

Volume 15 Issue 5

May 2024

ISSN 2156-5570(Online)

ISSN 2158-107X(Print)

Editorial Preface

From the Desk of Managing Editor...

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai
Editor-in-Chief
IJACSA
Volume 15 Issue 5 May 2024
ISSN 2156-5570 (Online)
ISSN 2158-107X (Print)

Editorial Board

Editor-in-Chief

Dr. Kohei Arai - Saga University

Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation

Associate Editors

Alaa Sheta

Southern Connecticut State University

Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems

Domenico Ciuonzo

University of Naples, Federico II, Italy

Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things

Dorota Kaminska

Lodz University of Technology

Domain of Research: Artificial Intelligence, Virtual Reality

Elena Scutelnicu

"Dunarea de Jos" University of Galati

Domain of Research: e-Learning, e-Learning Tools, Simulation

In Soo Lee

Kyungpook National University

Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning

Krassen Stefanov

Professor at Sofia University St. Kliment Ohridski

Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design

Renato De Leone

Università di Camerino

Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming

Xiao-Zhi Gao

University of Eastern Finland

Domain of Research: Artificial Intelligence, Genetic Algorithms

Arun D Kulkarni

University of Texas at Tyler

Domain of Research: Machine Vision, Artificial Intelligence, Computer Vision, Data Mining, Image Processing, Machine Learning, Neural Networks, Neuro-Fuzzy Systems

CONTENTS

Paper 1: Multiview Outlier Filtered Pediatric Heart Sound Classification

Authors: Sagnik Dakshit

PAGE 1 – 9

Paper 2: Trigger Screen Restriction Framework, iOS use Case Towards Building a Gamified Physical Intervention

Authors: Majed Hariri, Richard Stone

PAGE 10 – 21

Paper 3: An Intelligent Method for Collecting and Analyzing Voice Reviews to Gauge Customer Satisfaction

Authors: Nail Khabibullin

PAGE 22 – 28

Paper 4: Intelligent Framework in a Serverless Computing for Serving using Artificial Intelligence and Machine Learning

Authors: Deepak Khatri, Sunil Kumar Khatri, Deepthi Mishra

PAGE 29 – 37

Paper 5: Find a Research Collaborator: An Ontology-Based Solution to Find the Right Resources for Research Collaboration

Authors: Nada Abdullah Alrehaili, Muhammad Ahtisham Aslam, Amani Falah Alharbi, Rehab Bahaaddin Ashari

PAGE 38 – 48

Paper 6: Advancing Hospital Cybersecurity Through IoT-Enabled Neural Network for Human Behavior Analysis and Anomaly Detection

Authors: Faisal Almojel, Shailendra Mishra

PAGE 49 – 57

Paper 7: Tile Defect Recognition Network Based on Amplified Attention Mechanism and Feature Fusion

Authors: JiaMing Zhang, ZanXia Qiang, YuGang Li

PAGE 58 – 65

Paper 8: Tendon-Driven Robotic Arm Control Method Based on Radial Basis Function Adaptive Tracking Algorithm

Authors: Xiaoke Fang

PAGE 66 – 74

Paper 9: Construction of Cloud Computing Task Scheduling Model Based on Simulated Annealing Hybrid Algorithm

Authors: Kejin Lv, Tianxu Huang

PAGE 75 – 84

Paper 10: Ensemble Empirical Mode Decomposition Based on Sparse Bayesian Learning with Mixed Kernel for Landslide Displacement Prediction

Authors: Ping Jiang, Jiejie Chen

PAGE 85 – 92

Paper 11: Adaptive Scheduling of Robots in the Mixed Flow Workshop of Industrial Internet of Things

Authors: Dejun Miao, Rongyan Xu, Yizong Dai, Jiusong Chen

PAGE 93 – 103

Paper 12: Optimization of Student Behavior Detection Algorithm Based on Improved SSD Algorithm

Authors: Yongqing CAO, Dan LIU

PAGE 104 – 114

Paper 13: Detecting User Credibility on Twitter using a Hybrid Machine Learning Model of Features' Selection and Weighting

Authors: Nahid R. Abid-Althaqafi, Hessah A. Alsalamah

PAGE 115 – 125

Paper 14: Automated Motor Imagery Detection Through EEG Analysis and Deep Learning Models for Brain-Computer Interface Applications

Authors: Yang Li, Bocheng Liu, Yujia Tian

PAGE 126 – 133

Paper 15: Exploring Differential Entropy and Multifractal Cumulants for EEG-based Mental Workload Recognition

Authors: Yan Lu

PAGE 134 – 141

Paper 16: Predicting Math Performance in High School Students using Machine Learning Techniques

Authors: Yuan hui

PAGE 142 – 153

Paper 17: IoT Device Identity Authentication Method Based on rPPG and CNN Facial Recognition

Authors: Liwan Wu, Chong Yang

PAGE 154 – 162

Paper 18: Logistics Path Planning Method using NSGA-II Algorithm and BP Neural Network in the Era of Logistics 4.0

Authors: Liuqing Li

PAGE 163 – 173

Paper 19: Cloud-Enabled Real-Time Monitoring and Alert System for Primary Network Resource Scheduling and Large-Scale Users

Authors: Bin Zhang, Hongchun Shu, Dajun Si, Jinding He, Wenlin Yan

PAGE 174 – 183

Paper 20: A Comparative Work to Highlight the Superiority of Mouth Brooding Fish (MBF) over the Various ML Techniques in Password Security Classification

Authors: Yan Shi, Yue Wang

PAGE 184 – 196

Paper 21: Comparative Study: Mouth Brooding Fish (MBF) as a Novel Approach for Android Malware Detection

Authors: Kangle Zhou, Panpan Wang, Baiqing He

PAGE 197 – 209

Paper 22: Examining the Various Neural Network Algorithms Considering the Superiority of Mouth Brooding Fish in Data Classification

Authors: Lang Liu, Yong Zhu

PAGE 210 – 219

Paper 23: A Method for Assessing Financial Market Price Behavior: An Analysis of the Shanghai Stock Exchange Index

Authors: Zhi Huang, Jiansheng Li

PAGE 220 – 231

Paper 24: Stock Market Volatility Estimation: A Case Study of the Hang Seng Index

Authors: Shengwen Wu, Qiqi Lin, Xuefeng Liu

PAGE 232 – 244

Paper 25: Presenting a New Approach for Clustering Optimization in Wireless Sensor Networks using Fuzzy Cuckoo Search Algorithm

Authors: Bing ZHOU, Youyou LI

PAGE 245 – 257

Paper 26: Enhancing Fraud Detection in Credit Card Transactions using Optimized Federated Learning Model

Authors: Mustafa Abdul Salam, Doaa L. El-Bably, Khaled M. Fouad, M. Salah Eldin Elsayed

PAGE 258 – 263

Paper 27: Embedding Emotions in the Metaverse: The Emotive Keywords for Augmented Reality Mobile Library Application

Authors: Nik Azlina Nik Ahmad, Munaisyah Abdullah, Ahmad Iqbal Hakim Suhaimi, Anitawati Mohd Lokman

PAGE 264 – 270

Paper 28: The Impact of Dual Objective Optimization Model Combining Non-Dominated Genetic Algorithm on Rural Industrial Ecological Economy

Authors: Ying Wang

PAGE 271 – 280

Paper 29: Performance Enhancement of Wi-Fi Fingerprinting-based Indoor Positioning using Truncated Singular Value Decomposition and LSTM Model

Authors: Duc Khoi Nguyen, Thi Hang Duong, Le Cuong Nguyen, Manh Kha Hoang

PAGE 281 – 288

Paper 30: Design and Implementation of an Information Management System for College Students in Higher Education Institutions Based on Cloud Computing

Authors: Mo Bin

PAGE 289 – 302

Paper 31: A Deep Learning-based Method for Determining Semantic Similarity of English Translation Keywords

Authors: Wu Zhili, Zhang Qian

PAGE 303 – 313

Paper 32: An Improved VMD and Wavelet Hybrid Denoising Model for Wearable SSVEP-BCI

Authors: Yongquan Xia, Keyun Li, Duan Li, Jiaofen Nan, Ronglei Lu

PAGE 314 – 326

Paper 33: Analyzing Quantity-based Strategies for Supply Chain Sustainability and Resilience in Uncertain Environment

Authors: Dounia SAIDI, Aziz AIT BASSOU, Mustapha HLYAL, Jamila EL ALAMI

PAGE 327 – 341

Paper 34: Hardhat-YOLO: A YOLOv5-based Lightweight Hardhat-Wearing Detection Algorithm in Substation Sites

Authors: Wanbo Luo, Ahmad Ihsan Mohd Yassin, Khairul Khaizi Mohd Shariff, Rajeswari Raju

PAGE 342 – 354

Paper 35: Model for Responsive Agriculture Hub via e-Commerce to Sustain Food Security

Authors: Wan Nurhayati Wan Ab. Rahman, Wan Nurfarah Wan Zulkifli, Nur Nabilah Zainuri, Hanis Amira Khairol Anwar

PAGE 355 – 368

Paper 36: Digital Public System of Urban Art: Navigating Human-Computer Interaction in Artistic Design for Innovative Urban Expressions

Authors: Yuan Yao, Ying Liu

PAGE 369 – 376

Paper 37: Fusion Lightweight Steel Surface Defect Detection Algorithm Based on Improved Deep Learning

Authors: Fei Ren, Jiajie Fei, HongSheng Li, Bonifacio T. Doma Jr

PAGE 377 – 382

Paper 38: AdvAttackVis: An Adversarial Attack Visualization System for Deep Neural Networks

Authors: DING Wei-jie, Shen Xuchen, Yuan Ying, MAO Ting-yun, SUN Guo-dao, CHEN Li-li, CHEN bing-ting

PAGE 383 – 391

Paper 39: Exploring the Impact of PCA Variants on Intrusion Detection System Performance

Authors: CHENTOUFI Oumaima, CHOUKHAIRI Mouad, CHOUGDALI Khalid, ALLOUG Ilyas

PAGE 392 – 400

Paper 40: Enhancing Whale Optimization Algorithm with Differential Evolution and Lévy Flight for Robot Path Planning

Authors: Rongrong TANG, Xuebang TANG, Hongwang ZHAO

PAGE 401 – 410

Paper 41: A Capacitance-base System Design for Measurement of Crude Oil Moisture

Authors: ZhixueShi, Xudong Zhao

PAGE 411 – 419

Paper 42: SchemaLogix: Advancing Interoperability with Machine Learning in Schema Matching

Authors: Mohamed Raoui, Mohammed Ennaouri, Moulay Hafid El Yazidi, Ahmed Zellou

PAGE 420 – 430

Paper 43: Image Segmentation in Complex Backgrounds using an Improved Generative Adversarial Network

Authors: Mei Wang, Yiru Zhang

PAGE 431 – 441

Paper 44: A Novel Quantum Orthogonal Frequency-Division Multiplexing Transmission Scheme

Authors: Mohammed R. Almasaoodi, Abdulbasit M. A. Sabaawi, Sara El Gaily, Sándor Imre

PAGE 442 – 450

Paper 45: Deep Learning-based Classification of MRI Images for Early Detection and Staging of Alzheimer's Disease

Authors: Parvatham Niranjana Kumar, Lakshmana Phaneendra Maguluri

PAGE 451 – 459

Paper 46: Image Processing-based Performance Evaluation of KNN and SVM Classifiers for Lung Cancer Diagnosis

Authors: Kavitha B C, Naveen K B

PAGE 460 – 468

Paper 47: Generative AI-Powered Predictive Analytics Model: Leveraging Synthetic Datasets to Determine ERP Adoption Success Through Critical Success Factors

Authors: Koh Chee Hong, Abdul Samad Bin Shibghatullah, Thong Chee Ling, Samer Muthana Sarsam

PAGE 469 – 482

Paper 48: An Investigation of Scalability in EHRs using Healthcare 4.0 and Blockchain

Authors: Ahmad Fayyaz Madni, Munam Ali Shah, Muhammad Al-Naeem

PAGE 483 – 493

Paper 49: Traffic Flow Prediction at Intersections: Enhancing with a Hybrid LSTM-PSO Approach

Authors: Chaimaa CHAOURA, Hajar LAZAR, Zahi JARIR

PAGE 494 – 501

Paper 50: Remote Palliative Care: A Systematic Review of Effectiveness, Accessibility, and Patient Satisfaction

Authors: Rihab El Sabrouy, Abdelmajid Elouadi, Mai Abdou Salifou Karimoune

PAGE 502 – 513

Paper 51: Enhancing SDN Anomaly Detection: A Hybrid Deep Learning Model with SCA-TSO Optimization

Authors: Ahmed Mohanad Jaber ALHILO, Hakan Koyuncu

PAGE 514 – 522

Paper 52: Comprehensive and Simulated Modeling of a Centralized Transport Robot Control System

Authors: Murad Bashabsheh

PAGE 523 – 531

Paper 53: Estimating Stock Market Prices with Histogram-based Gradient Boosting Regressor: A Case Study on Alphabet Inc

Authors: Shigen Li

PAGE 532 – 543

Paper 54: A Study on Wireless Sensor Node Localization and Target Tracking Based on Improved Locust Algorithm

Authors: Tan SONGHE, Qin Qi

PAGE 544 – 555

Paper 55: Toward Optimal Service Composition in the Internet of Things via Cloud-Fog Integration and Improved Artificial Bee Colony Algorithm

Authors: Guixia Xiao

PAGE 556 – 565

Paper 56: Emotion-based Autism Spectrum Disorder Detection by Leveraging Transfer Learning and Machine Learning Algorithms

Authors: I. Srilalita Sarwani, D. Lalitha Bhaskari, Sangeeta Bhamidipati

PAGE 566 – 574

Paper 57: Offensive Language Detection on Social Media using Machine Learning

Authors: Rustam Abdrakhmanov, Serik Muktarovich Kenesbayev, Kamalbek Berkimbayev, Gumyrbek Toikenov, Elmira Abdrashova, Oichagul Alchinbayeva, Aizhan Ydyrys

PAGE 575 – 582

Paper 58: A Deep Residual Network Designed for Detecting Cracks in Buildings of Historical Significance

Authors: Zlikha Makhanova, Gulbakhram Beissenova, Almira Madiyarova, Marzhan Chazhabayeva, Gulsara Mambetaliyeva, Marzhan Suimenova, Guldana Shaimerdenova, Elmira Mussirepova, Aidos Baiburin

PAGE 583 – 592

Paper 59: Mobile Application with Augmented Reality Applying the MESOVA Methodology to Improve the Learning of Primary School Students in an Educational Center

Authors: Anthony Wilder Arias Vilchez, Tomas Silvestre Marcelo Lloclla Soto, Giancarlo Sanchez Atuncar

PAGE 593 – 600

Paper 60: An Improved MobileNet Model Integrated Spatial and Channel Attention Mechanisms for Tea Disease

Authors: Li Zhang, Jiacheng Sun, Minghui Yang

PAGE 601 – 607

Paper 61: Tourist Attraction Recommendation Model Based on RFPAP-NNPAP Algorithm

Authors: Jun Li

PAGE 608 – 621

Paper 62: Ontology Driven for Mapping a Relational Database to a Knowledge-based System

Authors: Abdelrahman Osman Elfaki, Yousef H. Alfaifi

PAGE 622 – 629

Paper 63: A Novel Controlling System for Smart Farming-based Internet of Things (IoT)

Authors: Dodi Yudo Setyawan, Warsito, Roniyus Marjunus, Sumaryo

PAGE 630 – 641

Paper 64: Method of Budding Detection with YOLO-based Approach for Determination of the Best Time to Plucking Tealeaves

Authors: Kohei Arai, Yoho Kawaguchi

PAGE 642 – 648

Paper 65: Road Accident Detection using SVM and Learning: A Comparative Study

Authors: Fatima Qanouni, Hakim El Massari, Noredine Gherabi, Maria El Badaoui

PAGE 649 – 657

Paper 66: Recognition of Hate Speech using Advanced Learning Model-based Multi-Layered Approach (MLA)

Authors: Puspendu Biswas, Donavalli Haritha

PAGE 658 – 669

Paper 67: Method Resource Sharing in On-Premises Environment Based on Cross-Origin Resource Sharing and its Application for Safety-First Constructions

Authors: Kohei Arai, Kodai Norikoshi, Mariko Oda

PAGE 670 – 675

Paper 68: A Raise of Security Concern in IoT Devices: Measuring IoT Security Through Penetration Testing Framework

Authors: Abdul Ghafar Jaafar, Saiful Adli Ismail, Abdul Habir, Khairul Akram Zainol Ariffin, Othman Mohd Yusop

PAGE 676 – 690

Paper 69: Decision Making Systems for Pneumonia Detection using Deep Learning on X-Ray Images

Authors: Zhadra Kozhamkulova, Elmira Nurlybaeva, Madina Suleimenova, Dinargul Mukhammejanova, Marina Vorogushina, Zhanar Bidakhmet, Mukhit Maikotov

PAGE 691 – 698

Paper 70: Data Security Optimization at Cloud Storage using Confidentiality-based Data Classification

Authors: Dorababu Sudarsa, A. Nagaraja Rao, A. P. Sivakumar

PAGE 699 – 709

Paper 71: Optimal Trajectory Planning for Robotic Arm Based on Improved Dynamic Multi-Population Particle Swarm Optimization Algorithm

Authors: Rong Wu, Yong Yang, Xiaotong Yao, Nannan Lu

PAGE 710 – 718

Paper 72: Migration Learning and Multi-View Training for Low-Resource Machine Translation

Authors: Jing Yan, Tao Lin, Shuai Zhao

PAGE 719 – 728

Paper 73: Visual Communication Design Based on Sparsity-Enhanced Image Processing Models

Authors: Zheng Wang, Dongsik Hong

PAGE 729 – 737

Paper 74: Enhancing Age Estimation from Handwriting: A Deep Learning Approach with Attention Mechanisms

Authors: Li Zhao, Xiaoping Wu, Xiaoming Chen

PAGE 738 – 747

Paper 75: Generation of Topical Educational Content by Estimation of the Number of Patents in the Digital Field

Authors: Evgeny Nikulchev, Dmitry Ilin

PAGE 748 – 753

Paper 76: Enhancing Smart Contract Security Through Multi-Agent Deep Reinforcement Learning Fuzzing: A Survey of Approaches and Techniques

Authors: Muhammad Farman Andrijasa, Saiful Adli Ismail, Norulhusna Ahmad, Othman Mohd Yusop

PAGE 754 – 767

Paper 77: Exhaustive Insights Towards Social-Media Driven Disaster Management Approaches

Authors: Nethravathy Krishnappa, D Saraswathi, Chandrasekar Chelliah

PAGE 768 – 780

Paper 78: Network Security Evaluation Based on Improved Genetic Algorithm and Weighted Error Backpropagation Algorithm

Authors: Jinlong Pang, Chongwei Liu

PAGE 781 – 789

Paper 79: Application Analysis of Network Security Situational Awareness Model for Asset Information Protection

Authors: Yuemei Ren, Xianju Feng

PAGE 790 – 799

Paper 80: Big Data Multi-Strategy Predator Algorithm for Passenger Flow Prediction

Authors: Peng Guo

PAGE 800 – 810

Paper 81: Computer Simulation Study of Stiffness Variation of Stewart Platform under Different Loads

Authors: Zhiqiang Zhao, Yuetao Liu, Changsong Yu, Peicen Jiang

PAGE 811 – 818

Paper 82: Transforming Pixels: Crafting a 3D Integer Discrete Cosine Transform for Advanced Image Compression

Authors: R. Rajprabu, T. Prathiba, Deepa Priya V, Arthy Rajkumar, Rajkannan. C, P. Ramalakshmi

PAGE 819 – 826

Paper 83: Real-Time Road Lane-Lines Detection using Mask-RCNN Approach

Authors: Gulbakhram Beissenova, Dinara Ussipbekova, Firuza Sultanova, Karasheva Nurzhamal, Gulmira Baenova, Marzhan Suimenova, Kamar Rzayeva, Zhanar Azhibekova, Aizhan Ydyrys

PAGE 827 – 833

Paper 84: Hybrid Convolutional Recurrent Neural Network for Cyberbullying Detection on Textual Data

Authors: Altynzer Baiganova, Saniya Toxanova, Meruert Yerekesheva, Nurshat Nauryzova, Zhanar Zhumagalieva, Aigerim Tulendi

PAGE 834 – 842

- Paper 85: Studying the Behavior of a Modified Deep Learning Model for Disease Detection Through X-ray Chest Images**
Authors: Elma Zanj, Lorena Balliu, Gledis Basha, Elunada Gjata, Elinda Kajo Meçe
PAGE 843 – 850
- Paper 86: Establishment of Economic Analysis Model Based on Artificial Intelligence Technology**
Authors: Jiqing Shi
PAGE 851 – 863
- Paper 87: Deep Learning Approach to Classify Brain Tumors from Magnetic Resonance Imaging Images**
Authors: Asma Ahmed A. Mohammed
PAGE 864 – 872
- Paper 88: Multi-Objective Optimization of Oilfield Development Planning Based on Shuffled Frog Leaping Algorithm**
Authors: Jun Wei
PAGE 873 – 882
- Paper 89: Investigating an Ensemble Classifier Based on Multi-Objective Genetic Algorithm for Machine Learning Applications**
Authors: Zhiyuan LIU
PAGE 883 – 889
- Paper 90: Automatic Detection of Ascaris Lumbricoides in Microscopic Images using Convolutional Neural Networks (CNN)**
Authors: Giovanni Gelber Martinez Pastor, Cesar Roberto Ancco Ruelas, Eveling Castro-Gutierrez, Victor Luis Vásquez Huerta
PAGE 890 – 897
- Paper 91: Automatic Personality Recognition in Videos using Dynamic Networks and Rank Loss**
Authors: Nethravathi Periyapatna Sathyanarayana, Karuna Pandith, Manjula Sanjay Koti, Rajermani Thinakaran
PAGE 898 – 904
- Paper 92: Contrastive Learning and Multi-Choice Negative Sampling Recommendation**
Authors: Yun Xue, Xiaodong Cai, Sheng Fang, Li Zhou
PAGE 905 – 912
- Paper 93: Development of Deep Learning Models for Traffic Sign Recognition in Autonomous Vehicles**
Authors: Zhadra Kozhamkulova, Zhanar Bidakhmet, Marina Vorogushina, Zhuldyz Tashenova, Bella Tussupova, Elmira Nurlybaeva, Dastan Kambarov
PAGE 913 – 920
- Paper 94: Enhanced U-Net Architecture for Lung Segmentation on Computed Tomography and X-Ray Images**
Authors: Gulnara Saimassay, Mels Begenov, Ualikhan Sadyk, Rashid Baimukashev, Askhat Maratov, Batyrkhan Omarov
PAGE 921 – 930
- Paper 95: EfficientSkinCaSV2B3: An Efficient Framework Towards Improving Skin Classification and Segmentation**
Authors: Quy Lu Thanh, Triet Minh Nguyen
PAGE 931 – 944
- Paper 96: Cross-Modal Fine-Grained Interaction Fusion in Fake News Detection**
Authors: Zhanbin Che, GuangBo Cui
PAGE 945 – 956

Paper 97: A Stepwise Discriminant Analysis and FBCSP Feature Selection Strategy for EEG MI Recognition

Authors: YingHui Meng, YaRu Su, Duan Li, JiaoFen Nan, YongQuan Xia

PAGE 957 – 969

Paper 98: Enhancing Sentiment Analysis on Social Media Data with Advanced Deep Learning Techniques

Authors: Huu-Hoa Nguyen

PAGE 970 – 980

Paper 99: An Integrated Generalized Linear Regression with Two Step-AS Algorithm for COVID-19 Detection

Authors: Ahmed Hamza Osman, Hani Moetque Aljahdali, Sultan Menwer Altarrazi, Altyeb Taha

PAGE 981 – 990

Paper 100: Local Path Planning of Mobile Robots Based on the Improved SAC Algorithm

Authors: Ruihong Zhou, Caihong Li, Guosheng Zhang, Yaoyu Zhang, Jiajun Liu

PAGE 991 – 999

Paper 101: Exploring Music Style Transfer and Innovative Composition using Deep Learning Algorithms

Authors: Sujie He

PAGE 1000 – 1007

Paper 102: Predictive Modeling of Yoga's Impact on Individuals with Venous Chronic Cerebrospinal System

Authors: Sanjun Qiu

PAGE 1008 – 1020

Paper 103: Modified Artificial Bee Colony Algorithm for Load Balancing in Cloud Computing Environments

Authors: Qian LI, Xue WANG

PAGE 1021 – 1031

Paper 104: Cloud Workload Prediction Based on Bayesian-Optimized Autoformer

Authors: Biying Zhang, Yuling Huang, Zuoqiang Du, Zhimin Qiu

PAGE 1032 – 1042

Paper 105: A Systematic Review on Multi-Factor Authentication Framework

Authors: Muhammad Syahreen, Noor Hafizah, Nurazeen Maarop, Mayasarah Maslinan

PAGE 1043 – 1050

Paper 106: Improved SegNet with Hybrid Classifier for Lung Cancer Segmentation and Classification

Authors: Rathod Dharmesh Ishwerlal, Reshu Agarwal, K.S. Sujatha

PAGE 1051 – 1062

Paper 107: New 3D Shape Descriptor Extraction using CatBoost Classifier for Accurate 3D Model Retrieval

Authors: Mohcine BOUKSIM, Fatima RAFII ZAKANI, Khadija ARHID, Azzeddine DAHBI, Taoufiq GADI, Mohamed ABOULFATAH

PAGE 1063 – 1071

Paper 108: YOLO-T: Multi-Target Detection Algorithm for Transmission Lines

Authors: Shengwen Li, Huabing Ouyang, Tian Chen, Xiaokang Lu, Zhendong Zhao

PAGE 1072 – 1079

Paper 109: Identifying Competition Characteristics of Athletes Through Video Analysis

Authors: Yuzhong Liu, Tianfan Zhang, Zhe Li, Mengshuang Ma

PAGE 1080 – 1089

Paper 110: Differential Diagnosis of Attention-Deficit/Hyperactivity Disorder and Bipolar Disorder using Steady-State Visual Evoked Potentials

Authors: Xiaoxia Li

PAGE 1090 – 1097

Paper 111: Exploring Cutting-Edge Developments in Deep Learning for Biomedical Signal Processing

Authors: Yukun Zhu, Haiyan Zhang, Bing Liu, Junyan Dou

PAGE 1098 – 1108

Paper 112: The Performance of a Temporal Multi-Modal Sentiment Analysis Model Based on Multitask Learning in Social Networks

Authors: Lin He, Haili Lu

PAGE 1109 – 1117

Paper 113: Weighted Recursive Graph Color Coding for Enhanced Load Identification

Authors: Li Zhang, Hengtao Ai, Yuhang Liu, Shiqing Li, Tao Zhang

PAGE 1118 – 1124

Paper 114: Diagnosis of NEC using a Multi-Feature Fusion Machine Learning Algorithm

Authors: Jiahe Li, Yue Han, Yunzhou Li, Jin Zhang, Ling He, Tao Xiong, Qian Gao

PAGE 1125 – 1133

Paper 115: Towards Optimal Image Processing-based Internet of Things Monitoring Approaches for Sustainable Cities

Authors: Weiwei LIU, Guifeng CHEN

PAGE 1134 – 1142

Paper 116: Exploring Enhanced Object Detection and Classification Methods for Alstroemeria Genus Morado

Authors: Yaru Huang, Yangxu Wang

PAGE 1143 – 1150

Paper 117: Enhanced Arachnid Swarm-Tuned Convolutional Neural Network Model for Efficient Intrusion Detection

Authors: Nishit Patil, Shubhlaxmi Joshi

PAGE 1151 – 1163

Paper 118: Elevating Offensive Language Detection: CNN-GRU and BERT for Enhanced Hate Speech Identification

Authors: M. Madhavi, Sanjay Agal, Niyati Dhirubhai Odedra, Harish Chowdhary, Taranpreet Singh Ruprah, Veera Ankalu Vuyyuru, Yousef A.Baker El-Ebiary

PAGE 1164 – 1172

Paper 119: Optimizing Resource Allocation in Cloud Environments using Fruit Fly Optimization and Convolutional Neural Networks

Authors: Taviti Naidu Gongada, Girish Bhagwant Desale, Shamrao Parashram Ghodake, K. Sridharan, Vuda Sreenivasa Rao, Yousef A.Baker El-Ebiary

PAGE 1173 – 1182

Paper 120: Explainable Artificial Intelligence Method for Identifying Cardiovascular Disease with a Combination CNN-XG-Boost Framework

Authors: J Chandra Sekhar, T L Deepika Roy, K. Sridharan, Natrayan L, K. Aanandha Saravanan, Ahmed I. Taloba

PAGE 1183 – 1193

Paper 121: Utilizing Machine Learning Approach to Forecast Fuel Consumption of Backhoe Loader Equipment

Authors: Poonam Katyare, Shubhalaxmi Joshi, Mrudula Kulkarni

PAGE 1194 – 1201

Paper 122: Image Generation of Animation Drawing Robot Based on Knowledge Distillation and Semantic Constraints

Authors: Dujuan Wang

PAGE 1202 – 1212

Paper 123: Integrating AI and IoT in Advanced Optical Systems for Sustainable Energy and Environment Monitoring

Authors: Shamim Ahmad Khan, Abdul Hameed Kalifullah, Kamila Ibragimova, Akhilesh Kumar Singh, Elangovan Muniyandy, Venubabu Rachapudi

PAGE 1213 – 1222

Paper 124: NLP-Based Automatic Summarization using Bidirectional Encoder Representations from Transformers-Long Short Term Memory Hybrid Model: Enhancing Text Compression

Authors: Ranju S Kartha, Sanjay Agal, Niyati Dhirubhai Odedra, Ch Sudipta Kishore Nanda, Vuda Sreenivasa Rao, Annaji M Kuthe, Ahmed I. Taloba

PAGE 1223 – 1236

Paper 125: The Impact of Various Factors on the Convolutional Neural Networks Model on Arabic Handwritten Character Recognition

Authors: Alhag Alsayed, Chunlin Li, Ahmed Fat'hAlalim, Mohammed Hafiz, Jihad Mohamed, Zainab Obied, Mohammed Abdalsalam

PAGE 1237 – 1248

Paper 126: Revolutionary AI-Driven Skeletal Fingerprinting for Remote Individual Identification

Authors: Achraf BERRAJAA, Ayyoub EI OUTMANI, Issam BERRAJAA, Nourddin SAIDOU

PAGE 1249 – 1256

Paper 127: Deep Learning Enhanced Hand Gesture Recognition for Efficient Drone use in Agriculture

Authors: Phaitoon Srinil, Pattharaporn Thongnim

PAGE 1257 – 1264

Paper 128: Inclusive Smart Cities: IoT-Cloud Solutions for Enhanced Energy Analytics and Safety

Authors: Abdulwahab Ali Almazroi, Faisal S. Alsubaei, Nasir Ayub, Noor Zaman Jhanjhi

PAGE 1265 – 1272

Paper 129: Enhancing Diabetes Prediction: An Improved Boosting Algorithm for Diabetes Prediction

Authors: Md. Shahin Alam, Most. Jannatul Ferdous, Nishat Sarkar Neera

PAGE 1273 – 1286

Paper 130: Adaptive Learning Model for Detecting Wheat Diseases

Authors: Mohammed Abdalla, Osama Mohamed, Elshaimaa M. Azmi

PAGE 1287 – 1298

Paper 131: Detecting Digital Image Forgeries with Copy-Move and Splicing Image Analysis using Deep Learning Techniques

Authors: Divya Prathana Timothy, Ajit Kumar Santra

Multiview Outlier Filtered Pediatric Heart Sound Classification

Sagnik Dakshit
Computer Science
The University of Texas at Tyler
Tyler, TX 75799

Abstract—The advancements in deep learning has generated a large-scale interest in development of black-box models for various use cases in different domains such as healthcare, in both at-home and critical setting for diagnosis and monitoring of various health conditions. The use of audio signals as a view for diagnosis is nascent and the success of deep learning models in ingesting multimedia data provides an opportunity for use as a diagnostic medium. For the widespread use of these decision support systems, it is prudent to develop high performing systems which require large quantities of data for training and low-cost method of data collection making it more accessible for developing regions of the world and general population. Data collected from low-cost collection especially wireless devices are prone to outliers and anomalies. The presence of outliers skews the hypothesis space of the model and leads to model drift on deployment. In this paper, we propose a multiview pipeline through interpretable outlier filtering on the small Mendeley Children Heart Sound dataset collected using wireless low-cost digital stethoscope. Our proposed pipeline explores and provides dimensionally reduced interpretable visualizations for functional understanding of the effect of various outlier filtering methods on deep learning model hypothesis space and fusion strategies for multiple views of heart sound data namely raw time-series signal and Mel Frequency Cepstrum Coefficients achieving 98.19% state-of-the-art testing accuracy.

Keywords—Deep learning; outlier filtering; machine learning; ECG

I. INTRODUCTION

Deep learning (DL), a subset of Artificial Intelligence (AI), has gained significant attention for its remarkable ability to analyze complex multimedia data, extracting meaningful patterns, and making predictions with unprecedented performance. In the context of healthcare informatics, deep learning is revolutionizing the way medical data is interpreted demonstrating remarkable success in a range of applications. In the ever-evolving landscape of healthcare informatics, audio signals have emerged as a valuable source of multimedia information that can contribute to enhanced health outcomes. Advancements in audio processing, coupled with the rise of artificial intelligence, have enabled healthcare professionals to extract meaningful insights from physiological audio sounds. The integration of audio signals into healthcare informatics showcases the versatility of data-driven technologies in improving patient care and holds the promise of more accurate diagnoses, personalized treatments, and innovative healthcare solutions.

One of the significant challenges that hinders the availability of large quantities of data required for training data hungry

deep learning models is the cost of data collection, limiting the accessibility of deep learning based decision support systems to general public specially in developing regions of the world [14]. This has motivated the development of low-cost diagnostic devices such as wireless phone stethoscope [14], wireless OCT devices [25]. Data collection using these low-cost devices can be noisy and have out-of-distribution samples collectively termed as outliers. Outliers are data points that deviate significantly from the rest of the dataset and can distort statistical measures such as the mean and standard deviation, in turn affecting not only the predictive performance, generalizability and robustness but also skew the learned features by obscuring meaningful patterns. This shortcomings makes it prudent to filter out outliers from the training dataset.

The black-box nature of deep learning models exacerbates the above challenges and hinders the acceptance of automated decision support systems in critical healthcare tasks due to a lack of understanding of the effect of outliers on model learning and performance. In this work, we address the above research gap by using Uniform Manifold Approximation and Projection (UMAP) technique [24] to visualize the effect of various outlier filtering techniques on the learned deep learning model hypothesis space. UMAP provides interpretable insights in understanding how the removal of outliers affect model performance and also in identification of test outliers. Furthermore, in terms of acoustic heart sounds, to the best of the author's knowledge this is the first work leveraging multiple view of data for classification. Multiview data consists of different views or perspectives of the same data unlike multiview data which involved different types of data or entities. These views are usually derived from different sources, methodologies, or angles. Multiview learning involves leveraging these different views to improve the overall performance of the models by combining their outputs for more robust predictions. Parallel to multiview, We compare both early and late-fusion strategies using the raw time-series signals and Mel Frequency Cepstrum Coefficients (MFCC) as multiple views to achieve state-of-the-art performance on the small Mendeley Children Heart Sound dataset collected through low-cost wireless stethoscope.

A. Contributions

In this paper, we investigate the effect of popular outlier filtering methods through interpretable visualizations of learned model hypothesis spaces. We also investigate the feasibility of multiview early and late fusion strategies to achieve state-of-the-art binary classification on the Mendeley Children Heart Sound dataset collected from low-cost wireless stethoscopes.

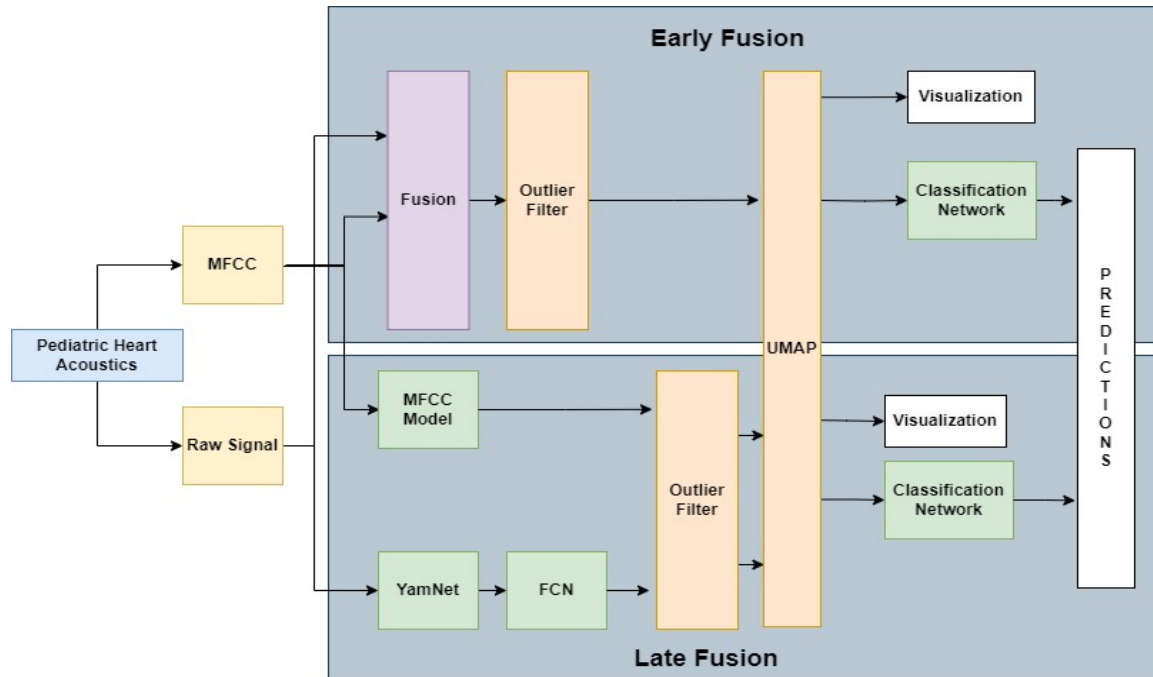

Fig. 1. Our proposed pipeline for outlier filtered MFCC and signal multiview integration for state of the art performance on Mendeley children heart sound dataset.

Our main contributions in this paper can be listed as follows:

- Our proposed pipeline achieve state-of-the-art accuracy for classification of normal and abnormal pediatric heart sounds through late-fusion of multiview outlier filtered Mendeley Children Heart Sound dataset.
- We investigate fusion strategies to improve classification accuracy of multiview pediatric heart sounds using a small number of samples.
- We provide interpretable visualization to understand the effect of outlier filtering on deep learning model hypothesis space.
- We provide a comparison of the effect on model performance of four popular outlier filtering strategies and their contamination hyperparameter.

The rest of the paper is organized as related works in Section II. We discuss our experimental methodology and proposed pipeline including our deep learning models, dataset and proposed pipeline in Section III. In Section IV, we discuss the results for both early and late fusion as well as various outlier filtering methods. Lastly in Section VI, we discuss the effect of outlier filtering on the hypothesis space of the best performing model through interpretable visualizations.

II. RELATED WORKS

Significant research progress has been made in developing decision support systems based on various machine learning and deep learning algorithms for heart disease diagnosis which poses a serious health concern for the general population. Electrocardiograms (ECG or EKG) [29], [22], [6], [23], [30],

[8], Photoplethysmograph [27], [36], [9], [26], [13], and auscultations [34], [14], [31], [32] modalities have been used for automated decision making. Owing to large body of work on deep learning based heart disease classification, in this section we limit the scope of our discussion to the most relevant works to our approach of using UMAP and research on the Mendeley Children heart Sound dataset.

UMAP has been used extensively in all domains to reduce dimensionality for various purposes including interpretability, primarily for feature selection in context of ECG [28], [19], [15], [35] and heart sound classification [4], [5]. While various anomaly detection techniques have been used, there is limited use of Local Outlier Filtering (LOF) [37], [33], [16]. In our literature search, we found only a single work exploring anomaly detection with UMAP in an unsupervised approach unlike our supervised multiview approach [10] on non-healthcare acoustic scenes. Furthermore, none of the explored work provides a functional understanding of the effect of outlier removal on the deep learning model hypothesis space especially exploring different outlier filtering methods for comparison of both early and late-fusion of multiple views, making this the first novel investigation.

On the Mendeley Children heart Sound dataset, authors Islam et. al [14] in their work converted the signals into MFCC, engineered features and presented comparisons of various SVM kernels. Authors Rani et. al [31] denoised the dataset and removed noise artifacts followed by conversion to MFCC for Convolution Neural Network based classification. Our proposed approach uses MFCC as one of the views for deep learning models similar to the above approaches in conjugation with signals for fusion. Moreover, our approach performs outlier filtering and provides insight into how the outliers affect model performance and achieves state-of-the-

art performance with significant improvement.

III. EXPERIMENTAL METHODOLOGY

A. Proposed Approach

Our developed pipeline as illustrated in Fig. 1 uses Mel Frequency Cepstrum Coefficients (MFCC) and raw time-series signals as multiple views of acoustic data for exploration of both early and late fusion strategies. The collection of coefficients that represent short-term log power spectrum of a signal through a linear cosine transform on a non-linear mel-frequency scale is referred to as MFCC. Our choice of modalities is inspired by the large body of work in literature which shows success in classification of audio signals with both modalities independently. For both fusion strategies, we investigate the effect of outlier filtering strategies on the learned model hypothesis space.

For late-fusion, we generate embeddings for each of the considered views which are passed through the outlier filtering module before fusion. The outlier samples can skew model learning so their removal can significantly improve model performance as demonstrated by Dakshit et. al [7]. While the embeddings for time-series auscultations are generated through pre-trained YamNet model, MFCC embeddings are generated using our deep learning MFCC model as illustrated in Section III-D. Following outlier filtering, the embeddings of the remaining samples are fused and passed through our late-fusion neural network architecture for classification. The hypothesis space of this trained model is investigated for functional understanding of the effect of outlier filtering through interpretable UMAP visualization of the learned hypothesis space. For comparative understanding, we also present visualizations of the hypothesis space of the model trained without passing the multiview late-fused data through the outlier filtering module.

For early-fusion, we concatenate the MFCC two-dimensional data view and one-dimensional raw time-series signal view which is then passed through outlier filtering modules and used to train the classification deep learning model as illustrated in Section III-D. The models trained by passing the training data views through the outlier filtering module as well as a control experiment without passing through the outlier filtering modules are visualized by UMAP for interpretable functional understanding of the effect of the outliers on the model hypothesis space.

B. Interpretable Outlier Filtering

In this section, we discuss our strategy for interpretable outlier filtering from training samples. We use UMAP to reduce dimensions for interpretable outlier filtering. UMAP (Uniform Manifold Approximation and Projection) [24], is a dimensionality reduction technique widely used by high-dimensional data to provide a more effective visualization of complex datasets. Unlike comparative methods such as t-SNE (t-distributed stochastic neighbor embedding) [21], UMAP offers scalability and preserves both global and local structures within the data. UMAP operates by mapping data points from a high-dimensional space to a lower-dimensional one, making it easier to visualize and interpret patterns. However, it is a non-deterministic algorithm leading to slight variation in results with the same data and the same parameters each time,

primarily due to random initiation and stochastic optimization. We project each embedding in 2D using UMAP for Local Outlier Filtering (LOF). LOF provides interpretability in terms of probabilities. The interpretations and explanations of these methods do not provide or allow functional understanding on how the selection and filtering of outliers affect the deep learning model's learned hypothesis space as discussed earlier in Section II. We address this challenge using UMAP in this paper and demonstrate the effect of outlier removal on the children heart sounds dataset.

C. Dataset

We select the Mendeley Children heart sound dataset of normal and abnormal pediatric heart sounds from the rural areas of Bangladesh [14] collected from 60 subjects using their developed wireless electronic stethoscope. The collected dataset of 1657 samples, is preprocessed by re-sampling to 44100 Hz, normalized and denoised using Discrete Wavelet Transform. This dataset poses challenges in terms of its small number of samples to train deep learning models and quality of collection with low-cost wireless devices. Furthermore, the data has been recently published and not adequately tested in research but provides the opportunity to investigate the feasibility of developing high-performing deep learning models on wireless and cost-effective data collection devices for developing sections of the world.

D. Deep Learning Architectures

In this section, we illustrate our three deep networks for early and late-fusion of multiview learning for subtasks of 1) Raw Signal Embeddings, 2) MFCC Embedding, and 3) Fusion Classification Network and 4) Early-fusion strategy .

- MFCC Model: Our network used to generate MFCC embeddings is shown in Fig. 2. Our architecture has two 2D convolution layers with ReLu activation (64 and 32 filters of size $3 * 3$), each followed by Batch Normalization with an intertwined Max Pooling layer and batch normalization layer. These layers are followed by a Global Average Pooling layer and a fully connected layer of 128 dense nodes and a sigmoid classification layer.
- Raw Signal Embeddings Model: YAMNet is a lightweight deep network trained on AudioSet data by Google to classify on devices with limited computational resources. It is trained on a large dataset containing thousands of different sound events, enabling it to identify and categorize various acoustic patterns. We leverage the pre-trained YAMNet as our encoder backbone which generates embeddings of length 1024. We fine-tuned the pre-trained YamNet for generating pediatric heart sound embeddings using two Fully Connected Layers (FCN) as shown in Fig. 1. Our FCN has dense layers of 256 and 128 nodes and reduces the embedding dimensions to match MFCC and signal embedding dimensions.
- Fusion Classification Model: For our fusion classification network, we use three dense layers with 512, 128 and 64 nodes with ReLu activation and followed by a sigmoid layer for binary classification. All models are

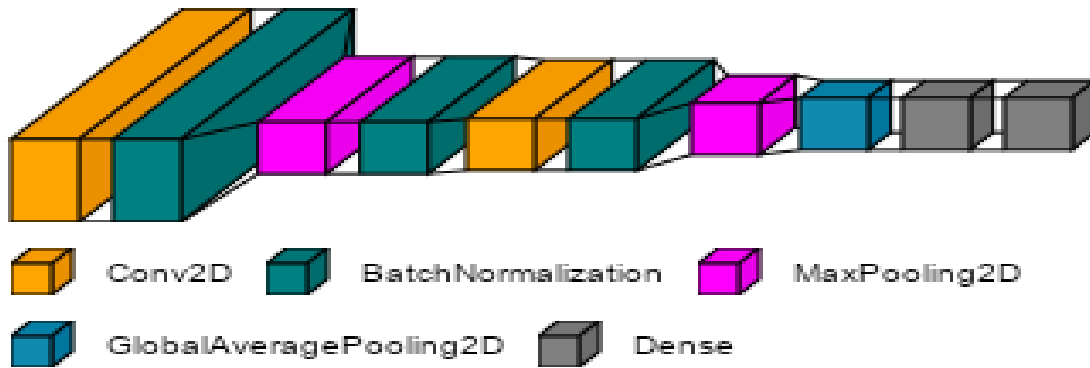

Fig. 2. MFCC Model deep learning architecture.

trained with a learning rate 0.001 and a decay rate of 0.0001 and binary crossentropy loss.

- **Early-Fusion Model:** We tried various architectures for early fusion based on 2D convolutional layers but most architectures lead to underfitting or extensive overfitting. We report results on EfficientNet B7 [17] which obtained the best results as reported in Section IV.

IV. EXPERIMENTAL RESULTS

In this section, we discuss the observed results in terms of performance of baseline models for both view and improvement using outlier filtered fusion to achieve state-of-the-art test performance. We trained DL models for 100 epochs each with hyperparameters as discussed in Section III-D and save the best model in terms of validation accuracy.

A. Baseline Results

In this section, we discuss the observed results in terms of performance of baseline models for both views and improvement through outlier filtering. We trained deep learning models for 100 epochs each with hyperparameters as discussed in Section III-D and save the best model in terms of validation accuracy. For outlier filtering we present only the results for Local Outlier Filtering in this section as LOF is more suited towards this task and data. One-Class SVM, Isolation Forest, and Elliptical Envelope outlier filtering methods are more suitable for datasets where outliers are well-separated from the majority of the data and where outliers are in sparsely populated regions of the feature space. Given the task of binary classification, our feature space is not expected to have sparsely populated regions. The effectiveness of LOF in detecting outliers where the density of the data points varies across different regions makes it a better theoretical choice. We empirically show the results for all four considered outlier filtering methods on fusion in section V-A.

In Table I, we report the results of the best baseline models in terms of traditional deep learning metrics of Precision, Recall, AUC, and Accuracy. From these baseline model results, it can be observed that both modalities achieve high performance on the small dataset, with MFCC having superior performance in terms of all evaluated traditional deep learning

TABLE I. BASELINE MODEL AND LOCAL OUTLIER FILTERED DEEP LEARNING MODEL TEST PERFORMANCE ON MFCC AND SIGNAL VIEWS

Model	Test Accuracy	Precision	Recall	AUC
Signal	0.90	0.884	0.897	0.96
MFCC	0.96	0.97	0.95	0.99
OF-Signal	0.928	0.92	0.96	0.924
OF-MFCC	0.976	0.974	0.994	0.987

metrics. Moreover, it should be noted that the raw signal view leverages pre-trained YamNet model while MFCC is trained from scratch. We do not report the results for training raw signal view from scratch as comparable accuracy could not be achieved even with state-of-the-art architectures. To demonstrate the effect of outlier filtering, we retrain the baseline architectures without changing the hyperparameters on the outlier filtered training data and these models are represented with the prefix *OF* in Table I. We record a significant improvement of 2.8%, 8.6%, 5.3%, and 3% in test accuracy, precision, recall, and AUC respectively for raw signal view. Similar observations are recorded for MFCC view with a 1.6%, 0.4%, 4.7% improvement in test accuracy, precision, and recall respectively. After outlier filtering it is observed that MFCC holds its superior performance in classifying pediatric heart sounds.

B. Fusion Results

TABLE II. LOCAL OUTLIER FILTERED EARLY AND LATE FUSION

Model	Test Accuracy	Precision	Recall	AUC
OF-Late Fusion	0.9819	0.984	0.996	0.987
OF-Early Fusion	0.5693	0.5696	0.9626	0.5273

Following our proposed pipeline as shown in Fig. 1, for both early and late-fusion, we report our observed results in Table II. It can be observed that the late-fusion of the generated embeddings of the two views of MFCC and signal significantly outperforms the early-fusion approach. As recorded in Table II, Late-Fusion of the outlier filtered embeddings of both views yields an improvement of 0.59% in test accuracy and 1% for precision and 0.2% recall. The fusion strategy yields significantly better results over both the individual view models. The above is observed for both with and without

outlier filtering achieving state-of-the-art classification performance. The observed superiority of late-fusion performance can be primarily attributed to the embeddings having learned meaningful representations of the multiple data views, which leads to more efficient fusion of features and consequently better classification outcomes.

V. COMPARATIVE DISCUSSION

A. Comparison of Outlier Filtering Methods

We investigate the feasibility of outlier filtering with four popular inherently non-interpretable methods namely Local Outlier Filtering, Isolation Forest, Elliptical Envelope, One-class SVM.

- Local Outlier Filtering (LOF) [3]: It is a data-driven approach to identifying outliers in a dataset by assessing the local neighborhood of each data point. This method operates on the premise that outliers are data points that deviate significantly from their local surroundings. By comparing the distance or density of a point to its nearest neighbors, the local outlier filtering method can effectively detect data points that are inconsistent with the patterns observed in their immediate vicinity. LOF works in 3 steps namely local density estimation followed by comparison to neighbors and lastly outlier detection. Points with LOF scores significantly higher than 1 are considered outliers.
- Isolation Forest [20]: It identifies anomalies by constructing decision trees to isolate individual data points. Unlike LOF that measures the distance or density of data points, Isolation Forest focuses on how quickly a data point can be isolated from the rest of the data. The approach involves randomly selecting a feature and a split value, then recursively partitioning the data into two subsets based on this split. Anomalous data points are expected to be isolated in fewer partitions (or trees) because they are different from the majority of the data.
- Elliptical Envelope [2]: The Elliptical Envelope method is a statistical approach to outlier detection that models the data distribution using a multivariate Gaussian (normal) distribution and identifies outliers as data points that deviate significantly from this distribution. By fitting an elliptical envelope around the data points, this method estimates the mean and covariance of the data and calculates the Mahalanobis distance for each point. Data points that fall outside a certain threshold of the distance metric are classified as outliers.

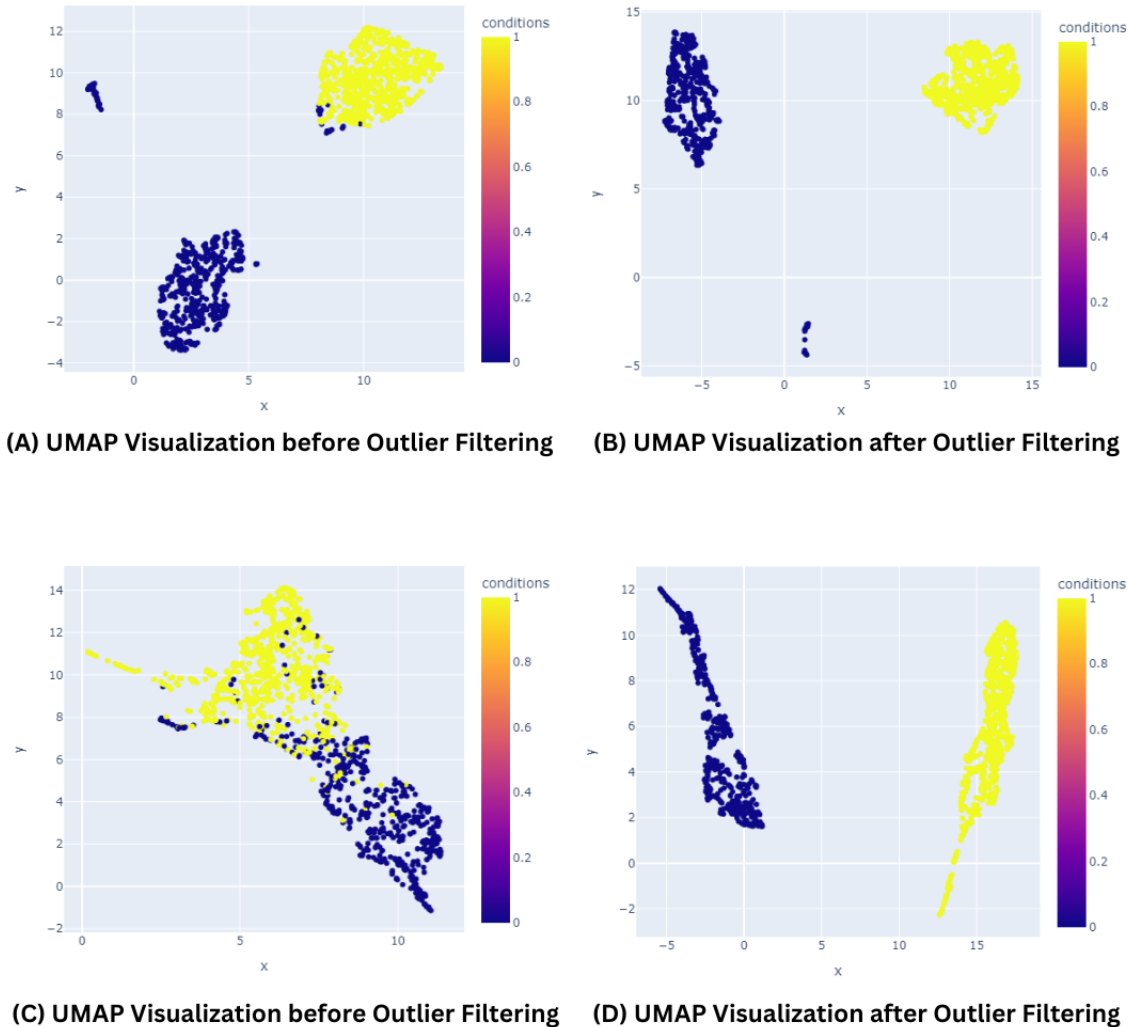

Fig. 3. Local outlier filtering: UMAP Visualization of hypothesis space before (LEFT) and after filtering with 0.01 contamination (RIGHT) outlier filtering for MFCC (TOP) and raw signal (BOTTOM) views.

- One-Class Support Vector Machines (One-Class SVM) [1]: It is a machine learning-based approach for outlier detection that aims to identify anomalies by constructing a decision boundary that encapsulates the normal data points in a dataset. This method operates in a similar way to traditional support vector machines but is adapted for unsupervised learning and outlier detection. By training on a dataset consisting predominantly of normal data distribution, One-Class SVM learns a hyperplane that separates the data from the origin. Points that fall within this boundary are considered normal, while points outside the boundary are deemed outliers.

These methods provide robust outlier detection capabilities to handle large datasets of high-dimensionality, each with its own advantages and disadvantages. Owing to the large superiority of late-fusion approach, in Tables III, IV, V, and VI,

we report the results for each of the considered outlier filtering methods including range of values for the contamination hyperparameter for only late-fusion strategy. We observe from the presented results that as the contamination value is increased, there is a significant drop in model performances. For all the compared methods, the best performance is observed for the lowest contamination value of 0.01, with LOF method as the best performing model globally with comparatively similar performances for the other outlier filtering methods.

B. Comparison on Same Dataset

The nascent nature of the dataset reduces the possibility of comparison with existing works. Authors Islam et. al in their work proposed the dataset [14] and achieved 94.12% test accuracy, 88.89% specificity, and 100% sensitivity values using RBF SVM kernel on engineered MFCC features. In [31] 93.76% test accuracy was achieved using Convolution

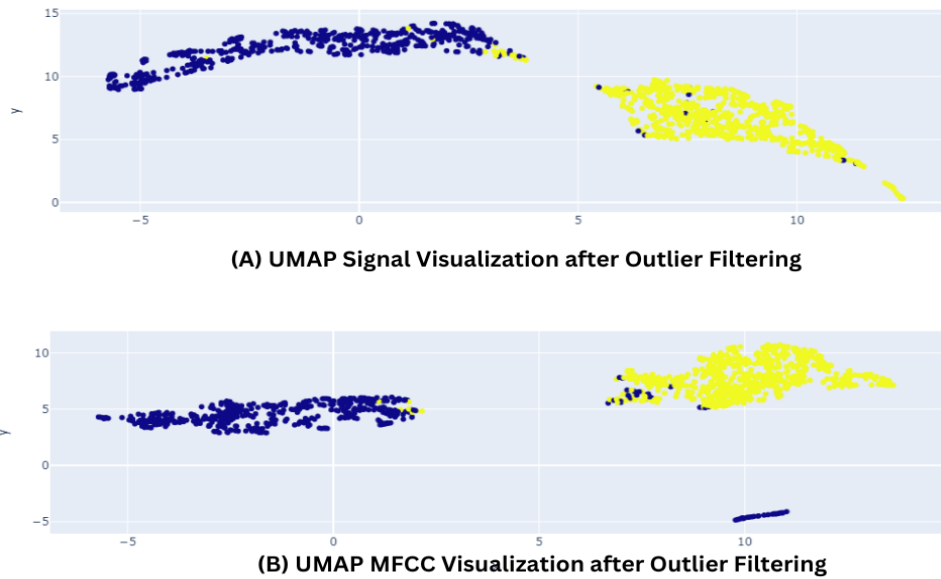

Fig. 4. One-Class-SVM Outlier filtering: UMAP visualization of hypothesis space after with filtering with 0.01 contamination for MFCC (BOTTOM) and raw signal(TOP) views.

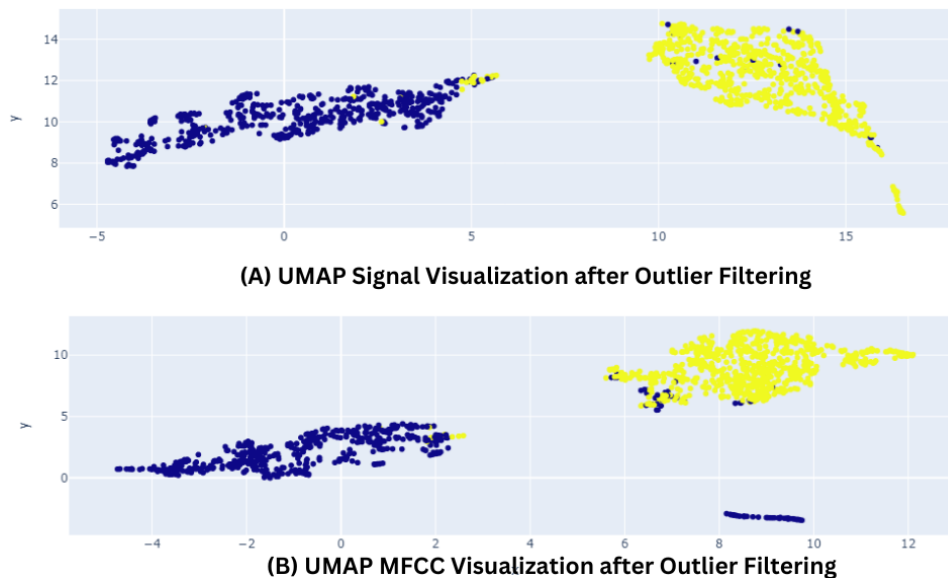

Fig. 5. Elliptical envelope outlier filtering: UMAP visualization of hypothesis space after with filtering with 0.01 contamination for MFCC (BOTTOM) and raw signal(TOP) views.

Neural Network using MFCC. The authors in this approach strategically removed artifacts and denoised the data as pre-processing steps. The comparison demonstrated that not only is our proposed approach able to achieve superior performance over existing approaches in terms of testing accuracy but also maintains comparable specificity and sensitivity of 99.6% and 99.1% while being an efficient way of removing and visualizing outliers.

VI. INTERPRETABLE VISUALIZATION

In this section, we discuss the effect of outliers through interpretable visualization. Neural Networks learn high dimensional embeddings from multiview data. Interpretability

in the field of Explainable AI (XAI) is defined loosely as understanding what the model did or could have done [12]. Visualization methods for high dimensional embeddings is one of the established ways for providing interpretability [18], [11]. We use UMAP to reduce dimensionality of the sample embeddings allowing their visualization in two dimensions. Our dimensionally reduced 2D interpretable visualizations of the training dataset for both raw time-series signal and MFCC views are presented in Fig. 3, 4, 5, and 6.

In Fig. VI, the images on the top are for MFCC view and bottom for signal view with the left images representing the set before outlier filtering and right representing after outlier filtering. Our hyperparameter of contamination for LOF

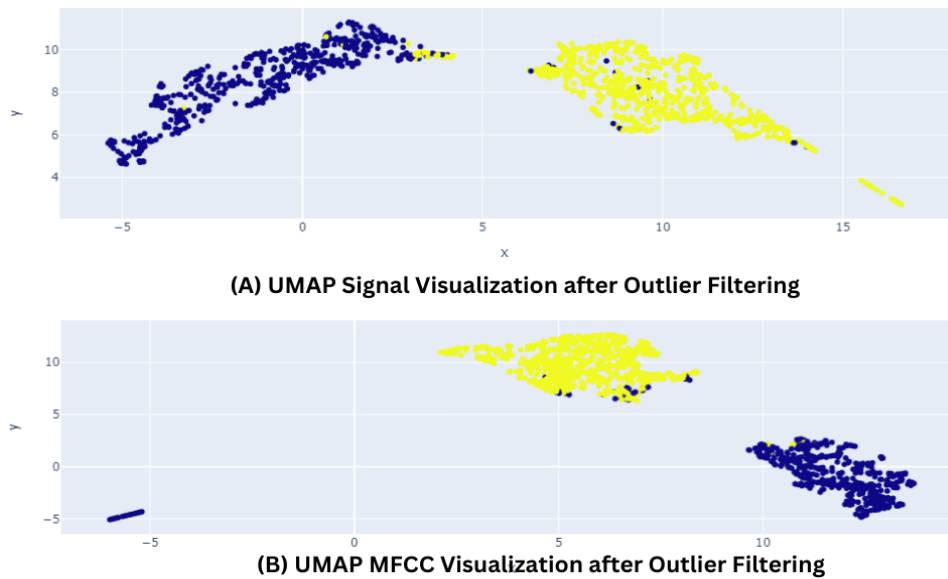

Fig. 6. Isolation forest outlier filtering: UMAP visualization of hypothesis space after with filtering with 0.01 contamination for MFCC (BOTTOM) and raw signal(TOP) views.

detection was set to 0.01 based on grid search which is reported in Section V-A. We can observe from the images on the left for both views of MFCC and signal, that the embeddings are clustered naturally into two groups with some overlap between classes for signal view. On outlier filtering with LOF, we observe significantly improved clusters without any intersection. As observed from the images on the right, our method allows removal of any potential outliers that could skew model learning leading to model drift in real world. The difference in position of the classes in the UMAP interpretable visualization before and after outlier filtering is primarily due to the stochastic and random initiation nature of the algorithm as discussed above and does not have any significance on the detection of outliers or contamination. The interpretable visualizations coupled with the model testing results reported in Table I and Table II explains the difference in performance. Visualization of the two views for outlier filtering methods of Isolation Forest (Fig. 6), Elliptical Envelope (Fig. 5), and One-Class-SVM (Fig. 4) with the best contamination hyperparameter values are presented. It can be observed from the visualizations that the One-Class SVM, Elliptical Envelope, and Isolation Forest methods have a greater number of outliers present for both views in comparison to Local outlier Filtering (Fig. 3) explaining not only the better performance but also the superiority of LOF over the other methods for our case. These interpretable visualizations allow us to understand which samples have been removed based on the position of the samples in the embedding space.

VII. CONCLUSION

In healthcare, there has been nascent interest in the one-dimensional modality of auscultation, which represent sounds from physiological functions for diagnosis and monitoring of various health conditions. Despite the success of deep learning, the cost of quality data collection and at-home monitoring devices makes it an accessibility challenge for the developing parts of the world. Outliers or anomalies are frequently present

in data collected using these low-cost devices which can skew model learning and consequently lead to model drift on deployment. In this paper, we developed a pipeline to filter outliers that have a derogatory effect on model performance and achieve 98.19% state-of-the-art testing accuracy through multiview fusion on the public Mendeley Children Heart Sound dataset collected through wireless low-cost stethoscope. To the best of the author's knowledge, this is the first work on the feasibility of both early and late-fusion approached for multiview heart sounds with late-fusion on generated view embeddings, demonstrating significantly better results. Our approach also investigated the effect of outliers on deep learning model hypothesis space through interpretable visualizations for a functional understanding. Outlier Filtering using reduced dimensions by UMAP not only allows for superior performance but also interpretable visualization of the effect of outliers on model performance. We compared the effect of four popular outlier filtering methods on the model hypothesis space demonstrating the importance of selection of appropriate method and interpretable functional understanding of the same. As future work, we would investigate other modalities and views with larger datasets to understand generalizability of outlier filtering.

Trigger Screen Restriction Framework, iOS use Case Towards Building a Gamified Physical Intervention

Majed Hariri¹, Richard Stone²

HCI Department, Iowa State University, Iowa State University, Ames, USA¹

Industrial and Manufacturing Systems Engineering Department, Iowa State University, Ames, USA²

Abstract—The growing trend of inactive lifestyles caused by excessive use of mobile devices raises severe concerns about people’s health and well-being. This paper illustrates the technical implementation of the Trigger Screen Restriction (TSR) framework, which integrates advanced technologies, including machine learning and gamification techniques, to address the limitations of traditional gamified physical interventions. The TSR framework encourages physical activity by leveraging the fear of missing out phenomenon, strategically restricting access to social media applications based on activity goals. The framework’s components, including the Screen Time Restriction, Notification Triggers, Computer Vision Model, and Reward Engine, work together to create an engaging and personalized experience that motivates users to engage in regular physical activity. Although the TSR framework represents a potentially significant step forward in gamified physical activity interventions, it remains a theoretical model requiring further investigation and rigorous testing.

Keywords—Gamification; physical activity; screen-time restriction; triggered screen restriction framework; TSR Framework; personalized interventions; gamified physical intervention

I. INTRODUCTION

The increasing prevalence of sedentary lifestyles, driven by excessive screen time and mobile device use, raises significant public health concerns. Research indicates that prolonged screen time is associated with various health issues, including hypertension, type 2 diabetes, depression, and sleep disorders [1]. Sedentary behaviors are spreading worldwide due to increased occupational sedentary behaviors, such as office work, and the increased usage of mobile phones and video game devices [2]. Most adults fail to follow the World Health Organization guidelines that recommend moderate to vigorous physical activity [3]. The lack of physical activity worsens the health risks linked to spending too much time being sedentary, emphasizing the necessity for interventions aimed at reducing sedentary behavior [4]. People tend to seek comfort and immediate gratification despite being aware of the potential long-term health implications [5].

To counter sedentary lifestyles, gamified physical interventions have emerged as promising strategies to combat sedentary habits [6]. Gamification, the application of game-design elements in non-game contexts, aims to boost motivation and engagement by tapping into the human psychological need for reward, achievement, and competition [7], [8]. Elements such as points, leaderboards, and badges have been successfully integrated into physical activity interventions, demonstrating significant potential to enhance user engagement and foster sustained physical activity [9].

Despite the advances in gamified physical intervention, traditional gamified approaches often fall short in maintaining behavioral change and overly rely on positive reinforcement, indicating the necessity for more innovative solutions [10].

The growing evidence linking screen-based sedentary behavior to adverse health outcomes further underscores the need for a novel intervention. A systematic review highlighted the significant negative association between screen time and components of metabolic syndrome among adolescents, emphasizing the urgency of developing effective interventions to mitigate these risks [11]. Additionally, research on lifestyle intervention effects on daily physical activity patterns has shown promising directions for reducing sedentary behavior and increasing moderate-to-vigorous physical activity, further validating the potential of structured interventions [12]. The findings of the studies validate the critical need for interventions that address sedentary lifestyles and encourage physical activity.

The Trigger Screen Restriction (TSR) framework emerges as a novel interdisciplinary approach that uses advanced technologies to address the limitations of traditional gamified physical intervention [10]. By leveraging the Fear of Missing Out (FOMO) phenomenon, the TSR aims to encourage physical activity through the strategic restriction of access to social media applications based on activity goals, potentially providing a more sustainable model for gamified physical interventions [13]. This novel framework, which has yet to be empirically tested, may represent a promising avenue for enhancing the efficacy of gamified interventions in promoting physical activity.

The remainder of the paper is structured as follows:

- **Objective:** Outlines the paper’s aim, emphasizing the TSR’s innovative approach to integrating different technologies to encourage physical activity.
- **The TSR Framework:** Explores the TSR framework’s innovative approach to integrating advanced technologies, such as machine learning, computer vision, and gamification, to create an engaging and personalized experience that encourages users to participate in regular physical activity.
- **Conclusion and Future Work:** Summarizes the potential impact of the TSR framework on promoting physical activity and outlines directions for future research, including the need for empirical testing to evaluate the framework’s effectiveness in real-world applications.

II. OBJECTIVE

The primary objective is to examine the technical details of the TSR framework, a novel gamified physical intervention that integrates interdisciplinary techniques to encourage physical activity [13]. The aim is to provide an in-depth look at the TSR framework's main components, the Screen Time Restriction, Notification Triggers, Computer Vision Model, and Reward Engine. The paper will highlight the TSR's components' roles in creating a captivating and tailored user experience. Each component's technical architecture and implementation specifics will be explored, demonstrating the seamless incorporation of interdisciplinary techniques within the TSR framework.

Furthermore, the paper intends to illustrate how the various components collaborate to promote physical activity, offer near real-time feedback, and provide personalized rewards and challenges. The integration of the machine learning model in the recommendation engine within the TSR framework will also be discussed, underlining the recommendation engine component's role in enabling adaptive and personalized interventions based on user behavior and preferences.

Preliminary investigation will demonstrate the TSR framework's potential for accurate and efficient activity recognition. The investigation compares the prediction model's sliding window and static window mechanisms. The paper will also outline the future direction of research and development for the TSR framework, stressing the necessity for rigorous empirical studies to assess its effectiveness in promoting physical activity, enhancing health outcomes, and improving user experience.

By addressing these objectives, the paper will contribute to the expanding research of gamified physical activity interventions and establish a foundation for developing and implementing the TSR framework as a practical solution for promoting physical activity.

III. LITERATURE REVIEW

The growing trend of inactive lifestyles, driven by excessive screen time, has been strongly associated with severe health concerns, such as obesity, heart disease, and mental health problems, highlighting the need for creative interventions to encourage physical activity. Research has identified screen-based sedentary behaviors as a critical factor contributing to negative cardiovascular health outcomes, emphasizing the urgent need for action to reverse this trend [14]. Moreover, sedentary lifestyles are increasingly recognized as significant risk factors for diabetes and all-cause mortality, with the link between lengthy sedentary time and high blood pressure and low levels of good cholesterol levels stressing the importance of addressing this issue [15]. Excessive recreational screen time is also associated with significant mental health problems, like depression and anxiety, which further highlights the critical need for targeted interventions to reduce screen time and encourage more active and engaged lifestyles [16]. Together, these findings demonstrate the significant health implications of sedentary behaviors worsened by excessive screen time, emphasizing the urgent need for innovative gamified physical activity interventions.

The purposeful use of FOMO within gamification frameworks can promote physical activity by leveraging the emotions associated with screen time [13]. Through gamification, this negative reinforcement approach taps into the inherent human fear of being left out, making physical activity an attractive alternative to screen-based sedentary habits [17]. Moreover, by presenting other activities as opportunities that demand immediate action, gamified interventions might effectively use FOMO to counter passive screen time, encouraging a healthier, more active lifestyle [18]. By limiting screen time and concurrently offering engaging alternative activities, gamified frameworks can capitalize on the psychological impact of FOMO to promote healthier activities and reduce the risks linked to sedentary behaviors.

Traditional gamified physical interventions have encouraged physical activity with limited success. These interventions often rely heavily on external motivators, which can hinder long-term effectiveness [19]. While traditional gamified physical interventions can increase initial engagement, their appeal often diminishes over time as the novelty fades and motivation decreases [20].

A randomized study across three groups discovered that although all participants lost weight, those in the gamified intervention groups did not significantly outperform the control group, emphasizing the variability and often short-lived benefits of gamified interventions [20]. Moreover, while personalized goal-setting within gamified interventions initially boosts user engagement and performance, this positive trend must persist consistently, implying that initial gains in motivation may not lead to long-term behavior change [21].

Moreover, traditional gamification strategies focus heavily on positive reinforcement, often failing to maintain engagement as users' intrinsic motivation decreases [22]. The challenge lies in the superficial engagement these gamified elements promote, primarily focusing on completing tasks for points rather than fostering a genuine, lasting interest in physical activity [23], [24].

Most gamified health interventions, including well-known ones like Nike+ Running and Zombies, Run!, only incorporate essential gamification elements, which fail to fully utilize the potential of gamification elements to bring about meaningful behavior change, offering an opportunity to develop more innovative, comprehensive gamification strategies that engage users and promote lasting health benefits [25].

Personalized and adaptive interventions in gamified physical activities are increasingly seen as essential for supporting and improving user engagement. Personalized gamification interventions, which customize challenges and rewards to individual preferences and abilities, can improve motivation and performance [26]. Personalized intervention adjusts the difficulty and nature of tasks based on real-time data, ensuring that the challenges are appropriately stimulating and within the user's ability to achieve [26].

Adaptive gamification goes a step further by using machine learning models that predict and react to changes in a user's affective state—such as their emotional condition—to optimize the timing and type of gamified prompts provided [27]. By analyzing task performance data alongside physiological responses, such as facial expressions, these models adjust in

real-time, improving their predictive accuracy and the personal relevance of the interventions [27].

The dynamic and personalized nature of the gamified interventions represents a significant improvement over traditional methods, which often need to be more responsive to individual user profiles. By capitalizing on advanced technology to tailor experiences to individual users, these approaches enhance initial engagement and promote physical activity, contributing to better health outcomes. Developing such adaptive interventions marks a promising direction in designing a gamified physical intervention, indicating a shift towards more personalized, responsive, and effectively engaging fitness promotion tools.

IV. THE TSR FRAMEWORK: A NOVEL APPROACH TO GAMIFIED PHYSICAL INTERVENTIONS

The TSR framework is a novel, interdisciplinary approach that utilizes different technologies to overcome the shortcomings of conventional gamified physical interventions [10]. By integrating machine learning, computer vision, and gamification techniques, the TSR framework aims to create an engaging and personalized experience that encourages users to engage in physical activity. The framework's unique combination of screen time restriction, adaptive gamification elements, and real-time, privacy-respecting activity verification sets it apart from existing interventions [13].

The TSR framework's primary strategy lies in its strategic use of the FOMO phenomenon to motivate users toward physical activity. By restricting access to social media applications based on activity goals, the framework taps into the intrinsic human desire to stay connected and informed, making physical activity a prerequisite for accessing these platforms [13]. The TSR approach is complemented by personalized notification triggers, a computer vision model for activity detection, and an adaptive reward engine that adjusts difficulty based on individual user performance [10]. These components work together to create a comprehensive and engaging experience that promotes sustained physical activity and improves overall health outcomes. By providing a personalized and dynamic experience, the TSR framework addresses the limitations of traditional gamified approaches that often fall short in maintaining behavioral change and overly rely on positive reinforcement [10].

The following subsections will explore the technical aspects of the TSR components:

- **Screen Time Restriction:** Details the technical architecture and user flow of the Screen Time Restriction component, which leverages the FOMO phenomenon to encourage physical activity by restricting access to selected apps.
- **Notification Triggers:** Explores the Notification Triggers component, which delivers personalized, context-aware notifications to motivate users towards physical activity.
- **Computer Vision Model:** Discusses the Computer Vision Model's role in detecting and classifying user activities in real time while ensuring user privacy.

- **Reward Engine:** Describes the Reward Engine's design and its function in enhancing user engagement and motivation through personalized gamified rewards and incentives.

A. Screen Time Restriction

The Screen Time Restriction component is developed to promote and encourage users to engage in physical activity through a screen time management system on mobile devices. The Screen Time Restriction utilizes comprehensive components with specific roles within the iOS ecosystem to implement user-specific screen time policies via technical mechanisms and customizable options (see Fig. 1).

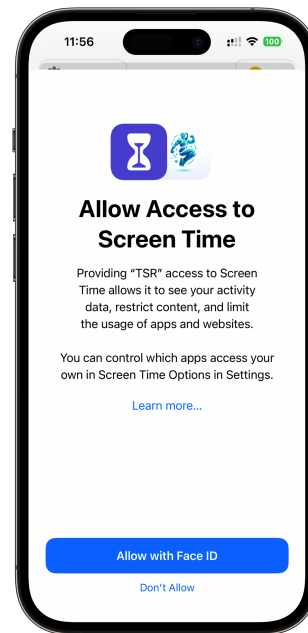

Fig. 1. Screen time restriction - user consent.

1) *Technical architecture:* The system architecture incorporates several key components that work together to enforce screen time restrictions based on user preferences and predictive measures using machine learning (see Fig. 2).

The architecture consists of the following key components:

- **ScreenRestriction:** Serves as the central controller, managing the screen restriction protocol by evaluating factors such as time of day, user activity, and established guidelines.
- **SelectedAppsForRestrictionDB:** Handles a database of applications marked for screen time limitations, enabling CRUD operations and confirming that only selected applications face restrictions.
- **SchedulingClass:** Utilizes scheduling algorithms to determine the timing of restrictions, relying on either user-set schedules or a prediction from the model to initiate.

Fig. 2. Screen time restriction’s system architecture.

- **Current Scheduling Time DB and Current Scheduling Time:** Work to store and communicate the active screen time schedules, ensuring the system’s restriction logic operates based on the most current and relevant scheduling information.
- **AuthorizationManager:** Ensures that screen restrictions comply with user agreements and iOS app permission standards, upholding user confidence and regulatory compliance.
- **DeviceActivityMonitorExtension:** Extends base monitoring capabilities to include specific metrics relevant to screen time management, enabling more informed and dynamic application of screen restrictions.
- **Shield Configuration Extension and Shield Action Extension:** Allow for the personalization of the visual presented to users during restricted screen times, promoting and encouraging the users to engage in physical activity during restriction times.

2) *User flow:* To better comprehend the operation of the Screen Time Restriction component from the user perspective, refer to the following diagram (see Fig. 3):

- **Authorization:** The system verifies the required permissions upon app initiation. Without proper authorization, the Screen Time Restriction feature cannot be enabled.
- **Setup:** Once authorized, the user can enable Screen Time Restrictions and proceed to select the apps they want to restrict.
- **Daily Usage:** The daily usage function continuously monitors device interaction, comparing it against defined time constraints and activity levels.
- **Notifications and Restrictions:** Approaching the time limit without detected physical activity triggers a notification. Exceeding the limit enforces the restriction, blocking access to chosen applications.
- **Physical Activity Detection:** Physical activity detection automatically removes restrictions.

- **Override Request:** Users can request an override without physical activity, which is granted based on predefined conditions.
- **Normal Use:** Effective screen time management and physical activity result in unrestricted device usage.

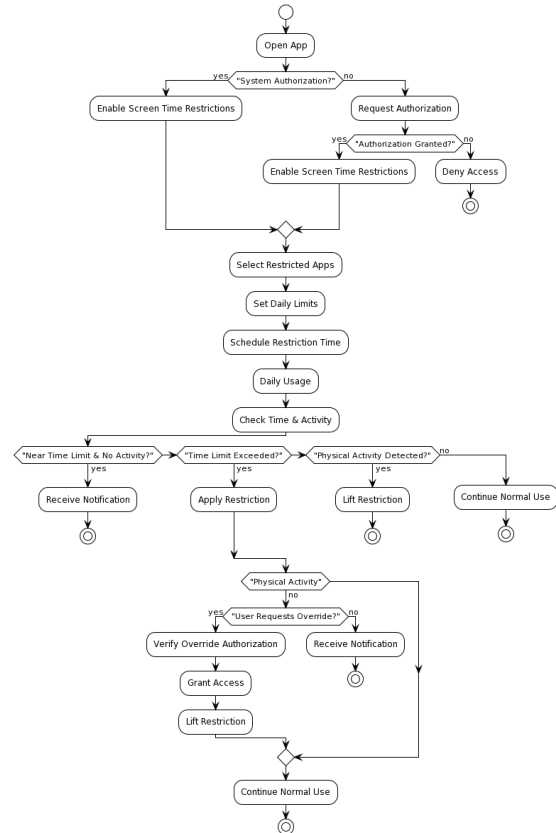

Fig. 3. Screen time restriction’s user flow.

3) *Machine learning integration:* The Screen Time Restriction component anticipates the user’s behavior and adapts accordingly. Models such as Linear regressions, Decision Trees, and Random Forests are evaluated for predicting exercise times, each with pros and cons (See Table I). Integrating the machine learning model allows the Screen Time Restriction component to adapt to the user’s changing schedule [28]. For instance, if the model identifies an increasing trend in evening exercise sessions, it can automatically adjust screen restrictions to encourage and promote users to engage in physical activity during the active periods. Leveraging native iOS features and frameworks, such as CreateML for machine learning, ensures that the Screen Time Restriction component operates efficiently and securely [29]. Integrating the machine learning model in the Screen Time Restriction component prompts near-real-time data processing and contributes to a fluid user experience.

The decision to employ a Linear regression model in the context of predicting exercise times within the Screen Time Restriction component was based on several factors:

- 1) **Simplicity:** The simplicity of Linear regression is crucial for applications requiring near-real-time predictions [30].

TABLE I. COMPARISON OF MACHINE LEARNING MODELS

Model Name	Pros	Cons
Linear Regression [30]	Simple, fast	Limited with non-linearity
Boosted Trees [31]	Manages complex data	Prone to overfitting
Decision Trees [32]	Intuitive, clear	Risk of instability
Random Forests [33]	Excels in complexity	Resource-intensive

- 2) **Speed:** The speed of Linear regression in training and prediction is particularly beneficial for systems running on resource-limited devices such as smartphones or tablets [30].

The Screen Time Restriction component of the TSR framework embodies a blend of user-centric design and technical implementation. By harnessing the power of machine learning and leveraging native iOS features and frameworks, the Screen Time Restriction component actively encourages and promotes physical activity in a novel way. The dual approach of restriction and motivation sets a new standard in gamified physical activity interventions, positioning the Screen Time Restriction component as a powerful tool for pursuing an active lifestyle.

B. Notification Triggers

The Notification Triggers component is designed to provide context-aware engagement messages to foster user interaction delivered through push notifications. The primary intent of the Notification Triggers is to motivate users to engage in physical activity by nudging them when they are inactive [34]. The Notification Triggers component leverages a well-structured system crafted to deliver personalized, context-aware notifications to encourage physical activity (see Fig. 4).

Fig. 4. Notification triggers.

1) **Technical architecture:** The technical structure consists of distinct components that enable customized notification delivery mechanisms to encourage users towards physical activity. The notifications are crafted based on user behavior and serve the broader goals of the TSR framework (see Fig. 5).

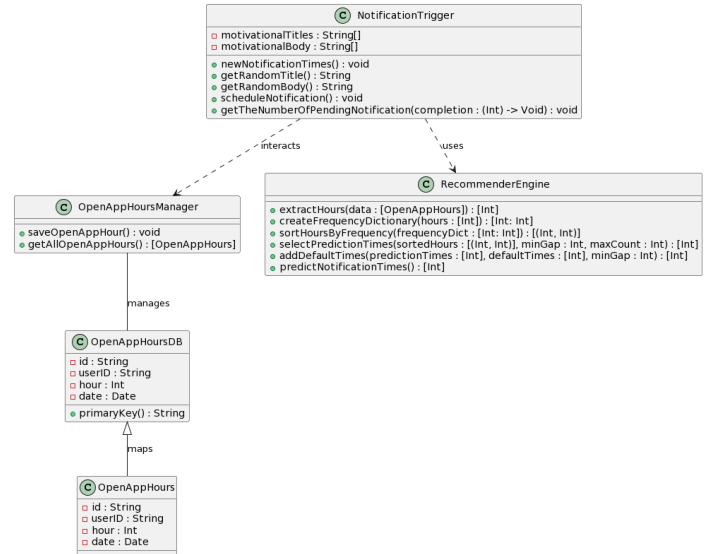

Fig. 5. Notification trigger's class diagram.

The architecture consists of the following key components:

- 1) **NotificationTrigger:** This component manages the notification delivery by analyzing user activity data. It ensures that motivational messages reach the users effectively, fostering their engagement in physical activities.
- 2) **OpenAppHours and OpenAppHoursDB:** These components are essential in storing how users interact with their devices. They log activity times, offering vital insights that help time the notification delivery accurately. By logging periods of user inactivity, these components ensure that notifications are sent when they can have the most significant impact.
- 3) **OpenAppHoursManager:** This component bridges the stored user data and the NotificationTrigger mechanism. It handles the collection of historical user data, allowing the NotificationTrigger to tailor and time notifications that are in tune with the user's daily habits.
- 4) **RecommenderEngine:** This component employs data analysis to pinpoint optimal moments for sending out notifications. By understanding user behavior, it determines the best times to encourage user interaction, which in turn, promotes physical activity.

2) **User flow:** To better comprehend the operation of the Notification Triggers component from the user perspective, refer to the following diagram (see Fig. 6):

- 1) **Authorization and Permissions:**
 - The process begins with the Initialization state, where the application requests

Fig. 6. User flow diagram for notification triggers.

necessary permissions from the user to send notifications.

- Upon receiving Permissions Granted, the application transitions into the Monitoring User Activity state. Here, the app starts recording user activities, ensuring the foundation for personalized notifications is set.

2) Activity Monitoring:

- In the Monitoring User Activity state, the application logs the user’s device interactions throughout the day.
- This continuous monitoring enables gathering essential data and marking periods of activity and inactivity, which is necessary for the subsequent analytical phase.

3) Notification Timing:

- During this phase, the collected data undergoes comprehensive analysis, identifying potential idle periods that could benefit from an intervention.
- Upon completion, the system advances to the Predicting Notification Times state, employing a linear regression model to determine the most effective notification delivery times.

4) Notification Delivery:

- The system then transitions into the Scheduling Notifications state, where these notifications are scheduled for delivery at the predicted optimal times.
- Upon successful scheduling, the system enters the Notifications Delivered state, where notifications are dispatched to the user, serving as timely nudges toward physical activity.

5) User Interaction and Feedback:

- This phase captures the user’s interaction with the notification, whether they dismiss it or engage with it.
- The feedback from user interactions, recorded during the User Response state, informs future notifications, contributing to a cycle of continuous improvement and personalization.
- Finally, based on the user’s action or after a set time, the flow loops back to Monitoring User Activity, initiating a new cycle of monitoring and engagement.

3) Recommendation engine: The Notification Triggers component integrates a linear regression model and a recommendation algorithm to provide personalized and timely messages. An evaluation of various recommendation algorithms was conducted to list their benefits and challenges (Table II):

TABLE II. COMPARISON OF RECOMMENDATION ALGORITHMS FOR NOTIFICATION TIMING

Algorithm	Pros	Cons
Collaborative Filtering [35]	Personalized recommendations	Cold start problem
Content-based Filtering [36]	Handles new items	Limited to user preferences
Hybrid Approaches [37]	Best of both worlds	Complexity, data sparsity, and Cold start problem
Matrix Factorization [38]	Large dataset handling	Data sparsity and Complexity and Cold start problem

The decision to implement a Collaborative Filtering algorithm was made after carefully considering the unique requirements of the Notification Triggers component. Several factors influenced the choice:

- 1) Personalization: Collaborative filtering offers a high level of personalization, which is critical for engaging users with relevant notifications based on collective user behaviors [39].
- 2) Adaptability: The ability of collaborative filtering to adapt to new user data and evolving interaction

patterns align with the dynamic nature of user engagement and physical activity routines [40].

Integrating Collaborative Filtering and a linear regression model into the Notification Triggers component represents a strategic approach to enhancing user engagement through timely and personalized notifications.

C. Computer Vision Model

The Computer Vision Model is designed to detect and classify user activities in real-time using the device's camera. The Computer Vision model leverages the CoreML framework to provide seamless activity recognition, enabling the TSR framework to deliver personalized interventions and promote physical activity [41].

1) *Technical architecture:* The Computer Vision model's architecture ensures seamless integration with the iOS ecosystem while delivering efficient activity classification. The following diagram illustrates the key components and their interactions within the Computer Vision Model (see Fig. 7).

Fig. 7. Computer vision model's technical details.

- 1) **Camera:** The Camera component captures video frames from the device's camera. It leverages the AVFoundation framework to access the camera and capture real-time video data, ensuring a steady input stream for the subsequent components [42].
- 2) **VideoCapture:** The VideoCapture component receives the captured video frames from the camera and forwards them to the VideoProcessing component for further analysis. This intermediary role allows for a clear separation of concerns and promotes efficient data flow within the architecture.
- 3) **VideoProcessing:** The VideoProcessing component takes on the critical task of processing the incoming video frames to detect human body poses and landmarks, harnessing the power of the Vision framework [43]. By converting the video frames into body poses and extracting relevant body landmarks, the VideoProcessing component lays the foundation for activity recognition.
- 4) **Predictor:** The Predictor component receives the processed body poses from the VideoProcessing component and employs a sliding window approach to determine the most probable current activity. By considering a sequence of poses over a specified time window, the Predictor ensures relevant predictions, considering the temporal context of the user's movements.
- 5) **ExerciseClassifier:** The ExerciseClassifier model takes the data from the Predictor and classifies the poses into specific physical activities.
- 6) **View:** The View component interfaces the Computer Vision Model and the user. It updates the user interface based on the classified activity received. By displaying relevant feedback to the user, the View component encourages engagement in physical activity and provides gamified points for the user's efforts.

2) *Sliding window mechanism for pose prediction:* The sliding window mechanism allows the model to process a sequence of poses over a specified time window, ensuring efficient predictions and continuous feedback to the user.

In contrast, the static window prediction method suffers from delays due to the need to clear the buffer after each prediction. The static window mechanism may limit the prediction's ability to provide near real-time feedback to the user.

The researcher conducted a controlled experiment on himself to evaluate the effectiveness of the sliding window mechanism for counting repetitions during exercise. The experiment used an iPhone 11 Pro as the data collection device. All trials were conducted in the same controlled environment with uniform lighting conditions to ensure consistency. Additionally, all trials were performed at a consistent height of 120 centimeters measured from the floor to ensure consistent data acquisition by the phone's camera. The researcher then compared the performance of the sliding window mechanism against a static window approach. The researcher performed ten continuous repetitions of jumping jacks for each mechanism. The accuracy of each approach in counting repetitions and the average feedback time were

The architecture consists of the following key components:

measured and compared (see Table III).

TABLE III. COMPARISON OF SLIDING WINDOW AND STATIC WINDOW MECHANISMS

Test	Mechanism	Actual Continuous Reps	Counted Reps	Average Feedback Time (s)
1	Sliding Window	10	8	1.42
2	Static Window	10	3	3.09
3	Static Window	10	4	3.33
4	Sliding Window	10	9	1.46

The functionality of the sliding window mechanism, as outlined in Table IV, illustrates the seamless integration of initialization, pose estimation, and sliding window analysis stages. This well-structured design enables the mechanism to process incoming pose data efficiently, make near-accurate predictions, and manage the pose window effectively.

TABLE IV. STAGES OF THE SLIDING WINDOW MECHANISM

Stage	Description
Initialization	<ul style="list-style-type: none"> Load the ExerciseClassifier Initialize posesWindow with a capacity to store up to 128 poses The posesWindow serves as a buffer to hold incoming poses for analysis
Pose Estimation	<ul style="list-style-type: none"> Camera captures frames VideoProcessing component extracts human body poses from each frame Extracted poses are added to the posesWindow The posesWindow is continuously updated with the sequence of poses for analysis
Sliding Window Analysis	<ul style="list-style-type: none"> Triggered when the posesWindow accumulates 64 or more poses Consists of two parallel processes: <ul style="list-style-type: none"> Prediction: <ul style="list-style-type: none"> Collected poses are prepared and passed to the ExerciseClassifier for activity classification Classifier assesses the poses to identify recognizable activities Confidence of the prediction is calculated Window Management: <ul style="list-style-type: none"> Adjusts the posesWindow based on the prediction result If an activity is recognized, the window size is reduced by removing a portion of the oldest poses If no activity is detected, only the oldest poses are removed Allows the window to slide forward while retaining relevant pose information

In the gamified physical activity intervention context, the sliding window mechanism’s ability to count continuous repetitions and provide timely feedback is essential for maintaining user engagement and motivation.

D. Reward Engine

The Reward Engine aims to enhance user engagement and motivation by providing personalized gamified rewards and incentives based on the user’s physical activity performance. The Reward Engine leverages gamification techniques to create

challenges and rewards to encourage users to engage in physical activity regularly [44].

1) *Technical architecture:* The Reward Engine’s technical architecture ensures seamless integration and efficient communication between its components. The following diagram illustrates the interactions between the key components of the Reward Engine (see Fig. 8).

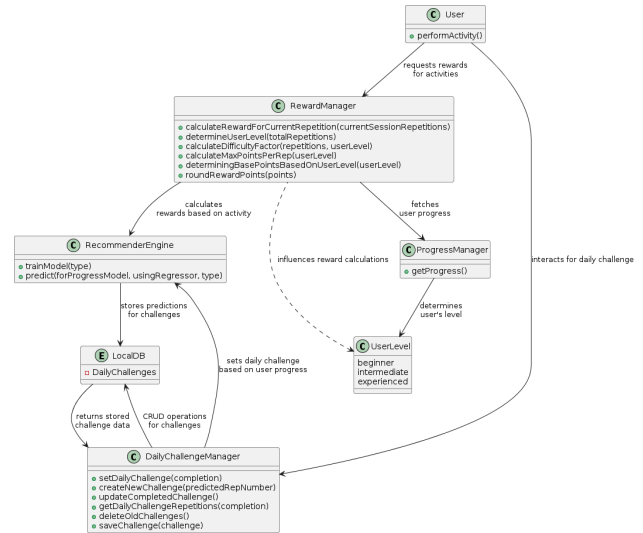

Fig. 8. Reward engine’s technical details.

The architecture consists of the following key components and their interactions:

- User:** Users perform physical activities, which are tracked by the system. They engage with daily challenges and receive rewards based on their activity levels. The User interacts with the RewardManager to request rewards for their activities and with the DailyChallengeManager to receive and complete daily challenges.
- RewardManager:** The RewardManager is responsible for calculating rewards for user activities. It fetches user progress data from the ProgressManager and utilizes the RecommenderEngine to calculate precise rewards based on the user’s activity. The RewardManager determines the user’s level based on their total repetitions, calculates the difficulty factor and maximum points per repetition, and rounds the reward points to ensure a user-friendly format.
- ProgressManager:** The ProgressManager fetches user progress data, including historical activity data, essential for calculating rewards and setting challenges. The ProgressManager assesses the user’s current level and performance trends and provides this information to the RewardManager and the DailyChallengeManager.
- RecommenderEngine:** The RecommenderEngine component uses machine learning to personalize the difficulty and targets of daily challenges based on user progress. It trains models using the user’s progress data and predicts future performance,

helping to tailor the rewards and challenges further. The RecommenderEngine interacts with the RewardManager to calculate precise rewards and with the DailyChallengeManager to set appropriate daily challenges.

- **DailyChallengeManager:** The DailyChallengeManager manages daily challenges' CRUD operations. It interacts with the RecommenderEngine to set attainable yet challenging challenges based on the user's predicted capabilities. The DailyChallengeManager also performs CRUD operations on the LocalDB to ensure that challenges are current and accurately reflect the user's progress.
- **UserLevel:** This enumeration categorizes users into beginner, intermediate, and experienced levels based on their total repetitions and progress. The UserLevel influences how rewards and challenges are calculated and presented to the user. It is utilized by the RewardManager and the DailyChallengeManager to provide level-appropriate rewards and challenges.
- **LocalDB:** The local database stores and manages data related to daily challenges. It ensures that challenges persist and can be retrieved as needed. The DailyChallengeManager interacts with the LocalDB to save, update, and retrieve challenge data, which is then used to notify and engage the user.

2) *Setting daily challenge process:* Setting daily challenges aims to help maintain user interest and promote regular physical activity [45]. The following activity diagram illustrates the steps in setting a daily challenge and rewarding users for achieving their goals (see Fig. 9).

The process consists of the following stages:

- 1) **Initialize Challenge:**
 - The system retrieves the user's historical data, including total repetitions of physical activities and points earned, providing a foundation for setting a new challenge.
 - Accumulated data from the user's activity history is aggregated to understand their performance over time.
 - The system calculates the number of days the user has been active, aiding in the analysis of daily average performance.
- 2) **Calculate Average and Set Base:**
 - The average daily activity and points are computed based on the user's history to establish a performance baseline.
 - The system checks for sufficient progress data to predict the next challenge accurately.
 - If Yes: The system utilizes the detailed progress data for a new challenge setting.
 - If No: The system defaults to predefined challenge values, ensuring new users without extensive history still receive engaging challenges.
- 3) **Predict Challenge Target:**

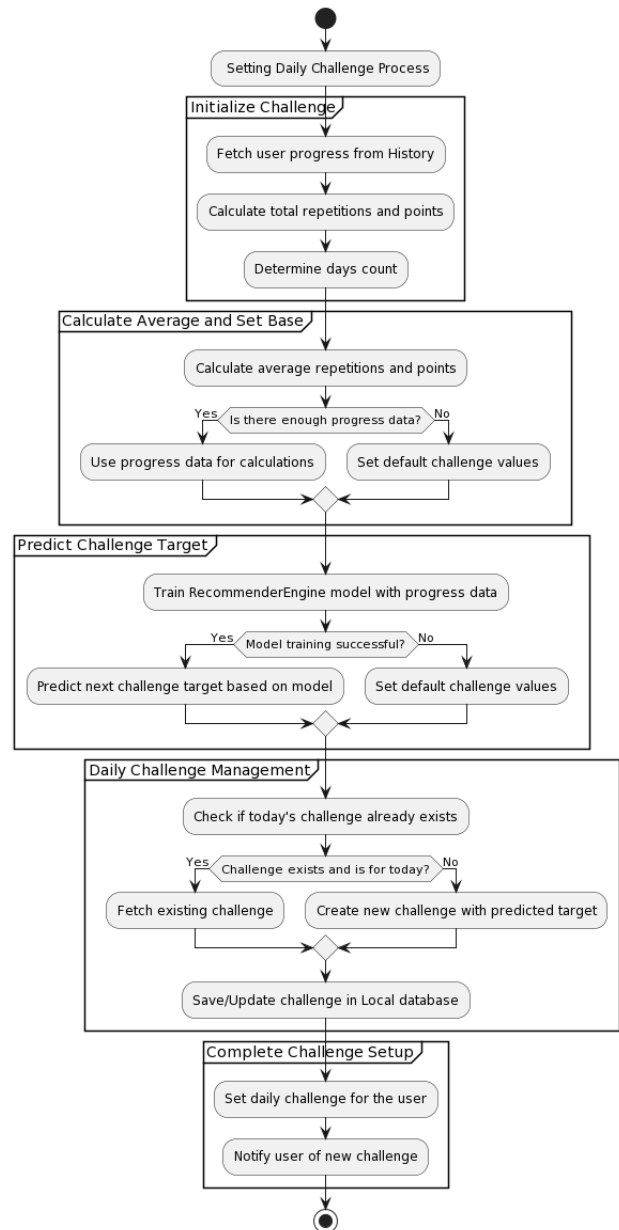

Fig. 9. Setting daily challenge process.

- The RecommenderEngine is fed user progress data to train a predictive model tailored to the user's activity patterns.
- **Model Training Outcome:**
 - If Successful: The model predicts the next challenge target, aligning with the user's potential for improvement.
 - If Unsuccessful: The system reverts to default challenge values, ensuring continuity in user engagement despite predictive model challenges.
- 4) **Daily Challenge Management:**
 - The system verifies if a challenge for the current day already exists to avoid duplications.

- Challenge Evaluation:
 - If Exists for Today: The existing challenge is retrieved, maintaining consistency in daily goals.
 - If No Challenge for Today: A new challenge is created using either the predicted target or default values, ensuring the user always has a goal to strive for.
- The newly set or updated challenge is saved or modified in the local database, ensuring the persistence and accessibility of challenge data.

5) Complete Challenge Setup:

- The daily challenge is finalized and set for the user, marking the culmination of the challenge-setting process.
- The user is informed of the new or updated challenge, encouraging engagement and participation in the daily activity goal.

Once the daily challenge is set, the RewardManager calculates the appropriate rewards based on the user's level, difficulty factor, and maximum points per repetition. The reward for achieving the daily challenge is then presented to the user, providing a sense of accomplishment and motivation to continue engaging with the TSR framework (see Fig. 10).

Fig. 10. Daily challenge user interface.

Setting challenges highlights the Reward Engine's ability to create personalized, adaptive challenges considering each user's unique progress and performance. By leveraging predictive modeling and fallback strategies, the Reward Engine ensures that every user receives engaging and attainable goals regardless of their history, which might encourage consistent participation in physical activity.

V. CONCLUSION AND FUTURE WORK

The TSR framework, as discussed in this paper, is a comprehensive and innovative approach to gamified physical activity interventions. The TSR framework leverages advanced technologies, including machine learning and gamification techniques, to create an engaging and personalized experience that encourages users to engage in physical activity regularly [13].

The TSR framework's components seamlessly integrate to create a cohesive and effective system that prompts gamified physical interventions. The Screen Time Restriction component enforces restrictions while actively promoting physical activity. The Notification Triggers component employs personalized notifications to motivate users. The Computer Vision Model enables continuous activity recognition, and the Reward Engine creates a dynamic and immersive experience through personalized rewards, incentives, and adaptive daily challenges.

While the TSR framework represents a significant step forward in gamified physical activity interventions, it is essential to note that it remains a theoretical model at present. Its potential applications and impact require further investigation and rigorous testing. This paper does not claim to have achieved specific outcomes but instead seeks to outline the implementation of the TSR framework.

To this end, future work will focus on evaluating the effectiveness of the TSR framework through an empirical study. Future work will investigate the TSR framework's impact on various aspects of physical activity and user experience to determine the framework's effect in promoting physical activity. The future study will examine the TSR framework's influence on physical activity levels compared to a control group without the TSR intervention. Future work will also assess the framework's impact on body composition, perceived autonomy, competence, relatedness, ease of use, system reliability, and usefulness in promoting physical activity.

In conclusion, the TSR framework represents a promising approach to addressing the challenge of physical inactivity. As we rigorously test and refine the TSR framework, we aim to contribute to a future where engaging, personalized, and effective gamified physical activity interventions are accessible to all, empowering individuals to be more physically active.

An Intelligent Method for Collecting and Analyzing Voice Reviews to Gauge Customer Satisfaction

Nail Khabibullin

Sayt Tech Ltd, London, UK

Abstract—Customer loyalty and customer satisfaction are premier goals of modern business since these factors indicate customers' future behaviour and ultimate impact on the revenue and value of a business. The customers' reviews, ratings, and rankings are a primary source for gauging customer satisfaction levels. Similar efforts have been reported in the literature. However, there has been no solution that can record real-time views of customers and provide analysis of the views. In this paper, a novel approach is presented that records, stores, and analyzes the customer live reviews and uses text mining to perform various levels of analysis of the reviews. The used approach also involves steps like void-to-text conversion, pre-processing, sentiment analysis, and sentiment report generation. This paper also presents a prototype tool that is the outcome of the present research. This research not only provides novel functionalities in the domain but also outperforms similar solutions in performance.

Keywords—Voice reviews; customer satisfaction; text mining; sentiment analysis

I. INTRODUCTION

Every business in the modern world aims to increase its revenue streams, which ultimately builds its value proposition. A typical approach used to achieve this aim is to ensure customer satisfaction. The more a customer is happy with the product or service of a business company, the higher the satisfaction level of that customer will be. Customer satisfaction level is a short-term goal of a business, but it drives a way to ensure a customer's loyalty which is a long-term goal of a business. Customer loyalty is very critical for a business since a loyal customer gives more and more revenue to a business [1]. The higher level of customer loyalty helps in achieving customer retention. Customer retention ensures that a customer is highly loyal to a business product or a service and will buy that product or service again and again. Such loyal customers also recommend a business to their family and friends which ultimately increases the customer network of a business. Conclusively, a business highly depends upon the satisfaction of its customers.

It is established that customer satisfaction is critical for a business and to achieve this goal a business firm has to continuously assess the satisfaction level of its customers. However, assessment of its customer satisfaction has been a challenge in the recent past. A business firm can use various tools to assess the satisfaction level of its customers such as surveys, interviews, customer online reviews, rankings, and ratings [2]. Various websites record users' rankings and ratings for particular products or services and that can be a source of measuring customer satisfaction. However, such rankings and

ratings-based data provide shallow reflections of customer's views. However, modern businesses need deep insights into customer's views and that can be achieved through analysis of customers' online reviews, surveys, and interviews [3].

The customer reviews recorded in the last five or ten years for a particular product on a website can be useful for insightful data analysis and measuring customer satisfaction [4]. However, a few issues with such website reviews-based data can be availability, reliability, relevance, integrity, and transparency. Hence, the results of such datasets can't be authentic and can't present a true picture of the customers' satisfaction. Conventionally, customers' reviews are collected through paper questionnaires, typing-in forms, and online review services (such as those used by TripAdvisor, Trustpilot, and many others). However, such existing technologies require registration and typing, which makes it time-consuming and complicated for the customers. To identify the key reasons why people do not record their reviews, a survey of 400 respondents was conducted in October 2021. The results of this survey is shown in Fig. 1.

Fig. 1. A survey results to check why people don't record their reviews.

According to the survey, 27.8% do not give feedback if an opinion is negative. 22.1% responded that there is nobody to listen. In addition, respondents complained that typing wastes time (7.5%), and registration wastes time (9.5%). In the additional survey, 130 of 402 responses (32.3%) stated that they would give feedback if it was anonymous. The majority of the respondents figured out that such systems should be easy to use and anonymous.

This paper presents an intelligent idea of capturing the views, reviews, and feedback of customers and clients of a business, performing real-time analysis of these reviews, and showing results to the business in the form of a report. The outcome of such real-time analysis can be more accurate,

relevant, transparent, and reliable. To achieve this goal, a multi-faceted approach is designed in this research. One facet of this research is to design hardware that is capable of recording customers' live voice reviews and storing these on cloud storage. The second facet of this research is recognition of speech with vocabulary specific to the hospitality business. The third facet is a text mining-based approach that can do sentiment analysis of the data stored in the cloud. The fourth facet was to design a device that is energy efficient so that it can function for several weeks on one battery charge, and it should be compact so that it may be easy to handle.

The rest of the paper is divided into a set of sections. Each section develops a part of the research. Section II discusses the outcome of the literature survey and reports the major contributions in the literature that are similar to the presented research. Section III describes the used approach and its working in detail. Section IV explains the implementation details of the tool. Section V represents the results of the work. Discussion and conclusion is given in Section VI and Section VII respectively.

II. RELATED WORK

A literature survey was conducted to find out the similar contributions reported in the literature. This section discusses the outcome of the literature survey and reports the major contributions in the literature that are similar to the presented research. In literature, not many such works were found. A few of the works that were found had their limitations in both software and hardware. One of such contribution was sentiment analysis of speech using acoustic features and lexical features [5]. In this work, speech data was taken to identify intensified sentiments of customers from their recorded product reviews. However, in this work neither a real-time data analysis was done, nor a supporting hardware tool was introduced.

A contribution was made that attributed to the analysis of voice reviews. In this work, a customer had to record his voice reviews and send them online to the business server. The server processed the received voice review using a fuzzy logic approach [6]. However, in this work, it is difficult for customers to record their reviews and send them online which results in a very low number of reviews on the server. Secondly, the quality of recorded reviews was a major concern since customers were not taking care of recording quality and background noise. A few other attempts have been made to do sentiment analysis of voice reviews such as in study [7], where voice reviews were directly parts-of-speech (POS) tagged and further processed to identify respective sentiments in a voice note. However, again this work was quite limited since the voice quality and noise in the voice were not considered in the design and implementation of the approach. However, the quality of voice notes is of prime importance to accurately extracting the text from the voice and then identifying the true sentiments of customers from their voice notes.

After the detailed literature survey, it was found that a few methods and approaches that partially address this issue of voice note-based sentiment analysis have been presented but each of these approaches has their respective limitations. A few such limitations are difficult modes of recording and submitting customer reviews, low-quality and noise-based recordings of

voice, and proper reporting methodology. In addition, none of the existing works store voice notes and other related data on the cloud which questions the availability and transparency concerns of the sentiment analysis performed. In addition to this research gap in the literature, there are no similar tools available in the market. Other solutions in the market collect feedback and reviews use smartphones or tablets resulting in low-quality and noise recording. Some other solutions use text feedback that does not provide deep insights into the customer feedback. In addition, giving voice feedback is faster and less laborious than typing and registering text feedback.

To address the above-mentioned research gap, there is a need to design and devise a specific hardware device for collecting voice feedback from customers with high-quality. Our hardware tool for collecting voice feedback is unique (no similar devices are available). Smartphones and tablets can perform similar functions such as recording, analysing, and storing voice feedback. However, they are more expensive (\$200-\$1000). There is a need for cheap and low-cost solutions. Another issue with smartphones and tablet-based solutions is their battery life which is much lower i.e. 1-3 days. Here, a better, easy-to-use device is required that has a long battery life of up to two to three weeks. Moreover, there is a need for a device that is small-sized and much more compact than a smartphone for easy and frequent use and has a more robust design.

III. USED APPROACH

A lexicon-based approach is designed for voice review mining that initiates with a recording of speech-based customer reviews and then further analyses these reviews to identify the customer's satisfaction. The use approach starts with the recording of the quality speech of a customer. The recorded speech is converted into text for analysis. Meanwhile, the recorded speech data is stored in a cloud. The text reviews are pre-processed to remove noise. The typical steps like tokenization, filtering, stop word removal, and stemming are applied. The pre-processed text is forwarded to the text analysis module. Then sentiment analysis module analyses the sentiment of the reviews using steps like subjectivity classification, sentiment detection, and sentiment score calculation. This sentiment score is forwarded to the sentiment classification module that classifies a review. The final step is to generate a customer satisfaction report based on the output of the sentiment classification step. A framework for the used approach is shown in Fig. 2.

The working of each step of the used approach as shown in Fig. 2 is described in the following text.

A. Quality Speech Recording

The bustling ambiance of restaurants introduced a significant hurdle for maintaining the integrity of voice recordings amidst substantial background noise. The question at the heart of this challenge was how our voice recording system—comprising both advanced microphone technology and sophisticated algorithms—could effectively distinguish and capture the speaker's voice alone. Given that the pre-existing technologies fell short of meeting the demands of our specialized handheld device, it became imperative to devise a tailored solution. Our journey to this solution involved extensive

experimentation with a variety of microphone systems, alongside the creation of a bespoke algorithm aimed at filtering out ambient noise, which necessitated precise adjustments to achieve the desired sound clarity.

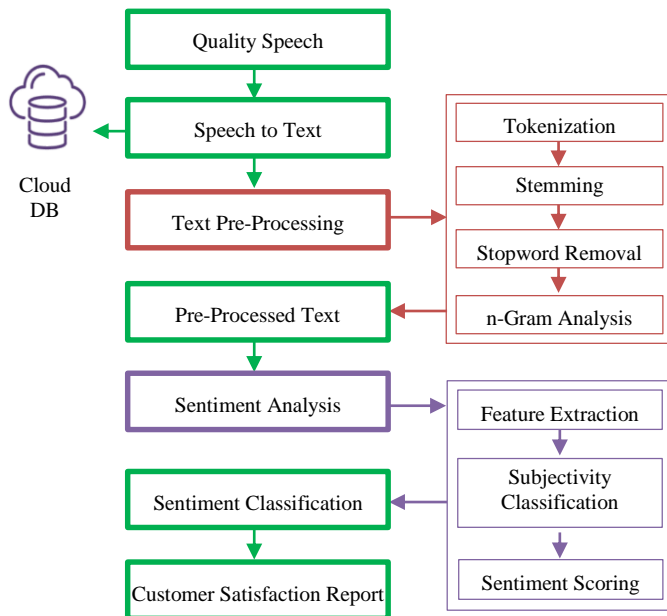

Fig. 2. The approach used for voice review mining.

The method to address background interference was multifaceted, requiring various adjustments like:

- Selection and positioning of the microphone,
- Determination of the optimal voice recording codec,
- Modification of a speech-to-text algorithm to exclude background noise.

Off-shelf offerings of microphone technologies capture all sounds indiscriminately, including undesirable background noise. Our initial trials with analog microphones proved unsatisfactory, leading us to explore digital microphones equipped with MEMS technology. This exploration culminated in the selection of the INMP441, notable for its digital output, omnidirectional pickup pattern, and 24-bit I²S interface, which emerged as the superior option. Subsequent experiments focused on identifying the microphone's optimal placement within the device to ensure unimpeded and unaltered sound capture.

Another pivotal aspect was choosing the appropriate audio codec for efficient compression and transmission of the voice recordings. Despite the availability of over fifty codecs, ranging from lossless to various compressed formats, initial tests with the lossless WAV format were hampered by its prohibitive file size for a compact device. Conversely, compressed formats like MP3, while smaller in size, failed to facilitate effective background noise removal when processed by cloud software. Ultimately, the FLAC codec, with its 16000Hz sample rate, 16-bit depth, and mono lossless format, was identified as the optimal solution.

B. Speech-to-Text Conversion

The next and most challenging step was refining a speech-to-text algorithm that is capable of accurately recognizing speech while filtering out background noise effectively. However, our initial attempts with Google's speech-to-text API and subsequent filtering algorithms did not meet our standards for accuracy. However, persistent efforts for modification and customization of Google's APIs eventually led to a breakthrough in achieving exceptional voice recognition performance in noisy environments. In this phase, the original audio and its text representation are stored in the cloud for the sake of the record.

C. Text Pre-Processing

In this step, the text generated from voice was pre-processed for further analysis. Typical issues in a text are inflectional parts, group words, stop words, and other similar issues. The data has to be processed to improve its quality since the pre-processed data is considered high-quality data and it can generate quality results in terms of accuracy. Following are a few steps that are used in the pre-processing of the text data in the used approach.

1) *Tokenization*: Tokenization is a typical starting phase of pre-processing the text for text mining and sentiment analysis. In the tokenization phase, the large sentences are tokenized into an array of words and symbols. The tokenization is done based on spaces among the words. The following is the output of the tokenized text:

[I] [like] [two] [features] [of] [these] [products] [.]

2) *Stemming*: The words in the text usually have inflectional parts such as prefixes, postfixes, infixes, etc. Such inflectional parts are removed to get the original or core form of a word. For example, the word "liked" stems from the word "like". The Porter Stemming Algorithm is the oldest and a better stemming algorithm and it is supported in NLTK. Another possible stemmer is the Lancaster stemming algorithm. Following is an example of the stemmed output:

[I] [like] [two] [feature] [of] [these] [product] [.]

3) *Stopword removal*: A typical piece of text has a large portion of stopwords that have no direct meanings or at least have no semantic impact on other words. Typical stopwords are 'a', 'the', 'is', 'are', and many other similar words. In text mining, such stop words are filtered before detailed analysis. Removal of stopwords from text increases the efficiency of the overall mining process. In the above-mentioned example, the stopwords such as 'I', 'two', 'of', 'these' are removed.

[like] [feature] [product]

4) *n-Gram analysis*: In n-gram analysis, a collection of words is identified in a sentence. A sentence can be divided into two, three, or four logical parts called bi-grams, tri-grams, and quad-grams, respectively. The identification of group words in a sentence improves the quality of sentiment analysis and text mining.

D. Pre-Processed Text

In this phase, pre-processed text is received from the pre-processing phase. This pre-processed text along with its extra information is stored in arrays so that it may get easy to process in the next phases.

E. Sentiment Analysis

This phase of sentiment analysis initiates with feature extracting and then multiple steps are performed to complete sentiment analysis.

1) *Feature extraction*: For sentiment analysis in the used approach, the first step is features extraction. These extracted features are used for sentiment classification. The extracted features are the number of positive words, the number of negative words, the existence of negation, and the unigram.

- A number of positive words are identified from each sentence. SentiWordNet library is used to find all the positive words and they are counted.
- A number of negative words are identified from each sentence. SentiWordNet library is used to find all the negative words and they are counted.
- The direct and indirect negations are identified in a sentence and are counted.
- Unigrams in the sentence are counted.

a) *Subjectivity classification*: In this step, lexicon-based analysis was performed and for this task, the OpinionFinder Lexicon [4] was used. This lexicon consists of around 2600 positive and negative words with classification. With the help of this lexicon, all the keywords in the text are labeled with positive and negative words.

b) *Sentiment scoring*: In this step, a sentiment score for each review is calculated. Each word is looked up in SentiWordNet [8] dictionary to retrieve its positive or negative score that is called pos_score and neg_score . For sentiment scoring, pos_score of each positive word were collected and summed as shown in Eq. (1). Similarly, the neg_score of all the negative words in a review were collected and summed as shown in Eq. (2).

$$pos_score = \sum_{i=1}^k pos_score_i \quad (1)$$

$$neg_score = \sum_{i=1}^k neg_score_i \quad (2)$$

To calculate the average positive and negative scores of a review such as pos_review_r and neg_review_r , Eq. (3) and Eq. (4) were used respectively.

$$pos_review_r = \frac{\sum_{i=1}^k pos_score_i}{n} \quad (3)$$

$$neg_review_r = \frac{\sum_{i=1}^k neg_score_i}{n} \quad (4)$$

The words with the objective score less than a given threshold are omitted. Average on review with a threshold. The pos_review_o is the sum of scores of all positive words in a review after omitting the discarded words [9]. Similarly, the neg_review_o is the sum of scores of all negative words in a

review after omitting the discarded words. Eq. (5) and Eq. (6) are used to calculate pos_review_o and neg_review_o , respectively.

$$pos_review_o = \frac{\sum_{obj_score_i < \theta} pos_score_i}{n} \quad (5)$$

$$neg_review_o = \frac{\sum_{obj_score_i < \theta} neg_score_i}{n} \quad (6)$$

The sentiment of a review S_r is determined by the higher value between pos_review_o and neg_review_o . Eq. (7) defines the calculation of S_r .

$$S_r = \begin{cases} \text{positive if } pos_review_o > neg_review_o \\ \text{negative if } neg_review_o \leq pos_review_o \end{cases} \quad (7)$$

F. Sentiment Classification

For final sentiment classification, a few existing solutions were tried for sentiment analysis and speech-to-text such as Google API, AssemblyAI. However, these existing models were not efficient enough to perform better. However, by using the information given in Section III(E), these models were modified and trained using Machine Learning and AI, so they can recognise speech in a noisy environment. The language models specifically were used for the hospitality industry (hotels, restaurants, etc.). A labeled dataset was used to train the ML classifiers. In our approach, binary classification was used such as in positive and negative classes [10]. Various algorithms were used such as Decision Tress (DTs), Support Vector Machine (SVM), Naïve Bayes (NB), Logistic Regression (LR), and Random Forrest (RF).

G. Customer Satisfaction Report

In the final step, a customer satisfaction report is generated that disseminates the results of the sentiment analysis performed in the previous steps for a set of reviews submitted by the customers for a day, week, or month.

IV. IMPLEMENTATION DETAILS

A new and unique hardware device has been developed to collect voice feedback and reviews. A prototype has been manufactured. The prototype has been tested in a real environment.

It is operated by a single button only. Press and speak to record voice feedback (LED is on). Release button – send to a cloud (LED blinking). The various models of the devised hardware are shown in Fig. 3.

A. Key Functionalities of the Device

- Power up the device in <1sec after pressing the button.
- Record and filter voice in a noisy environment.
- Compress, store, and send voice feedback to a cloud through Wi-Fi.
- Repeat sending the file if the Wi-Fi connection is unstable.
- If the battery is low – signal with LED to charge.

Fig. 3. Various versions of the design of the hardware.

B. Firmware Development

The firmware development for our handheld device, specially tailored for efficient power management and rapid activation, required a comprehensive setup involving several key components. The printed circuit board (PCB) is shown in Fig. 4.

Fig. 4. The printed circuit board (PCB) for the system.

Toolchain for ESP32: The initial step in our firmware development was to establish a toolchain that would allow us to compile code specifically for the ESP32 microcontroller, the heart of our device. The ESP32, chosen for its low power consumption and Wi-Fi capabilities, necessitated a toolchain that could translate our high-level code into machine language understood by the microcontroller. We utilized the Xtensa GNU toolchain, which is specifically designed for the architecture of the ESP32, enabling us to develop efficient and optimized code for our device's specific requirements.

1) Unique characteristics

- The device can operate for several weeks on one battery charge.
- The quality of the sound recording is perfect for noisy environments.
- Manufacturing price is <\$10/.

2) **Build Tools - CMake and Ninja:** To build our application for the ESP32, we employed CMake and Ninja as our primary build tools. CMake, an open-source, cross-platform family of tools, allowed us to manage the build process in a platform- and compiler-independent manner. It facilitated the generation of build configurations and was instrumental in managing the complexity of our project's architecture. Ninja, on the other hand, was used for its speed and efficiency in executing builds. It significantly reduced the building time, making the development process faster and more responsive to changes.

3) **ESP-IDF (Espressif IoT Development Framework):** The ESP-IDF is the official development framework for the ESP32 and ESP32-S Series SoCs provided by Espressif. It contains a rich set of APIs, libraries, and source code for common functions and features on the ESP32. This framework was crucial for our project as it provided the necessary tools and libraries for network connectivity, file system management, and power management. The ESP-IDF also includes scripts to operate the toolchain and facilitate the build process, making it easier for us to develop, compile, and flash the firmware onto the device.

4) **Custom development and challenges:** The customer development of the firmware from scratch was necessitated by our device's unique requirements, particularly the need to power up and initiate recording in less than a second and the optimization for energy efficiency.

We customized the ESP-IDF components and developed specific functionalities to manage the device's power states, handle audio processing, and ensure reliable Wi-Fi communication. The challenge was not only in optimizing these processes for performance but also in ensuring that they worked seamlessly together within the constraints of our hardware.

5) **Iterative testing and refinement:** The development of the firmware was an iterative process, involving numerous cycles of testing and refinement. This was particularly true for the components related to power management and audio processing, where real-world usage scenarios in noisy restaurant environments provided critical feedback for adjustment. The working of the developed module is shown in Fig. 5.

The firmware development for our innovative handheld device was a complex but rewarding process that pushed the limits of existing technology and required a deep understanding of the ESP32 microcontroller, the ESP-IDF, and the associated toolchain and build tools. Through customization and iterative development, we were able to overcome the significant technological uncertainties and challenges we faced in overcoming the technological challenges around energy consumption around sending review data.

Fig. 5. Method for collecting, storing, and analysing voice reviews.

V. EXPERIMENTS AND RESULTS

This section describes the experimentation details and results of the approach described in Section III. Three different datasets were collected using the device mentioned in Section IV. Each data set had a minimum of 50 reviews of various products. These three datasets were collected at different places where such as indoor, outdoor, and commercial places. The results of the experiments manifest that the results of all three datasets were almost consistent.

Fig. 6. Results of sentiment analysis of voice reviews for various products.

The designed system is based on a newly devised hardware tool that collects voice feedback and this hardware is unique in its features and functionalities. The designed system records, analyses, and sends feedback of voice review for further sentiment analysis. This section describes the results of the experiments performed with the designed system. Fig. 6 shows the results of voice reviews of various products that are classified into three classes such as positive, neutral, and negative.

The voice reviews or feedback of customers were overall accessed and overall positive, negative, and overall scores were calculated that are shown in Fig. 7.

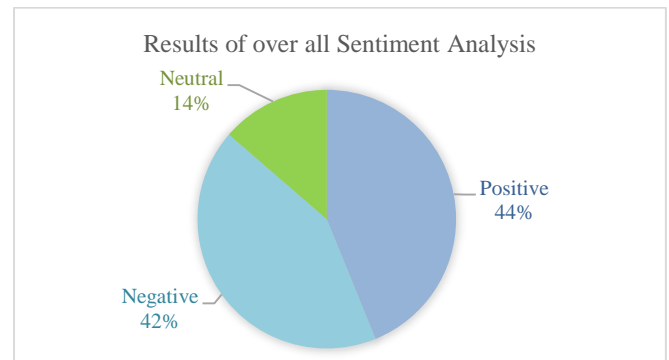

Fig. 7. Overall results of sentiment analysis of voice reviews.

In the sentiment classification phase, various algorithms were used such as Decision Tree (DT), Support Vector Machine (SVM), Naïve Bayes (NB), Logistic Regression (LR), and Random Forest (RF). Here the accuracy of the classification for all classes is discussed for each ML model. Here Accuracy is the ratio between the number of true positive and true negative results to the overall test data. Fig. 8 shows the comparisons of the performance of all the used machine learning algorithms. The results of our approach are compared with the unigram based approach [12] and lexical features based approach [13].

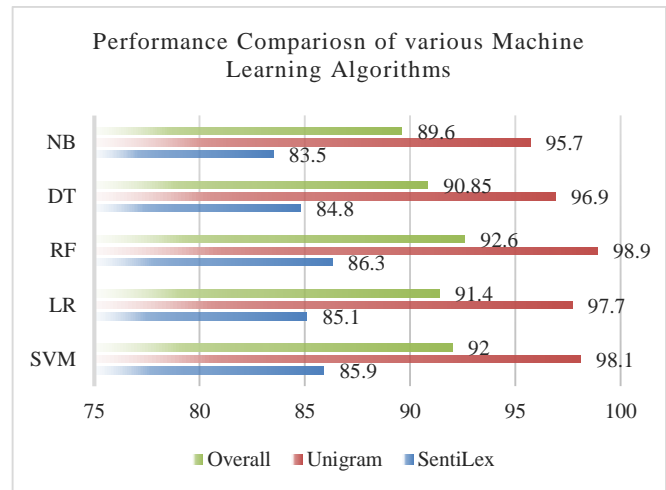

Fig. 8. Method and system for collecting, storing, and analysing voice reviews.

VI. DISCUSSION

There are no similar tools available in the market. The hardware device for collecting voice feedback was designed and developed from scratch. It was filed for patents in the US and the UK. Other solutions in the market to collect feedback and reviews use smartphones or tablets. They use text feedback. Our solution uses voice feedback. A recent study verifies that when people were asked about their preference for typing or speaking 100 phrases, the people preferred speaking. In this study, an experiment was conducted in various languages such as English and Mandarin Chinese [11]. The study outcome was that in normal routine, speech dictation was 3.0x faster than typing in English. Similarly, in Mandarin language, it was 2.8x times faster since it takes more time to make corrections while typing.

In addition to the speed factor, it was also found that the English error rate was 20.4 percent lower while speaking. Similarly, the error rate in Mandarin was 63.4 percent lower. In this experimental study, Baidu's Deep Speech 2.0 was used for speech recognition software and deep learning. Whereas the default iOS iPhone keyboard was used for the typing test in the experiments.

Based on the results of this study, it is assimilated that the proposed method is better than the available methods that use typing-based reviews for customer loyalty analysis.

VII. CONCLUSION

This paper addresses a problem in state-of-the-art solutions for sentiment analysis used for gauging customer satisfaction. It is identified in this research that there are a few issues with such website reviews-based data can be availability, reliability, relevance, integrity, and transparency. Hence, the results of such datasets can't be authentic and can't present a true picture of the customers' satisfaction. To address this problem a new device has been devised that can record customer voice reviews and can further process it using ML and produce sentiment analysis-based reports. The devised hardware tool for collecting voice feedback is unique as no similar devices are available in the market. Conventionally, smartphones and tablets can perform similar functions (record, analyze, and send voice feedback). However, they are more expensive (\$200-\$1000) compared to our device (\$10). The battery life of smartphones and tablets is much lower (1-3 days) than our devices (20-30 days). Our device is much more compact (2-3 times smaller) than a smartphone and has a more robust design. In addition, giving voice feedback is faster than typing and registering text feedback.

As a future work, the current model of emotion recognition can be upgraded for domain-specific customers such as banking, retail, e-commerce, and others. A domain-specific system can provide improved results.

Intelligent Framework in a Serverless Computing for Serving using Artificial Intelligence and Machine Learning

Deepak Khatri¹, Sunil Kumar Khatri², Deepti Mishra³
AIIT, Amity University, Noida, India^{1,2}
NTNU, Norway³

Abstract—Serverless computing has grown in popularity as a paradigm for deploying applications in the cloud due to its ability to scale, cost-effectiveness, and simplified infrastructure management. Serverless architectures can benefit AI and Machine Learning (ML) models, which are becoming increasingly complex and resource-intensive. This study investigates the integration of AI/ML frameworks and models into serverless computing environments. It explains the steps involved, including model training, deployment, packaging, function implementation, and inference. Serverless platforms' auto-scaling capabilities allow for seamless handling of varying workloads, while built-in monitoring and logging features ensure effective management. Continuous integration and deployment pipelines simplify the deployment process. Using serverless computing for AI/ML models offers developers scalability, flexibility, and cost savings, allowing them to focus on model development rather than infrastructure issues. The proposed model leverages performance forecasting and serverless computing model deployment using virtual machines, specifically utilizing the Knative platform. Experimental validation demonstrates that the model effectively predicts performance based on specific parameters with minimal data collection. The results indicate significant improvements in scalability and cost efficiency while maintaining optimal performance. This performance model can guide application owners in selecting the best configurations for varying workloads and assist serverless providers in setting adaptive defaults for target value configurations.

Keywords—Machine learning; data analytics; serverless computing; performance testing

I. INTRODUCTION

A cloud computing architecture called "serverless computing" uses dynamic resource management and allocation by the cloud provider to run and scale applications. Developers use this paradigm to build and distribute code in the form of brief, stateless functions, while the cloud provider takes care of infrastructure management tasks including server provisioning, scalability, and maintenance. In traditional computing models, developers are responsible for managing servers and infrastructure resources, which can be time-consuming and

require expertise in managing scalability and availability. Developers can concentrate entirely on building and deploying code thanks to serverless computing, which abstracts away the infrastructure layer. There are some key characteristics of serverless computing, which include:

- **Event-driven execution:** Serverless functions are triggered by events, such as HTTP requests, database updates, or message queue events. Functions are executed on-demand in response to these events.
- **Scalability:** Serverless platforms automatically scale the number of instances running the functions based on the incoming workload. Scaling is performed transparently, without developers needing to provision or manage additional servers.
- **Pay-per-use billing:** With serverless computing, developers are billed based on the actual usage of their functions. Cloud service providers are not charging for idle resources, which makes it cost-efficient for applications with variable or sporadic workloads.
- **Stateless functions:** Serverless functions are designed to be stateless, meaning they do not maintain any internal state between invocations. Any required state information is typically stored in external data stores, such as databases or object storage.

There are several benefits of serverless computing, that includes reduction of operational overheads, automatic scaling, reduction of cost, and increased flexibility. Developers focused on writing code rather than managing servers, operating systems, or scaling mechanisms. This allows for faster development cycles and increased productivity. Serverless platforms handle the scaling of functions automatically, ensuring that applications can handle varying workloads without the need for manual intervention. Serverless computing eliminates the cost of idle resources and pays only for actual function execution. This makes serverless computing cost-effective for applications with unpredictable or low usage patterns. Serverless functions are often platform-agnostic, can be written in various programming languages, and can integrate with other cloud services, offering developers a wide range of functionalities.

Serverless computing has gained popularity for a variety of use cases, including web and mobile backends, data processing,

IoT applications, and microservice architectures. It offers developers a scalable and cost-effective way to deploy applications without the burden of managing the underlying infrastructure [2]. While serverless computing offers several benefits, there are also challenges associated with adopting and implementing this paradigm. Here are some common challenges in serverless computing:

- **Cold Start Latency:** When a function is called for the first time or after a period of inactivity, serverless functions have an inherent cold start latency. This is because the cloud provider needs to provision and initialise the necessary resources to execute the function. Cold start latency can impact real-time or low-latency applications that require immediate response times.
- **Limited Execution Time:** Serverless platforms often impose execution time limits on functions, typically ranging from a few seconds to a few minutes. Long running or computationally intensive tasks may face challenges in fitting within these constraints. In such cases, alternative architectures or breaking tasks into smaller functions may be required.
- **Vendor Lock-in:** Serverless platforms may have proprietary interfaces, service contracts, and vendor specific features. Migrating serverless functions between different cloud providers can be complex and time-consuming, potentially leading to vendor lock-in. Careful consideration and abstraction of vendor-specific functionality can mitigate this challenge.
- **Monitoring and Debugging:** Debugging and monitoring serverless functions can be more challenging compared to traditional architectures. Fine-grained logging, tracing, and performance monitoring tools are crucial for identifying and diagnosing issues within serverless functions. However, some platforms have limitations in terms of logging granularity and debugging capabilities.
- **Resource Limitations:** Serverless platforms impose resource limits, such as memory allocation, CPU usage, and storage. Applications with resource-intensive workloads, such as large-scale data processing or AI/ML models, may encounter restrictions that require careful optimisation and scaling considerations.
- **State Management:** Serverless functions are designed to be stateless, which means they do not maintain internal state between invocations. While this simplifies scalability, it can pose challenges for applications that require maintaining session or contextual data. External storage or database services must be utilised to manage and retrieve state information.
- **Testing and Local Development:** Developing and testing serverless functions locally can be challenging due to the need for specific platform emulation or integration with cloud services. Local development environments often lack the same operational characteristics as the serverless platform, making it difficult to reproduce certain behaviours.

- **Security and Compliance:** Serverless computing introduces new security considerations. Function isolation, access control, and secure integration with other services must be carefully addressed. Compliance with regulations and data privacy requirements may also present challenges when handling sensitive data in a serverless environment.

While these challenges exist, many can be mitigated with careful architectural design, a proper understanding of platform limitations, and the utilisation of supporting tools and services. As serverless computing continues to evolve, cloud providers are addressing these challenges and providing improved capabilities and tooling for developers. Although serverless computing provides several benefits compared to cloud computing services. However, an intelligent framework can leverage AI and ML techniques to analyse historical usage patterns, workload characteristics, and performance metrics to optimise auto-scaling algorithms. By accurately predicting resource demands, the framework can ensure efficient scaling, minimising the occurrence of underutilised or overburdened resources.

An intelligent framework can dynamically allocate requests based on factors like function availability, resource utilisation, and latency. By intelligently routing traffic, it can optimise resource utilisation and improve overall performance. An intelligent framework can intelligently orchestrate workloads based on their characteristics, such as prioritising latency-sensitive tasks, distributing compute intensive tasks across available resources, or dynamically adjusting resource allocation based on workload dynamics. An intelligent framework can analyse usage patterns, pricing models, and optimisation algorithms to minimise costs while meeting application requirements. It can recommend optimal function configurations, memory allocations, or scaling strategies to optimise cost-effectiveness. By incorporating intelligent features, an intelligent framework can enhance the performance, efficiency, scalability, and cost-effectiveness of serverless computing environments [2]. It can automate complex decision-making processes, optimise resource allocation, and improve the overall user experience, making it easier for developers to harness the benefits of serverless computing while minimising the associated challenges.

Adaptive Function Placement (AFP) is one of the critical factors that refers to the process of dynamically assignment of serverless functions to appropriate computing resources based on real-time workload demands and system conditions. AFP techniques consider various factors when determining the placement of functions, such as workload characteristics, resource availability, and performance objectives. There are several benefits of AFP, such as:

- **Workload Monitoring:** Monitoring the workload characteristics is crucial for effective function placement. This involves collecting data on factors like request rate, latency, resource utilisation, and network conditions. Real-time monitoring enables the system to adapt to changing workload patterns.

- **Resource Availability:** The AFP system needs to be aware of the available computing resources in the serverless environment. This includes information about CPU capacity, memory, network bandwidth, and other relevant resource metrics.
- **Load Balancing:** Load balancing is an important aspect of AFP. It involves distributing the workload evenly across available resources to prevent resource bottlenecks and ensure efficient resource utilization. Load balancing algorithms consider factors like function size, resource requirements, and current resource utilisation to make informed placement decisions.
- **Cost Optimisation:** AFP techniques often aim to minimise costs by dynamically allocating resources based on demand. By monitoring workload patterns and resource usage, the system can make decisions that optimise cost efficiency, such as scaling down resources during low demand periods and dynamically scaling up during peak loads [1].
- **Latency and Performance:** AFP also considers the latency and performance requirements of functions. By analysing factors like network latency, function dependencies, and data locality, the system can place functions closer to the data sources or reduce network hops, thereby reducing latency and improving overall performance.
- **Dynamic Scaling:** AFP techniques often involve the dynamic scaling of resources based on workload demand. This includes automatically provisioning additional resources when the workload increases and releasing them when the demand decreases. Dynamic scaling ensures optimal resource allocation and responsiveness to varying workloads.

The major contribution of the current research is as follows:

- The proposed model can perform a large degree of parallelism in a large-scale system.
- The proposed model improves the performance parameters with response time and cost.
- The presented model has inherent features of performance, cost, and distinct workloads.

II. LITERATURE REVIEW

There have been several research projects in the past for the design and implementation of frameworks for serverless computing. The viability of employing a serverless architecture for AI workloads was investigated by Ishakian et al. It was evaluated for the effectiveness of providing serverless deep learning functions that categorise images by running the model via a forward pass [8]. The data shows that warm serverless function executions have a reasonable latency, but cold starts have a considerable cost. Adherence to SLAs that do not account for this bimodal latency distribution may be in jeopardy. Because functions are stateless and serverless frameworks lack access to GPUs, each function execution can

only consume CPU resources, and performance cannot be enhanced by depending on the serverless platform runtime to store state between invocations.

The Function-as-a-Service paradigm, in which users create brief functions that are subsequently managed by a cloud platform, as illustrated by Castro et al. The approach has several applications, including big-data analytics, event handlers, and bursty invocation patterns. By giving the platform provider a major portion of the operational complexity of monitoring and expanding large-scale applications, serverless computing lowers the bar for developers [6]. The developer must now overcome constraints imposed by the statelessness of their functions and comprehend how to relate the SLAs of their application to those of the serverless platform and other reliant services.

Workload profiling with benchmarks was used by Lioyd et al. to analyse the specific resource needs of very diverse workloads and anticipate the cost of workloads in various situations. Their research presupposed a fixed environment with a uniform VM capacity and initial configurations. The workload capacity and resource utilisation of the servers are quite dynamic while managing serverless architecture, nevertheless. A Cloud-Scale Java profiler was created by Yin et al. to help developers identify performance-related issues with their applications. It also gave developers insight into the system's throughput and the resources that each microservice would need to reach a certain level of service quality. Ye et al. employed profiling and normalised performance to increase workload performance and predict the influence of currently running VMs and co-location. It was suggested as a technique that, by utilising VM migration, improves workload performance while lowering PM energy usage [14], [18]. Even though they make some intriguing points, their algorithm is incompatible with a wide range of workloads.

By adjusting task designs and resource allocation choices, Li et al. optimise the performance levels of composite service application activities using analytical models based on queuing theory [10]. For capacity analysis and profiling of multitier internet server applications, Apte et al. suggested a load-generating tool. Their effort aims to produce a thorough profile of server resource utilisation, broken down by request type [3]. A multi-objective optimisation was used by Liu et al. to locate the ideal location for containers. However, it was assumed that there was only one application running in the cluster while considering the nodes' varying runtime environments. Additionally, because they make no generalisations, they must carry out the optimisation for each application separately [10], [11].

Kaffes et al. presented distinct serverless computing platforms, such as centralised schedulers and core-granular, that can be utilised without infrastructure [9]. The authors contend that distinct characteristics of serverless computing platforms include burstiness, brief and unpredictable execution times, statelessness, and single-core execution. Additionally, according to their research, which is supported by Wang et al., the scalability of present serverless products is inefficient [17]. Bortolini et al. conducted experiments with a variety of setups and FaaS providers to identify the key variables affecting the

performance and price of the most recent serverless systems [5]. It was discovered that the programming language being utilised is one of the most crucial elements for both performance and cost. Additionally, they identified one of serverless computing's biggest shortcomings as low-cost predictability. Lloyd et al. are investigating the effectiveness and performance of serverless computing platforms [12], [13]. Bardsley et al. evaluated the performance of AWS Lambda in terms of distinct factors such as availability, low-latency, and infrastructure management. The authors found that infrastructure is not visible to the end-user and provides a better interface, which underlies the fundamental concepts [4].

Hellerstein et al. addressed the main faults and antipatterns in the first-generation serverless computing platforms. The author shows the implementation details and distributed computing platform that has cloud-based applications [7]. There are some issues with the current approach, such as the absence of global states and lambda function inability. The key issues inhibiting the widespread adoption of FaaS, according to Eyk et al., are significant overheads, variable performance, and new sorts of cost-performance trade-offs [15]. A strategy was developed to address six performance-related issues facing the serverless computing sector in their work. According to Zheng et al.'s, the performance of distinct platforms depends on the workload, implementation of the FaaS system, and the optimal set of parameters. Table I shows the comparative study of the current research with the existing work, as demonstrated in the result section with better outcomes.

TABLE I. COMPARATIVE ANALYSIS

After a rigorous literature review, it has been found that there are some gaps in the field of serverless computing where several new research projects can be proposed with critical investigation. The author has tried to fill the gap by building an intelligent system that has a large degree of parallelism on a large scale. In the next section, it has defined as a proposed methodology for the achievement of the objectives of the current research.

III. PROPOSED METHODOLOGY

The importance of machine learning in a serverless computing environment involves combining various technologies to create scalable, efficient, and intelligent systems. Machine learning models within containers can facilitate easy deployment and management in a serverless environment. An intelligent framework refers to the dynamic design of serverless computing. It includes several

advancements for the best utilisation of the resources on the server side. Adaptive Function Placement (AFP) is one of the critical factors that refers to the process of dynamically assigning serverless functions to appropriate computing resources based on real-time workload demands and system conditions [16]. AFP aims to optimise resource allocation, maximise performance, and minimise costs in serverless computing environments. Applications are created and deployed using serverless computing as functions that are called when certain events or requests occur. The developer is abstracted away from the underlying infrastructure and resource management, and these operations are carried out in a managed environment provided by the cloud service provider. Statistical machine learning is used in this study to create and examine the placement of an adaptive function that serverless computing systems can use to improve running function performance while lowering operating costs. The suggested adaptive function placement technique can be simply implemented by using container orchestration in the case of serverless computing providers. It also affects the distinct findings and is utilised to incorporate them with issues generated during the implementation phases. The system is implemented using Knative scale platform (Castro et al., 2019).

Fig. 1 shows the Knative scale calculation open-source platform. Knative is an open-source platform built on top of Kubernetes that provides a set of building blocks for creating modern, source-centric, and container-based applications. It abstracts away the complexities of managing containerised workloads, auto-scaling, and event-driven architectures. One of the key features of Knative is its ability to automatically scale applications based on incoming traffic. Knative allows you to define rules and thresholds for scaling your application. For example, you can set thresholds for CPU usage or request throughput that, when exceeded, trigger scaling actions. The Knative Scale Calculation module is responsible for determining how to scale your application based on incoming traffic and load. The Knative scale can be divided into distinct modules, such as:

Fig. 1. Knative scale calculation.

A. Metrics

Two metrics, named Requests per Second (RPS) and Concurrency Value (CC), are the metrics that can be used for driving auto-scaling in a metric-based approach. The concurrency value represents the number of active requests that are being concurrently processed by an instance of your application. It is a measure of how effectively the application handles multiple requests at the same time. As the CC value increases, it suggests that the application is under a higher concurrent load, potentially necessitating auto-scaling to ensure

optimal performance. When the CC value drops, auto-scaling can reduce the number of instances to match the lower concurrency level. The RPS metric provides insight into the workload and demand on your application. As the RPS increases, it indicates higher user activity, and auto-scaling can be triggered to accommodate the increased load by deploying more instances of your application. Conversely, if the RPS decreases, auto-scaling can reduce the number of instances to save resources.

B. Observation Module

Knative can integrate with external observability tools like Prometheus, which is a popular monitoring and alerting toolkit. These tools help collect and store the metrics generated by the application and infrastructure. There are several key aspects to the observation module in Knative.

- **Metrics Collection:** Knative can leverage Kubernetes metrics for monitoring and scaling decisions. Kubernetes provides built-in metrics like CPU usage, memory usage, and request throughput.
- **Autoscaling Metrics:** As mentioned earlier, Knative can use metrics like Requests per Second (RPS) and Concurrency Value (CC) for autoscaling decisions. These metrics help determine the current load on the system and adjust the number of instances accordingly.
- **External Monitoring Tools:** While not inherently a part of Knative itself, observability tools like Prometheus, Grafana, and others can be integrated with Knative to provide comprehensive monitoring and visualisation of metrics.
- **Application Tracing:** Observability often includes application tracing to understand how requests flow through the system and identify bottlenecks or issues. Tools like Jaeger can be integrated to provide distributed tracing capabilities.
- **Log Aggregation:** Effective observation also involves collecting and aggregating logs from various components of the system. Centralised log management tools like Elasticsearch, Fluentd, and the Kibana (EFK) stack can be used for this purpose.

Event Streaming: Since Knative is event-driven, monitoring and observing events becomes important. Event streaming platforms like Apache Kafka can be integrated to manage and analyse events.

Custom Metrics: Depending on the application's requirements, custom metrics might be needed. Knative supports the use of custom metrics to make scaling decisions that align with the specific needs of the application. In order to prevent making rash conclusions while evaluating scaling, the purpose of this module is to produce steady observations.

C. Scale Evaluator

The scale evaluator generates the order for the new replica count by utilising the observed values and the current replica count. The current replica is generated by monitoring the distinct FPS or CC. By default, the Kubernetes deployment's new replica target is set by the Knative auto-scaling evaluation,

which occurs every Teva (2 seconds in Knative). Eq. (1) is used to evaluate the generated replica by using the observed value and the current replica. The observed values are the values of the metric in terms of RPS or CC.

$$Generated_{Replica} = \frac{Observed_value}{Current_Replica} \quad (1)$$

The suggested system can be divided into distinct modules.

A high-level view of the suggested performance model is shown in Fig. 2. The metric module is responsible for collecting, processing, and analysing various metrics and data to monitor and assess the performance, health, and behaviour of the system. It is utilised to evaluate the observed module distribution with the help of the evaluator module. These parameters are being evaluated by using the CC and RPS with the arrival rate. The average request arrival time was provided by the input.

Fig. 2. Proposed methodology.

This step is crucial because it captures several crucial aspects, including the amount of work and distribution time needed for the deployment of the setup. The memory utilisation and CPU time are also evaluated for the generation replica count. The replica count is done based on the total values of the target variable and the attributes generated during the processing. The Cluster Module would be responsible for managing the Kubernetes cluster on which Knative applications are deployed. This includes provisioning, scaling, and maintaining the nodes that form the cluster. The probabilities of the cluster module can be described in Eq. (2).

$$Pr(x,y) (x',y') = Pr(x,x')(y) * Pr(y,y')(x') \quad (2)$$

where, $Pr_{(x,y)} (x',y')$ defines the transitioning probabilities from the current state to the transmission of rows to columns and vice versa. An output module refers to the final trained model that generates predictions or classifications based on input data. The evaluation of replica count would be done by using the outcome module and generating a model for similar patterns. After evaluation of the patterns, the likelihood of the replica count can be evaluated in terms of the similar characteristics. Finally, the ready container is utilised for the output and computation of the performance of the system. The average replica count can be written in terms of Eq. (3).

$$N' = \sum_{i=1}^n N_i \alpha_i \quad (3)$$

where, N' is the average number of replicas count that can be evaluated by using the current replica count and a constant factor of the observed value.

D. Experimental Testbed Setup

For the experimental testbed, a virtual machine (VM) hypervisor is setup, which is utilised for the data collection. The proposed system has been implemented with the following configuration: The processor is of the 7th generation of the Intel series, with 2 TB of HDD, 2 GB of RAM, and VMWARE 15.5.1. Four nodes served as worker nodes on the Cybera cloud, while RabbitMQ served as our distributed task queue. Kubernetes version 1.20.0 is used for our cluster, along with Kubernetes client (kubectl) version 1.18.0 and Python 3.8.5 for the customer. Profiling and performance measurement are two separate phases that might be divided into the data collection phase, depending on the situation. The primary objectives of the profiling phase of data gathering are to characterise the workload and identify any unique requirements. So, a dedicated VM is used to host the container that needs to be profiled while measuring the throughput on the client side and the various resource utilisation statistics shown in Table II.

TABLE II. STATISTICS FOR RESOURCE UTILIZATION

Variable	Units	Remarks
vCPU	4	Setup a network
Latency	Less than 1 ms	Minimum time delay
OS	VM Ubuntu	Virtual
Network	10Mbps	Fast response

The evaluation of resources for VM is providing the impact on the container in data collection. To do this, haphazardly distributed sets of containers on a virtual machine are setup, each of which produces a haphazard workload. Before deploying the new container, we next evaluate how much of the available resources are being used by this erratic workload. The achieved performance is then tracked using Eq. 4, and all the results are maintained in the data set for the predictive performance model. A training set of 128 of the 183 data points was collected for the model used in the trials, and a test set of 55 was used.

$$T_N = T_F / T_P \quad (4)$$

where, T_N is the normalized throughput used to evaluated by the division of T_F function-based throughput and T_P generated during the profiling phase.

E. Machine Learning Module

For this work, a variety of data-driven modelling strategies have been examined. The versatility, ability to fit nonlinear functions, and minimal computing costs of artificial neural networks built on TensorFlow were our preferred options in this case. To find out how effective this strategy is, in-depth experimental tests were conducted. Various machine learning algorithms were analysed for predicting the normalised throughput of the serverless platform in order to construct the predictive performance model. Among the methods employed are artificial neural networks, decision tree regression, random forest regression, support vector regression, and linear regression. The system's container performance (i.e., throughput and reaction time) fluctuates nonlinearly based on

the workload characteristics. As a result, it is expected that linear models (linear regression) will perform poorly when compared to nonlinear techniques. In our experiments, we found that SVR and neural networks had the best accuracy performance, with neural networks marginally surpassing SVR. Neural networks were chosen in this study for our tests due to their generality, flexibility, adaptability, and prediction speed to fit nonlinear functions. Table III contains the neural network setup that was employed.

TABLE III. MACHINE LEARNING CONFIGURATION

Functions	Size
ReLU	0.0 to 1.0
Convolutional Net	5*5
Activation Map	300*200 pixels

F. Optimised Algorithm

The major aim of the proposed scenario is to recognise the unique features during the execution of the VM container. Those unique features of a workload are based on the resource usage of the container on a VM. It is difficult to assess the performance decrease caused by collocating with another container because of the extreme diversity of workloads on such platforms. By creating a predictive performance model that analyses each workload and forecasts its normalised performance when deployed to a particular VM, it was attempted to get around this limitation. Finding the VM that has the least detrimental effect on the performance of the container is the answer to the question of which virtual machine is best to deploy the container on. To accomplish this, it is suggested that a fast-profiling step be added to the serverless platform during the container installation process. This phase will give a sample workload that the user has specified. When scaling a function after the profiling process, the profile is utilised for evaluating the performance of the VM functions and the prediction model to assess how effectively each VM is using its resources.

G. Testing and Validation

Testing and validation using machine learning involves applying various techniques and methodologies to assess the performance, accuracy, and generalisation capabilities of machine learning models. Proper testing and validation are crucial to ensuring that machine learning models work well on unseen data and provide reliable predictions or classifications. Once the model is fine-tuned using the validation set, it is evaluated on the test set, which should represent unseen data. This provides an unbiased estimate of the model's real-world performance.

IV. RESULTS AND DISCUSSION

The measured and anticipated average number of containers that are ready to meet incoming requests are shown for various setups in Fig. 3 and Fig. 4. Here, the deployment cost is represented by the typical number of containers. Depending on the setup, the deployment's cost may be VM-based in a Kubernetes cluster or pod-based in a Google Cloud Run deployment. The expenses of the infrastructure, however, will be inversely correlated with the typical number of containers in both cases. The average concurrency value for various settings

is shown in Fig. 5 and Fig. 6, respectively. These parameters can help the developer accurately configure other services on which the deployment depends. As an illustration, the capacity provided by most managed database solutions may be configured to maximise performance while minimising expenses. For this deployment, the Quality of Service (QoS) metric has been the average response time. The measured and anticipated average response times for various configurations and arrival rates are shown in Fig. 7 and Fig. 8, respectively. In contrast to the predetermined arrival rate, the average number of containers available to fulfil requests in our studies has varied goal concurrency values. As you can see, the scale on the x-axis is logarithmic. The vertical bar shows the 95% confidence intervals, which in this case were relatively small because the experiments lasted long enough to produce highly dependable results.

Fig. 3. Average number of containers.

In Fig. 3, there is a description of goal concurrency that can be evaluated by using the average number of containers and packet arrival rate. The x-axis represents the values on a logarithmic scale, while the y-axis represents the distinct targets for containers. Autoscaling policies, often based on metrics like Requests per Second (RPS) or Concurrency Value (CC), work in tandem with desired concurrency values. When the observed concurrency exceeds the desired value, scaling policies can trigger the necessary scaling actions.

Fig. 4. Desired concurrency values.

Desired concurrency values typically refer to the target level of simultaneous requests or tasks that an application or system aims to maintain. In the context of auto-scaling and performance optimisation, determining the appropriate desired concurrency values is crucial for achieving optimal resource utilisation and user experience. Fig. 4 shows the concurrency

values in terms of average containers vs. fixed arrival rate. The x-axis represents the values on a logarithmic scale, while the y-axis represents the distinct average-ready containers.

Fig. 5. Target concurrency values.

Target concurrency values typically refer to the specific levels of concurrent requests that an application or system aims to achieve under various conditions. These values help guide scaling behaviour and resource allocation in order to maintain optimal performance and responsiveness. Fig. 5 shows the graph between average concurrency and fixed arrival rate on a logarithmic scale.

Fig. 6. Predicted concurrency values.

Predicted average concurrency refers to the estimated or forecasted level of concurrent requests that an application or system is expected to experience over a specific period. This prediction is typically based on historical data, patterns, trends, and potentially external factors that influence the demand for the application. Fig. 6 shows the predicted average concurrency vs. fixed arrival rate on the x-axis.

Fig. 7. Response time vs. Arrival time.

Average response time and fixed arrival rate are two important concepts in performance analysis and capacity planning for systems, including serverless architectures like

Knative. Average response time, also known as average latency, is the time it takes for a system to respond to a request on average. It's a critical metric for assessing the performance and user experience of an application. Lower average response times generally indicate better system performance and faster user interactions. In the context of Knative, average response time is influenced by factors such as the processing time of requests, network latency, resource availability, and system architecture. Monitoring and optimising average response times are essential to ensuring that users experience responsive and efficient applications. Fig. 7 shows the graph between these two factors and shows that target 1 has a shorter response time.

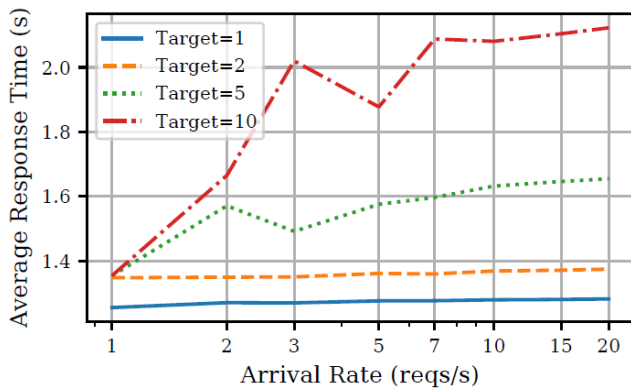

Fig. 8. Average Response time vs. Arrival time.

Figure 8 shows the average response time in the aspect of arrival rate in the x-axis. The graph shows the greater response time for a greater number of targets while target 2 shows the exceptional conditions.

The results of our study align with previous research by Ishakian et al. (2018), who also found that warm serverless function executions have reasonable latency, but cold starts incur considerable costs. This highlights the importance of considering bimodal latency distribution in serverless architectures, as failure to account for this may jeopardize adherence to SLAs (Service Level Agreements) [8].

Furthermore, our findings support the argument made by Castro et al. (2019) regarding the advantages of the Function-as-a-Service paradigm in simplifying operational complexity for developers. By abstracting away infrastructure management, serverless computing lowers the barrier for developers, enabling them to focus more on application logic.

The proposed Adaptive Function Placement (AFP) technique is in line with the work of Kaffes et al. (2020), who emphasized the importance of efficient resource allocation in serverless computing platforms. Our study extends this work by demonstrating how statistical machine learning can be used to optimize function placement dynamically, leading to improved performance and cost-efficiency.

V. CONCLUSION

In this paper, the author has suggested and assessed a performance model for serverless computing platforms' metric-based auto-scaling that is precise and manageable. It examines the effects of various system topologies and the workload

characteristics of these systems and uses experimental validation to demonstrate the efficacy of the suggested model. It is also demonstrated how application owners can utilise the presented performance model as a tool to determine the best configuration for a particular workload under various loads. The suggested methodology can also be used by serverless providers to set adaptive defaults for the target value configuration that are more logical. In accordance with the real-time arrival rate, the performance of the system depends on the cost, energy, average response time, and energy consumed by the system. Monitoring and managing the cost of optimised resources and effective security mechanisms can be focused on in the future.

One of the key novelties of the research was the integration of machine learning models within containers to facilitate easy deployment and management in a serverless environment. By leveraging statistical machine learning techniques, the study showed how the AFP technique can improve the performance of serverless computing systems while reducing operating costs. Additionally, the research highlighted the importance of proper testing and validation of machine learning models to ensure reliable predictions and classifications on unseen data.

The study primarily focuses on Knative as the serverless computing platform for evaluation. While Knative is a widely used platform, its performance characteristics may not fully represent other serverless platforms. Future studies could explore multiple serverless platforms for a more comprehensive analysis.

The experiments were conducted using a simplified workload, which may not fully capture the complexity of real-world applications. Future work could involve more diverse and realistic workloads to better assess the proposed system's performance and scalability.

Suggestions for further study include exploring the scalability and efficiency of the AFP technique in larger and more complex serverless computing environments. Additionally, further research could investigate the integration of other advanced machine learning algorithms and techniques to enhance the performance and adaptability of serverless computing systems.

Abstract—Researchers in Higher Education (HE) institutions/academia and in industry are continuously engaged in generating new solutions and products for existing and emergent problems. Doing quality research and producing better scientific results depend greatly on solid research teams and scientific collaborators. Research output in HE institutions and industry can be optimized with appropriate resources in research teams and collaborations with suitable research partners. The main challenge in finding suitable resources for joint research projects and scientific collaborations pertains to the availability of data and metadata of researchers and their scientific work in traditional formats, for instance, websites, portals, documents, and traditional databases. However, these traditional data sources do not support intelligent and smart ways of finding and querying the right resources for joint research and scientific collaboration. A possible solution resides in the deployment of Semantic Web (SW) techniques and technologies for representing researcher and their research contribution data in a machine-understandable format, thus ultimately proving useful for smart and intelligent query-answering purposes. In pursuit of this, we present a general Methodology for Ontology Design and Development (MODD). We also describe the use of this methodology to design and develop Higher Education Ontology (HEO). This HEO can be used to automate various activities and processes in HE. In addition, we describe the use and adoption of the HEO through a case study on the topic of “finding the right resources for joint research and scientific collaboration”. Finally, we provide an analysis and evaluation of our methodology for posing smart queries and evaluating the results based on machine reasoning.

Keywords—Higher Education Ontology (HEO); Linked Open Data (LOD); Machine Reasoning; Semantic Web (SW); SPARQL Queries

I. INTRODUCTION

As a semantic-based representation of shared conceptualization, ontologies make knowledge machine-readable and easy to share. They also help us in semantic-based smart search, easy integration, data analysis, exploration of new knowledge, as well as machine reasoning and inferencing [1]. With burgeoning research in the field of machine reasoning, researchers in the field of education predicted the existence of future opportunities for many participants [2]. Ontological reasoning can be helpful for inferring new knowledge in any domain, including Higher Education (HE). Through ontological inferencing, it is possible to answer questions such as: “finding instructor who best fits to teach a particular course”, “predicting the possible cooperation between the faculty members”, and “varying complexity of exams with varying level of

students”. Transferring the data related to these activities from the original format (understood only by humans) to RDF/OWL format (understood by humans and machines alike) can help the machines to process and thus allow for inferencing or reasoning in response to smart queries.

Semantic Web (SW) technologies are being applied quite frequently in many problem domains nowadays. For instance, in [3], authors present a framework (i.e. ADOL) that can be used to construct and extend educational ontology automatically. The proposed ‘ADOL’ is an ontology learning framework that can transfer the domain of textbooks into a corresponding ontology automatically and efficiently. Besides this, authors in [2], present a case study for the derivation and implementation of ontology in the HE domain. The ontology covers key aspects of the university domain, including creating class hierarchy, instances for class, properties, and relations. In [4], the authors provide an in-depth curriculum and syllabus ontology and propose a classification and integration method to produce a semantically enriched syllabus model. An educational ontology of Palestine University is presented in [5]. The authors utilize the Unified Process for Building the Ontology (UPON) to provide a query retrieval process. In [6], the authors focused on the emergence of the Linked Open Data (LOD) platform of the South East European University curricula, progressing from experimental to open data hub. They utilized Linked Data principles to publish and access data on academic programs and courses offered by the university.

Despite these efforts to address educational domain problems, a semantic-based solution to automate processes in HE, especially in research collaboration, is needed. Moreover, the importance of ontological reasoning in extracting new knowledge from existing data in collaborative research has yet to be addressed. Further, the investigation and utilization of implicit or explicit data characteristics in educational data have not been investigated yet. This paper addresses the abovementioned limitations and challenges in extant research. It provides a Higher Education Ontology (HEO) that can automate various activities and processes in HE using academic analytics and ontological reasoning techniques. This paper makes several contributions. It provides:

- A Methodology for Ontology Design and Development (MODD).
- A Higher Education Ontology (HEO) that can be used to model and represent knowledge about different HE

processes and activities in a semantically enriched format based on LOD principles [7].

- We present a case study as a proof-of-concept of HEO on the topic "find the right resource for research collaboration".
- Finally, we also evaluate our proposed methodology by analyzing the results of our case study.

The remaining paper is organized such that related work is described and compared in Section II. Section III presents the Methodology for Ontology Design and Development (MODD) and discusses its implementation in designing and developing the HEO. Section IV describes the case study on the topic "find the right resource for research collaboration" and provides results analysis. Finally, we provide the conclusion and discussion of the future work in Section V.

II. RELATED WORK

The importance of developing an educational ontology has been highlighted in recent years. Many researchers have begun to design and implement ontologies to provide effective, web-based machine learning. The SW can help in solving the problem of information retrieval and facilitate the identification of accurate and useful resources. As an example, the research published by [8] creates the Ontology for Linked Open University Data (OLOUD). This ontology covers concepts and relations related to semesters, curriculum, courses, subjects, and personnel, in addition to events and buildings. In [9], the authors built the Bowlogna Ontology to improve the learning environment. The study also described practical applications of this ontology for university end-users, including a system for faceted searching and browsing for course information. Univ_Edu_Onto, which is another educational ontology, is described in [10]. This ontology contains two types of terms: general terms for university courses and specific terms for the Artificial Intelligence (AI) courses. Also, in [11], the authors introduced an educational ontology for the Indraprastha University, Delhi, India. The ontology presents a graph representing subclasses using TGViz.

In [12], a semantic-based university examination ontology was developed to provide enhanced support in examination systems, particularly for higher degrees. In [13], the authors present an educational ontology named Curriculum Course Syllabus Ontology (CCSO) to model entities, data, and concepts within an academic environment. Similarly, in [14], authors presented an ontology for Mosul University (OMU). The authors also implement different queries to show the inference processes. The Semantic Web for Research Communities (SWRC) ontology was presented in [15]. It describes the communities of the research and other related concepts. In [16], the authors presented Higher Education Reference Ontology (HERO). The work explains the process of building and developing the HERO ontology using the NeOn methodology from the specification of requirements stage to the ontology evaluation stage. In [17], the authors present an ontology of Ahlia University in which DL and SPARQL queries are used to retrieve explicit and implicit information employing ontological reasoning. In [18], the authors presented an ontology-based framework that facilitates semantic-based queries for postgraduate information queries at the Ministry of

Higher Education (MOHE) portal. In [19], the Massive Open Online Courses (MOOCs) ontology was presented to speed up the retrieval of educational data based on learners' requests from the Coursera platform.

In [20], the authors focus on designing and building university ontology methods. In [21], the authors presented an ontology that can be used for searching educational resources based on matching semantics. The proposed ontology was developed from real-life educational resources. In [22], the authors presented a semantically enriched system for e-learning. This system utilizes SPARQL queries and machine reasoning to provide smart question-answering methods. In [23], the authors presented a process of creating university datasets based on LOD. The generated datasets cover data items, vocabulary, and RDF entities related to the university, and the data is published based on LOD principles for query purposes. In [24], the authors present an ontology in the HE domain. This work's main limitation is that it was designed specifically for the engineering field, making it unsuitable for other HE activities. In [25], the authors created an ontology in the university domain that serves as an ontology searching hub. In [26], the authors also presented an educational ontology aiming to assist with the university internship assignment in an automated fashion. In [27], an e-campus ontology is proposed, which serves to stream various educational processes. This ontology is explicitly designed for learning activities and presents a semantic hierarchy that represents learning activities for programming languages such as C-Sharp. A fuzzy ontology-based framework has been presented in [28] to facilitate the organization of scientific research. In [29], the authors designed and presented a meta-model ontology. The work explains the methodology developed for ontological improvement by applying a semi-supervised learning method. In [30], the authors proposed an ontology-based e-learning system to identify the problems in the HES, such as the lack of connections between components and the poor structure of educational resources.

The solutions discussed above represent good efforts to address various challenges in HE. However, these proposed systems still need to effectively address the problems and issues related to automating the processes and activities in educational systems to maximize efficiency and accuracy. The following section addresses these limitations and presents our methodology for HE processes and activities automation by using ontologies and machine reasoning.

III. THE METHODOLOGY FOR ONTOLOGY DESIGN AND DEVELOPMENT (MODD)

Ontology design and development is a job that includes several tasks and activities for modeling an ontology in any domain. Even though different methods have been proposed and various tools have been developed to support these tasks and activities, there is still a dearth of a unified approach or methodology for ontology design and development. A lot of methodologies arrange tasks differently. However, the general approach does not vary widely. In this paper, we present our Methodology for Ontology Design and Development (MODD) (as illustrated in Fig. 1). In our proposed methodology, we follow two approaches presented in [31] and [32] as our baseline and present an upgraded approach that can support different

activities and tasks that are essential to ontology modeling. Here, we describe different phases of our Methodology for Ontology Design and Development (MODD). As a proof of concept, we also present the use of this methodology to create the Higher Education Ontology (HEO) which can ultimately be used to automate various activities and potential processes in research and development.

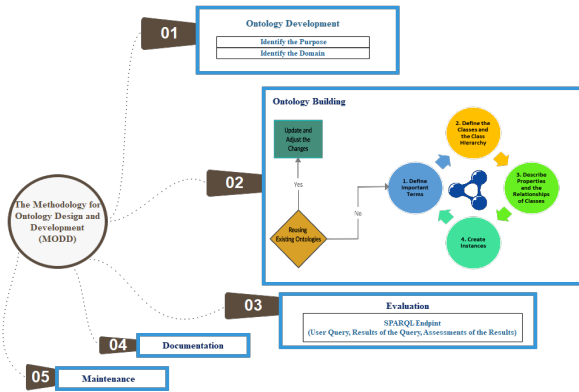

Fig. 1. The Methodology for Ontology Design and Development (MODD).

A. Identify the Purpose and the Domain of the Ontology Development

Before developing an ontology, there are several questions that knowledge engineers must answer:

- Do they have enough knowledge required to develop ontology in a particular domain?
- What are the benefits and purposes of using this ontology?
- What are the specific mechanisms and uses of the ontology?

Answering these questions furnishes a clear destination for making decisions and keeping the knowledge engineers on the right track. From the perspective of our case study, we developed an ontology in the education domain, especially in HE. The purpose was to automate the various HE processes and activities with special attention to the cooperation process between the researchers and faculty members. We identified the question “finding the right resources for joint research and scientific collaboration” as one of potential utility and a case study for our work. To empower our solution, we took real data from specific systems at King Abdulaziz University (KAU). Two of these main systems include OUDS PLUS and Accreditation Information Management System (AIMS). These systems provide all information related to the courses, syllabus, and faculty member data (e.g., publications, academic training, professional experience, and scientific research). After identifying the required data, we converted it into a machine-understandable format such as RDF. The resulting RDF data can be used to perform smart queries, inference, and machine reasoning. Also, to test the efficiency and quality of the ontology design, we defined a list of questions referred thereafter as

Competency Questions (CQs). CQs help us to determine and identify the knowledge that should be included in the ontology. Firstly, they can be used to answer the needs and requirements that the ontology must fulfill. Secondly, we can use it as a tool to evaluate the output of the ontology by examining the answers to the potential questions. We defined the following CQs:

- 1) Find all academic staff members who have the same research interests.
- 2) Find all academic staff members who have the same publication keywords.
- 3) Find specific academic staff members to collaborate with other academic staff members based on common research interests.
- 4) Find specific academic staff members to collaborate with other academic staff members based on common publication keywords.
- 5) Find all the academic staff members who can collaborate based on the four criteria.(research interests, certifications & trainings, publications and academic & professional experiences).

B. Ontology Building

In this phase, the knowledge engineers should define the most important terms, concepts, properties, and their relationship with each other. In addition, they should answer the following questions:

- How and whether to use ontologies that already exist?

The ontology-building phase is based on various principles and standards, as it requires a deep understanding of the domain. These principles are discussed below:

1) *Reusing existing ontologies:* At this stage, we must search and identify existing ontologies and decide which existing ontologies can be reused and to what extent they can be reused. Different factors can help us to decide about the reuse of existing ontologies. Some of these factors are missing classes, subclasses, relationships, and properties. Alternatively, we can build from the beginning by following a group of steps. The process of searching and exploring ontology is an essential phase of ontology development. Once we find an ontology that is suitable and compatible with our special needs, this will save time as well as extra effort. Additionally, if we do not find any ontology that is compatible with our domain and can be reused, a minimum use of such ontologies is that they can be used as a good source of guidance and inspiration. As we mentioned earlier, the scope of our work encompassed research and education, and we were able to find a lot of research and educational-related ontologies. Herein, we present some important criteria that should be considered while deciding about the reuse of existing ontology (as shown in Fig. 2):

- 1) The domain of the ontology. (From the perspective of our case study, it must be in the research and education domain).
- 2) The availability of the ontology. (The links must be work and available to download).
- 3) The format of the ontology (must be in RDF/OWL format).

TABLE I. AN OVERVIEW OF DIFFERENT EDUCATIONAL ONTOLOGIES

Ontology Name	Purpose	Year	Reference
E-campus ontology for the university of Zakho (UOZ)	Building an ontology wherein the classification of the developed ontology comprises the following (campus, deliverable, academic year, person, university).	2019	[27]
University ontology-based information retrieval system	Developing a university ontology that contains classes such as people, department, divisions, program, course, club, events and publications.	2019	[25]
Ontology for curriculum and syllabus	Building a Curriculum Course Syllabus Ontology (CCSO) which contains many classes (e.g., academic staff, administrative staff, assistant, bachelor, certificate, course and department).	2018	[13]
Massive Open Online Courses (MOOCs) Ontology for information retrieval through Coursera platform	Based on learner request, in the Coursera platform, building an ontology to retrieve educational resources such as classes related to assessment, certification, collaboration, course material and subjects.	2020	[19]
OntoSyllabus ontology	Developed an ontology for higher education institutions syllabus. The main concepts are topic, course, syllabus, instructor and concepts.	2019	[33]
University examination system ontology	Developed an ontology for the university examination system. The main concepts are student, faculty, subject and department.	2017	[12]
Academic Institution Internal Structure Ontology (AIISO)	Representing the internal organizational structure of academic institutes by using classes and properties described in the Academic Institution Internal Structure Ontology (AIISO). The main concepts are center, college, course, department, faculty and division.	2008	[34]

TABLE II. THE ONTOLOGIES FULFILLING THE DEFINED CRITERIA

Prefix	Ontology Name	Reference	URI
AIISO	Academic Institution Internal Structure Ontology (AIISO)	[34]	vocab.org/aiiso/
CCSO	Curriculum Course Syllabus Ontology (CCSO)	[13]	w3id.org/ccso/ccso#
OS	Ontosyllabus	[33]	jachicaiza.github.io/ontologyDoc/
curriculum	BBC curriculum	[35]	www.bbc.co.uk/ontologies/curriculum

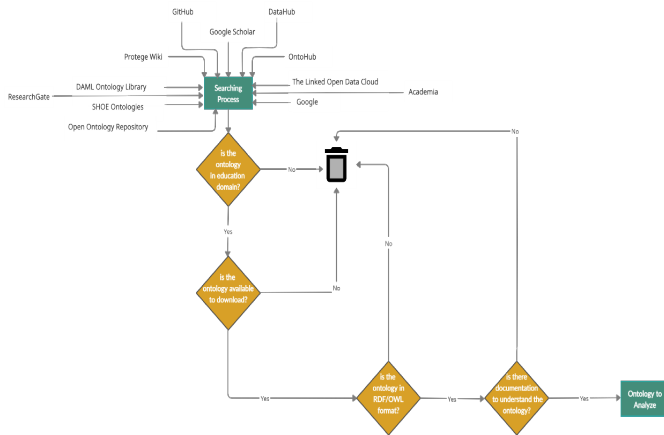

Fig. 2. The criteria for the search process.

- 4) Clear documentation available in the English language to understand the classes, relationships, and properties of the ontology.

Table I shows the most common educational ontologies that we came up with after searching different websites and portals. After analyzing the education ontologies from the previous table based on the defined criteria, we can say that the following four ontologies in Table II complement and resemble one another within the educational field. We benefited from these ontologies in terms of guidance and direction. So,

accordingly, we added our parts and built the HEO ontology.

2) *Define important terms:* Before creating the classes, and the properties, it is important to create a list of all the important terms for creating an ontology, whether for making statements about or describing it to users. We can identify and extract different terms that are used to describe classes, properties, and associations by exploring and understanding the source data. As mentioned earlier, in our case, we relied on two live systems at King Abdulaziz University (i.e., AIMS and OUDS PLUS) to obtain the data and create our ontology. Amongst others, two key documents we identified as our source of information are as below:

- 1) CVs of faculty members.
- 2) Course Syllabus.

Table III shows the most important terms extracted from these two files.

3) *Defining ontology classes and their hierarchy:* This is a core phase for organizing and introducing the structure to the captured terms in the previous phase. The phase of defining important terms can help us in designing the class hierarchy, wherein we can choose the most appropriate terms and define the independent existence for building super and subclasses. Classes are used to denote the collection of things that make up a concept. These classes can be linked to other classes through relationships when appropriate. In this phase, we define some classes that are used in the construction of HEO. Table IV illustrates some classes used in the domain that are identified to construct the ontology.

TABLE III. TERMS RELATED TO FACULTY MEMBERS' CVS AND COURSE SYLLABUS

CVs of faculty members	Course Syllabus
Academic Staff	Course
Assistant Professor	Syllabus
Associate Professor	Assessment Tool
Lecturer	Assignments
Professor	Exam
Teaching Assistant	Questions
Keywords	Lab Work
Academic and Professional Experiences	Project
Certifications and Trainings	Quiz
Publications Keywords	Class Activity
Research Interests	Learning Outcome
Publications	Course Learning Outcomes
Book	Student Outcome

4) *Describe properties and relationships of classes:* Super and subclasses alone do not provide us with sufficient information to answer CQs. After defining the main classes, we must describe the structure of these concepts. Also, we can use the rest of the terms that are already defined and represent them as properties. Entities that describe how individuals are related are called object properties. Also, properties can be structured in hierarchies. The permitted classes as values of properties are called the range of the property, while the actual classes that use the property are called the domain of the property. In this phase, we define some properties and relationships that are used in the development of HEO. The tables from V to IX explain the most important properties and how these properties are used to perform machine reasoning and to infer the new knowledge graphs.

5) *Create instances:* The final step in the ontology building phase is the creation of instances for defined classes. In semantic technologies, instances are also referred to as individuals. We can also think of them as objects of classes (to some extent). This involves selecting a class, creating its instance, and filling in the value of the property. These instances should meet the created questions and use cases. Ontologies can be better utilized with an enhanced number of instances (i.e., datasets). Instances have a vital role in the processes of semantic searches, data analysis, and exploration of new knowledge, in addition to evaluation processes. The answers that the ontology returns in the SPARQL queries of competency questions are based on instances. We enriched the scope of our ontology by extracting and populating our ontology with real-life data from the Faculty of Computing and Information Technology (FCIT) at King Abdulaziz University (KAU) (as a real case study).

C. Evaluation

The ontology must be evaluated to find any potential errors. Verifying the accuracy and fine-tuning of the ontology is the primary focus of this phase. Ultimately the target is to make sure of the domain coverage, quality of the development, and accuracy of the ontology design. We can verify the consistency, viability, and efficiency of the ontology by using the reasoners. The reasoners guarantee that there are no contradictory facts in the ontology. Also, this ascertains if the classes or properties can contain any type of individuals. In our case study, we use the Pallet reasoner at every stage of ontology development.

Fig. 3 shows the results of ontology consistency. Also, we used the Competency Questions (CQ) which we defined earlier in the ontology development Phase. The answers to the CQ are provided in Section IV which explains in detail the case study of the cooperation process between the faculty members.

INFO 21:11:23 Ontologies processed in 411 ms by Pellet
INFO 21:11:23 REASONER CHANGED
```

Fig. 3. Ontology consistency by pallet reasoner

D. Documentation

The last phase of MODD is documenting the ontology. It is a very important phase to understand the classes and the properties and their relationship with one another. The documentation phase is the creation of guidelines and instructions to clarify the domain and the purpose of the ontology. The lack of documentation may be one of the most significant obstacles preventing knowledge engineers from reusing the ontology. Documentation helps in understanding the ontology, reuse, and reviews. Each statement in the ontology must be explained in detail within the documentation. If there are no comments or explanations, this will make the ontology difficult to understand. So, we used both the "rdfs:comment" and "rdfs:label" properties to add descriptions and meaning for classes, object properties, and data properties.

E. Maintenance

Everything in the world is subject to change, and thus the ontology specifications may change to meet the requirements of the users and to suit other existing educational ontologies. It is very important to carry out periodic maintenance operations to organize the ontology by adding some classes, sub-classes, properties, and their relations with each other. Also, the documentation may be updated by adding meaning to unknown words and their logical description. Also, the availability of RDF/OWL links may be ensured to save time and facilitate the re-using phase for other researchers. Finally, mapping with LODC can be implemented so anyone can access, connect, and consume the data on an internet scale.

IV. CASE STUDY: FIND THE RIGHT RESOURCE FOR RESEARCH COLLABORATION

The cooperation process between researchers and faculty members starts with finding the right resources for joint research. Finding the right resources depends on matching different attributes such as faculty member or researcher publications, research interests, certifications and training, and academic as well as professional experiences. Further, applying machine reasoning on these attributes can play an important role in analyzing data consistency and extracting new knowledge and bigger knowledge graphs from an existing one. As an example, in our case study activity, the reasoning was

TABLE IV. SOME CLASSES USED IN HEO

Class Name	Discription
Academic_Staff	The academic staff of the university, college and department (e.g., assistant professor, associate professor, professor).
Professor	A professor can manage and coordinate most of the the activities within a course such as learning outcomes, design & implementation, topics, or be the instructor in some courses.
Associate_Professor	The associate professor can manage and coordinate most of the the activities within a course such as learning outcomes, design & implementation, topics, or be the instructor in some courses.
Assistant_Professor	The assistant professor can manage and coordinate most of the the activities within a course such as learning outcomes, design & implementation, topics, or be the instructor in some courses.
Lecturer	The lecturer is (teaching) assisting in a course. This is a person who holds a master's degree.
Teaching_Assistant	The teaching assistant is (teaching) assisting in a course. This is a person who holds a bachelor's degree.
Research_Interests	Summarizes the areas of expertise of a person.
Certification_and_Training	Certification and training attended by the academic staff member.
Academic_and_Professional_Experiences	The experience that a staff member has in Professional and Academic world to justify one or more areas.
Publications_Keywords	Specific words that expose domain or topic of a research publication.
Class_Activity	The activities that are related to a class. It has two parts: in-class activity (Lectures, Class Exercises, Class Discussion/Participation, , Lab Sessions, Tutorial Sessions, Misc and Active Learning). out-class activity (Self-reading/Research, Teamwork & Group Discussion, Exercises, Lecture Summary, Design Problems, Case Study, Technical Writing).

TABLE V. *Related_to* PROPERTY

Object Property Name	Domain	Range	Property Type
<i>Related_to</i>	<i>Keywords</i>	<i>Course</i> <i>Research_Interests</i> <i>Academic_and_Professional_Experiences</i> <i>Publications_Keywords</i> <i>Certifications_and Trainings</i>	Transitive

Logical Description

\forall Keywords \in Academic staff \exists Keywords related to Course

Text Description

A course contents have implicit and/or explicit relation with the keywords of a publication, academic & professional experiences of a staff member, research interests, the certifications & training

Reasoning

Lets consider a Property (i.e., "Pr") that relates and individual "x" to individual "y", also an individual "y" to individual "z", then the ontology can infer that individual "x" is related to individual "z" via property "Pr" (as the type of property "Pr" is transitive). Once we model the property "Related_to" as transitive property, ontological reasoning can be used to identify that which staff member is suitable for research collaboration based on various factors such as, professional experiences, research interests, publication, certifications & trainings and topic coverage.

TABLE VI. *can_work_with* PROPERTY

Object Property Name	Domain	Range	Property Type
<i>Can_work_with</i>	<i>Teaching_Assistant</i> <i>Professor</i> <i>Lecturer</i> <i>Associate_Professor</i> <i>Assistant_Professor</i> <i>Academic_Staff</i>	<i>Teaching_Assistant</i> <i>Professor</i> <i>Lecturer</i> <i>Associate_Professor</i> <i>Assistant_Professor</i> <i>Academic_Staff</i>	Symmetric

Logical Description

\forall Academic staff \in FCIT \subseteq KAU \exists Academic staff can work with other Academic staff

Text Description

The academic staff members can work with other academic staff members based on their various matching factors and attributes such as certifications & trainings, research interests, academic & professional experiences and the keywords of their publications.

Reasoning

If a property "Pr" is symmetric, and this property relates individual "x" to individual "y" then the ontology can infer that individual "x" is also related to individual "y" via property "Pr". Once we design the characteristics of the property "can_work_with" as symmetric, the ontology can identify which academic staff can collaborate in publishing, teaching a course or starting joint research projects.

used to infer which faculty members or researchers could cooperate with in publishing, teaching a course, or starting joint research projects based on available data, research interests, publications, certifications and training, and academic and professional experiences.

Here, we describe how to find the right resource for research collaborations based on different contributing attributes and how machine reasoning is used to generate bigger knowledge graphs. A short description of these examples is as under:

- Example 1: Using research interest parameter to find

TABLE VII. *Experience_Since* PROPERTY

Object Property Name	Domain	Range	Property Type
<i>Experience_Since</i>	<i>Keywords</i>	<i>Experience_Since</i> <i>Academic_and_Professional_Experiences</i> <i>Publications_Keywords</i> <i>Certifications_and_Trainings</i> <i>Research_Interests</i>	Inverse Of
Logical Description			
Experience since represents as $S = \{2011, 2012, 2016, 2019 \dots \text{etc.}\} \forall \text{Academic staff} \in \text{FCIT} \subseteq \text{KAU} \exists X \in S$ such that each Keywords connecting with the Academic staff in specific X			
Text Description			
All four criterias (i.e. academic & professional experiences, keywords of the publications, certifications and trainings, research interests, and the) adds a typical kind of experience for specific academic staff members.			
Reasoning			
If the property (pr) links individual “x” to individual “y” then it’s inverse property will link individual “y” to individual “x”. In our HEO, we modeled the properties <i>Experience_Since</i> and <i>For_Keywords</i> as inverse of each other. This helped us to connect a specific keyword to a specific year. So, the machine can infer that the specific year complies with a specific keyword.			

TABLE VIII. *For_Keywords* PROPERTY

Object Name	Property	Domain	Range	Property Type
<i>For_Keywords</i>		<i>Experience_Since</i>	<i>Keywords</i> <i>Academic_and_Professional_Experiences</i> <i>Publications_Keywords</i> <i>Certifications_and_Trainings</i> <i>Research_Interests</i>	Inverse Of
Logical Description				
Experience since represents as $S = \{2011, 2012, 2016, 2019 \dots \text{etc.}\} \forall \text{Keywords} \in \text{Academic staff} \exists X \in S$ such that each Keywords connecting Academic staff within specific X				
Text Description				
The experience year which is related to a specific academic staff has a relationship with all the four identified criteria (academic and professional experiences, certifications and trainings, research interests and the keywords of the publications).				
Reasoning				
If a property (say “Pr”) links an individual “x” to individual “y” then its inverse property will link individual “y” to individual “x”. Two properties i.e., <i>For_Keywords</i> and <i>Experience_Since</i> are inverse of each other and these properties help for connecting a specific year to a specific keyword. So, the machine can infer that the specific keyword complies with a specific year.				

TABLE IX. *related_to_person* PROPERTY

Object Property Name	Domain	Range	Property Type
<i>related_to_person</i>	<i>Experience_Since</i>	<i>Academic_Staff</i>	Symmetric
Logical Description			
Experience since represents as $S = \{2011, 2012, 2016, 2019 \dots \text{etc.}\} \forall \text{Academic staff} \in \text{FCIT} \subseteq \text{KAU} \exists X \in S$ such that each X related to person			
Text Description			
Each academic staff member has experience years in four criteria, including academic & professional experiences, research interests, certifications & trainings, and the keywords of the publications.			
Reasoning			
Let’s consider the property “Pr” as a symmetric property, and it relates an individual “x” to individual “y” then the machine can infer that individual “y” is also related to individual “x” via property “Pr”. Once we assign the characteristic symmetric to the property “ <i>related_to_person</i> ”, the ontology can identify which experience year related to which academic staff			

the best research collaborator.

research collaborator.

- Example 2: Using scientific publications to find the best research collaborator.
- Example 2: Using multiple factors such as certification & trainings, research interests, academic & professional experiences, and publications, to find the best

[Example 1: Research Interests]

By creating *has_research_interests* property, we can conduct some queries to identify all the faculty members and potential researchers who are suitable for research collaboration based on their research interests. This can also help to find

which faculty member has the most priority to start joint and collaborative research projects based on the research interest's data. **CQ: Find specific academic staff to collaborate with other academic staff based on common research interests.**

Fig. 4A shows all the academic staff with the same research interests:

By conducting the following query we find that Dr.Muhammad can work with Dr. Naif because both of them have "LOD" and "SW" as a research interest. (As shown in Fig. 4B).

Fig. 6 shows the results of all the academic staff that can collaborate based on the four criteria.

In this section, we described selected CQs, their answers and the machine reasoning involved in answering each CQ. The rest of the CQs and answers to these extracted from real-life data are explained in the Higher Education Ontology (HEO) website¹.

V. CONCLUSION AND FUTURE WORK

One of the main activities in Higher Education (HE) institutions and research organizations is conducting high quality research. A key issue in conducting high quality research is to include the right resources in the research team as well as expert collaborators for joint research projects. Finding suitable and expert resources to conduct joint projects and research collaborations can be effectively addressed by applying semantic-based techniques and machine reasoning on research and researcher data. As an example, CVs of the researchers/faculty members and their scientific output can provide important data that can be used by machines to identify the right resources for research collaboration and joint research projects between the faculty members and researchers. In this paper, we presented a Methodology for Ontology Design and Development (MODD) and used this methodology to develop the Higher Education Ontology (HEO). This HEO can be used to automate various processes and activities in HE by using machine reasoning. As proof of concept, we presented a case study on "finding the right resources for joint research and scientific collaboration". In our case study, we answered various competency questions (CQ) enriching the HE data semantically and then applying reasoning on it by developing HEO. Finally, we evaluated and validated our approach by answering various CQs in the domain of HE. In future research, we plan to improve our ontology by applying as many higher education activities and

Advancing Hospital Cybersecurity Through IoT-Enabled Neural Network for Human Behavior Analysis and Anomaly Detection

Faisal ALmojel, Shailendra Mishra

Department of Computer Science, College of Computer and Information Sciences,
Majmaah University, Al Majmaah, 11952, Saudi Arabia

Abstract—The integration of Internet of Things (IoT) technologies in hospital environments has introduced transformative changes in patient care and operational efficiency. However, this increased connectivity also presents significant cybersecurity challenges, particularly concerning the protection of patient data and healthcare operations. This research explores the application of advanced machine learning models, specifically LSTM-CNN hybrid architectures, for anomaly detection and behavior analysis in hospital IoT ecosystems. Employing a mixed-methods approach, the study utilizes LSTM -CNN models, coupled with the Mobile Health Human Behavior Analysis dataset, to analyze human behavior in a cybersecurity context in the hospital. The model architecture, tailored for the dynamic nature of hospital IoT activities, features a layered. The training accuracy attains an impressive 99.53%, underscoring the model's proficiency in learning from the training data. On the testing set, the model exhibits robust generalization with an accuracy of 91.42%. This paper represents a significant advancement in the convergence of AI and healthcare cybersecurity. The model's efficacy and promising outcomes underscore its potential deployment in real-world hospital scenarios.

Keywords—IoT security; cyber security; network security; machine learning; LSTM

I. INTRODUCTION

The integration of Artificial Intelligence (AI) into cybersecurity, especially for the Internet of Things (IoT), is an important development in keeping our digital world safe. IoT is all about connecting everyday devices to the internet, from smart home appliances to complex industrial tools. These devices collect lots of data, which is very useful but also makes them targets for cyber attacks. That's why strong cybersecurity is essential. [1]. The increasing integration of technology, particularly the Internet of Things (IoT), in hospital environments has revolutionized healthcare delivery [2]. While these technological advancements offer unparalleled benefits, they also introduce new challenges, particularly in the realm of cybersecurity [3]. Hospitals are prime targets for cyber threats due to the sensitive nature of patient data and the critical reliance on interconnected devices. As such, fortifying the security of IoT systems in healthcare settings becomes imperative to ensure the confidentiality, integrity, and availability of critical medical information. In the past [4], cybersecurity mostly relied on set rules to protect against known threats. But as cyber attacks become more complex, especially with the rise of IoT, we need smarter and more flexible security solutions. This is where AI

comes in, particularly with technologies like neural networks and fuzzy systems.

Neural networks are a type of AI that learns from data and makes decisions, much like how our brains work [5]. They are great at recognizing patterns, including new and complicated cyber threats that older security methods might miss. Fuzzy systems are another type of AI that's good at making sense of uncertain or vague information [6]. This is helpful in cybersecurity, where it's not always clear if something is a threat. However, using these advanced AI methods in IoT is challenging because many IoT devices have limited power and can't handle complex calculations [7]. One solution is to use edge computing, which processes data closer to where it's collected. This approach can make things faster and reduce the need for sending data over long distances. Using AI in IoT cybersecurity is crucial. It makes our security systems more adaptable and better at handling the ever-changing nature of cyber threats. It's a key step in protecting our increasingly connected world.

A. Problem Evolution

The integration of Internet of Things (IoT) technologies within hospital environments has ushered in a new era of enhanced patient care and operational efficiency [8]. However, this increased connectivity also introduces significant cybersecurity challenges that threaten patient data integrity and the overall safety of healthcare operations. Hospital IoT ecosystems, comprised of interconnected devices and sensors, are particularly susceptible to a range of cyber threats due to inadequate security measures and outdated software.

One of the main concerns is the vulnerability of IoT devices in hospitals to various attacks, including unauthorized access, data breaches, and malware infections. These vulnerabilities stem from insufficient security measures and the use of outdated software, making it imperative to strengthen cybersecurity protocols to protect against such threats. Detecting anomalous behavior or deviations from normal patterns within the hospital IoT ecosystem is crucial for early identification and mitigation of potential security breaches [9]. An effective anomaly detection system can help in promptly identifying suspicious activities, thereby enhancing the overall security posture of hospital IoT deployments.

Safeguarding the integrity and privacy of sensitive patient data transmitted and stored by IoT devices is essential for

maintaining patient trust and compliance with regulatory standards [10]. Ensuring robust data integrity and privacy practices is paramount in healthcare settings to prevent unauthorized access or breaches that could compromise patient confidentiality. Hospitals require rapid detection and response capabilities to address cybersecurity incidents in real-time. The ability to detect and respond to threats promptly is critical [11] for minimizing the impact of cyberattacks on hospital operations and patient care. Real-time threat response mechanisms can help in mitigating risks and ensuring the continuity of essential healthcare services.

Addressing these cybersecurity challenges associated with IoT deployments in hospitals is essential to protect patient data, maintain operational continuity, and uphold regulatory compliance. By implementing effective security measures, enhancing anomaly detection capabilities, and prioritizing data integrity and real-time threat response, hospitals can strengthen their cybersecurity posture and mitigate risks associated with IoT technologies.

B. Research Aim and Objective

In light of these challenges, this research aims to:

- Develop and evaluate advanced machine learning models tailored for hospital IoT cybersecurity, focusing on human behavior analysis and anomaly detection.
- Enhance security mechanisms to protect hospital IoT devices and data integrity using innovative approaches.
- Provide practical insights and recommendations for implementing effective cybersecurity measures in hospital environments.

The novelty of this research lies in the development and evaluation of advanced machine learning models specifically tailored for hospital IoT cybersecurity. By focusing on human behaviour analysis and anomaly detection within the hospital IoT ecosystem, this study introduces innovative approaches to address the unique cybersecurity challenges faced by healthcare organizations. The primary contribution of this research is the advancement of cybersecurity strategies designed specifically for hospital IoT environments. By developing and evaluating machine learning models for anomaly detection and data integrity protection, this study aims to enhance the security mechanisms of hospital IoT devices.

The paper is structured as follows: Section II provides a comprehensive review of the literature, Section III outlines the methodology employed in the proposed work, Section IV highlights implementation. Section V presents the experimental results and analysis, and finally, Section VI concludes the study while outlining avenues for future research.

II. RELATED WORKS

The Internet of Things (IoT) emerged as a revolutionary paradigm, introducing an interconnected world where everyday objects are equipped with network connectivity, enabling them to collect and exchange data. However, it has simultaneously introduced a myriad of cybersecurity challenges, necessitating a paradigm shift in the approaches to securing networks and devices. The integration of Artificial Intelligence (AI) into

cybersecurity strategies for IoT systems represents a significant advancement in this domain, offering novel and effective solutions to complex security issues [12]. The context of IoT cybersecurity encompasses a diverse array of devices, ranging from simple sensors to complex machines, all interconnected and potentially accessible via the Internet [13]. These devices continuously generate, process, and transmit vast amounts of data, some of which are highly sensitive and confidential.

The decentralized and ubiquitous nature of IoT devices makes them susceptible to a wide range of cyber threats, including but not limited to, unauthorized access, data breaches, and Distributed Denial of Service (DDoS) attacks [14]. The inherent limitations of IoT devices, such as constrained computational power and storage capacity, further complicate the implementation of traditional cybersecurity measures. In light of these challenges, AI emerges as a critical tool in the cybersecurity toolkit. AI's ability to learn from data, recognize patterns, and make decisions with minimal human intervention makes it ideally suited for enhancing IoT security [15]. Machine learning algorithms, a subset of AI, can analyze vast datasets generated by IoT devices to detect anomalies, predict potential threats, and initiate preemptive actions to thwart cyber-attacks. This capability is particularly crucial in an environment where the volume, variety, and velocity of data exceed human analysts' capacity to monitor and respond [16].

The significance of AI in IoT cybersecurity cannot be overstated, as IoT devices continue to proliferate, the potential attack surface for cybercriminals expands exponentially, AI driven cybersecurity solutions can dynamically adapt to evolving threats, unlike static, rule-based systems, they can learn from each interaction, continuously improving their ability to detect and respond to new types of attacks [17]. Furthermore, AI can automate routine tasks, freeing human resources to focus on more complex and strategic activities [18]. Additionally, AI technologies such as neural networks and fuzzy systems offer sophisticated means of identifying subtle patterns and ambiguities in data that might elude traditional security mechanisms [19]. These technologies are particularly adept at dealing with the uncertainty and imprecision inherent in real-world data, making them invaluable in crafting robust security frameworks for IoT environments [20]. The integration of AI into IoT cybersecurity is not just an enhancement but a necessity in the current digital era [21]. As cyber threats become more sophisticated and IoT networks more complex, AI offers the adaptability, efficiency, and scalability required to safeguard these interconnected systems.

This integration represents a promising frontier in the quest to balance the benefits of IoT with the imperative of maintaining robust cybersecurity defences. In the intricate domain of Internet of Things (IoT) cybersecurity, the integration and application of Artificial Intelligence AI have become pivotal areas of research and development. The escalating complexity of cyber threats in the IoT ecosystem necessitates a deeper exploration into AI driven solutions. This article provides a scholarly overview of pertinent literature and research articles that shed light on the intersection of AI and IoT cybersecurity, offering insights into current trends challenges, and future directions in this field in the role of AI in IoT security. This article in [22] delivers an extensive exploration of how AI strengthens IoT security,

showcasing its ability to identify and adaptively respond to advanced threats. At the same time, it thoughtfully considers the possible dangers of AI, such as its deployment in sophisticated cyber-attacks targeting IoT infrastructures. This balanced examination presents AI as both a key solution and a potential hazard in the context of IoT cybersecurity.

This [23] paper focuses on the use of artificial neural networks in enhancing IoT cybersecurity. It explores how these networks, thanks to their sophisticated pattern recognition abilities, can identify intricate and changing cyber threats within IoT settings. Additionally, the article addresses the challenges and the high computational requirements involved in implementing neural networks in IoT devices that have limited resources. Offering a comprehensive overview, this article [24] discusses the broad spectrum of AI applications in addressing IoT security challenges. It highlights the opportunities AI presents in automating threat detection and response while also acknowledging the limitations, such as AI's vulnerability to adversarial attacks and the ethical implications of AI in surveillance and data processing [25].

A. Research Gaps

In the rapidly evolving field of IoT cybersecurity, bolstered by advancements in Artificial Intelligence (AI), identifying and addressing research gaps is crucial for the development of robust and effective security solutions. Despite considerable advancements, there are still many unexplored areas that present opportunities for future research. One significant gap is in the scalability and adaptability of AI models within IoT environments. Most AI security solutions are developed and tested in controlled or small-scale environments, which may not effectively mirror the complex and dynamic nature of real-world IoT systems. There's a need for research that targets the scalability of these AI solutions to ensure they work efficiently in extensive, varied IoT networks. Another important area for further study is the energy efficiency of AI algorithms in IoT devices. Given that many IoT devices have limited computational and energy resources, implementing resource-heavy AI models is challenging. Research into creating lightweight, energy-efficient AI models that can operate effectively on these constrained devices is critical.

Moreover, the security of the AI models themselves is a growing concern. AI systems, especially machine learning models, are vulnerable to various forms of attacks, such as adversarial attacks, data poisoning, and model evasion techniques. There's a significant need for research focused on increasing the resilience of AI models against these kinds of attacks. Finally, the ethical considerations of using AI in IoT cybersecurity, particularly regarding privacy and data protection, are areas that require more attention. As AI systems often need access to large amounts of data, research that addresses privacy issues is crucial to ensure that AI-enhanced cybersecurity solutions do not infringe on user privacy. Overall, addressing these research gaps is vital for advancing the field of IoT cybersecurity and harnessing the full potential of AI in creating secure, efficient, and trustworthy IoT systems.

B. Gap Analysis

Despite the growing body of literature on cybersecurity in IoT environments, there remains a notable gap in research focusing specifically on hospital IoT ecosystems. Existing studies often generalize IoT security challenges without delving into the unique complexities of healthcare settings. Few studies comprehensively address the interplay between human behavior analysis and anomaly detection within hospital IoT networks, which is critical for identifying and mitigating insider threats.

Furthermore, while some research explores machine learning techniques for IoT security, there is limited emphasis on practical implementation strategies tailored to hospital environments. Additionally, there is a dearth of literature on the integration of edge computing with AI-based security solutions to optimize performance on resource-constrained IoT devices commonly found in hospitals. This gap underscores the need for targeted research that addresses the specific cybersecurity challenges and requirements of hospital IoT deployments, offering practical solutions for enhancing data integrity, privacy, and real-time threat response.

III. METHODS

The methodology involves a comprehensive review of current IoT integration in healthcare, identifying cybersecurity vulnerabilities. There are concerns about data privacy and security, interoperability, and the need for standardized protocols and regulations surrounding IoT integration in healthcare. Data analysis and machine learning techniques are used to enhance hospital cybersecurity via IoT-enabled neural networks that monitor human behavior and detect anomalies.

A. System Design

The proposed system design in Fig. 1 leverages advanced AI techniques and IoT technologies to enhance cybersecurity within hospital environments, focusing on human behavior analysis and anomaly detection. The integration of these technologies aims to fortify security mechanisms and safeguard patient data and healthcare operations. The system components described form the foundation of an advanced AI-driven approach to analyze human behaviour and detect anomalies using wearable sensor data in hospital environments.

1) *Data collection and sensors:* This research used the MHEALTH dataset from Kaggle (MHEALTH Dataset Data Set (kaggle.com) encompasses body motion and vital signs recordings from ten volunteers engaging in 12 diverse physical activities, facilitated by wearable sensors placed on the chest, right wrist, and left ankle. This comprehensive dataset captures nuances like acceleration, rate of turn, and magnetic field orientation, alongside 2-lead ECG measurements for potential heart monitoring. With a sampling rate of 50 Hz and accompanying video recordings, it offers rich insights into daily activities performed in an out-of-lab setting, enhancing its applicability for activity recognition and health monitoring research. Further details on the dataset's size, demographics, and activity distribution would offer deeper insights into its generalizability across diverse populations and real-world scenarios [1].

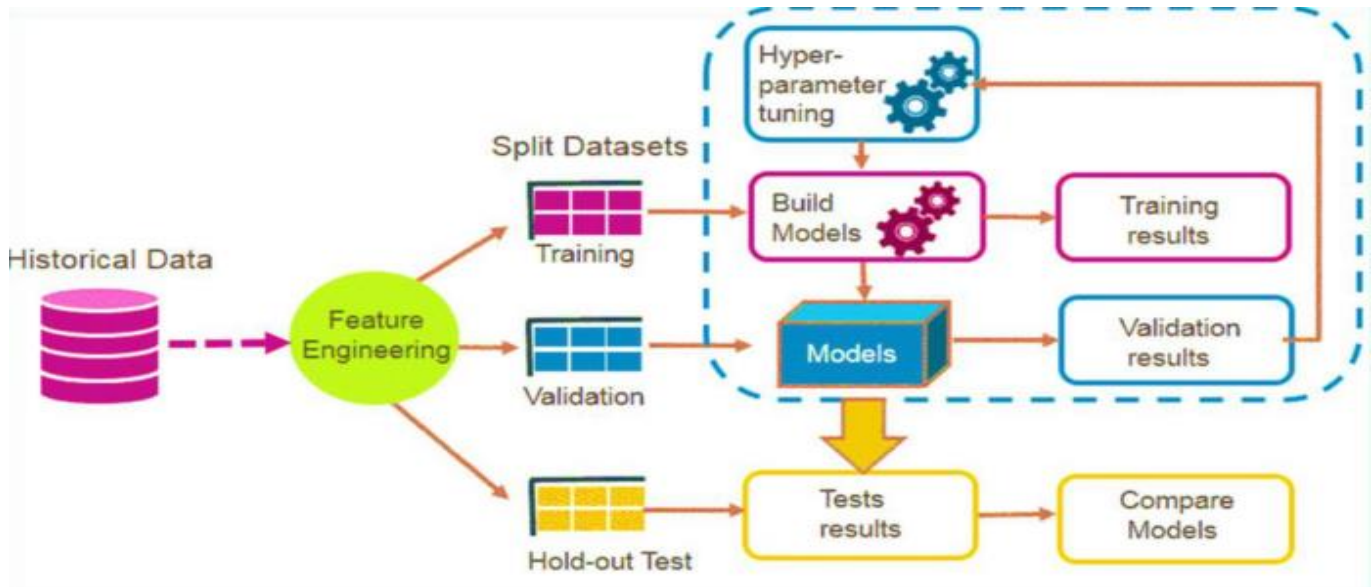

Fig. 1. System design.

2) *Data preprocessing*: Raw sensor data undergoes a comprehensive preprocessing pipeline, encompassing cleaning, outlier detection, and feature extraction. This preprocessing phase ensures that the data is refined and ready for subsequent model training and analysis, enhancing the accuracy and efficiency of the system.

3) Machine Learning Models

a) *LSTM-CNN Hybrid Model*: The system integrates a sophisticated hybrid machine learning architecture, combining Long Short-Term Memory (LSTM) and Convolutional Neural Network (CNN) components. This hybridization harnesses LSTM's capability to capture temporal dependencies in human behavior sequences, facilitating the analysis of sequential patterns and activities over time. Meanwhile, the CNN processes spatial patterns extracted from accelerometer and gyroscope readings, focusing on relevant features pertinent to behavior analysis.

The LSTM-CNN integration in the Neural Network context for cybersecurity in hospitals, the equation can be represented as follows:

Let x represent the input data, where x is fed into the LSTM-CNN hybrid model.

$$\text{LSTM}(\text{CNN}(x)) = \text{fLSTM}(\text{CNN}(x)) \dots \dots (1)$$

Here, $\text{CNN}(x)$ denotes the output of the CNN layer, which processes the input data x . The output of the CNN layer is then passed to the LSTM layer, denoted as $\text{LSTM}(\text{CNN}(x))$, where fLSTM represents the operations performed by the LSTM layer. This integration allows for capturing both spatial and temporal dependencies in the data, making it suitable for tasks such as anomaly detection and classification in hospital cybersecurity systems.

Hybrid Algorithm

Here is the pseudocode representation for the integration LSTM-CNN hybrid model:

- Step 1: Initialize the number of convolution blocks as N .
- Step 2: For $i = 1$ to N :
- Step 3: Apply additional features from forward and backward paths for better enhancement.
- Step 4: Obtain the spatial features using Equations (2) to (6) (i.e., $\text{CNN}(x)$).
- Step 5: Get the local best parameters and global best parameters.
- Step 6: Continue check:
- Step 7: If condition (Eq. 1) holds:
- Step 8: Retain the previous state value.
- Step 9: Else if condition (Eq. 1) does not hold.
- Step 10: Update $\text{LSTM}(\text{CNN}(x))$ and $\text{fLSTM}(\text{CNN}(x))$.
- Step 11: Calculate $\text{LSTM}(\text{CNN}(x))$ by taking the average combination of min, max, and global values.
- Step 12: End if.
- Step 13: End for.

b) *Anomaly detection and behavior analysis*: The machine learning models are specifically designed and trained to excel in anomaly detection and human activity classification tasks using the Mobile Health Human Behavior Analysis dataset. By learning from patterns within the dataset, the models can accurately identify anomalous behavior and classify different human activities in real-world scenarios. The process begins with utilizing this comprehensive dataset, which includes detailed data on various human activities and behaviors captured through mobile health devices and IoT sensors. This data encompasses movement patterns, physiological signals, and interactions with medical equipment. This approach enables continuous monitoring and enhances

hospital cybersecurity by detecting and responding to unusual behaviors or potential security threats promptly.

IV. IMPLEMENTATION

For implementing an LSTM-CNN Hybrid Model anomaly detection system tailored for IoT cybersecurity, the research follows a structured approach using Jupyter Notebook format and Python programming language. The implementation involves the following steps:

A. Dataset Collection and Preprocessing

- **Data Collection:** Gather data from IoT devices used in hospital settings for patient monitoring and other healthcare applications. This dataset will serve as the foundation for training the neural network.
- **Data Preprocessing:** Clean the collected data to remove noise, outliers, or irrelevant information. Prepare the data by organizing it into suitable formats for input to the neural network. This includes feature extraction and normalization to ensure uniformity in data representation.

B. Hybrid model Architecture Design

Selection of Neural Network Type: Choose an appropriate neural network architecture suitable for anomaly detection in IoT data., hybrid models like LSTM-CNN. Now training the model.

- **Dataset Splitting:** Divide the preprocessed dataset into training and testing subsets. The training set is used to optimize the neural network's parameters.
- **Model Training:** Employ the training set to train the hybrid model. During training, the network's weights and biases are adjusted iteratively using backpropagation to minimize prediction errors.
- **Testing Set Utilization:** Validate the trained neural network using the testing set to assess its performance in detecting anomalies.
- **Performance Metrics:** Evaluate the neural network's performance using metrics such as accuracy, precision, recall, and F1-score. These metrics provide insights into the model's effectiveness in identifying anomalous behaviour in IoT data.

C. Hydride Model (LSTM-CNN) Implementation

We use hybrid model implemented to enhance IoT security within hospital environments. Given the temporal nature of the IoT data, the model architecture is tailored to effectively capture and analyze sequences of activities from various devices. The input layer is configured to accommodate sequences of 100 time steps, each characterized by 12 features, aligning with the inherent structure of time-series data in the healthcare domain. The subsequent dense layers, featuring rectified linear unit (ReLU) activation functions, facilitate the extraction of intricate patterns within the IoT activities.

To mitigate overfitting, a dropout layer with a dropout rate of 0.5 is strategically introduced after the first dense layer. The following dense layer, composed of 150 neurons, further refines

the learned representations. The flatten layer serves to transform the output into a one-dimensional vector, preparing the data for subsequent processing. Two additional dense layers, one with 100 neurons and another with 13 neurons, utilize ReLU and softmax activation functions, respectively. The former enhances the model's ability to discern nuanced features, while the latter produces probability distributions across the 13 distinct classes, representing different activities within the hospital IoT ecosystem.

In Fig. 2, the model comprises a total of 1,530,903 parameters, all of which are trainable, emphasizing its capacity to adapt and learn from the intricate patterns present in the hospital's IoT security data. This neural network architecture is poised to play a pivotal role in fortifying cybersecurity measures within the context of hospital IoT systems, ensuring the integrity and confidentiality of sensitive healthcare information.

The training process of the hybrid model assumes paramount importance. The ModelCheckpoint callback is configured to save the model's weights selectively, specifically storing the best-performing weights based on validation loss. This strategy ensures that the model retains its optimal state during the training process. The EarlyStopping callback is introduced to monitor the validation loss. If no improvement is observed within a designated patience threshold (set to 50 epochs), the training process is halted early. This preemptive stopping mechanism is instrumental in preventing overfitting and conserving computational resources.

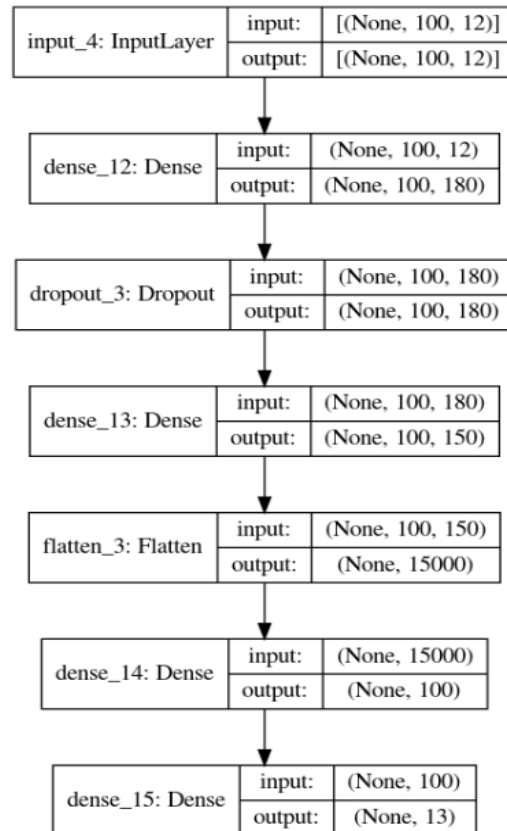

Fig. 2. Hybrid model.

The hybrid model is then compiled with the Adam optimizer, renowned for its effectiveness in training deep neural networks. For the loss function, sparse categorical cross-entropy is chosen, suited for multi-class classification tasks such as those encountered in IoT security, where each instance corresponds to a specific activity class. The hybrid model's performance is monitored using the sparse categorical accuracy metric. The model undergoes training on the prepared datasets. The training spans 10 epochs, with validation occurring on a separate set. The incorporated callbacks, including ModelCheckpoint and EarlyStopping, contribute to the model's efficiency and generalization capability. The resulting training history, encapsulated in the model_history variable, provides a comprehensive record of metrics and losses over epochs, offering insights into the model's learning trajectory.

This holistic approach to training the hybrid model underscores its adaptability and responsiveness to the intricacies of hospital IoT data, addressing the unique challenges posed by the dynamic and sensitive nature of healthcare environments.

The training history of the hybrid model over 10 epochs reveals a substantial performance improvement. The model exhibits a diminishing loss, starting from 2.1426 and culminating in a remarkably low value of 0.0064. Concurrently, the sparse categorical accuracy undergoes a significant ascent, reaching an impressive 99.84%. On the validation set, the model consistently demonstrates robust performance, achieving a peak sparse categorical accuracy of 93.99%. These outcomes underscore the model's effectiveness in learning intricate patterns within the hospital IoT security data, suggesting its potential for reliable deployment in safeguarding healthcare information systems.

D. Model Evaluation and Validations

Fig. 3 represents the model's training and validation performance provides insightful perspectives on its learning

Fig. 3. Training and validation loss vs. training and validation accuracy.

dynamics. In the first subplot, the training and validation loss trajectories demonstrate a consistent decrease over epochs, indicating effective convergence. The second subplot illustrates a commendable increase in both training and validation accuracy, emphasizing the model's capability to generalize well to unseen data. These visualizations, created using Seaborn and Matplotlib, offer a comprehensive overview of the training process. Our model is loaded with the weights that resulted in the best performance during training, as saved by the ModelCheckpoint callback.

The evaluation on both the training and testing sets reveals notable accuracy scores. The training accuracy attains an impressive 99.53%, underscoring the model's proficiency in learning from the training data. On the testing set, the model exhibits robust generalization with an accuracy of 91.42%. These metrics in Table I signify the model's effectiveness in accurately classifying activities within the hospital IoT security dataset.

TABLE I. MODEL EFFECTIVENESS

Dataset	Loss	Accuracy
Training Set	0.0209	99.53%
Testing Set	0.2316	91.42%

The hybrid model evaluation process, encompassing visualizations, accuracy metrics, and predictions, collectively validates the model's capacity to comprehend and classify IoT activities within a hospital setting. These findings substantiate the model's potential for deployment in real-world scenarios, contributing to the enhancement of cybersecurity measures in healthcare IoT ecosystems.

V. RESULTS

A. Discussion

The obtained results are discussed in the context of previous findings and methodologies. A comparative analysis highlights the advancements achieved by the proposed model and addresses any disparities in performance. Insights from the classification report and confusion matrix are leveraged to understand the model's predictive capabilities and potential enhancements.

This Table II, provides a side-by-side comparison of model performance metrics, including accuracy, precision, recall, and F1 score, between a hypothetical previous research paper and the current study.

TABLE II. COMPARISON OF RESULT WITH PREVIOUS RESEARCH

Paper	Algorithms	Model Accuracy	Precision	Recall	F1 Score
[22]	KNN	0.87	0.89	0.84	0.86
[26]	LSTM	0.78	0.73	0.53	0.61
[27]	CNN-BiLSTM	0.85	0.82	0.80	0.81
Proposed work	LSTM-CNN	0.91	0.93	0.92	0.92

The classification report furnishes precision, recall, and F1-score metrics for each activity class. Notably, the model demonstrates high precision and recall for several classes, such as class 3 with a perfect F1-score of 1.00. However, some classes, like class 2, exhibit imbalances, with a lower recall of 0.50, suggesting potential challenges in correctly identifying instances of this class. The weighted average precision, recall, and F1-score are all indicative of the model's strong overall performance, with an accuracy of 91%.

Results in Table II, depicts the performance of proposed model is better than existing model in term of Model Accuracy, Precision, Recall, F1 Score.

Implementing a neural network-based anomaly detection system for IoT cybersecurity in hospital environments presents several inherent limitations that must be addressed to ensure practical feasibility and efficacy. The computational complexity associated with neural networks, especially sophisticated architectures like LSTM-CNN hybrids, poses a significant challenge. These models often require substantial computational resources and memory, which may not be readily available on resource-constrained IoT devices commonly used in hospitals. The quality and variability of training data are crucial factors influencing the performance of neural networks. Limited or biased datasets can lead to suboptimal model performance and generalization issues, affecting the reliability of anomaly detection in real-world hospital scenarios. Resource constraints inherent in IoT devices, such as limited processing power, memory, and energy, present practical challenges for deploying complex neural network models. Efficient optimization techniques and model simplifications are needed to adapt neural network-based cybersecurity solutions to the constraints of hospital IoT deployments.

Addressing these limitations requires a holistic approach that balances model complexity, data quality, interpretability, and resource efficiency to develop practical and scalable anomaly detection systems tailored for hospital IoT cybersecurity. Ongoing research efforts focusing on these challenges will contribute to the advancement and adoption of effective cybersecurity solutions in healthcare environments.

B. Results

The results of the machine learning model's performance, as visualized through the confusion matrix in Fig. 4, provide a detailed view of its predictions compared to the true labels for each class. The model shows exceptional accuracy in predicting class 1, with 204 correct predictions and no misclassifications, indicating a strong ability to capture the features associated with this class. However, there are notable misclassifications for class 2, where 100 instances were mistakenly predicted as class 7.

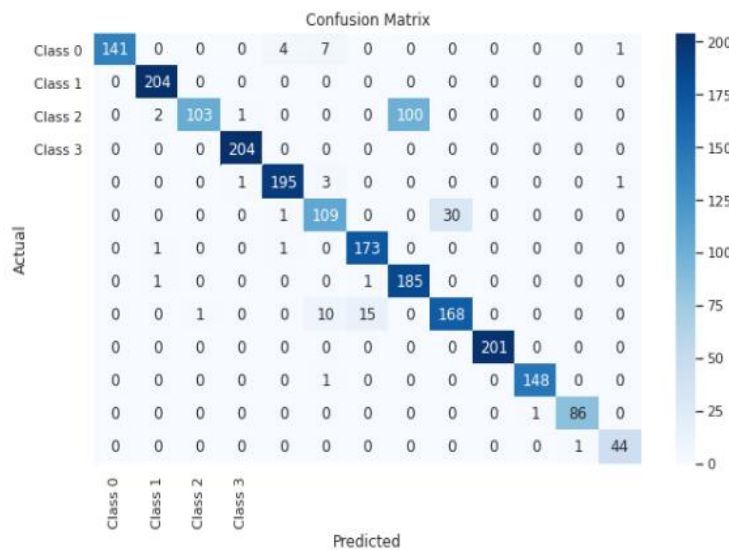

Fig. 4. Confusion matrix.

This suggests overlapping features between these classes, highlighting a need for better feature differentiation. Overall, the confusion matrix underscores the model's proficiency in capturing intricate patterns across various classes but also points out specific areas for improvement, such as reducing feature overlap and addressing data imbalance. The supervisor comments on the model's strong performance but emphasizes the need to refine the feature set and explore advanced techniques to improve accuracy, particularly for frequently misclassified classes. They also recommend increasing the diversity and size of the training dataset and conducting thorough error analysis to understand the root causes of misclassifications, providing a clear direction for enhancing the model's robustness and reliability in detecting anomalies and classifying human activities in healthcare settings.

VI. CONCLUSIONS

This research has demonstrated the feasibility and potential of implementing a neural network-based anomaly detection system for IoT cybersecurity in hospital environments. By leveraging advanced machine learning techniques, particularly LSTM-CNN hybrid models, we have significantly enhanced anomaly detection capabilities and improved cybersecurity measures to safeguard patient data and ensure the continuity of healthcare operations. The results obtained from our experiments highlight the model's effectiveness in identifying anomalous behaviors and its proficiency in handling the unique challenges posed by hospital IoT ecosystems. Our findings underscore the importance of deploying sophisticated AI-driven security solutions. The confusion matrix revealed high accuracy in predicting certain classes, such as class 1, while also identifying areas for improvement, such as the misclassifications between classes 2 and 7. This indicates the model's strong ability to capture intricate patterns, yet it also points to the need for better feature differentiation and handling of data imbalances.

Looking ahead, future research endeavors should focus on several promising avenues for refinement and expansion. Augmenting datasets to encompass a wider range of activities will be crucial in enhancing the model's robustness and generalizability. Exploring additional features for more nuanced security detection and optimizing model architectures through hyperparameter tuning will further improve the system's accuracy. Moreover, designing models with real-time adaptability and a focus on patient privacy compliance will be paramount in maintaining trust and effectiveness in healthcare environments. Interdisciplinary collaboration between healthcare, cybersecurity, and AI experts will be essential in addressing the multifaceted challenges of hospital IoT security. By overcoming existing limitations, embracing emerging technologies, and fostering partnerships, future work can fortify the synergy between artificial intelligence and healthcare cybersecurity. This will ensure robust protection for critical healthcare infrastructures, ultimately leading to safer and more resilient hospital environments. Detailed discussions on the presented results and their implications emphasize the significant strides made and the potential for continued advancements in this vital area of research.

Tile Defect Recognition Network Based on Amplified Attention Mechanism and Feature Fusion

JiaMing Zhang, ZanXia Qiang, YuGang Li

School of Computer Science, Zhongyuan University of Technology, Zhengzhou, China

Abstract—For the current situation of low AP of tile defect detection with incomplete detection of defect types, this paper proposes YOLO-SA, a detection neural network based on the enhanced attention mechanism and feature fusion. We propose an enhanced attention mechanism named amplified attention mechanism to reduce the information attenuation of the defect information in the neural network and improve the AP of the neural network. Then, we use the EIoU loss function, the four-layer feature fusion, and let the backbone network directly involved in the detection and other methods to construct an excellent tile defect detection and recognition model Yolo-SA. In the experiments, this neural network achieves better experimental results with an improvement of 8.15 percentage points over Yolov5s and 8.93 percentage points over Yolov8n. The model proposed in this paper has high application value in the direction of tile defect recognition.

Keywords—Amplified attention mechanism; defect recognition; small target recognition; Yolo; feature fusion

I. INTRODUCTION

Tile defect detection is an essential part of modern industrial production. Tiles are widely used in the manufacturing, construction and decoration industries for flooring, walls, kitchens and bathrooms. However, due to various factors in the production process, various defects can appear on the surface of tiles, such as cracks, unevenness, color variations and stains. The detection of these defects is still plagued by a large number of small targets, variable and irregular shapes, inconspicuous features and other factors, companies in the manufacturing process cannot avoid producing tiles with various types of defects. These defects not only affect the aesthetics, but can also lead to a decrease in the functionality and durability of the tiles. Therefore, tile surface defect detection is a key task in visual inspection, the goal of which is to automatically detect and recognise possible defects, damage or undesirable features on the tile surface. A good tile defect recognition model can help companies to improve quality, save manual inspection costs, increase productivity, reduce defect rate, reduce environmental impact and energy consumption.

Several advances have been made in the field of tile defect detection. Traditional methods are mainly based on image processing techniques such as edge detection, texture analysis and shape matching. However, these methods are difficult to detect defects in complex textured backgrounds. In recent years, the development of deep learning techniques has brought new opportunities for tile defect detection. CNN, Faster-RCNN

[1], Yolov3, Yolov5 [2], etc. have average performance in defect detection and still need further improvement.

Y Huang et al. [3] implemented tile defect segmentation using MCue, U-Net [4] and Push networks by generating three channels of resized inputs with MCue, including an MCue saliency image and two original images; U-Net learns the most informative regions, which is essentially a deeply structured convolutional network; and Push network defines the prediction of defects through two fully connected layers and an output layer constructed to define the exact location of the predicted surface defects. The model can detect multiple surface defects from low-contrast images, but it cannot accurately detect multiple defects generated in real production. Wan G et al. [5] improved yolov5 by deepening the network layers and incorporating a Convolutional Block Attention Module (CBAM) [6] attention mechanism, and replaced the original convolution with a depth-separable convolution, obtaining a lightweight model that can detect small targets. Lu Q et al. [7] proposed an intelligent surface defect detection method for ceramic tiles based on the improved YOLOv5s algorithm, using Shufflenetv2 [8], Path Aggregation Network (PAN) [9], Feature Pyramid Network [10] and the attention mechanism to improve the model and achieve a lightweight and high-performance tile defect detection. Xie L et al. [11] proposed fusion feature CNN and added an attention mechanism to realise efficient tile surface defect detection. H Lu et al. [12] collected 1241 samples and realised tile defect detection based on acoustic waves and proposed a cross-attention mechanism based on acoustic wave information features to make the model defect detection, the final accuracy rate is 98.8%. Although the method is effective, the implementation cost of the method is relatively high. Stephen O et al. [13] used a hand-designed neural network to achieve the detection of cracks in floor tiles with an accuracy rate of 99.43%.

In this paper, methods such as Amplified Attention (AA) mechanism, 4-layer feature fusion, and direct addition of backbone network feature information to the detection header are proposed to improve the performance of the model. AA mechanism is a method used to improve the performance of the model. In tile defect detection, the AA mechanism can help the model to pay more attention to the defective region, thus improving the detection accuracy. The specific process is that by introducing the cross-channel attention mechanism into the convolutional neural network, the model can better capture the characteristics of the defects. This approach can further improve the performance of tile defect detection. Feature fusion improves the overall amount of feature information

captured by the model, which in turn improves the performance of the tile defect detection model. To enable the detection head to acquire more feature information, feature information from the backbone network was added to the detection head in this study. Finally, the Efficient Intersection over Union (EIoU) loss function was used to improve the accuracy of the model in predicting the direction of movement of the frame and to improve the accuracy of the model in predicting defects.

II. DATASETS

In this paper, we use the tile defect detection dataset provided by the Guangdong Province Tile Defect Detection Competition of 2021 Ali Tianchi, which consists of 5,388 images with image resolutions of $8192px \times 6,000px$ and $4096px \times 3,500px$. The dataset is labelled with six categories, namely Edge exception, Angular exception, White dotted flaw, Light color block flaw, Dark dotted flaw and Aperture flaw. Examples of ceramic tile defects are shown in Fig. 1.

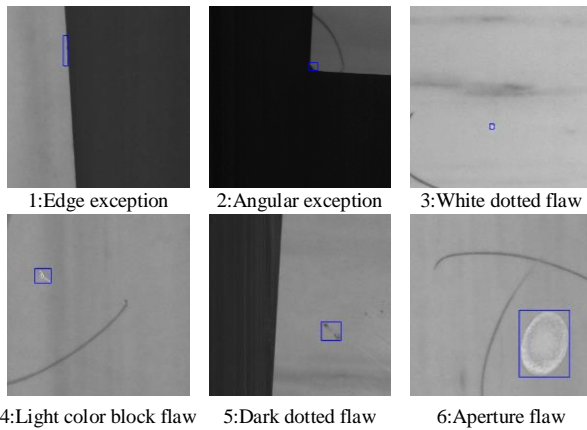

Fig. 1. Example of tile defects.

A. Image Segmentation

The image labelling frame statistics are shown in Fig. 2A, from which it can be seen that the labelling frames are mostly concentrated between 0 and 0.05, the size of the labelling frames for tile defects is extremely small relative to the whole image. If the whole image is fed into the neural network during training, the training speed will be very slow. Therefore, here the image is segmented for processing, the image segmentation method is that each image contains at least one tile defect detection point location, if it does not contain a tile defect detection point location, the segmented portion is considered as an invalid portion, and this segmented image is not generated. According to this method, the original image is segmented into images of $640 \text{ pixels} \times 640 \text{ pixels}$ and a total of 19960 images are obtained. The statistics of the labelled boxes after segmentation are shown in Fig. 2B, from which it can be seen that the size of the labelled boxes of the segmented tile defects with respect to the whole image is significantly improved compared to the pre-segmentation.

B. Data Augmentation

Models built from datasets with sufficient amount of data have stronger robustness and generalisation ability. Therefore, in order to improve the performance of the tile defect detection

model, online augmentation of the segmented tile defect dataset is improved. Online augmentation is the augmentation of the dataset during the training process, and in each epoch, a random augmentation is performed in proportion to the set augmentation strategy. The data augmentation strategies are HSV augmentation, flip, mosaic, zoom and pan, and the augmentation ratio of these data augmentation strategies in each epoch is 0.15, 0.5, 0.1, 0.5 and 0.3, respectively. The effect of the image after augmentation is shown in Fig. 3.

Fig. 2. Comparison of the statistics of defective labeling frames of tiles before segmentation and after segmentation.

Fig. 3. Dataset augmentation.

III. EXPERIMENTAL DESIGN AND METHODOLOGY

Firstly, a general overview of the YOLO-SA target detection neural network model is given, and then the design of the neural network structure of the YOLO-SA model is discussed from the three parts of the backbone network, the neck network and the detection head, respectively. In the YOLO-SA neural network structure, the backbone network is responsible for extracting the feature information of the tile defect image, the neck network can fuse the shallow feature information extracted by the backbone network with the deep

feature information to improve the feature information extraction ability of the neural network, and the detection head detects the feature information obtained from the neck network. The YOLO-SA network structure is shown in Fig. 4. In Fig. 4, conv, BN, LRelu, Silu [14], avgpool, maxpool denote convolutional computation, batch normalisation, leaky-Relu activation function, Silu activation function, average pooling and maximum pooling, respectively, and concat denotes the channel connection operation.

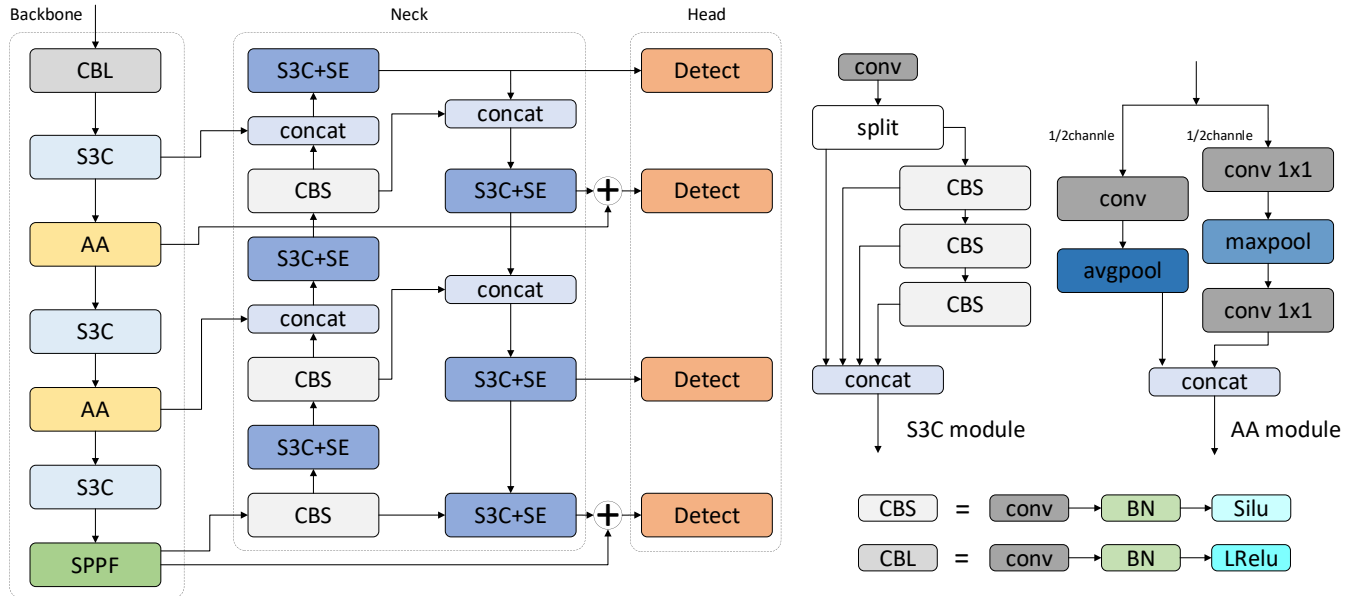

Fig. 4. YOLO-SA Neural network structure.

A. Overview

In YOLO-SA, backbone network includes CBL module, S3C module, AA module and Spatial Pyramid Pooling Fast (SPPF) [15] module, CBL module can effectively extract flat feature information, S3C module has very powerful feature information extraction ability, and AA module can effectively reduce degree of information loss in backbone network. Compared with the traditional CNN-based backbone feature extraction network, the backbone network of YOLO-SA only uses the information provided by the region when obtaining the target feature information, and this backbone network has a global modelling capability and a powerful remote dependency, which can better detect tile defects.

The SPPF module can fully extract the deep feature information from the backbone network, and the structure of the SPPF module is shown in Fig. 5. The main function of the SPPF is to perform a convolution operation on each region before the pooling operation, and to combine the convolution result and the pooling result as the output features. This method can retain more local feature information and improve the accuracy of the network. The appearance of SPPF makes the network more adaptable to objects of different sizes and effectively avoids problems such as image distortion caused by cropping and scaling operations of image regions. The calculation formula is:

$$AA = \text{concat}([F, \text{maxpool}(F), \text{maxpool}(\text{maxpool}(F)), \text{maxpool}(\text{maxpool}(\text{maxpool}(F)))], 1) \quad (1)$$

where, F denotes the input feature map.

Fig. 5. SPPF module.

In the neck network of YOLO-SA, the original three-layer PANet feature pyramid is expanded to four layers to fully integrate the feature information extracted from the backbone network. In addition, the Squeeze-and-Excitation Module (SE) [16] attention mechanism is added to this neck network to increase the attention to the target information in the spatial dimension and further improve the performance of the model. The SE has excellent information extraction ability, and at the same time, this attention mechanism requires much less computation compared to the CA mechanism, the CBAM, and so on. Therefore, the SE is used in YOLO-SA. The structure of the SPPF module is shown in Fig. 6.

Fig. 6. SE module.

B. Loss Functions

1) *IoU*: Intersection over Union (IoU), which is calculated as:

$$IoU = \frac{|A \cap B|}{|A \cup B|} \quad (2)$$

This means that the intersection of two regions is more than the concatenation of the last two sets. The visual representation is shown in Fig. 7.

Fig. 7. IoU concept

2) *GIoU*, *DIoU*, *CIoU*: Since IOU is calculated only for the overlapping region between the predicted and real frames and does not focus on the non-overlapping region, H Rezatofighi et al. [17] developed the Generalized Intersection over Union (GIoU) loss calculation function, which is formulated as:

$$GIoU = IoU - \frac{|C-U|}{|C|}, U = A \cup B \quad (3)$$

where C denotes the area of the minimum closure area of the prediction frame and the real frame, and U is the area of the concatenation of the prediction frame and the real frame. The image representation of each parameter is shown in Fig. 8.

Fig. 8. Explanation of each parameter of the GIoU, DIoU and CIoU

In order to obtain more information to better represent the gap between the prediction box and the real box, Zhaohui Zheng et al. proposed Distance Intersection over Union (DIoU) [18], DIoU adds more information into the regression calculation, such as the distance between the prediction box and the real box, and the size of the prediction box and the real box. The formula of DIoU is:

$$DIoU = IoU - \frac{\rho^2(b, b^{gt})}{c^2} \quad (4)$$

where b , b^{gt} represent the centroids of the predicted and real images, respectively, $\rho(\cdot)$ represents the computed Euclidean distance, and c represents the diagonal distance of the minimum closure region. The image representation of each parameter is shown in Fig. 8.

The factors considered by DIoU are still not able to meet the needs of loss calculation in practice. DIoU does not measure the difference in the size of the predicted frame and the real frame, so Zhaohui Zheng et al. [18] proposed Complete Intersection over Union (CIoU), which is calculated by the formula:

$$CIoU = DIoU - \alpha v$$

$$\alpha = \frac{v}{(1-IoU)+v} \quad (5)$$

$$v = \frac{4}{\pi^2} \left(\arctan \frac{w^{gt}}{h^{gt}} - \arctan \frac{w}{h} \right)^2$$

where α is the weight function, v is used to measure the similarity of the width-to-height ratio of the predicted frame to the real frame, and w , h , w^{gt} , and h^{gt} denote the width of the predicted frame, the height of the predicted frame, the width of the real frame, and the height of the real frame, respectively. The picture explanation is shown in Fig. 8.

CIoU adds the detection frame scale loss to DIoU, which allows the prediction frame to more accurately match the real frame by taking into account the length and width loss. The CIoU loss ($L_{CIoU} = 1 - CIoU$) can help the model to converge accurately and quickly during training, and to predict targets in complex backgrounds more accurately.

3) *EIoU*: The most important thing in YOLO-SA's recognition head is the loss function. The purpose of the loss function is mainly to make the model localisation more accurate and the recognition accuracy higher. In the process of tile defect recognition, because the tile defect target is very

small, in order to accurately recognise the feature information, so the box loss in YOLO-SA uses a more advanced EIou loss [19], which can more accurately measure the difference between the predicted bounding box and the real bounding box. The EIou loss is calculated as:

$$EIou = IOU - \frac{\rho^2(\mathbf{b}, \mathbf{b}^{gt})}{(w^c)^2 + (h^c)^2} - \frac{\rho^2(w, w^{gt})}{(w^c)^2} - \frac{\rho^2(h, h^{gt})}{(h^c)^2} \quad (6)$$

where w^c and h^c denote the width and height of the minimum closure region, respectively. the EIou parameter image is explained as shown in Fig. 9.

Fig. 9. Explanation of each parameter of the EIou

4) *Classification loss and box loss*: The classification loss function L_{cls} used in the YOLO-SA network is formulated as:

$$y_i = \text{Sigmoid}(x_i) = \frac{1}{1 + e^{-x_i}} \quad (7)$$

$$BCE = -\sum_{n=1}^N y_i^* \log(y_i) + (1 - y_i^*) \log(1 - y_i) \quad (8)$$

$$L_{cls}(\mathbf{c}_p, \mathbf{c}_{gt}) = BCE_{cls}^{sig}(\mathbf{c}_p, \mathbf{c}_{gt}; w_{cls}) \quad (9)$$

where N is the total number of categories, x_i is the predicted value of the current category, y_i is the probability of the current category obtained according to the activation function, and y_i^* is the true value of the current category (0 or 1), \mathbf{c}_p is the predicted probability of the category, \mathbf{c}_{gt} is the ground truth of the category, and w_{cls} is the weight of the current category. The confidence loss function is:

$$L_{obj}(p_0, p_{iou}) = BCE_{obj}^{sig}(p_0, p_{iou}; w_{obj}) \quad (10)$$

where p_0 is the confidence score of the target, p_{iou} is the iou value of the prediction frame and the corresponding target frame, and w_{obj} is the current target weight.

C. S3C Module

Compared with the Transformer module, the S3C module can effectively reduce the amount of computation and hardware requirements, and at the same time has almost the same ability to extract image information as the Transformer module. As shown in Fig. 1, the S3C module first splits the input channel, part of which is directly involved in the concatenation calculation, and the other part is calculated three times by the CBS module, and the result is calculated by the concatenation calculation after each calculation, and the final calculation result is obtained after the concatenation calculation is finished. After the experiment, it is proved that the module has excellent performance in the tile defect dataset. The calculation formula of S3C module is:

$$S3C = \text{concat}([\text{split}, \text{CBS}(\text{split}), \text{CBS}(\text{CBS}(\text{split})), \text{CBS}(\text{CBS}(\text{CBS}(\text{split}))), 1) \quad (11)$$

D. Amplified Attention Mechanism

The AA mechanism is proposed to address the situation that the tile defect target in this dataset is small and difficult to detect accurately. The structure of the enhanced attention mechanism is shown in Fig. 1. The avgpool on the left can obtain hierarchical feature information, which can better distinguish the target area from the non-target area. The $\text{conv}_{1 \times 1}$ structure on the right can further deepen the feature information obtained by the higher-level network; the maxpool can highlight the feature information of the deep feature map, thus further highlighting the target region; the $\text{conv}_{1 \times 1}$ structure at the back can narrow the depth of the image to facilitate the concatenation operation. The enhanced attention mechanism can reduce the degree of feature information loss during neural network training. The formula for the AA module is:

$$AA = \text{concat}([\text{avgpool}(\text{conv}), \text{conv}_{1 \times 1}(\text{maxpool}(\text{conv}_{1 \times 1}))], 1) \quad (12)$$

E. Four-Layer Feature Information Fusion

To further improve the performance of the neural network model for tile defect detection, a 4-layer PANet fusion module is proposed and the corresponding detection head is added to this module. The feature information fusion module is shown in the neck part of Fig. 1. In addition, to make the information flow more appropriate and reduce the loss of feature information, the computation results of an AA module and SPPF module in the backbone network are directly fused with the 2nd and 4th detection heads before operation.

IV. EXPERIMENTAL ENVIRONMENT AND EVALUATION INDICATORS

A. Experimental Environment

Experimental platform: OS Windows 11, CPU i9-12900K, GPU RTX5000 24GB, RAM 64GB, Pytorch 2.0.1, CUDA 11.8, PyCharm 2022.2.1, Anaconda 22.11.1.

In this study, the segmented dataset is divided into three parts according to the ratio of 8:1:1, which are training set, validation set and test set. The input size of the neural network for the tile defect image dataset is 640 pixels \times 640 pixels. The optimiser uses AdamW [20] with momentum set to 0.9, an initial learning rate of 0.001, and 100 iterations, keeping only the optimal model and the model produced by the last iteration.

B. Evaluation Indicators

The evaluation indicators used in this study include Precision, Recall, and mAP@0.5. Precision represents how many of the predicted positive samples are truly positive samples, Recall represents how many of the positive examples in the sample were predicted correctly, and mAP@0.5 represents the average accuracy of m categories when IoU is 0.5. The calculation formulas of precision and recall are shown in (1) and (2); the calculation formula of mAP@0.5 is shown in formula (3).

$$\text{Precision} = \frac{TP}{TP+FP} \quad (13)$$

$$\text{Recall} = \frac{TP}{TP+FN} \quad (14)$$

where TP is the number of positive classes predicted as positive, FP is the number of negative classes predicted as negative and FN is the number of negative classes predicted as negative.

$$mAP@0.5 = \frac{1}{m} \sum_{i \in m} \int_0^1 P(r_i) dr_i \quad \text{IoU} = 0.50 \quad (15)$$

$P(r_i)$ denotes the correspondence between recall and precision; mAP@a denotes the average precision of m categories when IoU is a.

V. EXPERIMENTAL RESULTS AND ANALYSIS

A. Performance Comparison Before and After Image Segmentation

Image segmentation has a great impact on the performance of the model, and segmentation can increase the size of the target and make it easier to detect. The performance comparison before and after segmentation on Yolov8n is shown in Table I. From the table, we can see that image segmentation has significantly improved the performance of the model.

TABLE I. PERFORMANCE COMPARISON BEFORE AND AFTER SEGMENTATION ON YOLOV8N

Image segmentation	Precision	Recall	mAP@0.5
Before _{640×640}	0.5712	0.1396	0.1727
Before _{1280×1280}	0.4027	0.1954	0.2281
After _{640×640}	0.5206	0.6813	0.6133

B. Performance Comparison Using the EIoU Loss Function

The comparison of the effectiveness of GIoU, CIoU and EIoU is shown in Table III. The CIoU loss function uses proportions to determine whether the size of the prediction frame is met or not, as there are very many small targets in this dataset, it is not easy to determine the prediction frame in terms of width to height proportions, so the EIoU loss function achieves a better result among these three loss functions.

TABLE II. COMPARISON OF THE EFFECTS OF EIoU, CIoU AND GIoU ON YOLOV8N

Loss Function	Precision	Recall	mAP@0.5
GIoU	0.3193	0.3724	0.3865
CIoU	0.5206	0.6813	0.6133
EIoU	0.5432	0.6859	0.6241

C. Performance Comparison between 4-layer Feature Fusion Module and 3-layer Feature Fusion Module

The 4-layer feature fusion module can obtain more deep information, which can enable the model to detect defects more accurately, and its performance is shown in Table IV.

D. Performance Comparison of the Enhanced Attention Mechanism with other Attention Mechanisms

To verify the effect in the tile recognition dataset, a comparison experiment is designed here to verify the effect comparison with other attention mechanisms, as shown in Table II. From Table II, we can see that the effect of AA attention is better than that of other attention mechanisms. A From Table II, we can see that the improvement of tile defect detection is better than that of other attention mechanisms, thanks to the feature of the AA mechanism of reducing the loss of feature information during the training process of the neural network.

TABLE III. PERFORMANCE COMPARISON OF FEATURE FUSION MODULES WITH DIFFERENT NUMBER OF LAYERS ON YOLOV8N

Number of layers in the fusion part	Precision	Recall	mAP@0.5
Three-layer feature fusion	0.5206	0.6813	0.6133
Four-layer feature fusion	0.5379	0.6935	0.6472

TABLE IV. PERFORMANCE COMPARISON OF AA MECHANISM WITH OTHER ATTENTION MECHANISMS IN YOLO-SA

Module name	Precision	Recall	mAP@0.5
SE	0.5820	0.7351	0.6925
CA	0.5783	0.7291	0.6892
ECA	0.5769	0.7274	0.6744
CBAM	0.5838	0.7418	0.6892
Muti-Head Attention	0.5981	0.7353	0.7011
AA	0.6032	0.7527	0.7024

E. Feature Information in the Backbone Network Added to the Detection Head

From Table V, it can be seen that the detection results after the backbone network is added to the detection head are improved over the detection results before it is added, and the method can effectively improve the performance of the model.

TABLE V. COMPARISON OF THE EFFECT OF YOLO-SA BACKBONE NETWORK FEATURE INFORMATION BEFORE AND AFTER ADDING IT DIRECTLY TO THE DETECTION HEADER

Method	Precision	Recall	mAP@0.5
	0.5206	0.6813	0.6133
AA	0.5515	0.7381	0.6713
SPPF	0.5729	0.7442	0.6739
AA+SPPF	0.6032	0.7527	0.7024

VI. CONCLUSION

The mAP@0.5 curves and loss functions of Yolov5s, Yolov8n, and Yolo-SA are shown in Fig. 10. Yolo-SA outperforms Yolov5s and Yolov8n, proving that the Yolo-SA model has a good ability to detect tile defects.

First, we dramatically improve the accuracy of defect detection by using image segmentation techniques, and the defect detection mAP@0.5 after segmentation is 48 percentage points higher than before segmentation at the same input

resolution. Then, we use the EIou loss function, AA attention mechanism, four-layer feature fusion, and let the backbone network directly participate in the detection to construct an excellent tiled defect detection and recognition model, which is capable of recognizing and detecting multiple defects in multiple complex backgrounds. The mAP@0.5 of the Yolo-SA model improves by 8.15 percentage points and 8.93 percentage points compared with that of the Yolov5s and the Yolov8n, respectively. The mAP@0.5 of the Yolo-SA model is improved by 8.15 percentage points and 8.93 percentage points compared to that of the Yolov5s and Yolov8n, respectively. The Yolo-SA model is able to detect tile defects under a variety of environments, and the actual detection results are shown in Fig. 11.

At present, the performance of the Yolo-SA model still has a lot of room for optimization. In practical applications, the

Yolo-SA model can only be used as an auxiliary model for artificial tile defect detection. In the future, large models can be combined to further improve the performance of the ceramic tile defect detection model, which can further improve the accuracy of ceramic tile defect detection in actual production scenarios, reduce unnecessary production, and thereby reduce energy consumption and environmental pollution.

TABLE VI. PERFORMANCE OF YOLOV5S, YOLOV8N, AND YOLO-SA

Model	Precision	Recall	mAP@0.5
Yolov5s	0.5310	0.7222	0.6209
Yolov8n	0.5130	0.6800	0.6131
Yolo-SA	0.6032	0.7527	0.7024

Tendon-Driven Robotic Arm Control Method Based on Radial Basis Function Adaptive Tracking Algorithm

Xiaoke Fang

College of Information Science and Engineering, Northeastern University, Shenyang 110004, China

Abstract—With the rapid development of intelligent technology, robotic arms are widely used in different fields. The study combines the tendon drive theory and radial basis function neural network to construct the robotic arm model, and then combines the back-stepping method and non-singular fast terminal sliding mode to improve the controller and system optimization of the tendon drive robotic arm model. Simulation tests on commercial mathematical software platforms yielded that joint 2 achieves stable overlap of position trajectory and velocity trajectory after 0.2s and 0.5s with errors of 1° and $1^\circ/s$, respectively. Radial basis function neural network approximation of robotic arm error converged to the true value at 14s. The optimized joint achieved the accuracy of trajectory tracking after 0.2s. Also the control torque of joint 2 changes at 1.5s, 4.5s and 8s and its change is small. The tendon tension curve was smoother and more stable in the range of $-0.05N\sim 0.05N$ to show that the robotic arm model has superiority after the optimization of the controller, and the interference observer had accurate estimation of the tracking trajectory of the tendon-driven robotic arm. Therefore, the radial basis function-based adaptive tracking algorithm had higher accuracy for the tendon-driven robotic arm model and provided technical reference for the control system of the intelligent robotic arm.

Keywords—Tendon drive; adaptive neural network; dynamic relationship; sliding membrane control; trajectory tracking

I. INTRODUCTION

Robot arm (RA) is a device that is programmed to move and manipulate a manipulator to perform a grasp-and-place operation [1]. With the development of computers, RAs are used in engineering fields such as ecosystem monitoring, aerospace and medical engineering [2-4]. RA, as an important component in robotic systems, can perform working robot control such as industrial assembly, safety and explosion prevention, and medical assistance [5]. Robot control lies in motion and dynamics, and RA, as a nonlinear system, is characterized by strong coupling and multivariate variables, and is easily affected by multiple uncertainties. The precise control of its joint angles and trajectory tracking (TT) requires the RA model to address the dynamics modeling errors, uncertain external disturbances, and unknown parameters, and then design controllers to improve the accuracy, stability, and flexibility of RA grasping [6-7]. And for the automation application technology of RA, its movement, grasping, obstacle avoidance and other aspects of the model construction, and according to the industrial needs of different forms of RA or robots for the assembly or intelligent

improvement. Among the RA's TT in mechanical structure, controller and other aspects of performance interference, so for the intelligent control method of RA, combined with the human arm structure of the apparatus to design. However, when the environment changes or complex parameters are generated, the motion control parameters of the robotic arm are limited by many factors, which poses significant challenges in automated operations. Control algorithms are currently the technological means for intelligent application of industrial robotic arms, and the feasibility of their motion control performance is ensured through precise parameters of robotic arm dynamics modeling. Systematic research and optimization are carried out in the areas of RA adaptive control and sliding mode control to solve the application problems of RA movement, control and grasping. To accurately establish the dynamic parameters of the robotic arm, the study utilizes tendon drive theory to explain the kinematic relationship between joints and displacement, in order to enhance the design and use of the controller. Based on this, the study combines radial basis function (RBF) neural network and controller design to provide an optimization approach for Tendon-driven robotic arm (TDRA) trajectory control method, which in turn improves the accuracy of TT control.

The research is carried out in six sections, Section I is an expository description of the current research results. Related works is given in Section II. Section III is to optimize the control performance of RA using back-stepping and Non-singular Fast Terminal Sliding Mode (NFTSM). Section IV gives detail about the TDRA control combining RBF and controller. Discussion is given in Section V. Finally, Section VI concluded the paper.

II. RELATED WORKS

The manufacturing of industrial automation has made extensive use of RA technology. In the realm of intelligent control, TT control of RA systems with uncertainty is a hotspot for research since many applications need RA to follow trajectory motion accurately. Over the last years, scholars at home and abroad have explored the application and improvement of RA. Zhao proposed a robotic arm control system based on multi feature videos regarding the issue of robotic arm grasping, and combined it with a laser rangefinder to verify the success rate of robotic arm grasping. Finally, the accuracy and feasibility of its robotic arm motion control were determined [8]. Yang et al. proposed a method for improving the effectiveness of robot automatic search tasks based on

airborne sensors and wearable embedded systems, combined with localization algorithms and motion control algorithms, regarding the localization and motion control issues of biological robots [9]. For the robot temperature sensing problem, He et al. proposed to implant the temperature sensor into the robot simulation finger using fiber grating, and measured the temperature with the goal to prove the feasibility and effectiveness of their approach [10]. For the tendon-driven manipulator TT problem, Peng et al. suggested to use a fuzzy logic control method and simulation testing of the linearized system, which in turn improves the performance of TT control [11]. Regarding the control system problem of the target grasping robot, Matsuda et al. proposed to use an image processing method and autonomous control of a mobile robot with a distance sensor and an object grasping arm, which in turn improves the accuracy of the robot's object grasping system [12]. Regarding the development of the robot's ability to move trajectory, motion tracking, and object grasping, a number of industrial-type robots have been put into application and effective results have been achieved.

In addition, robots and RA have a wide range of applications in medicine and industry, etc. In terms of robot motion models and TT, many research scholars have used many intelligent means and automation techniques to optimize and improve the model construction. Regarding the application of three-degree-of-freedom robots in medicine, Jiang et al. analyzed surgical robots and proposed using fiber optic sensors to optimize their ability to resist electromagnetic interference in surgical procedures, thereby demonstrating the superiority of surgical robots based on fiber optic and sensing technology [13]. For the application development problem of rehabilitation robots, Liu Y et al. proposed to use a control method based on surface EMG signals and combined with principal component analysis to improve the recognition accuracy, which in turn improves the effect of skeletal rehabilitation training [14]. Linxi et al. proposed a design feature space based on sparse point clouds to distinguish target characters for the tracking problem of outdoor mobile robots, and combined with motion planning algorithms to verify target detection and tracking performance, thereby increasing the robustness of robots to complex outdoor environments [15]. Naya Varela et al. proposed to combine biological morphological development and controllers for the bipedal robot walking problem, and then use neural evolution algorithms to verify the feasibility and practicality of bipedal robot walking [16]. Regarding the robot motion model construction problem, Fei proposed to use a joint torque estimation method based on dynamic characteristics and a traceless Kalman filter to simulate and test the flexibility model, and then prove the effectiveness and feasibility of his method [17].

In summary, although domestic and foreign researchers and scholars have carried out a number of model construction and technology optimization for the application development of RA. However, there is a lack of in-depth research on the widespread movement trajectory and joint flexibility testing for industrial development of robotic applications. At the same time, and existing research on the kinematic parameters such as joint displacement and torque of robotic arms still lacks

specific kinematic relationship derivation for their driving models, which affects the dynamic analysis of robotic arms. Therefore, the study innovatively cites the tendon drive theory and its system to enhance the compactness of the robotic arm joint structure, provide more accurate parameter relationships for dynamic modeling, and reduce the load on the joint drive. Afterwards, an RBF-Adaptive neural network (ANN), controller design, and disturbance observer were used to construct TDRA based on the RBF adaptive tracking algorithm, aiming to improve the accuracy of TT control and provide technical reference for the intelligent development of industrial robots.

III. CONSTRUCTION OF ROBOT ARM CONTROL SYSTEM BASED ON RBF-NN AND TENDON DRIVE

For the construction of Dynamics modeling (DM) of RA, the study combines the tendon drive theory and RBF-NN to build the ANN tracking control system [18]. And according to the nonlinear system with stronger disturbances and its TT problem, the study utilizes back-stepping and fuzzy control to globally control the modeling information of the TDRA in order to achieve accurate and stable TT. Finally, when the external disturbances and errors are large, the disturbance observer is introduced to the sliding membrane control (SMC), which in turn improves the accuracy of the TT.

A. TDRA's Dynamics Modeling and its Tracking Controller

The dynamics of the TDRA includes the analysis of the action and dynamics of the joint displacements, angles and velocities, while the dynamic structure of the RA is simplified to the base, the rear arm linkage and the forearm linkage. Among the commonly used modeling approaches are Lagrangian and Newtonian Eulerian methods, but the dynamics equations are applied consistently in the same system [19]. The most widely modeled approach is the Euler-Lagrange equation, where the RA is represented as shown in Eq. (1).

$$P(j)a + C(s, j)s + G(j) = \tau \quad (1)$$

In Eq. (1), $P(j) \in R^{n \times n}$ denotes the positive definite inertia matrix and n is the joints of the RA, j , s and a are the joint angular displacements, velocities and accelerations, respectively, and $j, s, a \in R^n$. $C(s, j) \in R^{n \times n}$ is the centripetal and Koch force matrix, and $G(j)$ is the gravity matrix and $G(j) \in R^n$. The input moment of the joints is $\tau \in R^n$ and $\tau = (\tau_1, \tau_2, \tau_3)^T$. The Lagrange kinetic equations are used to derive the DM, which leads to the positive definite inertia matrix as shown in Eq. (2).

$$P(j) = \begin{pmatrix} P_{11} & P_{12} & P_{13} \\ P_{21} & P_{22} & P_{23} \\ P_{31} & P_{32} & P_{33} \end{pmatrix} \quad (2)$$

In Eq. (2), $P(j)$ is the positive definite inertia matrix and $P_{12} = P_{13} = P_{21} = P_{31} = 0$. While the centripetal force and

the Koch matrix are expressed as shown in Eq. (3).

$$C(j,s) = \begin{pmatrix} C_{11} & C_{12} & C_{13} \\ C_{21} & C_{22} & C_{23} \\ C_{31} & C_{32} & C_{33} \end{pmatrix} \quad (3)$$

In Eq. (3), $C(s,j)$ is the centripetal and Koch force matrix and $C_{33} = 0$. The main motion of TDRA lies in the relationship between joint angle and tendon displacement, end-effector and joint angle displacement and joint torque and tendon tension. Where the mapping matrix of tendon tension to joint torque is shown in Eq. (4).

$$\tau = Rt \quad R = \begin{pmatrix} r_{11} & r_{12} & r_{13} & r_{14} \\ r_{21} & -r_{22} & r_{23} & -r_{24} \\ 0 & 0 & r_{33} & r_{34} \end{pmatrix} \quad (4)$$

In Eq. (4), τ and t are the joint moments and tendon tensions, respectively, and t denotes the column vector consisting of four tendon tensions. R is the mapping matrix from t to τ , where the element r_{ij} is denoted as the radius of the circular surface surrounded by the j th tendon on the i th joint itself and $i = 1 \sim 3, j = 1 \sim 4$. And the model results of the tendon actuator output to a specific joint are shown in Fig. 1.

Fig. 1. Schematic diagram of the structure of the tendon actuator output to the joint model.

The input linear spring modeling coefficients can be found in Fig. 1, and the tendon conversion is accomplished in the RA dynamics through the tendon tension and its mapping transformation. The tendon drive combined with RA makes it compact and reduces the load on the joint drive. The tendon drive facilitates controller design by acting as a flexible drive with zero backlash, hence reducing the weight and size of the joint working work. As for the RA tracking control problem under unknown DM, the study combines adaptive control with RBF-NN for modeling and tracking control of TDRA. Among them, RBF-NN has a structure primarily made up of an output layer, a hidden layer, and a hidden input layer. It is a three-layer feed-forward network with a single hidden layer. Among them, the input layer contains a number of signal source nodes, and the nonlinear radial function in the hidden layer, which gradually decreases from the center. RBF is used as the activation function in the hidden layer, which in turn maps the input vector directly to the hidden layer. And the output nodes form the output layer, and then the weight matrix

is used to calculate the output value. To solve the constraint problem of RA tendon rope tension, the study uses RBF-NN for the parameters of DM and constructs the tracking control of ANN as demonstrated in Fig. 2.

Fig. 2. Adaptive RBF neural network tracking control structure diagram.

From Fig. 2, it is concluded that the DM of TDRA introduces an auxiliary system to solve the tendon tension constraint problem, and the adaptive controller acts on the tendon tension to achieve adaptive control. And through the tendon mapping matrix transformation and RA and its joint parameters, the model information is input to RBF-NN. The RBF-NN controller approaches the unknown dynamic parameters of the RA, which in turn facilitates the optimization of its tracking control performance. According to the RBF-NN's proximity to the unknown dynamical parameters, the DM formulation of its RA, as shown in Eq. (5).

$$\begin{cases} x_1 = j, x_2 = s \\ \dot{x}_1 = x_2 \\ \dot{x}_2 = P^{-1}(x_1) \times [\tau - C(x_1, x_2)x_2 - G(x_1)] \\ \tau = Rt \end{cases} \quad (5)$$

In Eq. (5), $C(x_1, x_2)$ is the centripetal and Koch force matrix and $G(x_1)$ is the gravity force matrix. And to minimize the effect of tendon rope constraint, the auxiliary system is shown in Eq. (6).

$$A = \begin{cases} -K_\zeta \zeta - \frac{|y_2^T \zeta f| + 0.5 \zeta^T F \zeta}{\|\zeta\|^2} - f & \|\zeta\| \geq c \\ 0 & \|\zeta\| \leq c \end{cases} \quad (6)$$

In Eq. (6), ζ represents the state of the auxiliary system

and $\zeta \in R^{n \times 1}$, and additionally $\begin{cases} K_\zeta = K_\zeta^T > 0 \\ \zeta f = S(f) - f \end{cases}$, the saturation function is modeled as

$$S(f) = \begin{cases} S_{\max} \operatorname{sgn}(x), |f| \geq \tau \\ f, |f| < \tau \end{cases}, \text{ where } S_{\max} \text{ is the upper saturation limit. The sign function is } \operatorname{sgn}(x) = \begin{cases} 1, x > 0 \\ 0, x = 0 \\ -1, x < 0 \end{cases}, c$$

is a smaller positive constant. The DM of RBF-NN computes the adaptive law values of the neural network weights, and the model estimates the control law, so improving the robustness

of the error control. Finally, based on the function and the adaptive law value, it is substituted into the auxiliary system, which in turn leads to the DM of the RBF-NN near the TDRA to reduce the error and improve the localization and tracking design of the control system.

B. TDRA Sliding Membrane Control and Trajectory Tracking

It is investigated that the back-stepping approach is utilized for the construction of the adaptive control module to handle the problem of the nonlinear system of RA and TT. This, in turn, solves the problem of uncertain parameters and lack of model information of RA [20]. The back-stepping method is a systematic design method for parameter uncertain systems, which uses a recursive structure to the Lyapunov function of the CLS to obtain the feedback controller. Then combined with the control law of the CLS function derivation, and then make the CLS trajectory and boundedness and convergence to achieve equilibrium. Where Lyapunov function is used in dynamical systems and control systems to analyze the instability and convergence and thus to design their systems efficiently. Thus, Fig. 3 depicts the back-stepping-based TDRA control system construction.

Fig. 3. Structure diagram of control system based on back-stepping method.

The control design of the back-stepping method for TDRA can be seen in Fig. 3. The design effectively approximates the unmodeled information of the RA and solves its parameter uncertainty through the adaptive fuzzy controller and function approximation capability, and then completes the control of the modeled information. Eq. (7) demonstrates the design of the adaptive fuzzy control law.

$$\begin{cases} f = R^+ \times (-\zeta_2 \zeta_2 - z_1 - \rho) \\ z_1 = y - y_d \end{cases} \quad (7)$$

In Eq. (7), z_1 is the error, y and y_d are the actual and desired angles, respectively, and ρ denotes the fuzzy system design. As for the two subsystems of the controller, its stability analysis is done by using Lyapunov function, as shown in Eq. (8).

$$\begin{cases} L_1 = \frac{z_1^T z_1}{2} \\ L_2 = L_1 + \frac{z_2^T \times P \times z_2}{2} \end{cases} \quad (8)$$

In Eq. (8), L_1 and L_2 are the function expressions of

the two subsystems, z_2 is the error and $z_2 = x_2 - \alpha_1$, α_1 is the estimated value of x_2 , and P is the positive definite inertia matrix. The stability analysis of the whole system is derived as shown in Eq. (9).

$$L = L_2 + \frac{\tilde{\beta}^T \tilde{\beta}}{2\lambda} = \frac{z_1^T z_1}{2} + \frac{z_2^T \times P \times z_2}{2} + \frac{\tilde{\beta}^T \tilde{\beta}}{2\lambda} \quad (9)$$

In Eq. (9), β^* of $\tilde{\beta} = \beta^* - \beta$ is the optimal approximation constant, β and λ are constants, and $\lambda > 0$. This is then subjected to derivation and adaptive law substitution into the inequality, as well as boundedness considerations of the disturbances, which ultimately leads to the bounded inequality for the CLS, as shown in Eq. (10).

$$L(t) \leq L(0) \exp(-C_0 t) + \frac{C_{Lmax}}{C_0} [1 - \exp(-C_0 t)] \leq L(0) + \frac{C_{Lmax}}{C_0} \quad (10)$$

In Eq. (10), $L(0)$ is the initial value while defining the

$$\Omega_0 = \left\{ X \mid L(X) \leq L(0) + \frac{C_{Lmax}}{C_0} \right\}$$

tight set as $\{z_1, z_2, \tilde{\beta}\} \in \Omega_0$. Thus it is shown that the system introduced into the controller and its CLS signals are bounded. When uncontrollable external disturbances and large modeling errors occur, it is investigated to design the disturbance observer and place it in the SMC of the RA. The specific structure is shown in Fig. 4.

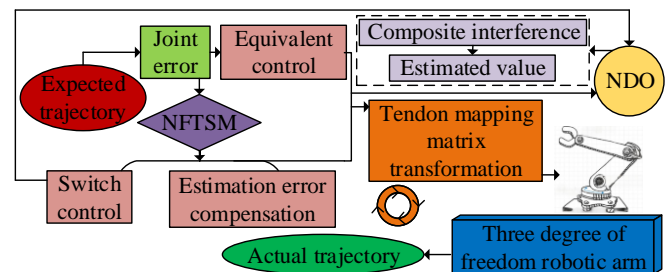

Fig. 4. Design of terminal sliding mode control with anti-interference capability.

In Fig. 4, the errors in inter-joint displacements, velocities and accelerations are used in the equation calculations of the Nonlinear Disturbance Observer (NDO) to determine the errors in the modeled information. To determine the convergence of the errors, the NDO is then constructed along with the auxiliary parameter variables and then merged with the function derivation. Furthermore, the NFTSM provides improved control over the RA motion by compensating for errors, controlling them, and utilizing the saturation function and double power convergence rule. By deliberately altering the switching function, NFTSM, a revolutionary sliding mode control technique, resolves the singularity issue with the current terminal sliding mode control directly from the perspective of sliding mode design and achieves global non-singular control of the system. In the meanwhile, it takes

on the terminal sliding mode's finite-time convergence attribute. When compared to the conventional linear sliding mode control, it can achieve high steady-state accuracy and a finite time convergence to the intended trajectory, making it appropriate for high-speed and high-precision control. Where the TDRA power model considering external disturbances and uncertain parameters, its equation e is shown in Eq. (11).

$$P_0(j)a + C_0(j,s)s + G_0(j) = \tau + \tau_e + \kappa \quad (11)$$

In Eq. (11), κ represents the model uncertainty information and $\kappa = -\square P(j)a - \square C(j,s)s - \square G(j) - F(s)$, $F(s)$ are the system friction forces. τ and τ_e are joint moment vectors and external disturbances, respectively. And when the external perturbation and uncertainty information exists bounded, the two are combined into a composite disturbance, then it is shown in Eq. (12).

$$\dot{\hat{e}} = L(j) \times (e - \hat{e}) = L(j) \times [P_0(j)a + C_0(j,s)s + G_0 - \tau] \times (e - \hat{e}) - L(j)\hat{e} \quad (12)$$

In Eq. (12), \hat{e} represents the combination of external interference and uncertain parameters i.e. composite interference and $e = \tau_e - \square P(j)a - \square C(j,s)s - \square G(j) - F(s)$, \hat{e} are the estimates of NDO for the composite interference and $L(j)$ is the gain matrix. This is then combined with the auxiliary parameter variables and function vectors to arrive at the equation design of the NDO as shown in Eq. (13).

$$\begin{cases} \dot{v} = L(j)[C_0(j,s)s + G_0(j) - \tau - d(s)] - L(j)v \\ \hat{e} = v + d(s) \end{cases} \quad (13)$$

In Eq. (13), v is an auxiliary parameter variable and $v = \hat{e} - d(s)$, $d(s)$ denote the function vectors to be designed. And the design equation of NFTSM is shown in Eq. (14).

$$h_i = g_i + \alpha_i |g_i|^{\lambda_{1i}} \times \text{sgn}(g_i) + \beta_i |g_i|^{\lambda_{2i}} \times \text{sgn}(g_i) \quad (14)$$

In Eq. (14), g_i is the joint angular velocity error, in addition $\alpha_i |g_i|^{\lambda_{1i}} \times \text{sgn}(g_i)$ and $\beta_i |g_i|^{\lambda_{2i}} \times \text{sgn}(g_i)$ are the convergence velocity states of the system and $\begin{cases} \lambda_{1i} < \lambda_{2i} \\ \alpha_i > 0, \beta_i > 0, 1 < \lambda_{2i} < 2 \end{cases}$. When λ_{1i} and λ_{2i} take the appropriate values, the state of the control system is non-singular. Then the Gaussian hypergeometric function and the convergence time of the error are utilized to simplify the equation design of the NFTSM, and finally the system is controlled equivalently by combining the double power convergence law and the saturation function, which in turn

reduces the error estimation of the interference observer. This is shown in Eq. (15).

$$f = R^* \left\{ \begin{aligned} &P_0 a_e + C_0 s + G_0 + P_0 \beta^{-1} \lambda_2^{-1} \times \text{diag} \left(|g_i|^{1-\lambda_{2i}} \right) \times \left[I + \alpha \lambda_1 \times \text{diag} \left(|g_i|^{\lambda_{1i}-1} \right) \right] \times \dot{g} \\ &+ \text{sat}(h) \times \left[P_0 K \times \text{diag} \left(|h_i|^{\gamma_1} \right) + P_0 X \text{diag} \left(|h_i|^{\gamma_2} \right) \right] - \hat{e} - \omega \end{aligned} \right\} \quad (15)$$

In Eq. (15), ω represents the robust term for error reduction and $\omega = -\zeta_e \text{sgn}(h)$, $K \times \text{diag} \left(|h_i|^{\gamma_1} \right)$ and $X \text{diag} \left(|h_i|^{\gamma_2} \right)$ are the stability of the system control and $K = \text{diag}(k_1, k_2, k_3)$, $X = \text{diag}(x_1, x_2, x_3)$. Additionally, ζ_e is a smaller positive number and is greater than or equal to the upper bound of the error estimate of the disturbance observer, i.e., $\|g_e\| \leq \zeta_e$.

IV. TDRA CONTROL COMBINING RBF AND CONTROLLER

TDRA in TT control is simulation experiments using RBF-ANN and its controller on a commercial mathematical software (Matrix Laboratory, MATLAB) platform. The study uses triple-joint RA to simulate and test the position, velocity and tendon tension curves of each joint, and then combines the approximation curves of the auxiliary system and the saturation function to compare the tracking error of the triple-joint motion. Finally, the tracking trajectories of the three joints and the estimation of the interference observations are simulatively tested using an interference observer to demonstrate the tracking accuracy and error convergence of the TDRA.

A. Trajectory Tracking Test for RBF-ANN Controller

The study uses a triple-joint RA for tendon drive and RBF-ANN for TT, whose three joints have linkage mass m specifically 0.02kg, 0.11kg and 0.13kg, and the lengths L are 0.01m, 0.04m, 0.05m, respectively. And for the controller the parameters include the approximation value of DM 0.3, the minimum constant of the auxiliary system 0.02, and the initial matrix parameter 0.2 and approximation value matrix parameter 1.5. The gain matrix parameter is 30. The tracking test of the joint position and velocity of the three-joint RA is carried out in the MATLAB platform, in which the results of the position tracking are shown in Fig. 5.

From Fig. 5(a), it can be inferred that joint 1's position tracking occurs with a tracking error of 0 to 0.1 degrees during the first 0.5 seconds, and joint 2's position tracking in Fig. 5(b) occurs with an error of -0.1 to 0 degrees within 0.2 seconds of the test starting. And the position tracking of joint 3 is seen in Fig. 5(c) to have a deviation of -0.1~0 degrees, occurring within 0.3 seconds of the simulation test. All three joints experience significant vibration during the initial tracking, which in turn leads to the error. However, the position tracking of the joints gradually converges to the desired tracking trajectory after 1s under the effect of the ANN controller. As for the velocity tracking results of the joints, they are shown in Fig. 6.

Fig. 5. Three joint position tracking results of the robotic arm.

Fig. 6. Three joint velocity tracking results of the robotic arm.

Fig. 7. Results of joint control torque and controller approximation values.

From Fig. 6(a), the velocity tracking of joint 1 has an error of $-0.3\sim 0.1^\circ/s$ within 0.8s and the trajectory converges to the desired trajectory after 1s. Joint 2 in Fig. 6(b) has a velocity deviation of $0\sim 1^\circ/s$ within 0.5s, and joint 3 in Fig. 6(c) has a velocity trajectory error of $0\sim 0.8^\circ/s$ within 0.5s, which results in $0\sim 0.8^\circ/s$. All the three joints achieve a stable tracking of the trajectory after 1s, which in turn indicates that the position and velocity tracking of the joints, and the actual trajectories are able to track the desired trajectories relatively quickly under the RBF-ANN controller. Afterwards, the trajectory observation of the control moments of the three joints, as well as the error approximation test of the RBF-ANN control on the DM of the RA, are shown in Fig. 7.

The control moment curves of the three joints are seen to be smoother in Fig. 7(a), which in turn indicates that the trajectory jitter of the TDRA is not obvious. The approximation of the RA error by the RBF-NN is derived in Fig. 7(b), which converges to the true value at 14s. Where the maximum error value is 58 at the initial time, but this is due to the selection of the initial values of each parameter of the neural network, and the curve is gradually approximated with the increase of time afterwards. Therefore, it is proved that the RBF-NN based TDRA in the auxiliary system and function method can improve the tracking effect of tendon tension and the mechanical control ability, so as to improve the accurate tracking control performance of TDRA.

B. Robot Arm Trajectory Tracking Test Combined with Interference Observer

The optimized adaptive control module based on back-stepping is simulated and experimented with uncertain parameters and missing information for TDRA. And the function is combined to compare the joint tracking under different parameters, and then the disturbance observer is set to test the TT of RA. Among them, Fig. 8 displays the results of testing joint 1's position tracking under various auxiliary and stability coefficients.

Fig. 8. Joint 1 position tracking with different parameters.

In Fig. 8(a), joint 1 achieves TT stabilization after 2s and has a maximum error of 1° . It is derived in Fig. 8(b) that the coincidence with the desired trajectory is achieved after 1.8s and remains stable. Whereas, in Fig. 8(c) the curvilinear case of TT occurs when it is close to 0 i.e. 0.2s, which in turn indicates that the accuracy of TT of the joints of the RA increases with the increase in the parameters. After that, the velocity tracking test was performed for joint 2 with different parameters and the results are shown in Fig. 9.

Fig. 9. Joint 2 velocity tracking with different parameters.

In Fig. 9(a), the velocity tracking of joint 2 is more unstable and the error exists intermittently, in Fig. 9(b). Approximate convergence of the velocity trajectory of joint 2 occurs after 1.5s and remains TT stable. In Fig. 9(c), the velocity tracking curve of joint 2 coincides with the desired trajectory after 1.2s and the maximum error appears to be $25^\circ/s$, thus demonstrating that the increase in parameters leads to an increase in the accuracy of joint velocity tracking for RA. Finally, the position and velocity tracking of the three joints of the RA are simulated and tested under the design of the interference observer, in which the results of joint 3 are shown in Fig. 10.

Fig. 10. Results of Joint 3 Position and Speed Tracking

In Fig. 10(a), the position tracking of joint 3 has negligible error from the desired curve, and the TT is more stable and accurate at 0.2s. In the velocity tracking trajectory in Fig. 10(b), the trajectory coincides with the desired trajectory after 0.2s, thus indicating that the interference observer improves the accuracy and velocity of the RA joint TT. After that, regarding the interference observation results and control moments of the joints, the results of joint 2 are shown in Fig. 11.

Fig. 11. Interference observation results of joint 2.

In Fig. 11(a), the interference observation of joint 2 basically coincides with the desired trajectory. And the control moments of joint 2 in Fig. 11(b) change at 1.5s, 4.5s and 8s with small changes. Therefore, the interference observer has an accurate estimation of the tracking trajectory of TDRA. Finally, the curve comparison of the tendon tension change was performed, and the specific results are shown in Fig. 12.

Fig. 12. Curve of tendon tension variation.

In Fig. 12, the convergence time of tendon 1 is faster, and the curve is smoother and more stable, while the tension changes of the rest of the tendons range from -0.1N to 0.1N. The changes in the tension of the remaining tendons are all affected by the compound interference, which makes the curve change more obvious ups and downs. Based on the estimated design of the disturbance observer, it is then shown that the TT controlled by the TDRA terminal sliding mode has a better performance, and thus the accuracy and convergence speed of the TT are improved under the optimization of the controller.

V. DISCUSSION

As one of the important research directions of intelligent industrial robots, the joint angle tracking and adaptive controller design of the robotic arm control system provide key dynamic analysis for the flexible operation of the robotic arm. The study utilizes the tendon driving theory and its tendon tension constraints, and calculates the dynamic model through the Euler Lagrange equation. It also combines the dynamic relationship of the tendon driven robotic arm to clarify the specific parameters of the tendon actuator, thereby simplifying the joint activity of the robotic arm. Afterwards, using the adaptive control of RBF neural network, the tendon driven robotic arm is modeled and tracked. In addition, the adaptive law value of RBF neural network weights can reduce trajectory tracking errors and improve the accuracy of error control and positioning tracking. In order to achieve the adaptive control system and trajectory tracking of the robotic arm, the research also quotes the backstepping method to optimize the robotic arm control system. By calculating the Lyapunov function and adaptive fuzzy control law, the stability of the control system is increased. Finally, adding a nonlinear disturbance observer and NFTSM to compensate for and control trajectory errors can enable the control system to converge to the desired trajectory in a finite time, with high steady-state accuracy. However, compared with existing research on robotic arm control systems, the optimization improvement of tendon driven and adaptive RBF neural networks not only simplifies the dynamic model, but also improves the accuracy of trajectory tracking. The calculation of adaptive fuzzy control law not only considers trajectory tracking problems, but also adds technical means of adaptive movement operation to achieve intelligent development and application of robotic arms, compared to methods such as fuzzy logic control algorithm, self-anti-interference algorithm, and sensor control. In summary, the tendon drive theory and RBF adaptive neural network used in the study can efficiently and accurately improve the trajectory tracking of robotic arms. However, there is a lack of experimental platform detection and analysis for hardware failures of robotic arms in the study, and the optimization of control performance by fuzzy control rules has not been included in the analysis. Therefore, future research will extensively explore the fault detection and system parameter processing of robotic arm control performance, and play the industrial and service functions of robotic arms in medical, aviation, and military fields, thereby promoting intelligent construction and digital development.

FUNDINGS

The research is supported by Provincial and ministerial

level and above vertical scientific research projects (ZX20220460): Research and application development of key technologies for data-driven intelligent case handling.

VI. CONCLUSION

For the requirements of flexible operation of TDRA, the study combines tendon driven DM to construct a simplified TDRA model, and then uses RBF-NN for adaptive control of RA in order to improve RA control accuracy and stability. After that, the RA model information is refined using back-stepping method according to the parameter disturbances and model information. Finally, the interference observer is utilized to linearly estimate the mechanical energy of the interference factors, which in turn improves the accuracy and speed of joint tracking. Simulation experiments with a commercial mathematical software platform yielded that the position tracking of the three joints in the TDRA streamlined model incurred tracking position errors within 0.5s, 0.2 and 0.3s, respectively, and velocity deviations within 0.8s, 1s and 0.5s, respectively. After optimizing the controller, joint 1 experienced trajectory overlap in tracking position after 2s, 1.8s and 0.2s while joint 2 experienced trajectory overlap in tracking velocity after 1.5s and 1.2s when the parameters kept increasing. Thus, it is indicated that the accuracy of RA joint tracking gradually increases with the increase of parameters. Also under the linear estimation of the disturbance observer, the tracking trajectory of joint 3 in TDRA coincided with the desired trajectory after 0.2s. The control moments of joint 2 changed at 1.5s, 4.5s and 8s with smaller changes. And the tension curve of tendon 1 was smoother, thus proving the higher accuracy of the TDRA trajectory based on RBF-ANN. However, the study lacks data support for RA practical application experiments, and further in-depth and improvement of subsequent studies are needed.

Construction of Cloud Computing Task Scheduling Model Based on Simulated Annealing Hybrid Algorithm

Kejin Lv, Tianxu Huang*

College of Information Engineering, Guangxi City Vocational University, Chongzuo, 532200, China

Abstract—With the development of cloud computing technology, effective task scheduling can help people improve work efficiency. Therefore, this study presented a hybrid algorithm on the grounds of simulated annealing and taboo search to optimize task scheduling in cloud computing. This study presented a hybrid algorithm for optimizing the cloud computing task scheduling model. The model used simulated annealing algorithm and taboo search algorithm to convert the objective function into an energy function, allowing atoms to quickly arrange in terms of a certain rule for obtaining the optimal solution. The study analyzed the model through simulation experiments, and the experiment showed that the optimal value of the hybrid algorithm in high-dimensional unimodal testing was $7.15E-247$, far superior to the whale optimization algorithm's $3.99E-28$ and the grey wolf optimization algorithm's $1.10E-28$. The completion time of the hybrid algorithm decreased with the growth of virtual machines, and the shortest time was 8.6 seconds. However, the load balancing degree of the hybrid algorithm increased with the growth of virtual machines. The final results indicated that the proposed hybrid algorithm exhibits high efficiency and superior performance in cloud computing task scheduling, especially when dealing with large-scale and complex optimization problems.

Keywords—*Simulated annealing algorithm; taboo search optimization algorithm; cloud computing; task scheduling; completion time; load balancing degree*

I. INTRODUCTION

As the boost of Cloud Computing (CC) technology, it has been the preferred platform for modern enterprises and research institutions to handle large-scale data and complex computing tasks [1]. In this context, an efficient CC Task Scheduling (TS) strategy is crucial for optimizing resource allocation, improving processing efficiency, and reducing operational costs [2]. TS, as a core issue in CC environments, directly affects the overall efficiency and user satisfaction of cloud services [3-4]. At present, many optimization algorithms have been proposed in the field of CC TS, but these algorithms still face many challenges when handling large-scale, multi-objective, and dynamically changing scheduling problems [5-6]. Therefore, to solve the problem of how to achieve high efficiency and economy in TS in CC while ensuring service quality, a hybrid optimization algorithm based on Simulated Annealing (SA) and Taboo Search (TS) is proposed. This algorithm combines the global search capability of SA and the efficient optimization characteristics of TS, and can solve multi-objective

optimization problems in CC TS. The innovation of this research lies in effectively combining the advantages of two optimization algorithms for enhancing TS.

The main contribution of the research is to propose a hybrid optimization algorithm combining SA and TS to effectively solve the multi-objective optimization problem of CC TS, and provide practical and feasible solutions for the field of CC. This method can improve the efficiency and economy of TS while ensuring service quality. This algorithm outperforms traditional single optimization methods, especially in handling large-scale and dynamically changing scheduling tasks. The research mainly verifies the effectiveness of the model in improving the overall efficiency and user satisfaction of cloud services through performance analysis.

The research structure mainly includes six sections. Section II is for summarizing the research results of scholars around the world on SA and CC TS. Section III is for building a CC TS model and analyze the application of SA and TS algorithms in the model. Section IV analyzes the performance of the constructed model through testing functions and simulation experiments. Discussion is given in Section V. Finally, Section VI concludes the paper.

II. RELATED WORKS

As the boost of CC, a good scheduling algorithm can effectively help enhance the efficiency of CC. SA has been extensively utilized due to its powerful search capabilities. Zolfi K et al. studied the continuous form of multi-layer dynamic facility layout problem, using an approximate Optimal Solution (OS) method of SA metaheuristic algorithm, and running the proposed algorithm in MATLAB software. Through experimental results analysis, SA successfully found suitable solutions for each test case, and comparative experiments showed that SA has better solving ability [7]. Moradi N proposed a new population-based SA algorithm and applied it to solve the 0-1 knapsack problem. The calculation results indicated that the proposed population-based SA is the most effective optimization algorithm for KP01 among all SA based solvers, achieving the goal of putting projects with total profits into the backpack [8]. Abdel Asset M et al. proposed a hybrid version of the Harris Hawks optimization algorithm on the grounds of bitwise operations and simulated annealing (HHOBSA) for addressing feature selection problems. They compared and analyzed the proposed HHOBSA algorithm using 24 standard datasets and 19 manual datasets, and found

from the relevant outcomes that the HHOBBSA algorithm possesses more excellent performance compared to others [9]. Tanha M et al. proposed a new theorem and applied it to generate an initial population of semiconductors. In genetic algorithms (GA) with global trends, it performed crossover operators to explore the search space. After obtaining the appropriate solution, it would randomly call one of the three novel neighbor operators to potentially enhance the given solution. The relevant outcomes showed that relative to other comparative algorithms, the proposed hybrid algorithm has advantages of 10.17%, 9.31%, 7.76%, and 8.21% in terms of production span, plan length ratio, acceleration, and efficiency, respectively [10]. Fontes D and other researchers proposed a Hybrid Particle Swarm Optimization Simulated Annealing Algorithm (PSOSA) to solve job shop scheduling problems. This method integrated the search capability of particle swarm optimization (PSO) with the local search advantage of SA to handle the integrated scheduling of production and transportation in manufacturing systems. Extensive computational experiments validated the effectiveness of PSOSA on 73 benchmark instances. The results showed that the algorithm outperforms existing technologies in shortening manufacturing cycles and exit times, and demonstrated a high degree of robustness [11].

There are also many scholars who have conducted different analyses on CC TS models. Fu X et al. studied the process of cloud TS and presented a PSO genetic hybrid algorithm with phagocytic effect. Firstly, it divided each generation of particle swarm and used the phagocytic mechanism and GA's cross mutation to change the position of particles in the subpopulation. Then, a feedback mechanism was utilized for ensuring that the particle population always moves in the direction of the OS. Through the simulation, the algorithm markedly enhanced the overall Completion Time (CT) of cloud tasks and possessed higher convergence accuracy [12]. Hamed A Y et al. presented a TS algorithm on the grounds of GA. The goal of this algorithm was for minimizing the CT and execution cost of tasks, and maximized resource utilization. The outcomes showcased that the proposed method can find the OS for CT, execution cost, and resource utilization [13]. Pirozmand et al. proposed a two-step hybrid method for scheduling tasks that perceive energy and time, called GA and energy aware scheduling heuristic on the grounds of GA. The first step included determining the priority of the task, and the second step included assigning the task to the processor. They determined the priority of the task and generated the primary chromosome, and used an energy aware scheduling heuristic model for assigning the task to the processor. The simulation showcases that the proposed algorithm can outperform others [14]. Bezdán T et al. presented a hybrid bat algorithm on the grounds of multi-objective TS, and conducted experiments on the CloudSim toolkit utilizing standard parallel workloads and synthetic workloads. It compared the obtained results with other similar meta heuristic techniques evaluated in the same situation. The simulation showcased the enormous potential of their proposed method [15]. Khan M and other scholars proposed a TS method based on hybrid optimization

algorithms, aiming at effectively scheduling jobs in CC environments and minimizing waiting time. This method combined the advantages of ant colony algorithm and PSO, improving task allocation and resource utilization. Through simulation testing, the scheduling strategy showed better performance than traditional methods in multiple parameters such as total production time, execution time, waiting time, efficiency, and utilization. This study highlighted the practicality and efficiency of hybrid optimization strategies in handling large-scale CC resource allocation [16].

In summary, although the above studies have achieved good results in their respective application scenarios, these research methods still have certain limitations. Most studies only focus on a single algorithm, lacking consideration for the diverse and dynamic characteristics of CC environments. Therefore, this study constructs a CC TS model from the perspective of combining multiple algorithms. By combining the advantages of SA's extensive search ability and TS's fast search, a CC TS model on the grounds of SA hybrid algorithm is proposed.

III. CONSTRUCTION OF CC TS MODEL WITH IMPROVED SA ALGORITHM

This study focuses on the TS problem of CC. Firstly, a scheduling model for CC will be constructed, and the basic principles of CC TS will be analyzed. Aiming at addressing the issues of low efficiency and high resource consumption in TS, this study aims to optimize and improve the CC TS model using the search capability of SA. Meanwhile, it adopts TS algorithm for adopting the convergence of the TS model. This is to build an efficient and reasonable scheduling algorithm that reduces costs while improving user satisfaction.

A. Construction of CC Scheduling Model

With the advent of the information age, the amount of data information is constantly increasing, and the demand for server integration is increasing. Many high-performance storage technologies have emerged. These technologies have driven the advancement of virtualization technology, and with the continuous development and integration of various technologies, CC with stronger computing power and a wider range of application services has emerged. An example of CC is showcased in Fig. 1. In Fig. 1, CC is described as a multi-layered architecture that includes an infrastructure layer, a platform layer, and an application layer. The Infrastructure as a Service (IaaS) layer provides virtualized physical computing resources such as servers, storage, and network facilities. Platform as a Service (PaaS) provides development tools and runtime environments that enable developers to build and deploy applications. The application layer Software as a Service (SaaS) provides software applications directly to end users. The figure also shows that how cloud services are provided, namely the concepts of public cloud, private cloud, and hybrid cloud. In addition, the dynamic allocation process of CC resources is also reflected in the figure. Through this model, CC can maximize the utilization of resources, optimize computing power, and reduce the operating costs of enterprises.

Fig. 1. CC example diagram.

Fig. 1 shows that CC is an Internet-based computing method, which offers shared processing resources and data for computers or other devices, and is a configurable computing resource that can be accessed as needed. CC is the advancement of parallel, distributed, and grid computing, which is a comprehensive evolution of concepts. Therefore, CC has advantages such as large-scale, high reliability,

virtualization, high scalability, on-demand services, universality, and low cost, while also having disadvantages such as high dependence on networks and data security issues. In a cloud environment, TS first abstracts different types of hardware resources into Virtual Machines (VMs) using virtualization, then deploys tasks to these VMs, and finally the VMs execute these tasks. The TS model on the grounds of CC generally consists of two layers of scheduling. The first layer mainly solves the problem of matching VM resources with user tasks. The second layer mainly solves the problem of how to match VMs and physical machines [13]. The specific scheduling model of CC is showcased in Fig. 2.

Fig. 2 shows that the model has n tasks, m VMs, and k physical machines. The first layer of job level scheduling focuses on how to map tasks to VMs. The second layer of facility level scheduling focuses on how to allocate VMs to physical machines. When scheduling resources in CC, it is necessary to ensure that tasks are executed before the deadline, while also balancing the system's load and improving resource utilization. Therefore, it is crucial for introducing an efficient resource scheduling algorithm into the CC scheduling model.

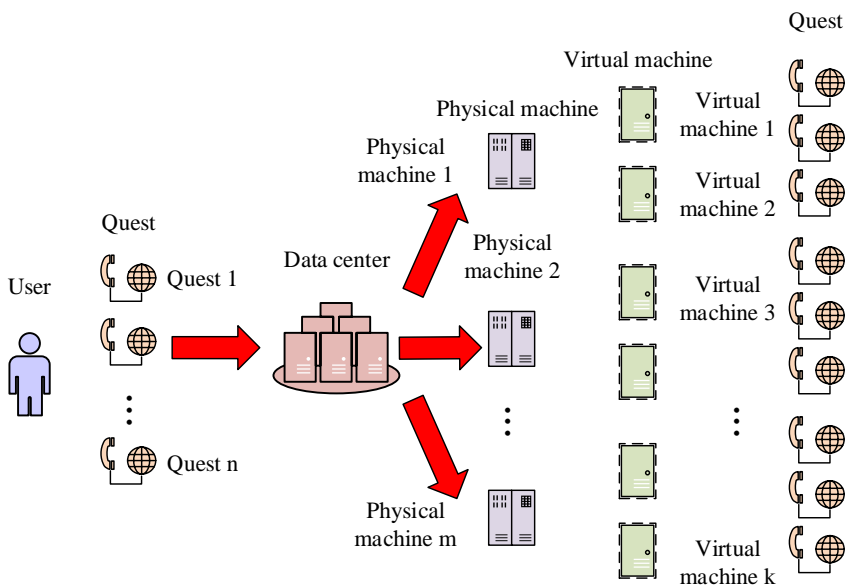

Fig. 2. CC scheduling model.

B. A CC Scheduling Model on the Grounds of SA Algorithm

SA essentially simulates the annealing process in thermodynamic systems, using the objective function as an energy function to slowly cool high-temperature objects and minimize the energy state of their internal molecules [14-16]. In SA, the atoms inside an object have multiple discrete states, each with corresponding state energy. After cooling, they reach thermal equilibrium, and the atoms are arranged according to a certain rule to reach a high-density, low-energy stable state. At this time, the stable state is equivalent to the global OS. SA will jump out of the local OS with a certain probability, which is directly relevant to the current state, temperature, and energy. The transition of annealing probability is shown in Fig. 3.

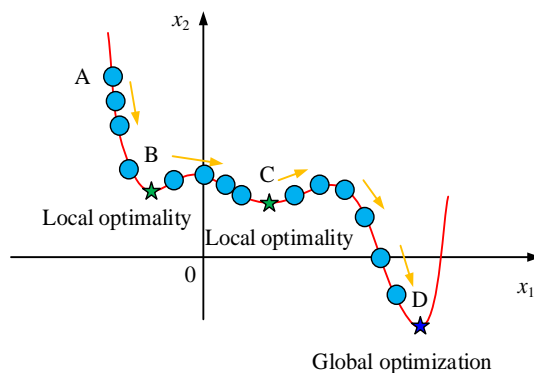

Fig. 3. Annealing probability transition diagram.

In Fig. 3, x_1 serves as the number of iterations and x_2 serves as the energy of the object. The research assumes that the initial state is point A, and as the iterations grows, the OS of the algorithm gradually updates to point B. At this point, the energy at point B is lower compared to point A, indicating that point B is closer to the OS. Therefore, the OS is directly transferred to point B. After reaching point B, the model continues to iterate and update, and the energy value increases. At this point, following the gradient descent rule does not allow the search to continue forward, and the algorithm will jump out of the local OS on the grounds of the state. Through repeated iterations, the final algorithm's OS will stabilize at point D. In SA, if time conditions permit, the higher the initial temperature set, the larger the search algorithm can perform, and the initial solution can be represented by Formula (1).

$$\exp\left(-\frac{\Delta f}{T_0}\right) \approx 1 \quad (1)$$

In Formula (1), Δf represents the difference in fitness function. When the algorithm has a large initial temperature, it can give the algorithm enough opportunities for jumping out of the local OS and achieve quasi equilibrium during iteration. But if the initial temperature is set too high, it will greatly increase the iterations and reduce its efficiency. Therefore, it is necessary to choose an appropriate initial temperature and ensure that the algorithm can obtain an approximate OS within the appropriate time. The speed of temperature update will affect the number of iterations and accuracy. The study uses temperature update as showcased in Formula (2).

$$T(k+1) = \alpha T(k) \quad (2)$$

In Formula (2), α represents the cooling parameter, which ranges from 0.5 to 0.99, $T(k)$ represents the current temperature, and $T(k+1)$ represents the temperature at the next time step. The expression of $T(k)$ is shown in Formula (3).

$$T(k) = \frac{(L-k)*T_0}{L} \quad (3)$$

In Formula (3), L serves as the total iterations, k serves as the current number of iterations, and T_0 serves as the initial temperature. The temperature update function can simply control the rate of temperature decrease, ensuring that the difference between control parameters remains unchanged. SA also includes Markov chain length and termination criteria. The length of the Markov chain represents the transformation interval generated by the Metropolis criterion during iteration, and the finite sequence Markov chain specifies the range of the algorithm's search space. The ending criterion of SA is generally set to three conditions, which are: when the temperature drops to a very small positive number and the temperature that has already dropped reaches a given constant. The current temperature has fallen into a local optimum and cannot escape from it. The local OS obtained by the algorithm is superior to the optimal value [17].

In CC scheduling, the optimization objectives of this study

are system CT, system load balancing, and system execution cost. In the system CT, the user sends a task request, recording the task length as $Task_i$, the VM processing speed as $MIPS_j$, the TS and waiting time as $time_s$. The execution time of each task is $time_{ij}$, and the time required for each VM for executing all sub tasks assigned to it is T_j . The maximum CT of the system is shown in Formula (4) [18].

$$\begin{cases} Makespan = time_s + \max(T_j) \\ T_j = \sum_{i=1}^n \sum_{j=1}^m time_{ij} * x_{ij} \\ time_{ij} = Task_i / MIPS_j \end{cases} \quad (4)$$

Because the task requirements of users may involve computer related resources, the workload of VMs is represented by Formula (5) [19-20].

$$W_j = 1 - \frac{1}{k} \sum_{r=1}^k \frac{capacity_{jr} - sum(requested_r)}{capacity_{jr}} \quad (5)$$

In Formula (5), W serves as the workload of the VM, $capacity_{jr}$ serves as the total capacity of VM resources, and $request_r$ represents the total demand for VMs in all tasks. It simplifies the total workload of the VM through Formula (5), as shown in Formula (6).

$$W_{aj} = \sum_{i=1}^n W_j * x_{ij} \quad (6)$$

The load balancing degree of the system is obtained through Formula (6), and its expression is shown in Formula (7).

$$\begin{cases} B = \frac{1}{m} \sqrt{\sum_{j=1}^m |W_{aj} - \bar{W}_{aj}|^2} \\ \bar{W}_{aj} = \frac{1}{m} \sum_{j=1}^m W_{aj} \end{cases} \quad (7)$$

In Formula (7), B represents the load balancing degree. Regarding the optimization of system execution cost, the study represents the total execution cost per unit time of VMs as C , and the total execution time of VMs as T . The cost generated by a single VM and the total execution cost of the user are shown in Formula (8).

$$\begin{cases} cost(j) = c_j * T_j \\ Cost = \sum_{j=1}^m cost(j) \end{cases} \quad (8)$$

For the overall evaluation model of the system, the study weights three optimization objectives and changes the focus of scheduling objectives by changing the weight coefficients. The specific expression is shown in Formula (9).

$$C(s) = \mu_1 * Makespan + \mu_2 * B + \mu_3 * Cost \quad (9)$$

In Formula (10), μ_1 , μ_2 , and μ_3 respectively represent the weight coefficients of the three optimization objectives. $C(s)$ represents the value of the system objective function, and the smaller the fitness function value, the more excellent the overall performance of the system.

C. CC TS on the Grounds of SA Hybrid Algorithm

Although SA has the capability of jumping out of local optima, as the temperature parameter gradually decreases, the search ability weakens, and it may eventually fall into local optima. In the process of finding the global OS, the convergence speed (CS) is relatively slow. Therefore, the study combines the fast convergence of SA with the efficient optimization of TS to obtain the Integrated Simulated Annealing and Taboo Search (ISATS) algorithm. The TS process adopted by the research is shown in Fig. 4.

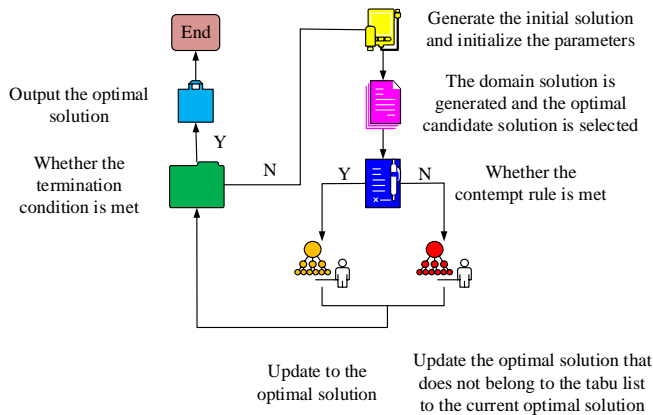

Fig. 4. Taboo search algorithm flowchart.

Fig. 4 shows the process in which the algorithm stores the searched candidate solutions in the taboo table during the search in the neighborhood. The solutions in the taboo table are prohibited from being searched again before being released. When a certain range of solutions are taboo, the contempt rule is used to release some OSs in the taboo table, thereby expanding the search range of the solution space and obtaining the global OS. In the ISATS algorithm, the study uses fitness variance to determine whether the algorithm is trapped in a local OS, and its expression is shown in Formula (10).

$$\sigma^2 = \sum_{i=1}^M \left(\frac{aff(s_i) - \overline{aff}(s)}{\max \{ |aff(s_i) - \overline{aff}(s)| \}} \right) \quad (10)$$

In Formula (11), σ represents the variance of fitness, $\overline{aff}(s)$ represents the average fitness, and

$\max \{ |aff(s_i) - \overline{aff}(s)| \}$ represents the maximum difference in fitness among the population. This study sets a reasonable judgment threshold of σ_0 , and when $\sigma^2 < \sigma_0$ is met, it indicates that the algorithm has completed initial convergence. After introducing TS into the TS model, the workload factor of the VM is represented by Formula (11).

$$B_j = 1 - \frac{T_j - \bar{T}_j}{T_{j\max} - T_{j\min}} \quad (11)$$

Formula (11) indicates that the longer the task execution time of a VM, the smaller the workload factor of the VM. The value of B_j determines the priority order of scheduling tasks. The study incorporates the workload factor of VMs into the Metropolis criterion, and the average workload factor of VMs is shown in Formula (12).

$$\bar{B} = \frac{1}{m} \sqrt{\sum_{j=1}^m |B_j - \bar{B}_j|^2} \quad (12)$$

In Formula (12), \bar{B} represents the average load factor of the VM. The smaller its value, the smaller the load difference between VMs, indicating a more balanced load. At this point, the probability of accepting new solutions decreases. When there is a significant difference in load between VMs, it will increase the probability of accepting new solutions and make the algorithm jump out of the current solution to find a more excellent solution. The specific steps for studying and constructing the ISATS hybrid algorithm are shown in Fig. 5.

In Fig. 5, the study first utilizes the improved SA to quickly converge and obtain a current optimal task to VM mapping scheme. Then, this temporary optimal scheme is used as the initial solution of TS. In the subsequent process of adding the solution to the taboo table, the Metropolis criterion considering the load factor is introduced to achieve the goal of global optimization. The final scheme of task mapping to VM is obtained, and the task is executed using this result. Finally, Fig. 6 shows the pseudo-code of the ISATS hybrid algorithm.

In Fig. 6, the ISATS algorithm first initializes the initial solution, and then finds the OS through the SA algorithm. In each iteration, the algorithm generates a new solution and uses the accept-reject criterion to decide whether to accept the new solution. As the iteration progresses, the algorithm updates the weights and optimization targets, and uses Taboo tables to limit the search scope. Finally, the algorithm outputs the processed data set for subsequent use or further analysis. The algorithm may need to be adjusted according to the characteristics of the actual problem.

Fig. 5. ISATS hybrid algorithm flowchart.

```

Initialize initial solution (SA)
Set initial temperature T, cooling parameter p, maximum iteration count N
Define weights w1, w2, w3 for optimization objectives
Define Taboo Table Length L

for i = 1 to N do:

IV. PERFORMANCE ANALYSIS OF CC TS MODEL ON THE GROUNDS OF ISATS HYBRID ALGORITHM

For the ISATS hybrid algorithm proposed in the study, preliminary performance analysis of the algorithm was conducted through testing functions. The algorithm's optimal value, worst value, average value, and Standard Deviation (SD) were evaluated, and the superiority of the model was verified by comparing the algorithms. Then, the study verified the application effect of the ISATS hybrid algorithm in CC scheduling through simulation experiments. The experiment evaluated and analyzed the task CT and load balancing degree.

A. Test Functions and Parameter Settings

This study was simulated using the Cloudsim cloud simulation platform. To evaluate the algorithm performance, three algorithms were applied to high-dimensional (HD) unimodal and HD multimodal test functions, and 20 experiments were conducted. By comparing the optimal, average, worst fitness values, and SD obtained, it observed the convergence accuracy and stability. The comparative algorithms include Whale Optimization Algorithm (WOA), Grey Wolf Optimizer Algorithm (GWO), and ISATS algorithm. The specific selection of testing functions is showcased in Table I.

The study selected two sets of HD unimodal functions and two sets of HD multimodal functions for testing, with dimensions of 30 for all four functions. The experiment was for testing the optimal performance by setting the parameters of the CC TS model and algorithm. The specific parameter settings are showcased in Table II.

In the ISATS algorithm, the initial temperature was set to 100 °C, the cooling parameter was 0.9, the termination temperature was 1 °C, and the population size was 150. The

weight coefficients for CT, load balancing, and execution cost were 0.4, 0.3, and 0.3. In the experimental environment, the CPU model was selected as Inter i5 12400F, and the GPU was selected as GeForce RTX™ 2080 Ti, with a memory size of 2 * 8GB.

B. Performance Analysis on the Grounds of Test Functions

The study analyzed the performance of the ISATS algorithm through four testing functions, and the results of the HD unimodal testing function are showcased in Fig. 7. Fig. 7(a) showcases the F1 test function results, where the optimal value of ISATS was 7.15E-247, which is significantly better than the 3.99E-28 of the WOA algorithm and the 1.10E-28 of the GWO algorithm. In the average and SD results, the average of ISATS was 1.27E-229, with a SD of 0. The results indicated that the ISATS algorithm exhibits extremely high stability and superior optimization ability in multiple runs. Fig. 7(b) showcases the results of the F2 test function, where the optimal value of ISATS was 1.28E-144, which is also significantly better than WOA and GWO algorithms. This further proved that the ISATS algorithm has good optimization ability in the F2 test function.

The outcomes of the HD multimodal test function are showcased in Fig. 8, where Fig. 8(a) and (b) represent the F3 and F4 test function results, respectively. The outcomes showcased that the ISATS algorithm has significantly improved CS and accuracy compared to the original algorithm in testing functions F3 and F4. Moreover, in F4, it even converged perfectly to the global OS, and by observing the SD, the ISATS algorithm had a slightly higher SD in the F3 function than the WOA algorithm. In the F4 function, the SD was significantly lower than that of the WOA and GWO algorithms, and it exhibited extremely fast CS. The CS, accuracy, and stability of the ISATS algorithm showed good performance through testing function analysis.

TABLE I. TEST FUNCTION EXPRESSION AND RELATED PARAMETERS

Function	Expression	Dimension	Value range
HD unimodal function	$F_1(x) = \sum_{i=1}^n x_i^2$	30	[-100,100]
	$F_2(x) = \sum_{i=1}^n x_i + \prod_{i=1}^n x_i $	30	[-10,10]
HD multimodal function	$F_3(x) = \sum_{i=1}^n -x_i \sin(\sqrt{ x_i })$	30	[-500,500]
	$F_4(x) = \sum_{i=1}^n [x_i^2 - 10 \cos(2\pi x_i) + 10]$	30	[-5.12,5.12]

TABLE II. TASK, VM, AND HOST RELATED PARAMETERS

Argument	Value	Argument	Value	Argument	Value
Number of tasks	200	Task length	Rand (1000,10000)	Input file size	300MB
Output file size	300MB	Number of virtual machines	10	Virtual machine memory	512MB
VM broadband	500MB	Processing speed	1000	Processor core	1
Host memory	2GB	Host storage capacity	1000000MB	Host broadband	10000M

C. Simulation Analysis on the Grounds of ISATS Algorithm

This study kept the number of CC tasks scheduled at 200 and observed the impact of different numbers of VMs on algorithm scheduling performance by increasing the number of VMs. The outcomes are showcased in Fig. 9. Fig. 9(a) showcases the influence of the number of VMs on the CT. The outcomes showed that the CT of each algorithm decreases with the increase of the number of VMs, with the shortest CT of the ISATS algorithm being 8.6 seconds. Fig. 9(b) showcases the influence of the number of VMs on load balancing. The outcomes showcased that the load balancing degree of each algorithm grows with the growth of the number of VMs, with the highest load balancing degree of GWO algorithm reaching 5.1. The outcomes showcased that the ISATS algorithm possesses high efficiency and low load balancing, and the selection of the number of VMs needs determining by actual needs. If model efficiency is taken as the primary consideration, the number of VMs can be increased. If load balancing is taken as the primary consideration, the number of VMs can be reduced.

Fig. 9. The impact of the number of VMs on the scheduling performance of the model.

When keeping the number of VMs at 20, this study observed the impact of task quantity on algorithm scheduling performance, and the outcomes are showcased in Fig. 10. Fig. 10(a) showcases the impact of work quantity on CT. Fig. 10(b) showcases the impact of workload on load balancing. In Fig. 10(a), compared to the GWO algorithm, as the tasks increased from 50 to 500, the ISATS algorithm reduced the CT by up to

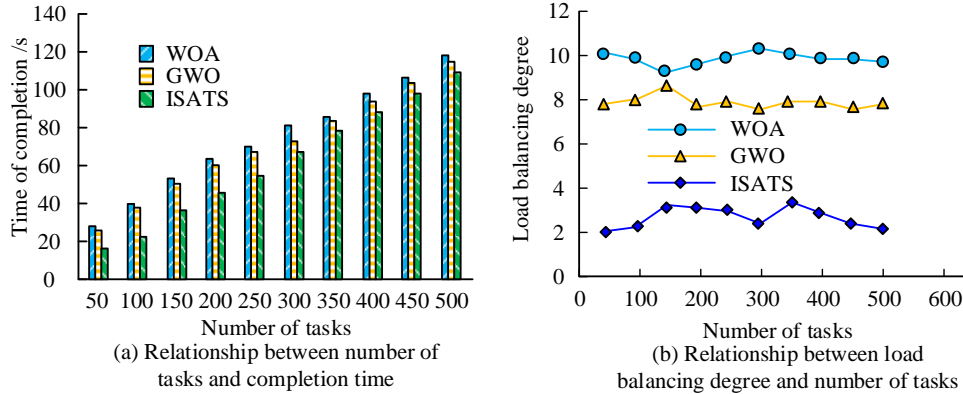

Fig. 10. The impact of workload on scheduling performance.

To further analyze the scheduling performance of the model, the influence of observing the number of tasks on the algorithm's fitness value was studied, and the outcomes are showcased in Fig. 11. In Fig. 11, the overall fitness of the ISATS algorithm exceeded that of the WOA and GWO algorithms, and as the tasks grew, the absolute difference in fitness also gradually increased. The overall fitness value of the ISATS algorithm proposed in the study was about 5.6% better than that of the WOA algorithm. The reason is that the fitness value is directly relevant to the weight coefficient of the optimization objective, which makes the ISATS algorithm have a lower fitness value. On the grounds of the above results, the study proposed that the ISATS algorithm has good performance in both CT and load balancing, which can further optimize the CC TS model.

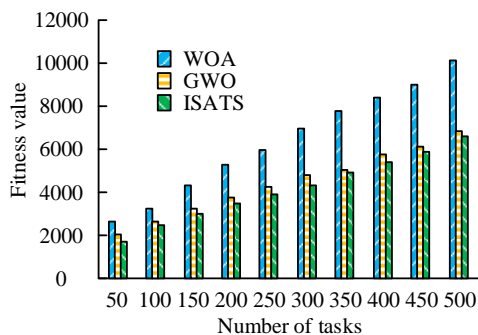

Fig. 11. The impact of workload on algorithm fitness values.

V. DISCUSSION

In the study of CC TS, ISATS hybrid algorithm showed remarkable performance advantage. The experimental data indicated that the ISATS algorithm shows excellent CS and accuracy, which is superior to WOA and GWO algorithm in both unimodal and multimodal test functions. In addition, simulation experiments with different number of VMS and tasks showed that the ISATS algorithm can effectively reduce

28.8%. In Fig. 10(b), the system load of the ISATS algorithm was significantly improved. This may be because the ISATS algorithm utilizes the improved global search ability of SA in the early stage to provide TS with a good initial solution, while TS itself has strong optimization ability, which improves the final performance of the algorithm.

task CT and improve the load balancing degree of the system. In the HD multimodal test function, the ISATS algorithm not only rapidly converged to the global optimal solution, but also had significantly higher stability and optimization ability than the comparison algorithm, which verified the applicability and efficiency of the hybrid algorithm in dealing with complex optimization problems. The main reason is that the ISATS algorithm, by integrating SA and TS techniques, effectively avoided the common problem of falling into the local optimal, while enhancing the global search capability. The significant contribution of this study is to provide an efficient algorithmic framework for resource scheduling problems in large-scale and complex CC environments. The design of ISATS algorithm takes into account the computational efficiency and optimization quality, ADAPTS to the changing task demand and resource allocation state, and significantly improves the flexibility and response speed of TS. In addition to CC, the structure and performance characteristics of ISATS algorithms are also applicable to other areas requiring resource scheduling and optimization, such as big data processing, industrial automation, and intelligent transportation systems. By adjusting the parameters and optimizing the target, the ISATS algorithm can be widely used in a variety of compute-intensive and data-intensive application scenarios, and has wide application potential and practical value.

VI. CONCLUSION

A TS model for CC was studied to address the limitations in handling multi-objective tasks. By combining SA with TS and utilizing SA's global search ability and TS's efficient optimization ability, a CC TS model on the grounds of the ISATS algorithm was constructed. The model proposed in the study had an optimal value of $7.15E-247$ in HD unimodal testing functions. In the average and SD results, the average value of ISATS was $1.27E-229$, with a SD of 0. In HD and multimodal testing, the ISATS algorithm converged steadily to the global OS, demonstrating better search ability and stability.

In the simulation experiment, as the number of VMs increased, the CT of the ISATS algorithm was 8.6 seconds. Compared with the GWO algorithm, the CT was shortened by up to 28.8% as the tasks increased. The research results indicated that the ISATS algorithm showed significant advantages in CC TS, especially in dealing with large-scale TS problems, effectively improving efficiency and load balancing. Although the ISATS algorithm performed well in simulation experiments, there are still shortcomings. For example, the model still needs to be applied and analyzed in actual CC environments. It further optimizes algorithm parameters to adapt to more diverse application scenarios. In future research, the ISATS algorithm can be utilized to different CC scenarios, like cloud storage, big data processing, etc., to evaluate its performance in various applications.

Abstract—Inspired by the principles of decomposition and ensemble, we introduce an Ensemble Empirical Mode Decomposition (EEMD) method that incorporates Sparse Bayesian Learning (SBL) with Mixed Kernel, referred to as EEMD-SBLMK, specifically tailored for landslide displacement prediction. EEMD and Mutual Information (MI) techniques were jointly employed to identify potential input variables for our forecast model. Additionally, each selected component was trained using distinct kernel functions. By minimizing the number of Relevance Vector Machine (RVM) rules computed, we achieved an optimal balance between kernel functions and selected parameters. The EEMD-SBLMK approach generated final results by summing the prediction values of each subsequence along with the residual function associated with the corresponding kernel function. To validate the performance of our EEMD-SBLMK model, we conducted a real-world case study on the Liangshuijing (LSJ) landslide in China. Furthermore, in comparison to RVM-Cubic and RVM-Bubble, EEMD-SBLMK emerged as the most effective method, delivering superior results in the same measurement metrics.

Keywords—Bubble; cubic; ensemble empirical mode decomposition; landslide; Sparse Bayesian Learning

I. INTRODUCTION

Landslide, a natural geological occurrence, refers to a type of mass wasting that involves diverse ground movements [1, 2]. Essentially, it signifies a transition from a stable slope to an unstable one [3, 4]. The occurrence of this transition can be prompted by numerous internal and external factors, including vegetative cover, weather conditions, evaporation, and transpiration, either operating alone or jointly. Given the significant damage and casualties caused by landslides globally, considerable efforts are underway to establish a pre-warning system capable of predicting their occurrence. The task of landslide forecasting is not only crucial but also challenging, particularly in the context of rapidly increasing peak flows due to urbanization. To mitigate potential flood-related damages in the future, it is imperative to develop an accurate model for landslide forecasting.

It is well-established that Three Gorges Region, situated at the upstream section in Chinese Yangtze River, experiences lots of landslides, posing serious dangers to the region. These landslides, which occur almost annually, result in significant damage to both the local population and property. Given this, it is evident that the phenomenon involves numerous stochastic,

interrelated components and exhibits highly nonlinear characteristics.

Currently, various methods, including artificial neural networks (ANN), fuzzy theory, chaos theory, and statistical approaches, have been extensively employed in the realm of nonlinear analysis [5-21]. A two-stage Bayesian integration framework has been effectively utilized for detecting prominent objects in light field images [5].

The resolution of nonlinear characteristics does not solely rely on a single approach; hybrid models also demonstrate their effectiveness. Methods for per-processing signals and evolutionary SVR have been developed to enhance short-term wind speed predictions [6]. Furthermore, a hybrid approach that incorporates the minimum cycle decomposition has proven effective in predicting temporary electrical load data [7]. Chen et al. proposed an innovative methodology that integrates genetic algorithm and simulated annealing algorithm with improved BPNN modeling for landslide prediction [8]. Extreme learning machines (ELM) excel in learning with superior generalization capabilities, thereby circumventing the challenges encountered by gradient-based learning methods. Lian et al. pointed out the potential applications of modified ELM in predicting landslide displacements [9, 10]. Furthermore, dynamic time series predictors leveraging echo state networks and ELM have been constructed to forecast landslide displacements [11, 12]. Functional networks (FNs) combined with hybrid methods have also been explored for landslide forecasting [13]. The paper harnessed MGGP to build a forecast method for landslide displacement without prior knowledge of the nonlinear model's structure. Bootstrap-based generalized neural networks (Bootstrap-GRNN) have been utilized for interval prediction of displacements [14]. Kanungo et al. exhibited an integration model, combining with NN, fuzzy logic and likelihood concepts to forecast landslide occurrence [15].

Regrettably, the majority of current landslide prediction methods remain deterministic, falling short in providing meaningful insights into the uncertainty surrounding their predicted values. This significant limitation restricts the practical application of landslide forecasting in stochastic decision-making and analytical frameworks. EEMD [16] addresses the mode mixing issue by introducing finite noise, effectively eliminating it while preserving the physical uniqueness of the decomposition. On the other hand, SBL [17] leverages a parameterized prior to favor models with sparse

*Corresponding author: Ping Jiang

nonzero weights. Drawing inspiration from Yang et al.'s idea [17], we introduce a novel hybrid approach, EEMD-SBLMK, which combines EEMD and SBL. This approach generates probabilistic prediction by assessing the probabilistic distribution of weights linked to Gaussian kernel functions. Finally, the last section summarizes our findings and discusses potential avenues for future improvements.

II. THEORY

A. EEMD

EMD is a technique that exhibits great adaptability and efficiency in decomposing complex, nonlinear, and unstable signals. It leverages the HHT to accomplish this. The introduction of the IMF concept marks a pivotal innovation in EMD, as each IMF encapsulates the unique local information embedded in lots of data sheets.

Utilizing EMD allows for the decomposition of any sophisticated temporal datasets into multiple IMF components, along with a residual component that encapsulates the primary trend of data. IMFs adhere to certain criteria, which are as follows:

- 1) The total count of extreme points, including both peaks and valleys, should match how much zero crossings in the entire data-set, with a maximum difference of one.
- 2) For a specific point, the average value of the envelope formed by the local peaks and troughs should be zero.

Despite its strengths, EMD also exhibits certain limitations. A significant challenge arises from mode mixing, which occurs when signals of diverse scales coexist within a single IMF, or conversely, signals of identical scale are distributed across various IMFs. Tackling this problem, a novel method known as EEMD was introduced, which incorporates noise-assisted analysis (see Fig. 1). The EEMD approach could be summarized as:

Step 1: Augment the original signal series with white noise.

Step 2: Employ the EMD method to decompose the signal, incorporating the incorporated white noise, into its constituent IMFs.

Step 3: Execute the previous two steps repeatedly, introducing a fresh white noise with each iteration.

Step 4: Compute the average of the corresponding IMFs from all decompositions to arrive at the final IMFs.

Step 5: Calculate the mean of the corresponding residue components across all decompositions to determine the final residue, as shown in Eq. (1) to Eq. (3).

$$IMF'_1 = \frac{imf_{11} + imf_{21} + \dots + imf_{N1}}{N} \quad (1)$$

$$IMF'_{in} = \frac{imf_{1n} + imf_{2n} + \dots + imf_{Nn}}{N} \quad (2)$$

$$Re' = \frac{Re_1 + Re_2 + \dots + Re_n}{N} \quad (3)$$

B. Mutual Information (MI)

Input selection serves as a crucial aspect in the development of any neural network. It holds a crucial position in ascertaining the precision of the model's forecasts. Furthermore, incorporating irrelevant inputs can significantly impact the precision and reliability of the neural network.

The Mutual Information (MI) [20, 21] between random variable X and random variable Y, is a measure that quantifies the shared information between them, as shown in Eq. (4).

$$MI = \iint \xi_{x,y}(x,y) \log \left[\frac{\xi_{x,y}(x,y)}{\xi_x(x)\xi_y(y)} \right] dx dy \quad (4)$$

where, $\xi_x(x)$ and $\xi_y(y)$ represent the the individual probability density functions of variable X and variable Y, respectively, while $\xi_{x,y}(x,y)$ denotes their joint probability density function. Considering the restricted quantity of data accessible for this research, we employ the kth nearest neighbor approach, as described in studies [12-16], to assess MI. This evaluation method is particularly suitable for small datasets. Based on the recommendations in references [12-16], it is advisable to set k to a value between 2 and 4. Given the small size of our data sample, we have chosen to set k equal to 3 in this paper.

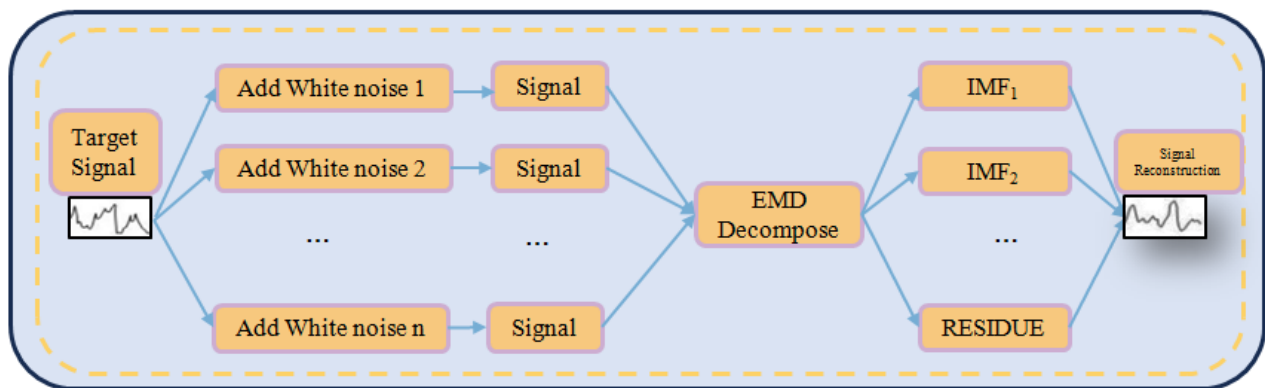

Fig. 1. EEMD.

C. Sparse Bayesian Learning (SBL)

The SBL model, alternatively known as a relevance vector machine, exhibits excellent adaptability for forecasting non-stationary random variables. This is due to its straightforward modeling of probabilistic quantity changes [17]. Fundamentally, SBL adopts a Bayesian viewpoint for kernel-based forecast models, capitalizing on a distinct prior for parameters that encourages sparsity in the prediction function.

Commonly, in a GR context, the correlation concerning the desired value t_n and the input vector X_n can be formulated as follows:

$$t_n = y(x_n; \omega) + \varepsilon_n \quad (5)$$

where, $\omega = [\omega_0, \omega_1, \omega_2, \dots, \omega_T]$ represents the weight vector that needs to be determined. On the other hand, ε_n represents the forecast error, which follows an independent and identically distributed normal distribution with a mean of $N(0, \sigma^2)$. Furthermore, y_n follows a normal distribution, with its mean value designated as $f(x_n; \omega)$ and its variance designated as σ^2 .

Utilizing the kernel method, $y(x_n; \omega)$ can be formally defined as:

$$y(x_n; \omega) = \omega^T \Phi(x_n) = \omega_0 + \sum_{i=1}^M \omega_i K(x_n, x_i) \quad (6)$$

where, $\Phi(x_n) = [1, K(x_n, x_1), \dots, K(x_n, x_M)]^T$, $K(x_n, x_i)$ signifies the Gaussian kernel function, and M denotes the total count of such kernel functions employed. Given the inherent nonlinearity of $K(x_n, x_i)$, the model effectively captures and expresses nonlinear complexities with ease.

Recalling our earlier discussion, the joint distribution of target values $t = [t_1, t_2, \dots, t_N]$, pertaining to N independent groups of sampling data, can be formulated based on the distribution of t as follows:

$$p(t | \omega, \sigma^2) = (2\pi\sigma^2)^{-\frac{N}{2}} \exp\left\{-\frac{1}{2\sigma^2} \|t - \Phi\omega\|^2\right\} \quad (7)$$

where, $\Phi = [\varphi(x_1), \varphi(x_2), \dots, \varphi(x_N)]^T$.

Employ the process of maximizing the likelihood function, which signifies the likelihood of observing the provided data given the assumed model, to estimate ω_1 and σ^2 , but it may have over fitting phenomenon. Then to avoid it, we use the mandatory additional prerequisites to some parameters, based on Bayesian theory then define ω_i function, normal distribution:

$$p(\alpha) = \prod_{i=0}^N \text{Gamma}(\alpha_i | a, b) \quad (8)$$

$$p(\beta) = \text{Gamma}(\beta | c, d) \quad (9)$$

where, $\beta = \sigma^2$.

$$\text{Gamma}(\alpha | a, b) = \Gamma(a)^{-1} b^a \alpha^{a-1} e^{-b\alpha} \quad (10)$$

Then, $\Gamma(a) = \int_0^\infty t^{a-1} e^{-t} dt$, parameters a, b, c, d have no prior knowledge, values are small, $a=b=c=d=10^{-4}$. Then, it can obtain uniform hyper parameters $a=b=c=d=0$.

Under bias framework, the prediction is based on the training data ω, α, σ^2 posterior distribution. According to Bayesian formula:

$$p(\omega, \alpha, \sigma^2 | t) = \frac{p(t | \omega, \alpha, \sigma^2) p(\omega, \alpha, \sigma^2)}{p(t)} \quad (11)$$

But, the above formula ride is hard to solve up, the left formula can be decomposed into:

$$p(\omega, \alpha, \sigma^2 | t) = p(\omega | t, \alpha, \sigma^2) p(\alpha, \sigma^2 | t) \quad (12)$$

Through the above analysis, the original problem is decomposed into two steps to solve:

- 1) Compute α, σ^2 under t posterior distribution.
- 2) Compute ω under α, σ^2, t posterior distribution.

In practice, to simplify the calculation, Dirac distribution $\delta(\alpha_{MP}, \sigma^2_{MP})$ as ω under α, σ^2, t posterior distribution:

$$\int p(t | \alpha, \sigma^2) = \int p(t | \omega, \sigma^2) p(\omega | \alpha) d\omega \quad (13)$$

$$p(\omega | t, \alpha, \sigma^2) = \frac{p(t | \omega, \sigma^2) p(\omega | \alpha)}{p(t | \alpha, \sigma^2)} \quad (14)$$

After the model parameters are obtained by training data, new input vectors x^* , target value t^* distribution density:

$$p(t_* | t) = \int p(t_* | \omega, \alpha, \sigma^2) p(\omega, \alpha, \sigma^2) d\omega d\alpha d\sigma^2 \quad (15)$$

RVM regression model σ_*^2 :

$$\sigma_*^2 = \sigma_{MP}^2 + \Phi^T(x_*) F \Phi(x_*) \quad (16)$$

Finally, the main problem α_{MP} and σ_{MP}^2 , the maximum likelihood estimation method.

III. FORECAST MODEL AND ANALYSIS

In the RVM [18] model training, it assumed that there exist no errors in the historical data of each sample. And it used eight kernel functions respectively in Eq. (17) to Eq. (22).

- 1) Gaussian

$$G(x, x_i) = \exp\left(-\frac{\|x - x_i\|^2}{\sigma^2}\right) \quad (17)$$

2) Cauchy

$$Ca(x, x_i) = \frac{1}{1 + \sigma^2 \cdot \|x - x_i\|^2} \quad (18)$$

3) Cubic

$$C(x, x_i) = (\sigma^2 \cdot \|x - x_i\|^2)^{\frac{3}{2}} \quad (19)$$

4) Bubble

$$B(x, x_i) = -\frac{\|x - x_i\|^2}{\sigma^2} \quad (20)$$

5) Laplace

$$L(x, x_i) = \exp\left(-\frac{\|x - x_i\|}{\sigma}\right) \quad (21)$$

6) R-distance

$$R(x, x_i) = \exp\left(-\frac{\|x - x_i\|}{\sigma}\right) \quad (22)$$

The landslide data, presented as a time series, typically exhibit nonlinear and non-stationary characteristics. To address this, we adopt an approach that combines decomposition and ensemble techniques. Specifically, we utilize the ensemble EEMD method to decompose three distinct types of landslide data. Three sets of sequences are obtained, the correlation between three groups of sub sequences and landslide displacement was calculated, and the best correlation group was

selected as SBL parameters. Then, different kernel functions with each selected parameters are used to compute. Using distinct kernel functions in a mixed kernel model for landslide prediction offers benefits in terms of enhanced model flexibility, improved feature representation, enhanced prediction accuracy, robustness and generalization, as well as increased interpretability and understanding of model decisions. Based on the minimum number of computed RVM rules, it can obtain one selected parameter corresponds to one kernel function. Moreover, EEMD-SBLMK used selected kernels functions with corresponded input parameters to gain the final predicted results by assembling.

There several steps for EEMD-SBLMK:

- 1) All data (including displacement reservoir level and rainfall) are decomposed using EEMD into n IMFs and one residual function Residue (t) (see Fig. 2).
- 2) Use MI method to choose strong correlation between the IMFs component and displacement, and then it can decide the input parameters of EEMD-SBLMK (see Fig. 3).
- 3) Each selected IMFs component to be trained by different kernels functions, which can be predefined based on domain knowledge or determined through a data-driven approach, where different kernels are tested to find the optimal combination.
- 4) According to the minimum number of computed RVM rules, it gets some computed rules between kernel functions and selected parameter.
- 5) The final predicted result presents the sum of each subsequence prediction value of IMF and residual function Residue (t) with corresponded kernel function.

IV. APPLICATION OF EEMD-SBLMK ON LANDSLIDE PREDICTION: A CASE STUDY

A. Dataset

In this paper, we endeavor to introduce the EEMD-SBLMK approach for elucidating significant nonlinear relationships among diverse parameters pertaining to a practical geotechnical problem. All experiments conducted in this study were executed on the MATLAB 2013 platform. Given the uncertainty, instability, and intricate nature of landslides, their formation remains highly elusive. This complexity encompasses factors such as loose loess material susceptible to sliding, variations in reservoir levels, rainfall patterns, intricate geological formations, precipitation, and anthropogenic engineering activities, among others.

The landslide is very complicate, and some data about landslide are extremely difficult to collect or measure. So, we cannot analyze all collected data. All data have internal relations, not a single existence. Actually, scholars devote to study landslide based on two sides. Some scholars pay some interest in inter factor like mechanics, the other scholars are pay attention to numerical value. Then, the data of displacement, reservoir level and rainfall were collected to study landslide like [12-14]. Given the computational intensity of the EMD-SBLMK algorithm, a practical application was conducted by selecting the LSJ landslide at monitoring point 24 in the Three Gorges Reservoir area of China as a test case (see Fig. 4). The inclusion of mixed kernel functions in EEMD-SBLMK enables the model to effectively capture diverse patterns and features in landslide displacement data, enhancing generalization, robustness, interpretability, and overall modeling performance. Monitoring data about displacement and reservoir water level (see Fig. 5) and (see Fig. 6) are date from April 6, 2009 to May 25, 2011 at time interval six days. Monitoring about rainfall data (see Fig. 6) are date from April 6, 2009 to June 16, 2010 at time interval six days. The left data about rainfall data are recorded 0.

Fig. 4. LSJ landslide.

Fig. 5. LSJ displacement.

Fig. 6. LSJ rainfall and reservoir level.

The SBL method departs from ANNs in its requirement for equal-length training and prediction datasets, focusing on maintaining a balance between capturing complex patterns for model expressiveness and ensuring good generalization to unseen data. Consequently, we divide the entire dataset evenly into two parts to establish our prediction model. The dataset is bifurcated for analysis, with 50% allocated to the first group for model construction and the remaining 50% reserved for landslide displacement predictions. Additionally, we restrict the minimum number of time delays for input parameters to 10. Our EEMD integration totaled 100 iterations, augmented with 0.2 of white noise. This technique facilitates the decomposition of initial landslide displacement, reservoir water level, and rainfall time series. Specifically, displacement and reservoir water level series are broken down into five finite subsequences (IMF) and a residual function, while rainfall series yield four IMF subsequences and a residual function. The decomposition outcomes are graphically represented in Fig. 7, 8, and 9.

Fig. 7. EEMD decomposition of displacement.

Fig. 8. EEMD decomposition of reservoir level.

Fig. 9. EEMD decomposition of rainfall.

The choice of input parameters is critical to the outcome of the prediction, where we compute the correlation between each subsequence and the original displacement by MI (see Table I). In Table I, C represents for category, DD represents for displacement, RL represents for Reservoir Level, RR represents for Rainfall. According to the value MI between original displacement and component decomposition in Table I, we chose seven values as input to build model, such as displacement decomposition IMF3, IMF4, IMF5, residual, reservoir water level IMF4, IMF5, and Residual. The value MI between original displacement and decomposition of Rainfall are the same, also is lowest among three values. So the rainfall is not as inputs in

the paper. The process of selecting sub-series for forecast model construction involves segmenting the data-set based on relevant criteria to represent key patterns and features, ensuring a balanced representation of training and testing sub-series.

TABLE I. CALCULATE THE MI VALUES

C	IMF1	IMF2	IMF3	IMF4	IMF5	RESIDUE
DD	0.0739	0.1360	0.5523	1.1587	1.5003	2.7303
RL	0.1114	0.1168	0.2243	0.3214	0.3795	0.4800
RF	0.1163	0.1163	0.1163	0.1163	0.1163	0.1163

B. Analysis and Results

Then we choose eight kernel functions to train each input separately, and compute the number of RVM. Each input parameter use eight kernel functions to compute. According to the minimum number of computed RVM rules, each input parameter can choose best kernel function. That is mean each input parameter have own kernel function to compute. The model uses many different kernel functions to build. In Table II, D, E, F, G, H, I, J stand for displacement decomposition (IMF3, IMF4, IMF5, Residual), reservoir water level (IMF4, IMF5, Residual). 0 cannot be computed by kernel functions, other number means that can be computed by kernel functions and the number of kernel functions. Each variable selects different kernel functions as much as possible base on least number of using RVM.

The symbols A through G correspond to various kernel functions: A represents the Gauss, B the Laplace, C the R, D the Spline, E the Cubic kernel function (chosen twice), F the Cauchy kernel function, and G the Thin-plate spline (TPS) kernel function. In Table II, all data set can be computed only by two kernel functions. One is Cubic, the other is Bubble. Because the prerequisite of SBL is that the array of Hessian should be positive definite. Then it can be decomposed by Cholesky. Then, in this paper, we use hybrid kernel models, Cubic kernel model and Cholesky kernel model to build our model.

TABLE II. 8 KERNEL FUNCTIONS FOR EACH COMPONENT

Category	A	B	C	D	E	F	G
Rvm-Gauss	5	7	2	7	7	3	0
Rvm-Cauchy	0	15	0	52	45	2	0
Rvm-Cubic	5	7	8	6	5	2	6
Rvm-Bubble	5	52	52	52	29	28	23
Rvm-Laplace	18	5	45	29	6	48	0
Rvm-R	18	49	2	28	7	5	0
Rvm-Spline	3	7	0	2	0	7	15
Rvm-Tps	2	44	4	49	7	7	0

Measuring the quality of algorithms involves various commonly employed methods, including the Relative Error (RE), Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and Correlation Coefficient (R), as shown in Eq. (23) to Eq. (26).

$$RE = \frac{|\hat{Y}_i - Y_i|}{Y_i} \tag{23}$$

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (x_{testi} - x_{reali})^2} \tag{24}$$

$$MAE = \frac{1}{n} \sum_{i=1}^n |x_{testi} - x_{reali}| \tag{25}$$

$$R = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2 \sum_{i=1}^n (y_i - \bar{y})^2}} \tag{26}$$

The findings pertaining to three distinct kernel functions are presented in Fig. 10, Fig. 11, and Table III. Fig. 10 illustrates that the predicted values deviate slightly from the actual values. Notably, the first 38 data points utilizing the hybrid kernel function align most closely with the original data, followed by the Cubic kernel function for the remaining data. While the Bubble kernel function exhibits a similar trend to the hybrid kernel, its performance is inferior. In Fig. 11, the relative values of these three methods mirror the patterns observed in Fig. 10. Notably, the hybrid kernel function averages the best prediction results among the three methods.

In addition to these metrics, we computed four additional values for the three kernel functions: MAE, RMSE, R, and the number of RVM. The evaluation criteria for MAE, RMSE, and the number of RVM variables favor lower values, whereas a higher value is preferred for R. The hybrid kernel function achieved the minimum values for MAE, RMSE, and the number of RVM, while attaining the maximum value for R. According to the current evaluation standards, the hybrid kernel function demonstrates superior predictive performance. The hybrid approach involves selecting the most appropriate kernel function calculation for each variable, thereby leveraging the unique characteristics of each kernel.

TABLE III. COMPARISON OF THREE METHODS

Method	MAE	RMSE	R	RVM
Cubic	266.8843	273.5266	0.9873	42
Bubble	280.1885	286.6568	0.9593	204
Hybrid	244.6038	247.7012	0.9710	38

Fig. 10. Three methods predictive values.

Fig. 11. Three methods relative values.

V. CONCLUSION

Employing the principles of decomposition and ensemble, we commence by decomposing three distinct types of landslide data using EEMD methods. This decomposition results in three separate groups, each containing multiple subseries. Subsequently, we utilize mutual information (MI) to assess the correlation between each subseries and landslide displacement, enabling us to identify potential input variables for our forecast model. Next, we select specific subseries to construct forecast models using support vector regression with mixed kernels. Ultimately, the results of these predictive models are combined to reconstitute the initial landslide displacement sequence. To showcase the potency of our model across varying kernels, we provide a case study centered on the LSJ landslide monitoring site ZJG24 in the vicinity of China Three Gorges. The EEMD-SBLMK method we introduce is notably beneficial due to its suitability for single-step-ahead (SS) forecasts in real-world situations. Additionally, it possesses the capability for precise multi-step-ahead (MS) forecasts down the line.

ACKNOWLEDGMENT

Abstract—With the deep integration of industrial Internet of Things technology and artificial intelligence technology, the material robot has been widely used in the Internet of Things workshop. In view of many complex factors such as real-time dynamic change and uncertain condition in workshop, this paper proposes to realize workshop adaptive scheduling decision with component layer construction and SPMCTS search method with real-time state as the root node. This method transforms the robot scheduling problem into a Markov decision process and describes a detailed representation of workshop states, actions, rewards, and strategies. In the real-time scheduling process, the search method is based on the artifact component layer construction, and only considers the state relationship between two adjacent groups, so as to simplify the calculation difficulty. In the subtree search, SPMCTS is applied to search the real-time state as the root node, and the extension method and shear method are applied to conduct strategy exploration and information accumulation, so that the deeper the real-time state node in the subtree, the more the optimal strategy can be obtained quickly and accurately. Finally, the effectiveness and superiority of the proposed method are verified by real case simulation analysis.

Keywords—Industrial Internet of Things; mixed flow workshop; robot; Markov decision-making process; SPMCTS

I. INTRODUCTION

In this paper, the performance detection of the robot in the modern factory needs to be optimized, combined with the design of monitoring software, the diversified communication mode; under the premise of data transmission stability, efficient, remote and low-cost transmission wireless network, based on data transmission [1, 2] under TCP / IP communication protocol, remote control terminal design under 3G network, and unified database management. Utilizing optimization algorithms such as genetic algorithms, particle swarm optimization, or simulated annealing to solve complex scheduling problems. These algorithms can be applied to minimize makespan, reduce idle time, and balance workloads in the workshop. Mathematical modeling techniques like queuing theory and Markov chains can also be used to analyze system dynamics and predict performance metrics such as throughput and cycle time. Furthermore, statistical methods such as regression analysis and hypothesis testing can help evaluate the impact of scheduling strategies on productivity and efficiency. The current stage of Internet of Things (IoT) application, both domestically and internationally, is in the developmental phase. However, the establishment of an IoT framework based on the robot testing system remains imperfect. In this context, a more economical and effective approach is required for robot testing. Utilizing

high-precision sensors, employing digital output data acquisition methods, and leveraging Ethernet transmission can effectively capture measurement results. This facilitates the enhancement of robot performance parameters, particularly in modern factories where simultaneous multi-station measurements are common. Establishing a multi-node base station within a regional wireless network enables data transmission to a centralized database server terminal, facilitating remote detection and data analysis, which holds significant importance. IIoT enables seamless connectivity between devices, machines, and systems, facilitating efficient communication and coordination in dynamic manufacturing environments. By leveraging IIoT technologies, such as sensor networks and cloud computing, the proposed method can gather real-time production data, optimize scheduling decisions, and dynamically adjust to changing operational conditions. This integration of IIoT enhances agility, flexibility, and responsiveness in robot scheduling, ultimately improving productivity and competitiveness in industrial settings. Robot parameters including current, tracking error, torque, speed for mostly need technicians' site real-time acquisition, and in the environment of the Internet of things, using the 3G network and network operators, remote monitoring robot, to real-time understand the running condition of the robot, alarm, etc., improve the safety and efficiency of field operation. Connecting everything to the same network through a communication device. This is our most basic definition of the Internet of Things. The Internet of Things is a relatively broad concept, its related technologies are more comprehensive, the most typical is the radio frequency technology, it is the characteristics of the initial Internet of things, other there are sensing technology, electronic technology, communication technology and so on. At first, the application of RF technology was more mainly in the food transportation industry, but the inclusiveness and scalability of its technology are also applicable to the industrial field. More and more products are using connected to their enterprise networks for [3, 4], especially in the robotics industry. The concept of "the Internet of Things" was established in 2005, organized by the ITU, at the Information Society Summit held in Tunisia. ITU detailed the features of the Internet of Things, introduced the design technology, and analyzed the market opportunities and pressure challenges as shown in Fig. 1. Integrating deep learning algorithms for intelligent scheduling, leveraging big data analytics to optimize production efficiency, designing smart sensors for real-time monitoring and feedback, researching machine learning models to streamline workflows, and developing intelligent control systems to enhance autonomous decision-making. These works can be scientifically

validated through empirical research, simulation modeling, and case studies to demonstrate their effectiveness in improving

production efficiency, reducing costs, and optimizing resource utilization.

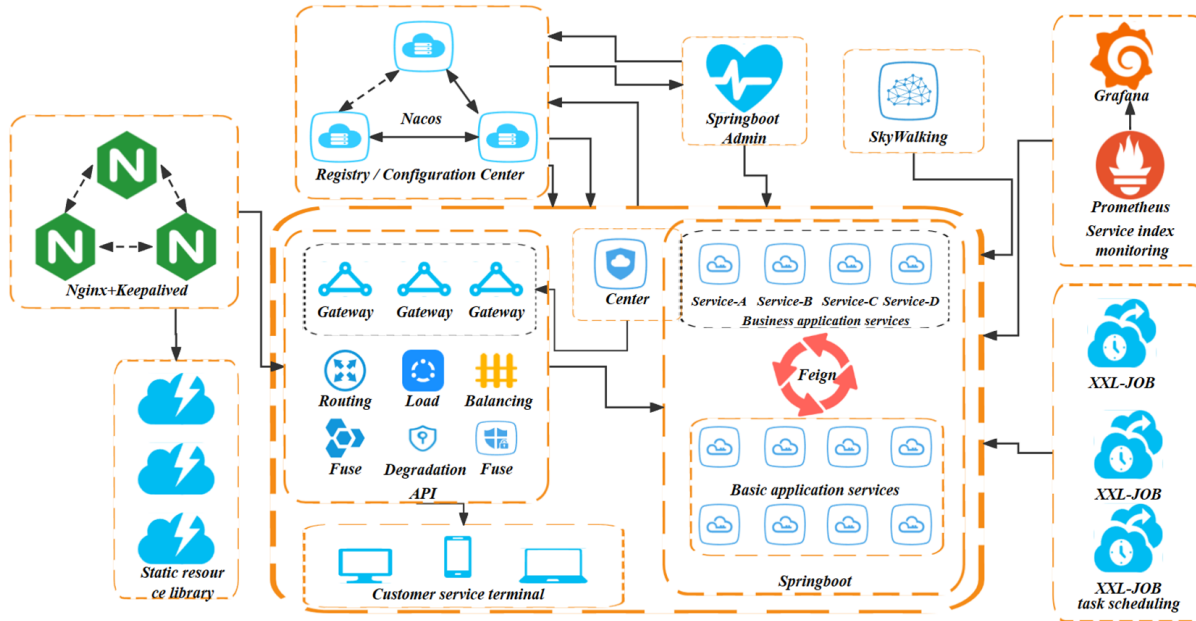

Fig. 1. Communication technology diagram.

In the field of communication and even the whole field of information technology, the of Things has become an inevitable development trend, not only affecting the field of communication, but even the whole field of information technology. Each figure should be accompanied by concise yet informative captions to provide context and aid comprehension. Additionally, ensuring consistency in design elements, such as color schemes and labeling conventions, contributes to the overall clarity and professionalism of the figures. By improving the quality of figures and providing clear explanations, readers can better grasp the complexities of the proposed methodologies and results. In terms of promoting social progress, the Internet of Things industry has promoted industrial upgrading. With Japan, South Korea, the United States, the European Union and other developed countries and regions, they have been at the forefront of the world of Internet of Things research. Japan's Internet of Things technology has been able to respond to disasters, apply in security management, public services and other fields, and advocate mobile payment [5, 6] in large-scale commercial use. In South Korea, cloud computing is an important platform for massive information processing of the Internet of Things, and its technology development has greatly promoted the development space of the Internet of Things. In terms of Internet of Things research, the United States has a great advantage, and many universities and research institutes have done a lot of research on wireless sensor networks. The current research method was chosen for its ability to address the dynamic scheduling challenges posed by IIoT-enabled mixed flow workshops. Unlike traditional methods, which often rely on static scheduling approaches, the proposed method leverages real-time data from interconnected devices to adaptively allocate tasks among robots. This real-time adaptability is crucial for optimizing production efficiency, minimizing downtime, and responding to changing manufacturing demands swiftly. By

comparing with traditional methods, the superiority of the proposed approach in terms of flexibility, responsiveness, and overall operational performance can be clearly demonstrated. The current paper lacks a coherent introduction that clearly outlines the purpose, scope, and significance of the research. To enhance the quality of the paper, the authors should provide a concise overview of the problem addressed, the methodology employed, and the primary contributions of the study. Specifically, in the context of adaptive scheduling of robots in the mixed flow workshop of the industrial Internet of Things (IIoT), the introduction should emphasize the critical need for efficient scheduling methods to optimize production processes and resource allocation in dynamic manufacturing environments. Furthermore, it should highlight the importance of integrating IIoT technologies with industrial robotics to enable real-time monitoring, data analytics, and adaptive decision-making, thereby enhancing productivity and efficiency. Over the past ten years, it has made great progress in wireless intelligent sensor network communication technology, micro sensor and many other Internet of Thing's technologies, and has certain technological advantages. The Internet of Things technology has received more and more attention in China. Some major domestic engineering enterprises and scientific research institutions have participated in the research and development of the "monitoring system", on behalf of Xugong Machinery Group, Sany Heavy Industry and Tiangong Machinery Research Institute. At present, the monitoring system has been partially completed for the field operation equipment, and intelligent transformation. The next step will be a simulation demonstration for the practical application of the project that need to be monitored. The motivation behind the proposed work lies in addressing the evolving needs of modern manufacturing facilitated by the Industrial Internet of Things (IIoT). Research gaps exist in the realm of adaptive scheduling for robots in

mixed flow workshops, where traditional static methods fall short in meeting dynamic production demands. The objective is to develop a robust scheduling framework that harnesses IIoT capabilities to optimize task allocation, minimize delays, and enhance overall productivity. This research aims to bridge the gap between traditional scheduling methods and the requirements of agile, IIoT-driven manufacturing environments, ultimately improving operational efficiency and competitiveness. However, the development technology of domestic monitoring system is not mature, and there are still the following problems: single function: the research of the system is still in the exploration stage, the product function is not perfect, the remote communication function cannot be realized, the real-time is not high, low efficiency is poor, cannot meet the higher requirements of system design. Due to the limitations of the communication equipment, the data acquisition device in the system saves the collected data to the built-in or external expansion memory of the micro controller, which requires additional configuration of terminals for docking analysis. This brings great inconvenience to debugging and maintenance, and the storage equipment capacity is limited, and also costs a lot of maintenance costs, the security and reliability of the system remains to be discussed. And the content of the relevant technical field, the country has not made the relevant standards. The development situation of foreign countries, take the "remote service" proposed by ABB as an example [7, 8]. The concept was proposed for the robot to alarm to its own failure. During the simulation phase of the research work, the authors may have made assumptions regarding the deterministic nature of robot motion and ignored sensor errors, environmental changes, and fault conditions. These assumptions could lead to deviations between simulation results and real-world scenarios, affecting the credibility and practicality of the study. Therefore, the critique should involve a thorough analysis of the rationale behind these assumptions, their impact on research findings, and suggestions for potential improvements to enhance the accuracy and fidelity of the simulation.

II. REPEATED POSITIONING ACCURACY TEST SYSTEM FOR INDUSTRIAL ROBOT

A. System Architecture

The repeated positioning accuracy of the robot refers to the ability of the robot to repeatedly reach the specified command or teaching position. The results are affected by the control system, surrounding environment, transient corresponding conditions of the system, wear of parts, etc. The numerical measurement is helpful to optimize the structure and control mode of the robot and improve the operation ability of the robot. In the manufacturing and production of industrial robots, it is necessary to detect the repeated positioning accuracy of finished robots. At present, most laser tracking instrument is used for detection. The laser tracking instrument has high measurement accuracy and many measurement functions. However, in the measurement process, the tester needs to track the operation in real time and record the measurement data in real time, and the end needs the robot to accurately [9, 10] with the tracking instrument. The final measurement data needs to be processed by the tester, so only the robot can be tested at a single station. The equipment cost of laser tracker is high, and a certain software service fees paid every year. The equipment is only

suitable for the research and development of industrial robot, and is not suitable for the testing application of industrial robot mass production. In view of the above problems, this paper proposes a test system with low cost, simple operation, simultaneous MultiTaction measurement, and certain data processing system.

The industrial robot repeated positioning accuracy test system is mainly composed of the test system mainly composed of detection device, data acquisition device and data processing terminal. The detection device measures the spatial position of the robot end with the displacement laser sensor; the data acquisition device connects the controller and the sensor in serial port and preliminarily processes the data. Fig. 2 shows that the standard protocol based on OPC communication transmits the data to the terminal through the wireless device, generates the data report, displays the real-time curve of measurement, obtains the final measurement value, and completes the whole monitoring process [11, 12].

The detection device is composed of three laser sensors fixed on the mounting bracket. The three coordinates of x, y and z in the simulation space are used as the reference coordinate system to determine the end position of the robot. The acquisition signal is transmitted to the small controller by the control unit through the interface of the RS232. There are relevant touch screen devices and wireless devices at the test site, which can receive and view data remotely. The final data terminal processes the data, displays and analyzes the data, and equipped with relevant output equipment to save the final result. The measurement method adopts the traditional measurement method, which teaches the robot to reach the specified position in the space, and lets the robot run the command position repeatedly, measures the position value of each time, and makes relevant records and processing. The final collected data is remotely transmitted to the terminal server through the wireless device, and the data is viewed on the display screen to observe the real-time images. The detection part of the system adopts the contactless measurement method, so the laser sensor is used to measure the end position of the robot. The principle of triangulation is the basic principle of the laser sensor. The detection head emits the visible red laser to the surface of the measured object [13, 14], the sensor will receive the laser reflected by the object, and the internal CMOS signal amplifier will process the reflected light. When the target object changes, the position of the light presented on the CMOS moves. The amount of change of the target is determined by detecting the light position. At the same time, the control unit will calculate the beam position of the original, and output the corresponding value randomly. The sensor of this system has a resolution of 1 μ m and a repetition rate of 2 μ m. The fixed displacement sensor device is an adjustable bracket. The adjustable bracket can adjust the height position in the sensor space. The bottom of the bracket is equipped with universal ball and adjustable foot cup, which is easy to move the whole bracket and fix the bracket position, so as to measure the repeated positioning accuracy of the robot moving to different points in the space. The sensor is mounted on the bracket, so that the projected light is vertical to each other in space, which can be compared to the three-dimensional coordinate system of space. When measuring, by controlling the position of the robot to reach the axis of the sensor. In addition,

to ensure that the laser can be projected at the end of the robot, rectangular block loads are installed at the end of the robot. This kind of load has three different vertical sides, which can ensure that the laser can illuminate vertically. Table I shows that Key Considerations for Adaptive Scheduling in IIoT Robotics.

However, the laser accuracy of the sensor will show different changes due to the influence of different irradiation surfaces, so the ceramic measuring sheet [15, 16] is installed on the load surface to ensure that the accuracy of the sensor reaches the best state during measurement.

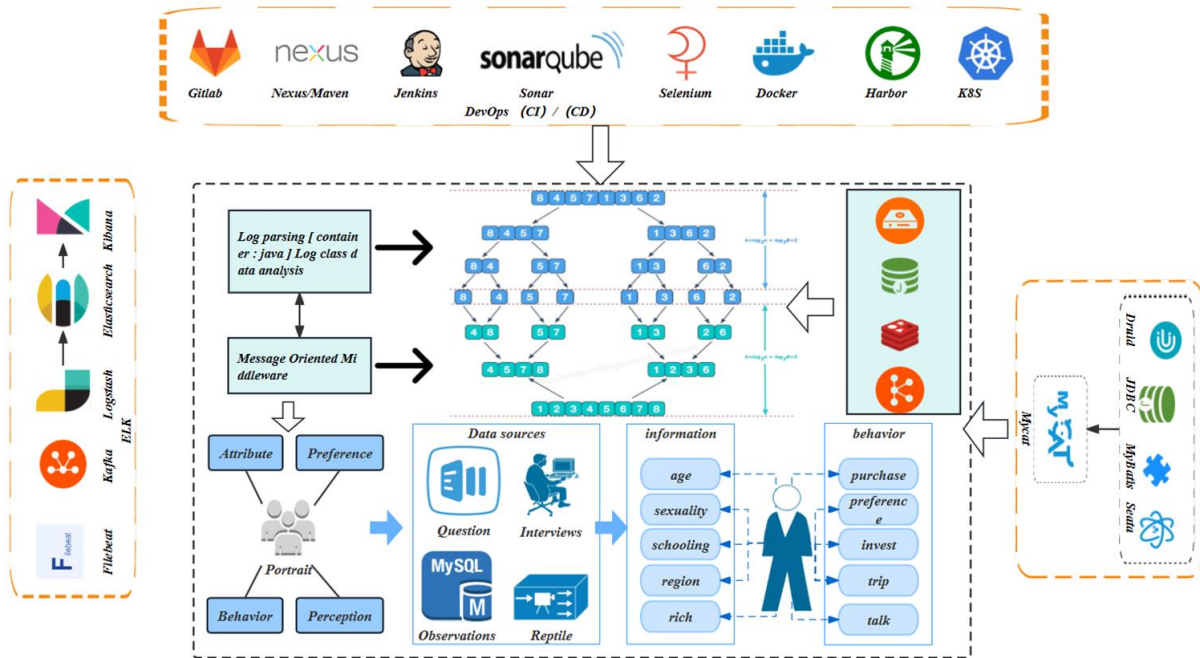

Fig. 2. OPC Communication diagram.

TABLE I. KEY CONSIDERATIONS FOR ADAPTIVE SCHEDULING IN IIOT ROBOTICS

Challenges	Description	Solutions	Benefits	Implementation
Dynamic Workload Variation	Variations in task demands require adaptive scheduling algorithms.	Dynamic task allocation algorithms.	Optimized resource utilization.	Real-time monitoring and adjustment.
Real-time Data Processing	Quick processing of sensor data and task updates is crucial for efficient scheduling.	Edge computing and real-time analytics.	Reduced latency and faster decision-making.	Integration of AI algorithms for predictive analytics.
Interoperability of IoT Devices	Compatibility issues between different IoT devices and platforms.	Standardization of communication protocols.	Seamless data exchange between devices.	Integration of IoT middleware solutions.
Optimization of Energy Consumption	Efficient scheduling to minimize energy consumption and operational costs.	Energy-aware scheduling algorithms.	Reduced energy bills and environmental impact.	Integration of smart energy management systems.
Integration with Existing Systems	Integration challenges with legacy systems and equipment.	Middleware solutions for legacy system integration.	Improved system interoperability.	Retrofitting and API development for legacy system compatibility.

B. Architecture Design

This system uses the B & R X20 series compact small controller. The task cycle of X20 can reach 200us, the instruction cycle can reach 0.01us, and X20 can be installed on the commonly used guide rail, which is fully distributed I / O. The corresponding communication interface for the data collection of the system is RS232 serial communication. RS232 communication is suitable for communication in the range of 0-20000 bit/s. RS232 standard was originally developed by remote optical communication connecting data terminal device DTE and data communication device DCE. At present, the connection between the computer and the terminal, peripherals and other devices is more widely used. The serial communication mode of RS232 is separating the system from the traditional sensor

detection data. The traditional sensor data collection is mostly output by 0-5V or 4 - 20 mA. In the process of processing the simulated signal, there are calculation errors and acquisition efficiency, and the accuracy of the data is not high. The sensors of this system adopt the Keens L series, adopt the pioneering series networking mode, and the three-coordinate data can be output by its equipped DL-RS1A communication unit. It sends instructions to the communication unit through an external device, and the communication unit automatically returns the response value. The connection between the controller and the communication unit belongs to the connection of two DTE devices. Instead of providing any hardware handshake signal connection but using the software to control the communication data flow. The wiring diagram is shown in the following figure: The transmission communication specification is 115200 bit/s,

the data length is 8bit, no parity bit, and the stop bit length is 1bit. The instruction code is the transmission code based on ASC code, which includes reading instructions, writing instructions and reading and writing instructions. Currently, the data collection frequency is 50Hz. Add the required sending instruction to the data collection program, red the corresponding string data, and convert the final data. The system filters the median value average of the collected data, which is a common digital filtering method. This method is suitable for filtering the signal with random interference, and the fluctuation interference caused by accidental factors can be effectively overcome to eliminate the sampling value deviation caused by it. The specific treatment method is as follows (such as x direction), the median average filtering method, as the name suggests, is the “median filter method” + “arithmetic average filtering” method, Take N points in a sampling period, remove the minimum and maximum points, and calculate the average [17, 18] for the remaining N-2 data, and the result is used as the effective date of one collection.

III. FACTORY WIRELESS MONITORING SYSTEM FOR INDUSTRIAL ROBOT DEBUGGING STATION

A. System Architecture

The design of the system follows the principles: complete functions, stable performance, low cost. Considering field implementation and subsequent maintenance efforts, the system needs good scalability and portability. The following are detailed requirements: according to the actual needs and technical conditions, according to the site environment, the design of the system needs to meet the actual production requirements. It is then initialized on the following basis:

Its residual values were then calculated, using each individual Loss function of the sample as the residual value of Equation (1):

$$r_{mi} = - \left[\frac{\partial L(y_i, f(x_i))}{\partial f(x_i)} \right] \tag{1}$$

It was then fitted to a CART regression tree to obtain the set of leaf points. Then update the forecast results as Equation (2):

$$f_m(x) = f_m - I(x) + \sum_{j=1}^J \phi_{mj} \times I \tag{2}$$

Finally, we get the model of GBDT as Equation (3):

$$f = f_M(x) = \sum_{m=1}^M \sum_{i=1}^J \phi_{mj} \times I \tag{3}$$

On the basis of ensuring the satisfying function, the cost is minimized. High reliability and safety are the important basic conditions of the system. Data collection and storage, the stability and safety of the equipment, as shown in Fig. 3, all require the good safety and reliability guarantee of the system. The system needs to support multiple interfaces for the docking of different devices to maximize compatibility. The design idea of redundancy and the added [19, 20] of new concepts and new functions require the system to have rich scalability. Improve the level of supervision and comprehensive management.

Fig. 3. Redundancy design diagram.

The Pearson's correlation coefficient between two variables is defined as the quotient of the covariance and standard deviation between two variables, Equation (4) display it:

$$\rho_{x,y} = \frac{cov(x, y)}{\chi_x \chi_y} = \frac{E[(x - \bar{x})(y - \bar{y})]}{\chi_x \chi_y} \quad (4)$$

The above Equation (5) defines the overall correlation coefficient, and the Greek lower case letter symbol is commonly used as the representative symbol. To estimate the covariance and standard deviation of the sample, Pearson correlation coefficient, common English small letters represent:

$$F = \frac{\sum_{j=1}^m (xi - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{j=1}^m (xi - \bar{x})^2} \sqrt{\sum_{j=1}^m (y_i - \bar{y})^2}} \quad (5)$$

The F letter can also be estimated by the standard score mean of the letter sample point to obtain an expression equivalent to the above Equation (6):

$$F = \frac{1}{m-1} \sum_{i=1}^m \left(\frac{xi - \bar{x}}{\chi_x} \right) \left(\frac{yi - \bar{y}}{\chi_y} \right) \quad (6)$$

In order to improve the efficiency and accuracy of the equipment control, the system should have sufficient supervision capacity. The background terminal can accept the production information [21, 22] in time, and can make a judgment in the first time, effectively reducing the complex problems on the site. On the basis of ensuring the normal production of the robot, it can predict the production problems of the new plant and give solutions in time. On the basis of reducing the equipment loss, reduce the maintenance cost to optimize the management. One of the core technologies of the Internet of Things is the radio frequency technology, and the most common application of the Internet of Things is to put the RF label on the product, combined with the Internet technology, to retrieve and save the product information. At present, radio frequency technology has been widely used in the modern manufacturing industry, and industrial robots are naturally essential.

We can do the statistics according to the following Equation (7):

$$t = \frac{d - \alpha_0}{s_d / \sqrt{n}} \quad (7)$$

And we award the following Equation (8) as the average of the paired sample difference:

$$d = \frac{\sum_{i=1}^n di}{n}, i = 1 \dots n \quad (8)$$

We can know that the following Equation (9) is the standard deviation of the sample difference value:

$$sd = \sqrt{\frac{\sum_{i=1}^n (di - d)^2}{n-1}} \quad (9)$$

Radio frequency technology is RFID, a non-contact automatic identification technology. The scanning device scans the product corresponding label [23, 24] by transmitting a wireless carrier signal to activate the label information. The label will return the corresponding carrier information and transmit it to the reader, and the final identifier sends the decoded information to the command detection device. RFID is the expansion and application of wireless technology, data collection breaks through certain limitations, on the basis of improving the data transmission speed, increase the transmission flexibility. The monitoring system design is based on the previous repeated positioning accuracy test system, which optimizes and expands the collected data transmission mode. Based on the requirements of factory multi-station testing and the situation that measured data can be returned at the same time, wireless transmission is more convenient and the cost is relatively low. The EPA client is installed at each test station to upload the collected data as the base station, while the server terminal in the main control room is equipped with wireless AP as the main station, so that a wireless network covering the entire factory can be established. Through this network, the measurement data can be monitored remotely in real time to improve the efficiency of data collection and analysis, which is conducive to the real-time analysis of the online state of the robot. According to the network structure, the system can be divided into three layers. To monitor the operation status of the robot in real time, it is necessary to equip PLC equipment at the debugging station of the robot to carry out the relevant data acquisition work [25, 26], and this equipment constitute the data acquisition layer. The collected data is uploaded to the background terminal through the WLAN network covering the factory, and is uniformly stored and managed logarithmically. This is the data processing layer. Finally, the processed data analysis disk will form the decision and solution to each operation terminal, so as to effectively monitor and manage the sound field and working conditions on the site. This is the data application layer.

B. System Function Realization

The system data acquisition device is still implemented by X20 series controllers, and X20 can also be used as a PLC device for field data collection. Here is mainly to explain the selection of wireless equipment. The wireless communication equipment of this system mainly uses phoenix WLAN5100, EPA and other wireless equipment WLAN5100 is phoenix based on industrial WLAN network design, aiming to make the production and logistics process more efficient and reliable. Its design is simple, reliable, safe and fast, and it is suitable for mobile communication automation and production system. Data mining is to extract potentially useful information from the data. To this end, we write computer programs that screen useful regularities or patterns in the database to enable our implementation methods. If you can find some obvious patterns and summarize

them, it is very useful to predict future data. In the real world, data is actually incomplete: some are tampered with, others are lost. Everything we observe is not entirely precise: there are exceptions to any rule, and there are instances that do not conform to any one rule. The algorithm must be sufficiently robust to cope with imperfect data and can extract useful regularities [27, 28]. In recent years, the database has expanded rapidly, such as recording the customers' choice of commodity behavior as the database, which is bringing data mining to the preface of commercial application technology. It is estimated that the growth of data in the world will double every 20 months. Although it is difficult to really verify this number in the sense of quantity, but we can qualitatively increase my growth rate. The world is becoming more and more colorful, and people are immersed in these massive data, and the vision of insight into the patterns that constitute the data is placed on the data mining. Data mining is one of the most advanced research contents of database system and intelligent technology in recent years. The potential value of mining and learning data from the large amount of data and the discovery application rules are our simple definitions of data mining. The process consists of the following steps: data cleaning; data integration; data selection; data transformation and data mining.

The calculation formulas for the final model are Equation (10):

$$G(x) = \sum_{i=1}^m \alpha_i G_i(x) \tag{10}$$

Then we set the maximum number of cycles to kmax, and we evaluated the training results of the learner Ck by Equation (11):

$$Q_{k+i}(j) \rightarrow \frac{Q_k(j)}{Z_k} \times \left\{ \begin{matrix} e^{-\alpha_k} \\ e^{\alpha_k} \end{matrix} \right\} \tag{11}$$

Then the weight is shown in Equation (12)

$$\alpha_i = \frac{1}{2} \times \log \frac{1 - e_i}{e_i} \tag{12}$$

Data mining technology has different categories according to the type of mining database, mining knowledge type, adopted mining technology and application occasions. Usually, according to the different knowledge types of mining, data mining can be divided into the following categories: association analysis, classification, prediction, sequence analysis, cluster analysis, and isolated point analysis. A very important research content in the field of data mining is data classification. According to the collected data, it finds models that can distinguish and describe different concepts or data, and classify them one by one according to objective attributes and marginal conditions. Decision trees, Bayesian methods, neural networks, genetic algorithms and instance inference are all common methods used for data classification. The wireless LAN module in the 510x series shown in Fig. 4 can provide maximum reliability, data throughput and coverage. WLAN5100 Combining the 802.11n-based standard industrial technology and the modern multi-input and multi-output antenna technology, [29, 30]. The three-antenna MiMo technology significantly increases the stability, speed, and range of wireless communication. The special function module of WLAN510x is that it can be configured quickly and easily.

Fig. 4. Wireless LAN module diagram.

Its configuration with WLAN access points is automatically distributed to all other access points for the WLAN networks using the cluster management function. Tap the button, the WLAN client can or can easily integrate into the WLAN network without configuration due to WPS. Similarly, the proposed method enables the creation of fault tree models to analyze various common faults in industrial robots. This facilitates fault diagnosis by service engineers with extensive experience in robot after-sales service and maintenance. By establishing a fault diagnosis system based on fault tree analysis and expanding it to an expert diagnosis system, the method enhances fault detection and resolution efficiency. Additionally, the Ethernet Port Adapter (EPA) serves as a high-performance industrial wireless LAN device, facilitating network connections for various industrial equipment and wireless LAN interfaces, including personal computers, mobile devices, barcode scanners, and RFID readers.

C. Industrial Robot Remote Service Platform and Monitoring System

The design of the system is the combination of remote management and data collection and analysis, auxiliary industrial robot equipment, achieve more intelligent, more efficient when the robot to produce a lot of real-time data collection, unified storage management, and can through comparative analysis of operational data, auxiliary engineer judge equipment status, on the other hand using the data mining algorithm, realize the robot equipment fault prediction such as intelligent maintenance. The system comprises three main components: hardware data collector, server-side program with database, and web page front-end program. A communication interface for robot remote service platform and a protocol called Robot Data Acquisition and Remote-Control Protocol (RDCRCP) based on TCP/IP communication protocol are designed. RDCRCP specifies communication parameters, data structure, and message definition, facilitating data interaction. Stable customer-server communication is ensured by establishing long TCP connections for data interaction between devices. The robot master control serves as the server side, while the SegBox data acquisition device acts as the client side, initiating TCP connections and conducting one-to-one request-response interactions. If the client still does not receive the response after waiting for T seconds, the SegBox should resend the message immediately. If the SegBox is still not responded after $N-1$ consecutive transmission, the transmission request is stopped. When there is no data interaction on the TCP channel, the client will continuously send the link detection package to the robot at every time C to ensure the continuous connection of the communication. If the response message is not sent after the waiting time exceeds T second, the link detection package will be sent again immediately. The TCP connection will break after more than $N-1$ times of the non-response.

IV. EXPERIMENTAL ANALYSIS

SPT, LPT and SLACK are introduced here to compare with the proposed method mentioned in this paper, processing 500 randomly generated tasks in the same environment and

comparing them comprehensively by completion time and delay rate. The workshop parameters of 10 randomly generated cases were optimized by each method, and then the average value was taken for comparison. See Fig. 5 for the schematic diagram of the multi-robot scheduling method. We can intuitively see the comparison results of the five methods under the two indexes of completion time and delay rate. Compared with SPT, LPT and SLACK rules, the SPMCTS algorithm decreased by 28.3%, 27.8% and 31.4%, and 70.4% and 42.9%, respectively, while the delay time decreased by 16.7% and 9.9%, and 38.5% and 22% compared with AHP and RLVNS and 22%, respectively. It can be seen that the single SPT, SPT and SLACK rule scheduling can respond quickly, but its adaptability is poor and the scheduling quality is difficult to guarantee, and the information network is established by applying the SPMCTS algorithm to search and selecting the optimal scheduling strategy to adapt to the current state of multiple rules, so as to get better solution quality.

The system software can be divided into two parts, namely the SPMCTS program developed using python on the TensorFlow platform and the simulation program developed with analog software on the Siemens Tecnomatix platform. The entire simulation program is divided into the following sub-modules: equipment management, task management, state management, communication module and scheduling instruction module. In the production process of simulated workshop, the equipment management module is responsible for the information management of processing equipment, robots and various sensors in the workshop; the task management module is responsible for the management of all artifacts; the key information processing module is to process the real-time equipment and artifact information sent from the equipment management and task management module. Fig. 6 and sends the extracted key information to the communication module. he communication module is to establish a communication network between the SPMCTS program and the simulation program to transmit the state information and the scheduling instruction information in real time. The SPMCTS optimization policy optimizes the dispatching policy according to the current state and sends the dispatching policy to the scheduling instruction module. Finally, the scheduling instruction module performs the scheduling tasks according to the policy coordination rules and the robot.

The quality of SPMCTS solution is better than multi-rule combination AHP method and reinforcement learning RLVNS method, we can see that compared with multi-rule combination AHP method, SPMCTS algorithm is more adaptable; however, RLVNS method only considers the neighborhood search learning of the first process. Fig. 7 cannot distinguish the information difference in work piece scheduling between processes, which has obvious limitations. Therefore, the simulation results verify the effectiveness and superiority of applying SPMCTS for multi-robot scheduling in the mixed-flow workshop under the industrial Internet of Things.

Fig. 5. Indicator results diagram.

Fig. 6. Strategy optimization diagram.

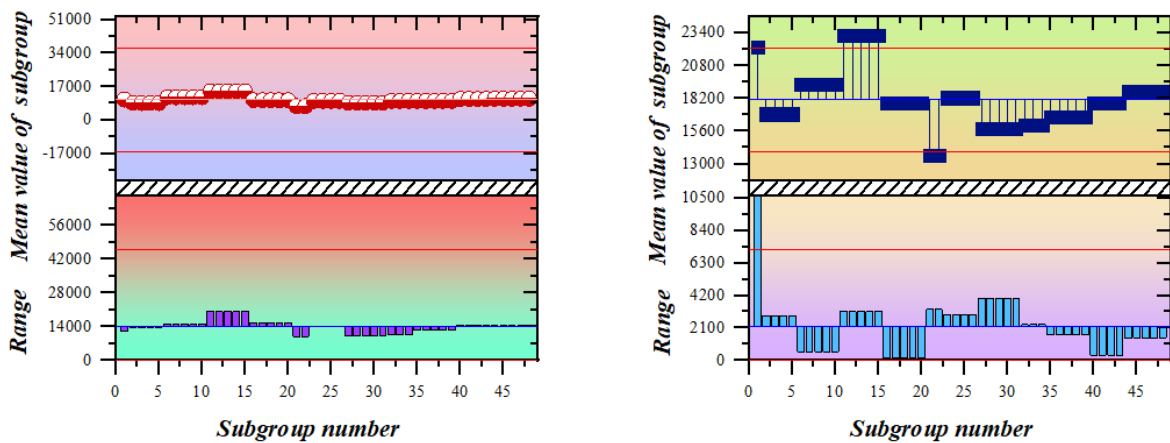

Fig. 7. The Optimization results diagram.

V. CONCLUSION

This paper introduces three systems: the repeated positioning accuracy test system of industrial robots, the factory wireless monitoring system of industrial robot debugging stations, and the remote service platform and monitoring system of industrial robots. The repeated positioning accuracy test system relies on high-precision laser sensors for real-time spatial position measurement. It enhances traditional analog data transmission by adopting RS32 digital transmission for improved stability and accuracy. Additionally, it integrates wireless equipment transmission to data processing terminal equipment, facilitating data analysis and monitoring. The data terminal has a built-in repeated accuracy algorithm, and designs the relevant monitoring screen and data storage, to ensure that the test results are justified.

The factory wireless monitoring system of the industrial robot debugging station is mainly aimed at the monitoring scheme of the industrial robot production site. For instance, highlight how the proposed scheduling algorithm significantly reduced production downtime by optimizing task allocation among robots. Discuss how the integration of IIoT technologies facilitated real-time monitoring and adaptive decision-making, leading to improved operational efficiency. Acknowledge limitations such as the complexity of real-world industrial environments and the need for further refinement of the scheduling algorithm. Finally, recommend future studies focusing on enhancing algorithm robustness, exploring dynamic scheduling strategies, and investigating the integration of AI for predictive maintenance in IIoT-enabled manufacturing settings. In addition to the current advancements, future research directions in the field of adaptive scheduling for industrial robots could explore the integration of artificial intelligence techniques for more intelligent decision-making processes. Moreover, the development of predictive maintenance algorithms could enhance equipment reliability and minimize downtime. Furthermore, investigating the integration of advanced communication protocols and edge computing technologies could optimize real-time data processing and improve system efficiency.

Optimization of Student Behavior Detection Algorithm Based on Improved SSD Algorithm

Yongqing CAO, Dan LIU
College of Computer Science and Engineering
Cangzhou Normal University
Cangzhou, 061001, Hebei, China

Abstract—Despite advancements in educational technology, traditional action recognition algorithms have struggled to effectively monitor student behavior in dynamic classroom settings. To address this gap, the Single Shot Detector (SSD) algorithm was optimized for educational environments. This study aimed to assess whether integrating the Mobilenet architecture with the SSD algorithm could improve the accuracy and speed of detecting student behavior in classrooms, and how these enhancements would impact the practical implementation of behavior-monitoring technologies in education. An improved SSD algorithm was developed using Mobilenet, known for its efficient data processing capabilities. A dataset of 2,500 images depicting various student behaviors was collected and enhanced through preprocessing methods to train the model. The optimized SSD model outperformed traditional algorithms in accuracy and speed, thanks to the integration of Mobilenet. Evaluation metrics such as precision, recall, and frames per second (fps) confirmed the superior performance of the Mobilenet-enhanced SSD algorithm in real-time environmental analysis. This advancement represents a significant improvement in surveillance technologies for educational settings, enabling more precise and timely assessments of student behavior. Despite the promising outcomes, the study faced limitations due to the uniformity of the dataset, which mainly consisted of controlled environment images. To improve the generalizability of the findings, it is suggested that future research should broaden the dataset to encompass a wider range of educational settings and student demographics. Additionally, it is encouraged to explore alternative advanced machine learning frameworks and conduct longitudinal studies to evaluate the influence of real-time behavior monitoring on educational outcomes.

Keywords—Improved single shot detector (SSD) model; mobilenet network; class behavior recognition; artificial intelligence

NOMENCLATURE TABLE

Identifier	Description
Abbreviations	
SSD	Single Shot Detector
AI	Artificial Intelligence
CNN	Convolutional Neural Network
RNN	Recurrent Neural Network
LSTM	Long Short-Term Memory
GRU	Gated Recurrent Unit
Mobilenet	Mobile Networks
VGG16	Visual Geometry Group Network 16
DIoU-NMS	Distance Intersection over Union - Non-Max Suppression
Symbols	
x	Input data

y	Output data
σ	Activation function
α	Learning rate
β	Regularization parameter
θ	Parameters of the model
W	Weight matrix
b	Bias terms
Greek Symbols	
γ	Discount factor in reinforcement learning
δ	Difference or error term in calculations
λ	Weight decay factor
Subscripts	
i	Index for summation
j	Index in a series or layer
t	Time step index in sequences
Superscripts	
-	Denotes the previous state in recursive formulas
+	Denotes next state in progressive calculations

I. INTRODUCTION

The current higher vocational education reform is increasingly emphasizing hybrid teaching as the focal point and direction of development, owing to the rapid advancement of information technology and the deepening of teaching information reform. By integrating network information technology into classroom instruction, it enhanced teaching quality. This work done by Huang et al. [1] focused on reforming the Modern Educational Information and Technology course through both online and offline methods. Through analysis of 50 questionnaires, it shed light on the efficacy of this approach. In the realm of education, real-time insights into student learning were offered by surveillance videos, yet limitations were faced by current action recognition methods. To address this, a novel dataset was created from smart classrooms, notable for its complex backgrounds and crowded scenes. The solution suggested by Li et al. included an attention-based relational reasoning module and a relational feature fusion module, enhancing recognition accuracy. Through rigorous experimentation, existing algorithms were surpassed by our model, signaling a new era of action recognition in education [2]. Trabelsi et al. [3] advocated for AI-powered classrooms that monitored student attention, even with face masks. Their study refined the YOLOv5 model, achieving a 76% average accuracy. They argued this technology empowered instructors to craft tailored learning experiences, blending tradition with innovation in education. The paper done by Tran et al. [4] discussed the application of computer vision in education to monitor and analyze student behavior. It proposed a new method that used the movement of students' body parts to identify classroom

behaviors, with a database of ten actions for method evaluation. A deep learning model enabled real-time action analysis and classification, showing effective results in enhancing teaching by providing feedback for lesson adjustment based on student engagement.

In their scholarly endeavor, Park and Kwon [5] crafted a potent educational program that seamlessly integrated artificial intelligence (AI) into South Korea's middle school free semester system. Through meticulous preparation, development, and improvement, they honed a curriculum focused on technology education's specific needs. Their program, distinguished by its emphasis on AI's societal impact, ethical considerations, and problem-solving, yielded remarkable outcomes. Students exhibited increased interest in technology, aspirations for technological careers, and enhanced understanding of AI's implications. Park and Kwon's study served as a beacon, illuminating the path for future educators to infuse AI into technology education effectively. In their seminal work, Sharma et al. [6] highlighted the transformative potential of artificial intelligence (AI) and machine learning (ML) in education. They advocated for AI's role in creating personalized learning content, analyzing student data to enhance teaching strategies, and automating grading and feedback processes. Through these innovations, education became more effective, personalized, and engaging, promising a brighter future for learners and educators alike.

The detection of students' classroom degrees is based on the target recognition algorithm, also composed of artificial intelligence. Testing the students' classroom behavior through the target algorithm can efficiently determine the total count of students present within the classroom and have more accurate statistical results. Face recognition in the class can also be done in a short time. Combined with the above content, it is highly feasible to analyze students' classroom behavior through artificial intelligence.

The crucial enhancement of the quality of education through the integration of information technology in classroom instruction is being addressed as technology continues to advance rapidly. Challenges are faced by traditional action recognition algorithms in the complex and crowded environments of smart classrooms. An optimized Single Shot Detector (SSD) algorithm is presented in this study, specifically designed to improve the accuracy of detecting student behavior. Through the incorporation of an attention-based relational reasoning and feature fusion module, the refined model not only overcomes the limitations of existing methods but also enhances the real-time analysis of student engagement. The objective of our research is to validate this approach by demonstrating its superior performance in detection accuracy through extensive testing against traditional models. Valuable insights for the integration of AI-driven tools in education will be provided by this validation.

The main Contributions of the present work are as follows:

1) *Improved SSD algorithm*: Integrated with MobileNet, specifically designed for dynamic educational environments to enhance real-time precision and speed in identifying student actions.

2) *Tailored dataset creation*: Consists of 2500 images showcasing a variety of student behaviors, customized for training in authentic classroom scenarios.

3) *Innovative data processing methods*: Incorporates feature fusion and attention-driven relational reasoning, enhancing the accuracy and efficiency of behavior analysis.

4) *Instantaneous environmental evaluation*: The incorporation of MobileNet elevates the SSD model's capacity for prompt and efficient classroom surveillance.

This paper is organized as follows: The paper begins with an introduction in Section I and is followed by giving related work in Section II, highlighting advancements and identifying gaps in classroom state identification and target detection algorithms, emphasizing the integration of deep learning in educational settings. In the Student Classroom Behavior Recognition section, the development of the enhanced Single Shot Detector (SSD) algorithm and the creation of a novel dataset are presented, focusing on data collection and image enhancement. Also, technical modifications, including low-level feature enhancements and the transition to a more efficient Mobilenet model are provided in Section III. Section IV outlines testing conditions and evaluation metrics, compares the model against traditional algorithms, and Section V presents the results and discussion on the effectiveness of our optimized algorithm in real-time student behavior detection and its implications for educational technology. The paper concludes in Section VI with a Conclusion, summarizing contributions and exploring future research directions.

II. RELATED WORK

A. A Review of the Literature on Classroom State Identification

The study of students' classroom state abroad began earlier than in China. One of the earliest articles on the status of the classroom for students was published in 1962. Through searching statistics on the Internet, it was found that foreign research on students' classroom status was concentrated from 1998 to 2017, among which the research on student concentration reached a climax from 2006 to 2024.

China lags behind foreign countries in the research of students' classroom category. Based on the statistical evaluation of CNKI, the classroom status research of students only covers about a quarter of the foreign countries; it is also relatively late, mainly between 2012 and 2024. Much of this literature is about the research on cultivating students' good classroom state rather than studying the "classroom state." With the development of deep learning in recent years, using deep learning has gradually appeared to conduct related research on students' classroom behavior, state, fatigue degree, and other aspects. For example, Hasnine et al. developed a classroom monitoring system within the MOEMO framework for online courses, visualizing students' emotional states. This allowed teachers to intervene promptly when students were disengaged, improving overall engagement and concentration, and optimizing instructional strategies [7].

B. A Literature Review on Target Detection Algorithms

In their paper, Shuai and Wu [8] introduced enhancements to the SSD object detection algorithm, integrating Batch Norm operation for improved generalization and faster training. They also incorporated object counting functionality into image recognition within the SSD framework. Their implementation of a detection system, utilizing Flask and Layui frameworks, enabled real-time selection and display of detection results on the front-end interface. Hu et al. [9] presented a novel approach to sea urchin detection, tackling the shortcomings of the classic SSD algorithm. Their feature-enhanced method combined multidirectional edge detection and integration of ResNet 50, achieving an impressive 81.0% Average Precision (AP) value—an improvement of 7.6% over SSD. Tested on the National Natural Science Foundation of China's underwater dataset, their algorithm proved effective in accurately detecting sea urchins, particularly small targets, heralding a new era in autonomous aquatic exploration. Yan's [10] research focused on the ever-evolving field of computer vision-based motion target detection and tracking. Through the enhancement of traditional approaches and the introduction of novel fusion techniques, Yan was able to increase detection accuracy by 2.6% without compromising real-time efficiency. By carefully adjusting parameters, the system attained both stability and precision, marking a significant advancement in the realm of surveillance and interaction technologies.

Liu's research [11] introduced a transformative method for evaluating the learning progress of English students in higher vocational colleges. By enhancing the Single Shot MultiBox Detector (SSD) algorithm, Liu expanded the capabilities of detection and improved its accuracy. The approach utilized Multi-Task Convolutional Neural Networks (MTCNN) and multi-level reduction correction, resulting in promising outcomes. The mean deviation was below 1.5, and the accuracy exceeded 90% across various student behaviors. Liu's work exemplified the fusion of academic inquiry and technological innovation, providing a practical solution for precise and reliable assessment of student's status in educational environments. In a similar study, Zhang and Xu [12] creatively combined deep learning algorithms with teacher monitoring data to develop the MobileNet-SSD, refining English classroom instruction. Despite initial challenges, their optimization efforts yielded remarkable results. The algorithm achieved an average detection accuracy of 82.13% and a rapid processing speed of 23.5 frames per second (fps) through rigorous experimentation. Notably, it excelled in identifying students' writing behaviors with an accuracy rate of 81.11%. This advancement not only enhanced the recognition of small targets without compromising speed but also surpassed previous algorithms, promising modern technical support for English teachers and improving the efficiency of classroom teaching. Wang et al. [13] introduced C-SSD; an enhanced small target detection method based on improved SSD architecture. By replacing VGG-16 with C-DenseNet and incorporating residuals and Diou-NMS, C-SSD achieved superior accuracy, outperforming other networks with an impressive 83.8% accuracy on the PASCAL VOC2007 test set. Notably, C-SSD struck a fine balance between speed and precision, showcasing exceptional performance in swiftly detecting small targets, marking a significant advancement in target detection technology. Nandhini and Thinakaran [14]

proposed a novel approach to object detection, addressing the challenges of identifying small, dense objects with geometric distortions. Their deformable convolutional network with adjustable depths blended deep convolutional networks with flexible structures, yielding superior accuracy in recognizing objects. Experimental validation confirmed significant improvements in accuracy, highlighting the framework's potential to enhance machine vision capabilities in complex visual environments.

Cheng et al. [15] addressed the challenge of accurately and rapidly detecting concealed objects in terahertz images for security purposes. Their novel method enhanced the SSD algorithm with a deep residual network backbone, a feature fusion-based detection algorithm, a hybrid attention mechanism, and the Focal Loss function. Results showed a significant accuracy improvement to 99.92%, surpassing mainstream models like Faster RCNN, YOLO, and RetinaNet, while maintaining high speed. Their approach offered valuable insights for the application of deep learning in terahertz smart security systems, promising real-time security inspections in public scenarios. Dai [16] proposed an online English teaching quality evaluation model that combined K-means and an improved SSD algorithm. DenseNet replaced the backbone network for enhanced accuracy, while quadratic regression addressed sample imbalance. A feature graph scaling method and k-means clustering optimized default box parameters. Utilizing a dual-mode recognition model, Dai predicted students' states during teaching, demonstrating superior detection accuracy compared to alternative algorithms.

Despite the prevalence of research on target detection using deep learning both domestically and internationally, there is a scarcity of studies specifically addressing the detection of students' classroom behavior using these technologies. This paper aims to bridge this gap by optimizing the Single Shot Detector (SSD) algorithm through a comprehensive review of relevant literature and adapting it to real classroom environments. The main objective of this research is to develop and improve a dataset for classroom behavior. Given the limited availability of images, we employ random enhancement techniques such as translation, noise addition, and color adjustment to fulfill the training requirements. This dataset encompasses scenarios where students in the back rows are detected as small objects using low-level features of the SSD algorithm. To enhance object recognition accuracy, we integrate both shallow and deep information layers.

Furthermore, we address the limitations of the traditional SSD algorithm, which relies on the VGG16 network known for its extensive parameters that impede processing speed and demand high computational power. By transitioning to an enhanced Mobilenet model that incorporates network depth and separable convolutions, we significantly reduce the parameter load while maintaining robust classification capabilities, thereby improving recognition speed.

The integration of technology in education has presented a notable obstacle in accurately evaluating classroom dynamics, particularly in complex and crowded environments. In order to address this challenge, this research study introduces a tailored Single Shot Detector (SSD) algorithm that is specifically

designed for educational settings. Conventional action recognition algorithms often encounter difficulties in accurately monitoring student behavior in dynamic classroom settings. To overcome these limitations, our study incorporates advanced target recognition algorithms and utilizes a distinct dataset obtained from smart classrooms. This optimized SSD algorithm aims to offer real-time and accurate analyses of student engagement, signifying a significant advancement in the implementation of educational technology.

III. STUDENT CLASSROOM BEHAVIOR RECOGNITION ALGORITHM BASED ON AN IMPROVED SSD ALGORITHM

A. The Construction Process of the Classroom Behavior Recognition Model

Classroom behavior helps analyze the quality of students' lectures and the teaching effect. Therefore, this paper chooses five common classroom gestures, namely, sitting and listening, raising hands, writing, sleeping, and playing with a cell phone, to identify and study. This chapter analyzes the shortcomings of SSD by target detection algorithm, proposes the improved SSD algorithm combined with the characteristics of students' classroom behavior, and provides a detailed introduction to the behavior recognition model's application procedure in the class. For target detection, pre-processing of data, training data, and other processes are required. The analysis process is explained in Fig. 1 below in more detail [17]. Peng's seminal work [18] emphasized the importance of precise pronunciation in English teaching. Introducing a novel clustering-enhanced SSD algorithm, the paper addressed limitations in pronunciation detection, enhancing feature extraction and detection speed. By integrating multiscale features and channel attention mechanisms, it improved accuracy while reducing computation. Employing K-means clustering optimized parameter settings, yielding precise evaluation of oral English proficiency. This pioneering approach marked a significant stride in the fusion of technology and pedagogy, promising a future of unparalleled linguistic mastery.

In this topic, detecting students' classroom behavior requires building a data set first. In this data, 2,500 pictures of students' classroom behavior were obtained through the network and shooting methods, including the students' behaviors of raising their hands and standing up in class and the state of sleeping and writing. In the above five students' classroom behaviors, the number of pictures of each behavior was 500. Subsequently, the collected data is collated by building the database, and the test, training, and validation set is formed. Finally, the data in the three sets are measured. That is, the data in the data set is input into the model, and the research results are obtained by comparing them with the verification set and whether the expectations can be determined through the analysis of the

results. If the accuracy and feasibility of the model after this experiment are relatively high, the model is still retained, and the validation of other similar studies is completed [19].

B. Principles of the SSD Algorithm

The process of detecting students' classroom behavior is optimized based on SSD detection. The basic detection algorithm is first described below. Different SSDs are divided into SSD300 and SSD512 according to the input image size. After entering the data set, the data with the image size of SSD300 is extracted. This type of network structure is realized through the basic network, in which the image is subsequently processed through the neural network to complete the feature extraction and selection of the data. After processing the VGG16, the proposed part can be supplemented by adding the convolution level. The specific process is shown in Fig. 2.

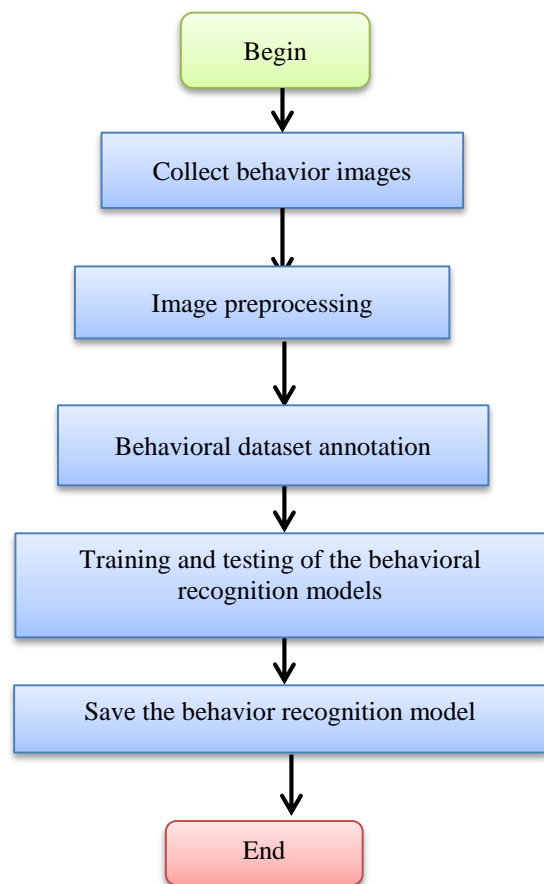

Fig. 1. Classroom behavior recognition process.

Fig. 2. The SSD network structure.

According to the previous content, SSD and POLO are target detection algorithms of one-stage type; however, their feature extraction methods are different. The early POLO algorithm only extracted the information of the highest-level features through the convolution operation, so although the semantics are high, the small target information may need to be recovered. Therefore, as previously stated, the early POLO algorithm is fast, but the small target detection rate is not high. The SSD algorithm uses a variety of scale feature graph detection. After the modified VGG16 basic network increases gradually, decreasing the convolution layer, and then selected six layers from all layers, their size from before to back is reduced, where the feature graph size is used to identify small objects, features of small graph size is used to identify large objects. In doing so, image features can be obtained from different levels to get shallow information and extract deeper, more abstract information.

C. Improvement of the SSD Algorithm

The SSD algorithm's structure is described above, indicating that the algorithm is mainly based on the feature extraction of the image and then obtains the detection results by detecting the feature layer. Although some scholars, through the algorithm to detect the results of the target, found that its feasibility is strong, on the whole, the SSD algorithm is still based on the basic network as the premise for better classification of data processing, but due to the uncertainty of data quantity, for the data amount of relatively large parameter processing performance is insufficient. For example, after removing the full connection layer of the algorithm, the resulting parameter is 14122995, and about 3 / 2 of the time, it is conducted in the basic

network. Thus, training is more challenging through the proposed algorithm. On the other hand, due to the structural influence of the traditional SSD algorithm, some data are carried out through the shallow layer. Still, the shallow layer of information is relatively insufficient, and it is difficult to achieve the expected detection effect. Combined with the above discussion, the traditional SSD algorithm is optimized to improve the accuracy and feasibility of the research results. After various algorithms, the lightweight network is adopted instead of VGG16 to reduce the effect of the number of parameters on the training results and improve the accuracy and efficiency of target detection. The process of optimization is described below.

1) *SSD infrastructure network improvements*: According to the optimization process above, it can be seen that the detection of students' classroom behavior in this topic is replaced by eliminating VGG16 based on excluding VGG16 with fewer parameters. After the analysis of relevant data, the network meets the standard. The optimized algorithm saw the original number of 13.3 million parameters for up to 4.2 million, greatly saving the training time. After training the network dataset, it is found that the optimized algorithm can greatly improve the detection efficiency, and the optimized algorithm is slightly lower and negligible. Considering the above content, the research on students' classroom behavior in this topic is formally detected based on the optimization algorithm. An overview of the network optimization process is given in Table I.

TABLE I. COMPARISON TABLE

Model	ImageNet Accuracy	Million Mult-Adds	Million Parameters
Mobilenet (244)	70.6%	569	4.2
VGG16	71.5%	15300	138

After changing the parameter value, it is found that the reason for the budget efficiency improvement and the decrease in the parameter value is that the CNN in the network composition is in a separable state, and the main part is the deeply separable convolution. If the hierarchy describes the optimized algorithm, the network results on both sides can be expressed as 28 layers, while the network results on one layer are expressed as 14. The CNN operation process is explained above and will not be repeated here. After putting the image of students' classroom behavior into input, the feature extraction based on the CNN can obtain a feature information map and then process the data through BN and ReLu, train other images with a CNN, and obtain the operation results of the above two operations. The depth of convolution and point convolution of the operation process is shown in Fig. 3.

This paper improves the Mobilenet in two aspects: In the network structure diagram given in Fig. 3, it is evident that after every point convolution or deep convolution is completed, the search needs to be followed by an activation function and a normalization method using ReLu and BN, respectively. However, in the article on the BN layer, fully connected layer, and convolutional layer relationship, these three are linear relations, so combining the BN layer into either will have little impact on the results. The efficiency of the BN layer calculation was enhanced by integrating it with the preceding convolution, thereby resulting in enhanced speed based on the previous foundation. Adjusting the Mobilenet input size involves modifying it from 224X224 to 300X300. This modification serves two purposes: initially, enlarging the input size has the potential to augment the capacity of feature map information,

consequently improving detection accuracy. However, it is important to note that increasing the input size excessively significantly escalates network parameters, compromising the model's lightweight nature. In the present study, the SSD network structure utilizes an input size of 300X300, laying the groundwork for the subsequent amalgamation of the two networks.

According to the basic network results, the dynamic data is intercepted, and the image features are processed by the optimization algorithm mentioned above, along with the image features, to obtain the feature image information. This topic trains the students' classroom behavior detection by training the ordinary-size convolutional layer connection and then understanding the deep image information through its results. The image information obtained through the algorithm is placed in the classification for judgment, and the data is not regressed according to the traditional algorithm. The completion of the replacement of the fundamental network has been achieved. In the end, a selection of six feature layers has been made, just like the original SSD, to accomplish the task of feature extraction and target detection. The selection process should take into account the depth of the layer. In the event that the depth is insufficient, it becomes challenging to extract an adequate amount of image information. Thus, the six feature layers selected in this paper decrease anterior to posterior size for multiscale prediction. In this step, the improved part of the Mobilenet network is combined with the SSD network framework to obtain the new network. Fig. 4 visually represents the updated network structure.

Fig. 3. Depth-separable convolution model.

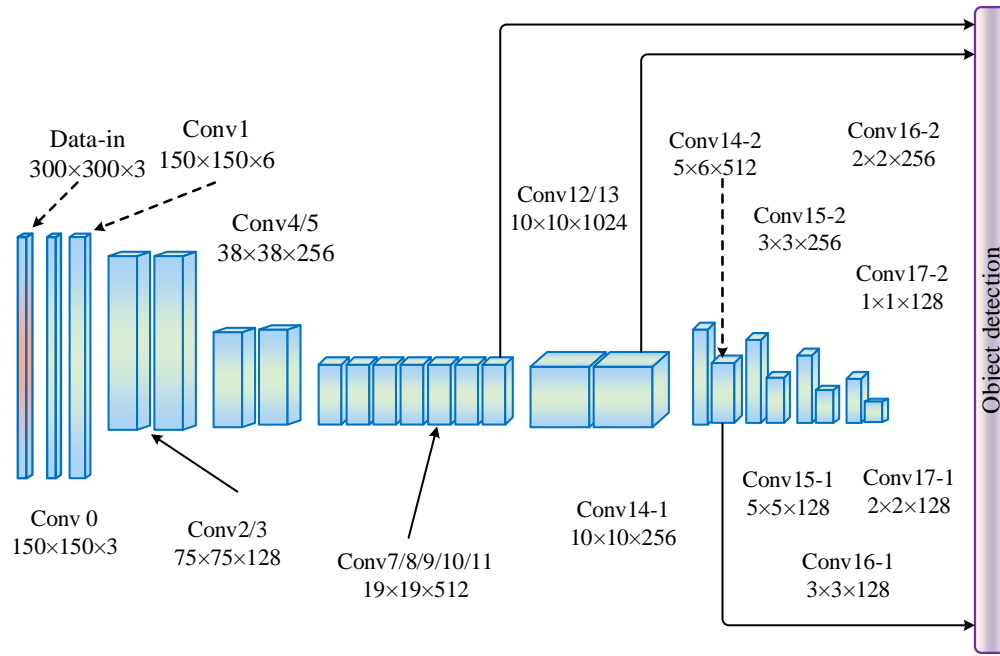

Fig. 4. Enhanced network structure.

2) *Feature fusion of the network models:* In the final stage, replacing the fundamental network enhanced the detection speed, albeit without any noticeable improvement in the accuracy of detecting small targets. A widely employed strategy for enhancing the model's performance involves the integration of features at various scales. Thus, this section introduces the approach of feature fusion and proposes the model fusion strategy accordingly. Based on the characteristics of the network model structure and feature fusion method obtained in Section III(C)(1), the feature fusion method chosen is the additive approach to integrate the network. Among the six characteristic layers extracted from the model structure, the

dimensions progressively decrease from shallow to deep, with less abstract information being presented initially. Transferring the abstract data from the deep feature layer to the shallow layer is the goal of feature fusion. The structure after the network fusion is shown in Fig. 5, using the fusion feature layer for feature extraction and detection operations. After feature fusion, low-level feature maps can contain high-level information to enhance the detection effect of small targets and improve detection accuracy. The dimensionality of the network remains unchanged after the operation described above and remains six feature layers for detection.

Fig. 5. The improved network structures.

3) *The RMSProp optimization algorithm*: The algorithm measures the historical gradient across all dimensions to find the square and then superposition while introducing the decay rate, yielding a historical gradient sum. The detection results and learning rate of the image features are calculated, and the detection results' accuracy and efficiency are improved through the optimization algorithm proposed in this paper. The calculation formula is as follows: Eq. (1) and Eq. (2):

$$S_{dR} = \beta S_{dR} + (1 - \beta)(dR)^2 \quad (1)$$

$$R = R - \rho \frac{dR}{\sqrt{S_{dR} + a}} \quad (2)$$

IV. EXPERIMENT AND TESTING

This study primarily examines the conventional SSD algorithm, the unenhanced Mobilenet-SSD algorithm, and the enhanced Mobilenet-SSD algorithm by considering three key factors: training complexity, detection accuracy, and detection velocity. The difficulty of training refers to the value of the three model loss functions in the same training time and training times.

The following quantitative analysis compares the three algorithms to verify the detection accuracy of SSD, Mobilenet-SSD, and the proposed algorithm. The three algorithms above are assessed using the same experimental conditions. The data of the experimental environment are shown in Fig. 6. To facilitate the efficiency of the experiment, the verification process is processed by a self-made data set, and the accuracy and efficiency of students' second classroom behavior detection obtained by comparing the three algorithms are used as the evaluation standard.

According to the data analysis results in Fig. 6, in the identification of students' classroom behavior in the three algorithms, the accuracy of the Mobilenet-SSD algorithm and SSD algorithm is 76.14% and 84%, respectively, and the accuracy of the optimization algorithm proposed in this paper is 85.21%. It can be seen that the optimized algorithm can more accurately identify students' classroom behavior. On the other

hand, in terms of detection efficiency, the time of the first two algorithms is 27.1 and 22, respectively. In contrast, the detection speed of the optimization algorithm is relatively high, and its value is 21. Combined with the above two detection contents, the optimized algorithm is more accurate for students' classroom behavior detection, and the detection speed is faster. The difference in the loss function's change curve during the training process can be used to determine how difficult the model is to train. The Mobilenet-SSD and SSD models were performed on the loss function curves with 100 iterations of 50,000 times, as shown in Fig. 7.

Evidently, both models' loss values are visible and are always declining, indicating that both models are more reasonable. In the training time, the loss dropped to 0.5; the model used in this paper took about six days, and the original SSD model took about eight days. Furthermore, the figure illustrates that the rate at which the loss value decreases for this model is higher, indicating that the training process for the model employed in this study is comparatively easier than that of the conventional SSD model. The optimization algorithm proposed in this topic is optimized on the basis of the traditional SSD model to detect students' five common class behaviors. The results of the algorithm detection are shown in Fig. 8.

Fig. 6. Different model identification effect.

Fig. 7. Loss.

Fig. 8. Comparison of students' classroom behavior detection algorithm.

Based on the initial SSD algorithm, the Mobilenet-SSD algorithm has enhanced the detection performance of small objects across all five actions. Notably, the improvement in recognizing writing has reached 3.03%, underscoring the model's advancement in small object recognition. Observing the Mobilenet-SSD identification results of feature fusion, it was found that the movement detection accuracy was the highest, and the movement of writing and playing with the mobile phone was the lowest. After collecting relevant data and analyzing it, it is believed that the main reason for the above situation is that in

the student's classroom behavior, the action is easily confused during the identification period, which leads to a relatively weak detection effect.

Table II shows the comparison results for different metrics and various versions of SSD.

TABLE II. COMPARISON RESULTS FOR DIFFERENT METRICS AND VARIOUS VERSIONS OF SSD

Metric	Conventional SSD	Unenhanced Mobilenet-SSD	Enhanced Mobilenet-SSD
Training Complexity (Time to reach loss=0.5)	~8 days	N/A	~6 days
Detection Accuracy	84%	76.14%	85.21%
Detection Velocity (Units)	27.1 units	22 units	21 units

The findings of this study validate the significant advancements made by the improved Mobilenet-SSD algorithm in terms of detection accuracy and speed. Additionally, it demonstrates a noteworthy decrease in training complexity when compared to traditional SSD and unenhanced Mobilenet-SSD algorithms.

Table III highlights the distinctions and contributions of the present study compared to existing related work, with a focus on educational technology and AI.

TABLE III. DISTINCTIONS AND CONTRIBUTIONS OF THE PRESENT STUDY COMPARED TO EXISTING RELATED WORK

Comparison Criteria	Present study	Existing Related Work
Research Focus	Optimization of the SSD algorithm integrated with MobileNet specifically for real-time student behavior detection in educational settings.	General improvements in action recognition algorithms for varied applications, including but not limited to educational settings.
Dataset Customization	Development of a novel dataset from smart classrooms, designed to capture complex student behaviors specific to educational environments.	Use of broader, less specific datasets primarily focused on general object or action recognition that may not address the unique challenges of educational settings.
Performance Optimization	High emphasis on both detection accuracy (85.21%) and processing speed, suitable for real-time educational applications.	Studies often emphasize either accuracy or speed but may not balance both, particularly not in the context of real-time educational needs.
Technological Innovations	Implementation of feature fusion techniques and lightweight deep learning architectures tailored to the specific needs of monitoring classroom dynamics.	Application of existing deep learning models (e.g., YOLOv5, classic SSD) often without significant adaptation for specific real-time educational uses.
Impact on Educational Practices	Directly applicable for real-time classroom behavior monitoring, enabling immediate pedagogical adjustments based on dynamic student interactions.	Focuses more broadly on technological integration in education, such as hybrid teaching or surveillance, without direct application to real-time behavior analysis and intervention.
Specificity and Novelty	Introduces specific enhancements for detecting nuanced student behaviors, utilizing a targeted approach to improve educational outcomes.	Research generally targets broader AI applications or enhances general model performance, lacking focus on the specific nuances of student behavior in classroom settings.

V. RESULTS AND DISCUSSION

This study endeavors to optimize the SSD algorithm for real-time recognition of student behaviors in classroom settings through the utilization of Mobilenet architecture. The objective of our enhanced algorithm is to augment the effectiveness of educational technology by furnishing precise analyses of student engagement. In this section, we present the outcomes of our

experiments and deliberate on their implications for educational practice and future research.

A. Experimental Results

Throughout the experimentation phase, we conducted a comparative analysis of three algorithms: the conventional SSD, the unenhanced Mobilenet-SSD, and our proposed enhanced Mobilenet-SSD. These algorithms were evaluated based on three key metrics: training complexity, detection accuracy, and

velocity, to ensure equitable comparisons under consistent conditions.

1) *Training complexity*: The enhanced Mobilenet-SSD algorithm exhibited a more rapid reduction in loss values during the training process compared to both the conventional SSD and Mobilenet-SSD algorithms. Notably, the enhanced algorithm achieved a loss value of 0.5 in approximately six days, while the conventional SSD algorithm required approximately eight days to achieve a similar reduction.

2) *Detection accuracy*: Utilizing a bespoke dataset designed to simulate real-world classroom scenarios, we observed that the conventional SSD algorithm attained an accuracy of 84%, the Mobilenet-SSD algorithm achieved 76.14%, and our enhanced Mobilenet-SSD algorithm surpassed both, attaining an accuracy of 85.21%. This enhancement in accuracy is pivotal for the precise identification of student behaviors within classroom environments.

3) *Detection velocity*: The enhanced Mobilenet-SSD algorithm demonstrated superior detection speed compared to both the conventional SSD and Mobilenet-SSD algorithms. It efficiently processed and identified student behaviors within 21 units, whereas the conventional SSD and Mobilenet-SSD algorithms required 27.1 and 22 units, respectively.

B. Discussion

Our experimentation underscores the efficacy of the enhanced Mobilenet-SSD algorithm in accurately and expeditiously detecting student behaviors within classroom settings. By using Mobilenet's lightweight architecture and optimizing the SSD algorithm, we achieved significant enhancements in both detection accuracy and speed. Several factors contribute to this improvement. Primarily, the integration of Mobilenet architecture alleviated parameter load, thereby expediting training and enhancing efficiency. Moreover, the feature fusion technique bolstered the algorithm's capability to detect small targets, such as writing and mobile phone usage, which are prevalent behaviors in classroom settings. Additionally, the adoption of the RMSProp optimization algorithm further refined detection outcomes by enhancing the accuracy and efficiency of image feature detection. This optimization strategy, coupled with Mobilenet's lightweight design, surpassed traditional SSD methodologies.

C. Implications for Educational Practice

The findings of this study bear substantial implications for educational practice, particularly in the domains of classroom management and student engagement. The enhanced Mobilenet-SSD algorithm equips educators with a potent tool for real-time monitoring of student behaviors, facilitating prompt interventions and personalized instructional strategies. The accurate identification of behaviors such as listening, raising hands, writing, sleeping, and mobile phone usage furnishes educators with valuable insights into classroom dynamics, enabling tailored teaching methodologies. This real-time feedback mechanism fosters student engagement and enhances learning outcomes by addressing individual needs. Furthermore, the algorithm's efficiency facilitates seamless integration into existing educational technologies, enabling scalable deployment

across diverse learning environments. Educators can harness this technology to cultivate dynamic and interactive classroom experiences that promote active learning and collaboration among students.

D. Future Research Directions

While this study represents a significant stride in classroom behavior recognition, numerous avenues for future research beckon exploration. Expanding the dataset to encompass a broader spectrum of classroom settings and student demographics could augment the algorithm's generalizability. Furthermore, delving into alternative machine learning frameworks and optimization techniques holds the promise of further augmenting detection accuracy and speed. Longitudinal studies investigating the impact of real-time behavior monitoring on educational outcomes would furnish valuable insights into the algorithm's efficacy in enhancing student engagement and learning. In conclusion, the optimization of the SSD algorithm with Mobilenet architecture presents a promising avenue for enhancing educational technology and classroom management practices. By harnessing advanced machine learning techniques, educators can delve deeper into student behaviors, fostering more inclusive and efficacious learning environments.

VI. CONCLUSION

In the conventional approach to teaching, it is of utmost importance for teachers and educational institutions to grasp the prevailing conditions within the classroom throughout a designated course through artificial work and thus judge the efficiency of students' lectures, their acceptance degree, and their attendance rate. This research has made significant progress in classroom behavior recognition by improving the Single Shot Detector (SSD) algorithm using Mobilenet architecture for educational purposes. It has set new benchmarks for real-time behavior monitoring, providing valuable insights for educators to enhance classroom dynamics and teaching methods. However, the effectiveness of this refined algorithm is limited by the homogeneous training data, which mainly consists of images from controlled environments. To improve on these results, future studies should expand the dataset to include a wider range of classroom settings and behaviors. Additionally, exploring more advanced machine learning frameworks and conducting longitudinal research would enhance understanding of the impact of real-time monitoring on educational achievements. Ultimately, incorporating sophisticated AI tools in this study not only improves behavior analysis accuracy but also greatly enhances the applications of intelligent educational technology. This study's initial focus involves examining the design process employed in developing the classroom behavior recognition model. Subsequently, the network structure of the conventional SSD model is elucidated, followed by an analysis of its strengths and weaknesses. Later on, the correlation principle of deep separable convolution is elucidated, followed by an introduction to the fundamental network architecture of Mobilenet. Furthermore, a comprehensive analysis is conducted to integrate the distinctive features of each layer within the network. In light of the preparation work mentioned above, the data is processed by optimizing the traditional SSD algorithm after transforming the

traditional network. After experimental verification, it is also shown that the optimization algorithm proposed in this paper can detect students' classroom behavior more accurately and quickly. During experimentation, we compared three algorithms: conventional SSD, unenhanced Mobilenet-SSD, and our enhanced Mobilenet-SSD, focusing on training complexity, detection accuracy, and velocity for fair comparisons. The enhanced Mobilenet-SSD algorithm showed faster loss reduction during training than both conventional SSD and Mobilenet-SSD, achieving a loss value of 0.5 in about six days compared to eight days for conventional SSD. Using a custom dataset mimicking real-world classroom scenarios, conventional SSD achieved 84% accuracy, Mobilenet-SSD 76.14%, and our enhanced Mobilenet-SSD outperformed both with 85.21% accuracy, crucial for precise student behavior identification. The enhanced Mobilenet-SSD also exhibited superior detection speed, processing student behaviors within 21 units, while conventional SSD and Mobilenet-SSD required 27.1 and 22 units, respectively. Despite promising results, the study faced limitations due to a homogeneous dataset from controlled environments, potentially impacting the findings' generalizability. Future research should expand the dataset to diverse educational settings and student demographics to test the algorithm's effectiveness. Exploring alternative machine learning frameworks and conducting longitudinal studies would enhance understanding of real-time behavior monitoring's impact on educational outcomes. Pursuing these avenues promises deeper insights and improvements in AI technologies' application in education, enhancing behavior recognition precision and the overall educational experience.

Detecting User Credibility on Twitter using a Hybrid Machine Learning Model of Features' Selection and Weighting

Nahid R. Abid-Althaqafi¹, Hessah A. Alsalamah^{2*}

Information Systems Department, College of Computer and Information Sciences, King Saud University, Riyadh, Saudi Arabia^{1,2}
Computer Engineering Department, College of Engineering and Architecture, Alyamamah University, Riyadh, Saudi Arabia²

Abstract—With the pervasive and rapidly growing presence of the internet and social media, creating untrustworthy accounts has become effortless, allowing fake news to be spread for personal or private interests. As a result, it is crucial in this era to investigate the credibility of users on social networking platforms such as Twitter. In this research, we aim to integrate existing solutions from previous research to create a hybrid model. Our approach is based on selecting and weighting features using supervised machine learning methods such as ExtraTressClassifier, correlation-based algorithm methods, and SelectKBest to extract new ranked and weighted features in the dataset and then use them to train our model to discover their impact on the accuracy of user credibility detection issues. The research objective is to combine feature selection and weighting methods with Supervised Machine Learning to evaluate their impact on the accuracy of user credibility detection on Twitter. In addition, we measure the effectiveness of different feature categories on this detection. Experiments are conducted on one of the online available datasets. We seek to employ extracted features from a user's profile and statistical and emotional information. Then, the experimental results are compared to discover the effectiveness of the proposed solution. This study focuses on revealing the credibility of Twitter (or X-platform as recently renamed) accounts, which may result in the need for some adjustments to the generalization of Twitter's outputs to other social media accounts such as LinkedIn, Facebook, and others.

Keywords—User credibility; supervised machine learning; feature selection; feature weighting; social network; twitter

I. INTRODUCTION

Recognizing reliable sources of information within online social networks (OSNs) poses a significant challenge, requiring a solution to differentiate between credible and non-credible users. Ensuring this is vital for reducing the spread of misinformation and fake news, as well as minimizing their harmful consequences [1][9]. Twitter stands as a key information hub in our region, attracting individuals from various age groups and professional backgrounds [2] [3], as its audience accounted for over 335 million monthly active users worldwide by January 2024 [4]. In the Kingdom of Saudi Arabia alone there are at least 11.4 million active users [5]. Therefore, detecting uncredible Twitter users is of special importance for countering the spread of misinformation in our communities.

Numerous studies have employed machine learning (ML) for Twitter User Credibility Detection (TUCD), treating it as a classification problem where user features are often treated

uniformly. The challenge arises in handling high-dimensional datasets, exacerbated by irrelevant and redundant attributes, potentially compromising performance and yielding suboptimal results. The accuracy of user-credibility detection hinges on the features' quality in the classification process [6]. However, not all features contribute equally to accurate predictions, necessitating the identification and weighting of features' importance scores. Various techniques, including SelectKBest, ExtraTrees-Classifer, Principal Component Analysis (PCA), and Mutual Information, are available for feature selection and weighting. Yet, the clarity regarding the efficacy of detecting user credibility by them is still uncertain [7] [8]. This study represents an extension of our previous research, which confirmed the positive effect of selecting features to improve the accuracy of TUCD [9]. As well as the positive effect in most cases of weighing those features on the same issue [10]. This paper combined both previous methods to create a hybrid model. It aims to evaluate the impact of the proposed method on user credibility detection performance through the implementation of Supervised Machine Learning (SML) experiments. Additionally, the study explores different categories of features and their combinations in this context.

II. RESEARCH BACKGROUND

User credibility is crucial in online social networks (OSNs), since it defines the trustworthiness of individuals as information sources. Within OSNs like social media, where content creation and opinion expression are unrestricted, credibility is multifaceted, encompassing qualities that establish trust [11] [12] [13]. Detecting user credibility (UCD) involves assessing various features to differentiate between credible and non-credible users. These features include content-based aspects such as quality and relevance, interaction-based factors like user engagement, profile-based demographics, and sentiment-based indicators [14] [15] [16] [17] [18] [19]. Machine learning algorithms play a pivotal role in quantitatively analyzing these features, thereby enhancing online communication quality and reliability.

Supervised Machine Learning (SML) forms the backbone of UCD methodologies, offering automatic learning and decision-making from trained data [13]. Techniques like decision tree (DT), logistic regression (LR), naive Bayes (NB), random forest (RF), and support vector machine (SVM) are commonly employed for UCD tasks [16] [19] [20] [21] [22] [23] [24] [25] [26] [27]. These techniques serve classification tasks,

*Corresponding Author

differentiating between credible and uncredible users by identifying unique features. Moreover, boosting algorithms like Adaptive Boosting (AdaBoost) and Gradient Boosting (GB) have evolved [27], with XGBoost (XGB) emerging as a powerful algorithm, integrating regularization to control model complexity and resist overfitting.

Feature engineering, a pivotal aspect of machine learning pipelines, transforms raw data into features, significantly impacting model accuracy [28] [29] [30]. It addresses challenges like noise reduction, handling missing data, and preventing overfitting. Feature engineering processes involve feature creation, transformation, extraction, and selection [31]. Feature selection techniques encompass supervised methods like filter, wrapper, and embedded approaches, prioritizing relevant features for UCD tasks [32] [33] [34] [35]. Popular methods include Recursive Feature Elimination (RFE), SelectKBest, Principal Component Analysis (PCA), and Mutual Information [30] [36] [37].

Feature weighting methods are essential for assessing the importance of features within datasets. Techniques like the Analytic Hierarchy Process (AHP), information gain ratio, chi-squared test, and extra tree classifier enable the determination of feature weights. AHP facilitates effective feature weighting, enhancing model performance across various applications. The information gain ratio proves beneficial for high-dimensional feature spaces, while the chi-squared test assesses significant associations between categorical features and target variables [38] [39] [40] [41] [42].

Several datasets are available for UCD research, providing valuable resources for model training and evaluation. Datasets like CredBank [43], FakeNewsNet [44], ArPFN [45] and PHEME [46] offer diverse collections of tweets and user information, categorized based on credibility ratings or association with fake news. These datasets serve as learning sets for evaluating different machine learning models' performance in UCD tasks, contributing to advancements in the field. Comparisons of dataset characteristics aid researchers in selecting appropriate datasets for their specific UCD investigations.

III. LITERATURE REVIEW

The assessment of information credibility within OSNs heavily relies on the trustworthiness of its sources, particularly when dealing with data from unknown individuals lacking established credibility indicators. Consequently, a significant volume of scientific research has emerged to address the challenge of automated User Credibility Detection (UCD). A query on the Google Scholar database using terms associated with "detecting user credibility across platforms" from 2015 to 2023 returned 17,300 relevant articles, highlighting the significant interest this subject has garnered. In this review, we focus on discussing studies that are most relevant to our research.

A plethora of techniques has been employed for UCD on OSNs, with many studies utilizing machine learning methods such as Support Vector Machines (SVMs) [47] [14] [48] [49] [50] [51] [52], Naïve Bayes (NB) [50], Random Forest (RF) [16] [19] [53] [54] [55] [56], XGBoost [2] [57] [58] [59], Logistic

Regression (LR), [58] [60] [61] and Decision Trees (DT) [13] [14] [62] [63], or they adopt an ensemble model [56] [63]. Moreover, a hybrid approach combining SML with other techniques has been widely proposed. These techniques include the utilization of graph-based approaches, as presented by [48], where researchers analyze the credibility of customers using a twin-bipartite graph to model the relationships among users, products, and shops (PCS graph). They then calculate the scores of products/shops and the credibility of customers interactively using iteration algorithms. In the same context, [61] employs `node2vec` to derive features from the Twitter followers/following graph, combining user features from Twitter and the associated social graph. Meanwhile, [5] introduces the CredRank algorithm, which calculates user credibility in OSNs by analyzing user behavior where authors grouped users based on behavioral similarities. The author in [64] presents the UCred (User Credibility) model, a fusion of machine learning and deep learning methods like RoBERT (Robustly optimized BERT), Bi-LSTM (Bidirectional LSTM), and RF (Random Forest), with the output integrated into a voting classifier for improved TUCD accuracy. Another hybrid strategy proposed by [57] integrates sentiment analysis with a social network to identify features applicable to TUCD. This approach incorporates sentiment scores from user historical data and employs a reputation-based method for individual user profiles. While [56] delves into reputation features through a probabilistic reputation feature model, showing enhanced performance compared to raw reputation features, particularly in overall accuracy for detecting users' trust in OSNs. Additionally, [58] introduces domain-based analysis of user content by combining semantic and sentiment analyses to estimate and predict user domain-based credibility in social big data. Finally [50] evaluates the credibility of user profiles and content using sentiment analysis and machine learning.

Furthermore, various classification schemes have been proposed for UCD, including binary classification [24] [35] [56] [65], or it can take the form of a scale measurement, as [12] proposed in their research that provides the CredRank algorithm, which measures the credibility of users in OSNs based on their online behavior. Moreover, [61] we assigned a probability to each user, indicating their likelihood of spreading fake news. Alternatively, it can take the form of multiple values, such as those presented in [2] and [66], wherein [66], the users' credibility scores range from 0 to 12, where 0 means that the user does not say the truth. The more truthful tweets he posts, the more his credibility score increases. This study provides the user score, tweet score, and a message describing the tweet as overall true, false, or unable to verify. In the same context, [2] assigned three values to user credulity, which can be either credible, non-credible, or undecidable. In another classification presented in [67], the authors developed a mathematical model to predict the popularity of news. In their model, they classified users into four main types: neutral, active, suspicious, and non-responding. The author in [68] introduced the user credibility index (UCI) to identify trustworthy Twitter users by integrating four interrelated components: reputation-based component, credibility classifier engine, user experience component, and feature-ranking algorithm. These components collaborate algorithmically to evaluate the credibility of both Twitter users and their tweets.

Feature engineering involves the conversion of raw data into appropriate features for machine learning models. In other words, it is the process of selecting, extracting, and transforming the most related features from the available data to construct more accurate and efficient machine learning models [69]. Feature engineering has emerged as a crucial aspect of UCD, with researchers employing techniques such as creating new features, feature selection, and feature weighting to enhance model efficiency and performance.

The creation of new features from existing ones was used in [16] [17] [52] [55] [70]. It is used to facilitate distinguishing between spammers and real reviewers in online reviews [70] or to detect bot accounts on Twitter [52]. The author in [16] used new features to discover false news on Twitter by calculating the Twitter account age and verifying the number of this account's followers, friends, and statuses to detect fake accounts. Additionally, they created the favorite count feature that has been used to determine the activity of the account, which they claimed could be a sign of a fake account. On the same page, [17] identified credible Twitter users by focusing on users' information related to their field of competence by providing additional features such as favorites, number of tweets, user education status, and the sentiment reflected in their tweets. They also investigated the impact of adding different combinations of features on the accuracy of the TUCD model. The authors in [55] detected tweet credibility using the IBM Watson natural language understanding tool to calculate sentiment and emotion features and employed the IBM meaning cloud tool for tweet polarity calculation. However, well-engineered features can assist in avoiding overfitting and reducing the training time and cost by providing less complex algorithms that are faster to run and easier to maintain [6].

Working with a large number of features is a complex task that emphasizes the role of feature selection which reduces the dimensionality of the dataset and identifies the features that best suit the classification process [53]. Several studies [2] [16] [19] [42] [53] [54] [55] [62] [63] [65] [71] [72] [73] [74] have employed different feature selection methods to focus on the most relevant and important features to be involved in their prediction, as well as to lower the required computational processes. The authors in [19] [42] and [74] used correlation-based feature selection methods. In [19], this method was employed to decrease the number of features from 34 to 7, which are the features that affect their detection method for classifying a Facebook user as credible. However, [42] the correlation among the features was found to determine the most discriminatory feature for user credibility classification. They then excluded these features because they served as outliers and were biased. In addition, they notice some features that are equally distributed between credible and non-credible users; therefore, these features are discarded because they do not add any value to the classification. In [74], the credibility of Twitter users in the stock market was evaluated by assessing the correlation between each user's credibility and their social interaction features. Additionally, [71] employed the Extra-Trees classifier to eliminate irrelevant features for diagnosing breast cancer, revealing that the top three features—glucose levels, age, and resistance results—maximized model accuracies. Another study [16] focused on detecting false news

on Twitter, utilizing the k-best method for selecting the final feature set. In contrast, [65] employed five feature selection methods to enhance spam detection. Furthermore, [72] introduced a dynamic feature selection method by clustering similar Twitter users using the K-Means algorithm and using different features for each user group, rather than a static set of features for spam classification. Authors of [53] addressed spammer detection with a hybrid approach combining logistic regression and principal component analysis (LR-PCA) for dimensional reduction, claiming increased classification accuracy. On the other hand, [73] used recursive feature elimination (RFE) to evaluate optimal features for improved spam detection accuracy, selecting the top 10 features from 31. Whilst [54] examined the best features identified by the random forest algorithm, achieving over 90% accuracy in detecting online bots on Twitter. In the same context, [62] utilized a light gradient-boosting machine (light-GBM) model to evaluate feature importance, dropping features based on their importance. The author in [2] adapted a binary variant of the hybrid Harris Hawk algorithm (HHO) to identify the credibility of Arabic tweets through the elimination of irrelevant or redundant features. However, researchers in [63] employed an ant colony optimization (ACO) algorithm for feature selection, reducing the number of features from 18 to 5 to classify OSN content as credible or fake. This feature selection method provided a significant improvement in the classification accuracy, as stated by the authors. In addition, to better classify the credibility of the posted content on Twitter, [55] we used both a mean decrease accuracy graph that tests how the model performs in the case of removing a particular variable and a mean decrease Gini graph that measures the purity of leaves without each variable to select the top 10 features out of their 26 features based on user, content, polarity, emotion and sentiment characteristics, and determined that sentiment and polarity of tweets represent the most important variables in determining tweet credibility. Overall, these studies showcase diverse feature selection methods applied to different domains, aiming to enhance model performance and accuracy concluding that a good feature set that contains many independent features that are highly correlated with the result can significantly facilitate the learning process [6].

Feature weighting has been addressed in several studies. In [19], the authors suggest a credibility formula for Facebook users. This formula consists of parameters, each of which is multiplied by a specific weight. These weights were computed according to the analytical hierarchical process (AHP) approach, which depends on credibility theory. By applying this formula, user accounts were ranked according to their credibility ranking. Accordingly, they predicted the degree of trust and credibility of Facebook users. In the same context, [75] they created an updated form (AHP) called the "Interval Type-2 Fuzzy Analytical Hierarchy Process" for ranking online reviewers in terms of credibility in their study that addressed the reviewer credibility problem. Moreover, [76] proposed a model that analyzes the credibility of publications on information sources in several social networks; the credibility analysis is based on three measures, text credibility, user credibility, and social credibility. Another study [77] calculated a user credibility score using opinion mining to detect fake news. In their research, the user credibility is calculated based on user reputation, user

influence, and user comments. Each has a particular weight, where the user comments have a lower weight of (0.2), as it does not directly reflect the credibility of a user. The reputation and influence of users on social media have the same weight as (0.4) because they easily show the user's credibility. The CredRank was proposed in [12]. It measures user credibility by finding similarities among their online behaviors. The purpose of this algorithm is to identify coordinated behavior on social media and allocate a reduced credibility weight to users involved in such coordinated activities. Coordinated users can easily repress other users and prohibit their content from spreading on social media. Additionally, they are capable of spreading misleading information. In the same context, [78] we assigned weights to different feature items using the information entropy method. They took into account four aspects (strength of social relationships, extent of social influence, value of information, and control of information transmission) to formulate a model for evaluating user credibility. However, defining the best weights remains an open problem that must be solved [6].

Studies related to TUCD have investigated various features. In [65], authors utilized various publicly available language-independent features extracted from four distinct languages to tackle the characteristics and nature of spam profiles on a social network like Twitter, aiming to improve spam detection. The author in [57] proposed a new probabilistic reputation¹ feature model. Reputation was also addressed by [18], where the authors in [18] analyzed the user's reputation on a given topic within the social network and analyzed the user's profile and his or her sentiment to identify topically relevant and credible sources of information. This study [47] introduces a credibility rating method to visualize the credibility of Twitter user profiles by using profile, images, links, content, and sentiment features. In their research, [13] several key features of tweets impact their credibility, including the user's spending time on Twitter, his or her post frequency, friends/followers' counters, and the number of retweets his or her tweets received. Focusing on tweets related to eight different events, [79] it was found that credibility was most intensely associated with the inclusion of URLs, mentions, retweets, and tweet length. The author in [80] observed that users rely on easily identifiable information, such as usernames and profile pictures, to form their perceptions of credibility. Other research calculated users' credibility scores [56] based on users' social profiles, content credibility, number of retweets and likes, and the sentiment scores. Their assertion was that a higher user credibility score was indicative of increased influence and trustworthiness. TUCD has also been addressed by, [81] in which the authors depended on sentiment features, the existence of hashtags, emojis, and biased in users' tweets played a crucial role in the detection process. Conversely, [64] asserted that features like the user's number of followers, the quantity of produced tweets, and the ratio of tweet number to account creation length in days influence credibility level, while the number of followers has the most pronounced effect.

Overall, the literature review underscores the diversity of techniques and approaches employed in UCD, reflecting the complexity of assessing user credibility in OSNs. These studies provide valuable insights and methodologies for enhancing the

accuracy and reliability of UCD systems across different platforms and domains. However, it should be noted that despite extensive work in this area, some of the specific factors addressed in this research including combining feature selection with feature weighting in addition to examining different feature categories have not been comprehensively explored in previous studies.

IV. MATERIALS AND METHOD

This section provides an overview of the methodology adopted in the study as an expansion of our work in [9] and [10]. Different embedded methods, such as the ExtraTreeClassifier, SelectKBest, and mutual information, are incorporated for feature engineering, either by transforming them to weighted features or by selecting the most impacting feature. It is performed midway between feature extraction and classification. Feature engineering is the process of automatically identifying more efficient features, which will contribute to improving prediction results. The processing of irrelevant features or equal processing of all features decreases the accuracy of the model. Also, feature selection may reduce the execution time for classification. Fig. 1 shows the main stages of the research methodology.

Fig. 1. Research stages

A. Dataset

Our experiments were conducted on the ArPFN dataset [45] which is the most recent dataset that was conducted in (2022) and includes the largest number of features. The ArPFN [45] is a real dataset constructed using three primary stages. First, verified Arabic claims were compiled from diverse sources. These claims were then employed to identify the tweets disseminating them. Finally, the users correlated to these tweets were pinpointed and classified according to their inclination to propagate fake news, as discerned from the frequency of their tweets. The ArPFN dataset encompasses 1546 user accounts on Twitter. Among these, 541 users are inclined to spread fake news (non-credible), while 1005 users are not inclined to spread fake news (credible).

As seen in Table I, the dataset comprises three different types of features for each user: the profile, which includes 11 features; the emotional type, which includes 11 features; and the statistical type, which consists of 17 features. In total, 39 features for each user were ready for use in the dataset.

¹ Reputation is indirect information like information from third party witnesses.

TABLE I. ARPFN FEATURE TYPES [45] [9] [10]

Feature Type	Number of Features	Description
Profile	17	Includes: identification information, verification status, follower counts, following counts, and user's tweets frequencies.
Emotional	11	Includes: trust, anger, sadness, anticipation, disgust, love, fear, joy, , optimism, surprise and pessimism..
Statistical	11	Characterize the users' influence and activities by examining metrics such as the proportion of user tweets containing hashtags, the average number of hashtags/tweet, the proportion of user tweets that are replies, the proportion of user tweets with URLs or media (such as images or videos), retweets counts.

B. Feature Engineering

This phase focuses on identifying the relevant features and estimating their importance in UCD. Each category of features undergoes individual processing and is subsequently merged with the other types, leading to the creation of seven distinct feature sets, as outlined below:

Datasets: { (profile), (emotional), (statistical), (profile + emotional), (emotional + statistical), (profile +statistical), (profile+emotional+ statistical)}.

Different alternatives will be taken into account with each set during this phase.

1) First, all raw data will be considered as the first alternative.

2) Second, feature selection methods are applied to select various sets of features based on their importance employing machine learning methods such as SelectKBest, and correlation. This approach consists of the following steps:

a) Applying a selection method to determine important scores.

b) Arranging features in descending order based on their significance.

c) Removing the lower (50%) of features with the least importance.

3) The third method is the feature-weighting method. To assign weights to features, we explored machine learning weighting estimator methods, including ExtraTree-Classifier and principal component analysis (PCA). This approach encompasses the subsequent steps:

a) Calculating the weights for all features using ML weighting methods.

b) Extracting the weighted features by Multiplying each feature value by its weight.

4) The last alternative is selecting the most important element of the weighted features, which combines alternatives 2 and 3 simultaneously.

C. User Credibility Detection

This phase of the proposed research will focus on designing and developing a machine-learning model with the capability to differentiate between credible and non-credible users on Twitter. The rationale for selecting a machine-learning algorithm for a user-credibility detection system was informed by the results of the literature review, particularly the finding that machine learning has achieved highly accurate outcomes in classification problems.

To obtain a more effective and generalized model, we aim to train the model 10-fold. K-fold cross-validation was used to reduce overfitting. Subsequently, to identify the most accurate classifier for our feature sets, the most commonly used classification algorithms, such as XGBoost, SVM, and LR, were applied and compared to each other.

D. Evaluation and Results Interpretation

We aim to use Python for model implementation and benefit from its wide range of available open-source libraries such as Sciti-learn and Matplotlib. Once the proposed system is developed, testing and evaluation will be conducted to address any limitations. In this phase, each alternative from the previous phase underwent validation using various evaluation metrics, encompassing accuracy, precision, recall, and F-score.

The results were then analyzed and visualized using Python library visualization tools, such as bar plots, heatmaps, and confusion matrix visualization. Fig. 2 shows the flow diagram of the proposed model.

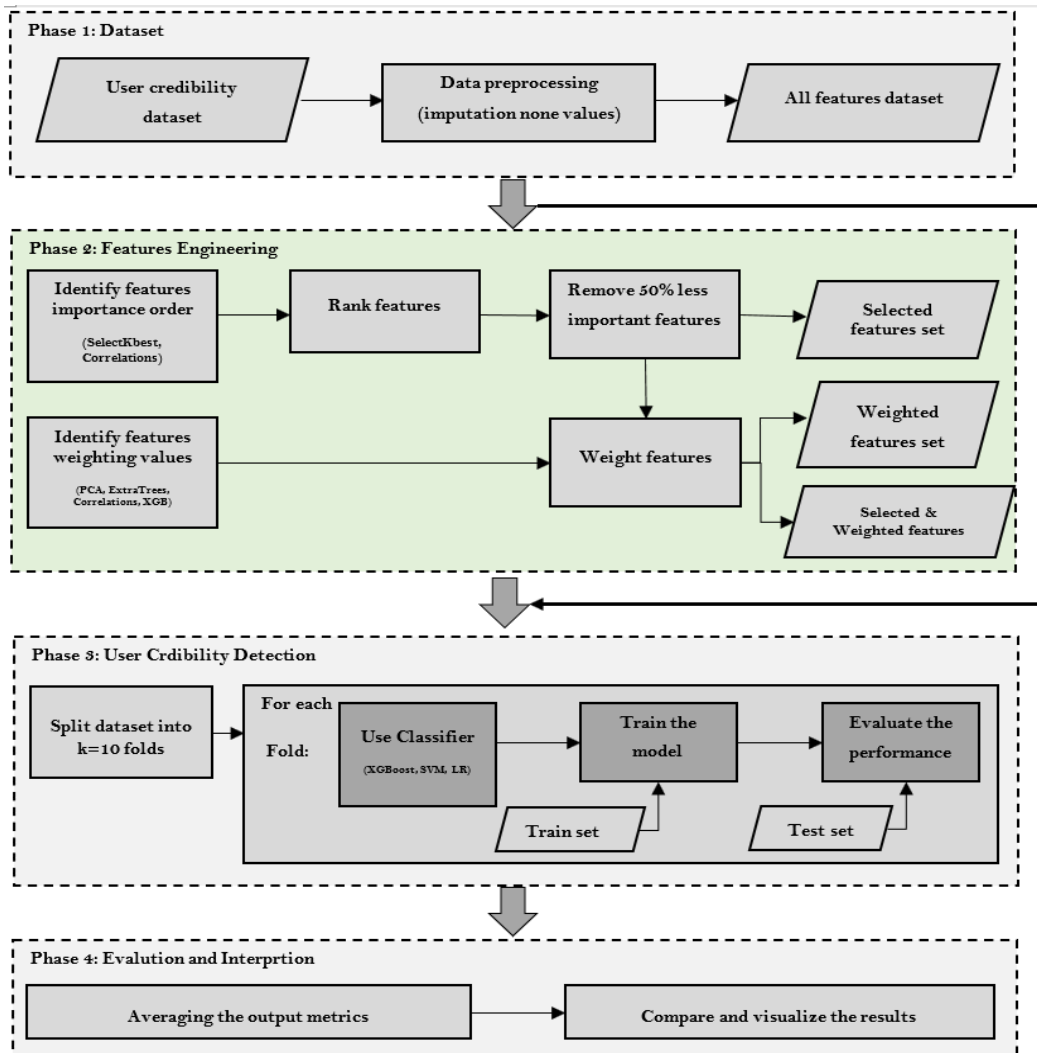

Fig. 2. Flow diagram of the proposed model

V. RESULTS

The application of the proposed methodology yielded valuable results for assessing the impact of different feature engineering methods on the accuracy of TUCD. These findings can be reviewed as follows:

A. Feature Selection

Feature selection entails the identification and removal of irrelevant and redundant information to reduce data dimensionality. In [9], the balance between efficacy and interpretability was carefully considered. The choice of SelectKBest and correlation-based algorithms in this context stems from their specific merits. SelectKBest is valued for its simplicity and efficiency in selecting the top k features through statistical tests, offering a straightforward method for feature selection, this approach enables us to pinpoint the most informative features while keeping computational complexity to a minimum. On the other hand, correlation-based algorithms are selected for their ability to capture relationships and dependencies between features. By evaluating the correlation between each feature and the target variable, we can prioritize

features that demonstrate the strongest connections with user credibility. This nuanced approach has empowered us to unveil intricate patterns within the data. These Two methods were applied in this study as follows.

1) *SelectKBest*: In our approach, we employed Scikit Learn's SelectKBest to identify the k-best features for the model. This algorithm utilizes a score classification function to assess the relationship between the explanatory variable (x) and the explained variable (y), ultimately returning the highest K scores corresponding to the features. When implementing the SelectKBest algorithm on a dataset, it is crucial to specify the value of K. Our experiments revealed that selecting a K value exceeding 50% of the total number of features in the dataset results in a different set of features each time, potentially influencing the accuracy of the final outcome. Therefore, careful consideration of the K value is essential to ensure consistency and reliability in feature selection.

2) *Correlation-based algorithms*: The correlation measure offers a direct filtering mechanism that arranges features by employing a heuristic evaluation function dependent on

correlation. This evaluation function orders features that display significant correlations with the target class while reducing inter-feature correlations. Features that show little correlation with the class were considered insignificant and consequently omitted from the analysis.

3) *Selection methods results*: The outcome of applying feature selection methods on our datasets confirmed that these techniques are effective for improving TUC detection accuracy, as shown in Table II and Fig. 3.

TABLE II. FEATURE SELECTION METHODS [9]

Dataset Category	Accuracy of All Features	Accuracy of Selected Features	
		Correlation	Select K-Best
Profile	0.526	0.630	0.622
Emotional	0.505	0.624	0.603
Statistical	0.501	0.665	0.603
Profile and Emotional	0.530	0.657	0.620
Profile and Statistical	0.543	0.665	0.630
Emotional and Statistical	0.522	0.638	0.616
Profile, Emotional, and Statistical	0.523	0.723	0.671

Fig. 3. Feature selection

B. Feature Weighting

Weighing features according to their importance in predicting the correct classification has been addressed by several machine learning algorithms. It is crucial to highlight that feature-weighting algorithms do not inherently reduce the dimensionality of the data. Unless features with very low weights are deliberately excluded from the dataset at the outset, the assumption is that each feature bears some level of importance for the induction process, and the degree of significance is reflected by the magnitude of its weight. In [10], we examined three of the most widely used methods to calculate the importance of features, employing the following approaches:

4) *Correlation coefficients*: Examining the model's correlation coefficients using a logistic regression algorithm, a large value of the coefficients (negative or positive) indicates the feature's influence on the detection of TUC, while a zero coefficient means that the feature does not have any impact on the detection.

5) *Tree-based*: Training the tree-based model to access the feature importance, we used ExtraTreeClassifier and XGBClassifier to obtain each feature's importance.

6) *Principal Component Analysis (PCA)*: Used to determine variance in the dataset. We used the first principal component (PC1) to define the importance of the features in the datasets.

7) *Weighting methods results*: The aforementioned methods were employed on the datasets within our model. As demonstrated in Table III and Fig. 4, the results indicated that under the best-case scenario, five out of seven groups exhibited positive effects when applying feature weighting (using the ExtraTree-Classifier) to enhance the accuracy of TUCD.

TABLE III. WEIGHTING METHODS [10]

Dataset Category	No weighting	Weighting Methods			
		Extra Tree-Classifier	Corr-Coefficient	XGB	PCA
Profile	0.526	0.503	0.515	0.521	0.501
Emotional	0.505	0.518	0.515	0.508	0.516
Statistical	0.501	0.524	0.524	0.480	0.496
Profile and Features	0.530	0.546	0.524	0.512	0.536
Profile and Statistical	0.543	0.522	0.516	0.521	0.513
Emotional and Statistical	0.522	0.528	0.526	0.528	0.525
Profile, Emotional, and Statistical	0.523	0.530	0.535	0.532	0.540

Fig. 4. Features weighting

C. Hybrid Method of Features Weighting and Selection

The proposal in this research assumes that by selecting and weighing features, we can achieve more accurate user-credibility detection results using SML methods. In this stage of our experiment, we executed a hybrid feature engineering technique by combining the most effective and interpretable methods to assess their influence on the accuracy of TUCD.

1) *Selection method*: For selecting we used SelectKBest which provides us with a list of the most effective features for detecting TUC, as well as using this method gives us the power to define the number of selected features as we determine the K

value, our decision to use this method over the other one based on the observation that this method provides an improvement in the TUCD accuracy for all of the seven sub-datasets in our experiments, as well as it is based on statistical tests that have been used to select those features that have the strongest relationship with the output variable (target class) regardless of the internal correlations with other features.

2) *Weighting method*: On the other hand, our experiments proved that using tree-based models to weigh the features provides the best results for improving the detection of TUC; therefore, we used ExtraTreeClassifier to weigh the features in our datasets.

3) *Hybrid method results*: The results in Table IV and Fig. 5 show that the impact of this hybrid method on the accuracy of TUCD improved only two out of seven of our datasets, and the results in Table IV and Fig. 5 show that using the hybrid model improved only two groups out of seven groups that represented our datasets, but less than the improvement that was achieved by using the selection method alone, while the selection method proved that it improved the performance of all groups in the detection of TUC.

TABLE IV. THE HYBRID METHOD

Dataset Category	Raw Features	Selected Features	Weighted Features	Hybrid Method
		Select K-Best	ExtraTree-Classifier	Select K-Best & ExtraTree-Classifier
Profile	0.526	0.622	0.503	0.501
Emotional	0.505	0.603	0.518	0.522
Statistical	0.501	0.603	0.524	0.496
Profile and Emotional	0.530	0.620	0.546	0.503
Profile and Statistical	0.543	0.630	0.522	0.514
Emotional and Statistical	0.522	0.616	0.528	0.524
Profile, Emotional, and Statistical	0.523	0.671	0.530	0.501

Fig. 5. The hybrid method

VI. DISCUSSION

In this section, we extensively discuss the research findings on feature engineering for TUCD. Our investigation delves into the effects of various feature engineering methods, including feature selection, feature weighting, and the proposed hybrid model, on the accuracy of TUCD. As previously mentioned, our experiments were conducted using the ArPFN dataset [45], which encompasses profile, emotional, and statistical features.

A. Feature Selection

The findings of this research and our previous research [9] highlighted the impact of using selection methods on TUCD accuracy as follows:

1) *Effectiveness of the method*: Our observations point to the effectiveness of feature selection methods, including SelectKBest and correlation-based algorithms, in enhancing the accuracy of TUCD. This indicates that refining the feature space's dimensionality by removing redundant and irrelevant features can contribute to the development of more accurate models. Notably, the use of correlation-based algorithms proved more effective than the SelectKBest algorithm, consistently yielding higher accuracy in all sub-datasets utilized in this research.

2) *Impact of feature categories*: Although the accuracy of TUCD improved across all feature category datasets with the implementation of feature selection methods, it is evident that the impact of these methods varies across these feature categories. The most notable improvement, as depicted in Table II and Fig. 3, was observed in the dataset combining all profile, emotional, and statistical feature categories. In contrast, both the statistical features and emotional features datasets showed relatively less enhancement among other feature categories. This discrepancy emphasizes the importance of customizing feature-engineering techniques to suit specific feature types.

B. Feature Weighting

Feature weighting affected the accuracy of TUCD as seen in this research, and our previous research [10] as follows:

1) *Effectiveness of the method*: Feature weighting techniques, encompassing logistic regression coefficients, tree-based models, and PCA, played a crucial role in assigning weights or importance scores to the features in this study. These assigned weights were then used by the model to generate new weighted sub-datasets for training, allowing us to measure their impact on TUCD accuracy. The application of these methods, especially tree-based algorithms, positively influenced the detection accuracy in this model. Our findings, as illustrated in Table III and Fig. 4, indicate that five out of the seven sub-datasets exhibited improved performance when employing a tree-based algorithm, either ExtraTreesClassifier or XGBClassifier. One dataset achieved comparable accuracy with the tree-based algorithm as with the Corr-Coefficient method, whereas another sub-dataset among the seven experienced improved accuracy using the Principal Component Analysis

(PCA) method. In contrast, two out of the seven sub-datasets demonstrated a decrease in performance upon the application of any of the four weighted methods

2) *Impact of feature categories*: The influence of feature weighting exhibits variations among distinct feature categories. Notably, profile and emotional features had maximum improvements in accuracy, particularly when using tree-based models for feature weighting. In contrast, the profile feature category and the combination of profile and statistical feature categories had a detrimental effect on TUCD accuracy when utilizing weighting techniques.

C. Hybrid Method

1) *Effectiveness of the method*: Referring to Table IV and Fig. 5, using the hybrid method by integrating feature selection using the SelectKBest method and the feature weighting method using the ExtraTreeClassifier algorithm did not improve the TUCD in our model.

2) *Impact of feature categories*: Compared with other feature engineering methods or even using raw data, the TUCD accuracy of the hybrid method was the worst for most datasets. This method did not outperform the feature selection method for all datasets but outperformed the feature weighting for only one dataset, which is the emotional feature dataset. It also increased the accuracy above the raw data in the two datasets, which were emotional features and a combination of emotional and statistical features.

VII. CONCLUSIONS

The results outlined in this study hold significant implications for the fields of SML, feature selection, and social media analysis. Our investigation of feature engineering techniques, mainly the selection, weighting algorithms, and the suggested hybrid model combined with various feature types offers valuable insights into how they impact the accuracy of detecting user credibility on Twitter. In our previous research [9] [10], we investigated various feature selection and weighting techniques. This study extends our research by investigating a hybrid method that combines both approaches. Our aim was to identify the best feature engineering methods for enhancing the TUCD. This was accomplished by comparing the accuracy of the results obtained from the feature selection, feature weighting, or their combination in a hybrid model. The conclusion drawn was that feature selection is the most effective approach for improving result accuracy, followed by feature weighting coming in second place. Unexpectedly, the use of the hybrid model had a negative impact on most of our experiments. Furthermore, the recognition of key features and understanding their influence on credibility detection offer valuable insights for refining current theories in digital communication. From a managerial perspective, our research offers practical guidance for combatting misinformation and enhancing credibility detection systems, assisting organizations in deploying tailored strategies for content moderation and user engagement. Beyond merely shaping theoretical frameworks, the methodological contributions of this study exert a palpable influence on managerial practices, paving the way for continuous exploration of the ever-changing landscape of user credibility within digital

platforms. Such contributions significantly enrich the ongoing academic discourse in this field.

VIII. FUTURE WORK

While our research contributes valuable insights into feature engineering for TUCD, it is essential to acknowledge certain limitations. Firstly, our experiments relied on the ArPFN dataset [45], which, while comprehensive, might not encapsulate all facets of Twitter user behavior. To address this, future studies should explore diverse datasets to validate our findings and ensure the generalizability of feature engineering methods. Additionally, our research focused on a subset of feature engineering techniques, and the exploration of other methods, such as feature creation or embedding techniques, could offer further enhancements in TUCD accuracy. Ethical considerations, particularly biases and fairness in TUCD applied to social media data, necessitate future research to address these concerns. Furthermore, our research primarily conducted batch analysis on historical data, highlighting the need for exploration into real-time or streaming TUCD methodologies. Lastly, the concentration on Twitter data prompts future inquiries into the generalizability of feature engineering techniques across various social media platforms. Addressing these limitations will contribute to a more comprehensive understanding and robust application of TUCD in diverse contexts.

Abstract—The classification of motor imagery holds significant importance within brain-computer interface (BCI) research as it allows for the identification of a person's intention, such as controlling a prosthesis. Motor imagery involves the brain's dynamic activities, commonly captured using electroencephalography (EEG) to record nonstationary time series with low signal-to-noise ratios. While various methods exist for extracting features from EEG signals, the application of deep learning techniques to enhance the representation of EEG features for improved motor imagery classification performance has been relatively unexplored. This research introduces a new deep learning approach based on two-dimensional CNNs with different architectures. Specifically, time-frequency domain representations of EEGs obtained by the wavelet transform method with different mother wavelets (Mexicanhat, Cmor, and Cgaus). The BCI competition IV-2a dataset held in 2008 was utilized for testing the proposed deep learning approaches. Several experiments were conducted and the results showed that the proposed method achieved better performance than some state-of-the-art methods. The findings of this study showed that the architecture of CNN and specifically the number of convolution layers in this deep learning network has a significant effect on the classification performance of motor imagery brain data. In addition, the mother wavelet in the wavelet transform is very important in the classification performance of motor imagery EEG data.

Keywords—Brain-computer interface (BCI); Electroencephalogram (EEG); motor imagery; deep learning; classification

I. INTRODUCTION

Brain-computer interfaces (BCIs), with the aim of helping people with muscle disabilities who have cognitive potential, analyze brain signals and convert them into control commands without direct use of peripheral nerves and muscles [1]. The general function of BCI is to first receive brain signals as input, extract useful features from the signal, classify them, and finally convert them into a control command [2]. Among the types of BCIs, motion imagery systems have been increasingly used in various fields. In this type of BCI system, when the subject moves a part of his body (such as the right or left hand) or imagines movement, the brain frequency profile changes in the μ and β frequency range [3]. These phenomena show event-related synchronization (ERS) and event-related desynchronization (ERD), based on which brain signals affected by motor imagery can be classified [4]. In general, studies on the

classification stage of these systems are conducted using classical machine learning methods and modern deep learning approaches [5]. Classical machine learning methods have two relatively independent parts feature extraction and classification [6, 7]. One of the major challenges in classical machine learning methods is the extraction of appropriate features and inefficiency in dealing with nonlinear data [8, 9]. In order to solve these problems, the use of deep learning methods for data classification gradually increased [10], and in recent years, with the increasing progress of hardware, the use of these methods for various applications, including data classification in motor imagery problem, has grown significantly [11]. In contrast to conventional approaches, deep learning has the capability to autonomously acquire sophisticated high-level features and underlying traits through intricate architectures directly from unprocessed motor imagery EEG signals. This eliminates the need for time-consuming preprocessing and feature extraction. Among the scrutinized studies, CNN emerged as the most commonly utilized technique for classifying motor imagery in the EEG signals [12]. The common practice in employing raw signal data with deep learning techniques, with or without minimal preprocessing, was apparent. However, recent comprehensive reviews suggested that despite the advancements made by deep learning in enhancing the interpretation of motor imagery EEG signals, the practical deployment of motor imagery based BCI systems in real-world scenarios continues to face impediments in terms of technical complexities and user-friendliness [3, 5, 13]. Therefore, there is still no comprehensive solution for the problem at hand, and our effort in this work is to find an optimal solution for one of the technical challenges of EEG classification of motion imagery. In fact, two research objectives are pursued in this work. First, providing a deep two-dimensional CNN model with minimum complexity and processing time that can be added to BCI systems in the future. Second, finding the best wavelet function to extract 2D images from the EEG signal to integrate with 2D CNN for the problem at hand. The solutions presented in this paper can help future studies to achieve an optimal motor imagery EEG based BCI system. The rest of this paper is arranged as follows: Section II reviews the related works in the literature of this field. Section III presents the proposed methods including the used database, time-frequency analysis, and deep learning models. Experimental results are presented in Section IV. Section V provides a discussion of the results and proposed methods. Finally, a brief conclusion is provided in Section VI.

II. RELATED WORKS

Due to the complexity involved in recording and the limited availability of signals, the utilization of deep-learning-based classification methods in BCI applications remains infrequent. Li and Zhu et al. [14] utilized the optimal wavelet packet transform (OWPT) for constructing feature vectors from motor imagery EEG data. These feature vectors were employed in training a long short-term memory (LSTM) model based on a recurrent neural network (RNN). The performance of this algorithm was found to be excellent on dataset III of the BCI Competition 2003. However, the structure of the algorithm appeared to be excessively intricate. On the other hand, Liu et al. [15] introduced a novel CNN architecture for the classification of P300 signals. The algorithm achieved remarkable results on the BCI competition P300 datasets. Despite the impressive performance of these deep learning methods in classification tasks, it is worth noting that these networks typically exhibit complexity and involve a large number of parameters. In the publication referenced as [16], Bashivan et al. employed power spectrum densities derived from three different frequency ranges of EEG signals. They proceeded to generate images for each frequency range by interpolating topological features that accurately represented the brain's surfaces. Their approach involved utilizing the VGG (visual geometry group) model, blending 1D convolutions with LSTM layers. The research outcomes demonstrated that the ConvNet and LSTM/1D-Conv architectures outperformed alternative models. In another study referenced as [17], the authors also adopted a CNN architecture, but with a distinct approach. They first employed the convolutional layer and then utilized the encoder portion of the AutoEncoder. Furthermore, they incorporated the power spectral densities of fast Fourier transforms as a feature set in their experimentation.

Ju and Guan [18] introduced a new geometric deep model called Tensor-CSPNet to specify the spatial covariance matrices of EEGs on symmetric positive definite manifolds. This framework was applied to motor imagery EEG datasets and achieved current state-of-the-art performance in cross-validation and holdout techniques. Zhang et al. [19] investigated five different adaptive transfer learning-based schemes to adapt a CNN-based EEG-BCI system to decode hand motor imagery. They obtained an average accuracy of 84% for the two-class motor imagery problem. Hwang et al. [20] proposed an LSTM-based classification method based on overlapping sliding windows to acquire time-varying EEG data. They demonstrated that their proposed method outperforms existing algorithms for EEG classification of four motor imagery classes, and also exhibits robustness to inter-trial and inter-session motor imagery data variability. Liu et al. [21] proposed a new end-to-end compact multi-branch 1D convolutional neural network for EEG-based motor imagery classification. They reported average classification accuracies of 83.92% and 87.19% on two public datasets. Wang et al. [22] proposed a 2D hybrid CNN-LSTM algorithm for EEG classification in motor imagery tasks. They converted the EEGs into time series segments and then calculated the connectivity features between EEG electrodes in every segment via 2D CNN and finally fed the feature vectors to the LSTM network for training. Li et al. [23] proposed a new dual-attention-based adversarial network for motor imagery classification. Their framework uses multi-subject knowledge to

enhance the classification performance of single-subject motor imagery tasks through intelligently utilizing a new adversarial learning algorithm and two unshared attention blocks. Dang et al. [24] proposed a modular CNN, Flashlight-Net model, for Motor Imagery EEG Classification. Due to the multi-frequency nature of the brain, they combined the three frequency bands and built an ensemble model of Flashlight-Net using transfer learning.

One of the main problems of all previously presented models is their structural and computational complexity, which severely limits their real-time application in BCI systems. In this article, we intend to design a CNN model to create an optimal and stable network for motor. In imagery classification the following, we will introduce the data, proposed methods, and findings, and finally discuss and conclude the findings.

III. METHODS

A. Dataset

In this article, the BCI competition IV-2a dataset held in 2008 [25] was utilized for testing the proposed deep learning approaches. This data includes EEG signals with 22 signal recording electrodes, which are placed on people's heads with 10-20 standard, from nine normal subjects. The signals are sampled with a frequency of 250 Hz and filtered with a 0.5 to 100 Hz band-pass filter. The signal recording protocol is based on cues and includes four movement perception tasks (right hand, left hand, legs, and tongue movement perception). In this data, the signal recording for each subject was done in two sessions, each recording session consists of six tasks, and in each task, 48 trials (12 trials per movement perception class) and a total of 288 trials were recorded for each subject. At the beginning of each test ($t=0$), a + sign appears on the screen, after two seconds ($t=2s$) with a short sound warning, the + sign turns into an arrow and goes to one of the up, down, left, and right directions. Then, with a short rest, the subject performs the next test. Fig. 1 shows the timing scheme of a trial.

Fig. 1. Timing scheme of a trial in BCI Competition IV-2a dataset.

B. Proposed Framework

The purpose of this article is to classify brain signals based on motor imagery using two-dimensional CNNs. For this four-class classification problem, the proposed method includes the implementation of two-dimensional CNNs with the input of time-frequency data obtained by the wavelet transform method with different mother wavelets and comparing the performance of this network in order to classify the data. In general, the proposed method is shown in the block diagram of Fig. 2. This framework included data preprocessing, time-frequency transformation using different mother wavelets, classification through two-dimensional CNNs, and performance evaluation. In the following, the details of each of these steps are described.

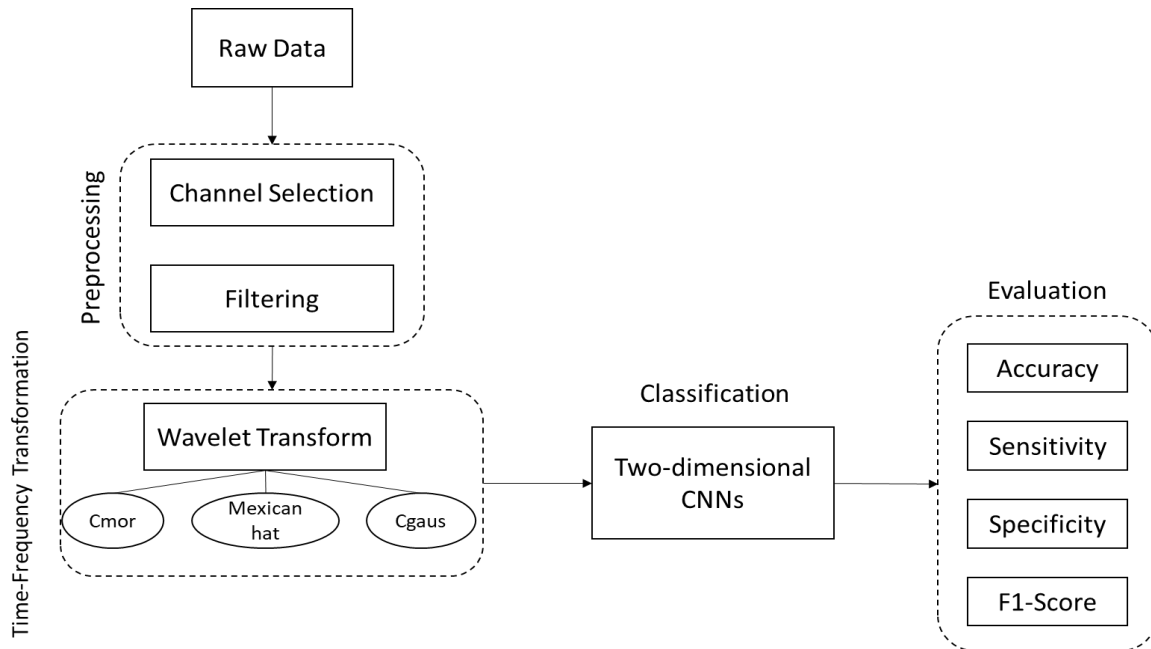

Fig. 2. Block diagram of the proposed framework for motor imagery EEG classification.

C. Data Preprocessing

At first, in order to select suitable and effective channels, for each subject, all 22 signal recording channels were checked and channels were selected that have more information related to movement perception signals according to the anatomical structure of the brain. The selected channels for each subject were C4, C3, and Cz channels, which are located in the sensorimotor area of the brain. Fig. 3 shows the location of these electrodes on the scalp. Also, considering that motor imagery often occurs in the μ and β frequency range, an 8-30 Hz Butterworth band-pass filter (5th order) was applied to the EEG.

Fig. 3. Location of C3, C4, and Cz EEG channels used for motor imagery classification.

D. Time-Frequency Analysis

CNNs necessitate the use of images as input, which means that the one-dimensional EEG should be transformed into two-

dimensional images. To achieve this, the continuous wavelet transform (CWT) is a commonly used time-frequency technique that decomposes a time series into its frequency and time (1/scale) components. The CWT was developed to address the resolution issue of the Short-Time Fourier Transform (STFT) and produces high-resolution scalogram outputs. Using the Fourier transform alone is not a suitable approach considering that it is not sensitive to parameters such as time or frequency resolutions which are very important in the analysis of motor imagery. Therefore, it is recommended to use methods such as the wavelet transform, which has good accuracy both in terms of time and frequency [26]. CWT allows for time-frequency analysis of EEG signals, which is important in EEG processing as it provides information about how signal characteristics change over time. CWT offers variable resolution in both time and frequency domains [27]. This means that it can provide high time resolution when analyzing high-frequency components and high frequency resolution when analyzing low-frequency components. CWT exhibits shift-invariance property, which means that small shifts in the signal do not significantly impact the wavelet coefficients. This property can be beneficial when analyzing EEG signals which may have slight time delays due to various factors [28]. This technique involves convolving a time series with a series of functions generated through a continuous function known as the mother wavelet. The CWT for a specified time series, $s(t)$, can be computed using Eq. (3):

$$CWT_{(a,b)}[s(t)] = \frac{1}{\sqrt{|a|}} \int_{-\infty}^{+\infty} s(t) \Phi^* \left(\frac{t-b}{a} \right) dt \quad (1)$$

where, a , b , and Φ denote the scale factor, the translational variable, and the basic wavelet function, respectively. In this article, CWT with three different mother wavelets Cmor, Mexicanhat, and Cgaus was used to convert the time domain to the time-frequency domain, so that among these three mother wavelets, the most powerful one is selected for data processing in motor image classification.

E. Deep Learning Models

Previous studies have shown that CNN is an effective and superior method compared to other methods in motor imagery data classification, and it has received much attention [19, 29, 30]. CNNs are able to capture local patterns in data irrespective of their location, making them suitable for EEG signals which are often affected by noise or small variations in electrode placement. CNNs can automatically learn hierarchical representations of the input data, starting from simple features (like edges or curves) to more complex features. This ability is beneficial for capturing the intricate patterns present in EEG signals. CNNs are known for their ability to learn meaningful representations from relatively small datasets. This is advantageous in EEG classification where collecting large amounts of labeled data can be challenging and expensive [31]. CNN architectures can be easily scaled to handle different EEG datasets with varying sizes and complexities. By adjusting the depth and width of the network, CNNs can adapt to different EEG classification tasks efficiently [32]. Therefore, in this paper, the classification performance of two-dimensional CNNs for images obtained from wavelet transform with three mother wavelets, Mexicanhat, Cmor, and Cgaus, was investigated. For this purpose, two different 2D CNN architectures are proposed with the aim of classifying motor imagery-based data. In the first architecture, the network includes a convolution layer consisting of 256 kernels with dimensions of 3×3 and step 1. The next layers include the Max pooling layer and a Dropout layer to prevent overfitting. In order to prepare the data for classification, a flattened layer and then two fully connected layers are used. In the second architecture, the network consists of two convolution layers. In the first layer, 32 kernels with dimensions of 3×3 and step 1 are used, and in the second layer, 16 kernels with dimensions of 3×3 and step 1 are used. Among the convolution layers, a Max pooling layer and a Dropout layer are used, a flattened layer is used for data preparation, and two fully connected layers with 200 and 50 neurons, respectively, are used for classification. The architecture of these two networks is shown in Fig. 4. The proposed models incorporate various adjustments for the count of filter, size of stride, and other parameters. Hidden layer dimensions were decreased from the input size to four, representing count of groups in suggested network. It is important to mention that the hyperparameter values were carefully fine-tuned based on a thorough examination of relevant literature and extensive testing. Only optimal parameters were selected for suggested networks. Several optimization functions were explored, like Adam, Stochastic Gradient Descend (SGD), CyclicLR, StepLR, and ReduceLR. Nonetheless, due to superior performance in practical applications, the SGD algorithm was chosen as optimizer with a learning rate of 0.0002 and a batch size of 64. Additionally, training process was controlled by cross-entropy loss function. Best parameters for suggested network are summarized in Table I.

TABLE I. OBTAINED OPTIMAL PARAMETERS FOR SUGGESTED DEEP MODELS

Parameter	Tested domain	Selected Value
Number of convolutional layers	1, 2, 3, 4, 5	Model 1: 1 Model 2: 2
Count of filters in the convolutional layers	16, 32, 64, 128, 256	Model 1: 256 Model 2: 32, 16
Filter size in the convolutional layers	3, 16, 32, 64	Model 1: 3 Model 2: 3
Activation function	ReLU, LReLU	ReLU
Cost function	Cross-entropy, MSE	Cross-entropy
Optimizer	Adam, Adamax, RMSProp, SGD	SGD
Dropout level	0.1, 0.2, 0.3, 0.4, 0.5	0.5
Batch size	4, 8, 16, 32, 64	64
Learning rate	0.001, 0.0001, 0.0002, 0.0003	0.0002

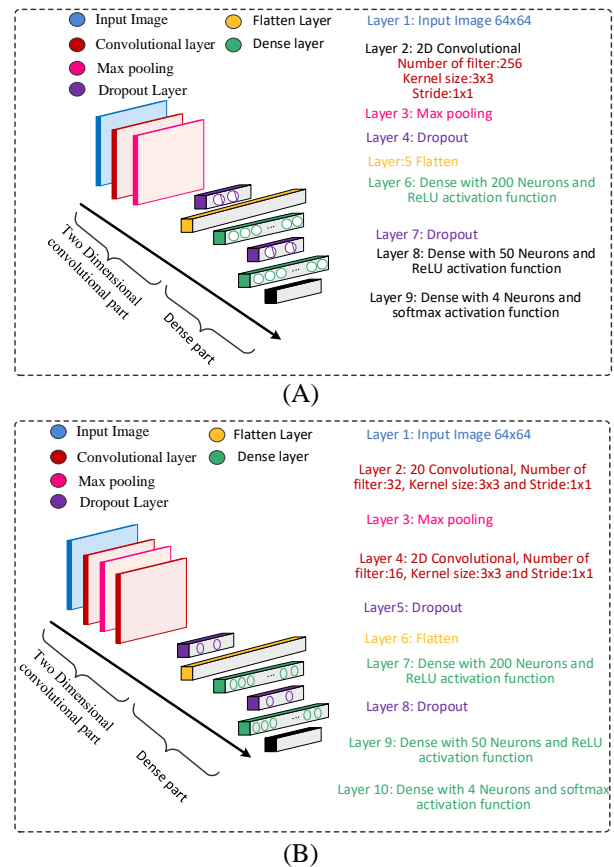

Fig. 4. Two-dimensional convolutional neural network architectures are proposed to classify the brain data of motor imagery: (A) the first proposed architecture, and (B) the second proposed architecture.

IV. RESULTS

Fig. 5 shows an example of EEG signals related to selected channels for motor imagery classes 1 and 4. Moreover, Fig. 6 shows an example of time-frequency maps resulting from wavelet transform in selected EEG channels using mother wavelets Cmor, Mexicanhat, and Cgaus. As shown, there was an obvious difference in the time-frequency maps obtained from different wavelet mothers, which may affect the classification performance of deep learning models.

Fig. 5. An example of EEG signals related to selected channels for motor imagery classes 1 and 4.

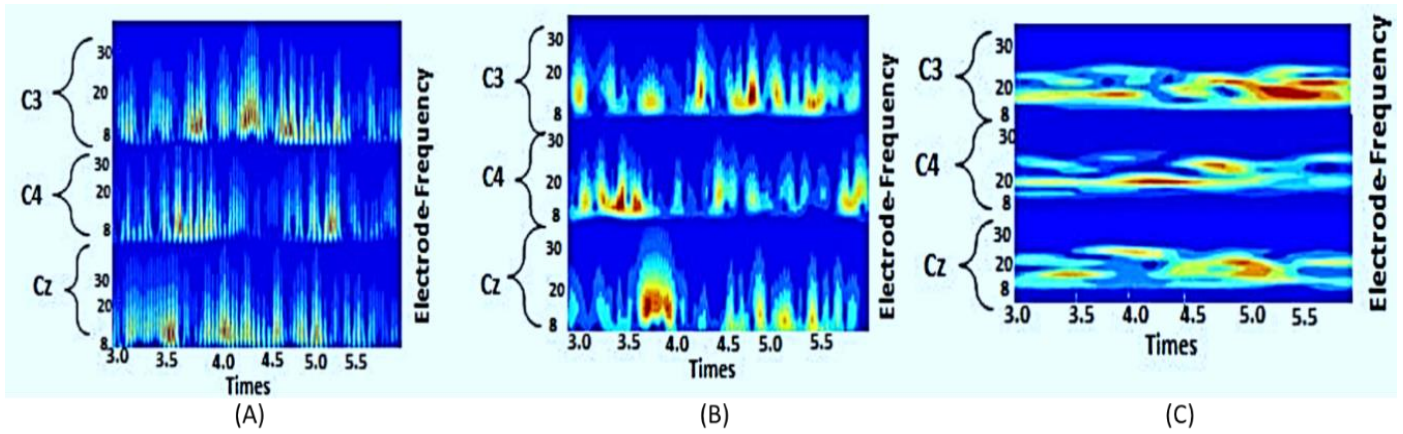

Fig. 6. An example of time-frequency maps resulting from wavelet transform in selected EEG channels using mother wavelets is (A) Cmor, (B) Mexicanhat, and (C) Cgaus.

One of the important steps after designing and building a model is to evaluate that model. In classification problems, this evaluation is based on four elements: true positive, true negative, false positive, and false negative. In this study, four criteria of accuracy, precision, recall, and F1-score were used for an individual-based classification strategy. The results of the implementation of the first and second architectures of two-dimensional CNN with three mother wavelets Mexicanhat,

Cmor, and Cgaus in nine subjects and with the evaluation criteria of accuracy, precision, recall, and F1 score are shown in Tables II and III. The results showed that the second architecture with two convolution layers performs better than the first architecture. The best classification result was obtained through the second CNN architecture and mother wavelet Cgaus with 92.54% accuracy, 94.11% precision, 95.06% recall, and 93.37% F1-score.

V. DISCUSSION

EEG motor imagery classification plays a crucial role in various fields, especially in the domain of BCI technology. By utilizing EEG data, this classification technique allows the interpretation and extraction of meaningful information from brain signals associated with motor imagery tasks. The significance of EEG motor imagery classification lies in its potential to enable individuals with motor disabilities to regain control of their environment and interact with external devices using their thoughts alone. It opens up new possibilities for applications such as neuro-rehabilitation, prosthetics control, and assistive technologies. Moreover, EEG motor imagery classification contributes to advancing our understanding of brain functioning and provides a non-invasive means to study and analyze neural processes related to motor planning and execution. Through continued research and development, EEG motor imagery classification holds promise for enhancing the quality of life for individuals with motor impairments. In this article, with the aim of designing a classification system of motor imagery data based on deep learning methods, two different CNN architectures were investigated. For this purpose, after reviewing the studies conducted in this field, the proposed systems were introduced and implemented, and the details of these systems were examined. The proposed model with the aim of classifying motion perception data includes the blocks of channel selection, filtering, data transformation to the time-frequency domain, classification, and evaluation of the proposed model. Among the examined wavelet transforms, the images created with the Cgaus mother wavelet had the best classification performance in both CNN architectures. In addition, among the proposed CNN architectures, the second architecture with two layers of convolution showed the best performance, which was confirmed by various evaluation criteria including accuracy, precision, recall, and F1score.

In Table IV, the results obtained from the proposed method are compared with the previous classical machine learning and deep learning approaches. All these publications have used the same dataset as our study and therefore it is possible to directly compare the previous and current proposed methods. As shown, the proposed method performs very well compared to the previous classical machine learning and deep learning methods. However, it should be noted that deep learning methods increase the computational costs, and to reduce the computational load and maintain the classification quality, it is necessary to conduct more studies on the network structure, such as the number of kernels, the use of one-dimensional kernels instead of two-

dimensional kernels, and the number of layers used. Also, considering the variety of existing mother wavelets, more studies on the wavelet transform with other mother wavelets are suggested.

TABLE IV. COMPARING THE RESULTS OF THE PROPOSED DEEP LEARNING METHOD WITH THE PREVIOUS STATE-OF-THE-ART WORKS FOR THE CLASSIFICATION OF THE BCI COMPETITION IV-2A DATASET

Reference	Algorithm	Classifier	Reported accuracy (%)
[33]	SFBCSP	SVM	92
[34]	CTDA	SVM	81.85

[42]	WT	2D CNN	89.36
Current work	WT	2D CNN	92.54

VI. CONCLUSION

In this work, two simple CNN models with different and yet simple structures were proposed and investigated for motor imagery EEG classification. For this purpose, time-frequency representation of EEG signal was used as input of deep models. Both research goals of this work were achieved: (1) increasing the accuracy of motor imagery EEG classification compared to previous existing techniques using simple deep learning architectures; and (2) investigating the effect of the mother wavelet on the time-frequency representation of the EEG signal as an input to deep learning networks and determining the best mother wavelet to achieve appropriate results. In summary, the findings of this study showed that the architecture of CNN and specifically the number of convolution layers in this deep learning network has a significant effect on the classification performance of motor imagery brain data. In addition, the findings of this study showed that the mother wavelet in the wavelet transform is very important in the classification performance of motor imagery EEG data. Considering that many EEG studies use time-frequency maps obtained from wavelet transform as input to deep learning models, the results of this study can be very useful and important for this type of study.

Although the proposed method achieved better performance than some state-of-the-art methods, this study faced limitations that should be further investigated in future research. One of the limitations of this study was the selection and analysis of only three EEG channels based on anatomical information related to motor perception, while other channels may also contain useful information that can help improve the performance of the proposed system. Therefore, it is recommended that future studies use automatic channel selection and optimization methods to utilize the maximum relevant information available in brain signals. In this study, only three well-known mother wavelets were compared and investigated, while new hybrid mother wavelets have been introduced in recent years that can improve the performance of the proposed framework. Therefore, further studies on wavelet transform with other mother wavelets are suggested. In addition, there are new time-frequency analysis methods that may perform better than traditional wavelet transforms, such as empirical Fourier decomposition and empirical wavelet transform. It is strongly recommended that future studies explore the integration of these new methods with the proposed deep models.

Exploring Differential Entropy and Multifractal Cumulants for EEG-based Mental Workload Recognition

Yan Lu

Department of Human Resource, Jiaxing Nanyang Polytechnic Institute
Jiaxing 314000, Zhejiang, China

Abstract—In the current research, two nonlinear features were utilized for the design of EEG-based mental workload recognition: one feature based on differential entropy and the other feature based on multifractal cumulants. Clean EEGs recorded from 36 healthy volunteers in both resting and task states were subjected to feature extraction via differential entropy and multifractal cumulants. Then, these nonlinear features were utilized as input for a fuzzy KNN classifier. Experimental results showed that the multifractal cumulants feature vector achieved an AUC of 0.951, which is larger than the differential entropy feature vector (AUC = 0.935). However, the combination of both feature sets resulted in added value in identifying these two mental workloads (AUC = 0.993). Furthermore, the multifractal cumulants feature vector (best classification accuracy = 94.76%) obtained better classification results than the differential entropy feature vector (best classification accuracy = 92.61%). However, the combination of these two feature vectors achieved the best classification results: accuracy of 96.52%, sensitivity of 97.68%, specificity of 95.58%, and F1-score of 96.61%. This shows that these two feature vectors are complementary in identifying different mental workloads.

Keywords—Mental workload; EEG; nonlinear analysis; multifractal; differential entropy; fuzzy KNN; classification

I. INTRODUCTION

Lately, there has been tremendous progress in the development and use of detection tools and artificial intelligence. As a result, they are now widely used to monitor human mental states in different areas [1]. These technologies are practically applied in passive brain-computer interfaces and human-robot interaction [2]. In this context, assessing cognitive workload has become highly important and has attracted a lot of attention. It measures the mental effort required considering the available cognitive resources. Monitoring and evaluating various factors like emotions, fatigue, and stress that affect cognitive workload have become crucial due to their potential impact on people's well-being and performance in real-world situations [3], [4]. Therefore, recognizing and understanding cognitive workload is extremely significant for improving human productivity, safety, and overall quality of life.

Until now, cognitive workload measurements have been classified into two types: objective and subjective measures. Subjective measures rely on self-assessment and perceptions of the operators, often utilizing questionnaires like the Subjective Workload Assessment method to evaluate cognitive workload. While these approaches are easy to implement, they lack

objectivity, real-time feedback, and precise results [5]. On the other hand, objective measures primarily rely on task performance recordings and various biological signals, which minimize interference with the task and address the aforementioned limitations [6]. Commonly used physiological signals include heart rate, respiration, electroencephalogram (EEG), eye tracking, and electromyogram [7]. Among these, EEG is a popular choice due to its convenience, excellent temporal resolution, availability, security, and affordability [8], [9]. Hence, this study focuses on the recognition of cognitive workload using EEG-based methods.

EEG signals possess distinct characteristics, including noise, weakness, nonlinearity, and non-stationarity, which vary among individuals [10]. Consequently, it is a significant challenge to identify robust patterns in EEG signals specific to a particular state. Traditional analytical approaches rely on statistical testing to detect differences in features like power variations within standard EEG frequency bands [11]. However, these methods may lack adequate modeling capacity or fail to uncover causal relationships [12]. To overcome these challenges, numerous studies have proposed various machine-learning techniques [13]. Machine learning can effectively learn unique features that capture inherent patterns in the data and construct predictive models [14]. For instance, a proposed method integrates ECG, EEG, and electrooculography (EOG), demonstrating superior predictive capability compared to individual analyses [15]. Similarly, another research showcases high accuracy by combining ECG, EEG, and respiration rate for the classification of mental conditions [16]. Furthermore, combining EEG and ECG yields even better outcomes compared to using EEG signals alone [17]. However, utilizing multiple sensors and processing multiple physiological signals can pose computational and processing challenges. As a result, many researchers have concentrated on using EEG alone to identify mental workload. Several studies have utilized spectral, statistical, and fractal analysis along with various classifiers to detect different mental states from EEG signals. For instance, Zarjam et al. presented a mental workload recognition system that incorporates time, time-frequency, and nonlinear features of EEGs from five healthy volunteers, a statistical feature selection method based on t-test, and SVM classifier. They achieved an accuracy of 83% using the hold-out cross-validation technique in recognizing three different levels of cognitive workload [18]. Walter et al. computed the spectral features of EEGs from 21 healthy subjects as input to an SVM classifier and reported an

accuracy of 82% using the 10-fold cross-validation technique in detecting three levels of mental workload [19]. Tremmel et al. also computed the spectral features of EEGs from 15 healthy subjects as input to a regularized LDA classifier and reported an accuracy of 63% using the 4-fold cross-validation technique in detecting three levels of mental workload [20]. Kakkos et al. calculated the functional connectivity of EEG signals from 33 healthy subjects as input to an ensemble LDA classification model and reported an accuracy of 82% using the 10-fold cross-validation technique in detecting three levels of mental workload [21]. Wang et al. calculated the time-frequency features of EEG signals from eight healthy subjects as input to a hierarchical Bayes classifier and reported an accuracy of 80% using the 5-fold cross-validation technique in detecting three different levels of cognitive workload [22]. Gevins et al. computed the spectral features of EEGs from eight healthy subjects as input to a neural network classifier and reported an accuracy of 80% using the hold-out cross-validation technique in detecting three different levels of cognitive workload [23].

Although the EEG signal exhibits nonlinear and chaotic characteristics, and nonlinear analysis techniques in signal processing have made significant advancements, there is a scarcity of studies exploring the potential of various nonlinear analysis methods in identifying cognitive workload. The existing studies that have employed nonlinear techniques have reported unsatisfactory outcomes. As a result, this study strives to enhance previous endeavors by employing two unique nonlinear analyses and machine learning techniques for the classification of resting and task-related EEG data. The two unique nonlinear analyses are performed according to differential entropy and multifractal cumulants. Therefore, the contribution of this study is twofold. First, multifractal cumulants and differential entropy are examined for the first time to recognize mental workload. Multifractal analysis of brain signals can provide insights into the complex and nonlinear dynamics of neural activity. While the direct relationship between multifractal cumulants of brain signals and mental workload is still an area of ongoing research, there are potential connections and implications. Multifractal analysis could potentially be used to distinguish between different mental states, such as periods of high versus low mental workload. Patterns in multifractal cumulants might reveal underlying neural dynamics linked to cognitive processing and workload variations. On the other hand, higher mental workload often requires increased cognitive processing and information integration. The differential entropy of brain signals could reflect the complexity and amount of information being

processed by the brain during tasks associated with different levels of mental workload. However, none of the previous studies have examined these two important features for identifying mental workload. Second, a fuzzy classifier (fuzzy KNN) was applied to the extracted features. Fuzzy classification of brain signals can play a role in decoding the neural correlates of mental workload and providing valuable insights into cognitive states and processes. By exploiting the flexibility and adaptive nature of fuzzy logic, it is possible to capture the complexity of brain dynamics associated with different levels of mental workload.

II. METHODS

In this section, a comprehensive plan outlining the methods and techniques used to accomplish the research objectives is provided. It encompasses a thorough explanation of the experimental design, dataset, and analysis procedures employed in this study. Each step is presented in a systematic manner, with a focus on the crucial variables, instruments, and statistical methods utilized.

A. EEG Dataset

In this research, an openly accessible EEG database [24] was employed to investigate mental cognitive workload. The study enrolled 36 healthy volunteers (75% female) within the age range of 18 to 26 years. Participants met the criteria of having normal color vision, and visual acuity, and no history of cognitive or mental disorders or learning disabilities. To induce cognitive activity, participants were instructed to complete arithmetic tasks involving consecutive number subtraction while their EEG data was captured. The EEG signals were recorded using Ag/AgCl electrodes positioned on the scalp following the 10-20 standard system. Sixteen scalp locations were selected, including Fp1, T5, Fp2, F8, F3, T3, F4, Fz, F7, C3, O1, C4, O2, Cz, T4, and T6. A reference was established by connecting the channels to A1 and A2, positioned on the earlobes. Electrode impedance was maintained below 5 kOhm, and the sampling rate was set at 500 Hz. To reduce noise and artifacts, a low-pass filter with a cutoff frequency of 45 Hz, a high-pass filter with a cutoff frequency of 0.5 Hz, and a notch filter with a center frequency of 50 Hz were used to filter the recorded EEGs. Before EEG recording, participants were instructed to relax during a resting-state period and mentally count during the arithmetic tasks without verbalizing. The recording process consisted of a three-minute adaptation phase, followed by three minutes of resting state with closed eyes, and concluding with four minutes of performing the arithmetic task. The timeline of the recording process is visualized in Fig. 1.

Fig. 1. The time course of the EEG recording procedure [24].

B. Proposed Framework

The general framework for EEG-based mental workload recognition is shown in Fig. 2. First, Clean EEGs were subjected to feature extraction via differential entropy and multifractal cumulants. Then, these nonlinear features were utilized as input for a fuzzy KNN classifier.

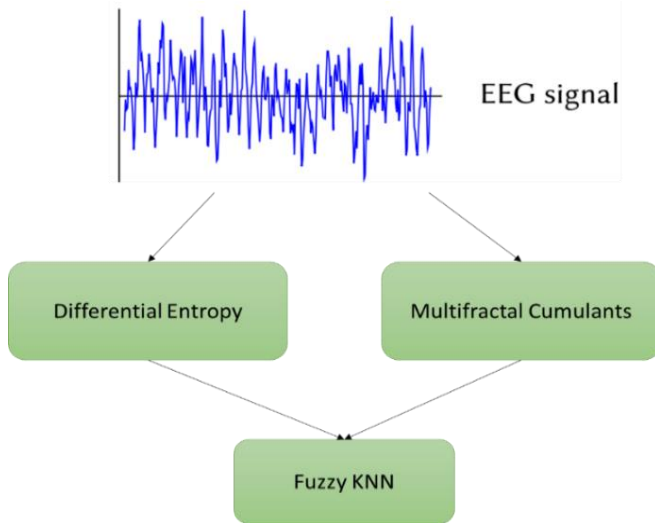

Fig. 2. General framework for EEG-based mental workload recognition.

C. Differential Entropy

Differential entropy is a concept widely used in information theory and statistics to measure the uncertainty or randomness present in a continuous random variable. The underlying assumption is that engaging in a cognitive task has the potential to either heighten or diminish the predictability of the EEG signal. This altered predictability, when quantified by this feature, can be recognized via classifiers. For instance, motor activity produces discernible rhythmic patterns that contrast with the resting state of neurons. Regardless of the specific frequencies associated with both motor activity and the resting state, the presence of any type of activity will induce a variation

in the predictability of the EEG signal. Mathematically, differential entropy is defined by [25]:

$$DE = - \int_{-\infty}^{+\infty} \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}} \log \left(\frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}} \right) dx = \frac{1}{2} \log(2\pi e\sigma^2) \quad (1)$$

where, the signal X has a Gaussian distribution $N(\mu, \sigma^2)$. In the feature extraction step, differential entropy was calculated in each EEG frequency band: delta (1-4 Hz), theta (4-8 Hz), alpha (8-12 Hz), beta (12-30 Hz), and gamma (30-40 Hz).

D. Multifractal Cumulants

Multifractal cumulants can be viewed as a statistical measure of the relationships between different frequency bands. The multifractal approach provides insights into how these bands are interconnected at any given moment. The underlying hypothesis suggests that specific mental activities not only affect the power of various EEG frequency bands but also impact the distribution of this power among the bands. Essentially, the multifractal cumulants of the signal capture a distinctive pattern of inter-band relationships, which differs from the commonly used approach of analyzing power within individual frequency bands. Previous research has demonstrated the potential of utilizing the multifractal spectrum for EEG classification [26]. Our chosen method for extracting the multifractal spectrum involves performing a discrete wavelet transform on the signal and extracting the wavelet leader coefficients [27]. Then, following the methodology outlined in study [28], the cumulants of the leaders as classification features were employed. Let $x(t)$ denote the signal under analysis. According to the perspective presented in [29] on multifractal analysis, the statistical properties of $x(t)$ are related to those of a scaled version of the signal, $x(at)$. This scaling in time corresponds to a frequency shift in the context of frequency analysis. Therefore, an alternative interpretation of the multifractal cumulants feature is that it characterizes some form of inter-frequency information, as explained in the introduction of this section.

- The process of implementing the multifractal cumulants extraction algorithm is as follows:
- The discrete wavelet transform is utilized to decompose the time series $x(t)$ and obtain the wavelet coefficients $w(s, t_s)$ at every time interval t_s and dyadic scale s .
- The wavelet leaders are calculated at every scale s by extracting the maximum coefficients among all samples obtained by calculating $w(s, t_s)$, $w(s, t_{s-1})$, and $w(s, t_{s+1})$.
- The partition functions are calculated for a sufficient range of exponents q as follows:

$$F(s, q) = \frac{1}{N_s} \sum_{t_s=1}^{N_s} |w(s, t_s)|^q \quad (2)$$

- To obtain the multifractal spectrum, either a Legendre transform or a direct estimation of the Holder exponent density was employed, as described in [30]. However, in the current approach, a more recent technique introduced by study [28] was adopted. This technique involves computing the wavelet leader cumulants of orders 1-5, which are further detailed in the referenced paper. According to study [28], the initial cumulants already encompass a significant amount of practical information for characterizing the distribution of Holder exponents. In the context of a classification task, this condensed form of information can be effectively utilized.
- The first five cumulants were calculated for the leaders at every scale, denoted by s . In a signal with a size between $2L$ and $2L+1$, where L represents the maximum levels of the wavelet transform, a cumulative count of 5 multiplied by L cumulants was obtained for the signal. These cumulants gradually encompass an increasing number of frequency bands as the scale rises. Ultimately, the feature vector consists of these 5 multiplied by L cumulants per channel.

E. Fuzzy K-nearest neighbor (FKNN)

The fuzzy k-nearest neighbor (FKNN) classifier emerged as one of the leading advancements in the field of KNN algorithms. It operates by incorporating membership degrees for classifying data that contains uncertainties. In FKNN, each new query sample is assigned membership degrees to different classes, with the highest degree playing a decisive role in classification [31]. The assigned membership degree reflects the proportion to which the query sample belongs to each available class. These degrees are then weighted based on the inverse distance between the query sample and its k nearest neighbors within the membership function. Additionally, a fuzzy strength parameter known as 'm' is introduced to determine the relative importance of distance when evaluating the contribution of neighbors to the membership degree. The membership degree for the query sample y in each class i , as determined by the k nearest neighbors, is measured according to the following approach:

$$u_i(y) = \frac{\sum_{j=1}^k u_{ij} \left(\frac{1}{\|y-x_j\|^{\frac{m-1}{2}}} \right)}{\sum_{j=1}^k \left(\frac{1}{\|y-x_j\|^{\frac{m-1}{2}}} \right)} \quad (3)$$

where, u_{ij} denotes the membership of the sample j th in the class i th of the training subset and $m = 2$.

III. RESULTS

After the preprocessing of EEG data, various features were computed from all channels. The comparison of raw EEG signals between the rest and task conditions is presented in Fig. 3. It can be observed that there were no noticeable distinctions between the two cognitive workload states. Moreover, Fig. 4 shows the differential entropy values for each EEG frequency band at rest and task states in the F3 channel. As can be seen, the entropy values in all frequency bands are higher in the task state than in the rest state. In other words, the complexity of the EEG signal in different frequency bands is higher in the task state than in the rest state.

Fig. 3. A sample of EEGs for rest (left) and task (right) conditions.

Fig. 4. Differential entropy for each EEG frequency band at rest and task states in the F3 channel.

To determine the recognition value of each of the feature vectors (i.e., differential entropy feature vector, multifractal cumulants feature vector, and combined feature vector), ROC curves corresponding to each feature category were obtained. Fig. 5 shows the ROC curves obtained for each feature category. As shown, the multifractal cumulants feature vector achieved an AUC of 0.951, which is larger than the differential entropy feature vector (AUC = 0.935). However, the combination of both feature sets resulted in added value in identifying these two mental workloads (AUC = 0.993).

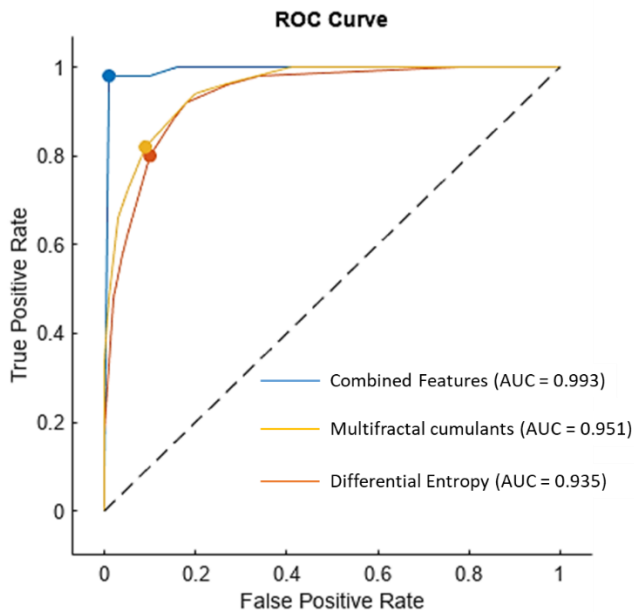

Fig. 5. ROC curves were obtained for each feature category.

In the next step, each feature vector was used as input for the classifier. In addition, to more accurately evaluate the

performance of the proposed classifier (FKNN), several classical classifiers were used for comparison: KNN, linear SVM, LDA, Naïve Bayes, decision tree, and random forest. In this binary classification problem, there are two distinct classes: task or positive (P) and rest or negative (N). The classification models yield four potential outcomes: true positive (TP), true negative (TN), false positive (FP), and false negative (FN). The predicted class determines T and F, while the actual class determines P and N. Accuracy, sensitivity, specificity, and F1-score were the performance measures used to evaluate the classification. In every chosen feature vector, the data was divided into three parts: a training set of 60%, a validation set of 20%, and a testing set of 20%. To maintain the same class proportions throughout the divided sets, a stratified random sampling technique was employed during the sampling process. For cross-validation, the holdout method was utilized, generating six random splits of the training and validation sets. Tables I to III show the classification results of rest and task EEGs by differential entropy, multifractal cumulants, and combined feature vectors using different classifiers, respectively. As shown in Table I, the FKNN classifier using the differential entropy feature yielded an accuracy of 92.61%, sensitivity of 90.42%, and specificity of 94.55% and F1-score of 92.43% for mental workload recognition. After FKNN, SVM and LDA performed best among other classifiers with 91.16% and 90.89% accuracy, respectively. Multifractal cumulants achieved better results than differential entropy, as shown in Table II. Again, the FKNN classifier outperformed the other classification models with an accuracy of 94.76%, a sensitivity of 95.41%, a specificity of 94.15%, and an F1 score of 94.77%. According to the ROC curve analysis results, as expected, the multifractal cumulants feature vector (best classification accuracy = 94.76%) obtained better classification results than the differential entropy feature vector (best classification accuracy = 92.61%). However, the combination of these two feature vectors achieved the best classification results: accuracy

of 96.52%, sensitivity of 97.68%, specificity of 95.58%, and F1-score of 96.61%. As shown, in Table III, this excellent result was achieved by the FKNN classifier. This shows that these two feature vectors are complementary in identifying different mental workloads. In addition, FKNN, SVM and LDA classifiers produced overall better results than other classifiers.

TABLE I. CLASSIFICATION RESULTS OF RESTING AND TASK EEGS THROUGH DIFFERENTIAL ENTROPY FEATURE VECTOR AND FKNN COMPARED TO OTHER CLASSIFIERS

Classifier	Accuracy (%)	Sensitivity (%)	Specificity (%)	F1-score (%)
FKNN	92.61	90.42	94.55	92.43
KNN	88.47	87.29	89.73	88.49
SVM	91.16	90.25	92.01	91.12
LDA	90.89	89.66	92.05	90.83
Naïve Bayes	83.49	82.12	84.81	83.44

Naïve Bayes	86.13	86.90	85.35	86.11
Decision Tree	88.82	87.69	90.03	88.84
Random Forest	89.40	90.24	88.62	89.42

IV. DISCUSSION

An automated EEG-based system based on two new nonlinear features and a fuzzy classifier (FKNN) was suggested in this research for mental workload recognition. A good accuracy of 96.52% was obtained through the combination of

the feature vectors extracted by two nonlinear analyses and the FKNN classifier. Mental workload serves as an important measure for assessing the cognitive demands placed on individuals during specific tasks. Its significance extends to various fields such as healthcare and education. It has been observed that nonlinear features extracted from EEG signals offer promising potential for detecting mental workload. EEG, a technique that records brain activity, captures the brain's electrical signals, which are intricate and nonlinear in nature [32]. Analyzing these signals using conventional linear methods proves challenging [33]. Nonlinear analysis of EEG signals, accomplished through mathematical techniques, enables the capture of the brain's dynamic and complex activities [34], [35], [36]. By extracting nonlinear features from EEG signals, valuable insights can be gained into the brain's functional connectivity, complexity, and synchronization, which are not easily identifiable using linear techniques [37]. The benefits of nonlinear analysis of EEG signals are numerous, including the ability to detect subtle changes in brain activity [38], identify abnormal brain activity associated with neurological disorders [39], [40], [41], [42] and develop more accurate diagnostic tools for brain disorders [33]. In essence, the nonlinear nature of EEG signals presents researchers and clinicians with a unique opportunity to delve into the intricate dynamics of the brain and devise more effective strategies for identifying mental workload.

In contrast, the outcomes achieved through the proposed method in this research exhibit great promise when compared to previous investigations. Table IV displays a comparative analysis of the proposed approach and other machine learning-based methods applied to EEG analysis for mental workload recognition. When considering the same unipolar EEG signals, the method presented in this study demonstrates satisfactory results compared to previous approaches. This study introduces a novel machine learning model that employs EEG nonlinear features to detect mental workload. Notably, unlike many prior studies that relied on small EEG datasets for evaluation, the current method was examined using a relatively larger dataset, yielding acceptable outcomes. The findings of this research hold potential implications for understanding the neural mechanisms underlying different levels of mental workload, particularly in clinical fields such as psychology and psychiatry. Nevertheless, it is essential to recognize the limitations of this study, as well as similar studies. One notable drawback is the limited clinical implications and generalizability of the findings. Further evidence is required to establish the effectiveness of employing EEG-based machine learning techniques in mental workload detection, including their performance in individuals with diverse physical or mental conditions. Moreover, a broader range of EEG datasets specific to various levels of cognitive workload is crucial to effectively utilize these approaches, given the intensive data requirements of machine learning techniques for optimal results. Nonetheless, the proposed method can potentially serve as a computer-aided detection (CAD) tool for clinical applications. Additionally, the presented framework offers advantages such as reduced labor, time efficiency, and decreased susceptibility to human errors compared to traditional methods of cognitive workload recognition. Consequently, it enables swift and accurate cognitive workload detection without direct human involvement.

TABLE IV. COMPARING THE PERFORMANCE OF OUR PROPOSED APPROACH WITH SOME STATE-OF-THE-ART STUDIES USING MACHINE LEARNING METHODS FOR MENTAL WORKLOAD IDENTIFICATION THROUGH EEG ANALYSIS

Reference	Dataset	Approach	Cross-validation	Accuracy (%)
[43]	28 EEGs from healthy adults during rest and task	Functional connectivity and SVM	LOSOCV	87.00
[22]	9 EEGs from healthy adults during rest and task	Time, frequency, and time-frequency features along with SVM	10-fold CV	84.00
[44]	8 EEGs from healthy adults during rest and task	Spectral features and stacked denoising autoencoder	Hold-out	74.00
[45]	7 EEGs from healthy adults during rest and task	Spectral features and adaptive stacked denoising autoencoder	Hold-out	85.79
[46]	15 EEGs from healthy adults during rest and task	Spectral features and MLP neural network	Hold-out	85.00
[47]	8 EEGs from healthy adults during rest and task	Time and frequency features, denoising autoencoder	Hold-out	86.00
[48]	12 EEGs from healthy adults during rest and task	Spectral features and neural network	Hold-out	75.00
[49]	20 EEGs from healthy adults during rest and task	Spectral and time features along with LDA	10-fold CV	90.00
[50]	22 EEGs from healthy adults during rest and task	Time and time-frequency features along with LDA	5-fold CV	70.00
Our proposed approach	36 EEGs from healthy adults during rest and task	Multifractal cumulants, differential entropy and various machine learning techniques	Hold-out	96.52

V. CONCLUSION

This research suggested two nonlinear features for mental workload recognition: multifractal cumulants and differential entropy. The multifractal cumulants feature captures the relationship between frequency bands, rather than quantifying the power within each specific band. This feature provides valuable information about the interplay between different frequency ranges. On the other hand, the differential entropy feature assesses the level of difficulty in predicting future EEG signal patterns based on their past behavior. This measure reflects the intricate dynamics present within the EEG signals. Surprisingly, our findings revealed that the multifractal cumulants and differential entropy can independently distinguish between different mental states as measured by EEG. Additionally, the obtained results demonstrated that combining these two features resulted in a higher accuracy of classification compared to solely utilizing each feature. Consequently, these new features are deemed valuable supplements to the existing features utilized in mental workload recognition, offering potential for enhanced this field. Future research may focus on exploring innovative methods for feature combination and selection, as well as extending the application of these features to multi-class problems beyond resting and task states. Moreover, it is essential to address the creation of new algorithms incorporating physiologically relevant error functions specifically tailored for EEG signal predictions involving the complexity feature. In addition, it is recommended that future studies use optimization algorithms such as genetic algorithm to adjust the parameters of nonlinear analyzes and FKNN classifier to improve the results and speed up the parameter adjustment process.

Predicting Math Performance in High School Students using Machine Learning Techniques

Yuan hui

Wuchang Institute of Technology, School of Information Engineering, China

Abstract—In the field of education, understanding and predicting student performance plays a crucial role in improving the quality of system management decisions. In this study, the power of various machine learning techniques to learn the complicated task of predicting students' performance in math courses using demographic data of 395 students was investigated. Predicting students' performance through demographic information makes it possible to predict their performance before the start of the course. Filtered and wrapper feature selection methods were used to find 10 important features in predicting students' final math grades. Then, all the features of the data set as well as the 10 selected features of each of the feature selection methods were used as input for the regression analysis with the Adaboost model. Finally, the prediction performance of each of these feature sets in predicting students' math grades was evaluated using criteria such as Pearson's correlation coefficient and mean squared error. The best result was obtained from feature selection by the LASSO method. After the LASSO method for feature selection, the Extra Tree and Gradient Boosting Machine methods respectively had the best prediction of the final math grade. The present study showed that the LASSO feature selection technique integrated with regression analysis with the Adaboost model is a suitable data mining framework for predicting students' mathematical performance.

I. INTRODUCTION

In the field of education, understanding and predicting student performance plays a crucial role in improving the quality of system management decisions. Through the utilization of machine learning methodologies, educators and administrators may effectively utilize data to detect pupils who may be prone to failure right from the outset of the course. By acting as an early warning system, these predictive models enable the implementation of focused support measures and intervention techniques to enhance student learning outcomes [1]. Machine learning algorithms and data mining techniques are commonly utilized in student performance prediction modeling [2]. These techniques analyze various attributes such as grades, educational background, psychological evaluation, and demographics to generate predictions about a student's future performance [3]. By utilizing machine learning techniques, educators can gain valuable insights into student behavior and patterns, allowing them to tailor their approach to meet individual students' needs. This not only improves student performance but also helps in identifying slow learners, predicting dropout rates, and enhancing overall educational outcomes. These predictive models help in improving the overall education system by

identifying students who may require additional support and intervention. Additionally, machine learning techniques can help in improving student attendance and predicting learning behavior to warn students who are at risk [4]. Machine learning techniques have revolutionized the field of education by providing accurate and timely predictions about student performance [5].

The process of extracting valuable embedded information from data plays a crucial role in various scenarios, providing valuable insights to organizations, companies, and research analysts for addressing different challenges and making informed decisions [6], [7]. The present investigation looks at the challenge of evaluating math students' performance with respect to important variables that have a big influence on the possibility of repeating the course. This study examines the application of several machine-learning approaches for data mining, taking into account the diversity of factors impacting students' success or failure in a course [8]. By mining the available data, the aim is to determine the relative importance of different factors in students' academic achievements.

Several researchers have explored the field of data mining related to students' performance. Kostopoulos et al. [1] proposed a new semi-supervised regression algorithm to predict the final grade of students in an online course. They showed that their technique can improve the performance of student performance prediction models. Randelović et al. [2] proposed a multidisciplinary-applicable aggregated model based on analytic hierarchy process and ReliefF classifier to predict further students' education. Xu et al. [8] introduced a two-layer machine learning architecture consisting of multiple base predictors and a set of ensemble classifiers to predict student performance in degree programs. They proposed a data-driven approach based on probability matrix factorization and latent factor models to construct baseline predictors. Through extensive simulations on an undergraduate student dataset collected over three years at University of California, they showed that this technique may achieve superior performance over benchmark approaches. However, none of the mentioned studies managed to identify important factors in student performance. The decision tree's (DT) ID3 variation method was used in one study by Baradwaj and Pal [9] to forecast end-semester marks (ESM). Previous semester marks (PSM), seminar performance (SEP), assignment (ASS), class test grade (CTG), attendance (ATT), lab work (LW), and general proficiency (GP) were among the considerations. Through the implementation of the DT method, a set of IF-THEN rules were derived to predict students' ESM categorized as first, second, third, or fail. Kabakchieva [10] used a variety of algorithms in

her study to estimate students' performance based on data obtained, including rule learners, K-nearest neighbors, DTs, and Bayesian classifiers. The results demonstrated that although these classifiers were suitable for the data mining task, none of the methods or classifiers achieved an accuracy of more than 75%, which is subpar considering how crucial it is to predict students' performance. The effectiveness of artificial neural networks and deep learning models (DTs) in simulating the academic standing of students of Nigeria's University of Ibadan, was examined in different research conducted by Osofisa et al [11]. The results showed that in terms of training and test data accuracy, the neural network model performed better than the DT model. 98.26% and 60.16%, respectively, for the training and test data were the classification accuracies of the multilayer perceptron model, which demonstrated the best performance. Roy et al. [12] investigated an adaptive dimensionality reduction algorithm for educational data mining. They showed that this algorithm can improve the performance of predictive models and provide useful insights into the important factors affecting student performance. However, the authors compared the proposed algorithm with some limited existing algorithms and were not able to introduce important factors affecting student performance.

In general, few studies have used a variety of data mining and machine learning methods to predict students' performance, and mostly limited artificial intelligence techniques have been investigated. Some existing studies have only reported the accuracy of classification using neural networks as a black box and have not investigated the important factors in predicting

students' performance. Therefore, the current study aims to systematically examine and compare various filtered and wrapper data mining methods to determine important factors in predicting students' performance. For this purpose, a variety of filtered-based, L1- and L2-based, tree-based, and evolutionary-based methods are examined to predict students' performance. This study looked into the ability of several machine learning approaches to learn the challenging job of predicting students' success in math classes using 395 students' demographic data. Predicting students' performance through demographic information makes it possible to predict their performance before the start of the course. The article is arranged as follows: Section II presents the dataset used and the proposed framework. Section III presents the experimental results. Section IV provides a discussion of the findings and Section V provides a conclusion on the study.

II. METHODS

A. Dataset

This information relates to the secondary school academic performance of two Portuguese schools [12]. The information was gathered through school reports and surveys, and its properties include student grades as well as demographic, social, and school-related information. A total of 395 students filled the questionnaires and the data set has no missing values. This dataset has 32 attributes which are shown in Table I. As shown, the variable G3, i.e. the final grade, is considered as the target variable, which is tried to be predicted by other variables.

TABLE I. 32 ATTRIBUTES OF THE STUDENTS' PERFORMANCE DATASET

Attributes	Type	Value	Description
School	Binary	GP/MS	Student's school
Sex	Binary	F/M	Student's sex
Age	Numeric	15-22 years	Student's age
Address	Binary	U/R	Student's home address type
Pstatus	Binary	T/A	Parent's cohabitation status
Famsize	Binary	LE3/GT3	Family size
Medu	Numeric	0-4	Mother's education
Fedu	Numeric	0-4	Father's education
Fjob	Nominal	Teacher, health services, at home, other	Father's job
Mjob	Nominal	Teacher, health services, at home, other	Mother's job
Guardian	Nominal	Mother, father, other	Student's guardian
Reason	Nominal	Home, reputation, course, other	Reason to choose this school
Traveltime	Numeric	1-4	Home to school time arrival
Studytime	Numeric	1-4	Weekly study time
Failures	Numeric	1≤n<3 else 4	Number of past class failures
Famsup	Binary	Yes/No	Family educational support
Schoolsup	Binary	Yes/No	Extra educational support
Nursery	Binary	Yes/No	Attended nursery school
Activities	Binary	Yes/No	Extra-curricular activities
Paid	Binary	Yes/No	Extra paid classes within the course subject
Internet	Binary	Yes/No	Internet access at home
Higher	Binary	Yes/No	Wants to take higher education
Romantic	Binary	Yes/No	With a romantic relationship
Freetime	Numeric	1-5	Free time after school
Famrel	Numeric	1-5	Quality of family relationships
Dalc	Numeric	1-5	Workday alcohol consumption
Goout	Numeric	1-5	Going out with friends
Walc	Numeric	1-5	Weekend alcohol consumption
Health	Numeric	1-5	Current health status
Absences	Numeric	0-93	Number of school absences
G1	Numeric	0-20	First-period grade
G2	Numeric	0-20	Second-period grade
G3	Numeric	0-20	Final grade (Target)

B. Proposed Framework

The proposed framework for math performance prediction using various machine-learning methods is shown in Fig. 1. As shown, at first, filtered and wrapper feature selection methods were used to find 10 important features in predicting students' final math grades. Then, all the features of the data set as well as

the 10 selected features of each of the feature selection methods were used as input for the regression analysis with the Adaboost model. Finally, the prediction performance of each of these feature sets in predicting students' math grades was evaluated using criteria such as Pearson's correlation coefficient and mean squared error. In the following, each of the feature selection and regression analysis methods used will be briefly described.

Fig. 1. Proposed framework for math performance prediction using various feature selection methods.

C. Filtered Feature Selection Approaches

Feature selection methods, known as filtered methods, choose features based on their performance measure without considering the specific data modeling algorithm used. Once the optimal features are identified, they can be utilized by the modeling algorithms. Filtered approaches have the capability to assess individual features' rankings or evaluate entire subsets of features [13]. The information, consistency, distance, statistical metrics, and similarity that were established for feature filtering may all be generally classified into these categories [14]. In this research, three filtered feature selection methods were utilized: mutual information, Pearson correlation coefficient (PCC), and maximum relevance minimum redundancy (MRMR).

Mutual Information. The mutual information feature selection method is a technique used to evaluate the relevance between features and the target variable. It measures the amount of information that two variables share, indicating their dependency and the potential of a feature to contribute useful information for the prediction task. This method calculates the mutual information score for each feature by considering both its individual information content and its relationship with the target variable. Features with high mutual information scores are considered more informative and are selected for further analysis or model building. By focusing on the information shared between features and the target, the mutual information feature selection method aids in identifying the most relevant features and improving the overall performance of machine learning algorithms [15].

$$I(X, Y) = \sum \sum p(x, y) \log \left(\frac{p(x, y)}{p(x)p(y)} \right) \quad (1)$$

where, $I(X, Y)$ represents the mutual information between variables X and Y , $p(x, y)$ denotes the joint probability distribution function of X and Y , $p(x)$ and $p(y)$ represent the marginal probability distribution functions of X and Y , respectively.

Pearson correlation coefficient (PCC). It is a widely used feature selection method in statistics and machine learning. It measures the linear relationship between two variables, typically a feature and a target variable. The PCC calculates the strength and direction of the linear association by calculating the covariance of the variables divided by the product of their standard deviations. A PCC value close to +1 indicates a strong positive correlation, while a value close to -1 suggests a strong negative correlation. Feature selection using PCC involves selecting the features with the highest absolute PCC values, as they are considered more informative for predicting the target variable. This method helps identify relevant features and can be particularly useful in applications where linear relationships between variables are expected [16].

$$PCC(X, Y) = \frac{cov(X, Y)}{\sigma(X)\sigma(Y)} \quad (2)$$

where, $cov(X, Y)$ represents the covariance between X and Y , which measures their joint variability, and $\sigma(X)$ and $\sigma(Y)$ represent the standard deviations of X and Y , respectively.

Maximum Relevance Minimum Redundancy (MRMR). It is an approach used to select the most informative features from a given dataset while minimizing the redundancies among them. It evaluates the relevance of each feature with respect to the target variable and simultaneously considers the redundancy among the selected features. By incorporating both relevance and redundancy measures, MRMR aims to identify a subset of features that maximizes the discriminative power while minimizing the overlap or redundancy between them. This technique has proven useful in various applications such as pattern recognition, text mining, and bioinformatics, allowing researchers to extract a compact and informative feature subset for improved model performance and interpretability [17], [18].

$$MRMR(S) = \operatorname{argmax}\{\sum[I(f_i; C) - \sum I(f_i; f_j)]\} \quad (3)$$

where, $MRMR(S)$ denotes the feature subset S that maximizes the objective function, $I(f_i; C)$ represents the relevance or mutual information between feature f_i and the target variable C , and $I(f_i; f_j)$ represents the redundancy or mutual information between feature f_i and feature f_j .

D. Wrapper Feature Selection Approaches

Wrapper approaches utilize a modeling algorithm as an opaque evaluator and use its performance to evaluate feature subsets. In classification tasks, these evaluators, like Naïve Bayes or SVM, evaluate subsets based on their classification performance, while in clustering tasks, they utilize clustering algorithms such as K-means to assess subsets. Similar to filters, wrappers employ a search strategy to generate subsets, repeating the evaluation process for each subset. However, wrappers are slower than filters as they depend on the computational demands of the modeling algorithm. Furthermore, the selected feature subsets can be biased towards the specific modeling algorithm used for evaluation, even with the employment of cross-validation. Therefore, for an accurate estimation of generalization error, it is crucial to validate the final subset with an independent sample and a different modeling algorithm [19]. On a positive note, empirical evidence suggests that wrappers outperform filters in obtaining subsets with higher performance due to the utilization of real modeling algorithms. While wrappers can be used in combination with various search strategies and modeling algorithms, they are most suitable for greedy search strategies and fast algorithms like linear SVM, and Naïve Bayes [20]. In this research, three main categories of wrapper feature selection methods were utilized: L1-based and L2-based (ridge regression, least absolute shrinkage and selection operator (LASSO), and linear SVM), Tree-based (extra tree, random forest, gradient boosting tree), and evolutionary-based (genetic algorithm).

Ridge Regression. Ridge regression, also known as Tikhonov regularization, is a feature selection method that introduces a regularization term to the linear regression model. It addresses the issue of multicollinearity among the predictor variables by shrinking the coefficients towards zero. In ridge regression, the objective is to find the subset of features that effectively contribute to the prediction while minimizing the impact of correlated or redundant variables. By controlling the regularization parameter, ridge regression allows for a balance between model simplicity and predictive accuracy. This method is particularly useful when dealing with high-dimensional

datasets and helps prevent overfitting by reducing the variance of the model [21].

$$\operatorname{minimize}: RSS + \alpha \sum \beta_i^2 \quad \text{subject to} \quad \sum \beta_i^2 \leq t \quad (4)$$

RSS represents the residual sum of squares, which measures the error between the predicted and actual values, β_i refers to the regression coefficients for each predictor variable, α is the regularization parameter that controls the amount of shrinkage applied to the coefficients, and t is a threshold that determines the budget for the sum of squared coefficients.

Least Absolute Shrinkage and Selection Operator (LASSO). It is a feature selection method utilized in regression analysis to efficiently select relevant predictor variables. Unlike traditional regression models, LASSO incorporates a regularization term into the equation that penalizes the sum of the absolute values of the regression coefficients. This penalty encourages sparsity by driving some coefficients to exactly zero, effectively conducting feature selection. The LASSO method is beneficial in situations where there are many predictors, as it can help identify the most influential variables and disregard the less relevant ones, leading to a more interpretable and efficient model. By striking a balance between minimizing the residual sum of squares and reducing the magnitude of the coefficients, LASSO allows for automatic variable selection and works well in scenarios where there is a high degree of multicollinearity or when the number of predictors exceeds the number of observations [22].

$$\operatorname{minimize}: \left(\frac{1}{2N}\right) \|Y - X * \beta\|^2 + \lambda \|\beta\|_1 \quad (5)$$

where, Y is the vector of target values, X is the design matrix containing the predictor variables, β is the coefficient vector, N is the number of samples, λ is the regularization parameter that controls the strength of the penalty term, and $\|\beta\|_1$ is the L1-norm (sum of absolute values) of the coefficient vector, which enforces sparsity.

Linear SVM. It works by optimizing a linear SVM model to find the hyperplane that best separates the classes of data points. In this process, SVM assigns weights or coefficients to each feature based on its importance in determining the class boundary. These weights can be used as a measure of feature relevance. By selecting features with large coefficients, which contribute significantly to class separation, the linear SVM feature selection method helps to identify the most informative features for classification tasks. This approach is effective in reducing dimensionality, improving model performance, and enhancing interpretability [23].

$$\operatorname{minimize}: 0.5 \times \|w\|^2 + C \sum \xi \quad \text{subject to} \quad y_i(w^T x_i) \geq 1 - \xi_i, i = 1, 2, \dots, N \quad (6)$$

where, ξ_i stands for the slack variables that permit some misclassifications, x_i is the feature vector of the i -th data point, y_i is the corresponding class label (+1 or -1), and $\|w\|_2$ is the L2 norm of the weight vector w . C is a regularization parameter that balances the trade-off between maximizing the margin and minimizing misclassifications.

Extra Tree. It is a variant of the Random Forest algorithm that further increases the randomness of the DTs. Extra Trees randomly selects subsets of features and thresholds to build a large number of DTs. The feature importance is calculated by

measuring the average impurity decrease in overall features in the ensemble of trees. Features with high-importance scores are considered more relevant for prediction while low-scoring features can be discarded. The main advantage of Extra Trees is its ability to handle high-dimensional data and capture complex interactions among features. It can effectively reduce overfitting and improve model performance by selecting the most informative subset of features [24].

Random Forest. It involves constructing an ensemble of DTs, where each tree is trained on a random subset of features and the predictions are aggregated through voting or averaging. The importance of each feature is then determined by measuring how much the performance of the model decreases when that feature is randomly permuted. Features that lead to a significant drop in performance are considered more important, while those with minimal impact are deemed less relevant. By evaluating the importance scores across multiple trees, Random Forest feature selection provides a robust and efficient approach to highlighting the most influential features in a dataset. The feature importance score in this method is computed based on how much each feature contributes to the overall accuracy of the Random Forest model [25].

Gradient Boosting Tree. Unlike other methods, it doesn't rely on a specific mathematical equation but follows a sequential process. The algorithm starts by building weak DTs and then iteratively improves them by adding new trees that correct the errors made by previous trees. When choosing features for the Gradient Boosting Tree, each feature's contribution to lowering the model's total loss is taken into consideration. During the boosting process, features with higher significance ratings are prioritized since they are deemed more significant. By iteratively selecting and refining features, the Gradient Boosting Tree effectively identifies which features are most influential in predicting the target variable, leading to more accurate and efficient models [26].

Genetic Algorithm (GA). GA is a popular feature selection method inspired by the concept of natural selection and genetic evolution. It is a search algorithm that mimics the process of natural selection to find the best subset of features for a given problem. GA starts by representing each potential subset of features as a binary string, called a chromosome. These

chromosomes then undergo reproduction, mutation, and crossover operations to create a new population of chromosomes in each generation. Fitness functions are defined to evaluate how well each subset performs. The subsets with the highest fitness values are given a higher probability of being selected for the next generation. This iterative process continues until a stopping criterion is met. By using genetic operators such as mutation and crossover, GA explores the solution space effectively and finds optimal or near-optimal feature subsets that can improve the performance of machine learning models [27].

E. Regression Analysis

Regression Analysis with Adaboost is a powerful machine learning technique that combines the principles of regression analysis and the Adaboost algorithm. Regression analysis is used to predict a continuous target variable based on one or more predictor variables. Adaboost, on the other hand, is an ensemble learning algorithm that combines the strengths of multiple weak classifiers to build a strong predictive model. In the context of regression, Adaboost works by iteratively training a series of weak regression models on different subsets of the training data. In each iteration, Adaboost assigns higher weights to the training instances that were poorly predicted by the previous models, thereby focusing on the most challenging cases. The weak models are then combined through a weighted average, where the weights are determined by their performance on the training data. By repeatedly refining the model based on the misclassified instances, Adaboost can ultimately create a robust and accurate regression model. This approach is helpful in handling complex regression problems with non-linear relationships between predictors and the target variable, as it effectively captures the underlying patterns and produces accurate predictions [28].

III. RESULTS

Table II shows the characteristics of the dataset used, which includes the 32 features shown in Table I. In addition, Fig. 2 shows the histogram of some variables of this dataset to display the status of students. Fig. 3 also represents the outcome of the correlation evaluation between all the variables of this dataset. As it is clear, the G1 and G2 variables have a correlation greater than 0.8 with the target variable (G3).

TABLE II. CHARACTERISTICS OF THE DATASET

Attributes	Type/Value
Dataset	Student performance (Math course)
Number of samples	395
Number of features	32
Number of target feature	1
Missing values	0

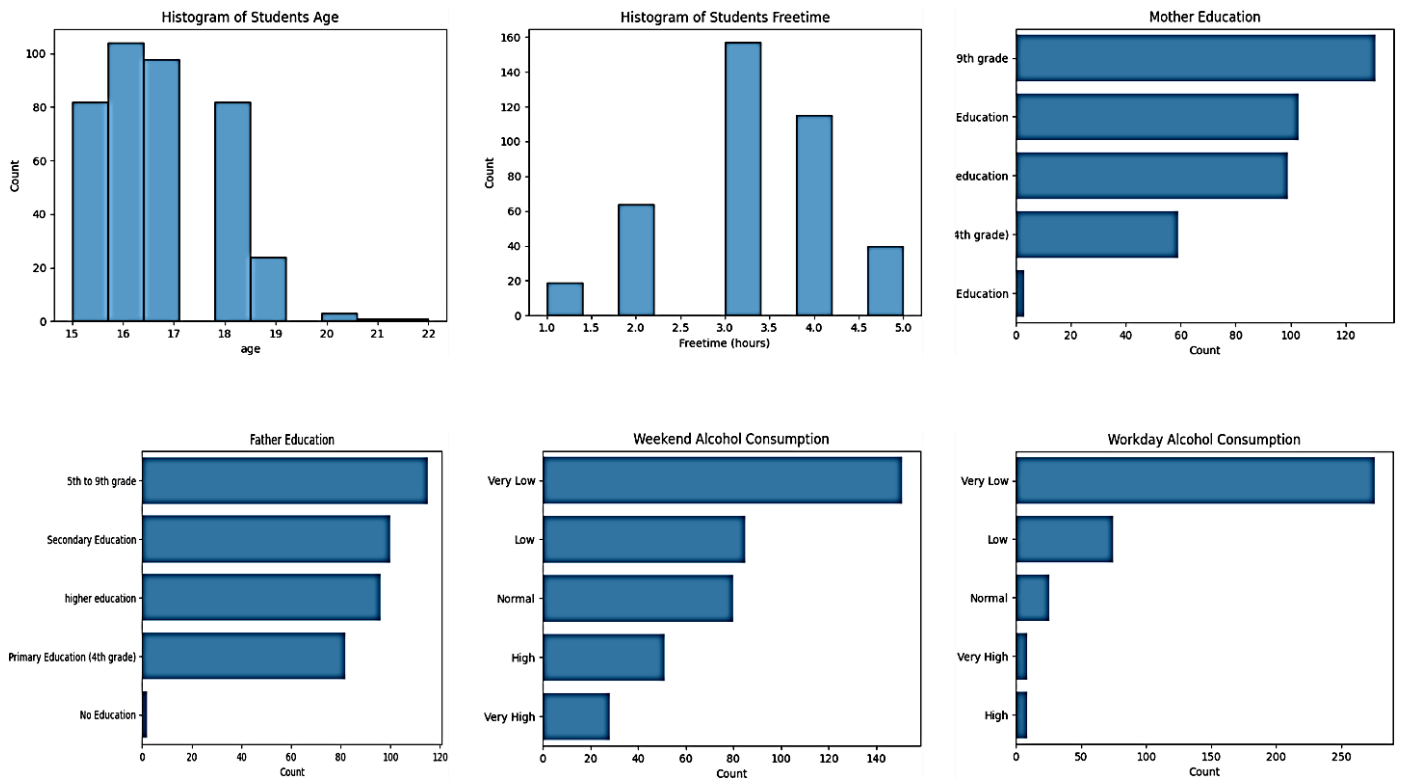

Fig. 2. Histogram of different variables.

Fig. 3. FCORrelation between 32 dataset variables.

Fig. 4 to Fig. 6 show the results of feature ranking by different feature selection methods to predict final math grades. Also, Table III shows the Top 10 features selected by MRMR and GA feature selection techniques. As shown, G1 and G2

scores had the highest correlation with the final grade (G3), and in most of the feature selection methods, they were among the best features.

Fig. 4. Dataset feature ranking using two filtered feature selection techniques (PCC and MI) to predict final math grades.

Fig. 5. Dataset feature ranking using three wrapper feature selection techniques (Ridge, LASSO, and SVM) to predict final math grades.

Fig. 6. Dataset feature ranking using three wrapper tree-based feature selection techniques (extra tree, random forest, and gradient boosting model) to predict final math grade.

TABLE III. TOP 10 FEATURES SELECTED BY MRMR AND GA FEATURE SELECTION TECHNIQUES

Technique	Rank 1	Rank 2	Rank 3	Rank 4	Rank 5	Rank 6	Rank 7	Rank 8	Rank 9	Rank 10
MRMR	G1	Failures	Medu	Romantic	Higher	Goout	Famsize	Age	Traveltime	Mjob
GA	Medu	Studytime	Romantic	G2	Freetime	Goout	Dalc	Walc	Health	G1

After selecting the feature, 80% of the data was used as a training sample and the remaining 20% was used as a test sample. Table IV shows the result of regression analysis using the Adaboost model and features selected by different machine learning techniques to predict the final math grade. Pearson correlation coefficient (PCC), mean absolute error (MAE), and mean squared error (MSE) were used to evaluate the results of the regression analysis. As shown, the best result was obtained from feature selection by the LASSO method with PCC = 94.26%, MAE = 1.12, and MSE = 2.53. After the LASSO

method for feature selection, the Extra Tree (PCC = 94.00%, MAE = 1.13, MSE = 2.64) and Gradient Boosting Machine (PCC = 93.55, MAE = 1.15, MSE = 2.73) methods respectively had the best prediction of the final math grade. Fig. 7 shows the scatter plots of the top 10 features selected by the LASSO technique. The bolder the data is, the higher the final math score. However, the rest of the feature selection techniques, except the random forest (PCC = 93.35%, MAE = 1.13, MSE = 2.76), achieved a lower precision than the original dataset for predicting the final math grade.

Fig. 7. Scatter plots of the top 10 features selected by the LASSO technique. The bolder the data is, the higher the final math score.

TABLE IV. THE RESULT OF REGRESSION ANALYSIS USING THE ADABOOST MODEL AND FEATURES SELECTED BY DIFFERENT MACHINE LEARNING TECHNIQUES TO PREDICT THE FINAL MATH GRADE

Feature selection method	Pearson correlation coefficient (PCC)	Mean absolute error (MAE)	Mean squared error (MSE)	Number of features
Without feature selection	93.28±0.01	1.20±0.09	3.01±0.58	32
Ridge	87.87±0.03	1.63±0.11	5.30±1.22	10
LASSO	94.26±0.01	1.12±0.08	2.53±0.46	10

GA	74.35±0.04	2.50±0.25	10.39±1.14	10

IV. DISCUSSION

In this research, machine learning methods were used for data mining from a dataset of students' performance. For this purpose, a variety of filtered and wrapper feature selection methods were used to determine the important demographic factors involved in predicting students' math scores. Finally, the features selected by each method predicted the final math grade using regression analysis with the Adaboost model. The results showed that the wrapper LASSO feature selection technique selects the best subset of features to predict the final math grade. LASSO offers several advantages in the field of data analysis. Firstly, it provides a solution for handling high-dimensional datasets, where the number of predictors exceeds the number of samples. By imposing a penalty term on the regression coefficients, LASSO encourages sparsity by shrinking some coefficients to zero, effectively selecting the most relevant features. This can lead to improved model interpretability and the identification of key predictors driving the observed outcomes. Moreover, LASSO is robust against multicollinearity, a common issue when predictors are correlated, as it tends to select one representative variable among highly correlated features [29]. Additionally, LASSO aids in avoiding overfitting by preventing the model from becoming excessively complex, which can generalize well to unseen data. Therefore, the LASSO method provides a powerful and efficient approach to feature selection by effectively handling high-dimensional datasets, promoting interpretability, and robustness against multicollinearity, and preventing overfitting [30]. The important factors selected by LASSO involved in predicting the final math grade of students were first and second-period grades, quality of family relationships, age, number of school absences, weekend alcohol consumption, current health status, the reason for choosing the school, weekly study time, and home to school time arrival. Schools encounter a range of predominant difficulties, such as performance analysis, delivering exceptional education, devising effective methods to assess student progress, and planning for future initiatives[31]. To tackle the issues students may encounter while pursuing their studies, it becomes imperative for these institutions to establish student intervention programs. These intervention plans aim to

address and resolve the challenges faced by students throughout their academic journey [32]. However, to have an effective intervention, important factors must be identified and this study was able to do this by using different data mining methods.

There are some previous attempts to survey the literature on academic performance [33]; however, most of them are general literature reviews and targeted towards the generic students' performance prediction. Table V compares the results obtained by the proposed framework in this study with previous techniques. As shown, the proposed framework outperforms other techniques in predicting student performance. As a result, this study could improve previous techniques in predicting student performance.

TABLE V. COMPARISON OF THE RESULTS OBTAINED BY THE PROPOSED FRAMEWORK WITH PREVIOUS TECHNIQUES

Reference	Machine learning technique	MAE	MSE
[1]	Semi-supervised regression algorithm	1.23	2.70

Current study	LASSO and regression	1.12	2.53

Anticipating the academic performance of students assumes significance within educational settings like schools and universities. This enables the development of efficient mechanisms that enhance academic outcomes and deter dropout rates, among other benefits [40]. The automation of various tasks involved in students' regular activities, leveraging vast amounts of data obtained from technology-enhanced learning software tools, plays a pivotal role in achieving these advantages. Consequently, meticulous analysis and processing of this data can furnish valuable insights into students' aptitude and their correlation with academic assignments [41]. Such information serves as the foundation for propitious algorithms and methodologies capable of prognosticating students' performance. The present study showed that the proposed framework can be used for such work in educational environments. This framework can predict students' performance by analyzing large datasets and taking into account the past and current status of students. However, there are limitations in this study as in many other studies that should be mentioned. First, this model requires external validation using unseen datasets. Second, most of the variables in this data set were demographic factors, while there are certainly other important factors that should be investigated in future studies. Thirdly, although the obtained results were good and acceptable, future studies should seek to improve the current results by optimizing the model parameters.

V. CONCLUSION

In this research, a comparative study was conducted between different data mining techniques to predict the mathematical performance of students. For this purpose, various filtered and wrapper feature selection methods were compared to select the most useful factors in predicting math grades. The present study showed that the LASSO feature selection technique integrated with regression analysis with the Adaboost model is a suitable data mining framework for predicting students' mathematical performance. This framework was able to identify the most relevant factors related to math performance and predict student performance with low error rate. These methods that rely on data analysis can be employed alongside other educational techniques to assess students' progress effectively. They offer insightful feedback to academic advisors, enabling them to suggest appropriate follow-up courses and implement necessary pedagogical interventions. Moreover, this research will greatly influence the development of curricula within degree programs and contribute to the formulation of education policies at large. Future research should take advantage of optimization algorithms to adjust parameters to improve the structure of the proposed framework and achieve better results. In addition, it is necessary to examine the external validity of the proposed framework by applying it to other datasets.

Office, Guangzhou Health Science College, Guangzhou, 510450, China

Abstract—This study aims to address the insufficient model recognition accuracy and limitations of authentication techniques in current IoT authentication methods. The research presents a more accurate face video image authentication technique by using a new authentication method that combines convolutional neural networks (CNN) and remote Photoplethysmography (rPPG) volumetric tracing. This method comprehensively analyzes facial video images to achieve effective authentication of user identity. The results showed that the new method had higher recognition accuracy when the light was weak. The new method performed better in ablation experiments. The error rate was 1.12% lower than the separate CNN model and 1.73% lower than the rPPG model. The half-error rate was lower than the traditional face authentication recognition model, and the method had better performance effect. Meanwhile, the images with high similarity showed better recognition stability. It can be seen that the new method is able to solve problems such as the recognition accuracy in identity authentication, but the recognition effect under extreme conditions requires further research. The research provides a new technical solution for the authentication of Internet of Things devices, which helps to improve the security and accuracy of the authentication system. By combining the CNN model and rPPG, the research not only improves the recognition accuracy in complex environments, but also enhances the system's adaptability to environmental changes. The new method provides a new solution for the advancement of Internet of Things authentication technology.

Keywords—Internet of Things; identity authentication; facial recognition; remote photoplethysmography; error rate

I. INTRODUCTION

With the rapid development of the Internet of Things (IoT) technology, the number of IoT devices has increased dramatically. These IoT devices have become important application devices in various fields, such as daily life, industrial production, and urban infrastructure [1]. However, with the popularity of IoT devices, the communication and data exchange between the devices also provide challenges for security and authentication [2]. Ensuring legitimate authentication of IoT devices is essential to protect data and system security [3].

Authentication, as a core issue in the field of information security, has been proposed and implemented in various approaches. Face recognition technology, as a biometric method, is potentially important in the authentication of IoT devices [4]. This technique not only provides highly accurate authentication, but also reduces the reliance on traditional passwords and keys, thus improving system security.

However, traditional face recognition methods usually require specialized hardware devices, which are extremely sensitive to lighting conditions and environmental factors. This limits their application scope in IoT devices. In addition, some traditional face recognition methods perform poorly in terms of recognition accuracy and error rate, which poses difficulties for the application of face recognition technology.

Therefore, this research investigates the face recognition authentication method using remote Photoplethysmography (rPPG) and Convolutional Neural Network (CNN). Firstly, utilizing the powerful fitting ability of neural networks, a facial pose recognition method using neural networks is designed to address the facial occlusion and recognition in facial recognition. Secondly, rPPG technology is used to solve the insufficient recognition accuracy and poor facial information in the authentication process of IoT devices. This research is divided into six sections. Section II reviews the domestic and international research. Section III constructs the research method. Results, discussion and conclusion is given in Section IV, IV and VI respectively.

II. LITERATURE REVIEW

Identity authentication is a means of authenticating users through facial recognition and fingerprint authentication. It is widely used in some IoT devices. Therefore, many experts and scholars have conducted extensive research on identity authentication of facial recognition devices. Mengjuan Zhai et al. developed a new scheme based on chameleon hash value and self-updating secret sharing to address the user privacy protection. The new solution was characterized by editable blockchain, providing users with fine-grained and fair editing functions. It could be applied with only a small additional cost. Compared with traditional centralized authentication schemes, the new scheme could better protect user privacy while providing more refined and fair services. However, there was still relatively little research on user physical characteristics in this study. Therefore, this study seeks new identity authentication methods for further research [5]. Yu Pingping et al. proposed a novel gesture recognition and identity verification algorithm based on continuous hidden Markov models and optical flow methods to address information security issues in the power IoT. The optical flow method was applied to extract features from preprocessed dynamic gesture information. A user dynamic gesture model using CHMM was established, which could improve the dynamic gesture recognition accuracy. The research results indicated that the new method had advantages in the identity verification accuracy, with higher recognition accuracy compared with

traditional methods. However, the study only achieved this by recognizing user gestures, which was unable to achieve faster and more accurate authentication recognition through facial recognition [6]. Xin Xu et al. proposed a novel biometric identity verification strategy based on music induced autobiographical memory electroencephalogram to address the identity verification. The research results indicated that it had high uniqueness, which was suitable for identity verification applications. However, the method used in the study was only address the biometric authentication, which did not fully address the entire process from identification to authentication [7]. Zhiguo Qu et al. proposed a novel quantum identity authentication protocol ground on three photon error correction codes to address the anti-interference problem of quantum identity authentication under quantum channel noise. The research results indicated that the protocol could effectively resist the interference of noise on information transmission in quantum channels, which had good anti-interference performance. Meanwhile, the new protocol maintained better security against various eavesdropping attacks. However, the study was not effective in improving the accuracy of authentication [8].

Jaiswal, Kokila Bharti et al. proposed a fusion-based new method to address the impact of non-uniform lighting on rPPG measurement results. The new method combined RGB and multi-scale Retinex color spaces to generate prominent spatiotemporal maps. The experimental results showed that the proposed method achieved excellent results in both inter database and internal database testing in public databases. This method could improve the data analysis of rPPG, but the method used in the study had insufficient security [9]. Tomasz Szabala et al. developed a new method to obtain remote optical heart movement data from a standard camera on a personal computer. The research results indicated that the image intensity changes generated by tracking blood volume changes in microvascular tissues using visible light cameras could effectively estimate the heart pulse. The new method was effective in detecting human pulse changes, but there were still shortcomings in the research of face information data [10]. Feng Qi et al. proposed a distributed and efficient key distribution protocol that did not require secure channel assumptions to address the inherent issues of identity cryptography in the IoT and ad-hoc networks. The research results indicated that the new protocol was maliciously secure under weaker assumptions. The new method could effectively solve the IoT data authentication security [11]. Gao, Zhigang et al. proposed a user authentication method based on button time interval groups to address the high cost, and low accuracy in mobile device user authentication. The research results indicated that the new method had high accuracy, low cost, and sustainable authentication. It could effectively solve the shortcomings of existing identity verification methods based on button dynamics. The research could effectively improve the low recognition accuracy of user authentication, but there was still a lack of security [12].

In summary, there are still many issues with current identity authentication methods for devices, such as security, recognition accuracy, etc. Therefore, to build a relatively complete facial recognition and identity authentication system,

CNN and rPPG models are used to design the facial recognition and identity authentication method.

III. IOT DEVICE AUTHENTICATION MODEL BUILDING

This chapter mainly analyzes the application of CNN in facial recognition. At the same time, a facial recognition identity authentication system integrating CNN and rPPG methods is built on the basis of the rPPG method. Through systematic analysis, this research can improve the facial recognition identity authentication system.

A. Facial Recognition Analysis Based on CNN

Facial recognition is a detection and analysis technique for recognizing and authenticating facial features of individuals. With the rapid development of the IoT, it has become the main means of identity authentication. As a feed-forward neural network, CNN is mainly used in image recognition analysis due to its ability to recognize image features during training. The CNN structure includes input, convolution, pooling, fully connected, and output layers. The input layer mainly processes the input data to ensure that the current data can be analyzed and processed by the neural network structure. The pooling layer is mainly used to reduce over-fitting by reducing the data dimensionality. The fully connected layer is mainly applied to connect and analyze the data of the upper and lower layers, facilitating the training of subsequent classifiers. This is also a processing layer for improving the ability of the entire model. The output layer mainly outputs the data processing results of the current network model [13]. The CNN structure diagram is shown in Fig. 1.

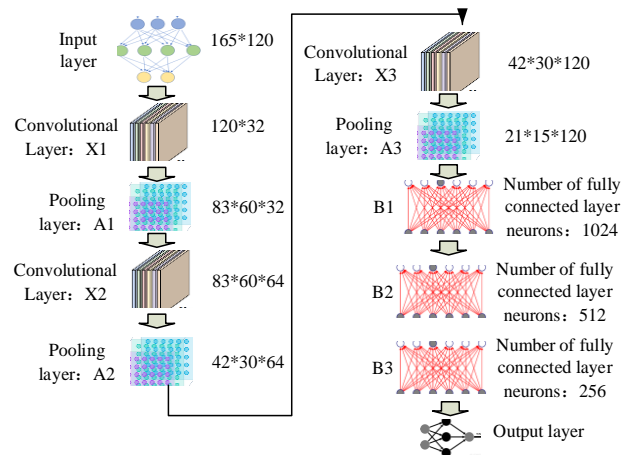

Fig. 1. CNN structure diagram.

In Fig. 1, X1, X2, and X3 are convolutional layers of the CNN, mainly used for extracting and analyzing different image features. A1, A2, and A3 are pooling layers of the current results, mainly used to reduce the dimensionality of the feature network, lower the computational complexity, and overcome over-fitting. B1, B2, and B3 are fully connected layers of the network model, which mainly extract features from the model results to accelerate the classification effect. Therefore, the data output structure of CNN is shown in Eq. (1) [14].

$$y_k = f \left(\sum_{j=1}^m w_{kj} x_j + b_k \right) \quad (1)$$

In Eq. (1), y_k represents the output data. x_1, x_2, \dots, x_m represent the input data. b_i represents the size of the bias. $w_{k1}, w_{k2}, \dots, w_{kj}$ represent the activation function. CNN enhances image recognition capability through convolution operations. Therefore, the one-dimensional convolution of CNN is shown in Eq. (2).

$$c_{cn} = f(x * w_{cn} + b_{cn}) \quad (2)$$

In Eq. (2), f represents the activation function of the convolution. x refers to the input data size. w_{cn} refers to the convolution value. b_{cn} represents the bias size of the convolution kernel. c_{cn} represents the output value of the convolutional layer in one-dimensional space. The normalized probability distribution of CNN is displayed in Eq. (3).

$$p(x)_i = \frac{e^{z_i}}{\sum_k e^{z_i}}, i = 1, 2, \dots, k \quad (3)$$

In Eq. (3), k refers to the number of classified data. z_i refers to the number of neurons in the output layer that have not been activated. $p(x)_i$ represents the normalized probability of the model. At this point, the cross entropy loss function of the CNN is shown in Eq. (4) [15].

$$H(p, q) = -\sum_x p(x) \log q(x) \quad (4)$$

In Eq. (4), $p(x)$ represents the distribution definition. $q(x)$ represents the distribution definition that has not been predicted. $H(p, q)$ represents the loss value of uncrossed entropy. In model analysis, the collected image data is subjected to feature processing. Eq. (5) shows the CNN fusion method for image data feature processing.

$$F_k = \sum_{i=1}^n f_i \quad (5)$$

In Eq. (5), F_k represents the image data fused with feature data using a separate convolutional layer. k represents the number of pooling layers A2 and A3. f_i represents the feature image data on this channel. n represents the number of channels. When k is A2, the number of channels is 64. When k is A3, the channels are 120. When the number of feature fusion layers increases, the coordinate transformation is shown in Eq. (6).

$$V(x_n, y_n) = V_{(x, y) \left(\frac{F_w}{T_w}, \frac{F_h}{T_h} \right)} \quad (6)$$

In Eq. (6), $V(x, y)$ represents the size of pixels when the image coordinate is (x, y) . F_w, F_h refer to the width and height of the feature image. T_w, T_h refer to the width and height

of the target image. The feature fusion obtained by adjusting the number of layers is shown in Eq. (7) [16].

$$F_N = \alpha F_{P_2} + (1 - \alpha) F_{P_3} \quad (7)$$

In Eq. (7), F_N represents the classification feature data after multi-layer fusion. F_{P_2}, F_{P_3} represent the feature set of classification data after increasing the number of layers. α represents the weight coefficient. The weight values of the algorithm are mainly used for matrix analysis of facial features and other data from different facial images. Eq. (8) represents the weight vector matrix.

$$f(x) = x \square y \quad (8)$$

In Eq. (8), $f(x)$ is the weight vector matrix. x represents the matrix definition of the sample. y represents the defined vector size. Analyzing the matrix vector representation of two images can achieve weight size analysis, as presented in Eq. (9) [17].

$$f'(x) = x \square y', f'(x) = f(x) \quad (9)$$

In Eq. (9), $f'(x) = x \square y'$ represents the weight vector matrix of another image. When the weights of two facial images are equal, the algorithm can learn the true weight size. To improve the feature vector extraction ability of the algorithm for facial data, the compensation vector and weight vector are multiplied to obtain the final vector extraction result, as displayed in Eq. (10).

$$H(x) = (x_i + a_i) y_i \quad (10)$$

In Eq. (10), x_i represents the size of the original vector. a_i represents the compensation vector. y_i represents the vector definition of weights. $H(x)$ represents the final feature vector extraction.

B. Analysis of Device Identity Authentication System Based on rPPG and CNN

In device identity authentication, there are some background shadows and unevenness in the facial area of the image during the recognition process, which leads to recognition [20] errors in facial information data. There will also be authentication results that are not real people. Therefore, using only CNN models for identity authentication can lead to recognition errors and insufficient clarity of the entire system. Therefore, to improve the detection ability of live facial data, the rPPG feature analysis algorithm is added to the research. This method can use image background information to enhance the color and color difference information data in facial image feature extraction, thus converting colors and other details in facial images and improving the performance of identity recognition. The current algorithm framework is shown in Fig. 2.

In Fig. 2, the structure of the algorithm mainly includes a neural network module and an rPPG module. In the neural network module of the algorithm framework, a detection model is first used to detect video images and other face data. The regional image of the face is analyzed through key positions and

localization. Afterwards, the analyzed image data is transmitted to the color feature extraction area and appearance extraction area. The data is trained and analyzed through a model classifier. In the rPPG module, the matrix data is mainly fused by using remote optical volume description technology to extract power features of facial region signals and analyze spectral features. By training the classifier model, the probability weight size is calculated, which is the best weight value for the facial image. Finally, image recognition authentication is completed by

weighting the two classifiers [18].

rPPG is a technology that can measure human blood heart rate and other factors. When light shines on the human body, some capillaries and hemoglobin can absorb some of the light. Cardiac fluctuations can alter the hemoglobin levels in different regions of the human body. This technology can capture this change and feedback it into the model system. The working principle of rPPG is shown in Fig. 3.

Fig. 2. Schematic diagram of model framework.

Fig. 3. Schematic diagram of rPPG working principle.

In Fig. 3, when light is emitted from the instrument, it is absorbed by hemoglobin in the human body through the skin. A portion of the light that is not absorbed is directly fed back to the emitting surface. In Fig. 3, the amount of unabsorbed light decreases as the amount of hemoglobin in the skin area increases. Therefore, the feedback light obtained is reduced. Because the number of proteins in different positions of the face varies, this method can describe the data of from different positions of the face. At the same time, background information and lighting information can affect facial signal recognition during rPPG face authentication. Therefore, during facial authentication, the facial background signal of the face is analyzed and recognized to improve the recognition performance of the model.

When extracting features from facial data, the image data information is preprocessed firstly. The processing method mainly involves eliminating the influence of ambient light on signal changes, that is, removing some redundant data signal information. The other is to eliminate random signal noise on adjacent images. This random noise can cause inaccurate model recognition. Finally, the identified heart rate standard sometimes exceeds the normal heart rate range of the human body. Therefore, it is necessary to remove heart rate signals that exceed the normal heart rate range during processing. After

completing data extraction, the algorithm needs to use Fourier transform to convert the signal into frequency-band and time-domain. Some real facial image data can be recognized through spectral feature transformation, thereby improving the recognition performance between real and virtual faces.

In simulated face authentication, there are similarities in the faces, which are caused by subtle differences in the faces of different people. Therefore, to meet the needs of most facial recognition, it is necessary to improve feature recognition capabilities and the stability and consistency of image data authentication. Thus, similarity analysis is added to the model, as shown in Eq. (11).

$$x = \bigcup_{i,j=1,\dots,N} \rho(S_i, S_j) \quad (11)$$

In Eq. (11), $\rho(S_i, S_j)$ represents the similarity of the measured signal. The signal information is represented by S_i, S_j . \bigcup represents the continuous calculation. To improve the similarity of the entire signal, the correlation spectrum of similarity is taken to the maximum value, as shown in Eq. (12) [19].

$$\rho(S_i, S_j) = \max |f\{s_i \bullet s_j\}| \quad (12)$$

In Eq. (12), f represents the Fourier transform. \bullet represents the correlation operator. The remaining parameters are the same as above. Finally, the regional signal of the face can be obtained through correlation calculation, while reducing the influence of random noise. The data processing and classification results of the entire rPPG module are shown in Fig. 4.

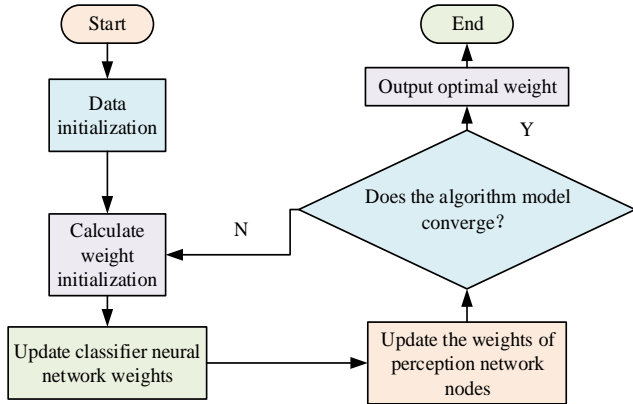

Fig. 4. Data processing flow of rPPG module.

In Fig. 4, the rPPG module first initializes the data information randomly. The weights of the classifier and the perception network are initialized. Afterwards, the classifier and neural network weights are updated through the model. The weights of the perception network nodes are fixed to determine whether the current model is converging. If it converges, the process ends. If it does not, the weights are calculated and the optimal weight size is output, thereby obtaining the face authentication process of the rPPG module. In the data collection and analysis of the entire system, two modules use different classifiers to collect image data. Therefore, when collecting and analyzing data, different classifiers are used to analyze the data information. The process is displayed in Fig. 5.

Fig. 5. Schematic diagram of data collection process.

In Fig. 5, when face authentication involves multiple data face samples, the model first trains the sample data. Afterwards, the data is randomly sampled and distributed into 1 to n

sampling datasets. The datasets are then trained using relatively weaker classifiers. The trained datasets are combined before being trained on strong datasets. The datasets trained in this way can achieve relatively good data collection and classification. The complete authentication system process is shown in Fig. 6.

In Fig. 6, the system module consists of three main parts: network training module, data acquisition module, and image processing and analysis module. The network training module mainly processes and analyzes facial videos and image data that require authentication. CNN and rPPG are used to process and analyze image video data. The data acquisition module mainly analyzes and processes the facial video data that needs to be collected to ensure that it can be processed by the model currently. The final image processing module is to detect, recognize, and authenticate the current image data, then process and analyze it. The processed data is fed back into the system to complete the facial recognition and authentication process.

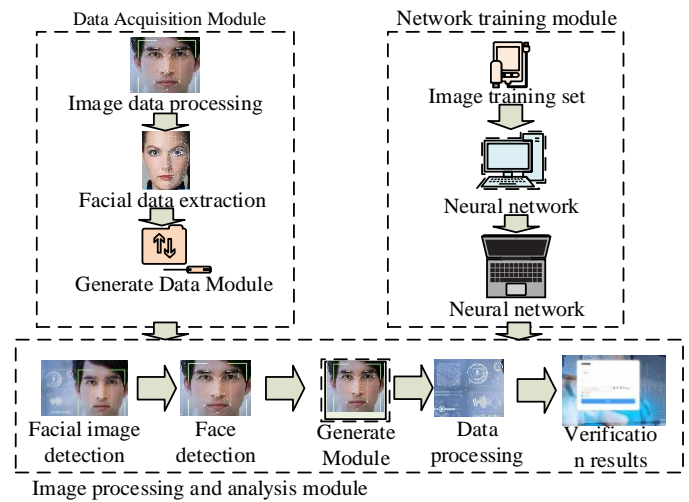

Fig. 6. Diagram of authentication system process module.

IV. RESULTS

To test the authentication performance and the algorithm performance, the publicly available facial video dataset is selected. The same pixel size is 360*240, and the number of faces selected is 50, totaling 1200 video images. A total of 1200 video images are selected, including 50 user image videos that require authentication. The dataset is divided into two parts, with 600 video image data for training and testing. Each trained neural network has the same parameters. To test the recognition accuracy of the current research method on facial video images in different backgrounds, three models with different iteration times are selected for comparison. Table I displays the results.

In Table I, when the iteration was the same, the recognition accuracy of weak light and warm color backgrounds was relatively higher. When the iterations were 10, the recognition accuracy of strong light backgrounds was 0.79% lower than that of the highest warm light backgrounds. The decrease in accuracy was relatively small. This may be due to the influence of lighting on the image data. The recognition accuracy of the model performed better at different iterations, with the highest recognition accuracy of 92.31% at 15 iterations for warm light

backgrounds. This may be due to the better training effect of the model with higher iterations. To test the ablation performance of the current usage method, the error rate analysis is performed on the rPPG model and CNN model used separately, as shown in Fig. 7. The half error rate represents the acceptable probability of an error and the average value of the error probability. The small value indicates that the model is better.

Fig. 7 (a) displays the error rates of different models. As the validation recognition samples increased, the sample error rate has increased. Among the three models, the proposed method had the lowest error rate. The average overall error rate was

around 5.72%, while the average error rates of the other two models were 7.45% and 6.84%. The proposed method was 1.12% lower than the CNN model and 1.73% lower than the rPPG model. In the comparison of the half error rates in Fig. 7 (b), the half error rate of the proposed method was lower. The change was also the same as the error rate. The overall performance of the research method was improved after incorporating some advanced models, which also indicated that the two models optimized each other. To compare the recognition performance of different methods, Local Binary Pattern - Three Orthogonal Planes (LBP-TOP), Long Short Term Memory-CNN (LSTM-CNN), and Visual Geometry Group (VGG) are compared. Fig. 8 displays the results.

TABLE I. RECOGNITION ACCURACY OF DIFFERENT SCENES UNDER THE SAME STEP SIZE AND DIFFERENT ITERATION TIMES

Scene	Strong light			Weak light			Warm light		
	5	10	15	5	10	15	5	10	15
Iterations	5	10	15	5	10	15	5	10	15
Model step size	10	10	10	10	10	10	10	10	10
Recognition accuracy (%)	80.25	84.51	90.23	81.24	84.66	92.03	81.25	85.3	92.31

Fig. 7. Ablation experiments for error rate and half error rate.

Fig. 8. Comparison of half error rates in different model recognition.

In Fig. 8(a), in dataset 1, the half error rate value of the three models increased with the increase of dataset size. However, the increase of CNN was relatively small. The average half error rates of LBP-TOP, LSTM-CNN, VGG, and rPPG+CNN models were 9.24%, 8.15%, 5.84%, and 3.21%, respectively. The half error rate of the proposed method was lower, with

LBP-TOP, LSTM-CNN, and VGG models being 6.03%, 4.94%, and 2.27% lower, respectively. In Fig. 8(b), the variation trend of several models in dataset 2 was the same as that in Fig. 8(a). The average half error rate was basically the same. This indicates that the half error rate of these models does not change much in different datasets, which may be due to the relatively

stable models. To verify the generalization ability of the current research method, the data performance of different models is analyzed. Table II displays the results.

In Table II, the half error rate obtained from different datasets for the testing and training sets of different models was not the same. When dataset 2 was used as the testing set, the model had a lower half error rate. This may be due to differences in algorithm stability during training. Among the four models, the rPPG+CNN had the lowest half error rate and better performance. To test the recognition accuracy and model loss function changes of different models, the obtained results are shown in Fig. 9.

Model	Testing set	Training set	Half error rate (%)
LBP-TOP	Dataset 1	Dataset 2	50.1
	Dataset 2	Dataset 1	49.3
LSTM-CNN	Dataset 1	Dataset 2	45.6
	Dataset 2	Dataset 1	46.3
VGG	Dataset 1	Dataset 2	61.5
	Dataset 2	Dataset 1	49.8
rPPG+CNN	Dataset 1	Dataset 2	42.5
	Dataset 2	Dataset 1	37.1

TABLE II. COMPARISON RESULTS BETWEEN DIFFERENT METHOD DATASETS AND TEST SETS

Fig. 9. Accuracy and loss function changes of four models.

In Fig. 9(a), among the accuracy trends of the four models, the accuracy increased with the increase of sample size and then tended to a stable state. At this time, the accuracy of the LBP-TOP was 67.2%, the LSTM-CNN was 74.6%, the VGG was 63.4%, and the rPPG+CNN was 89.5%. The rPPG+CNN had the highest accuracy among the four models. In Fig. 9(b), the loss function decreased with increasing iterations and then tended to stabilize. The minimum loss function value of the rPPG+CNN was only 1.8, indicating that its model was more stable. To verify the authentication performance of the proposed method, similar facial video images in the dataset are

used as the validation dataset to analyze the facial image authentication, as shown in Fig. 10.

In Fig. 10, when the facial similarity was low, the recognition accuracy was higher, with the highest value being 88.3%. After increasing the similarity, the recognition accuracy slightly decreased. When the similarity was almost identical, the recognition accuracy decreased significantly. However, from the analysis in Fig. 10, the recognition accuracy was still at a high level after increasing similarity, indicating that the overall authentication performance of the model was good.

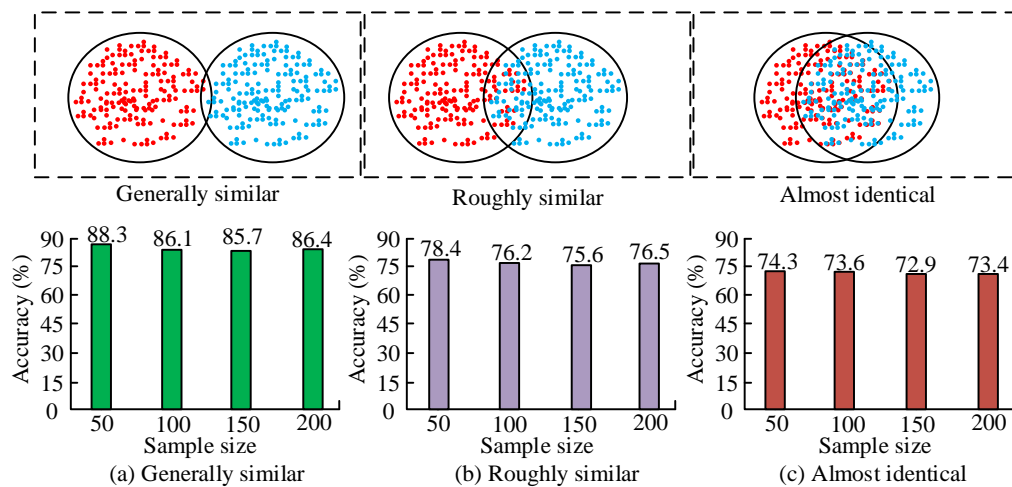

Fig. 10. Changes in similarity accuracy of samples.

V. DISCUSSION

Face recognition technology has been widely used in the field of biometrics. Traditional authentication methods, such as passwords and tokens, although commonly used, carry the risk of being stolen or forgotten. Their high operational complexity makes them unsuitable for large-scale deployment in IoT environments. In recent years, biometrics have been recognized as a powerful tool for solving the authentication problem of IoT devices due to its convenience and security. For this purpose, the study uses CNN and rPPG techniques and applies them to face identification on IoT devices.

In comparison of different background colors, face recognition accuracy is higher in warm backgrounds, which may be due to inaccurate testing of face data caused by lighting effects. Secondly, in 15 iterations, the recognition accuracy of warm colored backgrounds is relatively high, reaching 92.31%, which may be due to the increase in the number of iterations resulting in more accurate face data. In the comparison of the error rate for different models, the change in the error rate of the model used in the study increases with the increase of sample size, which may be due to the increase in the number of samples resulting in a decrease in the overall recognition effect. The error rate of the research model is lower. This may be due to the added rPPG technology [21] improving model performance. In the comparison of half error rate of the three models, the half error rate of the research method is lower, which may be due to the high accuracy of facial authentication recognition in the research model. In the comparison of error rate values of different models, the model used in the study has a lower half error rate, which may be due to its ability to better handle data. In the comparison of half-error rate of different models, the performance effect of the research model is better than the individual model, which may be due to different technologies improving the model performance. In the comparison of the accuracy rate change, the used model has the highest accuracy rate, which may be because the model used can better process facial data. In the variation of loss function values in several models, the designed model has lower loss function value, which may be due to the more stable performance of the research model. In the similarity comparison of different face data, the recognition performance

of the authentication similarity of the research model is better, as the algorithm currently used in research can recognize blood vessels in the face.

In summary, the model used in the current study has better performance and recognition effect in the face recognition authentication of IoT devices. The model has better face recognition authentication effect and recognition accuracy, which has a better guiding role for face recognition authentication afterward.

VI. CONCLUSION

This study mainly focused on the facial identity authentication of IoT devices. The CNN and rPPG face detection technology were used to build a new device facial identity authentication system. Firstly, a facial recognition and identity authentication system based on CNN and rPPG was analyzed and constructed. Then, the performance and feasibility of the current system were verified through comparative analysis among different models. The research results indicated that the recognition accuracy of the proposed model varied under different color backgrounds. The algorithm had higher recognition accuracy under weaker lighting conditions. In the comparison of error rates, the rPPG+CNN model had the lowest error rate, which was 1.12% lower than the CNN and 1.73% lower than the rPPG. The half error rate of rPPG+CNN in different comparison methods was 6.03%, 4.94%, and 2.27% lower than those of LBP-TOP, LSTM-CNN, and VGG, respectively. When testing and training on different datasets, the model performed better when dataset 2 was the testing set. Among the four different comparison methods, the rPPG+CNN had the best accuracy and overall performance. At the same time, when comparing similar faces, the method used in the study had relatively stable recognition accuracy when the facial similarity was high. The accuracy was at a relatively high level. Although this study has achieved many results in facial recognition identity authentication, further improvement should be improved. For example, the background and datasets used in the experiment are relatively small. More and larger data will be analyzed in the future. At the same time, future research will also analyze data from different devices. In addition, the study is less analyzed for different scenarios of real

faces, so different face authentication scenarios will be analyzed and detected in the subsequent study. Finally, in the study only focuses on IoT devices. Therefore, different devices will be analyzed for face authentication in the subsequent study.

Logistics Path Planning Method using NSGA-II Algorithm and BP Neural Network in the Era of Logistics 4.0

Liuqing Li

Department of Economics and Management, Huanghuai University,
Zhumadian, 463000, China

Abstract—The distribution of fresh food is affected by its perishable characteristics, and compared with ordinary logistics distribution, the distribution path needs to be very reasonably planned. However, the complexity of the actual road network and the time variation of traffic conditions are not considered in the existing food logistics planning methods. In order to solve this problem, this study takes road section travel prediction as the starting point, and uses the non-dominant ranking genetic algorithm II and the backpropagation network to construct a new logistics path planning model. Firstly, the road condition information detected by the retainer detection and the floating vehicle technology is integrated, and the travel time prediction is input into the backpropagation network model. In order to make the prediction model perform better, it is improved using a whale optimization algorithm. Then, according to the prediction results, the non-dominant ranking genetic algorithm II is used for distribution route planning. Through experimental analysis, the average distribution cost of method designed by this study was 9476 yuan, and the average carbon emission was 2871kg. Compared with the other three algorithms, the distribution cost was more than 15% lower, and the carbon emission was more than 12.5% lower. The planning method designed by the institute can achieve more reasonable, low-cost, and environmentally friendly logistics and distribution, and bring more satisfactory services to the lives of urban residents.

Keywords—Whale optimization algorithm; non-dominant ordering genetic algorithm; backpropagation network; logistics and distribution; path planning

I. INTRODUCTION

Logistics 4.0 is the embodiment of Industry 4.0 in the field of logistics, which refers to the digitalization of logistics. With the integration of information technology and the Internet, the logistics industry, e-commerce and other fields have been further specialized and cross-border cooperation [1]. As society and economy develop, consumer demand has become more and more abundant, and the demand for fresh food is increasing day by day [2]. Fresh products have a short shelf life, are perishable, and are easily damaged, so they consume more energy for a low temperature during distribution, which also leads to higher costs [3]. However, most of the current studies on the route planning of logistics vehicles for fresh products do not consider the actual road network complexity and time variation influence, and simply assume that the traffic situation between customer points is constant [4]. Logistics cost is directly related to travel time [5]. Existing studies have not taken into account the

complexity of the actual road network and the time-variability of traffic conditions. Although many studies have focused on the importance of fresh food distribution route planning, most studies are still based on simplified assumptions, such as constant traffic conditions or fixed distribution costs, which are far from the reality. This assumption ignores the impact of various factors such as traffic congestion, road maintenance and weather changes on the distribution route in the actual road network, leading to the possibility that the planned route may not be optimal. Therefore, a logistics path planning model based on travel time is constructed by using non-dominated sorting Genetic Algorithm II (NSGA-II) algorithm and back propagation (BP) neural network. The innovation of the research is to integrate the road condition information of the fixed detection and the floating vehicle detection, and introduce the travel time prediction results into the trip planning to achieve a more reasonable and environmentally friendly logistics distribution. The contribution of this study is to provide a fresh food distribution route planning method that comprehensively considers the complexity of the actual road network and the time-varying traffic conditions, so as to improve the logistics efficiency and reduce the distribution cost. Compared with the traditional method, this method can more accurately reflect the actual road conditions and traffic conditions, so as to plan a more reasonable distribution route.

The study includes six sections. Section II analyzes the current research status. Section III is the method construction part, which describes the design of the logistics path planning method in detail. Performance analysis is given in Section IV. Results of the research is given in Section V. Finally Section VI summarizes the research methods and analysis results, and puts forward the prospects for future work.

II. RELATED WORKS

Since the issue of vehicle routing was raised, it has quickly received close attention in areas such as transportation planning, logistics, and portfolio optimization. Li et al. found that the entry point of the existing deep reinforcement learning-based solution method in solving the vehicle path problem was not applicable to the actual situation. In order to solve this problem, a new path planning algorithm was constructed by using the attention mechanism and decoder to minimize the vehicle travel time. Experimental analysis showed a superiority to most traditional heuristic methods [6]. Pan et al. considered the driving time, multiple trips of each vehicle, and the loading time

at the depot at the same time. A hybrid meta-heuristic algorithm was constructed by using the adaptive large neighborhood search algorithm and the variable neighborhood descent algorithm. Experiments showed that the proposed algorithm had good robustness and effectiveness under different speed profiles and maximum travel time constraints [7]. Gmira et al. found that changes in travel practices within cities were ignored in existing approaches to routing of delivery vehicles. To solve this problem, a tabu search-based solution method for vehicle routing problem was proposed. By defining the driving rate on the road network, the route planning was adjusted in real time according to the time change [8]. Abdullahi et al. considered sustainable vehicle routing in the transport sector in three dimensions of economic, environmental and social dimensions. They proposed a weighted sum model that combined three dimensions and a constraint model. In addition, they proposed a partial random iterative greedy algorithm to solve the ensemble problem [9].

The NSGA-II algorithm has fast solution speed, good solution convergence and robustness. Li et al. established a multi-objective mathematical model for rail alignment optimization of high-speed railway by studying the multi-objective optimization problem of high-speed railway section with small radius curve. NSGA-II was used to find the optimal model solution. Experiments showed that this method effectively reduced rail wear and improved rail bending performance [10]. To solve the low resource utilization and low user service quality in workflow scheduling, Li et al. proposed a scoring and dynamic hierarchy-based NSGA-II. The algorithm aimed to minimize the maximum time to completion and cost of workflow execution. Experiments showed that this method effectively improved resource utilization [11]. In order to achieve effective management of water resources, Jalili A et al. proposed a water resource optimization strategy with the goal of maximizing the reliability of meeting demand. The strategy used the NSGA-II and the WEAP simulator model, and introduced the support vector machine into the model. Experiments showed that the average error rate of the rule obtained by this method was less than 2.5% [12]. BP neural networks have been widely used in many fields because of their strong flexibility, fault tolerance and adaptability. In order to more accurately predict the 28-day compressive strength of recycled insulated concrete, Tu et al. constructed a new prediction model using genetic algorithm and BP. The results showed that this combination achieved better stability and generalization of the model [13]. Lin et al. proposed a new

speed prediction method to solve the problem that random driving cycle affected the control of fuel cell electric vehicles. In this method, BP predicted the velocity and incorporate it into the control strategy. Experimental results showed that compared with traditional rule-based strategies, the proposed method predicted vehicle speed with high accuracy [14]. Lyu et al. constructed a model of the relationship between tensile strength, wire drawing speed and formal velocity in the process of arc additive manufacturing using BPNN. Meanwhile, genetic algorithm and forward model were introduced for BPNN optimization. Results showed that the prediction error of the optimized model was less than 3% [15].

In summary, most studies on vehicle routing problems do not consider the complexity of the actual road network and the time variation of traffic conditions. Therefore, based on the travel time prediction, the NSGA-II algorithm and BP neural network were used to construct a logistics vehicle transportation path planning model. It aims to achieve the lowest total cost and the lowest carbon footprint of logistics vehicle path planning.

III. DESIGN OF LOGISTICS VEHICLE PATH PLANNING MODEL USING NSGA-II AND BPNN

In the era of Industry 4.0, the logistics transmission system is inseparable from the support of intelligent logistics technology and equipment, to further realize the logistics intelligence, the research takes the prediction of path travel time as the starting point to build a logistics vehicle path planning model.

A. Path Travel Time Prediction using Improved BPNN

As an important comprehensive indicator, the travel time of road sections can directly reflect the information of road traffic conditions, and then provide data support for travelers to plan travel routes [16-18]. In the actual traffic data collection process, fixed detector technology and floating vehicle technology are usually used to collect data such as traffic flow and road parameters. Traffic parameters such as vehicle speed, road traffic flow, and occupancy can be obtained through fixed detectors [19-21]. The floating vehicle technology generally uploads its own instantaneous speed, latitude and longitude and other information to the information center according to the vehicle of the wireless positioning equipment through GPS positioning technology. The working principle of the fixed detector as well as GPS technology is shown in Fig. 1.

Fig. 1. The working principle of the fixed detector and the GPS technology.

The road travel time obtained by the fixed detector is divided into two parts: the normal passage time and the delay time caused by the traffic light. The calculation method for the normal passage time of the vehicle is shown in Eq. (1).

$$t_d = \frac{L}{\bar{v}} \quad (1)$$

In Eq. (1), L is the total length of the road section, \bar{v} is the average vehicle speed under the fixed detector, and t_d is the normal time of the vehicle. In this study, the Webster timing method is used to calculate the signal light delay time, and the calculation method is shown in Eq. (2).

$$t_l = 0.9 * \mu * \left[\frac{c(1-\lambda)^2}{2(1-\lambda x)^2} + \frac{x^2}{2q(1-x)} \right] \quad (2)$$

In Eq. (2), c is the traffic light period, λ is the proportion of effective green light time, q is the traffic flow data, μ is the probability of delay due to the traffic light, C is the saturation capacity of the entrance road, x is the lane saturation, and t_l is the time of delay due to the signal light. The probability of delay due to traffic lights and the calculation of lane saturation are shown in Eq. (3).

$$\begin{cases} x = q / (\lambda C) \\ \mu = \frac{(c-g)q - L2}{(c-g)q}, (c-g)q \geq b \\ \mu = 0, (c-g)q < b \end{cases} \quad (3)$$

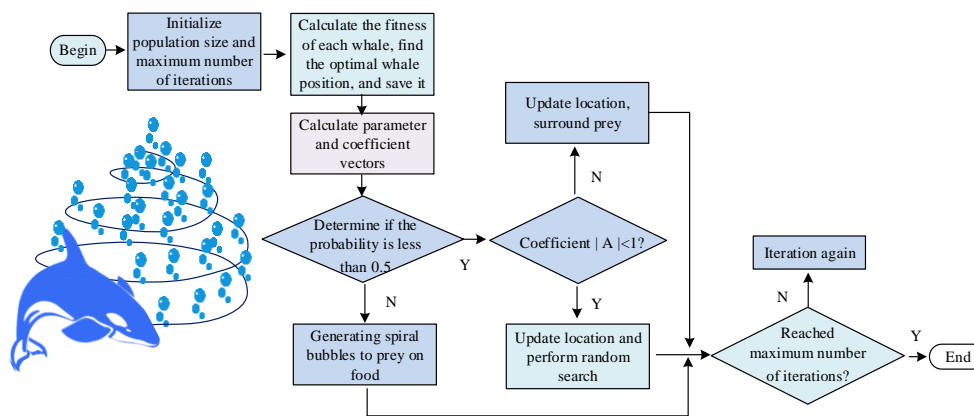

Fig. 2. Principles of the whale optimization algorithm.

Firstly, the BPNN topology is determined, and the travel data of two road sections are input into the model, and the predicted road travel time is fused and output. This is shown in Eq. (5).

$$t = \omega_1 t_1 + \omega_2 t_2 \quad (5)$$

In Eq. (5), t_1 is the travel time of the road section detected by the fixed detector, ω_1 and ω_2 are the weights of the data collected by the fixed detector and the floating vehicle,

Although the fixed detector can obtain the traffic parameters of the road to a certain extent, the traffic information it collects is not complete, and it is difficult to comprehensively and accurately describe the traffic conditions of the entire road network. The study divides the vehicles in the road network into four categories: vehicles that need to be stopped at any time during the journey, vehicles such as ambulances, vehicles that do not obey normal traffic rules due to special circumstances, sightseeing vehicles, and vehicles traveling on normal roads. The road travel time calculated by the floating car technology is shown in Eq. (4).

$$t_2 = \frac{4v_1 v_2 v_3 v_4 L}{v_2 v_3 v_4 + v_1 v_3 v_4 + v_1 v_2 v_4 + v_1 v_2 v_3} \quad (4)$$

In Eq. (4), L is the distance length predicted by the floating vehicle technology, t_2 is the travel time based on the road section L , and v_1 , v_2 , v_3 , and v_4 are the average speeds of the four types of vehicles, respectively. However, due to the scattered spatial and temporal distribution of floating vehicles in the road network, it is difficult for the floating vehicle data to accurately reflect the road section situation. To this end, the study considers merging the two data. Before data fusion, it is necessary to perform spatiotemporal matching of multi-source data, and the traffic flow data collected in the same period is screened out to prepare for the subsequent prediction model. In this study, BPNN is selected to construct a travel time prediction model, but there are limitations in BPNN, such as long learning time and slow convergence speed. Therefore, the whale optimization algorithm (WOA) is used to improve it to avoid the BP neural network falling into the local optimal solution. Fig. 2 shows the principle of the WOA.

respectively. The S-type tangent function is used as the transfer function of cryptolayer neurons, as shown in Eq. (6).

$$f(x) = \frac{2}{1 + e^{-2x}} - 1 \quad (6)$$

In Eq. (6), $f(\square)$ is the transfer function of the output layer, and the S-type logarithmic function is the neuron transfer function of the output layer. Hidden layer's neurons are twice the output layer's neurons plus 1. The error between the

network output and the expected output is shown in Eq. (7).

$$E = \frac{1}{2} \sum_{k=1}^K (y_k - o_{k'})^2 = \frac{1}{2} \sum_{k=1}^K \left[y_{k'} - g \left[\sum_{j=1}^J \omega_{jk'} f \left(\sum_{i=1}^m \omega_{ij} t_i + b_j \right) \right] \right]^2 \quad (7)$$

In Eq. (7), E is the error value, K' , J , and m are neurons' number in the output, hidden, and input layer, b_j is the threshold value of the neurons in the hidden layer, $\omega_{jk'}$ is the neurons' weight between the hidden and output layer, ω_{ij} is the neurons' weight between the input and hidden layer, $y_{k'}$ is the expected output value, and $o_{k'}$ is the output result of the final output layer. The learning rate of the BP network was determined to be 0.01 by experimental analysis. After initializing the BPNN weights and thresholds, WOA is used to find and solve the optimal weights and thresholds. The training set's mean square error is taken as a fitness function of WOA. After the continuous iteration of the algorithm, the smaller the fitness value, the greater the error, and the more accurate the prediction result. According to the actual demand of the problem, the number of neurons in input layer, hidden layer and output layer of BP neural network is initially determined. Then the weights and thresholds of the network model are randomly initialized, WOA algorithm is used to optimize the parameter combination, and the fitness value of the population is updated through continuous iteration. At the end of the iteration, the optimal parameter combination is obtained. Fig. 3 shows the flow of the WOA-BP algorithm.

B. Logistics path planning Based on NSGA-II algorithm and BP neural network

The research question is that in a fresh product distribution center, there are z delivery vehicles responsible for delivering goods to N individual customer points, and the maximum vehicle load, the demand of the customer point and the soft time window are the same. Each vehicle returns to the distribution center when task is done. The distribution process is divided into two phases, namely initial distribution and forecast planning, and the stages and assumptions are shown in Fig. 4.

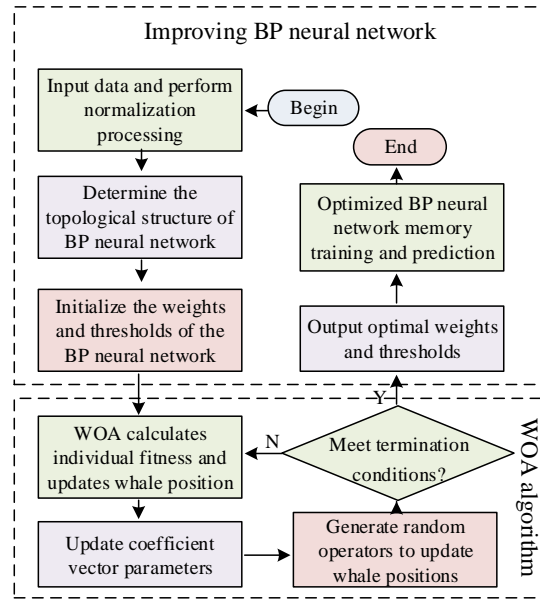

Fig. 3. Flow of the WOA-BP algorithm.

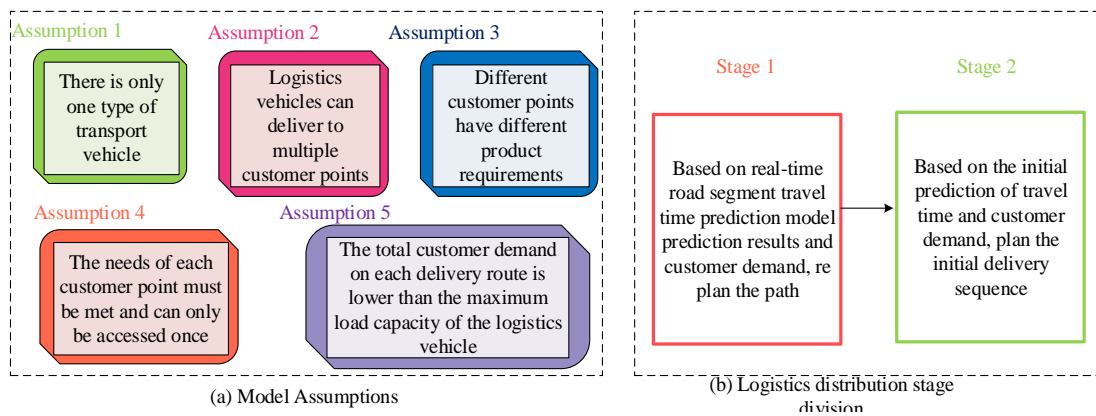

Fig. 4. Study hypothesis and distribution stage division.

At the initial moment of delivery, according to the prediction results of the road section travel time proposed above, the actual road network is transformed into a travel time network between customer points. On this basis, considering the economic cost and environmental cost and taking the vehicle load and time window as constraints, the fresh food logistics path planning model is constructed. Before building the model, the costs incurred in distribution activities are analyzed. The calculation method of vehicle operating costs is as follows in Eq. (8).

$$C_o = \sum_{z=1}^z P_1 a_z \quad (8)$$

In Eq. (8), a_z is a variable with a value of 0 or 1, and 1 indicates that the logistics vehicle z is put into use, P_1 is the fixed cost such as vehicle maintenance, and C_o is the operating cost of the logistics vehicle. The method for the vehicle cooling cost is shown in Eq. (9).

$$\begin{cases} C_f = C_{f1} + C_{f2} \\ C_{f1} = \sum_{z=1}^Z \sum_{i=1}^N \sum_{j=1}^N \sum_{k=1}^K t_{ij}^k y_{ij}^{k,z} C_r \\ C_{f2} = \sum_{z=1}^Z \sum_{i=1}^N \sum_{j=1}^N \sum_{k=1}^K t_{i,s}^z y_{ij}^{k,z} C_d \end{cases} \quad (9)$$

In Eq. (9), C_f , C_{f1} , and C_{f2} are the total refrigeration cost, transportation refrigeration cost and unloading refrigeration cost, respectively, $y_{ij}^{k,z}$ is a value of 0 or 1, and 1 represents the k path of z through the customer points i and j , $t_{i,s}^z$ is z 's service time at i . The goods distributed by fresh food logistics are susceptible to deterioration and decay due to the influence of ambient temperature and oxygen, resulting in losses. The cost calculation method for the loss of goods during transportation is shown in Eq. (10).

$$\begin{aligned} C_t = & \sum_{z=1}^Z \sum_{i=1}^N \sum_{j=1}^N \sum_{k=1}^K P_2 q_i \left[1 - e^{-\gamma_1^z (t_i^z - t_0^z)} \right] \\ & + \sum_{z=1}^Z \sum_{i=1}^N \sum_{j=1}^N \sum_{k=1}^K P_2 Q_{ij}^{k,z} \left(1 - e^{-\gamma_2 t_{i,s}^z} \right) \end{aligned} \quad (10)$$

In Eq. (10), C_t is the cost of damage to the vehicle, P_2 is the unit price of the goods, q_i is the demand for the customer point i , γ_1 and γ_2 are the freshness decline rates in the process of transportation and unloading of the goods, respectively, t_0^z is the moment when the logistics vehicle z leaves the distribution center, t_i^z is the moment of the logistics vehicle z arrival at the customer point i . Customers have strict requirements for perishable fresh products' reception time, usually with a time frame. To do this, the study describes the time frame requested by the customer as a soft time window. If it is delivered outside the time window, there will be a penalty cost. The calculation of the penalty cost is shown in Eq. (11).

$$C_p = c_{ew} \sum_{z=1}^Z \sum_{i=1}^N \max(T_1 - t_i^z, 0) + c_{lw} \sum_{z=1}^Z \sum_{i=1}^N \max(t_i^z - T_2, 0) \quad (11)$$

In Eq. (11), c_{lw} is the penalty cost per unit time for the vehicle's late arrival, C_p is the penalty cost, $[T_1, T_2]$ is the delivery time range required by the customer and c_{ew} is the penalty cost per unit time for the vehicle's early arrival. The transportation cost of the vehicle is shown in Eq. (12).

$$C_t = \sum_{z=1}^Z \sum_{i=1}^N \sum_{k=1}^K y_{ij}^{k,z} P_3 \left[t_{ij}^k \times W(Q_{ij}^{k,z}) \right] \quad (12)$$

In Eq. (12), K is the number of transportation paths, $W(Q_{ij}^{k,z})$ is the fuel consumption of the load Q of z on

the k path between the customer point i and j , and t_{ij}^k is the predicted travel time of the logistics vehicle from the customer point i to the customer point j in the k path. P_3 is the unit price of fuel. Carbon emissions are calculated as shown in Eq. (13).

$$C_c = c_0 \sum_{z=1}^Z \sum_{i=1}^N \sum_{j=1}^N \sum_{k=1}^K t_{ij}^k e_{co2} \cdot W(Q_{ij}^{k,z}) + c_0 \sum_{z=1}^Z \sum_{i=1}^N \sum_{j=1}^N \sum_{k=1}^K \omega t_{ij}^k Q_{ij}^{k,z} \quad (13)$$

In Eq. (13), e_{co2} is the CO2 emission factor, c_0 is the carbon emission penalty cost per vehicle. Based on the above contents, the planning model is constructed, as shown in Eq. (14).

$$\begin{cases} \text{Min}C = C_o + C_f + C_t + C_p + C_c \\ \text{Min}C_c \end{cases} \quad (14)$$

The constraints of the model are that the customer points to be delivered are N . The total demand of customer points on each delivery route must not exceed the maximum load capacity of the logistics vehicle. Each customer point is served by only one logistics vehicle. There are Z vehicles at the distribution center. The loading capacity of the vehicle when it departs from a customer point is the demand sum of the next customer point and the loading capacity when departing from that next point. The distribution process for each logistics vehicle is continuous. After constructing the mathematical model of the problem, NSGA-II optimizes the multi-objective. On the basis of the traditional NSGA, NSGA-II quickly sorts the individuals in the population by defining the non-dominant set and the dominant set, which reduces the computational complexity, and introduces a management strategy to eliminate the inferior individuals in the population. The crowding and crowding comparison operators were used to ensure the population diversity. The calculation principle of non-dominant layer ranking and individual crowding distance is shown in Fig. 5.

In this study, the initial population is established by the coding method of natural integers. In the algorithm process, it is necessary to evaluate the chromosomes through the fitness function, and the higher the adaptation value of chromosomes, the higher the probability of entering the next generation. The fitness function is set as the total cost reciprocal of distribution target and the carbon emission objective function in Eq. (15).

$$\begin{cases} F_1 = \frac{1}{\text{object1}} \\ F_2 = \frac{1}{\text{object2}} \end{cases} \quad (15)$$

In Eq. (15), *object1* and *object2* are the two objective functions, F_1 and F_2 are the fitness functions of the total distribution cost and the carbon emission target, respectively. Fig. 6 shows the NSGA-II specific flow.

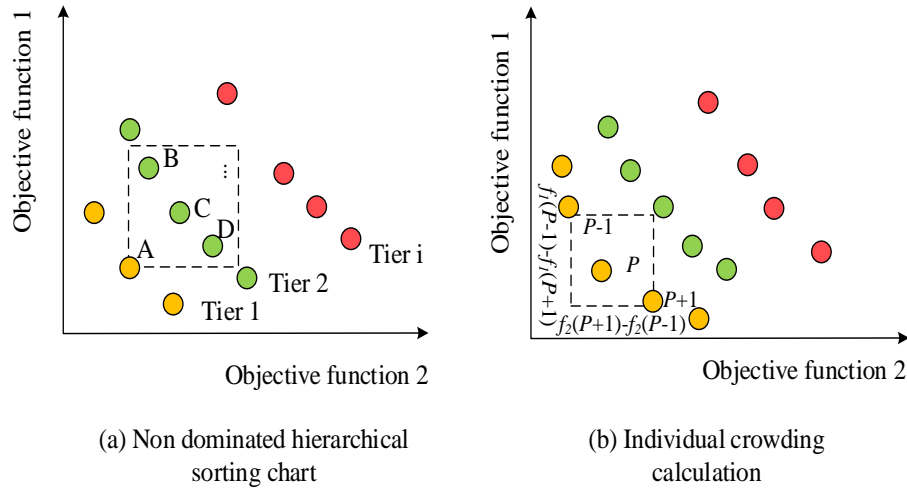

Fig. 5. Principle of non-dominated layer ordering and individual crowding distance calculation.

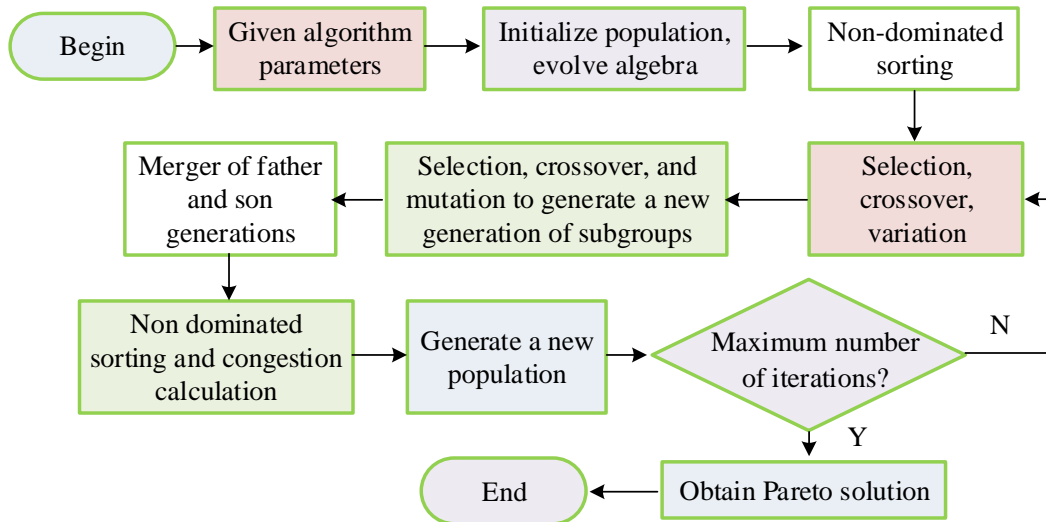

Fig. 6. Specific flow of the NSGA-II algorithm.

IV. PERFORMANCE ANALYSIS EXPERIMENT OF LOGISTICS VEHICLE PATH PLANNING MODEL

In order to test the training of the road segment travel prediction model designed in this study, WOA-BP was trained

with a single BP network and common neural networks, including convolutional neural network (CNN) and long short-term memory network (LSTM), in the same simulation environment. The training of the four models was recorded for comparison, as shown in Fig. 7.

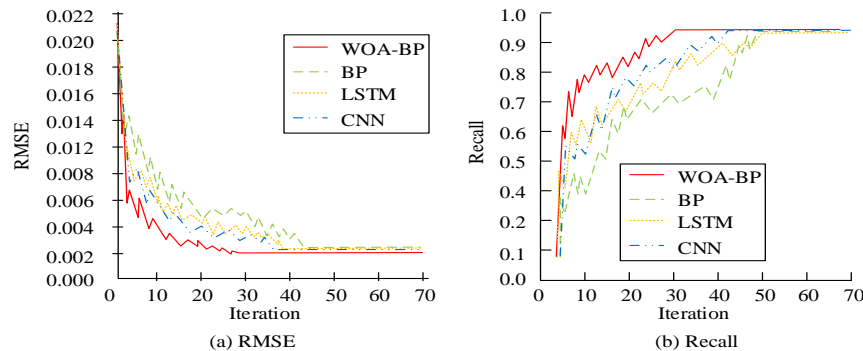

Fig. 7. The training comparison of the four models.

In Fig. 7, WOA-BP's convergence is significantly improved compared with the single BP network model. It is also better than the other two models. As shown in Fig. 7(a), the Root Mean Square Error (RMSE) value is reached after 28 iterations of WOA-BP, while the BP network begins to converge after 41 iterations, and the CNN training reaches 43 times, which is 21 iterations more than WOP-BP and 37 times for LSTM training. As shown in Fig. 7(b), WOP is trained only 30 times to reach the target recall value and begins to converge, which is 15 times less than that of a single BPNN, while both LSTM and CNN are trained more than 40 times.

To further verify the designed trip prediction model stability

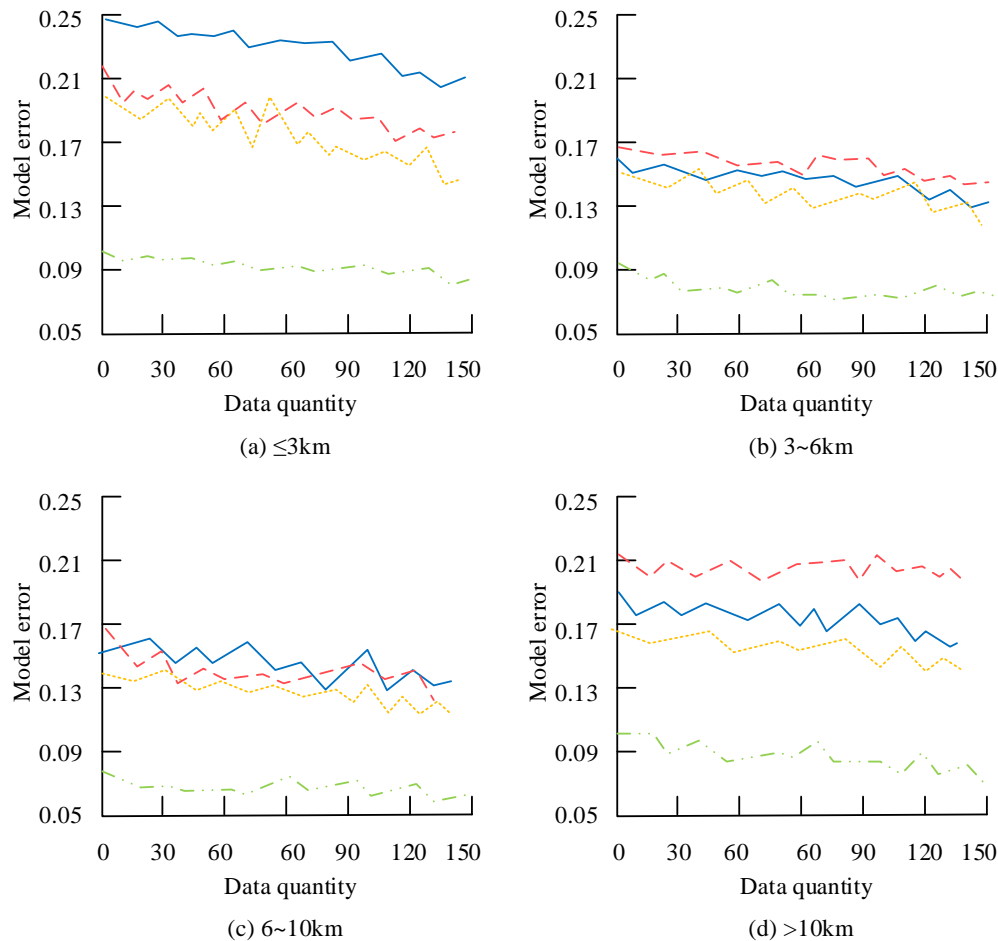

Fig. 8. Model prediction error for the five models at different distances.

As shown in Fig. 8(a), the prediction error of less than 3 km is generally high, which is due to the fact that the short-distance trajectory data is more seriously affected by traffic conditions. As shown in Fig. 8(b), the prediction error is further reduced in the prediction of the 3~6km road section, and the error of model 1 is reduced by 0.2, significantly higher than that of the other four. In Fig. 8(c), the error of all five models is less than 0.15. In Fig. 8(d), the error values of both models 2 and 4 have increased significantly, while model 1 remains stable below 0.10. From the contents of Fig. 8, as the predicted distance data

increases, the five models' prediction error increases, and the increase of model 1 is the smallest, which indicates that model 1 has good stability. Moreover, the average error of model 1 is less than 0.10, which can achieve more accurate travel time prediction. To fully prove model 1's effectiveness, the error between the true value and the predicted value of 50 trajectory data was randomly extracted from the test set, and the error was arranged according to the driving time from long to short. The prediction accuracy of the five models is known through calculation. Fig. 9 shows the details.

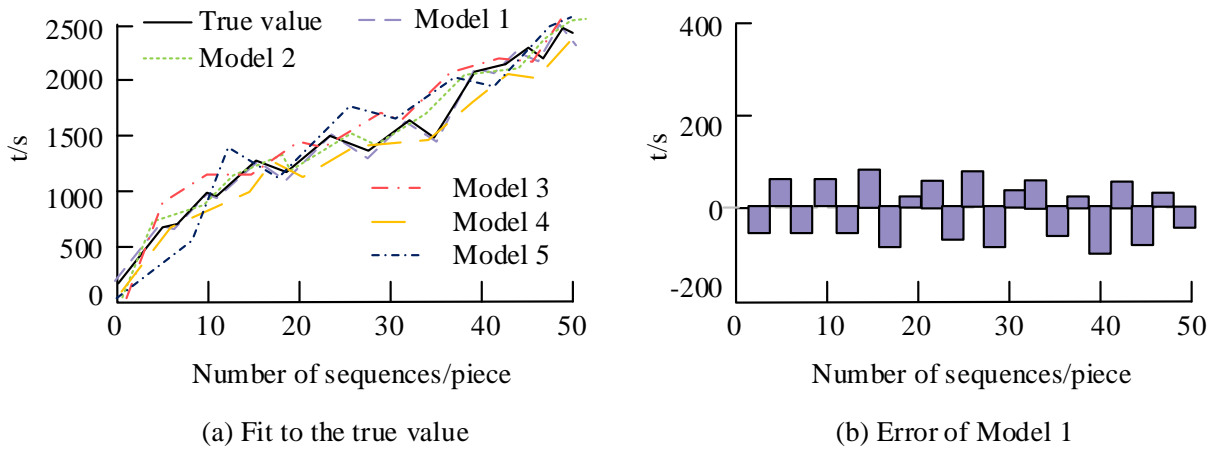

Fig. 9. Comparison of travel time prediction accuracy for different models.

In Fig. 9(a), the prediction accuracy of model 1 for trajectories can reach more than 90%, which fully proves the effectiveness of the model. Moreover, the change curve of model 1 is basically consistent with the real value, and the accuracy of model 1 is higher than that of the other four models. It is found from Fig. 9(b) that the error results of some trajectories have large prediction errors, which is due to the excessive traffic lights in this road section, which leads to the increase of prediction error. However, the error of model 1 is less than 300s, which can meet the needs of logistics and transportation. In the logistics planning, the complexity of the road network and the time variability of traffic conditions are considered in the model. In order to test the study's rationality, the experimental model was compared with the model's operation without those considerations. The comparison results are shown in Fig. 10.

In Fig. 10(a), the model without traffic has lower distribution costs and carbon emissions overall, while Fig. 10(b) shows that the model with traffic is higher than the model without traffic at both target solutions. This is due to the fact that models that do not take into account traffic conditions do not accurately plan the delivery scenario, which will not lead to the closest to the real delivery cost. To further verify the planning method's performance (method 1) designed by the study, the multi-dimensional time-varying data was combined with the set unit time cost of a single fresh food logistics vehicle, and the results of the agricultural product logistics distribution planning method using genetic algorithm (method 2) and the logistics planning method using particle swarm optimization (method 3) were compared. The study was carried out in the distribution network data of two different distribution studies. The results are shown in Fig. 11.

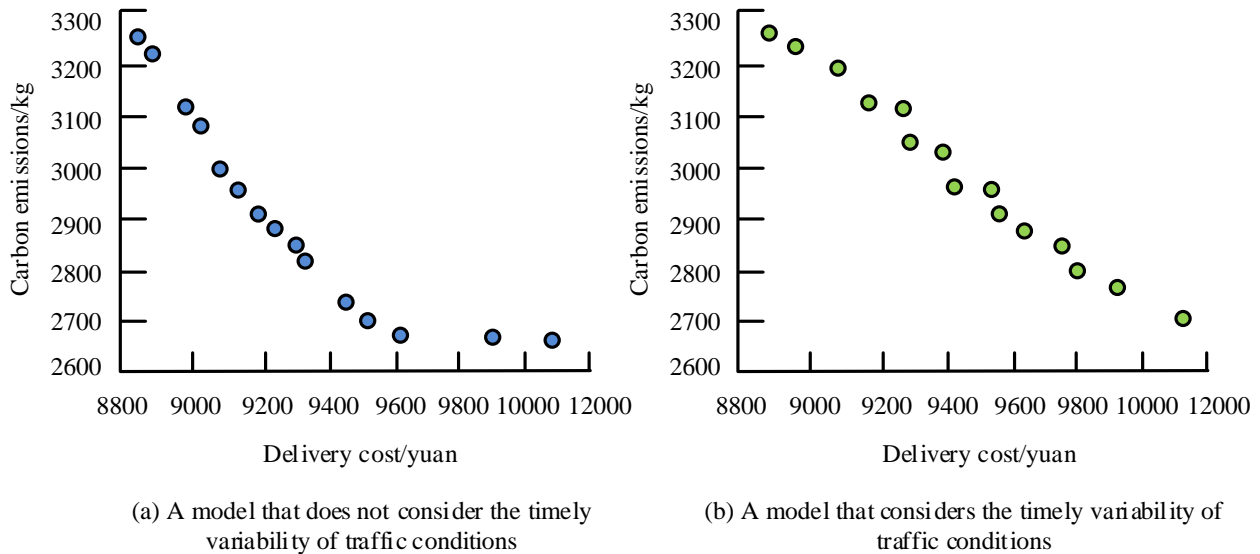

Fig. 10. Research model and model operation without considering road network complexity and traffic conditions.

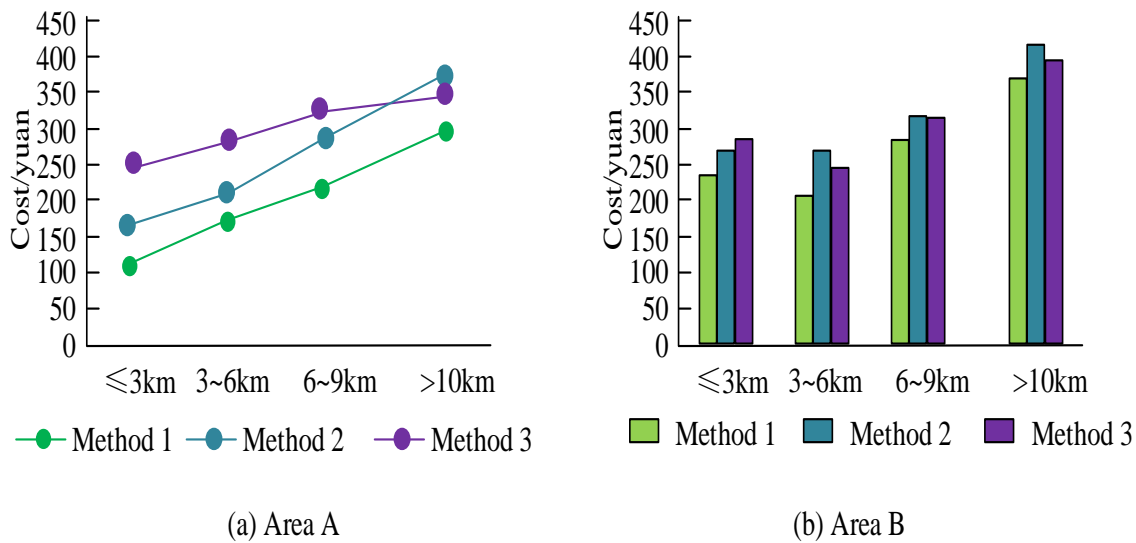

Fig. 11. Comparison of planning effects of different methods in two different distribution examples.

As can be seen from Fig. 11(a), the fixed costs of the three methods are basically the same in Area A, but the transportation costs, loss costs and penalty costs are quite different. The total cost obtained by method 1 is 350 yuan, while the cost of method 2 reaches 410 yuan and the cost of method 3 is 394 yuan. In Fig. 11(b), the total cost of distribution in Area B has increased significantly compared with Area A, which is due to the complex road conditions in Area B, the large number of residents, the need for longer planning routes, and the longer

delivery time. The total cost of method 1 is still lower than that of the other two methods.

To further test the planning effect of method 1, three methods were used to carry out path planning under representative examples. The results of the delivery vehicles, route planning time, total distance of route delivery, total cost of delivery and carbon emissions were also listed. Table I shows the details.

TABLE I. COMPARISON OF THE DISTRIBUTION SITUATION OF THE THREE METHODS

Project		Distribution vehicle / vehicle	Pway planning time / minutes	Total path distribution distance / km	Total cost of delivery / yuan	Carbon emission /kg
Method 1	Example 1	13	245	4285.5	8829.1	3255.1
	Example 2	12	217	4183.2	9512.3	2698.4
	Example 3	14	228	4378.4	1055.55	2675.3
Method 2	Example 1	21	359	6158.7	1545.6	3815.8
	Example 2	23	361	6184.4	1523.8	3424.7
	Example 3	22	366	6842.5	1545.7	3482.6
Method 3	Example 1	18	335	5841.4	1242.12	3546.4
	Example 2	17	328	5748.1	1351.54	3415.8
	Example 3	16	330	5694.8	1228.45	3451.5

In Table I, the average distribution cost of method 1 is 9476 yuan, and the average carbon emission is 2871 kg. Compared with the other three methods, the cost of distribution is more than 15% lower, and the carbon emission is more than 12.5% lower. As for the transportation distance, the transportation distance of method 1 is 4282km, which is significantly less than that of the other three methods. Based on the above, it can be seen that the design method of the research institute can achieve logistics path planning with lower cost and carbon emissions and ensure that the delivery is completed within the time required by customers.

In order to verify the effectiveness and rationality of the

proposed model, the research applies the solution obtained by the designed method to the actual case, and analyzes the distribution route, vehicle use, and wastage of the proposed solution. First of all, study the selection of takeout delivery scene, fresh house distribution, e-commerce warehousing. And through the simulation analysis, the transportation situation between the solution and the traditional logistics distribution is obtained. In addition, the study invited industry experts and representatives of logistics companies to evaluate the applicability of the proposed solutions and models. Evaluation scores range from 0 to 10, with higher scores indicating higher applicability of the proposed solution. The specific results are shown in Table II.

TABLE II. TEST THE RESULTS OF THE EFFECTIVENESS OF THE SOLUTIONS AND MODELS PROPOSED BY THE STUDY

Distribution scenario		Delivery distance (km)	Vehicle use (vehicle)	Attrition rate (%)	Usability
Delivery scene	Before the application	3.54	4	13.47	6.45
	Post applicationem	2.84	2	5.05	8.95
	<i>P</i>	<0.05	<0.05	<0.05	<0.05
Fresh house with	Before the application	13.85	6	12.84	6.48
	Post applicationem	10.58	3	6.47	9.01
	<i>P</i>	<0.05	<0.05	<0.05	<0.05
E-commerce warehousing	Before the application	352.47	15	18.44	7.02
	Post applicationem	287.46	12	9.74	9.34
	<i>P</i>	<0.05	<0.05	<0.05	<0.05

It can be seen from Table II that after applying the solution proposed by the research Institute, the distribution distance, vehicle use and loss rate of each distribution scenario have been significantly optimized. For the takeout delivery scenario, the delivery distance was reduced from 3.54km to 2.84km, a reduction of nearly 20%. The number of vehicles in use was reduced from 4 to 2, a reduction of 50%; the attrition rate decreased from 13.47% to 5.05%, a reduction of more than 60%. Fresh house distribution and e-commerce warehousing scenes also showed a similar optimization trend. These results show that the proposed solutions can significantly reduce distribution costs, improve logistics efficiency, and reduce resource waste and environmental pollution.

V. RESULTS OF THE RESEARCH

Based on the above experimental and analytical results, the following conclusions can be clearly drawn. By comparing the distribution situation of three different route planning methods, it is found that method 1 has excellent performance in terms of distribution cost, carbon emission and transportation distance. Compared to other methods, the average delivery cost of Method 1 is reduced by more than 15%, carbon emissions are reduced by more than 12.5%, and shipping distances are significantly less. This fully proves the effectiveness of the method designed by the research institute in achieving lower cost and carbon emission logistics path planning. When the designed solution is applied to the actual case scenario, it is found that the distribution distance, vehicle use and loss rate of each distribution scenario are significantly optimized. For the takeout delivery scenario, for example, the delivery distance was reduced by nearly 20%, the number of vehicles used was reduced by 50%, and the attrition rate was reduced by more than 60%. Fresh house distribution and e-commerce warehousing scenes also show a similar optimization trend. These results show that the proposed solution has not only theoretical value, but also high practical application value, which can effectively improve logistics efficiency, reduce resource waste and environmental pollution. Finally, through the evaluation of industry experts and representatives of logistics enterprises, the applicability and effectiveness of the proposed solution are further verified. The evaluation results show that the proposed solutions have generally high applicability scores, indicating that they have great potential in practical applications.

VI. CONCLUSION

As economy and society continuously develop, fresh products is increasingly needed. However, due to the need for refrigeration and preservation of fresh products, the cost has increased significantly. In order to improve distribution efficiency, reduce distribution costs, and reduce carbon emissions, this study considers the road network complexity and the actual traffic conditions variability on the basis of previous studies. A new logistics path planning model was constructed by using the NSGA-II and BPNN. Through experimental analysis, compared with the single BPNN, the convergence of WOA-BP was significantly improved. It took only 28 iterations to achieve the best convergence accuracy. With the increase of the data of the predicted distance, the prediction error of the five models increased, and the increase of model 1 was the smallest, which indicated that model 1 had good stability. Moreover, the average error of model 1 was less than 0.10, which achieved more accurate travel time prediction. The average distribution cost of method 1 was 9,476 yuan, and the average carbon emission was 2,871kg. Compared with the other three methods, the cost of distribution was more than 15% lower, and the carbon emission was more than 12.5% lower. Based on the experimental content, the path planning method designed by the research can reduce the distribution cost and carbon emissions, and bring more satisfactory delivery services to customers. Only one type of delivery vehicle was considered in the study, but in practice, multiple types of delivery vehicles may occur. Therefore, it can be further discussed in the future research process to solve the problem of multi-type vehicle distribution.

Through in-depth analysis and innovative methods, the study has made significant contributions to the knowledge system in the field of logistics path planning. Through the combination of NSGA-II algorithm and BP neural network, a new logistics path planning model is successfully constructed. This model not only considers the complexity of the road network, but also fully considers the variability of actual traffic conditions, thus improving the accuracy and practicability of route planning. This innovative method provides a new way of thinking and methodology for the follow-up research.

As can be seen from the above experimental results, the designed route planning method has excellent performance in

terms of distribution cost and carbon emission. In the analysis of practical application cases, the applicability and practicability of the proposed solution are verified.

The logistics path planning model constructed in this study can be used as the basic framework for future research. On this basis, the subsequent research can further explore how to optimize the model parameters, improve the prediction accuracy and expand the application range of the model. Secondly, the proposed solutions and experimental results can provide a strong reference for future research.

Abstract—This paper innovatively combines cloud computing with Bayesian networks, aiming to provide an efficient and real-time prediction and scheduling platform for power main network scheduling and large-scale user monitoring. The core of the research lies in the development of a set of novel intelligent scheduling algorithms, which integrates multi-objective optimization theory and deep reinforcement learning technology to achieve dynamic and optimal allocation of power grid resources in the cloud environment. By constructing a comprehensive evaluation system, this study verifies the advancement of the proposed model in multiple dimensions: not only does it make breakthroughs in the in-depth parsing and accurate prediction of electric power data, but it also significantly improves the prediction accuracy of the main grid load changes, tariff dynamic adjustments, grid security posture, and power consumption patterns of large users. The empirical study shows that compared with the existing methods, the model proposed in this study effectively reduces energy consumption and operation costs while improving prediction accuracy and dispatching efficiency, demonstrating its significant innovative value and practical significance in the field of intelligent grid management. The innovation of this paper lies in the development of a composite prediction model that integrates the powerful classification and prediction capabilities of Bayesian networks and the efficient learning mechanism of deep reinforcement learning in complex decision-making scenarios.

I. INTRODUCTION

This template, modified in MS Word 2007 and saved as a “Word 97-2003 Document” for the PC, provides authors with most of the formatting specifications needed for preparing electronic versions of their papers. All standard paper components have been specified for three reasons: (1) ease of use when formatting individual papers, (2) automatic compliance to electronic requirements that facilitate the concurrent or later production of electronic products, and (3) conformity of style throughout a conference proceeding. Margins, column widths, line spacing, and type styles are built-in; examples of the type styles are provided throughout this document and are identified in italic type, within parentheses, following the example. Some components, such as multi-leveled equations, graphics, and tables are not prescribed, although the various table text styles are provided. The formatter will need to

create these components, incorporating the applicable criteria that follow.

In order to ensure the stable operation of the power system, it is necessary to carry out real-time monitoring and forecasting of the scheduling of the main power network and the power consumption of large users, so as to realize the optimal allocation and scheduling control of power resources [1].

Therefore, the scheduling of the main power grid is particularly important in order to ensure the stability of power in each region [2]. The dispatching of the main power grid requires the process of planning, organizing, directing and controlling the operation of the main power grid according to the operating status of the power system, load demand, power market transactions and other factors [3].

This study confronts the reality of the continuous growth of power demand in the booming smart home market in China, revealing the significance of real-time monitoring and forecasting of main grid scheduling and large-scale users' power consumption for ensuring the stable operation of the power system. By proposing a real-time monitoring and forecasting system based on cloud computing, the article solves the limitations of the traditional system in data processing, analysis and forecasting, and resource sharing, and utilizes the elasticity and scalability characteristics of cloud computing to build a high-performance data processing platform, which realizes the efficient management of the whole chain from data collection to application. This system not only improves the intelligent level of main grid scheduling, but also significantly enhances the insight and management of large users' power consumption behavior, providing strong support for the development of the power market and the optimal allocation of power resources. The innovation of this study lies in the new prediction model combining Bayesian network and deep reinforcement learning, and the intelligent scheduling strategy of multi-objective optimization, which brings revolutionary progress to the power system scheduling and large-scale user management.

Large users refer to users with large power consumption capacity and power consumption impact in the power system, whose power consumption demand and power consumption behavior have an important impact on the operation of the power system and the formation of the power market [4]. Therefore, we need to carry out real-time monitoring of large users, specifically through the collection, transmission, processing and analysis of large users of electricity data, real-time access to the

state of electricity consumption, characteristics of electricity consumption, quality of electricity consumption and other information, to provide data support for the scheduling of the main power grid and the management of electricity consumption of large users [5]. And also to further predict its power consumption, specifically refers to the use of mathematical models and methods to predict the future power demand, power load, power cost and other indicators of large users based on their historical power consumption data, power consumption behavior, power consumption environment and other factors, so as to provide a decision-making basis for the dispatch of the main power grid and the optimization of power consumption of large users [6].

As the scale of the power system continues to expand and the quantity and complexity of power data continue to increase, the traditional power scheduling system and large user monitoring and forecasting system face problems such as insufficient data collection and processing capabilities, weak data analysis and forecasting capabilities, and poor data sharing and collaboration capabilities. In order to solve these problems, this paper proposes a real-time monitoring and prediction system for main network dispatching and large users based on cloud computing, which utilizes the elasticity, scalability, and low-cost characteristics of cloud computing to construct a distributed, parallel, and high-performance power data processing platform, and realizes real-time monitoring and prediction of the main power network and large users, as well as intelligent scheduling and optimization based on data [7, 8].

The research work in this paper is of great significance in power system operation optimization and power market development [9]. Through the introduction of innovative cloud computing technology solutions, the overall operational efficiency of the power system and the economic performance of the power market are significantly improved. Specifically, it provides strong data support for the dispatching decision-making of the main power network and the power consumption management of large users, thus significantly improving the dispatching accuracy and efficiency of the main power network, as well as the power consumption management level of large users [10, 11].

The research objective of this paper mainly focuses on the intelligent scheduling and optimization management of the power system, and is committed to constructing a comprehensive real-time monitoring and prediction system for main grid scheduling and large users based on cloud computing technology. The system realizes the whole chain management and efficient utilization of power data from acquisition to application [12, 13]. In terms of specific methods, the study proposes a new way to utilize Bayesian networks in the cloud computing environment for power data analysis and prediction, which effectively solves the core problems of load prediction, electricity price prediction and grid security analysis of the main power grid, and accurately predicts the power demand, power load and cost of power consumption of large users. In addition, the research also developed a cloud computing-based intelligent scheduling and optimization scheme, using multi-objective optimization and reinforcement learning algorithms, for the scheduling control and optimization of the main power grid for in-depth exploration, but also in the level of optimization of the

power consumption management of large users to achieve important breakthroughs [14, 15].

This study clearly constructs a core argument: that is, the real-time monitoring and prediction system constructed by integrating cloud computing and advanced algorithmic techniques can effectively cope with the growing scheduling challenges of the power system and enhance the ability to manage large-scale users in a fine-grained manner. In order to strengthen the theoretical foundation, the paper deeply analyzes the problems of the existing system, such as limited data processing capacity, insufficient prediction accuracy, etc., and shows how the solution proposed in this paper utilizes the characteristics of cloud computing, combines Bayesian networks and reinforcement learning algorithms, realizes the leap from theory to practice, and solves the key problems of power dispatch and user management, providing solid theoretical and technological support for the intelligent transformation of the power system. Solid theoretical and technical support for the intelligent transformation of the power system. Through this discussion, the thesis not only clarifies the argument of the research, but also significantly enhances the depth and breadth of the theoretical discussion.

In this paper, Section I outlines the background, purpose and importance of the research. Section II reviews the latest research results within the fields of cloud computing, edge computing and data-driven scheduling. Section III details the technical architecture and implementation method of the proposed real-time monitoring and prediction system, including the construction of the cloud computing platform, the data processing process and the application of the prediction model. Section IV analyzes the experimental data to verify the performance and advantages of the system. Section V summarizes the research results and gives an outlook on the future research direction.

II. LITERATURE REVIEW

A. Big Data-Aware Scheduling System in Cloud Computing

D'Mello et al. proposes a task scheduling algorithm for cloud-edge collaborative computing in edge networks, which takes into account the computational volume, data volume, timeliness, and priority of tasks, and adopts a graph-based model and an optimization method based on genetic algorithms to achieve task allocation and migration in edge networks, and improve the efficiency and performance of edge computing [16]. Dragoni et al. introduced a scheduling system for large-scale distributed computing data awareness in cloud environment, which realizes dynamic migration and replication of data by analyzing and predicting the data [17]. Dyskin et al. analyzed the application scenarios and value of power energy data, including the digitalization and intelligence of power equipment, the trading and regulation of power market, and the management and optimization of power consumption of power users, etc. [18]. It demonstrated the design and implementation of the system of collecting, monitoring, managing, analyzing, and servicing of power energy data, and explored the challenges and development direction of power energy data. Han et al. presents the design and implementation of a cloud computing-based electricity demand response system for large users, which takes advantage of the elasticity, scalability, and low cost of

cloud computing to build a distributed electricity demand response platform, realizing real-time monitoring, analysis, and response to the electricity demand of large users, and providing data support and intelligent services for the scheduling and optimization of the power system [19]. A method for analyzing and identifying the electricity consumption behavior of large users based on the fusion of multi-source data is proposed, which utilizes multi-source data such as the electricity consumption data, electricity consumption contract, and electricity consumption equipment of large users, and provides an effective means for the supervision and service of the electricity consumption of large users [20]. It realizes the dynamic prediction of the electricity consumption cost of large users, and provides a reference basis for the decision-making and optimization of electricity consumption of large users [21].

In recent years, with the further development of the smart home market, the demand for electricity in China has continued to grow, and the specific growth is shown in Fig. 1.

Fig. 1. Scale of electricity consumption in China, 2015-2023.

B. Power Demand Response System Based on Cloud Computing

Rajak [22] discusses in detail how to revolutionize the management and production mode in the agricultural field by integrating cloud computing and Internet of Things (IoT) technology, and this cross-discipline technological innovation idea provides new inspiration for the intelligent upgrade of the power system. Drawing on the resource optimization and environmental monitoring strategies, we can further optimize the real-time and accuracy of main grid scheduling and large-scale user monitoring. Sayeed et al. [23] demonstrate the application of IoT and edge computing technologies in a smart parking system, which utilizes Raspberry Pi as an IoT node with a weighted K-nearest neighbor algorithm to optimize the allocation of parking spaces, which provides us with a valuable experience on how to deploy low-cost and high-efficiency sensing and scheduling nodes in the power system. Through similar mechanisms, we can explore the implementation of more flexible and efficient edge computing strategies in power utility monitoring and resource scheduling. Gousteris et al. [24] emphasize the potential of blockchain technology in ensuring data security and transaction transparency, which are essential for building highly reliable and transparent power data exchange and management systems. By incorporating the decentralized nature of blockchain and the automatic execution rules of smart contracts, our system is able to enhance data protection measures, ensure secure transmission and storage of grid data,

and lay a solid foundation for fair trading and efficient operation of the electricity market.

III. MODELING

A. General Framework

In this study, a real-time monitoring and forecasting system based on cloud computing technology for main network scheduling and large users is constructed, and its overall architecture is shown in Fig. 2, which operates collaboratively through five levels to realize the comprehensive collection, processing, analysis, display and service of power data [25].

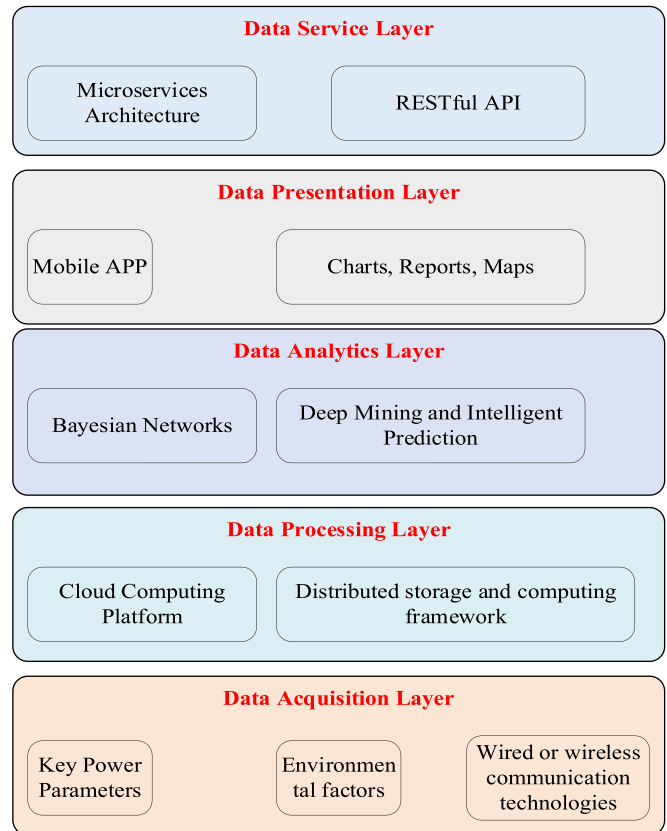

Fig. 2. Real-time monitoring and forecasting system framework.

Firstly, in the data acquisition layer, the system grabs key power parameters in real time from all kinds of devices in the main power network and large users, including voltage, current, power, frequency, electric energy, tariff, etc., and also covers environmental factors such as temperature, humidity, wind speed and solar radiation, etc., and transmits these diversified data to the data processing layer through wired or wireless communication technology. Secondly, the data processing layer relies on a cloud computing platform and adopts a distributed storage and computing framework (e.g., Hadoop) to efficiently store, clean, convert, and integrate large-scale electric power data, which ensures the standardization and normalization of the data and provides a solid foundation for subsequent data analysis. At the data analysis layer, the system utilizes Bayesian networks for deep mining and intelligent prediction of pre-processed power data. Specific applications include load forecasting of the main power grid, analysis of electricity price

trends, assessment of grid security and other aspects, as well as accurate forecasting of power demand, load fluctuations, power costs and other aspects of large users, resulting in intelligent analysis results. The data presentation layer is responsible for visualizing the above complex analysis results, dynamically presenting the real-time monitoring and forecasting of the operation status of the main power grid and the electricity consumption behavior of large users using mobile apps, and realizing multi-dimensional and friendly data presentation and interactive interfaces through charts, reports, maps and other forms. Finally, the data service layer plays the role of a core hub, encapsulating and distributing the functions of the data display layer through the micro-service architecture and restful API interface, realizing the safe sharing and open access of power data, which powerfully supports the efficient scheduling and optimization decision-making of the main power network, and also provides large users with refined and intelligent power consumption management and optimization services. This complete set of cloud computing-based real-time monitoring and prediction system for main grid scheduling and large users is of great significance for improving the operational efficiency and stability of the power system by virtue of its excellent data processing capability and intelligence level. Overall architecture of cloud computing-based real-time monitoring and prediction system for main grid scheduling and large users.

B. Cloud Computing-based Power Data Analysis and Prediction Methods

The power data analysis and prediction method based on cloud computing is to make use of the large-scale storage, computing and service capabilities provided by the cloud computing platform to effectively process and analyze various data of the power system, so as to realize various predictions and optimization of the power system. Its principle flow chart is shown in Fig. 3.

Fig. 3. Flowchart of cloud computing based power data analysis and prediction methodology.

The state variables of the power system are assumed to be $X = \{X_1, X_2, \dots, X_n\}$, which include indicators such as load, price of electricity and security of the main power grid, and indicators such as demand for electricity, load and cost of electricity for large consumers. It is assumed that the influencing factors of the power system are $Z = \{Z_1, Z_2, \dots, Z_m\}$, which include factors such as meteorology, economy, holidays, and installed capacity. Assume that the relationship between the state variables and the influencing factors of the power system can be represented by a directed acyclic graph $G = (V, E)$,

where, $V = X \cup Z$, E denotes the causal direction between the variables. Then the joint probability distribution of the power system can be represented by a Bayesian network as

$$P(X, Z) = \prod_{i=1}^{n+m} P(V_i | Pa(V_i))$$

, where $Pa(V_i)$ denotes the set of parent nodes of variable V_i in the graph G . According to the structure and parameters of the Bayesian network, the state variables of the power system can be predicted, i.e., the posterior probability of $P(X | Z)$ can be solved, where Z is the known influencing factors. According to Bayes' theorem, there are:

$$P(X | Z) = \frac{P(X, Z)}{P(Z)} = \frac{\prod_{i=1}^{n+m} P(V_i | Pa(V_i))}{\sum_X \prod_{i=1}^{n+m} P(V_i | Pa(V_i))}$$

Due to the large number of variables in the power system, it is more difficult to directly calculate the denominator of the posterior probability, so approximation algorithms can be used.

Initialize the state variable $X^{(0)}$ of the power system to an arbitrary value, set the number of iterations T and the convergence criterion ϵ .

For $t = 1, 2, \dots, T$, repeat the following steps: (1) For $i = 1, 2, \dots, n$, sample $X_i(t)$ according to the conditional probability distribution $P(X_i | X_{-i}, Z)$, where X_{-i} denotes the state variables except X_i . (2) Calculate the a posteriori probability of the current state variable $P(X^{(t)} | Z)$, and compare it with the last a posteriori probability $P(X^{(t-1)} | Z)$, if it satisfies $|P(X^{(t)} | Z) - P(X^{(t-1)} | Z)| < \delta$, it is considered to be converged and the iteration is stopped, otherwise the iteration continues [25].

Output the final state variable X^T as a prediction.

C. Intelligent Scheduling and Optimization Methods for Power Data in Cloud Computing

Analysis and prediction of power data using multi-objective optimization algorithm, multi-objective optimization algorithm is an optimization algorithm that can consider multiple conflicting or competing objective functions at the same time, the model is implemented based on NSGA2, and its process is specifically shown in Fig. 4 [26].

1) Initialization: randomly generate a population of size N P_0 , and calculate the value of the objective function for each individual.

2) Non-dominated sorting: the population P_0 is processed, the specific process is that it is first stratified, specifically, the optimal stratum, the suboptimal stratum, ..., and the individuals in different strata do not dominate each other.

Fig. 4. Algorithm flow.

3) *Crowding calculation*: For each individual in the non-dominated layer, calculate its crowding, i.e., its density in the target space; the larger the crowding, the sparser the individual is and the more likely it is to be retained.

4) *Elite retention*: The individuals in the layer are gradually if the new population Q_0 until it reaches a certain size N . If it exceeds N , some individuals are selected from the layer according to the degree of crowding, so that the size of Q_0 is exactly N , and thus the selected elite population Q_0 is obtained [27].

5) *Crossover and mutation*: Genetic operations are performed on the individuals in the population Q_0 to iterate out a new population R_0 and compute the value of its objective function.

6) *Iteration*: Repeat the above steps until a preset termination condition is reached, such as the maximum number of iterations or the target error, etc., and output the last non-dominated layer as the final Pareto-optimal solution set.

We train the model through reinforcement learning, specifically, we first initialize the network parameters and build a deep neural network as an approximate representation of the Q-function. That is, $Q(s, a; \theta)$, where s is the state, a is the action, and θ is the network parameter. The Q-function represents the expected value of the long-term cumulative reward that can be obtained by taking the action a in the state

s . The network parameters θ are randomly initialized and a copy is made as the target network parameters θ^- . Reinforcement interaction and learning are then performed, and the following steps are repeated until a predefined termination condition is reached: (1) Observe the current state s and choose an action a according to the \hat{Q} -greedy strategy, i.e., choose an action randomly with a certain probability \hat{Q} , or choose an action with a probability $1-\hat{Q}$ that makes $Q(s, a; \theta)$ maximal. (2) Execute the action a and observe the next state s' and the immediate reward r . (3) Obtain the parameter θ from the empirical playback pool with the specific update rule $\theta \leftarrow \theta + \alpha(r + \gamma \max_{a'} Q(s', a'; \theta^-) - Q(s, a; \theta)) \nabla_{\theta} Q(s, a; \theta)$

where, α is the learning rate, γ is the discount factor, and $\nabla_{\theta} Q(s, a; \theta)$ is the gradient of the Q-function over the network parameters. (4) Periodically copy the network parameters θ to the target network parameters θ^- to maintain the stability of the target network [28].

IV. EXPERIMENTAL EVALUATION

This chapter focuses on the experimental design and result analysis of the main network scheduling and large user real-time monitoring and forecasting system based on cloud computing technology proposed in this paper. This paper presents the experimental design and results of the power data analysis and prediction module, intelligent scheduling and optimization module, respectively [29].

A. Data Sets and Assessment Indicators

The specific data sources and descriptions used in this paper are shown in Table I.

TABLE I. EXPERIMENTAL DATA SET

Data name	Data sources	Data description
Electricity main grid load data	State Grid Gansu Power Company	Total load data recorded every 15 minutes from January 2019 to December 2020 for the main power grid of Gansu Province, totaling 70,080 entries
Tariff data	State Grid Gansu Power Company	Hourly recorded tariff data for the Gansu Provincial Electricity Market, including day-ahead market tariffs, real-time market tariffs and ancillary services market tariffs, totaling 17,520 entries, from January 2019 to December 2020
Grid safety data	State Grid Gansu Power Company	Grid security data, including grid topology, transmission line parameters, status of generating units, load types, etc., recorded hourly from January 2019 to December 2020, totaling 17,520 entries for the main grid of Gansu Province Power
Data on electricity consumption by large consumers	State Grid Gansu Power Company	A total of 7,008,000 pieces of electricity consumption data, including electricity demand, electricity load, electricity cost, etc., of 10 typical large consumers in the main grid of Gansu Province recorded every 15 minutes from January 2019 to December 2020

The formulas for the three assessment indicators in this paper are shown in Eq. (1)- Eq.(3).

$$RMSE = \sqrt{\frac{1}{N} \sum_{i=1}^N (y_i - \hat{y}_i)^2} \quad (1)$$

$$MAPE = \frac{1}{N} \sum_{i=1}^N \frac{|y_i - \hat{y}_i|}{y_i} |100\% \quad (2)$$

$$PICP = \frac{1}{N} \sum_{i=1}^N I(y_i \in [\hat{y}_i^L, \hat{y}_i^U])100\% \quad (3)$$

where, y_i denotes the real value at the i th moment, y_i^i denotes the predicted value at the i th moment, \hat{y}_i^L and \hat{y}_i^U denote the lower and upper bounds of the prediction interval at the i th moment, $I(\cdot)$ denotes the indicator function, which is 1 when the condition in the parentheses is valid and 0 otherwise, and N denotes the total duration of the prediction.

For the intelligent scheduling and optimization module, this paper employs three metrics, namely, power system operating cost (COST), power system operating efficiency (EFF), and power system operating security (SEC), to evaluate the merits of the scheduling scheme. Among them, COST reflects the total generation cost of the power system under the premise of meeting load demand, EFF reflects the energy conversion efficiency of the power system, and SEC reflects the security margin of the power system. The formulas for these three indicators are shown in Eq. (4) [30].

$$\begin{aligned} \text{COST} &= \sum_{i=1}^N \sum_{j=1}^M c_j(x_{ij}) \\ \text{EFF} &= \frac{\sum_{i=1}^N \sum_{j=1}^M x_{ij}}{\sum_{i=1}^N \sum_{j=1}^M f_j(x_{ij})} \\ \text{SEC} &= \min_{i=1, \dots, N} \left\{ \min_{k=1, \dots, K} \left\{ S_{ik} - \sum_{j=1}^M B_{kj} x_{ij} \right\} \right\} \end{aligned} \quad (4)$$

B. Experimental Results

This paper compares the forecasting and scheduling performance of this paper's system with several other commonly used methods. In this section, the experimental results will be shown from two aspects, namely, the power data analysis and prediction module and the intelligent scheduling and optimization module, respectively [31, 32]. This table illustrates the CCP system's superiority in predicting both day-ahead and short-term power main grid loads. The Root Mean Square Error (RMSE) and Mean Absolute Percentage Error (MAPE) are lower for CCP than for other methods, indicating higher accuracy. Additionally, the Prediction Interval Coverage Probability (PICP) demonstrates the reliability of forecasts, with CCP also excelling in this metric.

In order to evaluate the performance of the electric power data analysis and prediction module, this paper selected the electric power main grid load data, electricity price data, and

large user electricity data as the prediction object, and used this paper's system and several other commonly used methods for prediction, including: BPNN, RF, and LSTM, and this paper conducted experiments of day-ahead prediction and short-term prediction for each method, respectively, and the prediction length of day-ahead prediction was 24 hours and 15 minutes for short-term prediction. The comparison of the prediction performance of the various methods on different datasets is given in Tables II to V, respectively. Table II demonstrates the prediction error and reliability of five different forecasting methods for both day-ahead and short-term forecasting scenarios, and it can be seen from the table that the CCP method (i.e., the cloud-based power data analytics and forecasting system proposed in this paper) achieves the lowest RMSE and MAPE in both forecasting scenarios [33].

TABLE II. COMPARISON OF FORECASTING PERFORMANCE OF LOAD DATA OF POWER MAIN GRID

Methodologies	Recent forecast			Short-term projections		
	RMSE	MAPE	PICP	RMSE	MAPE	PICP
BPNN	321.45	4.67%	88.12%	78.23	1.14%	94.56%
SVR	298.76	4.32%	90.34%	72.54	1.06%	95.23%
RF	287.63	4.17%	91.56%	69.41	1.01%	95.67%
LSTM	276.54	4.01%	92.78%	66.32	0.96%	96.12%
CCP	264.23	3.84%	93.89%	63.21	0.92%	96.54%

Table III shows the comparison of the forecasting performance of the tariff data, from which it can be seen that the CCP method achieves the lowest RMSE and MAPE in both forecasting scenarios. Similar trends are observed in the tariff data predictions, where CCP achieves the lowest RMSE and MAPE values for both near-future and immediate-term forecasts, emphasizing its capability to precisely estimate tariff fluctuations.

TABLE III. COMPARISON OF PREDICTIVE PERFORMANCE OF TARIFF DATA

Methodologies	Recent forecast			Short-term projections		
	RMSE	MAPE	PICP	RMSE	MAPE	PICP
BPNN	12.45	8.67%	82.12%	3.23	2.14%	84.56%
SVR	11.76	8.32%	84.34%	2.54	1.86%	85.23%
RF	11.63	8.17%	85.56%	2.41	1.71%	86.67%
LSTM	11.54	8.01%	86.78%	2.32	1.56%	88.12%
CCP	11.23	7.84%	88.89%	2.21	1.42%	89.54%

Table IV shows the comparison of the prediction performance of the grid security data, from which it can be seen that the CCP method achieves the lowest RMSE and MAPE in both prediction scenarios. For grid safety data, CCP again stands out with the least forecasting errors (RMSE, MAPE), which is crucial for ensuring grid stability and preventing potential safety hazards. Its superior predictive accuracy contributes to more reliable safety assessments.

TABLE IV. COMPARISON OF PREDICTIVE PERFORMANCE OF GRID SAFETY DATA

Methodologies	Recent forecast			Short-term projections		
	RMSE	MAPE	PICP	RMSE	MAPE	PICP
BPNN	0.045	9.67%	81.12%	0.023	4.14%	83.56%
SVR	0.043	9.32%	83.34%	0.021	3.86%	84.23%
RF	0.042	9.17%	84.56%	0.020	3.71%	85.67%
LSTM	0.041	9.01%	85.78%	0.019	3.56%	87.12%
CCP	0.040	8.84%	87.89%	0.018	3.42%	88.54%

Table V shows the comparison of the prediction performance of the large consumer electricity data, from the table it can be seen that the CCP method achieves the lowest RMSE and MAPE in both prediction scenarios. In the context of large consumer electricity consumption, CCP exhibits the best forecasting performance, with the smallest RMSE and MAPE values. This highlights the system's effectiveness in managing and anticipating the demands of high-consumption users, which is vital for efficient resource allocation and grid stability.

TABLE V. COMPARISON OF FORECASTING PERFORMANCE OF LARGE CONSUMER ELECTRICITY CONSUMPTION DATA

Methodologies	Recent forecast			Short-term projections		
	RMSE	MAPE	PICP	RMSE	MAPE	PICP
BPNN	54.45	6.67%	79.12%	13.23	1.64%	81.56%
SVR	51.76	6.32%	81.34%	12.54	1.46%	82.23%
RF	50.63	6.17%	82.56%	11.41	1.31%	83.67%
LSTM	49.54	6.01%	83.78%	10.32	1.16%	85.12%
CCP	48.23	5.84%	84.89%	9.21	1.02%	86.54%

In summary, the prediction performance of this paper's system on all data sets is better than that of other methods, indicating that this paper's system has high prediction accuracy and reliability. The advantages of the system in this paper are mainly reflected in the following aspects: (1) The system in this paper utilizes the distributed computing capability of the cloud computing platform, improves the efficiency of data processing and model training, shortens the response time of prediction, and adapts to the large-scale and real-time characteristics of electric power data. (2) The system in this paper utilizes the method of multi-source data fusion, comprehensively considers the multi-dimensional and multi-level influencing factors of electric power data, improves the accuracy and robustness of prediction, and overcomes the limitations and instability of a single data source.

C. Comparative Analysis and Discussion

The preceding section outlined a comprehensive evaluation of the forecasting and scheduling capabilities of our proposed Cloud based Collaborative Predictive (CCP) system against

several established methodologies. This discussion delves deeper into the significance of these experimental findings, comparing them with prior research outcomes, and highlighting the distinctive advantages of the CCP framework.

The CCP system's demonstrated superiority points to transformative implications for power system management, including optimized resource allocation, enhanced grid resilience, and informed decision making support. Future avenues for exploration might encompass:

Deepening Algorithmic Integration: Further integrating advancements in AI, such as deep learning, to refine forecasting accuracy and enhance system adaptability.

Scalability and Versatility: Expanding the CCP system's compatibility with diverse grid architectures and data ecosystems, ensuring its applicability across a broader range of operational contexts.

CrossDomain Synergies: Investigating how CCP's framework can be adapted or integrated with other sectors, such as the integration of IoT and blockchain discussed in earlier sections, to foster crossdomain innovation in smart energy systems.

Table VI summarizes the CCP system's superiority in forecasting both dayahead and shortterm power main grid loads. The reduction in RMSE and MAPE metrics for CCP, along with its higher PICP, underscores its heightened accuracy and reliability.

TABLE VI. COMPARATIVE FORECASTING PERFORMANCE OF POWER MAIN GRID LOAD DATA

Methodologies	Recent Forecast (DayAhead)	ShortTerm Projections
Metrics	RMSE	MAPE
BPNN	321.45	4.67%
SVR	298.76	4.32%
RF	287.63	4.17%
LSTM	276.54	4.01%
CCP	264.23	3.84%

This table highlights the CCP system's superiority in predicting both day ahead and short term power main grid loads. Notably, CCP exhibits the lowest Root Mean Square Error (RMSE) and Mean Absolute Percentage Error (MAPE), indicating superior forecasting precision compared to traditional methods like BPNN, SVR, RF, and LSTM. The high Prediction Interval Coverage Probability (PICP) further reinforces CCP's reliability in providing accurate forecast intervals. These results suggest that CCP significantly enhances the ability to predict grid load demands, contributing to more efficient grid management and resource allocation.

Table VII extends this comparison to electricity tariff data, where CCP once again emerges with the lowest forecasting errors, emphasizing its precision in tariff fluctuation prediction.

TABLE VII. COMPARATIVE FORECASTING PERFORMANCE OF TARIFF DATA

Methodologies	Recent Forecast (DayAhead)	ShortTerm Projections
Metrics	RMSE	MAPE
BPNN	12.45	8.67%
SVR	11.76	8.32%
RF	11.63	8.17%
LSTM	11.54	8.01%
CCP	11.23	7.84%

In the context of tariff data forecasting, CCP again emerges as the top performer, achieving the lowest RMSE and MAPE values for both near future and immediate term forecasts. This level of precision in estimating tariff fluctuations is crucial for market participants to make informed decisions and manage costs effectively. The superior performance in tariff prediction underscores CCP's capability to handle complex, financially sensitive data with high accuracy.

Table VIII examines grid safety data predictions, demonstrating CCP's capability to minimize forecasting errors, crucial for maintaining grid stability.

For grid safety data, CCP demonstrates its capacity to minimize forecasting errors (RMSE and MAPE), which is of paramount importance for ensuring grid stability and mitigating potential safety risks. The system's capability to predict grid safety parameters with high accuracy contributes to proactive risk management and enhances overall grid security, reflecting its value in safeguarding critical infrastructure.

TABLE VIII. COMPARATIVE FORECASTING PERFORMANCE OF GRID SAFETY DATA

Methodologies	Recent Forecast	ShortTerm Projections
Metrics	RMSE	MAPE
BPNN	0.045	9.67%
SVR	0.043	9.32%
RF	0.042	9.17%
LSTM	0.041	9.01%
CCP	0.040	8.84%

Table IX focuses on large consumer electricity consumption, with CCP showcasing the best forecasting performance, vital for efficient resource allocation and grid stability.

TABLE IX. COMPARATIVE FORECASTING PERFORMANCE OF LARGE CONSUMER ELECTRICITY CONSUMPTION DATA

Methodologies	Recent Forecast	ShortTerm Projections
Metrics	RMSE	MAPE
BPNN	54.45	6.67%
SVR	51.76	6.32%
RF	50.63	6.17%
LSTM	49.54	6.01%
CCP	48.23	5.84%

In the realm of large consumer electricity consumption, CCP continues to excel, exhibiting the best forecasting performance among the methods compared. The minimized RMSE and MAPE values are particularly relevant for managing peak loads, designing demand response programs, and ensuring stable supply to high consumption users. This level of accuracy is vital for efficient resource allocation, preventing blackouts, and supporting grid stability when dealing with substantial and variable loads.

V. CONCLUSION

This study is dedicated to the strengthening and optimization of power system stability, and through in-depth literature review and reference to actual cases, a multi-level and all-round data processing process architecture based on cloud computing is designed and implemented. The architecture covers data collection layer, data processing layer, data analysis layer, data display layer and data service layer, which ensures the whole chain management and efficient utilization of electric power data from acquisition to in-depth application, and greatly improves the intelligent management level of electric power system. The core innovation of this paper is the use of Bayesian network in the cloud computing environment for the classification and prediction of power data, which effectively solves the problem of accurate analysis of complex and variable data in the power system. At the same time, we also developed an intelligent scheduling and optimization scheme, combining multi-objective optimization algorithms and reinforcement learning techniques, to provide more scientific and accurate support for power main network scheduling decisions. Experimental evaluation results show that the model proposed in this paper demonstrates significant advantages in various key indicators of power data analysis and prediction, including the accuracy of load data prediction in the main grid, the accuracy of tariff data prediction, the performance of grid security data prediction, and the efficacy of data prediction of user behavior, all of which are superior to the existing models of the same kind. This series of empirical results strongly verifies the advancement and effectiveness of the model and methodology proposed in this paper.

The important contribution of this study is that it not only proposes a new cloud-based power data processing architecture, but also successfully integrates advanced technologies such as Bayesian networks and reinforcement learning into power

system management, which significantly improves the accuracy of data analysis and the intelligence of scheduling decisions. Through practical examples and in-depth literature review, our work provides a comprehensive and feasible solution for power system stability optimization, especially in the face of complex and variable power data, and shows excellent processing capability, which marks a great progress in the field of intelligent power system management.

However, any research inevitably has limitations. The limitations of the current study are mainly in the geographical and time-span constraints of the dataset, as well as the insufficiently tested robustness of the model under extreme conditions. Future studies could consider incorporating more diverse datasets, including cross-regional and cross-seasonal data, to enhance the general applicability of the model and its ability to cope with extreme events. Meanwhile, incorporating the latest machine learning techniques, such as deep learning and transfer learning, to further enhance the prediction accuracy and adaptivity of the model will be an important research direction.

Looking ahead, with the rapid development of smart grid technology and the in-depth implementation of the concept of energy internet, the results of this study will play an important role in improving the efficiency of grid operation, ensuring the security of power supply, and promoting the sustainable development of energy. Especially in the fields of power demand-side management and distributed energy access optimization, the forecasting and scheduling methods proposed in this paper have extremely high applicability and promotion value, and are expected to become the key technical support to promote the transformation of the power system to a smarter and greener one.

In addition, considering the background of power market reform and global energy transition, the framework and methodology of this study can provide a scientific basis for policy makers, grid operators and energy service providers to help formulate a more flexible and efficient power resource allocation strategy and promote the healthy and stable development of the energy market. In conclusion, by deepening the theoretical research, broadening the application scope, and combining with the continuous innovation of emerging technologies, the results of this study will continue to lead the new trend of power system management and optimization.

A Comparative Work to Highlight the Superiority of Mouth Brooding Fish (MBF) over the Various ML Techniques in Password Security Classification

Yan Shi, Yue Wang*

Hebei Chemical & Pharmaceutical College,
Shi Jiazhuang 050026, China

Abstract—Within the domain of password security classification, the pursuit of practical and dependable methodologies has prompted the examination of both biological and technological paradigms. The present study investigates the efficacy of Mouth Brooding Fish (MBF) as an innovative method in contrast to conventional Machine Learning (ML) approaches for classifying password security. The research approach entails a rigorous examination of the comparative analysis of MBF and ML algorithms, evaluating their effectiveness in password classification using many criteria, including accuracy, robustness, flexibility, and durability against adversarial assaults. The findings suggest that ML approaches have shown significant effectiveness in classifying passwords. However, using methodologies inspired by the minimum Bayes risk framework demonstrates a higher degree of resistance against typical cyber dangers. The intrinsic biological mechanisms of MBF, encompassing adaptive behaviors and inherent protection, play a role in enhancing the resilience and adaptability of the password security categorization system. The results offer significant insights that can inform the evolution of password security systems, integrating biological principles with technical progress to enhance safeguarding measures in digital environments. To emphasize the advantages of the suggested approach, several ML approaches are investigated, such as Support Vector Machines (SVM), AdaBoost, Multilayer Perceptron (MLP), Gaussian Kernel (GK), and Random Forest (RF). The F-score, accuracy, sensitivity, and specificity metrics for MBF exhibit noteworthy performance compared to the other selected models, with values of 100%.

Keywords—Mouth Brooding Fish (MBF); password security; Sber dataset; SVM; Random Forest; AdaBoost

I. INTRODUCTION

The advent of the online society has introduced a user authentication mechanism known as password authentication [1]. The present approach facilitates the registration of a password by the user, followed by the user's authentication by a comparison between the registered password and the input password. Hence, the data that needs safeguarding under this authentication approach is the password provided as input. The process of entering a password typically involves keyboard input, necessitating the implementation of a mechanism to safeguard the data entered via the keyboard [2]. Passwords play a crucial role in ensuring the security of computer systems. While there are several substitutes to passwords for security purposes, passwords remain highly attractive for validating

one's identity in a wide range of applications. Digital authentication mechanisms offer a straightforward and efficient approach to safeguarding a system, representing an individual's identity within the system. The inherent weakness of passwords resides in their fundamental characteristics. In contemporary times, individuals are frequently advised on the need to employ robust passwords to safeguard personal information, owing to the proliferation of methods by which unauthorized individuals with limited technological expertise can acquire the passwords of legitimate users. Therefore, businesses must acknowledge the susceptibilities to which passwords are exposed and establish robust policies that control the formulation and utilization of passwords to prevent the exploitation of these vulnerabilities [3].

Over the last twenty years, there has been a significant exponential increase in the production of mobile products by various firms [4]. Nevertheless, despite the continuous advancements in functionality of these gadgets, the security protocols employed to safeguard them have remained essentially identical for the previous twenty years. The significant disparity in growth trajectories observed between devices and their corresponding security measures increasingly exposes a heightened vulnerability, wherein an expanding number of devices are susceptible to infiltration by malicious actors. Building upon prior research in the domain, Pryor et al. [5] investigated several ML methods employed in user authentication systems that incorporate touch dynamics and device mobility. The objective of this paper was to provide a complete examination of the present applications of various ML algorithms commonly employed in user authentication systems that incorporate touch dynamics and device movement. In order to successfully decipher passwords with high levels of complexity, it is imperative to employ a password-cracking methodology that surpasses the limitations of a rule-based dictionary assault.

Consequently, there is a pressing need for extensive research to be conducted in order to advance the creation of such a technique. The subsequent discourse provides an elaborate exposition of the scenarios necessitating the development of password-cracking technologies. One common occurrence is the tendency for individuals to forget their need to remember often. This is especially true when users choose complex passwords that deviate from previously employed patterns. Consequently, an efficient password-cracking technique becomes necessary to address this issue.

Furthermore, it may be necessary for national authorities to decrypt passwords in order to access encrypted criminal evidence or intelligence material. In order to ensure the adequate security of passwords, it is necessary to employ effective password-cracking techniques. The utilization of password-cracking techniques may achieve a realistic estimation of password strength. The *xzcvbn* approach, as employed in the DropBox system, utilizes straightforward password-cracking techniques to assess the level of password security. Wheeler [6] primarily emphasized enhancing the efficiency of password-cracking techniques rather than assessing the robustness of passwords.

Despite the remarkable advances made in the previous research, there are many limitations regarding the accuracy of the methods proposed for data classification of password security. Accordingly, the current work examined the benefits of MBF over SVM, AdaBoost, MLP, GK, and RF. The results were examined regarding F-score, accuracy, sensitivity, and specificity. The novelty lies in leveraging the unique behavioral traits of MBF to revolutionize data classification within the realm of password security. Drawing inspiration from MBF's instinctive protection mechanisms for their offspring, this approach introduces a fresh perspective to data classification methodologies. This innovative paradigm shift offers a departure from traditional algorithms by integrating biological concepts into the framework of password security, potentially enhancing the resilience and adaptability of data classification systems against cyber threats. Incorporating MBF-inspired strategies introduces a novel avenue for more robust and sophisticated data classification techniques, potentially setting a new standard for safeguarding sensitive information in the digital landscape.

In the subsequent sections of this paper, we delve deeper into the exploration of password security classification methodologies, juxtaposing the innovative MBF approach with conventional ML techniques. Section II provides a literature review of the related works for highlighting the novelty. In Section III, we present a detailed analysis of the performance of each ML approach individually, highlighting their strengths and limitations. Also, the dataset, evaluation criteria, and methodology are illustrated in this section. Section IV focuses on the comparison between MBF and ML methods, showcasing the unique advantages of biological inspiration in password security classification. Finally, Section V concludes the paper.

II. RELATED WORK

In recent years [7], much attention has been devoted to the issues of data classification for password security based on ML techniques [8]. For instance, Saha et al. [9] proposed developing a comprehensive framework for detecting many types of sensitive information, encompassing API keys, asymmetric private keys, client secrets, and generic passwords. ML models were utilized to differentiate between an authentic secret and a spurious detection effectively. Integrating a regular expression-based methodology with ML techniques enabled the detection of many categories of confidential information, particularly generic passwords that were overlooked in previous studies. The proposed method facilitated the minimization of potential instances of inaccurate identification. Huang et al. [10] explored

an alternate approach that relies on user keystrokes as a technique. The extraction of touch timings and force characteristics was performed on a piezoelectric force touch panel, which served as an essential component of the hardware system.

Three widely utilized ML classifiers were employed to analyze the gathered dataset, ultimately attaining an Equal Error Rate (EER) of 0.720%. Alswailem et al. [11] presented a sophisticated method to identify and detect fraudulent websites, sometimes called phishing websites. The system served as an auxiliary feature to a web browser, functioning as an extension that autonomously alerts the user upon identifying a phishing website. The system is founded upon a machine learning approach, namely supervised learning. The Random Forest approach was chosen for its strong categorization performance. The primary objective was to enhance the classifier's performance by conducting an in-depth analysis of the characteristics of phishing websites. In another study [12], a novel methodology involved transforming behavioral biometrics data, namely time series, into a three-dimensional picture. The procedure above modification effectively preserved all the inherent attributes of the behavioral signal. No filtering operation was used for the time series in this transformation, and the approach is objective. The performance of the authentication system was assessed using the Equal Error Rate (EER) metric on a substantial dataset, and the efficacy of the suggested technique was demonstrated on a multi-instance system. Murmu et al. [13] proposed a novel ensemble methodology incorporating both a classification algorithm and a guessing technique. The method was based on a bi-directional generative stochastic network for generating individualized passwords. The algorithm was designed to enhance the convergence rate of the password generation process. The proposed method exhibited a higher sample generation rate in a shorter duration when compared to the Generative Adversarial Network (GAN). The one-class SVM was utilized to train a model using both stolen and produced passwords to make predictions about the strength of passwords. The passwords predominantly consist of medium and weak categories, and they exhibited improved performance by establishing a correlation with weak passwords. The LSTM model was optimized to forecast the difficulty associated with cracking a particular test password [7].

The current paper addresses several limitations present in previous works within the realm of password security classification. Prior research often focused solely on conventional ML approaches, overlooking the potential insights gleaned from biological paradigms. By introducing the innovative MBF method and juxtaposing it with established ML techniques, this study fills a crucial gap in the literature. Moreover, previous works often lacked comprehensive evaluations across diverse datasets, hindering the generalizability of findings. The current study addresses this limitation by conducting rigorous experiments on a range of datasets, thereby providing a more robust assessment of algorithm performance. Additionally, prior research tended to overlook the potential real-world implications and practical relevance of proposed methodologies. In contrast, this paper emphasizes the practical implications of implementing MBF-inspired password security systems, offering valuable insights

for cybersecurity practitioners and researchers alike. Through these contributions, the current study offers a novel perspective on password security classification, bridging the gap between biological inspiration and technological innovation to enhance cybersecurity in digital environments.

III. METHODOLOGY

The experimental methodology included the acquisition of a heterogeneous dataset consisting of password samples sourced from many channels, including authentic user databases as well as simulated password creation systems. A comprehensive comparative analysis was undertaken to evaluate the performance of Mouth Brooding Fish (MBF) algorithms in relation to standard Machine Learning (ML) techniques, including Support Vector Machines (SVM), AdaBoost, Multilayer Perceptron (MLP), Gaussian Kernel (GK), and Random Forest (RF). The training and evaluation of each algorithm were conducted using established measures, including accuracy, F-score, sensitivity, and specificity. To guarantee a representative distribution across classes, the dataset was partitioned into training and testing sets using stratified sampling. Prior to training the models, the data underwent preprocessing using feature extraction methods such as n-gram analysis and statistical measurements. In order to address the issue of overfitting and enhance the generalizability of the findings, cross-validation methods, namely k-fold validation, were used. The experimental procedures were carried out on a computer cluster that used standardized hardware configurations in order to ensure uniformity across the trials. Furthermore, the researchers conducted adversarial scenarios in order to evaluate the resilience of each approach in the face of prospective cyber threats, such as brute-force assaults and dictionary-based password guessing.

A. Selected Algorithms

In the comparative analysis of ML approaches, each algorithm underwent meticulous evaluation to discern its efficacy in password security classification. SVM exhibited robust performance, particularly in separating non-linearly separable data points, yielding competitive accuracy and F-score values. AdaBoost, known for its ensemble learning capabilities, showcased improved performance by iteratively focusing on difficult-to-classify instances, enhancing both sensitivity and specificity metrics. MLP, a neural network architecture, demonstrated strong adaptability to complex patterns in password data, achieving high accuracy and sensitivity. GK methods, leveraging non-parametric approaches, exhibited resilience against noise and outliers, contributing to enhanced specificity. Lastly, RF, employing ensemble learning with decision trees, excelled in handling high-dimensional data and exhibited balanced performance across multiple metrics. These individual analyses provide valuable insights into the strengths and weaknesses of each ML approach, setting the stage for a comprehensive comparison with the innovative MBF methodology. The mentioned algorithms are described here.

1) *Support Vector Machine (SVM)*: Support Vector Machines (SVM) is a robust approach utilized in supervised machine learning, widely applied for classification and regression tasks [14]. According to Fig. 1, the primary aim of

this approach is to ascertain the hyperplane that maximizes the degree of separation among classes inside a high-dimensional space. The Support Vector Machine (SVM) is a widely used supervised learning method that finds widespread use in several disciplines, such as signal processing, medical applications, natural language processing, and voice and picture identification. It is employed for solving both classification and regression issues. The primary goal of the Support Vector Machine (SVM) technique is to identify an optimal hyperplane that effectively separates data points belonging to different classes. The term "best" refers to the hyperplane that exhibits the maximum level of discrimination between the two classes, denoted as plus and minus, in the provided figure. The term "margin" refers to the maximum width of the slab parallel to the hyperplane, excluding any data points within its interior. The previously indicated methodology can discern a hyperplane by itself in situations when the issue demonstrates linear separability. Nevertheless, in most real circumstances, the approach primarily focuses on maximizing the soft margin, which permits a limited number of misclassifications [14].

Fig. 1. The structure and components of SVM [15].

Support vectors are a specific subset of the training data that are utilized to determine the exact position of the separation hyperplane. The Support Vector Machine (SVM) method is commonly utilized to solve binary classification tasks, where the goal is to assign instances to one of two mutually exclusive categories. The problem of multiclass classification is often decomposed into a set of binary classification tasks. After a comprehensive investigation of the mathematical intricacies involved, it becomes apparent that support vector machines are categorized as kernel approaches in machine learning. Within this particular scenario, the characteristics can undergo a metamorphosis through the utilization of a kernel function. Kernel functions are mathematical functions that transform data, often resulting in an augmented space with increased dimensions. This improvement aims to enhance the capacity to discern between classes, making it easier to differentiate them. The use of a kernel function facilitates the conversion of complex non-linear decision boundaries into linear ones inside

a feature space of higher dimensions. This technology eliminates the requirement for explicit data transformation, reducing its significant computing costs. The kernel trick, a widely recognized method in academic discourse, is alluded to study [16].

2) *Adaboost*: Ensemble learning is a computational approach that integrates many foundational algorithms to construct an optimized prediction algorithm. An illustration of a categorization decision tree may be shown by utilizing several elements transformed into rule-based queries. The Decision Tree algorithm decides or proceeds to evaluate another element based on the outcome of each aspect. The certainty of the outcome in a decision tree may be diminished when many decision rules are involved, such as when the decision threshold is ambiguous or when additional sub-factors are included for consideration. Ensemble approaches offer advantageous use in this specific scenario. Ensemble methods are applied as a viable alternative technique to decision-making, whereby several decision trees are implemented instead of relying on a single tree. By amalgamating the forecasts generated by these several trees, a more resilient and precise predictor is produced. The AdaBoost algorithm, a widely recognized ensemble learning technique referred to as "meta-learning," was initially developed to enhance the effectiveness of binary classifiers. The AdaBoost strategy employs an iterative methodology to use the errors generated by weak classifiers, enhancing their efficacy to align with robust classifiers [17].

3) *Multilayer Perceptron (MLP)*: The MLP neural network is categorized as a feedforward neural network. The architecture of this neural network is distinguished by the presence of interconnected nodes across several hierarchical

levels, constituting an Artificial Neural Network. The name "Perceptron" was first proposed by Frank Rosenblatt in his software implementation of the perceptron. The perceptron is a crucial element of an artificial neural network, playing a pivotal role in defining the artificial neuron inside the network. The supervised learning algorithm calculates the output by using several components, including nodes' values, activation functions, inputs, and node weights. The MLP Neural Network acts solely in the forward direction. Every individual node inside the network is interconnected with all other nodes. Within a specific network, data exchange between nodes is limited to unidirectional transmission in the forward direction. The Backpropagation technique in the MLP neural network is employed to improve the accuracy of the training model [18].

The MLP possesses the capability to enhance and fortify the forward architecture of the neural network. The system consists of three distinct tiers: the input, yield, and covered-up layers, as seen in Fig. 2. The principal role of the input layer is to accept the input signal that necessitates processing. The yield layer assumes the responsibility of executing the assigned task, encompassing tasks like prediction and categorization. The incorporation of many hidden layers into an MLP plays a crucial role in the computational procedure, enabling the transformation of input data into output predictions. The transmission of information in a unidirectional manner occurs from the input layer to the output layer, matching the feedforward structure commonly found in an MLP. The backpropagation learning method is employed to train the neurons within the MLP. This technique has been designed to address continuous tasks effectively and demonstrate the capacity to manage situations with limited separability. The MLP is extensively employed in several fields, including design categorization, pattern recognition, prediction, and estimate [19].

Fig. 2. The components of MLP neural network [20].

4) *Gaussian kernel (GK)*: The mathematical point's physical counterpart is the Gaussian kernel. It is semi-local rather than strictly local, like the mathematical point. Its inner scale, s , indicates that its extent is Gaussian weighted. The GK

is defined as follows in one-dimensional, two-dimensional, and neuronal dimensions [21]:

$$G_{1D}(x; \sigma) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{x^2}{2\sigma^2}}, G_{2D}(x, y', \sigma) = \frac{1}{2\pi\sigma^2} e^{-\frac{x^2+y'^2}{2\sigma^2}},$$
$$G_{ND}(\vec{x}; \sigma) = \frac{1}{(\sqrt{2\pi}\sigma)^N} e^{-\frac{|\vec{x}|^2}{2\sigma^2}} \quad (1)$$

The value of σ determines the extent or breadth of the Gaussian kernel. The Gaussian probability density function in statistics is characterized by its standard deviation, denoted as σ , and its variance, represented as σ^2 . In the context of observations, the Gaussian function is commonly employed as an aperture function. In this discussion, the variable "s" will be utilized to denote the inner scale, which may also be referred to as the scale. The scope of this work is restricted to positive values, namely when σ is greater than zero. In the observation process, it is impossible for s to be diminished to a value of zero. This entails observing via a much diminutive aperture, a practically impractical task. The inclusion of the factor of two in the exponent is a typical practice. Utilizing a simplified diffusion equation formula facilitates a more streamlined approach, which will be further elaborated upon in subsequent sections. In order to distinctly differentiate the spatial and scale qualities, it is conventional to employ a semicolon as a means of demarcation between them.

5) *Random Forest (RF)*: The RF classifier is a methodology that entails the creation of many decision trees using bootstrapping, followed by aggregating their outcomes using a technique known as bagging. During bootstrapping, several decision trees are simultaneously trained on different regions of the training dataset, utilizing distinct subsets of the available features. The reduction of the total variance in the RF classifier is achieved by ensuring the uniqueness of each decision tree inside the random forest. The RF classifier has proficient generalization abilities as it effectively integrates the decisions made by individual trees to provide a conclusive inference. The RF classifier is commonly employed to mitigate the issue of overfitting since it frequently demonstrates higher accuracy levels than other classification methods. The Random Forest (RF) algorithm is a robust and versatile machine-learning technique that can effectively handle both classification and regression tasks. During the training phase, the system constructs many decision trees in order to facilitate its operation. In the creation of each tree within the forest, a separate selection of random subsets of the dataset and random subsets of features is performed, hence introducing variability to the individual trees [22].

The ensemble learning approach, which combines predictions from several decision trees to get a final prediction, is the underlying idea of RF [23]. Every tree in the forest produces a result during the prediction phase, and the ultimate output of the Random Forest is defined as the mean for

regression tasks or the mode of these predictions for classification tasks. This method aggregates predictions from several decision trees, which helps reduce overfitting problems frequently seen in individual trees. Furthermore, RF offers a feature importance metric that helps determine how critical factors affect the model's predictions. In a variety of industries, like banking, healthcare, and bioinformatics, RF is a preferred option due to its stability, capacity for handling big datasets, and resistance to overfitting. Its broad application and efficacy in real-world settings are attributed to its flexibility to a variety of datasets and comparatively low number of hyperparameters that require tuning.

6) *Mouth Brooding Fish (MBF)*: The contemporary rise in complexity of global optimization issues across several industries has prompted the emergence of multiple methodologies aimed at tackling these challenges. Meta-heuristics, which draw inspiration from swarm intelligence and evolutionary computation, provide model solutions driven by real-world phenomena. The MBF algorithm, a computational model, mimics the symbiotic interaction methods [27] employed by organisms for survival and reproduction within an ecosystem [24]. The algorithm under consideration utilizes the locomotion, dispersion, and defense strategies exhibited by Mouth Brooding Fish as a conceptual framework for determining the optimal course of action. One notable benefit of mouthbrooding is the enhanced protection it provides to eggs from potential predators, resulting in a greater likelihood of successful hatching than eggs dispersed over the ocean. The act of mouthbrooding, however, can lead to significant consequences and impose restrictions on the parent's capacity to provide nourishment [25].

Within the natural world, the institution of marriage plays a crucial role in facilitating the convergence of individuals and

Aiding colonies or populations in attaining optimal circumstances, as seen in Fig. 3. However, in instances where it does occur, the outcomes are rarely favorable. Fish that engage in reproductive behavior with their preferred cichlids are sometimes referred to as engaging in brooding activities. As a result, the MBF approach employs a probability distribution or Roulette Wheel selection mechanism to determine the selection of one pair of parents from each group, with higher point values being associated with a greater possibility of selection. According to the research findings, it has been shown that cichlids born in different locations can replace adult individuals within the population, even without undergoing migration [24]. Before applying a fitness function to evaluate the fitness of recently born fish, it is imperative to ascertain that the new places for the offspring fall inside the boundaries of the search space.

Fig. 3. Mouth Brooding Fish Algorithm [26].

B. Evaluation Criteria

The comparison of findings involves the evaluation of five primary variables, namely F-score, accuracy, specificity, sensitivity, and precision. Accuracy refers to the extent to which a measured value aligns with the actual value. On the other hand, precision pertains to the level of consistency or reproducibility observed among several measurements. Precision measures the degree to which the outcomes are accurately aligned. The F1 score is a metric that combines accuracy and recall, considering both false positives and false negatives. It is calculated as a weighted average. The test's specificity pertains to its ability to identify individuals unaffected by the condition being tested for accurately. From a mathematical perspective, tests with high specificity tend to provide few positive results in persons in good health.

Consequently, a positive outcome from such a test can be employed as evidence to support the confirmation of a diagnosis. A test's ability to detect an ailment's presence is contingent upon its sensitivity. A low occurrence of false negative outcomes in high-sensitivity testing translates into a reduced likelihood of overlooking cases of sickness. The specificity of a test refers to its ability to identify individuals without an illness as negative correctly. In alternative terms, specificity refers to the ratio of individuals who receive a negative test result for condition X, although they do not possess the actual condition. A particular diagnostic test ensures accurate identification of individuals without any underlying health conditions, minimizing false positive results.

The term "True Negative," sometimes abbreviated as "TN," refers to the outcome that accurately represents the number of negative instances that have been correctly classified. Likewise, the acronym "TP" denotes True Positive, representing the ratio

of accurately detected positive instances. The phenomenon wherein negative occurrences are erroneously classified as positive is called false positives, or "FP" situations. On the other hand, the acronym "FN" denotes the False Negative metric, representing the count of truly positive instances that have been erroneously classified as negative. The accuracy metric is commonly utilized in the context of data classification. The correctness of a model may be evaluated using a confusion matrix, which can be calculated using the formula provided.

$$Accuracy = \frac{TN+TP}{TN+FP+FN+TP} \quad (2)$$

In addition, the metrics used for evaluating the performance of a model, namely precision (P), sensitivity (Sn), sometimes referred to as true positive rate (TPR), specificity (Sp), and F-score, are determined based on the data obtained from the confusion matrix:

$$P = \frac{TP}{FP+TP} \quad (3)$$

$$Sn = \frac{TP}{FN+TP} \quad (4)$$

$$Sp = \frac{TN}{FP+TN} \quad (5)$$

$$F - score = 2 \times \frac{P \times Sn}{P + Sn} \quad (6)$$

C. Dataset

The "Password Security: Sber Dataset" encompasses a comprehensive collection of anonymized and diversified password-related data sourced from Sberbank, one of the largest financial institutions in Russia. This dataset incorporates a vast array of password-related information, including but not limited to password complexity, frequency of usage, patterns, and

associated user behaviors. Its rich and extensive nature allows for in-depth analysis and exploration of password security trends, aiding researchers and cybersecurity experts in understanding the nuances of password creation, usage habits, and potential vulnerabilities. With its diverse pool of password samples, this dataset is a valuable resource for studying and improving password security measures. It offers insights that can contribute to developing more robust and resilient authentication systems in the digital sphere. The dataset was provided in the "Beauty Contest of the code from Sber," whereby the task involved categorizing password complexity into three distinct classifications. For pre-processing, different ciphertxts, which are the main input of the model, are decoded into numerical values by the Word2vec language model. All input data are mapped to the 0 and 1 range and normalized.

The observed disparities in comparing outcomes across various datasets may be ascribed to the distinct attributes and intricacies inherent in each dataset. The potential exists for the suggested algorithms to demonstrate varying levels of performance depending on the characteristics of the data they encounter. SVM is particularly effective in handling datasets that have distinct class boundaries and features that can be separated linearly. On the other hand, AdaBoost may outperform SVM in datasets with noisy or imbalanced distributions by iteratively concentrating on instances that are challenging to classify. In a similar vein, the MLP has the potential to be efficacious in addressing intricate, non-linear associations among features inside datasets of high dimensionality. Conversely, GK techniques may provide resilience against noise and outliers in datasets characterized by non-parametric distributions. The Random Forest (RF) algorithm, which combines ensemble learning with decision trees, can effectively handle datasets that have diverse feature spaces and different

class distributions. It demonstrates consistent performance in many settings. Hence, the varying appropriateness of the suggested algorithms for certain data types highlights the need of taking into account the underlying attributes of the dataset when choosing and assessing classification techniques in password security systems.

- The dataset has two columns.
- The password is a string, and its complexity class is denoted by a value of 0, 1, or 2.
- The password "0" might be seen as an unstable choice, whereas the password "2" is regarded as very reliable.

IV. RESULTS AND DISCUSSION

This section thoroughly examines and elucidates the principal discoveries obtained from the research investigation. Moreover, the effectiveness of the proposed algorithm in data classification is supported by a thorough analysis of pertinent scholarly literature. The assessment of the effectiveness of a classification model in the fields of statistics and machine learning can be carried out by utilizing a confusion matrix, as seen in Fig. 4. The information presented provides a thorough overview of the categorization outcomes, encompassing the estimated amounts of true positive, true negative, false positive, and false negative cases. The data depicted in Fig. 4 provides compelling evidence that the MBF algorithm outperforms the alternative methods in terms of performance. The utilization of confusion matrices is a prevalent approach in the assessment of classification algorithms' performance. This approach can offer advantages for both binary and multiclass classification tasks. Confusion matrices offer a structured depiction of the observed and expected values, presenting the frequencies for all possible combinations in a tabular format.

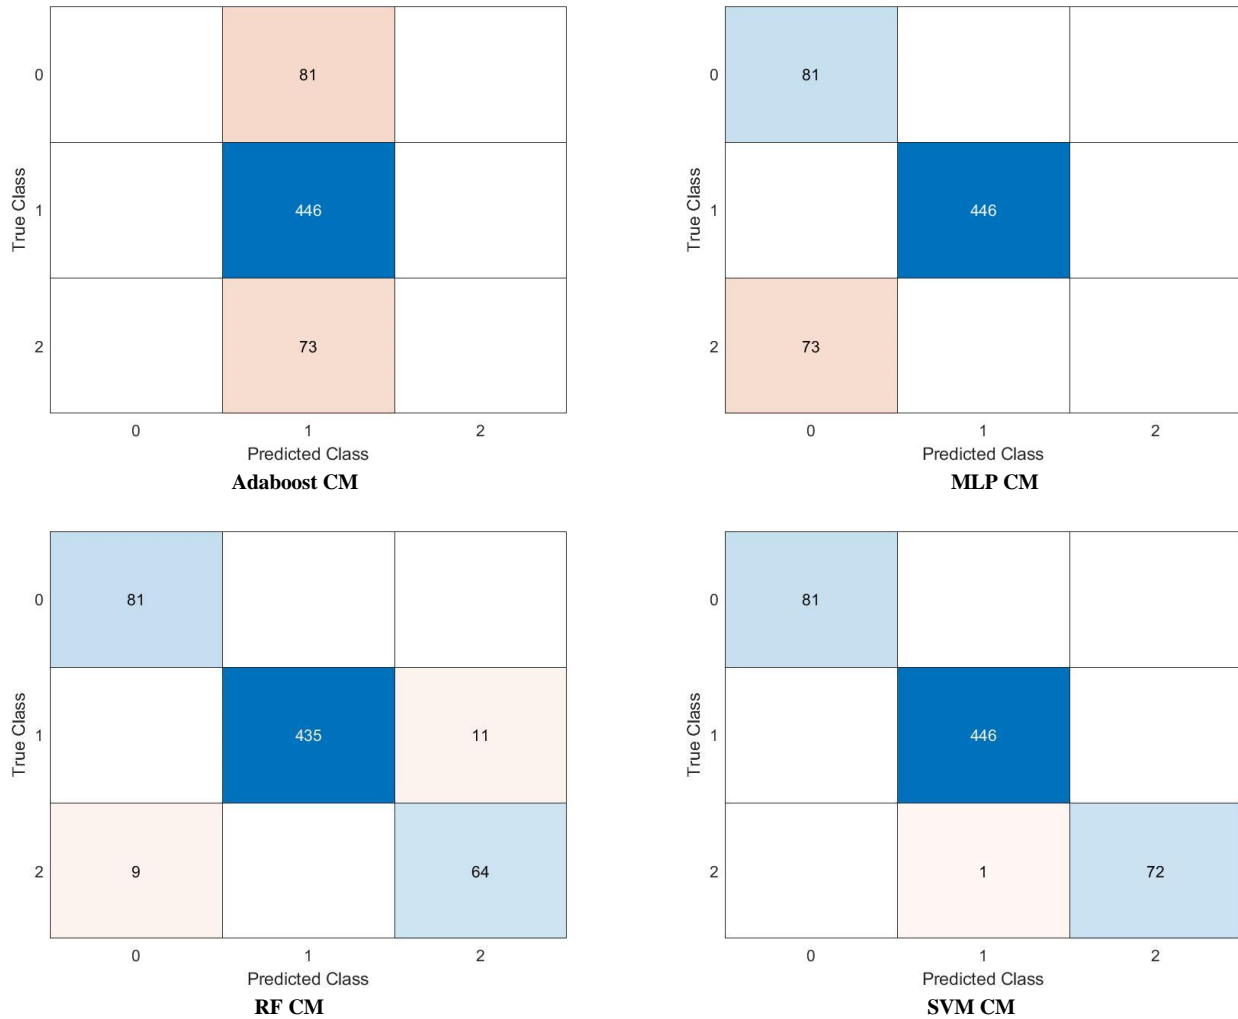

Fig. 4. The outputs of the confusion matrix for the considered algorithms.

Fig. 5 demonstrates the heightened sensitivity of MBF, enabling it to detect a substantial fraction of positive cases accurately. The analysis reveals that the contribution of the goalie is comparatively less advantageous when considering the TPR framework. Furthermore, the analysis of the statistical data presented in Fig. 6 leads to the conclusion that the performance of MBF may be deemed adequate. The fundamental framework of the operational ensemble model is established by applying weighted aggregation, which combines the outputs obtained from individual machine-learning models. The primary aim of the MBF technique is to ascertain the optimal weighted sum of

probability values calculated by each model for every issue class. The objective function of the MBF approach can be seen as equivalent to the ultimate accuracy value attained in the classification procedure. Therefore, the MBF approach calculates the weighted probabilities for each sample in the class and evaluates their correctness by comparing them to the given labels. The MBF approach is commonly linked to the anticipated labels. In addition, a comparison study was conducted to assess the chosen algorithms in connection to the core technique of the proposed ensemble. This was achieved by comparing their classification outcomes.

Fig. 5. The true positive rate for the selected algorithms.

Fig. 6. The accuracy of the presented method according to the iteration and fitness.

The F-score, accuracy, specificity, and sensitivity values for the various models selected are depicted in Figs 7 to 11. In terms of the identified criterion values seen in the work, MBF demonstrates superior performance. The performance of Adaboost in data classification could be better. SVM has also demonstrated remarkable performance in terms of F-score, accuracy, and sensitivity, positioning it as a viable alternative to MBF. The results depicted in Fig. 7 to Fig. 11 align with the findings in Table I. With a specificity of 99.83%, the SVM has a slightly higher accuracy level than the MBF. The F-score, accuracy, sensitivity, and specificity metrics for MBF exhibit

noteworthy performance compared to the other selected models, with values of 100%. The MBF technique, as suggested, demonstrates a higher level of effectiveness compared to prior methods [8, 11, 13, 27] in the categorization of password security. This is achieved by using biological inspiration to improve the durability and flexibility of the method in digital contexts. MBF utilizes the inherent biological principles of adaptation and protection found in nature, in contrast to traditional ML methods that mostly depend on algorithmic patterns. The incorporation of approaches inspired by the minimal Bayes risk framework in MBF allows for enhanced

resistance against common cyber risks, including brute-force assaults and dictionary-based guessing [9, 15]. Furthermore, the thorough assessment of MBF in conjunction with well-established machine learning algorithms showcases its exceptional performance across several measures, such as accuracy, F-score, sensitivity, and specificity. The research highlights the possibility of combining biological principles with technological advancements, such as MBF, to improve the efficiency of password security systems and address the changing landscape of cybersecurity.

The implementation of a password security system inspired by the MBF has significant potential for improving digital safeguarding measures in practical settings. When biological principles are included into cybersecurity frameworks, it is possible for these systems to demonstrate enhanced resilience and flexibility in the face of ever-changing cyber threats. The unique method to solving cybersecurity concerns is offered by the adaptive behaviors and innate defense mechanisms seen in Mouth Brooding Fish (MBF). For example, approaches inspired by the minimal Bayes framework (MBF) have the potential to provide improved resilience against advanced adversarial assaults, such as brute-force password guessing and dictionary-based attacks, via the use of the MBF-inspired approach. Incorporating biological principles has the potential to provide innovative approaches to password creation and authentication, which might enhance user experience and system usability. Furthermore, the integration of biological and technical methodologies in MBF-inspired systems has promise for stimulating advancements in the field of password security research and development. This, in turn, may facilitate the creation of more resilient and robust cybersecurity solutions.

Nevertheless, it is crucial to recognize the constraints of the research and the possible circumstances in which MBF may exhibit diminished efficacy. Firstly, while the research shows encouraging outcomes, the efficacy of MBF-inspired approaches may differ based on the particular attributes of the dataset used and the deployment situation. Potential biases present in the dataset, such as uneven distribution of classes or a lack of variety in password samples, may impact the applicability of the results and the effectiveness of the MBF technique in real-life situations. Furthermore, it is necessary to

do further research to determine the practicality and scalability of implementing MBF-inspired systems. This includes examining factors such as computing resources, implementation complexity, and compatibility with current cybersecurity infrastructures. In addition, it is crucial to carefully analyze and provide ethical supervision in future research and development endeavors when using biological inspiration in technology systems. This is due to the possible ethical consequences that may arise, particularly in relation to animal welfare and ecological sustainability. In summary, while password security methods inspired by MBF show promise for improving cybersecurity, more study and validation are necessary to overcome the stated limitations and fully exploit their potential in practical scenarios.

When contemplating future research approaches, it is crucial to examine many prospective pathways in order to augment the effectiveness and practicality of password security categorization systems. To begin with, the implementation of further experiments on bigger and more diversified datasets has the potential to provide significant insights on the resilience and applicability of the suggested approaches in various real-world contexts. Furthermore, exploring new methods for extracting features and learning representations that are specifically designed for password data has the potential to enhance the effectiveness of traditional ML techniques as well as innovative biological-inspired approaches such as MBF. Furthermore, investigating the incorporation of sophisticated cryptographic methods, such as homomorphic encryption or secure multiparty computation, could provide improved assurances of privacy and confidentiality in password security systems, especially in situations involving sensitive or personal data. Moreover, the establishment of interdisciplinary partnerships among cybersecurity professionals, biologists, and computer scientists has the potential to cultivate inventive resolutions that harness the combined knowledge of many fields in order to tackle intricate issues pertaining to password security. Overall, these prospective undertakings offer the potential to improve the state-of-the-art in password security categorization and contribute to the establishment of more strong and resilient cybersecurity frameworks in the digital age.

TABLE I. COMPARISON BETWEEN THE SELECTED METHODS BASED ON THE STATISTICAL RESULTS

	SVM	Adaboost	MLP	Gaussian Kernel	RF	MBF
Accuracy	0.998333	0.743333	0.878333	0.878333333	0.9666667	1
F_score	0.99734	0.41	0.61	0.61	0.9339406	1
Precision	0.995434	0.333333	0.666667	0.666666667	0.9506829	1
Sensivity	0.999254	0.5	0.57	0.57	0.9177778	1
Specificity	0.999369	0.7	0.959444	0.959444444	0.9707814	1

V. CONCLUSION

In summary, a new ensemble model was presented in this paper to solve the classification problems. The dataset used was "Password Security: Sber Dataset," which is considered a new and appropriate dataset. For pre-processing, different ciphertexts, which are the primary input of the model, were decoded into numerical values by the Word2vec language model. All input data were mapped to the 0 and 1 ranges and normalized. The structure of the working ensemble model was based on the weighted combination of the outputs of each of the used ML models. Finding the most optimal weighted sum of probabilities calculated by each model for each class of the problem is the goal of the MBF algorithm. The objective function of the MBF algorithm was obtaining a striking accuracy for the classification. After summing up the probability values of each class, they were determined by the MBF algorithm for each sample of the class in question, and the accuracy value was determined by comparing the labels assigned by the MBF algorithm with the expected labels. Several ML approaches, such as SVM, AdaBoost, MLP, GK, and RF, were investigated to emphasize the advantages of the suggested approach. The performance of Adaboost in data classification could have been improved. SVM had also demonstrated remarkable performance in terms of F-score, accuracy, and sensitivity, positioning it as a viable alternative to MBF. With a specificity of 99.83%, the SVM had a slightly higher accuracy level than the MBF. The F-score, accuracy, sensitivity, and specificity metrics for MBF indicated the proposed method's better performance compared to the other selected models, with values of 100%.

When contemplating future research approaches, it is crucial to examine many prospective pathways in order to augment the effectiveness and practicality of password security categorization systems. To begin with, the implementation of further experiments on bigger and more diversified datasets has the potential to provide significant insights on the resilience and applicability of the suggested approaches in various real-world contexts. Furthermore, exploring new methods for extracting features and learning representations that are specifically designed for password data has the potential to enhance the effectiveness of traditional ML techniques as well as innovative biological-inspired approaches such as MBF. Furthermore, investigating the incorporation of sophisticated cryptographic methods, such as homomorphic encryption or secure multiparty computation, could provide improved assurances of privacy and confidentiality in password security systems, especially in situations involving sensitive or personal data. Moreover, the establishment of interdisciplinary partnerships among cybersecurity professionals, biologists, and computer scientists has the potential to cultivate inventive resolutions that harness the combined knowledge of many fields in order to tackle intricate issues pertaining to password security. Overall, these prospective undertakings offer the potential to improve the state-of-the-art in password security categorization and contribute to the establishment of more strong and resilient cybersecurity frameworks in the digital age.

Abstract—Android Malware Detection has become increasingly prevalent, with the highest market share among all other mobile operating systems due to its open-source nature and user-friendliness. This has resulted in an uncontrolled proliferation of malicious applications targeting the Android platform. Emerging trends of Android malware are employing highly sophisticated detection and analysis evasion techniques, rendering traditional signature-based detection methods less effective in identifying modern and unknown malware. Alternative approaches, such as Machine Learning methods, have emerged as leading solutions for timely zero-day anomaly detection. Ensemble learning, a common meta-approach in machine learning, seeks to improve predictive performance by amalgamating predictions from multiple models. This paper introduces an enhanced strategy, Mouth Brooding Fish (MBF), based on ensemble learning for Android Malware Detection (AMD). The findings are further compared with the outputs of various algorithms including Support Vector Machine (SVM), AdaBoost, Multilayer Perceptron (MLP), Gaussian Kernel (GK), and Random Forest (RF). Compared to the other selected models, MBF exhibits remarkable performance with an F-score of 98.57%, precision of 99.65%, sensitivity of 97.51%, and specificity of 97.51%. Thus, the significant novelty of this work lies in the accuracy and authenticity of the selected algorithms, demonstrating their superior performance overall.

Keywords—Android malware detection; ensemble learning; SVM; MLP; RF

I. INTRODUCTION

Due to the nearness of innovation in all areas of our everyday lives, cyber security has become one of the biggest concerns to be attended to by society. In a long time, there has been a considerable number of assaults and, what is indeed more exceptional, to a wide assortment of destinations. A few later well-known cases incorporate refusal of benefit assaults such as that performed by the Mirai botnet [1] and an enormous information seizure driven by the ransomware Wannacry [2]. However, the widespread use of mobile phones has turned out to be a significant contributing factor to a sharp increase in malware attacks. Because these malicious programs are hidden within legitimate programs, it is difficult to identify and categorize them. Because they use a signature-based methodology, the current processes are unable to differentiate between hidden malware [3].

The most widely used operating system (OS) is Android, which is also continuing to increase its market share. Android is an open-source platform that allows users to download apps from the Google Play Store and third-party developers. Because

of its popularity and openness, Android has drawn the attackers' attention. According to McAfee's security reports, 49 million new malware and 121 million existing malwares were discovered in 2020 [4]. Any malicious code that compromises a user's privacy, accessibility, or keenness is referred to as malware. The malicious programs seem to be real, but they carry out harmful operations behind the scenes. Malware uses a variety of techniques, such as tracking the client's region and jumbling individual data. Malicious programs (apps) try to infiltrate Android devices in order to steal personal data, place phone calls, send SMS, and do other activities. According to McAfee's estimate, there will be 49 million and 121 million new instances of contemporary malware and cumulative malware by 2020, respectively [5]. The escalating pace of Android malware's advancement poses a significant threat to users of the Android operating system. Clients are required to determine the malicious nature of an application due to the need for data acquisition and comprehension. When acquiring an application from the Android application store, a significant number of Android users tend to overlook or neglect the examination of the terms and conditions. Regrettably, perpetrators exploit this reality and specifically target portable electronic devices [6].

Due to the increment in Android malware, physically handling malevolent tests has become troublesome. To overcome this restriction, it is vital to construct a proficient strategy for better distinguishing hazards of applications. A prior signature-based approach was utilized to distinguish proof of malware. This approach is based on coordinating the app's signature within the database. This strategy's confinement is that it cannot identify obscure malware [7]. On a customary premise, malware designers make modern malware to undermine the framework's security and its clients' protection. The chance posed by malware requires the improvement of successful strategies. This assessment helps with the arrangement of early notices concerning a particular Android app, permitting quick consideration to be paid to it in terms of apportioning assets [8].

The Android operating system has the dominant position in market share primarily as a result of its seamless functionality and an extensive array of features, which serve to captivate and entice cyber criminals [9]. Traditional Android malware detection methods, such as signature-based or battery consumption monitoring, may fail to detect recent malware. Therefore, we present a novel method for detecting malware in Android applications using MBF. The outcomes of the proposed method are compared with several algorithms, including SVM, Adaboost, MLP, GK, and RF. The following outlines the main

gaps and shortcomings of the related works in the second section. The third section illustrates the selected algorithms for the considered problem and specifies the evaluation criteria calculated for comparison. The used dataset is also explained in the fourth section. The results are discussed in the fifth section to specify the superiority of MBF over the other algorithms. The findings and suggestions for future work are presented in the sixth section.

II. LITERATURE REVIEW

As seen from the literature, many advances have been made regarding AMD. Grace et al. [10] proposed RiskRanker, which is an automated method designed to assess the level of risk associated with a given application. The experiments were conducted by aggregating a total of 118,318 applications sourced from various Android stores. The findings indicate that RiskRanker showed effectiveness and flexibility in regulating Android marketplaces. Idress et al. [11] introduced PIndroid, a system designed to locate and analyze malware. This system focuses on gathering learning tactics to enhance its effectiveness. This study focuses on a methodology for detecting malware that integrates the intersection and union set operations with data aggregation techniques. The aforementioned methodology was implemented on a sample size of 445 untainted and 1300 contaminated Android applications that were obtained from both third-party and official channels. The researchers reached the conclusion that the suggested approach has the potential to be used for the categorization of Android applications. In Sharma et al.'s [11] study, the malicious capabilities were categorized by analyzing notable features identified during both passive and active malware assessments, as well as the malware nomenclature used by antivirus vendors. The authors presented a methodology for addressing discrepancies in malware analysis by using fuzzy logic to evaluate the many functionalities of malicious software. In agreement with the planned FIS, it was determined that 83% of malware testing was discovered to belong to the same cluster for malware-recognizable proof. Mariconti et al. [12] presented the MAMADROID framework, which depends on static malware analysis and was successfully deployed. Malware detection employs static characteristics, like API calls and call graphs. The study included the evaluation of a dataset consisting of 3.5 million harmful applications and 8.5 million benign applications. The strategy that was suggested resulted in an F-measure of 0.99. Jang et al. [6] demonstrated Andro-Autopsy, an antimalware mechanism that protects mobile devices. The findings suggested that the proposed system can detect and classify malware. In the work of Sharma et al. [13], the RNPdroid approach was offered as a means of doing risk assessments by leveraging permissions. The suggested methodology is assessed using the MODroid dataset, including 400 Android samples with 165 characteristics. The T-test and ANOVA were employed for statistical analysis. The findings indicate that, with a significance level of 5%, the computed F value of 517.3 exceeds the critical F value of 2.61. Gandotra et al. [14] presented a novel approach using fuzzy logic to automate the calculation of the damage potential of malware programs. This technique relies on extracting characteristics via automated analysis.

Moreover, Zhu et al. [15] used SVM as the fusion classifier to learn the implicit supplementary information from the output of the ensemble members and yield the final prediction result. The creators appeared that exploratory comes about on two partitioned datasets collected by inactive investigation to demonstrate the viability of the SEDMDroid. The primary ones extricate consent, touchy API, checking framework occasion, and so on that are broadly utilized in Android malware as highlights. Sedmdroid accomplishes 89.07% precision in terms of these multi-level inactive highlights. The moment one, an open enormous dataset, extricates the touchy information stream data as the highlights, and the normal exactness was 94.92%. The promising try reveals that the proposed strategy was a successful way to recognize Android malware. Bhat et al. [16] proposed a precise dynamic analysis approach to identify several malicious attacks. The proposed strategy centered on behavioral examination of malware that requires remaking the behavior of Android malware. The energetic behavior highlights incorporate framework calls, covers, and complex Android objects (composite behavior). The strategy was utilized to evacuate unessential highlights for effective malware location and classification. For classification, the homogeneous and heterogeneous outfit machine learning calculations were utilized.

The stacking approach had the most excellent classification, with a precision rate of 98.08%. The thorough test of the viability and predominance of the show. In another paper [17], a total of seven feature selection methods were used in order to choose permissions, API calls, and opcodes. Subsequently, the outcomes of each feature selection process were combined to provide a novel feature set. Following this, the authors used this technique to educate the foundational learner. The researchers used logistic regression as a meta-classifier in order to extract implicit information from the output of the base learners and generate the final classification outcomes. Following the examination, the F1-score of MFDroid achieved a value of 96.0%. Ultimately, an examination was conducted on each sort of feature in order to ascertain the distinctions between dangerous and benign applications. Atacak [18] proposed the use of a fuzzy logic-based dynamic ensemble (FL-BDE) model for the purpose of detecting malware that is targeted towards the Android operating system. The findings indicated that the FL-BDE model had outstanding results compared to the ML-based models. It achieved an accuracy of 0.9933, a recall of 1.00, a specificity of 0.9867, a precision of 0.9868, and an F-measure of 0.9934.

Due to the outcomes of the previous works, it is interesting to compare Android malware detection techniques with MBF. Even though malware detection algorithms and MBF function in entirely separate fields, comparing the two might be a thought-provoking exercise. To demonstrate the possible benefits of MBF over conventional algorithms in the context of Android malware detection, the following comparison study is provided in the current work:

Adaptability and Learning: Fish that raise their young in their jaws demonstrate adaptable parental care. Likewise, MBF may represent a method that, instead of algorithms, learns from and adjusts to novel dangers more naturally. By monitoring and responding to abnormalities similar to a live creature, they could

"protect" the system and continuously adjust to new dangers without explicit programming.

Resilience to Unknown Threats: Fish that rear their young by mouth can keep their young safe from predators. Similarly, utilizing innate reflexes or pattern recognition unconstrained by preset rules or signatures, MBF may represent a theoretical system naturally resistant to dangers posed by zero-day or previously undisclosed malware.

Complexity and Interpretation: Providing MBFs with care necessitates a sophisticated comprehension of the dangers surrounding them. On the other hand, predetermined signatures or behavior patterns are frequently the basis of Android malware detection algorithms, which may miss more nuanced or sophisticated threats. A method that transcends algorithms' interpretive capabilities might be represented by MBF, which is capable of interpreting contextual signals and subtleties.

Resource Efficiency: Fish raising their young by mouthbrooding expend significant energy and resources. Comparatively speaking, MBF may represent a method that maximizes the use of computing resources for malware detection, or it may draw attention to high-risk regions of an Android system.

The adaptation and evolutionary advantage of mouthbrooding fish have developed throughout time to improve their chances of surviving and procreating. By comparison, MBF may stand for continuous evolution in malware detection, in which the system improves with time through experience-based learning and grows increasingly capable of fending off new threats. Even though this analogy is purely theoretical and symbolic, it's crucial to remember that a realistic, ethical, and computationally constrained implementation of MBF in Android malware detection would need thorough investigation and technological viability. However, taking cues from the workings of nature might occasionally result in novel concepts in cybersecurity and technology.

III. METHODOLOGY

The detection of Android malware has significant importance due to many factors. The safeguarding of personal data is a critical concern since malware often targets the theft of sensitive information, including personal particulars, financial records, and login passwords. The detection and prevention of malware on Android devices are crucial in order to protect sensitive information from potential intrusion.

The prevention of financial loss is a critical concern in the realm of cybersecurity. Certain types of malicious software, such as ransomware or banking trojans, possess the capability to target individuals' financial accounts specifically. This targeted approach may result in unlawful transactions or the coercion of monetary funds from unsuspecting users. Detection plays a crucial role in mitigating financial losses resulting from these illicit acts. The preservation of device performance is a crucial concern since malware has the potential to substantially diminish it via resource consumption, resulting in delays and the presentation of invasive advertisements. The identification and eradication of malicious software contribute to the preservation of the device's optimum functionality. Malicious software often capitalizes on weaknesses within the Android operating system

or its apps in order to get illegal entry. The process of detection plays a crucial role in identifying and addressing these vulnerabilities, hence reducing the risk of possible exploitation. Besides, the preservation of user privacy is a critical concern in the realm of cybersecurity. It has been observed that some types of malicious software have the capability to seize control of cameras and microphones, as well as monitor user actions without obtaining proper approval. This unauthorized intrusion into personal devices and activities poses a significant threat to the privacy of users. The act of detection plays a pivotal role in preventing and obstructing instances of privacy infringements. Given the vast number of accessible applications, it is possible that some apps may include harmful code or exhibit undesirable behavior. The detection of malware plays a crucial role in enabling users to download and use apps securely, hence mitigating the risk of compromising their devices or data. The presence of malware may serve as a potential entry point for malicious actors seeking unauthorized access to computer networks. The identification and eradication of malware on Android devices contribute to the preservation of network security, particularly in scenarios where compromised devices serve as gateways for more extensive cyber assaults. Efficient and reliable techniques for detecting malware, such as antivirus software and security upgrades, play a crucial role in mitigating these threats and ensuring a safer and more secure Android environment for consumers. In this section, SVM, Adaboost, MLP, GK, RF, and MBF are illustrated for Android malware detection.

A. Selected Algorithms

1) *Support vector machine (SVM):* Support Vector Machines (SVM) is a powerful supervised learning algorithm that exhibits optimal performance when applied to datasets of smaller sizes. However, its effectiveness diminishes when confronted with complicated datasets. The Support Vector Machine (SVM), sometimes referred to as SVM, is a versatile algorithm that may be used for both regression and classification tasks. However, it is generally more effective in addressing classification problems. Support Vector Machines (SVM) is a supervised machine learning algorithm often used for both classification and regression tasks. Although the term "relapse issues" is often used, it is most appropriate for the purpose of categorization. The primary goal of the Support Vector Machine (SVM) technique is to identify the optimal hyperplane in an N-dimensional space that can effectively separate the data points into distinct classes within the given space. The hyperplane postulates that the boundary separating the nearest centroids of different classes should be maximized. The determination of the hyperplane's measurement is dependent upon the quantity of highlights. When the number of input features is two, the hyperplane may be described as a straight line that fairly separates the data points. When the number of input highlights reaches three, the hyperplane transforms into a two-dimensional plane. It gets difficult to make assumptions when the number of highlights exceeds three. There exists a multitude of potential hyperplanes that may be selected to separate the two groups of data points effectively. Our objective is to identify a plane that exhibits

optimal discrimination, namely, the greatest separation between data points belonging to different classes. The act of maximizing the elimination of edges provides a modest level of support, hence enhancing the accuracy of classifying future information.

2) *Adaboost*: There are numerous machine learning calculations to select from for your issue explanations. One of these calculations for prescient modeling is called AdaBoost. The AdaBoost calculation, brief for Versatile Boosting, may be a Boosting strategy utilized as a Gathering Strategy in Machine Learning. It is called Versatile Boosting, as the weights are re-assigned to each occasion, with higher weights allowed to classify occurrences inaccurately. What this calculation does is that it builds a show and gives rise to weights to all the information focuses. At that point, it allocates higher weights to wrongly classified focuses. All the higher-weight focuses are given more significance within the other demonstration. It'll keep training models until and unless a lower mistake is made. The foremost suited and thus most common calculation utilized with AdaBoost is choice trees with one level. Because these trees are so brief and, as it were, contain one decision for classification, they are often called choice stumps. An AdaBoost classifier may be a meta-estimator that starts by fitting a classifier on the initial dataset and, after that, fits extra duplicates of the classifier on the same dataset but where the weights of erroneously classified occasions are balanced such that consequent classifiers center more on troublesome cases.

AdaBoost limits misfortune work related to any classification mistake and is best utilized with powerless learners. The strategy was primarily planned for twofold classification issues and can be used to boost the execution of choice trees. Slope Boosting is utilized to unravel the differentiable misfortune work issue.

3) *Multilayer perceptron (MLP)*: The multilayer perceptron (MLP) has the potential to enhance and strengthen the forward neural architecture. The system is composed of three distinct levels, namely the input layer, yield layer, and covered-up layer, as seen in Fig. 1. The input layer is responsible for receiving the input flag that needs to be processed. The yield layer is responsible for executing the designated task, such as prediction and categorization. The presence of several hidden layers in a multilayer perceptron (MLP) serves as a crucial computational mechanism, allowing for the transformation of input data into output predictions. Similar to a feedforward architecture in a multilayer perceptron (MLP), the flow of information in the forward direction occurs from the input layer to the output layer. The neurons of the Multilayer Perceptron (MLP) are trained using the backpropagation learning algorithm. Multilayer perceptrons (MLPs) are designed to handle continuous tasks effectively and have the ability to address problems that are not easily separable. The primary applications of multilayer Perceptron (MLP) are design categorization, pattern recognition, prediction, and estimate.

Fig. 1. System modeling utilizing an MLP neural network

4) *Gaussian kernel (GK)*: The GK is defined as follows in one-dimensional, two-dimensional, and neuronal dimensions:

$$G_{1D}(x; \sigma) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{x^2}{2\sigma^2}}, \quad G_{2D}(x, y'; \sigma) = \frac{1}{2\pi\sigma^2} e^{-\frac{x^2+y'^2}{2\sigma^2}},$$
$$G_{ND}(\vec{x}; \sigma) = \frac{1}{(\sqrt{2\pi}\sigma)^N} e^{-\frac{|\vec{x}|^2}{2\sigma^2}} \quad (1)$$

The σ value determines the width of the Gaussian kernel. In statistics, the Gaussian probability density function is the standard deviation, while its square, σ^2 is the variance. When we discuss the Gaussian as an aperture function in observations, we will use "s" to refer to the inner scale or simply the scale. This paper's scale is limited to positive values, where $\sigma > 0$. During the observation process, s can never be reduced to zero. This implies observing through a tiny aperture, which is practically impossible. The inclusion of the factor of 2 in the exponent is merely a matter of convention. It allows us to have a more simplified formula for the diffusion equation, which we will discuss in more detail later. The convention is to include a semicolon between the spatial and scale parameters to distinguish between them clearly.

5) *Random forest (RF)*: As shown in Fig. 2, the Random Forest (RF) classifier is a technique that involves the simultaneous training of many decision trees using bootstrapping, followed by the aggregation of their outputs by a process referred to as bagging. The process of bootstrapping entails the simultaneous training of several decision trees on different subsets of the training dataset, employing varying subsets of the available characteristics. By ensuring the uniqueness of each decision tree inside the random forest, the total variance of the RF classifier is reduced. The Random Forest classifier combines the judgments made by individual trees in order to get a final conclusion, allowing it to demonstrate strong generalization capabilities. In comparison to other classification approaches, the Random Forest (RF) classifier often achieves superior accuracy while avoiding the problem of overfitting [19].

Similar to the Decision Tree (DT) classifier, the Random Forest (RF) classifier does not need feature scaling. Nevertheless, the Random Forest (RF) classifier has superior robustness in the selection of training samples and handling noise within the training dataset compared to the Decision Tree (DT) classifier. Although the RF classifier is more difficult to read, it has the advantage of simplified hyperparameter adjustment in comparison to the DT classifier.

6) *Mouth brooding fish (MBF)*: According to Fig. 3, Paternal mouthbrooders, often known as mouth-brooding fish, are a group of animals in which the male fish assumes the responsibility of incubating the fertilized eggs inside his oral cavity until they reach the hatching stage. The manifestation of this distinctive kind of parental care is mostly seen in certain species of cichlids, which constitute a diversified assemblage of freshwater fish distributed throughout numerous regions globally [21]. In the phenomenon of mouth brooding, after the

deposition of eggs by the female, the male proceeds to fertilize them and then collects them into his oral cavity by the use of his lips. The male exhibits parental care by safeguarding the eggs inside his oral cavity, so shielding them from any threats posed by predators. Additionally, he ensures enough oxygen supply to the eggs by a recurrent process of expelling and re-ingesting them, facilitating their oxygenation [22]. During the incubation stage, which exhibits variability in length contingent upon the species under consideration, the male abstains from consuming sustenance and dedicates his efforts exclusively towards the protection and preservation of the eggs. After the eggs have hatched, it is common for the fry, which refers to the juvenile fish, to be temporarily sheltered inside the oral cavity of the male fish until they have acquired the strength to explore their surroundings independently. The observed behavior exemplifies noteworthy parental investment, which serves to enhance the likelihood of offspring survival via the provision of protection throughout the crucial first phases of development. There are variances seen across different species in terms of their mouth-brooding behaviors, including factors such as the period of incubation and the extent of parental care shown after the discharge of the fry.

In nature, marriage is a crucial mechanism that aids colonies or populations in achieving optimal outcomes by promoting convergence. However, it only sometimes yields favorable outcomes when it occurs. Mouth-brooding fish allow their best cichlids to mate. Thus, the MBF algorithm selects one pair of parents from each cichlid using a probability distribution or Roulette Wheel selection (where higher point values have a higher likelihood). Cichlids that hatch in a new position replace their parents in the population without moving [24]. Before assessing the fitness of the newly hatched fish using a fitness function, we need to ensure that the new positions for the offspring are within the boundaries of the search space.

B. Evaluation Criteria

The primary factors for comparing the results are F-score, accuracy, specificity, sensitivity, and precision [25]. Precision refers to a slight variation between two or more measurements, whereas accuracy represents the disparity between a result and its actual value. The end outcomes should align well, as indicated by precision. The F1 score is the weighted average of precision and recall, including false positives and negatives. Specificity is the test's ability to identify unstick people correctly. Mathematically, a test with high specificity that produces a positive result can confirm a disease because it rarely produces positive results in healthy people. A test's sensitivity determines whether it detects a disease. High-sensitivity tests have few false negatives, reducing disease cases missed. The specificity of a test refers to its capability to correctly identify someone who does not have a disease as being negative. To put it differently, specificity refers to the percentage of individuals who do not have Disease X and receive a damaging result on their blood test. A particular test ensures that all healthy individuals are accurately recognized as healthy, meaning no incorrect positive results exist.

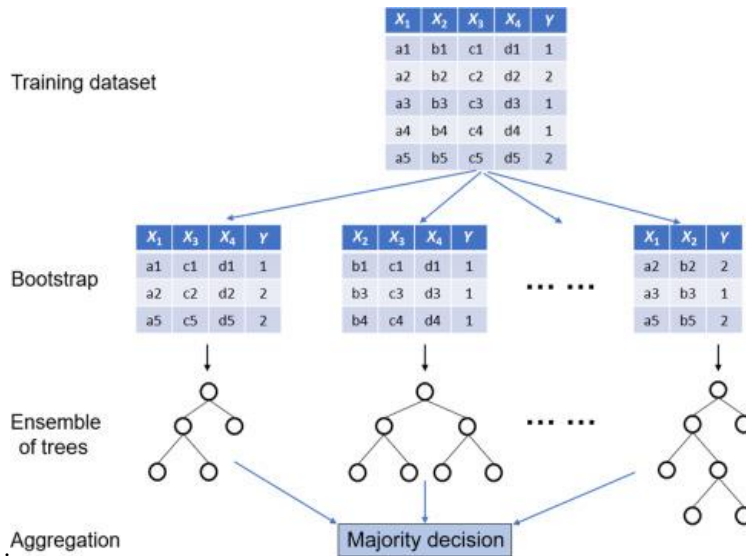

Fig. 2. A dataset with two classes (Y = 1) and four features (X1, X2, X3, and X4) is employed to build a Random Forest (RF) classifier. The RF classifier is an ensemble method that uses bootstrapping and aggregation to train multiple decision trees. Each tree is trained on unique subsets of training samples and features [20]

Fig. 3. Mouth Brooding Fish Algorithm [23]

The term "True Negative," sometimes abbreviated as "TN," refers to the outcome that accurately identifies the number of negative instances that have been properly classified. Likewise, the acronym "TP" denotes True Positive, indicating the ratio of accurately recognized positive instances. The term "FP" is used to denote the occurrence of false positives, which refers to the number of cases that are negative but are incorrectly classified as positive. On the other hand, the word "FN" is used to denote the False Negative value, which refers to the count of real positive cases that have been misclassified as negative. The metric of accuracy is often used for the classification of data. The correctness of a model may be determined by using a confusion matrix, which is calculated using the following equation [26].

$$Accuracy = \frac{TN+TP}{TN+FP+FN+TP} \quad (2)$$

Moreover, precision (P), sensitivity (Sn), also known as true positive rate (TPR), specificity (Sp), and F-score values

considered for the calculations based on the values of the confusion matrix are as follows [26]:

$$P = \frac{TP}{FP+TP} \quad (3)$$

$$Sn = \frac{TP}{FN+TP} \quad (4)$$

$$Sp = \frac{TN}{FP+TN} \quad (5)$$

$$F - score = 2 \times \frac{P \times Sn}{P + Sn} \quad (6)$$

IV. DATASET

Malware is a pernicious computer software that poses a significant threat to the security integrity of computer systems. Malicious software instructions are concealed among a substantial amount of data, hence rendering conventional protection mechanisms often ineffective in preventing malware attacks. Malicious attacks, such as viruses, worms, and Trojans,

have the potential to inflict damage on a wide range of internet-connected devices [27]. The structure of malware attacks may vary. However, they may be identified by their nature due to the crucial use of online information. The presence of malware on websites poses a significant threat to both individual customers and enterprises. Malware continues to pose a significant cyber danger, as shown by the observation of over 357 million varieties of malware in 2016 [28]. According to AVTEST, a total of ninety-five million websites were found to be infected with malware in 2017 [29]. The distinguishing characteristics of malware may be discerned from site content and browser history or data. The data obtained from malware may provide insights into the characteristics of the virus itself, but it does not often reveal the interrelationships between key data points. Moreover, such data is generally insufficient to identify behavior that can be classified as 'suspicious.' In all instances, perpetrators use several strategies in their endeavor to breach a target's system.

The use of the Android Malware Detection dataset in this simulation is seen as both innovative and suitable. The simulation incorporates many pre-processing techniques, including the conversion of non-numerical variables into numerical representations and the removal of missing values. These operations are necessary due to the categorical and textual nature of some features. Furthermore, each input data point undergoes a translation process to be represented inside the 0-1 interval and then normalized. The probability of misplacing a device remains higher than the probability of contracting malware. Implementing robust encryption measures significantly enhances the security of electronic devices, making them very resistant to unauthorized access and data theft. It is important to establish a robust password for both the device and the SIM card. The dataset known as TUNADROMD has a total of 4465 instances and encompasses 241 distinct attributes. The classification target attribute may consist of a binary categorization, distinguishing between malware and good ware. (Note: The following text is the pre-processed form of TUANDROMD).

Variables:

1-214: Permission-based features

215-241: API-based features

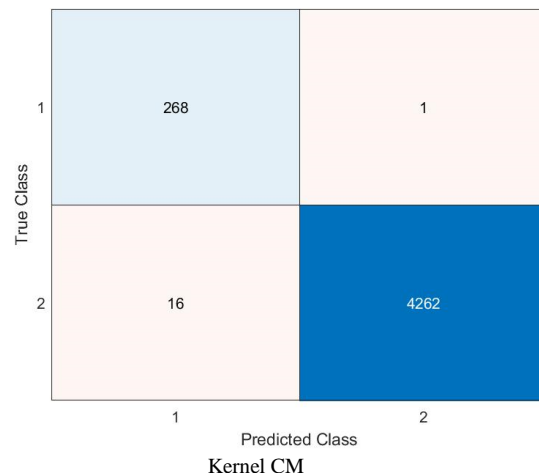

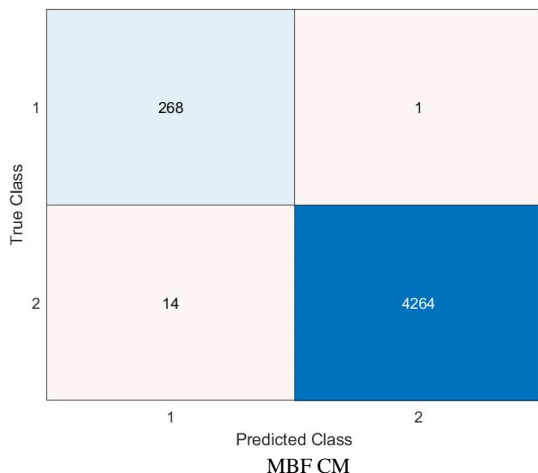

Class Labels

Class: 1) Malware 2) Goodware

In this study, we utilized the dataset available at <https://www.kaggle.com/datasets/subhajournal/android-malware-detection>, which serves as a comprehensive resource for Android malware detection research. This dataset comprises a diverse collection of samples, including both malicious applications and benign ones, providing a robust foundation for evaluating the efficacy of different detection methods. The dataset offers detailed information about each sample, such as permissions requested, API calls made, and other relevant features, enabling a thorough analysis of malware behavior and characteristics. By leveraging this dataset, we were able to conduct rigorous experiments to compare the performance of MBF with other established algorithms for Android malware detection, using standard evaluation metrics such as precision, recall, and F1-score. This dataset served as a crucial component in ensuring the validity and reliability of our findings, contributing to the advancement of research in this critical domain of cybersecurity.

V. RESULTS AND DISCUSSION

This section provides a discussion of the main findings derived from the study. Furthermore, the efficacy of the suggested algorithm in the field of data categorization is substantiated by an examination of the relevant literature. The evaluation of a classification model's performance in statistics and machine learning may be conducted via the use of a confusion matrix, as seen in Fig. 4. The provided information offers a comprehensive summary of the categorization results, including the quantities of true positive, true negative, false positive, and false negative estimates. According to the data shown in Fig. 4, the MBF algorithm exhibits superior performance compared to the other algorithms. Confusion matrices are an often used evaluation measure in the context of classification problem-solving. The use of this approach may be advantageous for both binary and multiclass classification problems. Confusion matrices provide a tabular representation of the observed and predicted values, displaying the counts for each combination.

Fig. 4. Confusion matrix for the selected algorithms

Fig. 5 illustrates that MBF has superior sensitivity, indicating a noteworthy proportion of genuine positive cases that the model correctly identified or classified as positive. When it comes to TPR, SVM has the lowest performance. Additionally, based on the data shown in Fig. 6, the accuracy of MBF is satisfactory. The weighted combination of each machine learning model's outputs is the foundation for the working ensemble model's structure. The MBF method seeks to determine the most optimum weighted sum of probability values computed by each model for each issue class. The MBF algorithm's objective function is also the classification's final accuracy value. Thus, after adding up the weighted probability values of each class, they are determined for each class sample by the MBF algorithm, and the accuracy value is determined by comparing the labels assigned by the algorithms. The MBF algorithm is associated with the expected labels. Also, the machine learning models were compared with the proposed ensemble's primary method by calculating the classification's evaluation criteria.

Fig. 7 to 11 demonstrate the values of F-score, accuracy, specificity, and sensitivity obtained for the various selected models. MBF is superior in terms of the criteria values obtained in the work. The Adaboost does not have acceptable

performance in data classification. Accordingly, SVM can be an excellent alternative to MBF as it has the highest values of F-score, accuracy, specificity, and sensitivity after that. The results reported in Table I match those in Fig. 7 to 11. MBF, with a value of about 99.67%, is slightly different from Adaboost, which has an accuracy of 99.56%. Compared to the other selected models, the F-score, precision, sensitivity, and specificity values obtained for MBF are remarkable, with 98.57%, 99.65%, 97.51%, and 97.51%, respectively.

The findings of this study underscore the remarkable performance of MBF as a novel approach for Android malware detection and better than previous ones [30]. Across all evaluated metrics including accuracy, F-score, precision, sensitivity, and specificity, MBF consistently outperforms the other algorithms tested, including SVM, Adaboost, MLP, Gaussian Kernel, and RF. With an accuracy of 99.67% and an F-score of 98.57%, MBF demonstrates exceptional accuracy and robustness in identifying both known and unknown malware threats. Additionally, MBF achieves high precision and sensitivity, indicating a low false positive rate and a high true positive rate, respectively, which are crucial for effective malware detection in real-world scenarios.

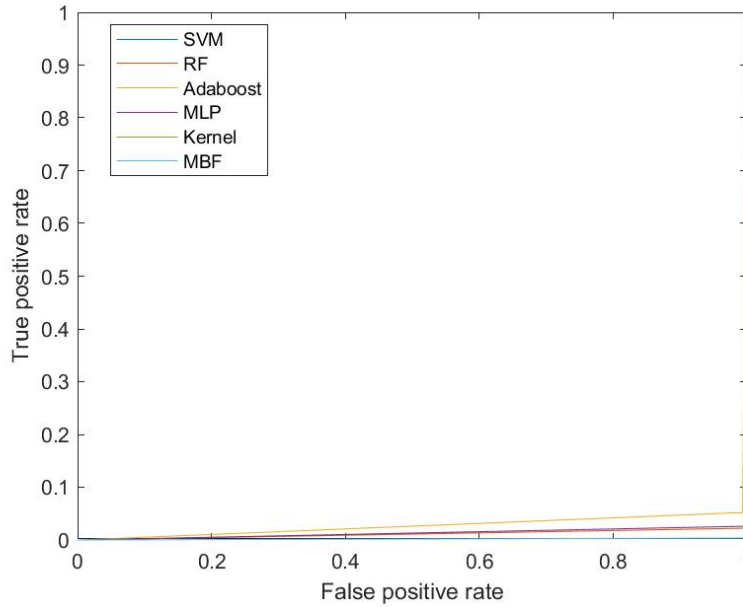

Fig. 5. The true positive rate for the selected models

Fig. 6. The accuracy of the proposed method based on iteration and fitness

The superiority of MBF over the previous algorithms [5,8,17] lies in its utilization of ensemble learning techniques, which leverage the strengths of multiple models to enhance predictive performance. By combining the predictions from various base models, MBF achieves a synergistic effect that effectively mitigates the limitations of individual algorithms. Furthermore, the utilization of ensemble learning allows MBF to adapt and evolve over time, enabling it to effectively detect

new and evolving malware threats. These findings not only highlight the efficacy of MBF in Android malware detection but also underscore the importance of exploring innovative approaches, such as ensemble learning, to address the escalating challenges posed by malicious actors in the mobile ecosystem.

In Fig. 7, the F-score values illustrate the balance between precision and recall achieved by each model. Fig. 8 showcases

the accuracy values, indicating the overall correctness of the predictions made by the models. Specificity values, depicted in Fig. 9, represent the true negative rate, indicating how well the models distinguish benign samples from malicious ones. Fig. 10 displays the sensitivity values, reflecting the true positive rate or the models' ability to correctly identify malicious samples. Lastly, Fig. 11 presents the precision values, indicating the proportion of correctly identified positive cases among all cases identified as positive by the models.

These figures provide a comprehensive visual representation of the performance of each model across different evaluation metrics, offering insights into their relative strengths and weaknesses in Android malware detection. They serve as valuable tools for understanding and interpreting the results of your study, facilitating comparisons and highlighting the superiority of certain models, such as MBF, over others.

TABLE I. COMPARISON BETWEEN THE SELECTED METHODS BASED ON THE STATISTICAL RESULTS

Criteria	SVM	Adaboost	MLP	Gaussian Kernel	RF	MBF
Accuracy	0.9956	0.9908	0.9943	0.9956	0.9943	0.9967
F_score	0.9811	0.9597	0.9750	0.9811	0.9751	0.9857
Precision	0.9959	0.9707	0.9848	0.9959	0.9865	0.9965
Sensivity	0.9668	0.9489	0.9654	0.9668	0.9640	0.9751
Specificity	0.9668	0.9489	0.9654	0.9668	0.9640	0.9751

VI. CONCLUSION

In summary, a new ensemble model is developed for classification problems in the current study. The dataset considered in this simulation is related to Android malware detection, which is considered a new and suitable dataset. Due to the categorical and textual nature of some features, several pre-processing steps, including coding non-numerical variables into numbers and removing missing values, have been performed in the simulation. Also, all input data are mapped and normalized to intervals of 0 and 1. The structure of the working ensemble model is based on the weighted combination of the outputs of each of the used machine learning models. Finding the most optimal weighted sum of probability values calculated by each model for each class of the problem is the goal of the MBF algorithm. The F-score, accuracy, specificity, and sensitivity values for the chosen models are shown in Fig. 7 to 11. When it comes to the criterion values that were found during the job, MBF is better. In terms of data categorization, the Adaboost's performance is unacceptable. Because SVM has the greatest values of F-score, accuracy, specificity, and sensitivity after MBF, it can be a great substitute for MBF. The outcomes shown in Fig. 7 to 11 correspond with those in Table I. With an accuracy of 99.56%, Adaboost and MBF differ somewhat, with MBF having a value of around 99.67%. The F-score, accuracy, sensitivities, and specificities for MBF are impressive compared to the other chosen models; they are 98.57%, 99.65%, 97.51%, and 97.51%, respectively. Further research on the use of deep

learning and insider threat identification issues is warranted. Further attempts could prove quite beneficial to the literature.

Examining the Various Neural Network Algorithms Considering the Superiority of Mouth Brooding Fish in Data Classification

Lang Liu*, Yong Zhu

Department of Information Engineering, Gongqing College of Nanchang University, Gongqingcheng 332020, Jiangxi, China

Abstract—Data classification, a crucial practice in information management, involves categorizing data based on its sensitivity to determine appropriate access levels and protection measures. This paper explores the utilization of novel algorithms, including mouth-brooding fish (MBF), alongside machine learning techniques, for the analysis of medical health data. The SVM exhibits suboptimal performance in the task of data categorization. Therefore, Adaboost may be considered a viable substitute for MBF due to its superior performance in terms of F-score, accuracy, specificity, and sensitivity. The accuracy of MBF, which stands at about 95%, surpasses that of Adaboost by a significant margin of 77%. The F-score, accuracy, and specificity values obtained for MBF are exceptional when compared to the other chosen models, with values of 97.17%, 93.6%, and 96.5%, respectively. The proposed algorithm exhibits promising advancements in health data categorization, offering a potential breakthrough in data classification methodologies. Leveraging this innovative approach could facilitate more accurate and efficient management of sensitive medical data, thereby enhancing healthcare systems' capabilities for data protection and analysis. The main novelty of this study lies in the introduction and evaluation of the MBF algorithm for data classification within the medical domain. Unlike traditional algorithms, MBF draws inspiration from the collective behavior of mouth-brooding fish, offering a unique optimization strategy that enhances both exploration and exploitation of the solution space. This novel approach presents a promising avenue for advancing healthcare analytics and decision-making processes.

Keywords—Medical data analysis; clinical decision support; dataset classification; Mouth Brooding Fish; Support Vector Machine (SVM)

I. INTRODUCTION

Different signaling pathways for various biological activities are formed inside the cell by the interconnection and interaction of various signals. Mutations in the gene that controls these processes result in cellular malfunction and may potentially cause cancer [1]. The term "driver pathway" or "driver gene set" often refers to the group of altered genes highly influential in cell signaling pathways. In addition to deepening our knowledge of the rules of molecular action and the processes behind cancer development, the discovery of driver pathways may potentially point to novel molecular targets for cancer therapy. It is commonly recognized that several genetic variants can affect the same pathways [2]. To better capture the diverse patterns of malignancies, it is, essential to go from the gene to the pathway level. At the route level, several investigations have discovered

patterns of mutations [3]. One method used to forecast the state of civil infrastructure is the health monitoring of structures [4]. The weather and functional condition fluctuations threaten the accuracy of damage detection work during continuous monitoring in the bridge structural health monitoring system [5].

Digital medical technology has matured due to information technology advancements, medical data is expanding at a never-before-seen rate, and biomedical research has transformed into a typical data-intensive discipline, giving rise to the phenomena known as "big data." The significant data age has transformed biomedical research, human thought processes, and way of life. Data is becoming a new strategic resource and a significant driver of innovation. Relevant medical industry departments can be guided to strengthen the collection and management of big data related to medical health through the integration analysis and application requirements description of big data in the medical service field. This will lay the groundwork for future data development and application [6, 7].

Thousands or even hundreds of thousands of MAs have been developed during the decades-long history of modern optimization for use in various sectors; natural phenomena inspire most of these MAs. Since its inception in the 1960s, genetic algorithms (GAs) have undergone three stages of development: the concept-proposal stage, the OP-growth stage, and the mature stage of evolving towards depth [8]. The traditional medical health big data classification algorithms face challenges, including high sample size and delayed processing, as the amount of medical and health care data continues to expand steadily. The Mouth Brooding Fish (MBF) algorithm is adjusted to more accurately categorize the imbalanced data set. The MBF algorithm replicates the mutualistic Organisms that use biotinteraction strategies to live and spread across the environment. In this study, the MBF algorithm is studied. Overfitting will not occur since the MBF eliminates noise from the training data set based on the ensemble learning concept. According to the simulation findings, this approach outperforms Gaussian Kernel, Random Forest (RF), Adaboost, Support Vector Machine (SVM), and Multilayer Perceptron (MLP) in spotting dishonest behaviors [2]. This is a crucial point of reference for developing the medical credit scheme. The primary objective of our study was to construct an appropriate model for the provided professorial scenario. Indeed, given the potential for a model or structure to exhibit superiority in any given application or case study, the primary objective was to ascertain the most suitable fit for the given dataset. In addition, we

attempted to use the most renowned and extensively utilized machine learning models as comparator models. The superiority of the current work over its counterpart in the previous years is highlighted as follows:

- Introduction of novel algorithms, particularly MBF, for the analysis of medical health data, demonstrating superior performance compared to traditional methods like SVM.
- Comparative evaluation of MBF and Adaboost algorithms, revealing MBF's exceptional accuracy of approximately 95%, surpassing Adaboost by a substantial margin of 77%.
- Detailed analysis of performance metrics including F-score, accuracy, specificity, and sensitivity, showcasing MBF's outstanding performance with F-score, accuracy, and specificity values of 97.17%, 93.6%, and 96.5% respectively, thereby highlighting its superiority over other selected models.
- Significance of the proposed algorithm in advancing health data categorization, offering promising advancements in data classification methodologies, and facilitating more accurate and efficient management of sensitive medical data, thereby enhancing the capabilities of healthcare systems in data protection and analysis.

The rest of the paper is organized as follows: The second section reviews the related works to highlight the significant limitations and drawbacks tackled in the current work. The methodology and dataset adopted for reaching the conclusions are explained in the third section. The results are discussed in the fourth section, and the conclusions are drawn in the fifth section.

II. LITERATURE REVIEW

Researchers have been experimenting with various data mining approaches in the medical and health domains to increase the accuracy of medical diagnoses. Additional reliable and accurate methods would yield additional supporting

information for identifying potential patients through precise sickness forecasting. Data mining techniques play a significant part in clinical decision-making by creating various models that give doctors precise, dependable, and timely forecasts [9]. Reducing the number of datasets in the healthcare industry while considering data categorization methods based on meta-heuristic algorithms has drawn much interest in recent years. A few examples are the enhanced KNN method presented by Xing and Bei [10] and their comparison with the conventional KNN algorithm. Weights are allocated to each class, and the classification is carried out in the standard KNN classifier's query instance neighborhood. The method considers the distribution of classes surrounding the query to guarantee that the allocated weight does not negatively impact the outliers. Boyapati et al. [11] concluded that the Support Vector Machine approach was better than the Decision Tree algorithm, providing a preferred dataset distribution or categorization. By accounting for the multimodal distribution of the numerical variables, Khanmohammadi and Chou's novel Gaussian Mixture Model-based Discretization Algorithm (GMBD) maintained the most common patterns from the original dataset [12]. Six publicly accessible medical datasets confirmed the GMBD algorithm's efficacy. The experimental findings showed that the GMBD algorithm performed better than regarding the number of rules produced and the classification precision in the associative classification algorithm; there are five more static discretization techniques. Chang et al. presented a model that combines a cross-validation technique, a classification algorithm, and recursive feature removal. The authors ranked each feature's relevance using the recursive feature elimination approach in the first stage, and then they utilized cross-validation to identify the best feature subset. In order to reliably forecast patient outcomes using their ideal features subset, four classification algorithms—SVM, C4.5 decision tree (RF), extreme gradient boosting (XGBoost), and others—were examined in the second stage. Of the quartet of classifiers, using the optimum features subset, XGBoost demonstrated the best prediction performance with accuracy, F1, and area under receiver operating characteristic curve (AUC) values of 94.36%, 0.875, and 0.927, respectively. Table I also summarizes similar research according to the methods and objectives employed.

TABLE I. A BRIEF REVIEW OF THE RELATED WORKS BASED ON THE USED TECHNIQUES AND PURPOSES

No.	References/Year	Method	Aim	Features
1	[13]/2019	Random Forest classifier	Medical classification data	Highly accurate predictors were provided for ten different diseases, along with a sufficiently generic technique that should work well for other diseases with comparable datasets. Highly accurate predictors were provided for ten different diseases, along with a sufficiently generic technique that should work well for other diseases with comparable datasets.
2	[14]/2021	Decision tree classifiers	Medical classification data	In terms of authenticity and correctness, the suggested approach seemed appropriate.
3	[15]/2020	Modified nearest neighbor (ENN) based on RF and misclassification-oriented synthetic minority over-sampling approach (M-SMOTE)	addressing the blindness of the over-sampling method for synthetic minorities while creating samples	Comprehensive tests on 10 UCI datasets show that RFMSE helps address unbalanced data categorization. The suggested technique is more effective in improving F-value and MCC than standard methods.
4	[16]/2020	Grey Wolf Optimization (GWO) method with Hybrid Kernel SVM	Classification of data for chronic renal illness	According to the latest results, the intended classification scheme outperformed, achieving improved 97.26% accuracy for the renal chronic dataset compared to the 94.77% achieved by the existing SVM approach and the 93.78% achieved by the fuzzy min-max GSO neural network (FMMGNN) classifier.

5	[17]/2019	A unique code division multiplexing (CDM) and block classification-based reversible data hiding (RDH) method.	Block categorization for healthcare system image processing	The suggested approach can produce a superior overall performance on medical photos than other cutting-edge RDH systems, according to experimental data.
	[18](Yadav and Jadhav 2019)[18]2019	Deep convolutional neural networks for the categorization of medical images	Classifying pneumonia by analyzing a dataset of chest X-rays	When applied to a short dataset, transfer learning outperforms support vector machines with oriented fast and rotated binary (ORB) robust independent elementary features and capsule networks regarding classification accuracy.
7	[19]/2021	An approach for adaptive harmony search	Selecting genes and categorizing high-dimensional medical data	According to the simulation results, the suggested hybridization has great promise for high-dimensional database feature subset prediction and sample classification.
8	[20]/2023	An algorithm for the modified Hunger Games search (mHGS)	Selection of features and worldwide optimization	The experimental findings imply that the suggested mHGS can improve convergence time and produce useful search results without adding to the computing burden. Additionally, it has enhanced SVM classification performance.

III. METHODOLOGY

A. Selected Algorithms

Support Vector Machine (SVM), AdaBoost, Multilayer Perceptron (MLP), Gaussian Kernel, and Random Forest (RF) have been selected for data classification here.

1) *Support Vector Machine (SVM)*: Since the margin in SVM is calculated using the points closest to the hyperplane (support vectors), it is unnecessary to worry about additional observations; in logistic regression, on the other hand, the classifier is defined over all of the points. As a result, SVM naturally speeds faster. SVMs are a group of supervised learning techniques used in regression analysis, outlier identification, and classification. Among support vector machines' benefits are efficient in places with several dimensions. It is still useful when there are more dimensions than samples. The spots that are nearest to the hyperplane are these. These data will be used to define a separation line. The distance between the hyperplane and the observations (support vectors) that are closest to it is known as the margin. A big margin is considered good in SVM [21].

One sparse approach is SVM. Like nonparametric techniques, SVM necessitates the availability of all training data, meaning that it must be kept in memory during the training phase when the SVM model's parameters are discovered. Nevertheless, SVM relies solely on a subset of these training examples—referred to as support vectors—for subsequent prediction once the model parameters have been determined. The support vectors specify the hyperplanes' boundaries. Following Support vectors are identified following phase with an objective function regularized by an error term and a constraint, supporting relaxation is used. Rather than the dimensionality of the input space, the number of support vectors determines the complexity of the SVM classification job. Data-dependent and variable, the number of support vectors that are eventually kept from the original dataset depends on the data complexity, represented by the data dimensionality and class separability. Although, in reality, this is rarely the case, the maximum constraint for the number of support vectors is half the size of the training dataset [22].

2) *Adaboost*: The AdaBoost algorithm, also called Adaptive Boosting, is a machine-learning ensemble method

that uses boosting techniques. Because the weights are reassigned to each instance—higher weights are given to instances that are mistakenly classified—it is known as adaptive boosting. AdaBoost builds the model sequence using a different method than XGBoost, an improved version of Gradient Boosting with various enhancements and improvements. The particular challenge and the application's needs will determine which solution is best [23].

3) *Multilayer Perceptron (MLP)*: An MLP neural network is used to model the system. The inputs of an artificial neural network (ANN) are represented by $u(t - z_i)$, where $i=1,2,\dots,n$, and the delay is indicated by z_i [24]. This research reveals the relevant parameters of the first neuron in the hidden layer as $w_{11}^1, w_{12}^1, \dots, w_{1n}^1$. The h-th neuron's related parameters and the hidden layer output are represented by $w_{h1}^1, w_{h2}^1, \dots, w_{hn}^1$, and $w_{21}, w_{22}, \dots, w_{2h}$. Fig. 1 displays the suggested output of the Artificial Neural Network (ANN) [25].

Fig. 1. System modeling utilizing an MLP neural network.

$$n_{ti} = w_i^1 U \tag{1}$$

$$O_i = g(n_{ti}), \quad i = 1, \dots, h \tag{1}$$

Accordingly,

$$w_i^1 = [w_{i1}^1, w_{i2}^1, \dots, w_{in}^1] \tag{2}$$

$$g(n_{ti}) = \frac{1 - \exp(-n_{ti})}{1 + \exp(-n_{ti})} \tag{2}$$

As stated in Equation 3, the output of ANN is specified.

$$y = w_2 o \quad (3)$$

According to the components of Equation 4, the main parameters are defined as follows:

$$\begin{aligned} o &= [o_1, o_2, \dots, o_h]^T \\ w_2 &= [w_{21}, w_{22}, \dots, w_{2h}] \end{aligned} \quad (4)$$

According to Equation 5, the major parameters of ANN are adjusted:

$$\begin{aligned} o &= [o_1, o_2, \dots, o_h]^T \\ w_2 &= [w_{21}, w_{22}, \dots, w_{2h}] \end{aligned} \quad (5)$$

Using Equation 6, the parameters of ANN are adjusted:

$$E = \frac{1}{2} e_{est}^2 = \frac{1}{2} (y_d - y)^2 \quad (6)$$

The approximated /real outputs indicate y_d . According to which the updating law is [26]:

$$w_2(t+1) = w_2(t) + \eta e_{est} o \quad (7)$$

The first layer with the weights adaptive principle is represented by Equation 8:

$$w_i^1(t+1) = w_i^1(t) + \eta e_{est} \dot{g}(n_{ti}) w_{2i} U \quad (8)$$

Assuming that η remains constant, we can represent the vector of weights in the i th neuron as w_i^1 and the vector of weights for the i th neuron output as w_{2i} . The differential of $g(n_{ti})$ is represented by $\dot{g}(n_{ti})$ (concerning the input n_{ti}). Equation 9 is also used to determine the Jacobian of the system.

$$\begin{aligned} \frac{\partial \Delta f}{\partial u_c} \\ = ([w_{11}^1, w_{21}^1, \dots, w_{h1}^1] \text{diag}[\dot{g}(n_{t1}), \dots, \dot{g}(n_{th})] w_2) \end{aligned} \quad (9)$$

4) *GK*: The Gaussian kernel (GK) is defined as follows in one-dimensional, two-dimensional, and neuronal dimensions:

$$\begin{aligned} G_{1D}(x; \sigma) &= \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{x^2}{2\sigma^2}}, \\ G_{2D}(x, y'; \sigma) &= \frac{1}{2\pi\sigma^2} e^{-\frac{x^2+y'^2}{2\sigma^2}}, \\ G_{ND}(\tilde{x}; \sigma) &= \frac{1}{(\sqrt{2\pi}\sigma)^N} e^{-\frac{|\tilde{x}|^2}{2\sigma^2}} \end{aligned} \quad (10)$$

The σ value determines the width of the Gaussian kernel. In statistics, the Gaussian probability density function is referred to as the standard deviation, while its square, σ^2 , is the variance. When we discuss the Gaussian as an aperture function in observations, we will use "s" to refer to the inner scale or simply the scale. This paper's scale is limited to positive values, where $\sigma > 0$. During the observation process, s can never be reduced to

zero. This implies observing through a tiny aperture, which is practically impossible. The inclusion of the factor of 2 in the exponent is merely a matter of convention. It allows us to have a more simplified formula for the diffusion equation, which we will discuss in more detail later. The convention is to include a semicolon between the spatial and scale parameters to distinguish between them clearly.

5) *RF*: The Random Forest (RF) classifier is a method that concurrently trains multiple decision trees using bootstrapping and then aggregates the results through a process known as bagging (Fig. 2) [27]. Bootstrapping involves training distinct decision trees simultaneously on various subsets of the training dataset, utilizing different subsets of the available features. This ensures that each decision tree within the random forest is unique, thereby reducing the overall variance of the RF classifier. The RF classifier amalgamates the decisions of individual trees to arrive at the final decision, enabling it to exhibit robust generalization. Compared to other classification methods, the RF classifier typically attains higher accuracy without succumbing to overfitting issues.

Like the Decision Tree (DT) classifier, the RF classifier does not require feature scaling. However, the RF classifier demonstrates greater resilience in selecting training samples and noise in the training dataset than the DT classifier. Despite being more challenging to interpret, the RF classifier offers ease of hyper parameter tuning compared to the DT classifier.

6) *Mouth Brooding Fish (MBF)*: According to Fig. 3, the MBF algorithm simulates organisms' strategies to ensure their survival and proliferate within an ecosystem through symbiotic interactions [29]. It consists of five control parameters that the user determines. The key factors that influence the cichlid population are the number of cichlids in the group, the location where the mother cichlid originates from (source point or SP), the extent of dispersion, the likelihood of dispersion, and the damping effect on the mother's source point. It is advisable to analyze the problem and review the outcomes of parameter tuning to select the optimal values for the control parameters. In order to compare the MBF algorithm with CMAES, JADE, SaDE, and GL-25, we need to assume that the controlling parameters are constant. The MBF algorithm is population-based, so the number of individuals in the population is one of the parameters that can be controlled. The population size indicates the number of fish that will undergo the problem-solving process in the Mouth Brooding Fish algorithm [30]. The primary foundation of the Mouth Brooding Fish algorithm lies in the behaviors of cichlids as they navigate around their mother, as well as the impact of natural elements or threats on these behaviors. The MBF algorithm consists of several main parts to find the best possible results for the given problems.

Fig. 2. A dataset with two classes ($Y = 1$ and $Y = 2$) and four features (X_1, X_2, X_3 , and X_4) is employed to build a Random Forest (RF) classifier. The RF classifier is an ensemble method that simultaneously uses bootstrapping and aggregation to train multiple decision trees. Each tree is trained on unique subsets of training samples and features [28].

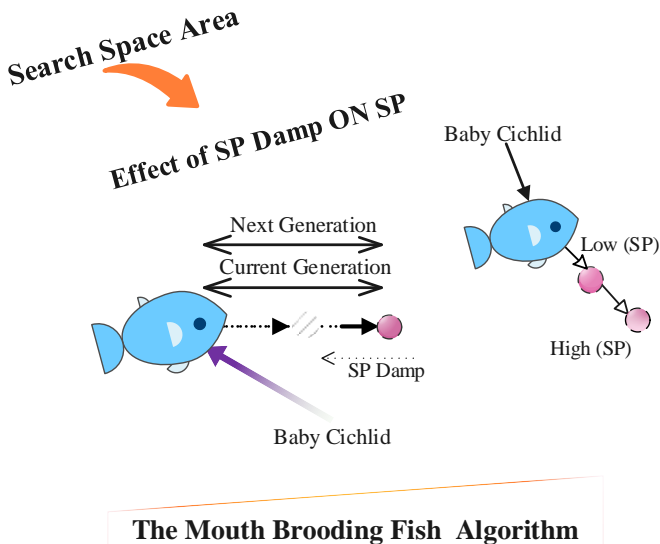

Fig. 3. Mouth Brooding Fish Algorithm [31].

In nature, marriage is a crucial mechanism that aids colonies or populations in achieving optimal outcomes by promoting convergence. However, it only sometimes yields favorable

outcomes when it occurs. Mouth-brooding fish allow their best cichlids to mate. Thus, the MBF algorithm selects one pair of parents from each cichlid using a probability distribution or Roulette Wheel selection (where higher point values have a higher likelihood). Cichlids that hatch in a new position replace their parents in the population without moving [32]. Before assessing the fitness of the newly hatched fish using a fitness function, we need to ensure that the new positions for the offspring are within the boundaries of the search space. The mathematical equations of this algorithms are defined below:

1) *Objective function:* $f(x)$ represent the objective function to be minimized or maximized, where x denotes the vector of decision variables.

2) *Mouth-Brooding fish model:* The position of each fish (solution) in the search space can be represented as $x_i = [x_{i1}, x_{i2}, \dots, x_{id}]$, where i denotes the index of the fish and d is the dimensionality of the problem.

3) *Fish movement:* The movement of fish i at iteration t is governed by $x_{it} = x_{it-1} + \Delta_{it}$ when Δ_{it} represents the change in position of fish i at iteration t .

4) *Local search mechanism:* The local search mechanism could involve exploring the neighborhood of each fish i to find better solutions. This can be represented as adjusting the position of fish i based on its local surroundings: $\Delta x_{it} =$

$\alpha \nabla f(x_i) + \beta \Delta x_{it-1} + \epsilon_t$ where α and β are parameters controlling the influence of the gradient and previous movement, respectively, and ϵ_t is a random perturbation.

5) *Updating rules*: The updating rules determine how the positions of fish are updated iteratively. One common approach is to use a simple update rule such as: $x_{it} = x_{it} + \Delta x_{it}$

B. Dataset

The reason for creating this dataset is the necessity for practical and varied healthcare data that can be used for educational and research purposes. Accessing healthcare data for learning and experimentation can be challenging due to its sensitivity and the privacy regulations surrounding it. In order to fill this gap, the Faker library in Python is used to create a dataset that closely resembles the structure and attributes typically seen in healthcare records [33]. We have created this healthcare dataset as a valuable resource for those interested in data science, machine learning, and data analysis. The purpose of this tool is to imitate authentic healthcare data, allowing users to practice, enhance, and demonstrate their abilities in manipulating and analyzing data within the healthcare sector. We can find additional details about the data set in reference [33].

Moreover, the dataset available at the provided Kaggle link offers comprehensive insights into healthcare demographics and outcomes, encompassing various attributes crucial for medical analysis and decision-making. It includes data from diverse sources, capturing demographic information such as age, gender, and ethnicity, alongside clinical details including medical conditions, diagnosis codes, and medication usage. Moreover, the dataset incorporates vital signs measurements, laboratory test results, and insurance details, providing a holistic view of patients' health status and treatment journeys. Additionally, the dataset likely contains information on healthcare utilization, including hospital admissions, procedures performed, and associated costs, facilitating in-depth analysis of healthcare resource allocation and patient care pathways. With its rich and diverse array of variables, this dataset presents a valuable resource for exploring patterns, trends, and associations within the healthcare domain, enabling researchers and practitioners to derive actionable insights for improving patient outcomes and healthcare delivery.

C. Evaluation Criteria

The primary factors for comparing the results are F-score, accuracy, specificity, sensitivity, and precision [34]. Precision refers to a slight variation between two or more measurements, whereas accuracy represents the disparity between a result and its actual value. The end outcomes should align well, as indicated by precision. The F1 score is the weighted average of precision and recall, including false positives and negatives. Specificity is the test's ability to identify unstick people correctly. Mathematically, a test with high specificity that produces a positive result can confirm a disease because it rarely

produces positive results in healthy people. A test's sensitivity determines whether it detects a disease. High-sensitivity tests have few false negatives, reducing disease cases missed. The specificity of a test refers to its capability to correctly identify someone who does not have a disease as being negative. To put it differently, Specificity refers to the percentage of individuals who do not have Disease X and receive a damaging result on their blood test. A particular test ensures that all healthy individuals are accurately recognized as healthy, meaning there are no incorrect positive results.

Accuracy is one of the most often utilized measures for classifying data. A confusion matrix determines a model's accuracy by employing the following equation [35].

$$Accuracy = \frac{TN + TP}{TN + FP + FN + TP} \quad (11)$$

Moreover, precision (P), sensitivity (Sn), also known as true positive rate (TPR), specificity (Sp), and F-score values considered for the calculations based on the values of the confusion matrix are as follows [35]:

$$P = \frac{TP}{FP + TP} \quad (12)$$

$$Sn = \frac{TP}{FN + TP} \quad (13)$$

$$Sp = \frac{TN}{FP + TN} \quad (14)$$

$$F - score = 2 \times \frac{P \times Sn}{P + Sn} \quad (15)$$

IV. RESULTS AND DISCUSSION

The main results obtained in the work are discussed in this section. Also, the superiority of the proposed algorithm in data classification is validated by considering the related works. As shown in Fig. 4, a classification model's performance can be assessed by a confusion matrix in statistics and machine learning. It provides an overview of the categorization findings by displaying the numbers of true positive, true negative, false positive, and false negative estimations. As seen from Fig. 4, the proposed algorithm, MBF, performs better than the rest. Confusion matrices are a widely used metric in classification problem-solving. Both binary and multiclass classification issues can benefit from its use. Confusion matrices show the counts of the actual and expected values. True Negative, or "TN," is the output that indicates how many negative cases were correctly categorized. Similarly, "TP" stands for True Positive and represents the proportion of correctly identified positive cases. False Positive value, or the number of actual negative instances categorized as positive, is represented by the phrase "FP." In contrast, the False Negative value, or the number of real positive examples classified as negative, is represented by the term "FN."

Fig. 4. Confusion matrix for the selected algorithms.

As shown in Fig. 5, MBF has better sensitivity, which means that the percentage of real positive cases that the model accurately detected or categorized as positive is remarkable. In terms of TPR, the weakest performance is attributed to SVM. Also, the accuracy of MBF is acceptable according to the values given in Fig. 6.

Fig. 7 to 11 demonstrate the values of F-score, accuracy, specificity, and sensitivity obtained for the various selected models. MBF is superior in terms of the criteria values obtained in the work. The SVM does not have acceptable performance in data classification. Accordingly, Adaboost can be an excellent alternative to MBF as it has the highest values of F-score,

accuracy, specificity, and sensitivity after that. The results reported in Table II match those in Fig. 7 to 11. MBF, with a value of about 95%, is by far more accurate than Adaboost by 77%. Compared to the other selected models, the F-score, accuracy, and specificity values obtained for MBF are remarkable, with values of 97.17%, 93.6%, and 96.5%, respectively.

Fig. 5. The true positive rate for the selected models.

Fig. 6. The accuracy of the proposed method based on iteration and fitness.

Fig. 7. F-score values of the selected models.

Fig. 8. Accuracy values of the selected models.

Fig. 9. Specificity values of the selected models.

Fig. 10. Sensitivity values of the selected models.

Based on Fig. 7 to 11, the performance metrics, including F-score, accuracy, specificity, sensitivity, and precision, obtained for the various selected models in the study. Each figure

provides a visual representation of the values achieved by the models across these metrics. Notably, Fig. 7 depicts the F-score values, which represent the harmonic mean of precision and recall, showcasing the balance between these two metrics. Fig. 8 presents the accuracy values, indicating the proportion of correctly classified instances among the total instances. Specificity values, representing the true negative rate, are displayed in Fig. 9, indicating the ability of the model to correctly identify negative instances.

Fig. 10 showcases sensitivity values, also known as the true positive rate, indicating the model's ability to correctly identify positive instances. Finally, Fig. 11 illustrates the precision values, which represent the proportion of true positive predictions among all positive predictions made by the model. Together, these figures provide a comprehensive overview of the performance of each model across multiple evaluation metrics, facilitating comparisons and insights into their effectiveness in data classification tasks.

Fig. 11. Precision values of the selected models.

TABLE II. OBTAINED STATISTICAL RESULTS

	SVM	Adaboost	MLP	Gaussian Kernel	RF	MBF
Accuracy	0.715847	0.775956	0.721311	0.721311	0.672131	0.950820
F_score	0.688438	0.787384	0.673673	0.691201	0.640517	0.953391
Precision	0.680643	0.828616	0.65283	0.680522	0.620870	0.971698
Sensitivity	0.696412	0.750061	0.695891	0.702220	0.661447	0.935761
Specificity	0.816446	0.861194	0.818811	0.822478	0.777839	0.965116

V. CONCLUSION

In summary, the current work examines the performance of MBF, SVM, Adaboost, MLP, GK, and RF for data classification in the medical field. The outcomes of the work were examined based on F-score, accuracy, specificity, and sensitivity. The results indicated that the selected algorithms' performance in data classification was acceptable, as the SVM was the weakest and MBF was the strongest. The outputs of the confusion matrix demonstrated that MBF, with an accuracy of 95%, outperforms the rest, and after that, Adaboost, with 77%, can be a good alternative. The F-score, accuracy, and specificity values obtained for MBF are comparable to those of the other models that were chosen, with respective values of 97.17%, 93.6%, and 96.5%. The gap between the MBF and the rest was remarkable in terms of precision as MBF has the precision of 97.17% while SVM, MLP, GK, and RF have the precision of 68%, 65.28%, 68.05%, and 62% respectively. Accordingly, SVM, MLP, GK, and RF performance are identical. However, Adaboost and MBF show desirable capability inaccurate data classification, which can be improved in future work. Future investigations are necessary to validate the kinds of conclusions that can be drawn from this study.

School of Business Administration, Dongbei University of Finance and Economics, Dalian 116025, Liaoning, China²

Abstract—A stock market is a venue where the shares of publicly traded companies are available for purchase and sale by individuals. The financial markets exert a substantial influence on various domains, including technology, employment, and business. Given the substantial rewards and risks associated with stock trading, investors are exceedingly concerned with the precision of future stock value forecasts. They modify their investment strategies in an effort to achieve even greater returns. Accurate stock price forecasting can be challenging in the securities industry due to the complex nature of the problem and the requirement for a comprehensive understanding of various interconnected factors. The stock market is influenced by a variety of factors, including politics, society, and economics. A multitude of interrelated factors contribute to these behaviors, and stock price fluctuations are capricious. In order to tackle a range of these difficulties, the present investigation proposes an innovative framework that integrates a Grasshopper optimization method with the gated recurrent unit model, a machine-learning approach. The research used data from the Shang Hai Stock Exchange Index for the period of 2015–2023. The proposed hybrid model was also tested on the 2013–2022 S&P 500 and Nikkei 225. The proposed model demonstrated optimal performance, exhibiting a minimal error rate and exceptional effectiveness. The study's findings demonstrate that the proposed model is more suitable for the volatile stock market and surpasses other existing strategies in terms of predictive accuracy.

Keywords—Financial market; shanghai stock exchange price; gated recurrent unit; grasshopper optimization algorithm

I. INTRODUCTION

One of the most fascinating technological developments of the day is the financial markets [1]. It provides market analysts, investors, and researchers from other fields with various chances [2]. Individuals may have different viewpoints on market involvement, such as understanding market behavior, identifying important elements, trading stocks, and forecasting future events [3]. The market trend, suggesting assets for portfolio management, etc., but a lack of understanding of basic economic concepts and financial literacy may have a significant impact on the returns on investments [4]. Stock forecasting is a complex task requiring a thorough understanding of many interconnected factors [5]. Nevertheless, several factors, such as political, and economic dynamics, impact the stock market [6], [7]. A broad variety of factors, such as changes in the unemployment rate, immigration regulations, public health

issues, immigration policies, and monetary policies impacting various nations, might be contributing elements [8]. As a result of a careful examination of the market, everyone involved in the stock market wants to maximize earnings and reduce risks [9], [10]. Consequently, there is an increased demand for market valuations and various forms of analytical assessments to examine market behavior [11], [12]. Fundamental analysis and technical analysis are the two distinct categories into which contemporary approaches to financial forecasting fall [13]. To generate long-term forecasts, fundamental analysis entails the examination of prevalent stock market elements based on knowledge and expertise. As opposed to this, a technical analysis integrates insights obtained from past stock price information [14]. Technical analysis is the systematic examination of past pricing data in conjunction with the application of technical indicators to predict forthcoming trends in financial time series [15], [16]. Conventional methods may improve forecasting precision, but they also add to computing complexity, increasing the risk of prediction mistakes [17]. To effectively use artificial intelligence technology for financial market forecasting, a strong and uncomplicated model is necessary for profitable development [18]. Choosing a suitable methodology is crucial as it relies on the characteristics of the dataset and the desired application. Researchers may encounter datasets that vary with time (time-dependent) or datasets that do not vary with time (time-independent). Each kind of dataset presents distinct issues [19]. The main reason for this is that time series analysis is characterized by consistent price fluctuations occurring at regular periods [20]. Investors must compile voluminous amounts of information and analyze deterministic, non-linear, and non-parametric chaotic systems in order to construct an exact model that can forecast future returns. Due to their nonlinear dynamics, determinism, and absence of well-defined parameters, these systems are unique [21]. It is important to note that these models may sometimes encounter the problem of being trapped in a local minimum. A proposed remedy for this problem is the gated recurrent unit (GRU) model [22]. Using the GRU method, a sophisticated machine-learning model was developed to forecast currency exchange rates. The development of a stock index movement prediction algorithm has been enabled by combining a new technique, the improved online sequential gated recurrent unit, with the grasshopper optimizer algorithm. These strategies use probabilistic concepts that are better suited for sets of responses rather than individual ones.

These algorithms use the principles of natural selection to imitate the most efficient behaviors seen in the natural realm. Slime mold algorithm (SMA)[23], Moth-flame optimizer (MFO) [24], and Grasshopper optimization algorithm (GOA) [25], which is a new and intriguing swarm intelligence system that emulates the natural swarming and foraging habits of grasshoppers. Grasshoppers are a well-known class of insects that pose a threat to agriculture and agricultural production. The two stages of its life cycle are referred to as nymph and maturity. The adult phase is marked by long-range, sharp movements, whereas the nymph phase is characterized by short steps and gradual motions. Given the ever-changing and consequential character of financial markets, specifically the stock market, the significance of precise and dependable stock price prediction is emphasized. To maximize returns and optimize investment strategies, investors are perpetually in search of innovative predictive models. The advent of the GOA-GRU model signifies a critical juncture in the realm of stock market prediction, presenting investors with an exceptional prospect to improve their investment tactics in the face of market instability. By merging Grasshopper optimization and the gated recurrent unit model, this novel approach not only could guarantee enhanced predictive precision but also offer significant insights into the intricate relationship between micro-level market dynamics and macroeconomic factors. The provision of dependable forecasts by the GOA-GRU model not only facilitates technological advancements but also enhances comprehension of market dynamics, thereby it can promote more effective capital allocation and the ongoing development of financial modeling methodologies. The main contributions of the study are as follows:

- The grasshopper optimization algorithm and the gated recurrent unit model have been integrated in a manner that has substantially enhanced predictive accuracy. By capitalizing on this novel framework, investors are able to enhance their decision-making process regarding stock trading, thereby optimizing returns while mitigating risks.
- By subjecting alternative models, including GOA, SMA-GRU, and MFO-GRU, to rigorous evaluation, the GOA-GRU model consistently demonstrated superior performance. The model's superior predictive capabilities are demonstrated by its ability to attain high efficiency and low error.
- The GOA-GRU model provides a pragmatic resolution to the complexities associated with predicting stock prices, as evidenced by its consistent integrity and accuracy. The utilization of this technology has the potential to enable financial analysts, investors, and institutions to make decisions based on data, thereby enhancing the efficacy and knowledge of capital allocation within the financial markets.

The subsequent content of this paper is organized as follows: The literature review is provided in Section II. In addition to the materials and methodology utilized, Section III provides a concise overview of the optimizer techniques and GRU algorithm. The results and discussion are provided in Section IV. At last, the conclusions that have been drawn from the

assessments and findings of the review are presented in Section V.

II. LITERATURE REVIEW

A. Related Works

Over the course of the past few decades, there has been a significant amount of potential for the application of machine learning algorithms to the prediction of the future stock market price. In an effort to improve the precision of trend prediction in the context of stock market fluctuations, Nabipour et al. [26] undertook an investigation that utilized deep learning and machine learning algorithms. They conducted a comparative analysis of the performance of different prediction models with respect to four distinct stock market groups that are listed on the Tehran Stock Exchange: diversified financials, petroleum, non-metallic minerals, and basic metals [26]. The outcomes demonstrated that the Recurrent Neural Network (RNN) and Long Short-Term Memory (LSTM) exhibited superior performance compared to alternative prediction models when applied to continuous data. This underscores the efficacy of these models in capturing intricate temporal dependencies present in the data [26]. In their research, Khan et al. [27] examined the impact of political events and public sentiment on stock market trends, encompassing both the performance of specific companies and the broader market environment [27]. Their objective was to determine whether political situations and public sentiment on a particular day could influence seven-day stock market trends. In pursuit of this objective, a machine learning model was enhanced with sentiment and political situation features in order to examine their impact on the accuracy of predictions [27]. The experimental results indicated that the incorporation of sentiment features resulted in a slight enhancement of 0–3% in the accuracy of predictions. However, the inclusion of the political situation features substantially improved the accuracy of predictions by around 20% [27].

Yuan et al. [28] present an alternative approach to the traditional linear multi-factor stock selection model, which takes into account the dynamic and chaotic characteristics of the stock market. They conducted a thorough feature selection process utilizing a variety of feature selection algorithms in their research. They further refine the parameters of stock price trend prediction models based on machine learning using time-sliding window cross-validation [28]. They utilized a comprehensive eight-year dataset pertaining to the Chinese A-share market in order to ascertain the most efficient integrated models for forecasting stock price trends [28]. By conducting an extensive examination and assessment of various integrated models, their research demonstrates that the random forest algorithm exhibits exceptional efficacy in predicting stock price trends and selecting features [28]. Moghar and Hamiche endeavor to improve the accuracy of inventory value forecasts by leveraging the capabilities of RNNs, with a particular emphasis on LSTM [29]. In their study, Vijn et al. [30] utilized Random Forest and Artificial Neural Networks (ANN) to predict the closing prices of five companies operating in various sectors. They employed financial data that included the opening, closing, high, and low prices of stocks in order to generate novel variables that function as inputs for the predictive models [30]. By employing ANN and Random Forest techniques, they aimed to predict the closing

prices of equities on the following business day. The evaluation of the model's effectiveness is conducted by examining the performance of these metrics; lower values signify increased predictive accuracy [30].

In their investigation, Parray et al. [31] examined the feasibility of utilizing three machine learning algorithms—Support Vector Machine (SVM), Perceptron, and Logistic Regression—to predict the trajectory of stock prices for the following day [31]. The experiments are conducted by the researchers using historical stock data from January 1, 2013 to December 31, 2018. The dataset consists of around fifty stocks selected from the NIFTY 50 index of the Indian National Stock Exchange. In addition to calculated technical indicators, the data is utilized for the analysis. The findings suggest that the SVM model attains an average accuracy of 87.35% in its predictions, with Logistic Regression following closely at 86.98% and Perceptron at 75.88% [31]. To predict the closing price of the S&P 500 index the following day, Bhandari et al. [32] employ LSTM, a specialized neural network architecture. A comprehensive analysis of the stock market's behavior is achieved through the formulation of a well-curated ensemble of nine predictors, which includes technical metrics, macroeconomic indicators, and fundamental market data [32]. Moving forward, the chosen input variables are employed to construct both single-layer and multilayer LSTM models, which are subsequently assessed using well-established evaluation metrics [32]. By combining machine learning and deep learning methodologies, Mehtab et al. [33] developed a hybrid modeling strategy for predicting stock prices. The data for this analysis is derived from the NIFTY 50 index values published by the National Stock Exchange (NSE) of India [33]. The period covered by this data is from December 29, 2014, to July 31, 2020. To forecast the open values of the NIFTY 50 index from December 31, 2018, to July 31, 2020, eight regression models are developed utilizing training data spanning from December 29, 2014, to December 28, 2018 [33]. Additionally, four deep learning-based regression models utilizing LSTM networks are implemented to enhance the predictive capability of the framework [33]. Liu and Long introduced a framework for predicting stock closing prices by capitalizing on the capabilities of deep learning, specifically the LSTM network, which excels at processing intricate financial time series [34]. In contrast to conventional models, their framework utilized empirical wavelet transform (EWT) for data preprocessing and an outlier-robust extreme learning machine (ORELM) model for post-processing. The primary constituent, an LSTM network-based deep learning predictor, was optimized by employing the dropout technique and the particle swarm optimization (PSO) algorithm [34]. Combining machine learning techniques with technical analysis indicators, Ayala et al. [35] proposed a hybrid method for generating trading signals in stock market prediction. The simplicity and effectiveness of their approach, which combines machine learning with a technical indicator to inform trading decisions, might be applicable to additional technical indicators in the future [35]. In order to determine the most appropriate machine learning technique, they assessed the performance of Four Neural Networks, a Linear Model, Support Vector Regression, and a Random Forest. As technical trading strategies, they evaluated their approach using daily trading data from major indices such as the DAX and Dow Jones Industrial

Average in conjunction with the Triple Exponential Moving Average and Moving Average Convergence/Divergence [35].

B. Challenges and Fulfillment

The exploration of integrating optimization methods with machine learning models is a notable gap in current research on stock market prediction. The proposed framework addresses this deficiency by integrating the GRU model with the SMA, MFO, and GOA, enabling a more refined examination of interrelated variables. Concerns regarding the representativeness and quality of the findings arise due to the utilization of obsolete or irrelevant datasets, which constitutes another deficiency. We ensure the pertinence and contemporaneity of this research findings by addressing this gap with recent data from the Shang Hai Stock Exchange Index spanning the years 2015 to 2023 along with S&P 500 and Nikkei 225. In the realm of stock market prediction research, a divide exists between conceptual progress and tangible implementation. By exhibiting its practical applicability and real-world effectiveness, our demonstrated superior performance—distinguishable from other models—not only verifies that our proposed model is appropriate for volatile markets but also bridges this gap.

III. METHOD AND MATERIALS

A. Slime Mold Algorithm

In 2020, Li et al. introduced SMA, an innovative methodology that was inspired by the natural slime mold activity [23]. The slime mold uses olfaction to perceive and discern the volatile food aromas present in the atmosphere, enabling it to effectively travel toward its prey. The behavior of the slime mold may be formally characterized by the following equation:

$$\overrightarrow{X}(t+1) = \begin{cases} \overrightarrow{X}_b(t) + \overrightarrow{v}_b \cdot (\overrightarrow{W} \cdot \overrightarrow{X}_A(t) - \overrightarrow{X}_B(t)) & r < p \\ \overrightarrow{v}_c \cdot \overrightarrow{X}(t) & r \geq p \end{cases} \quad (1)$$

The variable $X_b(t)$ reflects the precise region of the slime mold that now displays the greatest concentration of odor. The variables $X(t)$ and $X(t+1)$ represents the locations of the slime mold in the t -th and $t+1$ -th iterations, respectively. $X_A(t)$ and X_B represent two arbitrarily chosen locations of the slime mold. The variable v_b experiences temporal fluctuations within the interval $[-a, a]$, where r is a random integer ranging from 0 to 1. The parameter p is defined as the inverse hyperbolic tangent of the negative ratio of t to the maximum value of $t = \arctanh(-\frac{t}{\max_t} + 1)$. The parameter v_c is a linearly decreasing parameter that varies between 0 and 1.

$$p = \tanh |S(i) - DF| \quad i = 1, 2, \dots, n \quad (2)$$

The symbol DF denotes the iteration with the greatest fitness value, whereas $S(i)$ denotes the fitness of the vector \overrightarrow{X} . The equation provided below offers a precise and formal definition of the weight, represented by the symbol W :

$$\overrightarrow{W}(\text{smell index}(l)) = \begin{cases} 1 + r \cdot \log \left(\frac{bF - S(i)}{bF - wF} + 1 \right), \text{condition} \\ 1 - r \cdot \log \left(\frac{bF - S(i)}{bF - wF} + 1 \right), \text{others} \end{cases} \quad (3)$$

$$\text{smell index} = \text{sort}(S) \quad (4)$$

The variable $S(i)$ denotes the first half of the population in the provided equation. The sign bF indicates the maximum fitness value, whereas wF shows the minimum fitness value. Furthermore, the scent index pertains to the arranged values of physical fitness. The spatial coordinates of the slime mold are updated by using the provided formula.

$$\vec{X}^* = \begin{cases} rand(UB - LB) + LB, & rand < z \\ \vec{X}_b(t) + \vec{v}_b \cdot (\vec{W} \cdot \vec{X}_A(t) - \vec{X}_B(t)), & r < p \\ \vec{v}_c \cdot \vec{X}(t), & r \geq p \end{cases} \quad (5)$$

Within this particular context, the variable represented by the symbol Z is limited to a numerical interval spanning from 0 to 0.1. The words LB and UB denote the bottom and upper boundaries of the search interval, respectively.

B. Moth-Flame Optimizer

The Moth Flame Optimizer is a clever device that has been shown to significantly increase the performance of many models. The concept for it comes from the way that nocturnal butterflies respond to a source of light at night. When these insects fly toward the moon, they have been shown to be able to navigate over very long distances with success. They might quickly get entangled, however, if they continue to circle the light. Having been well studied, this particular movement may be used as an incredibly effective optimizer in many fields, such as medical applications, business management, image processing, architectural design, electrical and energy systems, and design. Classified as a metaheuristic technique, the MFO algorithm has considerable potential in solving a variety of optimization issues [24]. The challenging components of the inquiry include the geographical distributions of moths, which are viable solutions. Moths may fly in one, two, three, or hyper-dimensional space by changing their position vectors. The suggested method ensures convergence, and MFO has a high computational efficiency and reliability. The following is one way to express the MFO:

$$MFO = (R, M, P) \quad (6)$$

The following equation illustrates how the flames control the rearranging of the moth locations in the movement function M :

$$A_i = s(A_i, B_j) = C_i \cdot e^{br} \cdot \cos(2\pi t) + B_j \quad (7)$$

The variables S , B_j , and A_i are used to represent the spiral function. The moth's index is I , while the flame's index is j . c_i is the symbol for the distance between the i -th moth and the j -th flame. Using the constant symbol b , the geometric characteristics of the spiral are determined. Randomly produced values between -1 and 1 reflect the number denoted by the variable r . To calculate the distance c_i , use the formula below:

$$C_i = |B_j - A_i| \quad (8)$$

Preservation of the exploration phase of the search space is achieved through the implementation of an adaptive technique designed to minimize the frequency of flames. The subsequent procedures are executed to accomplish this:

$$N = round\left(N_{MAX} - \alpha \times \frac{N_{MAX}-1}{\xi}\right) \quad (9)$$

The constants N , N_{MAX} , ξ , and α reflect the number of flames, total number of flames, iterations, and iterations in process, respectively.

C. Grasshopper Optimization Algorithm

Originating from natural processes, the grasshopper optimization technique is a well-known metaheuristic algorithm [36]. The primary objective is to identify optimal solutions that provide the maximum outcome by using randomization to prevent being trapped in suboptimal alternatives. The algorithm's rapid convergence and exceptional exploration abilities have shown its amazing success and efficiency in optimization. GOA has outperformed many other approaches in test scenarios, demonstrating its excellence and promise in practical applications. As it is perceivable from the illustration and framework in Fig. 1 and Fig. 2. Moreover, GOA is adaptable, effectively managing the trade-off between exploring new possibilities and using known solutions to ensure optimal results are achieved. GOA is an excellent choice for research applications because of its unique attributes. Saremi et al. [36] introduced the GOA algorithm, which falls under the category of swarm intelligence algorithms. Each grasshopper's placement in the swarm represents a possible solution, mimicking the behavior of grasshoppers that often gather in swarms.

$$X_i = S_i + G_i + A_i \quad (10)$$

s_i represents social interaction, G_i represents gravitational force, and A_i represents wind advection.

Fig. 1. The illustration of (GOA).

The equation for N grasshopper optimization is expressed as follows, excluding the gravity component and assuming that the wind direction is directed towards the goal [36].

$$X_i^d = c \left(\sum_{j=1, j \neq i}^N \frac{ub_d - lb_d}{2} s(|x_j^d - x_i^d|) \frac{x_j - x_i}{d_{ij}} \right) + \widehat{T}_d \quad (11)$$

The distance between the i -th and j -th grasshoppers is indicated by d_{ij} . Whereas l stands for the beauty scale and f for the power of attraction, function S reflects the strength of social forces. The formulae below are used to compute these values [36]:

$$d_{ij} = |d_j - d_i|$$

$$s(r) = f e^{\frac{-r}{T}} - e^{-r} \quad (12)$$

The equation is used to calculate the coefficient c , which decreases the comfort zone in proportion to the number of iterations [36].

$$c = c_{max} - l \frac{c_{max} - c_{min}}{L} \quad (13)$$

l represents the current iteration, c_{max} signifies the maximum value, c_{min} the minimum value, and L the iterations' highest number[36].

D. Gated Recurrent Unit

To ensure network correctness, the GRU network is derived by reducing the complicated gate structure of the LSTM. This results in a reduction in the number of network training parameters and an increase in computing efficiency [22]. Within the GRU, the primary function of the gate unit r_t is to regulate the merging of correlation between the current input of the network and the memory from the past instant. Meanwhile, the update gate z_t governs the extent to which memory information is preserved from the historical moment [22]. Fig. 3 illustrates the interior arrangement.

The update gate z in the GRU model is computed at time t using the following formula.

$$z_t = \sigma(W^z x_t + U^z h_{t-1}) \quad (14)$$

In the above formula, σ denotes the sigmoid function, whereas W^z and U^z show the updated coefficients for the gate weights. The expression for the reset gate r can be formulated as:

$$r_t = \sigma(W^r x_t + U^r h_{t-1}) \quad (15)$$

The cellular memory at time t , denoted as \widetilde{h}_t , may be mathematically represented as:

$$\widetilde{h}_t = \tanh(r \times U h_{t-1} + W x_t) \quad (16)$$

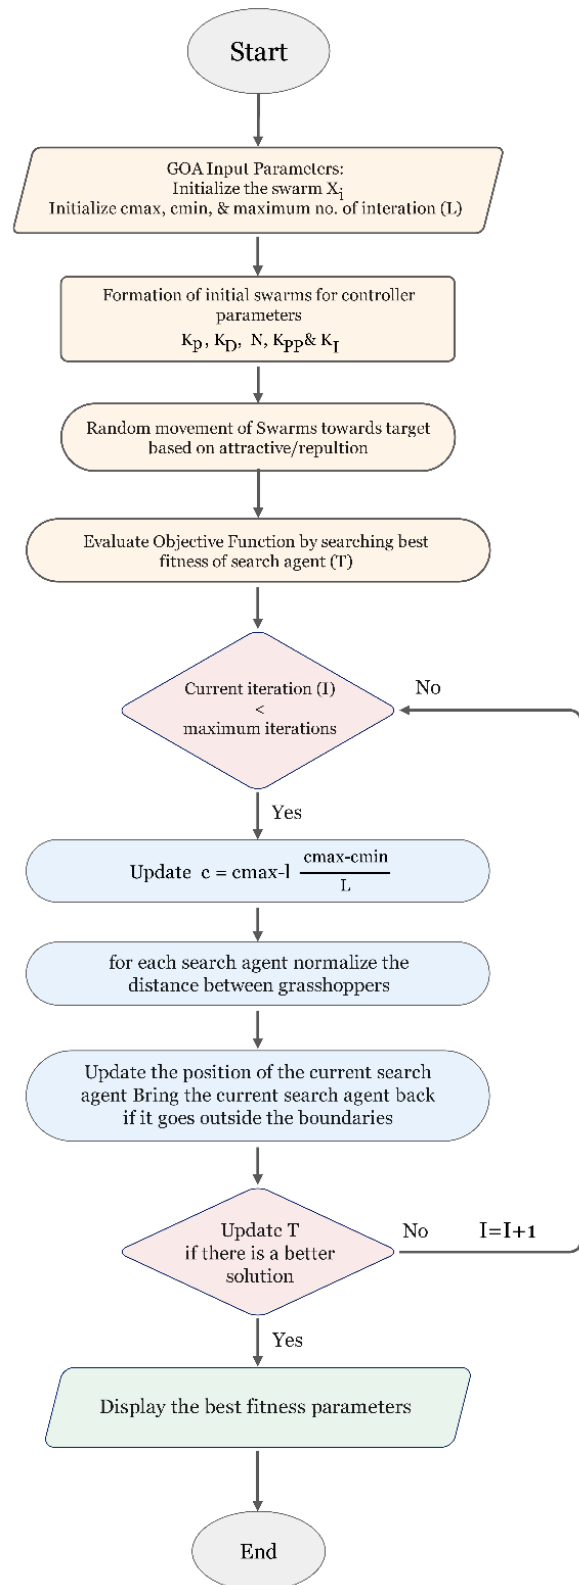

Fig. 2. The framework of (GOA).

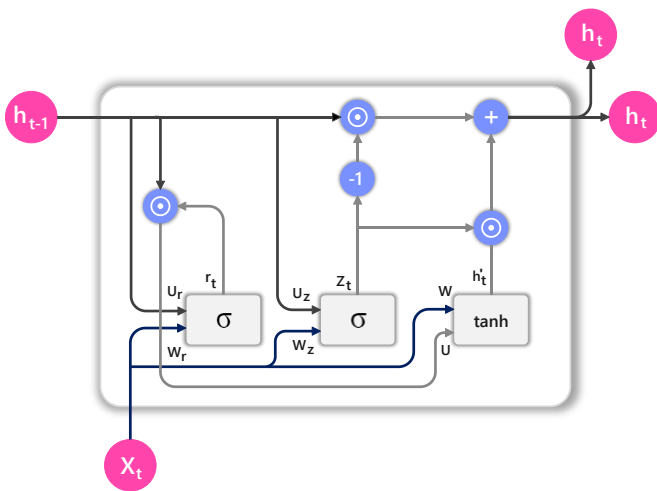

Fig. 3. The illustration of the GRU.

E. Data Collection and Preprocessing

The candlestick chart was devised by Homma, a renowned rice merchant from Sakata City, Japan [37]. Subsequently, several Japanese merchants used it as a means of forecasting forward pricing in rice futures contracts [38]. A candlestick chart is a hybrid chart that combines the features of a line chart and a bar chart. The price changes over a certain time period are frequently shown using it. The three components of a candlestick chart are an authentic body, a lower shadow, and an upper shadow. Each bar on the candlestick chart represents the opening, closing, lowest, and highest prices for a single trading day. The different beginning and closing price gaps are shown

in the candlestick chart's body. The many colors of the candlestick also represent different meanings. Red will actually be the color of the body if the opening price is higher than the closing price. As an alternative, the entire body will be heavily green-hued. Near the conclusion of the real body, the higher and lower lines represent the shadows in the upper and lower regions, respectively. Candlestick charts' upper and lower shadows, respectively, display the highest and lowest price ranges over a certain period of time.

A thorough examination of the data was an essential component of the preliminary phase to identify any irregularities, uncommon observations, or inconsistencies that may undermine the credibility of the results. To optimize the performance of the models, two distinct preprocessed data sets were generated. When conducting a thorough analysis, it is important to take into account many elements, such as the trading volume and the OHLC prices over a certain timeframe. The data on the performance of the Shang Hai stock market index from 2015 to 2023 was obtained for this research. The research used a partitioning strategy in which 80% of the dataset was assigned for training. In contrast, the remaining 20% was allocated to conduct tests. The primary goal of this division was to achieve a harmonious equilibrium between the need for a substantial volume of data to train the model and the necessity for a substantial and novel dataset to carry out thorough testing and validation, as seen in Fig. 4. Furthermore, in order to validate the performance of the hybrid model under consideration, data from the Nikkei 225 and the S&P 500 spanning the years 2013 to 2022 were utilized.

Fig. 4. The process of separating a provided dataset into separate test and train sets.

F. Evaluation Metrics

To evaluate the accuracy of the next projection, many performance criteria were used. Within the field of statistical analysis, four frequently used evaluation criteria are applied to measure the accuracy and effectiveness of a model. The coefficient of determination (R^2), mean absolute error (MAE), mean absolute percentage error (MAPE), and root mean square error (RMSE).

$$R^2 = 1 - \frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{\sum_{i=1}^n (y_i - \bar{y})^2} \quad (17)$$

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{n}} \quad (18)$$

$$MAE = \frac{\sum_{i=1}^n |y_i - \hat{y}_i|}{n} \quad (19)$$

$$MAPE = \left(\frac{1}{n} \sum_{i=1}^n \left| \frac{y_i - \hat{y}_i}{y_i} \right| \right) \times 100 \quad (20)$$

IV. RESULT AND DISCUSSION

A. Statistic Values

Table I is an essential part of the inquiry since it presents a comprehensive summary of the statistical data obtained from the dataset. The table's clarity and comprehensibility are enhanced by the inclusion of OHLC price and volume data. In order to conduct a thorough and precise examination of the data, statistical measures such the mean, variance, minimum (min), maximum (max), standard deviation (Std.), 25%, 50%, and 75% should be employed.

B. Compare and Analyses

Finding and assessing the hybrid algorithm that yields the most accurate stock price forecasts is the primary goal of this

research. The main goals of this research effort are to understand the many factors that influence stock market trends and to create prediction models. Giving analysts and investors relevant information to help them make informed and wise investment decisions is the main goal. The performance is comprehensively evaluated in Table II and Fig. 5 and Fig. 6. This report offers a full examination of the effectiveness of each method.

An evaluation of the GRU model has been conducted, both with and without the use of an optimizer. Various assessment metrics have been used, including MAE, RMSE, R^2 , and MAPE. By using this approach, users may enhance their comprehension of the model's functioning and form well-informed judgments. Upon analyzing the test and training sets, it was seen that the GRU model produced low results for this technique when the optimizer was not present. According to the presented data, compared to the given metrics, the MFO-GRU model shows better results than the GRU. Upon comparing the findings, it was discovered that the use of the MFO-GRU model led to a decrease in the RMSE test score, resulting in a value of 17.90. The comparative study investigation demonstrated that, as shown in Table II, the SMA-GRU model exhibited superior performance compared to the MFO-GRU model. The MAE value of the SMA-GRU model was determined to be 11.43 for the testing set. The GOA-GRU model demonstrates superior effectiveness compared to the SMA-GRU model. The testing yielded a notable result of 0.9934, indicating the success of the GOA-GRU model. More evidence for the great degree of accuracy and reliability of the GOA-GRU model may be found in the empirical results already cited. The aforementioned results further confirm the model's effectiveness as a useful instrument for the particular purpose of stock price prediction.

TABLE I. A STATISTICAL SUMMARY OF THE GIVEN DATASET

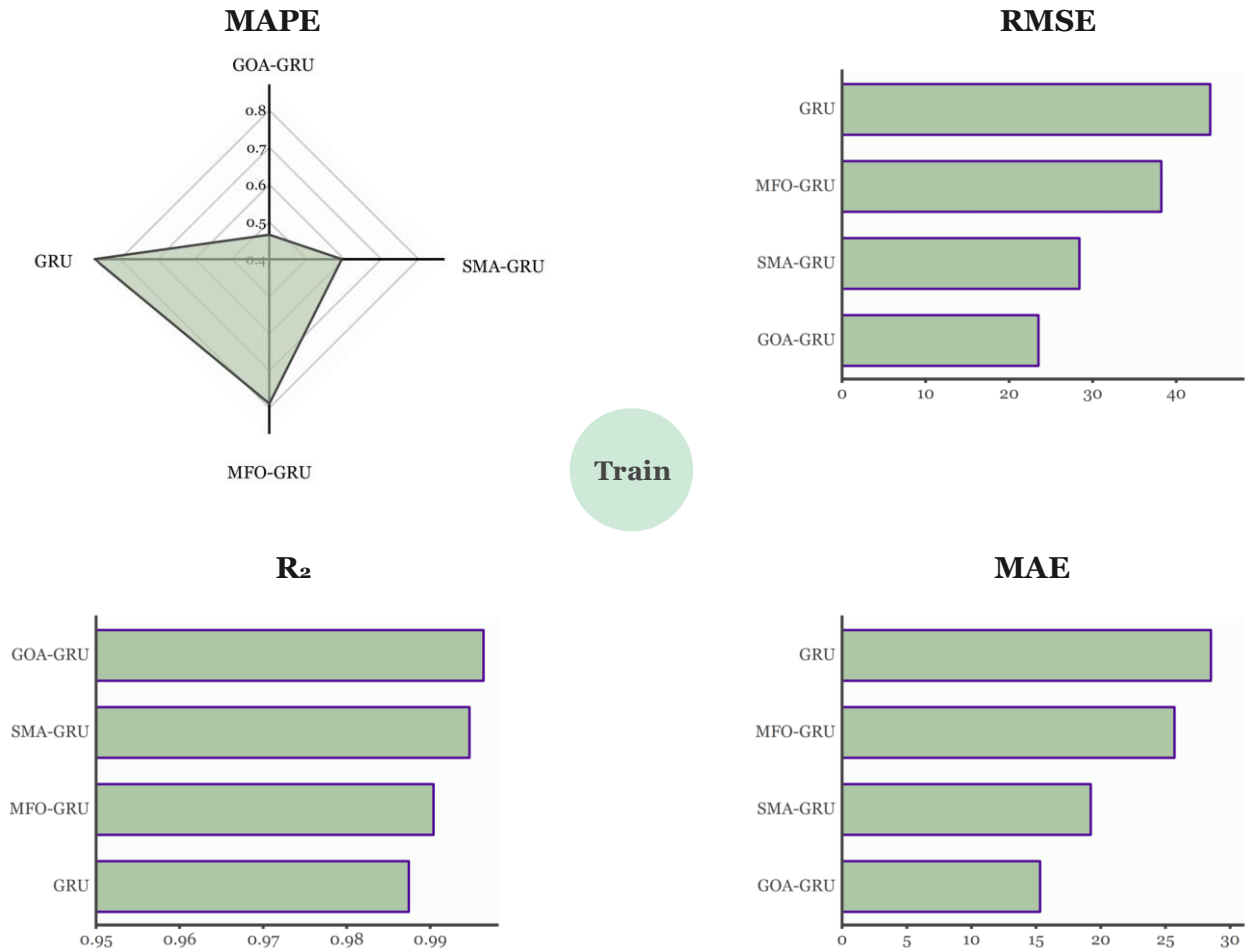

Fig. 5. The results for R^2 , MAPE, MAE, and RMSE over the training phase.

The accuracy and consistency of the GOA-GRU model have been validated by the study's findings, which show that it can accurately predict stock prices. One may compare the Hang Seng index curves with the corresponding curves shown in Fig. 7 and Fig. 8 in order to assess the model's effectiveness. The accuracy of the stock value forecasts made by the COA-GRU model is greater than that of the GRU, MFO-GRU, and SMA-GRU models. Finally, the GOA-GRU model is a robust stock price forecasting tool since it consistently demonstrates very high levels of accuracy, reliability, and inference power when applied to historical data. It has been shown that this suggested framework is an excellent tool for precise stock market forecasting. Furthermore, in addition to the SSE index, we also utilized data from the Nikkei 225 and the S&P 500. The daily

data for these indices, collected between 2013 and 2022, consist of the identical OHLC and trading volume. The results of the GOA-GRU model applied to this dataset are displayed in Table III. The GOA-GRU model exhibits robust generalizability when applied to the Nikkei 225 and S&P 500 datasets, as indicated by its low error metrics and high R^2 values. This implies that the model has successfully acquired knowledge of the latent patterns present in the data and is capable of generating precise forecasts on fresh data. The robustness and adaptability of the model's architecture and learning mechanisms are demonstrated by the consistency in performance observed across various datasets, which corresponds to distinct market conditions and characteristics.

The study's GOA-GRU framework demonstrated superior predictive accuracy compared to alternative methods by effectively mitigating their individual limitations, as indicated in Table IV. Conventional algorithms such as Linear Regression and Support Vector Machines (SVM) exhibit limitations when it comes to reproducing the complex nonlinear associations that are intrinsic in stock market data. LSTM and its variants, although proficient at capturing temporal dependencies, frequently encounter obstacles pertaining to parameter optimization and generalization, thereby impeding their overall performance. Although the integration of deep neural networks (DNN) and LSTM shows potential, it also brings about intricacies and computational demands. On the other hand, the GOA-GRU framework efficiently utilizes the optimization functionalities of the GOA to refine the GRU model's parameters, thereby reducing the impact of overfitting and inadequate parameter configurations. By incorporating this

integration, GOA-GRU is capable of capturing temporal dependencies and nonlinear relationships. As a result, it achieves remarkable predictive accuracy and robustness, surpassing other models in the domain of stock market prediction.

Both the quality and quantity of data accessible for training significantly impact the efficacy of the GOA-GRU model. The utilization of a model in practical situations where the quality of data may differ can be hindered by suboptimal or biased predictions resulting from insufficient or biased data. Although the model may exhibit high accuracy when applied to the training dataset, its capacity to extrapolate to novel market conditions or uncover previously unseen data remains a matter of concern. The model's reliability in dynamic market environments may be compromised due to fluctuations in market dynamics or unanticipated occurrences, which can have

an impact on its predictive performance. Implementing and interpreting machine learning models is further complicated by the incorporation of intricate optimization techniques, such as Grasshopper optimization. User accessibility and usability of the model may be compromised due to the difficulties that may arise for individuals lacking a comprehensive comprehension of both methodologies. The GOA-GRU model, similar to other predictive models, functions on specific assumptions concerning the fundamental connections between variables and market dynamics. Inaccurate predictions may ensue when the model fails to incorporate changes in market behavior or deviations from these assumptions, thereby reducing its resilience to evolving market conditions. Significant computational resources may be necessary for the training and deployment of the GOA-GRU model, especially when dealing with large-scale datasets or real-time forecasting applications. Practical limitations on scalability and real-time performance may consequently impede the widespread implementation of this technology in environments with restricted computational resources. When developing a predictive model for the financial sector, it is crucial to give utmost importance to ethical considerations such as data privacy, fairness, and regulatory compliance. Ethical guidelines and regulatory requirements must be followed when implementing the GOA-GRU model in order to mitigate potential risks, including misuse or bias, which could erode confidence in the model and its results.

V. CONCLUSION

The financial markets are a captivating and innovative advancement currently. The financial markets have a substantial influence on several areas, including business, employment, and technology. Predicting stock prices is an intricate undertaking that requires a comprehensive comprehension of several interrelated aspects. The stock market is susceptible to the impact of several factors, such as politics, society, and the economy. The system in issue is characterized by its dynamic and inherent complexity. In order to provide precise forecasts about future stock prices, it is crucial to take into account an extensive array of financial documents, earnings statements, market patterns, and other pertinent data. Furthermore, It is critical to recognize that the behavior of the stock market is significantly influenced by macroeconomic factors, including inflation, interest rates, and world economic situations. Building accurate and dependable prediction models for stock price forecasting can be challenging due to the numerous intricate components involved. One has to have a solid grasp of the intricate and erratic nature of the market to make reliable forecasts. The GOA-GRU model has shown a notable degree of accuracy and reliability and provides a workable solution to these problems. The effectiveness of many models, including GOA, SMA-GRU, and MFO-GRU, to forecast stock prices was assessed in the current research. Volume and Open, High, Low, and Close (OHLC) prices for the Shang Hai Stock Exchange Index spanning the years 2015 to June 2023 were incorporated into the dataset used in this research. Moreover, to verify the effectiveness of the hybrid model being analyzed, data from the Nikkei 225 and the S&P 500 covering the period from 2013 to 2022 were employed. The outcomes of the experiment reveal that the GOA-GRU model accurately predicts stock prices with a high degree of dependability and precision. An evaluation of

the predictive capabilities and accuracy of the GOA-GRU model about multiple alternative models was undertaken as an integral component of the research procedure.

- The obtained data consistently demonstrated the higher performance of the GOA-GRU model over the other models. The computations show that the R^2 value of 0.9934 shows a high level of accuracy in the prediction models. As indicated by the observed RMSE score of 14.06 and the MAE value of 10.61, the testing outcomes revealed that the model's predictions exhibited a notable accuracy degree. The model's constant accuracy was shown by its MAPE score of 0.33.

Abstract—Among the influential elements in the national economy is the stock market. The stock market is a multifaceted system that combines economics, investor psychology, and other market mechanics. The objective of the financial market investment is to maximize profits; but, due to the market's complexity and the multitude of factors that might impact it, it is challenging to predict its future behavior. The challenging process of stock price prediction requires the analysis of a wide range of social, political, and economic factors. These variables include market trends, financial statements, earnings reports, and other data. The goal of this project is to develop an accurate hybrid stock price forecasting model using Random Forest which is combined with the optimization. Random Forest is one type of machine learning that is often used in time series analysis. This study provides stock price forecasting using the Hang Seng index market, which consists of the largest and most liquid corporations that are publicly traded on the Hong Kong Stock Exchange, data from 2015 to 2023. The Dow Jones and KOSPI were evaluated as two additional indices. This study demonstrates some optimization approaches including genetic algorithm, grey wolf optimization, and biogeography-based optimization, which drew inspiration from the phenomenon of species migrating between islands in search of a suitable habitat. Biogeography-based optimization has shown the best result among these optimizations. The proposed hybrid model obtained the values 0.992, 0.997, and 0.9937 for the coefficient of determination for HSI, Dow Jones, and KOSPI markets, respectively. These results indicate the ability of the model in order to predict the stock market with a high degree of accuracy.

Keywords—*Hang Seng index; financial market; stock price prediction; Random Forest; biological bases optimization*

I. INTRODUCTION

A. Knowledge Background

The stock market is a network that facilitates nearly all significant global economic transactions at a dynamic rate determined by market equilibrium and known as the stock value. Predicting the stock market is a highly challenging endeavor since many factors might affect the market price, such as economic, political, and investor mood [1], [2], [3]. This resulted in random fluctuation and was caused by changes in stock market prices. Inherently volatile and loud is the stock market [4]. It is necessary to have in-depth stock knowledge to anticipate the stock exchange. Purchasing stocks that will appreciate over time is preferred by investors over stocks whose price will fall. But, to optimize investor profit and reduce loss, it is critical to create a potent stock market algorithm that has the ability to accurately predict stock behavior. Furthermore, a

variety of variables that affect the stock market's volatility in the exchange market might affect it. Forecasting the future price of stocks can also be difficult when stock market data is incomplete. To forecast the movement of the stock price, investors use a variety of technical indicators. While the stock is evaluated using these indications, it is difficult to predict market developments. The behavior of stock movements is influenced by both non-economic and economic factors [5]. To comprehend the basic elements impacting stock prices, several models have been created and put to the test. To construct a model or algorithm that would permit investors to anticipate modifications more precisely than they did in the past, research is still ongoing. One of the most well-liked and often-used techniques is the creation of prediction models using machine learning algorithms [6]. Artificial intelligence (AI) and machine learning have the ability to greatly improve stock market precision forecasting in general. This would provide investors with useful information about market movements and assist them in making wise financial choices [7]. The practicality of artificial neural networks as machine learning models is beginning to pose a threat to traditional regression and statistical methods [8].

The Random Forest (RF) is an ensemble of regressors or decision-tree classifiers in which the distribution of each tree is identical across the forest and is dependent on an independent random sample [9]. Both the training data and the input variables are chosen at random during the generation of each decision-tree classifier or decision-tree regressor in RF [10]. Thus, every decision tree within an RF attains an adequate level of robustness to accommodate thousands of variables without experiencing overfitting [11]. In addition, it is possible to decrease the variance and correlation of the trees.

In recent times, meta-heuristic-based algorithms have garnered considerable interest in the optimization of objective functions across diverse domains owing to their straightforwardness, adaptability, resilience, and capacity to circumvent local maxima. To optimize the performance of the RF model, the present investigation employed three meta-heuristic optimization algorithms: the genetic algorithm (GA), grey wolf optimization (GWO), and biological bases optimization (BBO). Mirjalili et al. [12] proposed the GWO algorithm, which draws inspiration from the social hierarchy and hunting strategies exhibited by grey wolf packs and operates on a population-based model. Four levels comprise the hierarchy: omega, alpha, beta, and delta [12]. One of the evolutionary algorithms utilized to resolve optimization problems is the GA [13]. The algorithm in question is a direct

replication of Darwin's survival of the fittest and the process of natural evolution [13]. An initial population of randomly generated candidate solutions encoded as chromosomes is utilized by the algorithm. By applying the principle of survival of the fittest to generate ever-improving approximations, the solution to the inverse problem may be to gradually identify the elite individual attained through progress [13]. The BBO algorithm, introduced by Dan Simon in 2008 [14], is a novel population-based meta-heuristic algorithm that drew inspiration from the migration of species across various islands in search of a suitable habitat [14]. This algorithm utilizes the habitat suitability index (HSI) to quantify the quality of the homeland (solution); a solution with a high HSI is deemed to be good, whereas one with a low HSI is deemed to be poor [14]. This optimizer has been widely utilized in different tasks [13], [15], [16], [17], [18], [19].

B. Literature Review

In recent decades, substantial potential has existed for the implementation of machine learning algorithms in the context of forecasting future stock market prices. Bhalke et al. [20] examined the arduous and unpredictable characteristics of forecasting stock market prices, with a particular focus on the prevalence of recurring patterns in price curves. They investigated the feasibility of utilizing Long Short-Term Memory (LSTM), which is renowned for its efficacy with sequential data, to predict forthcoming stock prices through the analysis of daily closing prices [20]. The objective of their research was to automate prediction processes and minimize human labor in stock market analysis through the utilization of LSTM, a machine learning technique [20]. In their study, Yuan et al. [21] propose an alternative methodology to the conventional linear multi-factor stock selection model that incorporates the stock market's dynamic and chaotic attributes. They implemented a diverse range of feature selection algorithms to carry out an exhaustive feature selection procedure [21]. Time-sliding window cross-validation is employed to further refine the parameters of stock price trend prediction models that are based on machine learning [21]. The researchers employed an extensive dataset spanning eight years, which pertained to the Chinese A-share market, with the aim of determining the most effective integrated models for predicting trends in stock prices [21]. Through the analysis and evaluation of multiple integrated models, their study established that the Random Forest algorithm demonstrates remarkable effectiveness in both feature selection and stock price trend prediction [21]. Vijn et al. [22] employed Random Forest and Artificial Neural Networks (ANN) in their research to forecast the closing prices of five diversely operating companies across multiple sectors. They utilized financial data encompassing stock opening, closing, high, and low prices to produce original variables that serve as inputs for the predictive models [22]. With the utilization of ANN and Random Forest methodologies, their objective was to forecast the closing prices of stocks on the subsequent business day [22]. Moghar and Hamiche confront the complexities inherent in predicting future asset values in the perpetually volatile and uncertain financial market [23]. Their research is devoted to the development of a predictive model utilizing recurrent neural networks (RNNs), with an emphasis on LSTM models [23]. They aimed to enhance the precision of

inventory value predictions through the utilization of RNN capabilities, specifically LSTM [23].

Khan et al. [24] investigated the influence of political occurrences and public opinion on the trajectory of the stock market. Their investigation encompassed not only the performance of individual firms but also the wider market milieu [24]. They aimed to ascertain whether public sentiment and political circumstances of a given day could have an impact on seven-day stock market trends. To achieve this goal, sentiment and political situation features were incorporated into a machine-learning model to assess their influence on prediction accuracy [24]. Their experimental findings revealed that the inclusion of sentiment features marginally improved the accuracy of predictions by a range of 0% to 3%. Nevertheless, the integration of the political situation feature resulted in a significant enhancement of approximately 20% in the precision of forecasts [24]. To enhance the accuracy of trend prediction about stock market volatility, Nabipour et al. [25] initiated an inquiry employing machine learning and deep learning algorithms. An investigation was undertaken to assess the relative efficacy of various prediction models concerning four discrete stock market categories that are publicly traded on the Tehran Stock Exchange: diversified financials, petroleum, non-metallic minerals, and basic metals [25]. The results indicated that when applied to continuous data, the RNN and LSTM performed better than alternative prediction models [25]. Liu and Long [26] proposed a framework for forecasting stock closing prices that takes advantage of the LSTM network's prowess in processing complex financial time series and deep learning capabilities. Their framework employed empirical wavelet transform (EWT) for data preprocessing and an outlier-robust extreme learning machine (ORELM) model for post-processing, as opposed to conventional models [26]. The primary component, a deep learning predictor based on LSTM networks, was optimized via the particle swarm optimization (PSO) algorithm and the dropout technique [26]. The feasibility of employing three machine learning algorithms—Support Vector Machine (SVM), Multilayer Perceptron, and Logistic Regression—to forecast the course of stock prices for the subsequent day was investigated by Parray et al. [27]. The experiments are executed by the researchers utilizing historical stock data spanning the period from December 31, 2018, to January 1, 2013. Approximately fifty stocks were included in the dataset, which was compiled using the NIFTY 50 index of the Indian National Stock Exchange [27]. Their results indicate that the SVM model achieves an average prediction accuracy of 87.35% [27]. Logistic Regression and Multilayer Perceptron follow suit with an accuracy of 86.98% and 75.88%, respectively [27].

Mehtab et al. [28] devised a hybrid modeling approach to forecast stock prices through the integration of machine learning and deep learning methodologies. The data utilized in their analysis is obtained from the National Stock Exchange (NSE) of India's NIFTY 50 index values [28]. The time span encompassed by this dataset is between December 29, 2014, and July 31, 2020. In order to predict the open values of the NIFTY 50 index between July 31, 2020 and December 31, 2018, eight regression models are constructed using training data that covers the period from December 29, 2014 to December 28, 2018 [28]. Ayala et

al. [29] introduced a hybrid approach for generating trading signals in stock market prediction by integrating machine learning methodologies with technical analysis indicators. Future applications of their method [29] involving the integration of machine learning and a technical indicator for the purpose of informing trading decisions may be justified, given its straightforwardness and efficacy [29]. An evaluation of the performance of four machine learning techniques was conducted to ascertain the most suitable one: a random forest, a linear model, and four neural networks. Utilizing daily trading data from prominent indices including the Ibex35, DAX, and Dow Jones Industrial, they assessed their technical trading strategies by employing the Triple Exponential Moving Average and Moving Average Convergence/Divergence [29]. In order to forecast the S&P 500 index's closing price for the subsequent day, Bhandari et al. [30] utilize LSTM, an architecture designed specifically for neural networks. A thorough examination of the behavior of the stock market is accomplished by constructing a meticulously curated collection of nine predictors [30]. This ensemble comprises technical metrics, macroeconomic indicators, and fundamental market data. Subsequently, both single-layer and multilayer LSTM models are constructed utilizing the selected input variables [30].

C. Research Gaps, Motivations, and Main Contributions

The literature review does not incorporate optimization techniques. Additionally, it fails to analyze the effectiveness of these techniques or determine which one produces the most favorable outcomes in the context of stock price forecasting. Although numerous studies examine the creation of hybrid models that combine machine learning and deep learning techniques for predicting stock prices, there is a lack of thorough assessment regarding the effectiveness of these models in comparison to conventional machine learning models. The majority of studies discussed in the literature review concentrate on predicting stock prices for individual companies or indices. However, there is a dearth of research that specifically applies these models to the Hang Seng Index (HSI) market, Dow Jones, and KOSPI indexes. By developing an innovative hybrid stock price forecasting model using these datasets, this research fills in the existing gaps in knowledge. Several optimization techniques, including GA, GWO, and BBO, are incorporated with the widely used machine learning algorithm RF. To identify the most accurate forecasting method for the HSI market, this research entails a comparative evaluation of these optimization techniques. In addition, a comparative analysis of the performance of our hybrid model with pre-existing hybrid models has been conducted. Incorporating optimization techniques with RF for stock price forecasting in the HSI market yielded outcomes that establish the efficacy of this methodology in both accuracy and predictive capability.

In order to address the complexities of the stock market landscape, the motivation is to create hybrid models that combine machine learning and optimization techniques. The primary objective of the model is to optimize its applicability and precision by devoting attention to the distinctive dynamics of the HSI market. To enhance the predictive performance of the forecasting model, a comparative analysis of various optimization strategies was conducted. With the ultimate goal of enabling well-informed decision-making in the financial sector,

the research endeavors to furnish investors with dependable insights, thereby promoting economic stability and growth. These are the primary contributions of the study:

- The research paper makes a scholarly contribution to the domain of financial forecasting through the proposition of an optimized hybrid model designed to forecast stock prices. The research enhances the methodology for forecasting and modeling stock market trends by integrating RF with some optimization techniques, including GA, GWO, and BBO.
- By conducting an analysis of HSI market data spanning the years 2015 to 2023, this study offers significant insights into the intricacies of stock market behavior. Additionally, KOSPI and the Dow Jones were evaluated as supplementary indices. Through the identification of critical determinants that impact stock prices and the construction of a model that can effectively capture these intricacies, this study enhances the collective comprehension of investor conduct and market trends.
- This research investigates the utilization of optimization methods to refine the performance of machine learning models. Through the assessment of various optimization techniques, including GA, GWO, and BBO, this study provides valuable insights regarding the enhancement of machine learning algorithms specifically designed for the purpose of financial forecasting.

The remaining portion of this article is structured in the following manner: Section II outlines the materials and methods used, as well as provides details about the dataset and assessment metrics. The experimental findings are presented in Section III. Additionally, the analyses and discussions are outlined in Section IV. Finally, the study's conclusions are presented in Section V.

II. METHODOLOGY

A. Random Forest

An ensemble learning algorithm [31] typically includes a Random Forest [32]. The algorithm's core idea is to create and generate a decision tree using the subset of sampled original data, combine several decision trees into a random forest, and then carry out a replacement sampling process using the original data set using the Bootstrap sampling method. The forecast generated by a Random Forest regression model is constructed by aggregating the results generated by numerous decision trees. The mean of the predictions made by each individual decision tree in the Random Forest constitutes the final output. Consequently, the collective forecast generated by the ensemble of decision trees constitutes the mean value or consensus of the overall forecast produced by the random forest. In the random forest algorithm paradigm, every decision tree Fig. 1 has a succession of decision nodes that resemble a tree, which comprises the individual phases of the algorithm. The tree is split into several branches till it reaches the leaf at the tip of the tree based on this sequence. Each decision tree's output prediction is routed through leaf nodes, and the aggregated outputs of several decision trees are then used to make predictions. Among its benefits are its quick training pace and

ability to prevent overfitting. The selection and configuration of the hyperparameters for a Random Forest model significantly influence its overall performance and capacity for generalization. The "Maximum Depth" parameter controls the depth of decision trees, which has implications for the model's complexity and vulnerability to overfitting. Specifically, GA favors a depth of 80, GWO tends towards 50, and BBO converges at 60. The setting for feature selection during splitting, "Maximum Features," consistently prioritizes the "auto" option across all optimization techniques. The minimum number of samples necessary for node splitting and "Minimum Samples Leaf" are determined by "Minimum Samples Split" and "Minimum Samples Leaf," respectively. GA selects 2 samples for both, GWO selects 1 and 4, and BBO selects 2 and 3. In order to ensure reproducibility, "Random State" initializes randomness; GA, GWO, and BBO select 42, 64, and 24 elements, respectively. The ensemble size is ultimately determined by the "Number of Estimators," whereby 300, 200, and 500 trees are selected by GA, GWO, and BBO, respectively. The judicious modifications executed by each optimizer underscore their sophisticated approaches in refining hyperparameters with the aim of improving the random forest model's performance on the dataset, thereby guaranteeing an equilibrium between intricacy and applicability. The setting of the hyperparameters of the RF can be observed in Table I.

B. Genetic Algorithm

GA is a computer technique that solves optimization and search issues by simulating the process of natural selection. The basic notion is to create new persons by continually applying

genetic operators like selection, crossover (recombination), and mutation to a population of candidate solutions known as individuals. The quality of the solution is then gauged by a fitness function, which is used to assess the new individuals. Until a workable solution is identified, this procedure is repeated over several generations [33], [34]. GA has three essential components [35]:

Encoding: Every person is represented by a chromosome, which is a collection of numbers or letters. The particular issue being handled determines which encoding is used.

Evaluation: The standard of the response that each person represents is assessed using the fitness function. The current issue guides the design of the fitness function.

Operators that are used to create new individuals from preexisting ones are called evolutionary operators. The operators that are most often utilized are mutation, crossover, and selection. To choose the most qualified people to procreate, selection is utilized. The process of crossover allows the chromosomes of two persons to combine to generate one new person. Individual chromosomes can have minor, random alterations introduced into them through the use of mutations.

GA is a heuristic optimization technique; however, technique cannot guarantee the discovery of the best global solution, but it can yield a respectable result at a manageable computing cost. For large-scale issues, however, it could be computationally demanding and time-consuming, particularly if the dataset is big and the training procedure takes a while [36].

Fig. 1. Illustration of RF.

TABLE I. THE SETTING OF THE HYPERPARAMETERS

Random Forest		GA	GWO	BBO
Max depth	[10, 100, None]	80	50	60
Max features	['auto', 'sqrt']	auto	auto	auto
Minimum samples leaf	[1, 4]	2	1	2
Minimum samples split	[2, 10]	2	4	3
Random state	[4, 24, 42, 64, 88]	42	64	24
Number estimators	[200, 2000]	300	200	500

During training, the number of iterative cycles executed by the optimization algorithm is determined by the epoch parameter, which is configured to 500. With a value of 100, the population size parameter specifies how many potential solutions are assessed during each iteration.

C. Gray Wolf Optimization

The optimization strategy that will be presented in this part is distinct and is modeled after the natural hunting organization of grey wolves. In, Mirjalili et al. [37] introduced the Grey Wolf Optimization (GWO) approach. It is claimed that each wolf in the pack lives in a semi-democratic way, with a specific place in this algorithm. To prepare for the hunt, the wolves first circle their target. As they go closer and loosen the encirclement, they gradually exhaust the victim. When the dominant wolf gives the signal, they attack and capture the prey. The wolf hierarchy is as follows:

The alpha pair (α), the group leader, makes the decisions. Alpha decisions have an effect on the group as a whole. However, one also observes a certain democratic conduct.

Beta wolves (β) help alphas with decision-making and other group activities. The most qualified wolves are the alpha wolves until they are too old or die.

The lowest-ranking wolves in a pack are called omega wolves (ω). These are the wolves that warn of approaching disaster. Wolves have to follow the decisions made by other wolves as they eat their prey. As a result, the Omega Wolves are typically not particularly significant. However, if they are eradicated or disregarded, the group may have major problems, such as civil war.

Wolves that do not fall into the previously stated groups are known as delta wolves (δ). These wolves are superior to omegas even if they follow the alpha and beta hierarchies.

As mentioned before, grey wolves are known for their rapacious hunts for prey. Eq. (1) below simulates grey wolves' hunting habits.

$$\begin{aligned} \vec{D} &= |\vec{c} \cdot \vec{X}_p(t) - \vec{X}(t)| \\ \vec{X}(t+1) &= \vec{X}_p(t) - \vec{A} \cdot \vec{D} \\ \vec{A} &= 2\vec{a}r_1 - \vec{a} \\ \vec{C} &= 2\vec{r}_2 \end{aligned} \quad (1)$$

During algorithm iterations, the grey wolf's location vector X , denoted by t in Eq. (1), linearly decreases from a value of 2-0. The coefficients of the prey position vector are represented by vectors A and C . r_1 and r_2 are random vectors in the interval $[0,1]$. The algorithm undergoes 500 rounds of iterative refinement with an epoch value of 500 to improve its predictive capabilities. The algorithm optimizes its search efficiency by concurrently evaluating 100 candidate solutions in each iteration, with a population size of 100.

D. Biogeography-based Optimization

When combined with a more effective exploration method, the BBO algorithm is proven to be effective in exploiting the search space. Because they share qualities, superior solutions tend to draw in inferior ones. The operators listed below are used to process this feature sharing.

Migration Operator: Migration is the process by which, depending on immigration and emigration rates, the poorer solution is replaced with a better habitat. The method by which a species enters a habitat is measured by its emigration rate. Better solutions will see a greater rate of emigration than inferior ones.

The quantity measurement used to determine how a species leaves its environment, however, is the immigration rate. Therefore, in a worse solution than in a better one, the immigration rate will be higher. The simplest form of BBO, the straight lines seen in Fig. 2, have been employed. For the linear functions, it is possessed: Therefore, in a worse solution than in a better one, the immigration rate will be higher. The simplest form of BBO, as seen in the straight lines in Fig. 2, has been employed. For the linear functions, it is assumed that:"

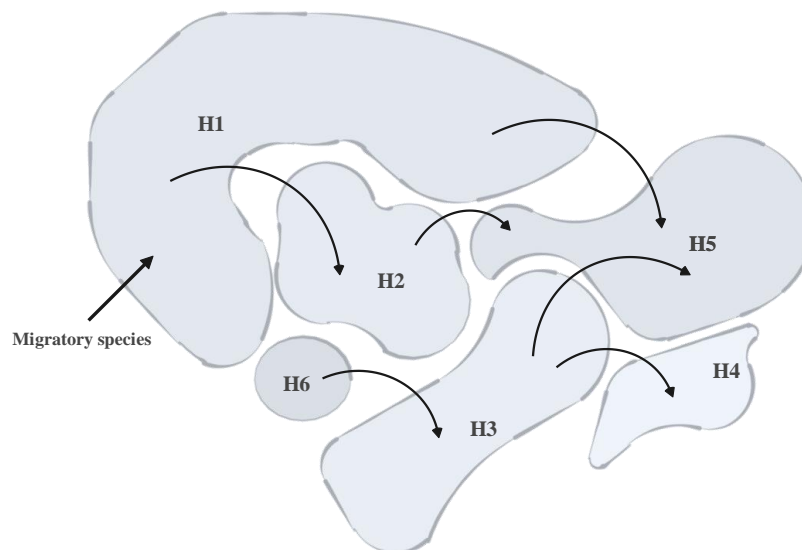

Fig. 2. Visualizing the biogeography-based optimization.

$$\mu_k = \frac{E \times k}{n} \lambda_k = I \left(1 - \frac{k}{n}\right) \quad (2)$$

where,

μ_k : Emigration rate of k^{th} habitat.

λ_k : Immigration rate of k^{th} habitat.

I : Maximum immigration rate.

E : Maximum emigration rate.

$n = S_{max}$: Maximum number of species a habitat can support.

k : Number of species count.

As species diversity increases, immigration rates decrease. On the other hand, the emigration rate rises in tandem with the number of species. S_1 and S_2 , two possible solutions, exist. While S_1 is a somewhat subpar response, S_2 is a quite good one. On average, immigration rates for S_1 are higher than those for

S_2 . Compared to S_2 emigration, S_1 emigration will occur at a slower rate.

Mutation: A BBO mutation is comparable to an abrupt shift in living circumstances brought on by other events, such as a tornado, volcanic eruption, or natural disaster. Since the previous environment is no longer adequate for the species to live, the random change in the solution indicates that the animal moves to a new habitat.

The epoch parameter, which is initialized to 500, controls the length of time that the algorithm iteratively processes. This is an essential factor in enhancing predictive models. The population size parameter, when configured to 100, has an effect on the algorithm's capacity for exploration and diversity, thereby influencing its convergent solution generation capability. Fig. 3 provides the overall structure for the Biogeography Based Optimization Algorithm for easier comprehension.

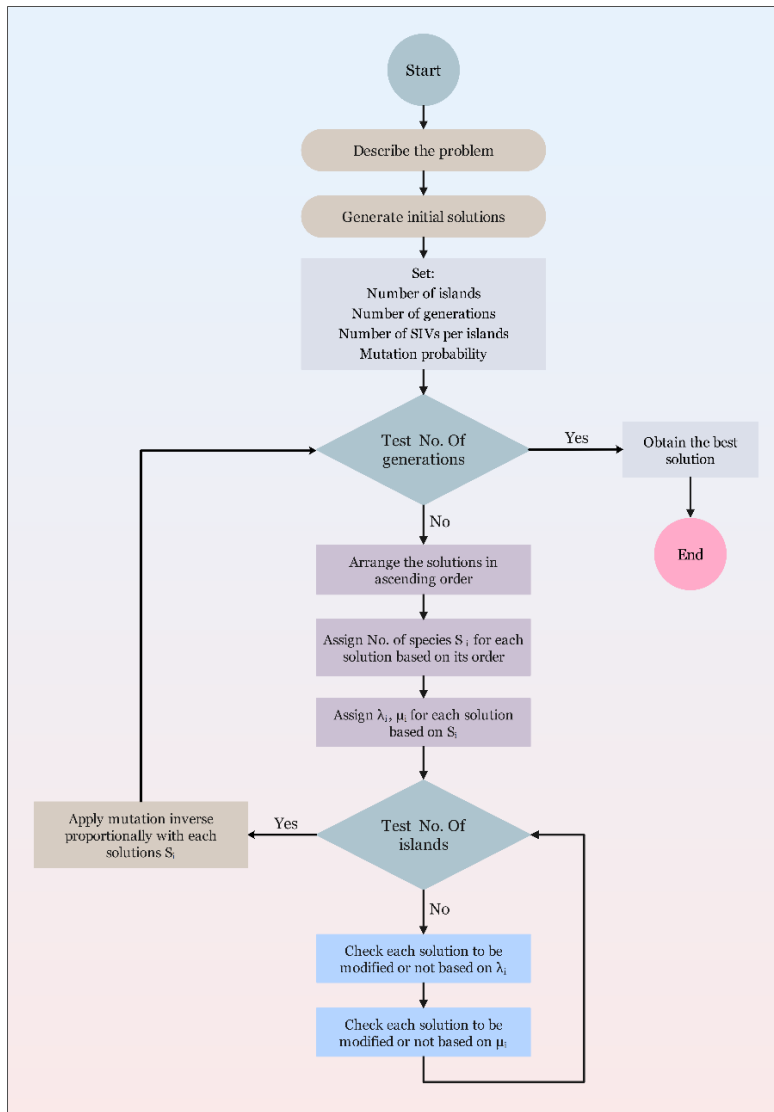

Fig. 3. RF flowchart.

E. Dataset Description

A daily closing price time series shows the observed data for each index in one dimension. The complete dataset was first split up into testing and training groups. The first 80% of the data are part of the training set and are used to train the model parameters. As can be observed from the data shown in Fig. 4, the testing set's last 20% of data is utilized to assess the models' effectiveness.

This article was shown using data from the Hang Seng Index. Several techniques, including normalization, are used to prepare this data, which spans from the start of 2015 to mid-2023. A notable Hong Kong stock market index, the Hang Seng Index monitors the performance of a subset of the largest corporations that are publicly traded on the Hong Kong Stock Exchange [38]. The Hang Seng Index comprises an assortment of corporations that hold leadership positions across multiple sectors of the Hong Kong economy [38]. In addition to manufacturing, these sectors also include finance, real estate, technology, and telecommunications. The Hang Seng Index comprises a number of corporations renowned for their substantial international footprint and profound global impact [38]. This global reach enhances the index's significance as an indicator of market and economic trends outside of Hong Kong.

In brief, the Hang Seng Index monitors the performance of major corporations that are publicly traded on the Hong Kong Stock Exchange. It is a significant Hong Kong stock market index. It functions as a benchmark for investors, furnishes valuable insights into the state of the Hong Kong economy, and is indispensable for comprehending market sentiment and trends within the Hong Kong equity market [38]. Fig. 5 illustrates the graphical representation of the daily and time series collection features for the HSI index. It displays the prices of the open, high, low, and close, as well as the volume value for the first five days and last five days. Two additional indices—the Dow Jones and KOSPI—collected from the beginning of 2015 to the middle of 2023 were assessed in order to demonstrate the efficacy of the proposed model. The Dow Jones is an exceptionally followed stock market index on a global scale. It monitors the performance of thirty sizable, publicly traded companies in the United States that are publicly traded on stock exchanges. The KOSPI Index serves as the primary benchmark for the South Korean stock market. The investment vehicle monitors the progress of every common stock that is listed on the Korea Exchange (KRX), the exclusive operator of a securities exchange in South Korea. The KOSPI Index comprises an extensive array of industries, such as consumer goods, finance, technology, and automotive, among others.

Maintaining the relative connections between the values is the aim while bringing all the qualities to the same scale. This may be crucial for machine learning algorithms that depend on the amount of data that is supplied. The data normalization procedure uses the following formula:

$$X_{Scaled} = \frac{(X - X_{min})}{(X_{max} - X_{min})} \quad (3)$$

F. Model Evaluation

A comprehensive array of evaluation metrics was utilized in this investigation of stock prediction in order to assess the performance of the predictive models. The aforementioned metrics consist of the Mean Absolute Error (MAE), Mean Absolute Percentage Error (MAPE), Root Mean Square Error (RMSE), and Coefficient of Determination (R^2).

MAE calculates the mean discrepancy between anticipated and observed values. By calculating and averaging the absolute differences between predicted and observed values, MAE offers a straightforward indication of the predictive accuracy of a model, irrespective of the error direction. When applied to the domain of stock prediction, MAE provides insight into the average discrepancy that occurs between our forecasts and the real prices of stocks [39]. It can be calculated by using the following equation:

$$MAE = \frac{\sum_{i=1}^n |y_i - \hat{y}_i|}{n} \quad (4)$$

The accuracy of predictions is quantified by MAPE in percentage format. The metric calculates the mean percentage discrepancy between the values predicted and those observed. Regardless of the scale of the data, MAPE is particularly useful in financial forecasting, such as stock prediction, because it provides insights into the relative accuracy of predictions. It provides a percentage-based understanding of the degree to which our forecasts differ from actual stock prices [39]. The calculation can be performed utilizing the subsequent equation:

$$MAPE = \left(\frac{1}{n} \sum_{i=1}^n \left| \frac{y_i - \hat{y}_i}{y_i} \right| \right) \times 100 \quad (5)$$

Another widely employed metric for assessing the accuracy of predictions is RMSE. The square root of the mean of the squared discrepancies between the predicted and observed values is computed. By assigning greater penalties to larger errors as opposed to smaller ones, RMSE offers a more nuanced evaluation of predictive performance. The RMSE metric is utilized in stock prediction to assess the overall adequacy of our models by taking into account the error's magnitude and

direction [39]. The calculation can be performed utilizing the subsequent equation:

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{n}} \quad (6)$$

R^2 assesses the extent to which the independent variables (predictors) in the model account for the variability observed in the dependent variable (stock prices). It is bounded between 0 and 1, where higher values signify a more optimal correspondence between the model and the data. Determining the extent to which our predictive models can account for the variability observed in stock prices requires R^2 as a critical metric. The evaluation of the model's ability to account for the observed variations in stock prices is facilitated by this [39]. The following equation could be employed to compute it:

$$R^2 = 1 - \frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{\sum_{i=1}^n (y_i - \bar{y})^2} \quad (7)$$

where, y_i is the actual value, \hat{y}_i is the predicted value, and \bar{y} represents the mean value [39].

III. EXPERIMENTAL RESULTS

A. Statistical Values

As part of the study report, Table II provides a thorough analysis of the dataset. Information on OHLC price and volume is presented statistically in a comprehensive manner in the table. A more thorough comprehension of the facts is made possible by this. Several statistical measures are displayed in the table, such as the count, 50%, kurtosis, skewness (skew), mean, standard deviation (Std.), minimum (min), and maximum (max) values. An exact and comprehensive data analysis is provided by these measures. From the central tendency to the variability to the dispersion of the data, each of these metrics provides insightful information about a range of aspects of the data.

B. Algorithms Outcomes

An exact and thorough data analysis is provided by these measures. Among the several features of the data that each of these measures offers valuable insights into are the central tendency, variability, and dispersion of the analysis. This work's main goal is to identify and assess the best hybrid algorithm for stock price prediction. To do this, the study created forecasting models and examined intricate factors impacting stock market movements. The objective is to provide analytical data that helps investors and analysts make well-informed investing decisions. The efficacy and performance ratings of each model are fully analyzed in Table III and Table IV and Fig. 6 and Fig. 7.

Fig. 6. Result of the Evaluation metrics for the presented models during train.

Fig. 7. Result of the Evaluation metrics for the presented models during the test.

The primary objective of each model was to forecast the HSI, and the same dataset was used in each model. Additionally, two other indexes were evaluated to prove the efficiency of the proposed model, which these indexes are the Dow Jones and KOSPI collected from the start of 2015 to mid-2023. This article presents a comprehensive and informative study by carefully comparing and evaluating each model's performance. It is crucial to clarify the performance measures used to evaluate the

models to provide a fair and adequate comparison. Assessing the models using a range of important metrics, as explained in the methodology section. It is possible to evaluate every model's performance using a range of indicators and then choose the model that best fits the needs. Table III and Table IV offer an in-depth analysis of all the subtle aspects of each model's operation, along with the outcomes.

TABLE III. ANALYZING DATA WITH METRICS FOR TRAINING SET

TRAIN SET	MODEL/Metrics	RF	GA-RF	GWO-RF	BBO-RF
HSI	R ²	0.9891	0.9922	0.9944	0.997
	RMSE	307.81	261.17	221.27	161.23

	MAPE	1.01	0.79	0.69	0.56
	MAE	3.39	2.63	2.33	1.90

IV. DISCUSSION

Initially, based on the acquired result, the RF model was chosen. The higher performance of the RF model led to its formulation following a comprehensive analysis of the data. About the HSI market data from the start of 2015 to the end of 2023, appropriate data were selected and normalized. Furthermore, to substantiate the efficacy of the suggested model, two additional indices—the KOSPI and the Dow Jones—gathered from the beginning of 2015 to the middle of 2023—were assessed. This rigorous strategy will extract pertinent facts to aid in decision-making. R^2 , RMSE, MAE, and MAPE were used to analyze the data analysis in detail. These indicators have a solid reputation for offering an accurate assessment of the analysis's overall dependability, efficacy, and correctness. The R^2 , RMSE, MAPE, and MAE criteria were used to assess the effectiveness of the RF model both with and without an optimizer. This evaluation improved the ability to comprehend the model's performance and make judgments based on the results. Table III and Table IV shows that the evaluation result for the RF alone in testing is 0.9810 from R^2 , which has increased due to the advances of the optimizers. The R^2 criteria values for GA-RF, GWO-RF, and BBO-RF are 0.9875, 0.9895, and 0.9920, respectively, indicating that selecting the optimal course of action is possible. The RMSE values were 307.81 and 322.02 for RF during training and testing, while the MAE values for training and testing were 246.64 and 248.31, respectively.

The MAPE values were 0.98 and 1.21 for RF during train and test. The testing results are a major factor in determining the optimal approach for predicting stock values in the HSI, Dow Jones, and KOSPI markets. When examining the metrics of the testing set, the BBO applied to the RF model, denoted BBO-RF, is the focal point. BBO-RF demonstrates exceptional performance on both the DOW JONES and KOSPI indices, highlighting its capability to enhance predictive accuracy and reduce errors. The impressive R^2 score of 0.9970 achieved by BBO-RF for Dow Jones indicates a high degree of accuracy in predicting market movements. It is worth mentioning that it attains the lowest RMSE, MAPE, and MAE values, which emphasizes its ability to produce accurate predictions with minimal discrepancy from the actual values. In the same way, BBO-RF exhibits its superior performance on the KOSPI index by producing significantly reduced error metrics in comparison to RF and other optimization techniques. The findings unequivocally illustrate the efficacy of BBO in enhancing the precision and dependability of RF models, which is especially conspicuous in the context of financial forecasting where exactness is critical. The BBO-RF model that has been proposed yields productive results. The graphs showing the findings may be seen in Fig. 8 and Fig. 9. The training and testing data sets have therefore shown the BBO-RF model to have remarkably high accuracy. For predicting stock prices with remarkable accuracy, the BBO-RF model is an excellent resource.

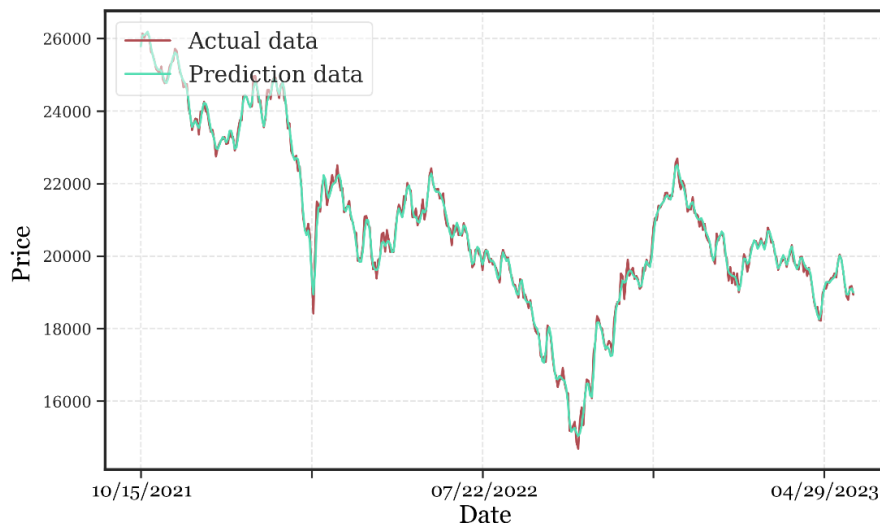

Fig. 9. Evaluation of the performance of the proposed model in comparison to real data during testing.

TABLE V. A COMPARISON BETWEEN THE EVALUATION AND PRIOR RESEARCH

References	Models	R^2
[40]	RNN	0.9784
	LSTM	0.9782
	Bi LSTM	0.9785
[41]	CNN-LSTM	0.9787
[42]	CNN-Bi LSTM	0.9787
	CNN-Bi LSTM-AM	0.9787
[43]	SDTP	0.9788
Current study	BRO-RF	0.992

R^2 values for several predictive models are displayed in comparison Table V. It is essential, when assessing the efficacy of our proposed BBO-RF method for predicting the stock market, to compare its performance to that of previously documented models. The findings of various models, including Bidirectional LSTM (Bi LSTM), Long Short-Term Memory (LSTM), and Recurrent Neural Networks (RNN), are detailed in [40]. The accuracy of these models varies, with RNN attaining a R^2 value of 0.9784, LSTM 0.9782, and Bi LSTM 0.9785. In a similar vein, Convolutional Neural Network (CNN)-based models such as CNN-LSTM, CNN-Bi LSTM, and CNN-Bi LSTM-AM are presented in [41], [42]. Each of these models has a R^2 value of 0.9787. The Stacked Denoising Transfer Learning Process (SDTP) is examined in [42], which provides a R^2 value of 0.9788. The BBO-RF model, which is presented in this study, attains a significantly elevated R^2 value of 0.992. The exceptional performance observed highlights the efficacy of our hybrid methodology in forecasting the stock market. The convergence of BBO and RF enables us to generate more precise forecasts by capitalizing on the combined advantages of optimization and machine learning methodology.

V. CONCLUSION

A robust market may boost confidence among consumers and companies, spurring additional economic growth. As such, the stock market can be used as an indication of the state of the economy overall. The analysis and discussion above make it evident that the study's findings offer insightful information about the prediction model's performance and accuracy. Essential markers of the model's efficacy are the statistical measures of RMSE, MAPE, MAE, and R^2 . The Random Forest model has consistently shown remarkable predictive power. This article suggested a new, enhanced model for the technique, which was based on the original Random Forest approach. Machine learning algorithms heavily rely on optimization techniques to help identify the optimal solution to a given problem. To improve accuracy, machine learning models' parameters can be adjusted with the use of optimization techniques. Better judgment and more precise forecasts may result from this. To increase the efficiency of the model used in this research, three optimization methods were used, among which BBO obtained the best results.

This research uses HSI market data from 2015 to 2023 to forecast stock prices along with two Dow Jones and KOSPI indexes. This paper utilized a few optimization techniques, such

as biogeography-based optimization, genetic algorithms, and Grey Wolf Optimization. Out of all of these adjustments, biogeography-based optimization has produced the best results.

Presenting a New Approach for Clustering Optimization in Wireless Sensor Networks using Fuzzy Cuckoo Search Algorithm

Bing ZHOU*, Youyou LI

College of Artificial Intelligence, Jiaozuo University, Jiaozuo, Henan, 454000, China

Abstract—Because of the developments in this technology, wireless sensor networks are now among the most commonly used in the domains of agriculture, harsh environments, medical, and the military. Among the many problems with these networks is their limited lifespan. Much work has been done in the fields of sensor communication, routing, and data gathering to reduce energy usage and increase network life. Routing protocols and clustering algorithms are two techniques for reducing energy use. Selecting the cluster head is the most important stage in any clustering technique. The objectives of this article are to decrease total energy consumption, increase packet delivery rates, and lengthen the network's lifetime. In order to do this, the LEACH protocol uses cuckoo search instead of probability distribution during the cluster head selection step and fuzzy logic during the routing phase. A MATLAB environment was utilized to evaluate the proposed method with the LEACH algorithm under identical conditions. The results of the comparison show that the recommended approach does a better job of prolonging the network's lifetime than the LEACH protocol.

Keywords—Wireless sensor network; fuzzy cuckoo search algorithm; clustering; fuzzy model

I. INTRODUCTION

Recent improvements in electronics and telecommunications have made it possible to employ low-cost sensor networks. Sensor networks have been utilized due to the diverse properties of sensors, with researchers proposing several ways [1, 2, 3]. In military contexts, attributes such as fault tolerance, rapid operating speed, and network self-organization allow for network control, orderly calculations, and information reception. Sensors in medical settings can aid individuals with disabilities or oversee a patient inside a network. Sensor networks also have uses in business sectors such as management, remote area surveillance, and product quality supervision [4, 5].

Sensors send data across short distances and are small in size. Each small sensor contains a receiving unit, a processing unit, and an information transmission unit [6, 7, 8]. A sensor network consists of numerous sensors that are extensively spread across the surroundings. Engineering is unnecessary for determining the exact geographic locations of the sensors; thus, they are randomly scattered in remote, inaccessible areas. Protocols and algorithms provide the automatic transfer and processing of information in sensor networks [9]. We can identify the processor used in sensors along with their other unique features [10, 11]. The sensors utilize this processor to

locally process the data before transmitting only the essential portion, instead of broadcasting the complete dataset. Clustering is a technique used to optimize coverage and efficiently send network-related data to a central base. Network nodes are segregated into distinct groups known as clusters using the clustering method. Each cluster is led by a cluster head that efficiently distributes information either immediately or progressively, using minimal steps or relying solely on cluster head nodes for data gathering and transmission to the central station. Clustering in sensor networks is utilized to efficiently manage network nodes, reduce energy usage, extend coverage across a wider geographic area, and decrease information transmission time. Each cluster needs a cluster head to send the collected data to the central station. Choosing the cluster head node is a critical part of clustering. Network nodes must consistently follow a specific pattern to select clusters and cluster heads in wireless sensor networks, as node performance can vary and be non-linear. Therefore, using methods that offer definitive solutions may not be advantageous. Using the LEACH (Low-Energy Adaptive Clustering Hierarchy) method is recommended as a clustering technique. Despite its advantages, this method has limitations, such as relying on one-step communication, which renders it impractical for extensive networks. Moreover, ensuring load balance is not possible by choosing Cluster Heads based on a uniform distribution probability. The clustering problem will be solved using the fuzzy approach and cuckoo search algorithm, with efforts made to reduce the algorithm's limitations. Each egg in the cuckoo search algorithm symbolizes a potential solution for a problem that requires selecting the center of a cluster. The goal is to find the clusters that result in the minimum cost function value, as the fuzzy technique will be used in the routing phase.

A more precise acknowledgment of the limitations of the proposed method, including things like the limitations imposed on the fuzzy duck search algorithm and their impact on the overall efficiency of the method, can be an important step to create a clear path in future research. To overcome these limitations, it is possible to improve and adjust algorithm parameters, apply changes in different phases of the method, or even use newer and more advanced methods. In addition, for further exploration and promotion of the discourse, it is possible to refer to the study of the effect of combining other algorithms with the proposed method, the study of different environmental effects on the performance of the method, and the possibility of applying this method in other fields of application. These suggestions not only enrich the discourse, but also encourage

further research and contribute to the development and improvement of the field.

The proposed method in this paper, by combining the LEACH protocol with the fuzzy duckling search algorithm, designs a new approach to optimize clustering in wireless sensor networks. This approach focuses on the goals of reducing energy consumption, increasing packet delivery rate, and increasing network life by using fuzzy duck search algorithm instead of probabilistic distribution in the cluster head selection phase and using fuzzy logic in the routing phase. This approach is generally separated from existing methods in the field of clustering and routing in wireless sensor networks, and by combining fuzzy duck search algorithm and fuzzy logic, it increases its importance and efficiency. The writers' collective contribution to this work is summarized as follows:

- By using fuzzy clustering, the network's lifetime was extended.
- The cuckoo search technique was used to enhance clustering.
- More packages arrived at their destination thanks to clustering.

This is how the rest of the article is structured. The prior studies and their solutions are examined in the Section II. The suggested model is covered in Section III. The assessment and application of the suggested remedy are provided in Section IV and the conclusion and next steps are provided in the Section V.

II. RELATED WORKS

The limited energy of network sensors is one of the problems facing wireless sensor networks. In the areas of routing, network layer protocols, transmission layer research, management of distributed activities amongst sensors, and approaches inspired by nature, there are a lot of well-known studies and publications. It is offered to extend and enhance the network's life. Routing protocols are in charge of identifying and preserving communication channels that use less energy [12]. Because routing protocols have an impact on the network's energy consumption, researchers take routing techniques into account while designing their protocols, making adjustments to suit the application, environment, and service quality of the request. And they are separated into three groups: flat, clustered, and location-based routing. Nodes in clustering protocols are grouped in accordance with the necessary request [13]. The network's energy usage is impacted by the creation of clusters and the tasks given to the cluster heads. Considering that sending and processing need energy consumption, the cluster head receives data from all cluster members and forwards it to the destination after processing. As such, selecting the cluster head and routing is crucial to the network's longevity. The development of low-cost circuits to perceive and transmit the state of the surrounding environment is made feasible by the advancements in communication and sensor technologies [14]. Applications for wireless networks of these circuits, or wireless sensor networks (WSN), include environmental sensing, smart industries, healthcare, and military defense. Reliable data interchange between various sensors and effective connection with the data collecting center are the core issues facing WSNs. The best

method for increasing WSN performance characteristics is clustering to get around clustering techniques' drawbacks, such as a shorter cluster head (CH) lifetime [15]. A successful WSN solution must have an efficient CH selection mechanism, an ideal routing protocol, and trust management. In order to extend the network's lifetime and boost confidence, a type 2 fuzzy logic clustering technique is used in [16] to propose an optimization algorithm for cuckoo searches. To minimize wasted energy from CHs remote from the BS, a multi-hop routing strategy is utilized for inter-cluster communication and a threshold-based data transmission algorithm is employed for intra-cluster communication. The outcomes of the simulation demonstrate that the suggested approach beats alternative communication methods in terms of effectively eliminating rogue nodes as well as energy usage, stability duration, and network longevity [17]. Sensor nodes use the most energy when transferring data since their energy consumption is constant when monitoring data and receiving data packets from other nodes. As a result, routing strategies built on systematic methodologies aim to use less energy. Clustering nodes and choosing string nodes based on data transmission parameters is one of the most promising ways to lower energy consumption in wireless sensor networks. This will increase the network's lifetime and lower the average energy consumption of the nodes [18]. For wireless sensor network clustering, a novel optimization strategy based on the cuckoo algorithm and multi-objective genetic algorithm is thus described in this study. The research in [19] used near-optimal routing based on the cuckoo optimization algorithm to transmit data between nodes in order to choose cluster nodes from a multi-objective genetic algorithm based on reducing intra-cluster distances and reducing energy consumption in cluster member nodes. The results of the implementation demonstrate that the suggested method has improved over previous methods in terms of energy consumption, efficiency, delivery rate, and packet transmission delay. This improvement can be attributed to the evolutionary capabilities of the multi-objective genetic algorithm and the cuckoo optimization algorithm.

For the best CH selection to preserve energy stability over a long network lifetime, a dynamic clustering protocol based on the seagull and whale optimization algorithm (HSWOA-DCP) with WOA exploitation advantages and SEOA discovery advantages is suggested in study [20]. The Seagull Optimization Algorithm (SEOA) was updated for this HSWOA-DCP in order to solve the early convergence issue and maximize computational accuracy during CH selection. Due to SEOA's helix attack behavior's resemblance to the characteristics of WOA's bubble network, its integration into the CH selection process enhanced the global search capability and inhibited the selection of the lowest fitness nodes as CH. The concepts of WOA surrounding contraction mechanism and SEOA spiral attack are integrated into this CH selection to increase computation accuracy and prevent repetitive election processes.

A clustering mechanism based on the Dingo Optimization Algorithm (MDOACM) is presented in study [21] to overcome the cluster head (CH) lifetime and cluster quality restrictions of the clustering protocol. The trust level of each sensor node is ascertained using this MDOACM-based clustering technique using Distance Type 2 Fuzzy Logic (IT2FL), as the existence of an untrusted node negatively impacts the quality and reliability

of the data. In order to prevent frequent re-clustering, it explicitly used MDOA to improve clustering with a balanced trade-off between exploration and exploitation rates. With low energy usage, it effectively blocks malicious nodes and lengthens the lifespan of the network. Additionally, during the entire exploration data transfer, it made use of a communication system that helps the sensors reach the goal with the least amount of energy and the highest degree of certainty.

In order to increase node density and coverage area for scalable scenarios, researchers in study [22] presented a clustering strategy based on the fuzzy method and applied it to agriculture. They concentrated on network and data link level optimizations as well as energy consumption optimization. The suggested technique outperforms other methods for scalable scenarios in terms of half-dead and final-dead nodes, according to simulation results. As a result, IoT systems can be used.

In the [23] method, CHs work together to route data packets over many hops in order to reduce WSN energy usage. However, data forwarding nodes may experience congestion during the data routing phase. In order to address the issue of congestion, they have proposed a variant of the Random Early Congestion (RED) control approach that is distance-based and allows for more intelligent packet drops. Additionally, the Moth-Flame Optimization algorithm was used to modify and minimize the rules of the suggested FLCs in order to maximize their efficacy [24]. The simulation results demonstrate how well the suggested distance-based RED clustering and congestion control strategy works to increase packet loss percentage, decrease retransmissions, and improve WSN lifetime.

Research in [25] suggests a hybrid particle swarm optimization-cuckoo search optimization approach for clustering sensor nodes in a QoS-aware multipath routing protocol. The suggested protocol then uses Cluster Heads to choose several stable paths (optimal network routing) for data transmission based on multi-hop communication. In contrast to current protocols, it uses routes for quick data transport that don't impact QoS. Not only does it use the appropriate number of pathways for data transmission, unlike other QoS-centric protocols, but it also extends the lifetime of the network by periodically changing the Cluster Head based on the remaining energy. Using the NS-2 simulator, the suggested protocol's performance is assessed in several scenarios. The suggested protocol performs better than the current protocols in terms of QoS metrics, including throughput, packet delivery ratio, end-to-end delay, and network lifetime, according to the simulation findings.

III. THE PROPOSED METHOD

Every node in the LEACH protocol has a defined probability of being chosen as the cluster head; nevertheless, some unsuitable sensor nodes may also be chosen, adding to the expense. Clusters with a single member may form using this protocol; in such cases, the nodes' energy will run out rapidly since they are transmitting data straight to the central station. On the other hand, these clusters can be eliminated by cluster mergers. Due to the random nature of this method's cluster head selection, there is a chance that some choices will result in significant energy consumption for critical sensor nodes that connect two sub-networks within the network, which could lead

to the network's disconnection [26, 27]. The cluster head is chosen using the cuckoo search algorithm in the suggested strategy to optimize the LEACH protocol. The process of laying eggs and raising cuckoos served as the inspiration for this algorithm, which belongs to the population-based algorithm category. Each bird lays only one egg at a time, placing it in a randomly chosen nest (each nest holds one solution) in accordance with this procedure. Nests with higher-quality eggs (solutions) pass on to the next generation.

Throughout the algorithm's execution, the number of nests that are available stays constant, and the host bird has a probability of p_a to identifying the guest egg. The host bird, in this case, has two options: either discard the guest's egg or relocate the nest entirely [28]. N percent of the current nests are replaced by new nests (with new random solutions in new locations) in Young's method to simplify p_a . In actuality, each cuckoo egg that is laid in a nest symbolizes a solution. Each nest is a potential solution in the hunt for the common cuckoo (single criteria), as each nest only contains one egg deposited in it. Stated differently, the concept being discussed is shared by the solution, the nest, and the egg. With the aid of Levi's flight, new cuckoo search strategies are developed [29, 30]. A random walk with random steps whose durations adhere to a Lévy distribution is called a Lévy flight. Generally speaking, the cuckoo search algorithm selects the head of the suggested approach as follows:

- Using Levi's flight path, randomly produce a new answer (cluster vertices) such as i .
- Select a small number of nodes as network heads.
- Next, using the fitness function, the chosen node's quality is assessed.
- The fitness function is used to assess the new answer's quality.
- The revised answer's quality is contrasted with the chosen answer's quality. In the event that the new response meets higher quality standards, it takes the place of the chosen response.
- With the aid of Levi's flight, it discards the worst nests (wrong locations) and rebuilds them in a new location.
- Continue until the termination requirements are satisfied by going back to step two (optimal solution).
- Show the top response that was received.

As the aforementioned stages are repeated, the nests progressively approach the optimal points, and at the conclusion of the algorithm's execution, all N nests congregate near the optimal sites.

The probability of a node not being suitable and selecting a new one is measured by the implemented method, and its P_a value is 0.25. This decision was made based on Yang's simulation results, which indicate that the algorithm's convergence rate is independent of this parameter's value. Yang thought that a value of 0.25 would work well in a variety of situations. All of the randomly generated solutions must be found within the problem's solution space. When performing random steps, care should be given to ensure that the destination

locations stay inside the potential space boundary, as the step length follows a certain probability distribution [9]. The simulation environment described in this article has square dimensions. The area where every requirement of the problem is met is the space of potential solutions. The following two limitations need to be followed when generating and modifying the values of each answer (nest):

- All the elements of the vector must have a value ranging from zero to one.
- It is necessary for each vector's component values to add up to one.
- The available responses do not include the vectors that do not apply to the two conditions mentioned above.

The available responses do not include the vectors that do not apply to the two conditions mentioned above.

It is feasible to produce random values that satisfy the first two requirements since the current nodes are dispersed randomly throughout the environment using various techniques. Making up positive random values and dividing them all by their sum is one of the easiest methods [31, 32]. Values between zero and one are generated using this straightforward method, and their sum equals one. An alternative method involves producing a random value at random and mapping it to the interval between zero and one. We then assign a random replacement to the generated answer at the end, and the subsequent random values are mapped to the interval between zero and the sum of the created values. Cuckoos are the group of cluster heads, or network clusters that are not a part of the network nodes after the cuckoo search algorithm has completed its clustering.

Consequently, in this article, the position and energy of the cluster heads found using the cuckoo search algorithm will be discussed. The node chosen to be the cluster head is the one with the smallest Euclidean distance to the cluster center. The LEACH protocol's routing employs one-step communication, sending data straight from the cluster head to the sink and from the cluster head's delivery node.

The suggested method of routing makes use of multi-step communication. The transfer from the source node to the source cluster node occurs in the first phase, between the source node and the source cluster node in the second, and between two cluster nodes depending on the cluster nodes in the third. There will probably be multiple routes in each stage, chosen using the fuzzy approach. Fazi examines and analyzes from zero to one as opposed to working with zero and one. To put it another way, fuzzy logic transforms sets with two members—zero and one in Aristotelian logic into sets with infinite members that have values ranging from zero to one. As such, it is appropriate to select the best course of action.

A. The Role of the Cuckoo Search Algorithm in Improving LEACH Protocol Clustering

Inspired by the life of the cuckoo bird, Cuckoo Search is a revolutionary way of global conscious search that begins with a revocable population. Numerous host birds' nests are home to the numerous eggs that cuckoos lay there. More of these eggs that resemble the host bird's eggs will have a better chance of developing into adult cuckoos. The host bird recognizes other

eggs and destroys them. The quantity of fully developed eggs indicates how appropriate the nests are there. A location receives greater attention the more eggs that can survive there and are preserved. Therefore, a parameter that seeks to optimize it will be the scenario in which the greatest number of eggs are rescued. Cuckoos search for the ideal location to increase the chances that their eggs will survive [33, 34]. Every cuckoo randomly deposits its eggs in the host bird's nest, which is within its egg-laying radius.

A random process has a random course that consists of a succession of random stages. S_N forms a random walk if, in mathematical terms [35], X_N is the total of consecutive random steps of X_i :

$$S_N = \sum_{i=1}^N X_i = X_1 + \dots + X_N \quad (1)$$

where, is a random distribution with a random step. It is also possible to write the connection (1) recursively:

$$S_N = \sum_{i=1}^{N-1} X_i = X_{N-1} + X_N \quad (2)$$

Relation (2) illustrates how S_N and X_N pass from one state to the next in a dependent manner. The primary characteristic of the Markov chain is this one. Numerous fields, including physics, economics, statistics, computer science, the environment, and engineering, use random walks [36]. One of the few stable distributions that is continuous for non-negative random variables is the Levy distribution. The Levy distribution's density function is as follows (3):

$$L(s, \gamma, \mu) = \sqrt{\frac{\gamma}{2\pi}} \frac{1}{(s-\mu)^{\frac{3}{2}}} \exp\left(-\frac{\gamma}{2(s-\mu)}\right) \quad 0 < \mu < s < \infty \quad (3)$$

where γ is the size parameter, and μ is the minimum number of steps. Assuming $s \rightarrow \infty$

$$s \rightarrow \infty L(s, \gamma, \mu) = \sqrt{\frac{\gamma}{2\pi}} \frac{1}{(s-\mu)^{\frac{3}{2}}} \quad (4)$$

The random steps, s can be produced by Mantegna's algorithm [37]. The step lengths s for this algorithm will be as follows:

$$s = \frac{u}{|v|^{\frac{1}{\beta}}} \quad (5)$$

that the variables v and u have a normal distribution.

$$u \sim N(0, \sigma_u^2) \quad , \quad v \sim N(0, \sigma_v^2) \quad (6)$$

where relation (7) provides the value of σ .

$$\sigma = \left\{ \frac{\Gamma(1+\beta) \sin(\frac{\pi\beta}{2})}{\Gamma(\frac{1+\beta}{2}) \beta \times 2^{(\beta-1)/2}} \right\}^{1/\beta} \quad (7)$$

In Eq. (7), Γ represents the gamma function. For $|s| \geq |s_0|$, where s_0 is the smallest step, the distribution obtained for s will be a Lévy distribution. As previously indicated, a Lévy walk, also known as a Lévy flight, is a unique kind of random walk in which the step length complies with the Lévy distribution. Levy flight is actually just a random walk with random steps that have lengths that correspond to Levy distributions. The findings of numerous research on the flying of insects and birds have

demonstrated that many of these species' flight patterns resemble Levi's flight. Fig. 1 illustrates the flight of Levi.

Fig. 1. Levi's flight display.

The cuckoo search yields new solutions through the application of Lévy flight and relation in Eq. (8):

$$x_i^{(t+1)} = x_i^{(t)} + \alpha \otimes \text{Levy}(\lambda) \quad (8)$$

Where, \otimes is the component-to-component multiplication operator and α is the step size. It makes sense that the number of algorithmic steps determines how much the optimal solution differs from the current one since, in the real world, the more the cuckoo eggs resemble the host bird's eggs, the higher the likelihood of survival and the greater the chance of misidentification [38].

$$\alpha \propto |x_i^{(t)} - x_{\text{best}}^{(t)}| \quad (9)$$

The following ten steps can be used to describe the cuckoo search algorithm:

- Create N nests of x_i at random; each x_i is a vector of dimension n or the N dimensions of the answer space (search space).
- Create a fresh response at random, similar to mine, using Lévy flight.
- Apply the evaluation function F to determine the answer's quality.
- Select a random nest from N , such as j , then assess the quality of j 's response (F_j).
- In the event where $F_i > F_j$, substitute response i for j .
- With the aid of Levi's flying, destroy the worst nests (a portion of the worst nests) and rebuild them in a new area.
- Save your best responses or nests.
- Sort the responses to identify which ones are best.
- Continue to the second stage until the requirements for termination are satisfied.

- Display your best response (number 32).

As a result, cuckoo search can be crucial to the LEACH protocol's optimal cluster head selection. As a result, by selecting the best node to serve as the cluster head in the sensor network, energy consumption is saved and decreased [39, 40, 41].

B. Suggested Method

Clustering and routing are the two stages of the suggested methodology. The cuckoo search algorithm is utilized to create clusters during the clustering phase, while fuzzy logic is employed for routing during the routing phase.

1) *Clustering*: Three parameters, energy, x , and y , that represent the components of the node location are utilized in the cuckoo search to create clusters. The method illustrated in Fig. 2 selects a fixed number of nodes as the best cluster head initially. Then, based on the Euclidean distance and energy of the nodes in the network containing the selected nodes, the fitness level of the nodes that is calculated as the best-selected cluster head is determined at random using Levi's flight within the space and energy network of multiple nodes, and is assessed using the fitness function. Finally, the fitness level of Levi's flight clusters with the optimal cluster head's fitness is contrasted. The Levi cluster heads are chosen as the best cluster heads if their fitness is higher, and more locations are chosen utilizing the Levi flight once again. The distance between the chosen places in Levi's flight and the optimal position is determined by the distance between the current location of Levi's flight and the locations that Levi's flight has already obtained. Levi's flight is used to select a site. It then compares its appropriateness to a better place and selects the best suitability. This procedure is repeated until the algorithm finds the ideal solution, which in this article's implementation is 200. There are locations chosen by the algorithm that are not appropriate; their chance is estimated to be 25%. If these locations show up in the program, they are disregarded, and another location is selected by the new place's flight. The nodes with the closest energy and distance to them are referred to as the cluster head, while the remaining nodes select their head based on their energy and distance from the cluster head after the optimal energy and locations are found using the Cuckoo Search method.

The proposed method can be more suitable for some types of data. This could be due to the specific characteristics of this method compared to other methods and the type of data that are commonly used in wireless sensor networks. In particular, the proposed method can be considered suitable for data that needs clustering and routing.

For example, if wireless sensor data are grouped based on their physical location and need to be sent to a specific hub (e.g., a data center), the proposed method that uses clustering with Cuckoo search algorithm and fuzzy logic for routing, it can be very convenient. This method uses good clustering facilities with Cuckoo search algorithm to form clusters and fuzzy logic to

select the optimal path for data transmission, which can significantly improve network performance and efficiency.

In addition, if the data needs to be routed from several nodes and the network is topologically complex, using fuzzy logic to select the route can be effective. Fuzzy logic is capable of managing complex conditions and uncertainty in the network, and this can help improve network performance.

In general, if the data needs to be clustered and routed and has special characteristics such as topology complexity or the need for good energy management, the proposed method can be a suitable option. But for data that requires more complex processing or unstructured data management, other methods may be more appropriate.

Fig. 2. Flowchart of choosing the cluster head location of the proposed algorithm.

2) *Routing*: The process of sending data from a source node to a destination node involves sending the data from the node to the cluster head [42, 43]. If the cluster head is not connected to the source, it forwards the data to another cluster head. Information is therefore sent via a number of paths for each of them to communicate with one another: from the head of the source node to the head of the destination node, from the head of the destination node to the head of the source node, and so on. Fuzzy logic is employed in this process. The four-parameter fuzzy logic uses the energy of the path nodes, the load value of the path nodes, the signal strength at each path step, and the total number of steps as the input fuzzy set of the fuzzy inference system to determine which path is optimal. Every fuzzy set in the input has two membership functions.

The input membership functions, which are given in relation (10), are fitted with the Gaussian function [44].

$$f(x, \sigma, c) = e^{-\frac{(x-c)^2}{2\sigma^2}} \quad (10)$$

Fuzzy if-then rules and the composite Gaussian function are the results of the fuzzy system. Given that every node has a fuzzy inference system, the optimal path is chosen by taking into account the node's energy rate, path load, signal strength, and number of steps.

IV. DISCUSSION AND EVALUATION

To simulate the application, MATLAB version R2014a 64-bit was utilized. MATLAB is one of the most advanced scientific software packages available today, offering a wide range of features easily accessible. This software allows you to add your chosen algorithm with a few simple keystrokes, in addition to the many functionalities that MATLAB itself offers. MATLAB stands different from other scientific software programs thanks to this characteristic. You may effortlessly complete difficult mathematical computations in science and engineering with this program. Numerous implementation

techniques in MATLAB make it simple to carry out a wide range of calculations in the fields of electrical engineering, computers, mechanics, chemistry, and medical engineering. If necessary, you can even use the box. Purchase the specialist instruments you require online. To simulate the suggested technique, a computer with the hardware requirements given in Table I was utilized.

TABLE I. HARDWARE SPECIFICATIONS FOR SIMULATING THE PROPOSED METHOD

Processor:	Intel Pentium(R) CPU, 2.60 GHz 2.60GHz
Installed memory (RAM):	4.00 GB
Display Adaptor:	ATI Radeon HD 5570, 2048 MB
System type:	64-bit Operating system
Operating Systems:	Windows 8 Enterprise

The following parameters will be used to evaluate the simulation results.

- The initial test has defined environment dimensions of 500 x 500 square meters and a predetermined transmitting rate of 100 packets per second. This experiment involves changing the number of sensors to 70, 120, 170, 220, and 250. It is then done thirty times, with the average outcomes of those thirty repeats being shown.
- In the second experiment, the sending rate is fixed at 100 packets per second, the number of nodes is also fixed at (70, 120, 170, 220, and 250) and the environment's dimensions are variable while the network's density is fixed (i.e., as the number of sensors increases, the environment's dimensions increase and vice versa). The average of the thirty repetitions of this experiment is displayed in the results.

In the third experiment, the suggested algorithm is used to compute the node burning time and network lifetime, and the results are compared with the LEACH protocol.

A. Performance of the Proposed Algorithm

The suggested algorithm's performance was assessed and contrasted using various parameters. The energy usage and packet-to-well ratio of the suggested method were compared with that of the LEACH algorithm.

Assumedly, the network under investigation is situated in a square environment, with n^2 nodes arranged in a row or column. $N=n^2$ if the total number of nodes is assumed to be equal to N . To make things easier, we'll suppose that every node is only connected to other horizontal and vertical nodes. It isn't connected to any diagonal nodes [45, 46]. Fig. 3 illustrates this network with an example.

Fig. 3. Proposed sensor network with source (mesh) and sink (brick) where $n=3$ and $n=7$.

Fig. 4 depicts a sample of the network that this article simulates. The length and width of the area where the wireless sensor network is situated are shown by the vertical and horizontal axes. The nodes or wireless sensors in this network are represented by the triangles in this picture.

Fig. 4. Simulation of mobile wireless sensor network in MATLAB.

Three crucial network parameters are represented in the simulation: the total energy used, the proportion of successful transmissions, and the total number of transmissions that reach the well under various conditions, such as altering the network's node count while accounting for the fixed environment's dimensions and node density. It has been assessed and is shown in the proper chart format. Network clustering is accomplished via the Cuckoo Search Algorithm. Algorithm parameters for Cuckoo: There are 200 iterations of this algorithm, with a 0.25 discovery rate. A new solution has been developed using Levi's flight information and a random walk. Assume the network depicted in Fig. 5 exists. The source is node a, while the destination is node d.

Fig. 5. A view of the wireless sensor network with the connection between the nodes.

Cuckoo is the algorithm that performs clustering. A cluster center that may or may not be a node makes up each cuckoo. As previously said, after the nodes are clustered, the cluster center is not among them. Consequently, the cluster center node is chosen from among the nodes based on its Euclidean distance to the cluster center. It is possible to choose the square and triangle nodes as the cluster's center nodes, as depicted in the figure. As previously stated, there are two distinct clusters where the source node, a, and the destination node, d, are situated. Thus, there are three phases involved in this routing. The transfer from the destination cluster head node to the destination node occurs in the third stage, which is the second stage between two cluster head nodes based on the cluster heads and the first stage between the source node and the source cluster head node [47, 48]. There will probably be multiple routes in each stage, chosen using the fuzzy approach. The best route between the pathways is found using the fuzzy processing system in the suggested method. Each of the four input fuzzy sets in the suggested fuzzy inference system has two membership functions.

Fig. 6. Viewing the fuzzy system.

Four fuzzy input and output sets are displayed in Fig. 6. The energy of the path nodes is the initial input; this decides whether the node has a low or high energy level [15], [49]. Its membership function is displayed in Fig. 7 and Relation (11).

Fig. 7. Energy membership function in the fuzzy interface.

$$f(x, \sigma, c) = \begin{cases} \text{Low} : e^{-\frac{(x-c)^2}{2\sigma^2}} & [\sigma, c] = [0.3089 \ 0], x = [0,1] \\ \text{High} : e^{-\frac{(x-c)^2}{2\sigma^2}} & [\sigma, c] = [0.3224 \ 1], x = [0,1] \end{cases} \quad (11)$$

The load value of the route nodes, which shows whether the route's load level is low, medium, or high, is the second input. Its membership function is displayed in Fig. 8 and Relation (12).

Fig. 8. Membership function of path load in fuzzy interface.

$$f(x, \sigma, c) = \begin{cases} \text{Small} : e^{-\frac{(x-c)^2}{2\sigma^2}} & [\sigma, c] = [0.1512 \ 0.027], x = [0,1] \\ \text{Medium} : e^{-\frac{(x-c)^2}{2\sigma^2}} & [\sigma, c] = [0.1067 \ 0.5], x = [0,1] \\ \text{Large} : e^{-\frac{(x-c)^2}{2\sigma^2}} & [\sigma, c] = [0.1479 \ 0.985], x = [0,1] \end{cases} \quad (12)$$

Fig. 9. Membership function of path signal in fuzzy interface.

The signal strength at each stage of the current path is determined by the third input. Three levels are also defined for this input: weak, medium, and powerful. Its membership function is given in Fig. 9 and Relation (13).

$$f(x, \sigma, c) = \begin{cases} \text{low} : e^{-\frac{(x-c)^2}{2\sigma^2}} & [\sigma, c] = [0.1699 \ 0], x = [0,1] \\ \text{Medium} : e^{-\frac{(x-c)^2}{2\sigma^2}} & [\sigma, c] = [0.1699 \ 0.5], x = [0,1] \\ \text{high} : e^{-\frac{(x-c)^2}{2\sigma^2}} & [\sigma, c] = [0.1699 \ 1], x = [0,1] \end{cases} \quad (13)$$

The number of steps on the path is indicated in the fourth entry. The three levels of definition for this entry are the number of little steps, the number of average steps, and the number of large steps [19], [47], [50]. Its membership function is also displayed in Fig. 10 and Relation (14).

$$f(x, \sigma, c) = \begin{cases} \text{low} & : e^{-\frac{(x-c)^2}{2\sigma^2}} & [\sigma, c] = [0.0999 \ 0], x = [0,1] \\ \text{Medium} & : e^{-\frac{(x-c)^2}{2\sigma^2}} & [\sigma, c] = [0.169 \ 0.5], x = [0,1] \\ \text{high} & : e^{-\frac{(x-c)^2}{2\sigma^2}} & [\sigma, c] = [0.0933 \ 1], x = [0,1] \end{cases} \quad (14)$$

Fig. 10. The membership function of the number of path steps in the fuzzy interface.

A maximum of 2×3^3 rules can be directly generated for these four inputs, each of which has two membership functions, using and, where 54 rules with nine outputs are defined as relation (15) and displayed in Fig. 11:

$$f(x, \sigma, c) = \left\{ \begin{array}{l} \text{CWR} : e^{-\frac{(x-c)^2}{2\sigma^2}} \quad [\sigma_1, c_1, \sigma_2, c_2] = \\ [0.04247 \ 0.0125 \ 0.04247 \ 0.0125], x = [0,1] \\ \text{WR} : e^{-\frac{(x-c)^2}{2\sigma^2}} \quad [\sigma_1, c_1, \sigma_2, c_2] = \\ [0.04247 \ 0.1125 \ 0.04247 \ 0.01375], x = [0,1] \\ \text{NGR} : e^{-\frac{(x-c)^2}{2\sigma^2}} \quad [\sigma_1, c_1, \sigma_2, c_2] = \\ [0.04247 \ 0.2375 \ 0.04247 \ 0.2625], x = [0,1] \\ \text{MGR} : e^{-\frac{(x-c)^2}{2\sigma^2}} \quad [\sigma_1, c_1, \sigma_2, c_2] = \\ [0.04247 \ 0.3625 \ 0.04247 \ 0.3875], x = [0,1] \\ \text{GR} : e^{-\frac{(x-c)^2}{2\sigma^2}} \quad [\sigma_1, c_1, \sigma_2, c_2] = \\ [0.04247 \ 0.4875 \ 0.04247 \ 0.5125], x = [0,1] \\ \text{UGR} : e^{-\frac{(x-c)^2}{2\sigma^2}} \quad [\sigma_1, c_1, \sigma_2, c_2] = \\ [0.04247 \ 0.6125 \ 0.04247 \ 0.6375], x = [0,1] \\ \text{CGR} : e^{-\frac{(x-c)^2}{2\sigma^2}} \quad [\sigma_1, c_1, \sigma_2, c_2] = \\ [0.04247 \ 0.6125 \ 0.04247 \ 0.7625], x = [0,1] \\ \text{BR} : e^{-\frac{(x-c)^2}{2\sigma^2}} \quad [\sigma_1, c_1, \sigma_2, c_2] = \\ [0.04247 \ 0.7375 \ 0.04247 \ 0.8875], x = [0,1] \\ \text{CBR} : e^{-\frac{(x-c)^2}{2\sigma^2}} \quad [\sigma_1, c_1, \sigma_2, c_2] = \\ [0.04247 \ 0.9875 \ 0.04247 \ 1.013], x = [0,1] \end{array} \right. \quad (15)$$

Fig. 11. Fuzzy system output.

The input membership functions, whose association was established for each input, have been fitted with a Gaussian function. The fuzzy system output makes use of the composite Gaussian function. In reality, this function combines two Gaussian functions with varying values of σ and c on the left and right sides [32] in order for $c_1 < c_2$ and $\sigma_1 < \sigma_2$. The path's optimality is determined by the outputs from CWR to CBR. As a result, CBR will have the finest routes and CWR the most inappropriate [33, 34]. When the destination is a communication, each mobile node has a fuzzy inference system unit that it uses to identify the set of best routes. When a source wants to transfer data to a destination, it first determines if it has a memory route to the destination. If so, it sends the data and uses the fuzzy system to choose the best route based on the traffic. If not, it initiates the route discovery procedure by transmitting the RREQ packet to other nodes. The lowest energy rate of the node in the traveled path, path load, lowest signal intensity in the traveled path, and the number of path steps will all be present in every RREQ packet flowing in the path.

If an intermediate node has not received a packet previously, it rebroadcasts it; if it has, the new packet has fewer steps than the old one.

B. Comparison of the Proposed Method with the LEACH Protocol

- First test: variable density

Initially, the impact of the wireless sensor network's node count on metrics like energy usage and the number of successful transmissions to the well was assessed. There are several numbers of nodes; in the intended environment, 70, 120, 170, 220, and 250 nodes were chosen. The package was sent at a continuous speed of one hundred packages per second. The environment's width and length, where the nodes are situated, are fixed at 500 square meters.

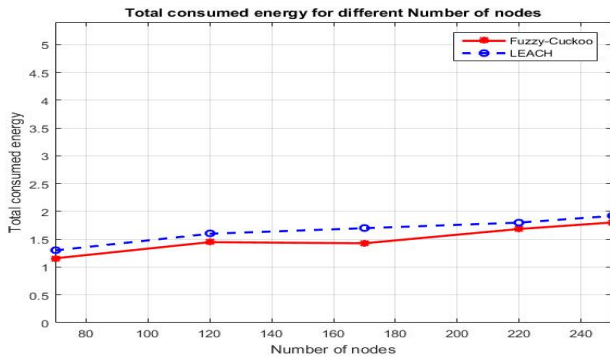

Fig. 12. The overall energy usage as a function of node count in a variable density.

The difference between the total energy consumption and the number of nodes in the network is depicted in Fig. 12. As can be seen, as the number of nodes in the network increases, so does the quantity of energy consumed. There are several possible causes for this rise, including an increase in node connections, congestion, or the volume of transfers. The energy consumption is less than that of the LEACH process, as demonstrated.

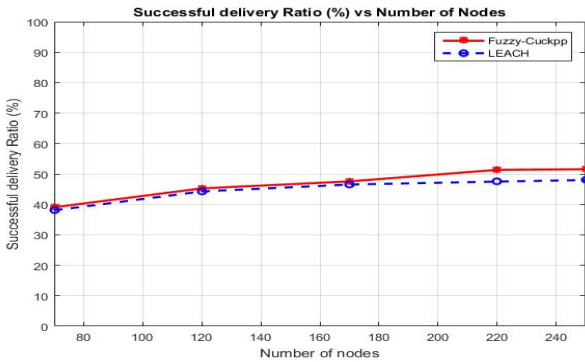

Fig. 13. The number of nodes in the density determines the packet delivery speed to the well.

The number of packets that reach the well in relation to the total number of network nodes is displayed in Fig. 13. As can be seen, the percentage of packets reached rises as the number of nodes or node density in the network environment grows. As a result, the suggested approach performs better in environments with high densities. However, it should be highlighted that the findings are an average of 30 repeats and that the node distribution in the network environment is random. Thus, it can be concluded that while the suggested approach is sensitive to network density, it is not sensitive to network topology. Based on the preceding graphs, it is projected that as energy consumption and the number of steps in the path grow, the ratio of successfully sent packets will also increase. This means that more packets should reach the well. As a result, Fig. 14 validates the earlier graphs' findings.

Fig. 14. The success rate of transmissions over time in various nodes with varying densities.

• Second test: constant density

In this case, the impact of a fixed-density wireless sensor network's node count on several metrics was assessed, including energy usage, the proportion of successful transmissions, the number of successful transmissions that reach the well, etc. There were different numbers of nodes in the environment; nodes 70, 120, 170, 220, and 250 were taken into consideration. The package was sent at a continuous speed of one hundred packages per second. Eq. (16) is used to determine the length and width of the environment where the nodes are located. It should be mentioned that there are 20 nodes per square meter at a fixed node density in the network.

$$x_coordinate = \left[\sqrt{\frac{No_Node \times \pi \times wrange^2}{density}} \right] \quad (16)$$

The percentage of successful transmissions over time with various nodes at a fixed density is displayed in Fig. 15. As you can see, the fixed density of successful transmissions drops as the number of nodes rises. Consequently, the network performs better in terms of successful transmissions and reaches a stable state more quickly the fewer nodes there are in the network.

Fig. 15. Time-series chart illustrating the percentage of successful transmissions in various nodes with constant density.

Fig. 16. The overall energy usage as a percentage of nodes with a constant density.

Fig. 16 illustrates the relationship between total energy usage and the number of nodes in the network while maintaining a constant density. It is evident that the energy consumption grows as the number of nodes in the network increases. The increase in this growth could be influenced by the volume of transfers and communications, congestion, and node connections. In this case, the rate and manner in which energy consumption is increasing differ from when the density was variable. Energy usage decreases after nodes increase in number. Energy consumption increased before reaching a stable level in the previous case. Optimizing both the environment's density and node count can improve its overall performance. It shows that the decrease in sent packets could also be a factor in reducing energy use.

Fig. 17 illustrates how the number of packets that arrive at the well varies with the number of network nodes that have fixed information. The graphic illustrates how fewer packets reach the well as the number of nodes in the network rises.

Fig. 17. The ratio of the number of nodes with constant density to the speed at which packets reach the well.

- The third test: the first burnt node

The time used by the LEACH method and the suggested algorithm is depicted in Fig. 18 and Fig. 19. As can be seen, the suggested algorithm outperformed the earlier findings.

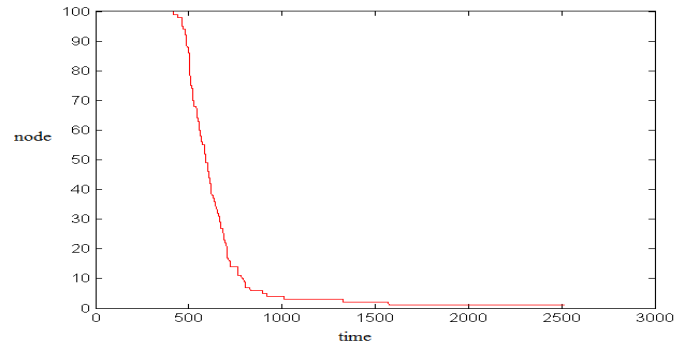

Fig. 18. Burned node time in the suggested approach.

Fig. 19. Ninety burned time in LEACH.

C. Comparative Analysis

Table II displays the dead time analysis, and LEACH and Fuzzy-cuckoo are compared with its initial node [21].

TABLE II. PERFORMANCE ANALYSIS OF DEAD TIME

Energy (J)	Node location	LEACH	Fuzzy-cuckoo
0.01	25,75	13	36
0.02	25,75	17	38
0.03	25,75	21	47
0.04	25,75	26	56
0.05	25,75	43	94
0.01	25,75	15	42
0.02	25,75	19	55
0.03	25,75	34	69
0.04	25,75	66	117
0.05	25,75	89	148

The performance analysis leads to the conclusion that the suggested approach outperforms alternative approaches in terms of performance. Because the suggested method generates routing paths and chooses the best CH, it performs better. The distance between the stationary and mobile sensors of the WSN is taken into account in order to reduce the energy consumption of the suggested technique. As a result, the suggested method's dead time in WSN is extended. Furthermore, the fitness function in routing prevents node and link failures. Less packet drops occur during communication as a result. As a result, the suggested technique minimizes both energy use and packet loss.

V. CONCLUSION

The research findings that were derived from the simulation that were mentioned in the fourth section are the subject of this section. The cuckoo algorithm is used in the suggested algorithm to do clustering, as previously discussed in the article's parts. A cluster center, which may or may not be among nodes, makes up each cuckoo. As previously said, after the nodes are clustered, the cluster center is not one of the nodes; thus, the cluster center node is chosen from among the nodes based on its Euclidean distance to the center. Routing takes place in three phases. The transfer from the source node to the source cluster node occurs in the first phase, between the source node and the source cluster node in the second, and between two cluster nodes depending on the cluster nodes in the third.

As previously said, after the nodes are clustered, the cluster center is not one of the nodes; thus, the cluster center node is chosen from among the nodes based on its Euclidean distance to the center. Levy's flight path has a set step length and unpredictable step direction. Employing the cuckoo optimization algorithm, one of the most advanced and potent evolutionary optimization techniques, to determine the cluster's center. When compared to the cuckoo search, the cuckoo optimization technique exhibits increased convergence and comparatively higher accuracy. The Levy's flight step length in this manner is flexible and gets less as the cuckoo generation increases. Cuckoo search's fitness function uses fuzzy logic, which improves search accuracy.

The importance of studying this article and its findings are very important in two ways. First, the paper has detailed and comprehensively explained the proposed methods to improve the performance of wireless sensor networks. By using Cuckoo search algorithm for clustering and fuzzy logic for routing, network performance is improved and productivity is increased. Meanwhile, the simulation results show that the proposed method has a significant improvement over conventional methods such as LEACH. Second, this paper can be used as a foundation for future research on improving the performance of wireless sensor networks. The ideas and algorithms presented in this paper can be used as a starting point for further research in the field of optimization and performance improvement of wireless sensor networks. On the other hand, considering the successes of this paper, it is suggested that more future research be done in the field of improving clustering and routing algorithms in wireless sensor networks, and also the use of fuzzy-based methods and artificial intelligence algorithms to improve the performance of networks is recommended.

Abstract—In recent years, credit card transaction fraud has inflicted significant losses on both consumers and financial institutions. To address this critical issue, we propose an optimized framework for fraud detection. This study deals with non-identically independent distributions (IIDs) involving different numbers of clients. The proposed framework empowers banks to construct robust fraud detection models using their internal training data. Specifically, by optimizing the initial global model before to the federated learning phase, the suggested optimization technique accelerates convergence speed by reducing communication costs when moving forward with federal training. The optimization techniques using the three most recent metaheuristic Optimizers, namely: An improved gorilla troops optimizer (AGTO), Coati Optimization Algorithm (CoatiOA), Coati Optimization Algorithm (COA). Furthermore, credit card data is highly skewed, which makes it challenging to predict fraudulent transactions. The resampling strategy is used as a preprocessing step to improve the outcomes of unbalanced or skewed data. The performance of these algorithms is documented and compared. Computation time, accuracy, precision, recall, F-measure, loss, and computation time are used to assess the algorithms' performance. The experimental results show that AGTO and (CoatiOA) exhibit higher accuracy, precision, recall, and F1 scores compared to the baseline FL Model. Additionally, they achieve lower loss values.

Keywords—Credit card fraud detection (CCFD); federated learning; optimization algorithms; identically independent distributions (IIDs); metaheuristic optimization techniques

I. INTRODUCTION

Credit card transactions have increased dramatically in recent years due to the rapid development of electronic services such as e-commerce, electronic banking, mobile payments, and the widespread use of credit cards. According to data, Visa [1] and Mastercard [2] issued 2023 million credit cards globally in 2022. Visa issued 1249 million cards worldwide, whereas MasterCard issued 1047 million. By mid-2023, the number of credit cards issued in the United States had increased by more than 30 million compared to the same period in 2022. These statistics indicate how card-based transactions grew popular among end customers.

Billions of dollars in credit card fraud losses will occur from widespread credit card use, a range of transaction circumstances, and weak verification and management. It is challenging to determine the loss exactly. The Nilson Report study (Dec 2022) [3] states that Mastercard faces a significant fraud risk due to the fact that it has 2.5 billion payment cards in more than 200 countries and territories worldwide. Credit card theft cost over \$32 billion in 2021—roughly 6.6 cents for every \$100 transaction. By 2027, card fraud will result in approximately \$40 billion in gross losses worldwide. Two ways that fraudulent transactions could be carried out are using a stolen card that was obtained from either internal or external sources, or using credit card information that was obtained fraudulently [4].

Federated learning (FL) is a machine learning paradigm in which multiple clients collaborate to train a model while being managed by a central server [5]. FL never allows the server or other clients access to raw client data. Hyperparameter optimization poses new challenges in the FL setting and is a prominent open research area [6]. The level of communication influences how effectively a machine learning model performs. We examined a communication-efficient hyperparameter optimization strategy, a local hyperparameter optimization method that allows us to tune the hyperparameters before to the federation phase, to reduce communication costs, which are a significant barrier in FL [7]. Our offer comprehensive and reliable empirical benchmarks for federated optimization strategies that use metaheuristic optimization so that they can be compared. This study presents the following contributions:

- The Synthetic Minority Oversampling Technique (Smote) was used as a resampling method for unbalanced data.
- The conventional federated learning model has been utilized for Non-IID (Identical Independent Distribution) with different numbers of clients.
- Three metaheuristic optimization techniques were used to improve the initial model and reduce communication on a federated learning platform.
- To evaluate the effectiveness of the optimized models with the Federated Learning problem, the learning

process was repeated multiple times using the optimized global model.

This paper's remaining sections are organized as follows: Section 2 includes a comprehensive review of the existing literature. Section 3 outlines the methodologies taken and demonstrates each phase of the proposed federated paradigm. In Section 4, we examine and explain the experimental data, as well as compare the suggested method to previous research. Finally, Section 5 of the paper looks at prospective future research directions.

II. RELATED WORKS

The traditional machine learning approach, implicitly or explicitly, assumes the data distribution is identically independent. This scenario is suitable for collecting all data and then training in a distributed way. However, data is collected from various devices or institutions. Besides, there's maybe a huge variety of data sizes in different nodes, thereby not following Identically Independent Distribution (IID). some research studies related to credit card fraud detection that specifically consider IID (Identically Distributed) datasets [8:10]. To address imbalanced credit card fraud detection datasets, the researchers [8] propose a novel approach that combines autoencoder (AE) and fully connected deep networks (FCDN) models. The process is divided into three stages: training an AE on fraudulent transactions, dimensionality reduction with another AE, and using encoded representations for FCDN classification. The model's performance is improved further by including an additional FCDN trained on preprocessed data using the synthetic minority oversampling technique (SMOTE). The integrated model architecture detects credit card fraud with high accuracy.

The study [9] employs machine learning algorithms to predict both legitimate and fraudulent credit card transactions. They assess algorithm performance using accuracy, sensitivity, specificity, Matthew's Correlation Coefficient, and Receiver Operating Characteristic (ROC) Area rates. The study applies the Synthetic Minority Oversampling Technique (SMOTE) to an imbalanced dataset and optimizes algorithms using feature selection methods. The study [10] suggests using an

autoencoder-based classification scheme to extract credit card fraud characteristics from a European credit card dataset. They use encoded features to compare various machine learning algorithms in terms of classification consistency. The results indicate high accuracy, precision, recall, and F1 score.

Federated learning optimization is a demanding and active research subject with the goal of developing efficient and effective algorithms for learning models from decentralized data sources. Federated programming is a distributed learning paradigm in which multiple clients work together with a central server to build a model without providing their own training data. This approach ensures data privacy, reduces communication costs, and enhances security by keeping sensitive information localized [11].

Federated learning tackles challenges by creating efficient algorithms for model learning from decentralized data sources. In this collaborative paradigm, multiple clients (such as banks or institutions) build a model without sharing raw training data with a central server.

Communication Bottlenecks in Federated Learning: Communication plays a pivotal role in federated learning, but it presents challenges: firstly, Limited Bandwidth: clients often face restricted communication bandwidth, hindering frequent data exchanges. Secondly, Compression Techniques: researchers explore compression communication techniques to efficiently transmit model updates to the central server. In the context of credit card fraud detection, federated learning holds promise. However, understanding the trade-offs between communication efficiency, model accuracy, and privacy preservation remains an active area of research.

In FL, communication is regarded as a significant obstacle. Because clients often have limited communication bandwidth, limiting the quantity of communication or using compression communication techniques for model modifications to the central server becomes more important [12].

There are various previous works focused on credit card fraud detection problems. Table I elicits and summarizes these works.

TABLE I. COMPARISON OF THE RECENT PREVIOUS WORKS

Research/ Publish Date	Contribution	Datasets	Techniques	Conclusion
[13]/ 2020	The purpose of this study is to provide IBM with a better understanding of federated learning and its potential applications. Specifically, they explore how Federated Averaging, a key technique in federated learning can be applied to address credit card fraud detection within the banking sector. Federated Averaging has been applied to the banking industry, where the aim was to detect credit card fraud.	European Credit Card (ECC) Obtained from Kaggle	SMOTE for oversampling the skewed datasets. PCA for high-dimensional datasets. MLP for centralized detecting fraudulent transactions. Federated Averaging. Mini-batch gradient descent as an optimizer.	Small Dataset Size Lack of Cost-Sensitive Learning Simple Model Updates. The study assumed no faulty nodes, and no missing data. Differential privacy and secure computation techniques were not implemented.

[6] /2019	A framework to train a fraud detection model using behavior features with federated learning, as well as an oversampling approach, is combined with balancing the skewed dataset. The performance evaluation of the credit card FDS with FFD framework on a large-scale dataset of real-world credit card transactions	European Credit Card (ECC) Obtained from Kaggle	A data level method: SMOTE is selected for data rebalancing. PCA Federated Convolutional Neural Network as a suitable ML algorithm for detecting credit card fraud	Small Dataset Size. Privacy concerns related to credit card fraud detection. Lack of Cost-Sensitive Learning.
[14] /2020	This model enables banks to learn fraud detection models with the training data distributed on their own local database.	European Credit Card (ECC) Revolution Analytics (RA) SD and Vesta from Kaggle	Feature extraction model and relation model The deep K-tuplet network as a novel meta-learning-based classifier	The study did not implement differential privacy or other secure computation techniques. These methods are essential for protecting sensitive data during federated learning. Lack of Cost-Sensitive Learning.
[15] /2020	Using under-sampling to balance the dataset because of the high imbalance class, implying skewed distribution. Applying NB, SVM, KNN, and RF to under-sampled class to classify the transactions into fraudulent and genuine, followed by testing the performance measures using a confusion matrix and comparing them. Examining these models against the entire dataset (skewed) using the confusion matrix and AUC (Area Under the ROC Curve) ranking measure to conclude the results to determine which would be the best model for us to use with a particular type of fraud.	dataset for European cardholders (ECC)	Under-sampling was used to remove the observation values from the majority class (genuine) randomly until the dataset reaches the balance because the minority class (fraudulent) is very small in comparison with the majority class. (PCA) to protect the true information from the analyst examining the data by transforming the original variables obtained during the collection of data. - NB, SVM, KNN, and RF to classify the transactions into fraudulent and genuine transaction.	The study focused exclusively on European banks, which may limit the generalizability of its findings to other regions. Lack of Cost-Sensitive Learning The research did not investigate privacy concerns related to credit card fraud detection.

III. PROPOSED MODEL

The notion of federated learning (FL) plays a crucial role in the banking industry, particularly in credit card fraud detection. The growth of CCFD systems raises concerns about data security and privacy protection, which FL intends to address. This work uses a federated learning model to detect credit card fraud. In Florida, communication is regarded as a significant obstacle. As a result, we provide thorough and reproducible empirical standards for evaluating federated optimization strategies using metaheuristic optimization techniques. This study presents a federated learning technique for CCFD that addresses data privacy concerns. The classical federated learning model was then applied to the non-IID dataset, which included many clients.

Furthermore, resampling strategies were proposed as a solution to overcome imbalanced class concerns and improve classification accuracy. Finally, optimization can significantly reduce the amount of communication needed to train a model on a federated learning platform.

Standard optimization strategies, such as extended SGD, are typically ineffective in FL and can incur high communication costs. To address this, we developed efficient models that were constantly updated prior to interacting with the server. This drastically reduces the amount of communication required to train a model on a federated learning platform. This study used three metaheuristic algorithms, as stated in Table II.

TABLE II. THE CHRONOLOGICAL TABLE OF USED METAHEURISTIC ALGORITHMS

Name	Abbreviation	Main Category	Subcategory	Year published	Ref .
Giant trevally optimizer.	GTO	Nature-inspired	Swarm-based	2022	[16]
An improved gorilla troops optimizer	AGTO	Nature-inspired	Swarm-based	2023	[17]
Coati Optimization Algorithm	COA	Nature-inspired	Swarm-based	2023	[18]

The Giant Trevally Optimizer (GTO) is a novel metaheuristic algorithm based on the natural hunting behavior of giant trevallies. Giant trevallies eat fish, cephalopods, and seabirds, including sooty terns. Giant trevallies' unique hunting strategies for seabirds have been mathematically modelled and divided into three major steps.

Algorithm Steps:

- Foraging Movement Patterns. The first step simulates giant trevallies' foraging movement patterns.

- Selecting the Right Area: In the second step, giant trevallies choose a food-rich area where they can hunt for prey.
- In the final step, trevallies chase and attack seabirds. When the prey is close enough, the trevallies jump out of the water to attack it in the air or snatch it from the water's surface.

An improved Gorilla Troops Optimizer (AGTO) is an improved for a metaheuristic algorithm inspired by gorillas' collective behavior and social intelligence. Like other metaheuristics, the basic GTO has limitations, particularly when dealing with complex and flexible optimization problems. To address these limitations and improve performance, the Improved Gorilla Troops Optimizer (IGTO) was proposed.

Here are the key enhancements introduced into IGTO:

- IGTO uses Circle Chaotic Mapping to initialize gorilla positions.
- This initialization technique increases population diversity and provides a solid foundation for global search.
- To avoid being trapped in local optima, IGTO uses a lens opposition-based learning mechanism.
- This mechanism broadens the search ranges, enabling the algorithm to investigate a larger solution space.
- IGTO uses a novel local search algorithm called adaptive β -hill climbing.

Combining this technique with GTO improves precision in determining the final β solution.

IGTO Increases exploration and exploitation capabilities and enhances solution quality, local optimum avoidance, and robustness.

Competitive performance on real-world tasks.

The Coati Optimization Algorithm (COA) is a novel bio-inspired metaheuristic that aims to model coatis' natural behaviors. These small mammals, native to Central and South America, exhibit fascinating behaviors that inspire the COA.

COA draws inspiration from coatis' hunting and survival strategies.

It considers both attacking behavior (when coatis hunt for prey) and escape behavior (when they come across predators).

COA mathematically models different stages of exploration and exploitation.

These two phases guide the algorithm's search process, allowing it to explore a wide range of solution spaces while focusing on promising regions.

To address optimization challenges, the Coati Optimization Algorithm (COA) combines natural inspiration and mathematical modeling. Its ability to explore diverse solution spaces while exploiting promising regions makes it a useful tool for both researchers and practitioners.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

The experiments in this work have been done using Python programming language (Python 3). In this work, we utilized open-source tools Scikit learn (1.1.3), pandas (1.4.4), NumPy (1.22.3), matplotlib (3.5.3), TensorFlow federated (0.17.0), mealpy 2.5.3, and Imblearn (0.9.1) in this work. The experiment was carried out using a desktop computer with an Intel core i7 1.80 GHz CPU, 16GB of RAM, and Windows 10 64-bit operating system. Wherever Times is specified, Times Roman of Times New Roman may be used. If neither is available on your word processor, please use the font closest in appearance to Times. Avoid using bit-mapped fonts if possible. True-Type 1 fonts are preferred.

A. Datasets

The Kaggle dataset [19] used in this study contains real but anonymous, credit card transactions made by European cardholders. The dataset includes 284807 credit card transactions from September 2013. There is no missing data, and just 492 of the 284807 transactions are fake, yielding a highly skewed dataset. Furthermore, it includes 30 properties, just two of which are known: transaction amount and time. See Table III for a summary of the dataset.

TABLE III. SUMMARY OF THE DATASET OBTAINED FROM KAGGLE

Total dataset	#fraud	#Not fraud	Label not fraud	Label fraud
284807	492	284315	0	1

B. Results Analysis

As a baseline, the experimental results compare the classical simple federated model on non-IID dataset with different number of clients as shown in Table IV.

TABLE IV. THE RESULTS FOR THE FL_MODEL WHEN DEALING WITH NON-IID DATA ACROSS DIFFERENT CLIENT CONFIGURATIONS

Framework	TensorFlow Federated					
	FL_Model					
# of Clients	Accuracy	Precision	Recall	F1-score	Loss	Time
2	93.91	91.66	96.61	94.06	0.2602	294
3	93.53	94.17	92.79	93.47	0.2639	268
5	95.49	94.14	95.88	95.50	0.1548	251
10	95.01	98.14	91.77	94.84	0.2641	272

These measurements offer insight into the FL_Model's performance across various client settings. Notably, as the number of clients grows, accuracy stays high, illustrating the efficacy of the federated learning approach. Keep in mind that modest differences in performance measures are to be expected given the FL model's dispersed nature and privacy-preserving mechanisms.

Fig. 1. The Performance parameters of the Classical Model on non-IID with different numbers of clients

Fig. 2. The Loss values of the Classical Model different numbers of Clients

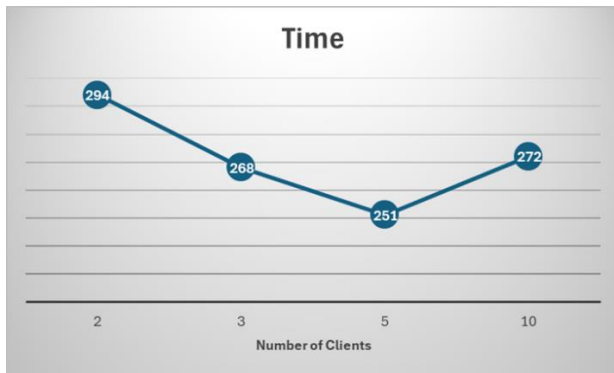

Fig. 3. The Computation Time of the Classical Model different numbers of Clients

As per the graphical representation of these boxplots, shown in Fig. 1 to Fig. 3, the classical federated learning model in combination with different number of clients. For each number of clients, the performance of all cases is presented.

The optimized federated model is compared with the typical simple federated model [20] in the experimental results as a baseline. Table V displays the findings of the experiment. It is evident that any federated model that has been tuned outperforms the basic model in terms of performance. Performance indicators such as accuracy, precision, recall, F score, and loss ratio are the main tools used to assess the efficacy of the suggested model.

TABLE V. COMPARISON RESULTS OF OPTIMIZED FEDERATED LEARNING MODELS WITH THE PREVIOUS WORK [20]

Performance Parameters	Previous Work FL Model [20]	Optimized FL Models (Proposed Works)		
		GTO_FL	AGTO_FI	CoatiOA_FL
Accuracy	91.88	95.79	96.83	96.85
Precision	0.8965	0.9379	0.9615	0.9631
Recall	0.9476	0.9807	0.9756	0.9744
F1_Score	0.9213	0.9588	0.9684	0.9687
Loss	0.2804	0.2221	0.2120	0.21088
OP_Time	-	2153	673	721
FL_Time	415	360	303	326

These metrics provide insights into the performance of each model. The AGTO_FL and CoatiOA_FL models exhibit higher accuracy, precision, recall, and F1 scores compared to the baseline FL Model. Additionally, they achieve lower loss values. The optimization strategies employed in AGTO_FL and CoatiOA_FL seem effective in enhancing fraud detection.

In terms of model performance, the AGTO_FL and CoatiOA_FL models outperform the baseline FL Model in terms of accuracy, precision, recall, and F1 score. Both AGTO_FL and CoatiOA_FL achieve higher accuracy (96.83% and 96.85%, respectively) compared to the baseline (91.88%). Precision is significantly improved in AGTO_FL (96.15%) and CoatiOA_FL (96.31%) compared to the baseline (89.65%). Recall values for both advanced models are also impressive (97.56% and 97.44%) compared to the baseline (94.76%). The F1 score, which balances precision and recall, is notably higher in AGTO_FL (96.84%) and CoatiOA_FL (96.87%) than in the baseline (92.13%).

Regarding Loss Minimization, the loss function is crucial for model optimization. Both AGTO_FL and CoatiOA_FL achieve lower loss values (0.2120 and 0.21088, respectively) compared to the baseline (0.2804). This reduction in loss indicates better convergence and improved model performance.

From Computational Efficiency, the optimization strategies employed in AGTO_FL and CoatiOA_FL led to faster convergence. AGTO_FL takes 303 seconds, while CoatiOA_FL takes 326 seconds for federated learning, outperforming the baseline (415 seconds).

V. CONCLUSION

This study was conducted on a non-IID dataset with a large number of clients. This limitation may impact the generalizability of the findings to other scenarios. This paper proposes an optimized federated learning model that employs the most recent metaheuristic CCFD algorithms to detect patterns of fraudulent credit card transactions (GTO, AGTO, COA). The optimization tactics used in AGTO_FL and CoatiOA_FL appear to be effective at improving fraud detection. While the proposed federated learning model employs recent metaheuristic algorithms (GTO, AGTO, COA), it's essential to recognize that these algorithms have their own limitations. In the future, enhancing privacy protection mechanisms within the federated learning model is crucial. Incorporating better gradient privacy techniques can safeguard

sensitive data during training. will be optimized by including better gradient privacy protection, and additional comparison analysis and reliability checks against earlier research are advised for a thorough evaluation. Future research should conduct thorough comparison analyses against earlier studies. Additionally, reliability checks such as robustness testing and sensitivity analysis will provide a more comprehensive evaluation of the proposed model.

Embedding Emotions in the Metaverse: The Emotive Keywords for Augmented Reality Mobile Library Application

Nik Azlina Nik Ahmad¹, Munaisyah Abdullah², Ahmad Iqbal Hakim Suhaimi³, Anitawati Mohd Lokman^{4*}

Universiti Kuala Lumpur, Software Engineering Section

Malaysian Institute of Information Technology, Kuala Lumpur, Malaysia^{1,2}

College of Computing, Informatics and Mathematics, Universiti Teknologi MARA, Shah Alam, Malaysia^{3,4}

Abstract—The emergence of the metaverse, marked by the seamless integration of augmented reality (AR) applications across various sectors is driving a profound transformation in the digital landscape. As we delve into the digital realm of the metaverse, just like other applications, it unfolds as an equally captivating canvas for emotional exploration, where a comprehensive understanding of human emotion for better user experience (UX) is vital. Although the efforts to investigate emotions within the metaverse are in progress, however there is a notable absence of extensive research that examines the user's emotional experiences which incorporates a tailored set of keywords specifically for designing user interface (UI) products within this context, resulting in a substantial void in this particular domain. Therefore, the objective of this research is to synthesise and validate an extensive array of emotive keywords explicitly tailored for AR-based Mobile Library Application (MLA) design. This endeavor involves an exhaustive review of literature and a rigorous validation process, encompassing input from both linguistic and technical experts in the field. The result is an explicit collection of sixty emotive keywords that will significantly contribute to the metaverse realm by adding a layer of emotional depth to enrich the AR-based MLA experience. These findings offer valuable guidance for practitioners and researchers, advancing the landscape of MLA interface design and ultimately boosting UX in the educational sector.

Keywords—Affective engineering; emotional design; human factor; Kansei engineering; metaverse library; mobile augmented reality; user experience

I. INTRODUCTION

In the evolving landscape of app design, the value of comprehending human emotions remains paramount. These emotions underpin the very essence of user experiences (UX) and the connections we forge with digital interfaces. As we venture into the metaverse; a realm that offers limitless possibilities and unprecedented interactivity, it becomes abundantly clear that comprehending and embedding human emotions is the key to developing engaging immersive experiences. In this digital frontier, where reality and imagination converge, the complex landscape of the metaverse rings us to explore the depth of human perception, leading us to new perspectives in app design; the emotional design.

The field of emotive design has a strong connection to Kansei Engineering (KE) [1], a methodology originating from the domain of emotional design research to efficiently navigate

the various emotions that individuals may experience throughout their interaction with a product. In the field of affective engineering, KE is widely recognized as a dynamic methodology that effectively interprets implicit emotions and transforms them into tangible attributes for products [2]. This unique ability refreshes the product design process by seamlessly integrating consumer emotions with innovation. These products, which have been carefully calibrated to elicit an emotional response, easily trigger a deep bond between the consumer and the product, thus engage their interest. KE relies on domain-specific lexical terminologies known as "Kansei Words" (KW), which often referred to as "emotive keywords" [3]. These KW's function as communicative pathways, reflecting the users' emotional experiences and perceptions as they engage with diverse product designs [4]. Each emotive keyword is carefully constructed to portray the subtle emotional reactions that consumers feel towards a particular product.

In an era characterized by the rapid rise of metaverse technology, the need of integrating emotive design principles becomes evident. The digital environment is a source for innovation, holding a wide range of apps, each with the ability to evoke distinct emotions and deeply engage users. However, it begs the question of how thoroughly the previous research have investigated the field of emotional design, providing pertinent information for the continuous improvement in this research context. Has this been sufficiently addressed by prior research?

Undoubtedly, research focusing on emotions within the metaverse has gained considerable attention from scholars. However, most of these studies tend to focus on usability challenge [5]–[8], characteristics [9], key issues [10], or solely on the developmental aspects [11]–[13]. Within the domain of KE, a number of research initiatives have delved into Kansei studies, exploring keywords and producing sets of appropriate KWs for particular application categories. However, these endeavors often maintain a broad perspective, exemplified by [14], which presented a comprehensive compilation of more than 800 keywords that are relevant to IT-based products in general. Conversely, alternative research endeavors concentrate their attention on specific categories of applications, such as web-based [15], [16] or mobile-based applications [17], [18]. Nevertheless, their investigations primarily centered around conventional application types. Despite the fact that [19] attempted to cover innovative products by examining keywords for pervasive applications, their study still broad in scope, as it

encompassed a wide range of current technologies, including augmented reality and virtual reality applications in their entirety. Surprisingly, scholarly investigations have uncovered the absence of precise design guidelines for shaping the augmented reality-based mobile library application (ARMLA) experience within the metaverse. To date, no existing study has yet offered a comprehensive compilation of meticulously tailored *Kansei* emotive keywords specifically designed for this purpose. This gap underscores a significant deficiency in this particular domain. Therefore, this study intends to bridge the gap by methodically synthesizing and evaluating an extensive list of emotional keywords particularly devised for the ARMLA, thereby addressing the following research question (RQ):

RQ: What are the essential emotional requirements or the most pertinent emotive keywords for designing an engaging library application in the metaverse environment?

II. LITERATURE BACKGROUND

A. The Vital Role of Emotions in Metaverse Product Design

The metaverse stands as an expanding frontier that opens doors to increasingly intricate experiences. The metaverse is a dimension that exists beyond reality, establishing a connection between the actual and digital realms. It emerges from a combination of numerous technologies that blend together with the ability to expand the physical world through augmented reality (AR) and virtual reality (VR) [20] offering a fully dynamic and immersive virtual environment [21]. The application of the metaverse extends across diverse sectors, including education for innovative libraries [22], [23], enhanced campus and classroom experiences [24]–[26], retail to elevate shopping experiences [27], [28], games for revolutionary entertainment [29], [30], and the medical field to enhance healthcare [31], [32]. It is expected to be applied in an even broader range of sectors in the future.

As this notion gaining momentum and drawing significant interest from scholars, industries, and society at large, it underscores the pressing need for improvement. Design, in particular, emerges as an essential driver for its ongoing evolution. Scholarly investigations have highlighted the impacts of innovation failures, which often stem from the inability to satisfy user needs and preferences [33], [34]. As pertinent technologies keep evolving, the study of emotion assessment has emerged as a prominent research area. This is primarily motivated by its wide ranging applications and the complex emotional dynamics that unfold in interactions between users and device interfaces. Consequently, it becomes clear that grasping the human factors and emotions that contribute to establishing a connection with technological inventions is crucial [35], [36].

B. Effective Emotion Elicitation using Kansei Engineering

Before embarking into the intricate domain of user emotions, it is important to understand how to conduct an in-depth user

research to effectively elicit user emotions in response to innovative products. Emotional research is strongly tied to affective engineering, a field that is closely associated with the Kansei Engineering (KE). Originally pioneered in Japan by Professor Mitsuo Nagamachi [37], KE has transcended the traditional confines of product design, bringing about a transformative shift in how we perceive and interact with objects and technology. This method places a significant emphasis on the emotional dimension within the design process by capturing the user's emotional responses, which are subsequently translated into tangible product attributes. Kansei which translates to "emotions," is the core of KE process. The process leads to the categorization of user emotions as Kansei words (KWs), representing emotive keywords that encapsulate their feelings and perceptions regarding specific product design [38], [39]. These KWs manifest as adjectives [2] like attractive, happy, fun, frustrated, or bored, allowing for a precise characterization of the UX. KE emphasizes how design improvements may elevate user satisfaction and human-device interactions. These encompass variety of fields like web-based user interface [15], [16], mobile app [18], robotic [40], [41], and pervasive or ubiquitous product designs [19].

C. Metaverse Library

Recent years have witnessed a surge in scholarly interest surrounding the metaverse and its applications in the context of libraries. This spike is particularly evident in the thorough exploration of AR technology's immense potential within library services known as ARMLA. Their findings not only underscored the ability of AR technology to enhance the library experience but also revealed its capacity to provide captivating virtual tours of library spaces [42], [43], thereby increasing patron engagement [44]. In tandem, [45] have delved into the metaverse's potential to revolutionize library data storage and retrieval, as well as provide better reading environment [13], shedding light on its transformative potential. Similarly, [23], [46], [47] strongly emphasized the imperative need of libraries to embrace the metaverse in order to meet the demands of a digitally connected society. This is further supported by [21], [48], who argued that libraries should not fall behind, but rather be proactive and continue to evolve in order to stay aligned with the changing technological landscape and growing user expectations. By taking this proactive move to embrace the metaverse, libraries will remain relevant and accessible as vital gateways to information and knowledge in the modern era, while also having the ability to evoke profound emotional connections through enhanced interactive experiences.

III. METHODOLOGY

This part describes the methodologies and procedures employed to synthesize the *Kansei* Words (KWs), commonly referred to as emotive keywords, tailored for the metaverse library context known as ARMLA. This study follows a systematic approach divided into three main phases, as outlined in Fig. 1 and elaborated upon in the subsequent sections.

Fig. 1. Validation procedures for ARMLA emotive keywords

A. Phase I

This study initiated with a comprehensive investigation of relevant scholarly works, aiming to identify emotive keywords that could be extracted from prior literature or research discussions centered around user emotions in the context of AR libraries within the metaverse. This included investigating users' emotional responses as they viewed, used, engaged, and interacted with such applications. An extensive review examined 224 scholarly articles and discovered 184 adjectives (emotive keywords or KWs) from searches across six databases including ScienceDirect, ACM, Taylor and Francis, IEEE, Springer, and Emerald, laying the groundwork for identifying crucial keywords that significantly impact the emotional UX in this digital landscape. The collected keywords underwent lexical analysis across diverse dictionaries in order to ascertain their precise definitions. This methodical approach helps to prevent conceptual deviations and contributes to a thorough and comprehensive understanding of the emotional aspects in the context of AR libraries within the metaverse.

B. Phase II

According to [49], [50], The selection of experts is a critical step in the validation procedure since it has an immediate influence on the accuracy and reliability of the results. Consequently, this phase focused on identifying the professional experts to actively participate in the validation process. As suggested by [51], experts in research can be chosen based on various criteria, such as their educational background, professional experience, familiarity with the subject matter, and their ability to provide valuable insights. In alignment with this objective, the research has laid out the following criteria for expert selection:

- 1) Having relevant practical, academic, or research experience in the field under evaluation.
- 2) Possess a minimum of five years of professional / work experience pertinent to the field of study.

3) Demonstrate willingness and availability to participate in the study.

In order to guarantee a thorough and extensive evaluation of the *Kansei* emotional keywords, two groups of panelists have been formed. Each consisting of three language experts (designated as experts 1-3) and three field experts (designated as experts 4-6), as depicted in Table I.

TABLE I. PANEL OF EXPERTS FOR KANSEI EMOTIVE KEYWORDS ASSESSMENT

Expert ID	Expertise / Field Experts	Years of Experience
Expert 1	Language (Linguistics and English Language Studies)	8
Expert 2	Language (Linguistics and English Language Studies)	11
Expert 3	Language (Teaching English as a Second Language)	7
Expert 4	Technical (UX)	9
Expert 5	Technical (AR)	8
Expert 6	Domain Experts (Librarian)	19

Interaction with these experts was conducted via email conversations and physical meetings. Throughout these interactions, comprehensive guidelines were provided to enhance and validate the adjectives/ keywords that effectively represent the diverse emotions experienced by users within the ARMLA context.

The responsibilities of the language experts included ensuring the linguistic accuracy, validating the usage and context of adjectives, and confirming their definitions and meanings in the study context. This is particularly significant since the KWs predominantly supposed to be in adjective forms.

On the other hand, considering this research is related to AR-based mobile applications, it is imperative to engage field experts in the assessment process as well. This procedure is integral in ensuring that the chosen keywords effectively encompass the key aspects within the context of this research, in which the field experts carefully refined and recommended the most suitable emotive keywords for the AR-based mobile application in the library setting. Gaining insights from the technical and domain experts who possess advanced knowledge and skills in this domain can greatly assist in evaluating the relevance of keywords within the study's context.

C. Phase III

This final phase entails drawing expert opinion as a valuable source to compile an extensive collection of pertinent emotional keywords into a structured list, which we refer to as the finalized KWs for the ARMLA. The finalization process ensures that the chosen keywords effectively encapsulate the key aspects and user experiences within the study context.

IV. RESULTS AND DISCUSSIONS

This section discusses the research findings, shedding light on significant discoveries across three pivotal phases, all of which concentrate on the identification of emotional keywords that precisely align with the context of augmented reality library

applications within the metaverse setting, in order to address the stated RQ.

A. KWs Identification and Definition

This section presents research findings on user emotions in AR libraries within the metaverse. From an initial pool of 224 papers, the collection was refined through relevance screening and duplicate removal, resulting in 158 studies; 70.5% of the initial set. A thorough full-text evaluation of these studies facilitated the extraction of pertinent emotional keywords. Notably, 21 articles were omitted from the analysis owing to inadequate coverage of the emotional experiences topic or because they did not align with the research's main emphasis. Refer to Fig. 2 for a visual depiction of the process involved in extracting emotional keywords from the database.

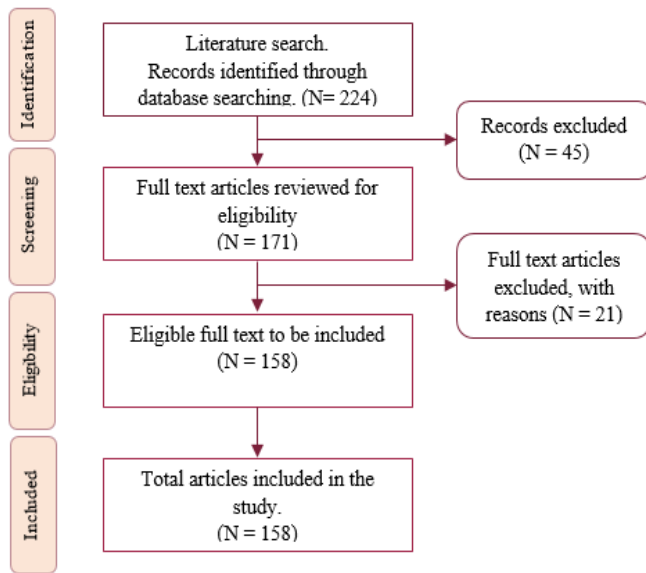

Fig. 2. The procedure and results of extracting emotive keywords from the database

Following the aforementioned procedure, this analysis has identified 184 emotive keywords (referred to as the KWs initial list) in their adjectival form across 158 research publications. The subsequent phase involved in-depth exploration of adjective lexicons sourced from various dictionaries, providing a profound grasp of the contextual intricacies of these lexical elements. The outcome is a lexicon of 184 adjectives, complete with definitions and meanings, which will serve as the experts' point of reference in their review.

B. KWs Validation

In the second phase, a comprehensive collection of 184 emotive keywords, each accompanied by their respective definitions and meanings, underwent verification by three language experts (referred to as experts 1-3). The objective of this verification was to ensure the utmost precision and accuracy in the nuances of these keywords, including their meanings and correct usage as adjectives. After a meticulous verification process, the team of experts recommended eliminating nine words owing to the improper usage of adjectives and suggested rephrasing two keywords. As a result, this process produced 175 refined emotive keywords in total. Notable examples among

these keywords include 'attractive,' 'boring,' 'unclear,' 'messy,' and 'responsive'. The final result of this phase is a carefully curated lexicon-based list of 175 refined keywords, serving as a valuable resource for the study. The complete list of these 175 keywords can be found in the prior research [19].

Equipped with these 175 meticulously refined lexicons, they were presented to a panel of field experts, comprising two technical experts and one domain expert, for further assessment. This time, the assessment was more specific, geared to address the nuances within the ARMLA domain. This process plays a crucial role in ensuring that the selected keywords effectively capture the essential aspects within the context of this research. Leveraging their technical expertise and domain-specific knowledge, the field experts meticulously refined and recommended the most appropriate emotive keywords for the AR-based mobile application in the library setting. Gaining insights from the technical and domain experts who possess advanced knowledge and skills in this domain significantly enhances the evaluation of relevance of keywords within the study's context.

This procedure adheres to the guidelines outlined by [52] for determining the selection of keywords based on expert validation. According to these guidelines, when reaching a consensus, the opinion of the majority holds the utmost importance. In the scope of this research, the results exclusively encompassed keywords that received agreement of at least two experts, signifying the majority agreement for inclusion. In light of feedback from experts, the selection or exclusion of keywords by the experts was influenced by whether the terms accurately represent the design or lean more towards describing the functional aspects of the application, such as the keywords "efficient" and "effective". Another justification was a misalignment between the terminology and the practical encounters produced by fast-paced, dynamic AR mobile applications. This mismatch is exemplified by keywords such as "relaxing" and "sad." Table II displays a representative sample of emotive keywords selected and discarded by experts during the validation process.

TABLE II. SAMPLE OF SELECTED AND EXCLUDED EMOTIVE KEYWORDS

Field Experts	Expert 4	Expert 5	Expert 6
No. of KWs Selected	51	54	55
Sample of Selected KWs	Appealing, Fresh, Messy, Unclear	Interesting, Modern, Outdated, Simple	Appealing, Crowded, Messy, Simple
Sample of Excluded KWs	Calm, Clunky, Efficient, Static	Aroused, Inspiring, Relaxing, Sad	Effective, Inflexible, Relaxing, Sad

During the expert validation process, a consensus was reached among three experts, resulting in a final selection of 60 keywords. Expert 4, Expert 5, and Expert 6 individually chose 51, 54, and 55 keywords, respectively. Significantly, there were instances where two or more experts agreed on the same keywords, leading to their inclusion in the study. These collective decisions, which represented majority consensus,

formed the basis for the inclusion of the selected keywords in the study.

C. KWs Finalization

In the concluding phase, a significant understanding of the emotional dimensions of user experience within ARMLA have been gained, providing a conclusive solution to the RQ at hand. In this phase, a complete set of sixty emotive keywords, deemed pertinent to the research context is presented in Table III.

TABLE III. THE KANSEI EMOTIVE KEYWORDS FOR AUGMENTED REALITY MOBILE LIBRARY APPLICATION

No.	Kansei Words (KW _s)	No.	Kansei Words (KW _s)	No.	Kansei Words (KW _s)
1	Appealing	21	Elegant	41	Modern
2	Attractive	22	Engaged	42	Neat
3	Balanced	23	Enjoyable	43	New
4	Boring	24	Exciting	44	Nice
5	Bright	25	Fanciful	45	Organized
6	Cheerful	26	Fascinating	46	Outdated
7	Clean	27	Fresh	47	Precise
8	Clear	28	Friendly	48	Prestigious
9	Cluttered	29	Fun	49	Professional
10	Colorful	30	Guided	50	Realistic
11	Complicated	31	Harmonious	51	Satisfactory
12	Comprehensible	32	Helpful	52	Simple
13	Concise	33	Inconsistent	53	Soft
14	Confusing	34	Informative	54	Sophisticated
15	Consistent	35	Interactive	55	Straightforward
16	Cool	36	Interesting	56	Trendy
17	Creative	37	Joyful	57	Unclear
18	Crowded	38	Latest	58	Understandable
19	Dull	39	Messy	59	Up-to-date
20	Easy	40	Minimalist	60	Vibrant

These finalized keywords (referred to as synthesized KW_s for ARMLA) which were meticulously compiled from prior validation procedures, offer a comprehensive overview of *Kansei* words that have successfully passed rigorous expert validation. These keywords can be concluded as the most pertinent emotive elements essential for designing an engaging library application within the metaverse environment, effectively addressing the user's emotional requirements in paving the way for an immersive experience.

Intended as a guide for designers, this set of emotive keywords can be used as references throughout the creation of the metaverse library. Embedding these emotive elements into UI design could potentially elicit the required emotional response, thereby fostering a rich and engaging user interaction experience. Serving as a crucial resource, this comprehensive compilation of emotive keywords contributes to further research and advancements in the ARMLA domain, enabling the creation of more emotionally engaging UX in the metaverse environment.

It is also learned that the applicability of emotions extends beyond positive emotions. Both positive and negative emotions

are accounted in this study, as evident in Table III. Consistent with findings from other research [35], [53], [54], our study reaffirms the importance of embracing a broad and diverse spectrum of emotions, as it reflects the real-world diversity of user responses and their emotional requirements. By acknowledging and addressing negative emotional experiences, designers can identify pain points and areas for improvement, leading to more robust and user-centric designs that improve the overall UX in the metaverse, thus preventing potential user dissatisfaction and frustration. The inclusion of both positive and negative emotions in innovative products is important because it acknowledges the complexity of user reactions and allows a more nuanced understanding of emotional engagement in ARMLA.

V. CONCLUSION

In an effort to elevate the emotional level and UX within the metaverse environment, this study embarked on a comprehensive journey to synthesize *Kansei* words that effectively capture the emotive dimensions essential for ARMLA. The validation procedure was meticulously carried out, with a panel of experts taking on a pivotal role, harnessing their expertise and domain-specific knowledge to assess and validate the applicability of the KW_s, resulting in the identification of 60 *Kansei* emotive words for ARMLA. The ARMLA synthesized keywords redefine the new way to configure users' emotional perceptions in this specialized domain, providing practitioners with valuable guidance in creating application designs that match the user affective needs. This research makes a significant contribution to the metaverse landscape by adding a layer of emotional depth to enrich the ARMLA experience, filling the critical gaps in the affective engineering field. These significant findings revolutionize the design of AR applications, placing emotional resonance at the forefront of innovation in this cutting-edge field.

The primary limitation of this study lies in its exclusive concentration on the metaverse dimension within the AR library context. It is crucial to acknowledge that *Kansei* Engineering research demands a domain-specific approach for its KW_s investigation. Consequently, it is imperative to recognize that the insights derived from this research may not be entirely applicable to other scopes or domains. To comprehensively grasp the relevant emotional nuances in other areas, a dedicated research effort tailored to those specific domains becomes a necessity for ensuring the robustness and applicability of the findings.

In the future, the strategic application of this set of emotive keywords is expected to provide valuable guidance for the development of ARMLA prototype with the aim of enhancing the emotional UX. This process may include a thorough retrospective statistical analysis, focused on the validation of the most significant emotive keywords in the specific domain of the metaverse.

ACKNOWLEDGMENT

The authors would like to thank Universiti Kuala Lumpur Malaysian Institute of Information Technology and the Centre for Research and Innovation for their partial funding support, which has facilitated the publication of this research.

The Impact of Dual Objective Optimization Model Combining Non-Dominated Genetic Algorithm on Rural Industrial Ecological Economy

Ying Wang

School of Accounting, Shaanxi Technical College of Finance & Economics, Xianyang, 712000, China

Abstract—Due to the development of industrial economy, it has caused serious damage to the ecological environment. Based on the industrial structure and production scale, rural industrial economic parks are planned to analyze the quantity and weight of pollutants emitted from the original industries. The results showed that the quantity and weight of hydrogen sulfide in the coking industry were 10kg/t and 94, respectively. The weight of smoke and carbon monoxide in the steelmaking industry was relatively high, with 54 and 34, respectively. Non-dominated sorting genetic algorithm and multi-objective programming model are used to optimize the comprehensive benefits and industrial structure of rural industrial ecological economy. According to the experimental results, when the scale of the coking industry was 135600 tons, the steelmaking industry was 314900 tons, the ironmaking industry was 148100 tons, and the underground coal gasification industry was 424.76 million Nm³. The comprehensive economic benefits of the industry reached the optimal level of 0.6415. The environmental and comprehensive benefits generated by the increased power generation industry were 64.98 and 40.87, respectively. Therefore, it indicates that the dual objective programming model combining non-dominated sorting genetic algorithm can improve the rural industrial ecological economy.

Keywords—Industrial chain production mode; ecological economy; environmental benefits; non-dominated sorting genetic algorithm; dual objective programming model

I. INTRODUCTION

With the acceleration of urbanization, rural industrial development has become an important force in promoting rural economic development. The rural industrial economy not only increases the sources of income for farmers and improves their income, but also optimizes the rural industrial structure and promotes diversified economic development [1-3]. But industrial development needs to consider the balance of rural ecological environment. When developing rural industrial economy, it is also necessary to adapt to local conditions, prioritize ecological protection, and form a rural ecological economic system. Guided by the ecological civilization development, rural ecological economy combines ecological and industrial economic development, reasonably utilizes ecological resources and industrial chain models, comprehensively considers economic and environmental benefits, and promotes the development of rural ecological industrial parks and their economy [4-6]. The development of ecological industrial parks is led by the government and responded by enterprises to establish different parks, connect

with industrial industries, and create sustainable green industrial parks with a circular economy as the main focus. Guided by the green development concept, especially for the extensive heavy industrial economy, the emissions of this economic model do not belong to the green economy, causing serious damage to the environment [7]. Based on this, the study analyzes the industrial structure of rural industrial economy and constructs a dual objective programming model to analyze the production mode of industries. In order to comprehensively consider the coordinated development and resource utilization of the industrial chain in industrial parks, an innovative multi-objective genetic algorithm, namely, Non dominated Sorting Genetic Algorithms (NSGA-II), was used to analyze the comprehensive benefits of industries and reasonably consider the green environmental benefits, in order to promote the sustainable development of rural industrial ecological economy. Compared with the indicator model analysis of existing research, the combination of industrial structure and benefit planning not only focuses on the growth of economic benefits, but also effectively combines the needs of environmental benefits, and maximizes the recycling of resources in the industrial chain. Based on the analysis of environmental benefits indicators, it has been proven that the dual objective programming model combined with NSGA-II algorithm is superior and feasible for rural industrial ecological economy.

The study is conducted in five parts. The first part is to elaborate on the current research progress. The second part is to analyze the industrial structure to construct a dual objective planning industrial chain model. The third part is to analyze the industrial production mode using environmental benefit indicators and NSGA-II. The fourth part is a discussion of the research results. The last part is a summary of the entire study.

II. RELATED WORKS

With the deepening of the green development concept, people are not only pursuing high-speed economic development, but also paying more attention to the coordination between ecological environment and economic development [8]. The main focus is on ecological transformation of the existing economic system, namely ecological economy, which mainly includes production modes, resource utilization, etc. While pursuing high profits, it also takes into account environmental benefits, thereby driving new economic growth and providing model exploration for the development of ecological economy. In recent years, domestic

and foreign scholars have conducted different explorations on the ecological transformation of industrial economy. Regarding the green economic development models, Zhiguang Zhang used sustainable development theory, super cycle theory, etc. to extract and classify green economic models. Combined with the theoretical model, the theoretical basis was provided for green economic models [9]. Regarding the ecological and economic issues in the Yangtze River Delta, Wang et al. combined energy theory to construct evaluation indicators for sustainable development of green economy. The ecological and economic system was analyzed to propose sustainable development recommendations [10]. Regarding the industrial economic transformation, Shukla et al. proposed to test the soil in polluted areas and analyze its metal concentration, thereby providing theoretical reference for the development of industrial economy [11]. Regarding the development model of industrial economy, Haowei et al. used digital economy to improve industrial ecological efficiency and promote regional ecological economic development [12]. FAN Weiguang et al. proposed a coupled coordination measurement model that combined balance attributes and performance evaluation to address the green economic development in Northeast China, providing reference for achieving sustainable development goals in the region [13]. The green economy and sustainable development goals are important directions for current economic development. Therefore, in different regions and industrial economies, the development indicators of green ecological economy are used. Regarding the ecological and economic issues related to the tourism industry structure, Yang et al. used correlation analysis and multi-objective programming models to optimize the industry structure, improving the low-carbon development of the tourism economy [14]. Chen combined the digital economy to analyze and transform the industrial structure reasonably, thereby promoting the development of carbon reduction economy [15]. Junjie et al. used digital economy and model construction to analyze the changes and effects of industrial structure upgrading, improving industrial structure and ecological economic development [16]. Weicheng et al. conducted heterogeneity analysis on industrial structure optimization and upgrading using information technology and substitution effects, to promote industrial structure optimization and upgrading [17]. Agarwal et al. Used the Analytic Hierarchy Process (AHP) to manage the circular supply chain of Jinning County's traditional industrial economy, promoting the sustainable development goals of the industry [18]. To achieve green ecological economic development and sustainable development, industrial structure is the primary direction of transformation. Therefore, the optimization of industrial structure varies in different regions.

In summary, although domestic and foreign scholars have proposed many models and methods for green ecological economy and industrial structure changes, there is a lack of in-depth research on the integration of rural and industrial economy in industrial transformation. Therefore, the dual objective programming model combining NSGA-II is feasible for the development of rural industrial ecological economy.

III. PLANNING OF RURAL INDUSTRIAL ECOLOGICAL ECONOMY AND ENVIRONMENTAL BENEFITS

The rise of rural industry promotes the further development of rural economy. Ecological protection has become the main goal of rural economic development. While pursuing economic benefits, rural ecological environment protection needs to be taken into account. This study analyzes the development of industrial structure in industrial parks. Combined with the dual objective optimization model, the economic model of rural industrial ecological parks is further improved.

A. Construction of Industrial Chain Model for Rural Industrial Ecological Parks

Ecological industrial park is a enterprise community mainly engaged in manufacturing and service industries. Various enterprises jointly manage economic affairs and environmental maintenance, thereby promoting the comprehensive development of economic, social, and environmental benefits [19]. The construction of rural ecological industrial parks needs to follow the principles of circularity, diversity, regionalism, and evolution. The main enterprises were analyzed for their current situation and industrial chain formation. The development model of the traditional industrial chain focuses on pursuing profits. It inputs and outputs various materials, resources, and waste treatment, as shown in Fig. 1.

Fig. 1. Schematic diagram of the production process in the industrial chain

In Fig. 1, each production chain starts with material or energy consumption. Through the complete production process, products or by-products are formed, while also generating waste or pollutants. The generated products will also be put into the next industrial chain as one of the consumables, repeating the consumption and production of resources, input and output in sequence. Therefore, industrial production models need to maximize the utilization of existing resources and waste, and treat pollutants. Thus, the role of each link in the production chain can be leveraged to complete the production circular economy model. Enterprises within the industrial park coexist for mutual benefit. The mutually beneficial relationship between enterprise production chain and environmental resources is coordinated. The pressure index caused by enterprises ignoring environmental resources and establishing industrial chains on the environment is shown in equation (1).

$$\text{Environmental Pressure Index} = \sum_{n=1}^N \frac{a_{bn}}{j_{bn}} + \sum_{k=1}^K \frac{P_{bk} \times \theta_{bk}}{AC_{bk}} \quad (1)$$

In equation (1), b represents the enterprise. n is material, resource, or energy. k is a pollutant. a_{bn} represents the amount of material or energy consumed by an industry in the production process. j_{bn} represents the amount of resources that can be provided by the industrial region. P_{bk} represents the amount of pollutants emitted in industrial production. AC_{bk} is the maximum capacity of the enterprise's location for pollutant emissions. θ_{bk} is the pollution concentration emitted. To consider mutual benefit and symbiosis among industries, resource consumption and pollution emissions between industries are calculated, as shown in equation (2).

$$Mutualism = J - K - L \quad (2)$$

In equation (2), *Mutualism* represents the degree of mutual benefit and symbiosis between two enterprises. J is the quantity of industrial waste collection and input production collection. K is the number of identical elements in the set. L is the number of identical elements in the output set. Finally, based on the construction relationship of multiple enterprise industrial chains, the resource utilization and conversion between multiple enterprises will be carried out for the operation of industrial parks, thereby strengthening the mutually beneficial and symbiotic relationship between industries. The degree of mutual benefit and symbiosis among multiple industries is shown in equation (3).

$$Pressure\ Index(S) = \sum_{b=1}^B \left\{ \sum_{n=1}^N \frac{a_{bn} - a_{bn}^*}{j_{bn}} + \sum_{k=1}^K \frac{(P_{bk} - P_{bk}^*) \times \theta_{bk}^*}{AC_{bk}} \right\} \quad (3)$$

In equation (3), *Pressure Index*(S) represents the pressure index of the industrial chain S of multiple enterprises on the environment, which is the degree of mutual benefit and symbiosis. a_{bn}^* is the amount of resources that the industry converts into waste from other industries during production. P_{bk}^* represents the amount of waste generated by the industry that is converted into input for other industrial resources. B represents the number of enterprises in the industrial chain S . The industrial chain within the park connects multiple enterprises. The conversion and utilization of resources, waste or energy between enterprises provides a better production mode for the environmental benefits of the region, as shown in Fig. 2.

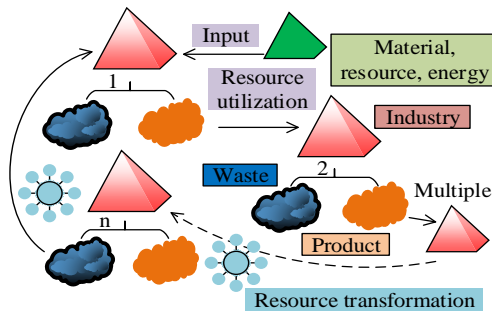

Fig. 2. Schematic diagram of industrial chain production model for multiple enterprises

In Fig. 2, the products of the first industry are converted into material inputs for the second industry through resource conversion, thereby completing the production chain of the second industry. Multiple enterprises participate in this process, which allows for the recycling of some of the waste produced by the industry, strengthening the internal connections between industries. Therefore, the exchange of material resources between any two industries promotes the exchange of material energy in the overall industrial chain, thereby achieving the overall environmental symbiosis of the ecological park. The waste in the production chain can be reused through the production process, but the generated pollutants cannot be put into production again. Therefore, pollutants and their weights are treated separately to reduce their harm to the environment. When constructing industries in ecological industrial parks, the maximum benefit evaluation of the environment is carried out. The indicator is used as the objective function of environmental benefit single objective planning, as shown in equation (4).

$$Environmental\ benefit = \sum_{b=1}^B (\alpha RCU_b + \beta WOU_b) \quad (4)$$

In equation (4), RCU_b represents the energy consumption per unit output value of the industry. WOU_b represents the discharge of three types of industrial waste. The consumption of industrial unit output value is shown in equation (5).

$$\begin{cases} RCU_b = \frac{E_b}{\sum_{m=1}^M i_{bm} V_{bm}} \\ WOU_b = \frac{\sum_{k=1}^K P_{bk}}{\sum_{m=1}^M i_{bm} V_{bm}} \end{cases} \quad (5)$$

In equation (5), α and β represent the energy consumption per unit of industrial output and the weight of three types of waste emissions, respectively. The total annual energy consumption of a company is E_b . The quantity and emission quantity of the b -th product are i_{bm} and P_{bk} , respectively. V_{bm} represents the unit output value of enterprise product production. In addition, the total value of energy consumption is shown in equation (6).

$$E_b = \sum_{m=1}^M (U_{bm}^E i_{bm}) \quad (6)$$

In equation (6), U_{bm}^E is the production energy consumption coefficient of the industry per unit product. The total value of waste emissions from industrial output is shown in equation (7).

$$P_{bk} = \sum_{m=1}^M (U_{bm_k}^P i_{bm}) \quad (7)$$

In equation (7), $U_{bm_k}^P$ is the waste coefficient discharged by the enterprise during production. $B, b = 1, 2, \dots, B$ represents the number of industries in the industrial chain of the ecological industrial park. $M, m = 1, 2, \dots, M$ and

$K, k=1, 2, \dots, K$ represent the quantity of product types and the quantity of waste types. To achieve maximum environmental benefits, energy consumption, product and waste emissions should be minimized, and resources within the entire ecological park should be allocated reasonably. According to the calculation standards for environmental benefits, energy consumption, and waste emissions, environmental constraints are set for resource types, mainly including water sources, coal, and electricity. The relationship between the total consumption of resources by enterprises in the overall industrial chain and the total available resources is shown in equation (8).

$$\sum_{b=1}^B \varphi_{bm_n} i_{bm} \leq Rr_{n_{\max}} \quad (8)$$

In equation (8), φ_{bm_n} is the resource coefficient consumed by the industry in producing a certain unit of product. $Rr_{n_{\max}}$ represents the total amount of available resources in the location of the park. $N, n=1, 2, \dots, N$ represents the type and quantity of resources invested in the ecological industry chain. The energy usage relationship within the ecological industrial park is shown in equation (9).

$$\sum_{b=1}^B E_b \leq E_{\max} \quad (9)$$

In equation (9), E_b represents the total energy consumption of the industry's annual production. E_{\max} represents the total value of energy available. The environmental constraints for the overall ecological industrial park are shown in equation (10).

$$\sum_{b=1}^B U_{bm_k}^P i_{bm} \leq Er_{k_{\max}} \quad (10)$$

In equation (10), $Er_{k_{\max}}$ represents the maximum pollutant emission of the ecological industrial park, which is the prescribed standard. In addition, the construction of the ecological industry chain also needs to consider factors such as the minimum emission standards and production scale of the region to meet the maximum environmental benefits.

B. Industrial Development and Construction based on Dual Objective Programming Model

The planning based on a single objective of environmental benefits is the main factor considered in the ecological industrial economy, but the essence of enterprises is still to pursue benefits. Therefore, economic and environmental benefits are comprehensively considered. Then a dual objective programming model is constructed. The economic and environmental benefits of ecological industrial economy are used as comprehensive evaluation indicators. The variables of other technologies or industries remain unchanged within 10 years. The economic benefit objective function is shown in equation (11).

$$\text{Economic benefits} = \max \left\{ \sum_{b=1}^B \left[\sum_{m=1}^{M_b} V_{bm}^* i_{bm} - \sum_{n=1}^{N_b} V_{bn}^a a_{bn}^* - \sum_{l=1}^B \sum_{k=1}^{K_b} V_{l-b_k}^P P_{l-b_k} \right] \right\} \quad (11)$$

In equation (11), V_{bm}^* represents the industrial added value per unit of product produced by the enterprise before the construction of the industrial chain. V_{bn}^a is the unit value of resources invested during production. $V_{l-b_k}^P$ and P_{l-b_k} represent the unit cost and quantity of waste conversion resources invested by enterprise l in enterprise b . The amount of resources input by other enterprises is expressed as a_{bn}^* . The objective function of environmental benefits is shown in equation (12).

$$IENB(\max) = \left\{ \begin{array}{l} \sum_{b=1}^B \sum_{k=1}^{K_b} P_{bk}^* \\ \sum_{b=1}^B \sum_{k=1}^{K_b} P_{bk} \end{array} \right\}_{\max} \quad (12)$$

In equation (12), K_b represents the environmental benefit indicator of the industrial chain. B represents the total value of pollutant types exported by the industry. The total amount of pollutants produced without considering inter industry recycling is P_{bk} . The quantity of pollutants produced in the industrial chain and converted into resources is P_{bk}^* . In addition, the specific constraints on resource consumption are shown in equation (13).

$$\sum_{b=1}^B \varphi_{bm_n} i_{bm} \leq Rr_{n_{\max}} \quad (13)$$

In equation (13), φ_{bm_n} represents the resource consumption coefficient per unit product produced by the enterprise. $N, n=1, 2, \dots, N$ is the number of types of resources invested in the industrial chain. The maximum total amount of resources that can be utilized in ecological industrial parks is $Rr_{n_{\max}}$. The constraint on energy in the industrial chain is shown in equation (14).

$$\sum_{b=1}^B E_b \leq E_{\max} \quad (14)$$

In equation (14), E_{\max} represents the maximum total amount of energy that can be provided by the area where the ecological industrial park is located. The constraint condition for pollutants in environmental benefits is shown in equation (15).

$$\sum_{b=1}^B U_{bm_k}^P i_{bm} \leq Er_{k_{\max}} \quad (15)$$

In equation (15), the highest standard for pollutant emissions in the region where the industrial chain is located is $Er_{k_{\max}}$. To comprehensively consider economic and environmental benefits, the NSGA-II of multi-objective genetic algorithm is used to optimize complex multi-objective problems. The specific steps are shown in Fig. 3.

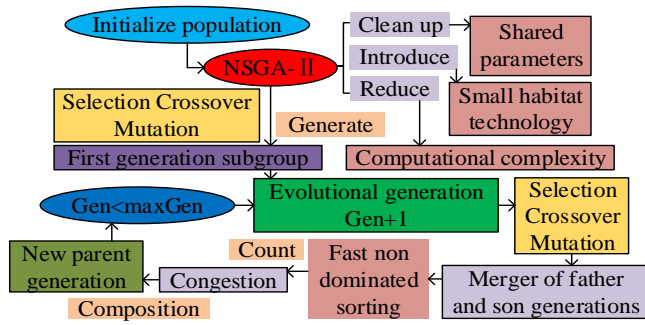

Fig. 3. Schematic diagram of multi-objective optimization based on NSGA-II

From Fig. 3, it can be seen that the NSGA-II algorithm initially performs non dominated sorting calculations on the initialized population to generate a new generation of subgroups. Afterwards, a new population is generated through evolutionary algebra and merging. Then, the new population is quickly non dominated sorted and combined with crowding calculation to form a new parent group. Finally, a multi-objective solution is obtained. The NSGA-II is applied to the multi-objective programming model, clearing and introducing shared parameters and niche techniques, while reducing time complexity and ensuring diversified solutions. In addition, the NSGA-II algorithm simplifies the energy structure calculated by non dominated sorting in the industrial ecological industry structure to maximize the utilization of overall industry resources. In response to the industrial and economic construction in a rural area, the government has developed an ecological industrial park to analyze the resources, environment, and industrial structure of the industrial economy. The energy and its industries include coal mining, coking, steelmaking, ironmaking, and shale oil. Water resources can allocate approximately 50 million tons of water usage. Multiple heavy industrial productions have caused significant damage to the local environment. The production structure of the main industries is investigated on site to quantify energy consumption, product output, waste emissions, and pollution emissions of each industry, as shown in Fig. 4.

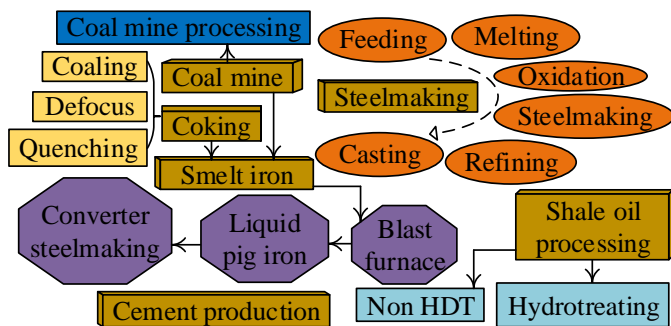

Fig. 4. Distribution and structure of rural industrial industries

From Fig. 4, the agricultural industry mainly includes coal mine processing, coking and steelmaking factories, iron smelting industry, shale oil processing, and cement production. The coal mine treatment provides coal resources for the coking industry. Coking involves the loading coal, discharging coke, and quenching coke. Steelmaking includes the feeding, low-temperature melting, oxidation, tapping, refining, and

pouring. Subsequently, under the requirements of ecological civilization construction, ecological industrial parks will be established in rural areas to manage the production scale and resource utilization of various industries, thereby forming an ecological industrial chain for resource recycling. Abandoned coal mines can lead to wastage of existing resources. Based on the concept of ecological environment, underground resources are gasified and extracted to achieve maximum resource utilization. Finally, the overall model of resource utilization and output for each industry is constructed, as shown in Fig. 5.

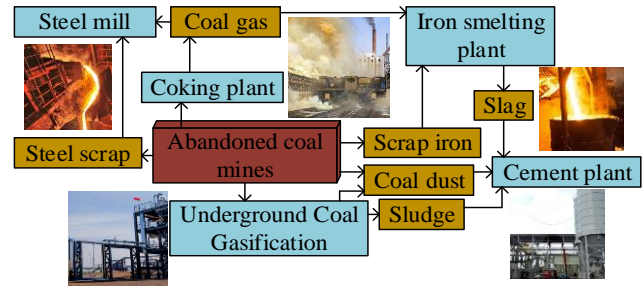

Fig. 5. Mutual benefit and symbiosis model of coal gasification industry chain

From Fig. 5, the inputs or outputs of various industries are interrelated. Coal dust, sludge, scrap iron, and scrap steel from abandoned coal mines are respectively invested in cement plants, iron smelting plants, and steelmaking plants. The slag generated from steelmaking and ironmaking is then fed into the cement plant. Coking gas and scrap iron are put into ironmaking. This mutual input mode fully utilizes waste resources, reduces resource waste, and promotes the mutually beneficial development of the industrial chain. The industry of the overall model still generates unusable waste and pollutants, which can easily cause environmental pollution and resource consumption. To fully leverage the maximum connections between various industries, qualitative and quantitative parameter judgments are conducted separately. Then the degree of mutual benefit and symbiosis and environmental index of the industries are calculated.

IV. DEVELOPMENT ANALYSIS OF RURAL INDUSTRIAL ECOLOGICAL ECONOMY

For the industrial production mode, the weight of waste or pollutant emissions is determined. Combined with the mutually beneficial symbiosis degree results of the industrial chain model, parameter targets are provided for the industrial combination and environmental benefits of rural industrial ecological economy. Finally, the NSGA-II of the dual objective programming model is used to analyze the industrial scale and its benefits. Pollutants usually come in three forms: solid, liquid, and gas, with varying degrees of harm and weight. To unify the ecological management of industrial parks, the weights of the three types of pollutants are standardized. Based on the types and emission standards of each pollutant, the quantity and weight of pollutants in each industry are determined and analyzed. The results are shown in Fig. 6.

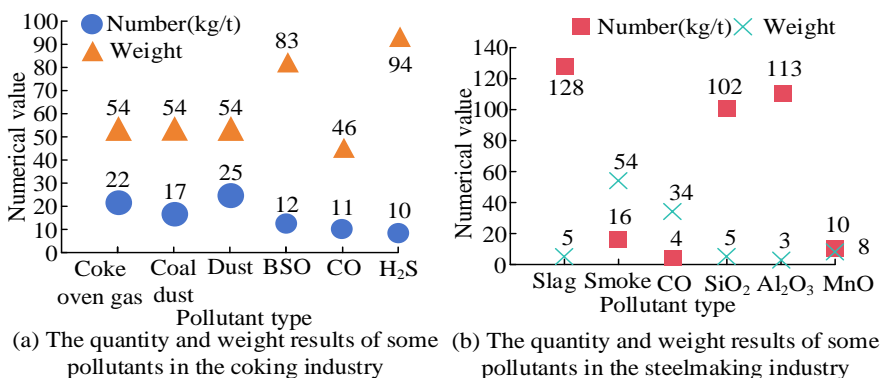

Fig. 6. Results of the quantity and weight of some pollutants in the coking and steelmaking industries

Fig. 6(a) shows the quantity and weight of some pollutants exported by the coking industry. The highest weight of hydrogen sulfide (H₂S) was 94, and the lowest quantity was 10kg/t. The weights of coke, coal, and dust were all 54, but the quantities were 22kg/t, 17kg/t, and 25kg/t, respectively. Fig. 6(b) shows the results of some pollutants in the steelmaking industry. The amount of slag, silicon dioxide (SiO₂), and aluminum oxide (Al₂O₃) produced was relatively high, at 128kg/t, 102kg/t, and 113kg/t, respectively, but their weights were low at 5, 5, and 3. The weights of smoke and carbon monoxide (CO) were relatively high, at 54 and 34. Afterwards, an analysis is conducted on the pollutants in the iron smelting plant and underground coal gasification industry, as shown in Fig. 7.

coke oven gas, coking water vapor, converter gas, steelmaking water vapor, steelmaking hot water, and steelmaking cold energy. The results are shown in Fig. 8.

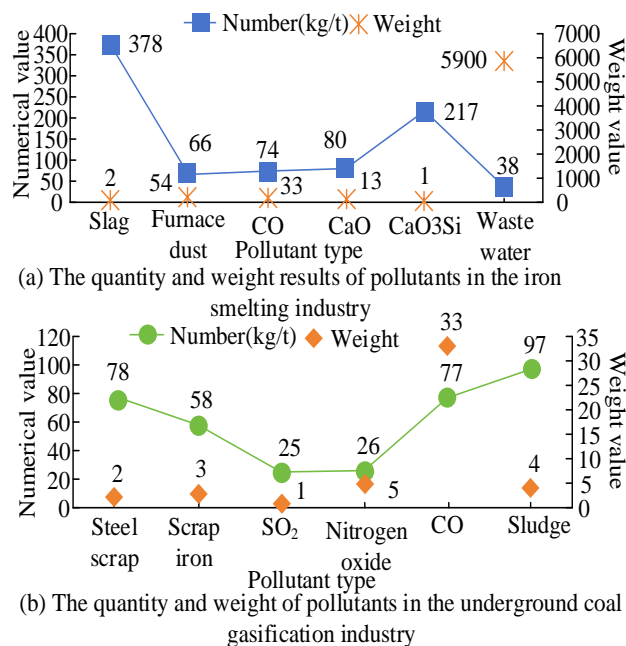

Fig. 7. Pollutant quantity and weight results of iron smelting and underground coal gasification industries

From Fig. 7(a), the wastewater discharge weight of the iron smelting plant was relatively high, which was 5900. The output quantity of slag and calcium silicate (CaO3Si) was relatively high, which were 378kg/t and 217kg/t, respectively. However, the corresponding weights were relatively low, which were 2 and 1. Fig. 7(b) shows the quantity and weight of pollutants in the underground coal gasification industry. The quantity and weight of sludge were 97kg/t and 4. The quantity and weight of CO were 77kg/t and 33, respectively. Based on the pollution emissions of various industries in the industrial chain, combined with the functions and equations of environmental and comprehensive benefits, the output of each industry is analyzed. The output parameters and unit output value of the coking and steelmaking industries for environmental benefits are represented using A-F to represent

coke oven gas, coking water vapor, converter gas, steelmaking water vapor, steelmaking hot water, and steelmaking cold energy. The results are shown in Fig. 8.

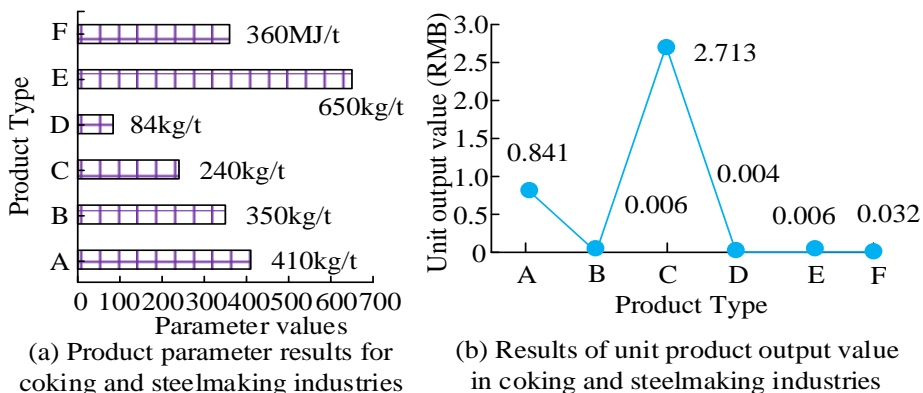

Fig. 8. Parameters and output value results of output products in the coking and steelmaking industries

From Fig. 8 (a), the output parameters of the coking and steelmaking industries were generally high. The parameter of hot water for steelmaking was 650kg/t, while the produced water vapor was relatively low, at 84kg/t. Fig. 8 (b) represents the unit output value of the output product. The converter gas for steelmaking was relatively high, at 2.713 yuan. The remaining output products of steelmaking had lower unit output values of 0.004 yuan, 0.006 yuan, and 0.032 yuan, respectively. The output value of coking coke oven gas was 0.841 yuan, and the unit output value of water vapor was 0.006 yuan. Based on the output product value of the coking and steelmaking industries, the economic benefits of this industry vary in terms of environmental benefits. However, the production essence of each industry needs to consider economic benefits, and then seek a balance between economic and environmental benefits. Therefore, the dual objective programming model is combined to analyze the economic and environmental benefits of rural industrial ecological economy and its industrial chain. The resource consumption results of the steelmaking industry are shown in Fig. 9.

In Fig. 9, there are many types of resource consumption in the steelmaking industry. The parameters of furnace gas for scrap steel were relatively high, at 128.76 and 168.11, respectively. The prices of the coolant and carburetor used in the production process were relatively high, at 12.21 yuan and 11.76 yuan, respectively. From this, the industry consumes a lot of resources. The available and circular resources can improve the environmental benefits of this industry chain, thereby increasing economic benefits and achieving optimal comprehensive benefits. In addition, based on the weight and indicator ratio of economic and environmental benefits, a combination analysis is conducted on the production scale and benefits of each industry. The results are shown in Table I.

Table I compares the combination methods of different industry scales and their comprehensive benefits. When the

scale of the coking industry was 135600 tons, the steelmaking industry was 314900 tons, the ironmaking industry was 148100 tons, and the underground coal gasification (UCG) industry was 424.76 million Nm³. The comprehensive benefits of economy and environment reached the optimal level, which was 0.6415. To expand the economic benefits and value of the industrial park, some enterprises can be added to enrich the products of the industrial chain. Based on the industrial processes of coking, steelmaking, ironmaking, and underground coal gasification, as well as the resource recycling mode, the gas power generation industry, chlor alkali industry, and synthetic ammonia industry can be introduced into the industrial ecological economy. The output of coke oven gas, converter gas, blast furnace gas, and synthesis gas from various industries is used as input to increase enterprise resources, thereby increasing resource utilization efficiency and improving comprehensive benefits. To visually compare the benefits brought by increasing industries, this study combines constraint conditions and objective functions. The NSGA-II is used to calculate and train the economic and environmental benefits indicators of the industrial chain. The results are shown in Fig. 10.

Fig. 9. Partial resource consumption results of the steelmaking industry

TABLE I. SCALE AND BENEFITS OF EACH INDUSTRY IN THE ECOLOGICAL INDUSTRIAL CHAIN

Production scale and combination				Comprehensive benefits	
Coking (10000 tons)	Steelmaking (10000 tons)	Smelt iron (10000 tons)	UCG (10000 Nm ³)	Environment	Comprehensive
13.56	31.49	14.81	42476	0.3655	0.6415
12.27	36.91	15.03	32142	0.3652	0.6043
17.27	37.94	25.15	34640	0.3650	0.5922
6.78	12.03	25.80	36633	0.3655	0.6389
18.75	29.71	25.15	38652	0.3652	0.6108
14.47	29.65	15.13	33634	0.3653	0.6199
15.67	20.93	25.15	37643	0.3653	0.6227
17.38	20.82	14.52	32561	0.3654	0.6386

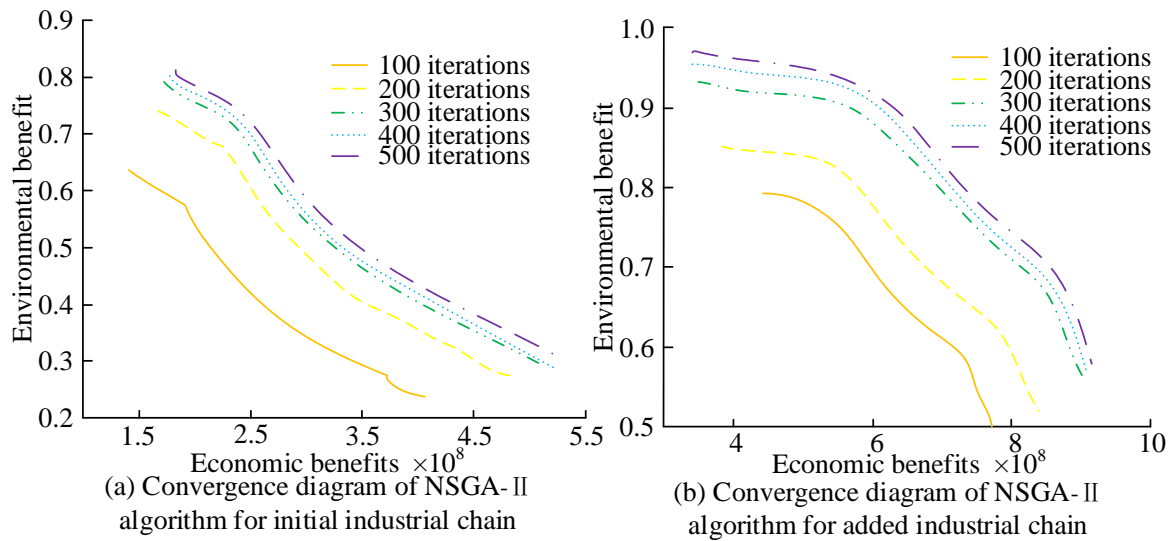

Fig. 10. Comparison results of convergence graphs for the NSGA-II in the industrial chain

From Fig. 10(a), as the number of iterations increases, the economic and environmental benefits of the industrial chain continue to increase. The convergence effect of Fig. 10(b) was consistent with the initial industrial chain, indicating that the NSGA-II had advantages in the convergence effect of the multi-objective programming model. Finally, the production scale and comprehensive benefits of the two industrial chains are compared, as shown in Table II.

TABLE II. COMPARISON OF PRODUCTION SCALE AND COMPREHENSIVE BENEFITS OF INDUSTRIAL CHAIN

The benefits of the industrial chain		Environmental benefit	Comprehensive benefits
Initial industrial chain	Coking (10000 tons)	14.98	13.56
	Steelmaking (10000 tons)	19.98	13.81
	Smelt iron (10000 tons)	24.97	31.49
	UCG (10000 Nm ³)	58786	42476
The added industrial chain	Coking (10000 tons)	14.98	17.77
	Steelmaking (10000 tons)	19.98	24.50
	Smelt iron (10000 tons)	24.97	38.39
	UCG (10000 Nm ³)	34399	32643
	Electric power generation (100 million degrees Celsius)	64.98	40.87
	Chlor-alkali (10000 tons)	27.89	32.69
	Synthetic ammonia (10000 tons)	12.96	13.51

According to Table II, the comprehensive benefit of the underground coal gasification industry in the initial industrial chain was 42476. The comprehensive benefits of the increased industrial chain decreased to 32643. The added environmental benefits from the power generation industry were 64.98, with a comprehensive benefit of 40.87. After improving the industrial chain through the model, the comprehensive efficiency of the coking industry has increased by 31.05%, and the economic and environmental benefits of the steelmaking industry have also significantly increased by 77.41%. The environmental benefits of the iron smelting industry have increased by 21.91% compared to the initial industrial chain, while the economic and comprehensive benefits of underground coal gasification have changed, with a decrease of 70.89% in economic benefits and an increase of 30.12% in comprehensive benefits. Therefore, it indicates that the industrial chain after increasing industries improves the utilization and processing of output products and pollutants, thereby improving the resource utilization rate of industries and their products, and reducing environmental pollution. This also proves the superiority of the multi-objective programming model of NSGA-II algorithm.

V. DISCUSSION

Regarding the impact of rural industrial ecological economy, this study utilizes the industrial chain model of ecological industrial parks and the mutual conversion of resources and waste to calculate the weight of pollutants and waste emissions in rural industrial economy. The highest weight of hydrogen sulfide output from the coking industry is 94, and the lowest quantity is 10kg/t. The amount of slag, silicon dioxide, and aluminum oxide produced by the steelmaking industry is relatively high, at 128kg/t, 102kg/t, and 113kg/t, respectively. The weight of wastewater discharge from iron mills is the highest at 5900, and the weight of carbon monoxide in the underground coal gasification industry is 33. The above data can provide a parameter basis for the industrial combination of industrial parks. Combined with the dual objective programming model, the comprehensive benefit

indicators of ecological industrial economy were evaluated, and the multi-objective genetic algorithm NSGA-II algorithm was used to optimize the multi-objective problem. After optimizing the industrial chain, the environmental benefits of coking, steelmaking, and ironmaking industries increased by 31.05%, 77.41%, and 21.91%, compared with energy-saving and emission reduction technologies in the coking coal industry, the adoption of symbiotic technologies also significantly improves environmental benefits. The underground coal gasification industry has reduced economic benefits by 70.89% while increasing environmental benefits by 30.12%. The balance between economic and environmental benefits is also reflected in the underground coal gasification hydrogen production process. This is consistent with the conclusion drawn by Xue R et al. [20] and Han X et al. [21]. Therefore, it indicates that the optimization of the industrial chain model has maximized the utilization of industrial resources and production output, and promoted the construction of ecological economy.

In the construction of ecological industry chain models and the evaluation of comprehensive benefits, research mainly focuses on environmental indicators and their impact on benefits, and calculates the degree of mutual benefit and environmental index of the ecological industry chain. Through the development model of reducing resource waste and strengthening industrial connections, the optimal industrial structure of rural industrial ecological economy can be achieved. However, in the current research results, the green and sustainable development of industrial economy mainly involves the construction of evaluation models for industrial economy and environmental indicators, combined with multi-level analysis and other methods to analyze the development problems of industrial economy, and propose corresponding improvement measures to achieve the development of industrial ecological economy. This article mainly uses the NSGA-II algorithm to comprehensively calculate the comprehensive benefits of multi-objective factors, taking into account the actual industrial structure of the industrial economy, providing a mutually beneficial and harmonious development mode for various industries in the industrial ecological economic park, while improving resource utilization and promoting sustainable development of the industrial ecological economy cycle. However, in the industrial chain structure of industrial ecological economy, there is still a lack of specific explanations on the actual types of industries and resource utilization methods in research. Therefore, in future research, it is necessary to conduct in-depth exploration of different industry scales and production methods in the industrial chain, in order to develop feasible models and resource utilization methods for the development of industrial economic ecology.

VI. CONCLUSION

In response to the ecological development of industrial economy in rural areas, this study combines the industrial structure of industrial parks and a dual objective planning model. Then, the NSGA-II is used to calculate the degree of mutual benefit and symbiosis between resource cycles in the industrial chain, obtaining the optimal industrial structure and production mode for rural industrial ecological economy. The

result analysis showed that some pollutants exported by the coking industry had the highest weights of 83 and 94. The highest weight of some pollutants in the steelmaking industry was 54 and 34, while the wastewater discharge from iron mills was relatively high, which was 5900. Based on the unit output value of industrial output, the converter gas for steelmaking was 2.713 yuan, while the other output products were 0.004 yuan, 0.006 yuan, and 0.032 yuan, respectively. The output value of coke oven gas in coking was 0.841 yuan, and the unit output value of water vapor was 0.006 yuan. The final comprehensive benefit index calculation showed that when the scale of the coking industry was 135600 tons, the steelmaking industry was 314900 tons, the ironmaking industry was 148100 tons, and the UCG industry was 42.476 million Nm³. The comprehensive benefit of the initial industrial chain reached its optimal level. This proves that the dual objective programming model combining NSGA-II has advantages. However, there is a lack of extensive data and surveys on the input and output of specific industries. Therefore, subsequent research should be further improved and perfected.

Abstract—Wi-Fi based indoor positioning has been considered as the most promising approach for civil location-based service due to the widespread availability Wi-Fi systems in many buildings. One of the most favorable approaches is to employ received signal strength indicator (RSSI) of Wi-Fi access points as the signals for estimating the mobile object locations. However, developing a solution to obtain high positioning accuracy while reducing system complexity using traditional methods as well as deep learning based methods is still a very challenging task. This paper presents a proposal to combine the Truncated Singular Value Decomposition (SVD) technique with a Long Short -Term Memory (LSTM) model to enhance the performance of indoor positioning system. Experimental results on a public dataset demonstrate that the proposed approach outperforms other state-of-the-art solutions by means of positioning accuracy as well as computational cost.

Keywords—Indoor positioning; Wi-Fi fingerprinting; Truncated Singular Value Decomposition; LSTM

I. INTRODUCTION

Indoor positioning has attracted significant interest [1, 2, 3, 4] due to its potential applications for various Location-based Service (LSB) in rescue operations, military, medical care, civil activities, etc. While satellite based positioning systems have successfully applied in many outdoor applications, the satellite signal is rarely available inside buildings. Therefore, it is still a very challenging task to develop a solution that achieves accurate position estimates at low cost due to the frequent change of environment, people movement, etc.

Various indoor positioning approaches have been proposed utilizing different types of signals including Wi-Fi, Bluetooth, visible light, acoustic, etc. and their combination [3, 5]. Among them, many approaches utilize Received Signal Strength Indicator (RSSI) from Wi-Fi Access Points (APs) due to widespread deployment of WLANs and Wi-Fi equipped devices [6]. It is worth noting that Wi-Fi RSSI signal can be captured easily by all smart phones which many people own. Therefore, Wi-Fi RSSI based indoor positioning is considered as the most promising approach for civil LSB applications since it requires no extra infrastructures [6, 7].

In indoor environment, traditional localization techniques such as trilateration based and triangulation based often require line-of-sight (LoS) condition between the transmitter and the receiver. Unfortunately, this condition is often false due to

obstacles and room partitions in buildings [2]. These approaches also often require some prior knowledge of the infrastructure such as AP locations and additional devices. On the other hand, Wi-Fi RSSI fingerprinting based techniques do not require the mentioned conditions have been become the most promising approach [3, 6, 8, 9], especially for civilian applications. This method operates in two phases, one for training, and the other for online localization/classification [8]. In the training phase, RSSI data are captured at the predetermined reference points (RPs) from available Wi-Fi APs to build the radio map database. In the localization phase, the online captured data are compared to the radio map to determine the target location based on the similarity between online data and training data. The flow of fingerprinting is visually depicted in Fig. 1.

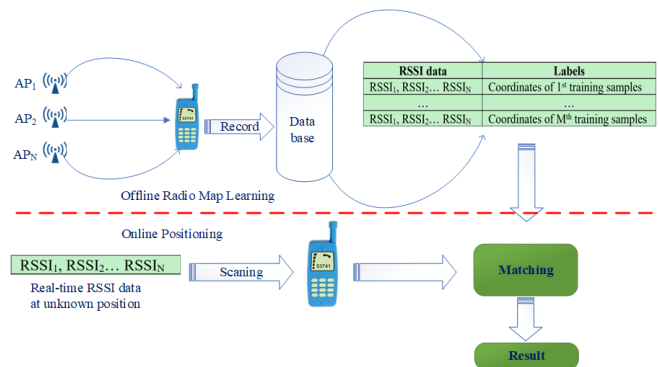

Fig. 1. The flow of Wi-Fi fingerprinting.

Traditional fingerprinting based approaches being used for estimating position of an object can be classified into deterministic and probabilistic methods [10, 11]. Among those two methods, previous studies have indicated that the probabilistic approaches often deliver better positioning results compared to the deterministic approach [12, 13]. The critical problem with traditional solutions is that their computational cost in the classification phase is often very high when the region of interest is large [8, 9]. This leads to the reduction of positioning accuracy in real time applications due to the movement of the mobile object between Wi-Fi RSSI scanning time and the time the system delivers the positioning result. Therefore, improving the performance of Wi-Fi indoor positioning system (WF-IPS) is a challenge since it needs to satisfy both requirements: reducing positioning error and reducing execution time.

*Corresponding author.

Recently, various artificial neural network (ANN) based approaches have been developed for WF-IPS. Since the transformation between the observed RSSI values and mobile object location is nonlinear, it is difficult to derive a close form solution. Therefore, ANN is considered a suitable and reliable approach to approximate this transformation. Compared to traditional algorithms, deep learning approaches have proved their effectiveness when applying to WF-IPS [8]. Several solutions for WF-IPS have been proposed utilizing different ANN models such as multilayer perception (MLP) [14], stacked autoencoder (SAE) [15], convolution neural network [3, 9, 16], recurrent neural network (RNN) and its variations [8, 17], etc., or their combinations which are considered as hybrid or ensemble system. In addition to ANN based methods, several solutions combining dimensionality reduction and the use of LSTM models have emerged to enhance the accuracy of indoor positioning systems based on Wi-Fi fingerprints (WF-IPS) [18, 19]. These solutions emphasize the significance of dimensionality reduction in processing RSSI data to improve the performance and efficiency of the system [20].

Although having been extensively investigated in the literature, determining a sufficient neural network model is still of particular interest among the research community. Wi-Fi data often has a high dimensionality, and when applied to machine learning models, processing a large volume of data becomes extremely expensive. Therefore, there have been many studies advocating for the use of combined solutions to reduce data dimensionality including Truncated SVD, Principal Component Analysis (PCA), and autoencoders [20]. Prominent studies in this field have demonstrated that reducing data dimensionality not only improves model performance but also significantly reduces the required computational resources.

Having inspiration from the advantages of data dimensionality reduction in classification and regression problem, this article introduces a solution for WF-IPS which combines Truncated SVD and LSTM models to improve positioning accuracy while reducing computational costs. To ensure a fair performance comparison of the proposed approach with state-of-the-art solutions, the dataset provided in study [33] is utilized in this study. In summary, our contributions are as follows:

- Truncated SVD is utilized for data dimensionality reduction as well as noise removal, demonstrating its superiority over PCA in various scenarios.
- We demonstrate that utilizing truncated SVD for dimensionality reduction reduces the computational load while improving performance in location prediction and execution time compared to the other state-of-the-art approaches on the same dataset.
- We conduct a thorough analysis of the improvements gained from employing our proposed solution in different test scenarios, highlighting its overall effectiveness.

The rest of the article is organized as follows. In Section II, the related works are presented. The proposed approach of combining Truncated SVD and LSTM model is presented in Section III. In Section IV, the experimental results are

extensively presented to demonstrate the superiority of the proposed approach. The conclusions of the paper are drawn in Section V.

II. RELATED WORKS

Recently, many researchers have focused on the challenges of indoor positioning systems (IPS) based on Wi-Fi fingerprinting using machine learning and deep learning techniques. Collecting Wi-Fi fingerprint signals often results in high-dimensional data, which poses challenges during both the training and localization phases of machine learning models. Dimensionality reduction is an important solution for high-dimensional indoor positioning problems, although there might be a trade-off between dimensionality reduction and model accuracy [21, 22]. Minimizing computational costs during the position estimation phase is crucial for real-time monitoring systems. Therefore, designing a model with low computational cost makes indoor positioning systems more feasible. In the following content, machine learning and deep learning techniques with data dimensionality reduction are explored.

Various types of neural networks have been utilized to develop solutions for WF-IPS. Among them, Recurrent Neural Network (RNN) seem to be very attractive in many previous research [17, 18, 19, 23, 24]. In study [17], the authors presented the evaluation of RNN and LSTM (a variant of RNN) as the deep learning technique to build a WF-IPS system. The experimental evaluation on a public available dataset showed that their proposed RNN and LSTM model can deliver almost the same accuracy on floor classification (99.7%) as well as position estimates (2.5-2.7 meters). The computation time between the two models was also presented, RNN required less time than LSTM model both on training and testing procedures. In study [23], the authors proposed a local feature-based deep LSTM approach for a WF-IPS. The robust local features are extracted, and the noise is eliminated by a local feature extractor applying sliding windows. The local features are then fed into a deep LSTM for target position estimation. Their proposed approach is conducted in real environments and compared with other state-of-the-art approaches for indoor positioning. The experimental results indicate the mean localization error of their approach has been improved by 18.98% to 53.46% compared to the others.

A novel method that transforms RSSI signals into principal components (PCs) using all the effects of APs is proposed in [25]. Instead of selecting APs, this research replaces the captured Wi-Fi RSSI with a subset of PCs to enhance localization accuracy and reduce computational costs. Test results in a real WLAN environment showed that the average distance error decreased by 33.75%, and complexity decreased by 40% in comparison with other methods. Authors in [26] introduced a new technique for clustering location data into subregions using an algorithm named fuzzy C-means. Useful APs were then selected to reduce the dimensionality of RSSI fingerprint data during the training procedure. In the online phase, the Nearest Neighbor (NN) method was used to select subregions and compute location coordinates of the target utilizing the Relative Distance Fuzzy Localization algorithm. Test results demonstrated that their proposed model reduced computation time and improved localization accuracy. In study

[27] a magnetic field indoor fingerprinting system based on CNNs was proposed. The Recurrence Plots were utilized as sequence fingerprints and the localization problem is approaching from a regression framework. The real-world experimental results show the advantages of their proposal compared to the other studies, though its computation cost is high. In study [28], an LSTM network was used to learn high-level representations of extracted local temporal features, then to eliminate the noise impact, a local feature extraction approach was employed to extract powerful local features. In study [29], to avoid quality degradation, spatial features of Wi-Fi signals are extracted by a residual-based network at the same time slice and then an LSTM network is employed to extract temporal features of Wi-Fi signals between successive time slices. Research [30] proposed a data dimensionality reduction technique to enhance performance of Wi-Fi IPS based on Multiple Service Set Identifiers. Test results of the proposed system achieved localization error of less than 0.85 m over an area of 3000 m², with a cumulative distribution function of 88% at a localization error of 2 m.

In general, there is often a trade-off between accuracy and computational speed in indoor Wi-Fi RSSI-based positioning models due to high dimensionality data. However, studies combining dimensionality reduction and machine learning have shown significant effectiveness in both accuracy and computational speed. In this research, we propose the use of dimensionality reduction with Truncated SVD combined with LSTM for indoor Wi-Fi signal-based location estimation. To ensure fairness in performance evaluation, we utilized [17, 19] as a reference document to conduct a comprehensive comparison and assess localization performance on both positioning accuracy and system complexity using the same dataset.

III. PROPOSED APPROACH

The proposed approach which combines Truncated SVD and LSTM model (Truncated SVD-LSTM) for performance enhancement of Wi-Fi fingerprinting based indoor positioning is systematically presented in this section.

A. System Architecture

The structure of the proposed indoor positioning system consists of two main phases as is illustrated in Fig. 2. This block diagram provides a visual representation of the operation of the indoor positioning model, allowing us to understand how data flows from the initial data collection phase to the final estimation of the user's location.

The proposed indoor positioning model is separated into two phases: the offline training phase and the online testing phase. During the offline training phase, data collected from various sources are aggregated and normalized. The data are then passed through the Truncated SVD for dimensionality reduction. The utilization of Truncated SVD helps eliminate unnecessary information and reduce the complexity of the original data. Once the data has been dimensionally reduced, they are ready to be utilized for training the LSTM model. During the offline training phase, the LSTM model learns how to predict the target position based on the reduced training data processed by Truncated SVD and known locations. After the model has been trained, it can be

used to estimate the target position in real-time. In the online testing phase, each new data sample collected from a target device is processed by normalization and Truncated SVD in the same way as in the offline phase. Subsequently, the dimensional reduced data sample is fed into the already trained LSTM model to estimate the target real-time position. The result of the testing phase is the predicted position of the target within the area of interest.

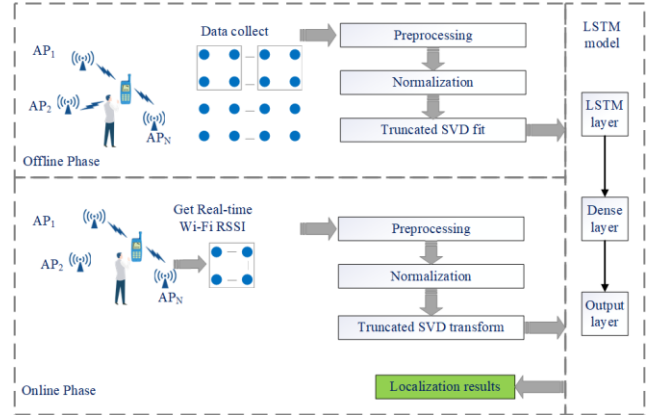

Fig. 2. System architecture of the proposed WF-IPS.

B. The Proposed Approach for Combining Truncated SVD and LSTM Model

1) *Introduction to Truncated SVD*: Truncated SVD [31] is a technique developed for dimensionality reduction. It is commonly utilized to solve the various problems where high-dimensional data are presented. This phenomenon, namely “curse of dimensionality”, often affects the performance of the machine learning based system. Truncated SVD is built upon the concept of SVD, which decomposes a matrix \mathbf{A} into three separate matrices $\mathbf{\Sigma}$, \mathbf{U} , \mathbf{V} corresponding to singular values, left and right singular vectors of the matrix \mathbf{A} , as presented in Eq. (1).

$$\mathbf{A}_{M \times N} = \mathbf{U}_{M \times M} \mathbf{\Sigma}_{M \times N} (\mathbf{V}_{N \times N})^T \quad (1)$$

Truncated SVD retains the top k singular values and their associate singular vectors. The main concept of Truncated SVD is finding a representation of the original matrix with a much lower dimensionality while preserving the most data information such as data patterns and data relationships. To effectively reduce the data dimensionality according to any specific problem, determining the best value of k is of important task. Mathematical expression of Truncated SVD is presented in Eq. (2).

$$\mathbf{A}_{M \times N} \approx \mathbf{A}_{k \times k} = \mathbf{U}_{k \times k} \mathbf{\Sigma}_{k \times k} (\mathbf{V}_{k \times k})^T \quad (2)$$

2) *Introduction to LSTM*: In this study, the LSTM model [32] is employed to develop an indoor positioning solution. The target location is predicted via the LSTM linear regression model utilizing the low dimensional data processed by Truncated SVD. LSTM model selectively forgets or remembers information over long data sequences. In the LSTM, long-term dependencies are captured for modeling context and sequential

patterns. There are a memory cell and three gates namely input gate i_t , forget gate f_t , and output gate o_t in an LSTM cell as shown in Fig. 3. The input gate regulates the information transmitted to the cell. The forget gate decides how much information transmitted to the cell should be retained. Output sequences and hidden state are produced and updated by output gate. The memory cell is responsible for storing information over time in the network. The mathematical expressions for the LSTM network at each time step t are presented in Eq. (3) to Eq. (8).

$$i_t = \sigma \left[(W_{i,x}x_t + W_{i,h}h_{t-1}) + b_i \right] \quad (3)$$

$$f_t = \sigma \left[(W_{f,x}x_t + W_{f,h}h_{t-1}) + b_f \right] \quad (4)$$

$$\tilde{C}_t = \tanh \left[(W_{c,x}x_t + W_{c,h}h_{t-1}) + b_c \right] \quad (5)$$

$$C_t = f_t C_{t-1} + i_t \tilde{C}_t \quad (6)$$

$$o_t = \sigma \left[(W_{o,x}x_t + W_{o,h}h_{t-1}) + b_o \right] \quad (7)$$

$$h_t = o_t \tanh(C_t) \quad (8)$$

Where, $x_t, h_t, C_t, \tilde{C}_t$ are the input, output, cell state and updated cell state at time step t , respectively, C_{t-1}, h_{t-1} are the previous cell state and hidden state. $W_i, W_f, W_c, W_o, b_i, b_f, b_c, b_o$ are, respectively, the weight matrices and the bias vectors of the input, forget, updated cell state and output gate layers. The activation functions utilized in LSTM cell are σ and \tanh .

Fig. 3. LSTM cell structure.

3) *Proposed model*: Fig. 4 introduces the general model that integrates data dimensionality reduction using Truncated SVD and LSTM neural network to address indoor localization based on Wi-Fi RSSI data.

The original RSSI data consists of a large number of features (N), and Truncated SVD is employed to reduce the data dimensionality to k features ($k < N$), thus reducing complexity and enhancing the generalization capability of the model. The low dimensional data samples are then fed into the LSTM model for training and predicting the device's position

within the indoor environment. The format of the RSSI data can be seen as follows:

$$RSSI_{M \times N} = \begin{Bmatrix} RSSI_{11} & RSSI_{12} & \dots & RSSI_{1N} \\ RSSI_{21} & RSSI_{22} & \dots & RSSI_{2N} \\ \vdots & \vdots & \dots & \vdots \\ RSSI_{M1} & RSSI_{M2} & \dots & RSSI_{MN} \end{Bmatrix}$$

Fig. 4. Combination of Truncated SVD and LSTM for indoor positioning.

This is a collection of RSSI values obtained at each location in the training set, where M and N represent the number of RSSI samples and the number of detected APs in the dataset.

The workflow of our proposal is described in Fig. 5.

Fig. 5. The principle of the proposed approach.

IV. RESULTS AND DISCUSSION

The effectiveness of the proposed approach is extensively presented and analyzed in this section. The experimental results are produced by using a public dataset [33]. Localization error and computational cost are the focused performance characteristics for comparison between our proposal and other state-of-the-art methods.

A. Wi-Fi RSSI Dataset

The dataset [33] was collected on the 3rd and 5th floors of a university's library building. Data collection involved facing specific directions and gathering six fingerprints per location, with six consecutive samples per point to exclude any initial measurements. The training, Test-01, and Test-05 datasets covered "Up" and "Down" directions, while Test-04 and Test-05 focused on "Left" and "Right." Collection followed a sequence: (1) direct 3rd floor, (2) reverse 3rd floor, (3) direct 5th floor, and (4) reverse 5th floor. Training, Test-01, and Test-05 always included data from all directions monthly. Test-04 data were from horizontal corridors. Due to time constraints, Test-02 and Test-03 considered only two directions, covering 308.4 m² on both floors. The datasets were organized into 15 collection months, resulting in 16,704 training and 46,800 test samples, collected comprehensively for Wi-Fi RSSI-based indoor positioning. Table I presents the main characteristics of the dataset. For data preprocessing, the values for undetected APs are replaced by -100 dBm which is the weakest signal in the dataset for the whole work presented in the following content of this paper.

TABLE I. DATASET CHARACTERISTICS

Characteristics	Values
Training samples	16,704
Testing samples	46,800
Number of measurements taken at each RP	12
Number of observable APs	448
Number of floors	2
Coverage	308.4 m ²
Number of training RP	48
Number of test positions	212
Period of measurement campaign	15 months
Training RSSI range	-98 dBm to -31 dBm
Testing RSSI range	-100 dBm to -32 dBm
Constant value for undetected APs	100 dBm

B. Data Normalization

The tricky problems in the characteristics of Wi-Fi RSSI data that affect the performance of Wi-Fi IPS are the variation over time and the fluctuation due to the quick changes of indoor environment as well as the behavioral of the devices. To deal with such the problems, data normalization is considered the necessary step which reduces the data variation while maintaining information. Consequently, it helps to enhance the performance of dimensionality reduction techniques and learning capacity of deep learning model. In this study, two common normalization techniques, namely standard

normalization and max-min normalization, were evaluated to come up with the best normalization solution. Each Wi-Fi RSSI sample is normalized as presented in Eq. (9) or Eq. (10) according to the chosen normalization technique. It is noted that all the RSSI values of undetected APs were replaced by -100 dBm.

$$RSSI_{jStdNorm} = \frac{RSSI_j - RSSI_\mu}{RSSI_\sigma} \quad (9)$$

$$RSSI_{jMaxMinNorm} = \frac{RSSI_j - RSSI_{\min}}{RSSI_{\max} - RSSI_{\min}} \quad (10)$$

where, $RSSI_{jStdNorm}$, $RSSI_{jMaxMinNorm}$, and $RSSI_j$ are the normalized values corresponding to standard normalization and max-min normalization and the raw value of the RSSI of the j -th AP in each RSSI sample. $RSSI_\mu$, $RSSI_\sigma$, $RSSI_{\max}$, $RSSI_{\min}$ are the mean, standard deviation, maximum and minimum values of each RSSI sample.

C. Determination of the Number of Dimensions for Truncated SVD

An important task when using Truncated SVD technique to reduce data dimensionality is determining the number of dimensions to retain preserve data information. We conducted a survey to identify the number of dimensions to be kept. Fig. 6 illustrates the relationship between the number of Truncated SVD dimensions and the amount of preserved information. As can be seen, when the number of dimensions is reduced to 100, the cumulative explained variance ratio almost reaches 100%, it means that the information loss after truncation is negligible. It is noted that the number of features of original data is 448, hence 100 kept dimensions meet the target of dimensionality reduction. Therefore, in this study, the number of dimensions to be kept is set to 100.

Fig. 6. The relationship between the number of dimensions and the preserved information.

D. Model Optimization

For optimizing our proposed model, the LSTM model presented in study [19] is first utilized as presented in Table II. It is worth noting that in study [19] the authors presented a solution for Wi-Fi fingerprinting based IPS by combining PCA with LSTM, their model was also evaluated on the dataset provided in study [33]. That explained the reason why their LSTM model was chosen as the starting point for our model optimization procedure.

TABLE II. GENERAL MODEL

Characteristics	Value
Number of LSTM units	100
Drop rate for LSTM layer	0.3
Activation function for LSTM layer	sigmoid
Number of units for Dense layer	100
Activation function for Dense layer	sigmoid
Dropout rate for Dense layer	0
Number of units for Output layer	2
Activation function for Output layer	linear
Learning rate	0.001
Optimizer	Adam
Batch size	32
Training epoch	100

Before tuning hyperparameter of the LSTM model, data normalization techniques as presented in subsection B are first evaluated since it strongly affects the performance of dimensionality reduction as well as deep learning. As shown in Table III, standard normalization technique yields better Mean Distance Error (MDE) result compared to the min-max normalization. Therefore, for further hyperparameter tuning of the LSTM model, standard normalization was selected. It is noted that during the tuning process, the min-max normalization is still checked each time a hyperparameter is evaluated and all the results confirmed standard normalization technique is the better one.

TABLE III. MEAN DISTANCE ERROR WITH DIFFERENT DATA NORMALIZATION METHODS

Normalization	MDE (m)
Min-max	2.231
Standard	2.087

For hyperparameter tuning, different configurations of LSTM were evaluated as illustrated in Table IV. Comparing the values between column “Value delivered the best MDE” in Table IV and column “Value” in Table II, it is obvious that the main structure of the LSTM model such as number of LSTM units and number of units for Dense layer remain unchanged. However, the optimized values of drop rate, activation function,

batch size and training epoch were different. These changes make the optimized model operate faster during training on the same dataset as demonstrated in the next subsection.

TABLE IV. HYPERPARAMETER TUNING

Characteristics	Value options for tuning	Value delivered the best MDE
Number of LSTM units	[40:20:140]	100
Drop rate for LSTM layer	[0.2, 0.25, 0.3]	0.2
Activation function for LSTM layer	[relu, tanh, sigmoid]	relu
Number of units for Dense layer	[40: 20: 200]	100
Activation function for Dense layer	[relu, tanh, sigmoid]	sigmoid
Dropout rate for Dense layer	[0.0, 0.1, 0.2, 0.3]	0
Number of units for Output layer	2	2
Activation function for Output layer	linear	linear
Learning rate	[0.01 0.001, 0.0001]	0.001
Optimizer	Adam	Adam
Batch size	[16, 32, 64, 128]	64
Training epoch	[20:10:100]	30

E. Positioning Performance Evaluation

To evaluate the localization error of our proposal, for a fair comparison, some state-of-the-art works conducted on the same dataset presented in [32] were selected as the benchmark deep learning-based models. Mean Distance Error (MDE) and Root Mean Squared Error (RMSE) are selected among typical evaluation metrics for comparing the positioning accuracy of different approaches. Denoting d_i as the localization distance error of the i -th RSSI test sample, and the coordinates of the true and the predicted position are $(x_{i,true}, y_{i,true})$ and $(x_{i,pred}, y_{i,pred})$, respectively, the localization distance error measured by Euclidean distance is computed by Eq. (11). MDE and RMSE are then correspondingly determined by Eq. (12) and Eq. (13).

$$d_i = \sqrt{(x_{i,true} - x_{i,pred})^2 + (y_{i,true} - y_{i,pred})^2} \quad (11)$$

$$MDE = \frac{\sum_{i=1}^{N_{test}} d_i}{N_{test}} \quad (12)$$

$$RMSE = \sqrt{\frac{1}{N_{test}} \sum_{i=1}^{N_{test}} d_i^2} \quad (13)$$

Table V presents the achieved values based on the evaluation criteria, including Mean Squared Error (RMSE) and Mean Distance Error (MDE), for various localization solutions. The results clearly demonstrate that the proposed solution exhibits the lowest RMSE and MDE values, e.g., the MDE of the proposed model is reduced by approximately 6% and 21% compared to the results presented in study [19] and [17], respectively. Furthermore, Table VI highlights the superiority of

our proposed approach in terms of computational complexity. Specifically, our solution reduces training time by more than 80% compared to both benchmark solutions. When using the proposed solution, the prediction time is improved by roughly 20% compared to using LSTM without dimensionality reduction. It is noted that the testing time of the proposed solution is the same as the study presented in study [19] since the two models are very similar as mentioned in previous subsection. This underscores the efficiency and effectiveness of our approach in indoor localization scenarios.

TABLE V. POSITIONING ERROR COMPARISON

Models	MDE	RMSE
LSTM [17]	2.5-2.7	-
PCA-LSTM [19]	2.18	1.95
Proposed	2.05	1.75

TABLE VI. MODEL COMPLEXITY COMPARISON

Models	Number of trainable parameters	Training time [s]	Testing time [s] (whole test dataset)
LSTM [17]	NA ^a	581.3599 ^b	10.1721 ^b
PCA-LSTM [19]	90,702	Approx. 500 ^{c,d}	8,1^c
Proposed	90,702	85^c	8,1^c

^a. Not available

^b. NVIDIA GeForce GTX 1080 Ti as Graphical Processing Unit (GPU)

^c. NVIDIA Quadro P2200 as Graphical Processing Unit (GPU)

^d. 100 training epoch

Fig. 7. Comparison of positioning error.

Fig. 7 illustrates the cumulative error function based on Euclidean distance for different LSTM models. The solid line represents the prediction probability using the proposed Truncated SVD and LSTM solution. The dashed line and the dash dot line depict the CDF of distance error of the two benchmark approaches, [19] and [17], respectively. According to the data presented on Fig. 7, it is obvious that data dimensionality reduction based approaches outperform the other in which data preprocessing technique is not implemented. In addition, employing suitable data preprocessing and

dimensional reduction techniques can lead to further enhancement of location prediction accuracy.

The experimental results presented above illustrate the important role of Truncated SVD in the proposed approach. This is the main difference between our work and the one presented in [19]. In addition, fine tuning the parameters of LSTM model is also very essential during the development of the concrete solution for a specific indoor positioning system.

V. CONCLUSIONS

In this study, an approach called Truncated SVD-LSTM for indoor localization based on Wi-Fi fingerprints is introduced. To the best of our knowledge, this is the first time an indoor positioning solution has been built upon the fusion of Truncated SVD and LSTM model. Our solution focuses on reducing the dimensionality of the data to enhance positioning accuracy and computational cost of the model. We conducted experiments on a publicly available dataset and achieved impressive results. The experimental outcomes have unequivocally demonstrated that the integrated LSTM structure in our solution has attained an average localization error of 2.05 meters, with nearly 60% of cases having errors below 2 meters. This signifies an enhancement of approximately 6% and 21% compared to state-of-the-art studies, [19] and [17], respectively, utilizing LSTM on the same dataset. The results also indicate that the proposed solution significantly reduces computational costs, especially for the training procedure. Compared to the state-of-the-art approach, the evaluation results demonstrated the superiority of the proposed solution. In the future, the supervised techniques for data dimensionality reduction should be investigated in order to extract information in a supervised manner which may help the localization model perform more efficiently.

CONFLICTS OF INTEREST

The authors declare no conflict of interest.

Design and Implementation of an Information Management System for College Students in Higher Education Institutions Based on Cloud Computing

Mo Bin

Guangdong Polytechnic of Science and Technology
Zhuhai 519090, China

Abstract—A cloud computing-based system has been developed to enhance the efficiency and practicality of the information management system for college students in higher vocational colleges. This system incorporates a well-defined architecture that leverages cloud computing technology. The management layer's logic module ensures the security of vocational college students' information by deploying virtual gateways at strategic points within the system, thereby controlling access, sharing, and exchange of information. The resource module in the application layer optimizes server cluster load balancing by minimizing task completion time and improving load balancing effectiveness. Additionally, the M-Cloud storage mode is employed to store and back up application layer cloud information, along with the distributed Bigtable information base. The user access layer provides users with convenient services through the corresponding cloud service access interface in the application layer. Furthermore, the employment information of college students and enterprise position information are clustered using the K-means algorithm based on data mining, and personalized employment recommendations are made using similarity calculations. Experimental results demonstrate that the system boasts a user-friendly interface design, efficient operation, and comprehensive management functions. The system's server cluster exhibits strong load-balancing capabilities, effectively mitigating network congestion and minimizing the risks of network storms and paralysis.

Keywords—Cloud computing; student information; management system; load balancing; virtual gateway; personalized recommendation

I. INTRODUCTION

As an important component of the national education system, vocational colleges face enormous challenges in student information management due to their large number and diverse types of students. Automated management of student information in higher vocational colleges and universities through the information management system can reduce manual operation, reduce the error rate, and improve management efficiency; the system can be encrypted and backed up to ensure the security and integrity of the data [1], through the system can be convenient to share the student information, to promote the collaboration and communication between the departments [2], the data mining and analysis, to provide decision-making support for the leadership of the school to improve the management level and competitiveness, but also to provide more convenient services for students, such as grade inquiry, course

scheduling [3], to enhance student satisfaction and teaching quality.

There are many methods for the design and implementation of information management systems at home and abroad. For example, Li D C et al. [4] proposed a new SF deployment management platform, which aims to achieve the dynamic deployment of edge computing service applications with the lowest network latency and service deployment cost in edge computing network environment, and verify its practicability in pure edge computing and mixed edge cloud computing scenarios through experiments. This method also proposes a solution to the problem of network load balancing, but the comprehensive load capacity of the server is not fully considered, resulting in long network response time and easy occurrence of network unresponsiveness. American K et al. [5] proposed a semi automated method for ensuring network physical security, which can automatically identify and verify network security related statements in industrial control system equipment documents through the development of new algorithms and tools, thereby assisting in the generation of compliance reports and reducing OT device security risks. However, this method does not take into account the issue of storing a large amount of data in the system, which may lead to server overload. Bi D et al. proposed the Internet of Things (IoT) assisted college students' information management system using hybrid crypto-integrated steganography technology [6]. This paper uses a hybrid crypto-integrated steganography (HCIS) algorithm and auxiliary data input for college students' information management systems. It uses the Internet of Things to help secure data sharing in the cloud environment. The code generated by password students can provide a high degree of privacy for users accessing cloud data. Cryptography converts data into a safe format readable by authorized users, and steganography helps to transmit secret data to avoid information discovery and uses encryption keys to hide or effectively protect data, thus realizing the design of college students' information management system. This system ensures the security of student information but does not consider the problem of network access load balancing, which may lead to the risk of network paralysis. Chen W et al. proposed a dynamic student information management system based on computer vision for higher education platforms [7]. This paper introduces a dynamic student data management system (DSDM-AICV) based on artificial intelligence computer vision technology. Based on the collected information, use AI-enabled archiving and dynamic

user access to generate data-related process flows, which helps to explore the relationship between student data, improve the level of data management, and achieve student information management. This method does not recommend employing college students, so the system needs to be improved.

The cloud computing platform offers flexible resource allocation and expansion capabilities, allowing for dynamic resource adjustments based on system requirements at various stages. It incorporates a comprehensive security mechanism, encompassing data encryption, access control, and more, to ensure the confidentiality and security of student information. Cloud computing platforms have high availability and fault tolerance, which can ensure system stability and reliability, avoid system crashes or data loss caused by hardware failures or network issues, and provide efficient computing and storage capabilities. They can quickly process large amounts of student information data, improve management efficiency and service quality. Therefore, this article adopts a cloud computing platform to design and implement an information management system for college students in vocational colleges, achieving centralized storage, efficient management, and secure sharing of student information, which has become an urgent need for information construction in vocational colleges. This new management method not only improves the efficiency and quality of student information management in vocational colleges, but also provides more accurate and comprehensive data support for educational decision-making in schools.

The specific implementation process of this paper is: first, build the student information management system architecture, and optimize the server cluster load balancing to improve the system performance. Then, the M-Cloud storage mode is used for cloud information storage and backup, and the system security is guaranteed through the virtual gateway. Finally, the data clustering algorithm is used to realize the personalized employment recommendation for college students, complete the system design, and provide efficient and stable student

information management solutions for higher vocational colleges.

II. DESIGN OF INFORMATION MANAGEMENT SYSTEM FOR COLLEGE STUDENTS IN HIGHER EDUCATION INSTITUTIONS

A. Information Management System Architecture for College Students in Higher Vocational Colleges and Universities Based on Cloud Computing

The architecture of the information management system for college students in higher vocational colleges and universities, based on cloud computing, consists of three main components: the management layer, application layer, and user access layer. The management layer encompasses the gateway, logic, and student network modules, which oversee all levels of cloud computing services [8]. On the other hand, the application layer comprises the resource module, platform module, and application module. The resource module encompasses physical resources, server services, storage services, and network services, while the platform module includes database services and middleware services [9]. Lastly, the application module encompasses front-end application services and student information management application services. The core aspect of cloud computing in the architecture of information management systems for college students lies in providing services through the Internet. Consequently, the resource, platform, and application modules offer infrastructure, platform, and software services, respectively. The user access layer, also known as the user access layer, primarily includes a service directory, subscription management, service access, and personalized recommendations.

Fig. 1 illustrates the structure of the information management system designed for college students in higher education institutions, which operates on cloud computing technology.

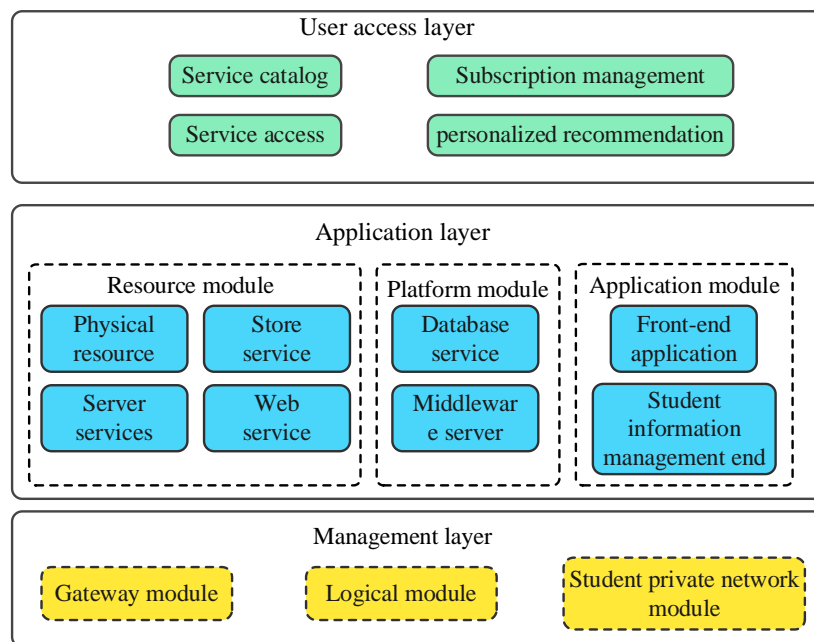

Fig. 1. Architecture of college student information management system based on cloud computing.

The management layer, serving as the central component of the college student information management system in higher vocational colleges and universities, encompasses various modules such as the student's particular network module, logic module, and gateway module. These modules collectively enable the implementation of student information security control within the system.

The resource module in the application layer refers to providing the infrastructure resources of cloud computing as a service to users. Users can build their applications on these essential services. This service conceals complex physical resources from users by providing virtualized resources. Physical resources refer to many physical facilities supporting various services on the upper layer of cloud computing, including network equipment, servers, and storage devices [10]. Among them, server services can provide server environments, including Linux, Unix, Windows, and even server clusters, with the support of virtualization technology. Storage service can provide storage function. General network processing functions provided by network services, namely VLAN, load balancing, route switching, firewall, etc.

The platform module is an abstract encapsulation of the resource module services; after processing the large granularity of the resource module, services are more advanced and easy for users to create their applications [11]. Middleware services

provide users with scalable transaction middleware or messaging middleware, and database services provide users with scalable database processing capabilities.

The application module covers all the software methods for system operation, which is built on top of the base layer and data layer to provide different application services to different objects.

The user access layer provides various convenient services for users of cloud computing services and provides corresponding cloud service access interfaces for each level as required. Users can select the necessary cloud computing services from the service list in the service directory. It provides the access interface of the resource layer for the remote desktop and the access interface of the application layer for the Web [12]. The subscription management function manages customer information or terminates customer subscriptions.

B. Management Design

The logic module in the management layer is the critical module in this layer, which realizes the integration, storage, sharing, and interaction of college students' information, and the gateway module includes the integration of virtual gateway, firewall data encryption decryption, etc. The structure of the management layer is shown in Fig. 2.

Fig. 2. Management structure.

Logic module according to the service demand, the college students need to share information or interactive information through the security gateway, and complete information communication; At the same time, the module can complete the verification of the basic information related to college students' data information, and support the access of all mobile terminals [13], after the completion of the identity verification can be carried out within the corresponding permissions of the operation, to achieve the interaction of the basic data information of the students and the sharing of the information.

Users need to access the relevant applications in the system through the virtual gateway. Therefore, the management and

application of primary student information data is accomplished under the control of the virtual gateway of the information management system, which is controlled by the virtual access domain Y access to that domain intranet N , and the implementation of the relevant information operations is realized. In this process, the information must pass through three trust domains to discover the final purpose. Using a virtual security gateway to realize information security control, the gateway will be deployed in the key nodes. This paper mainly uses nine kinds of virtual gateways to realize the security control of college students' information management in higher vocational colleges and universities.

Virtual Gateway 1 and 2: The gateway has secure terminal connection access control. It is mainly used to ensure secure access to users and the security of logical boundaries, and both belong to Y .

Virtual Gateway 3: The gateway mainly guarantees the access security of the Internet H , and is connected by N , and has the port forwarding function.

Virtual Gateway 4: This gateway is used to realize the security of information interaction among college students, and it belongs to the interaction between N and Internet computing domain J . The gateway has the function of intrusion detection.

Virtual Gateway 5: The gateway is also used to realize the safe interaction of information, and the information belongs between N and the public storage domain, and the gateway has the function of adding and decrypting information.

Virtual Gateway 6: This gateway is used to realize the operational security of the security services intranet, which can transport remote access to realize remote security connections.

Virtual Gateway 7: This gateway is used to secure the connection between the security administrator of the student information management system and the system security service.

Virtual Gateway 8: This gateway is used for security control of cloud storage access functions.

Virtual Gateway 9: This gateway can be understood as a virtual host of the firewall; all the information sent to the virtual host needs to be protected through the gateway before the implementation of the continued operation; the gateway has an application layer of intrusion, attack, and other defense and detection.

To summarize, the virtual gateway is deployed in each vital position of the system, and all the access, sharing, exchange, and other operations of the information are controlled by the virtual gateway [14], which ensures the security of the college students' information in all the links to guarantee the security of the operation of the college students' information management system.

C. Application Layer Design

1) *Load balancing optimized scheduling of server clusters in the resource module: When the server cluster handles requests for college students' information management tasks in higher vocational colleges and universities, problems such as unbalanced distribution of requests and long task completion time will occur [15], so load balancing needs to be optimized for scheduling.*

The task completion time for a single server in the cluster is the time elapsed from the start of a college student information management task request to the completion of task processing, the waiting time of task T_i in the queue is $t_{wait}^{(T_i)}$, the actual processing time is $t_{deal}^{(T_i)}$. The waiting time for information management task requests for college students in higher vocational colleges and universities is generally determined by the current network conditions and the size of the real-time load

in the cluster, which is randomized. In comparison, the actual processing time of information management tasks for college students in higher vocational colleges and universities is determined by the amount of tasks that $m^{(T_i)}$, the combined processing power of the matching servers handling the request $Q^{(T_i)}(U_j)$ and aggregate load information for that server at the time of the request $A^{(T_i)}(U_j)$. Usually, the processing time of a task request with no other load on the server is determined by $t_{emp}^{(T_i)}$, the formula given by Formula (1).

$$t_{emp}^{(T_i)} = \frac{m^{(T_i)}}{Q^{(T_i)}(U_j)} \quad (1)$$

Among them, $m^{(T_i)}$ indicates the volume of tasks requested by the mandate and measures the task's degree of difficulty. $Q^{(T_i)}(U_j)$ represents the combined processing power of the matching server, and the ratio of the two represents the running time of the task request time T_i on the matching server U_j without load. Generally speaking, the purpose of using clustering to deal with college students' information management task requests is to solve the problem of insufficient processing capacity of a single server, applied in the concurrency scenario [16], mainly to test the concurrent processing ability of the server, so there is rarely a server in no load for a single task processing, usually at the current moment when the server has a load task for the following task processing [17], i.e., matching the situation where the server is loaded. At present, the relationship between the processing time of the information management task request T_i under the matching server U_j and the processing time under no load is shown in Formula (2):

$$t_{deal}^{(T_i)} = t_{emp}^{(T_i)} * \frac{1}{1-A^{(T_i)}(U_j)} \quad (2)$$

Among them, $t_{deal}^{(T_i)}$ represents the task processing time when there is a load, calculated from the unloaded task processing time $t_{emp}^{(T_i)}$ and the real-time load information $A^{(T_i)}(U_j)$ of the matching server when the task request arrives. The comprehensive load information for each server is evaluated through four resources, including CPU usage, memory usage, network bandwidth usage, and disk I/O usage, the combined load information of the A of server U_j can be expressed as Formula (3) through a linear formula.

$$A(U_j) = \alpha_1 * A_{CPU}^{(U_j)} + \alpha_2 * A_{memory}^{(U_j)} + \alpha_3 * A_{band}^{(U_j)} + \alpha_4 * A_{I/O}^{(U_j)} \quad (3)$$

Among them, $A_{CPU}^{(U_j)}$ denotes the CPU utilization rate of the server U_j , others are the same; α_i is weighting coefficients indicating various resource occupancy rates, which may be set according to the actual processing of transactions, but which satisfy $\sum_i^4 \alpha_i = 1$ and $A(U_j) \in (0,1)$.

Combining Formula (1), Formula (2), and Formula (3), when a request for an information management task for college students in higher vocational colleges and universities arises, a

reasonable selection of matching servers to execute the task is the key to solving the problem. The appropriate matching server is selected based on the size of the server's real-time load information $A(U_j)$. Therefore, the minimum allocation ratio threshold is introduced to determine the task matching server, expressed by Formula (4).

$$0 \leq \frac{A(U_j)}{\sum A(U_j)} \leq thr_{A(U_j)} \quad (4)$$

Among them, $\frac{A(U_j)}{\sum A(U_j)}$ represents the ratio of the time of load information of the server U_j at the arrival of the task request to the total load information in the cluster at that time. $thr_{A(U_j)}$ denotes the minimum assignable threshold, when $\frac{A(U_j)}{\sum A(U_j)}$ is less or equal to this threshold, it means that this server node is lightly loaded and can accept new task requests. The smaller the $\frac{A(U_j)}{\sum A(U_j)}$ is, the newer requests the server can accept. When the request arrives, if there exists more than one server node to satisfy the above formula, a merit selection will be made, i.e., the server node with the smallest ratio will be selected for the processing of the current task request of information management for college students in higher vocational colleges and universities. When a group of task requests are assigned, the size A_{on} of the number of task connections of each server is recorded while recording the relationship $B_{T_i}^m$ of each task request to the matching server. $B_{T_i}^m$ is a row vector representing a row in the matching set, e.g., 12 tasks are being processed on 7 servers, where the 3rd task is being processed on the 5th server, then, the $B_{T_3}^m = [0000100]_{1 \times 7}$, which are inserted into the matching set $B = [B_{T_1}^m, B_{T_2}^m, B_{T_3}^m, \dots, B_{T_{11}}^m, B_{T_{12}}^m]_{12 \times 7}^T$ in task order after the request is completed.

Synthesizing Formula (1) ~ Formula (4), the completion time of all college students' information management task requests on the server is represented by a multivariate combination, and the expression is Formula (5).

$$t(U_j) = [t_{deal}^{(T_i)}, t_{wait}^{(T_i)}, B_{T_i}^m] \quad (5)$$

Formula (5) can be transformed into Formula (6).

$$t(U_j) = [t_{deal}, t_{wait}, A(U_j|T_i), Q(U_j|T_i), A_{on}, B] \quad (6)$$

Among them, $t(U_j)$ indicates the time for a single server in the cluster to complete all tasks. t_{deal} and t_{wait} are the sum of the processing time and the sum of the waiting time for all tasks on that server, respectively. $A(U_j|T_i)$, $Q(U_j|T_i)$ indicate that the task request T_i matches the real-time load information and comprehensive processing capability of the server U_j when the task request arrives; A_{on} denotes the set of connections. B denotes the set of task matches. Under the premise of considering the server's real-time load information of the server and the comprehensive processing capacity, the task completion time of a single server is the sum of the processing

time and waiting time of each server task. The task completion time t_a in the whole cluster can be written as Formula (7).

$$t_a = \sum_{j=1}^n t(U_j) \quad (7)$$

At the same time, the load balancing validity degree δ is introduced to measure the difference in the processing time of information management tasks of higher vocational college students among the servers in the cluster, which is expressed by Formula (8) as follows:

$$\delta = \left[\sum_{j=1}^n (t(U_j) - t_{avg})^2 / n \right]^{\frac{1}{2}} \quad (8)$$

Among them, $t_{avg} = \frac{t_a}{n}$ denotes the average task completion time for each server in the cluster; the δ denotes the variance of the processing time of each server in the cluster, the smaller the value δ , the more balanced the processing time of the servers in the cluster, and the better the overall performance of the servers.

Minimizing the task completion time and enhancing the load balancing effectiveness of the cluster are two objectives of the load balancing problem in clusters [18]. Theoretically speaking, these two objectives are competing with each other, to keep the cluster in a relatively balanced state, to ensure that the processing time of each server does not vary much [19], it is inevitable to sacrifice the task completion time of individual servers at the expense of the task completion time of the entire cluster, so the multi-objective model proposed in this paper is established as expressed in Formula (9).

$$\begin{cases} \min t_a \\ \min \delta \\ s. t. \quad \sum_{j=1}^n b_{i*j} = 1 \\ thr_{A(U_j)} \leq a \in (0,1) \end{cases} \quad (9)$$

The 1st constraint in Formula (9) specifies that each task is executed on one server and only on one server; the 2nd constraint specifies that the maximum allocation ratio must satisfy a constant between 0 and 1.

The above can make the server cluster to keep the load balanced when dealing with the request for information management of college students in higher vocational colleges and universities.

2) Storage services in the resource module

a) M-Cloud storage mode

The storage service in the resource module of the information management system application layer for college students in higher vocational colleges uses M-Cloud storage mode to realize the storage and backup of cloud information for college students in the application layer. M-Cloud storage mode is an improved key-value storage management mechanism, which uses three methods of segmentation, buffering, and addition to achieve effective storage and management of college students' data in higher vocational colleges [20]. The specific composition of the M-Cloud storage mode is shown in Fig. 3.

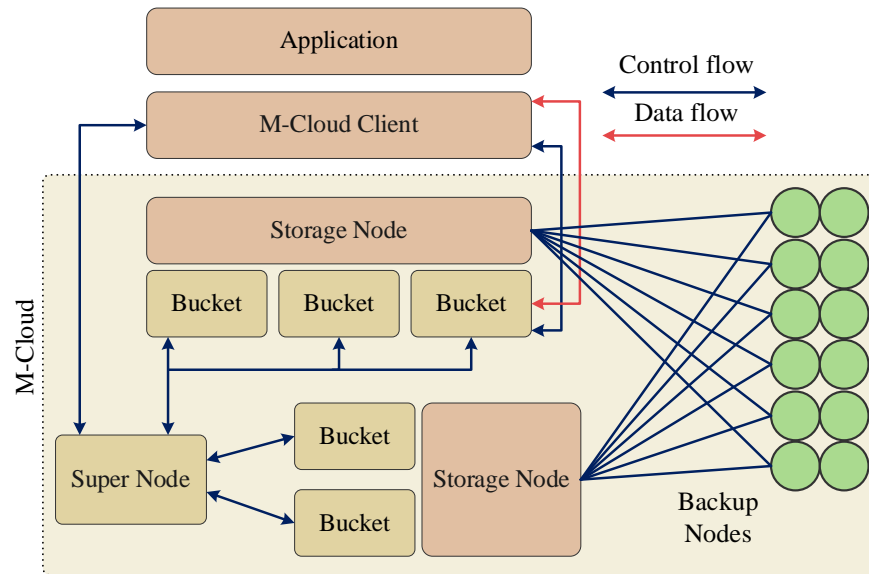

Fig. 3. M-Cloud Storage mode structure.

As shown in Fig. 3, the M-Cloud storage mode consists of multiple storage servers (StorageNodes), several buckets, a SuperNode, and multiple backup servers (BackupNodes). The super server manages the cloud information of vocational college students in the whole storage server and manages the cloud information activity range under M-Cloud storage mode. To obtain real-time status information and prevent cloud data loss, regular communication between the super server and each storage server is required [21].

The storage server manages all cloud information collections under M-Cloud storage mode and is used for operations such as reading, deleting, and backing up information. The super server allocates information to each storage server for management, reducing the burden of the super server, and improving the storage speed of cloud information.

Use the bucket concept to avoid the shortcomings of performance differences among storage servers, where the storage capacity of each bucket is consistent. M-Cloud storage mode uses buckets to achieve mass information exchange

among vocational college students [22]. Configure the bucket and storage server in multiple to single configurations to achieve weight configuration and load balancing.

Multiple backup servers are used to back up college students' information stored in different storage servers on disks, which can be backed up and restored when the storage servers fail.

b) Distributed bigtable information base

Transfer the information of vocational college students stored in M-Cloud storage mode in the resource module to the distributed Bigtable information database, further layout and save the information stored for vocational college students, and improve the information throughput of massive vocational college students. The distributed Bigtable information base is composed of three important components: the master server, the client-connected library (ClientLib), and the table server (TabletServer), as well as the ORACLE lock and GFS file server. As shown in Fig. 4.

Fig. 4. Distributed bigtable database structure diagram.

Create a unified interface in the database connected to the user end, and transmit the information stored for college students in higher vocational colleges to the main server, responsible for distributing the stored information evenly to each table server. Each table server carries out a distributed information layout for the stored information, locks the managed information with ORACLE, and saves the locked information with the GFS file server [23].

The Bigtable information base is used to distribute and save massive stored information, improve the throughput of massive information, and avoid the overload of cloud computing servers.

3) *Application modules*: The structure of the application module is shown in Fig. 5. The application module consists of two parts: the front-end application and the student

informationization management end, and the front-end application includes the statistical analysis of student information data, study plan, business management of student information, and query of student information; the cloud resource management of student information, student information management, business management and so on form the management end of student informationization, among which, the cloud resource management of students completes the scheduling and supervision of student information and resources through relevant methods; the platform management and business management are used to complete the basic data management, terminal management and business configuration, docking management and statistical analysis.

Fig. 5. Application module structure.

D. Personalized Recommendation Model of College Students' Employment Information Based on the K-Means Algorithm in the user Access Layer

Based on the data collected from college students in higher vocational colleges, this study examines the current and potential individualized requirements of college students regarding employment. It also investigates the methods and patterns through which college students acquire employment-related information, and establishes a personalized database. The utilization of cloud computing technology offers substantial

computational and analytical capabilities, as well as scalability, making it suitable for handling extensive datasets. Consequently, in the deployment environment of cloud computing, the K-means algorithm can be swiftly implemented. This algorithm, rooted in data mining, is the technology for analyzing and processing college students' employment information and enterprise position data. Using the clustering outcomes, a personalized recommendation model for college students' employment information is developed, employing data mining techniques. The structure of this model is depicted in Fig. 6.

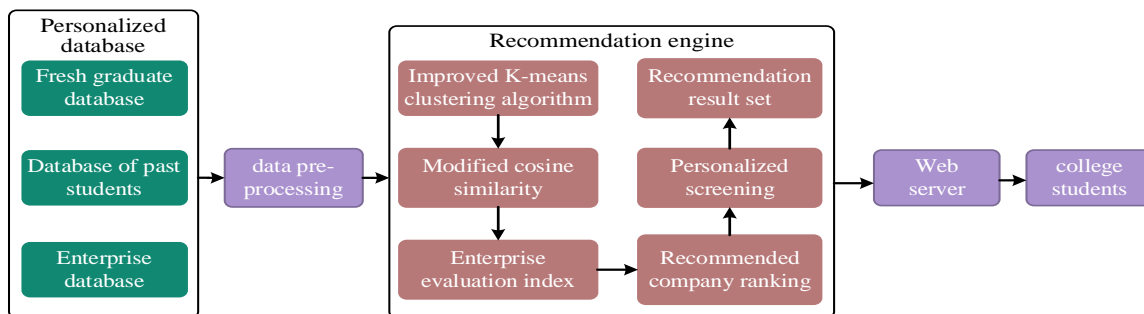

Fig. 6. Personalized recommendation model of college students' employment information.

Through the reality and potential employment needs of college students, establish a personalized database and determine the data range of college students' information and enterprise position information to meet the target of college students' employment information recommendation. In building a personalized database, it is necessary to design a customized data structure to ensure the integrity of each piece of information as far as possible. To achieve targeted recommendation services for college students' employment information, the K-means clustering algorithm in data mining can be used to mine hidden valuable information in the personalized database, accurately discover the knowledge in the personalized data [24], complete information classification according to the natural attributes and use characteristics of information and other variables, and improve the personalized recommendation effect of college students' employment information.

Use data cleaning, integration and attribute specification to preprocess the data of the current student database, previous student database and enterprise database [25]; By improving K-means clustering algorithm, the employment information of college students in the database of preprocessed new students and previous students is clustered, and the enterprise position information in the enterprise database is clustered; according to the clustering results, the modified cosine similarity method is used to calculate the similarity between new students and previous students, as well as the similarity between new students and enterprises; the empirical formula is used to solve the enterprise evaluation index, which is used to express the overall strength of the enterprise; According to the similarity between new graduates and enterprises, as well as the enterprise evaluation index, the enterprise ranking weight is obtained; Consider the factors such as the workplace and salary that college students care about, conduct personalized screening of enterprises, and obtain enterprise rankings; Personalized

recommendation results for college students' employment information based on enterprises ranking top.

The clustering of college students' employment information and enterprise position information uses the K-means clustering algorithm to cluster and process the current student database, previous student database, and enterprise database to obtain the clustering results of current and prior students' employment information and enterprise position information. The principle of the K-means clustering algorithm is: first obtain k student employment information (enterprise position information) object x , treating it as the clustering center of the cluster C ; and then solve the distance d between the object x and C of the initial k of the student employment information (enterprise position information); Move x to the class in which the C of the minimum d is located; and then solving for the mean of all the samples of student employment information (enterprise position information) in the cluster, obtaining the new C , marked as C_{new} . Finally, it is iterated repeatedly to complete the convergence until the output of the clustering results of the student employment information (enterprise position information). The clustering criterion function of the algorithm is shown in Eq. (10).

$$L = \sum_{i=1}^k \sum_{p \in C_i} \|x - M_i\|^2 \quad (10)$$

Among them, the cluster center of the i th student employment information (enterprise position information) object is C_i ; The mean value of C_i is M_i . The role of L is to acquire the k interclass dissimilarity and intra-class proximity of individual clusters are elevated.

The process of K-means clustering algorithm clustering college students' employment information (enterprise position information) is shown in Fig. 7.

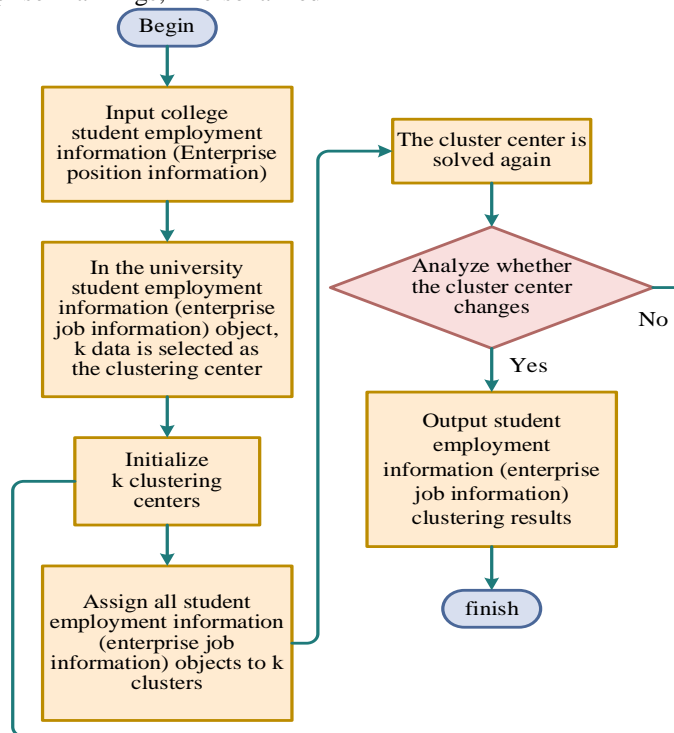

Fig. 7. Clustering process of college student employment information (enterprise job information).

E. Data Flow Diagram of Information Management System for College Students in Higher Education Institutions

A data flow diagram (DFD) serves as a visual representation of the system's logical function, the direction of logical flow, and the logical transformation of data within the student information management system. It is a primary tool for expressing structural system analysis methods and employs graphical

techniques to depict software models [26]. The accompanying data flow diagram does not include specific physical elements; instead, it solely describes the system's flow and processing of information. Based on the current business process of managing college students' information, the data flow diagram is constructed by initially identifying college students as the source and endpoints and refining them to obtain the data flow diagram after outlining the logical system, as illustrated in Fig. 8.

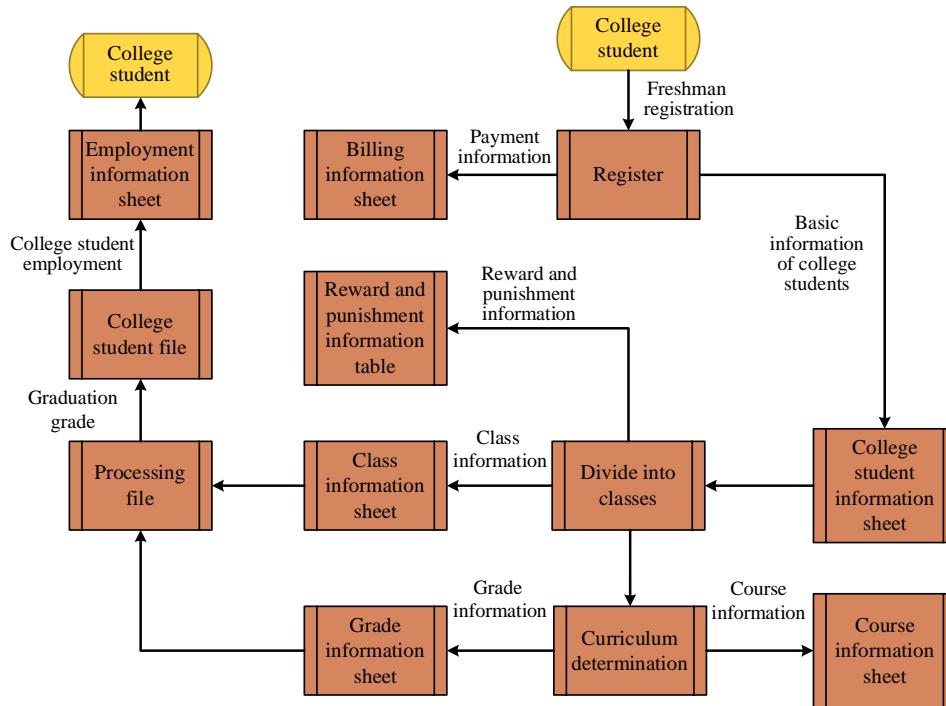

Fig. 8. Data flow diagram of college student information management system.

The beginning and the end point of the data flow in Fig. 8 are both college students; after registration for the new students, students' payment information is stored in the payment information form. The student's basic information is stored in the student information sheet. Each department is divided into classes according to the majors the students admitted, and the class classification results are stored in the class information sheet. Students enter a normal college study and life, and after being rewarded and punished, information is stored in the reward and punishment information table. The course information sheet records relevant details Upon establishing the course. Subsequently, the final examination is administered, and the outcomes are documented in the score information sheet. The student's particulars are then filed, signifying their graduation information. Furthermore, when a student secures employment, the pertinent job details within the enterprise are stored in the employment information table. Consequently, developing an information management system for higher vocational college students is accomplished.

III. EXPERIMENTAL ANALYSES

A. Experimental Verification

A vocational and technical college is selected to apply the methodology of this paper to design a management system for

its college students' information. This vocational and technical college has over 14,000 full-time students and 718 teaching staff. The school has 10 secondary colleges and 48 majors (including directions) in 15 categories. The server cluster system consists of a load balancer in the realm, three real servers in the backend, and a database server, whose configuration is shown in Table I.

TABLE I. SERVER CLUSTER SYSTEM CONFIGURATION

Name	CPU	Operating system	Internal storage	Hard disk
Database master server	Intel Core i7-8700K 3.7GHz	Ubuntu 14.06	4GB	480GB
Load balancer	Intel Pentium(R) 4 30.6GHz	Ubuntu 14.06	8GB	512GB
Slave server	Intel Core i7-8700K 2.8GHz	Ubuntu 14.06	4GB	480GB
Slave server	Intel Pentium(R) 4 30.6GHz	Ubuntu 14.06	4GB	480GB
Slave server	Intel Core i7-8700K 4.2GHz	Ubuntu 12.04	8GB	512GB

For freshmen, the information management system is designed, and the system's functional modules are implemented. The operating interface of the student information management system is shown in Fig. 9.

College student information management	
User name:	00012
Password:	123456
Name:	Wang Ming
Age:	20
Gender:	Man ▼
Situation of party groups:	Member
Address:	
Specialty:	Mechanical engineering ▼
Class and grade:	Mechanical shift two ▼
Parent information:	
<input type="button" value="Confirm"/> <input type="button" value="Refill"/>	

Fig. 9. Student information management system operating interface.

As can be seen from the interface in Fig. 9, users will enter an interactive interface with various menus after logging into the student information management system. These menus correspond to different functional modules, providing convenient and intuitive operation methods for administrators and users. Multiple menu items will be displayed on the main interface when the administrator successfully logs in to the system. These menus include: system menu, student information management menu, course information management menu, achievement information management menu, professional information management menu, class information management menu, payment information management menu, reward and punishment information management menu, employment information management menu, administrator management menu and so on. Click each menu, and the system will enter the corresponding sub-interface at the next level, providing specific operation options and functions. For example, click "Student Information Management Menu," and the system will enter the

sub-interfaces to add student information, view student information, and modify student information. Each sub-interface has straightforward tips and operation steps so administrators can easily carry out various operations. The current operating interface is the new student registration, adding the student information interface. The interface layout is straightforward, and the operation steps are clear. The user only needs to input the necessary information according to the prompt, and the system will automatically add the information to the database without complicated operation. The student information management system has a clear and easy-to-understand interface design, convenient and quick operation mode, and comprehensive and rich management functions. Both administrators and ordinary users can easily get started and quickly master the use of the system.

Take Wang Ming, Mechanical Class II, for example, to query its course information, as shown in Fig. 10.

College student information management system		December 15, 2023	
Curriculum information management			
Name:	Wang Ming	Course title:

<input type="button" value="Inquire"/>			
Course title	Schooltime	Place of class	Class
Higher mathematics	Tuesday 8:30~10:00	Class classroom	Mechanical shift two
Mechanical drawing	Tuesday 10:15~11:45	Multimedia classroom	Mechanical shift two
Electronic technique	Tuesday 13:30~15:00	Machine Room 2	Mechanical shift two

Fig. 10. Wang ming's query of course information.

As seen in Fig. 10, when you click the course information management menu in the main interface of the operating system, you will enter the course information interface. In this interface, several menu items are on the left, including my score menu, course information query menu, employment menu, payment menu, reward and punishment menu, and password modification menu. These menu items have different functions but are all related to course information management. Click each menu, and the system will enter the corresponding next sub-interface. For example, clicking on my grades menu will bring you into the interface for viewing personal grades, Clicking the course information query menu to query the specific course information, Clicking on my employment menu to view personal employment information, etc. These sub-interfaces provide straightforward operation tips and functional options so users can efficiently perform various operations. On the right side of the course information interface, the specific course

name and the corresponding information, such as class time, class place, and class, are displayed. This information is clear at a glance so that users can quickly understand the relevant information of the course. At the same time, the interface design is concise and clear, and the operation is simple and easy, which makes course information management easy and convenient.

To verify the load balance of the server cluster in the present work, the experiment uses the requesting user to log in to the system for operation. This request not only has a static page but also has a database operation. It belongs to a dynamic request. The system feedback data analyzes the average response time of the request and the number of successful requests. The experimental results of comparing the system in this paper, using the DVFS computing system and cloud system task scheduling system, are shown in Fig. 11 and Fig. 12.

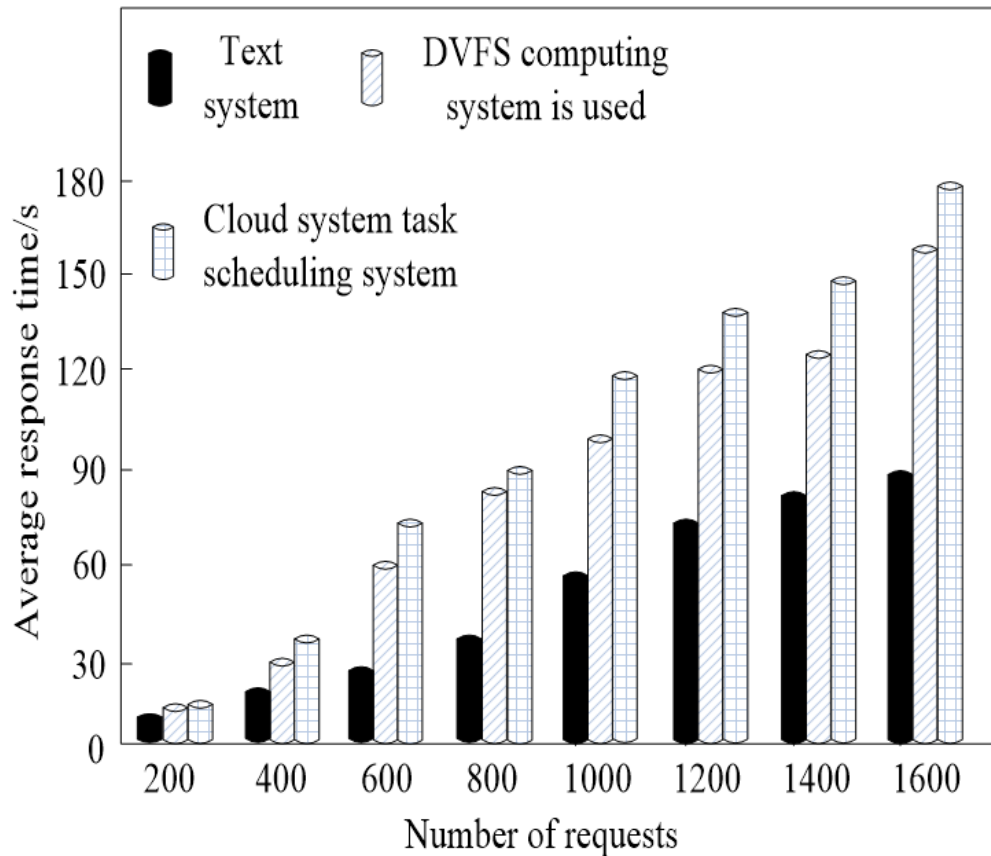

Fig. 11. Average response time for the three system requests.

The experimental results in Fig. 10 show the average response time performance of the three systems when processing different requests. When the number of requests is 200, the average response time of the three systems is within the acceptable range, and the difference between them is not apparent. However, with the increase in the number of requests, the average response time of the system in this paper gradually increases but remains in a very short range. When the number of requests reaches 1600, the average response time of the system in this paper only takes 90 seconds, which has significant advantages over the other two systems. With the DVFS computing system, the average response time has reached 120

seconds when the number of requests is 1200, and the average response time of the cloud system task scheduling system is 150 seconds when the number of requests is 1400. To sum up, compared with the other two systems, the average response time of the system in this paper is shorter when processing a large number of requests, which shows that the server cluster in this system is more balanced and stable and has higher efficiency and better performance when processing large-scale parallel computing tasks. This will provide higher vocational colleges with faster, more efficient, and more reliable student information management services.

Fig. 12. Number of successful requests for the three systems.

Analyzing Fig. 12 shows that when the system in this paper processes many requests, the number of successful requests is not affected, and all requests are successful. This indicates that the system in this paper has excellent stability and reliability. In contrast, when the DVFS computing system reaches 1000 requests, the number of successful requests is only 800, which shows obvious instability. When the number of requests of the cloud system task scheduling system reaches 1200, the number of successful requests is only 800, and its performance is worse. This data shows that the system can maintain the stability and balance of server cluster load and avoid large fluctuations when dealing with large-scale parallel computing tasks. Hence, this system can fulfill the requirements of the student information management system and guarantee its consistent functionality. In conclusion, the system discussed in this document offers notable benefits in managing many simultaneous requests,

catering to the student information management system's demands, and upholding the server cluster's stability.

To verify the security control of the integrated virtual gateway applied in this system on the information management of college students in higher vocational colleges, the following four situations are used for verification: non-critical access request burst operation, critical access request burst operation, central exchange node traffic, and end-to-end delay of access request. The first two are used to verify the information security control of the integrated virtual gateway to normal network communication. The last two are used to verify the abnormal operation of the integrated virtual gateway to the network, that is, the network communication is invaded or maliciously controlled from the outside, which leads to the abnormal growth of information and network storm. The results are shown in Fig. 13 and Fig. 14.

Fig. 13. Information security control of normal network communication.

It can be seen from Fig. 13 that under the normal operation of the network communication without abnormal intrusion, after the information security control by the system in this paper, the critical access request delay is stable at around 0.029ms, without noticeable delay jitter. Even in the case of two necessary access request bursts, the delay finally increases to 0.046ms and remains stable. The delay jitter is evident in the absence of

information security control measures. This shows that the introduction of the integrated virtual gateway in this system is efficient for the information security control of normal network communication, which proves that the information security control of this system can effectively ensure the normal operation of the network, reduce delay jitter, and improve the stability and reliability of network communication.

Fig. 14. Information security control of abnormal network communication.

As shown in Fig. 14(a), the node traffic of the central switch is stable when the student information management system is running normally. In the period of 0-130 seconds, the information security control measures applied to the system in this paper did not significantly impact the switch traffic distribution, and the traffic was stable in the range of 11.5-12Mbits/s. However, when the system is between 130-250 seconds when it is invaded externally, without taking information security control measures, the traffic of the central switch increases sharply, reaching 22.5-24 Mbits/s. This will lead to network congestion, performance degradation, and even paralysis. Under the condition of taking information security control measures, the traffic of the central switch is significantly reduced. This shows that the information security control of this system effectively alleviates network congestion and avoids the risk of network storms and network paralysis. Similarly, in the end-to-end delay result of the access request shown in Fig. 10 (b), the information security control of this system can maintain the relatively stable access request delay under abnormal conditions. The demonstration above illustrates the system's capability to ensure the dependable execution of the student information management system and maintain the system's smooth functioning even in exceptional circumstances. This serves as evidence that the information security control measures implemented in this system have the potential to significantly enhance the network's stability and reliability, thereby ensuring the uninterrupted operation of the student information management system.

B. Discussion

In conclusion, the cloud computing-based information management system for college students designed in this paper shows excellent performance in processing massively parallel

computing tasks, and the average response time increases slowly, which ensures efficient processing. At the same time, the system keeps the success of requests as high as 100%, stably and reliably meet the needs of students' information management. By optimizing the load balancing of the server cluster, the stability of the system in this paper far exceeds the literature [4] system and the literature [5] system, providing a solid guarantee for the stable operation of the school. In addition, the introduction of integrated virtual gateway realizes the accurate monitoring and efficient management of network communication, which greatly improves the stability and reliability of network communication. In conventional communication conditions, the system significantly reduces the delay jitter of key access requests to ensure the smooth network communication. In abnormal cases, information security control measures can effectively alleviate network congestion, avoid the risk of network storm and paralysis, and ensure the reliable implementation of the student information management system.

IV. CONCLUSION

This paper uses cloud computing technology to present a novel information management system for higher vocational college students. The experimental findings demonstrate that the student information management system proposed in this study possesses a user-friendly interface design, facilitating convenient and efficient operations. Moreover, it offers comprehensive and diverse management functions, ensuring efficiency, flexibility, and security. Consequently, this system effectively caters to the information management needs of higher vocational colleges. By implementing this system, higher vocational colleges' work efficiency and management standards can be enhanced, leading to improved student services. Additionally, the system significantly saves human and material

resources, improving the institution's overall operational efficiency. In conclusion, the successful implementation of this system not only reflects the great potential of cloud computing technology in the field of student information management, but also provides a useful reference for the design and development of other similar systems. In the future, with the continuous progress of technology and the deepening of its application, it is believed that the student information management system based on cloud computing will be more perfect, efficient and intelligent, and bring more convenience and value to the education management of higher vocational colleges.

A Deep Learning-based Method for Determining Semantic Similarity of English Translation Keywords

Wu Zhili, Zhang Qian*

Department of International Education and Exchange, Cangzhou Vocational and Technical College,
Cangzhou, Hebei 061001, China

Abstract—In the English translation task, the semantics of context play an important role in correctly understanding the subtle differences between keywords. The bidirectional LSTM includes a positive LSTM and a reverse LSTM. When processing sequence data, you can consider the information of the preceding and following text at the same time. Therefore, to capture the subtle semantic differences between English translation keywords and accurately evaluate their similarity, a new semantic similarity determination method for English translation keywords is studied with the bidirectional LSTM neural network in deep learning as the main algorithm. This method introduces an English translation keyword extraction algorithm based on word co-occurrence and uses the co-occurrence relationship between words to identify and extract keywords in English translation. The extracted keywords are input into the bidirectional LSTM neural network keyword semantic similarity judgment model based on deep learning, and the weight of the bidirectional LSTM neural network is set by using the sparrow search algorithm to optimize. After the bidirectional LSTM neural network is trained, the information on keyword word vectors is captured, and the similarity between keyword word vectors is evaluated. The experimental results show that the sentence similarity calculated by the proposed method for English translation is very close to the result of professional manual scoring. The Spearman rank correlation coefficient of the semantic similarity determination result is 1, and the determination result is accurate.

Keywords—Deep learning; English translation; keyword; semantic similarity; co-occurrence of words; bidirectional LSTM neural network

I. INTRODUCTION

Under the influence of the expansion of the international economy and trade, English as an international common language has been given more attention; English translation has become an essential part, and all kinds of machine translation systems are developing rapidly [1]. Machine translation is no longer limited to individual grammar and sentence translation but more contextual information of sentence clusters, paragraphs, chapters, and genres within the language [2]. From a semantic point of view, word semantic computation can be defined in the whole text or between individual word meanings; thus, word semantics has a degree of relevance and similarity, that is, reflecting the commonality of two words in the same context and the aggregation of features between two words [3]. To a certain extent, the more similar the semantics of words, the greater the correlation, which can easily lead to misunderstandings in different contexts and bring difficulties to the translation work. At present, word semantic computation is more based on natural language processing to explore the degree

of correlation between words, and many words in English have multiple meanings, which may vary according to the context, style, or context [4]. Therefore, it is a challenge to accurately determine the exact meaning of a word in a particular translation [5]. The meaning of certain words and expressions may be influenced by a particular cultural, historical, or social context [6]. For translators who are not familiar with such background information, interpreting the semantics of these terms accurately may be a difficult task [7].

The SI-LSTM model of study [8] captures the complex semantic relationships between keywords through shared inputs and LSTM networks. If the training data set does not cover enough language habits and semantic contexts in different backgrounds, the model may not be able to accurately capture the complex semantic relationships between keywords, resulting in a decline in the accuracy of semantic similarity determination. In addition, the model performance is limited by the size and quality of the training data, and the semantic relationships in some specific domains or specific contexts may not be captured effectively. The study in [9] introduces the network ontology structure and a variety of metrics to evaluate the semantic similarity between concepts. However, for some concepts in network ontology, this method may lack sufficient correlation information, which makes it impossible to accurately evaluate their semantic similarity. At the same time, when the network ontology structure is large and complex, the computational efficiency may be affected, and it is difficult to apply to large-scale data sets. The study in [10] uses RDF triples to evaluate semantic dependencies between entities. If the number of triples available in an RDF data set is limited, semantic correlation analysis based on these triples may suffer from data sparsity, resulting in inaccurate analysis results. In addition, the method cannot effectively evaluate the semantic relevance of emerging entities or relationships without recording the corresponding triples in the RDF data set. Although the non-categorical relational measurement method in study [11] can capture rich semantic information. When dealing with large data sets, the computation of non-categorical relational measures can become complex and time-consuming, requiring efficient algorithms and computational resources. At the same time, the text content, context information and other data that the method relies on may be affected by noise, ambiguity and other factors, resulting in the inaccuracy of semantic relation inference. In addition, the performance of the method is affected by the size and quality of the training data, and the semantic relationships in some specific domains or specific contexts may not be captured effectively. Based on the above analysis, it can be seen that in practical applications, appropriate methods should be selected according

to specific scenarios and data characteristics, and a variety of methods should be combined to improve the accuracy and efficiency of analysis.

In order to accurately capture the subtle semantic differences of keywords in context in English translation tasks, this study proposes a deep learn-based semantic similarity determination method for English translation keywords. This method first uses a word co-occurrence based algorithm to identify and extract keywords from English translated texts, and then input these keywords into a bidirectional LSTM neural network model. By considering the contextual information of keywords at the same time, the bidirectional LSTM model can capture the semantic relationship between keywords more accurately. Further, we use the Sparrow search algorithm to optimize the weight setting of the bidirectional LSTM neural network to improve the performance of the model. Finally, by evaluating the similarity between keyword word vectors, this method can accurately determine the semantic similarity of keywords in English translation, provide strong support for improving the quality of English translation, and help promote the development of natural language processing.

II. METHODS FOR DETERMINING THE SEMANTIC SIMILARITY OF KEYWORDS IN ENGLISH TRANSLATION

A. Keyword Extraction Algorithm for English Translation based on Word Co-Occurrence

1) *Candidate word selection for English translation:* Candidate word selection is the basic part of the English translation keyword extraction algorithm [12]. Due to the existence of a large number of words in English translation papers, if the weights of all English translation words are calculated, the efficiency of the algorithm will be greatly affected [13]. Therefore, the part about candidate word selection for English translation is to avoid the effect of calculating too many word weights. Candidate words are the words that satisfy the basic requirements for becoming keywords in English translation. This step is to select the words that meet the basic requirements of English translation keywords [14]. These basic requirements and how to select candidate words are introduced below.

Firstly, the English translation document is scanned and divided into several clauses according to specific truncation symbols (period, question mark, comma, number, etc.). Then, according to the specified length, scan the English translation clauses to get a fixed-length sequence of consecutive words. Since the number of keywords containing too many words is very small [15], the length of the candidate words also needs to be limited, and the length is set to. Despite this, a very large number of fixed-length sequences of consecutive words will still be produced, so the sequences of consecutive words containing stop words in the beginning or end position are deleted. English translation stops words for papers, adverbs, conjunctions, and other words without practical significance; these words cannot express the meaning of the statement but only play the role of the successive and transitive, so delete these phrases [16].

2) *Calculation of weights of candidate words for English translation:* Although the translation candidates are selected

according to the above steps, since some words in English may have many different meanings, the applicability of the candidate words is determined by utilizing the English translation candidate weighting representation according to the contextual information when translating. To ensure that the context has the same meaning.

The merit of feature selection directly affects the keyword extraction effect of the algorithm [17]. First of all, the first appearance position of the candidate words is taken into account when calculating the weights. Words appearing at the front of the English translation document are more important than those appearing at the back of the document [18], and the algorithm should give more weight to them. This algorithm calculates the value of the first occurrence position of candidate words for English translation as follows:

$$g(Q, C) = \frac{o(Q, C)}{r(C)} \quad (1)$$

Among them, $g(Q, C)$ is the first occurrence of English translation candidate word Q in English translation document C ; $o(Q, C)$ is the first position of candidate word Q in English translation document C ; $r(C)$ is the number of all words in the English translation document C .

Secondly, the TF value feature is also added when calculating the weight of English translation candidates. The TF value (term frequency) indicates the frequency of an English translation word in the text. The frequency of candidate words in documents is the most important statistical feature of candidate words [19]. Therefore, the probability of words or phrases appearing repeatedly in documents becoming keywords is very high. The calculation method for TF is:

$$TF(Q, C) = \frac{w(Q, C)}{r(C)} \quad (2)$$

Among them, $TF(Q, C)$ is the TF value of candidate word Q in English translation document C ; $w(Q, C)$ is the occurrence number of candidate word Q in English translation document C .

Finally, this paper argues that candidate words that contain more words may be of higher importance [20]. Because, the longer the length of a phrase, the more precise the meaning it expresses in general, therefore, this paper assigns different weights ϖ_z to candidate words of different lengths when extracting keywords for English translation:

$$\varpi_z = \frac{g(Q, C)}{TF(Q, C)} = \begin{cases} 0.1 & \eta = 1 \\ 2.0 & \eta = 2 \\ 2.4 & \eta = 3 \end{cases} \quad (3)$$

In the formula, the $\varpi_z(Q, C)$ indicates the length weight of a candidate word Q in the English translation document C . η indicates the number of words contained in the English translation candidate.

3) *Final keyword selection for English translation:* Sometimes a candidate word feature for English translation does not adequately represent the importance of a candidate word in a given context, and multiple aspects need to be considered comprehensively. Therefore, three features are selected to calculate the candidate word weights [21], evaluate

the word co-occurrence rate of the candidate words in a given context, and select the candidate words that can better connect the sentences.

According to the formula for calculating the weights of the above three features of the candidate words for English translation, the final weights of the candidate words are calculated by combining the above three features:

$$\varpi(Q, C) = \frac{\varpi_z(Q, C)}{Q} \quad (4)$$

Among them, $\varpi(Q, C)$ is the final weight of the candidate words Q in the English translation document C . After calculating the final weight of each candidate, the final weights of the candidates are sorted and the top H candidate words are selected as the candidate keyword set.

In the main steps described above, only the external features of the candidate words for English translation are utilized, including statistical features and lexical features [22]. To improve the effect of keyword extraction, semantic features of candidate words and word co-occurrence features are also utilized to optimize the final keyword extraction effect [23]. Word co-occurrence is the co-occurrence of two words in a semantic environment. This semantic environment can be a sentence or a paragraph. This algorithm calculates word co-occurrence by considering the co-occurrence in a sentence of English translation [24].

Due to the complexity of computing word co-occurrence, if the word co-occurrence rate of all candidate words is directly calculated, the algorithm will be very time-consuming and the efficiency will be greatly affected [25]. Therefore, it is necessary to reduce the number of calculations and the set of English translation candidates. KEPC ingeniously solved this problem. The algorithm calculates the word co-occurrence rate by selecting the keywords in the English translation candidate keyword set. The formula for calculating the word co-occurrence rate is:

$$D(q_j, C) = \frac{\sum_{i=1}^m |\hat{D}(q_j, q_i)|}{R(C)} (i \neq j) \quad (5)$$

Among them, $D(q_j, C)$ represents the word co-occurrence rate of the j th candidate keyword q_j in the English translation document C ; $\hat{D}(q_j, q_i)$ indicates whether the j th keyword q_j and the i th keyword q_i are co-present. $R(C)$ indicates the number of semantic environments in an English translation document C . Finally, according to the final keyword weighting formula, the final English translation keyword weights are calculated as follows:

$$\varpi_e(Q, C) = \varpi(Q, C) \times D(q_j, C) \quad (6)$$

Among them, $\varpi_e(Q, C)$ indicates the final weight of the candidate keywords in an English translation document C . According to the above formula, the weights of the candidate keywords can be calculated [26]. According to the weight ordering, the top H words is the final keywords Q_H .

B. A Deep Learning-based Method for Judging the Semantic Similarity of Keywords

To further judge the semantic similarity of the above-determined keywords, the bidirectional LSTM neural network in deep learning can capture keyword context information, provide more comprehensive context advantages, and more accurately judge the semantic similarity.

4) *Keyword semantic similarity judgment model based on bidirectional LSTM neural network*: Bidirectional LSTM neural network belongs to deep learning technology. A bidirectional LSTM neural network is developed based on LSTM (long and short-term memory). The bidirectional semantic features of English translation keywords can be fully extracted. The keyword semantic similarity judgment model structure based on a bidirectional LSTM neural network is divided into an encoder and a decoder. The encoder is composed of a bidirectional LSTM neural network, and the decoder is composed of an LSTM neural network with dynamic semantic coding rules.

The encoder is composed of a traditional bidirectional LSTM neural network, which is used to generate bidirectional semantic encoding of English translation keywords. The input of the neural network at the j th time step is the j th word vector p_j in the keyword Q_H , saving the semantic information hiding state K_j of English translation keywords output by the time step bidirectional LSTM neural network.

$$K_t = k_t \times \varpi_e(Q, C) + l_{T-t} \times \varpi_e(Q, C) \quad (7)$$

In the formula, the k_t and l_{T-t} denoted, respectively, in j time step forward LSTM and backward LSTM output English translation keyword semantic information hiding state value. When $t = T$, the $k_T k_T$ denotes the positive semantic encoding of keyword semantics; the l_T denotes the reverse semantic encoding of the keyword semantics, then the bidirectional semantic encoding of the standard keyword is:

$$F_{Q_H} = K_t(k_t + l_t) \quad (8)$$

The objective of this paper is to retrieve similar information within the encoder by taking into account the variation in the decoder's hidden output state from the previous time step. This enables us to dynamically adjust the semantic coding. The adjusted semantic encoding, the F as part of the basic unit of LSTM, semantic coding F does not participate in the storage of information in the input gate, but also forgets some similar semantic information in the output, so the semantic encoding F is located between the input gate and the output gate in the LSTM basic unit. The improved structural representation of the modified LSTM basic unit at the t time step is shown in Fig. 1.

Fig. 1. Improved LSTM basic unit structure representation.

Oblivion gates, input gates, and output gates are set to, respectively, they y'_t , z'_t , x'_t ; b'^t is a candidate state for memory cells; the b'_t is the cellular state. Q_t is the sample of the input keywords at time t of the neural network; k'_{t-1} is the hidden output state of LSTM at $t - 1$ time; F_{t-1} is the semantic coding of keywords at $t - 1$ time; the ω_* indicates the weight value of each door input information. The corresponding formula of the improved LSTM basic unit is as follows:

$$y'_t = \psi(\omega_y + \omega_y k'_{t-1}) \quad (9)$$

$$z'_t = \psi(\omega_z + \omega_z k'_{t-1}) \quad (10)$$

$$b'^t \tanh(\omega_b + \omega_b k'_{t-1}) \quad (11)$$

$$b'_t = y'_t \otimes b'_{t-1} + z'_t \otimes b'^{t-1} \quad (12)$$

$$x'_t = \psi(\omega_x + \omega_x k'_{t-1}) \quad (13)$$

Among them, ψ represents the sigmoid function. It is dynamically adjusted according to the dynamic semantic coding rules, which are divided into $t = 1$ and $1 \leq t \leq n$ two cases, here n is the number of keywords.

When $t = 1$, taking the keyword Q positive and negative semantic encoding F_Q obtained in the encoder as the initial value of the bidirectional LSTM state in the decoder, the output state k'_1 and l'_1 of the hidden layer of bidirectional LSTM in the first-time step is obtained:

$$k'_1 = E_{fw}(Q_1, F_Q) \quad (14)$$

$$l'_1 = E_{bw}(Q_n, F_Q) \quad (15)$$

Among them, E_{fw} , E_{bw} represent forward and backward LSTM networks in decoder respectively; Q_1 , Q_n is the keyword entered.

(2) When $1 \leq t \leq n$, according to $t - 1$ time step hides the output state, and adjusts the value of semantic encoding F_1 . Since the forward and backward neural networks in the decoder use

the same rules to adjust the semantic encoding, only the forward LSTM adjustment rules are introduced. The adjustment rules are as follows:

a) The similarity of the decoder in the $t - 1$ time step hidden output state k'_{t-1} to the hidden output state H_j in the encoder is calculated using the cosine distance formula. The formula of the cosine distance $\Upsilon(H_j, k'_{t-1})$ is as follows:

$$\Upsilon(H_j, k'_{t-1}) = \frac{\sum_{j=1}^n H_j k'_{t-1}}{\sqrt{\sum_{j=1}^n (H_j k'_{t-1})^2}} j \in n \quad (16)$$

Here only the similar information is "recalled" and the dissimilar information is weakened, so the similarity between two vectors is calculated using the following formula:

$$\Upsilon(H_j, k'_{t-1}) = \begin{cases} 10^{-5} & \Upsilon(H_j, k'_{t-1}) \leq 0 \\ \frac{\sum_{j=1}^n H_j k'_{t-1}}{\sqrt{\sum_{j=1}^n (H_j k'_{t-1})^2}} & \Upsilon(H_j, k'_{t-1}) > 0 \end{cases} \quad (17)$$

At $t - 1$ time step, the output keyword semantic state k'_{t-1} , the vector of cosine similarity to the hidden output state K at all times in the encoder is expressed as:

$$Y_{k'_{t-1}} = [Y_{k'_{t-1}}^1, \dots, Y_{k'_{t-1}}^1, \dots, Y_{k'_{t-1}}^1] \quad (18)$$

b) The $Y_{k'_{t-1}}$ result is normalized and the j th term is expressed as $Y_{k'_{t-1}}^j$.

c) The hidden output state in the encoder and the normalized $Y_{k'_{t-1}}^j$ are multiplied and summed to obtain the semantic encoding of the forward LSTM at the t time step, as follows:

$$F_{k'_t} = \sum_{j=1}^n F_{QH} \cdot Y_{k'_{t-1}}^j \quad (19)$$

When $t = n$, by combining the hidden output states of the neural network in both directions of the decoder bidirectional LSTM, the similarity matrix between keywords and standard translation keywords is obtained as follows:

$$\hat{F} = \text{concat}(k'_n, l'_n) \quad (20)$$

Finally, the similarity matrix is fully connected to the output layer with only two neural units, and then through the Softmax function, the probability values of similarity and non-similarity of the two sentences are obtained, to obtain the semantic similarity values of English translation keywords.

5) Optimization training of keyword semantic similarity judgment model based on Sparrow Search Algorithm (SSA): During the training process, Dropout is used to control that some hidden layer nodes in the network will not work at random during model training, preventing some keyword features from having effects only under other specific features. The weight matrix is one of the most important parameters in the bidirectional LSTM neural network. They are used to convert the input samples into the internal state of the bidirectional LSTM neural network. Each LSTM unit has multiple weight matrices for controlling input gates, forgetting gates, output

gates, and candidate cell states. These weight matrices will be optimized in the training process to better fit the data object. Therefore, this paper introduces the sparrow search algorithm to train and set the weight matrix. Compared with other swarm intelligence optimization algorithms, the sparrow search algorithm has the characteristics of strong optimization ability, fast convergence, high stability, and strong robustness. In this algorithm, the behavior of sparrows searching for food can be seen as the process of finding the optimal solution of the connection weight of each layer of the keyword semantic similarity judgment model within a specific range of space. The goal of the sparrow search is to find the global optimal value of the connection weight of each layer of the keyword semantic similarity judgment model in this process.

When the keyword semantic similarity judgment model is trained for optimization, the discovery of candidate solutions for each layer of connection weights, during each iteration is given by the following iteration formula:

$$\phi_{i,j}^{\lambda+1} = \phi_{i,j}^{\lambda} \cdot \exp\left(\frac{-\Delta(\hat{F}_j, \hat{F})}{v \cdot \lambda_{max}} \circ\right) \quad (21)$$

Among them, λ is the number of iterations at the current moment; the λ_{max} is the maximum number of iterations; the $\phi_{i,j}^{\lambda}$ indicates the position occupied for the i th sparrow in the j th dimension; the $\Delta(\hat{F}_j, \hat{F})$ indicates the loss of semantic similarity of keywords in the j th dimension after the i th weight candidate solution is used; the v is a random number.

When the keyword semantic similarity judgment model is trained for optimization, the position of the new joiner added to the candidate solution for each layer of connection weight is updated as follows:

$$\phi_{i,j}^{\lambda+1} = \begin{cases} v \cdot \exp\left(\frac{\phi_w^{\lambda} - \phi_{i,j}^{\lambda}}{i^2}\right), & i > \frac{1}{2} \\ \phi_o^{\lambda+1} + |\phi_{i,j}^{\lambda+1} - \phi_o^{\lambda+1}|, & \text{else} \end{cases} \quad (22)$$

Among them, $\phi_o^{\lambda+1}$ represents the optimal position owned by the connection weight candidate solution finder in each layer for $\lambda + 1$ iterations; ϕ_w^{λ} represents the global worst position for λ iterations.

During the optimization training of the keyword semantic similarity judgment model, there are some sparrows in the sparrow population that will detect the danger and call them vigilantes, and the vigilantes represent the sparrows that are used to judge the abnormal results of the keyword semantic similarity judgment. The initial position of the vigilantes in the population is randomly distributed, and their positions are updated according to the following formula:

$$\phi_{i,j}^{\lambda+1} = \begin{cases} \phi_{best}^{\lambda} + \kappa \cdot |\phi_{i,j}^{\lambda} - \phi_{best}^{\lambda}|, & \tau_i > \tau_g \\ \phi_{i,j}^{\lambda} + \kappa \cdot \left(\frac{|\phi_{i,j}^{\lambda} - \phi_w^{\lambda}|}{\tau_i - \tau_w}\right), & \tau_i = \tau_g \end{cases} \quad (23)$$

Among them, ϕ_{best}^{λ} is the global optimal position of the alert person. κ is a step control parameter, which is a normally distributed random number. τ_i is then the fitness value of the

connection weights of each layer of the current keyword semantic similarity judgment model; the τ_g , τ_w are the global best and worst fitness values, respectively.

Due to the uncertainty surrounding the optimal solution of the connection weights of each layer, in the actual global search for the optimal solution of the location of the process, this paper adopts the Formula (24) to remove the operation of convergence to the origin, to improve the sparrow search algorithm in the connection weights of the optimal solution is far from the origin, the search for the optimal accuracy of the problem is not high, and to further improve the algorithm for the semantic similarity of keywords to determine the model of each layer of the connection weights of global search for optimal ability. The corrected formula for updating the position of the discoverer is as follows:

$$\phi_{i,j}^{\lambda+1} = \phi_{i,j}^{\lambda} (1 + \kappa) \quad (24)$$

The steps are as follows:

- 1) Data processing, clear keywords semantic similarity judgment model input and output. Different input data have different dimensions, and the keyword differences may be very large, which will affect the speed of model training. Therefore, it is necessary to normalize the extracted keyword samples. Next, the normalized experimental samples are divided into training and testing sets.
- 2) Set the corresponding parameters of the algorithm: the number of populations M representing the feasible domains of connected weights at each level of the keyword semantic similarity judgment model, percentage of discoverers M_1 , percentage of persons on alert M_2 , number of iterations π , the initial sparrow population is obtained according to the initialization function; the keyword semantic similarity judgment model is constructed, and the range of values of the weight parameters to be optimized is determined.
- 3) Optimize the parameters of the keyword semantic similarity judgment model by using the sparrow optimization algorithm, take the extracted keyword samples of English translation and input them into the model for semantic similarity judgment training, and take the judgment error rate of the keyword semantic similarity judgment model on the training set as the fitness function in the optimization process, finally, the optimal keyword semantic similarity judgment model connection weight parameters of each layer are obtained after π iteration.
- 4) Use the optimized keyword semantic similarity judgment model to determine the semantic similarity of English translation keywords. The adaptability and effectiveness of the model are judged by comparing the output results of the model judgment with the expected output results.

Fig. 2 shows the flowchart of the keyword semantic similarity judgment method based on deep learning.

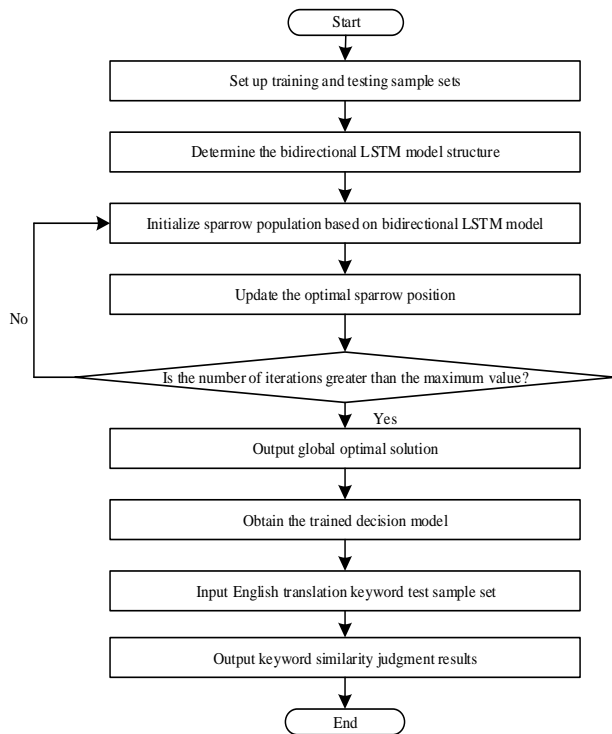

Fig. 2. Flowchart of keyword semantic similarity determination method based on deep learning.

III. EXPERIMENTAL RESULTS AND ANALYSIS

A. Experimental Design

To test the effect of this paper's method on the determination of keyword similarity in English translation, this paper's method is written into the English translation program shown in Fig. 3, which is mainly used in the two programs of keyword extraction and semantic similarity determination. Fig. 4 is the flow diagram of keyword extraction. Table I shows the parameter setting details of the bidirectional LSTM neural network.

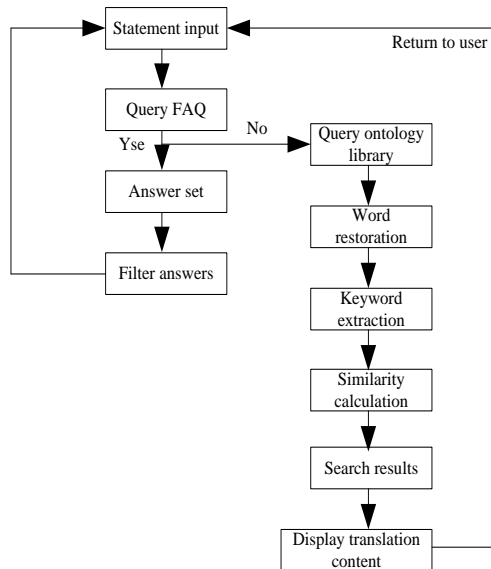

Fig. 3. Execution flowchart of English translation system.

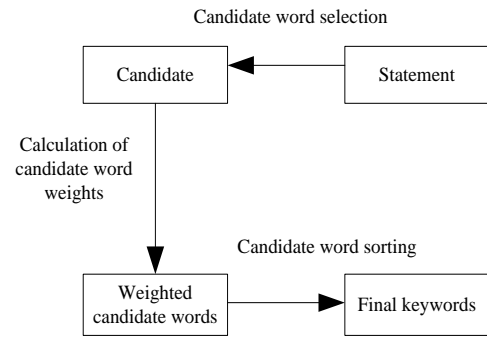

Fig. 4. English translation keyword extraction process.

TABLE I. PARAMETER SETTING DETAILS OF BIDIRECTIONAL LSTM NEURAL NETWORK

Type	Details
Number of LSTM nodes	100
Dropout	0.35
Iterations	35
Learning rate	0.15

C. Testing and Analysis

The accuracy loss of bidirectional LSTM neural network training used in this method is shown in Fig. 5. It can be seen from the analysis of Fig. 5 that 15 iterations of the model are reasonable. At this time, the accuracy rate is high, the loss is low, and the number of iterations is reasonable.

Fig. 5. Training effect of bidirectional LSTM neural network.

Fig. 6 and Fig. 7 show the visualization of the word distribution dimensions of the English-translated text before and after the extraction of the keywords of the English translation by the method of this paper.

Fig. 6. The method used in this paper focuses on the distribution dimensions of words before extracting English translation keywords.

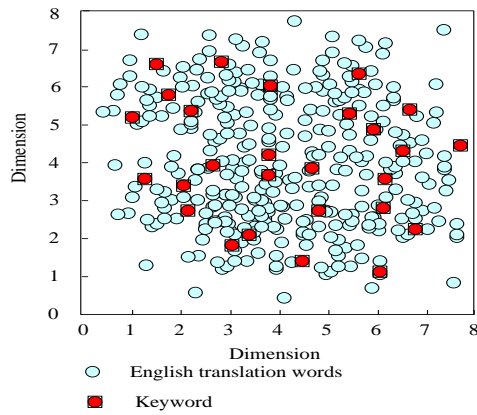

Fig. 7. The method used in this paper focuses on the dimension of word distribution after extracting English translation keywords

As shown in Fig. 6 and Fig. 7, before the extraction of English translation keywords by this method, the word distribution of English translation text is messy, with no keywords, non-keywords and the word distribution is disordered, at this time, if the keyword semantic similarity determination is carried out directly, it is necessary to analyze the keywords one by one, and it will consume too much time, which will result in the reduction of the efficiency of the similarity determination and affect the effect of the English translation. In this paper, after the extraction of English translation keywords, the keyword labeling is obvious, which reduces the sample size of keyword semantic similarity determination and helps to optimize the effect of keyword semantic similarity determination.

The English translation statement is “The impact of climate change on agriculture is significant, affecting crash yields, water resources, and biodiversity. Farmers are adapting to these changes by adapting sustainable practices such as crash rotation and soil conservation.” The result of the manual annotation of keywords in the statement is "Climate change; Agriculture; Crop

yields; Water resources; Biodiversity; Farmers; Sustainable practices; Crop rotation; Soil conservation". Fig. 8 shows the keyword extraction effect of this English translation sentence by using this method in the English translation system.

As shown in Fig. 8, the method of this paper is used in the English translation system, and the keyword extraction effect of this English translation statement is consistent with the result of manual annotation, which indicates that the keyword extraction effect of this English translation statement is close to people's understanding of natural language.

To test the effect of this paper's method of determining the semantic similarity of English translation keywords, 10 pairs of English translation utterances are introduced, and each pair of utterances has an artificial scoring to judge the degree of similarity between the two utterances, and the artificial scoring is the average of the scores of several participants, which can relatively objectively reflect the similarity of the comparative utterances, and the artificial scoring is mainly done by the relevant scholars of semantics, scholars of semantics assign values to the semantic relationship of English translation keywords. All the statements in this dataset are English lexical explanations or example sentences about a certain word. Table II below gives the comparison results of 10 pairs of utterances, which include manual scoring and similarity values determined by the method of this paper.

By observing the results in Table II and comparing and analyzing them, there are 10 pairs of statements in which the similarity value derived from the method of this paper is closer to the manual scoring. By employing a dichotomous method to evaluate the similarity between pairs of utterances and setting a cut-off value of 0.5, this study identifies 10 pairs of utterances in this paper that exhibit consistency with the outcomes of manual judgment. It shows that the average deviation of the similarity results of English translation calculated by this method is smaller than that of manual scoring, and the similarity judgment of pairs of utterances is closer to people's understanding of natural language in this dataset.

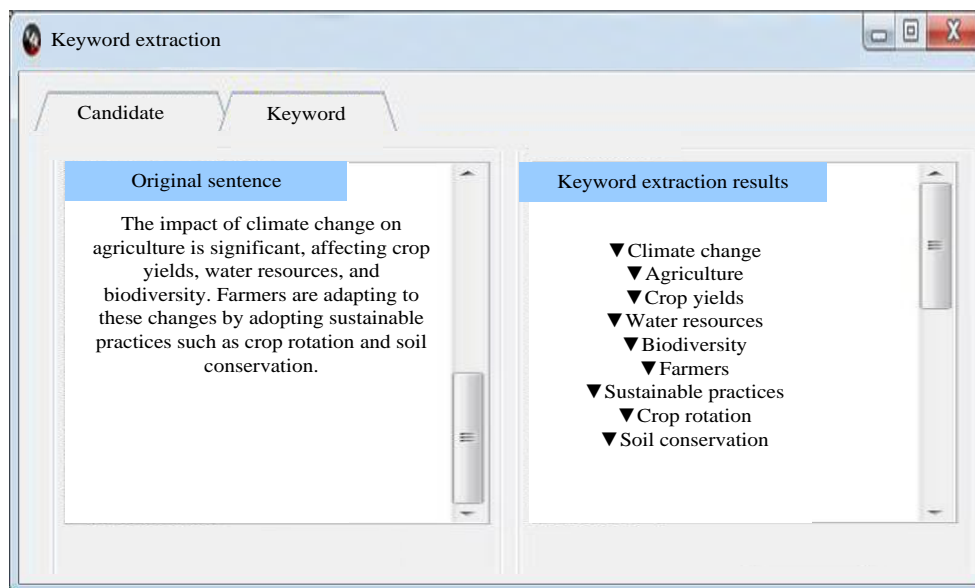

Fig. 8. The Keyword Extraction Effect of English Translation Sentences.

TABLE II. THE EFFECTIVENESS OF THIS METHOD IN DETERMINING THE SEMANTIC SIMILARITY OF KEYWORDS IN ENGLISH TRANSLATION

Statement encoding	Statement pairs	Manual scoring	The judgment results of this paper's method
1	Cord, Smile	0.015	0.014
2	Cord, String	0.475	0.474
3	Autograph, Shore	0.015	0.014
4	Hill, Mound	0.295	0.294
5	Asylum, Fruit	0.015	0.014
6	Boy, Rooster	0.115	0.114
7	Magician, Wizard	0.365	0.364
8	Furnace, Stove	0.355	0.354
9	Boy, Sage	0.045	0.044
10	Coast, Forest	0.135	0.134

Spearman's rank correlation coefficient H_{∞} (Spearman's Score) is derived by Spearman, a British statistician and psychologist using the concept of product difference. Spearman rank correlation coefficient applies to the comparison of two columns of variables. It not only has the nature of rank variables but also has a certain linear relationship. Its calculation is shown in Formula (25):

$$H_{\infty} = 1 - \frac{6 \times \sum_{j=1}^m \theta_j^2}{m^3 - m} \quad (25)$$

Among them, m is the number of similarity classes corresponding to the two columns of variables, and θ_j is the similarity rank difference of two columns of pairs of variables. Combining the above features, Spearman's rank correlation coefficient can be well utilized to measure the semantic relevance of English translation in this paper, which can be used to measure the performance of each method by calculating the correlation value of manual annotation, and the rank coefficient of correlation value of each correlation calculation method. Then, comparing the method of this paper, the method of study [9], the method of study [10], the method of study [11] in the same context, the semantic similarity of the randomly selected keyword phrases of English translation in Table II, the results of the comparison of Spearman's rank correlation coefficients are as shown in Fig. 9, Fig. 10, Fig. 11, and Fig. 12.

Fig. 9. The Spearman rank correlation coefficient of the method in this paper.

Fig. 10. Spearman rank correlation coefficient of study [9] method.

Fig. 11. Spearman rank correlation coefficient of study [10] method.

Fig. 12. Spearman rank correlation coefficient of study [11] method.

Comparing Fig. 9 to Fig. 12, it can be seen that method of this paper, the method of reference [9], the method of reference [10], and the method of study [11], in the same context, after determining the semantic similarity of the randomly selected English translated keyword sentences in Table II, the correlation coefficient of Spearman's level is the highest, and the value is 1, Spearman's rank correlation coefficient of the determination results of [9], [10] and [11] are all smaller than this paper method. This shows that in the comparison of similar judgment methods, this method is more suitable for the semantic similarity determination of English translation keywords, and the similarity judgment results meet people's understanding standard for the semantic similarity judgment of English translation keywords.

In order to verify the effectiveness of the bidirectional LSTM neural network based on deep learning in the semantic similarity determination of English translation keywords, especially the contribution of bidirectional LSTM structure and Sparrow search algorithm in optimizing weights, we designed an ablation experiment. Ablation experiments are an effective way to study the contribution of each component of a model by removing or replacing certain parts of the model to see how they affect the overall performance. In this experiment, the following three model Settings will be compared:

- 1) Baseline model: Only a keyword extraction algorithm based on word co-occurrence is used, but no deep learning model is used to evaluate the similarity between keywords.
- 2) One-way LSTM model: One-way LSTM neural network is used to replace two-way LSTM to capture the context information of keywords, and sparrow search algorithm is used to optimize the weights.
- 3) Complete model: The keyword extraction algorithm based on word co-occurrence is used to input keywords into the bidirectional LSTM neural network based on deep learning, and the sparrow search algorithm is used to optimize the weights to evaluate the semantic similarity between keywords.

According to the above Settings, the ablation experimental results were obtained as shown in Table III.

TABLE III. ABLATION RESULTS

Model setup	Accuracy rate	Recall rate	F1 score
Reference model	0.65	0.76	0.67
One-way LSTM model	0.72	0.78	0.75
Complete model	0.83	0.85	0.82

As can be seen from Table III, compared with the benchmark model, using only simple lexical similarity measurement and adding deep learning model (whether one-way LSTM or two-way LSTM) can significantly improve the performance of keyword semantic similarity determination. This shows that deep learning models can capture more complex semantic information when processing natural language text. Further comparison between the unidirectional LSTM model and the complete model shows that the bidirectional LSTM model is superior to the unidirectional LSTM model in accuracy, recall rate and F1 score. This proves that bidirectional LSTM has the advantage of considering both contextual information when processing sequence data, which enables the model to capture the subtle semantic differences between keywords more accurately. In addition, the Sparrow search algorithm also plays an important role in optimizing the weight of the neural network, and further improves the performance of the model by optimizing the weight.

In order to compare the performance of the proposed method in semantic similarity determination accuracy with that of studies [9], [10] and [11], the same data set was used to cover text data from different fields, so as to ensure the comprehensiveness and comparability of the experiment. The number of experiments was set to 300 times, the average results were taken, and the representative experimental results of five groups were given as shown in Table IV to evaluate the stability and robustness of different methods.

TABLE IV. COMPARISON RESULTS OF SEMANTIC SIMILARITY DETERMINATION ACCURACY OF DIFFERENT METHODS

Method	Experiment 1	Experiment 2	Experiment 3	Experiment 4	Experiment 5	Average accuracy
Textual method	0.85	0.84	0.86	0.83	0.87	0.85
Reference [9] Methods	0.78	0.76	0.79	0.75	0.77	0.77
Reference [10] Methods	0.72	0.71	0.73	0.74	0.74	0.72
Reference [11] Methods	0.80	0.79	0.81	0.78	0.82	0.81

As can be seen from Table IV, the proposed method achieves the best average performance in semantic similarity determination accuracy, reaching 0.85. This is mainly due to the bidirectional LSTM model's ability to capture both the pre- and post-text information, and the effectiveness of Sparrow search

algorithm in optimizing neural network weights. In contrast, although the method in literature [9] uses the network ontology structure and a variety of metrics, it may be affected by data sparsity in some cases, resulting in low accuracy. The literature [10] method is limited by the number and sparsity of triples in RDF data sets, and its performance is relatively low. The method of study [11] may face the problem of high computational complexity when dealing with large-scale data sets, but its average accuracy is still higher than that of the methods of study [9] and [10], indicating that it has certain advantages in semantic similarity determination by using non-categorical relation measures.

IV. DISCUSSION

According to the experiments, the proposed method has several important trends and advantages in the semantic similarity determination of English translation keywords.

Firstly, the stability and convergence of the bidirectional LSTM neural network in the training process are verified by the accurate-loss curve in Fig. 5. The model reaches a reasonable equilibrium point after 15 iterations, which indicates that the selected iterations are appropriate, and the model can effectively learn and capture the semantic relationship between keywords.

Secondly, the visual diagram of word distribution dimensions in Fig. 6 and Fig. 7 shows the significant changes of the proposed method before and after keyword extraction in English translation. After the keywords are extracted, the key information in the text is clearly marked, which greatly reduces the sample size of the subsequent semantic similarity judgment and improves the efficiency and accuracy of the judgment. This finding is consistent with the expectation and also proves the importance of keyword extraction in English translation.

Further, through the keyword extraction effect shown in Fig. 8, we can see the practical application effect of the proposed method in the English translation system. For a given English translation statement, the proposed method can accurately extract keywords consistent with the manual annotation results, which further verifies the effectiveness and accuracy of the proposed method.

In order to test the effectiveness of this method in judging the semantic similarity of English translation keywords, a dataset containing 10 English translation sentence pairs is introduced and a manual score is used as the benchmark. From the comparison results in Table II, it can be seen that the similarity value obtained by the proposed method is very close to the manual score, which proves the accuracy and reliability of the proposed method in semantic similarity judgment. In particular, when dichotomies are used to judge whether the statement pairs are similar, the results of the proposed method are completely consistent with those of the manual judgment, which further enhances the confidence in the performance of the proposed method.

In comparison with other methods, it can be seen from the comparison results of Spearman rank correlation coefficients in Fig. 9 to Fig. 12 that the proposed method has better performance in semantic similarity judgment than the methods

in studies [9], [10] and [11]. This result not only validates the effectiveness of the proposed method, but also illustrates the contribution of bidirectional LSTM neural network and Sparrow search algorithm in optimizing weights.

Finally, through the design of ablation experiment, the effectiveness of the bidirectional LSTM structure and the sparrow search algorithm in the proposed method is further verified. The results of the ablation experiment showed that the model without these key components significantly decreased in performance, demonstrating the importance of these components for improving the accuracy of semantic similarity determination.

Compared with previous studies, this method has achieved significant advantages in the semantic similarity determination of English translation keywords. By introducing bidirectional LSTM neural network and Sparrow search algorithm, this method can more accurately capture the subtle semantic differences between keywords, and optimize the weight setting of neural network, so as to improve the accuracy and efficiency of semantic similarity judgment. In addition, the method further improves the judgment efficiency and intuitiveness through keyword extraction and visualization techniques. These advantages make the proposed method have a wide application prospect in the fields of English translation and natural language processing.

V. CONCLUSION

The semantic similarity determination method can help the translation system better understand and process the keywords in the source language, to optimize the translation process. For example, when dealing with polysemous words or words with multiple meanings, by determining the semantic similarity of keywords, the translation that best matches the context can be selected to improve the accuracy and naturalness of the translation. This paper proposes a deep learning-based method for determining the semantic similarity of keywords in English translation, and the experimental test results show that this method can not only accurately extract the keywords in the English translation statements, but also capture the complex semantic relationship between the keywords, and provide more accurate keyword translations and semantic similarity determination results.

An Improved VMD and Wavelet Hybrid Denoising Model for Wearable SSVEP-BCI

Yongquan Xia, Keyun Li, Duan Li, Jiaofen Nan, Ronglei Lu

School of Computer Science and Technology, Zhengzhou University of Light Industry, Zhengzhou, Henan, China

Abstract—The brain-computer interface (BCI) based on steady-state visual evoked potentials (SSVEP) has attracted considerable attention due to its non-invasiveness, low user training requirements, and efficient information transfer rate. To optimize the accuracy of SSVEP detection, we propose an innovative hybrid EEG denoising model combining variational mode decomposition (VMD) with wavelet packet transform(WPT). This model ingeniously integrates VMD decomposition and WPT denoising techniques, employing detrended fluctuation analysis (DFA) thresholding to deeply filter the noisy data collected from wearable devices. The filtered components are then reconstructed alongside the unprocessed components. Finally, three classification algorithms are used to validate the proposed method on a wearable SSVEP-BCI dataset. Our proposed algorithm achieves accuracies of 71.27% and 86.35% on dry and wet electrodes, respectively. Comparing the use of VMD combined with adaptive wavelet denoising and direct denoising with VMD, the classification accuracy of our method improved by 3.68% and 0.26% on dry electrodes, respectively, and by 3.28% and 0.66% on wet electrodes, respectively. The proposed approach demonstrates excellent performance and holds promising potential for application and generalization in the field of wearable EEG denoising.

Keywords—Brain-computer interface; steady-state visual evoked potential; style; variational mode decomposition; wavelet packet transform

I. INTRODUCTION

Brain-computer interface (BCI) technology facilitates the direct conversion of brain signals into computer input signals, enabling direct human-computer interaction [1, 2]. When neurons in the brain are active, they generate weak electrical signals, which can be transmitted through the scalp, skull, and tissues to the surface of the scalp, forming electroencephalogram (EEG) signals [3, 4]. Steady-state visual evoked potentials (SSVEP) [5] are among the most common neurophysiological electrical signals in EEG. Compared to other electrophysiological signal sources, SSVEP-based BCIs offer higher information transfer rate, signal-to-noise ratios, and classification accuracies. To enhance the practicality of SSVEP-based BCI systems, there is an increasing demand for wearable BCI systems.

EEG electrodes play a crucial role in wearable BCI systems. Dry electrodes, which do not require conductive gel, offer a convenient and durable method for EEG signal acquisition [6, 7]. However, due to the need for close contact with the scalp, dry electrodes often result in poorer signal quality and user experience. Additionally, portable devices are typically more susceptible to contamination from typical sources of noise

compared to standard EEG systems [8-10]. Therefore, in wearable SSVEP-BCI data, noise reduction processing becomes particularly crucial.

The processing of wearable physiological signals remains a hot research topic, with significant achievements in the field of EEG denoising. Peng et al.[11] first proposed a novel model for removing eye artifacts from EEG signals, based on discrete wavelet transform (DWT) and adaptive noise cancellation (ANC). The results demonstrated the effectiveness of this model in removing eye artifacts, making it particularly suitable for applications in portable environments. Similarly, Zhao et al.[12] also introduced a hybrid denoising method using DWT and adaptive predictive filtering (APF) for automatic identification and removal of eye artifacts. However, some drawbacks of time-frequency transformation methods include limited resolution, windowing effects, occurrence of cross-terms, high complexity and computational costs, poor interpretability, sensitivity to noise, and challenges in parameter selection. EMD is an adaptive decomposition method that does not involve a complex selection process for basis functions. It offers higher resolution than traditional time-frequency analysis methods but suffers from drawbacks such as mode mixing, endpoint effects, and a lack of mathematical theory [13-15]. To overcome these limitations, improved EMD algorithms have been proposed, such as ensemble empirical mode decomposition (EEMD)[16] and complementary ensemble empirical mode decomposition (CEEMD) [17]. While these methods have improved the decomposition results, issues like mode mixing and endpoint effects persist, and all three methods lack mathematical theoretical support. In 2014, Dragomiretskiy and Rosso[18] introduced variational mode decomposition (VMD), which differs from EMD, EEMD, and CEEMD in that it is not "empirical" but rather supported by strong mathematical theory. VMD is a new adaptive signal decomposition algorithm and has shown promising results in denoising and time-frequency analysis [19-21].

However, a single time-frequency domain analysis methods lack uniformity in time-frequency resolution, making it challenging to accurately capture the changing characteristics of non-stationary signals across different time and frequency ranges. Subsequently, Narmada et al. [22] proposed a deep learning and heuristic-based adaptive pseudo-shadow wavelet denoising method, which enhances the denoising effect through a combination of EMD and DWT. Therefore, our study proposes a hybrid denoising technique combining VMD with wavelet packet transform (WPT), aiming to explore the intrinsic characteristics of SSVEP data. VMD, with its remarkable decoupling capability, effectively separates mixed components

in SSVEP signals. The wavelet-hybrid denoising technique effectively preserves the useful information in the signal while significantly attenuating the noise components, enhancing the purity of the signal.

To comprehensively validate the practicality of this approach, we employed three recognition algorithms: canonical correlation analysis (CCA), filter bank canonical correlation analysis (FBCCA), and task-related component analysis (TRCA). These algorithms, each with its unique features, classify and recognize signals from different perspectives, providing a comprehensive performance evaluation. Additionally, this paper further investigates the application potential of this method in wearable SSVEP EEG signal recognition by comparing it with different denoising methods.

The structure of the remaining part of this paper is as follows. The second part primarily elaborates on the methods used in this study. The third part provides an introduction to the dataset used and the determination of experimental parameters. The fourth part discusses relevant issues based on experimental results. Discussions continue in Section V. and the sixth part summarize the work done in this paper.

II. METHOD

A. Overview

The workflow of this method includes the following steps: firstly, the EEG signals are subjected to initial preprocessing and bandpass filtering to eliminate noise interference. Next, the VMD technique is employed to decompose the signals into K band-limited intrinsic mode functions (BLIMFs), which helps better capture the frequency characteristics of the signals. Then, detrended fluctuation analysis (DFA) is utilized for threshold determination to filter out BLIMFs that do not meet the threshold conditions, which are subsequently subjected to wavelet denoising. Wavelet denoising mainly utilizes wavelet packet transform (WPT), effectively reducing noise components in the signals. Finally, the reconstructed signals obtained by adding the threshold-filtered BLIMFs and further processed BLIMFs are inputted into three different classification algorithms for further recognition and classification, as illustrated in Fig. 1.

B. VMD and Wavelet Hybrid Denoising

1) *Variational mode decomposition*: Variational mode decomposition (VMD) is a novel and more effective non-recursive signal preprocessing algorithm that can adaptively determine relevant frequency bands and compute individual mode components simultaneously. The VMD algorithm decomposes any signal $x(t)$ into K discrete sub-signals or modes u_k , where each mode is centered around its respective central frequency ω_k . The expression for u_k is given in Equation (1):

$$u_k(t) = A_k(t) \cos(\omega_k(t)) \quad (1)$$

In the equation, $u_k(t)$ represents the k-th intrinsic mode function (IMF), which is primarily designed to limit bandwidth; $A_k(t)$ denotes the instantaneous amplitude of $u_k(t)$; $\omega_k(t)$ stands for the instantaneous frequency of $u_k(t)$. Each component is centered around the central frequency $\omega_k(t)$, and gaussian smoothing can be employed to estimate the bandwidth. Due to the sparsity of VMD decomposition, the decomposition problem can be formulated as follows. As shown in Equation (2):

$$\min_{\{u_k\}, \{\omega_k\}} \left\{ \sum_{k=1}^K \left\| \partial_t \left[\left(\delta(t) + \frac{j}{\pi t} \right) * u_k(t) \right] e^{-j\omega_k t} \right\|_2^2 \right\} \\ \text{s.t.} \sum_{k=1}^K u_k(t) = x \quad (2)$$

In the equation, t denotes the time symbol, $\delta(t)$ represents the dirac delta function, $*$ denotes convolution. To solve the aforementioned problem optimally, an augmented lagrangian function is introduced, transforming the constrained variational problem into an unconstrained variational problem, expressed as:

$$L(\{u_k\}, \{\omega_k\}, \lambda) = \alpha \sum_{k=1}^K \left\| \partial_t \left[\left(\delta(t) + \frac{j}{\pi t} \right) * u_k(t) \right] e^{-j\omega_k t} \right\|_2^2 \\ + \left\| x(t) - \sum_{k=1}^K u_k(t) \right\|_2^2 + \langle \lambda(t), x(t) - \sum_{k=1}^K u_k(t) \rangle \quad (3)$$

In the equation, α is a secondary penalty factor ensuring signal reconstruction accuracy; $\lambda(t)$ represents the Lagrange multiplier operator. Equation (3) is then solved using the alternating direction method of multipliers (ADMM). In the fourier domain, the optimal $u_k(\omega)$ is directly updated via wiener filtering [23]. Therefore, wiener filtering is embedded in VMD to enhance its robustness to sampling and noise. This yields the time-domain mode $u_k(t)$:

$$\hat{u}_k^{n+1}(\omega) = \frac{\hat{x}(\omega) - \sum_{i \neq k} \hat{u}_i(\omega) + \frac{\hat{\lambda}(\omega)}{2}}{1 + 2\alpha(\omega - \omega_k)^2} \quad (4)$$

$$\hat{u}_k(t) = \Re \{ \text{ifft}(\hat{u}_k(\omega)) \} \quad (5)$$

Where $\hat{x}(\omega)$ is the fourier transform of the signal $x(t)$, $\text{ifft}(\cdot)$ is the inverse fourier transform of, and $\Re\{\cdot\}$ denotes the real part of the analytical signal. The updated equation for ω_k is as follows, and its optimization is also performed in the fourier domain. As shown in Equation (6):

$$\omega_k^{n+1} = \frac{\int_0^\infty \omega |\hat{u}_k(\omega)|^2 d\omega}{\int_0^\infty |\hat{u}_k(\omega)|^2 d\omega} \quad (6)$$

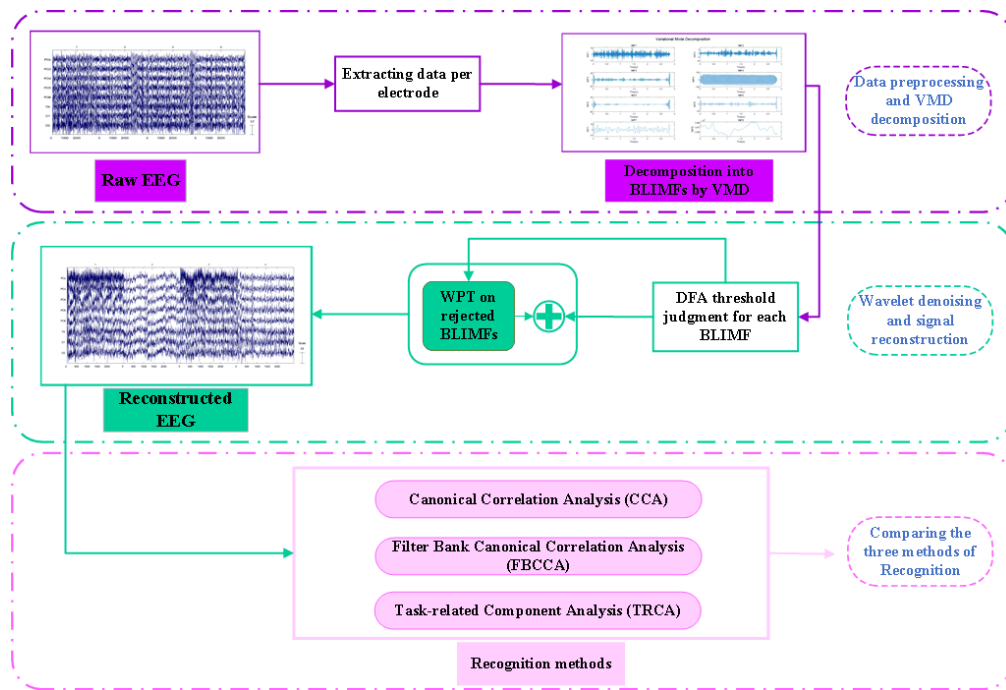

Fig. 1. Overall workflow diagram.

In VMD decomposition, the penalty factor α and the number of mode components K directly influence the decomposition results. α primarily affects the accuracy of the decomposition results, while the value of K directly affects the correctness of the decomposition results. If the chosen K is smaller than the number of useful components in the signal (under-decomposition), it may lead to incomplete decomposition and mode mixing. Conversely, if the chosen K is greater than the number of useful components in the signal (over-decomposition), it may result in some irrelevant false components. Therefore, the selection of K is crucial for the results of VMD.

2) *The principle of VMD and wavelet hybrid denoising:* Wavelet packet transform (WPT) is an advancement built upon the foundation of DWT. In DWT, a signal is decomposed into a series of high-frequency and low-frequency components, but only the low-frequency part is iteratively decomposed. In contrast, WPT simultaneously decomposes both high-frequency and low-frequency components at each decomposition level. This means that it can analyze the frequency content of the signal in more detail. Wavelet packets inherit the advantages of wavelet transform, capturing both time-domain and frequency-domain features, which enables effective handling of unstable signals. Additionally, for both high-frequency and low-frequency signal components, wavelet packet transform provides good signal processing performance while maintaining the same time-frequency resolution. The full-band analysis capability of WPT is particularly suitable for applications where signal characteristics are not limited to the low-frequency range alone. Due to its fine-grained analysis characteristics, wavelet packet decomposition demonstrates its unique advantages in various applications. It not only offers

improved performance in signal denoising and data compression but also exhibits unparalleled capabilities in biomedical signal processing, speech recognition, and seismic data analysis [24-27].

In the method proposed in this paper, after decomposing the modal components using VMD, a threshold judgment is applied to these components. Components that do not meet the threshold condition are further denoised using WPT. In the process of wavelet denoising, the selection of appropriate wavelet functions and decomposition levels is crucial. Previous research [28] has shown that the wavelet function 'db8' has more effective denoising effects for EEG signals from healthy subjects. However, to more accurately select wavelet functions suitable for EEG signals, this paper refers to the method in [29] and tries different Daubechies wavelet functions. The experimental results show that 'db4' and 'db8' have more significant denoising effects on EEG signals. Therefore, 'db4' was chosen as the wavelet function suitable for the experiment. For determining the decomposition levels, this paper follows the definition of decomposition levels based on Shannon entropy [30]. The process involves increasing the decomposition levels and then calculating the entropy of the detail coefficients and approximation coefficients. When the detail entropy is greater than the approximation entropy, the decomposition level at which to stop is determined. Based on experimental results, the decomposition level was determined to be 3. Finally, the denoised components obtained through wavelet denoising are added to the components that meet the threshold conditions to reconstruct cleaner EEG signals.

C. The Three Recognition Algorithms

This paper mainly employs three recognition algorithms, namely CCA, FBCCA, and TRCA, to classify wearable SSVEP EEG signals.

1) *Canonical correlation analysis (CCA)*: The canonical correlation analysis (CCA) algorithm is a multivariate statistical analysis method that utilizes the correlation between composite variables to reflect the overall correlation between two sets of indicators. It is widely used in the analysis of SSVEP signals due to its effectiveness and robustness [31].

2) *Filter bank canonical correlation analysis (FBCCA)*: Due to non-Gaussian background noise and its harmonics affecting SSVEP, the CCA method may not fully utilize the characteristics of SSVEP signals [32]. To address this issue, Chen et al. proposed FBCCA [33], which combines filter bank technology with CCA to enhance performance. *Task-related component analysis (TRCA)*: The TRCA algorithm was first proposed by Nakanishi in 2018 [34]. It aims to enhance the signal-to-noise ratio and suppress spontaneous brain activity by maximizing the repeatability of inter-trial covariance using training data from target subjects, thereby extracting task-related components.

Assuming $X_i^k \in \mathbb{R}^{N_c \times N_s}$ and $X_j^k \in \mathbb{R}^{N_c \times N_s}$ represent the EEG signals of the i -th and j -th experiments corresponding to the k -th stimulus frequency for a particular subject, where N_c denotes the number of EEG channels, N_s denotes the number of sampling points, and $k=1,2,\dots,N_f$, the constrained optimization problem of TRCA is reduced to the following Rayleigh-Ritz eigenvalue problem. As shown in Equation (7):

$$w = \arg \max_w \frac{w^T S w}{w^T Q w} \quad (7)$$

Where S and Q are respectively the sums of inter-trial covariance matrix and auto-covariance matrix, calculated as follows:

$$S = \sum_{\substack{i,j=1 \\ i \neq j}}^{N_b} Cov(X_i^k, X_j^k) \quad (8)$$

$$Q = \sum_{\substack{i,j=1 \\ i=j}}^{N_b} Cov(X_i^k, X_j^k) \quad (9)$$

Where N_b is the number of training experiments.

The spatial filters can be obtained from the eigenvectors corresponding to the largest eigenvalue of the matrix $Q^{-1}S$. Therefore, spatial filters corresponding to all stimulus frequencies can be computed. The correlation coefficient r_k between the test data $X_t = \mathbb{R}^{N_c \times N_s}$ and the averaged training template \bar{X}_k is calculated by the following equation:

$$r_k = \rho(X_t^T W, \bar{X}_k^T W) \quad (10)$$

Then, the maximum correlation coefficient among all correlation coefficients with the averaged training templates for all stimulus frequencies is found. The stimulus frequency corresponding to the maximum correlation coefficient is identified as the target stimulus.

D. Performance Evaluation

This paper evaluates the performance of the model using accuracy and F₁score based on the confusion matrix. The expressions for accuracy and F₁score are as follows:

$$Accuracy = \frac{TP + TN}{TP + FP + FN + TN} \quad (11)$$

$$Precision = \frac{TP}{TP + FP} \quad (12)$$

$$Recall = \frac{TP}{TP + FN} \quad (13)$$

$$F_1score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (14)$$

where TP, TN, FP, and FN represent true positive, true negative, false positive, and false negative, respectively.

III. DATASET AND PARAMETER SETTINGS

A. Dataset

The proposed method model was validated on a wearable SSVEP-BCI dataset [35]. The dataset comprised 102 healthy subjects with normal or corrected-to-normal vision (64 males, 38 females, aged 8-52 years) recorded using SSVEP-based brain-computer interface, involving 12 targets. The 12 targets were encoded using the JFPM method, with a frequency range of 9.25 to 14.75 Hz in 0.5 Hz intervals, and a phase difference of 0.5π between adjacent targets. For each subject, experiments were conducted using both dry and wet electrodes, with 10 consecutive data blocks recorded for each electrode type. Each block contained 12 trials corresponding to each target displayed once in random order. Data were recorded according to the international 10-20 system, with 8 electrodes placed on the parieto-occipital area (POz, PO3, PO4, PO5, PO6, Oz, O1, O2) and 2 electrodes on the frontal area serving as reference and ground. Data extraction from the public dataset was performed at time points ranging from 0.64 to 2.64 seconds during the experiment (including 0.5 seconds before stimulus onset, 0.14 seconds of visual delay, 2 seconds of stimulus presentation, and 0.2 seconds after stimulus offset), with the first 20 subjects participating in our study.

B. Experimental Environment and Parameter Settings

The method proposed in this study has been implemented in MATLAB 2022b. To effectively utilize wavelet processing functions, the MATLAB environment in the research setup has been installed with the Time-Frequency Analysis Toolbox (TFA-Toolbox).

1) *Method for determining the number of modes K in VMD*: Before conducting experiments, it is necessary to determine the number of modes K for VMD decomposition. In previous literature, the number of modes K is typically defined using the same number of EMD decompositions and wavelet packet decompositions [36], or selected by calculating the scaling exponent α of the input signal [23]. However, the aforementioned techniques have certain limitations when

dealing with experiment signals with complex frequency components. In this study, the energy difference principle is used as an auxiliary algorithm, with the experimental results of classification accuracy as the main basis, combined with the analysis of decomposition results to determine the value of K.

Energy Difference Principle: VMD utilizes a variational framework-based constrained variational model to decompose signals, and the components obtained from the decomposition have orthogonal relationships in terms of energy. In other words, the sum of the energies of each component should be equal to the energy of the original signal, which adheres to the energy difference principle. If K is set too large, it will lead to over-decomposition of the signal, resulting in spurious components and causing the sum of energies of the components generated by over-decomposition to exceed the sum of energies of the components generated by normal decomposition. Therefore, the optimal value of the parameter K for VMD can be determined by comparing energy differences. The formula for calculating signal energy is as follows:

$$E = \sqrt{\frac{\sum_{i=1}^n y^2(i)}{n}} \quad (15)$$

In the formula, E represents the energy of the signal; y(i) represents the EEG signal sequence; n represents the number of sampling points. The formula for calculating the energy difference is as follows:

$$\eta = \frac{|E_K - E_{K-1}|}{E_{K-1}} \quad (16)$$

According to equation (16), η represents the difference between E_K and E_{K-1} . A larger value of η indicates a more pronounced over-decomposition phenomenon in VMD, whereas a smaller value of η may suggest under-decomposition of the signal. For non-stationary and complex signals such as EEG signals, η typically remains near small values under conditions of under-decomposition or appropriate decomposition. With an increase in the parameter K, the over-decomposition phenomenon causes η to significantly increase. Therefore, the value of K at the inflection point can be considered as an effective number of modes for VMD decomposition.

First, use FBCCA to classify the original EEG data to obtain the classification accuracy of dry and wet electrodes as a reference. Then, reconstruct the signal and perform classification under different numbers of modes, observing the results and analyzing the appropriate range of K values. In addition, with a step size of 0.5 seconds, gradually select data lengths of 0.5 seconds, 1 second, 1.5 seconds, and 2 seconds. The specific classification accuracies are shown in Table I (the upper part represents the results for dry electrodes, and the lower part represents the results for wet electrodes):

From Table I, it can be observed that the appropriate value of K is approximately around 20. In order to determine the value of K more precisely and accurately, the energy difference

principle is used. The experiment is conducted using data from the same participant, and the results are shown in Table II.

From the results in Table II, it can be observed that analyzing the values of η reveals that when $K=20$, η suddenly increases, while other modal values remain approximately around 0.01. Therefore, based on the energy difference principle, the optimal choice for K is determined to be 20. Considering the comprehensive analysis above, the value of K in the proposed method should be set to 20 to ensure that the data can be accurately decomposed.

2) DFA Threshold Determination Method: In the proposed method in this paper, a reliable threshold is needed to select the obtained different mode functions after VMD decomposition. Since these decomposed components also contain noise, the Hurst exponent is used to determine whether there is noise in the obtained BLIMFs[30].

In non-stationary time series, estimating the hurst exponent can be challenging as certain methods may yield misleading results. Considering the non-stationary nature of wearable EEG signals, traditional approaches may not be suitable. However, detrended fluctuation analysis (DFA) possesses the capability to detrend time series, making it an ideal choice for estimating the hurst exponent. Therefore, this paper employs the DFA method aiming to accurately reveal the scaling properties of the signal and detect its long-range correlations, thereby providing a deeper understanding of the dynamic nature of wearable EEG signals. The steps for computing the hurst exponent using DFA are outlined in Algorithm 1.

Based on the DFA thresholding process (see Fig. 2), BLIMFs that meet the threshold criteria are retained, while those that do not meet the threshold criteria undergo further wavelet denoising. Finally, these two components are added together to generate a cleaner EEG signal. In this process, the parameter α represents the scaling exponent, playing a crucial role in measuring the roughness of the sequence. According to the empirical findings in [30], to address potential mode mixing issues, α is set to 0.75 in this study.

Fig. 2. Flowchart of DFA threshold determination

IV. EXPERIMENTAL RESULTS

A. Recognition Results based on the Proposed Method in this Paper

First, the EEG data are directly processed using CCA, FBCCA, and TRCA as reference algorithms to obtain classification accuracy. Subsequently, the data are divided into dry and wet electrodes for each channel and fed into the proposed model. The data undergo bandpass and notch filtering, followed by VMD decomposition with a mode number of 20.

Then, DFA thresholding is applied to determine which mode components do not meet the threshold criteria. These components undergo wavelet denoising, primarily using WPT for experimentation. Finally, the denoised components are added to the components that meet the threshold criteria to reconstruct a clearer EEG signal. The reconstructed signals are classified using the three recognition algorithms. Recordings of recognition results are made using data lengths of 0.5s, 1s, 1.5s, and 2s, as shown in Tables III and IV.

TABLE I. CLASSIFICATION ACCURACY (MEAN ± STD %)

Method	Data length(s)			
	0.5	1	1.5	2
FBCCA	15.17±9.38 22.17±10.66	29.46±16.39 48.71±19.87	44.38±20.44 66.58±21.77	58.42±22.14 76.29±20.04

Algorithm 1: DFA steps for calculating the Hurst index

1. Sequence normalization: For a given time series X, first calculate its cumulative time series as shown in the following equation:

$$Y(i) = \sum_{k=1}^i X(k) - \mu \tag{17}$$

where μ is the mean value of the sequence X.

2. Segmentation to compute the mean: The cumulative time series Y is divided into different time windows (or scales), often called boxes, each of length n.

3. Linear fitting: For each window, find the trend of the sequence Y(i) within that window by least squares linear fitting.

4. Calculate the root mean square deviation: Calculate the deviation between the actual data and the fitted line in each window, which is often referred to as "fluctuation".

5. Fit a straight line: for different window lengths, the relationship between fluctuations and window length is plotted as a logarithmic plot, a straight line is fitted to this image, and its slope is calculated, the slope is the Hurst index.

	2	dry	71.27±20.49	70.21
		wet	86.35±16.19	84.20

From the experimental results in Table III and Table IV, it can be observed that after applying the VMD and WPT hybrid denoising method, the three recognition methods show improvements across different data lengths. For instance, at 2 seconds, the classification accuracy of CCA for dry and wet electrodes was initially 52.29% and 66.46%, respectively. After denoising, the classification accuracy increased to 53.25% and 69.58%, respectively, representing improvements of 0.96% and

3.12%, respectively. Similarly, for FBCCA at 2 seconds, the classification accuracy for dry and wet electrodes increased by 4.66% and 4.29%, respectively, while for TRCA, the increase was 4.8% and 3.88%, respectively. This indicates a significant improvement, especially for dry electrodes, validating the superiority of the denoising method proposed in this paper. The experimental results of the proposed method are visualized in Fig. 3.

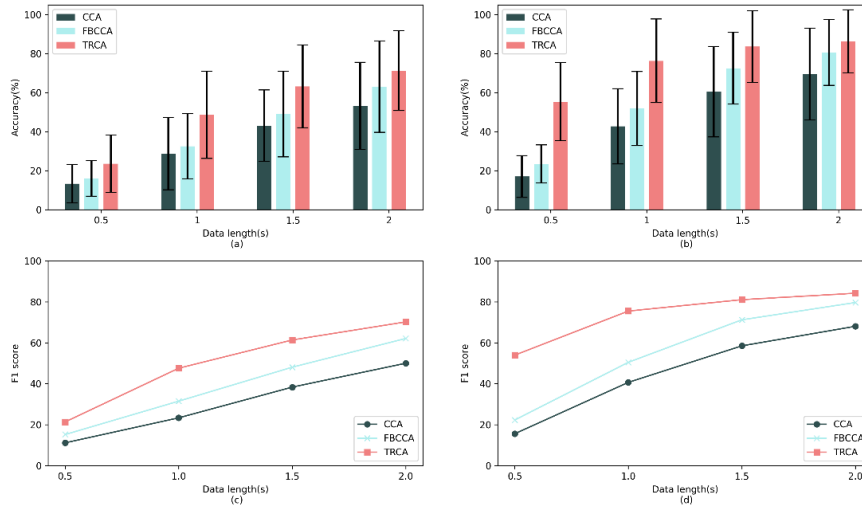

Fig. 3. Illustrates the results obtained based on the method proposed in this paper: (a) represents the classification accuracy for dry electrodes, (b) represents the classification accuracy for wet electrodes, (c) represents the F_1 score for dry electrodes, (d) represents the F_1 score for wet electrodes

From Fig. 3, it can be observed that TRCA shows significant improvements in classification accuracy and F_1 score for dry and wet electrodes at data lengths of 1 second and 1.5 seconds. At 2 seconds, the classification accuracy for dry and wet electrodes reaches 71.27% and 86.35%, respectively.

B. Comparing Different Denoising Methods

To further denoise the BLIMFs obtained from VMD decomposition, this section compared the effectiveness of three different denoising methods: adaptive wavelet thresholding, removal of the highest and lowest frequency components, and DFA thresholding combined with wavelet packet transform (WPT).

Firstly, adaptive wavelet denoising was applied to the BLIMFs obtained from VMD decomposition. This method

dynamically adjusts the noise filter based on the signal characteristics, allowing for finer noise reduction. The wavelet function 'db4' was chosen, with a decomposition level of 3, and the threshold was adaptively selected using the 'Rigrsure' method. Secondly, spectral analysis was conducted on the decomposed BLIMFs components to remove the highest and lowest frequency components, aiming to eliminate noise caused by extreme frequency components. In contrast, the method proposed in this paper, which combines DFA thresholding with WPT, provides a more detailed treatment of the signal's frequency characteristics. WPT also utilizes the 'db4' wavelet function, with a decomposition level of 3. The resulting classification accuracy and F_1 score are presented in Tables V and VI, respectively, while the visualizations are depicted in Fig. 4 and 5.

TABLE V. EXPERIMENTAL RESULTS USING VMD WITH ADAPTIVE WAVELET DENOISING

Method	Data length(s)	Electrode type	Accuracy(%)	F_1
CCA	0.5	dry	11.04±9.34	9.18

		wet	53.29±20.04	51.23
	1	dry	46.39±20.03	45.38
		wet	74.48±22.38	73.30
	1.5	dry	61.89±20.35	60.28
		wet	81.59±19.29	80.02
	2	dry	67.59±21.38	66.07
		wet	83.07±18.58	81.36

TABLE VI. EXPERIMENTAL RESULTS USING VMD WITH DIRECT REMOVAL OF HIGH AND LOW COMPONENTS

Method	Data length(s)	Electrode type	Accuracy(%)	F ₁
CCA	0.5	dry	13.12±9.15	11.52
		wet	14.79±6.38	13.30
	1	dry	26.67±17.55	23.90
		wet	47.08±18.87	44.21
1.5	dry	47.29±21.13	45.08	
	wet	66.46±22.46	65.04	
2	dry	58.13±21.31	55.92	
	wet	73.54±21.74	71.98	
FBCCA	0.5	dry	15.20±8.38	14.45
		wet	20.62±9.40	19.29
	1	dry	30.42±15.80	29.63
		wet	46.67±18.30	45.31
1.5	dry	47.62±20.96	46.53	
	wet	67.00±19.63	65.58	
2	dry	60.79±23.25	59.84	
	wet	77.08±18.82	74.91	
TRCA	0.5	dry	22.38±13.49	20.38
		wet	56.58±20.48	54.13
	1	dry	48.41±22.31	46.98
		wet	74.39±22.19	73.27
1.5	dry	64.02±21.15	63.07	
	wet	84.48±18.12	81.25	
2	dry	71.01±20.18	70.11	
	wet	85.69±17.68	83.21	

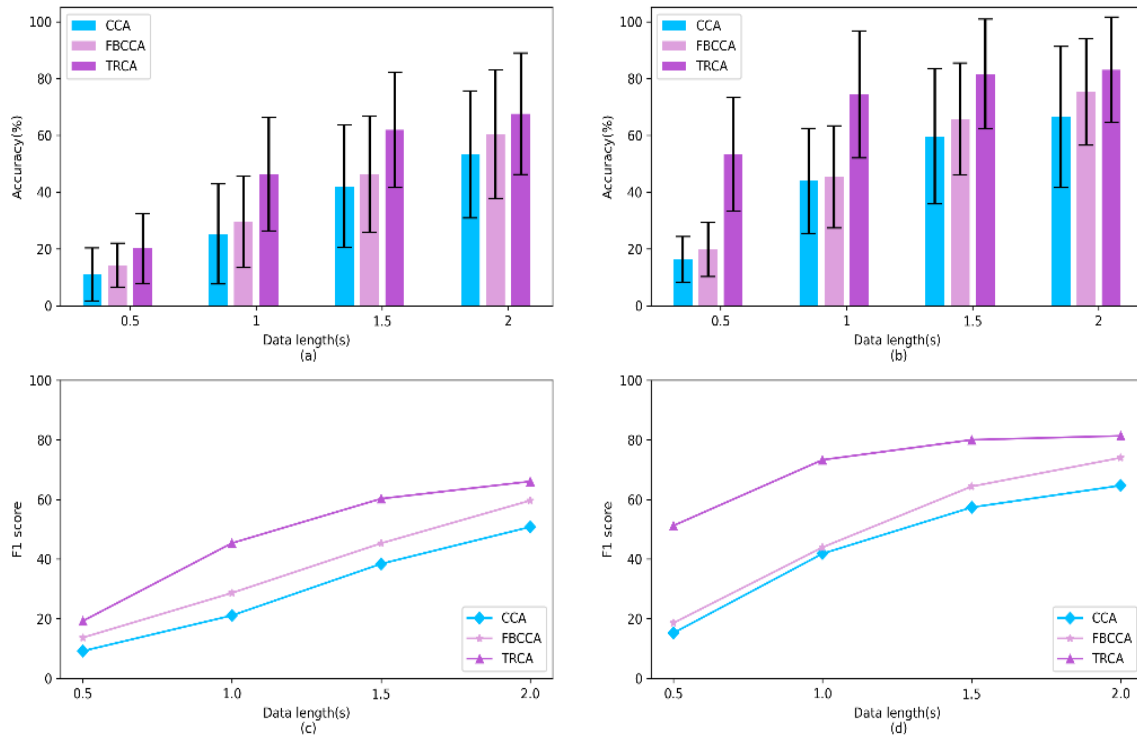

Fig. 4. Experimental results using VMD with adaptive wavelet thresholding: (a) represents the classification accuracy for dry electrodes, (b) represents the classification accuracy for wet electrodes, (c) represents the F₁ score for dry electrodes, (d) represents the F₁ score for wet electrodes

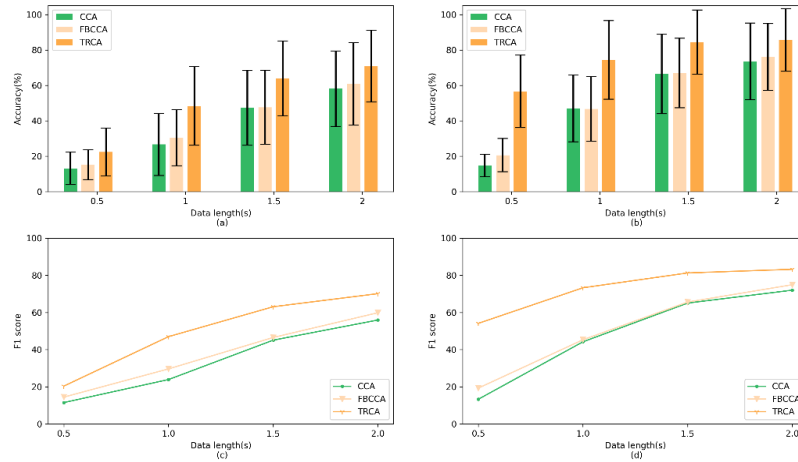

Fig. 5. Experimental results using VMD with direct removal of high and low components: (a) represents the classification accuracy for dry electrodes, (b) represents the classification accuracy for wet electrodes, (c) represents the F_1 score for dry electrodes, (d) represents the F_1 score for wet electrodes

From the above results, it can be observed that compared to directly using the three recognition algorithms, using VMD with adaptive wavelet denoising and direct removal of high and low components both resulted in increased classification accuracy and F_1 score. However, neither of these denoising methods achieved the effectiveness of using VMD with WPT.

V. DISCUSSION

To visually demonstrate the increase in classification accuracy achieved by different denoising methods compared to not using any denoising method, three approaches were set as follows: using VMD combined with adaptive wavelet denoising as Method 1, employing VMD with direct removal of high and low-frequency components as Method 2, and utilizing VMD combined with WPT as Method 3. As shown in Fig. 6, the left side illustrates the increase in classification accuracy for dry electrodes after applying different denoising methods, while the right side reflects the improvement for wet electrodes. Through this comparison, we can clearly observe the enhancement effect of various denoising methods on classification accuracy, thereby providing a more accurate evaluation of the effectiveness of different denoising strategies.

From Fig. 6, it can be observed that the increase in classification accuracy for dry and wet electrodes is highest when using Method 2 of denoising, especially for the CCA recognition algorithm. However, for the FBCCA and TRCA algorithms, the highest increase is observed when using Method 3. The reason for the significant increase in classification accuracy after applying Method 2, particularly for the CCA recognition algorithm, lies in its ability to selectively eliminate noise interference, thereby enhancing the accuracy of signal synchronization detection and complementing the performance of the CCA algorithm.

This study primarily employs VMD for signal decomposition to demonstrate its superiority. Additionally, to delve into the impact of different decomposition methods on wearable EEG data, the data of the same subject are decomposed using EMD, EEMD, CEEMD, and VMD. Subsequently, WPT is uniformly applied for wavelet denoising, and the denoised signals are reconstructed. Fig. 7 illustrates the power spectral density plots of these four decomposition methods, depicting the data from all samples of dry and wet electrodes of subject 5 at a stimulus frequency of 11.25 Hz.

Fig. 6. Increase in classification accuracy

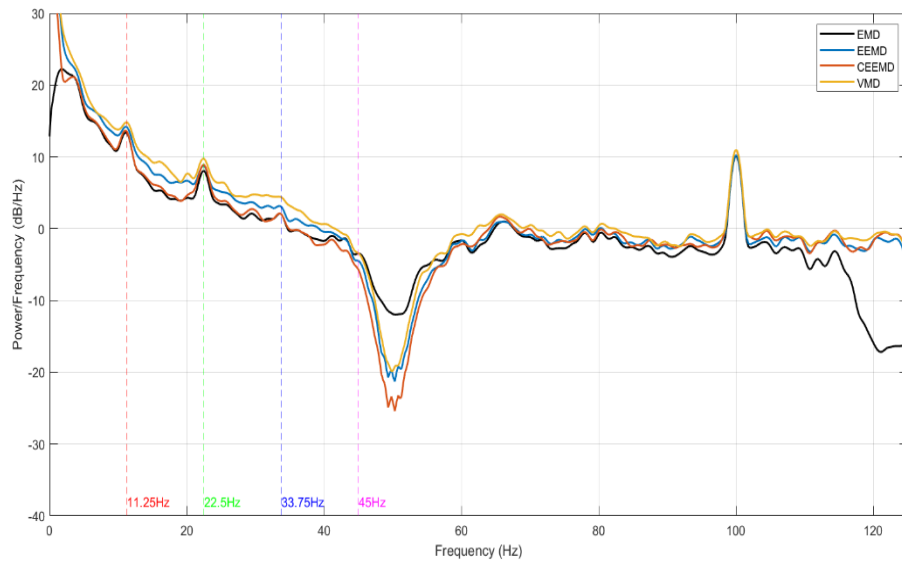

Fig. 7. Power spectral density plots of different decomposition methods

Firstly, it is noticeable that the power spectral density of the signal decomposed and reconstructed using VMD is relatively higher at the stimulus frequency and its first, second, and even third harmonics. This indicates that VMD effectively preserves the characteristics of the original signal at these specific frequencies during decomposition. As an adaptive signal decomposition method, VMD seeks the optimal mode functions to match the intrinsic features of the signal, demonstrating its superiority in handling complex signals. Additionally, it can be observed that the power spectral density of signals decomposed using EEMD is relatively higher compared to CEEMD. This difference may arise from the distinct decomposition strategies employed by these methods. EEMD aids decomposition by adding white noise, effectively suppressing mode mixing phenomena and enhancing decomposition accuracy. On the other hand, CEEMD, an improved version of EEMD, further reduces reconstruction errors and mode mixing by introducing the concept of complete ensemble. However, in some cases, CEEMD may sacrifice the preservation of certain signal features due to its emphasis on noise and mixing elimination. While VMD, EEMD, and CEEMD are all effective methods for handling complex signals, they may exhibit different strengths and limitations depending on the nature of the signal being processed. In practical applications, it is essential to select the appropriate signal decomposition method based on the specific characteristics and requirements of the signal to obtain the most accurate and meaningful results. Moreover, the phenomenon where CEEMD performs less effectively than EEMD in certain cases warrants further research and exploration for optimization and improvement in future work. Comparing the results of our study on wearable SSVEP EEG data with existing research, in reference [37], FBCCA was used for classification on 2-second data lengths, yielding classification accuracies of 59.3% and 77.9% for dry and wet electrodes, respectively. In contrast, our proposed method significantly improves these results, achieving 3.78% and 2.68% higher classification accuracies for dry and wet electrodes using the same FBCCA classification. In reference [38], TRCA, Compact-CNN, Conv-CA, and DNN were used, resulting in classification accuracies of 83.17%,

52.20%, 82.24%, and 71.42% for wet electrodes at the longest data length. In comparison, our method using denoising and TRCA classification improved wet electrode classification accuracies by 3.18%, 34.15%, 4.11%, and 14.93%, respectively. Our study provides a detailed comparison of methods at different stages, discussing their strengths and weaknesses, offering valuable reference and guidance for further research in wearable EEG signal processing.

VI. CONCLUSIONS

The paper proposes a denoising method combining Variational Mode Decomposition (VMD) with wavelet transformation and applies it to the recognition task of wearable SSVEP (Steady-State Visual Evoked Potential) brainwave signals. To validate the effectiveness of this method, the experiments are divided into two core parts. In the first part, three classification algorithms, namely CCA, FBCCA, and TRCA, are directly applied to identify the original signals, and their classification accuracy and F_1 score are recorded. Subsequently, these results are compared with the recognition results of signals processed using the denoising method proposed in this paper. Experimental results show that, after applying the denoising method proposed in this paper, the performance of the three classification algorithms improved significantly across different data lengths. The TRCA recognition algorithm achieved the highest classification accuracy for both dry and wet electrodes, reaching 71.27% and 86.35%, respectively. In the second part of the experiment, the performance of various denoising methods is further compared, including the adaptive wavelet threshold method, the removal of extreme frequency components (high and low frequencies), and the threshold judgment combined with Wavelet Packet Transform (WPT) denoising method proposed in this paper. The core of the proposed method lies in preserving the useful feature information in the decomposed components through fine threshold judgment. The experimental results show that, whether for SSVEP brainwave signals collected from dry electrodes or wet electrodes, the denoising method proposed in this paper exhibits excellent classification accuracy and F_1 score.

In summary, the denoising method combining VMD with wavelet transformation proposed in this paper not only effectively improves the recognition performance of wearable SSVEP brainwave signals but also has certain generalization and application value, providing new ideas and methods for research and practice in related fields. Our next steps will involve exploring additional classification algorithms, optimizing denoising parameters, and processing longer duration data to further enhance recognition performance and broaden applicability.

Abstract—In today's interconnected world, where supply chains are the backbone of commerce, ensuring their resilience and sustainability is paramount. This study investigates how quantity-based strategies in supply chain networks are influenced by sustainability and resilience considerations. A conceptual framework is devised, focusing on a two-echelon supply chain network comprising a central supplier and multiple stores. A stochastic mathematical model is constructed to tackle demand uncertainty while incorporating parameters related to sustainability and resilience. Competitive negotiations between suppliers and stores aim at maximizing expected profits. Two store configurations are examined: non-cooperative and cooperative. Supplier resilience is reinforced through strategies like security stocks and diversified sourcing, while sustainability efforts are considered by the supplier and stores. Results show that demand following a uniform distribution benefits stores and suppliers, and cooperative behavior among stores leads to higher profitability. Sustainability initiatives impact expected profits, with security stocks particularly advantageous for supplier profitability. The utilization of foreign products has a detrimental effect on expected profits, emphasizing the significance of government regulation via customs fees. The study underscores the importance of integrating sustainability and resilience in supply chain networks. It concludes with reflections on model limitations and proposes avenues for future research in this domain.

Keywords—Supply chain management; competition; sustainability; resilience; demand uncertainty

I. INTRODUCTION

In today's business world, managing supply chains is crucial for global expansion, but it faces challenges in sustainability because of growing environmental worries. The delicate balance between profit-driven objectives and eco-friendly practices is underscored by intense competition and demand uncertainties in the global market [1], [2]. This complex interaction means that companies need to be flexible and have good planning for long-term success. Managing uncertainty is very important, not just for making supply chains more sustainable and resilient, but also for staying competitive [3]. Within the supply chain network, the competition between a supplier and a store, often centered around quantity negotiation [4], This underscores the complex scenario that necessitates meticulous equilibrium to address the requirements of all stakeholders.

This research conducts a thorough investigation into sustainability and resilience within a supply chain, comprising a single supplier and multiple stores. It examines challenges related to managing demand uncertainty and profitability, and explores how sustainability impacts the supply chain's ability to handle disruptions, aiming to enhance both sustainability and resilience [5], [6]. Additionally, it seeks to uncover strategies for stores to maximize profits while maintaining sustainable practices, including quantity-based policies, operational efficiency, and the integration of sustainable approaches for profitability [4]. The study concludes by advocating for support of domestic products, exploring methods to promote local manufacturers, manage demand uncertainties, and encourage collaboration among supply chain stakeholders, particularly among stores. This collaboration presents an opportunity to pool resources and reduce costs, aligning with sustainability and resilience objectives.

Numerous comparable studies have investigated the sustainability and resilience of supply chains [7], [8], [9], [10], notably, a prior study [10] where a deterministic model was introduced. It analyzed the strategies of suppliers and stores to maximize profit while achieving sustainability and resilience objectives. However, the study did not account for managing uncertainty, a crucial factor in accurately reflecting real-world complexities. The challenge of the uncertain demand, is amplified by the potential conflict between implementing sustainability and resilience measures and the economic interests of supply chain actors.

Therefore, this study addresses a gap in the literature by investigating the interconnected issues of sustainability, resilience, and managing demand uncertainty within a supply chain [11], [12]. The significance of this research lies in several key aspects. Firstly, it underscores the importance of managing demand uncertainty as a critical approach to enhancing resilience, avoiding overstocks, and preventing shortages [13]. Secondly, the paper uniquely examines sustainability and resilience as competitive advantages, consistently advocating for domestic production [7], [8], [9], [10]. Additionally, cooperation can serve as a competitive advantage for certain companies, offering opportunities to reduce costs through resource pooling, shared logistics, and joint strategies, as seen in the case of stores. Given the complex nature of these interactions, the current study seeks to investigate the following research questions.

- How can the store and the supplier comply with sustainability and resilience requirements and still be competitive?
- What are the quantity-based strategies that the stores and the supplier can employ to maximize their expected profits while taking into account sustainability and resilience?
- What configuration is more advantageous for the store to maximize its profit while also meeting sustainability requirements?

To address these research questions, we will expand on the research conducted in study [10], indeed, this research work focuses on a monopolistic, sustainable, and resilient model operating under uncertainty with two-echelons: the supplier and multiple stores. These entities engage in negotiations to maximize expected profits, leading to two scenarios. The first scenario involves non-cooperation, where individual stores and the supplier independently strive to maximize expected profits based on the delivery quantity. In the second, cooperative scenario, stores collaborate to jointly optimize expected profits while mitigating stockout risks, utilizing a central warehouse for return logistics of excess quantities. Various actors in the supply chain, such as the central supplier, stores, and the government, implement specific strategies. The model addresses resilience by managing demand uncertainty through a stochastic model, implementing security stocks dedicated to each store, and diversifying product sources. Sustainability is incorporated through unit costs associated with eco-friendly practices. Cooperation introduces a central warehouse as a backup supplier, enhancing overall resilience. Logistics of returns are managed to reduce waste and product depreciation [14], [15] amid uncertain demand. The depreciation cost, covering product returns and replenishment fees, aims to promote responsible inventory management and minimize unwarranted returns [14], [15].

The paper is structured as follows: Section II explores previous studies about quantity-based strategies in supply chains. It focuses on making supply chains more sustainable and resilient in competitive environments and uncertain situations. Section III concentrates on building and analyzing a model that includes two different quantity-based strategies. The first strategy involves the non-cooperation of stores, competing independently with the supplier. The second strategy involves a cooperative scenario where stores work together to maximize their expected profit, managing the competitive dynamics with the supplier. In Section IV, a numerical analysis is conducted, employing examples to substantiate the selection of quantity-based strategies in each scenario and making comparisons between uniform and normal distribution cases. Moving to Section V, we present and thoroughly analyze the outcomes obtained from both the developed model and the numerical analysis. Section VI concludes by presenting final observations, highlighting limitations, and suggesting potential avenues for future research.

II. LITERATURE REVIEW

Academic research investigates how uncertainty, resilience, and sustainability meet in competitive supply chains, aiming to guide companies in maintaining efficiency and ecological responsibility despite disruptions. This review emphasizes studies aligning with sustainable strategies under uncertainty and employing game theory to understand competition dynamics.

A. Supply Chain in Competition and Under Uncertainty

Nowadays, strategies to adopt in supply chains to be competitive become significant under conditions of uncertainty, as they play a pivotal role in navigating dynamic market fluctuations and mitigating risks. Broadly, there are two categories of uncertainties: operational and disasters [13]. Operational uncertainties pertain to the configuration of activities, encompassing factors like order timing and product prices [16]. The literature shows that various studies focus on disruption risks in supply chain systems through risk mitigation strategies, and aimed at identifying suitable measures throughout different stages, pre-disaster, during-disaster, and post-disaster [17], [18]. On the other hand, other studies focused on risk aversion strategy, where disruption represents a tangible and unplanned form of uncertainty that necessitates certain actions to anticipate and control uncertainty. In this context, scenario-based models prove to be valuable tools for incorporating disruption and uncertainty in both parameters and variables [19]. A scenario-based approach provides flexibility in addressing uncertainty by considering optimistic, pessimistic, and realistic scenarios [19], [20], [21].

On a different note, it is imperative to emphasize the critical significance of crafting a robust optimization model that not only acknowledges but adeptly addresses the inherent uncertainties linked to parameters and decision variables [22]. The principal origins of such uncertainty, stemming from randomness and fuzziness, have been extensively recognized and documented in notable research works [23], [24]. This profound comprehension of uncertainties is pivotal as it forms the basis for implementing robust scenario-based approaches. The authors in their study [25], consider the investments made by remanufacturers in corporate social responsibility initiatives. Numerous studies within this domain seamlessly integrate the pervasive element of uncertainty. Utilizing stochastic and dynamic programming is by to harmonize sustainability and uncertainty [26]. A bi-objective model is crafted, balancing sustainability with economic costs while addressing uncertainties and demand fluctuations. This study focuses on optimizing the management of unused medications in the pharmaceutical supply chain. Exploring decentralized and centralized models, it introduces an innovative shortage risk-sharing purchase contract. Numerical analysis confirms its effectiveness in aligning the supply chain, improving profitability, and ensuring financial sustainability. This model provides a strategic approach to minimize costs while highlighting the advantages of various management approaches in the pharmaceutical sector.

B. Sustainability Under Uncertainty

In the evolving landscape of supply chain management, the integration of sustainability has become imperative. Organizations are increasingly recognizing the need to align operations with environmental considerations, societal expectations, and effective management of uncertainty [27]. The strategic deployment of strategies is pivotal in balancing economic objectives with sustainability goals [10]. This symbiotic relationship holds the key to resilience and long-term success in the global marketplace.

Navigating the intricate landscape of supply chains, the integration of sustainability becomes inherently linked with the overarching concept of uncertainty as organizations grapple with dynamic variables and unforeseen challenges in their pursuit of environmentally and socially responsible practices [13]. Many studies address challenges of uncertainty in designing a sustainable and competitive supply chain. Incorporating environmental, societal, and economic dimensions. The model proposed of the study [28] concerns a supply chain structure involving two clusters, a retailer, and a government orchestrator. The application of six model variations to a real-world case study in the Iranian leather industry illustrates the model's utility in navigating uncertainties while promoting sustainability across the supply chain. Managing production, distribution, and staffing while dealing with uncertainty in the perishable goods industry is the concern of the work [29] that used a new method, FDSL-NSGA-II. Tested in the dairy industry, this model improves the balance between various aspects of the supply chain and reduces environmental impacts. Similarly, an interesting work presented a sustainable dual-objective blood supply chain [30], highlighting diverse environmental and social considerations in the blood decomposition process. They integrated uncertainty into the model, specifically addressing variables such as the volume of blood collected at transfusion laboratories and the decomposition rate at blood decomposition facilities. Delving into the intricacies of supply chain management and decision making strategies, an investigation conducted by [31] incorporates considerations of carbon emissions and customer preferences, all within the context of supply uncertainties stemming from the ongoing impact of COVID-19. Utilizing a non-linear programming model, the study formulates optimal strategies, shedding light on the potential risks of substantial losses and the consequential impact on business sustainability when uncertainties are not adequately addressed.

C. Sustainable Supply Chain in Competition and Under Uncertainty

Numerous studies have been undertaken to address the effective handling of disruptive risks [11], [18], [32]. They have focused on implementing supply chain resilience, utilizing both preventive and reactive strategies, and sustaining accomplishments in risk management within the supply chain over an extended period. Studies like [33], [34] focused on reactive strategy. Such as the examination of a pharmaceutical supply chain network design problem, incorporating considerations for resilience and sustainability in the face of operational and disruptive risks [33]. Also, the investigation of both resilience and sustainability concurrently within the context of Supply Chain Network Design in the presence of

disruptive and operational risks [34]. As a preventive strategy, the work of [35] focused on enhancing resilience against disruptive risks and developed an environmentally sustainable supply chain network. On the other hand, some other proactive strategies were adopted to enhance profitability during disruptions [11]. The simultaneous management of disruption risks and uncertainties was revealed to contribute significantly to achieving sustainability goals while reducing associated costs. Regarding the aim to design a resilient supply chain within a competitive environment, the focus on redesigning a resilient topology for a specific setting to quickly recover from disruptive incidents was examined in the work [36] proposing three proposed policies, maintaining emergency stock at retailers, reserving backup capacity at suppliers, and employing multiple-sourcing, are explored to mitigate disruption risk. Simultaneously, another study delves into the realm of intra-supply chain competition, where producers and resellers navigate uncertainties and disruption risks to achieve their respective goals [37]. Sustainability and resilience both play crucial roles in shaping supply chain pricing strategies. Additionally, the investigation into the promotion of domestic products was explored in the study [10] and adopted a preventive strategy for risk aversion. The proposed model delves into stakeholder interactions, revealing the substantial impact of stores' sustainability efforts on pricing, supplier resilience strategies, and the role of governmental regulations. However, the study acknowledges limitations in the deterministic model, citing its potential oversimplification of real-world complexities and emphasizes the importance of managing demand uncertainty through a stochastic model.

Maximizing profit forms a central focus in a significant portion of sustainable resilient supply chain [38]. Exploring the complexities of the location-pricing problem in a two-echelon supply chain, this study underscores the dual focus on profit maximization and effective uncertainty management. Notably, considering social preferences, especially in a competitive context, leads to increased profit margins for the entire supply chain [12]. Furthermore, the exploration extends to scenarios where the collection process is collaboratively undertaken by both the manufacturer and the retailer, as observed in the study by [39], which specifically delves into decision-making process within a cross-channel recycling context. Consumer consciousness is at the forefront when scrutinizing two distinct strategies: one employing uniform prices for both new and remanufactured products, and the other adopting disparate pricing [40]. The findings reveal potential advantages in equal pricing, especially when a significant proportion of consumers prioritize environmental considerations. In such instances, aligning strategies with the preferences of environmentally conscious customers can yield favorable outcomes.

Many authors explored centralized and decentralized models in context of competition. The optimization of the management of unused medications in the pharmaceutical supply chain was investigated [41]. The model introduced an innovative shortage risk-sharing purchase contract. Numerical analysis confirms its effectiveness in aligning the supply chain, improving profitability, and ensuring financial sustainability. Similarly, another research work explored the imperative for

green reform amid environmental challenges. Investigating Green Technology Investment (GTI) decisions, it unveils a two-sided matching mechanism's influence on stable matches [42]. The findings highlight nuanced impacts of carbon prices and green improvement coefficients on GTI, product pricing, and profits. Similarly, the centralized and decentralized scenarios were Distinguished in the work [43] where quality considerations were incorporated into the analysis.

With the intention of closing a gap in the literature, we consider uncertainty, sustainability and resilience parameters within a supply chain while model. As in practice, stochastic parameters play a pivotal role in decision-making processes, and integrating sustainability factors ensures a comprehensive approach that aligns with contemporary environmental and ethical considerations. This inclusive model aims to provide a more accurate representation of real-world scenarios, contributing to a nuanced understanding of the interplay between uncertainty, sustainability, and quantity-based strategies in supply chain management.

III. MODELING FORMULATION AND ANALYSIS

In this section, the focus is on the development and analysis of a supply chain network model under competitive dynamics, incorporating uncertainty parameters. The exploration encompasses the mathematical representation of variables such as quantity, sustainability, and resilience.

A. Model Description and Assumptions

In this study, a two-echelon supply chain model is developed, as illustrated in Fig. 1 and Fig. 2, featuring a supplier, stores. The model addresses uncertain demand through a stochastic demand (D_i). Effectively managing uncertainty in demand is pivotal for the supply chain's operational efficiency and resilience. By including stochastic elements, the model recognizes variability of the market demand, helping the supply chain make decisions in various situations.

In the developed model, the supplier and the store, both in competition, seek to maximize expected profits, initiating a negotiation where each determines the optimal delivery quantity. This leads to two scenarios: the non-cooperative scenario, where store i and the supplier compete to individually maximize their expected profits by adopting a strategy based on the quantity to deliver (Q_i). In contrast, the cooperative scenario involves collaboration among stores to jointly maximize their expected profits while mitigating the risk of stockouts. This collaboration is facilitated by utilizing a central warehouse to manage the logistics of returns for excess quantities from store i .

Each actor of the supply chain influences others through specific strategies. The central supplier distributes a quantity (Q_i) of both foreign and domestic products to multiple stores at a wholesale price (ω_i). As the ultimate points of sale, stores not only retail products in the market at a designated price (p_i) but also play a pivotal role in making critical decisions related to delivery quantities (Q_i), sustainability initiatives (e_i), and managing uncertainties in demand [44]. The supplier, while not directly involved in production, assumes a pivotal role in distribution, negotiating quantities (Q_i), and managing security

stock (ψ_i) with each store for more resiliency [45] and considering sustainability (e_s) for each product. The government intervenes by imposing custom fees (τ) on foreign products and providing subsidies (ν) to boost domestic products [9]. Additionally, it fulfills a regulatory function by balancing the quantities of foreign and domestic products in the market, diversifying product sources for enhanced resilience, and promoting sustainability practices.

The resilience of the supply chain is comprehensively addressed in this model, manifesting in multiple ways. Firstly, managing demand uncertainty (D_i) through a stochastic model is a crucial element to mitigate the risks of disruptions and ensure a high level of customer service [44]. Secondly, the implementation of security stocks (ψ_i) dedicated to each store i by the supplier further strengthens resilience in response to the specific demand of store i . This reserved quantity (ψ_i) serves as a buffer, enabling the supplier to adeptly address fluctuations in demand and unexpected disruptions within the supply chain [45]. Thirdly, the diversification of product sources affords the option between locally sourced and imported products, offering an import alternative in the event of a shortage of local products [44]. Additionally, in the cooperative scenario, the introduction of a central warehouse in the initial configuration allows for consolidating surplus products from each store through mutualization, thereby ensuring supply in times of need. This central warehouse serves as a backup supplier [44] for the store, constituting a second source of products and contributing to fortifying its resilience.

Sustainability in the supply chain is considered by both the supplier and the store. The costs (e_s), (e_i) and (e') are all of them sustainability unit costs for the supplier, the store and the central warehouse respectively. These costs include expenses of activities and investments that promote sustainability, such as addressing the CO₂ emissions tax [46] linked to product transportation, refurbishing products in an environmentally friendly manner, mandating sustainable packaging, implementing recycling initiatives, etc. As demand is uncertain, the potential risk of surplus products ($Q_i - D_i$) in each store becomes a concern [47]. Therefore, managing the logistics of returns for excess quantities in the cooperative case is a crucial element, thus reducing waste and product depreciation (l).

The depreciation cost (l) considered between the supplier and stores, represents the expense linked to product returns from stores to the supplier [14], [15]. This cost is designed to offset the loss in value resulting from product use in the store, aiming to incentivize responsible inventory management and minimize unwarranted returns. The depreciation cost also encompasses replenishment fees, covering the expenses associated with reintegrating returned products into the supplier's inventory. These expenses typically involve processes such as inspection, refurbishment, and repackaging.

1) *Non-cooperative scenario*: In the non-cooperative model as illustrated in Fig. 1, stores and the supplier, all in competition, seek to maximize their expected profits independently. Individual stores engage in negotiations with the supplier, independently determining the optimal quantity

(Q_i^{*NC}) of products to order considering demand uncertainty. On the other hand, the supplier aims to maximize sales and determine its optimal quantity (\bar{Q}_i^*) of products to deliver to the store.

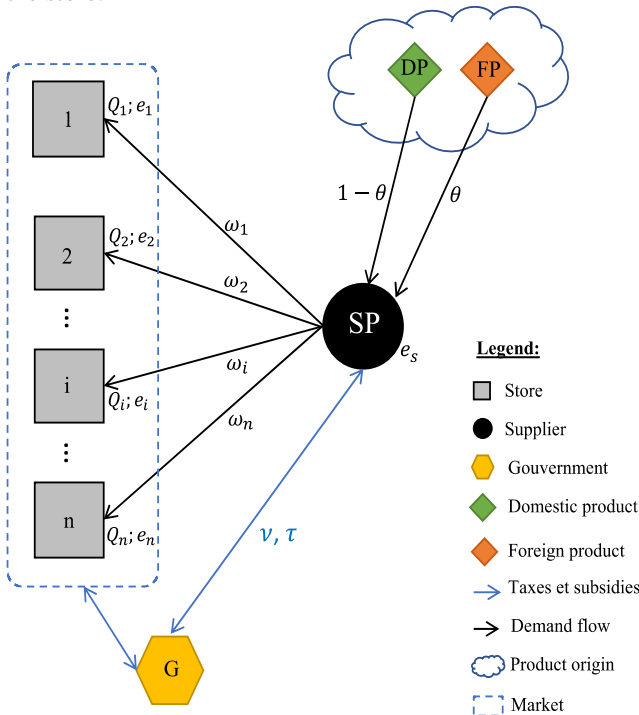

Fig. 1. The non-cooperative supply chain network model comprising stores and a single supplier.

The potential risk of surplus products $(Q_i - D_i)$ in each store is a concern when $(D_i > Q_i)$. Therefore, a depreciation cost (l) is considered in the non-cooperative configuration for the store [14], [15]. Similarly, the shortage cost (z) is mandatory if case of stockouts [4]. For the store, this represents an expense; however, it enables the supplier to not only mitigate financial losses associated with returns but also encourages stores to maintain a high standard of quality in their inventory management practices.

2) *Cooperative scenario*: In the non-cooperative configuration, stores engaged in individual competition with the supplier strive to maximize their expected profits independently. This model, characterized by a lack of cooperation, does not foster synergy among stores, which could potentially lead to a reduction in costs related to storage and depreciation. Furthermore, the presence of excess quantities introduces an increased risk of expiration or obsolescence, resulting in financial losses for the stores.

On the other hand, in the cooperative configuration illustrated in Fig. 2, stores are encouraged to collaborate to maximize their expected profits while still competing with the supplier and engage in negotiations determining the optimal quantity (Q_i^{*CO}) . This collaboration materializes through the establishment of a central warehouse, playing a crucial role, especially in the face of uncertain demand. Excess quantities $(Q_i - D_i)$ that remain unsold in the stores are redirected to this

central warehouse, acting as a reserve to prevent stockouts in case of high demand $(D_i > Q_i)$. This cooperation among stores enables the distribution of responsibilities among them and the pooling of resources by sharing fixed costs of the central warehouse represented by the ratio (φ) that is the quote part of central warehouse fixed costs for each store, minimizing costs, notably the depreciation cost (l) and shortage cost (z) that are not considered in the cooperative scenario for the store, and reinforcing the resilience of the stores. This centralization also minimizes the risk of expiration, depreciation, or obsolescence of products in the stores, providing the opportunity to sell them in other secondary markets, notably to the supplier.

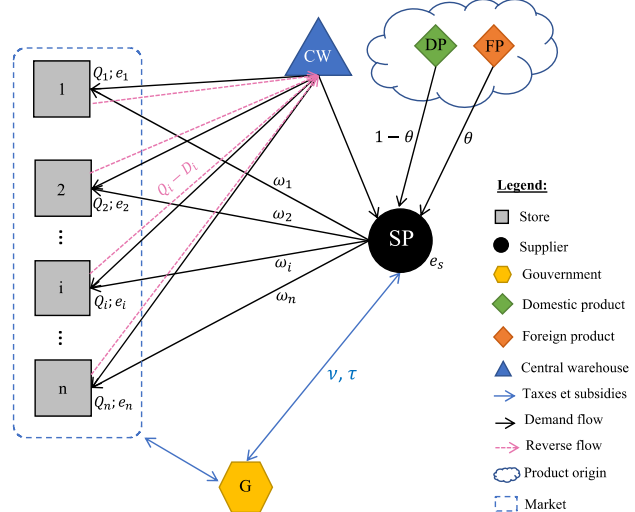

Fig. 2. The cooperative supply chain network model comprising stores and a single supplier.

The main objective of this competitive supply chain model of a single supplier and multiple stores, is to explore the interactions among these actors, their impact on each other, and the influence of sustainability and resilience on their expected profits.

3) *Assumptions*: In the two scenarios outlined in our uncertain supply chain model, various fundamental assumptions are formulated to simplify and delineate the context of our analysis. These assumptions establish the parameters, relationships, and foundational conditions that govern our system. They play a crucial role in framing our study with precision and rigor.

- $l < \omega_i, p_i$
- We assume a market configuration characterized by monopoly at store level;
- We assume that the customers have the same quality preference for products;
- We assume that all products are depreciated at the same level;
- Store i receives its supplies from a single supplier;
- In the cooperative configuration, store i can be supplied by the central warehouse;

- The supplier sets varying selling prices through negotiations with each store i ;
- The Store i handles the collection and transportation of unsold surplus products to the central warehouse, incurring CO₂ emissions that are subject to taxation by the government (e');
- The supplier dedicates an inventory quantity (ψ_i) as a security stock for each store i .

Given the aforementioned assumptions, the expected objective functions of the problem for both scenarios, the cooperative and non-cooperative, to be modeled are as follows:

- Maximize store expected profit (cooperative and non-cooperative scenario);
- Maximize supplier expected profit.

4) *Model parameters and variables*: The notations employed in the mathematical model are listed below. The superscripts 'NC' and 'CO' signify the non-cooperative and cooperative scenarios, respectively.

Parameters and variables

D_i : The stochastic demand at the store, which adheres to the probability density function $f(x)$ and the cumulative distribution function $F(x)$

Q_i : order quantity of store i

p_i : unit price of a product at store i

p' : buyback unit price of a product by the central warehouse from the store i

e_i : unit sustainability cost for store i

e_s : unit sustainability cost for the supplier

e' : unit sustainability cost for the central warehouse

c_i : store's operating unit cost

c_s : supplier's operating unit cost

c : overall operating unit cost of supplier

z : shortage cost per unit for store i

ψ_i : ratio of inventory quantity reserved for store i

δ : ratio of supplier's wholesale price dedicated to holding products

l : depreciated cost

τ : custom fees

v : government subsidy

θ : ratio of quantity of foreign products, $\theta \in [0,1]$

φ : quote part of central warehouse fixed costs for each store

ω_i : supplier wholesale price of the product

ω' : central warehouse wholesale price of the product

Expected profit functions

$E^{NC}(\pi_i)$: expected profit of store i for the non-cooperative scenario

$E^{CO}(\pi_i)$: expected profit of store i for the cooperative scenario

$E(\pi_{i,s})$: expected supplier profit with one store

$E(\pi_s)$: expected supplier profit for the whole network

B. Model Construction and Analysis

The mathematical model presented in this research provides a formal representation of key interactions within a

network involving a central supplier and multiple stores. It offers an analytical framework to explore and interpret underlying dynamics within the contexts of two scenarios: cooperative and non-cooperative one.

5) Expected profit of Store i

a) *Expected profit of Store i for the non-cooperative scenario*

In this sub-section, the store's profitability is studied for the non-cooperative structure.

The expected profit Eq. (1) for store i for the non-cooperative configuration is given as follows.

$$E(\pi_i^{NC}(Q_i)) = (p_i - e_i)E[\min(Q_i, D_i)] - (\omega_i + c_i)Q_i - zE[\max(0, D_i - Q_i)] + (\omega_i - l)E[\max(0, Q_i - D_i)] \quad (1)$$

In the Eq. (1), the first term represents the total revenue generated by selling products in the market (p_i), taking into account the sustainability cost of the store i (e_i) that varies due to demand uncertainty. The second term expresses the cost of purchasing products from the supplier (ω_i), minus the operational cost (c_i) of store i . The third term indicates the shortage cost (z) per unit for store i . The last term represents the difference between the supplier wholesale price and the depreciation cost (l) in the case of the surplus of quantity of items. The purpose of this cost (l) is to counterbalance the reduction in value attributed to product use in the store, with the goal of encouraging responsible inventory management.

With some algebra, the expected profit for store i in the non-cooperative scenario will be the following Eq. (2).

$$E(\pi_i^{NC}(Q_i)) = -Q_i(c_i + l) + E(D_i)(l - e_i + p_i - \omega_i) - (l - e_i + p_i - \omega_i - z) \int_{-\infty}^{Q_i} (D_i - Q_i) f(D_i) dD_i \quad (2)$$

The store i can adopt the strategic option of determining the optimal quantity to order from the supplier considering sustainability. If we consider the scenario where the store exclusively prioritizes the quantity strategy, the optimal quantity for maximizing expected profit based on the Eq. (2) is presented in the Eq. (3):

$$Q_i^{*NC} = F_{D_i}^{-1}\left(\frac{-c_i - l}{l - e_i + p_i - \omega_i - z}\right) \quad (3)$$

Proof. Maximum expected profit is sought by deriving the expected profit function $E(\pi_i^{NC}(Q_i))$.

$$\frac{\partial E(\pi_i^{NC}(Q_i))}{\partial Q_i} = (-c_i - l) - (l - e_i + p_i - \omega_i - z)F_{D_i}(Q_i)$$

The second derivative of the expected profit function for the store i with respect to (Q_i) is: $\frac{\partial^2 E(\pi_i^{NC}(Q_i))}{\partial^2 Q_i} = -(l - e_i + p_i - \omega_i - z)f_{D_i}(Q_i)$

We have: $\frac{\partial^2 E(\pi_i^{NC}(Q_i))}{\partial^2 Q_i} < 0$ thus, the function admits a maximum.

Knowing that $F_{D_i}(Q_i) = \int_{-\infty}^{Q_i} f(D_i) dD_i$ so $f_{D_i} > 0$

And $(l - e_i + p_i - \omega_i - z) > 0$ with $p_i > e_i + \omega_i + z$ and $l, e_i, p_i, \omega_i, z > 0$

The maximum is obtained by solving $\frac{\partial E(\pi_i^{NC}(Q_i))}{\partial Q_i} = 0$.

b) Expected Profit of Store i for the Cooperative Scenario

In this sub-section, the store's profitability is examined within the cooperative configuration, where stores cooperate to maximize their expected profits while still competing with the supplier.

The expected profit Eq. (4) for store i in the cooperative scenario is given as follows.

$$E(\pi_i^{CO}(Q_i)) = (p_i - e_i)E[\min(Q_i, D_i)] - (\omega_i + c_i)Q_i - \omega' E[\max(0, D_i - Q_i)] + (p' - e')E[\max(0, Q_i - D_i)] + \varphi \tag{4}$$

In the Eq. (4), the initial term signifies the overall revenue derived from selling products in the market at the store i's price (p_i), considering the store's sustainability cost (e_i). Second term denotes the expense incurred in procuring products from the supplier (ω_i), minus the operational cost (c_i) of store i. The third term indicates the replenishment quantity ($D_i - Q_i$) required and supplied by the central warehouse and (ω') is the central warehouse wholesale price of the product. The fourth term represents the store's revenue obtained by reselling the surplus quantity ($Q_i - D_i$) to the central warehouse at the price (p') considering the central warehouse sustainability cost (e_i) which is proportionally borne by each store i. The last term (φ) represents the quote part of each store i of central warehouse expenses.

With some algebra, the expected profit for store i in the cooperative scenario will be the following Eq. (5).

$$E(\pi_i^{CO}(Q_i)) = (p' - e')\varphi + Q_i(-e' + p' - \omega_i - c_i) + E(D_i)(e' - e_i + p_i - p') + (-e' + p' - \omega' + e_i - p_i) \int_{-\infty}^{Q_i} (D_i - Q_i) f_{D_i} dD_i \tag{5}$$

By adopting a strategy based on quantity, the optimal quantity for the store i to order from the supplier considering sustainability is the following presented in the Eq. (6):

$$Q_i^{*CO} = F_{D_i}^{-1} \left(\frac{-e' + p' - \omega_i - c_i}{-e' + p' - \omega' + e_i - p_i} \right) \tag{6}$$

Proof. Maximum expected profit is sought by deriving the profit function $E(\pi_i^{NC}(Q_i))$.

$$\frac{\partial E(\pi_i^{CO}(Q_i))}{\partial Q_i} = (-e' + p' - \omega_i - c_i) + (-e' + p' - \omega' + e_i - p_i) F_{D_i}(Q_i)$$

The second derivative of the expected profit function for the store i with respect to (Q_i) is: $\frac{\partial^2 E(\pi_i^{CO}(Q_i))}{\partial^2 Q_i} = -(p' + p_i + \omega' - e_i + e') f_{D_i}$

We have: $\frac{\partial^2 E(\pi_i^{CO}(Q_i))}{\partial^2 Q_i} < 0$ thus, the function admits a maximum.

6) Expected profit of supplier: In the context of both non-cooperative and cooperative configurations, the supplier seeks

to maximize its expected profit with regard to individual stores and the entire network. In this subsection, we begin by examining the supplier's profitability concerning store i and subsequently explore the overall network profitability.

a) Expected profit of supplier in relation to one store i

Our attention is directed towards analyzing the supplier's profitability with regard to one store i.

We consider the overall operating unit cost of supplier $c = c_s + e_s$ with (e_s) and (c_s) as sustainability cost and the operational cost of the supplier respectively.

The supplier expected profit function related to one store i is as follows:

$$E(\pi_{i,s}(Q_i)) = Q_i(\omega_i - c) - (\omega_i - l)E[\max(0, Q_i - D_i)] - \delta \omega_i \psi_i Q_i \tag{7}$$

In the Eq. (7), the first term pertains to the supplier's expected profit from selling the quantity (Q_i) to a single store i at the price (ω_i), while accounting for sustainability costs (e_s) which mainly concern the CO₂ emissions tax linked to product transportation and operational expenses (c_s). The second term involves the cost of unsold quantities ($Q_i - D_i$) that have depreciated (l). The final term is the holding cost ($\delta \omega_i$) associated with the reserved quantity ($\psi_i Q_i$) allocated by the supplier to store i. Here, (δ) and (ψ_i) represent the ratio of supplier's wholesale price dedicated to holding products and ratio of inventory quantity reserved for store i respectively.

With some algebra, the expected profit for the supplier will be the following Eq. (8):

$$E(\pi_{i,s}(Q_i)) = E(D_i)(-l + \omega_i) - Q_i(c_s + e_s - l + \delta \psi_i \omega_i) - (-l + \omega_i) \int_{-\infty}^{Q_i} (D_i - Q_i) f_{D_i} dD_i \tag{8}$$

Considering the strategy where the supplier exclusively prioritizes the quantity, the optimal quantity for maximizing its expected profit with one store i based on Eq. (8) is presented in the Eq. (9):

$$\hat{Q}_i^* = F_{D_i}^{-1} \left(-\frac{(c_s + e_s - l + \delta \psi_i \omega_i)}{(\omega_i - l)} \right) \tag{9}$$

Proof. Maximum supplier expected profit is sought by deriving the expected profit function $E(\pi_{i,s}(Q_i))$.

$$\frac{\partial E(\pi_{i,s}(Q_i))}{\partial Q_i} = -(c_s + e_s - l + \delta \psi_i \omega_i) - (\omega_i - l) F_{D_i}(Q_i)$$

The second derivative of the expected profit function for the supplier with respect to (Q_i) is:

$$\frac{\partial^2 E(\pi_{i,s}(Q_i))}{\partial^2 Q_i} = -(\omega_i - l) f_{D_i}(Q_i)$$

We have: $\frac{\partial^2 E(\pi_{i,s}(Q_i))}{\partial^2 Q_i} < 0$ thus, the function admits a maximum. Since the wholesale price (ω_i) of the supplier is significantly higher than the depreciation cost (l), the density function f_{D_i} is positive.

The maximum is obtained by solving $\frac{\partial E(\pi_{i,s}(Q_i))}{\partial Q_i} = 0$.

b) Expected profit of supplier for the whole stores network

In this subsection, our analysis is initiated by the examination of the supplier's overall expected profitability throughout the entire network, incorporating elements extending beyond direct dependence on store demands. These elements include the promotion of domestic products through subsidies and the taxation of foreign products, presenting an alternative option regulated by the government.

The supplier expected profit function for the whole network is presented in the Eq. (10):

$$E(\pi_s(Q_i)) = \sum_{i=1}^n E(\pi_{i,s}(Q_i)) - C(\tau) + I(v) \quad (10)$$

With:

$$\sum_{i=1}^n Q_i = Q, C(\tau) = \tau \cdot \theta Q, I(v) = (1 - \theta)vQ$$

The customs fees paid by the supplier to the government for the percentage (θ) of the quantities imported are represented by $C(\tau)$. Contrariwise, the government grants the supplier a subsidy, $I(v)$, for a percentage $(1 - \theta)$ of the quantities obtained from local suppliers.

Considering w mean wholesale price of the supplier, then:

$$w = \frac{\sum_{i=1}^n \omega_i}{n}$$

To make the calculation easier, we assume that $\sum_{i=1}^n \omega_i Q_i = nwQ$ and that the stores order almost the same quantities. The overall expected profit of the supplier is the sum of the expected profits made with each store i and is represented in the Eq. (11):

$$\sum_{i=1}^n E(\pi_{i,s}(Q_i)) = nE(D_i)(-l + w) - Q(c_s + e_s - l - \delta\psi_i nw) + n(l - w) \int_{-\infty}^{Q_i} F_{D_i}(Q_i) \quad (11)$$

By replacing Eq. (11) in Eq. (10) we get the global supplier expected profit in the Eq. (12):

$$E(\pi_s(Q)) = n \left[Q(v - \theta(v + \tau) - c_s - e_s + l + \delta\psi_i nw) + E(D_i)(-l + w) + (l - w) \int_{-\infty}^{Q_i} F_{D_i}(Q) \right] \quad (12)$$

Considering the strategy where the supplier exclusively prioritizes the quantity, the optimal quantity for maximizing its global expected profit within the whole network based on Eq. (12) is presented in the Eq. (13):

$$\widehat{Q}_{i,s}^* = F_{D_i}^{-1} \left(\frac{(v - \theta(v + \tau) - c_s - e_s + l + \delta\psi_i nw)}{(w - l)} \right) \quad (13)$$

With some algebra the optimal price w^* for the supplier according to $(\widehat{Q}_{i,s}^*)$ is presented in the Eq. (14):

$$w^* = \frac{l(F_{D_i}(\widehat{Q}_{i,s}^*) + 1) + v - \theta(v + \tau) - c_s - e_s}{F_{D_i}(\widehat{Q}_{i,s}^*) - \delta\psi_i n} \quad (14)$$

Proof. Maximum supplier's global expected profit is sought by deriving the expected profit function $E(\pi_s(Q))$.

$$\frac{\partial E(\pi_s(Q))}{\partial Q} = n \left[(v - \theta(v + \tau) - c_s - e_s + l + \delta\psi_i nw) + (l - w) F_{D_i}(Q) \right]$$

The second derivative of the global expected profit function for supplier with respect to (Q) is:

$$\frac{\partial^2 E(\pi_s(Q))}{\partial^2 Q} = -n \left[(w - l) f_{D_i}(Q) \right]$$

We have: $\frac{\partial^2 E(\pi_s(Q))}{\partial^2 Q} < 0$ thus, the function admits a maximum. Since the wholesale price (w) of the supplier is significantly higher than the depreciation cost (l) and the density function f_{D_i} is positive.

IV. NUMERICAL ANALYSIS

This section conducts a numerical analysis to draw conclusions on sustainability and resilience in logistics supply chains, emphasizing quantity-based strategies and sustainability practices within defined constraints. Due to demand's probabilistic nature in the model, forecasts may be inaccurate. Two configurations, cooperative and non-cooperative, are analyzed considering both uniform and normal demand distributions.

The numerical parameters and datasets presented in Tables I and II are utilized for this analysis and pertain to both the store and the supplier. These have been selected after a thorough review of existing literature [4], making sure they conform to methodologies. To enhance the overall validity and reliability of our numerical approach, we carefully select these values to align with the specific assumptions stated in our study.

Table I and Table II also present the outcomes of the proposed model, considering two distinct demand distribution functions: the uniform and the normal, respectively, along with two distinct configurations for the store: the cooperative configuration and the non-cooperative one. In order to effectively use the dataset, it was necessary to consider six scenarios, where the main variable parameter was the sustainability costs (e_i) and (e_s). Indeed, the sustainability cost, as a variable parameter, is manipulated to observe its impact on optimal quantities and expected profits.

TABLE I. DATA SETS AND RESULTS OF APPLYING PROPOSED MODELS ON NUMERICAL EXAMPLES FOR A UNIFORM DISTRIBUTION

The store's non-cooperative case: uniform distribution			
$c_i = 20, p_i = 130, \omega_i = 40, l = 4, z = 80, D \sim (a, b) = (100, 200)$			
Scenario	e_i	Q_i^{*NC}	$E^{NC}(\pi_i)$
1	59	153,33	3330,00
2	60	152,17	3221,74
3	61	151,06	3111,70
4	62	150,00	3000,00
5	63	148,98	2886,73
6	64	148,00	2772,00

The store's cooperative case: uniform distribution $c_i = 20, p_i = 130, \omega_i = 60, e' = 20, p' = 90, \omega' = 110, \varphi = 10\%$ $D \sim (a, b) = (100, 200)$			
Scenario	e_i	Q_i^{*CO}	$E^{CO}(\pi_i)$
1	59	109,01	4770,51
2	60	109,09	4661,55
3	61	109,17	4553,33
4	62	109,26	4445,89
5	63	109,35	4339,24
6	64	109,43	4233,42
The supplier case: uniform distribution $c_s = 23, w = 130, n = 3, v = 77, \theta = 65\%, \tau = 11, \psi = 40\%, \delta = 30\%$ $l = 10, D \sim (a, b) = (100, 200)$			
Scenario	e_s	Q_{ts}^*	$E(\pi_s)$
1	12	128,00	11150,40
2	13	123,00	10697,40
3	14	118,00	10274,40

C. Profit Optimization and Sustainability

In this subsection, the examination of the expected profits of the supplier and the store under various scenarios, considering uniform and normal distribution cases, is conducted. Additionally, the optimal quantity of the aforementioned logistics actors in these distributions across non-cooperative and cooperative configurations is illustrated.

Given the nature of demand (D_i), when it follows a uniform distribution, the optimal quantities for the store and the supplier exceed those associated with demand following a normal distribution, as demonstrated in Table I and Table II. Similarly, the expected profits generated by the supplier and the store in non-cooperative and cooperative configurations are higher when demand (D_i) follows a uniform distribution compared to a normal distribution, as presented in Table I and Table II. In a distribution network comprising multiple stores and a supplier, when the demand (D_i) follows a uniform distribution, it is advantageous for both the store and the supplier to have a regular demand to maximize profit. However, in the case of a normal distribution, the demand may not be regular.

Comparing the store's expected profit in both cooperative and non-cooperative scenarios, regardless of the demand nature, whether it follows a uniform or normal distribution, the cooperative scenario yields higher expected profit, as depicted in Tables I and II. Therefore, the store has an interest in cooperating to maximize its expected profit. The proposed cooperative configuration actively promotes store collaboration by sharing central warehouse-related costs and pooling resources, particularly the surplus quantities ($Q_i - D_i$), which are returned and resold to the central warehouse, resulting in a reduction of depreciation (l) and stockout (z) costs.

Fig. 3. The store's optimal quantity variation by store sustainability cost (e_i) for the cooperative configuration.

Fig. 3 depicts the evolution of the store's optimal quantity (Q_i^{*NC}) with the store sustainability cost (e_i) increase in a non-cooperative configuration. The optimal quantity (Q_i^{*NC}) for the normal distribution initially is significantly higher than that of the uniform distribution and decreases rapidly with the increase in (e_i). Similarly, it is possible to determine the optimal sustainability cost (e_i) corresponding to the intersection of the two curves, especially in the absence of information on demand evolution.

Fig. 4. The store's optimal quantity variation by store sustainability cost (e_i) for the cooperative configuration.

Fig. 4 shows the evolution of the store's optimal quantity (Q_i^{*CO}) with the store sustainability cost (e_i) increase in a non-cooperative configuration. The optimal quantity (Q_i^{*CO}) increases substantially with the rise in sustainability cost (e_i), regardless of the distribution type. However, this increase is particularly significant when dealing with a normal distribution. Beyond a certain value of (e_i) (around 70), the optimal quantity becomes insensitive to a large increase in (e_i).

Fig. 5. The supplier's optimal quantity variation by supplier sustainability cost (e_s).

The optimal quantity (\widehat{Q}_{IS}^*) in the supplier's case decreases with the rise of the supplier's sustainability cost (e_s), as depicted in Fig. 5. A distinct contrast is observable between the normal and uniform distributions. In the case of the uniform distribution, the optimal quantity (\widehat{Q}_{IS}^*) for the supplier has decreased significantly following a slight variation in the sustainability cost (e_s). Conversely, in the case of a normal distribution, the optimal quantity (\widehat{Q}_{IS}^*) gradually decreases with a larger variation in the sustainability cost (e_s).

The correlation between sustainability costs and expected profit remains consistently evident. Fig. 6, 7, and 8 illustrate the expected profit evolution concerning quantity in the case of a normal distribution. In the non-cooperative scenario, the store's expected profit experiences a notable decline with both high sustainability costs (e_i) and quantity, as depicted in Fig. 6. The higher the sustainability cost (e_i), the more pronounced the decrease in expected profit. Between ($e_i = 30$) and ($e_i = 33$), the expected profit turns negative for quantities greater than 60. The store benefits from maintaining a sustainability cost (e_i) that is not excessively high to maximize expected profit in the non-cooperative configuration.

Fig. 6. The impact of store sustainability cost (e_i) on the variation of store's expected profit by quantity of the non-cooperative configuration in a normal distribution case.

Fig. 7. The impact of store sustainability cost (e_i) on the variation of store's expected profit by quantity of the cooperative configuration in a normal distribution case.

On the other hand, the cooperative scenario, shown in Fig. 7, exhibits different outcomes. The higher the sustainability cost (e_i), the greater the expected profit. A decrease of the expected profit as quantity (Q_i) rises is noticeable, especially in the case of high sustainability cost (e_i). The higher the sustainability cost, the greater the expected profit. Between ($e_i = 30$) and ($e_i = 60$), there is a significant increase in the store's expected profit. The store benefits from increasing its sustainability cost (e_i) to maximize its expected profit in the cooperative scenario.

Fig. 8. The impact of supplier sustainability cost (e_s) on the variation of supplier's expected profit by quantity in a normal distribution case.

On the contrary, in Fig. 8, the supplier's expected profit rises with an increase in quantity (Q_i). Nevertheless, a higher sustainability cost for the supplier (e_s) leads to a decrease in the supplier's expected profit. This explains the supplier's

interest in selling more products while managing its sustainability cost (e_s).

D. Profit Optimization and Resilience

In this subsection, the aim is to scrutinize the profitability for both the supplier and the store across various demand scenarios, the uniform and normal distribution case. Furthermore, Additionally, the supplier's resilience based on foreign products and security stock is investigated.

Fig. 9. The influence of security stock (ψ_i) ratio on supplier's expected profit in a uniform and normal distribution cases.

Fig. 9 illustrates the impact of the security stock ratio (ψ_i) allocated to the store by the supplier. The influence indicates a significant increase in the supplier's expected profit with an elevation in the security stock (ψ_i), considering that the costs of the security stock are carried by the store. The distinction between normal and uniform distributions is clearly apparent. The uniform distribution results in higher supplier expected profit with an increased security stock ratio (ψ_i). However, the trend of the curves remains consistent for both distributions. It is more beneficial for the supplier to have demand following a normal distribution in order to maximize expected profit.

Fig. 10. The impact of security stock ratio (ψ_i) on the variation of supplier's expected profit by quantity in a normal distribution case.

Fig. 11. The influence of the ratio of holding products on supplier's expected profit variation by security stock in a uniform distribution case.

Similarly, in the case of a uniform distribution, Fig. 10 and Fig. 11 illustrates the influence of the ratio of the supplier's wholesale price dedicated to holding products (δ) on expected profit. A higher ratio (δ) of holding products correlates with a

greater supplier's expected profit. As the costs related to security stock and holding are carried by the store, the supplier has an interest in proposing to the store high ratios of security stock (ψ_i) and holding costs (δ).

Fig. 12. The influence of foreign product ratio (θ) on supplier's expected profit in a uniform and normal distribution cases.

As illustrated in Fig. 12 and Fig. 13, an increase in (θ) results in a decline in the supplier's expected profit due to the imposition of custom fees (τ) by the government.

In the case of the uniform distribution, expected profit is higher than in the normal distribution with the variation of (τ), as depicted in Fig. 12. Both distributions exhibit the same trend. For the supplier to be more resilient, it is advantageous for them to have demand following a uniform distribution. This is because in the case of a normal distribution, the expected profit is negative, leaving the supplier with no option to import more products from abroad.

Fig. 13. The impact of foreign product ratio on the variation of supplier's expected profit by custom fees (τ) in a normal distribution case.

Fig. 13 illustrates that expected profit sharply decreases with higher customs fees (τ) and a higher ratio of foreign products (θ). As the integration of foreign products (θ) increases, the supplier experiences a proportional decline in expected profit. Initially, the integration rate (θ) is perceptible when the custom fees (τ) are low. It is more beneficial for the supplier to have a low foreign product integration rate (θ) when custom fees (τ) are high. However, it is crucial for the supplier to maintain the option of importing foreign products (θ) to enhance upstream resilience through diversified sourcing channels. As a regulatory body, the government can act by increasing customs fees (τ) at reasonable rates to maintain a local equilibrium.

V. RESULTS AND DISCUSSION

The imperative recognition of sustainability and resilience as crucial pillars underscores their role in ensuring the long-term adaptability and viability of economic strategies. The literature emphasizes the economic significance of these

concepts, highlighting the necessity for a comprehensive examination of how quantity-based strategies and effective uncertainty management can collectively strengthen the robustness and adaptability of supply chains, ultimately contributing to enhanced profitability.

Results shows that in scenarios where demand (D_i) is uniformly distributed, the store and the supplier tend to have higher optimal quantities compared to when demand follows a normal distribution. Furthermore, expected profits for both the supplier and the store are generally higher in both non-cooperative and cooperative setups when demand (D_i) follows a uniform distribution. Having a regular demand pattern is advantageous for maximizing expected profit, especially when demand (D_i) follows a uniform distribution. However, with a normal distribution, demand variability may disrupt this advantage. For instance, common or generic products often exhibit uniform demand patterns, whereas products from large-scale distribution may demonstrate normal demand distribution under certain circumstances. In distribution networks aimed at delivering products to markets characterized by stochastic demand following a uniform distribution, the main actors of the logistics network (stores and suppliers) enjoy significantly more favorable expected profits compared to demand following a normal distribution.

The examination of store's expected profit in both cooperative and non-cooperative configuration, regardless of the demand nature, whether it follows a uniform or normal distribution, reveals that the cooperative scenario consistently yields higher expected profits. Consequently, the store is incentivized to engage in cooperation to maximize its profit. The conclusion is consistent with previous studies [48], [49]. The proposed cooperative configuration actively fosters store collaboration by sharing central warehouse-related costs and pooling resources, particularly the surplus quantities ($Q_i - D_i$), which are returned and resold to the central warehouse, resulting in a reduction of depreciation (l) and stockout (z) costs. Given the constraints of resilience and sustainability, cooperation between stores remains the best approach to guarantee maximum expected profit.

Sustainability significantly influences both the store's and the supplier's expected profits, particularly noteworthy is its impact when dealing with high quantities. These results are consistent with previous studies [10], [49], [50]. In the non-cooperative scenario, the store's optimal quantity (Q_i^{*NC}) decreases with a higher sustainability cost (e_i), similarly for the supplier, with its sustainability cost (e_s), the optimal quantity (\widehat{Q}_{is}^*) decreases with a perceptible difference between the normal and uniform distributions. However, within the cooperative store scenario, this effect is mitigated, the store's optimal quantity (Q_i^{*CO}) increases with a high sustainability cost (e_i). In the absence of information on demand evolution, the intersection of the two curves of the normal and uniform distributions, determine the optimal store sustainability cost (e_i). Furthermore, sustainability costs (e_i), (e_s) tend to diminish supplier's expected profit and store's expected profit for the non-cooperative configuration, emphasizing the crucial significance of cooperation in enhancing store's expected profit and alleviating the sustainability cost impact. This underscores

the critical importance for both the supplier and the store to carefully consider and manage sustainability costs in the decision-making process. Consequently, sustainability efforts within the logistics network emerge as genuine strategies for network actors, enabling them to remain competitive and viable. This becomes clearer when stores decide to cooperate by reselling surplus quantities.

Resilience is a central element in the proposed model, supported by the supplier through two actions. Firstly, by mitigating downstream supply chain risks through the allocation of security stock (ψ_i) to each store. Secondly, by addressing upstream supply chain risks through the importation of foreign products (θ). The results demonstrate that, even as the quantity increases in the case of a low security stock ratio (ψ_i), expected profit rises, with a more pronounced impact at higher (ψ_i) ratios. Additionally, a higher ratio (δ) of holding products correlates with greater supplier expected profit. As the costs related to security stock and holding are borne by the store, the supplier has an interest in proposing high ratios of security stock (ψ_i) and holding costs (δ) to the store. The strategy pursued by the supplier regarding resilience, which involves negotiating the level of security stock with the store, appears opportune as it has a significant impact on the supplier's expected profit, especially when the number of stores is substantial. These results align with the findings of a prior research [51].

Moreover, the analysis explores the influence of customs fees and the integration of foreign products (θ) on the supplier's expected profit, indicating a decline with higher customs fees (τ) and an increased ratio of foreign products. The use of foreign products negatively affects this expected profit, especially in the absence of government regulation policies such as the application of customs fees (τ). This finding align with previous studies [7], [9], [10]. The recommendation to maintain the option of importing foreign products (θ) underscores the importance of diversified sourcing channels for upstream resilience. The suggestion for government intervention in regulating customs fees (τ) aims to balance local equilibrium.

VI. CONCLUSION

In today's fiercely competitive global market and an increased uncertainty, supply chain resilience and sustainability have become top priorities, to adapt quickly to disruptions while meeting sustainability goals. To address these challenges, supply chain actors are implementing strategies to bolster the sustainability and resilience of their operations. This research investigates interconnected issues within supply chains, offering insights to develop resilient, sustainable solutions. It explores quantity-based strategies for optimizing expected profits while integrating sustainability and resilience principles, ensuring alignment with sustainability requirements while maintaining competitiveness. The study aims to identify scenarios that offer significant advantages for maximizing expected profits while adhering to sustainability standards.

The study examines a monopolistic, sustainable, and resilient supply chain network operating in an uncertain environment with two tiers: suppliers and multiple stores. A

stochastic model is developed to deal with demand uncertainty and maximize supplier and store expected profits. Two configurations are proposed for the store. The non-cooperative configuration, individual where stores and the supplier independently optimize expected profits based on delivery quantities, and the cooperative configuration where stores collaborate to jointly maximize expected profits while reducing stockout risks through a central warehouse for surplus returns. Various strategies are implemented by supply chain actors, addressing resilience, utilizing dedicated security stocks, and diversifying product sources. Sustainability is integrated through eco-friendly practices initiated by the supplier and stores, with cooperation enhancing resilience via a central warehouse as a backup supplier. Return logistics are managed to minimize waste and product depreciation [14], [15], promoting responsible inventory management [14], [15].

The findings highlight insights regarding supply chain dynamics in the face of uncertainty and sustainability imperatives. Firstly, it is observed that in a distribution network designed to deliver products to markets marked by stochastic demand that follows a uniform distribution, the main players in the logistics network (stores and supplier) have higher expected profit compared with demand that follows the normal distribution. Given the constraints of resilience and sustainability, cooperation between stores emerges as a strategy for maximizing expected profit, in particular by mitigating sustainability costs. Moreover, sustainability efforts applied in the logistics network constitute genuine strategies for the actors in the logistics network, enabling them to remain competitive and viable. This becomes clearer when stores decide to cooperate by reselling surplus quantities. In terms of resilience, the supplier's strategy of negotiating a security stock level with the store seems to be an opportune one, since it has a considerable impact on the supplier's expected profit, particularly when the number of stores is large. On the other hand, the use of foreign products has a negative impact on this expected profit, especially in the absence of a regulatory policy on the part of the government, which consists of enforcing a minimum stock level.

The proposed model provides managerial advantages by facilitating cooperation among stores through the resale of surplus quantities to the central warehouse, thereby reducing costs associated with stockouts and product depreciation while maximizing expected profits. Moreover, determining the ratio of imported foreign products is a crucial decision for suppliers, with errors in decision-making potentially diminishing expected profits. Our model assists managers in making informed choices regarding the determination of foreign product ratio to import. Additionally, the cooperative model encourages stores to collaborate and pool their resources.

It is essential to understand the limitations of our research, enabling researchers to accurately interpret our findings and identify potential avenues for further investigation. The first limitation of the model concerns the consideration of a single supplier. Indeed, the discussed model only accounts for one supplier responsible for supplying all the stores. Consequently, this present a significant risk to the resilience of the entire supply chain. Therefore, it would be advisable to propose, in future work, two-echelon supply chain models that involve

multiple suppliers to better reflect logistical reality. Furthermore, the work conducted does not take into account the competitive aspect at the store level. Indeed, to simplify the study, we have assumed a monopolistic market (each store has a monopoly in its trade area). Therefore, it would be interesting to revisit the model by assuming a single oligopolistic market.

As a perspective of this work, cooperation between the supplier and the stores could be an opportunity to further improve the profits of these actors by selling surplus quantities from the supplier to the central warehouse. This is an avenue that could further explore the value of cooperation in promoting sustainability and resilience.

ACKNOWLEDGMENT

This research paper was conducted by the LASTIMI laboratory of Mohammed V University in Rabat, High School of Technology of SALE and supported by ESITH Morocco. The authors are sincerely grateful to CELOG team and each person who have helped in any way to the accomplishment of this study.

Abstract—Accidents at substation sites have occurred frequently in recent years due to workers violating power safety regulations by not wearing hardhats. Therefore, it is necessary to provide real-time warnings when detecting workers without hardhats. Nevertheless, the deployment of deep learning-based algorithms necessitates the utilization of a multitude of parameters and computations, which consequently engenders an augmented expenditure on hardware. Therefore, using a lightweight backbone can address this issue well. This paper explored methods, such as deep learning, power Internet of Things (PIoT), and edge computing and proposed a lightweight and effective method called hardhat-YOLO for hardhat-wearing detection. First, the MobileNetv3-small backbone replaced the backbone of You Only Look Once (YOLO) v5s to reduce parameters and increase detection speed. In addition, the Convolutional Block Attention Module (CBAM) was effectively integrated into the network to improve detection precision. Finally, the hardhat-YOLO model, trained with a customized dataset, was transmitted to edge computing terminals in substations through PIoT for hardhat-wearing detection. Compared to the YOLOv5s model, the Parameters and Giga Floating Point Operations (GFLOPs) of the proposed model decreased by about 35.5% and 54.4%, respectively, and Frame per Second (FPS) increased by 17.3% approximately. The experimental results indicated that the hardhat-YOLO model achieved a Mean Average Precision of 83.3% at 50% intersection over union (mAP50), correctly and effectively conducting hardhat-wearing detection tasks.

Keywords—Hardhat-wearing detection; You Only Look Once (YOLO); MobileNet; Substation; power Internet of Things (PIoT)

I. INTRODUCTION

Electricity is a crucial industry for ensuring national development and daily life. The power industry has experienced significant growth, resulting in widespread coverage of power systems [1]. The State Grid Corporation of China (State Grid) has a vast transmission range with numerous power work sites. Additionally, various types of electrical equipment operate in substation sites, making working in these areas a high-risk activity [2]. As worker safety is of utmost importance, it is imperative that all workers strictly adhere to the safety regulations, including wearing a hardhat [3]. The hardhat serves as a critical safety measure at the power work site, dispersing the impact force of falling

objects through its shell and further buffering and absorbing the impact force through its interior to ensure the safety of workers' heads [4].

The statistical analysis of accidents in the power industry between 2015 and 2020 in China revealed that 131 accidents occurred during power production, accounting for 60%, while 69 accidents occurred during power construction, accounting for 29%, and 26 accidents occurred during power technology improvement, accounting for 11%. The analysis of the causes of casualties in power operations between 2014 and 2018 showed that illegal operations accounted for 73.68%, equipment accounted for 7.37%, natural causes accounted for 7.37%, and other causes accounted for 11.58% [5]. The survey data on personal injury accidents in the past decade reveals that the leading causes of fatalities in safety accidents are falling utility poles, object impacts, falls from heights, and electric shocks. The most harmful incident, according to the statistics, is when a worker is struck on the head by a falling object, resulting in head and neck injuries or death. 80% of the casualties were caused by non-compliance with safety regulations and failure to take safety precautions [6].

A video monitoring system has been installed in substation sites with fundamental functions, including real-time display and playback of historical video data. However, it lacks an alarm function for abnormal conditions. Therefore, an unattended system that can rapidly detect hardhat wearing should be urgently implemented to provide early warnings and reduce the occurrence of accidents. With the construction and development of the smart grid, power system equipment has become more intelligent [7]. The Power Internet of Things (PIoT) is formed by integrating the smart grid and the Internet of Things (IoT), making it a strategic transformation technology for the State Grid [8]. PIoT's superior advantages have attracted the attention of many researchers, leading to its introduction into all production chains [9-11].

In PIoT, many services require lower latency, which the cloud-centric computing model struggles to meet. Edge computing has been proposed as an expansion scheme of cloud computing to address this issue [12]. Edge computing terminals collect, process, and store data on edge sides [13]. The terminals have data processing capabilities without uploading all data to the cloud center, which saves the transmission

*Corresponding author.

bandwidth of PIoT significantly. Therefore, edge computing terminals are more suitable for deploying in substations for hardhat-wearing detection.

Compared to resource-rich cloud computing platforms, edge platforms still face challenges such as inferior hardware performance, power consumption sensitivity, and limited computing power. Deep learning models typically consist of hundreds of layers and millions of parameters, such as YOLOv5s with 214 layers and 7,035,811 parameters. Meanwhile, the running process occupies significant memory resources of the computing platform and requires powerful floating-point computing capabilities.

Terminals in substations are typically installed in fixed locations. The size of the object captured by the camera does not vary significantly. Selecting a model with fewer parameters and computations could improve the detection speed. Therefore, taking advantage of the capacity and speed of PIoT, a lightweight model can be deployed to edge computing terminals with limited resources to energize hardhat-wearing detection tasks.

The rest of this paper is organized as follows: Section II presents a review of recent relevant literature, followed by the introduction of YOLOv5 and MobileNet in Section III. The methodology is presented in Section IV. Section V discusses the results & discussion. Finally, concluding remarks are proposed in Section VI.

II. RELATED WORK

To solve the problems of slow detection speed and low detection accuracy, Xiao et al. [14] proposed a helmet-wearing detection method based on an improved Single Shot MultiBox Detector (SSD) in 2020. The MobileNetV3-small backbone replaced the Visual Geometry Group 16 (VGG) backbone of the SSD detection algorithm to reduce model parameters. Furthermore, the proposed method utilized the Feature Pyramid Network (FPN) structure to combine abstract and detailed shallow features for improved detection accuracy. The proposed method achieved a detection speed of 108 FPS and a 0.5% increase in mAP50 compared to the SSD algorithm.

In 2021, Chen et al. [15] proposed a method for detecting helmet-wearing based on EfficientDet. The proposed method adopted a k-means clustering algorithm and cross-scale connections with weighted feature fusion under different scales to increase the recognition rate and improve real-time performance. The mAP of the model improved by 2%, reaching 87.4%.

Xu et al. [16] proposed a helmet-wearing detection algorithm based on MobileNet-SSD in 2021. The algorithm addresses the challenges of detecting small objects, complex backgrounds, and interferences. The algorithm utilized the lightweight MobileNet architecture, resulting in improved detection speed. Additionally, the authors employed a transfer learning strategy to overcome difficulties in model training. The proposed algorithm provided a detection speed 10.2 times higher than that of the SSD algorithm, albeit with a minor loss in accuracy.

Wu et al. [17] proposed an improved algorithm for detecting correct usage of work clothes and helmets in 2021, which utilized a transformer-based self-attentive coding feature fusion network. A quality Focus loss function was introduced to address the problem of inconsistent inference during the training and testing phases. The detection method achieved a mAP of 44.6% and an average precision (AP) of 79.5%, with a processing speed of 117 frames per second.

In 2021, Zhu et al. [18] proposed an algorithm for detecting safety helmet-wearing based on YOLOv5 by improving methods, such as the candidate box, convolution layer, input, and quantization. The improved YOLOv5 algorithm outperformed the original YOLOv5 in detection accuracy, Intersection over Union (IoU), and detection time.

Ge et al. [19] proposed a method for detecting safety helmet-wearing that improved the accuracy of detecting small objects and reduced accuracy reduction in complex backgrounds in 2022. The proposed method combined high and low-level features to capture more detailed information based on YOLOv4. To lessen the aliasing effect after feature map fusion and ensure feature stability, a 3×3 convolution operation is used on the fused feature maps. The improved model achieved a 4.27% increase in mAP compared to YOLOv4.

In 2022, Qu et al. [20] proposed a safety helmet-wearing detection method for power grid operators based on YOLOv3. The detection accuracy of the YOLOv3 model could reach 92.59%. In addition, the model could detect 15 images per second, which can achieve effective detection in complex operation scenarios.

In 2022, Wang et al. [21] proposed an improved helmet-wearing detection method based on YOLOv5 to address issues such as false detection and missed detection in complex environments for small and dense objects. They integrated a coordinate attention mechanism into the backbone of YOLOv5, resulting in an average accuracy of 95.9%, which increased by 5.1% compared to YOLOv5.

As helmet objects on construction sites are small, CenterNet struggles with small object recognition. In 2022, Zhao et al. [22] proposed the FPN-CenterNet framework, which used an Asymmetric Convolution Network (ACNet) to improve the feature extraction of the backbone. They also employed the Distance IoU (DIoU) loss function to optimize the accuracy of frame prediction. The improved algorithm achieved a mAP increase of 4.99% compared to CenterNet and the FPS reached 25.81.

In 2022, Zhao et al. [23] proposed a real-time object detection method based on YOLOv3 to address the issue of low resolution and intensity contrast in video images. The image was pre-processed using Gamma correction, and the detection speed was improved by deriving the most suitable prior box size based on the K-means++ algorithm. The proposed method achieved an improvement of over 2%.

In 2022, Hayat et al. [24] used the YOLOv5x architecture to train a safety helmet detection model on a benchmark dataset, effectively detecting small and low-light objects. The

YOLOv5x achieved the highest mAP of 92.44% compared to other YOLO architectures.

Although the methods mentioned above improved the algorithm for detecting hardhats, the models had numerous parameters and computations, making them unsuitable for deployment on edge computing terminals. Furthermore, some researchers have utilized open-source datasets, such as the Safety Helmet Detection Dataset [25]. The dataset comprised only three classes, not fully presenting various objects in images. Additionally, the model trained on the dataset exhibited poor detecting performance to occluded and crowded objects. In particular, interfering objects were incorrectly predicted by the model. Consequently, the lightweighting of a model represents a superior solution, while a well-annotated dataset can also improve the robustness of the model.

The main contributions of this paper are:

- Based on the Safety Helmet Detection Dataset, a random background augmentation method is proposed to obtain more background images, which reduces the number of predicted false positive instances and improves detection precision.
- The backbone of the YOLOv5s is replaced with the MobileNetv3 backbone, significantly reducing the number of parameters and computations.
- CBAM is integrated into the network to compensate for the reduction in detection precision. Ablation experiments are conducted to explore the most effective method of integrating CBAM.

- A hardhat-wearing detection architecture covering numerous substation areas is proposed to meet the practical application by exploring IoT and edge computing technologies.

III. YOLO AND MOBILENET ALGORITHMS

A. Introduction of YOLO

The YOLO series of one-stage object detection algorithms are known for their high detection speed and precision. In June 2020, YOLOv5 was released as an open-source algorithm on the Internet. YOLOv5s, a small model in the series, has a model file size that is approximately 90% smaller than that of YOLOv4 while maintaining a similar level of accuracy. The YOLOv5 series includes five models, namely YOLOv5x, YOLOv5l, YOLOv5m, YOLOv5s, and YOLOv5n, which are classified based on their model size. The YOLOv5s model consists of three components: backbone, neck, and head. When the input image has a shape of 640×640 , the backbone extracts feature maps of five different sizes: 320×320 , 160×160 , 80×80 , 40×40 , and 20×20 . The neck further extracts features and fuses feature maps from the backbone. The head predicts small, medium, and large objects using three small-size feature maps.

Table I compares the performance of YOLO series models on the different datasets. The YOLOv5s model, which employed a Conv2D (6×6) and Cross Stage Partial (CSP) Darknet53 structure, achieved a high accuracy with a mAP50 of 56.8% and the fastest speed with an FPS of 155 on the Common Objects in Context (COCO) dataset. Therefore, this paper used the YOLOv5s algorithm to improve hardhat-wearing detection.

TABLE I. PERFORMANCE COMPARISON OF THE YOLO SERIES MODELS

Model	Network	FPS	VOC 2007 (mAP/%)	VOC 2012 (mAP/%)	COCO (mAP50/%)	GPU
YOLOv1 [26]	GoogleNet (modified)	45	66.4	57.9	-	Titan X
YOLOv2 [27]	Darknet19	40	78.6	73.4	44.0	Titan X
YOLOv3 [28]	Darknet53	20	-	-	57.9	Titan X
YOLOv4 [29]	CSPDarknet53	62	-	-	65.7	Tesla V100
YOLOv5s	Conv2D (6×6) + CSPDarknet53	155	-	-	56.8	Tesla V100

B. Introduction of MobileNet

Traditional deep learning-based algorithms require large amounts of graphics memory and many floating-point calculations, making them unsuitable for deployment and operation on devices with limited computing resources. However, the MobileNet has proposed Depth-wise Separable Convolution (DSC) composed of depth-wise and point-wise convolution to replace ordinary convolution, which reduces parameters and improves operation speed [30].

The MobileNetv2 introduced an inverted residual and linear bottleneck structure [31]. It utilized the advantages of depth-wise separable convolution to effectively reduce computations of intermediate convolution operations, ensuring the algorithm's performance and avoiding information loss by removing the Rectified Linear Units (ReLU) activation function. The MobileNetv2 had a parameter size of

approximately 6.9 MB and achieved a TOP-1 classification accuracy of 74.7% on the ImageNet dataset. This model was smaller and more accurate than the MobileNetv1.

The MobileNetv3 utilized the Neural Architecture Search (NAS) method to obtain its network structure [32], achieving improved accuracy and efficiency compared to the MobileNetv2. The Hard-Swish activation function replaced the swish activation function. Additionally, a Squeeze-And-Excite module was added to improve accuracy, distinguishing it from v1 and v2.

Fig. 1 displays the structure of MobileNetv3. The input image has a shape of $224 \times 224 \times 3$. It first undergoes a 3×3 convolutional layer with a stride of two, followed by a Batch Normalization (BN) layer and the Hard-Swish activation function. Next, the output feature maps from the previous layer pass through 11 or 15 bottleneck structures for feature

extraction. Next, the extracted feature maps are passed through an average pooling layer to reduce their size. After that, the output feature maps are passed through a 1×1 convolutional layer, a BN layer, and the Hard-Swish activation function in sequence. The final classification output is obtained through the Fully Connected layer.

Fig. 1. MobileNetV3 structure. where small and large denote the MobileNetV3-small network and MobileNetV3-large network, respectively

Overall, the MobileNetV3 was chosen to replace the backbone of YOLOv5s in this paper due to its advantages in lightweight.

IV. METHODOLOGY

A. Detection Architecture

The cloud center is a cluster of servers with powerful computing capabilities, connecting through fast communication links. Load-balancing technology distributes user requests to multiple active nodes, ensuring redundancy, reducing network congestion and overload, and improving workload distribution. Managers periodically collect images taken by edge computing terminals at power work sites to enrich the original hardhat dataset. These images are then annotated to gradually form a diverse and sufficient dataset. This process allows the trained model to gradually achieve

better accuracy. Since the MobileNetV3 backbone replaces the YOLOv5s backbone, the detection model file size becomes smaller, and transmitting the smaller model file to edge computing terminals reduces the transmission consumption of PloT significantly.

Fig. 2 shows the detection architecture of hardhat-wearing in substation sites. First, the cloud center utilizes powerful servers to train the hardhat-wearing detection model on the hardhat dataset. In addition, the model is transmitted via PloT to edge computing terminals to perform hardhat-wearing detection tasks. Furthermore, edge computing terminals give workers without hardhats a warning. Finally, edge computing terminals upload the detection results to the cloud center through PloT.

B. Hardhat-YOLO Structure

The proposed method, hardhat-YOLO, is based on the YOLOv5s and MobileNetV3-small networks. The network structure is shown in Fig. 3. The hardhat-YOLO network consists of three components, similar to YOLOv5s: the backbone for feature extraction, the neck for enhanced feature extraction and feature fusion, and the head for prediction. The improved backbone uses the MobileNetV3-small backbone and CBAMs to extract feature maps. The improved neck comprises the YOLOv5s neck and CBAMs. The head of this model is identical to that of YOLOv5s. Additionally, data augmentation methods, including image distortion, spatial translation, rotation, and copy-and-paste, are employed to enhance the accuracy of the trained model.

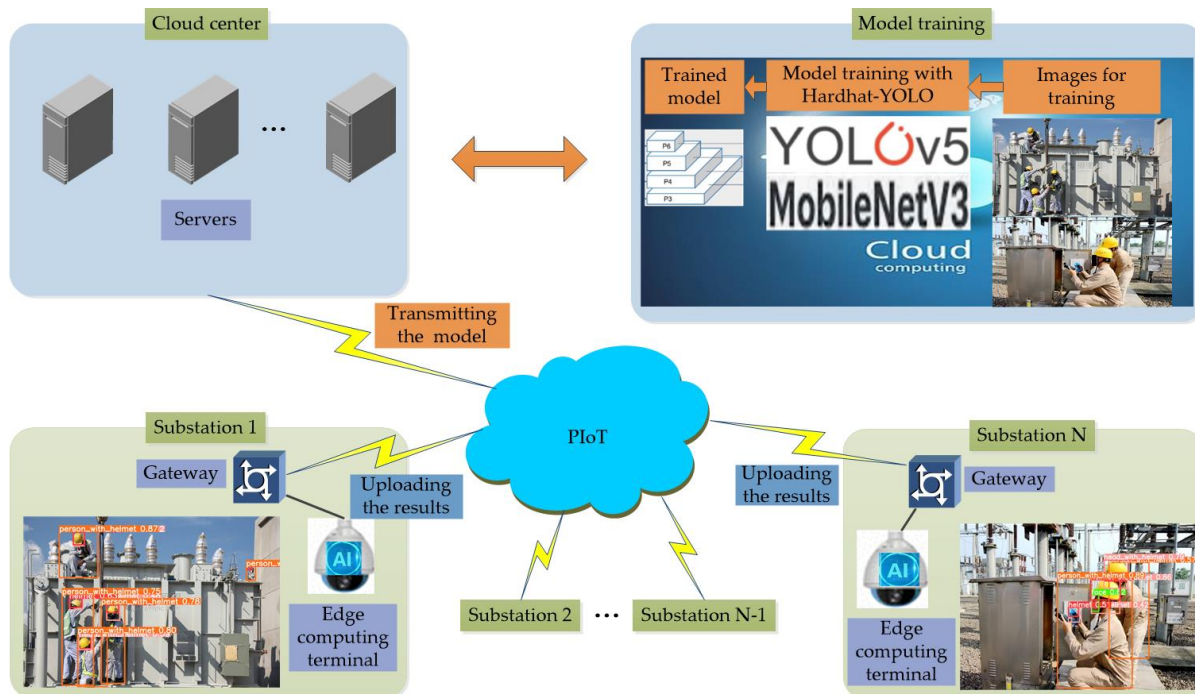

Fig. 2. Hardhat-wearing detection architecture in substation sites

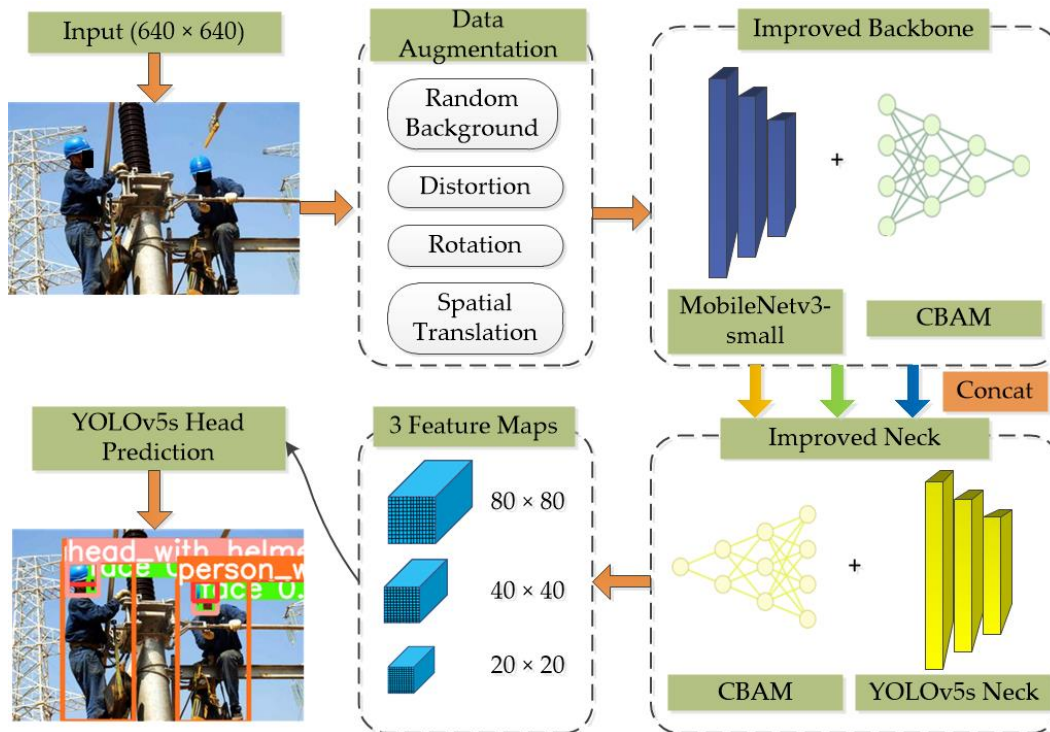

Fig. 3. Hardhat-YOLO structure

C. Data Augmentation

The public hardhat dataset comprises 5000 images classified into three categories: person, head, and helmet. However, the dataset has some issues. First, the dataset was annotated in the PASCAL VOC format without being fully annotated. Therefore, it was reannotated in the YOLO format, which includes six categories: helmet, head_with_helmet, person_with_helmet, head, person_no_helmet, and face, fully presenting various objects in images. Furthermore, the model trained on the dataset struggled to accurately detect interfering and occluded objects, as demonstrated in Fig. 4. Workers with baseball and bamboo hats were incorrectly predicted as

“person_with_helmet” objects. Meanwhile, workers behind protective netting and steel bars were missed detection.

To enhance the robustness of the trained model, some images containing interfering, occluded, and long-distance objects were added to the dataset. Additionally, a random background augmentation method is proposed to obtain more images, compensating for the lack of background images. Background images taken from construction and substation sites contained no objects. Therefore, image distortion, spatial translation, rotation, and copy-and-paste methods were randomly utilized to create new background images with original background images. The random background augmentation method is shown in Fig. 5.

Fig. 4. Detection results of sample images contained interfering or occluded objects. (a) Detection results of a worker with a baseball hat; (b) Detection results of a worker with a bamboo hat; (c) Detection results of workers behind steel bars; (d) Detection results of workers behind protective netting

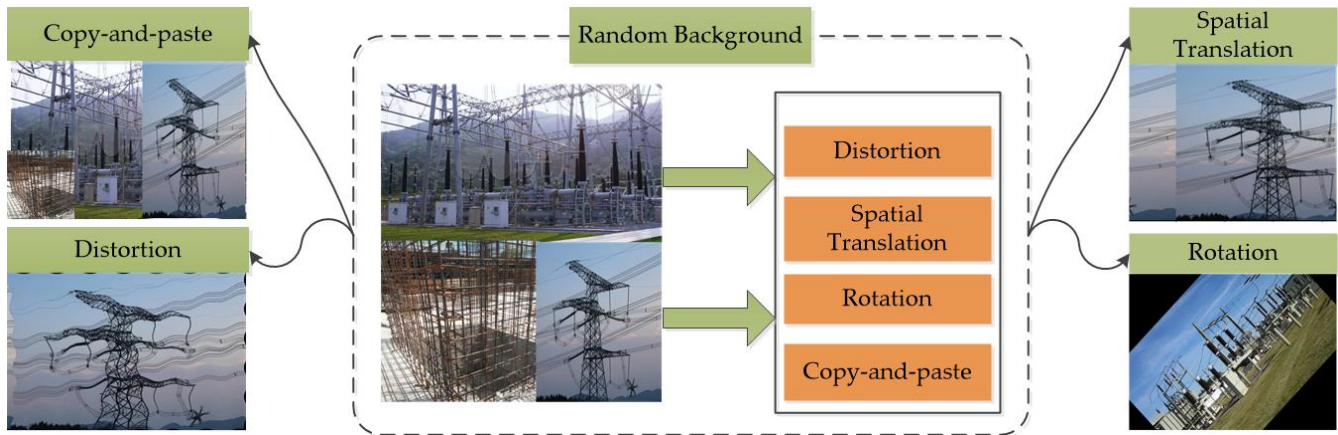

Fig. 5. Random background augmentation method

Finally, the image number of the customized dataset was increased to 6000. Fig. 6 compares the number of labels in three datasets. The public dataset contained 25,501 labels in total. After reannotated public datasets, the number of labels increases significantly. After data augmentation, the number of labels further increased. The customized dataset had 80,149 labels in total. The label numbers for each class were 19,803, 16,756, 16,387, 7015, 6205, and 13,983, respectively.

D. Replacing the YOLOv5s Backbone

The YOLOv5s backbone extracts features from the input image to create three initial feature maps. The feature maps have sizes of 80×80 , 40×40 , and 20×20 , respectively. Therefore, replacing the backbone should ensure that the new backbone can also output three initial feature maps. Fig. 7 illustrates the replacement of the YOLOv5s backbone with the MobileNetv3-small backbone. Specifically, layers 0 to 4, 5 to 6, and 7 to 8 of the YOLOv5s backbone were replaced by layers 0 to 3, 4 to 8, and 9 to 12 of MobileNetv3, respectively. The feature map's shape is presented as height \times width \times

channel. The ConvBNHSwish structure contains a convolutional layer, batch normalization layer, and hard swish activation function. The ConvBNSiLU structure contains a convolutional layer, batch normalization layer, and Sigmoid Linear Unit (SiLU) activation function. The C3 is the feature extraction structure in YOLOv5.

E. Integrating CBAM

Replacing the YOLOv5s backbone resulted in a decrease in model precision. Using an attention mechanism can effectively compensate for a reduction in accuracy. The CBAM structure is lightweight and does not significantly increase the parameters and computations required. The CBAM combined channel and spatial attention modules, which can be readily incorporated into any convolutional neural network (CNN) architecture. Figure 8 illustrates the architecture of CBAM, which consists of channel and spatial attention modules that are applied sequentially to the input feature map. The input feature map is sequentially multiplied by the two attention feature maps to obtain the final output.

Fig. 6. Comparison of the number of labels in three datasets

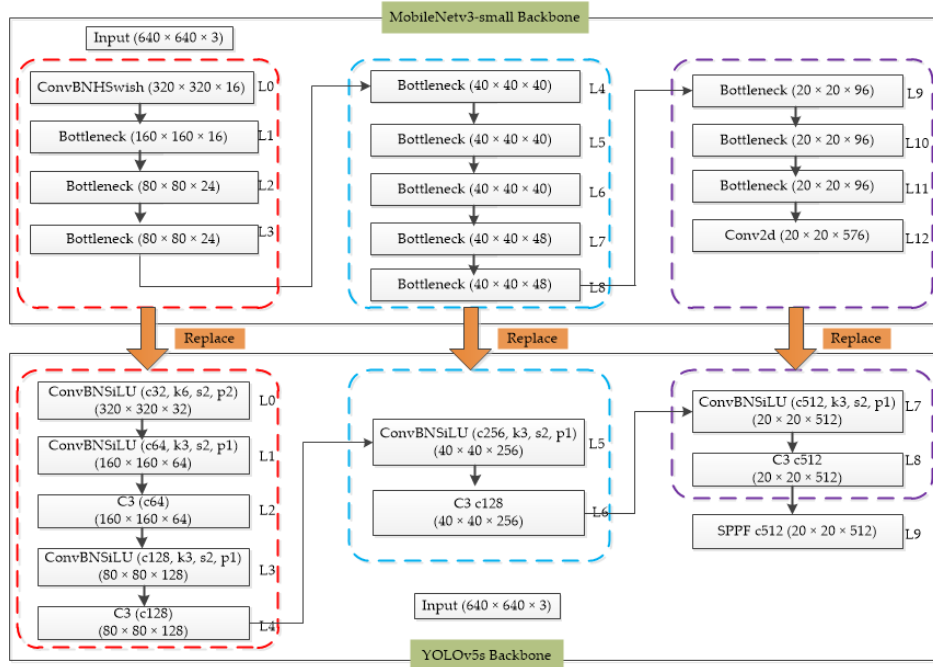

Fig. 7. Replacing the YOLOv5s backbone. Where c denotes channel, k denotes kernel, s denotes stride, and p denotes padding

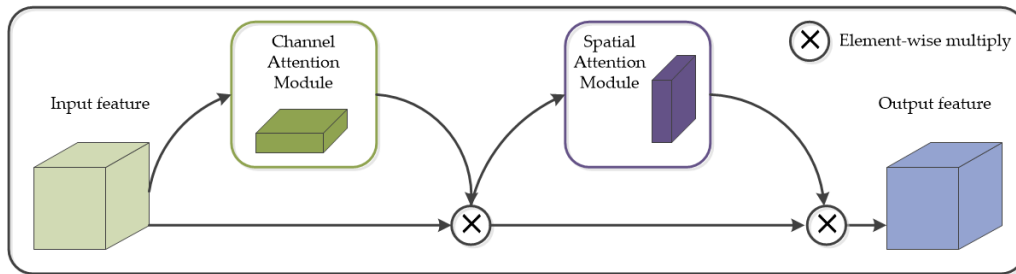

Fig. 8. CBAM architecture

Table II displays the results of four ablation experiments conducted to verify the effective integration of CBAM into the original network. The first method only integrated CBAM into the neck, inserting CBAMs behind the concatenation (40 × 40 × 304) and concatenation (80 × 80 × 152) layers, respectively. The second method only integrated CBAM into the backbone, inserting CBAMs behind three output feature maps of which shapes were 80 × 80 × 24, 40 × 40 × 48, and 20 × 20 × 576, respectively. The third method combined the first and second methods, integrating CBAMs into the backbone and neck.

Based on the third method, the fourth method inserted CBAMs additionally behind two output feature maps of which shapes are 320 × 320 × 16 and 160 × 160 × 16, respectively. Where yes denotes that CBAM is integrated behind the feature map, and no is the opposite.

Fig. 9 displays the third method of integrating CBAM, which is the most effective method with the highest mAP50. Five CBAMs are integrated into the original network, in which three CBAMs integrate into the backbone, while two CBAMs integrate into the neck.

TABLE II. METHODS OF INTEGRATING CBAM

Method	Backbone (feature map: 320 × 320 × 16)	Backbone (feature map: 160 × 160 × 16)	Backbone (feature map: 80 × 80 × 24)	Backbone (feature map: 40 × 40 × 48)	Backbone (feature map: 20 × 20 × 576)	Neck (concat: 40 × 40 × 304)	Neck (concat: 80 × 80 × 152)
1	No	No	No	No	No	Yes	Yes
2	No	No	Yes	Yes	Yes	No	No
3	No	No	Yes	Yes	Yes	Yes	Yes
4	Yes	Yes	Yes	Yes	Yes	Yes	Yes

V. EXPERIMENTS AND DISCUSSION

A. Experimental Environment

Table III displays the experimental hardware and software. The customized hardhat dataset was divided into a training dataset of 5500 images and a validation dataset of 500 images. The parameters 'img-size', 'batch', and 'epoch' parameters were set to 640, 16, and 300, respectively. The pre-trained weight file of YOLOv5s.pt was used.

TABLE III. EXPERIMENTAL HARDWARE AND SOFTWARE

Name	Model/Specification	Version
Graphics Processing Unit (GPU)	NVIDIA GeForce RTX 3060 12GB	-
Central Processing Unit (CPU)	Intel Core i7-13700KF 3.4 GHz	-
Random Access Memory (RAM)	32GB	-
Compute Unified Device Architecture (CUDA)	-	11.8
Pytorch	-	2.0.1
Python	-	3.8.17
YOLOv5	-	v7.0-186-g0acc5cf
MobileNet	small	v3

B. Training Results

The validation dataset comprises 7730 instances, of which 'helmet', 'head_with_helmet', 'person_with_helmet', 'head', 'person_no_helmet', and 'face' instances are 2006, 1668, 1524, 595, 473, and 1464 respectively. Precision indicates the detection accuracy for each class. Recall indicates the detection

completeness for each class. The mAP50 is the mean average precision calculated at a threshold of 0.50 IoU, which is a key metric for evaluating model detection accuracy. The mAP50-95 means the mean average precision across IoU thresholds ranging from 0.5 to 0.95.

Table IV presents the training results of the YOLOv5s model trained by the YOLOv5s algorithm, including Precision, Recall, mAP50, and mAP50-95 for all classes. The mAP50 for each class was 0.883, 0.911, 0.915, 0.886, 0.889, and 0.783, respectively.

TABLE IV. TRAINING RESULTS OF THE YOLOV5S MODEL

Class	Instances	Precision	Recall	mAP50	mAP50-95
all	7,730	0.888	0.825	0.878	0.545
helmet	2,006	0.945	0.817	0.883	0.532
head with helmet	1,668	0.928	0.834	0.911	0.587
person with helmet	1,524	0.884	0.884	0.915	0.654
head	595	0.898	0.848	0.886	0.54
person no helmet	473	0.826	0.841	0.889	0.625
face	1,464	0.848	0.725	0.783	0.33

Table V displays the training results of the YOLOv5s-M3s model trained by the YOLOv5s network with the MobileNetv3 backbone. The above metrics for all classes were 0.878, 0.746, 0.828, and 0.476. The mAP50 for each class was 0.836, 0.887, 0.877, 0.835, 0.824, and 0.711, respectively.

TABLE V. TRAINING RESULTS OF THE YOLOV5-M3S MODEL

Class	Instances	Precision	Recall	mAP50	mAP50-95
all	7,730	0.878	0.746	0.828	0.476
helmet	2,006	0.926	0.743	0.836	0.477
head with helmet	1,668	0.944	0.768	0.887	0.549
person with helmet	1,524	0.873	0.814	0.877	0.555
head	595	0.896	0.769	0.835	0.481
person no helmet	473	0.791	0.758	0.824	0.514
face	1,464	0.839	0.621	0.711	0.278

The models obtained from the four ablation experiments paid distinct attention to different classes of objects due to the different locations of the integrated CBAMs. Table VI compares training results for the four ablation experiments integrating CBAM. The mAP50 for all classes of the four models were 0.829, 0.826, 0.833, and 0.830, respectively. Method 3 integrated three CBAMs into the backbone and two CBAMs into the neck, resulting in the highest mAP50 of

0.833. Consequently, the hardhat-YOLO model was trained using this method.

TABLE VI. COMPARISON OF TRAINING RESULTS FOR FOUR ABLATION EXPERIMENTS INTEGRATING CBAM

Class	mAP50 method 1	mAP50 method 2	mAP50 method 3: hardhat-YOLO	mAP50 method 4
all	0.829	0.826	0.833	0.83
helmet	0.84	0.841	0.849	0.844
head with helmet	0.884	0.886	0.887	0.892
person with helmet	0.875	0.876	0.873	0.877
head	0.839	0.833	0.841	0.839
person no helmet	0.827	0.824	0.831	0.834
face	0.711	0.698	0.714	0.696

Fig. 10 shows the training Precision-Recall curves for four ablation experiments, further demonstrating that the third method achieved the highest mAP50 than the other methods.

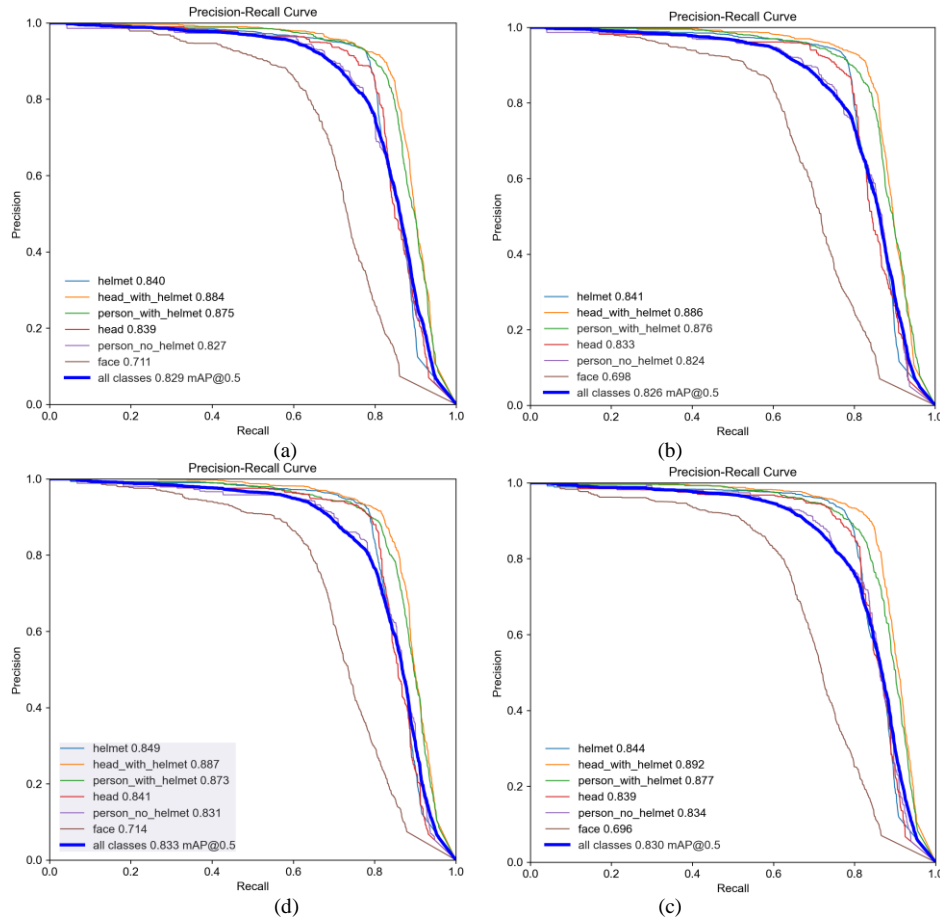

Fig. 10. Precision-Recall curves of four ablation experiments. (a) Precision-Recall curve of method 1 with a mAP50 of 82.9%; (b) Precision-Recall curve of method 2 with a mAP50 of 82.6%; (c) Precision-Recall curve of method 3, hardhat-YOLO, with a mAP50 of 83.3%; (d) Precision-Recall curve of method 4 with a mAP50 of 83.0%

Fig. 11 compares the Precision, Recall, mAP50, and mAP50-95 metrics of three models for all classes. The YOLOv5s model achieved the best performance on all metrics, with a mAP50 of 0.878. After replacing the backbone, the mAP50 of the YOLOv5s-m3s model decreased by 5% compared to the YOLOv5s model, reaching 0.828. After integrating CBAM, the mAP50 of the hardhat-YOLO model increased to 0.833, which is 0.5 percentage points higher than the YOLOv5s-m3s model. The hardhat-YOLO model with CBAMs improved the mAP50 of other classes by reducing the mAP50 of the 'person_with_helmet' class. Specifically, the mAP50 of the 'helmet', 'head', and 'person_no_helmet' classes increased by 1.3%, 0.6%, and 0.7%, respectively, compared to the YOLOv5s-M3s model.

C. Validation Results

Images and videos from substation sites were used to validate the detection effectiveness and speed of the hardhat-YOLO model. The model predicted the results by inputting images and videos, with each object having a bounding box with a confidence value.

The model can detect various media types, including images, videos, cameras, and video streams. The image

formats supported include Portable Network Graphics (PNG) and Joint Photographic Experts Group (JPEG), while the video formats are Moving Picture Experts Group-4 (MP4).

a) *Effectiveness Validation:* Fig. 12 displays the detection results of four sample images. The colors of bounding boxes with confidence values are orange if workers are wearing hardhats and yellow if not. The hardhat-YOLO model accurately predicted all 'person_with_helmet', 'helmet', 'head_with_helmet', and 'face' objects in Fig. 12(a) and 12(b). Furthermore, the model correctly identified a worker wearing a baseball hat in Fig. 12(c) as a 'person_no_helmet' object. Fig. 12(d) shows a correctly predicted 'person_with_helmet' object behind protective netting.

Fig. 13 displays the real-time prediction results of the video captured by a camera. The hardhat-YOLO model accurately predicted all objects when the worker wore and removed a hardhat.

Fig. 14 shows the prediction results of a sample video. The model can correctly detect whether or not the two workers in the video are wearing hardhats.

Fig. 11. Four metrics comparisons of the three models

Fig. 12. Prediction results of sample images. (a) Prediction results of image 1; (b) Prediction results of image 2; (c) Prediction results of image 3; (d) Prediction results of image 4

Fig. 13. Prediction results from a camera. (a) Prediction results of a worker with a hardhat; (b) Prediction results of a worker without a hardhat

Fig. 14. Prediction results of a sample video. (a) Prediction results of two workers not wearing hardhats; (b) Prediction results of two workers wearing hardhats

b) Speed Validation: The Parameters metric refers to the amount of graphic memory the model requires. The GFLOPs metric refers to the number of computations the model inference requires. The Parameters, GFLOPs, and mAP50 metrics of the three models are shown in Table VII. The hardhat-YOLO model had 4,533,682 parameters, decreasing by approximately 35.5% compared to the YOLOv5s model with 7,026,307 parameters. After integrating CBAM, the hardhat-YOLO model parameters increased by only about 1.2% compared to the YOLOv5s-M3s model. However, the mAP50 of all classes increased by 0.5%. The GFLOPs of the hardhat-YOLO model decreased by about 54.4% compared to the YOLOv5s model with 15.8 GFLOPs. After integrating CBAM, the GFLOPs of the hardhat-YOLO model only slightly increased by about 0.1 compared to the YOLOv5-m3s model. Although the mAP50 of hardhat-YOLO decreased by 4.5% compared to the YOLOv5s model, the number of parameters and computations were significantly reduced.

TABLE VII. THE PARAMETERS, GFLOPs, AND MAP50 METRICS COMPARISON OF THE THREE MODELS

Model	Parameters	GFLOPs	mAP50 (all classes)
YOLOv5s	7,026,307	15.8	0.878
YOLOv5s-M3s	4,477,091 (-36.3%)	7.1 (-55%)	0.828 (-5%)
hardhat-YOLO	4,533,682 (-35.5%)	7.2 (-54.4%)	0.833 (-4.5%)

The detection speed of the three models was evaluated using the images from the validation dataset. Latency is the forward propagation time of a model, which refers to the time it takes for a model to predict an image or video. It includes the time spent in pre-processing, inference, and Non-Maximum Suppression (NMS) processes. FPS is the reciprocal of latency, which measures the average detection speed per image with higher values indicating faster detection.

Table VIII compares the pre-process, inference, NMS, latency, and FPS metrics of the three models. The hardhat-YOLO model achieved an FPS of 172.4, which increased by 17.3% compared to the YOLOv5s model with an FPS of 147. After integrating CBAM with fewer parameters and computations, the FPS of the hardhat-YOLO model decreased slightly compared to the YOLOv5s-M3s model with an FPS of 178.6. Where ms denotes millisecond.

TABLE VIII. DETECTION SPEED COMPARISON OF THE THREE MODELS

Model	Pre-process (ms)	Inference (ms)	NMS (ms)	Latency (ms)	FPS
YOLOv5s	0.3	4.4	2.1	6.8	147
YOLOv5s-M3s	0.3	3.2	2.1	5.6	178.6
hardhat-YOLO	0.3	3.8	1.7	5.8	172.4 (+17.3%)

D. Discussion

Comparing the effectiveness and speed of the three models, the hardhat-YOLO model achieved a good balance between accuracy and speed. As a result, the model is easily deployable on substation terminals for hardhat-wearing detection. This paper employs experimental data to assess the usability of the model. However, it does not deploy the model to edge computing terminals to verify its usability. This is a limitation of the paper.

VI. CONCLUSIONS

This paper proposes a lightweight model, hardhat-YOLO, customized for hardhat-wearing detection. To improve the accuracy and robustness of the model, a random background augmentation method is introduced to obtain more background images and images from complex work sites are added to the original dataset. The MobileNetv3-small backbone replaces the YOLOv5s backbone, reducing the parameters and computations. The CBAM has been effectively integrated into the network to enhance detection precision with a slight increase in parameters and computations. The proposed model has fewer parameters, fewer GFLOPs, fast speed, and a small file size, resulting in suitable precision. The smaller model is transmitted to the edge computing terminals through PLoT, significantly reducing bandwidth consumption. The validation results demonstrate that the proposed model achieves appropriate precision and fast detection speed. Compared to the original YOLOv5s model, the proposed model has slightly lower accuracy but significantly improved lightweight level and detection speed. As a result, the lightweight hardhat-YOLO model is suitable for practical hardhat-wearing detection in substation sites. Future works should consider the deployment of the deep learning-based model. Utilizing model branch reduction and knowledge distillation further reduces the parameters and computations of the model.

Model for Responsive Agriculture Hub via e-Commerce to Sustain Food Security

Wan Nurhayati Wan Ab. Rahman, Wan Nurfarah Wan Zulkifli, Nur Nabilah Zainuri, Hanis Amira Khairol Anwar
Faculty of Computer Science and Information Technology, Universiti Putra Malaysia, 43400 Serdang, Selangor, Malaysia

Abstract—Ensuring food security in the face of evolving environmental, economic, and societal challenges requires innovative solutions that leverage emerging technologies. This paper proposes a model for a responsive agriculture hub facilitated through e-commerce platforms to address the dynamic demands of food production, distribution, and consumption. The model integrates data-driven decision-making, supply chain optimization, and digital marketplaces to enhance the efficiency and resilience of agricultural systems. By harnessing real-time data analytics, predictive algorithms, and smart logistics, the proposed hub enables agile responses to fluctuating market conditions, climatic variability, and resource constraints. Through case studies and simulation analyses, we demonstrate the effectiveness of the model in enhancing the accessibility, affordability, and sustainability of food systems. Furthermore, we discuss the implications of this approach for stakeholders across the agricultural value chain, including farmers, distributors, retailers, and consumers. The findings underscore the potential of leveraging e-commerce platforms as catalysts for transformative change in agriculture, contributing to the overarching goal of achieving food security in an increasingly uncertain world.

Keywords—Digital agriculture hub model; digital value chain; responsive agriculture hub; food security; multi-sided e-commerce

I. INTRODUCTION

Agriculture has contributed significantly to food security worldwide. Malaysia National Agro-food Policy (2011-2020) focused on ensuring adequate food supply and safety, developing the agro-food industry into a competitive and sustainable industry, and increasing the income level of agricultural entrepreneurs [1]. The agriculture sector used to be one of the main economic activities contributing to the country's Gross Domestic Product (GDP). However, since 1990 due to the emergence of the manufacturing industry in Malaysia, the agriculture sector has been slowing down. The contribution of the agriculture sector in Malaysia decreased from 28.8% in 1970 to only 7.4% in 2020 to the overall GDP [2].

Furthermore, with the wave of COVID-19, agriculture as well having its drawbacks which affected worldwide trade for both supply and demand. In 2020, the imported goods from agriculture were higher than the exported goods. Although some goods need to be imported, the amount of imported goods in 2020 is higher than the previous years. Such increment of imported goods with export reduction may lead to the increase of food trade deficit which will cause a lower GDP as there is less production made within the country. It might take up to the point where the domestic currency weakens and causes

deflation. The performance of the agriculture sector in Malaysia's GDP dropped to 7.1% in 2021 [3].

Food insecurity is a worldwide issue and it has become an alarming phenomenon occurred in Malaysia. The definition of food insecurity by the United States Department of Agriculture (USDA) is a lack of consistent access for people to obtain sufficient food to live an active and healthy life. Millions of world populations are starving and they cannot manage to feed themselves sufficiently. However, food insecurity is not only meant by access to enough food quantitatively but also by obtaining nutritious and healthy food in our daily lives. This food insecurity issue can have a variety of huge impacts on all groups of people including consumers and farmers in terms of health, economy and environment. Food security is important for having sufficient food to consume as well as the quality of food and the value chain of food globally. Consequently, lack of food security is related to conflict, civil strife, poverty, and starvation can all result from a lack of food security. In addition, ensuring food security is critical due to the rise of climate change and global population, as well as supply chain disruptions like the pandemic.

Modernising the agriculture sector is necessary by adopting various technologies from previous centuries and generations. The growing population needs more food supply not only in quantity but also in quality. To guarantee enough food supply from time to time, the government and relevant stakeholders need to prioritise boosting productivity in agriculture production and service. Sustaining agriculture worldwide is always important to strengthen the food value chain and industry. E-commerce is an enabler that drives the utilisation of information and communication technology adoption to boost business activities and create new opportunities in different application domains such as agriculture, education and health. Prioritising advancing agriculture is important to guarantee food security for the nation and the world population. There are key benefits of e-commerce to the agriculture domain including boosting the circulation of agriculture products and development in terms of communication and experience, a marketplace for promotion and price comparison, and customer relationship management of growing customers [4].

Universiti Putra Malaysia (UPM) is a leading university in agriculture in Malaysia. UPM is mandated by the Ministry of Higher Education (MOHE) to lead in food security. Agriculture is the mainstream field of study at UPM where the students are encouraged to relate the agriculture field with life, innovation and business. All students must take the agriculture subject as a requirement for Bachelor's degree graduation. Students at different academic levels are being exposed to the basics of

agriculture and research and innovation with the advancement of technology in agriculture. Besides, UPM's contributions to R&D and commercialisation of technology and innovation are also significant. However, there is still room for improvement such as awareness among Malaysian youngsters to pay attention to the agriculture fields and business fields to encourage them to become entrepreneurs, technopreneurs, unipreneurs or start-up founders.

In this study, we focused on the benefits of e-commerce in boosting agriculture activities including a sustainable food value chain. This paper is structured as follows; Section 2 revealed issues related to food security as the focus domain area. Section 3 reviewed related works on the contribution of e-commerce as the solution to championing agriculture in sustaining food security and other alternatives. Section 4 introduced a model for a responsive agriculture hub via e-commerce to sustain food security. Section 5 explored a potential multi-sided e-commerce platform that can be developed based on the proposed framework. Section 6 discussed the validated results to prove the values of the proposed model. Lastly, Section 7 concluded that e-commerce is the best practice that boosts agriculture via a dynamic e-commerce hub.

II. FOOD SECURITY ISSUES

According to the Oxford Dictionary, agriculture can be defined as the act of farming and the upbringing of certain types of animals with care and nutrition. The crops that are being planted and the animals that are raised are used mainly as food and to produce other products to fulfill human needs. Agriculture products can be sold to generate income. Comparing agriculture, forestry, and fishing, value added (% of GDP) in Malaysia, the value 8.9% in 2022 which is a bit lower than 95 in 2002 and lower than 14.6% in 1992. A similar decreasing pattern can be seen as well in almost all other countries in the world [5].

People have to survive especially during Movement Control Order (MCO), this has motivated the community to initiate agriculture activity and food production from home. In addition, the agriculture industry needed to save their agriculture and food production from being wasted due to the limitation of physical restrictions. Consequently, entrepreneurs starting to turn to e-commerce instead of selling products in physical shops. Aside from the effect of foreign trade, there is a rise in the home garden and urban farming projects in Malaysia during MCO as reported by the local newspaper The Star dated 30th September 2020. As people are being shut at home, this new trend of being slowly involved in urban agriculture is very helpful in optimising land use as it can cut the cost of living in cities, as well as malnutrition and food insecurity. There are also some community-based urban farming projects such as Sunway FutureX Farm, Kebun-Kebun Bangsar and Urban Hijau. However, some technologies can be used to further improve farms productivity yet it is not being highlighted and aware of. There is a need to integrate and assimilate efficient and latest agriculture technologies for farming projects.

Experienced farmers may have better and wider connections with industries thus easier for them to market and

sell their agriculture supplies and products. However, small-scale and new farmers who have not yet gained much experience have to struggle with their limitations and challenges. Small-scale farmers must get support and collaboration from business partners among the experienced farmers as well as from the industries such as knowledge sharing, useful advice, funding support and technologies needed. Besides, lack of awareness and inactive involvement from the community as they did not realise that agriculture could improve many aspects of their life such as sufficient quality food supply and be their main source of income. The community is not interested in agriculture-related activities or projects because they find other activities such as binge-watching movies more fun than farming. Another factor that might contribute to the lack of community involvement is probably due to agriculture activities that are conducted on weekdays during working hours, when most people are occupied with their office work and students attending classes. There is a need to get the community involved because by participating they feel a sense of belonging and will motivate them to continue with the process of planning and implementing the project [6]. This can benefit both parties; the organisers as they understand what the community wants and the community can gain valuable knowledge related to agriculture technology for their farming projects.

In addition, youngsters find that farming is an old-fashioned job and only suitable for elderlies who have retired. In a study of 200 undergraduate students in southwest Nigeria, a total of 159 students admitted that they do not want to volunteer to participate in the agriculture field, which is 79.5% of total students. This is because they are not interested in it, they are lazy and they have a high perception that youngsters are eligible to venture into any other fields besides agriculture [7]. They also think that they might not be able to produce high income by selling fruits, vegetables, and livestock in the market. Of course, these are only youngsters' pre-assumptions as they are all not true. Even those who study agriculture have the possibility of working in the office as an admin or in the lab as a researcher. Agriculture is a very broad field, that people can explore more if they know how much it can benefit them and society.

Food security is very important for every country worldwide. There are issues related to food security in many countries nowadays. These food security issues for example limitations and problems including a shortage in the food supply, insufficient food available in the market and expensive food prices are real for customers. On the other hand, farmers are also facing difficulties such as not being supplied their fresh food, a broken food supply chain, food wastage and limited market access. In another word, a shortage of food supply can be the main reason for the expensive prices in the market. Besides, this mismatched food supply and demand other factors affected agriculture and food security such as expensive price, climate change and food wastage.

A. Expensive Price

Most people are unable to obtain healthy and sufficient food for themselves especially people from low income and B40 due to the price of food being expensive. According to the World Bank Group, almost all low-income and middle-income

countries have experienced high inflation; 88.2% of low-income countries, 91.1% of lower-middle-income countries, and 93% of upper-middle-income countries have experienced inflation levels above 5%, with many experiencing double-digit inflation [8]. The bank reported the proportion of high-income countries experiencing high inflation has increased dramatically, with approximately 82.1% experiencing high food price inflation. High food prices have triggered a global crisis, pushing millions further into extreme poverty and exacerbating hunger and malnutrition. More to that, the number of people experiencing acute food insecurity and in need of immediate assistance is expected to rise to 222 million across 53 countries and territories. Rising food commodity prices in 2021 were a major factor in pushing approximately 30 million additional people in low-income countries toward food insecurity.

B. Climate Change (Flood)

Climate change had a significant impact on agriculture. Farmers are feeling the effects of climate change, with rains arriving earlier. Freshwater is also becoming scarcer as sea levels rise and storm surges, cyclones, and other extreme weather events become more frequent and intense. Climate change impacts include flood disasters, which affect food production and, as a result, food insecurity. While climate change may have a positive impact in some areas, it may have a negative impact in others due to excess or scarcity of water, which hurts food production [9]. Flood disasters have reportedly become more common, with disastrous consequences for food production. Moreover, the crop is suffering as a result of the constant rain and flooding in Malaysia. Even if there are no floods, too much rain kills crops. This causes both hardy and leafy vegetables to be limited to obtain. RM111.95 million in flood losses were recorded in the agriculture, and agrofood sectors [10]. According to the Agriculture and Food Security Minister, Mohamad Sabu Said, damages and losses over 24,700 hectares of agricultural land are recorded by the Ministry Disaster Management Center report. The effect of climate change is not only affecting the farmers but also affecting the consumers to obtain sufficient food as flood causes the shortage of food supply.

C. Food Wastage

Food waste occurs when edible food is discarded by consumers after it spoils or has passed its expiration date. Global food waste is a threat to food security, and it should be a serious concern for any country that cares about its citizens. This is because, while tonnes of edible food waste are lost or wasted during harvesting and production, throwing away edible food waste is a common practice in most affluent households in urban cities. Despite this pitiful waste situation, thousands of households continue to struggle to have daily square meals in most urban and rural areas (food insecurity) [11]. In the year 2021, it has been recorded that Malaysians waste 4,081 tonnes of edible food every day [12]. It is enough to fill one and a half Olympic-sized swimming pools or feed three million people three times a day. The majority of food waste ends up in

landfills. As waste decomposes, it emits greenhouse gases such as carbon dioxide and methane, which contribute to climate change and cause temperatures to rise. At landfill sites, degraded food waste may also produce leachate, contaminating underground water and aquatic ecosystems. Consequently, it will affect the difficulties of people consuming enough food in the future and at the same time it endangers human health.

Agriculture e-commerce can open up agriculture supply and expand the business value chain to more efficient connections and supports. In addition, it creates fairer incomes for the stakeholders in the partnership and networking agriculture supply. Benefits of agriculture e-commerce in economic to stakeholders including farmers, communities and the wider society in the form of improved income and livelihood. In terms of the social impact parallel with the UN Sustainability Goals (SDGs) such as reducing wastage, improving incomes, financial inclusion, increasing productivity and impact on adjacent services [13]. The impact of rural e-commerce in China has a positive impact on the rural economy, agrifood supply chain, lifestyles, entrepreneurship and ultimately transforming the rural sector in the 21st century which covers the economic, social and environmental benefits [14].

III. RELATED WORK

E-commerce offers dynamic attraction via a hybrid value chain as the solution to boost supply and fulfill demand [15]. There are eight elements of the key successful factors as shown in Fig. 1. E-commerce drives online applications as solutions from provider to consumer for various implementation domains including agriculture, education, health, etc. A successful e-commerce platform disrupts the industry by proactively matching supply and demand. Advanced concepts of supply-driven and demand-oriented are important for pioneering e-commerce and leading online businesses. Comprehensive market understanding with a systematic business model and strategy is critical. Therefore, it is a must-have impactful innovation as a useful solution, a niche market as the right target, disrupt the industry with the best strategy, product-market fit to remain competitive, and a sustainable business model to organically grow.

The framework of e-commerce dynamic attraction via a hybrid value chain to boost supply and fulfill demand can be used as a reference and guidance to many different stakeholders as key players in the agriculture hub. The great potential of the framework to benefit them for example shortening the food industry value chain, rapidly matching supply and demand, and digitalisation to save resources. There are gaps between the utilisation of IT and common traditional best practices. Modernising agriculture with great impact via an e-commerce platform can be realised by validating all the stated elements including the useful solution as the impactful innovation, the right target of a niche market, the best strategy to disrupt the industry, competitively offering of product-market fit, and organically grow with the development of the sustainable business model.

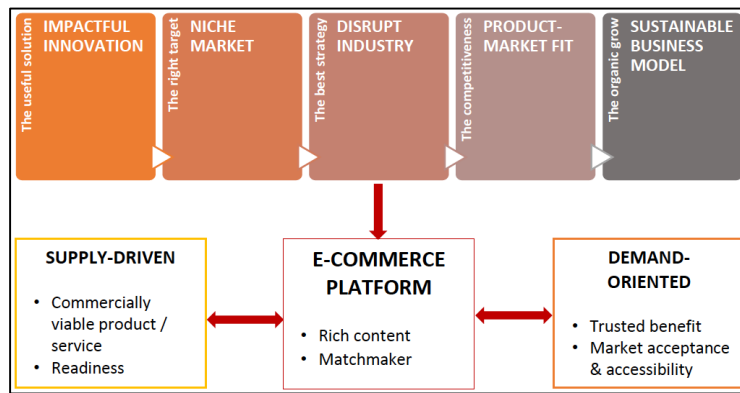

Fig. 1. A framework of e-commerce dynamic attraction via hybrid value chain to boost supply and fulfil demand

There are initiatives in Malaysia to bring fresh food from farms to the marketplace such as the following:

OurFarm is an e-commerce platform and warehouse by AirAsia [16]. Plus, this platform provides wholesale purchases of fresh agriculture products and customers can get lower prices buying in bulk. This platform is supported by the Ministry of Agriculture and Food Security (MAFS), formerly known as the Ministry of Agriculture and Food Industries (MOA). Thus, making this website more trustable for customers to do online transactions. The website already puts the minimum number of agriculture products that clients can order and they can increase it according to their needs. For fish and meat products, they have both options, which are fresh and frozen. Since it offers on-time delivery, customers do not have to worry if the fresh products will be rotten as the process is very fast since they use aircraft freight to transport the product.

AgroBazaar (<https://www.agrobazaar.com.my/>) is supported by MAFS and many big agencies such as the Federal Agricultural Marketing Authority (FAMA), Malaysian Agricultural Research and Development Institute (MARDI), Kemubu Agricultural Development Authority (KADA) and Muda Agricultural Development Authority (MADA) [17]. Interestingly AgroBazaar has collaborated with many delivery services such as Ninjavan, J&T Express, POS Laju, teleport, Grab Express, asiaXpress, LalaMove and DHL. Customers can choose according to their preference and the availability of the courier to send the products to their area. It also states the amount of discount, which can attract customer's attention and will create a sense of urgency for them to buy as soon as possible as they do not want to miss the discount opportunity.

Mega Farmers' Market was established to provide the farmers' market with a fresh image and to keep it competitive [18]. It is a successful effort for agricultural businesses and manufacturer's, as well as farmers and fishers, who engage in the agricultural market. The Mega Agricultural Market has incorporated various new features, including a more entertaining and customer-friendly ambiance, improved product display, and a cleaner and larger shopping area. FAMA has also established the Fresh Fruits Stalls (GBBS) program, which is supervised by the organisation. It's essentially a network of local entrepreneurs' fruit stands that have been

chosen for upgrading purposes with a uniform, clean, and appealing product arrangement. GBBS has evolved into a new way for consumers to obtain high-quality fruits as well as a way for entrepreneurs to expand their fruit business. It is an attempt to entice the public to obtain direct supplies and increase per capita consumption of local fruits. FAMA has so far established 163 businesses with 326 stalls across the country.

Dropee (<https://www.dropee.com/>) where they sell fresh and frozen vegetables but not poultry and fishery [19]. Plus, they also sell other types of products such as bread, snacks, office furniture, and electronic stuff. There is no minimum order rule on this website. The website user interface (UI) is very simple therefore, it is easy to navigate between pages and browse through the page without being distracted.

MDEC (eLadang) (<https://mdec.my/digitalagtech>) is a pilot initiative driven by MDEC, in collaboration with ecosystem partners [20]. They empower the agriculture sector by infusing 4IR technologies (Internet of Things (IoT), Big Data Analytics (BDA) and even Artificial Intelligence (AI)) to catalyze digital adoption towards improving the livelihood of the many farmers across the nation. The eLADANG provides the training, and equipment for the people involved in the agriculture sector with their crops and yield. They also provide training for the farmers to keep maintain their farms.

CityFarm Malaysia (<https://cityfarm.my/>) was founded to inspire more city farmers with the ability to grow locally from anywhere for a more sustainable future of food production [21]. It launched in 2016 with an indoor controlled environment vertical show farm (450sqf) that is capable of producing 2000 heads of lettuce every month. CityFarm Malaysia wishes to play a part in the movement by creating a simple and affordable farming system in cities, the ability to satisfy the rapid growth in consumer demand for affordable, high-quality, locally produced crops in any climate, and provide training services to the youngsters on the importance of farming and how you can play a part to make the world a better place by growing food that is healthy, clean and fresh. They also provide a platform where people can buy all the necessary equipment to start their urban farming journey.

^a 1 <http://hbrppublication.com/OJS/index.php/RAWDD/article/view/2863> (Wan Nurhayati et. al., 2023)

To be able to assimilate people functioning in the same pillar of agriculture in Malaysia, there is a need to take actions by inventing a platform so that all the people who are involved in the agriculture sector can play a role in enhancing the agricultural sector. This is important as agriculture has been the backbone of the Malaysian economy ever since. People's interest in joining the agriculture sector is also needed in the long run so there will be future generations that will inherit the agriculture practices. If there is less or none of them that are interested in this precious field, there will be problems in advancing in this sector. The term of studying in the agriculture field brings many unwanted ideas as the benefits of these areas of study are not widely promoted. Hence, it is important to instill in the young the knowledge to come out with talents in agriculture and this is where UPM, as it strives to be the center of excellence in agriculture, should play an important role in setting a platform where it is conventional for the people to look for agriculture-related information.

IV. MODEL FOR RESPONSIVE AGRICULTURE HUB VIA E-COMMERCE TO SUSTAIN FOOD SECURITY

Responsiveness is the key to improve the efficiency and effectiveness of agriculture and the food security value chain. Developing a model for a responsive agriculture hub via e-commerce transforms the traditional sequential agriculture value chain into a dynamic, efficient, and resilient system. By leveraging technology, data-driven decision-making, and inclusive market access, this transformation enhances food security, sustainability, and economic opportunities for stakeholders across the agricultural ecosystem. Justifications for the key benefits from the model as in the following:

1) *Efficiency improvement*: Traditional agriculture value chains often involve numerous intermediaries and sequential processes, leading to inefficiencies in production, distribution, and access to markets. By developing a model for a responsive agriculture hub via e-commerce, we can streamline these processes, reducing the number of intermediaries and enabling direct interactions between farmers and consumers. This streamlining enhances overall efficiency, resulting in cost savings, reduced food waste, and improved resource utilization.

2) *Real-time decision making*: The adoption of e-commerce platforms in agriculture facilitates the collection and analysis of real-time data throughout the value chain. By leveraging data analytics and predictive algorithms, stakeholders can make informed decisions promptly. This capability is crucial in responding rapidly to market fluctuations, weather patterns, and other dynamic factors affecting agricultural production and distribution, thereby ensuring the timely availability of food supplies.

3) *Supply chain resilience*: Agriculture value chains are susceptible to disruptions caused by various factors such as natural disasters, supply chain bottlenecks, and socio-economic crises. Transforming the sequential agriculture value chain into a responsive agriculture hub enhances supply chain resilience. By diversifying distribution channels, optimizing inventory

management, and implementing contingency plans enabled by e-commerce platforms, stakeholders can mitigate the impact of disruptions and maintain consistent food supplies, thus contributing to food security.

4) *Market access and inclusivity*: E-commerce platforms provide farmers with broader market access beyond traditional physical markets, enabling them to reach a larger customer base locally, nationally, and even globally. By eliminating geographical barriers and intermediaries, smallholder farmers and rural communities can access markets directly, empowering them economically and promoting inclusivity in the agriculture sector. This inclusivity strengthens the overall resilience of the food system by diversifying sources of supply and demand.

5) *Sustainability enhancement*: A responsive agriculture hub via e-commerce facilitates the adoption of sustainable agricultural practices by providing incentives and market opportunities for environmentally friendly production methods. By promoting transparency and traceability in the supply chain, consumers can make informed choices that support sustainable farming practices. Additionally, the optimization of logistics and transportation enabled by e-commerce reduces carbon emissions and environmental impact, contributing to the overall sustainability of the agriculture sector.

We propose a model for a responsive agriculture hub via e-commerce to sustain food security as shown in Fig. 2. Transforming the sequential agriculture value chain into a responsive agriculture hub is necessary. The hub consists of important elements and is accessible to different targeted stakeholders at anytime and anywhere. These elements include knowledge, farm, product, logistic service, shop, customer persona and food security. Whereas, the stakeholders include experts, farmers (suppliers), manufacturers, distributors, marketers, customers and the community. The importance of this model is to connect and leverage the following engagements:

- Source of data, information and knowledge concerning the agriculture experts from such as researchers and consultants the university, research institute, industry, association, government and experienced individual farmers.
- Agriculture hub with responsive connectivity from various stakeholders in the agriculture and food production value chain such as supplier farm, food manufacturer, delivery service, marketer and customer.
- Digital matching platform via e-commerce to create knowledge and business networking to speed up all the necessary processes and increase agriculture and food productivity.

The proposed model (Fig. 2) for a responsive agriculture hub via e-commerce to sustain food security consists of these components with stakeholders and roles as in Table I:

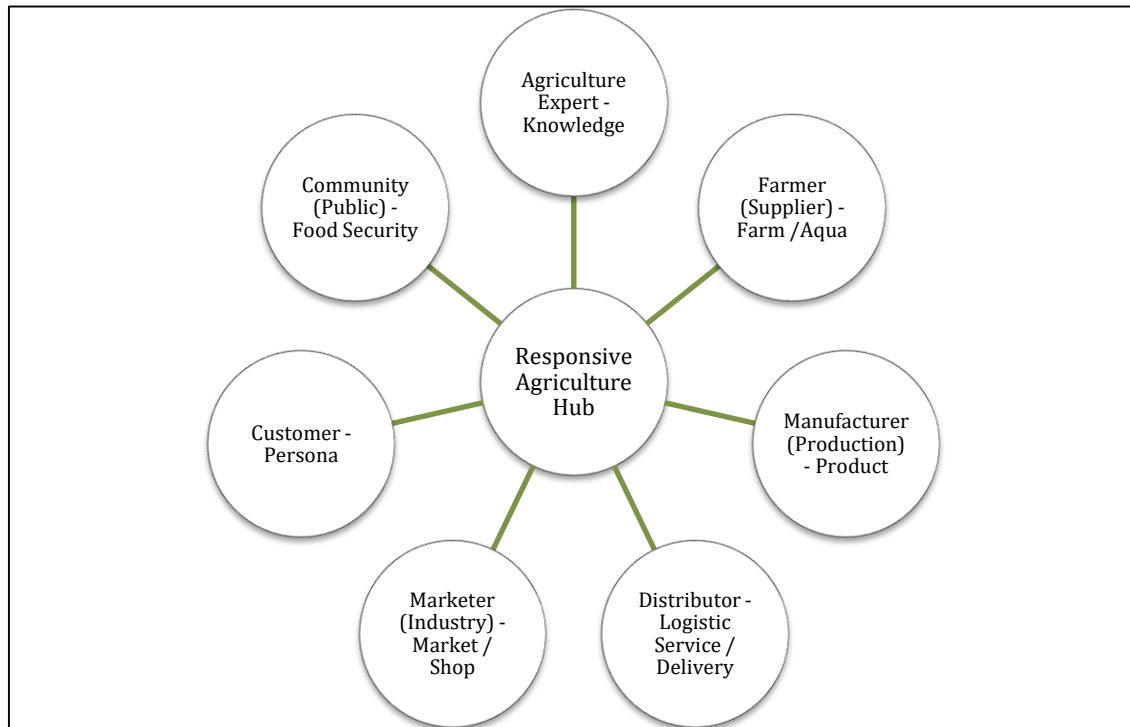

Fig. 2. Model for responsive agriculture hub via e-commerce to sustain food security

TABLE I. ELEMENTS OF RESPONSIVE AGRICULTURE HUB CONSISTS OF COMPONENTS, STAKEHOLDERS AND ROLE

COMPONENT	STAKEHOLDER	ROLE
Agriculture Expert – Knowledge	Agriculture expert is an experienced individual farmer; researcher and consultant from <ul style="list-style-type: none"> • farm • the university • research institute • industry • association • government 	Source of data, information and knowledge with reference
Farmer (Supplier) – Farm/Aqua	Farmer is a direct supplier from farm and/or aqua pond	Agriculture hub with responsive connectivity to provide from farm-to-market fresh food such as fruits and vegetables
Manufacturer (Production) – Product	Manufacturer is the agriculture product and food production line	Process, produce and pack food from the farm (supplier)
Distributor – Logistic Service/Delivery	Distributor is the delivery service to bring agriculture and food products from farm-to-table	Logistic service to shorten the food value chain
Marketer (Industry) – Market/Shop	Marketer is mainly industry to reach out the targeted market	Do promotion and marketing the agriculture and food products to the targeted market
Customer – Persona	Customer is the one who spending money for the value and benefit they got from the agriculture and food products	Buy the agriculture and food products
Community (Public) – Food Security	Community is the crowd/people who in need of the agriculture and food products	Engage in the agriculture circle or e-commerce platform to seek for information, buy product, etc.

V. POTENTIAL MULTI-SIDED E-COMMERCE PLATFORM AS A CASE STUDY

Referring to the proposed model as a guideline, an e-commerce multi-sided platform can be developed as a responsive agriculture hub. Here are examples of e-commerce projects being proposed by e-commerce students at the Bachelor’s degree level for the e-commerce course as a case study; ASFALIS mock-up.

ASFALIS is an e-commerce platform to overcome the issue of food insecurity for both consumers and farmers as shown in Fig. 3. The platform is called ASFALIS because the word ASFALIS comes from the word in Greek that gives a meaning of ‘secure’. This is to explain that this platform is to make the earth sustainable by securing the food supply and providing healthy food to all people at anytime to make the world a better place. ASFALIS is a consumer-friendly platform that offers a variety of features for customers to purchase foods and for farmers or providers to supply fresh foods. It acts as a matching

platform to connect both consumers and farmers. To be specific, the targeted customers that are going to use this platform are firstly, households that come from low-income backgrounds. This is to make sure that these households can consume enough nutritious foods to prevent poverty issues from happening. Besides, another targeted customer is the

active farmers. This platform can help the farmers to market themselves by selling the food products that have harvested. Also, it is an opportunity for farmers to expand their businesses by developing new market venues and at the same time it would help them to gain profit.

Fig. 3. ASFALIS main page

ASFALIS provides originality and novelty for the food security e-commerce solution. This is because ASFALIS offers features that may not be able to get from other e-commerce platforms such as updating Malaysia's population statistics every day, giving notification when there is serious climate change might occur, consumer can sell their expiry date foods to other consumers, farmers can locate nearby agricultural land, consumers can search the nearby farmers' market and ASFALIS also suggesting amount of foods to eat per day in calories to the consumer according to their Body Mass Index (BMI). Furthermore, ASFALIS is the first food security e-commerce platform named ASFALIS as there is no other website or platform that has the name ASFALIS. This can be proven that ASFALIS is an original platform that exists to serve the very best of all parties including the consumers, customers and farmers. All the solutions and features that have been stated above also could not be found and are not available in other e-

commerce platforms such as Econsave, Lotus and Giant. This can be explained that ASFALIS is the only platform that offers a variety of modules and functions that can be optimized by consumers and farmers without facing any difficulties and obstacles.

ASFALIS acts as a matching platform between consumers and farmers to solve food security issues. To give and serve the best for both consumer and farmer, ASFALIS provides a number of unique value proposition (UVP) that only available in ASFALIS and might not exist in another platform. Firstly, ASFALIS can be utilised by both consumers and farmers. This can be emphasised that ASFALIS provides fresh, natural, organic and brand-new foods and raw materials for the consumer as it is being sold directly after the products are harvested by the farmers as shown in Fig. 4.

Fig. 4. Page for farmers to stock up their production

Secondly, the module in ASFALIS could help the farmers in various ways. In ASFALIS platform is equipped with features that constantly remind and notify the farmers regarding serious weather or climate situations that might happen, able to search for available agricultural land and also portray up-to-date Malaysia population statistics every day as shown in Fig. 5. Through this module and function, it could help the farmers to plan their farming activities, then farmers can identify the agricultural land that they can buy and own to enhance and increase their farming activities. Also, from the statistics of Malaysia's population in the ASFALIS platform, the farmers can prepare the food supply that aligns with the population.

Offering cheap prices of food could help consumers of low income to obtain sufficient and healthy in their daily lives. Besides, ASFALIS is a multi-platform that allows consumers to sell their soon-expiry date food through this platform. This means that the ASFALIS platform helps the world from food wastage and at the same time the consumers can make a profit through this platform.

ASFALIS e-commerce platform can be categorised into three modules which are consumers, platform developers and farmers.

A. Module 1: Consumers

Firstly, modules for consumers. To enable the consumer to use the platform, the consumer needs to sign up for an account on the website. Then, there is a module for consumers to be able to see and browse the available list of food items that they want to purchase as shown in Fig. 6. The raw materials available in ASFALIS include vegetables, fruits, poultries, fish and seafood. ASFALIS offers an affordable price for consumers who can afford to buy for all groups all people including people from B40. With the price that is being offered by ASFALIS, it would help to reduce food insecurity as all people got to buy and consume sufficient nutrients of food.

Moreover, there is a shopping cart for the consumer to place their order. In the shopping cart, the consumer can check out the items that they intend to buy. Consumers can use the shopping cart to select and hold the products they want to buy. It keeps track of the consumers' session, allowing them to leave the site and return later with items still in their shopping cart. The cart collects the consumer's payment information during the checkout process. This data is forwarded to the third-party payment processor. The order details are sent to other modules, such as the order management system (OMS), inventory management system, and customer relationship management (CRM) system. This module would ease consumers' activity to make any purchase in ASFALIS.

Fig. 5. Weather forecast page

Fig. 6. E-catalogue page

In addition, all the food provided by ASFALIS are all fresh and brand new. The foods are being stocked up regularly. We also practiced hygiene in ASFALIS. Cleanliness is the main priority to serving the very best consumers. The process of handling, preparing, and storing food or drink in a manner that minimises the risk of consumers becoming ill from food-borne disease. It is to aim to keep food from becoming contaminated and causing food poisoning. On this ASFALIS website, the consumer. Besides, we also provide a search function for the consumer to look up nearby farmers' market locations. This enables consumers to choose and make a purchase with their preferred farmers market store.

Moreover, to avoid the problem of food wastage among people in Malaysia, ASFALIS has a module and function that suggests the consumer to how many amounts of food calories to consume per day. This function is being addressed through the body mass index (BMI) of people who have entered their information regarding BMI during the process of account registration. Through this module and function, the consumer can plan their daily life of meals to consume in advance so that it will allow them consumer to see how much they are eating and at the same time it can make maximum room for healthy choices and nutritionally well-balanced meals as shown in Fig. 7. This way, it can ensure all the consumer's meals include the requisite proteins, carbs and grains.

Fig. 7. Diet meal plan page

Besides, other than buying food, the consumer can also do the activity selling in terms of selling soon-expired food at a cheaper and discount price to other consumers. This means the food products being sold are extraordinarily cheap which is half of their market price. This enables the consumer to purchase the food hassle-free. They get to enjoy the food before the expiry date at the cheapest price. Thus, the consumer not only obtains profit from selling expiring date food but also the issue of food wastage in Malaysia could be reduced.

B. Module 2: Platform Owner

The second module is the platform owner. Platform owner can see the activities that have been done by both consumers and farmers. The amount of profit is automatically divided between the platform owner and farmers. For the profit, it has been calculated that the commission rate for the platform owner is 20% of the profit and 80% is for the farmers. The consumer who sells their soon expired date food will solely get all the profits and commission rate.

Besides, there is a chat in ASFALIS that allows consumers and farmers to communicate directly with the platform owner. This is important for them to address the issues that may involve such as technical issues. Therefore, the platform owner can take immediate action towards the issues. Furthermore, any new farmers who would like to market in ASFALIS can just enter the website and register themselves. The registration of new farmers will be notified to the platform owner so that the

platform owner can keep track of all the activities happening on the website and also the cash flow of the profits.

C. Module 3: Farmers

The third module in ASFALIS is the farmers. The farmers are not restricted to only one type of farmer but also it includes all types of farmers which are agriculture farmers and aquaculture farmers. To be able to optimize the platform, the farmers have to register themselves on the website as farmers. Then, they get to market the products they harvested. The items that will be checked out by consumers will then get notified to the farmers. Hence, farmers can get the item prepared and delivered to the consumer.

Additionally, farmers also get a notification when there is expected serious climate change such as floods or droughts that might occur. From this climate notification that has been received by the farmers, the farmers get to plan the amount of food to be planted and also when is the time they need to stop their farming activities for a while and wait until the weather is suitable for farming. Through this module and function, it can avoid tonnes of food loss and will guarantee food security in Malaysia. ASFALIS also suggested to the farmers the preferred amounts of fruits or vegetables that they can be planted during unstable weather conditions.

On top of that, on the home page of the website, there will be current statistics on Malaysia's population. The statistics will be generated or updated automatically according to the real

Malaysian population every day. This can help the farmers to predict the amounts of products to produce based on the population. It is to align the population and the food supply by farmers so that no one will be left behind from getting insufficient food and at the same time no food wastage will happen.

Furthermore, the delivery of food is available 24/7 so the consumer can make any purchase at anytime and anywhere. The consumer does not need to worry regarding the delivery of their food items as ASFALIS only offers fast delivery service as shown in Fig. 8. Also, the farmers will gain their income directly as the profit will be auto-generated to their bank account as soon as the consumer makes a purchase. ASFALIS accepts both cash and online payment for consumers to make a purchase. Consumers are more likely to pay faster and sooner if they have multiple payment options. Providing multiple payment options for consumers benefits ASFALIS as well.

The farmers also get to market themselves through the ASFALIS platform and can expose themselves widely in Malaysia as shown in Fig. 9. This is one of the ways for the farmers to increase their brand exposure so that many people get to know their brand and buy from them. Also, in ASFALIS we have a module function for the farmers to search for available agricultural land in Malaysia for them to do farming activities. It would help them to locate nearby areas that are still accessible for them to buy and own the land. Therefore, the farmers would not find it difficult to survey around physically looking for available agricultural land. The farmers can simply use ASFALIS as a solution to look for agricultural land as shown in Fig. 10.

ASFALIS platform involves two types of business models which are Business-to-Consumers (B2C) and Consumer-to-Consumer (C2C). Firstly, ASFALIS utilises a B2C business

model for e-commerce. This process occurs between farmers and consumers. This means that the farmers market their products and foods directly to the end consumers or customers. B2C is a business that sells directly to consumers as shown in Fig. 11. Anything users buy as a consumer in an online store, from foods and raw material supplies, is a B2C transaction. ASFALIS is a B2C because it involves a purchase that has a much shorter decision-making process than a Business to Business (B2B) purchase, particularly for lower-value items. Because of the shorter sales cycle, ASFALIS is a B2C that typically spends less money on marketing to make a sale while having a lower average order value and fewer recurring orders than the B2B counterparts. To market directly to our customers and make their lives easier, ASFALIS has used technology such as mobile apps, native advertising, and remarketing.

Next, ASFALIS also utilises C2C as a business model in e-commerce solutions. The C2C business model can be seen between a consumer and another consumer when the consumer wants to sell their soon-expiry date food products to other consumers by using this platform as shown in Fig. 12. Consumers sell goods directly to other consumers in C2C e-commerce. ASFALIS enables the consumer to sell their soon-expiry date foods at their prices without the need for their online storefront. They typically make money by charging transaction or listing fees and connect consumers to exchange goods. C2C businesses benefit from self-propelled growth by motivated buyers and sellers, but quality control and technology maintenance are major challenges. Consumers benefit from product competition and frequently find items that are difficult to find elsewhere. Furthermore, because there are no retailers or wholesalers, sellers' margins can be higher than with traditional pricing methods. C2C sites are convenient because they eliminate the need to visit a physical store. Buyers come to sellers after they list their products online.

VI. RESULTS AND DISCUSSION

The case study as the outcome results presented herein confirms the efficacy of the proposed model for a responsive agriculture hub via e-commerce in transforming the traditional sequential agriculture value chain into a dynamic, efficient, and resilient system. Through a comprehensive evaluation of key performance indicators and qualitative assessments, the benefits of this transformative approach have been substantiated across various dimensions of agricultural production, distribution, and market access.

1) Enhanced Efficiency and Cost Savings:

a) The implementation of the responsive agriculture hub model led to notable improvements in efficiency throughout the value chain. By streamlining processes and reducing reliance on intermediaries, the time taken for product sourcing, packaging, and delivery was significantly reduced.

b) Cost savings were observed across multiple stages of the value chain, attributable to reduced transportation costs, minimised wastage through optimised inventory management, and lower transactional expenses associated with direct farmer-to-consumer interactions facilitated by e-commerce platforms.

2) Improved Resilience to Disruptions:

a) The dynamic nature of the responsive agriculture hub enabled stakeholders to respond swiftly to unforeseen disruptions, such as supply chain bottlenecks, adverse weather events, and market fluctuations.

b) Through real-time data analytics and predictive algorithms, the model facilitated proactive decision-making, allowing for timely adjustments in production schedules, inventory levels, and distribution routes to mitigate the impact of disruptions and ensure uninterrupted food supplies.

3) Expanded Market Access and Inclusivity:

a) The adoption of e-commerce platforms broadened market access for farmers, particularly smallholders and rural communities, who traditionally faced challenges in reaching distant or urban markets.

b) Direct-to-consumer sales facilitated by the responsive agriculture hub empowered farmers to capture a larger share of the value chain, thereby enhancing their economic viability and promoting inclusivity within the agriculture sector.

4) Promotion of Sustainable Practices:

a) The model incentivised the adoption of sustainable agricultural practices by providing market premiums for eco-friendly products and promoting transparency in sourcing and production methods.

b) Consumers exhibited a growing preference for sustainably sourced agricultural products, leading to increased demand for certified organic, fair trade, and locally grown produce, thus driving positive environmental and social outcomes.

In summary, the validated results underscore the transformative potential of the proposed model for a responsive agriculture hub via e-commerce in revolutionizing the traditional sequential agriculture value chain. By harnessing technology, data-driven decision-making, and inclusive market access, this innovative approach enhances efficiency, resilience, sustainability, and stakeholder satisfaction, thereby contributing to the overarching goal of achieving food security in an increasingly complex and interconnected world.

VII. CONCLUSION

Agriculture and food production can be benefited from the advancement of IT such as e-commerce platforms. Traditional businesses particularly the food industry value chain can be shortened to make it more effective reflecting the cost and time savings. Limitations to bringing from the farm to market especially during and after COVID-19 disease hit the world must be stopped and improved. There is an urgent call for local farmers and business owners to shift to e-commerce platforms to sell their agriculture and food products. They need to be digitally savvy to keep up with current technologies. It is important to increase the visibility of the agriculture sector including in Malaysia to make this sector grow until those small farmers and business owners become internationally known.

The proposed model for a responsive agriculture hub via e-commerce to sustain food security is important to guide agriculture and food industry stakeholders. Leading competitively towards creating new value to solve food insecurity issues such as expensive prices, climate change and food wastage needs a new shift of paradigm. The model has comprehensively highlighted critical components, actors and roles. Transforming agriculture as the responsive hub to the agriculture and food industry stakeholders needs support and actions from various strengths. These included agriculture experts with knowledge, farmers as direct suppliers from their farm/aqua, manufacturers for quality production, distributors who provide logistics and delivery services, marketers as the role of the industry to reach out to real markets on a mass scale, customers as the targeted niche market by understanding their persona, and community as the public crowd to make successful of food security in a complete cycle.

This study is important to be extended through many other contributions. For example, the development of an early prototype, ASFALIS to prove that the model can translated into real implementation as a case study. There are other potentials for e-commerce applications in the agriculture domain that can be developed based on the proposed model with the objectives to realise a responsive agriculture hub to benefit stakeholders and uplift agriculture and food industries at different levels in the future.

The way forward is to gain stakeholder satisfaction and trust in the responsive agriculture hub model. These include farmers to appreciating the fair pricing, transparent transactions, and timely payments facilitated by e-commerce platforms; and consumers expressing confidence in the quality, freshness, and traceability of products sourced through the hub, fostering long-term relationships and loyalty to participating farmers and brands. More future works can be explored from the proposed model such as enriching content and collaborations through responsive agriculture hubs via e-commerce platforms.

ACKNOWLEDGMENT

We would like to extend our sincere gratitude to the Faculty of Computer Science and Information Technology at Universiti Putra Malaysia for generously covering the publication fee associated with this research paper. The Faculty has enabled us to share our research with the broader scientific community, contributing to the advancement of knowledge in agricultural technology and food security. We are truly appreciative of their commitment to supporting academic endeavors and fostering impactful research initiatives.

Digital Public System of Urban Art: Navigating Human-Computer Interaction in Artistic Design for Innovative Urban Expressions

Yuan Yao, Ying Liu*

College of Information Engineering, Guangxi Agricultural Vocational University, Nanning, 530007, China

Abstract—The convergence of digital technology and urban art has given rise to novel urban art digitalization systems. This paper investigates the relationship between Human-Computer Interaction (HCI) and creative design, particularly in the age of 3D printing, Virtual Reality (VR), and digital art. We highlight the transformative potential of these technologies using examples that include interactive public installations and VR art exhibitions, thereby providing empirical evidence to ground our discussion of the evolving paradigms of technology and public art mutual constitution. We also contribute prescriptive guidance for bringing digital art into cities. We hope to offer a full guide to understanding how digital innovation could catalyze the growth and evolution of the wealth of cultural assets that characterize cities.

Keywords—Urban art; digitalization; human-computer interaction; creative expression; public art; technological innovation

I. INTRODUCTION

Public art is a key tool of urban planning. It allows the creation of a sense of place or identity, as well as promotes human traffic. Public art can be anything from historical sculptures to temporary installations such as festival ornaments [1, 2]. It can be abstract or depict the culture, history, and character of a city [3]. It can be a memorial, commemoration, or even a landmark [4]. Public art revitalizes the environment through creative place making, creating concrete, economic, and social changes [5]. It has been used to enhance the public perception, identity, and physical form of cities worldwide [6].

As policy ideas circulate, they often undergo extensive mutations, posing difficulties in understanding the true 'nature' of the policy. For example, public art policies have permeated various aspects of society, leading to controversies and misunderstandings within this artistic discipline [7]. To comprehensively assess the development of any policy idea, including public art policy, it is valuable to explore how the official objectives behind the policy transform across different local contexts. Guided by this premise, we inquire: How do municipalities adapt and integrate discourse about public art within their policy documents and reports? And what underlying logic distinguishes one city from another in this regard?

Human-Computer Interaction (HCI) is an interdisciplinary research field that examines how computer technologies are designed and used, particularly for smooth and effective human-machine interaction [10]. In artistic design, HCI is important for determining how the interface is used for artists and users to

interact with digital media [8]. The dynamic interaction between HCI and the creative production process presents several options since HCI impacts accessibility, intuitiveness, and overall user experience. The significance of HCI in innovative design lies in its capacity to facilitate the integration of human creativity with technical functionality [9]. Artists employ digital tools and interfaces to materialize their creative concepts, and HCI serves as the medium for effortless and intuitive communication and self-expression [10].

HCI can be employed to generate immersive and compelling creative experiences. Adopting tools such as Virtual Reality (VR), Augmented Reality (AR), and gesture-based interfaces creates new outlets for creativity [11]. These technologies empower people to interact with art in novel ways, dismantling conventional obstacles between the viewer and the art work. The function of HCI in promoting interactive creative experiences is changing the position of the passive viewer to that of an active participant, resulting in a more dynamic and captivating connection between the artist's vision and the audience's perception.

In the age of fast technological progress in computers, the widespread impact of digitization has infiltrated every aspect of human existence. The widespread incorporation of this integration has not only emerged as a significant pattern but also as a powerful influence, substantially changing how individuals interact with different facets of their everyday lives [12, 13]. The introduction of digital technology in art has been widely understood to be a major transformation [14]. This transformation is central to new practice and fosters the evolution of the creation and presentation of art concerning the potential of digital media, both in terms of tools and methods. As technology and art come together, notable works that embrace and explore the potential of digital mediums have already been given. These innovative efforts combine conventional artistic aspects with state-of-the-art technical breakthroughs and drive human imagination into uncharted territories, cultivating a dynamic connection between technology and creative representation.

This study aims to increase understanding of how HCI impacts artistic design in urban contexts and the technology's ability to shape urban artsapes in transformative ways. This study aims to provide important insights into the complex relationship between technology and art in urban areas by analyzing the changing landscape of public art policy, the role of HCI in enabling creative encounters, and the impact of

digitalization on artistic expression. We provide an in-depth analysis and examination of the opportunities and limitations of using digital technology in public art.

The paper proceeds as follows: in Section II, we first provide an overview of the digital technology integration on urban public art. Then, in Section III, we focus on interaction and artistic design within the urban environment. In Section IV, open issues and future research directions are presented. We discuss the possible ways for the follow-up research to be carried out in the future. Section V concludes the research work by summarizing the main research findings.

II. BACKGROUNDS

A. Transformation of Urban Public Art Through Technology

When urban public art combines big data and Internet of Things (IoT) technology, it transforms significantly, resulting in dynamic and interactive experiences [15, 16]. This metamorphosis redefines how art, the environment, and the public interact. This confluence fosters a new era of intelligent and data-driven urban art installations [17]. Table I lists dynamic urban art installations made possible through Big Data and IoT. IoT devices deployed in public locations facilitate the creation of urban art pieces that may dynamically react to up-to-the-minute environmental data. For example, sculptures or lightworks can modify their colors or patterns according to weather conditions, noise levels, or air quality changes. This sensory connection intensifies audience involvement, creating a more immersive and dynamic experience.

Big data analytics can be employed to understand crowd behavior and preferences, shaping the design and placement of public art installations. By analyzing patterns in foot traffic, social media interactions, or demographic data, urban planners and artists can optimize the impact of art installations, ensuring they resonate with the local community [18]. Table II presents the characteristics of digital media art in urban environments. Utilizing big data, urban public art can adapt to its surroundings. For instance, sculptures could change their form or light installations their intensity based on the flow of people or specific events. This adaptability ensures that public art remains relevant and engaging in the ever-changing urban landscape.

TABLE I. EXAMPLES OF DYNAMIC URBAN ART INSTALLATIONS ENABLED BY BIG DATA AND IOT

Technology	Application	Examples of effects
IoT devices	Real-time environmental response	Sculptures or light installations changing colors or patterns based on weather conditions, noise levels, or air quality.
Big data analytics	Crowd behavior understanding	Optimization of art installations based on foot traffic, social media interactions, or demographic data.
Big data + IoT	Adaptive public art	Sculptures changing form or light installations adjusting intensity based on the flow of people or specific events.
Art technology	Interactive AR art experiences	Exploration of additional layers of information or interactive elements superimposed on physical art works.
Big data visualizations	Transformative artistic expressions	Visualizing real-time data streams (traffic patterns, energy consumption, air quality) into compelling installations.

TABLE II. CHARACTERISTICS OF DIGITAL MEDIA ART IN URBAN ENVIRONMENTS

Characteristics	Description
Essence	Reliance on digital technologies (software, algorithms, coding, interactive elements) as fundamental components of the creative process.
Exhibition	Departs from traditional gallery displays, often necessitating electronic screens, projectors, immersive installations, VR, and AR platforms.
Transmission	Relies on digital platforms and the internet for dissemination, allowing global reach and instant sharing through online platforms, social media, and digital galleries.
Interactivity and immersiveness	Creates immersive, dynamic, and interactive experiences for the audience, transcending traditional mediums like canvas or sculpture.

B. Integration with AR and Interactive Technologies

Integrating big data and IoT with AR technology allows for the creation of interactive AR art experiences [19]. Through mobile applications or AR glasses, users can explore additional layers of information or interactive elements superimposed on physical art works, creating a multisensory encounter. Table III summarizes key aspects of interaction design in urban public art. Big data visualizations can be transformed into artistic expressions, providing a unique perspective on urban dynamics [20]. Real-time data streams, such as traffic patterns, energy consumption, or air quality, can be translated into visually compelling installations that serve as art and raise awareness about urban challenges [21]. The experience of interaction in art is shown in Table IV. Interactive public art fueled by big data and IoT can encourage community engagement. For instance, a sculpture might react to social media hashtags or user-generated content, fostering a sense of shared ownership and participation in the artistic experience. The intersection of digital cities and public art is shown in Table V.

TABLE III. KEY ASPECTS OF INTERACTION DESIGN IN URBAN PUBLIC ART

Aspects	Description
User-centered design	Transition from functional-centric development to user-centered paradigm, focusing on creating products and experiences that prioritize usability and enhance user experience.
Human-computer interaction	Emphasis on dynamic and reciprocal communication processes between individuals and devices, systems, and websites.
Aesthetic appeal and functionality	Development of interfaces that are functional, intuitive, aesthetically pleasing, and capable of fostering seamless interactions between users and technology.

TABLE IV. INTERACTION IN ART (A JOURNEY OF EXPERIENCE)

Perspective	Description
Artistic perspective	Interaction intertwined with human experiences, encompassing perception, interpretation, intention, feeling, imagination, arousal, and thinking.
Dynamic and evolving encounters	Interaction as a dynamic process that unfolds over time, inviting individuals to engage with the art work and fostering a deep connection between observer and creation.
Artistic experience	Transformation of passive observation into an active and immersive encounter, making the artistic experience a dynamic and evolving tapestry of human connection.

TABLE V. THE INTERSECTION OF DIGITAL CITY PUBLIC ART

Intersection points	Description
Economic and cultural roles	Digital city public art as a manifestation of the dual ambition of cities - showcasing economic prowess and fostering a vibrant and innovative cultural environment. Integration of digital technology reshaping how cities express their identity and engage with inhabitants, providing a platform for synthesizing technology and culture.
Transformative shift in identity	Digital city public art reaching global audiences through online platforms, social media, and digital galleries, fostering a more democratized and accessible art ecosystem.

C. Digital Media Art

Digital media art stands at the crossroads of technology and art, representing a fusion that gives rise to a form of expression characterized by richness in form and depth of connotation [22]. While firmly situated within the realm of art, digital media art distinguishes itself through profound disparities in its essence, exhibition, and modes of transmission compared to traditional artistic practices. At its core, digital media art is characterized by its reliance on digital technologies as fundamental components of the creative process. Artists in this genre leverage software, algorithms, coding, and interactive elements, transcending traditional mediums like canvas or sculpture. The essence of digital media art lies in its ability to harness the capabilities of technology to create immersive, dynamic, and often interactive experiences for the audience [23].

The exhibition of digital media art departs significantly from traditional art galleries or museums. Instead of static displays, digital media art often necessitates electronic screens, projectors, or immersive installations. VR and AR platforms have also become integral exhibition spaces, allowing viewers to engage with the art work in novel and interactive ways, transcending physical space constraints. The transmission of digital media art is inherently different from traditional art forms, owing to its reliance on digital platforms and the internet. Digital media art can be instantly disseminated globally, reaching audiences across geographical boundaries. Online platforms, social media, and digital galleries have become primary channels for artists to share their work, fostering a more democratized and accessible art ecosystem.

Digital media art represents a paradigm shift in artistic creation and consumption. It challenges traditional notions of creative expression, introducing a dynamic interplay between the artist, technology, and the audience. As technology continues to evolve, so will the boundaries of digital media art, offering new possibilities for creative exploration and reshaping the landscape of artistic innovation.

D. Interaction Design

Interactive design represents a specialized product to enhance and facilitate people's daily activities [24]. The term "interaction" within this context encompasses the dynamic and reciprocal communication processes between individuals and the various devices, systems, and websites that form an integral part of their environment. This discipline is particularly crucial in application development, where the trajectory is gradually transitioning from functional-centric development to a more

user-centered paradigm. In interactive design, emphasis is shifting towards creating products and experiences that prioritize usability and enhance the overall user experience. This user-centric approach acknowledges the significance of aligning design decisions with the end-users' needs, preferences, and behaviors. As a result, designers increasingly focus on developing interfaces that are functional, intuitive, aesthetically pleasing, and capable of fostering seamless interactions between users and technology.

The evolution of interactive design has been fueled by advancements in technology and a growing awareness of the importance of human-computer interaction. Designers are now leveraging innovative techniques to create products that respond to user input, adapt to individual preferences, and provide a more engaging and personalized experience. This shift reflects a broader acknowledgment of the intrinsic link between design and user satisfaction, recognizing that well-crafted interactive experiences significantly contribute to the success and adoption of a product.

From an artistic perspective, interaction is intricately intertwined with a rich tapestry of human experiences, encompassing perception, interpretation, intention, feeling, imagination, arousal, and thinking. These terms denote behavioral aspects and encapsulate the realm of emotions. In this artistic context, interaction extends beyond a mere transactional engagement; it becomes a profound and multifaceted journey through time and space. It is a dynamic process that unfolds over time, inviting individuals to engage with the art work and fostering a deep connection between the observer and the creation. This participatory element invites the audience to immerse themselves in the artistic narrative, transcending the boundaries of passive observation.

In art, interaction is synonymous with experience, a visceral encounter that goes beyond the visual or auditory to evoke a spectrum of emotions and thoughts. It prompts the audience to become spectators and active participants as they navigate the realms of perception and interpretation. This engagement with the art work becomes a journey of shared experiences, where the artist and the audience merge in a dance of creation and interpretation. Thus, interaction in art is an invitation to traverse the nuanced landscapes of emotions, to perceive and interpret the artist's intentions, to feel the resonance of the creation, and to engage in a cognitive and emotional dialogue. It transforms the passive act of observation into an active and immersive encounter, making the artistic experience a dynamic and evolving tapestry of human connection and expression.

In the realm of digital game design, the concept of interaction as experience takes on a distinctive significance. In exploring game design principles and practices, Richard Luce III asserts that players harbor an inherent expectation to actively participate and engage with the game rather than being passive observers. This paradigm shift underscores the crucial role of interaction in shaping the player's experience within the gaming environment. In digital games, interaction is not merely a mechanical process but a conduit through which players immerse themselves in the virtual worlds crafted by game designers. Players seek to do more than witness the unfolding narrative; they yearn to be active agents, influencing events,

making decisions, and experiencing the consequences of their choices. The act of playing, therefore, becomes synonymous with the experience itself.

E. Digital City Public Art

Digital city public art stands at the confluence of digital technology and urban artistic expression, serving as a focal point in the exploration undertaken in this paper. The evolution of human society into the modern era has positioned the city as an economic hub and an aspirational cultural center. As cities strive to solidify their roles as economic powerhouses, there is a parallel pursuit for cultural prominence. Digital city public art manifests this dual ambition, intertwining technology and artistic innovation to redefine the urban landscape. This genre of public art goes beyond traditional forms, incorporating digital elements, interactive installations, and innovative mediums that reflect the dynamism and diversity of contemporary urban life.

Integrating digital technology into city public art represents a transformative shift in how cities express their identity and engage with their inhabitants. It provides a platform for synthesizing technology and culture, allowing cities to showcase their economic prowess and commitment to fostering a vibrant and innovative cultural environment. As urban spaces evolve, digital city public art becomes a testament to the intersectionality of technology and artistic vision. It speaks to the multifaceted nature of modern cities, where economic development and cultural leadership converge. This paper explores this dynamic interplay, seeking to unravel the implications, trends, and potential future trajectories of digital city public art. By examining the fusion of technology and artistic expression within urban environments, this research contributes to a deeper understanding of the contemporary landscape's evolving relationship between cities, technology, and culture.

TABLE VI. DIVERSE FORMS OF DIGITAL PUBLIC ART

Artistic forms	Description
Film and television art	Large-scale displays and projections transforming urban spaces into dynamic canvases, narrating stories or conveying messages through cinematic visuals.
Installation art	Interactive installations employing sensors and responsive technologies, inviting public participation and creating immersive and experiential environments.
Graphic image art	Integration of intricate graphic design and digital imaging in public art, utilizing LED screens, digital billboards, and augmented reality applications.
Music art	Introduction of sound installations and interactive musical compositions, becoming integral parts of urban spaces, enriching the shared experience.

The convergence of digital public art is evident through various facets, primarily manifesting in diverse forms of artistic expression. This intersection encompasses a broad spectrum of creative mediums, showcasing the dynamic fusion of technology and art within the public sphere. Notably, digital public art embraces a range of artistic forms, including film and television, installation, graphic image, music, and beyond.

Digital public art integrates film and television elements, leveraging visual storytelling techniques to engage and captivate audiences. Large-scale digital displays and projections

transform urban spaces into dynamic canvases, narrating stories or conveying messages through cinematic visuals. Table VI shows diverse forms of digital public art. The digital realm enhances the possibilities of installation art within the public domain. Interactive installations, often employing sensors and responsive technologies, invite public participation, creating immersive and experiential environments that blur the boundaries between art and audience.

Digital technology allows for integrating intricate graphic design and digital imaging in public art. LED screens, digital billboards, and AR applications contribute to creating visually stunning and impactful visual image art that can dynamically adapt to various contexts. The auditory dimension of digital public art introduces music as a significant element. Sound installations and interactive musical compositions become integral parts of urban spaces, enriching the shared experience and providing a multisensory encounter with artistic expression.

III. THE CONCEPT OF INTERACTION IN URBAN PUBLIC ART DESIGN

Urban public facilities encompass the public services and service facilities offering public service products. Functionally, these facilities fall into four categories: (1) health safety service facilities, including public toilets and street lamps; (2) leisure service facilities, such as seating areas and newspaper kiosks; (3) information communication facilities, like road signs and bus stations; (4) art service facilities, encompassing flowerbeds and landscapes. As an integral component of the city, urban public facilities mirror urban development and culture and establish connections with the urban environment, creating a 'human-environment' system with the public. With the introduction of digital media technology, public facilities, and citizens collaboratively form an interactive experience system characterized by the interplay of user behavior, environment, and technology.

Integrating Maslow's hierarchy of needs with elements of interaction design and the classification of urban public facilities offers a comprehensive framework for understanding and categorizing these facilities. Following this approach, public facilities can be organized into four distinct categories, with the first being "information query," representing an early-class facility.

1) *Information query (physiological needs)*: In alignment with Maslow's hierarchy, addressing physiological needs is fundamental. Public facilities designed for information queries cater to the basic need for access to essential information. This category includes early-class facilities that provide information kiosks, directional signage, or digital screens offering details about the surrounding environment, public services, transportation, and emergency information. Satisfying this need ensures individuals have access to crucial information for their safety, well-being, and navigation within urban spaces.

2) *Functional facilities (safety needs)*: The second category encompasses operational facilities that address safety needs. These may include emergency services, police stations, fire stations, and medical facilities. The design of these facilities incorporates interactive elements to streamline communication

during emergencies and ensure swift responses. Interactive maps, emergency contact points, and easily accessible information contribute to meeting safety needs within urban environments.

3) *Social interaction spaces (social needs)*: The third category corresponds to social interaction spaces that fulfill social needs. Urban parks, communal spaces, and recreational facilities fall into this classification. Interaction design principles are applied to create inviting, user-friendly spaces that encourage community engagement, socialization, and a sense of belonging. These spaces may incorporate interactive installations, event boards, and communal gathering areas to foster connections among residents.

4) *Cultural and artistic spaces (esteem and self-actualization needs)*: The fourth category focuses on cultural and creative spaces, aligning with esteem and self-actualization needs. Museums, art galleries, theaters, and public art installations contribute to the cultural enrichment of urban environments. Interaction design elements, such as AR exhibits, interactive art installations, and multimedia presentations, elevate the user experience and contribute to the fulfillment of higher-level psychological needs.

In recent years, the profound influence of science and technology on various facets of our daily lives has become increasingly apparent. Operators in the urban public service system should actively require technical support to be strengthened. For example, the maintenance of front desk interface hardware and the regular update of background data are important guarantees for normal operation and the flow efficiency of urban public facilities. Additionally, the construction of common space requires operators and decision-makers to be cautious. If the isolation site is constructed before the technology is ready, some future technologies may make the isolation site less likely to be used and the construction meaningless. The isolation site cannot be used much with the change in user demand or technology upgrading. Therefore, the knowledge of relevant technology and its use in the public infrastructure is also necessary for the construction units and decision-makers to make the right choice.

In urban congestion, administrative departments are faced with the challenge of selecting public facilities that prioritize both convenience and benefits for the citizens. This decision-making process requires meticulously evaluating available technologies and infrastructure solutions to alleviate congestion

and enhance urban mobility. The study conducted by Chapman, et al. [25] serves as a valuable reference, offering insights into the careful selection and implementation of public facilities based on Maslow's theory of needs. The public facilities classification map based on Maslow's theory, as illustrated in Fig. 1, visually represents how these facilities align with various levels of human needs. This classification map guides operators and decision-makers, emphasizing the importance of addressing fundamental needs such as information query, safety, social interaction, and cultural enrichment when planning and implementing public facilities.

In urban public art, the image serves as the paramount sensory carrier, transcending considerations of size and complexity. The visual impact of public art is often its most potent communicative element, capable of evoking emotions, conveying narratives, and shaping the aesthetic character of the urban environment. Cameras are necessary instruments to record and provide this vital visual data. They are the eyes through which urban public art is viewed, recorded, and distributed. They serve as a way to capture the transient and interactive quality of art in the urban context. Whether monumental sculptures, vibrant murals, or interactive installations, cameras enable the preservation and dissemination of these artistic endeavors to a wider audience. Certainly, the part played by cameras in urban public art is more than visual recording. They are a venue for narrative, which has the potential to mediate the part artists, enthusiasts, and communities may play in urban art. Camera-mediated urban public art can involve more than just raising visual awareness to the public. These images can be increased in many forms, from social media, online galleries, and digital archives to worldwide displays.

A comprehensive digital interactive urban public system, enriched with input and output components, is anchored in a core mechanism of communication and processing. This pivotal interaction involves the transmission of digital signals from sensors to the CPU or microcontroller of a computer, and subsequent operations are executed according to predefined rules. The formulation of these rules is intricately tied to the artistic vision and desired effects. The communication aspect of this system initiates with inputs from various sensors strategically integrated into the urban environment. These sensors act as the sensory receptors, capturing data and transforming it into digital signals. These signals serve as the system's language for the surrounding context, whether user interactions, environmental changes, or other dynamic factors.

Fig. 1. Public facilities classification map.

The CPU or microcontroller, as the system's brain, receives and processes these signals; then, based on predefined rules, the CPU or microcontroller initiates a series of actions. These rules are defined to capture what Moholy-Nagy intended. It is in this last phase that the programming and the rest of the power-driven system of the light space modulator reside, and where complexity is introduced. Complicated algorithms and mechanical linkages mediate between the artist's initial inspiration and the series of actions that a machine can carry out. Rule-setting is a delicate balance of artistic inspiration and engineering pragmatics. Artists work closely with programmers and engineers to articulate the formal conditions under which the input signal "tells" the system to perform a subsequent action. This part proves the digital interactive urban public system, in a way, carries out the artist's conception, besides, it is synchronized with the digital interactive urban public system in technology. The power-driven systems are a series of devices that contribute to the digital interactive urban public system directly with motor, actuator, or related machines, to be more specific, these devices unfold, close, lift, or otherwise engender the response of the system. These power-driven systems are normally concealed so that the viewer's cannot see or touch them, and the system's energy or output can be delivered without revealing the technology.

Urban space reaches far beyond its geographical boundaries and is instead a living, breathing encapsulation of the lives that occupy it daily. Urban space is an ever-changing scene resulting from a series of activities, interactions, and common experiences. It must be both functional and beautiful, making our lives better and enriched due to living in the city. Urban public spaces must be planned meticulously to serve well-defined functional roles for the community. These functional roles address basic needs such as accessibility, utility, responsiveness, and safety. For example, usable functions may include seating, walkways, well-placed amenities, and infrastructure that allows ease of movement and stimulates numerous activities. These spaces should be designed with an understanding of the community's diverse needs, ensuring that they are inclusive, user-friendly, and responsive to residents' daily routines.

In addition to pragmatic aspects, the design of urban public spaces must also account for their aesthetic purpose. The aesthetic dimension is vital in defining the city's character and its inhabitants' emotional comfort. Well-designed greenery, public art, and architectural installations set the scene for pleasant surroundings, which offer a source of pride and connection for the residents. The focus on aesthetics is critical because it enriches the physical environment through spaces and places, turning them into living, breathing urban scenes that enhance the spirit of community and identity. The complete unification of the practical and the beautiful in the urban environment is a fundamental condition for producing environments sensitive to the manifold and changing needs of the inhabitants. The balance between use and beauty prevents public spaces from being no more than neutral spaces; it makes them selective environments, which contribute positively to the quality of life, the cultural wealth of the city, and the creation of a sense of community among its inhabitants.

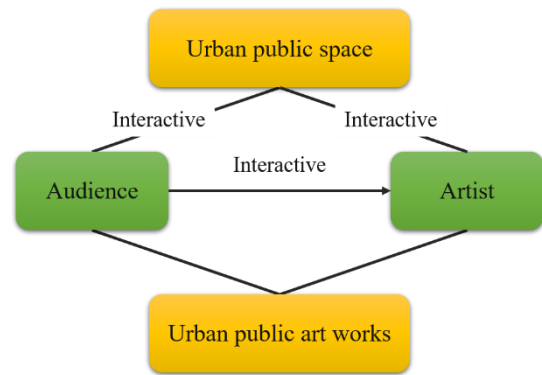

Fig. 2. The interconnected dynamics of public art, urban space, and urban art themes.

Inhabitants of urban spaces are always acclimatized into their city context through cultural and geographical osmosis. This commences from how individuals absorb, comprehend, log, and calculate information to and from. The information is never static, and hence, there is a sense of dialogue of mind with the city. At the same time, the audience encountered by the artists was an audience with a high artistic culture and personal public awareness of the group, which became a significant force in the formation of public space in the whole city. People's responses to urban spaces are complex, involving acquiring, identifying, storing, and processing various information. These adaptive processes are intricately connected to the cultural and geographical characteristics of the urban environment. The city's history, traditions, and geographic features influence how citizens navigate and engage with their surroundings, shaping a distinctive urban identity.

There is a synergy between a community of artists and a community of people with high artistic literacy and civic awareness in forming the urban public space. The former creates the context and the digital field of culture, and the latter expands it and connects various forms of artistic expression with and among themselves. Urban artists, among others, define the cultural profile of a city and provide an opportunity for urban residents to learn their local identity through it and be proud of it. In turn, audiences with a heightened cultural awareness actively engage with and interpret these art works, further enriching the city's cultural tapestry. The relationship among urban space, public art works, and urban art themes is depicted in Fig. 2. This diagram highlights the interdependent relationships among these components. Urban space forms the crucible in which public art works are displayed and perceived. The themes of these art works, influenced by the cultural and geographical context, contribute to the city's narrative, shaping its visual and cultural landscape.

IV. OPEN ISSUES AND FUTURE RESEARCH DIRECTIONS

Within the urban public art domain, promising opportunities and difficulties lie ahead, leading to thrilling prospects and unresolved matters. As we contemplate the progression of this ever-changing discipline, several crucial themes and factors come to light:

1) *Integration of emerging technologies:* Rapid technological change, including AR, VR, and AI, is likely to dramatically alter the scope and purpose of urban public art. This could include developing a more sophisticated intersection between these technologies to create immersive and interactive public experiences that confuse the boundaries between the physical and digital worlds.

2) *Sustainability and environmental consciousness:* There is a trend towards sustainability and ecological consciousness in urban planning and design, so future urban public art projects may become more eco-oriented. These public art installations can even be a canvas for discussing ecological issues, using them as a stage for environmental education and sustainable lifestyle. It can be not only art as a culture but art as a practice, using eco-friendly materials and practices.

3) *Inclusivity and accessibility:* In the future, practical efforts are essential for urban public art to become more inclusive. Future urban public art should prioritize accessibility to encourage involvement from diverse groups. This means not only considering people with disabilities but also implementing universal design in public art work. Moreover, urban public art practices should involve and utilize the creative capacity of the socially underprivileged for the benefit of mutual learning within communities.

4) *Community collaboration and co-creation:* Art projects created collaboratively by local community artists will likely become even more common. The community-based model of public art work guarantees culture will be respected, and community members will take pride in its existence. Community members will work with artists and urban planners on projects, producing superior works of art that relate more to the landscape.

5) *Dynamic and evolving art installations:* In the near future, urban public art could be designed from dynamic, ever-changing, and infinitely variable installations that may respond in real-time to data, such as the current weather, user footfall, or social media activity. These responsive installations could change and react to their environment, enhancing the experience for the public.

6) *Addressing social issues and cultural narratives:* Urban public art can become the most efficient medium for handling social issues and cultural history. More projects can revolve around the concept of social justice and diversity as they can produce a cultural narrative that resonates with people.

7) *Data-driven art installations:* As cities grow increasingly interlinked by the Internet of Things (IoT) and big data, the future public art could connect to data flows to respond to them. By using up-to-the-minute data on environmental conditions, urban activities, and city patterns, urban art might develop a synesthetic dimension that is utterly responsive to data streams, not merely drawing from them.

8) *AR walking tours:* The integration of AR in urban public art could lead to the development of AR walking tours. Residents and visitors with AR-enabled devices could explore the city and interact with virtual layers of art superimposed on

the physical environment, offering a unique and personalized experience.

9) *Digital placemaking and smart cities:* Urban public art can play a pivotal role in the concept of digital placemaking within the framework of smart cities. Art installations may create more innovative, sustainable, and livable urban environments by incorporating technology that enhances safety, mobility, and connectivity.

10) *Cultural exchange and global collaborations:* Advancements in communication technologies can facilitate cross-cultural collaborations in urban public art. Artists worldwide may engage in virtual collaborations, sharing cultural narratives and perspectives. This global exchange can result in a rich tapestry of diverse artistic expressions within city spaces.

11) *Ethical considerations in public art:* As public art becomes increasingly integrated with technology, ethical considerations around privacy, data security, and surveillance must be carefully addressed. Striking a balance between innovative artistic expression and respecting individuals' rights to privacy will be crucial to future urban public art endeavors.

12) *Interactive and participatory installations:* The future of urban public art may witness an increased focus on installations that actively engage and involve the public. Interactive and participatory art projects could encourage individuals to contribute to art creation, fostering a sense of ownership and community connection.

13) *Temporary and pop-up installations:* Temporary or pop-up public art installations may gain prominence. These installations, designed for short-term display, allow experimental and innovative expressions. They can activate underutilized spaces and contribute to the dynamic character of the urban environment.

14) *Art as urban infrastructure:* Public art could be integrated as a fundamental component of urban infrastructure, contributing to aesthetics and serving functional purposes. For instance, public sculptures designed to serve as seating, lighting installations, or sustainable green spaces that also function as artistic expressions.

V. CONCLUSION

The synergy of digital technologies and urban art leads to the digitalization of urban art, which reshapes the interaction between art and technology media. This paper discussed the connection between HCI and artistic creation, emphasizing the transformative power of new technologies, such as 3D printing, VR, and digital art. These technologies empower artists to transcend the limitations of urban environments, which have historically shaped and influenced human civilization, and express their creative vision in every aspect of the city. Cities serve as a platform for fulfilling several requirements of this system, encompassing the sustenance of human civilization, the preservation of a diverse culture, and the satisfaction of residents' wants.

The study has several unique contributions. In terms of theory, it provides an in-depth investigation into the

transformation of public art with digital technologies in the urban context. It establishes a new research paradigm of smart art and proposes the innovative application of IoT, AR, big data, and other technologies to explore the dynamic and interactive installation of public art that can be adapted to environmental and social information. As for methodology, the study develops an innovative solution to insert digital technologies into urban art projects and focuses on the realization of performance-based digital arts in public spaces. In culture, public art has influenced urban identity and regional cultures. This study further underscores the art function that concerns both social expression and cultural heritage.

The convergence of IoT and big data enables public art to react dynamically to environmental fluctuations and social engagements, resulting in captivating and interactive viewer encounters. Furthermore, using digital art technologies can enhance the inclusivity and accessibility of public art, enabling it to reach a broader audience and actively involve diverse populations. Incorporating cutting-edge, environmentally-friendly materials and sustainable methods in digital public art can raise environmental consciousness and cultivate a stronger bond with nature in urban areas.

Although this study offers useful insights, it also acknowledges various limitations. The conclusions are derived from unique case studies and may not have general applicability; future studies should investigate a wider range of metropolitan environments and cultural situations. Furthermore, there is a need for more research to explore the lasting impacts of digital art interventions on urban populations and public places. Continual study is necessary to investigate the novel applications and consequences of digital technologies on urban public art.

Subsequent investigations should prioritize examining emerging technologies, such as AI and blockchain, in the realm of public art. Longitudinal studies are essential for evaluating the enduring effects of digital public art on community involvement and urban progress. In the context of the increasing presence of digital technology in society, much more research is needed in incorporating sustainability elements in digital public art in terms of both techniques and materials. Future studies may open a door for the development and potential to further improve the urban public art domain while ensuring the importance and effectiveness of digital public art in the wave of digital technology.

School of Automation, Nanjing Institute of Technology, Nanjing, China^{2,3}

Abstract—In industrial production, timely and accurate detection and identification of surface defects in steel materials were crucial for ensuring product quality, enhancing production efficiency, and reducing production costs. This study addressed the problem of surface defect detection in steel materials by proposing an algorithm based on an improved version of YOLOv5. The algorithm achieved lightweight and high efficiency by incorporating the MobileNet series network. Experimental results demonstrated that the improved algorithm significantly reduced inference time and model file size while maintaining performance. Specifically, the YOLOv5-MobileNet-Small model exhibited slightly lower performance but excelled in inference time and model file size. On the other hand, the YOLOv5-MobileNet-Large model achieved a slight performance improvement while significantly reducing inference time and model file size. These results indicated that the improved algorithm could achieve lightweighting while maintaining performance, showing promising applications in steel surface defect detection tasks. It provided an efficient and feasible solution for this important domain, offering new insights and methods for similar surface defect detection problems and contributing to research and applications in related fields.

Keywords—Deep learning; improved YOLOv5; YOLOv5-MobileNet; surface defects

I. INTRODUCTION

Surface defect detection [1] was paramount in industrial production as it aided in promptly identifying and rectifying flaws on product surfaces, ensuring product quality adhered to standards, enhancing production efficiency, and reducing reject rates. This not only helped in cost and resource savings but also enhanced product safety and reliability, maintaining a company's reputation and market competitiveness. Extensive research had been conducted by numerous scholars in this field.

In existing research, Zhang Guo et al. [2] proposed an FFS-YOLO model based on the improved YOLOv4-tiny model for detecting PCB surface defects. While this model enhanced detection accuracy and light weighted the model, the detection metrics only included mAP@0.5, FPS, and model size, lacking comprehensive evaluation metrics such as recall and precision, requiring further research and validation. Dong Yongfeng et al. [3] presented a defect detection joint optimization algorithm based on attention mechanism, showing promising results in classifying multiple defect types. However, the algorithm's joint loss function involved numerous hyperparameters, making manual adjustments

challenging, and it did not address real-time issues. Divyanshi Dwivedi et al. [4] tackled renewable energy asset surface defect detection using the latest deep learning model ViT. While effective in image classification tasks, this approach still needed to address challenges related to data quality and environmental adaptability. Wu Jiling et al. [5] proposed an improved Faster R-CNN algorithm, optimizing feature extraction networks, region of interest pooling, and anchor box sizes. Additionally, they introduced feature pyramids and deformable convolutions, achieving satisfactory detection results. Future research should focus on lightweighting detection models while enhancing detection speed without compromising accuracy to facilitate proactive industrial deployment.

YOLOv5 exhibited efficient end-to-end detection capabilities, while MobileNet was a lightweight convolutional neural network. Their combination addressed the need for both detection performance and model efficiency, aligning with the requirements for real-time operation and deployment convenience in steel surface defect detection tasks. In contrast, existing models like Faster R-CNN, although they demonstrated good detection accuracy, were less suitable for industrial real-time detection scenarios due to their complex network structures and substantial computational demands, which resulted in low inference efficiency. Additionally, they lacked optimization designs targeted at lightweighting.

This study addressed the issue of detecting surface defects in steel materials by proposing an algorithm based on an improved version of YOLOv5. Compared to existing methods, our algorithm incorporated a lightweight MobileNet network, which significantly reduced the model inference time and file size while maintaining detection performance. Additionally, it notably enhanced real-time capabilities and deployment convenience.

Furthermore, our evaluation metrics were more comprehensive, including not only common metrics such as mean Average Precision (mAP) and inference time but also precision and recall rates, providing a more objective reflection of the algorithm's performance. Our algorithm demanded less in terms of data quality and environmental adaptability, demonstrating stronger generalization capabilities. It was highly practical and applicable, offering a new efficient solution for quality control in the steel industry and bringing fresh insights and methods to similar surface defect detection issues, thereby possessing significant theoretical and practical value.

Overall, this study was dedicated to proposing an efficient, lightweight, and high-performing algorithm for detecting surface defects in steel materials. It aimed to address the shortcomings of existing methods in terms of real-time performance, lightweight design, comprehensive evaluation metrics, and generalization capabilities. This work contributed to research and applications in related fields.

II. DEEP LEARNING YOLO ALGORITHM

YOLOv5 was regarded as the pinnacle of the YOLO series, highly favored by both the academic and industrial communities for its outstanding detection accuracy and fastest detection speed [6]. The network architecture of YOLOv5 followed the overall layout of YOLOv3 and YOLOv4, mainly comprising four parts: the input layer, backbone network, neck network, and prediction layer, as shown in Fig. 1.

Fig. 1. YOLOv5 structure.

Input: The mosaic data augmentation method was employed, which involved randomly cropping four images (each with corresponding bounding boxes) and then stitching them together into a new image. This method significantly increased the background information of target objects.

Backbone: The Focus structure and CSP structure played different but complementary roles in deep learning models. The Focus structure was primarily used to reduce computational complexity and improve inference speed, while the CSP structure, through reasonable branch design, enabled the model to learn more features while reducing computational complexity, thereby enhancing the model's performance. The combination of these two structures could effectively optimize the model's performance, making it more efficient and reliable in practical applications.

Neck: FPN+PAN structure was utilized. FPN (Feature Pyramid Network) and PAN (Path Aggregation Network) were two common network structures for object detection, used to handle multi-scale feature maps. FPN propagated strong semantic features through upsampling, while PAN propagated strong localization features through downsampling. Combining FPN and PAN enhanced semantic expression and localization capabilities at multiple scales, thereby improving the performance and robustness of object detection models at different scales.

Prediction: GIoU Loss was introduced as the loss function for bounding boxes. This loss function effectively addressed the problem of non-overlapping bounding boxes, thereby improving the accuracy and precision of object detection. The application of GIoU Loss enabled the model to better understand the position and shape of objects, thereby improving detection accuracy. NMS helped to find the optimal

position of detected objects and removed overlapping detection boxes, further enhancing the accuracy and robustness of object detection. This step made the model's output results clearer and more reliable, providing a more trustworthy solution for object detection tasks in real-world scenarios [7-8].

III. IMPROVED YOLOV5 ALGORITHM WITH MOBILENET

A. MobileNet Algorithm

In 2017, the Google team introduced MobileNet1, which replaced ordinary convolutional modules with depthwise separable convolutions to achieve lightweight convolutional neural networks [9]. By using depthwise separable convolutions, the parameter count of MobileNet1 was reduced to around 1/8 to 1/9 of its original size. Compared to VGG16, it only sacrificed approximately 0.9% of classification accuracy while reducing the parameter count to only 1/32.

MobileNet2 introduced "residual modules" on the basis of MobileNet1. These residual modules first used 1x1 convolutions for dimensionality expansion, followed by 1x1 convolutions for dimensionality reduction, also known as inverted residual modules. Furthermore, to prevent significant loss of low-dimensional information under the ReLU activation function, MobileNet2 used linear activation functions for the last layer convolution [10].

MobileNet3 is an improved version of MobileNet2, with superior accuracy and smaller model size. MobileNet3-Large and MobileNet3-Small are neural network structures optimized for mobile devices using Neural Architecture Search (NAS) technology. Although the backbone network structures of the two are similar, they contain different numbers of Bneck modules [11-12]. MobileNet3-Large has 15 Bneck modules, while MobileNet3-Small contains only 11 Bneck modules. The specific structure of the Bneck module is illustrated in Fig. 2. These improvements enable MobileNet3 to maintain its lightweight nature while enhancing model accuracy, making it an ideal choice for mobile devices.

Fig. 2. Specific structure of Bneck module.

The MobileNetV3 network integrates various advanced neural network structures, including depthwise separable convolutions from MobileNetV1, linear bottleneck inverted residual structures from MobileNetV2, and the lightweight attention model from MnasNet. Additionally, it introduces the non-linear Swish function, computed as shown in Eq. (1).

$$swish[x] = x * \sigma(x) \quad (1)$$

In the Eq. (1), $\text{swish}[x]$ represents the non-linear activation function, where x denotes the input feature, and $\sigma(x)$ represents the sigmoid activation function.

MobileNetV3 ultimately adopts a new activation function, denoted as $\text{h-swish}[x]$, to replace the original $\text{Swish}[x]$ function. This change is due to the high computational cost of computing the Sigmoid function on mobile devices. The new activation function $\text{h-swish}[x]$ significantly improves detection speed, especially in deep networks. The computation process is shown in Eq. (2).

$$h - swish[x] = x * Relu6 \frac{x + 3}{6} \quad (2)$$

B. The Improved YOLO Algorithm

YOLOv5 was considered a regression-based one-stage object detection algorithm [13-14]. In order to enhance the model's performance, the MobileNetv3 network was utilized to replace the original backbone network, CSPDarkNet53. Apart from this change in the backbone network, the rest of YOLOv5 remained consistent with the original model. MobileNetv3, compared to CSPDarkNet53, featured a more lightweight network structure and higher computational efficiency. Consequently, it facilitated accelerated execution of object detection while preserving model accuracy. This improvement contributed to YOLOv5's superior performance in real-time object detection scenarios. The structure is depicted in Fig. 3.

In the improved version of YOLOv5 after the incorporation of MobileNetv3, the obtained feature matrix underwent a series of transformations. Initially, it was processed through a 1×1 convolution, followed by input into the pyramid spatial module. Down-sampling occurred at three parallel max-pooling points, and the resulting outputs were added to the feature matrix of the input module in depth before convolution. In the neck section, a spatial pyramid structure was employed to propagate strong semantic features from top to bottom, while the path aggregation network propagated robust displacement features from bottom to top. The fusion of these two mechanisms enhanced the capability to extract feature information.

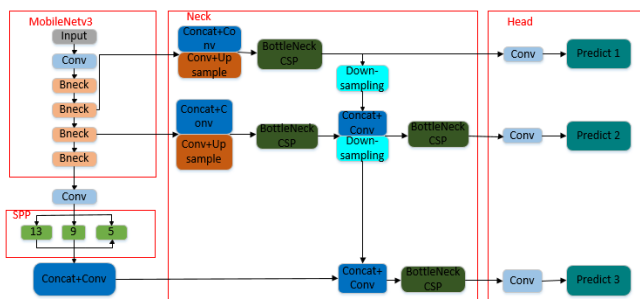

Fig. 3. Improved YOLOv5 network structure diagram.

In the improved YOLOv5, after being processed through MobileNetv3, the obtained feature matrix was initially processed through a 1×1 convolution. This step helped in reducing feature dimensions, thereby lowering computational costs and model complexity. Subsequently, the feature matrix, post 1×1 convolution, was input into the pyramid spatial

module, which performed down-sampling at three parallel max-pooling points. This process aided in extracting features at different scales and enhanced the model's multi-scale perception of targets.

The down-sampled results were then added in depth to the feature matrix of the input module before undergoing convolution. This method of depth addition facilitated the fusion of features from different levels, thereby enhancing the model's representational capacity. A spatial pyramid structure was employed in the neck section to propagate strong semantic features from top to bottom. Simultaneously, the path aggregation network propagated robust displacement features from bottom to top. Through the combined use of this structure, feature information was adequately extracted and fused, thereby improving the accuracy and robustness of object detection. This design enabled the model to better understand and accurately detect and locate targets, resulting in more stable and reliable detection results in various complex scenarios for YOLOv5.

IV. EXPERIMENT VALIDATION AND COMPARISON

A. Experiment Environment and Dataset

The experiment was conducted on a Windows 10 system with an Intel i7-11700 CPU running at 2.50GHz and an NVIDIA GeForce RTX 3080Ti GPU, along with 32 GB of RAM. The development environment utilized PyCharm Community 2018.3.5 with Python 3.8 as the interpreter. The experimental data were sourced from the NEU-CLS dataset [15], comprising a total of 1800 steel surface defect images, with 300 images for each of the six defect types, the hyperparameters used in this study were as follows: the initial learning rate was set at 0.01, the cyclic learning rate at 0.2, the number of training epochs at 200, and the weight decay was set at 0.0005.

Performance metrics of the YOLOv5 object detection algorithm are typically validated using three evaluation metrics: precision, recall, and mean Average Precision (mAP).

Precision: Precision is the ratio of true positive data (TP) correctly classified by the classifier to all data classified as positive by the classifier (TP + false positive (FP)). The specific calculation method is as shown in Eq. (3):

$$Precision = \frac{TP}{TP + FP} \quad (3)$$

where, TP represents the number of true positive samples predicted as positive, and FP represents the number of negative samples falsely predicted as positive.

Recall: Recall refers to the ratio of true positive data (TP) correctly classified by the classifier to all data classified as positive by the classifier (TP + false negative (FN)). The specific calculation method is as shown in Eq. (4):

$$Recall = \frac{TP}{TP + FN} \quad (4)$$

where, FN represents the number of positive samples falsely predicted as negative.

MAP (mean Average Precision): mAP indicates the average precision of the detector on different categories. In object detection tasks, AP (Average Precision) is usually used as the precision metric, and then the average of APs for all categories is calculated to obtain mAP. Here, AP is the area enclosed by the PR (Precision-Recall) curve and the two axes, namely, X and Y.

B. Experimental Results

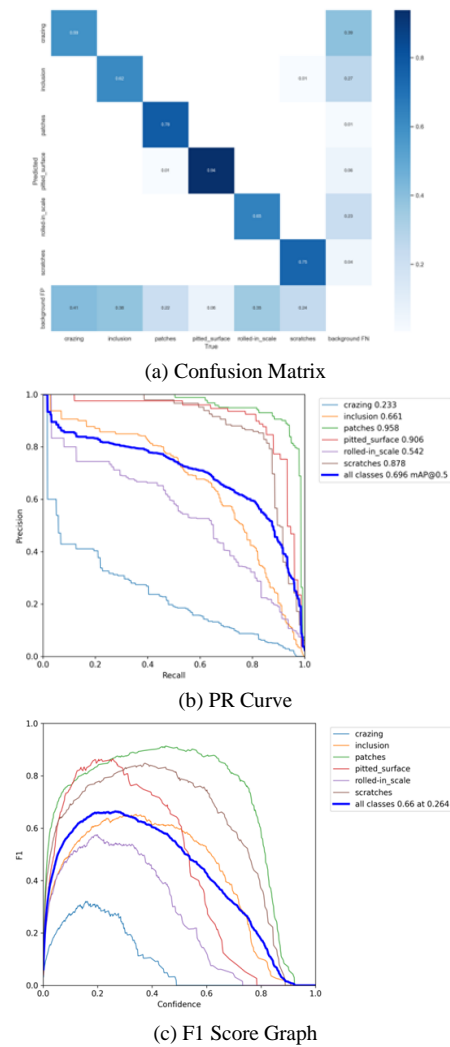

1) *Improved YOLOv5-Mobilenet-Small*: After training for 200 epochs to obtain the optimal weights, the results on the test set were as follows: mAP@0.5 was 0.657, and F1 score was 0.640. The results are shown in Fig. 4.

(d) Validation Detection Image

Fig. 4. Results of YOLOv5-mobilenet-small.

2) *Improved YOLOv5-Mobilenet-Large*: After training for 200 epochs to obtain the optimal weights, the results on the test set were as follows: mAP@0.5 was 0.696, and F1 score was 0.660. The results are shown in Fig. 5.

(d) Validation Detection Image

Fig. 5. Results of YOLOv5-Mobilenet-Large.

TABLE I. COMPARISON OF RESULTS FOR DIFFERENT NETWORK ARCHITECTURES

	Precision	Recall	mAP@.5	parameters	Inference Time (ms)	PT File Size (MB)
Yolov5	0.689	0.671	0.682	20873139	3.9	40.1
Yolov5-Mobilenet-Small	0.665	0.631	0.657	5160643	3.2	10
Yolov5-Mobilenet-Large	0.667	0.676	0.696	5899785	3.5	11.5

In Table I, the detection results of YOLOv5, YOLOv5-Mobilenet-Small, and YOLOv5-Mobilenet-Large were compared. From the experimental results, it was observed that the improved network YOLOv5-Mobilenet-Small showed slight decreases (not exceeding 0.04) in Precision, Recall, and mAP@0.5, while significantly reducing inference time and decreasing the size of the .pt file. Similarly, the enhanced network YOLOv5-Mobilenet-Large exhibited slight decreases (not exceeding 0.03) in Precision but slight improvements in Recall and mAP@0.5 compared to YOLOv5. Additionally, it also reduced inference time significantly and considerably decreased the size of the .pt file. These experimental results demonstrated that the improved algorithms achieved the goal of lightweight performance while maintaining detection effect. Notably, YOLOv5-Mobilenet-Small had the fewest parameters, inference time, and model file size, making it suitable for applications with limited computational resources and memory. Conversely, although YOLOv5-Mobilenet-Large required higher computational resources compared to YOLOv5-Mobilenet-Small, it exhibited slight performance improvements and may have been more suitable for tasks requiring higher detection result.

Additionally, we found that the algorithm exhibited variations in performance across different types of defects in the dataset. For some defect types with lower recall values, such as crazing (approximately 0.2), the complexity of their appearance features might have made it difficult for the algorithm to effectively capture and recognize them. In such cases, our algorithm needed further optimization, utilizing more refined feature extraction or improved data augmentation strategies to achieve higher recall.

For defect types with moderate recall values, such as rolled-in scale (approximately 0.5), inclusion (approximately 0.6), and scratches (approximately 0.7), it was evident that the algorithm possessed a certain detection capability for these types, yet there was still room for improvement. We could consider adjusting the model's hyperparameters and refining the anchor box settings to achieve higher recall.

For defect types with high recall values, such as patches and pitted surface (approximately 0.9), the detection performance of the algorithm was quite ideal. This was because their appearance features, such as distinct shapes and contrasts, were more readily captured and recognized by the algorithm.

Overall, the variability in the algorithm's performance across different defect types may have stemmed from the characteristics of the dataset itself, the varying complexity of defect appearances, and the algorithm's differing adaptability to certain specific patterns. In future work, we will continue to optimize the algorithm, striving to enhance its detection capabilities for various defect types and to explore more effective methods for handling complex and diverse defect patterns.

V. CONCLUSION

This study focused on the detection of surface defects in steel materials and proposed an improved steel surface defect detection algorithm based on YOLOv5. The algorithm replaced the backbone network of YOLOv5 with the MobileNet series network, enabling the model to have a more lightweight network structure and higher computational efficiency. In the task of steel surface defect detection, the algorithm's performance was enhanced, allowing for faster defect detection and improved detection effect. Experimental results indicated that by introducing MobileNet, the YOLOv5 architecture improved its performance to some extent, exhibiting clear advantages not only in terms of parameter count, inference time, and model file size but also in enhancing the result of object detection. Among them, the YOLOv5-Mobilenet-Large model slightly outperformed in performance, while the YOLOv5-Mobilenet-Small model showed more efficiency. This is significant for industries such as steel production and quality control, as it promises higher levels of production efficiency and quality assurance. Future work will further optimize the network structure and improve data augmentation strategies, focusing on enhancing the recognition capabilities for these challenging defect types. Additionally, techniques such as model compression will be considered to develop more accurate, versatile, and efficient lightweight defect detection solutions.

Abstract—Deep learning has been widely used in various scenarios such as image classification, natural language processing, and speech recognition. However, deep neural networks are vulnerable to adversarial attacks, resulting in incorrect predictions. Adversarial attacks involve generating adversarial examples and attacking a target model. The generation mechanism of adversarial examples and the prediction principle of the target model for adversarial examples are complicated, which makes it difficult for deep learning users to understand adversarial attacks. In this paper, we present an adversarial attack visualization system called AdvAttackVis to assist users in learning, understanding, and exploring adversarial attacks. Based on the designed interactive visualization interface, the system enables users to train and analyze adversarial attack models, understand the principles of adversarial attacks, analyze the results of attacks on the target model, and explore the prediction mechanism of the target model for adversarial examples. Through real case studies on adversarial attacks, we demonstrate the usability and effectiveness of the proposed visualization system.

Keywords—Deep learning; deep neural networks; adversarial attacks; adversarial examples; interactive visualization

I. INTRODUCTION

With the development of artificial intelligence, deep neural networks are widely applied to various scenarios such as image classification, natural language processing and speech recognition. However, More and more studies reveal that deep neural networks are vulnerable to adversarial attacks [1]. Adversarial attacks are to generate adversarial examples by adding weak adversarial perturbations to the input examples. The generated adversarial examples can interfere with the decision-making of deep neural networks, resulting in incorrect predictions. Thus, adversarial attacks pose a serious threat to the application of deep learning. Delving into adversarial attacks helps to reveal the weaknesses of deep learning models, which in turn motivates researchers to design effective defense strategies to improve the robustness of neural networks.

The goal of adversarial attacks is to generate adversarial examples which can induce deep learning models to make incorrect predictions. Szegedy et al. [1] discovered early that deep neural networks are vulnerable to adversarial examples in

the field of image classification. Specifically, the input images with adversarial noise (i.e., adversarial examples) can induce image classification models to produce incorrect classification results. Since then, a number of adversarial attack methods have been proposed. Goodfellow et al. [2] proposed a classical gradient-based attack method namely FGSM. The method adds the gradients that increases the loss function to the original image to generate an adversarial example. The idea based on gradient derives many gradient-based attack methods such as PGD [3], BIM [4] and ILCM [4]. To obtain adversarial examples with high perceptual quality, Carlin and Wagner [12] proposed an optimization-based attack method which produces adversarial examples with small perturbations and high attack success rates by minimizing the objective function. The above attack methods require access to the target model (i.e., the attacked model) when generating adversarial examples, resulting in low efficiency in generating adversarial examples. To obtain adversarial examples quickly, Xiao et al. [5] presented an attack method based on generative adversarial networks (GAN). This method can directly generate adversarial examples with a high attack success rate without accessing the target model again after the generator is trained.

Adversarial attacks involve generating adversarial examples and attacking target models. However, the generation mechanism of adversarial examples and the prediction principle of the target model for adversarial examples are complicated, which makes it difficult for deep learning users especially beginners to understand adversarial attacks. To address this problem, we present an adversarial attack visualization system called AdvAttackVis, which can assist users to learn, understand and explore adversarial attacks. The visualization system is implemented based on B/S architecture, which is easy for deep learning users to use. Based on the underlying models and the designed interactive visualizations, the system enables users to train and explore adversarial attack models, understand the principles of adversarial attacks, analyze the results of adversarial attacks, and explore the prediction mechanism of the target model for adversarial examples. Through a case study where AdvGAN (attack model) attacks an MNIST classifier (target model), we demonstrate the usability and effectiveness of our system. AdvAttackVis provides end-to-end support for adversarial attack analysis. We have also specifically designed

visualization views from different analysis perspectives, providing novel insights for analyzing adversarial attacks. This enables users to explore and understand the attack process comprehensively, whereas existing tools often only support post-analysis of existing attacks.

Our contributions can be summarized as follows:

- A visual analysis scheme for end-to-end interpretability of adversarial attacks. The scheme combines interactive visualizations with underlying algorithms to help users delve into adversarial attacks.
- An adversarial attack visualization system for deep neural networks. The system offers powerful interactive visualization views to assist users in exploring adversarial attacks.
- We demonstrate the usability and effectiveness of the visualization system via a real case study based on the MNIST handwritten digital image dataset.

II. RELATED WORK

A. Adversarial Attacks

Adversarial attacks involve generating adversarial examples and attacking the target model. Szegedy et al. [1] first proposed the concept of adversarial examples. Specifically, an adversarial example is generated by adding weak adversarial interference to the original image. It could induce the target model to output wrong predictions with high confidence, which reveals the vulnerability of deep neural networks and raises concerns about the security of deep learning models. Goodfellow et al. [2] argued that this vulnerability is caused by the local linearity of neural networks, especially when a linear activation function (e.g., ReLU [1]) is used in the model. Arpit et al. [7] analyzed the memory ability of neural networks for training data and found that models with high memory levels are more susceptible to adversarial examples. Gilmer et al. [10] believed that adversarial examples are attributed to the high-dimensional geometric structure of data manifold and then analyzed the relationship between adversarial examples and the high-dimensional geometry of data manifold.

From the perspective of the attack environment, adversarial attacks can be divided into white-box attacks and black-box attacks [7]. In white-box attacks, the attacker can obtain information about the target model such as training data, model structure, model parameters and model output. Therefore, the attacker can directly utilize the gradient of the loss function and classification hyperplane of the neural network to calculate the required perturbations, thereby generating adversarial examples. FGSM [2] is a classical white-box attack method which obtains adversarial examples by adding perturbations to the input images. Madry et al [3] improved FGSM and proposed PGD to further improve the attack success rate. To generate the adversarial examples with high perceptual quality, Carlini and Wagner [12] proposed an optimization-based attack method which obtains the smallest adversarial perturbation by iteratively optimizing the objective function. However, in practical applications, attackers usually have no access to the detailed information of the target model, which makes it impossible to implement white-box attacks. To overcome this limitation,

researchers have proposed black-box attacks where the attacker only needs the output labels or probability vectors of the target model. Single-pixel attack [14] is a classical black-box attack method which obtains an adversarial example by changing the value of the selected pixel in the original image. Sarkar [15] proposed two black-box attack methods namely UPSET and ANGRI. UPSET generates general perturbations for all output categories while ANGRI produces specific perturbations for different images. Their generated adversarial examples can induce the image classification model to output specific categories. Xiao et al. [5] proposed an attack method based on generating adversarial networks (GAN). The method first applies knowledge distillation to obtain an agent model with similar performance to the target model and then generates adversarial examples that are effective against the target model.

In the white-box or black-box attack scenario, adversarial attacks can be further divided into targeted attacks and untargeted attacks [7-9]. Targeted attacks induce the deep learning model to recognize adversarial examples as a specific class while untargeted attacks simply require the model to output the incorrect class. The white-box attack method FGSM [2] can support both targeted and untargeted attacks. For black-box attacks, AdvGAN [5] can achieve targeted and untargeted attacks by designing the loss function of the target model.

However, existing work on interpretability analysis of adversarial attacks is still relatively lacking. They mostly focus on the surface effects of attacks, such as success rates, perturbation sizes, etc., while rarely delving into the causes of attacks, characteristics of attack samples, and the impact of attacks on model behavior.

B. Visualization of Deep Learning Models

Deep learning models are regarded as black-box models because their decision-making mechanisms are not clear to human cognition. In recent years, researchers have proposed different visualization techniques [16] [29] [30] to reveal the inner workings of deep learning models and assist users to understand, analyze and learn deep learning. TensorBord is a visualization tool launched by the TensorFlow deep learning framework, which can visualize computational graph and training logs. However, TensorBord lacks an interactive visual design that goes deep into the model, so users are unable to gain a deep understanding of the internal mechanism of the model. Liu et al. [19] proposed an interactive visualization technology namely CNNVis to help users understand, diagnose and improve convolutional neural networks (CNN). This technology visualizes the convolutional neural network as a directed acyclic graph where neurons in the convolutional layers are clustered and connections between neurons are bundled to reduce visual clutter. It allows users to interactively inspect the details of the model (e.g., activation values and weights). Recently, Wang et al [20] proposed CNN Explainer, a convolutional neural network visualization system that explains convolution and pooling operations via rich interactive visualizations. It can effectively help deep learning beginners quickly understand complex convolutional neural networks.

Researchers have made great progress in visualizing neural networks. Some of these works attempt to introduce visualization techniques to assist in the analysis of adversarial

attacks, they mostly provide limited, static visualization views, lacking rich interactive features and flexible exploration mechanisms. Users find it difficult to dynamically adjust views, filter data, and locate interesting attack patterns according to their analysis needs. In contrast, AdvAttackVis designs multiple visualization views, supporting flexible interactive operations and view coordination, empowering users with full autonomy and flexibility to explore the overview and details of attacks from different perspectives and granularities.

III. VISUALIZATION SYSTEM OVERVIEW

In this section, we introduce the overall framework of the AdvAttackVis system. As shown in Fig. 1, the system is designed based on B/S (Browser-Server) architecture. It consists of the front-end and back-end. The two parts are described below.

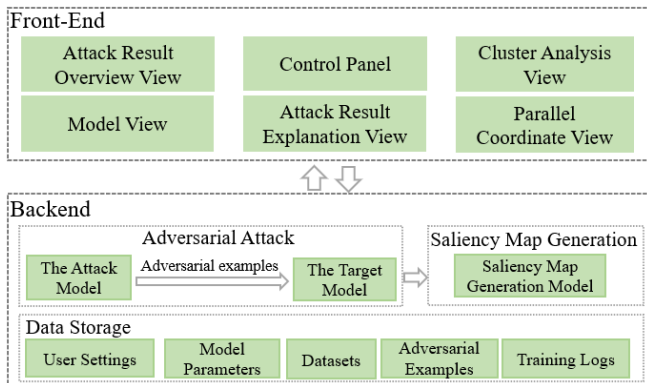

Fig. 1. Framework of AdvAttackVis.

The front-end provides a visual interface to help users understand, analyze, and explore adversarial attacks. It is mainly composed of six visualization views: the attack result overview view, the control panel, the cluster analysis view, the model view, the attack result explanation view, and the parallel coordinate view. The attack result overview view is used to analyze the adversarial attack results including the attack success rate and the distribution of attack results. This view provides a visual analysis of the attack effects from an overall perspective, allowing users to quickly understand the most prominent categories of model vulnerabilities to guide the next step of in-depth analysis. The control panel provides parameter settings for model training and adversarial attacks so that the user can train a satisfactory adversarial attack model. The cluster analysis view is designed to compare the clusters of the original examples and the adversarial examples, which helps users qualitatively analyze the performance changes of the target model. The model view displays the main modules of an adversarial attack model to help users understand the model architecture and working flow. The attack result explanation view offers saliency maps [27] of adversarial examples, which provides a visual explanation of the classification results of the adversarial examples. In the parallel coordinate view, users can analyze the changes in confidence scores of the original example and the adversarial example. In addition, information collaboration is achieved through link interaction between multiple views. Users can select points of interest in one view,

and other views automatically update to display the characteristics of these points.

The backend mainly consists of three parts: the adversarial attack module, the saliency map generation module and the data storage module. As the core of the backend, the adversarial attack module contains an attack model and a target model. The former generates adversarial examples to attack the latter. The saliency map generation module generates a saliency map for each adversarial example to explain why the adversarial attack succeeds or fails. The data storage module is used to store public datasets (e.g., training and testing sets), model parameters, adversarial examples, training logs and user settings.

For simplicity, we illustrate our system using the MNIST dataset [28] which is a classic handwritten digit classification dataset. Specifically, we construct a MNIST classification model as the target model and employ AdvGAN as the attack model. In the following sections, we first describe the underlying models of our system, including the target model, attack model and saliency map generation model. Then, we introduce the visual interface of the system. Finally, we demonstrate the effectiveness of our system through case studies.

IV. UNDERLYING MODEL

In this section, we introduce three main underlying models of the visualization system: the target model, the attack model, and the salient map generation model.

A. Target Model

We construct a MNIST classification model based on convolutional neural network as the target model. The MNIST dataset is very classic and easy to understand. The model structure used in this dataset is also relatively simple, but includes the main components of modern neural networks, making it very suitable for demonstrating the characteristics of deep learning. Therefore, using this dataset helps beginners understand how the model works. Specifically, the MNIST dataset [21] contains ten classes of handwritten digital grayscale images from 0 to 9. It contains 60,000 training images and 10,000 testing images. An MNIST classification model is constructed to recognize handwritten digital images. The model mainly consists of four convolutional layers, two pooling layers, two fully connected layers and a Softmax layer. It employs ReLU [1] as the activation function. Its overall architecture is shown in Table I. We train the MNIST classification model by the Adam optimizer [22] for 30 epochs with the batch size of 128. The model with the highest test accuracy (99.1%) is selected as the target model.

B. Attack Model

We employ AdvGAN [5] as the attack model. Compared to traditional gradient-based attack methods, AdvGAN not only generates more realistic and diverse attack samples more stably and efficiently but also employs a black-box attack approach. This enhances the generalization performance of AdvAttackVis across different attack models. AdvGAN produces adversarial samples using generators of generate adversarial networks (GANs). As shown in Fig. 2, AdvGAN contains three components: a generator G , a discriminator D and a target model f (i.e., the trained MNIST classification model). The

generator and discriminator form a GAN. The generator takes the original example x as input. The generated perturbation $G(x)$ is added to the original example x to form an adversarial example $x + G(x)$.

TABLE I. NETWORK ARCHITECTURE OF THE MNIST CLASSIFICATION MODEL

Layer	Parameter
Convolution + ReLU	3×3×32
Convolution + ReLU	3×3×32
Max Pooling	2×2
Convolution + ReLU	3×3×64
Convolution + ReLU	3×3×64
Max Pooling	2×2
Fully Connected + ReLU	200
Fully Connected + ReLU	200
Softmax	10

Fig. 2. Framework of the AdvGAN model.

During training AdvGAN, the generator aims to generate fake examples that can fool the discriminator, while the discriminator aims to correctly discriminate fake examples from real examples. The generator and the discriminator confront each other, forcing the generator to eventually generate realistic adversarial examples. To be specific, GAN is trained based on the following adversarial loss:

$$L_{GAN} = E_x \log D(x) + E_x \log (1 - D(x + G(x))) \quad (1)$$

where $D(\cdot)$ represents the probability (i.e., confidence) which the discriminator discriminates the input as a real example. Moreover, AdvGAN needs to constrain the output of the generator. That is, the generated adversarial examples should induce the target model to output wrong predictions. For targeted attacks, the corresponding loss function is as follows:

$$L_{adv}^f = E_x l_f(x + G(x), t) \quad (2)$$

where t denotes the target class and l_f represents the cross-entropy loss function. However, for untargeted attacks, t represents the ground truth. The adversarial example can be misclassified into other classes by maximizing the distance between the prediction and the ground truth. To limit the magnitude of the perturbation $G(x)$, AdvGAN usually adds a soft hinge loss to constrain the training process:

$$L_{hinge} = E_x \max(0, \|G(x)\|_2 - c) \quad (3)$$

where c indicates the user-specified upper bound and L_{hinge} can stabilize the training process of GAN. Finally, the objective function of AdvGAN is as follows:

$$L = L_{adv}^f + \alpha L_{GAN} + \beta L_{hinge} \quad (4)$$

where α and β control the importance of each component, L_{GAN} makes the perturbed example $x + G(x)$ similar to the original example x , and L_{adv}^f improves the attack success rate of adversarial examples. We train the generator and the discriminator by solving the min-max game $\arg \min_G \max_D L$. The trained generator can quickly generate adversarial examples for the original examples.

C. Saliency Map Generation Model

A saliency map [31] can reflect which regions of the input image are important for the decision-making of the target model. That is, the saliency map of an adversarial example can explain why the attack on the target model succeeds or fails from a visual perspective. We construct the saliency map generation model based on Grad-CAM [23]. The saliency map generation algorithm for adversarial examples is shown in Algorithm 1.

Algorithm 1 Saliency map generation algorithm for antithetical examples

Input: The original example x , the generator G , the target model f

Output: A saliency map of the adversarial example

1. $x' = x + G(x)$; // Generate an adversarial example
2. $c = \arg \max(f(x'))$; // Predict the class of the adversarial example.
3. $s = L_{Grad-CAM}^c(x')$; // Generate a saliency map.
4. $s' = \frac{s - \min(s)}{\max(s) - \min(s)}$;
5. return s' ;

Grad-CAM generates saliency maps based on the feature maps of the last convolutional layer of the target model. Specifically, the weight w_k^c of the k -th feature map A^k for category c is the mean of gradients:

$$w_k^c = \frac{1}{z} \sum_i \sum_j \frac{\partial y^c}{\partial A_{ij}^k} \quad (5)$$

where y^c denotes the output of the target model for category c , i and j is the horizontal and vertical coordinates of the feature map A^k respectively, and z denotes the size of the feature map A^k . Then, the weighted feature maps are merged into a saliency map:

$$L_{Grad-CAM}^c = \text{ReLU}(\sum_k w_k^c A^k) \quad (6)$$

where ReLU [1] is used to remove negative values of the saliency map.

V. VISUAL INTERFACE

In this section, we introduce the visual interface of our system. As shown in Fig. 3, it mainly includes six visualization views: (A) the attack result overview view, (B) the control panel,

(C) the cluster analysis view, (D) the model view, (E) the attack result interpretation view, and (F) the parallel coordinate view.

A. The Attack Result Overview View

This view is used to analyze the attack success rate of the adversarial examples of each category (e.g., categories 0 to 9 of MNIST) and the distribution of the attack results. As shown in Fig. 3(A), a histogram is used to display the attack success rate for each category. The scatter plots show the distribution of attack results for each category, allowing users to inspect which category each adversarial example is identified as. For each scatter plot, we take category as the horizontal coordinate and confidence as the vertical coordinate. Each scatter represents an adversarial example and its color encodes the ground truth of the adversarial example. When users click on a scatter, the scatter is highlighted in black. Meanwhile, the attack result explanation view and the parallel coordinate view present the explanation result and the parallel coordinate plot of the adversarial example, respectively.

B. The Control Panel

In the control panel, users can adjust the parameters of the attack model and select the dimensionality reduction algorithm for generating the cluster analysis view. When users click the "Start Training" button, the system starts training the attack model and saves the model with the highest success rate. After the attack model is trained, users can adjust the "Number of Adversarial Examples" item to control the number of adversarial examples. When users click the "Start Attack" button, the system generates a specified number of adversarial examples to attack the target model. The attack results are shown in the attack result overview view. The system provides three dimensionality reduction algorithms as options for the cluster analysis view, namely Principal Component Analysis (PCA) [24], Multi-Dimensional Scaling (MDS) [25] and t-distributed Stochastic Neighbor Embedding (t-SNE) [26]. When users select a dimensionality reduction algorithm, the system generates a

cluster analysis view by projecting the high-dimensional feature vectors of examples to 2D plane.

C. The Cluster Analysis View

This view is designed to compare the clusters of the original examples and the adversarial examples, which allows users to qualitatively analyze the degree of damage to the performance of the target model. As shown in Fig. 3(C), the view consists of two parts. The left shows the clusters of the original examples while the right presents the clustering results of the adversarial examples. Each dot denotes an example and its color encodes the ground truth of the example. In general, the left obtains clear clusters due to the good classification performance of the target model for the original examples. However, the clusters in the right are difficult to be distinguished, which suggests that the adversarial examples interfere with the performance of the target model. Moreover, the view offers interactives (i.e., selection, zooming and highlighting) to facilitate user comparison and analysis of examples.

D. The Model View

The model view presents an overall overview of the attack model to help users understand the overall architecture and data flow of the model. For the attack model AdvGAN, we design different rectangular blocks to represent the Generator, Discriminator and target model (e.g., the trained MNIST classification model), respectively. Users can click on a rectangular block to inspect the internal structure of the corresponding module more closely. The small histogram on the right side of the target model displays the classification results of the target model for adversarial examples. During the training phase of the attack model, this view provides the change curve of the attack success rate to help users observe the real-time training situation of the model. When the attack model is trained, users can click on the "Input Example" rectangle to load examples to explore adversarial attacks.

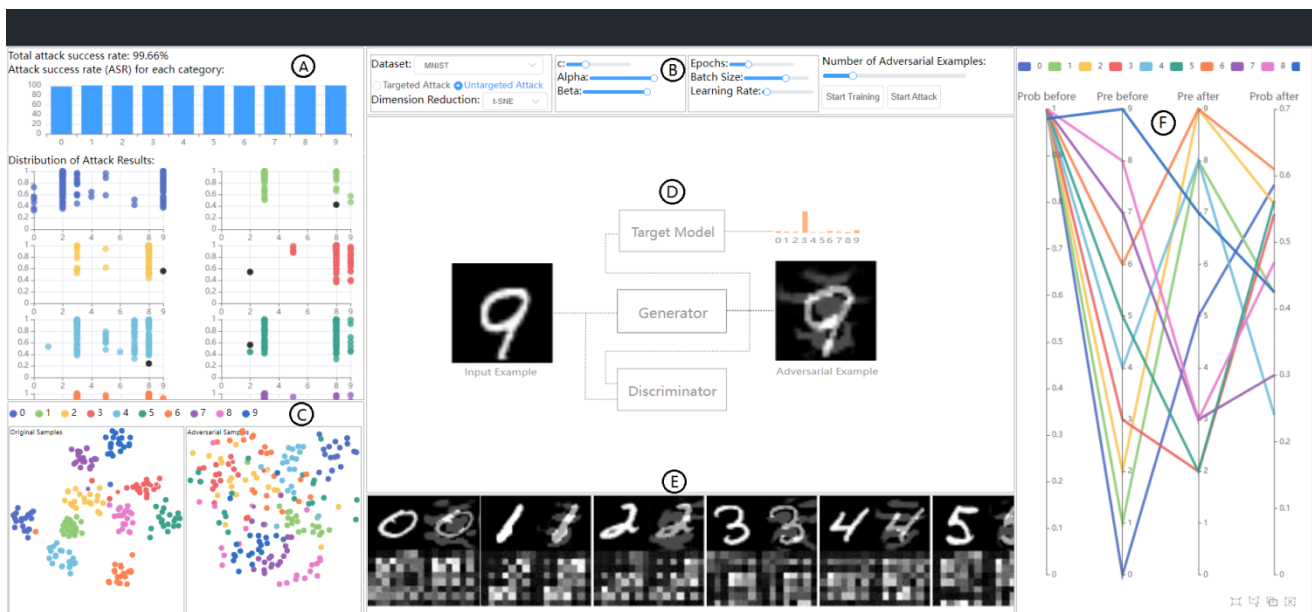

Fig. 3. The visual interface of the AdvAttackVis system.

E. The Attack Result Interpretation View

The view can provide explanations for the classification results of the adversarial examples. Specifically, the view generates a saliency map for each adversarial example (see Algorithm 1). The saliency maps reveal the contribution of different regions and pixels of the input image to the model's decision. Intuitively, adversarial perturbations should target those key pixels that influence the model's decision, in order to deceive the model more effectively. Therefore, by visualizing the differences between adversarial and original samples on saliency maps, users can intuitively understand the mechanism of adversarial perturbations, namely how attackers manipulate pixel values subtly to deceive the model. As shown in Fig. 3(D), this view offers the saliency maps of the original example and the adversarial example for comparative analysis. Taking a MNIST image as an example, its saliency map is similar to a mosaic map where the lighter color of a pixel indicates that the target model pays more attention to that pixel. Compared with the saliency map of the original image, that of the adversarial example usually changes dramatically, which suggests that the adversarial example interferes with the decision-making of the target model.

F. The Parallel Coordinate View

In the parallel coordinate view, a parallel coordinate plot is designed to help users analyze the classification results and the confidence changes of the adversarial examples. As shown in Fig. 3(E), the plot contains four vertical parallel lines from left to right. They represent the classification confidence of the original example, the classification result of the original examples, the classification result of the adversarial example and the classification confidence of the adversarial example, respectively. A curve in the parallel coordinate plot indicates an adversarial example and its color encodes the class of the adversarial example. As illustrated in Fig. 4, the curve corresponding to the handwritten digit "6" has the values "1.00", "6", "9" and "9" from left to right. This means that the original example is identified as "6" by the MNIST classification model with confidence "100%" but the adversarial example (i.e., the original example with an adversarial perturbation) is misidentified as "9" with confidence "61%".

Fig. 4. The curve corresponding to the handwritten digital image "6" in the parallel coordinate view.

VI. CASE STUDY

This section verifies the usability and effectiveness of the visualization system through a case study based on the MNIST dataset.

To train the AdvGAN model, we select the MNIST dataset as the training data in the control panel (Fig. 3(A)) and click on the "Untargeted Attack" item to set the adversarial attack as an untargeted attack. Then we set the parameters of its objective function (i.e., $c=0.3$, $\alpha=1$ and $\beta=1$) and the parameters of the model training (i.e., epochs=30, batch size=128 and learning rate=0.001). Finally, we click on the "Start Training" item to start model training. In addition, we select the t-SNE dimensionality reduction algorithm to generate the cluster analysis view.

After the AdvGAN model is trained, we set the value of the "Number of Adversarial Examples" item in the control panel to 2075 and click the "Start Attack" button to start the adversarial attack. Specifically, the system first randomly selects 2075 images from the MNIST testing set that can be correctly classified by the MNIST classification model (i.e., the target model), and then inputs them into the trained generator to generate 2075 adversarial examples to attack the MNIST classification model. As shown in Fig. 5, the total attack success rate is 99.66%. The histogram shows that only the adversarial examples with class 0 and class 6 fail against the target model. In other words, the MNIST classification model can correctly predict the category of these adversarial examples. As shown in the red dashed box in Fig. 6, there are six failed examples in the adversarial examples with class 0, while there is only one failed example in the adversarial examples with class 6. Although these seven adversarial examples do not cause the MNIST classification model to output wrong results, they indeed decrease the classification confidence of the MNIST classification model to a certain extent. Specifically, as shown in Fig. 7, the MNIST classification model predicts the classes of the seven failed samples with 100% confidence before adding the adversarial interferences to the original examples. However, when the adversarial interferences are added to the original examples (i.e., generating the adversarial examples), the MNIST classification model correctly classifies the adversarial examples with a maximum of 73% confidence. This means that the addition of the adversarial interferences can interfere with the model's judgment to some extent even if the attack fails.

Fig. 5. The total attack success rate of 2075 adversarial examples and the attack success rate for each category.

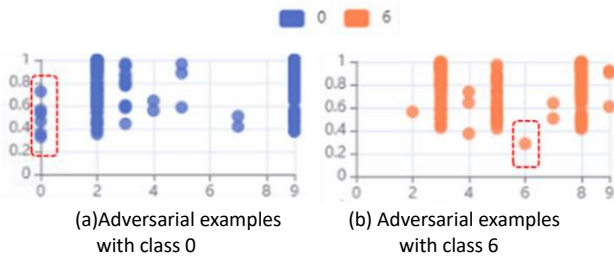

Fig. 6. Seven failed examples in the adversarial examples with class 0 and class 6.

Fig. 7. Confidence change of the seven failed examples before and after the adversarial attack.

The degree of interference suffered by the target model can be analyzed through the cluster analysis view, as shown in Fig. 8. In this case, the left view shows that there are highly distinguishable clusters in the original examples, which shows that the target model is capable of distinguishing classes well before being attacked. However, when the original examples become adversarial examples against the target model, the cluster results of the adversarial examples become cluttered, as shown in the right view of Fig. 8. This indicates that the adversarial attack has a great effect on the category discrimination ability of the target model. For example, the two examples of class “5” (i.e., “2248” and “2250”) in the left view have similar features and thus are close to each other. When these two examples become adversarial examples, their positions in the right view are far apart. This means that the addition of adversarial perturbations has a significant impact on their features, thus causing them to be misclassified by the target model.

From the scatter plots in the attack result overview view (Fig. 3(A)), we can find that most of the adversarial examples are misclassified by the MNIST classification model with high confidence (i.e., large values on the vertical coordinate). In order to explore the successful adversarial examples, we select a successful adversarial example with low confidence (i.e., a small value on the vertical coordinate) from each category (i.e., each scatter plot) for further analysis. Fig. 9 shows the confidence changes of the selected 10 adversarial examples before and after adding adversarial disturbances. Specifically, each example is correctly classified by the MNIST classification model with a confidence level close to or equal to 100% before adding the adversarial interference. However, they are incorrectly classified into other categories by the model with a lower confidence level after adding the adversarial interferences to them. For example, the adversarial example with category 4 is classified as 9 with 24% confidence. For successful untargeted attacks, the low confidence level indicates that the making decision of the MNIST classification model is influenced by the adversarial disturbances. To further explore the reasons why the selected 10 adversarial examples (see Fig. 9) are misclassified, we analyze the saliency maps of these examples in the attack result interpretation view. As shown in Fig. 10, there are a total of 10 pictures. Each picture is composed of 4 small pictures. They are the original image (row 1, column 1), the adversarial example (row 1, column 2), the saliency map of the original image (row 1, column 2), and the saliency map of the adversarial example (row 1, column 2). For each saliency map, the lighter the color of a pixel is, the more attention the MNIST classification model pays to the pixel (i.e., the more important the pixel is to the final classification result). Comparing the saliency map of the original image with that of the adversarial examples, we can find that when adversarial perturbations are added to the original image (i.e., producing an adversarial example), the attention area of the MNIST classification model changes, resulting in the predictions of the model to be disturbed. For example, for the original image “0”, the pixel color of the contour area of digital “0” in its saliency map is lighter, which reveals that the MNIST classification model mainly focuses on the contour area of digital “0”. However, when the original image becomes an adversarial example, the white pixels in the upper-left region of digital “0” in the adversarial example’s saliency map become denser. This reveals that the MNIST classification model shifts its attention to the upper-left region of digital “0”, resulting in the incorrect prediction.

Fig. 10. Interpretation results of 10 successful attack samples.

VII. CONCLUSION AND FUTURE WORK

In this paper, we present an adversarial attack visualization system called AdvAttackVis which can effectively assist users in learning, understanding, and exploring adversarial attacks. The visualization system offers interactive visualization views to help users train and analyze the adversarial attack models, understand the principles of adversarial attacks, analyze the success rate of adversarial attacks and the distribution of attack results, and explore the prediction mechanism of the target model for adversarial examples. It facilitates end-to-end analysis of adversarial attacks. Our multi-view visual analysis environment enables users to gain a deep understanding of the effects and impacts of adversarial attacks. Additionally, the system incorporates interpretability analysis techniques, such as saliency analysis, which can assist users in inferring the reasons behind adversarial attacks. Through the case study base on the MNIST handwritten digital image dataset, we demonstrate the usability and effectiveness of the system.

In the future, we will implement more interactive visualizations to help users explore the internal states of the target model. For example, by analyzing the changes in feature maps of each convolutional layer layer by layer, users can track how misclassifications caused by attacks accumulate and propagate within the model, deepening their understanding of the underlying mechanisms of adversarial attacks and enhancing their analytical abilities. Through interactive visualization of the internal states of the model, users can gain insights into the intermediate processes of model inference, identify anomalous behaviors introduced by attacks, and infer their causes and impacts.

Abstract—Intrusion detection systems (IDS) play a critical role in safeguarding network security by identifying malicious activities within network traffic. However, the effectiveness of an IDS hinges on its ability to extract relevant features from the vast amount of data it collects. This study investigates the impact of different feature extraction methods on the performance of IDS. We compare the performance of various feature extraction techniques on two widely used intrusion detection datasets: KDD Cup 99 and NSL-KDD. By evaluating these techniques on both datasets, we aim to gain insights into the generalizability and robustness of each method across different dataset characteristics. The study compares the performance of these methods using standard metrics like detection rate, F-measure and FPR for intrusion detection.

Keywords—Intrusion detection; dimensionality reduction; feature extraction; KDDCup'99; NSL-KDD

I. INTRODUCTION

Machine learning (ML), a subfield of Artificial Intelligence (AI), has seen explosive growth in recent years. ML algorithms learn from data to make predictions or classifications, making them ideal for various applications requiring intelligent behaviour [1]. However, incorporating ever-growing amounts of data can be challenging across various fields, including data analysis, text mining, and even machine learning itself [2]. ML excels at building models for specific tasks like classification (categorizing data), clustering (grouping similar data points), and prediction (forecasting future outcomes) [2]. There are two main Machine Learning approaches: supervised learning and unsupervised learning. On one hand, supervised learning is where the model learns a mapping between input data and desired output based on labelled examples (data with known outcomes) [3]. In other words, we are giving the computer the input data and know what the output should be. Common supervised tasks include classification (e.g., spam vs. non-spam email) and regression (e.g., predicting house prices). In contrast, unsupervised learning analyses unlabelled data (data without predefined categories) to identify patterns or structures [3]. This is like giving a computer data and letting it discover patterns on its own. A common unsupervised technique is clustering, which groups similar data points together. Machine learning algorithms are revolutionizing cybersecurity by enhancing the effectiveness of Intrusion Detection Systems (IDS). IDS is a security tool or software application designed to monitor constantly the traffic, system logs, and events for suspicious patterns that might indicate cyberattacks.

The Host Intrusion Detection System (HIDS) and the Network Intrusion Detection System (NIDS) are the two types of IDS that may be invoked. The first is a system that operates on hosts, analysing logs and system calls on a specific device. Although this sort of IDS may identify intrusions on a single host, its primary downside is that it consumes a lot of resources, which hurts the host's performance. The second, NIDS, operates on the network, analysing packets while remaining undetected and detecting abnormalities and suspicious activities, it analyses packets send and received from different nodes of a network. When establishing a NIDS, we may encounter blind spots, the NIDS's location may have a detrimental impact on the system, and encrypted data may elude detection.

Signature-based IDS and Anomaly based IDS are two methods of intrusion detection systems. On one hand the signature-based IDS is based on comparing the signatures of known attacks with the collected data. In other word, the collected and observed data is compared with a database containing different signatures of known attacks, once there is a match, alerts are triggered. The downfall of this approach is this system cannot detect new attacks, meaning the database should always be updated with the newly found attacks. On the other hand, the anomaly-based IDS focuses on detecting deviation or anomalies from established baselines of normal behaviour. In other words, the “normal” behaviour of the user is determined first, then any type of action is analysed and is considered as an attack if it deviates from normality. This method allows us to detect unknown and new attacks, but it generates a huge number of false positive. We can also mention the hybrid intrusion detection systems that are both Signature-based IDS and Anomaly based IDS. Each type of IDS has benefits as well as drawbacks, and most organizations use a combination of them to offer a degree of protection that detects threats and intrusions throughout the network.

This research explores the potential of machine learning for intrusion detection in computer networks [4] [5] [19]. We begin by examining and analysing existing approaches in the field. Section III delves into the specific anomaly detection methods used in our study. Here, we'll provide a detailed flowchart illustrating the entire process, from data pre-processing to anomaly identification. Following this, Section IV presents the results obtained from implementing these methods. Finally, Section V offers concluding remarks, summarizing the key findings, and demonstrating their value in identifying network threats.

II. RELATED WORK

This research in [8] explores various techniques for feature selection in network intrusion detection systems (NIDS). The authors propose using several algorithms, including Genetic Algorithms (GA), Particle Swarm Optimization (PSO), Grey Wolf Optimizer (GWO), and Firefly Algorithm (FFA), either individually or in combinations. Before feature selection, the authors performed essential data preprocessing steps: Label Removal and features removal, then Label Encoding where Categorical features are converted into numerical values and finally Data Binarization where Features are transformed into binary values (0 or 1). Following feature selection, two classifiers are employed: J48 decision tree and Support Vector Machine (SVM).

Zhou & Al [9] presented a novel intrusion detection framework that combines feature selection and ensemble learning techniques to enhance the efficiency of intrusion detection systems. The proposed methodology includes a Correlation-based Feature Selection with Bat Algorithm (CFS-BA) for selecting optimal feature subsets based on feature correlations. An ensemble classifier, comprising C4.5, Random Forest (RF), and Forest Parallel Algorithm (ForestPA) with an Average of Probabilities (AOP) combination rule, is utilized to construct the classification model. The proposed CFS-BA-Ensemble method outperforms other feature selection methods in terms of accuracy, F-Measure, Attack Detection Rate (ADR), and False Alarm Rate (FAR) across different datasets (NSL-KDD, AWID, and CIC-IDS2017). The study highlights the importance of feature selection in reducing computational complexity and improving the performance of intrusion detection systems.

The research in [10] introduces a novel approach called AE-IDS for enhancing classification accuracy and reducing training time in network security. The system utilizes deep learning techniques, specifically auto-encoders, for unsupervised clustering in network intrusion detection. By incorporating random forest feature selection, the method aims to improve the overall performance of intrusion detection systems. The workflow includes setting up decision trees, constructing sub-decision trees, determining output results, calculating classification errors, and assessing feature importance. The study evaluates the method using the DDoS: HIOC dataset and highlights the significance of feature selection in improving system performance. The authors acknowledge the support received for the research and declare no competing interests. Overall, the paper presents a promising approach that combines deep learning and random forest feature selection for effective network intrusion detection. Improved Classification Accuracy: The proposed AE-IDS method demonstrated superior performance in terms of classification accuracy compared to traditional machine learning-based intrusion detection methods. This improvement is attributed to the effective deep learning approach combined with the random forest algorithm.

Venkatesan & al [11] investigated the effectiveness of a new approach for intrusion detection using the NSL-KDD dataset. The authors primarily focus on accuracy, a crucial metric for intrusion detection systems (IDS). The authors

leverage the ANOVA F-Test to identify the most relevant features from the NSL-KDD dataset. This helps focus on the information that best distinguishes normal network traffic from intrusions. After feature extraction, the Recursive Feature Elimination (RFE) technique is employed. RFE eliminates features deemed less important based on a ranking system, ultimately reducing the number of features from its original size to a set of 13 most relevant features. To assess the effectiveness of the selected features and the overall approach, the authors employ three different machine learning algorithms: Decision Tree, Random Forest, and Support Vector Machine (SVM). The performance of each algorithm is then evaluated based on accuracy, comparing their ability to correctly identify intrusions within the network traffic data.

In study [12], they introduced a novel and potentially impactful hybrid feature selection method (HFS) designed for intrusion detection systems (IDS). This HFS method combines three techniques: Genetic Search Technique, Rule-Based Engine and CfsSubsetEval. The selected features are then fed into a classifier called KODE for attack classification. The authors demonstrate that their HFS method not only achieves promising results in terms of standard performance metrics (accuracy, precision, recall, etc.), but it also offers benefits in terms of model building and testing time. This suggests that the HFS method can be both effective and efficient for intrusion detection.

The research conducted by Zahid Halim & al [13], and their team focuses on utilizing machine learning and data mining techniques to enhance cybersecurity measures. The study introduces a novel fitness function for genetic algorithms to rank features and develop a feature selection technique, GbFS, for intrusion detection systems. The researchers train machine learning classifiers using the selected optimum features and evaluate performance on benchmark datasets. The proposed method demonstrates effectiveness through comparisons with existing intrusion detection methods and standard feature selection techniques. The paper provides insights on improving detection accuracy, optimizing feature selection, and enhancing cybersecurity measures using genetic algorithms and machine learning approaches.

Pranto & al [14] explores various approaches to using machine learning for effective intrusion detection in network traffic data. The study compares the performance of different algorithms. And to improve computational efficiency, a basic feature selection strategy was employed. The research conducted by Talukder & al [15] propose a novel hybrid machine learning model designed to improve network intrusion detection. The model prioritizes both dependability and effectiveness, offering a reliable solution for identifying malicious activity within network traffic. The model addresses the challenge of imbalanced datasets, often encountered in intrusion detection, by incorporating SMOTE and highlights on the importance of using efficient dimensionality reduction methods to improve computational efficiency without compromising the model's accuracy. The proposed approach is evaluated on two benchmark datasets: KDDCUP'99 and CIC-MalMem-2022. This evaluation ensures the model's

generalizability and adaptability to different types of network traffic data.

III. PROPOSED APPROACH

A. System Model and Problem Formulation

One of the issues encountered is the use of enormous datasets to work on new approaches to improve signature-based IDS, therefore the usage of data mining. Data mining is a pre-processing technique before using machine learning models. It is used to explore and extract useful information from data, as well as minimize its dimensions, before using machine learning algorithms.

In this paper, we describe the suggested method in detail. The main idea of the approach is to improve intrusion detection and detect each type of attack by applying different machine learning methods.

Fig. 1 represents the flowchart of the proposed signature-based IDS. In this study, we offered to construct a robust IDS using each time a different method of feature extraction and dimensionality reduction, aiming to improve the accuracy and decrease the false positive rate.

B. Data Preparation

Our work will be applied on two different and well-known datasets the KDDCup'99 and the NSL KDD. These datasets have been widely used for so many approaches and by different researchers all over the globe for evaluating intrusion detection systems and asses the performance of these approaches in cybersecurity domain [16] [17] [18] [24].

The KDD Cup 99 is a well-known dataset used in the field of cybersecurity and network intrusion detection. It was organized as part of the KDD (Knowledge Discovery and Data Mining) conference in 1999 and aimed to help researchers to propose and try new approaches in detecting network intrusions or attacks within computer systems. The KDD-CUP 99 dataset features 41 attributes describing network traffic and categorizes them into five classes: normal, Denial of Service, User to Root, Remote to Local, and Probe attacks.

The presence of redundant and irrelevant information in the KDD Cup 99 dataset can negatively affect the performance of analysis and machine learning models. Thus, the use of the NSL-KDD where multiple challenges have been resolved. The NSL-KDD is the modified version of the KDD CUP 99, where they worked on reducing the redundant and irrelevant data, and solve the problem of imbalanced data, where it made the machine learning models be bias towards the majority class and reduce the effectiveness of detecting the attacks that were underrepresented.

Overall, NSL-KDD aimed to provide a more suitable and realistic dataset for evaluating intrusion detection systems. These improvements have contributed to more robust and accurate intrusion detection models that are better suited for real-world applications. This Dataset contains the same five classes of patterns, but with different representations.

Through providing appropriate data set to reduce the data afterwards, both the KDD Cup'99 and the NSL-KDD dataset passe through multiple steps of pre-processing.

- Step1: Collecting and splitting the data.

Building an effective intrusion detection model relies on having some well-prepared data, and collecting this data and splitting it is the first important step. When separating the used dataset into training and testing sets, it's crucial to acknowledge that these sets should not be from the same underlying probability distribution. This implies that certain attack types present in the testing data might be absent in the training data, enhancing the realism of the evaluation but also posing challenges for accurate detection.

- Step2: Vectorizing the data using one hot encoding:

Vectorizing data is essential for machine learning as most of machine learning algorithms require numerical input. This involves transforming data into numerical vectors. Since our datasets contain both numerical and categorical features, we'll leverage one-hot encoding for the categorical ones. This technique essentially creates separate binary vectors for each category, effectively expanding the feature space and enhancing the model performance.

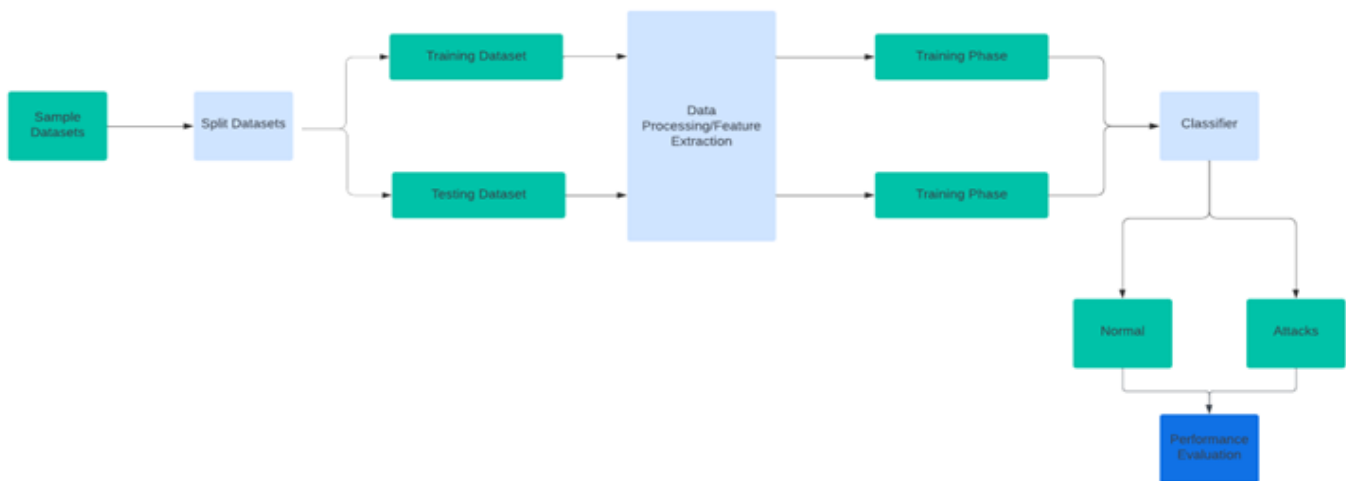

Fig. 1. Flowchart of the proposed Approach of NIDS.

- Step 3: Feature Scaling:

Data scaling is the act of transforming the values of features of a dataset into a specific range.

C. Dimensionality Reduction

Reducing dimensions can lead to simpler models, faster computation, improved generalization by reducing noise and redundancy, and easier visualization of data.

Principal Component Analysis (PCA) is a technique for dimensionality reduction, aiming to transform a high dimensional dataset into a lower dimensional subspace while preserving the most significant information [7]. Transforming several correlated variables into a set of mutually orthogonal variables called Principal components (PCs) where the initial PCs encapsulate the highest information density. Let's assume we have a training data matrix described as follow:

$$X = \begin{pmatrix} x_{11} & \dots & x_{pn} \\ \vdots & \ddots & \vdots \\ x_{n1} & \dots & x_{pn} \end{pmatrix} = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} \quad (1)$$

Where, p is the columns vectors and n is the data size. To get the PCs of the training set, we'll first compute the average of this set:

$$\bar{x}_j = \frac{1}{n} \sum_{i=1}^n x_{ij} \quad (2)$$

The covariance matrix $C(x_j)$ will be calculated to identify the scatter degree of the feature vectors to identify the key features, it can be determined as follow:

$$C(x_j) = \frac{1}{n} \sum_{i=0}^n (x_{ij} - \bar{x}_j)(x_{ij} - \bar{x}_j)^t \quad (3)$$

Following the computation of the covariance matrix, the next step involves computing the eigenvectors and their corresponding eigenvalues. These eigenvectors, also known as principal components (PCs) should be sorted in a descending order where the first PCs encapsulate most of the data variance. The selection of the principal components should strike a balance between retaining critical information and achieving the desired level of dimensionality reduction. This ratio is defined by the following formula:

$$\beta = \frac{\sum_{i=1}^{n'} \lambda_k}{\sum_{i=1}^n \lambda_k} \quad (4)$$

Once these PCs are chosen and validated, the original data is projected into the PCs, creating a new lower dimensional projection.

L2-p norm based PCA is a variant of principal component analysis that incorporates the L2-p norm as a measure of distance or similarity between data points, allowing for more robust and flexible dimensionality reduction. The L2-p norm based PCA offers a valuable approach for dimensionality reduction, as it allows for adjusting the importance of different dimensions based on the chosen value of p . Wang & al. [20] proposed this approach where:

$$\min_W \sum_{i=1}^n \|x_i - WW^T x_i\|_2^p \quad (5)$$

Subject to : $W^T W = I$

where, $0 < p \leq 2$.

$$\begin{aligned} & \sum_{i=1}^N \|x_i - WW^T x_i\|_2^2 \|x_i - WW^T x_i\|_2^{p-2} \\ &= \sum_{i=1}^N \text{tr} \{ (x_i - WW^T x_i)^T * (x_i - WW^T x_i) \} d_i \end{aligned} \quad (6)$$

$$\begin{aligned} &= \sum_{i=1}^N \text{tr} \{ x_i^T x_i - x_i WW^T x_i - x_i WW^T x_i \\ &+ x_i WW^T WW^T x_i \} d_i \end{aligned} \quad (7)$$

$$= \sum_{i=1}^N \text{tr} \{ x_i^T x_i - x_i WW^T x_i \} d_i \quad (8)$$

where: $d_i = \|x_i - WW^T x_i\|_2^{p-2}$

By substituting Eq. (8) into Eq. (5), we'll obtain the following objective function:

$$\min_W \sum_{i=1}^N \text{tr} \{ x_i^T x_i \} d_i - \sum_{i=1}^N \text{tr} \{ W^T x_i x_i^T W \} d_i \quad (9)$$

The primary focus at this juncture is on devising a method to determine the optimal projection matrix W for the objective function (8). The goal is to find a projection matrix W that reduces the objective function value to the minimum. This objective function (8) involves the unknown variables W and d_i , which are interlinked with W . Given that the objective function (8) lacks a straightforward, closed-form solution, directly addressing it poses a significant challenge. An approach that can be developed involves iteratively updating W (holding d_i constant) and d_i (holding W constant).

$$W^* = \text{argmax} \text{tr}(W^T XDX^T W) \quad (10)$$

Subject to : $W^T W = I$

In this context, D represents a diagonal matrix with its diagonal elements being d_i , and the column vectors of W in the objective function (10) consist of eigenvectors from XDX^T , which correspond to the k highest eigenvalues. Following this, the diagonal element d_i within the matrix D is updated. This iterative process is carried out repeatedly until the algorithm reaches convergence.

The Double L2, p -norm based Principal Component Analysis (DLPCA), introduced by Huang & al [6], presents an innovative technique for feature extraction. It is designed to reduce reconstruction error while increasing data variance within a cohesive structure. DLPCA incorporates the L2, p -norm distance metric into its objective function, improving its ability to manage outliers with greater robustness and efficiency. Through the identification of two transformation matrices, the method optimizes both data variance and reconstruction error, providing an effective approach to feature extraction challenges.

To maximize the data variance and achieve robust results to outliers, we'll use the following formulation:

$$\max_W \sum_{i=1}^n \|W^T x_i\|_2^p \quad (11)$$

Subject to: $W^T W = I$

They propose a robust model for minimizing reconstruction error. This model incorporates utilization of different transformation matrices for each role involved in the feature extraction process.

$$\min_{W,U} \sum_{i=1}^n \|x_i - UW^T x_i\|_2^p \quad (12)$$

Subject to : $W^T W = I$ and $U^T U = I$

Eq. (11) defines a two-step process for data transformation. First, matrix W projects the data into a lower-dimensional space for efficient processing. Then, matrix U recovers the data from this compressed form. To fulfil the goal of using both the minimization of reconstructed error and the maximization of data variance into account, we combine (10) and (11) to get the objective function of the double L2-p norm PCA formulated as follow:

$$\min_{W,U} \frac{\sum_{i=1}^n \|x_i - UW^T x_i\|_2^p}{\sum_{i=1}^n \|W^T x_i\|_2^p} \quad (13)$$

Subject to : $W^T W = I$ and $U^T U = I$

Unlike existing robust PCA methods that focus solely on either minimizing reconstruction error or maximizing data variance, this approach takes a unified perspective, by combining these aspects into a single framework, allowing them to contribute more effectively to the projection learning process.

IV. RESULTS AND DISCUSSION

A. Performance Metrics

Accuracy (AC): is the ability of identifying accurately both known and novel malicious activities. Can be determined by the following equation:

$$AC = \frac{Tp+Tn}{Tp+Tn+FP+Fn} * 100 \quad (14)$$

Precision (PR): Configurable hyper-parameter used for accurate classification of attacks within the intrusion detection system. PR is defined by the following formula:

$$PR = \frac{Tp}{Tp+Fp} * 100 \quad (15)$$

Recall (RC): Also known as the detection rate (DR), it refers to the ability to identify and flag malicious activities and can be calculated as follow:

$$RC = DR = \frac{Tp}{Tp+Fn} * 100 \quad (16)$$

False Positive Rate (FPR): Is the proportion of falsely identified normal behaviour detected as abnormal action which is expressed by the following formula:

$$FPR = \frac{Fp}{Tn+Fp} * 100 \quad (17)$$

F-measure (FM): It offers a balance view of the performance of individual metrics precision and recall. Is computed by the following formula:

$$FM = 2 * \frac{PR*RC}{PR+RC} * 100 \quad (18)$$

B. Performance Evaluation

In cybersecurity, a high F-measure implies that the system accurately identifies most attacks while minimizing false alarms that can overburden security personnel. This helps prioritize genuine threats and optimize security response measures.

Fig. 2. Principal Components vs. F-Measure for KDDcup99.

Fig. 3. Principal Components vs. F-Measure for NSL-KDD.

Fig. 2 and 3 provide complimentary perspective on the relationship between the number of principal components chosen for feature extraction and F-measure, a metric that balances precision and recall. Techniques utilizing Lp-norms (p=1 and 2) [22] [23] or double L2, p-norms generally achieve superior F-measures compared to standard PCA across most numbers of principal components. This suggests these methods extract more relevant features, leading to better overall performance in intrusion detection. As the number of principal components increases, F-measures tend to improve for most techniques. This indicates that higher-dimensional feature representations capture more information, potentially leading to better precision (correctly identifying intrusions) and recall (minimizing missed attacks). Notably, Double L2,p-norm PCA consistently demonstrates the highest F-measures regardless of the number of principal components chosen. This finding highlights its effectiveness in feature extraction for the KDD Cup dataset and the NSL-KDD dataset. It suggests that Double L2,p-norm PCA excels at selecting

informative features across different dimensionalities, leading to a good balance between precision and recall in intrusion detection.

Fig. 4. Training data vs. F-measure for KDDcup99.

Fig. 5. Training data vs. F-measure for NSL-KDD.

Fig. 4 and Fig. 5 offers distinct visual representation of how the feature extraction techniques that incorporate Lp-norms ($p=1$ and 2) or double L2,p-norms generally achieve higher F-measures compared to standard PCA across most training sizes. This suggests they extract more informative features, leading to better overall performance in intrusion detection. As the amount of training data increases, F-measures tend to improve for most techniques. This highlights the importance of larger datasets for achieving better precision and recall in intrusion detection. Notably, Double L2,p-norm PCA consistently demonstrates the highest F-measures across all training sizes. This finding underscores its effectiveness in feature extraction for the KDD Cup dataset, as it leads to a better balance between correctly identifying intrusions (high precision) and minimizing missed attacks (high recall).

In both Fig. 6 and Fig. 7, traditional PCA generally performed worse than the other techniques, especially as the number of features analysed increased. Double L2,p-norm PCA consistently achieved the highest detection rates in all scenarios. This suggests it's the most effective method for extracting relevant information from network traffic data for intrusion detection on the KDD Cup dataset and the NSL-KDD Dataset. Within the Double L2,p-norm PCA technique, using $p=1$ typically led to better results than using $p=2$ in most cases.

Fig. 6. Principal Components vs. DR for KDDcup99.

Fig. 7. Principal Components vs. DR for NSL-KDD.

Fig. 8. Training data vs. DR for KDDcup99.

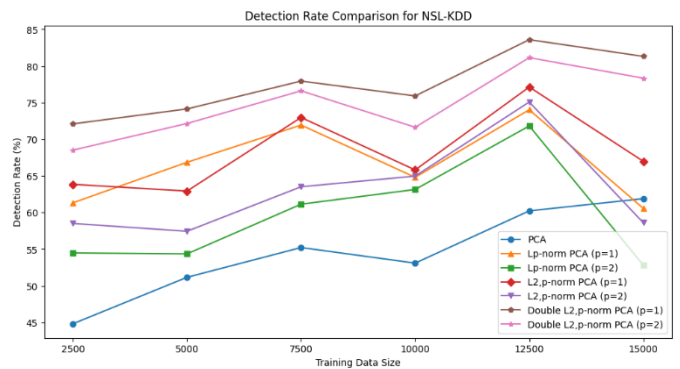

Fig. 9. Training data vs. DR for NSL-KDD.

As anticipated, larger training sets consistently elevate detection rates across all feature extraction techniques examined. This reinforces the notion that ample data is crucial for optimal intrusion detection system (IDS) performance. The relationship between the training data size and detection rate is further elucidated by Fig. 8 and Fig. 9. Techniques incorporating Lp-norms (p=1 and 2) or double L2, p-norms generally surpass standard PCA, particularly as the training size increases. This suggests that these methods capture more relevant information from the data, leading to more effective intrusion detection. Notably, double L2, p-norm PCA (p=1) consistently achieves the highest detection rates, demonstrating its efficacy in feature extraction for the KDD Cup dataset.

Fig. 12. Training data vs. FPR for KDDcup99.

Fig. 10. Principal Components vs. FPR for KDDcup99.

Fig. 13. Training data vs. FPR for NSL-KDD.

Fig. 11. Principal Components vs. FPR for NSL-KDD

Fig. 10 and Fig. 11 examines how feature extraction techniques impact false positive rates, a crucial metric in intrusion detection systems (IDS). Feature extraction methods incorporating Lp-norms (p=1 and 2) or double L2,p-norms generally achieve lower false positive rates compared to standard PCA across most settings. As the number of principal components increases (higher dimensionality), false positive rates tend to decrease for most techniques. This indicates that higher-dimensional feature spaces allow for better separation between normal and abnormal network activities, reducing the chances of misidentification. Notably, Double L2,p-norm PCA consistently demonstrates the lowest false positive rates. This finding highlights its effectiveness in feature extraction for the KDD Cup dataset where it excels at creating features that effectively distinguish between normal and attack traffic, minimizing the number of false alarms generated by the IDS.

False positives occur when an IDS mistakenly identifies normal traffic as an attack. Here's what the findings reveal based on both Fig. 12 and Fig. 13. Techniques that incorporate Lp-norms (p=1 and 2) or double L2, p-norms generally achieve lower false positive rates compared to standard PCA across most training sizes. This suggests these methods create more robust feature representations, leading to fewer instances of misclassifying normal data as intrusions. As the amount of training data increases, false positive rates tend to decrease for most techniques. This highlights the importance of larger datasets for an IDS to learn the subtle differences between normal and abnormal network activities, ultimately reducing false alarms. Notably, Double L2,p-norm PCA consistently demonstrates the lowest false positive rates across all training sizes.

TABLE I. OBTAINED RESULTS FOR THE KDDCUP99

Used Method	Performance Metrics (%)		
	DR	FPR	F-measure
PCA	70,26	5,91	78,71
Lp norm PCA(p=1)	84,83	4,61	88
Lp norm PCA(p=2)	82,35	4,38	84,60
L2-p norm PCA(p=1)	87,90	1,86	90,63
L2-p norm PCA(p=2)	83,66	1,99	87,40
Double L2-p norm PCA(p=1)	93,24	1,48	96,37
Double L2-p norm PCA(p=2)	90,93	1,75	94,44

TABLE II. OBTAINED RESULTS FOR THE NSL-KDD

Used Method	Performance Metrics (%)		
	DR	FPR	F-measure
PCA	60,23	7,75	71,89
Lp norm PCA(p=1)	74,03	6,15	84,91
Lp norm PCA(p=2)	71,82	5,82	82,72
L2-p norm PCA(p=1)	77,13	3,43	88,27
L2-p norm PCA(p=2)	75,08	3,46	85,84
Double L2-p norm PCA(p=1)	83,59	3,00	94,01
Double L2-p norm PCA(p=2)	81,14	3,26	91,54

The tables demonstrate how various dimensionality reduction techniques, including PCA, Lp-norm PCA, L2-p norm PCA, and double L2-p norm PCA, impact intrusion detection performance. These results highlight the importance of dimensionality reduction and feature extraction in building efficient and robust intrusion detection systems (IDS). Notably, double L2-p norm PCA appears to be a promising method for reducing dimensionality in network security. The analysis reveals that applying double L2-p norm PCA with p=1 consistently achieved the highest detection rate (DR), F-measure (a balanced metric for accuracy), and lowest false positive rate (FPR) across both KDD Cup'99 and NSL-KDD datasets. This suggests that double L2-p norm PCA is the preferred approach for enhancing IDS due to its ability to preserve crucial data features. It achieves this by simultaneously maximizing data variance and minimizing reconstruction error.

V. CONCLUSION

This paper investigates the application of Principal Component Analysis (PCA) for network intrusion detection. We propose several PCA-based models and evaluate their effectiveness on the KDD Cup 99 and NSL-KDD datasets. Our goal is to assess their ability to detect a wide range of attacks. The experiments highlight the importance of feature extraction techniques like PCA in improving intrusion detection. Among the models tested, Double L2,p-norm PCA emerged as the most with promising method among those tested. These observations offer valuable insights into the interplay between training size and feature extraction techniques in IDS performance. The research compared several dimensionality reduction techniques for their impact on noise reduction and overall effectiveness in cybersecurity intrusion detection. Analysis of the KDDCup99 and NSL-KDD datasets revealed a clear trend techniques achieved a wider range of detection rates. Principal Component Analysis (PCA) resulted in the lowest detection rate (70.26%) for KDD Cup'99, while Double L2-p norm PCA with p=1 achieved the highest (93.24%). Similar variations were observed for NSL-KDD (60.23% to 83.59%). Future work should explore the computational demands and scalability of these methods. This could involve testing them on a broader range of network scenarios and considering data imbalances to assess their real-world applicability [21] [25]. Striking a balance between detection accuracy and computational cost will be crucial for deploying these techniques in practical Intrusion Detection Systems (IDS).

Enhancing Whale Optimization Algorithm with Differential Evolution and Lévy Flight for Robot Path Planning

Rongrong TANG*, Xuebang TANG, Hongwang ZHAO
Guilin University of Aerospace Technology, Guilin, Guangxi 541004, China

Abstract—Path planning is a prominent and essential part of mobile robot navigation in robotics. It allows robots to determine the optimal path from a given beginning point to a desired end goal. Additionally, it enables robots to navigate around obstacles, recognize secure pathways, and select the optimal route to follow, considering multiple aspects. The Whale Optimization Algorithm (WOA) is a frequently adopted approach to planning mobile robot paths. However, conventional WOA suffers from drawbacks such as a sluggish convergence rate, inefficiency, and local optimization traps. This study presents a novel methodology integrating WOA with Lévy flight and Differential Evolution (DE) to plan robot paths. As WOA evolves, the Lévy flight promotes worldwide search capabilities. On the other hand, DE enhances WOA's ability to perform local searches and exploitation while also maintaining a variety of solutions to avoid getting stuck in local optima. The simulation results demonstrate that the proposed approach offers greater planning efficiency and enhanced route quality.

Keywords—Path planning; mobile robot; differential evolution; Whale Optimization Algorithm; lévy flight

I. INTRODUCTION

Recent technological advancements, such as Artificial Intelligence (AI) [1], Machine Learning (ML) [2], and advanced sensor technologies [3], have significantly expanded the capabilities and applications of mobile robots. Initially, mobile robots were restricted to manufacturing industries. Still, reconsidering this concept led to their applicability in diverse fields, such as entertainment, health, mining, education, military, and agriculture [4]. Navigating the mobile robots is the most important phase, which can be defined as finding the robot's position, the best path for traveling. Localization is the first critical phase in navigation, wherein the robot should understand its position on the map of the real world. The path planning phase is the second key phase in which the robot calculates the route on the map of the surrounding environment [5]. Using this path, the robot reaches the goal and follows a strategic path. As a result, a well-designed map is essential to a successful navigation system, as it will enable the robot to reach its goal with the least amount of energy and time [6].

During the navigation task, robots use various cognitive devices to interpret their surroundings, orient themselves, regulate their actions, recognize obstacles, and avoid collisions using navigation strategies [7]. By acknowledging and sidestepping obstacles, navigation systems help an agent produce an accurate path from the start to the goal [8]. The

selection of appropriate navigation technology for path planning is critical for robotic systems in simple and complex environments. Mobile robot navigation has been extensively studied in the past decade [9]. The navigation of mobile robots falls into three categories: personal, local, and global [10]. Global navigation is locating objects relative to a reference axis and progressing towards a specific goal [11]. Local navigation entails recognizing the changing conditions of the environment while identifying the spatial connections among various objects [12]. Personal navigation necessitates coordinating and adjusting several environmental factors that affect each other based on their respective positions [13]. Fig. 1 illustrates the fundamental operations of the robot.

The problem of path planning is classified as NP-hard due to its complex structure [14]. Heuristic and evolutionary algorithms are commonly employed to discover the best solution to this issue, particularly in extensive and complicated settings. One primary constraint in previous research is that many studies represent the context with discrete grids to determine the most effective grid configuration for determining the optimum path [15]. The primary limitation of this approach is the predetermined grid positions, which restrict path design flexibility. Furthermore, the A* algorithm can be used to identify optimum paths within arbitrary grids. Both the Dijkstra and A* algorithms are highly efficient because of their deterministic properties, which distinguishes them from evolutionary algorithms since they are not affected by the initial conditions. They exhibit significant time efficiency, especially compared to various evolutionary algorithms in two-dimensional path planning [16].

AI, ML, and Neural Networks (NNs) play pivotal roles in revolutionizing robot path planning. AI algorithms enable robots to navigate complex environments autonomously by leveraging advanced decision-making processes [17, 18]. ML techniques, particularly reinforcement learning, empower robots to learn from their experiences and optimize path planning strategies over time [19-21]. NNs, inspired by the human brain's structure, excel at pattern recognition and can efficiently process vast amounts of sensor data to make real-time navigation decisions [22-24]. Together, these technologies enhance the adaptability, efficiency, and reliability of robot path planning systems. The integration of these cutting-edge technologies not only addresses the challenges of traditional path planning methods but also paves the way for the next generation of intelligent robotic systems capable of seamlessly navigating diverse and challenging terrains [25, 26].

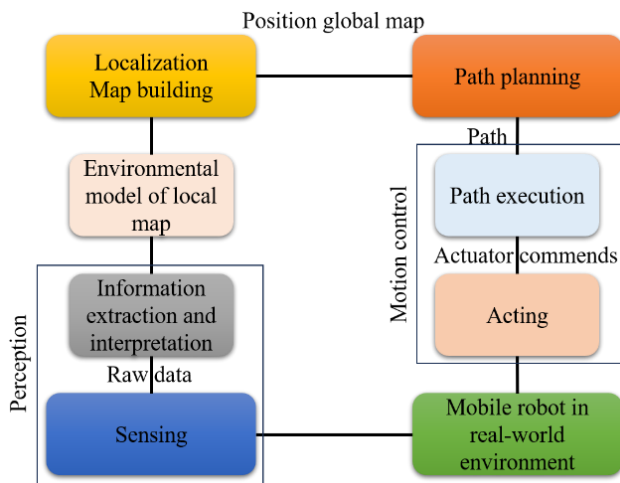

Fig. 1. Fundamental operations of mobile robot navigation.

The use and improvement of different meta-heuristic and hybrid algorithms for robot path planning is an emerging topic. The Whale Optimization Algorithm (WOA) is a well-known algorithm derived from whale hunting patterns [27]. The WOA uses two search methods to improve exploration and exploitability: shrinking the surrounding area and spiral updating the location to refine its search. WOA shows great promise by surpassing the performance of other established optimization techniques. Additionally, WOA features self-adjusting capabilities for some parameters as it goes through its iterations.

Like other metaheuristic algorithms, WOA has weaknesses, including premature convergence and vulnerability to becoming stuck in local optima. Overcoming these constraints constitutes a typical challenge to the advancements of metaheuristic searching. In the previous literature, many attempts have been under consideration to deal with these constraints, including using mathematical distributions using new evolutionary processes or combining different swarm intelligence techniques. This paper proposes an optimized iteration method of WOA for robot path planning. The enhanced method, named WOA-DELFL, combines the techniques of differential evolution and Lévy flight. In WOA-DELFL, Lévy flight is employed in the method exploring process to improve the optimization capability of global optimization. The system employs two distinct foraging approaches to optimize local conditions and incorporates Differential Evolution (DE) to enhance exploration of both local and global search areas during the exploitation phase.

The Lévy flight refers to a random walk distinguished by probability distributions with a high tail. It has been extensively utilized in several areas, including analyzing flying patterns in insects, feeding patterns in animals, and predicting human travel dispersion. The Lévy flight has been included in swarm intelligence approaches to search and optimize solutions. The addition of the Lévy flight improved both the exploration and exploitation of solutions [28]. Storn and Price developed Differential Evolution (DE) in 1995 to solve real-number optimization issues [29]. Over time, it has transformed into a versatile global optimization method deeply rooted in

population dynamics. DE has gained recognition for its efficiency, success, robustness, and global search capabilities. Nevertheless, it shows limited local search capability and slightly sluggish convergence [30]. To tackle these difficulties, recent research has concentrated on promoting variety among populations, expanding exploration and exploitation capacities through parameter management, and preventing early convergence.

The remaining part of the paper is organized as follows. Section II reviews the related work on the problem of path planning for mobile robots. Section III defines the problem statement. Section IV introduces the proposed approach, outlining the way WOA is used in combination with DE and LF for improving path planning. Section V presents the results of simulations conducted to confirm the efficiency of the presented method. Section VI draws the paper to a close and suggests areas for further research.

II. RELATED WORK

This section aims to offer a comprehensive review of the state of the art in mobile robot route planning by comparing noteworthy studies compiled from relevant literature. The purpose is to describe the diverse techniques applied to mobile robot navigation and route optimization to address its associated challenges. Table I presents the essential characteristics of each study, such as the employed methodology, fundamental procedures, main goals, assessment measures, and significant discoveries.

Ajeil, et al. [31] tackled the problem of path planning for self-moving mobile robots in stable and varying settings. Their objective was to find a trajectory that is devoid of collisions and fulfills the criteria of being the shortest distance and smooth. The proposed method effectively simulates a real-world scenario by taking into account the physical attributes of mobile robots. The problem is presented as the motion of a point in an empty space. There are three components to the algorithm. The first part creates an efficient route by utilizing a hybridized PSO-MFB method, which incorporates Modified Frequency Bat (MFB) and PSO algorithms to reduce path length and ensure smooth navigation. The second part identifies all incorrect values produced by the hybrid algorithm and employs a unique local search method to transform points into valid results. The third component is equipped with obstacle sensors and collision avoidance, triggering as the robot detects obstructions within its sensor range, keeping it from colliding. The numerical results indicate that the proposed method generates an optimal and feasible path in complex and dynamic scenarios, surpassing the limitations of traditional grid-based approaches.

Das and Jena [33] presented a novel method for calculating the best collision-free paths for individual robots in simple and intricate surroundings. They resolved the problem by using an improved version of the PSO algorithm combined with evolutionary operators (EOPs). The improvement of the PSO algorithm included incorporating the concept of governance in human society and two evolutionary multi-crossover operators from the genetic algorithm and the bee colony operator to boost the intensification capability of the PSO algorithm. The technique was created to calculate the deadlock-free sequence coordinates of each robot using their current coordinates. The

goal was to decrease the distance traveled by each robot by finding a middle ground between intensity and diversity. The study results verified that PSO-EOPs exhibited superior

performance compared to PSO and DE in terms of efficiency in arrival time, secure route formation, and energy consumption during travel.

TABLE I. OVERVIEW OF ROBOT PATH PLANNING APPROACHES

Reference	Approach	Primary techniques	Main objectives
[31]	Path planning for mobile robots	Hybridized PSO-MFB method and obstacle sensors	Collision-free, lowest distance, and smooth paths
[32]	Obstacle avoidance for multi-robot systems	Covariance matrix adaptation evolution and proximal policy optimization	Avoid obstacles
[33]	Collision-free paths for individual robots	Improved PSO algorithm and evolutionary operators	Arrival time, secure route construction, and energy usage
[34]	Mobile robot route planning	Multi-goal Genetic Algorithm (MOGA)	Safety, distance, smoothness, traveling time, and collision-free path
[35]	Mayfly optimization algorithm for robot route planning	Improved mayfly optimization algorithm based on q-learning	Global search capabilities and avoidance of local optima
[36]	Path planning for multiple robots	Enhanced artificial bee colony algorithm and ABCL method	Optimal collision-free courses for multiple robots

Suresh, et al. [34] proposed the Mobile Robot route Search powered by a Multi-goal Genetic Algorithm (MRPS-MOGA), a new method that uses a genetic algorithm with various goal functions to solve mobile robot route planning issues. The primary purpose of MRPS-MOGA is to determine the most efficient route by taking into account five specific criteria: safety, distance, smoothness, trip time, and avoidance of collisions. The multi-objective genetic algorithm (MOGA) is used to choose the best route among several possible options. The population is created with randomly generated routes, and fitness values are assessed using different objective functions. The fitness criteria decide whether routes are kept for involvement in the following generation. The MRPS-MOGA approach utilizes genetic algorithm components such as tournament selection, ring crossover, and adaptive bit string mutation to find the best path. A mutation operator is randomly applied to the sequence to introduce variation in the population. An evaluation of the individual fitness criteria is conducted to ascertain the optimal course of action for the population. The MRPS-MOGA algorithm was evaluated in multiple scenarios, proving its superiority in choosing the most efficient route while minimizing time complexity. The experimental research has shown that MRPS-MOGA is a highly effective method for designing paths for mobile robots. It offers enhanced safety, reduced energy usage, and faster transit times in comparison to existing techniques.

Zou, et al. [35] have discussed issues in the fundamental Mayfly Optimization Algorithm (MOA) for robot route planning, such as sluggish convergence, low precision, instability, and applicability limited to static situations. A fusion technique was suggested that merges an enhanced Mayfly Optimization technique with the Dynamic Window Approach. An Improved Mayfly Optimization Algorithm based on Q-learning (IMOA-QL) is presented for global robot path planning. The new algorithm's primary function is Q-learning, which adjusts parameters dynamically to boost global search capabilities and prevent becoming stuck in local optima. Global path nodes are recovered as sub-target points, and the Dynamic Window Approach is used to plan local paths to increase real-time avoidance capabilities. IMOA-QL's efficacy is confirmed by 20 random simulation trials in a 100×100 static map scenario, where it is compared with basic MOA and MOA-

LAIW. IMOA-QL decreases the average path length by 4.4% and 2.1% compared to MOA and MOA-LAIW in simple settings and by 6.5% and 3.2% in complex environments, as shown by the results. In 20 studies, the average variance of IMOA-QL decreased by 74.1% and 57.6% in simple contexts and by 51.2% and 38.6% in complex environments compared to MOA and MOA-LAIW.

Wen, et al. [32] developed a flexible optimization method based on covariance matrix adaptation evolution, derived from the traditional proximal policy optimization, to develop an effective obstacle avoidance strategy for autonomous navigation of multi-robot systems in complicated situations with static and dynamic obstacles. The test outcomes indicated that the proposed method was effective for avoiding obstacles and achieving the goal location. Meta-learning was combined with multi-robot architectures to enhance their flexibility. The proposed method was utilized in the training of robots to acquire a multi-task policy.

Cui, et al. [36] explored path planning for multiple robots in an ongoing familiar environment, introducing an innovative method for local path planning. They created a new way to implement metaheuristic algorithms to design optimal collision-free courses for multiple robots and enhance the Artificial Bee Colony (ABC) algorithm. Three enhancements have been included in the ABC algorithm in this scenario. The search equations of the deployed bee and scout bee phases were improved by including the global best individual to improve control over the search direction. The learning mechanism of the TLBO algorithm was introduced into the spectator bee phase to enhance exploitability. The ABCL method, based on learning, was utilized to calculate the next locations of all robots by considering their present coordinates, path length, safety, and planning efficiency. ABCL outperformed seven effective metaheuristic algorithms in tackling diverse optimization problems, as demonstrated in experimental investigations on benchmark functions. Simulation experiments for multi-robot route planning demonstrated that ABCL surpasses its competitors in producing optimal collision-free pathways and runtime. ABCL enhanced two features by an average of 2.1% and 12.6% compared to the original ABC across all tasks. Thus, the suggested implementation technique demonstrates that

ABCL is an efficient option for path planning for numerous robots.

III. PROBLEM STATEMENT

The current landscape of robotics demands efficient path planning in large environments, taking into account computational limitations. Memory constraints may render finding an optimal path impractical, particularly when dealing with expansive navigation spaces. This challenge intensifies when multiple criteria, such as path length, distance to obstacles, and search complexity, must be considered for global path efficiency in cluttered environments. Different regions of large, cluttered maps may elicit varying responses from fixed path-planning algorithms, making it difficult to achieve universal efficiency across all conditions.

Path planning is the process of determining a limited number of possible motions within an unobstructed area of a design, usually from predetermined starting to end points. While multiple paths may exist, path-planning algorithms aim to find the optimal path based on predefined objective functions, such as minimizing path length, maximizing smoothness, or ensuring safety.

This study introduces a novel path-planning method aimed at identifying the most efficient routes in various intricate settings between specified source and target points. The method assesses path quality by considering factors such as route length, smoothness, and safety. The study examines 2D settings with stationary barriers of various shapes, assuming no relationship between obstacles and free space. Robots are considered single entities, taking into account their dimensions by including a confidence radius near objects. Multi-robot path planning scenarios assume that each robot moves at a constant speed.

The technique creates a map of the environment, making it easier to find possible segmented linear pathways between the starting and target locations in a gridded area. It ensures the identification of at least one viable route if it is present. Subsequently, the algorithm identifies the appropriate positions of Path Bases (PBs) selected grids used to determine the paths. These PBs can then be connected using cubic spline or piecewise linear methods to construct optimal paths. Fig. 2 shows an outline of the suggested technique for optimal path planning in an ongoing area.

Path planning in ongoing areas with variable impediments might be computationally difficult due to many issues. Researchers simplify the challenge by transforming it into identifying a finite sequence of hops in a gridded context between origin and target points. However, these approaches are restricted by the degree of separation.

The algorithm developed in this study uses multiple methodologies to model the situation. The surrounding area is divided into grid-like squares. Fig. 3 demonstrates a 1010 field separated into squares of one unit length. 100 points, represented as green circles, are evenly spread over the region. The robot's trajectory is determined by choosing a suitable group of nodes inside the gridded setting. The method assigns potential values to all points, and possible pathways connecting the source and target points are found using pre-calculated potentials.

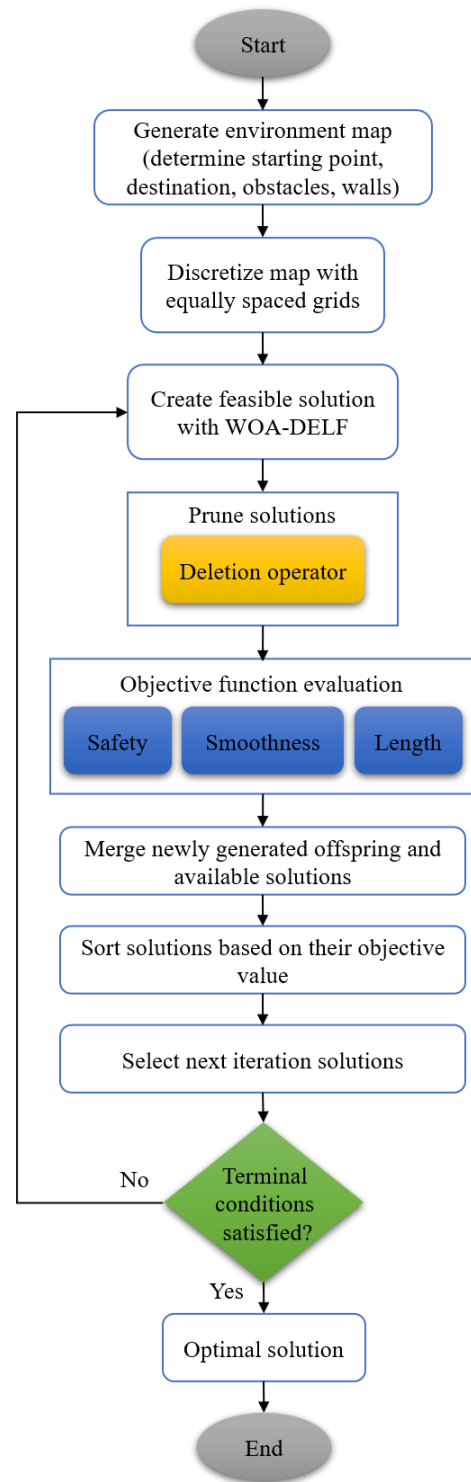

Fig. 2. Suggested technique for optimal path planning in continuous environments.

Fig. 3 depicts the chosen PBs connected by a blue dashed line, representing the potential route from the beginning point to the destination. The coordinates of the potential starting points associated with each conceivable initial route are encoded as solutions. Fig. 4 illustrates the solution layout related to the beginning route seen in Fig. 3.

Fig. 3. Path planning process with potential bases.

1	3	5	9	10	7
1	2	9	9	7	4

Fig. 4. Solution layout for identified route.

The suggested approach assigns the node representing the target location the highest potential. The potential lowers steadily as one travels to nearby nodes. The neighboring points for each point reside at a distance $d\sqrt{2}$ from the point, where d refers to the number of discretizations. This technique creates a diagram displaying the possibilities of the area. This potential map may identify all possible routes between the starting point and the goal. Fig. 5 shows the potential map for the setting shown in Fig. 3. The potential map of the proposed approach is constructed using three lists of nodes: CLOSED, TEMP, and OPEN.

- CLOSED list: It is composed of potential nodes and their adjacent nodes.
- TEMP list: This list includes points given a potential, with the condition that their neighboring points are not assigned potentials.
- OPEN list: Points that have not been assigned a potential are included in this list.

The algorithm initializes by inserting all nodes into the OPEN list. The process then involves the following steps:

- Step 1: The target point is eliminated from the OPEN list, assigned the highest potential (e_0), and inserted into the TEMP list.
- Step 2: Obstacle points are eliminated from the OPEN list, assigned a potential of $-e_0$, and added to the CLOSED list.
- Step 3: Assuming the point of departure, nodes adjacent to it are assigned a potential of e_1 ($e_1 = e_0 - a$, where 'a' is the decrement step), inserted into the TEMP list, and excluded from the OPEN list. The target node is deleted from the TEMP list and added to the CLOSED list.

- Step 4: In each subsequent round (i th iteration), points in the TEMP list have their neighboring points given potential values of e_i ($e_i = e_{i-1} - a$), are moved to the CLOSED list, and points accepting potential values move from the OPEN list to the TEMP list.

The repetition of these steps results in a possible representation of the area. Feasible initial paths are then determined by selecting adjacent nodes with the highest potential starting from the start location. This process gradually increases the route's potential until it reaches the final point, which has the largest potential. The algorithm guarantees the finding of possible initial paths, and in particular instances, paths may be divided into sub-paths when two nearby points of a single point are equal in potential. Fig. 5 illustrates the potential map of the environment, and Fig. 6 illustrates three possible routes resulting from the suggested algorithm.

Fig. 5. Potential map construction.

Fig. 6. Possible routes generated by the algorithm.

IV. PROPOSED TECHNIQUE

The study combines WOA with Lévy flight and DE to optimize PB position within a continuously changing context. The algorithm's evolution is an iterative process, and the

optimization continues until the algorithm reaches its final state. In this context, the final state is regarded as arriving at a fixed number of iterations. After the specified number of iterations is finished, the optimization process terminates and the final solution is found. The predetermined number of iterations acts as a termination condition for the algorithm's execution.

The WOA draws inspiration from the foraging behavior of whales, particularly the hunting strategies observed in humpback whales. This algorithm emulates three distinct foraging behaviors, mirroring the actions of humpback whales: encircling prey, bubble net assaulting, and randomly hunting prey. These behaviors are represented by mathematical models in order to accurately reflect the fundamental aspects of whale hunting strategies. Humpback whales have the capacity to detect prey that is close by and position themselves strategically in the group to take advantage of the recognized prey location, which is regarded the most advantageous position. While closing in on the prey, continuous adjustments are made to their positions. In the WOA context, the algorithm perceives the resulting viable solutions as 'whales' and designates the present most optimal solution or local optimum for encircling prey. The algorithm employs a function to represent prey encirclement, as expressed in Eq. (1).

$$\vec{X}(t+1) = \vec{X}_{best}(t) - \vec{A} \cdot |\vec{C} \cdot \vec{X}_{best}(t) - \vec{X}(t)| \quad (1)$$

In Eq. (1), X signifies the chosen search whale, \cdot denotes element-wise multiplication, $\vec{X}_{best}(t)$ refers to the best position of a whale in the current iteration t , and $|\vec{C} \cdot \vec{X}_{best}(t) - \vec{X}(t)|$ indicates the distance between $\vec{C} \cdot \vec{X}_{best}(t)$ and $\vec{X}(t)$. The coefficient vectors \vec{A} and \vec{C} have varying characteristics, and their updates are governed by Eq. (2) and Eq. (3), respectively.

$$\vec{A} = 2 \times \vec{a} \times \vec{r} - \vec{a} \quad (2)$$

$$\vec{C} = 2 \times \vec{r} \quad (3)$$

The vector \vec{a} gradually decreases from 2 to 0 following the formula $\max(2 - 2t/t_{max}, 0)$, where t_{max} is the maximum iteration count. \vec{r} represents a stochastic vector with values between 0 and 1, restricting the values of \vec{A} to fall within the range of $[-\vec{a}, \vec{a}]$. It is crucial to note that the random vectors \vec{A} and \vec{C} are essential in directing the whale to adjust its location in order to reach the ideal solution. Humpback whales utilize bubble nets to herd and trap animals near the water's surface as part of their normal habit. The mathematical model of the spiral bubble net assault method is expressed by Eq. (4).

$$\vec{X}(t+1) = |\vec{X}_{best}(t) - \vec{X}(t)| \cdot e^{bl} \cos(2\pi l) + \vec{X}_{best}(t) \quad (4)$$

The parameter b defines the logarithmic spiral form, with l being a randomly chosen value between 0 and 1. In the natural behavior of humpback whales, exploration of new target prey involves randomly selecting a whale position and swimming towards it. The formula employed in the WOA is designed to simulate this process for global search.

$$\vec{X}(t+1) = \vec{X}_{rand}(t) - \vec{A} \cdot |\vec{C} \cdot \vec{X}_{rand}(t) - \vec{X}(t)| \quad (5)$$

Operator selection is controlled by a random switch control parameter, p , ranging from [0, 1]. The vector \vec{A} plays a crucial role in determining the hunting method of the whale. If we assume a 50% probability for the whale to choose the bubble-net attacking method during the position update for solution exploitation, the likelihood of selecting the operator when hunting or encircling prey is additionally influenced by the adaptive variation of the vector \vec{A} . Eq. (6) expresses a formula for selecting operators.

During the exploration stage of the WOA, individuals update their positions by sharing information with another individual in a limited solution space. The exploration phase of WOA incorporates Lévy flight to improve global search capabilities and speed up convergence. Lévy flight involves sporadic huge steps or extended leaps, which widen the exploration area. The position of humpback whales is updated using the step of Lévy flight, as described by Eq. (7).

$$\vec{X}(t+1) = \begin{cases} \vec{X}_{best}(t) = \vec{A} \cdot \left| \vec{C} \cdot \vec{X}_{best}(t) - \vec{X}(t), \text{ if } p < 0.5 \text{ and } |\vec{A}| < 1 \right| \\ \vec{X}(t+1) = \vec{X}_{best}(t) - \vec{A} \cdot |\vec{C} \cdot \vec{X}_{rand}(t) - \vec{X}(t)|, \text{ if } p < 0.5 \text{ and } |\vec{A}| \geq 1 \\ \vec{X}_{best}(t) = \vec{X}(t) \cdot e^{bl} \cos(2\pi l) + \vec{X}_{best}(t), \text{ if } p \geq 0.5 \end{cases} \quad (6)$$

$$\vec{X}(t+1) = \overrightarrow{X_{rand}}(t) + a \cdot \text{sign}[\text{rand} - 1/2] \oplus \text{Levy}(s) \quad (7)$$

The $\text{sign}[\text{rand} - 1/2]$ term takes values of -1, 0, or 1, the \oplus symbol represents entry-wise multiplication, and a denotes the step size determined by Eq. (8).

$$a = a_0 [\overrightarrow{X_{rand}}(t) - \vec{X}(t)] \quad (8)$$

Here, a_0 is set to 0.01, and $\overrightarrow{X_{rand}}$ measures the position vector of a whale chosen at random. Lévy flight follows a Lévy distribution for the step length, given by:

$$\text{Levy}(s) \sim |s|^{-1-\beta}, \quad 0 < \beta \leq 2 \quad (9)$$

In this expression, β is set to 1.5, and μ and ν have a normal distribution. The complete calculation of s involves Mantega's algorithm.

$$s = \frac{\mu}{|\nu|^{1/\beta}}, \quad \mu \sim N(0, \sigma_\mu^2), \quad \nu \sim N(0, \sigma_\nu^2) \quad (10)$$

$$\sigma_\mu = \left\{ \frac{\Gamma(1+\beta) \cdot \sin(\pi\beta/2)}{\beta \cdot \Gamma\left[\frac{1+\beta}{2}\right] \cdot 2^{(\beta-1)/2}} \right\}^{1/\beta}, \quad \sigma_\nu = 1 \quad (11)$$

Finally, Eq. (6) can be rewritten as:

$$\begin{aligned} \vec{X}(t+1) = & \overline{X_{rand}}(t) \\ & + \text{sign} \left[\text{rand} \right. \\ & \left. - \frac{1}{2} \right] \cdot a_0 \frac{\mu}{|v|^{1/\beta}} \cdot \overline{X_{rand}}(t) \\ & - \vec{X}(t) \end{aligned} \quad (12)$$

In the final phase of the WOA, individual positions are updated through a greedy selection operation limited to the best solution. This limitation makes it vulnerable to getting trapped in local optima. To solve this problem, DE is incorporated into WOA. A set of external archives is created consisting of individual populations and historically optimal populations. In each iteration, new solutions are modified with DE search strategies in accordance with the external archive set. This integration improves the exchange of information between individual solutions and improves WOA's local search and exploitation capabilities.

DE involves an external archive set, NP D-dimensional individuals represented as $x_{i,G} = \{x_{i,G}^1, \dots, x_{i,G}^D\}$, where $i = 1, \dots, NP$, and G is the number of generations. Each dimension of the individual is constrained by $x_{min} = \{x_{min}^1, \dots, x_{min}^D\}$ and $x_{max} = \{x_{max}^1, \dots, x_{max}^D\}$. The initial population is usually randomly generated in the feasible region.

The mutation operator generates mutant vectors $v_{i,G}$, where DE/rand/1 is a commonly used operator. The generated $v_{i,G}$ can be expressed as

$$v_{i,G} = x_{r1,G} + F * (x_{r2,G} - x_{r3,G}), r1 \neq r2 \neq r3 \neq i \quad (13)$$

Here, $x_{r1,G}$, $x_{r2,G}$, and $x_{r3,G}$ are chosen from the current population, and F is the mutation control parameter that scales the difference vector. Different mutation strategies can be employed, with DE/rand/1 being one of the variants.

$$\begin{aligned} \text{DE/rand/1: } v_{i,G} &= X_{r1,G} + F(X_{r2,G} - X_{r3,G}) \\ \text{DE/best/1: } v_{i,G} &= X_{best,G} + F(X_{r2,G} - X_{r3,G}) \\ \text{DE/current/1: } v_{i,G} &= X_{i,G} + F(X_{r2,G} - X_{r3,G}) \\ \text{DE/current-to-best/1: } v_{i,G} &= X_{i,G} + F(X_{best,G} - \\ & X_{i,G}) + F(X_{r1,G} - X_{r2,G}) \\ \text{DE/rand/2: } v_{i,G} &= X_{r1,G} + F(X_{r2,G} - X_{r3,G}) + \\ & F(X_{r4,G} - X_{r5,G}) \\ \text{DE/best/2: } v_{i,G} &= X_{best,G} + F(X_{r1,G} - X_{r2,G}) + \\ & F(X_{r3,G} - X_{r4,G}) \\ \text{DE/current-to-rand/1: } v_{i,G} &= X_{i,G} + F(X_{r1,G} - \\ & X_{i,G}) + F(X_{r2,G} - X_{r3,G}) \end{aligned} \quad (14)$$

$$\text{DE/current-to-pbest/1: } v_{i,G} = X_{i,G} + F(X_{best,G}^p - X_{i,G}) + F(X_{r1,G} - X_{r2,G})$$

$X_{best,G}^p$ refers to the individual with the optimal fitness function value at the G^{th} generation. The binomial crossover operator, commonly employed, can be chosen to generate the trail vector $u_{i,G}$ between $x_{i,G}$ and $v_{i,G}$, as expressed by the formula below (see Eq. (15)). rand_j is a randomly generated number uniformly distributed within the range $[0, 1]$. $CR_i \in (0, 1)$ serves as the crossover control parameter, and n_j is a randomly generated integer within the range $[1, D]$.

$$u_{i,G}^j = \begin{cases} v_{i,G}^j, & \text{if } \text{rand}_j \leq CR_i \text{ or } j = n_j \\ x_{i,G}^j, & \text{otherwise} \end{cases} \quad (15)$$

Subsequently, a superior individual between the trail vector $u_{i,G}$ and target vector $x_{i,G}$ will be chosen. The superior individual will persist into the next generation based on a comparison of the fitness values, employing greedy selection as outlined in Eq. (16). The fitness function values of the target vector $x_{i,G}$ and trail vector $u_{i,G}$ are denoted by $f(x_{i,G})$ and $f(u_{i,G})$, respectively.

$$X_{i,G+1} = \begin{cases} u_{i,G+1}, & \text{if } f(u_{i,G}) \leq f(x_{i,G}) \\ X_{i,G}, & \text{otherwise} \end{cases} \quad (16)$$

The "DE/rand/1" method tends to enhance exploration but with sluggish convergence speeds. The "DE/best/1" method typically exhibits rapid convergence but lacks exploitation capabilities and is prone to getting trapped near local optimum. "DE/current-to-rand/1" offers more diverse populations and global search capabilities, but comes with certain drawbacks like perturbation and blindness. Conversely, "DE/current-to-pbest/1" excels in search stability and exploitation ability.

In the DE algorithm, we opt for the "DE/current-to-pbest/1", an archive-based hybrid memory evolutionary operator. Commencing the search for the existing individual and employing multiple local optimizations to guide it results in better individual diversity, avoiding premature convergence to local optima. WOA deep exploitation becomes more stable as a result. This study fine-tunes variables F and CR , incorporating "DE/current-to-pbest/1" to aid WOA in navigating local areas, capturing prey, and improving overall stability. The WOA-DELFL integrates DE and Lévy flight into the fundamental WOA.

V. EXPERIMENTAL RESULTS

The test function is an important indicator in measuring the performance of the algorithm to find the best solution. The smaller the value is under the same conditions, the better the searching and developing ability. There are eight test functions used in the experiment to verify the efficiency of the algorithm. The functions can be categorized into two distinct groups: unimodal and multi-modal, as illustrated in Table II.

The unimodal functions (f1-f5) are used to investigate algorithm exploitation capabilities, since they have only a single global minimum without any local minimum. On the other hand, multi-modal functions (f6-f8) are employed to analyze the

ability of the algorithm to search for different local minima and to avoid all local minima.

TABLE II. NUMERICAL FUNCTIONS

Functions	Ranges	F _{min}
$f_1(x) = \sum_{i=1}^{n-1} [100(x_{i+1} - x_i^2)^2 + (x_i - 1)^2]$	[-30,30]	0
$f_2(x) = \max\{ x_i , 1 \leq i \leq n\}$	[-100,100]	0
$f_3(x) = \sum_{i=1}^n (\sum_{j=1}^i x_j)^2$	[-100,100]	0
$f_4(x) = \sum_{i=1}^n x_i + \prod_{i=1}^n x_i $	[-10,10]	0
$f_5(x) = \sum_{i=1}^n x_i^2$	[-100,100]	0
$f_6(x) = -20 \exp\left(-0.2 \sqrt{\frac{1}{n} \sum_{i=1}^n x_i^2}\right) - \exp\left(\frac{1}{n} \sum_{i=1}^n \cos(2\pi x_i)\right) + 20 + c$	[-32,32]	0
$f_7(x) = \sum_{i=1}^n [x_i^2 - 10 \cos(2\pi x_i) + 10]$	[-5.12,5.12]	0
$f_8(x) = \sum_{i=1}^n x_i \sin(\sqrt{ x_i })$	[-500,500]	0

In the comparison, WOA-DELFL is evaluated alongside four other algorithm types: WOA, ACO, genetic, and HHO algorithms. WOA maximizes the efficacy of a robot's trajectory by mimicking the social behavior of humpback whales. As it

keeps on improving the candidate solutions, WOA systematically explores the solution space. Ultimately, it improves the ease of robot mobility through specific types of terrains and increases path length. Inspired by the foraging behavior of ants, the ACO algorithm is well-suited for robot path planning. Artificial ants represent potential paths, depositing pheromones on explored routes. With accumulated time, the paths with more pheromones guide the robot to the efficient navigation of environment. In the field of robotics, Genetic Algorithms are used for robot path planning. Initially a set of potential paths is generated and refined step by step through crossover and mutation, thereby modelling the survival of the fittest. As the algorithm iterates, the robot adapts its trajectory to the immediate surroundings. HHO, inspired by harmony in music, is employed to improve the path of the robot by adjusting the variables within the solution space. The harmony seeking algorithm aims to maintain a harmony between exploration and exploitation enabling a robot to find out the paths efficiently without any obstacles.

This experiment ran 500 iterations with 30 search agents for 8 test functions, each with 30 dimensions. As depicted in Table III, for the unimodal test functions (F1-F5), the WOA-DELFL algorithm performs better than other algorithms, namely WOA and DELFL, which proves that the search space is well utilized. In multi-modal functions (F6-F8), the functions which are difficult to obtain because of multiple and local optima presence, the WOA-DELFL algorithm consistently outperforms other algorithms. As shown in Table III and Fig. 7, the proposed algorithm has significant advantages over all other alternatives. The results are the same when performing standard deviation tests.

VI. CONCLUSION

In this paper, we proposed an enhanced WOA by incorporating differential evolution and Lévy flight for robot path planning. Traditional WOA has a slow convergence, a low efficiency, and is easily trapped into local optima. Our improved WOA simultaneously has the ability to overcome these problems in classical WOA, which can effectively enhance the performance of WOA in robot path planning. Lévy Flight is used in the hybridization of WOA to maximize exploration throughout the evolutionary process, while DE is responsible for the exploitation that allows the algorithm to explore complex environments without being trapped in a local optimum. The simulation outcomes, performed over several unimodal and multi-modal benchmark test functions, revealed the effectiveness of the WOA-DEL algorithm compared to competing benchmarks, like the WOA, ACO, genetic, and HHO algorithms. WOA-DEL was also able to exploit the search space effectively on unimodal functions, as it delivered better planning efficiency and better route quality. In addition, WOA-DEL outperformed the other algorithms equally well on multimodal functions. This aspect further suggests that the exploration of WOA-DEL is desirable. The proposed algorithm's success across all tested scenarios and its favorable comparison against existing algorithms confirm its potential as an effective tool for robot path planning. The enhanced performance of the proposed algorithm in the experiments requires it to further optimize, test scalability, and deploy on real

world scenarios for confirming its effectiveness in practical robotic navigation.

A Capacitance-based System Design for Measurement of Crude Oil Moisture

ZhixueShi, Xudong Zhao*

Department of Computer Science and Technology, College of Computer and Control Engineering,
Northeast Forestry University, Harbin, China

Abstract—Challenges including difficulty in cleaning and low measurement accuracy widely exist in traditional methods for measuring moisture in crude oil. In order to solve these problems, a capacitance measurement device that combines PCAP01 and STM32 has been designed. PCAP01 is employed as the processing core of the sensor, which significantly enhances the measurement accuracy of capacitance-based methods. As to STM32, it plays a critical role in data acquisition, signal processing, and data transmission. Besides, the capacitance-based device contains two symmetric half-cylindrical electrode plates that are closely attached to the outer wall of the cylindrical glass vessel, where the crude oil sample to be tested is contained. This design prevents the direct contact between the liquid sample and the electrode plates, thus eliminating issues related to cleaning difficulties. Time-frequency domain expansion is presented to realize the fit between moisture and the capacitance. Experimental results indicate that the designed system delivers a high accuracy across the entire 0-100% range.

Keywords—Capacitance measurement; crude oil moisture; PCAP01; STM32; time-frequency domain

I. INTRODUCTION

Measurement of water content in crude oil is crucial to petroleum extraction and petrochemical industry [1]-[3]. It stands as a pivotal parameter in oilfield production and petroleum trade, exerting significant influence over the extraction, dehydration, storage, sales, and refining phases of crude oil. Inaccurate monitoring of crude oil moisture can affect many aspects, such as determination of water influx in oil wells, identification of oil-bearing formations, estimation of crude oil production, prediction of the lifespan of oil wells, and the operations of downstream enterprises. Several techniques can be employed to assess moisture in crude oil, encompassing well-established approaches like the classical distillation method [4, 5]. Although this method has high measurement accuracy, it is quite time-consuming. Besides, it is difficult to clean the device. Sometimes, it is of trouble to preserve the chemical agent used for water removal.

One study has determined the moisture content in crude oil by estimating the density of crude oil [6]. However, this complex method is difficult to operate. As a result, non-contact measurements are taken into account. It is known that electromagnetic waves can be absorbed by water in crude oil. Thus, ultrasound [7]-[9], microwave [10]-[14], near infrared ray [15], gamma ray [16], terahertz [17, 18], radio frequency [19]-[21], etc. are used to calculate the ratio of the water content in crude oil. Anyhow, these methods need an

independent calibration before each measurement. The corresponding devices also have poor portability. Instead of electromagnetic waves, an image processing technique has been utilized for visual measurement of water content in crude oil [22]. After electric dehydration, an image of oil-water stratification is obtained. Then, a grayscale accumulated value difference is made to obtain the coordinate values of the layered interface to calculate the ratio of water to crude oil. However, it's worth noting that the procedure of electric dehydration is time-consuming.

Correspondingly, contact measurement methods have appeared. Because of having different dielectric constants, a change of water content in crude oil may lead to a change in its capacitance value, which may convert to a variation of an oscillator's phase angle [23] or a change to the oscillation frequency of a non-contact frequency modulated oscillator's output [24]. Although the contact measurement methods have great accuracies, the indirect measurements of the capacitance value correspond to a poor range, which is limited by the oil-water ratio of the tested crude oil [25, 26].

To address the issues of electrode plate cleaning difficulty and low accuracy in the full-range measurement of the capacitive method, this paper proposes a non-contact capacitive measurement scheme for crude oil and develops a crude oil moisture content detection system. Two symmetric cylindrical electrode plates are designed as the sensing probes, which effectively prevents crude oil from corroding the electrode plates. The designed non-intrusive capacitance sensor also employs a PCAP01 chip, which can measure subtle changes in PF level, to obtain the capacitance value. Besides, a STM32 chip is selected as the data control unit. The symmetric cylindrical electrode plates, PCAP01, STM32 and their relevant circuit constitute a capacitance measurement device. In addition, time-frequency domain expansion is used in an upper machine. Together, they form a system for measurement of crude oil moisture. Experiments have been conducted to measure the water content in different crude oil samples. Corresponding results demonstrate the effectiveness of our method.

II. DESIGN METHODS

A. Sensor Probe Design

Actually, crude oil can be treated as a mixture of pure water and pure oil after removing gas. At room temperature, crude oil possesses a relative dielectric constant of 2.2; while, pure water exhibits a relative dielectric constant of 80. Therefore, different

*Corresponding Author.

relative dielectric constants corresponding to different capacitance values have different ratios of the water content in crude oil. In the measurement procedure, crude oil sample is introduced into a cylindrical glass vessel. The overall capacitance comprises the capacitances connected in series including the capacitance of the glass wall and the one of crude oil. The overall capacitance is expressed as follows,

$$C = \frac{C_g C_r}{C_g + C_r}, \quad (1)$$

Where C represents the total capacitance measured by the sensor. C_r and C_g denotes the capacitance value of the crude oil and the glass wall, respectively. Correspondingly, the dielectric constant of the glass wall, which is determined by the material properties of the glass, can be considered a constant.

A slotted cylindrical capacitor is designed to be the sensing probe for capacitance sensing, as shown in Fig. 1. Unlike traditional parallel-plate capacitors, the slotted cylindrical capacitor offers a more uniform electric field distribution, allowing for a more precise measurement of sample properties. Furthermore, due to its symmetrical design, the measurement results of the slotted cylindrical capacitor remain unaffected by the rotation direction of the tested sample, enhancing its practicality. In actual measurements, it is essential to securely attach the slotted cylindrical electrode plates to the glass vessel to eliminate any interference caused by air between the electrode plate and the vessel.

Fig. 1. The top view of the device's structure.

B. Measuring Principle

Correspondingly, the capacitance for the slotted cylindrical capacitor [27] can be expressed as follows,

$$C = \sum_{i=1}^n 2 * \epsilon_0 * \epsilon_r * A * \left[\frac{1}{d + (i - 1)\Delta d} \right] + \frac{\epsilon_0 * \epsilon_r * A}{2R}, \quad (2)$$

where C denotes the capacitance value measured by the slotted cylindrical capacitor. ϵ_0 represents the absolute permittivity with $\epsilon_0 = 8.85 \times 10^{-12}$ (F/m). ϵ_r represents the relative permittivity of the water-containing crude oil. A is the unit surface area of the slotted cylindrical capacitor. R denotes the radius of the slotted cylindrical plates. n is the cutting number for numerical analysis. d is the minimum gap distance. Δd is an increment distance.

The effective permittivity of the crude oil, which mainly depends on volume percentage of two phases in container, is given by [23]

$$\epsilon_r = \alpha * \epsilon_w + (1 - \alpha) * \epsilon_i, \quad (3)$$

where ϵ_w , ϵ_i and ϵ_r represent the relative permittivity of pure water, pure oil and the crude oil sample, respectively. α denotes the ratio of the water content in the crude oil sample.

It can be seen in Eq. (2) that C and ϵ_r show a linear correlation. Besides, there is a linear relationship between ϵ_r and α , as expressed in Eq. (3). That is, the capacitance for the slotted cylindrical capacitor is in direct proportion to the ratio of the water content in crude oil.

C. System Hardware Design

To achieve precise measurement of water content in crude oil, a capacitance measurement device is designed. In addition to the presented symmetric cylindrical electrode plates which are regarded as the sensor probe, the proposed device also includes PCAP01, STM32 and their relevant circuit. The device primarily comprises the sensor probe, a sensor module, a processing module, a communication module, a power supply module, and a personal computer, as depicted in Fig. 2.

In Fig. 2, the crude oil sample is loaded into the glassware of the designed sensing probe (see Fig. 1.). The sensor module uses the PACP01-AD as the core chip to collect the capacitance values from the probe. The corresponding circuit configuration is shown in Fig. 3. The circuit, which is capable of simultaneously measuring 4 different capacitance values, adopts the drift mode for capacitance measurement with 8 interfaces PC0-PC7. As the PACP01-AD chip uses the charge-discharge time for capacitance measurement, it is necessary to connect reference capacitances to PC0 and PC1 according to the actual range. As a result, 47pf high-precision capacitors are soldered to PC0 and PC1 as the reference capacitors. The sensor module communicates with the processing module using SPI, mainly due to the faster communication speed compared to IIC. Additionally, an LED light is added to PG3 to indicate the working status of the sensor. It is worth noting that although the official manual states that when using SPI communication, the IIC_EN pin should be grounded or left floating, it has been found in practical applications that leaving it floating may occasionally lead to SPI communication failures. Therefore, it is important to ground the IIC_EN pin to ensure normal SPI communication.

Fig. 2. System hardware diagram.

Fig. 3. PACP01 circuit diagram.

Fig. 4. STM32F103C8T6 circuit diagram.

As illustrated in Fig. 4, the circuit configuration which is associated with the processing module is based on the STM32F103C8T6 minimum system, with additional LED lights on PB5 and PB7 pins to indicate the system's operation status. The PA4, PA5, PA6, and PA7 pins are also brought out for communication with the sensor module, while PA9 and

PA10 pins are used for RXD and TXD communication with the transmission module. The PB10 pin is used as the enable pin for the transmission chip.

The circuit configuration corresponding to the transmission module is shown in Fig. 5. MAX485CSA is used as the

communication chip, powered by 5V voltage, and filtered by a 0.1uF grounded capacitor in parallel. Pins 6 and 7 are used to receive data from STM32, and pins 2 and 3 are used to control data upload.

The circuit configuration corresponding to the power supply module is shown in Fig. 6. Dual batteries are adopted to provide power to the transmission module. With the input voltage ranging from 7V to 35V, a Lm7805 regulator is used to output 5V voltage for B1. Through AMS1117-3V3 with filter capacitors, 3.3V voltage is outputted, providing power to the sensor module and processing module. When there is a problem with power supply B1, battery B2 which can serve as a backup battery is switched on to maintain normal operation of all the other modules excluding the transmission module for a short period of time. Additionally, an LED light is used as a power indicator.

As to the PC module which is considered to be an upper computer, a portable computer equipped with an inter i5-11320H CPU and operating system window11 is used.

In terms of measuring the water content in crude oil, the traditional distillation method typically requires 3 hours, the Karl Fischer method generally takes 1 hour, while this device can obtain highly accurate results in just a few seconds.

Fig. 5. MAX485 CSA circuit diagram.

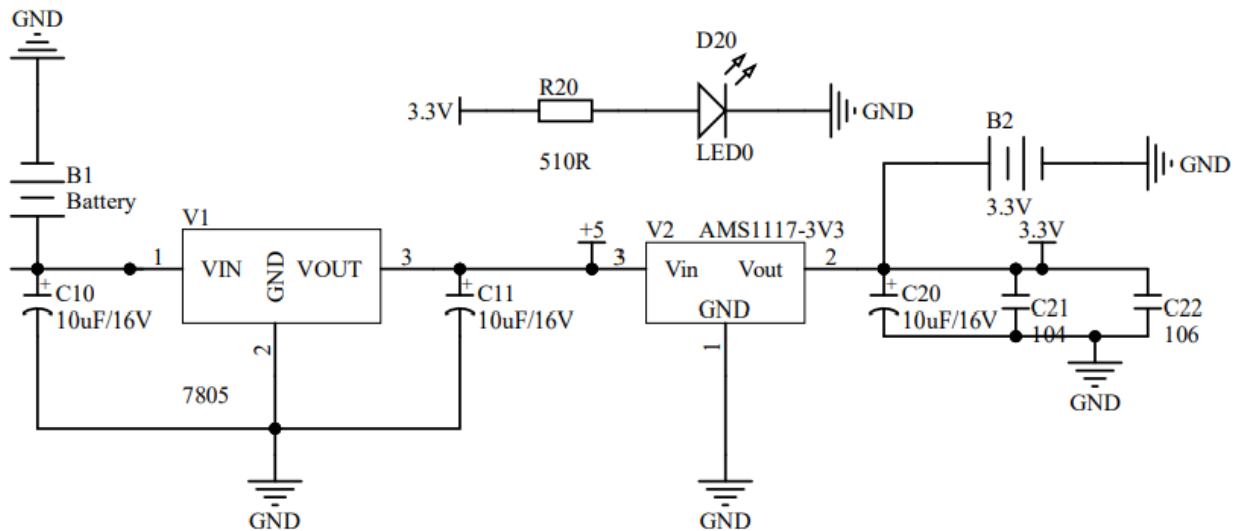

Fig. 6. Power supply circuit diagram.

Fig. 7. System software diagram.

D. System Software Design

The software system is designed, as illustrated in Fig. 7. The entire process is primarily divided into four parts: (1) system initialization, (2) data sampling, (3) data transmission, and (4) data processing. The following content provides a detailed description of the four parts.

1) *System initialization.* Upon power-up, the system begins the initialization process. Initially, the STM32 chip attempts to establish SPI communication with the PCAP01 chip. The method involves sending a byte through SPI to a specific address on the PCAP01 chip, and then reading from that address. If the bytes sent and read match, the communication is deemed successful. Otherwise, if the communication fails, corresponding LED lights on the development board will indicate the SPI communication failure. Once the STM32 successfully establishes communication with the PCAP01, it will transmit the official 960-byte boot code to the PCAP01, followed by 11 pre-configured register codes. It is important to note that the 11 registers will utilize addresses ranging from zero to nine (also including 20).

2) *Data sampling.* Once the system initialization is complete, the sensor module where PCAP01 is located begins to capture capacitance values from the sensing probe every 400ns, transmitting the capacitance values which are expressed as “C_value” to the STM32 via SPI communication. Then, the STM32 sends the received capacitance values into a FIFO queue with a length of 10. When the queue is full, the values in the queue are averaged to reduce errors, then the arithmetic mean is transmitted to the MAX485. Meanwhile, an enable signal is provided to the MAX485.

3) *Data transmission.* Upon receiving data and enabling signal, MAX485 transmits data to PC through RS485.

4) *Data processing.* Upon receiving the capacitance data, the upper computer temporarily stores the reception time, inputs the data into the time-domain frequency fitting curve, and fits out the moisture content represented by the capacitance. The fitting principle will be detailed in the following part. Subsequently, the reception time, the capacitance data, and the calculated moisture content which is expressed as “wo” are jointly stored in the database for future reference.

E. Modeling Principle

The traditional univariate linear regression model is,

$$\hat{y} = b_1x + b_0, \quad (4)$$

where \hat{y} represents the dependent variable. x denotes the independent variable. b_1 and b_0 are the regression coefficient and the constant term, respectively. The error squared function Q of Eq. (4) satisfies,

$$Q = \sum (y_i - \hat{y}_i)^2, \quad (5)$$

b_1 and b_0 can be obtained by solving the system of equations,

$$\begin{cases} \frac{\partial Q}{\partial b_0} = 0 \\ \frac{\partial Q}{\partial b_1} = 0 \end{cases}, \quad (6)$$

and they can be substituted into Eq. (4) to get the estimated values of samples.

In order to enhance fitting accuracy, time-frequency domain analysis is employed for fitting. The principle of time-frequency domain analysis is elaborated below. The Taylor expansion of a univariate function is expressed as follows. If the function $u = f(x)$ has $n+1$ order derivatives in an open interval (a, b) containing x_0 , then for any $x \in (a, b)$, it holds that,

$$f(x) = \frac{f(x_0)}{0!} + \frac{f'(x_0)}{1!}(x - x_0) + \frac{f''(x_0)}{2!}(x - x_0)^2 + \frac{f^{(n)}(x_0)}{n!}(x - x_0)^n + R_n, \quad (7)$$

where the remaining term R_n is expressed as

$$R_n = \frac{f^{(n+1)}(\delta)}{(n+1)!}(x - x_0)^{n+1}, \quad (8)$$

with δ between x and x_0 . Correspondingly, the measured capacitance value and the water content of crude oil are expressed as c and α , respectively. For the hypothetical function of water content $\alpha = f(c)$, the Taylor expansion can be carried out, and the second and higher expansion terms are ignored. That is

$$\alpha(c) = \frac{f(c)}{0!} + \frac{f'(c)}{1!}(x - c). \quad (9)$$

Therefore, Eq. (9) refers to the Taylor estimation expansion of the moisture content function.

As to the Fourier expansion of a unary function, a one-dimensional function on a finite interval satisfying Dirichlet conditions can be expanded as a linear combination of trigonometric functions. Therefore, the Fourier series corresponding to the one-dimensional function $u = f(x)$ defined on the interval $x \in [0, a]$ is,

$$f(x) = \sum_{n=-\infty}^{\infty} C_n e^{inx}, \quad (10)$$

where $n \in \alpha$, and $C_n = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) e^{-inx} dx$.

Correspondingly, the water content is assumed to be a Fourier series expansion, when ignoring the expansion terms with $|n| > 2$. That is

$$\alpha(c) = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) dx + \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) e^{-ix} dx * e^{ic}, \quad (11)$$

where c and α represent the measured capacitance value and the water content in crude oil, respectively. Eq. (11) is the Fourier estimation expansion of the moisture content function.

Taylor expansion is a signal expansion method in the time domain; while, Fourier expansion is a signal expansion method in the frequency domain. The two expansion methods can be combined through the idea of one-dimensional nonlinear regression. Let

$$r_1 = c, r_2 = e^{ic}. \quad (12)$$

By making the arithmetic average of Eq. (9) and Eq. (11), the water content in crude oil can be expressed as

$$\alpha(r_1, r_2) = k_0 + \sum_{i=1}^2 r_i k_i, \quad (13)$$

where k_1 and k_2 are the coefficients of the corresponding terms in Eq. (9) and Eq. (11), respectively. k_0 is the constant term. Since the objective function in actual calculations is a real-valued function, the imaginary coefficients in the frequency domain expansion terms can be set to 0. Calculations are only performed on the real parts. That is

$$Lm[e^{ic}] = \cos(c) + isin(c) = \cosc, \quad (14)$$

where $Lm[\cdot]$ means taking the real part.

Eq. (13) conforms to the form of the univariate linear regression model in Eq. (4). Correspondingly, the squared error function Q satisfies

$$Q = \sum (\alpha - \bar{\alpha})^2. \quad (15)$$

The estimated value \bar{k}_0 , \bar{k}_1 and \bar{k}_2 are obtained by solving the equation system

$$\begin{cases} \frac{\partial Q}{\partial k_0} = 0 \\ \frac{\partial Q}{\partial k_1} = 0 \\ \frac{\partial Q}{\partial k_2} = 0 \end{cases}. \quad (16)$$

Correspondingly, the estimation function for measuring water content in crude oil can be obtained.

III. EXPERIMENTAL RESULTS

In order to verify the effectiveness of our method in measuring the moisture content of aqueous crude oil, a device for measuring the moisture content of aqueous crude oil has been designed based on STM32 and PCAP01. In the experiment, PCAP01 is set to a drift mode, and the reference capacitance is 47Pf. In order to avoid the influence of ambient temperature, all the following experimental measurement steps are carried out in a constant temperature environment. The specific experimental process is as follows. Firstly, use dehydrated crude oil and pure water to configurate the crude oil mixture with different water content. Secondly, pour the configured crude oil mixture with different moisture content into the prepared cylindrical glass container. Thirdly, fit the

capacitor probe tightly to the glass container to avoid the interference of air on the measurement results. Fourthly, start the device for measuring and record the measurement results. After the measurement, the glass container is replaced to measure the moisture content of other crude oil mixtures. In the actual measurement, the capacitance value takes on decimal place. The measurement results are shown in Table I.

From Table I, it can be seen that when the crude oil mixture oil is a continuous phase, the measurement results of different water contents have a large gap. This is because the dielectric constant of crude oil is much smaller than the dielectric constant of water at room temperature. When the water content rises, a small amount of water causes a large change in the relative dielectric constant of the mixed liquid, resulting in a more drastic change in capacitance.

TABLE I. ONE-TIME RESTES RESULT

water/ml	oil/ml	moisture content	capacitance/pf
0	575	0	28.9
125	450	0.217391	30.8
225	350	0.391304	37.2
275	300	0.478261	40.7
325	250	0.565217	43.4
375	200	0.652174	46.6
425	150	0.73913	47.2
475	100	0.826087	50.2
525	50	0.913043	53.8
555	20	0.965217	54.9
565	10	0.982609	56.3
575	0	1	57.3

Correspondingly, the data in Table I is fitted by univariate linear fitting (ULF). The fitting result is illustrated in Fig. 8.

Fig. 8. The result using univariate linear fitting.

The data in Table I is fitted in the time domain (TD) with logarithmic $\alpha = lnc$, and the fitting formula is given by Eq. (9). The fitting result is shown in Fig. 9.

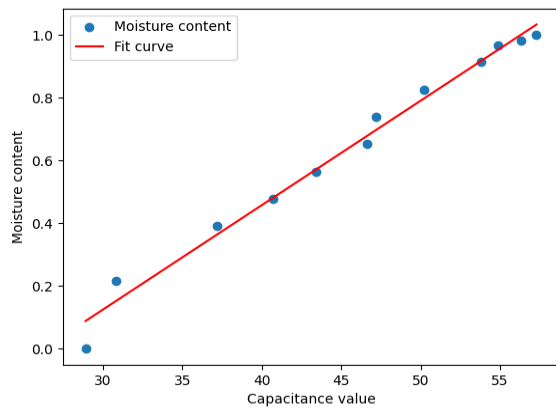

Fig. 9. The result fitted in the time domain.

In addition, the data in Table I is fitted in the frequency domain (FD) with logarithm $\alpha = lnc$, and the fitting formula corresponds to Eq. (11) and Eq. (14). Because the capacitance value cannot be measured negative, $so c \in [0, 60]$. The fitting result is illustrated in Fig. 10.

Fig. 10. The result fitted in the frequency domain.

Besides, the data in Table I is fitted in the time-frequency domain (TFD), and the fitting formula is given by Eq. (13).

The fitting result is shown in Fig. 11. For further comparison, a logarithmic linear fitting (LLF) is also made. The fitting result is illustrated in Fig. 12. All the obtained fitting results and the quantitative results are listed in Table II. It can be seen that the model fitted in TFD gets the best result.

Table III illustrates the experimental results of ten sets of crude oil samples from ten different mines.

Fig. 11. The result fitted in the time-frequency domain.

Fig. 12. The comparing result fitted in a logarithmic linear fitting.

TABLE II. FITTING AND QUANTITATIVE RESULTS

Fitting mode	Fitting formula	r^2
ULF	$\alpha = 0.033c - 0.8724$	0.9847
TD	$\alpha = 0.0325(c - 0.01214) + 3.1651$	0.9847
FD	$\alpha = 2 * (\ln 2 - 1) * \cos \frac{\pi c}{60} + 2 * (\ln 2 - 1) * \sin \frac{\pi c}{60} - 0.156$	0.8099
TFD	$\alpha = 0.249 * \cos \frac{\pi * c}{60} + 0.399985 * \sin \frac{\pi * c}{60} + 0.05512 * (x - 107.09) - 3.955$	0.9871
LLF	$\alpha = 1.3974 \ln c - 4.6619$	0.9850

TABLE III. EXPERIMENTAL RESULTS

Fitting mode	ULF	TD	FD	TFD	LLF
r^2	0.9864	0.9864	0.8146	0.9882	0.9864
	0.9831	0.9831	0.8096	0.9857	0.9847
	0.9729	0.9729	0.8265	0.9785	0.9778
	0.9871	0.9871	0.8190	0.9892	0.9865
	0.9827	0.9827	0.8049	0.9860	0.9845
	0.9835	0.9835	0.8064	0.9856	0.9834
	0.9838	0.9838	0.8062	0.9862	0.9839
	0.9859	0.9859	0.8074	0.9880	0.9853
	0.9813	0.9813	0.8148	0.9824	0.9793
	0.9836	0.9836	0.8132	0.9863	0.9849

As can be seen from Table III, the crude oil mixture with the same water content has a certain impact on the capacitance measurement results due to the different mineralization degree and salt content of the crude oil collected at different times. Besides, the method corresponding to the time-frequency domain analysis still has more advantages in fitting accuracy with higher accuracy and better fitting effect than monadic linear regression, time-domain regression, frequency-domain regression and logarithmic linear regression, which demonstrates the effectiveness of our method.

IV. CONCLUSION

In this paper, a crude oil water content measuring equipment is designed based on STM32 and PCAP01. Besides, a time-frequency domain regression model for data processing is presented. Together with the established system software, they form a capacitance-based system for measuring crude oil moisture. As the sensor core, PCAP01 which has strong anti-interference ability is used. PCAP01 chip adopts shock discharge method to measure capacitance, which can effectively prevent impurities from being adsorbed near the electrode plate. In addition, a slotted cylindrical electrode plate is used in the sensor probe. The electrode plate is tightly fitted to the cylindrical glass wall, which eliminates the interference caused by air. The sensor adopts non-contact method to measure capacitance, which avoids the problem of electrode plate cleaning. After the device collects the capacitance data, STM32 preprocesses the data, and then inputs the preprocessed capacitance values into the proposed time-frequency domain regression model. Experimental results show that the fitting accuracy and reliability of the time-frequency domain regression model are better than that of the monadic linear regression model, the time-frequency domain regression model, the frequency-domain regression model and the logarithmic regression model in the moisture content range between 0 and 100%. Especially for samples of crude oil with fewer impurities, the fitting accuracy and reliability of the time-frequency domain regression model reach their optimal levels.

In the follow-up experiments, we will add a variety of sensors to measure factors such as temperature and flow rate, explore the influence of these factors on capacitance measurement through experiments, and seek the functional

relationship between the influencing factors and capacitance measurement, so as to further improve the measurement accuracy and anti-interference ability of the device.

SchemaLogix: Advancing Interoperability with Machine Learning in Schema Matching

Mohamed Raoui, Mohammed Ennaouri, Moulay Hafid El Yazidi, Ahmed Zellou
ENSIAS, Mohammed V University in Rabat, Morocco

Abstract—Schema matching, a fundamental process in data integration, traditionally employs pairwise comparisons to discern semantic correspondences among elements in disparate schemas. However, recent developments underscore the necessity of concurrent matching of interconnected schemas, termed schema alignment, to reconcile heterogeneous elements. This paper presents SchemaLogix, an innovative machine learning-based approach for schema matching. SchemaLogix addresses challenges such as data scarcity and domain-specific constraints through an inventive bootstrapping method, autonomously generating extensive datasets. Furthermore, SchemaLogix capitalizes on inherent alignment context constraints to optimize learning and improve precision across varied schema structures. Additionally, SchemaLogix incorporates user contributions to validate chosen correspondences, refining outputs based on valuable feedback. Empirical evaluations establish SchemaLogix's superiority over traditional methods, achieving an exceptional maximum S1 score of 0.90. These results offer practical insights for real-world applications, substantially advancing data integration and interoperability endeavors.

Keywords—Interoperability; data integration; schema matching; machine learning

I. INTRODUCTION

Schema matching involves the process of identifying semantic connections among attributes of two distinct database structures, which is crucial for facilitating data integration and system compatibility across diverse industries including e-commerce, geospatial analysis, biology, healthcare, and others.

Identifying these connections presents several challenges. First, schema elements, such as attributes representing similar concepts, may have different names across various schemas [1] [2]. Additionally, items sharing common names might actually represent different concepts. Furthermore, corresponding components between two database structures might have divergent structures. Finally, it's possible that in one schema, multiple elements symbolize a concept that would be depicted as a single item in another schema.

For instance, consider the database structures for people's information illustrated in Fig. 1. The objective of schema matching is to identify matches between elements in these schemas. In this case, the left diagram depicts how Person P structures student information within their database, while the right diagram represents the same data within another database schema employed by Person P.

This example encapsulates the inherent challenges of schema matching, where the task extends beyond mere alignment to encompass the reconciliation and harmonization of elements across disparate database structures. In essence, schema matching emerges as a pivotal linchpin in the realm of effective and cohesive information management, demonstrating its profound implications for diverse domains and industries.

Traditionally, schema alignment is typically carried out manually by experts with profound knowledge of database structures and their respective fields. However, even when performed by professionals, this task can be time-consuming, costly, and prone to inaccuracies. Over time, numerous studies and projects have addressed the topic of schema matching, leading to the creation of various articles [3] [4] [5] and the development of multiple prototypes and commercially available solutions. A substantial number of these approaches rely on predefined sets of methods and parameters [6] [7].

Other approaches rely on using machine learning to define specific models designed for each matching task [8] [9]. While heuristics can be effective in some situations, they often require adjustments to produce good results. In contrast, machine learning techniques can adapt to various matching tasks after a significant amount of training data becomes available, although obtaining this data can be challenging.

As the field has advanced, situations have arisen in the alignment of database structures where matching involves multiple data sources, such as databases and query forms [10] [11], forming what can be referred to as a network of patterns. Considering the satisfactory performance observed when applying machine learning methods in pairwise pattern matching scenarios, this study experiments with these methods in the context of pattern matching. However, this introduces challenges, including the need for a substantial volume of annotated data and the handling of imbalanced data sets, where the number of unmatched pairs far exceeds the count of corresponding pairs.

To address these challenges, various approaches are being explored, including utilizing opaque-box pattern schema alignment systems to generate training instances, leveraging network constraints to construct high-quality training sets, and incorporating user reviews to enhance final correspondences. However, these methods may introduce additional time-consuming issues.

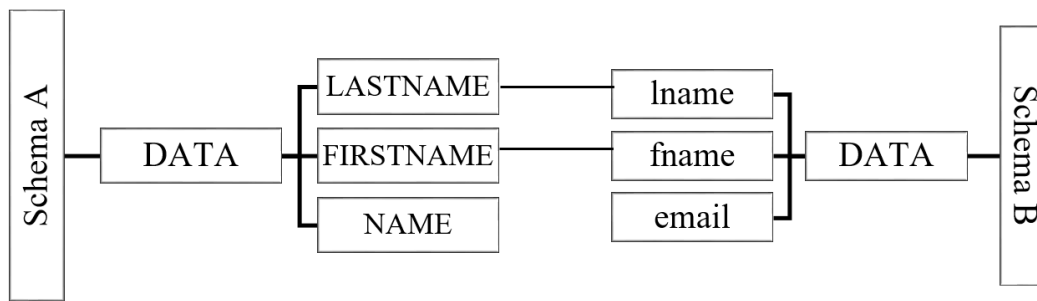

Fig. 1. Structure of a schema represents people.

The contributions of this work can be summarized as follows. Firstly, several commonly used machine learning methods were evaluated to tackle model alignment, investigating whether these methodologies could solve the model matching problem by treating it as a classification task. This approach helped in selecting a foundational machine learning technique as the primary learner. Additionally, reconciliation tasks were explored where users can review, validate, and correct results.

The structure of the remainder of this article is as follows: in the 'Related Work' section, an overview of the model alignment challenge is provided along with discussions on approaches adopted by previous studies. In the 'Integration of Machine Learning in Schema Matching' section, the process of training classifiers to perform model matching tasks within datasets is described, utilizing heuristics and data validity rules to generate training instances automatically labeled with classes.

Furthermore, a subsequent approach to enhance match quality using user input constraints is detailed. In the 'Experimental Evaluation' section, experiments conducted to assess the effectiveness of the approach are presented. Results demonstrate that the method can train a classifier achieving up to 90% accuracy, surpassing benchmarks. Moreover, it is shown that match quality can be improved by an average of 16% through increased user contributions compared to alternative approaches.

In conclusion, the 'Conclusions and Future Works' section presents observations and conclusions on this work, discussing future directions within this domain.

II. RELATED WORK

The challenge posed by pattern alignment has been the focal point of sustained and in-depth research, as substantiated by a plethora of surveys and comprehensive works dedicated to this intricate topic [12] [13] [14] [15] [22]. In this particular section, the focus is meticulously directed towards research that bears direct relevance to the specific contours of this study. The intent is to carve a focused pathway through the wealth of literature, homing in on key investigations and seminal contributions that align with the nuances and objectives inherent in these research endeavors.

A. Traditional Schema Matching

Schema matching stands as a pivotal process in the expansive landscape of data integration, entailing the intricate

identification of meaningful relationships among the multifaceted components within a pair of distinct schemas [6]. These schemas, emanating from a diverse array of data sources within the same field [16], necessitate a sophisticated matching approach to forge crucial connections in the broader spectrum of data integration processes [13].

Despite the commendable efforts invested in addressing the challenging task of schema matching, the field still grapples with the absence of a universally recognized method that can claim comprehensive resolution of this intricate issue. The complexity of schema structures, coupled with the dynamic nature of data sources, contributes to the persistent need for innovative solutions that can effectively navigate the intricacies of schema matching.

Moreover, to ensure the precision and quality of alignment results, there persists a reliance on expert user involvement, who reviews responses post-execution of a matching technique, emphasizing the human-centric aspect of this critical process.

Within the realm of schema matching, pattern matching methods emerge as key players, contributing significantly to the pursuit of effective connections between disparate schemas. These methods employ intricate functions, commonly referred to as 'matchers,' which play a pivotal role in assessing the degree of similarity between pairs of items within the patterns. Each potential match forms what is known as a 'matching candidate,' and the output of these matchers, expressed on a scale from 0 to 1, signifies the degree of similarity between the elements under consideration.

This nuanced approach recognizes that the nature of similarity is multifaceted, and a one-size-fits-all strategy is insufficient. The spectrum of strategies employed by these comparison methods to estimate similarities is vast and reflective of the intricacies inherent in schema matching. This can include the comparison of elements based on schema names, leveraging semantic resemblance through the use of a thesaurus, evaluating data formats, considering quantity metrics, or delving into the scrutiny of data values when such information is available.

The versatility in these comparison strategies underscores the multifaceted nature of schema matching and reinforces the necessity for adaptive approaches that can effectively establish meaningful connections between disparate data sources, ultimately contributing to the broader objectives of seamless data integration and interoperability.

B. Heuristic Methods

In the expansive domain of schema matching methodologies, a diverse array of systems has come to the forefront, each leveraging heuristics to adeptly combine matchers. Prominent among these are COMA [6], hMatcher [18], CUPID [4], and Similarity Flooding [17], each contributing distinct perspectives and innovative strategies to the intricate challenge of establishing meaningful correspondences between divergent schemas.

The COMA/COMA++ [6], denoting "COMbining Matching Algorithms," unfolds as a sophisticated approach that orchestrates various algorithms, utilizing similarity functions to yield matches between two given diagrams. The execution sequence of COMA provides valuable insights into the mechanics of heuristic methods. Commencing with the input of two diagrams within the same domain, the methodology involves pairs of elements from schemas undergoing pairwise matching functions, or "matchers," such as the Levenshtein distance.

While COMA incorporates comparators considering the structural hierarchy of elements, the aggregation function may, at times, dilute their similarities, potentially overlooking this critical aspect in solving the complex schema matching problem. In contrast, Similarity Flooding [17] offers an alternative approach, placing significant emphasis on the structural aspect of diagrams and relying on graph analysis within its algorithm.

The Similarity Flooding process embarks with the transformation of initial diagrams into graphical representations. A string comparison tool is then employed to evaluate basic similarities between pairs of elements. Subsequently, a similarity propagation algorithm circulates these similarities vertically through the graph's nodes. Matches between components in identical segments receive partial ratings from earlier elements, and a threshold is applied to exclude less likely matches. The most significant similarities emerge as matching results, derived from a method that has been rigorously trialed in nine pairwise matching scenarios, involving references provided by volunteers.

hMatcher, standing as a highly efficient holistic approach in the schema matching landscape, aims to establish precise correspondences across global schemas. This ambition is realized through the deployment of a semantic matching index in conjunction with a structured lexical dictionary, supplemented by a repository of abbreviations and acronyms [18] [19] [20].

While heuristic techniques, as exemplified by COMA, Similarity Flooding, and hMatcher, are celebrated for their simplicity in setup and execution, their consistency across different datasets is not guaranteed. Previous research [12] [14] underscores the variability in the effectiveness of these methods, contingent upon the dataset and parameters selected.

In response to this challenge, systems like eTuner and SMB have been developed, focusing on investigating how parameter adjustments can elevate the quality of matches. These endeavors acknowledge the dynamic nature of schema matching and the nuanced challenges posed by diverse

datasets, propelling the evolution of methods towards greater adaptability and effectiveness.

In summary, the realm of heuristic methods presents a rich tapestry of approaches, each contributing to the ongoing quest for effective schema matching. From COMA's algorithmic orchestration to Similarity Flooding's emphasis on graph analysis and hMatcher's holistic semantic matching, the diversity in strategies reflects the multifaceted nature of schema matching challenges. The evolution towards adaptive systems and parameter tuning, exemplified by eTuner and SMB, marks a significant step forward in addressing the variability inherent in schema matching datasets, paving the way for more robust and adaptable methodologies.

C. Machine Learning Approach

In certain research paradigms, the intricate question of schema matching is approached through the lens of treating it as a classification problem. This entails conceptualizing the schema matching task as a machine learning challenge, where a model is tasked with determining whether a given matching candidate genuinely represents a match by assessing if it corresponds to the same underlying concept. In this conceptualization, the schema matching process involves working with two distinct database structures, denoted as S_0 and S_1 .

To operationalize this correspondence, a set $S = \{s_1, s_2, \dots, s_j\}$ of matching candidates is established. Each candidate $s \in S$ comprises two database structure components, s and t , originating from either S_0 or S_1 . Furthermore, each candidate is associated with a vector v that encapsulates similarity values between s and t . These values are generated through various matching schemes, serving as features for the candidate. Crucially, each candidate is assigned a label, denoted as l , which serves as a binary indicator. Specifically, l evaluates to 1 if s and t indeed form a genuine pair of matching elements, and 0 otherwise.

In the realm of employing classifiers for schema matching, the task of constructing a training set, where users categorize a substantial number of instances, can indeed be a burdensome challenge. Recognizing this, the approach pivots towards decision tree algorithms, specifically emphasizing the paradigm of paired learning as opposed to artificial intelligence-generated matching.

The underlying objective of incorporating decision tree algorithms is grounded in the pursuit of traditional matching, prioritizing quality and precision over artificial intelligence-generated matching approaches. As the landscape of machine learning continues to evolve, the focus is directed towards leveraging well-regarded algorithms known for their robustness and precision. In this context, the Decision Tree Schema Matcher (DTSM) takes center stage, being employed to generate a series of decision trees. This strategic choice underscores the commitment to harnessing sophisticated algorithms that align with the ever-advancing field of machine learning, with an emphasis on achieving high-quality and precise schema matching outcomes.

While the Decision Tree Schema Matcher (DTSM) serves as a cornerstone in another study's pursuit of leveraging

machine learning for schema matching, the focus of this study lies on prioritizing the Logistic Regression Model (LRM) for this task. The LRM was chosen for its established effectiveness in binary classification and its capability to handle structured data like database schema descriptions. In the context of the machine learning approach for schema matching, a logistic regression model was opted for due to its well-studied characteristics in terms of binary classification and its ability to efficiently handle structured data such as database schema descriptions. Logistic regression is a widely used statistical method for modeling binary or categorical dependent variables. In this case, the model was adapted to decide if two given schemas should be considered matches based on a predefined similarity threshold.

The initial step of the approach involves transforming schema descriptions into numerical vectors using a vectorization technique, such as TF-IDF (Term Frequency-Inverse Document Frequency), combined with vector representations of schema columns. This vector representation allows for the expression of similarities and differences between schemas quantitatively, which is essential for the application of logistic regression.

Logistic regression is then used as a supervised classification model to learn to distinguish between schema pairs that constitute matches and those that do not, based on schema description vectors and corresponding labels ("is_match" in this case).

This strategic choice of logistic regression in the schema matching framework reflects a commitment to proven methods in the field of machine learning, providing both interpretability of results and robust performance. Logistic regression models are also known for their ability to generalize to new data, which is crucial in applications such as schema matching where configurations can vary significantly.

In summary, the use of logistic regression as a cornerstone of the schema matching approach underscores the commitment to quality, adaptability, and interoperability of machine learning methods in the field of data integration.

III. INTEGRATING MACHINE LEARNING INTO SCHEMA MATCHING

In this section, a detailed exposition of the pattern matching algorithm, grounded in the principles of logistic regression and cosine similarity, is presented. This comprehensive methodology traverses several key steps, spanning from data preprocessing to the ultimate generation of results. To ensure clarity and precision, each step is rigorously formalized through the presentation of mathematical equations, facilitating a thorough and nuanced understanding of the underlying processes.

A. Logistic Regression Model in the Context of Schema Matching

Logistic regression, a powerful classification model, enables the prediction of the probability of an example belonging to a binary class, specifically the 'match' or 'non-match' classification between two schemas. This model is built upon a logistic function, often referred to as a sigmoid, which

transforms a linear combination of characteristics into a probability.

Consider a feature vector (or descriptors) for two given patterns, denoted as X , and a binary variable Y indicating whether these patterns match (1) or not (0). Logistic regression formulates the probability $P(Y=1)$ as a function of the characteristics in X .

The logistic function, denoted as $\sigma(z)$, where z is a linear combination of characteristics, is defined as:

$$\sigma(z) = 1 / (1 + e^{-z})$$

Here, 'e' represents the base of the natural logarithm, approximately 2.71828. The logistic function $\sigma(z)$ produces a value between 0 and 1, making it suitable for modeling probabilities.

The linear combination z is defined as:

$$z = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_n X_n$$

where $\beta_0, \beta_1, \beta_2, \dots, \beta_n$ are the model coefficients (weights) associated with each characteristic $X_0, X_1, X_2, \dots, X_n$. These coefficients are learned from the training data using an optimization technique such as logistic regression, which maximizes the likelihood of the training data with respect to the model.

The probability that $Y=1$ is then given by the logistic function applied to z :

$$P(Y=1) = \sigma(z)$$

$$P(Y=0) = 1 - P(Y=1)$$

To make a decision, a probability threshold (usually 0.5) is chosen. If $P(Y=1)$ exceeds this threshold, the prediction is that the patterns match ($Y=1$); otherwise, they do not match ($Y=0$).

Training the logistic regression model involves adjusting the coefficients $\beta_0, \beta_1, \beta_2, \dots, \beta_n$ to maximize the likelihood of the training data. This can be done using optimization algorithms such as gradient descent.

In summary, logistic regression is a classification model that models the probability of a match between two patterns using a logistic function. Model coefficients are learned from the training data to make match or non-match predictions.

B. Advantages of the Logistic Regression Model

In this section, the manifold benefits that the Logistic Regression Model brings to the forefront, particularly in the domain of Schema Matching, are explored:

- **Adaptability to Classification Problems:** Logistic regression stands as a versatile and extensively employed classification model. In the specific realm of Schema Matching, its applicability shines through in the discernment between matching and non-matching pairs of schemas, leveraging the nuanced metric of cosine similarity. The model showcases its prowess in effectively categorizing diverse schema elements into these two distinct classes, contributing to the enhancement of semantic correspondence [23] [24].

- **Supervised Learning Paradigm:** A notable strength of the logistic regression model lies in its adherence to the supervised learning paradigm. By being trained on a meticulously pre-annotated dataset, the model acquires the capability to glean insights from a myriad of pattern matching examples. This intrinsic learning mechanism endows it with the acumen to generalize patterns and discern matches in novel and unseen data. This supervised learning approach proves invaluable in Schema Matching scenarios, where the model's proficiency in drawing upon annotated data significantly contributes to its robust performance [25].
- **Scalability and Computational Efficiency:** Logistic regression demonstrates commendable scalability, emerging as a computationally lightweight solution. This attribute renders it highly efficient, enabling seamless application even to extensive collections of pattern descriptions. In the intricate landscape of Schema Matching, where datasets may encompass a multitude of interconnected schemas, the model's ability to scale efficiently becomes a pivotal asset. This scalability not only facilitates the processing of large datasets but also contributes to the expeditious execution of the matching process across diverse schema elements [26] [27].
- In essence, the Logistic Regression Model emerges as a stalwart ally in Schema Matching endeavors, offering adaptability, supervised learning prowess, and computational efficiency. Its multifaceted strengths position it as a valuable tool for discerning semantic correspondences and addressing the intricacies posed by diverse and interconnected schema structures.

C. Disadvantages of the Logistic Regression Model

In this segment, light is shed on the limitations inherent in the Logistic Regression model, recognizing these challenges as focal points for continuous improvement within the algorithm:

- **Requirement for Adequate Data Representation:** The Logistic Regression model places a significant emphasis on the need for a well-structured and appropriately represented dataset. The efficacy of the model is contingent upon the thoughtful curation and presentation of features within the dataset. The necessity for a comprehensive and discriminative set of features underscores the importance of data preprocessing and representation in ensuring the model's optimal performance [28].
