenditure and velocity profile tracking [11]. Quantitative methods, such as simulation techniques, mathematical models, and decision-making methods, are commonly used in energy efficiency research. Qualitative methods like content analysis and in-depth interviews are also utilized in some studies. Different types of journal articles, including articles, conference proceedings, and review articles, contribute to the diverse methodologies used in energy efficiency research [12]. The study involves data collection for fuel consumption estimation via sensors. The methodology involved the framework design for assessing consumption based on load, slope, distance, and pavement type, enhancing optimization tools' accuracy. The IoT framework collected data from sensors in the truck, storing it for SVR, RF, and ANN algorithms' use. Sensor acquisition was implemented using Python with threads for modularity and fault tolerance [13] [14].

The study developed black-box and white-box models using RF and XGBoost to estimate the fuel consumption of ships. A simulation of several winds along with wave strategies was handled to validate the estimated outcomes, showing the effectiveness of the data-cleaning method in modeling fuel consumption accurately. The models achieved acceptable accuracy in forecasting fuel consumption, highlighting the significance of data quality and the impact of acceleration and deceleration processes on prediction reliability [15]. Related work directs on forecasting the fuel consumption of a public bus applying ML techniques. Predictor variables like distance, speed, longitude, latitude, elevation, and day of the week were used for forecasting fuel consumption. Exploratory data analysis was conducted on the dataset collected from the bus in Sri Lanka, considering factors like route, time, and terrain. ML models such as random forest, gradient boosting, and neural networks were compared for predictive accuracy, with random forest showing the best performance [16]. The study applies deep learning, and linear and non-linear simulations to fuel utilization modeling of trucks using telematic data and road characteristics. Random Forest (RF) algorithm is used to classify the influence of parameters. The research includes 14 variables significantly correlated with fuel consumption, such as gross vehicle weight, road gradient, and engine revs, which are used in developing the models. The RF algorithm allows for the selection of significant variables and is robust to outliers, making it widely used for fuel consumption predictions in various fields [17].

The methodology for data preparation and feature engineering was detailed in the study. Granville's method was mentioned to calculate the hull fouling directly [18]. Another study related to heavy vehicle consumption estimation included the ensemble method as well as consumption in commercial buildings. The study utilizes a dataset comprising relevant variables such as vehicle specifications, driving conditions, and environmental factors to train and evaluate the models. The existing study presents a comprehensive study on the application of RF, SVR, and ANN algorithms to forecast fuel consumption in commercial buildings. The research aims to address the challenges associated with accurately predicting fuel usage in diverse building types and operational contexts.

The study begins by compiling a dataset comprising relevant variables such as building characteristics, occupancy patterns, and fuel consumption information. The findings indicate that ML models outperform traditional statistical methods of anticipating fuel utilization in construction devices. Research influences the understanding of forecasting systems, offering insights that can inform decision-making processes in transportation, logistics, and fleet management industries. Site managers can optimize fuel usage, reduce operational costs, and enhance sustainability in heavy vehicle operations [20] [21].

The related study delves into the utilization of ML methodologies to forecast fuel consumption in mining excavators. The study addresses the critical need for accurate fuel consumption prediction in the case of the mining sector to optimize running costs along boost efficacy. To initiate the research, a comprehensive dataset is assembled, encompassing pertinent variables such as excavator specifications, operating conditions, environmental factors, and historical fuel consumption records. This dataset involves training along with testing RF, Gradient Boosting, KNN, and MLR techniques. Various ML techniques are employed, including linear, nonlinear, and ensemble methods. Each model undergoes training on the dataset to recognize correlations of independent features with fuel consumption metrics. Machine Learning phases from exploratory data analysis to performance measurement of models evaluated. In conclusion, the research influences effective perceptions for the estimation of fuel consumption in mining excavators, offering a data-driven approach to optimize fuel usage, reduce operational costs, and improve sustainability in mining operations. By implementing ML techniques, contributors in the mining industry can make informed decisions to enhance productivity, profitability, and environmental stewardship [22].

The application of predictive maintenance techniques to enhance the reliability and efficiency of construction equipment was demonstrated. The study focuses on harnessing log data generated by the equipment during operation to predict potential failures and schedule maintenance proactively. The methodology involves collecting and preprocessing log data from construction equipment, including variables such as operating conditions, sensor readings, and maintenance logs. Feature engineering techniques are employed and prepared for model training. RF, Logistic Regression, and XGBoost algorithms are applied to the preprocessed data with classification models. These models are trained to classify equipment conditions as either normal or indicative of a potential failure. Cross-validation techniques and performance are employed for the predictive maintenance models. The outcomes exhibit the possibility and efficacy related to the predictive maintenance of log records from construction equipment [23].

The authors investigate the enhancement of thermal conductivity in green buildings through the application of nano insulations. The study employs Gaussian Process Regression (GPR), SVR, and DT methods to optimize the selection and deployment of nano insulations for improved thermal insulation performance. The methodology involves collecting data on various nano insulation materials, including their

properties, compositions, and thermal conductivity characteristics. ML algorithms are utilized to analyze this data and identify correlations between nano insulation attributes and thermal conductivity improvement. The most influential factors contributing to thermal conductivity enhancement were observed. Regression algorithms are employed to develop predictive models for estimating thermal conductivity improvement based on the selected features. The algorithms are tested using experimental data of nano insulation performance in real-world green building scenarios. The findings related to the study provide insights into the optimal selection and deployment of nano insulations for improving thermal conductivity in green buildings. It can reduce heating along cooling costs, and promote sustainability in building design and construction [24].

The existing study explores vehicle trip data for model estimation with artificial intelligence methods to analyze trip-specific variables and accurately forecast fuel consumption. Using ANN, MLR, and RF methods, investors in the transportation industry can optimize fuel usage, improve route planning, and reduce operational costs for heavy-duty vehicle fleets [25].

Another study investigates a method for predicting vehicle fuel consumption using driving behavior data obtained through smartphones. The study utilizes sensor-based data embedded in smartphones for analyzing driving patterns and developing RF, SVR, and Back Propagation neural network predictive models for fuel consumption. The methodology involves collecting driving behavior data from smartphones, including variables such as acceleration, braking, speed, and route information. Feature engineering techniques are applied to preprocess the data and extract relevant features indicative of fuel consumption patterns. This reveals the feasibility of using smartphone-based driving behavior data to predict vehicle fuel consumption accurately and leads towards fuel-efficient driving strategies, optimize vehicle performance, and reduce fuel costs for drivers and fleet operators [26].

A. Research Gap

As is commonly understood, predicting fuel usage may depend on factors such as route features, vehicle specifications, and driving habits. This study tackles the scientific hurdle of identifying which factors have the highest influence related to fuel consumption in vehicles. A significant challenge lies in the difficulty of obtaining accurate consumption from equipment. Reliable consumption data of fuel are essential for accurately training ML algorithms, making it imperative to secure these data with certainty. However, it's common for this information to be unreliable, often underestimating the actual values.

The complexity of advanced recent tools makes it impractical for integration into such uses. Nevertheless, with the rapid advancement of remote monitoring systems, ML applications in this field have achieved success across various sectors. These encompass earthworks productivity, slope safety, jet grouting compressive strength, as well as pavement management and monitoring. The Indian construction sector encounters difficulty in accurately estimating fuel consumption owing to its limited digitalization. Estimating the fuel

consumption necessary for construction equipment at job sites is imperative.

III. PROPOSED METHODOLOGY

The objective of the proposed study is to forecast the fuel consumption of construction equipment from the IoT-enabled sensor data received from devices. This study used the highly utilized equipment on the job site. These include the Backhoe Loader equipment data. Real-time data is collected from the smart sensing devices in daily behavior. The systematic flow of the proposed study is represented in Fig. 1. Fuel consumption forecasting flow diagram. The proposed system is majorly distributed in phases of data preprocessing, feature computation, and selection, forecasting of data, and performance evaluation phase.

Fig. 1. Fuel consumption forecasting flow diagram.

A. Data Collection from Devices

IoT-enabled smart sensor data from devices is captured and daily logs are received from March 2022 to January 2023 for the construction equipment as Backhoe Loader. The data contains features related to fuel, features for operating run hours, features for distance, and speed. Distance covered by the equipment is captured from the latitude and longitude, Fuel-related features are captured from fuel level sensors while actual operating run hours, start run hours, and end run hours are captured from the hour meter sensor.

IoT-enabled smart sensing devices are attached to the construction equipment which help to capture data through IoT gateways. Onboard sensors and external sensors are capable of sharing these features by transmitting the data to the server using IoT gateways. Start fuel level and end fuel level values are captured. Start run hours and end run hours values are captured. Distance is computed using latitude and longitude values along with speed calculations from distance computed value.

The statistics of the data are explored in Table I.

TABLE I. DATA CHARACTERISTICS

Main Features	Mean	Std. Dev	Min	Max
Trip Distance	6.55	5.41	2.11	31.75
Run Hours	4.88	2.66	0.08	12.53
Average Speed	5.96	3.75	2.09	21.04
Fuel consumption	18.21	10.78	0.2	55

B. Preprocessing of Data

Preprocessing of data is crucial for ensuring with reliability of the dataset. Adequate and proper data is responsible for the effective and accurate ML model building. Data Preprocessing involves data cleaning along with data integration steps.

The data cleaning (see Fig. 2) step handles the duplicate data and noisy data. Equipment duplicate raw data points were removed from the iterations.

Fig. 2. Data preprocessing steps.

Noisy data is identified and removed using the outlier detection method. The Z-score outlier removal method is a statistical technique used to discover as well as eliminate outliers built on respective variance from average in terms of standard deviations. The importance of outlier detection and removal confirms integrity with consistency related to research findings. the concept of Z-scores and how they are used to measure the deviation of individual data points. The formula for calculating the Z-score of a data point is explained in Eq. (1).

$$Z = \frac{(D-M)}{SD} \quad (1)$$

Where,

D - Data point,

M - Mean,

SD - Standard deviation.

This method highlights the number of standard deviations of data points left with the average data point. A value of 0 reveals the intimation of lying the point exactly at the mean, positive scores signify above the average data point, and negative scores denote below the average point. The threshold criterion commonly used for outlier detection is based on Z-scores, such as considering points beyond a certain threshold as outliers. The process of identifying outliers using Z-scores is more effectively used.

The data Integration step involves the parameter identification for where the dataset contains MachineId as well as Equipment number, Entrydate as Date, these types of parameters were present in the dataset Correct parameters are

identified and integrated into the dataset. Data value identification is performed on the datatypes of the parameters to collect all parameters in the same data type format such as for Entrydate in DateTime format, other Run hours were present in DateTime. To apply ML models numeric data need to calculate. All parameters in numeric format ensure scaling on a similar scale for feature engineering, leading to performing ML models effectively.

C. Features Selection

Feature selection is an essential phase for the machine learning pipeline that involves selection with a group of significant features. Subgroups of features were identified from the original parameter set. This step ensures the improvement in the model's performance, reduces overfitting problems, and boosts interpretability. Complex feature spaces with high dimensions may result in heightened computational demands, diminished model efficacy, and susceptibility to overfitting. A correlation matrix is used to select highly correlated features. Distance covered by equipment, total run hours of that equipment with average speed of the equipment are the highest correlated parameters for fuel consumption prediction.

D. Forecasting of Data using ML Model

ML models play a crucial role in predicting values across various domains due to several important reasons. Machine learning models demonstrate proficiency in recognizing intricate patterns and correlations within datasets that conventional statistical approaches may overlook. This capability allows them to capture intricate associations of input parameters with the target parameter, enabling accurate predictions. ML models are highly adaptable. This flexibility allows them to effectively model a wide range of real-world phenomena and achieve estimates with diverse data. ML models can scale efficiently and manage substantial amounts of data, making them suitable for applications where massive datasets are involved. Whether it's analyzing millions of transactions in finance or processing vast amounts of sensor data in IoT applications, ML models can effectively manage the workload. Many real-world phenomena exhibit non-linear associations of input parameters with the target parameter. Non-linear ML algorithms are capable of capturing and modeling these non-linear relationships, allowing for more accurate predictions compared to linear models.

Some ML models can constantly be trained for new instances of data that reflect estimates that persist appropriately with accurate behavior in vibrant circumstances. ML models can automate the process of forecasting, removing the necessity for manual examination and human involvement in repetitive tasks. This automation not only saves time and resources but also reduces the likelihood of errors associated with manual prediction methods. ML methods share transparency that allows stakeholders to understand how predictions are made and gain perceptions of the factors influencing the anticipated consequences.

1) *Multiple Linear Regression (MLR)*: It is a foundational and extensively employed approach for modeling the association between a dependent variable and numerous independent variables, assuming a linear correlation between

them, implying that they can be represented as a straight line. MLR is a statistical method used to ascertain the quantitative association among two or more variables [2] [22] [25]. In regression analysis, target variables are observed or measured, while the independent variables are factors considered to significantly impact the target variable under evaluation. Predictions can be made by estimating the relationships between variables through analysis.

2) *Support Vector Regressor (SVR)*: The Support Vector Regression (SVR) function denotes the relationship between dependent and independent parameters while minimizing error. Its core objective is to identify a hyperplane with the maximum number of support vectors within the decision boundary, allowing for continuous value predictions. This involves employing kernels, a set of numerical operations, to transform input data into meaningful configurations. SVR aims to fit between the boundary lines and the hyperplane, adjusting coefficients within a specified tolerance margin [1][7][13][14]. SVR computes a hyperplane to fit the training data while minimizing margins, aiming to find coefficients and a bias term that reduces the variance of anticipated value with original values within a tolerance margin. This optimization problem is typically formulated as a quadratic programming problem and solved using optimization techniques. Kernel functions such as sigmoid, linear, and polynomial are commonly used, chosen based on the complexity of feature relationships and data nature. SVR is highly effective for datasets with dense relationships and high-dimensional feature spaces, ensuring robust predictions and reduced sensitivity to outliers [19][21][24][26].

3) *Decision Tree Regressor (DT)*: This algorithm is widely employed in supervised learning, supporting both regression and classification analyses [4][5]. It operates by sequentially portraying decisions and their potential outcomes, encompassing chance events, asset prices, and utility considerations. This model utilizes conditional control statements in the form of branching rules, making it a versatile tool for analyzing various types of data. A nonparametric supervised learning technique, the DT algorithm constructs a tree-like structure comprising root nodes, interior nodes, and leaf nodes. Each branch and leaf node represent decision criteria and predicted outcomes, forming a hierarchical representation of the data. The DT regressor essentially represents a piecewise constant function, partitioning the feature space into non-overlapping regions, each linked with a constant predicted value. The final prediction for a given input sample is the sum of the predicted values of the leaf nodes to which the sample belongs [24].

E. Performance Evaluation

Measuring the performance of ML models is necessary for assessing their efficiency and determining their appropriateness related to real-world purposes. Measuring metrics are generally used to estimate regression models, with Mean Squared Error

(MSE), Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), and R-squared (R²) score.

1) *Mean Squared Error (MSE)*: The Mean Squared Error (MSE) quantifies the average of the squared variances between predicted and actual values, assigning more significance to larger deviations, thus rendering it responsive to outliers. Calculated by averaging these squared variances across the dataset, lower MSE values signify superior model accuracy.

2) *Mean Absolute Error (MAE)*: MAE evaluates the average absolute disparity between predicted and actual values, offering less sensitivity to outliers compared to MSE since it does not square the errors. MAE is computed by averaging the absolute disparities between predicted and actual values across the entirety of the dataset. Similar to MSE, superior model performance is indicated by lower MAE values.

3) *Root Mean Squared Error (RMSE)*: RMSE, being the square root of MSE, offers a comprehensible scale for interpretation. It gauges the average magnitude of errors in units akin to the dependent variable. RMSE is calculated by taking the square root of the MSE. Lower RMSE values indicate better model performance, and it is often preferred when errors are expected to be normally distributed.

4) *Coefficient of determination (R²) score*: The R² score signifies the fraction of the variability in the dependent variable elucidated by the independent variables in the model. Its scale spans from 0 to 1, where a score of 1 denotes an impeccable fit, while 0 suggests that the model fails to elucidate any variability. In instances where the model performs poorer than a horizontal line, the R² score can be negative. Enhanced model performance is denoted by higher R² values, with 1 representing the pinnacle of performance.

When assessing machine learning models, it's crucial to examine a blend of these metrics to obtain a well-rounded view of their performance. While MSE, MAE, and RMSE offer insights into error magnitudes, the R² score quantifies the model's overall adequacy of fit. By interpreting and comparing these metrics, researchers, and practitioners can make informed decisions about model selection and refinement to achieve optimal results in various applications.

IV. RESULTS AND DISCUSSION

This study undertook an expectation task aimed at examining various alternative models for forecasting fuel consumption of related construction equipment in selected datasets. The study evaluated the appropriateness of MLR, SVR, and DT models for this purpose. Using authentic dataset inputs, regression models were trained and assessed. MSE, MAE, RMSE, and R² scores are used for measuring the performance of ML models. Table II represents the performance measurement of ML models as MLR, SVR, and DT are used to forecast the fuel consumption of backhoe loader equipment.

TABLE II. PERFORMANCE MEASUREMENT OF MODELS

Model	MAE	MSE	RMSE	R2
MLR	9.18	152.54	12.35	0.43
SVR	9.62	259.14	16.09	0.56
DT	9.70	227.38	15.07	0.61

As per the performance metrics offered in Table I, all three fuel consumption prediction models, namely MLR, SVR, and DT, demonstrate relatively similar predictive abilities. MLR achieved the lowest Mean Absolute Error (MAE) of 9.18, indicating its ability to predict fuel consumption with the smallest average absolute deviation from the actual values. DT achieved the top R2 score with 0.61, suggesting the largest proportion of variance in the fuel consumption data among the three models. SVR yielded intermediate results between MLR and DT relations with MAE, MSE, RMSE, and R2 scores, demonstrating moderate performance in predicting fuel consumption.

The relatively low R² (0.43) indicates that MLR explains only 43% of the variance in the target variable. MAE and RMSE values indicate the average errors, with RMSE being higher due to its sensitivity to larger errors (squared differences). MLR is a linear model that attempts to establish a linear relationship between the input features and the target variable. It minimizes the sum of squared residuals to find the best-fitting linear hyperplane in the feature space. SVR has a higher R² (0.56) compared to MLR, indicating it captures more variance in the target variable (56%). This suggests SVR handles non-linear relationships better than MLR. The higher MAE and RMSE values compared to MLR might be due to SVR being more sensitive to outliers or the choice of kernel and its parameters. Despite capturing more variance (higher R²), the higher errors (MAE, MSE, RMSE) suggest that the SVR model might not be well-tuned or that it could be overfitting/underfitting the data. SVR aims to find a hyperplane in a high-dimensional space that maximizes the margin between the hyperplane and the data points. It uses kernel functions to handle non-linearity. It focuses on minimizing a margin of error and uses support vectors to define the hyperplane. DT has the highest R² (0.61), meaning it explains 61% of the variance in the target variable, suggesting it captures the data's underlying structure better than MLR and SVR. The MAE is slightly higher than MLR, but the significant improvement in R² indicates that DT models better handle non-linearity and interactions between features. The MSE and RMSE values are lower than SVR but higher than MLR, which may indicate that DT captures more variance. DT models split the data into subsets based on feature values, creating a tree-like structure where each node represents a feature split that contributes to reducing the target variance. It is a non-linear model that can capture complex relationships by recursive partitioning.

Overall, the Decision Tree model appears to offer the best balance between accuracy and explanatory power among the three models evaluated. However, further analysis and comparison with additional metrics may be necessary to make a conclusive determination about the optimal model for predicting fuel consumption.

V. CONCLUSION

This study demonstrates the effectiveness of machine learning approaches in forecasting fuel consumption for construction equipment, with a particular focus on Backhoe Loader (BL) fuel consumption estimation. As the construction industry increasingly integrates technology, accurate predictions become essential to optimizing fuel usage and operational efficiency. Through this analysis, accurate forecasts of fuel consumption are generated, empowering construction companies to facilitate well-informed decisions concerning equipment usage, resource allocation, and equipment productivity. The study employed Multiple Linear Regression, Support Vector Regression, and Decision Tree Regression models, trained on the dataset. Comparative analysis of the coefficient of determination reveals that the Decision Tree technique yields more precise results compared to other models, as indicated by measures of accuracy. The findings of this study provide valuable insights for decision-makers involved in cost estimation for construction projects, highlighting the significant role of fuel consumption in project expenses. By employing advanced ML techniques, construction operations can be enhanced in terms of efficiency, sustainability, cost-effectiveness, and environmental impact mitigation.

Image Generation of Animation Drawing Robot Based on Knowledge Distillation and Semantic Constraints

Dujuan Wang

School of Information Engineering, Heilongjiang Polytechnic, Heilongjiang 150070, China

Abstract—With the development of robot technology, animation drawing robots have gradually appeared in the public eye. Animation drawing robots can generate many types of images, but there are also problems such as poor quality of generated images and long image drawing time. In order to improve the quality of images generated by animation drawing robots, an animation face line drawing generation algorithm based on knowledge distillation was designed to reduce computational complexity through knowledge distillation. To further raise the quality of images generated by robots, the research also designed an unsupervised facial caricature image generation algorithm based on semantic constraints, which uses facial semantic labels to constrain the facial structure of the generated images. The outcomes denote that the max values of the peak signal-to-noise ratio and feature similarity index measurements of the line drawing generation model are 39.45 and 0.7660 respectively, and the mini values are 37.51 and 0.7483 respectively. The average values of the gradient magnitude similarity bias and structural similarity of the loss function used in this model are 0.2041 and 0.8669 respectively. The max and mini values of Fréchet Inception Distance of the face caricature image generation model are 81.60 and 71.32 respectively, and the max and mini time-consuming values are 15.21s and 13.24s respectively. Both the line drawing generation model and the face caricature image generation model have good performance and can provide technical support for the image generation of animation drawing robots.

Keywords—Knowledge distillation; semantic constraints; robot; image; generation

I. INTRODUCTION

A. Background

With the development of technologies such as artificial intelligence, drawing robots have also emerged. As a human-computer interaction task, drawing robots have been applied in many scenarios in life, such as social entertainment. Drawing robots can generate corresponding artistic portraits based on given user photos through algorithms and perform drawing. There are two core issues in drawing robot technology. One is how to use a computer to convert facial photos into high-quality portrait paintings, and the other is how to plan the trajectory of portrait lines so that robots can quickly draw portraits on paper. Current painting robots mainly involve interactive systems and image synthesis algorithms [1-2]. It is very meaningful to draw animations through drawing robots, especially animation images of human faces and portraits, which can reduce the time and labor costs of traditional manual painting. At present, regarding the generation of anime face line drawings, commonly

used methods include block-based mechanisms, projection-based methods, generative adversarial learning, and optimization and variants of generative adversarial learning [3]. However, these technologies also have certain shortcomings, resulting in poor image generation quality, long image generation time, and high computational complexity [4].

B. The Method Designed by the Manuscript

With the advancement of deep learning technology, knowledge distillation technology is gradually applied to the compression of different models to reduce the computational complexity of the model [5]. In order to improve the quality of images generated by animation drawing robots, an animation face line drawing generation algorithm based on knowledge distillation was designed, which uses deformable convolution to align features of different scales. The research also designed an unsupervised facial caricature image generation algorithm based on semantic constraints, which uses facial semantic labels to constrain the facial structure of the generated image.

C. The Purpose, Innovation, and Contribution

The research targets to raise the quality of images generated by animation drawing robots from multiple perspectives, reduce the drawing robot's drawing time and operation complexity, and provide good technical support for the wide application of animation drawing robots. The innovation points of the research are mainly reflected in two points. The first point is to combine knowledge distillation, deformable convolution and loss function in the model. The second point is to improve the quality of image generation by drawing robots from the perspectives of anime facial line drawing and facial comic images. The contribution of the research is the improvement of image quality generated by anime drawing robots, the improvement of drawing speed, and the reduction of computational complexity.

D. The Structure of the Manuscript

The research is structured into five sections. Section II is a literature review related to the animation drawing robot image generation. Section III is the specific design of the animation face line drawing generation algorithm and the face caricature image generation algorithm. Results and discussion is given in Section IV and finally, Section V concludes the paper.

II. LITERATURE REVIEW

With the advancement of technologies such as artificial intelligence and robotics, intelligent robots are gradually being utilized to different fields in society. With the development of

the animation industry, more and more researchers have conducted research on image generation for animation drawing robots. Experts such as Ko D K have designed a high update rate method for image generation problems. The method involves low update images, current gripping position and motor current. The research also equipped the robot's gripper with cameras and gripping force sensors. The outcomes denoted that the method designed by this research can generate high update rate images [6]. Liu R and other scholars designed a flexible and robust robot system to solve the problem of autonomous drawing on three-dimensional surfaces, and took two-dimensional drawing strokes and three-dimensional target surfaces as inputs. The system also involves visual recognition, grasping posture reasoning and motion planning. The outcomes denoted that the system is flexible and robust, capable of generating robot motion and successfully drawing three-dimensional strokes [7]. Researchers such as Khanam Z analyzed the impact of gamma radiation on robot vision sensors in nuclear sites by analyzing two images at different dose rates, namely dark images and bright images. Experiment outcomes show that the electrical characteristics change significantly, and when the gamma dose rate is as high as 3Gy/min, the imaging sensor data is unreliable for visual odometry [8]. In order to design a painting robot with style conversion, Wang T and other experts designed a robot-based real-time collaborative drawing system RoboCoDraw. The system involves a generative adversarial network and a random key genetic algorithm. Style transfer is achieved through the generative adversarial network, and path optimization is achieved through the random key genetic algorithm. The results show that the system can generate cartoon face images from real face images [9].

Wu P L and other experts designed an art robot drawing system in order to create pencil sketches. This system can address the issue of pencil wear through tactile sensing function. In addition, this research also uses neural style transfer technology to extract the content and style features of the image, and performs edge detection and further layering on the newly generated image. The results show that the system has good effectiveness in painting and the painting time is less than 30 minutes [10]. In order to allow non-professionals to operate robots as easily as professionals, researchers such as Jens P introduced text-based programming that minimizes robot manufacturing. Furthermore, the drawing of manual instructions on the workpiece before robot machining is investigated. The results show that the method designed by the institute can help non-professionals operate the robot as easily as professionals [11]. Scalera L and other experts conducted drawing experiments to evaluate the performance of the robot architecture, allowing the experimenters to use their eyes to operate the robot's manipulator. Experimental results show that gaze-based human-computer interfaces are beneficial for amputees and patients with various forms of movement disorders [12]. In order to give a brief report on Drawing Fields, Herrmann E W and other scholars explained the use and origin of Drawing Fields. In addition, the report discusses the cultural, ecological and technological resonances of Drawing Fields. The

results show that each painting in Drawing Fields corresponds to a different theme [13].

Overall, there is currently massive research related to image generation for animation drawing robots. However, these studies also have certain deficiencies, such as low quality of image generation, single image style, long time-consuming painting, and high computational complexity. In addition, existing methods also have other challenges and limitations, such as inadequate facial feature preservation, incomplete detail texture processing, and high storage space requirements [14-15]. Therefore, to raise the quality of images generated by animation drawing robots, an animation face line drawing generation algorithm based on knowledge distillation was studied and designed, and an unsupervised face comic image generation algorithm based on semantic constraints was also designed. The research targets to raise the quality of images generated by animation drawing robots from multiple perspectives.

III. DESIGN OF FACIAL PORTRAIT GENERATION ALGORITHM FOR ANIMATION DRAWING ROBOTS

For the image generation problem of animation drawing robots, the research starts from two directions: animation lines and comic images, and designs a face line drawing generation algorithm based on knowledge distillation and an unsupervised face comic image generation algorithm based on semantic constraints. The study uses knowledge distillation to reduce computational complexity and facial semantic labels to constrain the facial structure of the generated image.

A. Construction of Animation Face Line Drawing Generation Algorithm based on Knowledge Distillation

To raise the quality of the images generated by the animation drawing robot, reduce the drawing time of the image and reduce the complexity of the operation, starting from the face portrait image, two image generation algorithms for animation lines and comics were designed. For the generation of face line images, the research uses knowledge distillation to reduce computational complexity, and uses deformable convolution to align features of different scales. Finally, the study uses boundary loss, style loss and coherence loss to further enhance the quality of line drawings generated by anime drawing robots. The model structure of the line drawing generation algorithm designed by the institute is shown in Fig. 1.

From Fig. 1, the model of the line drawing generation algorithm mainly includes pre-trained teacher network, learning network, distillation loss, input and output. The pre-trained teacher network is a modified model that produces line drawings with better results, and then the study will transfer its intermediate layer knowledge to the student network through knowledge distillation. The network structure used in the study is a two-level nested U-shaped structure to obtain more contextual information. The network structure involves the encoder, decoder and saliency map fusion module, and the U-shaped residual module is involved in the encoder. The structural comparison of the original residual block and the U-shaped residual block is denoted in Fig. 2.

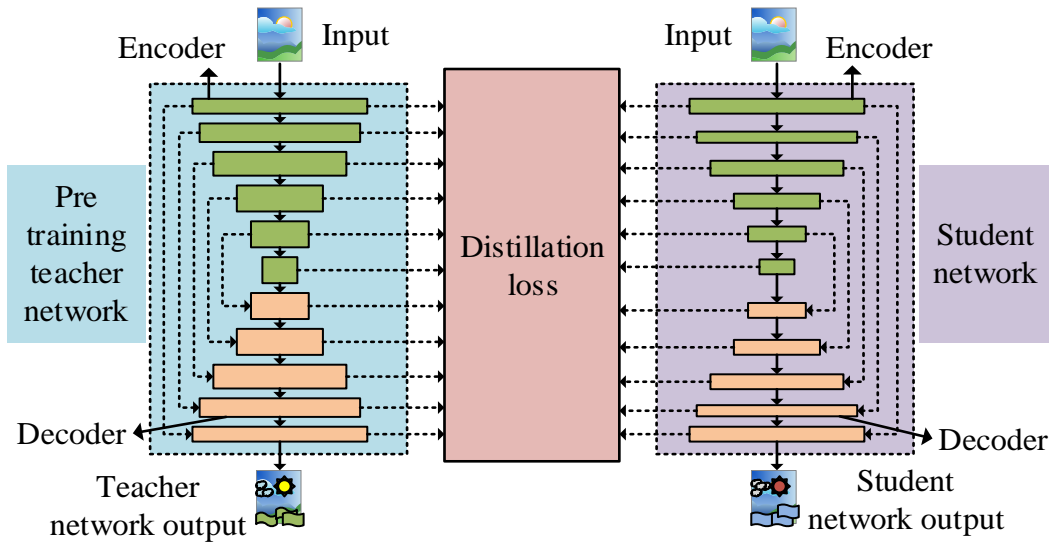

Fig. 1. The model structure of line drawing generation algorithm.

Fig. 2. Structure of U-shaped residual module.

As can be seen from Fig. 2(a), the original residual block mainly includes convolutional layers, modified linear units, intermediate feature maps and feature fusion. From Fig. 2(b), the U-shaped residual block involves convolutional layers, modified linear units, U-shaped structural blocks, multi-scale features and feature fusion. Because the structures of the teacher network and the learning network are both nested U-Nets, in order to avoid damage to target boundary prediction, the research needs to align the upsampling and downsampling features before performing feature fusion. To align features, deformable convolutions were used. The output features at any position after convolution \hat{a}_p are shown in Eq. (1).

$$\hat{a}_p = \sum_{n=1}^N \omega_n \times a_p + p_n \quad (1)$$

In Eq. (1), $N = m \times m$, $m \times m$ means the size of the convolution layer and n means the sequence number. ω_n is the

weight of the n th convolution sample position, p_n representing the pre-specified offset of the n th convolution sample position. Deformable convolution can adaptively apply to additional offsets at different sample positions, so Eq. (1) can be re-expressed as shown in Eq. (2).

$$\hat{a}_p = \sum_{n=1}^N \omega_n \times a_p + p_n + \Delta p_n \quad (2)$$

In Eq. (2), Δp_n represents the additional offset. When deformable convolution is applied to the position information of the down-sampled feature map and the offset field is used as a parameter, the deformable convolution can be aligned by the spatial distance between the position information of the up- and down-sampled feature maps. Therefore, the study selected deformable convolution as the feature alignment function. In order to obtain the trained teacher network, the study introduces boundary loss, style reconstruction loss and coherence loss. In order to further reduce the computational load and model size of the teacher network, the research uses knowledge distillation to

transfer the thinking process and results of the teacher network to the student network, so that students can reach or even exceed the level of the teacher model with a smaller model. To achieve this process, the study adopts feature-based knowledge transfer. The feature-based knowledge distillation loss is shown in Eq. (3) [16].

$$L_{zs}(f_t(x), f_s(x)) = L_F(\Pi_t(f_t(x)), \Pi_s(f_s(x))) \quad (3)$$

In Eq. (3), $f_t(x)$ and $f_s(x)$ are the feature maps of the middle layer of the teacher network and student network respectively, $\Pi_t(f_t(x))$ and $\Pi_s(f_s(x))$ both are conversion functions. $L_F(\cdot)$ represents the distillation loss of matching feature map similarity. The expression of distillation loss is denoted in Eq. (4) [17].

$$L_{dis} = \sum_h^k kl(f_{s_h}, f_{t_h}) / d_h \quad (4)$$

In Eq. (4), $kl(\cdot)$ represents the kl divergence function and d_h is the number of channels of the corresponding encoder and decoder. h is the serial number of the channel number. f_{s_h} and f_{t_h} represent the amount of channels of the teacher network and student network, respectively, and k are the number of channels. In addition to boundary loss, style reconstruction loss and coherence loss, the teacher network and student network also involve binary cross-entropy loss and distillation loss, so the loss function of the teacher network is denoted in Eq. (5).

$$L_{teacher} = \beta_1 L_{bce} + \beta_2 L_{style} + \beta_3 L_{boundary} + \beta_4 L_{filter} \quad (5)$$

In Eq. (5), β_1 , β_2 , β_3 and β_4 are all weight coefficients, L_{bce} , L_{style} , $L_{boundary}$ and L_{filter} are binary cross-entropy loss, style loss, boundary loss and coherence loss respectively. The student network not only needs to use all the loss functions involved in the teacher network, but also needs to use distillation loss. Therefore, the final loss function of the student network is shown in Eq. (6).

$$L_{student} = \beta_1 L_{bce} + \beta_2 L_{style} + \beta_3 L_{boundary} + \beta_4 L_{filter} + \beta_5 L_{dis} \quad (6)$$

In Eq. (6), β_5 it is also the weight coefficient.

B. Design of Unsupervised Face Caricature Generation Algorithm Based on Semantic Constraints

To raise the quality of images generated by animation drawing robots, research has designed an algorithm for generating facial line images. To further raise the quality of images generated by robots, an unsupervised face caricature image generation model based on semantic constraints was designed. The study uses an unsupervised face caricature image generation model to enrich the image style drawn by the robot, and uses group activation mapping and attention modules to avoid the impact of unimportant features on the generated caricature images. In order to better preserve the facial features of human faces, research uses facial semantic labels to constrain the facial structure of the generated images. The network structure of the algorithm in this chapter mainly contains two generators and two discriminators, and both the generator and the discriminator contain attention modules. The specific structure of the face caricature image generation algorithm is shown in Fig. 3.

As can be seen from Fig. 3, the generator mainly includes downsampling, residual block, encoder, auxiliary classifier and group class activation mapping (Group Class Activation Mapping, Group-CAM). The discriminator mainly involves downsampling, encoder, auxiliary classifier and group activation mapping. The face caricature generation algorithm also involves decoders, features, feature weights, face parsing modules and classifiers, where the decoder contains adaptive residual blocks and upsampling. Class activation mapping can retain the spatial information of the image and use it to guide generator training. In addition, class activation mapping can also determine the method of input image categories and enhance the capabilities of the generator and discriminator [18-19]. However, there is a large amount of meaningless data in the saliency map generated by the class activation map in the model, so the study improved it to form the final Group-CAM. The structure of the Group-CAM model is shown in Fig. 4.

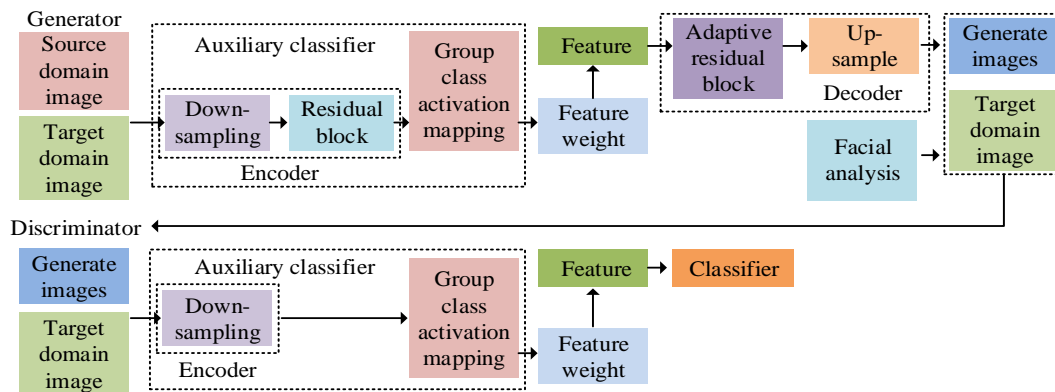

Fig. 3. The specific structure of facial comic generation algorithm.

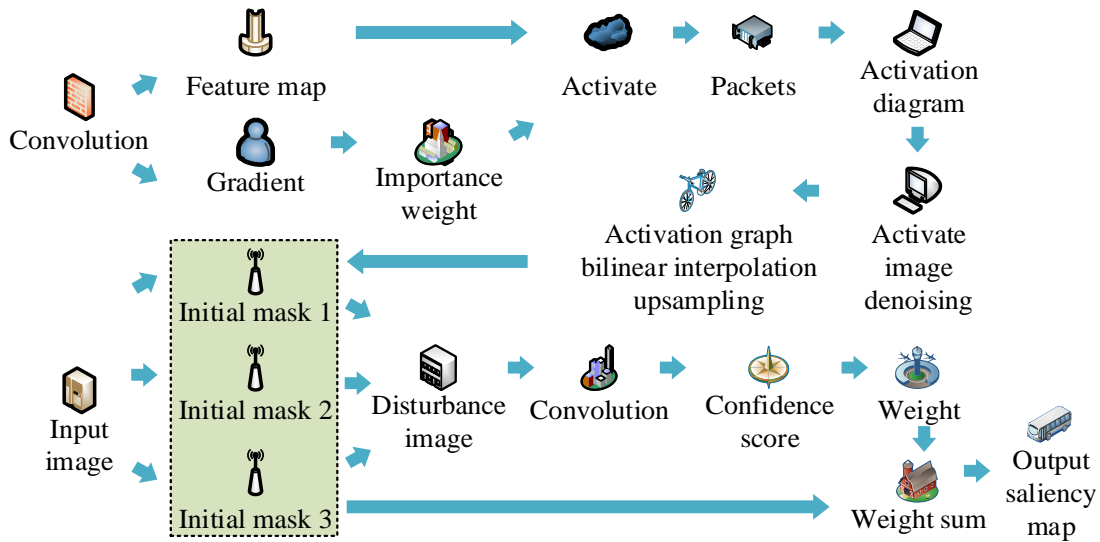

Fig. 4. The structure of the Group-CAM model.

From Fig. 4, the Group-CAM model involves input images, convolutions, feature maps, gradients, importance weights, activations, number of groups, activation maps, activation map denoising, activation map bilinear interpolation upsampling, Initial mask, perturbed image, confidence score, weight sum and saliency map. The initial category mask of the target convolutional layer is shown in Eq. (7).

$$\Upsilon_k^c = \frac{1}{Q} \sum_l \sum_j \frac{\partial F_c(I_0)}{\partial R_{lj}^k(I_0)} \quad (7)$$

In Eq. (7), Q represents the amount of pixels R^k and R^k is the amount of channels of the target layer feature map. $F_c(I_0)$ represents the predicted probability that the input image I_0 is in the class c , l and j the sum is the given number of groups. R_{lj}^k is the sum of the channel numbers of the feature map of the l th group and the j th group of target layers. The initial mask in each group is shown in Eq. (8).

$$M_q = \text{ReLU} \left(\sum_{k=q \times g}^{(q+1) \times g - 1} \Upsilon_k^c R^k \right) \quad (8)$$

In Eq. (8), $q \in \{0, 1, \dots, G-1\}$, G denotes the amount of groups of all feature maps and their corresponding importance weights. g denotes the amount of feature maps in each group. Since the initial mask is visually noisy, the study uses a denoising function to process it, and scales the value of the initial mask to $[0, 1]$ through normalization. The initial mask processing process is shown in Eq. (9).

$$M'_q = \frac{M_q - \min(M_q)}{\max(M_q) - \min(M_q)} \quad (9)$$

In Eq. (9), M'_q represents the smoother mask generated by the activation map, $\min(M_q)$ and $\max(M_q)$ are the mini and max values of the initial mask, respectively. Afterwards, the study uses bilinear interpolation for upsampling. When generating saliency maps, blur operations are required. The calculation of the blurred image is shown in Eq. (10) [20].

$$I'_q = I_0 \square M'_q + \tilde{I}_0 \square (1 - M'_q) \quad (10)$$

In Eq. (10), \tilde{I}_0 represents an image with the same dimensions as I_0 , and \square represents multiplication. The calculation of the confidence score χ_q^c is shown in Eq. (11).

$$\chi_q^c = F_c(I'_q) - F_c(\tilde{I}_0) \quad (11)$$

In Eq. (11), $F_c(I'_q)$ and $F_c(\tilde{I}_0)$ represent the predicted probability of the image I'_q and \tilde{I}_0 in the class c respectively. The calculation of the final saliency map is shown in Eq. (12).

$$L_{\text{Group-CAM}}^c = \text{ReLU} \left(\sum_q \chi_q^c M'_q \right) \quad (12)$$

To better preserve the facial features of human faces, research uses facial semantic labels to constrain the facial structure of the generated images. For the acquisition of facial semantic labels, the BiSeNet model was selected in this study. The BiSeNet model structure mainly includes input images, spatial branch paths, feature fusion modules, output semantic labels and contextual branch paths. The specific structure of the BiSeNet model is indicated in Fig. 5 [21].

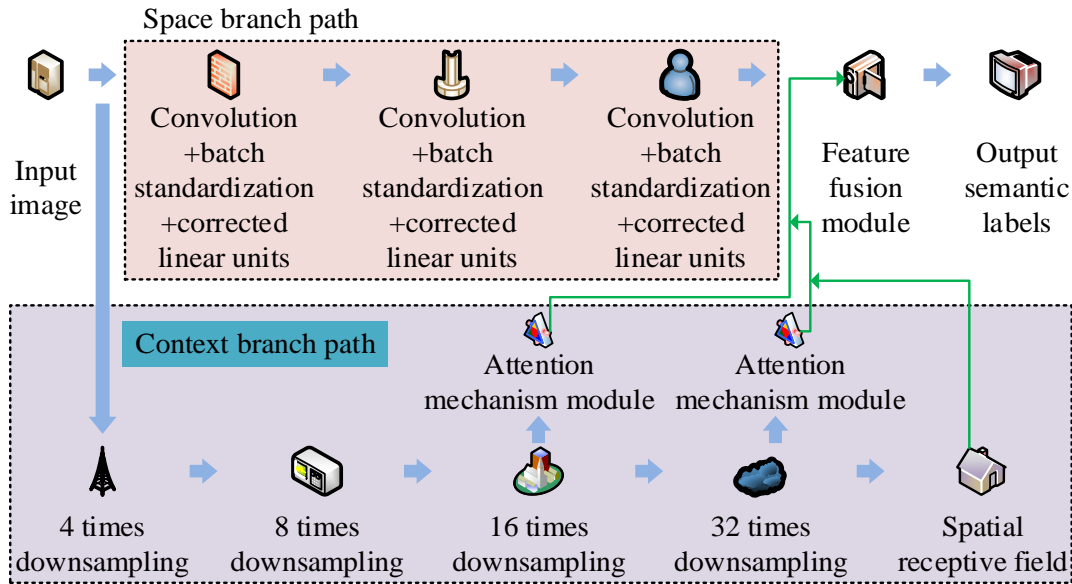

Fig. 5. The specific structure of the BiSeNet model.

From Fig. 5, the spatial branch path involves three groups of convolution + batch normalization + modified linear units. The contextual branch path includes 4x, 8x, 16x and 32x downsampling, attention mechanism module and spatial perception wild. In order to allow the generator to retain the characteristics of the comic domain, the study performed strong blur processing on the image, and then calculated the gradient magnitude similarity deviation. The local gradient amplitude is similar as shown in Eq. (13).

$$GMS(\theta) = \frac{2y_u(\theta)y_v(\theta) + c}{y_u^2(\theta) + y_v^2(\theta) + c} \quad (13)$$

Eq. (13), θ is the position of the pixel, which $y_u(\theta)$ denotes the gradient amplitude of the θ pixel in the horizontal direction. $y_v(\theta)$ represents θ the gradient amplitude of the pixel in the vertical direction, which $GMS(\theta)$ is the local gradient field of each small patch. The calculation of gradient amplitude similarity deviation is shown in Eq. (14) [22].

$$GMSD = \sqrt{\frac{1}{T} \sum_{\theta=1}^T (GMS(\theta) - GMSM)^2} \quad (14)$$

Eq. (14), T denotes the total amount of pixels and $GMSM$ denotes the average value of the local gradient field. The loss functions used in the face caricature image generation algorithm include generative adversarial loss, cycle consistency loss, identity loss, class activation mapping loss and weighted sum total loss. The total loss is calculated as denoted in Eq. (15).

$$\min \max \delta_1 L_{lsgan} + \delta_2 L_{cycle} + \delta_3 L_{identity} + \delta_4 L_{cam} + \delta_5 L_{gmsd} \quad (15)$$

Eq. (15), δ_1 , δ_2 , δ_3 , δ_4 and δ_5 are all constant weight factors, L_{lsgan} , L_{cycle} , $L_{identity}$, L_{cam} and L_{gmsd} respectively represent the generative adversarial loss, cycle consistency loss,

identity loss, class activation mapping loss and gradient magnitude similarity bias loss.

IV. RESULTS AND DISCUSSION

The research verifies the performance of the animation face line drawing generation algorithm and the face caricature image generation algorithm, and explains the data set and experimental environment. The performance verification uses ablation experiments, and uses indicators such as peak signal-to-noise ratio (PSNR), gradient amplitude similarity deviation, and structural similarity to assess the effectiveness of the algorithm.

A. Performance Verification of Animation Face Line Drawing Generation Algorithm

In order to verify the effectiveness of the line drawing generation algorithm, an ablation experiment was conducted. Ablation experiments involve studying the designed model and loss function. Performance evaluation indicators include PSNR, Feature Similarity Index Measure (FSIM), Gradient Magnitude Similarity Deviation (GMSD), structural similarity (Structure Similarity Index Measure, SSIM) and Fréchet Inception Distance (FID). PSNR, FSIM, GMSD, SSIM and FID are all important indicators for measuring image quality. Among them, PSNR is mainly used to compare the differences between the original signal and the processed signal, FSIM is used to quantify the degree of distortion of images in visual perception. GMSD measures the similarity of gradient images and is used to evaluate the clarity of images. SSIM measures the structural similarity between the original image and the processed image, such as brightness, contrast, and structure. FID measures the quality of image generation models. The data set applied in the experiment is the Apdrawing data set, and the algorithm performed a total of 280,000 iterations. In addition, in the line drawing generation algorithm, the values of β_1 , β_2 , β_3 and β_4 are 10, 1, 1000, and 1/1000, respectively. The operating system applied in the experiment is Windows 11, the processor is Intel Core i9-13900KS, the maximum turbo frequency is

6.00GHz, the basic power consumption of the processor is 150W, the maximum memory is 192GB, the basic frequency and maximum dynamic frequency of the graphics card are 300MHz and 1.65GHz respectively. The comparison of PSNR and FSIM of different models is shown in Fig. 6.

From Fig. 6, the models included in the experiment include the U²-Net model, the improved U²-Net (teacher network) model, the student network model, the student network + knowledge distillation model and the line drawing generation model designed by the institute. From Fig. 6(a), the max PSNR values of the five models are 34.58, 36.70, 33.55, 38.64 and 39.45 respectively, and the mini values are 31.58, 33.87, 30.33, 36.35 and 37.51 respectively. From Fig. 6(b), the max FSIM

values of the five models are 0.7457, 0.8539, 0.7257, 0.7559 and 0.7660 respectively, and the mini values are 0.7224, 0.8305, 0.7066, 0.7351 and 0.7483, respectively. The larger the PSNR and FSIM values are, the better the quality of the images generated by the model is. The PSNR value of the line drawing generation model designed by the institute is significantly greater than the comparison model, which shows that the performance of the model designed by the institute is better. Both the teacher and the student network models after introducing knowledge distillation have improved in PSNR, which can identify the performance of the modules added by the institute. The comparison of GMSD and SSIM of different models is shown in Fig. 7.

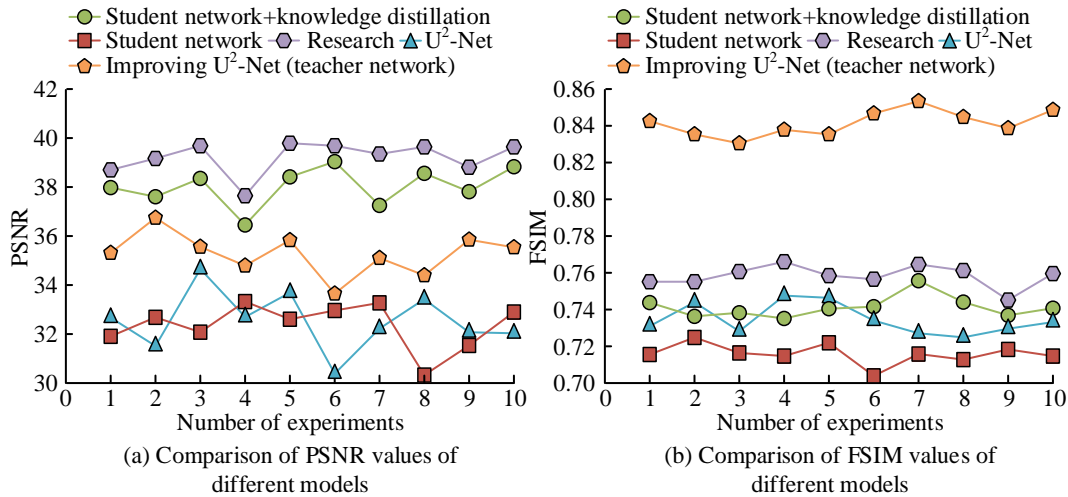

Fig. 6. Comparison of PSNR and FSIM of different models.

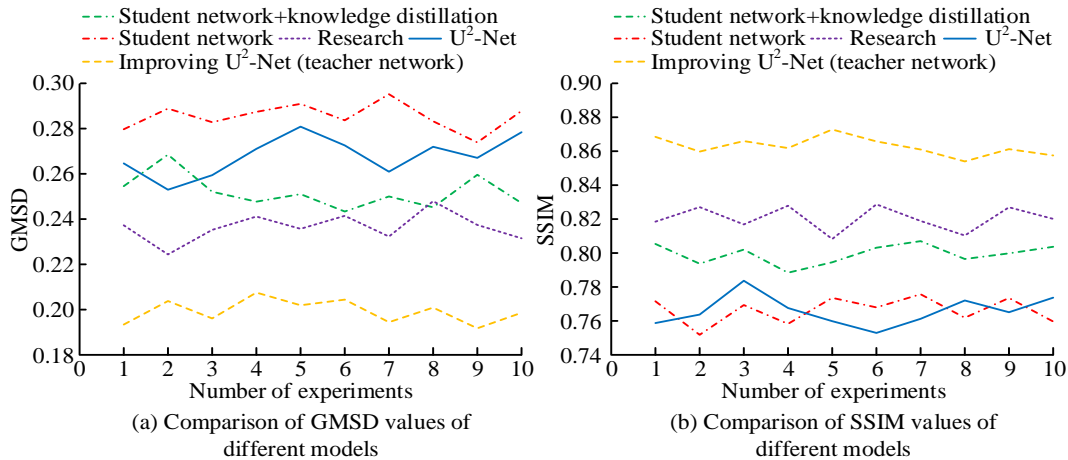

Fig. 7. Comparison of GMSD and SSIM of different models.

From Fig. 7(a), the max GMSD values of the U²-Net model, teacher network model, student network model, student network + knowledge distillation model and research design model are 0.2801, 0.2141, 0.2931, 0.2642 and 0.2432 respectively, the minimum values are 0.2588, 0.1927, 0.2732, 0.2411 and 0.2213, respectively. From Fig. 7(b) that the max SSIM values of the five models are 0.7810, 0.8769, 0.7747, 0.8084 and 0.8285, respectively, and the mini values are 0.7573, 0.8591, 0.7534, 0.7865 and 0.8098 respectively. The larger the GMSD value is, the worse the fidelity of the image is. The larger the SSIM value

is, the more similar the image structure is to the real label, and the better the image quality is. The GMSD value and SSIM value of the model designed by the institute have obvious advantages, which also shows that the performance of the model designed by the research is better. The comparison of indicators under different loss function constraints is shown in Fig. 8.

In Fig. 8, the experiment involves a total of 8 combinations of loss functions, which are named A1, A2, A3, A4, A5, A6, A7 and A8 respectively. From Fig. 8(a), the average PSNR of the

eight loss function combinations are 33.58, 33.67, 33.70, 33.29, 33.65, 33.74, 33.70 and 35.70 respectively, and the average FSIM are 0.7346, 0.7752, 0.7880, 0.7679, 0.7783, 0.7814, 0.7880 and 0.8428 respectively. The PSNR value and FSIM value of the loss function combination A8 used in the study are significantly larger than other loss function combinations. From Fig. 8(b), on GMSD, the average values of the eight loss function combinations are 0.2701, 0.2591, 0.2440, 0.2382, 0.2425, 0.2279, 0.2440 and 0.2041 respectively. A8 has the smallest GMSD value. The average SSIM values of the eight loss function combinations are 0.7710, 0.7413, 0.7856, 0.7746, 0.7983, 0.7872, 0.7856 and 0.8669 respectively. A8 has the largest SSIM value. The loss function combination A8 used in the study is beneficial to the image results generated by the final model. In order to better validate the performance of the line drawing generation algorithm, other similar models were selected for comparison. The comparison models include the facial portrait line generation algorithm based on unpaired training data designed by R. Yi et al. [23], the bipartite graph inference generative adversarial network designed by H. Tang et al. [24], and the facial image generation algorithm based on edge optimization and generative adversarial network designed by F. Zhang et al. [25]. The comparison of image generation time and FID using different methods is shown in Table I.

From Table I, it can be seen that in terms of image generation time, the maximum value of the research and design line

drawing generation algorithm is 13.88s, and the minimum value is 11.36. The minimum time consumption of facial portrait line generation algorithm based on unpaired training data, bipartite graph inference generative adversarial network, and facial image generation algorithm based on edge optimization and generative adversarial network are 20.62, 23.42, and 16.38, respectively. In addition, the minimum values for the four methods in FID values are 67.52, 115.05, 123.01, and 101.59, respectively. It can be seen that the research and design of line drawing generation algorithms takes less time and the model quality is better. To verify the robustness and generalization ability of the learning network, the image generation effect analysis was conducted. The specific image generation effect is shown in Fig. 9.

From Fig. 9(a) that in the generated image of anime face line drawings, details such as the hair of anime characters are better generated, the lines are smooth and clear, and the features are accurately grasped. The facial features of anime characters are well preserved, such as eyes, noses, etc. In addition, the physical details of anime characters are also well preserved. From Fig. 9(b), when the image generation range is expanded from the face to the whole body, the generated line drawing image effect is also very good, and the hair, charm, body structure and other characteristics of the anime characters are well preserved. The algorithm designed by the research has good generalization ability and robustness.

Fig. 8. Comparison of indicators under different loss function constraints.

TABLE I. COMPARISON OF IMAGE GENERATION TIME AND FID USING DIFFERENT METHODS

Model	Time consumption/s					FID				
	Number of experiments					Number of experiments				
	1	2	3	4	5	1	2	3	4	5
R. Yi et al. [23]	21.36	20.62	21.37	22.09	21.75	115.05	117.84	121.10	117.78	116.59
H. Tang et al. [24]	25.42	24.17	24.04	25.83	23.42	123.01	125.24	127.70	130.51	129.32
F. Zhang et al. [25]	17.87	16.38	17.16	18.33	19.01	104.23	103.83	109.78	101.59	106.60
Manuscript	12.97	11.71	13.88	12.55	11.36	67.52	69.04	68.54	70.13	68.66

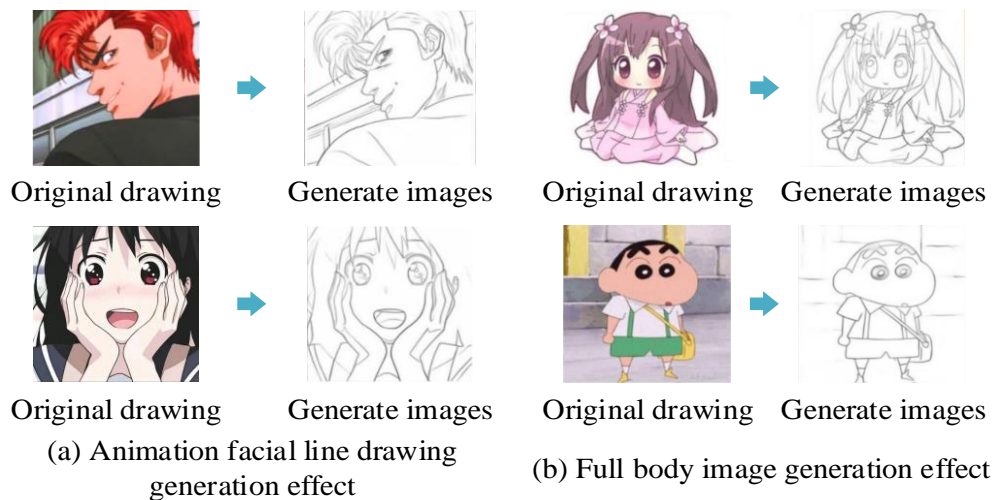

Fig. 9. Specific image generation effects.

B. Performance Verification of Face Caricature Image Generation Algorithm

To assess the effectiveness of the face caricature image generation algorithm, an ablation experiment was conducted. Ablation experiments are mainly carried out from the overall model. The overall model compares U-GAT-IT (baseline), U-GAT-IT+semantic constraints and the comic image generation model designed by the research institute [26]. The indicators used in the experiment include FID, Mean Squared Error (MSE), PSNR and SSIM. Among them, MSE is an indicator used to measure the difference between a model's predicted values and actual observed values, and is commonly used to evaluate the degree of fit of a model on a given data. The data sets used in the experiment include the Flickr-Faces-High-Quality (FFHQ) data set and the Avatar data set. The operating system and processor used in the experiment are the same as those in Section III(A) and will not be repeated here. The facial comic image generation algorithm uses an Adam optimizer with a learning rate of $1e-4$ and a training batch size of 1. In addition, the values of the algorithm on δ_1 , δ_2 , δ_3 , δ_4 , and δ_5 are 1, 10, 10, 1000, and 10 respectively. The comparison of FID values and MSE values of different models is shown in Table II.

From Table II, it can be seen that the maximum FID values of the U-GAT-IT model, U-GAT-IT + semantic constraints and the comic image generation model designed by the institute are 144.68, 103.49 and 81.60 respectively, and the minimum values are 139.54, 139.54 and 81.60 respectively. The FID index can express the similarity of feature distributions of two sets of images, and the smaller the FID value, the more similar the feature distributions are. In addition, the max MSE values of the three models are 3.27, 2.98, and 1.42 respectively, and the mini values are 3.04, 2.65, and 1.21 respectively. The MSE metric can also evaluate the quality of images generated by the model. The FID value and MSE value of the model designed by the institute are significantly lower than the baseline model, and the FID value and MSE value of the U-GAT-IT + semantic

constraint model are also significantly lower than the baseline model. This shows that the comic image generation model designed by the research has better performance, and also proves the effectiveness of the semantic constraints and group activation mapping modules. The comparison of PSNR values and SSIM values of different models is indicated in Table III.

From Table III, the max PSNR values of the U-GAT-IT model, U-GAT-IT + semantic constraints and the research design model are 32.65, 36.97 and 39.65 respectively, and the mini values are 31.87, 35.36 and 38.44 respectively. In terms of SSIM values, the max values of the three models are 0.7357, 0.7743 and 0.8284 respectively, and the mini values are 0.7123, 0.7615 and 0.8117, respectively. The PSNR value and SSIM value of the model designed by the institute are significantly greater than those of the baseline model and the U-GAT-IT + semantic constraint model, which shows that the performance of the model designed by the institute is better and the quality of the images it generates is better. To better verify the performance of the model designed in the study, the study selected other advanced unsupervised models for comparison. Comparative models include Cycle-consistent Generative Adversarial Network (CycleGAN), Adaptive Convolutions (AdaConv) and No Independent Component Encoding Generative Adversarial Network (NICEGAN). The comparison of FID and time consumption of different models is shown in Fig. 10.

From Fig. 10(a), in terms of FID values, the maximum values of CycleGAN, AdaConv, NICEGAN and the research design model are 263.57, 365.96, 119.47 and 81.60 respectively, and the minimum values are 251.75, 352.64, 102.31 and 71.32 respectively. From Fig. 10(b), in terms of time consumption, the maximum values of the four models are 22.54s, 21.31s, 19.32s and 15.21s respectively, and the minimum values are 20.46s, 19.89s, 17.65s and 13.24s respectively. Whether it is in terms of FID value or model time consumption, the performance of the research design model has more advantages.

TABLE II. COMPARISON OF FID AND MSE VALUES FOR DIFFERENT MODELS

Model	FID					MSE				
	Number of experiments					Number of experiments				
	1	2	3	4	5	1	2	3	4	5
U-GAT-IT	139.54	140.87	144.68	143.92	142.85	3.27	3.11	3.21	3.04	3.18
U-GAT-IT +semantic constraints	97.45	103.49	102.71	99.21	95.86	2.65	2.78	2.98	2.82	2.73
Research	71.32	75.64	81.60	73.17	77.48	1.42	1.37	1.29	1.32	1.21

TABLE III. COMPARISON OF PSNR AND SSIM VALUES FOR DIFFERENT MODELS

Model	PSNR					SSIM				
	Number of experiments					Number of experiments				
	1	2	3	4	5	1	2	3	4	5
U-GAT-IT	32.57	32.24	31.98	32.65	31.87	0.7123	0.7344	0.7357	0.7224	0.7234

C. Discussion

Aiming at the improvement of image quality generated by anime drawing robots, this study designs facial line drawing generation algorithms and comic image generation algorithms from the perspectives of anime lines and comic images. The results show that the maximum PSNR of the knowledge distillation based generation algorithm is 39.45, and the minimum value is 37.51, which is significantly better than the comparison model. Researchers such as M. Yuan have designed a cross task knowledge distillation method and a multi-stage knowledge distillation paradigm to address the issue of text synthesized images, achieving improvements in visual quality and semantic consistency of synthesized images [27]. The generation algorithm based on knowledge distillation is similar to the research results of M. Yuan et al. The maximum and minimum FID values of the comic image generation model based on semantic constraints are 81.60 and 71.32, respectively,

with a maximum time consumption of 15.21 seconds. The performance is superior to the comparison model. In order to solve the problem of low image generation quality under limited data, Y. Gou et al. designed a cross domain semantic relationship loss to improve the performance of image generation models under limited data. The comic image generation model based on semantic constraints is similar to the research results of Y. Gou et al. [28].

V. CONCLUSION

To raise the quality of images generated by animation drawing robots, an animation face line drawing generation algorithm based on knowledge distillation was designed, and an unsupervised face comic image generation algorithm based on semantic constraints was also designed. The results show that the maximum PSNR values of the U²-Net model, teacher network model, student network model, student network + knowledge distillation model and line drawing generation model

are 34.58, 36.70, 33.55, 38.64 and 39.45 respectively, and the minimum values are 31.58, 33.87, 30.33, 36.35 and 37.51. The performance of the line drawing generation model designed by the institute is better, and the modules added by the institute are effective. The average values of the loss functions PSNR, FSIM, GMSD and SSIM of the line drawing generation model are 35.70, 0.8428, 0.2041 and 0.8669 respectively. Investigate the combinations of loss functions used that are beneficial to the image results generated by the final model. The maximum FID values of the U-GAT-IT model, U-GAT-IT + semantic constraints and comic image generation model are 144.68, 103.49 and 81.60 respectively, and the minimum values are 139.54, 95.86 and 71.32 respectively. The maximum and minimum time consumption of the comic image generation model are 15.21s and 13.24s respectively. The performance of the comic image generation model is better, and the semantic constraints and group activation mapping modules used in the study are effective. The performance of the comic image generation of research model can be further improved on some images. Future research can introduce the Spade module to maintain the structure and improve the quality of image generation on facial features. In addition, future research can also extend knowledge distillation to multi-task models to improve the performance of learning network models.

Abstract—The increasing demand for sustainable energy solutions and environmental monitoring necessitates advanced technologies. This work combines the capabilities of AI, in the form of a GRU-Auto encoder, with IoT-connected Advanced Optical Systems to create a comprehensive monitoring system. Current monitoring systems often face limitations in real-time analysis and adaptability. Conventional methods struggle to provide timely insights for sustainable energy and environmental management due to the complexity of data patterns and the lack of dynamic adaptability. Our proposed methodology introduces an optimized GRU-Auto encoder, which excels in learning complex temporal patterns, making it well-suited for dynamic environmental and energy data. The integration with Advanced Optical Systems ensures a continuous influx of high-quality real-time data through IoT, enabling more accurate and adaptive analysis. The study involves optimizing the GRU-Auto encoder through hyper parameter tuning and gradient clipping. The model is integrated into an IoT platform that connects with Advanced Optical Systems for seamless data flow. Real-time data from environmental and energy sensors are processed through the AI model, providing immediate insights. Performance is evaluated based on the system's ability to accurately predict environmental trends, optimize energy consumption, and adapt to dynamic changes. Comparative analyses with traditional methods show advantages of the suggested strategy in terms of efficiency and accuracy. This research presents a significant development in the field of study of sustainable energy and environment monitoring, offering a robust solution for real-time data analysis and adaptive decision-making. The integration of an optimized GRU-Auto encoder with IoT-connected Advanced Optical Systems showcases promising results in improving overall system performance and sustainability.

I. INTRODUCTION

Pollutants that degrade the natural environment pose a major hazard to the environment and the well-being of humans. Human activities such as mineral extraction, fast urbanization,

industrialization, and unregulated development of resources from nature are regarded as the primary causes of worldwide environmental contamination Tripathy et al. [1]. Synthetic microfiber pollution caused by the home laundry of synthetic clothes has recently been identified as an important cause of synthetic micro plastic contamination in the marine environment using several monitoring methods [2]. These are fine, soft, lightweight luxury fibres created from synthetic or natural fibres that are used for a large number of tasks ranging from industrial filtration to household cleaning [3]. Microfibers are comprised of polypropylene, polyamide (nylon), and polyethylene terephthalate; thus they are porosity and dry, making them great for cleansing. The widespread usage of synthetic microfibers in all industries has resulted in the build-up of microfibers trash in both soil and maritime environments, posing a significant hazard to the environment today and in years to come [4]. Microfibers are a serious marine contaminant because of their durability, ubiquity, and synthetic nature.

The overuse of petroleum and coal has caused global warming and serious environmental contamination. Electronic devices and wireless sensor networks that track the surrounding environment need conventional sources of power like cells and electrical wire nets [5]. Yet, typical sources of power for WSNs have drawbacks, such as complicated wiring, short lives, difficult servicing and repair in remote regions, and possible pollution of the environment. Considering these factors, scientists are frantically looking into other renewable energy sources like wind, solar power, heat, and water waves. Wind is regarded as one of the most important energy sources. It has various advantages, including high energy capability, frequent and prevalent presence in nature, and eco-friendliness [6]. Typical wind energy harvesting requires huge dimensions and quantities, distant sites, and high manufacture and construction expenses, limiting its use to autonomous WSNs. As a result, scientists are working to miniaturise wind-powered generators for autonomous WSNs in real-world applications [7]. The wind energy generated by running trains and automobiles in tunnels and adjacent tube lines may be captured and utilized to power self-contained environmental monitoring devices. There is a

high need for power to illuminate extensive tunnels for safety reasons [8]. In addition, lit posters and dynamic LED displays for passengers may be fascinating uses to be driven by the generated flowing wind in subway lines and man-made tunnels.

With the rapid growth of industry and agriculture, along with the widespread use of synthetic medications in human life, the water, air, and the planet's environments have been contaminated by a variety of toxic pollutants, including heavy-metal ions, organic substances, dyes, drugs, chemicals, bacteria, viruses, gases, and others [9]. The presence of even trace amounts of toxicity can endanger the environment and cause irreparable harm to individuals. As a result, the rapid, actual time, sensitive, and specific detection of harmful contaminants in natural habitats became critical. Conventional bioanalysis methods, like UV-vis spectroscopy, high-efficiency liquid chromatography-mass spectrometry, atom absorption spectroscopy, and more, have been extensively used to determine a variety of substances, and analytical substances with extremely low concentrations have been successfully detected [10]. These devices are costly and require sophisticated operation. Furthermore, finding it is time-consuming. These restrictions limited the extensive use of the aforementioned methodologies for easy, rapid, and reliable bioanalysis and identification of diverse toxins [11].

Air pollution harms the well-being of people and is seen as a major worldwide concern, particularly in nations where the gas and oil sectors are prevalent. The main objective of environmental monitoring isn't just to collect data from multiple positions, but also to supply researchers, developers, and legislators with the data they need to make decisions about how to handle and enhance the environment, as well as to present useful data to end users. Air pollution in India is a serious health issue [12]. Based on a 2016 study, at least 140 million people in India inhale air that is 10 times or greater filthy above the WHO tolerable limitation, and India is host to 13 of the globe's 20 cities with the lowest annual pollutant levels. Pollution from industries accounts for 51% of total pollution, followed by cars (27%), agricultural burning (17%), and fireworks (5%). Every year, air pollution causes two million premature mortalities in India. Thus, it is vital to monitor environmental conditions and reduce air pollution. Researchers use a temperature and humidity sensor to determine the temperature and humidity of the atmosphere, which helps us anticipate environmental conditions [13]. The MQ7 sensor detects carbon monoxide in the surroundings, whereas the MQ135 monitors air quality. The server keeps and displays the present values for each of the four variables. A lookup database is created that contains an array of moisture and temperature and is used to anticipate the present climate. For instance, if the humidity is high while temperature is low, the likelihood of rain increases.

The study aims to solve the developing issues of monitoring and controlling sustainable energy and environmental factors by offering an innovative combination of AI and the IoT in the field of Advanced Optical Systems. The widespread use of Advanced Optical Systems, which include advanced environmental detectors and energy monitoring equipment, has paved the way for a thorough awareness of our surroundings.

However current monitoring approaches have significant drawbacks concerning real-time analysis, flexibility to variable modifications to the environment, and the sophisticated processing of the complicated temporal patterns associated with gathered data. To address these gaps, we provide a cutting-edge method that makes use of a GRU-Autoencoder. The GRU-Autoencoder, selected for its ability to capture complicated temporal correlations within data, is optimized through thorough parameter adjustment. This AI model is at the heart of our methodology, providing a solid platform for real-time, adaptive evaluation of environmental and energy data. The research goes beyond AI innovation and embraces the Internet of Things concept. Advanced Optical Systems are completely connected with an IoT platform, creating a network for safe and efficient communication. This connectivity not only provides continuous data flow, but also enables the development of an evolving system that can adapt to changing environmental circumstances. The fundamental aims of this study derive from the complex interplay of AI, IoT, and Advanced Optical Systems: to improve the precision and effectiveness of sustainable energy and environmental monitoring. This work contributes to the increasing body of knowledge in the sector, providing a potential pathway for the creation of adaptive systems that can usher in a new era of sustainable resource management. We want to illustrate our approach's disruptive potential by thoroughly examining the suggested methodology, which includes model optimization, data processing, IoT integration, and actual time performance evaluation. The findings of this study have ramifications for a wide range of industries, from energy generation and use optimization to active environmental leadership, laying the path for a more resilient and environmentally friendly future. The key findings from this study are as follows:

- Presents an innovative integration architecture that integrates a GRU-Auto encoder with Advanced Optical Systems and the IoT for sustainable energy and environmental monitoring.
- Improves the GRU-Auto encoder's efficiency using rigorous optimization strategies, such as hyper parameters tweaking, to collect and analyse complicated temporal trends in real-time data.
- Integrates Advanced Optical Systems seamlessly with an IoT platform, guaranteeing safe and efficient connection, ongoing information flow, and flexibility to adapt in ambient circumstances.
- Real-time transfer of information from gadgets connected to the Internet of Things to the artificial intelligence algorithm allows for adaptive study of environmental changes and dynamic energy usage patterns.
- Helps the progress of sustainable management of resources by offering precise information about environmental trends, optimizing energy usage, and encouraging educated making decisions for a healthier future.

The study, which begins with a detailed literature analysis in Section II, sheds light on the present state of AI, IoT, and

optical systems in sustainable energy and environmental monitoring. Section III summarises the issue statement, noting the limits of standard monitoring systems and proposing a creative integrated solution. Section IV discusses the study approach, which includes data collecting, system design, AI algorithm development, and rigorous testing processes. Section V summarises the study's findings, demonstrating the usefulness of the integrated system through performance assessments. Section VI dives into topics, including ramifications, methodological comparisons, and prospective applications. Section VII is a detailed conclusion that summarises significant findings and the transformational potential of the combined AI and IoT method for developing sustainable energy and environmental monitoring techniques.

II. RELATED WORKS

Ullo et al. [14] explains that Air quality, water pollution, and radiation contamination are significant environmental issues. Appropriate monitoring is essential so that the globe may attain sustainable development while preserving a healthy society. With advancements in IoT and the introduction of sophisticated sensors, environmental monitoring has evolved into a smart environmental monitoring (SEM) system. Given this context, the current publication attempts to conduct an in-depth evaluation of important developments and study works on SEM, including monitoring of air and water quality, radioactive pollution, and agricultural systems. The examination is structured around the aims for which SEM methods are utilized, and every purpose is then analysed based on the sensors utilised, machine learning methods used, and classification approaches used. The comprehensive analysis followed an exhaustive study that made crucial recommendations and implications for SEM research based on conversations regarding results and study patterns. The authors looked at advances in sensor technology, IoT, and machine learning technologies might convert environmental monitoring into a truly smart monitoring system. A method based on powerful machine learning methods, denoising techniques, and the construction of acceptable norms for wireless sensor networks (WSNs) is being developed. One possible disadvantage is the extended scope, since researching other elements such as sound pollution and catastrophes may raise the level of difficulty and financial requirements of the study.

The population has grown dramatically in recent decades, as has socioeconomic progress. In terms of environmental change caused by societal and economic growth, the maritime environment has a substantial impact on global climate change. As a result, current communications and information technicians are interested in monitoring the maritime environment. Several maritime monitoring systems have been developed in recent years. The Internet of Things is particularly important in this regard. IoT-based maritime surveillance systems, many sensors are used in real-time to track and measure numerous physical factors. These sensors operate on battery power. When the battery empties, monitoring action may be interrupted till the batteries is replaced. Reddy et al. [15] focuses on establishing a system of predictions for forecasting the battery's lifespan in advance of time and alerting technicians so that surveillance is not stopped, utilising Principal Component Analysis (PCA) and Deep Neural Network (DNN).

The method is assessed utilising raw data acquired from a real-time coastal monitoring system located along the Chicago Park District's beach water. The collected findings are contrasted and evaluated using two frequently utilised state-of-the-art methods: Linear Regression and XGBoost. The findings reveal that the suggested PCA-based DNN Predictions Model beats the other strategies by 12% in correctness and 30% in reduced time complexity. Using the suggested forecasting framework to different real-time IoT networks may bring hurdles in terms of adjusting the method to varied network designs, and evaluating the influence of the bio-inspired method on decreasing dimensionality might entail new computing complications.

Okafor et al. [16] explains that the present growth in global climate change issues has made environmental monitoring an important study subject. Existing environmental monitoring systems, on the other hand, are expensive to acquire and hard to implement, needing substantial resources, facilities and experience. It is unable to produce with these methods high density within-situ networks, like those necessary to develop finer scale simulations to support robust monitoring, resulting in huge gaps in the acquired dataset. Low-Cost Sensors may provide high-resolution spatiotemporal metrics that can be utilised to enhance current environmental surveillance datasets. LCS, on the other hand, require periodic correction for them to produce accurate and trustworthy data because they are typically influenced by surroundings when installed in the field. Calculating LCS can assist enhance data quality and assure correct data collection. But successful validation necessitates recognising variables that influence sensor quality of data for a specific measurement. The current study compares the efficacy of three features selection algorithms, namely Forward Feature Selection, Backward Elimination (BE), and Exhaustive Feature Selection, to identify parameters that impact the data dependability of low-cost connected gadget sensors used to monitor environmental systems. Using the information fusion technique, sensor data was merged with environmental characteristics to create a single validation equation for evaluating sensors using Linear Regression and Artificial Neural Networks. The research found that calibration may increase the value of low-cost IoT sensor data, and it can also make choosing features and data fusing easier, resulting in more dependable, precise, and trustworthy data for calibrating systems. The study found that the cairclipO3/NO2 sensor offered readings that had a significant relationship with prior measures, whereas the cairclipNO2 sensor showed no relevant link with the source information.

Coulby et al. [17] Monitoring indoor environmental quality (IEQ) is becoming increasingly important for well-being as well as health. New building regulations, climate objectives, and the introduction of work-from-home practices are driving demand for flexible monitoring systems with onward Cloud connection. Affordable Micro-Electromechanical Systems (MEMS) sensors can meet these objectives, allowing for the creation of customized multifunctional devices. Researchers report findings from the creation of MEMS-based IoT-enabled multifunctional devices for IEQ tracking. Research was carried out to determine inter-device variation and validity against benchmark sensors/devices. For the multifunctional IEQ track, interclass relations and Bland-Altman studies showed strong

inter-sensor consistency and excellent agreement for the majority of sensors. All affordable sensors were shown to be responsive to environmental changes. Numerous sensors indicated poor accuracy with high precision, indicating that they might be corrected using reference devices to improve accuracy. The multimodal devices created here was shown to be suitable for its intended function of giving general signs of environmental changes for ongoing IEQ monitoring. However, increasing the installation of the multifunctional device for ongoing surveillance may pose logistic and operational problems that must be handled with care in practical applications.

Kashid et al. [18] explains that Nowadays, environmental preservation is critical for humans to ensure secure and prosperous living. Tracking requirements vary greatly, depending on geography and expanding to specialized uses that require flexibility. The suggested system describes the deployment of an IoT that may evolve into a variety of programs and has the versatility necessary to exchange and improve without the need to systematize complex equipment. The solution is essentially built on independent Wi-Fi sensor nodes, tiny Wi-Fi receivers connected to the internet, and a cloud architecture that provides data storage and transit to remote customers. The solution enables administrators at home to not only monitor the current situation on their mobile phones but also expose remote Internet Websites. All evaluations are kept at various stages to enable secure conformance and accessibility to preserved information in the case of a group breakdown or reachability. The suggested gadget is useful for monitoring temperature, humidity, and other parameters. This value is predicted using machine learning approaches like regression and editing. Pre-data processing is necessary for removing the data through error rate, verification of information, and so on. Machine learning algorithms are extremely strong and accurate when working with data predictions.

In the last few years, environmental monitoring has grown into an SEM system, making use of improvements in IoT, sensor technology, and machine learning. Studies, such as those done by Ullo et al., emphasize the need to monitor air quality, quality of water, radiations contamination, and agricultural systems for environmentally friendly growth. Yet, the inclusion of other elements such as noise pollution and catastrophes in SEM study may present difficulties. Reddy et al. offer by creating a method for forecasting the charge life of IoT-based maritime monitoring devices, which improves continuous monitoring. Although the suggested model beats previous strategies, it may be difficult to adapt to different real-time IoT networks. Okafor et al. tackle the expense and complicated nature of environmental monitoring systems by investigating sensors with low prices and testing choosing features methods for validation. The research reveals how calibration may improve data quality, especially for certain sensors. Coulby et al., on the other hand, focus on the quality of indoor environment monitoring utilizing MEMS-based IoT-enabled multimodal devices, emphasizing its dependability while admitting scaling limitations. Kashid et al. provide a system

based on the IoT for environmental monitoring that emphasizes flexibility and simplicity of installation. The system stores and transports data using Wi-Fi node sensors and a cloud platform. Machine learning approaches are used to forecast variables such as temperature and humidity, demonstrating the system's accuracy. In general, these investigations provide helpful insight into the problems, improvements, and possible downsides in the area of environmental monitoring, emphasizing the need for constant creativity and adaptability in the context of new technology.

III. PROBLEM STATEMENT

Despite the advances in EMS highlighted in the papers, problems remain. One disadvantage is the possible difficulty of converting IoT-based marine monitoring models to various real-time IoT networks, which limits their general application. Furthermore, the scalability limits in MEMS-based IoT-enabled interior environment monitoring devices emphasize the difficulty in expanding the dependability of such systems to greater scales. Existing methods may fail to offer timely, smart, and precise tracking of energy use, emissions, and environmental factors [19]. The lack of a seamless connection between AI and IoT technologies impedes the creation of a comprehensive solution for effective and sustainable monitoring procedures. The originality of this research resides in solving the constraints associated with existing environmental monitoring devices by proposing an extensive approach that incorporates AI and IoT into Advanced Optical Systems. Traditional monitoring systems sometimes suffer from immediate evaluation and flexibility, which limits their usefulness in sustainable energy and environmental management. The suggested solution solves these issues by employing an optimized GRU-Auto encoder, which is well-known for its ability to learn complicated temporal patterns. This unique AI model is optimized for changing environmental and energy data, increasing the systems adaptively. The combination of Advanced Optical Systems and IoT allows for a constant and high-quality stream of real-time data, resulting in more precise and adaptable assessments. By merging cutting-edge AI skills with IoT connection and overcoming the limits of traditional approaches, we can considerably improve the area of sustainable energy and environmental monitoring.

IV. INTEGRATING AI AND IoT FOR SUSTAINABLE ENERGY AND ENVIRONMENT MONITORING

The study technique includes defining the scope by identifying difficulties in current sustainable energy and environmental monitoring systems. The study's basic AI model is a GRU-Auto encoder, which is optimized for efficiency using hyper parameter tweaking. Different data from Advanced Optical Systems, including environmental sensors and energy monitoring devices, undergo rigorous pre-processing. Integration with IoT allows for safe connectivity and immediate information transfer to the GRU-Auto encoder. The process closes with a thorough performance evaluation, applying specific criteria to measure the system's accuracy in anticipating environmental trends and optimizing energy use, providing important conclusions for sustainable resource management. Fig. 1 explains the overall conceptual diagram.

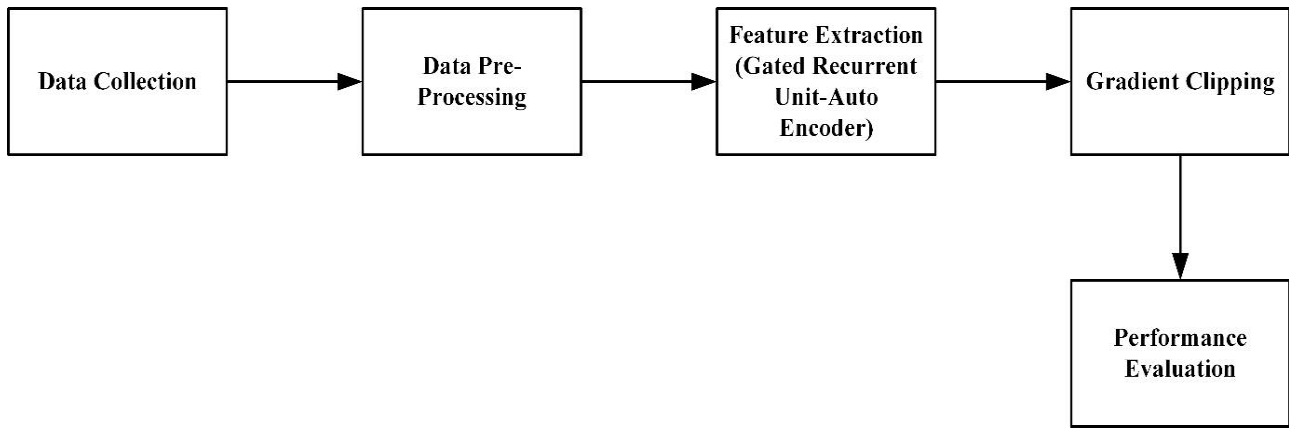

Fig. 1. Conceptual diagram.

A. Data Collection

The data was collected from three identical, made specifically sensor arrays. Every array was linked to a Raspberry Pi device. All of these three IoT gadgets were installed in a real location with varying environmental conditions. Each IoT device gathered seven distinct values from all four sensors at regular times. Sensor outputs include smoke, temperature, CO, humidity, sunlight, LPG, and motion. The information ranges from 07/12/2020 00:00:00 UTC to 07/19/2020 23:59:59 UTC. There are 405,184 rows of information. The sensor values, together with a unique device ID and date, have been transmitted as a single message, utilizing the ISO standard Message Queuing and Telemetry Transport (MQTT) networking protocol [20]. Table I depicts the dataset criteria.

TABLE I. DATASET DESCRIPTION

Device	Humidity	Light	Motion	Smoke	Temp
b8:27: eb:bf:9d:51	51.0	False	False	0.020411	22.7
00:0f: 00:70:91:0a	76.0	False	False	0.013275	19.700001
b8:27: eb:bf:9d:51	50.9	False	False	0.020475	22.6
1c:bf: ce:15:ec:4d	76.800003	True	False	0.018628	27.0

B. Data Pre-processing

The data preliminary processing layers are positioned in the heart of the IoT systems topologies, allowing raw data's to be collected and pre-processed utilising contemporary data mining techniques. It also finishes information collection or breakdown, data cleaning, matching or assessment, sharing as appropriate, and occasionally triggers alarms or warnings depending on established standards.

C. Data Cleaning

Data is filthy when a large amount of inaccurate data (e.g., instrument failure, communication error, and human or computer mistake) is discovered in the actual world. The acquired data may be partial, missing key features of interest or value, noisy, and inconsistent, with errors in codes or names. In this study, unfinished (missing data) and noise are considered into account.

D. GRU-Auto Encoder

As a model for deep learning, RNN uses a structure known as loops to gather temporal information from the input sequences. GRU and LSTM networks are two examples of upgraded RNNs that can successfully gather time-based information while also addressing the gradient disappearing problem. Compared to LSTM, the GRU network has reduced training variables, resulting in improved training efficiencies at comparable accuracy. Thus, the GRU networks are used in the present research to extract and merge the temporal aspects of the input information. Fig. 2 depicts the basic GRU construction, which comprises of update gate z and reset gate r . The update gate z represents the number of information transmitted from the hidden state that was previously present to the present time point, whereas the reset gate r determines whether it ignores the prior hidden state. Eq. (1) describes the operation of each GRU, with the hidden state h representing the secret time data recovered by every unit [21].

$$H^{t1} = f(H^{t1-1}, x_{(t)}) \tag{1}$$

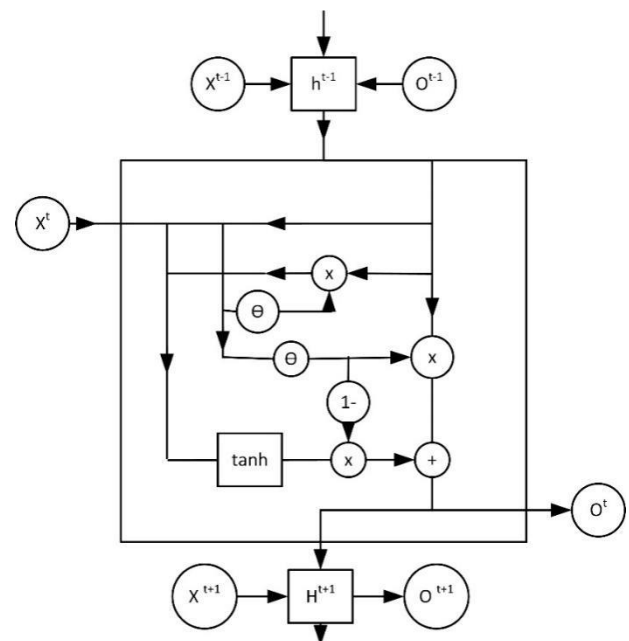

Fig. 2. GRU Architecture.

where, H^{t-1} and H^t represent the hidden states at time $t-1$ and time t , respectively, while $x_{(t)}$ signifies the input series of data at time t . Therefore, the reset gate r and the gate for updating z may be determined as follows in Eq. (2) and Eq. (3):

$$r^t = \sigma(W^r x_{(t)} + U^r h^{t-1} + b^r) \quad (2)$$

$$z^t = \sigma(W^z x_{(t)} + U^z h^{t-1} + b^z) \quad (3)$$

σ is the exponentially activating equation, while W^r, W^z, U^r , and U^z are the adaptive coefficient matrices. b^r and b^z indicate the bias. The concealed state at that point can be reconstructed in Eq. (4) and Eq. (5):

$$H^t = (1 - z^t) \odot H^{t-1} + z^t \odot H^t \quad (4)$$

$$\tilde{H}^t = \tanh(W^v x^{(t)} + U^v (r^t \odot H^{t-1}) + b^v) \quad (5)$$

where, W^v and U^v are the adaptable Coefficient matrix and b^v is the bias [21].

The collection of M sensors (also known as data generators), marked $\{m^1, \dots, m^M\}$, are employed to record the behaviour of the turbo compressor. Each sensor m^i provides a vibration observing sequence $x^i = (x_1^i, x_2^i, \dots)$. The data generator $m^i_{i \in \{1 \dots M\}}$ is modeled with an LSTM-based autoencoder AE^i that is trained by continuous gradient descent to minimize the reconstruction error term among the initial signal and the reconstructed one [22].

AEs are a nonlinear generalization of principal component analysis. They both fall under the category of unsupervised representational learning, which "tries to characterize the data-generating distributions through the identification of a set of characteristics or latent variables that vary to capture the majority of the framework of the data-generating distribution". These latent variables constitute the "information bottleneck" because of their small size, forcing the model to learn crucial properties from the initial signal. This occurs through a pair of processes: encoding and decoding, both based on the LSTM unit.

LSTM units are a strong sort of RNN that avoids the long-term dependency issue while memorizing information over time. The main element of these parts is the cell state, which is meant to maintain information over a period. At every interval t , information is introduced to and eliminated from this cell state using distinct gates: the forget gate f^t defines the degree to which data remains from earlier time-step; the input gate i^t manages the movement of data from the present input x^t , and the gate that outputs the data o^t enables the framework to obtain data from the cell.

Informally, given a series of inputs $x = (x^{t_1}, \dots, x^{t_2})$ between two predetermined t_1 and t_2 , irrespective of the data generator, at every one time step, the present state of the cell c^t , and also the present secret state h^t , are calculated employing the prior cell state c^{t-1} and the present input sample in Eq. (6-11):

$$i^t = \sigma(W^{ii} x^t + b^{ii} + W^{hi} h^{t-1} + b^{hi}) \quad (6)$$

$$f^t = \sigma(W^{if} x^t + b^{if} + W^{hf} h^{t-1} + b^{hf}) \quad (7)$$

$$g^t = \tanh(W^{ig} x^t + b^{ig} + W^{hg} h^{t-1} + b^{hg}) \quad (8)$$

$$o^t = \sigma(W^{io} x^t + b^{io} + W^{ho} h^{t-1} + b^{ho}) \quad (9)$$

$$c^t = f^t c^{t-1} + i^t g^t \quad (10)$$

$$h^t = o^t \tanh(c^t) \quad (11)$$

where, the matrix values W and b reflect its biases and weights. The subscripts correlate to the respective gates, such as W^{hi} for the hidden-input gates matrix and W^{io} for the inputs and outputs gate matrix. These are learned using gradient descent, whereas σ and \tanh are the logistic and hyperbolic tangent operations, accordingly, which are employed to inject irregularities within the model.

The first element encrypts a sequence of characters or a set of sequences with LSTM units and changes its hidden state by Eq. (1). They call this procedure $h^t = LSTM(h^{t-1}, x^t)$. The final hidden state has sufficient details regarding the framework of the entire input pattern that has been processed to retrieve the initial sequence through decoding [22]. Every generator is evaluated independently to provide an encoding c^{m^i} at the final time-step t_2 utilizing the previous hidden state h^{t_2-1} as Eq.. (12):

$$c^{m^i} = LSTM(h^{t_2-1}, x^{t_2}) \quad (12)$$

To determine the behaviour of the generators m^i by including a set of associated ones $\{m^j | j \in J\}^{J \subseteq \{1 \dots M\}}$, an encoder c^{m^j} is learned using the rest of the concatenation signals, and the secret state is thus modified as follows in Eq. (13).

$$c^{m^j} = LSTM(h^{t_2-1}, [x_j^t]_{j \in J}) \quad (13)$$

This encoded information is also known as context vectors, particularly in the area of machine transformation because they record the context, or significance, of a specific sequence of words.

This encoded information, which reflects the initial signal's reduced form, is used to track its restoration. At every time step, the decoder receives the encoded value c^{m^i} (or c^{m^j}) and both the ground truth example and the earlier reconstructed example. This is known as the teacher-forcing method, as opposed to the free-running option. Likewise, to the encoders, the state that is hidden (h^t) is modified in Eq. (14):

$$h^t = LSTM(h^{t-1}, y^{t-1}, c^{m^i}) \quad (14)$$

Let $y^i = (y_i^{t_1}, \dots, y_i^{t_2})$ be the auto encoder's results that correspond to the input pattern $x^i = (x_i^{t_1}, \dots, x_i^{t_2})$ of the information generator m^i got through a linear model of the hidden state. They characterize the total expense function J concerning x^i and the reconstructed y^i as the mean square error as Eq. (15).

$$MSE(x^i, y^i) = \frac{1}{t_2 - t_1} \sum_{t=t_1}^{t_2} (x_i^t - y_i^t)^2 \quad (15)$$

Forward and backward transmission of the errors in reconstruction among the decoder and encoder parts allows the framework to reduce the disparity between the initial signal and its reconstructed form and, in addition, results in a space of latent information (the encoding) which reflects important

characteristics of the data distribution [22]. Fig. 3 shows the Architecture of Auto encoder.

Algorithm: GRU-Auto encoder for Sustainable Energy and Environment Monitoring.

- 1) Import and pre-process data.
- 2) Separate data into testing and training sets.
- 3) Normalise data.

E. Gradient Clipping

The problem of ballooning gradients presents a substantial difficulty, particularly in deep architectures. This problem occurs when the distributions of the loss function grow overly big, resulting in unstable and divergence training. To address this issue, the gradient clipping approach uses a threshold setting. If the calculated gradient norm exceeds the threshold during backpropagation, the whole gradient vector is correspondingly scaled down to ensure that it does not exceed the limit. This precise control enhances the reliability of the training procedure, reducing the possibility of model divergence and allowing for smoother convergence. By carefully choosing the threshold and implementing gradient clipping, professionals improve the resilience of neural network training, especially in complicated circumstances where the bursting gradient issue may hamper progress. This approach is a key asset in the collection of tactics that focus on improving the dependability and efficacy of deep learning models.

F. Integration with IoT and Real-time Data Flow

During the implementation phase, Advanced Optical Systems are smoothly integrated into an IoT platform, resulting

in a single environment for efficient data transmission. This connection is formed through the use of Application Programming Interfaces (APIs) or middleware, which allows for effective communication between Advanced Optical Systems and the IoT platform. Simultaneously, strong communication protocols like HTTPS are used to improve data security. This guarantees the encryption of the incorporated data during transmission, preventing unauthorized access. The ongoing real-time stream of information is then controlled via protocols such as MQTT, allowing for the constant transmission of secured information from devices connected to the Internet of Things to the GRU-Auto encoder. This constant information flow, together with the flexibility inherent in the GRU-Auto encoder architecture, enables the model to stay in sync with changing environmental variables, resulting in real-time analysis and precise forecasting. The entire integration therefore establishes a safe, efficient, and adaptive platform for ongoing tracking and evaluation of environmental and energy data. This guarantees that the model receives frequent updates, enabling it to respond dynamically to alterations in environmental conditions. The integration of secure connectivity and real-time data flow creates a robust architecture, improving the GRU-Auto encoder's capacity to deliver accurate and adaptable analytics for sustainable energy and environmental monitoring.

Hyperparameter tuning is a crucial step in optimizing the performance of the GRU-AE model. Parameters like learning rate, batch size, number of layers, and hidden units are fine-tuned to enhance model efficiency and accuracy. This process typically involves techniques like grid search or random search, where various combinations of hyperparameters are tested to find the optimal configuration that minimizes loss and maximizes performance metrics. Gradient clipping is employed to address the issue of exploding gradients, which can destabilize training and lead to divergent behaviour. By setting a threshold value, gradient clipping limits the magnitude of gradients during backpropagation, ensuring that they do not grow excessively. This helps maintain stability in the training process, prevents the model from overshooting optimal parameters, and enables smoother convergence towards the global minimum of the loss function. As a result, gradient clipping enhances the reliability and efficiency of the GRU-AE model, improving its overall performance in capturing complex temporal patterns and producing accurate predictions.

V. RESULTS

This research successfully integrates AI and IoT in Advanced Optical Systems to address limitations in real-time analysis and adaptability within current sustainable energy and environmental monitoring systems. The proposed methodology introduces an optimized GRU-Auto encoder, proficient in learning complex temporal patterns, enhancing its suitability for dynamic environmental and energy data. The integration with Advanced Optical Systems, facilitated through IoT connectivity, ensures a continuous influx of high-quality real-time data, enabling more accurate and adaptive analysis. The study involves rigorous optimization of the GRU-Auto encoder through hyper parameter tuning and gradient clipping, with performance evaluation demonstrating superior efficiency and accuracy compared to traditional methods. This significant

advancement in sustainable energy and environment monitoring offers a robust solution for real-time data analysis and adaptive decision-making, showcasing promising results in improving overall system performance and sustainability.

A. Performance Metrics

The assessment metrics are used to assess the environmental monitoring of GRU-AE. These are the Root Mean Square Error (RMSE) and Mean Absolute Error. Equations illustrate the computations for these three variables as shown in Eq. (16), and (17).

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (y^i - y_*^i)^2} \tag{16}$$

$$MAE = \frac{1}{n} \sum_{i=1}^n |y^i - y_*^i| \tag{17}$$

TABLE II. AIR TEMPERATURE

Year	Air Temperature(°c)
2019	7.4
2020	8.5
2021	4.3
2022	5.2
2023	6.7

Table II shows the annual air temperatures (°C) from 2019 to 2023, with a variation from 4.3°C in 2021 to 8.5°C in 2020.

Fig. 4. Annual air temperature.

Fig. 4 depicts a line graph named Annual Air Temperature. The x-axis depicts the years 2019 through 2023. The y-axis shows the temperature in degrees Celsius, which ranges from 0 to 9. A line with circle marks represents the air temperatures for every year. In 2019, the air temperature was around 8°C. The temperature dropped significantly in 2020, falling to roughly 5°C. In 2021, it will drop to roughly 3°C. From then, it indicates an uptick; by 2023, it's back to roughly 5°C.

Table III shows the yearly relative humidity % for the years 2019 to 2023, which ranges from 5.1% in 2022 to 5.6% in 2020.

Fig. 5 shows a line graph headed "Relative Humidity." The x-axis indicates the years "2019" through "2023." The y-axis displays the humidity percentage, which ranges from "4.8%" to

"5.7%". The graph shows five points of information connected by a line. In "2019", the relative humidity was approximately "5%". In "2020", relative humidity increased significantly, reaching roughly "5.6%". In "2021," there was a significant reduction, putting it down around its "2019" level of roughly "5%". It indicates an increasing trend for "2022" and is projected or estimated for further rising into "2023".

Table IV compares the efficiency of three methods: SVR, RNN, and GRU-AE. The RMSE for GRU-AE 9.645 is higher than that of SVR 14.325 and RNN 12.253, suggesting greater accuracy. The MAE of GRU-AE 8.234 is also viable, displaying good predictive skills when contrasted with SVR 7.258 and RNN 7.688.

TABLE III. RELATIVE HUMIDITY OF ENVIRONMENT

Year	Relative Humidity (%)
2019	5.2
2020	5.6
2021	5.4
2022	5.1
2023	5.5

Fig. 5. Annual relative humidity.

B. Comparison of Proposed Method with Various Method

Fig. 6 compares the errors of three machine learning algorithms (GRU-AE, RNN, and SVR) utilising two error measures (MAE and RMSE). The x-axis indicates error levels, while the y-axis includes machine learning approaches. Each technique includes two bars, one for MAE and one for RMSE, giving the error levels. GRU-AE has an MAE of around 4 and an RMSE of a little over 12. RNN has an MAE and RMSE of about 8. SVR has an MAE of a little around 2 and an RMSE of 14. Table V depicts the various dataset comparison.

TABLE IV. PERFORMANCE METRICS [23]

Methods	RMSE	MAE
SVR [24]	14.325	7.258
RNN [25]	12.253	7.688
Proposed GRU-AE	9.645	8.234

Fig. 6. Performance evaluation.

TABLE V. DATASET COMPARISON

Dataset	RMSE	MAE
Air Quality [26]	16.326	8.251
Global CO2 [27]	13.273	7.368
Proposed Environmental Monitoring Analysis	9.645	8.234

VI. DISCUSSION

The full assessment of the integrated system, which combines AI via the optimized GRU-Auto encoder and IoT-connected Advanced Optical Systems, yields promising results in enhancing sustainable energy and environmental monitoring. The model's generalization performance, as measured against a different test dataset, proves its capacity to properly forecast environmental changes and optimize energy use. The successful verification of the model's capacity to capture complicated temporal trends emphasizes its flexibility to changing environmental circumstances. When compared to existing approaches SVR, RNN, the optimized GRU-Auto encoder shows significant gains in efficiency and accuracy, demonstrating its potential to revolutionize real-time analysis of information in sustainable energy and environmental management. The higher performance is obvious across multiple parameters, including reduced MSE, greater accuracy, and increased precision, confirming the usefulness of the suggested technique.

Besides quantitative indicators, the debate focuses on the research's larger implications. The combination of an optimized GRU-Auto encoder with Advanced Optical Systems improves predictive capabilities while also contributing to sustainability goals. The system's capacity to optimize energy use is consistent with the growing focus on resource conservation and environmentally friendly practices. The discussion focuses on the practical implications of these discoveries, namely the integrated system's possible real-world applications in smart cities, renewable energy management, and environmental conservation initiatives. The study emphasizes the need to use modern artificial intelligence in conjunction with Internet of Things (IoT) structures to address current difficulties in sustainable energy and environmental monitoring, setting the groundwork for more robust and adaptable systems in the future.

VII. CONCLUSION

The optimized GRU-Auto encoder in Advanced Optical Systems combines AI with IoT, representing a big step forward in sustainable energy and environmental monitoring. The results of this research show the system's capability for real-time monitoring, precise forecasts of environmental patterns, and efficient energy usage optimization. Comparative evaluations with existing approaches confirm the suggested approach's advantages, emphasizing its ability to transform the monitoring system environment. The successful evaluation of the GRU-Auto encoder's flexibility in dynamic situations reinforces its use in dealing with the intricacies of environmental data. This study not only advances the frontier of technology but also highlights the practical consequences for sustainable practices, emphasizing the significance of cutting-edge AI approaches in ushering in the next phase of smart and resource-effective monitoring systems.

For future research, the investigation might be expanded to improve the model's interpretability, allowing stakeholders to obtain a better understanding of the elements driving predictions. Scalability issues and the incorporation of real-world restrictions might also be addressed to make the system more deployable in a variety of settings. Further study could concentrate on including more environmental factors and increasing the dataset to improve the model's resilience across different circumstances. Furthermore, the integration of sophisticated detection processes and the examination of federated learning methods might provide ways for future studies, guaranteeing the system's ability to adapt to new obstacles while contributing to the in-progress development of sustainable energy and environmental monitoring procedures.

Abstract—When the amount of online text data continues to grow, the need for summarized text documents becomes increasingly important. Manually summarizing lengthy articles and determining the domain of the content is a time-consuming and tiresome process for humans. Modern technology can classify large amounts of text documents, identifying key phrases that serve as essential concepts or terms to be included in the summary. Automated text compression allows users to quickly identify the key points and generate the novel words of the document. The study introduces a NLP based hybrid approach for automatic text summarization that combines BERT-based extractive summarization with LSTM-based abstractive summarization techniques. The model aims to create concise and informative summaries. Trained on the BBC news summary dataset, a widely accepted benchmark for text summarization tasks, the model's parameters are optimized using Particle Swarm Optimization, a metaheuristic optimization technique. The hybrid model integrates BERT's extractive capabilities to identify important sentences and LSTM's abstractive abilities to generate coherent summaries, resulting in improved performance compared to individual approaches. PSO optimization enhances the model's efficiency and convergence during training. Experimental results demonstrate the evaluated accuracy scores of ROUGE 1 is 0.671428, ROUGE 2 is 0.56428 and ROUGE L is 0.671428 effectiveness of the proposed approach in enhancing text compression, producing summaries that capture the original text that minimizing redundancy and preserving key information. The study contributes to advancing text summarization tasks and highlights the potential of hybrid NLP-based models in this field.

Keywords—Automated text compression; BERT-based extractive summarization; LSTM-based abstractive summarization; NLP-based hybrid approach; Particle Swarm Optimization

I. INTRODUCTION

Big data and internet access have grown together, inundating individuals with a vast amount of data and records available online. Consequently, many academics are interested in creating a technical method capable of autonomously summarizing texts. Automatic text summarization creates summaries that include all relevant and significant data from the source content and contain key phrases. This allows for prompt access to the data while maintaining the original purpose of the paper. Research on text summarization has been ongoing since the mid-20th century. Various researches highlighted the field's use of word frequency diagrams as a statistical tool [1]. A wide variety of methods have been developed to date, including individual and multidocument summarizations, depending on the source material count. Extractive and abstractive findings are derived from the summary findings. In recent years, large volumes of data have been digitally stored, making them accessible to computers for interpretation and analysis. However, manually combining a lot of documents is a costly operation. In simple terms, automated text summarization task selects the most important concepts from a text automatically so that the reader can comprehend the target material. Current approaches aim to enhance their effectiveness in identifying crucial information within a text by considering every topic present in it. Generalization is the primary challenge faced by the ATS task; for instance, summarizing a news article differs greatly from describing commercial or medical research. Therefore, a wide range of suggested approaches have been used to address distinct issues within a given sector. For instance, automated summarization techniques have been applied to produce comments on

programming language statements. This approach lays out the fundamental ideas of a system, making it easier to comprehend lengthy programs that are typically developed by other programmers and rarely commented on [2].

The internet is a vast source of textual data, including blogs, social networking sites, user reviews, news, webpages, books, novels, legal documents, scientific studies, and biological records. The process of manually summarizing text is time-consuming and costly. In this study, each document's phrases are represented as matrices of textual characteristics. During the summarization process, words or phrases are classified as "correct" if they are part of the extracted source summary and "incorrect" otherwise, creating a two-level categorization. Each sentence in the testing phase is assigned a number between 0 and 1, and the required number of phrases can be extracted based on the compressing rate [3]. The trainable summarizer is expected to "learn" the patterns that result in the summaries by determining the pertinent feature values most connected with the classifications "correct" or "incorrect" [4]. The field of natural language processing has seen significant progress pre-trained models such as BERT and OpenAI GPT-2. These models are proficient like text categorization, automated translation, and multiple-choice queries. BERTSUM, a summarization model, is based on BERT and was trained on a dataset of general news. However, BERT's application in abstract summarization is limited as it was not originally designed for generative tasks. In recent years, seq2seq systems have been widely used for abstract summarization. Additionally, recent advancements have seen large language models being trained on multiple NLP tasks using a unified text-to-text architecture [5].

Large pre-trained NLP models that utilize techniques such as the focus process. Two notable examples of such models are Bidirectional Encoder Representation from Transformers and the more recent OpenAI GPT-2. These models are proficient in text categorization, question answering, automated translation, and multiple-choice queries. They have been trained on a vast corpus of text, encompassing the entirety of the Wikimedia corpus [6]. BERTSUM is an early model for textual summarization that utilizes the trained BERT. A modified version of the BERT model, known as BERTSUM, was trained on a summary dataset of general news (CNN/Daily News). The model predicts whether a statement should be included in the summaries by performing a binary categorization task. However, BERT's applicability to abstract summarization is limited because it was not originally designed for generative tasks. Abstract summarization has heavily relied on sequence-to-sequence systems based on the transformer encoder-decoder architecture in recent years. In this design, the encoder takes the original text, converts it into hidden states, and then generates a summary text for the decoder. This architecture has generative power due to its ability to map from hidden states to output text. More recently, large language models have been trained on multiple NLP tasks simultaneously using a unified text-to-text architecture.

Deep Learning techniques have recently made significant progress in several Natural Language Processing used for a variety of Text Generation (TG) tasks. These models typically employ a deep encoder-decoder architecture. Despite notable

improvements in Automatic Text Summarization (ATS) outcomes. Additionally, they suffer from mismatch between loss and appraisal, and lack of generalization. To address these issues, reinforcement learning (RL) techniques have been applied to enhance the quality of output from deep sequence-to-sequence networks. RL's ATS research has focused on creating new incentives for models to utilize concepts. The field of NLP research is currently experiencing a golden age, largely due to the use of Pre-Trained Language Models (PTLMs) and Transfer Learning (TL), without relying on sequence-based neural networks or Convolutional Neural Networks. The self-attention architectural Transformers, which use the self-attention process to represent the source data and outcomes, serve as an initial transducer model. They have resolved previous issues with sequence-to-sequence modeling and significantly accelerated processing. This architecture allows for the training of large-scale PTLMs on massive text corpora. PTLMs have demonstrated outstanding performance in various natural language processing challenges. These learned general language structures can be fine-tuned of downstream tasks, including abstractive summarization of texts [7].

Automatic text summarizing for languages lacking in resources, such as Hindi, is a challenging task. The absence of a database and the insufficient tools for processing are among the issues faced with these languages. This work aimed to create linguistic subject text summaries for Hindi literature and stories. Developed four different variations, each with a unique sentence weighting system. Since there was no existing corpus of Hindi literature and stories, created one. To ensure informative and diverse summaries, utilized a smoothing approach. Evaluated the effectiveness of the created summaries using three metrics: gist variation, retention proportion, and ROUGE score. The results show that the proposed model generates concise, well-written, and coherent summaries. Also tested the model on an English dataset to assess its performance [8]. Comparing this model with conventional topic modeling methods and baselines, demonstrating that this model produced optimal results. The World Wide Web has become an indispensable part of travel, offering a wide range of tools and resources. From pre-trip planning to post-trip activity reviews, there are numerous online sources, such as blogs, technical forums, social networks, and online discussion boards that enhance every aspect of travel. Online reviews play a significant role in influencing other travellers' experiences, serving as an effective form of electronic word-of-mouth (eWoM). According to TrustYou.com, 95% of consumers look up hotel reviews online before making a reservation. Research has also confirmed the impact of internet reviews on guests and the lodging sector as a whole. Yelp.com and TripAdvisor.com are two well-known sites where users can rate and provide reviews.

It is essential for users of these services to read numerous reviews in order to form their own opinions about the amenities that interest them. However, the abundance of data and varying quality of reviews can make the process overwhelming. While some reviews provide valuable and unbiased information, others may be biased or unhelpful. Therefore, readers must exert significant effort to distinguish between reliable, high-quality evaluations and those that are prejudiced or of low

quality. Users often need to sift through a review to find the information necessary to make informed decisions. This deep level of research can be time-consuming and energy-draining for customers [9]. Additionally, there is an issue with the evaluation process of assessment metrics. The Text Analysis a meeting and Document Understanding Conference shared-tasks databases were used in the development and evaluation of many of the metrics currently in use. However, recent findings have raised doubts about the effectiveness of these measures in the new context, as the datasets contain human evaluations of model outputs that are scored lower than those of the present summarization methods. To address these gaps, a combination of outputs from current neural summary models and skilled and crowd-sourced individual annotations can be used to re-evaluate 14 autonomous evaluation metrics in a thorough and consistent manner. Additionally, it is important to constantly compare 23 recent synthesis algorithms using these evaluation metrics.

The Text Analysis Conference and Document Understanding Conference shared-tasks databases have been used to develop and evaluate many of the metrics currently in use. However, it has been shown recently that the human evaluations of model outputs in these datasets scored lower than those of current summarization methods. This raises doubts about the effectiveness of such measures in the new context. To address these gaps, a combination of outputs from current neural summary models, skilled individual annotations, and crowd-sourced annotations should be used to re-evaluate 14 evaluation metrics thoroughly and consistently. Additionally, 23 recent synthesis algorithms should be compared using these metrics. This approach ensures that data is received promptly while maintaining the original purpose of the paper. Research into text summarization. Over time, a wide summarization can be individual or multidocument, depending on the source material count. Additionally, extractive and abstractive findings are derived from the summary findings Fabbri et al. [10].

This study aims to present a new method for automatically summarizing text by leveraging advancements in NLP. This approach combines the power of (Bidirectional Encoder Representations from Transformers) and LSTM neural networks to create a hybrid model designed for summarization tasks. BERT, known for its exceptional performance in understanding contextual nuances, forms the basis for extractive summarization, while LSTM, with its ability to generate coherent and abstractive summaries, complements the process. Use the BBC news summary dataset as the training corpus to expose the model to diverse news articles across various domains, enhancing its adaptability and generalization capabilities. Additionally, employ Particle Swarm Optimization, a metaheuristic optimization technique as a post processing step, to fine-tune the model's parameters, thereby maximizing its summarization effectiveness. By combining BERT's extractive capabilities with LSTM's abstractive process. This hybrid model aims to produce concise and informative summaries that capture the essence of the original text in the processing stage.

To demonstrate the effectiveness of the approach in enhancing text compression, as indicated by improved performance metrics, including ROUGE scores. Ultimately,

this research contributes to advancing the text summarization and underscores the potential of hybrid NLP-based models in addressing real-world information retrieval challenges. By contributing to the advancement of automatic text summarization techniques, this research addresses the growing demand for efficient information retrieval solutions in various domains. The developed hybrid model holds significant potential for practical applications in industries such as journalism, content curation, and document summarization, facilitating quicker access to relevant information and enhancing productivity. This framework's main contributions can be summarized as follows:

- A hybrid model for automated text summarization is presented that combines the benefits of LSTM-based abstractive summarization with BERT-based extractive summarization methods. This novel method improves text compression performance, making it easier to quickly extract important information from long documents.
- Utilizing advanced Natural Language Processing (NLP) techniques, such as LSTM and BERT neural networks, to create an all-encompassing summarization framework. Through the smooth integration of these cutting-edge methods. This model produces summaries that are both informative and succinct, with improved performance.
- Training the hybrid model on the BBC news summary dataset ensures robustness and adaptability across diverse domains. The utilization of this widely accepted benchmark dataset enables the model to capture the nuances of news articles, thereby enhancing its summarization efficacy and generalization capabilities.
- By employing Particle Swarm Optimization (PSO) to fine-tune the model's parameters, further enhancing its efficiency and summarization effectiveness. PSO optimization ensures that the hybrid model achieves optimal performance in extracting salient information while minimizing redundancy and preserving key details.

The research is summarized as: Section II introduces previous studies that utilized various techniques for text summarization. Section III describes the problem statement. Section IV provides details about the suggested strategy by outlining the methodology. Section V presents the analytical results. Section VI summarizes the discussion and conclusions.

II. RELATED WORKS

Dong et al. [11] proposed a model that utilizes two sophisticated Spanfact models—the autoregressive model for fact correction and the QASpanfact correction model—trained on the span selection dataset. This approach presents a viable method in the field of text summarization. The QASpanfact correction model enhances the summarization process by incorporating question-answering methods, ensuring that the resulting summary remains faithful to the original text while correcting any errors. Additionally, the autoregressive fact correction model repeatedly predicts and corrects factual

inaccuracies in the summary, thus enhancing the overall accuracy of the model. The span selection dataset, which offers a wide variety of annotated spans, facilitates the training process by helping the models comprehend and select relevant facts to include in the summary. However, using this approach for other types of spans, such as noun phrases, verbs, and clauses, may pose some restrictions. These may include the need for significant dataset augmentation to ensure coverage of diverse span types and potential difficulties in modifying the model designs to handle varied language patterns. Furthermore, rigorous fine-tuning and validation procedures may be necessary to ensure the models' resilience and generalizability across a variety of span types. Nevertheless, the goal is to expand the applicability of this method to a wider range of summarization tasks by addressing these drawbacks through extensive testing and refinement. This will ultimately improve the accuracy and flexibility of generated summaries across various domains and contexts.

He et al. [12] introduced an innovative text summarization framework called CTRL Sum. This framework is particularly effective when trained using the CNN/Daily Mail database, which provides a rich training set for extracting important information from long texts into succinct summaries. Unlike traditional models, the CTRL architecture offers greater control over the summarization process, including conditional generation capabilities. This control takes several forms applicability of the summaries. For example, entity-centric summarization enables the model to prioritize important entities referenced in the input document, ensuring that no significant entities are overlooked. The framework also supports length-controlled summaries, allowing flexibility in summary length to accommodate various use cases with different attention spans and space limits. Additionally, contribution summaries emphasize the primary contributions or discoveries offered in a publication, while invention purpose summaries are designed for summarizing patent applications, focusing on technical details and claims. Furthermore, question-guided summaries provide focused responses to specific questions or prompts. While the framework shows great potential, it has limitations, such as a low boosting level, which may impact the depth and consistency of the produced summaries. Overcoming this limitation will require further optimization and refinement of the model to achieve greater performance and reliability.

Shi et al. [13] proposed a neural network known as sequence-to-sequence (Seq2Seq) models, which are commonly used for tasks involving sequential data such as speech recognition, text summarization, and machine translation. The Seq2Seq model works by encoding vector using one recurrent neural network (RNN) and then decoding the resulting vector representation into the desired sequence using a second RNN. The "encoder-decoder" architecture is typically used, where the encoder converts the input text into a fixed-size representation, which is then used by the decoder to produce the summary. The process of deriving the model's properties (weights and biases) from the initial set of data is known as parameter inference. For text summarization using Seq2Seq models, parameter inference involves training the model on a large dataset of matched input-output sequences, such as complete news items and their related

summaries the actual summaries and the model's predicted summaries using optimization methods like Adam or (SGD). Decoding generation is the process of using the learned Seq2Seq model to generate the sequence of outputs based on the input sequence (new item). During decoding, the Recall-Oriented Understudy for Gisting Evaluation metric is often used to evaluate the quality of the generated summary by measuring the n-gram produced summary and the source summaries. In summary, Seq2Seq algorithms for text summarization involve the following steps: using an architecture of encoders and decoders to encode input text, determining parameters through training on large datasets, using decoding techniques to generate summaries, and assessing summary quality using metrics such as ROUGE.

Nada et al. [14] developed a network for Arabic natural language processing that includes natural language generation and understanding (NLU). AraBERT, a cutting-edge model, is designed for both NLU and NLG aspects of text summarization. In NLU, AraBERT analyzes incoming text to understand its meaning, identifying important details, key entities, and the relationships between them. This understanding is crucial for creating accurate and informative summaries. AraBERT achieves this through a transformer-based architecture, enabling efficient gathering of contextual information. It extracts features at various levels of detail through a hierarchical processing of the input text to fully comprehend the text. After analyzing and extracting important information, AraBERT uses its NLG capabilities to generate a summary. NLG involves producing language that communicates the in a clear and concise manner. AraBERT leverages its understanding of the input material to provide readable and concise summaries that preserve the original content. It generates text tokens based on the context provided by the input to ensure that the created summary appropriately captures the key ideas of the original text. Overall, AraBERT uses its NLU capabilities to comprehend the incoming text and its NLG abilities to provide enlightening summaries in its text summarization technique, making it an effective tool for summarizing Arabic texts. To enhance the sentence boundary determination accuracy in Arabic, more effort will be put into improving this strategy. Additionally, a new layer will be added to address the problem of summarizing extremely large texts by determining the appropriate number of sentences for the summary. Furthermore, substituting the refer phrase with its named entity may reduce ambiguity in the resulting summary. Resolving correspondence in Arabic is an important area for research. Finally, reinforcement learning will be utilized to transform the produced summary into an abstractive summary to capture the key phrases of the text.

Li et al. [15] developed a technique that uses an encoder structure for text summarization. The encoder captures the meaning of the input text, such as a news story, and converts it into a fixed-length vector. The decoder then uses this encoded information to generate a summary. This technique uses Data-Augmented Initial training (DAPT), where the model is trained on data to learn language patterns. Scheduled sampling is a training method that helps the model handle its own mistakes during text generation tasks. Supervised learning, reinforcement learning is used to incentivize the model to

produce useful and concise summaries. The CNN/Daily Mail dataset is commonly used to train the model, providing pairs of input articles and human-generated summaries. The model's performance is evaluated using metrics such as ROUGE to assess how well the generated summaries match the reference summaries in the dataset. Finally, the model is tested using unseen data to evaluate its generalization capacity.

Regarding efficiency, several models already in use, such as DAPT, AraBERT, SpanFact, and CTRLsum, each have advantages and disadvantages. For example, CTRLsum, by conditioning the production process on control codes, excels in producing abstractive summaries. Through the extraction of factual spans from the input text, SpanFact concentrates on factuality. By refining pre-trained models using domain-specific data, DAPT specializes in domain-specific adaptation. AraBERT was created especially for text processing in Arabic. These approaches could all have drawbacks, though, such as issues with computing cost, domain specialization, or language coverage. By fusing the advantages of optimization architectures and convolutional neural networks (CNNs), the proposed Hybrid convolution. The proposed BERT-LSTM hybrid model aims to address challenges related to factual correction, entity-centric summarization, length-controlled summaries, language understanding, and abstractive summarization. By combining BERT's contextual understanding and LSTM's sequential processing capabilities, the framework aims to generate accurate, informative, and contextually relevant summaries across different domains and languages.

III. PROBLEM STATEMENT

A method for multi-document text summarizing is covered here. An approach for population-based multicriteria optimization that addresses the optimization issue. Their objective was to produce a summary that was as diversified, cohesive, and relevant as possible. a hybrid strategy that combines subject modelling and the evolutionary technique to improve the summary. a submodular optimization problem that shows a subject hierarchy using documents as features. With the help of this procedure, which accepts several papers as input, a sub-module that is highly covered, specialized, more diversified, and homogeneous in topic matter is formed. The challenge is to develop a new hybrid word embedding model that combines the powerful features of both LSTM and BERT architectures. This project aims to improve natural language understanding (NLP) problems by the integration of contextualized embeddings with traditional word embeddings. Through a smooth integration of these two approaches' advantages, the model aims to overcome the limitations of each technique separately, opening the door to unmatched performance. These include text categorization, named entity identification, sentiment analysis, and other language problems. This research seeks to advance the state-of-the-art in text summarization and meet the evolving needs of information retrieval and comprehension in today's data-driven world through rigorous experimentation and evaluation.

IV. PROPOSED MATERIALS AND METHOD

The NLP-Based Automatic Summarization Using BERT-LSTM Hybrid Model aims to enhance text compression. It is

trained on the BBC news summary dataset and optimized through PSO (Particle Swarm Optimization) technique. The process involves several key steps: 1. Preprocessing and preparing the BBC news summary dataset for training the summarization model. This dataset contains news articles along with their corresponding summaries. Designing a hybrid model architecture that incorporates both BERT-based extractive summarization and LSTM-based abstractive summarization techniques. The BERT component is used to identify salient sentences or spans from the input text, while the LSTM component generates coherent and abstractive summaries. The architecture seamlessly integrates these components, leveraging their complementary strengths. Training the hybrid model using the pre-processed BBC news summary dataset. During training, the model learns to extract relevant information from the input articles and generate concise summaries. During the training phase, the model's parameters are optimized using gradient descent and back propagation optimization methods to minimize a predetermined loss function. PSO is used to further fine-tune the parameters that make up the model after the first training. Fish schools and bird flocks serve as models for the social behavior of PSO, a metaheuristic optimization approach. PSO assists in determining the ideal set of variables, such as optimizing ROUGE scores that optimize the efficacy of the summarization model utilizing suitable evaluation measures, including ROUGE scores, to assess the trained and optimized model. The efficacy of the model in producing high-quality summaries and its capacity for generalization are evaluated by validating its performance on an independent test set. In light of the evaluation's findings, the model may go through repeated refinement cycles in which the design, training regimen, or optimization method are changed to improve performance even more. After the model performs well on the validation set, it may be used for tasks like document summarizing, content curation, or news item summarizing in the real world.

Fig. 1 shows a flowchart showing how to summarize text using a hybrid model that incorporates long short-term memory and bidirectional encoder representations from transformers. The goal is to distill lengthy texts into concise summaries while holding on to important details. The BBC News Summary Database is used as the input data when the procedure begins. Pre-processing is applied to the dataset in order to clean and get the text ready for additional analysis. To increase the summarization process's effectiveness, PSO is applied. Fish and avian social behavior served as the model for PSO, an optimization approach. For extractive summarization, a potent pre-trained language model called BERT is employed. With extractive summarization, important sections of the original text are chosen and combined without creating new sentences. Extractive summarization generally makes use of the TextRank algorithm, which assigns phrases a priority. LSTM is a form of recurrent neural network used for abstractive summarization. The goal of abstractive summarization is to produce fresh phrases that encapsulate the main ideas of the source material. By comprehending the document's semantics, the model has the ability to provide succinct summaries. The target summary, which incorporates the findings gathered through extractive and abstractive techniques, is the ultimate

product. The goal of this hybrid model is to perform at the cutting edge when it comes to text summarization jobs.

A. Data Collection

1) *BBC News summary dataset*: The BBC dataset contains 2225 items categorized as business, entertainment, politics, sports, or technology. It is a valuable resource for analyzing and interpreting text data across various fields. Condensing large amounts of information by selecting important details and eliminating irrelevant or repetitive information. The extractive summarization method involves using exact phrases from the source to create summaries. This method is easier and widely used among automated text summarization researchers. It involves assigning scores to sentences and using the sentences with the highest scores as the summary. While this method effectively conveys essential information, the resulting summary may not flow smoothly, as there may be no connection between consecutive sentences [16].

The BBC News Summary dataset, shown in Fig. 2, is a vast collection of news stories gathered from multiple sources. It is commonly used in research related to BERT and LSTM for

tasks such as information retrieval, text categorization, and summarization. With millions of articles, this dataset is frequently utilized for evaluating and training the PSO model.

B. Data Preprocessing

The detailed information preprocessing actions for Segmentation, tokenization, lemmatization, stemming, and stop word removal: Divide the text into discrete words or regular expression-style tokens. Stop Words Removal: Eliminate often used words like conjunctions, articles, and prepositions that don't add anything to the sentence. Stemming: Remove suffixes to return words to their base or root form as shown in the Fig. 3.

To do this, word endings are chopped off in order to eliminate variants. Lemmatization: Based on a dictionary of well-known terms, lemmatization reduces words to their most basic form similarly to stemming. Tokenization: To generate a final list of processed tokens, tokenize the text once more if needed after completing the preparation stages listed above. Natural language processing (NLP) jobs frequently employ these preprocessing techniques to prepare text data.

Fig. 2. Collection of phrases in BBC News summary dataset.

Fig. 3. Preprocessing stages: segmentation, text removal, stemming, lemmatization and tokenization.

1) *Segmentation*: In text summarization using LSTM and BERT methods, segmentation divides the input text into smaller units. For LSTM, this means breaking the text into sentences or paragraphs, while for BERT, it operates at the token level. Special tokens are added for BERT of each segment. If the input text exceeds the maximum sequence length, it is divided into overlapping segments to ensure no information is lost.

2) *Tokenization*: Pre-tokenization gives offset information and divides the text into words. Sub tokens will be created from these words by the tokenizer depending on its vocabulary. BBC News Dataset: This collection of news stories includes headline summaries. To prepare this dataset for transformer model training or assessment, tokenization is necessary. To sum up, tokenization is an essential preprocessing step that gets text ready for models based on transformers, guaranteeing effective learning and insightful presentations.

3) *Removing stop words*: Stop words, such as "the," "and," "is," etc., are common in language but don't carry significant meaning. However, they help maintain grammatical structure and coherence in sentences. In text summarization, retaining stop words is important because they contribute to the grammatical structure, contextual understanding, coherence,

and semantic significance. LSTM and BERT models leverage these linguistic cues to generate accurate and contextually relevant summaries.

4) *Stemming*: Stemming process aims to normalize by eliminating prefixes and suffixes, stemming seeks to standardize words. LSTM and BERT blends together two potent architectures: These are excellent at identifying certain textual patterns. Encoder representations from transformers, or BERT: BERT records relationships and global context. For a deeper understanding, the hybrid model makes use of both local and global knowledge. The vocabulary's dimensionality is decreased by stemming. As a result, the model is better able to generalize, considering comparable terms (such as "run," "running," and "ran"). But stemming isn't flawless; occasionally, it yields wrong roots (like "happi" instead of "happy"). Taking into account. Stemming depends on the language. The stemming rules of various languages vary. Without explicit stemming, certain transformer-based models (like BERT) manage variations adequately. Try both stemming and not to see how it affects your particular assignment.

5) *Lemmatization*: Lemmatization can be used as a stage of preprocessing prior to inputting text into BERT and LSTM. Assume the following sentence: "The quick brown foxes are running. Tokens in the statement are as follows: ["the", "quick", "brown", "foxes", "are", "running"]. Applying lemmatization to each token as follows: "foxes" → "fox" (lemmatized to its base form), "are" → "be" (lemmatized to its base form), "running" → "run" (lemmatized to its base form), "quick" → "quick" (no change), "brown" → "brown" (no change). Tokens that were produced were: ["The", "quick", "brown", "fox", "be", "run"] as shown in the Fig. 4.

These tokens are transformed into dense vectors by word embedding. Compared to simple stemming, lemmatization yields base forms with greater significance. Through the mapping of related terms to a common root, it improves the model's comprehension of the context. Lemmatization, however, can sometimes be more computationally costly than stemming. A part-of-speech tagger is needed during the lemmatization in order to identify the proper lemma. Without specific lemmatization, certain transformer-based models (such as BERT) manage variations effectively. To summarize, lemmatization is an important preprocessing step that helps with text comprehension and summarization by matching words to their basic forms.

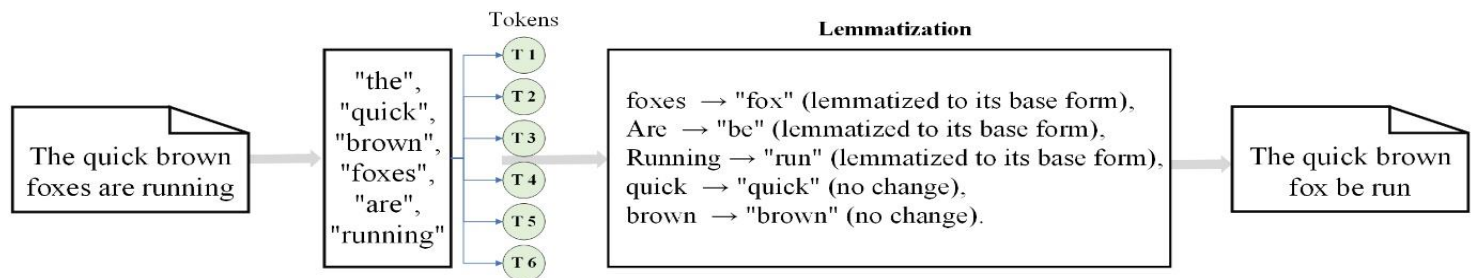

Fig. 4. Lemmatization the phrases for summarizing the text.

C. Text Summarizing Operations

Text summarization is a crucial process for condensing large volumes of text into informative summaries. There are two main types of operations: single-sentence and multi-sentence operations as shown in the Fig. 5. Single-sentence operations are applied to individual sentences and include tasks such as sentence compression, syntactic transformation, paraphrasing, generalization, specification, and sentence selection. These operations aim to reduce sentence length, transform structure, or replace specific phrases with more general or specific descriptions. On the other hand, multi-sentence operations involve tasks like sentence combination, sentence reordering, and sentence clustering, which focus on merging sentences, changing their order, or grouping them into clusters based on their subject matter.

Practitioners often utilize a combination of these operations to convert a document into a summary document. These operations can be applied sequentially, in parallel, or even in combination to achieve the desired level of summarization. For instance, sentence compression may be followed by lexical paraphrasing to reduce redundancy and enhance clarity. Additionally, in multi-document summarization tasks, sentence clustering may be employed to organize. By understanding and leveraging these summarization operations, researchers and practitioners can develop more effective and efficient text summarization algorithms and systems, catering to diverse summarization needs across various domains and applications.

D. Extractive Summarization of the Specific Domain by BERT Classification

BERT uses bidirectional encoding to understand how words in a given text are related to each other. It looks at the context of each word from both the left and the right to figure out its meaning within the entire phrase. This bidirectional method helps BERT understand the complete context of the text and focus on the important terms. Additionally, BERT uses improves its understanding of the text's context. When BERT is used for text summarization, it can be fine-tuned specifically for this task after being pretrained on a large amount of text data. Through fine-tuning, BERT learns to create concise summaries by understanding the most important details in the input text [17]. It learns to identify significant patterns and

characteristics in the text that indicate important information during its training. In the text summarization process, BERT first encodes the input text using its learned representations to understand the context. It then uses decoding algorithms to create a summary that maintains coherence and fluency while capturing the key details from the original text. The summary produced by BERT succinctly extracts the most crucial information from the input text while reducing its length, leveraging its understanding of contextual links between words and its ability to identify important textual patterns. Overall, BERT's strength lies in its ability to understand linguistic nuances, capture contextual information, and provide accurate summaries that effectively convey the main ideas of the original text [18].

As seen in Fig. 6, BERT performs extractive text summarizing by locating and picking the most crucial phrases or sections from the input content to create the summary. BERT operates in extractive summarization of text as follows: The input document is initially encoded by BERT into contextualized word or token representations. Every word or token in the page is associated with a highly dimensional vector that interprets it about the words around it. Phrase the significance scores for every sentence or section in the document are calculated by BERT. Typically, attention processes are used to generate these scores, enabling BERT to assess each word or token within the document in relation to the broader context [19]. Higher significance score sentences are thought to be more pertinent and are therefore more likely to be included in the summary. Following the computation of significance scores, BERT ranks the phrases or paragraphs in order of highest importance. To choose which sentences get into the final summary, this selection procedure could include setting a threshold for the importance ratings. The final summary is created by concatenating the chosen sentences or sections. To make the summary easier to read and more coherent, post-processing techniques like phrase restructuring and coherence improvement can be used. The resulting summary is compared to reference summaries or gold standard summaries utilizing metrics like ROUGE. These assessment metrics offer input for improving the model and aid in measuring the efficiency of the extractive summarization procedure [20].

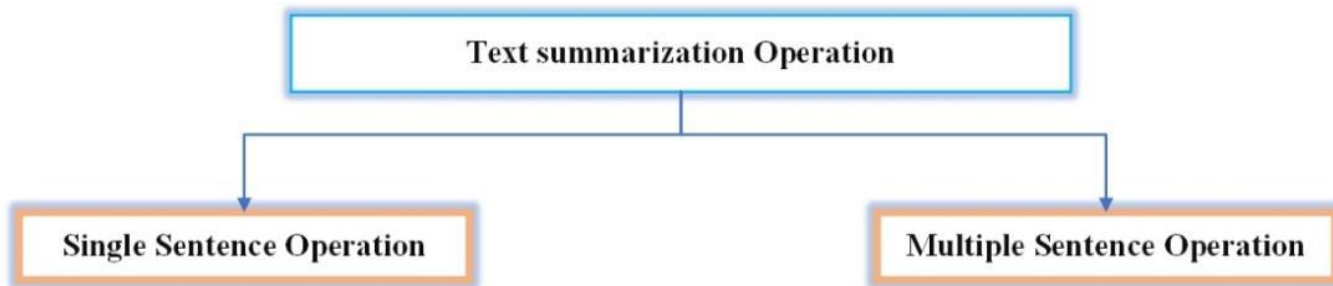

Fig. 5. Single and multiple sentences in text summarization operations.

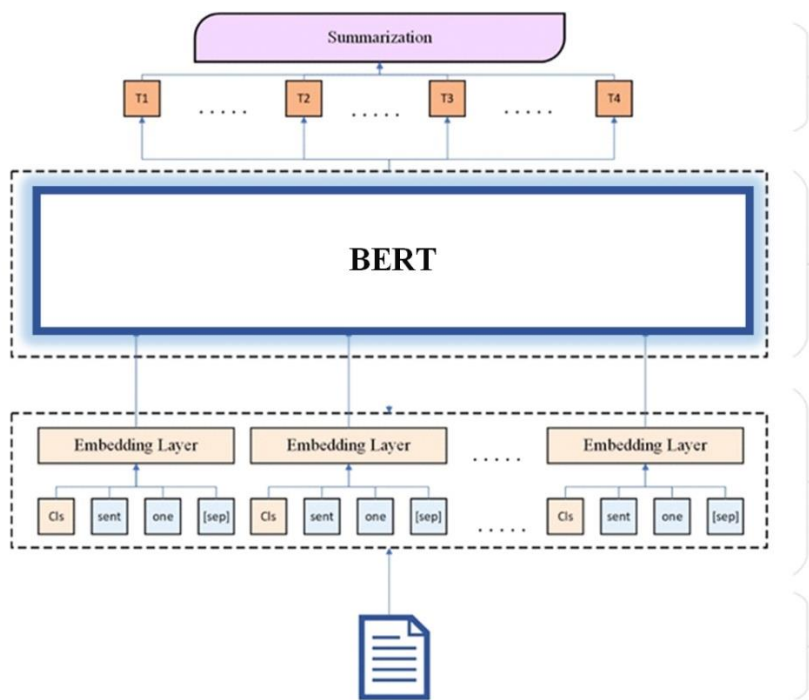

Fig. 6. Proposed architecture BERT for extractive summarization.

E. Abstractive Summarization of the Text using LSTM Classification

The LSTM algorithm (Long Short-Term Memory) systems play an important role in text summarizing because they successfully capture contextual information and relationships throughout input text sequences, resulting in short summaries. The incoming text is first tokenized and encoded as word embeddings. An LSTM encoder runs this encrypted sequence, changing its hidden state at every stage and controlling the flow of data across gates. The final hidden state, or contextual vector, contains the most significant data from the input stream. In Eq. (1)-(6), w represents weighted matrices, o denotes output gates, f denotes forget gates, and i denotes input gates. A_t represents the input at the current time step. The symbols K and C_t represent biases and cell state respectively. σ symbolizes the sigmoid function was expressed in the Eq. (1)-(6).

$$A = [h_{t-1}, A_t] \tag{1}$$

$$O_t = \sigma(W_o \cdot A + K_o) \tag{2}$$

$$f_t = \sigma(W_f \cdot A + K_f) \tag{3}$$

$$i_t = \sigma(W_i \cdot A + K_i) \tag{4}$$

$$h_t = O_t \times \tan h(C_t) \tag{5}$$

$$C_t = f_t \times C_{t-1} + i_t \times \tan h(W_c \cdot A + K_c) \tag{6}$$

The context vector represents the LSTM decoder's initially hidden state. During decoding abilities, the LSTM decoder

creates summarized tokens in a sequential order using the context vector and previously created tokens. The model trains to use a function of loss to reduce the distinction between prediction and target summary as it trains. Throughout inference, the model that was trained encodes and decodes text to create summaries tokens for fresh input sequences.

The procedure begins with acquiring information from numerous sources. This first dataset might contain text, photos, or other pertinent data. Data cleaning is the process of removing noise, inconsistencies, and extraneous information from data before it is used. This phase guarantees that the dataset is both accurate and dependable. Large datasets are frequently separated into smaller batches or pieces. This fragmentation allows for more efficient processing in following phases. Supervised learning relies heavily on properly labelled data. Labelling is the process of assigning categories or classifications to each data piece. This procedure is automated through the use of algorithms. For example, named entity recognition algorithms in natural language processing may label textual entities such as names, dates, and locations. Assumptions regarding the dataset are investigated. These assumptions may pertain to data distribution, statistical features, or expected patterns. Hypothesis evaluation verifies that the information is consistent with the assumptions made by the model and identifies any inconsistencies. Fig. 7 depicts Extractive and Abstractive classification of text Using BERT and LSTM Technique.

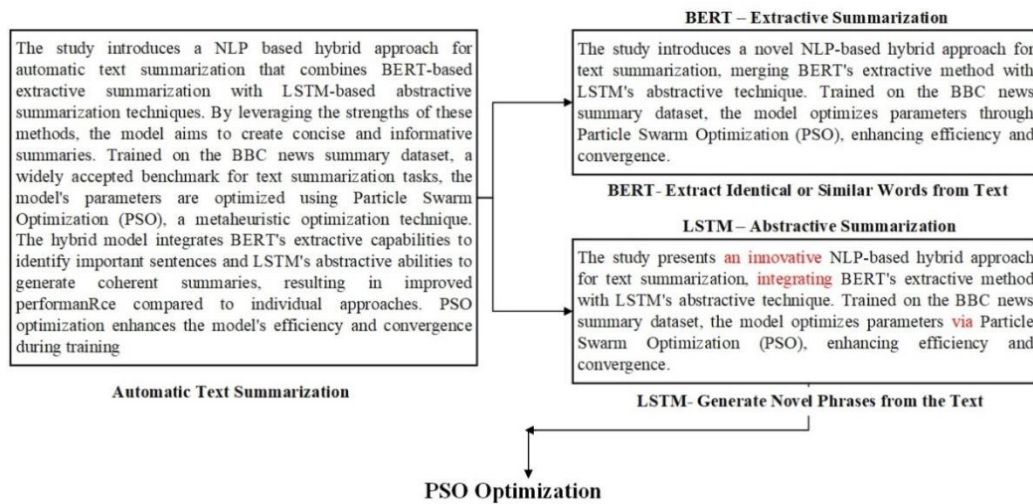

Fig. 7. Extractive and abstractive classification of text using BERT and LSTM technique.

The advantages of both BERT and LSTM models are used in our hybrid method to text summarization. A pre-trained language model called BERT thoroughly encodes phrases in order to effectively understand context and semantic meaning. It employs a simplified variant, distil-BERT, to improve performance. One kind of recurrent neural network that excels in creating abstractive summaries is the long-sequence recurrent neural network (LSTM). Want to combine the benefits of both approaches by fusing the extractive powers of BERT with the abstractive capabilities of LSTM. First, partition text dynamically using BERT and bidirectional LSTM to find relevant chunks for summarization. In the second step, use a two-stage transformer-based method, fine-tuning individual tasks to improve the model and achieve a well-balanced and efficient summarizing strategy.

F. Optimizing the Text Summarization through Particle Swarm Optimization

A technique for population-based optimization called Particle Swarm Optimization was developed after studying the social dynamics of bird congregations. It is a member of the swarm intelligence algorithm family and excels at tackling computationally difficult NP-hard tasks. PSO represents every possible solution to an optimization issue as a particle inside of a swarm. Every particle has a location that represents a possible solution; the objective is to identify the optimal solution by varying the particle placements throughout a series of iterations. PSO keeps two different kinds of information on every particle:

1) *Personal Best (pBest)*: In the event of a search history, this is the best spot that the particle has found to date.

2) *Global Best (gBest)*: The following is the optimal location that every particle inside the swarm has discovered.

The position update of each particle in PSO is guided by both its personal best and the global best positions. The velocity of each particle is adjusted according to the following Eq. (7):

$$V_k = W \cdot V_k + C_1 \cdot r_1 \cdot (PBest_k - d_k) + C_2 \cdot r_2 \cdot (gBest_k - d_k) \quad (7)$$

where:

- V_k is the velocity of the k th particle.
- W is the weight of the particle's previous velocity.
- $c1$ and $c2$ are coefficients of acceleration.
- $r1$ and $r2$ are random numbers sampled.
- $PBest_k$ of the K^{th} particle is the personal best position.
- $gBest_k$ is the global best position in the swarm.
- d_k represents the current position of the K^{th} particle.

After updating the velocity, the position of each particle is adjusted using the new velocity in the Eq. (8):

$$d_k = d_k + V_k \quad (8)$$

The parameters w , $c1$, and $c2$ are adaptive and need to be tuned to achieve the best performance for a specific optimization problem.

To identify the optimum solution to the optimization issue, PSO, in short, iteratively changes the placements of particles inside a swarm depending on their velocities, personal bests, and global bests. This method resembles the social behavior of flocks of birds, whereby individual birds modify their locations in response to the movements of the flock as a whole and the positions of other birds.

V. RESULTS AND DISCUSSIONS

A. Evaluation Accuracy of BBC News Dataset for Summarizing

Text summarizing methods must be evaluated using datasets like Gigaword, CNN/Daily Mail, and BBC News Summary in order to determine how well these models perform in extracting important information from the input papers and producing succinct, illuminating summaries. An explanation of each dataset's evaluation procedure is provided below:

1) *Evaluation measures of CNN/Daily Mail Collection:* One of the most popular benchmarks for text summarizing tasks is the CNN/Daily Mail dataset. It is made up of summaries of news stories that have been manually created. A text summarization model is usually evaluated by training it on a subset of the dataset and assessing its performance on a test or held-out validation set. Table I Shows evaluation measures of text summarisation over the cnn/daily mail datasets.

To evaluate the quality of the produced summaries, metrics like ROUGE are frequently employed. ROUGE calculates the amount of word and n-gram overlap, among other criteria, that

exists between the produced and reference summaries. In order to evaluate the generated summaries' overall quality, coherence, and fluency in comparison to the reference summaries, human review can also be carried out.

2) *Evaluation measures of gigaword collection:* The headlines in the Gigaword dataset are succinct descriptions of the news stories that are paired with them. Training and testing a summarization model on a subset of the Gigaword dataset constitutes the evaluation procedure, which is akin to that of the CNN/Daily Mail dataset. Table II Shows Evaluation Measures of Text Summarisation Over The Gigaword Dataset.

TABLE I. EVALUATION MEASURES OF TEXT SUMMARISATION OVER THE CNN/DAILY MAIL DATASETS

Model	ROUGE1 SCORE	ROUGE2 SCORE	ROUGE-L SCORE
Words-lvt2k	36.45	14.3	33.66
Pointer-generator	38.53	16.28	35.38
Reinforcement learning	41.16	15.75	39.08
Adversarial network	40.92	18.65	37.71
ATSDL	35.9	18.8	28
BERT	42.6	18.8	38.5
DEATS	40.85	18.08	37.13
BiSum	37.01	15.95	33.66

TABLE II. EVALUATION MEASURES OF TEXT SUMMARISATION OVER THE GIGAWORD DATASET

Method	ROUGE1	ROUGE2	ROUGE-L
RCT	38.28	19.20	35.63
SEASS	37.16	18.55	34.64
Words-lvt5k-1sent	29.62	10.43	26.25
RAS-Elman ($k = 10$)	29.98	9.27	25.07
FTSumg	38.28	18.66	35.25
ABS+	29.19	9.50	24.82

Once more, ROUGE measures are frequently employed in conjunction with human assessment to gauge the caliber of the generated headlines.

3) *Comparing Evaluation measures of BBC News Summaries with Existing dataset:* The BBC News Summary dataset comprises summaries authored by humans for news stories sourced from the BBC website. Training and testing a summarization model on a subset of the dataset constitutes the evaluation procedure for this dataset, which is identical to that of the other datasets. For quantitative assessment, the overlap between the produced summaries and the reference summaries is measured using ROUGE metrics. The readability, coherence, and informativeness of the produced summaries may also be evaluated by humans. The assessment of text summarizing algorithms is often conducted using a combination of quantitative metrics (such as ROUGE scores) and qualitative assessment by human review on datasets such as CNN/Daily Mail, Gigaword, and BBC News Summary. These assessments make it easier for practitioners and academics to comprehend how well the models work and pinpoint areas where text summarizing systems need to be improved.

B. Generated Summarization of Distributed Source

During training, the model learns to predict summary tokens with the fewest differences between predicted and target summaries. This is performed by optimizing a loss function (for example, cross-entropy loss) using techniques like as backpropagation through time (BPTT). The model's parameters (weights and biases) are periodically adjusted in response to the computed loss, improving the model's ability to produce accurate summaries over time. The input text is encoded, and the encoder generates the contextual vector. Using the context vector, the decoder starts decoding summary tokens until it reaches the conclusion of the sequence Tokens are generated or the maximum length is achieved. The resultant summary is decoded from the token sequence and returned as the final outcome. The LSTM and BERT model successfully predicts the output summary based on contextual information learned from the input text, resulting in a brief and informative summary sequence. The optimized model is trained using the hybrid architecture on the text summarization dataset. Feeding sequences into the model, creating summaries, and adjusting

the model parameters by the loss computed during fine-tuning are all part of the training process.

Using metrics like ROUGE, the model's performance is assessed on a different validation dataset after training to gauge how well the generated summaries compare to reference summaries. In the end, the trained model is put to the test on hypothetical data in order to evaluate its ability to generalize and provide summaries for brand-new input texts. Metrics like ROUGE scores, which assess the quality of the summaries produced, will be included in the implementation results of the summarization of texts employing a hybrid BERT and LSTM model. These findings would show how well the model extracts the most important information from the input text and creates succinct, illuminating summaries. Furthermore, qualitative assessment carried out by hand-examining the generated summaries can reveal information about the overall quality, coherence, and fluency of the summaries created by the model.

C. Performance Assessment

Metrics for performance assessment are crucial for evaluating machine learning models' efficacy and dependability quantitatively, especially when it comes to categorization tasks like text summarization. Below is a thorough description of a few measures employed in performance evaluations:

1) *Accuracy*: The percentage of correct forecasts to all projected outcomes is referred to as accuracy. When a data set is balanced, this metric performs effectively. This metric's results may not accurately indicate how well the model did when there is an overwhelming category in the data set is given in Eq. (9):

$$Accuracy = \frac{True\ Negative + True\ Positive}{True\ Positive + False\ Positive + True\ Negative + False\ Negative} \quad (9)$$

2) *Precision*: It is calculated by dividing the total number of sentences in the applicant (i.e., system) and source

summaries by the total count of sentences in each candidate summary, as shown in Eq. (10):

$$Precision = \frac{T * p}{T * p + F * n} \quad (10)$$

3) *Recall*: Recall measures the model's capacity to count the number of positive out of all true positives. Whenever a negative result is costly for modeling quality, for instance in identifying models, this method is useful and is given in Eq. (11):

$$Recall = \frac{T * p}{T * p + F * n} \quad (11)$$

4) *F1-Score*: In the Equation, metrics for recall and accuracy. The harmonic mean of recall and accuracy is known as the F-measure. The F1 score, produced for this purpose, examines the correlation among the positive information in the data set and the classifier's prediction is given in Eq. (12):

$$F1\ score = \frac{2T * p}{2T * p + F * p + F * n} \quad (12)$$

Using standard data set BBC News Summary from a field, including as news stories, academic papers, and legal papers, assessed the methodology. In terms of summarization quality parameters like ROUGE scores and semantic coherence, the hybrid convolutional neural BERT model superior to baseline procedures; - its summarization effectiveness is further enhanced through the incorporation of a domain-specific document analysis, especially in highly specialized fields where conventional approaches are unable to capture domain-dependent variations. The ROUGE used in the suggested scheme to evaluate the summarizer on the basis of N-grams, where N = 1, 2., n. Here, N = 1 and N = 2 are taken into consideration for the assessment of the proposed technique. Three metrics—precision, recall, and F1-score—are used by the ROUGE tool. The BBC News Summary data collection is used to assess the suggested methodology.

TABLE III. COMPARING THE PERFORMANCE OF PROPOSED METHOD WITH EXISTING METHOD

Approach		Recall	Precision	F1score
FLSTM [21]	ROUGE 1 score	0.350	0.361	0.286
	ROUGE 2 score	0.163	0.114	0.103
	ROUGE L score	0.350	0.361	0.365
DEATS [22]	ROUGE 1 score	0.14545	0.457142	0.220689
	ROUGE 2 score	0.09740	0.34883	0.152284
	ROUGE L score	0.14545	0.457142	0.220689
Sequence to Sequence Neural Network [23]	ROUGE 1 score	0.3287	0.23	0.1123
	ROUGE 2 score	0.234	0.232	0.123
	ROUGE L score	0.32	0.23	0.123
Proposed (Hybrid BERT-LSTM)	ROUGE 1 score	1.0	0.57	0.671428
	ROUGE 2 score	1.0	0.402325	0.564285
	ROUGE L score	1.0	0.5	0.671428

The above Table III contrasts various machine learning techniques for text summarization: FLSTM: Achieved good ROUGE scores by training on a combination of BBC News Summary data. Neural network with Sequence-to-Sequence training on BBC News Summary dataset: demonstrates competitive performance. DUC 2004 in tandem, achieving good ROUGE scores. Suggested framework (BERT and LSTM): Trained on BBC News Summary, greatly surpassing competitors across all measures. These ratings assist in assessing the quality of summaries and help researchers select the best strategy for their particular work.

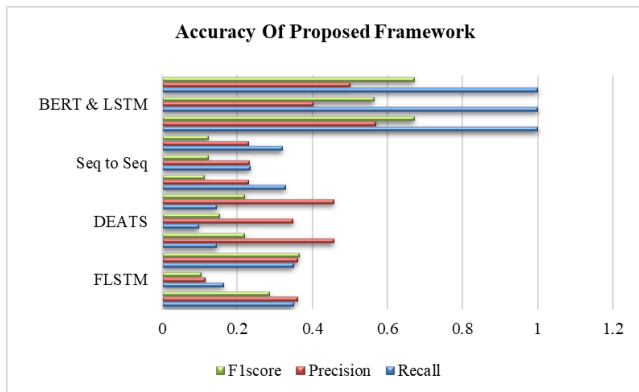

Fig. 8. Performance evaluation of LSTM with GRU Transformer with existing framework.

By contrasting the generated descriptions with prior summaries, the ROUGE criteria are frequently used to evaluate the accuracy of automatic summarizing. The greatest similar subsequence between the ones produced and reference summaries is calculated using ROUGE-L. It assesses how successfully the resulting summary preserves the initial document's consistency and semantic meaning. Traditional summarizing techniques including the use of extractive summarization techniques (e.g., seq2seq, QAspanfact, CTRLsum, FLSTM with attention) were contrasted with the combination convolutional LSTM model. The combination of models regularly beat the previous standards in terms of linguistic coherence and ROUGE scores, according to the results. The hybrid model successfully grasped the text's global and local context by fusing BERT with layers of convolution. Rich context-relevant data was stored by LSTM, and structural characteristics were extracted with the use of convolutional layers. Compared to models that relied just on one architecture, this combination produced summaries that were more cohesive and useful. The efficiency evaluation of an LSTM using a GRU Transformer within the current architecture is displayed in Fig. 8.

VI. CONCLUSION AND FUTURE ENHANCEMENT

The BERT-LSTM hybrid model, which was refined using particle swarm optimization for NLP-based automated summarizing, has demonstrated a great deal of promise for improving text compression, especially when it comes to training on the BBC News Summary dataset. By utilizing the advantages of LSTM for sequential processing and BERT for contextual comprehension, the model is able to provide succinct and enlightening summaries while efficiently

capturing the main ideas of the input text. It has proven via experiments to perform better in text compression than conventional techniques, obtaining larger compression ratios without sacrificing critical information. Looking ahead, there are a number of ways to improve the suggested model going forward and its use. First, by investigating datasets that are bigger and more varied than the BBC News Summary dataset, the model's capacity for generalization and its adaptation to different text domains and languages may be improved. Furthermore, the model's performance and efficiency may be increased by fine-tuning its parameters and design through ongoing experimentation and optimization strategies like particle swarm optimization. Moreover, the use of sophisticated attention processes or transformer-based architectures may facilitate the model's ability to capture more intricate links within the text and improve the quality of summarization.

Furthermore, taking into account how dynamic news material is, adding real-time updating mechanisms or reinforcement learning strategies might allow the model to adjust and improve its output summaries in response to changing news stories and user preferences. Furthermore, investigating ensemble learning strategies, which integrate many models to provide more reliable summaries, might improve the system's robustness and quality of summarization even further. Finally, assessing the model's effectiveness in real-world applications and user feedback may yield insightful information for additional improvement and optimization. In summary, further research and development in NLP-based automatic summarization using hybrid models such as BERT-LSTM, optimized through particle swarm and trained on datasets like the BBC News Summary, holds great promise for improving text compression methods and enabling more effective information extraction and distribution across a range of domains.

Abstract—Recognizing Arabic handwritten characters (AHCR) poses a significant challenge due to the intricate and variable nature of the Arabic script. However, recent advancements in machine learning, particularly through Convolutional Neural Networks (CNNs), have demonstrated promising outcomes in accurately identifying and categorizing these characters. While numerous studies have explored languages like English and Chinese, the Arabic language still requires further research to enhance its compatibility with computer systems. This study investigates the impact of various factors on the CNN model for AHCR, including batch size, filter size, the number of blocks, and the number of convolutional layers within each block. A series of experiments were conducted to determine the optimal model configuration for the AHCD dataset. The most effective model was identified with the following parameters: Batch Size (BS) = 64, Number of Blocks (NB) = 3, Number of Convolution Layers in Block (NC) = 3, and Filter Size (FS) = 64. This model achieved an impressive training accuracy of 98.29% and testing accuracy of 97.87%.

Keywords—Arabic Handwritten Character Recognition (AHCR); Optical Character Recognition (OCR); Deep Learning (DL); Convolutional Neural Network (CNN); Characters Recognition (CR)

I. INTRODUCTION

Handwritten character recognition (HCR), also known as handwriting recognition or optical character recognition (OCR), involves converting handwritten text or characters into digital text for computer processing and comprehension. This process entails analyzing and interpreting the shapes and patterns of handwritten characters to identify specific letters, numerals, or symbols. HCR is essential for facilitating the computer understanding and interpretation of human handwriting, thereby bridging the gap between digital and analog domains [1, 2, 3]. The Arabic script, while rich in history and complexity, poses significant challenges in the domain of digital text processing, particularly in handwritten character recognition (HCR) [26]. Arabic is considered a low-resource language in computational linguistics due to the limited availability of annotated datasets and comprehensive research compared to languages like English or Chinese. This disparity stems from several inherent features of the script and the linguistic nuances of the language [5].

Arabic handwriting recognition is particularly challenging due to the script's cursive nature, where most letters within

a word are connected, and the same letter can have up to four different shapes depending on its position within a word. Additionally, the presence of diacritical marks adds another layer of complexity, as these marks can significantly alter the meaning and pronunciation of words, yet they are often omitted in everyday writing [28,29].

The scarcity of extensive and varied datasets hampers the development of robust models capable of effectively handling the wide variability in handwriting styles. This gap highlights the urgent need for more focused research and resource development to enhance Arabic HCR technologies. An overview of the Arabic alphabetic characters used in such datasets can be seen in Fig. 1. This figure presents each Arabic character alongside its English transliteration, offering insights into the complexities of Arabic script recognition and the challenges involved in designing effective OCR systems for such scripts. Handwritten character recognition systems often employ machine learning algorithms and techniques to train models using extensive datasets of handwritten samples. The stages through which data progresses in handwritten character recognition systems are succinctly illustrated in Fig. 2.

This figure outlines a systematic workflow beginning with the initial step of splitting the dataset into distinct sets for training and testing. Following this, the data undergoes preprocessing, which typically involves normalization, scaling, and possibly augmentation techniques to enhance the robustness of the data before it is fed into the model. The subsequent phase involves training the Convolutional Neural Network (CNN) where the model learns to identify and classify the handwritten characters based on the features extracted from the training data. The final stage is testing, where the trained CNN is evaluated on a separate set of data to assess its performance and accuracy in recognizing new, unseen handwritten characters.

Pattern recognition (PR) involves the identification and acknowledgment of different elements in inputs such as images, sounds, or sequences of characters. The process typically includes measuring the object to identify distinctive features, extracting features related to these defining characteristics, and then comparing the outcomes with established patterns to ascertain a match or absence thereof between the two [6,7].

Convolutional Neural Networks (CNNs) are deep learning algorithms used for analyzing visual data like images and videos. They use multiple layers of interconnected neurons to

learn and extract hierarchical representations. CNNs are effective in computer vision applications like image recognition, object detection, and segmentation. They use convolutional layers, pooling layers, and fully connected layers to learn local patterns, reduce computational complexity, and make predictions based on extracted features. as shown in Fig. 4 [8,9,10,11].

Arabic, a Semitic language from the Arabian Peninsula, is spoken by millions, particularly in the Middle East and North Africa. It is one of six UN-recognized official languages and has significant cultural, religious, and historical significance

[1,12].

Arabic handwriting recognition technology is crucial in the Middle East and North Africa, enhancing communication, education, and commerce. Implementing in businesses streamlines customer orders, digitizes essential documents, and allows individuals to input Arabic text without language switches or transliteration, improving efficiency and accessibility [7,13,14,15,16]. Technological advancements in machine learning and deep neural networks are enhancing Arabic handwriting recognition, enhancing cultural heritage preservation and paving the way for future breakthroughs [13,15].

This study focuses on Arabic Handwritten Character Recognition (AHCR) using Convolutional Neural Networks (CNNs). The proposed study investigated the impact of various factors on the CNN model's performance, such as batch size, filter size, number of blocks, and the number of convolution layers within the block. The remaining sections of the paper are structured as follows: Section 2 provides an overview of related works, Section 3 details the proposed methodology, Section 4 presents the experimental results, and Section 5 concludes the study and outlines directions for future research.

II. RELATED WORKS

El-Sawy et al. [8], for this research, a substantial dataset of handwritten Arabic characters, comprising 16,800 unique character types, was acquired (referred to as AHCD) show Table I. The study suggests the implementation of a deep learning model based on Convolutional Neural Networks (CNNs). Through optimization using specific techniques, the proposed CNN model attained an accuracy level of 94.9%. Younis et al. [9], the study used deep neural networks for recognizing handwritten Arabic characters, incorporating batch normalisation and dropout techniques. The CNN model achieved accuracies of 97.2% and 94.8% for the AHCD and AIA9K datasets, demonstrating its effectiveness in this area. De Sousa et al. [17], the study demonstrates offline Arabic handwriting recognition using two extensive Arabic numeral and letter datasets. Four convolutional neural networks were used, with two training sessions and AHCD character dataset. The system achieved a validation accuracy of 98.60% and classification accuracy of 98.42%.

Najadat et al. [18], the researchers developed a Convolutional Neural Network (CNN) architecture for the AHCD dataset, enabling character classification in a unified pipeline. By adjusting CNN parameters, they achieved an accuracy of 97.2% in Arabic character recognition. Almansari et al. [19], the project aims to combine a multilayer perceptron (MLP) neural network with a convolutional neural network (CNN) to create a deep learning architecture using Python. The research evaluates the performance of the Arabic Handwritten Characters Dataset (AHCD), showing a 95.27% accuracy increase after CNN training, but a 72.08% decline after MLP training.

Alyahya et al. [20], the study evaluated the ResNet-18 architecture's effectiveness in distinguishing handwritten Arabic letters using two ensemble models. The original ResNet-18 achieved 98.30% accuracy, while ensemble models with fully connected layers and dropout layers achieved 98.00% and 98.03% accuracy.

Shams et al. [11], the study developed a hybrid model using DCNN, SVM, and k-means clustering for multi-stroke Arabic character recognition, outperforming the El-Sawy model in training and evaluation.

Altwaijry et al. [2], researchers developed a CNN-based model using the Hijja dataset and AHCD, achieving an accuracy of 88% on the Hijja dataset and 97% on the AHCD dataset, focusing on Arabic-based recognition algorithms.

AlJarrah et al. [4], a Convolutional Neural Network (CNN) was developed to recognize handwritten Arabic letters, trained on a dataset of 16,800 images. After analyzing 40 and 256 data sets, the CNN achieved an accuracy rate of 97.2%.

Kamal et al. [21], the proposed 18-layer pipeline, which includes convolution, pooling, batch normalization, dropout, global average pooling, and dense layers, achieved 96.93% accuracy on AHCD and MadBase datasets, making it suitable for real-world applications.

Wagaa et al. [22], the study proposes a convolutional neural network for Arabic letter classification using seven optimization methods. It employs data augmentation strategies and dropout regularization to address overfitting. The method outperforms existing models, achieving high recognition accuracy on the AHCD and Hijja datasets.

Elkhayati et al. [23], researchers have developed a Convolutional Neural Network (CNN) model to improve the recognition of isolated handwritten Arabic characters (IHAC) by reducing complexity and improving performance. Drawing inspiration from psychology and cognitive science, the model uses virtual max-pooling at the flattening layer, focusing on typical IHAC characteristics.

Khudeyer et al. [24], the study shows that using ResNet50 in combination with random forests yields more accurate predictions, with a 95% accuracy rate for the AIA9K, AHCD, and Hijja datasets, surpassing the modified ResNet50 architecture's 92.37%, 98.39%, and 91.64% accuracy rates.

Bin Durayhim et al. [25], it used the Arabic Handwritten Character Dataset (AHCD) to train three models: a convolutional neural network (CNN), a pre-trained CNN (VGG-16), and a fully-trained CNN. The models achieved an accuracy of 98.0% across the AHCD dataset, with even higher accuracy on the Hijja dataset.

III. METHODOLOGY

The AHCD classification problem involves identifying individual Arabic characters from isolated images. This task is a fundamental problem in the field of OCR and has extensive applications in digital text processing, automated reading systems, and educational technologies Fig. 3. In the AHCD classification task, each input is an image of a handwritten Arabic character, and the goal is to assign the correct label from a set of possible Arabic letters. The AHCD includes images of 28 basic Arabic letters, each written by numerous individuals to capture a wide range of handwriting styles. Let X represent the set of all possible images in the AHCD, where each image $x \in X$ is a grayscale bitmap of fixed size, which is 32×32 pixels. Let Y denote the set of Arabic character labels, where $Y = \{y_1, y_2, \dots, y_{28}\}$, corresponding to the 28 letters of the Arabic alphabet. The classification task can be defined as learning a function $f : X \rightarrow Y$ that maps each image x to a label y . The function f is typically represented by a parameterized model f_θ , where θ denotes the parameters of the model. The goal of learning is to find the optimal parameters θ^* such that the predictive accuracy of f_{θ^*} on unseen data is maximized.

1) *Data representation:* Each image x is represented as a vector $\mathbf{x} \in \mathbb{R}^n$, where n is the number of pixels in the image (e.g., $32 \times 32 = 1024$ pixels). This vectorization is typically achieved by flattening the 2D pixel array into a 1D vector.

TABLE I. COMPARISON OF ARABIC HANDWRITTEN CHARACTER RECOGNITION STUDIES

Ref/Year	Datasets Used	Method	Result (%)	Work Limitations
El-Sawy et al.[8] 2017	AHCD	CNN	94.9	Limited optimization techniques for CNN
Younis et al.[9] 2018	AHCD, AIA9K	Deep CNN with batch normalization	97.6 (AHCD), 94.8 (AIA9K)	Susceptibility to overfitting despite regularization
De Sousa et al.[17] 2018	AHCD, MADbase digits	Ensemble of CNNs	99.74 (digits), 98.60 (AHCD)	Complexity in managing multiple CNN models
Najadat et al.[18] 2019	AHCD	CNN	97.2	Lack of advanced parameter tuning
Almansari et al.[19] 2019	AHCD	MLP and CNN	95.27, 72.08 (MLP)	MLP model reduces overall performance
Alyahya et al[20] 2020	AHCD	Deep ensemble networks with ResNet-18	98.30, 98.00, 98.03	Complexity and computational demand of ensemble models
Shams et al.[11] 2020	AHCD	DCNN, SVM, k-means clustering	95.07 CRR, 4.93% ECR	Integration challenges between DCNN, SVM, and clustering
Altwaijry et al.[2] 2021	Hijja, AHCD	CNN	88 (Hijja), 97 (AHCD)	Lower performance on children's handwriting dataset
AlJarrah et al.[4] 2021	16,800 images of Arabic letters	CNN	97.7 with data augmentation	Data augmentation may not generalize well
Kamal et al.[21] 2022	AHCD, MadBase	18-layer deep learning pipeline	96.93	Potential overfitting due to deep architecture
Wagaa et al.[22] 2022	AHCD, Hijja	CNN with optimization methods	High accuracy	Overfitting despite using multiple optimization methods
Elkhayati et al.[23] 2022	IHAC	CNN with virtual max-pooling	Improved performance	Limited exploration of virtual max-pooling impacts
Khudayer et al.[24] 2023	AIA9K, AHCD, Hijja	ResNet50 with SVM and RF	Increased accuracy	Integration complexity of CNN with traditional ML
Bin Durayhim et al.[25] 2023	Hijja, AHCD	CNN, VGG-16, Mutqin prototype for children	Outperforms VGG-16 and literature models	Challenges in training deep networks for children's handwriting

2) *Model*: In this study applied classification model by using Convolutional Neural Network (CNN). The CNN takes the image vector x and outputs a vector z of raw class scores, one for each class.

3) *Objective function*: The learning process involves minimizing a loss function that quantifies the error between the predicted label and the true label for each image in a training set. A common choice for classification tasks is the cross-entropy loss, defined as:

$$L(\theta) = - \sum_{(x,y) \in D} \log p(y | x; \theta) \quad (1)$$

where, D is the training dataset and $p(y | x; \theta)$ is the softmax probability of the correct label y given the input x and model parameters θ .

4) *Evaluated the parameter*: The parameters θ are typically learned which iteratively updates the parameters to minimize the loss function.

5) *Evaluation*: The performance of the model f_{θ^*} is evaluated using accuracy metrics, which is the proportion of correctly classified images in a test set.

The CNN model was selected for its numerous capabilities in image recognition, such as the automatic extraction of features and classification. In this research, we investigate the application of this model in the recognition of handwritten Arabic characters using the AHCD dataset as shown in Fig. 4.

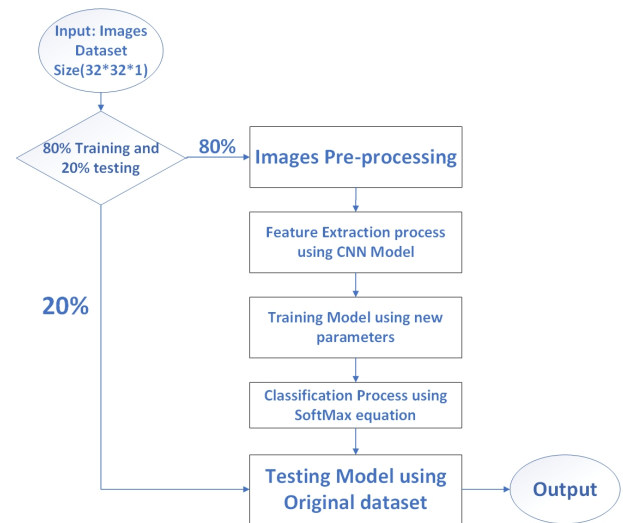

Fig. 3. The Base model.

The Eq. (2) represents the calculation of the output $X(i)$, where $X(i)$ is obtained by summing the element-wise multiplication of the input variables X_i and their corresponding weights W_i , from $i = 1$ to $k - 1$, and then adding the bias term B_i .

$$X(i) = \sum_{i=1}^{k-1} X_i * W_i + B_i \quad (2)$$

Fig. 4. CNN Model.

Eq. (3) defines the Rectified Linear Unit (ReLU) activation function, denoted as $Relu(x)$. This activation function is a fundamental component in neural networks, commonly used to introduce non-linearity into the model. The ReLU function returns the maximum of 0 and the input value x . In other words, if the input x is positive, the function outputs x , otherwise, it outputs 0. This simple yet effective activation function helps in overcoming the vanishing gradient problem and speeding up the convergence of neural network training.

$$Relu(x) = \max(0, x) \quad (3)$$

The Eq. (4) defines the softmax activation function, denoted as $Softmax(x_i)$. This function is commonly used in the final layer of a neural network for multi-class classification tasks. It calculates the probability distribution over N classes for a given input vector x . The softmax function transforms the raw scores x_i into probabilities by exponentiating each score and normalizing them by the sum of all exponentiated scores across all classes. Essentially, it ensures that the output values lie between 0 and 1 and sum up to 1, representing the likelihood of the input belonging to each class. This makes it suitable for determining the class probabilities in classification tasks, allowing the model to make confident predictions about the input data[11,27].

$$Softmax(x_i) = \frac{e^{x_i}}{\sum_{y=1}^N e^{x_y}} \quad (4)$$

The Arabic Handwritten Character Recognition (AHCR) application of convolutional neural networks (CNNs) is the main emphasis of this work. The suggested study looked into how different parameters, including batch size, filter size, number of blocks, and number of convolution layers per block, affected the performance of the CNN model. Using the Arabic Handwritten Characters dataset (AHCD), we ran several experiments before determining that the following parameters would yield the best model configuration:

- 1) We are examining the impact of batch size on the model's accuracy. The images, represented as numerical pixels, are stored on the computer, and data is processed in batches based on the chosen batch size. Initially, we implemented a batch size of 32 and conducted multiple experiments, progressively increasing the model size and the number of convolution layers. Subsequently, we repeated the experiments with a

batch size of 64, following the same procedures as in the initial set of experiments as shown Fig. 10 and 13.

- 2) We are exploring the impact of model size on the performance. Each model comprises a series of blocks, with each block incorporating convolution layers, max-pooling, and dropout Fig. 5. We initiated the study with the most straightforward model, consisting of two blocks Fig. 7, and then progressed to models with three Fig. 6 and four blocks Fig. 5. Throughout this process, we assessed the model's accuracy while varying the number of convolution layers within each block.
- 3) We investigate how the number of convolution layers within each block influences the outcomes. Blocks containing a series of convolution layers were tested, starting with one layer and progressing to two and three layers. The results were carefully observed after implementing each model. Fig. 5, 8, and 9.
- 4) We explore the impact of filter size on the model's accuracy. In the convolution layer, a filter is utilized to identify features in the image. This study aims to assess whether the filter size influences the model's accuracy. The investigation commenced with a filter size of 16, followed by transitions to filter sizes of 32 and, ultimately, 64, with corresponding tables displaying the results.

Fig. 6. CNN model with one convolutional layer and three blocks.

IV. ARABIC HANDWRITTEN CHARACTERS DATASET

Arabic Handwritten Characters Datasets play a crucial role in the field of computer vision, particularly in the development

Fig. 7. CNN model with one convolutional layer and two blocks.

Fig. 8. CNN model with two convolutional layers and four blocks.

Fig. 9. CNN model with three convolutional layers and four blocks.

and enhancement of Optical Character Recognition (OCR) systems for the Arabic script. These datasets are meticulously designed to mimic real-world handwriting variability, providing a robust resource for researchers and developers to train, test, and validate various machine learning models tailored to recognize Arabic characters. A variety of datasets have been developed to address the specific needs of the Arabic OCR community, ranging from datasets comprising isolated letters to those including complete words or numerals. These datasets vary by the number of samples, the demographics of the participants (e.g., age range, native language skills), and the conditions under which the handwriting samples were collected (e.g., controlled environments versus natural writing settings). Table II describes the common datasets used in this domain, presenting the properties of each dataset.

1) *AHCD*: This widely used dataset is crucial for benchmarking Arabic handwritten character recognition algorithms. It comprises isolated forms of Arabic letters from multiple writers, making it a robust dataset for training models.

2) *AIA9K dataset*: Contains a diverse set of Arabic handwritten characters and numerals, designed to be a comprehensive resource for developing and testing recognition algorithms that handle both letters and digits.

3) *MADBase dataset*: Styled similarly to the popular MNIST dataset but focused on Arabic numerals, it is extensively used in digit recognition tasks and is one of the largest datasets for Arabic digits.

4) *HACDB dataset*: Similar to AHCD but compiled independently, this dataset is primarily used in academic research for developing new recognition technologies and for testing existing ones.

5) *Hijja dataset*: Specifically focuses on children's handwriting, providing a unique challenge due to the variability in

young writers' script. Access is usually restricted to promote controlled studies and development.

A. The Arabic Handwritten Characters Dataset (AHCD)

The Arabic Handwritten Characters Dataset (AHCD) is an essential resource in the field of pattern recognition and machine learning, specifically geared towards the development and testing of algorithms for Arabic handwritten character recognition. This dataset is particularly valuable due to the unique characteristics of the Arabic script, which includes cursive writing and varying shapes of characters depending on their position within a word. AHCD contains images of isolated characters, which are manually segmented from handwritten words or text lines. The dataset typically includes tens of thousands of images, representing a substantial variety of handwriting styles from multiple writers. The dataset usually covers the entire standard set of Arabic characters, which includes 28 basic letters. However, it includes additional forms like ligatures and character variations, depending on the dataset's specific version or extension. The characters in the dataset are often stored as grayscale images, which may vary in resolution but are typically normalized to fit a standard size (e.g., 32x32 or 64x64 pixels) to facilitate uniform processing across different machine learning models and techniques. Each image in AHCD is labeled with the corresponding Arabic character, which allows for supervised learning algorithms to be trained effectively. The dataset, accessible to the public, contains 16,800 characters written by 60 individuals aged 19-40, with 90% using right hand. Participants wrote every character ten times on two forms [8].

B. Data Pre-processing

Data preprocessing is a critical step in the pipeline of applying CNN to AHCD dataset. Effective preprocessing improves the model's learning efficiency and predictive performance by ensuring the input data is optimally conditioned. Here's an overview of the preprocessing steps commonly employed when preparing AHCD for training with a CNN.

1) *Grayscale normalization*: Since the AHCD consists of grayscale images, normalizing these images can be crucial for CNN performance. Normalization involves scaling the pixel values to a range [0,1] from the original range of [0,255].

2) *Image resizing and verification*: AHCD images are typically 32x32 pixels, which suits most CNN architectures designed for character recognition. In this step we verify and ensure that all images conform to this dimension.

3) *Data augmentation*: To enhance the model's ability to generalize from the training data to unseen data, applying data augmentation is a beneficial strategy. We applied various techniques such as rotation, width and height shifts, shearing, and zooming to introduce a variety of transformed images derived from the original training set.

4) *Label encoding*: The labels for the AHCD are categorical Arabic letters. These labels need to be converted into a format suitable for classification, typically one-hot encoding.

TABLE II. COMMON ARABIC HANDWRITTEN CHARACTERS DATASETS

Dataset Name	Number of Characters	Image Format	Includes Digits?	Availability Online
AHCD	16,800 images	Grayscale, 32x32 pixels	No	Yes, freely available
AIA9K Dataset	9,000 images	Grayscale, 32x32 pixels	Yes	Restricted, limited access
MADBase Dataset	70,000 digits	Grayscale, 28x28 pixels	Yes (only digits)	Yes, freely available
HACDB Dataset	16,800 characters	Grayscale, 32x32 pixels	No	Yes, freely available
Hijja Dataset	47,434 characters	Grayscale, variable sizes	No	Yes, freely available

V. EXPERIMENTAL SETUP

A. Splitting the Dataset

It is standard practice to divide the dataset into training and testing subsets in order to evaluating the performance. In this study, we systematically partitioned AHCD into distinct subsets for training and testing purposes. Recognizing the importance of robust model training and the necessity for thorough performance evaluation, we allocated 80% of the dataset to training and 20% to testing. This configuration ensures that the model is exposed to a comprehensive variety of data during training, enhancing its ability to generalize, while also reserving a substantial portion of data for unbiased evaluation of its performance on unseen data.

B. Evaluation Metrics

In the assessment of models trained on AHCD, selecting the right evaluation metric is crucial to accurately measure the model's performance. For this study, we have chosen accuracy as the primary metric. This choice is predicated on accuracy's straightforward interpretability and its relevance in classification tasks where the distribution of classes is relatively balanced, as is the case with AHCD. Accuracy measures the proportion of total correct predictions made by the model compared to the total predictions made. In the context of handwriting recognition, where each character needs to be identified correctly from a set of 28 possibilities, accuracy provides a direct evaluation of how often the model correctly recognizes the characters. Furthermore, since the AHCD dataset is evenly distributed across different classes (i.e., each Arabic character), the use of accuracy helps to ensure that the performance measure is not biased by uneven class representation which can sometimes affect other metrics like precision and recall. Mathematically, accuracy is defined as the ratio of correctly predicted observations to the total observations. It can be expressed with the following equation:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \quad (5)$$

Where TP denote the true positives, TN the true negatives, FP the false positives, and FN the false negative. In the specific case of a multi-class classification like the AHCD, where each instance is classified into one of many classes (and where true negatives aren't a direct consideration for each class), the formula simplifies to focusing on the true positives of each class against all classifications made. In addition to accuracy, it is essential to evaluate model performance using metrics that provide different perspectives on the behavior and efficacy of the model. Specifically, loss and error classification rate (ECR) are critical metrics for this purpose. These metrics,

when used alongside accuracy, offer a more comprehensive view of a model's performance, especially in scenarios where accuracy alone might not fully capture the model's predictive capabilities. The loss function quantifies how far the predictions of the model are from the actual labels, providing a measure of the model's prediction errors. The choice of loss function can vary depending on the specific model and task, but for classification tasks involving neural networks, Cross-Entropy Loss is commonly used. This is particularly true for multi-class classification problems like those involving the AHCD dataset.

The Cross-Entropy Loss for a multi-class classification model is defined as:

$$L = - \sum_{i=1}^N \sum_{c=1}^M y_{ic} \log(p_{ic}) \quad (6)$$

Where, N is the number of samples in the dataset, M is the number of classes, y_{ic} is a binary indicator (0 or 1) if class label c is the correct classification for observation i , p_{ic} is the predicted probability of observation i being of class c . Error Classification Rate (ECR) is a straightforward metric that complements accuracy by focusing on the proportion of incorrect predictions. It is particularly useful for identifying how often the model fails, which can be critical for applications where failures have high costs. The ECR can be mathematically represented as:

$$\text{ECR} = 1 - \text{Accuracy} = \frac{\text{Number of incorrect predictions}}{\text{Total number of predictions}} \quad (7)$$

VI. RESULTS AND DISCUSSION

In this section, we systematically analyze the performance variations of a convolutional neural network (CNN) on the Arabic Handwritten Characters Dataset (AHCD) across multiple configurations. The detailed results, spanning from Table III to Table VIII, allow us to discern the nuanced effects of altering batch sizes, filter sizes, the number of blocks, and the number of convolutional layers within each block on key performance metrics such as test accuracy and error classification rate (ECR).

Starting with Table III, we observe that the network configuration with two blocks and three convolutional layers per block achieves the highest test accuracy of 96.10% and the lowest ECR of 3.90%. This indicates that a moderate increase in network depth within a controlled number of blocks can significantly enhance the model's ability to generalize, particularly beneficial for the complex script characteristics of the Arabic language.

TABLE III. RESULTS WITH BATCH SIZE 32 AND FILTER SIZE 16

Batch Size = 32, Number of Blocks = 2, Filter Size = 16				
Number of Conv Layers	Loss	Train Acc (%)	Test Acc (%)	ECR (%)
1	0.2492	91.77	93.93	6.07
2	0.1622	94.61	95.46	4.54
3	0.1418	95.29	96.10	3.90
Batch Size = 32, Number of Blocks = 3, Filter Size = 16				
Number of Conv Layers	Loss	Train Acc (%)	Test Acc (%)	ECR (%)
1	0.3227	89.79	94.04	5.96
2	0.1940	93.40	95.70	4.30
3	0.2299	92.79	94.67	5.33
Batch Size = 32, Number of Blocks = 4, Filter Size = 16				
Number of Conv Layers	Loss	Train Acc (%)	Test Acc (%)	ECR (%)
1	0.6028	79.34	89.66	10.34
2	0.3242	90.23	94.08	5.92
3	0.3221	90.74	92.34	7.66

Furthermore, Table IV shows a similar trend where the configuration with three blocks and two layers achieves the highest test accuracy in the set at 97.07%. This configuration strikes an optimal balance, effectively capturing the intricate features of Arabic characters without overfitting, a common issue when excessively deep networks are employed.

In contrast, the results from Table V highlight a potential overfitting scenario as deeper networks (four blocks) yield poorer performance. The lowest test accuracy recorded is significantly less optimal when the network depth is increased without sufficient data to support the complexity, underscoring the delicate balance required between network architecture and available training data. Accordingly, the results from Table VI, where a larger batch size of 64 is utilized, suggest that while larger batches can stabilize training, they do not automatically translate into better generalization, especially when the network becomes too deep or too shallow. The optimal performance is again noted in configurations that balance depth with breadth adequately. Moreover, Table VII presents an intriguing outcome where the best test accuracy does not always correlate with the lowest ECR. This suggests that while certain configurations may optimize for one metric, they may compromise on another, highlighting the trade-offs that may need to be considered in practical applications of handwriting recognition technologies.

Lastly, the insights gathered from Table VIII reinforce the complexity of configuring CNNs for handwritten character recognition. The highest accuracy achieved (97.87%) with three blocks and two layers per block in a large batch and filter setting emphasizes that while increased resources (like larger filters) can enhance performance, the architectural setup must still avoid excessive complexity to prevent training difficulties and ensure robustness against overfitting.

Across all tables, from Table III to Table VIII, one consistent observation is that the configurations with two to three blocks generally provide better performance metrics—both in terms of higher test accuracy and lower ECR. This pattern suggests an optimal depth that effectively captures the complexities of Arabic script without causing the models to overfit or become computationally infeasible. In the context of the experiments that varied filter sizes and batch sizes, it's evident that increasing the filter size tends to improve performance, but only up to a certain point. For example, Table IV and Table VII

show that a filter size of 32 offers a good compromise between capturing sufficient detail and maintaining model efficiency.

However, as seen in Table V and Table VIII, further increases in filter size sometimes result in only marginal gains or even slight reductions in performance. This outcome could be attributed to the model capturing excessive noise along with relevant features, especially when not complemented by a corresponding increase in other parameters like the number of layers or blocks. Moreover, the data points us towards an interesting trend where larger batch sizes do not always correlate with better performance, particularly when it comes to generalizing the model's capabilities to unseen data.

This is apparent from the results in Table VI compared to those in Table III. While larger batch sizes can stabilize the training process and lead to rapid convergence, they might also hinder the model's ability to navigate through narrower, potentially more optimal paths in the loss landscape during training. The highest accuracy achieved, as shown in Table VII, where configurations with moderate filter sizes and balanced block and layer setups reached an accuracy of 97.29%, underscores the necessity of tuning these parameters thoughtfully. It also highlights that while certain configurations perform exceptionally well under specific circumstances (such as with certain batch sizes or filter sizes), these configurations may not universally translate to other setups, emphasizing the bespoke nature of CNN architecture design for specific datasets like the AHCD.

A. Result Analysis

This research delves into the intricacies of recognizing Arabic handwritten characters (AHCR) using convolutional neural networks (CNNs), focusing particularly on assessing how various parameters—batch size, filter size, number of blocks, and the number of convolution layers within each block—affect the model's efficacy. The experiments conducted on the AHCD (Arabic Handwritten Characters Dataset) have illuminated some critical findings on optimizing CNN architectures for this task. Through a series of structured experiments, depicted in Tables III, IV, V, VI, VII, and VIII, alongside Fig. 10, 11, 12, 13, 14 and 15, we have comprehensively analyzed the performance impact of the aforementioned parameters. Key insights from this analysis have significantly advanced our understanding of AHCR using CNNs.

TABLE IV. BATCH SIZE 32 AND FILTER 32

Batch Size = 32, Number of Blocks = 2, Filter Size = 32

1) *Optimizing batch size and filter size:* A critical observation from our study is that larger batch sizes generally enhance the model's learning stability and performance. Specifically, a batch size of 64 consistently showed improved accuracy across various configurations (Fig. 13, 14, and 15), suggesting that it allows the network to better generalize from the training data by averaging out noise across larger data samples per gradient update.

2) *Influence of the number of blocks and layers:* Our findings further indicate that an optimal number of blocks, typically around two to three (as shown in Table IX and Fig. 11 and 14), effectively balances the depth of the net-

work with computational efficiency and prevents overfitting. Notably, increasing the number of blocks beyond this range tends to degrade performance, possibly due to the complexity and increased risk of overfitting, as observed in the lower performances in configurations with four blocks (Fig. 15).

3) *The impact of filter size:* The filter size also plays a pivotal role in the network's ability to capture relevant features from the handwriting images. Our results indicate that a filter size of 64 strikes a balance between capturing detailed features and avoiding the capture of irrelevant noise, particularly when paired with appropriate batch sizes and block numbers (Table IX). This size seems to provide sufficient granularity for

effectively learning the intricacies of Arabic script without overwhelming the model with too much information.

The highest accuracy achieved, as illustrated in Table IX, was 97.87%, using a model configuration of three blocks and three layers per block, with a batch and filter size of 64. This configuration is recommended for achieving the best results in AHCR tasks with CNNs. It showcases the necessity of a balanced approach to CNN architecture design, especially in the context of Arabic handwriting recognition, where precision in capturing character nuances is critical. The detailed exploration of these factors provides a robust guideline for tuning CNNs for Arabic handwriting recognition. The insights gained

enhance the performance of AHCR systems also contribute to the broader field of pattern recognition, offering a clear example of how careful, context-specific tuning of neural network parameters can lead to significant improvements in performance.

VII. CONCLUSION

This study extensively examined the influence of various parameters such as batch size, filter size, number of blocks, and the number of convolutional layers within each block on the performance of a convolutional neural network (CNN)

TABLE IX. THE FIVE BEST RESULT

Model Parameters				
Test Accuracy (%)	Batch Size	Num of Blocks	Filter Size	Num of Layers
97.87	64	3	64	3
97.70	64	4	64	2
97.58	64	2	64	2
97.52	64	3	64	2
97.34	64	4	64	1

and a filter size of 64, which proved particularly effective in capturing the complexities of Arabic script. Increasing the batch size from 32 to 64 consistently improved the model's performance across various configurations, highlighting the benefits of larger batch sizes in stabilizing training and enhancing performance in AHCR tasks. Models configured with three blocks and three convolutional layers each typically outperformed alternatives with fewer or more blocks/layers, suggesting an optimal balance between model depth and breadth, crucial for achieving good generalization without overfitting. The use of larger filter sizes (64) was advantageous over smaller sizes (16 and 32), enabling the model to better capture detailed features of the handwritten characters, critical for the accurate recognition of Arabic script.

A. Limitations and Future Work

The limitation of this study that the research was confined to the AHCD dataset. To establish the robustness and generalizability of the model, further testing is essential on a diverse array of AHCR datasets, including those featuring more variable handwriting styles or cursive text.

For future research directions, we will focus on integrating attention mechanisms, which could focus the model on relevant parts of the input data. Exploring ensemble models that combine the strengths of multiple network architectures could significantly enhance the capability to recognize challenging character classes or subtle nuances in handwriting. Additionally, extending the current model to handle continuous cursive Arabic handwriting and multi-line text recognition could substantially broaden the applicability of the research, making it more suitable for real-world scenarios, such as document analysis and automated transcription. Moreover, investigating the model's performance on mixed-language documents, particularly those combining Arabic with other scripts, could

model tailored for Arabic Handwritten Character Recognition (AHCR) using the AHCD dataset. The optimal model configuration achieved an impressive training accuracy of 98.29% and testing accuracy of 97.87%. This configuration utilized a Batch Size of 64, three blocks, three convolutional layers per block,

further enhance its practicality and utility in multicultural and multilingual contexts.
