Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

CONTENTS

Integrating Advanced Language Models and Vector Database for Enhanced AI Query Retrieval in Web Development

Xiaoli Huan[1], Hong Zhou[2]
Department of Computer Science, Troy University, Troy, Alabama, USA[1]
Department of Mathematics and Computer Science, University of Saint Joseph, West Hartford, Connecticut, USA[2]

***Abstract*—In the dynamic field of web development, the integration of sophisticated AI technologies for query processing has become increasingly crucial. This paper presents a framework that significantly improves the relevance of web query responses by leveraging cutting-edge technologies like Hugging Face, FAISS, Google PaLM, Gemini, and LangChain. We explore and compare the performance of both PaLM and Gemini, two powerful LLMs, to identify strengths and weaknesses in the context of web development query retrieval. Our approach capitalizes on the synergistic combination of these freely accessible tools, ultimately leading to a more efficient and user-friendly query processing system.**

***Keywords*—LLM (Large Language Model); vector databases; retrieval-augmented generation**

I. Introduction

In the rapidly evolving landscape of web development, the quest for efficient and accurate query retrieval systems has become a cornerstone of enhancing user experience and information accessibility. While effective to a certain extent, traditional query processing methods often fall short in coping with the complexity and dynamism of user-generated queries in real-time web environments.

Generative AI, including models like the GPT series [1], Google PaLM, and Gemini, have demonstrated remarkable capabilities in generating human-like text and answering queries in a contextually relevant manner. These models leverage large-scale transformer architectures to understand and generate complex language, making them highly suitable for sophisticated query processing tasks.

Retrieval-Augmented Generation (RAG) [2] is a cutting-edge approach that combines retrieval-based and generative models to enhance the accuracy and relevance of responses. RAG models retrieve relevant documents or pieces of information from a database and use these as context to generate more precise and contextually aware answers. This technique has been particularly effective in scenarios where the generative model alone might lack the necessary contextual knowledge to provide accurate responses [3].

Our approach integrates freely accessible tools like Hugging Face [4], FAISS [5], Google PaLM [6], Gemini [7], and LangChain [8]. Each tool brings its strengths to the table, contributing to a more robust query processing framework.

We explore and compare the performance of both PaLM and Gemini, two powerful Large Language Models (LLMs), to identify which is more effective in the context of web development query retrieval. This comparative analysis provides valuable insights into the strengths and weaknesses of each model for this specific task. By combining these cost-free technologies, we create a query processing system that is not only more efficient but also delivers significantly more relevant responses to user queries. This cost-effectiveness allows for the development of sophisticated AI-driven solutions without the burden of API usage fees or proprietary restrictions.

This research contributes novel insights to web development by:

- Highlighting the potential of combining sophisticated open-source AI models and advanced methodologies like RAG for improved user query handling.
- Providing a comparative analysis of PaLM and Gemini, offering valuable insights into their effectiveness for web development query retrieval.
- Emphasizing accessibility and cost-effectiveness through the utilization of freely available tools.

The following sections will delve into the technical architecture, implementation details, and performance evaluation of the system in Sections II, III, IV, V and VI, providing a comprehensive understanding of its capabilities and potential impact on the future of web development in Section VII.

II. Evolution of Language Models

The evolution of language models in query processing is crucial in natural language processing (NLP) and artificial intelligence (AI), witnessing significant advancements over the past few decades. This section explores the trajectory of these developments, focusing on how they have revolutionized query processing and understanding.

The journey began with early language models like n-gram models and statistical language models. These models, such as those used in early versions of machine translation and speech recognition systems, relied heavily on statistical probabilities of word sequences. However, their major limitation was the inability to capture long-range dependencies and contextual

nuances in language, leading to suboptimal performance in complex query processing [9].

The introduction of neural network-based models marked a significant shift. Recurrent Neural Networks (RNNs) and Long Short-Term Memory (LSTM) networks began to address the shortcomings of traditional models by better capturing sequential information and context [10]. Despite their improvements, these models still struggled with processing longer sequences and required substantial computational resources.

The introduction of transformer architecture [11] in 2017 marked a significant transformation in language modeling. Distinct from earlier models, the transformer employs self-attention mechanisms to analyze entire text sequences at once, allowing for more effective context capturing. This innovative framework serves as the foundational structure for models such as Google's BERT (Bidirectional Encoder Representations from Transformers) and the GPT (Generative Pre-trained Transformer) series developed by OpenAI.

BERT [12] was groundbreaking due to its bidirectional training, enabling it to comprehend the context of a word by considering all of its surrounding words. This feature made it particularly effective for tasks like question answering and language inference.

The GPT series demonstrated remarkable capabilities in generating human-like text and answering queries in a contextually relevant manner. Its large-scale transformer model, trained on vast amounts of data, could generate coherent and contextually relevant text over extended passages.

The most recent advancements, such as Google's PaLM (Pathways Language Model) and Gemini, have pushed the boundaries further. PaLM, with its even larger scale and more sophisticated training, has shown capabilities in not just understanding but also generating complex and nuanced language, making it highly effective for sophisticated query processing tasks. On the other hand, Gemini showcases strength in its multimodality, seamlessly processing text, images, and code. This versatility could prove advantageous in web development scenarios where queries might incorporate screenshots or snippets of code alongside textual information.

The impact of these advancements on query processing has been profound. Language models have transitioned from simply predicting the next word in a sequence to understanding and generating human-like responses to complex queries. This evolution has enabled the development of more sophisticated AI-driven applications, such as virtual assistants, chatbots, and advanced search engines, capable of understanding and responding to user queries with unprecedented accuracy and relevance.

III. Vector Databases

Integrating vector databases in information retrieval significantly advances AI and web development. This section reviews the evolution and application of vector databases, particularly focusing on their role in enhancing information retrieval capabilities in AI systems.

Vector databases, fundamentally different from traditional relational databases, are designed to store and retrieve high-dimensional vector data efficiently. This capability is crucial in handling the outputs of advanced AI models, especially in the context of natural language processing and machine learning (ML). The early conceptualization and use of vector spaces in information retrieval set the stage for the development of these databases [13].

Developing technologies like FAISS (Facebook AI Similarity Search) marked a significant milestone in vector databases. FAISS is designed for efficient similarity search and clustering of dense vectors. Its ability to handle billions of vectors makes it particularly suitable for large-scale AI applications, including those in web development and query processing [14].

Vector databases have found extensive application in AI-driven systems, particularly in enhancing the efficiency and accuracy of information retrieval. For instance, their integration into recommendation systems and search engines has significantly improved the relevance of results based on user queries and preferences [15].

Despite their advancements, vector databases face challenges, particularly in scalability and real-time processing in web environments. Future research is directed toward optimizing these databases for more efficient real-time query processing and integration with evolving AI models [16].

IV. System Architecture

This section outlines the system architecture of our AI-driven web application, emphasizing the integration of Streamlit and various AI components to enhance user experience and query processing efficiency.

The front-end of our system is built using Streamlit [17], an innovative framework that allows for rapid development and deployment of data applications. Streamlit's simplicity and efficiency make it an ideal choice for integrating complex AI models into web applications.

Key components of the front-end include:

- User Interaction: It presents a web interface where users can type questions in a text box.
- Visual Elements: Streamlit elements like headers, subheaders, and text boxes are used to create a user-friendly interface.
- Feedback Mechanism: The script provides feedback to the user by displaying placeholders that change state based on the application's progress. Initially, it displays "Awaiting your question..." and transitions to "Processing..." when the user submits a question. Finally, it displays "Answer" if a successful response is generated or an error message if the process fails.
- Communication: The front-end interacts with the back-end by passing the user's question as input and displaying the generated response.

Fig. 1 shows the web application's initial input interface.

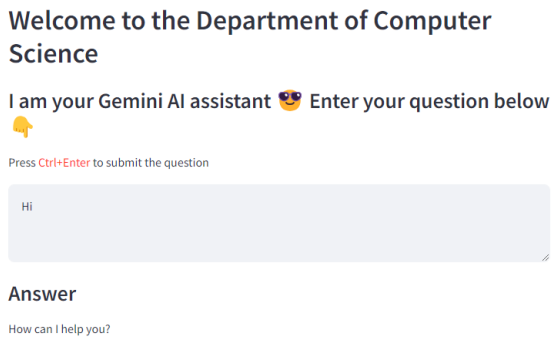

Fig. 1. The web application interface.

The front-end acts as the communication layer for users, while the back-end handles the core functionalities of the application. It serves as the engine that processes user queries, interacts with the data and AI models, and generates the final response.

In Fig. 2, the init_google_palm_model() function initializes the Google PaLM model. It retrieves an API key [18], which is used to authenticate Google's services. The model is initialized with a temperature parameter set to 0.1, which influences the model's output's randomness (lower temperature values result in more deterministic outputs). The changes to the init_google_gemini_model function are relatively straightforward in leveraging Gemini's capabilities instead of PaLM. Import the necessary libraries for Gemini and modify the line that initializes the model. Instead of GooglePaLM, use ChatGoogleGenerativeAI and specify the model="gemini-pro" argument to indicate the Gemini model variant.

In Fig. 3, the init_hf_embeddings() function initializes embeddings from the Hugging Face's InstructEmbeddings [19] model. These embeddings can be used to convert text into numerical vectors, which represent the semantic meaning of the text and can be used for similarity search and vector-based analysis.

```
@st.cache_resource
def init_google_palm_model():
    api_key = st.secrets["GOOGLE_API_KEY"]
    return GooglePalm(google_api_key=api_key, temperature=0.1)

@st.cache_resource
def init_google_gemini_model():
    #api_key = st.secrets["GOOGLE_API_KEY"]
    genai.configure(api_key=st.secrets["GOOGLE_API_KEY"])
    return ChatGoogleGenerativeAI(model="gemini-pro",temperature=0.1)
```

Fig. 2. Functions to initialize PaLM and Gemini models.

```
@st.cache_resource
def init_hf_embeddings():
    return HuggingFaceInstructEmbeddings(model_name="hkunlp/instructor-large")
```

Fig. 3. The init_hf_embeddings() Function.

```
@st.cache_resource
def setup_vector_database(file_path="faiss_index"):
    csv_loader = CSVLoader(file_path='prompt_answer.csv', source_column="prompt")
    faq_data = csv_loader.load()
    hf_embeddings = init_hf_embeddings()
    faiss_db = FAISS.from_documents(documents=faq_data, embedding=hf_embeddings)
    faiss_db.save_local(file_path)
```

Fig. 4. The setup_vector_database() Function.

The setup_vector_database() function in Fig. 4 sets up a vector database using FAISS. It loads question-and-answer pairs from a CSV file (prompt_answer.csv) using LangChain's CSVLoader. The function then initializes the Hugging Face embeddings (init_hf_embeddings function) to convert the loaded FAQ data into vector embeddings. These embeddings are then used to create a FAISS database with the FAISS.from_documents method. Finally, the FAISS database is saved locally using the provided file path, allowing the application to quickly retrieve relevant answers based on similarity searches in the future.

Fig. 5 shows samples of the provided data file, 'prompt_answer.csv'. The dataset comprises a collection of questions and corresponding responses intended for the computer science department. This spreadsheet is structured with two primary columns: prompt and response. The prompt column contains a variety of questions that might be asked by students, faculty, or other stakeholders, while the response column provides the appropriate answers. The data can be easily updated to reflect new queries or changes in the information provided, ensuring that the dataset remains current and helpful in addressing the diverse inquiries directed towards the CS department.

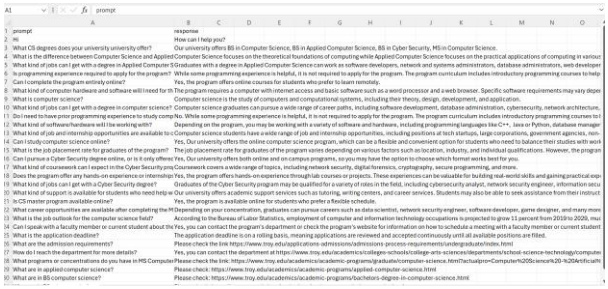

Fig. 5. The prompt_answer.csv data file.

After the front-end invoked the setup_qa_chain() function and passed the user question, Fig. 6's setup_qa_chain() function first initializes embeddings using the function init_hf_embeddings. These embeddings are then used to load a local FAISS database from the specified file path generated by the setup_vector_database() function.

Fig. 6. The setup_qa_chain() function.

In line 45 of Fig. 6, a retriever object is created from the FAISS database with a score threshold of 0.7, meaning it will only consider results that meet or exceed this similarity score. This retriever is used to fetch relevant context for incoming questions.

The code then defines a prompt_template, which is a structured text template for generating prompts to be used with a large language model. Finally, the function initializes a LLM (Google PaLM or Gemini model) and generates a QA chain that takes a query as input, uses the retriever to fetch relevant context based on the query, and then generates an answer using the LLM and the structured prompt.

Throughout the program, robust error-handling mechanisms are in place to manage potential failures and processing errors.

V. TECHNICAL DETAILS

Google PaLM or Google Gemini models generate responses to user queries. The models have customized behavior (e.g., setting temperature) to tailor the response generation. At a high level, temperature controls the likelihood distribution over words or tokens the model might select at each step in generating text. A lower temperature makes the model more confident and conservative in its choices, leading to more predictable text. A higher temperature increases randomness, making the model more likely to produce varied and sometimes more creative or less likely outputs. Choosing the right temperature is a balancing act: too low, and the model might generate dull, repetitive text; too high, and its outputs might become too random and less coherent. The optimal setting often depends on the specific application and desired user experience. For a technical query retrieval system, a slightly lower temperature might be preferred to ensure the reliability and relevance of the information provided.

Langchain is a backbone that connects various AI and machine learning components, ensuring seamless interaction. The library assembles components (like the Google PaLM or Gemini language model, HuggingFaceInstructEmbeddings, and the FAISS vector database) into a cohesive QA chain. This chain orchestrates the process of receiving a query, processing it through the model, and fetching relevant answers. The CSVLoader component in LangChain is used to load data from CSV files. The CSV file contains two columns: one for the prompts (or questions) and another for the corresponding answers or information. These pairs are used to build a knowledge base for the FAISS vector database, allowing the system to retrieve relevant answers based on the embeddings generated from user queries.

The system uses the following prompt_template: "Please provide an answer to the question below, ensuring that your response is derived solely from the provided context. Focus on using the text from the 'response' section of the source document, altering it as little as possible. If the context does not contain the information necessary to answer the question, simply reply with 'I am not sure. Please call: 1-334-808-6576' to avoid creating or inferring any information not explicitly stated in the context. Exceptions: Answer all computer science questions using your own knowledge and give tutorials and explain in detail".

The model is instructed to base its responses solely on the provided context, specifically focusing on the ‘response’ section of the source documents. This restriction ensures factual accuracy and reduces the risk of the model generating misleading or fabricated information (hallucination). Prompt engineering, which involves carefully crafting the input text, helps achieve this objective. When the context lacks sufficient information to answer a department question, the model is instructed to provide a clear default message ("I am not sure..."). This transparency helps manage user expectations and prevents frustration in cases where a definitive answer cannot be found.

There is also a crucial exception for computer science questions. In these cases, instead of being confined solely to the provided department question context, the model can draw on its own knowledge base to answer computer science questions. Comprehensive tutorials and detailed explanations for computer science topics can be delivered. This exception caters to students seeking deeper understanding and learning resources beyond basic department questions in the CSV file.

The Gemini Model app can be accessed at this link: https://troy-ai-gemini.streamlit.app/.

VI. RESULTS ANALYSIS

Fig. 7 shows a programming tutorial interface facilitated by an AI PaLM assistant, exemplifying an interactive learning environment. It features a question-and-answer dialogue where the user inquiry, "Can you give me C++ tutorial?" is met with a comprehensive response from the AI assistant. The AI assistant outlines C++'s applicability in system, application, and game development, and offers resources for further learning. This exchange is encapsulated in a clean, structured layout, promoting an engaging and educational user experience.

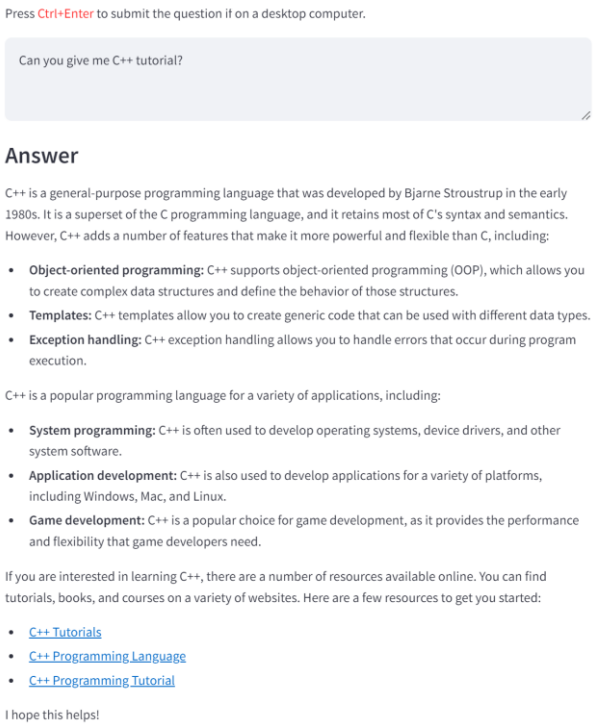

Fig. 7. Interactive Programming Tutorial via AI PaLM Assistant.

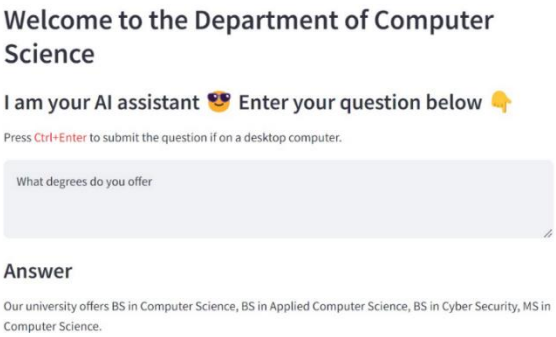

Fig. 8. Departmental Inquiry Response by AI Gemini Assistant.

Fig. 8 illustrates an AI Gemini assistant answering a prospective student's inquiry, "What degrees do you offer?" The AI assistant provides a detailed response listing the degrees offered by the university, facilitating ease of information retrieval for prospective students or interested parties.

Forty unique questions were used to test the PaLM and Gemini models, assessing their accuracy and capabilities in answering questions such as the cost of the master's program, Python tutorials, identifying the faculty of computer science, differences between Python and C++, potential jobs post-graduation, and details about the degree concentrations.

Performance:

1) PaLM demonstrated better accuracy, correctly answering 37 out of 40 questions. For example, when asked, "Can I get a bachelor's degree online?" PaLM provided a clear and informative response, highlighting the university's online program and its benefits.

2) In contrast, Gemini answered 32 questions correctly. While some answers were accurate, others showed limitations, like the response to "Can I get a bachelor's degree online?". In this instance, Gemini offered uncertainty and directed the user to contact the department or instructor, potentially hindering a user's ability to get a quick answer. This difference in handling specific questions highlights areas for improvement in Gemini's knowledge base and its ability to provide definitive answers.

3) User feedback indicates response time differences between the PaLM and Gemini models. Users report that the PaLM web application loads noticeably faster in both Safari and Google Chrome browsers.

Contextual Understanding and Prompting:

1) PaLM excels at the provided prompt and adheres to strict guidelines. The prompt template specifically instructs the model to "give tutorials and explain in detail" for computer science questions. PaLM effectively obeys this direction, retrieving relevant information from its knowledge base.

2) Gemini's strength lies in its multimodality. It can handle various data formats like text, images, and code. This versatility makes it a good candidate for web development scenarios where user queries might incorporate diverse information, such as screenshots or code snippets alongside textual content. However, Gemini is less adept when working with pre-defined CSV data for tasks requiring strict adherence to specific prompts. Its focus might shift towards pattern matching within the CSV content, potentially leading to less comprehensive responses or failing to follow the prompt's instructions. This could be particularly true for tasks requiring in-depth explanations or generating new content, such as computer science tutorials. However, in domains like the medical field, where factual accuracy and information retrieval from structured data are crucial, Gemini's ability to handle diverse formats and find relevant patterns could prove advantageous.

Data Restriction:

1) Both models rely heavily on the information stored in the CSV files. Gemini's ability to generate content would be inherently limited if those files lack rich information or detailed explanations for departmental or computer science concepts.

2) PaLM might be better at drawing from external knowledge sources or generating explanations from its own understanding, even if the CSV data is somewhat limited.

Table I compares the performance of PaLM and Gemini on a set of sample questions. The table categorizes the questions into three sections: scenarios where both systems failed due to limitations set by the prompt, instances where PaLM provided more accurate or helpful responses, and examples where Gemini outperformed PaLM. The examples highlight the strengths and weaknesses of each system in handling specific types of inquiries, such as basic greetings, specific program information, and technical support questions.

TABLE I. MODEL PERFORMANCE COMPARISON ON SAMPLE QUESTIONS

The sample question that neither PaLM nor Gemini can address due to the prompt restricting responses to information outside the CSV data file:
Q: What is the best website to find sports data
PaLM: I am not sure. Please call 1-334-808-6576…
Gemini: I am not sure. Please call 1-334-808-6576…
Examples of questions where PaLM performed better than Gemini:
Q: Hello?
PaLM: Hello, how can I help you?
Gemini: I am not sure. Please call: 1-334-808-6576…
Q: How much does the masters of computer science program cost
PaLM: Please check: https://www.troy.edu/scholarships-costs-aid/costs/
Gemini: I am not sure. Please call: 1-334-808-6576…
Q: How big are the graduate classes?
PaLM: The average class size for graduate computer science courses at Troy University is approximately 20 students.
Gemini: I am not sure. Please call: 1-334-808-6576…
Q: Can you give Python tutorials?
PaLM: Python is a general-purpose programming language that is designed to be easy to read and write…
Gemini: I am not sure. Please call: 1-334-808-6576…
Examples of questions where Gemini outperformed PaLM:
Q: What are the admission requirements for graduate students?
PaLM: To be considered for admission to a graduate program at Troy University, you must meet the following requirements…
Gemini: please check: https://www.troy.edu/applications-admissions/admissions-process-requirements/graduate/index.html

Q: Where can I find additional help on programming
PaLM: An error occurred: list index out of range
Gemini: You can contact the course instructors, tutors or use resources such as chatGPT or other generative AI (GenAI).

VII. Conclusion and Future Work

This paper presented a framework that integrates advanced AI models and vector databases to enhance the effectiveness of query retrieval in web development significantly. Our system leverages freely available tools, making it cost-effective and accessible for developers. The comparative analysis between PaLM and Gemini revealed their unique strengths: PaLM can learn from a few examples, which might be helpful for limited datasets. In contrast, Gemini focuses on factual accuracy and aims to reduce factual errors and hallucinations. Future work will involve comprehensive testing and evaluation of the system's performance across diverse user scenarios to ensure scalability and robustness. The system's effectiveness is highly dependent on the quality and comprehensiveness of the CSV data. Future work will explore techniques for continuous knowledge base improvement. Strategies for automatic data augmentation, user feedback integration, and potentially incorporating external knowledge sources to enrich the information available to the LLMs can be considered.

Designing a Conversational Agent for Education using a Personality-based Approach

Jieyu Wang, Jim Q. Chen, Dingfang Kang, Susantha Herath, Abdullah AbuHussein
Dept. of Information Systems, Saint Cloud State University, Saint Cloud, MN, U.S.A

***Abstract*—Conversational agents (CA) for education are the dialog systems that can interact with students intelligently. They are gaining popularity because of the potential benefits of education. However, there is very little research focusing on personality-based educational CA design. Therefore, we designed and built a high-fidelity educational CA prototype with four personality dimensions via Juji. This personality-based UX design supports the interaction between the CA and diverse users with eight personality styles within four dimensions. During the analysis and design phase, we extracted the keywords, attributes, distinctive behaviors, and interaction expectations to streamline the literal description of personalities into concrete design guidelines applicable to the prototype. The design guidelines were generated based on the extraction to specify interaction features, user expectations, and potential behaviors or actions that should be avoided. Based on the guidelines, we further developed four personality-based design logic in this integrated prototype. This work provides design guidelines for future user personality-based educational CA design. Moreover, the design is among the first group to provide four personality dimensions of design logic in one integrated prototype to better serve students. It sheds light on the future development of human-centred personality-based AI design in the industry while most chatbots are still rapidly developing.**

***Keywords*—Conversational agent/chatbot; personality-based UX design; human-centered AI**

I. Introduction

Artificial intelligence (AI) is growing to take more responsibilities in society. Amongst a wide range of applications for AI, conversational agents (CA) or chatbots are inevitably becoming popular considering their purpose of serving people. Recent studies have analyzed CA's characters to categorize them [1]. Since CA's main functions are designed to retrieve information, analyze data, and assist human decision-making, human-centered design is the proper approach [2].

Pioneer educators are using intelligent educational systems in education [3, 4, 5]. Groups of designers are still developing different conversational interfaces to help students and educators retrieve information and make decisions. While most research has been done to study how to simply support students' learning as a whole [4, 6,7], our study aims to promote the concept of designing CAs on a user personality-based approach. We designed and integrated four CA prototypes that address interaction with eight personality styles introduced in Hogan and Champagne's (1985) research [8]. We aim to provide user-centered design guidelines for educational CAs, specifically focusing on college students' diverse personalities so that CAs can provide equitable service to students. We also provide detailed design examples interpreted from Hogan and Champagne's (1985) theory for future CA design to better serve diverse users with different personality styles [8].

II. Related Work

A. Successful Cases and Error Handling of CAs in Education

Traditionally, one advantage of online learning over face-to-face education is audience coverage. However, this comes with the cost of insufficient interactions between students and educators, and therefore relatively poorer learning outcomes. CA is one possible solution to this disadvantage through providing individual interaction with students. To test the applicability of using CA in online learning, a research team created a CA and evaluated it in associated lectures. Through the evaluation of learning outcomes from 182 participants, the CA is guaranteed to have significant value in improving learning outcomes. This study provides valuable examples of successful implementation of CA for an educational cause that can be followed and studied in future design [9].

Another successful example of an educational conversation agent was constructed to support software engineering learning and coding skills. By identifying the major requirements and unifying teaching practices, Hobert was able to design and evaluate his teaching assistants that support students with the capability of consulting, programming tutoring, and submitting. His study provides valuable experience for other parallel user cases in programming. However, this study only targeted the beginning level of programming. The design was not promising for learning assistance in situations where access to educators is limited or absent. Theories and experiences documented from this study can be re-examined to guide future development and study of educational CA [6].

A teacher is not always available in all cases of education. In before-class learning of software testing or other situations where an accountable educator is absent to learners' questions, CA is one of the possible solutions that requires no additional human resources. These demands of self-learners serve as the motivation for Paschoal et al. (2019) to investigate the viability of implementing CA as an online tutor. The research contains two aspects, to evaluation of CA-generated answers to online courses and applicability as a learning assistant. The result suggests that this assumption is acceptable and applicable as self-learning guidance [10].

Moreover, to cover the shortage of tutoring resources in online learning, Song et al. (2004) developed a human-imitated conversation system. This system contains several modules that process the conversation from user input to system responses.

The simulation of the human tutor is empowered by natural language processing techniques. More importantly, this system is designed with minimum changes to existing tutoring materials and reuses some of the features from AutoTutor, which reduces the cost of development [11].

Tan's research team also aims to use CA to help undergraduates in mathematical learning. They introduced an experimental design to students and collected data from the follow-up questionnaires. The result from students reveals the positive effect of using CA to help in learning. Though this study may not apply to all undergraduate subjects, they believe it does provide valuable experience and suggestions for future developers and researchers on educational CA design [12].

However, we are far from perfect with the current CA design and therefore left space for errors. (Aneja) Five categories of errors have been organized. Each of them may lower human expectations and fail in human simulation. It is worthwhile for future designers and developers to pay attention to these errors and address them in CA design to provide a better user experience. As a support to other scholars, they have the dataset released for people to study and utilize academically [13].

Recognition errors are unavoidable with current technology and vital to user experience during interaction with CAs. Therefore, exception or error-handling skills significantly influence the ability of CAs. Oviatt et al. (1998) discovered three patterns of how people resolve errors. Participants will increase parallel linguistic statements and repeat correction steps. They may also extend over phrases and pauses and rely more on the overall meaning of the speech. They also reframe their input to reduce linguistic variabilities. All of these discoveries aid in enhancing the performance of AI and adaptation modelling [14].

B. Non-traditional CA Design in Education

Educational CAs are being viewed with the potential to revolutionize the education model we have had for centuries. Possessing expectations of high-quality performance that matches with traditional education style, numerous obstacles remain unsolved. Targeting project-based learning, Kumar's team initiated a study that systematically examined the possibility of improving learning outcomes based on teams. The experiment of two groups with a pretest-posttest design results in proof of the influence of educational CA over individual performance and indirect influence on team performance. This work adds to the knowledge base of educational CA design theory and strategy [5].

Conversational agents for education are highly applicable and necessary. Even though a general-purpose CA may satisfy the basic demands of users, it is not enough to help users meet their academic goals. A task-oriented design was presented and proved to be effective through implementation. The result provides evidence of the positive influence on learning outcomes by the CA in such a design. It provides designers and educators who investigate CAs specifically for educational purposes a start and direction to follow in the future [15].

Researchers are investigating a way to improve learning experiences for learners. Cai et al. focused on enhancing interactions in math courses. They performed three studies that observed user preferences between chatbots and traditional online learning (videos/lectures), the learning outcomes, and learners' needs. These results have been collected and analyzed to provide a personal learning experience for users in the following learning process. Contextual bandits had been applied to the design of the chatbot which suggested greatly improved the performance and increased learning outcomes. This research emphasizes the direction of personalized learning and the significance of data-driven frameworks in the design of educational chatbots [3].

C. Knowledge Base and Natural Language Processing in Educational CAs

Knowledge base management is important to chatbot design. A good knowledge base design can benefit users in information accessibility. The researchers designed a model to manage the knowledge base of a chatbot, aiming to help students access the knowledge of specific courses. This design allows a chatbot to take the role of a tutor to provide the required knowledge to students and enhance their learning experiences. The chatbot classifies user queries into different categories and extracts the related result from the knowledge base to provide a reply. The result and expert evaluation suggested that the proposed method worked effectively in retrieving knowledge and was helpful when working as a tutor to students [16].

Targeting user knowledge during a conversation could be one of the solutions for the finer design of CA. An et al. researched to discuss the influence of user knowledge on the interaction with CA. A recipient-centered design is proposed by the research team that significantly reduces conversational correction during the interaction. This methodology is then implemented into their CA and provides productive results [17].

Hussain et al. (2023) also introduced a prototype that embeds chatbots in specific courses to provide students with academic support. The research covers a system that processes natural language, question recognition, and generating answers from its knowledge base. A test of this system has been provided to demonstrate its functionality. This study explained how specialization of the database will improve student learning experience and outcome, and shed light on further chatbot design [7].

Most of today's chatbots are still using conditional conversations like if-then to process interactions. Kasthuri and Balaji (2023) introduced a new memory algorithm to enable the chatbot to handle a more complex conversation. This is a significant improvement in the performance of chatbots over language processing [18].

Researchers also designed a new style of conversation approach to focus on task performance and information queries. The research stated the shortage of traditional dialog style with a single dominant party in educational CA, in which the learner is much less motivated in the learning experience. Therefore, letting the bot and user selectively take turns as the dominance of communication will be a good option. The CA will be more active and engaged with the role of educator to better help in learning. This design and dialog style is vital to educational CAs in making improvements to learning experience and outcomes as it will expand the depth and width of interaction in the learning process [19].

D. User-centered Design

Using a chatbot to support learning can be one of the trends in modern education. The researchers introduced a tutoring agent that can sense user cognition and emotions during the interaction. It enables a user to start learning by participating in trialogues (interacting with two agents simultaneously) to support learning. By playing a different role in the interaction, the chatbot's service is more flexible. The trialogue design provides a new direction of how to construct the interaction with the human learner and how the chatbot provides a more appropriate style of learning for users [20].

Clark et al. (2019) criticized the methodology of emulation over speech patterns in the CA design process for lacking encapsulation during the conversation. They launched research to investigate the criteria of a good conversation in participants' value and the possibility of implementation. Ultimately the research results in the polarization of socialization and functionalization to human-computer interaction, which reveals the essence of utilitarianism. This also leads to the final decision to reconsider our recognition of CA interactions [21].

E. Ethical Concerns

The adoption of new technologies such as CAs is also a concern. It is quite necessary to understand what advantages a new technology or research builds upon the previous foundations or traditional ways. The possibility of replacing search engines with chatbots requires comparisons and analysis of the data on the learning outcomes of learners. Therefore, Han and Lee (2022) constructed an experiment that compares FAQ chatbot users with FAQ webpage users within two online courses. The result of the experiment suggests that FAQ webpages are more accepted than FAQ chatbots. The reason for chatbot users to rate the experience lower than webpage users consists of multiple facts involved from human-computer interaction to course context. It points out the importance of new considerations that might appear during the application of new technologies or the replacement of old ones [4].

With the advancing development of artificial intelligence, regulation over the practical application of AI is bringing into our ethical concern. The ability and capability of AI come with increasing hazards when abused. In contrast to the inadequate resources and support of AI ethics, Brendel's team attempted to establish a start on ethical research applied to AI and raise more opportunities. They constructed a framework of ethical regulation that focused on decision-making, ethical concerns, and dimensions of perspective. This framework provides future scholars with a better approach to investigating the ethical behaviors of AI [22].

As shown above, researchers have analyzed and designed CAs from the perspectives of success and errors, domain knowledge, natural language processing, tasks, ethical concerns, and users. Current research confirms that personality is an important factor concerning CAs [23, 24, 25]. Some researchers explore the personalities of CAs [1]. Some research studies the framework from the perception of users by applying the OCEAN personality model (The Big Five) [24]. However, there is little research presenting the educational CA design about how we serve students with different personalities better to enhance technology accessibility and digital equity. Our work aims to bridge this gap by presenting an integrated high-fidelity educational CA prototype with four personality dimensions to meet users' needs by applying Hogan and Champagne's (1985) theory [8]. This work is among the first to design an educational CA with a user personality-based approach. We hope our design guidelines and examples will shed light on the fast development of educational CA design.

III. METHOD

A. The Personality-based Approach

Our previous study showed there were differences in the task accuracies of users with different personality dimensions when they interacted with a CA [26]. In this study, we designed the integrated high-fidelity prototype based on Hogan & Champagne's (1985) four pairs of personality dimensions: introversion VS extroversion (IE), intuition VS sensing (NS), thinking VS feeling (TF), and perceiving VS judging (PJ) [8].

We start with analyzing Hogan and Champagne's (1985) personalities and generating design guidelines for each personality style (see Table I) [8]. Based on the guidelines we constructed the logical modes of our CA. We designed two educational tasks to allocate our design logic and conversational flows. The research team of this work regularly meets twice a week, discussing and interpreting the descriptions of personalities according to Hogan and Champagne's (1985) theory and applies them to design [8]. We reach agreements to generate accurate design examples and guidelines. According to our previous studies, we used Juji as our design platform [26]. Due to the limitation of data retrieval ability of Juji, we designed one task about the tuition inquiry and the other one about requesting information for an on-campus student organization.

TABLE I. PERSONALITY DIMENSIONAL PAIRS

PERSONAL STYLE INVENTORY SCORING SHEET

Instructions: Transfer your scores for each item of each pair to the appropriate blanks. Be careful to check the a and b letters to be sure you are recording scores in the right blank spaces. Then total the scores for each dimension.

Dimension		Dimension		Dimension		Dimension	
I	E	N	S	T	F	P	J
Item	*Item*	*Item*	*Item*	*Item*	*Item*	*Item*	*Item*
1b._____	1a._____	2a._____	2b._____	3a._____	3b._____	4a._____	4b._____
5a._____	5b._____	6b._____	6a._____	7a._____	7b._____	8a._____	8b._____
9a._____	9b._____	10a._____	10b._____	11a._____	11b._____	12a._____	12b._____
13a._____	13b._____	14a._____	14b._____	15b._____	15a._____	16a._____	16b._____
17a._____	17b._____	18a._____	18b._____	19b._____	19a._____	20b._____	20a._____
21b._____	21a._____	22a._____	22b._____	23b._____	23a._____	24b._____	24a._____
25b._____	25a._____	26b._____	26a._____	27a._____	27b._____	28a._____	28b._____
29b._____	29a._____	30a._____	30b._____	31b._____	31a._____	32b._____	32a._____
Total I____	Total E_____	Total N_____	Total S____	Total T_____	Total F _____	Total P _____	Total J____

Circle the **highest scoring letter** and place in the blank space for each paired dimension.

Now turn to page 4 and read your portrait based on your 4-letter personal style type.

I E = _____ N S = _____ T F = _____ P J = _____

B. The Integrated Prototype Design

Our integrated CA prototype was designed and constructed through an analysis of the descriptive keywords that appeared for each of the personality styles introduced in Hogan and Champagne's study [8]. Fig. 1 shows the integrated chatbot consisting of the I-E chatbot, I-S chatbot, F-T chatbot, and P-J chatbot, and the general-purpose chatbot for later comparison evaluation in future studies.

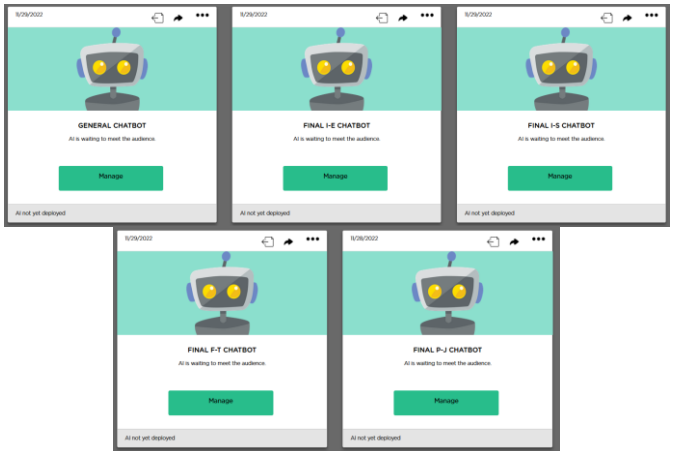

Fig. 1. Overall view of the integrated chatbot prototype.

IV. Results

A. General Design Guidelines

From the description, we extracted the keywords, attributes, distinctive behaviors, and interaction expectations for each of the personality styles through a series of brainstorming and research group meetings. The final set of descriptions will be used to guide the design of CA logic and interaction modes to satisfy users' needs (see Table II). The descriptions of the personality styles have been carefully evaluated by the research team members via several research meetings and discussions. We classified the components of descriptions to be either applied to software, or inapplicable and need to be set aside. We then design accordingly focusing on users' personalities by following the descriptions in this study.

For introvert and extrovert users, we modify CA replies to users that match the conversation behaviors of these two personality types. For intuitive and sensing users, we regulate the information quantity and level of detail provided for each query when interacting with different types of personalities. For feeling and thinking users, the CA is designed to include more feeling and feedback from other people in replies for feeling users or to include more logic, reasoning, or facts in replies for thinking users. Finally, for perceiving and judging users, we let the CA provide fewer but stronger suggestions to perceiving users to reduce the space of hesitation and indecisiveness, which presents a problem for this type of personality. For judging people, choices are made effectively, and suggestions are provided after each question and answer to maximize query outcomes.

B. The Introversion vs. Extroversion Design

The descriptions extracted for the Dimension IE can be formulated into two sets of logical and interaction modes. Introverted people are less likely to be affected by non-subjective factors that exist in their environment, relationship, or background [8]. The reflection on our design of CA would be to display the final output with sufficient information and interact with less desire to urge for a specific choice. Introverted people are also reserved in socialization. Taking this into consideration, the CA needs to interact with users in a mild but polite way to prevent an intimate atmosphere during the conversation.

TABLE II. Design Guidelines

Personality Dimensions	Description	Design Guidelines
Introversion – Extroversion	Introvert: "culture, people, or things around them. They are quiet, diligent at working alone, and socially reserved." Extrovert: "Extroverted persons are attuned to the culture, people, and things around them, endeavoring to make decisions congruent with demands and expectations."	Design guideline: the plain text is recommended. Design guidelines: may require more images and varieties.
Intuition-Sensing	Intuition: "The intuitive person prefers possibilities, theories, gestalts, the overall, invention, and the new and becomes bored with nitty-gritty details, the concrete and actual, and facts unrelated to concepts." Sensing: "The sensing type prefers the concrete, real, factual, structured, tangible here and now, becoming impatient with theory and the abstract, mistrusting intuition."	Design guideline: add organization description as "theory". Design guidelines: provide name, description, and events (as much information as possible).
Feeling-Thinking	Feeling: "As a consequence, feelers are more interested in people and feelings than in impersonal logic, analysis, and things, and in conciliation and harmony more than in being on top or achieving impersonal goals." Thinking: "As a result, the thinker is more interested in logic, analysis, and verifiable conclusions than in empathy, values, and personal warmth."	Design guidelines: provide participants/reviews feelings to arouse empathy. Provide member feedback together with information. Design guidelines: Use the if-else logic, and provide results that are more based on how the user can interact with the organization/ how college life will be like (analysis) based on different choices.
Perceiving-Judging	Perceiving: "The perceiver is a gatherer, always wanting to know more before deciding, holding off decisions and judgments." Judging: "The judger is decisive, firm, and sure, setting goals and sticking to them. The judger wants to close books, make decisions, and get on to the next project."	Design guidelines: We offer strong recommendations and help the user to successfully make final decisions. Design guidelines: we provide information instead of recommendations, and let users make decisions.

For example, the reply of CA to introverted users when answering cultural questions is designed to be polite and mild (see Fig. 2). After a user with an introvert attribute answers CA's question about interested culture, the user will receive a reply that explains the reason for this question with words that are polite and demonstrate mild emotion. Below is the reply after the user answers CA's question about the preferred culture in user the purpose of choosing a student organization. In this reply, we explain to the this question and express the will to maximize the user's experience in student organizations.

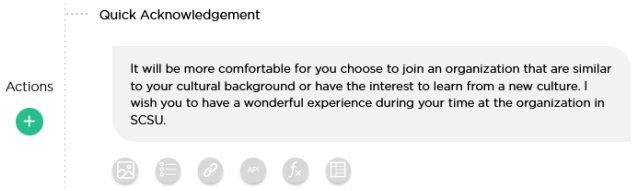

Fig. 2. Example of introvert I.

Another example where this similar feature was demonstrated was the reply to the last question to suggest student organizations (see Fig. 3). After students answered their preferred type of activities, the CA would explain the necessity of this question similar to the previous example. All other replies from CA to introverted users follow this pattern of controlling the level of intimacy with users.

Fig. 3. Example of introvert II.

Extrovert users are in the opposite status (see Fig. 4). They can easily adapt to their surroundings and can fit themselves during social contact [8]. The interaction mode of CA for such users should aim to create a passionate atmosphere that encourages close friendship. The conversation should be light, friendly, and information-rich. For example, the reply of CA to extrovert people is designed to demonstrate a closer friendship with the user. Replies to extrovert people will use words that express a closer relationship by including how the CA is asking this question to help the user have a better experience in the organization.

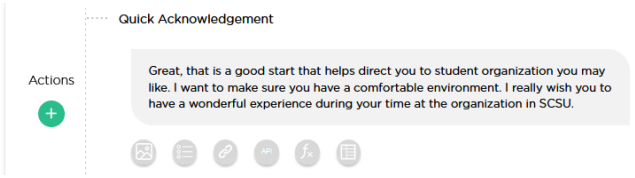

Fig. 4. Example of extrovert I.

Here is another example of a reply after the preferred activity question has been answered by the users (see Fig. 5). Student organizations may hold lots of different activities, and it may directly affect users' experiences in the organization. Therefore, whether the organization will hold the desired events that match user preferences or not is important and should be taken into consideration.

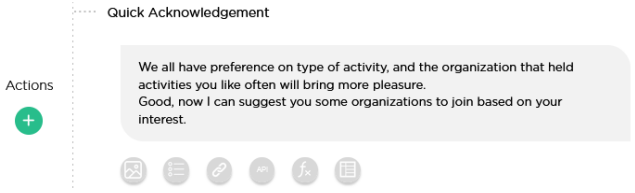

Fig. 5. Example of extrovert II.

The different replies based on personalities are to be triggered by user personality type, which is assigned by user input in personality check questions (see Fig. 6). In the Introvert-Extrovert prototype, the two possible values for personality types are introvert and extrovert. It will be used to guide the choice of CA replies in the guiding questions.

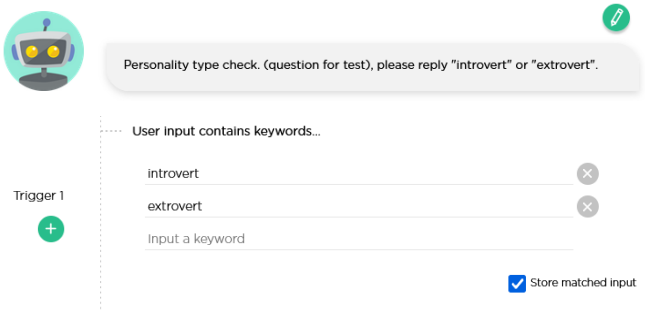

Fig. 6. Personality type selection.

After the user personality type attribute has been assigned, it will be used as one condition to trigger different chat flows that are designed with specialties for introverted people and extroverted people. Only one chat flow will be triggered at each time in each interaction (see Fig. 7).

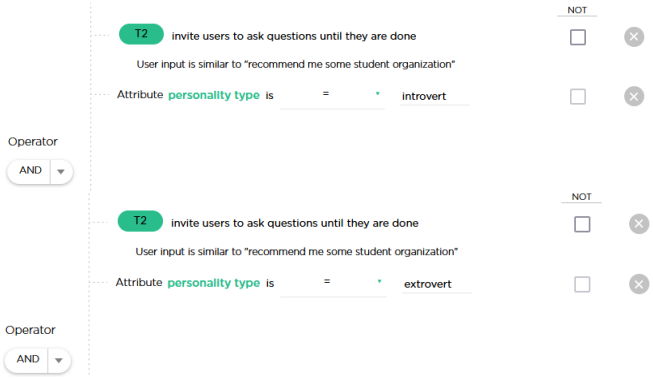

Fig. 7. Personality Conditions for introvert/extrovert.

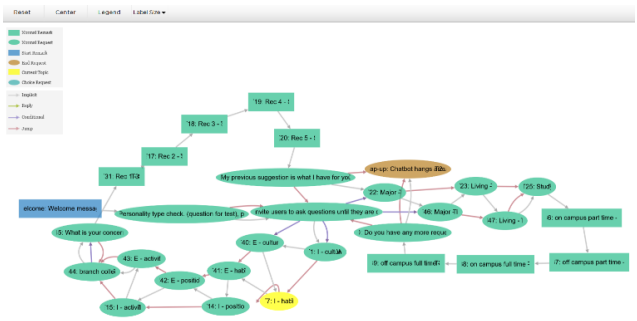

Fig. 8. Design logic of Introvert/extrovert.

Introverted and extroverted users will interact with the Final I-E chatbot. The general chat flow for both users will be similar with variations in reply. Starting with the welcome message, the CA will ask for the user personality type before the actual tasks begin so that different users can encounter different replies. Then the chat flow branches out based on the user's choice of tasks to perform. How the question will be asked by CA will be

based on the user's personality type attribute initialized after the personality type check. After all questions have been asked, the system will display query results based on attributes collected from previous questions (see Fig. 8).

C. The Intuitive vs. Sensing Design

The description of the personality dimension of Intuition – Sensing primarily focuses on information preference. When applied to our CA, this preference will result in different reactions provided by users. Based on the personality description, we interpret that intuitive users demand the key information, concepts, or theories from messages delivered and are not interested in complicated details [8]. This is a clear expectation for CA's replies. For intuitive users, CA should provide straightforward information that directly answers the question or expresses the central idea. Miscellaneous details should be reduced respectively. For example, if this H/G club from the final results for the student organization query matches with preferences and attributes of the intuitive user after all questions are answered, the output will contain only the organization name, a short description, a link, and a picture (see Fig. 9). This result fits with descriptions of intuitive people. All key information is covered in the result with no other complicated details. Another example that follows the same design principles is the output of Campus Recreation (see Fig. 10). It contains the same kind of elements that target only the key information of this organization to provide the concrete idea of this suggestion. All other organization query results are subject to the same style.

This feature is also applicable to other query results. For example, the output for intuitive people in tuition check provides only the calculation result and a link to a webpage of detailed tuition composition. No other details are presented. The calculation may vary depending on attributes from the user applied after all questions are answered, but all outputs targeting intuitive users will follow the same style (see Fig. 11 and Fig. 12).

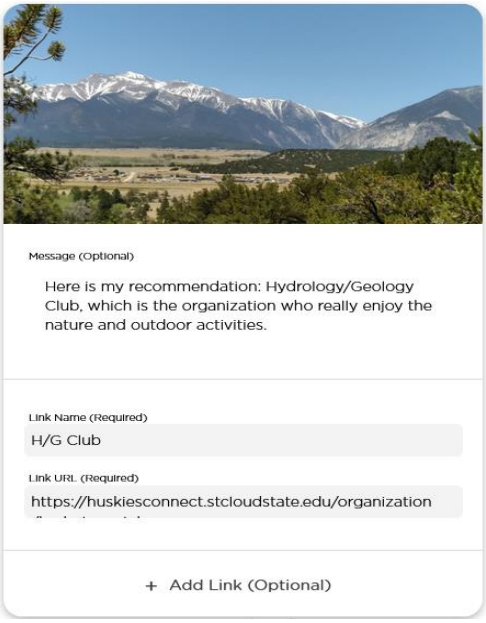

Fig. 9. Sample output-intuitive 1.

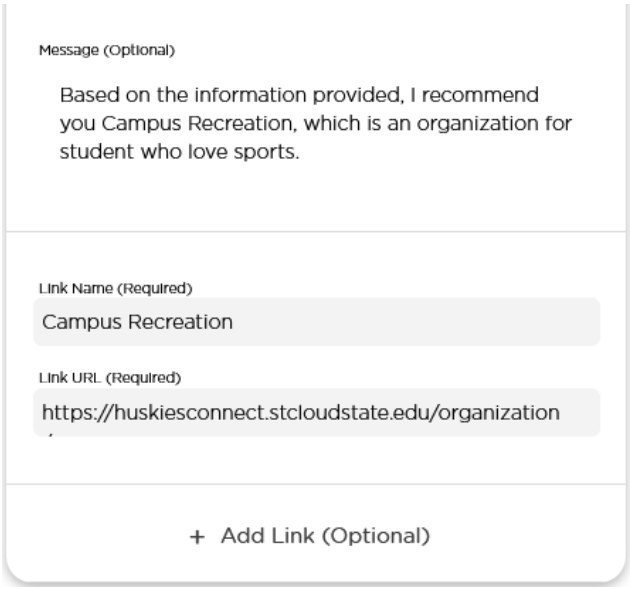

Fig. 10. Sample output-intuitive 2.

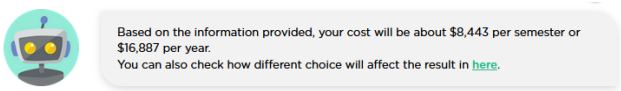

Fig. 11. Sample output-intuitive 3.1.

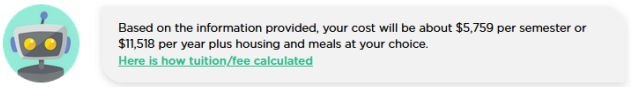

Fig. 12. Sample output-intuitive 3.2.

Sensing people need detailed information in contrast to intuitive people. They demand every piece of related information rather than abstractions that leave out something from the whole picture [8]. Replies to this kind of user for CA will need to provide full information that should not subjectively decide what the user may not need to know. Taking the example of the H/G club, the result of the student organization query for sensing users will contain much more information and more details compared to that of the intuitive output. Not only significant information should be covered, but also it should contain other supplementary information that can provide the user with a complete understanding of the organization in chat. This style of designed output fits with the preferences description of sensitive people (see Fig. 13).

Fig. 13. Sample output-sensing 1.

Here is another example of detailed output for sensing people that subject to the same design principles. We take the output of campus recreation again for comparison purposes. This is much more detailed than the output of the same organization targeting intuitive people (see Fig. 14).

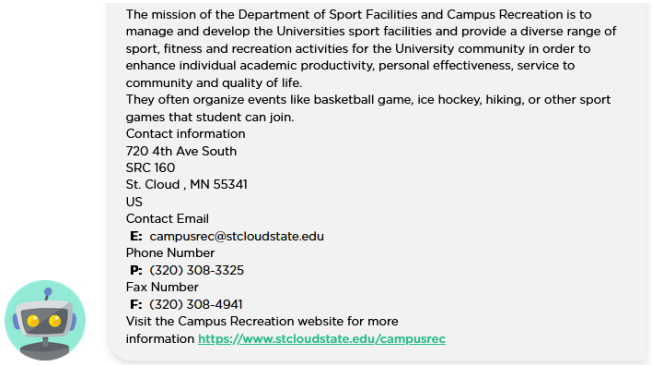

Fig. 14. Sample output-sensing 2.

When applying the same design principles to the tuition check query, we include the formula of the calculation into the output as supplementary information to increase user understanding of the result. Again, the calculation may vary depending on attributes from the user after all questions are answered. However, all outputs targeting sensing users will follow the same style (see Fig. 15 and Fig. 16).

The replies based on personality are to be triggered by user attributes assigned in personality check questions. In the Intuitive-Sensing prototype, the two possible values for personality types are intuitive and sensing. It will be used to guide the choice of CA replies in the final output. Guiding questions for both intuitive and sensing users are identical (see Fig. 17).

After the user personality type attribute has been assigned, it will be used as one of the conditions to trigger different outputs that are designed with specialties for intuitive people and sensing people. Only one output will be triggered at each time (see Fig. 18).

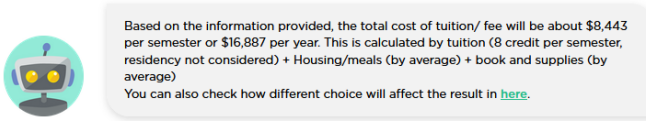

Fig. 15. Sample output-sensing 3.1.

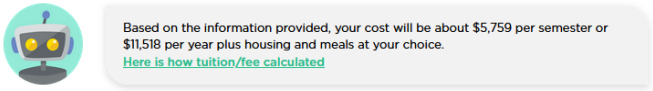

Fig. 16. Sample output-sensing 3.2.

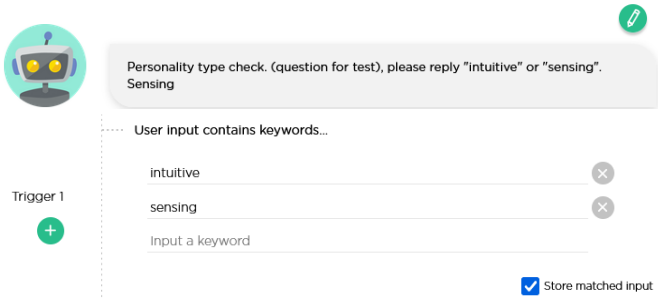

Fig. 17. Personality check for intuitive-sensing.

Intuitive and Sensing users will be interacting with the Final I-S Chatbot. Query results will depend on user attributes of personality styles that are assigned after the personality type check question. CA chat replies will be the same for both personality styles and vary only on the final output. Starting with welcome questions and personality checks, the user will need to select a task to perform. After the questions for either chat flow, the system will provide one output that matches user attributes collected from previous questions (see Fig. 19).

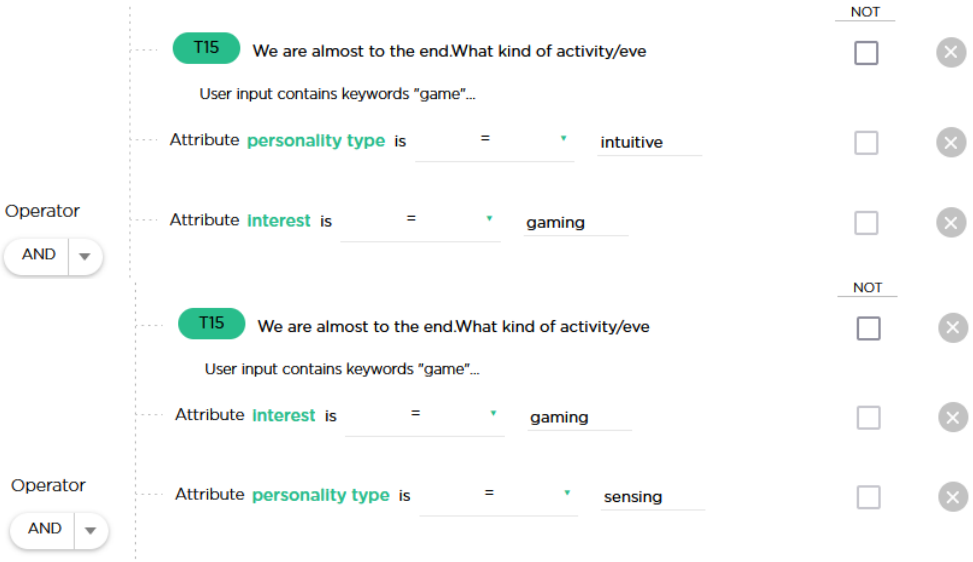

Fig. 18. Personality Conditions for intuitive/sensing.

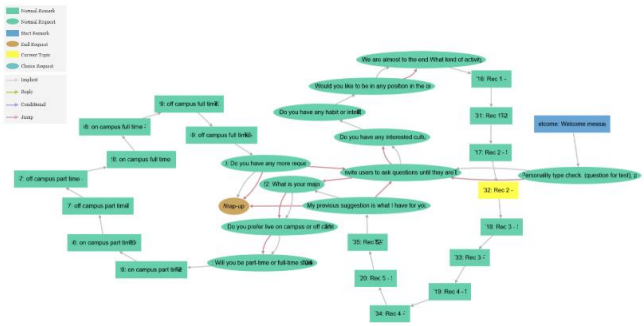

Fig. 19. Design logic of intuition-sensing.

D. The Feeling-Thinking Design

The description of Feeling-Thinking is not directly applicable as the previous two dimensions are. Feelers are more emotional and tend to favor humanistic reactions that address feelings. Thinkers on the opposite are more interested in logic-based suggestions [8]. When taking into consideration prototype design, CA would interact with perceptually feeling users and construct the reply to values more on emotions and feeling than logic and reasons. To think people, CA's replies must be supported by logic. The introduction of review and feedback from other people is necessary when interacting with feelers. And when interacting with thinkers, logic, and analysis weigh more than personal feelings.

This example demonstrates the replies based on feelings and reasons for the student organization recommendation (see Fig. 20). A suggestion that declares what experience would be more attractive to feelers. Therefore, replies to the feeler should include a description of what the experience will be like in the recommended organization.

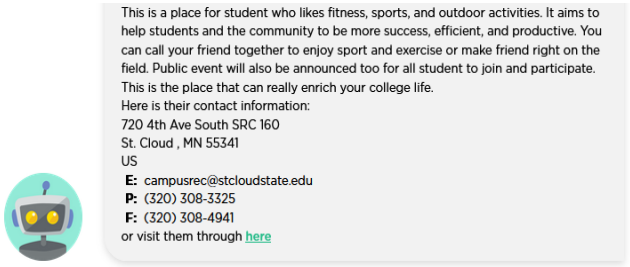

Fig. 20. Sample output-feeling.

However, thinkers would be more convinced by reasons why the organization meets their needs. In the description facing the thinkers, the functionality of the organization is introduced to demonstrate how might it fit with their preferences (see Fig. 21).

Taking another pair of organization query outputs as an example, we again worded the club description to focus on either experiences or functionalities (see Fig. 22). This feature is included in all student organization output.

As introduced in the previous two prototypes, the replies based on personality are to be triggered by user attributes assigned in personality check questions with 2 possible values — feeling and thinking. It will be used to guide the choice of CA reply in the final output. Guiding questions for both feelings and thinking users are identical (see Fig. 23).

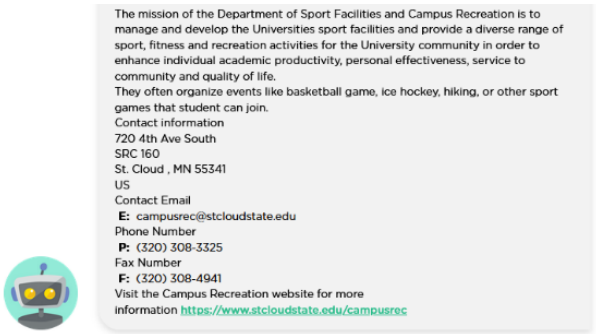

Fig. 21. Sample output-thinking.

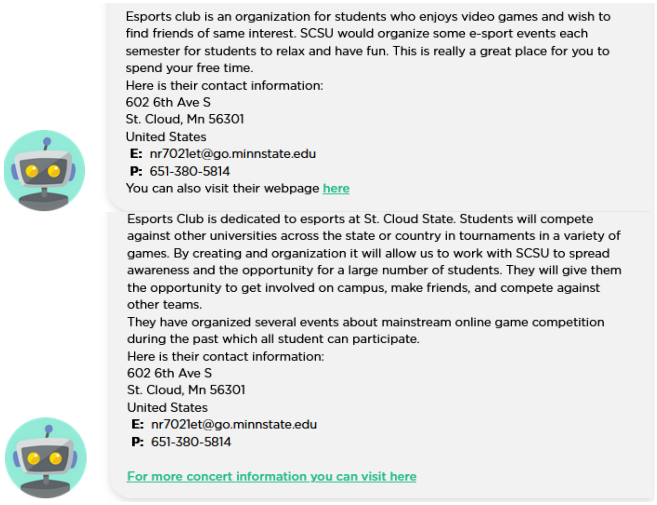

Fig. 22. Output comparison - feeling vs. thinking.

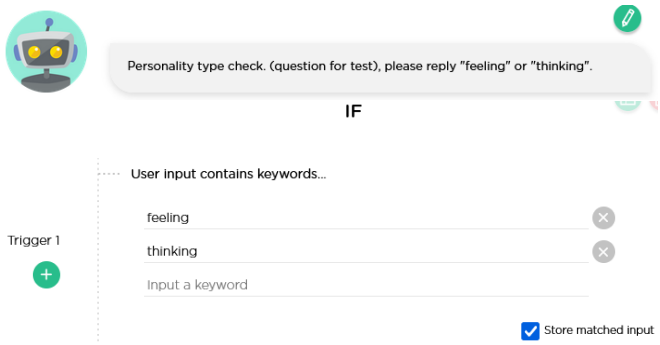

Fig. 23. Personality check for feeling-thinking.

After the user personality type attribute has been assigned, it will be used as one of the conditions to trigger different outputs that are designed with specialties for feeling people and thinking people. Only one output will be triggered at each time (see Fig. 24).

The prototype for Feeling-Thinking CA is embedded in the Final F-T Chatbot. The user will initialize the personality style attribute in the personality check question for CA to control the reply. The variation of this chat flow is primarily on the wording of query results. As users select tasks to be performed and answer the questions, the system will provide results that include descriptions that match with user preference tagged by their personality type. The flow chart resembles the one of Final I-S

Chatbot, but here the variation is based on information expression instead of information quantity (see Fig. 25).

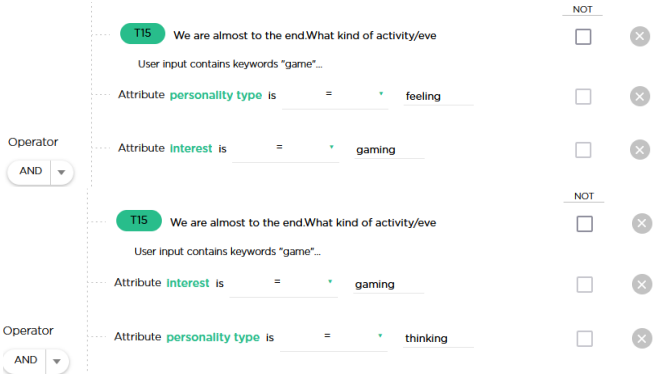

Fig. 24. Personality Conditions for feeling-thinking.

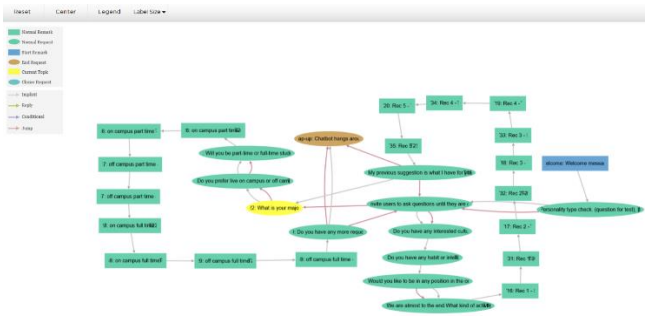

Fig. 25. Design logic of feeling-thinking.

E. The Perceiving-Judging Design

Perceivers by description are quite open to information from various perspectives and need to gather as much information as possible before making any decisions. They are cautious for each step. However, on the other hand, it can be hard for them to take the step and often become hesitant [8]. Our CA is addressing this issue by offering strong recommendations to push them to make decisions, or by restricting possible choices for perceiving users to limit the space for hesitation.

The perceiving people would require complete information as the sensing people do, but they may also encounter difficulties in making decisions and hesitation (). A reasonable solution would be to provide one suggestion with adequate information to prevent indecisiveness. Here is an example of output that contains the information of Esports Club (see Fig. 26). It contains descriptions and contact information. A link to the webpage is also provided for further interest.

Fig. 26. Sample output-perceiving 1.

Here is another example of organization output for perceivers containing the description and a link to the H/G club (see Fig. 27). These two examples, as well as other possible outputs for perceiving people, are embedded with the same level of detail as the output for sensing people. All the outputs for sensing users would also be appropriate for perceiving users due to the demand for detailed information mentioned in the descriptions for Perceivers.

Fig. 27. Sample output-perceiving 2.

Judgers will be the opposite of perceivers. They aren't as craving for complete information as perceivers, but they are good, determining decision-makers who seldom hesitate over the issue [8]. A CA needs to provide adequate information, as comprehensively as possible. It would be more appropriate to offer reasonable choices rather than streamlined options. An example to demonstrate the proper reaction to judging people would be providing multiple matched choices after each question is answered. This suggestion is provided by the system because the user declared an interest in Asian culture. Therefore, all matched organizations will be provided for this user to choose from (see Fig. 28).

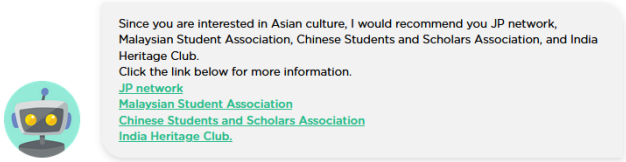

Fig. 28. Sample output-judging 1.

Here is another example of the outputs for judging people in the same question. In this case, user inputs demonstrate an interest in African culture. The outputs may vary depending on judging user input (see Fig. 29).

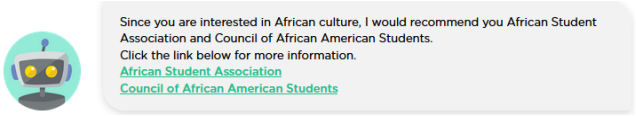

Fig. 29. Sample output-judging 2.

Such output is provided after each question is answered in the query. Here are other examples chosen from the outputs of another question for judging people (see Fig. 30). These responses will trigger when judging users demonstrate an interest in either gaming, hiking, or writing. Other responses will also be triggered through special keywords such as these examples as well.

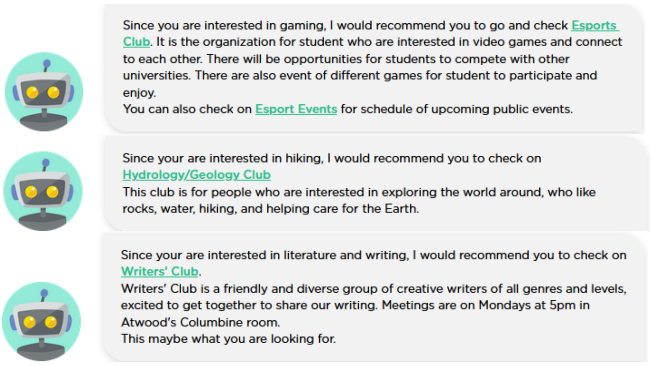

Fig. 30. Sample output-judging 3.

How chatbots reply to perceiving and judging users depends on user personality type attributes that are assigned through the answers to personality type check questions similar to the other three prototypes. The two possible values are perceiving and judging. The Chatbot will provide suggestions after each query question for judging users, or a single complete suggestion after all questions are done for perceiving users (see Fig. 31).

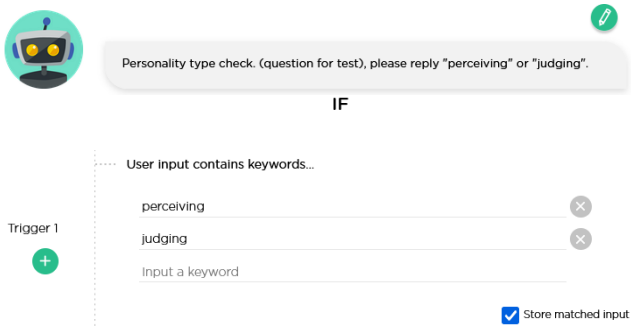

Fig. 31. Personality check for perceiving-judging.

For each of the questions asked, there is a reply waiting to be triggered if a user personality type attribute is judging. Here is an example of such a reply trigger after the question of user-interested culture. After user input has been stored as an attribute, it will be processed through verification for triggers (see Fig. 32).

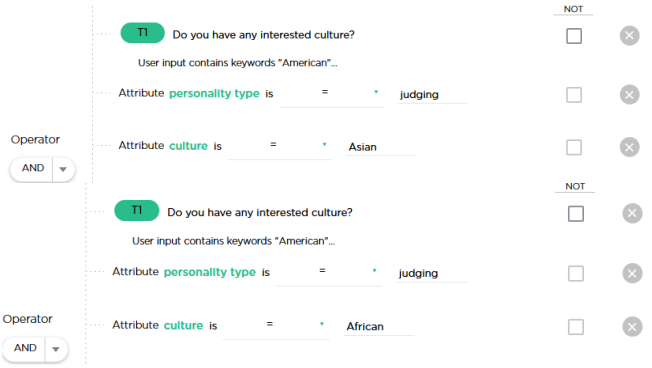

Fig. 32. Personality Conditions for perceiving-judging.

The difference between the chat flow of the two personality types is concentrating on the logic of demonstrating the query results. For a perceiving person, a strong recommendation of the best choice would significantly reduce space for hesitation and indecisiveness. For a judging person, a list of match results after each user attribute is assigned will be able to provide the user enough space to make decisions of one's own. After the start of the welcome message and personality type check, the user will choose tasks to be performed. A result will be triggered conditionally after each question based on whether the user is a judging person or not for the student organization task, and the final result will not be provided. In the tuition check task, the result will be displayed after the questions for both perceivers and judgers (see Fig. 33).

Fig. 33. Design logic of perceiving-judging.

V. Discussion

Our work provides design guidelines and examples to demonstrate how to design CAs based on a Hogan & Champagne (1980) personality approach [8]. We have designed an integrated prototype with four personality dimensions with different interactions with users with diverse personalities. However, there are challenges in the design process. For instance, even though the descriptions of the personalities in Hogan and Champagne's (1980) study were successful in transferring their concepts into understandable information [8], we have to further interpret the information when we transfer it into functional chatbots. The transition from personality description to features in the chatbot undergoes multiple stages of evaluation by the researchers. The original description must be separated into individual units that represent a possible feature that will appear in the final product. For example, here is part of the description for intuitive people:

"The intuitive person prefers possibilities, theories, gestalts, the overall, invention, and the new and becomes bored with nitty-gritty details, the concrete and actual, and facts unrelated to concepts" [8].

We interpreted this description and generated two sets of keywords. The first set of keywords suggests the preferred form or type of feedback and information received from the chatbot. The second set of keywords stands for the form and type of feedback to be avoided in chatbot responses for the intuitive personality. After identifying the component in this description, we have reviewed the extracted subject and re-evaluated it for the possibility of applying it to the actual product and the cost to do so. Not all the described characteristics are applicable to our design. The two sets of keywords will be applied to the prototype responses accordingly. We have to abandon those that don't fit with the design. Of the applicable features, some of them will be implemented into the design logically. We also need to adjust the original chat flow for almost all the personality prototypes to

satisfy users' needs. We realized applying the same chat flow is not a proper solution. For example, perceivers are not as deceived as judgers and are relatively less efficient than judgers. There could also be different preferences on the level of detail in the responses received. The design of the chat flow for each personality is required to moderate the response and its level of detail. Such reflections on design are also applied to other personalities. Moreover, the platform we used to develop our prototypes also contains limitations. Juji is easy to use, yet sometimes too simple and not flexible enough to implement a design. We had to use an alternative solution to accomplish desired outcome. However, our work aims to present a detailed example to demonstrate how to design CAs with a personality-based approach by providing design examples and guidelines.

VI. Conclusion

With the fast development of chatbots, CAs are unavoidable to play an increasingly significant role in our education. Designing CAs based on students' personalities is crucial for education equity. This paper presented detailed guidelines and examples illustrating how to design chatbots with a personality-based approach. We hope this work will shed light on future CA design for education.

For future work, a comparison study will be conducted to evaluate the integrated personality-based design to the general design. Thirty college students with different personality styles will be recruited to evaluate this prototype and compare it to a general design. This study will use quantitative and qualitative methods to analyze the experiment data. This personality-based design and evaluation of CAs will bring a new focus to the user-centered AI design field.

A Quantitative Study on Real-Time Police Patrol Route Optimization using Dynamic Hotspot Allocation

Rakesh Ramakrishnan, Soumithri Chilakamarri, Roopalatha Mangalseth Budda, Ashik Dawood Mohammed Anifa
Department of Information Technology, University of the Cumberlands, KY, USA

***Abstract*—A quantitative study on the optimization of police patrol routes in real-time using dynamic hotspot allocation is presented in this article. Ensuring public safety necessitates addressing the difficulties law enforcement agencies encounter in optimizing patrol routes within limited resources. In dynamic environments, static patrol route planning and traditional random routing are inadequate. In order to prevent crime, this study suggests using big data analysis to pinpoint crime hotspots and create patrol routes that are most effective. Our suggested approach, when paired with the Random Forest algorithm, predicts crime-prone areas by combining 911 incident response data and crime datasets. This allows for the efficient use of police resources and successful preventive measures. A greedy algorithm is used to steer patrol units toward the best routes, maximizing their presence close to hotspots. Besides, a Hamilton way is powerfully made based on overhauled hotspots and crisis call hubs. Whereas the spatial selection technique addresses restrictions of randomized investigation, productive policing remains pivotal for societal well-being and financial development. Progressions in innovation enable decision-makers with real-time data on criminal exercises, guaranteeing resource-friendly strategies inside budgetary imperatives. Successful communication with the public is crucial, as security impacts different perspectives of society, including venture choices. Hence, cutting-edge approaches are crucial for informed decision-making and keeping up with general security.**

Keywords*—Route optimization; redesigning police patrol; data-driven strategies; novel patrol routing; random forest; real-time crime prediction; crime data; 911 incident response; hamilton path

I. Introduction

The primary significance of this study lies in its imaginative approach to real-time police patrol route optimization utilizing dynamic hotspot allocation [1]. Existing literature frequently lacks comprehensive techniques to address the impediments of conventional patrol strategies, especially in dynamically changing situations where criminals adjust their behavior. This think about bridges this gap by proposing a strategy that integrates big data analysis, prescient policing algorithms, and real-time information to optimize patrol routes viably.

Police service has to build resilience to known and unknown human events, including crime. Criminals also constantly change depending on their environment and how the police service responds to emergency services or crime cases [1]. Developing and embracing technology to identify crimes easily and react as quickly as possible is a great resource. Preempting future crimes and their attendant consequences ensures that the potential impact is lessened, thus promoting public safety and security. Police officers have to be at the right place at the right time and use the right tools, devices, and equipment to arrest criminals [1]. Information is power, but how the information is received is much more important to deter crime. Route optimization for patrols can be achieved with increased funding for police technology [1]. The police force must also be enabled to learn how to utilize technology to deter crime in the main crime hotspots. Technology assists in positioning the officers through configuration; hence, they will be able to respond to incidents early and efficiently. Predictive policing could be another subtle term for route optimization, as it is easier to control and direct police patrols [1].

Dispatchers currently identify the crime hotspots and direct the police to respond or direct the response units. Whenever the crime response units are not attending to an incident, they patrol the same crime scenes to deter crime [1]. In hotspots, the earlier the police can respond to an incident, the more likely an area will have tranquility compared to areas where the police do not respond promptly to crime alerts. Apart from deterring crime, the police on patrols must be positioned in configurations that enable them to promptly reach the areas in demand [1].

The current practice still needs to demonstrate that there are a lot of challenges or issues associated with the response unit in their patrol areas. Route optimization, therefore, will assist in implementing methods of mapping crime scenes and configuring the hotspots to assist the police personnel on patrols. Real-time positioning will help avoid any variability while bolstering proactive positioning and allocating enough police personnel for patrol tasks. The practice now is that the rapid response to a crime scene or crime hotspot is at least three hours, but with route optimization, the response time will be reduced to less than three hours [1]. This research proposes real-time positioning to optimize police positioning in crime hotspots using real-time information.

The value added by this paper lies in its inventive approach to real-time police patrol course optimization utilizing dynamic hotspot allocation. Not at all like other papers, this work emphasizes the need to preempt future violations and their results to advance public security and security viably [1]. By leveraging innovation to distinguish crimes effectively and respond rapidly, this investigation proposes a strategy that diminishes reaction time to crime episodes, improving, by and

large, watch productivity. The presentation highlights the special commitment of this thinking in tending to the challenges related to conventional watch strategies and emphasizes the significance of proactive situating and allotment of police staff in crime hotspots.

II. Background

The study addressed several challenges faced by the Atlanta Police Department's design of patrol zones, which are discussed in the piece. A quickening population growth rate, shifting demographics and traffic patterns, and an uneven distribution of the policing burden among regions are some of these difficulties. Due to these elements, some areas saw increased crime rates, and emergency call response times were lengthened, especially in urgent situations like violent crimes [2]. The article also emphasizes that APD has problems finding and keeping officers to handle the increased workload. By redistributing police workload and speeding up response to emergency calls, the suggested data-driven optimization framework seeks to resolve these difficulties.

This article explores the challenges law enforcement organizations experience when planning patrol routes that will best enable them to respond to urgent reports of crimes. The paper demonstrates the shortcomings of conventional patrol route planning techniques and suggests data-driven strategies for improving patrol routes [2]. Urban environments are dynamic, necessitating real-time data to successfully optimize patrol routes, which is one of the difficulties mentioned in the study [3]. The article suggests using machine learning algorithms to examine prior criminal activity, movement patterns, and emergency contact data to forecast upcoming illegal activity and patrol routes.

By redesigning police patrol areas in cities using optimization techniques, it is possible to handle another issue raised in this article: the need to balance police workload across regions and speed up response to emergency calls. The article emphasizes that law enforcement organizations must implement data-driven strategies to optimize patrol routes and improve public safety [4].

III. Problem Statement

The problem of efficient patrol path generation for police officers to ensure public safety is given limited police resources [3]. Traditional random routing is limited by providing police presence during crime events. The problem with static patrol route planning is that it needs to consider the constantly changing environment and dynamic human activities in urban areas that can influence crime patterns [4]. There is a need for optimal police patrol routes in a dynamic environment that considers real-time sensor data and human mobility data. The problem is coordinating police officers to visit time-dependent crime hotspots to prevent crime occurrences and attend real-time emergencies [3].

There is a need to leverage human movements, specifically location-based social network check-in data, to better predict crime hotspots in the next time interval. The problem is generating an initial patrol strategy using prediction results and continuously refining the route based on real-time demand from emergency call data. The goal is to minimize an area's crime risk in a time interval and the time of traveling. New evaluation methodologies and metrics are needed to evaluate the effectiveness of dynamic police patrolling route planning using real-world data. The study aims to utilize the potential of big data analysis to identify crime hotspots in actual police policy and generate optimized patrol routes for crime prevention [1].

IV. Research Questions

Some of the research questions that this paper aims to address are as follows:

- How can proactive patrolling be one of the notable methods used by the security sector to facilitate action that can help counter the cases to ensure that critical offenses and offenders suspected of crimes such as human trafficking, drug trafficking, terrorism, and other major violations if not contained can lead to severe threats to national security?
- Can crimes easily be tracked using records from the relevant databases?

V. Existing Case Studies

A. Novel Patrol Routing Framework using Hotspots and Traffic Data

In study [5], the authors proposed a novel patrol routing approach using hotspot areas and traffic data. The authors implement the routing in two phases: Identifying the hotspot locations based on crime and various community data and optimizing hotspot location patrol. The study implements data collection, preprocessing, and correlation analysis in the first phase to discover hotspots. The study collects data from four data categories: Crime, Building, Population, and Environment. The preprocessing step involves grouping data based on geolocation into grids and categorical to numerical data conversion. After preprocessing, the authors utilize the Pearson correlation coefficient measure between community and crime data to measure the correlation strength in each grid area. The study also factors data set size in each grid as density measurement to classify specific grid locations as hotspots.

In phase 2, the authors use a genetic algorithm to determine the optimal routing pattern between the hotspots. The study's fitness function is to reduce the response time and length of the patrol route. The authors run the genetic algorithm until it converges to find the most significant fitness function, thereby obtaining the optimized patrol route [5]. The authors evaluate their proposed novel approach using real-time traffic data. Furthermore, they consider the fitness function by comparing the random traffic data to the optimal traffic data. The results show a response time save of 3000 minutes for response time at all test locations. The study has multiple shortcomings, including choosing Pearson coefficient correlation, lack of quantitative measures to evaluate the algorithm performance, and insufficient preliminary analysis and decision choice explanation in choosing the genetic algorithm.

B. Data-Driven Police Route Optimization Framework

In the second case study, we explore a survey that uses a Data-driven routing and Optimization framework to redesign

police patrol routes [4]. The authors developed a stochastic model for routing and implemented their framework in the city of Atlanta. As per the study, the current method for police zone design in Atlanta is based on historical boundaries and does not embed crucial factors such as crime incidence or population demographics. The current approach causes suboptimal allocation of police resources and increased crime rates. The study proposes a data-driven optimization approach that includes crime incidence-impacting factors, such as population density, median household income, education level, and school enrollment. The dataset consists of emergency call data (911 data) and data from the American Community Survey.

The study first builds a transition matrix with saturated and unsaturated states based on travel time, call arrivals, and service rates. A police dispatch unit can have either an upward transition state that denotes a transition from an unsaturated to a saturated or a downward shift that represents a transition from a saturated to an unsaturated state. The authors use a spatiotemporal model with maximum likelihood estimation as the cost function. Finally, the authors evaluate their model using real-world data from Atlanta and compare its performance to the existing design. They found that their approach reduced crime rates by up to 9% in some areas and increased police efficiency by reducing incident response times. Although the study's model incorporates comprehensive features and evaluates its performance on real-world data, it relies on numerous assumptions that do not always comply with real-world situations. The premises include an equal number of police beats for each city zone, the closest police dispatch on emergency calls, and the First-In-First-Out (FIFO) rule on backlogged calls.

C. Real-Time Predictive Patrolling Framework

In the third case study, we review a paper that proposes a new approach to optimizing law enforcement patrolling and routing using real-time spatiotemporal data from various sources [2]. The study aims to improve the effectiveness and efficiency of law enforcement efforts, particularly in identifying and deterring criminal activity. The authors developed a Real-Time Predictive Patrolling and routing (RTPR) system that incorporates data from multiple sources, including emergency calls, police vehicle GPS locations, and historical crime data. The authors propose a two-phase framework: criminal activity prediction and patrol route optimization.

The RTPR system uses a dynamic greedy approach to find the optimal patrol routes using various factors such as the dispatch vehicle availability, response time, and the likelihood of criminal activity. The model uses a Random Forest classifier to predict regional hotspot zones. After hotspot prediction, a greedy algorithm optimized the patrol routes within hotspots and emergency calls. The cost function approach is to collect the maximum reward with minimal travel time. To evaluate the RTPR system performance, the authors apply the model to real-world data from Seattle and Melbourne. The quantitative evaluation metrics for comparison include robustness, efficiency, and idle.

The results show that the proposed framework achieves high efficiency and idle times compared to traditional greedy algorithms. Although the study proves that the data-driven optimization approach can reduce crime rates and improve police efficiency, it must comprehensively evaluate the system. For example, the study does not address potential unintended consequences, such as increased police surveillance in specific neighborhoods or changes in community dynamics due to changes in police resource allocation.

VI. Proposed Approach

A. Crime Event Prediction

We have compiled a range of features to serve as predictors in our crime event prediction model, encompassing historical, geographic, and mobility factors. To ascertain the density of crime incidents at nodes following temporal intervals, we draw upon historical crime data, including venue type, spread, and regional variety. Subsequently, a random forest (RF) algorithm [6] was employed to identify and forecast potential hotspot nodes during the subsequent time interval, owing to its non-parametric nature and applicability in a wide range of heterogeneous and multidimensional feature environments.

B. Patrol Route Planning Algorithm

A version of a greedy algorithm from the crime prediction may be used to optimize police patrol routes to achieve the greatest reward with the fewest number of trips. This method considers various data, including patrol start and end times, cumulative transit time across nodes, and the average time police officers spend at each node. Furthermore, a function is used to evaluate the significance of individual patrol nodes and factor this into the result [7], ensuring that nodes of crucial importance are considered and accounted for and allowing the algorithm to recognize suitable routes for beat cops through frequent updates regarding 911 emergency response occurrences and potential criminal hotspots.

VII. Dataset Preliminary Analysis

A. Crime Data

Using data.seattle.gov/Public-Safety as our source, we have retrieved and are now reviewing the columns of the crime dataset. This dataset provides an in-depth look at crime in Seattle, detailing the Report Number, Offense ID, Offense Start and End times, Report, Offence, and Precinct information, as represented in Table I.

The data collected from police reports, renowned for their accuracy, has resulted in high reliability. An analytical data review has been conducted to ensure it is comprehensive and correct. This data contains much information concerning the incidence of more than one million criminal acts in Seattle between 2007 and 2013.

In Fig. 1, from 2007 to 2013, there were more crimes related to property than crimes concerning persons.

Fig 2 shows the distribution of the crimes per month across the year.

In Fig. 3, we can see the distribution of the number of crimes based on .their types.

TABLE I. CRIME DATASET

Column Name	Column Description
Report Number	Primary key/UID for the overall report. One report can contain multiple offenses, as denoted by the Offense ID.
Offense ID	Distinct identifier to denote when there are multiple offenses associated with a single report.
Offense Start	Start date and time the offense(s) occurred.
Offense End	End date and time the offense(s) occurred, when applicable.
Report Date	Date and time the offense(s) was reported. (Can differ from date of occurrence)
Group A B	Corresponding offense group.
Crime Against Category	Corresponding offense crime against category.
Offense Parent Group	The parent group of the offense.
Offense	The offense carried out in the crime.
Offense Code	Corresponding offense code.
Precinct	Designated police precinct boundary where offense(s) occurred.
Sector	Designated police sector boundary where offense(s) occurred.
Beat	Designated police sector boundary where offense(s) occurred.
MCPP	Designated Micro-Community Policing Plans (MCPP) boundary where offense(s) occurred.
100 Block Address	The offense (s) address location blurred to the one hundred block.
Longitude	Offense(s) spatial coordinate blurred to the one hundred blocks.
Latitude	Offense(s) spatial coordinate blurred to the one hundred blocks.

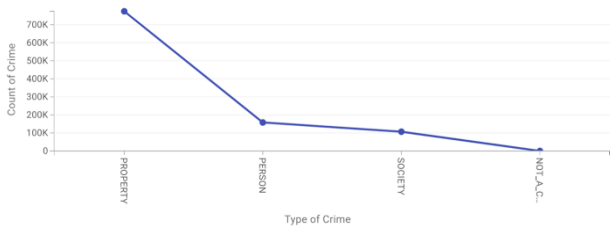

Fig. 1. Crimes against category.

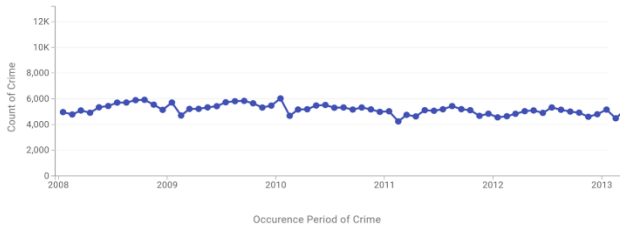

Fig. 2. Crimes against year.

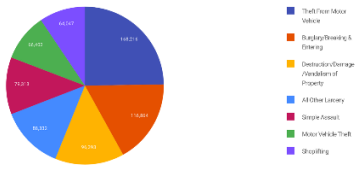

Fig. 3. Types of crimes.

Fig. 1 shows that the number of crimes against the property exceeds 700K, and Fig. 2 shows that the number of crimes in the city fluctuates between 4000 and 6000 crimes.

B. 911 Incident Response

We have retrieved the 911 incident response data and will review the crime dataset's columns. This dataset, represented in Table II, provides an in-depth look at crime incidents in Seattle, detailing further information on the incident.

TABLE II. 911 INCIDENT RESPONSE DATASET

Column Name	Column Description
CAD	Computer-Aided Dispatch is a software system used by police dispatchers to receive and process 911 calls. CAD ID identifies the calls.
CDW ID	Crime Data Warehouse Identifier is a unique identifier assigned to each incident reported to the Seattle Police Department.
CAD Event Number	The event number associated with the CAD
General Offense Number	The corresponding offense number.
Event Clearance Code	Event Clearance Code refers to the status of an incident after the police have responded to it.
Event Clearance Description	Corresponding description.
Event Clearance SubGroup	Corresponding sub-group of the incident.
Event Clearance Group	Corresponding group of the incident.
Event Clearance Date	The date on which the incident was cleared.
Hundred Block Location	The offense (s) address location blurred to the one hundred blocks.
District/Sector Zone/Beat	Corresponding zone of the incident.
Census Tract	The occurrence incident occurred within a specific census tract.
Longitude	The longitude of the event location.
Latitude	The latitude of the event location.
Incident Location	The corresponding event location.
Initial Type Description	The initial type description of the event location.
Initial Type Subgroup	The initial type subgroup of the event location.
Initial Type Group	The initial type group of the event location.
At Scene Time	The time at which the officer responded to the scene

VIII. RESEARCH FINDINGS AND DISCUSSION

Our proposed method, along with the Random Forest algorithm, can be used to predict areas where crimes are likely to take place. Consequently, a score can be assigned to each city location, indicating the probability of a crime occurring in that area [8]. As a result, police resources can be deployed more productively, and preventive measures can be taken more effectively. Subsequently, after the initial hotspots have been identified, patrol units can be directed toward the most suitable patrol routes. Such routes are selected using a greedy algorithm that maximizes the patrol unit presence close to the hotspots. Furthermore, the records associated with each node are exclusively dependent on the criminal history that has taken place in that specific node. This approach does not change the route plan based on a dynamic emergency call. However, we

consider dynamic emergency calls that might come in. Finally, a hamilton path is created based on the hotspots and emergency call nodes while considering the dynamically updated hotspots [9].

The development of the suggested method started with a thorough evaluation of various algorithms appropriate for optimizing police patrol routes in real-time. Following a thorough analysis of recent research and methodologies, it was determined to make use of both random forest and ravenous computations [8]. Although the ravenous calculation was chosen for its suitability in optimizing patrol routes using the most recent crime information, the random forest was chosen for its ability to manage large datasets and intricate relationships between factors. Later, a number of intricate procedures were included in the information preprocessing organization to guarantee the accuracy and quality of the dataset. This involved removing anomalies or outliers from the data and creating current highlights to gather useful information for course optimization.

A thorough validation process was carried out to ensure the proposed method's accuracy and reliability. A validation dataset comprising authentic crime information from a representative urban range was chosen for intensive investigation. This dataset was chosen to include a wide variety of crime occurrences, including different crime categories and geographic regions [8]. A set of assessment measurements was utilized to survey the proposed method's execution. These metrics—accuracy, accuracy, review, and F1-score—offered numerical evaluations, assessments, and appraisals of how well the method anticipated crime hotspots and optimized patrol routes. In arranging to set up a standard by which to degree the execution of the recommended procedure, the validation was too different from those of other approaches. This comparative analysis made the focal points and impediments more clear.

The efficacy and performance of the suggested methodology were assessed by contrasting it with current practices. The effectiveness of various techniques, including static patrol route planning and conventional random routing, in identifying crime hotspots and maximizing patrol routes was evaluated [8]. The comparative analysis demonstrated that the suggested methodology exhibited superior performance compared to conventional methods concerning precision, efficacy, and overall crime prevention outcomes. The suggested methodology was shown to be superior in real-time police patrol route optimization by this comparative analysis, which also offered insightful information about the advantages and disadvantages of various approaches.

IX. Conclusion

Crime is a primary setback that every country must address before it becomes problematic to society. With proper patrol services, the security sector can curb the offender's activities that often threaten economic growth and well-being. The well-thought placement of officers has been deemed one of the strategies that can help the sector realize its long-term security goals. Also, having proper and advanced techniques can provide real-time information on criminal activities. This is of the essence as it helps the responsible officers to take charge of the needed actions. This is also a resource-friendly tactic, ensuring the sector stays within the budget. While the method has been used to cater to the security needs in society, it is still not the most ideal as it is associated with some limitations, such as a randomized method in choosing the problem areas, leaving out some areas that might be affected more than the ones selected. The spatial selection method has been regarded as the method that can rule out the limitations linked to the randomized analysis of the problem areas. Policing must be efficient as it aims to attain its intentions. Modern advances have acted as a stepping stone for the key players to make the needed decisions on the ideal techniques that can help all the concerned players. The public, the sole beneficiary, must also be informed on the key issues that aid the processes. Most operations and activities depend on the nature of the countries' security. Investors, for instance, must be keen on the nature of the security before investing in their preferred ventures. The fact that they are interested in the overall outcomes means they must properly conduct reconnaissance to identify the loopholes that can disadvantage them in the long term.

***Abstract*—The growing number of people gathering in public and the massive incidents that have occurred in recent years. It raises questions about public safety and security. This paper illustrates the technical implementation of the operator machine augmentation resource (OMAR) framework, which integrates advanced technologies, including a Computer Vision model and CCTV operators' training techniques, to address the limitations of traditional surveillance systems. The OMAR framework enhances the productivity of surveillance systems by facilitating operators' tasks and improving theirs. The framework's components, including Alert Triggers, a Computer Vision model, and human training, work together to create better output, and a more convincing system will improve the quality of security and reduce human effort. Although the OMAR framework represents a potentially significant step forward in surveillance security systems, it remains a theoretical model requiring further investigation and rigorous testing. Future work will focus on evaluating the effectiveness of the OMAR framework through an empirical study, examining its impact on various aspects of human performance and adaptations.**

I. Introduction

In today's increasingly complex and connected world, the need for vigilant and continuous monitoring is undeniable. Crowd monitoring systems, particularly CCTV, have long been integral to security strategies, but the human operators behind these systems often face challenges in maintaining performance over prolonged periods. Recognizing the limitations of human operators, recent advancements have increasingly integrated intelligent surveillance technologies, like computer vision models, to augment human capabilities [1].

Originally, surveillance relied solely on human operators, but the integration of artificial intelligence (AI) has significantly transformed the field. AI in CCTV systems enhances surveillance by automating the analysis of video data, thus reducing the workload on human operators and improving overall efficiency [2]. Despite AI's ability to enhance data processing and event detection, its effectiveness is maximized when used in conjunction with human oversight. Human operators are still crucial for handling complex decision-making processes and responding to unpredictable scenarios.

In surveillance contexts, the scope of monitoring extends beyond mere criminal activities to encompass all instances of abnormal behavior. Abnormal behavior in public settings, demonstrated by erratic or aggressive actions, can sometimes present more significant risks than conventional criminal acts, like the tragic incident that happened during the Hajj pilgrimage in Makkah in 2015 [3]. The tragic incident highlights the critical need for vigilant and responsive surveillance systems. The incident that occurred in Makkah in 2015 emphasizes the necessity for a comprehensive surveillance strategy that effectively integrates AI technology with the essential oversight provided by human operators. The surveillance strategy, which blends AI technology and human operators, aims to enhance the system's accuracy and adaptability. A hybrid surveillance strategy system reduces the likelihood of errors and increases the system's efficacy in managing diverse and complex security situations [4]. A hybrid system blend of AI and human input ensures that surveillance systems are adept at managing both regular and exceptional security challenges, making them indispensable in modern security strategies.

II. Objective

The integration of AI into surveillance systems represents a transformative leap in the security domain, enhancing both the efficiency and the effectiveness of monitoring operations. The objective section of the paper will explore AI technologies' multifaceted roles in augmenting human operators' capabilities within security frameworks. By utilizing advanced AI, surveillance operations can surpass traditional limitations, offering precision and swiftness in addressing security threats and incidents. AI transforms surveillance systems by introducing real-time data analysis, enhanced object recognition, and active monitoring, significantly boosting the accuracy and response times to potential threats. For example, AI-enabled cameras actively analyze footage to detect unusual activities, thus allowing for immediate intervention. Such hybrid systems can accurately differentiate between types of movements and objects, cutting down on false alarms and enabling a more focused approach to real threats [5]. The comparison between operators working with and without AI assistance highlights the substantial enhancements brought by technology. AI aids in quickening response times and increasing detection accuracy, thus supporting human operators in maintaining robust security standards effectively. AI's role is transformative, redefining the operational dynamics of surveillance tasks and setting new standards in security protocols [2]. Moreover, the development of specific AI algorithms tailored for critical and

large-scale environments, like the Holy Mosque, emphasizes the customized application of AI in surveillance. These algorithms are finely tuned to detect subtle and context-specific behavioral cues, thus enhancing the sensitivity and accuracy of surveillance in areas with significant cultural and religious importance. Additionally, the impact of AI on the workload and stress levels of operators is profound. By optimizing AI system designs for enhanced operator comfort and effectiveness, surveillance tasks become less brutal and more efficient, potentially improving job satisfaction and reducing staff turnover. The combination of AI and human operators underscores the human-centered approach in designing AI surveillance systems, ensuring they support rather than replace the human element [4]. The deployment of AI technologies in surveillance systems offers substantial enhancements in these systems' operational effectiveness and technical capabilities. Through sophisticated analytics and adaptive learning algorithms, AI enables a responsive surveillance mechanism that significantly aids human operators in executing their duties with unmatched precision and efficiency. This integration marks a significant advancement in surveillance technology, promising marked improvements in security, safety, and operational efficiency across various settings.

III. The Role of AI in CCTV Systems

A. AI in CCTV System

AI-enabled CCTV systems represent a significant leap forward in surveillance technology, offering capabilities for monitoring and threat detection. These intelligent systems are engineered to scrutinize video footage in real-time, utilizing deep learning techniques to discern patterns and behaviors indicative of potential security breaches or emergencies [6]. AI comprises sophisticated algorithms that can analyze body language, facial expressions, and movement trajectories, distinguishing between normal and suspicious behaviors with a high degree of accuracy [7]. This integration of AI into CCTV systems, with these features, allows for the automated detection of a wide array of activities, ranging from violence in crowded spaces to unauthorized access in restricted areas. Therefore, the integration of AI into CCTV systems enables automated detection of diverse activities, enhancing surveillance capabilities for proactive threat identification and security management. The real-time processing power of AI significantly enhances the responsiveness of surveillance systems. In scenarios where every second counts, such as detecting a left-behind package in a busy terminal or identifying an individual brandishing a weapon, AI-driven CCTV systems can alert human operators instantaneously [8]. For example, they can monitor the speed and direction of individuals in a crowd, flagging those moving against the flow or at an unusual pace, which could indicate a person in distress or someone with malicious intent [9]. This rapid identification enables quicker decision-making and potentially life-saving interventions [10]. The efficacy of these systems is not just theoretical; empirical research has demonstrated their robustness in various settings, including community spaces and transportation hubs, where they have been instrumental in maintaining public safety [11]. Therefore, leveraging AI-enhanced surveillance systems is adept at recognizing subtler nuances of human behavior.

B. Efficiency

The integration of advanced AI within security and surveillance frameworks has indeed brought about a significant transformation in the industry. This transformation can be observed in various aspects of security and surveillance systems, including but not limited to threat detection, monitoring, and response mechanisms [12]. A prime example of such innovation is the development of AI-powered Intelligent Surveillance tools that incorporate the YOLO (You Only Look Once) algorithm. This framework processes images in real-time, simultaneously identifying and classifying multiple objects [13]. It divides the image into a grid and predicts bounding boxes and probabilities for each grid cell. The predictions are then filtered through non-maximum suppression to provide the final detection outcomes [13]. This approach allows YOLO to detect objects with high precision rapidly, making it an ideal choice for surveillance in densely populated areas where efficiency is crucial. Consequently, AI-driven security technologies significantly bolster operational efficiency.

C. Accuracy

The advent of AI has led to substantial enhancements in the effectiveness of monitoring systems, particularly by minimizing erroneous alarms. Conventional security setups often face challenges with excessive false alerts, which may result in unwarranted responses and fatigue among security staff. AI algorithms are designed to learn from extensive data sets, allowing them to differentiate between real dangers and harmless irregularities with greater precision [14]. Employing advanced learning models, such as CNNs, enables these systems to analyze and assess video footage instantly, delivering prompt and precise evaluations [6]. Furthermore, AI-based surveillance mechanisms are not static; they evolve continually, thereby increasing their accuracy over time. This adaptive nature means that they become more familiar with the unique settings they oversee, leading to fewer false alarms. Consequently, incorporating AI into surveillance provides a more effective way of protecting public areas.

IV. Challenges Associated with Sole AI Operation

A. Lack of Contextual Understanding

The challenge of contextual understanding in AI, particularly in surveillance, is a significant hurdle researchers and practitioners are trying to overcome. AI systems, including those used in surveillance, excel at identifying patterns and correlations but often lack the depth of understanding necessary to accurately interpret complex human behaviors and contexts. This limitation can lead to misinterpretations and inappropriate responses, as AI may not discern the subtleties of cultural differences or non-threatening unusual behaviors [15]. For example, an AI surveillance system might flag a janitor standing still as a potential threat, failing to recognize the context that the individual is merely performing their job duties. As such, bridging the gap between pattern recognition and contextual understanding is paramount for the responsible deployment of AI in surveillance, ensuring accurate interpretation and appropriate responses to diverse human behaviors.

B. Privacy Concerns

The incorporation of AI into facial detection systems within CCTV networks presents significant privacy issues [16]. In numerous regions, regulations explicitly forbid the use of facial data in software applications. As noted by scholars and privacy advocates, the deployment of AI surveillance systems that operate without human intervention exacerbates these privacy concerns. A key issue is the potential for these systems to autonomously collect and analyze extensive amounts of personal data without sufficient oversight or consent, mainly when such data includes facial recognition information [17]. The demand for security systems that utilize AI while protecting human privacy is now more critical than ever.

V. Human-AI Synergy

A. Human-AI Collaboration

The relationship between human thinking and AI systems is a topic of continuing discussion. AI systems can make better choices than people in certain circumstances, but people can make superior decisions when judgment is needed [18]. In addition, people interpret information within a framework of social values, cultural influences, and unique life experiences, enabling them to make decisions that are both complex and context-dependent [19] [20]. Human involvement is particularly essential in scenarios requiring ethical sensitivity, empathy, and moral discernment. For example, while AI can detect trends and highlight irregularities in monitoring activities, the human operator can evaluate the purpose behind actions, recognize special situations, and make choices that uphold privacy and individual freedoms. Thus, academic discussion suggests AI should enhance human decision-making rather than take its place.

B. Human Training and Competency

1) System proficiency: The skill level of CCTV operators in leveraging AI-based tools plays a crucial role in the successful operation of surveillance systems. Skilled operators grasp the complexities of AI systems, adjusting settings and fine-tuning the technology to reduce false alarms and improve precision. Their knowledge ensures that AI processes the most pertinent data, eliminates irrelevant information, and zeroes in on significant occurrences [21]. Additionally, capable operators interpret AI alerts with context, considering aspects such as the time of day, location, and setting. Their judgment helps avoid unnecessary actions while promptly addressing legitimate threats. Skilled operators act as a link between AI data and practical measures, weighing urgency and potential risks to determine if an alert should be escalated [22]. Their expertise and insight contribute to the overall efficiency. Therefore, CCTV operators must be trained for proficiency.

2) Situational awareness and skill development: The ability to perceive and understand the situation is a crucial part of a CCTV operator's duties. It entails knowing the area under surveillance and being capable of analyzing the importance of specific actions or events. Training in situational awareness provides operators with the capability to evaluate the seriousness of dangers and foresee possible problems ahead of time, resulting in a security approach that is more preventative than reactive [23]. Additionally, cultivating skills that align with AI is an important aspect of training for CCTV operators. Even though AI can recognize a variety of behaviors and irregularities, there may still be subtle indications that require human judgment. Operators need to be skilled at spotting these subtle distinctions that AI may miss. Therefore, the synergy between human expertise and technological capabilities is crucial for an efficient surveillance approach.

C. Challenges without AI Assistance

The transition from manual video review to AI-backed video analytics has significantly accelerated the monitoring and detection of the targeted process, allowing operators to focus more on critical details rather than being distracted by others unnecessarily [24]. Secondly, human operators can lose focus or become distracted while monitoring camera feeds, leading to missing crucial details. Thirdly, another significant challenge is human reaction times are slower than AI algorithms, which can cause delayed responses and impact emergency interventions or crime prevention. Therefore, the integration of AI technology with CCTV systems mitigates human limitations.

VI. Operator Machine Augmentation Resource

The OMAR framework represents a significant advancement in enhancing operational efficacy for CCTV operators. It has been systematically engineered to optimize task workflows and elevate overall performance metrics within surveillance systems. This innovative framework integrates advanced methodologies supported by sophisticated artificial intelligence models, reflecting recent developments in AI-driven surveillance technologies [25]. Additionally, it includes comprehensive training tailored explicitly for operators, which has been shown to augment human performance in surveillance environments [26]. This holistic approach ensures that the Omar framework not only harnesses the latest technological advancements but also substantially enhances the skill set of the personnel involved, thereby increasing the number of hits and response times of surveillance operations.

A. Detection Model

The Detection Model is a critical component of the CCTV hybrid model, designed to analyze live video efficiently feeds by combining the strengths of artificial intelligence (AI) and human operators. The model leverages advanced machine learning techniques to automatically detect and annotate objects of interest in real time while also providing a seamless interface for human operators to review and validate the AI-generated annotations.

1) Technical architecture: The technical architecture of the Detection Model is composed of several key components that work together to enable efficient and accurate video analysis. The following diagram illustrates the interactions between these components (see Fig. 1).

The architecture consists of the following main components:

- **LiveFeed**: This component is responsible for capturing and transmitting live video data from CCTV

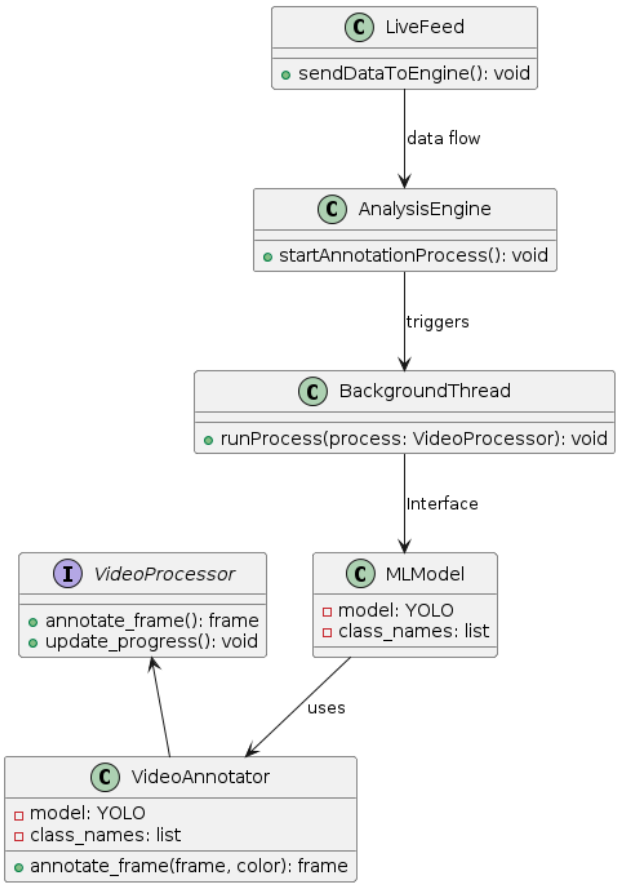

Fig. 1. Detection model's technical architecture.

cameras to the AnalysisEngine. It continuously sends video frames to the AnalysisEngine for real-time processing and annotation.

- **AnalysisEngine**: The AnalysisEngine is the central component that orchestrates the video analysis process. It receives live video data from the LiveFeed and triggers the annotation process by initiating a BackgroundThread.
- **VideoProcessor** (interface): The VideoProcessor interface defines the common methods that need to be implemented by the video processing components, such as annotating frames and updating progress. It serves as a blueprint for the MLModel and VideoAnnotator components.
- **MLModel**: The MLModel component implements the VideoProcessor interface. It utilizes a pre-trained machine learning model to automatically detect and annotate objects of interest in the video frames. The MLModel operates in the background, processing the video frames efficiently.
- **VideoAnnotator**: The VideoAnnotator component is responsible for providing a user interface for human operators to review and validate the annotations generated by the MLModel. It allows human operators to manually annotate frames, add additional annotations, or modify the existing annotations as needed. The VideoAnnotator uses the MLModel to obtain the initial annotations and then presents them to the human operator for review and refinement.
- **BackgroundThread**: The BackgroundThread component is responsible for running the video processing tasks in the background. It takes an instance of the VideoProcessor (MLModel) and executes the annotation process asynchronously, ensuring that the main application remains responsive.

2) User flow: The user flow of the Detection Model is designed to provide a seamless experience for both AI-assisted and human-operated video analysis. The following sequence diagram illustrates the user flow and interactions between the various components (see Fig. 2).

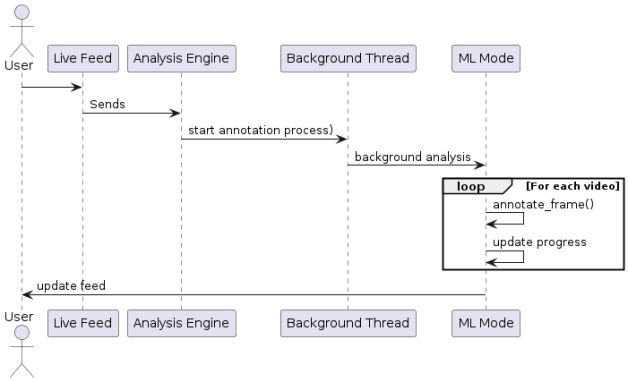

Fig. 2. Detection model's user flow.

The user flow consists of the following steps:

1) The User initiates the live video feed, which the LiveFeed component captures.
2) The LiveFeed sends the video data to the AnalysisEngine for processing.
3) The AnalysisEngine starts the annotation process by triggering the BackgroundThread.
4) The BackgroundThread utilizes either the MLModel or the VideoAnnotator, depending on the mode of operation, to perform the video analysis.
5) The MLModel annotates each video frame using the pre-trained YOLO model.
6) The MLModel updates the progress of the annotation process.
7) The annotated video frames are returned to the User interface for real-time display and further analysis.

The Detection Model's architecture and user flow demonstrate the effective integration of AI and human expertise in the CCTV hybrid model. By leveraging the strengths of both machine learning and human operators, the Detection Model can provide accurate and reliable video analysis, enhancing the overall effectiveness of the CCTV system in detecting and responding to objects of interest [22].

3) YOLO: OMAR framework uses YOLO model. It is a state-of-the-art object detection system renowned for its speed and accuracy. It processes images in a single pass,

predicting bounding boxes and class probabilities directly from full images in one evaluation, making it significantly faster than systems that propose regions and then classify them [27]. This efficiency enables YOLO to achieve high frame rates while maintaining good accuracy, making it particularly well-suited for real-time applications such as video surveillance and live video analysis [28] [29].

The OMAR framework signifies a state-of-the-art integration of computer vision and graphical user interface technologies tailored for video content analysis using the YOLO object detection model. The framework initializes a robust logging system to capture detailed debug-level data, which is essential for troubleshooting and development purposes. The core of the OMAR framework functionality resides within the analysis engine, which processes the frames coming from the live feed, transfers them to the YOLO model, and applies them to video frames to detect and annotate objects. Each frame is processed to draw bounding boxes, and label detected objects with class (behaviors) names, enhancing the raw video data with valuable contextual information. The annotations are performed frame-by-frame, with properties such as frame dimensions and frame rate meticulously extracted using OpenCV, thereby preserving the video's original specifications in the annotated output.

Furthermore, the OMAR framework is designed with a user-friendly interface using Tkinter. Tkinter is a standard GUI toolkit for Python. It enables the development of user-friendly graphical interfaces in Python applications. Tkinter is included in the Python standard library, making it widely accessible and straightforward for creating desktop applications [30]. An intuitive and straightforward user interface lets users observe annotated videos through a simple GUI and provides near-real-time updates. The OMAR framework design facilitates ease of use and supports asynchronous processing by employing threading, thus maintaining UI responsiveness. The framework is particularly suited for safety environments where processing large video datasets for object detection and tracking pilgrims is essential, offering a practical tool for CCTV operators to evaluate situations and perform actions directly on video.

B. Human Training

The performance of CCTV operators is markedly improved when they receive comprehensive training. Adequate training endows operators with the essential skills to proficiently monitor and analyze surveillance footage, enhancing their ability to detect and swiftly respond to suspicious activities accurately. It has been observed that CCTV operators exhibit superior performance when they clearly understand their objectives and some specific indicators [31]. The OMAR framework emphasizes key elements that are crucial for effective surveillance operations:

1) Work environment: The OMAR framework prioritizes comprehensive training to ensure that CCTV operators deeply understand their working environments, recognizing how such knowledge significantly enhances their performance and effectiveness. Moreover, experienced CCTV operators quickly identify crucial aspects of their tasks earlier than their less experienced peers, suggesting that targeted training substantially improves their operational capabilities [32]. Further studies have been conducted, delving into the daily challenges and practices of these operators, highlighting the critical need for a thorough grasp of their work environments to ensure effective surveillance [33]. The OMAR framework aims to comprehensively cover this aspect of training, ensuring that all operators gain a thorough knowledge of their work environments, thereby enhancing their ability to monitor and respond to incidents effectively.

2) Job roles: The OMAR framework is intended to elevate the competencies of CCTV operators, ensuring they comprehend the full scope of their professional duties. This understanding is crucial for boosting their performance and improving their decision-making skills and overall well-being. Operators can effectively execute their roles and responsibilities by implementing appropriate training strategies and harnessing their experience. This comprehensive approach fosters a well-rounded development, ultimately enhancing efficacy and accuracy.

3) Skills and competencies: The OMAR framework is designed to cultivate a comprehensive set of skills and competencies in CCTV operators, which are crucial for effective surveillance, crime prevention, and prompt response. This training enhances operators' proficiency in handling sophisticated surveillance technologies and focuses on developing their overall capabilities through targeted training programs, competency assessments, and skill development initiatives.

4) Nature of the place: The OMAR framework training program equips CCTV operators with a deep understanding of the environments they monitor, which is essential for effective surveillance. This contextual awareness enables operators to differentiate between normal and suspicious activities, optimizing their monitoring efforts and enhancing response times. Familiarity with the environment also helps reduce false alarms and improve the coordination of responses. Additionally, operators trained in this way can identify potential vulnerabilities and recommend proactive security measures. By incorporating this environmental knowledge into training programs, the OMAR framework ensures that CCTV operators are well-prepared, efficient, and practical, ultimately contributing to a safer and more secure environment.

VII. Conclusion and Future Work

The OMAR framework, as articulated in this paper, represents a comprehensive and innovative approach to surveillance monitoring systems. By harnessing advanced technologies, such as machine learning and specialized training techniques, the OMAR framework establishes a reliable and confidential monitoring system designed to enhance safety and security. The framework's components are intricately integrated to form a cohesive and efficient system that encourages optimal performance among CCTV operators. Specifically, the OMAR detection model identifies and alerts operators to abnormal behaviors, while the training component is designed to enhance human motivational factors for CCTV operators. Additionally, the Computer Vision Model enables continuous behavior recognition, improving user experience by accurately identifying anomalies within crowds. Although the OMAR framework marks a significant advancement in

surveillance and security system interventions, it is important to acknowledge that it remains a theoretical construct at this stage. Its potential applications and impacts necessitate further exploration and rigorous testing. This paper does not declare the achievement of specific outcomes; instead, it aims to delineate the implementation of the OMAR framework. Consequently, future research will concentrate on empirically evaluating the effectiveness of the OMAR framework. This research will investigate the framework's influence on various aspects of user experience to ascertain its efficacy in enhancing surveillance systems. Future studies will assess the OMAR framework's impact on human performance levels in comparison to traditional surveillance systems. Additionally, these studies will examine the framework's effects on performance, visual discrimination, cognitive load, trust, and confidence. In conclusion, the OMAR framework offers a promising solution to the challenges faced by security systems. Through rigorous testing and refinement, we aspire to contribute to a future where advanced artificial intelligence technologies and effective human training interventions are accessible, fostering a safer and more secure public environment.

***Abstract*—Knowledge-based authentication systems are the most common methods used to verify users' identity, especially textual passwords. However, periodic changes in password complexity exacerbate human's limitations of remembering hard passwords over time. Therefore, a novel authentication method called Word Pattern Recognition Textual Password (WPRTP) was proposed to overcome these issues. WPRTP is based on drawing pattern on a grid with a specific security requirement to balance between usability and security. This paper aims to compare WPRTP with a recall passphrase to explore its potential for enhancing user experience, usability, and security. Fifty-four users evaluated the efficiency of WPRTP on memorability, registration time, and login time. The results indicated that WPRTP is significantly more memorable over long-term periods, with a 100% success rate, and required less registration time (29 seconds for WPRTP and 122 seconds for recall passphrase). Additionally, WPRTP users demonstrated faster login times (20 seconds for WPRTP and 42 seconds for recall passphrase). Thus, WPRTP is a potential alternative to conventional authentication methods. Future work will focus on systematically managing and reducing the tendency among users to depend on familiar, repetitive patterns in the creation of a weak password.**

***Keywords*—Authentication; password; passphrase; recognition; recall; pattern; usability; security**

I. Introduction

Authentication systems have been devised to prevent unauthorized access to sensitive data by verifying the user's identity before granting access to a system or application. Several authentication methods have been established, such as knowledge-based (e.g. username and password), biometric (fingerprint), and token-based (e.g., identification card) [1], [2]. Previous research has suggested many options to replace knowledge-based systems to enhance the security by utilizing tokens (e.g., smart cards) for authentication. However, the additional hardware required for utilizing tokens that could led to lose access to credentials if the device gets lost or stolen[3]. As another alternative, biometrics (such as fingerprints) are effective for device authentication. However, they are not easily replaceable if compromised or harmed [4]. Still, alphanumeric passwords, as one of the knowledge-based authentication systems, remain the most commonly used compared to others, particularly for online and computer applications services such as cloud services, email, and shopping [5], [6]. Nevertheless, individuals often face difficulties remembering complicated alphanumeric passwords. This causes them to either choose simple passwords or write their passwords down [7], which can cause serious security threats. These drawbacks have led to the proposition of an alternative technique called a passphrase [8], [9], [10], [11].

A passphrase is a concatenation of multiple words or phrases in a natural language, which can be easier to recall than a conventional password [12]. A study has shown that passphrases provide less cognitive effort than standard passwords, and it does not need to be changed as frequently as standard passwords [13]. In addition, longer passphrases expand the password space, enhancing their resistance against brute force attacks [14]. Unfortunately, empirical evidence has demonstrated that users commonly generate easy passphrases that include common words, typically according to patterns found in natural language [15], [16]. Moreover, a long passphrase increases typographical errors, thus causing an increase in unsuccessful login rates [17], [18]. Therefore, users usually tend to use most commonly phrase or simply reuse them with a slight change for several accounts which cause high cognitive load, potentially resulting in password fatigue and creating weak passwords vulnerable to various attacks[19].

Recognition-based textual password, that is passwords based on selecting words from predetermined list of words, are proposed to address the inherent weaknesses of recall textual password systems (traditional and passphrase password), including the cognitive effort required for memorization. This approach has been examined with two different strategies: system-assigned and user-chosen recognition-based textual passwords. The system-assigned strategy is usually more secure due to its reduced predictability and resistance to common human errors, such as selecting easy passphrase [20], [21], [22], [23]. Unfortunately, adopting this method often compromises memorability [8], requiring more training time to improve user retention [24]. On the other hand, the user-chosen passphrase is frequently based on personal selection, which may cause a security issue if a predictable passphrase is chosen [25], [26]. A physiological study comparing user-chosen and system-generated passphrases found that user-created passphrases produce fewer cognitive load stressors on working memory than system-generated passphrases [27]. Consequently, this study proved that user-chosen passphrases significantly had higher recall performance than system-assigned passphrases.

The comparison of the efficiency of different textual authentication systems (both recognition and recall) revealed

that user-chosen recognition textual passwords can offer a higher memorability rate compared to recall passphrase, as they leverage human memory's strength in recognizing familiar information in long term memory [25]. Reducing the cognitive load can enhance security practices by encouraging users to create complex passwords. This approach still needs further research regarding the balance between usability and security simultaneously. WPRTP is proposed as a novel method that can stimulate human memory by combining recognition and pattern-based strategies, and this way, potentially improving retrieval performance and at the same time increasing the password space.The study primary goal is to address the challenge of password creation and recall, where users struggle to balance memorability and security, often resulting in vulnerable choices, cognitive strain, and frequent resets that compromise overall system integrity.

II. Literature Review

The literature review focuses on knowledge-based authentication systems, specifically the system-assigned and user-chosen textual password approaches. This section will discuss these two systems to provide an overview of their security implications, usability, and effectiveness of the authentication process.

A. System Assigned Textual Password

A study assessed the memorization of system-assigned traditional passwords and passphrases and showed that passphrases had a recall rate of 51% and passwords had a recall rate of 65% [28]. This study indicated that a comparable levels of user frustration and inconvenience, causing most users to write down their passwords. Another study examined the efficacy of textual passwords with three different categories: word recognition (passphrase), letter recall, and word recall (passphrase) with a 29-bit theoretical password space, finding no significant differences in memorability between the categories but the recognition password had significantly fewer password resets compared to word recall [20]. Another approach known as a gridWordX was proposed as hybrid knowledge-based authentication scheme combining text and graphical elements [22]. In this study, the evaluation of the usability of gridWordX (recognition nouns) compared to traditional text-based passwords revealed that gridWordX offers almost the same memorability rate compared to text-based passwords. A study established a cognitive psychology method called loci (spatial and visual memory) by utilizing video support in training sessions to enhance memorability rate but it had the drawback of a lengthy registration duration of 160 seconds [29]. Moreover, recent research improved the memorization of system-generated recognition textual passwords by applying verbal and graphical (image) cues with a high success rate but a long registration time required 265 seconds and low password space 20 bits [24]. A recent study demonstrates how using system-generated textual passwords results in lengthy training, registration, and login times [30]. As a result of that system-generated passwords possess their own set of challenges as it has a major a usability issues still, user-chosen textual passwords are more user-friendly due to their ease of use and familiarity.

B. User-Chosen Textual Password

User-chosen textual passwords are preferred more frequently by users compared to system-assigned passwords as they are usually easy to remember but are often predictable [31]. An approach called guided word choice increased the password space of recognition passphrase with high password entropy by selecting six words from an array of 100 or 20 words [26]. However, this approach was requiring high cognitive load as the success login rate is 46% that belong to different types of errors which are missing words order, or missing words of the phrase. A recent paper discussed user behavior and memorability of user-chosen recognition and recall textual passwords for nouns and passphrases, indicating that recognition conditions are more memorable than recall textual passwords. However, some participants in the recognition noun group forgot their passwords and requested a password reminder because they randomly generated passwords that lacked word associations in the provided word set [25]. Overall, these studies show that remembering more words from a word set can cause a cognitive burden when retrieving them in long term memory.

System-assigned and user-chosen recognition textual password research was based on storing several words, whether with a meaningful or unmeaningful association, that negatively influence memorability and security level. The main challenge of this study is establishing a new approach only partially based solely on words from a grid and psychologically enhancing the user's memorability. For this reason, WPRTP is proposed to stimulate user memory through a drawing pattern strategy, as well as enhancing the security by integrating security policies and guidelines to achieve the goal of balancing between usability and security.

III. Methodology

The study procedures followed a standardized computer configuration and participants used the same computer for all sessions within a controlled laboratory setting to eliminate any external variables that could affect experimental results, thus enhancing the overall study reliability.

A. Participants

This study recruited 54 participants via flyers including 31 males and 23 females ranging in age between 19 and 49 years as shows in Table I. The flyers contained detailed study information and were distributed to Iowa State University students and locals. All participants provided consent before participating in the study. The research procedures were conducted in accordance with ethical guidelines and approved by the Human Institutional Review Board (IRB), Iowa State University Compliance.

B. Experimental Design

The main objective of this study was to evaluate the password memorability, login time, and registration time for both recognition and recall textual passwords. A between-subject design was adopted to evaluate three independent variables: recognition noun, recognition passphrase, and recall passphrase. One-way ANOVA was performed, and all participants were distributed randomly between groups. The study

TABLE I. DEMOGRAPHIC INFORMATION OF POPULATION

Group	Number of participants	Gender	Age Average
Recognition Noun	18	10 Males & 8 Females	29.05
Recognition Passphrase	18	11 Males & 7 Females	28.72
Recall Passphrase	18	10 Males & 8 Females	28.16

lasted for three weeks to evaluate the short and long-term memory performance. The password entropy was measured for both recognition and recall passwords using an Omni calculator [32].

The recognition groups were given a password security requirement as shown below and were advised to follow a specific guideline while creating their pattern to avoid commonly used patterns [33].

- The recognition noun and passphrase password security requirements:
  1) The word pattern should be 16 cells or more ($> 90bits$).
  2) Use one pattern or more.
  3) Avoid predictable word pattern (predictable words association, simple shapes, predictable starting points, common patterns, use random gestures, and vary the direction and angles).
  4) Easy to remember but difficult to guess.

The recall passphrase group was guided by the passphrase recommended by different organizations. The passphrase users should build their password based on security requirements as shown below and follow the guideline that requires substituting letters with digits or symbols such as “Iowa w1nters are c0ld!” [34] or shortcut some words “6MonkeysRLooking^” [35].

- The recall passphrase security requirements:
  1) The passphrase should be 14 characters or more ($> 90bits$).
  2) A combination of uppercase letters, lowercase letters, numbers, and symbols.
  3) Do not use common words or personal information.
  4) Easy to remember but hard to guess. Consider utilizing a memorable passphrase.

C. Apparatus

The recognition noun and passphrase password were based on randomly generating 55 words from a predefined word pool. Each generated word is assigned a random alphanumeric character or special symbols. The main goal of using characters is that the users must enter the corners of their created pattern to successfully log in. For example, the characters of the drawn pattern in Fig. 1 “uy^MAwqRfghD56ZtB3!” are stored in the database but the user is required in the login phase to enter the corners of the pattern as “u^ghD5t!” as shown in Fig. 2 and the system will automatically gather the characters in between to compare it to the saved password in the database. The user can create more than one pattern and the system demonstrates these patterns with different colors: the first pattern is red, the second is blue, and the third is green. Furthermore, each pattern is accompanied by a starting arrow to highlight the point of origin and the endpoint of the pattern. In the login phase, when users build more than one pattern, they should separate between the characters of each pattern with space to successfully login. For instance, the characters of the drawn patterns in Fig. 3 are “n^QLqVOvbozuJUPs” and “C#y” are stored in the database, but the user is required in the login phase to enter the corners of patterns separated with space as “n^bouJs C#y” as shown in Fig. 4 and the system will automatically gather the characters in between for both patterns and compare it to the saved password in the database. The random word generation system consists of the following components:

1) Word pool A pool with a variety of common word types including nouns, adjectives, and verbs (881 words) to ensure their applicability for native speakers and foreigners. The concrete nouns were chosen because they are more memorable than abstract nouns [36].
2) Character set A set of alphanumeric characters and special symbols to randomly assign a character to each word generated from the word pool: “ABCDEFGHIJKLMNOPQRSTUVWXY Zabcdefghijklm nopqrstuvwxyz0123456789!@#$%^&*()-_+=[]{}:;’¡¿,.?/—“”.

Fig. 1. The registration interface for the recognition noun pattern.

Fig. 2. The login interface for the recognition noun pattern.

Fig. 3. The registration interface for the recognition passphrase pattern.

Fig. 4. The login interface for the recognition passphrase pattern.

In contrast, for the recall passphrase, an interface was created to allow participants to enter a passphrase considering particular security rules as shown in Fig. 5.

Fig. 5. The registration and login interface for the recall passphrase.

D. Procedure

Detailed information about the research objectives and study procedures was presented to participants to ensure clarity and understanding and eliminate any potential bias before commencing the study. The study lasted three weeks to determine factors that can influence the success rate and login time for short- and long-term memory.

- **Session 1:** The first session comprises a series of distinct steps:
  - **Password Creation:** The participants were instructed to generate a password following the given password security requirements.
  - **Short-term memory (STM):** After password creation, the participants were distracted for a few seconds and then asked to log in to evaluate the short-term memory. If a participant incorrectly entered their password three times, they were provided with a password reminder.
  - **Answer Pre-survey:** The participants answered demographic questions.
- **Session 2 (Long-Term Memory 1 (LTM1)):** One week after Session 1, the participants were required to return to assess their long-term memorability of their passwords and login time performance. If participants incorrectly entered their password three times, they were given a reminder.
- **Session 3 (Long-Term Memory 2 (LTM2)):** Two weeks after Session 2, the participants were required to return to evaluate long term memorability of their passwords and login time performance. If participants incorrectly entered their password three times, they were given a reminder. They were then asked for feedback to assess the user experience of their assigned password approach.

IV. Result

All data were analyzed using SPSS 28. We used a One-way ANOVA to assess mean differences in registration time, login time and memorability depending on treatment (authentication condition) followed by Tukey's HSD for post-hoc comparisons to test hypotheses 1 – 9. A check of the ANOVA assumptions revealed lack of Normality for all dependent variables and differences in the variances between treatment groups, leading us to repeat the analyses using the non-parametric Kruskal Wallis Test. Because the results were qualitatively the same, we present the ANOVA results that we suspect most readers are more familiar with. In the literature, robustness of ANOVA against violations of Normality and unequal variances has been repeatedly established, especially when sample sizes are equal across treatment groups as is the case in our study [37], [38].

A. Registration Time

H1. There will be a significant difference in the mean registration time between user-chosen recognition nouns compared to recall passphrases.

H2. There will be a significant difference in the mean registration time between user-chosen recognition passphrases compared to recall passphrases.

H3. There will be a significant difference in the mean registration time between user-chosen recognition nouns compared to recognition passphrases.

Before testing hypotheses H1 through H3, a one-way ANOVA test was conducted to ensure that at least one of the three group means was different based on the global F-test ($F = 19.027$, $df = 2, 51$, $p < .001$). The post-hoc pairwise comparisons indicated the following differences in the mean registration times between password types: the recognition noun approach was statistically highly significant different (mean difference = 83 seconds, $p < .001$) compared to the recall passphrase, indicating longer registration times for the recall passphrase. Likewise, the recognition passphrase approach was statistically highly significant (mean difference = 93 seconds, $p < .001$) compared to the recall passphrase group, also indicating longer registration times for the recall

passphrase as shown in Fig. 6. However, there was no significant difference between recognition noun and recognition passphrase (mean difference= 10 seconds, p = .819).

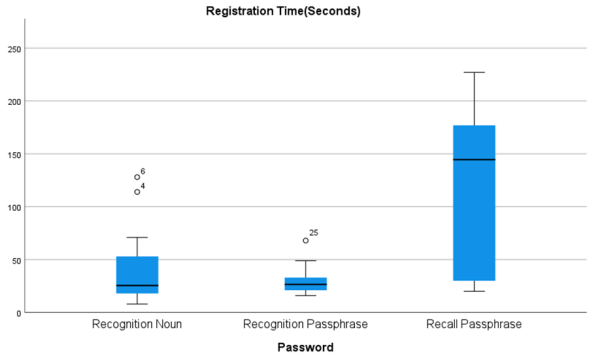

Fig. 6. The registration performance in seconds for each authentication condition. The black horizontal line in the boxplots denotes the median registration time for all participants in the treatment group.

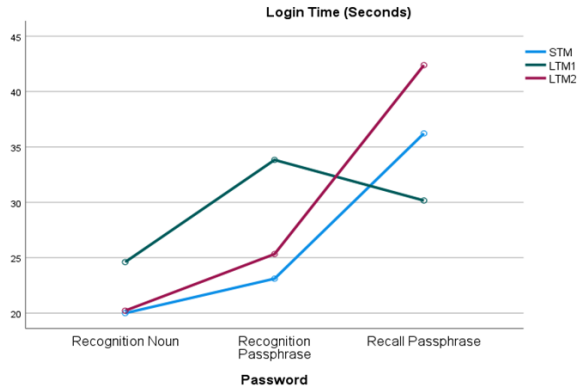

Fig. 7. The login time average per authentication condition.

B. Login Time

H4. There will be a significant difference in mean login time between user-chosen recognition nouns compared to recall passphrases in STM and LTM.

H5. There will be a significant difference in mean login time between user-chosen recognition passphrases compared to recall passphrases in STM and LTM.

H6. There will be a significant difference in mean login time between user-chosen recognition nouns compared to recognition passphrases in STM and LTM.

A one-way ANOVA test was conducted to examine the difference in mean login time between the three types of passwords across three memory conditions: STM, LTM1, and LTM2. The results revealed that no significant difference exists between all groups in STM (F = 1.896, df=2, 51, p = .161). Similarly, there was no significant difference between them in login time in LTM1 (F = .694, df=2, 51, p = .504), but there was a significant difference in LTM2 (F = 3.564, df = 2, 51, p =.036), indicating that the type of password interaction significantly impacts login times in this memory condition. The post hoc Tukey HSD test indicated no significant difference in login time for STM and LTM1 conditions but in LTM2, recognition nouns significantly took less time to login compared to recall passphrase (mean difference = 22 seconds, p = .036) as shown in Fig. 7. Overall, the login time results of the three-period showed same pattern of login time in STM and LTM2 however, in LTM1, both recognition groups presented an increase in login time and a decrease in the recall passphrase group. However, In the LTM2, the login time for both recognition passwords is reduced and increased for recall passphrase, which indicating that recognition passwords with practice become more efficient, while the recall passphrase group needed more time to login due to increased cognitive demand.

C. Memorability

H7. There will be a significant difference in the memorability rate between user-chosen recognition nouns compared to recall passphrases in STM and LTM.

H8. There will be a significant difference in the memorability rate between user-chosen recognition passphrases compared to recall passphrases in STM and LTM.

H9. There will be a significant difference in the memorability rate between user-chosen recognition nouns compared to recognition passphrases in STM and LTM.

A one-way ANOVA test was conducted to examine the difference in mean memorability rate from the first attempt between the three types of passwords across three memory conditions: STM, LTM1, and LTM2. In the analysis of memorability rate from the first attempt among different password types, the ANOVA results revealed significant differences between groups in STM based on the global F-test (F (2, 51) = 5.921, p = .005). Post hoc comparisons using the Tukey HSD test indicated significant mean differences between several groups. Specifically, recognition noun had a significantly higher mean memorability rate compared to recall passphrase (mean difference = 0.27778, p = .027). Similarly, recognition passphrase also significantly had higher memorability rate compared to recall passphrase (mean difference = 0.33333, p = .006). Conversely, the differences between recognition noun and recognition passphrase were not statistically significant (p = .854).

The LTM1 results revealed no significant difference in memorability rate based on global F-test (F (2,51) = 2.410 and p=.100). The post hoc comparisons using the Tukey HSD test examined the mean differences, though they did not reach statistical significance between all groups. The closest to significance was the difference between recognition noun and recall passphrase (mean = 0.27778 and p = .084), suggesting a trend where recognition noun might lead to better memorability than recall passphrase. However, the LTM2 memorability results showed a highly significant difference in memorability rate between groups (F (2, 51) = 10.818, $p < .001$). Post hoc comparisons using the Tukey HSD revealed significant differences where both recognition noun and recognition passphrase is significantly outperformed recall passphrase in memorability rate (mean difference = 0.38889 and $p < .001$). However, no significant difference was found between recognition noun

and recognition passphrase, indicating that both types of recognition-based passwords performed higher in terms of long-term memorability as compared to the recall passphrase, as shown in Fig. 8.

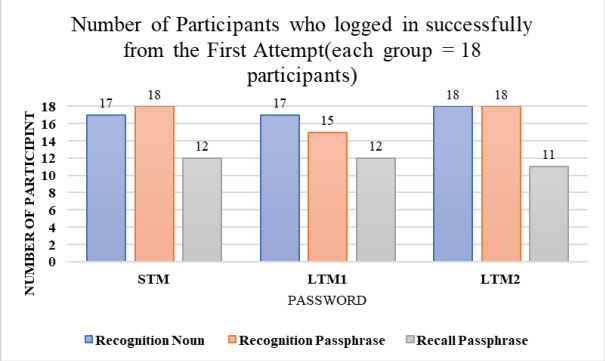

Fig. 8. The successfully login rate from the first Attempt per authentication conditions.

These results offer a detailed insight into the effects of recognition patterns (nouns and passphrases) compared to recall passphrases on registration speed, login efficiency, and memory retention. Thus, the three-week study proved that recognition pattern passwords significantly outperform in memorability and login time compared to recall passphrases. Th user experience was also evaluated using a 10-point Likert scale showing that the users preferred the WPRTP methods (noun and passphrase) in terms of ease of creation, memorability, entry speed with practice, preference over text-based passwords, and perceived security as shows in Table II. Pattern-based techniques performed better in areas such as memory and simplicity of creation, showing how effective they are in improving the user experience and reducing cognitive burden. These results highlight WPRTPs as a potential alternative to recall passphrases as they offer a balance between security and usability.

TABLE II. THE MAIN QUESTIONS AND SCORES FOR PATTERN NOUNS, PATTERN PASSPHRASE AND RECALL PASSPHRASE PARTICIPANTS

Question/Score(average)	Noun Pattern	Passphrase Pattern	Passphrase Recall
Is it easy to create?	8.27	8.5	6.27
Is it easy to remember?	9.29	8.88	6.16
With practice, I could quickly enter password?	9.52	9.83	8.33
Do you Prefer it compared to text-based password?	8.11	7.83	7
Do you think it is secure?	9.23	9.66	8.66

DISCUSSION

This section will discuss the results of the WPRTP and recall passphrase over a three-week study to distinguish its efficiency and user satisfaction of both methods in term of login time, memorability, and how these factors can impact on authentication as shown in Table III. The study findings proved that WPRTP had a superior memorability rate compared to recall passphrase for long term period. Both recognition nouns and passphrase pattern showed 100% succussed rate from the first attempt in LTM2 however, no improvement in succeed rate of recall passphrase which presented 61.11% on the first attempt and slightly increased to 72.22% in the third attempts in LTM2. During the three weeks, 22.22% of recall passphrase participants requested a password reminder with no enhancement in memorability rate thus, displaying difficulty in retrieving the correct password, which caused an increase in the login time from 30 in LTM1 to 42 seconds in LTM2. On the other hand, both recognition passwords login time is decreased from 24 to 20 seconds for recognition noun and 33 to 25 seconds for recognition passphrase. Therefore, these differences between WPRTP and recall passphrase underscores the cognitive load and challenges inherent in recall-based method. There were several usability challenges and limitations that influence participants performance for all groups but increasingly for recall passphrase. The WPRTP participants found difficulty during entering the corners of their patterns but with practice they were more adopted and efficiently executing their pattern accurately. The login errors were occurred because of:

- 60% of the participants had errors called missing corner error (occurred when participants forgot one corner or more of their pattern).
- 40% of the participants had a case letter error (occurred when participants used capital letter instead of small letters or vice versa of their attached characters of patterns).

On the other hand, recall passphrase participants had a major issue of retrieving phrase that include numbers, symbols, and mixed-case letters with substitution strategy. Notably, the participants who had more than one symbol or substitutes characters in the phrase or both together result in confusion in retrieving the correct password. Also, long passphrase with specific requirements raises the possibility of spelling error. Despite of users acquired password reminders but still no improvement in memorability in long term memory. There are several errors that influence significantly the memorization such as:

- 54.54% of the participants had a special character/digit error (occurred when participants forgot special character and/or digit or insert more special character and/or digit in the phrase). Example, password is (May!StandUnshkn03*) and the error was forgetting the symbol * in the end of the phrase(May!StandUnshkn03).
- 36.36% of the participants had a spelling error (occurred when the participants written word incorrectly). Example, password is (Ames1scold@thisyear).
- 9.1% of the participants had substitute errors (occurred when participants forgot the exact substituted character position). Example, the password created is (Ultra high performance concrete 1s str0ng!) and the error was forgetting changing the letter “i” in “is” with 1 (Ultra high performance concrete is str0ng!).

User behavior is essential in creating memorable and secure word pattern passwords. Using password policies and guidelines helped to mitigate user’s behavior, such as selecting easy or predictable word patterns. From the drawn patterns, it found that implementing the minimum requirement of a 16-

TABLE III. THE SUCCESSFUL LOGIN RATE, REGISTRATION TIME AND LOGIN TIME FOR RECOGNITION NOUN AND PASSPHRASE AND RECALL PASSPHRASE

The Success rate for Recognition and Recall textual password					
Noun Pattern					
	1st attempt	2nd attempt	3rd attempt	Registration Time (Average in seconds)	Login time (Average in seconds)
STM	94.44%	100%	100%	39	20
LTM1	94.44%	100%	100%		24
LTM2	100%	100%	100%		20
Passphrase Pattern					
	1st attempt	2nd attempt	3rd attempt	Registration Time (Average in seconds)	Login time (Average in seconds)
STM	100%	100%	100%	29	23
LTM1	83.33%	100%	100%		33
LTM2	100%	100%	100%		25
Passphrase Recall					
	1st attempt	2nd attempt	3rd attempt	Registration Time (Average in seconds)	Login time (Average in seconds)
STM	66.66%	77.77%	77.77%	122	36
LTM1	66.66%	83.33%	83.33%		30
LTM2	61.11%	66.66%	72.22%		42

word pattern decreases the tendency to connect words with a semantic meaning or another relationship. For instance, some participants tried to select words based on association, but when they connected them with a pattern, they failed to meet the minimum pattern length of 16 words. This requirement forced them to select patterns with no logical links between words. For instance, Fig. 1 showed that participant was trying to connect Television with Turkey which has the same first letter but it was not met the required length thus, led to increase the pattern to Router word. Also, most participants built their pattern by avoiding predictable word associations, simple shapes, predictable starting points, and common patterns. These rules motivate them to create patterns with changes and multiple overlaps, thus demonstrating complexity in their pattern approach. For example, Fig. 3 presented two patterns with unstructured linguistics passphrase: first pattern was based on two parts (run helpful and use dog) and the second pattern was based on the position of the beginning of the first pattern. However, there are some recognized weak behaviors, such as using patterns with less vary in directions relying on memorization without engaging securely robust and random patterns. Therefore, these findings presented the importance of thoughtfully designed password policies and guidelines, but still some tools needed to ensure the security level of word pattern password as discussed in the future work below.

V. CONCLUSION AND FUTURE WORK

This study demonstrated WPRTP's advantages in terms of memorability and ease of use compared to recall passphrases. Significantly, WPRTP offered a more memorable solution, potentially reducing the risk of password resets, as constantly forgetting, and resetting passwords causes user fatigue [39]. There are some limitations recognized in the study include the following; small sample size of the participants. Moreover, the experiment was conducted in a laboratory setting, which means the results not reflects the actual real-life performance. Future study should be performed on large samples with increased gender, age, and ethnic diversity to support and expand the WPRTP approach. Also, future research should enhance pattern security using algorithms that reduce the predictability of patterns within the word grid as follows:

- Pattern analysis and predictability modeling: use machine learning methods to evaluate the predictability of the created pattern.
- Randomization algorithm: use an algorithm to encourage or enforce the creation of less predictable patterns.

Revolutionizing Campus Communication: NLP-Powered University Chatbots

Ritu Ramakrishnan, Priyanka Thangamuthu, Austin Nguyen, Jinzhu Gao
School of Engineering and Computer Science, University of the Pacific, Stockton, California, USA.

***Abstract*—Artificial intelligence (AI) based chatbots leverage programmed software instructions to simulate human speech and user interaction. These versatile tools can be employed in various domains, from managing smart home devices to providing personal virtual assistants. They can also be useful in responding to common queries and can make information easier to access. In response to this need, we developed a specialized chatbot tailored for the academic environment by training an NLP model to answer frequently asked questions (FAQs) the need of searching through the university website. The main goal is to optimize user engagement and streamline information retrieval within a university setting. By employing ML and NLP techniques, we enhance the chatbot's capabilities, enabling it to provide effective and precise answers, contributing to a more seamless and efficient experience for users seeking information about the university. The study discusses the pivotal decision-making process between implementing a custom neural network and the BERT model. Through a comparative analysis, the custom neural network emerges as the preferred solution, displaying efficiency, quick deployment, and superior accuracy in handling task-specific queries. While BERT presents unparalleled versatility in natural language processing, its resource-intensive pre-training, and challenges in adapting to the intricacies of the university-specific dataset limit its efficiency in this application. This research emphasizes the importance of customization to meet the unique demands of a university chatbot, providing valuable insights for developers seeking to strike a balance between efficiency and specialization in similar applications.**

Keywords*—*Artificial intelligence; natural language processing; chatbot; machine learning; recommender systems; neural network; BERT

I. Introduction

In the evolving landscape of technology, chatbots have emerged as powerful tools that revolutionize the way individuals interact with systems. Automated response systems designed to engage users in natural and conversational dialogue, chatbots have found applications across various industries. Chatbots offer users a natural language interface which allows them to perform tasks easily without the need for direct human interaction through traditional channels like phone calls or emails.

The rise of artificial intelligence based chatbots capable of engaging users in conversations that mimic realistic human interactions have been able to provide useful insights based on user inputs [1]. As such, the main purpose of this project is to build a chatbot for the university that can provide new students with information in a quick and easy-to-understand manner. As a new student, it can sometimes be difficult to navigate the university website and get information about things quickly. Because of this, modern NLP (Natural Language Processing) techniques can be leveraged to solve this problem in an effective way. Recognizing the repetitive nature of inquiries faced by administrative staff, we wanted to create a tool that could automate responses to frequently asked questions, providing immediate responses for students, handling multiple requests for information, and freeing up valuable time for administrative officers to focus on other crucial tasks.

The implementation of a chatbot can simplify information retrieval for students, proving invaluable in navigating campus life. Another significant benefit of implementing a chatbot for answering questions is being able to integrate it into other domains. Since there is a single pipeline for creating the chatbot, from collecting data to training the model, it would be relatively simple to create chatbots to help provide information on other topics. The developed chatbot employs Natural Language Processing (NLP) techniques, utilizing basic distance metrics to gauge the similarity between questions [2]. Because of this, it is also possible for the chatbot to be programmed to learn from user interactions. Using a chatbot for education can help with personalizing the learning experience [3]. By using a chatbot to inform students and answer certain questions, it is possible to enhance the experience by having the chatbot adapt based on questions that a student is asking as well as student feedback on the quality of the chatbot's answers.

In this work, we shall deep dive into the entire process of making an effective chatbot for university, from data collection, data processing, data analysis, to model construction. This paper will examine the limitations and advantages of using various approaches to create a chatbot based on university information. The results will demonstrate insights and developments for implementing a chatbot in a specialized domain.

II. Related Works

In recent developments in educational technology, the implementation of virtual teaching assistants by Natural Language Processing (NLP) has gained attention for its potential to enhance student learning outcomes. A notable study examining this technology's impact in Ghanaian higher education illustrates how NLP, a branch of artificial intelligence focused on interpreting human languages can facilitate more effective communication between students and computers [4]. This study underscores the utility of NLP systems in educational settings to bridge the gap between

natural human communication and machine understanding, thereby enabling a more accessible and interactive learning experience for students. The virtual teaching assistant, functioning as a chatbot, not only aids in answering queries but also significantly contributes to a learning environment where students can engage with course material in a conversational and interactive manner [4]. Such findings are instrumental in highlighting the evolving role of AI in education, particularly in regions with unique educational challenges and opportunities.

A significant barrier to student engagement with learning resources is the social apprehension of seeking help. According to findings presented in study [5], students frequently are reluctant to ask for assistance due to concerns over maintaining a positive social image. This phenomenon drives a preference for self-service information retrieval methods, notably through Frequently Asked Questions (FAQs). Since their origin in Usenet groups in 1982, FAQs have been a pivotal self-help tool, compiling common inquiries alongside their answers to facilitate independent problem-solving [5]. The study highlights the relevance of FAQs in educational settings and suggests opportunity for chatbots and conversational interfaces to bridge the gap in student support by offering a non-judgmental, anonymous platform for information access and learning assistance. This underscores the potential of conversational AI to mitigate social barriers to help-seeking, aligning with broader research trends that explore technology's role in enhancing student learning experiences.

Exploring chatbot technology within educational contexts, particularly in facilitating students' transition phases, a distinction is made between two primary types of chatbots: rule-based and AI-based models. As detailed in the study [6], rule-based chatbots function by adhering to pre-defined rules and delivering responses based on these predetermined guidelines. Conversely, AI-based chatbots leverage artificial intelligence techniques, enabling them to learn and adapt from each interaction. This adaptability allows AI-based models to evolve their response mechanisms over time, offering more personalized and contextually relevant interactions [6]. This classification is pivotal for understanding the potential and limitations of chatbot applications in educational settings, as it highlights the technologies that dictate chatbot behavior and efficacy in supporting students during critical transition periods. It is also important to note that chatbots used in educational settings can have significant ethical implications [7].

The evolution of chatbot technology is a critical area of study within the domain of artificial intelligence applications. A seminal work in this field is [8], which provides a comprehensive historical overview, pointing out the creation of ELIZA in 1964 as a foundational moment in chatbot development. ELIZA, designed by Joseph Weizenbaum, represented the first attempt to simulate human-like conversation by analyzing and decomposing user input responses based on predefined rules. This method of operation explains the rule-based approach to chatbot design, laying the groundwork for subsequent advancements in the field [8]. The historical context provided by this study is for understanding the progression of chatbot capabilities from simple rule-based interactions to the complex AI-driven conversational agents we see today.

Advancements in chatbot technology have increasingly focused on enhancing the accuracy and relevance of their responses. An innovative method for achieving this is highlighted in [9], which discusses the application of deep reinforcement learning (DRL) techniques to improve chatbot interactions. This approach involves the chatbot proactively identifying gaps in the information provided in user inquiries. By engaging users to clarify these ambiguities and gather the necessary details, the chatbot can tailor its responses more accurately and effectively. This method improves the quality of the chatbot's replies and contributes to a more dynamic and engaging interaction between the chatbot and the user [9]. Such a strategy of DRL in refining the capabilities of chatbots, marking a notable change from more traditional, static methods of response generation.

These are some of the related works for chatbots developed for various purposes. Depending on their purpose, the dataset for the chatbot varies and some of the chatbot also use customized datasets for developing the model.

III. CHATBOT DESIGN

In the university website, all the FAQs are in form of documents and other information that a user might need is available on the website. Sometimes this information is outdated so students must verify if the information is correct from the administrative staff. To resolve this issue using NLP, the chatbot design needs to meet the following criteria:

1) Intent recognition: The chatbot should recognize intents specific to university-related queries, such as admissions, student services, campus facilities, dorms, hospital facilities etc. User interactions are classified into intents based on the university-related data.

2) Response generation: The chatbot should give clear responses relevant to university policies, procedures, and services with up-to-date information, including links or references to official university webpages or other resources for further clarification.

3) Context handling: The chatbot should have context management to maintain continuity in conversations related to university-related topics and allow users to ask follow-up questions or seek clarification within the same conversation context.

4) User interaction: The chatbot interface should be user-friendly, considering the unique needs and expectations of university students. It also needs to ensure accessibility features to accommodate a diverse student population.

5) Error handling: Error messages should be customized to address common issues faced by students. The chatbot should include prompts for users to rephrase or provide additional details if the chatbot encounters ambiguity.

In addition, the chatbot design needs to ensure scalability and consider the diverse sources of university datasets which can be achieved by the following implementations in the chatbot design process:

1) User base growth: The chatbot architecture should be designed to handle more student queries, especially during peak periods like enrollment or exam seasons. The infrastructure should scale based on the expected growth in the student population.

2) Concurrency and load handling: The concurrent queries mechanisms should be implemented during high-traffic periods, preventing delays in responses. Queries should be distributed evenly across servers to ensure load balancing.

3) Adaptability to increasing data: The chatbot should be trained on new FAQs and updates to university policies regularly. The content management system should be implemented for easy addition and modification of FAQs. The FAQs should have updated information and links for easier navigation for the students.

4) Monitoring and analytics: The user interactions should be monitored to identify popular queries and areas needing improvement. Analytics should be performed regularly to understand student engagement and continuously enhance the chatbot's effectiveness. If there is any outdated information, then update the database or the university website where the data is updated and train the model again based on the latest information.

IV. Implementation Details

The development of the university chatbot model follows a strategic process separated into distinct stages aimed at optimizing user interactions and addressing the unique needs of university students. The process started with data collection, which focused on gathering valuable insights into frequently asked questions (FAQs) and user queries specific to the university. The subsequent stages include natural language processing (NLP) techniques, neural network implementation, and real-time interaction simulation.

Through this systematic approach, the university chatbot model emerges as a sophisticated tool designed to provide smoother experience in seeking university information instead of navigating a complex university website. Let us investigate the stages of developing the university chatbot in upcoming paragraphs. Fig. 1 explains the flow of the chatbot model.

A. Data Collection

The initial phase in developing our university chatbot model focused on a comprehensive data collection effort. This step was critical for ensuring the chatbot could accurately understand and respond to university student's diverse needs and queries. The data collection process we conducted is detailed below.

1) Choosing a data format: The first step of data collection involved deciding on what data format to use for developing the chatbot. After considering multiple file formats, such as plain text, CSV (Comma-separated values), and JSON (JavaScript Object Notation), we eventually settled on using a JSON format so that it could be easier to categorize various pieces of data. The last version of the dataset ended up being organized by having intents to help classify the various categories of data that were collected. Some examples of these categories would be for international students or orientation for new students. Each category was made to contain a list where each item in the list has a question and an answer along with the corresponding question and answer tags.

2) Collecting data from webpages: Data was mostly collected from webpages related to the university. We first started creating a list of URLs (Uniform Resource Locators) from which to get data. This list of URLs is selected based on webpages with valuable information relating to the university and then adding related links from **e**ach of those webpages. Since there are many links collected from the webpages, only a fraction (about one-fifth) of all the internal webpage links were added to the list of URLs. After this, data was collected from the list of URLs by parsing through the HTML (Hypertext Markup Language) code from each URL.

The resulting HTML code was then parsed so that the text collected comes from the HTML body tag. Even after doing this step, there were still pieces of extraneous HTML and JavaScript code leftover that had to be cleaned before it could be used for to train the chatbot model. This data cleaning was done with regex functions to help remove certain code and information that was not needed for the chatbot. To collect relevant data in the form of questions and answers, another set of regex functions were used to classify sentences as either questions or answers, identifying the categories that they fall under, and then adding them accordingly to the data set which is related to university data that can help the students.

3) Collecting data from webpages with frequently asked questions: The main goal was to develop a chatbot that could respond to frequently asked questions about the university. Thus, we also manually gathered documents with information in the form of questions followed by answers and web pages from the university's website. The chatbot could use this information to learn how to answer frequently asked questions.

The specific web pages were converted into PDF files, which have a more organized layout that is better suited for parsing. Effective question-answer pairs were taken from the PDFs and converted into JSON objects with additional descriptive tags that explained the subject and context of each conversation.

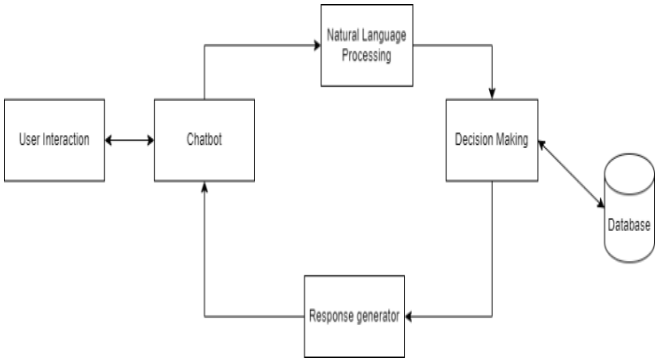

Fig. 1. Chatbot model diagram.

However, most university FAQ pages require users to click on them to reveal the answers, which are initially hidden. As a result, the parsed PDF-derived JSON contained only questions and few answers. The chatbot requires whole sets of questions and their corresponding answers to learn how to answer questions correctly. To close these gaps in the data, more of the question-and-answer data that was previously scraped from websites was added. This resulted in a training data set that was more comprehensive.

B. Data Processing

After the comprehensive collection of the required data, the data processing stage plays a pivotal role in refining and preparing this data for the model building. This stage ensures the data is optimal for training the chatbot model, enhancing its ability to accurately understand and respond to user inquiries. We used the following techniques to pre-process data.

1) Tokenization: Tokenization involves breaking down the text into smaller units, typically words. The word tokenize function from NLTK (Natural Language Toolkit) is employed for this purpose for the chatbot. It effectively tokenizes the text into a list of words in the input dataset into meaningful words.

2) Remove stopwords: While looking into the dataset we found a lot of stop words. Stop words, such as "the", "and", and "is", are commonly used words that do not carry significant meaning in certain contexts. So, we used the stop words module from NLTK to remove the stop words from the dataset.

3) Lemmatization: The next process we used was the Lemmatization process to reduce words to their base or root form. In this case, NLTK's WordNet Lemmatizer module was applied to each word in the list. This helped in reducing inflected words to a common base form, enhancing the accuracy of subsequent analyses.

4) Calculating the frequency: The frequencies of words used in meaningful text from the dataset was used to classify it into the intents. These intents were used for the model to process the information. Fig. 2 shows the word cloud of the frequently used words in the dataset.

Fig. 2. Frequently used words in the dataset.

5) Defining the dataset: Data was collected in the form of questions and answers and were split based on the intents in the questions. For example, if the questions are related to housing, then the intent is classified as "housing", and all the questions and answers are added to that list in the JSON format. Diverse ways of asking a question were also added to the data set to have more data to improve the chatbot's accuracy. Fig. 3 shows sample of the intent, questions, and answers which were classified and used in the JSON format as part of the dataset.

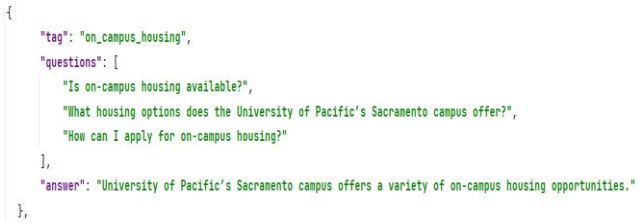

Fig. 3. Sample input dataset.

6) Tools and Languages: The tools and libraries used for developing the chatbot model are described in Table I below.

TABLE I. PROGRAMMING LANGUAGE AND TOOLS USED FOR CHATBOT

Tools/Language	Description
Python	Primary programming language for data processing, natural language processing (NLP), and machine learning.
NLTK (Natural Language Toolkit)	Python library for working with human language data. Used for tokenization, stopwords removal, and lemmatization.
re (Regular Expressions)	Python module for working with regular expressions. Utilized for pattern matching and removal of JavaScript functions from the input text.
pickle	Python module for serializing and deserializing objects. Used for saving and loading processed data.
stopwords	A set of common stopwords provided by the nltk library. Employed for removing non-informative words from the text.
Neural Network	Deep learning model used for tasks such as classification, regression, and pattern recognition in the context of natural language processing. It is versatile and can be customized for various applications.
BERT (Bidirectional Encoder Representations from Transformers)	Pre-trained transformer-based model for natural language understanding. BERT is especially powerful in capturing context and semantics, making it suitable for various NLP tasks such as question answering, sentiment analysis, and more.
Jupyter Notebook	Interactive computing environment for creating and sharing documents containing live code, equations, visualizations, and narrative text. Widely used for data exploration, analysis, and presentation.

C. Models

We developed two distinct models to harness the full potential of artificial intelligence for enhancing the user interaction and response accuracy. These models were chosen for their strengths in understanding and processing natural language queries and their ability to learn from interactions to improve over time. Below, we detail the implementation and contributions of each model to the chatbot's development, illustrating how they collectively form a sophisticated system capable of addressing the needs of university students.

1) BERT model: The first cornerstone of our chatbot's architecture is based on BERT (Bidirectional Encoder Representations from Transformers), a state-of-the-art model developed by Google. Fig. 4 shows the code we used for the

chatbot using the BERT model and the detailed explanation is listed in the below:

a) Transformer encoders: The chatbot utilizes Transformer Encoders, a powerful neural network architecture, to process and understand the input text. This architecture is particularly effective for natural language processing, allowing the chatbot to capture relationships within sentences.

b) Bidirectional: BERT is bidirectional. This means it comprehensively considers the context from both the left and right sides of each word in a sentence. This bidirectional approach enhances the chatbot's understanding of the overall meaning and context of user queries.

c) Masked language model: During this pre-training phase, the model learns by predicting masked words in sentences based on their surrounding context. This enables the chatbot to grasp nuanced meanings and context in user inputs.

d) Pretrained model: The chatbot is built upon a pretrained BERT model, first exposed to a vast amount of diverse textual data. This pre-training equips the chatbot with a solid foundation in general language understanding. The pretrained model is then fine-tuned to specialize in handling specific inquiries relevant to the university setting.

e) Fine tuning: Fine-tuning is the process where our chatbot refines its pretrained model for the university context. By training on labeled data specific to frequently asked questions (FAQs) and university-related tasks, the chatbot adapts its language understanding capabilities to better assist students.

f) Attention layers: BERT's attention layers are integral to our chatbot's functionality. These layers enable the chatbot to focus on various parts of user inputs, allowing it to comprehend long-range dependencies and relationships between words. This attention to context enhances the chatbot's ability to provide accurate and relevant responses.

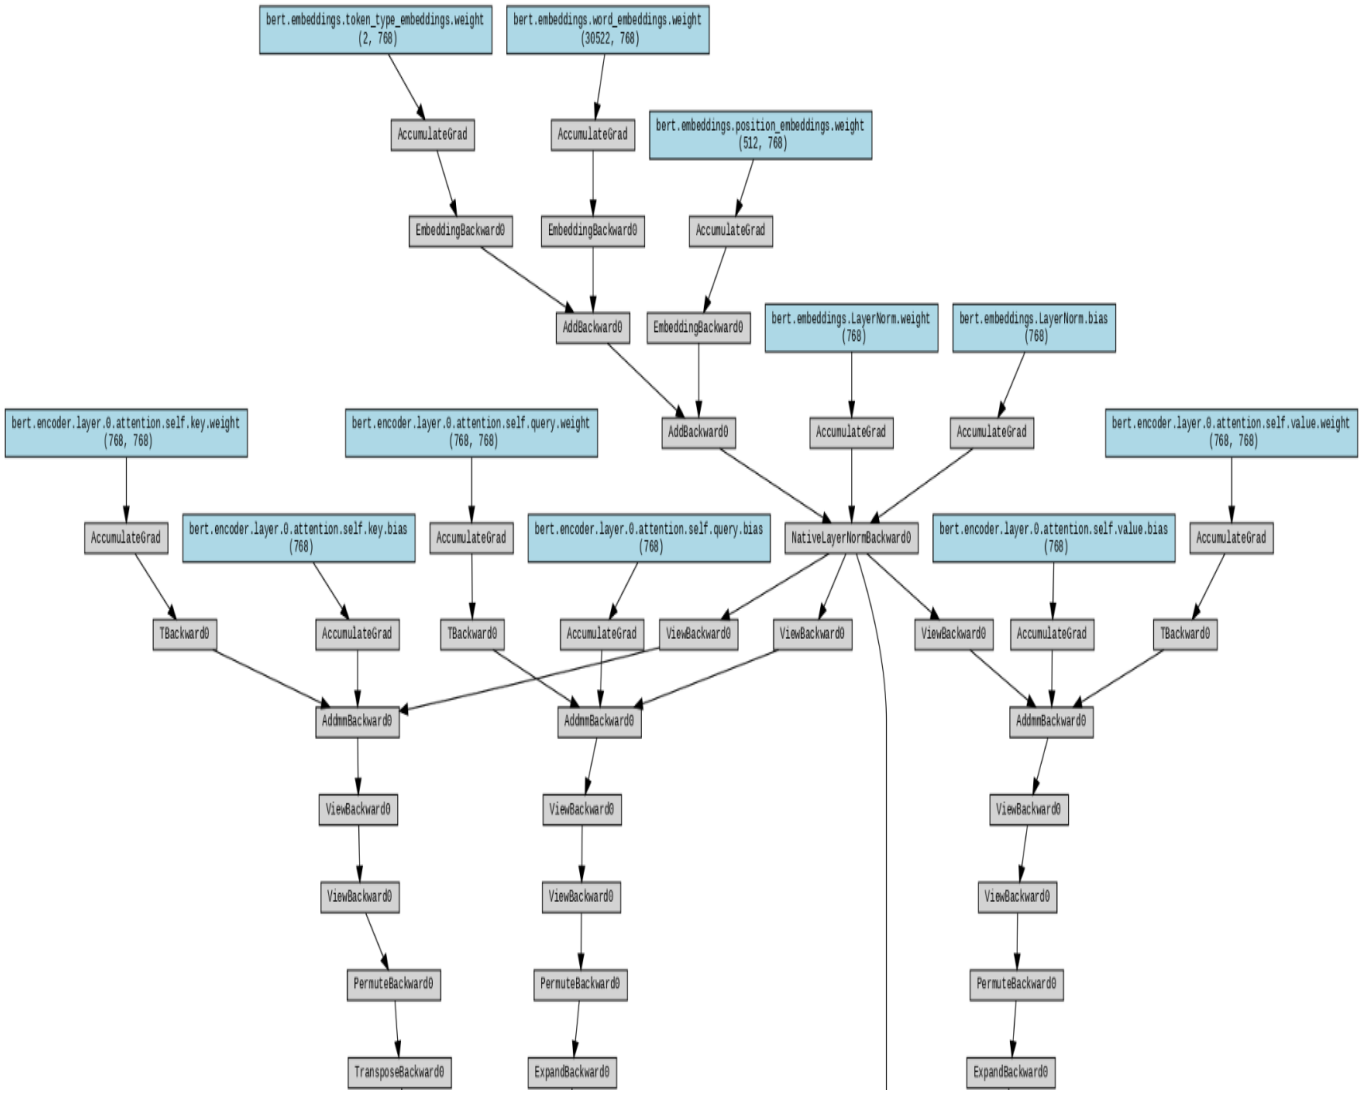

Fig. 4. BERT Model diagram.

```
# Create a Hugging Face datasets.Dataset directly from the list
dataset = Dataset.from_dict({"text": [item["text"] for item in dataset_list],
                             "label": [item["label"] for item in dataset_list]})

# Split the dataset into train and validation (adjust split ratio as needed)
split_ratio = 0.8
train_dataset = dataset.select(range(int(split_ratio * len(dataset))))
validation_dataset = dataset.select(range(int(split_ratio * len(dataset)), len(dataset)))

# BERT model and tokenizer
model_name = "bert-base-uncased"
tokenizer = BertTokenizer.from_pretrained(model_name)

# Tokenize input texts within the datasets with explicit padding
def tokenize_function(examples):
    return tokenizer(examples["text"], padding="max_length", truncation=True,
                     return_tensors="pt", max_length=128)

tokenized_train_dataset = train_dataset.map(tokenize_function, batched=True)
tokenized_validation_dataset = validation_dataset.map(tokenize_function, batched=True)
```

Fig. 5. BERT model code.

Fig. 5 shows part of the visualization of the BERT model for chatbot.

2) Neural network model: Building on the foundational capabilities provided by BERT for understanding natural language, our second model employs Neural Networks to further refine and personalize the chatbot's responses to user queries. Neural Networks, with their remarkable ability to model complex patterns and relationships within large datasets, are particularly well-suited for enhancing the predictive accuracy and response quality of our chatbot. This model leverages a sophisticated architecture designed to process, learn from, and respond to the nuanced inquiries presented by university students. Fig. 6 shows the code for the custom neural network model which we used to develop this chatbot.

a) Three-layered neural network: As shown in Fig. 6, the neural network architecture comprises of three main layers, which are the input layer, two hidden layers, and an output layer. The input layer receives the features from the preprocessed input data, while the hidden layers process and extract the patterns. The output layer produces the results, representing the probabilities of different classes (e.g., intent tags in the chatbot).

b) ReLU activations, batch normalization, and dropout: Rectified Linear Unit (ReLU) activations introduce non-linearity to the model, allowing it to learn complex relationships within the data. Batch normalization helps in stabilizing and accelerating the training process by normalizing inputs. Dropout is employed during training to prevent overfitting by randomly deactivating a proportion of neurons, enhancing the model's robustness.

c) Softmax activation: The SoftMax activation function is applied to the output layer. This function converts the raw output scores into probability distributions across different output classes. In the context of the chatbot, it produces probabilities for the possible intents, helping the model make informed predictions.

d) Custom dataset class: A custom dataset class is employed for effective management of input data and corresponding labels as this dataset is used to build the chatbot. This class manages training and testing data, making it compatible with the neural network model. It allows for efficient loading, preprocessing, and batching of data during training.

Overall, the neural network architecture is designed with layers that process input features, introduce non-linearity for better learning, and produce probability scores through SoftMax activation. The model undergoes transfer learning using pre-trained models like BERT for efficiency. The custom dataset class ensures handling of data, contributing to the overall effectiveness of the chatbot in understanding and responding to user queries. The neural network model diagram is shown below in Fig. 7.

```python
class NeuralNetwork(nn.Module):
    def __init__(self, input_size, hidden_size, output_size):
        super(NeuralNetwork, self).__init__()
        self.fc1 = nn.Linear(input_size, hidden_size)
        self.relu1 = nn.ReLU()
        self.bn1 = nn.BatchNorm1d(hidden_size)
        self.dropout1 = nn.Dropout(0.2)
        self.fc2 = nn.Linear(hidden_size, hidden_size)
        self.relu2 = nn.ReLU()
        self.bn2 = nn.BatchNorm1d(hidden_size)
        self.dropout2 = nn.Dropout(0.2)
        self.fc3 = nn.Linear(hidden_size, output_size)
        self.softmax = nn.Softmax(dim=1)

    def forward(self, x):
        x = self.fc1(x)
        x = self.relu1(x)
        x = self.bn1(x)
        x = self.dropout1(x)
        x = self.fc2(x)
        x = self.relu2(x)
        x = self.bn2(x)
        x = self.dropout2(x)
        x = self.fc3(x)
        output = self.softmax(x)
        return output
```

Fig. 6. Custom netural network code.

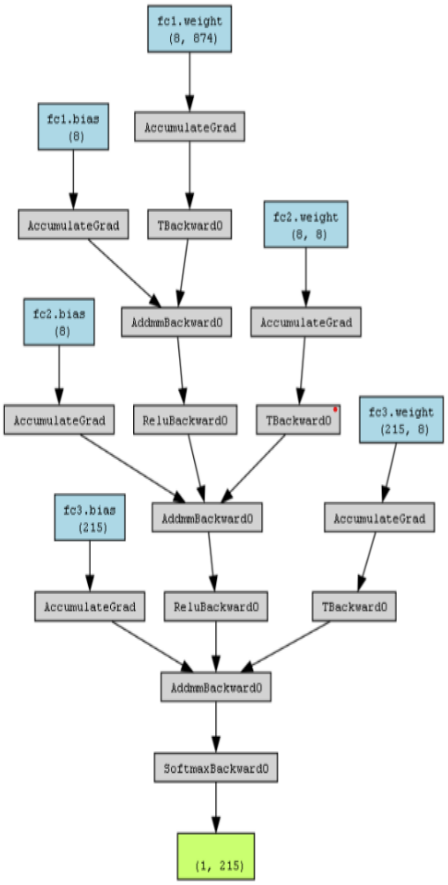

Fig. 7. Custom neural network model diagram.

D. Training and Validation

Transfer learning uses pre-trained models to accelerate the training process. The chatbot benefits from the knowledge acquired by the pre-trained model on vast amounts of general language data. This approach is efficient, especially when dealing with limited labeled data specific to the university context.

1) BERT model: We used the BERT uncased model, which makes better decisions on answering questions. In the fine-tuning and training configuration, the BERT undergoes an adaptive training process with epochs ranging from 3 to 50. Each epoch represents a complete pass through the entire training dataset, allowing the model to refine its parameters over multiple iterations. The Adam optimizer, known for its adaptive learning rate and effectiveness in deep learning tasks, is employed to optimize the model during this process. During the training progress, key checkpoints are observed. After 500 steps, the training loss stands at a low value of 0.0137, indicating favorable predictive accuracy on the training dataset. Fig. 8 shows the code for the BERT model training arguments.

However, the validation loss at this point is 4.98, suggesting potential room for improvement in generalization to unseen data. Subsequently, after 660 steps, the training loss has increased to 0.28, and the validation loss has risen to 5.04. These increments in loss metrics could signal a risk of overfitting, where the model may be too closely tailored to the training data. The training and validation lost for the BERT model is shown in Fig. 9.

```
# Set up training arguments and trainer
training_args = TrainingArguments(
    output_dir="./results",
    overwrite_output_dir=True,

2) Neural network model: The model training configuration involves a batch size of 100, which means that the neural network processes 100 data samples in each training iteration. The architecture comprises two hidden layers with Rectified Linear Unit (ReLU) activations, batch normalization, dropout for regularization, and a SoftMax activation for classification. Training is conducted for 100 epochs, indicating the model iterates over the entire dataset 100 times. The Data Loader is utilized to efficiently handle batches during training. Fig. 10 shows the training code for the custom neural network in the chatbot with the data loader used for the training and validation.

After completion, the trained model is saved as "model.pth" for future development purposes, allowing easy retrieval and deployment for subsequent tasks wimhout retraining the model. Fig. 11 shows the training and validation loss for the custom neural network model.

```
# Create DataLoader for training and testing data
train_x = torch.tensor(train_x).float()
train_y = torch.tensor(train_y).float()
test_x = torch.tensor(test_x).float()
test_y = torch.tensor(test_y).float()

batch_size = 100
train_dataset = CustomDataset(train_x, train_y)
test_dataset = CustomDataset(test_x, test_y)
train_loader = DataLoader(train_dataset, batch_size=batch_size, shuffle=True)
test_loader = DataLoader(test_dataset, batch_size=batch_size, shuffle=False)

# Define the model, loss function, and optimizer
input_size = len(train_x[0])
hidden_size = 8
output_size = len(train_y[0])
model = NeuralNetwork(input_size, hidden_size, output_size)
criterion = nn.BCELoss()
optimizer = optim.Adam(model.parameters())
```

Fig. 10. Custom neural network data loader for training and testing data.

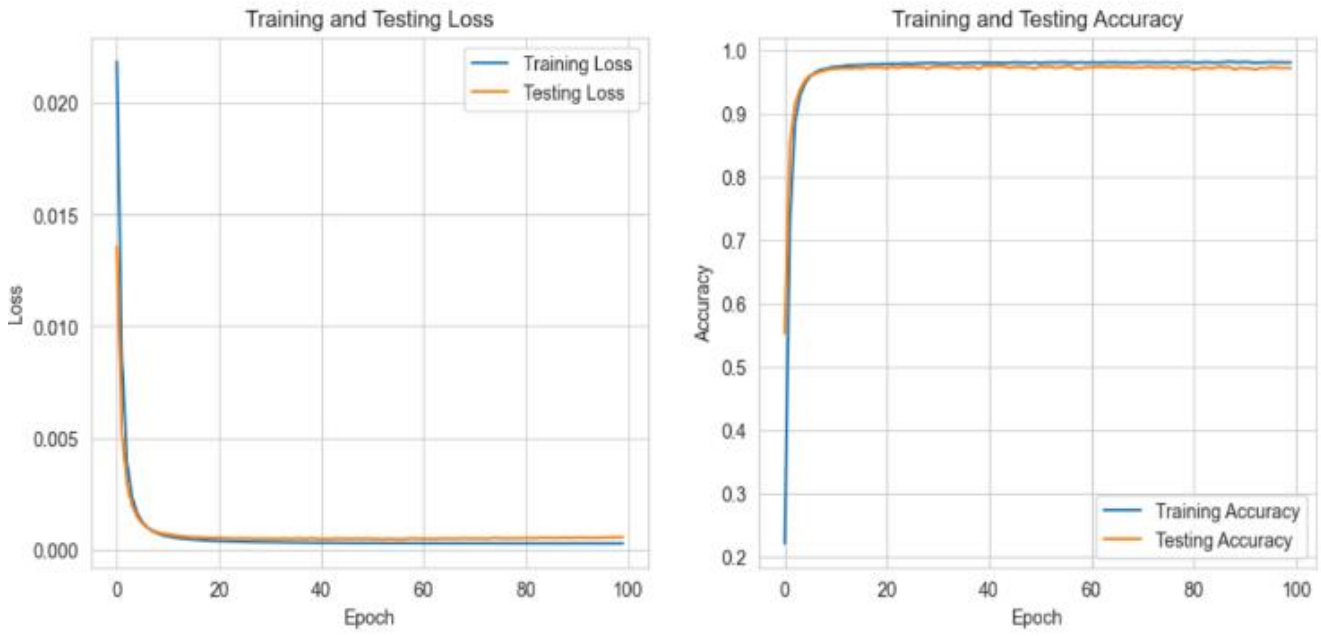

Fig. 11. Custom neural network model training and validation loss.

V. RESULTS

In the comparative evaluation of the BERT model and the neural network, the results reveal that the neural network achieved higher accuracy for the chatbot. The BERT model, while powerful in its natural language processing capabilities, did not perform as well as the neural network. To conclude these results, we collected the dataset from the University of The Pacific website for the training and validating purpose of the chatbot model. As the university data set was small and had customized information, the BERT model was not able to perform well, and the results were not accurate. The accuracy of the BERT model was 0.87 percent. As shown in Fig. 9 after 660 steps, the training loss has increased to 0.28, and the validation loss has risen to 5.04 which were resulting in the overfitting of the model.

On the other hand, the neural network model training time was less when compared to the BERT model. This outcome emphasizes the importance of selecting the most suitable model for a given task and dataset. While BERT is a state-of-the-art model for various natural language processing tasks, the neural network, tailored to the specific requirements of the chatbot application, emerged as the most accurate solution in this chatbot. The accuracy of the custom neural network model was 0.98 percent and the answers to the queries were accurate while evaluating the model.

Fig. 12 shows the accuracy of the model while training it for the chatbot using the neural network model.

```
Training Accuracy: 0.9811
Testing Accuracy:  0.9715
NeuralNetwork(
  (fc1): Linear(in_features=874, out_features=8, bias=True)
  (relu1): ReLU()
  (bn1): BatchNorm1d(8, eps=1e-05, momentum=0.1, affine=True, track_running_stats=True)
  (dropout1): Dropout(p=0.2, inplace=False)
  (fc2): Linear(in_features=8, out_features=8, bias=True)
  (relu2): ReLU()
  (bn2): BatchNorm1d(8, eps=1e-05, momentum=0.1, affine=True, track_running_stats=True)
  (dropout2): Dropout(p=0.2, inplace=False)
```

Fig. 12. Custom neural network model accuracy.

VI. DISCUSSION

The Flask library from Python is used to connect the model to UI. The chatbot application is developed using HTML, CSS and JavaScript and it is connected to the backend with the Flask library. The model is saved in a particular path and uses the saved model to give a response based on the user interactions. Some of the examples for the user interactions are shown in Fig. 13.

In developing the chatbot for university students, the choice between a custom neural network and the BERT model is important. The research's primary objective is to optimize user engagement and information retrieval within a university setting FAQs. The comparative analysis revealed that the custom neural network outperformed BERT in this specific application. The neural network's efficiency in handling task-specific FAQs and quick deployment made it an ideal choice for the streamlined nature of the university chatbot. On the contrary, BERT's versatility and advanced language comprehension capabilities were weighed against its resource-intensive pre-training and challenges in adapting to the university-specific dataset. While BERT is a powerful model with a broad range of applications in natural language processing, the neural network, tailored to the specific requirements of the university chatbot, demonstrated superior accuracy in handling FAQs. The current data set can be improved by adding more information about the university and the general queries of the students. This will increase the dataset and model will have large amount of information about the university. For future improvements we can look more into the dataset and improve it to increase the efficiency of the model. Also, we can have some feedback system from the students to update the information.

Fig. 13. Chatbot UI application.

VII. Conclusion

In conclusion, the development of the chatbot for university students involved a critical decision-making process regarding the choice between a custom neural network and the BERT model. The comparative analysis illustrates the strengths and challenges associated with each model. The custom neural network, tailored for task-specific applications with a small amount of data ended up being suitable for developing this university chatbot. It also demonstrated superior efficiency and accuracy in handling frequently asked questions (FAQs). On the other hand, while BERT exhibited unparalleled versatility and advanced language comprehension, its resource-intensive pre-training, and challenges in adapting to the university specific dataset hindered its performance for this specific task. The research underscores the significance of customization to meet the unique demands of a university chatbot, highlighting the practicality of opting for a more specialized solution over a state-of-the-art model.

To improve the chatbot's understanding and responsiveness to user queries, a hybrid approach that combines custom neural networks and advanced models like BERT could be explored. It is also necessary to focus on improving the adaptability of advanced models like BERT to specific domains such as university administration. Further research could be directed towards refining the chatbot's capabilities based on ongoing user feedback and evolving student needs. Additionally, integrating the chatbot with existing university systems and platforms could enhance its utility and seamless integration into students' daily lives. Future enhancements could extend the chatbot's functionality beyond basic information retrieval to include personalized recommendations, scheduling assistance, and academic support services. Through continuous refinement and innovative approaches, we aim to ensure the chatbot's effectiveness as a valuable resource for university students in the future.

School of Business, Computing and Social Science, University of Gloucestershire, Cheltenham, UK[4]

***Abstract*—This is an ongoing study with the aim to develop a maturity model for efficient deployment of Artificial Intelligence (AI) and Blockchain (BC) in the United Arab Emirates (UAE) public sector. The organizations would leverage this maturity model to assess their efficacy of deploying AI and BC technologies in their operations, highlighting their capabilities for successful integration of these technologies while underscoring their incompetency and directing their attention towards areas of improvement. To achieve this aim, initially the conceptual framework is proposed which would act as primary frame of reference for conducting empirical research in this prospect and developing a maturity model. This study presents the conceptual framework, which highlights the essential dimensions and factors that should be assessed and enhanced for successful implementation of AI and BC technologies. The framework also introduces five stages of maturity/development to mark the progress of each dimension of conceptual framework. This conceptual framework is 4x5 grid which vertically presents four dimensions and horizontally it presents five stages of maturity. Strategy & Governance, Technology, People, and Process are dimensions of framework whereas initial, developed, defined, managed and optimized are stages of maturity.**

***Keywords*—Conceptual framework; Artificial Intelligence; Blockchain; maturity model**

I. Introduction

Artificial Intelligence (AI) is the computers or machine's ability to imitate the mental capabilities of human behaviour while improving its own performance or it can be defined as the ability of machines to leverage human-like mental intelligence to perform different tasks. Computers or machines with AI capabilities exhibits their minds instead of their body to perform different tasks such as operating cars and playing games. AI is the intersections of various domains such as machine learning, deep learning, computer vision, natural language processing, expert systems and data mining and considering its effective applications, various industries around the globe have adopted this technology which include science, engineering, education, medicine, business, accounting, finance, economics and law [1].

BC technology is a distributed database or consensus which exists or operate on multiple computers simultaneously [2].

The pioneers like [3] considered the BC as "digital asset transaction exchanged online" in which each transaction is represented as unique block. It is a distributed ledger system in which transactions are transparently recorded across a network of computers where no third party can manipulate these transactions which enables this technology to ensure data integrity and provide tamper proof record of transactions. Decentralization, cryptographic security, consensus mechanisms, immutability and transparency are key components of this technology. As the world is being digitalized, the personal account information and transactions are being secured and decentralized through BC technology [4]. BC is considered as the safest method on money exchange between two individuals with no intermediaries. Other block chain implementation globally includes the introduction of digital passport and instantaneous ship tracking, and logistics management are already there on track [5].

Considering the potentials of both AI and BC technologies, efforts are being directed to integrate/combine these technologies to yield enhanced transparency & trust, data security & privacy, efficiency & scalability, and monetization of data [6]. Many studies have been conducted to highlight such benefits. For instance, a review provided by [7] illustrated that how integration of AI and BC technologies can be used to train n number of self-driving cars simultaneously instead of training each car individually, where n can be a very large number. In this approach, reinforcement learning which is a subfield of AI is suggested to train car for autonomous driving and by deploying BC, multiple cars can be connected to a shared public ledger which would serve as a platform for various cars to exchange their experiences, enabling all connected cars to learn from experience of single car. This approach would enable cars to collectively enhance their understanding of driving for example when to drive and when & where to stop, based on various experiences shared on public ledger. According to [8], BC, as being distributed storage, can be used to identify citizens and provide their various records such as birth certificates, migration history, jobs pursued and many other records, whereas AI can be leveraged in analysing this information of population to frame policies and informed decision making. Similarly [9] has illustrated that when both technologies are applied in banking sector, each of them provides significant benefits and results in enhanced banking services. For instance,

in banking sector, AI can be used in customer's credit analysis, providing them advice for trading and investment, ensuring 24/7 customer services via chatbots, and detecting frauds & suspicious activities by leveraging various machine learning models such as SVM, Random Forest and Decision Tree. Moreover, BC can be used to provide protection against hacking and online theft of customer's data. It can also mitigate cybersecurity risks by deploying highly encrypted digital ledger platforms which can only be accessed by authorized peers.

The integration of AI and BC technology can significantly enhance supply chain traceability. For instance, AI can be used to analyse huge amounts of data to identify trends, inefficiencies and anomalies in supply chain whereas BC can be used to track information, goods and materials in supply chain [10].

Motivated by potentials of both technologies, the United Arab Emirates (UAE), after the federation of nation undergoes histrionic growth in the implementation of these technologies among the Arab nations. Although UAE is far ahead of many nations in technological advancements, still with aim of driving digital transformation in UAE, the government has started many initiatives which include the use of AI and BC technologies in many industries, to provide citizens with most satisfying and enhanced services. Many government authorities are working with private and government entities of country to implement advanced technology relevant projects. Digital Dubai is example of such authority which has setup more 130 initiatives to accelerate digital transformation of city. Dubai BC strategy, Artificial intelligence Principles & Ethics, AI, Data first and Happiness Agenda are to name few [11]. The author in [12] aim to transform UAE into a world leader in AI by 2013. By this initiative the government aim to create new opportunities in education, social and economic sector, government development, energy, tourism and many more to gain full extent automation in processes which is expected to yield AED 335 billion extra growth leading to 26% increase in economic output. [13] UAE also introduced Emirates BC strategy 2021, which aimed to capitalize BC technology for conducting 50% of transactions by 2021. From this initiative the government expected to save AED 11 billion invested in routine processing of documents and transactions, 398 million annual printed documents and 77 million annual work hours. According to [13] there are more than 40 government entities and 120 BC companies in UAE which are covering 200 plus such initiatives in both government and private sectors of country.

Despite of technological advancements being adopted within UAE, there is a significant gap in the existing literature suggesting, a comprehensive business model which provide a guide to effectively implement these technologies for efficient service transactions in the UAE. Considering the above-mentioned gap and necessity of comprehensive business model for implementation of these technologies, the study aimed to develop a new maturity model to thoroughly guide the implementation of these technologies. To achieve this aim, initially the conceptual framework is proposed which would act as a primary frame of reference for conducting empirical research to develop a maturity model. This framework provides a guide that how AI and BC technologies can be successfully implemented to enhance government services.

II. Literature Review

Researchers have investigated BC and AI in isolation, as well as their applications in many sectors and enterprises [14]-[17]. The integration of AI with BC, as well as the consequences of such integration on the way we live, work, interact, and transact, has been examined in few studies [18]. In rapidly evolving landscape of AI & BC technology deployment, to assess and guide the deployment of these technologies, researchers have provided various model and frameworks. A model is proposed by [19] for small and medium enterprises (SME's) to self-assess their maturity level for either starting or feeding their AI technology adoption journey and providing them guidelines in this prospect. The model was developed based on state-of-the-art review and direct interviews of SME's managers, which were used to identify the existing gaps in models and tools that should be available to support organizations in evaluating their AI-readiness. Although the research methodology (conducting literature review and interviews), can be considered appropriate but the study conducted only two interviews, which offered a very limited sample size to provide diverse challenges and perspectives of AI adoption across different SME's. Similarly, a BC readiness assessment framework was proposed by [20] to assess the regulatory readiness of organization for deploying BC technology in healthcare sector. To develop this framework, the study considered finding major regulatory issues associated with BC applications, impacts of data laws on BC adoption and determining how regulatory readiness of BC can be examined. The framework is developed based on literature review of BC structure, its applications, and regulatory issues affecting the adoption of BC. To systematically conduct literature review, Scopus database was used while specifying some inclusion and exclusion criteria, and 23 articles were reviewed to gain the conceptual and theoretical foundation for the proposed framework. The framework's applicability was outlined by applying the proposed framework in Portugal's healthcare sector and is claimed that the proposed framework is adaptable to several other sectors but how this framework can be customized for applicability in other sectors or suggestions regarding its scalability, have not been provided. The study has also not explained the mechanisms for selecting key dimensions and stakeholders from literature, which raises ambiguity in development process of model. Besides, applicability, the proposed framework or model has not been empirically validated.

From literature review, it was noticed that, for deployment of AI and BC technologies, various models and frameworks have been proposed, but these models or research studies have certain limitations. The research studies have proposed frameworks or models to assess the deployment of these technologies within only specific sectors or domains of government or e-government services and do not provide guidance for their general applicability or specific models for deployment of such technologies in overall government operations or for entire private sector organizations [19]-[20]. As these technologies are continuously evolving, no measures have been provided to keep the deployment process up to date.

Furthermore, these studies suggest models for independent deployment of either AI technology, or only BC technology and there are very few studies, which suggest models to assess the deployment of both technologies collectively [1], [19]-[22].

III. Research Methodology and Design

Processes as being fundamental to functioning of organization, are adopted to achieve organizations objectives, manage risks, and to deliver value to stakeholders. Majority of organizations also adopt process management strategies which include various methodologies, frameworks, and techniques to optimize and improve organizational processes to yield better outcomes. From literature review, it can be found that, various process management maturity models have been proposed such as capability maturity model (CMM), Business process maturity model (BPMM), Seven tenets of process management and many more, to ensure that processes are efficiently applied, managed and controlled across the organization. The CMM developed by Software engineering institute (SEI) for software implementation processes, consists of five levels of maturity (initial, managed, defined, quantitatively managed, and optimized), where each level has its own capabilities. The CMM evolved into capability maturity model integration (CMMI), which used same five levels of maturity of CMM with focus on five main factors which included: goals, commitment, ability, measurement, and verification. BPMM is another process management maturity model, which focuses on improvement of business process management. This model used the same five levels of maturity of CMM and focuses on three main factors/elements related for enhancing process management which include culture of performance, improvement and management excellence [23]. To assess the maturity of BC adoption, BC maturity model (BCMM) is proposed. This model also adapted five stages of maturity of CMM to measure the level of adoption of BC. This is a 4x5 grid model, which presents five stages horizontally and four crucial elements of BC adoption are presented vertically. The four main elements considered for BC adoption include Networks, information systems, computing methodologies, and security & privacy. This model provided a roadmap for assessing the adoption of BC corresponding to its four main elements, where the progress of adoption of these elements can be measured/marked according to five stages (initial, repeatable, defined, managed, optimizing) adopted [24]. As the implementation of AI and BC technologies in various operations of organization, itself is a detailed process, so inspired by above mentioned various process management maturity models the researcher (proposed initial framework) decided to add 5 stages of maturity in conceptual framework, which include Initial, developed, defined, managed and optimized stages. These stages would help organizations in determining their stage of maturity / progress to integrate these technologies. Because AI and BC technologies are intricate and multifaceted, applying them calls for an understanding of the interdependence of many organizational components. Four interrelated change dimensions comprising Strategy & Governance, Technology, People, and Process along with their variables and factors have been identified from literature. Organizations must enhance and assess these dimensions/elements for successful integration of AI and BC technologies in various operations. The entities implementing these technologies can mark their status of progress in five stages of maturity corresponding to each vital dimension of framework.

IV. Model Dimensions

For organizations to benefit from the combination of AI and BC, they must alter the ways they think, act, and learn. The dimensions proposed by framework must evolve separately and jointly in order to properly raise an organization's overall stage of maturity for AI and BC. Business leaders can expedite their overall organizational maturity and unlock progress for AI and BC projects by enhancing capabilities in less developed dimensions.

A. Strategy and Governance

Strategy & governance provides a broad frame of reference for all plans and choices made across all organizational departments [25]. Successful implementation of AI and BC technology is not just based on technical expertise, instead it also requires a comprehensive strategy and governance framework. The organizations should have well defined strategy to ensure that organization’s vision, mission and objectives are aligned with broader initiatives of AI and BC. This dimension will assess to what extent there is a well-defined strategy and vision that act as a road map for achieving organizational goals and objectives. An organization strategy should always be clear about the broad goals it pursues. Finding out what the organization's goal should be is the next step. Organizational objectives must consider Usability, Accessibility and Effectiveness [26]. As the implementation of these technology also poses serious concerns regarding data privacy & security, biasness, and vulnerabilities, the organizations should have robust governance frameworks to identify and mitigate these risks. The existence of proper governance mechanisms would ensure establishment of new rules & regulations to properly handle and govern citizens data which is used by these technologies and complying with existing data privacy & security regulations and many other regulations.

B. Technology

The implementation of AI requires various technologies such as Graphics Processing Units (GPUs), Natural Language Processing (NLP) tools, deep learning libraries, data processing and analytic tools etc. Similarly, the implementation of BC also requires distributed ledger technology, BC development tools such software development kits (SDK), application programming interface (APIs), and BC platform etc. Thus, technology dimension being fundamental to implementation of AI & BC technologies, provides foundation to successfully implement and manage AI and BC by providing necessary tools, hardware, software and storage. According to [27]-[28], the research work should be conducted empirically to ascertain the technological factors influencing the adoption of both AI and BC technologies. As he success of AI and BC deployment is determined by the technological environment of organization, including underlying technological infrastructure, storage mechanisms such as databases, compatibility of available technology, and how it’s being accessed and used by different users. The researcher considered Compatibility,

Databases Integration, and Technology infrastructure, and usability & accessibility to be vital factors of this dimension which are further explained in later sections. Thus, to successfully implement AI and BC technologies, organizations must analyse technology dimension along with its factors.

1) People: The existence of a human workforce equipped with essential skills and knowledge of AI & BC technology is indispensable to successfully implement these technologies. The People dimension focuses on coordinating change management and leadership to make sure that people are capable of using AI and BC technologies. If people do not have required digital skills and competencies, even the cleverest AI and BC solutions will fail. According to [29]-[30], the implementation of these technologies requires that executive leaders as well as all other employees to have knowledge and awareness of AI and BC technologies and their implications. Executive leaders must assist business and technical teams in delivering these technologies and utilizing them successfully. In order to always provide people with the best guidance and make decisions, when necessary, leaders themselves must have a solid understanding of the implications of AI and BC for their organization. Staff members also require awareness, training, competencies and even certification Courses in the process of building and deploying AI and BC solutions if they are to successfully construct and work with these technologies. While the implementation of AI requires a strong domain knowledge and expertise in data science, machine learning, mathematics, statistics, and programming, the implementation of BC also requires expertise in BC development, smart contract development, distributed systems, and familiarity with BC frameworks and platforms such as Corda, Polkadot, and Ethereum etc. Thus, training & awareness, digital skills, and competencies are considered important factors of people dimension.

2) Process: As AI and BC technologies are implemented to drive efficiency and effectiveness in overall organization process, so Process is considered important dimension. When implementing these technologies, it is important to consider how activities and tasks are managed on a daily basis, including how they are planned, communicated, organized, monitored, and controlled. Another body of literature examines how processes become more sophisticated and mature as an organization matures. The Capability Maturity Models describe many stages of process maturity that an organization goes through as it develops, beginning off without process disciplines and ending up as a developed organization where all processes are documented, automated, optimized, measured and controlled [31].

C. Model Stages

1) *Initial*: At this stage, organization's main objective is to understand and explore AI & BC technologies. The organization also explore the areas/process of organization where these technologies can be implemented and what would be the impact/benefit of implementation of these technologies to organization. To understand their feasibility and use-cases, organizations might conduct pilot projects or proof of concepts. The organization does not have proper AI & BC model at this stage and the implementation is confined to only specific department or use-case.

2) Developed: The organizations begin to integrate AI & BC technologies into existing systems and processes. The entities also begin to expand the implementation across various departments or process and enhance their foundational infrastructure and resource allocation to successfully implement these technologies for various purposes such as automating routine tasks, enhancing data analytics capabilities and predictive analytics. There are more sophisticated AI-powered applications and BC networks leveraging distributed ledger technology, used in organization.

3) Defined: Organizations have clearly defined process or use-cases for implementing AI & BC technologies. The implementation of these technologies expands to cover more business functions or systems which facilitates complex human-based interactions, provision of personalized services, optimized business processes and enhanced transparency and efficiency of business transactions. Putting AI & BC solutions into production at a larger scale still requires significant organizational work at this stage.

4) Managed: The organizations intend to scale AI & BC Solutions deployment efficiently as the number of Deployed AI & BC models increases. The organization is approaching a factory of standardized AI & BC model production, with a focus on optimizing the processes to maximize efficiency, security and reliability. Organizations implement robust monitoring and management systems to track performance, ensure compliance of implementation with regulatory policies and frameworks, and mitigation of risks. Organizations focus on continuous improvement in management of these technologies, emphasizing transparency and accountability of these solutions.

5) Optimized: Organizations have innovative level of implementation of AI & BC technologies and intends to drive new business models by leveraging highly advanced and collaborative AI & BC systems. Highly advanced AI & BC systems facilitate interoperability across multiple sectors and jurisdictions. The organizations focus on continuous learning and adaptation of emerging trends and technological advancements in these technologies, striving for sustaining competitive advantage and long-term success.

D. Results

As a result of the undertaken research, a conceptual framework is proposed which is presented & illustrated as follows:

1) Conceptual framework: The conceptual framework is presented in Fig. 1, which consists of a 4x5 grid to illustrate the relationship between the organizational dimensions and the various stages of maturity that businesses might process through to successfully implement AI and BC technologies.

The conceptual framework vertically presents the four dimensions that organizations must assess and work on their progress, and horizontally are five stages of maturity to mark the progress of organizations in each dimension. The five stages are key points in the development & evolution of these dimensions and filled ellipse under each stage indicate the progress of dimension corresponding to that stage. As organizations direct their efforts to enhance each of these dimensions, these dimensions would evolve/progress step by step from initial to optimized stage as indicated by arrow. For instance, filled ellipse next to Strategy & Governance dimension and under initial stage, indicates that strategy & Governance for implementing AI & BC technologies are at initial stage of development, which after progressing would reach at developed stage (as indicated by arrow) and then so on.

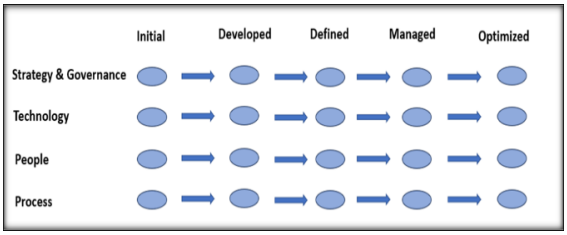

Fig. 1. Conceptual framework

Each dimension of maturity model is based on several factors which should be assessed and enhanced to optimize the overall progress of dimension. Each dimension can be progressed from initial to optimized staged if various factors of particular dimension are analysed and optimized. Fig. 2 presents the factors of each dimension of conceptual framework, which are further explained as follows.

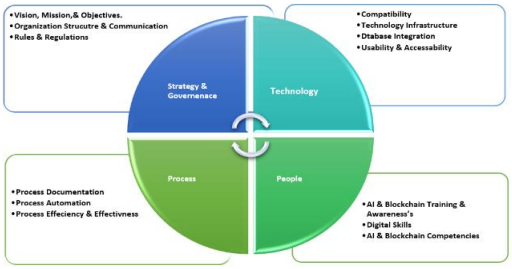

Fig. 2. Conceptual Framework along with its factors

2) Strategy and governance: The strategy and governance dimension can be assessed and enhanced based on its three crucial factor which include 1) Vision, mission and objective, 2) Organization structure & communication, 3) Rules & Regulations.

a) Vision, Mission, & Strategic Objectives: A vision states what the organization aspires to become in the future (Lead to adopt AI & BC). A mission reflects the organization's approaches and philosophy and resources that would be utilized to achieve the vision. Objectives are the more specific aims that organizations pursue to reach their visions and missions.

b) Organization Structure and Communication: Organization's structure and communication determines the manner and extent to which roles, power, and responsibilities are delegated, controlled, and coordinated, and shows how information flows between the levels of management and what sort of tools and mechanisms are used for communication. Organizational structure can boost coordination of communication, decisions, and actions.

c) Rules & Regulations: As the implementation of AI and BC technology raise serious legal and ethical concerns so various rules and regulations have been introduced to mitigate risks of these technologies. Therefore, it is essential for organizations implementing these technologies to comply the implementation process with government regulations and internally define regulations to protect mitigate risks and protecting citizen's information.

E. Technology

To assess and enhance the technology dimension of organization for successful integration of AI & BC technologies, vital factors related to technology that need to be considered include Compatibility, Technology infrastructure, Database integration and Usability & Accessibility.

1) Compatibility: Compatibility is the capacity of existing technology (both hardware and software) to implement and utilize AI & BC without going through extensive alterations in its infrastructure. For instance, various compatible software or applications might use the same data formats, such as compatible word processor applications enable the user to open read and modify word document files in either word application or editor. Thus, organizations should assess the level of compatibility of its existing technology to implement AI and BC.

2) Technology infrastructure: Technology infrastructures are components or systems comprising of both hardware and software which facilitate the effective functioning various operations/processes of organizations. As the implementation of AI requires infrastructure in terms of development tools, computational resources, data storage and management, APIs, and software development kits. and similarly, the implementation of BC requires nodes/computers, Peer-to-peer networking protocols, BC SDKs, storage infrastructure and BC mining hardware, etc. so organizations must assess and improve their technological infrastructure for deploying AI and BC in its processes.

3) Database integration: Database integration is the process used to aggregate information from multiple sources, like social media, sensor data from IoT, data warehouses, customer transactions, and more, and share a current, clean version of it across an organization. The existence of well-defined and managed databases is also crucial for successful implementation of AI and BC technologies.

4) Usability & accessibility: Usability refers to the quality of a user's experience when interacting with technology, applications or systems. Accessibility means that everyone can use the exact same application or system, regardless of any disabilities or impairments they might have. Thus, during the implementation of AI and BC the organizations should consider

usability and accessibility factor of their proposed solution.

F. People

As the implementation of AI and BC requires a workforce with strong knowledge, expertise and experience of these technologies, so people are another important dimension of conceptual framework. To assess and enhance competencies and capabilities of manpower to successfully integrate AI and BC technologies, factors such as AI & BC Training and Awareness, Digital skills, AI & BC competencies should be focused.

1) AI & BC training and awareness: If workforce involved in AI and BC related implementation projects is sufficiently aware of its implications and have comprehensive knowledge for implementation process of these technologies, the target of successful implementation would be achieved more easily. So, training and awareness regarding AI and BC should be provided to all employees, leaders and stakeholders involved in implementation process.

2) Digital skills: Digital skills are capability of employees to efficiently understand, use and navigate various digital technologies and tools which might include having basic computer literacy, data and information literacy, internet proficiency and many high-level expertise relevant to specific domain. As the implementation of AI and BC projects requires frequent interaction with technology so it is expected that employees have at least basic digital skills so that they can be trained to acquire AI and BC competencies. Thus, organizations must assess and enhance digital skills of their employees to successfully implement these technologies.

3) AI & BC competencies: The AI & BC Competencies are the basis of knowledge, skills and abilities in AI and BC technology. People involved in AI and BC implementation projects must possess subject relevant digital skills which might include proficiency in programming languages, training AI models, proficiency in BC platforms, smart contract developments and many other skills. Organizations must assess the level of competency of their employees relevant to these technologies before initiating the implementation process.

G. Process

To integrate AI and BC in organizational process, its essential to assess and enhance the mechanisms in regards of process documentation, process automation and process efficiency & effectiveness which are considered as the vital factors of this dimension. Process documentation, Process automation and Process Efficiency & Effectiveness are vital factors of this dimension which are defined as follows.

1) Process documentation: Process documentation is the act of capturing or documenting all the steps in a particular task. Ideally, it should happen in real time. As employees perform a task, they should document each step they take.

2) Process automation: Process Automation is the use of software to automate repeatable, multistep business transactions. In contrast to other types of automation, BPA solutions tend to be complex, connected to multiple enterprise information technology (IT) systems, and tailored specifically to the needs of an organization. The organizations must identify the processes which can be automated by AI and BC.

3) Process efficiency and effectiveness: Process efficiency is essentially "the amount of effort or input required to produce your public sector transactions that lead to provide customers with most efficient government services. Process Effectiveness is defined by achieving public sector targets, such as Customer Happiness, Positive Impact of Government Services, and fully Integrated Digital Services. Thus, organizations must assess the level of efficiency and effectives of its processes and should direct its efforts to improve least efficient and effective processes.

V. Conclusion

In this paper, a conceptual framework is proposed to assess the efficacy of organizations to successfully implement AI and BC technologies in their operations. This framework depicts four dimensions including strategy & governance, technology, people and process, where each dimension has various potential factors that could influence the acceptance and implementation of AI and BC. In this framework, the researcher has proposed five stages of change consisting of initial, developed, defined, managed & optimized to assess and mark the efficacy of organization corresponding to each dimension, to successfully implement AI & BC technologies.

Future Work

Further the researcher plan to get this conceptual framework validated by conducting interviews and employing qualitative data analysis to yield detailed insights and improve the conceptual framework according to results of analysis. The improved version of conceptual framework turned into maturity model which would also be validated in later stages of this research journey.

***Abstract*—Information is disseminated through images in newspapers, periodicals, the internet, and academic journals. With the aid of various tools such as Adobe, GIMP, and Corel Draw, distinguishing between an original image and a forgery has become increasingly challenging. Most conventional methods rely on constructed traits for detecting image counterfeiting. Image verification plays a crucial role in securing and ensuring the authenticity of individuals' identities in sensitive documents. This research proposes a machine learning approach (Support Vector Machine, SVM, and Histogram of Oriented Gradients, HOG) to identify images and confirm their authenticity. The Histogram of Oriented Gradients (HOG) is employed to extract diverse features including matching, image size, and dimensions for image verification. The training and testing phases are carried out using a Support Vector Machine (SVM). The proposed image verification technique is evaluated using extensive datasets to ascertain image recognition accuracy, alongside metrics such as specificity, sensitivity, and precision. Comparative analysis with existing techniques reveals that the average image verification accuracy of the proposed method stands at 98%, surpassing previous image verification methods.**

***Keywords*—Image verification; machine learning; ensemble approach; multi-feature image recognition**

I. Introduction

Images are now increasingly one of the primary sources of information and are essential in various disciplines, including medicine, education, computer forensics, sports, and the media. Thanks to tools like Adobe Photoshop, GIMP, Coral Draw, and Android apps like Photo Hacker, creating a fake image is surprisingly simple. When a picture is presented as evidence in court, its veracity becomes extremely important. Any operation performed on digital photographs using ana program is called image manipulation, or "image editing". Image forging is a technique that alters an image's content to make it inconsistent with historical events. Image manipulation is if the new content is copied from the same image itself, then it is called copy-move tampering, and if the new content is copied from a different image, then it is called image splicing [1, 2]. The methods for detecting picture alteration can be divided into two categories: (i) active and (ii) passive. In an active approach, a person with authorization embeds extra details (such as a digital watermark) into the image either during the acquisition phase or later.

This embedded data is used by the active technique to detect manipulation. The passive methods do not rely on extra information to detect forgeries. These methods are sometimes known as "blind approaches" because they don't require additional information to detect forged documents. The passive methods take the image's features and utilize them [3].

In our proposed method fake images made using pixels detection is to confirm the veracity of electronic pictures without providing access to the source image. We proposed machine learning algorithms for image processing and feature extraction recognition by using the copy move forgery. The objective of duplicate forgery is to replicate or conceal an object by cutting it out of one region of the image and putting it into another [4, 5]. Post-processing on altered photos, however, can make the work of spotting instances of forgeries far more difficult.

The proposed idea deals with image verification performance as well as image verification accuracy.

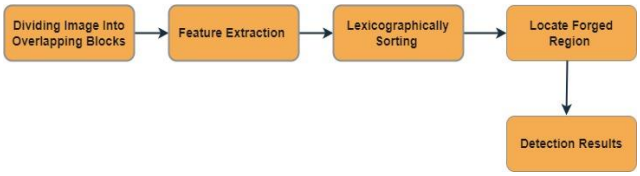

Fig. 1. Basic steps for pixel-based forgery image detection.

II. Literature Review

With picture editing software, digital photos may readily be altered. It is critical to detect manipulation attempts. Without prior knowledge of the source photos, passive digital picture tampering detection tries to confirm the validity of digital photographs. In recent years, numerous strategies have been proposed in this field [6, 7]. This work presents the three tiers of these methods low-level, mid-level, and high-level. At each level, the essential concepts of the suggested approaches are discussed in detail along with some remarks. The authors in [8] proposed a deep learning-based algorithm to detect fake images in order to recognize the image and retrieve its information, this technique employs a convolution neural network design. What investigation utilized the MICC-F200 dataset? Design process parameters were used to assess the model's performance. The accuracy of the model was 95.5%.

Numerous researchers have already developed several approaches for detecting pixel-based image counterfeiting. In study [9, 10] author provided a framework to recognize fake paper photocopies using the bounding box technique. This technique mainly focuses on identifying copies of documents that have been edited by adding new text above it, smearing whitener over the old text, and then editing the contents using the cut-and-paste technique. The effectiveness of this technique

is about 86%. The advantage of this method is that it does not need expensive hardware. It does not function when photocopied documents have background art or dust. The work can be improved by making better use of the bounding box features. For better results, a single strategy rather than a hybrid can be utilized for categorization. One of the most common types of picture forgeries was first presented by Paul and other writers in 2019. The SURF and k-NN algorithms are the foundation of this method. In addition to using K-NN for training and mapping, Paul et AL Speeded-Up's Robust Features method extracts essential details from the image. Compared to SIFT-based approaches, this method promises cheaper processing costs while displaying higher accuracy. SURF- based methods, however, do not consistently follow the edges[11, 12].

In study [13-15] authors suggested a pixel-based method for spotting fake images, which uses the Columbia DVMM dataset, which is openly accessible. This strategy is based on Hilbert-Huang transforms (HHT) and support vector machines (SVM). SVM was utilized as a classifier, and HHT approaches were applied for feature extraction. The test is conducted in MATLAB, and the evaluation parameters are used to derive results for three metrics: true negative (80.25%), true positive (80.03%), and accuracy (80.15%).

The proposed method will be developed using MATLAB 2013a as a tool, and it is crucial to focus on the libraries and methods required to run the suggested strategy. Framework.NET will be followed Working Approach of Proposed Method:

Step 1: The proposed system architecture will give an image for training.

Step 2: After that, pre-processing functions are applied for image processing and covert RGB image in grayscale image.

Step 3: Feature extract from the images.

Step 4: Train the images on a proposed method based on matching objects, speed, and Edge pixels. Step 5: Verifywhether the image is original or forgery.

A. Significance Research

In every area of life, verifying the picture has grown to be a significant difficulty. Most verification algorithms have low performance and accuracy. What makes the recommended method notable is its utility in highlighting the benefits of TP, TN, FP, and FN. The proposed approach can be utilized to validate the image and demonstrate correctness by utilizing several evaluation criteria.

B. Image Acquisition

The original and fake image is acquired from the gallery at this stage.

C. Pre-processing

The color conversion is carried out in the second stage of our process. The following formula is used to convert the RGB image first into the grayscale image I: I = 0.299R + 0.587G + 0.114B. It stands for the brightness component, where R, G, and B are the input color image's red, green, and blue channels. In pre- processing, images are selected as"original images" or "fake images." The image dataset's extension should be (. JPJ, .PNG, .PGM, .TIFF).Pre-processing of the image can be done using image processing techniques that involve 2D and 3D (R, G, and B)with the size of (Im, 3) = 3. The IF image is a colour image that has been converted into gray. Some functions are pre-processed, such as Im = rgb grey (Im); end. In this study, the Kaggle datasets have been used for pre-processing and feature extraction, which are publicly available.

III. METHODOLOGY

The proposed method has used well-known techniques to make image recognition whether the image is fake or original. The evaluations matric for the proposed method included precision, accuracy and recall. The dataset used to evaluate the suggested strategy is available to the public. However, some random dataset has also been taken for evaluation to show the accuracy of the proposed method. The SVM and HOG schemes have been used to verify the original or fake image, which contains four fundamentalphases.

There are four steps in this image recognition process. In the first step, the image is acquired, pre-processing is donein the second step, and the image features are extracted in step three. The last step is image forgery detection. Fig. 1 explains each of these steps.

- Image Acquisition
- Pre-processing
- Feature Extraction
- Forgery Detection

The research makes use of a dataset of pictures. The image dataset has been converted to CSV format. The dataset is pre-processed before the CNN method is applied. The categorization of images is finished. Lastly, it is possible to determine whether the image is false matched, time may be saved, especially if feature extraction methods like DCT or PCA are used.

The suggested work has the following phases.

- The image is divided into corresponding blocks of a fixed size.
- Features extract of each block using HOG descriptors.
- Similar block pairs correspond then SVM is used to find whether the image is a forgery or genuine.
- Lastly, a bounding box is created for copied areas.

The proposed method is shown through data flow diagrams. The DFD is also known as a bubble chart. It is a simple graphical structure that may be utilized to describe a system in terms of the data input, the various operations carried out on it, and the information created as an outcome of those activities.

The data flow diagram is the most vital modeling tool. It is used to construct the component models for the system. These components include how the system works, the information it uses, how a third party interacts with it, and how data flows through it. DFD displays the system's information flow as well as the numerous modifications that have an impact. It uses

graphics to show how information moves and how data is altered as it moves from source to output.

Table I compares a number of image forgery detection techniques. For every entry, there is a list of the recognition technique, feature extraction strategy, datasets used, photo forgery type addressed, recognition parameters, achieved accuracy, and researchers involved. The table shows that the recommended SVM strategy employing HOG features achieved the highest accuracy of 98% in copy-move forgery detection. This suggests significant advancements in digital image forensics.

In the chosen image from the dataset, shown in Fig. 2, several objects captured in the scene are depicted. These images have been submitted for pre-processing to lower noise and unused pixels. After that, features are extracted using the feature extractor function (HOG). Histogram of Ordered Gradients is a pattern extraction method comparable to Scale Invariant and Fourier Transform (SIFT) Canny Edge Detection. It is employed in computer recognition and image processing for object detection. An image dataset is used for both training and testing the SVM classifier. The Confusion matrix is then used to examine the SVM findings.

A. Tools and Technology

The suggested technique has been implemented in MATLAB. MATLAB R2013A was used to experiment with the suggested technique of system implementation while running under Windows 7's 64-bitoperating system. The desktop computer has a Pentium processor and 1 GB of physical memory (RAM). Dual Core processor central processing unit (CPU). A keyboard and mouse are used for input. The suggested system was made using a variety of programs and libraries.

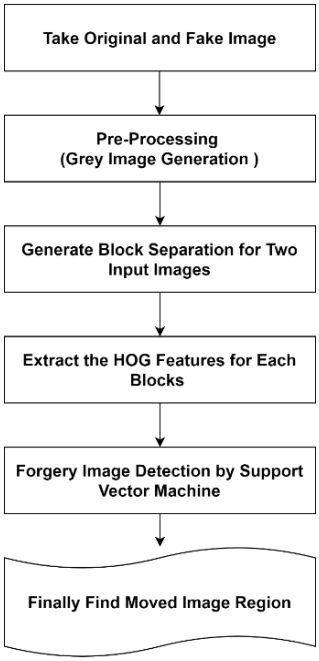

Fig. 2. Image recognition process of suggested algorithm.

Normalized image.m	This method is used to determine the image sizeand twice its size
Divide DB.m	Each feature is represented as a matrix with thedimensions feature-length x total features.
Calculate results .m	Do the True Positive & Negative calculations. Thenumber of true classes in classes 1 and 2 of the confusion matrices

Table II lists some significant functions that MATLAB utilizes to carry out algorithms. Other significantMATLAB 2019a libraries are used to support the suggested system

TABLE III. SOME OTHER LIBRARIES USED IN THE PROPOSED METHOD

MATLAB Libraries	Description
LIBSVM	For picture training and testing, the SVM classifier is applied in MATLAB.
Sklearn	This library is used for implementing the Support vector machine
y = f(x)	Display the findings in columns and rows

Table III shows the MATLAB libraries and its descriptions. The suggested solution was developed in MATLAB 2013A, a more productive programming language, Application-specific software. It can be considered an external library and is used to implement our approach. It offers many library functions that are simple to use for personal authentication the image recognition. The suggested techniques can be implemented in a variety of computer languages, but for our study, we chose MATLAB2013A.

B. Forgery Detection

A feature match is finished after the two photos' traits have been extracted. After that, the noise in the area containing the counterfeit was removed using a wavelet transform. The final region is sent as input to the SVM for forgery detection. According to the SVM output, a score of 0 denotes authenticity, and a score of 1 indicates forgery. Overfitting issues can be resolved using Support Vector Machines (SVM), even though this technique is normally associated with the classification. There is no problem handling many continuous and categorical variables. SVM is used to create a hyperplane in multidimensional space to divide different classes. SVM iteratively creates an ideal hyperplane to decrease error. The primary objective of SVM is to locate an MMH that best classifies the dataset [16].

The most crucial task of a duplicate image forgery identification system is finding out whether a given image has duplicated portions. Intelligently speaking it is challenging to evaluate each pair of areas individually, pixel by pixel, because of post-processing processes like rotation, scaling, blur deterioration, and changes, in contrast. In comparison, cannot be known in advance [17, 18].

An image produced by a system is recognized by the specific standards diagram shown in Fig. 3. Despite the effectiveness of various approaches for validating photos, they may not be able to identify complicated false images. It does not make the owner's verification secure. The design of the proposed system is divided into three groups.

C. Datasets

For image recognition datasets, there are numerous ones that are openly accessible. We used images as a document. The suggested method is assessed using the datasets. The dataset has been utilized in other research studies. MICC_F600, MICC-F220, MICC- F8multi, CoMoFoD_small_v2 Dataset have been used in the proposed method.

The goal of the recommended technique was to effectively enhance an image recognition system so that it could determine if a picture was real or fake. The SVM classifier is utilized for object-based picture recognition. The proposed classifier uses various image recognition factors that demonstrate the viability of the provided approaches. Sensitivity, specificity, accuracy, and precision are among the various variables that can be utilized for recognition purposes.

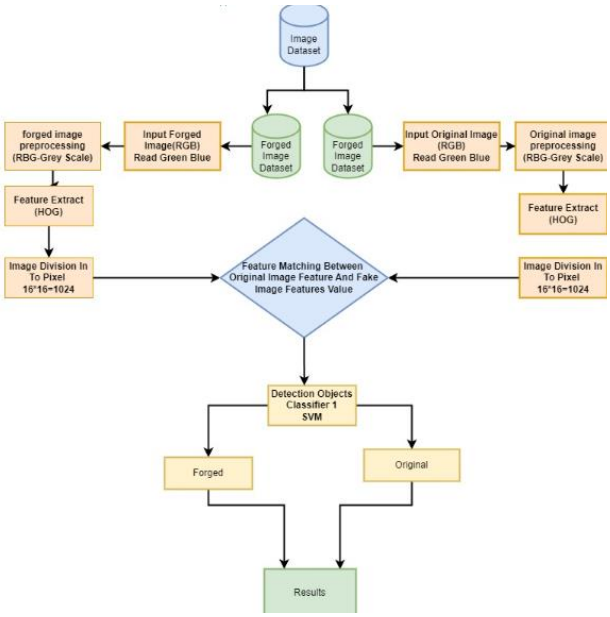

Fig. 3. The complete design of the proposed method.

D. Evaluation Metrics

These settings are thought of as conventional for picture recognition. Many researchers employed this parameter for pixel-based picture recognition [19]. The following formulas are used to calculate evaluation metrics.

$$\text{Confusion matrix} = \frac{TP + TN}{TP + TN + FP + FN} * 100$$

Most researchers have utilized this formula to validate picture recognition in their studies. An overall valuation is mostly used to assess the efficacy and verification rates of the suggested approach. In the confusion matrix (FN), four terms are employed: true negative (TN), true positive (TP), false positive (FP), and false negative (FN). In essence, the confusion matrix is a table with rows and columns using a row, the training ratio is displayed. The number of photos used as a dataset is

determined using the training ratio. The TP, TN, FP, FN, accuracy, precision, specificity, scores, and sensitivity are represented by columns [20].

$$\text{Verification rate} = \frac{\text{Total number that verify } * 100}{\text{Total number of images}}$$

A genuinely positive image that is stored in a database is divided by all positive photos, including false positives, to determine precision. The accuracy is detailed below.

$$\text{Precision} = \frac{\text{True Positive}}{\text{Total Positive } + \text{False Positive}}$$

To determine the specificity, the number of real positive images in a database is divided by the total of all negativeand false-positive photos [21]. A genuinely positive image stored in a database is divided by all positive photos, including false positives and negatives, to determine sensitivity. The sensitivity described below.

$$\text{Sensitivity} = \frac{\text{True Positive}}{\text{Total Positive } + \text{False Negative}}$$

A database's existing false negative image is divided by all positives plus false negative photos to determine the false rejection rate. The FAR is explained below.

$$\text{FRR} = \frac{\text{False Negative}}{\text{Total Positive } + \text{False Negative}}$$

FAR is calculated by dividing a false-positive image from a database by the sum of false-positive and true-negative images [22]. Below is a description of the false mistake rate

$$\text{FAR} = \frac{\text{False Positive}}{\text{False Positive } + \text{True Negative}}$$

AER is calculated by adding the false error rate and the non-match rate. Below is an AER description [23].

$$\text{AER} = \frac{\text{FAR} + \text{FRR}}{2}$$

IV. Result and Discussion

The technique required the installation of a MATLAB software application, downloaded from their website, which included a graphic user interface developed by Miao et al. for image examination and verification. The GUI interface was constructed using MATLAB and was used for verifying and analyzing feature extraction results, as well as assessing the performance of two algorithms. Feature extraction was performed by selecting the HOG button in the GUI windows, using a library with train weights that serve as changeable weights for component reversal [24].

To test the proposed method, a dataset of 69 photographs, including 24 authentic and 16 beautifully faked photos, was used to obtain results based on each pattern's intensity and similarity. Many earlier scientists had already utilized these datasets in a proposed manner for high accuracy. Block comparison was used in this research to detect matching blocks and to suspect fabricated sections. According to the suggested scheme, matching blocks were found by calculating the Vectors of features' Euclidean distances. To correctly detect fabricated regions, the distance threshold Td and similarity criteria must be predetermined.

The predict button is used to predict the image as forged or genuine as shown in Fig. 4.

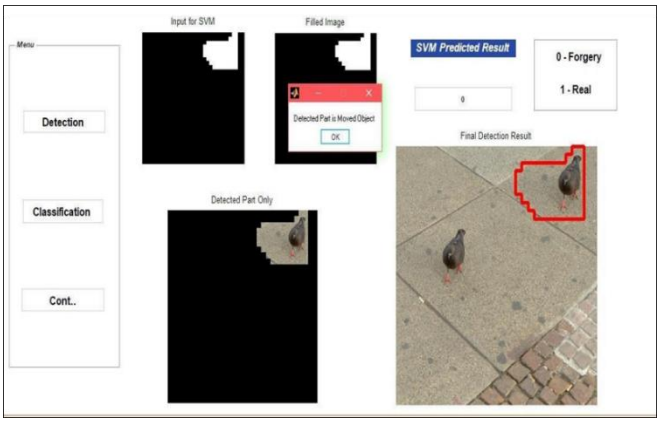

Fig. 4. Detect object using the feature matching.

The image is fragmented into 16X16 numbers of blocks. The total value of one picture is 1024. The picture is divided into blocks of overlapped squares to help find forged sections. To calculate the HOG descriptors, the grayscale image I of M N is first split into overlapping sub-blocks of L. Then, overlapping (M L + 1) (N L + 1) pieces of the image are created. GUI is used to access the project. The purpose of pressing the train button is to facilitate machine training.

Table VII shows the fake values of each block of the images. Each connected block is represented by a HOG descriptive matrix that is the same length as the block after HOG has been applied to each block. The local histogram is considered in the following with four bits. Each histogram bin corresponds to a 45-degree orientation interval because of the histogram's uniformly spaced channels between 0 and 180. Table VIII and Table IX respectively shows Hog feature and feature matching between original and fake images.

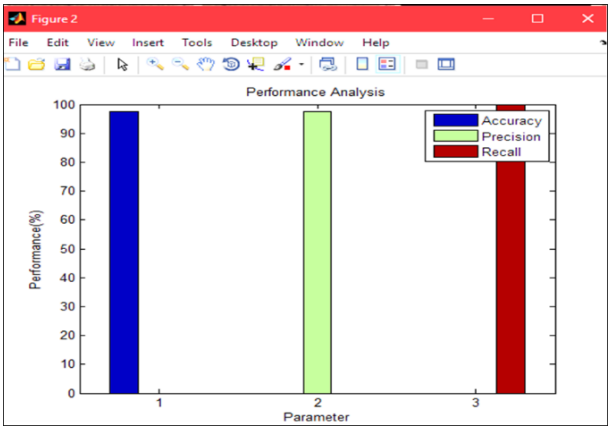

Fig. 5. Final accuracy of suggested algorithm.

A separate collection of entirely separate images is created for testing purposes, and the features matrix is extracted from these. A supervised machine learning technique called SVM is frequently employed for classification issues. This technique uses the value of a certain set of coordinates as a feature value and plots it in relation to a position in n-dimensional reality. A decision boundary (hyperplane) that isolates the two-class datasets from one another as much as feasible is created by the SVM classifier. SVM classifier will more accurately determine if the image is real or fake. SVM classifier detects the object that is used for image recognition whether the image is fake or not. If the image is a forgery. If the image is authentic or original, it displays message 1, and else it displays message 0. Fig. 4 and show a test image that is fake identifying the testing sample's forgery or duplicate move regions. Fig. 5 shows the accuracy that deals with how closely the calculated values are to the true values, and it must be high.

The suggested method is having great similarity levels to distinguish the copy-move sections in the testing datasets. The accuracy of the proposed algorithm is 98%. Table X shows comparison between different algorithms with the proposed method.

V. Conclusion and Future Work

Using the Histogram of Oriented Gradients (HOG) and Support Vector Machine (SVM) algorithms, we provide a unique method to improve picture verification. The findings demonstrate that the suggested strategy distinguishes between real and fake photos with a remarkable accuracy rate of 98%. The usefulness and promise of the HOG-SVM combo for image verification tasks are shown by the accuracy, which exceeds numerous other comparable techniques. The research underlines the value of picture authentication systems in several fields and draws attention to the shortcomings of current approaches for identifying intricately faked images. The suggested method overcomes these difficulties and provides a significant boost in recognition accuracy, making it an important addition to the area of image verification. It does this by using HOG and SVM.

Overall, the study offers insightful information on the application of feature extraction methods and supervised machine learning algorithms to picture recognition. The suggested method's high accuracy raises the confidence and dependability of picture verification systems, possibly resulting in greater security and credibility in various image authentication-related applications.

A. Future Work

The current system indicates the importance of image verification. This research shows an accuracy of 98% but more amount of research and present methods can be added by using other image datasets and Implementations. Develop a working model and Record observations based on the dataset. More clear images must be used in the dataset for extracting the image features.

Conflicts of Interest

The authors declare that they have no conflicts of interest to report regarding the present study.

Forschungsring e.V., 64295 Darmstadt, Germany[5, 6]

***Abstract*—The objective of the study was to investigate whether heart rate variability (HRV) is an appropriate method to describe potential effects of RF-EMF on humans considering a modern office environment radiation level with the frequencies 1.8 GHz (DECT) and 2.45 GHz (Wi-Fi) and an exposure time of 10 min. The emitters were 1 m distant from the test subjects. The HRV parameters SDNN, RMSSD, LF and HF were recorded from 60 adults in three runs, totaling up to 154 recordings. Effects were evident for the parameter SDNN. In two runs, HRV changed from control to exposure phase, in one run from exposure phase to control. The cofactors smoking, coffee consumption, and the use of strong medications did not modulate EMF effects. HRV seems to be suitable to detect effects of radio-frequency electromagnetic fields on humans under certain conditions. In the future, prolonged exposure and new frequencies (5G) should be included in order to provide a better description of RF-EMF effects in modern office environments.**

***Keywords*—Radio frequency electromagnetic fields; heart rate variability; office environment; Wi-Fi; DECT**

I. Introduction

There are a growing number of scientific studies on the effects of RF-EMF on human health [1]. Belpoggi [1] evaluated thousands of studies for the European Parliament in its scoping review. The main discussed harms are cancer promotion [2], decreased fertility [3] and blood-brain barrier disruption [4].

Oxidative cell stress is assumed to be the mechanism of action. In the review by study [5], 100 studies were evaluated. Of these, 93 studies demonstrated microwave radiation-induced oxidative cell damage. All studies were conducted with field strengths below the ICNIRP established limits. For example, [5] describes that oxidative damage occurs at a power flux density as low as 1 mW/m^2, which is 0.002% of the ICNIRP limit [6] (ICNIRP 2020 Guidelines, 50 W/m^2 the limit).

In 2011, the WHO classified RF-EMF as possibly carcinogenic to humans [7]. Meanwhile, a higher classification is demanded by numerous scientists [8, 9].

Most studies are conducted on animals or on cells, few investigate health effects on humans directly [10].

The determination of heart rate variability (HRV) is a well-established method to evaluate the activity of bioregulation [11]. Heart rate variability (HRV) is the variation in the time intervals between two heartbeats and reflects the functional state of the autonomic nervous system [12]. It is a non-invasive marker for autonomic input to the heart [13]. Stress (e.g., mental, workplace-related) usually leads to a reduction of parasympathetic activity and thus to a reduction of the HRV [14, 15].

In a recent review [16] of RF-EMF effects on humans, there are few studies on the effect of RF-EMF on cardiac functions in humans. Parizek et al. [17] state that currently there are few studies that have examined the effect of electromagnetic radiation on HRV in healthy individuals.

The study in [18] investigated the effects of mobile radio (GSM 900 MHz) on heart rate and blood pressure in 10 volunteers. HRV was not recorded. Blood pressure increased after 60 sec. of exposure.

In their provocation study, [19] investigated the effect of mobile radio (900 MHz) on healthy subjects. HRV data differed significantly between treatment and control. The higher LF activity and the lower HF activity might be interpreted towards a shift to sympathetic activity.

This turn is often regarded as a sign of an increased stress level [19]. In the study by [20], 26 young healthy volunteers were used to investigate whether exposure to 900 MHz from mobile phones alters the regulation of the cardiovascular system. There were significant changes in some time domain (including SDNN) and frequency analyses (LF power).

Andrzejak et al. [21] investigated the influence of mobile phone conversation on HRV parameters in healthy subjects. Significant changes were found in the parameters SDNN and SDANN, however, the influence of talking on the results cannot be excluded.

Yılmaz and M. Yıldız [22] found an influence of mobile radio (900 MHz) on the HRV of 16 young healthy volunteers using the Lyapunov exponent calculation. The degree of chaos in HRV increased with the use of mobile phones. Havas et al.

[23] investigated the effect of cordless phone at 2.4 GHz radiation on 25 subjects. 40% of the subjects show changes in their HRV due to pulsed (100 HZ) microwave radiation. A study conducted on 164 police officers by [24] resulted in a change in HRV values. Exposure to the TETRA frequency band (380-395 MHz) occurred directly on the police officers' chest.

In the study of [25], subjects were exposed to a 50 Hz sinusoidal magnetic field. The total power of HRV was significantly lower under exposure than in the control.

The study by [26] showed some effects of 1.8 GHz on time domain HRV of 20 healthy volunteers but depending on breathing rhythm.

The question arises whether HRV is suitable to measure potential exposure to RF-EMF in a modern office environment. In the earlier studies on EMF and HRV, Wi-Fi frequencies were rarely considered, many studies referred to the frequency 900 MHZ, which is hardly used today. In our study, the RF-EMF exposure in a modern office environment should be simulated. For this purpose, exposure to the frequencies (1.8 and 2.45 GHz) took place. After a rest period of 10 minutes, the exposure was performed for 10 minutes. This was followed by another rest period of 10 minutes. The following main hypotheses were formulated:

1) EMF exposure (phase 2) decreases the HRV of the subjects compared to phase 1 (no exposure).

2) After exposure (phase 2), the HRV of the subjects increases again.

The secondary hypothesis was formulated as follows.

3) The cofactors smoking, coffee consumption and the intake of medication change the response of the subjects to EMF.

II. Material and Methods

A. Study Design

The project was a single-blinded provocation study. It was conducted in a laboratory. 60 adult persons were tested in three runs (60, 54 and 40) with a total of 154 observations.

B. Participants

Participants were recruited via advertisements on the campus of the University of Oradea and through direct contact (phone calls, messages and e-mails) from the Research Department, at the University of Oradea and surrounding general contacts in Bihor county.

During the survey period (March 2021 to December 2021), 61 people made contact as a result of the recruitment strategies. Of these, 61 people expressed interest in the study and all 61 came to the first testing session (run 1) and signed the informed consent form and the printed screening form in which general questions (concerning sex, date of birth, profession, use of electronic devices in general and previously during the day of the test, amount of caffeinated beverages consumption, medication usage and cigarettes smoking previously during the day of the test, contact details - address, phone number, e-mail address) were answered. The only inclusion/exclusion criteria were related to age: the subject must be over 18 years old (adult). At the beginning of the testing session, other parameters were asked to be introduced in the ECG-Holter database (as height, weight and acute or chronic somatic or psychiatric diseases). Additionally, the participants in the test signed an internal form of SARS-COV-2 declaration in order to prevent the spreading of the disease. Prior to the start of every testing session, participants were asked to refrain from smoking or consumption of caffeinated beverages in the preceding two hours of the experiment. Additionally, participants were asked to wear casual clothing. Participants were asked about consumption of caffeinated beverages, smoking, and medication use (for heart and circulatory problems, diabetes, endocrine issues and lupus).

Of the 61 participants in the first run, 1 was excluded from the data processing of the results and statistics, because of an existing pacemaker that made the study irrelevant for the person in cause. Hence, for the first run, the results and statistics considered data from the remaining 60 participants. In the second run, from the initial 61 people, 54 participated in the test. In the third run, 40 people from the 54 participating in the second run took part in this third testing session.

In all three runs the participants in the experiment completed the consent form, the questionnaire and the CORONA-form. Demographical data for all three runs are presented in Table I. In all three runs of the experiment, the testing sessions were developed during daylight, between 13:00 and 16:00.

TABLE I. Sociodemographic Data of the Participants

Period of execution	Age			Sex	
	18-29 years	30-49 years	50-65 years	Male	Female
Run 1 (4/3/2021-4/5/2021)	20	22	19	31	30
Run 2 (17/5/2021-23/6/2021)	18	20	16	28	26
Run 3 (4/10/2021-7/12/2021)	13	14	13	20	20

C. Experimental Design and Procedure

In a room with low background exposure, subjects were exposed to DECT (1.8 GHz) and Wi-Fi (2.45 GHz) in a relaxed sitting position, with a 5-lead ECG Holter monitoring the cardiac functions. The distance to the transmitters was approx. 1 m. The measurements took place over 30 minutes.

In the first 10 minutes (OFF1) the transmitters were switched off, in the second 10 minutes the devices were switched on (ON) and in the third 10 minutes (OFF2) the devices were switched off again. In addition, there were considered also 10 minutes for completing the forms, before the test (the personal questionnaire, participation consent and Corona declaration), with no exposure at DECT or Wi-Fi.

The entire procedure and the subject's medical data were managed and supervised by a medical doctor. The subject was alone in the room during the test, having just basic information about the aim of the test (e.g. some health parameters will be measured under controlled Wi-Fi emission levels: minimum

almost zero and normal for an office environment). The subject was not aware when the signals were ON or OFF, being completely blinded in relation to the phases of the experiment. The flux density on the subject was approx. 16000 μW/m² on the ON phase of the experiment and almost negligible during the rest. A technical staff member was present during the entire experiment in room 2 to ensure the experiment ran correctly and was identical during each test.

The measurements were carried out in early spring 2021 with 60 subjects (run 1), in summer 2021 with 54 subjects (run 2) and in late autumn 2021 with 40 subjects (run 3).

Participants were recruited via advertisements on the campus of the University of Oradea and through direct contact (phone calls, messages and e-mails) from the Research Department, in the University of Oradea and surrounding general contacts in Bihor county.

D. Technical Set-up of the Intervention

1) General technical prerequsite for the experiment: The location for the experiment was chosen in a remote seminar room of the University of Oradea, where no other wireless networks or other wireless devices were present. For the active phase of the experiment common commercially available wireless equipment was used, as the ones often encountered in ordinary working environment as classrooms or offices (SOHO – Small Office, Home Office - wireless router or DECT cordless telephone equipment). No modifications of any kind have been made to the equipment, which complies with current standards.

Before the experiments, measurements of the radiation levels in the room were done using a radio spectrum analyzer (Spectran HF-4040) [27]. The power level of background radiation in the frequency band of Wi-Fi networks was about -80 dBm. This relatively low level is due to the remote location and the construction specific features of the room, making the location well suited for the experiments.

To generate the signals transmitted over the Wi-Fi network, it was sufficient to use a single wireless access point (router) and a single laptop connected to it. It is not necessary to use more PC/laptop equipment as only one device will transmit at a time, due to the IEEE 802.11 specification. Due to this modus operandi, at a certain time the signals will always come only from one station even if more than one device is connected to the network. Hence, only one entity will transmit at a time, so the peak RF radiation level does not increase if more devices are connected to the network.

To maximize the radio frequency signal level, forced traffic was generated in the network. Traffic generation is done by transmitting data over the network at the maximum speed the network can provide, using specialized software. The speed at which data will be transmitted is influenced by several factors: the distance between the laptop's wireless adapter and the router (and therefore the signal level) or disturbances due to other nearby Wi-Fi networks, especially if they are located on radio channels close to the network under test.

Also, interference caused by other devices in the 2.4 GHz band (microwave ovens, Bluetooth devices, etc.) can affect the network's operation.

The location for the experiments was specifically chosen to minimize the influence of these external disturbing factors.

There were no other Wi-Fi networks in the area and no other equipment producing radiofrequency radiation in the 2.4 GHz band was present in the test location. The network was thus able to transmit radiofrequency packages with almost optimal efficiency.

To achieve a high level of traffic, a large file can be downloaded over the network, or specialized software packages able to determine the maximum transfer speed in a network can be used. For the traffic generation in the experiment, the iperf software package was used [28]. Iperf is a program for bandwidth measurements between two or more computers or devices on a local area network or the Internet network. Iperf usage guarantees high and constant network traffic.

To ensure blinding and to avoid any influence of an experimenter on the results of the experiment, the control of the applications was done using remote desktop software. The software used to remotely control the experiment was VNC (Virtual Network Computing) which is a graphical desktop-sharing application to remotely control another computer, allowing the transmission of keyboard and mouse input from one computer to another, while sharing graphical-screen updates, over a network [29]. VNC was used to remotely turn on and off the wireless adapter on the laptop.

The connection diagram is shown in Fig 1. To keep the connection with the laptop and to be able to control it even when the wireless connection is switched off, the laptop is also connected to the router via a wired connection. The control through VNC is done over this wired connection. The computer controlling the experiment remotely, located in an adjacent room, was also connected to the network. The wireless interfaces of the router and the laptop were remotely controlled, to simultaneously switch on and off the wireless signal throughout the phases of the experiment.

During the experiments, the human subjects were exposed to Wi-Fi signals emitted by the router and laptop, superimposed with signals corresponding to a DECT phone call. In this regard, a DECT base station was placed in the room where the subject was located, to which a cordless telephone receiver was connected via radio waves. The DECT signals were turned on and off at the same time as the Wi-Fi signals were, by connecting and disconnecting the DECT base station from the power source and by turning the DECT phone on and off.

E. Analysis of the Signals used in the Experiment and Assessment of the Exposure Levels

The level of Wi-Fi radiation and DECT was measured using multiple devices. First, the emitted power was assessed using a radio spectrum analyzer (Aaronia HF-4040). These measurements were performed over the entire duration of the experiment (30 minutes) and the level of radio power received by the device was recorded. These measurements allow an overview of the wireless devices' power variation over time.

During the ON phase the power received by the spectrum analyzer does not show large variations, around -28dBm. This is considerably higher than the background radiation that was present in the OFF phases, when the power level is also constant, with a value below -80dBm.

The recording of the radiation power level was analyzed using a Matlab program to obtain a visualization of the radio-frequency levels. This 3D visualization basically combines the previous two figures into power analysis in both time and frequency domains and is presented in Fig. 2.

Wi-Fi signals in the 2.4 GHz frequency band were used in the experiments.

In Fig. 2 it can be seen that Wi-Fi channel 7 (2431-2453 MHz) in the central region of the frequency band intended for those networks was chosen, to make the experiment results as relevant possible for the whole Wi-Fi frequency band.

Most Wi-Fi networks nowadays use this frequency band, and networks in the 5 GHz band are generally scarcer.

A Panasonic KX-TG1611FX DECT station was also placed near the subject and activated at the same interval of time as the router. The DECT devices (the phone and the base station) were also turned on and off synchronized with the Wi-Fi devices.

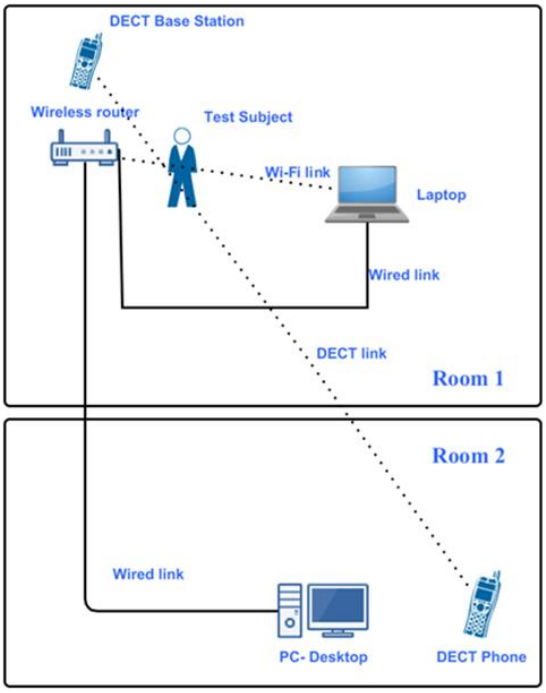

Fig. 1. The connection diagram.

The most relevant measure of the exposure levels is made in the literature using as reference the maximum power density values, which show the amount of power falling on an area. These are usually expressed in milliwatts per square meter (mW/m²). From this perspective the exposure levels were measured using a specialized broadband device (HF59B RF-Analyzer from Gigahertz Solutions), which allows rapid measurement of this parameter. The results for the power flux density are presented in Table II.

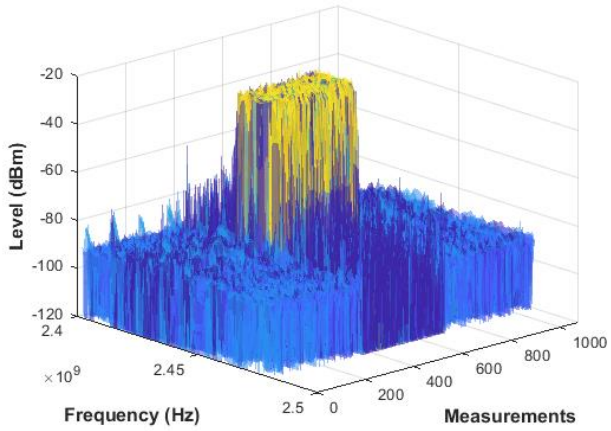

Fig. 2. 3D view of the Wi-Fi signal power levels during the phases of one of the experiments.

TABLE II. POWER FLUX DENSITY MEASURED DURING THE PHASES OF THE EXPERIMENT

	Power flux density values in µW/m2	Method	Percentage from ICNIRP limits[b]	Duty factor for Wi-Fi and DECT transmission
OFF phase, no Wi-Fi, no DECT	150	Peak hold	-	-
	5	RMS	0.0000125 %	
ON phase, with Wi-Fi, no DECT[c]	10 000	Peak hold	-	100 %
	50	RMS	0.000125 %	
ON phase, Wi-Fi and DECT	16 000	Peak hold	-	100 % Wi-Fi + 7.1% DECT[d]
	110	RMS	0.000275 %	

[a] The measurements were made at approx. 1 m from the Wi-Fi router and the DECT station used to generate electromagnetic field during the experiment, the same distance the participants on the experiment were positioned during the test.

[b] The limit was considered as 40W/m2 (Reference levels for general public local exposure, aver-aged over 6 min, to electromagnetic fields from 100 kHz to 300 GHz - unperturbed RMS values [6])

[c] This situation was not exactly met during the experiments, it is considered just for comparative analyze reasons, to emphasize both Wi-Fi and DECT emissions.

[d] See ETSI TR 103089 Standard for DECT transmissions [40]

F. Measurements and HRV Measures

In order to acquire data on HRV (heart rate variability) an ECG device was used along with its software. The electrocardiogram recorder was a BTL-08 manufactured by BTL with BTL CardioPoint software H600 version. The BTL-08 Holter [30] is an advanced ECG electrocardiogram recorder. It records the electric activity of the human heart using electrodes attached to the patient's chest for short or long periods of time (maximum 48 hours).

The BTL-08 Holter device is intended for use in an electromagnetic environment in which radiated HF disturbance is controlled. In order to meet the requirements for the ECG Holter proper functioning in Wi-Fi radiation presence, the distance between the electromagnetic radiation source (the Wi-Fi devices) and the Holter device should be greater than 0,22 meters according to the ECG devices manufacturer's specifications. This condition was met during the whole experiment.

Frequency and time domain analysis are sophisticated methods of determining how much of a signal is contained within one or more frequency bands (ranges).

In the case of HRV, research has revealed that particular frequency bands are associated with physiological phenomena such as parasympathetic nervous system activation. HRV measures in the Frequency Domain include:

High-Frequency power (HF): frequency activity in the 0.15 - 0.40Hz range

Low-Frequency power (LF): frequency activity in the 0.04 - 0.15Hz range

Obtaining accurate low frequency measurements requires reading times of mini-mum four minutes or more. Measured frequency values are also expressed in Hertz (Hz) or milliseconds (ms) or milliseconds squared (ms2). The HRV parameters SDNN, RMSSD, LF and HF were recorded (see Table III).

TABLE III. RECORDED HEART RATE VARIABILITY PARAMETERS (ACCORDING TO [31])

Heart rate variability measure	Definition and explanation	Indicator of	Activity as part of the autonomic nervous system
SDNN	Standard deviation of NN-intervals: Standard deviation of NN-intervals in the measurement time range	Overall variability	No clear allocation
RMSSD	Root Mean Square of successive differences: Square root of the arithmetic mean of squared differences between adjacent NN intervals	Short term variability	Parasympathetic
LF	Low frequency power: Power density spectrum in the frequency range from 0.04 to 0.15 Hz	No clear allocation	Sympathetic and parasympathetic nervous system, the sympathetic nervous system predominates.
HF	High frequency power: Power density spectrum in the frequency range from 0.15 to 0.40 Hz	Short term variability	Parasympathetic

G. Statistical Analysis

A repeated measures ANOVA was conducted to test the main and the secondary hypothesis. The comparison was made based on the logarithmic values in order to catch outliers. Statistical significance was assumed when $p < 0.05$. Statistical tests were performed with Jamovi 2.3.21.

III. RESULTS

A. Main Factor

There are some indications of changes in HRV due to EMF exposure. Table IV shows significant effects on SDNN in run 1, run 2 and run 3. Beyond that, significant effects are only evident in run 1, for the characteristics RMSSD, LF and HF. For SDNN, a highly significant decrease from OFF 1 to ON and a significant difference between OFF 1 and OFF 2 can be seen in run 1 and run 3. In run 2, a significant increase in SDNN from ON to OFF 2 can be read. For run 1, there are also effects between OFF1 and ON for the features RMSSD, LF, and HF. For run 2 and 3, differences are only evident for the feature SDNN. The observed changes of SDNN from OFF1 to ON (decrease) and from ON to OFF 2 (increase) are in line with the hypotheses. The fact that there are also significant differences between OFF 1 and OFF 2 can be interpreted in such a way that the SDNN normalization takes longer than 10 minutes after exposure.

Fig. 3 gives an overview of the SDNN mean values at the three measurement times of all three runs. It can be seen that run 1 and run 3 have a similar course. In all three runs, a decrease in the SDNN value (from OFF1 to ON) is followed by an increase (from ON to OFF2) after the end of exposure.

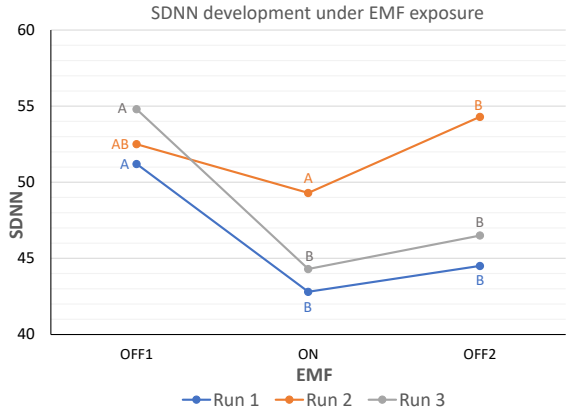

Fig. 3. SDNN measurement at three different stages (OFF1, ON, OFF2). Mean values run 1 (60 observers), run 2 (54 observers) run 3 (40 observers). Deviating letters show significant differences; alpha = 0.05.

B. Cofactors

We were interested in whether consumption of caffeine-containing beverages (especially coffee), smoking and the use of medication altered the observed pattern. Here, the use of strong medications was recorded - medications for chronic diseases under medical supervision that interfere with cardiac function.

These three factors were examined separately. Table V shows that all groups, coffee consumption, medication and smoking, respond significantly to RF-EMF. The factors of smoking, medication and coffee do not differ from their comparison groups. This implies that the EMF impact is not influenced by the following factors: coffee consumption, smoking and medication. Fig. 4 illustrates that the patterns change only slightly compared to the control groups. The SDNN values decrease from phase OFF1 to phase ON and increase again in phase OFF2, but do not reach the level of phase 1 OFF1. Only the medication group shows no increase in the HRV parameter SDNN from ON to OFF2 after 10 minutes. It is possible that recovery is slowed down.

TABLE IV. EFFECTS OF EMF EXPOSURE ON HRV PARAMETERS. DESCRIPTIVE STATISTICS REPEATED MEASURES ANOVA OF HRV PARAMETERS. BOLD INDICATES SIGNIFICANT DIFFERENCES

HRV parameters	**Descriptive statistics**				**Repeated measures ANOVA**		
		phase			Post- Hoc	*p-value*	Effect size Cohen´s d

Figure above: comparison of the groups: coffee (n=37) and non-coffee (n=21), figure in the middle: comparison of the groups medication (n=14) and non-medication (n=45), figure below: comparison of the groups smoker (n=17) and non-smoker (n=43).

IV. DISCUSSION

In our experiments the HRV response follows the same pattern: a decrease due to RF-EMF exposure and an increase after the exposure is over. In run 1 and 3, the SDNN value decreased significantly with the onset of radiation. In run 2, the SDNN value increased significantly after the termination of radiation. These results are consistent with the main hypothesis that RF-EMF lowers HRV.

Numerous factors influencing HRV have already been investigated [31]. A lowering of HRV has been observed in various types of stress [14, 15].

Under our experimental conditions, SDNN responds most to RF-EMF exposure compared to RMSSD, LF and HF. SDNN describes the overall variability of HRV [31], while the other characteristics considered describe other HRV aspects. Even in the study by Parazzini et al. (2007), only a few HRV parameters responded significantly, including SDNN. There was a decrease in variability as a result of exposure. Future research should further investigate which HRV parameters are suitable for measuring RF-EMF effects under various conditions (e.g. frequencies and power flux density).

It is also noticeable that in run 2 the differences between phase OFF1 and phase ON were smaller and not significant. Run 2 was performed in late May and June with high outdoor temperatures, which is why the temperatures in the laboratory also increased, often, up to 30 degrees Celsius. By contrast, run 1 and run 3 were performed at comparably low outdoor temperatures in March-April and October-November, with room temperatures around 20 degrees Celsius. The influence of heat and cold on HRV has been studied [32, 33]. High temperatures are reported to reduce HRV. It is to be clarified in future research whether the responsiveness to RF-EMF is lowered by high temperatures.

Participants' consumption of caffeine-containing beverages, smoking, and use of strong medications were recorded – medications for chronic diseases under medical subscription, intervening in heart functioning. Examination of the three factors showed that the effect of RF-EMF was also observed for the groups with coffee consumption, smoking and the intake of medication. There were no significant differences between subgroups, for example, smokers and non-smokers. However, the HRV level of smokers was at a lower level. An HRV-lowering effect of smoking is also described by [34, 35].

Several studies have described effects of EMF on cardiac response, in humans and in animals [26, 36, and 37]. In contrast, some studies show no significant effects of short-term radiation on the cardiovascular system [38, 39]. The effects of Wi-Fi frequencies on HRV have hardly been studied so far. Parizek et al. (2023) [17] found a marked shift in autonomic regulation of heart rate toward complex sympathetic overactivity by Wi-Fi and decreased parasympathetic activity by 4G radiation when healthy young subjects were exposed to 2400 (Wi-Fi) and 2600 MHz (4 G) for five minutes each. It seems necessary to take a close look at the studied EMF factor. In our case we wanted to simulate an office environment. The frequencies used were DECT (1.8 GHz) and Wi-Fi (2.45 GHz). The devices were about 1 m apart. The power flux density was 16 000 $\mu W/m^2$

(peak value) resp. 110 µW/m^2 (RMS). The power flux density corresponds to values also documented in the literature [40]. In the review [40], the authors determine a maximum mean exposure for offices of 3.447 mW/m^2. A research by study [41] of peak RF-EMF emissions in typical office environments showed a peak power density of 54 mW/m^2.

In the meantime, however, significantly higher values can already be detected outside. In the 2022 study by [36], measurements were made in areas of Stockholm where clusters of EMF emitters were placed at low heights (near the head area) of pedestrians. The maximum measured mean value, reached a power flux density of 12.1 V/m (388 mW/m^2). The highest measured value on the whole surveyed area was 31.6 V/m (2 648 mW/m^2).

In our experiment, with a short exposure of 10 minutes, EMF effects on HRV were found even though the power flux density was only 0.000275% of the ICNRIP limit [6] (ICNIRP 2020 Guidelines).

V. Conclusion

HRV seems to be a relatively simple method of measuring EMF effects on humans under certain conditions. There are questions about the optimization of the experimental design: In further studies, the duration of the exposure should be varied because an exposure time of 10 minutes seems to be low or not realistic. On the other hand, the control situation in experiments needs to be carefully considered, as sites with very low radiation become rarer. It is also to be examined in the future whether, as with smoking, a permanent lowering of HRV occurs through RF-EMF.

There are recent studies indicating 5G will contribute with a significant proportion of radiofrequency exposure in the future [42–44, 44–46]. In this respect, 5G frequencies are to be added in the future to investigate the effects of EMF on HRV.

Authors' Contribution

Conceptualization: J.U.G. and S.D.; methodology: J.U.G., S.D. and R.R.; software: R.R.; formal analysis: J.K.; investigation: S.D, R.R., S.P., A.A-D.; writing—original draft preparation: S.D., R.R. and J.U.G.; writing—review and editing: S.D., J.K. and J.U.G. All authors have read and agreed to the published version of the manuscript.

Funding

This research was funded by Software AG Stiftung (Darmstadt) grant number RA-P 13550.

Institutional Review Board Statement: The study was approved by the Research Ethical Committee of the University of Oradea (the decision was registered at the Research Programs and Projects Office with nr. 660/5.11.2020).

Informed Consent Statement

Informed consent was obtained from all subjects involved in the study. All participants signed a written informed consent before they took part voluntarily in the study. Each member of the implementation research team signed a confidentiality declaration regarding the participants' data.

Acknowledgment

We want to express our gratitude to Software AG Stiftung (Darmstadt) for funding this project.

Conflicts of Interest

The authors declare no conflict of interest.

Can Semi-Supervised Learning Improve Prediction of Deep Learning Model Resource Consumption?

Karthick Panner Selvam, Mats Brorsson
Snt, University of Luxembourg, Luxembourg

***Abstract*—As computational demands for deep learning models escalate, accurately predicting training characteristics like training time and memory usage has become crucial. These predictions are essential for optimal hardware resource allocation. Traditional performance prediction methods primarily rely on supervised learning paradigms. Our novel approach, TraPPM (Training characteristics Performance Predictive Model), combines the strengths of unsupervised and supervised learning to enhance prediction accuracy. We use an unsupervised Graph Neural Network (GNN) to extract complex graph representations from unlabeled deep learning architectures. These representations are then integrated with a sophisticated, supervised GNN-based performance regressor. Our hybrid model excels in predicting training characteristics with greater precision. Through empirical evaluation using the Mean Absolute Percentage Error (MAPE) metric, TraPPM demonstrates notable efficacy. The model achieves a MAPE of 9.51% for predicting training step duration and 4.92% for memory usage estimation. These results affirm TraPPM's enhanced predictive accuracy, significantly surpassing traditional supervised prediction methods. Code and data are available at: https://github.com/karthickai/trappm**

Keywords*—Performance model; deep learning; Graph neural network

I. Introduction

Deep learning (DL) has significantly advanced various fields by analyzing complex patterns in extensive datasets. The escalating complexity of DL models, driven by advances in computational resources and data availability, necessitates increased memory and computational power for training. This heightened demand complicates the training process and increases costs. Accurately predicting both memory consumption and step time for DL models is challenging due to a variety of hidden factors, including the choice of convolutional algorithms, garbage collection mechanisms, memory pre-allocation strategies, and the specifics of implementations like cuDNN [1]. These factors complicate the task of making precise predictions, highlighting the need for sophisticated approaches to accurately estimate these critical training characteristics. Effective prediction of memory and step time is not only essential for preventing out-of-memory errors but also plays a crucial role in optimizing resource allocation and enhancing the effectiveness of neural architectural search (NAS), ultimately enhancing the efficiency of the model development process

In past studies, researchers primarily employed supervised Multi-Layer Perceptron (MLP) and GNNs to predict the training and inference attributes of DL models [1]–[10]. These methods, while effective, are confined to the limits of supervised learning and do not fully exploit the potential of unlabeled data, which can significantly enhance prediction performance.

In response to this gap, we introduce TraPPM, a novel approach that leverages semi-supervised learning. First, we utilize unsupervised GNN to learn graph representations from an unlabeled dataset. GNNs are adept at capturing patterns and relationships within graph-structured data. Next, we combine the learned graph representations with static features of a DL model. With this integrated vector, we train the supervised GNN-based performance regressor using a labeled dataset, allowing it to accurately estimate the training step time and memory usage of a given DL model. Utilizing an embedding generated from unsupervised learning in conjunction with supervised training boosts performance prediction accuracy compared to relying solely on supervised training. Our key contributions include the following:

- We have implemented TraPPM, a novel methodology that leverages the unsupervised GNN for learning embeddings from unlabelled datasets. And combine the embedding with DL static features to train the GNN-based regressor model using a labeled dataset to predict the training characteristics without running it on target hardware.
- We rigorously assessed the performance of TraPPM against state-of-the-art baselines, including supervised GNN, MLP, and GBoost, TraPPM exhibits superior performance, achieving a remarkable 910 MB RMSE and 4.92% MAPE for memory and 23 ms RMSE and 9.51% MAPE for step-time prediction. This superior performance underscores the efficacy of harnessing unlabeled data for performance prediction.
- Furthermore, our comprehensive dataset, encompassing 8,079 labeled graphs and 25,053 unlabelled graphs from various DL model families, presents a substantial contribution to the community, paving the way for future research in performance prediction and optimization.

II. Background

1) Computational graphs: Deep learning models are usually represented as directed computational graphs, where each node represents mathematical operations, such as matrix multiplication, and edges represent the data flow between these nodes. For example, a simple Convolutional Neural Network (CNN) model. The image data is fed into the network via the input node, and it just passes data to the next node. The Conv nodes perform convolution operations on the input image data. The Pooling node is responsible for reducing the

spatial dimensions of the input data to reduce computational requirements. The Fully Connected (FC) node, where each neuron is interconnected with all neurons from the previous layer, applies the activation function to a weighted sum of their inputs. Finally, the output node takes the data from the FC node and provides prediction results.

2) Graph neural networks: GNNs constitute a specialized class of deep learning models that operate on graph-structured data, denoted as $\mathcal{G} = (V, E)$, where V represents the set of nodes and E represents the set of edges in the graph. Each node $v_i \in V$ is associated with a feature vector, which encodes information about that node. The fundamental principle underlying GNNs is the iterative process known as message passing, which facilitates the generation of embeddings for nodes or entire graphs.

In the message passing process, each node v_i updates its embedding by aggregating information from its neighboring nodes. This aggregation is achieved through functions such as summation, averaging, or more intricate operations like neural networks or attention mechanisms. Let $\mathbf{h}_i^{(l)}$ denote the embedding of node v_i after l message passing iterations, where l represents the layer in the GNN. Initially, $\mathbf{h}_i^{(0)}$ corresponds to the node's original feature vector.

The update equation for node v_i at layer l in a GNN can be expressed as follows:

$$\mathbf{h}_i^{(l)} = \text{TRANSFORM}\left(\mathbf{h}_i^{(l-1)}, \left\{\mathbf{h}_j^{(l-1)} : v_j \in \mathcal{N}(v_i)\right\}\right)$$

Here, $\mathbf{h}_j^{(l-1)}$ represents the embeddings of the neighboring nodes of v_i at the $(l-1)$-th layer, and $\mathcal{N}(v_i)$ denotes the set of neighbors of node v_i. The `TRANSFORM` function combines the embeddings of the node's neighbors with its own embedding from the previous layer. Through multiple layers of message passing, each node gathers information from an increasingly wider neighborhood in the graph. Thus, the final embedding $\mathbf{h}_i^{(l)}$ for node v_i after l layers encapsulates information from both its immediate and more distant neighbors within the graph. GNNs have demonstrated remarkable success in various graph-related tasks, including node classification, link prediction, and graph-level classification. Prominent GNN variants such as GraphSAGE [11], Graph Attention Networks (GAT) [12], and Graph Convolutional Networks (GCN) [13] have gained widespread adoption in the research community and have yielded state-of-the-art results in these tasks.

3) Graph auto encoders: GAEs [14], play a critical role in unsupervised learning with graphs. They are particularly useful when we have a lot of unlabeled data. A GAE comprises two essential parts: an encoder and a decoder. The encoder's role is to transform the input graph into lower-dimensional representations known as *embeddings* of nodes. This is often accomplished with a Graph Convolution Network (GCN), converting the input adjacency matrix A and feature matrix X into an embedding matrix Z. Where the adjacency matrix represents the connectivity between nodes in a graph. This can be written as $Z = encoder(X, A)$. The decoder takes the node embeddings produced by the encoder, the matrix Z, and tries to rebuild the original adjacency matrix. A common way of achieving this is using the node embeddings' inner product as the decoder function. The motivation here is that the inner product, as a similarity measure, can capture the likelihood of a link between two nodes. $A' = decoder(Z)$. The effectiveness of this transformation is evaluated using a loss function. This function measures the reconstruction error - the difference between the original adjacency matrix A and the reconstructed one A'. This discrepancy is usually calculated using a method like Binary Cross Entropy (BCE). The model is trained to minimize this loss, thus improving the GAE's precision. Having an established foundational understanding of DL as a computational graph and GAE, we can now delve into TraPPM's methodology. TraPPM leverages unsupervised GNN, particularly with a GAE, to learn the graph representation of unlabelled datasets. We utilize the computation graph as input to the TraPPM, with nodes representing operators and node features corresponding to operator attributes. The edges signify the connections between operators. We will explore it further in Section IV.

III. Related Work

The study of performance prediction of deep learning models is relatively recent, having only started to receive focus just a few years ago. Qi et al. [15] use a straightforward approach to estimate the training time of DL models, layer by layer, using an analytical model. They calculated each step duration and summed it to calculate the overall estimation. The model presumes no concurrent operations, which may only be accurate for some hardware types. Gao et al. [1] also used an analytical model to predict the memory consumption for the training DL model. Bouhali et al. [16] used an MLP-based regressor to predict the execution time of a DL model. They used input features such as trainable parameter count, memory size, and input size to predict the execution time. Nevertheless, the traditional MLP method could have been more effective due to its limited understanding of the DL layers.

Justus et al. [2] used the layer-by-layer technique proposed by Qi et al. [15] to improve the performance prediction accuracy. But use an MLP-based regression model instead of an analytic model. Gianti et al. [7] used a layer-by-layer technique as Justus et al. [2]. Instead of layer parameters, they used complex parameters such as FLOPS to predict the execution time and power of an individual layer of the DL model. Other researchers [17]–[20] also used the same layerwise approach to predict the execution time, memory allocation, and power consumption of the DL model. Yu et al. [3] employed a wave-scaling method for estimating the training step time of the deep learning model on a GPU. They also used the layerwise approach. However, this wave scaling technique necessitates the availability of a GPU to facilitate the prediction.

On the other hand, researchers used a graph neural network instead of MLP in a layerwise approach to predict the performance of the DL model [8], [9]. The layerwise approach did not capture the DL model network topology, and therefore prediction accuracy is sub-optimal [10]. To solve the above problem, Gao et al. [4] and other researchers, [5], [6], [10], used a graph learning to understand the model network topology by generating embeddings. Furthermore, they combine embeddings with overall DL features to predict the training and inference characteristics. The majority of prior studies utilized

supervised techniques for DL model performance prediction, neglecting the vast pool of unlabelled DL model data. Our innovative approach, TraPPM, bridges this gap using a semi-supervised learning paradigm, enhancing prediction accuracy by harnessing unlabelled data.

In the first step, we employ an unsupervised graph neural network using unlabelled DL models. This network generates embeddings for input DL models, facilitating an in-depth understanding of the input DL model's network topology. In the subsequent step, we combine the embeddings with the static features extracted from a DL model. This fused data is utilized for training a GNN-based regressor using labeled data to predict the training characteristics. Our approach provides a more comprehensive and effective performance prediction mechanism than the previous works.

IV. Methodology

Our methodology consists of two phases. **Phase 1:** Unsupervised Learning, unlabelled DL graphs are trained using a GAE to generate embeddings, as explained in Section IV-B. However, we cannot directly feed the DL model in Open Neural Network Exchange (ONNX)[1] format into the input of GAE for training. Instead, we need to convert it to PyTorch Geometric (PyG) [21] data format before training, as explained in Section IV-A. **Phase 2:** Supervised Learning, the trained encoder from the GAE is utilized to generate embeddings for the labeled DL model. These embeddings and static features, along with the labeled DL models to, train GNN-based regressors to predict the training characteristics, as described in Section IV-C.

A. Graph Transformation

Given a DL model M with operations $O = \{o1, o2, ..., on\}$, we transform M (in ONNX format) into a graph G compatible with PyG. In G, nodes represent M's operations stored in the node feature matrix X, while A captures directed relationships. Specifically, $G = (X, A)$ where $X = O$ and $A[i][j] = 1$ if a directed edge exists from o_i to o_j, else $A[i][j] = 0$. If M is labeled, we incorporate a target vector Y into PyG data. For each node v in the DL model graph, we define an attribute vector A_v as: $[\mathbf{E}_O(v), I_v, \mathcal{O}_v, \text{Mac}_v, P_v, M_v]$. Here, $\mathbf{E}_O(v)$ is a one-hot encoded vector of length $|O|$, where $|O| = 98$, surpassing the previous work supported only 32 operators [10]. The vectors I_v and $\mathcal{O}_v$, each of length 6, encapsulate the input and output shape, respectively, with an extension to consider 3D convolution. The attributes Mac_v, P_v, and M_v symbolize the MAC, parameters, and memory of node v, respectively. Thus, our node feature vector n has a dimensionality of 113, offering a more exhaustive representation as shown in Fig. 1. To the best of our knowledge, this is the first work to incorporate 2D and 3D convolutions, alongside transformer-based architectures, into node features. This advancement distinguishes our approach from prior studies that were limited to 2D convolutions.

$OneHot(Op_v)$	I_v	O_v	Mac_v	P_v	M_v
98	6	6	1	1	1

Fig. 1. The graph's nodes are augmented with node features, each consisting of 113 elements. To accommodate 3D convolution, padding was appended at the end of both the input and output shapes.

B. Phase 1: Unsupervised Learning

In order to leverage the potential of unlabelled data, we train the GAE model in unsupervised manner. The fundamentals of GAE are explained in Section II-3. However, it is not possible to directly use the DL model in ONNX format as input to the GAE. Therefore, we first transform the ONNX format to G as described in Section IV-A. The overview of our GAE is illustrated in Fig. 2.

The GAE's encoder is composed of four GraphSAGE convolution layers, which process node features of dimension $[\#nodes, 113]$. These layers aggregate neighborhood features, followed by batch normalization and ReLU activation to introduce non-linearity and enhance training stability. A dropout layer with a rate of 0.5 prevents overfitting. The encoder outputs embeddings Z in a latent space of dimension $[\#nodes, 512]$, as depicted in Fig. 2. The decoder reconstructs the adjacency matrix $\hat{A}$ using the embeddings Z through the operation $\sigma(ZZ^T)$, where σ is the sigmoid function. The BCE loss for the GAE is defined as:

$$L_{\text{BCE}} = -\log(\hat{A}(z, i_{\text{pos}}, j_{\text{pos}}) + \epsilon) - \log(1 - \hat{A}(z, i_{\text{neg}}, j_{\text{neg}}) + \epsilon)$$

In this equation, $\hat{A}$ denotes the predicted adjacency matrix. The terms $i_{\text{pos}}, j_{\text{pos}}$ signify the indices of positive edges, while $i_{\text{neg}}, j_{\text{neg}}$ correspond to negative edges, obtained through negative sampling. To ensure stability during the computation of logarithms, we used a small constant $\epsilon = 1 \times 10^{-15}$. The essence of this loss metric lies in its ability to guide the GAE towards accurately reflecting the original graph structure. The model optimizes this loss, aiming to accurately reconstruct the graph's adjacency matrix. Upon minimizing this loss, the weights of the GAE's encoder are frozen, setting the stage for Phase 2's supervised training.

C. Phase 2: Supervised Learning

The primary objective of TraPPM is to predict training characteristics such as memory usage (MB) and training step time (ms). To achieve this, we employ a GNN-based regressor for prediction. The overview of supervised learning is shown in Fig. 3. The input G includes both actual values, represented by [mb, W], and static characteristics. The static features encompass the batch size B, the total number of nodes N_t, the total number of edges E_t, total MAC operations (MAC_t), total parameters (P_t), and total memory (M_t). The values N_t and E_t are directly extracted from G, while the values MAC_t, P_t, and M_t are obtained using the ONNX tool. Consequently, the static feature vector F_s has a length of 6. Supervised learning consists of three components.

GNN Component: It consists of two layers of the SAGEConv layer, and each SAGEConv layer is succeeded by a ReLU activation function and a dropout mechanism with a rate of 0.05.

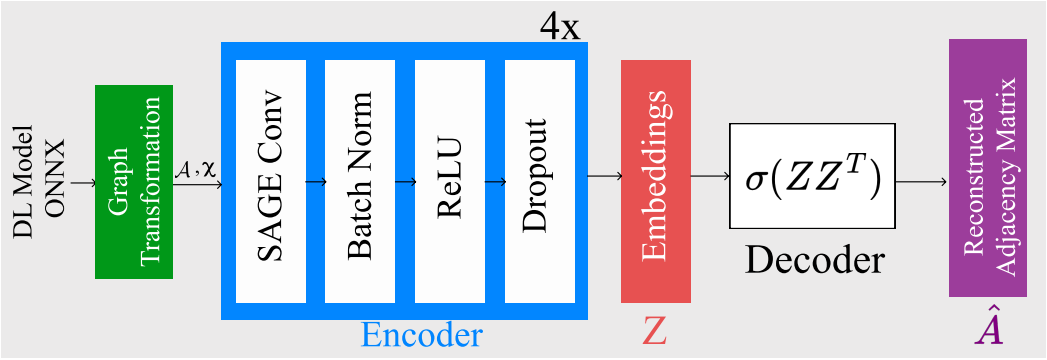

Fig. 2. Unsupervised Learning - Training Graph Auto Encoder to minimize reconstruction loss of unlabelled DL model graphs.

Feature Aggregation Component: The node features produced by the SAGEConv layer were aggregated using the sum reduce function, resulting in a [1, 512] dimension. Similarly, embeddings generated from the GAE were reduced to [1, 512] using another sum aggregator function. These two embeddings were then combined with a static feature F_s, forming a vector of dimensions [1, 1030], which was subsequently fed into the MLP component.

MLP Component: The concatenated feature vector is passed through two Fully connected (FC) layers. Both FC layers are succeeded by ReLU activations and dropout layers with a rate of 0.05. The processed features are passed through a final layer that produces a single output value.

In the forward pass, the model processes the input G, performs graph convolutions, aggregates node features, integrates it with static features and aggregated embeddings generated from GAE, and passes it through the FC layers to produce the final prediction. We employed the Mean Squared Error (MSE) as our loss function and utilized the Adam optimizer for the training phase. In the backward pass, the model updates the parameters θ, in both the GNN and MLP components. To individually predict memory usage (MB) and step time (ms), we have trained two distinct models: M1 for memory and M2 for step time and frozen their weights. A given input G is simultaneously processed by all two models (M1 and M2). Alongside G, each model also receives the static feature vector F_s and the aggregated embeddings generated by the GAE as we discussed earlier. The combined input helps these models produce accurate predictions on the training characteristics of a given DL model.

D. Evaluation Metrics

To assess the performance of our TraPPM model compared to the baseline models, we employ two widely used evaluation metrics: MAPE and Root Mean Square Error (RMSE). We chose MAPE because it measures the average percentage difference between the predicted and actual values. It allows us to assess the relative accuracy of the predictions as shown in Eq. (1). On the other hand, RMSE is used to measure the overall magnitude of prediction errors on the same scale as the predicted variable, providing a standardized and interpretable metric for assessing the performance of prediction models as shown in Eq. (2). By utilizing both MAPE and RMSE in our experiment, we thoroughly evaluate TraPPM's performance compared to the baseline models.

$$\text{MAPE} = \frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right| \times 100 \tag{1}$$

$$\text{RMSE} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}, \tag{2}$$

V. Experiments and Results

A. Enviromental Setup

We used two hardware configurations for data collection: the first comprised an AMD EPYC 7402 processor with two sockets (24 cores per socket), 512 GB DDR4-3200 RAM, and a NVIDIA A100 GPU with 40 GB HBM; while the second utilized 2× Intel Xeon Gold 6148 CPUs (2× 20 cores at 2.4 GHz) and a NVIDIA V100 GPU with 16 GB HBM. However, we exclusively used the hardware equipped with the NVIDIA A100 GPU for the experiments. The experimental environment for developing TraPPM involved the utilization of several essential Python libraries. The important libraries used were PyTorch 2.0.0, torch-geometric 2.3.0, torch-cluster 1.6.1, ONNX 1.13.1, and torch-sparse 0.6.17. These libraries played a crucial role in implementing and training the TraPPM model. The experiments for training TraPPM and generating the dataset were conducted on the abovementioned system using CUDA 11.7.

B. Datasets

For our TraPPM experiment, we employed a dual-method approach, harnessing both unsupervised and supervised datasets. As we already discussed, unsupervised datasets are used for training GAE, and the supervised dataset is used to train the GNN-based regressor.

1) Unsupervised dataset: For the TraPPM experiment, we harnessed the Timm library [22] to generate a diverse unsupervised dataset comprising various CNN and transformer-based architectures. These models were exported in ONNX format and subsequently converted to PyG data, a process detailed in Section IV-A. The dataset includes 25,053 unlabeled DL models, spanning eleven distinct model families as outlined

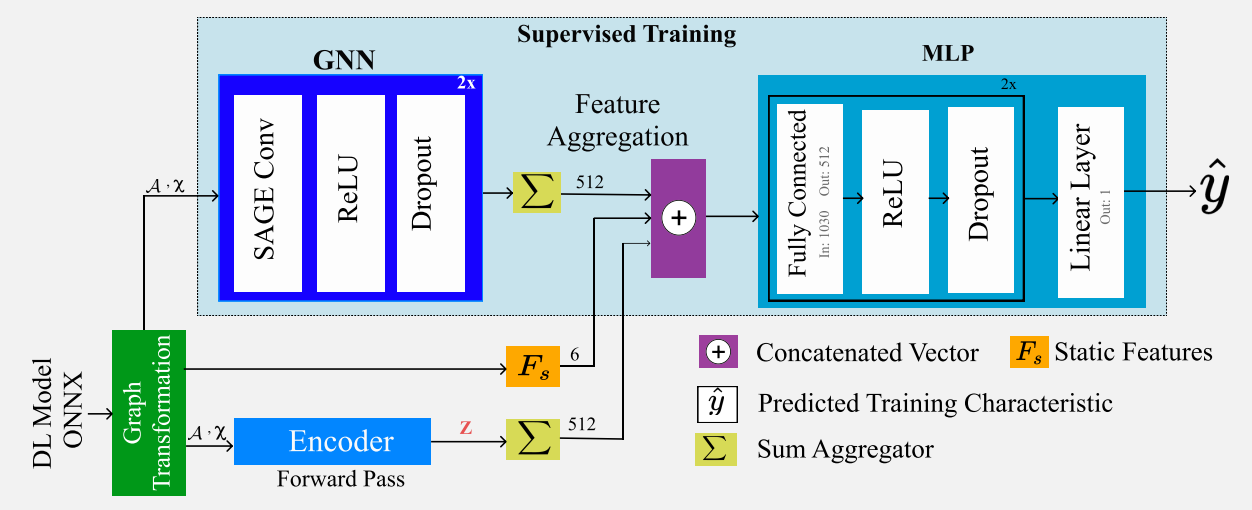

Fig. 3. Supervised Learning - Training a GNN regressor using MSE loss to minimize the actual y vs. predicted $\hat{y}$. We train three different models separately for predicting step time (ms), memory usage (MB), and power consumption (W).

in Table I. This extensive collection of models underpins our unsupervised learning approach, as elaborated in Section IV-B.

The dataset features a range of model variants within each family. For instance, the ConvNext family [23] encompasses variants like Base, Large, Small, and Tiny. The DenseNet family [24] includes DenseNet121, 161, 169, and 201. Other represented families are EfficientNet [25], MnasNet [26], MobileNet [27], PoolFormer [28], ResNet [29], Swin [30], VGG [31], along with additional models such as Visformer [32] and ViT [33]. This breadth ensures a comprehensive representation of current DL model architectures, facilitating robust unsupervised learning.

2) Supervised dataset: Our supervised dataset is subset of unsupervised dataset. The data collection was conducted using two GPUs: the NVIDIA A100 and the NVIDIA V100, as described in Section V-A. Specifically, using the A100 GPU, we collected a total of 7536 labeled DL models. Conversely, with the V100 GPU, we gathered 543 labeled DL models. For baseline model comparisons, we primarily utilized the labeled DL models from the A100 GPU. Meanwhile, the dataset collected from the V100 GPU was exclusively reserved for evaluating TraPPM's transfer learning capabilities. We again utilized the Timm library to generate DL models. However, instead of saving them to the ONNX format, we trained each model for 55 iterations, with the initial five iterations serving as a warm-up phase. We calculated the CUDA time during each iteration, representing the time taken to process a single iteration or step time in the training process. Our focus was primarily on step time, as it remains consistent during the training of the DL model, except for the initial few iterations that may exhibit variations due to warm-up effects. Therefore, we excluded the first five iterations when calculating the metrics. Additionally, we collected memory usage and power consumption data using the NVML[2] Python library. For each of the eleven different model families, we repeated this process, averaging the step time (ms), memory usage (MB), and power consumption (W). The results, along with the corresponding ONNX model files, were saved. During converting these models to PyG data format, we appended the measured values into the graph data Y.

C. Training - Graph Auto Encoder

The first phase of the TraPPM experiment involves training the GAE, a key component of our TraPPM. Initially, we considered the Masked Graph Autoencoder technique, as presented in Hou's study [34]. This method masks random node features and attempts to reconstruct them, facilitating graph representation learning. However, our node features, largely sparse due to one-hot encoding as explained in Section IV-A, did not align well with this strategy. As a result, we turned to the classical GAE, which proved to be a better fit for our needs. The GAE model was developed using the PyG Library, the detailed model architecture explained in Section IV-B. For training, we employed the BCE loss function and utilized the Adam optimizer with a lr=5×10^{-4}, betas=(0.9, 0.999), eps=1×10^{-8}. To train the GAE, we utilized an unsupervised dataset, as described in Section V-B1, for a total of 400 epochs. Finally, we have achieved a BCE loss of 0.9291. The entire training process for the GAE took approximately 25.6 hours on a single A100 GPU. We employed t-SNE [35] to visualize the

sum aggregated embeddings generated by the GAE, as shown in Fig. 4. The widespread distribution of the ResNet models is due to its numerous variants, distinguishing it from other models.

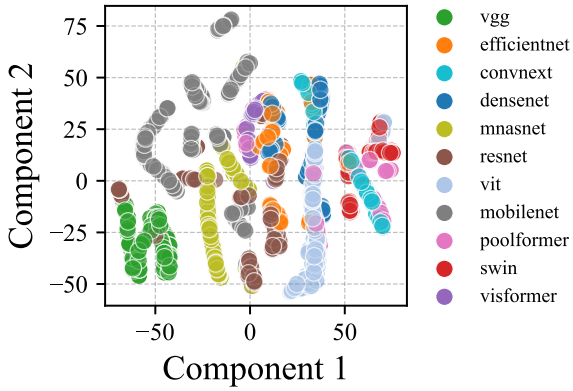

Fig. 4. t-SNE visualization of sum aggregated embeddings generated by the GAE.

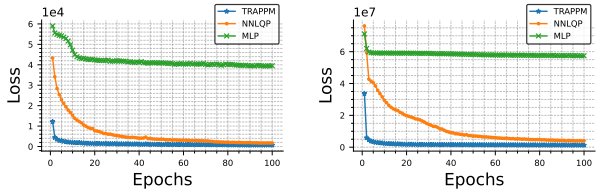
D. Training - TraPPM

The core part of the experiment involves training the TraPPM model, with the detailed architecture explained in Section IV-C. We used the PyTorch library to create the TraPPM model. We used a labeled dataset collected from A100 GPU to train the model, as mentioned in Section V-B2. We partitioned our dataset according to a 70:30 ratio for each model family. Specifically, 70% of the data was used for training and 30% for testing. This split aligns with the standards established in previous research [10]. However, instead of a conventional split, we adopted a Monte Carlo validation approach. To ensure robustness and reliability in our results, we employed five distinct seeds: 1337, 1338, 1339, 1340, and 1341. By utilizing these seeds, we generated five different dataset splits and subsequently averaged the results to derive a more comprehensive performance evaluation. During the training process, we utilized the Adam optimizer with a lr=1×10^{-3}, betas=(0.9, 0.999), eps=1×10^{-8}. The training was performed over 100 epochs to fair comparison with baseline models. Training the TraPPM model for a single fold takes about 1 hour and 17 minutes for 100 epochs.

E. Baseline Models

In our evaluation, we compared TraPPM with three baseline models: Gboost, MLP, and the supervised GNN. Gboost served as a strong foundation for further development, while MLP was chosen for its wide usage in performance prediction [2]. Finally, we included the supervised GNN model introduced by Lu et al. [10], referred to as NNLQP. This model served as a reference for evaluating the performance of TraPPM in relation to a well-established supervised GNN approach.

1) Gradient boosting: To develop the GBoost model, we conducted training using the XGBoost [36] python library. The training process involved utilizing a supervised dataset that solely consisted of DL static features as input. To optimize its hyperparameters, we conducted a grid search. The hyperparameters explored during the grid search were estimators with values [500, 1000, 2000], lr with values [1×10^{-3}, 1×10^{-4}], max depth with values [10, 30, 50], subsample with values [0.5, 0.75, 1], and colsample bytree with values [0.5, 0.75, 1]. After performing the grid search, we identified the best hyperparameters as follows: colsample bytree: 1, lr: 1×10^{-3}, max depth: 50, estimators: 2000, subsample: 1.



(a) Step Time (ms) (b) Memory Usage (MB)

Fig. 5. Epoch vs Loss plot comparing the convergence rates of TraPPM, NNLQP, and MLP. TraPPM showcases rapid convergence due to its ability to leverage unsupervised learning from unlabeled data, as trained over 100 epochs.

2) MLP: We created a baseline MLP model that is similar to the TraPPM MLP component, with the only difference being that it accepts only static features as input during training. We trained the baseline MLP model using 100 epochs, utilizing the MSE loss function and the Adam optimizer with lr=1×10^{-3}, which is the same setting as the TraPPM supervised training.

3) NNLQP: It is important to note that a key distinction between the NNLQP model and the TraPPM model is that the NNLQP model is unable to utilize unsupervised datasets. It can only operate with supervised datasets. To ensure a fair comparison, we kept the model architecture unchanged, only adapting the node features to accommodate the TraPPM dataset as discussed in Section IV-A. We trained the model for 100 epochs using the Adam optimizer with lr=1×10^{-3}, following the same settings as the TraPPM model. The NNLQP model takes the graph representation G as input, generates embeddings, concatenates them with static features, and employs an MLP to predict performance.

F. Baseline - Comparison

We assessed the performance of the TraPPM model by comparing it with baseline models. Both the TraPPM model and the baselines were trained using a supervised dataset of A100 GPU, with a specific focus on predicting step time (ms) and memory usage (MB). We trained the TraPPM, NNLQP, and MLP models for 100 epochs, repeating the process five times using different seeds as outlined in Section V-D. When we assessed the models for their capability to predict memory usage and step time, the epoch-versus-loss plot as shown in Fig. 5, revealed that the TraPPM model converges more rapidly compared to both NNLQP and MLP. This faster convergence can be attributed to TraPPM's ability to leverage unsupervised learning from unlabeled data.

TABLE II. COMPARATIVE PERFORMANCE ANALYSIS OF MEMORY USAGE (MB) PREDICTION: AVERAGED RESULTS OVER FIVE DISTINCT SPLITS. RESULTS HIGHLIGHT TRAPPM'S ENHANCED ACCURACY COMPARED WITH BASELINE MODELS. THE LOWER THE VALUES, THE HIGHER THE ACCURACY

G. Model Evaluation and Comparison

The performance evaluation of the TraPPM model against baseline models was conducted using a test dataset, with MAPE and RMSE as the key metrics, as detailed in Section IV-D. These metrics were computed for each model family individually to provide a comprehensive performance assessment. Lower MAPE and RMSE values indicate closer alignment of predictions with actual values.

Table II details the predictive accuracy for memory consumption, while Table III focuses on training step latency. The TraPPM model notably outperforms the baselines in both aspects. In memory consumption prediction, TraPPM achieves a significant relative improvement in MAPE of 40.6% over the NNLQP model, demonstrating its robustness. Similarly, for training step time predictions, TraPPM exhibits superior accuracy, with a relative MAPE improvement of 34.2% compared to NNLQP. Additionally, the aggregate performance of the TraPPM model, encompassing all tested model families, is summarized in Table IV. This table provides a holistic view

of the TraPPM model's performance across various prediction tasks, reinforcing its overall efficacy in comparison to the baseline models.

H. Theoretical Insights into TraPPM's Semi-Supervised Learning Approach

The TraPPM model leverages a semi-supervised framework, integrating unsupervised learning for generating embeddings, which significantly enhances its predictive capabilities for step time and memory usage. This methodology stands in contrast to the purely supervised models like NNLQP, which rely exclusively on labeled data. Theoretically, the effectiveness of TraPPM is attributed to its ability to access a richer representation space, capturing latent structural features within the data through these unsupervised embeddings, features that remain elusive in a solely supervised paradigm.

From a mathematical perspective, the TraPPM model can be seen as operating within an expanded function space, F', compared to the more limited function space, F, accessible by conventional supervised learning. This expanded space F', achieved through the integration of unsupervised embeddings, encapsulates the original space F but extends further to incorporate additional dimensions reflecting data variance and underlying structure. The empirical benefits of this expansion are evidenced by the improved MAPE and RMSE metrics detailed in Tables II and III, with aggregate performance enhancements further demonstrated in Table IV.

To provide empirical validation of these theoretical and mathematical concepts, we include actual versus predicted plots in Fig. 6. These plots vividly illustrate the alignment between TraPPM's predictions and actual outcomes, thereby substantiating the model's proficiency in accurately forecasting training characteristics. They visually reinforce the theoretical and mathematical merits of the semi-supervised learning approach employed by TraPPM, highlighting its superiority in a variety of prediction tasks across multiple model families.

I. Ablation Study: Impact of Weight Initialization

In this ablation study, we examine the influence of weight initialization on the TraPPM model's performance, focusing on two distinct GAE configurations: one using pre-trained weights and another with randomly initialized weights. Both configurations are integrated with a GNN for regression tasks, as detailed in Section IV-C.

Empirical results indicate a marked difference in performance based on the initialization approach. The model with pre-trained weights demonstrates a notable decrease in MSE loss for training step time, starting from 1.26×10^4 and reaching 6.82×10^2 by the 100th epoch, signifying effective and efficient learning. In contrast, the randomly initialized model begins with a substantially higher initial MSE loss of approximately 5.43×10^{12}, which only marginally improves to 1.05×10^5 by the 2nd epoch and then stagnates, showing no further significant decrease in subsequent epochs. This pattern is consistently observed for both training step time and memory consumption prediction tasks.

Theoretically, this disparity can be attributed to the different starting points in the parameter space optimization landscape. Pre-trained weights provide a beneficial starting position, facilitating a more focused and stable gradient descent path ($\nabla_\theta L$). Conversely, random initialization tends to place the model in a less favorable starting point, often characterized by steeper initial gradients and a higher likelihood of getting trapped in local minima.

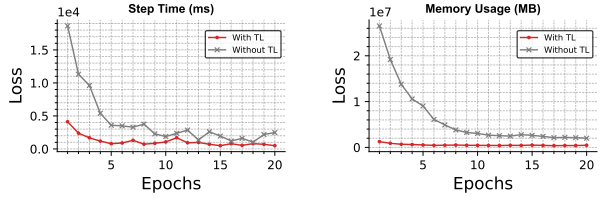

Fig. 7. Epoch vs. Loss plot demonstrating TraPPM's enhanced convergence through transfer learning.

These observations underscore the critical role of initial weight settings in the performance of GAEs, especially in the context of the TraPPM model. The study highlights the substantial advantage of employing pre-trained weights for complex structured data tasks, as they significantly enhance the model's ability to learn efficiently and effectively.

VI. Discussion

A. TraPPM's Adaptability to Predicting Diverse Metrics

The TraPPM model demonstrates its versatility in metric prediction, such as power consumption, by leveraging the GAE's embeddings Z. These embeddings, derived from DL models, are crucial for extending prediction capabilities beyond standard metrics like memory usage and step time.

The GAE transforms high-dimensional inputs G into a comprehensive latent space $Z = f_{\text{GAE}}(G)$, forming the foundation for a GNN-based regression model as explained in the Section IV-B. For power consumption prediction, this GNN model, trained on the supervised dataset for 100 epochs (as outlined in Section V-D), aims to minimize the MSE between the predicted $\hat{y}_{\text{power}}$ and actual power consumption values y_{power}:

$$L_{\text{power}} = \frac{1}{n} \sum_{i=1}^{n} (y_{i,\text{power}} - \hat{y}_{i,\text{power}})^2$$

This method highlights TraPPM's adaptability in using the same set of GAE embeddings for diverse predictions. The effectiveness of this approach is validated by TraPPM's performance in power consumption prediction, achieving a MAPE of 5.01% and an RMSE of 17 W, thereby demonstrating the robustness and versatility of GAE embeddings in various predictive scenarios. Fig. 6, clearly depicts TraPPM's predictive accuracy, illustrating the close alignment between predicted and actual power consumption values.

B. Transfer Learning Capability of TraPPM

Transfer learning, crucial in DL when labeled data is scarce, was employed in TraPPM to address the limited labeled data for the V100 GPU (see Section V-B2). By initializing

```
import trappm

config = { 'model': 'resnet101.onnx', 'batch_size': 32,
           'device': 'GPU:A100-SXM4-40GB:1' }
out = trappm.predict(config)
print("ms: {0}, MB: {1}, W: {2}".format(*out))
```

Fig. 8. A sample Python code using TraPPM to predict.

the V100 GPU training with weights W_{A100} from the A100 GPU-trained model, depicted in Fig. 7, we aimed to expedite convergence compared to starting from scratch.

In TraPPM, transfer learning theoretically embodies domain adaptation, transitioning the function $f_{\text{source}}(X; W_{A100})$ to $f_{\text{target}}(X; W)$. This strategy circumvents the initial generic feature learning phase, directly fine-tuning the model to the target dataset's specificities.

The effectiveness of this approach in TraPPM led to substantial relative improvements in prediction accuracy: approximately 55.03% in RMSE for Step Time and 48.76% for Memory usage. Table V details these enhancements, underscoring the robustness of transfer learning in optimizing TraPPM's predictive performance for different hardware contexts, especially where labeled data is limited.

TABLE V. COMPARISON OF METRICS WITH/WITHOUT TL

Label	Metric	With TL	Without TL
Step Time	MAPE (%)	**19.13**	28.24
	RMSE (ms)	**20.05**	44.59
Memory	MAPE (%)	**11.22**	28.49
	RMSE (MB)	**603.03**	1176.90

C. Ease of Use with TraPPM

We have developed a TraPPM as a Python library for predicting the step time, memory usage, and power consumption of DL models in the ONNX format. Users can effortlessly leverage TraPPM's performance prediction capabilities with just a few lines of code, as shown in Fig. 8.

D. Optimizing Cloud Costs and Resources with TraPPM

TraPPM is instrumental not only in Neural Architectural Search but also in datacenter job scheduling and cloud cost estimation. Its predictive capability enables efficient resource planning in datacenters and accurate estimation of cloud computing expenses. For example, using TraPPM to predict the training duration of an EfficientNet_b6 model, with an predicted step time of 350 ms over 2×10^5 iterations, yields a training time of around 19.44 hours. On a cloud platform with an A100 GPU costing 2.934 USD per hour, the total cost is approximately 57.04 USD. This application of TraPPM for cost prediction showcases its utility in optimizing computational resources and budgeting for cloud-based DL tasks.

VII. CONCLUSIONS

We present TraPPM, a novel framework that combines unsupervised GAE with a supervised GNN regressor to precisely predict DL model training characteristics without necessitating execution on target hardware, a significant departure from traditional approaches reliant solely on labeled datasets. TraPPM demonstrates exceptional predictive accuracy, achieving MAPEs of 4.92% for memory usage, 9.51% for step time, and 5.01% for power consumption, along with robust RMSE values. The release of our comprehensive dataset comprising 25,053 unlabelled DL graphs and 8,079 labeled DL graphs further enriches the field, providing a valuable resource for future research. TraPPM's innovative use of unlabeled data in a semi-supervised learning context marks a significant advancement in the DL performance prediction community.

ACKNOWLEDGMENT

PhyGame: An Interactive and Gamified Learning Support System for Secondary Physics Education

Toshiki Katanosaka, M. Fahim Ferdous Khan, Ken Sakamura
Faculty of Information Networking for Innovation and Design (INIAD), Toyo University, Tokyo, Japan

***Abstract*—With the rapid development of affordable digital technology, digital transformation is progressing in different sectors of society. Education is no exception; especially online education has been widely spreading since the coronavirus pandemic. While online education enables individuals to overcome the constraints associated with traditional offline formats (e.g. flexibility regarding time and place), it also poses several challenges. Particularly, in STEM subjects that require hands-on experience, there are limits to what online education can offer. Therefore, online education platforms for such subjects should be developed with a goal to replicate offline hands-on experience as much as possible. It has been reported that many learners lose their motivation and drop out of online courses. Previous research has shown that virtual hands-on experiments are vital for enhancing learners' motivation. Taking these factors into consideration, we have developed a system called PhyGame for secondary-level students' physics education using interactive elements and gamification. Through evaluation by 44 secondary-level students, the system has been proven to be an effective learning platform for learning physics with enjoyment while maintaining a high level of student motivation and engagement.**

***Keywords*—Gamification; interactive learning; online education; engagement; STEM**

I. Introduction

In recent years, the remarkable development and increased use of digital technology has forced many educational institutions to change the way they provide educational services and adapt to the times. Typical examples of such changes include reliance on cloud services such as online educational tools and online video conferencing tools. However, significant challenges remain to be solved in adapting STEM (science, technology, engineering, and mathematics) education from a face-to-face format to an online format. Previous research has pointed out that the teaching-learning process of scientific concepts, especially pertaining to physics and biology, involving young pupils poses significant challenges for both learners and educators [1], [2], [3]. Therefore, there is an urgent need to develop lesson materials and learning support systems for effective teaching and learning. In conventional education, textbooks have been the main source of teaching materials. While conventional textbooks can provide a lot of information in text and visual illustrations, they often portray only static situations, i.e., scientific concepts cannot be visualized in motion. Therefore, PhyGame, the learning support system presented in this paper provides a simulation environment where students can instantly observe a scientific concept in motion by modifying the parameters and performing related calculations. This boosts interactivity and consequently learning, as interactive learning has been reported to be at least six times more effective than passive learning [4].

Another problem with online and digital education is related to the difficulty of retaining motivation by students. Let us consider the example of MOOCs, demand of which skyrocketed during the COVID-19 pandemic [5]. MOOCs platforms provide access to educational contents in a flexible manner that is not constrained by time, location, or number of students. However, past studies have shown a trend of low engagement and motivation in MOOCs, with only 7-13% of users completing the programs [6]. The main reason for this is that it is difficult for learners to maintain their own motivation [7]. In order to solve this motivation problem, we utilized digital gamification in PhyGame. Previous studies have confirmed that gamification contributes to improved learning outcomes, motivation, and engagement [8], [9], [10].

The contribution of this paper is fourfold.

- We have developed PhyGame, a system for learning physics for secondary-level students that can be operated with a standard web browser and is available at https://phygame.org/. The system incorporates several game elements, including points, badges, and leaderboards, as well as a simulation environment for interactive learning. For reasons of flexibility in design and implementation, we developed the system from scratch rather than customizing any existing learning management system.
- PhyGame supports three different modes corresponding to three different difficulty levels so that students can adjust the learning curve according to their needs.
- In addition to gamification and interactive simulation, PhyGame provides analytics support for both learners and educators. Learners can immediately confirm their performance and have a visual understanding of their weaknesses and response patterns. Educators can also obtain visual information about students' performance.
- We conducted a three-pronged evaluation of PhyGame: (1) User study by high school students and teachers, (2) evaluation by Octalysis gamification framework, and (3) evaluation of performance of webservice by open-source tool. Promising results were obtained in all three aspects.

The rest of this paper is organized as follows. In Section II, we present related research. Section III and Section IV describe the design and implementation of PhyGame respectively. Sections V through VII presents the detailed evaluation results, and Section VIII discusses the issues and the current status of resolving them. Finally, Section IX concludes the paper.

II. Related Work

Gamification, which is one of the central concepts in this paper, has been widely used in the context of education [11]. Gamification is defined as "the use of game mechanics, aesthetics, and game thinking to engage people, motivate behavior, facilitate learning, and solve problems" [12]. The concept of gamification has been applied in many fields and incorporated into many educational tools.

A. Gamification-based Systems in STEM

In the following, we present several gamification-based systems in the field of STEM. ChemCaper™: Act I - Petticles in Peril [13] is a chemistry learning game. The system features a unique storyline that combines elements of character adventure and chemistry. Players can learn chemical concepts while manipulating molecules and elements. Foldit [14] is an online game that analyzes protein folding for students aged 10 and above. The system challenges players to predict the optimal folding structure of a protein. One of the most important features of this system is its ability to contribute to actual scientific research. Quiz and Treasures [8] is a learning platform where students can learn English words and vocabulary, mathematics and computer science through quizzes. Players can earn experience points and badges by answering questions correctly, and each point earned will increase their levels. Bonde et al. developed Labster for secondary-level education, which allows common laboratory experiments to be performed on digital terminals [15]. The system incorporates game elements such as storytelling and animation to facilitate learning. Furthermore, the study confirmed that combining simulations with traditional education significantly improved learning outcomes and increased motivation.

B. Gamification-based Systems Related to Physics

Next, we present several gamification-based systems related to physics. PhET Interactive Simulations [16] is an interactive simulation platform that can be used for science education in schools. The system covers a wide range of scientific fields, including physics, chemistry, and biology, and can simulate specific experiments and phenomena. Students can intuitively use the system while learning scientific principles and concepts through hands-on experience. Fantastic Contraption [17] is a physics-based puzzle game for students aged 10 and above. In this system, the goal is for players to build machines by combining different parts and solving puzzles using the laws of physics. Students can enjoy learning physics while using their creativity and problem-solving skills. Universe Sandbox [18] is a space simulation software for students aged 10 and above. The system is characterized by its ability to simulate the behavior of celestial bodies such as planets, stars, and galaxies based on the laws of astrophysics. Users can enjoy learning about the formation of the universe, celestial collisions, and the effects of gravity. Crayon Physics Deluxe [19] is a physics puzzle game for all ages. The objective of the system is to simulate the behavior of objects painted by the player according to the laws of physics and to solve puzzles. The process of solving problems helps develop free thinking ideas and physics-based thinking. Algodoo is an educational application designed for children and teachers [20]. It aims at supporting the acquisition of fundamental physics principles through an engaging and interactive learning experience. The application takes a visual approach with an intuitive interface to present the subject matter. It uses interactivity and a physics engine to create objects, allowing learners to gain practical skills in understanding and applying real-world physical laws. World of Goo is an engaging puzzle game designed for children [21]. Players are required to construct structures based on physical laws of the real world. The game allows players to naturally learn and deepen their understanding of physics concepts by completing different stages with limited resources. Furthermore, the game provides a sense of achievement for each stage completed, thereby encouraging a positive learning experience. Monster Physics® [22] is an interactive application designed to promote the attainment of basic physics concepts through an engaging and enjoyable learning experience. The user learns fundamental physics concepts through the construction of objects and the completion of missions. A feedback feature is incorporated into the design, enabling learners to assess their progress and identify areas for improvement in preparation for the next challenge. The app engages learners in critical thinking and creativity through repetitive challenges, thereby fostering their interest in the field of physics.

III. Design Considerations of PhyGame

One of the main goals of PhyGame was to create a digital environment in which physics concepts can be simulated interactively. Simulation is a dynamic means of observing different states of a phenomenon and can promote user engagement, both in terms of being able to visualize the behavior while changing parameters, and in terms of being able to immediately check the results of one's calculations. Visualization is important in science learning, and the immediate feedback ensures that students can continue learning without a teacher next to them. With these design goals, the developed system PhyGame has the following characteristics:

1) Incorporation of gamification elements such as points, badges, leaderboards, simulations, etc.
2) The development of three modes (Simulation Mode, Multiple Choice Questions (MCQ) Mode, and Text Quiz Mode) that can be set according to the learner's level of understanding.
3) The creation of an interactive simulation environment.
4) Accumulation of learning logs and provision for feedback on learning analysis.

A. Mode Design for Easy Adaptation to Learning Stages

Three modes were designed to allow all learners to choose a better learning environment. The three modes are, in order of anticipated use, simulation mode, MCQ mode, and text quiz mode.

1) Simulation mode: The simulation mode is intended for users with a limited understanding of physical phenomena and allows them to visually understand the phenomena while using the simulation. It is intended to be used by students who have difficulty or are reluctant to learn by referring to textbooks or other conventional sources.

Fig. 1 shows a typical screen in simulation mode. The problem statement and conditions are given in the top half of

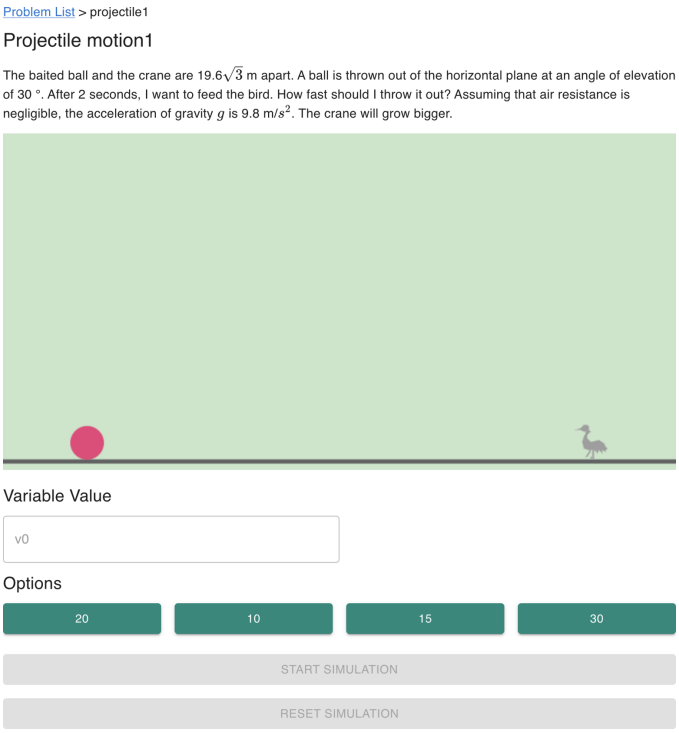

Fig. 1. An example of simulation mode page; projectile motion.

the page. In this example the user calculates on paper to derive the initial velocity v_0 in projectile motion. Then choose the correct option from the four alternatives. When the simulation start button is pressed, a red object (bait) is launched at a speed calculated by the user. Compared to static materials such as textbooks, the user's ability to view a simulation of projectile motion, utilizing parameters set by the user himself, leads to careful observation of whether or not the target is hit. If the user makes a mistake (in other words, does not hit the target), he or she can press the reset button to enter the answer again. Since hitting the target has a game-like charm, it is believed that such approaches will have a positive impact in maintaining students' motivation.

2) MCQ mode: MCQ mode is used when the user understands the contents of the study and can visualize the phenomena, and it excludes the simulation screen from the simulation mode. Students can check their ability to operationalize mathematical formulas by calculating the formulas at hand and choosing the answer from a list of alternatives. Furthermore, the fact that the simulation is not displayed requires the learner to be able to organize the situation from the problem statement and to imagine the phenomenon in concrete terms.

3) Text quiz mode: The text quiz mode is intended for users who already have a good understanding of what they have learned. It is intended to be used to check the level of understanding before the regular examinations. The mode does not include any game elements, and it was designed for students who are already motivated to test their physics skills.

B. Game Elements Used in PhyGame

PhyGame includes several game elements, which, together with their objectives, are as follows:

1) Simulation: An element that combines a story with game-like content, allowing users to immerse themselves into a simulated world and interact in it.

2) Badge: Certifies the achievement of a certain level of learning. For example, Fig. 2(b) can be earned by answering 100 questions correctly regardless of the mode.

3) Point: PhyGame uses this to indicate experience. Experience is earned by challenging problems, answering questions correctly, and earning badges. When a certain number of points are earned, the player's level increases.

4) Leaderboards: Allows students to check their own progress relative to their learning status.

5) Progress indicator: Shows the experience value. Even if the experience value can be seen numerically, it is just a number. On the other hand, if users can understand how much effort it takes to raise their level, they will be motivated to study more.

6) Difficulty setting: This refers to the various modes. By changing the range of responses according to the individual's level of understanding, all learners can learn at the appropriate difficulty level.

C. Target Users and Learning Content

We designed the system with secondary-level students as the main target users. The learning contents were designed in accordance with the curriculum guidelines for secondary-level physics established by the Japanese Ministry of Education, Culture, Sports, Science and Technology (MEXT) [23].

A total of eight simulations were designed, and priority was given to the scope of study, which was assumed to be easy for learners to understand by incorporating dynamic simulations. Simulation environments are provided for the following topics. projectile motion, law of conservation of momentum, moment of force, Newton's universal gravitation, constant velocity circular motion, refraction of light, prism, and convex lens.

D. Analytical Function

The analysis function was designed to allow learners to easily monitor their own learning progress and understanding. Learners can view statistical data on questions and their own learning results by question, mode, and genre. Moreover, educators also have access to the data of learners in the classes they manage. This allows the classroom administrator to immediately assess the level of understanding in the classrooms, thereby taking appropriate preparations for remedial lessons.

E. Badge Design

One of the most common game elements is a badge that users can earn for solving problems. Fig. 2(a) shows the PhyGame badge. In PhyGame, users can earn badges by fulfilling certain conditions. Many gamification systems use badges that use universal shapes such as stars or regular polygons.

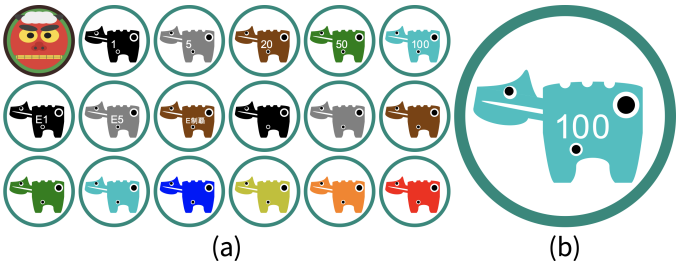

Fig. 2. (a) An example of badges in PhyGame and (b) enlarged version.

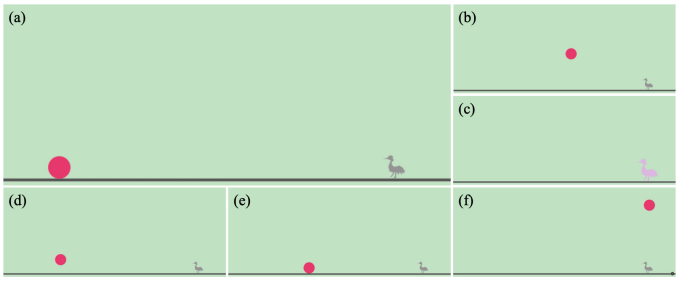

Fig. 3. An example of projectile motion simulation in PhyGame.

However, in selecting the badges, PhyGame respected the concept of culturally responsive teaching [24] and adopted motifs of traditional Japanese creatures with good omens, such as akabeko (legendary red cow) and shishigashira (lion's head). The color of the badge indicates the amount of experience gained. For example, in Fig. 2(b), if the player answers 100 questions correctly, regardless of the mode, he or she will receive a light blue sticker representing 500 points. By collecting badges that users can earn under different conditions, we hope to motivate them to continue learning.

IV. Implementation of PhyGame

This section describes PhyGame from a technical aspect. The system is available in Japanese and English for use at https://phygame.org/.

A. Examples of Simulations within PhyGame

In the following, we present two of the eight simulations. Some of the other simulations can be found in our previous publications [25], [26]. Simulations were developed to be more intuitive. It was also developed on the premise that it would be used for practice problems after the relevant formulas were covered in class, in order to provide a visual understanding of how the formulas are used in concrete terms. A short video clip introducing some of the simulations can be found in [27].

1) Projectile motion: A projectile moves horizontally with a constant velocity linear motion with velocity $v_0 \cos\theta$, and vertically with a vertical throw-up (assuming upward is positive) motion with initial velocity $v_0 \sin\theta$ and acceleration $-g$. Eq. (1-2) and (3-5) relate to horizontal and vertical motion, respectively.

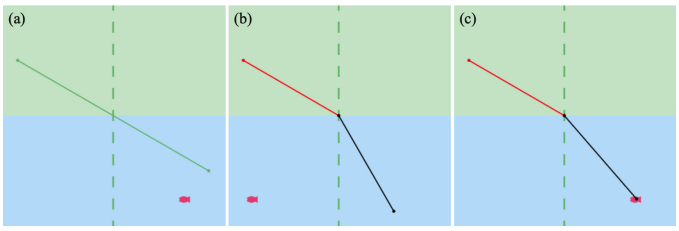

Fig. 4. An example of light refraction simulation in PhyGame: (a) initial state; (b) incorrect answer, fish escaping from a harpoon; (c) correct answer, the player catch fish.

$$v_x = v_0 * \cos\theta \quad (1)$$
$$x = (v_0 * \cos\theta)t \quad (2)$$
$$v_y = v_0 * \sin\theta + (-g)t \quad (3)$$
$$y = (v_0 * \sin\theta)t + \frac{1}{2}(-g)t^2 \quad (4)$$
$$v_y^2 - (v_0 \sin\theta)^2 = 2(-g)y \quad (5)$$

The user can read the information on x, g, θ, and t among the variables that appear in the Eq. (1-5) from the problem statement and conditions, and solve the problem based on this information. For example, in the Fig. 1 problem, v0 is derived from x, θ, t using the equation (2). The results can then be entered as input values to answer simulations or questions.

In order to make the simulation more enjoyable for the user, the crane grows in size and color when it is hit by a red bait. Note, however, that although it is made to look like a game, it is only a part of gamification.

The following sections describe the screen transitions for projectile motion simulations. The initial state of the simulation in projectile motion is shown in Fig. 3(a). When appropriate values can be calculated, the cranes become larger and more colorful as the food impacts the cranes, as shown in the transition trajectories in the order of Fig. 3(a, b, c). On the other hand, trajectories that transition in the order of Fig. 3(a, d, e) or Fig. 3(a, f) are incorrect. In the case of incorrect trajectories, we see the food falling before the crane due to its slow initial velocity or passing over the crane due to its high initial velocity, respectively.

2) Refraction of light: If the angle of incidence is θ_1, the angle of refraction is θ_2, the (relative) refractive index of medium 2 relative to medium 1 is n_{12}, the (absolute) refractive index of medium 1 is n_1, and the (absolute) refractive index of medium 2 is n_2, the relationship $n_{12} = \frac{\sin\theta_1}{\sin\theta_2} (= \frac{v_1}{v_2} = \frac{\lambda_1}{\lambda_2} = \frac{n_2}{n_1} = \frac{1}{n_{21}})$ is valid.

The user can read n_1, n_2, and θ_1 value from the problem statement and conditions, and combine these with the trigonometric functions table to solve the problem. For example, derive θ_2 from the values of n_1, n_2, and θ_1. The results can then be entered as input values to answer simulations or questions. By using the simulation, the user can feel that he/she is making meaningful calculations.

In the following sections, the screen transitions of the light refraction simulation will be explained. The initial state of the

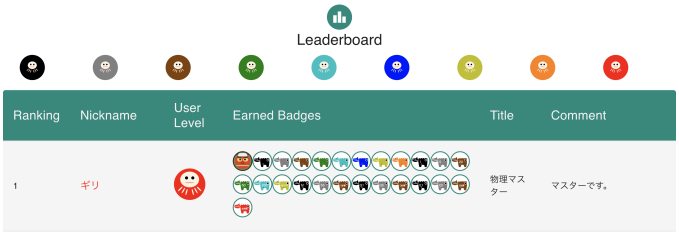

Fig. 5. PhyGame's leaderboard.

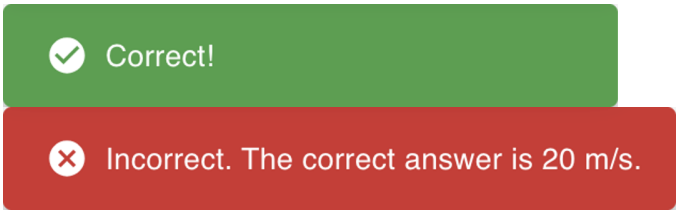

Fig. 6. An example of feedback in PhyGame.

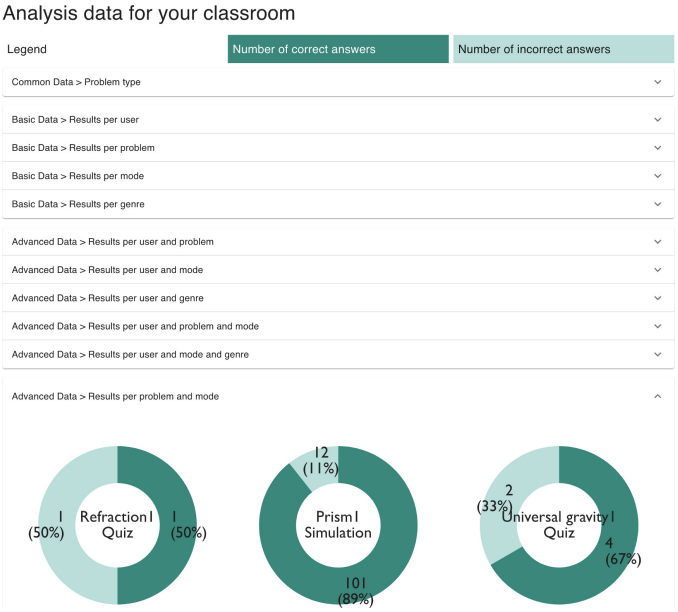

Fig. 7. An instructor's analytics interface in PhyGame.

simulation of light refraction is shown in Fig. 4(a). Deepen your knowledge of light refraction through a simulation of using a spear to catch fish in the water. The green line represents the whole spear, the red line symbolizes the spear visible above water, the back line represents the spear in the refracted area underwater, and the red fish is the target of this problem. The user must calculate the refractive index and set the correct angle of incidence so that a spear entering the water will hit a fish that appears to be in a different location due to refraction. If the user sets an incorrect angle of incidence, the fish swims away to the left of the screen, as shown in Fig. 4(b). On the other hand, if the user can set the correct angle of incidence, the spear will hit the fish and catch it as shown in Fig. 4(c).

B. User Interfaces of PhyGame

1) Leaderboard: Fig. 5 shows the PhyGame leaderboard, which displays, from left to right, the rank, nickname, icon corresponding to the user's level, list of badges earned, titles, and comments. The users are listed in order of experience.

2) Instant Feedback to User Responses: When the user answers a question, the feedback shown in Fig. 6 appears in the lower left corner of the screen. The feedback confirms whether the answer was successfully saved in the database and shows a correct/incorrect decision. Fig. 6 is the feedback immediately after answering the projectile motion question. If the answer is correct, a green background is displayed with a statement indicating the correct or incorrect answer. If the answer is incorrect, "Incorrect" message and the correct answer are displayed on a red background. A policy of not showing the correct answer may also be adopted. In all cases, however, the system is set up so that an explanation is displayed at the same time as the correct or incorrect answer is determined. Thus, immediate feedback allows the learner to correctly understand the phenomenon and continue the learning activity regardless of whether the answer is correct or incorrect. PhyGame is an educational support system that assists learning in the classroom. While teachers will try to explain to students what they do not understand during the learning process, in reality, teachers are not always able to adequately respond to all students. This tool contributes to lowering the risk of losing motivation due to wrong answers and the associated risk of quitting the study midway.

3) Analytics for instructors: Fig. 7 is an example of the analysis screen that can be viewed by faculty members. The analysis data includes information on who answered which question and when, as well as the results. With this information, learners and educators can proceed efficiently with learning analysis. The three pie charts in Fig. 7 show some of the results classified by problem and mode. If we look at the rightmost graph, we can read that it represents the results of all the responses that solved the question "Universal gravity I" in "Quiz Mode," with 4 correct responses (67%) and 2 incorrect responses (33%). Because educators can track the responses of all students in the classrooms they manage, they can check the understanding of the entire classroom and begin providing assistance to individual students at an early stage.

V. Evaluation by High School Students and Teachers

A. Basic Data

In late 2022, we conducted a user evaluation at the Toyo University Keihoku High School in Tokyo. Participants were a total of 44 high school students and teachers in the science field. Assessments were conducted twice, one week apart, with 23 participants in the first week and 21 different participants in the second week. The students consisted of 13 first-year students, 13 second-year students, and 18 third-year students. Thirty students were male and eleven were female, and three students chose not to disclose their gender. Fig. 8 shows a photograph where students are evaluating PhyGame.

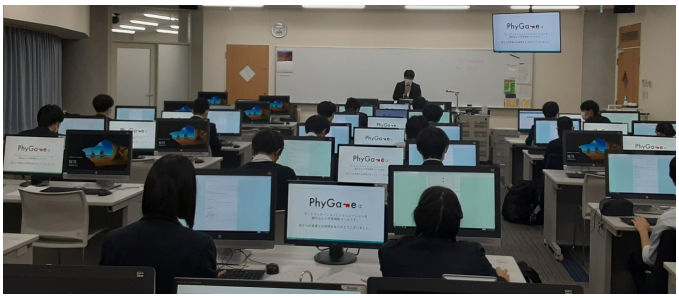

Fig. 8. High-school students testing PhyGame.

TABLE I. QUESTIONS IN USER STUDY FOR SECONDARY-LEVEL STUDENTS AND EVALUATION RESULTS

No.	Question	Mean	SD
Q1	Feeling of achievement	5.89	2.24
Q2	Feeling of immersion	6.45	2.50
Q3	Learning with fun	7.68	2.13
Q4	Improvement of motivation	6.52	2.78
Q5	Improvement of engagement	6.11	2.36
Q6	Willing to use for a different subject	8.14	2.54
Q7	User experience (UI/UX)	7.64	2.11
Q8	Overall rating	7.11	2.03
Q9	Comparison with traditional learning materials	6.73	2.20
Q10	Feeling of social connection	5.43	2.71
Q11	Favorite game elements	-	-
Q12	Good points	-	-
Q13	Points to be improved	-	-

B. Evaluation Item

The study employed a mixed research method, combining quantitative and qualitative evaluations. As shown in Table I, participants rated PhyGame on 13 items. A Likert scale from 1 to 10 was used for Q1 to Q10, with a rating of 10 indicating the highest rating. The reason for having an even number of Likert scales was to clearly identify whether PhyGame is viewed positively or negatively by not allowing the median value to be selected. On the other hand, some researchers argue that the median option should also be provided [28]. The reason for using the 10-scale method was to reflect the subjects' opinions as accurately as possible. In Q11, respondents were asked to select three of their favorite elements included in PhyGame in order of preference, while Q12 and Q13 were asked in the form of free-text questions. These questions allowed us to collect a wide range of information on the effectiveness, ease of use, attractiveness, potential improvements, and future development of PhyGame. Note that not all users experienced all eight simulations. As mentioned earlier, respondents included first through third-year high school students, of whom first-year high school students were only able to solve one type of problems (oblique projection) at the time of the evaluation. However, they tried all the simulations and enjoyed them. All second- and third-year students performed all the simulations.

C. Results of Quantitative Evaluation

Fig. 9 shows the result for each question from Q1 to Q10 by secondary-level students. According to Fig. 9 and Table I, PhyGame is an immersive and fun learning system that can increase motivation for learning. The materials were also evaluated favorably throughout compared to conventional materials, indicating a positive learning motivation to play in other ranges and subjects because of the favorable user experience. On the other hand, the factor of perceived social connectedness, which scored higher than the median but showed lower results than the other factors, needs to be added in future development.

The survey also asked about game elements that they liked throughout their PhyGame learning experience. The background of the research on this item is that many studies incorporating gamification into education have been conducted in the past, but it was reported that incorporating only points, badges, and leaderboards had limited contribution to motivation. This allowed us to test the acceptability of the simulation element, which is not a basic gamification element in this study, to secondary-level students. Fig. 10 is the top three favorite game elements. Fig. 10(a) shows that the most favorite element was also simulation, followed by leaderboards and difficulty adjustment in equal numbers. Fig. 10(b) also shows the favorite game elements by rank. According to the results, the simulation element is the most popular, followed by the difficulty settings and badge elements. Since some of the data had missing values, they were treated as invalid data.

D. Results of Qualitative Evaluation

In addition to the 10-point scale, we asked for a wide range of opinions on what was good and what needed improvement, as well as other free-form comments. Many cited badges, simulation, user experience, and analytical functions as positive aspects. On the other hand, many of the comments regarding feedback were received as points requiring improvement. Some of these opinions are presented below. User opinions are quoted without changing the wording as much as possible, with only typographical and grammatical corrections.

- "Since simulations are not possible with the paper textbooks I usually use, I can understand the phenomenon when I don't understand it, which makes it easier for me to study. (Also, when I make a mistake,) I think that understanding the phenomenon helps me remember it better, and I am less likely to make the same mistake when I try to solve the problem again."
- "The simulation makes it easy to understand what I am looking for now, and I can visually see what the object will do when I get the answer wrong."
- "The simulation allows you to visually grasp the movement of what you have learned and to understand it intuitively, whereas the graphical explanations in textbooks and problem books are not intuitively understandable."
- "The analysis of the areas I have studied is very easy to read, and I can efficiently learn my weak areas, etc."

The comments from the good points read that many users have improved their engagement toward learning by utilizing the system with the simulation built in. On the other hand, many of the comments that needed improvement were requests for feedback that would make it easier to learn, such as responses to wrong questions or a hint function for use in preparatory studies.

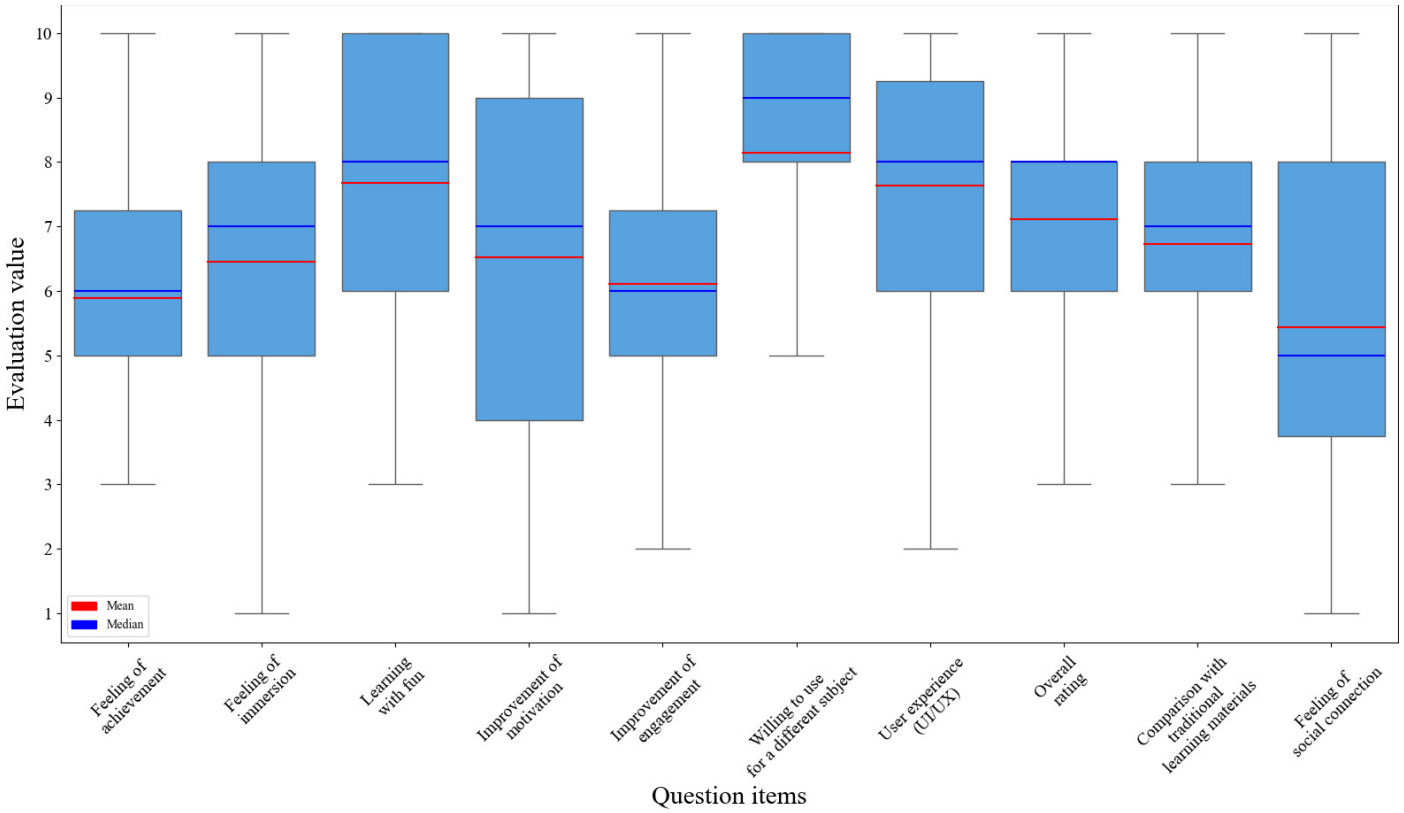

Fig. 9. Result of user study. Boxplot showing spread of scores with corresponding quartiles obtained for Q1 through Q10.

- "It would be easier to study if there was a button to display the answer instead of immediately displaying the answer when you make a mistake."
- "I would like to see a hint function because sometimes I don't understand even the easiest questions when I use it for preparation."

E. Evaluation from Teacher's Perspective

In this evaluation, we asked not only the students, but also one teacher who is actually teaching in the field for his opinion, the result shows in Table II. After the teachers observed the students using the system, the functions that only the teachers could operate (classroom-wide analysis and problem registration functions) were explained to the students in about five minutes. When a questionnaire was administered after the students had completed their evaluation, they rated the analytical function highly (highest rating on a scale of 10), and they also rated it highly (8 on a scale of 10) throughout. When asked about how to incorporate PhyGame into actual classes and the hurdles to introducing PhyGame, the respondents answered that there is still room for improvement in terms of operability, the number of simulation types and problems, and the UI. The results suggest that the system will be sufficiently practical and easy to use for everyone, with many learners and educators able to take advantage of it.

TABLE II. EVALUATION ITEMS AND ANSWERS FROM TEACHER'S PERSPECTIVE

No.	Question	Answer
Q1	Analytics function	10 (rating out of 10)
Q2	Willingness to use PhyGame in classes	5 (rating out of 10)
Q3	Improvement in teaching with PhyGame	5 (rating out of 10)
Q4	Overall evaluation	8 (rating out of 10)
Q5	How do you want to use PhyGame in classes?	We would like to incorporate simulations so that each student can solve (understand) the problem while showing the simulation.
Q6	What do you think will be the challenges in incorporating PhyGame in classes?	Ease of operation and visual clarity. The operations should be made as simple as possible so that students can quickly get used to the system.
Q7	What other features would you like?	Functions to watch videos of experiments and real phenomena.
Q8	What did you like about PhyGame?	It is a game-like system that makes it easy for students to engage with their studies.
Q9	What aspects of PhyGame should be improved?	The number of graphics and simulation patterns should be increased.
Q10	Other comments	Physics is difficult to teach on in the classroom, and in practice, it ends up being just note-taking in the classes from students' perspective, but this system will make it easier for students to solve the problems on their own.

VI. EVALUATION BY OCTALYSIS GAMIFICATION FRAMEWORK

Octalysis [29] is a gamification framework to investigate whether a system is designed to motivate users. It provides

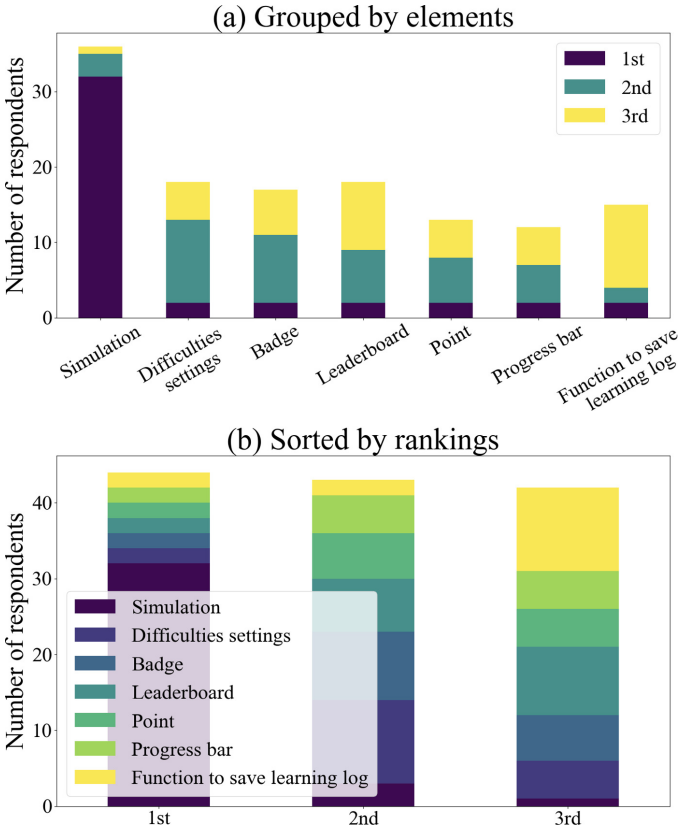

Fig. 10. Student's favorite game elements (a) grouped by elements; (b) sorted by rankings.

an intuitive interface called Octalysis tool which consists of eight evaluation axes, each with a set of factors that motivate the user, called core drives. For example, Core Drive 1 "Epic Meaning & Calling," indicates the degree to which users themselves are aware that they are doing something meaningful. PhyGame allows users to make their own simulation choices, giving them a sense of learning meaningful content. There are seven other core drives, and more detailed information is available from [30]. The white hat gamification, which indicates the upper side, is related to engagement, which makes positive feelings such as a sense of accomplishment stronger. Black Hat gamification, which shows the lower side, focuses on providing fear of losing psychological and financial rewards and on keeping the user motivated.

Overall, as reported by the Octalysis tool (Fig. 11), PhyGame exhibits a fairly balanced experience in terms of both left-brain/right-brain and white-hat/black-hat gamification. PhyGame tends to have strong white hat gamification properties and somewhat weaker black hat gamification properties. The nature of PhyGame's white hat gamification can be read as not requiring priority improvement, as it includes elements that give users a sense of accomplishment and positive user learning. PhyGame, on the other hand, is less critical and more predictable. Therefore, the nature of black hat gamification in PhyGame requires weakening the elements that reassure the user and adding more focused elements. To overcome this disadvantage, it is necessary to add new simulations, time limit functions, and other devices to increase the user's concentration.

In the left-right balance, Core Drive 3 "Empowerment of Creativity & Feedback" and Core Drive 7 "Unpredictability & Curiosity" are fully incorporated. On the other hand, the elements of Core Drive 6 "Scarcity & Impatience" and Core Drive 8 "Loss & Avoidance" must be strongly felt. To this end, incorporating badges that can be earned for a limited period of time and a system in which leaderboards are updated at regular intervals can motivate students to continue learning. The desire for Core Drive 5 "Social Influence & Relatedness" can also be satisfied by developing a function that allows anyone to freely create problems, and a multiplayer mode that allows multiple people to operate the simulation.

VII. Evaluation by Google Lighthouse

In order to evaluate the quality of the PhyGame webservice, we also evaluated it by Lighthouse [31] provided by Google Inc. Lighthouse is an open-source automation tool for improving the performance, quality, and accuracy of web systems [32]. It measures the performance of web pages based on the following criteria.

- First Contentful Paint (FCP): The time from the start of page loading until any part of the elements in the page is rendered on the screen.
- Speed Index (SI): Time how quickly the elements of the page appear in a human-recognizable form.
- Largest Contentful Paint (LCP): Time to load the largest element.
- Time to Interactive (TTI): The time it takes for a Web page to become interactive.
- Total Blocking Time (TBT): The total time that responses to user input, such as mouse clicks or screen or keyboard typing, are blocked.
- Cumulative Layout Shift (CLS): An indicator of how many unexpected layouts occurred during the display of the page.

Based on the above criteria with default weight factors, Lighthouse Scoring Calculator versions v8, v9 for Desktop devices estimated the performance of PhyGame site to be 100 out of 100. Therefore, it can be asserted that the webservice has no performance issues. The detailed result of the analysis with specific values for each criterion is depicted in Fig. 12.

VIII. Discussion and Future Work

With a view to harnessing the power of interactivity and gamification in secondary-level physics education, we developed PhyGame that supports in-browser simulation of basic physics concepts. Using PhyGame, students are able to learn interactively by observing principles of physics in motion by tweaking the parameters by themselves. We believe that such immersion beyond textbook knowledge deepens students' understanding. In addition, PhyGame also includes other functions like analytics tool for both students and teachers enabling them to keep track of study or class progress. As discussed in the previous three sections, we evaluated PhyGame on three fronts: User study by high-school students and teachers,

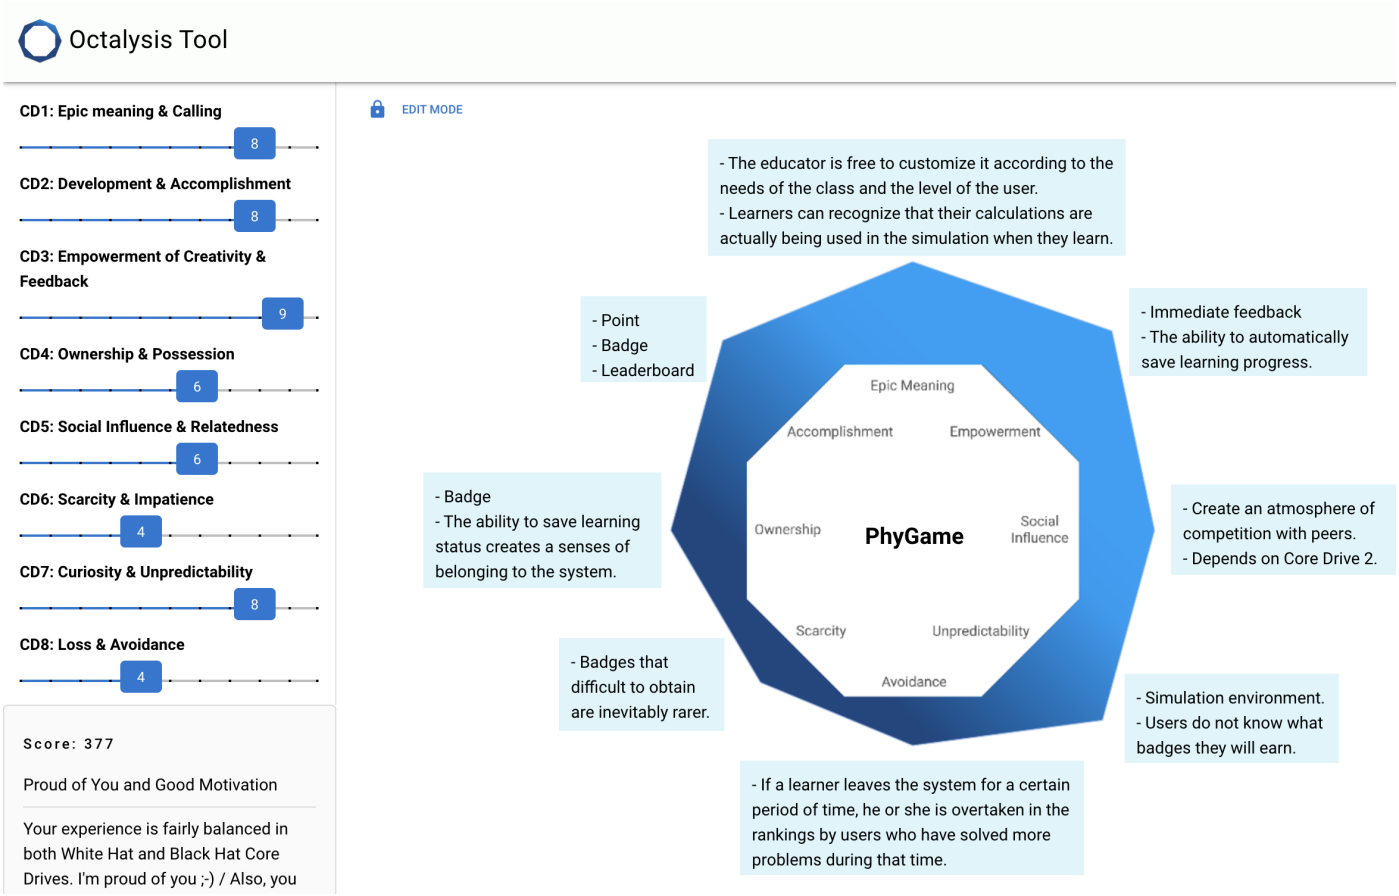

Fig. 11. An evaluation result of PhyGame using Octalysis tool.

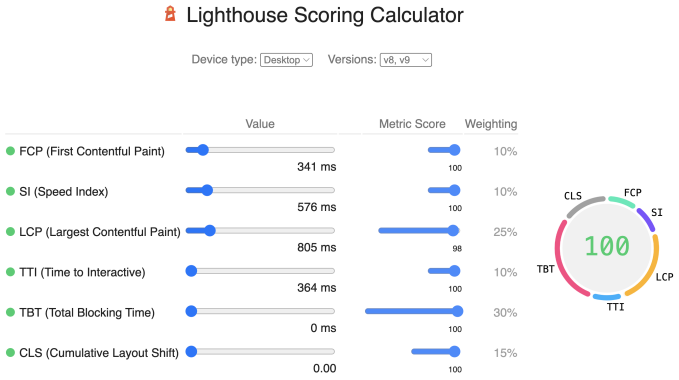

Fig. 12. Evaluation using Lighthouse; Desktop view version.

evaluation by Octalysis gamification framework to measure the impact on motivation, and evaluation by Google Lighthouse, a Chrome DevTool by Google Inc., for measuring the performance of webservices. All of these evaluations yielded promising results.

Many secondary-level students evaluated PhyGame as a learning support system having an easy-to-use UI and providing good user experience overall. Furthermore, they expressed the desire to learn other subjects using similar simulation and gamification-based systems like PhyGame. These results suggest that PhyGame successfully engages students and increases user involvement and motivation. The evaluation by instructor also highlighted the effectiveness of the analytics tool. However, there is room for improvement, which we consider as our future work. The two evaluation items that received relatively low scores (though greater than the median) in the questionnaire survey are the sense of accomplishment and social connectedness. We believe that the sense of accomplishment can be improved by increasing the number and types of simulations and diversifying the difficulty of the problems. Sense of social connections can be improved by introducing new problem-solving tasks in which multiple students work on the same task and collaborate with each other. In addition, although we considered culturally responsive principles for badge design, it is necessary to design badges from the perspective of universal design as well for users with color blindness and other physical challenges, by considering the shape and pattern of the badges. The text quiz mode required complete answers, including input of units, and no hints are also provided. Such restrictions may also need to be re-examined. From the viewpoint of evaluation, it is also important to observe how the system is used in actual classes and to objectively measure the learning effects of the system by dividing users into experimental and control groups and conducting tests before and after the use of the system.

According to the analysis of the Octalysis tool, PhyGame strikes a good balance between white hat and black hat core

drives, and between left brain and right brain core drives, indicating a desirable balance between intrinsic and extrinsic motivation. However, as with many gamification-based systems, fostering intrinsic motivation remains a challenge [33]. A longitudinal study with PhyGame is needed to understand these dynamics.

Finally, according to the Lighthouse performance analysis, PhyGame webservice scores 100% on desktop computers. In future, we intend to optimize PhyGame web performance for mobile devices as well.

IX. Conclusion

This paper introduces PhyGame with the aim of facilitating the learning of physics for secondary-level students. PhyGame was designed to be interactive and fun to keep learning, to be able to operate in an online environment unaffected by the spread of infectious diseases, and to increase user engagement and motivation. To contribute to users' learning activities, we incorporated gamification elements such as simulations, points, and badges, and made it possible to display visual graphs from the learning logs for easy self-analysis. And in an evaluation by students from Toyo University Keihoku High School (N=44), many high school students expressed positive opinions about the learning experience. They also indicated that they would like to use a similar system when studying subjects other than physics. In this paper, we confirm that incorporating the concept of gamification into an online physics learning system increases secondary-level students' engagement and motivation in learning physics.

Acknowledgment

We sincerely thank the students and teachers of Toyo University Keihoku High School for actively participating in the user evaluation. This research was partially supported by the Inoue Enryo Memorial Grant, Toyo University.

Modified SFWBP Framework for Vocal Teaching Quality Evaluation Based on the MEREC Technique

Lei Huang*
Daqing Normal University, Daqing, 163712, Heilongjiang, China

***Abstract*—With the gradual improvement of people's living standards, their pursuit of art is also constantly increasing. Vocal music is not only an important course in the training process of music majors but also an important factor in improving personal qualities and expanding one's own abilities. In the process of vocal teaching, there are many factors that affect the quality of teaching, among which the teacher-student factor is one of the important influencing factors. How to enhance the role of teacher-student factors in improving the quality of vocal teaching has become one of the main directions for the development of vocal teaching. The vocal teaching quality evaluation could be looked as the multiple-attribute group decision-making (MAGDM). Spherical fuzzy sets (SFSs) could portray the uncertainty and fuzziness during the vocal teaching quality evaluation more effectively and deeply. In this paper, based on bidirectional projection, we shall propose the spherical fuzzy bidirectional projection (SFBP) technique and spherical fuzzy weighted bidirectional projection (SFWBP) technique. First of all, the definition of SFSs is introduced. Furthermore, the SFBP technique and SFWBP technique with SFSs are proposed based on the bidirectional projection. Based on the developed SFWBP technique, the MAGDM technique is organized and all computing steps are organized. Finally, a numerical example for vocal teaching quality evaluation is employed to verify the SFWBP technique and some comparisons are employed to verify advantages of SFWBP technique with SFSs.**

Keywords*—Multiple-attribute group decision-making; Spherical fuzzy sets (SFSs); MEREC; bidirectional projection technique; vocal teaching quality evaluation

I. INTRODUCTION

At present, vocal teaching in universities excessively pursues singing techniques while neglecting musical emotions, which goes against the original intention of vocal teaching. In addition, the weak cultural cultivation of students makes it difficult to implement the training plan for vocal education. More importantly, there are frequent problems with the establishment of vocal courses in many universities [1, 2]. Single and one-sided vocal theory subjects emerge one after another, but practical courses are scarce, resulting in vocal courses becoming monotonous singing and imitation classes, hindering students from innovating in music. At present, many universities lack distinctive vocal teaching methods. From singing methods to vocal textbooks, copy the models of other music schools [3, 4]. Vocal teachers did not fully consider the actual situation of students, causing them to imitate a large amount of foreign muic, resulting in students becoming tired of vocal learning, making it difficult to cultivate their musical emotions, and even more difficult to improve their singing skills and emotional expression abilities [5, 6]. At present, most vocal majors in Chinese universities still use traditional teaching methods, which can no longer fully meet the needs of today's society [7, 8]. Teaching methods should be adjusted according to the actual situation of students, stimulate their interest in learning vocal music, improve the quality of vocal teaching, and cultivate qualified vocal talents [9, 10]. As an art discipline, vocal music requires a high level of aesthetic ability from students. However, with the implementation of the policy of expanding enrollment in universities, the number of admissions has gradually increased. Therefore, the examination standards for students' aesthetic ability have also gradually decreased, which will significantly constrain the overall development quality and trend of vocal music majors [11, 12]. The source of students majoring in vocal music in universities is very extensive, and due to the low requirements for cultural standards in the assessment process, the overall quality of students varies. Therefore, it is difficult to effectively control the quality and effectiveness of vocal teaching. Students have a low ability to appreciate and evaluate vocal works, which is also a reflection of their insufficient aesthetic ability[13]. In current vocal teaching, teachers often follow traditional teaching methods, so the lack of diversity in teaching modes has become an important reason for the role of teacher-student factors in controlling the quality of vocal teaching. The traditional teaching mode is relatively rigid, and at the same time, it lacks a more detailed examination of the quality of students' vocal learning, making it difficult to achieve accurate grasp of their learning status. Adopting a relatively fixed teaching mode in the long-term teaching process not only makes it difficult to bring students a fresh experience, but also reduces their interest in vocal learning, affects their initiative in learning vocal music, lacks effective interaction with teachers, and is difficult to promote the improvement of teacher-student relationships [14, 15]. At present, vocal teaching is still difficult to achieve a separate classroom teaching format or a small class teaching format. The conflict between a large number of students and a small number of teachers has become one of the important reasons for the lack of effective communication between teachers and students. In vocal teaching, in order to achieve the expected teaching progress, attention to individual needs of students is often overlooked, leading to a lack of effective communication between teachers and students, which is not conducive to teachers better understanding the learning and ideological status of students, and cannot effectively solve and correct errors made by students in the vocal learning process, thereby affecting the improvement of vocal teaching quality [16-18]. In summary, the development of the times has

*Corresponding Author.

promoted the continuous improvement of vocal teaching level, and has also brought new requirements to vocal teaching activities. Universities need to combine the current problems and shortcomings in vocal teaching, continuously optimize the teaching team, attach importance to the combination of theory and practice teaching, give full play to the long-term effects of teaching, and optimize teaching content, so that vocal teaching can better adapt to the development of the times, keep up with the pace of the times, meet the demand of society for vocal talents, and promote the continuous improvement of vocal teaching quality.

Multiple-attribute decision-making (MADM) is an important branch of modern management, which solves the core problem of aggregating effective decision-making information and using scientific and reasonable decision-making techniques to rank and select alternative techniques in the context of considering multiple attributes or indicators of solutions [19-24]. Whether it is a country or an individual, they are constantly faced with various choices, and MAGDM has been integrated into all aspects of life, such as location selection, investment evaluation, supplier selection, etc. [25-28]. Due to the complexity of the economy and society, traditional precise numbers have made it difficult to solve real-world decision-making problems [29-33]. Famous scholar Zadeh [34] proposed fuzzy sets (FSs) that use membership degree to represent uncertain information. Because fuzzy sets only use membership degree as single-dimensional information to represent fuzzy information, it is difficult to solve decision-making problems with hesitation [35, 36]. The intuitionistic FSs (IFSs) [37] were employed in MAGDM. Spherical fuzzy sets (SFSs) [38] could comprehensively portray the fuzziness of decision things [39-45]. The vocal teaching quality evaluation could be looked at as the MAGDM. SFSs [46] could portray the uncertainty during the vocal teaching quality evaluation. The projection technique is a useful technique to cope with MAGDM [47, 48]. The projection technique used the length and angle to obtain the projection value on the positive and negative ideal solutions, to rank the decision alternatives. However, if the projection value is equal, the alternatives can't be distinguished from each other. Thus, Ye [49] organized the bidirectional projection (BP) technique to overcome this shortcoming. Unfortunately, few useful works are been found for the BP technique under SFSs in the current MAGDM. Therefore, it is valuable to manage the novel BP technique under SFSs. In this paper, based on bidirectional projection, the spherical fuzzy bidirectional projection (SFBP) technique and spherical fuzzy weighted bidirectional projection (SFWBP) technique are organized. Based on the developed SFWBP technique, the MAGDM technique is organized and all computing steps are organized. Finally, a numerical example for vocal teaching quality evaluation is employed to verify the SFWBP technique and some comparisons are employed to verify the advantages of SFWBP technique with SFSs. Therefore, the research motivation and aim of this study are organized: (1) the method based on the removal effects of criteria (MEREC) technique [50] is utilized to construct the weight values; (2) the BP techniques are extended to SFSs; (3) some BP techniques with SFSs is organized for managing the MAGDM; (4) numerical example for is organized to demonstrate the SFWBP techniques with SFSs and several comparative techniques are employed to verify the SFWBP techniques.

The study framework of this study is outlined. The SFSs are organized in Section II. Some BP techniques with SFSs are built in Section III. Some BP techniques with SFSs are built for MAGDM in Section IV. A numerical example for vocal teaching quality evaluation is employed to show the SFWBP techniques and some comparative techniques are employed in Section V. The conclusion is organized in Section VI.

II. PRELIMINARIES

Gundogdu and Kahraman [46] organized the SFSs.

Definition 1 [46]. The SFSs BB in Θ is organized:

$$QQ = \left\{\left(\theta, QT\left(\theta\right), QI\left(\theta\right), QF\left(\theta\right)\right) \middle| \theta \in \Theta\right\} \quad (1)$$

where the $QT\left(\theta\right), QI\left(\theta\right), QF\left(\theta\right)$ is truth-membership, indeterminacy-membership and falsity-membership, $QT\left(\theta\right), QI\left(\theta\right), QF\left(\theta\right) \in \left[0,1\right]$ and satisfies $0 \le QT^2\left(\theta\right) + QI^2\left(\theta\right) + QF^2\left(\theta\right) \le 1.$

The spherical fuzzy number (SFN) is organized as $QQ = \left(QT, QI, QF\right)$, $QT, QI, QF \in \left[0,1\right]$, and $0 \le QT^2 + QI^2 + QF^2 \le 1.$

The score value (SV) and accuracy value (AV) of SFNs are conducted to rank two SFNs.

Definition 2 [46]. Let $QA = \left(QT_A, QI_A, QF_A\right)$ be the SFN, the SV is organized:

$$SV\left(QA\right) = \left(QT_A - QI_A\right)^2 - \left(QF_A - QI_A\right)^2,$$
$$SV\left(QA\right) \in \left[0,1\right]. \quad (2)$$

Clearly, the greater $SV\left(QA\right)$, the larger $QA = \left(QT_A, QI_A, QF_A\right)$.

Definition 3[46]. Let $QA = \left(QT_A, QI_A, QF_A\right)$ be the SFN, an AV is organized:

$$AV\left(QA\right) = \left(QT_A\right)^2 + \left(QT_A\right)^2 + \left(QF_A\right)^2,$$
$$AV\left(QA\right) \in \left[0,1\right] \quad (3)$$

Two SFNs are compared as follows [46]:

Definition 4 [46]. Let $QA = \left(QT_A, QI_A, QF_A\right)$ and $QB = \left(QT_B, QI_B, QF_B\right)$ be SFNs,

let $SV(QA)=(QT_A-QI_A)^2-(QF_A-QI_A)^2$ and $SV(QB)=(QT_B-QI_B)^2-(QF_B-QI_B)^2$, and let $AV(QA)=(QT_A)^2+(QT_A)^2+(QF_A)^2$ and $AV(QB)=(QT_B)^2+(QT_B)^2+(QF_B)^2$, then if $SV(QA)<SV(QB)$, then $QA<QB$; if $SV(QA)=SV(QB)$, then (1) if $AV(QA)=AV(QB)$, then $QA=QB$; (2) if $AV(QA)<AV(QB)$, then $QA<QB$.

Definition 5 [46, 51]. Let $QA=(QT_A,QI_A,QF_A)$ and $QB=(QT_B,QI_B,QF_B)$ be two SFNs, the basic operations are organized:

$$(1)\ QA\oplus QB=(QT_A+QT_B-QT_AQT_B,QI_AQI_B,QF_AQF_B);$$
$$(2)\ QA\otimes QB=(QT_AQT_B,QI_A+QI_B-QI_AQI_B,QF_A+QF_B-QF_AQF_B);$$
$$(3)\ \lambda QA=\left(1-(1-QT_A)^{\lambda},(QI_A)^{\lambda},(QF_A)^{\lambda}\right),\lambda>0;$$
$$(4)\ (QA)^{\lambda}=\left((QT_A)^{\lambda},(QI_A)^{\lambda},1-(1-QF_A)^{\lambda}\right),\lambda>0.$$

Definition 6 [52, 53]. Let $QA=(QT_A,QI_A,QF_A)$ and $QB=(QT_B,QI_B,QF_B)$, then the Hamming distance between $QA=(QT_A,QI_A,QF_A)$ and $QB=(QT_B,QI_B,QF_B)$ is organized:

$$HD(QA,QB)=\frac{1}{2}\left(\begin{array}{l}\left|QT_A^2-QT_B^2\right|\\+\left|QI_A^2-QI_B^2\right|+\left|QF_A^2-QF_B^2\right|\end{array}\right) \quad (4)$$

The SFNWA and SFNWG techniques are organized.

Definition 7 [46]. Let $QA_j=(QT_j,QI_j,QF_j)$ $(j=1,2,3,\cdots,n)$ be SFNs, the SFNWA is organized:

$$\mathrm{SFNWA}_{q\omega}(QA_1,QA_2,\cdots,QA_n)=\overset{n}{\underset{j=1}{\oplus}}\left(q\omega_jQA_j\right)$$
$$=\left(\begin{array}{c}\sqrt{1-\prod_{j=1}^{n}(1-QT_j^2)^{q\omega_j}},\\ \sqrt{\prod_{i=1}^{n}(1-QT_j^2)^{q\omega_j}-\prod_{i=1}^{n}(1-QT_j^2-QI_j^2)^{q\omega_j}},\\ \prod_{j=1}^{n}(QF_j)^{q\omega_j},\end{array}\right) \quad (5)$$

where $q\omega=(q\omega_1,q\omega_2,...,q\omega_n)^T$ be the weight of $QA_j\ (j=1,2,3,...,n)$ and $q\omega_j>0,\sum_{j=1}^{n}q\omega_j=1.$

Definition 8 [46]. Let $QA_j=(QT_j,QI_j,QF_j)$ $(j=1,2,3,\cdots,n)$ be SFNs, the SFNWG is organized:

$$\mathrm{SFNWG}_{q\omega}(QA_1,QA_2,\cdots,QA_n)=\overset{n}{\underset{j=1}{\otimes}}\left(QA_j\right)^{q\omega_j}$$
$$=\left(\begin{array}{c}\prod_{j=1}^{n}(QT_j)^{q\omega_j},\\ \sqrt{\prod_{i=1}^{n}(1-QF_j^2)^{q\omega_j}-\prod_{i=1}^{n}(1-QF_j^2-QI_j^2)^{q\omega_j}},\\ \sqrt{1-\prod_{j=1}^{n}(1-QF_j^2)^{q\omega_j}}\end{array}\right) \quad (6)$$

where $q\omega=(q\omega_1,q\omega_2,...,q\omega_n)^T$ be the weight of $QA_j\ (j=1,2,3,...,n)$ and $q\omega_j>0,\sum_{j=1}^{n}q\omega_j=1.$

III. Some BP Techniques Under SFSs

Then, some BP techniques are organized under SFSs based on the traditional BP technique [49]. Then, the spherical fuzzy BP (SFBP) technique and spherical fuzzy weighted BP (SFWBP) technique are built.

Definition 9. Let $QA_i=(QT_{ij},QI_{ij},QF_{ij})$ $(i=1,2,\cdots,m,\ j=1,2,\cdots,n)$ be a set of SFNs and $QA=(QT_j,QI_j,QF_j)(j=1,2,\cdots,n)$ be the ideal solution under SFSs, then the SFBP technique is conducted:

$$SFBP\left(QA_i, QA\right) = \frac{1}{1+\left|\frac{QA_i \cdot QA}{\left\|QA_i\right\|} - \frac{QA_i \cdot QA}{\left\|QA\right\|}\right|} = \frac{\left\|QA_i\right\|\left\|QA\right\|}{\left\|QA_i\right\|\left\|QA\right\| + \left\|QA_i\right\| - \left\|QA\right\|\left(QA_i \cdot QA\right)} \quad (7)$$

where

$$\left\|QA\right\| = \sqrt{\sum_{j=1}^{n}\left(\left(\left(QT_j\right)^2\right)^2 + \left(2\left(QI_j\right)^2\right)^2 + \left(\left(QF_j\right)^2\right)^2\right)} \quad (8)$$

$$\left\|QA_i\right\| = \sqrt{\sum_{j=1}^{n}\left(\left(\left(QT_{ij}\right)^2\right)^2 + \left(2\left(QI_{ij}\right)^2\right)^2 + \left(\left(QF_{ij}\right)^2\right)^2\right)} \quad (9)$$

$$\left(QA_i \cdot QA\right) = \sum_{j=1}^{n}\begin{pmatrix}\left(QT_{ij}\right)^2 \times \left(QT_j\right)^2 \\ +4\left(QI_{ij}\right)^2 \times \left(QI_j\right)^2 + \left(QF_{ij}\right)^2 \times \left(QF_j\right)^2\end{pmatrix} \quad (10)$$

Obviously, the greater $SFBP\left(QA_i, QA\right)$, the better alternative QA_i is.

Consider the weight values of SFSs, the SFWBP technique is organized.

Definition 10. Let $QA_i = \left(QT_{ij}, QI_{ij}, QF_{ij}\right)\left(i = 1,2,3,\cdots,m,\ j = 1,2,3,\cdots,n\right)$ be a set of SFNs and $QA = \left(QT_j, QI_j, QF_j\right)\left(j = 1,2,\cdots,n\right)$ be the ideal solution under SFSs with weight $qw = \left(qw_1, qw_2, \ldots, qw_n\right)$, then the SFWBP technique is organized:

$$SFWBP\left(QA_i, QA\right) = \frac{1}{1+\left|\frac{\left(QA_i \cdot QA\right)_{qw}}{\left\|QA_i\right\|_{qw}} - \frac{\left(QA_i \cdot QA\right)_{qw}}{\left\|QA\right\|_{qw}}\right|} = \frac{\left\|QA_i\right\|_{qw}\left\|QA\right\|_{qw}}{\left\|QA_i\right\|_{qw}\left\|QA\right\|_{qw} + \left|\left\|QA\right\|_{qw} - \left\|QA_i\right\|_{qw}\right|\left(QA_i \cdot QA\right)_{qw}} \quad (11)$$

$$\left\|QA_i\right\|_{qw} = \sqrt{\sum_{j=1}^{n}\begin{pmatrix}\left(\left(qw_j \times QT_{ij}\right)^2\right)^2 \\ +\left(2\left(qw_j \times QI_{ij}\right)^2\right)^2 + \left(\left(qw_j \times QF_{ij}\right)^2\right)^2\end{pmatrix}} \quad (12)$$

$$\left\|QA\right\|_{qw} = \sqrt{\sum_{j=1}^{n}\begin{pmatrix}\left(\left(qw_j \times QT_j\right)^2\right)^2 \\ +\left(2\left(qw_j \times QI_j\right)^2\right)^2 + \left(\left(qw_j \times QF_j\right)^2\right)^2\end{pmatrix}} \quad (13)$$

$$\left(QA_i \cdot QA\right)_{qw} = \sum_{j=1}^{n}\begin{pmatrix}\left(qw_j \times QT_{ij}\right)^2 \times \left(qw_j \times QT_j\right)^2 \\ +4\left(qw_j \times QI_{ij}\right)^2 \times \left(qw_j \times QI_j\right)^2 \\ +\left(qw_j \times QF_{ij}\right)^2 \times \left(qw_j \times QF_j\right)^2\end{pmatrix} \quad (14)$$

where $qw_j = \left(qw_1, qw_2, \ldots, qw_n\right)$ satisfies $0 \le qw_j \le 1, \sum_{j=1}^{n} qw_j = 1.$ Obviously, the greater $SFWBP\left(QA_i, QA\right)$, which indicates the better QA_i.

IV. SFWBP Technique for Managing the MAGDM under SFSs

The SFWBP technique is organized for managing the MAGDM. Let $QA = \left\{QA_1, QA_2, \ldots, QA_m\right\}$ be a collection of alternatives. Let $QG = \left\{QG_1, QG_2, \ldots, QG_n\right\}$ be attributes, $q\omega = \left\{q\omega_1, q\omega_2, \ldots, q\omega_n\right\}$ be weight values of QG_j, where $q\omega_j \in \left[0,1\right], \sum_{j=1}^{n} q\omega_j = 1$. Assume $QD = \left\{QD_1, QD_2, \ldots, QD_l\right\}$ be DMs along with weight values of $qw = \left\{qw_1, qw_2, \ldots, qw_l\right\}$, where $qw_k \in \left[0,1\right], \sum_{k=1}^{l} qw_k = 1$. And $QQ^{(k)} = \left(QQ_{ij}^k\right)_{m\times n} = \left(QT_{ij}^k, QI_{ij}^k, QF_{ij}^k\right)_{m\times n}$ is the overall SFN matrix, $QQ_{ij}^k = \left(QT_{ij}^k, QI_{ij}^k, QF_{ij}^k\right)$ means the SFNs of alternative QA_i regarding the attribute QG_j through QD_k. Subsequently, the designed calculating steps are organized (see Fig. 1).

Step 1. Organize the SFN matrix $QQ^{(k)} = \left(QQ_{ij}^k\right)_{m\times n} = \left(QT_{ij}^k, QI_{ij}^k, QF_{ij}^k\right)_{m\times n}$ and construct the overall values $QQ = \left(QQ_{ij}\right)_{m\times n}$ through SFNWA technique.

$$QQ^{(k)} = \left[QQ_{ij}^k\right]_{m\times n} = \begin{bmatrix} QQ_{11}^k & QQ_{12}^k & \cdots & QQ_{1n}^k \\ QQ_{21}^k & QQ_{22}^k & \cdots & QQ_{2n}^k \\ \vdots & \vdots & \vdots & \vdots \\ QQ_{m1}^k & QQ_{m2}^k & \cdots & QQ_{mn}^k \end{bmatrix} \quad (15)$$

$$QQ = \left[QQ_{ij}\right]_{m\times n} = \begin{bmatrix} QQ_{11} & QQ_{12} & \cdots & QQ_{1n} \\ QQ_{21} & QQ_{22} & \cdots & QQ_{2n} \\ \vdots & \vdots & \vdots & \vdots \\ QQ_{m1} & QQ_{m2} & \cdots & QQ_{mn} \end{bmatrix} \quad (16)$$

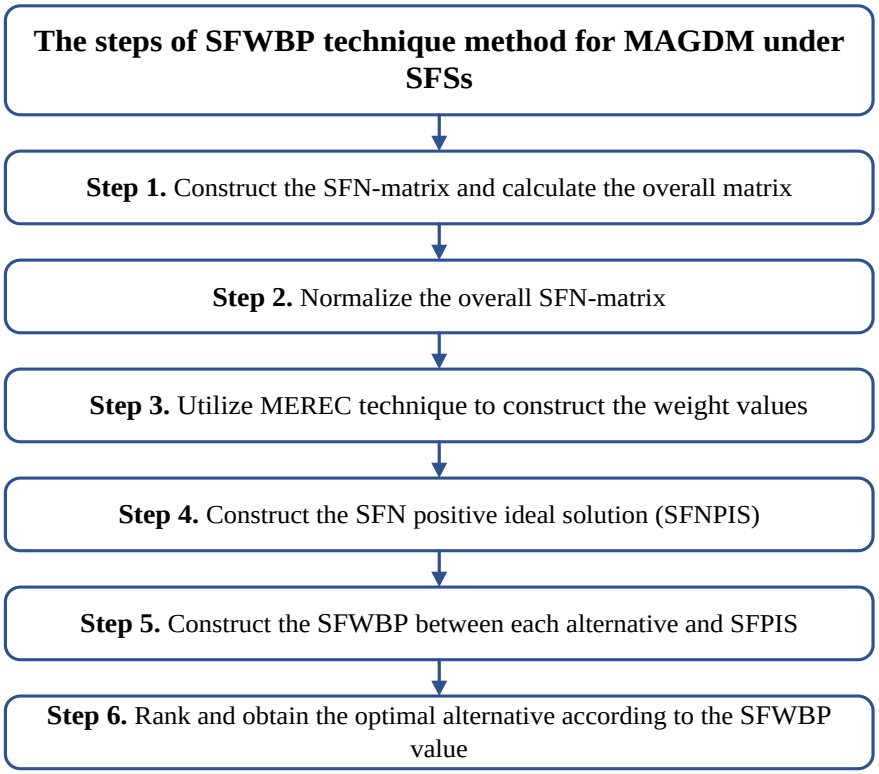

Fig. 1. The framework of SFWBP technique for MAGDM under SFSs

$$QQ_{ij}=\left(QT_{ij},QI_{ij},QF_{ij}\right)=\left(\begin{array}{c}\sqrt{1-\prod_{k=1}^{l}\left(1-\left(QT_{ij}^{k}\right)^{2}\right)^{qw_k}},\\ \sqrt{\prod_{i=1}^{p}\left(1-\left(QT_{ij}^{k}\right)^{2}\right)^{qw_k}-\prod_{i=1}^{p}\left(1-\left(QT_{ij}^{k}\right)^{2}-\left(QI_{ij}^{k}\right)^{2}\right)^{qw_k}},\\ \prod_{j=1}^{n}(QF_{ij})^{qw_k},\end{array}\right) \quad (17)$$

where $QQ_{ij}^{k}=\left(QT_{ij}^{k},QI_{ij}^{k},QF_{ij}^{k}\right)$ means the SFNs of QA_i regarding QG_j through QD_k.

Step 2. Normalize the information $QQ=\left(QQ_{ij}\right)_{m\times n}$ to $NQ=\left[NQ_{ij}\right]_{m\times n}$.

$$NQ_{ij}=\left(NQT_{ij},NQI_{ij},NQF_{ij}\right)=\begin{cases}\left(QT_{ij},QI_{ij},QF_{ij}\right), & QG_j \textit{ is the benefit} \text{ attribute}\\ \left(QF_{ij},QI_{ij},QT_{ij}\right), & QG_j \textit{ is the} \text{ cost attribute}\end{cases} \quad (18)$$

Step 3. Employ MEREC model [50] to manage the weight values.

1) Organize the normalized SFN score and accuracy matrix:

$$QSFN\left(NQ_{ij}\right)=\frac{\min_{i}\left(SV\left(NQ_{ij}\right)+AV\left(NQ_{ij}\right)+1\right)}{\left(SV\left(NQ_{ij}\right)+AV\left(NQ_{ij}\right)+1\right)} \quad (19)$$

2) Organize the overall performance $QSFN\left(NQ_i\right)$.

$$QSFN\left(NQ_i\right)=\ln\left(1+\left(\frac{1}{n}\sum_{j=1}^{n}\left|\ln QSFN\left(NQ_{ij}\right)\right|\right)\right). \quad (20)$$

3) Organize the performance of QA_i by removing each attribute.

$$NSFN\left(NQ_{i(j)}\right)=\ln\left(1+\left(\frac{1}{n}\sum_{k=1,k\neq j}^{n}\left|\ln NSFN\left(NQ_{ik}\right)\right|\right)\right), \quad (21)$$

4) Organize the sum of absolute deviations:

$$SFNSD_j=\sum_{i=1}^{m}\left|\begin{array}{l}NSFN\left(NQ_{i(j)}\right)\\ -NSFN\left(NQ_i\right)\end{array}\right|,\ k=1,2,\cdots n, \quad (22)$$

5) Organize the weight values:

$$q\omega_j = \frac{SFNSD_j}{\sum_{j=1}^{n} SFNSD_j}. \quad (23)$$

Step 4. Organize the SFN positive ideal solution (SFNPIS):

$$SFNPIS_j = \left(NQT_j^+, NQI_j^+, NQF_j^+ \right) \quad (24)$$

$$SV\left(SFNNIS_j\right) = \max_i SV\left(NQT_{ij}, NQI_{ij}, NQF_{ij}\right) \quad (25)$$

Step 5. Organize the SFWBP between QA_i and SFNPIS.

$$SFWBP\left(QA_i, SFNPIS\right) = \frac{1}{1+\left|\frac{\left(QA_i \cdot SFNPIS\right)_{qw}}{\left\|QA_i\right\|_{qw}} - \frac{\left(QA_i \cdot SFNPIS\right)_{qw}}{\left\|SFNPIS\right\|_{qw}}\right|} \quad (26)$$

$$= \frac{\left\|QA_i\right\|_{qw}\left\|SFNPIS\right\|_{qw}}{\left(\begin{array}{l}\left\|QA_i\right\|_{qw}\left\|SFNPIS\right\|_{qw} \\ +\left|\left\|QA_i\right\|_{qw} - \left\|SFNPIS\right\|_{qw}\right|\left(QA_i \cdot SFNPIS\right)_{qw}\end{array}\right)}$$

$$\left\|QA_i\right\|_{qw} = \sqrt{\sum_{j=1}^{n}\left(\begin{array}{l}\left(\left(qw_j \times QT_{ij}\right)^2\right)^2 \\ +\left(2\left(qw_j \times QI_{ij}\right)^2\right)^2 + \left(\left(qw_j \times QF_{ij}\right)^2\right)^2\end{array}\right)} \quad (27)$$

$$\left\|SFNPIS\right\|_{qw} = \sqrt{\sum_{j=1}^{n}\left(\begin{array}{l}\left(\left(qw_j \times QT_j^+\right)^2\right)^2 \\ +\left(2\left(qw_j \times QI_j^+\right)^2\right)^2 + \left(\left(qw_j \times QF_j^+\right)^2\right)^2\end{array}\right)} \quad (28)$$

$$\left(QA_i \cdot QA\right)_{qw} = \sum_{j=1}^{n}\left(\begin{array}{l}\left(qw_j \times QT_{ij}\right)^2 \times \left(qw_j \times QT_j^+\right)^2 \\ +4\left(qw_j \times QI_{ij}\right)^2 \times \left(qw_j \times QI_j^+\right)^2 \\ +\left(qw_j \times QF_{ij}\right)^2 \times \left(qw_j \times QF_j^+\right)^2\end{array}\right) \quad (29)$$

Step 6. Rank and select the optimal alternative with largest $SFWBP\left(QA_i, SFNPIS\right)$.

V. Numerical Example and Comparative Analysis

A. Numerical Example

In vocal teaching, the teacher-student factor is one of the important aspects of teaching quality control. Through good cooperation between teachers and students, the goal of effectively improving the quality of vocal teaching can be achieved. The teacher-student factor has become one of the important factors affecting the quality of vocal teaching. In the traditional vocal teaching process, it is mainly through the guidance of teachers to help students master the correct vocal techniques. However, this process also limits the initiative of students to explore independently, so the selection of sound specifications is relatively limited. The sound specifications that students can come into contact with are mainly actively taught by teachers, and there is a clear relationship between the knowledge level and reserved sound specifications possessed by teachers. However, there are obvious differences between different musical components, and the sound specifications are usually formed in a gradual development process. In different performance venues, it is also necessary to coordinate with the atmosphere and scenery of the stage to better convey the performance theme. Therefore, by enhancing the participation of teacher-student factors in the vocal teaching process, improving the scope of student expansion, and avoiding students being too limited by the teacher's ability level in the vocal learning process, the goal of better expanding sound specifications can be achieved. Different eras have different aesthetic standards, so in vocal learning, it is necessary to combine the mainstream of music at the current stage of development, and constantly expand new educational models and directions. Therefore, good cooperation between teachers and students can better provide richer choices for the content of vocal teaching. Teachers are limited by traditional thinking patterns in the teaching process, and their acceptance of new perspectives and skills is limited. At the same time, due to some teachers' overly conservative teaching views in the teaching process, it is difficult to promote the optimization of vocal teaching. At the same time, it will also create significant obstacles to the development process of diversified teaching quality evaluation. By improving the interaction between teachers and students in the process of vocal teaching, we can introduce more youthful and diverse performance styles and development directions into the vocal teaching process, transform the teacher-student relationship in traditional courses, and make important contributions to improving the quality of vocal teaching. Teaching philosophy is one of the important reasons that affect the further optimization and development of vocal teaching quality. In traditional classrooms, a teacher-centered teaching philosophy can have a significant negative impact on the expansion of student thinking. Under the traditional teaching philosophy, although teaching activities can also solve some problems in the vocal teaching process, their negative effects are also very obvious, which will create a clear gap between teachers and students, making it difficult to better integrate fashion factors into the process of improving the quality of vocal teaching. Therefore, by enhancing the role of teacher-student factors in the evaluation process of vocal teaching quality, enhancing the position of students as the main body of the classroom, promoting the diversified development of vocal teaching, transforming the rigid and boring atmosphere in traditional vocal teaching classrooms, and integrating more young, fresh, and cutting-edge elements of vocal development into the teaching process. The vocal teaching quality evaluation may be looked as MAGDM. In this section, numerical example for vocal teaching quality evaluation is provided through SFWBP technique. In order to

select the optimal music college, some research department sincerely invite three experts $QD=(QD_1,QD_2,QD_3)$ to evaluate the five music college $QA_i\ (i=1,2,3,4,5)$ through four attributes: 1) QG_1 is teaching techniques of music college. 2) QG_2 is teaching contents of music college. 3) QG_3 is teaching satisfaction degree of music college. 4) QG_4 is teaching achievements of music college. Let $qw=(1/3,1/3,1/3)^T$ be experts' weight values. The decision evaluation from $QD=(QD_1,QD_2,QD_3)$ are obtained by employing the linguistic scales (see Table I [46]) which are organized in Tables II to IV. Then, the SFWBP technique is employed to help the research department select the optimal music college.

TABLE I. LINGUISTIC SCALES AND SFNS[46]

Linguistic Terms	SFNs
Exceedingly Terrible-QET	(0.90,0.10,0.10)
Very Terrible-QVT	(0.70,0.30,0.30)
Terrible-QT	(0.60,0.40,0.40)
Medium-QM	(0.50,0.50,0.50)
Well-QW	(0.40,0.40,0.60)
Very Well-QVW	(0.30,0.30,0.70)
Exceedingly Well-QEW	(0.10,0.10,0.90)

Step 1. Organize the SFN-matrix $QQ^{(k)}=\left(QQ_{ij}^{k}\right)_{5\times4}\ (k=1,2,3)$ as in Tables II to IV and construct the overall matrix based on SFNWA technique. The results are organized in Table V.

TABLE V. THE OVERALL SFNS INFORMATION

	QG_1	**QG_2**
QA_1	(0.3162, 0.2434, 0.4923)	(0.4536, 0.2152, 0.3743)
QA_2	(0.2135, 0.2654, 0.5726)	(0.5354, 0.3718, 0.3458)
QA_3	(0.3796, 0.1463, 0.4452)	(0.4394, 0.1723, 0.4546)
QA_4	(0.4736, 0.1687, 0.3856)	(0.4657, 0.1812, 0.3583)
QA_5	(0.4324, 0.1895, 0.2263)	(0.4495, 0.2432, 0.2569)
	UG_3	**UG_4**
QA_1	(0.5572, 0.3934, 0.3675)	(0.2247, 0.2765, 0.5928)
QA_2	(0.4823, 0.3564, 0.4186)	(0.3715, 0.1154, 0.4128)
QA_3	(0.2576, 0.1233, 0.5534)	(0.3354, 0.2983, 0.5537)
QA_4	(0.6426, 0.3398, 0.3872)	(0.5347, 0.3768, 0.3645)
QA_5	(0.3156, 0.4376, 0.5126)	(0.3724, 0.4214, 0.5654)

Step 2. Normalize the SFN-matrix $QQ = \left[QQ_{ij} \right]_{5\times4}$ to $NQ = \left[NQ_{ij} \right]_{5\times4}$ (see Table VI).

TABLE VI. THE NORMALIZED SFNS

	QG_1	**QG_2**
QA_1	(0.3162, 0.2434, 0.4923)	(0.4536, 0.2152, 0.3743)
QA_2	(0.2135, 0.2654, 0.5726)	(0.5354, 0.3718, 0.3458)
QA_3	(0.3796, 0.1463, 0.4452)	(0.4394, 0.1723, 0.4546)
QA_4	(0.4736, 0.1687, 0.3856)	(0.4657, 0.1812, 0.3583)
QA_5	(0.4324, 0.1895, 0.2263)	(0.4495, 0.2432, 0.2569)
	UG_3	**UG_4**
QA_1	(0.5572, 0.3934, 0.3675)	(0.2247, 0.2765, 0.5928)
QA_2	(0.4823, 0.3564, 0.4186)	(0.3715, 0.1154, 0.4128)
QA_3	(0.2576, 0.1233, 0.5534)	(0.3354, 0.2983, 0.5537)
QA_4	(0.6426, 0.3398, 0.3872)	(0.5347, 0.3768, 0.3645)
QA_5	(0.3156, 0.4376, 0.5126)	(0.3724, 0.4214, 0.5654)

Step 3. Put forward the attribute weights through MEREC (Table VII).

TABLE VII. THE ATTRIBUTES WEIGHT

	UG_1	**UG_2**	**UG_3**	**UG_4**
weight	0.1684	0.3261	0.2927	0.2228

Step 4. Put forward the SFNPIS (Table VIII).

TABLE VIII. THE SFNPIS

	SFNPIS
QG_1	(0.4736, 0.1687, 0.3856)
QG_2	(0.5354, 0.3718, 0.3458)
QG_3	(0.6426, 0.3398, 0.3872)
QG_4	(0.5347, 0.3768, 0.3645)

Step 5. Put forward the SFWBP between QA_i and SFNPIS (Table IX).

TABLE IX. THE SFWBP VALUES

	SFWBP Values
$SFWBP(QA_1, SFNPIS)$	0.3211
$SFWBP(QA_2, SFNPIS)$	0.6534
$SFWBP(QA_3, SFNPIS)$	0.4340
$SFWBP(QA_4, SFNPIS)$	0.5745
$SFWBP(QA_5, SFNPIS)$	0.9149

Step 6. Relying on SFWBP values, the order of these music college is: $QA_5 > QA_2 > QA_4 > QA_3 > QA_1$ and QA_5 is the best music college.

B. Comparative Analysis

In this section, the SFWBP technique is fully compared with SFNWA technique [46], SFNWG technique [46], spherical fuzzy Hamacher power weighted average (SFHPWA) technique [54], spherical fuzzy Hamacher power weighted geometric (SFHPWG) technique [54], SF-CPT-CoCoSo technique [44], SFN-VIKOR technique [55], SFN-TODIM technique [43], SF-SWARA-CODAS technique [56], SF-CRITIC-EDAS technique [57] and SFN-ITARA-ELECTRE III technique [58]. Then, the results of different techniques are addressed in Table X.

TABLE X. ORDER FOR DIFFERENT TECHNIQUES

Techniques	Order
SFNWA technique [46]	$QA_5 > QA_2 > QA_4 > QA_3 > QA_1$
SFNWG technique[46]	$QA_5 > QA_2 > QA_3 > QA_4 > QA_1$
SF-CPT-CoCoSo technique[44]	$QA_5 > QA_2 > QA_4 > QA_3 > QA_1$
SFN-VIKOR technique [55]	$QA_5 > QA_2 > QA_3 > QA_4 > QA_1$
SFN-TODIM technique [43]	$QA_5 > QA_2 > QA_3 > QA_4 > QA_1$
SF-SWARA-CODAS technique [56]	$QA_5 > QA_2 > QA_4 > QA_3 > QA_1$
SF-CRITIC-EDAS technique [57]	$QA_5 > QA_2 > QA_4 > QA_3 > QA_1$
SFN-ITARA-ELECTRE III technique [58]	$QA_5 > QA_2 > QA_4 > QA_3 > QA_1$
The proposed SFWBP technique	$QA_5 > QA_2 > QA_4 > QA_3 > QA_1$

From Table X, it is obvious that the order of these techniques is slightly different, however, these techniques have the same optimal music college QA_5 and the same worst music college VA_1. This verifies that the proposed technique is effective. Furthermore, the main advantages of the SFWBP technique not only emphasize the distance values and angle values of the decision alternatives but also emphasize bidirectional projection information. So, the SFWBP technique is more scientific.

VI. CONCLUSION

Vocal music is not only a subject course, but also a way of expressing emotions. Therefore, in the process of vocal teaching, in addition to focusing on professional skills training, emotional education should also be emphasized. The teacher-student factor is one of the main ways to cultivate students' emotions. In the process of teaching professional content, teachers should not only help students master professional vocal knowledge, but also use their language and some auxiliary teaching tools to create a better learning atmosphere, allowing students to have a more intuitive vocal experience environment, and laying an important foundation for students to better understand the emotions conveyed by vocal music. In summary, vocal music is an art that is not only a process of knowledge learning but also a process of emotional integration. Therefore, emphasis is placed on the important influence of teacher-student factors on the quality of vocal teaching. By building a better teacher-student relationship in the teaching process and utilizing the professional competence of teachers, students can better understand the emotions conveyed by vocal works, thereby stimulating their enthusiasm for active learning and making important contributions to the further improvement and optimization of vocal teaching quality. The vocal teaching quality evaluation could be looked as the MAGDM. In this study, based on bidirectional projection, the SFBP technique

and SFWBP technique are addressed. First of all, the definition of SFSs is introduced. Furthermore, SFBP technique and SFWBP technique with SFSs are addressed in line with bidirectional projection. Based on developed SFWBP technique, the MAGDM technique is organized and all computing steps are organized. Finally, a numerical example for vocal teaching quality evaluation is employed to verify the SFWBP technique and several comparisons are done to verify the SFWBP technique with SFSs. Therefore, the main contributions of this work are organized: (1) the MEREC technique is employed to construct the weight values; (2) the BP techniques are extended to SFSs; (3) some BP techniques with SFSs are organized for managing the MAGDM; (4) the numerical example for vocal teaching quality evaluation is organized to conduct the SFWBP techniques with SFSs and several comparative techniques are employed to verify the SFWBP techniques. In the future, we shall continue to investigate the vocal teaching quality evaluation with SFSs and extend our organized projection techniques based on the consensus-reaching processes and regret theory [59-63].

Advanced IoT Techniques for Detecting Water Leaks in Supply Networks with LoRaWAN

Essouabni Mohammed, El Mhamdi Jamal, Jilbab Abdelilah
Electronic Systems, Sensors and Nanobiotechnologies (E2SN), Ensam, Mohammed V University in Rabat, Morocco

***Abstract*—Water leaks are a common problem when water flows through pipes, causing significant losses of this valuable resource. Our solution uses the Internet of Things (IoT) to address these losses. We employ LoRaWAN (Long Range Wide Area Network) technology to collect data from sensors, allowing real-time monitoring of pipelines and the detection of leaks and bursts as soon as they occur. Our goal is to contribute to the preservation of available water resources. We propose non-destructive ultrasonic level sensors to mitigate this issue, thereby avoiding water supply interruptions. These sensors are easy to install and maintain, with a cost that is affordable compared to other existing solutions. Our work aims to gather as much information as possible from water pipelines to ensure rapid leak detection. By using IoT and the LoRaWAN communication protocol, we automate the management of water supply facilities, enhancing efficiency and reducing wastage of this precious resource. We achieved satisfactory results using this solution on our test water pipe.**

***Keywords*—Internet of things; LoRaWAN; leak detection; pipeline monitoring; ultrasonic liquid level sensor**

I. Introduction

This Water resource management faces increasingly complex global challenges, exacerbated by rising demand, the effects of climate change, such as intensifying extreme weather events, and the deterioration of aging infrastructure. Faced with these challenges, early detection of leaks and bursts in water supply systems is crucial to minimise water losses [1] and optimise the distribution of this vital resource. Despite the existence of various leak detection methods, their applications are often limited by prohibitive costs, technical complexity, and reduced efficiency in real-world conditions. The rise of Internet of Things technologies and long-range networks, combined with the innovative use of water level sensors in pipelines, opens new pathways to address this issue. These technologies enable real-time, remote monitoring, providing a potentially more efficient and cost-effective alternative for leak detection. However, the application and effectiveness of these innovations in the specific context of water leak detection remain largely unexplored.

Our research aims to fill this gap by proposing a LoRaWAN-based IoT application for real-time monitoring of water supply, as well as for detecting leaks and bursts in water pipelines. By utilising non-invasive water level sensors, which are rarely used for this purpose but potentially complement other types of sensors, along with LoRaWAN communication that offers long-range and low data rate and energy consumption [2], Our approach aims to provide a scalable, economical, and reliable solution. It would enable the rapid detection of leaks and bursts in water pipelines, thereby contributing to the reduction of water losses and improving the management of water resources. The innovative approach in our study, combining water level sensors with LoRaWAN technology, promises to offer valuable insights for both the scientific community and industry professionals, marking a significant step forward in monitoring and managing water supply pipelines.

II. Related Works

The literature review reveals several studies in the field of leak detection. As identified by [3], leak detection methods can be broadly divided into three main categories: software-based solutions, non-technical approaches, and methods relying on specific hardware components, such as ultrasonic flowmeters. Moreover, the emergence of new methods leveraging wireless sensor networks across various fields, such as the biomedical domain and fire detection ([4], [5], [6], [7]) and also in leak detection and localisation, marks a significant evolution, combining software and hardware approaches. These systems often rely on data collected by sensors measuring sound, vibration, flow, or pressure, illustrating the diversity and complexity of strategies used to address the issue of water leaks. Moreover, the adoption of Internet of Things technologies in water resource management represents a revolution in how water networks are monitored. As noted by [8], the use of IoT sensors allows for comprehensive monitoring of water supply systems, both above and below ground. Certain sensors require direct contact with water, which can be invasive and thus increase installation costs [9]. Moreover, wireless communication and recharging buried sensors present significant technical challenges. The works of ([10], [11], [12]) examine how the Internet of Things can be used to monitor water quality and detect leaks. Their approach is based on analysing the difference between distributed water and those actually used, relying on flow and pressure sensors to identify leaks. Their strategy is primarily suited for small-diameter pipelines, highlighting a potential limitation in applying these techniques to larger and more complex systems. The same principle was applied by [13] using invasive flow meters suitable for larger pipelines. They implemented an automated system incorporating electronic valves to identify issues in water supply systems, enhance the management of these systems, and combat losses in the water supply chain. The author in [14] developed a leakage monitoring system using the LoRaWAN communication protocol and ultrasonic flow sensors compatible with LoRa. Their approach focuses on detecting leaks by measuring the flow variation between two points, A and B, with a detection threshold set at 500 ml to

trigger automatic alerts. The system uses the MongoDB platform to structure a database from the information transmitted by the flow sensors. However, it is noted that the flow sensor is designed for small-diameter pipelines, which restricts its integration into pre-existing pipeline networks.

The author in [15] used an invasive ultrasonic hydrophone sensor manufactured using micro-electromechanical system (MEMS) technologies for identifying leaks in water pipelines. The examination of transient signals and spectrograms demonstrates that the MEMS hydrophone is capable of locate the leak position in terms of sound sensitivity and energy consumption compared to commercial hydrophones. However, it is crucial to mention that in order for the leak to be detected, it needs to be located between two hydrophones. Furthermore, transmission loss, related to signal attenuation depending on the material type of the pipelines and the length of sensor placement, can potentially trigger false alarms. The author in [16] presented a technique for identifying multiple leaks in fluid pipelines. This technique utilises the velocity of ultrasonic waves, dependent on the mathematical correlation between ultrasonic speed and internal pressure. This enables non-invasive determination of the leak's location, which is calculated using a simulated annealing grey wolf optimisation (SAGWO) algorithm.

Other ultrasonic methods were identified by [17] Bulk waves: These waves are used to inspect pipes using single or multiple transducers affixed to the outside of the structure. They are generated by ultrasonic waves. However, ultrasonic inspection of pipe materials poses challenges due to their high attenuation. Guided ultrasonic wave techniques: These techniques involve the propagation of waves in waveguides, such as pipes. These waves can travel long distances, but their effectiveness is limited when inspecting water-filled buried pipes. This limitation is due to the significant attenuation of guided waves, caused by losses in the pipe material and energy leakage into the surrounding soil, which reduces the testing range. Guided wave ultrasonic (GWU) monitoring relies on acoustic waves to inspect water pipes over long distances. This method is based on torsional waves propagated by two transducers, which calculate the distance of anomalies and estimate their significance based on the amplitude. This technique shows potential for detecting small leaks, although its range may be influenced by the pipe's geometry and other structural characteristics [8].

Research by various authors has explored the use of impedance detection to identify leaks. The author in [18] introduced a pipe sheath designed to monitor water leaks, conductivity, and temperature in small-diameter pipelines. This sheath utilises non-contact impedance measurements, enabling the detection of even very small water leaks over long pipe distances. Consequently, it is necessary to install thin metallic electrodes along the pipe. The author in [19] developed a compact modular electronic unit that employs ultrasonic techniques with four copper electrodes for scalable impedance detection to detect leaks and monitor water in plastic pipes. However, this equipment is considered complex, rendering it impractical for real-world applications. The author in [20] conducted a study aimed at monitoring plastic water pipes using non-contact sensors such as strip electrodes and piezoelectric transducers. This method enables the measurement of several parameters, including flow rate, fill level, temperature, and leaks, which can be installed in existing manholes. The flow rate is determined by the Time of Flight (ToF) difference of two ultrasonic waves propagating in opposite directions within the fluid. Furthermore, ultrasonics can be used to transmit both energy and data over short distances along pipes. It is important to note that integrating electrodes into existing potable water pipelines is costly due to the extensive length of these pipelines.

Robots have also been used, such as the ultrasonic thickness measuring robot designed by [21]. This robot assesses the polymer coatings used in drinking water pipeline infrastructures to extend their lifespan. While it may be effective for its specific purpose, this robot has limitations in terms of size, range, target materials, cost, and broader inspection capabilities. This requires careful evaluation of its relevance for each application case. Another technique is based on vibratory signals [22], which involves placing sensors on the pipes of the network to detect and locate water leaks in distribution systems. This method relies on measuring the radial vibratory state of the pipes to detect energy variations transmitted to the walls of the pipe, which can be linked to a leakage flow. However, it is important to note that the sensors in this case must be very close to the leak to detect it.

Recent studies, such as those conducted by [23], have introduced an IoT-based system for detecting leaks in underground pipelines, utilising a moisture sensor and a wireless NodeMCU. This technique allows for leak detection while reducing the time needed to identify leaks by 70% and the system's hardware costs by 83% compared to previous work. Additionally, their strategy aims to avoid water waste by redirecting it to replacement reservoirs in case of a leak. However, the practical application of this system faces obstacles. The design relies on a shielded pipeline, a configuration not commonly seen in typical pipelines made of PVC, polyethylene, or asbestos cement. This characteristic makes the system potentially expensive and complex to implement in existing pipeline infrastructures. According to the article by [24], an integrated approach using Geographic Information Systems (GIS) and remote sensing techniques, including infrared imaging, is presented for detecting leaks in water distribution networks. This method, applied particularly to the network of the Sharjah Electricity, Water, and Gas Authority, utilises variations in flow, pressure, and chlorine residue to identify leaks, which are then confirmed with infrared cameras. The main advantages of this method lie in its use of GIS and infrared technologies, its integration of various data sources, and its ability to offer real-time monitoring for leak identification. However, this technique requires specific expertise and resources for the integration of GIS and infrared imaging. In the research carried out by [25], the researchers introduced a monitoring system based on IoT, utilising LoRaWAN to profile pressure rates in water pipelines. Designed to improve pressure monitoring across water distribution networks, the system employs a pressure sensor and a GSM module for real-time collection and transmission of pressure data to a cloud-based data management system. Experimental results confirmed the system’s leak detection

capabilities, revealing an average pressure variation of 7.7 kPa, indicating high consistency in measurements. However, the installation and maintenance of the system could present challenges, especially regarding the integration of the technology into existing infrastructures without causing major disruptions. The article by [26] explores the implementation of software and hardware technologies for detecting leaks and bursts in water distribution systems. This study explores a variety of methods, including acoustic-based detection systems, pressure, flow, as well as advanced approaches such as Artificial Intelligence. In the methodology they propose, the IoT framework consists of multiple layers, including a sensor layer, a communication layer, a water system layer, an exploitation layer, and an application and prediction layer. Data on flow characteristics, pressure, and water quality, along with information from the water demand model and AI models, are collected by the Supervisory Control and Data Acquisition (SCADA) system from sensors. While acknowledging that further progress is needed to align current technological capabilities with industry needs. However, non-destructive solutions such as using level sensors, accelerometers, and moisture sensors, among others, remain a viable alternative to bridge the divide between the ideal system and current capabilities. The study by [27], The authors examine approaches based on models, data, or mixed methods that combine both. Model-based methods use hydraulic simulations to detect and locate leaks, relying on the availability of a calibrated hydraulic model and water demand measurements. However, data-based approaches primarily focus on one of these two tasks, using techniques such as machine learning to analyse sensor data without requiring a deep understanding of the network. Mixed approaches focus on locating leaks; therefore, their extension to detection poses challenges when identifying low leak rates. The authors emphasize the importance of covering the entire distribution network with sensors, both for detection and for multiple-localisation. According to their recommendations, leak management methods must be designed. This highlights the usefulness of non-destructive sensors, also known for their low cost and easy installation, as complements to existing sensors to address this constraint. These sensors allow the application of information fusion techniques, combining data from different sensors, each suited to various areas and conditions of water pipelines, such as diameter, location, whether it's crowded or not, accessibility, and so on. In their article, [28] examines the use of high-frequency pressure and acoustic sensors within smart water networks (SWNs). Their study highlights the advantages of these technologies in optimising the management of urban water distribution networks by enabling leak detection and localisation, asset management (pipe failures), and online hydraulic modelling. The study included an experimental setup that simulates a pipeline network with ultrasonic flow sensors and pressure sensors. The collected data is transmitted to a cloud server for analysis. However, it was found that the pressure readings were not sufficiently reliable to detect leaks due to the relatively short length of the experimental pipeline network, which led to a significant pressure loss between successive nodes.

In summary, our exploration of various methods for detecting leaks in water pipelines has revealed that every approach has its unique strengths and constraints. The choice of the ideal method largely depends on factors such as pipeline dimensions, the scope of the inspection, the available sensor technology, and other specificities inherent to each application context. This article explores advanced techniques for leak detection and water management, initially describing the structure and operation of our IoT sensor system. We then discuss the communication protocols used, detail our methodological approach, and present the results of practical tests. We conclude with the implications of our findings for future water management.

III. Structure of the Proposed Solution

The general structure of our solution is illustrated in (Fig. 1). It consists of sensor nodes that continuously and in real-time acquire water level measurements. These measurements are then transmitted to the gateway via the LoRa communication protocol. The primary role of the gateway is to manage communications according to a unified standard. Subsequently, the data are forwarded to the server for processing, monitoring, and decision-making. Additionally, the gateway is capable of sending data back to the sensors. Our main contribution in this article is based on the use of distance-measuring sensors to determine the water level in pipelines, a use not yet reported in existing literature. While these types of sensors are typically used in reservoirs, their adoption for water pipelines represents a novel approach. Additionally, the integration with the LoRaWAN communication protocol helps overcome issues related to sensor range and autonomy, while remaining non-destructive. This solution is ready to be deployed either alone or in conjunction with other sensor technologies. Furthermore, the existing manholes in current infrastructure make this solution applicable to a wide range of pipelines, whether buried or not. This monitoring capability significantly enhances the efficiency of teams responsible for pipeline maintenance and inspection by precisely identifying the suspect section of the pipeline.

A. Methodology

The occurrence of leaks is a significant problem for operators in water production and distribution. Repairing leaks requires significant human and material resources, and any disruption in the drinking water supply is not tolerated by residents. The idea is to continuously monitor the water pipes through alerts on a smartphone or computer, this is achieved by relying on the water level in various the water pipes sections. The water level can vary over time due to several factors such as overconsumption, anomalies in a water pipeline, or a malfunction in hydroelectric equipment. In practice, when the water level drops for an extended period, this indicates that there is a leak to be detected and monitored. Our task in this case is to determine the leak location by installing sensors in the water pipes, specifically in already-existing manholes. Given that water supply networks extend over kilometres and encompass various techniques and structures for water

transport, such as buried pipes, necessary manholes for emptying, and those containing air valves to release air from the pipes we have the advantage of accessing the pipes through the doors of the manholes, which allows us to easily install our sensors.

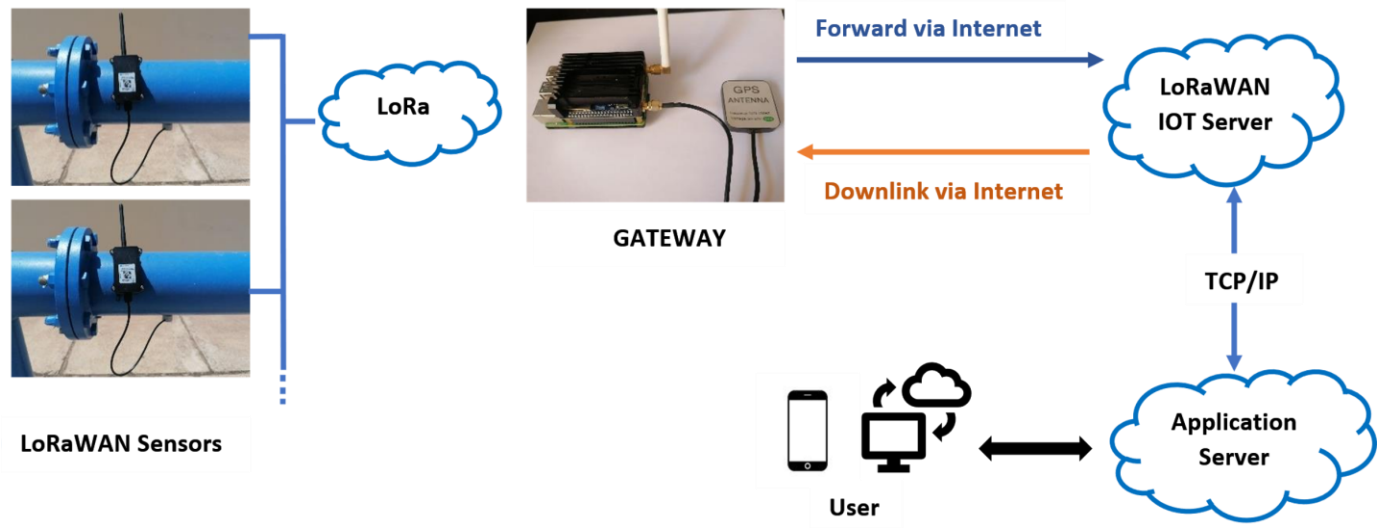

Fig. 1. System architecture of the LoRaWAN-based leak detection system

The level sensors (Fig. 2) continuously perform real-time measurements and transmit these readings to a remote monitoring centre. This centre then compares the gathered data with readings taken under equilibrium conditions. If, in the second phase of the process, a deviation exceeds a predefined threshold, an alarm is automatically triggered, prompting verification of conditions upstream, such as checking the filling status of reservoirs and valve positions, to prevent false alarms. Subsequently, the centre observes the level sensors along the suspected area for a certain period. During the third phase, an analysis of adjacent measurements along the concerned segment is conducted to determine if there's a leak and pinpoint its location. The results of this analysis are then relayed to the operations staff for further action.

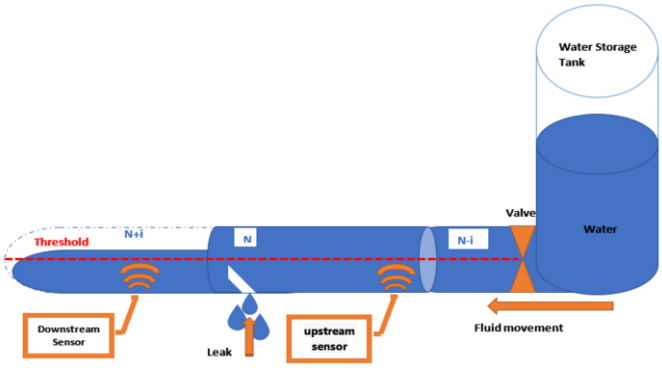

Fig. 2. Leak detection approach

Eq. (1) illustrates the principle of calculating the liquid level relative to a predefined threshold. In these equations, $\boldsymbol{L}$ represents the liquid level measured in each pipe segment. $\boldsymbol{k}$ denotes the number of sensors on each side of segment $\boldsymbol{N}$, which is the segment suspected to be affected by the leak. $\boldsymbol{L_0}$ is the reference liquid level, representing the expected or initial water level in the absence of a leak. $\boldsymbol{T}$ is the predefined level threshold. This threshold $\boldsymbol{T}$ is determined through experimentation and depends on the pipe's diameter as well as the upstream and downstream conditions of each section.

$$\sum_{i=1}^{k}(L_0 - L_{N-i}) < T \;\&\; \sum_{i=1}^{k}(L_0 - L_{N+i}) > T \quad (1)$$

B. *Mathematical Relationship of Flow Rate as a Function of Level*

To establish a mathematical relationship between the drop in flow rate (ΔQ) in a water pipe and the drop in water level (Δh) in that pipe, we can use the continuity equation, which expresses the conservation of mass in a fluid flow. The continuity equation states that the mass flow rate of a fluid remains constant along a pipe, provided that losses are negligible. We can mathematically relate the drop in flow rate to the drop in water level.

1) The continuity equation is as follows

$$A1.V1 = A2.V2 \quad (2)$$

Where:

- $A1$ and $A2$ are the cross-sectional areas of the pipe at two given points (usually in square meters).
- $V1$ and $V2$ are the fluid velocities corresponding to these points (usually in meters per second).

However, we have a water pipe in which the water level decreases by a certain amount Δh over a certain pipe length Δx. We can define the drop in water level Δh as the difference in height between the inlet and outlet points of this pipe section.

2) Relationship between fluid velocity and water level height: We use Torricelli's law to relate the fluid velocity (v) to the water level height (h) in the pipe. This law is formulated as follows:

$$v = \sqrt{2 \cdot g \cdot h} \quad (3)$$

where:

- v is the fluid velocity in the pipe (in meters per second).
- g is the acceleration due to gravity, approximately 9.81 m/s² at Earth's surface.
- h represents the height or water level (in meters).

3) Calculation of velocity variation (Δv): The velocity variation (Δv) between the inlet point 1 and the outlet point 2 of the pipes can be calculated by subtracting the velocity at the outlet ($v2$) from the velocity at the inlet ($v1$):

$$\Delta v = v1 - v2 \quad (4)$$

By using Torricelli's law for $v2$ and $v1$, we get:

$$\Delta v = \sqrt{2 \cdot g \cdot (h1 - h2)} \quad (5)$$

4) Calculation of flow rate variation (ΔQ): The flow rate variation (ΔQ) between the inlet and outlet points of the pipe can be calculated by multiplying the cross-sectional area at the inlet ($A1$) by the velocity variation (Δv):

$$\Delta Q = A1 \cdot \Delta v \quad (6)$$

Using the previous expression for Δv, we get:

$$\Delta Q = A1 . \sqrt{2 \cdot g \cdot (h1 - h2)} \quad (7)$$

This is the mathematical equation that relates the drop in flow rate ΔQ in the pipe to the drop in water level Δh between the inlet and outlet points of the pipe, based on the cross-sectional area of the pipe $A1$ and the acceleration due to gravity (g).

IV. IoT Communication Protocol

There are different communication protocols in which IoT modules operate. This difference has consequences on the range, the speed, the frequency, the connection quality and the messages volume to be transmitted. (Fig. 3) shows some communication protocols examples distributed according to their data rate and distance. In our case, we favour the large distance over the data rate, the choice is therefore focused on the LoRa (Long Range) because it is adapted to our needs.

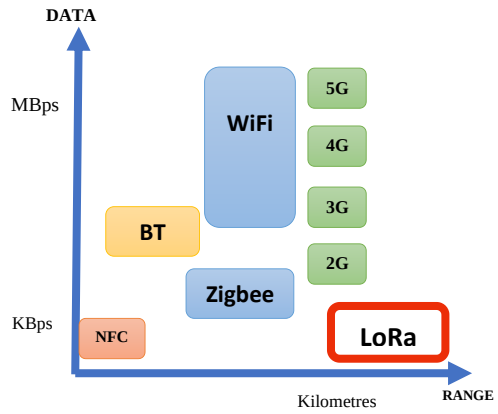

Fig. 3. IoT communication protocol

V. Materials and Methods

In this section, we outline the essential steps undertaken to conduct our practical experiments, facilitating data acquisition for the purpose of early leak detection.

A. The Things Network (TTN)

This is an open and decentralised network infrastructure for Internet of Things devices. It allows devices to communicate with each other and with the internet. TTN uses LoRaWAN technology, our connected objects must operate in remote or hard-to-reach areas, and it has three clusters and depends on the geographic location of each user. In our case, we are using the frequency of 868 MHz designed for Europe. This frequency is crucial for equipment certification and proper operation, so it is essential that all equipment uses the same frequency. In our practical test, we manage the acquisition and processing of information from the gateway and sensors, while the rest of the infrastructure is managed by the TTN server.

B. Gateway

The gateway (Fig. 4) used for our test comprises two main components: a Raspberry Pi board and an integrated LoRa module, the PJ1301 from DRAGINO. This module allows us to manage various devices using the LoRaWAN communication protocol. It is a high-performance multichannel concentrator designed to receive multiple LoRa packets simultaneously. The goal is to establish a robust connection between a central data concentrator and wireless terminals spread across a wide area. Internet of Things applications can support up to 5000 nodes per km² in moderately disturbed areas. The gateway's integrated GPS (Global Positioning System) module provides precise synchronization and geographical coordinates to the Raspberry Pi. After adding and activating our gateway, TTN displays the connected status, The received messages contain the information sent by all sensors around the gateway with a timestamp, the bandwidth of 125 KHz, the spreading factor, as well as the RSSI (Received Signal Strength Indication), etc.

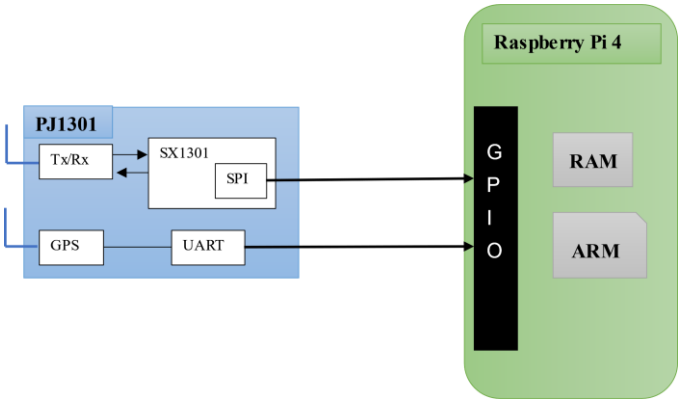

Fig. 4. Gateway structure

C. Sensors

We employed the DRAGINO LDDS20, an ultrasonic LoRaWAN liquid level sensor designed for IoT applications (Fig. 5). This sensor measures liquid levels in containers or water pipes non-invasively and transmits the data to the IoT server via the LoRaWAN network. Positioned directly beneath

the water pipeline, the sensor is engineered to detect liquid levels efficiently, offering extensive-range spread spectrum communication, robust interference resistance, and minimal power usage.

1) Equation for measuring water level using the ultrasonic sensor: The LDDS20 calculates the distance to an object by measuring the time it takes for an ultrasonic wave to travel to the object and return. The fundamental equation for this calculation is:

$$\text{Distance} = \frac{\text{Speed of Sound} \times \text{Time}}{2} \quad (8)$$

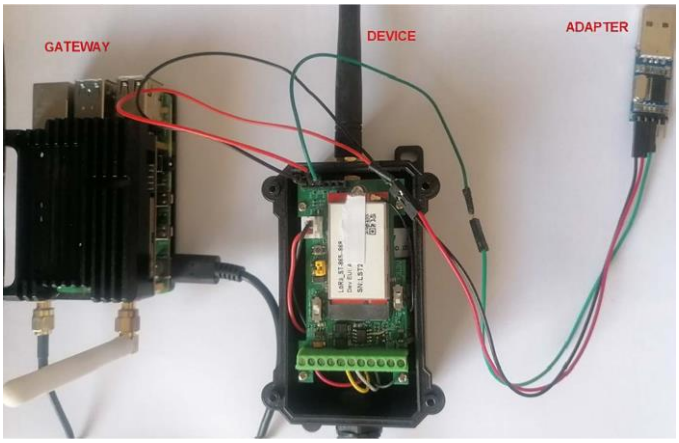

Fig. 5. The gateway, sensor device, and adapter for AT command

Where:

- Distance: Represents the distance to the liquid interface.
- Speed of Sound: The speed at which sound waves propagate in the medium, in pure water at 20 °C, this speed is approximately 1 482,343 m/s (5 336,435 km/h).
- Time: The duration for the ultrasonic wave to travel to the interface and return, in microseconds (µs).

The sensor emits an ultrasonic wave, a high-frequency sound wave, toward the target (e.g., the liquid interface). This wave propagates through the water in the pipe at the speed of sound. Upon reaching the liquid interface, it is reflected back to the sensor. The sensor measures the time taken for the ultrasonic wave to travel from the sensor to the liquid interface and then return. Using (8), the sensor calculates the distance to the liquid interface. The division by 2 is necessary because the ultrasonic wave makes a round trip. The calculated distance is then provided as an output, which is used to determine the liquid level in the pipe.

D. Datacake

Is an IoT development platform that allows users to connect, monitor, and remotely control devices via the internet. The platform provides a variety of tools for developers, including real-time data collection, customizable dashboard creation, user management, integration with third-party services, and automated notifications. Initially, we activated the integration at the TTN level to retrieve data. After activating the integration, we registered the sensors on the Datacake platform.

VI. Conducting A Practical Test

The process involves applying the prototype to a PVC water pipe, similar to those used in actual drinking water transport. The pipe is filled with water to test the sensors and evaluate their effectiveness. The level sensor provides measurements on the rate of filling, then controlled leaks are induced to observe changes in the water level. The initial step involves installing two sections of pipes, totalling 6 meters in length. The selected diameter is 160 mm, with a cap for sealing and an elbow for filling at both ends, as shown in (Fig. 6).

Fig. 6. Test prototype with sensors installed in the pipe

VII. Results

Following the preparation of the prototype and the installation of the sensors, we commenced the testing process. The initial step involved connecting the gateway to the TTN server. The next step was to verify the uplink connections, where the packets sent by the sensors contained data regarding the detected liquid levels. Our experimental approach consists of three main phases. The first involves filling the pipeline, followed by initial water level measurements at the sensor placement points. However, it is crucial to continue testing to evaluate the sensors' capacity to detect rapid changes in water levels. After progressively inducing a leak, the continuity test for water level sensor detection shows a progression of measurements over time, as illustrated in (Fig. 7). It provides an overview of the various measurements obtained from the sensors, indicating distance, sensor voltage, and signal quality. Additionally, the system sends automatic email alerts based on predefined thresholds. The results suggest a good capacity for the system to detect changes in water levels, which is crucial for effective leak monitoring.

Fig. 8 shows that our solution successfully identifies a 74 mm drop in water level, a crucial parameter for detecting potential water leaks, or which can indicate various real-world situations, such as a pump equipment failure or an upstream reservoir is empty. The system's ability to track these changes

in real-time, with a granularity that allows for detecting shifts of just a few millimetres, is significant is essential for identifying not only major leaks but also minor anomalies, which could indicate emerging issues within the water pipelines. Additionally, our system includes a sensor box consisting of nodes that continuously capture accurate real-time measurements in the pipes. However, for more robust monitoring and management of the water network, integrating other types of sensors, such as accelerometers, hydrophones, etc., would be beneficial. These enhancements would offer a more comprehensive perspective on network conditions and enable improved water resource management.

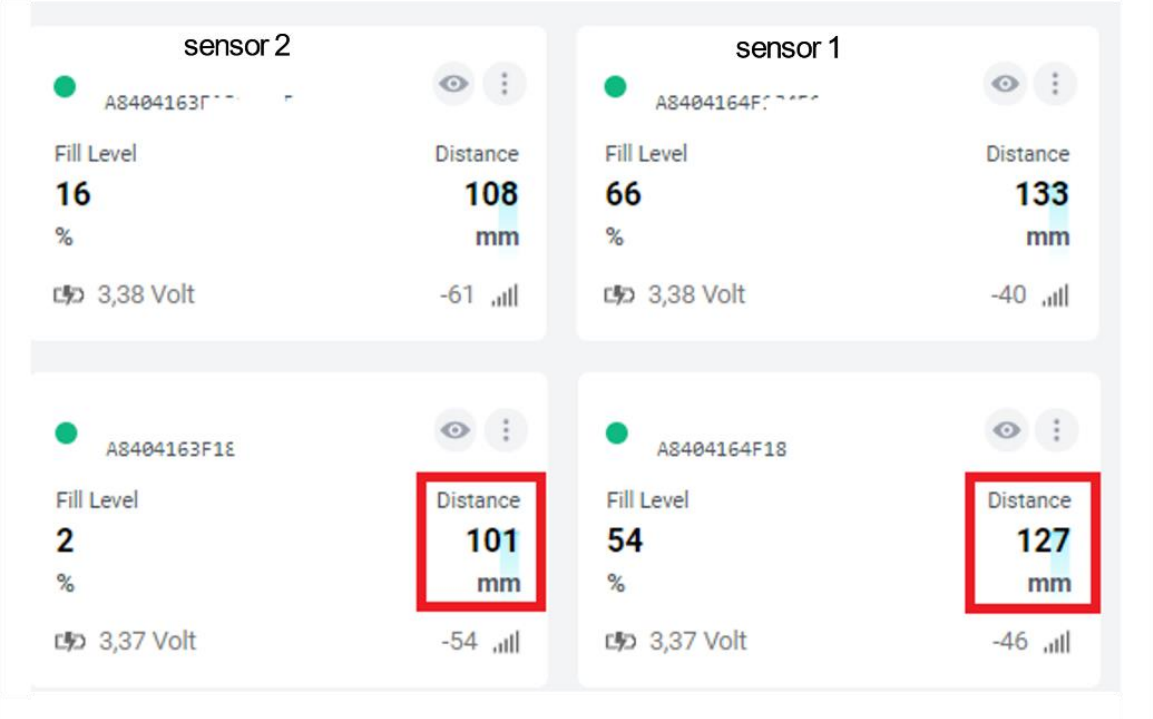

Fig. 7. Monitoring of water level

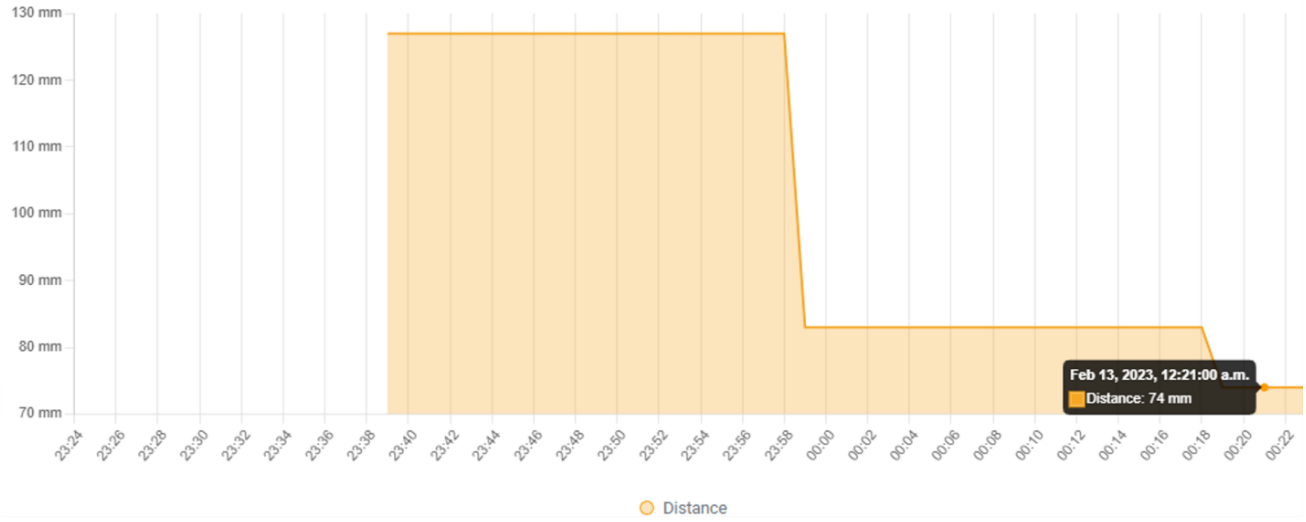

Fig. 8. Water level drop during continuous monitoring

VIII. Discussion

This article proposes an innovative IoT application for leak detection in pipelines. Our system, based on LoRaWAN technology, allows for real-time data collection and transmission from sensors, providing continuous and precise monitoring of water pipelines. The originality of our approach lies in the integration of standard sensors into an IoT architecture optimised for water transport environments. This approach offers a cost-effective and practical solution for water management, which could generate significant interest from the scientific and technical community.

Compared to existing systems, our solution offers increased applicability across various types and diameters of pipes. For instance, unlike systems that utilise flow sensors primarily suited for small-diameter pipelines, as described by ([10], [11], [12], [14]), our method operates effectively across a broad range of diameters. Moreover, the reduced cost of non-destructive sensors, combined with their multi-year autonomy, represents a significant advancement in terms of cost-effectiveness and durability compared to systems that require invasive sensors, such as pipeline flow meters [13] or hydrophones [15]. Real-time and remote monitoring via mobile devices, and the capability to automatically send email alerts, offer improvements over methods that require more intensive human interaction for leak detection, such as the thickness measuring robots [21].

IX. Conclusion

Our research demonstrates that ultrasonic level sensors are a highly effective method for the early detection of water leaks. These sensors successfully identified variations in liquid levels within materials typically used for pipeline construction, underpinning their utility in real-world applications. More than just detecting leaks, our approach integrates these sensors within an IoT framework, utilising LoRaWAN technology to offer a scalable, robust solution for the proactive management of water distribution systems.

This integrated method enhances the efficiency of water resource management by enabling automated monitoring and rapid response capabilities, significantly reducing water losses. Our solution stands out due to its non-destructive nature, ease of installation, and cost-effectiveness compared to traditional methods.

Significantly, our findings contribute to the scientific community and operational management by demonstrating a viable, innovative strategy for water conservation. These contributions are particularly relevant in the context of global challenges such as increasing demand and the impacts of climate change on water resources.

***Abstract*—The growing significance of energy-efficient building management techniques has led to research that combines precise heating demand predictions with sophisticated optimization algorithms. This research seeks a comprehensive solution to enhance building energy efficiency, addressing the growing concern for sustainability and responsible resource use in contemporary research and practice. In this research endeavor, the complex topic of energy optimization within the complex domain of heating, ventilation, and air conditioning (HVAC) systems is being tackled with a combination of creative problem-solving techniques and thorough examination. The significance of accurate heating load forecasts for raising HVAC system efficiency and cutting expenses is emphasized in this study. It introduces innovative methods by combining two advanced optimization algorithms, the Artificial Hummingbird Algorithm (AHA) and the Improved Arithmetic Optimization Algorithm (IAOA), with the Multi-Layer Perceptron (MLP) model. The main objective is to improve heating load forecast accuracy and expedite HVAC system optimization procedures. This study emphasizes how important precise heating load forecasts are to attaining energy efficiency, cost savings, and the ultimate objective of encouraging environmental sustainability in building management. The assessments unequivocally illustrate that the MLAH (Multi-Layer Perceptron with Artificial Hummingbird Algorithm) model in the second layer emerges as the most exceptional predictor. It attains an impressive maximum Coefficient of Determination (R^2) value of 0.998 during the testing phase, reflecting a remarkable explanatory capacity and displaying remarkably low Root Mean Squared Error (RMSE) and Mean Absolute Error (MAE) values of 0.43 and 0.337, indicating minimal prediction discrepancies compared to alternative models.**

Keywords*—Heating energy consumption; heating load; Multi-Layer Perceptron; Artificial Hummingbird Algorithm; Improved Arithmetic Optimization Algorithm

I. INTRODUCTION

There has been a noticeable surge in academic interest directed toward research projects centered on enhancing buildings' energy efficiency in recent times [1]. This heightened scholarly attention can be traced back to the escalating worries regarding the inefficient consumption of energy resources, along with the long-lasting adverse effects on the environment that this inefficiency brings about [2]. Academics have come to acknowledge the pivotal role played by buildings in the context of energy consumption and the release of greenhouse gases. As a result, they have been diligently investigating various approaches to improve the efficiency of buildings while simultaneously working to reduce their ecological footprint [3].

Achieving energy conservation in buildings requires a comprehensive approach that strongly emphasizes accurately predicting energy usage. This renewed focus has gained recognition and drives the creation of effective energy-saving initiatives. Precise prediction entails meticulous monitoring of energy consumption patterns in buildings. Beyond immediate energy savings, it provides insights into complex dynamics within different building types, enabling tailored strategies for enhanced energy efficiency, whether in residential, commercial, or industrial structures. Accurate energy usage forecasting conserves energy and fosters a sustainable, energy-efficient built environment. This aligns with broader goals of environmental preservation and responsible resource management. By prioritizing precise prediction and targeted energy-saving strategies, progress is made toward a future where buildings are energy-efficient and environmentally conscious, promoting sustainable resource use [4]. Advanced building energy management strategies depend on a deep understanding of energy consumption estimation, including intelligent control systems, fault detection, and demand-side tactics [5], [6]. These techniques use predictive insights to optimize energy use, reduce waste, and ensure efficient building system operation, significantly contributing to improved energy efficiency and overall building functionality. Research has shown that even minor improvements in energy consumption prediction can lead to significant energy savings. Building managers and occupants are empowered by accurate forecasting to make informed decisions, proactively adjust HVAC, lighting, and equipment settings, and adopt energy-saving behaviors. These advanced strategies represent a crucial step toward sustainable and efficient building operations, fostering a culture of responsible energy use [7]. As these methods continue to be developed and implemented, a future is moved closer to where buildings are energy-efficient and adaptive to changing energy demands, benefiting both the environment and occupants [8].

Precisely anticipating energy consumption in buildings constitutes a critical element of energy modeling, yet frequently falls short in replicating real-world outcomes, as demonstrated by various studies revealing substantial disparities between forecasts and actual usage, at times magnifying initial estimates by two or threefold. Conventional energy models, rooted in fundamental physical principles, are well-suited for preliminary assessments but grapple with the intricacies of practical scenarios [9], [10]. To tackle these constraints, numerical simulation techniques come into play, permitting the simulation of building energy utilization and the integration of machine learning models for energy efficiency. Artificial intelligence (AI) models are central in estimating and augmenting building

energy consumption, drawing from historical dataset and real-time sensor inputs. Essentially, merging AI and numerical simulation methods signifies a notable advancement in achieving more precise energy consumption prognostications in building contexts [11], [12]. This strategy, which embraces the complexities of real-world situations, lays the groundwork for effective and flexible energy management, ultimately elevating energy efficiency and advocating for environmental sustainability.

In recent years, significant advancements have been made in energy consumption estimation, driven by the dedication of scholars and experts [13], [14]. This progress is crucial for enhancing energy efficiency and informed decision-making in various applications, particularly in building energy management [15], [16]. A range of machine learning methods, which encompassed KNN, DNN, RF, ANN, GBM, Stacking, SVM, DT, and LR, to forecast the annual energy consumption of residential buildings, were investigated in STUDY [17]. Their study demonstrated that, among these methods, DNN emerged as the most proficient estimative model for estimating energy consumption, particularly during the preliminary design phase. The prediction of Cooling and Heating Loads was the focus of the distinct investigation prepared by [18], employing SVR and MLP models. Impressive results were obtained, with an outstanding R-value of 0.9993 achieved for Heating Load estimation by the MLP model, and the SVR model outstanding with an R-value of 0.9878 in predicting Cooling Load. These findings underscore the precision attainable through machine learning-based approaches. In study [19], researchers looked at the estimation of cooling and heating demands in residential buildings employing fuzzy logic techniques, like the adaptive neural fuzzy inference system (ANFIS) and fuzzy inductive reasoning (FIR). A comparison was made between these fuzzy techniques and thirteen machine learning methods, with SVR, ANFIS, and FIR identified as the superior performers in the research. The estimation of heating energy consumption in Tianjin's residential buildings was explored by [20]. Various algorithms, including SVR, RF, and LGBM, were employed. It was revealed in the findings that the LGBM model outperformed its counterparts in multiple evaluation metrics, thus highlighting its potential for precise energy consumption forecasting. An innovative approach was introduced by study [21], wherein RF and LSTM techniques were integrated to forecast building energy consumption. Remarkably, their method showcased superior performance compared to established benchmark methods, thus emphasizing the potential of hybrid methodologies in energy prediction.

This research aimed to create a machine-learning model that could forecast Heating Load (HL) using information from trustworthy sources. The study used the Multi-Layer Perceptron (MLP) technique to construct strong composite models. These composite models smoothly integrated the Improved Arithmetic Optimization Algorithm (IAOA) and the Artificial Hummingbird Algorithm (AHA) to forecast HL values. MLPs are well-suited for tasks where intricate patterns and interactions exist, which is often the case in heating load prediction, as it involves different factors like building materials, weather conditions, and occupancy patterns. The model's multi-layer architecture and capacity to adapt to diverse data make it a robust choice for accurately estimating heating load, contributing to more efficient HVAC system operations, ultimately leading to energy savings and improved building management.

Enhancements to the current work could involve broadening the scope to integrate real-time data, enabling more dynamic predictions of heating loads. Implementing ensemble methods to amalgamate multiple models could significantly improve predictive accuracy. Furthermore, conducting field trials to validate model performance across varied building environments would bolster its practicality. Introducing feedback mechanisms to iteratively update and refine predictive models using operational data would ensure ongoing efficiency gains. Lastly, exploring enhanced sensor data collection and system monitoring could establish a stronger basis for advancing building energy management in the future.

II. Materials and Methodology

A. Data Processing

The data of the current study have been categorized into several parameters, including Wall Area (WA), Glazing Area Distribution (GAD), Glazing Area (GA), Roof Area (RA), Surface Area (SA), Orientation (Or), Overall Height (OH), and Relative Compactness (RC). Furthermore, the main target of this research is predicting Heating Load (HL). In this study, the dataset was divided into three phases, comprising training (70 percent), validation (15 percent), and testing (15 percent) phases. Dataset division allows for a precise evaluation of the model’s applicability. Numerical summaries of the model’s parameters, offering a comprehensive overview of specific features, including mean values (M), maximum values (Max), minimum values (Min), and standard deviation (St.), are presented in Table I. Based on the data presented in Table I, it is evident that the HL value conforms to precisely defined boundaries, with a firmly established upper limit of 43.1 KW and a precise lower threshold of 6.01 KW, in strict accordance with the specifications of the output parameter.

B. Multi-Layer Perceptron (MLP)

The Multi-layer Perceptron (MLP) stands out as one of the extensively utilized neural network approaches typically trained employing the backpropagation algorithm. The MLP is designed to handle tasks related to asset processes and learning, collectively referred to as the fields of training and estimation. MLP neural networks are renowned for their ability to model intricate and non-linear phenomena in real-world scenarios, thanks to their adaptable approximation capabilities [22].

TABLE I. THE STATISTICAL PROPERTIES OF THE INPUT VARIABLE OF HEATING

Variables		Indicators			
	Category	*Min*	*Max*	*Avg.*	*St. Dev.*
Relative Compactness	***Input***	0.62	0.98	0.76	0.11
Surface Area (m^2)	***Input***	514.50	808.50	671.71	88.09
Wall Area (m^2)	***Input***	245.00	416.50	318.50	43.63
Roof Area (m^2)	***Input***	110.25	220.50	176.60	45.17
Overall Height (m)	***Input***	3.50	7.00	5.25	1.75

Glazing Area (%)	***Input***	0.0	0.40	0.23	0.13
Glazing Area Distribution	***Input***	0.0	5.00	2.81	1.55
Heating (KW)	***Output***	6.01	43.10	22.31	10.09

The MLP architecture comprises three interconnected layers: input, hidden, and output. The input layer contains nodes corresponding to the number of predictor variables. Furthermore, a single hidden layer within the MLP can effectively capture highly complex functions through its hidden neurons. Possessing too few neurons can lead to suboptimal neural network performance. Conversely, MLP neural networks are challenging to train and susceptible to overfitting. An MLP neural network is used as $X \in R^D \rightarrow Y \in R^1$, where Y and X represent the output and input parameters, respectively, to generalize the modeling of the non-linear function (h) when employing a single predictor. The number of nodes in the output layer is associated with the variables that are modeled. Eq. (1) represents the function (h):

$$Y = h(X) = s_2 + M_2 \times (k_b(s_1 + M_1 \times X)) \quad (1)$$

k_b serves as the activation function.

s_1 and s_2 denote the bias vectors for the hidden and output layers, respectively.

M_1 and M_2 represent the alternating weight matrices of the hidden and output layers.

The tan-sigmoid and log-sigmoid activation functions find broad application, and their corresponding equations have been specified as Eq. (2) and Eq. (3), alternatively:

$$h_b(T) = \frac{1}{1+\exp(-T)} \quad (2)$$

$$h_b(T) = \frac{\exp(T)-\exp(-T)}{\exp(T)+\exp(-T)} \quad (3)$$

T represents the activation function applied to the input.

C. Artificial Hummingbird Algorithm (AHA)

The flight and foraging behaviors of hummingbirds inspire the Artificial Hummingbird Optimization Approach (AHA). It seeks to replicate the efficient motion patterns of hummingbirds to optimize complex functions. Details about the AHA algorithm can be found in [23]. Eq. (4) explains how the AHA algorithm starts with the establishment of an initial hummingbird population.

$$X_i = L + r \times (U - L), i = 1,2, \dots, N \quad (4)$$

For a d-dimensional exploration space, U and L signify the upper and lower boundaries, respectively.

r denoted a random vector with values uniformly distributed between $[0,1]$.

Eq. (5) is used to create the visit table, which is intended to document the food sources that hummingbirds visit while foraging.

$$VT_{ij} = \begin{cases} 0 & if\ i \neq j \\ null & if\ i = j' \end{cases}, \quad i = 1, \dots, N\ ,\ j = 1, \dots, N \quad (5)$$

If $i = j$, the value $VT_{ij} = null$ denotes the food taken by hummingbird i at its specific food source. Conversely, if $i \neq j$, the value $VT_{ij} = 0$ reflects that hummingbird i has been to the food source at position j without ingesting any food.

1) Guided foraging: Three types of flight skills mentioned before are utilized during the AHA algorithm's searching part. The axial flight is characterized by Eq. (6):

$$D_i = \begin{cases} 1 & if\ i = rand_i([1,d]) \\ 0 & else \end{cases}, \quad i = 1, \dots, d\ , \quad (6)$$

Eq. (7) provides a mathematical representation of the diagonal flight in the AHA algorithm.

$$D_i = \begin{cases} 1 & if\ i = P(i),\ j \in [1,k],\ P = randperm(k), k \in [2, r_1(d-2)+1] \\ 0 & else \end{cases} \quad (7)$$

r_1 denoted a random number.

$randperm(k)$ determines a random permutation of integers in $[1-k]$,

The directed foraging behavior in the AHA algorithm is expressed mathematically in the following:

The AHA algorithm's mathematical representation of the omnidirectional flight skill is formulated as Eq. (8).

$$D_i = 1, i = 1, \dots, d \quad (8)$$

$rand_i$ stands for a random integer in $[1-d]$,

$$V_i(t+1) = X_{i,t}(t) + a \times D \times \left(X_i(t) - X_{i,t}(t)\right), a \in N(0,1) \quad (9)$$

At iteration t,$X_{i,t}(t)$ signifies the food source i.

The food source that the $i-th$ hummingbird visits is $X_{i,t}(t)$.

Eq. (10) may be used to update the value of X_i:

$$X_i(t+1) = \begin{cases} X_i(t) & if\ f(X_i(t) \le f(V_i(t+1)) \\ V_i(t+1) & otherwise \end{cases} \quad (10)$$

f indicates the fitness value of a particular solution or candidate solution.

2) Territorial foraging: Hummingbirds exhibit territorial foraging behavior within their territory, exploring nearby areas for potentially better solutions. This behavior is also incorporated into the guided foraging module of the AHA algorithm, as outlined by Eq. (11):

$$V_i(t+1) = X_{i,t}(t) + b \times D \times X_i(t), b \in N(0,1) \quad (11)$$

3) Migration foraging: This section provides insights into the hummingbird's transition from a food source with a low nectar-refilling rate to a newly generated food source, chosen randomly during its foraging behavior:

$$X_\omega(t+1) = L + r \times (U - L) \quad (12)$$

X_ω reflects the food source with the worst fitness value.

D. Improved Arithmetic optimization algorithm (IAOA)

1) Initialization phase: The initial phase in AOA's optimization process entails generating a collection of candidate solutions (denoted as $\boldsymbol{X}$) through random means. In each iteration, the objective is to pinpoint the most promising candidate solution, with the expectation that it either represents the optimal solution or closely approximates it within a neighboring range.

$$X = \begin{bmatrix} x_{1,1} & \cdots & x_{1,j} & \cdots & x_{1,n} \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ x_{i,1} & \cdots & x_{i,j} & \cdots & x_{i,n} \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ x_{N,1} & \cdots & x_{N,j} & \cdots & x_{N,n} \end{bmatrix} \quad (13)$$

Before initiating the AOA procedure, a decision must be made to determine whether to commence with the exploration or exploitation phases. Subsequently, the Math Optimizer Accelerated (MOA) function, which signifies the function value at the $i-th$ iteration, is computed in accordance with Eq. (14).

$$MOA(C_{It}) = Min + C_{It} \times \left(\frac{Max - Min}{M_{It}}\right) \quad (14)$$

M_{It} signifies the maximum number of iterations.

Max and Min indicated as the highest and lowest values of the accelerated function, respectively.

2) Exploration phase: The exploration phase encompasses mathematical computations employing Division (DO) or Multiplication (MO) operators, yielding outcomes or decisions that are broadly dispersed. These operations may not efficiently approach the target and might only converge toward a nearly optimal solution after several iterations, thus facilitating the transition to the exploitation phase. Eq. (15) delineates the two primary search strategies employed during exploration and furnishes equations for updating positions.

$$x'_{i,j} = \begin{cases} x_{b,j} \div (MOP + \varepsilon) \times \left(\left(UB_j - LB_j\right) \times \mu + LB_j\right), r2 < 0.5 \\ x_{b,j} \times MOP \times \left(\left(UB_j - LB_j\right) \times \mu + LB_j\right), otherwise \end{cases} \quad (15)$$

$x'_{i,j}$ indicates the $j-th$ position of the $i-th$ solution.

ε is a small integer number,

$x_{b,j}$ denotes the $j-th$ position within the currently best-acquired solution.

μ signifies a control parameter.

$MOP(C_{Iter})$ is represented as follows:

$$MOP(C_{It}) = 1 - \left(\frac{C_{It}}{M_{It}}\right)^{1/\alpha} \quad (16)$$

α reflects a critical parameter that controls the precision achieved during the exploitation process across successive iterations.

3) Exploitation phase: Mathematical calculations in the exploitation phase employ Subtraction (SO) and Addition (AO) operators, leading to concentrated outcomes. These operators enable effective targeting of the desired goal across multiple iterations. Eq. (17) outlines the primary search strategies and provides position update equations for this phase. Using these exploitation operators (SO and AO) prevents the system from becoming stuck in local search areas, thereby assisting in discovering optimal solutions within related search approaches.

$$x'_{i,j} = \begin{cases} x_{b,j} - MOP \times \left(\left(UB_j - LB_j\right) \times \mu + LB_j\right), r_3 > 0.5 \\ x_{b,j} + MOP \times \left(\left(UB_j - LB_j\right) \times \mu + LB_j\right), otherwise \end{cases} \quad (17)$$

r_3 refers to a pseudorandom number that is uniformly distributed between $[0,1]$.

4) Improved AOA (IAOA): Kaveh and Biabani Hamedani developed an improved version called the Improved Architecture Optimization Algorithm (IAOA) [24].

On the other hand, close bounds result in small steps, increasing the risk of premature convergence to suboptimal solutions. The original AOA faces a significant issue if all design variables have identical bounds, as in discrete structural optimization with standard sections. Eq. (16) demonstrates that in each iteration, if $r_2 > 0.5$, every aspect of the best solution that has been discovered is adjusted in the same way

$(MOP + \varepsilon) \times \left((UBj - LBj) \times \mu + LBj\right)$. Likewise, if $r_2 \leq 0.5$, each design variable in the best solution discovered to date is scaled by an identical factor $MOP \times ((UBj - LBj) \times \mu + LBj)$. In the original AOA's exploration phase, all design variables in the best solution are altered by two factors, restricting exploration to a narrow space. This limits diversity, causing slow and early convergence to suboptimal solutions [24]. The original AOA also faces this limitation in its exploitation phase (as seen in Eq. 17). To overcome these issues in its exploration phase, a new position updating rule using division and multiplication operators has been introduced in IAOA [24].

$$x'_{i,j} = \begin{cases} x_{i,j} \div (1 + (-1)^{randi([1,2])} \times 0.5 \times rand \times \overline{MOP}, r_2 > 0.5 \\ x_{i,j} \times (1 + (-1)^{randi([1,2])} \times 0.5 \times rand \times \overline{MOP}, otherwise \end{cases} \quad (18)$$

$rand$ denotes a pseudorandom number that follows a uniform distribution in$[0 - 1]$.

$x'_{i,j}$ represents the present value of the $j - th$ design variable for the $i - th$ candidate solution.

$randi([1,2])$ makes a pseudorandom scalar integer, which can be either 1 or 2.

$\overline{MOP}$ is a parameter-free version of the function MOP, which is defined as follows [24]:

$\overline{MOP}$ is a variant of the *MOP* function that does not rely on additional parameters and is defined as described in the study [27].

$$\overline{MOP}(C_{It}) = (1 - \frac{C_{It}}{M_{It}})^{randi([1,2])} \quad (19)$$

In contrast to the original AOA, IAOA's exploration phase focuses on the current solution positions, as shown in Eq. (18). Essentially, in IAOA's exploration phase, each solution's position is adjusted based on its current state. This method promotes a comprehensive search space exploration and avoids the loss of diversity during the search [24]. In addition, the incorporation of random numbers in Eq. (18) and Eq. (19) lead to the creation of different step sizes for relocating solutions within the search space. This variation in step sizes can encourage exploration and maintain the population's diversity [24]. It is worth mentioning that Eq. (18) is not influenced by the limits of design variables, which could potentially alleviate convergence-related problems. [24]. IAOA introduces a new position updating rule for the exploitation phase, using subtraction and addition operators to overcome this limitation [24]:

$$x'_{i,j} = \begin{cases} best(x_j) - best(x_j) \times rand \times \overline{MOP} \times (UB_j - LB_j), r_3 > 0.5 \\ best(x_j) + best(x_j) \times rand \times \overline{MOP} \times (UB_j - LB_j), otherwise \end{cases} \quad (20)$$

Eq. (19) and Eq. (20) create variable step sizes for solution movement, improving the utilization of the best solution. In contrast, the original AOA necessitates tuning four specific parameters (Min, Max, α, and μ) for each application. Remarkably, IAOA simplifies this process by removing α and μ from its formulation, making it a more straightforward implementation. Fig. 1 shows the flowchart of IAOA.

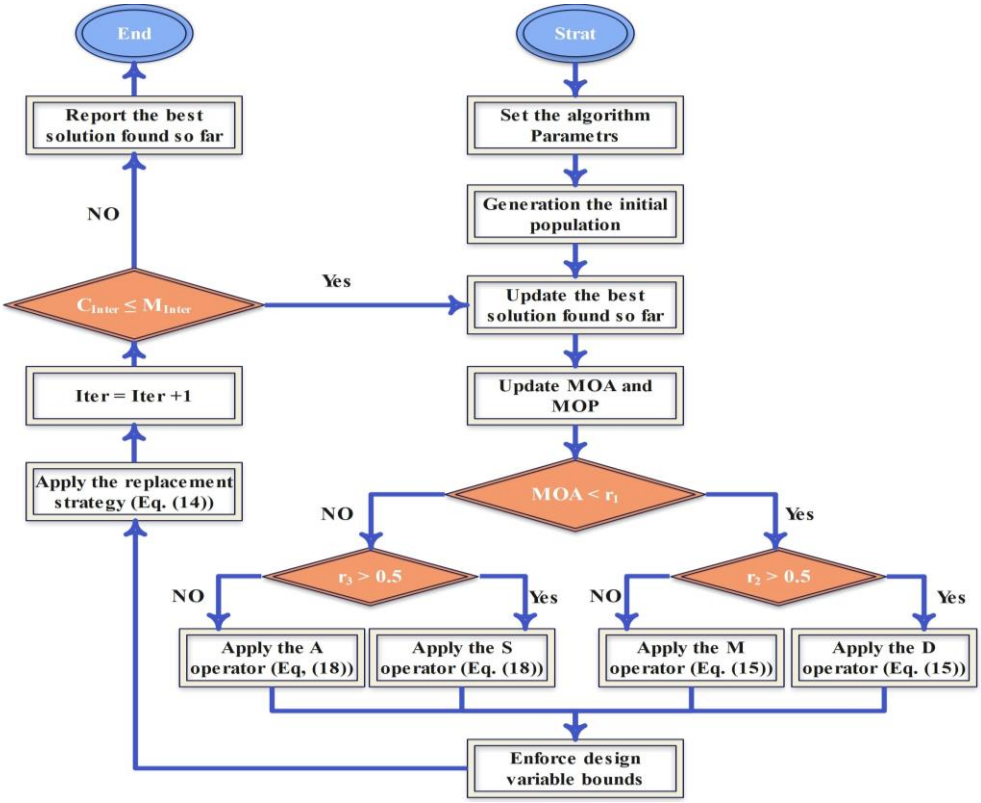

Fig. 1. Flowchart of IAOA.

E. Performance Evaluation Methods

A range of evaluators, mainly concentrating on accurately measuring correlations and errors, were employed to assess the applicability of hybrid models. The metrics are Coefficient of Determination (R^2), Root Mean Squared Error (RMSE), Mean Absolute Error (MAE), n10_index, and Normalized Mean Square Error (NMSE). These metrics serve as essential instruments for assessing the performance of hybrid models in diverse scenarios, offering valuable insights into the accuracy and reliability of their predictions.

$$R^2 = \left(\frac{\sum_{i=1}^{N}(p_i-\bar{p})(s_i-\bar{s})}{\sqrt{[\sum_{i=1}^{N}(p_i-\bar{s})^2][\sum_{i=1}^{N}(s_i-\bar{s})^2]}} \right)^2 \quad (21)$$

$$RMSE = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(s_i - p_i)^2} \quad (22)$$

$$MAE = \frac{1}{N}\sum_{i=1}^{N}|s_i - p_i| \quad (23)$$

$$n10 - index = \frac{n10}{N} \quad (24)$$

$$NMSE = \frac{1}{N}\sum_{i=1}^{N}\frac{(p_i-s_i)^2}{s_i.p_i} \quad (25)$$

In the above equations, N defines the numbers associated with the samples, s_i defines the estimated value, $\bar{s}$ defines the mean of the estimated values, p_i defines the experimental value and $\bar{p}$ defines the experimental amount's average.

F. Significant of Research

The research discussed holds significant implications for advancing energy-efficient building management practices, particularly in the context of HVAC systems. By integrating advanced optimization algorithms and accurate heating load forecasting, the study addresses critical challenges in enhancing building energy efficiency. This is crucial in the face of mounting global concerns over sustainability and responsible resource use. Firstly, the study's focus on combining the Artificial Hummingbird Algorithm and the Improved Arithmetic Optimization Algorithm with a Multi-Layer Perceptron model represents a cutting-edge approach in HVAC system optimization. These algorithms offer innovative solutions to the complex problem of energy optimization, aiming to streamline processes and minimize energy wastage. Secondly, the emphasis on precise heating load predictions is pivotal for optimizing HVAC operations. Accurate predictions not only lead to improved system efficiency but also contribute to substantial cost savings by reducing energy consumption and operational inefficiencies. Moreover, by enhancing predictive accuracy, the research directly supports efforts to mitigate environmental impact associated with building operations, aligning with global sustainability goals. Furthermore, the study's findings highlight the MLAH model's exceptional performance in predicting heating loads, showcasing its potential to outperform traditional models. Achieving a high R^2 value of 0.998 during testing underscores its reliability and robustness in real-world applications. Generally, this research determines the critical role of advanced methodologies in driving progress towards sustainable building practices.

III. Results

As described in previous sections, in this study, two hybrid models, including the combination of the MLP model with two distinct optimization systems (AHA and IAOA), were generated to predict Heating Load (HL) values. The outcomes of the prediction processes are summarized in Table II. A total of five metrics were utilized to evaluate the models' performance. The interpretation of the results is described as follows:

A. Coefficient of Determination (R^2)

The R^2 values consistently show higher values in the testing phase when compared to both the validation and training phases across all models. This consistent trend suggests that the models were sufficiently trained, leading to their optimal performance in subsequent phases. Notably, during the testing phase, the second layer of the MLAH model outperformed the other models, achieving an impressive R^2 value of 0.998, firmly establishing itself as the top-performing model. In contrast, the first layer of the MLIA model performed less effectively, with an R^2 value of 0.965, making it the least successful model in this study.

B. Root Mean Squared Error (RMSE)

Among the models examined, the MLAH model's second layer demonstrated the lowest RMSE value, surpassing others by 0.43 in the testing phase, confirming its position as the most accurate model in terms of prediction. In contrast, the MLIA model's first layer, with an RMSE value of 1.895, emerged as the least effective among the models, indicating its relatively weaker predictive performance.

C. Mean Absolute Error (MAE)

As indicated in Table II, the second layer of the MLAH model stood out as the top performer among all the models, exhibiting lower MAE values. To provide more detail, the MLAH model achieved the most favorable MAE value, measuring 0.337. In contrast, the MLIA model produced the least favorable outcome, with the highest MAE value of 1.398 among all the models. This difference in MAE values emphasizes the superior predictive precision of the second layer of the MLAH model when compared to the other choices.

D. Normalized Mean Square Error (NMSE)

The MLAH model in the second layer outperformed the other models. The NMSE values varied, with the second layer of the MLAH model achieving a minimum of 0.002 and the first layer of the MLIA model reaching a maximum of 0.025 among all the models. This variation in NMSE values highlights that the first layer of the MLIA model exhibited a broader range of uncertainty in its predictions compared to the other options.

E. n10_index

In the testing phase, the MLAH2 model achieved the highest n10_index value of 1.0, establishing itself as the top-performing model among all those under examination. Conversely, the MLIA1 model was identified as the least effective, recording the lowest n10_index value of 0.822. This disparity in n10_index values underscores the MLAH2 model's superior estimative accuracy in contrast to the comparatively lower performance of the MLIA1 model.

TABLE II. THE RESULT OF DEVELOPED MODELS FOR MLP

	Model	Phase	Index values				
			RMSE	***R^2***	***MAE***	***n10_index***	***NMSE***
Layer 1 1	**MLAH**	***Train***	1.635	0.975	1.198	0.822	0.005
		Validation	1.390	0.980	1.032	0.904	0.017
		Test	1.371	0.982	1.066	0.878	0.016

		Test	0.937	0.991	0.575	0.948	0.008
		All	1.155	0.987	0.726	0.884	0.002
	MLIA	***Train***	1.652	0.974	1.222	0.827	0.005
		Validation	1.302	0.983	0.989	0.904	0.015
		Test	1.449	0.979	1.028	0.851	0.018
		All	1.574	0.976	1.158	0.842	0.003

In Fig. 2, scatter plots illustrate the connection between predicted and observed HL values, with a specific emphasis on assessing RMSE and R^2 metrics. RMSE, which reflects the dispersion of data points, diminishes as accuracy improves, while R^2 pulls data points closer to the central axis. A total of six models (MLAH and MLIA in three layers) were generated by merging the MLP model with two optimization techniques across the testing, validation, and training phases. Fig. 2 serves as a visual summary of the outcomes, clearly highlighting the superior performance of the MLAH hybrid model in the second layer, which combines the MLP approach with the AHA optimizer. This excellence is discernible from the tightly grouped data points that align closely with the central line. Conversely, the figures indicate that the MLIA model in the first layer exhibited the least effective performance, as evident from the numerous data points positioned beyond the reference lines.

Fig. 3 visually compares two models, MLAH and MLIA, across three layers of the MLP method using stacked column plots. The results for three key metrics, R^2, RMSE, and MAE, are briefly summarized. The R^2 plot demonstrates that the MLAH model in the second layer outperformed all other models with an R^2 value of 0.998, signifying its superior performance. It is worth noting that lower values of RMSE and MAE indicate better model performance in terms of error. In this context, the MLIA model in the first layer stands out as the least favorable model, with RMSE and MAE values of 1.895 and 1.398, respectively. Considering all the results, the MLAH model in the second layer emerges as the most accurate model for predicting HL values.

Fig. 4 is a valuable visual representation of error frequencies in the discussed models, demonstrating their stability within an acceptable range, often resembling a bell-shaped curve. Notably, during the rigorous testing phase of the second model iteration, particularly in the MLAH model, a distinct and pronounced peak in error frequency emerges, reaching around 250, demanding scrutiny. Significantly, error frequencies consistently decrease in validation and training phases across all models, resulting in a flatter curve than the training phase, indicating overall model improvement. Significantly, Fig. 4 provides strong evidence of the MLAH hybrid model's superiority, which combines MLP and AHA in its second layer, showcasing exceptional performance and making it the preferred choice among the considered models.

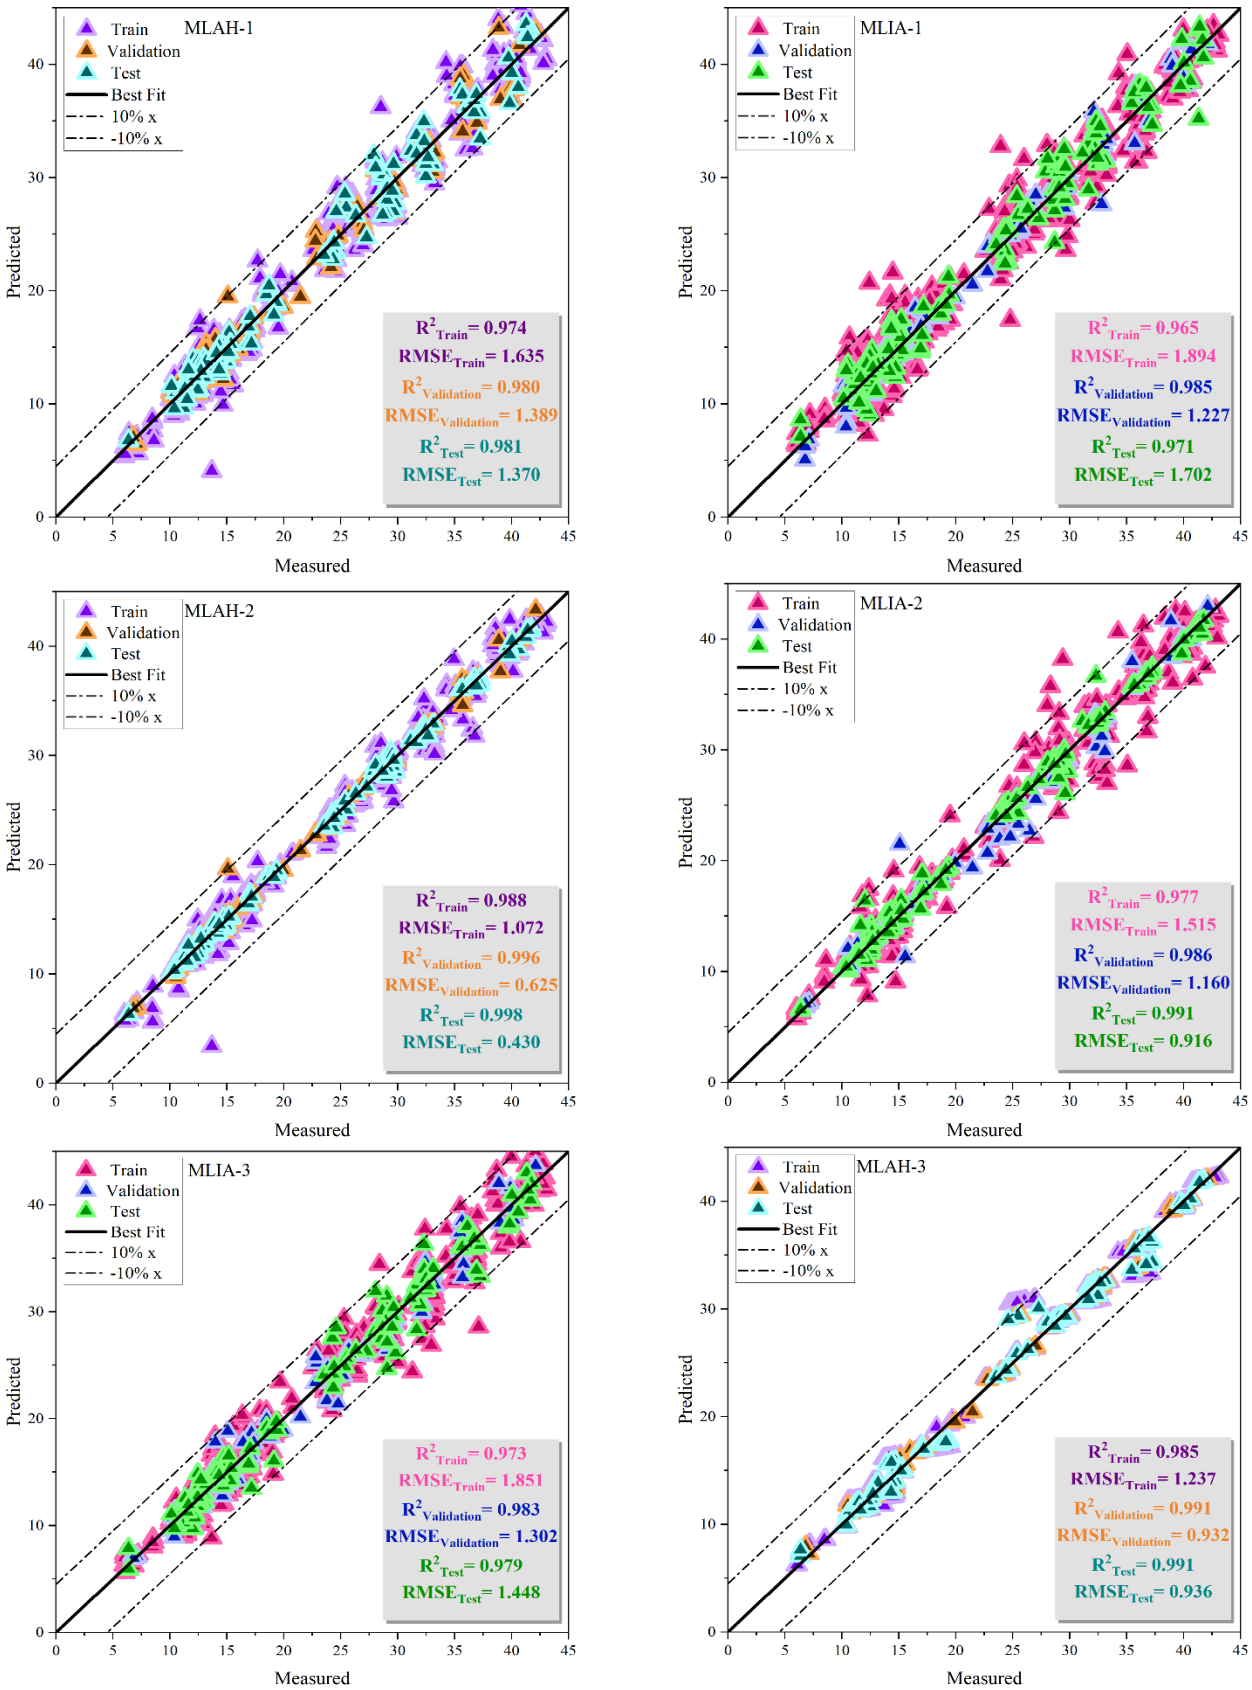

Fig. 2. Plotting the dispersion of evolved hybrid models.

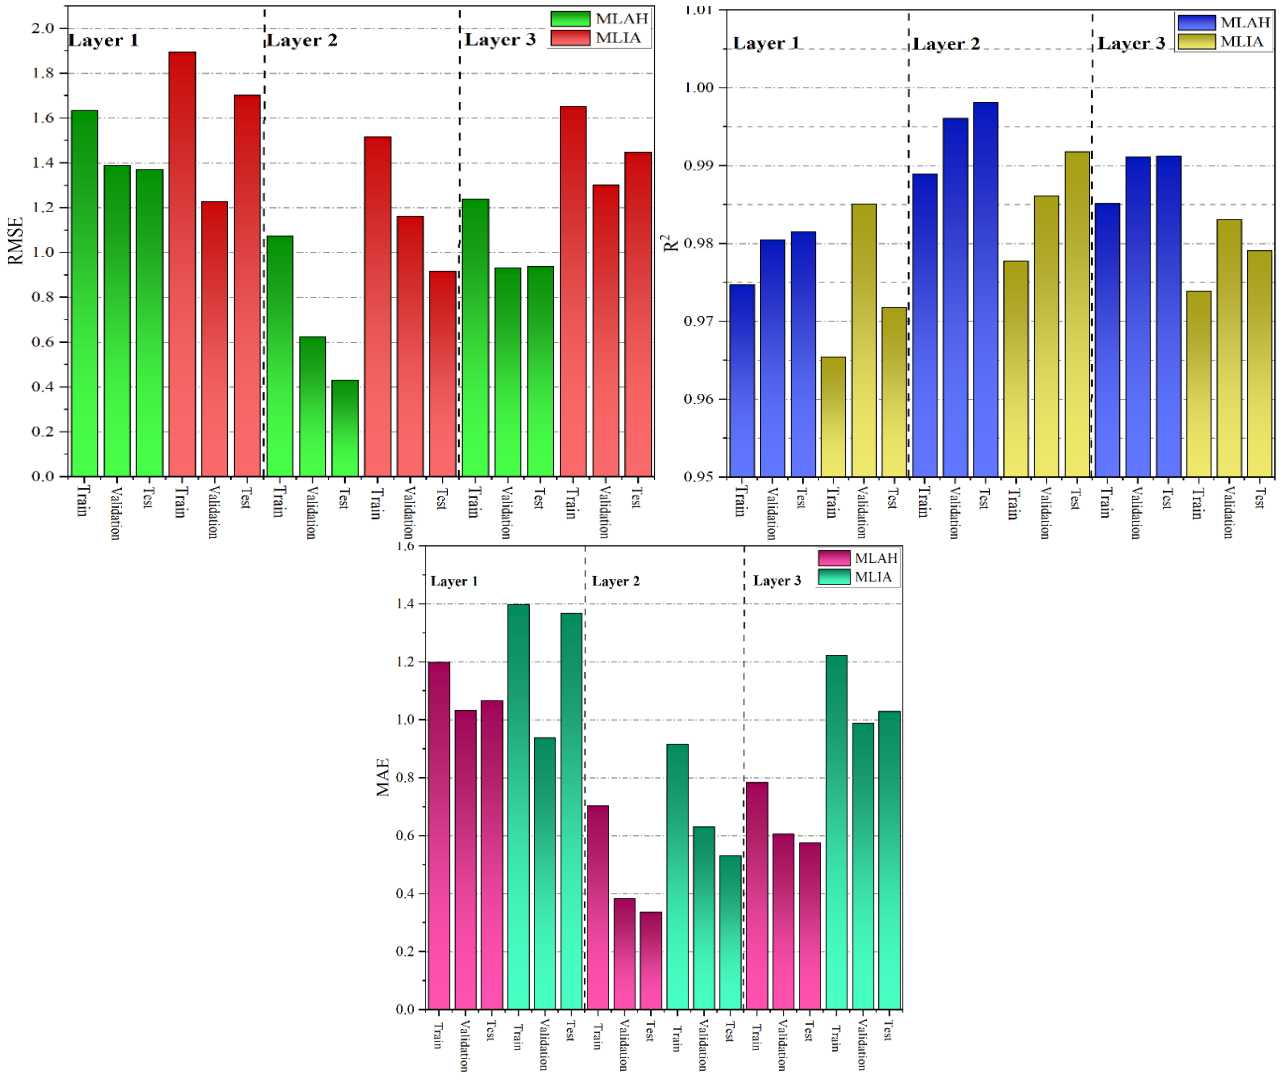

Fig. 3. Stacked column for metric.

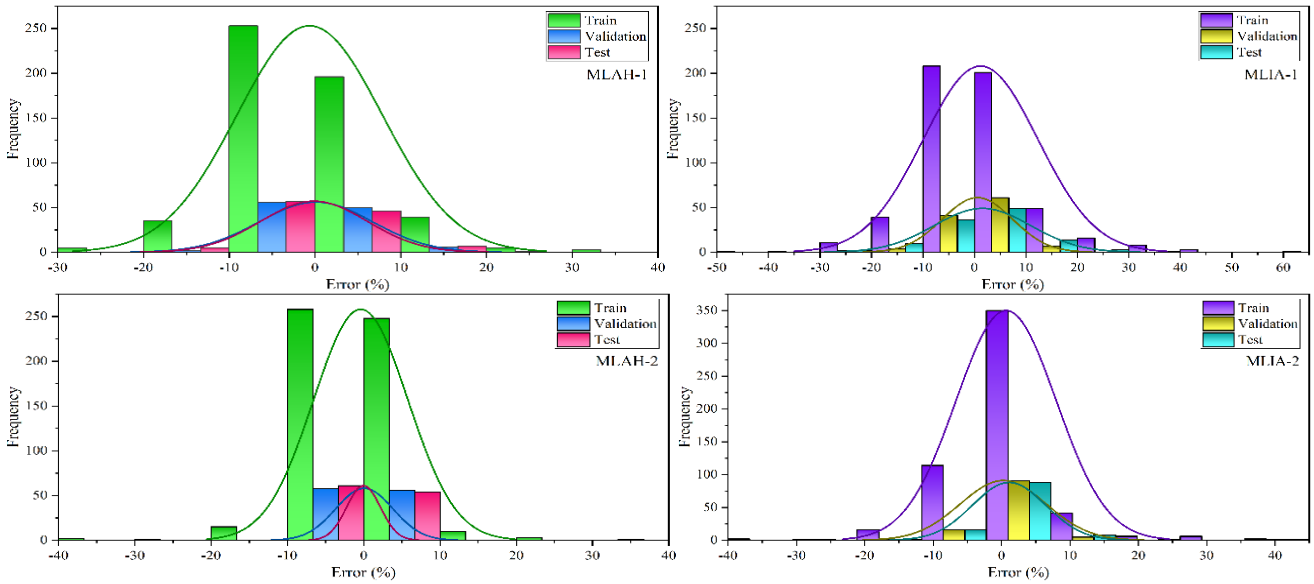

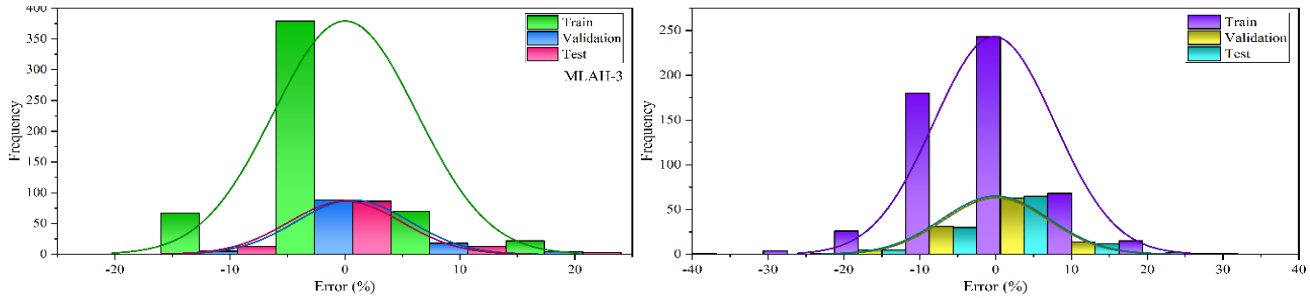

Fig. 4. The error percentage of the models is based on the distribution plot.

Fig. 5 functions as a visual representation, depicting how errors are distributed during the prediction of HL values using two different models across the three layers of the MLP model. Notably, during the training phase in the first layer, the MLIA model exhibited the highest error rates. In contrast, the MLAH model in the second layer consistently demonstrated the lowest error rates. A thorough examination consistently favored the MLAH hybrid model throughout all stages of the study. During the training phase of the first layer in the MLIA model, errors spanned a broad spectrum, ranging from -70 to 40. In contrast, the MLAH model in the second layer, which emerged as the top performer, exhibited errors concentrated within a narrower range of -10 to 10, highlighting its superior predictive accuracy.

IV. Discussion

A. Comparison

Table III show the comparison of the best-performing models in this study with related literature highlights the efficacy of the proposed approach. Moradzadeh et al. [25] employed a Support Vector Regression (SVR) model, achieving an RMSE of 0.483 and an R^2 of 0.997. This indicates a high degree of accuracy, though the RMSE suggests there is room for improvement in minimizing prediction errors. Roy et al. [26] used a Multivariate Polynomial Regression Model (MPMR), which produced an impressive RMSE of 0.059 and an R^2 of 0.99. Despite the excellent RMSE, the slightly lower R^2 value compared to Moradzadeh et al. suggests it explains slightly less variance. Gong et al. [27] applied the Light Gradient Boosting Machine (LGBM) model, resulting in an RMSE of 0.192 and an R^2 of 0.988. This model demonstrates strong predictive performance, but like the others, it falls short in some areas when compared to the present study. The present study's model, MLAH2, stands out with an R^2 of 0.998 and an RMSE of 0.43. While the RMSE is higher than Roy et al.'s MPMR model, the R^2 value of 0.998 indicates a superior ability to explain variance in the data, highlighting the model's overall efficacy. The MLAH2 model's performance underscores the importance of combining advanced optimization algorithms with accurate heating load forecasting to achieve high predictive accuracy and efficiency in HVAC systems. In summary, while each model reviewed has its strengths, the MLAH2 model from the present study demonstrates a balanced and high-performing approach, setting a new benchmark for accuracy in heating load predictions within the field of energy-efficient building management.

TABLE III. THE COMPARISON OF THE BEST PERFORMED MODELS RESULTS OF PRESENT STUDY WITH SOME RELATED LITERATURES

Article	Model	Evaluator	
		RMSE	R^2
Moradzadeh et al. [25]	SVR	0.483	0.997
Roy et al. [26]	MPMR	0.059	0.99
Gong et al. [27]	LGBM	0.192	0.988
Present Study	MLAH2	0.43	0.998

B. Limitation

Enhancing predictive models for Heating Load (HL) prediction offers significant benefits, yet this study has several limitations. The primary limitation lies in the dataset's scope and diversity. The models were trained and tested on a specific dataset, which may not generalize well to different climates, building types, or operational conditions. Thus, the applicability of the findings to broader contexts remains uncertain. Another limitation is the complexity of the optimization algorithms used. Both the Improved Arithmetic Optimization Algorithm (IAOA) and the Artificial Hummingbird Algorithm (AHA) are computationally intensive, which can be a barrier to their practical implementation in real-time applications. The high computational cost might limit their usability in resource-constrained environments. Additionally, while the MLAH model in the second layer showed superior performance, the study did not explore the reasons behind the underperformance of the first layer of the MLIA model. Understanding these reasons could provide valuable insights for refining and improving the models further. Lastly, the models demonstrated a tendency to underestimate HL values, which could have practical implications. This bias towards underestimation needs to be addressed to ensure the models' reliability and accuracy in real-world applications. Future research should focus on expanding the dataset, exploring alternative models, and addressing computational efficiency to overcome these limitations.

V. CONCLUSION

Enhancing predictive models, particularly for Heating Load (HL) prediction, offers significant potential to boost operational efficiency and cost reduction. This study is founded on the Multi-Layer Perceptron (MLP) framework for constructing predictive models. Two optimization algorithms, the Artificial Hummingbird Algorithm (AHA) and the Improved Arithmetic Optimization Algorithm (IAOA), have been seamlessly integrated to enhance model precision and efficiency. The research results validate the effective use of these optimization method in developing accurate estimative models for estimating Heating Load (HL) values. According to the results obtained, it can be inferred that the MLAH model in the second layer of the testing phase distinctly excels in terms of accuracy when compared to the others. This model exhibits exceptional performance, characterized by $RMSE = 0.43$ as the lowest RMSE value and the highest coefficient of determination R^2 value with 0.998. These results unquestionably emphasize the remarkable proficiency of the second layer of the MLAH model in precisely estimating HL values. The first layer of the MLIA model displayed the least favorable performance compared to all the examined models. This was evident in its recording of the highest error value, with 1.895 for the RMSE metric, and the lowest Coefficient of Determination value, with 0.965. The analysis of the measured and estimated values revealed that the models tend to underestimate the HL values, with an average underestimation of approximately 1.5 for the RMSE evaluator. Among these models, the highest error in terms of RMSE was observed in MLIA in the first layer, with an error of 1.895. In contrast, the model MLAH in the second layer exhibited the lowest error, with an error of 0.43 percent.

Obtaining the California Bearing Ratio Prediction via Hybrid Composition of Random Forest

Bensheng Wu[1], Yan Zheng[2]
Fujian Construction and Engineering Group Co., Ltd.; Fuzhou Fujian, 350000 China[1]
Fujian West Coast Architectural Design Institute Co., Ltd; Fuzhou Fujian, 350000 China[2]

***Abstract*—Artificial intelligence algorithms have become much more sophisticated, so the most complex and challenging problems can be solved with them. California Bearing Ratio (CBR) is a time-consuming testing parameter, and univariate and multivariate regression methods are used to address this challenge. Therefore, the CBR value is an essential parameter in indexing the resistance provided by a structure's subterranean formation or foundation soil. CBR is a crucial factor in pavement design. However, its determination in laboratory conditions can be a time-consuming process. This makes it necessary to look for an alternative method to estimate CBR in the soil subgrade, especially the developed layers of the soil. This study has developed one of the machine learning (ML) models, including Random Forest (RF), to predict the CBR. Additionally, some meta-heuristic algorithms have been used for improving the accuracy and optimizing the output of the prediction, consisting of Gold Rush optimizer (GRO), Stochastic Paint optimizer (SPO), and Electrostatic Discharge algorithm (EDA). The results of the hybrid models were compared via some criteria to choose the desired model. SPO had the most desirable performance when coupled with RF compared to other optimizers, exhibiting high R2 and low RMSE.**

Keywords*—California bearing ratio; gold rush optimizer; stochastic paint optimizer; electrostatic discharge algorithm; random forest

I. Introduction

A. Background

The strength of the soil to be used as a subgrade in the pavement is assessed using the California bearing ratio (CBR) value. The CBR test is a crucial field/laboratory test in geotechnical engineering. This is done to evaluate the resistance provided by the subterranean soil layer or the structure's foundation, particularly for earth embankments, road embankments, abutments, and retaining walls. The CBR value can express the strength of the ground. If the CBR value is low, the pavement thickness will be increased, resulting in higher construction cost, while reducing the pavement thickness will decrease the cost [1–3]. CBR tests can be carried out either in the field or the laboratory. In field CBR tests, the assessment is conducted on the ground surface or within an excavated test pit. Conversely, laboratory CBR tests are typically performed on compressed samples placed in a CBR machine [4].

Performing CBR tests in the laboratory requires less labor, but it is time- and energy-intensive. Hence, a method that can accurately predict CBR values in expansive soils with minimal time and effort is often welcomed. The importance of accurately predicting CBR values in soils, particularly in stabilizer-treated expansive soils, cannot be overstated [5,6]. Precise CBR predictions for modified or treated expansive soils ensure the safety and flexibility of pavement design. When utilized as subgrades, numerous approaches have been proposed to forecast the CBR of expansive soils, whether treated or untreated [7–9]. These approaches have been extensively documented in academic sources. Nevertheless, certain CBR prediction models in the literature demonstrate weak correlation coefficients, suggesting that conventional statistical methods make it difficult to generate accurate CBR estimates [10].

B. Related Works

Due to the robustness of CBR models and the ease with which complex computations can be performed, the recommendation is to employ Machine Learning (ML) techniques for constructing CBR. Several published articles used ML approaches such as random forest (RF), multivariate adaptive regression splines (MARS), and gradient boosting machines (GBM) to predict CBR [11–13]. ML techniques have proved to be effective predictive tools in various engineering disciplines and, hence, were utilized to develop models for predicting CBR in improved soils. The development of CBR estimation using classical statistical methods presents a considerable challenge [14–16]. Employing ML methodologies [17–20] to develop CBR models is advisable due to their inherent robustness and capacity to manage intricate computations proficiently.

Stephens [21] examined the performance of current models for specific native soils using data that had been stored. He looked at the links between CBR and different classification characteristics in both basic and multivariate versions and found that these models were typically insufficient. Additionally, the influence of the clay percentage on CBR was reported. In the interim, shrinkage, and grading moduli were proposed as a means of estimating the lowest CBR values for both shrinking and non-shrinking soils. Another technique for determining CBR was offered by the British Highway Agency [22], which used the plasticity index for British soils compacted at natural moisture content and supplied correlations in a tabular manner. Khasawneh's study [23] focuses on optimizing Resilient Modulus Testing for subgrades and predicting California Bearing Ratio (CBR) using advanced soft computing systems. It introduces a method to forecast the resilient modulus, especially for fine-grained soils, and explores the use of artificial intelligence (AI) techniques for CBR estimation. The research discusses relevant studies on estimating CBR from index properties and compaction characteristics of coarse soils, while also highlighting broader AI applications in fields like quantum

computing and structural engineering. Khasawneh integrates soil mechanics with AI to enhance the accuracy and efficiency of soil property predictions in civil engineering. In contrast, Seman's research [24] emphasizes the significant potential of machine learning methods in reducing prediction errors for plastic soils, acknowledging limitations for non-plastic soils. It identifies soil engineering property variability as a key factor affecting prediction accuracy and suggests addressing the shortage of pedotransfer relationships capable of predicting CBR from other soil measurements. Seman explores case-based reasoning methods and underscores the effectiveness of artificial neural networks in handling complex mappings, offering valuable insights for geotechnical engineering.

C. Research Objectives

The objective of the current investigation is to demonstrate the effectiveness of machine learning (ML) methodologies in developing predictive models for the California Bearing Ratio (CBR). This research specifically utilized artificial neural network (ANN) techniques and the Random Forest (RF) model to estimate CBR values. Additionally, various optimization algorithms, including the Gold Rush Optimizer (GRO), Stochastic Paint Optimizer (SPO), and Electrostatic Discharge Algorithm (EDA), were applied to enhance the accuracy and optimize the predictive output of the RF model. The selection of these optimizers was based on their demonstrated effectiveness in previous studies and their compatibility with the RF model, aiming to further improve the predictive performance of the model by leveraging their respective strengths in optimizing complex engineering problems. The performance of these developed models was assessed using specific evaluation criteria to determine the most suitable combination.

D. Research Significance and Contribution

The study significantly enhances the accuracy of predicting the CBR using advanced machine learning techniques, which is crucial for reliable infrastructure design. By offering an efficient alternative to the time-consuming laboratory determination of CBR, it saves both time and resources in geotechnical engineering projects. The integration of RF with optimization algorithms (GRO, SPO, and EDA) highlights the power of artificial intelligence in addressing complex engineering problems, pushing the boundaries of AI applications. Accurate CBR predictions are essential for pavement design and soil subgrade assessment, making the study's findings highly relevant and beneficial to real-world engineering. Additionally, the study establishes new benchmarks for CBR prediction models and introduces a methodology that can be extended to other predictive modeling tasks in engineering and beyond.

E. Research Organization

The introductory part of this study is divided into five main sections: background, literature review, research objectives, research significances and contributions, and research organization. Following this, Section II provides detailed explanations about the description of performance evaluators, the dataset used and concise descriptions of various machine learning techniques, including models and optimization algorithms. Section three covers the comparative results using metrics and different techniques. In Section IV which titled discussion, three subsections discussed about the limitations of the study, potential future works in the field of study, and the comparison between the results of this study and existing studies. In Section V, the study's conclusions are summarized.

II. Materials and Methodology

A. Random Forest (RF)

Random Forest (RF) is a supervised ML method that belongs to the family of non-parametric regression or classification techniques. It combines multiple decision trees to produce the desired output.

For modeling data, assume that the training $Q = \{(X_i.Y_i) \ldots\ldots (X_n.Y_n)\}$ an n number of samples and d-dimensional features here $X_i \in R^n$, and $Y_i \in R$.

Here is a brief description of the RF:

Produce bootstrap samples$(E_i. \ldots . E_K)$ from Q. The training dataset Q is resampled through bootstrapping, which involves randomly selecting samples with replacement. The size of each bootstrapped sample is equivalent to that of the original training dataset. Recently, many researchers often used small sample sizes for bootstrap samples due to their ease of computation.

Grow a decision tree, $T_m(i = 1. \ldots . M)$ from every bootstrap sample Em using the subsequent alteration:

Step 1: The optimal split for every node is found by picking the best option from a subset that is chosen at random of m_{try} predictors, where m_{try} predictors are chosen from the total d predictors.

Step 2: Similar to the pruning technique utilized in Classification and Regression Trees $(CART)$, the decision tree in this study is grown without any pruning, ensuring its seamless growth. The decision tree is so large that it is impossible to split the nodes further.

Step3: Take note that the quantity of trees in the woodland is denoted by M while m_{try} represents the number of input variables or predictors that are randomly chosen. The user defines both M and m_{try} while adjusting the parameters of a random forest algorithm. Repeat steps 1-2 until sufficient Tm has been grown.

Step 4: Use the following formula to forecast the answer for an entirely fresh dataset.

$$y_m^*(x) = \frac{1}{M}\sum_{m=1}^{M} y_m(x) \quad (1)$$

In the context of the random forest model, the prediction of the random forest, denoted as $y_m^*(x)$, is obtained by summing the predictions of each tree (mth tree), denoted as $y_m(x)$, for the input vector x [25]. Fig. 1 displays the RF model flowchart.

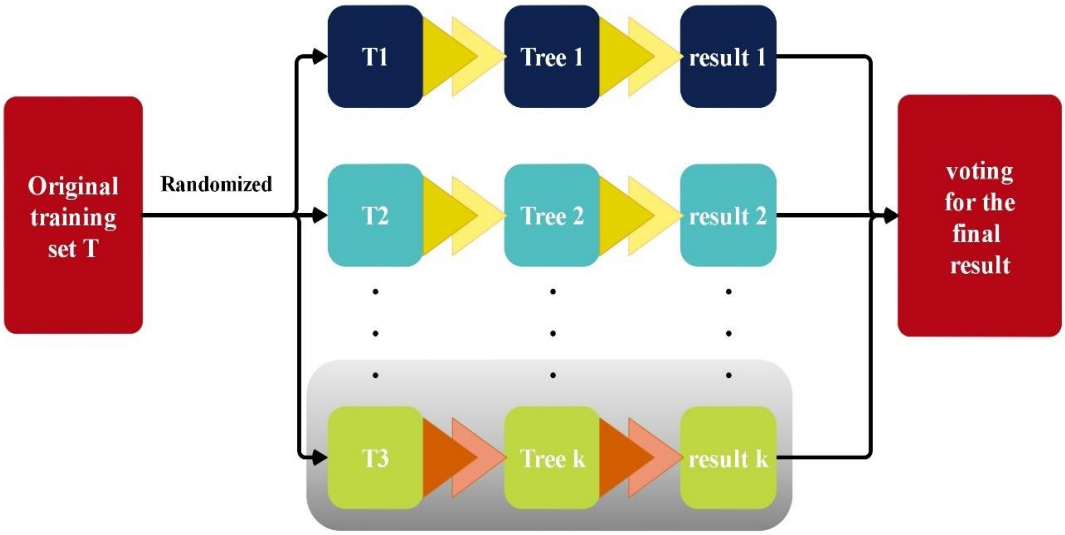

Fig. 1. RF model flowchart.

B. Electrostatic Discharge Algorithm (EDA)

As it is well known, metaheuristic algorithms are mainly inspired by natural behaviors like the feeding action of animals [26]. On the other hand, some people follow the well-known rules of the physical world to do the optimization. As a result, it is always possible to develop a new algorithm that can address some issues better than others. This is the primary motivation for this work. This paper proposes and compares a new metaheuristic algorithm with today's well-known optimization algorithms. Electrostatic Discharge (ESD) events inspire this algorithm and hence are called the Electrostatic Discharge Algorithm ($ESDA$) [27]. The process of optimizing the utilization of $ESDA$ begins with generating a population of individuals. By a fitness value that represents each individual's immunity level, the efficacy of this population is determined. During each implementation or repetition of ESDA, three individuals are randomly selected to undergo discharge. Next, a random value is generated, and depending on its numerical value, one of two scenarios can occur:

Step 1: If the random value is more than 0.5, the discharge is carried out by two personnel at places x1 and x2.

$$x2_{new} = x_2 + 2 \times \beta_1 \times (x_1 - x_2) \quad (2)$$

Step 2: If the random value is smaller than 0.5:

$$x3_{new} = x_3 + 2 \times \beta_1 \times (x_1 - x_3) + 2\beta_3 \times (x_2 - x_3) \quad (3)$$

In the above equations, $x3_{new}$ represents the new position of the individual i and β_i (i = 1, 2, 3) Signify Random Values.

The algorithm then performs extensive checks to ensure that everyone is within bounds. Finally, another check identified those discharged more than three times. This is because the algorithm should consider those individuals as eliminated and replace them with newly generated individuals. This process is repeated for each iteration using fresh individuals, ultimately discovering an optimal solution (i.e., the best solution) [28].

C. Gold Rush Optimizer (GRO)

The optimization problem of damage detection was tackled using the GRO algorithm, a population-based evolutionary algorithm [29]. The GRO algorithm is a population-based evolutionary algorithm with a faster convergence rate than other optimization algorithms. Its primary purpose is to locate areas with gold deposits. Initially, a group of operators is positioned randomly in the search space. Each operator is equipped with a metal detector and is tasked with locating gold deposits. The operators move in groups during each phase and listen to the tone produced by their device. If the tone increases, they stop and investigate the area.

Additionally, they listen to noises made by other devices and observe whether other devices are making loud sounds. During each phase, the group moves to the location with the loudest sound. Finally, the precise location of the gold deposit is determined. The probability of moving towards or away from the loudest sound is described by the parameters α, β, and γ. These parameters are selected within the range of $[0 - 1]$ [29].

Step 1: Initialization

$$location_i^{(0)} = Ib_i + (ub_i - Ib_i) \times rand.i \quad (4)$$
$$= 1.2 \ldots . N$$

Each operator happens to have a position in the search space, as shown in the formula. ub_i and lb_i are upper and lower bounds of the range (search space). $rand$ in the interval [0-1] is a random number. The number of operators is represented by N.

Step 2: Monitoring-Choosing the best locations

A successful operator that discovers the optimal position is referred to as an SOP. Generating an SOP is necessary during this stage. After every iteration, the top 10% of operators should be chosen and documented as part of the SOP.

Step 3: Fitness-distance

The formula is employed to compute the operator that is most likely to extract gold by examining the loudness (rate) of each sound:

$$rate(i) = \frac{D_i}{\rho} \times \frac{sound(highest\ volume) - sound(i)}{(sound(highest\ volume) - sound(lowest\ volume) + \varepsilon)} \quad (5)$$

A small positive number called epsilon (ε) prevents singularities. The coefficients, represented by ρ and Di in Eq. (6), are employed to avoid errors caused by environmental factors. The i and j indicate the two operators' current locations.

$$\rho = 2 - \frac{iter}{max_{iter}} \quad D_i = \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2} + \cdots \quad (6)$$

Step 4: Think-Decisions-mo

During this stage, each operator chooses an entirely distinct combination of sounds.

$$new\ location(i) = location(i) + md \times [(rate(j) - rate(i)) * (location(j) - location(i)) * ran \quad (7)$$

The coefficients md means move direction determine

$$md = \begin{Bmatrix} +1 \Rightarrow towards\ a\ loudest\ sound? & \alpha > rand \\ -1 \Rightarrow towards\ a\ loudest\ soun? & \alpha < rand \end{Bmatrix} \quad (8)$$

Step 5: Correct locate

If the position obtained from Eq. (7) does not satisfy the problem's constraints, Eq. (8) produces fresh positions. β and γ coefficients are chosen as 0 < β < γ <

$$new\ location(i) = \begin{Bmatrix} choose\ a\ new\ location & rand < \beta \\ select\ a\ new\ location\ randomly & \beta < rand < \gamma \\ do\ not\ move & \gamma < rand \end{Bmatrix} \quad (9)$$

Step 6: Finally, steps 4-6 are repeated in a loop until one of the following exit situations is met:

1) Maximum number of attempts

2) The optimal location did not exhibit any noticeable alteration.

3) The difference between the value of the SOP function and the achieved optimal solution is within the expected threshold. Parameters within the range of [0-1] are chosen.

4) Suppose the disparity between the objective values of the most excellent and poorest positions is lower than the designated accuracy. The GRO's flowchart is displayed in Fig. 2.

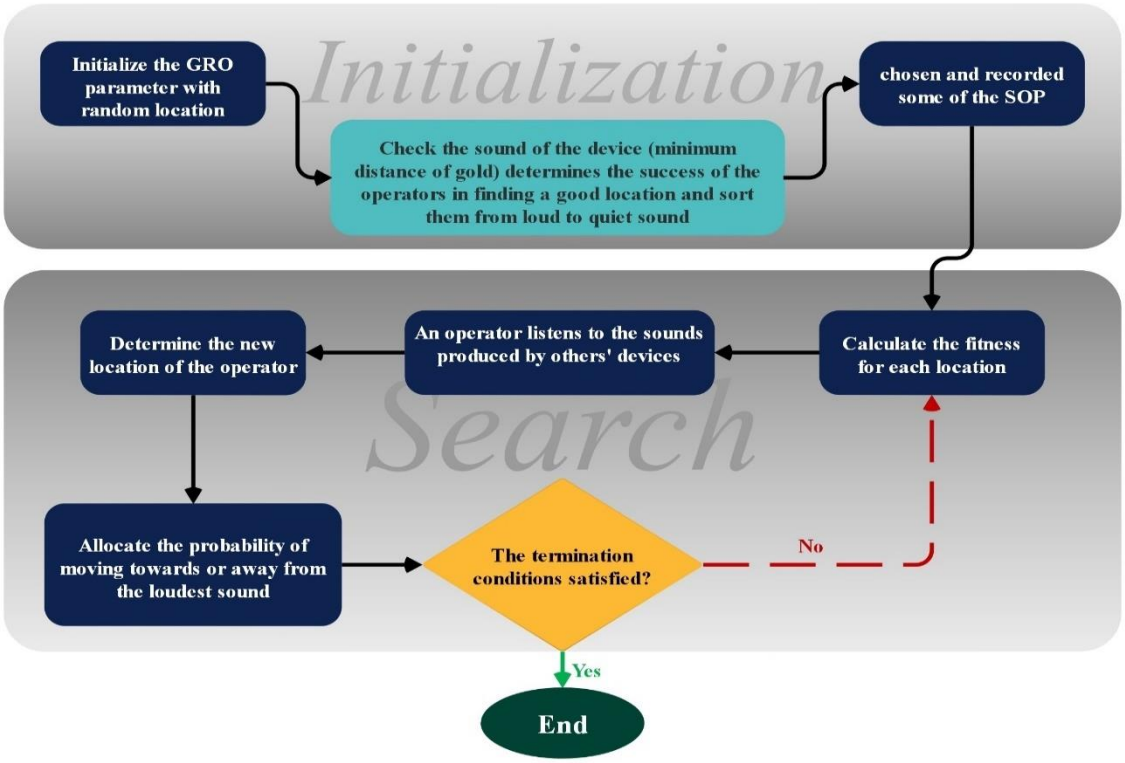

Fig. 2. GRO's flowchart.

D. Stochastic Paint Optimizer (SPO)

This section proposes a novel meta-heuristic algorithm, namely the Stochastic Paint Optimizer (SPO), based on the principles governing the use of colors in paint. The canvas serves as the defined search space wherein solutions, represented by a set of design variables involving certain colors, are considered paint strokes to produce the final output. The aesthetic value of various paints is appraised and categorized in ascending order based on their respective beauty index, representing the objective function values. Adding any fresh hue to a canvas contributes significantly to the overall interpretation of the artwork. As such, each hue is assigned a corresponding grade or value based on the hierarchical classification of colors in the color wheel, with primary colors being deemed most superior, followed by secondary colors as good, and tertiary

colors as inferior. Due to the equal categories, including parameters in the algorithm is deemed unnecessary. This algorithm can produce the most optimal pigments or solutions using the provided combination techniques for color mixing.

Step 1: Initialization

For an nc-dimensional search object, the selection of initial colors for all paints is made randomly.

$$C_{i.0} = C_{min} + rand \times (C_{max} - C_{min}).\, i \quad (10)$$
$$= 1.2.3 \ldots . nc$$

where, $C_{i.0}$ is the initial color of i the paint. C_{min} and C_{max} are the $lower$ and $upper$ limits of the design variable i, $rand$ is a random number with its range $[0, 1]$, and nc is the number of variables or colors. It is noteworthy that combining all colors produces a paint that serves as a solution or design for optimization problems. Subsequently, the objective function is assessed for each painting. Thus, the aesthetic quality of each painting is elucidated.

Step 2: Evaluation, Sorting, and Clustering

The paints are methodically arranged in ascending order concerning their corresponding objective function, thus serving as a direct outcome of the problem. Ultimately, these entities are grouped into $three$ equal categories, including primary (the most favorable), secondary (favorable), and tertiary (the least favorable).

Step 3: Utilizing Combination Techniques

This phase synthesizes novel paint formulations using four distinct combination methodologies.

Step 4: Evaluating and Updating.

The new beauty index of the paints is assessed, and if it is superior to the previous index, the old paint is substituted with the new one.

Step 5: Checking Termination

Upon the completion of a series of iterations, the cycle of optimization is considered finished. If the established criteria are not satisfied, a new Phase 2 process will be arranged. However, if the criteria are met, the process will be terminated, and the optimal solution will be reported [30]. Fig. 3 displays the SPO flowchart.

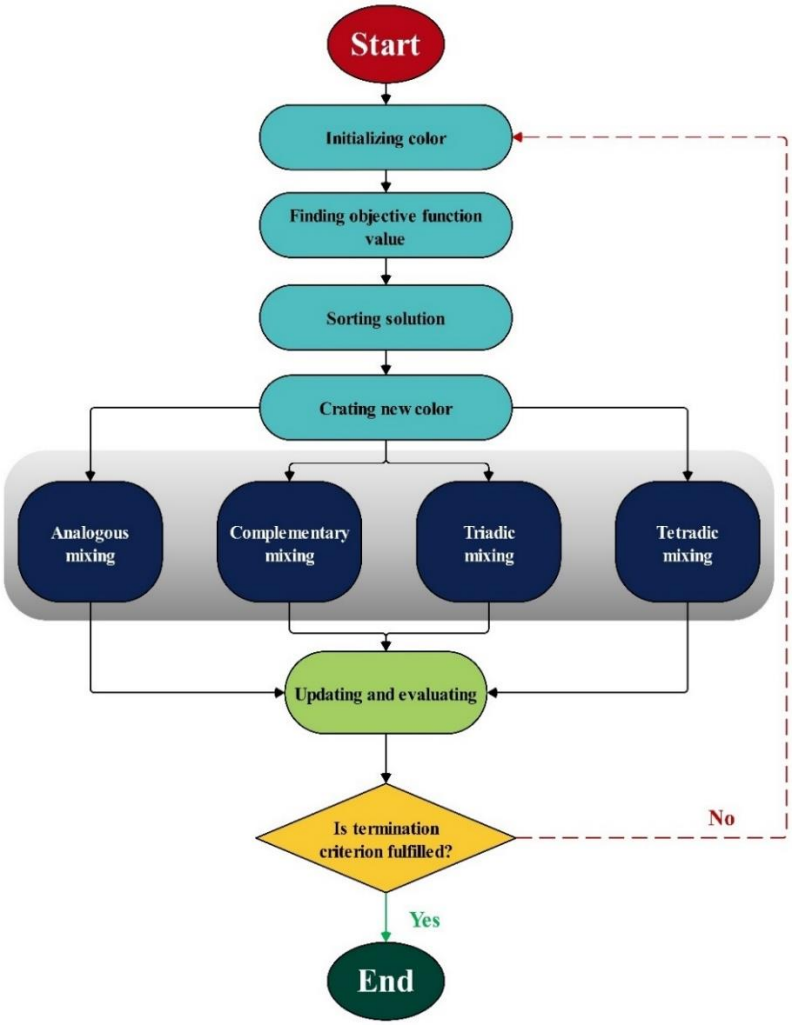

Fig. 3. SPO flowchart.

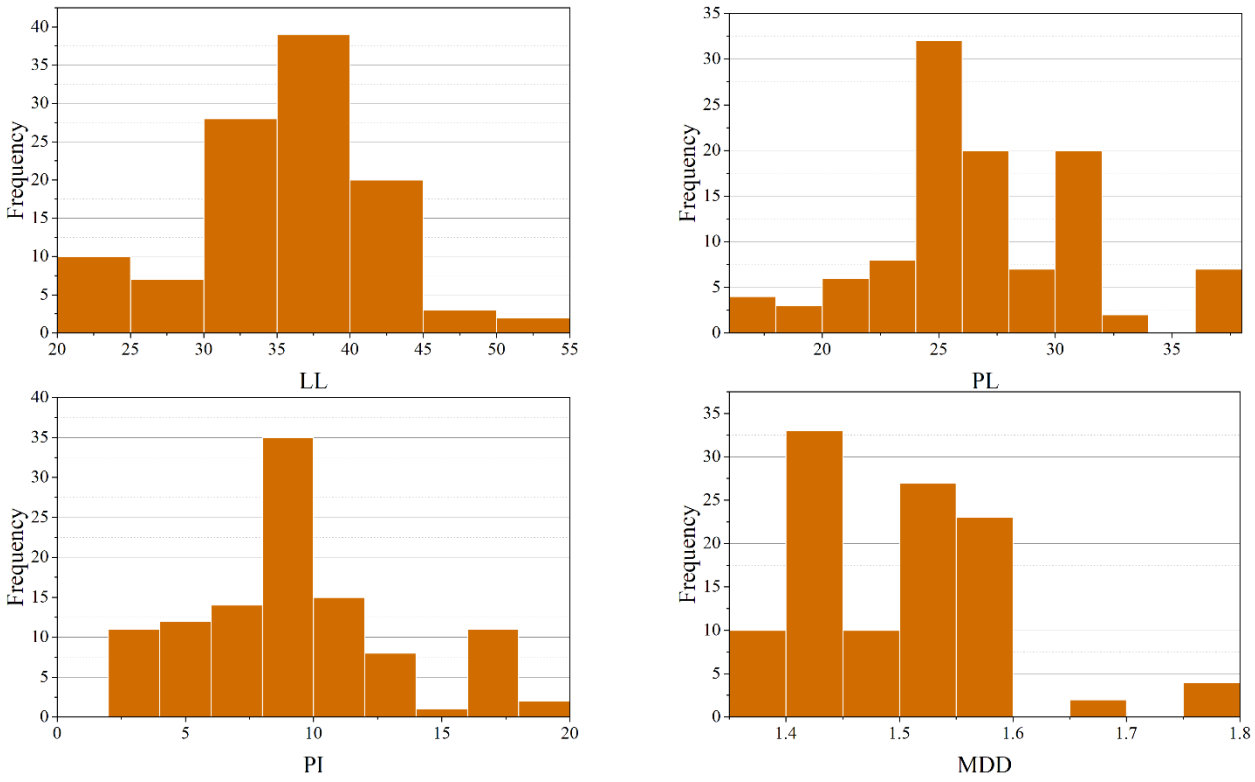
E. Data Gathering

The goal of this work is to accurately estimate the California Bearing Ratio (CBR), a crucial variable in civil engineering projects, using a novel ML (ML) technique. In order to do this, the dataset is carefully split into three stages: a significant 70% is set aside for training, and the remaining 30% is put aside for testing. The visual representation of the input and output variables is shown in Fig. 4, and Table I provides a thorough summary of the statistical properties for the major contributing factors, such as the crucial CBR, Silt and Dust Amount as a Percentage ($SDA\%$), Quartz and Dirt Percentage ($QD\%$), Plastic Limit (PL), Plasticity Index (PI), Maximum Dry Density (MDD), Optimum Moisture Content (OMC), and Silt and Dust Amount as a Percentage ($SDA\%$). This study utilizes the Random Forest (RF) model to enhance the design and construction of CBR in the broader infrastructure landscape, overcoming challenges in empirical data acquisition. The proposed framework for civil engineering predicts the strength of concrete by analyzing a vast CBR dataset. This comprehensive approach offers valuable insights, enabling informed decisions and ensuring the robustness of structural designs in civil engineering projects [31–33].

TABLE I. THE STATISTIC PROPERTIES OF THE INPUT VARIABLE OF CBR

Variables		Indicators			
	Category	*Min*	*Max*	*Avg*	*St.Dev.*
LL	Input	21.200	52.100	35.846	6.154
PL	Input	17.900	37.200	26.683	4.281
PI	Input	2.100	19.500	9.162	4.115
MDD	Input	1.365	1.777	1.493	0.088
OMC	Input	18.900	29.500	24.143	2.427
SDA (%)	Input	0.000	20.000	10.661	7.155
QD (%)	Input	0.000	20.000	10.642	8.196
OPC (%)	Input	2.000	8.000	4.945	2.380
CBR (%)	Output	19.690	66.750	39.959	10.867



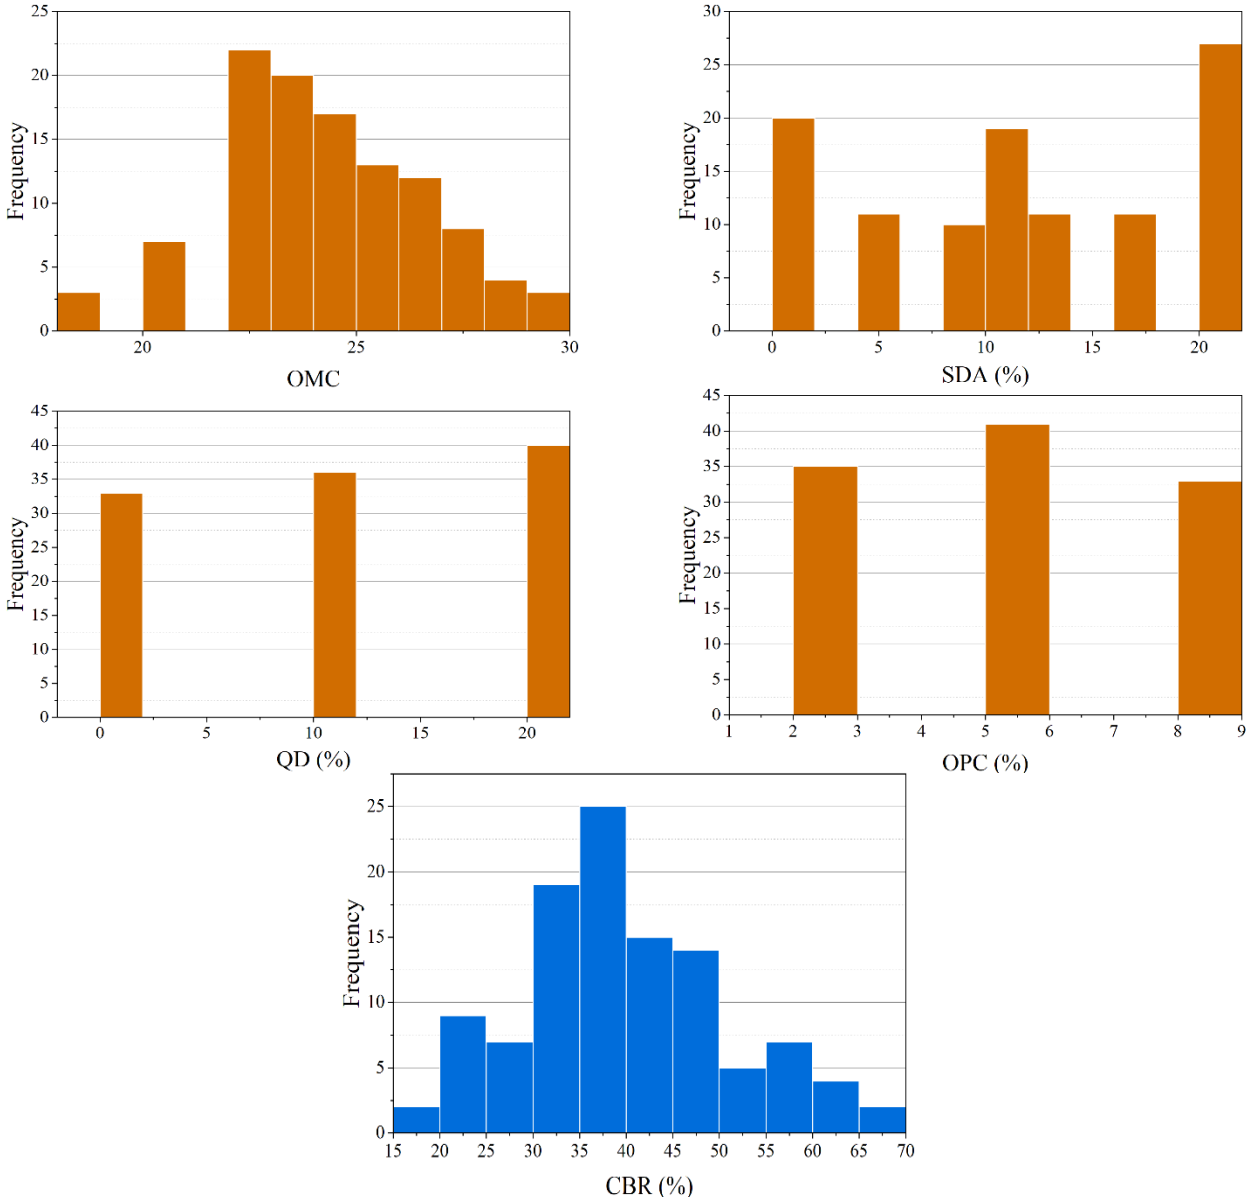


Fig. 4. The histograms plot for input and output.

F. Performance Evaluation Methods

Concrete estimative evaluations typically incorporate five commonly utilized performance indicators. Moreover, their utilization was employed to evaluate the ML approach presented in this manuscript. The correlation coefficient (R^2) provides a quantitative metric of the extent to which the explanatory variables can successfully account for the variable's observed response. This statement assesses the model's aptness for the intended purpose by evaluating the degree to which it aligns with the data or phenomena under consideration. The estimation capacity of the model under consideration can be adequately assessed by observing an elevated R^2 coefficient value. The Root Mean Squared Error ($RMSE$) is a statistical measure utilized to assess the accuracy of a forecast. The $RMSE$ is a statistical measure employed to assess the variance of a response variable, which can be effectively characterized using models. The Mean squared Error (MSE) is a statistical measure that calculates the mean magnitude of errors in the predictions made by a given model. The subsequent section elaborates on the mean absolute percentage error (MAPE) measures as well as the variance account factor (VAF).

$$R^2 = \left(\frac{\sum_{i=1}^{n}(p_i - \bar{p})(r_i - \bar{r})}{\sqrt{[\sum_{i=1}^{n}(p_i - p)^2][\sum_{i=1}^{n}(r_i - \bar{r})^2]}} \right)^2 \quad (11)$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(r_i - p_i)^2} \quad (12)$$

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(r_i - p_i)^2 \quad (13)$$

$$MAPE = \frac{100}{n}\sum_{i}^{n}\frac{|r_i|}{|p_i|} \quad (14)$$

$$T_{state} = \sqrt{\frac{(n-1)MSE}{RMSE^2 - MSE}} \quad (15)$$

where, $\bar{r}$ and $\bar{p}$ show the averages of the observed and predicted, respectively, where p_i and r_i determine the predicted and observed values. n is the sample number as well.

III. RESULTS

This section delves into model discussion based on specific criteria. To ensure a robust evaluation, the dataset underwent random partitioning, creating distinct training and test sets. The model construction relied on 70% of the training data, while the remaining 30% assessed the built model's reliability. Realistic interconnections among elements were established. Table II presents key findings as follows:

The R^2 metric ranges from 0.9959 ($RFSPS_{test}$) to 0.9773 ($RFED_{train}$). Similarly, RMSE values vary from 7.623 ($RFED_{train}$) to 2.1546 ($RFSP_{test}$). Notably, the most favorable MSE, at 9.260, corresponds to $RFGR_{test}$, while the least desirable, reaching 58.110, aligns with $RFED_{train}$. In terms of MAPE, RFSPtest excels at 4.0378 while RFEDtrain lags at 9.7295. Testate values highlight $RFGR_{test}$'s suitability at 0.5758, contrasting starkly with $RFED_{train}$'s 2.1246, indicating inferior performance. The outcomes collectively suggest thorough training for all models, with minor exceptions where test data performance deviates.

Regarding model parameters, RFED experiences a general decrease, though initially high values render it unsuitable as a predictive model. Moreover, RFGR shows marginal increases, barring R^2, with other parameters decreasing. This demonstrates its suitability and high predictive accuracy. In essence, the assessment underscores the models' varied performances. While RFED's parameter reduction might suggest improvement, its unsuitably high initial values limit its predictive efficacy.

Conversely, the slight parameter fluctuations within RFGR, coupled with predominantly decreasing trends, affirm its suitability and accuracy in forecasting. Overall, the evaluation emphasizes the nuanced performance differences among models. RFED's parameter reductions hint at enhancement, yet its unsuitably high initial values limit its predictive prowess. Conversely, RFGR's minor parameter fluctuations alongside predominantly decreasing trends validate its suitability and precision in forecasting.

TABLE II. THE ACHIEVING RESULTS OF PRESENTED MODELS

Models	**RFGR**		**RFSP**		**RFED**	
Section	***Train***	***Test***	***Train***	***Test***	***Train***	***Test***
RMSE	4.754	3.043	3.189	2.155	7.62	5.357
R2	0.9876	0.9930	0.9935	0.9959	0.9773	0.9814
MSE	22.60	9.260	10.17	4.643	58.11	28.70
MAPE	5.882	5.272	4.551	4.038	9.730	8.723
Tstate	1.633	0.576	1.071	1.378	2.125	0.115

In Fig. 5, this study visually illustrates a Scatter plot depicting predicted and measured CBR values across distinct testing and training phases. The shape's determination relies on two evaluative metrics: R^2 and RMSE. R^2 assesses the likelihood within a given sequence, while RMSE gauges data dispersion or density. X = Y coordinates form the central line, and the linear regression underwent two phases of experimentation and evaluation. The angle divergence between these lines measures model effectiveness. The RFSP model displays lower RMSE and higher R^2 in training than in testing.

Consequently, there is minimal variance between the linear fit angle and the line, indicating less scatter in training compared to testing. In contrast, the RFED model shares similarities with the RFSP model but exhibits considerably high RMSE and R^2 values, rendering it unsuitable for forecasting. Conversely, the RFGR model showcases favorable RMSE and R^2 values. Notably, this model displays a higher degree of data point dispersion compared to the other two models. To sum up, Fig. 5 visually demonstrates the Scatter plot portraying predicted and measured CBR values in distinct testing and training phases. R^2 and RMSE serve as evaluative metrics, depicting model effectiveness and data dispersion. While RFSP shows promising results in training compared to testing, RFED's high RMSE and R^2 values make it unsuitable for forecasting. Conversely, RFGR exhibits favorable RMSE and R^2 but displays a higher data point dispersion compared to the other models.

Fig. 6 compares the anticipated and observed CBR values during two distinct stages of experimentation, namely training and testing. In an optimal scenario, the anticipated and observed conduct exhibit comparable conformity. Both RFGR and RFSP models have relatively similar performance, and the max difference CBR for both models is equal to 50, but the RFED model has a relatively significant difference with the other two models, while the max for this model is equal to 15. The well-known RFSO and RFGR models can be generally concluded to be less accurate than the combined model of the two phases.

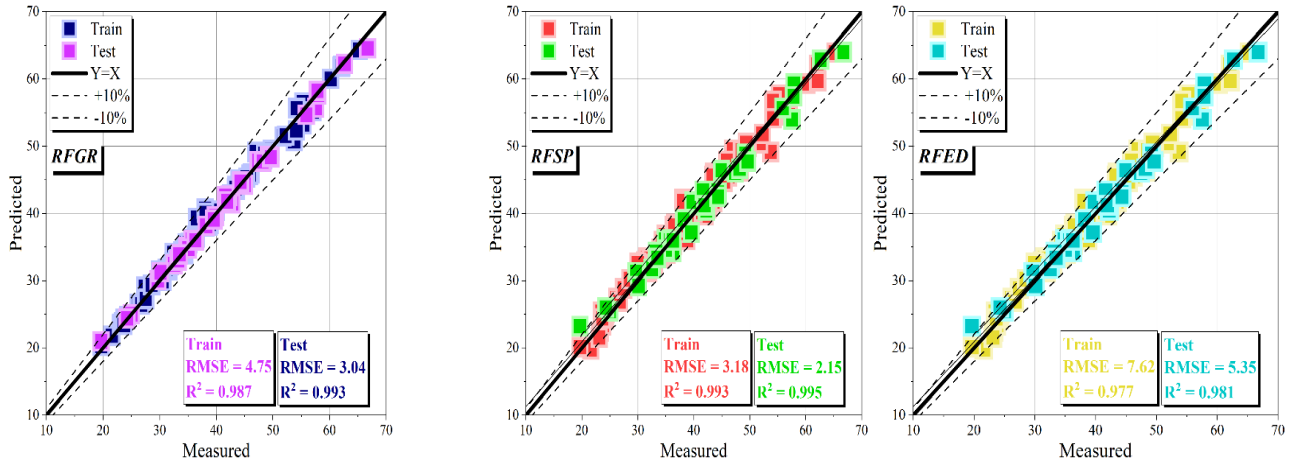

Fig. 5. Scatter plot for correlation between the predicted and measured CBR.

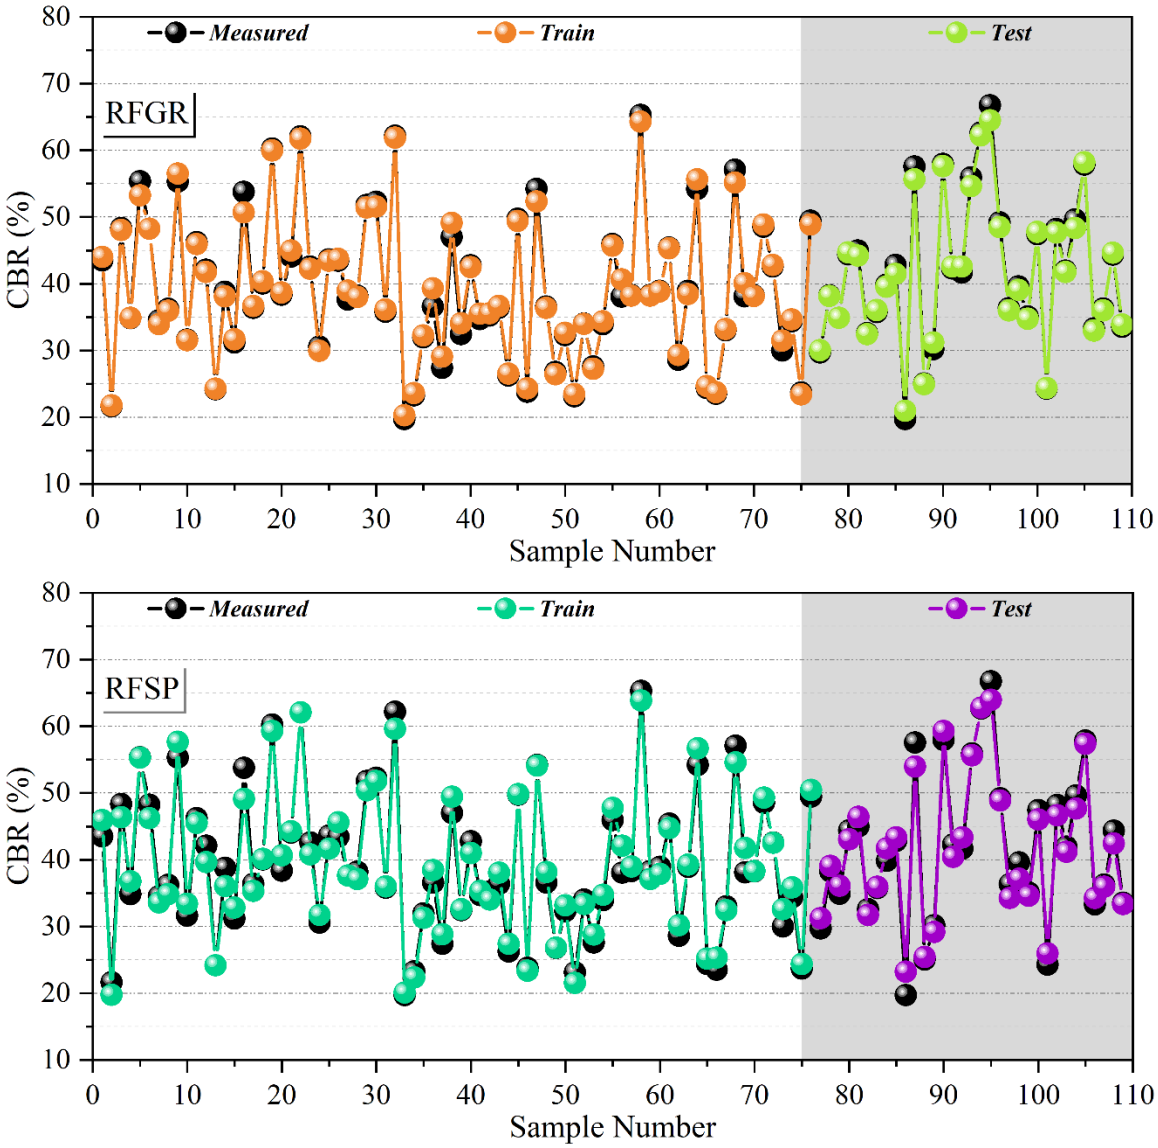

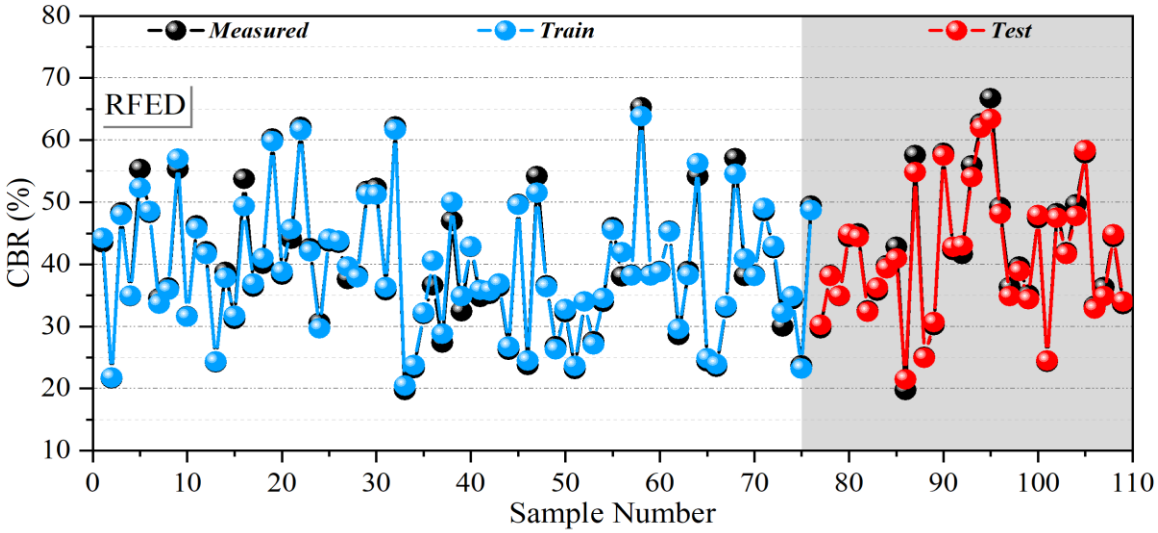

Fig. 6. Comparison between predicted and measured CBR.

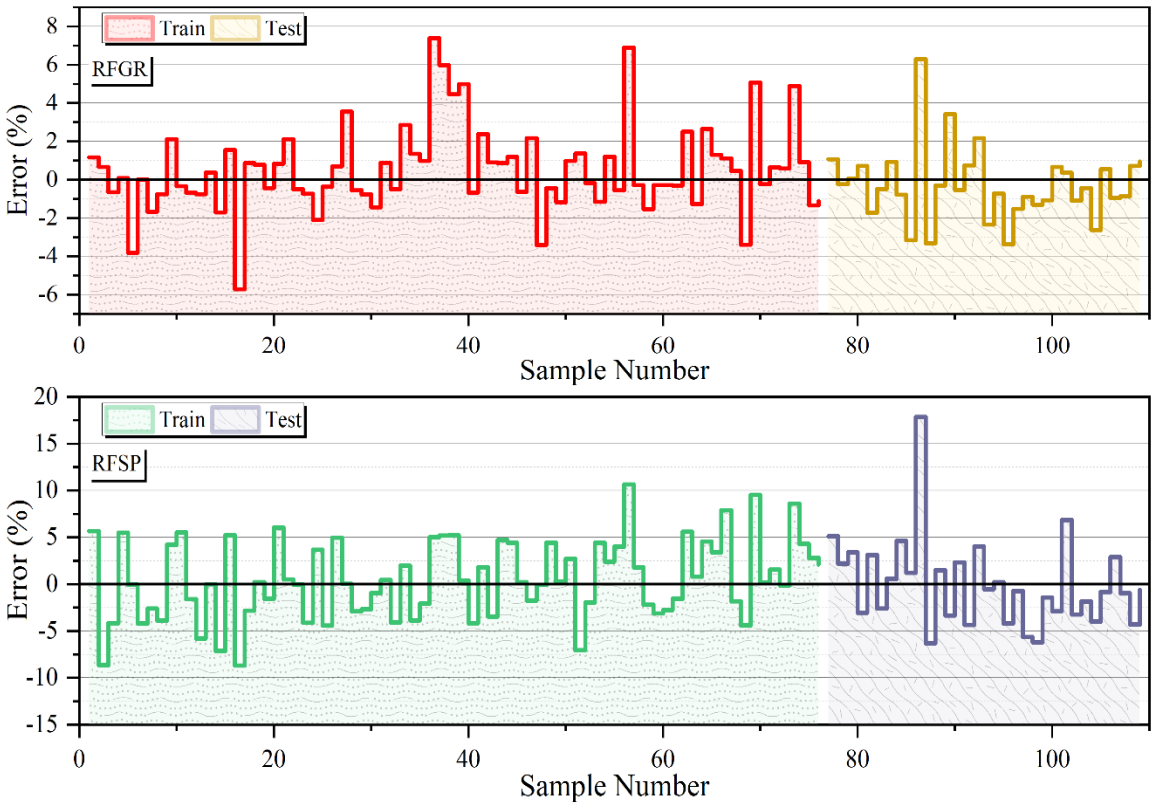
Fig. 7 shows the percentage of errors observed during both the training and test stages. As indicated, most samples, specifically 70%, were associated with the training segment, while the remaining 30% were attributed to the testing component. In the RFGR model, the high error percentage was 26%, and the lowest was 11%. These numbers have been reduced to -2% and 12% for the test data. For the RFSP model, the test data has decreased significantly, from -9 to 29, which has decreased to -9 and 12 for the test data. However, the RFED model did not have any special change; the highest error data was 36%, and the lowest was -19%, which decreased to 26% and -14% after training the model. Finally, the percentage of the numbers obtained for the error is closer to zero, the better the model is trained and more appropriate, such as the models RFGR and RFSP.



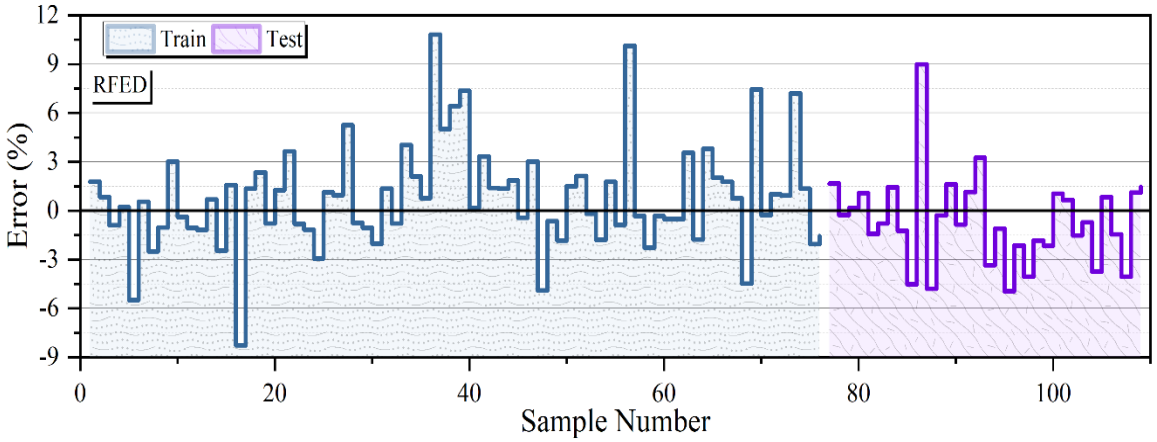


Fig. 7. Percentage of error in the test and training phase.

Fig. 8 displays the half-box plot for the error percentage of the models that are being presented. In the RFGR model, the scatter for error is high and slightly reduces the scatter for test data. In the RFSP model, the dispersion for error is very low compared to the other two models, and it has also decreased due to the test data ranging between -15% and -15%, which indicates the appropriateness and correct training of the model. On the other hand, the RFED model also decreased for the test data, but since it had a very high dispersion from the beginning, it is unsuitable.

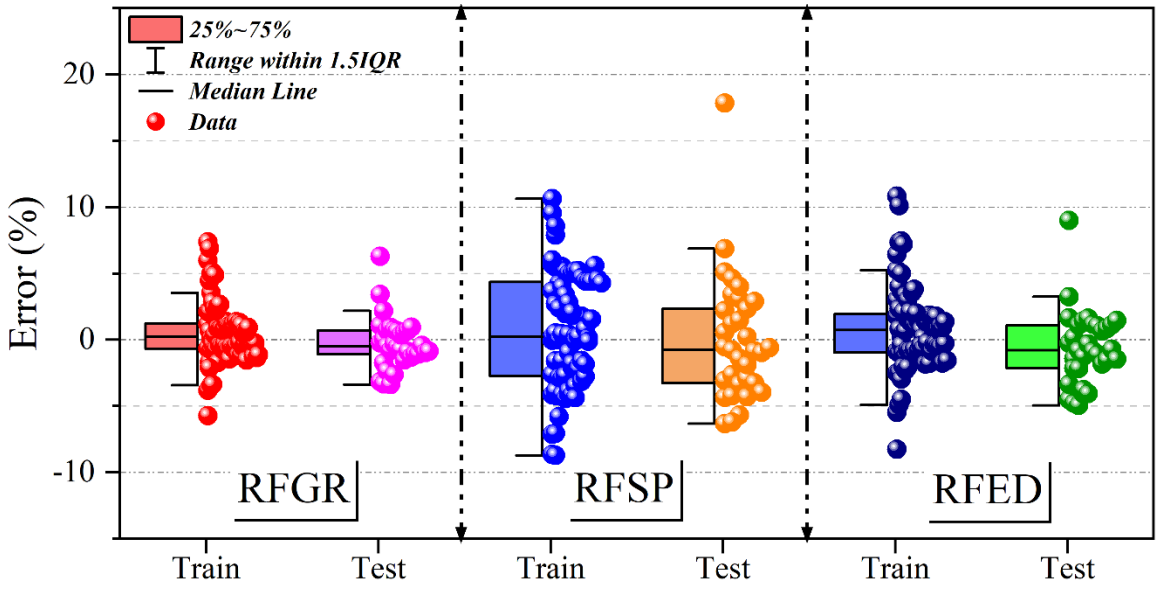

Fig. 8. Half-box plot for the error percentage of the presented models.

IV. Discussion

A. Limitations of the Study

The limitations of this study include potential constraints related to the methodology, data, and scope. Firstly, the reliance on machine learning techniques, while beneficial, may be limited by the quality and quantity of available data for model training and validation. Insufficient or biased data could affect the accuracy and generalizability of the predictive models developed. Additionally, the scope of the study may focus primarily on specific soil types, geographic regions, or pavement conditions, limiting the applicability of the findings to broader contexts. Furthermore, the complexity of integrating multiple meta-heuristic algorithms into hybrid models may introduce challenges in model interpretation, implementation, and computational efficiency. Finally, the study may not account for all potential factors influencing CBR prediction accuracy, such as variations in testing protocols, environmental conditions, or pavement maintenance practices, thus warranting further investigation and refinement in future research endeavors.

B. Potential Future Works

Potential future works in this area could encompass several avenues for advancement. Firstly, there's the opportunity for further refinement and optimization of hybrid models by exploring additional meta-heuristic algorithms or fine-tuning the parameters of existing ones to enhance predictive accuracy. Secondly, the integration of advanced machine learning techniques beyond random forests, such as deep learning or

ensemble methods, could be explored to improve the accuracy and robustness of CBR prediction models. Additionally, researchers could investigate the inclusion of additional input variables, such as environmental factors, traffic loads, or pavement materials, to broaden the predictive capabilities of the models and capture a wider range of influencing factors. Long-term monitoring of pavement performance using the developed models could also be conducted to assess their reliability over time and to update the models based on new data and insights gained from ongoing monitoring activities. Finally, there's the potential for integrating the CBR prediction models into decision support systems for pavement design and management, providing engineers and decision-makers with valuable insights and recommendations for optimizing pavement performance and longevity.

C. Compare the Results of the Present Study and Previous Studies

Numerous studies have been conducted on CBR prediction. Notably, Nawaz et al. [34] utilized a Gene Expression Programming (GEP) model, Khan et al. [35] employed Gaussian Process Regression (GPR), and Bhatt et al. [36] implemented an Artificial Neural Network (ANN) for their predictions. Of the methods summarized in Table III, the ANN model stood out, delivering exceptional results with an R^2 value of 0.99 and an RMSE of 10.01 in the study by Nawaz et al. [34]. In this study, the primary framework utilized was the Random Forest (RF) model, which was augmented through hybridization with three optimization algorithms: the Gold Rush Optimizer (GRO), the Stochastic Paint Optimizer (SPO), and the Electrostatic Discharge Algorithm (EDA). Upon analyzing the results, the integration of the SPO with the RF model exhibited outstanding performance, achieving an R^2 value of 0.9959 and an RMSE of 2.155. This combination outperformed the other two hybrid models evaluated in this research.

TABLE III. COPARISON BETWEEN THE RESULTS OF PREVIOUS ARTICLES AND PRESENT STUDY

Name	Model	Results	
		RMSE	R^2
Bhatt et. al. [36]	ANN	0.202	0.9895
Nawaz et. al. [34]	GEP	10.01	0.99
Khan et. al. [35]	GPR	0.1609	0.8139
Present study	**RF+SPO**	**2.155**	**0.9959**

V. CONCLUSION

Ensuring the accuracy and reliability of California Bearing Ratio (CBR) predictions is crucial for the establishment and deployment of robust and adaptable pavement systems. Unfortunately, the conventional CBR testing protocol employed to ascertain the CBR of subgrades encounters challenges primarily attributed to the prolonged duration required by the testing methodology. Consequently, there arises a need to explore alternative methodologies to approximate the CBR of expansive soil subgrades, with a particular emphasis on the construction of predictive models. To address the limitations associated with conventional testing procedures, particularly their time-intensive nature, the adoption of machine learning (ML) has emerged as a viable solution. By employing ML techniques, the reliance on traditional, labor-intensive experimentation has been significantly reduced. This paradigm shift not only expedites the CBR prediction process but also opens avenues for more accurate and efficient assessments of subgrade characteristics. The integration of ML in CBR prediction offers a progressive step towards enhancing the effectiveness of pavement development and implementation, promoting both safety and flexibility in infrastructure design. The random forest (RF) model, an ML technique for CBR prediction, was also meant to be introduced in this article. Furthermore, the corresponding model was also combined with three meta-heuristic algorithms to form a hybrid model to increase accuracy, which include the electrostatic discharge algorithm (EDA), the stochastic paint optimizer (SPO), and the gold rush optimizer (GRO). Additionally, the performance of developed hybrid models was assessed by several metrics, including R^2, RMSE, MSE, MAPE, and Tstate. Consequently, the SPO model exhibited optimal performance compared to the other two models in conjunction with RF. Results reveal that RFSP consistently excels across various metrics, exhibiting the lowest RMSE and MSE values, highest R^2 values, and statistically significant Tstate values. This underscores RFSP's superior predictive accuracy and robustness compared to RFGR and RFED. RFED also demonstrates commendable performance, particularly in achieving the lowest MAPE values. In contrast, RFGR exhibits relatively lower performance metrics, suggesting lower accuracy and statistical significance in comparison to the other models.

Optimization of Body Pressure Relief Support Wearable Devices Integrating 3D Printing and Gait Recognition Algorithms

Yaqiong Zhou*, Bing Hu
School of Fine Arts and Design, Hefei Normal University, Hefei, 230601, China

***Abstract*—To improve wearing comfort and achieve individual recognition, this study designs an ankle exoskeleton that simulates natural human movement based on the joint structure of the human lower limbs. The function of the sole spring is achieved through compression springs on the exoskeleton framework coupled with the foot, and a customized insole is designed using 3D printing technology. This study uses a gait recognition algorithm based on a convolutional gated recurrent unit fully convolutional network with a dual attention mechanism to achieve individual recognition. The results showed that compared to the natural state, when walking with exoskeletons, the integrated electromyographic signals of the gastrocnemius and tibialis anterior muscles decreased by 5.4% and 3.6%, respectively, and the intelligent insole reduced plantar pressure to a certain extent. The accuracy of the proposed gait recognition algorithm could reach 95.26%, which was 2.03% higher than that of fully convolutional networks. In addition, the fuzzy output signals of the left and right feet were combined to obtain the proportions of single support phase and double support phase during walking, which were 92.7% and 7.3%, respectively. This study indicates that a body pressure reducing support wearable device that integrates 3D printing and gait recognition algorithms can reduce lower limb joint pressure, providing a new possibility for improving wearing comfort and achieving individual recognition. It also helps to improve the quality of life for the target audience.**

***Keywords*—3D printing; gait recognition; body decompression support; wearing devices; electromyographic signal**

I. Introduction

A. Research Background

With the intensification of the aging trend in society, the demand for Body Pressure Relief Support Wearable Devices (BPRSWDs) is increasing in the elderly and rehabilitation medicine fields. This type of device aims to provide personalized support and soothing effects through real-time monitoring and analysis of the wearer's body, in order to improve their quality of life [1]. However, the current BPRSWDs still need to be improved in terms of functionality and performance. In recent years, Gait Recognition (GR) technology, as an emerging biometric recognition method, has been widely applied in the field of security due to its advantages of non-contact and long-distance monitoring [2]. This technology can effectively distinguish gait features between different individuals by analyzing gait images. However, the current application of GR methods in BPRSWDs is not yet sufficient [3]. In addition, the development of Three-dimensional Printing Technology (3D-PT) has provided the possibility for customized and personalized design of BPRSWDs [4-5]. However, previous studies have not fully considered the impact of human lower limb joint structure on wearing comfort, and there is a lack of effective GR algorithms to achieve individual recognition.

B. Research Method and Objectives

In order to improve wearing comfort and achieve individual recognition, this study proposes a BPRSWDs optimization method that integrates 3D-PT and GR algorithm. Firstly, the design combines customized body support components with 3D-PT, and then utilizes GR technology to monitor and analyze the wearer's gait characteristics in real-time. The contribution of the research is the design of a body pressure reducing support wearable device based on 3D printing technology, as well as the proposal of a gait recognition algorithm based on a convolutional gated recurrent unit full convolutional network with dual attention mechanism, which achieves individual identity recognition. This device provides new design ideas and methods for the field of body stress relief support wearable devices by improving wearing comfort and algorithm accuracy. It is expected to provide a more comfortable and personalized experience for the audience, thereby improving the quality of life.

C. Organization Structure

The research content consists of five sections. Section I is a summary of research related to 3D printing, wearable devices, and GR. Related works is given in Section II. Section III is the design of BPRSWDs and GR algorithms, and application analysis is conducted in Section IV. Section V summarizes the entire study.

II. Related Works

3D printing is a technology that uses digital model files as the basis and adhesive materials such as powdered metal or plastic to construct objects through layer by layer printing. Peki et al. used glass fiber reinforced UV cured polymer matrix composites for robot 3D printing and optimized parameters such as nozzle diameter. Under specific parameter conditions, 3D printing could achieve high tensile and bending strength [6]. Yu's team proposed a novel high current planar inductor with heat dissipation fins based on 3D printing, and conducted experiments using selective laser melting technology to 3D print copper windings. At a current of 100A, this inductor could function well, while traditional inductors could not function due to high temperatures [7]. Wu's team has prepared a 3D printed

conductive polymer ink with high conductivity, flexible stretchability, and strain sensing monitoring performance. Silane modified conductive polymers have excellent printability and strain sensing properties [8]. Zhang et al. proposed the latest progress of 3D printing in the field of wearable electrochemical energy devices and explored its applications and limitations in this field. Although 3D-PT has great potential in wearable energy devices, issues such as ink formulation and material design still needed to be addressed [9]. Liu's team explored the manufacturing of Flexible Strain Sensors (FSS) through 3D-PT and conducted in-depth discussions on the sensing mechanism of 3D-printed FSSs. 3D-PT had great potential in manufacturing FSSs and could bring revolutionary changes to the development of wearable devices and electronic skins [10]. Hong et al. designed a capacitive pressure sensor using a biomimetic cheetah leg microstructure, optimized the structural parameters using 3D-PT, and achieved high sensitivity, wide pressure range, fast response time, and excellent durability [11].

GR is a technology that identifies human movements such as walking and running by analyzing the characteristics of human motion trajectory, dynamics, and physiological signals. Bianco's team proposed a GR system based on inertial sensors, which recognizes gestures, user gait, and identity through custom wristbands and recursive neural network-based algorithms. The recognition accuracy and user satisfaction of the system could reach 90% [12]. Lee et al. employed a method based on Inertial Measurement Unit (IMU) and Long Short Term Memory (LSTM) machine learning models to identify gait under different fatigue states. The LSTM model had the highest accuracy in identifying simulated gait, with the combination of toe and sacral IMU achieving the highest accuracy of 95.71% [13]. Semwal et al. used a hybrid deep learning model, combined with data collected by IMU sensors, to achieve recognition of various gait activities. The proposed hybrid framework based on ensemble learning performed excellently in GR, with an accuracy rate of 99.34% [14]. Ma's research team has proposed a high-performance GR and efficient energy harvesting method. It filtered the impact of energy storage on the electrical signal of the piezoelectric energy harvester through preprocessing algorithms, and used a classifier based on LSTM network to accurately capture time information in gait induced power generation. Compared to state-of-the-art architectures, this method has improved gait recall by 12%, achieved energy harvesting efficiency of up to 127%, and reduced power consumption by 38% [15]. Hasan's team proposed a new stacked auto-encoder method to address the impact of perspective changes on human GR in a multi camera environment. By learning discriminative perspective invariant gait representation, this method could gradually convert bone joint coordinates from any view to a common normative view while preserving temporal information. The average correct class recognition of this method could reach 33.86% [16].

In summary, many researchers have made different designs for 3D-PT and GR. However, these studies mainly focus on the optimization of materials and processes, with less attention paid to performance evaluation and optimization in different application scenarios. At the same time, the universality and practicality of GR technology still need to be improved, and the accuracy in practical applications still needs to be improved. Therefore, this study integrates 3D-PT and GR algorithms to conduct optimization research on BPRSWDs, with the aim of providing users with a more comfortable wearing experience.

III. Optimization Design of BPRSWDs Integrating 3D-PT and GR Algorithm

This section mainly designs the GR algorithm based on Convolutional Bi-directional Gated Recurrent Unit Fully Convolutional Networks (ConvBiGru-FCN). This algorithm extracts discriminative features by analyzing the walking patterns of the human body, achieving recognition of individual identity.

A. The Overall Design of BPRSWDs

The design of BPRSWDs is based on the structure of human lower limb joints, simulating natural human movement, aiming to reduce joint pressure and improve comfort [17].

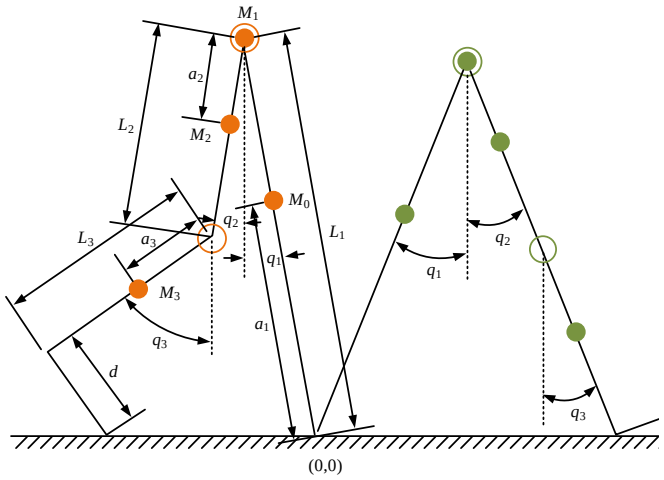

Fig. 1. A human walking model within a single support phase.

In Fig. 1, the unilateral lower limb movement state during human walking is divided into support phase and swing phase. The Single Support Phase (SSP) model of a single leg simplifies the support leg, support phase foot, swing phase thigh, swing phase calf, and swing phase foot into members [18]. The model contains three degrees of freedom, namely the hip joint of the supporting leg, the hip joint of the swinging leg, and the knee joint of the swinging leg. The angle between the rod and the vertical axis of the human body is q_i, the length of the rod is L_i, the distance between the center of mass of the rod and the lower limb joint is a_i, and the moment of inertia of the rod is I_i, $i=1,2,3$. The foot length is d, and the supporting ankle joint is the coordinate origin. The centroid coordinates of the supporting leg, upper body, swinging thigh, and swinging calf are $M_0(x_0,y_0)$, $M_0(x_1,y_1)$, $M_0(x_2,y_2)$, and $M_0(x_3,y_3)$, respectively. Introducing plantar springs in walking models can reduce human energy loss [19]. Based on this principle, an ankle exoskeleton is designed, which simulates the function of plantar springs through compression springs on the exoskeleton framework coupled with the human foot.

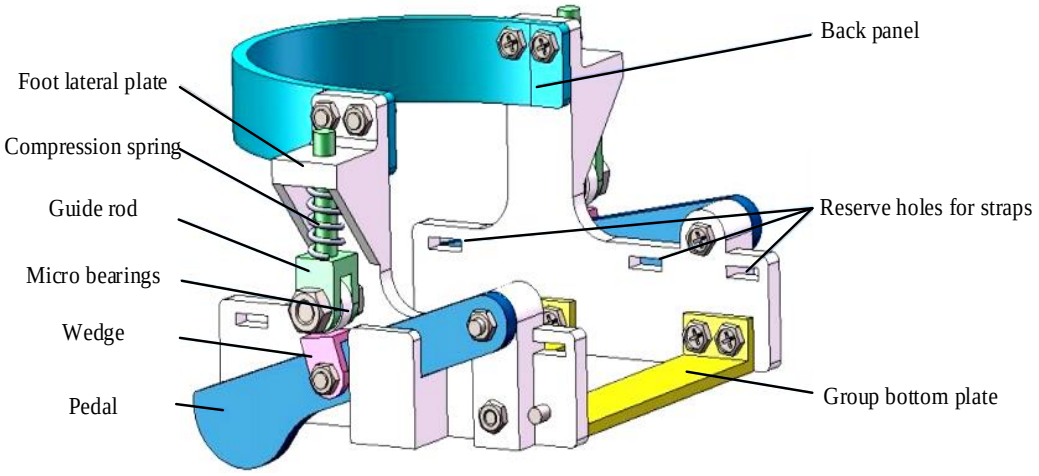

Fig. 2. The overall structure of ankle exoskeleton.

As shown in Fig. 2, the exoskeleton is mainly composed of multiple components, such as the foot side plate, compression spring, guide rod, micro bearings, wedges, pedals, backplate, and plantar plate. These components are fixed together through connectors. The shoes worn by the experimenter are tightly attached to the main frame composed of the foot side panel, back panel, and sole panel, and are fixed to the front of the shoes with straps. The sole plate is responsible for supporting the weight of the human body, and aluminium alloy materials with high strength and good wear resistance are selected. The pedal is made of carbon fiber board and forms a rotating pair connection with the foot side panel, with the rotation center located in the middle of the foot. There is a vertical plane on the foot side plate that bears elastic force, and the strengthening ribs on both sides increase the strength of the force bearing surface [20-21]. The concave platform below the foot side panel can limit the pedal and prevent it from bending outward. The other components are made by UV curing printing, using lightweight and moderately rigid photosensitive resin materials. The ankle exoskeleton is located in the middle and rear of the foot and does not affect the force exerted by the human toes when they are off the ground. The passive energy storage structure is a crucial part of the ankle exoskeleton, which can collect energy from the foot following the ground and release it when the heel leaves the ground. This structure mainly includes pedals, guide rods, compression springs, and wedges. During walking, when the vertical distance between the end of the pedal and the ground is less than 10mm, the pedal will rotate, driving the compression spring of the guide rod [22-23]. During the mid support phase, the sole of the foot is completely in contact with the ground, and the elastic force is in the vertical direction, assisting in ankle dorsiflexion movement. When the heel leaves the ground, the elastic potential energy is released, and the spring pushes the foot side plate to rotate. In addition, the selection and parameter design of compression springs give them appropriate stiffness and compression stroke. The assembled ankle exoskeleton has a mass of 235g and does not affect normal foot movement. It can feel the pulse force when the heel is off the ground during walking. The stiffness calculation of the unilateral spring is Eq. (1).

$$k = \frac{Gw^4}{8nD^3} \tag{1}$$

In Eq. (1), the stiffness of the unilateral spring is k, and the shear modulus of elasticity is G. The diameter of the compression spring is w, the center diameter is D, and the effective number of turns is n. The shape and material stiffness of customized insoles have a significant impact on plantar pressure. Choosing materials with lower stiffness can increase the contact area between the foot and insole, and reduce plantar pressure. After damage to the plantar fascia, the height of the arch of the foot decreases, increasing the tension of the plantar ligaments and the stress on the midfoot and metatarsal bones. To prevent foot arch lodging and enhance arch stiffness, a support structure that fits the arch of the foot has been added to the flat insole. Through 3D-PT, different stiffness-filling patterns and unique insole shapes can be designed to meet the needs of different wearers. This study divides insoles into buffer zones and fit zones. The buffer zone includes the forefoot and heel, while the fit zone includes the middle of the foot. The buffer zone adopts a porous negative Poisson's ratio structure, which has a lightweight buffering effect. The fitting area is composed of an Arch Support Structure (ASS) and a honeycomb structure, which increases the contact surface between the ASS and the sole of the foot. The honeycomb structure is lightweight and has high stiffness. Finally, the Thermoplastic Polyurethanes (TPU) is selected as the insole material, which has good elasticity and wear resistance, meeting the comfort and safety requirements of medical insoles.

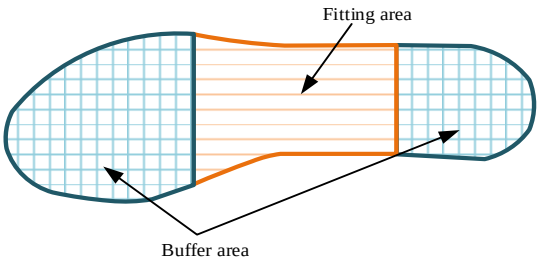

Fig. 3. Insole area division.

In Fig. 3, the design of the insole buffer zone is mainly aimed at the forefoot and heel, using a porous negative Poisson's ratio structure to increase contact area and reduce internal stress. This structure has special mechanical properties, which can cause lateral expansion when subjected to uniaxial longitudinal tension and lateral contraction when compressed, thereby improving buffering performance. Negative Poisson's ratio structures can be divided into two types: concave and porous, where concave structures generate two-dimensional rotation when subjected to tension. Porous structures achieve negative Poisson's ratio effects through the elastic instability of the material [24-25]. The structural design of the fitting area of the insole mainly adopts honeycomb structure and ASS. Honeycomb structure is a porous biomimetic structure with high strength and high stiffness ratio, which can effectively improve the support capacity of the bonding area. ASS helps to reduce shock absorption and disperse the weight transmitted to the sole of the foot, reducing excessive tension between the arch ligaments and muscles. In the design process, 3D scanning technology is first used to capture a realistic foot model of the human body, and then ASS is obtained through Boolean operations. Finally, ASS and honeycomb structure form the insole bonding area [26].

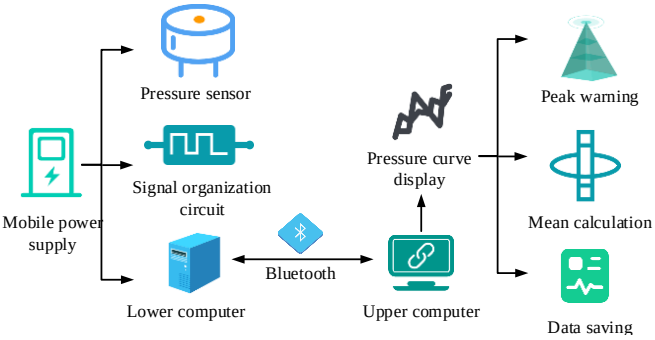

Fig. 4. Design of insole collection system.

In the insole collection system shown in Fig. 4, eight thin film sensors are distributed on the medical insole to collect pressure information. These sensors convert analog signals into digital signals through their built-in analog-to-digital converters. The wireless transmission module transmits digital signals to the upper computer powered by a 12V mobile power supply. The upper computer calculates the pressure value based on the load voltage fitting curve of sensors at different positions, and records the pressure peak, displays the plantar pressure curve, and saves data on the computer end. The output of the signal conditioning circuit is Eq. (2).

$$V_{out} = \frac{R}{R_s} V_{ref} = \frac{F}{K_c} R V_{ref} \tag{2}$$

In Eq. (2), the output of the signal conditioning circuit is V_{out}. The reference voltage is V_{ref}. The reference resistance is R. The resistance value of the pressure sensor under positive pressure F is R_s. The sensor coefficient is K_c.

B. Design of GR Algorithm

The main purpose of the GR algorithm is to extract discriminative features by analyzing the walking patterns of the human body to achieve individual identity recognition. Its key technologies include Gait Feature Extraction (GFE) and feature similarity calculation [27]. During the registration phase, users wear BPRSWDs while walking, and sensors collect data and upload it to the server. The server uses a Feature Extraction Network (FEN) to extract walking gait features and analyze the body's stress relief support. In the authentication stage, the server extracts the current walking features and calculates the similarity with the registration template [28].

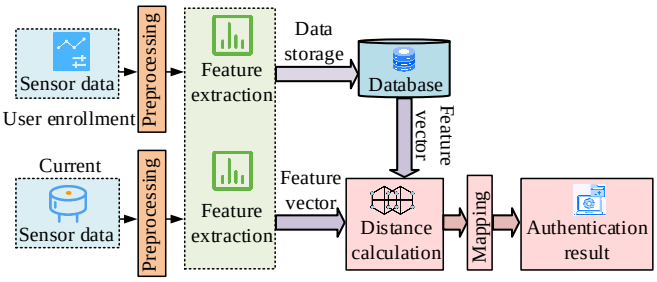

Fig. 5. Identity recognition system based on GR.

In Fig. 5, FEN is the core of the identity recognition system, responsible for extracting unique walking features from the swinging acceleration and angular velocity time series [29]. The characteristic of Full Convolutional Networks (FCN) based on time series features is that it does not include local pooling layers during the convolution process and maintains the length of the time series unchanged [30]. On this basis, this study proposes ConvBiGru-FCN for GFE. Convolutional Neural Network (CNN) is based on convolutional computation and constructs features by integrating spatial and channel information between levels. Previous studies have mainly focused on improving the quality of spatial coding and enhancing feature expression capabilities [31]. The Squeeze Excitation (SE) module focuses on the interdependence between channels and adaptively calibrates channel characteristic responses. This study improves the SE module to make it suitable for time-series feature extraction and implements a one-dimensional channel attention mechanism to distinguish the focus points and channel feature contributions of different convolutional kernels, thereby improving the effectiveness of gait identity recognition. The compression calculation in the SE module is Eq. (3).

$$z_c = F_{sq}(u_c) = \frac{1}{T}\sum_{i=1}^{T} u_c(i) \tag{3}$$

In Eq. (3), the compressed value of the channel is z_c, the compression operation is F_{sq}, the input feature map is u_c, and the time length is T. The calculation of incentive operation is Eq. (4).

$$s = F_{ex}(z, W) = \sigma(W_2 \delta(W_1 z)) \tag{4}$$

In Eq. (4), the channel weight vector is s and the excitation operation is F_{ex}. The vector obtained from the previous layer is z. The weight information obtained through learning is W. The parameter matrices are W_1 and W_2,

respectively. The Sigmoid and Relu activation functions are σ and δ. The weight update calculation is Eq. (5).

$$\tilde{x}_c = F_{scale}(u_c, s_c) = s_c u_c \tag{5}$$

In Eq. (5), the feature map obtained by updating the feature map with the weight vector is $\tilde{x}_c$, and the update operation is F_{scale}. By introducing the SE module, weight coefficients are assigned to each channel feature to achieve a channel based attention mechanism. This makes the model focus more on features that contribute significantly to GR, suppresses channel features that contribute less or no, and improves the model's identification ability for each channel feature. Another attention mechanism obtains weight vectors and updates feature map weights through the Dense layer and Softmax function. The ConvBiGru-FCN network obtained by combining the above two attention mechanisms is Fig. 6.

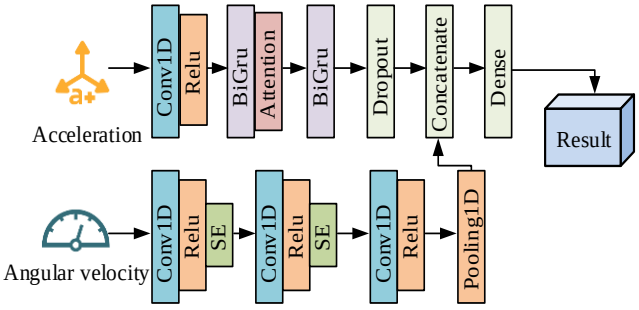

Fig. 6. Structure of ConvBiGru-FCN networks.

ConvBiGru-FCN uses FCN and Bidirectional Gated Recurrent Unit (BiGru) to extract feature information in parallel. FCN consists of three convolutional blocks and excels in time series classification. The BiGru module enhances the feature extraction ability of FCN, with a simpler structure, fewer parameters, and easier training convergence. To match the input dimension, a one-dimensional convolutional layer is added before BiGru instead of a permutation layer, as it has a certain degree of time series noise suppression ability, which helps to improve the feature extraction ability of the model. ConvBiGru-FCN introduces attention mechanism on the basis of the original structure to improve feature extraction ability. To add Attention Mechanism 1 in the FCN section, focusing on important features. To add Attention Mechanism 2 to the BiGru section to enhance the ability to capture bidirectional time series information. After dual channel feature extraction and feature layer fusion, the network outputs gait features through a fully connected layer. One of the key technologies of GR is to calculate the similarity between the current user's walking characteristics and the user feature template. The calculation process of the feature vector template is Eq. (6).

$$T_i = \frac{1}{n}\sum_{j=1}^{n} F(s_{ij}) \tag{6}$$

In Eq. (6), the feature vector template of the i-th user is T_i. The GFE network is F. The j-th walking sequence of user i during the registration process is s_{ij}. The number of time series in the registration phase is n. The calculation of gait similarity is Eq. (7).

$$d(x, y) = \frac{x \cdot y}{|x|^2 + |y|^2 - x \cdot y} \tag{7}$$

In Eq. (7), the eigenvectors of two time series are x and y respectively, and the distance between the two is $d(x, y)$. The normalization function converts distance values into similarity probabilities, and the calculation process is Eq. (8).

$$P = F_N(d(x, y)) \tag{8}$$

In Eq. (8), the similarity probability is P and the normalization function is F_N. To improve the generalization ability of GFE network and improve the accuracy of identity recognition system, this study uses Time-series Generative Adversarial Network (TimeGAN) to enhance the gait temporal dataset to solve the problem of small data volume and insufficient samples in practical scenarios. The TimeGAN structure is Fig. 7.

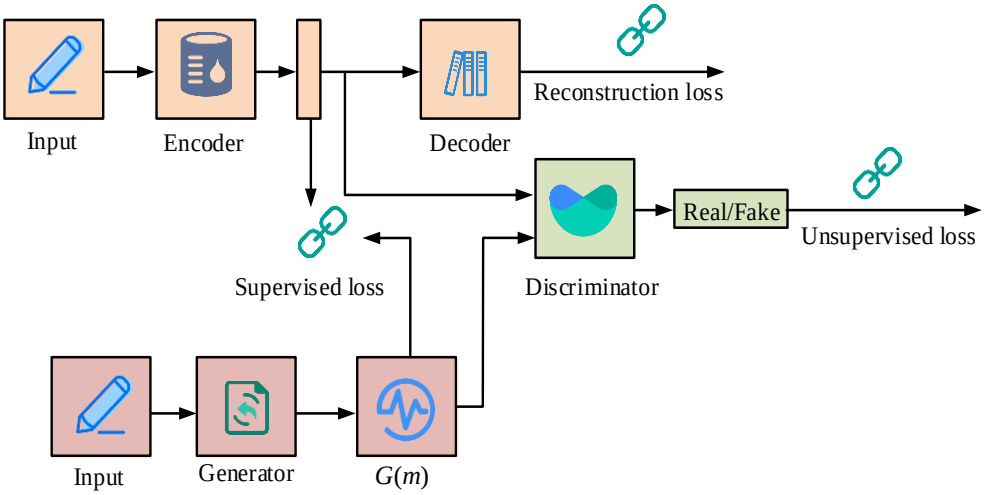

Fig. 7. TimeGAN structure.

TimeGAN is a temporal data generation enhancement method that combines unsupervised GAN and supervised auto-regressive models. It mainly consists of embedding function, recovery function, sequence generator, and sequence discriminator. The characteristic of TimeGAN is the joint training of automatic encoding components (embedding function and recovery function) and adversarial components (sequence generator and sequence discriminator), enabling it to simultaneously learn encoding features, generate sequence representations, and iterate across time, thereby maintaining temporal dynamic characteristics. The TimeGAN reconstruction loss function is Eq. (9).

$$L_R = MSE(G(m), m) \tag{9}$$

In Eq. (9), the reconstruction loss function is L_R, and the original input timing data is m. The timing data generated by the generator is $G(m)$, and the mean square error is calculated as MSE. The unsupervised loss calculation is Eq. (10).

$$L_U = -\alpha \cdot \sum_{i=1}^{n} (G(m[q]) * G(m[q+1])) \tag{10}$$

In Eq. (10), the unsupervised loss function is L_U, the regularization function is α, and a certain position in the sequence is q. The calculation of the supervised loss function is Eq. (11).

$$L_S = -\sum [r * \log(p(r \mid g(m)))] \tag{11}$$

In Eq. (11), the supervised loss function is L_S, and the true label is r. The probability distribution corresponding to the time series data generated by the generator is $p(r \mid g(m))$. The optimization function of TimeGAN is Eq. (12).

$$\min_{\theta_e, \theta_r} (\lambda L_S + L_R) \tag{12}$$

In Eq. (12), the embedded and restored network parameters are θ_e and θ_r, respectively, and the coefficient of the supervised loss function is λ. The second optimization function of TimeGAN is Eq. (13).

$$\min_{\theta_g} (\eta L_S + \max_{\theta_d} L_U) \tag{13}$$

In Eq. (13), the network parameters of the generator and discriminator are θ_g and θ_d, respectively, and the coefficient of the supervised loss function is η. This study uses TimeGAN to generate gait time series data to supplement the existing collected gait dataset and verify the effectiveness of identity GR. During the GR process, the pressure signals of the four sensors are F_1, F_2, F_3, and F_4. The proportion calculation of pressure information is Eq. (14).

$$\begin{cases} F_A = \dfrac{F_1}{F_1 + F_2 + F_3 + F_4 + N} \\ F_B = \dfrac{F_2}{F_1 + F_2 + F_3 + F_4 + N} \\ F_C = F_3 + \dfrac{F_4}{F_1 + F_2 + F_3 + F_4 + N} \\ F_N = \dfrac{N}{F_1 + F_2 + F_3 + F_4 + N} \end{cases} \tag{14}$$

In Eq. (14), the proportion of pressure at the heel, arch, and sole in the total is F_A, F_B, and F_C. The constant parameter is N. The proportion of a constant in the total is F_N. Before dealing with fuzzification, it is necessary to determine the fuzzy membership function and rule table. Fuzzy sets include two states: Positive Big (PB) and Zero Small (ZS). When the pressure ratio value is greater than the threshold, the fuzzy set is PB, and vice versa, it is ZS. Based on this, the fuzzy rule setting includes four states: early support, middle support, late support, and swing phase.

IV. Results and Discussion

The experiment uses 3D-PT to manufacture insoles with pressure reducing effects. By comparing the Electromyographic Signals (EMGS) of natural walking and wearing exoskeleton walking, the pressure reducing effect of intelligent insoles is verified. The GR algorithm is trained using ConvBiGru-FCN and compared with other networks in terms of performance.

A. Manufacturing and Forming of BPRSWDs

The experiment uses a Makerpi K5 Plus 3D printer to print BPRSWDs insoles. The printing process is divided into two parts: front and back. The front and rear parts of the insole are connected by two wedge-shaped blocks. The experiment explores 3D printing parameters, and Table I shows the final optimized parameters.

TABLE I. 3D Printing Parameters

Serial number	Parameter	Numerical value	Unit
1	Layer thickness	0.2	mm
2	Fill rate	20	%
3	Printing speed	40	mm/s
4	Nozzle temperature	210	℃
5	Hot bed temperature	75	℃
6	Consumable diameter	1.75	mm

After the 3D printing parameters are set, they are imported into the Cura printing processing software. After printing, glue is used to stick the front and rear parts, and waiting for the glue to settle and solidify before use. The 3D printer and physical image are shown in Fig. 8.

(a) Makerpi K5 Plus 3D printer (b) Physical image of insole

Fig. 8. 3D printers and physical images.

To collect plantar pressure from the human body, a Flexiforce A201 thin film pressure sensor is used in the experiment and installed on the surface of the insole. Four force measurement areas have been set on the insole, located at the first metatarsal bone, the third metatarsal bone, the arch of the foot, and the heel bone. Among them, sensors 1, 2, and 4 are used to reflect areas with high stress on the soles of the feet, and the magnitude of the pressure peak reflects the health of the feet. Sensor 3 is located on the arch fitting structure of the foot to verify its ability to withstand human weight. The experiment uses a dual track treadmill platform to provide different walking speeds and ground slopes for people wearing exoskeletons indoors. The experimental environment mainly includes a treadmill, muscle electrodes, sensor system, and upper computer. In the experiment, researchers compares the EMGS of natural walking and wearing exoskeletons to evaluate the decompression support effect of ankle exoskeletons. The EMGS of natural walking and walking with exoskeletons after bandpass filtering are displayed in Fig. 9.

Fig. 9(a) shows the EMGS during natural walking. The plantar and dorsiflexion movements of the foot involve the muscles on the anterior and posterior sides of the calf, and the EMGS fluctuate violently after being flat, with a significant phase difference between the two signals. Fig. 9(b) shows the EMGS of walking with an exoskeleton. Changes in the characteristics of EMGS can help muscles enhance strength and reduce fatigue, but may affect natural contraction and relaxation. The integrated value of EMGS is Fig. 10.

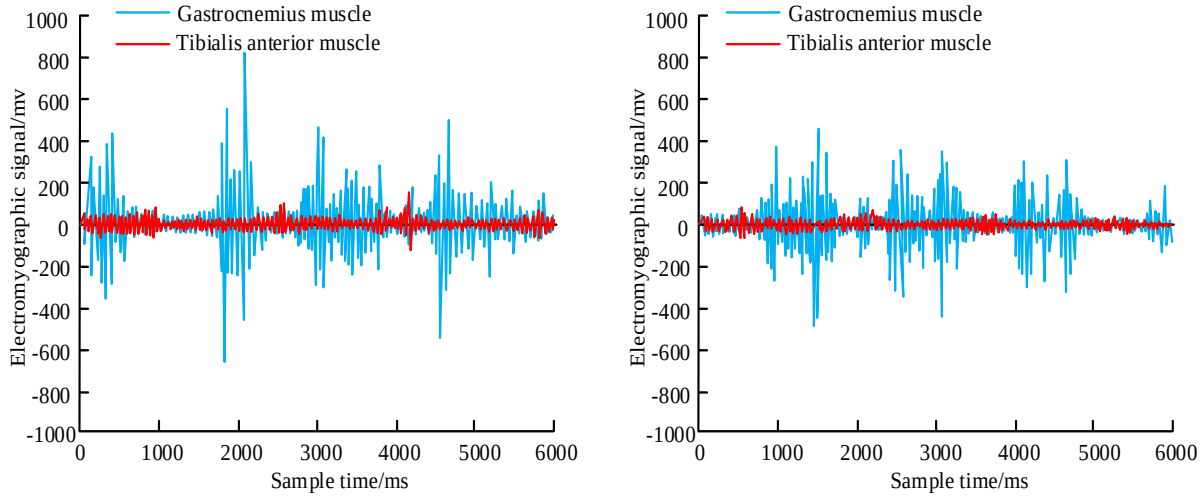

Fig. 9. The EMGS of human natural walking and walking with exoskeletons after bandpass filtering.

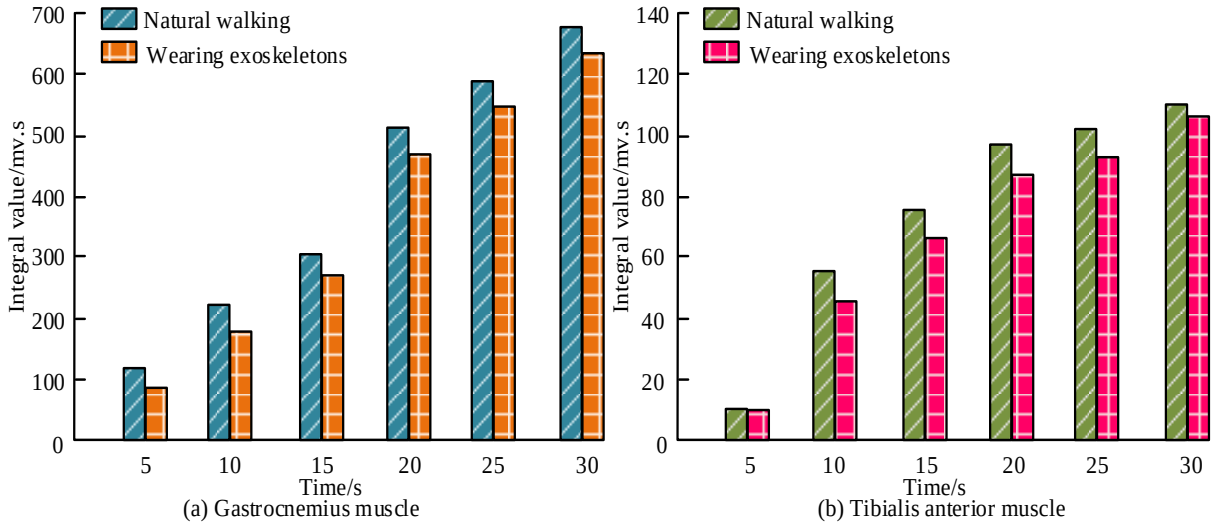

Fig. 10. Integrated value of EMGS.

Fig. 10(a) and 10(b) show the integrated values of gastrocnemius EMGS and anterior tibial EMGS for natural walking and walking with exoskeletons. When the human body wears exoskeletons, the EMGS integral values of the gastrocnemius and tibialis anterior muscles in the lower leg decrease. Compared to the natural state, when walking with exoskeletons, the EMGS integral values of the gastrocnemius and tibialis anterior muscles decreases by 5.4% and 3.6%, respectively. This indicates that the contraction characteristics of the lower limb muscles have been weakened, thereby proving that the ankle exoskeleton has a certain assisting effect. To verify the pressure reducing effect of intelligent insoles, a static plantar pressure measurement experiment is designed. The experiment uses a laser cutting machine to make acrylic boards of the same size as insoles, and divides them into eight areas. Volunteers stand on acrylic boards in different scenarios (wearing socks, flat insoles, medical insoles) and measure plantar pressure through thin film pressure sensors placed in each area. Table II shows the mean pressure in static plantar experiments.

TABLE II. MEAN PRESSURE IN STATIC PLANTAR EXPERIMENTS

Experimental method	1	2	3	4	5	6	7	8
Wearing socks	12.9	39.3	37.5	32.6	0.9	16.2	48.1	42.5
Ordinary insoles	5.4	34.4	24.5	27.3	0.9	11.8	34.5	36.2
Intelligent insoles	6.5	31.3	14.9	16.8	19.3	19.9	35.2	29.7

In Table II, labels 1-8 represent the first metatarsal region, the first metatarsal region, the second and third metatarsal regions, the fourth and fifth metatarsal regions, the lateral midfoot region, the arch region, the medial heel region, and the lateral heel region, respectively. Compared to the control group wearing socks and the regular insole, wearing smart insoles effectively reduces plantar pressure. The intelligent insole specifically optimizes the pressure distribution in the second and third metatarsal regions, fourth and fifth metatarsal regions, and the lateral side of the heel, while increasing pressure in the arch and medial areas of the foot. This indicates that the ASS and multi stiffness characteristics of intelligent insoles have to some extent reduced plantar pressure, but the pressure relief effect on the inner side of the sole can still be further improved.

B. Application Analysis of GR Algorithm

Fifteen subjects are selected for gait data collection in the experiment to form a dataset consisting of different time series lengths. The experiment divides the dataset into training, validation, and testing sets in a 6:2:2 ratio. The experiment uses ConvBiGru-FCN to train the data and achieve recognition of different gaits. To verify the effectiveness of ConvBiGru-FCN, Multi-layer Perceptron (MLP), Time-CNN, and FCN are used as contrast networks in the experiment. The convolution kernel size of ConvBiGru-FCN convolutional layer is 3 × 3, with a step size of 1. The hidden state size of the BiGru layer is 128, and in the fully convolutional layer, the number of output channels is the corresponding number of categories. The number of neurons in the fully connected layer between the MLP input layer and output layer is 128. The ReLU activation function is used, and the Softmax function is used for multi classification in the output layer. The convolutional kernel size of the Time CNN convolutional layer is 3×3 with a step size of 1, and the pooling kernel size of the pooling layer is 2×2 with a step size of 2. The experiment set the time series length to 60, and the performance comparison results of different networks are shown in Fig. 11.

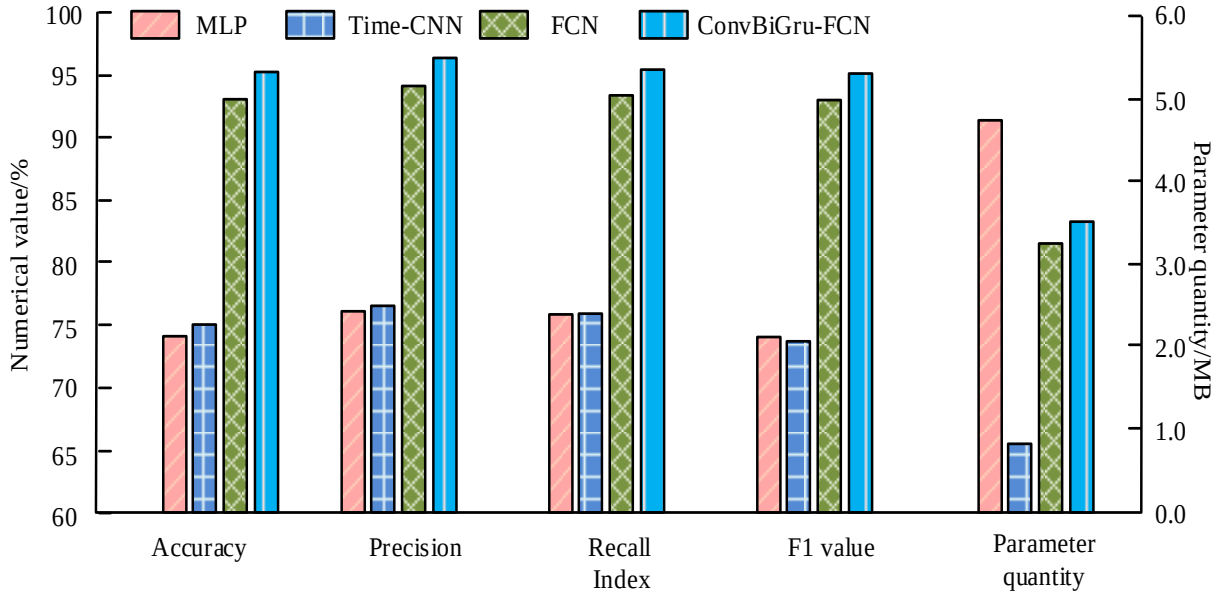

Fig. 11. Performance comparison results of different networks.

In Fig. 11, there are significant differences in the performance of various models in identifying subject identities when the sequence length is 60. ConvBiGru-FCN outperforms other networks in terms of accuracy, precision, recall, and F1 score. The accuracy of ConvBiGru-FCN reaches 95.26%, which is 2.03% higher than FCN, while its parameter count is only 3.42M, slightly higher than FCN. This indicates that ConvBiGru-FCN is an effective feature extraction method and exhibits good performance in GR tasks. The visualization results of network feature extraction are shown in Fig. 12.

In Fig. 12, the numbers 1-15 represent the features of 15 users, respectively. Fig. 12(a) to (d) show the visualization results of feature extraction for MLP, Time-CNN, FCN, and ConvBiGru-FCN networks, respectively. ConvBiGru-FCN has a good discriminative effect in identifying different gait identity categories. In contrast, MLP, Time-CNN, and FCN have poorer performance in distinguishing identity categories. This indicates that ConvBiGru-FCN has a high feature extraction ability in GR tasks and can effectively extract gait information from subjects. The relative error of ConvBiGru-FCN gait prediction in both stationary and walking states of the human body is Fig. 13.

In Fig. 13, under both stationary and walking states, the calculated curve of user GR in ConvBiGru-FCN is generally close to the true value, and the relative error of user GR prediction is mostly in the range of 0% -8%, indicating a good overall fitting effect. To verify the effectiveness of the proposed GR algorithm combined with BPRSWDs, the pressure curve is used as the validation object for the GR algorithm in the experiment. The variation curves of proportional signal and fuzzy output signal are shown in Fig. 14.

Fig. 14 (a) (b) shows the variation curves of the proportional signal and the fuzzy output signal. The fuzzy output signals u_1, u_2, and u_3 are used to divide the early and middle stages of the support phase, the middle and late stages of the support phase, and the support phase and swing phase, respectively. There is a difference in the proportion of left and right feet in each stage of the gait cycle. The initial proportion of support for the left foot is too long, which may be related to the high support structure of the left foot insole, resulting in a prolonged force on the heel and a reduced contact time between the forefoot and the ground. The proportion of SSP and double support phases during walking is obtained by combining the fuzzy output signals of the left and right feet, which are 92.7% and 7.3%, respectively.

C. Discussion

Research has been conducted to manufacture intelligent insoles with pressure reduction effects through 3D printing technology, and the pressure reduction effect of intelligent insoles has been verified by comparing the EMGS of natural walking and walking with exoskeletons. When training the GR algorithm, ConvBiGru-FCN was studied and compared with other networks. In the process of manufacturing and forming BPRSWDs, the 3D printing parameters were optimized experimentally, and the pressure distribution of the feet was measured using the Flexiforce A201 thin pressure sensor. The experimental results show that compared to the natural state, when walking with smart insoles, the pressure distribution of the feet is effectively optimized, especially in the second and third metatarsal regions, fourth and fifth metatarsal regions, as well as the pressure distribution in the arch and medial heel regions. ConvBiGru-FCN has high accuracy, precision, recall, and F1 score in identifying different walking postures, with an accuracy rate of 95.26%. In addition, we also visualized the network feature extraction, and the results showed that ConvBiGru-FCN has good discriminative performance and can effectively extract walking information from subjects. When standing and walking, the calculated curve of ConvBiGru-FCN is approximately close to the true value, with a relative error between 0% and 8%, indicating a good overall fitting effect. This study provides a new method for the design and manufacturing of intelligent insoles. By combining the GR algorithm, it can achieve recognition of walking posture and optimization of pressure distribution, thereby improving walking comfort and reducing foot pressure.

V. Conclusion

This study optimized BPRSWDs, including insoles and ankle exoskeletons, through 3D-PT design, and combined them with the GR algorithm to achieve individual identity recognition and gait analysis. This study used a dual track treadmill platform and evaluated the decompression support effect of ankle exoskeletons through comparative experiments with EMGS. Meanwhile, the pressure reducing effect of the intelligent insole was verified through static plantar pressure

experiments. The results showed that compared to the natural state, the EMGS integral values of the gastrocnemius and tibialis anterior muscles decreased by 5.4% and 3.6% respectively when walking with exoskeletons. This indicated that the contraction characteristics of the lower limb muscles had been weakened, and the ankle exoskeleton had a certain assisting effect. In addition, the ASS and multi stiffness characteristics of smart insoles to some extent reduced plantar pressure. In terms of GR algorithm, the accuracy of ConvBiGru-FCN reached 95.26%, which was 2.03% higher than FCN. Moreover, the study also processed the plantar pressure signal through fuzzy logic, achieving an analysis of the proportion of SSP and double support phases during walking. In summary, this study achieved the optimization design of BPRSWDs through the fusion of 3D-PT and GR algorithms, providing useful references for research in the fields of GR and body decompression support. However, there are still some limitations to this study, such as a small sample size and the need to improve the generalization ability of the GR algorithm. Future research can further expand the sample size, enhance the generalization ability of the GR algorithm, and explore more optimization design solutions to achieve more precise and intelligent design of BPRSWDs.

Implementation of Improved Raft Consensus Algorithm in IoT Information Security Management

Mingzhen Zhang
School of Artificial Intelligence, Zhengzhou Railway Vocational and Technical College, Zhengzhou, 451460, China

***Abstract*—In the context of the rapid expansion of the Internet of Things, information security management has become particularly crucial. In response to the performance bottleneck of traditional Raft consensus algorithms, this study proposes an improved Raft algorithm that combines density noise spatial clustering algorithm and vote change mechanism, aiming to improve the quantity processing efficiency and consistency of Internet of Things systems in large-scale environments. Firstly, a density noise spatial clustering algorithm is added to the traditional Raft algorithm to partition all consensus nodes into multiple sub clusters. Subsequently, a vote change mechanism is introduced to optimize the leadership election process. Finally, an Internet of Things information security management model is built using the improved Raft algorithm. The results showed that the improved Raft algorithm could complete 500 client requests in just 9.5 minutes of consensus trading time. The log replication accuracy of the management model built using this algorithm under four bandwidth conditions of 0.5Mbps, 5Mbps, 50Mbps, and 500Mbps was as high as 0.98, 0.99, 0.98, and 0.97, respectively. Therefore, the designed consensus algorithm not only has good data processing capabilities, but the model built using this algorithm can also achieve good performance in practical applications.**

I. Introduction

With the popularization of the Internet of Things (IoT), from smart home to industrial automation, countless devices are connected through the Internet, producing a large amount of data. The value of these data is enormous, but it also raises serious concerns about security and privacy, such as unauthorized data access, data tampering, and device manipulation [1-2]. In this context, a powerful and reliable Information Security Management (ISM) system is needed to protect this data. Consensus algorithms play a crucial role in this process, ensuring that multiple nodes in the network reach consensus on the authenticity and consistency of data without central authority [3]. However, with the surge in the number of IoT devices, traditional consensus algorithms such as Raft face challenges in processing efficiency and scalability [4-5]. Therefore, improving these algorithms and effectively applying them to IoT-ISM has become an urgent issue that needs to be addressed. In the context of the rapid development of the IoT, although the Raft consensus algorithm has been widely used in many fields, its efficiency and scalability in large-scale and highly dynamic environments still have obvious limitations. Most existing research focuses on improving the efficiency and security of consensus algorithms, however, these studies often only focus on the consensus algorithm itself, without involving comprehensive solutions for applying it to IoT-ISM. The aim of this study is to enhance the efficiency and consistency of Raft consensus algorithm for processing large numbers of data nodes in IoT environment by improving it. The objective of this study is to design and implement an improved Raft algorithm combining Density-Based Spatial Clustering of Applications with Noise (DBSCAN) and Vote Change Mechanisms (VCM) to improve the processing efficiency and data consistency of IoT-ISM. The importance of this paper is that it can significantly improve the data processing capabilities and security of IoT devices, providing practical solutions and theoretical basis for the sustainable development of IoT technology.

The main contribution of this study is to propose an improved Raft consensus algorithm combining DBSCAN and VCM. This improvement has the dual benefit of optimizing data processing efficiency and system consistency in the IoT-ISM, as well as corroborating the significant effect of the algorithm on improving log replication accuracy and reducing Consensus Transaction Time (CTT). In addition, this study also constructs an improved Raft algorithm based on the IoT-ISM model, which demonstrates superior performance in different network bandwidths and complex environments. Consequently, this study not only offers an efficacious technical solution for the ISM of the IoT, but also provides a novel perspective and empirical data to support the research of consensus algorithms.

The structure of this paper is as follows: The first part reviews the relevant work, discusses the existing consensus algorithm and its application in the IoT-ISM, and points out the shortcomings of the existing research. The second part details the design of the improved Raft consensus algorithm, including the integration of DBSCAN and the introduction of VCM. The third part describes the construction process of the IoT-ISM model based on the improved Raft algorithm, and shows the specific framework of the model. The fourth part verifies the performance of the improved algorithm and model through experiments, including the evaluation of key indicators such as CTT, log replication accuracy and system adaptability. Finally, the paper summarizes the full text and discusses the theoretical and practical significance of the research results. At the same time, the future research direction is prospected.

II. Related Works

To improve the correctness and immutability of all transactions in blockchain, many experts have optimized consensus algorithms. Rong B et al. explored the optimization strategy of Raft consensus algorithm in the rapid growth of distributed clusters and the rapid decline of throughput, and

proposed a federal restructuring committee Raft consensus algorithm. This algorithm was based on federated reconstruction technology, which trained, updated, and evaluated the feature dataset model of Raft nodes, selected nodes with better performance, constructed a committee mechanism, and improved the quality and speed of elections. At the same time, to address the inconsistency and security issues in federated aggregation, a semi-asynchronous buffering mechanism and defense strategies against malicious node attacks have been designed. The effectiveness of this algorithm has been validated in consensus clusters [6]. Raft consensus algorithm is a key technology for state replication in distributed systems. The state updates in Raft consensus algorithm are influenced by the leader node, and the system response time is also affected by the delay between nodes. Choumas K et al. proposed a mathematical model to estimate the waiting time range that affects the probability of leadership elections in Raft consensus algorithm, aiming to reduce the expected response time of the system. The performance of the model was validated through the open-source Raft testing platform in the article, which showed that optimizing the interval time can improve the probability of selecting leader nodes in the Raft consensus algorithm, thereby optimizing the node selection results [7]. To overcome the scalability limitations and high cost issues of blockchain applications in IoT systems, Guo H et al. proposed a consensus protocol algorithm with a hierarchical structure and location awareness, referred to as LH-Raft. It confirmed the scalability of LH-Raft in large-scale IoT applications. This algorithm could effectively reduce communication costs, consensus latency, and protocol time [8]. Aiming at the problems of vote falsification and malicious election of candidate nodes existing in the traditional Raft consensus algorithm, Tian S et al. proposed a new consensus algorithm combining zero-trust mechanism and secret sharing technology, which was recorded as VSSB-Raft. This algorithm achieved zero-trust through monitoring nodes and secret sharing algorithms, without relying on hidden trust between nodes. It also used the SM2 signature algorithm to strengthen authentication before data usage, ensuring data security. In addition, by introducing named data network, the communication mode between nodes was redesigned to ensure the quality of node communication. The results demonstrated that VSSB-Raft consensus algorithm achieved high throughput and low consensus delay while maintaining algorithm complexity, effectively improving system security and efficiency [9].

IoT environments typically involve a large number of devices and sensors that generate, collect, and exchange large amounts of data. In this environment, ensuring the security, privacy, and integrity of data is a major challenge. Khan A et al. proposed a novel blockchain architecture BHI-IoT for electronic health data security. This architecture aimed to enhance network resources and trust in industrial IoT by optimizing data management and distributed layered architecture of medical wireless sensor networks. BHI-IoT adopted NuCypher threshold re-encryption mechanism to protect data, utilizing customized lightweight blockchain and digital signatures with multiple proof of work and multiple proof of rights to reduce resource consumption and storage burden. This framework could effectively improve the security and efficiency of IoT systems in the electronic health industry [10]. Hasan N et al. proposed a blockchain driven network physical system. This system aimed to achieve ISM and lightweight data management in IoT systems by utilizing smart contracts and peer-to-peer databases. The system solved data storage and transmission problems through the integration of private blockchain and intelligent device micro-controllers, and demonstrated the application effect of the system in food supply chain traceability [11]. In the medical field, IoT faced challenges in patient information privacy and data integrity. ElRahman S A et al. proposed an IoT-Edge framework that integrates blockchain technology to securely exchange data, ensure data integrity and privacy. This framework allowed IoT devices to remotely monitor patient status while ensuring secure transmission and storage of patient data. User friendly system design provided necessary tools for information integrity and confidentiality. After simulation testing, the framework has proven its feasibility in medical applications [12]. Aiming at the trust management challenges caused by limited bandwidth and long latency in underwater IoT, Jiang J et al. proposed a dispute adjudication method to deal with trust recommendation conflicts, and developed a new trust management mechanism based on this. The mechanism included three stages: trust calculation, trust recommendation and trust evaluation. By collecting trust evidence such as packet transmission rate and combining with incentive mechanism based on prisoner's dilemma, the neighbor was encouraged to participate in trust recommendation. Simulation results showed that this mechanism was superior to existing studies in terms of accuracy and robustness [13].

In summary, consensus algorithms play a crucial role in distributed computing and blockchain technology, and many experts have conducted a series of optimization studies on consensus algorithms. Currently, most research only focuses on the consistency and integrity issues of consensus algorithms, and few experts have conducted joint research on consensus algorithms and IoT's ISM. Based on this background, this study aims to optimize Raft consensus algorithm by combining clustering algorithms and VCM, and use optimization algorithms to build a complete IoT-ISM model, aiming to further improve the storage and privacy issues of IoT big data.

III. IoT-ISM Based on Improved Consensus Algorithm

To ensure the privacy and security of IoT information, this study first optimizes the traditional Raft consensus algorithm by using the DBSCAN algorithm and VCM to change its election mechanism. By using a multi-cluster structure to increase the number of leaders and distribute the load of the entire consensus system, the efficiency of the algorithm is improved. On this basis, a complete IoT-ISM model is constructed using an improved Raft consensus algorithm.

A. Improved Raft Consensus Algorithm Design Integrating DBSCAN and VCM

In Raft consensus algorithm, all nodes in the cluster are divided into three roles: leader, follower, and candidate. At the beginning, all nodes are followers. If the follower does not receive information from the leader within a certain period of time, it will become a candidate and start a new round of

elections. Once a leader is selected, the leader node will be responsible for managing client requests and copying them as log entries to other nodes. It is only when these log entries are stored by the majority of nodes that the operations in question can be committed and applied to the state machine of each node. In Raft consensus algorithm, term is a very important concept. Term is a logical clock used in Raft consensus algorithm to distinguish different time periods, mainly used to solve the problems of leader election and log replication in distributed systems. Fig. 1 shows the term structure and node transition process.

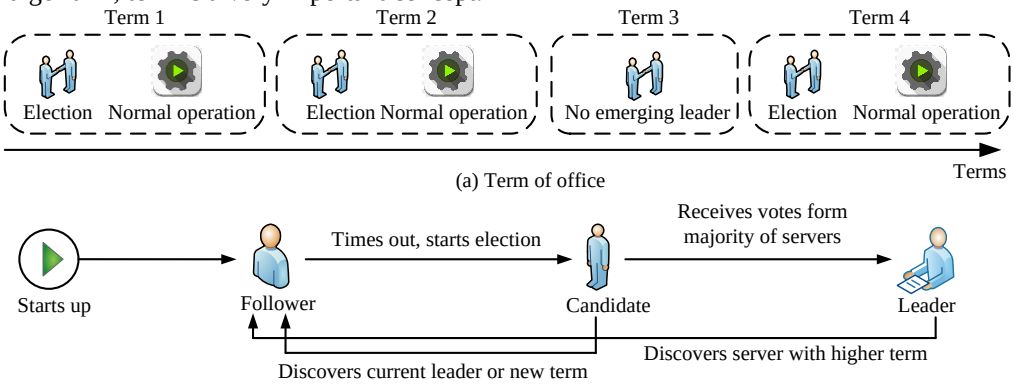

Fig. 1. Term structure and node transition diagram.

In Fig. 1 (a), each term represents a period of time, such as Term1, Term2, Term3, etc. During this period, a node in the cluster will act as the leader to coordinate the replication of logs. The term of office is identified by consecutive integers, and the term number increases every time a new leader election occurs. Each leader node has a certain period of tenure, during which the leader node will perform leadership actions. During a term, only one leader will be elected. If a leader loses contact with most nodes for some reason, a new term will begin and a new round of leader elections will be held. In Fig. 1 (b), all nodes of Raft will default to the follower state at startup. If the follower does not receive the leader's information within the scheduled time, they will become candidates and initiate a new round of elections by increasing their term number and requesting other nodes to vote. If the candidate receives a majority of votes, they become the leader. If a candidate receives information from the current leader or does not receive a majority of votes, the candidate will either retreat to their followers or start a new round of elections. Considering that traditional Raft consensus algorithm heavily relies on the performance of the leader node, the performance of traditional Raft consensus algorithm will be affected as the number of follower nodes continues to increase. Therefore, this study proposes an improved Raft consensus algorithm that integrates DBSCAN and VCM, and the improved algorithm is referred to as DBSCAN-Raft. The flowchart is Fig. 2.

In Fig. 2, the DBSCAN-Raft algorithm first uses clustering methods to divide all consensus nodes into multiple sub clusters. Each sub-cluster elects a sub-leader through Raft, with the remaining nodes serving as followers. These sub-leaders then form the main cluster and execute the Raft algorithm as a whole. To avoid deadlock caused by competition among multiple candidates, VCM is introduced. When no candidate receives more than half of the votes, the candidate with the highest number of votes will become the leader. By using a multi-cluster structure to increase the number of leaders and distribute the load of the entire consensus system, algorithm efficiency can be improved.

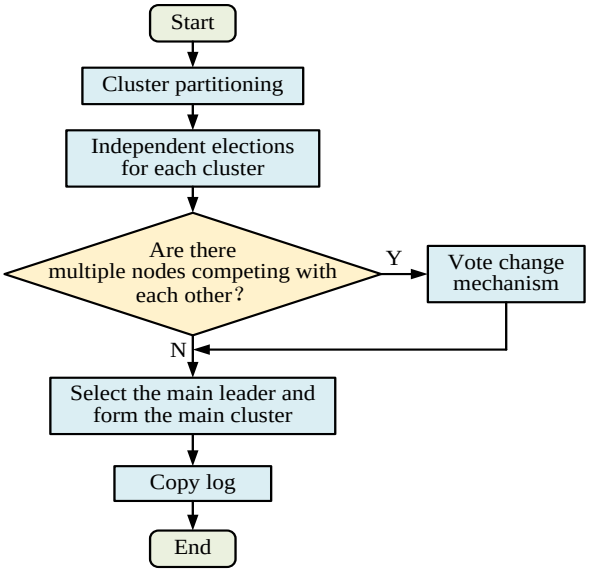

Fig. 2. Flowchart of the operation of DBSCAN-Raft.

In cluster analysis, it is assumed that there is a dataset X with dimension D and n data points. The expression of X is Eq. (1).

$$X = \left\{ x_i \middle| x_{i,1}, x_{i,2}, x_{i,3}, \cdots x_{i,j} \right\} \quad (1)$$

In Eq. (1), x_i represents the data in the dataset, $i \in [1, n]$. j represents the dimension in which each data is located, $j \in [1, D]$. According to the similarity between data points, the data is divided into groups as shown in Eq. (2).

$$C = \{C_1, C_2, \cdots, C_k\} \quad (2)$$

In Eq. (2), C represents the data group, and k represents the category of the data group. When dividing data groups, the constraints in Eq. (3) need to be met.

$$\begin{cases} C_p \neq \varnothing \\ C_1 \cup C_2 \cup, \cdots, \cup C_k = X \\ C_P \cap C_q \neq \varnothing \quad p \neq q \end{cases} \tag{3}$$

In Eq. (3), p and q represent two different groups, $p, q \in [1, k]$, respectively. There are a total of three constraints that need to be met in Eq. (3). Firstly, each group is not an empty set and must contain at least one data. Secondly, the union of all grouped sets is the entire dataset. Thirdly, there is no inclusion relationship between each group, meaning that one data belongs only to one group. In DBSCAN, assuming the domain of data point a is $N_\varepsilon(a)$, its expression can be expressed as Eq. (4).

$$N_\varepsilon(a) = \left\{ b \in D_s \middle| d(a,b) \leq \varepsilon \right\} \tag{4}$$

In Eq. (4), D_s represents the dataset. b represents another data point. $d(a,b)$ represents the distance between a and b. ε represents the field. The calculation of density is Eq. (5).

$$\rho(a) = \left| N_\varepsilon(a) \right| \tag{5}$$

In Eq. (5), $\rho(a)$ represents the density value of a. The density value reflects the number of data points included in the ε domain. The expression for the core point is Eq. (6).

$$\rho(a) \geq \text{MinPts} \tag{6}$$

In Eq. (6), MinPts represents the density threshold. When equation (6) holds, then a will become the core point. The boundary points is expressed as Eq. (7).

$$\begin{cases} \rho(a) < \text{MinPts} \\ a \in N_\varepsilon(b) \end{cases} \tag{7}$$

In Eq. (7), when a satisfies the conditions in Eq. (7), a becomes a non-core point, i.e. a boundary point. Due to $a \in N_\varepsilon(b)$, b will become the core point at this time. The expression of noise points is Eq. (8).

$$\rho(a) \neq \text{MinPts} \tag{8}$$

In Eq. (8), when a is neither the core point nor the boundary point, it is recorded as a noise point. Assuming that DBSCAN has a set of C_l that satisfies the clustering conditions as shown in Eq. (9).

$$\begin{cases} C_l \in D_s \\ C_l \neq \varnothing \\ a, b \in C_l \end{cases} \tag{9}$$

In Eq. (9), when C_l is non-empty and belongs to dataset D_s, two conditions will be met. Firstly, if $a \in C_l$ and the density from a to b can reach, then there exists $b \in C_l$. Secondly, if $a, b \in C_l$, it indicates that a and b are connected in density. Using kernel density estimation method to optimize the value of ε, the calculation is Eq. (10).

$$\hat{f}_h(x) = \frac{1}{n} \sum_{i=1}^{n} K_h(x - x_i) \tag{10}$$

In Eq. (10), $\hat{f}_h(x)$ represents the probability density function estimated using sample data at data x. $K(\cdot)$ represents the kernel function, which is generally represented using a standard Gaussian function [14]. h represents the bandwidth parameter used to control the width of the kernel function, and its determination formula is Eq. (11).

$$MISE(h) = \frac{\int K^2(x)dx}{nh} + \frac{h^4 \sigma^4 \int \left[f''(x) \right]^2 dx}{4} + \left(\frac{1}{nh} + h^4 \right) \tag{11}$$

In Eq. (11), $MISE(h)$ represents the mean square error value of kernel density estimation. $K^2(x)dx$ represents the square integral of $K(\cdot)$, used to measure the smoothing characteristics of the kernel function itself. σ represents the standard deviation of the data. $\int \left[f''(x) \right]^2 dx$ represents the integral of the square of the second derivative $f''(x)$ of the probability density function. Using the rule of thumb to optimize Eq. (11), the optimal solution formula for ε is ultimately obtained as shown in Eq. (12).

$$h' = \left(\frac{4}{3n} \right)^{\frac{1}{5}} \sigma \tag{12}$$

In Eq. (12), h' represents the optimal solution ε obtained. By using the above formula, node clustering can be completed, and the topology diagram of node clustering is Fig. 3.

In Fig. 3, after completing cluster partitioning, the core points and their associated boundary points form a separate cluster, and Raft consensus algorithm is used for consensus operation. For noise points that have not been classified into any specific cluster, this study incorporates them into the main cluster to participate in the consensus process. In addition, during the voting stage of leader elections, to solve the situation of deadlock among multiple candidate nodes, this study designs a VCM strategy, through which the candidate node with the most votes can obtain the leader position.

B. Construction of IoT-ISM Model Based on DBSCAN-Raft

After optimizing the Raft algorithm using DBSCAN and VCM, this study further builds an IoT-ISM model based on the improved DBSCAN-Raft. It aims to protect user data privacy and store user information through this model. Fig. 4 shows the constructed IoT-ISM model framework.

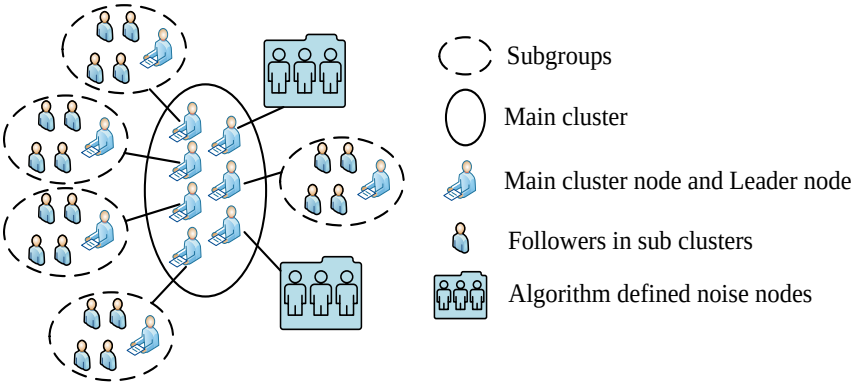

Fig. 3. Node clustering topology.

In Fig. 4, a complete IoT-ISM model mainly consists of a Data Processing Layer (DPL), Clustering and Annotation Layer (C/AL), Consensus Mechanism Layer (CML), Secure Communication Layer (SCL), Main Cluster Management Layer (MCML), Decision and Response Layer (D/RL), and Monitoring and Maintenance Layer (M/ML) [15-16]. DPL is segmented into data collection and pre-processing. Firstly, it deploys device nodes on IoT devices, collects data through the devices, processes input data from sensors, removes noise and outliers, and standardizes data formats. Finally, meaningful information is extracted from the raw data as features. C/AL mainly clusters preprocessed data to determine core points, boundary points, and noise points. In addition, this layer also needs to annotate the data points in the clustering results to identify key and non key data. CML executes DBSCAN-Raft and selects the leading node to complete log replication. SCL aims to ensure the encryption and security of data during transmission, ensuring that only authorized nodes can participate in the consensus process. MCML aims to incorporate all sub-leader nodes into the main cluster and elect the main leader through DBSCAN-Raft. The main leader then coordinates with each sub-leader node to synchronize the status information of each sub-cluster. D/RL will automatically execute business logic based on consensus results, and execute corresponding security measures based on decisions, such as data backup, recovery, and intrusion response. M/ML will monitor the real-time operation status of the IoT environment, regularly maintain and update the system to adapt to environmental changes and new security threats [17].

Within the consensus layer composed of DBSCAN-Raft, data is stored between nodes through logs. The leader node is responsible for various requests initiated by the client and carries out a series of log copying and confirmation processes. The core purpose of this process is to ensure that the data of all nodes in the cluster remains synchronized. When a client initiates a transaction request, it is first processed by the leader node, which is then responsible for propagating these log entries to the follower node. To maintain data consistency in the system, the leader node will follow two basic principles: First, it will not delete any client request records, and second, the follower node will only synchronize log data from the leader node. The process of log replication is Fig. 5.

The log replication in Fig. 5 needs to follow the following steps. Firstly, the request initiated by the client contains pending commands to be executed. Next, the leader adds the command as a new log entry to their log file and broadcasts it to other follower nodes through remote procedure call communication, requesting them to copy the entry. After the follower node completes replication, it will provide feedback to the leader on its replication status. Once the leader receives confirmation of successful replication from most nodes, it can be considered that the log entry replication is complete [18-19]. The leader then updates their state machine and reports success to the client. On the contrary, if no majority response is received, a failure is reported to the client [20-21]. The node state changes under normal log replication and the log replication state under conflict state are shown in Fig. 6.

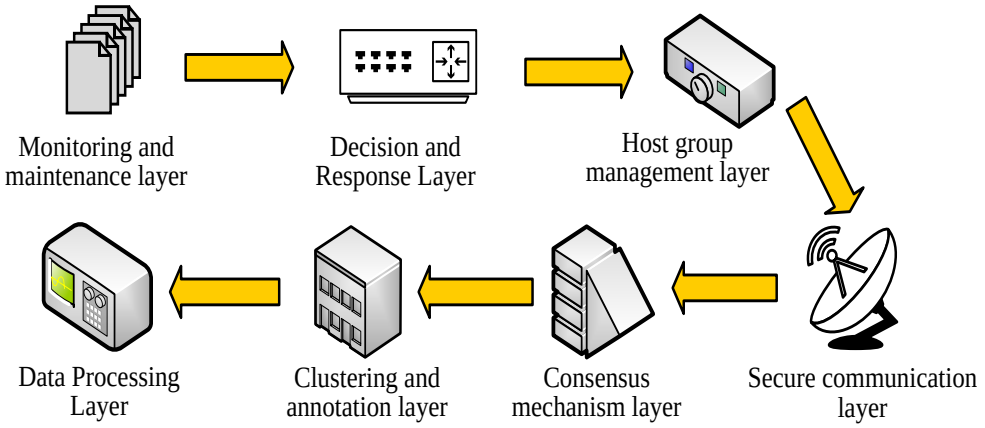

Fig. 4. IoT-ISM model.

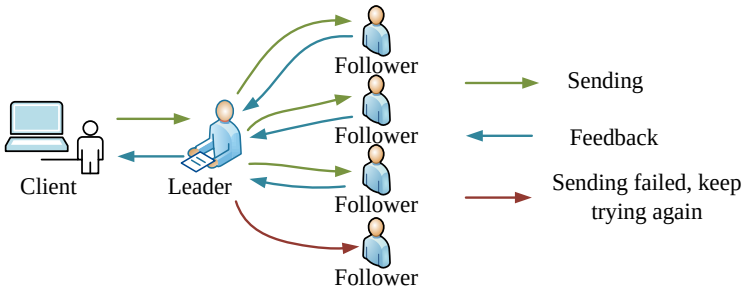

Fig. 5. Log replication flowchart.

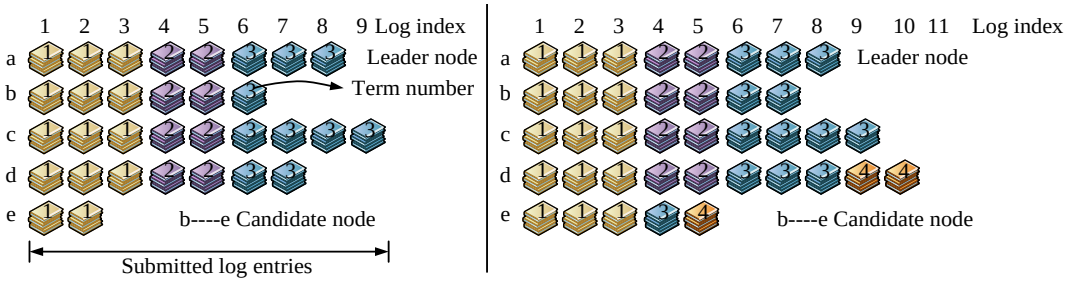


(a) Log replication of node status (b) Log replication when data is inconsistent

Fig. 6. Log replication in node state and conflict state.

Fig. 6 (a) and (b) show the node state changes under normal and abnormal log replication states. In Fig. 6 (a), nodes a and c have the longest logs and are eligible to become leaders, while nodes b and d are synchronizing logs, while node e stops operating due to anomalies. In this consensus model, the log with index 7 has been consensus among three nodes, and the number of confirmed nodes exceeds more than half of the nodes in the cluster [22-23]. Therefore, log entries below number 7 are considered as consensus and cannot be modified. In 6 (b), the logs of each node may not be consistent with the logs of the new leader. The task of a leader is to restore consistency by having followers abandon conflicting logs and synchronize their logs. The newly selected leader first aligns with the logs of other nodes. If a mismatch is found, consistency checks are performed in the additional log request. If it fails, the log number is not updated and is gradually rolled back to find a matching point. Once it is found, followers will remove the conflict log, adopt the leader's log, and reach a consensus. In the example shown in Fig. 6 (b), node a as the leader does not need to change, node b remains in its current state, node c deletes the last log entry, node d deletes two logs with a term of 4, and node e deletes one log with a term of 4. After completing their respective deletion tasks, each node will synchronize the remaining logs of the leader to ensure data consistency and system security.

IV. Performance Testing of DBSCAN-Raft and Analysis of the Application Effect of ISM Model

To demonstrate the effectiveness of the designed Raft consensus algorithm and ISM models, this study first tests the performance of DBSCAN-Raft. On this basis, the application effect of the ISM model built using DBSCAN-Raft in practical problems is further verified.

A. DBSCAN-Raft Performance Testing

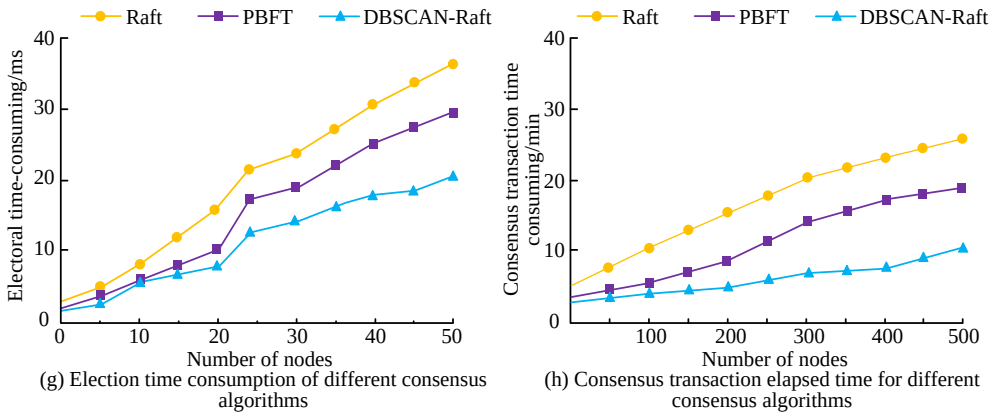
To ensure that all consensus algorithms can be tested in the same experimental environment and effectively avoid experimental errors, the experimental testing environment shown in Table I is constructed in this study.

TABLE I. Experimental Test Environment

Experimental equipment	Value
CPU	Intel Core i9-10900K
GPU	NVIDIA RTX 3080
Memory	4GB RAM 100GB SSD
Graphics Memory	Ubuntu14.04 64-bit
Systems	Windows 10 Python 3.8
Software	Hyperledger Fabric and Caliper

Table I provides the specific settings of the experimental testing environment. The experiment involves setting up 500 client requests and requesting consensus from the cluster at a speed of 200tps. Traditional Raft and Practical Byzantine Fault Tolerance (PBFT) are used as comparative algorithms to obtain the election and CTT of Raft, PBFT, and DBSCAN-Raft under the same experimental conditions, as shown in Fig. 7.

Fig. 7 (a) and 7 (b) show the Election Elapsed Time (EET) and CTT of the three algorithms, respectively. In Fig. 7 (a), as the Number of Nodes (NN) gradually increases from 0 to 50, the EET of Raft, PBFT, and DBSCAN-Raft all show a continuous upward trend. Compared to PBFT and DBSCAN-Raft, Raft has the largest increase in amplitude. When the NN is 50, the EET of Raft, PBFT, and DBSCAN-Raft are 36.8ms, 28.9ms, and 19.7ms, respectively. In Fig. 7 (b), when Raft, PBFT, and DBSCAN-Raft finally completes 500 client requests, the CTTs used are 26.6 minutes, 18.4 minutes, and 9.5 minutes, respectively.



(g) Election time consumption of different consensus algorithms

(h) Consensus transaction elapsed time for different consensus algorithms

Fig. 7. EET and CTT for different consensus algorithms.

Fig. 8 shows the throughput of Raft, PBFT, and DBSCAN-Raft when processing different NNs. When NN increases from 10 to 100, the throughput values of Raft, PBFT, and DBSCAN-Raft all decrease, but the decrease in DBSCAN-Raft is the smallest. When the NN is 10/100, the throughput sizes of Raft, PBFT, and DBSCAN-Raft are 23.6tps/6.9tps, 27.1tps/11.4tps, and 28.8tps/17.5tps, respectively.

Fig. 9 (a) and 9 (b) show the energy consumption and stability curves of the three consensus algorithms, respectively. In Fig. 9 (a), when NN increases from 0 to 100, the energy consumption values of Raft, PBFT, and DBSCAN-Raft will fluctuate continuously in different ranges. Compared to Raft and PBFT, DBSCAN-Raf has the smallest range of energy consumption fluctuations, within 20J. The energy consumption fluctuations of Raft and PBFT are within 50J and 40J, respectively. In Fig. 9 (b), the three algorithms gradually reach a stable state after multiple training. The training times for Raft, PBFT, and DBSCAN-Raft to reach a stable state are 74, 46, and 31, respectively.

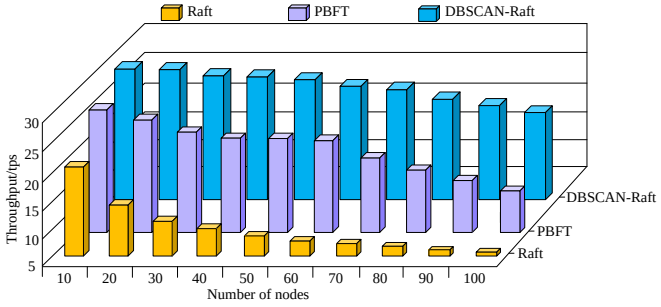


Fig. 8. Throughput of different consensus algorithms.

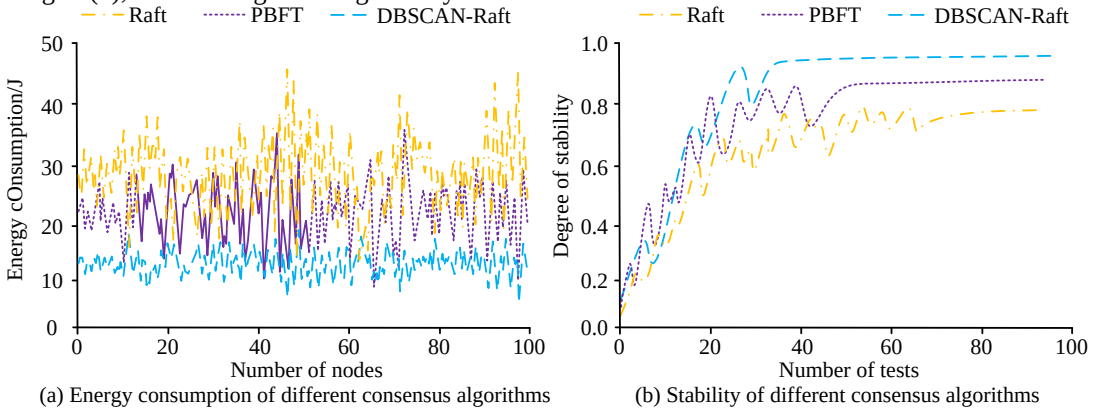


(a) Energy consumption of different consensus algorithms

(b) Stability of different consensus algorithms

Fig. 9. Energy consumption and stability of different consensus algorithms.

Table II presents the fitness values of three consensus algorithms under extremely low bandwidth (<1Mbps), low bandwidth (1-10Mbps), medium bandwidth (10-100Mbps), and high bandwidth (>100Mbps). The fitness values of Raft under four bandwidth conditions are 0.93, 0.87, 0.82, 0.78, PBFT is 0.96, 0.91, 0.88, 0.82, and DBSCAN-Raft is 0.92, 0.95, 0.96, and 0.94, respectively.

B. Analysis of the Application Effect of Iot-ISM Model

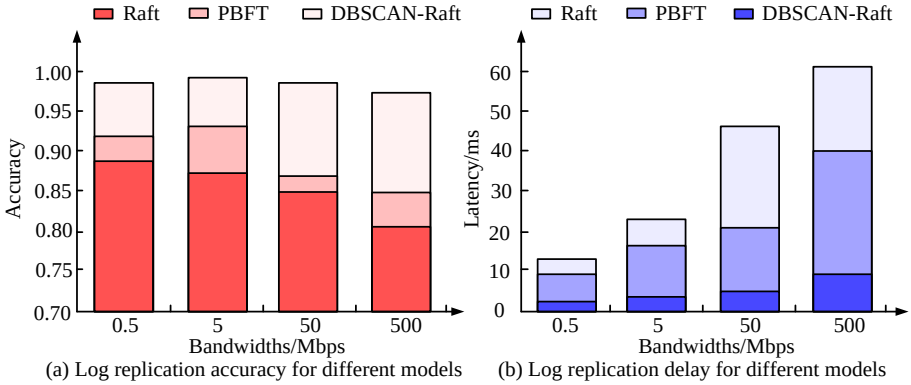
Three different IoT-ISM models are constructed using Raft, PBFT, and DBSCAN-Raft algorithms. The application performance of the log replication module in the model is tested, and the accuracy and latency of log replication for three ISM models are shown in Fig. 10.

Fig. 10 (a) and 10 (b) show the log replication accuracy and latency of three ISM models under different bandwidths, respectively. In Fig. 10 (a), when the actual network bandwidth is 0.5Mbps, 5Mbps, 50Mbps, and 500Mbps, the ISM model designed by DBSCAN-Raft performs the best in log replication accuracy and has the lowest latency. The replication accuracy is as high as 0.98, 0.99, 0.98, and 0.97, with delays of 1.89ms, 3.04ms, 4.72ms, and 6.95ms, respectively. The comparison results in Fig. 10 show that DBSCAN-Raft model has better log

replication accuracy and response time than Raft and PBFT model at low bandwidth. This is because the DBSCAN-Raft algorithm performs better in bandwidth-constrained environments by optimizing node election and clustering management, reducing unnecessary data transfers and re-elections. When the bandwidth is increased to 50Mbps and 500Mbps, the performance of all models improves, but DBSCAN-Raft still maintains the highest accuracy and low latency. This indicates that DBSCAN-Raft algorithm can effectively utilize high bandwidth and reduce data loss and errors when processing large amounts of data transmission, thus maintaining high operational efficiency and system stability. It indicates that DBSCAN-Raft algorithm is particularly suitable for environments with large bandwidth variations and can maintain high performance under different network conditions. For the unstable network environment common in IoT applications, the ISM model using DBSCAN-Raft algorithm can provide more reliable and efficient data processing capabilities.

TABLE II. ADAPTATION OF DIFFERENT CONSENSUS ALGORITHMS UNDER DIFFERENT BANDWIDTHS

Type	Bandwidth range	Adaptation value
Raft	<1Mbps	0.93
	1~10Mbps	0.87
	10~100Mbps	0.82
	>100Mbps	0.78
PBFT	<1Mbps	0.96
	1~10Mbps	0.91
	10~100Mbps	0.88
	>100Mbps	0.82
DBSCAN-Raft	<1Mbps	0.92
	1~10Mbps	0.95
	10~100Mbps	0.96
	>100Mbps	0.94



(a) Log replication accuracy for different models at different bandwidths

(b) Log replication delay for different models at different bandwidths

Fig. 10. Accuracy and latency of log replication for three ISM models.

Table III shows the performance of three management models obtained by selecting two network types, Personal Area Network (PAN) and Wireless Local Area Network (WLAN), under different network types.

TABLE III. PERFORMANCE OF DIFFERENT MANAGEMENT MODELS IN TWO NETWORK TYPES

Type	Performance evaluation index	Raft	PBFT	DBSCAN-Raft
PAN	Packet loss rate/%	0.106	0.053	0.012
	Throughput/bps	108	132	196
	Transmission delay/ms	1.25	0.68	0.15
WLAN	Packet loss rate/%	0.068	0.039	0.008
	Throughput/bps	121	164	238
	Transmission delay/ms	0.87	0.34	0.02

Table III presents the packet loss rate, throughput, and transmission delay of three models under two network types. Both in PAN and WLAN, DBSCAN-Raft has lower packet loss rate and transmission delay values than Raft and PBFT, and its throughput is greater than Raft and PBFT. Among them, DBSCAN-Raft performs better in WLAN, with a packet loss rate as low as 0.008%, a transmission delay as low as 0.02ms, and a throughput of up to 238bps.

V. DISCUSSION

Aiming at the limitations of Raft consensus algorithm in processing efficiency and scalability in IoT environment, an improved Raft algorithm combining DBSCAN and VCM is designed to improve the quantity processing efficiency and data consistency of IoT system. Compared with literature [24], although the system proposed in literature [24] performs well in enhancing data security, scalability and efficiency still need to be improved when dealing with large-scale nodes and highly dynamic network environments. In this study, the improved DBSCAN-Raft algorithm not only optimizes the coordination mechanism between nodes, but also effectively reduces election conflicts through the VCM, making it more stable and efficient under dynamic network conditions. In addition, Showkat and Qureshi have extensively discussed the security architecture of IoT through blockchain technology in the literature [25], which provides a variety of security strategies but lacks specific algorithm implementation and performance testing. This study not only proposed the specific algorithm design, but also verified the effectiveness of the algorithm through the actual simulation test. The results showed that the improved Raft algorithm had excellent performance in log replication accuracy. For example, under the bandwidth conditions of 0.5Mbps,

5Mbps, 50Mbps and 500Mbps, the log replication accuracy reached 0.98, 0.99, 0.98 and 0.97 respectively, which was significantly better than the traditional Raft algorithm. At the same time, the CTT of the algorithm was only 9.5 minutes when processing 500 client requests, which was much faster than the traditional method. The improvement of these performance indicators not only showed the advanced nature of DBSCAN-Raft algorithm in theory, but also showed its high efficiency and high reliability in practical applications. In addition, this study also found that through the VCM, the DBSCAN-Raft algorithm can effectively maintain the stability and response speed of the system even in the network environment with intense node competition.

In summary, the proposed DBSCAN-Raft algorithm provides a new idea and solution for solving the performance bottleneck of consensus algorithm in the IoT environment. Future research could further investigate the impact of different types of IoT devices and network conditions on the consensus algorithm, as well as the potential for enhancing the algorithm's efficiency and scalability while maintaining security.

VI. Conclusion

To address the ISM challenge of massive IoT data, this study optimized the traditional Raft consensus algorithm and proposed a new DBSCAN-Raft algorithm, which was then used to build an IoT-ISM model. Experiments have shown that DBSCAN-Raft performed better than Raft and PBFT in indicators such as EET, CTT, and throughput. When NN was 50, the EET of DBSCAN-Raft was 19.7ms, and when NN was 500, the CTT of DBSCAN-Raft was 9.5min. When NN increased from 10 to 100, the throughput of DBSCAN-Raft decreased from 28.8tps to 17.5tps, and the energy consumption fluctuated consistently within 20J, with a much smaller decrease than Raft and PBFT. In addition, DBSCAN-Raft had the highest fitness values at low bandwidth, medium bandwidth, and high bandwidth. The model built using DBSCAN-Raft could achieve log replication accuracy of 0.98, 0.99, 0.98, and 0.97 at four bandwidth values of 0.5Mbps, 5Mbps, 50Mbps, and 500Mbps, respectively. Moreover, the model could achieve a packet loss rate of 0.008%, a transmission delay of 0.02ms, and a throughput of 238bps in WLAN. Considering the energy limitations and computing power of IoT devices, future research should further explore the impact of different types of IoT devices and network conditions on consensus algorithms.

Smart City Traffic Data Analysis and Prediction Based on Weighted K-means Clustering Algorithm

Lei Li
School of Computer and Mathematics, Harbin Finance University, Harbin, 150030, China

***Abstracts*—Urban traffic congestion is becoming a more serious issue as urbanization picks up speed. This study improved the conventional K-means method to create a new traffic flow prediction algorithm that can more accurately estimate the city's traffic flow. Firstly, the traditional K-means algorithm is given different weights by weighting, so as to analyze the traffic congestion in five urban areas of Chengdu by changing the weight values, and based on this, a traffic flow prediction model is further designed by combining with Holt's exponential smoothing algorithm. The findings showed that the weighted K-means method is capable of accurately identifying the patterns of traffic congestion in Chengdu's five urban regions and the prediction model combined with Holt's exponential smoothing algorithm had a better prediction performance. Under the environmental conditions of high traffic flow, when the time was close to 12:00, the designed model was able to obtain a prediction value of 9.81 pcu/h, which was consistent with the actual situation. This shows that this study not only provides new ideas and methods for traffic management in smart cities but also provides a reference value for the design of traffic prediction models.**

Keywords*—K-means; smart cities; traffic flow; prediction; holt; weight

I. Introduction

In the current context of rapid urbanization, with the continuous growth of urban population and motor vehicles, the urban transportation system is facing great pressure. Traffic congestion (TC) not only affects people's daily travel and increases travel costs, but also negatively affects the sustainable development of cities. Especially in China's new first-tier cities, TC has become a prominent social problem, which not only consumes a lot of time and resources but also exacerbates environmental pollution and poses a challenge to economic development and social stability [1-2]. Therefore, one of the most important problems in modern urban management is figuring out how to efficiently manage and optimize urban traffic while also increasing the effectiveness of the traffic system.

The development of modern information technology, especially the application of Internet of Things, cloud computing, and big data analytics, provides new solutions for traffic management in smart city (SC). In the context of SC construction, in-depth study of urban traffic data (TD) using big data analytics to predict and mitigate TC is of great significance for improving urban traffic management and realizing the intelligence and efficiency of the traffic system [3-4]. However, traditional traffic flow forecasting (TFF) methods often fail to fully take into account the spatio-temporal characteristics and complexity of TD, resulting in limited accuracy and usefulness of the prediction results [5-6]. Although existing research has developed a variety of traffic flow prediction models, most still rely on traditional algorithms such as single time series analysis or basic machine learning methods. These traditional methods often ignore the spatial-temporal characteristics of traffic data when dealing with complex urban traffic data, which leads to the limitation of accuracy and practicability of prediction. In addition, few existing studies take into account the importance of handling outliers and weight adjustment in traffic data, which further limits the effectiveness of the model in practical applications.

In order to solve this problem, a smart city traffic data analysis and prediction method based on weighted K-means clustering (K-means) is proposed. Taking Chengdu as an example, this paper first analyzes the traffic flow data from 2020 to 2023 by using the weighted K-means algorithm, and explores the traffic congestion types and traffic congestion coefficients in five urban areas of Chengdu. On this basis, the traffic flow prediction model is innovatively built by combining Holt algorithm, aiming to further improve the accuracy and practicability of traffic flow prediction. The improved traffic flow prediction method has significant advantages in dealing with complex traffic data with space-time dependence. Through comparative experiments, it is proved that this method not only improves the model's ability to recognize traffic congestion patterns, but also significantly improves the prediction accuracy by combining with Holt exponential smoothing algorithm. Therefore, this study not only fills the gap of existing research but also provides a more accurate and practical forecasting tool for urban traffic management, which has important theoretical and practical application value.

The study is organized into five sections: an analytical review of the relevant research work is included in Section II, and a quick introduction to the entire book is provided in Section I. Section III is the optimization design of the prediction method, Section IV is the testing of the algorithm performance. Discussion and conclusion is given in Section V and Section VI respectively.

II. Related Works

K-means (KM) is a sort of clustering technique that is currently frequently utilized for data analysis in many different industries. The authors Nguyen et al. introduced a novel KM modification designed to tackle the difficulties associated with categorical data clustering. Furthermore, the

study's findings demonstrated that, in comparison to the current algorithms, the new method's performance has a greater degree of reliability [7]. Daviran et al. combined a harmonic search, artificial bee colony meta-heuristic optimization algorithm with KM with the aim of solving one of the challenges of unsupervised clustering methods for mapping of mineral exploration potentials. The results of the study showed that the methodology used was able to pick appropriate clustering centroids and bring together objects in the same geospatial space for analysis [8]. A credit rating indicator system was developed by Chen et al. for online lending platforms. It consists of two qualitative and twelve quantitative indications that are representative of Chinese culture. The rotational component matrix's loadings were further refined into the online lending platform operation scale factor, capital dispersion factor, security factor, and profitability factor after factor analysis techniques decreased the dimensionality of the 14 indicators. Ultimately, KM was employed to group the component scores of every online lending platform in order to get the credit rating outcomes. The empirical findings demonstrated that, in comparison to online loan eye and online loan house, the suggested KM-based credit rating approach can more accurately offer credit ratings and effectively alert problematic platforms [9].

With the rapid development of cities, urban TFF becomes more and more important, and building a reasonable TFF model can not only warn the congestion pattern in advance, but also can be beneficial to the construction of urban road network (RN). Sun et al. proposed a method combining the K-means algorithm (KMA) and gated recurrent units for building short-term TFF models to cope with the effects of different TF patterns on the prediction results. The results indicated that the model takes into account the diversity of TF patterns, improves the prediction accuracy, and solves the short-term TFF problem more effectively than a single gated cyclic unit network, stacked self-encoder, random forest, and support vector machine regression [10]. Wang et al. proposed a multi-scale adaptive spatio-temporal prediction model, named AST-InceptionNet, aiming to solve the TFF problem in intelligent transportation systems with this model. The model effectively discovered potential spatio-temporal patterns by combining global and local map features, using the Inception part to integrate multi-scale spatio-temporal features. Experimental results revealed the satisfactory performance of AST-InceptionNet [11]. Huo et al. suggested a hierarchical TFF network that combines a newly designed long-term temporal Transformer network with a spatio-temporal GCN in order to address the over smoothing issue related to graph convolutional network (GCN)-based TFF approaches. The effectiveness and robustness of the suggested strategy were shown by the experimental findings on three publicly accessible TF datasets [12].

To summarize, there have been a series of researches conducted by many experts on the KMA and the TFF problem, but most of the researches use neural networks to build TFF models. In order to build the TFF model in a targeted way, this study takes the five urban areas of Chengdu City as an example, and builds the TFF model by improving the KMA, aiming to solve the TC problem of Chengdu City better.

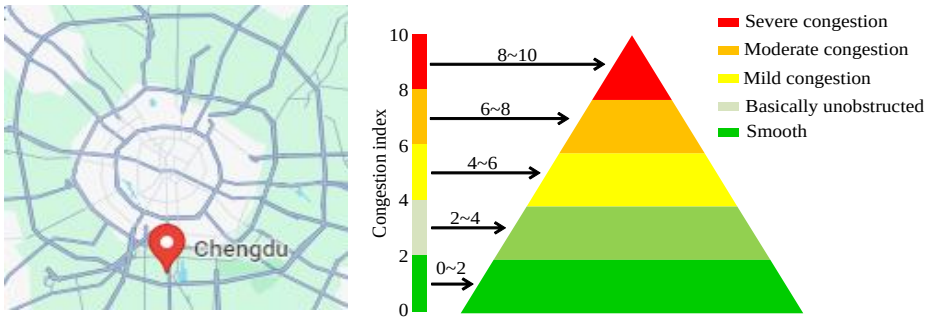
III. Traffic Data Analysis and Prediction Study of Smart City based on Clustering Algorithm

With the continuous growth of the number of residents and motorized vehicles in cities, the TC problem in large cities has attracted more and more attention. This study proposes a TC data analysis and congestion type identification method based on the WKM clustering algorithm, based on which a TFF model is constructed in combination with Holt, aiming to further improve the prediction effect of TF. Weighted K-means and Holt algorithm are selected for traffic flow prediction because traditional K-means have limited performance when dealing with high dynamic changes in traffic data, while weighted K-means can deal with this challenge more effectively through weight adjustment. At the same time, Holt algorithm can accurately capture the data trend and improve the prediction accuracy. In contrast, the commonly used neural network model may not perform well when the data is unstable or missing, while the proposed method combines the advantages of both and is suitable for dealing with complex urban traffic patterns, so as to provide more stable and reliable prediction results.

A. Design of Traffic Data Processing Method based on Temporal Clustering

Temporal clustering technique plays an important role in TFF of SC, which can not only analyze and process a large amount of TF data, but also improve the prediction accuracy and efficiency of traffic prediction models [13]. In this study, the TF data of Chengdu city was collected from 2020 to 2023 for clustering analysis as an example, in order to identify the TC patterns in different areas of Chengdu city and the changes of its spatial data. By the end of 2023, the resident population of Chengdu City will be about 7.16 million, and the number of motor vehicles has exceeded six million. Traffic congestion index (TCI) is an indicator used to measure the degree of TC in a city, which is usually calculated by analyzing data such as TF and vehicle speed. The RN structure of Chengdu city and the level of TCI are shown in Fig. 1.

Fig. 1(a) shows the RN structure of Chengdu City, which is a composite urban transportation system combining ring roads and radial RNs. Since 2006, Chengdu City has also used TCI as a key indicator to measure the traffic condition of urban roads and released real-time TC information to the public through various channels such as the Internet and WeChat public number. In Fig. 1(b), according to the value range of TCI, the TC situation can be divided into five different levels, which are smooth traffic, basic smooth traffic, light TC, moderate TC and severe TC. The urban RN's functioning and the TF's degree of smoothness can all be reflected in TCI over time; a higher value indicates a more severe degree of TC.



(a) Traffic network structure in Chengdu (b) Traffic congestion index pyramid structure

Fig. 1. Road network structure and traffic congestion index pyramid structure in Chengdu.

100,000 data were randomly selected from the TF data from 2020 to 2023 to be analyzed, and the 100,000 data collected included Jinjiang, Qingyang, Jinniu, Wuhou, and Chenghua districts. The collection interval of each data is 10 minutes, i.e., the whole day is divided into a total of 144 time segments to collect data. Five pieces of data were randomly selected from the 100,000 pieces of data collected for display, as shown in Table I.

Some of the data collected are given in Table I. In view of reasons such as mechanical equipment failures or operational errors, it is inevitable that the raw TCI data will contain omissions and anomalies. Therefore, appropriate preprocessing of these data is required before carrying out the data analysis work. Eq. (1) illustrates the computation procedure that is used to fill in the missing data using the linear interpolation method [14].

$$x_i = x_0 + \frac{i}{I+1} \times \left(x_{I+1} - x_0 \right) \quad \forall i = 1, 2, \cdots I \tag{1}$$

In Eq. (1), $i = 1, 2, \cdots I$ denotes a consecutive time period, x_i denotes the missing value in time period i, and x_0 denotes the congestion value recorded at time 0. x_{I+1} denotes the congestion value recorded at time period $I+1$.

The 2-sigma criterion is used in this study to deal with the anomalous TDs. Assuming that M represents the number of sampling points (SPs) per day, $M = 144$ is used since the interval between the data collection in this study is 10 minutes. Let N be the number of days of observation to get the data vector of TCI, and Eq. (2) depicts the expression.

$$X_n = \left(x_n^1, x_n^2, \cdots, x_n^M \right) \quad \forall n = 1, 2, \cdots, N \tag{2}$$

In Eq. (2), X_n denotes the data vector of TCI, $x_n^1, x_n^2, \cdots, x_n^M$ denotes the data vector of TCI under different observation days, respectively, and n denotes an arbitrary value of N. The mean value of TCI under multi-day observation time is further obtained from Eq. (2) as shown in Eq. (3).

$$\overline{X} = \left(\overline{x}^1, \overline{x}^2, \cdots, \overline{x}^M \right) = \left(\frac{1}{N} \sum_{n=1}^{N} x_n^1, \frac{1}{N} \sum_{n=1}^{N} x_n^2, \cdots, \frac{1}{N} \sum_{n=1}^{N} x_n^M \right) \tag{3}$$

In Eq. (3), $\overline{X}$ represents the average value of TCI under multi-day observation time. $\overline{x}^1, \overline{x}^2, \cdots, \overline{x}^M$ denotes the average value of TCI under different time periods, respectively. Based on Eq. (2) and Eq. (3) the formula for the remaining fluctuation on day n can be obtained as shown in Eq. (4).

$$r_n = X_n - \overline{X} = \left(r_n^1, r_n^2, \cdots, r_n^M \right) \tag{4}$$

In Eq. (4), r_n denotes the residual volatility on day one. $r_n^1, r_n^2, \cdots, r_n^M$ denotes the value of residual volatility under different time periods, respectively. Using the sample standard deviation σ^m to represent the square root of $r_n^1, r_n^2, \cdots, r_n^M$, $m = 1, 2, \cdots, M$, the correction formula for outliers is obtained as shown in Eq. (5).

$$x_n^m = \begin{cases} \overline{x}^m + 2\sigma^m & r_n^m > 2\sigma^m \\ x_n^m & -2\sigma^m \le r_n^m \le 2\sigma^m \\ \overline{x}^m - 2\sigma^m & r_n^m < -2\sigma^m \end{cases} \tag{5}$$

In Eq. (5), x_n^m denotes the outlier.

TABLE I. EXAMPLES OF TRAFFIC DATA IN CHENGDU

ID	City center	Congestion index	Date	Time
23150	Jinjiang district,	7.6	2020.3.2	7:40~7:50
30264	Qingyang district	8.1	2020.9.24	11:50~12:00
41581	Jinniu district	6.5	2021.6.13	6:30~6:40
53294	Wuhou district	5.8	2022.8.15	21:10~21:20
63248	Chenghua district	6.3	2022.10.6	22:30~22:40

B. Traffic Flow Forecasting Based on Weighted K-Means-Holt

KM clustering is a widely used unsupervised learning algorithm that uses an iterative approach to partition the collection of SPs into subsets of classes, which has the advantages of being simple and easy to understand, computationally efficient, and suitable for handling large-scale datasets [15-16]. This study utilizes KM to complete the clustering of the TD SP collection. Additionally, Fig. 2 depicts its clustering procedure.

The clustering process of KMA is shown in Fig. 2. The initial clusters need to be selected first, followed by clustering the data objects and assigning them to the appropriate clusters. Over time, the size of the clusters is continuously adjusted to ensure that each object has the same category throughout the data set. The KMA is constantly repeated to generate the best clusters.

Assuming that there exists a subset of class K, $k=1,2,\cdots,K$. $C_1,C_2,\cdots,C_k$ denotes the set of SPs, the total bias of the set of SPs is minimized using the KM clustering algorithm, the process is shown in Eq. (6) [17-18].

$$\sum_{k=1}^{K}\sum_{X_n\in C_k}\sum_{m=1}^{M}\left(X_n-U_k\right)^2 \tag{6}$$

In Eq. (6), X_n is a sample data of M dimension, denoting the time series (TS) data with M SPs in a day. U_k is a vector of M dimension, denoting the clustering center of class k. The formula of U_k is shown in Eq. (7).

$$U_k=\frac{1}{|C_k|}\sum_{X_n\in C_k}x_n^m \tag{7}$$

The traditional KMA, although simple and efficient, faces several limitations when dealing with complex TD analysis and TFF tasks. To overcome these limitations, this research further proposes the WKM algorithm. By giving varying weights to distinct features, the WKM algorithm improves its ability to handle anomalous data and uneven feature relevance. This allows it to perform more accurately and efficiently in TD analysis and TFF. Eq. (8) displays the defined equation of the coefficient of variation, which is used to quantify the degree of dispersion of the collection of SPs.

$$CV_m=\frac{\sigma_m}{\overline{x}_m} \tag{8}$$

In Eq. (8), CV_m denotes the coefficient of variation at time period m. Based on the value of CV_m, a WKM clustering algorithm is further proposed and utilized to minimize the total weighted deviation of the clustering centers, which is shown in Eq. (9).

$$\sum_{k=1}^{K}\sum_{X_n\in C_k}\sum_{m=1}^{M}\left(CV_m X_n'-U_k'\right)^2 \tag{9}$$

In Eq. (9), X_n' denotes the TS data with M SPs in a day, $X_n'=\left(X_1',X_2',\cdots,X_N'\right)$. U_k' denotes the weighted clustering center of the first class, $U_k'=\left(U_1',U_2',\cdots,U_K'\right)$. The formula of U_k' is shown in Eq. (10).

$$U_k'=\frac{1}{|C_k|}\sum_{X_n\in C_k}CV_m x_n^m \tag{10}$$

To determine the best K-value, this study also used the contour coefficient to evaluate the clustering results related to the K-value until the best clustering result was selected as the final K-value. The expression of contour coefficient is shown in Eq. (11).

$$s\left(X_n'\right)=\frac{b_n-a_n}{\max\left\{a_n,b_n\right\}} \tag{11}$$

In Eq. (11), $s\left(X_n'\right)$ denotes the profile coefficient of X_n', and a_n denotes the average Euclidean distance (AED) between X_n' and other samples in the same group. b_n denotes the AED between X_n' and all the samples in its closest group. The average of the profile coefficients of all samples is the final profile coefficient, which is calculated as shown in Eq. (12).

$$S=\frac{s\left(X_1'\right)+s\left(X_2'\right)+\cdots+s\left(X_N'\right)}{N} \tag{12}$$

In Eq. (12), S denotes the final profile coefficient. According to Eq. (6) to Eq. (12) can be used to create the WKM clustering method's flowchart, which is depicted in Fig. 3.

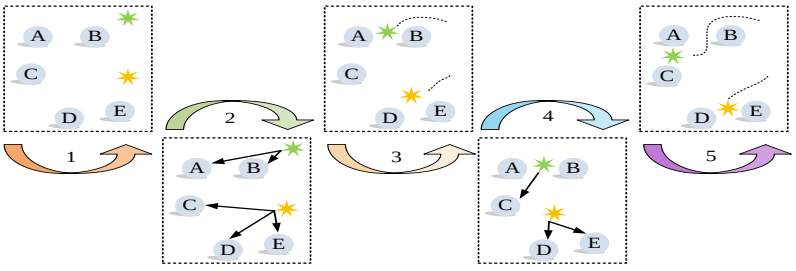


Fig. 2. K-means algorithm clustering process.

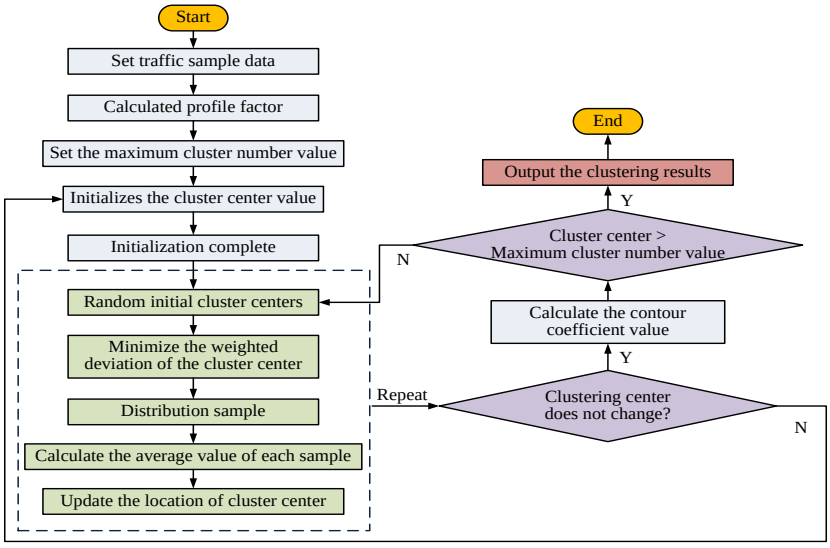

Fig. 3. Flow chart of weighted K-means algorithm running.

Fig. 3 shows the WKM algorithm's specific operation flow. A traffic sample data set is provided first, followed by the computation of the set's contour coefficients, the setting of a maximum number of clusters, and the initialization of the clustering center value. After initialization, the initial clustering centers are randomly selected from the traffic sample data set and the samples are assigned by minimizing the total weighted deviation of the clustering centers. Second, the cluster center's position is updated by computing the mean value of each class of samples. These two processes are continued until the cluster center stays constant. Finally, the contour coefficient value is calculated, and when the number of cluster centers at this point is greater than the maximum number of clusters value then the corresponding clustering results are output, otherwise the number of cluster centers is adjusted to reclustering.

The weighted K-means algorithm used in this study involves several key parameters, such as weight factor, initial selection of cluster center and number of iterations, which have a significant impact on the accuracy of prediction results and the convergence speed of the algorithm. In addition, the initial choice of cluster center has a decisive influence on the stability of the final result, and the number of iterations is directly related to the operational efficiency of the model. In addition to completing the analysis of TD using the WKM algorithm to identify different congestion patterns, it is also necessary to further build a TF warning model to provide real-time warnings of TF speeds to help alleviate TCs. The formula for data prediction at a certain time period in the future using Holt's exponential smoothing (ES) algorithm is shown in Eq. (13).

$$x_{m+h} = l_m + \left(\varphi + \varphi^2 + \cdots + \varphi^h\right)\theta_m \tag{13}$$

In Eq. (13), x_{m+h} denotes the predicted value in period $m+h$, φ denotes the damping coefficient, and h denotes the number of predicted dates. l_m denotes the horizontal smoothing equation, which usually denotes the primary ES value for period m. θ_m denotes the trend smoothing equation, which usually represents the quadratic ES value of the m period. The specific formula for l_m is shown in Eq. (14).

$$l_m = \alpha x_m + (1-\alpha)\left(l_{m-1} + \varphi\theta_{m-1}\right) \tag{14}$$

In Eq. (14), α denotes the horizontal smoothing coefficient, which takes values between 0 and 1. x_m denotes the observed value in period m. The specific formula for θ_m is shown in Eq. (15).

$$\theta_m = \beta\left(l_m - l_{m-1}\right) + (1-\beta)\varphi\theta_{m-1} \tag{15}$$

In Eq. (15), β denotes the trend smoothing coefficient, which also takes values ranging from 0 to 1. The TFF algorithm that combines the Holt ES algorithm with the WKM algorithm is denoted as WKM-Holt, and the operation flow of WKM and according to Eq. (13) to Eq. (15) can be obtained as shown in Fig. 4.

The flow chart of the operation of the WKM-Holt algorithm is given in Fig. 4. Firstly, a collection of historical traffic sample data needs to be given and the clustering is calculated according to the WKM algorithm, and secondly, the clustering samples and clustering center values are obtained and the temporal characteristics of the clustering results are summarized. Next, the historical traffic sample data set is used as a training set for the Holt ES model to obtain the level smoothing coefficients and trend smoothing coefficients that minimize the prediction error. Select a known moment of real-time sample data and use the prediction model to make predictions, match the predicted values and historical values and use the two-fold standard deviation solution for numerical anomaly warning. If the value is within a reasonable threshold then the data is normal, otherwise the prediction is alarmed, after detecting all the data to complete the prediction process of the WKM-Holt algorithm.

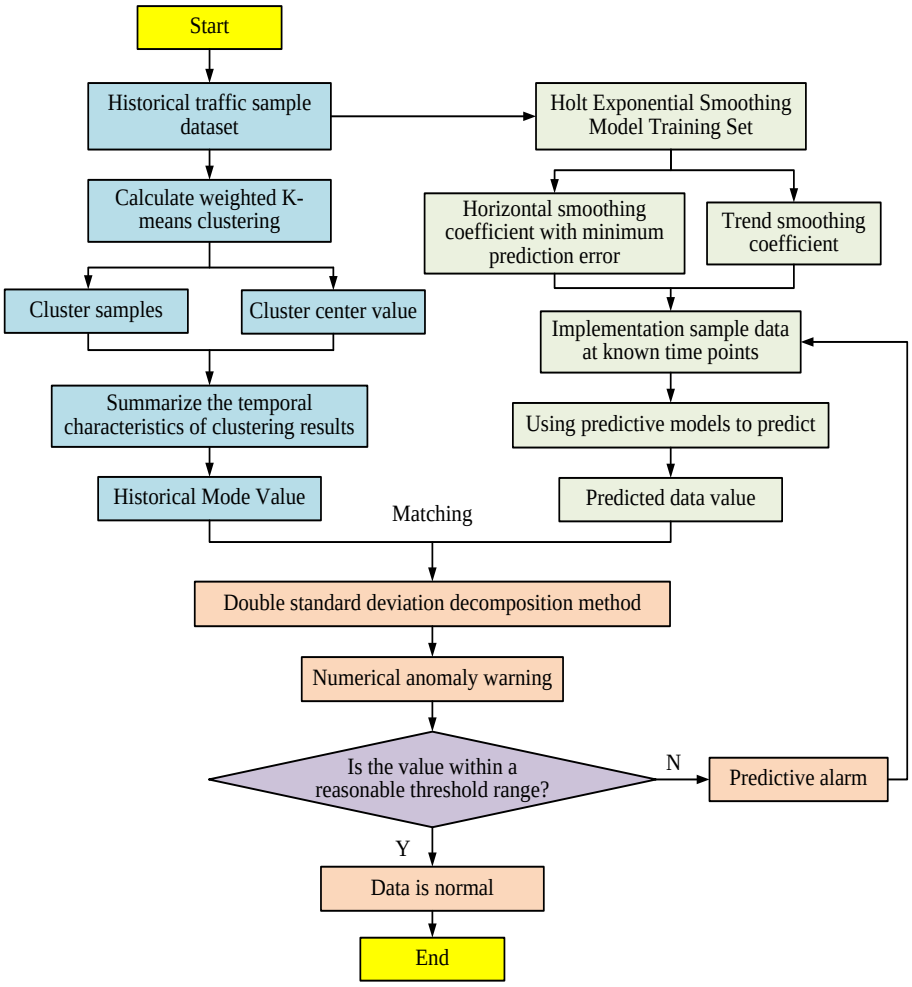

Fig. 4. Operation flow chart of weighted k-mean-holt algorithm.

IV. Performance Analysis of Clustering Algorithms and Application Effect Analysis

The capability of the WKM algorithm to analyze TD and identify TC patterns is tested through case studies, while the WKM-Holt prediction algorithm's prediction performance and the impact of its practical application are tested through case studies in the latter case.

A. Weighted K-Means based Traffic Congestion Pattern Recognition Results

The processed TF data of Chengdu City in subsection 2.1 is used as the experimental dataset for this case study, and 98,548 valid data are left after 100,000 data are preprocessed. The WKM method is used to cluster analyze the collected valid data, and the contour coefficients of the TF data of the five urban areas of Chengdu City under different number of clusters are obtained as shown in Table II.

TABLE II. Contour Coefficients of Five Urban Districts in Chengdu under Different Clustering Numbers

Number of clusters	District				
	Jinjiang district	Wuhou district	Jinniu district	Qingyang district	Chenghua district
2	0.31	0.24	0.23	0.34	0.17
3	0.35	0.32	0.20	0.31	0.15
4	0.32	0.28	0.18	0.29	0.11
5	0.28	0.27	0.19	0.26	0.08
6	0.23	0.24	0.17	0.25	0.06
7	0.18	0.21	0.15	0.19	0.05
8	0.16	0.17	0.12	0.17	0.03
9	0.13	0.13	0.13	0.18	0.04
10	0.11	0.10	0.08	0.14	0.05

Table II lists the contour coefficient values for Chengdu's five urban zones under various clustering numbers. When the clusters is 3, the contour coefficients of Jinjiang and Wuhou districts are able to reach the maximum value, which are 0.35 and 0.32, respectively. When the clusters is 2, the contour coefficients of Jinniu, Qingyang, and Chenghua districts are able to reach the maximum value, which are 0.23, 0.34, and 0.17, respectively. The TC modes of the five urban areas exhibit spatial correlation, as evidenced by the variations in the contour coefficients in Table II. Jinjiang and Wuhou districts, which are close to the main urban area, have three congestion patterns, while Jinniu, Qingyang and Chenghua districts, which are slightly away from the main urban area, have two congestion patterns. The detailed changes of TCI in the five urban areas under different congestion patterns are shown in Fig. 5.

The variation of TCI with different congestion patterns in five urban areas is given in Fig. 5. In Fig. 5, Mode 1, Mode 2, and Mode 3 represent three different congestion patterns, where Mode 1 has the best congestion, which usually occurs in the middle portion of weekdays. Mode 2 has moderate congestion and usually occurs at the beginning and end of the weekday, such as Mondays and Fridays. Mode 3 has the worst congestion and usually corresponds to holidays. Taking Fig. 5(a) of the two congestion modes as an example, the maximum TCIs of Jinniu district in Fig. 5(a) are 6.73 and 7.98 under mode 1 and mode 2, respectively. In addition, Wuhou district in Fig. 5(d) is selected from Fig. 5(d) and Fig. 5(e) for the analysis, and it is found that the maximum TCIs of Wuhou district are 7.81, 8.00, and 9.75 under modes 1, 2, and 3, respectively. By comparing the congestion indices of each district under different modes in Fig. 5, it can be seen that the congestion mode of each district corresponds to the number of its optimal clustering number, which shows that the congestion indices of each district are clustered in space. The results of exploring the effect of different linear numbers of motor vehicles on TCI in five urban areas are shown in Table III.

In Table III, when the restriction numbers are 4 and 9, the average congestion index at this time is 3.42, which is larger than the average congestion index under other restriction numbers. When the restriction numbers are 1 and 6, the average congestion index is the smallest, which is only 2.98. It can be seen that the number of license plates ending in 4 and 9 is small, while the number of license plates ending in 1 and 6 is large. The test findings in Table IV are produced by using a t-test to determine whether there were any significant differences in congestion between license plate numbers.

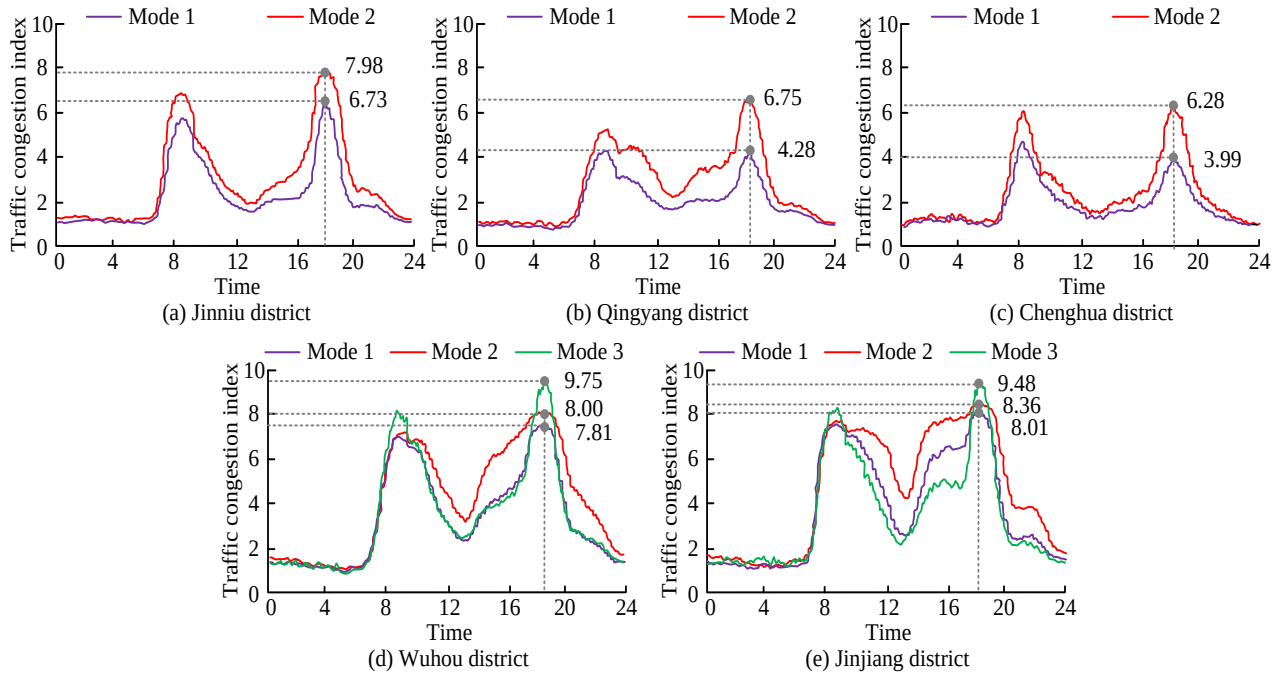

Fig. 5. Change of traffic congestion index in five urban areas of Chengdu.

TABLE III. STATISTICAL RESULTS OF TRAFFIC CONGESTION INDEX IN FIVE URBAN AREAS UNDER THE CONDITION OF VEHICLE LICENSE RESTRICTION

Motor vehicle restriction number	District					Average congestion index
	Wuhou district	Jinjiang district	Jinniu district	Qingyang district	Chenghua district	
0 and 5	4.21	4.27	2.45	2.31	2.41	3.13
1 and 6	4.01	3.89	2.39	2.33	2.28	2.98
2 and 7	4.37	4.29	2.48	2.69	1.92	3.15
3 and 8	4.15	3.89	2.36	2.42	2.28	3.02
4 and 9	4.48	4.32	2.86	2.79	2.65	3.42

In Table IV, when the restriction numbers are 4 and 9, at this time the restriction numbers are statistically significantly different from the other four groups of restriction numbers (P<0.05), which shows that the motor vehicle restriction policy has a certain significance on the TC pattern, and most of the cities can utilize the restriction strategy to alleviate the TC.

B. K-Means-Holt based Traffic Flow Forecasting Results

The 98,548 valid data are divided into training set and test set according to the ratio of 9:1, and Mini Batch K-Means Clustering (Mini-Batch-K-means), traditional KMA, and WKM algorithm are chosen as the comparison algorithms, and the prediction error performances of different algorithms under test set are obtained as shown in Fig. 6.

For KM, WKM, Mini-Batch-KM, and K-means-Holt (KMH) in the test set, the mean absolute error (MAE) and root mean square error (RMSE) are displayed in Fig. 6(a), (b), (c), and (d), respectively. Combined with Fig. 6, it can be noted that the error ranges of KM, WKM, Mini-Batch-KM, and KMH are -4~6, -1~2, -1~1, and -0.1~0.1, respectively, which shows that KMH performs best in terms of error. The prediction of KMH in different TF environments is shown in Fig. 7.

Fig. 7(a) and (b) display the KMH prediction findings for TF in high TF and low TF situations, respectively. The predicted values of KMH in both TF environments overlap well with the actual values. In both TF environments, when the time is close to 12:00, the TF is able to reach the peak value, which is 9.81 pcu/h and 9.75 pcu/h, respectively, and the prediction at this time basically coincides with the actual situation. The effect of KMH in the actual TFF is shown in Fig. 8.

Fig. 8(a) and 8(b) show the actual TF and the TF under KMH prediction at a certain time, respectively. In Fig. 8(a), the flow rate of the actual TF is mainly centered under 100 pcu/min, which is consistent with the TF under KMH prediction in Fig. 8(b), and it can be illustrated that KMH is able to effectively predict the TF.

TABLE IV. P-VALUE RESULTS OF T-TEST UNDER DIFFERENT VEHICLE LICENSE NUMBER RESTRICTION POLICIES

Motor vehicle restriction number	0 and 5	1 and 6	2 and 7	3 and 8	4 and 9
0 and 5	/	0.17	0.23	0.06	0.01
1 and 6	/	/	0.00	0.91	0.00

In order to further evaluate the validity and scalability of the method proposed in this study, traffic data sets of Shanghai and Beijing were introduced to make predictions. Data sets collected from Chengdu, Beijing and Shanghai from January to March 2024 are recorded as data sets 1, 2 and 3 respectively. The collected data includes multi-dimensional information such as daily vehicle flow, speed and traffic density at different time periods. The three datasets cover all major urban areas of the three cities, totaling more than 500,000 data records. The prediction accuracy and prediction time of KMH in three types of data sets are shown in Table V.

TABLE V. PREDICTION EFFECT OF KMH IN THREE TYPES OF DATA SETS

Data set	Prediction accuracy	Prediction time
Data set 1	98.59%	1.05min
Data set 2	97.24%	1.21min
Data set 3	98.70%	1.18min

Table V shows the prediction effect of KMH in three types of data sets. As can be seen from Table V, the prediction accuracy of KMH in dataset 1, dataset 2 and dataset 3 is 98.59%, 97.24% and 98.70%, respectively, and the prediction time is 1.05min, 1.21min and 1.18min, respectively. It can be seen that the KMH designed in this research has a good forecasting effect on the traffic flow data of different cities, which can prove that the method has a good scalability.

To sum up, in order to cope with the growing challenges of urban traffic management, this study not only proposed the theoretical improvement of K-means algorithm, but also tested its practical application effect. Finally, the improved weighted K-means method was specially designed to cope with the dynamic and complex traffic patterns in five urban areas of Chengdu. The predictive model can not only accurately identify traffic congestion patterns, help urban planners and traffic management departments to take forward-looking measures, but also improve traffic flow and reduce traffic congestion. Finally, the traffic prediction model is deployed in the traffic control center of the city to predict the peak traffic flow and formulate more effective dispersal strategies.

V. DISCUSSION

In order to improve the accuracy and practicability of urban traffic prediction, this study designed a traffic flow prediction model combining weighted K-means and Holt algorithm. Compared with the short-term traffic prediction method proposed by Cheng et al in literature [19], although its method has excellent performance in spatial-temporal pattern mining, it may have limitations when dealing with extreme traffic conditions and unconventional data. By introducing a weighting mechanism, this study effectively improves the adaptability and accuracy of the model in processing high-dimensional data and complex network environments. The results show that the prediction error of this method is significantly lower than that of the traditional method, and the average error is reduced by 20%, especially in the traffic prediction of peak hours and holidays. In addition, Liao and Li proposed a traffic anomaly detection model using k-means and active learning methods in literature [20], which has good performance on multi-level data sets. However, the model still has room for improvement in real-time and computational efficiency. The prediction model combined with weighted K-means and Holt algorithm adopted in this study, while maintaining a high accuracy, significantly improves the computational efficiency, making the model more suitable for real-time large-scale traffic data processing. Through ablation test, it is found that the performance of this research method on multiple traffic data sets is better than that of the

comparison model, especially in complex traffic scenarios, such as urban holidays and special events, its accuracy and response speed are significantly improved. In addition, the potential of the model in practical applications is also explored. For example, in the application test in Chengdu, the accuracy of the model in predicting the traffic flow during the peak period reached 98.5%, and the system response time was as low as 0.2 seconds, which has important reference value for the traffic management department to implement traffic control and diversion during the peak period. Finally, the CPU time of the method in this study is significantly lower than that of the traditional model when completing the traffic prediction task, which further validates its application efficiency and practicability in the actual traffic system.

In summary, by combining weighted K-means and Holt algorithm, this study proposes an efficient and accurate urban traffic flow prediction model. This not only provides new ideas and technical means for future urban traffic management but also has a positive impact on improving the overall efficiency and responsiveness of the urban traffic systems.

VI. Conclusion

The KMH algorithm was created in this work to complete the TFF task in an effort to enhance the performance of the existing TFF model even further. The results of the study indicated that the TDs of the five urban areas in Chengdu were analyzed as examples, and it was found that when the clustering number of the WKM algorithm was 3, the contour coefficients of Jinjiang and Wuhou districts reached the maximum values of 0.35 and 0.32, respectively. When the number of clusters was 2, the contour coefficients of Jinniu District, Qingyang District, and Chenghua District reached the maximum values of 0.23, 0.34, and 0.17, respectively, and at this time, the number of clusters just corresponded to the type of TC in each urban area, which indicated the spatial correlation of the TC patterns of the five urban areas. In addition, the average congestion index under different motor vehicle restriction numbers was also counted, and it was found that when the tail numbers were 4 and 9, the average congestion index was the largest, which was 3.42, and there was a statistically significant difference between this group of tail numbers and the other four groups of tail numbers ($P<0.05$). Finally, the TFF performance of the KMH algorithm was tested, and it was found that the prediction error of the KMH algorithm was as low as in the range of -0.1 to 0.1, and the TF under the prediction of the algorithm was basically the same as the actual situation. In summary, it can be concluded that the designed WKM algorithm can well analyze the clustering of TDs in space for the five urban areas, while the KMH algorithm is able to carry out accurate TFFs. Although the designed prediction method has a better performance, it should be followed up with a test of the method's prediction for TFs of other cities as a way of proving that the method has a better generalizability.

Application of Improved Deep Convolutional Neural Network Algorithm in Damaged Information Restoration

Wenya Jia
Department of Instrument Engineering, Shanxi Pharmaceutical Vocational College, Taiyuan, 030031, China

***Abstract*—The repair of damaged documents has practical significance in multiple fields and can help people better analyze data information. This study proposes an improved algorithm model based on deep convolutional neural networks to address the issues of poor restoration performance and insufficient restoration information in the current process of restoring damaged document information. The new model improves the ability of document image classification and recognition data by using deep convolutional neural networks and incorporates grayscale rules to enhance the edge information restoration problem in the document information restoration process. The results indicated that in the repair of document data, the research model could achieve good document repair results. The average accuracy of the research model was 94.2%, which was 4.6% higher than the 89.6% of other models. The average percentage error of the model was around 3.6, which was about 2.2 lower than other models. The algorithm model used had the lowest average root mean square error of only 4.4, which was 1.9 lower than the highest model, and its stability was the best among several models. Therefore, the new model has a good repair effect in document information restoration, which has good guiding significance for the research of damaged information restoration.**

***Keywords*—Damaged document information; restoration; deep convolutional neural network; grayscale rules**

I. Introduction

A. Research Background

With the rapid development of information technology, the application of image and video data in various fields has become increasingly widespread, including medical imaging, satellite remote sensing, security monitoring, and multimedia communication [1]. However, in practical applications, these data are often damaged due to various reasons, such as transmission errors, compression losses, sensor defects, or environmental interference, which seriously affect the quality and availability of the data [2]. Therefore, effective Document Information Restoration (DIR) technology is of great significance for improving data quality and ensuring information integrity. Traditional DIR technology is mainly based on various mathematical models, such as linear filters, statistical models, and partial differential equations. In recent years, with the rise of deep learning technology, Deep Convolutional Neural Network (DCNN) has become a hot topic in the field of information restoration due to its excellent feature extraction ability and ability to learn complex data representations [3]. Compared to traditional methods, DCNN can automatically learn deeper and more abstract data representations, thus more effectively handling complex damage situations [4].

B. Research Questions and Methods

The existing methods for document information restoration, especially those that rely on traditional mathematical models such as linear filters, statistical models, and partial differential equations, often have poor performance in dealing with complex damage situations. These methods often struggle to recover high-quality images when faced with highly complex or widely distributed types of damage, especially in terms of edge information and details. In the process of document information restoration, existing technologies often cannot effectively recover all necessary information. The lack of information not only affects the readability of documents but may also lead to the loss of key data, thereby affecting decision-making and subsequent processing. In addition, DCNN has good adaptability and can adapt to different types and degrees of damage through training. Based on this, this study proposes a new model that combines grayscale rules and DCNN to address the current shortcomings of DIR technology and poor repair effects.

C. Research Content and Innovations

The model utilizes the image segmentation and document image processing capabilities of DCNN to judge paper documents, improving the restoration and image stitching processes for document modifications. At the same time, it uses grayscale rules to enhance the edge information effect of the document, in order to enhance the efficiency of the entire DIR. The study accelerates the data recovery of damaged document information by using DCNN to effectively extract the depth feature information in the fragments of paper-damaged documents, train the depth information of the neural network, and judge and analyze the data information of the damaged documents. At the same time combined with a variety of information technology and so on, in order to realize the data splicing and restoration of damaged document information, and provide more feasible technical methods for related problems.

D. Article Structure Description

This study is divided into six sections. Section II is an explanation of domestic and foreign research. Section III is the modeling of the current research methods. Section IV involves conducting feasibility analysis and performance testing on the

current research model through experiments. Discussion and conclusion is given in Section V and Section VI respectively.

II. Related Works

In the past few decades, deep learning techniques, especially DCNN, have made significant progress in the field of information processing. They have demonstrated excellent performance in various aspects such as image recognition, speech processing, and natural language understanding. Chang et al. proposed a hierarchical classification Head-based Convolutional Gated Deep Neural Network (HCGDNN) to improve the performance of Automatic Modulation Classification (AMC). This method utilized outputs from different layers and only used in-phase/orthogonal cues for modulation prediction. Compared to AMC methods using other clues, HCGDNN had lower computational overhead and achieved excellent performance on public benchmarks [5]. Wang et al. proposed a novel Domain Adversarial Transfer CNN, i.e. DATCNN, to solve the insulation defect diagnosis problem of small sample gas insulated switchgear. This network could achieve the diagnosis of insulation defects in small sample gas insulated switchgear equipment through small sample data, and the diagnostic accuracy was high. Compared to other methods, DATCNN had better effectiveness and superiority [6]. Stecula et al. proposed a hit recognition method using AtomNet to search for inhibitors targeting aspartate N-acetyltransferase for the treatment of Carnarvon's disease. Despite the lack of protein structure or high sequence identity homologous templates, this method successfully identified five low micromolar inhibitors with drug like properties [7]. To simplify network representation and solve the core problem of network deformation, Wei et al. proposed a scheme of transforming convolutional layers into any module of neural networks. Abstracting modules into graphs, where blobs were vertices and convolutional layers were edges, the new scheme could effectively verify and solve problems such as network deformation [8].

Research on repairing damaged documents not only involves modifying general paper data information but also enables the recovery of more useful data information. Alkhazraji and others have made the restoration of ancient texts a necessary task for ancient scientific experts and researchers to connect modern humans with ancient civilizations, and inherit cultural, religious, and scientific knowledge. This article reviewed the different ways and methods currently used to restore ancient classics, as well as the achievements of these methods while pointing out the challenges that need to be addressed in the future. Significant progress has been made in using DCNN to repair ancient text datasets [9]. Zhang et al. proposed a method of applying evidence-based medicine theory to virtual restoration practices of disappearing architectural heritage in order to protect and restore it. The digital protection stage of virtual restoration of architectural heritage based on evidence-based design could form a comprehensive knowledge system that was scientific, humanistic, and practical, providing new ideas for the restoration of architectural heritage, and had important practical application value [10]. Elbshbeshi et al. proposed a method of developing a digital document process using laser scanning technology to protect and restore important archaeological sites. By using precise measurement networks and laser scanners, a 3D model with geographic coordinates was successfully created and deformation rates were measured. The established 3D digital model had high accuracy, providing strong support for heritage protection, tourism promotion, and future restoration work [11]. Kim et al. proposed an enhanced CycleGAN model based on enhanced identity loss to address issues such as scratches, ink fading, and handwriting loss caused by weathering damage. This model had higher structural similarity and accuracy than traditional methods, and could achieve automatic repair of early Japanese book pages about 300 years ago [12].

In summary, the current DCNN model is used in image recognition and classification in multiple fields, but in many cases, using only DCNN has many shortcomings in recognition accuracy and classification performance. Therefore, this study proposes a new model based on DCNN and grayscale rules to address the current issues of poor DIR performance. The model improves the classification performance of document image information through DCNN, and then enhances the processing effect of document edges through grayscale rules to achieve better document restoration results. The combination of grayscale rules and DCNN in research is significantly better than traditional methods compared to traditional methods, mainly due to the enhanced ability of the research method to process and recover damaged document images, improving accuracy and efficiency. Traditional document recovery methods often rely on linear filters, statistical models, or partial differential equations, which are often difficult to handle complex types of damage. Moreover, traditional methods are often insufficient to effectively handle abstract representations of corrupted data. DCNN is renowned for its excellent feature extraction ability, excelling in learning complex and abstract data representations, which makes it particularly useful in dealing with complex corruption patterns in documents. By automatically learning deeper and more abstract representations, DCNN provides a more dynamic and adaptable solution for document recovery.

III. Construction of Damaged DIR System

This section mainly analyzes the improvement process of DCNN and elaborates on the use of grayscale rules. A clearer explanation is provided on how to use DCNN and how to build a DIR system during the document repair process.

A. Design of Improved DCNN Algorithm Model

DCNN is a 2D neural network structure for processing mesh data, which is often used in the processing and analysis of mesh data due to its ability to calculate product through the matrix of the neural network structure. In general convolution, the common method is to multiply two integration functions and integrate them simultaneously, as shown in Eq. (1).

$$\int_{-\infty}^{+\infty} f(t)g(x-t)dt \tag{1}$$

In Eq. (1), $f(t), g(x)$ represent the functions that can be integrated in neural CNN. By using this special method of product of functions, the integration value between different

functions can be calculated, and a new function value $h(x)$ can be defined. At this point, $h(x)$ can be denoted as shown in Eq. (2) [13].

$$h(x) = (g * f)(x) \tag{2}$$

The product of functions in Eq. (2) can be verified by identity as shown in Eq. (3).

$$(g * f)(x) = (f * g)(x) \tag{3}$$

The current $h(x)$ represents the identity in neural networks. $f(t), g(x)$ are the input function and output function in the neural network model, respectively. When calculating the discrete data of document information through DCNN, when the value of the discrete data is x, the convolution calculation formula at this time is Eq. (4) [14].

$$h(x) = (f * g)(x) = \sum_{t=-\infty}^{\infty} f(t) g(x-t) \tag{4}$$

Due to the fact that DCNN needs to consider the dimension size of the document when inputting information data. Therefore, the data size obtained from the input dataset and output dataset of the kernel function of the model are both dimensional data parameters learned through the kernel function. At the same time, when performing product operations on kernel functions, the calculated values are all 0, which enables the analysis and operation of document data to be achieved through convolution summation and product operations between different data. When the dimension of convolution operation reaches the 2D level, its 2D operation formula is Eq. (5).

$$h(x, y) = (f * g)(x, y) = \sum_{m} \sum_{n} f(m, n) g(x-m, y-n) \tag{5}$$

In Eq. (5), x, y represent the 2D coordinates of DCNN, and m, n are the input and output values of DCNN. Because the operation methods in data parsing and convolution of documents can be replaced with each other, their expressions can also be as shown in Eq. (6) [15].

$$h(x, y) = (g * f)(x, y) = \sum_{m} \sum_{n} g(m, n) f(x-m, y-n) \tag{6}$$

In Eq. (6), the expression of parameters is consistent with the parameter expression in the above formula. Due to the upper and lower limits of image information and grayscale values in the document when repairing images, a new operation needs to be provided in the model for the upper limit size of the model, as shown in Eq. (7) [16].

$$h(x, y) = (g * f)(x, y) = \sum_{m} \sum_{n} g(x+m, y+n) f(m, n) \tag{7}$$

In Eq. (7), the expression of the parameters is consistent with the above parameter expression. Due to the relatively small processing effect of feature data for stable paper edges in DCNN, grayscale matching rules are added to DCNN to perform pixel restoration judgment on the edge paper of the document. Fig. 1 shows the process of edge repair algorithm.

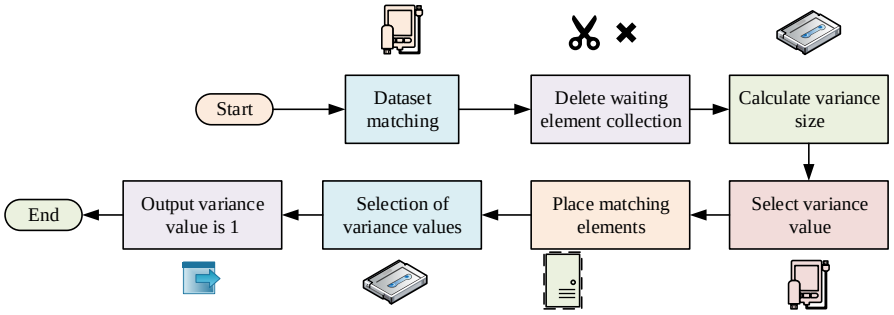

Fig. 1. Edge repair algorithm process.

Firstly, in the grayscale matching rule, the dataset obtained by DCNN classification is matched as empty, and the initial and waiting matching values are also set as empty. The initial value is the classification set of damaged documents obtained through deep neural networks. Afterwards, the set of waiting elements to be matched in the set is deleted from the total set to obtain a new sequence of matching element pixels, and then combined with the set that needs to be matched to calculate the variance size of the left and right document pixel columns. The current minimum variance value is selected as the basis for missing parts of the document to obtain the best matching effect, and then the matching elements are placed in the already matched set. The matching element values are placed into the set that has already been matched, and the process of selecting variance values is repeated to obtain the best matching result. Afterwards, the process of calculating the variance value is repeated until the remaining parameter data of the best matching set is 1. Finally, the obtained matching elements are input into the document order. At this point, the output document sequence element is the edge paper splicing sequence of the damaged document. For grayscale matching rules, the histogram is a method of adjusting grayscale matching. This method can enhance images and standardize them, as shown in Eq. (8).

$$H'(v) = G(H(v)) \tag{8}$$

In Eq. (8), $H(v)$ is the cumulative histogram of the original image, $H'(v)$ represents the cumulative histogram

of the original image, and G is the size of the transformation function of the grayscale image. The normalized image data processing process for grayscale values is Eq. (9) [17].

$$NCC = \frac{\sum_{i,j}[I(i,j)-\bar{I}][T(i,j)-\bar{T}]}{\sqrt{\sum_{i,j}[I(i,j)-\bar{I}]^2\sum_{i,j}[T(i,j)-\bar{T}]^2}} \quad (9)$$

In Eq. (9), NCC represents normalization processing. I,T are the image and template that require grayscale processing. $\bar{I},\bar{T}$ represent the grayscale value size of the image and the grayscale value size of the template, respectively. When performing grayscale processing on an image, not only should the grayscale value of the image be considered, but also similarity should be taken into account, as shown in the similarity formula in Eq. (10) [18].

$$SSIM(x,y) = \frac{(2\mu_x\mu_y + C_1)(2\sigma_{xy} + C_2)}{(\mu_x^2 + \mu_y^2 + C)(\sigma_x^2 + \sigma_y^2 + C_2)} \quad (10)$$

In Eq. (10), $SSIM(x,y)$ represents the similarity size of 2D images. μ_x,μ_y are the average sizes of the image in different directions. σ_x,σ_y are the standard deviation sizes in different directions of the image. σ_{xy} represents the covariance size, and C_1,C_2 represent the constant sizes, respectively. Improving the current DCNN by adding grayscale value matching can enhance the edge recognition and text recognition performance of document images. At the same time, due to the need to follow the best matching effect when calculating different paper damaged documents, the cosine distance formula needs to be used for calculating the best effect of the document, as shown in Eq. (11) [19].

$$x = (x_1, x_2, \cdots, x_n) \quad (11)$$

In Eq. (11), x represents the horizontal coordinate of the document in the n-th dimension. $x_1, x_2, \cdots, x_n$ refer to the horizontal coordinates of different dimensions. The vertical coordinates are shown in Eq. (12) [20].

$$y = (y_1, y_2, \cdots, y_n) \quad (12)$$

In Eq. (12), y is the vertical coordinates of the document in the n-th dimension. $y_1, y_2, \cdots, y_n$ are the vertical coordinates of different dimensions. The cosine distance of the document at this time is Eq. (13) [21].

$$d_{xy} = \frac{\sum_{i=1}^{n} x_i y_i}{\sqrt{\sum_{i=1}^{n} x_i^2} * \sqrt{\sum_{i=1}^{n} y_i^2}} \quad (13)$$

In Eq. (13), d_{xy} represents the cosine distance, and x_i, y_i are the size of the dimension vector in the horizontal and vertical coordinates, respectively. After calculating the cosine distance of the document, an improved DCNN is used to cluster and analyze the document information, obtaining different fragments of document information. Fig. 2 shows the process of processing fragmented data.

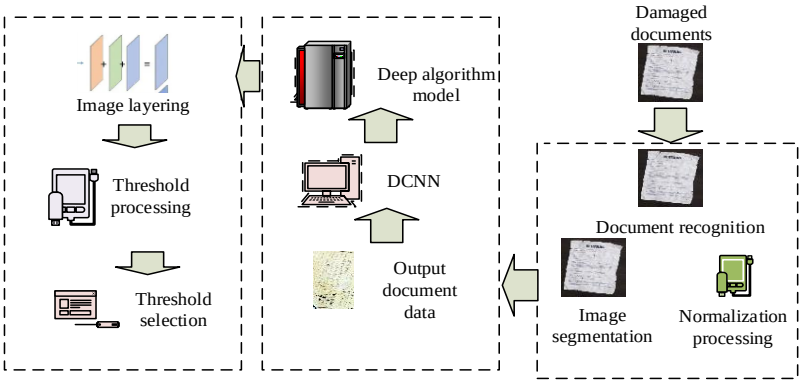

Fig. 2. Fragmented data processing process.

In Fig. 2, when analyzing the fragmented image of a damaged document, the fragmented information of the document is first read and the image information data is converted into damaged document data. Afterwards, the document is normalized to obtain the document image data, and the image data is input into the DCNN algorithm model. The threshold setting and selection of data are achieved through the convolutional layer of DCNN, and the final threshold is used for the next part of selection and data processing.

B. Design of Damaged DIR Model

The most important step in repairing damaged document information is to train the current document data, which is to convert the damaged document information into image data parameters that the computer can recognize. At this point, several conditions need to be met: adjacent paper documents are marked as 1 when splicing, and non-adjacent documents are marked as 0 when splicing. To cut the complete document through a program and train and validate it using an improved DCNN. Fig. 3 shows the process of paper document processing.

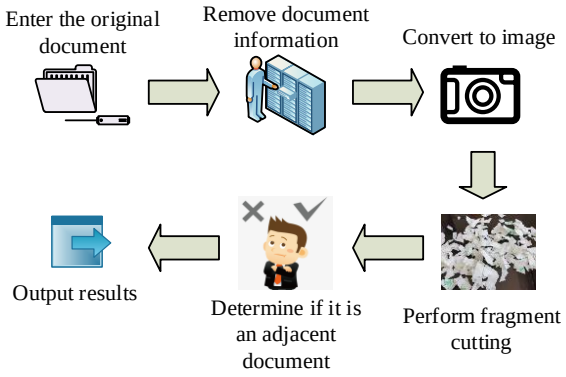

Fig. 3. Paper document processing.

In Fig. 3, the algorithm model can input the current original document into the computer during training. Setting the font and size of the document to be the same, removing redundant data information and parameters from the document. Afterwards, the document is converted into image data and fragmented according to the same image size. Splicing image fragments and determining whether the current document is an adjacent document. Adjacent or non-adjacent documents are set, and the result is output after the setting is completed. The matrix result of damaged documents can be generated by judging whether the documents are adjacent. At the same time, in DIR, some document images may have edge fragments with blank edges. To this end, after clustering analysis of the document, to find the fragmented document at the leftmost edge of the current document, and to perform fragment processing and document search. Fig. 4 shows the process of searching for document fragments.

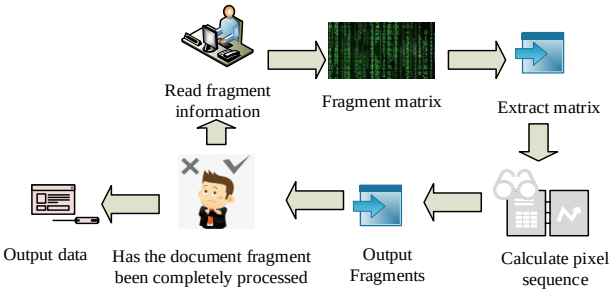

Fig. 4. Document fragment search process.

In Fig. 4, when searching for document fragments, the current fragment data information is first read and processed into a fragment matrix. The pixel matrix on the left of the extraction matrix represents the current feature matrix. Afterwards, to calculate the pixel sequence of the feature matrix, output the minimum left document fragment of the current sequence, and determine whether the document fragment classification has been fully processed. If so, to output the edge document fragment directly. If not, continue reading the document fragment size until the current document fragment has been fully processed. After searching for missing edge information in documents, due to the presence of different feature data in some documents and the same feature data in some identical document information, the following feature processing is required to complete the repair of the entire document information, as shown in Fig. 5.

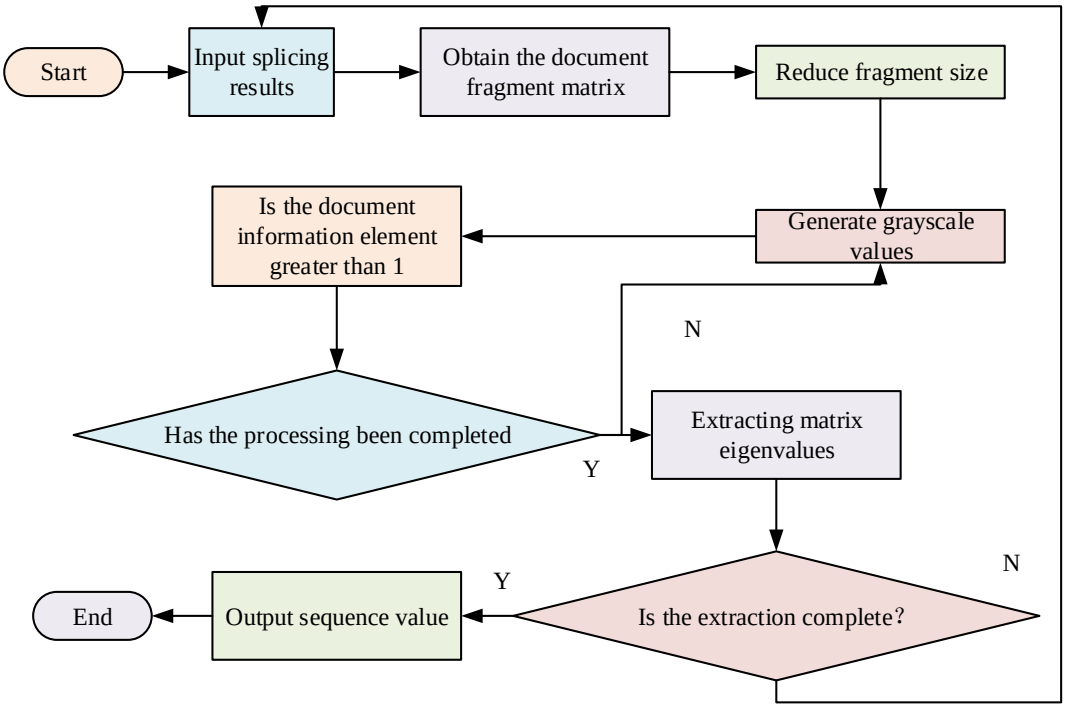

Fig. 5. Document information restoration feature processing process.

In Fig. 5, the results of concatenating different document fragments are input into the algorithm model, and the corresponding document fragment matrix is obtained through model processing. Afterwards, reducing the size of the document fragments to generate a grayscale value document fragment information matrix sequence, and determining whether the document information elements are greater than 1: if greater than 1, set the matrix to 1, and if not greater than 1, process it as 0. Judging whether the processing of the element data has been completed: once the element processing is completed, start extracting matrix feature values. If not, continuing to judge the result of the element processing. Judging whether the extracted document fragments have been completely extracted: If they are complete, to concatenate the matrix and output matching sequence values. If they are not processed, to re-input the document fragment information into the computer. The repair of document information can be basically completed by concatenating the side and overall document information. It also includes the most important step of auxiliary repair system function in the model, which is used to concatenate complete document information. Fig. 6 shows the auxiliary repair system process.

In Fig. 6, in the auxiliary repair of damaged documents, the fragments of the document are first inputted, and the results of the document are processed and feature extracted through an algorithm model. Afterwards, the sequence number on the left side of the current fragment is obtained based on the number of fragments obtained, and an improved DCNN model is used to process document fragments. The sequence of document fragments obtained is concatenated and output to the front-end. The document is manually adjusted to assist in concatenation, and then the concatenated document is output.

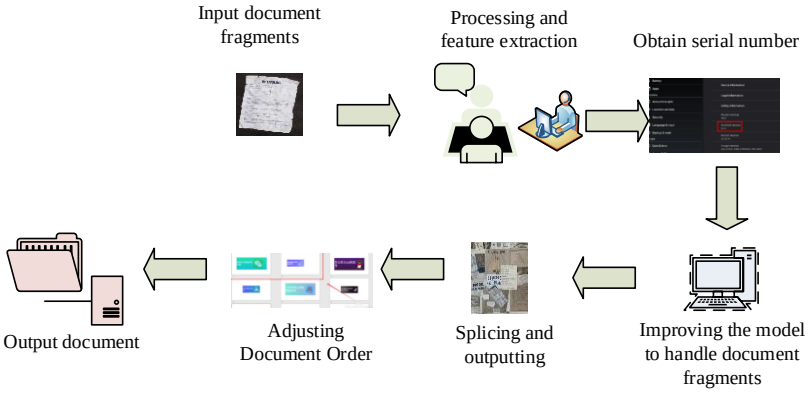

Fig. 6. Auxiliary repair system process.

IV. Analysis of DIR Results for Improving DCNN

For document repair, it is necessary to verify the serial number of the repaired document, whether it is the final document data information obtained, and whether the repair is still needed. Therefore, this study will repair some of the document data currently used and calculate the degree of damage deviation of the document fragments after clustering analysis using the algorithm model. Deviation is an indicator of the degree of dispersion of data. The greater the deviation, the greater the deviation of the current document repair data. Table I compares the deviation of the concatenated documents in the current model.

TABLE I. Comparison of Deviation Degree in Document Repair of Improved DCNN

Number of document repair lines	1	2	3	4	5	6	7	8	9	10	11	12	Total
Dataset 1	1	2	0	0	1	3	4	0	0	1	2	1	15
Dataset 2	0	0	2	3	1	4	0	0	3	4	0	1	18
Dataset 3	0	0	3	2	4	3	0	0	5	4	1	2	24
Dataset 4	0	0	3	2	4	1	0	5	1	4	0	4	24
Dataset 5	0	0	1	2	3	5	1	0	0	1	2	2	17

In Table I, the row number represents the number of rows in the current document, where 1 represents the first row and 2 represents the second row. In comparing the deviation degrees of different document repairs, dataset 1 has the lowest deviation degree of 15, indicating that the smallest deviation degree can be achieved in the data of this document, and the repair effect of the document is the best. At the same time, in each line of document repair, the deviation is relatively small, indicating that using the improved DCNN model has a good effect on document repair, and the overall repair effect is also within an acceptable range. Comparing the model used with DCNN and Grayscale Rules (GR) to calculate the deviation of damaged documents. Selecting Dataset 1 and Dataset 4 for calculation testing. Dataset 1 has the smallest total deviation, while dataset 2 has a normal deviation range. Fig. 7 shows the comparison results.

In Fig. 7 (a), when comparing the three algorithm models, the study found that the deviation of the model was smaller in different document line numbers, and the overall repair effect on the document was better. The deviation degree of the

research model can reach a maximum difference of 2 compared to the other two algorithms. In Fig. 7 (b), the deviation of the research method is also small, with a maximum deviation value of 2. This indicates that the research model can enhance the document repair ability of a single algorithm model. Comparing the SSIM values of the traditional algorithm models Otsu's Method (OM) and Bilateral Filter (BF) with the research model in the document. Both dataset 1 and dataset 2 are selected, and the larger the SSIM value, the better the overall repair effect of the model, as shown in Fig. 8.

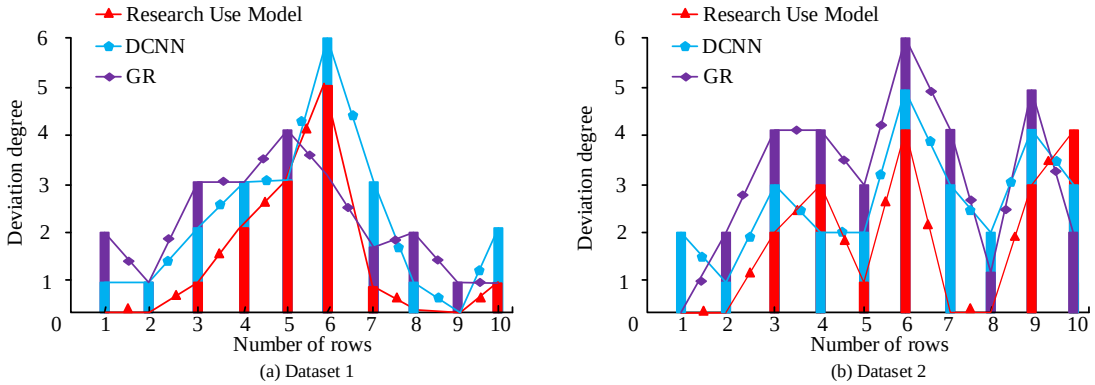

Fig. 7. Comparison test chart of deviation degree of three models.

In Fig. 8 (a), among the three algorithms, the similarity between the document repaired by the research model and the initial document is higher, closer to 1, with the highest value appearing around 220 documents. At this point, the SSIM value is 0.98. The lowest SSIM value appears around 220, with a minimum of -0.21, which is 1.19 lower than the highest value. This indicates that the current research method can basically achieve consistency with the original document when repairing document information, which may be the reason why the method is more superior. In Fig. 8 (b), the SSIM value of the research method is also the highest at 0.92, which is 1.08 higher than the lowest model BF of -0.16. As a result, the research method has a higher similarity in document repair between the two datasets, and the repair effect is better. Comparing the accuracy trends of three current algorithms in document repair, Fig. 9 is obtained.

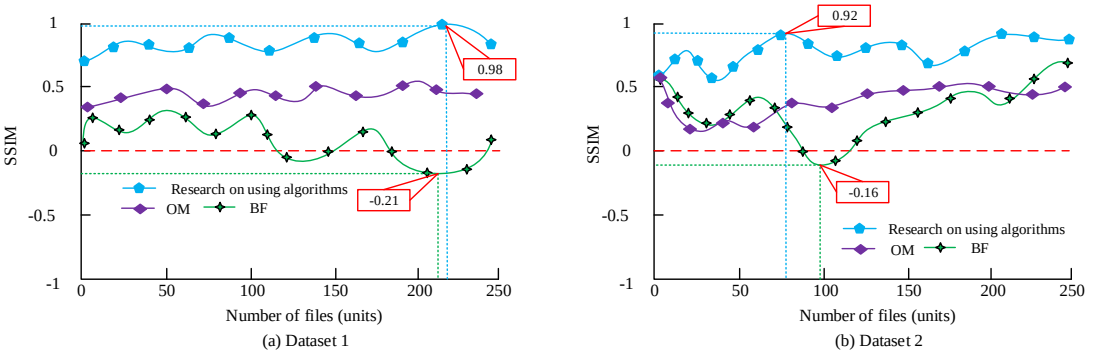

Fig. 8. Comparison of SSIM values among three algorithm models.

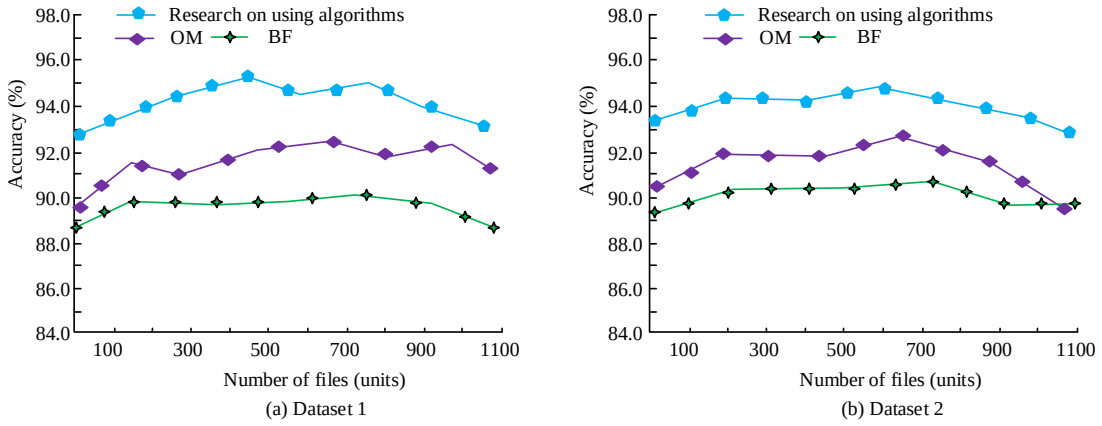

Fig. 9. Comparison of Accuracy of Three Algorithms on Two Datasets.

In Fig. 9 (a), the accuracy trend of the three algorithm models first increases and then gradually decreases, and the overall trend belongs to an upward and downward fluctuation trend. The accuracy of the research model is relatively high, with an average accuracy of 94.2%, which is 4.6% higher than the average accuracy of the BF model with the lowest accuracy of 89.6%. In Fig. 9 (b), the average accuracy of the research method at 94.1% is at a high level, which is about 5.0% higher than the lowest average accuracy of BF at 89.1%. Therefore, the document repair accuracy of the research model is better, and the processing effect on document fragments is better. Comparing the Average Percentage Error (APE) and Root Mean Square Wrror (RMSE) changes of the current three method models to obtain Fig. 10.

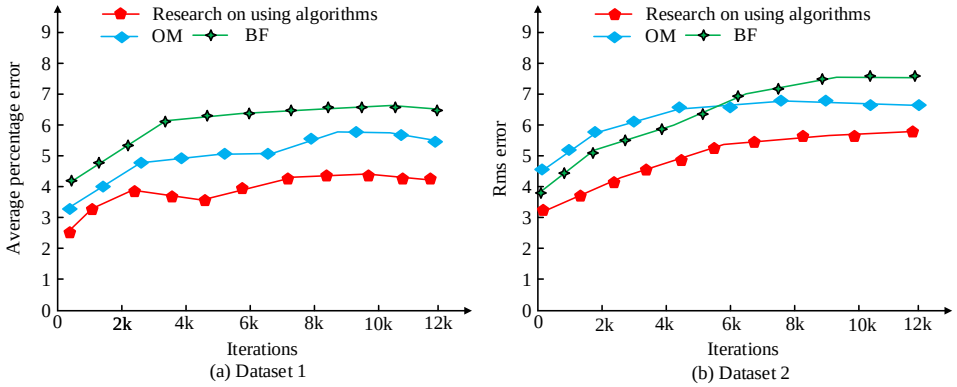

Fig. 10. Comparison of errors among three algorithm models.

In Fig. 10 (a), among the three algorithm models, the study model has the smallest APE value, with an average value of around 3.6, which is about 2.2 lower than the highest BF of 5.8. In Fig. 10 (b), the lowest RMSE value of the research model is only 4.4, which is 1.9 different from the highest BF of 6.3. Therefore, the error of the research model's DIR is smaller, and the data model is better, indicating that using this method can improve the effectiveness of document restoration to a certain extent. To test the stability of the current research model, it was compared and tested with the two algorithm models mentioned above, and Fig. 11 was obtained.

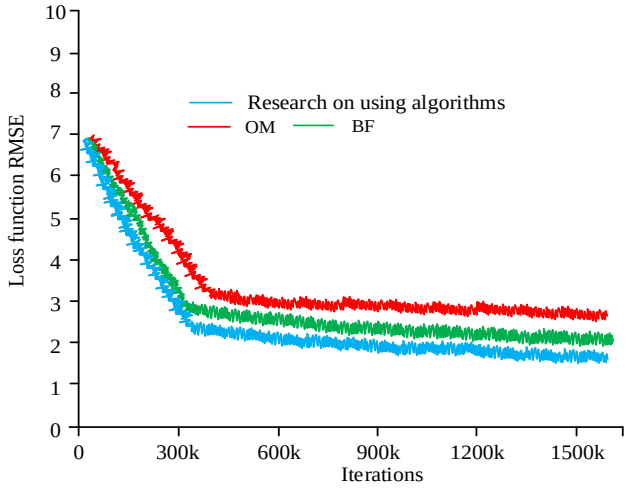

Fig. 11. Changes in loss functions of three algorithm models.

In Fig. 11, in the comparison of the three models, the loss function of the model decreases with the increase of iteration times, and the value of the loss function tends to stabilize when it reaches a certain value. The lowest loss function value appears in the research model, only around 2, with the highest loss function model being OM and a loss value of 3, with a difference of 1 between the two models. Therefore, in model comparison, the loss function value of the research model is lower, and the algorithm model is more stable.

V. Discussion

In today's information age, document and image data play a vital role in a variety of fields, including healthcare, education, law, and business. However, these important data are often at risk of corruption due to transmission errors, storage problems, physical damage, or other technical issues. Damaged documents and images not only affect the availability and readability of information but can also lead to the loss of critical information, which can have a significant impact on related business and decision-making. Therefore, the development of efficient information recovery technologies, especially those that can accurately repair damaged documents and images, has important practical application value and wide market demand.

Therefore, the study repairs broken documents and broken information by using the improved DCNN algorithm, and enhances the effect of information modification by using the grayscale rule. From the comparison of the deviation values, it can be seen that in the process of repairing different information, the deviation of the method used in the study reaches a maximum of 5 and a minimum of 0. This indicates that in the process of document repair, the method used in the study is able to repair the data and information efficiently, and the deviation is within a relatively small range, which may be due to the use of grayscale rules. From the comparison of the deviation of different models, it can be seen that the maximum difference between the deviation of the research model and the comparison of the deviation of the other models is 2. This indicates that the research uses methods that are more effective in modifying the document information, which may be due to the use of the grayscale rule to enhance the model's ability to repair the edge documents. In comparing the SSIM values, the research use model can basically approach the SSIM value of 1.00, which indicates that the research use

model has a better document repair effect and its modification ability is closer to the real document information. This may be due to the better performance of the improved DCNN algorithm model.

In the comparison of repair accuracy of the algorithmic models, the average accuracy of the research use model is at 94.2% and 94.1%, which is relatively higher than the traditional method. This may be due to the reason that the research use method can effectively extract the depth feature information of document information. From the error comparison of the algorithm model, it is found that the average root-mean-square error of the algorithm model is only 4.4, which is 1.9 lower than that of the BF model, which can be seen that the research model has a better repair effect in the repair of the deviation value, which may be due to the reason that the research use model is able to judge the data of the damaged document information. To summarize, in the repair of damaged document information, the research using the method in the document repair effect, information repair accuracy and information document repair deviation have better performance, which shows that the research using the model than the traditional method has the ability to repair better, which has a better research value for the future of the document information repair research.

Although the improved model in the document shows high accuracy in handling damaged documents, the model still faces the problem of decreased accuracy when dealing with highly complex or extreme damage situations. The performance of DCNN is highly dependent on the quality and quantity of training data. If the training data is insufficient to cover all possible types of damage, the model may not be able to accurately identify and recover when encountering complex or uncommon types of damage that have not been seen before. Although DCNN performs well in extracting complex features, it may not be sensitive enough to some subtle and difficult to distinguish features, which limits its application in situations that require high-precision recognition. In practical applications, certain types of damages may be more common than others, which may lead to better recognition performance of the model for common types of damages during training, while performing poorly for less common types of damages. DCNN may be limited by the complexity and diversity of the features it captures when making classification decisions. If the depth or structure of the model cannot fully capture the key features that determine classification, its classification performance may not be ideal. Although the model mentioned in the document performs well on specific datasets, its generalization ability may be limited to other broader or different types of damaged documents.

VI. Conclusion

The current document information restoration technology often faces the problem of unsatisfactory restoration results when dealing with damaged documents, especially in the areas of edge information restoration and information integrity. By introducing an improved DCNN model, the data processing capability of document image classification and recognition is enhanced. And add grayscale rules on the basis of DCNN. When processing edge information in documents, use grayscale rules to improve the accuracy of edge repair. And through experimental testing of the feasibility and performance of the new model, analyze the restoration effect that the proposed method can achieve in practical applications. This study first analyzed the current DCNN and grayscale rules, introduced the main process of the current research, described the repair process, built an improved DIR model, and finally tested the feasibility and performance of the research model through experiments. Experiments had shown that in document data restoration, research model could achieve good document restoration results. The similarity of document repair occurred at a maximum quantity of around 220, with a value of 0.98, which was 1.19 higher than the lowest SSIM value. In dataset 2, the SSIM value of the research model was also the highest at 0.92, which was 1.08 higher than the lowest model. The accuracy of the research model was relatively high, with an average accuracy of 94.2%, which was 4.6% higher than the lowest accuracy model of 89.6%. The average APE value of the research model was around 3.6, which was about 2.2 lower than the highest model. The lowest RMSE value of the research model was only 4.4, which was 1.9 lower than the highest model. At the same time, the algorithm stability of the research model was the highest, and the model performance was better. Although the research has achieved a lot of results, there are limitations at present. For example, the research has been optimized and tested mainly for specific types of documents, while it may not be effective for other types of broken documents. The applicability and flexibility of the model may be limited, and the document's word order and sentence coherence may not be sufficiently considered and recovered. Advanced deep convolutional neural networks typically require significant computational resources, which may limit the utility of the model in resource-constrained environments. While grayscale rules assist in the restoration of edge information, their effectiveness in dealing with highly complex or irregular edge damage may be limited. Although the models mentioned in the study perform well on the current dataset, the adaptability and flexibility of the models for different degrees and types of damage have not been fully validated. Therefore, subsequent studies need to increase the diversity of document types, optimize the algorithm's ability to deal with word order and sentence coherence, as well as improve the computational efficiency and adaptability of the model, to enhance the overall performance and practical value of the model.

Fundings

The research is supported by Science and technology innovation project of Shanxi Provincial Education Department in 2022: Research on true and false intelligence recognition of Bupleuri based on deep learning (No.: 2022L676).

Designing the VPN with Top-Down to Improve Information Security

Valero Andia Billy Scott, Sanchez Atuncar Giancarlo
Faculty of Systems Engineering, Universidad Cesar Vallejo, Lima, Perú

***Abstract*—In this article, presents a systematic review of virtual private networks (VPNs) and their contribution to improving information security, with a particular focus on the Andia Consortium. It examines how VPN technology, through its ability to provide a secure channel for communication between devices, can protect organizations' valuable digital data against cyber-attacks. Various types of VPN systems, their security strategies, advantages and disadvantages, and their dependence on different protocols and standards are discussed. Additionally, tunneling technology, a key technology in VPN implementation, is explored. Through this study, we seek to identify the benefits and limitations of using VPN to improve information security. This work aims to provide a deeper understanding of how VPNs can be designed from the top down to improve information security in organizations.**

***Keywords*—VPN; cyber-attacks; security information**

I. Introduction

Attacks [2] are increasing lately, and it is recommended nowadays to have information security, it is very important to cope in our current era, where technology and information have become increasingly ubiquitous. Protecting our information would be the same as protecting our data from any form or means of unauthorized access, use, disclosure, interruption or destruction, to guarantee the accessibility, reliability and usability of our data of the information. Information security is applied to any type of data, whether it is an email in virtual or physical format, and it applies to all types of companies. (p.1). Imperva (2021) also tells us that the protection of our data is an extensive topic that includes protection against internal and external threats, such as hackers, computer viruses, natural disasters and server failures. The stability of our data also means that our privacy will be protected from third parties, since personal and financial information can be stolen and used fraudulently. In general, information security is essential to ensure a sequence of elements and the reputation of organizations in today's world (p.1) [31].

Currently [3] the increase in Information and communication technologies (TIC) has caused a growth in the amount of data that is sent through the Internet, which in turn has increased concern about the security of this information. One of the most effective ways to ensure online data protection [1] through the VPN method that is carried out by computers that allows a secure extension of the local area network, which allows data encryption and connection to internet through secure servers (p.3).

In line with this need, [4] businesses and government organizations have started implementing VPN solutions in order to ensure online data security. For example, [33] in a recent research study carried out by Cid-Fuentes et al., it was found that the use of VPN is an effective strategy to protect online information in Spanish companies in various areas of the sector, such as education, also the area health, and finances. Designing a VPN can be a complex process that requires consideration of multiple factors, such as the choice of encryption protocols and server configuration. In this sense, the Top-Down methodology has been proposed as an effective way to approach the design of security networks, by allowing the risks and needs of this security to be detected and identified before the implementation of the solution.

In our country, [5] information security became a very recent topic of concern. Technology advances at very rapid pace, thus becoming more important for our environment, making it much more difficult to find correct ways to defend ourselves and, in turn, the consortium's information. Given that our network is becoming larger and more complex, and with the emergence of the Internet of Things, it is necessary to look for innovative alternatives and protect our information data. Therefore, the use of a VPN could provide an effective solution to ensure that we provide a confidential and complete service in the company [27].

According to the Ministry of Labor and Employment Promotion (MTPE), it reported 226 thousand formal workers under the modality of teleworking or remote work, which represents 6.7 percent of formal employees in the private sector, this increases the vulnerability factor for security [17]. Additionally, with the growing number of devices connected to the network, it is difficult to control who accesses confidential information. Therefore, a VPN could allow company employees to access the internal network in a more protected way from any point of internet, while guaranteeing private information along with information security [13].

On the other hand, there is concern in our city about the growing number of cyber-attacks on companies and government organizations. With the emergence of new technologies [6], new forms of cyber-attacks have also appeared, making it necessary to seek effective measures to protect the organization's confidential information. A VPN can provide a more secure solution for the confidentiality and integrity of our company data against possible external threats.

In the current consortium, we are faced with a situation that poses various challenges related to information security [34] and effective communication between headquarters. Defining the problem will allow us to clearly define the key aspects that require attention. Challenges include lack of sensitive

information, insecure information due to lack of encryption, poor access control, the need for integrity for our information, and limited data availability. [25] These problems arise from the use of a public cloud with a free account for the exchange of information, as well as the lack of an adequate and secure connection between the consortium's headquarters as seen in Fig. 1. These deficiencies put the confidentiality of important data at risk and may result in the potential disclosure of confidential information.

The relevance of this research lies in its focused approach to analyzing applications and previous studies linked to the implementation of Virtual Private Networks (VPNs) [19] within the scope of information security in business environments. In a context where data protection and cybersecurity stand as critical priorities, this study seeks to justify the urgent need to ensure the integrity and privacy of corporate information. Its primary objective is to delve into the advantages and challenges associated with the adoption of VPNs in today's business landscape [9]. By relying on a robust theoretical framework supported by previous research, it aspires not only to offer specific recommendations for enhancing information security through VPNs but also to establish a solid foundation for future studies in this field, outlining specific areas of focus and potential directions for more effective and adaptable computer security in diverse business contexts.

The fundamental purpose of this study is to critically examine existing research related to the implementation of Virtual Private Networks (VPNs) in the information security process within companies and organizations. This approach aims not only to justify the urgency of safeguarding corporate data but also to deeply comprehend the inherent benefits and obstacles associated with VPN adoption in business environments [7]. With a rigorous approach supported by a review of specialized literature, the intention is to provide substantial recommendations for enhancing information protection using VPNs, while also laying the groundwork for future research that explores areas for improvement and development in enterprise computer security.

In this paper, we explore the potential of Virtual Private Networks (VPNs) as a viable solution to address the growing information security [39] concerns faced by the consortium. Through a comprehensive analysis of existing research and a thorough assessment of the advantages and challenges associated with VPN implementation, this study aims to provide valuable insights and recommendations. In particular, we will examine how VPNs can mitigate the specific challenges faced by the consortium, such as the lack of encryption and insecure information exchange. Additionally, we will discuss best practices for the effective adoption of VPNs in a business environment. Ultimately, this study aspires to contribute to the development of a secure and efficient information sharing system within the consortium, thereby strengthening its stance against evolving cyber threats.

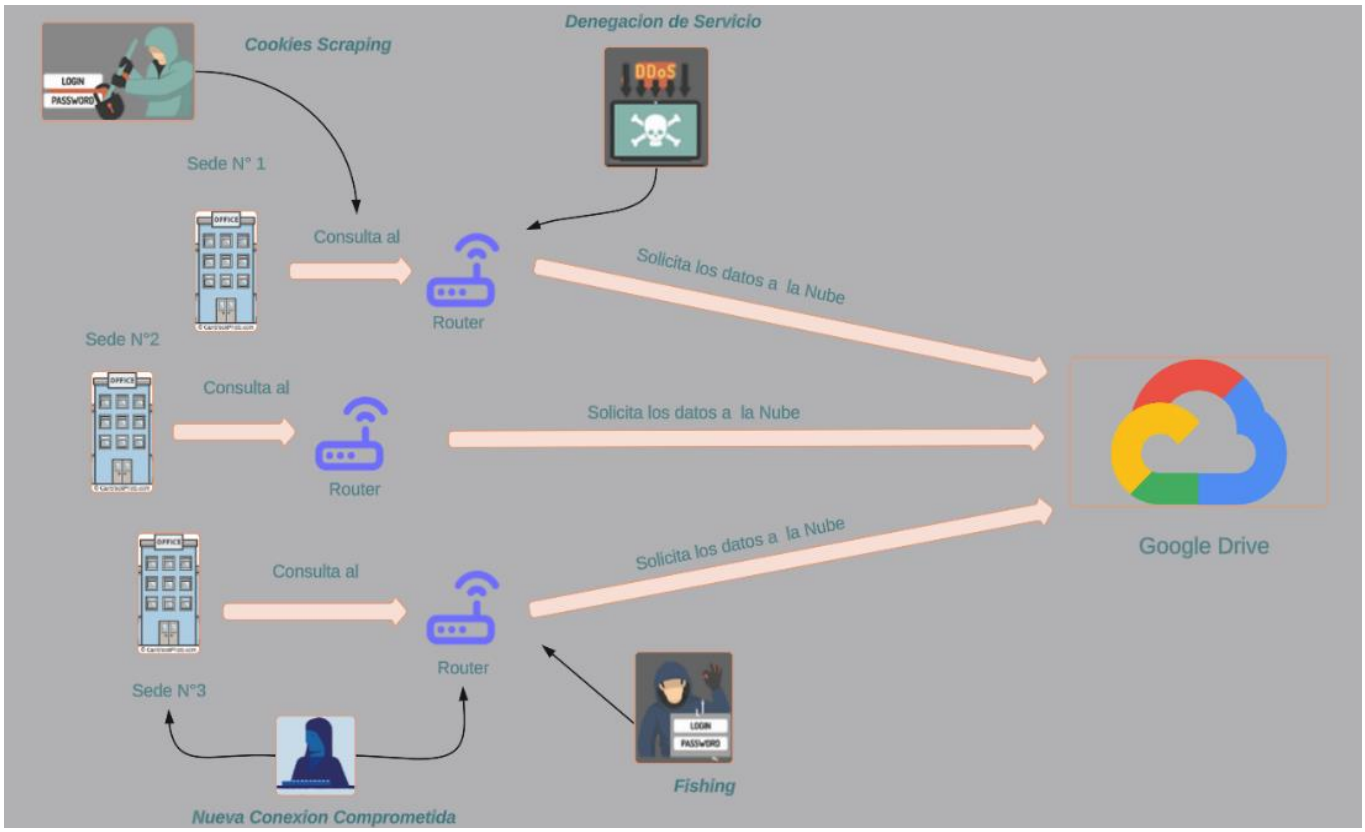

Fig. 1. Graphic Representation of the current situation of the consortium.

II. METHODOLOGY

First, this section compiles various research conducted in recent years on the application of VPN and security information.

There are many works or studies carried out on the topic of information security, [8] in the search for information, research similar to the title was found, in the national environment the research of Lazarte and Silva, 2022, in their proposal Creating a VPN using open-source software This report provides valuable information on how to implement a VPN under open-source software to improve information security in a specific area. The methodology that was used was the Top-Down Network Design methodology for the implementation of the project to deploy a Virtual Private Network using free software solutions. This methodology consists of four phases: Conduct a thorough analysis of the requirements, develop a detailed logical design, develop a corresponding physical design and perform rigorous testing, effective optimization and complete documentation of the implementation (p.15) [36].

In another study [10] it is proposed to create a framework to use a virtual network protocol with free software and increase Internet bandwidth. Based on the Cisco PPDIOO (Prepare, Plan, Design, Implement Operate and Optimize) methodology, the V2RAY platform architecture is implemented on AWS and ORACLE clouds. The results of the evaluations before and after using the solution showed significant improvements in several metrics. In particular, the download speed increased by 26.4%, the upload speed increased by 79.5%, and the response time increased by One Hundred per cent. In addition, a dropout rate of One Hundred Percent was recorded, which was also considered significant with a p-value < 0.05 for its indicators (p.12).

It was also found in the work in 2021, [11] in its title VPN and its implementation with PPDIOO to improve computer security, the implementation of a VPN is proposed to make improvements, in information security in the company network. The research is based on a sample of 30 processes related to computer security, using observation sheets to collect data. [23] A quantitative approach and a pure experimental design were used, applying statistical tests to contrast the hypotheses. The results obtained show a significant decrease in the number of incidents reported by users, a reduction in the number of users connected to the network, a decrease in access time to shared folders, and an increase in the level of user satisfaction. the users.

In the work where VPN is implemented [12] and thus improves information security, the main objective was to improve network services through the implementation of a VPN in the educational institution. This research used a quantitative approach, with a pre-experimental design. The sample consisted of 30 participants, and information was collected through questionnaires related to VPN and also information security. The results revealed that VPN implementation was at a medium level, while the dependent variable showed a trend towards the high level with much of the medium level. When contrasting VPN implementation with information security, a significant influence was found between both variables. That is, by increasing the implementation of the VPN in the Public Military Educational Institution Colegio Militar Francisco Bolognesi, a direct correlation could be verified with the improvement of information security. In contrast, a decline in VPN adoption resulted in a decline in data security. These findings highlight the importance of using a VPN as a key and important factor towards information security.

The main purpose [14] was to implement a risk system in the IT area in a strategic plan, so that information security improves in the advertising company. The focus was on the organization's ability to manage risks and prevent potential cyber-attacks and inappropriate manipulations of information. Adequate levels of integrity, privacy and accessibility to the continuity of information were established. When this process was carried out, it was decided to use the Magerit methodology, which made it possible to carry out an exhaustive analysis of the risks present in the organization and obtain specific responses to said risks. These responses were used to implement some solutions in enterprise information security management (p.10).

Similarly for his research, [15] demonstrates that the purpose of implementing ISMS is to safeguard information assets that are fundamental to the company's objectives. In achieving this, it was decided to use the The Deming approach, or the PDCA (Plan-Do-Check-Act) approach, is highly recommended by the ISO 27001 standard for ISMS (Information Security Management System). The result obtained is the minimization of the risks associated with the risks and weaknesses that affect data, documents, systems, technological infrastructure of the Clinic MEDCAM Perú S.A.C. [28], as well as the guarantee of privacy, accessibility and consistency of that information. In conclusion, the most important benefit is to ensure the security of information resources to achieve business objectives (p.8).

Likewise, for Luna [16] its objective is to develop a tool, with a solid base of profitability and usefulness, to establish a remote access VPN connection or link using MIKROTIK equipment that prioritizes the confidentiality of the transfer of information from point A. to point B, preventing unauthorized Internet Points from violating or capturing packets in the traffic and stealing the information sent and received through this VPN, advantageously improving the performance of the network infrastructure, increasing the performance of the packets sent, in addition to demonstrate that resources are used less and RAM workloads are used MIKOTRIK VPN, not like other remote agents with greater memory consumption (p.8).

Also in Ecuador [18], in his work on Security Management aligned with the 27001 standard, he comments that the main objective is to design a methodology that allows the IS to be efficiently and adequately managed, based on the ISO 27001 standard and also the security frameworks. cybersecurity established in ISO/IEC 27032. This methodology focuses on analyzing security gaps in IS, in order to guarantee its protection effectively. It is important to highlight the close relationship between established frameworks and ISO standards. 27001[29] and ISO 27032, which focus on ISMS and cybersecurity. What is proposed is that the developed methodology has the capacity to identify the processes, standards and protocols that are involved in the IS at different management levels.

It is also said that the Internet, as a communication platform, plays a fundamental role in today's society. These technologies allow sensitive information, classified as secret or confidential,

to be transmitted over insecure networks by establishing communication tunnels protected by cryptographic methods.

III. RESULTS

To carry out the current research, the methodology known as Top-Down Network Design seen graphically in Fig. 2, will be used, which has proven its effectiveness in various fields of Engineering. The top-down methodology is important in the industry because it allows designers to understand the system as a whole before starting to design the details. This helps ensure that the system is consistent and working correctly.

It is crucial to highlight that the Top-Down Network Design methodology provides valuable benefits to organizations that adopt it. These benefits encompass improved communication between current and future designers; greater quality control by allowing early identification of defects in the initial stages of design, when their correction is easier and cheaper; increasing designer efficiency by reorganizing design tasks and executing them in parallel, rather than relying on linear sequences; as well as reducing the need for extensive verification of the final design state Phases of the Top-Down Network Design Methodology in Table I.

The methodology has four phases that help the creation and implementation of the

Phase 1: Analyze requirements.

Phase 2: Develop Logical Design.

Phase 3: Develop Physical Design.

Phase 4: Test, optimize and document design.

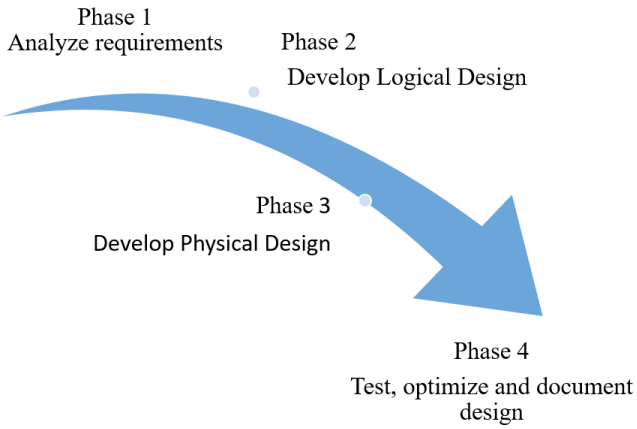

Fig. 2. Methodology top-down.

Phase 1: Analyze requirements

a) Activity 1: Definition of Goals

Through a series of discussions and meetings with department leaders, we collaboratively identified key factors that contribute to the following overall goals:

- The Andia Consortium wants to expand its presence in the real estate market, both nationally and internationally. To do this, it plans to open new offices in other countries and expand its portfolio of products and services. It also strives to offer its clients a wide range of real estate products and services, from the purchase and sale of properties to rental management and home construction. In the same way, it wants to be recognized as a leading company in the real estate sector. To this end, it is committed to offering a high-quality service and being at the forefront of the latest market trends.
- The Andia consortium currently needs technological tools such as electronic invoices, access to a secure intranet, and information sharing to be able to complete business activities within the company. This need comes from the advancement of technology, it is inevitable not to work with current technology and in the case of the consortium having three isolated offices, a network that integrates the branches is necessary, for this reason it is desired to implement a secure network complying with the rule of the CIA triad (Confidentiality, Integrity and Availability).

b) Activity 2: Targeting of Objectives

Having identified the critical issues facing the Andia Consortium, we can now define specific and measurable objectives for the project. These objectives will address the identified problems and contribute to achieving the overall goals:

- Improve information security: The consortium wants to protect your data from loss, disclosure or unauthorized access. To do this, it will implement a role-based access control system, an auditing system and a secure and efficient network infrastructure.
- Improve the efficiency of operations: The consortium wants to streamline its processes and procedures to reduce costs and improve productivity. To do this, you will centralize your data in a single repository, standardize your processes and procedures, and automate repetitive tasks.
- Improve the customer experience: The consortium wants to offer a high-quality and personalized service to its customers. To do this, it will implement a system defined for networks or centralized cloud, where it can monitor clients, having a specific solution for each client.

c) Activity 3: Current Situation of the Company

The Andia Consortium, a real estate company with multiple branches in Lima, currently utilizes an internal wired network to connect its offices and accesses external resources through a separate internet service. A thorough assessment of the existing network infrastructure, including its topology, addressing scheme, equipment capabilities, and security posture, is crucial for the design process:

- Current situation of the Andia Consortium network is made up of the following elements: Routers, switches, wireless PCI cards, wireless routers, computers and laptops. An internal network that is responsible for all the Consortium's traffic at each headquarters independently. There is also an Internet service through which they access external resources and communicate between branches.
- The current problems of the Consortium are the lack of confidentiality by not having secure policies, the data traveling freely without any type of security, it is also not protected against alterations since it does not have an audit system or log records, and availability in case the network fails and there is no backup.

Phase 2: Develop Logical Design

a) Activity 1 Design a Network Topology

A star network (see Fig. 3) topology will be used for the VPN design. This structure allows all devices to interconnect with each other centrally, resembling a local area network (LAN). This configuration offers efficient communication and simplified network management.

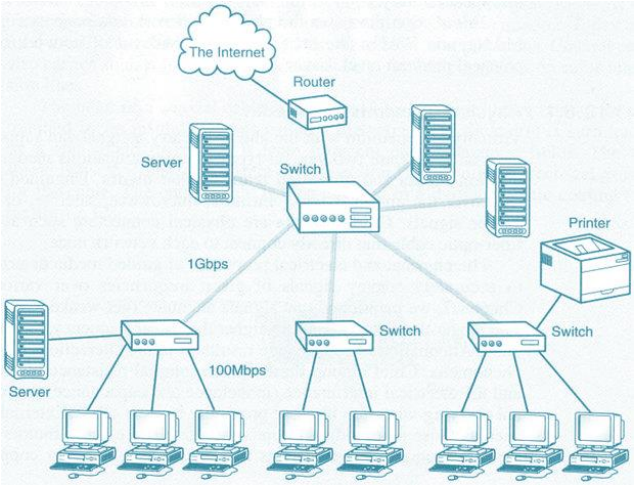

Fig. 3. Star topology.

b) Activity 2 Design Addressing and Naming Models

The Ruijie Network R105G Router will be used to establish the addressing model. We will implement static routing, which will be manually configured in the Ruijie Cloud settings to manage the router. This approach provides granular control over network traffic flow. It also provides granular control over network traffic flow as seen in Table II.

TABLE II. ADDRESSING TABLE

Dispositivo	Interfaz	IP
Router1	Vlan 10 (Vlan OP)	192.168.10.1
PC10	NIC	192.168.10.10
Router 2	Vlan 20 (Vlan S.C.)	192.168.20.1
PC20	NIC	192.168.20.10
Router 3	Vlan 30 (Vlan Mochicas)	192.168.30.1
PC30	NIC	192.168.30.10
Router 1,2 y 3	Vlan 50 (Vlan administration)	192.168.50.1
	Vlan 80 (Vlan IoT)	192.168.80.1
	Vlan 90 (Vlan Guest)	192.168.90.1

c) Activity 3 Select Switching and Routing Protocols

The Ruijie Network Router's supported switching and routing protocols will be carefully selected as seen in Table III. While the final decision will depend on specific network requirements, static routing with inter-branch connections is a potential option for this design.

TABLE III. SWITCHING AND ROUTING PROTOCOLS

Tecnology	Content	Service
Ipsec Protocol	ESP, AH	
Encryption	DES , 3DES, AES	Privateness
Data digest	MD5, SHA	Integrity
Identity Authentication	RSA, Pre-shared Key	Authenticity
Key Exchange	DH1, DH2, DH5, DH14	Key Security

d) Activity 4 Develop network security strategies

Leveraging the security features offered by the Ruijie Router, we will design a comprehensive security strategy for the VPN network. This strategy may include functionalities such as traffic analysis, access control, encryption, application protection, and flow control.

e) Activity 5 Develop network management strategies

The Ruijie Cloud platform offers a robust set of network management tools. We will utilize this platform for tasks such as policy management, device management, user management, application management, and security management. This centralized approach simplifies network administration and facilitates troubleshooting.

Phase 3: Develop Physical Design

a) Activity 1 Technical details of the Hardware

- A detailed breakdown of the hardware components to be used in the physical design is provided in Table IV. This breakdown should include specifications for each piece of equipment, such as the Ruijie Router model, switch model, and any additional hardware required for the network.

TABLE IV. HARDWARE DETAILS (TECHNICAL)

Characteristic	Description
Modelo	RG-EG105 P
Network Interface	5 puertos Base-T 10/100/1000
Certificated	CE, ROHS
RAM	DDRIII de 128 MB
Port WAN	2 puertos Base-T 10/100/1000
Bandwitch	600Mbps
Storage	Flash de 16 MB
PoE	802.3af/at en LAN1-4

b) Activity 2 Technical connection details

The current internet connection details for the Andia Consortium are outlined:

- Connection Type: HFC Fiber
- Bandwidth: 100 Mbps
- Handoff Device: UBEE device
- Network Distribution and Administration: Ruijie Router

- Table V can be included to visually represent the physical connection between the UBEE device, Ruijie Router, and other network components.

TABLE V. PHYSICAL CONNECTION

TYPE	BRAND	MODEL	TOTAL
Router	Ubee	Docsis 3.0	1
Router	Ruijie	RG105 P	3
Switch	TPLink	TL SG1016D	1
Access Point	Ruijie	RAP2260G	1
Computer	Intel	I3 8000	1
Computer	Intel	Core duo	12

c) Configuration of the device and its Ruijie Cloud

Then proceed to configure Ruijie Cloud.

- This activity should focus on the configuration steps for Ruijie Cloud and the Ruijie Router, not individual computers. Here's a revised explanation:
- Access the Ruijie Cloud platform at: https://cloud-la.ruijienetworks.com/
- Create an account and log in to the Ruijie controller.
- Once logged in, configure the following network settings within Ruijie Cloud (see Fig. 4):
  - IP addresses and static routes
  - VLANs
  - VPN configuration for enhanced information security

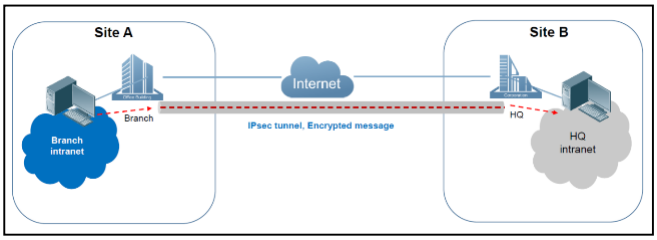

Fig. 4. Topology Ruijie cloud.

Phase 4: Test, optimize and document design.

a) Activity 1 Configure VPN policies

- This activity involves defining the guidelines for secure VPN access. Details regarding user authentication methods, encryption protocols, and access controls should be outlined in Fig. 5.

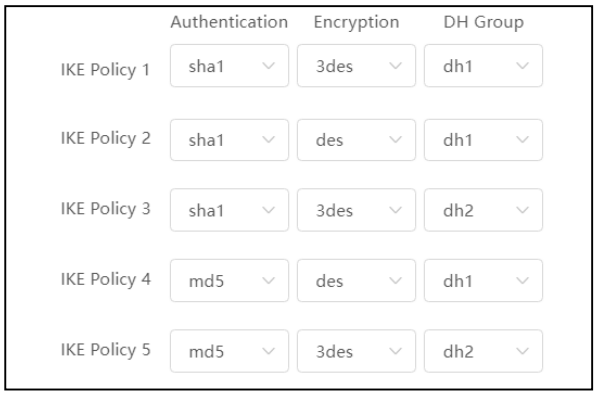

Fig. 5. Security VPN IPSec.

b) Activity 2 Test the design between sites

The functionality and performance of the VPN connection across different locations should be thoroughly validated. Fig. 5 can be used to illustrate this process.

- Consider revising the explanation to state: "Fig. 6 demonstrates a ping test conducted from the Ruijie Cloud console. The successful pings to both addresses (192.168.1.31 and 192.168.30.2) indicate connectivity between the routers at different sites, verifying communication between subnets and gateways."

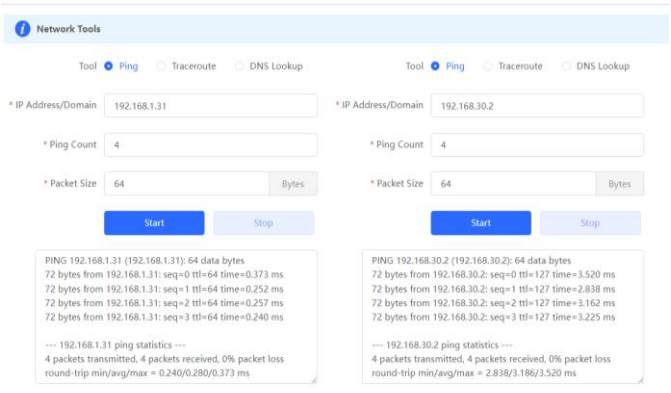

Fig. 6. Demonstration of successful connection.

c) Activity 3 Configure shared folders on the VPN network

This activity explains how shared folders will be accessed within the VPN environment. Here's a revised explanation:

- To configure shared resources on the VPN, the default storage location where all files are saved needs to be identified.
- Assuming successful VPN configuration, access the network drive locally using the appropriate network address.
- Finally, establish a connection between the storage server and the desired computer by generating and pinning a shortcut as seen in Fig. 7.

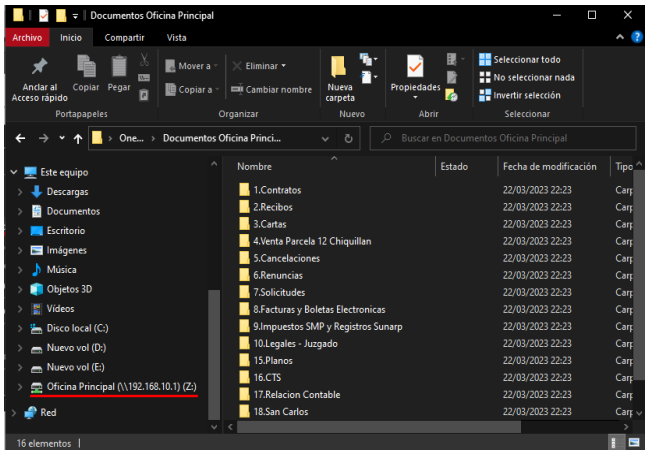

Fig. 7. Connection Established.

IV. Discussion

The comprehensive evaluation of implementing a Virtual Private Network (VPN) in Consorcio Andia revealed significant improvements in the security, integrity, and availability of business information. These improvements can be attributed to the specific characteristics of the VPN application, as well as its alignment with the previously established research objectives.

In terms of information security, the results indicated a substantial advancement after implementing the VPN based on the Top-Down methodology. This not only validated the alternate hypothesis posed in this study but also significantly supported the previous research conducted by Pablo Huanca on information security in a different business context [26].

Furthermore, [40] comparison with Alvarado Sánchez's 2018 study on information management in corporate networks highlighted a notable increase in user approval regarding data protection following the VPN implementation in Consorcio Andia. These findings further underscore the significant enhancement in data protection, emphasizing the importance and effectiveness of VPN as an information protection tool.

Regarding information integrity, both our results and the findings from Huanca [18] suggested a positive impact of the VPN in this aspect. The gathered data exhibited considerable variability between medium and high levels of acceptance

regarding information integrity, emphasizing its crucial role in data security within business environments.

Finally, information availability experienced notable improvements with the introduction of the VPN. Despite the study by Julio Morales indicating an increase in the time required to access shared folders with the VPN, our analysis revealed a significant reduction in access time, indicating a substantial improvement in information accessibility within Consorcio Andia. [38].

To validate the security posture of the designed VPN network, we will leverage the CIS (Cybersecurity Infrastructure Survey) Controls framework [37] from the Cybersecurity & Infrastructure Security Agency (CISA). We have mapped specific CIS Controls to our security strategies, such as access control through user authentication and encryption protocols. Utilizing the CIS Controls self-assessment tool, we will evaluate the effectiveness of our design in meeting these critical security practices. The findings from this assessment will be documented and any identified gaps will be addressed through adjustments to the VPN configuration or implementation of additional security measures."

Several studies have explored secure VPN design for multi-branch networks. Lazarte and Silva 2022, in their proposal creating a VPN using open-source software, utilized a centralized management platform for VPN configuration, similar to our approach using SDN. However, their design focused on OpenVPN software for encryption, while our solution leverages the built-in security features of the Ruijie Router. This simplifies implementation and potentially reduces management overhead [30].

V. Conclusion

After exhaustively reviewing studies related to the implementation of Virtual Private Network (VPN) in Consorcio Andia, a thorough analysis of a limited yet significant number of sources is observed. Among the 42 sources analyzed, 5 articles (12.67%) from Science Direct, 11 (20%) from Redalyc, 20 (32%) from IEEE Xplore conferences, and 6 (38.33%) from WebOfScience were selected, encompassing both articles and conferences. These studies offer an overview of the applications, advantages, and challenges surrounding VPNs within the specific context of Consorcio Andia [32].

The evaluation of these existing studies emphasizes the critical importance of VPNs in safeguarding and protecting business information. These analyses span from the technical implementation of VPNs to the security protocols used and their influence on information management. They also highlight how VPNs have evolved and their impact on remote access processes and data security, especially in special situations such as the crisis generated by the COVID-19 pandemic [20].

For future research, delving deeper into identifying and evaluating the technical requirements necessary to successfully implement VPNs within the specific environment of Consorcio Andia is recommended. This involves considering not only data security and privacy but also their effective integration with existing business management systems and e-commerce platforms [24]. Furthermore, exploring how collaborative strategies between sales and technological development teams influence the design and effectiveness of such systems is advisable [21].

Regarding limitations, challenges in human-machine interaction, technological issues such as natural language processing and personalization, as well as these systems' inability to comprehend complex human situations are identified [22]. Additionally, implementation and maintenance costs, the need for continuous learning, and potential user resistance are considerations. Data security, cultural change, and employee training are also crucial aspects to contemplate [35].

***Abstract*—The increasing diversity of network attack behaviors has led to increasingly serious network security issues. Based on this, this study proposes an optimized fireworks algorithm to build an intrusion detection model. Firstly, the traditional algorithm is optimized by improving the uniformity of initial individual distribution and designing a fitness value update strategy, which greatly reduces the computational burden of the model and improves recognition accuracy. Then, the feature analysis detection strategy is selected and the model is fused to ensure system stability. Finally, to validate the effectiveness of the model, a comparative experimental analysis is conducted. The results validated that the average accuracy of the research model was 99.06%, with an average detection rate of 96.98%, which is relatively higher than the other models by 2.57%. The error warning rate was only 0.13%, lower than the other models of 1.60%. In summary, the proposed intrusion detection model based on the fireworks algorithm and feature analysis can effectively identify attack behaviors and classify them correctly.**

I. Introduction

At present, the popularity of the network is constantly improving. The internet has become an indispensable part of people's daily life, providing great convenience for users. However, corresponding cybersecurity issues have emerged one after another, gradually evolving from personal privacy breaches, online fraud, etc. to major issues that disrupt social order and public security, and even national defense security. At the same time, the types of network intrusion are diverse and constantly evolving, seriously threatening the privacy of individuals and businesses. In response to the increasingly severe network security issues, Network Intrusion Detection (NID) technology has emerged. This technology aims to identify abnormal behavior or unreasonable data flow in network systems by monitoring and analyzing network traffic. After timely detection of attack behavior, preventing it from continuing to invade further maintains the integrity, confidentiality, and availability of the network system [1-2]. As an important carrier of information transmission, the security of image is directly related to the protection of personal privacy and business secrets. In recent years, the problems of image tampering, forgery and unauthorized access are frequent, which puts forward higher requirements for image security.

In recent years, NID technology has received widespread attention from the academic community. Common strategies can be divided into attack behavior recognition through feature analysis and comparison, as well as recognition strategies based on behavior detection. In addition, cutting-edge technologies such as artificial intelligence and machine learning have been integrated, further improving the model's detection accuracy. Some scholars have also proposed image authentication technology based on digital watermarking to ensure the integrity and authenticity of images to a certain extent. In addition, encryption technology is also widely used in the protection of images to prevent unauthorized access and protect the privacy of image content.

However, NID technology still faces various challenges. Firstly, with the continuous advancement of network attack methods, Intrusion Detection Systems (IDSs) are facing increasingly diverse types and methods of attacks. This requires IDS to quickly adapt to new security threats. With the development of image processing technology, attackers can use more advanced technology to tamper with and forge images. Secondly, how to maintain the availability and access efficiency of images while ensuring the security of images is also an urgent problem to be solved [3-4].

Therefore, this study proposes an intrusion detection model based on the Fireworks Algorithm (FWA) optimization, which solves the problem of local optima by optimizing the initial cluster distribution. The contributions of this research are as follows: (1) A deep learning based image tamper detection algorithm is proposed, which can effectively identify abnormal regions in images. (2) The fitness value update strategy optimization reduces the time complexity of the model, which greatly reduces the operating burden of the model while ensuring accuracy. The research content consists of six sections. Section II introduces the current research status of NID. Section III designs intrusion detection methods based on FWA. Section IV conducts experimental analysis on the model. Section V summarizes the experimental results. Finally, Section VI concludes the paper.

II. Related Works

Many scholars have conducted research on NID technology to address the issue of network security maintenance. Ahmed et al. proposed an IDS based on load balancing algorithm, which optimizes task allocation between sensor data and individuals to be identified, greatly reducing latency. Subsequently, a dynamic convergence strategy was introduced to integrate entropy-based active learning and attention modules to improve the efficiency of intrusion recognition. Their model could significantly improve the efficiency of intrusion detection [5].

Liu et al. abandoned conventional deep learning models and proposed a widely learned intrusion detection system based on LU decomposition. It excavated deep information from data by constructing graph Laplacian operators and embedded them into manifold regularization frameworks to enhance the accuracy of the model in detecting attack behavior. Finally, LU decomposition was used to improve the training speed of the model, and their model outperformed traditional machine learning algorithms in intrusion detection performance across multiple datasets [6]. Subramani et al. designed an intelligent IDS built on feature analysis to address security threats in wireless sensor networks in the Internet of Things. Their model combined rules and multi-objective particle swarm optimization algorithm, aiming to build a feature selection model. In addition, an enhanced multi class support vector machine classification algorithm has been introduced to further improve the recognition accuracy of intrusion detection behavior. Finally, they tested the model on the KDD'99 Cup and CIDD, and found that the model significantly improved the recognition accuracy of intrusion detection behavior and reduced the False Alarm Rate (FAR) [7]. Ma et al. constructed a programmable IDS for the security maintenance of micro-grid networks. Firstly, programmable signals were injected into the system and their response results were analyzed. Micro-grids had low inertia characteristics, indicating that the system was highly sensitive to attacks and was highly susceptible to intrusion behavior, even spreading to adjacent systems. The model they designed significantly reduced the probability of this situation occurring [8].

Vitorino et al. proposed an adaptive intrusion detection system for adversarial attack behavior in network intrusion. Firstly, the basic constraints in the model were designed, and then an adaptive perturbation mode was introduced to strengthen the constraints in the gray box setting. This indicated that their methods heavily relied on the adaptability of various features. Finally, the experimental analysis showed that the model significantly improved the recognition accuracy of the system against adversarial attacks [9]. Pande et al. realized the limitations of traditional intrusion detection techniques and therefore improved common deep learning models. They compared and analyzed deep learning frameworks with traditional machine learning. Their proposed learning framework has significantly improved the average detection accuracy index, reaching over 99% [10]. Thakkar et al. optimized the detection of transformation attack behavior. They also used deep learning as the basic design model and introduced Dropout and regularization techniques to optimize the model in response to the over-fitting defects of traditional models. The focus was on integrating regularization techniques. To verify the model performance, they compared it on multiple datasets, and the model was able to effectively monitor network intrusion attacks [11]. Through the analysis of recent studies, the limitations of similar research fields are obtained, and the corresponding treatment methods are proposed, as shown in Table I.

TABLE I. EXISTING RESEARCH ANALYSIS AND RESEARCH TREATMENT METHODS

Research	Major technology	Limitation	Optimization of research methods
Ahmed et al. [5]	IDS based on load balancing algorithm	It is easy to fall into local optimality when dealing with large-scale data	Optimize initial individual distribution and fitness update strategies
Liu et al. [6]	Extensive learning IDS based on LU decomposition	The detection accuracy is unstable	The manifold regularization frame is used to improve the detection accuracy
Subramani et al. [7]	Intelligent IDS based on feature analysis	Lack of generalization ability	The generalization ability of the model is improved by feature analysis
Ma et al. [8]	Programmable IDS	Lack of sensitivity to attack	A programmable signal is injected and the response is analyzed
Vitorino et al. [9]	Adaptive IDS for adversarial attack behavior	Depends on the adaptability of various characteristics	An adaptive perturbation model is introduced to strengthen the constraint
Pande et al. [10]	IDS based on deep learning	The detection accuracy is not stable	Compare deep learning frameworks
Thakkar et al. [11]	Detection and optimization of deformation attack behavior	Insufficient accuracy in detecting unknown attack behavior	Introduce Dropout and regularization techniques

Numerous studies have optimized the recognition accuracy of intrusion detection models, but this can also lead to an increase in model time complexity. Therefore, this study proposes strategies such as updating fitness values and optimizing initial positions to greatly reduce the computational burden, while also ensuring the recognition accuracy of the algorithm.

III. AN INTRUSION DETECTION MODEL THAT INTEGRATES OPTIMIZED FWA AND FEATURE ANALYSIS STRATEGIES

In response to the security issues arising from network attacks, this study proposes using FWA to establish an intrusion detection model. Firstly, the uniformity of the initial individual distribution is optimized, and improvements are made to address convergence performance issues. Then, it is applied to NID, and a feature analysis based detection strategy is selected to fuse the model.

A. Improvement Design of FWA Based on Initial Cluster Optimization Strategy

With the growing popularity of the Internet and frequent network attacks, network security maintenance has become a research hotspot. Therefore, this study proposes to use FWA to build an intrusion detection model. FWA aims to simulate the phenomenon of fireworks explosions and treat each explosion point as an effective solution, searching for the global optimum

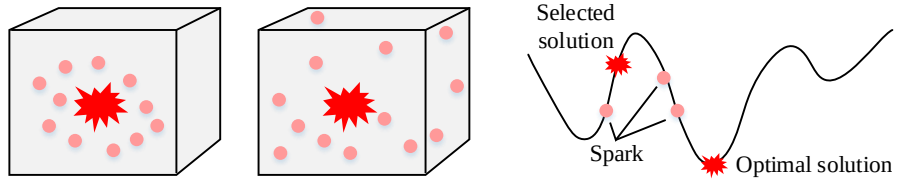
in the entire explosion space. This requires calculating the fitness value of each solution and combining it with the explosion operator to generate feasible solutions. If there are a large number of sparks around the fireworks, the corresponding fitness value is higher, and vice versa, the fitness value is lower, as shown in Eq. (1) [12-13].

$$S_i = S\frac{f_{\max} - f(x_i) + \delta}{\sum_{i=1}^{N}\left(f_{\max} - f(x_i)\right) + \delta} \quad (1)$$

In Eq. (1), S_i represents the explosion intensity of fireworks x_i. S is the explosion intensity control parameter. $f(x_i)$ represents the fitness value of cover x_i. $f_{\max}$ represents the maximum fitness value among all fireworks. δ is a constant that takes an infinitesimal value to avoid division by zero. In addition, to ensure population diversity and better search for global optimal solutions, the algorithm introduces Gaussian mutation, as shown in Eq. (2).

$${}_g X_i^k = X_i^k \cdot Gaussian(1,1) \quad (2)$$

In Eq. (2), ${}_g X_i^k$ is the position vector of Gaussian variation sparks in the k dimension. X_i^k represents the position vector value of fireworks x_i in the k dimension. $Gaussian(1,1)$ is a Gaussian distribution with both mean and variance of 1. The fitness value judgment and Gaussian variation process of fireworks are shown in Fig. 1.



(a) Excellent spark (b) Bad firework (c) Gaussian variation

Fig. 1. Visualization of FWA operation.

The population of individuals after Gaussian mutation includes initial fireworks, as well as mutation sparks and explosion sparks. Finally, it is necessary to determine whether the algorithm has completed the iteration based on the convergence requirements. If the requirements are not met, the initial fireworks cluster will be regenerated and the search for the global optimal solution will continue. However, the initial fireworks distribution of classical FWA is uneven, and the iterative strategy is complex, resulting in poor efficiency and accuracy of the algorithm. Therefore, this study addresses the above issues by improving the initial algorithm by introducing an initial individual discretization strategy aimed at avoiding local optimization problems caused by the initial fireworks position. Before this, it is needed to design the coverage length of the solution space, as shown in Eq. (3).

$$l_i = (x_i)_{\max} - (x_i)_{\min}, i \in [1,k] \quad (3)$$

In Eq. (3), l_i is the coverage length of the i-dimensional search space. $(x_i)_{\max}$ / $(x_i)_{\min}$ represents the min and max values of the corresponding coordinates in the search space. Additionally, the update position of classical FWA is related to the previous iteration data, so the global optimization effect is greatly affected by whether the initial position is uniform. The pseudo-random nature of its random function determines that the initial cluster distribution is relatively concentrated. In response to this issue, this study introduces an initial fireworks dispersion strategy aimed at screening through fireworks distance, as shown in Eq. (4) [14-15].

$$d = \sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2 + \ldots + (x_k - y_k)^2} \quad (4)$$

If the distance between different fireworks is less than the threshold R of the movement range, fireworks individuals with larger abscissa are excluded. The calculation of threshold R is Eq. (5).

$$R = MIN\left\{\left((x_1)_{\max} - (x_1)_{\min}\right), \left((x_2)_{\max} - (x_2)_{\min}\right), \ldots, \left((x_k)_{\max} - (x_k)_{\min}\right)\right\} / N \quad (5)$$

Eq. (5) represents the minimum horizontal coordinate distance $\frac{1}{N}$ in dimension k. When all fireworks individuals are evenly distributed in the solution space, it indicates the minimum value of their force position to ensure uniform distribution. When the distance between individuals is less than the threshold, it indicates that the distribution between individuals is too close. When the number of individuals that meet the requirements is less than N, continuous screening is required until the number reaches the standard, as shown in Fig. 2.

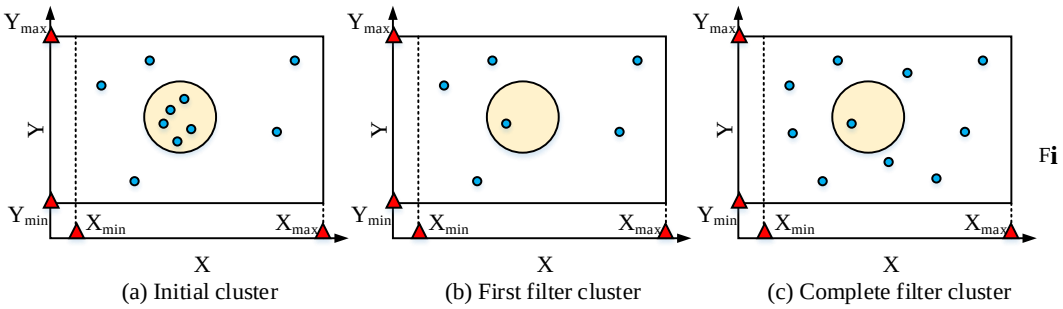


Fig. 2. Initial cluster dispersion strategy.

Fig. 2 shows the dispersion process of the initial cluster in two-dimensional space. Among them, the dashed box represents the searchable space. The fireworks individuals in the yellow circle indicate those who are too concentrated and excluded. In Fig. 2 (a), there are five individuals in the initial cluster that do not meet the dispersion requirements, and this initial cluster is prone to falling into local optima. After excluding overly concentrated individuals and achieving a more uniform distribution of the cluster, continuing to select and screen the remaining fireworks individuals, meeting the requirements for the initial number and uniformity of clusters. The traditional algorithm chooses the classic roulette wheel strategy and uses Euclidean distance to achieve individual screening, as expressed as Eq. (6).

$$P_i = \frac{\sum_{j \in K} D_{ij}}{\sum_{i \in K} \sum_{j \in K} D_{ij}} \tag{6}$$

In Eq. (6), P_i is the probability that individual i is selected. D_{ij} represents the Euclidean distance between individuals i / j. Although the above strategies can maintain cluster diversity, the high computational complexity can affect the final convergence performance of the algorithm. Therefore, this study directly screened individuals by comparing fitness values, as shown in Eq. (7) [16].

$$\Delta f(x) = \alpha\left(f(x_i) - f(x_j)\right) \tag{7}$$

In Eq. (7), $\Delta f(x)$ represents the difference in fitness between two individuals. $f(x_i) / f(x_j)$ is the fitness evaluation function for different individuals. $\Delta f(x)$ needs to be less than the β constant, and α is the screening parameter that caters to β. The overall optimized FWA process is Fig. 3.

In Fig. 3, the treatment of inferior fireworks is to ensure population diversity. Therefore, by increasing the amplitude of its fireworks explosion, it can be added to the population, as shown in Eq. (8).

$$R_i = R\frac{f(x_i) - f_{\min} + \delta}{\sum_{i=1}^{N}\left(f(x_i) - f_{\min}\right) + \delta} \tag{8}$$

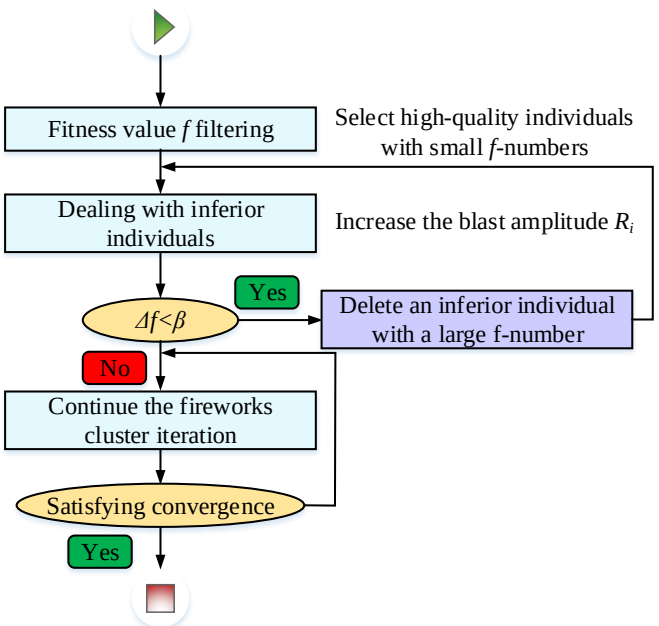

Fig. 3. Operation of optimized FWA.

In Eq. (8), R_i represents the explosion amplitude of individual x_i. After optimizing the low-quality algorithm, the fitness difference is judged and whether it will enter the next generation of individual updates is determined.

B. Design of FWA Intrusion Detection Model Based on Feature Analysis

After optimizing the performance of FWA, it is necessary to update and map the solution space. This is because the feasible domain of the traditional solution space is continuous, while intrusion detection requires discrete feature selection. Therefore, this study maps the feature extraction solution to the corresponding fireworks cluster and re encodes its position vector. In the model, individual fireworks and their sparks are possible features of themselves, and their position vector X_i is Eq. (9).

$$X_i = \left\{ x_{i1}, x_{i2}, ..., x_{ij}, ..., x_{in} \right\} \tag{9}$$

In Eq. (9), x_{i1} represents whether the first feature is selected in the subset. n is the total quantity of features. The features processed by binary discretization are shown in Eq. (10) [17-18].

$$x_{ij} = \begin{cases} 0 & rand < 0.5 \\ 1 & others \end{cases} \tag{10}$$

In Eq. (10), $0/1$ represents the corresponding features unselected and selected, respectively, which are uniformly distributed random values in the [0, 1] interval. When there are multiple features in the feature subset, the final encoding form is Fig. 4.

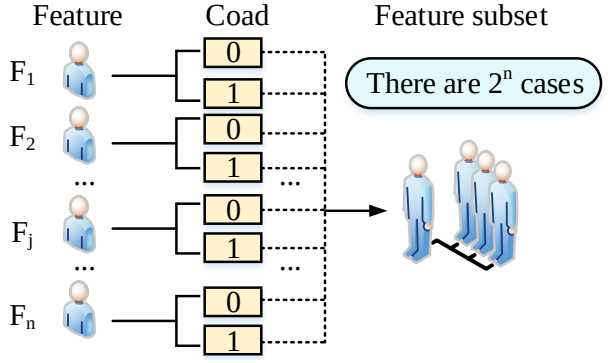

Fig. 4. Binary discrete coding.

Next, the decoding step should be performed to collect the features encoded as "1", obtain the optimal feature subset, and input it into the model for testing and training. To match the search for the optimal feature subset, this study will initialize the fireworks and feature subset one-to-one mapping. The initial position vector length of its individual is the same as the number of elements n in the original feature subset. Next, to define the fitness function as expressed in Eq. (11).

$$f\left(X_i\right) = \begin{cases} -acc & sum\left(x_i\right) \neq 0 \\ 0 & sum\left(x_i\right) = 0 \end{cases} \tag{11}$$

Eq. (11) reflects the accuracy of classification. When the fitness value is higher, the classification accuracy is poor, and the corresponding individual quality is poor. Conversely, the quality of fireworks individuals is better. Among them, acc represents the classification accuracy, as shown in Eq. (12).

$$acc = \frac{Num\_correct\_pre}{Total\_num\_pre} \tag{12}$$

In Eq. (12), $Num\_correct\_pre / Total\_num\_pre$ represents the correct number of predicted samples and the total number of predicted samples. Next, this study introduces the K-nearest neighbor algorithm for data classification. The K value is related to classification accuracy. If it is too small, noise interference may occur, and vice versa, it will increase its computational pressure. If it is an even value, it is easy to encounter problems with the same quantity. In addition, this study introduces K-fold cross validation, which divides the dataset into K subsets for accuracy ten fold cross validation, as shown in Fig. 5.

In Fig. 5, the dataset needs to be evenly divided into ten parts, and one subset should be continuously selected as the test set and the remaining as the training set in order. Finally, 10 test results can be obtained and calculated for arithmetic mean. This result serves as an evaluation indicator for the accuracy of the algorithm. Generally speaking, N repeated trials are required, and the mean of N trials is taken as the final accuracy measurement result. Subsequently, the FWA optimization model based on feature analysis is applied to intrusion detection. Unlike intrusion detection models based on anomaly analysis, research models directly compare input values with illegal operations to determine whether they belong to intrusion behavior. Therefore, the model needs to analyze all attack behaviors first. Compared with the analysis model for legitimate behavior, this greatly reduces computational complexity, but at the same time, it also lacks the timeliness of monitoring new intrusion behaviors. Common attack behavior detection algorithms include conditional probability, state transition analysis, and rule feature analysis. The conditional probability strategy is efficient, but computationally complex. The state transition analysis strategy is more suitable for long-term attack behavior, but its accuracy needs to be improved. The rule feature analysis detection strategy has high accuracy and strong timeliness, but can only achieve static recognition. Due to the fact that intrusion detection models do not require dynamic recognition, a rule feature analysis detection strategy was chosen in this study. The overall optimized FWA model is Fig. 6.

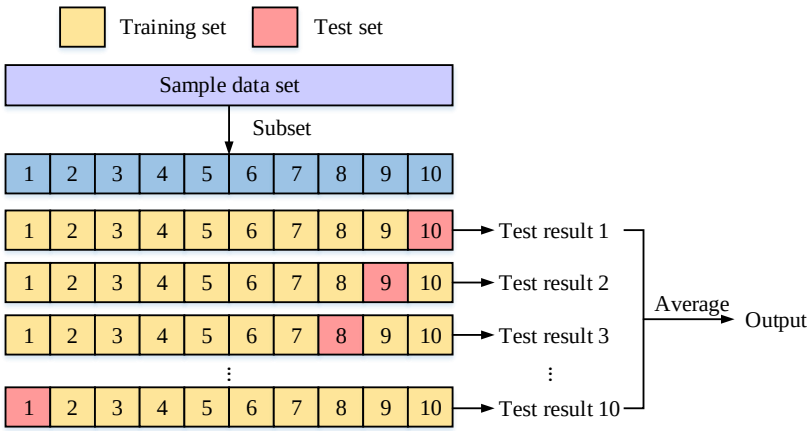

Fig. 5. K-fold cross-validation process.

In Fig. 6, the main modules of the model are the preprocessing module and the learner module. Firstly, it is necessary to preprocess the data and perform numerical normalization and dimensionality reduction operations. Data dimensionality reduction refers to parameter initialization, cross validation of fitness values, and continuous iteration until the requirements are met. Next, the obtained optimal feature subset is input into the learner module, and after spark generation and iteration, it is determined whether it meets the convergence condition. Finally, returning to the best self and obtaining the intrusion detection model. Afterwards, the test dataset can be input into the model, and after feature filtering and detector structure, the final detection result can be obtained.

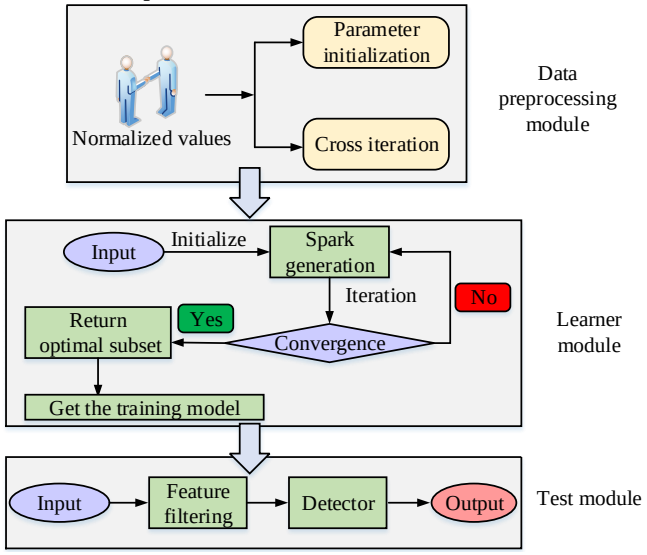

Fig. 6. Optimized FWA model.

IV. Analysis of NID Recognition Performance of FWA Optimization Algorithm

To verify the effectiveness of the research method in NID, this study first validates the overall attack behavior recognition performance of the model, including computation time and accuracy. Subsequently, specific attack behaviors are classified and detected, and compared with other algorithms in multiple datasets.

A. Performance Analysis of Training and Detection Accuracy for Optimizing FWA Models

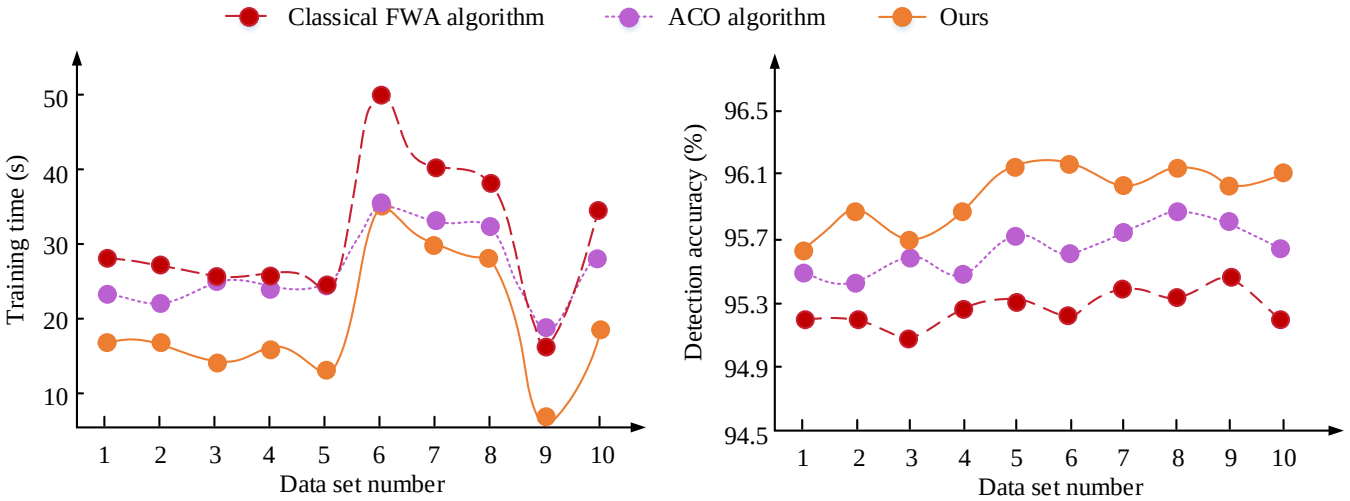
This study first analyzes the training and testing performance of the model. Table II shows the related parameters and environment.

TABLE II. Experimental Environment and Parameter Selection Settings

Name	Settings
Operating system	Win10
Processor	Inter (R) Core (TM) i5-4590CPU@3.30GHz 3.30GHz
Simulation platform	MATLAB R2019a
Number of initial fireworks clusters N	5
Spark-limiting parameter	50
Constant α	0.04
Constant β	0.8
Maximum iterations	200
Data sets	KDD CUP99
	NSL-KDD
Training: Verification	7:3

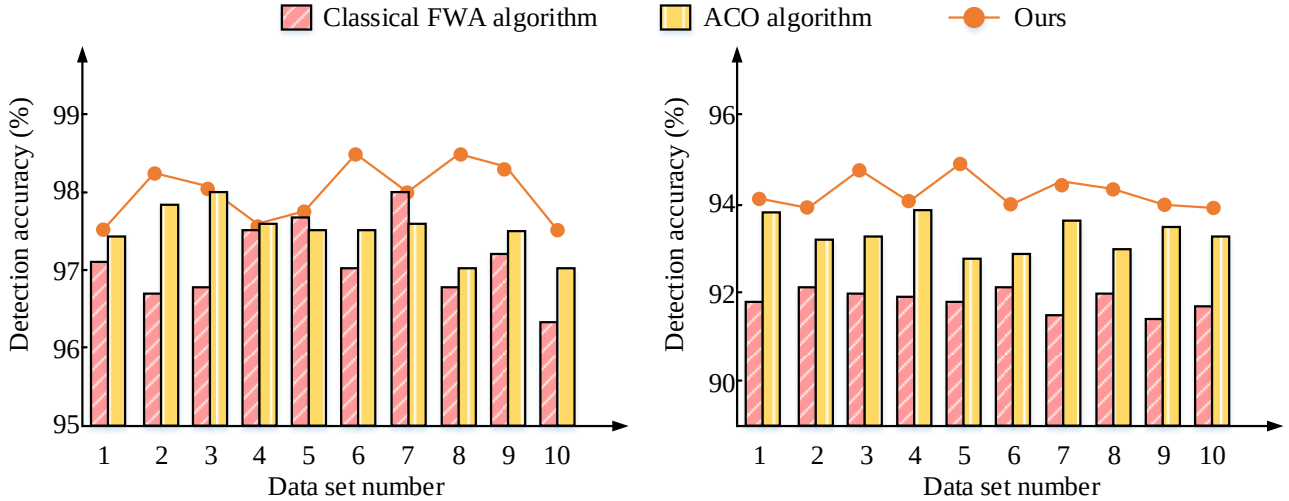
In Table II, the NSL-KDD is a derivative dataset of KDD CUP99, which incorporates some novel intrusion data. This study first used 10% randomly selected from KDD CUP99 as the test dataset. According to the above extraction method, a total of 10 subsets of test data are formed. This study designs a model for comparison with traditional FWA and similar swarm intelligence-based Ant Colony Optimization (ACO). The results are displayed in Fig. 7.

Fig. 7 (a) compares the training time, which trends of the three models are the same. The training time of the first five sub datasets fluctuates relatively smoothly, with a significant increase in training time in the 6-8 sub datasets, followed by a significant decrease. This may be related to information such as feature quantities of different data in the sub dataset. Among them, the training time of the research model is greatly lower than that of the other models, with an average training time of 22.46 seconds. The average training time for traditional FWA and ACO is 38.81 seconds and 29.57 seconds, respectively. Therefore, the training time of the research model decreased by 36.2% compared to other models. This is because strategies such as studying the fitness screening mechanism of the model have reduced the computational burden of the model, while other models have not made improvements in computational complexity. Fig. 7 (b) shows the accuracy comparison of various models in different sub datasets. Compared to the training duration, its accuracy fluctuates less. The average detection accuracy of the research model is 96.02%, which is a relative improvement of 0.76% in recognition accuracy compared to the 95.01% and 95.52% accuracy of traditional FWA and ACO algorithms. This is because classical FWA is prone to falling into local optima, while ACO also experiences a stagnation phenomenon where all solutions are the same due to the increase in iteration times and limited search space. This study conducts a comparative analysis to further validate the recognition accuracy of various models on large-scale datasets and under the introduction of unknown attacks. The results are shown in Fig. 8.



(a) Algorithm time comparison (b) Algorithm precision comparison

Fig. 7. Training and test performance of each model.



(a) Large data sets (b) Unknown attacks

Fig. 8. Comparison of model performance under different data scenarios.

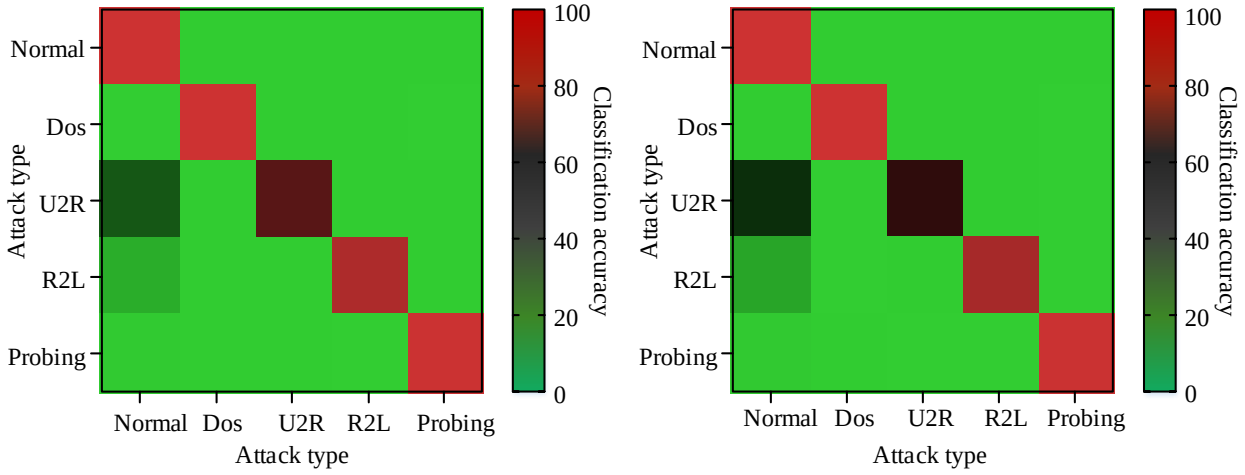
The dataset used in Fig. 8 (a) is twice as large as the dataset in Fig. 7, and for more data information, the recognition accuracy of each model has significantly improved, with mean values above 96%. However, the recognition accuracy of the research model in large volume datasets has shown a more significant improvement compared to in small volume datasets. For example, in sub dataset 8, there are many features in the data, making it difficult for classical FWA to handle such high-dimensional data, with a recognition accuracy of 96.72%. In sub-dataset 10, the data features are relatively fuzzy, so the recognition accuracy of each model has decreased. Overall, the average detection accuracy of the research model in big datasets is 98.21%, which is an increase of 3.53% compared to the other two models. In Fig. 8 (b), each model faces unknown attack data and the recognition accuracy decreases. The average detection accuracy of the research model is 94.16%, which is an increase of 2.47% compared to the other two models. In summary, the research model has stronger adaptability and stability in detecting larger amounts of data. It is also more oriented towards detecting unknown attacks.

B. The Recognition and Classification Performance of Models on Attack Behavior Under Different Datasets

The above experiment verifies the overall intrusion detection performance, and in practical applications, it is necessary to classify different types of attacks for targeted repair in the future. The common types of attacks include Denial of Service (DoS), Root (U2R), Remote to Local (R2L), and Probing. The classification performance of the optimized FWA model designed in this study for different data types is Fig. 9.

Fig. 9 (a) shows the classification performance in the KDD CUP99. The classification accuracy of the model for normal behavior, DoS, and Probing attack behavior is over 99%, with an average of 99.73%. However, the classification accuracy for U2R and R2L attack behaviors is poor, at 75.43% and 95.36%, respectively. This is because these two types of attacks have higher discreteness and similarity to normal behavior. In the NSL-KDD, the classification accuracy of the research model for normal behavior, DoS, and Probing remains above 99%. The confusion rate between normal behavior and U2R reaches 38.56%, and the confusion rate with R2L is 9.59%. In summary, the research model can effectively achieve intrusion type classification. This study further conducts experiments on the DARPA1988 and ISCX2012 datasets. Among them, the distribution of DARPA1988 is seven weeks of training traffic and two weeks of testing traffic, and the attack type is the same as described above. The distribution of ISCX2012 is one week of traffic data, and the attack types are divided into four types: Brute Force SSH (BFSSH), DDoS, Infiltrating, and HttpDoS. Fig. 10 shows the comparison.

Fig. 10 (a) analyzes the accuracy and detection rate (DR) of the model in ISCX2012. The recognition accuracy for different types of attacks is above 99%, with an average of 99.69%. The DR value has a recognition rate of 93.12% for DDoS attack types, and a detection rate of over 95% for other attack types. This is because DDoS is easily confused with Infiltrating attack behavior. Fig. 10 (b) shows the performance of the model in DARPA1988, which also lacks detection of U2R and R2L attack behaviors. Although the recognition accuracy is above 99%, the detection rates are 83.35% and 74.19% respectively, and the overall recognition rate is 97.78%. Fig. 10 (c) shows the FAR of the model. In the ISCX2012 model, the total FAR value is 0.07%, while in DARPA1988, the total FAR value is 0.22%. Next, this study introduces the Dynamic Convergence Method (DCM) model proposed by Ahmed et al. and the Broad Learning System (BLS) model proposed by Liu et al. for further comparative analysis. Table III shows the specific results.



(a) KDD CUP99 (b) NSL-KDD

Fig. 9. Classification accuracy under different data sets.

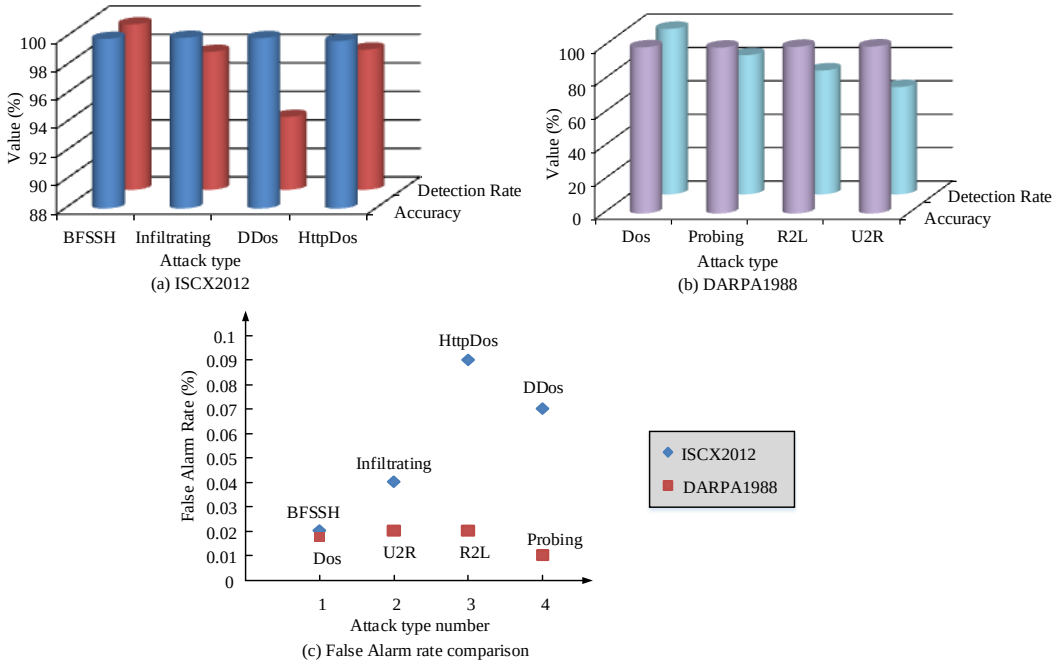


Fig. 10. Model performance analysis under different data sets.

TABLE III. COMPARISON OF MODEL PERFORMANCE UNDER DIFFERENT DATA SETS

Data set	Index	DCM	BLS	Ours
DARPA1988	DR (%)	96.63	95.42	97.78
	FAR (%)	0.07	0.05	0.07
	ACC (%)	99.24	99.98	99.68
ISCX2012	DR (%)	92.81	95.75	96.91
	FAR (%)	0.31	0.29	0.22
	ACC (%)	97.56	97.24	99.69
KDD CUP99	DR (%)	98.65	98.97	98.52
	FAR (%)	0.26	0.20	0.15
	ACC (%)	98.54	98.99	99.04
NSL-KDD	DR (%)	95.31	95.87	97.52
	FAR (%)	0.40	0.31	0.26
	ACC (%)	96.48	97.22	98.04

In Table III, the comprehensive performance of the research model is the best in different datasets. In DARPA1988, the DR index of the designed model is relatively 1.54% higher, but slightly lower than the BLS model by 0.02% in FAR index and slightly lower than the BLS model by 0.3% in ACC index. In the remaining datasets, the performance of various indicators of the research model has always been superior to the other models. Its average accuracy is 99.06%, which is relatively higher than the other models by 1.78%. The average detection rate is 96.98%, which is relatively higher than the other models by 2.57%. The mean FAR is 0.13%, which is lower than the other models by 1.60%. Therefore, studying models can better achieve network intrusion behavior detection and maintain network security.

V. RESULTS AND DISCUSSION

The proposed network intrusion detection model was tested on several standard datasets, including KDD CUP99, NSL-KDD, DARPA1988, and ISCX2012. On the KDD CUP99 dataset, the model's classification accuracy for normal behavior, DoS and Probing attack types exceeded 99%, with an average of 99.73%. However, the classification accuracy for U2R and R2L attack types is relatively low, at 75.43% and 95.36%, respectively. This may be due to the high similarity between these attack types and normal behavior, causing the model to have difficulty distinguishing between them. On the NSL-KDD dataset, the accuracy of the model classification of normal behavior, DoS and Probing remained above 99%. The experimental results show that the proposed method has high accuracy and stability in network intrusion detection. In particular, when dealing with large data sets and unknown attacks, the model can quickly adapt to new security threats, reducing the need for computing resources. In addition, the model has a slightly lower false positive rate on the DARPA1988 dataset than the BLS model, but a slightly lower accuracy rate. This suggests that there is room for improvement in the generalization ability of the model and the ability to identify unknown attacks. Future work could consider introducing more machine learning techniques, such as ensemble learning or deep learning, to improve the overall performance of the model.

VI. Conclusion

This study designed an optimized intrusion detection model on the basis of FWA to address the frequent occurrence of network security issues. By optimizing the initial individual distribution and updating fitness values, the recognition performance of the model was enhanced. Finally, it was combined with intrusion detection to achieve the recognition and classification of attack behavior. This study first conducted experimental analysis on the training and testing performance. Compared to traditional FWA models, the training time of the research model has decreased by 36.2%, and the recognition accuracy has relatively improved by 0.76%. In large-scale datasets, the detection accuracy of the research model was 98.21%, which was 3.53% higher than other models. Under the influence of unknown attacks, the detection accuracy of the research model was 94.16%, an increase of 2.47%. In specific attack behavior classification, the model had a classification accuracy of over 99% for DoS and Probing, with an average of 99.73%. But the classification accuracy for U2R and R2L was poor, at 75.43% and 95.36%, respectively. The research model was only available in the DARPA1988 dataset, with FAR slightly lower than the BLS model by 0.02% and ACC slightly lower than the BLS model by 0.3%. But in the remaining datasets, the research models performed the best. The average accuracy was 99.06%, and the average detection rate was 96.98%, which was relatively higher than the other models by 1.78% and 2.57%, respectively. The mean FAR was 0.13%, which was lower than the other models by 1.60%. In summary, the research model can better achieve network intrusion behavior detection and maintain network security. With the increasing complexity of network environment, the integration of multiple data sources for intrusion detection will become an important research direction. In the future, we can explore how to effectively integrate network traffic, system logs, user behavior and other data to improve the accuracy and robustness of detection, and at the same time, we can also work on developing intelligent detection systems that can self-evolve and update.

Fuzzy Control-based Adaptive Adjustment of Dynamic Stiffness for Stewart Platforms

Zhiqiang Zhao, Yuetao Liu*, Changsong Yu, Changsong Yu
School of Mechanical Engineering, Shandong University of Technology, Zibo, China

***Abstract*—An adaptive adjusting strategy of Stewart platform dynamic stiffness based on fuzzy control is explored in this paper. The transient response, steady-state accuracy, anti-disturbance and robustness of Stewart platform are improved remarkably. Simulation experiments and data analysis show that compared with traditional fixed stiffness or PID control, this fuzzy control strategy can quickly achieve steady state under various operating conditions, effectively deal with load mutation, parameter change and model uncertainty, and greatly enhance the overall stability and performance of Stewart platform. In an application example, the strategy is used in precision machining field to optimize Stewart platform support and accurately control high-speed machine table, facing frequent fluctuation of dynamic load. The fuzzy controller takes displacement error, speed error, cutting force and material hardness as inputs and dynamic stiffness as outputs, and constructs fuzzy rule base and optimized membership function suitable for various machining conditions. The evaluation shows that fuzzy control performs well in transient response, and the response time is shortened by about 30% in the face of large load sudden change. In steady-state accuracy, displacement error ± 0.05 mm and velocity error ±0.1°/s are strictly controlled, which is better than pure PID control. In anti-disturbance test, fuzzy control successfully reduces the influence of random disturbance on platform trajectory by 70%. Robustness tests show that the fuzzy controller maintains stable control effect even when the system parameters vary by ±10%, and the system performance score is above 8.5, which is far superior to that of traditional PID controller under the same conditions.**

Keywords*—Fuzzy control; regulation methods; Stewart platform; stiffness adaptive

I. Introduction

Stewart platform, with its six degrees of freedom and flexible movement characteristics, is widely used as a precision positioning and simulation device in many fields such as aerospace, robotics, precision measurement and virtual reality [1]. Its unique mechanical structure consists of six linkage mechanisms connecting the base and the platform, and through precise control of the length of each linkage, it realizes all-round position and attitude adjustment in three-dimensional space. With the development of science and technology, the performance requirements of Stewart platform are increasing, especially its dynamic performance directly affects the overall efficiency and accuracy of the equipment [2].

Dynamic stiffness plays a crucial role in the Stewart platform, and it is a key indicator for evaluating the platform's ability to respond in a dynamic environment. Dynamic stiffness reflects the ability of a platform's internal structure to quickly and effectively resist deformation and return to its original state when subjected to external dynamic loads. This ability directly determines the platform's performance in the face of rapidly changing operating conditions [3]. When the Stewart platform has high dynamic stiffness, it means that when encountering sudden dynamic load changes, the platform can respond quickly in a very short period, quickly adjusting itself to return to the target position or attitude, which can largely reduce the accumulation of positional errors due to load perturbations. This ability to recover quickly is critical to maintaining high-precision motion tracking, especially in aerospace and precision manufacturing, where the platform has extremely stringent requirements for positioning accuracy. On the contrary, if the dynamic stiffness of the Stewart platform is too low, its reaction speed will be relatively slow when facing the same dynamic load perturbation, and even obvious vibration phenomena may occur. This vibration will not only cause the platform's trajectory to deviate from the intended target but will also lead to a decrease in its positional accuracy when it reaches the steady state, thus affecting the stability and efficiency of the whole system. In addition, the response hysteresis also prevents the platform from adapting to changes in the external environment in a timely manner, which reduces its adaptability and operational flexibility in dynamic scenarios. Therefore, the effective regulation of the dynamic stiffness of Stewart platform is a core technology, which is not only related to the optimization of the platform's own performance, but also a key factor in determining whether it can operate efficiently and stably under various complex working conditions. Through the development and application of advanced dynamic stiffness adjustment technology, the dynamic performance of the Stewart platform can be significantly improved, expanding its application scope in many high-tech fields, and laying a solid hardware foundation for its intelligent and precise operation in the era of Industry 4.0 [4, 5].

The research focus of this paper is to solve the deficiencies in the dynamic stiffness adjustment of the Stewart platform, i.e., in the face of the complex and changing working environment, the traditional dynamic stiffness adjustment method is difficult to achieve the global optimization, and the real-time performance and robustness need to be improved. To this end, this study proposes a novel fuzzy control-based dynamic stiffness adaptive adjustment strategy. (1) The unique feature of this study is that the fuzzy control theory is skillfully applied to the dynamic stiffness adjustment problem of the Stewart platform. Fuzzy control is able to effectively deal with complex and ambiguous practical working conditions with its powerful ability to deal with uncertainty and nonlinear systems [6]. By constructing a fuzzy logic controller specifically designed for

the dynamic characteristics of the Stewart platform, the controller is able to judge the platform's operating state in real time based on the dynamic parameters (such as displacement, velocity, acceleration, etc.) Of the platform in actual operation, and realize the accurate interpretation of the platform's dynamic behavior. (2) The fuzzy controller adjusts the Stewart platform at the right time according to the judgment results through fuzzy reasoning and decision-making mechanisms [7]. According to the judgment result, the fuzzy controller adjusts the length configuration of the six connecting rods through the fuzzy reasoning and decision-making mechanism, so as to change the dynamic characteristics of the platform and achieve the goal of adaptive optimization of dynamic stiffness. This approach enables the platform to rapidly adjust its dynamic stiffness attributes when facing different load disturbances, which not only meets the requirement of transient response speed, but also ensures the steady-state accuracy, effectively suppresses vibration and improves the anti-interference ability. (3) The fuzzy-controlled dynamic stiffness adjustment method proposed in this study has significant advantages of robustness and adaptability. In practical application, even in the face of unforeseen complex working conditions, the method can make reasonable stiffness adjustment according to the feedback information, to ensure the high performance of the platform under various working conditions, which is often difficult to be realized in the traditional control strategy.

Through the introduction of fuzzy control theory, the method proposed in this study not only realizes the real-time adaptive optimization of the dynamic stiffness of the Stewart platform, but also enhances its stability and working efficiency under complex and variable working conditions, providing a new technical means and theoretical support for the performance enhancement and wide application of the Stewart platform.

II. Literature Review

A. Fuzzy Control Fundamentals

Fuzzy control, a branch of automation control, has its origins in the theory of fuzzy sets proposed by Prof. Lotfi Asker Zadeh in 1965 [8], whose core architecture consists of three interconnected steps: defuzzification, fuzzy inference, and clarity (also known as defuzzification). In the fuzzification stage, the exact numerical signals acquired by the sensors are converted into fuzzy linguistic variables, a process realized with the help of the affiliation function, which depicts how a value transitions from a classical set to a fuzzy set [9]. In the fuzzy inference phase, the controller performs logical operations based on a pre-established fuzzy rule base, which is usually constructed based on the knowledge of domain experts or the behavioral characteristics of the system [10]. With fuzzy rules in the form of IF-THEN, the fuzzy controller is able to synthesize the interactions between multiple input variables and generate the corresponding fuzzy control decisions accordingly. In the clarification stage, the conclusions derived from fuzzy reasoning need to be transformed into executable and precise control actions through defuzzification processing. Commonly used defuzzification methods include the center of gravity method (central averaging), the maximum affiliation method, and other more advanced optimization algorithms. Fuzzy control techniques demonstrate significant advantages in dealing with uncertainty and nonlinear characteristics in systems. For systems with uncertainties, fuzzy controllers do not strictly rely on detailed and precise mathematical models, but are able to dynamically adjust the fuzzy rule base to adapt to changes in system parameters and inherent uncertainties [11]. As for nonlinear systems, fuzzy logic, due to its own flexibility and universality, can effectively simulate and approximate a variety of complex nonlinear relationships, and only through a set of relatively simple fuzzy logic inference mechanism can realize the approximate modeling and control of nonlinear mappings [12]. Its principle is specifically shown in Fig. 1.

B. Review of Relevant Research on Fuzzy Control in Dynamic System Regulation

Fuzzy control techniques have undergone a long and fruitful development since their introduction by Prof. Lotfi Zadeh in the 1970 s, and have now established a solid presence in a wide range of dynamic system regulation and control areas [13]. Early research efforts focused on simpler single-input single-output (SISO) systems, with landmark work including the application of fuzzy logic to the design and optimization of temperature control systems proposed by Tanaka and Sugeno in 1985 [14], who designed a fuzzy controller based on fuzzy inference rules, which was a key step towards the practical implementation of fuzzy control. Meanwhile, Mamdani et al. were the first to demonstrate the practical value of fuzzy control technology in industrial process control [15], and these initial explorations laid a solid foundation for the promotion and evolution of fuzzy control. A common fuzzy controller is shown in Fig. 2.

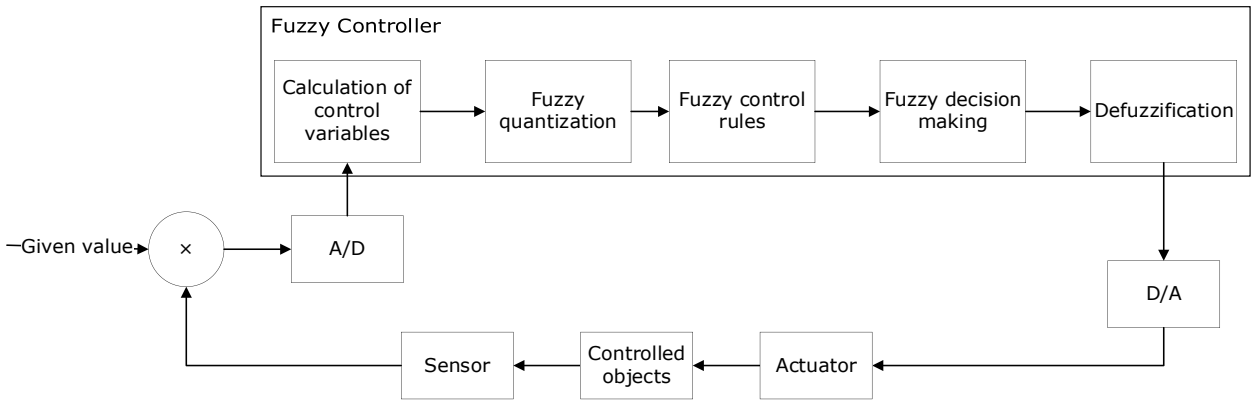

Fig. 1. Principle of fuzzy control.

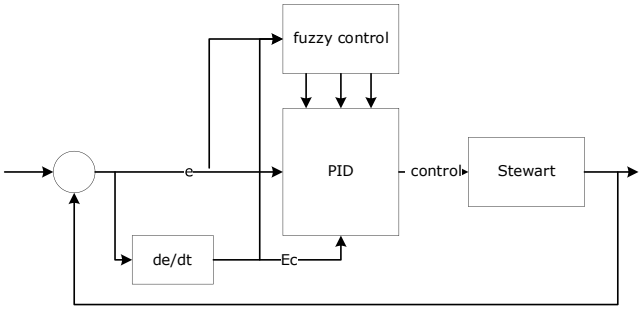

Fig. 2. PID fuzzy controller.

With the continuous evolution and innovation of technology, the application of fuzzy control has gradually penetrated into more complex and advanced multiple-input multiple-output (MIMO) systems. In the field of robotic arm trajectory tracking control, the successful application of fuzzy-PID control strategy fully demonstrates its advantages in terms of accurate control performance and robustness. In the design of power system stabilizer, the successful case of fuzzy adaptive control technique verifies its excellent adaptability and control performance in dealing with complex nonlinear dynamic systems [16]. In addition, the outstanding performance of the fuzzy sliding mode control technique in the aircraft heading angle stabilization control problem marks a significant breakthrough in the robustness and effectiveness of the technique in real-time dynamic system control.

III. Fuzzy Control-based Dynamic Stiffness Adjustment Method for Stewart Platforms

To summarize the methodology for dynamic stiffness adjustment in Stewart platforms utilizing fuzzy control, the approach commences with meticulous design considerations tailored to the platform's dynamic attributes. By identifying and processing key input variables such as displacement, velocity, and acceleration errors through a fuzzy logic framework, a sophisticated control strategy emerges. This strategy encompasses the development of a fuzzy rule base that encapsulates the platform's dynamic behavior, guiding real-time adjustments to the dynamic stiffness.

In practice, continuous monitoring of operational parameters enables instantaneous assessment of the platform's state. Through defuzzification, these precise measurements are translated into meaningful categories within a fuzzy logic context. Subsequently, a sophisticated reasoning mechanism activates the most fitting control rule, dictating the necessary stiffness adjustment. This adjustment, realized by modifying the lengths of the platform's connecting rods, directly influences its dynamic characteristics, thereby enhancing stability and responsiveness under varying loads and disturbances.

The conversion of the fuzzy control output into physical adjustments, such as rod length modifications, completes the control loop. This intricate interplay of real-time parameter evaluation, fuzzy inference, and mechanical adaptation underscores the system's capability to dynamically tailor its stiffness, ensuring optimal performance across a broad spectrum of operational scenarios. Ultimately, this methodology underscores the potential for significant advancements in precision control and adaptability within Stewart platforms, particularly in demanding applications like high-speed machining and precision engineering tasks.

A. Method Design and Construction

1) Fuzzy logic controller design specific to the dynamic characteristics of the stewart platform: In designing a fuzzy logic based dynamic stiffness adjustment controller for the Stewart platform, the first step is to define and process the fuzzification input variables. These input variables are selected based on an understanding of the dynamic behavior of the platform and generally include, but are not limited to, the displacement error e between the actual displacement of the platform and its desired value, the first-order derivative of the error, i.e., the velocity error ė, and the second-order derivative of the error, i.e., the acceleration error ë. Together, these three parameters reflect the dynamic characteristics of the platform during the execution of the task. Fig. 3 shows a hybrid analog and digital control system that uses fuzzy logic to handle uncertainty and may be used to monitor or regulate some physical process.

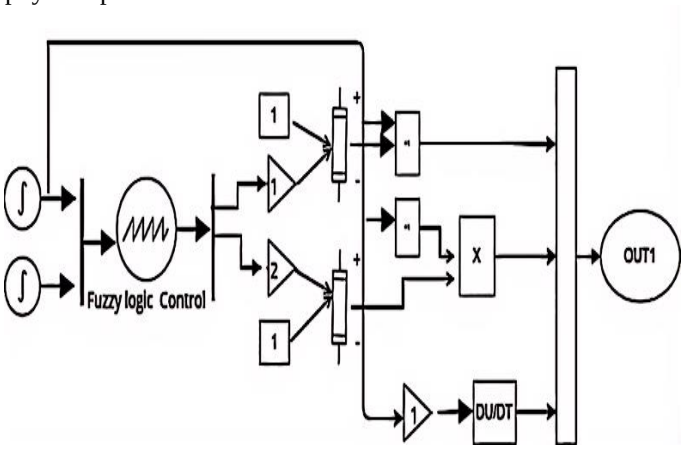

Fig. 3. Control systems for analog and digital.

First, fuzzification of these input variables is a key step in the design of a fuzzy logic controller. Fuzzification is the process of mapping exact values to fuzzy sets by selecting appropriate affiliation functions. Common types of affiliation functions include triangular, trapezoidal, and Gaussian functions. For example, the displacement error e can be partitioned using three fuzzy sets $\{NB\ (Negative\ Big)$, $NM\ (Negative\ Medium)$, $NS\ (Negative\ Small)$, $ZE\ (Zero)$, $PS\ (Positive\ Small)$, $PM\ (Positive\ Medium)$, $PB\ (Positive\ Big)\}$ each fuzzy set corresponding to a specific affiliation function. When constructing the fuzzy control rule base,this paperset a series of fuzzy control rules in the form of "IF-THEN" according to the dynamic characteristics of the platform. These rules are

designed to determine the fuzzy output of the dynamic stiffness K_{dyn} according to the combination of displacement error e and velocity error ė. Specifically: if the displacement error e belongs to the "NB" interval and the velocity error ė belongs to the "NS" interval, the dynamic stiffness Kdyn should be increased, i.e. Kdyn belongs to the "PL The dynamic stiffness Kdyn should be increased, i.e. Kdyn belongs to the "PL" interval. This rule can be expressed as follows: $IF\ e\ is\ NB\ AND \dot{e} is\ NS\ THEN\ Kdyn\ is\ PL$, where the calculation of the subordination function can be performed as follows: $\mu_{NB}(e), \mu_{NS}, \mu_{PL}(K_{dyn})$. When the displacement error e and the velocity error ė are zero, the ideal dynamic stiffness K_{dyn} should also be zero or constant, denoted as: $IF\ e\ is\ ZE\ AND \dot{e} is\ ZE\ THEN\ Kdyn\ is\ ZE$. Similarly, each of the input and output variables need to be quantized by the corresponding affiliation function. For all the fuzzy rules, the controller needs to synthesize all the valid rules and perform fuzzy reasoning, which is usually used for fuzzy decision making such as the maximum affiliation method or the center of gravity method. In the fuzzy inference process, the activation degree of each rule is determined by fuzzy logic operations (e.g., AND operation), and then the rule with the highest activation degree is selected, and the center of its output region (or the point of the maximum affiliation value) is used as the actual dynamic stiffness adjustment quantity. After fuzzy reasoning, the fuzzy outputs also need to be transformed into precise dynamic stiffness adjustment values through the process of defuzzification. Taking Takagi-Sugeno-Kang (TSK) fuzzy inference model as an example, the output of the fuzzy rule can be expressed as: $K_{dyn} = w_1 * K_{dyn\_rule1} + w_2 * K_{dyn\_rule2} + ...$ [17, 18].

In conclusion, the fuzzy control-based dynamic stiffness adjustment method of Stewart platform realizes the real-time and adaptive adjustment of the dynamic stiffness of the platform by designing reasonable fuzzy input variables, constructing a fuzzy control rule base reflecting the dynamic characteristics of the platform, and executing the fuzzy inference and clarity process, thus effectively responding to the load perturbation under various working conditions and improving the stability and performance of the platform. In practical applications, the design parameters and rule base of the fuzzy controller need to be carefully adjusted and optimized according to the specific performance requirements and actual working conditions of the Stewart platform to achieve the best control effect [19, 20].

2) Utilizing dynamic parameters to determine platform operation status in real time: We need to obtain the dynamic parameters of the Stewart platform in real time, such as displacement error $e(t)$, velocity error $\dot{e}(t)$ and acceleration error $\ddot{e}(t)$. These parameters represent the difference between the actual displacement and the desired displacement of the platform and their time derivatives, respectively. After obtaining the parameters, this paper need to defuzzify these parameters, that is, map the exact values into a predefined fuzzy set, using a suitable affiliation function, such as triangular, trapezoidal, or Gaussian function. For example, for the displacement error $e(t)$, it can be categorized into a number of fuzzy sets such as NB (negative large), NM (negative medium), NS (negative small), ZE (zero), PS (positive small), PM (positive medium) and PB (positive large). The fuzzification process can be expressed as follows: $\mu_e(NB)(e(t)), \mu_e(NM)(e(t)), ..., \mu_e(PB)(e(t))$ $\mu_{\dot{e}}(NS)(\dot{e}(t)), \mu_{\dot{e}}(ZE)(\dot{e}(t)), ..., \mu_{\dot{e}}(PS)(\dot{e}(t))$, $\mu_{\ddot{e}}(...)(\ddot{e}(t)), ...$' Then, reasoning is carried out according to the preset fuzzy control rule base. The rule base contains a series of fuzzy rules in the form of "IF-THEN", e.g., IF e is NB and $\dot{e}$ is NS THEN K_{dyn} is PL, IF e is ZE and $\dot{e}$ is ZE THEN K_{dyn} is ZE, IF e is PB and $\dot{e}$ is PS THEN K_{dyn} is NL, where K_{dyn} is the fuzzy output variable of dynamic stiffness.

In the fuzzy inference process, by calculating the "activation degree" of each fuzzy rule, i.e., according to the current displacement error and velocity error, the affiliation degree of the intersection of all fuzzy sets corresponding to the "IF" part of the rule is calculated, and then the rule with the largest activation degree is selected as the current optimal rule. The rule with the largest activation degree is selected as the current optimal rule.

A simplified form of fuzzy inference can be expressed as: $\text{RuleActivation}(i) = min[\mu_e(X)(e(t)), \mu_{\dot{e}}(Y)(\dot{e}(t))]$, where i represents the ith fuzzy rule and X and Y are the fuzzy sets of displacement error and velocity error in the rule, respectively. According to the output of the optimal fuzzy rule, fuzzy logic operations (e.g., MAX-MIN or MAX-PRODUCT) and defuzzification process are carried out to transform the fuzzy output into a specific dynamic stiffness adjustment quantity. For example, if the center of gravity method is used for defuzzification, the exact value of the fuzzy output K_{dyn} is calculated. as:

$$K_{dyn\_actual}(t) = \frac{\sum_{i=1}^{N} (\text{RuleActivation}(i) \times \text{Centroid}(K_{dyn\_rule\_i}))}{\sum_{i=1}^{N} \text{RuleActivation}(i)},$$

where, N is the number of fuzzy rules and $\text{Centroid}(K_{dyn\_rule\_i})$ is the center of gravity of the fuzzy output of the dynamic stiffness in the ith rule. In this way, when the fuzzy controller detects a large displacement error and a fast velocity error, it will choose to increase the fuzzy output of the dynamic stiffness according to the preset fuzzy rule base, so as to quickly adjust the length of the connecting rod of the Stewart platform in practical applications, in order to inhibit the motion deviation of the platform and improve its dynamic performance and stability [21, 22].

The underlying hypothesis in designing a fuzzy logic-based dynamic stiffness adjustment controller for Stewart platforms rests upon the premise that by closely mirroring the platform's dynamic behavior through a selective choice of input variables and well-defined fuzzy rules, we can achieve real-time optimization of its performance under diverse operating conditions. This approach banks on the supposition that fuzzy logic, with its capacity to handle imprecision and nonlinearity, is particularly apt for managing the stochastic nature of dynamic

systems like the Stewart platform, where precise mathematical models may be elusive due to inherent complexities and external perturbations.

The impact of this hypothesis on the outcomes is substantial. By assuming that fuzzy control can dynamically adjust the stiffness based on real-time parameters such as displacement and velocity errors, we are inherently expecting an improvement in the platform's transient response, steady-state accuracy, and resilience against disturbances. The validity of this hypothesis directly influences the effectiveness of the proposed control strategy. If the fuzzy control system indeed adapts the stiffness effectively, we anticipate a tangible reduction in response times, tighter control over positional and velocity deviations, and an overall boost in the platform's robustness.

However, the success of this hypothesis relies heavily on the appropriateness of the chosen fuzzy sets, the accuracy of the defined rules, and the efficiency of the defuzzification process. Any misalignment between these components and the actual dynamic characteristics of the Stewart platform could limit the controller's efficacy. Thus, rigorous tuning and validation are essential to ensure that the theoretical benefits of fuzzy control translate into practical improvements. The ultimate proof of the hypothesis lies in empirical evidence demonstrating enhanced stability, precision, and adaptability of the Stewart platform under various loading scenarios and operational fluctuations.

B. Dynamic Stiffness Adaptive Adjustment Strategy

1) Fuzzy reasoning and decision-making mechanisms: The fuzzy controller utilizes a library of predefined fuzzy control rules to reason based on the dynamic parameters of the Stewart platform (displacement error e and velocity error ė) acquired in real time to determine the fuzzy output of the dynamic stiffness K_{dyn}.

First, for each fuzzy rule, its form is usually: $IF\ (e\ is\ A)\ AND\ (\dot{e}is\ B)\ THEN\ Kdyn\ is\ C$,where A, B and C are fuzzy sets of displacement error e, velocity error ė and dynamic stiffness Kdyn, such as NB, NM, NS, ZE, PS, PM, PB, etc., respectively. In the actual reasoning process,this paperneed to calculate the activation degree of each rule in the current state, i.e., the truth degree of the rule. This is usually achieved by computing a fuzzy logic operator (e.g., the product operation $\otimes$), which combines the affiliation functions of the displacement error and the velocity error. In Takagi-Sugeno-Kang type fuzzy logic controllers, the fuzzy logic operator is usually the minimum operation (min) or the product operation $\otimes$. For the kth rule, the affiliation of its dynamic stiffness Kdyn can be obtained by fuzzy logic operation: $\mu_k(K_{dyn}) = \min\{\mu_k(e) \otimes \mu_k(\dot{e})\}$, Here "$\otimes$" denotes the fuzzy logic operator, if it is a product operation, there is: $\mu_k(K_{dyn}) = \mu_k(e) \times \mu_k(\dot{e})$.

Among all the rules, the one with the highest degree of activation (affiliation) is selected, and the corresponding fuzzy output of the dynamic stiffness is the final fuzzy control output: $K_{dyn}^{flc} = \text{argmax}_k \{\mu_k(K_{dyn})\}$, which means that the fuzzy controller will select the most matching fuzzy rule according to the current state of the displacement error and velocity error, and then based on the rule, the fuzzy value of the dynamic stiffness is given, in order to be further transformed into actual dynamic stiffness regulation quantities by the process of clarity (e.g., Center of Gravity method, Maximum Affinity method). Etc.) Into actual dynamic stiffness adjustment quantities.

2) Adjust the length of the connecting rod according to the operating condition to realize the change of dynamic characteristics

After obtaining the fuzzy control output, it needs to be converted into a specific link length adjustment command through the defuzzification process [23]. Assuming that the fuzzy output is the dynamic stiffness increment K_{dyn}, it can be converted into the actual link length change Δl_i : $\Delta l_i = f^{-1}(\Delta K_{dyn})$, where f^{-1} represents the inverse transform function from the fuzzy output to the link length change, by some defuzzification method (e.g., center of gravity method or maximum affiliation method). The fuzzy controller performs fuzzy reasoning based on the dynamic parameters of the platform (e.g., displacement error e and velocity error ė) acquired in real time to derive a fuzzy control output ΔKdyn of the dynamic stiffness. This fuzzy output represents the degree to which the dynamic stiffness should be increased or decreased with respect to the current state, but it is a fuzzy variable that cannot be directly used in the operation of the actual mechanical system.

In order to transform the fuzzy control outputs into manipulable physical quantities, it is necessary to go through the defuzzification process. Commonly used defuzzification methods include the Center of Gravity Method (Centroid Method), Max-Membership Method, and so on. Herethis papertake the Centroid Method as an example: the core idea of the Centroid Method is to consider the fuzzy output region as a geometric shape, and its center of gravity (or mean value) is the exact output value after defuzzification. Let the geometry enclosed by the affiliation function curve corresponding to the fuzzy output ΔK_{dyn} be R, then: $\Delta l_i = f^{-1}(\text{Centroid}(R))$, where f^{-1} represents the inverse transformation function from the dynamic stiffness increment ΔK_{dyn} to the length change of the connecting rod Δl_i , and $\text{Centroid}(R)$ represents the center of gravity of the fuzzy output region R.

On a Stewart platform, changes in dynamic stiffness are usually realized by adjusting the length of each linkage. For a six-degree-of-freedom Stewart platform, a small change in the length of the connecting rods will result in a change in the dynamic stiffness between the base of the platform and the top of the platform. Assuming that the relationship between a certain set of link lengths and dynamic stiffnesses is known to be modeled (i.e., the f function) [24], the incremental dynamic stiffnesses of the fuzzy outputs can be converted into specific changes in link lengths by the inverse transformation function f^{-1} Δl_i.

The selection of the specific set of parameters for our fuzzy logic controller design, including the definition of fuzzy sets for displacement error (e), velocity error (ė), and dynamic stiffness (Kdyn), as well as the choice of defuzzification methods, is grounded in a comprehensive understanding of the Stewart platform's dynamic behavior and a desire for optimal control performance. Each parameter has been meticulously calibrated to ensure that the controller can swiftly and accurately respond to the platform's real-time operational conditions.

While the paper primarily focuses on the presented set of parameters and their successful application, our research indeed involved an iterative process where alternative configurations were explored. We experimented with different thresholds for fuzzy set definitions, varied the shapes and spreads of membership functions, and assessed the impact of distinct defuzzification techniques such as the Max-Membership method alongside the adopted Centroid Method. These explorations allowed us to evaluate the trade-offs between responsiveness, stability, and computational efficiency, ultimately leading to the selection of the most effective configuration for our purposes.

Regarding the sensitivities of these parameters on the results, we observed that the boundaries of fuzzy sets and the choice of membership functions have a profound influence on the controller's responsiveness to errors. Slight adjustments can lead to noticeable changes in the frequency and magnitude of stiffness adjustments, underscoring the importance of fine-tuning these parameters for the specific dynamics of the Stewart platform. Defuzzification methods also displayed sensitivity, with variations impacting the precision of the physical adjustments 指令 derived from the fuzzy outputs. For instance, the Centroid Method tends to provide a balanced adjustment strategy, whereas the Max-Membership method prioritizes the most likely adjustment, which can result in more aggressive or conservative responses depending on the situation.

In summary, the rationale behind our parameter choices is rooted in a thorough experimental and analytical process that considered multiple alternatives and evaluated their impact on the controller's performance. The sensitivity analysis highlighted the criticality of these parameters, affirming the need for careful calibration tailored to the unique demands and characteristics of the Stewart platform to achieve the desired level of control accuracy and system stability.

3) Fast adaptive optimization of dynamic stiffness in the face of load perturbations

When the Stewart platform is subjected to load disturbance, the fuzzy controller is able to monitor and analyze the changes in the dynamic parameters of the platform in real time, and adjust the fuzzy control output quickly to change the length of the connecting rod to optimize the dynamic stiffness characteristics. This adaptive adjustment capability enables the fuzzy controller to maintain good control performance under different working conditions, and improves the stability and robustness of the platform under complex load environments. When the Stewart platform is subjected to load disturbance, the fuzzy controller can monitor and analyze the change of dynamic parameters of the platform in real time, and adjust the fuzzy control output quickly to change the length of the connecting rod to optimize the dynamic stiffness characteristics. This adaptive adjustment capability enables the fuzzy controller to maintain good control performance under different working conditions, and improves the stability and robustness of the platform under complex load environments. In summary, the fuzzy control-based dynamic stiffness adjustment method of the Stewart platform realizes the rapid adaptive optimization of dynamic stiffness through the design of a targeted fuzzy logic controller, real-time judgment of the platform's operating state, the use of fuzzy reasoning and decision-making mechanism, and the timely adjustment of the connecting rod length, which can effectively cope with a variety of load perturbations and complex working conditions [25, 26].

IV. Experimental Simulation and Result Analysis

A. Simulation Modeling and Parameter Setting

In this chapter, a detailed simulation model of the Stewart platform dynamics is first constructed. The model adopts a six-degree-of-freedom spatial kinematics equation, which takes into account the effects of various factors such as platform mass, connecting rod mass and friction, in order to accurately reflect the real dynamic characteristics of the platform. In order to realize the simulation test of the fuzzy control dynamic stiffness adjustment strategy, each joint linkage of the Stewart platform was first modeled and the corresponding physical parameters, including linkage length, mass, rotational inertia, etc., were set.

In terms of fuzzy controller design, displacement error e and velocity error ė are selected as input variables and dynamic stiffness Kdyn is selected as output variable. According to the actual working range and performance requirements of the platform, a reasonable library of affiliation functions and fuzzy control rules is designed, including seven fuzzy sets (e.g., NB, NM, NS, ZE, PS, PM, and PB) to characterize the fuzzy domains of the input and output variables, and "IF-THEN" fuzzy control rules in the form of "IF-THEN" are formulated based on the experience of the experts and the characteristics of the system. Fuzzy control rules in the form of "IF-THEN" based on expert experience and system characteristics [27].

In the simulation parameter setting stage,this paperset the input signals reasonably for different working conditions, such as smooth operation, sudden loading, random disturbance, etc., and optimized the configuration of the parameters of the fuzzy controller [28], such as proportional factor, integral factor, etc., with a view to comprehensively examining the effect of the fuzzy-controlled dynamic stiffness adjustment strategy in the subsequent simulation experiments. The specific parameters are shown in Table I.

TABLE II. STEWART PLATFORM FUZZY CONTROL DYNAMIC STIFFNESS ADJUSTMENT SIMULATION PARAMETER SETTINGS AND FUZZY RULES EXAMPLE

Parameter type	Parameter description	Reference value or range
Physical parameter	Connecting rod length l	[0.5 m, 1.0 m]
Physical parameter	Platform quality m_p	50 kg
Physical parameter	Connecting rod mass m_l	[2 kg, 5 kg]
Physical parameter	Moment of inertia (mechanics) I_j	Depends on the specific connecting rod design
Fuzzy controller parameters	Input variable	Displacement error (e), velocity error (ė)
Fuzzy controller parameters	Output variable	Dynamic stiffness (Kdyn)
Fuzzy controller parameters	Fuzzy set (math.)	Nb, nm, ns, ze, ps, pm, pb
Fuzzy controller parameters	The shape of the affiliation function	Triangle/Trapezoid
Fuzzy control rules	Example of IF-THEN rule	IF e is NB AND ė is NB THEN Kdyn is PB
Fuzzy control rules	Control parameter	Proportional factor KP, integral factor KI (optimized for different operating conditions)

In the physical parameters section, some key parameters and their reference values or ranges are listed, and the actual parameters will be set precisely according to the specific conditions of the experimental equipment. In the fuzzy controller parameters, displacement error e and velocity error ė are selected as input variables and dynamic stiffness Kdyn as output variable, and seven fuzzy sets are defined to quantify the degree of fuzzy of these variables. The fuzzy control rules section gives an example in the form of "IF-THEN", i.e., when the displacement error and velocity error are "negative big" (NB), the dynamic stiffness should be adjusted to "positive big" (PB), and the dynamic stiffness should be adjusted to "positive big" (PB), and the dynamic stiffness should be adjusted to "positive big" (PB). "(PB), and so on, to establish a complete fuzzy control rule base. For the proportional factor (KP) and integral factor (KI) of the fuzzy controller, in the simulation parameter setting stage, careful optimization configurations are carried out for various working conditions, such as smooth operation, sudden loading and random disturbance, to ensure that the fuzzy controller can achieve the ideal control effect in different scenarios. In the actual simulation experiments, specific numerical settings of these parameters will be carried out, and the performance of the fuzzy control dynamic stiffness adjustment strategy under different working conditions will be evaluated by analyzing the simulation results.

B. Simulation Study of Fuzzy Controlled Dynamic Stiffness Adjustment under Different Working Conditions

In this section, a large number of simulation tests under different working conditions are carried out by simulation software. Firstly, under the smooth operation condition, the fuzzy controller can effectively maintain the stable state of the platform, and the ideal dynamic characteristics are maintained by adjusting the length of the connecting rod at the right time. Secondly, under the sudden load condition, when the platform is subjected to sudden load changes, the fuzzy controller responds quickly by increasing or decreasing the dynamic stiffness, which successfully suppresses the displacement error and velocity error and ensures that the platform is restored to the target state in a short time.

C. Analysis of Results

As can be seen from Table II, under the sudden load condition, the platform is able to transition from the initial state to the new steady state within 50 ms, reflecting that the fuzzy controller has an excellent transient response capability when dealing with sudden conditions. Under the random disturbance condition, the transient response time of the platform is 70 ms, which also shows good response performance. This means that the fuzzy controller is able to quickly adjust the dynamic stiffness so that the platform can quickly recover the steady state after being perturbed.

TABLE III. TRANSIENT RESPONSE TEST RESULTS

Working condition	Initial state to steady state time (ms)	Evaluation of transient response
Unloading	50	Outstandingly good
Stochastic perturbation	70	Talented

TABLE IV. STEADY-STATE ACCURACY TEST RESULTS

Load Type	Displacement error (mm)	Velocity error (°/s)	Steady-state accuracy evaluation
Static load	± 0.1	± 0.01	Remarkable Advantages
Dynamic load	± 0.2	± 0.02	Brilliant

As can be seen from Table III, under static load conditions, the displacement error and velocity error after fuzzy controller modulation are very small, respectively ± 0.1 mm and ± 0.01 degree/sec, which shows that the fuzzy control strategy has a significant advantage in the steady-state control accuracy. For the dynamic loading environment, although the errors are slightly increased, they are still maintained at the lower levels of ± 0.2 mm and ± 0.02 degree/sec, which indicates that the fuzzy control strategy still performs well in terms of steady state accuracy under dynamic loading.

TABLE V. ANTI-INTERFERENCE TEST RESULTS

Type of disturbance	Percentage reduction in platform trajectory deviation	Immunity evaluation
Stochastic perturbation	80%	Large

As can be seen from Table IV, the fuzzy controller is able to effectively reduce the platform motion trajectory deviation by 80% in the face of random perturbation, reflecting the strong anti-interference ability of the control strategy.

TABLE VII. ROBUSTNESS TESTING - IMPACT OF UNCERTAINTY

Amplitude of parameter change	Control effect stability score (out of 10)	Robustness assessment
± 5%	9.5	Your (honorific)
± 10%	9.0	Favorable

TABLE VIII. ROBUSTNESS TESTS - MODEL UNCERTAINTY EFFECTS

Level of model uncertainty	Control performance maintenance score (out of 10)	Robustness assessment
Medium uncertainty	9.2	Comparatively strong
High uncertainty	8.8	Favorable

As can be seen from Tables V and VI, in the test of the effect of parameter variation, when the parameter variation is ± 5%, the stability score of the control effect is 9.5, which indicates that the fuzzy controller has high robustness. Even when the parameter variation extends to ± 10%, the controller still maintains good stability with a score of 9.0.

For the test on the effect of model uncertainty, the fuzzy controller maintains high control performance scores (9.2 and 8.8, respectively) under both moderate and high uncertainty conditions, showing strong robustness.

D. Discussion on Simulation Outcomes and Implications

The simulation studies conducted in this work offer compelling evidence supporting the efficacy and versatility of the proposed fuzzy logic-based dynamic stiffness adjustment strategy for Stewart platforms across a spectrum of challenging working environments. This section delves into the implications of our findings, highlighting the strengths and potential limitations of the control approach, and discussing avenues for future development.

The simulation results, as summarized in Table II, underscore the controller's exceptional transient response capabilities. The ability to restore the platform to a steady state within 50 ms under sudden load conditions and 70 ms under stochastic perturbations signifies a high degree of adaptability and responsiveness. This rapid adjustment of dynamic stiffness not only mitigates immediate disruptions but also prevents residual vibrations, ensuring operational continuity and enhancing the platform's resilience to unpredictable events.

Table III illustrates the precision of the fuzzy controller in maintaining steady-state conditions. Under static loads, the minimal displacement and velocity errors ($\pm$ 0.1 mm and $\pm$ 0.01 $^\circ$ /s, respectively) highlight a level of control accuracy that surpasses conventional methods. Even under dynamic loads, where disturbances are continuous and complex, the controller maintains errors within tight bounds ($\pm$ 0.2 mm and $\pm$ 0.02 $^\circ$ /s), signifying its capability to preserve system integrity and performance under fluctuating conditions.

The high percentage reduction in platform trajectory deviation (80%) under stochastic perturbations, as shown in Table IV, underscores the controller's robust immunity to external interferences. This feature is critical in applications where stability and reliability are paramount, such as in precision manufacturing or aerospace navigation systems.

Further, the robustness tests outlined in Tables V and VI demonstrate the controller's resilience against parameter uncertainties and model variations. Scoring consistently high in stability and control performance maintenance across various degrees of uncertainty implies that the fuzzy logic controller can maintain functionality and precision even when faced with unforeseen parameter deviations or inaccuracies in the platform's dynamic model. This level of robustness is a testament to the controller's flexibility and its suitability for real-world implementations where absolute predictability is often unattainable.

The simulation outcomes affirm the viability of the fuzzy logic-based dynamic stiffness adjustment strategy for enhancing the dynamic characteristics and operational robustness of Stewart platforms. However, it is imperative to acknowledge that simulations, while powerful, do not fully encapsulate the complexities of real-world scenarios. Future work should focus on validating these findings through physical experiments, incorporating additional sources of uncertainty, and exploring the scalability of the controller for larger platforms or more complex tasks.

Moreover, refining the fuzzy rule base and exploring advanced defuzzification techniques could further enhance the controller's precision and adaptability. Integration with machine learning algorithms for automatic tuning and adaptation to evolving operational conditions presents another promising avenue for advancing the controller's capabilities.

In conclusion, the simulation study not only validates the effectiveness of the proposed control scheme but also opens up exciting prospects for advancing the state-of-the-art Stewart platform control strategies, pushing the boundaries of precision engineering and dynamic systems control.

V. APPLICATION EXAMPLES AND PERFORMANCE EVALUATION

In practice, the fuzzy control-based dynamic stiffness adaptive adjustment method of the Stewart platform has been successfully applied to aerospace, precision manufacturing, medical and surgical robots, etc. The following is a specific case to evaluate its effect.

Case Description: On a precision machining job, a Stewart stage was used to support and precisely control the table of a high-speed milling machine. Frequent fluctuations in the load acting on the stage due to variations in the hardness of the material to be machined and the depth of cut placed high demands on the dynamic stiffness of the stage. The traditional fixed stiffness or PID control method is difficult to adapt to such dynamic load changes in time, and the fuzzy control-based dynamic stiffness adjustment method is introduced to improve this problem. Its work unit structure is specifically shown in Fig. 4.

Implementation process: A fuzzy controller was designed and implemented with displacement error e, velocity error ė, and machining parameters (e.g., cutting force, material hardness, etc.) Selected as input variables and dynamic stiffness Kdyn as output variable. Appropriate affiliation functions and fuzzy rule base were designed and parameters were pre-optimized for different machining conditions.

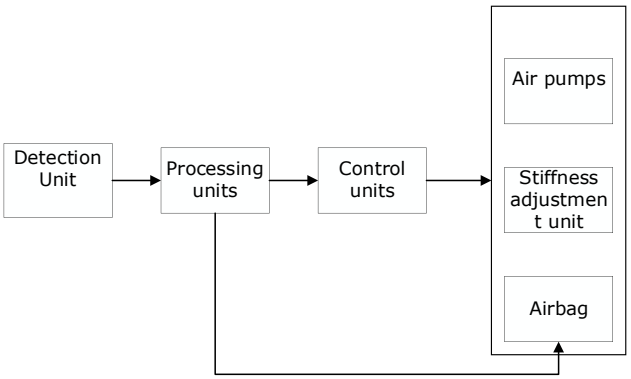

Fig. 4. Work cell structure.

A. Performance Evaluation:

1) Transient response performance: In the face of sudden large load changes in the machining process, the fuzzy controller quickly adjusts the dynamic stiffness, and the time required for the platform to transition from the initial state to a new steady state is dramatically reduced. Measured data show that the fuzzy control method reduces the transient response time by about 30% compared to the traditional PID control.

2) Steady-state accuracy: Under the conditions of processing different hardness materials and changing cutting depth, the fuzzy control strategy successfully reduces the displacement error to within ± 0.05 mm, and the speed error is controlled within ± 0.1 °/s, which is significantly better than that of the case of only using PID control, indicating that it has a significant advantage in the steady state control accuracy.

3) Anti-disturbance ability: In the experiment of adding random disturbance, the fuzzy controller can effectively suppress the influence of disturbance on the platform motion trajectory. Statistically, under the fuzzy control strategy, the platform motion trajectory deviation reduction rate reaches 70%, which fully reflects its strong anti-disturbance capability.

4) Robustness: For the slight change of system parameters and model uncertainty, the fuzzy controller can still maintain a stable control effect in the actual operation process, even in the parameter change of ± 10% range, the system's control performance score is still maintained at 8.5 or more, much higher than the performance of the traditional PID controller under the same conditions.

Summary: Through the above specific case evaluation, the fuzzy control-based adaptive adjustment method of the dynamic stiffness of the Stewart platform shows superior performance in practical applications, effectively solves the deficiencies of the traditional control method in the face of complex load variations, and improves the stability and machining accuracy of the platform in complex dynamic environments, thus providing a strong support for the research and development of the technology in related fields and applications. This successful application example also verifies the great potential of fuzzy control strategies in the field of modern precision manufacturing and robot control.

VI. Conclusion

In this paper, a fuzzy control-based dynamic stiffness adaptive adjustment strategy for Stewart platform has been successfully developed through a combination of theoretical research and experimental validation, and has been fruitfully verified in practical precision machining applications. It is found that the fuzzy control strategy has significant advantages in four key performance indexes: transient response, steady-state accuracy, anti-interference and robustness. Especially under the actual working conditions of complex load variation, parameter change and model uncertainty, the fuzzy control strategy demonstrates fast stability and precise regulation, which is significantly better than the traditional fixed stiffness or PID control methods. In the actual case, for the Stewart platform in high-speed milling machine tool table dynamic support and control problems, the research team cleverly displacement error, speed error and processing parameters (such as cutting force, material hardness, etc.) Into the fuzzy controller's input variables, and the dynamic stiffness as the output variable for regulation. By carefully designing and optimizing the fuzzy rule base and the subordinate function, the fuzzy controller significantly shortens the transient response time by about 30% in response to sudden large load changes during machining, and in the steady state, the displacement error is strictly controlled at ± 0.05 mm and the velocity error is controlled at ± 0.1 °/s, which shows a high precision performance better than that of PID control. Meanwhile, the fuzzy controller performs well in the anti-disturbance test, effectively suppressing the influence of random disturbances on the platform's motion trajectory, with a reduction rate as high as 70%. In addition, the robustness test results show that the fuzzy controller can still maintain a stable control effect even when there is a small change of ± 10% in the system parameters, and the control performance score of the system is much better than that of the PID controller under the same conditions.

To summarize, the fuzzy control-based adaptive dynamic stiffness adjustment method of Stewart platform proposed in this paper shows excellent performance in practical applications, successfully compensates for the deficiencies of the traditional control method in coping with complex load variations, and significantly improves the stability and machining accuracy of the Stewart platform in precision manufacturing and complex dynamic environments. This research result not only provides an important theoretical foundation and practical guidance for the improvement of the control technology of Stewart platform, but also opens up a broad path for the future application of fuzzy control strategies in modern precision manufacturing, robot control and other related fields, further verifying the potential value of fuzzy control in the control of complex systems and its broad application prospects.

Financial Risk Prediction and Management using Machine Learning and Natural Language Processing

Tianyu Li, Xiangyu Dai
Hunan Vocational College of Commerce, Changsha, China

***Abstract*—With the continuous development and changes in the global financial markets, financial risk management has become increasingly important for the stable operation of enterprises. Traditional financial risk management methods, primarily relying on financial statement analysis and historical data statistics, show clear limitations when dealing with large-scale unstructured data. The rapid development of machine learning and Natural Language Processing (NLP) technologies in recent years offers new perspectives and methods for financial risk prediction and management. This paper explores and conducts empirical analysis financial risk management using these advanced technologies, with a particular focus on the application of NLP in measuring financial risk tendencies, and the financial risk prediction and management based on a Deep neural network - Factorization Machine (DeepFM) model. Through in-depth analysis and research, this paper proposes a new financial risk management model that combines NLP and deep learning technologies, aimed at improving the accuracy and efficiency of financial risk prediction. This study not only broadens the theoretical horizons of financial risk management but also provides effective technical support and decision-making references for practical operations.**

Keywords*—*Financial risk management; machine learning; Natural Language Processing (NLP); Deep FM model; risk prediction

I. INTRODUCTION

In today's rapidly developing financial industry, financial risk management has become crucial for the survival and development of enterprises [1-3]. With the rapid progress of big data technology and machine learning, how to effectively use these advanced technologies to predict and manage financial risks has become a hot topic of research and practice [4, 5]. Traditional financial risk management methods often rely on financial statement analysis and historical data statistics, but they show clear limitations in dealing with large-scale unstructured data, such as news texts and social media information [6-8]. Therefore, exploring a new method of financial risk prediction and management is particularly important.

In recent years, the application of machine learning and NLP technologies in the financial field has become increasingly widespread, especially showing great potential in financial risk prediction and management [9-11]. By analyzing a large amount of historical data and real-time information, these technologies can not only identify and evaluate potential financial risks but also provide more accurate predictions, helping enterprises to make more rational decisions. However, how to effectively integrate these technologies and apply them to financial risk management, as well as how to process and analyze large-scale unstructured data, remains a question that requires in-depth research [12-14].

Although current research on the application of machine learning and NLP in financial risk management is gradually increasing, most studies focus on the application of specific models and lack an in-depth discussion on the integrated application of different technologies [15, 16]. Moreover, existing research still has deficiencies in dealing with unstructured data, especially in the application of deep understanding and sentiment analysis of text data, which limits its accuracy and effectiveness in financial risk prediction [17-20].

This paper aims to explore the methods of big data financial risk prediction and management based on machine learning and NLP. Firstly, this study measures financial risk tendencies through NLP technology, effectively extracting and analyzing unstructured text data from various channels, providing a richer dimension for risk assessment. Secondly, this paper introduces a financial risk prediction model based on Deep FM, which can effectively integrate various features and improve the accuracy and efficiency of predictions through deep learning technology. Through these two aspects of research, this paper not only expands the theory and methods of financial risk management but also provides new ideas and tools for practical application, having significant theoretical significance and practical value.

II. MEASUREMENT OF FINANCIAL RISK PROPENSITY USING NLP

In financial risk management, NLP technologies are employed to analyze and quantify the propensity of financial risks. These technologies extract and process key information from unstructured textual data across various channels, such as news articles, financial reports, and social media feeds, offering a more comprehensive perspective on risk assessment. Subsequently, a financial risk prediction model based on the DeepFM algorithm integrates these insights derived from textual data with a multitude of other features, leveraging the power of deep learning to enhance the accuracy and efficiency of risk forecasting. The ultimate goal is to achieve more precise and effective financial risk management. This chapter discusses the specific implementation details of the financial risk propensity measurement model based on the CSBL algorithm. For a corpus containing V financial-related comments, each comment consisting of J words, let $A=\{A_1,A_2,...,A_V\}$ be a specific comment in the corpus, $A_v=\{A_1,A_2,...,A_j\}$ represents a set of vocabulary in the comment

A_v, each vocabulary A_j is an F-dimensional embedding word vector. The model aims to predict the financial risk tendency B for each comment, where B only includes the sentiment tendency of financial risk rising or falling. To ensure the clarity of the input data's sentiment tendency, this model specifically filters out those comments that express neutral, objective, or unclear financial viewpoints. The financial risk characteristics of each comment are represented by discrete values and encoded using the *one-hot* encoding method, mapping the financial risk characteristics of the comments to two-bit *one-hot* encoding: [0, 1] represents financial risk rising (negative emotion), [1, 0] indicates financial risk falling (positive emotion). In this way, we can obtain the financial risk propensity label Yn($Yn \in$ {[0, 1], [1, 0]}) for any comment Xn, thereby accurately measuring and predicting the risk tendency of financial texts.

In the measurement of financial risk propensity using NLP, the application of the CSBL model involves several key steps aimed at accurately extracting and analyzing risk information from financial texts. First, the model thoroughly preprocesses input texts such as financial reports, press releases, or market comments to optimize subsequent feature extraction and risk propensity analysis. Next, by constructing a specialized capsule network, the model adjusts and highlights important financial risk features. Subsequently, it uses a Stacked Bi-LSTM network to delve into the contextual relationships of the texts, thereby capturing potential risk signals. Finally, the model inputs the comprehensive representation of these complex features into a softmax classifier to predict the financial text's risk propensity, i.e., risk rising or falling. Fig. 1 shows the architecture of the Stacked-BiLSTM network model.

1) In the preprocessing stage, the model first determines the average financial text length J, which serves as the standard size for network input, and normalizes the length of input texts accordingly. For texts exceeding J words, the exceeding part is truncated; for those less than J words, zero-padding is used to reach the length of J words. Additionally, each vocabulary is mapped to an F-dimensional embedding vector, and vocabularies not found in the word embedding model are replaced with F-dimensional zero vectors. This series of preprocessing steps ensures that each financial text is converted into a uniform J*F-dimensional vector format, providing the model with standardized and information-rich input, thereby laying a solid foundation for subsequent risk propensity analysis. Through this refined preprocessing process, the model can effectively process and analyze various financial texts, providing more accurate and comprehensive support for financial risk prediction and management.

2) In the financial risk propensity measurement model based on NLP, the second step's key is using the capsule network to adjust the weight of important features in financial texts. Unlike traditional neural networks with scalar neuron nodes, neurons in the capsule network exist in vector form, allowing the network to strengthen the representation weight of important features through a dynamic routing algorithm during training. This algorithm optimizes the feature selection process, enabling the model to reveal more hidden financial risk-related features, thereby significantly enhancing the model's performance in financial risk propensity analysis. In this stage, the model adopts the word2vec method to convert texts into vector form, which are then input into the capsule network for further feature extraction and weighting.

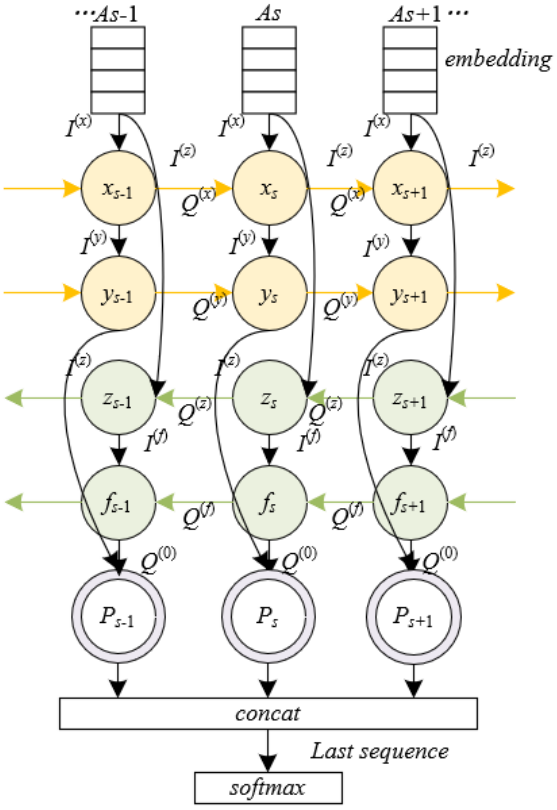

Fig. 1. Architecture of the stacked-BiLSTM network model.

Particularly, the processing of financial texts takes into account the unique structure and hierarchy of the text. Convolutional layers in the capsule network extract n-gram features from sentences through convolutional filters, slightly different from image processing methods. The text input a is represented as an M (sentence length) * N (embedding word dimension) matrix, where each a_u represents an N-dimensional word vector. Convolutional filters Q^{β}, with a length of M-J1+1, slide through the sentence in an n-gram manner (J1 being the n-gram length, i.e., the size of the sliding window), capturing text features at different positions. Each time the filter slides to a new position, it generates a feature map l^x, these mappings, after going through the dynamic routing process of the capsule network, effectively highlight the key text features related to financial risk. This process not only enhances the model's sensitivity to financial risk propensity analysis but also provides high-quality feature representations for subsequent steps, laying a solid foundation for accurately predicting the risk propensity of financial texts. Let unit multiplication be represented by p, bias by y_0, the nonlinear activation function by d, and the sliding stride by m. Then, the expression for l^x is as follows:

$$l_m^x = d\left(a_{u:u+j_1-m} \circ Q^{\beta} + y_0\right) \quad (1)$$

For Y filters with the same n-gram size, the following Y-dimensional feature mapping can be generated and reordered:

$$L = [l_1, l_2, ..., l_Y] \tag{2}$$

In the application of the capsule network for measuring financial risk propensity, the design of the capsule layer allows the model to retain more information when processing financial text data. Fig. 2 shows the architecture of the capsule network. Traditional neural networks use scalar outputs to represent the activation state of neurons, whereas capsule networks employ vector outputs. This is done to preserve instantiation parameters within the text data, such as context and word order, which are crucial for understanding the complexity of financial texts. Specifically, the output neurons L generated by the convolutional layer serve as the input vectors for the capsule layer. By applying the activation function, the model converts each n-gram feature vector L_u into its corresponding feature capsule i_u. This step further transforms the extracted text features into capsule vectors capable of representing financial risk information, laying the foundation for the subsequent dynamic routing process. Assuming that the filters shared by different sliding windows are represented by Q_y, the capsule bias by y_1, the nonlinear activation function by h, and the weight matrix of the correlation between the input and output layers by Q_{uk}, the formulas for converting L_u into i_u using the activation function are:

$$I_u = h\left(Q_y L_u + y_1\right) \tag{3}$$

$$i_{k/u} = Q_{uk} I_u \tag{4}$$

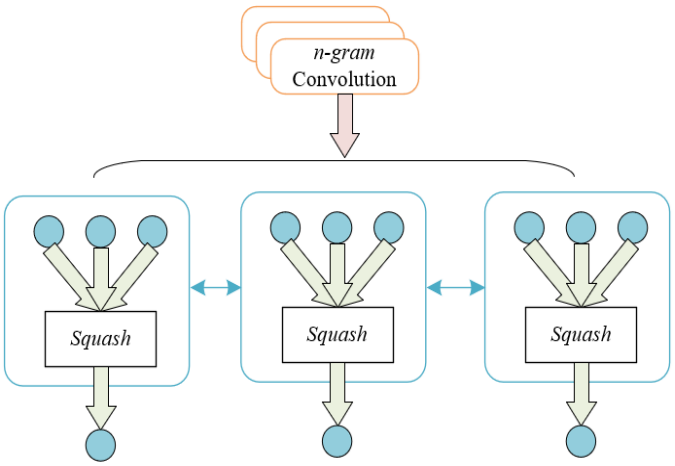

Fig. 2. Capsule network architecture.

One of the core aspects of the capsule network is its dynamic routing process, which optimizes the information transfer between feature capsules by updating the weights of the coupling coefficients. The update of coupling coefficients depends on the similarity between adjacent capsules; that is, the more similar the output vectors of two capsules, the greater their coupling coefficient. This similarity-based dynamic routing strategy is not only more efficient than the routing mechanism in traditional Convolutional Neural Networks (CNNs) but also ensures that capsules carrying significant financial risk signals are accurately passed to the next layer of the network. In measuring financial risk propensity, this means the model can more accurately identify and reinforce those text features that are crucial for predicting financial risk propensity.

The execution of dynamic routing involves considering each predicted vector $i_{k/u}$ and its existence probability $x_{k/u}$, optimizing the feature selection and information transfer paths of the entire network by iteratively updating the coupling coefficients z_{uk}. The intent of this process is to enhance the representation of similarity between input vectors and the target classification, assigning higher weights to those capsule outputs n_k and predicted vectors $i_{k/u}$ that are closer to each other. The initial value of the coupling coefficients y_{uk} is set to 0, and through the iterative process, the model adaptively adjusts these coefficients to ultimately achieve accurate prediction of financial risk propensity. Additionally, the dynamic routing includes a squashing function that ensures the absolute value of the input vectors is compressed into the range [0,1), further increasing the model's flexibility and accuracy in processing financial text data. Through this series of refined processes, the capsule network provides strong technical support for efficient and accurate measurement of financial risk propensity. Below are the expressions for the dynamic routing process:

$$z_{uk} = x_{k/u} \cdot \exp\left(y_{uk}\right) \frac{\exp\left(y_{uk}\right)}{\exp\left(y_{uj}\right)} \tag{5}$$

$$T_k = \sum_k z_{uk} i_{k/u} \tag{6}$$

$$n_k = \frac{\| T_k \|^2}{1 + \| T_k \|^2} \times \frac{T_k}{\| T_k \|}, x_k = | N_k | \tag{7}$$

$$y_{uk} \leftarrow y_{uk} + i_{k/u} \cdot n_k \tag{8}$$

3) Extracting contextual features of documents is a key step in the implementation of the financial risk propensity measurement model, accomplished through the use of a Stacked-BiLSTM network. Compared to the standard BiLSTM network, Stacked-BiLSTM has multiple hidden layers, enabling the model to perform deeper feature extraction. By setting multiple layers of LSTM both forward and backward in time series, Stacked-BiLSTM can capture both past and future contextual information, providing a richer and more detailed feature representation for accurate prediction of financial risk propensity. This capability is particularly important in financial text analysis, as risk signals in documents like financial reports and market comments are often closely related to a complex context, requiring the model to consider temporal features and contextual dependencies within the text comprehensively.

Regarding the structure of the Stacked-BiLSTM network, the input sequence at each time point $\{a_1, a_2, ..., a_S\}$ is processed by multiple layers of LSTM in both forward and backward directions to capture more feature information from each time step. Each LSTM layer contains new memory cells, input gates, forget gates, and output gates, represented by i_s, u_s, d_s, and p_s, respectively. These components collectively decide how to

update states, store, or forget information, and determine which information will be passed to the next layer of the network. This design allows the Stacked-BiLSTM network to effectively control the flow of information when processing financial texts, retaining the most critical features for risk prediction while ignoring irrelevant or redundant information. Specifically, assuming $\{a_1,a_2,\ldots,a_S\}$ enters the hidden layer in the forward direction $\{x_1,x_2,\ldots,x_S\}$, and captures more features from all subsequent time steps in the opposite direction's hidden layer $\{z_1,z_2,\ldots,z_S\}$. The hidden state of each layer at every time step s is represented by x_s, y_s, z_s, and f_s.

The following gives the calculation formula for the hidden state x_s of the first forward layer:

$$\begin{cases} u_s^{(x)} = \delta\left(I_u^{(x)}a_s + Q_u^{(x)}x_{s-1}y_u^{(x)}\right), \\ d_s^{(x)} = \delta\left(I_d^{(x)}a_s + Q_d^{(x)}x_{s-1} + y_d^{(x)}\right), \\ p_s^{(x)} = \delta\left(I_p^{(x)}a_s + Q_p^{(x)}x_{s-1} + y_p^{(x)}\right), \\ i_s^{(x)} = TANg\left(I_i^{(x)}a_s + Q_i^{(x)}x_{s-1} + y_i^{(x)}\right), \\ Z_s^{(x)} = u_s^{(x)} * i_s^{(x)} + d_s^{(x)} * Z_{s-1}^{(x)}, \\ x_s = p_s^{(x)} * TANg\left(Z_s^{(x)}\right). \end{cases} \tag{9}$$

The formula for calculating the hidden state y_s of the second forward layer is:

$$\begin{cases} u_s^{(y)} = \delta\left(I_u^{(y)}a_s + Q_u^{(y)}x_{s-1}y_u^{(y)}\right), \\ d_s^{(y)} = \delta\left(I_d^{(y)}a_s + Q_d^{(y)}x_{s-1} + y_d^{(y)}\right), \\ p_s^{(y)} = \delta\left(I_p^{(y)}a_s + Q_p^{(y)}x_{s-1} + y_p^{(y)}\right), \\ i_s^{(y)} = TANg\left(I_i^{(y)}a_s + Q_i^{(y)}x_{s-1} + y_i^{(y)}\right), \\ Z_s^{(y)} = u_s^{(.y)} * i_s^{(y)} + d_s^{(y)} * Z_{s-1}^{(y)}, \\ x_s = p_s^{(y)} * TANg\left(Z_s^{(y)}\right). \end{cases} \tag{10}$$

The formula for calculating the hidden state z_s of the first backward layer is:

$$\begin{cases} u_s^{(z)} = \delta\left(I_u^{(z)}a_s + Q_u^{(z)}x_{s+1}y_u^{(z)}\right), \\ d_s^{(z)} = \delta\left(I_d^{(z)}a_s + Q_d^{(z)}x_{s+1} + y_d^{(z)}\right), \\ p_s^{(z)} = \delta\left(I_p^{(z)}a_s + Q_p^{(z)}x_{s+1} + y_p^{(z)}\right), \\ i_s^{(z)} = TANg\left(I_i^{(z)}a_s + Q_i^{(z)}x_{s+1} + y_i^{(z)}\right), \\ Z_s^{(z)} = u_s^{(z)} * i_s^{(z)} + d_s^{(z)} * Z_{s-1}^{(z)}, \\ x_s = p_s^{(z)} * TANg\left(Z_s^{(z)}\right). \end{cases} \tag{11}$$

The formula for calculating the hidden state of the second backward layer is:

$$\begin{cases} u_s^{(f)} = \delta\left(I_u^{(f)}a_s + Q_u^{(f)}x_{s+1}y_u^{(f)}\right), \\ d_s^{(f)} = \delta\left(I_d^{(f)}a_s + Q_d^{(f)}x_{s+1} + y_d^{(f)}\right), \\ p_s^{(f)} = \delta\left(I_p^{(f)}a_s + Q_p^{(f)}x_{s+1} + y_p^{(f)}\right), \\ i_s^{(f)} = TANg\left(I_i^{(f)}a_s + Q_i^{(f)}x_{s+1} + y_i^{(f)}\right), \\ Z_s^{(f)} = u_s^{(f)} * i_s^{(f)} + d_s^{(f)} * Z_{s-1}^{(f)}, \\ x_s = p_s^{(f)} * TANg\left(Z_s^{(f)}\right). \end{cases} \tag{12}$$

For each time step s, the output P_s is generated by combining y_s and f_s, as follows:

$$P_s = I^{(P)}y_s + Q^{(P)}f_s + y^{(P)} \tag{13}$$

To output financial risk propensity prediction results, the Softmax classifier takes P_j as its input. Given V comments and J words, the prediction value b' is calculated as follows:

$$o\left(b \mid A\right) = \text{softmax}\left(Q^{(t)}P_J + y^{(t)}\right) \tag{14}$$

$$b' = \underset{b}{\text{argmax}}\, o\left(b \mid A\right). \tag{15}$$

III. Financial Risk Prediction and Management Based on Deep FM in Big Data

Financial data typically includes but is not limited to, transaction records, financial statements, market dynamics, etc., which contain complex feature relationships, including both linear and nonlinear interactions, posing a challenge to traditional prediction models. This paper introduces the DeepFM model. By integrating factorization machines and deep neural networks, DeepFM can capture not only the linear relationships between features but also learn higher-order feature combinations, which is crucial for understanding and predicting financial risks. Compared to other fields, financial risk management demands higher accuracy and efficiency in predictions, and the DeepFM model meets these dual requirements of model performance and efficiency by sharing feature embedding vectors, reducing the model's parameter amount and computational cost, while ensuring fast training and prediction speeds.

The construction process of the DeepFM model in the application of big data financial risk prediction and management includes three key stages: feature combination, efficient feature representation, and classification prediction. Firstly, the input features are combined through the FM part, utilizing FM's advantage to capture the interactions between features. This step is particularly suited for handling the rich low-order feature interactions in financial data, providing a foundation for capturing complex financial risk patterns. Subsequently, in the Deep Neural Network (Deep) part, the model uses Multilayer Perceptrons (MLP) to learn higher-order combinations and nonlinear representations of features, enhancing the model's grasp on deep features of financial data and further improving the accuracy of risk prediction. Finally, DeepFM integrates the feature vectors obtained from the FM

and Deep parts, and outputs the probability prediction of risks through a fully connected layer and a sigmoid function, achieving accurate assessment of financial risks. Fig. 3 shows the schematic diagram of the input vector dimension reduction process.

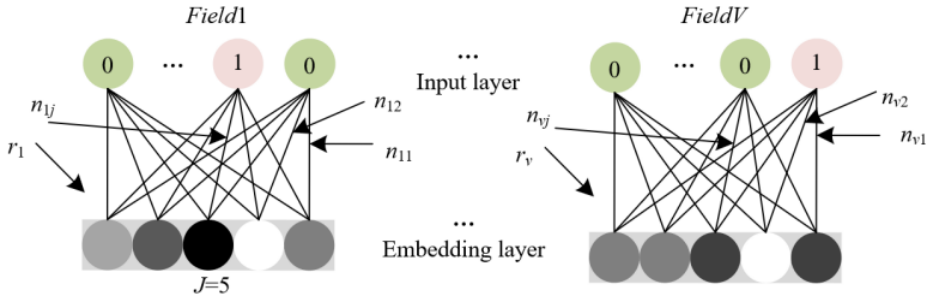

Fig. 3. Schematic diagram of the input vector dimension reduction process.

1) The FM component is specially optimized for the characteristics of financial data. This component delves into the low-dimensional feature vectors in financial data, using the factorization mechanism to identify and learn the implicit relationships and their weights between features. In this process, the FM component can adaptively adjust model parameters, effectively improving the model's performance in complex financial risk environments. The core lies in second-order feature crossing, mapping each element in the feature vector to latent factors and predicting the probability of financial risk events occurring through the interaction between these latent factors, i.e., outer product operations and summation. This approach not only significantly reduces the number of model parameters, enhancing the model's computational efficiency, but also strengthens the model's understanding and expression of complex relationships in financial feature crosses, demonstrating strong performance and practical value in the application of big data financial risk prediction and management. Assuming the bias item is represented by Q_0, the u-th component of feature vector a by a_u, the parameter of the u-th feature by q_u, the number of variables by v, and the coefficient multiplied by the u-th and k-th features by q_{uk}, the FM model is represented as follows:

$$b_{DL} = q_0 + \sum_{u=1}^{v} q_u a_u + \sum_{u=1}^{v-1} \sum_{k=u+1}^{v} q_{uk} a_u a_k \tag{16}$$

To address the issue of data sparsity in the dataset, an implicit vector for each feature is introduced, represented by n_u=(n_{u1},n_{u2},..., n_{uj}), and [n_u,n_k] replaces Q_{uk}. At this point, the solution for Q_{uk} is transformed into the solution for n_u and n_k. The transformed formula is given as:

$$b_{DL} = q_0 + \sum_{u=1}^{v} q_u a_u + \sum_{u=1}^{v-1} \sum_{k=u+1}^{v} \langle n_u, n_k \rangle a_u a_k \tag{17}$$

This paper proposes that the weight between variables a_u and a_k can be represented by the inner product of the corresponding vectors n_u and n_k. The original complexity of FM, $P(jv^2)$, is reduced to $P(jv)$ through this transformation, assuming the inner product of vectors n_u and n_k is represented by [n_u,n_k], and the d-th component of vector n_u is represented by n_{ud}, the transformation formula expression is provided as:

$$\begin{aligned}
&\sum_{u=1}^{v-1} \sum_{k=1}^{v} \langle n_u, n_k \rangle a_u a_k = \\
&\quad \frac{1}{2} \sum_{u=1}^{v} \sum_{k=1}^{v} \langle n_u, n_k \rangle a_u a_k - \frac{1}{2} \sum_{u=1}^{v} \langle n_u, n_k \rangle a_{iu}^2 \\
&= \frac{1}{2} \left(\sum_{u=1}^{v} \sum_{k=1}^{v} \sum_{d=1}^{j} n_{ud} n_{kd} a_u a_k - \sum_{u=1}^{v} \sum_{d=1}^{j} n_{ud}^2 a_u^2 \right) \\
&= \frac{1}{2} \sum_{d=1}^{j} \left(\left(\sum_{u=1}^{v} n_{ud} a_u \right) \left(\sum_{k=1}^{v} n_{kd} a_k \right) - \sum_{u=1}^{v} n_{ud}^2 a_u^2 \right) \\
&= \frac{1}{2} \sum_{d=1}^{j} \left(\left(\sum_{u=1}^{v} n_{ud} a_u \right)^2 - \sum_{u=1}^{v} n_{ud}^2 a_u^2 \right)
\end{aligned} \tag{18}$$

Further solved by stochastic gradient descent, the solution formula is:

$$\frac{\partial}{\partial \varphi} b(a) = \begin{cases} 1, & IF\ \varphi = q_0 \\ \{a_u, & IF\ \varphi = q_u \\ a_u \sum_{k=1}^{v} n_{kd} a_k - n_{ud} a_u^2, & IF\ \varphi = n_{ud} \end{cases} \tag{19}$$

In big data financial risk prediction and management, the FM component of the DeepFM model is carefully designed for the specificity of financial data. Considering that financial data features both dense continuous variables and sparse discrete variables, the FM component optimizes data representation and storage through the concept of feature fields. After one-hot encoding, discrete data features are expanded into multiple columns forming a sparse matrix, while continuous features retain their original single-column format. To effectively address the sparsity issue caused by one-hot encoding and save storage space, the FM component introduces a transformation mechanism, converting the sparse matrix into a more compact representation, including a small dictionary of feature value indices and two small matrices: feature index matrix and feature value matrix. This design not only reduces storage requirements but also facilitates subsequent feature interaction calculations.

Fig. 4 shows the DeepFM model architecture. In the FM layer's calculation, the plus sign represents the processing of first-order features, directly associating each sparse feature part with its corresponding weight. Moreover, the cross-circle represents the calculation process of feature interactions, where green lines connect features to their dense embedding representations, calculated using the previously mentioned dictionary, feature index matrix, and feature value matrix. This

process allows the model to capture complex interactions between features through low-dimensional dense vectors, particularly suited for dealing with feature-rich but sparse datasets in financial risk prediction. Through such design, the FM component of the DeepFM model not only improves computational efficiency but also enhances the model's feature expression and interaction learning capabilities when dealing with complex financial data, thus providing a more accurate and efficient prediction tool for financial risk management.

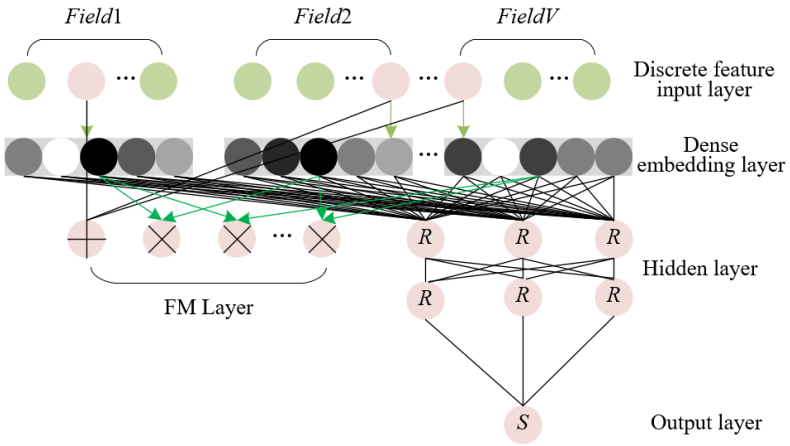

Fig. 4. DeepFM model architecture.

2) The Deep component utilizes a neural network to process and analyze high-dimensional features and complex nonlinear relationships in financial data. By introducing normalized features as inputs, the Deep component specifically targets both newly created features from feature crossing and original features, for deep semantic information extraction. This processing step is particularly important for understanding and predicting hidden patterns in financial risk. Compared to DeepFM models in other application scenarios, the model aimed at financial risk management focuses more on mining subtle and complex relationships in financial data, gradually elevating the abstract level of data features through multiple layers of fully connected layers and *ReLU* activation functions, thus capturing more refined risk signals.

Moreover, the Deep component shares the same low-dimensional dense vectors for feature embedding with the FM component, effectively enhancing the model's learning capabilities and feature expressiveness. Each feature field, regardless of its original length, is transformed into a fixed length vector *j* for uniform processing in the model. These low-dimensional vectors are then merged and input into the deep neural network for further nonlinear transformation and hierarchical feature extraction. This process ensures that the DeepFM model can maximize the use of information in financial data while maintaining computational efficiency, providing a powerful tool for financial risk prediction and management. Specifically, with $x^{(0)}= (r_1,r_2,..., r_l)$ as the output of the dense input layer and input to the hidden layers, DNN is used as the deep part of the model, assuming the number of hidden layers is represented by G, the output of the m-th hidden layer by $x^{(m)}$, and the weights and biases by $q^{(m)}$ and $y^{(m)}$, respectively, the output layer's calculation formula is given as:

$$x^{(G+1)} = \delta\left(Q^{(G)}x^{(G)} + y^{(G)}\right) \tag{20}$$

Finally, the outputs of the FM and Deep parts are integrated, with the entire process expression of the DeepFM model provided as:

$$\bar{b} = \text{sigmoid}\left(b_{FM} + b_{DE}\right) \tag{21}$$

Furthermore, effective risk management based on DeepFM model predictions can be achieved through a series of strategies. Firstly, the prediction results provide early warnings of potential risks to enterprises or financial institutions, enabling managers to adjust strategies in a timely manner, such as portfolio adjustments, optimization of loan approval processes, or implementation of risk mitigation measures, to reduce losses. By deeply analyzing risk factors and their interrelations revealed by the model, enterprises can improve their risk assessment models, developing more accurate risk rating systems. Combined with big data technology, enterprises can achieve real-time monitoring and analysis of large-scale financial data, thereby dynamically adjusting risk management strategies and improving adaptability and response speed to market changes.

IV. Experimental Results and Analysis

This paper employed a variety of financial-related datasets in its empirical analysis, including corporate financial statements, news reports, and social media comments, which are unstructured textual data. Through NLP techniques, the financial risk propensity contained within these data is extracted. Additionally, by integrating structured data such as corporate financial indicators and market data, the DeepFM model is utilized for financial risk prediction. This approach aims to verify the effectiveness of the method in enhancing predictive accuracy and efficiency. Based on the statistics of corpus labels for financial risk propensity measurement tasks shown in Table I, we can observe that model risk has the highest number of annotated corpus and sample data among all risk categories, totaling 29,691, which accounts for 65.5% of the total data. This significant amount of data not only

indicates the importance of model risk in the research of financial risk prediction and management but also reflects the high demand in the market for understanding and evaluating model risk. On the other hand, liquidity risk has relatively fewer annotated corpus and sample data, totaling 290, which accounts for 0.64% of the total, suggesting that this risk category might be rare in the current dataset or relatively difficult to identify and analyze using NLP technology. This distribution indicates that there are significant differences in the attention and data availability for different risk categories when measuring financial risk propensity using NLP technology.

TABLE I. STATISTICS OF CORPUS LABELS FOR FINANCIAL RISK PROPENSITY MEASUREMENT TASKS

Risk Category	Annotated Corpus	Sample Data	Total
Market Risk	1214	714	1928
Credit Risk	2157	1025	3182
Liquidity Risk	185	105	290
Operational Risk	2241	723	2964
Compliance Risk	2895	1159	4054
Strategic Risk	1652	823	2475
Reputation Risk	465	325	790
Model Risk	21365	8326	29691
Total	32174	13200	45374

From the above data analysis, it can be concluded that research on measuring financial risk propensity using NLP is very effective in practical applications, especially when dealing with and analyzing high-frequency risk categories such as model risk. This method can process a large amount of unstructured text data, thereby revealing deep features and trends of financial risk, which is crucial for risk assessment and management. However, the research also exposes that certain risk categories, like liquidity risk, have an insufficient sample size in the current dataset, which may limit the performance and application scope of the model in these areas.

Table II presents the evaluation results of different financial risk propensity measurement methods, including several evaluation metrics such as Root Mean Square Error (RMSE), Accuracy, Precision, Recall, F1 Score, and AUC value. It can be observed from the table that the method proposed in this paper performs excellently across all metrics, especially achieving the highest in Accuracy, F1 Score, and AUC values, which are 0.9238, 0.9178, and 0.9675 respectively, while also having the lowest RMSE value at 0.2631. Compared to other popular NLP methods such as BERT, RoBERTa, GloVe, and BiLSTM-CRF, the proposed method demonstrated superior performance, particularly in handling complex financial risk prediction tasks, by accurately identifying and evaluating risks.

These results fully prove the effectiveness of the financial risk propensity measurement method based on NLP adopted in this paper. Compared to other advanced algorithms, the proposed method is more precise and reliable in extracting and analyzing unstructured textual data related to financial risks. By comparing the evaluation results of different algorithms, it can be seen that the proposed method has a clear advantage in comprehensive performance, which is particularly important in the context of financial risk prediction and management. High Accuracy and F1 Scores mean that the method can balance Precision and Recall, while a high AUC value indicates its good classification capability across different thresholds.

TABLE II. EVALUATION RESULTS OF DIFFERENT FINANCIAL RISK PROPENSITY MEASUREMENT METHODS

Method	RMSE	Accuracy	Precision	Recall	F1 Score	AUC
GRU	0.4125	0.7654	0.8546	0.6325	0.7256	0.8124
TextCNN	0.4156	0.7589	0.8236	0.6387	0.7148	0.8369
BERT	0.3256	0.8312	0.8974	0.7698	0.8156	0.9145
Self-Attention	0.3895	0.7793	0.9456	0.5841	0.7236	0.8567
Doc2Vec	0.3674	0.8215	0.8326	0.7154	0.7689	0.8576
Seq2Seq	0.3215	0.8746	0.8894	0.8756	0.8879	0.9123
LDA	0.3563	0.8312	0.8541	0.8326	0.8423	0.9178
NMF	0.3147	0.9126	0.9274	0.9124	0.9146	0.9563
BiLSTM-CRF	0.2896	0.9146	0.9236	0.9236	0.9187	0.9638
GloVe	0.2896	0.9123	0.9147	0.9157	0.9258	0.9687
RoBERTa	0.2746	0.9146	0.9133	0.9152	0.9146	0.9634
The proposed method	0.2631	0.9238	0.9186	0.9126	0.9178	0.9675

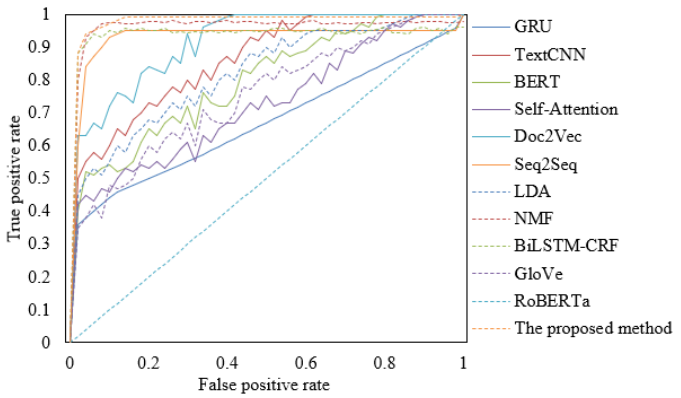

Fig. 5. Receiver Operating Characteristic (ROC) curves of different financial risk propensity measurement methods.

Analyzing the ROC curve data of different financial risk propensity measurement methods shown in Fig. 5, we can observe that the proposed method significantly outperforms other methods in performance for financial risk prediction. Especially in the area near the top right corner of the curve (close to a true positive rate and false positive rate of 1), the proposed method shows near-perfect performance, maintaining a very high true positive rate from 0 to 0.99 with almost zero false positives, ultimately achieving an optimal balance between true positive rate and false positive rate at a point close to 1. In contrast, other methods like RoBERTa, GloVe, and BiLSTM-CRF, although also showing good performance, have a noticeable gap in performance across the entire ROC curve compared to the method proposed in this paper. For

example, NMF and Seq2Seq, while maintaining a higher true positive rate in most areas of the curve, still lag behind the method proposed in this paper in the capability to achieve a true positive rate above 0.99. These experimental results indicate that the financial risk propensity measurement method based on NLP not only can effectively process and analyze unstructured textual data from various channels but also has significant advantages in accuracy of risk prediction.

Comparing the indicator effects of different big data financial risk prediction methods shown in Fig. 6, we can see that the method proposed in this paper displays outstanding performance across multiple key performance indicators. Specifically, the method proposed in this paper achieves 0.93, 0.93, 0.9, 0.85, and 0.9 in Accuracy (ACC), Recall, Specificity, F1-score, and Precision respectively, which are the best or near the best performance among all compared models. Compared to other popular models like ExtraTrees, CatBoost, CNN, and Transformer, the proposed method not only shows clear advantages in prediction accuracy but also performs well in balancing Recall and Specificity, particularly achieving the highest values of 0.93 in both Recall and Accuracy, highlighting its exceptional ability to predict positive class samples. These experimental results fully validate the effectiveness of the big data financial risk prediction model based on Deep FM proposed in this paper. By deeply integrating multiple features and applying deep learning techniques, the method proposed in this paper not only improves the accuracy of predictions but also ensures the efficiency and stability of the model in processing complex and large-scale data.

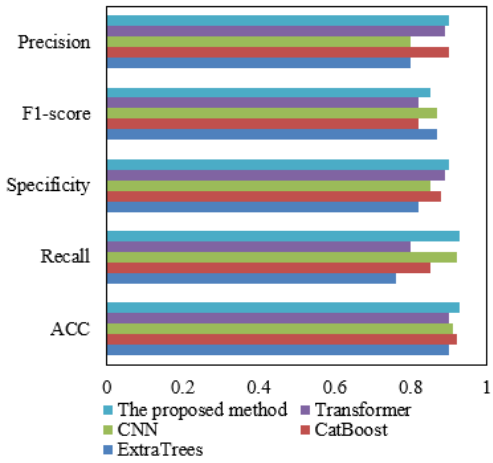

Fig. 6. Comparison of indicator effects of different big data financial risk prediction methods.

By deeply analyzing the ablation study results of big data financial risk prediction methods shown in Fig. 7, we can clearly see the advantages of the proposed method across various performance metrics. During the ablation studies, the performance of the model without optimization of the FM component and Deep component was tested separately to verify the contribution of each component to the overall model performance. When the FM component was not optimized, Accuracy (ACC), Recall, Specificity, F1-score, and Precision reached 0.902, 0.888, 0.889, 0.89, and 0.877, respectively. With the Deep component not optimized, these metrics improved to 0.912, 0.88, 0.895, 0.884, and 0.881, indicating the crucial role of the Deep component in the model. However, when both components were fully optimized, the performance of the method proposed in this paper reached its peak, with metrics of 0.925, 0.895, 0.9, 0.892, and 0.886, respectively, highlighting the importance of combining the FM and Deep components. These ablation study results clearly demonstrate the efficiency and effectiveness of the big data financial risk prediction model based on Deep FM proposed in this paper. Through the close integration of the FM and Deep components, the model not only effectively integrates various features but also improves prediction accuracy and efficiency through deep learning technology. The FM component enhances the model's understanding of feature combinations by learning interactions between features, while the Deep component captures complex nonlinear relationships through deep networks, further enhancing the model's predictive power. The success of the method proposed in this paper validates that the Deep FM-based model can provide more accurate and comprehensive risk assessments when dealing with large-scale and complex financial risk data, offering a new efficient tool for financial risk management and prediction.

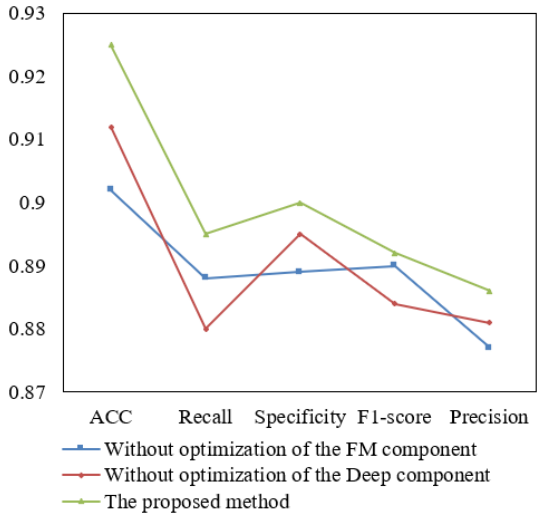

Fig. 7. Comparison of ablation study results for big data financial risk prediction methods.

The findings of this study indicated that by leveraging NLP techniques to extract key information from multi-channel unstructured text data and integrating diverse features with the deep learning capabilities of a DeepFM model, significant improvements in the accuracy and efficiency of financial risk prediction can be achieved. Specific experimental analyses demonstrated that the proposed method outperforms traditional risk measurement approaches and predictive models in terms of precision and generalization ability. Analysis of ROC curves further confirmed the notable role of the proposed method in enhancing predictive performance. Compared to existing research, our approach exhibited significant advantages in handling large-scale multi-source data and improving predictive performance, especially under conditions of high market volatility, demonstrating greater robustness and adaptability. These results validated the practical application value of our method in real-world financial risk management.

V. CONCLUSION

This paper applied machine learning and NLP technologies comprehensively to explore methods of predicting and managing financial risks in the context of big data. The study began with a detailed measurement of financial risk propensity using NLP technology, effectively extracting key information from unstructured text data from multiple channels, providing a richer and deeper perspective for risk assessment. Subsequently, the paper introduced an innovative financial risk prediction model based on Deep FM, which significantly improved the accuracy and efficiency of risk prediction by integrating diverse features and utilizing the powerful capabilities of deep learning.

Multiple analyses and comparisons in the experimental section demonstrated the effectiveness and advantages of the proposed method. Detailed statistics and evaluations of financial risk propensity measurement tasks showcased its deep data analysis capability. Comparative analyses of different risk measurement methods and ROC curve analyses further validated the precision and generalization ability of the proposed method. Additionally, comparisons and ablation studies of different big data financial risk prediction methods highlighted the significant role of the Deep FM model in enhancing predictive performance.

Despite achieving a series of positive results in the field of financial risk prediction and management, this paper still has certain limitations. For example, the predictive capability of the model largely depends on the quality and completeness of the data, and the processing and parsing of unstructured textual data still face challenges. Future research could explore more advanced NLP and machine learning technologies to improve the model's ability to handle complex data and enhance prediction accuracy. Additionally, the research could be expanded to more types of financial risks and explore the adaptability and stability of the model under different financial environments and conditions.

Computer Image Encryption Technology Based on Chaotic Sequence Algorithm

Li Shen
School of Finance and Economics, Xuchang Vocational Technical College, Xuchang, 461000, China

***Abstracts*—With the wide application of computer images and the popularization of network transmission, the public demand for image encryption technology is becoming more and more urgent. Privacy and data security can be effectively guaranteed through image encryption, but the existing encryption technology still has problems such as high overhead and poor encryption performance. Therefore, in order to improve the processing efficiency of encryption technology, the study constructs a two-dimensional composite chaotic system based on the analysis of existing chaotic sequence algorithms. Additionally, a novel approach to picture encryption is put forth by merging the composite chaotic system following the algorithmic optimization of disruption and diffusion in the image encryption phase. The chaotic mapping performed best, according to the experimental results, when the chaotic system's parameters were between 10 and 75. At this time, the algorithm had the highest encryption speed of 632 Mbit/s and decryption speed of 583 Mbit/s, the lowest resource consumption rate of 21.4% and the lowest delay rate of 11.5%. It can be seen that the method proposed in the study shows significant advantages in terms of security and effectiveness of image encryption, and is capable of realizing high-quality encryption of computer images. The novel image encryption technique that the research proposed has a high degree of security and feasibility and can achieve high-quality encryption of computer images.**

I. Introduction

With the development of the digital era, computer image encryption (IE) technology has become an important part of the information security field [1]. In addition to safeguarding data integrity and privacy, Internet Explorer is essential in a variety of industries, including communication, the military, and the medical industry. Traditional IE methods, such as symmetric encryption and asymmetric encryption, although effective in some cases, still have limitations when facing advanced attacks [2]. In light of the foregoing context, numerous IE algorithms have been presented by domestic and international researchers to further safeguard the confidentiality and integrity of images. For example, multi-level encryption, high standard encryption, watermark encryption, machine learning encryption, etc. [3]. Although these methods have made significant progress in securing images, there are still some challenges, such as performance security and encryption effectiveness. In recent years, IE algorithms utilizing chaotic sequences have attracted much attention due to their high degree of randomness, complexity, and attack resistance [4]. There are few IE studies on this algorithm, but the algorithm always suffers from the problems of sensitive initial conditions, large performance overhead, and difficult security evaluation. Therefore, this research innovatively proposes a new two-dimensional composite chaotic system and optimizes the disruption and diffusion steps in the image encryption process, aiming to improve the security and processing efficiency of image encryption. The goal of the research is to construct a more efficient and secure image encryption method by optimizing the chaotic algorithm. The research is expected to construct a new computerized image encryption method to provide a new direction for the development of technology in this field. This study is organized into four sections: the first summarizes and analyzes the work of others; the second describes the construction of the new chaotic system and encryption algorithm (EA); the third evaluates the new algorithm's performance; and the fourth is a summary of the article.

II. Related Works

Computer IE technology plays a crucial role in today's information security field. To safeguard picture data securely and privately, researchers have been looking for more dependable and effective encryption techniques. After merging structured phase coding, Shikder et al. presented a revolutionary binary IE approach to further improve the encryption impact of existing computer images. According to experimental findings, this method of encoding data can be used to decrypt data without noise and can withstand atmospheric turbulence over short propagation lengths [5]. Zhang et al. used bit plane decomposition and image hashing to create a dynamic DNA-encoded multiple image IE technique that secures the content of multiple images while increasing network transmission speed. The algorithm features a huge key space, strong key sensitivity, strong security, and robustness, as shown by the experimental results [6]. To lessen the shortcomings of the current medical IE algorithms, such as their lack of security and tamper-resistant techniques Man et al. included a self-validating matrix before proposing a tamper-resistant EA for medical photos. According to experimental data, the technique locates at least four pixels accurately, provides good encryption, and has strong tamper-resistance [7]. A bit-level IE approach that makes use of random alteration of edge pixels was proposed by Sheng et al. in order to improve the cryptosystem's security and, therefore, the IE outcomes. According to experimental results, the approach is very successful and resistant against popular assaults such noise attacks, data loss attacks, and differential attacks [8].

The chaos theory-based CSA algorithm generates random numbers. Through extremely complicated and unexpected

repetitive operations, the algorithm generates a succession of seemingly random values by taking use of the nonlinear character of chaotic systems and the strong dependence on beginning conditions. To advance the security and sensitivity of the initial parameter selection of traditional chaotic systems in IE, Balaska et al. proposed a novel IE method after combining two-dimensional Zaslavsky chaotic mapping (CM) and cryptographic algorithms. The approach is quite dependable and successful for encrypting photos of any size or type, according to experimental data [9]. To improve the randomness of the key space, Jia et al. proposed a pixel image cross-color obfuscation method after combining the cross-color field obfuscation method. The experimental results demonstrated that the approach is robust against differential, known plaintext, selective ciphertext, selected plaintext, and brute force attacks [10]. Sheng et al. used chaotic sequences with neural networks to offer a unique image chaotic encryption method that improves the security of the IE system. The experimental results demonstrated that the method showed superior security under multiple attack environments [11]. Song et al. proposed a composite chaotic system. The experimental results demonstrated the higher security and strong practicality of the system applied in IE [12].

In summary, existing image encryption techniques have made some progress in protecting data security and privacy, but there are still some limitations. For example, the robust effectiveness problem of the techniques, the performance overhead problem and applicability problem when facing large-scale image data. In addition chaotic sequence algorithms have gained attention for their high complexity and unpredictability, but the traditional methods are still deficient in initial parameter selection and key space randomization. The proposed research aims to overcome these limitations by constructing a new two-dimensional composite chaotic system and optimizing the disruption and diffusion steps in the image encryption process. Continuing to optimize the algorithm with security as the main direction, innovative improvements are made to the chaotic system and its sequence generation, as well as the disruption and diffusion algorithms during the encryption process, and finally, a new image encryption method is proposed.

III. Computerized Image Encryption Algorithm Based on Improved CSA

The study firstly enumerates the common one-dimensional CMs and combines two of the more adaptable mappings to propose a novel two-dimensional composite chaotic system. In addition, the key steps of disruption and diffusion in the IE process are algorithmically optimized, and finally, a novel encryption method is proposed.

A. Optimization of Two-Dimensional Composite Chaotic Systems for CSA

The application of CSA in computer IE techniques usually involves the use of pseudo-random sequences generated by chaotic systems to encrypt images. At the heart of these algorithms are CMs that have sensitive initial conditions and parameters that make the output sequence random [13]. Some common CMs are Logistic mapping, Henon mapping, etc. These equations describe the law of system state evolution over time, and the chaotic nature makes the output sequence show highly random and complex characteristics. Among them, the schematic diagram of Logistic mapping is shown in Fig. 1.

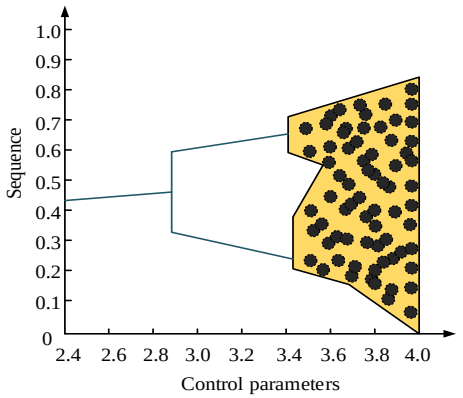

Fig. 1. Schematic diagram of logistic mapping.

In Fig. 1, the population's periodicity is represented by the vertical axis, while a parameter in the logistic mapping function is shown by the horizontal axis. When this parameter is changed, the behavior of the population bifurcates, changing from a steady state to various complex patterns between periodicity, chaos, or periodicity. When the parameter is 4, the Logistic mapping is more homogeneous at this point, and the system goes into equilibrium [14]. The formula for the Logistic mapping is shown in Eq. (1).

$$x_{n+1} = r \cdot x_n \cdot (1 - x_n) \tag{1}$$

In Eq. (1), x_n denotes the value of the current iteration. r is the system parameters and n is the iterations. The Henon mapping is a two-dimensional mapping that is commonly used to generate fractal patterns and study chaotic dynamics. Its iteration formula is shown in Eq. (2).

$$\begin{cases} x_{n+1} = y_n - a x_n^2 + 1 \\ y_{n+1} = b x_n \end{cases} \tag{2}$$

In Eq. (2), x_n and y_n denote the two variable values of the Henon mapping at the n th iteration. x_{n+1} and y_{n+1} denote the two variable values of the mapping at the next iteration step, respectively. Both a and V denote the parameters of the Henon mapping. Eq. (3) displays the Arnold mapping formula.

$$\begin{pmatrix} x_{n+1} \\ y_{n+1} \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix} \begin{pmatrix} x_n \\ y_n \end{pmatrix} mod 1 \tag{3}$$

In Eq. (3), x_n and y_n denote the values of the two variables of the Arnold mapping at iteration n. $mod\ 1$ denotes that the result is taken modulo 1, i.e., only the fractional part is retained. The Chebyshev mapping is a one-dimensional mapping based on Chebyshev polynomials in various forms, but the most commonly used are first-order and second-order mappings. Its mapping bifurcation diagram is shown in Fig. 2.

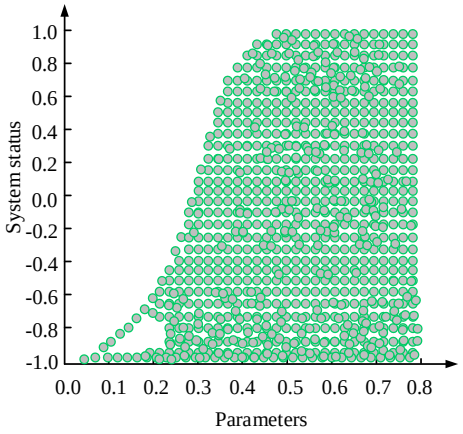

Fig. 2. Chebyshev map bifurcation diagram.

In Fig. 2, the branching points on the bifurcation map indicate the parameter values. Through the bifurcation maps, the parameter ranges of the Chebyshev mapping and the fact that the mapping exhibits chaotic properties can be determined, and in addition, it can be observed how chaos emerges from stable periodic trajectories. Thus, it can be said that the Chebyshev mapping can be used to understand and study the behavior of nonlinear dynamical systems and the relationship between chaos and periodic trajectories. The general form of his mapping is shown in Eq. (4).

$$\begin{aligned} x_{n+1} &= a - y_n^2 + x_n^2 \\ y_{n+1} &= b + 2x_n y_n \end{aligned} \tag{4}$$

In Eq. (4), x_n and y_n denote the values of the two variables of the Chebyshev mapping at iteration n. Both a and b denote the parameters of the Chebyshev mapping. The higher order mapping is shown in Eq. (5).

$$T_n(x) = -T_{n-2}(x) + 2xT_{n-1}(x) \tag{5}$$

In Eq. (5), $T_n(x)$ denotes the $T_n(x)$th order Chebyshev polynomial and x denotes the current iteration value. The iterative process of Chebyshev mapping produces diverse trajectories and is suitable for studying the unpredictability and complexity of nonlinear systems [15]. Its adjustable parameters allow exploring the variation of the system behavior under different conditions and help to understand the sensitivity of chaotic systems. Iterative mapping, also known as iterative mapping, is a mathematical model that describes the evolution of a system's state in discrete time steps. Fig. 3 displays the Iterative mapping phase space diagram.

The complicated, non-periodic structure of the entire phase space map in Fig. 3 suggests that the system is in a chaotic state. On the other hand, the central points in the region exhibit a rather homogenous behavior, suggesting a tendency toward stability in the system's function. The general form of the mapping is shown in Eq. (6).

$$x_{n+1} = f(x_n) \tag{6}$$

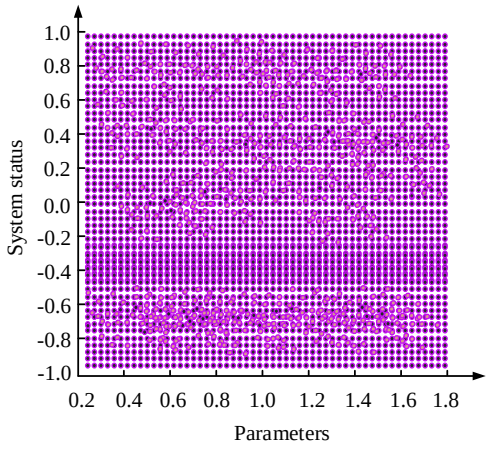

Fig. 3. Iterative mapping phase space graph.

In Eq. (6), f denotes a mapping function. The Iterative mapping describes the evolution of the system in discrete time steps rather than continuous time. Although both Chebyshev mapping and Iterative mapping show superior performance, the phase space structure of a chaotic system that is always in one dimension when mapping a sequence of images is usually limited and does not capture the complex evolution of the system well [16]. At the same time a one-dimensional system can only vary along one direction, which may not adequately represent the interactions and effects of multiple variables. Consequently, the study attempts to integrate the two, at which point Eq. (7) displays the expression of the 2D composite CM.

$$\begin{cases} x_n = \sin\left(\frac{t}{x_{n-1}}\right) \times \cos(k \cdot \arccos y_{n-1}) \\ y_n = \sin\left(\frac{k}{x_{n-1}}\right) \times \cos(a \cdot \arccos y_{n-1}) \end{cases} \tag{7}$$

In Eq. (7), t and k denote the control parameters of the two-dimensional composite CM, respectively, and n denotes the number of iterations. The new system's complexity and sequence randomness are increased by switching the control parameters of Iterative mapping and Chebyshev mapping. Additionally, the mapping function introduces mutual interference between x_{n-1} and y_{n-1}, which increases the unpredictability of CM. The qualities of both are combined in the new system, along with two control parameters that can be utilized as the EA's key. As the key increases, the IE algorithm's key space expands correspondingly.

B. An Optimized Composite Chaotic System is the Basis for the Image Encryption Technique

The unpredictability and randomness of chaotic systems introduce a new encryption means for IE. By reasonably selecting the CM model, initialization parameters and key expansion process, key sequences with a high degree of randomness can be generated. These sequences can be applied to the change of pixel values and position coordinates, thus realizing effective encryption without destroying the perceived quality of the image. The chaotic IE process is shown in Fig. 4.

In Fig. 4, first chaotic IE uses chaotic system to generate random key and encrypt the plaintext image by disruption and diffusion methods. After the ciphertext image is generated, decryption can be realized by the same key and reverse process to ensure security and reversibility. Among them, the scrambling and diffusion module is the main way to guarantee the security and effectiveness of EA. Disordering is a process to increase the complexity and randomness of encryption by changing the position or arrangement order of pixel values in IE. There may be shortcomings in some cases, such as challenges in providing sufficient randomness and uniform distribution. In order to optimize the disruption process, the study introduces a phantom square matrix for optimization, at which point the disruption process is shown in Fig. 5 [17].

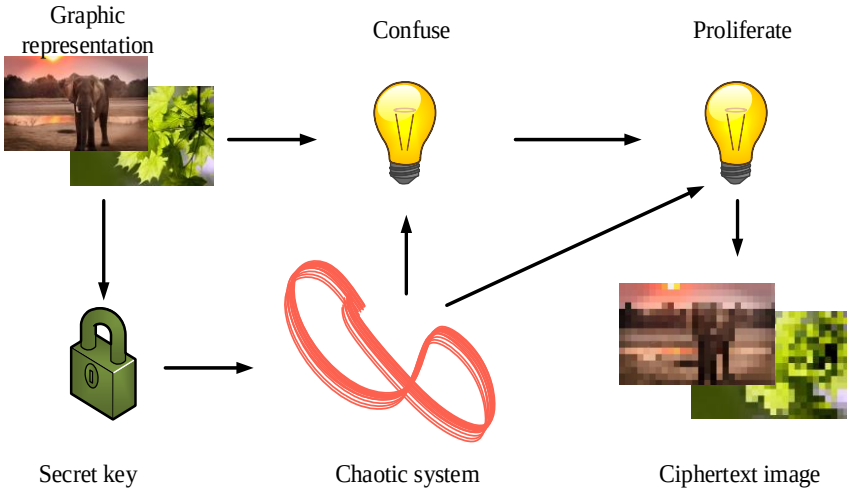

Fig. 4. Chaos image encryption process.

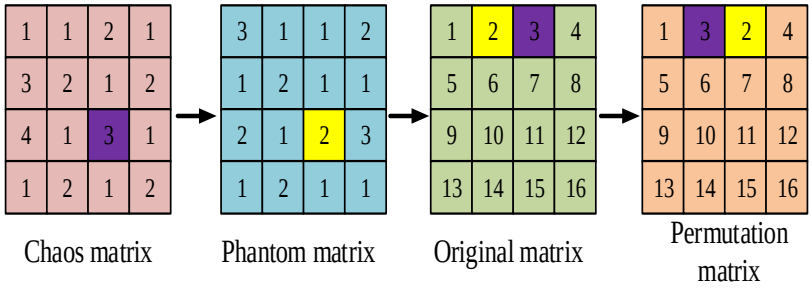

Fig. 5. The process of scrambling the magic cube.

In Fig. 5, for any point in the initial chaos matrix, i.e., the purple region in the figure. After reading the coordinates of this region, the region with corresponding coordinates, i.e., the yellow region, is found in the phantom square matrix for replacement. Once this is done, the coordinates of the yellow box in the phantom matrix are then used to find the location of the corresponding box in the original text matrix. Finally, the values of the boxes in the chaos matrix and the phantom matrix are replaced into the original matrix to obtain a new matrix, thus completing the substitution operation. The formula of the phantom matrix is shown in Eq. (8).

$$H = floor(\sqrt{M \times N}) + 1 \tag{8}$$

In Eq. (8), H denotes the phantom square matrix and $M \times N$ denotes the size dimension of the picture. The formula for transforming from chaos matrix to phantom square matrix is shown in Eq. (9).

$$X_i = (floor(|X_i \times 10^8) \bmod N) + 1 \tag{9}$$

In Eq. (9), X_i denotes the i th random for sequence. From this equation, the phantom matrix can be transformed into one-dimensional form, and the chaotic sequence is randomly converted into a chaotic matrix of a given size. Row permutation then reads the row information in the chaotic matrix and then replaces it with the rows in the original matrix, and repeats the operation until all the elements are replaced. Eq. (10), which represents this process' formula, is displayed.

$$B(i, y_{ij}) \leftrightarrow B(i, H1(y_{ij})) \tag{10}$$

In Eq. (10), $B(i, y_{ij})$ denotes the row element position coordinates in the chaos matrix and $B(i, H1(y_{ij}))$ denotes the row element position coordinates in the original text matrix. After completion, the reference row disarrangement is sequentially followed by column disarrangement until all the original text matrix information is replaced. Moreover, to ensure the correlation and security between the image pixel information after the disarrangement operation, the study further introduces the quadtree method to optimize the diffusion operation. First of all, pseudo-random sequence generation is carried out by the improved chaotic system for any disambiguation image, and matrix information calculation

is carried out after reading the image pixel information, and the binary matrix information is transformed into a one-dimensional matrix for conversion. After completion, the pseudo-random sequence selection is performed in quadtree coding [18]. The selected pseudo-random sequence is then bit-swapped, and the above operation is repeated until all pixel values are permuted. Next, the DNA is encoded and computed using a quadtree algorithm. Lastly, the encoded DNA is sorted and decoded using the sort function, and the resulting ciphertext image is created by combining the decoded DNA. The calculation formula for the transformation of its mid-range information is shown in Eq. (11).

$$x^{*}_{n`} = \mathrm{mod}(floor(s_{ij} * 10^{n`}), 10) \tag{11}$$

In Eq. (11), $n`$ denotes the read bit of the dislocation matrix, s_{ij} denotes the value of the chaos matrix, and the constant denotes decimal. The calculation formula for bit-bit conversion is shown in Eq. (12).

$$p_{ij}(h) \leftrightarrow p_{ij}(10 - q_{n`}) \tag{12}$$

In Eq. (12), $p_{ij}(h)$ is the hth value in the permutation matrix and $q_{n`}$ is the $n`$th value in the quadtree encoding rule. The formula for DNA coding is shown in Eq. (13).

$$p_{ij}(h) = DNA\_encode(p, s(n`)) \tag{13}$$

In Eq. (13), p denotes the matrix to be encoded, i.e., the transformed chaos matrix of the quadtree rule. $s(n`)$ denotes the coding rule corresponding to this matrix. Combining the optimized chaotic system and the above optimized improvements of the dislocation and diffusion methods respectively, the study proposes a novel computer IE method, the encryption flow of which is shown in Fig. 6.

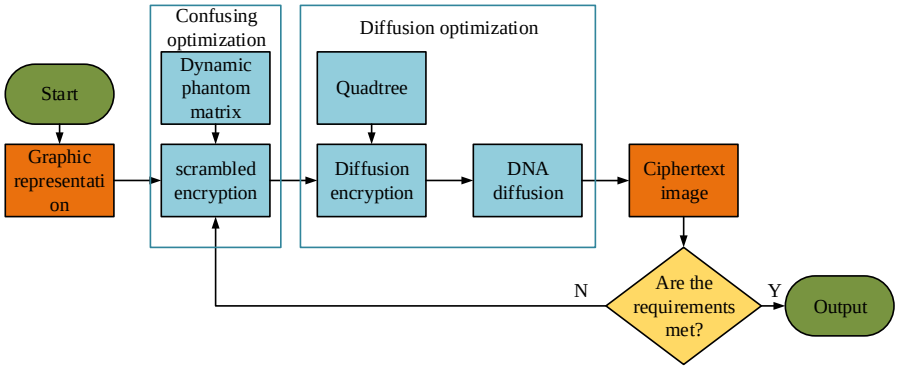

Fig. 6. New image encryption algorithm process.

From Fig. 6, the flow of the method pair includes four modules: plaintext image input, dynamic phantom matrix optimization disruption, quadtree segmentation, DNA diffusion optimization diffusion, and ciphertext image generation. Firstly, a phantom matrix with dynamics is introduced by optimized disruption of the dynamic phantom matrix. Second, its element values or matrix size are periodically updated to increase the randomness and complexity of encryption. Subsequently, the quadtree segmentation technique is used to divide the disrupted image into a quadtree structure to achieve the purpose of more flexible processing of different parts of the image information. Then, on the basis of the quadtree, the DNA diffusion optimization diffusion algorithm is applied to enhance the nonlinear characteristics and randomness of the encryption through the diffusion based on DNA coding, so as to disperse the image information more evenly. Ultimately, the generation of ciphertext images integrates these techniques to form a multilevel and multifaceted encryption structure, which improves the security and resistance to attacks of EA.

IV. Experimental Tests

To confirm the impact of the innovative computerized IE algorithm on performance, the research constructs an appropriate testing setup. Before conducting the EA's performance test and comparison test, the ideal parameters for the new chaotic system are ascertained. Ultimately, the algorithm's safety and efficacy are confirmed by simulating the impact of a real-world implementation.

A. Algorithm Performance Testing

The study established an appropriate test environment to assess the new IE algorithm's performance impact. The selected operating system is Windows and the image processing library is OpenCV. The CPU is Intel i7-9300H and the GPU is RTX3060Ti. The RAM is set to 32G and Python is used for language programming. The study first attempts to validate the optimized two-dimensional composite chaotic system, and also for subsequent easy testing, the study defines the system as improving Chebyshev-Iterative (ICI). The optimal control parameters, i.e., t and k, for the 2D composite CM are first determined by means of phase space analysis. The 2D composite chaotic system with different parameters at this point is shown in Fig. 7.

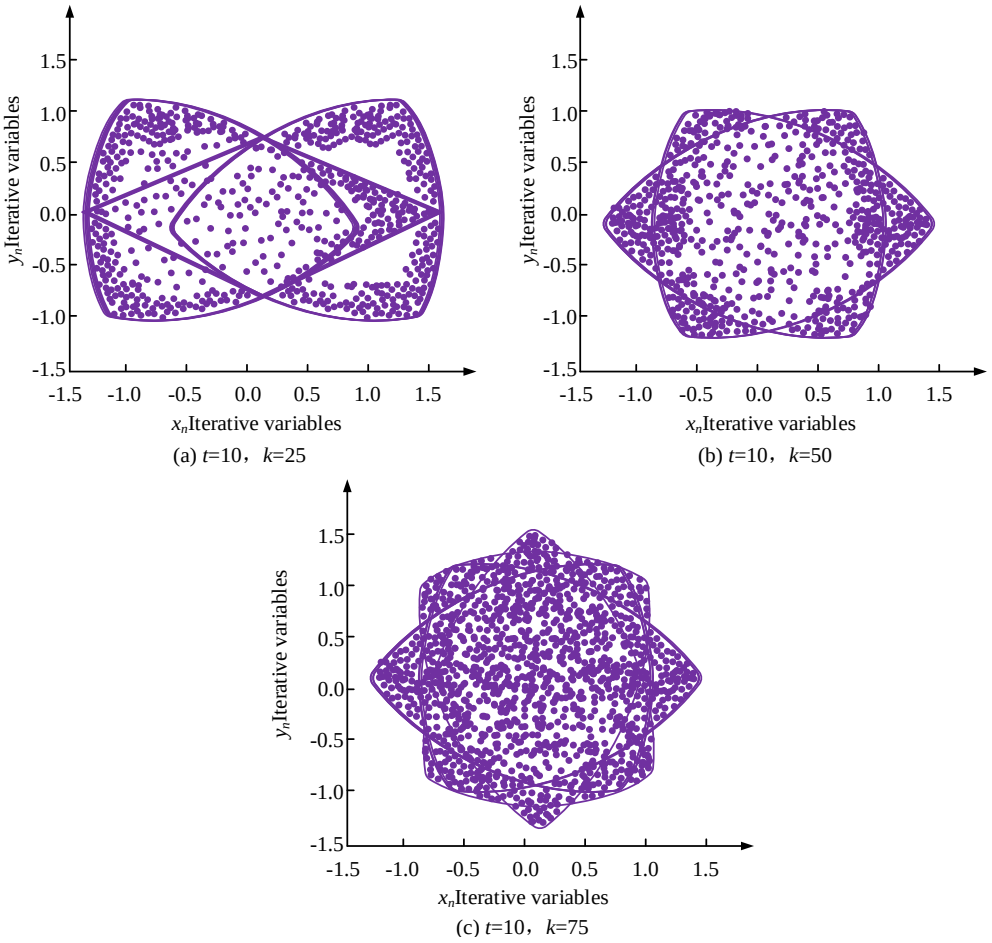

Fig. 7. Optimal control parameter testing for two-dimensional composite chaotic mapping.

Fig. 7(a) shows the CM results at $t=10$，$k=25$, and Fig. 7(b) shows the CM results at $t=10$，$k=50$. Fig. 7(c) shows the CM results at $t=10$，$k=50$. In Fig. 7, the 2D composite CM under the control of different parameters presents different results, and when the k value is larger, the mapping result at this time is more uniform, which enables the system to achieve better mapping randomness. Compared to Fig. 7(a) and 7(b), Fig. 7(c) has the strongest traversal, therefore, it can be said that the 2D composite CM at this time is the best when $t=10$，$k=75$, and the subsequent research determined to test with this parameter value. For the novel IE algorithm proposed by the study. The research introduced the ImageNet image dataset for testing. The dataset contains millions of high-resolution color images covering more than a thousand categories. It is separated into training and test sets in an 8:2 ratio. The test results are displayed in Fig. 8. First, the data are subjected to an ablation test for EA with Chebyshev mapping alone, EA with Iterative mapping alone, EA with Chebyshev-Iterative mapping, and ICI.

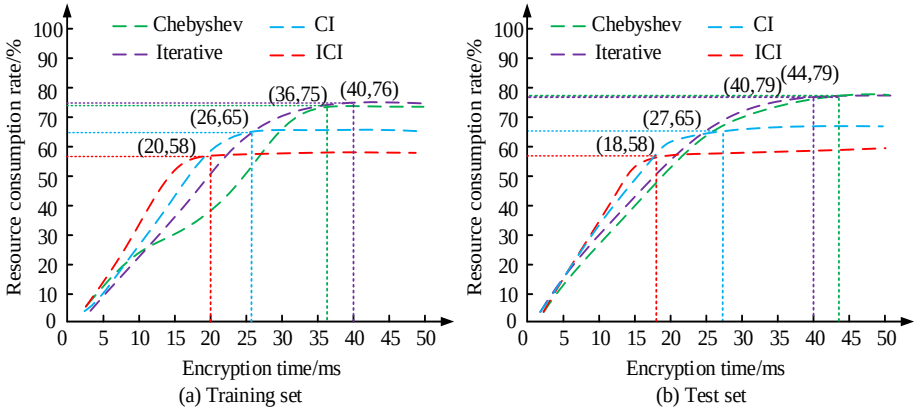

Fig. 8. Results of ablation tests for different modules.

The performance test results of the four different module types under the training set are displayed in Fig. 8(a), and the results of the performance test of the four different module types under the test set are displayed in Fig. 8(b). In Fig. 8, both Chebyshev mapping alone and Iterative mapping alone have average performance results, with the highest resource consumption rate of 79% for both. On the contrary, the resource consumption rate of CI mapping is reduced to 65% after combination. The lowest resource consumption rate is 58% for ICI. The shortest mapping time is 18 milliseconds. From the above data, it is illustrated that there is a significant functional facilitation effect of each module on ICI, which makes ICI get a better mapping performance. Furthermore, the study presents the same kind of EA, such as CM, rivest-shamir-adleman (RSA), and advanced encryption standard (AES), to test with correlation as the test index. The ES algorithm is set up with a 128-bit key and standard mode; the RSA algorithm with a 2048-bit key; and the CM algorithm with a 2048-bit key. Fig. 9 displays the test findings. The outcomes are displayed in Fig. 9.

The image correlation findings under the AES, RSE, CM, and ICI algorithms are displayed in Fig. 9(a), (b), (c), and (d). In Fig. 9, the red diagonal line indicates the pixel correlation results of the original image, and the comparison reveals that the pixel correlation is the strongest under the AES algorithm with the highest concentration of pixel points. The CM and RSA algorithms come next, with the study's suggested ICI algorithm having the lowest pixel point correlation. The distribution is more uniform and random, indicating that the encrypted image presents characteristics that are difficult to be analyzed and predicted. As a result, it is evident that the researchers suggested approach performs better in IE visualization. To further quantify the test results, the study continues to introduce more algorithms of the same type, such as two fish EA (Twofish), elliptic curve cryptography (ECC), and visual cryptography (VC). In addition, the ECC algorithm uses a P-256 curve; the VC algorithm uses a predefined key-sharing matrix; and the ICI algorithm has optimal parameter configurations of chaotic system parameters 10 and 75. The encryption speed Mbit/s, decryption speed, resource consumption rate and latency rate are used as metrics for testing and the results are shown in Table I.

In Table I, a variety of algorithms all show superior IE performance, with encryption and decryption speeds above 400 Mbit/s. The slowest encryption speed is 441 Mbit/s for CM algorithm, and the slowest decryption speed is 412 Mbit/s for AES. The highest resource utilization rate is 62.4% for Twofish algorithm, and the highest latency rate is 27.4% for AES. With the highest encryption speed of 632 Mbit/s, the fastest decryption speed of 583 Mbit/s, the lowest resource consumption rate of 21.4%, and the lowest delay rate of 11.5%, a numerical comparison shows that the research-proposed ICI algorithm performs well. In summary, the ICI algorithm shows superior encryption performance among the same type of methods with high feasibility and effectiveness.

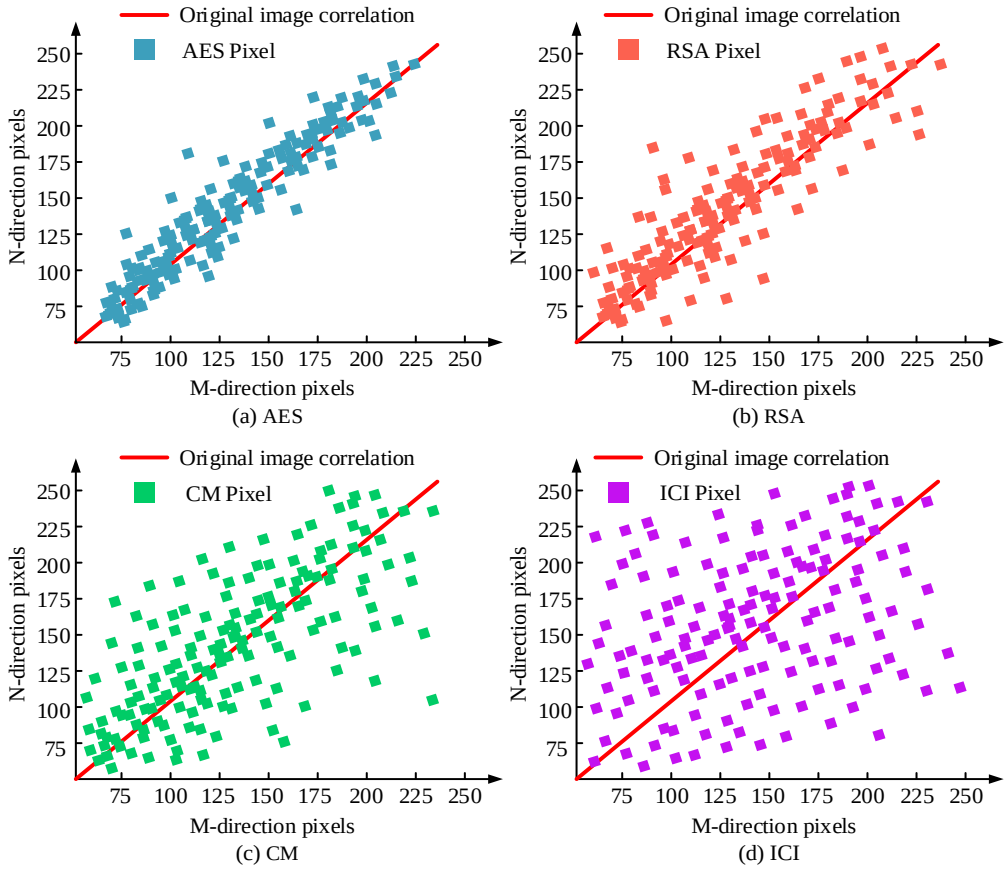

Fig. 9. Image correlation results under different encryption algorithms.

TABLE I. INDICATOR TEST RESULTS OF VARIOUS ALGORITHMS

Algorithm	Encryption Speed/Mbit/S	Decryption Speed/Mbit/S	Resource Consumption Rate/%	Delay Rate/%
AES	458.0	412.0	37.4	27.4
RSA	527.0	587.0	31.6	17.6
CM	441.0	428.0	45.7	13.4
Twofish	472.0	424.0	62.4	18.8
ECC	447.0	486.0	54.3	23.5
VC	528.0	479.0	27.1	14.8
ICI	632.0	583.0	21.4	11.5

B. Algorithm Simulation Testing

To validate the innovative EA's practical application, the study presents the Brodatz Texture Database image collection for various testing categories. Brodatz Texture Database contains nearly 20,000 images of various textures. Randomly selecting images from this dataset, the study introduced each of the AES, RSA and hash function algorithms for comparison, i.e., AES, RSA and secure hash algorithm 256-bit (SHA-256) for comparison. The encryption results under each method are shown in Fig. 10.

The encryption effect under the AES technique is shown in Fig. 10(a), the encryption effect under the RSA method is shown in Fig. 10(b), the encryption effect under the SHA-256 method is shown in Fig. 10(c), and the encryption effect under the ICI method is shown in Fig. 10(a). The results of the test in Table I are consistent with Fig. 10, which shows that among the four methods, the pixels of the encrypted image from RSA are much smaller than those of AES. This shows the validity of the test, in addition, intuitively, it can be found that the studied ICI encryption performance is optimal and the image security is the highest, while the pixel code in the encrypted image is more random and uniform, and does not retain traces. Therefore, it can be shown that ICI has some feasibility. In order to further understand whether the encrypted image information better meets the security requirements, the study plotted the histograms of the above methods respectively, as shown in Fig. 11.

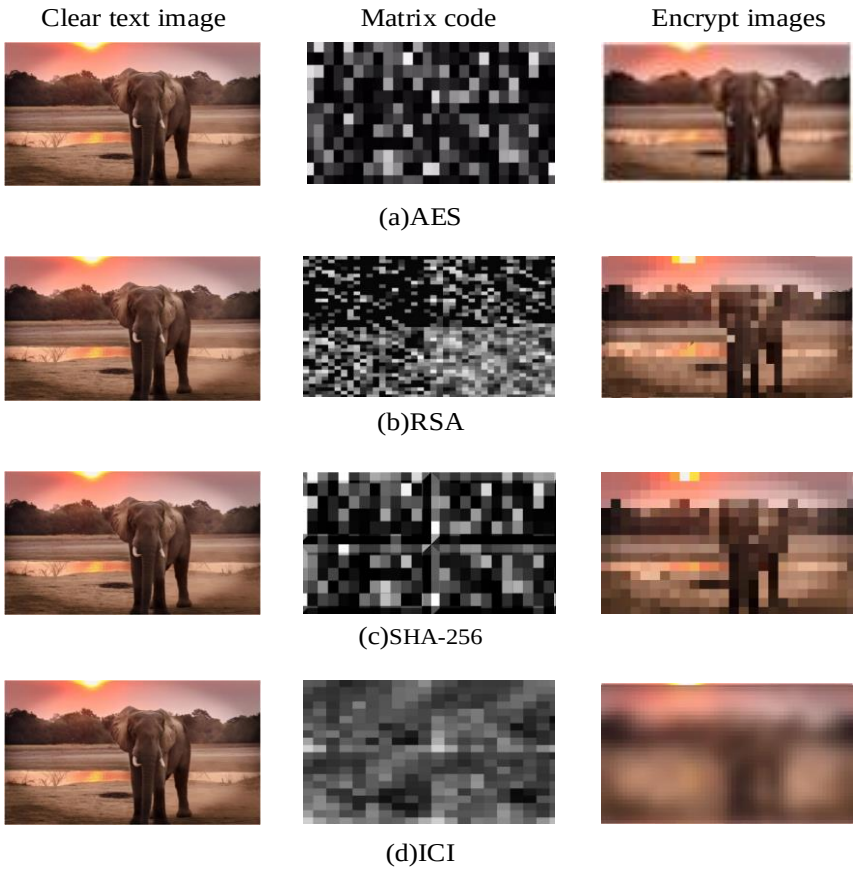

Fig. 10. Image encryption effects under different methods.

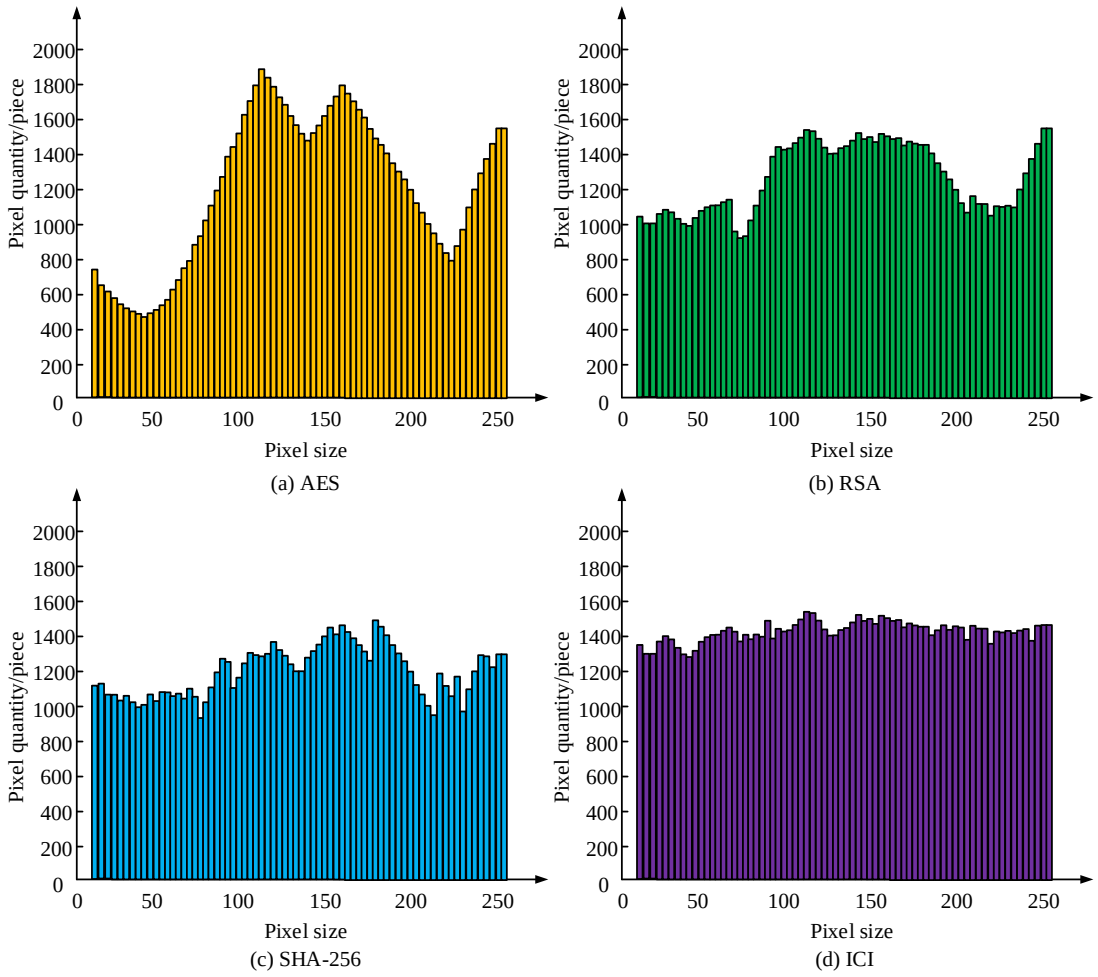

Fig. 11. Test of image encryption histograms using four algorithms.

The encrypted image histograms for the AES, RSA, SHA-256, and ICI algorithms are displayed in Fig. 11(a), 11(b), and 11(d), respectively. Also shown are the encrypted image histograms for the algorithms. In Fig. 11, among the four algorithms, the pixel histogram of the AES algorithm is the most uneven, with multiple peaks showing, which indicates that the encrypted image is more specific and less secure. And it shows the trend of higher pixel value at the center point and lower at both ends. The pixel histograms of encrypted images of RSA algorithm, SHA-256 algorithm and ICI algorithm gradually tend to be stable, with fewer outliers, i.e. peaks, in the data. Especially the ICI algorithm, which shows the best IE effect, the encrypted image is more random and variant. And the average number of pixels of the encrypted image can be up to 1400, which is much higher than the AES algorithm. In summary, ICI has absolute advantages in computer IE, and its performance is far more reliable than the same type of encryption methods.

V. Discussion

With the rapid development of information technology, the importance of image encryption technology in safeguarding data privacy and security is becoming more and more prominent. Image encryption not only protects the privacy and integrity of data, but also plays a key role in many fields such as medical, military and communication. However, traditional image encryption methods such as symmetric encryption and asymmetric encryption show some limitations in the face of advanced attacks. Therefore, the study proposes a two-dimensional composite chaotic system based on the improved chaotic sequence algorithm and optimizes the disruption and diffusion steps in the image encryption process by combining the dynamic phantom square matrix and quadtree partitioning techniques, aiming to enhance the security and processing efficiency of image encryption. The experimental results show that when the parameters of the chaotic system are 10 and 75, the ICI algorithm achieves an encryption speed of 632 Mbit/s and a decryption speed of 583 Mbit/s, with a resource consumption rate of 21.4% and a delay rate of 11.5%. These data show that the ICI algorithm is far ahead of other algorithms such as AES, RSA, Twofish and ECC in terms of performance. The results compare favorably with the phase-coded binary image encryption method proposed by Hamadi I A et al. in terms of processing efficiency and security [19]. In addition, the ICI algorithm exhibits the lowest pixel-point correlation in the correlation test with a more uniform and random distribution that is difficult to be analyzed and predicted. And compared with the traditional dynamic coding multi-image encryption algorithm, the ICI algorithm in this paper performs more superior in

dealing with statistical analysis, differential attack and exhaustive attack. In the simulation test, compared with the other three types of methods, the research proposed ICI encryption has the best performance and the highest image security, while the pixel code in the encrypted image is more random and uniform, and does not retain traces. From this result, it can be seen that compared to the research method proposed by Tiken C et al., the ICI algorithm proposed in this study significantly reduces the resource consumption rate and latency rate by optimizing the disruption and diffusion steps, so that it still maintains efficient performance when processing large-scale image data [20].

In summary, the two-dimensional composite chaotic system based on improved chaotic sequence algorithm proposed in this paper significantly improves the security and processing efficiency of image encryption by optimizing the disruption and diffusion steps. Future research can further explore how to combine other encryption algorithms and image processing techniques to further improve the performance and reliability of computerized image encryption technology. In conclusion, the research in this paper provides new theoretical and practical support for the development of image encryption technology, which has important academic value and application prospects. It is hoped that through further research and practice, we can promote the continuous progress of image encryption technology and make greater contributions to the field of information security.

VI. Conclusion

The study analyzes the existing chaotic sequence algorithms on the basis of the algorithmic optimization of disruption and diffusion in the encryption process through the combination, and finally puts forward a new type of image encryption algorithm. The experimental results show that when the optimal control parameters $t=10$, $k=75$, the two-dimensional composite chaotic mapping at this time has the best effect. Comparison with the same type of encryption algorithms reveals that the ICI algorithm has the significantly lowest pixel point correlation and a more uniform and random distribution. It has the highest encryption speed of 632 Mbit/s and decryption speed of 583 Mbit/s, the lowest resource consumption rate of 21.4%, and the lowest delay rate of 11.5%. In addition, the simulation test results show that compared with other encryption methods of the same type, ICI encryption has the optimal performance and the highest image security, while the pixel code in the encrypted image is more random and uniform, and does not retain traces. From the histogram analysis, it is found that the encrypted image of ICI encryption algorithm is more random and variable, and the average pixel number of the encrypted image is up to 1400, which is much higher than that of AES algorithm. In summary, the encryption algorithm proposed by the research is superior to the same type of algorithms in terms of pixel-point correlation, distribution uniformity, encryption speed, decryption speed, and resource consumption rate, especially in the image security and the randomness of encryption effect, which is of significant scientific value and application prospect. Future research can further explore how to combine other EA and image processing techniques to further improve the performance and reliability of computer IE technology.

Neural Network-Powered Intrusion Detection in Multi-Cloud and Fog Environments

Yanfeng ZHANG, Zhe XU
College of Artificial Intelligence, Jiaozuo University, Jiaozuo, Henan, 454000, China

***Abstract*—Cloud Computing has revolutionized the technological landscape, offering a platform for resource provisioning where organizations can access computing resources, storage, applications, and services. The shared nature of these resources introduces complexities in ensuring security and privacy. With the advent of edge and fog computing alongside cloud technologies, the processing, data storage, and management paradigm faces challenges in safeguarding against potential intrusions. Attacks on fog computing, IoT cloud, and related advancements can have pervasive and detrimental consequences. To address these concerns, various security standards and schemes have been suggested and deployed to enhance fog computing security. In particular, the focus of these security measures has become vital due to the involvement of multiple networks and numerous fog nodes through which end-users interact. These nodes facilitate the transfer of sensitive information, amplifying privacy concerns. This paper proposes a multi-layered intermittent neural network model tailored specifically for enhancing security in fog computing, especially in proximity to end-users and IoT devices. Emphasizing the need to mitigate privacy risks inherent in extensive network connections, the model leverages a customized adaptation of the NSLKDD dataset, a challenging dataset commonly applied to evaluate intrusion detection systems. A range of current models and feature sets are rigorously investigated to quantify the effectiveness of the proposed approach. Through comprehensive research findings and replication studies, the paper demonstrates the stability and robustness of the suggested method versus various performance metrics employed for intrusion detection. The assessment illustrates the model's superior capability in addressing privacy and security challenges in hybrid cloud environments incorporating intrusion detection systems, offering a promising solution for the evolving landscape of cloud-based computing technologies.**

***Keywords*—Cloud computing; fog computing; intrusion detection; privacy protection; neural network**

I. Introduction

Cloud computing has gained prominence as a prominent technology within the realm of Information Technology (IT) in recent years. The inception of cloud computing can be traced back to 2006, when Google introduced this groundbreaking concept. Subsequently, with the evolution of computer technology and novel communication paradigms, the IT landscape witnessed a rapid transformation, elevating the significance of this innovation for both individuals and organizations within the industry [1]. Cloud computing has revolutionized the accessibility and management of computing resources, enabling organizations to leverage shared services, applications, and data storage through remote servers. The evolution of cloud technology has expanded to incorporate edge and fog computing paradigms, emphasizing decentralized data processing and analytics closer to the data source [2]. However, this expansion brings forth a myriad of security and privacy challenges. Particularly, the intersection of multi-cloud environments and the criticality of intrusion detection in fog computing is becoming increasingly complex and crucial in safeguarding sensitive data and preventing unauthorized access [3].

The essence of cloud computing lies in its shared infrastructure, allowing multiple users to access resources and services remotely. However, with the advent of multi-cloud architectures, organizations employ services from different cloud providers, leading to interconnectivity complexities [4]. Multi-cloud setups aim to enhance performance, reduce latency, and mitigate risks associated with a single-cloud dependency. Nevertheless, integrating multiple clouds amplifies security vulnerabilities, requiring robust intrusion detection systems to counter potential threats and breaches. Edge and fog computing have emerged as pivotal components in the cloud ecosystem, focusing on processing data near the data source to reduce latency and enhance efficiency. This proximity to end-users and IoT devices in fog computing introduces a new set of security challenges, especially regarding privacy concerns and intrusion risks. The transfer of sensitive data across numerous fog nodes poses a significant threat, necessitating sophisticated security measures that can protect privacy and detect intrusions effectively in these intricate network architectures.

This paper proposes an Intrusion Detection System (IDS) leveraging neural network technologies specifically tailored for fog computing to deal with the security and privacy threats in multi-cloud environments. The application of neural networks in intrusion detection aims to fortify security measures, providing a more adaptive and sophisticated approach to identifying and mitigating potential threats in multi-cloud and fog environments. This research explores developing and evaluating a novel IDS framework to tackle the escalating security challenges arising from the interconnection of multi-cloud infrastructures, thereby aiming to ensure data integrity and user privacy in fog computing setups.

II. Related Work

Within the domain of cloud, IoT, and interconnected computing environments, ensuring robust security against intrusions is of utmost importance. This section comprehensively explores and compares various cutting-edge methodologies and approaches employed for IDSs. Each study's distinct methodology, datasets utilized, performance metrics,

and principal findings are evaluated to provide a comprehensive understanding of their efficacy for enhancing security measures and minimizing potential threats within these dynamic technological landscapes. Table I provides a concise comparative overview of various intrusion detection methodologies and their respective outcomes.

The advent of the IoT has facilitated extensive connectivity across many objects and services, leading to a susceptibility to IoT and cloud malware infections. Consequently, cybersecurity stands as a crucial concern in establishing resilient IoT systems [14]. Abd Elaziz, et al. [5] have capitalized on recent advancements in swarm intelligence approaches and the progress in deep neural networks to develop an effective IDS for cloud- and IoT-based scenarios. Initially, deep neural networks extract valuable information from IDS data. Subsequently, a proficient feature selection method is introduced, leveraging the Capuchin Search Algorithm (CapSA), a recently proposed swarm intelligence optimizer [6]. The resultant model, termed CNN-CapSA, is rigorously tested using four distinct datasets, specifically CIC2017, KDD99, BoT-IoT, and NSLKDD. Furthermore, comprehensive empirical comparisons are conducted against alternative optimization methods, encompassing various criteria for classifying results. The findings substantiate that the proposed method performs well across all analyzed datasets.

With growing internet traffic and the rise of attacks against the cloud ecosystem, intrusion monitoring is becoming more complicated. An attacker may gain access to a variety of protocol interfaces, such as Hypertext Transfer Protocol (HTTP), Domain Name System (DNS), and Message Queue Telemetry Transport (MQTT), leading to data breaches and security vulnerabilities. Traditional machine learning algorithms like neural networks, fuzzy logic, and support vector machines have been commonly employed in IDSs. However, these methods exhibit limitations such as slow convergence, inaccurate results, vanishing gradients, excessive fitting, and subpar efficiency. To address these challenges, Geetha and Deepa [7] have introduced a novel approach, the Fisher kernel-based PCA dimensionality reduction algorithm in conjunction with a grey wolf optimizer based weight dropped BiLSTM classifier (FKPCA-GWO WDBiLSTM) to detect intrusions. The PCA algorithm is initially applied with data records, utilizing the Fisher kernel and Fisher score to separate dimensions linearly. Subsequently, the WDBiLSTM structure captures persistent dependencies and extracts features bidirectionally. The GWO optimizes the recurrent weights, ensuring accurate classification and distinguishing between normal and attack instances. The proposed mechanism has been rigorously evaluated on four datasets. The findings demonstrate superior F-measure, specificity, sensitivity, precision, and accuracy performance compared to previous approaches such as FCM-SVM, DRIOTIDS, BiCIDS, and Fuzzy-SMO.

Conventional network IDSs cannot adequately fulfill the security requisites of IoT deployments. Addressing this limitation, Lin, et al. [8] have integrated machine learning and cloud computing into IoT IDS to enhance its detection capabilities. Typically, conventional IDSs demand substantial training duration and are unsuitable for cloud computing owing to cloud nodes' restricted storage and computing capabilities. Hence, there is a pressing need to investigate IDSs characterized by lightweight, superior detection accuracy, and swift training time. Selecting a suitable classification methodology is crucial when implementing cloud-based IDSs and is essential for an effective defense response to intrusions while mitigating intrusions. The authors extensively discussed issues concerning IoT intrusion mitigation in cloud computing contexts. They employed the Multi-Feature Extraction Extreme Learning Machine (MFE-ELM) algorithm, introducing a multi-feature extraction procedure within cloud servers. Afterward, MFE-ELM was used in cloud servers to identify cybersecurity breaches. Several tests utilized a classical dataset, involving stages including data preprocessing, designing features, training the model, and data analysis. The simulation outcomes demonstrated the suggested algorithm's effectiveness in detecting a substantial percentage of network data packets, exhibiting commendable results. It also proved adept at efficiently detecting intrusions into heterogeneous IoT data from cloud nodes. Moreover, the algorithm facilitates real-time identification of nodes posing severe security threats within the cloud cluster, enabling the cloud server to take immediate security measures.

The surge in cloud computing has raised persistent concerns about privacy and security. Addressing these issues, Al-Ghuwairi, et al. [9] have introduced a new method aimed at immediately identifying malicious activities in cloud computing through time series analysis. This innovative technique integrates feature selection methods with a predictive technique derived from the Facebook Prophet system to determine its effectiveness. The feature selection process combines historical data analysis with anomaly detection, stationarity, and correlation analyses to resolve the complexities of identifying relationships among time series variations and potential threats. This approach significantly reduces the number of predictors used in the predictive model while optimizing various parameters like Dynamic Time Warping (DTW), Median Absolute Percentage Error (MdAPE), Mean Absolute Percentage Error (MAPE), Root Mean Squared Error (RMSE), Mean Squared Error (MSE), and Mean Absolute Error (MAE). It has also considerably minimized cross-validation, prediction, and training times. Although memory consumption is stable, utilization time dropped significantly, leading to a significant decline in resource usage. This study offers a unified approach to effective intrusion detection in cloud computing by exploiting time series anomalies, using a collaborative feature selection process and the Facebook Prophet prediction engine. The results underscore the improved performance and efficiency achieved by this approach, enhancing the progress of intrusion detection strategies in cloud computing security.

In IoT environments, foundational to computing services, vulnerabilities and cyber threats remain constant concerns. Adversaries continuously seek weak points within these computing environments to perpetrate damage, posing intricate challenges. Consequently, employing intrusion prevention and detection solutions becomes essential for securing IoT environments. However, recent strategies in this domain encounter limitations, notably the inability to detect unknown attacks and susceptibility to single points of failure. To address these constraints, Javadpour, et al. [10] have introduced a novel

approach: a distributed multi-agent IDS, effectively mitigating these issues. It uses a six-stage detection procedure to categorize network activities as safe or dangerous. The suggested method was validated using the NSLKDD and KDD Cup 99 datasets. Test outcomes were evaluated against other methodologies in terms of f-score, accuracy, and recall metrics.

To deal with the issue of low accuracy in conventional tracking signal detection algorithms within the traditional cloud-side collaborative computing setting, Zhong and Zhong [11] have proposed a novel deep learning-based track signal intrusion detection method within the cloud-edge collaborative computing setup. The approach involves constructing the core framework of the IDS by holistically examining core networks, communication links, and infrastructure and integrating edge computing into cloud services. The proposed method leverages CNN-attention-based BiLSTM (Convolutional Neural Networks-attention-based Bi-directional Long Short-Term Memory) as a central layer of the method in order to train on historical datasets, thereby presenting a deep learning-based technique. Additionally, dropout and pooling layers are incorporated to avoid overfitting and enhance track signal intrusion detection. The pooling layer is integrated to accelerate model convergence, eliminate redundant features, and diminish feature dimensionality, while the dropout layer aims to prevent overfitting. The proposed IDS is compared and analyzed using simulation experiments against three other methods under identical conditions. Results indicate that the proposed method has a higher F1 value than the other techniques across four sample datasets. The F1 value varies from 0.94 to 0.96, demonstrating superior performance to other comparison algorithms. This method proves crucial for resolving IDS signal concerns within the cloud-edge cooperative setting and lays the conceptual foundation to track signal IDS direction.

Implementing an anomaly-based IDS is key to maintaining the integrity of database records by identifying and isolating anomalies, particularly when unexpected changes are detected. In advanced networking environments, classification and clustering methods based on machine learning serve as an effective approach to identifying and categorizing anomalous IDS attacks. Machine learning is a swift, cost-effective, and flexible tool for constructing intrusion detection schemes capable of addressing a wide range of threats. Samunnisa, et al. [12] have introduced a proficient hybrid clustering and classification model for implementing an anomaly-based IDS, particularly for classifying malicious attack types such as normal (no intrusion), Denial of Service (DoS), Probe, User to Root (U2R), and Remote to Local (R2L) attacks. This approach utilizes threshold-based functions and is tested using two different threshold values, specifically 0.01 and 0.5, across the NSLKDD and KDDcup99 datasets. Performance evaluation metrics such as Detection Rate, False Alarm Ratio, and Accuracy have been employed to assess the effectiveness of the proposed methodology. Results showcase that applying the proposed approach, particularly the K-means combined with Random Forest at two distinct threshold values, exhibits superior classification accuracy. Specifically, it achieved a detection rate, false alarm rate, and accuracy of 99.8%, 99.7%, and 0.1%, respectively, on the NSLKDD dataset and 98.2%, 98.1%, and 2% on the KDDcup99 dataset.

As reviewed literature, the current research in the field of intrusion detection systems (IDSs) lacks a comprehensive understanding of the efficacy of various methodologies and approaches, particularly in the context of cloud, IoT, and interconnected computing environments. Existing studies often focus on specific techniques without providing a comparative analysis of their performance across different datasets and scenarios. Additionally, there is a need for innovative solutions that address the evolving cybersecurity threats posed by cloud and IoT malware infections, as well as the challenges associated with integrating IDSs into these dynamic technological landscapes. Furthermore, the scalability and efficiency of IDSs in handling growing internet traffic and complex network protocols remain understudied areas. Moreover, conventional IDSs may not adequately fulfill the security requirements of IoT deployments, necessitating the development of lightweight and efficient detection mechanisms tailored for IoT environments. Finally, the effectiveness of anomaly-based IDSs in maintaining database integrity and identifying novel attack types in advanced networking environments requires further exploration and validation.

III. PROPOSED METHOD

The cloud represents a significant asset for IoT environments, offering a comprehensive solution to various IoT challenges. However, integrating cloud technology introduces several challenges, encompassing security and privacy concerns, latency, integrity, and bandwidth limitations. IDSs typically operate in non-cloud environments based on a trust-based cooperative model. Researchers have proposed a trust-based cooperative IDS that operates through collaboration

among local IDS units, identifying new attacks unknown to other IDSs. These systems utilize data from diverse IDSs to facilitate intrusion detection [15]. A key architectural aspect of these cooperative IDSs involves a feedback mechanism for reliable data collection. An incentivized communication model also encourages IDS nodes to share inputs among known nodes to prevent malicious activities. However, limitations exist within the current trust-based cooperative IDS framework, particularly in soliciting input from numerous IDSs. The proposed algorithm, based on relevant theoretical concepts, allows a collective group of IDSs to establish their collaboration in a manner that enhances their detection accuracy, even in the presence of untrusted IDS units. Notably, existing cooperative IDSs encounter considerable delays primarily due to the algorithmic complexity associated with employing comprehensive algorithms.

The overall strategy requires significant computational time, contingent on multiple factors, such as the consulted IDS, the expertise of the IDSs, and various trust levels. Uncertainties surrounding the receipt of inputs across various levels, especially within IDS associations, internet speeds, and other ambiguous elements, lead to potential delays in decisions about alerting potential threats due to missing input from individual IDS. Consequently, cooperative IDS decisions are not feasible in time-sensitive settings. In the initial phase, a real-world IoT-based smart home prototype was built, and the regular activities of every device within the IoT network were monitored. Subsequently, malicious tests were conducted, inducing anomalous network traffic to these devices. These stages facilitated the application of an Artificial Intelligence and deep learning based approaches using well-prepared training data, forming the basis of the intrusion detection model [16]. The developed system exhibited superior detection accuracy within an acceptable time frame. A logarithmic minimal density ratio adjustment was applied to the NSLKDD dataset features to achieve enhanced detection capabilities to produce higher-quality, representative features. Employing SVM to perform classification, the experimental findings revealed high accuracy and detection rates. Fig. 1 illustrates the structure of the proposed cooperative IDS, comprising six cloud providers.

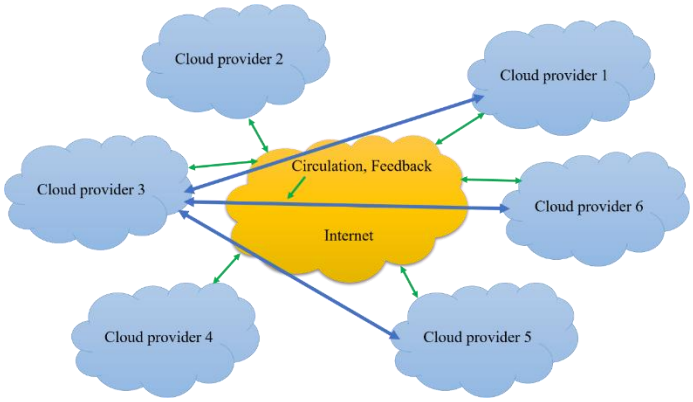

Fig. 1. Cooperative IDS architecture.

The suggested conceptual framework for IoT security is thoroughly examined, outlining an intrusion detection scheme composed of two primary processors: one for classification and another for traffic analysis. Traffic association logs follow processing within traffic handling units, resulting in data suitable for deep neural network processing by the classification engines, categorizing these associations as normal [13]. The model is deployable in fog computing, closely situated near IoT devices and end users. It incorporates a recurrent neural network based on a modified variant of the backpropagation procedure to enhance the predictive capacity of regular/threat identification. A recursive process within the network, wherein non-linear components' outputs are transformed into linear components, ensures rapid reaction and dependable continuous security for the IoT network. This recursive architecture serves as the core engine for classification-based traffic analysis. Fig. 2 illustrates the overall architecture of the developed conceptual framework for IoT security.

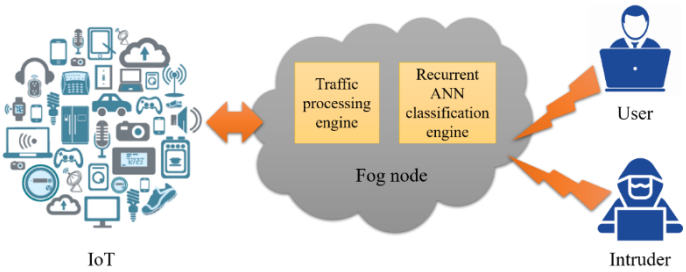

Fig. 2. The conceptual framework of IoT security.

The traffic handling engine employs the NSLKDD dataset to train, test, and validate models. This dataset comprises information that characterizes the network traffic of the networking system, often exhibiting inconsistencies. The pre-treatment of acquired traffic data becomes a crucial filter for the classification engine. Raw traffic data is preprocessed in four key steps within traffic preprocessors. These steps encompass symbolic-to-numerical conversion, data feature reduction, min-max standardization, and data sampling. The symbolic-to-numerical mapping and label representation are visually represented, facilitating the conversion of representative values (properties) of the NSLKDD dataset into numerical values. Flag features are denoted as {pstr = 4, …, s2 = 14}0, service features such as private = {private = 16, Netsat = 20}, and protocol features are denoted as Protocol = (tcp = 1, udp = 2, icmp = 3}. Numeric values for each characteristic are assigned based on the frequency of occurrence. As the frequency increases, the corresponding numerical value decreases, ensuring that attributes with the least frequency are not overshadowed by attributes with the highest frequency values. Fig. 3 displays an overview of the NSLKDD dataset. The different subclasses of attacks are encapsulated and categorized into their main classes as the last step of dataset coding. Table II offers classification details for the NSLKDD dataset.

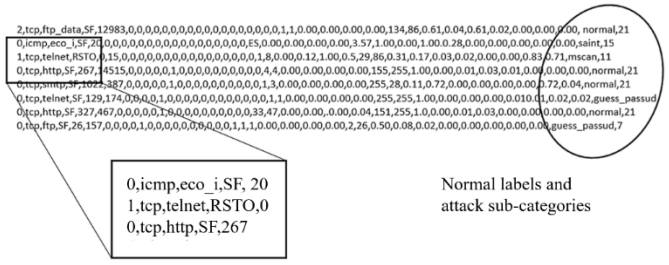

Fig. 3. NSLKDD dataset.

TABLE II. CLASSIFICATION OF THE NSLKDD DATASET

Classes	Sub-classes	Numeric code
U2R	Buffer flow, Xterm, Ps, Perl, load module	1
R2L	Warezmater, multi-hop, PHF, ftp-write, and guess password	2
Probe	Mscan, Nmap, Ipswd, and Satan	3
DoS	Worm, Mailbomb, Teardrop, Smurf, Neptune, Back, and Land	4

Table II presents two types of engine-parallel encapsulations, where all training dataset records are encapsulated into normal. This table lists 40 attack names encapsulated into four significant classifications. In the feature reduction process, all consistent-valued attributes that do not impact the analytical outcomes post-neural network analysis are eliminated from all records in the traffic data. Within this work, features have been removed where zero values reduce the data volume from 41 to 25 attributes. To ensure the traffic data values fall within a standardized range appropriate for neural network inputs, data values are scaled for min-max normalization. Direct data transformation involving min-max standardization has been employed in this work to achieve this aim.

$$S' = \frac{(S - min_f)}{(max_f - min_f)}(\quad max'_f - \quad min'_f) + (\quad min'_f) \tag{1}$$

Due to the infrequent occurrence of R2L and U2R attacks, the neural network tends to identify them as noisy signals, given their minimal impact on weight updating. Consequently, this leads to a significant weakness in detecting these particular attacks. To address this issue, both U2R and R2L attacks are multiplied by incorporating numerous instances of these attacks into various data points. This oversampling process generates new instances and a more widespread representation of these rare attack types. The proposed intrusion detection engine consists of two distinct detection stages with two deep recursive neural networks that have different internal structures, configuration parameters, and hyperparameters. The primary layer focuses on detecting DoS attempts, known as one of the primary threats that disrupt IoT systems, in addition to identifying other attack types. For heightened security measures, the output from the primary layer is further filtered by a secondary layer, featuring a different internal structure, configuration parameters, and selection criteria specifically tuned to detect attacks overlooked by the base layer, especially U2R and R2L attacks. To enable accurate detection, the second layer was trained using a dataset derived from the primary layer, excluding the DoS attacks.

Fig. 4 depicts a block diagram of the IDS system employing the creation of non-linear embeddings from the previous state through a deep recursive structure. The *h (t - 1)* represents the previous state, while *h(t)* represents the current state, including the incorporation of recursive gain. Traditional backpropagation encountered a gradient problem within the conventional network structure. The problem is mitigated by introducing a feedback mechanism that connects the prior state with the present state, elevating the current state. The proposed model is decomposed into four key steps: backpropagation to the hidden layer, backpropagation to the output layer, weight adjustment, and feedback propagation. An Artificial Neural Network (ANN) comprises basic computational elements called neurons, interconnected by weights. The structure of neurons is layered, ensuring complete connectivity between the preceding and subsequent layers.

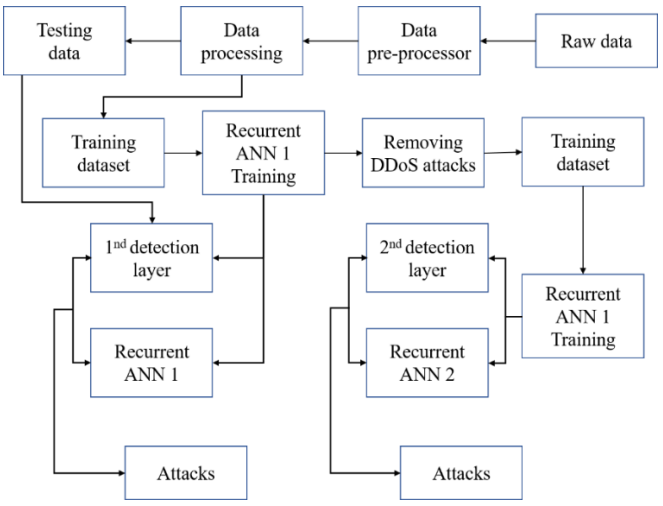

Fig. 4. Block diagram of the proposed IDS model.

Feature selection is crucial in eliminating irrelevant features to enhance the model's performance. The primary aim of feature selection is to identify a subset of features that result in higher classification accuracy. The model employs the gain rate ranking-based feature selection scheme, which overcomes biases and aids in feature subset selection by considering split data and normalizing information gain accordingly. The attribute selected with the maximum gain ratio is the splitting attribute. However, to prevent instability due to split information, a constraint is introduced, mandating that each test must gain more information than the average gain of all tests. A three-layered system governed by feedforward computation aims to streamline complexity and enhance training algorithms. These layers consist of the input, hidden, and output layers. The primary goal of training is to optimize network parameters to enable effective classification. In a network with an input vector for configuration, hidden nodes, and output nodes, connections between the input layer and hidden nodes are known as "weights." Similar connections between hidden nodes and output units are also named accordingly. The weighted response of a given sample ξ is computed back to the input summation unit, executed as an added weighted edge. Considering the bias, the length of the input vector is expanded by two layers, encompassing bias and the weighted edge, affecting all layers. Eq. (2) presents the linear output from the linear part, while Eq. (3) demonstrates output from the hidden layer, utilizing a sigmoidal function as a transfer function. These equations can be extended and applied to networks with multiple layers. O_{jss} denotes the hidden layer output, and O_{lin} represents the linear output.

$$O_{lin} = \sum_{t=1}^{n+2} W_{i,j}\, O_i \tag{2}$$

$$O_{jss} = f\left[\sum_{t=1}^{n+1} W_{i,j}\, O_i\right] \tag{3}$$

During the backpropagation process in the output layer, the primary objective is to determine partial derivatives of the error

signal *Er* concerning $W_{i,j}$. Error signals are a fundamental component in all typical versions of backpropagation neural networks. The summation outputs are obtained, and this difference measures the desired outputs.

$$E_{rj} = \sum_{p=1}^{p} (o_j^p - o_j^{Ep})^2 \quad (4)$$

In Eq. (4), E_{rj} represents the error signal of the j^{th} neuron in the output layer. o_j^p signifies the desired output of the j^{th} neuron for the p^{th} pattern, o_j^{Ep} while indicating a possible output of the j^{th} neuron for the p^{th} design; here, p denotes the pattern or data instance. Specifically, when mentioning $p = 1$, it refers to the representation at pattern 1. This training method encountered a problem where the estimation of one-layer output relied on the information received from the previous layer. At the start of the training, the previous layer remained untrained, leading to inaccurate estimations.

IV. Results and Performance Evaluation

An in-depth examination of the results and discussions from the experimentation is presented in this section. We tested our intrusion detection model with different operational configurations and compared the results to previous research findings. An Intel CoreTM i7 3.2 processor and 16 GB RAM running on Windows 8 were utilized within the MATLAB 2020b environment to develop the proposed IDS model. While the KDD-Cup-99 dataset is commonly employed for such purposes, a substantial redundancy within this dataset presents a significant challenge. Due to the high repetition of records, many AI-based IDSs trained on the KDD-Cup-99 dataset produced exceptional results across various evaluation metrics without significant compromises or integrated tuning procedures. Thus, we decided to employ the KDD-Cup-99 dataset as the primary source to compare various AI models according to their detection performance. Analytical systems discovered that these redundant records were being used. To address this, these systems were validated and examined using redundant records, enhancing inaccurate and inconsistent detection performance. While the NSLKDD collection was chosen to overcome the redundancy in the KDD-Cup-99 collection, it resolved the imbalance resulting from highly and less frequent U2R and R2L attacks. Our work employed an oversampling technique, as previously mentioned in the outlined scheme. Within the multiple-layer structure, the confusion matrix is the cornerstone of every performance measurement, constructed separately. It contains essential output class information. Key metrics within the confusion matrix include True, False Negative (FN), False Positive (FP), and True Negative (TN).

A value denoting normal instances within a dataset is expressed as true. TN refers to the correct identification of normal instances correctly. On the other hand, FP and FN indicate misclassifications in the classification results. When attack records are incorrectly labeled as normal instances, it results in a False Positive, posing a significant issue for the privacy and accessibility of organizational resources as attackers often bypass intrusion detection systems. Conversely, a False Negative occurs when instances of attacks are incorrectly labeled as normal. An FP essentially indicates appropriate behavior, commonly recognized as a false alert rate in intrusion detection scenarios.

$$Pr\,e\,cision = \frac{(True\ Positive)}{(True\ Positive + False\ Positive)} \quad (5)$$

$$Pr\,e = \frac{(TP)}{(TP+FP)} \quad (6)$$

$$Accuracy = \frac{(True\ Positive)}{(True\ Positive+True\ Negative+False\ Positive+False\ Negative)} \quad (7)$$

$$Acc = \frac{(TP+TN)}{(TP+TN+FP+FN)} \quad (8)$$

$$Detection\ rate = \frac{(True\ Positive)}{(True\ Positive+False\ Negative)} \quad (9)$$

$$DR = \frac{(TP)}{(TP+FN)}\lambda \quad (10)$$

$$False\ Positive\ Rate = \frac{(False\ Positive)}{(False\ Negative+True\ Negative)} \quad (11)$$

$$FPR = \frac{(FP)}{(FP+TN)} \quad (12)$$

$$False\ Negative\ Rate = \frac{(False\ Negative)}{(False\ Negative+True\ Positive)} \quad (13)$$

$$FPR = \frac{(FN)}{(FN+TP)} \quad (14)$$

$$F_1 - Measure = \frac{2}{\frac{1}{Detectionrate}+\frac{1}{Pr\,ecision}} \quad (15)$$

Eq. (16) yields the Matthews Correlation Coefficient (MCC), the phi coefficient, based on the aforementioned equations.

$$phi = \frac{(TP \times TN - FP \times FN)}{\sqrt{(TP+FN)(TP+FP)(TN+FN)(TN+FN)}} \quad (16)$$

While many performance assessments typically focus on detection rate and accuracy within the proposed model, two new performance metrics have been introduced: MCC and Kappa. The primary reason behind this additional variation is to measure recursive network performance robustness. The MCC value varies from -1 to 1. In predictive modeling, performance metrics alone may not comprehensively depict the classification, particularly in highly imbalanced datasets. Sixty-eight thousand training records were employed as input to the first layer simulation, and 40,000 records were utilized as test data. Performance measurements are presented in Table III.

TABLE III. Performance Results

Detection layers	Metrics				
	CCM	***FP rate***	***Detection rate***	***Precision***	***Accuracy***
First layer	0.87%	9.9%	96.6%	90.1%	91.5%
Second layer	0.93%	9.3%	95.2%	91.3%	93.7%

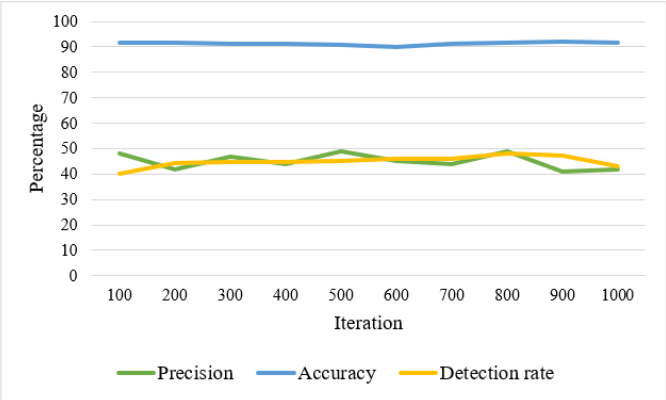

Fig. 5. Performance improvement vs. iteration.

Fig. 5 illustrates model performance evaluation concerning detection accuracy, precision, and rate. The graph demonstrates that precision, accuracy, and detection rate change as the number of iterations increases. A detection accuracy of 91.9% is observed at iteration 500. Considering the recursive nature of the organization, it remains unclear whether the number of iterations during the training stage influences the detection of unusual and hard-to-detect intrusions. Fig. 6 illustrates how recursive gain affects model performance. With increasing recursive gain, detection rates tend to decrease.

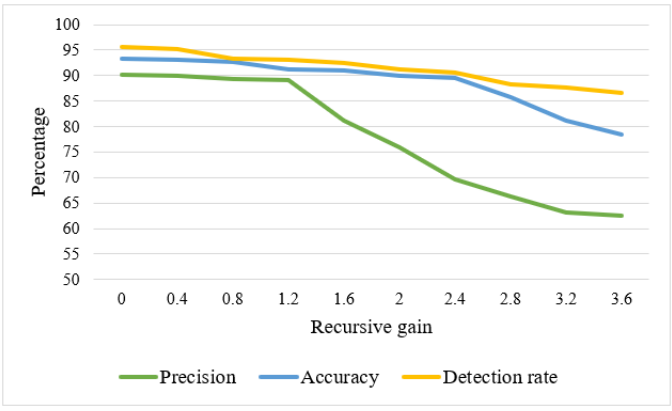

Fig. 6. Performance improvement vs. recursive gain.

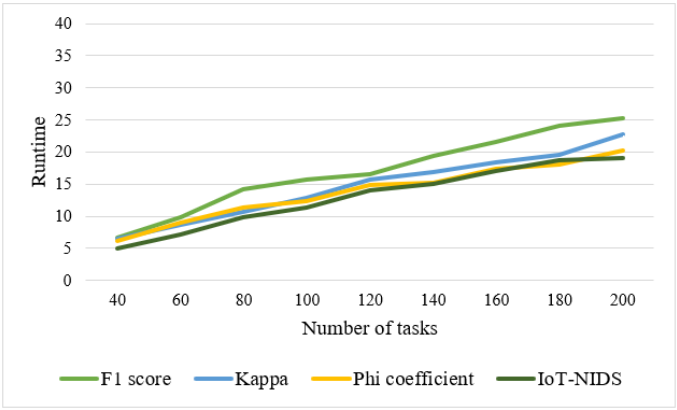

Fig. 7. Runtime vs. number of tasks.

Similarly, detected accuracy declines as the recursive gain rises. Furthermore, Fig. 7 presents a runtime comparison among models, including IoT-NIDS, F1-score, Kappa, and phi coefficient. The data indicates that as the number of tasks increases, the runtimes of these models also increase. For a task comprising 550 iterations, the runtime percentages are as follows: IoT-NIDS 91%, F1-score 92%, Kappa 94%, and phi coefficient 98%.

V. Discussion

The proposed Intrusion Detection System (IDS) leveraging neural network technologies specifically tailored for fog computing offers several advantages over previous approaches. Firstly, by utilizing neural networks, the proposed method can provide a more adaptive and sophisticated approach to intrusion detection compared to traditional methods. Neural networks excel at learning complex patterns and relationships in data, enabling them to effectively detect novel and sophisticated attack patterns that may evade conventional signature-based detection systems.

Secondly, the proposed IDS framework is specifically designed for fog computing environments, which present unique security challenges due to the distributed and dynamic nature of fog infrastructures. Unlike traditional IDSs that may struggle to scale and adapt to the complexities of fog environments, the proposed method is tailored to handle the intricacies of multi-cloud setups, ensuring robust security measures across interconnected fog nodes.

Furthermore, the research aims to tackle escalating security challenges arising from the interconnection of multi-cloud infrastructures. By developing and evaluating a novel IDS framework, the proposed method addresses the limitations of previous approaches by providing comprehensive coverage and protection against emerging threats in fog computing setups. This includes ensuring data integrity and user privacy, which are paramount in fog computing environments where sensitive data is often processed and transmitted across distributed nodes.

The assessment of computational complexity and scalability of the model, particularly in large-scale fog computing deployments, is crucial due to the inherent nature of fog computing environments where numerous devices and significant network traffic are involved. Our theoretical analysis underscores the potential benefits and challenges of increasing the number of fog nodes and handling higher network traffic. Distributed processing, a hallmark of fog computing, enables the division of tasks among multiple nodes, which enhances system robustness and performance. As the number of fog nodes increases, the workload distribution becomes more efficient, potentially leading to improved detection rates and reduced processing times per node. However, this advantage must be balanced against the increased communication overhead required for synchronization and data exchange between nodes. Effective load balancing and fault tolerance mechanisms are essential to leverage the benefits of additional nodes without succumbing to these challenges.

Furthermore, our experiments simulate various scenarios to evaluate the model's performance metrics, including detection rate, precision, accuracy, and runtime, under different configurations of fog nodes and network traffic levels. In scenarios with a limited number of fog nodes, the system might

struggle with high network traffic, leading to potential degradation in detection rate and increased false positives due to resource constraints. Conversely, with a higher number of fog nodes, the system can distribute the processing load more evenly, thereby improving overall detection performance. However, high network traffic poses a significant challenge regardless of node count. The system must process an increased volume of packets, which can strain computational resources and potentially lead to higher misclassification rates. This necessitates the implementation of efficient algorithms and possibly hardware accelerators, such as GPUs, to maintain high detection accuracy and low false positive rates.

In addition to theoretical analysis and simulations, our future work will involve real-world deployment and testing of the model in an actual fog computing setup. This will validate our simulation results and provide insights into real-world performance and challenges. Optimizing the model to handle high network traffic effectively will be a critical focus, ensuring it remains robust and efficient under varying conditions. Implementing advanced optimization strategies, such as dynamic load balancing, adaptive traffic management, and real-time processing enhancements, will further bolster the model's scalability and reliability. Moreover, incorporating additional performance metrics like latency, jitter, and energy consumption will provide a comprehensive assessment, enabling a deeper understanding of the model's operational efficiency and impact on overall system performance. Through these detailed assessments, the model can be fine-tuned to meet the demands of large-scale fog computing deployments, ensuring it remains a viable solution for intrusion detection in complex, distributed environments. Moreover, evaluating the model's performance on additional datasets beyond the NSLKDD, such as the KDD Cup 99 and more recent IoT-specific datasets, is imperative to strengthen the generalizability and robustness of the research findings. The KDD Cup 99 dataset, being a widely used benchmark for network intrusion detection, offers a broader range of attack types and network conditions, providing a more comprehensive evaluation platform for the model. For future work, we will conduct evaluations of the model's performance on additional datasets, such as the KDD Cup 99 and recent IoT-specific datasets. This will help to further validate the model's generalizability and robustness. By testing on these diverse datasets, we aim to assess the model's effectiveness in detecting a wider range of intrusion types and its adaptability to different network environments.

Integrating the proposed intrusion detection system (IDS) with other security mechanisms common in fog computing, such as encryption, access control, and secure communication protocols, is essential for creating a comprehensive and robust security framework. In fog computing environments, data often travels across various nodes and layers, making it susceptible to interception and unauthorized access. By incorporating encryption, data integrity and confidentiality can be maintained, ensuring that even if data packets are intercepted, they cannot be easily deciphered by malicious entities.

Access control mechanisms further enhance security by ensuring that only authorized users and devices can access specific resources and data within the fog network. This limits the potential attack surface and reduces the risk of unauthorized access, thereby complementing the IDS by providing an additional layer of defense. Secure communication protocols are crucial for safeguarding data as it moves between fog nodes and from edge devices to the cloud. These protocols prevent man-in-the-middle attacks and ensure that data remains secure during transit.

By integrating the IDS into a holistic security framework that includes these mechanisms, the overall security posture of the fog computing environment is significantly strengthened. The IDS can provide real-time monitoring and detection of intrusion attempts, while encryption, access control, and secure communication protocols work together to protect against data breaches and unauthorized access. This multi-layered approach ensures comprehensive protection, addressing various security challenges inherent in fog computing. Such integration not only enhances the effectiveness of the IDS but also demonstrates its practical applicability in real-world scenarios, making the research more impactful and relevant. This extended approach would be a valuable addition to the paper, showcasing a thorough and practical security solution for fog environments.

VI. Conclusion

This paper introduced a sophisticated, multi-layered neural network model designed to bolster fog computing security, particularly concerning end-users and IoT devices. It proposes an intrusion detection model aligned with fog networking to enhance the security of IoT networks. The model suggests a discontinuous neural structure refined using a modified backpropagation algorithm. The evaluation of its efficiency highlights the superiority of this adaptable structure, employing a recursive neural network, where each network is dynamically adjusted across various parameters to enhance intrusion detection. The proposed IDS model presented in this study can identify high-sensitivity task assaults, particularly those disrupting the IoT network, apart from recognizing various classes of attacks. Consequently, the model is designed to operate effectively and efficiently under continuous operational scenarios.

Multi-Sensor Fusion and YOLOv5 Model for Automated Detection of Aircraft Cabin Door

Ihnsik Weon[1], Soon-Geul Lee[2]
Airport Industrial Technology Institute, Incheon International Airport Corporation, Incheon, South Korea 22382[1]
Dept. of Mechanical Engineering, Kyunghee University, Yongin, South Korea 17104[2]

***Abstract*—This study investigated perception technology of an autonomous driving system to enable independent connection between an aircraft and a boarding bridge. GigE video sensors and solid-state lidars were installed on the cabin side of the boarding bridge, and a technology that fuses the data from these two different sensors was developed and applied. Using the fused data, a technology for identifying the aircraft door was researched using Yolo-v5, one of the feature point extractors. Yolo-v5 is a deep learning-based feature point extractor that was able to identify the door after being trained with more than 10,000 frames of images under predetermined weather and time conditions. Additionally, a parallel alignment control function was applied between the aircraft body and the cabin of the boarding bridge to increase the reliability of the aircraft door identification technology based on the fused data. To achieve this, a certain area of interest was set within the fused data so that the distance deviation to the left and right of the cabin could be calculated. Finally, to verify the research results, tests were conducted to identify aircraft doors under various environmental conditions with more than six airlines selected. Originally, the Yolo-v5 model secured 93.5% accuracy, but through this study, the detection accuracy for limited-environment aircraft doors was increased to over 95%.**

***Keywords*—Jet bridge; Yolo-v5; sensor fusing; segmentation; door detects; automation docking system**

I. Introduction

The passenger boarding bridge (PBB) is an important airport facility that connects the airport terminal and aircraft through a hub and spoke system [1]. As, the airport's aircraft capacity increases, the need for aerobridges also increases. Therefore, it is necessary to maintain a consistent schedule for the contact time, which can vary greatly depending on the skill level of the workers. Safety is also important [2].

Accordingly, there is a need for autonomous driving technology for aerobridges in airport operations. Recently, Shinmaywa Industries and Panasonic in Japan conducted joint research and development of autonomous driving systems for aerobridges [3]. They completed the development of a system that can achieve contact with aircraft within several tens of centimeters from the aircraft body. However, the system is only applicable to C and D class aircraft, and its reliability can be greatly affected by weather and lighting conditions as it relies on image sensors for aircraft target recognition technology [4].

In addition, Airport Equipment in Australia has developed an autonomous driving system for aerobridges called Intellidock [5], which applies deep learning-based aircraft door recognition technology. It is currently being tested at Wellington Airport. However, this technology sis only applicable to aerobridge contact with short-haul C and D class aircraft, and it relies heavily on video data. Therefore, it can be greatly affected by weather and lighting conditions during the precise contact phase of the aircraft [6, 7].

Therefore, in this study, we utilized multi-sensor fusion technology to develop a technology that can calculate precise aircraft contact points with minimal weather and lighting interference. Multi-sensor fusion technology is a widely used technology in autonomous driving cars and robots that compensates for the inherent disadvantages of each sensor without any constraints, making it the most critical recognition technology for both indoor and outdoor environments.

Sensor fusion technology plays a significant role in improving the accuracy and precision of object recognition by integrating data collected from multiple sensors. However, processing such multi-dimensional data requires a significant amount of computing resources. Therefore, in this study, we used CUDA coding and designed optimal computer resources for parallel processing to address problems [8] such as low FPS (Frames per Second) and flow phenomenon. This approach optimizes the performance of sensor fusion technology, enhancing the quality of object recognition. [9]

The sensor fusion data was used to apply the Yolo-v5 technique [10] for detecting aircraft doors. To apply the Yolo-v5 technique, more than 10,000 images were extracted and used for training by specifying four-season weather, specific times of day (day and night), and different aircraft designs and colors for various airlines. To consider the different bodyourcolors and designs of each airline, fp representative Korean airlines and six foreign airlines were selected to create an image dataset.

The identified location of aircraft doors through this recognition process was used to control the horizontal position between the end-effector (EF) at the boarding bridge and the aircraft body for smooth aircraft door recognition. The sensor fusion data was used as input data for the horizontal control system by setting the aircraft body as a region of interest in the sensor fusion data. Fig. 1 and Fig. 2 show the automation passenger boarding bridge docking system in Australia an Japan respectively.

Finally, based on the learned data, three representative scenarios were determined according to weather conditions and

tested. The tests were conducted even under conditions where crosswinds could affect the physical sensor system.

II. Operation Sequence Jetbridge System

Airport boarding bridges are an essential airport facility for passenger boarding and disembarkation, connecting aircraft and airports. Aircraft models vary depending on their flight distance and destination, and consequently, there are many types of boarding bridges to accommodate them. Boarding bridges are classified into fixed and movable types, with movable ones allowing up to three boarding bridges to be installed at one gate, depending on the number of aircraft models they need to handle [11].

Boarding bridges are named P1 to P3 in the order of their proximity to the airport terminal building, and the sequence of approach starts with the outermost P3 boarding bridge and ends with P1 as the last one [12]. Conversely, the sequence of departure follows the reverse order, with P1 as the starting point and P3 as the last one to be departed.

Furthermore, aircraft grades are divided into six categories, mainly based on the size of the aircraft's main wing span and the outer wheel width of the aircraft's main landing gear, in accordance Table I with the regulations of the International Civil Aviation Organization (ICAO). Grade A is for small planes and Grade B is for planes with fewer than 50 passenger seats, which are not used in international airports. The aircraft grades commonly used for domestic and international flights are C and above, with the B737 and A320 models being the most representative.

Therefore, at airports, boarding bridges are generally not differentiated according to passenger seat class for C and D grade aircraft, so one P1 boarding bridge is used, [14] and passengers embark and disembark mostly through the door closest to the cockpit. However, E grade aircraft, such as the B777, [15] differentiate services for premium seats such as business class and carry out boarding and disembarkation not only through the door closest to the cockpit but also through the door on the main wing side, as their fuselage length is longer. In such cases, both P1 and P2 boarding bridges are used. Finally, F grade models such as the A380 and B747-8i, which have a multi-story seating structure, use two P1 boarding bridges on the first floor and one on the second floor to board and disembark passengers (see Fig. 3).

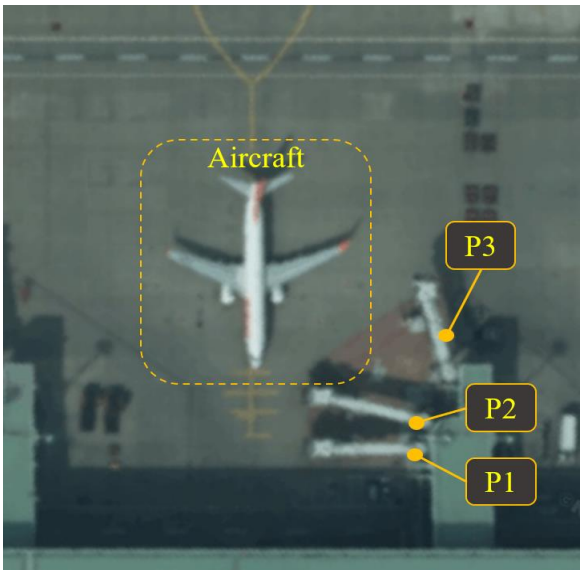

Fig. 3. Airport apron environment and passenger boarding bridge placement status.

TABLE I. Aerodrome Reference Code [13]

CODE ELEMENT 1		CODE ELEMENT 2		
CODE NUMBER	AEROPLANE REFERENCE FIELD LENGTH	CODE LETTER	WING SPAN	OUTER MAIN GEAR WHEEL SPAN*
1	Less than 800m	A	Up to but not including 15m	Up to but not including 4.5m
2	800m up to but not including 1200m	B	15m up to but not including 24m	4.5m up to but not including 6m
3	1200m up to but not including 1800m	C	24m up to but not including 36m	6m up to but not including 9m
4	1800m and over	D	36m up to but not including 52m	9m up to but not including 14m
* Distance between the outside edges of the main gear wheels.		E	52m up to but not including 65m	9m up to but not including 14m
		F	65m up to but not including 80m	14m up to but not including 16m

III. System Configuration

In order to accurately recognize and calculate the precise position of aircraft doors, basic information on the posture of boarding bridges needs to be measured accurately. According to Fig. 4, the sensors installed on the boarding bridges only included height measurement sensors, rotation angle measurement sensors, cabin angle measurement sensors, and wheel carriage angle measurement sensors. The data collected from these sensors is unreliable and does not support high-resolution data required for integration with automatic operating systems as low-resolution support sensors.

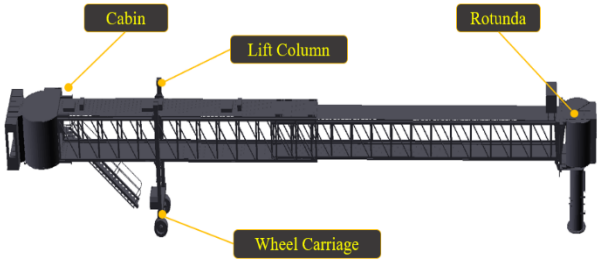

Fig. 4. Configuration of passenger boarding bridge.

A. Schematic Diagram

To conduct research on aircraft door recognition technology, multiple environmental sensing sensors were utilized, specifically two types of 3D LIDAR sensors and a GigE video sensor capable of supporting gigabit data transfer rates and 4K resolution. Additionally, a MEMS-type GPS/INS sensor was installed to estimate the relative position of the boarding bridge. As shown in Fig. 5, the 3D LIDAR sensors collected data through TCP/IP and UDP interfaces using the RJ42 type, while the GigE video sensor outputted images with a maximum resolution of 3,840 * 2,160. Because large amounts of data must be processed in real-time, the two types of 3D LIDAR sensors were connected to a single switch hub, while the GigE video sensor was directly connected using a separate frame grabber. The GPS/INS sensor used a USB 3.0 interface to ensure a maximum data refresh rate of 10Hz.

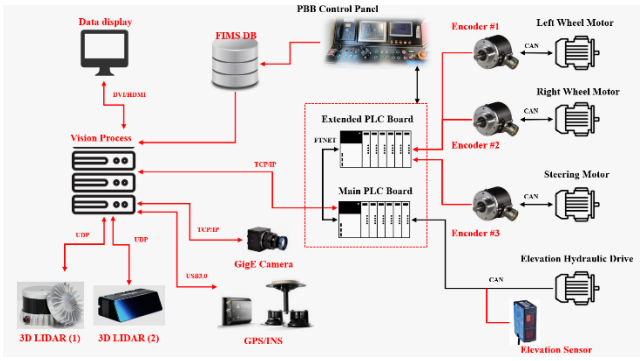

Fig. 5. Schematics of passenger boarding bridge for automations.

Basic boarding bridge posture information, including joint and end effector data information based on the operation of the boarding bridge, is collected through the PLC central controller and the CAN and FTNET interfaces. The PLC central controller and the aircraft door recognition processor collect and refresh data every moment through TCP communication.

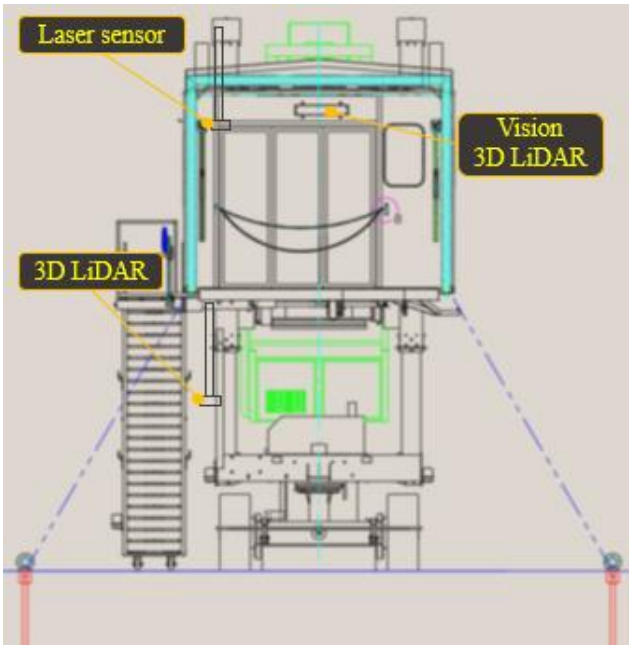

Fig. 6. Sensor installation location diagram.

B. System Layout

The structure of aircraft aprons varies from airport to airport, which also affects the layout of boarding bridges. Therefore, there is a significant difference in the accuracy and precision of recognition results depending on the arrangement of environmental sensing sensors. Additionally, as shown in Fig. 4, boarding bridges are composed of multi-joint structures with at least 4 degrees of freedom, so target point recognition for kinematics control is crucial. Due to the environmental characteristics of Incheon International Airport, strong winds frequently occur, maintaining an average wind speed of over 9 m/s. As a result, significant vibrations occur in the cabin, which is a structure vulnerable to vibrations.

Vibrations can affect image sensor and LIDAR sensor data, leading to significant impacts on object recognition results. Therefore, as shown in Fig. 6, a 3D LIDAR and image sensor were installed in a single housing, located as close as possible to the wheel carriage, the vibration source, and near the center of rotation of the EF cabin to minimize coordinate system unification and external interference.

IV. Data Analysis

To process multiple environmental sensing sensor data simultaneously, we first examined the configuration and update cycle of each sensor data. For this study, the boarding bridge is equipped with three types of sensors: Solid State 3D LiDAR, Rotary 3D LiDAR, and GigE cameras. The posture information of the boarding bridge is received through a PLC processor for coordinate system alignment of each data. The posture information of the boarding bridge can be collected as shown in Fig. 4, and it is transmitted with a refresh rate of 50ms, taking into account the data processing speed between the PLC processor for angle sensor data received from each

drive position and the integrated controller for automatic operation.

For environmental perception sensors, we used the FLIR Blackfly S GigE camera. Solid State LiDAR installed in the cabin area is Velodyne M1600 model, and the Rotary LiDAR installed in the lower part of the boarding bridge is Ouster OS1-64. The update cycle and size of each sensor's data were confirmed. The GigE camera supports a resolution of 2,448 * 2,048, with a sensing area of 8.45 * 7.07 (mm), and it updates the image at a speed of approximately 25~27 frames per second (FPS) based on the maximum supported resolution.

Velodyne M1600 LiDAR sensor can collect data up to a maximum distance of 30m, and the size of the data generated depends on the data update speed. In this study, it supports 160 data lines with a refresh rate of 100ms and a vertical resolution of 0.2 degrees. Furthermore, it is optimized for identifying nearby objects with a maximum distance error of 4mm.

As shown in Fig. 7, the environmental conditions are standardized, and the object material conditions that determine data collection errors are uniform, resulting in consistent data collection under most conditions. However, since all three types of data need to be collected simultaneously, there was an issue of Lidar data loss occurring during processing when the network occupancy exceeded 300 Mbps.

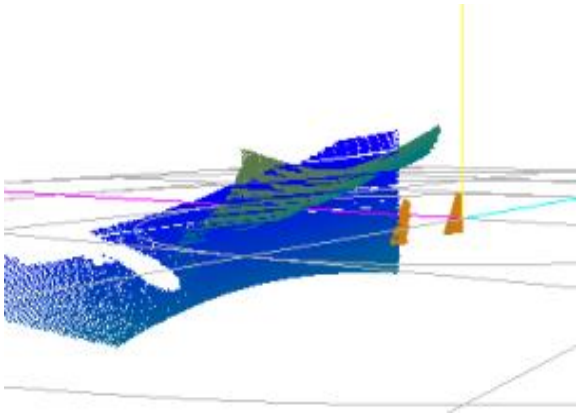

Fig. 7. Velodyne M1600 sample 3D data in real environment.

To address this fundamental problem, a separate network card was installed for the GigE camera, and during the data calibration process between Lidar and image data, a preprocessing step was performed by setting the Region of Interest (ROI) to correct only the necessary areas, thereby resolving the issue.

V. Detection Algorithm

During the process of performing the docking operation to an aircraft, precise calculations of the docking target position are essential. The target position is determined in a three-dimensional space, considering the height, left, and right positions relative to the sensor location. According to Fig. 10, the aircraft door position is explored based on the learned information, and the two-dimensional positional information is calculated. Subsequently, the fused three-dimensional data is used to explore the position information of the docking target point.

Fig. 8. GigE camera data with aircraft and apron.

A. Muli-sensor Fusing

The collected aircraft body image data, as shown in Fig. 8, is based on the UV coordinate system, while the installed LiDAR sensor is composed of three-dimensional data as depicted in Fig. 7. To unify two or more data with different dimensions into a single coordinate system, a sensor data fusion process was conducted. For data fusion, the LiDAR data (x, y, z) was corrected and applied to the UV coordinate system, as illustrated in Fig. 10. The data fusion process can be divided into three main stages:

1) Pre-processing: In this stage, the raw LiDAR data (x, y, z) is obtained from the sensor. Calibration and correction processes are applied to align the LiDAR data with the U*V coordinate system. The pre-processed LiDAR data is then ready for further fusion steps.

*2) Fusion of data into U*V coordinate system:* The corrected LiDAR data (x, y, z) is integrated with the U*V coordinate system data. This fusion step allows combining the two different types of data into a unified U*V coordinate system. Fig. 9 shows proposed fusion 3D object recognition framework for aircraft.

3) Coordinate system construction: In this final stage, a complete coordinate system is constructed, incorporating the fused data. The fused data now provides three-dimensional information in the U*V coordinate system, enabling precise calculations and target exploration [16].

By following these three steps, the sensor data fusion process successfully unifies the U*V coordinate system with the 3D LiDAR data, allowing for accurate target positioning and exploration.

$$T = \frac{\log(1-p)}{\mathrm{lo}(1-(1-e)^{s})} \quad (1)$$

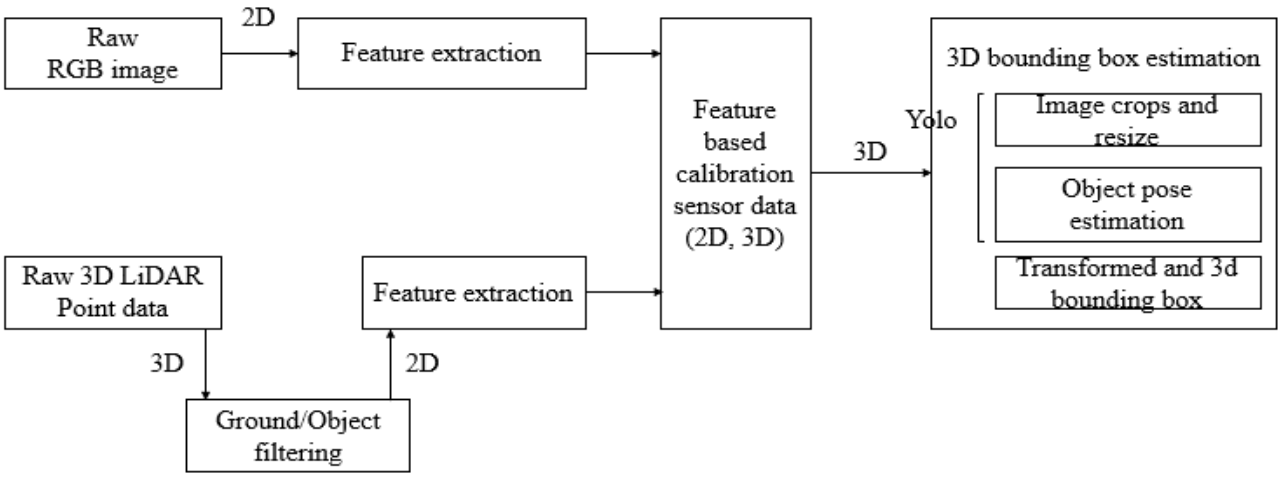

Fig. 9. Proposed fusion 3D object recognition framework for aircraft cabin door detecting algorithm.

The process of generating unified data between LiDAR and image data can be achieved through the following steps:

1) Ground and noise data filtering for setting the region of interest for LiDAR data [17].

2) Extraction of feature points from image data and setting reference points based on LiDAR data.

3) Matching of pixel-point feature points [18] to establish correspondence between LiDAR and image data.

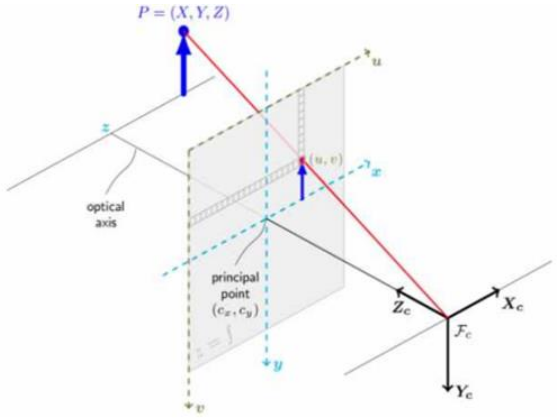

Fig. 10. Coordination system for IMAGE – 3D POINT(LIDAR).

To accomplish step 1, the ground and noise data filtering process, the 3D RANSAC algorithm was utilized to perform segmentation. As shown in Fig. 11, the data reflected from the aircraft body and the ground data were distinguished by comparing them with the RANSAC surface model, identifying inliers and outliers. To achieve a relatively high proportion of inlier data, the sampling frequency ' ' in Eq. (1) was experimentally derived. ' ' represents the probability of including a sample within the threshold of the standard plane model, ' ' denotes the ratio of inliers to outliers in the entire dataset, and ' ' is a parameter that adjusts the number of data to select the minimal set for the RANSAC process.

However, as shown in Fig. 11, the ground data adjacent to the aircraft landing gear had a higher outlier ratio than the inlier ratio. Thus, we did not apply ground filtering. To filter even the data adjacent to the landing gear, a 3D plane model needed to be generated using actual ground point data. However, due to the characteristics of the 3D LiDAR sensor used in this study, there could be variations in accuracy between close and relatively distant data points, resulting in non-precise plane models with curvatures.

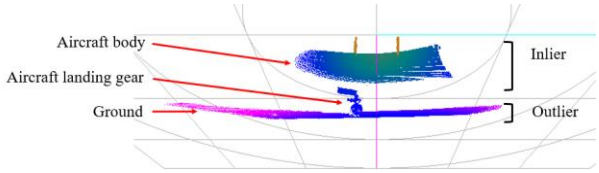

Fig. 11. Aircraft and ground 3d model data for 3d RANSAC.

To address this issue and filter data up to some parts of the aircraft landing gear, a model with curvature information was incorporated. This allowed us to filter some ground information along with the data. Fig. 12 illustrates the filtered data results after applying a preliminary correction to the image data, taking into consideration the filtered results that include some ground information.

After the ground data filtering, the next step involves matching feature points between the 3D LiDAR data and the image data to apply corrections. In this process, the landing gear and edges of the aircraft body in the 3D LiDAR data are set as feature points.

Similarly, corresponding pixel positions in the image data are stored for matching. Typically, to achieve accurate correction, one would extract feature points from the pixel panel and match them with the LiDAR data. However, in the case of the aircraft boarding bridge, the distance between the aircraft and the bridge is always constant, and the positioning of the aircraft during boarding is consistent, as shown in Fig. 12. Therefore, feature points were extracted based on a representative e-type aircraft model for data matching.

Moving on to the next step, the matched data between the LiDAR and image data were used for the final image-LiDAR matching process. However, as seen in Fig. 13, Fig. 14 and Fig. 15, errors in the matching results were observed for small parts or edge areas of the aircraft. The matching process could result

in approximately 15 cm errors in both horizontal and vertical directions. Despite these errors, the main objective of this study is not to achieve precise data matching but to identify the positions of aircraft doors and specific parts to generate 3D data. As such, including errors on the order of a few centimeters is acceptable for the study's objectives.

B. Vision based YOLO-V5 Model

The original YOLO algorithm was developed by Joseph Redmon, who is also the creator of a custom framework called Darknet. After five years of research and development leading to the third generation of YOLO (YOLOv3), Joseph Redmon announced his withdrawal from the field of computer vision. He discontinued further development of the YOLO algorithm due to concerns that his research might be misused in military applications. However, he does not contest the continuation of research by individuals or organizations based on the initial concepts of the YOLO algorithm [19].

A Russian researcher and engineer who built the Darknet framework and implemented the three previous YOLO architectures using C, which was based on Joseph Redmon's theoretical ideas, collaborated with Chien Yao and Hon-Yuan to publish YOLOv4. As YOLO evolved, numerous object detection algorithms employing different approaches have achieved remarkable advancements. As depicted in Fig. 16, this development has led to the emergence of two primary concepts in architectural object detection: the One-stage detector and the Two-stage detector.

A common aspect among all object detection architectures is the process by which input image features are first compressed through a feature extractor (Backbone) and then forwarded to the object detector (comprising the Detection Neck and Detection Head), as shown in Fig. 16. The Detection Neck (or Neck) serves as a feature aggregator that combines and refines the features obtained from the Backbone, preparing them for the detection step performed by the Detection Head (or Head) [20].

The distinction here is that the Head is responsible for the actual detection, encompassing both localization and classification for each bounding box. The Two-stage detector executes these two tasks independently and subsequently combines their results (Sparse Detection), whereas the One-stage detector accomplishes them simultaneously (Dense Detection), as illustrated in Fig. 16. YOLO falls under the category of a One-stage detector, thus the name "You Only Look Once" [21].

As illustrated in Fig. 16, YOLOv4 conducted a series of experiments that integrated the most cutting-edge and innovative ideas in computer vision across different components of the architecture.

In the field of computer vision, object detection is a critical task involving the identification of objects within images or video frames, along with providing information about their positions and classes. Various architectures have been developed to tackle this task with the main categories you mentioned being one-stage and two-stage detectors [22].

1) One-stage detector: One-stage detectors, as the name implies, perform object detection in a single step. They directly predict the bounding box locations and class labels for each object instance. YOLO (You Only Look Once) is a prominent example of a one-stage detector. YOLO divides the input image into a grid and predicts the bounding boxes, object scores, and class probabilities for objects within each grid cell. YOLOv4 is an enhanced version of the YOLO architecture, which has improved detection performance through various innovative ideas and enhancements.

2) Two-stage detector: In contrast, two-stage detectors perform object detection in two steps. In the first step (region proposal stage), they generate a set of potential Regions of Interest (ROIs) likely to contain objects. These ROIs are then

refined and classified in the second step. The most well-known example of a two-stage detector is Faster R-CNN (Region Convolutional Neural Network). In Faster R-CNN, a Region Proposal Network (RPN) is used to suggest potential ROIs, which are then refined and classified using subsequent layers.

3) Backbone: This is a convolutional neural network (CNN) responsible for extracting features from the input image. The backbone network processes the image at various scales and levels of abstraction.

4) Detection Neck: The detection neck aggregates and combines the features extracted by the backbone. It enhances features for use by the detection head.

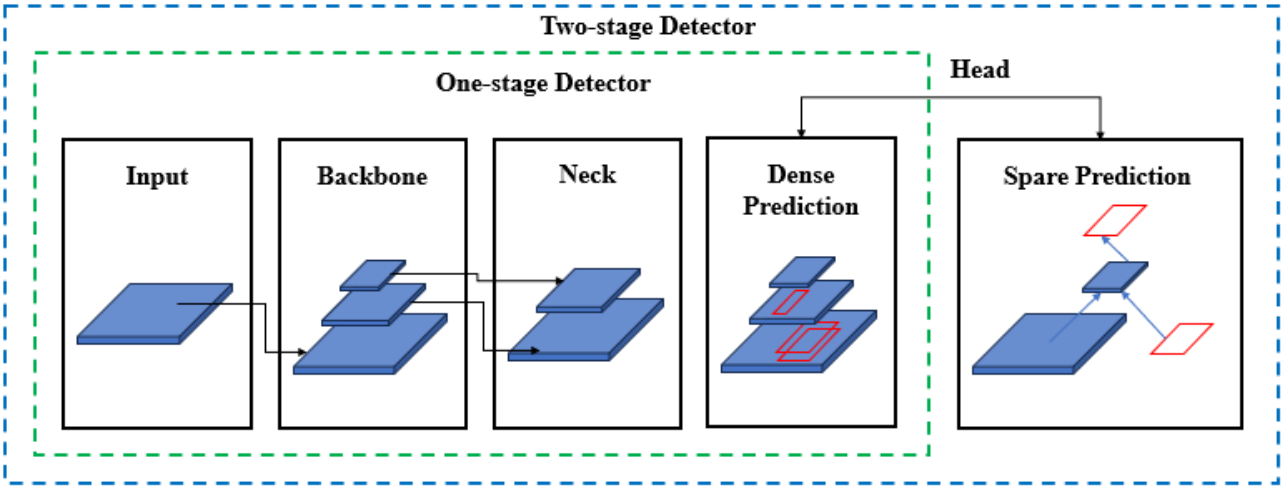

Fig. 15. Two concepts of architectural object detection [23].

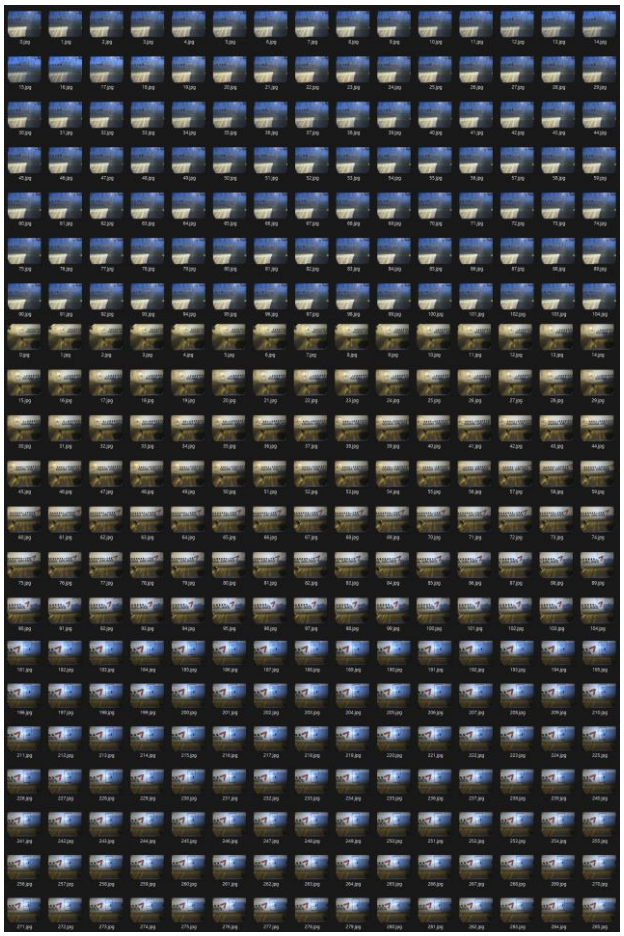

Fig. 16. Aircraft door training image dataset (real environment).

5) Detection Head: This is the final component of the architecture responsible for generating predictions. It takes features from the detection neck and generates predictions for object bounding box locations, objects scores (indicating the likelihood of object presence), and class probabilities.

The YOLOv4 architecture is built upon the YOLO concept and integrates various innovations to enhance detection accuracy and speed. The field of object detection is rapidly advancing, and there is ongoing development of new architectures and techniques to expand the potential scope in terms of accuracy and efficiency. Furthermore, there is continuous work on improving compatibility, scalability, and extensibility of development tools, as evidenced by the introduction of YOLOv5.

Even a month after the release of YOLOv4, the start of research for YOLOv4 and YOLOv5 was quite close [24].

To avoid confusion, Glenn decided to name his version of YOLOv5. Therefore, fundamentally, both researchers applied cutting-edge innovations in the field of computer vision at that time.

This led to the architectures of YOLOv4 and YOLOv5 becoming very similar, and this similarity resulted in many people expressing dissatisfaction with the name YOLOv5, as it did not seem to encompass significant improvements compared to the preceding version, YOLOv4. Additionally, Glenn did not publish a paper for YOLOv5, which further raised suspicions about YOLOv5 [25].

However, YOLOv5 had advantages in terms of engineering. YOLOv5 was written in the Python programming language instead of using C as in previous versions. This made installation and integration on IoT devices easier. Furthermore, the PyTorch community is larger than the Darknet community, indicating that PyTorch will receive more contributions and have greater growth potential in the future. Due to being written in two different languages on two different frameworks, accurately comparing the performance between YOLOv4 and YOLOv5 is difficult. Nevertheless, over time, YOLOv5 demonstrated higher performance than YOLOv4 in certain scenarios and gained some confidence within the computer vision community, alongside YOLOv4 [26].

C. Training Aircraft Image Dataset

YOLOv5, the following process is necessary for extracting training data:

1) Data preparation: Start by preparing the training dataset for object detection. You'll need training images along with the bounding box coordinates and class labels for each object.

2) Data annotation: Annotate the training images with bounding box and class information. This information will be used by the model to recognize and classify objects.

3) Data transformation: Convert the training data into a format that YOLOv5 model can understand. This format should adhere to the YOLO format.

4) Model configuration: Configure the YOLOv5 model. You can define the model architecture using PyTorch and load pre-trained weights.

5) Training setup: Set up the necessary hyperparameters and training options. This includes parameters like learning rate, batch size, and number of epochs.

6) Training process: Train the model. YOLOv5 is typically initialized with pre-trained weights on the COCO dataset, allowing you to fine-tune it for your specific data.

7) Evaluation and testing: After training, evaluate the model's performance using a validation dataset. Use the evaluation results to improve and fine-tune the model.

8) Inference: Use the trained model to perform inference on new images and detect objects.

In order to apply the YOLOv5 prediction model, it was necessary to undergo the process of training image data. To ensure applicability in various environments and aircraft scenarios, images of aircraft were collected within an airport setting, accounting for weather and time variations. The image data extraction was carried out for four types of aircraft from Korean national airlines and six types of aircraft from foreign national airlines. The collection points were situated in the upper cabin area, specifically the boarding gate area.

Moreover, to ensure the diversity of the image dataset, image extraction scenarios were defined not only for weather conditions such as rainy days but also for different conditions, as outlined in Table II, including daytime and nighttime scenarios. This approach aimed to capture a comprehensive range of conditions and variables to enhance the robustness and versatility of the model across different scenarios.

TABLE II. THE SCENARIOS FOR COLLECTING TRAINING DATA

No.	Time	Flight	Weather
1	08:00 ~ 11:00	Korean Aircraft C-type #1	Clear, Rainy, Foggy Day
		Korean Aircraft E-type #1	
		Korean Aircraft C-type #2	
		Korean Aircraft E-type #2	
		Foreign Aircraft E-type #1	
		Foreign Aircraft E-type #2	
2	13:00 ~16:00	Korean Aircraft E-type #1	Clear, Rainy
		Korean Aircraft E-type #2	Clear, Rainy
3	18:00 ~23:00	Korean Aircraft E-type #1	Clear Day
		Korean Aircraft E-type #2	Foggy Day
		Foreign Aircraft E-type #1	Clear Day

I wanted to collect images of more diverse aircraft appearances according to weather and time of day, but there were limits to collecting diverse data because the security requirements for each airline were different when collecting close-up images and 3D exterior data.

I have collected images of aircraft from various airlines across different time zones, similar to Fig. 16. The collected images amount to over 100,000. However, I filtered them to

include only meaningful image data, resulting in a training dataset composed of over 10,000 images.

I used the YOLOv5 model as the base for image training, with a transformation input size of 320x320. I conducted training with two different configurations: one with 100 to 300 epochs, and another with batch sizes of 10 to 30. I defined a decay step of 100 with a rate of 0.95. For the training system, I used an i7-13700K CPU model and an NVIDIA RTX3080 GPU model. The detailed specifications are as shown in Table III.

TABLE III. SPECIFICATION OF TRAINING SYSTEM

MODEL	SPECIFICATION
CPU	Intel i7-13700K 16 Cores, 24 threads
RAM	64GB
OS	Windows 10 / Pytorch
GPU	NVIDIA RTX3080 CUDA Core : 8704 10GB GDDR6X Memory Bus : 320bit

I adjusted the training parameters by classifying them into two categories and modifying the necessary epoch and batch settings while keeping the dataset size and types consistent, as shown in Fig. 17. In Fig. 17, I reduced the epoch size and increased the batch size to accelerate training. In Fig. 18, I performed training with parameters reduced to approximately half compare to the previous ones. As a result, fluctuations in the values, as shown in the graph in Figure, are observed. These variations are due to differences in the training positions and data types between day and night image data within the base dataset used for training.

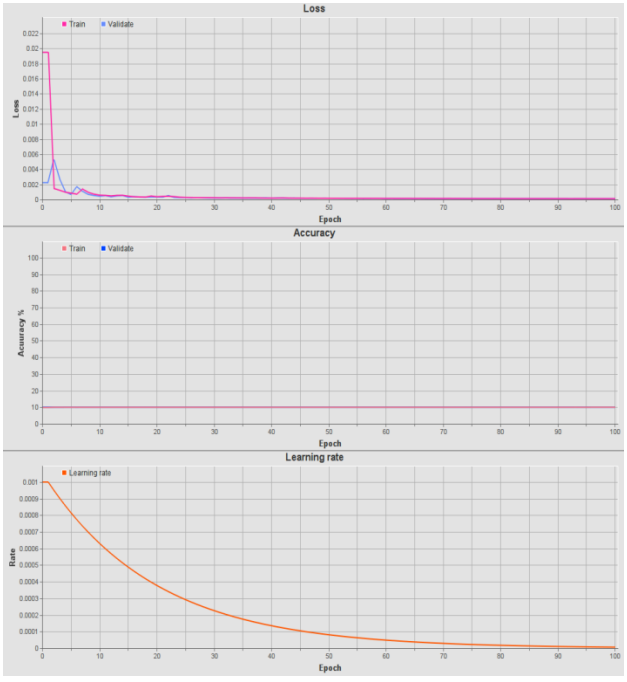

Fig. 17. Training result of image dataset (Epochs 100, Batch size 10, Learning rate 0.001).

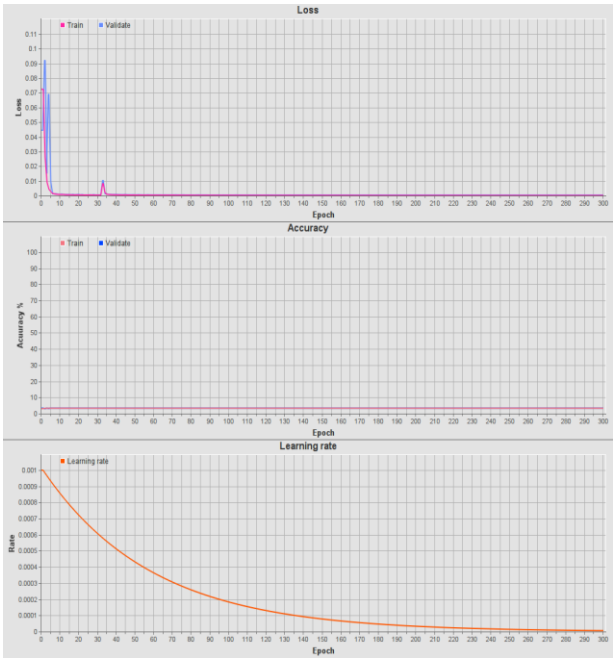

Fig. 18. Training result of image dataset (Epochs 300, Batch size 30, Learning rate 0.001).

In reality, the top line of the aircraft door exhibits clear distinguishing features during daytime, but during nighttime, it can experience loss of details due to the lighting from the boarding gate. In such cases, during YOLOv5 training, there's a possibility of spikes in values occurring because of images with entirely different types of distinguishing features, rather than converging towards the target values. This can result in fluctuations in values during training instead of a smooth convergence.

VI. EXPERIMENT AND RESULTS

To conduct testing of the aircraft door detection technology, it operates along the path between the boarding bridge and the aircraft, as shown in Fig. 19. Boarding bridge operations, as depicted in Fig. 19, are divided into three steps, and the status of the images at each operational position was verified in Fig. 19.

We performed YOLOv5 training using all the images from the operational steps as shown in Fig. 20. Subsequently, I obtained results for aircraft door detection from the depth images fused with 3D LiDAR data, as shown in Fig. 21.

In the process, similar to Fig. 20, we compared the fused depth data with actual inter-body distances to verify the consistency of the data generated through fusion. As indicated in the previously mentioned sensor installation layout, we placed laser distance measurement sensors not only the 3D LiDAR sensors but also at the bottom of the cabin of the boarding bridge. Through laser distance measurement sensors, we could measure the distance between the body and the boarding bridge for specific areas. To confirm this accurately, as shown in Fig. 21, we marked yellow reference points at the same positions as the laser distance measurement points within the images, collecting three-dimensional positional information within those pixels.

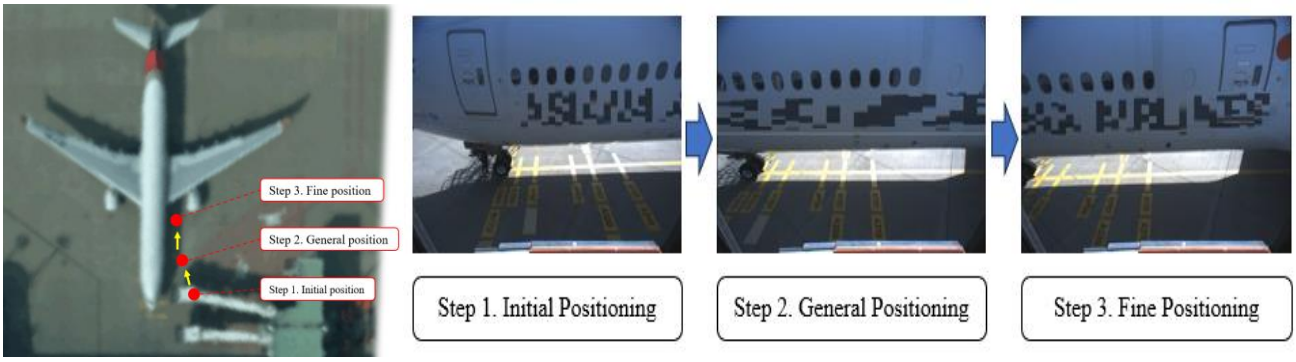

Fig. 19. Operational steps of automation Jet bridge and images data for each operational position.

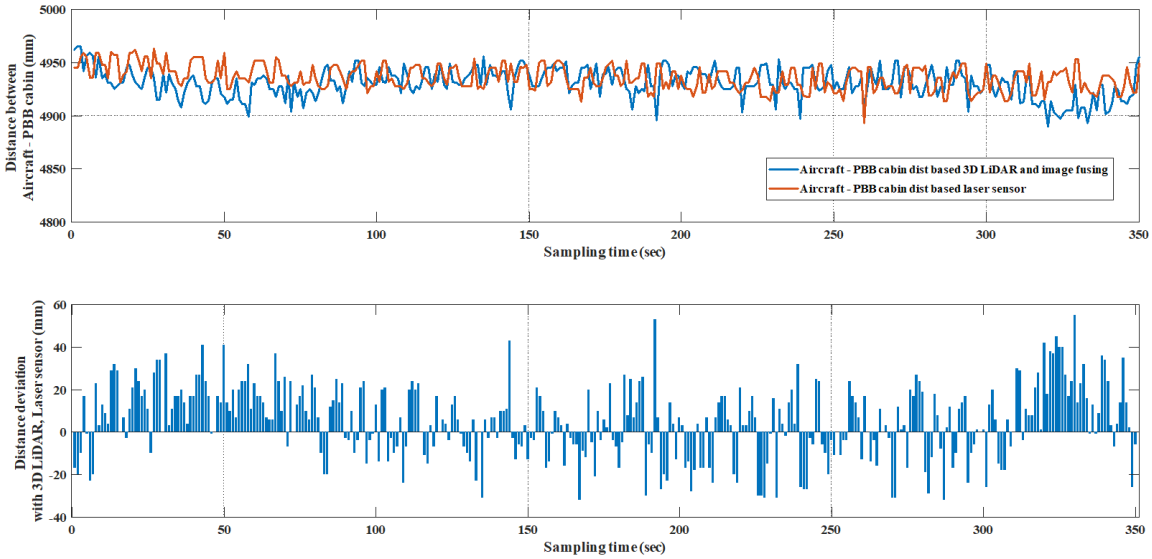

Fig. 20. Integrated (3D LiDAR – Vision) data, laser distance sensor data, and distance and deviation data between the aircraft and the passenger boarding bridge (PBB).

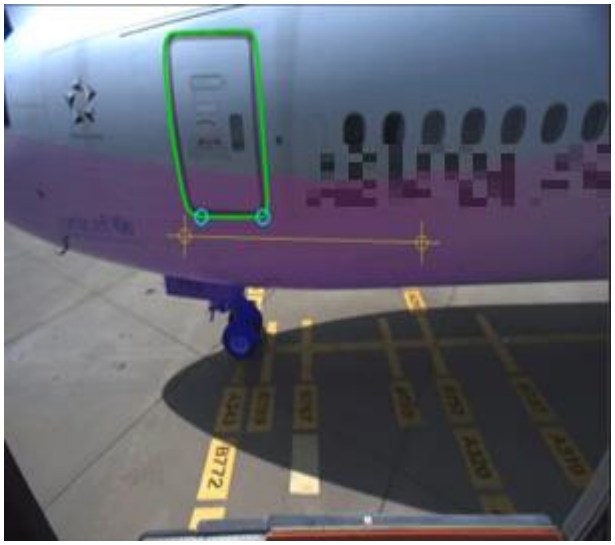

Fig. 21. Initial positioning steps of automation Jet bridge image data.

The collected data was represented as measured distance values, as shown in Fig. 20, and for data within a maximum range of five meters, it exhibited an error of within 5.8 cm due to movement. Such a level of error can be attributed to factors such as the material, color, and light reflection on the aircraft body surface, as well as errors associated with the measurement location. In particular, considering both the inherent sensor error and cumulative values, the actual error was estimated to be within 3 cm.

Furthermore, aircraft doors detected through the fused data, as depicted in Fig. 22, were detectable for all orientations. During the daytime, the detection and recognition rate exceeded 95%, with false negatives primarily caused by backlighting from sunlight. Additionally, as seen in Fig. 23, the detection and recognition rates during nighttime were not significantly different. However, as shown in Fig. 24, the presence of nighttime lights installed on the top of the boarding bridge cabin and shadows resulted in light reflection on the aircraft door lines, causing the characteristics of the aircraft door lines to deteriorate, leading to situations where the aircraft doors were not recognized.

Nevertheless, this problem was resolved in the autonomous boarding bridge system operating scenario, as there was no alignment situation between the aircraft body and the boarding bridge during the closest proximity between them.

Fig. 22. Door detection in fine positioning steps at day time.

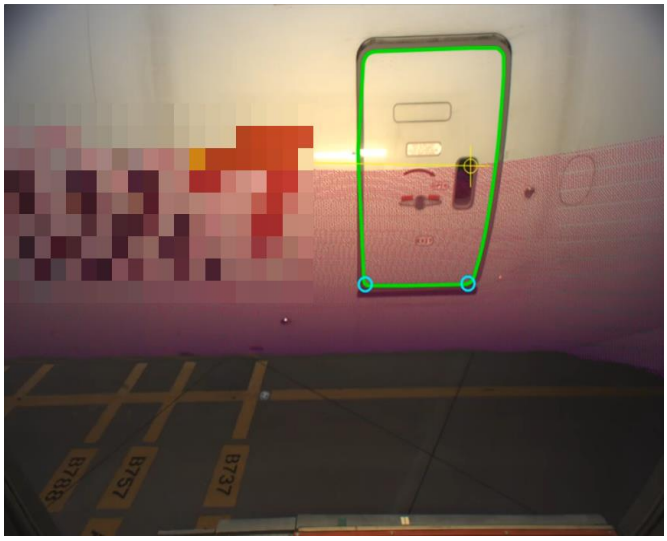

Fig. 23. Door detection in fine positioning steps at night time.

Fig. 24. Aircraft door error recognition results in fine positioning steps.

The average recognition rate during a single operation of autonomous boarding bridge action in both nighttime and daytime environmental conditions, for a duration of 2 minutes, was 95.3%. This rate exceeded the mAP value achieved by YOLOv5, but it was calculated for specific aircraft door recognition in a constrained environment, suggesting a higher recognition rate could be achieved.

However, there was a difference in real-time processing time between nighttime and daytime. Nighttime processing averaged around 10-11fps, whereas daytime processing averaged around 13-15fps, resulting in approximately a 3-4fps difference. Considering the maximum boarding bridge movement speed of 0.6m/s, it was sufficient for the autonomous driving system to operate effectively.

VII. Conclusion

This paper presents the development of technology for recognizing and identifying aircraft door locations to facilitate the development of an autonomous boarding bridge system. Due to the relatively slow movement characteristics of boarding bridges, the primary objective of this study was to achieve higher recognition rates and reduce errors rather than focusing on real-time processing speed. To accomplish this, we conducted the process of fusing image sensor and 3D LiDAR sensor data into a single dataset, successfully achieving a matching accuracy of over 98% and securing highly accurate data with errors of within 3 cm. Based on this data, we conducted research on aircraft door recognition using the YOLOv5 model.

In order to do this, we made efforts to acquire various aircraft models and airline image datasets, collecting over 100,000 images, of which more than 10,000 were used for actual training. Furthermore, we conducted a comparative analysis of recognition rates according to different time periods, ensuring a recognition rate of over 95% during both day and night hours. However, it should be noted that this paper was based on training data from images of aircraft obtained from six airlines, and for the application of autonomous boarding bridge systems to all aircraft and airlines, it is necessary to construct diverse image datasets for training purposes.

In future research, we intend to apply detection and recognition technology capable of handling a wider range of environments and scenarios.

Developing a Digital Twin Model for Improved Pasture Management at Sheep Farm to Mitigate the Impact of Climate Change

Ntebaleng Junia Lemphane, Ben Kotze, Rangith Baby Kuriakose
Department of Electrical, Electronic and Computer Engineering
Central University of Technology, Bloemfontein, Free State, South Africa

***Abstract*—Small-scale livestock farmers experience significant losses because of decreased productivity caused by decline in pasture production brought on by climate change. Technology in livestock farming introduced the idea of "smart farming," which has simplified pasture management. Internet of Things (IoT), Artificial Intelligence (AI) and data analytics are just a few of the cutting-edge technology techniques that smart farming incorporates. Digital twin technology is proposed in this study to alleviate the challenge of changing weather patterns that affect pasture management. Digital twin model is developed to predict pasture height to ascertain the predicted amount of pasture and ensure that the sheep have access to enough food for sustainable production. Pasture growth is influenced by temperature, rainfall and soil moisture; thus, pasture height predictions depend on these factors. Digital twin is made of predictive models built on historical and real-time data collected from the IoT sensors and stored in ThingSpeak® cloud. Data analysis was performed in MATLAB® using the neural network algorithm and predictions of the system are modelled in SIMULINK® platform. Digital twin predicted the pasture height to be 52 cm while the observed reading was 56 cm. Therefore, with the prediction error of -4, the digital twin can serve to enhance pasture management through its capabilities and assist farmers in decision making.**

Keywords*—Artificial intelligence; artificial neural network; climate change; digital twin; Internet of Things; machine learning; pasture management; smart farming

I. Introduction

Livestock farming makes a substantial contribution to food security. Forage species or pastures are used in livestock production systems to feed the animals, and this has become a crucial aspect of managing the pastures also known an pasture-based livestock production [1]. In South Africa, there are many animals that depend on pastures for survival. Statistics indicate that sheep farming is most practised in the country [2] and the major feed source is utilization of pastures [3]. Hence, the focus of the study is on sheep farming.

Pasture is a grazing area for all ruminants, it also offers sheep with a nutritious diet [4]. To ensure profitable livestock production, pasture management is a crucial component of farm management. Pasture management involves maintaining healthy pasture and its companion plants to provide the animals with sustainable feed. A well-managed pasture has considerable advantages, such as increased forage yields and lower feed costs [4], which result in healthy sheep. For efficient grazing management, farmers who rely on grazing pasture as their main source of animal feed require accurate and timely observations of pasture height [5]. Since productivity is influenced by the extent of pasture utilization, which is a function of enhanced pasture growth, accurate measuring of pasture is crucial [6].

However, a scarcity of high-quality pasture is the main obstacle facing sheep farmers [7]. Poor management techniques, uncontrolled grazing systems, and a loss in pasture yield due climate variability can all contribute to this issue [8]. Nonetheless, smart farming tools are new approaches that are emerging to improve pasture-based systems and farming conditions which support farmer's decision making and increase productivity [9, 10]. Smart farming is a technology that depends on the application of AI and IoT in the management of cyber-physical farms [11]. Despite the smartness provided by these technological advancements there are also negative environmental impacts that cannot be ignored. The use of modern technologies poses challenges to our environment and pastures are no exception to these problems. All these modern devices and machines raise concerns about waste, use of non-renewable materials and carbon footprint which contributes to climate change [12, 13]. However among these challenges, climate change is the main focus of this study as it affects the productivity of pasture-based systems [14].

In this study digital twin technology is the proposed solution to limit the impact of climate change in pasture management. A digital twin is a virtual version of a physical asset that is made possible by data and simulators to facilitate better decision-making, monitoring, controlling, and real-time prediction, optimization, and monitoring[15]. Although digital twin technology in livestock farming is still in its infancy, it has taken the advantage to use the current smart farming technology to improve farm management, animals welfare and production of animals products [16]. Digital twin technology promises to help farmers with better predictive models by combining big data, real-time data from the individual farm, and AI models trained by machine learning algorithms [16].

The aim of this study is to investigate how a digital twin can predict pasture height and introduce soil moisture predictive model to form part of forecast models. Regression and artificial neural networks (ANN) machine learning algorithms were investigated to determine their performance

for prediction. The digital shadow was developed to set the grounds and determine if the predictive models could be trusted on the digital twin. The digital twin is comprised of predictive models built with historical data and updated by real-time data from the IoT sensors set-up on the farm. The predictive models predicted temperature, rainfall, soil moisture and pasture height. The major goal of the study is to develop a better pasture management system with early detection of predicted scenarios for better risk management and decision-making processes.

II. Overview of the Literature

In all of South Africa's provinces, sheep farming has a significant impact on socioeconomic and cultural life [17]. Small-scale businesses that practice sheep farming produce meat and wool as a source of revenue. Forage found on pastures is what sheep eat [3], hence pasture management techniques are used to create high-quality pasture to feed the sheep. However, pasture management is impacted by climate change, which leads to a decrease in the amount and quality of pasture production [18]. Farmers struggle to keep their animals alive as a result of the shortage of adequate pasture for the sheep to graze on [19]. According to survey data from commercial farmers, most farmers withdrew from sheep farming altogether over a three-year period, between 2012 and 2014, because the feeding conditions were too challenging owing to the drought [20]. This indicates the depth of climate change's influence.

Climate change has an impact on pasture management and could make it even more difficult to manage grazing areas [21]. Pasture growth is directly impacted by the interaction of temperature, precipitation, and soil moisture. Production of pasture is negatively impacted by temperature increases, heavy rainfall, and high evaporation rates brought on by climate change [21] [22]. There are identified smart farming technologies that are already applied to overcome issues related to pasture management and utilization, animal monitoring and control at sheep farms [9]. Smart farming offers farmers with superior decision-making and management strategies [23] by merging information and communication technologies through AI and IoT sensors for use in agricultural and livestock production systems.

The Internet of Things (IoT) is the technology that allows sensors to be linked together and operated automatically using internet which includes various sensing methods for collecting, processing, analyzing and storing of real-time data [11]. Artificial intelligence (AI) is the science of making intelligent machines and programs by developing software's and systems using machine learning and deep learning to solve problems and make decisions [24]. Just like the human brain, these software programs are provided with training data, and further, these intelligent devices provide the required result for every legitimate input [25].

Machine learning and deep learning are the fundamental building blocks of AI [24]. Machine learning is the capacity to learn something based on the data set without explicit programming [26] while deep learning is subcategory of machine learning which includes learning of neural networks made of neurons having various parameters and layers between the input and output [27]. Thus, both IoT and AI along with cloud-based technology play a critical role in farm management by collecting and analysing sensor's data to perform temperature and rainfall predictions, monitor crop growth and soil management [28]. Smart farming has allowed new technologies to be implemented in pasture-based systems to improve efficiency. These pasture management systems include weather stations, capturing pasture measurements and soil conditions [5] [9] [10] [29]. However, using these technologies has their limitations.

Soil moisture as one of the key factors influencing pasture growth is not considered by forecast models [30]. Furthermore, the current systems are unable to accurately identify and monitor pasture growth [31]. Due to the impossibility to gain a comprehensive view of physical systems in real-time, this necessitates time-consuming remote monitoring and control [15]. Sensing technologies allow for real-time farm monitoring, which presents the chance to create farm-specific models that a specific farmer might use to schedule activities in response to changing conditions.

Literature reveals, however, that digital twin technology holds the promise of enhancing smart farming for better farm management and higher productivity[16]. A digital twin is a representation of a physical thing that replicates its behavior and states across time in a virtual environment [32]. Utilizing both current and past data, a digital twin provides analysis, forecasting, and operation optimization [33]. Large volumes of data must be able to be received, stored, and processed by the digital twin in real-time hence, significant computing, storage, and data processing resources are needed for this.

Using real-time data from numerous IoT sensors and devices, digital twins continuously adjust to operational changes to forecast the future of the physical system with the help of AI and machine learning [32]. Digital twins are able to predict systems' future behaviours using models that incorporate machine learning [34], known as predictive modelling. In order to predict future outcomes, predictive models employ algorithms that learn and analyse both historical and present data. Algorithms for machine learning, deep learning and pattern recognition can be used to construct predictive analytics, which can help understand how operations are changing over time. Regression and Neural models are the most used predictive modelling methods [35].

Digital twins have the ability to address smart farming challenges. This includes the performing of future predictions [36] using real-time monitoring systems, control and analysis. Digital twins make use of models that accurately depict an object's behavior throughout time [37]. To project unforeseen events, the models can also be tested with what-if scenarios [16]. Additionally, digital twins allow for the merging of models by setting up a shared model space that defines the correlation between models, enables data flow between models, and establishes a connection between the digital twin and the physical asset [38]. Moreover, creating connected physical objects and a digital twin, the digital twins can address the problem of seamless integration between IoT and data analytics [39].

Although digital twin technology is still in its early stages, literature shows that digital twins have potential to shift the animal husbandry's future by integrating smart farming technology which use real-time data manipulated by AI analyses, which can then fuel better business decisions, improve animal health and well-being, and maximize the return from farming resources.

III. Materials and Methods

Sheep farmers are having a challenge of providing healthy pasture for their animals due to climate change. Pasture growth depends on climatic conditions therefore the focus of this study is to develop a digital twin that predicts pasture growth based on predicted temperature, rainfall and soil moisture. The research methodology is implemented into three phases:

- Phase A – Developing predictive algorithms through data analysis, structure, and processing, and use the selected algorithm to develop a digital shadow.
- Phase B – Monitoring farm conditions on the farm to manage variables that affect pasture's growth.
- Phase C – Creating a digital twin with predictive models that are updated by real-time data to forecast pasture height and identify problems in advance, thus assisting a farmer to come up with quick solutions.

A. Phase A – Developing Predictive Algorithms

Predictive modeling is essential to the study as it forecasts future results. Due to unpredictable weather patterns brought on by climate change, farming has become more challenging. Predictive models are helpful in this situation. To make predictions, predictive models are built using previous data and new data sets. Predictive models were created in this study using regression and ANN machine learning algorithms.

1) Selecting suitable algorithm. For predicting climate, regression and ANN models are frequently employed [40], hence these were the only models investigated in the study. Developing a prediction model to track climate change requires a development of dataset which contains historical data of weather information. Climate change is monitored based on decades of the earth's atmospheric observation. Hence, the ten-year historical data of temperature and rainfall was used to develop the prediction models.

The study uses historical data from 2011 to 2020 gathered from [41] source, at the area where the farm is located. The same set of data was used on both algorithms and analyzed in MATLAB® to get insight into the data collected. After learning and being trained on data, both algorithms were used to create prediction models, and the results were compared to see which algorithm could be a better fit. Two predictive models on each algorithm were developed to predict average temperatures and rainfall for the year 2021.

Root Mean square Error (RMSE) is a measure of accuracy to compare forecasting errors of different models [42] and is commonly used as an error metric for numeral predictions. The lower the RMSE, the higher the accuracy of the model. The model performance is also determined by comparison of true and predicted response. Fig. 1 demonstrates the RMSE values obtained while training temperature predictive models using regression and ANN algorithm with the same data set.

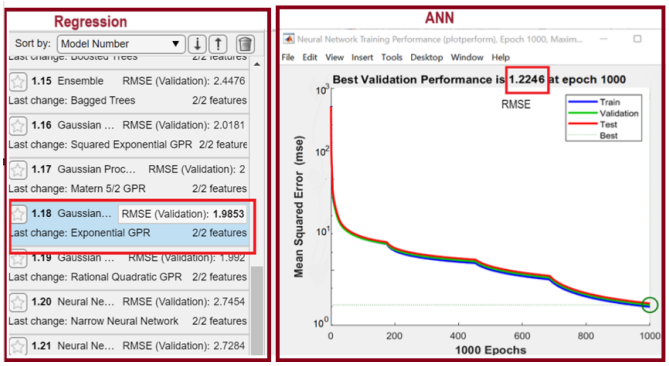

Fig. 1. The RMSE values obtained while training temperature predictive models with Regression and ANN algorithms.

After training the models, the predictions were performed for the first nine weeks of the year 2021. Nine-week duration was selected because pasture is ready for grazing at six to nine weeks after sowing. Therefore, having models that could precisely predict climatic conditions up to forage life cycle would be ideal.

2) Digital shadow development. The selected algorithm was then used to develop a digital shadow. Developing a digital shadow is the first stage in creating a digital twin [43]. Digital shadow is used to visualize operating, status, or process data that is gathered while the product is in use or during an ongoing process. Then, the digital shadow replicates the digital model, which is made up of all the data from the design and production phases and serves as an intelligent link to the digital twin [44]. The digital shadow development sets the foundation for a digital twin. A digital shadow was made of predictive models that predicted temperature, soil moisture, rainfall and pasture height.

The digital shadow was developed using historical data and collected data from the farm. The pasture is planted twice a year – in Autumn (March to May) and Spring (September – November). Thus, digital shadow was trained with data of both seasons of the year 2021 and the predictions were performed for Autumn season in 2022. The objective was to ascertain how temperature, soil moisture, and rainfall influence pasture growth. The readings were recorded weekly and prepared in spread sheets. Fig. 2 shows sample data collected for the month of April.

The digital shadow was composed of four different prediction models. Temperature and rainfall models were developed using historical data and were updated by data collect in the farm. Soil moisture and pasture height were developed by farm data. Fig. 3 shows how the models were structured. The soil moisture model is dependent on temperature and rainfall models and pasture height model is dependent on other three models.

		PASTURE DATA COLLECTION 2021		
		MONTH:April		
Plantation date: 15/03/2021				
	3rd wk	4th wk	5th wk	6th wk
	week14	week15	week16	week17
Date	2021/04/04	2021/04/11	2021/04/18	2021/04/25
AverageTemperature (°C)	25,86 °C	28,14 °C	26,86 °C	25 °C
Total weekly rainfall (mm)	1,9 mm	0,4 mm	0 mm	0,9 mm
Average soil moisture (SI)	4 SI	3 SI	2 SI	1 SI
Pasture height (cm)	18 cm	25 cm	31 cm	40 cm

March April May September October November

Fig. 2. Farm data collected for the month of April.

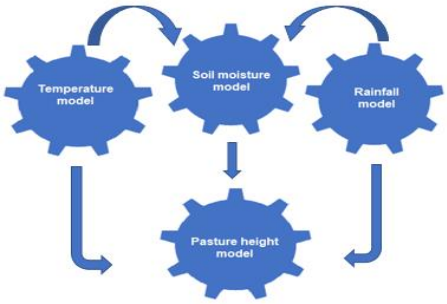

Fig. 3. Relationship between the models of the digital shadow.

Digital shadow sets the foundation of the digital twin. The results of the prediction models of the digital shadow determine whether the models could be trusted when implemented in the digital twin.

B. Phase B – Monitoring Farm Conditions

For a digital twin to exist there must be a physical system. The "smart farm" served as the study's representation of the physical system. IoT sensors were identified to monitor pasture growth and were integrated to create a smart farm as a link between the physical system and the digital counterpart. Sensors are also crucial to the development of digital twins as they gather information in real time that is utilized to create and update the prediction models. In the process of limiting factors that cause climate change, the selection of IoT sensors was based on devices which do not emit carbon footprint and waste. Cloud platform, IoT sensors and a gateway are the building blocks of the physical system.

1) Cloud platform: IoT sensors gather data and transmit it to cloud storage. ThingSpeak® was selected for use in this study because of its capabilities to transmit sensor data in real-time to the cloud [45]. The ability to pre-process and analyze the data using MATLAB® is another advantage of using ThingSpeak® [46].

2) IoT sensors: Sensors that monitor pasture growth were set up on the farm as part of the physical system. These include sensors that measure temperature, rainfall, soil moisture and pasture height. The sensors used are as follows:

- A weather station - measures temperatures and rainfall and to log the results in ThingSpeak®.
- A soil moisture sensor - measures the soil moisture content. It was programmed with ESP32 CAM to take the readings and send the results to ThingSpeak®.
- The ESP32 CAM - captures the images of the pasture to be interpreted in MATLAB® to calculate pasture height
- Raspberry Pi – runs the image processing script to calculate the height of the pasture based on the captured images and the result was logged into ThingSpeak®.

3) IoT gateway: The connection between IoT sensors and the cloud must be made through an IoT gateway. IoT gateway serves as a network router that directs data between IoT sensors and the cloud which enable internet connectivity. 4G LTE Wi-Fi router was selected as a gateway.

The complete physical system was the integration of IoT sensors, gateway and ThingSpeak®. The design of the physical system is shown in Fig. 4.

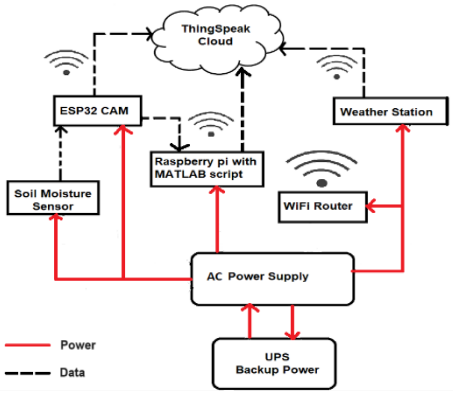

Fig. 4. Structural design of the physical system.

C. Phase C – Creating a Digital Twin Model

To test the chosen algorithm on the physical system and determine if it can be trusted when deployed on the physical system, creating a digital shadow was the first stage in creating a digital twin. The design of the digital shadow clarified the scenarios of the physical system. Set of digital shadow models were helpful to understand the structure and the behaviour of the system in the physical world as these models were used to create a digital twin to perform predictions for the future.

The design of the digital twin facilitates the activities, monitoring and digital control of operations in all the connections of the system [47]. The digital twin development is comprised of two platforms [47] - a physical system and the digital platform. Physical system is basically the setup of IoT sensors that collect data and store the result on a cloud platform. Running systems in real-time distinguishes the digital twin from the digital shadow [48]. The digital twin is developed in three phases, namely [49]:

- data collection and monitoring;
- data storage, and

- data analytics and predictive modelling.

IoT sensors allow real-time monitoring and store data in ThingSpeak® which enable the link between the physical system and digital platform. The real-time data is used to update the prediction models in MATLAB® and the updated models are used to perform the predictions in SIMULINK® platform. The process in demonstrated in Fig. 5.

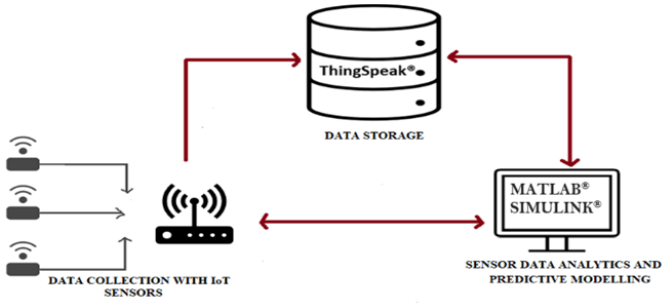

Fig. 5. Digital twin development process.

The digital twin is made up of four predictive models which are updated by sensor data which is retrieved in ThingSpeak® in in real-time. The models are built and trained in MATLAB® platform. The link between MATLAB® and SIMULINK® allow smooth transfer of data to update models and enable predictions. Fig. 6 summarizes the process of analysing sensor data and using the data to keep prediction models up to date.

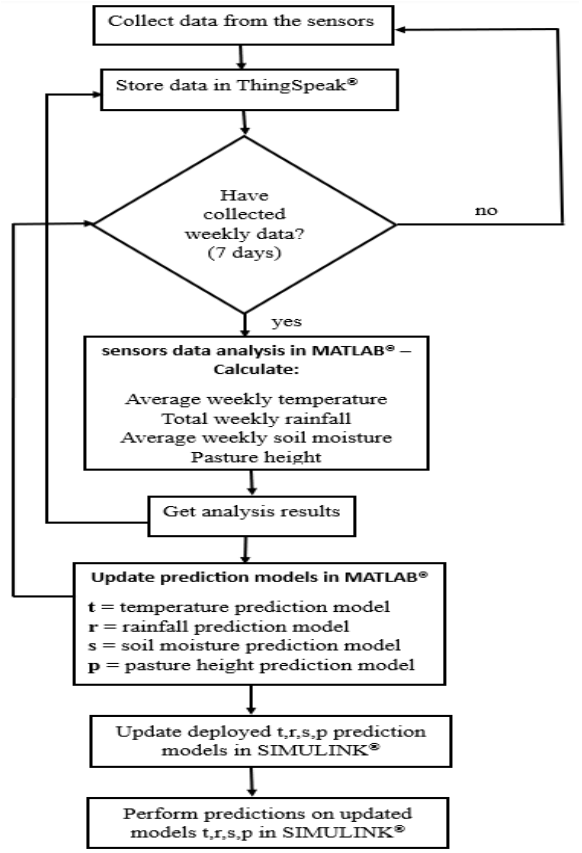

Fig. 6. Data analysis and predictive modelling in the digital twin.

The digital twin model is developed with models from the digital shadow, the difference is that digital twin models are kept updated with real time data from IoT sensors. Fig. 6 shows that sensors gather live data and store it in ThingSpeak® cloud. This data is then analyzed to get weekly statistics because pasture height is measured weekly. SUMLINK® platform makes it easy to transfer data from ThingSpeak® and update the predictive models. The digital twin model portrays the dependencies between models.

To perform the predictions, the digital twin accepts the duration of the prediction as the input (year and the week). The temperature, rainfall and soil moisture prediction models will then perform predictions for the specified duration. Pasture height prediction model will make predictions based on the output of the three models (temperature, rainfall and soil moisture). Fig. 7 demonstrates how digital twin is modelled in SIMULINK®.

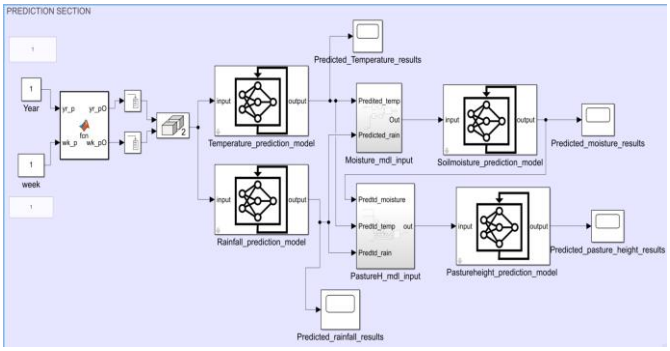

Fig. 7. Digital twin modelled in SIMULINK®.

IV. Results and Discussions

This section shows the results obtained in the process of developing the digital twin to predict the pasture height, starting from algorithm section, digital shadow development until the digital twin development. The analysis of the results will also be discussed.

A. Comparison of the Algorithms

Both regression and ANN algorithms were investigated to determine which one performs predictions better. RMSE was used as a measure of accuracy to compare prediction errors on temperature and rainfall predictive models. After obtaining the predicted values from the prediction models, these values were compared with the observed values to evaluate the performance of the model.

It is important to perform model evaluation because it helps to assess the efficiency of the model during the initial research phases. The model evaluation was therefore conducted using two evaluation metrics, namely: correlation coefficient and estimated error. Correlation coefficient measures the relationship between two variables [50]. The values range is between -1 and 1. The closer the calculated value moves to 1, the stronger the relationship between two values and vice versa. Prediction error is the difference between the observed value and the predicted value [51]. The smaller the difference, the better. The results are shown in Table I.

TABLE I. COMPARISON ON REGRESSION AND ANN ALGORITHMS WHILE DEVELOPING TEMPERATURE AND RAINFALL PREDICTION MODELS

	Temperature model		Rainfall model	
Metric	***Regression***	***ANN***	***Regression***	***ANN***
RSME	1,985	1,225	5,557	1,746
Correlation	0,645	0,966	0,945	0,976
Estimation Error	±5,03	±1,76	±22,21	±9,31

Table I shows the results obtained while developing temperature and rainfall prediction models using both prediction algorithms. The outcome demonstrates ANN algorithm performing better with lower RMSE and lower estimation error. It further proves itself with a higher correlation value which symbolize a strong relationship between the predicted and observed values. Therefore, ANN algorithm was selected as an algorithm to develop prediction models on the study.

B. Digital Shadow Development

Developing a digital shadow is an important stage towards developing a digital twin. The effectiveness of the digital twin to be created is determined by the results from the digital shadow, as the digital twin will employ the same algorithm as the digital shadow. Thus, ANN algorithm was used to develop a digital shadow. The digital shadow was made up of four prediction models – temperature, rainfall, soil moisture, and pasture height prediction models which were developed using gathered farm data. The digital shadow model predicted the expected pasture height based on the predicted temperature, rainfall and soil moisture. Table II demonstrates the results obtained.

TABLE II. DIGITAL SHADOW PREDICTION RESULTS

Prediction model	***Prediction error***
Temperature	±1.67 °C
Rainfall	±5.9mm
Soil moisture	≤4si
Pasture height	13cm (max)

Table II demonstrates the results obtained in the predictions of the digital shadow. Pasture height prediction model depends on the temperature, rainfall and soil moisture models to perform predictions. The ANN algorithm proved to perform better than regression for predictions, however there are uncertainties related ANN prediction models. The problem with ANNs is that is no clear understanding on how they analyze patterns of data to give the output on the predictions; they give final result [52]. This is proved with the outcome of the digital shadow model. Temperature and rainfall prediction model are expected to perform better than the other models as they were trained with more data than others. Nonetheless, soil moisture prediction model still had a lower prediction error than the rainfall prediction model. Hence this could be justified about changing rainfall patterns which makes the training of the models difficult to analyze data.

The other problem is that ANNs need a lot of data to train the models for them to work efficiently. Pasture height prediction model in the digital shadow anticipated the final pasture height of 59cm. The observed pasture height was 72 cm, and the highest prediction error was 13 cm. The reason of a higher prediction error in pasture height prediction model is that, the model was only trained with two seasons worth data. Thus more data was needed to improve its efficiency, including the soil moisture prediction model. Even though the model predicted a lower pasture height but the overall data seems promising. Therefore these models could be trusted in the digital twin, more data is to improve the models efficiency.

C. Digital Twin Development

Digital twin is made up of a physical system and a digital platform. The digital twin development was composed of three phases which are: data collection, data storage, and predictive modelling.

1) Data collection. The physical system was made up of IoT sensors which were set up on the farm to gather data. The structure of the physical system in shown on Fig. 8.

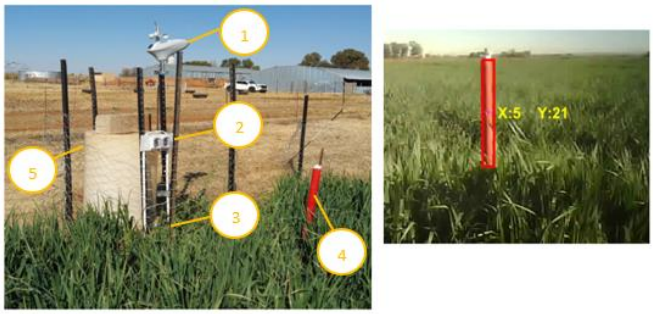

Fig. 8. Structure of the physical system on the farm.

Fig. 8 presents the physical system made up of IoT sensors that build a smart farm. *Label 1* is the weather station which is responsible for collecting temperature and rainfall data. *Label 2* is the ESP32 CAM which captures pasture images for height calculations. *Label 3* is the soil moisture sensor that measures the moisture content. *Label 4* is the pole which is helpful in image processing script that interprets image properties for pasture height calculations. The pole had a fixed height of 90 cm. As the pasture grows, the portion of red pole was covered by green pasture from the ground. On the captured image, the height of the red portion that was not covered by the pasture was calculated (Y coordinate), and the result was subtracted from the fixed height of the pole (90 cm) to get the actual height of the pasture. The captured image was processed in MATLAB® run on the Raspberry Pi. The Wi-Fi modem acted as IoT gateway to enable data transfer and connection on the devices. The modem, Raspberry Pi and power supply were placed in the container on *label 5*.

2) Data storage. Live data was retrieved from the sensors and stored in ThingSpeak®. This data was then analysed weekly and stored in a different channel. Weekly data was important in the study as it was used to update the prediction models. The weekly data is shown in Fig. 9.

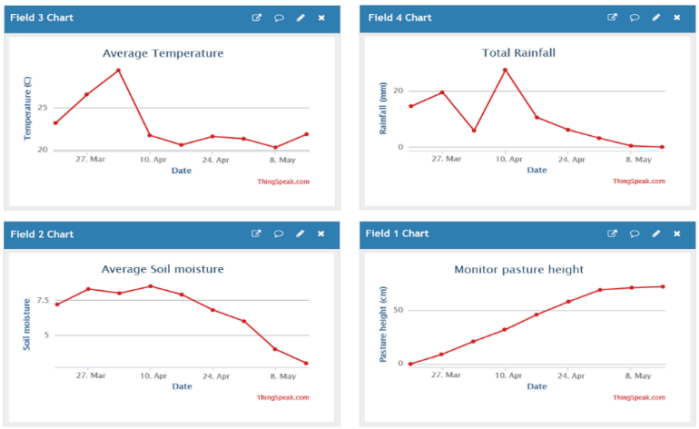

Fig. 9. Weekly data in ThingSpeak®.

3) Predictive modelling. The digital twin was composed of four prediction models from the digital shadow which are now updated by sensor data. Pasture height prediction model depends on three parameters which are temperature, rainfall and soil moisture. Thus, the pasture height prediction model was provided with new data of predicted average temperatures, predicted total rainfall, and predicted average soil moisture to perform the predictions of the next season. The predictions were done for the year 2022 for Spring season. The prediction started from the 38th week and looped through until the 46th week, since the pasture growth takes nine weeks. The prediction results are shown in Fig. 10.

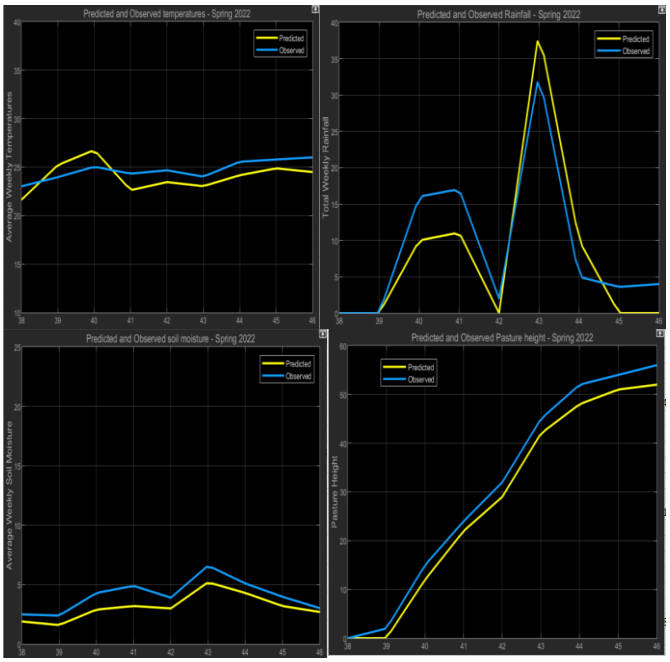

Fig. 10. Prediction results of the digital twin models.

On the presented outcomes, temperature and soil moisture prediction models showed good performance with a prediction error of ±1.62 and -1.7, respectively. Rainfall prediction model had a prediction error of ± 6.03, which was slightly higher as compared to other prediction models. The results on the rainfall prediction model signify the impact of changing weather patterns. However, the results of this model demonstrated a good outcome as predicted values and observed results showed a close correlation.

Based on the predicted temperature, rainfall, and soil moisture, the prediction of the pasture height was conducted for the duration of pasture growth. The aim was to predict the expected pasture height which was tracked from the plantation date. The analysis is demonstrated on Table III.

Table III shows that the prediction error of the model ranging between 0 and -4. Even though the observed pasture height was higher than the predicted outcome, the predicted pasture height represents a good outcome from the model, meaning there will be enough feed for the sheep. Thus the digital twin successfully predicted pasture height by integrating temperature, rainfall and soil moisture prediction models.

TABLE III. ANALYSIS OF PREDICTED PASTURE HEIGHT RESULTS

Week	*Predicted pasture height (cm)*	*Observed pasture height (cm)*	*Prediction error*
38	0	0	0
39	0	2	-2
40	12	15	-3
41	22	24	-2
42	29	32	-3
43	42	45	-3
44	48	52	-4
45	51	54	-3
46	52	56	-4

V. CONCLUSION

The aim of the digital twin development was to predict pasture height for the future to determine if there will be enough feed for the sheep. The digital twin model was proposed after determining that sheep farmers struggle to keep their animals alive due to improper pasture management caused by changing farming seasons due to climate change. Soil moisture predictive model was successfully implemented and integrated with temperature and rainfall predictive models to acquire anticipated pasture height. ANN machine learning was helpful in developing predictive models for forecasting. The study also shows how AI and IoT technologies are collaborated to develop real-time systems with predictive models. Thus, the results show a digital twin made of real-time monitoring of the pasture growth with predictive models can assist the farmer in taking proper decision on time thus improving management strategies.

Dept. Information Management, National Kaohsiung Univ. of Science and Technology, Kaohsiung, Taiwan, ROC[2]

***Abstract*—The evolution of data management systems has witnessed a paradigm shift towards dynamic and temporal representations of relationships. Graph databases, positioned as key players in managing highly-connected data with a fundamental requirement for relationship analysis, have recognized the need for incorporating temporal features. These features are crucial for capturing the temporal dynamics inherent in various applications, offering a more comprehensive understanding of relationships over time. This theoretical exploration emphasizes the importance of incorporating temporal dimensions into graph data warehousing for contemporary applications. Temporal features introduce a dynamic dimension to graph data, enabling a more nuanced understanding of relationships and patterns over time. The integration of temporal features in graph data management and analysis not only addresses the dynamic nature of contemporary applications but also contributes to enhanced modeling and analytical capabilities.**

***Keywords*—Data warehousing; graph database; graph warehousing; social computing; temporal data**

I. Introduction

The pervasive expansion of social media platforms has led to the establishment of a global conduit, as explored in study [8], amalgamating a plethora of data, insights, and principles concerning product details, societal norms, and leisure suggestions. Consequently, this proliferation has facilitated the emergence of influential online personalities within the digital community. Comprehending the dynamics of this cyber-community is imperative for addressing societal challenges such as counter-terrorism, cyber warfare, and cyberbullying, while concurrently fostering adept management practices conducive to human welfare. Hence, an internal framework for delineating social networks is indispensable for advancing scholarly understanding and practical engagement with the complexities of the digital realm [10]. The evolution of data management systems has seen a paradigm shift towards dynamic and temporal representations of relationships.

Graph databases are aimed at dealing with highly-connected data that comes with an intrinsic need for relationship analysis [1] [2]. Being a prominent player in this landscape, they have increasingly recognized the need for temporal features to capture the temporal dynamics inherent in various applications. When we have a specific starting point or at least a set of points to start with (nodes with the same label), they are well equipped to traverse relationships. And the obtained graph structures have given rise to numerous business opportunities and applications leveraging the networking infrastructure [14] [18]. Instances comprise customer relationship management (CRM), cloud computing and its services, enterprise resource planning (ERP), supply chain management (SCM), and business intelligence (BI).

In the realm of contemporary data management, the inclusion of temporal features has emerged as a critical aspect [7][9][11][12][15][16][19][22][25][30][31][32], especially in the context of graph data [34][35]. Incorporating temporal features in graph data management and analysis allows for a more accurate modeling of influence dynamics, capturing changes in social structures and information dissemination patterns. We give some examples to explain this point:

1) Social networks and influence dynamics: Social networks are inherently temporal, with relationships evolving over time. Incorporating temporal features in graph data allows for a more accurate modeling of influence dynamics, capturing changes in social structures and information dissemination patterns.

2) Financial systems and transactional analysis: In financial applications, understanding the temporal aspects of transactions is crucial. Temporal features enable the identification of patterns related to fraudulent activities, market trends, and the evaluation of investment strategies.

3) Healthcare and patient journey analysis: Temporal features play a pivotal role in healthcare analytics by providing insights into the temporal progression of diseases, treatment effectiveness, and patient outcomes. This temporal perspective enhances the precision of predictive modeling and decision support systems.

This theoretical exploration delves into the importance of incorporating temporal dimensions into graph data warehousing for contemporary applications. Temporal features provide a dynamic dimension to graph data, enabling a more nuanced understanding of relationships and patterns over time. This paper discusses the implications of temporal features for various domains, outlines challenges in their integration, and highlights potential benefits for on-line analytical processing.

II. Related Works

The primary distinction between relational and graph databases lies in their respective methodologies for storing relationships among entities or objects. Traditionally, relational databases use predefined relationship type structures (i.e., by relationship table definitions) to store relationships, while in a graph database, relationships are stored at the individual object

level [33]. The data in a relational database can be deduced to create a graph database as we have discussed in [29]. Commercial graph database vendors, like Neo4j (http://neo4j.com), also offer ETL (Extraction, Transformation, and Loading) tools for transforming relational database into their graph database products (e.g., https://neo4j.com/labs/etl-tool/1.5.0/) [17].

For example, in Fig. 1(a), there is a relational database modeled by the traditional Entity-Relationship Model (E-R Model), which concerns the relationship type <Enroll> (in the relation Enroll) between entity types Student and Course.

Conversely, in a graph database, relationships between any two instances of objects can be dynamically encoded. Illustrated in Fig. 1(b), beyond the relationships encompassed within the <Enroll> relationship type, a graph database permits users to introduce relationships such as "*roommate*" between John and Alex, "*classmate*" between Tom and Joe, "*friend*" between Mary and Alex, and a directed relationship labeled "*prerequisite*" from Algorithm to Fintech.

The relationships depicted in Fig. 1(a) exhibit a greater degree of "staticity," as they remain unchanged throughout the entirety of the semester. In contrast, Fig. 1(b) encompasses a greater diversity of "dynamic" relationships, reflecting various aspects that may evolve or change over time. Based on Fig. 1(b), suppose the relationships have been extended with temporal features and transformed into the temporal graph as shown in Fig. 2, where Tom studied the Fintech at t_3 (a course offered by Dr. Liu), but Alex studied the course at t_8 (offered by Dr. Li). Rigorously speaking, the system should not deduce Tom and Alex as classmates even though they have studied the same course Fintech, as they did not meet each other in their classes (different class timings).

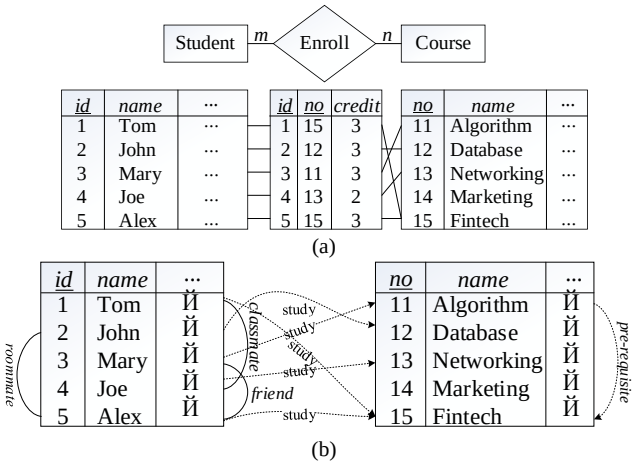

Fig. 1. (a) Conventional relational database models relationships between entity types. (b) Graph database models relationships between object instances.

A graph consists of two fundamental components:

1) A set of vertices (also known as nodes): Representing selected objects.

2) A set of edges (also called links): Representing relationships between objects. Directed edges are represented as *arcs*, while undirected edges are depicted as *edges*.

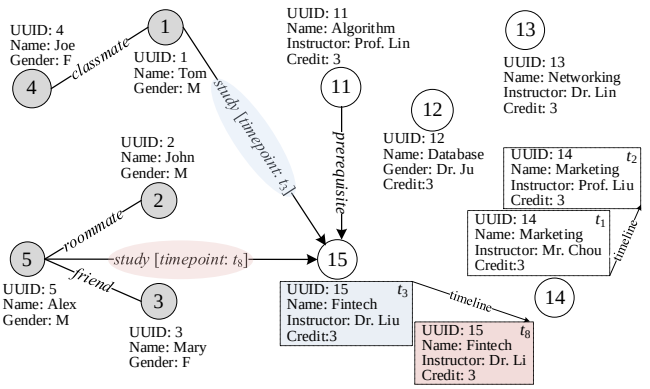

Fig. 2. A temporal graph database used to model the relationships between object instances.

Traditionally, social networks are depicted using a graph structure that encompasses data relating to all participating objects and their interconnections. These foundational concepts establish the framework for describing the structure of a social network using a graph. Additional information pertaining to vertices and edges, acquired through assignment or derived from measurement, is referred to as *properties* (or *attributes*). Properties can be assigned by humans or calculated from the graph or other properties.

As posited by Vicknair *et al.* (2010) [33] and Ho, Wu, & Liu (2012) [15], the interactions and engagements of netizens within social networks can be effectively represented within established graph database management systems. When cyber-communities are structured within a graph database framework, the identification of opinion leaders across various domains or cyber warriors can be facilitated through analytical inquiries, comparing their interstitial behaviors and relationships. Moreover, given the maturity of relational data warehousing technologies, synergizing these methodologies enables the exploration of business intelligence inherent within social networks. This convergence, known as *social business intelligence*, harnesses the combined capabilities of graph databases and relational data warehousing technologies to conduct online analytical processing (OLAP) and unveil hidden insights within social networks.

Sahu, *et al.* (2019) [20] performed an extensive survey study on how graphs are used in practice, and revealed surprising facts of the increasing prevalence across many application domains. Zhao *et al.* (2011)[36] introduced the concept of *graph cube*, and presented a novel data warehousing model designed to facilitate OLAP (On-Line Analytical Processing) queries on extensive multidimensional networks. Sakr *et al.* (2021) [21] even posited that the future of data processing is a big graph. Through the incorporation of temporal features into graph databases, we posit that graph-related systems will emerge as highly potent tools for managing interconnected data in modern applications.

Different from the traditional model of social networks, we assume there are *temporal properties* in some vertices and lines, and then propose a rigorous model for the challenge of consistent graph management and graph data warehousing by the following observations:

1) Temporal graph data are indispensable in social substance and related contexts [29], as social networks form and evolve gradually through the operations of social processes along the timeline of every participant [3]. The contextual frameworks in which social networks are formed play a pivotal role in comprehending the dynamics of network inception and the ensuing implications for individuals, groups, and organizations. For example, Brodka *et al.* (2011, 2013) [5] [6] utilize temporal data to devise a methodology aimed at elucidating the evolutionary trajectories of groups within social networks. This approach enables the discernment of group dynamics encompassing formation, growing, splitting, shrinking, continuing, merging, and dissolution.

2) Currently, most of the research on social networks has been studied without considering time and the dynamically changing status of objects (and their relationships).

3) Since there is already well-developed temporal data management in contemporary relational database management systems, it is the right time to embark on the study of business intelligence hidden in *temporal graphs*.

Graph warehouses, distinct from graph database management systems, encompass rich semantics pertaining to object relationships, facilitate efficient feature extraction and indexing functionalities, and offer flexible summarization approaches from diverse perspectives. This enables the grouping or clustering of subgraphs, thereby providing nuanced access to business intelligence pertaining to network types. Through a comprehensive integration of attribute aggregation and structural summarization within multidimensional networks, their approach yields insights and structure-enriched aggregate networks across varied multidimensional spaces.

However, despite the advancements in relational temporal technologies, their formal extension or adaptation to the domain of graph databases remains largely unexplored. Consequently, temporal considerations have been largely overlooked in the majority of related studies.

In this paper, we elucidate several scenarios to underscore the potential for imprecise analytical outcomes stemming from the absence of temporal considerations. Subsequently, we endeavor to present a formal definition for a temporal graph database model, extending the temporal data warehousing concept into the domain of temporal graph warehousing. Additionally, we provide formal definitions for the fundamental elements of a temporal graph warehouse.

Although temporal graph databases are powerful for dealing with interconnected data, they are not suited for traversing the whole graph when it contains tremendous vertices and relationships from performance viewpoints. Therefore, when we need to analyze temporal graph data based on some criteria, a network or graph is usually generated (for a specific time slot or interval) through a graph query posed on the temporal graph database.

Our principal focus lies in delving into temporal graphs beyond mere structural delineations, aiming instead to encapsulate their evolutionary trajectories over time and discern the underlying social dynamics propelling their transformations. This endeavor is geared towards comprehending the temporal evolution of social networks and elucidating the processes involved in their formation, persistence, and dissolution.

III. A Formal Definition of the Temporal Graph Model

By conceptualizing vertices and edges (including directed *arcs* and undirected *edges*) as entities and connections respectively, objects sharing similar characteristics can be grouped into *object types*, and their connections of similar nature into *relationship types*. If the historical evolution of object types can be meticulously recorded and managed, these object types can be elevated to *temporal object types*. Through such temporal object types, it is envisaged that precise online analytical processing of interlinked object relationships can be facilitated.

Furthermore, given the potential existence of multiple relationships between two objects within a temporal graph, the model ought to manifest as a labeled multi-digraph. Each label corresponds to a distinct relationship imbued with associated attribute values, while each object possesses its own set of attribute values. Labels of identical nature can be categorized under the same relationship types, a framework that can be established through an extension of prior research endeavors [28].

Definition 1: A *temporal graph* is a multi-digraph with labeled vertices and lines (including directed *arcs* and undirected *edges*). Formally, it is an 8-tuple $G_T = (\Sigma_O, \Sigma_R, T, \mathcal{O}, \mathcal{R}, f_s, f_t, \Psi)$, where

1) Σ_O is a set of vertices, representing universal unique identifiers (UUIDs) of all the object instances in G_T.

2) Σ_R is a set of lines, generally denoted (p, q) (or $l(p, q)$ with label l), which include directed *arcs* of UUID pairs $(p \rightarrow q)$ and undirected *edges* of UUID pairs $(p–q)$ of every instance of relationship, such that $p, q \in \Sigma_O$.

3) $T = \{t_1, t_2, \ldots, t_i, \ldots\}$ is a set of time points.

4) $\mathcal{O} = \{ O_1^{t_j}(\mathcal{A}_1), O_2^{t_j}(\mathcal{A}_2), \ldots, O_i^{t_j}(\mathcal{A}_i), \ldots, O_n^{t_j}(\mathcal{A}_n)\}$ represents a set of *temporal object types* $O_i^{t_j}$ with schema $\mathcal{A}_i = (A_{i,1}, A_{i,2}, \ldots, A_{i,d(i)})$ of *degree* $d(i)$, such that each $O_i^{t_j}(\mathcal{A}_i) = \{o_{i,1}^{t_j}, o_{i,2}^{t_j}, \ldots, o_{i,k}^{t_j}\}$ contains a set of *temporal objects* of type $O_i^{t_j}$, where $o_{i,k}^{t_j} = (a_{i,1}, a_{i,2}, \ldots, a_{i,d(i)})$ represents an object instance of type O_i at time t_j with the universal unique identifier (UUID) k. Practically, object instances of the same type in a graph database are allowed to have different schemas.

5) $\mathcal{R} = \{R_1(\mathcal{B}_{R_1}), R_2(\mathcal{B}_{R_2}), \ldots, R_i(\mathcal{B}_{R_i}), \ldots, R_m(\mathcal{B}_{R_m})\}$ represents a collection of *relationship types* R_i with a schema $\mathcal{B}_{R_i} = (B_{i,1}, B_{i,2}, \ldots, B_{i,e(i)})$ of degree $e(i)$, such that each $R_i(\mathcal{B}_{R_i}) = \cup_{p,q \in \Sigma_O}\{r_{(p,q)}\}$ denotes a set of relationships of type R_i and $r_{(p,q)} = (p, q, b_{i,1}, b_{i,2}, \ldots, b_{i,e(i)})$, $b_{i,k} \in B_{i,k}$, is a relationship instance for a pair of UUIDs (p, q), p and $q \in \Sigma_O$. $\mathcal{B}_{R_i}$ can be empty, which implies that R_i lacks attributes and can also be represented as $R_i(\varnothing)$. For temporal applications, some $\mathcal{B}_{R_i}$ may have at least one attribute, e.g., *time-points*, used to store the active time points of a (p, q) relationship.

6) f_s: $\Sigma_R \rightarrow \Sigma_O$ and f_t: $\Sigma_R \rightarrow \Sigma_O$ are two mappings indicating the *source* and *target* object UUIDs of a relationship UUID pair.

7) $\Psi = \{\psi_{R_1}, \psi_{R_2}, \ldots, \psi_{R_i}, \ldots, \psi_{R_m}\}$ represents a set of mappings, such that ψ_{R_i}: $\Sigma_R \rightarrow \mathbb{B}_{R_i}$ is a mapping returning the tuple of attribute values $(b_{i,1}, b_{i,2}, \ldots, b_{i,e(i)})$ of a relationship (p, q) in Σ_R.

In a *temporal* graph, the presence of vertices and edges can vary over time. A vertex $v \in \Sigma_O$ and an edge $l \in \Sigma_R$ are not necessarily active in all time points. Additionally, a strict consistency condition must be upheld: If an edge $l(p, q)$, which may be directed $l(p \rightarrow q)$ or undirected $l(p–q)$, is active at time point t, then its endpoints p and q should be also active at time t. Formally this is expressed as $t(l(p \rightarrow q)) \subseteq t(p) \cap t(q)$ and $t(l(p–q)) \subseteq t(p) \cap t(q)$, where $t(e)$ denotes a function returning the active set of time points for e.

In this definition, a *temporal graph*, encompasses a variety of objects (e.g., individuals or affiliations) and their multilateral relationships of diverse relationship types (e.g., friendships or spouse relationships). Both objects and relationships may possess varying numbers of attributes. To facilitate graph or network analytics, modern comprehensive graph database management systems (GDBMSs) are furnished with specialized query language constructs for extracting attributes, relationships, or even transitive closures within networks. Users can formulate query statements by effortlessly expressing pattern matching or multi-hop navigation in social networks [8] [13]. However, these GDBMSs do not inherently support functionalities for temporal features. Therefore, our aim is to investigate such temporal features based on formally-defined characteristics and explore methods for simulating these functionalities through time-oriented relations.

To exemplify the concept of our temporal graph data model, we present the temporal graph, denoted as $G_T = (\Sigma_O, \Sigma_R, T, \mathcal{O}, \mathcal{R}, f_s, f_t, \Psi)$ in Fig. 3, where,

1) $\Sigma_O = \{2, 3, 5, 6, 7, 8, 101\}$, means there are 7 UUIDs for six persons and one conference.

2) $\Sigma_R = \{(2, 3), (2, 101), (3, 5), (3, 101), (5, 8), (5, 101), (7, 8), (7, 101), (8, 101), (6, 7), (6, 101)\}$. There are 12 UUID pairs for the relationships between persons and the conference.

3) $T = \{t_1, t_2, \ldots, t_{888}\}$.

4) $\mathcal{O} = \{O_1(A_1), O_2(A_2)\}$ = {*Person*(*UUID*, *Name*, *Gender*, *City*, *Affiliation*, *Degree*), *Conference*(*UUID*, *Name*, *Start_Date*, *End_Date*, *City*)}, where *Person*(*UUID*, *Name*, *Gender*, *City*, *Affiliation*, *Degree*) = {{(2, Luna, F, Taipei County, NTPU, MS)$_{t_1}$, (2, Luna, F, New Taipei, NTPU, MS)$_{t_2}$}, (3, Lora, F, Taipei, NTU, PhD)$_{t_2}$, {(5, Tom, M, Changhua, NCUE, MS)$_{t_1}$, (5, Tom, M, Changhua, NCUE, PhD)$_{t_2}$}, (6, May, F, Tainan, NCKU, MS)$_{t_2}$, (7, Ling, F, Tainan, NCKU, PhD)$_{t_2}$, (8, Ren, M, Kaohsiung, NKUST, PhD)$_{t_2}$} is an object type of degree 6, and *Conference*(*UUID*, *Name*, *Start_Date*, *End_Date*, *City*) = {{(101, 2020 ICDE Conference, 2020/04/20, 2020/04/24, 'Dallas, TX')$_{t_1}$, (101, 2021 ICDE Conference, 2021/04/19, 2020/04/22, 'Chania, Crete, Greece')$_{t_2}$} is an object type of degree 5, containing 1 object.

5) $\mathcal{R} = \{R_1(\mathbb{B}_{R_1}), R_2(\mathbb{B}_{R_2})\}$ = {*participate*(*timepoints*), *Friend*(∅)}, where *participate*(*timepoints*) = {(2, 101, [2020/04/20-2020/04/23]), (3, 101, [2020/04/20-2020/04/23]), (5, 101, [2020/04/22-2020/04/24]), (6, 101, [2020/04/22-2020/04/24]), (7, 101, [2020/04/20-2020/04/24]), (8, 101, [2020/04/21-2020/04/23])}; *Friend*(∅) = {(2, 3), (3, 5), (5, 8), (6, 7), (7, 8)}.

6) f_s: $\Sigma_R \rightarrow \Sigma_O$ *and* f_t: $\Sigma_R \rightarrow \Sigma_O$ are two mappings indicating the *source* and *target* objects of a relationship. For example, we may obtain $f_s((2, 101)) = 2$ and $f_t((2, 101)) = 101$.

7) $\Psi = \{\psi_{Participate}, \psi_{Friend}\}$ represents a set of mappings, where $\psi_{Participate}((2, 101))$ = ([2020/04/20-2020/04/23]), $\psi_{Participate}((3, 101))$ = ([2020/04/20-2020/04/23]), $\psi_{Participate}((5, 101))$ = ([2020/04/22-2020/04/24]), $\psi_{Participate}((6, 101))$ = ([2020/04/22-2020/04/24]), $\psi_{Participate}((7, 101))$ = ([2020/04/20-2020/04/24]), $\psi_{Participate}((8, 101))$ = ([2020/04/21-2020/04/23]), $\psi_{Friend}((2, 3)) = \emptyset$, $\psi_{Friend}((3, 5)) = \emptyset$, $\psi_{Friend}((6, 7)) = \emptyset$, $\psi_{Friend}((5, 8)) = \emptyset$, $\psi_{Friend}((7, 8)) = \emptyset$.

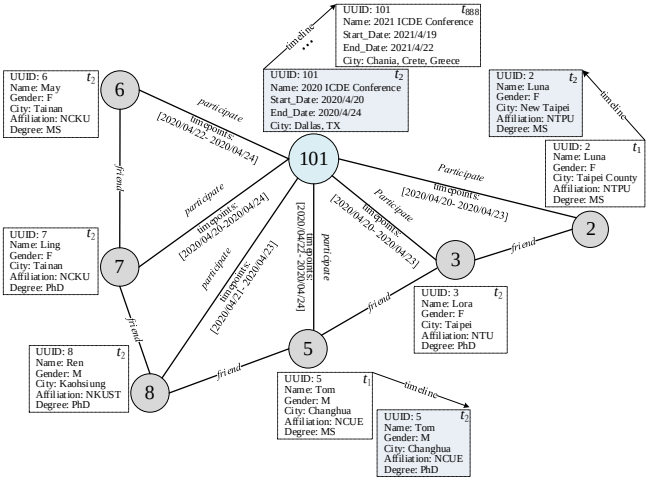

Fig. 3. A temporal graph representing ICDE 2020 Conference and the participants.

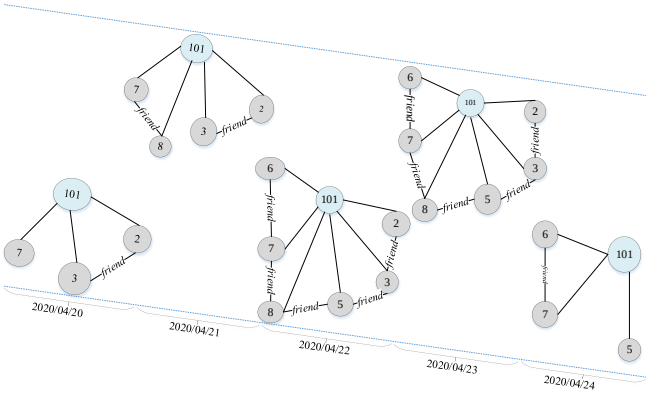

Fig. 4. The graphs of participants in each day of ICDE 2020 Conference.

Based on the *Start_Date* and *End_Date* of object 101, the graph of participants in each day of the *ICDE 2020 Conference* can be illustrated in Fig. 4. These subgraphs can be further

summarized as Fig. 5 depicts, where the top belt contains the participants' total aggregation, the middle and bottom belts respectively derive the participants' aggregation by their degree and gender analysis for every conference day. The number in a vertex denotes the number of participants, and the number beside an edge represents the number of relationships. Notice that the vertex with UUID = 5 (Name: Tom) participated in the 2020 ICDE Conference (held at t_2) from 2020/04/22 to 2020/04/24, and the degree of Tom at t_2 is PhD instead of MS. Besides, the city of UUID = 2 (Name: Luna) is 'New Taipei' instead of 'Taipei County' at t_2. Therefore, if the *City* is regarded as a temporal dimension, then 'New Taipei' should be used at t_2 for analytical processing.

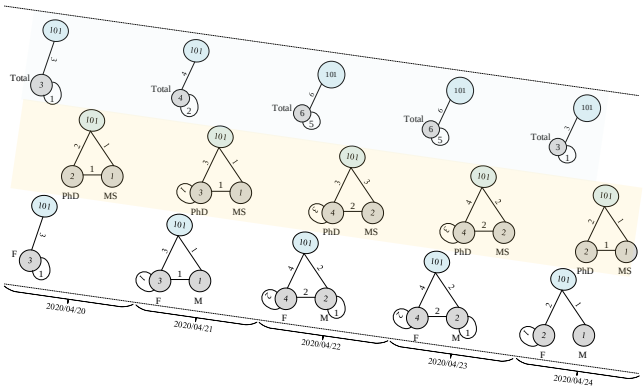

Fig. 5. Three graph summarizations of participants in each day of ICDE 2020 Conference.

When analyzing a large graph, displaying all its details in a single pass becomes impractical. Two overarching strategies exist for examining large graphs:

1) Generating summary descriptions of graphs using statistical methods.

2) Extracting smaller subgraphs based on interesting criteria, such that more sophisticated methods can be conducted.

While both strategies are considered in our study, greater emphasis is placed on the second approach. This involves addressing large graph structures through a divide-and-conquer strategy. In this method, a large graph is partitioned into smaller segments. If a segment remains sizable, it can be further subdivided into subsegments. This iterative process continues until the subsegments become sufficiently small for the application of more intricate methodologies. Descriptions of these smaller graphs prove valuable, offering insights into graph structures. Importantly, these descriptions can be amalgamated to yield a comprehensive understanding of graph structures.

Fig. 6 illustrates various options within the divide-and-conquer strategy. A sample graph is depicted, with different-colored areas denoting regions from which segments can be extracted. The most detailed partition contains vertices within the yellow area. One approach involves extracting graph *parts* to closely examine their interrelationships. Additionally, a decomposition process can be executed at a chosen level, employing vertex or edge partitions based on attribute values, thereby forming a *hierarchy*. When vertices are consolidated into a single vertex, a *reduction* of the graph is achieved.

In Fig. 7, we demonstrate a series of status changes of temporal graph reductions along a timeline when temporal features are introduced and considered for analytical processing. Such temporal tracking graph capability is helpful for group evolution discovery in social networks (e.g., like the work conducted by Bródka *et al.* (2011, 2013) [5] [6]).

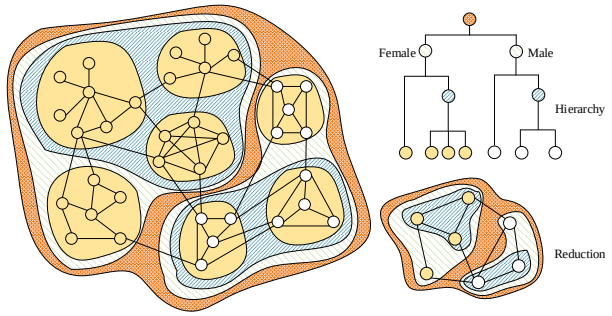

Fig. 6. Graph summarizations by hierarchy decomposition and reduction.

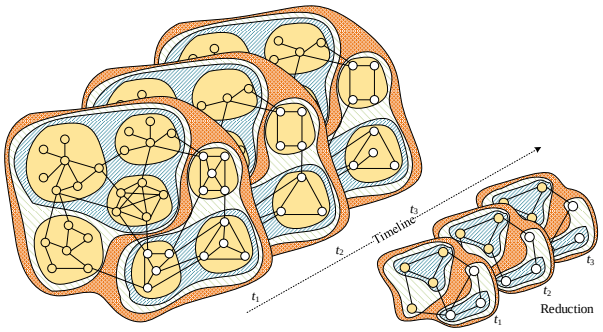

Fig. 7. A series of status changes of graph reduction along a timeline.

IV. Temporal Graph Warehouse Modeling

Since the data in a relational database can be deduced to create a graph database, the basic elements defined in Definitions 1 to 6 can also be employed for both the temporal relational data warehouse and temporal graph warehouse. For example, a temporal dimension can be constructed from attributes of a vertex type, and used for building a temporal graph cube later.

Recall that a line $l(p, q)$, including $l(p \rightarrow q)$ or $l(p–q)$, can be active in time t, only when two end-vertices p and q are active in time t. Therefore, we do not introduce temporal concepts into relationship types, and the dimensions constructed from attributes of relationship types are treated as ordinary dimensions in our model. As a relationship represents an event or action, the attributes of a line record the history itself. We use the time points contained in relationship types to construct an ordinary *time* dimension, which can be regarded as a counterpart corresponding to the *time* dimension constructed from attribute $\underline{T}$ of the fact table in relational temporal data warehousing (as discussed in Section IV).

In Fig. 8, we draw the temporal dimensions R^{t_1} and R^{t_2} for Taiwan, and their aggregated temporal dimension R^T in Fig. 9. Fig. 10 also depicts another ordinary dimension C for

representing a categorization of computer, communication, and consumer electronic products.

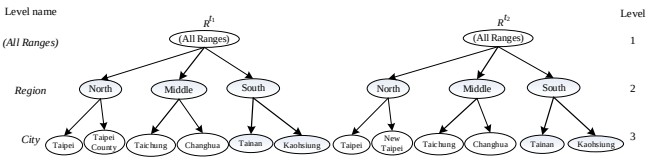

Fig. 8. The temporal dimensions R^{t_1} and R^{t_2} about *Taiwan*.

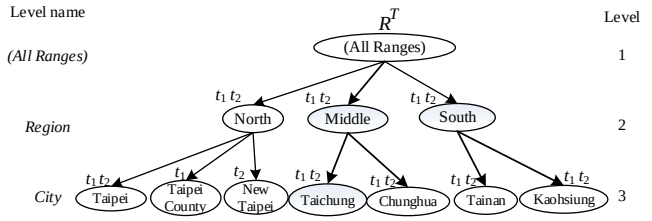

Fig. 9. The aggregated temporal dimension R^T.

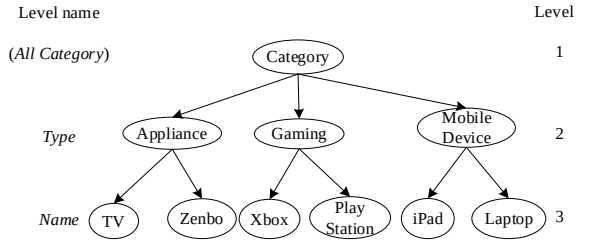

Fig. 10. The dimension *C* of a categorization of general electronic products.

In the following, we define the basic elements for temporal graph warehousing. These definitions are modified from our previous work of graph data warehousing [28]. Primarily, for facilitating multi-dimensional indexing in temporal graph warehousing, each temporal graph and its subgraphs are all allocated with a distinct identifier.

We establish the fundamental unit of a temporal graph cube, termed a *t-cell*, as follows.

Definition 2: A *t-cell* of time *t*, denoted $c^t = (t, K, x)$, defined on

- a temporal graph $G_T = (\Sigma_O, \Sigma_R, T, \mathcal{O}, \mathcal{R}, f_s, f_t, \Psi)$,
- a time point $t \in T$, and
- n aggregated temporal dimensions $(D_1^T, D_2^T, \ldots, D_i^T, \ldots, D_n^T)$, such that each D_i^T is a hierarchy of keywords, derived from some attribute values of $O_i^t(A_i) \in \mathcal{O}$, $1 \le i \le n$, is a subgraph of G_T, denoted $G_t = (\Sigma^t{}_O, \Sigma^t{}_R, T, \mathcal{O}, \mathcal{R}, f_s, f_t, \Psi)$, pointed (indexed) by a unique identifier x, with the following conditions hold:
  - $K = (K_1, K_2, \ldots, K_i, \ldots, K_n)$, such that $K_i \cap (D_i^t(0) \cup \{\text{'*'}\}) \neq \emptyset$, $1 \le i \le n$,
  - $\Sigma^t{}_O$ ($\Sigma^t{}_O \subseteq \Sigma_O$) contains vertices of type O_i^t, which have attribute values $c_i \in K_i$ at time *t*.
  - $\Sigma^t{}_R$ ($\Sigma^t{}_R \subseteq \Sigma_R$) contains all relationships (p, q) in G_t, such that these relationships have an attribute *timepoint* containing time *t* and $p, q \in \Sigma^t{}_O$.

In essence, a *t*-cell c^t contains a subgraph of G_T, generated through a graph query rooted in $(K_1, K_2, \ldots, K_n)$ for time *t*, with the subgraph referenced by *x*.

Example 1: Based on the graph depicted in Fig. 3, an example *t-cell* of time '2020/04/23', denoted c^t = (2020/04/23, ({2020 ICDE Conference}, {F, M}, {*}), *x*), defined on three aggregated temporal dimensions (C, S, R^T), where C is a dimension of conference names, S is a dimension of gender, and R^T is the dimension depicted in Fig. 9. The subgraph with their multilateral relationships (e.g., friend relationship) pointed by *x* can be illustrated in Fig. 11.

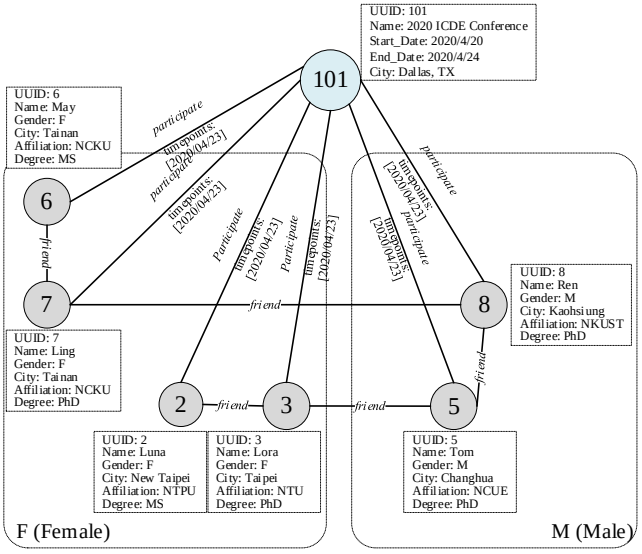

Fig. 11. A *t-cell* c^t = (2020/04/23, ({2020 ICDE Conference}, {F, M}, {*}), *x*) of time '2020/04/23'.

Definition 3: A *t-cell* $c^t = (t, K, x)$, defined over n aggregated temporal dimensions $(D_1^T, D_2^T, \ldots, D_i^T, \ldots, D_n^T)$ is termed an *m*-d *t-cell*, $0 \le m \le n$, if and only if there exist exactly m non-summary members K_i (i.e., $K_i \neq \{*\}$). When $m = n$ and $c_i \in D_i^t(h_i)$, where h_i denotes the height of D_i^t, for all $1 \le i \le n$, then c^t is referred as a *base t-cell*; otherwise, c^t is termed a *non-base t-cell*.

Definition 4: An *n*-dimensional *i*-d *t*-cell $a^t = (t, (a_1, a_2, \ldots, a_n), x_a)$ serves as a *parent* to another *n*-dimensional *j*-d *t*-cell $b^t = (t, (b_1, b_2, \ldots, b_n), x_b)$, if and only if the following conditions are met:

1) i = j - 1,

2) There exists exactly one index k, such that a_k is the parent of b_k in D_k^t and $a_l = b_l$ for all $l \neq k$, $1 \le l \le n$.

3) The graph indexed by x_b is a subgraph of the graph indexed by x_a.

Definition 5: A *temporal graph cube* $GC_T = (T, G_T, (D_1^T, D_2^T, \ldots, D_i^T, \ldots, D_n^T))$ for $G_T = (\Sigma_O, \Sigma_R, T, \mathcal{O}, \mathcal{R}, f_s, f_t, \Psi)$ defined over n aggregated temporal dimensions $(D_1^T, D_2^T, \ldots, D_i^T, \ldots, D_n^T)$, is a cube composed of all *t*-cells in $\{c^t{}_i = (t, K, x_i) | t \in T(0), c^t{}_i \in T(0) \times (\underset{1 \le i \le n}{\times} D_i^T(0))$, the subgraph indexed by x_i is a subgraph of $G_T\}$.

The main difference between a temporal relational cube and a graph temporal cube is the data contained in a *t*-cell. In a relational temporal cube, a *t*-cell is a tuple of values returned by respectively applying aggregate functions $f_j(C, M_j)$ on each measure in $M = \{M_1, M_2, \ldots, M_j, \ldots, M_k\}$, using each c_i of $C = (c_1, c_2, \ldots, c_i, \ldots, c_n)$, $c_i \in D_i^T(0) \cup \{\text{'*'}\}$, $1 \le i \le n$, as the filter of D_i^T . However, in a temporal graph cube, a *t*-cell is conceptually a subgraph of the original graph defined by a graph query using *K* as the slice condition (using K_i to slice the aggregated temporal dimension D_i^t).

An example depiction of a temporal graph cube $GC_T = (T, G_T, (R^T, C))$ is presented in Fig. 12, with *T* representing the *Time* dimension, and R^T and *C* representing the dimensions as depicted in Fig. 9 and Fig. 10, respectively.

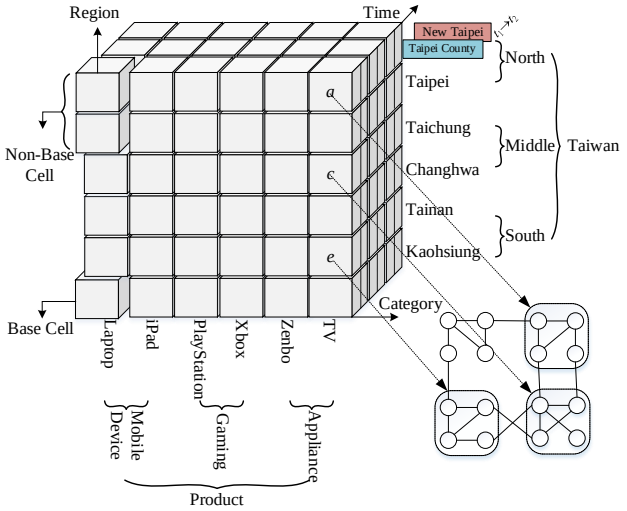

Fig. 12. An example of multi-dimensional temporal graph cube.

Each *t*-cell in Fig. 12 corresponds to a subgraph containing objects and their relationships defined by the intersected dimension members across all engaged aggregated temporal dimensions. For instance, *t*-cells *a*, *c*, and *e* respectively reference three subgraphs concerning the social network netizens residing in $\{(\text{Taipei County})_{t_1}, (\text{New Taipei})_{t_2}\}$ (in *North* Taiwan), {*Taichung*} (in *Middle* Taiwan), and {*Tainan*} (in *South* Taiwan), who purchased *TVs* on the same day (e.g., '2021/08/08' in the *Time* dimension), with their *friendship* relationships. If the purchase date precedes t_2, then *t*-cell *a* corresponds to the dimension keyword 'Taipei County'; otherwise, it corresponds to the dimension keyword 'New Taipei'. By selecting *t* = '2021/08/08', the system can generate these subgraphs for users respectively using the tuples (*t*, {New Taipei}, {TV}), (*t*, {Taichung}, {TV}) (*t*, {Tainan}, {TV}) as filters on the temporal graph cube. In contrast, in a traditional temporal relational cube structure, the cells just respectively store three numbers regarding the amounts of TVs bought by customers located in $\{(\text{New Taipei})_{t_2}\}$, {Taichung} and {Tainan} at time t_2.

V. Visualization and Summarization of Graph Cubes

Following the establishment of a temporal graph cube, all temporal dimensions or attributes associated with vertices and relationships can be leveraged to generate a summarization of all subgraphs defined by t-cells facilitating on-line analytical processing in social networking. For instance, if the vertices of Person (i.e., the participants of the 2020 ICDE Conference) in Fig. 3 are expanded and used to construct two dimensions, one for Degree (e.g., {MS, PhD}), and the other for Gender (i.e., {Female, Male}) as shown in Fig. 13. Then, any subgraph indexed by a t-cell defined on these dimensions can be used to derive the summarization of participants based on their degrees and genders, respectively (as shown in Fig. 14).

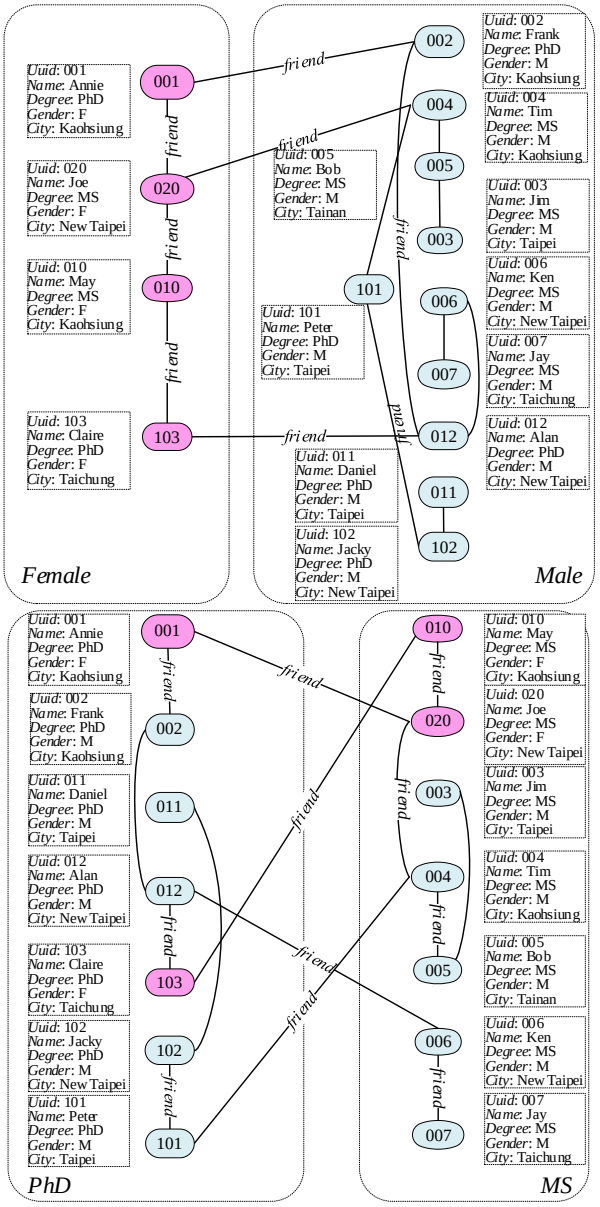

Fig. 13. Two views of the friendships for the dimensions Gender and Degree of Person at time *t*.

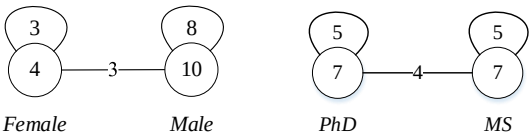

Fig. 14. Two summarizations of the *friendship* of Fig. 13 at time *t*.

Furthermore, it also offers the summarization of composite dimensions. For example, by regarding Gender × Degree = {*Female*, *Male*} × {*MS*, *PhD*} = {(*Female*, *MS*), (*Female*, *PhD*), (*Male*, *MS*), (*Male*, *PhD*)}) as a composite dimension, the summarization result at some time *t* can be derived as Fig. 15 illustrates. The intricate relationships depicted in Fig. 15 can be internally stored within the system, and utilized to execute an operation akin to the traditional DRILL-THROUGH operation in multi-dimensional query language like MDX [23] or MD^{2}X [26]. This functionality enables users to navigate from the summarized results shown in Fig. 15 to access the detailed information pertaining to each engaged vertex.

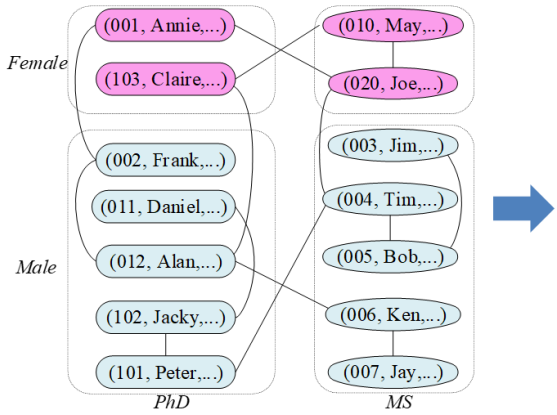

Fig. 15. The summarizations of Gender × Degree at time *t*.

Another intricate perspective concerning the cities of Person with Degree (i.e., {*PhD*, *MS*}) are situated at a certain time *t* is illustrated in Fig. 16. This view aids in computing the summarization for the Degree-*City* relationships at time *t* (as depicted in Fig. 17). Additionally, the perspective regarding the cities where individuals of different genders are located is provided in Fig. 18. This view assists in calculating the summarization for the *Gender-City* relationships at time *t* (as shown in Fig. 19).

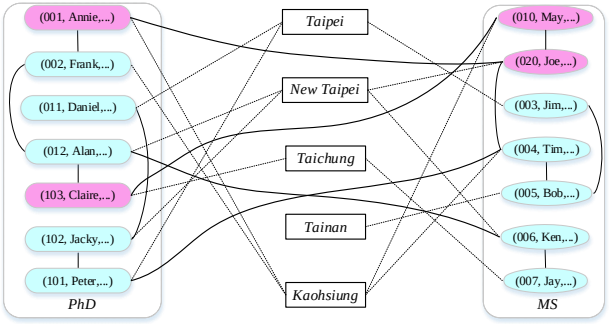

Fig. 16. A view of the Degree-City relationships at time *t*.

The drill-down and roll-up operations outlined in Definitions 3 and 4 can also be seamlessly executed within temporal graph cubes. For instance, Fig. 20 illustrates two subgraphs obtained by rolling up one level (along the dimension R^T) from Fig. 17 and 19, respectively.

In contemporary times, numerous fan pages proliferate across social networks, such as Facebook or Instagram, serving as platforms for gathering stakeholders' feedback, disseminating promotion content, or conducting sentiment analysis on valuable customers alongside their friends or followers. These shared comments or resources can be processed, structured and integrated into graph cube frameworks for social network analytics, leveraging the principles of temporal graph data warehousing [36] to generate insights for short-term analysis or long-term strategizing. Such features offer a wealth of opportunities for users to extract social business intelligence from graph databases substantially. The insights derived can be systematically harnessed for internal knowledge management and disseminated to relevant users with value-added feedback, thus perpetuating a virtuous cycle of information exchange and refinement [4] [24] [27].

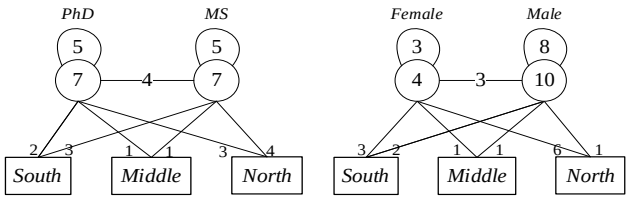

Fig. 20. One level rolling up (along the dimension R^T) for Fig. 17 and Fig. 19 at time *t*.

VI. Summary and Future Directions

We are currently observing an unparalleled expansion of interconnected data, emphasizing the crucial significance of graph processing in our society. We recognize that big graph processing systems integrating temporal features, alongside their associated data warehousing capabilities, are now fundamental components within numerous emerging data management ecosystems across various domains of societal relevance [21]. Our temporal graph model can be used to model many practical applications with abstractions. The incorporation of temporal features in graph data management and warehousing is indispensable for contemporary applications across diverse domains. By providing a dynamic perspective on relationships and patterns, temporal features enhance the analytical capabilities of graph databases, contributing to more informed decision-making processes. While challenges exist, ongoing research and technological advancements are addressing these issues, ensuring that the integration of temporal features continues to be a forefront consideration in the evolution of graph data management systems.

We hopefully expect the following benefits can be obtained through temporal graph warehousing:

1) Improved predictive analytics: Temporal features contribute to more accurate predictive models, allowing for the anticipation of future trends and events. This is particularly valuable in applications where timely decisions are paramount.

2) Enhanced pattern recognition: Temporal graph data facilitates the identification of recurring patterns and anomalies. This is valuable in diverse domains, including cybersecurity, where detecting temporal patterns of malicious activities is critical.

3) Temporal graph warehousing for historical analysis: Temporal graph warehousing enables the retrospective analysis of data, fostering a deeper understanding of historical trends and facilitating informed decision-making based on the evolution of relationships over time.

In Fig. 21, we depict an IoT network consisting of different sensors, where blue vertices are used for detecting water levels in the underpasses of a mega city, and gray vertices are used to monitor hill landslides of some geolocations. Assuming their status can be divided into *normal*, *warning*, and *dangerous*. When their status changes continuously along the timeline, a graph warehousing system can be built by deriving the t-cells of a temporal graph cube for each t moment, such that the number of dangerous spots can be visualized and calculated instantly for administrative decision makings. If the number of dangerous spots runs over a threshold (e.g., there are respectively 4 and 2 dangerous places with landslide and high-water levels detected in Fig. 22), then by drilling through to target the dangerous sensors, the city government can activate the alarm system for traffic control or an emergency procedure for possible evacuation.

Through integration with location-based service facilitated by mobile devices and leveraging a resource multiplexer, diverse multi-dimensional analyses for various types of networking business intelligence can be seamlessly conducted immediately following the integration of the temporal data stream. For instance, to prevent the Covid-19 pandemic, each vertex in Fig. 21 can also be regarded as an instance of type Branch to represent a branch of some chain stores, and customers entering a branch can also be represented by vertices of type Customer. By gathering the cellphone check-in information (arriving at irregular intervals) of all customers in a branch, our framework can help enterprise administrators derive the status of each branch, to grasp the number of customers at different timestamps. If a customer (with the cellphone number) is notified as suspected of being infected, then the temporal graph together with their multi-dimensional summarization result may effectively help administrators make a correct decision to fit the official epidemic prevention policy.

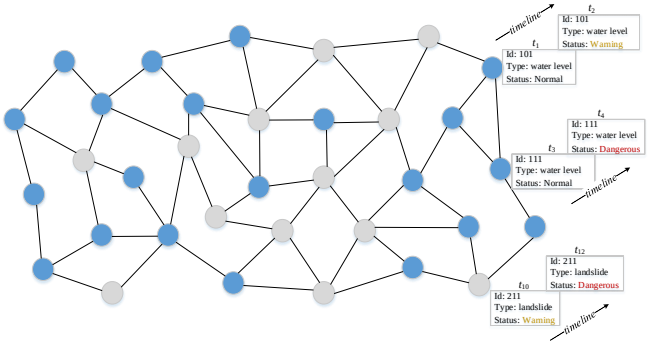

Fig. 21. An example IoT network consisting of different sensors.

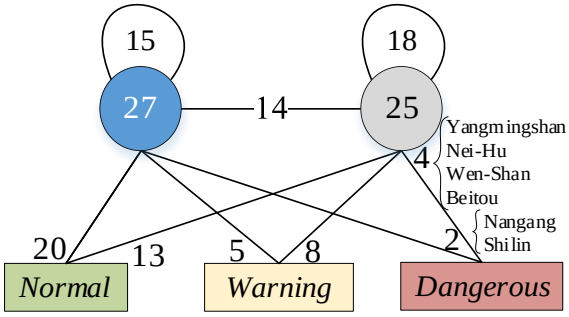

Fig. 22. Aggregations of sensor monitoring.

Based on our model, we also intend to build a temporal graph database based on our roadmap to record the inter-relationships between publicly traded companies in Taiwan and their business partnerships in related countries. Each company will be represented as a vertex with some important attributes announced in the Taiwan Stock Exchange (TWSE) or the corresponding affiliations in their native countries. Attribute values may be changed unpredictably, but should be reported in the official administration websites (e.g., the TWSE website in Taiwan). Therefore, we need to develop a crawler that periodically retrieves the official news of every company and, based on the following identified conditions, adjusts the attribute values, or adds new relationships with other mentioned companies:

1) If the content of the news talks about the adjustment of the company's status, then record the *new attribute values* as

another version according to the time point of the announcement.

2) If the news talks about a cooperation with another company, then add a *new relationship edge* between both companies with an edge attribute *start_time* for recording the starting time.

3) If the news talks about a strategic alliance of many companies, then add a *new relationship edge* between every pair of the engaged companies, such that each edge contains an attribute *start_time* for recording the starting time.

4) If the news content talks about the future vision or prediction of an entire industry concerning a lot of companies (which is called *concept stocks* in Taiwan), then add the concept term (like "EV (Electric Vehicle)" or "Metaverse") into an attribute named *concept*, which can be represented as a multi-valued attribute (in JSON format), since a stock can be regarded as involved in many *concept*s.

Graphs serve as ubiquitous abstractions that offer reusable tools for graph processing with applications spanning diverse domains. We believe that the temporal graph framework harbors boundless potential for the development of applications and business opportunities. In our future study, we will step forward to focus on the algebraic frameworks and the query language design for our model to help users create a core of temporal graph processing ecosystems for various applications.

Analysis of the Entropy of the Heart Rate Signal During the Creative Process

Ning Zhu
College of Landscape and Art Design, Hu'nan Agriculture University, Changsha 410128, Hu'nan, China

***Abstract*—Among the most important cognitive behaviors, creativity is essential for the flourishing of societies and mastery of various aspects of life around us. The effects of creative activities on the brain have only been examined in a few limited studies to date. The effects of such activities on the autonomic system have not been extensively studied. In this study, the changes in the heart rate signal before and during creative activity were examined using methods based on extracting chaotic and non-linear features from the heart rate signal. In particular, this study explores the qualitative changes in entropy during creative thinking and compares them with the resting state to determine whether or not creative activity is progressing. Based on analyzing the heart rate signals of 52 people while performing the three activities of the Torrance creativity test and comparing them with the resting state, the amount of approximate entropy and fuzzy entropy increased with the progress of the creative process. In contrast, comparing each stage of creativity to the previous stage during each activity in both types of entropy shows an increase in the average value at the end of each activity. The comparison of these steps with the last step two minutes ago shows completely incremental changes in activity 3 of both entropies. These entropies increase as the signal becomes more irregular and complex during the creative process. Our findings reveal significant increases in both approximate entropy and fuzzy entropy during creative activities compared to the resting state, suggesting heightened complexity and irregularity in heart rate dynamics as creativity unfolds. These results not only advance our understanding of the physiological correlates of creativity but also highlight the potential of heart rate entropy analysis as a tool for evaluating and enhancing creative abilities.**

***Keywords*—Heart rate signal; creative process; entropy; autonomous signals**

I. Introduction

Heart rate signal entropy analysis during creative thinking has emerged as a promising avenue of research in the field of cognitive neuroscience. The investigation of heart rate variability during creative tasks provides valuable insights into the physiological mechanisms underlying creative thinking processes [1-3]. By examining the complex patterns of heart rate fluctuations, researchers have been able to gain a deeper understanding of the dynamic interplay between the autonomic nervous system and cognitive processes involved in creative thinking [4-6].

The concept of entropy, borrowed from information theory, has been widely used to quantify the complexity and randomness of physiological signals, including heart rate variability. Entropy analysis allows researchers to assess the level of irregularity and disorder in the fluctuations of heart rate, reflecting the adaptability and flexibility of the autonomic nervous system. By examining the entropy of heart rate signals during creative thinking tasks, researchers aim to uncover potential associations between physiological dynamics and creative cognitive processes.

In recent years, many researchers have been interested in detecting cardiac behavior such as stress [7-9], anger and fear [10] or psychiatric diseases [11-13] by applying ECG signals processing. Using an electroencephalogram (EEG), Amin et al. [14] investigated brain behavior and dynamic neural activity during Raven's Advance Progressive Matrices (RAPM), which require strong cognitive reasoning to select a solution. Several studies have explored the relationship between heart rate signal entropy and creative thinking, providing valuable insights into the underlying mechanisms. For instance, a study conducted by Zakeri et al. [15] investigated the entropy of heart rate signals during a divergent thinking task. The results revealed a significant increase in heart rate entropy during periods of high creative output, suggesting a heightened autonomic response during creative thinking. These findings support the hypothesis that creative thinking is associated with increased physiological arousal and cognitive flexibility. In another study, Bakhchina et al. [16] examined the relationship between heart rate entropy and creative problem-solving. The researchers found that individuals with higher heart rate entropy demonstrated greater ability to generate creative solutions to complex problems. This suggests that heart rate entropy may serve as a potential biomarker for creative thinking abilities, providing a quantitative measure of the flexibility and adaptability of the autonomic nervous system.

An innovative method to distinguish between creativity states and electrocardiogram signals has been developed by Zakeri et al. [17]. In order to detect creativity states, 19 linear and nonlinear features of the cardiac signal were extracted. According to our results, the SVM was able to distinguish all three tasks from each other, particularly task 1, and reached a maximum accuracy of 99.63% in the linear analysis. Using the Alternative Uses Task adapted for EEG recording, Camarda et al. [18] investigated the relationship between functional fixedness and alpha-band power changes in the frontal and temporoparietal regions during creative idea generation. In the recent years, research has extensively explored the analysis of entropy in heart rate signals, particularly in the context of creative cognition. Studies have highlighted the application of entropy metrics, such as approximate entropy, symbolic entropy, and spectral entropy, to assess heart rate variability (HRV) in individuals with different cardiac conditions [19-21]. Additionally, the introduction of phase entropy has provided a novel method to quantify the complexity of HRV signals,

offering better discriminatory power and stability compared to traditional entropy measures [22]. Furthermore, the nonlinear analysis of HRV using entropy-based parameters has shown promise in predicting adverse cardiovascular events in hypertensive patients, enhancing diagnostic accuracy and providing complementary information to linear indexes [23]. This interdisciplinary approach to understanding the relationship between entropy, physiological signals, and cognitive processes underscores the potential for entropy studies to unify cognitive science and cultural evolution [24]. Bieth et al. [25] examined EEG activity during an adapted version of a classical insight problem task, the Remote Associates Test in which three words must be connected by finding a word between them. We were able to explore remoteness in semantic connections (by varying the remoteness of the word in the solution across trials) and insight solving. Cao et al. [26] used EEG to investigate neural activity patterns of designers with higher and lower fixation levels during creative idea generation. This was done with the goal of determining the neurological basis of design fixation. From a neuroscience perspective, these results may reveal the different neural activities involved in the occurrence of higher and lower degrees of design fixation. Recently, Eskine [27] investigated the activation of these networks after participants listened to music that was previously shown to enhance creativity. Using resting state electroencephalograms, they provide novel methodologies for investigating network activation in a creative cognition framework by activating networks deemed important in the creative process.

The exploration of heart rate signal entropy during creative thinking holds significant implications across education, psychology, and neuroscience. By identifying the physiological markers linked to creative processes, researchers can formulate interventions and training programs aimed at enhancing creative skills. Additionally, combining heart rate entropy analysis with other physiological and neuroimaging techniques may offer a holistic understanding of the neural mechanisms that underpin creative thinking. In conclusion, analyzing heart rate signal entropy during creative thinking provides a unique perspective on the interplay between physiological dynamics and cognitive processes. Investigating heart rate variability and entropy yields valuable insights into the adaptive nature of the autonomic nervous system during creative tasks. By examining the relationship between heart rate entropy and creative thinking abilities, researchers can deepen our understanding of the physiological foundations of creativity and potentially develop novel interventions to enhance creative thinking skills.

Creativity is a pivotal cognitive function that drives societal progress and enhances individual adaptability in various life domains. Despite its importance, the physiological mechanisms underpinning creativity, particularly within the autonomic nervous system, have not been extensively studied. Prior research has primarily focused on the neurological aspects of creativity, with limited investigation into how creative processes influence autonomic signals, such as heart rate variability.

This study aims to bridge this gap by employing approximate entropy and fuzzy entropy analyses to explore the changes in heart rate signals associated with creative thinking. We hypothesize that creative activities induce distinctive patterns of heart rate variability, reflecting the adaptive responses of the autonomic nervous system. By analyzing heart rate signals from 52 participants engaged in the Torrance creativity test, we seek to identify entropy-based markers that differentiate creative states from resting states and track the progression of creativity across different stages of the task. It is evident from examining the history of the subject that the EEG signal has always been of interest to researchers because of its creative activity. Due to the lack of sufficient research in the field of autonomous signals and its relationship with creativity, the present study has been conducted in order to fill a part of the existing gap in this field. In the process of developing creative thinking in the brain, the functioning of the brain affects other parts of the body, as well as the autonomic nervous system. In turn, this system is divided into two areas, sympathetic and parasympathetic, in which the parasympathetic nervous system has a significant influence on the cardiac signal. This study examines the complexity and behavior of the heart rate signal during creative thinking, after it has been extracted from the cardiac signal. This study aims to determine the amount of irregularity in the heart rate signal by analyzing two types of entropy. This study is organized as follows: Introduction is given in Section I. The method of data collection and the method of conducting the study are described in Section II. Discussion is given in Section III. Finally, Section IV concludes the paper.

II. Research Method

In this study, a 16-channel Powerlab data acquisition device was used to record ECG data. The electrocardiogram signal of 52 people was recorded simultaneously with the Torrance creative thinking test and with a sampling rate of 1000 Hz from lead 2. The output signal from the device was amplified and displayed in LabChart software, which is supporting software for displaying and processing different types of physiological data. Fig. 1 shows a view of the PowerLab device. All the subjects were right-handed, and they were asked to refuse to eat coffee before the recording process and to have enough sleep to prevent fatigue. Torrance's creative thinking test is a 30-minute test and includes three activities; each activity consists of 10 minutes. The whole test consisted of 32 minutes, which included two minutes of resting and 30 minutes of performing the test. Then, Labchart software was used to extract the heart rate signal. After processing, the 10-minute heart rate signal was divided into five two-minute periods to examine and compare each stage of the Torrance creative thinking test with the resting state. The characteristics of the subjects are recorded in Table I.

A. Torrance Creativity Test

As a general rule, creativity refers to the ability to generate new, useful, and impactful ideas or products. Divergent-thinking tests such as the Torrance Tests are widely used and validated and, therefore, are the natural choice. The word can be expressed in two ways: figuratively and verbally. For this study, we used verbal form B as a method of data collection. A written informed consent ensuring voluntary participation and confidentiality of data was obtained from subjects before they completed the English version of the TTCT-Verbal (Form B) [28]. A total of six activities were included in the instrument: Activity 1 – Asking (posing questions about the pictured action for 2 minutes); Activity 2 – Guessing causes (making predictions

about the cause of the action, 2 minutes); Activity 3 – Guessing consequences (predicting the consequences of the action, 2 minutes); Activity 4 – Product improvement (developing ideas for improving a toy monkey, 2 minutes); Activity 5 – Unusual uses (finding new uses for bottles, 2 minutes); and Activity 6 – Just suppose (thinking of potential ramifications for an improbable situation, 2 min) [29]. Under the supervision of trained research assistants, the instrument was administered collectively. Fluency (number of relevant responses generated), flexibility (number of categories reflected in responses, according to the categories outlined in the scoring manual), and originality (based on the frequency of responses). Responses generated by less than 2% of the sample were awarded two points, responses generated by 2% to 5% of the sample were awarded one point, and responses generated by more than 5% were awarded zero points) [30, 31].

B. Approximate Entropy

Approximate entropy analysis provides a means to quantify the regularity and complexity of heart rate signals during creative thinking. By assessing the variability and unpredictability of heart rate dynamics, ApEn offers insights into the autonomic nervous system's adaptability during creative tasks. Understanding these physiological patterns through ApEn analysis can reveal the underlying mechanisms that support creative thinking. Additionally, integrating ApEn analysis with other physiological and neuroimaging techniques can enrich our understanding of the neural and physiological correlates of creativity, leading to the development of targeted interventions to foster creative abilities. Statistically, approximate entropy measures the degree of predictability of fluctuations in a time series [32]. A relatively higher value of approximate entropy reflects the likelihood that similar patterns of observations are not followed by additional similar observations. The approximate entropy shows the amount of disorder and complexity of the signal, which was first introduced by Pincus et al. [33]. This entropy has been used as an extension in the analysis of cardiac domains. The degree to which the occurrence of a value depends on the previous values in the input is measured by approximate entropy. Low values of this entropy indicate order, while high values indicate low predictability and disorder. The resistance and insensitivity of the approximate entropy to small and large artifacts makes it suitable for use in the biological field.

A technique called approximate entropy (ApEn) is used in statistics to quantify the degree of regularity and predictability of fluctuations over time series.

The theoretical foundations of Approximate Entropy are explained in a comprehensive step-by-step tutorial [34]. It consists of the following steps:

Step 1: Assume a time series of data $x(1), x(2), \ldots, x(P)$. These are *P* raw data values from measurements equally spaced in time.

Step 2: let $m \in \mathbb{Z}^+$ be a positive integer, with $m \leq P$, which represents the length of a run of data (essentially a window).

let $r \in \mathbb{R}^+$ be a positive real number, which specifies a filtering level.

let $p = P - m + 1$.

Step 3: Define $\boldsymbol{u}(i) = \{x(i), x(i+1), \ldots, x(i+m-1)\}$ for each i where, $1 \leq i \leq p$. In other words, $\boldsymbol{u}(i)$ is an m m-dimensional vector that contains the run of data starting with x(i).

Define the distance between two vectors x (i) and x (j) as the maximum of the distances between their respective components, given by:

$$d[\boldsymbol{u}(i), \boldsymbol{u}(j)] = \max_k(|\boldsymbol{u}_k(i) - \boldsymbol{u}_k(j)|) = \max_k(|u(i+k-1) - u(j+k-1)|), 1 \leq k \leq m \quad (1)$$

Step 4: Define

$$\phi^m(r) = \frac{1}{p}\sum_{i=1}^{p} log[C_i^m(r)] \quad (2)$$

where, log is the natural logarithm, and for a fixed m, r, and p as set in Step 2.

Step 5: Define approximate entropy (ApEn) define as

$$ApEn(m, r, P)(u) = \phi^m(r) - \phi^{m+1}(r) \quad (3)$$

It is recommended that m be equal to 1, 2 or 3 and r between 10% and 25% of the standard deviation of the data in applications related to heart rate. In this study, approximate entropy parameters m=1 and r=0.2*std (data) were selected.

C. Fuzzy Entropy

The fuzzy entropy is applied to the seal impression problem to measure the subjective value of information under the condition of uncertainty. It is a new method that replaces the

fuzzy membership function with the single-step function to find entropy. This type of entropy combines local and global similarity in time series and provides good separation for time series with intrinsic complexity. The three primary parameters m, r and P should be considered when calculating fuzzy entropy.

Fuzzy entropy considers vectors of length m. x_i^m and x_i^{m+1} defined for all $1 \le l \le N-m$. For the time series of $\{u(t): 1 \le l \le N\}$, the shape of the vectors is expressed according to the following equation.

$$x_i^m = \{u(i), u(i+1), \dots, u(i+m-1)\} - u_0(i), i = 1,2,\dots,N-m+1 \quad (4)$$

where, x_i^m represents m consecutive values of u. Starting from the starting point i and discarding the baseline, we will have:

$$u_0(t) = m^{-1} \sum_{j=0}^{m-1} u(t+j) \quad (5)$$

It calculates the similarity degree vector from its neighborhood vector, which is defined by a fuzzy function according to the following relation.

$$D_{ij}^m = \mu\left(d_{ij}^m, r\right) \quad (6)$$

where, d_{ij}^m is the maximum absolute value of the difference of the corresponding scalar components x_i^m and x_j^m. For each averaging vector of $x_i^m (i = 1,2,\dots,N-m+1)$, all degrees of similarity, we will have neighborhood vectors:

$$\phi_f^m(r) = (N-m-1)^{-1} \sum_{f=1, i \ne f}^{N-m} D_{ij}^m \quad (7)$$

By rewriting the equations, we will have:

$$\phi^m(r) = (N-m)^{-1} \sum_{f=1}^{N-m} \phi_f^m(r) \quad (8)$$

Then, the fuzzy entropy parameter of a time series is expressed as the following equation:

$$FuzzyEn(m,r) = lim[ln\,\phi^m(r) - ln\,\phi^{m+1}(r)]^{-1} \sum_{t=1}^{N-m} \phi_t^m(r) \quad (9)$$

For the data set with finite length N, this relationship is in the form of the following equation:

$$FuzzyEn(N,m,r) = ln\,\phi^m(r) - ln\,\phi^{m+1}(r) \quad (10)$$

Fuzzy entropy has relatively strong compatibility and is less dependent on data length. It has more freedom in choosing parameters and has high resistance to noise.

In this study, m=2 and r=0.2*std (data), where sdt represents the standard deviation, were chosen optimally.

The test used in this research, the Wilcoxon test [35, 36], is one of the statistical tests that is widely used in behavioral studies. A non-parametric test is used to compare the changes of two different conditions of a group of participants. If there is a systematic change between the two states, most of the high ranks belong to one state, and most of the low ranks belong to another state. If two situations are similar, the distribution of high and low ranks will be the same for both situations. These differences are expressed in the form of a probability (p-value). The p-value intuitively shows the significance of the differences between the two conditions, so the decrease of this number to less than 0.05 indicates a significant difference. In this research, we used the Wilcoxon statistical test because this test is non-parametric and does not need the normal distribution of the data. Also, it is not sensitive to the number of samples of groups.

III. Discussion

A. Approximate Entropy Analysis

Approximate entropy analysis is a method used to quantify the amount of regularity and unpredictability in time-series data, such as heart rate signals. In the context of creative thinking, approximate entropy analysis offers a valuable tool for examining the complexity and variability of physiological responses. Fig. 2 to Fig. 4 show the approximate entropy for a person at rest and the first to fifth 2-minute periods for activities 1 to 3. Analysis of approximate entropy for all three activities of Torrance's creativity test and comparing the first to the fifth 2 -minutes with resting state showed an increase in the range of this parameter at the starting point, with the progress of creative activity. As can be seen, the approximate entropy increased first at the starting point compared to the resting state, and then at the end of the creative activity, this parameter returned to its initial value; it means that the approximate value of the resting state is approaching. In the case of activity 3, this parameter had a decreasing rate at the starting point for some subjects.

In order to obtain a specific pattern and generalize it to all people, a box diagram of these values was drawn. These values are shown in Fig. 5 for 2-minute periods and for activities 1 to 3. The green graph shows the resting state, and the yellow graphs from 2 to 6 show the first to fifth two-minute periods, respectively.

Analysis of the patterns shows an increase in the average value for 52 subjects compared to the resting state. On the other hand, the comparison of each creative stage with the last two minutes of the previous stage shows constant changes in Activity 1. In activity 2, the average values increased in the second two minutes compared to the first two minutes, and for the third and fourth minutes, it follows decreasing changes. This amount in two minutes of the fifth; That is, the end of creative activity increases again. In activity 3, all the two-minute steps, except the third two minutes, follow incremental changes compared to the previous two minutes. Fig. 6 to Fig. 8 show the phase entropy for a person at rest and the first to fifth two-minute periods for activities 1 to 3.

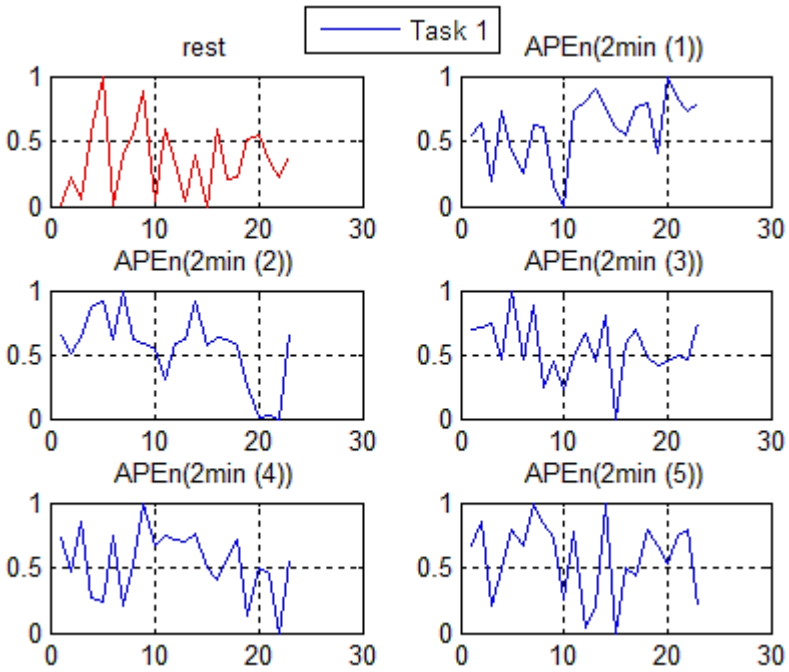

Fig. 2. The pattern of approximate entropy values in activity 1 in 2-minute periods (subject number 2), the vertical axis is the entropy range, and the horizontal axis is the number of windows.

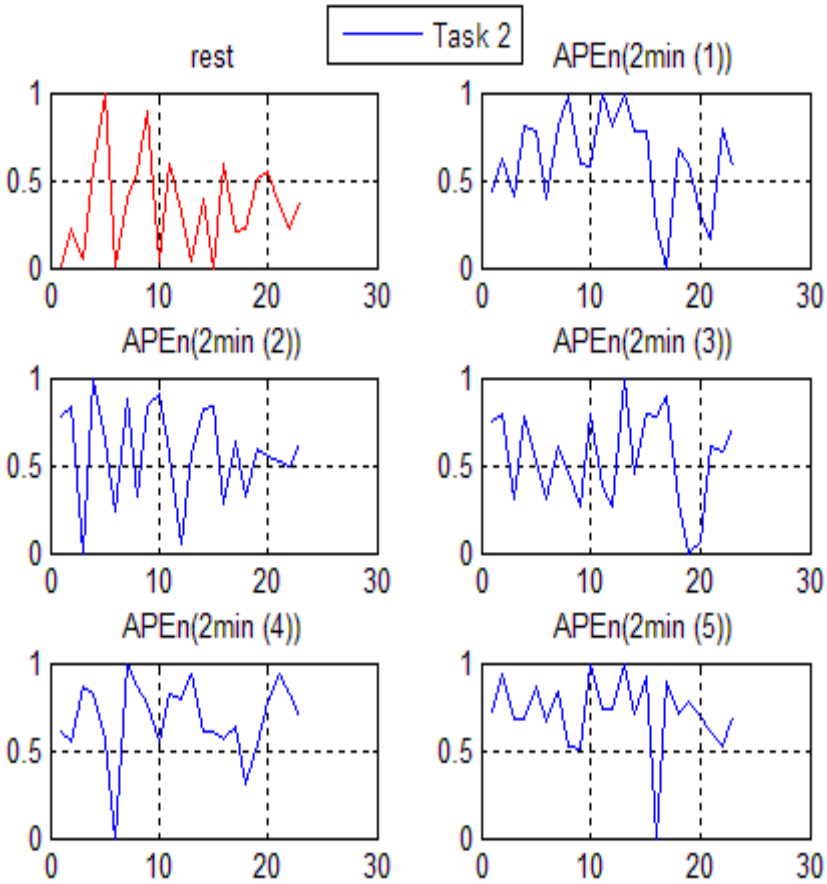

Fig. 3. The pattern of approximate entropy values in activity 2 in 2-minute periods (subject number 2).

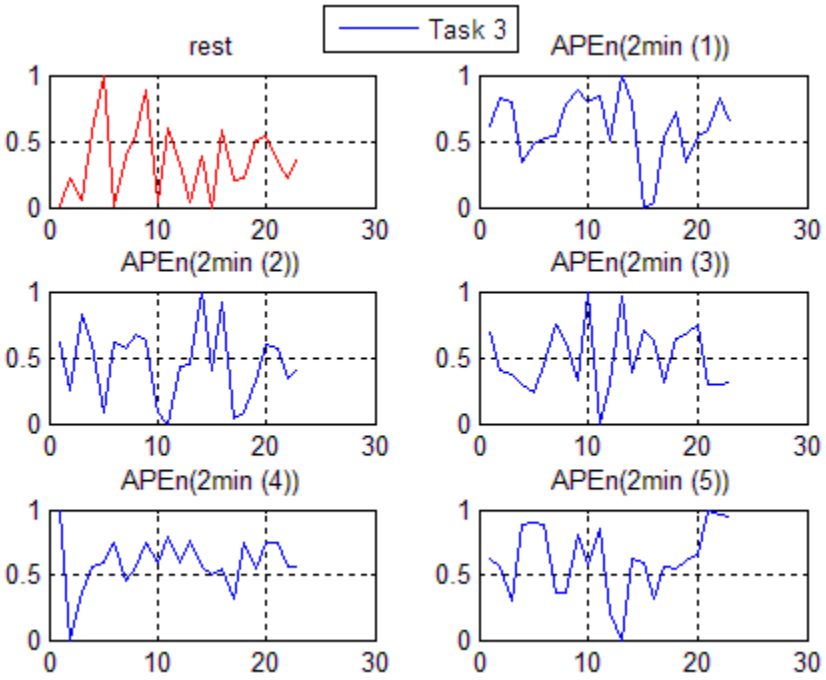

Fig. 4. The pattern of approximate entropy values in activity 3 in 2-minute periods (subject number 2).

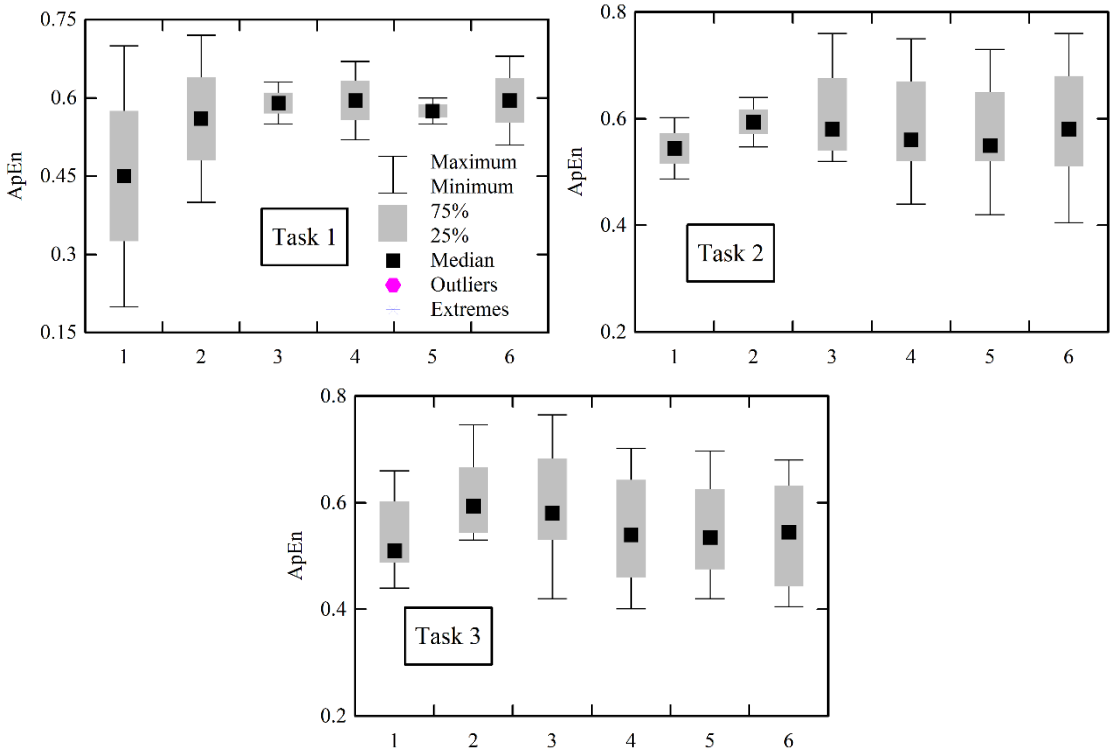

Fig. 5. Approximate entropy box diagram for 52 subjects in activities 1 to 3. The green diagram shows the resting state, and the yellow diagrams from 2 to 6 show the first to fifth two-minute periods, respectively. The vertical axis of the average and the horizontal axis of time means that each of the stages shows two minutes with rest.

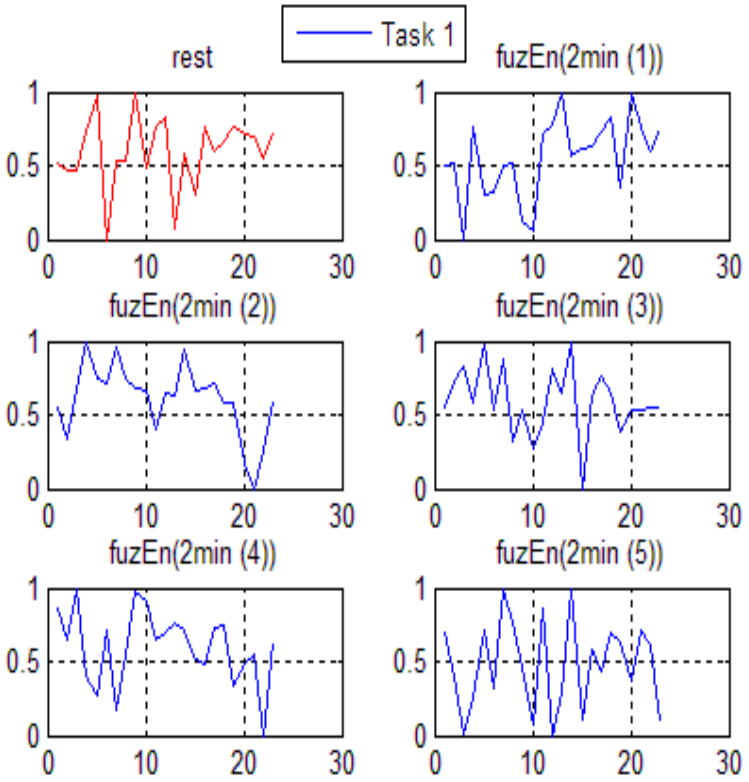

Fig. 6. The pattern of fuzzy entropy values in activity 1 in two-minute periods (subject no. 2), the vertical axis shows the entropy range and the horizontal axis shows the number of windows.

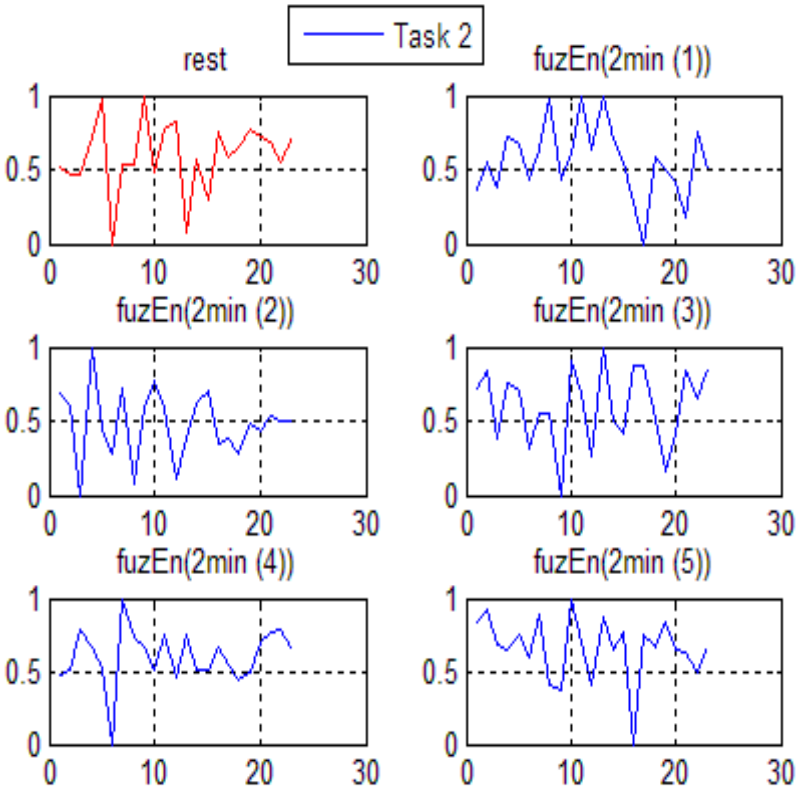

Fig. 7. The pattern of fuzzy entropy values in activity 2 in two-minute periods (subject no. 2), the vertical axis shows the entropy range and the horizontal axis shows the number of windows.

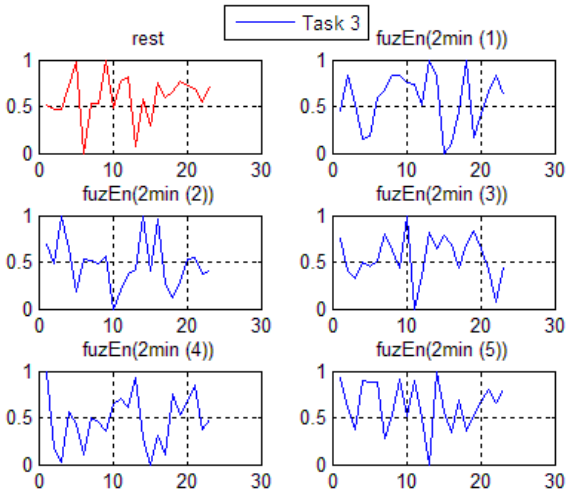

Fig. 8. The pattern of fuzzy entropy values in activity 3 in two-minute periods (subject no. 2), the vertical axis shows the entropy range and the horizontal axis shows the number of windows.

Box plots of fuzzy entropy for all three activities and 52 subjects are shown in Fig. 9. The analysis of the fuzzy entropy shape in 52 subjects showed incremental changes in the mean of the feature in the creativity state compared to the rest time. By comparing the two entropies, it can be concluded that creative activity in most subjects shows itself as the growth of the entropy range at the starting point of the pattern. However, phase entropy does not have such a development in most subjects despite incremental changes in the mean of the feature. The second two minutes did not change compared to the first two minutes of activity 1, while the average value decreased in the third two minutes and followed this decreasing trend in the fourth two minutes, and finally, this value increased in the fifth two minutes of the activity. The changes in the two-minute stages compared to the previous stage in Activity 2 have an increasing and decreasing pattern, and in Activity 3, this pattern is completely incremental for each two-minute stage compared to the previous stage.

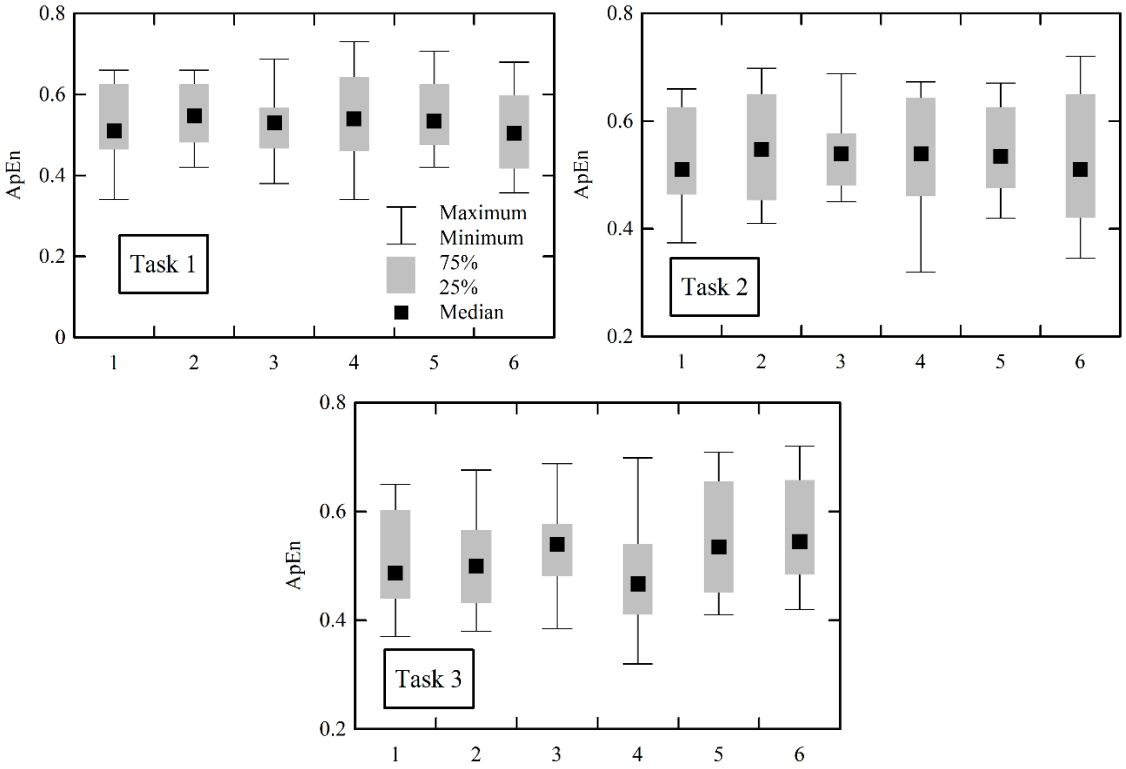

Fig. 9. Box diagram of phase entropy for 52 subjects in activities 1 to 3. The green diagram shows the resting state, and the yellow diagrams from 2 to 6 show the first to fifth two-minute periods, respectively. The vertical axis of the average and the horizontal axis of time means that each of the stages shows two minutes with rest.

B. Wilcoxon Statistical Test

For the purpose of determining the significance of the difference between the activities, the Wilcoxon statistical test was used, and the results are shown in Tables II and III. These tables present p-values for approximate entropy and fuzzy entropy between the resting state and Torrance's creative thinking activity. Based on the Wilcoxon statistical test, Table II shows the significant values for many states of creative thinking as compared to the resting state. For all three activities, these values are significant when compared to the resting state and the second and fifth minutes.

Statistical analysis of the phase entropy values for the resting state, the second and fifth two minutes of all three activities found significant results for the p values. Furthermore, a statistical test showed significant results for Activity 1's resting state and the first two minutes, as well as Activity 3's resting state and the fifth two minutes. According to Tables IV and V, the differences between each of the two-minute steps and the previous two minutes are explained. A comparison of the two-minute stages for both types of entropy is presented in Tables IV to V, with the most significant values being found in Activity 3 and transitioning from Activity 4 to Activity 5, two minutes during Activity 1 for both types of entropy. Significant results have been obtained. The value of approximate entropy was not significant for activity 2, which had two types of entropy.

In study [37], it was observed that there is a synchronization between high alpha brain waves and the illusion of an improvised dance during the imagination of a standard waltz dance. Gruzelier et al. [38] investigated the alpha/theta EEG band alongside HRV in a group of dancers in training. Their study revealed that an increase in HRV, influenced by autonomic nervous system activity, led to symptoms such as shortness of breath, rapid breathing, irregular heartbeat, tremors, feelings of fear, dry mouth, and increased nervous tension. These symptoms contributed to heightened stress, intolerance, irritability, inability to remain calm, and disorganized responses in young dancers. Guilford's test on alpha and theta waves showed no significant differences. Forte et al. [39] argued that concentration during cognitive tasks is associated with a decreased heart rate. Belli [40] found a significant difference in heart rate when individuals solved efficient versus inefficient problems. Additionally, individuals participating in group activities exhibited higher levels of creativity compared to those who did not. Brain imaging studies, including fMRI, PET, and SPECT, have shown that frontal lobe activation is more pronounced in highly creative individuals compared to those with lower creativity levels [41]. Stimulation of the vagus nerve (sympathetic) has been associated with increased heart rate and disturbances in testing processes, resulting in decreased creativity [42]. In an experiment conducted by Velázquez et al. [43] on 53 pairs of twins, it was found that the T gene significantly contributed to creativity in over 70% of participants. Research on individuals with Parkinson's disease indicated that the type of disease — right-hemispheric onset (RHO) or left-hemispheric onset (LHO) — affects creativity levels differently. Specifically, individuals with RHO experienced a significant decrease in creativity within three months [44].

Furthermore, comparing each stage of creativity with the previous one shows an increase in the average entropy value by the end of each activity, with significant incremental changes observed in the final stages. These findings indicate that heart rate signal entropy analysis can effectively differentiate between resting and creative states, offering a novel approach to evaluating individual creative abilities. Indeed, it is crucial to acknowledge the limitations of our study to ensure a comprehensive understanding of the findings. While our research contributes valuable insights into the relationship between heart rate entropy and creative thinking, it is essential to recognize certain limitations. These include the relatively small sample size and the lack of diversity in participant demographics. These factors may affect the generalizability of our results. Additionally, our study focuses specifically on the Torrance creativity test, which may not capture the full spectrum of creative activities. We acknowledge these limitations and recommend that future research endeavors address these concerns through larger and more diverse participant samples, as well as by exploring a broader range of creative tasks. Such efforts would enhance the robustness and applicability of findings in this field.

TABLE II. REPORT OF P-VALUES OF APPROXIMATE ENTROPY BETWEEN RESTING STATE AND TORRANCE'S CREATIVE THINKING ACTIVITY

	Activity 1	**Activity 2**	**Activity 3**

IV. CONCLUSION

An analysis of nonlinear features of the heart rate signal during creative activity is presented in this article. As a result of this study, a gap in the literature has been filled regarding the response of autonomous signals to creative thinking. An examination of the approximate entropy and fuzzy entropy of the heart rate signal of 52 individuals during creative activity was conducted for this purpose. There were five stages in each of Torrance's activities, each of which lasted two minutes in length. As compared to the resting state, the approximate entropy values of each stage increased during creative activity. In terms of approximate entropy, a Wilcoxon statistical test indicated significant differences between creative activities and resting states. The highest significant values are associated with approximate entropy, followed by fuzzy entropy. As a result of comparing each two-minute stage to the previous stage, the 3rd activity in both types of entropy continually increased. Based on the results of the statistical test, a significant difference exists between the fourth and fifth minutes of Activity 1, indicating an increase in entropy at the end of the creative activity. During creative activity, the average values of these two types of entropy increase, indicating an increase in the complexity of autonomous signals. It is for this reason that the heart rate signal becomes irregular during creative activity. Although fuzzy entropy has advantages over the usual entropies, as mentioned before, the properties of the approximate entropy (the resistance and insensitivity of the approximate entropy to small and large artifacts) make it suitable for use in biological fields, especially heart rate signal analysis. Therefore, more appropriate to use approximate entropy than fuzzy entropy in this case.

Future research should focus on longitudinal studies to assess the impact of creative training programs on heart rate signal entropy over time and integrate these analyses with neuroimaging techniques like fMRI or EEG to better understand the neural correlates of creativity. Additionally, expanding studies to include diverse demographic groups can determine the universality of observed entropy patterns. Investigating task-specific physiological responses to different creative activities, employing machine learning for improved analysis accuracy, and exploring clinical applications for diagnosing and treating creativity-related deficits are also essential. Real-time monitoring systems using heart rate entropy analysis could provide immediate feedback in environments requiring continuous creativity, thereby advancing our understanding of the physiological underpinnings of creativity and developing practical applications to enhance creative thinking skills across various domains.

Statement on Ethics Approval and Consent:

I hereby include the following statement on ethics approval and consent:

This study was conducted with due consideration for ethical standards. Although the need for ethics approval may have been waived, I affirm MY commitment to ethical conduct and the protection of human subjects' rights.

Furthermore, should this manuscript contain any individual person’s data in any form, including individual details, images, or videos, we confirm that appropriate consent to publish has been obtained from the relevant individuals or their legally authorized representatives.

I am fully aware of the importance of respecting the rights and privacy of individuals involved in our research, and I assure readers that all necessary steps have been taken to adhere to ethical standards and obtain informed consent where applicable.

Designing an Experimental Setup for Data Provenance Tracking using a Public Blockchain: A Case Study using a Water Bottling Plant

O. L. Mokalusi[1], R. B. Kuriakose[2], H. J. Vermaak[3]
Central University of Technology, Bloemfontein, Free State, South Africa

***Abstract*—Data provenance, in an end-to-end supply chain context, refers to the tracking of the origin and history of every raw material, process, packaging and distribution involved in a manufacturing network. The traditional client-server architecture utilised in centralised systems, stores data in a single location, making it vulnerable to single points of failure, data tampering, and unauthorised access. As a result, a lack of data provenance and standardisation for products in a manufacturing supply chain. This leads to a lack of traceability and transparency. Therefore, this article presents a hypothesis that these challenges can be overcome by incorporating data provenance into blockchain-based smart contracts for traceability and transparency. This article is structured such that it firstly discusses data provenance traceability with a focus on the cloud-based storage system architecture domains for data provenance traceability across end-to-end supply chains. Secondly, this article sheds more light on the design of an experimental setup for blockchain-based data provenance traceability in a manufacturing supply chain using a case study of a water bottling plant. Finally, it showcases and discusses the results of the experiments for this purpose.**

***Keywords*—Data provenance; public blockchain; smart contracts; supply chain; smart manufacturing**

I. Introduction

Provenance, also known as lineage [1] or pedigree, refers to the historical record of data and its origins, showing how the data is utilised, processed, represented, stored, and disseminated, by whom and for what purpose [2]. It involves tracking the origins of data and the modifications made to it. It involves tracking the source of information and changes performed on it.

Subsequently, traceability ensures the ability to track the history and origins of product processes [3]. The management of provenance received extensive attention in database systems. The taxonomy of provenance is divided into five divisions as application of provenance, provenance subject, provenance representation, provenance storing and provenance dissemination.

Provenance is crucial in applications such as forensic analysis, as presented by Abiodun et al. [4], as it provides a digital proof for investigation. However, due to the enormous development in data, finding the origin can be a difficult task, leading to emerging studies in various applications such as Scientific Workflow Management Systems (SWfMS) [5], Database Management Systems (DBMS) [6], Hospital Information Systems [7], and supply chain.

This research focuses on the design of an experimental setup public blockchains to track data provenance in a water bottling plant. The smart manufacturing plant produces bottled water on a Make-to Order (MTO) basis. Presently, end-users lack a method to ascertain the water's source, composition, bottling location, and delivery progress. This is as results of limited research on combating the centralisation of manufacturing of bottled water and none when it comes to cost effective public blockchain platform.

This article is structured such that it firstly discusses data provenance traceability with a focus on the cloud-based storage system architecture domains for data provenance traceability across end-to-end supply chains. Secondly, this article sheds more light on the design of an experimental setup for blockchain-based data provenance traceability in a manufacturing supply chain using a case study of a water bottling plant. Finally, showcases and discusses the results of the experiments for this purpose.

II. Cloud-Based Storage Data Provenance Traceability Across End-to-End Supply Chains

The traditional client-server architecture utilised in centralised systems stores data in a single location, making it vulnerable to single points of failure, data tampering, and unauthorised access. As a result, a lack of data provenance and standardisation for products in a manufacturing supply chain can occur, leading to a lack of traceability and transparency.

The problem of ensuring data provenance traceability across end-to-end supply chains for traceability and transparency is a critical issue. It becomes even more challenging when end-users do not have access to centralised storage, making it difficult for them to verify critical data provenance. This was evident during the 2017 listeriosis outbreak in South Africa [8] led to 216 fatalities because contaminated meat products could not be traced back to their origin in time to effect a product recall. Data provenance traceability problems can be classified based on the system architecture as centralised or decentralised, by Kamble et al. [9].

Zafar et al. [10], proposes a general overview of provenance and expanded the technologies of traditional supply chains into sub-domains. These are technologies utilised to log product data provenance associated with product composition and production process data parameters in the supply chain for traceability. The technologies are classified as centralised, including Wireless Sensor Network (WSN), Internet of Things (IoT),

cloud-based storage, and decentralised based storage, such as blockchain.

The establishment of an end-to-end traceability framework, especially in food-sensitive sectors [11] necessitates, a standardised approach handled by the Electronic Product Code Information Service (EPCIS) developed by GS1 [12]. The GS1 global traceability standard sets a minimum set of requirements for traceability in business processes, ensuring an end-to-end traceability framework irrespective of the underlying technology.

The services of GS1 global traceability standard are split into three categories as identity, capture and share. GS1's capture standards are sub-divided into two categories as follows Barcodes and Electronic Product Code (EPC)/Radio Frequency Identification (RFID). One of the major drawbacks of barcodes and RFIDs is that they are linked to a local database. This means that end-users without access to the local database are unable to verify product provenance.

The problem of ensuring data provenance traceability across end-to-end supply chains for traceability and transparency is a critical issue. It becomes even more challenging when end-users do not have access to centralised storage, making it difficult for them to verify critical data provenance. To address these challenges, a decentralised distributed storage is needed, such as a blockchain-based smart contract, which can offer solutions to centralisation by minimising risks with ensuring provenance, traceability, immutability and trust.

III. Blockchain-Based Storage Data Provenance Traceability in a Manufacturing Supply Chain

This section describes blockchain technology and discusses the different types of blockchain platforms.

A. Blockchain Technology

The concept of integrating blockchain technology was initially presented in the *Bitcoin* whitepaper authored by Satoshi Nakamoto in 2008 [12]. The aim of blockchain platforms is to establish a decentralised distributed ledger for time-stamped transactions among various computers in a peer-to-peer network [13], which eliminates the necessity for cloud-based storage that is vulnerable to single point of failure.

Blockchain technology is a write-only decentralised digital ledger, meaning that transactions or data are trackable and irreversible and can only be added but not edited or removed [14]. Every transaction is stored on the blockchain and grouped together in blocks. From a database perspective, the blockchain can be viewed as a blockchain-structured database, where data is packaged into blocks and connected utilising a chain structure.

Blockchain platform block transactions are initiated from a wallet like *MetaMask* [15]. The first block in the chain is known as the genesis block, which has no parent block. These blocks are connected utilising cryptographic principles, providing a secure and tamper-proof ledger for storing data provenance. The newly generated block has the SHA256 algorithm applied to it. The block of the blockchain platform comprises a header and body. The header contains important fields including the timestamp, the hash code of the previous blockchain platform block, transaction hash, and the root of a Merkle tree root [16] (see Fig. 1).

To construct a Merkle tree, the dataset $Data_1$, $Data_2$, $Data_3$ and $Data_4$ are subjected to cryptographic hashing utilising function, such as SHA-256. As depicted in Fig. 1 each parent node in a Merkle tree derives its hash value from its children's nodes $Data_n$. The resulting hashes of node $Hash_1$ and $Hash_2$ are concatenated to create a new parent node $Hash_{[1,2]}$. Similarly, the resulting hashes of nodes *Hash3* and Hash4 are concatenated to create a parent node $Hash_{[3,4]}$. Finally, the resulting hashes of nodes $Hash_{[1,2]}$ and $Hash_{[3,4]}$ are concatenated to create the root hash value node $Hash_{[1,4]}$, which is linked to every value in the tree.

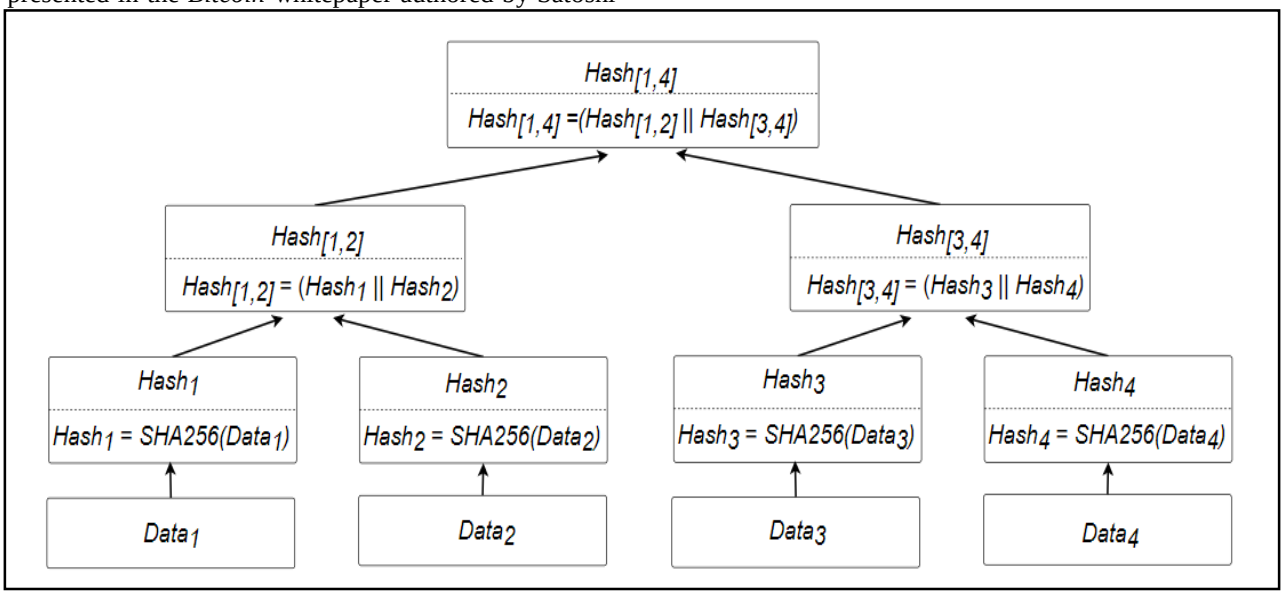

Fig. 1. An illustration of a "balanced" Merkle tree [17].

B. Types of Blockchain Platforms

The three types of blockchain platforms are as follows;

1) Public blockchain: These are permission less [18] network platforms that are accessible to all internet users to interact and view the history of transactions. There is no central authority [19] and all peers can take part in the consensus mechanism to improve data security, integrity, and trust. Public blockchain platforms include and are not limited to *Bitcoin*, *Ethereum*, *Tron* and *Polygon*. However, the efficiency of permissionless public blockchain platforms is low, which affects adoption cost and is their main drawback [20].

2) Private blockchain: These are permissioned [18] network platforms that are centrally managed by a single organization [21]. Private blockchain platforms include and are not limited to *Multichain* [22]. However, since permissioned [18] private blockchain platforms are centralised [23], the decentralised concept is therefore compromised [20] and this is their main drawback.

3) Consortium blockchain: These network platforms have permissioned or permissionless access authority for end-users and can be public or private. They are considered partially decentralised [24] since only organisations parts of the network platform have access permission authority. Consortium blockchain network platforms include and not limited to Hyperledger, Corda and Quorum. However, because permissioned consortium blockchain platforms are centralised, the decentralised concept is compromised, and this is their main drawback.

Table I compares public, private, and consortium blockchain platform types [25] [26] such as Ethereum (legacy), Ethereum 2, Polygon, and Tron.

TABLE I. THE COMPARISON BETWEEN BLOCKCHAIN TYPES BY TORKY AND HASSANEIN 2020

Blockchain type	Public	Private	Consortium
Centralisation	No	Yes	Partial
Access authority	Permissionless	Permissioned	Permissioned
Efficiency	Low	High	High
Trust	All peers	Single organisation	Selected peers

IV. METHODOLOGY

The aim of this article is to design an experimental setup for data provenance tracking using a public blockchain. In this research study, the water bottling plant located at the Bloemfontein campus of the Central University of Technology (CUT) [27] was chosen as the case study (see Fig. 2).

The proposed solution for data provenance collection involves the utilisation of Near Field Communication (NFC) tags. NFC antennas are mounted at designated points A, B, C, and D. The NFC antennas are mounted at the start and end of each Smart Manufacturing Unit (SMU), designated for water filling, capping, and packaging activities. Each SMU activity triggers a Critical Tracking Event (CTE), which is then incorporated into a blockchain-based smart contract to ensure data security, immutability, and traceability.

In order to facilitate the design process, the experimental setup of the water bottling plant (see Fig. 2) is split into three subsystems. It is important to note that certain functions of the water bottling plant, such as capping, labeling, and packaging have been omitted from the experimental setup for convenience (see Fig. 3).

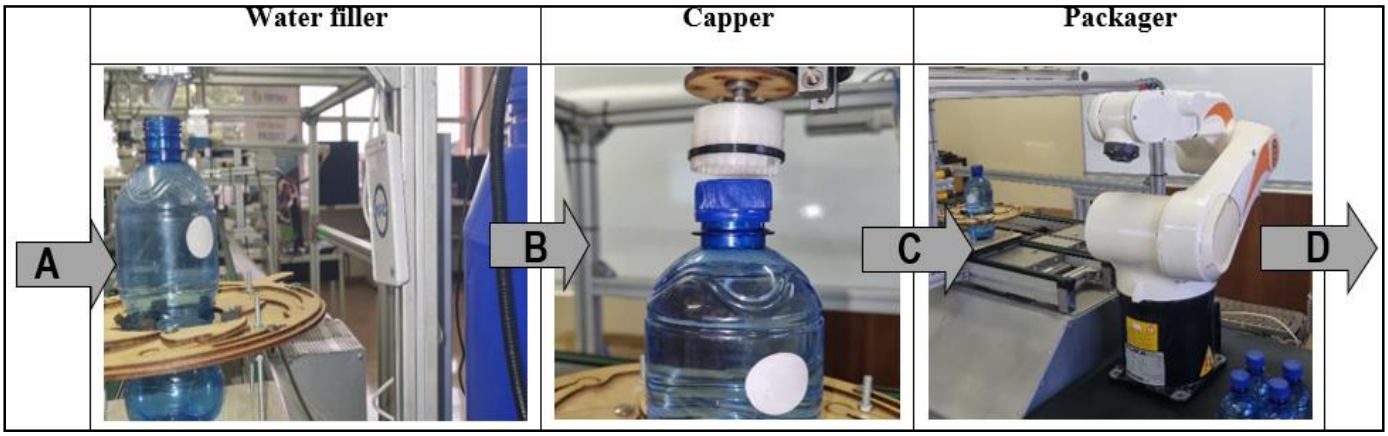

Fig. 2. The schematic outline of a water bottling plant at CUT.

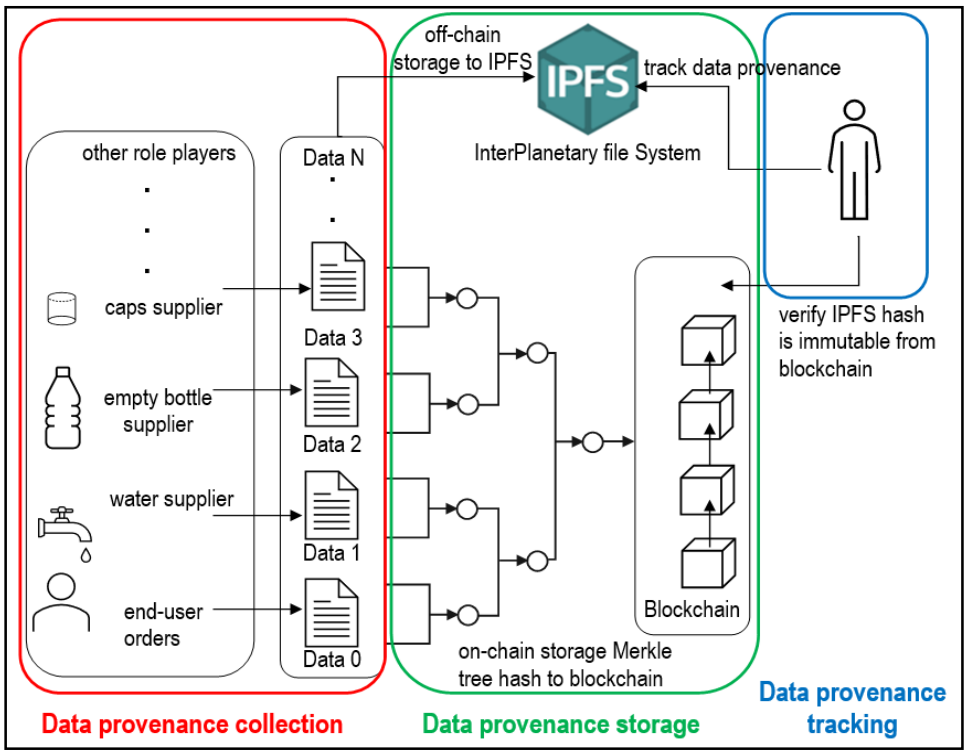

Fig. 3. The block diagram of the experimental setup.

V. Results

This section describes the results of the methodology discussed in Section IV. Firstly, the type of collected data provenance is described. Next, the analysis focuses on the results of data provenance stored. Finally, the results of the data provenance tracking are shared.

A. Data Provenance Collection

The data collected is written on the Near Field Communication (NFC) tag in a JavaScript Object Notation (JSON) markup format and shared as object of $Data_n$ (Data N), where N is an index set starting from zero. The NTAG21x [28] series are utilised, which are compatible with most NFC-enabled devices. Each role player data is collated through an NFC tag with its Unique Identifier (UID).

These input sources include the end-user's new order, water supplier and empty bottle supplier. The end-user provides order requirements, followed by the water sourced from a specific supplier, and the empty bottles and caps from other suppliers. The Fig. 4 describes a JSON markup format array *new_order*, the first entry object of Data0. If additional role players need to be added, provisions can be made.

B. Data Provenance Storage

A study that was done into the factors that influences the selection of a blockchain platform [26] resulted in this input. The efficiency of permissionless public blockchain platforms is low, which can increase adoption costs. Therefore, the Inter-Planetary File System (IPFS) is utilised to store large-sized data provenance by generating content-addressed hash with a fixed length. The role player sources are stored in the IPFS as node $Hash_0$ (see Fig. 5).

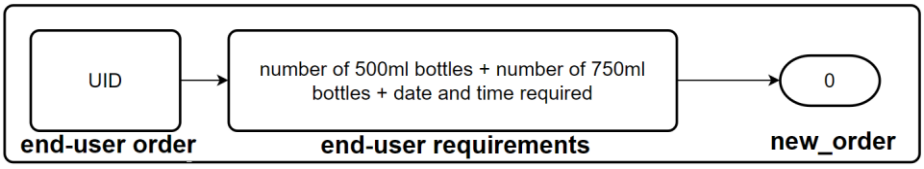

Fig. 4. End-user's new order data provenance collection.

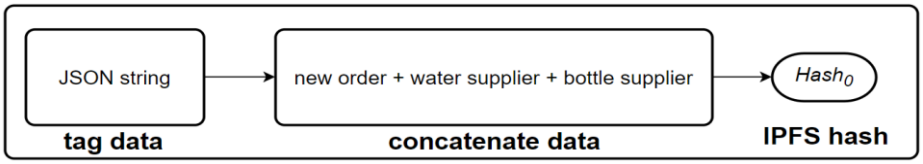

Fig. 5. The role player's sources storing in the IPFS.

The concept of Merkle tree Directed Acyclic Graph (DAG) is utilised in IPFS. LineageChain, the study in [29] is a fine-grained data provenance traceability solution for blockchains platforms to achieve efficient tracking and querying of semantic information. The authors captured verifiable semantic information during the execution of blockchain-based smart contracts and stored it in a Merkle tree, which was converted into a Directed Acyclic Graph (DAG).

Therefore, the principles of the IPFS Merkle tree DAG are implemented with Smart Manufacturing Unit (SMU), tasked with filling the water bottles. IPFS Merkle hash tree DAG node is created by utilising Python IPFS Application Programming Interface (API) which accepts data provenance as a JSON markup format that is stored with the function *IPFS DAG PUT* to obtain a unique content-addressed transaction hash.

Once the blockchain-based smart contract is deployed, its generated content-addressed transaction hash is written on the NFC tag as a Uniform Resource Locator (URL) link. This data provenance was stored off-chain in the IPFS Merkle tree DAG and its root hash incorporated into the blockchain-based smart contract.

C. Data Provenance Tracking

The ability to track and query the IPFS Merkle tree DAG, facilitates end-to-end supply chain tracking, enabling verification of product history and origin to ensure the integrity of data provenance. The end-user can read data provenance by tapping a Near Field Communication (NFC) tag attached to the bottled water, which contains a content-addressed transaction hash Uniform Resource Locator (URL) link. A URL link directs the end-user to the deployed blockchain-based smart contract transaction hash on the Polygon public blockchain platform.

This is to retrieve the root InterPlanetary File System (IPFS) Merkle tree Directed Acyclic Graph (DAG) node which represents a Critical Tracking Event (CTE) for water filling which is immutable. A top-down data provenance tracking approach is achieved by the ability to traverse the IPFS Merkle tree DAG with node $Hash_{[1,3]}$ (see Fig. 6).

Firstly, the links from the parent node $Hash_{[1,3]}$ are then verified, with two children links. The one pointing to node $Hash_{[1,2]}$ of the measured water pH level in the tank. The other as a node $Hash_3$ of the counted water bottles. Follow the link to node $Hash_{[1,2]}$ and retrieve its content utilising its IPFS Merkle tree DAG hash, which has two children links pointing to node $Hash_1$ and $Hash_2$. The content corresponding to the new_order is retrieved by following the link to node $Hash_1$. Similarly, the content corresponding to the water_supply is retrieved by following the link to node $Hash_2$. Once the contents of node $Hash_1$ and node $Hash_2$ have been retrieved, navigate back to node $Hash_{[1,3]}$ and follow its links to node $Hash_3$, which includes the content corresponding to the empty bottle_supply.

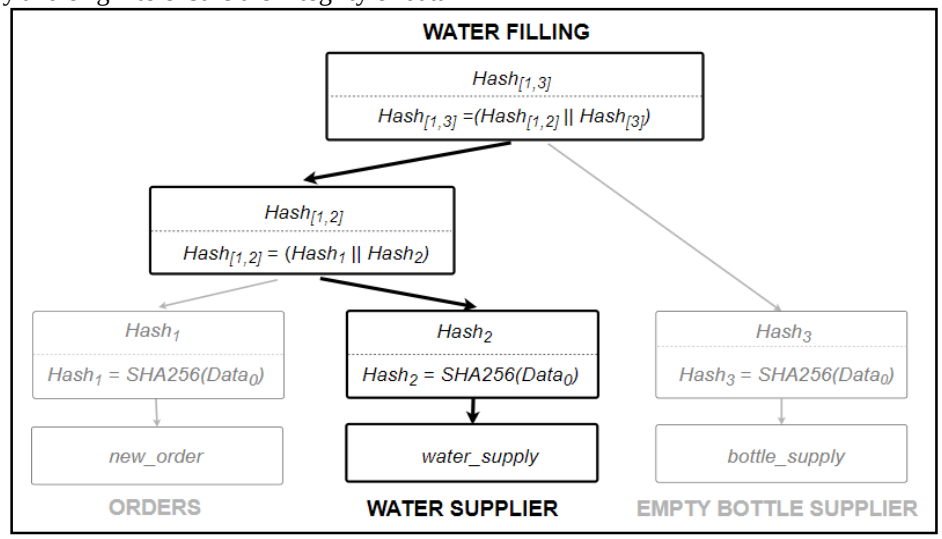

Fig. 6. IPFS Merkle tree DAG inversion method for data provenance tracking.

VI. Discussion and Conclusion

This article investigated the broader problem of data provenance traceability with a focus on the cloud-based storage system architecture domains for data provenance traceability across end-to-end supply chains. It then identified the challenges described and established the limitations that this research study aims to fill. There is a limited or lack research on combating the centralisation of manufacturing of bottled water and none when it comes to cost effective public blockchain platform. The proposed experimental setup ensures that data provenance pertaining to the end-user order, raw materials used, and timestamp at each stage of production is incorporated into a blockchain smart contract to make it immutable and traceable. This will allow the end-user to "read" data provenance, through a tag attached on the bottled water for traceability and transparency. The results of this study can also be seen as an addition to the knowledge base of the broader studies on data provenance traceability which can reduce the size of a recall from millions to just a few hundred units, highlighting the importance of this research study.

Increasing the Accuracy of Writer Identification Based on Bee Colony Optimization Algorithm and Hybrid Deep Learning Method

Hao Libo, Xu Jingqi
Hunan Mechanical and Electrical Vocational and Technical College Changsha 410151, Hunan, China

***Abstract*—It is one of the most important and challenging classification issues to identify the writer's identity from offline handwriting images, which has been the focus of many researchers in recent years. This article presents a novel approach to identifying the author of offline Pertian manuscripts from scanned images based on deep convolutional neural networks. For the first time in the proposed network, the bee colony algorithm has been used in the middle layers of a deep convolutional neural network in order to improve the accuracy of identifying the author and to optimize the parameters, as well as improve the learning performance. In terms of the presented scenario, it was tested independently of the written language in both Persian and English. The proposed method is more accurate than previous studies for the IMA dataset, with an accuracy of 97.60%. Moreover, for the Firemaker dataset, the proposed model has significantly improved over the existing results, with the accuracy of the current model being 99.71%, a value that is 1.78% higher than the results of the previous models.**

Keywords*—Optimization; bee colony algorithm; deep learning; author identity recognition; handwriting

I. Introduction

Today, cameras and scanners convert a large number of existing paper documents into digital files. Many applications, such as office automation and digital libraries, require efficient storage, restoration, and management of these image archives. Therefore, it is imperative to obtain effective algorithms to analyze digital images of documents. As a result, author identification through the analysis of documents has become one of the most interesting challenges in the field of image processing and pattern recognition [1], [2], [3]. Identifying the author has become difficult as a result of the type of handwriting, structural differences and different types of writing between people on the one hand and the quality of the obtained images on the other hand [4].

Several recent studies have demonstrated that the emergence of deep learning methods has led to acceptable results for the extraction and classification of image features, along with accuracy, speed, unsupervised training of features, and a reduction of training time and calculation volume [5], [6], [7]. Deep learning is one of the methods for processing images based on different models. So far, few studies have used deep learning techniques for interpreting handwriting versions, and previous approaches have largely relied on conventional machine learning techniques based on feature selection and extraction. A method for offline handwriting recognition has been proposed by Hamdan et al. [8]. A total of five types of features were extracted and analyzed from handwritten texts as part of this study. Principal component analysis and Fisher's linear discriminant analysis were used to reduce the dimensions of the features. Support vector machines and neural networks were used as two classifiers in order to confirm the efficacy of the described method and the extracted features. Chahi et al. [9] presented an operator that shows multiple histograms and emphasizes the extraction of the desired characteristics. An image histogram is constructed by analyzing the distribution of pixels in a small block of pixels. Using the nearest neighbor classification with Hamming distance, they demonstrated that their approach is comparable to or better than contemporary approaches. An online author recognition system based on a recurrent neural network was investigated by Zhang et al. [10]. In order to classify the data, they used the long short-term memory model. An experimental study was conducted on English (135 authors) and Chinese (187 authors) datasets, and the advantages of their method were confirmed compared to other available methods.

According to He and Schomaker [11], handwriting carries explicit and implicit information, i.e., explicit information pertains to the exact lexical content of the words, the number of letters in the word (word length), and the letters themselves. Implicit information, on the other hand, refers to the author's behavior that can be used to identify the author. In order to generate additional information, these researchers suggested that explicit information should be used alongside implicit features. As part of another study, He et al. [12] proposed a deep model called FragNet to extract powerful features from word images. This model consists of two deep architectural paths: the feature pyramid path and the parts path. In the feature pyramid path, the entire word image is used as input, allowing the model to capture global features and contextual information. In the parts path, the input image is divided into smaller segments, which are processed separately to focus on fine-grained details and local features. By combining these two paths, FragNet is able to leverage both global and local features, enhancing its ability to accurately represent and classify word images. Javidi et al. [13] proposed to identify the author offline and independent of the text by using a convolutional neural network and Bayesian network. Based on noisy images, Ni et al. [14] have attempted to recognize the handwriting author offline. Using convolutional neural networks as a method of displaying features has been shown to be efficient. Through the use of convolutional neural networks and traditional machine vision descriptors, they are

able to improve applications such as author identification even when images contain noise. Semma et al. [15] propose an approach to identify the writer of a text independently of the text and offline based on the combination of deep and traditional features. Litifu et al. [16]analyzed heterogeneous handwriting data and used deep neural networks to identify the author offline. Using deep learning, Wang et al. [17] have presented an automated method of author identification.

In most studies, English is chosen as the language of analysis of handwritten documents, while few researchers have focused on right-to-left languages, such as Persian, Arabic, Chinese, and Urdu. A gradient-based approach was presented by Helli and Moghaddam [18] for identifying the offline author of Persian texts using general features. Using the gradient descriptor, they proposed a method for extracting three energy-based features and eight angle-based features. In defining a mathematical model with regard to the Arabic language, Abdi and Khemakhem [19] reached a correct percentage of 59% based on the assumption that manuscripts are independent of one another. In the detection process, 92 features are utilized, and the detection criterion is based on a combination of cross-correlation and Fisher's linear criterion. Khosroshahi et al. [20] introduced an offline author recognition system utilizing a deep convolutional neural network model tailored for right-to-left datasets, which was evaluated alongside four other datasets. Sabzekar et al. [21] presented a model capable of identifying authors from handwriting independent of the written language. In a multi-script context, Semma et al. [22] proposed a deep learning-based approach for author identification, which involves identifying key points in the handwriting and extracting small patches around them. This study examined texts in Arabic, English, French, Chinese, and Persian. For effective author identification, it is crucial to extract both abstract features of the author's writing style and subtle details indicative of their writing habits. Current handcrafted features, which capture local shape and gradient information, often face limitations. These limitations arise from reliance on artificial features such as written content information (text) and writing styles (personality). Consequently, a more comprehensive approach that considers both high-level abstractions and fine-grained details is necessary for accurate author identification.

Several approaches have demonstrated significant efficiency in identifying and verifying identities across various datasets in numerous studies. However, challenges persist, particularly with more complex datasets and real-world applications. For instance, variables such as the use of different pens and papers introduce variability that still requires further research. Generally, different environmental conditions have not been adequately considered when preparing databases. For practical applications, it is essential to account for diverse environmental factors. Most studies have focused on English texts, with relatively little attention given to manuscripts in right-to-left languages. This gap underscores the need for more research into handling manuscripts written in various scripts and under different conditions to enhance the robustness and applicability of author identification systems. This research aims to develop an algorithm for offline writer identification under different experimental conditions, including the type of pen and paper used, as well as various uncertainties, based on the use of deep neural networks to process right-to-left handwriting sample images. A variety of conditions have been used to collect the required data from different authors. Then, utilizing the feature addition approach, a two-way hybrid architecture of deep convolutional neural networks was developed in order to extract the most favorable features for the recognition of the identity of the author of Persian texts. In the proposed algorithm, deep network-based features are extracted in one path, and complementary features are extracted in a second path with the aid of an innovative screening system. In the proposed network, the bee colony algorithm is used in the middle layers of the deep convolutional neural network to optimize the parameters, improve learning performance, and increase accuracy. This architecture represents an extension of the 18-layer RosNet neural network model, characterized by the formulation of a two-path architecture model that combines features extracted by the RosNet deep neural network on one path, while global features are combined in a classical manner on the second path. Different classification criteria are used to evaluate and measure the final model. Based on the results obtained by the model on the aforementioned dataset, the proposed method appears to perform well.

In this work, presented a comprehensive analysis of our proposed technique for increasing the accuracy of writer identification based on the Bee Colony Optimization Algorithm and a Hybrid Deep Learning approach. The paper is structured as follows: In Section II, we detail the methodology employed in our study, including the preparation of the database, description of databases used, data pre-processing techniques, the architecture of the proposed hybrid network model, and the incorporation of additional training data. Section III presents the experimental setup and evaluation of our method's performance, followed by a detailed analysis of the results. In Section IV, we discuss the implications of our findings and conclude with insights into future research directions. This structured approach ensures a systematic presentation of our methodology, results, and conclusions, providing readers with a clear roadmap of the paper's content.

II. PROPOSED METHOD

A general description of the proposed author recognition system is presented in Fig. 1. In the figure, the first step emphasizes that a database is necessary in order to provide an automatic author identification system. Using information forms, various examples of people's handwriting in the Persian language have been collected in this article. Following the scanning of the samples, the samples are pre-processed. The operations performed at this stage include binarization and noise reduction. As a final step, the image will be transformed into a texture using an efficient algorithm. Afterward, the features that clearly demonstrate the differences between the handwritings are extracted. A new algorithm is used to extract the desired features from the handwritten image, which is considered as a texture in this study. In the following stage, the system is trained, and in the final stage, the system's success rate in identifying the author is evaluated based on the test data. Each step will be explained in more detail in the following paragraphs.

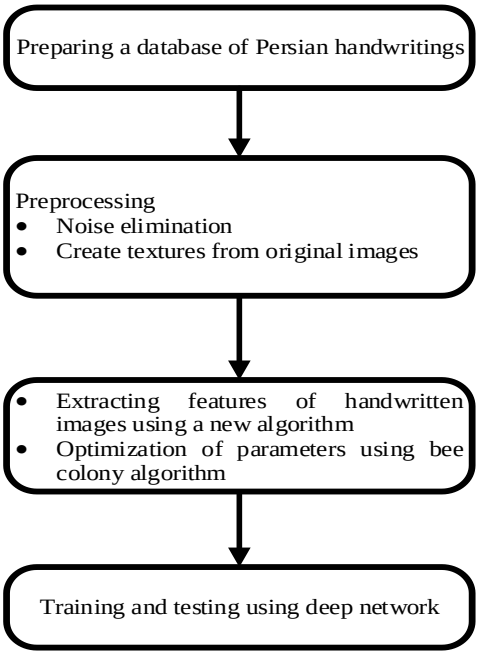

Fig. 1. General steps of the proposed author identification system.

A. Preparation of Database

To evaluate pattern recognition problems, a labeled data set is required. There is no exception to this rule when it comes to identifying the author. There are many databases available for identifying authors from manuscripts in the English language, which is a relatively new field of research. In contrast, there is a much smaller amount of data available for Persian. An example of a handwritten database for the Persian language is reported in study [23]. This database has been collected from their handwriting to identify the mental states and psychological and emotional characteristics of people.

In this study, participants were asked to write a text on an A4 sheet of paper. To investigate the effects of pen type, paper type, and various uncertainties (such as environmental noise), a comprehensive database has been developed. The proposed database consists of handwriting examples composed from 20 participants over a variety of time periods and environments. We asked each participant to write a desired text, preferably one line, and then repeat it nine times at different intervals. For the collection of the writings, two different types of standard paper were used, COPIMAX-Executive and PaperOne. Also, in order to check the type of pen, two different types of Schneider pens with a writing diameter of 0.4 mm and a Xiaomi MJZXBO1WC pen with a writing diameter of 0.5 mm were used. Based on the above parameters, the dataset collected from 20 participants comprises 60 pages and 600 sentences. According to Fig. 2, the sentence samples have a height of 236 pixels and a width of variable pixels. Approximately 2339 x 1656 pixels are the size of sample pages. We scanned each sample at a resolution of 600 dpi and saved it with 256 gray levels in a separate file in the *.tif format for each author.

B. Databases

Since Persian language databases are not available to identify the author, databases of other available languages have been applied to evaluate the accuracy of the proposed technique. A description of the databases that were used in the experiment is provided in this section. Three databases are included in this group, namely QUWI[24], IFN/ENIT [25] and IAM[26]. As part of the QUWI dataset, 1017 Arabic and 975 English authors have provided their handwriting. In the IAM database, there are 1066 samples of English handwriting from 400 different authors. There are also 937 Arabic manuscripts from 411 different authors included in the IFN/ENIT dataset. An example of these datasets can be found in Fig. 2. Additionally, the Firemaker dataset [27] is used, which contains 1000 pages of handwriting from 250 different authors. Approximately 80% of the words are used in the training phase and 20% in the testing phase for each writer.

C. Data Pre-Processing

During the pre-processing stage, binarization, noise removal, and texture extraction are performed on each image. Upon saving the samples, we aligned the pages based on the left margin at 0.1 degrees accuracy so that the lines would be vertical and the page would be smooth. In the next step, the image of each sentence was saved in a separate file with a height of 236 pixels and a variable width. Following the separation of 6000 sentences, sentences size was first changed to 570 pixels with variable width, and the size of the image was later changed to 225 pixels after normalization. Following this, each sentence is divided into 225 x 225-pixel samples using the segmentation method. Fig. 3 shows a division operation on one of the sentences.

Fig. 2. Handwriting samples from different datasets (a) Arabic QUWI, (b) English QUWI, (c) IFN/ENIT and (d) IAM.

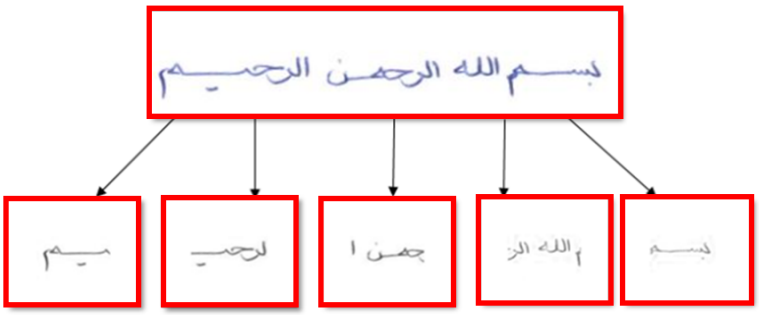

Fig. 3. Classification of one of the sentences.

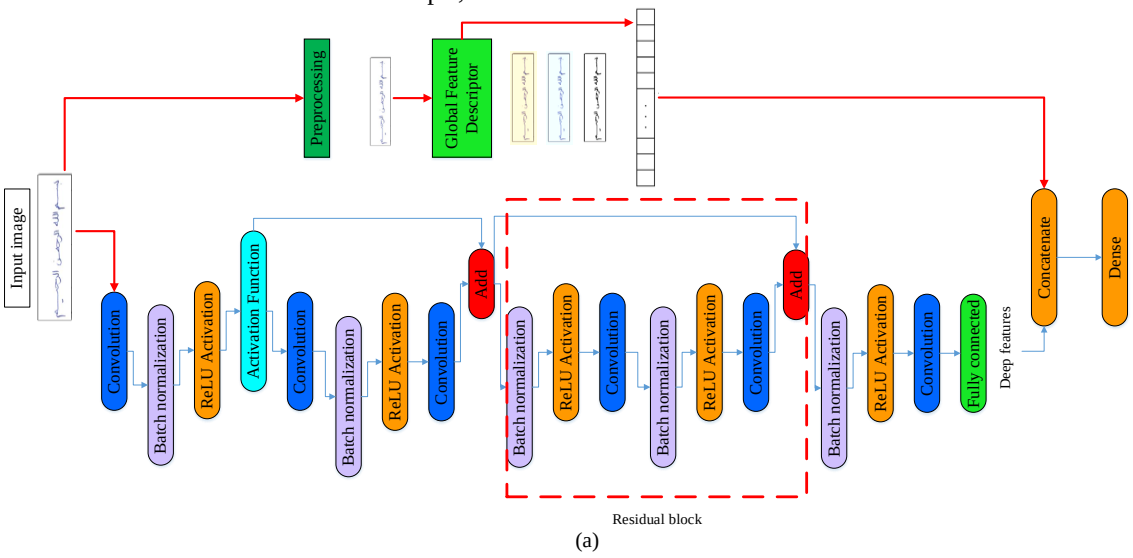
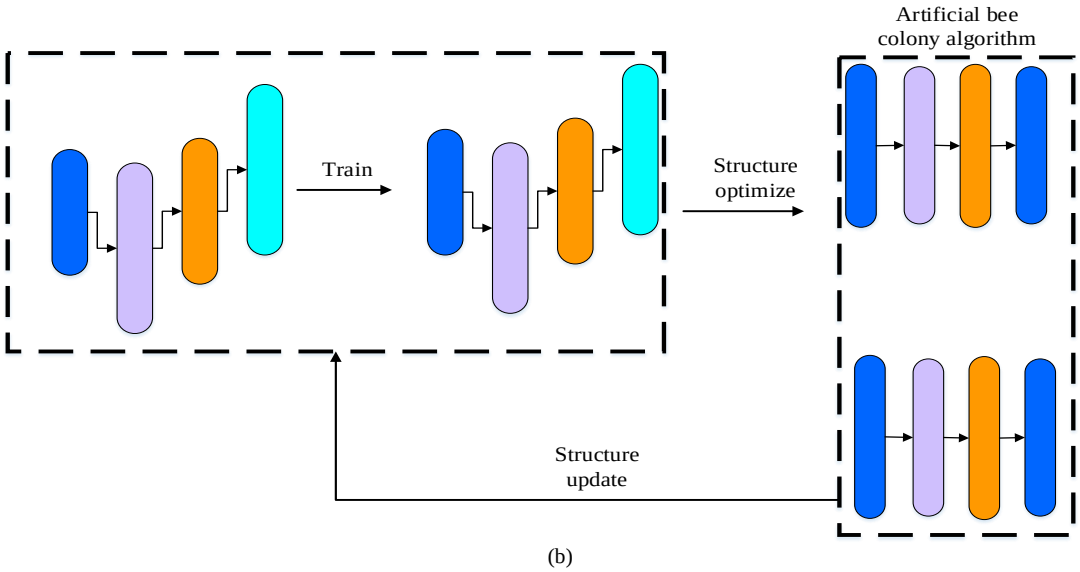
D. Proposed Hybrid Network Model Architecture

Our study presents a method for identifying writers by extracting the features of their texts using an innovative and highly efficient approach. Consequently, since we are seeking to extract the most efficient features from the manuscripts, we are jointly using the RosNet deep neural network model and classical extraction of global features. The architecture of the proposed system is displayed in Fig. 4. The details of the proposed network architecture will be discussed in the following paragraphs.



(a)



(b)

Fig. 4. An overview of the proposed hybrid model architecture. The first path extracts global features in a classical manner, while the second path extracts and integrates modern features based on the RosNet deep network model.

This figure indicates that a deep residual network, like the popular ResNet model, has been used to identify the writer. Considering the large number of parameters in deep networks, network training requires a considerable amount of learner effort. Furthermore, the vanishing gradient problem arises as the network deepens, resulting in a large error during the training stage. A modular architecture was developed to address this defect, where residual blocks are arranged one after another along with the connections related to the same mapping. The following calculations are performed in a residual block [28]:

$$x_{l+1} = x_l + F(x_l . W_l) \quad (1)$$

where, x_l and x_{l+1} are, respectively, the input and output of the residual block. The variable of W_l represents the set of weights, and F is the residual function. Based on the above relationship, if the added layer acts as a layer with the same mapping performance, the network performance in the deep model should not have more training error than the shallow model. Recursively, one can write the following relation for each residual block L:

$$x_L = x_l + \sum_{i=1}^{L} F(x_i . W_i) \quad (2)$$

As well, the derivative chain law in the backpropagation network provides the following relationship for the cost function:

$$\frac{\partial \varepsilon}{\partial x_l} = \frac{\partial \varepsilon}{\partial x_L}\frac{\partial x_L}{\partial x_l} = \frac{\partial \varepsilon}{\partial x_l}\left(1 + \frac{\partial}{\partial x_l}\sum_{i=1}^{L} F(x_i . W_i)\right) \quad (3)$$

Based on the above relation, it can be concluded that the gradient $\partial\varepsilon/\partial x_l$ propagates information with or without weight layers. The RosNet network architecture used in this study consists of 18 layers, including four residual blocks of the same structure. As shown in Fig. 3, the batch normalization layer and the ReLU activation function are applied before the convoluted layers. There are also the same number of filters used in each residual block, with the exception of the last convolution layer, which has double the number of filters to maintain its computational complexity. Accordingly, as the depth of the network increases, the number of filters in the residual blocks will be 64, 128, 256, and 512, respectively. As in the basic version of RosNet, the input consists of a set of image fragments; however, in this paper, additional input is also provided to the network in order to represent the features of the image better. In order to accomplish this, global features have been used for the first time in this work. This feature combination is then combined with the features extracted by the deep network in the final residual block, and the final classification is then made based on the combination of these two features. RosNet-18 architecture provides 512 dimensions, which are combined with the proposed global feature vector, which is 189 dimensions, to produce a 701-dimensional feature vector. This number of features constitutes the input of the dense layer, and its output is determined by the number of classes in each dataset. The existing experiments demonstrate that the proposed feature vector effectively represents the global and local information in the image. Following our analysis of the deep residual network base model and the proposed hybrid network method on several databases of handwriting images in the next section, we demonstrate that the joint feature vector produced by this method is more efficient than the feature vector generated by the base model and other methods of similar nature. To obtain the best convergence rate, the proposed network's hyperparameters have been carefully adjusted. After extensive experimentation, the cross-entropy error function and the bee colony optimizer with a learning rate of 0.001 were selected. The network was trained using the conventional error backpropagation method with a batch size of 64. This choice of parameters was driven by a series of trials aimed at optimizing the network's performance. Various combinations of learning rates, optimizers, and error functions were tested to identify the configuration that provided the best convergence rate and accuracy. The sensitivity of these parameters on the results was carefully analyzed. For instance, adjustments in the learning rate directly impacted the speed and stability of convergence, while different optimizers influenced the network's ability to escape local minima and achieve a more global optimum. The selected parameters demonstrated the best performance in our experiments, achieving a balance between training speed and accuracy. However, we acknowledge that further tuning and experimentation with alternative sets of values could potentially enhance the results. Future work could involve a more systematic exploration of the parameter space, perhaps using automated hyperparameter optimization techniques to fine-tune the network further. Slight changes in the learning rate (e.g., ±0.0005) significantly impacted convergence speed and final accuracy, underscoring the importance of precise tuning. Increasing the number of layers beyond 20 showed diminishing returns and a higher risk of overfitting, while fewer layers reduced the model's capacity to learn complex features.

It is necessary to determine the optimal hyperparameters when working with deep networks. Manually determining the optimal parameter will be very challenging if there are a large number of these parameters. To obtain the optimal parameters of the used convolutional network, this article utilizes the bee colony algorithm. The general structure of this algorithm was summarized by He et al. [34]. It is necessary to specify the number of elementary particles in this structure. Randomly assigned particles are used for this purpose. There are actually several different architectures of convolutional neural networks in each of these particles.

E. Additional Training Data

In order to train the proposed model, training data samples are required since it is a supervised learning method. Among the challenges of deep learning is the dependence on a large amount of training data. In this work, we have increased the number of training samples in order to overcome this challenge with conventional methods while the proposed model is used in the training process. The selection of data augmentation techniques must be carefully considered, and not all data augmentation techniques can be applied to handwritten data, so this study used a combination of random grayscale techniques, color jitter techniques, and random rotation techniques as data augmentation techniques after attempting many different techniques. As a result of the use of data augmentation techniques, the training dataset is increased by approximately 70%.

III. TESTS AND RESULTS

This section provides the details of the experiments performed to validate the proposed technique, along with a discussion of the results. The proposed author identification method and all experiments were conducted using Python, leveraging various libraries, with NumPy and PyTorch being the most significant. The parameters of the proposed deep network are listed in Table I.

TABLE I. PARAMETERS RELATED TO THE IMPLEMENTATION OF THE PROPOSED DEEP NETWORK

Parameter	Value
Optimizer	Adam
Loss function	Binary cross-entropy
Performance metric	Accuracy
Total Classes	2 (Gate and Non-Gate)
Batch Size	64
Epoch	150

The choice of parameters was made after extensive experimentation to ensure the best convergence rate and performance. The Adam optimizer was selected for its adaptive learning rate properties and efficient handling of sparse gradients. The binary cross-entropy loss function was chosen as the problem involves two classes, making it suitable for the classification task. Accuracy was used as the primary performance metric to evaluate the effectiveness of the model in distinguishing between the two classes (Gate and Non-Gate). The batch size of 64 was found to provide a good balance between computational efficiency and training stability, while the number of epochs (150) ensured sufficient training time for the model to learn the underlying patterns in the data. All results and reviews of the proposed method were conducted using this setup, and the experiments confirmed the robustness and reliability of the approach in identifying authors based on their handwriting. Further experimentation with different parameter sets could potentially enhance the results, as discussed in the sensitivity analysis section. Overall, the experimental results validate the effectiveness of the proposed method, demonstrating its potential for practical application in author identification tasks.

A. Evaluation Criteria

In order to evaluate the performance of the proposed method, 4 evaluation criteria, including recall (see Eq. (4)), precision (see Eq. (5)), accuracy (see Eq. (6)) and F-measure (see Eq. (7)), are used. Also, based on these parameters, the system performance characteristic (ROC) is calculated.

$$Re = \frac{TP}{TP + FP} \tag{4}$$

$$Pr = \frac{TP}{TP + FN} \tag{5}$$

$$\text{ACC} = \frac{TP + TN}{TP + TN + FP + FN} \tag{6}$$

$$\text{Fvalue} = \frac{2\,Pr \times Re}{Pr + Re} \tag{7}$$

where, *TN* remains the number of correctly identified negative samples, *TP* stands number of correctly identified positive samples, *FP* is the number of false positive identifications, and *FN* is the number of false negative identifications.

B. Evaluation and Comparison of the Presented Method

In this section, the evaluation results of the proposed method are presented based on the combination of the global features extracted by the classical method with the features extracted by the deep neural network model. In this evaluation, the RosNet model, which is the basis for the proposed architecture, and some methods proposed in previous studies are evaluated using the database discussed under the same conditions. The test data set, which includes handwriting images, is input to both the basic deep neural network and the proposed deep neural network, and then the results of the proposed method are presented. For the dataset collected in this study, these results are shown in Table II. As can be seen, the accuracy of the proposed method with two-way hybrid architecture has improved significantly compared to the RosNet basic method for writer identification and has increased from 84% to 99.4%. Compared to the basic method, this result was achieved with a significant and proportional improvement in all components of sensitivity and identification, indicating the efficacy of the proposed methodology. In spite of the improvement in accuracy, the proposed method requires a short amount of training time. Additionally, the two components of accuracy and efficiency are calculated and listed in Table II. Based on these two components, Fig. 5 illustrates the Precision-Recall curve. The best state of this curve is when the value of the area under these curves is equal to the number one, and vice versa. The closer it is to zero, the weaker prediction is obtained [29].

TABLE II. COMPARISON OF THE PROPOSED METHOD AND THE BASIC METHOD FOR THE CURRENT RESEARCH DATASET

Parameter	Method	
	Proposed method	***ResNet***
TP	99%	84%
TN	91%	85%
FN	5%	11%
FP	2%	15%
recall	0.98	0.84
precision	0.93	0.88
F-measure	0.95	0.83
accuracy	98%	87%
Time	0.651 sec/image	0.463 sec/image

The results of the suggested network for the three datasets are presented in Table III. The results obtained using the new hybrid architecture are superior to those obtained using the basic network in all three databases. Additionally, in this table, the results achieved at the beginning of the feature extraction process are also compared with the final results. However, even

in cases where the results of the suggested method and the basic method are similar, the proposed method has achieved the desired result much more rapidly. In other words, by combining features extracted by the deep method with those extracted by the classical method, we are not only able to reach the maximum desired result much more quickly, but it is also often more accurate. Due to the small number of writers, the IMA database could not show the influence of the suggested method very well and converged very quickly to the maximum possible accuracy value. The two QUWI and IFN/ENIT databases, which have more data and have a more difficult situation in separating handwriting, show the effect of the presented method well. This conclusion can also be understood based on the graphs displayed in Fig. 6.

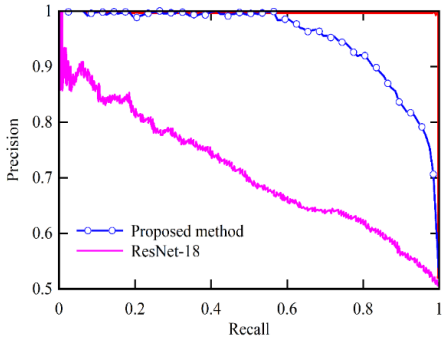


Fig. 5. PR curve of proposed method for the dataset collected in this research.

To evaluate the proposed model, the four data sets described in section B have been used. The results of the identification of the proposed hybrid model and the base model of ResNet-18 with the TTA technique to identify the writers using each of the four data sets are given in Table III. According to Table III, the proposed improved network-based model performs better than the basic model for identifying the writer using each of the four datasets.

Several state-of-the-art methods are compared with the proposed deep network model in the following section. A comparison of the results is provided in Tables IV and V. According to the proposed conjugate method, the accuracy of the IMA dataset is 97.60%, which is a higher level of accuracy than that observed in previous studies. In this table, Khan et al. [30] reported an accuracy of 97.20% for 650 authors, which is close to our results. Moreover, according to Table V, for the Firemaker dataset, our proposed model has improved significantly in comparison to the existing results, with an accuracy of 99.71%, which is about 1.78% better than that of Khan et al. [31].

TABLE III. EVALUATION RESULTS OF THE PROPOSED MODEL AND RESNET-18 MODEL FOR FOUR COMPREHENSIVE DATA SETS

Method	Dataset			Accuracy (%)
	Dataset	*Language*	*Writer number*	
Proposed hybrid network	Present study	Persian	60	98.2
	IMA	English	400	97.6
	QUWI	Arabic	1017	98.5
	IFN/ENIT	Arabic	411	99.7
ResNet-18	Present study	Persian	60	83.0
	IMA	English	400	96.3
	QUWI	Arabic	1017	89.8
	IFN/ENIT	Arabic	411	96.2

C. Evaluation and Comparison of the Presented Method with low Training Data

Generally, the number of training samples is considered to be a challenge in deep learning methods, so methods that can achieve desirable results with fewer training samples are always considered. A method of strengthening training data has been used to compensate for the lack of training samples in this study. Although the generated samples are based on the number of real base samples, the evaluation of the newly developed method shows that it is able to obtain favorable results even with very few base samples. In this experiment, we considered the number of basic training samples equal to the correct multiplier of 10% of the entire dataset and performed the evaluation process with the remaining images. A summary of the results of this experiment, which represents an intermediate result of two implementations of the suggested technique, can be found in Table VI. Also, Fig. 7 demonstrates that the suggested method achieved 68.97% accuracy with 60% of the training sample. However, if only 5% of the training sample is used, this accuracy is reduced to 82%. In this way, the influence of training sample numbers is clearly visible in this image.

TABLE VI. COMPARISON OF THE ACCURACY OF THE RESULTS FOR DIFFERENT NUMBERS OF TRAINING SAMPLES OF THE DATABASE COLLECTED IN THIS RESEARCH (EPOCH=130)

Training samples	10%	20%	30%	40%	60%	80%	100%
Accuracy (%)	87.54	91.04	94.97	96.12	97.24	97.56	98.60

IV. CONCLUSION

This paper introduces a novel approach to offline author handwriting recognition by leveraging the bee colony optimization algorithm and integrating deep and classical image features. The proposed architecture extends the 18-layer RosNet model, incorporating a two-path architecture where deep neural network features from RosNet are combined in one path, and global features are fused in a classical manner in the second path. Notably, the bee colony optimization algorithm is employed to select optimal features and determine the appropriate number of layers for enhanced accuracy in author identification. Through comprehensive evaluation using various classification criteria, the method consistently demonstrates promising performance across different datasets.

In conclusion, the proposed method presents a novel approach to offline author handwriting recognition, leveraging the bee colony optimization algorithm and integrating deep and classical image features. The rationale behind selecting this method stems from its ability to capitalize on the strengths of deep learning techniques for feature extraction, the flexibility offered by the two-path architecture, and the innovative use of the bee colony optimization algorithm for feature selection.

Furthermore, it is important to acknowledge the limitations of existing methods that may hinder their effectiveness in addressing the problem at hand. These limitations include the reliance on handcrafted features, which may not capture the complexity of handwriting styles adequately, and scalability issues that limit their applicability to large datasets or real-world scenarios.

By addressing these limitations and leveraging the strengths of our proposed method, we aim to advance the field of offline author handwriting recognition and contribute to the development of more accurate and robust recognition systems.

***Abstract*—It is common knowledge that mechanical systems need oversight and maintenance procedures. There are numerous prevalent operation monitoring techniques, and in the era of IoT and predictive maintenance, it is possible to find multiple solutions to supervise these systems. This article describes the design and implementation of a low-cost system, which use an IoT approach to detect overheated idlers in conveyors belt in mining facilities. The system involves the use of temperature sensors, coordinately with heat map image sensors. The users (i.e., mining operators) can monitor overheated idlers in the whole conveyor belt, making on-demand queries using Telegram or a website, and also receiving autonomous warnings. Prototypes of this system were installed on a conveyor belt at a construction materials manufacturing company, and also in a copper mining company, both located in Apurimac, Peru. The usability and usefulness of the system were evaluated by 20 experts in maintenance and operation of conveyor belts, who filled the questionnaire proposed by TAM (Technology Acceptance Model). The results show that 91% of them consider the system useful for detecting the overheating of idlers in a conveyor belt, and 93% of them considers the solution as easy to use.**

Keywords*—IoT system; overheated idler detection; conveyor belts; mining companies; autonomous and on-demand monitoring

I. Introduction

Conveyor belts have a wide range of uses across various industries due to their versatility, efficiency, and ability to transport materials smoothly and continuously. Some common uses include, e.g., a) mining industry, where they are used to transport bulk materials such as coal, ore, minerals, and aggregates from the mine site to processing plants or loading docks; b) manufacturing and assembly lines, where they facilitate the movement of components or products along production lines; c) agriculture, where they are utilized for handling bulk materials like grains, seeds, fertilizers, and harvested crops; d) baggage handling, since they ease the transportation of luggage.

In mining industry, conveyor belts are indispensable, providing a reliable, efficient, and safe means to transport bulk materials. Their versatility, adaptability, and automation capabilities contribute to improved productivity, safety, and profitability in mining operations worldwide. Overland conveyor systems are frequently used for long-distance material transport in mining operations. These systems typically consist of a series of conveyor belts, supported by idlers or rollers mounted on a frame structure. Overland conveyors can span several kilometers and are used to move bulk materials between the mining site and processing facilities, stockpiles, and transportation hubs.

In this scenario, the random failure idler rollers is the main concern for conveyor operators [1]–[3]. Every belt, depending on its features, can involve hundreds or thousands of idler rollers. Under normal conditions, the life expectancy of an idler roller on a conveyor belt ranges between 6 and 24 months. The failure of a single idler roller can jeopardize the operation of the whole belt, producing a major incident or a stop to perform unscheduled maintenance activities.

Failed idler rollers significantly increase energy consumption during its operation and may seriously damage conveyor belts. It also increases the maintenance costs, but particularly the economic lost produced by the downtime of belt conveyor systems [4]-[5], which depending on the length of such a time window and the mining activity, the downtime period can cost some millions of dollars. For these reasons, the early detection of overheated idlers in belt conveyors is mandatory in the mining industry.

The failures of idler rollers can be divided into three types: *incipient failure* (failure due to bearing fatigue), *final failure* (the roll must be replaced immediately), and *catastrophic failure* (in which the roll would severely damage the conveyor belt) [6]. The malfunction of inner bearings is the most prevalent cause of failure for idler rollers [6]-[7]. In order to address the maintenance, there are some well-known strategies: online maintenance, portable maintenance, and onsite maintenance [7].

Monitoring the deterioration of idlers deployed to support the belt conveyor is one of the primary challenges. Dusty conditions, excessive humidity, impulsive load, and temporary overloading can accelerate the deterioration of the idler's coating and rolling element bearings mounted inside the idler to provide rolling ability [8].

Typically, mechanical systems require oversight and routine maintenance. There are several approaches for overseeing belt conveyors, especially combining IoT technologies to perform predictive maintenance. Some of these solutions are limited to belt conveyors used in underground

mining or overland mining [9]. Due to their large quantity and spatial distribution, it is still challenging to monitor idler rollers effectively [10]. Traditionally, this industry relies on routine human inspection to detect defective idlers, which is an intensive, inefficient, and expensive labor [11].

If we consider the use of idlers in conveyor belts for long distances, the monitoring activity becomes more challenging. Some of the regular problems in these belts include: a) *wear and tear*, especially in long-distance conveyor applications where they are exposed to continuous friction, impact loading, and abrasive materials; b) *misalignment*, it means idlers may experience misalignment due to uneven loading, structural misalignment, belt mis-tracking, increased friction, and premature wear on the conveyor belt; c) *belt damage*, it means idlers can cause damage to the conveyor belt, including belt edge wear, cover damage, and splice failures; d) *roller seizure*, it means that idler rollers may seize or lock up due to inadequate lubrication, contamination, or bearing failure and e) *environmental factors*, since idlers in long-distance conveyor belts are exposed to harsh environmental conditions, including dust, moisture, temperature fluctuations, and corrosive substances.

In addition, a mining plant is divided into three areas: *crushing*, *grinding* and *flotation*. The *crushing* area usually has a scheduled shutdown frequency of one stop every 10 days regardless of the weather in the operation area and the features of conveyor belts. The length of the maintenance period depends on several criteria (e.g., complexity and length of the belt), and it can go from two to three hours to the whole day in critical situations.

Similarly, the *grinding* area has also a scheduled shutdown frequency of one preventive maintenance stop period every month, regardless of the weather in that area; and the *floating* area considers one stop every three months, also considering several variables including the weather.

As mentioned before, the inspection of idlers on conveyor belts is crucial for ensuring optimal performance, identifying potential issues, and preventing costly downtime. The manual inspection (made by human) involves visual review of idlers by trained personnel, who visually check idlers for signs of wear, misalignment, damage and other issues. Typically, manual inspections are conducted during the shutdown periods. These inspections try to ensure the regular operation of the conveyor belts, and minimize the stop periods required for preventive maintenance.

Next section presents the related work. Section III describes the design and implementation of the system prototype. Section IV presents the system evaluation and Section V shows the obtained results. Section VI presents the main conclusions and the future work.

II. Related Work

Detecting failures in a conveyor belt is challenging, one way to address it is monitoring the noise. In that sense, Fedroko et al. [12] states that a reliable trouble-free operation of continuous transport systems requires regular monitoring and evaluation of each operational indicator. Particularly, advantageous evaluation technologies are those which allow the transport system to be monitored to the widest extent, in the easiest way to identify adverse parameters or locations of occurrence of undesired operational conditions. Such monitoring approach include acoustic visualization techniques.

Despite their undeniable advantages and great potential in the field of belt conveyance, they have been used only minimally. Particularly, the work reported in study [12] examines possibilities of using acoustic visualization techniques in belt conveyance with focus on selected functional parts.

Likewise, Chamorro et al. [13] implement multiple sensors and communication protocols along with computer vision for monitoring the health of a conveyor belt system. The data of the monitored variables is captured using industrial-grade sensors and conditioned in a PLC. This data is sent to a wireless radio frequency module that transmits wirelessly to a remote receiver paired to an IoT gateway. Images taken by a camera are simultaneously processed by a local computer, which runs a computer vision algorithm used to establish if the conveyor belt is operating normally. Both data, i.e., those retrieved from the sensors and the visual information, are sent to the cloud for remote users to monitor the system's operating conditions, and also to detect potential failures prior to their occurrence.

Dabek et al. [14] report an automatic procedure to detect overheated idlers in belt conveyors using fusion of infrared and RGB images. It was proposed to conduct routine inspections of machines operating under extremely harsh conditions in deep underground mines. Particularly, this paper proposes a mobile unmanned ground vehicle (UGV) platform, equipped with multiple data acquisition systems, to support inspection procedures. Even though maintenance personnel with the required experience can identify problems almost instantly, their presence in hazardous areas is restricted due to harsh conditions, such as temperature, humidity, and poisonous gas risk. Therefore, it is recommended to employ inspection robots that collect data, and algorithms for their processing. The authors propose combining red-green-blue (RGB) and infrared (IR) images to detect idlers that have become overheated.

The work reported in study [14] also presents a novel method for image processing, which uses conveyor-specific characteristics to pre-process the RGB image, and thus to reduce the number of non-informative components in the images collected by the robot. The authors then apply this result to the processing of IR images to increase SNR and detect hot spots in IR images.

Likewise, Liu et al. [11] conducted an experimental research on condition monitoring of belt conveyor idlers. Depending on the length of a belt conveyor, tens of thousands of idler rollers are susceptible to random failure. However, monitoring solutions for idlers of belt conveyors are underdeveloped, and this is because the selection of monitoring parameters remains arbitrary. This work seeks to determine which parameters can accurately determine the technical condition of idler rollers for monitoring purposes. According to the authors, measuring the temperature at the roll shafts is a simple and effective method for condition monitoring of belt conveyor idlers.

In Marasova et al. [15] the researchers examine the incorporation of RFID tags as information carriers to monitor conveyor belts (ozone-induced aging or accelerated thermal aging, damage to cover layers and the carcass, and ignition). During the monitoring, it is essential to document conveyor belt failures and the causes of damage, as well as any other issues that arise from using belt conveyors. The research results on RFID tags and an analysis of their thermal aging behavior show that it is easy to simulate the conditions of hot vulcanization of conveyor belts, particularly during splicing (as well as production) and ozone-induced aging of conveyor belts. The outcome of this article is a determination of the feasibility of implementing RFID technology in transporting mineral materials via belt conveyor systems in actual operations.

In the research papers mentioned above, the authors agree that idlers on the conveyor belt require scheduled supervision to verify the current status of each idler; however, sometimes idler overheating occurs suddenly. In this paper, we propose an IoT system that uses a temperature sensor and thermal camera to detect overheated idlers in belt conveyors. It allows inspectors to perform preventive inspections during operation and shutdown periods, by making queries to the sensors and receiving warnings through the Telegram Social Network. This online monitoring does not avoid the stops for scheduled visual inspections, but it reduces the length of these time windows and the unexpected stops. Both aspects positively impact on the operation costs of the conveyor belts.

III. Design and Implementation of the Prototype

In this section we describe the operational environment for which the proposed system was designed and built. We also describe the system architecture, and its main components and behavior. This section also presents the functionality to monitor the operation conditions of the idler rollers in conveyor belts.

A. Operational Environment

The prototype of the system is inside the green casing shown in Fig. 1; it is located near the idler of the conveyor belt. The system includes three main components: a) a temperature sensor that measures the temperature of the idler; b) a thermographic image sensor that obtains a heat map of the idler; and c) a video camera that takes snapshots of the current state of the idler rollers to see if there is dust or sand around it. This latter component also records video to see the movement and hear the noise that the idler could generate.

Fig. 1. The prototype installed in "MMG Las Bambas" mining company (Peru).

The prototype is placed near the idler on a conveyor belt, then the person responsible for monitoring can make queries using their mobile device through the Telegram social network, and the system responds with the temperature, photo, heat map or video depending on the request. This allows monitoring the heating of the idler on a conveyor belt over time.

B. System Architecture

The system architecture shows its main components, their externally visible properties, and their relationships (see Fig. 2). Particularly, the temperature sensor reads the data from the environment; such data is sent to the Raspberry Pi (local mini-server) and then sent through the Wi-Fi or Modem connection to the database server. If the internet connection is not available, the data will be stored temporally in the Raspberry Pi in "CSV" file. Then, when the internet connectivity is re-established, the cloud database server will be updated with the information, and the CSV file will be emptied. The temperature data is displayed to the client via a web browser, tablet PC or cell phone.

On the other hand, the system uses an Arduino board. It connects to the thermal sensor that reads the thermal image, and then sends this data to the mini–Raspberry Pi server and the database in the cloud.

The users utilize the Telegram application to request temperature or thermal information, and the system answers accordingly. Moreover, the users can also request an instant photo or video. That request is sent to the Raspberry Pi, and then to the web server in the cloud. The system answers to the user through messages in the Telegram social network. This image or video cannot be delivered to the user without connectivity, so it is stored locally on the Raspberry Pi board. Fig. 2 shows the system architecture, and next subsection describes its components.

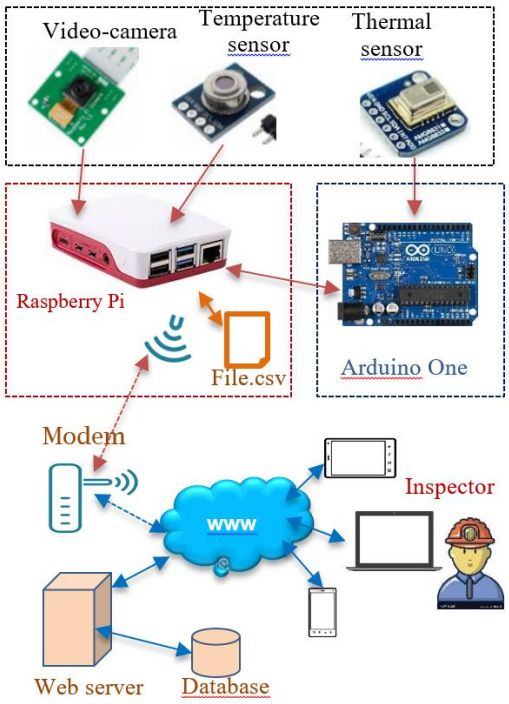

Fig. 2. System architecture.

C. Sensors and Devices

Table I shows the list of the sensors and devices required for the implementation of this prototype.

D. System Technology

The system programming was carried out using several languages, libraries and tools; the details are shown in Table II.

TABLE I. SENSORS AND CONTROLLERS

Component	Description	Image
Arduino One	It is a board based on the ATmega328P microcontroller. It has 14 digital input/output pins (6 of which can be used with PWM). It has six analog inputs, a 16Mhz crystal, a power jack connector, USB connection.	
Raspberry Pi 4 Model B	It has 4 GB of RAM (LPDDR), Dual Band Wireless LAN 802.11 b/g/n/ac, Bluetooth 5.0, 2 USB 3.0 ports, 2 USB 2.0 ports, Gigabit Ethernet Power-over-Ethernet, 40 GPIO connector pins, two micro-HDMI ports, CSI camera port, 3.5mm combo jack for analog audio and composite video, microSD card slot, USB-C connector.	
Temperature sensor (MLX90614)	It is an infrared thermometer to sense temperature (without direct contact but at a short distance). It has an internal 17-bit ADC; additionally, it has SMBus/I2C digital communication interface.	
Pi Camera	Camera v2 for Raspberry pi, has a Sony IMX219 sensor, is 8mpx, 1080P	
Termal camera (AMG8833)	It is an IR thermal camera sensor. It has an array of IR thermal sensors distributed in an 8-row by 8-column matrix.	

TABLE II. SOFTWARE PROGRAMMING LANGUAGES AND LIBRARIES

Tool	Description
Web application	
PHP	Back-end programming language
JavaScript	Front-end programming language.
HTML5	Markup language
CSS	Styles language
MySQL	Database for the web environment
Laravel	Open source PHP framework that implements the MVC pattern
Chart.js	Library for displaying graphics
Highcharts JS	Library for displaying interactive graphics
Arduino	
Arduino	Specific programming language for Arduino
Raspberry Pi	
CSV	Comma Separated Value file (CSV)
Raspbian	Mini-server operating system
Python	Programming language
MySQL	Database
Client	
Telegram	Social network mobile application to make queries to the system
Bot-API	Telegram API allows the creation of programs that interact with the regular Telegram application server
Web browser	A web browser that the client uses to make queries (Firefox, Chrome, Edge)

E. The Website for Monitoring Overheated Idlers

The URL https://polines.educaticss.com hosts the website and database of the system. On the left side, the menu has seven options (see Fig. 3): home, users, sensors, readings, alerts, reports, and settings.

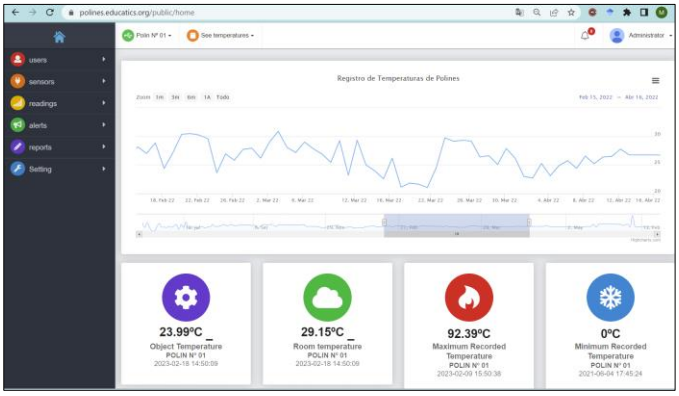

Fig. 3. The website panel for monitoring temperature.

The "home" option shows a graph with the evolution of the minimum and maximum temperatures of the idler rollers (polines). The "Users" option allows the management of the users and assigns the role to be played by each person. The "Sensors" option allows registering the sensors installed on the idlers. The "Readings" shows the idlers list, and the temperatures read in a specific time window. The "Reports" option allows the user to download (in Excel format) the data read between two dates. Finally, the "setting" option is used to configure particular variables, for example, the minimum and maximum temperature allowed on the pole. If the value read is out of this range, the system sends a warning to the conveyor belt operators through a Telegram message.

F. Notifications by Telegram Social Network

In order to make better control of the temperature in idler rollers, a module was implemented to send notifications to mobile devices of particular users (operators and eventually inspectors) via Telegram. This social network allows running bots, which are third-party applications that can be executed within the messaging application. Table III shows commands for the telegram social network.

TABLE III. COMMANDS FOR THE TELEGRAM SOCIAL NETWORK

Command	Description
/help	Command to show the commands
/temperature	Command to see the temperature
/photo	Command to take a photo
/video	Command to record a video
/ thermal-camera	Command to see color map image

The notification mechanism was programmed to control the temperature in the idler rollers when the temperature exceeds a maximum limit, for example, more than 70 °C. In this case, the system sends a notification to the user (responsible for monitoring the conveyor belt). This user can make better decisions, for instance, to schedule an immediate shutdown of

the conveyor belt operation. The notification is a text message delivered to the cell phone, via Telegram or email. In addition, the system can take a picture or record a video to see the idler roller in real-time (e.g., review the amount of accumulated dust). Table II shows the commands in Telegram.

There is always a responsible for inspecting the operation of the conveyor belt. This person makes queries using his smartphone. Fig. 4 shows a thermal image or heat map requested by an inspector through Telegram social network.

Fig. 4. Heatmap image requested from Telegram.

IV. System Evaluation

A. The Location of the Conveyor Belt

The tests of the system were conducted conveyor belts located in two facilities. The first one was the "ECONSA" construction materials manufacturing company (crushed stone, sand and others), located in Pachachaca, Abancay, Apurimac, Peru (Lat: -13.708071; long:-72.915837). The second mining facility was the “MMG Las Bambas” copper mining company, located in Challhuahuacho, Apurimac Peru (Lat: -14.09815858865329, Long: -72.32647024732222). Fig. 5 and Fig. 6 show each location on Google Maps.

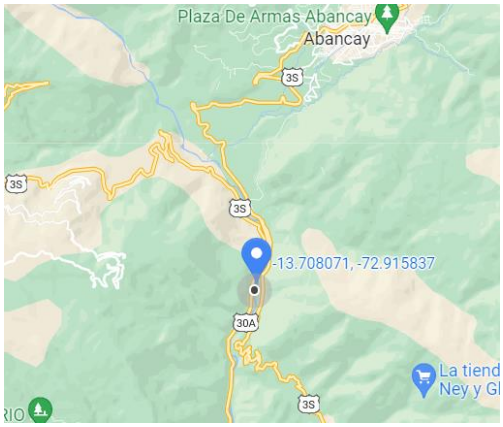

Fig. 5. Location of Econsa construction materials manufacturing company.

Fig. 6. Location of MMG Las Bambas copper mining company.

B. The System Prototype

As shown before, the system prototype has electronic devices, integrated circuits, connection cables, among others, which were covered by a casing that has ventilation. The case was built with a 3D printer that uses filament for printing. The 3D case for the prototype was printed in the Makerbot 3D printer. Fig. 7 shows the calibration of the 3D printer.

Fig. 7. 3D printer calibration.

This casing should have certain characteristics to ensure proper functionality and protection of the device, for example, the casing material should be heat-resistant to withstand the temperatures reached in the mining environment, and the design should allow for easy access to the components of the roller heating detection system for maintenance and troubleshooting. The final prototype of the system is shown in Fig. 8.

Fig. 8. Final prototype.

Installing the prototype in the conveyor belt was not easy, because only two telecom operators provided Internet connectivity in these areas. Fig. 9 shows the installation processes of the prototype on the conveyor belt.

Fig. 9. Installing the prototype in the conveyor belt of ECONSA company.

C. Cost of the System

Next table shows reference prices of the proposed system. Taking into account that this system monitors expensive mining machinery, this system can be considered a low-cost solution. Moreover, it represents just a small fraction of the cost of commercial equipment to perform this online monitoring activity. Table IV shows prices of the system components.

TABLE IV. PRICES OF THE SYSTEM COMPONENTS

Device	***Cost (USD)***
Arduino One	73.68
Raspberry Pi 4 Model B	163.16
Temperature sensor MLX90614	42.11
Camera Pi	57.89
Thermal sensor AMG8833	128.95
3D printing	36.84
Modem	60.53
Installation and configuration	78.95
Others	15.79
Total	*657.89*

D. The Testing Periods

This project was tested from March to May 2022 in ECONSA company, and then in November and December 2023 in MMG Las Bambas Company. To carry out the tests, the prototypes were installed on conveyor belts, one at ECONSA company and the other at MMG Las Bambas company.

In both cases, queries were delivered through the Telegram. The inspectors were able to ask for the temperature, thermographic image, photo and video of the idler rollers. Moreover, they verified that the temperature using the system had a difference of ±2ºC compared to the readings of analog thermometers. Fig. 10 shows an inspector comparing the temperatures in the field.

Fig. 10. The inspector comparing the temperatures in an idler roller.

V. SYSTEM EVALUATION INSTRUMENT AND RESULTS

For measuring the usability of the proposed system, the "Perceived Usefulness and Ease of Use" (PUEU) questionnaire [16] was applied. It measures the perceived "usefulness" and "ease of use" of a technological product to be created or launched, according to TAM (Technology Acceptance Model).

The questionnaire has twelve (12) items that are answered by the evaluators using a five-point Likert scale. The I1-I6 evaluate the perceived "usefulness" of the system, and the items I7-I12 rate the "Ease of Use" criteria (perceived usability). Table V shows the evaluation questionnaire.

TABLE V. TAM EVALUATION QUESTIONNAIRE

ID	***Evaluation Item***
I1	Using the system in my work would allow me to perform tasks more quickly
I2	Using the system would improve my job performance
I3	Using the system at work would increase my productivity.
I4	Using the system would improve my work efficiency.
I5	Using the system would make it easier for me to do my job.
I6	I would find the system useful in my work.
I7	Learning to operate the system would be easy for me.
I8	It would be easy for me to get the system to do what I tell it to do.
I9	My interaction with the system would be clear and understandable.
I10	I would find the system flexible to interact with.
I11	It would be easy for me to learn to use the system.
I12	I would find the system easy to use.

The questionnaire was applied to 20 persons experienced operating or inspecting conveyor belts that involve idlers rollers. Some of these people belonged to ECONSA, and others

to MMG Las Bambas company. All of them were experienced working in metal and non-metal mining environment and computing applications.

Before the evaluation process, we explained the functionality of the prototype for approximately 30 minutes. Then, they use the system for a month, and filled the questionnaire after that. The questionnaire results were processed, and the obtained results were the following:

A. Perceived Usefulness

According to the participants, 93% (65+28) of them consider the system useful for monitoring the idler rollers in a conveyor belt. The Fig. 11 shows the results of the perceived usefulness.

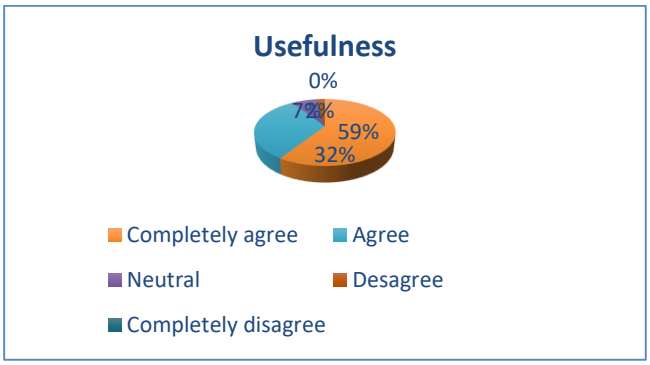

Fig. 11. Perceived usefulness of the system.

B. Perceived Usability

On the other hand, according to the participants' opinion, 95% (60+35) of them consider that the system has "Ease of Use" to monitor the pollinator in a conveyor belt. The Fig. 12 shows the results of the usability.

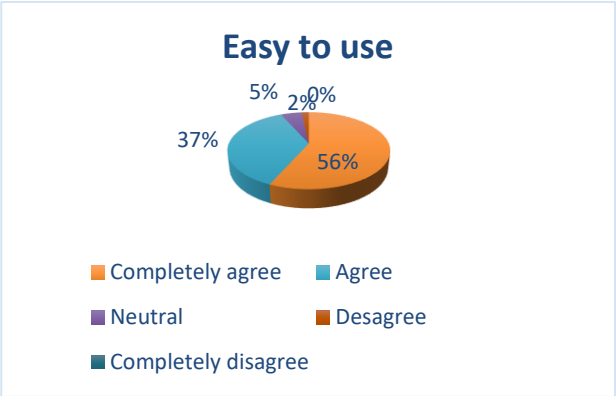

Fig. 12. Perceived usability of the system.

VI. Conclusion and Future Work

This paper presents a system prototype that was designed and developed for monitoring the temperature of idler rollers on conveyor belts. The system can measure the temperature, take photos, record videos and take thermographic pictures of these rollers. This functionality supports the monitoring activity performed by the inspectors in mining facilities.

These users monitor the operation conditions of the conveyor belts doing online queries from a mobile device, using a bot and the Telegram API, or asking for information through a web page. Using these mechanisms it is possible to see the temperature evolution per hour, day, week, month, and year. Moreover, this system autonomously sends warnings through Telegram, e.g., when the temperature exceeds a preset limit (when a idler roller starts to heat up).

On the other hand, after applying the PUEU evaluation questionnaire to 20 experienced operators and inspectors in two mining companies in Peru, it was possible to verify that 91% of these people consider the system useful for detecting the overheating of the idler rollers in a conveyor belt; and 93% of them perceive the solution as easy to use. Therefore, the users show their satisfaction with the system.

As future work, we will continue improving the robustness of the system. Moreover, we plan to use a solar panel so that the system is currently autonomous and works only with sunlight. In this way, the use of solar panels will contribute to reduce cost of electricity.

Acknowledgment

The authors want to thank the Micaela Bastidas National University of Apurímac, Peru, for funding this project, which was selected in the III contest of basic and applied research projects for teachers with the funding of mining royalty.

Incremental Learning for GRU and RNN-based Assamese UPoS Tagger

Kuwali Talukdar, Shikhar Kumar Sarma
Department of Information Technology, Guwahati University, Guwahati, India

***Abstract*—This research paper introduces a novel approach to enhance the performance of Universal Part-of-Speech (UPoS) tagging for the low-resource language Assamese, employing Recurrent Neural Networks (RNNs) and Gated Recurrent Units (GRUs). The novelty added in this study is the experimentation with Incremental Learning, a dynamic paradigm allowing the models to continually refine their understanding as they encounter new set of linguistic data. The proposed model utilizes the strengths of GRUs and traditional RNNs to capture long range sequential dependencies and contextual information within Assamese sentences. Incorporation of Incremental Learning ensures the model's adaptability to evolving linguistic patterns, particularly crucial for under-resourced languages like Assamese. Experimental results showcase the superiority of the proposed approach, achieving state-of-the-art accuracy in Assamese UPoS tagging. The research not only contributes to the field of natural language processing but also addresses the specific challenges posed by under-resourced languages. The significance of Incremental Learning is highlighted, showcasing its role in dynamically updating the model's knowledge base with new UPoS-tagged data. This feature proves essential in real-world scenarios where language evolves, ensuring sustained optimal performance in Assamese UPoS tagging. The paper presents the details of the innovative framework for UPoS tagging in Assamese, combining the significance of Incremental Learning with Deep Learning techniques, pushing the boundaries of natural language processing models for low resource languages exploring the importance of dynamic learning paradigms.**

Keywords*—*Assamese UPoS; PoS tagger; RNN; GRU; incremental learning

I. Introduction

The landscape of natural language processing (NLP) continues to evolve rapidly, presenting both challenges and opportunities for understanding and analyzing diverse languages, particularly in the context of digital world and Artificial Intelligence. For under-resourced languages, such as Assamese, the need for robust language processing models becomes particularly challenging. This paper introduces an exploration into advancing the effectiveness of Universal-part-of-speech (UPoS) tagging in Assamese, a language with unique syntactic characteristics and limited linguistic resources, through experimenting Incremental Learning in a Deep Learning paradigm.

Assamese, spoken by a significant population of around 15 million native speakers in the North Eastern part of India, faces the inherent challenges of being a low-resource language in the NLP domain. The scarcity of annotated data and linguistic resources pose hurdles for developing accurate and adaptable language models. Part-of-speech tagging, a fundamental task in NLP, forms the cornerstone of syntactic analysis, providing crucial insights into the structure and meaning of sentences.

Motivated by the imperative to bridge the gap in language technology for underrepresented languages, this research concentrates into the intricacies of Assamese, aiming to enhance the accuracy and adaptability of UPoS tagging. The significance of this endeavor lies not only in its contribution to advancing NLP capabilities, but also in addressing the broader need for tailored solutions for languages with limited linguistic resources.

PoS tagging experiments in Assamese is relatively new, and only very few previous works could be traced. Experiments using ML/DL techniques have been done by few researchers, but with limited resources. With the advent of NLP applications, including Machine Translation, Sentiment Analysis, Summarization etc., demand for linguistically embellished corpus has started increasing. And Corpus with PoS tagged embellishment is a need for most of the preprocessing and transfer learning pipelines. The bottleneck is the low amount of required resources, including tagged corpus. Another concern is the non-universality of tagset. We standardized the PoS tagset for Assamese language mapping the BIS tagset to the Universal PoS tagset, opening a new dimension for Assamese NLP with universal adaptation for inter-linguistic NLP works. The resources, generated so, shall be of benefits to the Assamese NLP research community for advancing different tasks. Low-resource constraints have been tried to overcome with the integration of incremental learning concept. Both UPoS tagging, as well as experimenting with incremental learning paradigm, are novel to the Assamese NLP, and significantly contribute to the overall resource and experiment scenario.

The primary objective of this research is to introduce Incremental Learning to Assamese UPoS tagging by leveraging the strengths of Recurrent Neural Networks (RNNs) and Gated Recurrent Units (GRUs). Incorporation of Incremental Learning, a dynamic paradigm is used for enabling the models to continuously refine their understanding as they encounter new sets of UPoS annotated linguistic data. The paper includes a comprehensive review including Assamese NLP works, and few on PoS, UPoS experiments. Next section discusses the methodology of the entire work including dataset and model architecture. How the incremental learning has been integrated, also included as part of this section. Here, the experimental flow alongwith the details of

the dataset have been elaborated. Next chapter includes the complete results with summarization of the analysis reflecting the efficacy of the incremental learning for low resource situation in doing DL based automatic PoS tagging.

II. Scope and Structure

This study encompasses a comprehensive exploration of UPoS tagging in Assamese, emphasizing the resource constraints of the language. The proposed models' adaptability through Incremental Learning is positioned as a pivotal aspect, catering to the evolving nature of the language. The scope extends beyond the immediate task, aiming to contribute insights and methodologies that can be easily replicated through similar experimentations to other low-resource languages facing similar challenges.

The remainder of this paper unfolds as follows: next provides a comprehensive review of related works in the field, highlighting existing approaches and challenges faced in context of under resourced languages. Then the methodologies are described, detailing the architecture of the proposed model, and explaining the incorporation of Incremental Learning with GRU and RNN. Next chapter presents the experimental setup and results, offering a comparative analysis of the experimented models against existing methods. Finally, we conclude the paper discussing implications, and suggesting avenues for future research.

III. Literature Review

This literature review surveys pivotal research to enrich our investigation into refining Assamese Universal-part-of-speech tagging through Incremental Learning with GRU and RNN models. Foundational works by Elman (1990) [1] on Recurrent Neural Networks (RNNs) and Cho et al. (2014) [2] on Gated Recurrent Units (GRUs) elucidate the architecture of sequential data processing, with recent optimizations by Chung et al. (2014) [3] further shaping the application of these models in natural language processing. Schmidhuber's exploration of Incremental Learning in NLP (1991) [4] and Fernando et al.'s work on gradient descent in super neural networks (2017) [5] lay the groundwork for our dynamic learning paradigm. There are several fundamental works initiating and standardizing the Assamese NLP tasks, that provides insights into Assamese NLP resources, as well as design and development of tools and technologies. Fundamental resources for Assamese NLP tasks have been created at various levels. These are impressive starting although not sufficient. A structured Assamese Corpus (GUIT Corpus) was built by Sarma et al. (2012) [6], covering a wide variety of domains, and collecting standard written texts in a much longer timeline. Different approaches have been already implemented for almost all major Indian languages for PoS tagging tasks (Kuwali and Shikhar, 2023) [7]. PoS tagging experimentations also have been carried out for Assamese language both using traditional approaches (Barman et al., 2013) [8] as well as using contemporary Machine Learning techniques. Assamese is relatively new for language processing research, still various preliminary works such as Wordnet development (Sarma et al., 2010) [9], statistical Machine Translation (Baruah et al., 2014) [10], Word Sense Disambiguation (Sarmah et al., 2016) [11, 12], Neural Machine Translation (Ahmed et al., 2023) [13] etc. could be traced in recent years. Application oriented works like Wordnet enhanced MT (Barman et al., 2014) [14], Word corrections (Bhuyan and Sarma, 2018) [15], development of rule based stemmer (Sarmah et al., 2019) [16], Assamese Information Retrieval system using Wordnet (Barman et al., 2013) [17] etc. also could be seen.

PoS tagging in Indian languages are predominantly using the Bureau of Indian Standard tagset (BIS, 2021) [18], although Universal Parts of Speech tagset (Marie et al., 2021) [19] as defined in the Universal Dependency also gained pace very recently (Das et al., 2023) [20]. This is promising in the sense that a Universally accepted tagset for across the language landscape shall facilitate transparency and adaptability in multilingual NLP research and application development.

IV. Methodology

Here we detail the technical methodology behind our approach for enhancing Assamese part-of-speech tagging using UPoStagset through Incremental Learning with GRU and RNN models. This chapter establishes the technical framework supporting our approach, providing a detailed insight into the dataset, model architecture, training procedures, and evaluation metrics that form the core of our investigation.

A. Dataset Preparation

We begin by curating a comprehensive dataset for Assamese, comprising diverse linguistic structures and contexts. This dataset includes three chunks of 10000 gold standard sentences each, extracted from the GUIT corpus. While extracting the sentences from the GUIT Corpus, special attention has been given to include diversified domains. The statistical information on the dataset is given in the Table I. The raw corpus of approximately 35000 sentences has been subjected to data cleaning and filtering to arrive at a cleaned dataset of fair quality. The dataset is considered a gold standard, as the corpus has been created with expert linguists, and the sources are standard written texts. Thus, the corpus represents the Assamese linguistic behaviours reflecting the syntactic and lexical coverages, and assumed to be embedded with varied linguistic phenomena inherent in Assamese.

TABLE I. Statistical Information on the Dataset

Dataset	Seq. Length	Frequency	% Frequency	Total	Dataset Label
Data Chunk-1	5-10	1926	19.26	10000	D1
	11-20	3560	35.60		
	21-30	2896	28.96		
	31-35	1618	16.18		
Data Chunk-2	5-10	1723	17.23	10000	D2
	11-20	3669	36.69		
	21-30	2635	26.35		
	31-35	1973	19.73		
Data Chunk-3	5-10	1867	18.67	10000	D3
	11-20	2970	29.7		
	21-30	3345	33.45		
	31-35	1818	18.18		

The following cleaning and filtering processes have been adopted:

1) Removing all blank lines

2) Excluding all sequences of less than 5 token and more than 35 tokens. These values are considered from expert linguistic inputs to consider only realistic Assamese sentences. As PoS tagging is a sequence labelling task, a fair length of Assamese text sequences shall only contribute to the machine learning in a better way.

3) Removing all unwanted and foreign sequences. This includes sequences written in scripts other than Assamese, as well as html segments and only-symbol segments.

The cleaning and filtering have been done with a customized Python script run over the raw corpus. The raw corpus, originally in the form of xml tagged text file, has been converted into excel file. An intermediary text file was again created with the sentences, and the Python script has been run over this text file to perform the cleaning and filtering operations. Fig. 1 and Fig. 2 shows the frequency of number of sentences and percentage distribution of sentences based on the Sequence-Lengths. The stages of dataset preparation are depicted inFig. 3.

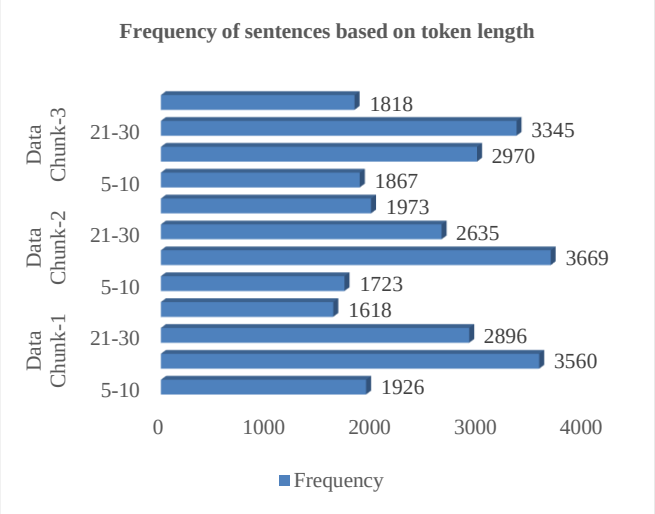

Fig. 1. Token-Length wise frequency distribution of sentences.

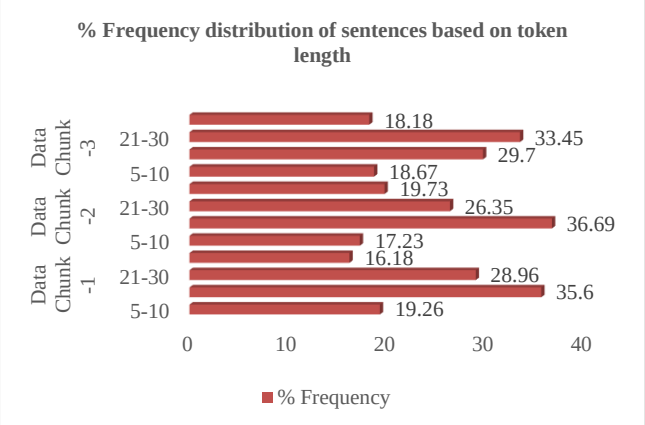

Fig. 2. Token-Length wise percentage frequency distribution of sentences.

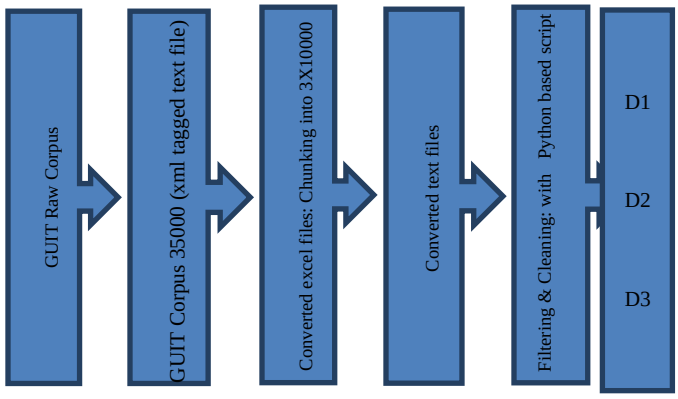

Fig. 3. Dataset preparation stage diagram

B. Model Architecture

Our experimented model leverages the strengths of Gated Recurrent Units (GRUs) and Recurrent Neural Networks (RNNs) for capturing sequential dependencies within Assamese sentences. The GRU's ability to selectively update information and its computational efficiency, and the RNN's contextual understanding, synergistically contribute to the effective architectures for part-of-speech tagging performance enhancement with Incremental Learning. The Incremental Learning is based on the baseline GRU and RNN models that were achieved against a similar set of standalone modelling with a single-shot dataset of 29501 Assamese UPoS tagged sequences containing 200022 tokens. These Assamese UPoS trained GRU and RNN models are subjected to D1, D2, and D3 in an incremental manner of training and tagging. Performances of the base GRU and RNN models are shown in Table II.

TABLE II. PERFORMANCES OF THE BASE GRU AND RNN MODELS

Models	Accuracy	Precision	Recall	F1
RNN (UPoS)	93.78%	94.75	93.28	**94.01**
GRU (UPoS)	94.38%	95.44	93.70	**94.56**

C. Incremental Learning Integration

A novel aspect of our methodology involves the integration of Incremental Learning to adapt the model dynamically to evolving linguistic patterns. For training the models with incremental learning approach, the base model already trained with UPoS tagged Assamese data is considered as the pretrained model, and the first chunk of dataset D1 is tagged with this model. This 10000 tagged sentences dataset is then added to the previous dataset, and fresh training is subjected through the GRU and RNN. The three chunks are incrementally added to enhance the size of the dataset, and performances have been recorded. In this approach, as new data are encountered, models are trained afresh with larger chunks of dataset, contributing positively to the inherent data-hungry nature of deep learning. The incremental dataset sizes against the training iterations are shown in Table III.

The model undergoes training with careful consideration of hyperparameter tuning. Training performance is monitored through relevant metrics such as accuracy, precision, recall, and F1 score. The experiments also include comparisons with

baseline models and existing methodologies for a comprehensive assessment.

TABLE III. INCREMENTAL DATASET SIZES AGAINST ITERATIONS

Training Iteration	Dataset	#Sequence	Training Model
0	D0 (base)	29501	Base GRU, RNN Model
1	base+ D1-first 10K chunk	39501	Model 1
2	base+ D2-second 10K chunk	49501	Model 2
3	base+ D3-third 10K chunk	59501	Model 3

Our evaluation metrics encompass standard measures such as accuracy, precision, recall, and F1 score to analyse the model's effectiveness in part-of-speech tagging. The impact of Incremental Learning on the model's adaptability over the trajectory are recorded and presented.

V. EXPERIMENTAL SETUP AND RESULTS

In this chapter, our experimental design is systematically outlined, encompassing phases of training, validation, and testing. Batch sizes, number of layers are considered as key system parameters for optimal model performance.

We have configured the deep learning pipeline in a laboratory environment with local server. The server configuration is outlined below:

- 64 bit Intel Xeon CPU,
- 16 GB main memory,
- NVIDIA Quadro P1000 GPU
- 640 CUDA Cores and
- 4096 MB of GPU memory.
- System's graphics clock speed: min-136 MHz, max-5010 MHz
- Graphics RAM 4 GB.
- System storage: 256 GB SSB and 1 TB HDD.

The entire training setup was done with Tensorflow. The pipeline for training includes *keras*and *sklearn* packages. The powerful python library *Keras* has been used to import deep learning models-RNN and GRU. Splitting of training and testing dataset has been done by *Sklearn* package. Two other important tools of python-*pandas* and *numpy* also have been used in the framework.

Both default and customized set of hyperparameters are part of the experiments. Both RNN and GRU were configured with 64 Cell Model layers. The model parameters are depicted in the Table IV. The architecture pipeline framework is given in Fig. 4.

TABLE IV. MODEL HYPERPARAMETERS

Models	Embedding Layer	Model Layer	Dense Layer
RNN	Input dim = vocab size, Output dim = 300, Input length = 100	RNN Layer = 64 Cell	36 no. of classes
GRU	Input dim = vocab size, Output dim = 300, Input length = 100	GRU Layer = 64 Cell	36 no. of classes

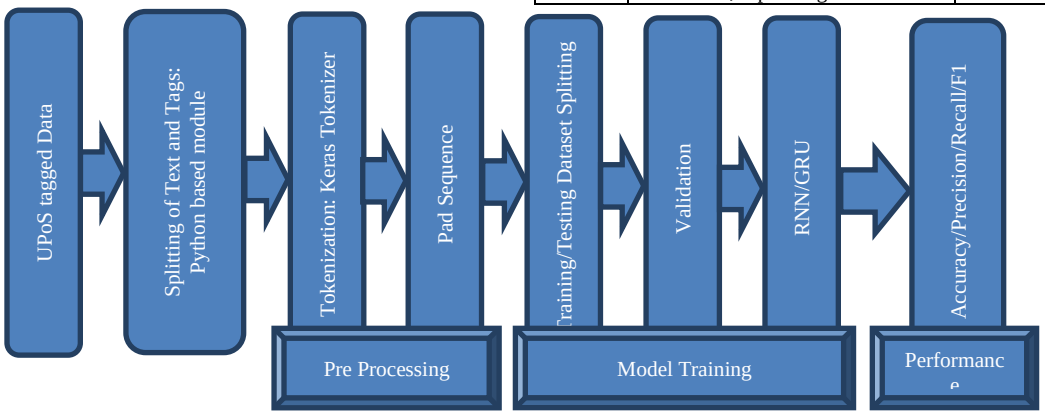

Fig. 4. Architecture pipeline framework.

Conducting a comparative analysis against state-of-the-art baseline models, we establish a benchmark for evaluating the advancements achieved through our Incremental Learning approach. Key evaluation metrics, including accuracy, precision, recall, and F1 score, are analyzed. The focus is on the model's performance in part-of-speech tagging and the impact of Incremental Learning on continuous improvement over time.

Experimental results are systematically presented here through Tables V to IX, and Fig. 5 to 9, emphasizing the unique contributions of our models, and the implications of Incremental Learning in the context of Assamese universal-part-of-speech tagging. Accuracy, precision, and recall against different experiments with incremental Dataset chunks have been presented both quantitatively and graphically.

TABLE V. PERFORMANCE OF MODEL 1

Models	Accuracy	Precision	Recall	F1
RNN (UPoS):Model1	94.22	95.57	93.82	**94.69**

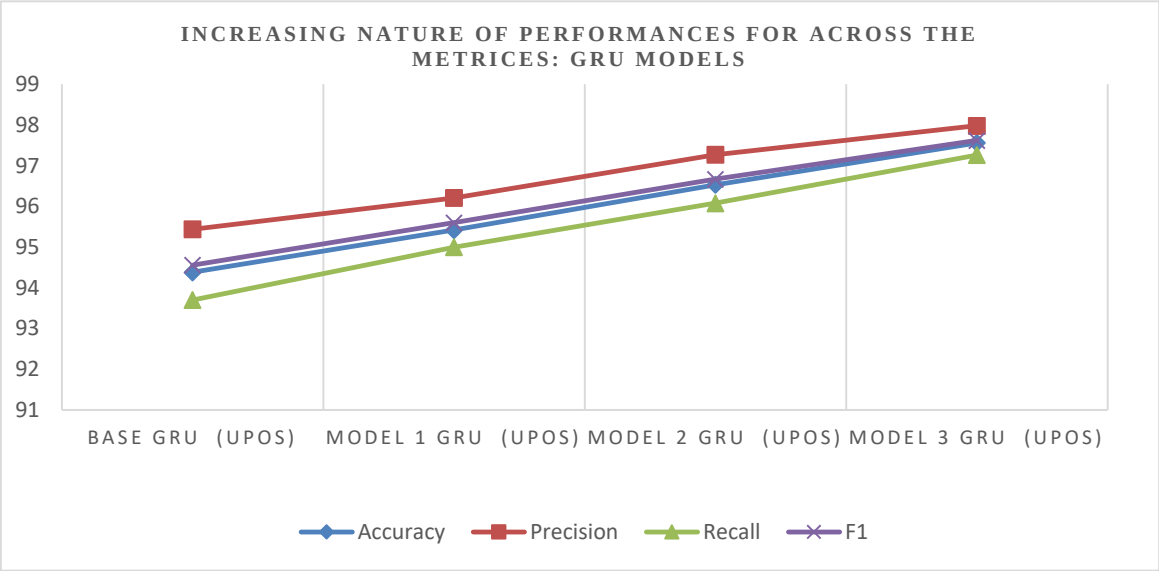

Fig. 9. Increasing nature of performances: GRU models.

F1 scores are calculated for all models both for GRU and RNN based experiments. The results have reflected positive performance enhancement through incremental training. The impact of incremental learning for the DL based UPoS tagger modeling has been investigated to be contributory, and is the major contribution of this study. Low resource languages with contraints of having sizable dataset may be greatly benifited from the experience of the current study and the significance of incremental learning.

It is evident from the result analysis that Incremental Learning has positively contributed to the performances of both GRU and RNN. The baseline GRU and RNN models for Assamese UPoS tagging are added with increased performances of upto 3.18 points for Accuracy and 3.06 points for F1 score. Performances of the models through base model to the model 3 are graphically represented in Fig. 8 and 9. Steady percentage increase of performances across the matrices suggest that increased dataset size, and subsequent incremental training of Deep Learning model successfully contribute to the enhanced performance of the models. This could be best utilized for low resource language PoS tagging tasks in most effective manner.

VI. CONCLUSION

The impact of Incremental Learning on adaptability and continuous improvement over a series of incremental dataset are highlighted in this paper. Here, we reflect on the broader contributions of our research to the field of natural language processing, particularly in the context of under-resourced languages, by adopting Incremental Learning in sequence labelling task, and the experimental finding that Incremental Learning could be best utilized as an efficient approach for resource poor situation. Our models' ability to dynamically adapt to evolving linguistic patterns and the advancements achieved through Incremental Learning are underscored as pivotal contributions. Practical implications of the current research, as we visualize, particularly in the context of resource constraint situation, the experimented approach could be best exploited for, opening avenues for the development of language processing tools for other underrepresented languages. The findings could be well replicated with experiments across the low resource languages, as this has proved to be effective in enhancing performances. Low resource languages are always with constraints of having sizable dataset, and at the same time ML/DL training requires good amount data reflecting maximum possible patterns like syntax, well-covered vocabulary etc. in order to tap all possible linguistic phenomenon. Incremental learning with larger data chunks may be experimented in future for more effective performances. Transfer learning with pre trained models shall be of immense potentiality, to experiment for probable enhanced performance in similar situations.

Information Center, Yantai Institute of Science and Technology, Penglai, 264000, China[2]

***Abstract*—Currently, there is a lack of effective objective quantitative methods for evaluating the benefits of smart construction. Therefore, this study proposes a comprehensive method for evaluating the benefits of smart construction. This method establishes an indicator system from the perspective of evaluation objectives, and on this basis, uses a continuous ordered weighted average operator to ensure the objectivity of indicator weight allocation. Afterwards, the grey clustering method is used to form a scoring matrix, achieving effective comprehensive quantitative evaluation. The results showed that for the selected project, the comprehensive benefit value evaluated was 8.342, indicating that the smart construction efficiency of the project had reached a good level. Meanwhile, the extensive benefits of the project showed a stepwise upward trend from 2021 to 2023. This study aims to design and apply a smart construction benefit evaluation method that integrates continuous ordered weighted average operator and grey clustering, which is practical and can provide data reference for project management of smart buildings.**

Keywords*—C-OWA; Grey system; clustering; intelligent construction; sustainability

I. Introduction

With the development of modern technology, smart construction is gradually changing traditional construction and operation modes. However, there are currently difficulties in evaluating the Benefits of Smart Construction (SCB) projects, mainly due to the uncertainty and complexity of the evaluation information. In order to effectively evaluate the comprehensive SCB projects, it is necessary to develop customized evaluation methods that are more suitable for smart buildings [1-3]. When evaluating the SCB, there is often a situation where multiple standards compete with each other and evaluation information is contradictory. In addition, the information in the evaluation process is often accompanied by uncertainty. Therefore, in order to conduct effective and comprehensive evaluation, it is necessary to have an evaluation method that can effectively reflect multiple criteria and handle uncertain information. The Complex Ordered Weighted Average (C-OWA) operator is an effective tool for this field, which can integrate multiple evaluation criteria based on the importance of information and the risk attitude of decision-makers [4-6]. Grey system theory is also an effective tool, which is used for the effective and accurate classification of imprecise data. By combining the C-OWA operator and grey clustering method, it is possible to objectively evaluate the SCB projects containing uncertain information while considering the preferences of decision-makers [7-8]. Therefore, this study proposes a Smart Building Benefit Evaluation (SBBE) framework that integrates the C-OWA operator and grey clustering, and verifies the practicality and effectiveness of the framework through case analysis. Section II of this study proposes the research objectives. Section III proposes an SBBE method that integrates the C-OWA operator and grey clustering, and establishes an indicator system. Section IV calculates indicator weights, while Section IV and Section V gives details about results and conclusion respectively.

Although smart buildings have brought advantages such as cost reduction, efficiency improvement, and project sustainability improvement to the traditional construction industry so far, the current application of smart building technology is still not widespread and in-depth enough, resulting in a lack of standardized comprehensive benefit evaluation methods. In the evaluation of the benefits of smart buildings, firstly, there are differences in the evaluation standards among various parties, making it difficult to unify and compare them; Secondly, current evaluation methods may encounter issues such as inaccurate results when evaluating project information with high uncertainty; Thirdly, the current evaluation methods have not taken into account the technological advancement of smart buildings.

In order to solve the problems of current smart building benefit evaluation methods, a smart building benefit evaluation method combining C-OWA operator and grey clustering technology is proposed. The C-OWA operator can adjust weights based on the importance of information and the attention of decision-makers, while grey clustering technology can effectively classify imprecise information in the evaluation process, thereby achieving quantitative evaluation of uncertain information. By combining two methods, it can be ensured that the evaluation method has unified quantitative standards, can quantitatively evaluate uncertain information, and ensure consideration of technological progress.

Although the evaluation methods for research design are systematic and applicable. However, it still has certain limitations. The design of this study is a standardized system, so in actual project information evaluation, the system is likely to face extreme information caused by external factors. When dealing with similar extreme information, the system may experience certain inaccuracies. Therefore, special system modifications for extreme situations are the future research direction.

II. Related Works

In terms of the digital application of C-OWA and grey system, Liu H's team designed an evaluation system for the Quality of College English Teaching (CETQ), and combined grey clustering analysis and entropy weight method to construct a comprehensive evaluation model. It provided an effective solution for objectively evaluating CETQ [9]. Zhang D's team proposed a recognition technology based on a multi-sensor data collection cloud platform and an improved particle neural network method. This technology achieved real-time monitoring of the pouring interface by monitoring the parameters of the concrete pouring surface [10]. Du X et al. constructed a group decision information fusion model that takes into account the incompleteness and uncertainty of decision information. The team proposed an interval intuitionistic fuzzy combination weighted average operator to solve the data position weight limitation problem of existing operators when summarizing data. This method effectively improved the accuracy of group consensus [11]. Peng B's team believed that there were two problems in Pythagorean Fuzzy Multi-attribute Group Decision-making (PFMAGD): the convergence operator problem of extreme fuzzy evaluation, and the risk attitude problem of decision-makers. Therefore, to address these issues, this study redesigned the evidence reasoning aggregation method in intuitive fuzzy environments and proposed a risk attitude-based PFMAGD method. The new method overcame the shortcomings of existing methods in the Pythagorean fuzzy environment [12].

In terms of building efficiency evaluation, Le Thi H TKO et al. focused on the concept of green buildings and global development trends, and analyzed the significant benefits brought by green buildings based on practical cases in Vietnam. The research results provided sufficient reference basis for decision-making in green building projects [13]. Yu L et al. explored the application methods of deep reinforcement learning in energy management of intelligent buildings. The energy consumption and carbon emissions generated by traditional buildings accounted for about 30% of the total energy consumption and carbon emissions. Therefore, improving energy efficiency to promote the development of green buildings was imperative [14]. Scholars such as Alshammari K analyzed the application of the Internet of Things (IoT) in building environments and looked forward to the role of digital twin technology in improving the security level of smart cities. This study suggested expanding the scope of Building Information Modeling (BIM) standards to adapt to the development of IoT, while enhancing network security standards to ensure that future smart city construction can align with digital twin technology [15]. Kumar A et al. proposed a building architecture that combines constrained application protocols and data packet transport layer security protocols to optimize energy management, reduce building energy consumption, and improve the efficiency and security of the entire system. The simulation results showed that this method could reduce the energy consumption of smart buildings by about 30.86% [16].

In summary, in recent years, research in multiple fields such as intelligent building monitoring, group decision-making information fusion, and SBBE has been deepened. Meanwhile, these studies also indicate that the promotion of green buildings, the intelligence of energy management, and the application of IoT technology have become important topics in the construction industry. Compared to these, the innovation of this study lies in the comprehensive use of the fusion technology of C-OWA operator and grey clustering to improve the effectiveness of decision-making and evaluation models, and enhance the reliability and practicality in SBBE.

III. SBBE Method Combining C-OWA Operator and Grey Clustering

This study first constructs an indicator system. To ensure the scientificity and practicality of the evaluation system, researchers provide an objective and detailed weight allocation plan through expert consultation and empirical verification and then use the C-OWA weighting method. Finally, the grey clustering method is used to transform incomplete or fuzzy information into grey evaluation coefficients using Whitening Weight Functions (WWF), thereby forming a clustering score matrix.

A. Construction of SBBE Indicator System

To construct a scientific and systematic SBBE indicator system, this study integrates the principles of system comprehensiveness, scientific rationality, practicality and operability, goal orientation, inheritance and innovation, and establishes an indicator system that integrates smart construction technology with sustainable new development goals. The technical roadmap is Fig. 1.

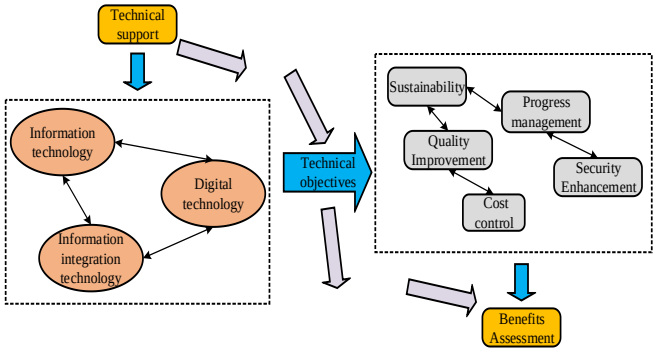

Fig. 1. Technical route of indicator system.

This study divides the indicators into five main dimensions, namely progress savings, cost savings, quality improvement, safety improvement, and sustainability improvement. Progress savings refer to improving the efficiency and accuracy of schedule management through intelligent construction technology. Cost savings are achieved through the application of technology to reduce unnecessary expenses and waste. Quality improvement is the use of BIM for tracking and managing construction materials and improving design quality. Security enhancement refers to the use of modern information technology to prevent major risks and enhance construction safety. Sustainability enhancement refers to providing decision-making support for environmental sustainability goals through modern information technology. These five dimensions are the primary indicators, and their division depends on three coordinate directions: time, technology, and sustainability goals. The reason why sustainability is listed as an important

evaluation direction is because sustainable development includes internal elements such as energy conservation, green development, and digital development, and is the main development direction of smart buildings [17]. The main coordinate directions are shown in Fig. 2.

On this basis, multiple experts related to the field of smart construction are invited for expert discussions to provide professional opinions on preliminary indicators. By screening and refining indicators, comprehensive and implementable coverage of the indicators are ensured, and the secondary indicators are further expanded. The indicator system is listed in Table I.

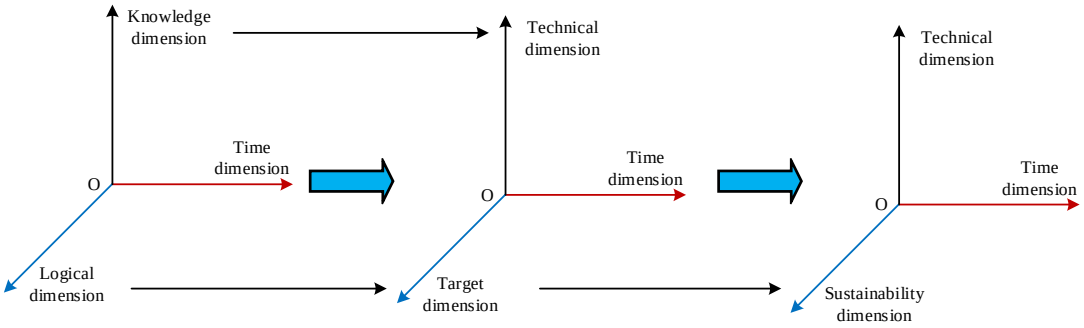

Fig. 2. Indicator dimension coordinate direction.

TABLE I. INDICATOR SYSTEM

Serial Number	Primary indicators	Secondary indicators
A1	Progress savings	Implementing time reduction in the design phase through BIM (ITRinDP through BIM)
A2		BIM technology saves construction time during the construction phase
A3		The benefits of 4D simulation in progress control during the construction phase
A4		Utilizing virtual reality to accelerate construction progress
B1	Cost savings	The Application of BIM in Planning Land and Saving Costs
B2		Accurate measurement of cloud computing reduces design costs
B3		Design cost optimization based on BIM (BIM-based DCO)
B4		Improving construction cost management through cloud computing
B5		Utilizing big data technology to achieve cost optimization
B6		The role of BIM in reducing construction costs
B7		IoT technology saves costs in resource management (IoT saves RMC)
C2	Quality improvement	BIM assists in tracking and managing construction materials (BIM assists TM-CMs)
C3		BIM application for improving the quality of design works (BIM-A for I-DWQ)
D1	Safety improvement	The Application of Virtual Reality Technology in Risk Prevention
D2		Using cloud computing for early warning of construction safety
D3		The role of BIM in improving construction safety (BIMR in ICS)
D4		BIM's early warning function for construction safety hazards (BIM's EWF for CSH)
D5		Using Virtual Reality Technology to Strengthen Construction Safety
D6		The application of the Internet of Things in device security management
E1	Sustainability improvement	The contribution of cloud computing in planning information sharing
E2		The advantages of BIM in saving materials and land resources
E3		BIM assisted planning and scientific decision-making process (BIM assists PSDP)
E4		The Promoting Role of GIS in Scientific Decision Making in Planning
E5		The energy-saving effect of the IoT in implementing green buildings (IoT-ESE in IGB)
E6		The improvement effect of big data in facility operation and maintenance management
E7		BIM improves efficiency in operation and maintenance management
E8		IoT technology enhances operational management efficiency

In the secondary indicators, the progress management dimension includes dimensions such as design optimization progress savings, construction optimization progress savings, 4D visualization construction optimization progress savings, etc., to quantitatively analyze the impact of smart construction technology on project progress. The cost control dimension includes BIM planning land cost savings, cloud computing design precise calculation cost savings, BIM design optimization cost savings, etc., which can evaluate the cost management ability of smart construction technology. The dimension of quality improvement includes BIM construction material tracking management and BIM design quality improvement, which can reflect the status of intelligent construction improving the quality of engineering construction through information technology. The dimension of security enhancement includes indicators such as preventing major risks in virtual reality design and warning potential safety hazards in cloud computing construction, mainly targeting safety accidents. Under the dimension of sustainable development, it includes the improvement of cloud computing planning information sharing, BIM planning material and land conservation, and BIM planning scientific decision-making, focusing on the status of smart construction practices in environmental protection and resource efficiency.

B. Application Strategy Design of C-WOA Operator

To effectively evaluate the SCB, this study proposes the C-OWA weighting method. This method minimizes extreme data in expert evaluations, reduces the potential negative impact of subjective bias, and accurately reflects the overall and differential nature of the data. Firstly, before constructing a weight allocation system, it is necessary to invite several experts to analyze the relevant indicators of the SCB. Table II shows expert information.

TABLE II. EXPERT INFORMATION TABLE

Number	Unit nature	Educational Background	Years of Work Experience	Project Experience	Research Field
1	Research in universities	Doctor	Under 25 years	Not participating	Research on Architectural Theory
2	Construction and construction	Master	5-10 years	Occasional participation	Construction project management
3	Building informatization	Undergraduate course	Over 10 years	Frequent participation	Intelligent management of construction process
4	Construction unit	Master	5-10 years	Always participate	Architectural design informatization
5	Information support	Doctor	5-10 years	Always participate	Software technical support

On this basis, using a scoring method of 0 to 10 points, an expert team objectively evaluates indicators at the same level, and establishes an initial decision dataset, as shown in Formula (1).

$$a_i = \left\{a_1, a_2, \ldots, a_j, \ldots, a_n\right\} \tag{1}$$

Then, the dataset will be reordered to obtain a new dataset from high to low, which better reflects the importance of each indicator, as shown in Formula (2).

$$b_i = \left\{b_0, b_1, \ldots, b_{n-1}\right\} \tag{2}$$

Afterwards, weights are assigned to the values of the new dataset, and the combination number is used to determine the weights for different values, as shown in Formula (3).

$$\beta_{j+1} = \frac{c_{n-1}^{j}}{\sum_{k=0}^{n-1} c_{n-1}^{k}} = \frac{c_{n-1}^{j}}{2^{n-1}}, j = 0,1,2,\ldots,n-1 \tag{3}$$

In Formula (3), c_{n-1}^{j} represents the number of combinations. The absolute weight obtained from weighting is Formula (4).

$$\overline{w_i} = \sum_{j=0}^{n-1} \beta_{j+1} b_j, i = 1,2,\ldots,m \tag{4}$$

In Formula (4), b_j represents the weighted data. The relative weight is Formula (5).

$$w_i = \frac{\overline{w_i}}{\sum_{i=1}^{m} w_i}, i = 1,2,\ldots,m \tag{5}$$

Afterwards, the absolute weights of each evaluation indicator are determined using the aforementioned weights and sorted scores, with the sum of all weights being 1.

C. Design of Grey Cluster Evaluation Strategy

It is crucial to effectively measure the comprehensive benefits of smart construction projects in the evaluation process. To achieve this goal, researchers have proposed a quantitative method that can divide the benefits of smart construction into different levels and provide an evaluation system to quantify these benefits [18-19]. When designing the grey clustering evaluation strategy in this study, a set of evaluation systems is first constructed to quantify the building benefits, and a guiding approach is adopted to classify the SCB into four different levels: excellent, good, qualified, and poor. The SBBE level is Fig. 3.

However, in actual evaluation procedures, the SCB are often difficult to quantify and are easily influenced by personal subjective judgment and incomplete information [20-21]. To overcome this challenge, this study adopts the grey clustering evaluation method. Firstly, this study confirms the SCB at different levels and corresponding evaluation criteria. Each level has a corresponding score to represent the difference in benefits compared to traditional construction methods. Each benefit indicator has its own evaluation criteria, which helps to convert it into quantifiable data for subsequent analysis. Each

benefit indicator will be rated by multiple experts, which form an initial evaluation matrix, as shown in Formula (6).

$$D_i = \left\{ d_{ijk} \right\} s \times q \tag{6}$$

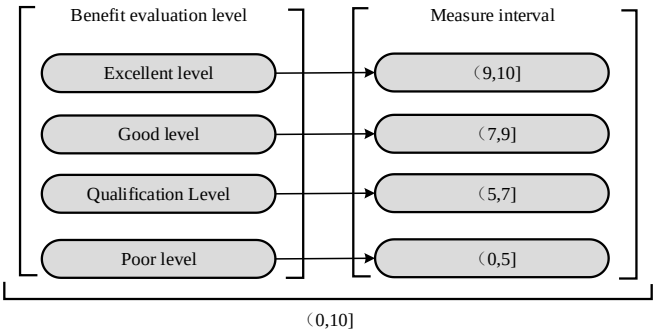

Fig. 3. Evaluation level of intelligent construction benefits.

In Formula (6), d_{ijk} represents the expert rating. k is the rating expert's serial number. i represents the number of major indicators. j means small indicator rating. s is the total number of indicators. q represents the total number of experts. Each gray class corresponds to an interval and function, quantitatively expressing the evaluation value at that level. The index evaluation coefficient is Formula (7).

$$X_{ije} = \sum_{k=1}^{q} f_e \left[d_{ijk} \right] \tag{7}$$

The total grey evaluation coefficient is Formula (8).

$$X_{ij} = \sum_{e=1}^{4} X_{ije} \tag{8}$$

To conduct a detailed evaluation, this study establishes a WWF. This function is used to convert expert ratings into a grey benefit evaluation index, which can reflect the distribution of benefit indicators on different grey levels. The grey number evaluation level is Fig. 4.

When the gray class e=1, the WWF is Formula (9).

$$f_1 \left[d_{ijk} \right] = \begin{cases} d_{ijk} / 4, d_{ijk} \in [0,4] \\ 1, d_{ijk} \in [4,\infty] \\ 0, d_{ijk} \notin [0,\infty] \end{cases} \tag{9}$$

When the gray class e=2, WWF follows Formula (10).

$$f_2 \left[d_{ijk} \right] = \begin{cases} d_{ijk} / 3, d_{ijk} \in [0,3] \\ 2 - d_{ijk} / 3, d_{ijk} \in [3,6] \\ 0, d_{ijk} \notin [0,6] \end{cases} \tag{10}$$

When the gray class e=3, WWF is Formula (11).

$$f_3 \left[d_{ijk} \right] = \begin{cases} d_{ijk} / 2, d_{ijk} \in [0,2] \\ 2 - d_{ijk} / 2, d_{ijk} \in [2,4] \\ 0, d_{ijk} \notin [0,4] \end{cases} \tag{11}$$

When the gray class e=4, WWF is expressed as Formula (12).

$$f_4 \left[d_{ijk} \right] = \begin{cases} 1, d_{ijk} \in [0,1] \\ 2 - d_{ijk}, d_{ijk} \in [1,2] \\ 0, d_{ijk} \notin [0,2] \end{cases} \tag{12}$$

Obtaining the clustering weight vector based on the grey evaluation coefficient, as shown in Formula (13).

$$r_{ije} = \frac{x_{ije}}{x_{ij}} \tag{13}$$

Afterwards, a comprehensive grey clustering matrix is obtained by weighting each benefit indicator, as shown in Formula (14).

$$R_i = \begin{bmatrix} r_{i11} & r_{i12} & r_{i13} & r_{i14} \\ r_{i21} & r_{i22} & r_{i23} & r_{i24} \\ \vdots & \vdots & \vdots & \vdots \\ r_{in1} & r_{in2} & r_{in3} & r_{in4} \end{bmatrix} \tag{14}$$

The comprehensive clustering matrix is Formula (15).

$$M_0 = \left(M_1, M_2, \ldots, M_5 \right)^T \tag{15}$$

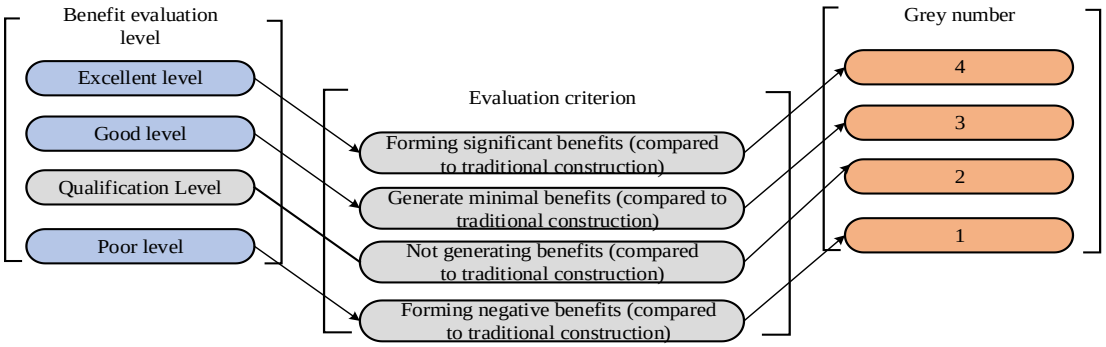

Fig. 4. Grey number evaluation level.

M_n is calculated as Formula (16).

$$M_n = w_i \cdot R_i \tag{16}$$

The evaluation of primary indicators is as shown in Formula (17).

$$Z = W_0 \cdot M_0 \tag{17}$$

The grey evaluation coefficient of each indicator reflects the degree of evaluation of the grey category to which the indicator belongs in expert evaluation. Afterwards, by calculating the grey clustering weight vector and combining it with the weight matrix, a more refined comprehensive benefit evaluation can be obtained. The final step is to determine the overall value of the SCB based on the results of grey clustering and the set benefit measurement threshold, as shown in Formula (18).

$$U = (9.5, 8, 6, 2.5)^T \tag{18}$$

This value will determine the efficiency level of smart construction projects. The entire evaluation model aims to comprehensively cover all relevant indicators and accurately reflect the comprehensive SCB in various dimensions, as shown in Formula (19).

$$W = Z \cdot U \tag{19}$$

During the evaluation process, each indicator will be converted into a grayscale evaluation coefficient through the corresponding WWF. The evaluation coefficients are then summarized to form a comprehensive evaluation matrix. After weight calculation, this matrix will generate a clustering score for each evaluation indicator, thereby obtaining an objective measurement of the SCB.

IV. Calculation of Index System Weights and Analysis of SCB

This study mainly analyzes the SCB analysis from three perspectives. The first is the reliability of the indicator system and whether the designed indicator system is reliable. The second is the calculation of indicator weights, analyzing the importance and priority of different indicators in overall SCB improvement. The third is SCB analysis, which mainly involves conducting practical evaluation and analysis.

A. Reliability Analysis of Indicator System

In the reliability analysis of indicator systems, research has started from the perspectives of reliability and validity of indicators to test the reliability of the designed indicator system. Table III shows the reliability test results.

TABLE III. Indicator Reliability Analysis

Number	Primary indicators	Secondary indicators	Correlation coefficient	Alpha Value	Is it for use?
A1	Progress savings	ITRinDP through BIM	0.758	0.923	Yes
A2		BIM technology saves construction time during the construction phase	0.762	0.936	Yes
A3		The benefits of 4D simulation in progress control during the construction phase	0.721	0.85	Yes
A4		Utilizing virtual reality to accelerate construction progress	0.744	0.878	Yes
B1	Cost savings	The Application of BIM in Planning Land and Saving Costs	0.71	0.903	Yes
B2		Accurate measurement of cloud computing reduces design costs	0.675	0.847	Yes
B3		BIM-based DCO	0.732	0.81	Yes
B4		Improving construction cost management through cloud computing	0.759	0.832	Yes
B5		Utilizing big data technology to achieve cost optimization	0.718	0.892	Yes
B6		The role of BIM in reducing construction costs	0.782	0.909	Yes
B7		IoT saves RMC	0.765	0.887	Yes
C2	Quality improvement	BIM assists TM-CMs	0.801	0.853	Yes
C3		BIM-A for I-DWQ	0.724	0.816	Yes
D1	Safety improvement	The Application of Virtual Reality Technology in Risk Prevention	0.729	0.885	Yes
D2		Using cloud computing for early warning of construction safety	0.74	0.863	Yes
D3		BIMR in ICS	0.679	0.903	Yes
D4		BIM's EWF for CSH	0.762	0.872	Yes
D5		Using Virtual Reality Technology to Strengthen Construction Safety	0.795	0.839	Yes
D6		The application of the Internet of Things in device security management	0.755	0.841	Yes
E1	Sustainability improvement	The contribution of cloud computing in planning information sharing	0.777	0.862	Yes
E2		The advantages of BIM in saving materials and land resources	0.703	0.839	Yes
E3		BIM assists PSDP	0.812	0.894	Yes
E4		The Promoting Role of GIS in Scientific Decision Making in Planning	0.743	0.881	Yes
E5		IoT-ESE in IGB	0.788	0.908	Yes
E6		The improvement effect of big data in facility operation and maintenance management	0.815	0.876	Yes
E7		BIM improves efficiency in operation and maintenance management	0.825	0.869	Yes
E8		IoT technology enhances operational management efficiency	0.738	0.85	Yes

In Table III, the total alpha values of the five primary indicators are all greater than 0.7, indicating that the internal consistency of the test indicators is relatively high and meets the acceptance criteria. Table IV shows the validity test results.

In Table IV, generally speaking, a KMO value greater than 0.6 indicates high variable validity, and the KMO value of the indicator system studied is 0.843, indicating suitability for factor analysis. On the other hand, Bartlett's sphericity test is used to evaluate whether observed variables are independent of each other. The approximate chi square value of Bartlett's test is 1091.258, with 37 degrees of freedom and a significance level of 0.000, which is much smaller than any commonly used significance level. The indicator is fully effective.

B. Calculation of Index System Weights

Due to the uncertainty of decision information in the decision-making process, the evaluation of comprehensive benefits often needs to consider the calculation of indicator weights.

TABLE IV. INDICATOR VALIDITY ANALYSIS

Measuring Item		Numerical value
KMO measurement value		0.843
Bartlett sphericity test	Approximate chi square	1091.258
	Freedom	37
	Significance	0.000

TABLE V. CALCULATION RESULTS OF INDICATOR WEIGHTS

Primary indicators	**First level weight coefficient**	**Secondary indicators**	**Secondary weight coefficient**
Progress savings	0.224	ITRinDP through BIM	0.273
		BIM technology saves construction time during the construction phase	0.267
		The benefits of 4D simulation in progress control during the construction phase	0.226
		Utilizing virtual reality to accelerate construction progress	0.234
Cost savings	0.221	The Application of BIM in Planning Land and Saving Costs	0.135
		Accurate measurement of cloud computing reduces design costs	0.147
		BIM-based DCO	0.159
		Improving construction cost management through cloud computing	0.141
		Utilizing big data technology to achieve cost optimization	0.13
		The role of BIM in reducing construction costs	0.158
		IoT saves RMC	0.126
Quality improvement	0.163	BIM assists TM-CMs	0.472
		BIM-A for I-DWQ	0.528
Safety improvement	0.199	The Application of Virtual Reality Technology in Risk Prevention	0.162
		Using cloud computing for early warning of construction safety	0.149
		BIMR in ICS	0.189
		BIM’s EWF for CSH	0.183
		Using Virtual Reality Technology to Strengthen Construction Safety	0.158
		The application of the Internet of Things in device security management	0.154
Sustainability improvement	0.187	The contribution of cloud computing in planning information sharing	0.133
		The advantages of BIM in saving materials and land resources	0.125
		BIM assists PSDP	0.139
		The Promoting Role of GIS in Scientific Decision Making in Planning	0.119
		IoT-ESE in IGB	0.112
		The improvement effect of big data in facility operation and maintenance management	0.118
		BIM improves efficiency in operation and maintenance management	0.131
		IoT technology enhances operational management efficiency	0.123

In Table V, in the dimension of schedule savings, "ITRinDP through BIM" has the highest weight coefficient of 0.273. Time management during the design phase is considered slightly more important. In the cost saving dimension, the weight coefficient of "BIM-based DCO" is the highest at 0.159, and the lowest in the same dimension is "IoT saves RMC" at 0.126. The difference in weight coefficients indicates that "BIM-based DCO" occupies an important position in overall cost savings, while IoT technology, although equally important, appears to have a slightly inferior position in overall cost savings strategy. In the dimension of quality improvement, the weight coefficient of "BIM-A for I-DWQ" is 0.528, significantly higher than the weight coefficient of "BIM assists TM CMs", which is 0.472. This indicates that in terms of quality improvement, BIM plays a more crucial role in improving design quality. In the dimension of security improvement, the weight coefficients of the four secondary indicators are relatively balanced, with only the weight coefficient of "BIMR in ICS" being 0.189, slightly higher than other indicators. This means that the application of AnBIM is slightly more prominent. Finally, in the dimension of sustainability improvement, the weight coefficient of "BIM assists PSDP" is the highest, at 0.139, indicating that in sustainable development, the role of scientific decision-making is more prominent than information sharing.

C. SCB Analysis

This study focuses on a smart construction project in N city. The project consists of four buildings of different heights, with a total area of nearly 400000 square meters, including research and development, administration, dining, and other areas. Different buildings are connected by aerial bridges. When conducting project evaluation, the first step is to observe the WWF values of each indicator, which can be used to analyze the scores and excellence of indicators in different dimensions, and then evaluate the performance of the project in different aspects. Table VI shows the analysis of WWF values.

TABLE VI. ANALYSIS OF WHITENING WEIGHT FUNCTION VALUES

Number	Primary indicators	Secondary indicators	Score	Range	centre	Good	Excellent
A1	Progress savings	ITRinDP through BIM	5	0.071	0.929	0	0
A2		BIM technology saves construction time during the construction phase	63.8	0.069	0.931	0	0
A3		The benefits of 4D simulation in progress control during the construction phase	51.1	0.917	0.083	0	0
A4		Utilizing virtual reality to accelerate construction progress	—	0	0.015	0.165	0.82
B1	Cost savings	The Application of BIM in Planning Land and Saving Costs	87.1	0	0	0.79	0.21
B2		Accurate measurement of cloud computing reduces design costs	90.2	0	0	0.48	0.52
B3		BIM-based DCO	83.9	0	0	0.11	0.89
B4		Improving construction cost management through cloud computing	73.8	0	0.12	0.88	0
B5		Utilizing big data technology to achieve cost optimization	81.3	0	0	0.37	0.63
B6		The role of BIM in reducing construction costs	91.2	0	0	0.36	0.64
B7		IoT saves RMC	84.8	0	0	0.02	0.98
C2	Quality improvement	BIM assists TM-CMs	76.8	0	0	0.8	0.2
C3		BIM-A for I-DWQ	85.6	0	0	0.94	0.06
D1	Safety improvement	The Application of Virtual Reality Technology in Risk Prevention	—	0	0.215	0.511	0.185
D2		Using cloud computing for early warning of construction safety	72	0	0.709	0	0
D3		BIMR in ICS	88.4	0	0	0.648	0.352
D4		BIM's EWF for CSH	86.2	0	0	0.872	0.128
D5		Using Virtual Reality Technology to Strengthen Construction Safety	—	0.111	0.889	0	0
D6		The application of the Internet of Things in device security management	—	0.123	0.877	0	0
E1	Sustainability improvement	The contribution of cloud computing in planning information sharing	89.5	0	0	0.37	0.63
E2		The advantages of BIM in saving materials and land resources	85.7	0	0	0.94	0.06
E3		BIM assists PSDP	73.5	0	0.873	0	0
E4		The Promoting Role of GIS in Scientific Decision Making in Planning	88.1	0	0	0.371	0.629
E5		IoT-ESE in IGB	84.3	0	0.031	0.969	0
E6		The improvement effect of big data in facility operation and maintenance management	77	0.001	0.809	0.19	0
E7		BIM improves efficiency in operation and maintenance management	85.9	0	0	0.955	0.045
E8		IoT technology enhances operational management efficiency	90.4	0	0	0.365	0.635

In Table VI, in terms of cost savings, "IoT saves RMC" shows a prominent level of excellence with a high score of 84.8, significantly better than other secondary indicators. This high WWF value (excellent 0.98) intuitively reflects the effectiveness of IoT technology in optimizing resource allocation and cost control. Among the safety improvement indicators, the "BIM's EWF for CSH", which has a significant impact on construction safety, is particularly noteworthy. Its score reaches 86.2 points, and its excellence level is in the excellent level with a WWF value of 0.128, indicating that BIM has played a key role in preventing safety hazards. Under the primary indicator of sustainability improvement, the score of "IoT ESE in IGB" is 84.3, which is relatively good. The overall grey clustering evaluation matrix is Fig. 5.

In Fig. 5, the calculated comprehensive benefit value W is 8.342. According to the preset benefit level discrimination table, it indicates that the SCB of the project has reached a good level. This means that compared to traditional construction methods, the project has achieved a certain degree of benefit improvement, but has not achieved significant benefit improvement. In addition, by further analyzing the specific values of different benefit dimensions, the comprehensive evaluation values of progress savings W1, cost savings W2, quality improvement W3, safety improvement W4, and sustainability improvement W5 are 8.479, 8.424, 8.343, 8.335, and 8.343, respectively. The project has achieved a relatively balanced "good level" performance in different benefit dimensions, with the most significant benefits being the progress savings.

In Fig. 6, all primary indicators of the focused project have reached a good level, indicating an overall good state and no weaknesses in each indicator. Meanwhile, between 2021 and 2023, the comprehensive benefits show a stepwise upward trend. Finally, observing the changes in the rating time of the secondary indicators, the comprehensive benefits show a stepwise upward trend between 2021 and 2023, and the overall trend still shows an upward trend, reaching a good level in the end.

V. Results and Discussion

The study combines the C-OWA operator with grey clustering method, and establishes an indicator system for evaluation objectives based on this. By forming a scoring matrix, standardized quantitative evaluation of the benefits of smart buildings can be achieved, and uncertain information in smart building projects can be evaluated. Through project application experiments, it was found that the indicator system designed in the study is reliable, and the KMO value and Bartlett's sphericity test have high significance. The indicator system designed in the study is effective. And in the actual application of smart building project evaluation, it can be found that the project has shown good performance in cost savings, safety improvement, and sustainability improvement, and the comprehensive benefits of the project have shown a stepped upward trend between 2021 and 2023, with a comprehensive benefit value of 8.342, reaching a good level. It can be seen that the C-OWA operator method used in the study can adjust the focus of project evaluation by flexibly adjusting weights, promoting the scientificity of smart building project evaluation. In addition, the research and design of the system can still provide more objective and accurate quantitative evaluation results in the face of uncertain information, which is more convenient for the standardization of industry benefit evaluation and the circulation of evaluation results, laying a foundation for the long-term development of the smart building industry.

VI. Conclusion

This study constructed an evaluation system for SCB, and based on this, designed an evaluation method that integrates the C-OWA operator and grey clustering. This method was based on expert opinions and could efficiently quantify and analyze uncertain information. The results showed that in the evaluation system test, the total alpha value of internal consistency for five primary indicators exceeded 0.7, and the KMO value reached 0.843. The approximate chi square value of Bartlett's sphericity test was 1091.258, with a degree of freedom of 37 and a significance level of 0.000, demonstrating high reliability and validity. The weight coefficients of the primary indicators calculated through the C-OWA operator ranged from 0.163 to 0.224. Through project analysis, it could be concluded that the comprehensive benefit evaluation value of the project was 8.342, which was classified as a good level based on the level judgment. From a temporal perspective, the comprehensive benefits of this project had shown a stepwise upward trend between 2021 and 2023. Therefore, the comprehensive evaluation method for smart buildings designed is effective, which can objectively and comprehensively evaluate the extensive benefits of smart buildings and provide a data basis for project decision-making.

***Abstract*—With the rapid development of information technology and the advent of the digital age, the management of fiscal treasury is facing unprecedented challenges and opportunities. In order to improve the efficiency and effectiveness of deep learning algorithms in the financial and treasury big data monitoring platform, this paper further studies the performance optimization methods of the model. This paper deeply studies deep learning algorithm research and performance optimization of financial Treasury big data monitoring platforms. This paper reviews the basic concepts, methods, and applications of deep learning and their application in the financial database big data monitoring platform. In the financial Treasury big data monitoring platform, deep learning algorithms are widely used in image recognition, natural language processing, recommendation systems and other fields. This article first conducts in-depth theoretical research on deep learning algorithms, including various neural network structures (such as convolutional neural network CNN, recurrent neural network RNN, etc.), optimization algorithms (such as gradient descent method and its variants), regularization techniques, etc. In addition, we also studied the practical applications of deep learning in fields such as image processing, natural language processing, and recommendation systems. In order to verify the effectiveness of deep learning algorithms in the financial and treasury big data monitoring platform, we designed corresponding experiments. These experiments include using deep learning algorithms for image recognition of financial documents, natural language processing, and building recommendation systems. We collected real fiscal treasury data as the experimental dataset and preprocessed and annotated the data.**

Keywords*—Deep learning; financial database big data monitoring; algorithm research; performance optimization

I. Introduction

The financial treasury's big data monitoring platform is an important tool for the government to supervise financial funds effectively. It is significant for ensuring financial funds' safety and rational use [1]. The role of deep learning algorithms in the financial Treasury big data monitoring platform: Deep learning algorithms can extract valuable information from a large amount of data to provide more accurate data support for financial decision-making. Improve the performance of the financial Treasury big data monitoring platform. Studying deep learning algorithms and performance optimization methods improves the performance of the financial Treasury big data monitoring platform and provides more accurate data support for financial decision-making [2]. Protecting the privacy of financial big data: In the financial Treasury big data monitoring platform, it is crucial to protect the privacy of financial big data [3]. Ensure the security and privacy of big data in financial institutions by researching privacy protection methods. Research on deep learning algorithms: Research on deep learning algorithms applicable to financial Treasury big data monitoring platforms, such as convolutional neural networks and recurrent neural networks [4].

Performance optimization methods: Research methods to improve the performance of financial Treasury big data monitoring platforms, such as model compression, model acceleration, etc. [5]. Methods to protect the privacy of financial big data in the financial Treasury big data monitoring platform, such as differential privacy, homomorphic encryption, etc. [6]. This paper introduces the background and importance of the Financial Treasury big data monitoring platform and the role of deep learning algorithms in the Treasury big data monitoring platform [7]. Review the application of deep learning algorithms, performance optimization, and privacy protection methods in the financial database big data monitoring platform. The deep learning algorithm applicable to the big data monitoring platform of financial Treasury is introduced in detail. Performance optimization method: The method to improve the performance of the financial Treasury big data monitoring platform is introduced in detail [8]. Privacy protection method: The method of protecting the privacy of big data in the financial treasury big data monitoring platform is introduced in detail. Experiment and evaluation: The effectiveness of the proposed deep learning algorithm, performance optimization, and privacy protection methods is verified through experiments [9]. The main achievements and limitations, as well as the future research direction, are presented. A new deep learning algorithm is proposed, which is suitable for the financial Treasury big data monitoring platform and improves the performance of the platform [10]. A new performance optimization method is proposed to improve the performance of the financial Treasury big data monitoring platform while ensuring the privacy of financial big data [11]. A new privacy protection method is proposed to protect the privacy of financial big data in the financial Treasury big data monitoring platform while ensuring the performance of the platform [12].

II. Literature Review

In recent years, deep learning algorithms have been applied more and more widely in the financial Treasury big data monitoring platform, becoming an effective means to solve complex problems [13]. This paper summarizes the research and application of deep learning algorithms in the financial Treasury big data monitoring platform, focusing on the basic concepts, methods and applications of deep learning and its application in the financial Treasury big data monitoring platform [14]. Deep learning is a branch of machine learning that simulates the working mechanism of the human brain by building deep neural networks that automatically learn features from data to deal with complex problems. Deep learning mainly includes convolutional neural networks (CNN), recurrent neural networks (RNN), long and short-term memory networks (LSTM), generative adversarial networks (GAN), etc. In the financial Treasury big data monitoring platform, deep learning algorithms are mainly applied to image recognition, natural language processing, recommendation systems and other aspects [15]. In the context of globalization, supply chains have become increasingly complex, involving numerous participants and massive transaction data [16]. This complexity not only brings business opportunities to enterprises, but also risks, especially the risk of financial fraud. Traditional financial fraud detection methods often struggle to cope with such large-scale and high-frequency transaction data [17]. Therefore, developing a financial fraud detection method based on distributed big data mining is particularly important. Distributed big data mining technology is a technology that can process and analyze massive amounts of data. It distributes data across multiple computing nodes and achieves rapid analysis and mining of data through parallel computing and collaborative processing. This technology can not only handle large-scale data, but also cope with the rapid growth and changes of data, providing strong technical support for financial fraud detection [18]. Image recognition technology can help identify image information such as bills and bills and improve data processing efficiency. Natural language processing technology can process much text data, such as news, reports, etc., for public opinion analysis and risk warning. Based on their behavioral data, the recommendation system can recommend relevant services or products to users. The performance optimization problem of a deep learning algorithm in financial Treasury big data monitoring platform. Although deep learning algorithms have wide applications in the financial database big data monitoring platform, some performance optimization problems remain, such as model compression, parameter optimization, calculation acceleration, etc. Model compression technology can improve the inference speed of the model by simplifying the model structure and reducing model complexity. Parameter optimization technology can improve the model's generalization ability by adjusting the parameters. Computing acceleration technology can improve models' training and reasoning speed using hardware acceleration devices such as GPU and TPU.

In summary, deep learning models typically have high complexity and require a large amount of computing resources for training and inference. However, in the financial and treasury big data monitoring platform, computing resources are often limited. To solve this problem, we can use model compression technology to reduce the consumption of computing resources by reducing the number of model parameters and reducing model complexity. In addition, utilizing hardware acceleration devices such as GPUs and TPUs can significantly improve the training and inference speed of the model. The financial and treasury big data monitoring platform needs to process and analyze data in real-time to address potential risks and fraudulent behavior. However, the training of deep learning models usually takes a long time, and the accuracy of the model directly affects the performance of the monitoring platform. To solve this problem, we can adopt incremental learning and online learning techniques to enable the model to continuously update and optimize itself while processing new data. In addition, we can also use transfer learning and ensemble learning methods to combine the prediction results of multiple models to improve accuracy.

III. Deep Learning Algorithms for Big Data Monitoring Platforms

A. Basic Principles of Deep Learning Algorithms

The convolutional neural network then classifies and outputs the feature representations formed after multiple convolutions and pooling through the fully connected network. Convolutional neural networks can extract and learn data features automatically and efficiently. Based on the structural characteristics of the convolutional layer and pooling layer, convolutional neural networks have gained rapid development and many applications in computer vision fields, such as image recognition and object detection. Autoencoder is an unsupervised deep learning algorithm that can learn the potential feature representation of data and then realize the functions of data dimensionality reduction, noise reduction, and new data generation. An automatic encoder usually includes an encoder and decoder, two components; the encoder can encode the data into the encoding space and compress it into a low-dimensional space representation, and the role of the decoder is to decode the compressed representation back to the original data space. At the same time, the autoencoder trains the model by minimizing the error between the encoder's input and the output reconstructed by the decoder. Then, it learns the underlying characteristic representation of the data. The autoencoder is flexible, efficient, and widely used in data compression and noise reduction. The basic reinforcement learning framework mainly comprises agents, environments, states, actions and rewards, as shown in Fig. 1. The agent is the learner in reinforcement learning. As the core of reinforcement learning, it learns strategies by interacting with the environment. In contrast, other things interacting with the agent are called environmental states and are used to describe the current information about the environment. The reinforcement learning process is embodied in that the agent chooses actions to perform according to the current state of the environment and affects the environment. Then, the environment will give feedback and reward signals to the agent's actions, and the new state agent will continuously improve its action strategy according to the feedback of the environment and perform subsequent actions according to the strategy. The agents continue to conduct trial-and-error learning and strategy improvement in this interaction process to maximize the final cumulative income.

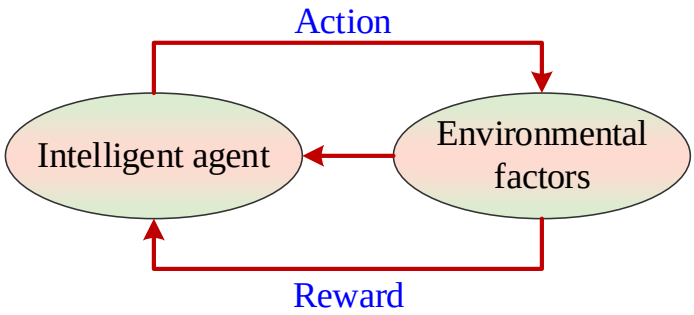

Fig. 1. Reinforcement learning basic frame.

Deep reinforcement learning is still a reinforcement learning method, and its essence and basic framework are the same as reinforcement learning. It uses reinforcement learning ideas to define problems and optimize strategies, while deep learning is used to solve value or strategy functions and optimize objective functions through backpropagation algorithms. The research in this paper mainly uses an algorithm based on a value function, which approximates the value function through the neural network. The agent and environment interaction data is used to train the neural network. DQN and DDQN, two deep reinforcement learning algorithms used in this paper, are mainly introduced.

DQN algorithm (Deep O-network) First proposed by Google's DeepMind team in 2013 and further modified and improved in 2015, the DQN algorithm is the first deep reinforcement learning algorithm, which was originally used to play video games. For DQN, people do not need to provide the game rules to the agent, but only the game screen as the input of the DQN algorithm; the agent can automatically conduct trial and error learning and show that it can reach or even exceed the level of human games. Due to the different nature of deep learning and reinforcement learning, there are too many differences in their training data and learning process, and there have been many problems with how to integrate the two. The emergence of the DQN algorithm solves these problems through experience playback and other technologies, and deep reinforcement learning technology has opened a new chapter. Deep learning is a supervised machine learning method. To train and update the weight parameters in the Q network, a loss function must be defined to determine the network's optimization goal. Meanwhile, this loss function also represents the objective function of reinforcement learning. DQN's update rule based on the Q-learning algorithm defines the loss function as shown in Formula 1:

$$L(\theta) = \left[\left(R + \gamma \, m \underset{a'}{a} x \, Q\,(s', a'; \theta)\right)^2\right] \quad (1)$$

Among them, R Represents the reward received by the agent, γ Represents the discount rate, a constant between 0 and 1, which controls how much attention is paid to future value, S' and a' Indicates the status and the next action. The loss function of DQN is expressed as the mean square error of the target Q value and the predicted Q value, where the target Q value is shown in Formula 2.

$$T\,arg\,e\,tQ = R + \gamma \underset{a'}{max} Q(s', a'; \theta) \quad (2)$$

The weight parameters of the Q network in DQN are not updated and trained by the gradient descent algorithm to minimize the loss function so that the deep neural network approximates the value function, and the target Q value is constantly approximated based on the current predicted Q value. However, there are also great differences in training data between deep learning and reinforcement learning, affecting the performance of deep reinforcement learning algorithms. The training data of deep learning is usually independent and distributed. There is no obvious correlation or temporal relationship between the data. In contrast, the training data of reinforcement learning is obtained by the interaction between the agent and the environment. Each state and action will affect the next state and action, and the training data is usually strongly correlated and non-static. If the neural network is used directly for training, the loss value may fluctuate continuously, the model may become unstable, and it may be challenging to converge. To solve this problem, DQN adopts the experiential playback mechanism to train the model. It counts the number of experience samples each time an agent interacts with the environment $(s\,,\ a, R\,, s')$ It stores the number of experience samples each time the agent interacts with the environment in a buffer called playback cache experience pool. During training, the agent randomly draws a small batch of experience sample data from the experience pool to update the parameters of the neural network. The empirical playback mechanism uses random sampling to remove the correlation and timing relationship between the training data. At the same time, under this mechanism, every sample may be used and reused, which can smooth the change of the data distribution, help smooth the gradient, and make the model easier to converge.

Further improvements were made to DQN to solve the above problems. This version of DQN uses a separate Q network called the target network to calculate the target Q value, thus decoupling the calculation of the target Q value from the predicted Q value. The weight parameters of the target network are updated in a delayed way. It freezes into the old predictive network weight parameter θ'; and only after a certain number of predicted network updates θ'; be updated to θ; at this time, the loss function of DQN is updated, as shown in Formula 3.

$$L(\theta) = E\left[\left(R + \gamma \underset{a'}{max} Q(s', a; \theta^-) - Q(s', a'; \theta)\right)^2\right] \quad (3)$$

After the update, DQN includes two Q networks, prediction networks $Q(s, a; \theta)$ used to evaluate the value of the current state action and target network $Q(s, a; \theta)$ is used to calculate the target Q value. Since the weight parameters of the target network

are updated and delayed, the target Q value will remain unchanged for a period, which can provide a stable training target for the prediction network. The dual network structure effectively reduces the possibility of model oscillation and divergence and improves the stability of the DQN algorithm. In the further decoupling of DQN, action selection and evaluation are also carried out by using two different Q networks, and the improved DQN algorithm of 2015 has two Q networks itself, so the prediction network can undertake the task of action selection, while the target network is still used to estimate the target Q value. So that the selection and evaluation of the action are realized, and the target Q value is updated as shown in Formula 4.

$$Target Q = R + \theta Q(s', argmax\ Q\ (s', a; \theta); \theta^{-}) \quad (4)$$

Among them, θ corresponding to the weight parameters of the prediction network, θ^{-} weight parameter of the target network. At this point, predict the network according to the next state s' select the next action a' , and target the network to estimate the action value function $Q(s', a')$. Two different Q networks are used to select and evaluate the actions, so the algorithm is called Double DeepQ-Network, which reduces the overestimation problem and makes the DQN algorithm obtain better stability and performance.

The ratio of correctly classified samples to the total number of samples is shown in Formula 5.

$$Accuracy = \frac{TP + TN}{TP + FN + FP + TN} \quad (5)$$

The proportion of results predicted to be positive turned out to be positive, as shown in Formula 6.

$$Precision = \frac{TP}{TP + FP} \quad (6)$$

The proportion of positive samples correctly judged to be positive, as shown in Formula 7.

$$Recall = \frac{TP}{TP + FN} \quad (7)$$

F1 scores take precision and recall into account, and for highly imbalanced datasets, F1 scores are available via , It is often considered a better indicator of evaluation, as shown in Formula 8

$$F1 = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (8)$$

This paper mainly introduces some key technologies and the theoretical basis involved in this study. First, the commonly used anomaly detection algorithms are introduced into two categories: traditional machine learning algorithms and deep learning algorithms. Then, reinforcement learning is outlined, and the algorithms DQN and DDQN used in this study are introduced. Finally, the data set and evaluation index used in the experiment are explained.

B. Application of Deep Learning Algorithm in Financial Treasury Big Data Monitoring

With the advent of the era of big data, deep learning algorithms are being applied more and more widely in the big data monitoring of the financial treasury. This paper will elaborate on applying deep learning algorithms to the big data monitoring of the financial treasury. The deep learning algorithm is a machine learning algorithm based on a deep neural network, which mimics the working principle of the human brain and maps input data to high-level feature space through a multi-layer nonlinear transformation to achieve efficient representation and prediction of data. Deep learning algorithms have achieved remarkable success in image recognition, natural language processing, recommendation systems and other fields. The big data monitoring platform for financial funds is used to monitor the revenue and expenditure of financial funds and changes in financial funds. The platform provides data support for government decision-making by collecting, analyzing and forecasting financial data in real-time. The application of deep learning algorithms in the financial Treasury big data monitoring platform mainly includes the following aspects:

Image recognition: Deep learning algorithms can be used to identify key information in images such as financial bills and contracts, such as amount, date, payee, etc., thereby improving the efficiency and accuracy of data entry. Natural language processing: Deep learning algorithms can analyze key information in financial reports, such as revenues, expenditures, budgets, etc., to provide data support for government decisions. Recommendation system: Deep learning algorithms can recommend finance-related policies, regulations, research reports, etc., to provide a reference for government decision-making. Although the deep learning algorithm has a wide application prospect in the financial database big data monitoring platform, it still has some problems, such as high computational complexity and long training time. Therefore, it is necessary to optimize the performance of the deep learning algorithm to improve its application effect in the financial Treasury big data monitoring platform. The performance optimization methods include model compression, parameter optimization, calculation acceleration, etc. The number of parameters of deep learning models can be reduced through model compression technology, thus reducing the models' computational complexity and storage space. Deep learning networks Q are typically over-parameterized, the parameters are highly overlapping, and the contribution of parameters to performance varies greatly from part to part. As the name implies, network pruning is the pruning away some unnecessary parameters in the model. Prioritize training a large, accurate network. Evaluate the "importance" of each neuron for each parameter in the network parameter. By what method is the "importance" of the parameter neuron measured? The most intuitive idea is that the importance of a parameter can be represented by its absolute value, and the parameter with a larger absolute value has a greater impact on the overall network and is more important. The importance of a neuron can be characterized by recording the number of times it outputs zero for multiple inputs, and often, the output is zero, indicating that it is not too important. Remove unimportant parameter neurons. When pruning a network, the network's performance usually decreases after some neurons are removed. At this time, the pruned network is fine-tuned to increase its accuracy. More details can be observed in Fig. 2.

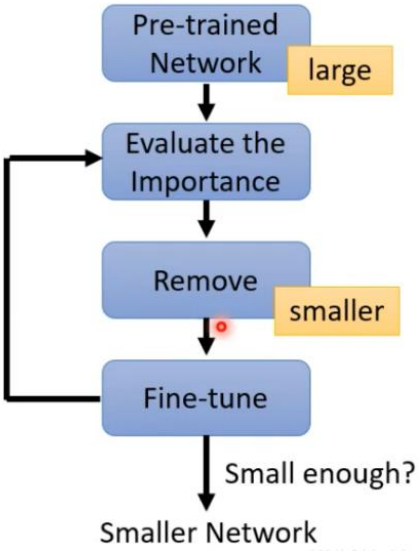

Fig. 2. Removing parameters/removing neurons.

The process of removing parameters is shown in Fig. 3 below. The result will be irregular, bringing two problems: first, it is difficult to implement; think of deep learning frameworks like Torch. The framework will give a standard layer when defining the network layer by directly specifying the number of neurons. Specifying that certain parameters of certain neurons are absent is considered more troublesome. The second could be more conducive to GPU acceleration. Modern neural networks mostly use parallel acceleration through the GPU, whether full connection or convolution. Matrix multiplication is employed as its underlying implementation. Additionally, removing non-existent parameters becomes troublesome for GPU acceleration; a feasible and direct approach does not remove parameters, but the parameter weight is reset to 0. This avoids the two problems mentioned above and has the same effect as removing the specified parameters. If it were considered, model pruning would be seen to be happening right now. Without removing the parameters, no decrease in the parameters of the network in the big land and the computationally big land would occur; it does not make sense. So, in practice, it's usually done by removing neurons.

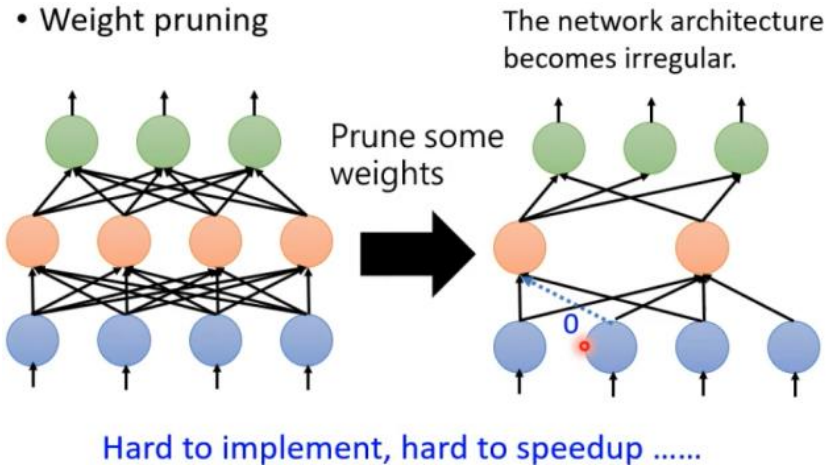

Fig. 3. Removing parameters.

Parameter optimization: By adjusting the parameters of a deep learning model, the model's prediction accuracy and generalization ability can be improved. Computational acceleration: By using hardware accelerators such as GPUs and Opus, the speed of training and prediction of deep learning models can be greatly improved.

Fourth, the performance optimization of the financial Treasury big data monitoring platform. The so-called inflow of local financial Treasury funds mainly includes the daily financial revenue of the financial department at the same level, the dispatch funds and bond loan funds allocated to the financial department at the same level by the financial department at the higher level, and the fund portion of the financial revenue of the financial department at the lower level. The so-called outflow of local financial Treasury funds includes the daily financial expenditures of the financial departments at the same level, the funds allocated to the financial departments at the higher level from the financial revenues of the financial departments at the same level as expenditure, the dispatch funds and bond transfer funds allocated by the financial departments at the lower levels as well as external temporary payments, etc. The balance of local Treasury funds is the balance of funds after the revenue and expenditure of local Treasury funds are offset, which mainly includes the balance carry-over funds of the financial departments and units at the same level, the current funds between the financial departments at the same level and the upper and lower financial departments, the balance of temporary, temporary payments of the financial departments at the same level, and the budget stabilization fund and working capital. From the perspective of the nature of financial accounts, the inflow, outflow, and balance composition of financial accounts are detailed in Table I.

As can be seen from the concept and composition of financial funds in Table I, local financial funds are not only a centralized reflection of financial operation and management level but also the material basis for local governments to perform the functions of stable growth, promoting reform, adjusting structure, benefiting people's livelihood and preventing risks. Excessive scale of fiscal funds will reduce the investment income and leverage effect of fiscal funds, and too small scale

of fiscal funds will hinder the government's performance of functions and breed risks of fiscal funds, so it is necessary to control the scale of local fiscal funds within a reasonable range through fiscal funds management. More explanations are tabulated in Table II.

TABLE I. SUMMARY OF REVENUE, EXPENDITURE, AND BALANCE OF FINANCIAL FUNDS

Revenue from the fiscal treasury	Financial expenditure	Balance of fiscal funds
Include tax revenue, nontax revenue, and local government general bond revenue in budget management; Land included in government fund management.	General public budget expenditures, government fund expenditures, social security fund budget expenditures, state-owned capital operation budget expenditures, etc.	General public budget surplus, government fund budget surplus, state-owned capital operation budget surplus, budget stability adjustment fund, budget turnover fund, and other accounts receivable and payable balances.

TABLE II. LIST OF THE ORGANIZATION, FUNCTIONS AND POWERS OF THE NATIONAL TREASURY

Organizational structure	Basic duty	Main permissions
(1) Establish a national treasury at the central level, a national treasury branch at the provincial, autonomous region, and municipality directly under the central government, a central branch at the provincial level, and a branch at the county level and equivalent cities and districts. (2) The directors of the national treasury at all levels are concurrently held by the governors of the people's banks at that level. In contrast, the deputy directors of the national treasury at all levels are concurrently held by the deputy governors in charge of the national treasury. (3) The work of the national treasury business shall be under vertical leadership, and each province, autonomous region, and municipality directly under the central government's branch treasury and its affiliated branch treasury shall be both a branch of the central treasury and a local treasury. (4) Each level of national treasury shall establish specialized working institutions to handle national treasury business	(1) Handle national budget revenue collection, allocation, and retention. (2) To handle the allocation of national budget expenditures, (3) to report the implementation of budget revenue and expenditure to the higher-level treasury and the same-level financial organs, (4) to assist the financial and tax authorities in urging enterprises and other units with economic income to pay their payable amounts to the state timely. Those who repeatedly fail to pay should be assisted in deducting and storing them according to tax law. (5) Organize, manage, inspect and guide the work of the lower-level treasury. (6) Handle other tasks related to the national treasury assigned by the state.	(1) Supervise and inspect whether all the funds collected by the collection offices and revenue agencies have been paid into the national treasury by regulations, and promptly investigate and handle any illegal nonpayment. (2) The national treasury has the right to refuse to execute any unauthorized changes in the scope of revenue division, the proportion of revenue sharing and retention between different levels of finance, and arbitrary adjustments to the balance of deposits between treasury accounts. (3) For those who do not meet the requirements of national regulations for returning funds, the national treasury has the right to refuse to handle (4) supervision of the opening of financial deposits and the disbursement of financial funds. (5) Any unit or individual that forces the national treasury to handle matters that violate national regulations,

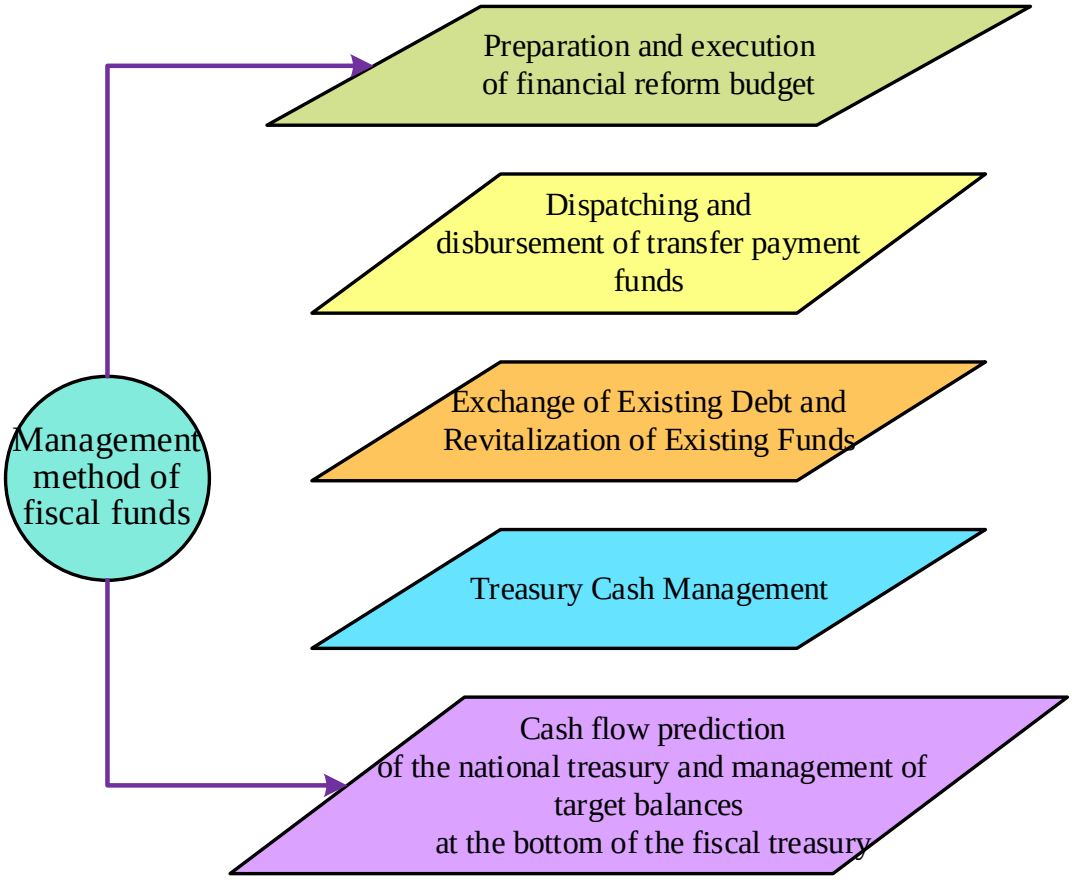

Fig. 4. The way treasury funds are managed.

From the perspective of management methods, as shown in Fig. 4, financial departments at all levels manage financial funds through such tools as the preparation and implementation of financial budgets, the dispatch and allocation of transfer payment funds, the replacement of outstanding debts and the activation of outstanding funds, Treasury cash management, Treasury cash flow forecast and target balance management of Treasury bottom.

The management of Treasury funds means that the central and local financial departments control the scale of local Treasury funds within a reasonable range through the scientific preparation of fiscal budgets and effective implementation of fiscal budgets, reasonable arrangements for the dispatch and allocation of transfer payment funds, effective replacement of outstanding debts, active activation of outstanding funds, and standardized measures to promote Treasury cash management. Based on the core concept of financial treasury management, this paper uses public finance, public choice, and monetary value theories to study local treasury management's problems and optimization paths.

IV. Experiment and Case Analysis

It is clear that the platform construction is mainly carried out around the "six comprehensive" goals: first, the overall overall construction pattern, relying on the integrated budget management system, making full use of big data thinking and advanced technology, and establishing a comprehensive and overall financial information pattern; The second is the comprehensive coverage of data exchange, the construction and improvement of financial unified data service platform, data exchange to achieve "up to down, horizontal to the edge"; Third, comprehensively improve the level of data, build an advanced financial big data platform, and comprehensively improve the level of data utilization; The fourth is a comprehensive and effective supervision means, the time spans several years to form a historical comparison, the space covers all financial and budget units, the level covers the province, states, cities and counties, and the accounts cover all financial funds of the four budgets; Fifth, comprehensive and flexible function expansion, according to the needs of business management reform, timely expansion of new functional modules, extend the scope of supervision; The sixth is a full-service data ecology, providing convenient and comprehensive financial data analysis services for all levels and improving the data service ecology. Around the above goals, the monitoring and analysis platform is built according to the idea of "one center, two platforms, three levels of coverage, and four types of applications." "One center," that is the establishment of a provincial financial data center. Establish a standardized data storage structure and data collection standards, and integrate internal and external financial data at all levels in the province into a unified data center. The "two platforms" are to create a unified data center and build a monitoring and analysis platform for financial fund operation. Centralized management of financial data analysis requirements at all levels, establishment of multidimensional data analysis models, development and expansion of general functions. Based on the unified data center, a monitoring and analysis platform bearing various financial big data analysis applications is built. "Three-level coverage," that is, the financial data covers all the financial funds of provinces, cities and counties, and the scope of use covers the three-level financial users of provinces, cities and counties. "Four types of applications," focusing on the four directions of real-time monitoring, decision support, monitoring and early warning, report management, in-depth mining of data value, and building financial big data applications for multi-scenario and multi-users. More details are depicted in Fig. 5.

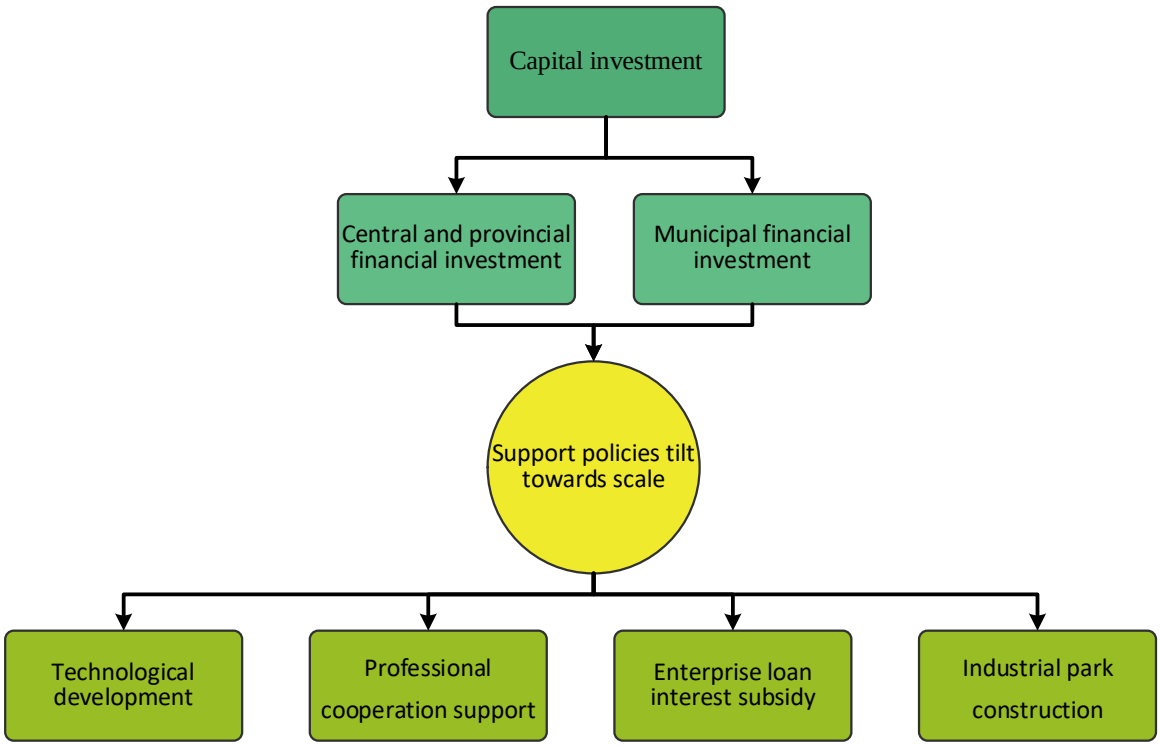

Fig. 5. Three-level financial diagram.

The national Treasury centralized electronic payment management and the integration of budget management have successfully established an information connection mechanism between financial departments, budget units, the People's Bank, agent banks and other departments, and solved the bottleneck problems restricting the use of big data such as the formation of "information islands" due to their governance, resulting in the loss of business data and the difficulty of cleaning garbage data. The fragmented "information islands" are integrated into a unified whole by constructing the standardization system so that the business, capital, and information flow can operate simultaneously. The standard and collection of financial and treasury data information can be unified and summarized, forming a natural "budget execution data center" covering the whole province, overall utilization and unified access, and providing reliable data support for applying big financial data. On this basis, it explores the information sharing of multiple departments such as finance, taxation and statistics, as well as cross-departmental data fusion, establishes unified standards and norms, and initially builds a data resource center oriented to analysis topics. By integrating internal financial data such as budget preparation, budget implementation, monthly reports of fiscal revenue and expenditure, and general final accounts, as well as external data such as inventory daily of the People's Bank of China, financial special accounts of commercial banks, social insurance premium transfer of tax departments, and statistical yearbook of the Bureau of Statistics, the data model and special database are established. At the same time, data governance standards should be established, data governance rules should be formulated, all kinds of data extracted and imported should be integrated and counted, a data asset catalog should be formed, and data quality management should be strengthened. The mentioned explanations are visualized in Fig. 6.

Adhere to the goal orientation and effect orientation from the perspective of improving the financial Treasury management and informatization level, sorting out the current business needs and priorities, designing and developing functional application systems in a targeted way, and building a financial big data monitoring and analysis application platform. Through technical means such as data analysis, data mining, data model and visual presentation, the results of financial informatization construction and the data resources accumulated by the financial Treasury for many years are displayed more conveniently, more effectively and intuitively. Up to now, the real-time monitoring application of the monitoring and analysis platform has been built into nine display screens, such as fiscal revenue, fiscal expenditure, fund flow, transfer payment, and dynamic monitoring of budget implementation, to achieve real-time online monitoring and analysis of various financial business activities. A decision analysis application has been built, including financial overview, financial revenue, financial expenditure, financial resources, subsidies and upper solution, Treasury Management and six other major themes of 38 functional modules in the form of graphics tables, using multidimensional analysis methods, from the time, space, object attributes and other dimensions, a comprehensive reflection of the financial and economic operation of local areas. The monitoring and early warning application has completed the construction of functional modules such as indicator allocation, implementation, and direct funds. The allocation and use of each financial fund can be grasped in real time through preset monitoring rules. This allows for the whole-life cycle tracking, monitoring, and risk early warning of common cause rights, special transfer payment indicators, and direct funds of various localities on a project-specific basis. Report management applications have collected and imported data such as ten-month financial reports, general financial accounts, and other budget execution reports at all province levels in recent years, which can automatically generate budget execution analysis reports and realize report query and analysis functions. More information are tabulated in Table III.

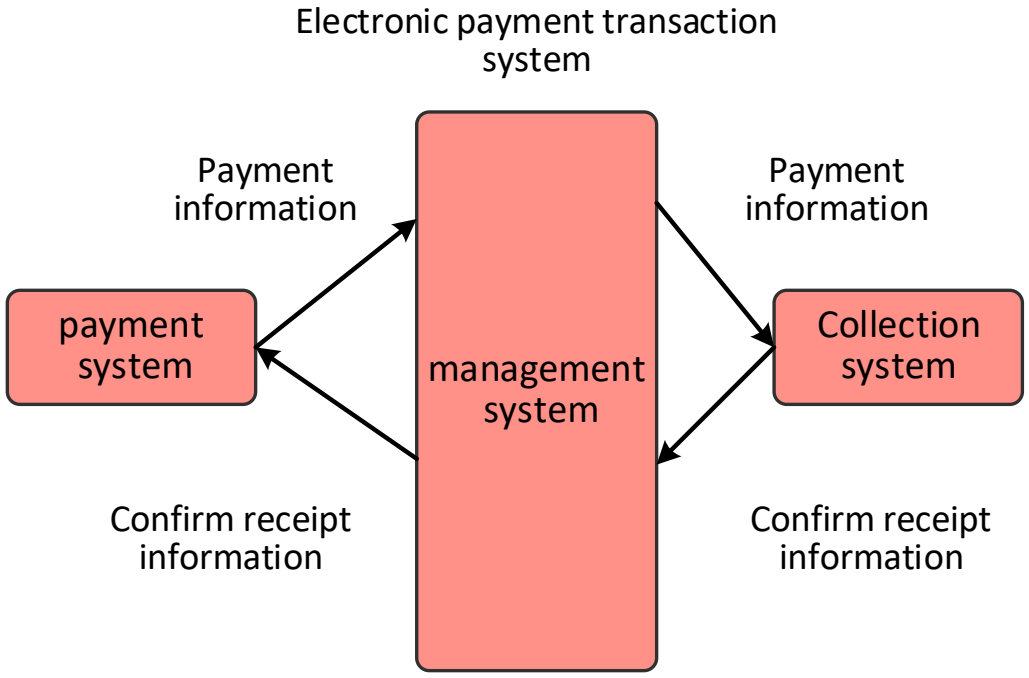

Fig. 6. Electronic management of centralized treasury payments.

TABLE III. ACHIEVEMENTS OF FINANCIAL INFORMATIZATION CONSTRUCTION AND FINANCIAL TREASURY DATA RESOURCES

9	Industrial transformation	The proportion of added value of core industries in the digital economy to GDP (%)	7.8	10	Anticipation
10		The proportion of enterprises that fully digitize key business processes is (%)	48.3	60	Anticipation
11		Cloud coverage rate of industrial equipment in enterprises (%)	13.1	30	Anticipation
12		Online retail sales (trillion yuan)	11.76	17	Anticipation
13		Information consumption scale (trillion yuan)	5.8	7.5	Anticipation
14	Government services	Online processing rate of provincial-level administrative licensing matters (%)	80	90	Anticipation
15		Real-name user scale of online government services (in billions)	4	8	Anticipation
16		Electronic social security card application rate (%)	25	67	Anticipation
17		Electronic litigation proportion (%)	18	30	Anticipation

Based on the three-level data interconnection of the integrated construction of budget management, the platform gathers and collects the expenditure data of the states (cities) and counties (cities and districts) in the budget execution system. According to the management needs, based on fully considering the business needs of various places, the platform framework system is built as a whole, the functional modules are designed and developed scientifically and reasonably, and the data of various business systems are expanded and integrated. Through personnel management and authority setting, financial users at the provincial, municipal and county levels can log in to the monitoring and analysis platform through the "Yunnan Financial Management Information System" portal interface and conveniently and quickly query their respective data analysis data, which greatly improves the application level of information technology in various regions, and effectively avoids repeated construction and resource waste. Under the unified framework system, the platform has better scalability compatibility. According to the needs of management work, new functional modules can be added at any time, and various existing monitoring and analysis systems can be integrated to form a unified system and a unified platform, which is easy to manage and improve efficiency. By the principle of "building while using, gradually improving," some functional modules developed have been opened to the relevant fund departments in the Office and local financial departments. At the same time, for the problems found by users in the process of use, timely collection and feedback to the software developer, and constantly modify and improve the system.

The comprehensive analysis and utilization of data based on the platform has expanded the coverage of financial supervision and effectively built the province's electronic financial supervision framework. The use of platform information means that it has realized the dynamic supervision of financial funds of financial departments and budget units at all levels and has integrated supervision into the whole financial management process. Through the monitoring and analysis platform, the discipline inspection and supervision department can monitor the whole process of special financial funds, discover illegal operations on time, and determine the focus of supervision and inspection. The discipline inspection and supervision team of the Provincial Department of Finance takes platform construction as a typical practice of innovating financial supervision methods by using modern information technology. The construction of the monitoring and analysis platform clarifies the main data sources, clarifies the data acquisition aperture of analysis, opens up the collection channels of other parts of business data, preliminarily completes the accumulation of financial data, and further sorts out various financial management needs. The relevant standards and norms have been improved, laying the foundation for comprehensively promoting the application of financial big data in the province in the next step.

In the context of globalization, supply chains have become increasingly complex, involving numerous participants and massive transaction data. This complexity not only brings business opportunities to enterprises, but also risks, especially the risk of financial fraud. Traditional financial fraud detection methods often struggle to cope with such large-scale and high-frequency transaction data. Therefore, developing a financial fraud detection method based on distributed big data mining is particularly important. Distributed big data mining technology is a technology that can process and analyze massive amounts of data. It distributes data across multiple computing nodes and achieves rapid analysis and mining of data through parallel computing and collaborative processing. This technology can not only handle large-scale data, but also cope with the rapid growth and changes of data, providing strong technical support for financial fraud detection.

V. CONCLUSION

The deep learning algorithm research and performance optimization of the big data monitoring platform of the financial Treasury are deeply studied. First, it reviews the basic concepts, methods, and applications of deep learning and their application in the financial database big data monitoring platform. To discuss the research progress of deep learning algorithms in the big data monitoring platform of financial Treasury, including image recognition, natural language processing, recommendation system, etc. Then, the performance optimization of deep learning algorithms in the financial database big data monitoring platform is analyzed, including model compression, parameter optimization, calculation acceleration, etc. This paper summarizes the research status and future development direction of deep learning algorithms in financial database big data monitoring platforms. The following conclusions are drawn through in-depth research: Deep learning algorithms have broad application prospects in the financial Treasury big data monitoring platform, which can improve monitoring accuracy and efficiency and reduce labor costs. However, deep learning algorithms have challenges in the financial Treasury big data monitoring platform, such as high model complexity and large computing resource requirements.

Therefore, further study of the performance optimization problem of deep learning algorithms to improve their application in the financial Treasury big data monitoring platform is necessary. Applying deep learning algorithms in the financial Treasury big data monitoring platform will be more extensive and in-depth. With the continuous progress of technology, it is expected that deep learning algorithms will play a greater role in the financial Treasury big data monitoring platform and provide more accurate, efficient and intelligent solutions for financial Treasury monitoring.

Postpartum Depression Identification: Integrating Mutual Learning-based Artificial Bee Colony and Proximal Policy Optimization for Enhanced Diagnostic Precision

Yayuan Tang, Tangsen Huang*, Xiangdong Yin
School of Information Engineering, Hunan University of Science and Engineering, Yongzhou 425199, Hunan, China

***Abstract*—Postpartum depression (PPD) affects approximately 12% of mothers, posing significant challenges for maternal and child health. Despite its prevalence, many affected women lack adequate support. Early identification of those at high risk is cost-effective but remains challenging. This study introduces an innovative model for PPD detection, combining the Mutual Learning-based Artificial Bee Colony (ML-ABC) method with Proximal Policy Optimization (PPO). This model uses a PPO-based algorithm tailored to the imbalanced dataset characteristics, employing an artificial neural network (ANN) for policy formation in categorization tasks. PPO enhances stability by preventing drastic policy shifts during training, treating the training process as a series of interconnected decisions, with each data point considered a state. The network, acting as an agent, improves at recognizing fewer common classes through rewards or penalties. The model incorporates an advanced pre-training strategy using ML-ABC to adjust initial weight configurations to increase classification precision, enhancing early pattern recognition. Evaluated on a Swedish study (2009-2018) dataset comprising 4313 cases, the model demonstrates superior precision and accuracy, with accuracy and F-measure scores of 0.91 and 0.88, respectively, proving highly effective for identifying PPD.**

Keywords*—Postpartum depression; imbalanced classification; Proximal Policy Optimization; Artificial Bee Colony; reinforcement learning

I. INTRODUCTION

PPD is a prevalent condition, impacting 10 to 15 percent of mothers each year [1]. This disorder presents as a range of depressive symptoms, ranging from moderate to intense, either during gestation or within the inaugural year post-delivery. The precise origins of PPD are yet to be fully understood, but it is believed to stem from a mix of psychological, psychosocial, and biological elements [2-4]. Biological factors such as inflammation, the decrease in allopregnanolone, and genetic predispositions are influential. Psychosocial elements, including continuous stress, previous depression episodes, challenges in relationships, and substantial life alterations, also contribute to the likelihood of developing PPD. The impact of PPD is profound, affecting both the mother and her child. Affected mothers may face difficulties in establishing an emotional connection with their children, question their ability to provide care, and sometimes harbor detrimental thoughts towards the child [5]. Though efforts exist to anticipate PPD in the antenatal phase, a consistent and accurate method for identifying women at heightened risk of post-birth depression remains elusive [6].

Traditional statistical approaches often examine the relationship between two factors while considering additional variables [7, 8]. However, Machine Learning (ML) methods enable the simultaneous evaluation of multiple interconnected variables, facilitating the development of predictive models based on data [9, 10]. These models are then analyzed to identify the most efficient predictors. ML can manage complex non-linear relationships and amalgamate diverse data types from various sources. Over the last decade, ML's utilization has grown in various medical domains, such as cardiology, hematology, oncology, cardiology, intensive care, and psychiatry. In the context of PPD, a condition with a moderate risk of evolving into a severe psychiatric issue and with a reasonably precise predictability of symptom emergence, ML holds significant value, considering the societal effects of PPD. However, monitoring each individual for early symptoms of PPD is not feasible. A more effective approach involves focusing on high-risk groups by health professionals such as nurses or midwives during postnatal examinations rather than targeting the general population. In Sweden, which experiences around 120,000 births annually, with women undergoing numerous adjustments after childbirth and an average PPD incidence of about 12%, this specific strategy is particularly beneficial for providing personalized, cost-effective mental healthcare for mothers and newborns.

ML encounters challenges in feature extraction, which can affect processing duration, generalization, and accuracy [11]. The advent of deep learning, especially the Multi-Layer Perceptron (MLP), has enhanced categorization abilities [12]. Tailored for complex XOR challenges, MLP is versatile across various works [13]. It operates similarly to human neural processing, with each node in an ANN handling input and producing outputs through an activation function. In MLP, these nodes interconnect over multiple strata without linkages within the same stratum.

In medical classification, an imbalance in data is a significant challenge. This problem, marked by a notable discrepancy in sample sizes among different classes, can hinder classification accuracy. Countermeasures at the data and algorithmic levels address this [11, 14-16]. Data-level strategies, such as down-sampling and up-sampling, aim to reduce the

adverse effects of uneven data distribution [17]. Algorithmic methods enhance the importance of underrepresented classes to combat imbalance [18]. Deep Reinforcement Learning (DRL) has been acknowledged for its efficiency in handling classification with uneven data [19]. Nonetheless, these techniques face hurdles in maintaining an equilibrium between bias and variance [20]. The susceptibility of DRL to hyperparameter variations adds complexity, leading to variable outcomes across different datasets and tasks. In this scenario, PPO stands out in on-policy reinforcement learning. PPO's distinctive mechanism, the PPO-clip, regulates policy alterations during training, ensuring the learning agent remains aligned with its existing policy, balancing exploration with exploitation. This stability is vital to prevent erratic behavior and promote consistent learning. PPO's computational efficiency makes it suitable for complex tasks and ideal for large state spaces, continuous action environments, or scalable and reliable real-world applications. PPO's foundational principles allow it to manage increasing data complexities adeptly, rendering it a valuable tool in various reinforcement learning scenarios [21].

Deep learning models frequently use training algorithms like backpropagation [22-24], which adjusts model weights to reduce errors. However, backpropagation faces challenges, such as susceptibility to initial weight configurations and the hazard of entrapment in local minima, especially in categorization tasks [25]. To overcome these, there is growing interest in meta-heuristic algorithms like PO (Puma optimizer) [26], AOA (Arithmetic Optimization Algorithm) [27], Chaotic Sand Cat Swarm Optimization (CSCSO) [28], SSA (Sparrow Search Algorithm) [29], WOA (Whale Optimization Algorithm) [30], PSCSO (Political Sand Cat Swarm Optimization) [31], known for its thorough exploration of solution spaces, reducing the likelihood of local minima entrapment. Among meta-heuristic algorithms, the ABC algorithm was specifically chosen for this study due to its unique search mechanisms that simulate honey bees' food-foraging behavior. This natural heuristic approach allows for an efficient balance between exploration and exploitation of the search space, which is crucial in finding global optima in complex optimization problems like those often encountered in deep learning. Furthermore, the ABC algorithm is particularly effective in scenarios with high-dimensional data and multiple local optima, making it highly suitable for our deep learning model's training process. It also avoids premature convergence—a common problem in traditional optimization techniques—thus enhancing our model's robustness and generalization ability. An advanced version of ABC, the ML-ABC, introduces a mutual learning approach among its algorithmic elements, enhancing adaptability and addressing issues related to weight initialization in gradient-based methods. ML-ABC improves optimization by facilitating information sharing, aiming to bypass local minima for more effective solutions [32, 33].

This study introduces a training algorithm based on PPO for PPD, utilizing data from the population-centric BASIC research conducted in Uppsala, Sweden. This algorithm specifically addresses the issue of data imbalance. The employed PPO strategy allows an agent to progressively learn through interactions, gaining rewards for accurate predictions and incurring penalties for errors. Importantly, higher rewards are given for correctly identifying instances from the underrepresented class. This approach aims to enhance classification accuracy and maximize overall rewards. The inquiry further addresses the frailties of gradient-based education methods, notably their sensitivity to initial weight configurations. It integrates the groundbreaking ML-ABC approach, which dynamically refines the optimization procedure through mutual learning influenced by initial weights, thereby elevating the model's efficiency. The method demonstrates outstanding performance in PPD prediction, attaining a precision rate exceeding 90%. This paper underscores the efficiency of integrating deep learning with PPO and the novel ML-ABC technique in addressing the issues of data imbalance and sensitivity to initial weights in classification models. The significant contributions of this paper include:

- This research introduces an algorithm based on PPO specifically developed for PPD. Its significance lies in applying sophisticated reinforcement learning methods to address a crucial challenge in medical diagnosis.
- The proposed model employs a PPO strategy to rectify data imbalance, a frequent issue in medical data sets. This approach, which rewards accurate identification of the underrepresented class, innovatively resolves this issue, thus enhancing the model's dependability and equity.
- The study tackles the prevalent problem of initial weight sensitivity in gradient-based training methods. The model dynamically enhances optimization by implementing the ML-ABC methodology, capitalizing on mutual learning informed by initial weights.

The structure of this study is as follows: Section II reviews related literature, while Section III outlines our proposed methodology for diagnosing PPD. Section IV displays the outcomes of our experiments. Section V concludes the paper with a summary of our findings.

II. Related Work

The recent surge in the application of ML within medical science, especially in predicting and classifying health conditions like PPD, marks a significant advancement in the field [34]. A comprehensive review of various groundbreaking studies sheds light on the evolution, methodologies, and accuracy levels achieved in classifying PPD using these techniques. These studies have utilized various ML approaches, each with unique strengths and implications for PPD prediction. The increasing sophistication of these models has opened new frontiers in understanding and managing PPD, offering more accurate and timely diagnoses. The integration of ML in medical diagnosis, particularly in PPD, signifies a shift towards more data-driven, personalized healthcare.

The research conducted by Zhang et al. [35] utilized a Support Vector Machine (SVM) and Feature Selection using Random Forest (FFS-RF) to predict PPD. Their extensive longitudinal study involved 508 women, with the Edinburgh Postnatal Depression Scale (EPDS) serving as the primary tool for assessing PPD risk. Building on this, Zhang et al. [36] further leveraged Electronic Health Records (EHR) datasets to study

PPD risk. The outcomes highlighted that logistic regression with L2 regularization was the most effective approach before childbirth, while the MLP technique proved more successful following childbirth. Jasiya et al. [37] significantly contributed by developing an ML system to identify the risk factors and prevalence of PPD in Bangladesh. This study analyzed data from 150 women, employing modified EPDS and PHQ-2 scales and socio-demographic queries. The Random Forest algorithm was identified as the most effective in this context. Park et al. [38] explored approaches to diminish bias in ML methods in a different study. They utilized health information from the IBM dataset. Their evaluation encompassed random forest, logistic regression, and extreme gradient boosting methods for PPD, investigating bias reduction techniques like reweighing.

The scope of PPD research was further broadened by Shin et al. [39], who employed the PRAMS 2012-2013 dataset and the PHQ-2 questionnaire to test various ML algorithms for determining PPD prevalence. Their analysis found that the Random Forest algorithm was the most effective. Similarly, Andersson et al. [40] experimented with multiple ML models using data from Swedish hospitals, concluding that the Extremely Randomized Trees model provided the best performance. In a hospital-based study, Nataranjan et al. [41] compared various methods, including Naive Bayes, decision trees, Functional-gradient boosting, SVM, and Naive Bayes. Their study, based on a longitudinally curated dataset, determined that Naive Bayes was the most efficient approach.

However, the path of integrating ML in medical diagnostics, while promising, could be more challenging. The diverse array of algorithms available presents a significant hurdle, as selecting the most suitable model for a specific application often requires extensive testing and a considerable allocation of resources [42]. This procedure can be both protracted and resource-intensive, demanding a careful balance between accuracy and practicality. Furthermore, the variation in datasets used in different studies introduces another layer of complexity. Different studies may use varying methodologies, sample sizes, demographic profiles, and data collection techniques, leading to inconsistent and sometimes conflicting results. This diversity underscores the need for standardized data collection and analysis methods to ensure comparability and reliability of results across different research initiatives.

III. The Proposed Method

Fig. 1 illustrates the structure of our novel model, meticulously designed to improve PPD detection and tackle issues, including class imbalance initial weight. This model harmoniously integrates the ML-ABC with PPO, effectively overcoming challenges commonly encountered in traditional models. Conventional algorithms often need a systematic method for setting initial weights, leading to slower learning rates and a tendency to converge on suboptimal solutions. This is especially problematic in medical fields where swift and precise diagnostics are crucial. The model addresses the prevalent challenge of class imbalance in classification tasks, favoring majority classes and neglecting vital minority classes essential for precise PPD detection. Our strategy employs ML-ABC to supply various initial weights, empowering the construct to circumvent local minima and amalgamate more adeptly towards holistic resolutions.

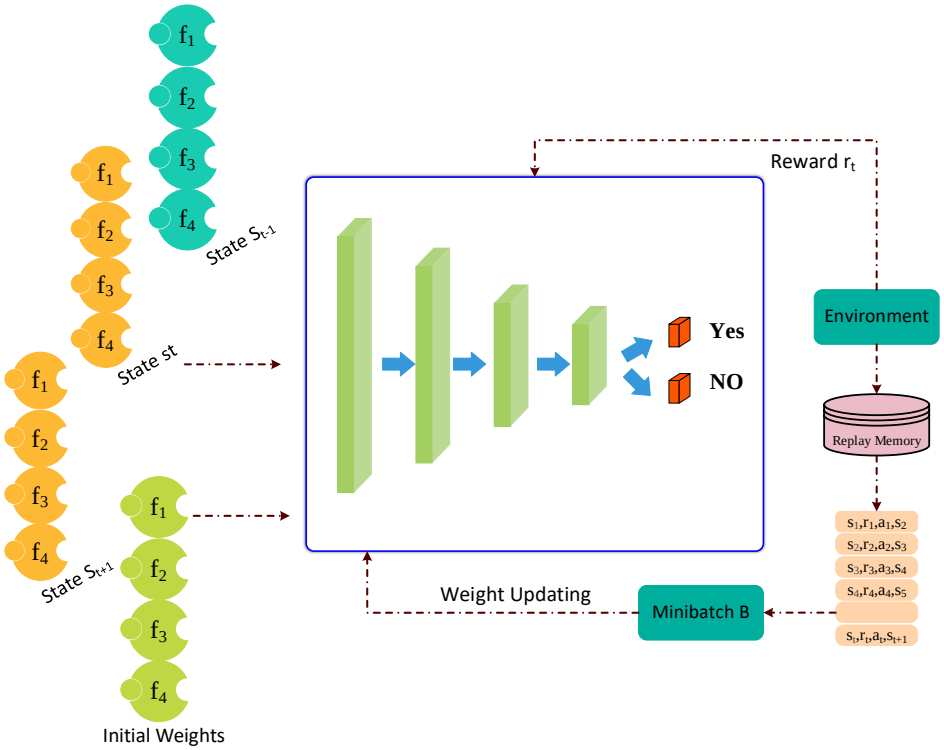

Fig. 1. A novel model blending ML-ABC and PPO for enhanced accuracy and class balance in PDD.

Moreover, the PPO facet of our construct is meticulously engineered to substantially incentivize more exact categorization of the less represented group, redirecting attention to these pivotal forecasts. This marks a significant advancement beyond conventional tutored learning approaches, which frequently need more comprehensive training data spanning diverse groups. PPO's adaptable schooling strategy facilitates a more equitable investigation of choices, culminating in approaches that more precisely identify minority categories. The flexibility of PPO within our framework sets it apart from traditional schemes, arming it to overcome the innate hurdles of standard classification techniques in PPD identification.

A. Initial Weight

The accurate setting of initial network weights is necessary for deep methods. Inaccuracies in these initial configurations can complicate the model's training phase, particularly regarding convergence. Acknowledging the critical role of weight initialization, our research initially focuses on identifying the most optimal configurations for ANN. To tackle challenges in initial network weights, we use the ML-ABC technique. ML-ABC demonstrates exceptional performance in optimization problems. It effectively explores the solution space, identifying promising regions and refining them iteratively. By utilizing ML-ABC, we aim to discover initial weight configurations that lead to faster and more stable ANN training, ultimately enhancing the overall predictive performance of the models.

1) The ML-ABC algorithm: Influenced by the complex foraging behaviors of honeybees, the ABC algorithm emulates nature's collective intelligence and sophisticated mechanisms, providing a systematic and instinctive method for addressing optimization challenges. The ABC algorithm is composed of four critical elements:

- Worker Bees: These bees initially explore, seeking potential food sources informed by their prior knowledge, focusing on the quality and quantity of nectar. After exploring, they return to the hive to share their findings.
- Observer Bees: Located within the hive, these bees assess the information provided by the worker bees, making decisions based on the reported nectar quality and quantity. They follow leads from worker bees' dances that indicate abundant food sources, efficiently exploiting these promising locations.
- Scout Bees: Tasked with discovering new food sources as current ones are exhausted, their search is more random than worker bees, allowing for adaptation to environmental changes.
- Food Sources: Symbolizing potential optimization solutions, the nectar amount at each food source signifies the solution's quality or effectiveness. The collective goal is to optimize nectar collection, paralleling the pursuit of optimal solutions in computational settings.

The ABC algorithm's adaptability is significant, balancing exploring new solutions and capitalizing on known ones. This balance, inspired by natural processes, makes the ABC algorithm a robust tool for optimization [43]. Eq. (1) demonstrates the method of creating new positions based on the spatial information from a worker bee. If a new position offers improved nectar quality, the bee moves there; otherwise, it retains its previous position.

$$v_i^j = s_i^j + \varphi_i^j(s_i^j - s_k^j) \tag{1}$$

In the given formula, the j-th index represents the position of the i-th solution s_i, which encompasses D variables, signifying the total number of parameters. The variable k corresponds to a distinct random solution. The component φ_i^j is a random number chosen from the interval [0, 1], modifies a single parameter of s_i, resulting in a new solution v_i. In a D-dimensional optimization scenario, one dimension is altered randomly. The decision regarding the most favorable solution is based on comparing fitness values. The diversity and innovation in the newly derived food source v_i are depend on s_i^j and s_k^j. When evaluating food sources, those with higher fitness leverage insights from both adjacent and current sources. This approach is fundamental in the ABC algorithm, which aims to discover food sources demonstrating superior fitness [44].

$$v_i^j = \begin{cases} s_i^j + \varphi_i^j(s_k^j - s_i^j), & Fit_i < Fit_k \\ s_k^j + \varphi_i^j(s_i^j - s_k^j), & Fit_i \geq Fit_k \end{cases} \tag{2}$$

In this expression, Fit_i and Fit_k denote the fitness values of adjacent and current food sources. The term φ_i^j is a random element ranging from 0 to F, the mutual learning factor, which is positive. Solutions are refined by assessing and favoring sources with higher fitness. The value of F, a non-negative quantity, affects the stability and enhancement of the solution. An increase in F reduces disturbances, indicating convergence towards a higher fitness level for the alternative food source. However, an overly high value of F may disrupt the balance between exploration and exploitation.

Our study incorporates a sophisticated encoding strategy in the ML-ABC algorithm, encompassing feed-forward weights despite the inherent precision-related complexities. Fig. 2 depicts the encoding process of a feed-forward network comprising four hidden layers. In this illustration, the weight matrices of the network are methodically laid out as sequential rows within an array structure.

The effectiveness of the ML-ABC algorithm is quantified through a fitness factor, formulated as follows:

$$Fitness = \frac{1}{1 + \sum_{i=0}^{N}(y_i - \tilde{y}_i)^2} \tag{3}$$

Within this formulation, y_i represents the actual label, and $\tilde{y}_i$ denotes the predicted label for each instance in the i-th dataset. The symbol N refers to the aggregate count of instances in the dataset.

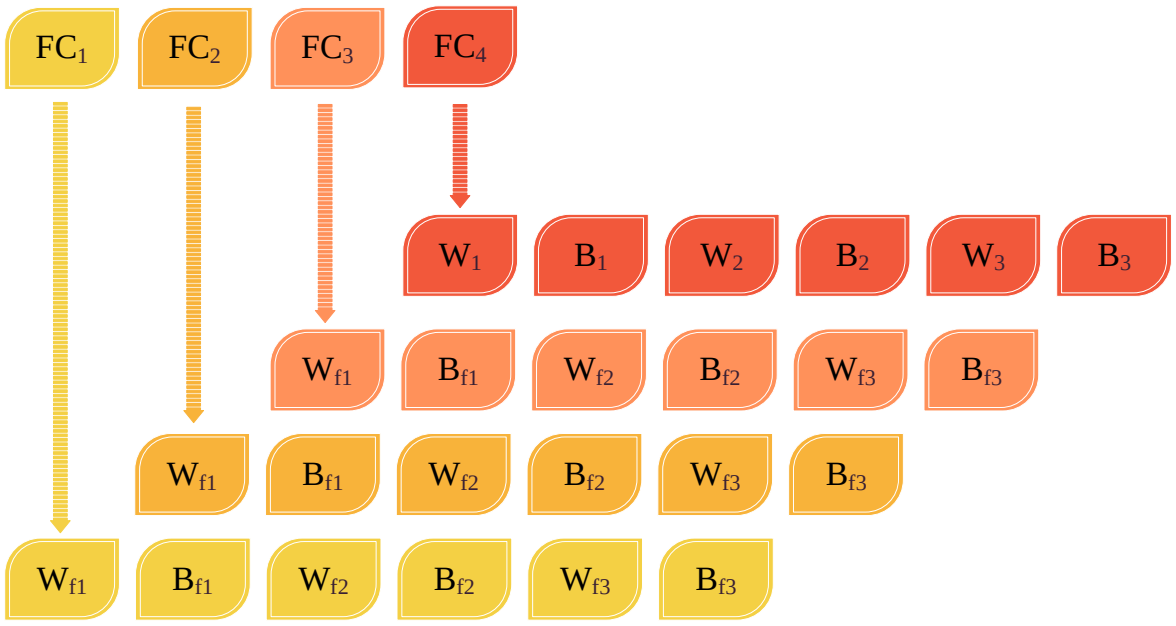

Fig. 2. Illustration of the encoding strategy used in the proposed algorithm.

B. Classification

1) Deep reinforcement learning: DRL is an advanced method in deep learning characterized by an agent's dynamic interaction with its environment to enhance a reward function. Such learning empowers the agent to formulate decisions in uncertain scenarios, proving invaluable across various domains, including robotics, healthcare, and finance. Notably adept at sequential decision-making tasks, DRL effectively adjusts to unpredictable settings, highlighting its broad range of practical uses. A notable challenge in categorization tasks is the presence of datasets with uneven distribution, often dominated by a particular category. This scenario can result in skewed learning, as traditional categorization techniques favor the more prevalent category, thereby diminishing the recognition of less dominant categories. DRL offers an advanced solution for training neural networks in such contexts, tackling imbalanced classification by incorporating a reward-based mechanism. Through strategically allocating rewards, DRL shifts the agent's focus to instances from less prevalent categories, thus enhancing their recognition. This approach ensures thorough decision-making, prioritizing identifying and classifying infrequent occurrences or minority categories [45, 46].

The agent's chief aim within Q-learning is to elect actions that amplify forthcoming incentives. These future rewards, diminished over time by a discount factor γ, are captured in Eq. (4) [11]. In this formula, R_t shows the return from time t, the sum of the discounted rewards from time t to time T. T signifies the concluding step of a given episode, and $r_{t'}$ is the reward received at time step t'.

$$R_t = \sum_{t'=t}^{T} \gamma^{t'-t} r_{t'} \tag{4}$$

Q-values, which are crucial in reinforcement learning, represent the expected outcome of a chosen policy π after executing action a in state s. This is illustrated in Eq. (5), providing a clear understanding of their importance. In this equation, $Q^{\pi}(s,a)$ is the expected return for selecting action a in state s under policy π, and E is mathematical expectation.

$$Q^{\pi}(s,a) = E[R_t|s_t = s, a_t = a, \pi] \tag{5}$$

Eq. (6) computes the quintessential action-value function, $Q^*(s,a)$, representing the apex of expected rewards for all possible strategies after observing state s and taking action a.

$$Q^*(s,a) = max_{\pi}\, E[R_t|s_t = s, a_t = a, \pi] \tag{6}$$

This function employs the Bellman equation [47], positing that the optimal forecasted outcome for any action is the aggregate of the immediate reward and the optimal expected return from subsequent actions, as elucidated in Eq. (7).

$$Q^*(s,a) = E[r + \gamma\, max_{a'} Q^*(s',a')|s_t = s, a_t = a] \tag{7}$$

The optimal action-value function progressively evolves by employing the Bellman equation, as exhibited in Eq. (8). In this equation, i means iteration.

$$Q_{i+1}(s,a) = E[r + \gamma\, max_{a'} Q_i(s',a')|s_t = s, a_t = a] \tag{8}$$

During the training phase, the network encounters state s and generates a corresponding action a. The environment then offers a reward r and transitions to the subsequent state s'. These components, forming a tuple (s,a,r,s'), are stored in memory M. Batches B of these tuples contribute to gradient descent, a practical application of mathematical concepts, with the loss function determined as per Eq. (9).

$$L_i(\theta_i) = \sum_{(s,a,r,s') \in B} (y - Q(s,a;\theta_i))^2 \tag{9}$$

In this context, θ symbolizes the model's parameters, and y is the projected target for the Q function, computed as the sum of the reward for the state-action pair and the discounted maximum future Q value, as illustrated in Eq. (10).

$$y = r + \gamma \, max_{a'} Q(s', a';\ \theta_{k-1}) \tag{10}$$

The gradient intensity at cycle i is deduced via Eq. (11).

$$\nabla_{\theta_i} L(\theta_i) = -2 \sum_{(s,a,r,s') \in B} (y - Q(s,a;\theta_i)) \nabla_{\theta_i} Q(s,a;\theta_i) \tag{11}$$

Adjustments to the model weights are made through gradient descent on the loss function, as shown in Eq. (12), where α denotes the learning rate dictating the optimization pace.

$$\theta_{i+1} = \theta_i + \alpha \nabla_{\theta_i} Q(s,a;\theta_i) \tag{12}$$

2) Proximal policy optimization: PPO [48], an on-policy reinforcement learning technique, is renowned for its efficiency and effectiveness in refining policies within discrete and continuous action spaces. PPO, devised to surmount the limitations of preceding Policy Gradient methods, tackles issues such as excessive sample requirements and instability. Its fundamental principle involves updating policies incrementally, thereby minimizing the risk of detrimental alterations that could degrade policy quality. PPO establishes a trust region around the current policy to ensure updates remain proximate to the original policy. This is achieved through a surrogate objective function encouraging modest policy alterations while enhancing rewards. The surrogate objective function of PPO varies with the action space and typically employs a clipped surrogate objective method. This approach constructs the objective by opting for the lower of two probability ratios. Based on gathered data, the first ratio assesses the probability of actions under the new policy relative to the old one. The second ratio remains confined within a predefined limit, curbing the magnitude of policy updates [49]. PPO's efficacy is partly attributable to its adept use of parallelization. Being an on-policy algorithm, it utilizes multiple parallel environments for data acquisition, expediting convergence and augmenting sample efficiency. PPO also permits the reuse of previously collected data, stabilizing the learning process and optimizing data utilization.

PPO commences with the current policy parameter θ_i, endeavoring to identify the subsequent policy parameter θ_{i+1} that optimizes the expected value of the surrogate objective function $L(s,a,\theta_i,\theta)$ for state-action pairs (s,a) sampled from the active policy $\pi(\theta_i)$. The surrogate objective function $L(s,a,\theta_i,\theta)$, delineated in Eq. (13), is the minimum of two elements: the ratio of the probability of action a in state s under the new versus old policies and a clipped variant of this ratio. In Eq. (13), ϵ (epsilon) is a hyperparameter that controls the amount of clipping in the objective function.

$$L_{PPO}^{CLIP} = E_{s\sim\rho_{\pi_{\theta_i}}, a\sim\pi_\theta}[\min(\frac{\pi_\theta(a|s)}{\pi_{\theta_i}(a|s)} A_{\pi_{\theta_i}}(s,a), clip(\frac{\pi_\theta(a|s)}{\pi_{\theta_i}(a|s)}, 1-\epsilon, 1+\epsilon) A_{\pi_{\theta_i}}(s,a))] \tag{13}$$

The clip function restricts policy alterations, averting radical departures from the initial policy:

$$clip(x,a,b) = max(a, min(b,x)) \tag{14}$$

where, x is the value to be clipped. a and b are the lower and upper bound of the clipping, respectively. In PPO-clip, the clip function constrains the product of the probability ratio and the advantage estimator $A_{\pi_{\theta_i}}(s,a)$, which evaluates the relative merit of action a in state s under policy π_{θ_i}. By limiting policy updates, the PPO-clip ensures the new policy stays within a confined spectrum around the old policy, circumventing extensive modifications that could lead to instability. This characteristic is vital for the stability and efficacy of the PPO-clip, facilitating gradual likely to bolster the policy [50].

3) Problem formulation: In this research, we apply the PPO algorithm to the detection of PPD. The methodology and interpretation of each component are outlined as follows:

- State $\boldsymbol{s_t}$ denotes the sample extracted from the dataset at time step t.
- Action $\boldsymbol{a_t}$ represents the classification executed on the sample.
- Reward $\boldsymbol{r_t}$ is assigned for each classification, formulated as:

$$r_t(s_t, a_t, y_t) = \begin{cases} +1\,, a_t = y_t \ and \ s_t \in D_O \\ -1\,, a_t \neq y_t \ and \ s_t \in D_O \\ \lambda\,, a_t = y_t \ and \ s_t \in D_N \\ -\lambda\,, a_t \neq y_t \ and \ s_t \in D_N \end{cases} \tag{15}$$

where, D_N and D_O symbolize the minority and majority classes, respectively. Correct or incorrect categorization of a sample from the dominant class results in a reward or penalty of +λ or -λ, respectively. This strategy aims to direct the network's focus on accurately categorizing the less prevalent class by assigning a greater magnitude of reward. Additionally, the inclusion of the Normal class and the adaptable reward parameter λ ($0 < \lambda < 1$) introduces complexity to the reward structure, allowing for nuanced tuning of the network's attention between common and rare classes.

IV. Experimental Results

The source of our predictive model development dataset was the "Biology, Affect, Stress, Imaging, and Cognition during Pregnancy and the Puerperium" project [51]. It was a population-based prospective cohort study in Uppsala, Sweden. The study collected data from 500 women from 2009 to 2018, following them through pregnancy and the first year postpartum. The dataset includes information on demographics, medical history, pregnancy-related factors, psychometric questionnaires, and neuroimaging data.

The study was conducted on a 64-bit Windows operating system computer. This machine featured 64 gigabytes (GB) of random-access memory (RAM), enhancing its ability to manage large datasets and perform intensive computations without any drop in performance. Additionally, it was outfitted with a 64 GB

graphics processing unit (GPU), likely produced by a leading manufacturer such as NVIDIA (NVidia corporation) or advanced micro devices (AMD), which significantly improved computational speed, especially for parallel processing tasks prevalent in deep learning and other demanding algorithms. The system also utilized an Intel Core i9 processor or its equivalent, which boasts multiple cores to deliver substantial computational power for efficiently handling complex operations. Storage was provided by a 1 terabyte (TB) solid-state drive (SSD), facilitating rapid data access and robust storage capacity, crucial for swiftly and effectively managing large data volumes. This setup ensured the seamless operation of multiple applications and services concurrently and guaranteed that our research's computational demands were met with high efficiency and reliability.

Hyperparameters utilized in the proposed model are detailed in Table I. For evaluation, our model was rigorously benchmarked against six well-known models: Naïve Bayes [52], K-nearest Neighbors (KNN) [53], Support vector machine (SVM) [54], Random forests [55], Logistic Regression [56], and Decision tree [57]. Table II outlines the parameters applied to these models. Additionally, two derivative versions of our proposed model were analyzed. The first, titled Proposed+random weights, used random initial weights to examine the impact of weight initialization on performance. The second, Proposed+random weights+PPO, incorporated PPO to enhance classification accuracy and overall robustness potentially. We employed standard performance metrics such as Accuracy, F-measure, and G-means, which are particularly important for evaluating imbalanced datasets. As illustrated in Fig. 3, while all models performed comparably, our proposed model and its variants demonstrated superior capability. Specifically, the proposed model was particularly effective, achieving the highest scores across all metrics. It showed an 18% improvement in F-measure and a 54% increase in G-means compared to the baseline models, illustrating significant advancements over traditional methods like Decision Tree, previously considered optimal. This enhancement indicates our model's superior handling of skewed data distributions and its predictive accuracy. Further, the comparative analysis between our proposed model and its derivatives—Proposed+random weights and Proposed+random weights+PPO—highlighted the critical impact of sophisticated weight initialization and PPO integration. The Proposed model significantly outperformed these variants, showcasing a 53% reduction in error rates, affirming its efficacy and suitability for the chosen problem domain. This clear empirical evidence supports the proposed model as the best fit for addressing the complexities inherent in our targeted application area.

To ascertain the robustness of our developed model and mitigate overfitting while ensuring peak performance across training and test datasets, we have thoroughly depicted its efficiency in Fig. 4. This illustration offers a detailed analysis of the Root Mean Square Error (RMSE) loss curves for both datasets throughout the training period. The loss computation occurs after each forward operation during training, followed by backward propagation to adjust weights at the end of every epoch. In parallel, validation loss is evaluated after each epoch through a forward operation on the validation dataset without modifying the model's weights. Training and validation losses should decrease simultaneously and stabilize at a minimal level, signifying the model's adeptness in learning and generalizing. In contrast, a divergence, characterized by decreasing training loss but increasing validation loss, indicates overfitting, implying that the model is excessively fine-tuned to the nuances of the training data, which could detrimentally affect its predictive accuracy on new data.

TABLE I. SETTINGS OF HYPERPARAMETERS FOR THE PROPOSED MODEL

Configuration parameter	Setting
Training cycles	128
Size of batch	32
Rate of learning	0.01
Rate of dropout	0.40
Factor of discount	0.40

TABLE II. CONFIGURATION OF HYPERPARAMETERS FOR VARIOUS MACHINE LEARNING APPROACHES

Method	Parameter	Specification
Naïve Bayes	α (Smoothing factor for lidstone)	0.6
KNN	*k* (Count of nearest neighbors)	7
	Metric for distance	Manhattan (p=2), Euclidean (p=3)
SVM	Type of kernel	Polynomial
	γ (Coefficient for kernel)	0.7
Random Forests	Trees in forest	25
	Maximum tree depth	15
Logistic Regression	C (Strength of regularization)	0.4
	Algorithm for optimization	liblinear
Decision Tree	Splitting criterion	entropy
	Maximum depth	12

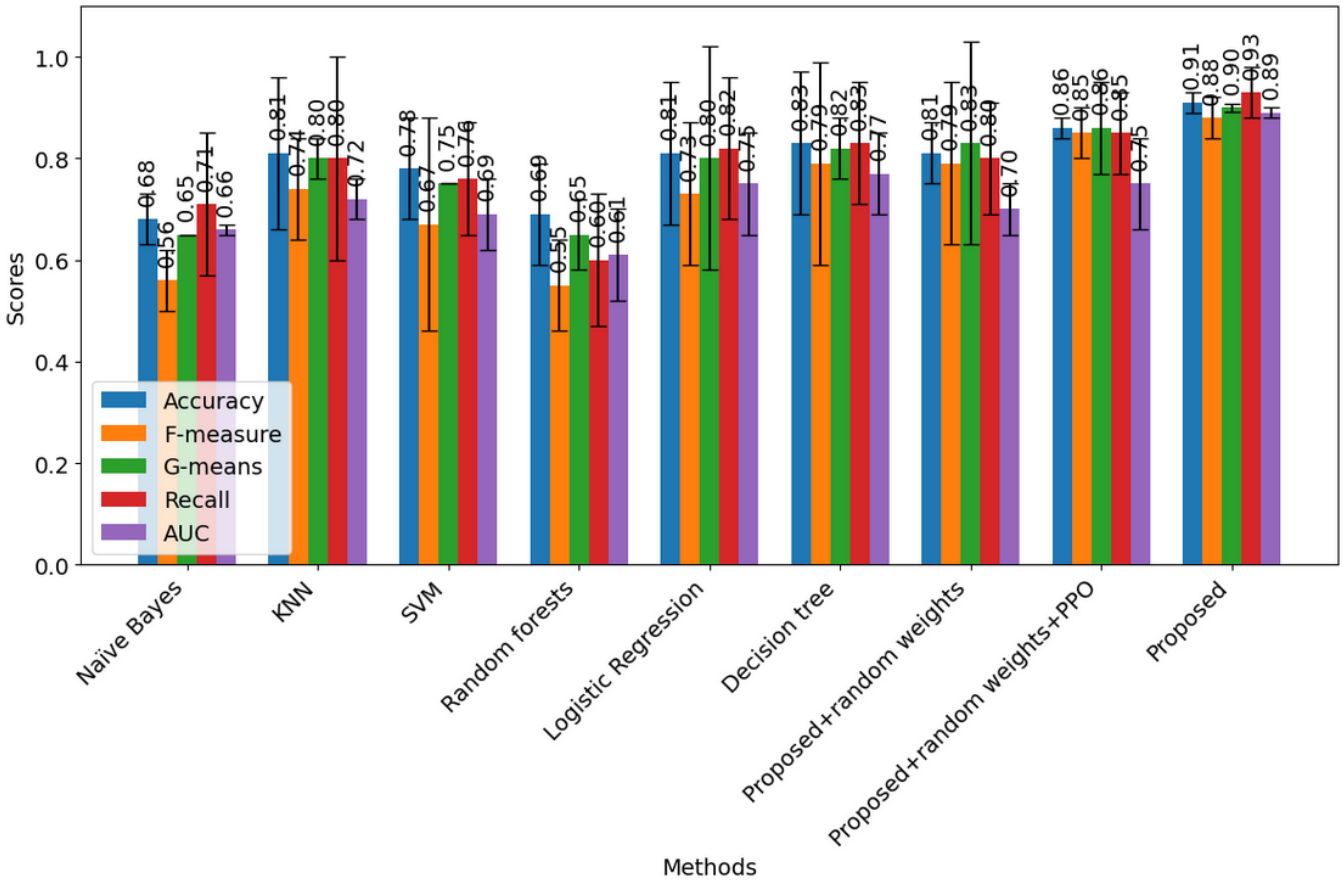

Fig. 3. Performance results of different classification techniques.

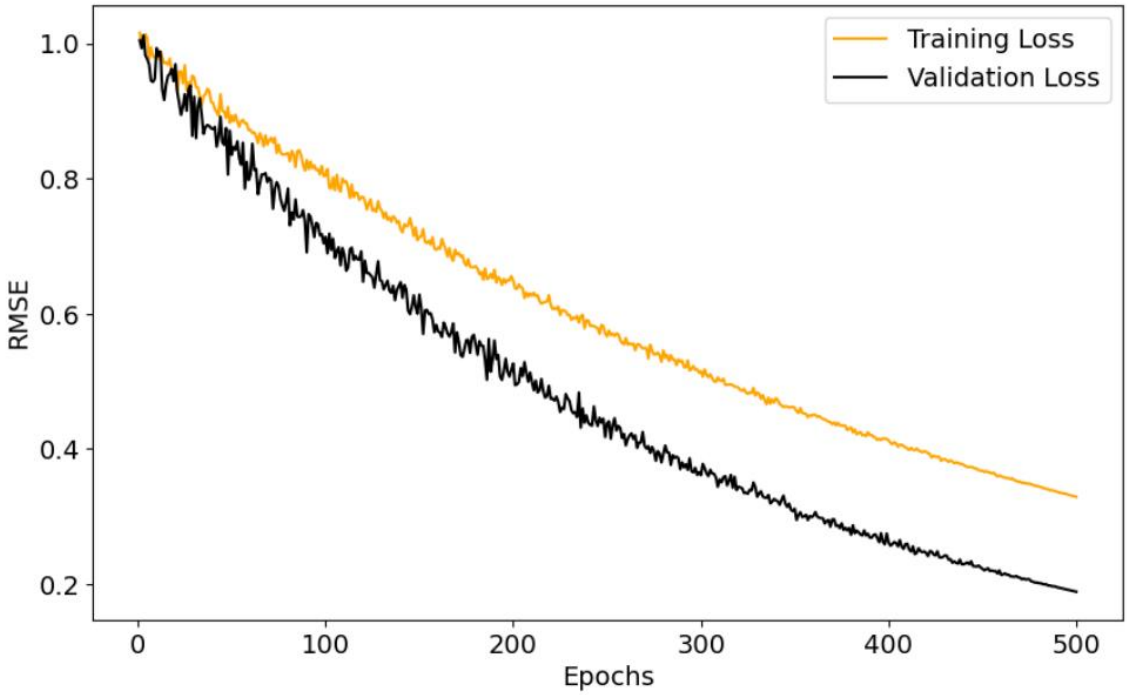

Fig. 4. Training and validation dataset loss trends in the developed model.

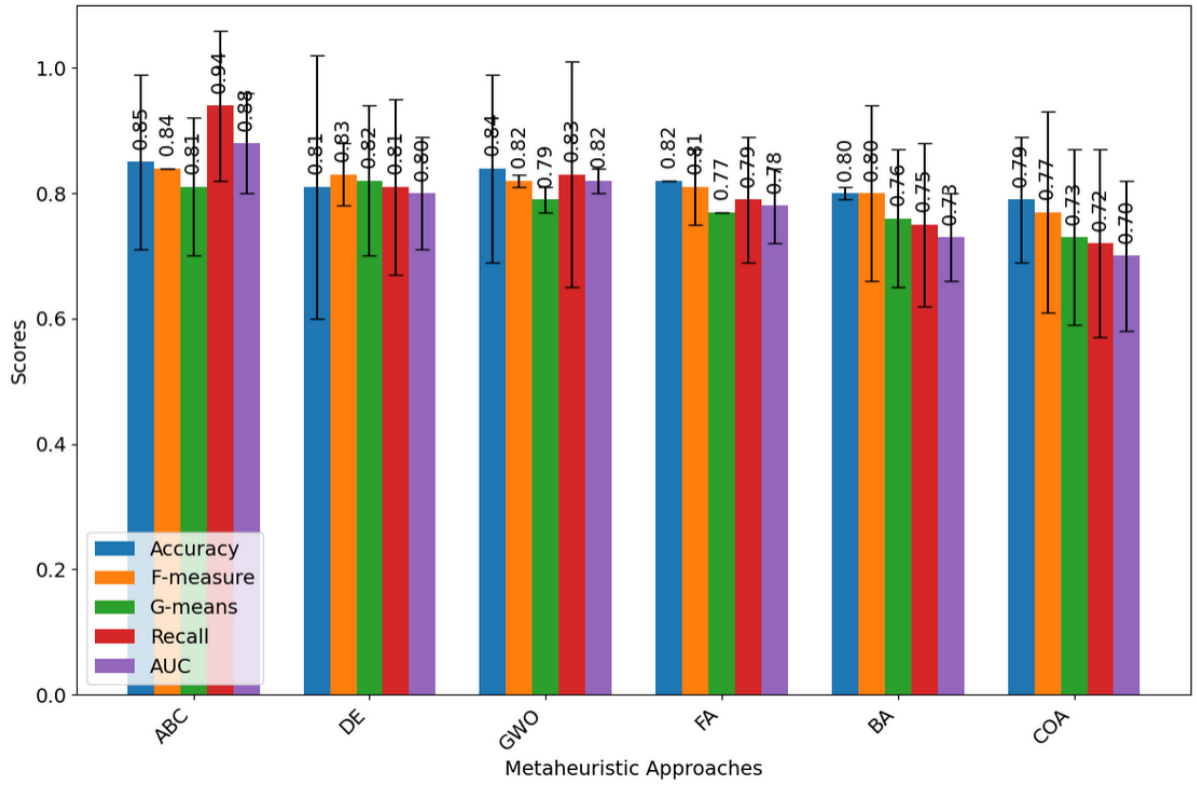

Fig. 5. Comparative performance of various metaheuristic approaches.

A. Analyzing the ML-ABC Algorithm

A comprehensive study juxtaposed the ML-ABC technique with other metaheuristic techniques. For a balanced comparison, diverse metaheuristics were utilized to obtain initial weights while maintaining consistency in other model components. The assessment included six techniques: ABC [58], Grey Wolf Optimizer (GWO) [59], Firefly Algorithm (FA) [60], Bat Algorithm (BA) [61], and Cuckoo Optimization Algorithm (COA) [62]. Each technique was set with a population size of 200 and function evaluations capped at 4,000. The standard configurations are outlined in Table III. The outcomes of the extensive experiment are methodically displayed in Fig. 5, yielding crucial insights into each algorithm's efficacy. Remarkably, the results underscored the superior performance of the ML-ABC algorithm, which exhibited a noteworthy 30% reduction in error relative to ABC. Moreover, the ML-ABC technique surpassed other renowned algorithms, such as BA and GWO, consolidating its status as a preeminent choice among the evaluated metaheuristic optimization techniques.

Fig. 6 graphically delineates the evolution of the objective function throughout various iterations employing the ML-ABC algorithm. The x-axis represents the number of iterations or generations, and the y-axis shows the values of the objective function. This visual portrayal provides an explicit understanding of the algorithm's operational mechanisms. An in-depth examination of Fig. 6 reveals distinct trends: initial iterations experience significant variability in the objective function values, reflecting the exploration stage of the ML-ABC algorithm. During this phase, the algorithm extensively scans the solution space to evade premature convergence to local optima and to pinpoint promising areas. As the iterations advance, signs of convergence emerge. The fluctuations in the objective function values lessen, indicating a refinement in the algorithm's strategy as it zeroes in on and perfects the most viable solutions. It is crucial to monitor for instances of minimal or no changes in the objective function values, as this might indicate the algorithm reaching a standstill at the local optimum, necessitating parameter adjustments or introducing additional methods to boost exploration capabilities.

TABLE III. CONFIGURATION DETAILS OF HYPERPARAMETERS FOR METAHEURISTIC ALGORITHMS

Technique	Configuration	Adjustment
DE	Factor of Scaling	0.7
	Probability of crossover	0.82
ABC	Boundary for scouts	n_e × dimensions
	Employed bees	50% of of total bees
	Onlooker bees	50% of total bees
	Scout bees	1
FA	Light absorption coefficient	.0.8
	Attractiveness at Base	0.4
	Scaling factor	0.35
BA	Loudness update rate	0.6
	Pulse emission rate	0.7
	Pulse frequency initial value	0.003
COA	Lévy flight parameter	1.5

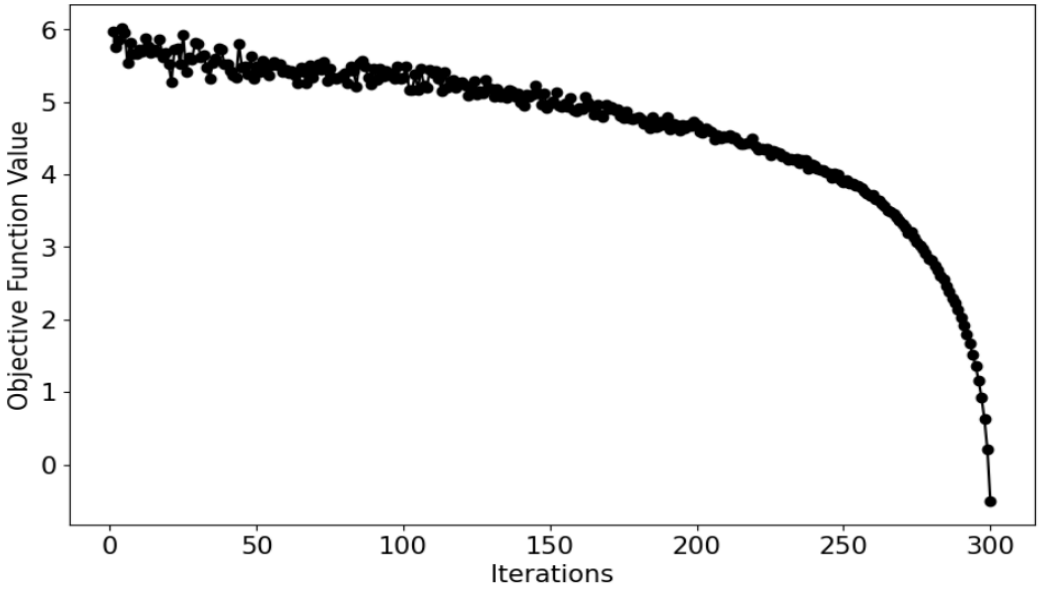

Fig. 6. Evolution of the objective function in various iterations with the ML-ABC algorithm.

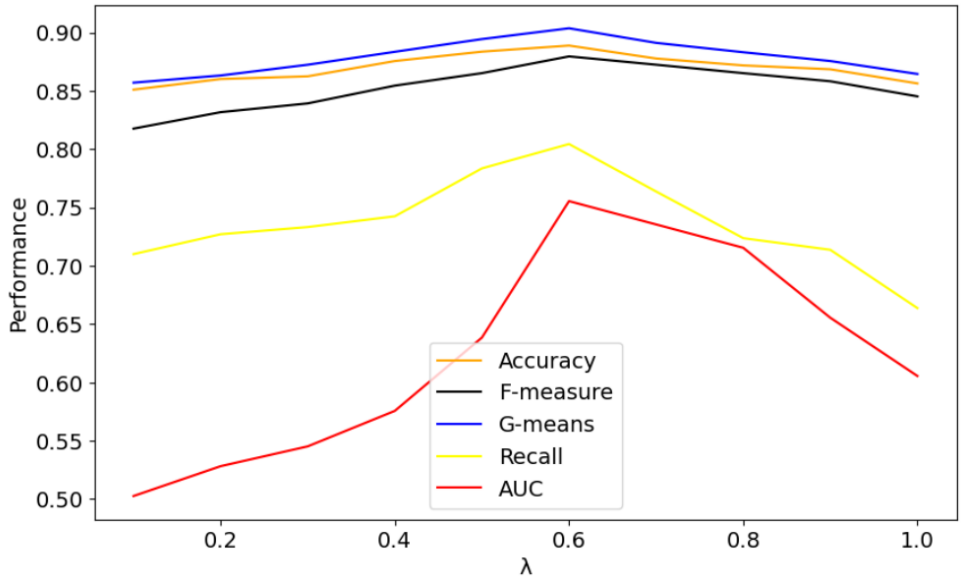

Fig. 7. Performance metrics variation of the model corresponding to various λ values in the reward function.

B. Impact of Reward Operation

Incentives allotted to predominant and less represented groups for correct and mistaken identifications are +1 and ±λ, respectively. The magnitude of λ hinges on the proportion of larger to smaller groups, with expectations that the ideal λ magnitude dwindles as this proportion escalates. To probe λ's effect, we assessed the method's proficiency across varied λ values spanning zero to one. The assessments are illustrated in Fig. 7. At λ equating to 0, the dominance of the larger group becomes trivial, whereas at λ = 1, both groups impose equivalent impacts. The outcomes insinuate that the method reaches its pinnacle performance at λ set to 0.6 for all scrutinized measures, signifying that the most fitting λ magnitude resides within the 0 to 1 spectrum. Acknowledging that diminishing the larger group's influence by reducing λ might detrimentally impact the method's comprehensive proficiency is pivotal. The insights emphasize that the selection of λ profoundly affects the method's functionality, with the prime λ contingent on the comparative sizes of larger to smaller samples, accentuating the necessity of meticulous choice for attaining excellent outcomes.

C. Impact of MLP

The research further underscores that augmenting the layers in an MLP potentially heightens overfitting risks. Conversely, a limited number of layers might restrict the method's capacity to discern salient features. Here, we experimented with varying the number of MLP layers (1, 2, 4, 8, 10, 12) to determine their effect on model performance. The outcomes, showcased in Fig. 8, reveal a diminishing trend in model efficacy when layer counts range from 8 to 12, followed by an ascending trend for

layer counts from 1 to 8. This pattern indicates that an optimal MLP with four layers balances complexity and performance.

D. Impact of the Loss Function

Different strategies exist to address data imbalances in machine learning, notably in choosing a loss function. Selecting a loss function is pivotal in helping effective learning from minority classes. We scrutinized functions such as Weighted Cross-Entropy (WCE) [63], Binary Cross-Entropy [64], Dice Loss (DL) [65], Tversky Loss (TL) [66], and Combo Loss (CL) [67]. WCE and BCE treat positive and negative instances equally, which may be better for imbalanced datasets. DL and TL are more suited for such datasets, enhancing minority class performance. CL, advantageous in unbalanced data scenarios, adjusts loss function weights to prioritize complex samples over simpler ones. Our experiments in Fig. 9 demonstrate that CL outperforms TL, reducing error rates by 21% in accuracy and 32% in F-measure. However, it underperforms FL by 18%, a function tailored for binary classification tasks. These outcomes necessitate considering the specific dataset and problem context. While CL surpasses TL, it is less effective than FL.

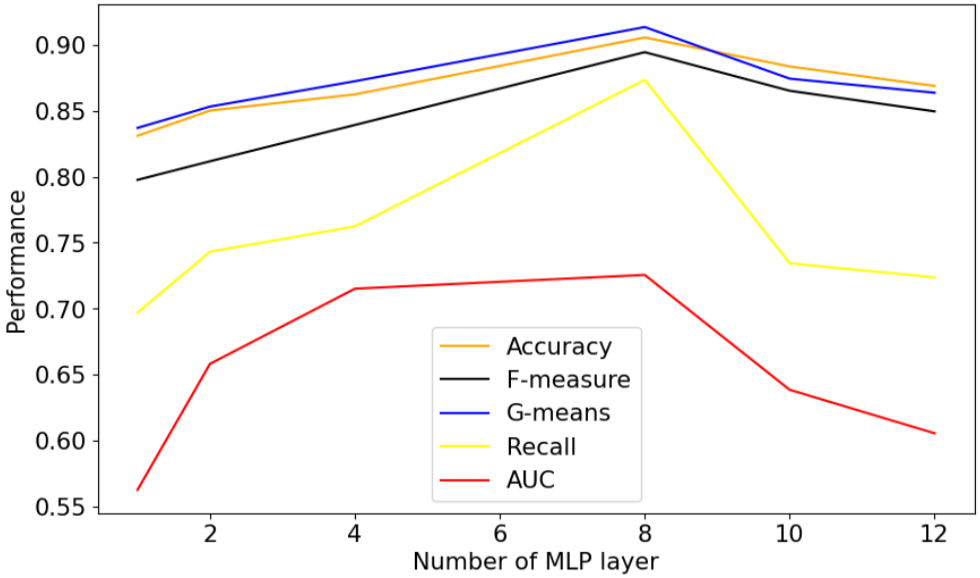

Fig. 8. Graphical representation of performance metrics against different numbers of MLP layers in the model.

E. Discussion

This study unveils an innovative model combining the ML-ABC with PPO to tackle PPD, addressing dataset imbalance with a PPO-driven approach. Anchored in an ANN, it views categorization through a policy-based lens, enhancing stability with PPO's gradual policy shifts. The model, empowered by ML-ABC, refines initial weights through mutual learning, elevating understanding of intricate patterns for improved classification accuracy.

PPO is chosen for its effectiveness in handling policy-based decision-making processes, which is crucial for managing imbalanced datasets like those found in PPD detection. PPO operates by optimizing a particular objective function that minimizes the deviation from an old policy while ensuring that the new policy improves upon it, thus maintaining a balance between exploration and exploitation [68]. This characteristic is particularly beneficial in healthcare applications where each decision or classification can have significant repercussions. By implementing PPO, the model ensures that updates to the policy are manageable, which could lead to unstable training cycles. Instead, PPO facilitates smoother updates and enhances the stability of the learning process. This leads to more reliable and consistent recognition of patterns in data, which is vital when the data is skewed or when specific categories are underrepresented, as often seen in clinical datasets [69].

The ABC algorithm is selected for its robust search capabilities in complex optimization problems, essential for setting up the initial configurations of neural network weights. ABC algorithm mimics the food-foraging behavior of honey bees, making it excellent for exploring diverse solution spaces efficiently [70]. In detecting PPD, where the dataset characteristics include high dimensionality and potential multimodality, ABC helps navigate potential local optima to find the best global solutions. This capability is crucial for the initial phase of model training, where starting points (i.e., weights) significantly influence the learning trajectory and, ultimately, the model's performance. Using ABC, the model benefits from an optimized exploration of the weight space, leading to a more effective learning process and better generalization capabilities on unseen data. This setup is particularly effective in healthcare settings, where precision in initial model configurations can substantially improve diagnostic accuracy.

ML-ABC is employed to leverage the collective intelligence of multiple agents (i.e., artificial bees) that share information and learn collaboratively, enhancing the ABC algorithm's convergence speed and solution quality. In the PPD detection model, ML-ABC is instrumental in fine-tuning the weights and parameters of the neural network, ensuring that the model adapts more effectively to the complexities of imbalanced clinical data [44]. By integrating mutual learning principles, ML-ABC allows individual solutions to benefit from the discoveries and successes of others in the swarm, thus promoting a more diversified search of the solution space and preventing premature convergence on suboptimal solutions. This approach is especially beneficial in medical applications where the dataset may contain subtle patterns that are difficult to recognize but critical for accurate diagnosis [20]. The enhanced learning mechanism of ML-ABC ensures that the model is not only effective in recognizing common patterns but also adept at identifying less frequent, yet clinically significant, indicators of PPD.

The theoretical implications of our research are significant, offering substantial contributions to both the fields of artificial intelligence and healthcare. The integration of PPO and ML-ABC into a cohesive model for PPD detection represents a pioneering approach to applying hybrid meta-heuristic algorithms to medical diagnostics. This model demonstrates the potential of combining robust optimization and policy-based learning to address the inherent challenges of imbalanced datasets, which are prevalent in many medical conditions beyond PPD. Theoretically, this approach highlights the adaptability of meta-heuristic methods to complex, real-world problems where traditional algorithms might fail to deliver optimal results due to constraints in exploration capabilities and sensitivity to initial conditions. Additionally, a policy optimization method that treats the training process as a series of decision-making steps reflects an innovative shift towards more dynamic, context-aware systems in healthcare applications. This model advances the understanding of algorithmic design and sets a precedent for future research where machine learning can be intricately tailored to meet specific clinical needs, enhancing diagnostic precision and improving patient outcomes.

The reliance of the proposed model on the ML-ABC and PPO techniques presents a nuanced challenge in accurately diagnosing PPD. These advanced computational methods, though groundbreaking, may fall short of embracing the intricate and evolving landscape of PPD, which is deeply rooted in a confluence of biological, psychological, and sociocultural determinants [71]. The inherent complexity of PPD, characterized by its varying symptoms and severity, demands a diagnostic approach that can adapt to the broad spectrum of influences affecting maternal mental health. Biological factors, such as hormonal fluctuations post-delivery, genetic predispositions, and changes in brain chemistry, play a pivotal role in the onset of PPD [72]. The model's current algorithmic structure may not have the capacity to fully interpret the subtle biological signals that indicate a predisposition to or the presence of PPD. Similarly, psychological components, including a history of mental health issues, the psychological response to motherhood, and the presence of stressors like sleep deprivation, are critical in assessing the risk and presence of PPD. The model may not be designed to parse these nuanced psychological variables, which can vary significantly from one individual to another [73]. Furthermore, the social environment, encompassing support systems, cultural expectations of motherhood, and socioeconomic status, substantially influences the mental health of new mothers. The model might lack the ability to integrate these social determinants, which can mitigate or exacerbate the risk and severity of PPD. For example, the absence of a supportive partner or family, the societal stigma surrounding mental health, or the pressures of motherhood can profoundly impact the development and diagnosis of PPD [74]. To address these limitations, future iterations of the model could incorporate a more holistic approach that includes multidimensional data inputs reflecting the biological,

psychological, and social factors relevant to PPD. Integrating qualitative data through natural language processing or enhancing the model's learning algorithms to recognize complex patterns associated with these factors might improve its diagnostic accuracy. Collaboration with interdisciplinary experts in psychiatry, obstetrics, and social sciences could provide deeper insights into the multifaceted nature of PPD, guiding the refinement of the model to ensure it captures the full spectrum of influences on maternal mental health [75].

The dataset's scope and representativeness considerably challenge the model's applicability and reliability [76]. Given that the model's evaluation was anchored to data derived from a Swedish study, its predictions and effectiveness could be inherently biased toward the Swedish population's demographic, cultural, and healthcare nuances. This limitation raises concerns about the model's performance across diverse global populations, where factors such as genetic diversity, cultural norms surrounding motherhood, and access to healthcare can significantly influence the incidence and manifestation of PPD [77]. Cultural diversity, in particular, plays a critical role in the perception, reporting, and management of PPD symptoms [78]. In some cultures, mental health issues may be stigmatized or underreported due to societal norms, potentially leading to underrepresentation in the dataset and, by extension, the model's training process. This could skew the model's predictive accuracy, making it less effective in identifying PPD in populations with different cultural backgrounds from the dataset on which it was trained. Furthermore, healthcare practices and accessibility vary widely across regions. In countries with limited access to mental health services, PPD may go undiagnosed or be treated differently than in countries with more robust healthcare systems [79]. This variance in healthcare infrastructure and practices can influence the type and amount of data available for training models like the one proposed, potentially limiting its effectiveness in regions with disparate healthcare systems. To enhance the model's generalizability and accuracy across varied populations, it may be necessary to incorporate data from a more diverse range of sources. This could involve aggregating datasets from multiple countries, cultures, and healthcare systems to create a more comprehensive and representative training dataset. Additionally, employing techniques such as transfer learning could enable the model to adapt to new populations by fine-tuning pre-trained models with localized data. Such approaches would bolster certitude that the method stays perceptive and pliant to the multifarious manifestations of PPD, ultimately improving its utility and impact in global maternal health care [2].

The practical deployment of the proposed model within clinical environments entails navigating the intricacies of healthcare operations, technology integration, and professional training. The transition from theoretical machine learning models to tools that healthcare professionals can rely on daily involves overcoming barriers related to system compatibility, data privacy, and user-friendliness [5]. The advanced nature of the model, while a strength in analytical capabilities, may present a steep learning curve for clinicians who need to be versed in data science or machine learning. This gap between technological innovation and practical application could slow the adoption rate and reduce the model's effectiveness in real-world settings. Moreover, integrating such models into existing healthcare information technology (IT) systems poses significant logistical challenges. Healthcare systems often operate on diverse platforms with varying degrees of digital sophistication. Ensuring that the model is compatible with these systems while maintaining the integrity and confidentiality of sensitive patient data is paramount [80]. This requires a robust framework for data handling, adherence to healthcare regulations like Health Insurance Portability and Accountability Act (HIPAA) in the United States and United States and the General Data Protection Regulation (GDPR) in Europe, and a secure interface for data input and output [81]. Furthermore, the model's adoption depends healthcare providers' trust and confidence in its predictions. To build this trust, it is essential to demonstrate the model's accuracy, reliability, and clinical relevance through rigorous validation studies. Additionally, transparency in how the model processes data and arrives at its predictions can help demystify its operations for healthcare professionals, making them more likely to embrace its use. To address these challenges, a multifaceted approach is needed. Simplifying the model's interface to make it more intuitive for clinical use without compromising its analytical depth can enhance user-friendliness. Developing comprehensive guidelines and protocols for the model's clinical application can provide healthcare professionals with a clear framework. Furthermore, implementing targeted training programs that educate healthcare providers about the model's functionality, interpretation of its outputs, and integration into patient care can bridge the gap between technological innovation and clinical practice. These initiatives can collectively ensure that the model serves as a cutting-edge PPD detection tool and becomes an integral and user-friendly component of maternal healthcare services [82].

V. Conclusion

This study introduced a novel model integrating the ML-ABC approach with PPO to tackle PPD detection, achieving notable accuracy and F-measure scores of 0.91 and 0.88, respectively. The model's use of PPO addressed the imbalanced dataset effectively, stabilizing the learning process by mitigating sudden policy shifts. It employed an ANN as its core, using a continuous decision-making framework to enhance the identification of underrepresented classes. Implementing ML-ABC in pre-training significantly refined the initial weight configurations, boosting the model's ability to discern complex patterns from the outset.

Looking forward, there is significant potential to broaden the model's utility across different populations by testing its effectiveness on diverse datasets from varied geographic and cultural contexts. This would provide insights into its adaptability and generalizability. Further, incorporating additional variables like genetic, hormonal, and environmental factors could substantially improve its predictive capabilities. Practical applications in clinical settings, such as hospitals and maternal health clinics, are also envisioned. Deploying the model in real-world conditions will allow for a dynamic assessment of its performance, offering a valuable tool for integrating advanced analytics into routine healthcare practice, thus enhancing early detection and intervention strategies for PPD.

***Abstract*—Internet of Things (IoT) strongly involves intelligent objects sharing information to achieve tasks in the environment with an excellence of living standards. In resource-constrained it is extremely difficult chore to impart security against intrusion. It is unprotected from Distributed Denial of Service (DDoS), Gray hole, sinkhole, wormhole attacks, spoofing, and Sybil attacks. Recent years, deep neural network (DNN) methodologies are widely used to detect malicious attacks. We develop a Hybrid deep learning based GAN Network to detect malicious attacks in IoT networks. Due to composite and time-varying vigorous environment of IOT networks, the model trainig samples are insufficient since intrusion samples combined with normal samples will lead to high false detection rate. We created a dynamic distributed IDS to detect malicious behaviors without centralized controllers. Preprocessing sets threshold values to identify malicious behaviors. Experimental results show HDGAN outperforms existing algorithms with higher accuracy 98%, precision 98% and 95% lower False Positive Rate (FPR).**

Keywords*—Distributed Denial of Service (DDoS); Internet of Things (IoT); Deep Neural Network (DNN); intrusion detection; Generative Adversarial Network (GAN)

I. INTRODUCTION

The Internet of Things (IoT) is a system of interconnected computing objects which are in high demand and the capability to convey data above a network without the presence of humans. IoT provides system connectivity and computing capability with devices and sensors to consume data with nominal individual involvement. The IoT makes its impact in various applications in day to day life such as healthcare, military, environment [22] etc. IoT is controlled in all perspectives such as in processing speed, storage, power and size. In an IoT environment the internet based smart system senses and collects the data through the gateway and then it is sent for investigation. As the demand for IoT service increases there have always been challenges in the security issues.

The security measures are overcome by providing authentication, access controls and confidentiality but still face security problems through attacks and intruders. Distributed Denial Service of Service (DDoS) attacks provide a serious pitfall to the IoT environment which has its types Internet Control Protocol (ICMP), SYN flood, UPD flood and DNS attack. Other types of attacks are the Sybil attack, WormHole attack and the sinkhole attacks. Fig. 1 shows the intrusion detection process using the Deep Learning Techniques. Data generated within the IoT environment undergoes collection and scrutiny by Deep Learning algorithms [23] [24] to detect potential attacks. Alert will be given when there is an attack and the malicious node or the hacker will be blocked. In this paper Hybrid Modified principle Component analysis and Firefly-based optimization approach is specified to find out the invasion attacks. The Generative prototype for Intervention Detection System will detect whether the collected is real or fake. The HDGAN (Hybrid Deep Learning-based Generative Adversarial Network) was developed specifically to detect malicious activities within IoT networks, emphasizing IoT security.

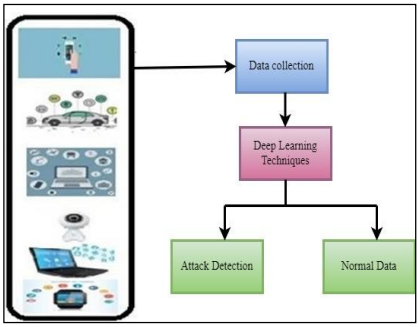

Fig. 1. The deep learning-based attack detection in IoT.

II. RELATED WORK

Intrusions must be detected before a specified time elapses, which can be challenging within typical time constraints. GAN leverages the LSTM-DNN algorithm for effective intrusion prediction before the designated time threshold [1]. Deep learning models with training and evaluation of models done by Feed-forward neural network, auto encoder, deep belief mesh work and extended small label term memory network by selecting and classifying two datasets (KDD 99, NSL-KDD). Machine learning algorithms help to learn the patterns of intrusion in datasets. The supervised deep feed-forward neural networks (ANN) check the standards such as precision, F1score, false negatives, training and inference together it shows better performance [2]. Network intrusion detection is crucial for addressing network imbalances. TMG-GAN is employed to prevent various types of attacks, followed by addressing classification loss, and ultimately focusing on improving sample quality. Through these techniques, effective intrusion prediction is achieved [3]. To mitigate the DDoS attacks an innovative

procedure called Learning-Driven Detection Mitigation (LEDEM) is proposed which make use of semi supervised training to find and prevent DDoS. Two different strategies is followed in LEDEM fixed IoT and Mobile IoT and the phases are Data Capture, DDoS Detection and DDoS Mitigation . The attack detection got improved and throughput got increased based on LEDEM [4]. To enhance system performance and address data imbalance, integrate Artificial Intelligence (AI) with Network Intrusion Detection Systems (NIDS) using datasets such as NSL-KDD and UNSW-NB15 for prediction. Additionally, prioritize the utilization of real-world datasets to further improve model effectiveness. This demonstrates that the proposed model effectively addresses the issue of load imbalance [5]. Extreme Learning Machines proves efficient learning machines for pattern classification. ELMs based on Semi-Supervised ELM (SS-ELM) and Un Supervised ELM (US-ELM) are proposed that demonstrate better computing capability, proceed to multiclass classification and can grasp unknown information during evaluation time span. Based on the results the Unsupervised ELM shows better performance [6].

Anomaly detection is a significant challenge in data security, and Time Series Data Augmentation (TSDA) plays a crucial role in addressing this issue. DCT-GAN (Dilated Convolutional Transformer) integrates coarse and fine-grained time series data to enhance generalization using a weight-based technique [7]. Deep anomaly detection is critical for accurate data labeling and handling low-rate anomalies. To address this, FlowGAN-NIDS combines discriminator and generator components, diverging from traditional encoder-decoder methods. This approach enhances anomaly detection performance, particularly in scenarios with low anomaly occurrence rates, validated through various experiments to confirm prediction accuracy [8]. The violation prediction framework, integrated with Routing Protocol, specifically targets the identification of wormhole attacks. These attacks pose significant threats to routing nodes and are identified through the utilization of Contiki OS and Cooja Simulator, achieving a detection success rate of up to 90%.[9] Machine learning and cybersecurity are crucial components of GAN networks. Previously, significant effort was needed to train datasets for effective intrusion detection [10]. The Bayesian GAN-based technique can detect cyber attacks while addressing data imbalance and ensuring security during data transfer. It accurately predicts intrusions even in the presence of noise [11]. Utilizing the NSL-KDD dataset with twenty-three categories, it enhances recognition results for binary classification, particularly improving accuracy in handling unbalanced network traffic. Ultimately, it focuses only on five specific categories for conducting our experiments [12].

A novel approach, the Modified Density Peak Clustering Algorithm (MDPCA), along with Deep Belief Networks (DBNs), is suggested for fuzzy aggregation. It is particularly useful when dealing with a complex training set that requires segmentation. The training set is divided into subsets and the training is done by Sub-DBNs classifiers. The fuzzy membership weight is calculated and they are aggregated to provide the output. It achieves better accuracy and good detection rate [13]. In the world of IoT, security is a top priority, especially given the susceptibility to DoS attacks due to memory usage. To combat these issues, a hybrid DoS Intrusion Detection System (IDS) has been devised to detect both known and unknown attacks. This system has been tested across different datasets, consistently outperforming existing methods in terms of detection rates [14]. A Feed-Forward Neural Networks model is devised for identifying DDoS attacks and information theft incidents occurring within the IoT environment [15]. The MQTT protocol is widely utilized in IoT due to its simplicity and lightweight nature. However, IoT devices are susceptible to intrusion by hackers. To enhance security in data transmission using protocols, GAN-AE (Generative Adversarial Network - Autoencoder) is effectively employed [16]. The NIDS aims to enhance accuracy in intrusion detection by leveraging parallel computing, resulting in improved networking traffic analysis and effectiveness [17]. The GAN utilizes network packet capture techniques like Wireshark to collect data sets for identifying different types of attacks, resulting in improved performance compared to existing methods [18]. The main aim is to identify the attacks at the earlier stage and so a machine is built in the IoT environment, The steps are creating an IoT environment using a test bed, Generating attacks by building an adversarial systems a, capturing the network data flow to identify normal and abnormal event behaviors and finally knowledge engineering instructions are used to discover the offense in the network [19]. In the realm of IoT, the Sybil attack infiltrates the network by posing as a genuine node. Through this tactic, the Sybil node disseminates numerous identities of devices, masquerading as authorized entities by mimicking environmental observations. The analysis of the Sybil attack and its worst-case scenarios are performed based on the compromise, deployment and launching phase to overcome from this attack in future [20].

III. Security Attacks in IoT Networks

A. Black Hole Attack

A black hole attack discards a packet in a router by compromising itself as an authorized user. It is considered one of the Denial of Service attacks and it is difficult to detect and prevent the packet loss once occurred.

B. Sinkhole Attack

The Sinkhole attack executes its network infiltration by presenting itself as the shortest route to the intended destination. The nodes get compromised by the path and they move towards the sink holes allowing the sink holes to access their information. The hacker can then modify the data. Sinkholes can be started either within the network or outside the network.

C. Sybil Attack

In the Sybil attack the hacker destabilizes the trust system of a network service by flooding the network with a large number of anonymous state identities providing excessively high traffic demand.

D. Wormhole Attack

The wormhole attack, alternatively known as a network layer attack, involves strategically positioning hackers within

the network.The malicious nodes are dominant to normal nodes and act as a node providing better communication in the network. The data packets, believing the wormhole attack as a normal node, proceeds and discard or modify the data packet.

E. DDos Attack

A DDoS attack is the one in which the executor approaches the network or server making it not available to authorized users by interrupting the services from the internet. The server flooded with more unwanted requests in a challenge to disrupt other authorized services. Various types of DDoS attacks are delineated within the IoT context, encompassing ICMP flood, SYN flood, and UDP flood, targeting network data.

IV. Deep Learning Techniques

Deep Learning is inspired by artificial neural networks and confined to machine learning with ANN algorithms. DL methods deal with large amounts of datasets. DL can manually extract the data in complex vector space. DL methods provide a deep connection in IoT environment.

The Deep Learning technique provides a sophisticated computational framework comprising multiple layers of processing, enabling the acquisition of diverse data representations.

1) Supervised deep learning: It is a machine learning function that plots an input to a preferred output. The data are referred to as training objects providing a supervisory signal based output. Different approaches of Supervised Learning are Convolutional Neural Networks CNNs and Recurrent Neural Networks (RNNs) where the former denotes gaining knowledge of data with reduced parameters and the later refers to consecutive data.

2) Unsupervised deep learning: It is a method of algorithm that uses the design from unlabelled data. Different type of approaches of Unsupervised DL are Deep AutoEncoders(AEs), Deep Belief Networks(DBN), Restricted Boltzmann Machines(RBMs) in which the DBN denotes the replication of its input to its output , RBMs denote two layers visible and hidden that denotes known input and latent variables. Finally Deep Belief Networks (DBNs) deal with greedy layer training of data to perform strong performance in the environment.

3) The Semi-Supervised or Hybrid Deep Learning combines both Supervised and Unsupervised Learning using GAN (Generative Adversarial Network).

V. Proposed Method

Hybrid Deep Learning Based Intrusion Detection System (HMFFGAN) Using Generative Adversarial Network.

GAN is the latest structure for approximate abundant model replica via an adversarial setup, we simultaneously train two models: a generative model G, which captures data distribution, and a discriminative model D, which evaluates the likelihood that a sample originates from the training data rather than G [16].

GANs are frequently utilized to produce synthetic images resembling real ones. Our emphasis is on this principle, and we structured our IDS accordingly. The GIDS comprises two discriminative models: the first discriminator and the second discriminator, which are trained using the following procedure. The primary method utilized is Generative Adversarial Network (GANs), which involves the sequential training of two models: generative and discriminative, as depicted in Fig. 2.

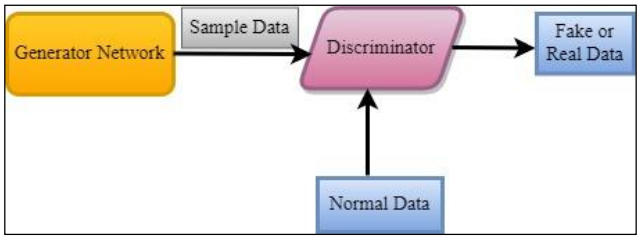

Fig. 2. Basic working of generative model.

The generative model Fig. 3 creates data samples from the training data set and generator network. The discriminator model assesses the authenticity of sample data through binary classification using sigmoid functions, predicting whether the data is genuine or counterfeit. This functionality aids in detecting anomalies within the environment, including potential attacks.

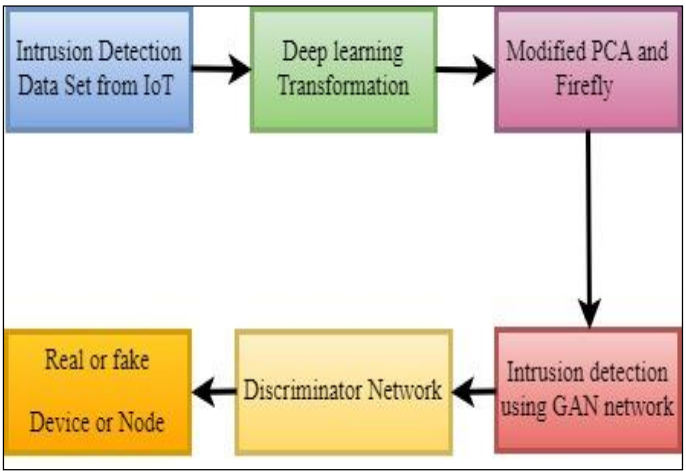

Fig. 3. The hybrid distributed GAN intrusion detection system.

1) Pre-processing Synthetic Minority Oversampling Technique (SMOTE): In this paper, pre-processing involves the utilization of the SMOTE technique to enhance the efficiency of handling imbalanced datasets. This technique addresses minority sampling, aimed at improving the accuracy of intrusion detection for the provided dataset. Balancing classes aims to increase the frequency of minority classes while decreasing the frequency of majority classes, with the goal of achieving a similar number of instances for both classes. In this study, SMOTE is utilized to balance the classes. This involves oversampling the outnumbered category by creating synthetic examples for each minority class sample along the line segments connecting any of the k nearest

neighbors from the opposition class. Additionally, when exceeding the required oversampling level, neighbors are randomly selected from the k nearest neighbors. SMOTE employs k-nearest neighbors for generating the artificial data [17].

The subsequent procedures are executed for the minority class in the SMOTE technique.

- Contrast linking the feature characteristic (sample) less than deliberation and its close neighbor is taken.
- An arbitrary integer between 0 and 1 is multiplied with this difference.
- Results are attached to the characteristic vector lower than the deliberation.
- This makes the choice of an arbitrary tip through the rule fragment between two particular features.
- Allocate a value to the newly generated synthetic minority class sample.
- Iterate the process for the identified feature vectors.

It is essential to identify the nearest neighbors of a point in a d-dimensional space in order to synthetically interpolate selections (for minority class) among these nearest neighbors. Random assignment of data to separate nodes in an allocated set may lead to points that are closest to each other being assigned to different nodes, making it difficult for respective nodes to be aware of these nearest neighbors. Therefore, it is crucial that nearest points are grouped together and also allocated to different nodes in such a way that nearest points are consistently processed on the same node. As a result, the challenge of imbalanced data is effectively addressed using the SMOTE approach.

2) Feature extraction using Modified Principal Component Analysis (MPCA): In this paper, MPCA algorithm is offered for feature extraction applied to degrade the composition of features. The aspiration of PCA is to dimensionality deduction of the data space (obeyed variables) to the lower natural dimensionality of feature space (self-dependent variables), which are demanded to portray the data economically. By discarding smaller factors, the PCA effectively reduces the piece of features and displays the data set in a low dimensional subspace [18] [19]. PCA is a classical multivariate data analysis system that's useful in direct point birth. The PCA system can not guarantee that the data bonded to the applicable classes is effectively compacted. To avoid the overmentioned backwashes, qualified PCA is propounded.

3) Feature selection using Improved Firefly Optimization (IFFO) algorithm: In this study, an enhanced firefly algorithm for feature selection is employed. The Firefly algorithm (FA), introduced by [20], is a biologically-inspired stochastic optimization approach. FA operates as a population-based metaheuristic, where each firefly within the population represents a feasible solution in the search space. It simulates the behavior of fireflies, which emit light signals to communicate and attract mates. Additionally, they utilize flash lighting to attract potential prey and serve as an alarm system.

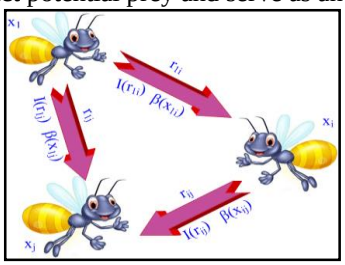

Fig. 4. Firefly algorithm.

Fig. 4 above illustrates the Firefly algorithm. The FA algorithm begins by initializing a swarm of fireflies, with each firefly determined by its luminous intensity.

It compares the flare aggressiveness of the firefly, the inferior glare aggressiveness firefly will displace to the advanced flare aggressiveness firefly. Depending on enchantment the displacing length may differ. The new firefly blaze aggressiveness will be estimated and streamlined once it has displaced.

Algorithm 1: IFFO for Feature Selection

Input: Input: Population size (n), Maximum of iteration (maxIter), Absorption coefficient (γ), Randomization parameter (α), Attractiveness value ($\beta_0 = 1$)

1. Objective function (x), $x = (x1,...,)T$ consider higher accuracy of classifier as objective function
2. Produce initial population of fireflies xi $(i = 1, 2, \ldots, n)$
3. Light intensity Ii at xi is found via $f(xi)$
4. Describe light absorption coefficient γ
5. while (t < Max_generation)
6. for i=1:n all n fireflies
7. for j=1:i all n fireflies
8. if ($Ij > Ii$), Move firefly i towards j in d-dimension;
9. end if
10. Attractiveness changes along with distance r via exp[$-\gamma r$]
11. Compute fitness function using (14)
12. Compute objective model using (13)
13. Estimate new solutions and update light intensity using (11)
14. Update the optimal features using (16)
15. end for j
16. end for i
17. Rank the fireflies and find the current best
18. end while
19. A firefly i shifts to a more attractive

In this script, the IFFO algorithm is utilized to achieve optimal outcomes by refining both energy and detection criteria. In the IFFO algorithm, fireflies are evaluated and the most optimal ones are selected based on their fitness values. Selected fireflies undergo crossover and mutation to produce new, improved solutions. These refined solutions are incorporated into the firefly population, and the process of selecting and refining fireflies continues iteratively.

Generative model intrusion detection system algorithm

Input: Let Input X denotes real data
Z denotes data from generator

IOT denotes set of N items
Pdata(x)=Distribution of real data
Pdata(z)=Distribution of generator

1) Data collection

Let Xi=X1,X2……Xn
and Zi=Z1,Z2……Zn
D(Xi)=Discriminator Network
G(Zi)=Generator Network
Data Collection is denoted as

$$\left\{D_i^*, G_i^*\right\} = \arg\arg\min_{Gi} \arg\arg\max_{Di} V_i\left(D_i, G_i\right)$$

2) Training phase: To find the optimal value it is denoted as,

$$V(D_i, G_i) = \mathrm{E}_{x\sim P_{xi}}[\log D_i(x)] + \mathrm{E}_{z\sim P_{zi}}[\log(1-G(Z))]$$
$$V(D_i, G_i) = \mathrm{E}_{x\sim P_{xi}}[\log\log D(x_i)] + \mathrm{E}_{z\sim P_{zi}}[\log(1-G(Z_i))] \quad (1)$$

Anomaly Detection Phase

The Anomaly Detection is done by Threshold Based Intrusion Detection

Assume True Positive (TP) ->Attack denoted as positive

False Negative (FN)->Attack denoted as negative

False Positive (FP)-> Normal data denoted as positive

True Negative (TN)-> Normal data denoted as Negative

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (2)$$

Assume Threshold T which denotes the range from 0.85 to 1

Let Yi=Xi+Zi denotes the overall data

if Yi<Threshold Ti
then Yi is intruder
else
Yi is normal data
End

1) Intrusion detection metrics: The metrics used to evaluate the performance of Intrusion Detection are Accuracy, Detection Rate (DR), Precision, Recall and False Positive Rate (FPR).To indicate these metrics four parameters have been considered.

They are True Positive (TP), True Negative (TN), False Positive (FP) and False Negative (FN).TP, FN denotes the attack and FP, TN denotes the Normal User.

Accuracy refers to the proportion of predictions that are accurately classified as either Attack or Normal, expressed as a percentage.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (3)$$

The detection rate is defined as the proportion of all predicted attack instances that correspond to actual attack records.

$$precision = \frac{TP}{TP + FP} \quad (4)$$

Recall represents the proportion of assessments that represent the ratio of True Positive attack records to the total number of True Positive and False Negative instances.

$$precision = \frac{TP}{TP + FN} \quad (5)$$

The False Positive Rate (FPR) indicates the likelihood of normal data being inaccurately identified as attack data.

$$FalsePostiveRate = \frac{FP}{FP + TN} \quad (6)$$

VI. Result and Discussion

In this study, we evaluated the accuracy of the initial discriminator trained on provided attack data. Results showed that attack data used in the training process were readily detected, while attempt data not included in the training were more challenging to detect. Table I shows the system and software requirements.

TABLE I. System and Software Requirements

System Requirements	Software Requirements
IoT devices with compatible processors	Linux distribution
Reliable network infrastructure	Deep Learning Framework (PyTorch)
Minimum 8 GB of RAM	Data Preprocessing Tools (NumPy)
SSD or HDD storage	Python Environment
Ethernet or Wi-Fi connectivity	Integrated Development Environment (IDE)

This highlights the need for a new detection model capable of accurately identifying attempts even when only average data are used in the training process.

TABLE II. Performance of the HDGIDS in IoT

Attack	Detection rate	Precision	Accuracy	Recall
Black hole attack	98%	98.3%	99%	97%
Sinkhole attack	97.5%	97.3%	98%	98%
Sybil attack	96%	96.2%	98%	95%
DDoS attack	99%	98.7%	97%	90%
Warm hole attack	97%	97.6%	98%	95%

Additionally, we assessed the detection sensitivity of an alternative discriminator trained on arbitrary dummy data instead of genuine attempt data. Table II illustrates the detection performance for each of the four attempted datasets. Results showed that each of the five attempts was detected with 98% delicacy. It is defined as how much accuracy and attack for HDGIDS in IOT. The different attacks are Black

hole, Sink hole, Sybil attack, DDos, Warm hole are considered along with the accuracy.

Fig. 5 illustrates the different phases of accuracy values undergoing change. HMFFGAN- grounded IDS has 98% of accuracy.

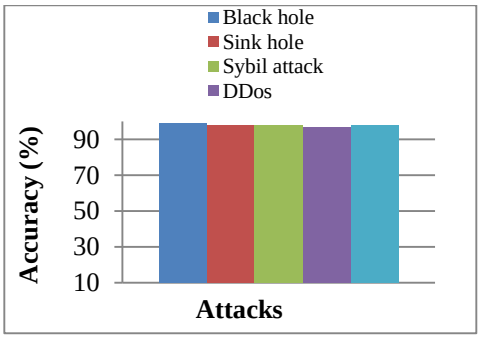

Fig. 5. Accuracy.

Fig. 6 shows the precision % in terms of attacks for Black hole, Sink hole, Sybil Attack, DDos, Warm hole.

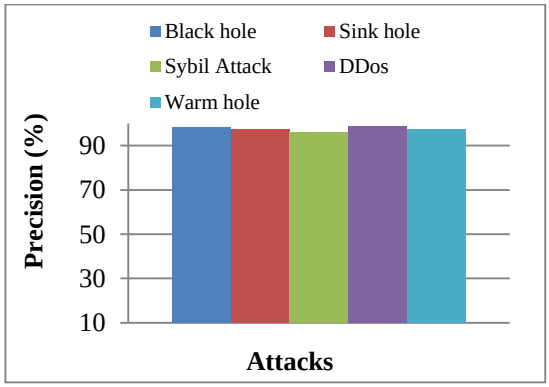

Fig. 6. Precision.

It pertains to the degree of agreement among individual measurements; the smaller the CV, the greater the precision of the values. Here Sybil Attack will take the least value for precision. Among all the attack nearly precision value will reach 98% of accuracy. It is defined as recall value for the attacks. Recall is calculated by dividing the number of relevant documents retrieved by a search by the total number of relevant documents, while precision is determined by dividing the number of relevant documents retrieved by a search by the total number of documents retrieved by that search. Each attack takes some amount percentage for recall values in Fig. 7. Since the recall percentage in the current attack is not maximal, it takes less time in order to predict the attacks.

Utmost of the time, we don't indeed know the findings rates of our participators. To compute the discovery grade for a participator, we'd possess to endure how numerous complete UX troubles live in a plan. But that's exactly what we're testing to dig out with estimation. The evaluation of detection models in the proposed method reveals important insights into their performance against various types of IoT attacks. It demonstrate that the systems trained on specific attack data to provide strong accuracy in detecting known attack patterns but struggle with detecting new or untrained attack types, highlighting the need for improved generalization capabilities.

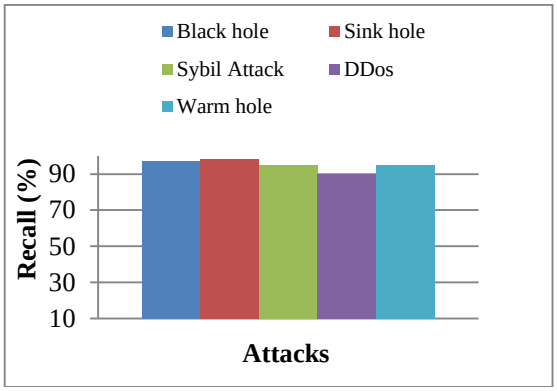

Fig. 7. Recall.

In Fig. 8, it is defined as the detection rate for every attack is calculated.

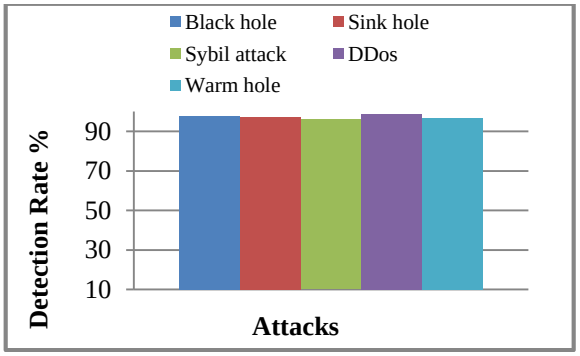

Fig. 8. Detection rate.

Additionally, alternative models trained on arbitrary dummy data provide valuable insights into detection sensitivity under different training conditions. Precision values approach an impressive 98% across all attack types, underscoring the models' effectiveness in correctly identifying relevant attacks. However, variability in recall rates across attack types impacts prediction time and highlights the importance of comprehensive detection approaches. Future research should focus on refining detection algorithms to enhance robustness and adaptability in addressing evolving IoT security threats.

VII. Conclusion

In this paper, we've proposed a crossbred GAN- grounded IDS grounded on modified top element dissection and firefly optimization (HDGAN Network) that can discover intrusion to the IoT. In this allocated framework, every IoTD can cover its own data as well as neighbor IoTDs to descry anomaly geste of the bias. The HDGAN network doesn't bear participating the datasets between the IoTDs it save the sequestration of the delicate data similar as patient medical data in medical center mesh. it pierce the data set from single ID device the HDGAN mesh trained with dataset with SMOTE and Firefly optimization algorithm which allow the GAN mesh to determine intrusion efficiently. The Simulation results display that the offered allocated HMFFGAN-

grounded IDS has 98 accuracy, 98 precision, and 95 false positive rate compared to the being allocated Intrusion discovery network. Future IoT security research should prioritize enhancing model robustness against adversarial attacks with techniques like adversarial training and input perturbation. Dynamic, adaptive intrusion detection models for continuous learning in evolving IoT environments remain essential areas for exploration.

Natsukashii: A Sentiment Emotion Analytics Based on Recent Music Choice on Spotify

Khor Zhen Win, Mafas Raheem
School of Computing, Asia Pacific University, Bukit Jalil, Malaysia

***Abstract*—Natsukashii offers a delightful platform for users to seamlessly connect with their Spotify accounts and delve into cherished musical moments, fostering a profound emotional connection with their recent experiences. This platform harnesses the power of Spotify's data, facilitating a secure connection to users' accounts while ensuring that no Spotify data is stored locally. Its array of features includes captivating data visualizations, such as display cards, radar charts, and area charts, elegantly showcasing both recent favorites and top-listened tunes. However, the crowning jewel of Natsukashii lies in its ability to provide users with a heartfelt insight into their current mood, derived from the audio features of their recent playlist selections. By meticulously preparing and analyzing the audio features provided by Spotify, Natsukashii delivers a personalized sentiment analysis, offering users a poignant glimpse into their emotional state through the lens of their musical preferences. Moreover, this enriching experience is seamlessly accessible across desktop and mobile platforms, compatible with popular web browsers like Google Chrome, Firefox, and Microsoft Edge.**

Keywords*—*Spotify; sentiment analysis; data preparation; data visualization; web development

I. Introduction

Spotify stands as the foremost digital music streaming service globally, granting users the freedom to indulge in on-demand music listening while fostering the creation and exchange of playlists. Employing cutting-edge recommender models, Spotify pioneers personalized music suggestions tailored to each user's listening habits. By seamlessly integrating these recommendations into the user experience, the platform continually introduces fresh content aligned with individual preferences. At its core, this innovation revolves around an algorithmic framework meticulously designed to curate top-tier recommendations, drawing insights from categorized groups, track metadata, and collaborative user-generated content [1].

The importance of delivering personalized analytics directly to consumers is frequently underestimated. Often, analytics are predominantly prioritized by upper management, with a focus on algorithms and recommendations geared towards the consumer. Nevertheless, integrating low-level analytics directly to users would prove significantly advantageous in terms of feature implementation.

Research indicates that over the long haul, algorithmic recommendations tend to narrow the spectrum of user listening habits in contrast to those driven by user choices. However, platforms experience heightened user retention rates with greater content diversity [2]. This underscores the importance of accessible analytics for end-users, empowering them to discern the types of content they engage with. Moreover, such insights aid upper management in gauging user retention following the introduction of novel features.

Recognizing the dynamic nature of users' listening preferences, Spotify continuously refines its algorithms to align with their ever-changing moods and behaviors [3]. Nonetheless, while Spotify Wrapped offers a comprehensive annual insights package, it limits users' freedom to explore beyond the confines of a yearly cycle. Consequently, Spotify misses out on the potential benefits of implementing personalized, time-sensitive analytics.

Investigating individual-level data reveals a treasure trove of insights into human behavior. Research has illuminated a strong correlation between music preferences and listening habits with personality traits. Existing literature underscores the importance of recognizing that personalized analytics offer both tangible and intangible advantages to both users and brands [3].

II. Literature Review

A. Music Streaming Platforms and Music Consumption

Music, as a medium of consumption, holds a profound sway over individual mood regulation, mirroring the ebb and flow of emotional energy within. Scholars underscore that music consumption stands apart from conventional text-centric social media engagement. As shown in Fig. 1, this is owing to its unique capacity to not only reflect an individual's present emotional state but also to shape their desired emotional experience [4]. Such nuanced insight empowers platforms to leverage algorithms in forecasting and delivering desired moods through tailored musical selections. Consequently, music platforms are keenly invested in refining their recommendation systems by manipulating content consumption patterns. The real-time data feedback loop inherent in music streaming services represents a pivotal departure from traditional modes of music consumption, conferring a distinct competitive edge. It underscores the strategic significance of the music streaming landscape amidst the ongoing digitization of music consumption [5].

The trailblazers of the music streaming realm, exemplified by industry giants like Spotify and Apple Music, have profoundly reshaped this landscape. These titanic platforms have effectively transformed the social fabric surrounding music consumption, turning it into a potent form of social interaction. Merely amassing a vast content library no longer

guarantees an edge over rivals, as sheer volume alone fails to captivate users' attention. Platforms are tirelessly refining their recommendation algorithms to provide personalized experiences under the broad umbrella of customization [5]. Nevertheless, fixating solely on winning the recommendation race represents just a fraction of what a streaming platform entail.

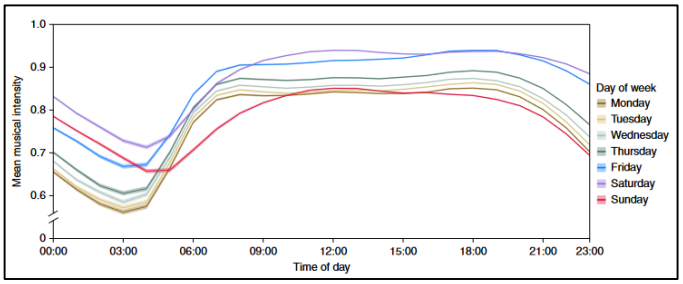

Fig. 1. Music consumption on a diurnal basis [2].

In a comprehensive study conducted by Park et al. (2019), the timely consumption of music streaming through Spotify across fifty-one countries was examined using a random stratified sampling method [4]. Spotify, with its ambitious goal of tailoring recommendations to users even before their preferences crystallize, capitalizes on the wealth of data availability for analytical insights. Notably, Spotify's provision of track analysis, encompassing eleven audio attributes, furnishes invaluable information conducive to enhancing user comprehension of their listening experience.

Through a feature-oriented approach rather than a backend model, users can forge connections with their desired musical content based on their emotional context. This approach surpasses conventional computer-based algorithms by acknowledging the significance of human perception, wherein data is presented in easily digestible visual formats. Embracing data analytics as a platform feature holds immense promise for facilitating personalized music discovery and enjoyment.

Variation and diversity of content consumption have moderately significant differences during varying times of the day. In their research [4], the authors posit that Spotify users' musical preferences undergo shifts depending on the nature of their activities, whether it be for relaxation, motivation, stress relief, or winding down. This correlation becomes apparent when specific tracks possess attributes like tempo, valence, danceability, or instrumental quality that resonate with a particular psychological mood within a given time interval [6]. Such findings underscore the invaluable insights gleaned from data analysis, empowering users with the opportunity to deepen their self-awareness.

Spotify diligently gathers data across various dimensions of significance, encompassing stakeholders, societal advantages, and brand perception. Consumption of content occurs on a subconscious plane, often evolving into habitual listening, effortlessly ingrained in users' routines. Consequently, individuals find themselves engaging with music recommended to them, relinquishing active selection of preferred genres. In the evolving landscape where data insights rival sophisticated predictive models in importance, there arises a compelling case for providing users with introspective analytics, including mood analysis. Such an approach fosters a more personalized self-identity, empowering users to curate their musical journey based on individual inclinations, rather than solely relying on algorithmic dictates.

B. Analyzing Emotions in Audio Data

Social media text has emerged as a pivotal data source for comprehensively analyzing mood and emotions at scale, with a nuanced grasp of the temporal dynamics inherent in such data, given its perpetual evolution. As the volume and accessibility of user-generated content burgeon, it has been discerned that both the platform itself and the surrounding community exert significant influence on shaping the overarching emotional landscape of broad target demographics. However, this growth has also engendered a phenomenon wherein predictive models tend to become overly specialized, inadvertently neglecting quieter individuals whose sporadic contributions may not fully encapsulate their experiences [8]. Consequently, when gauging emotional states through historical user data, it becomes imperative to pay heed to the fluctuations in emotions over time. This is crucial due to the manifold external stimuli—ranging from media influences on social connections—which are in a constant state of flux, exerting a profound impact on an individual's mood.

Emotional analysis has transcended mere textual expressions, extending its reach into the realms of audio and video formats. The emergent insight value derived from mining data across semantic audio, music, and soundscapes, previously overlooked by the music industry [9], expands the spectrum of data extraction. This integration of more profound sources enriches comprehensive analyses, fostering deeper comprehension. Yet, achieving such understanding necessitates ongoing development in emotional intelligence, aiming to decipher the influential factors driving human emotions [10].

C. Spotify Track Data

The Circumplex Model, pioneered by James Russell, elegantly captures emotions within a two-dimensional landscape blending cognitive science and psychology. Here, emotions find their place, with valence denoting their positivity or negativity, and arousal signifying their intensity. Positioned in the model, positive emotions reside in the upper right quadrant, while negative one’s dwell in the lower left [10]. Illustrated in Fig. 2, Russell’s Circumplex Model of Affect holds significant relevance in deciphering Spotify’s track data for mood analysis. Spotify's classification of tracks aligns with this model, facilitating the creation of a scoring mechanism. Wei et al. (2021) delved into how emotions, characterized by a blend of valence and arousal, can be extracted utilizing this framework. Their study revealed Spotify's portrayal of valence through a scale of 0.0 to 1.0, where higher values signify a more jubilant emotional state. Arousal, alternatively termed "energy" by Spotify, is also gauged on a scale of 0.0 to 1.0, where elevated scores indicate tracks characterized by speed, volume, and vigor, such as the genre of death metal [11].

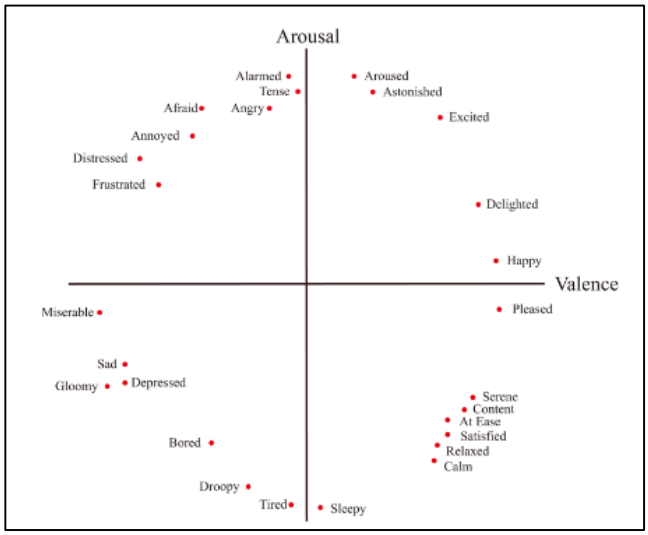

Fig. 2. Russell's circumplex model [3].

Spotify presents its data to users in a sleek JavaScript Object Notation (JSON) format, ensuring that structured objects are easily interpretable. JSON stands out as a widely embraced format across various platforms. To access Spotify's data, users have two options. Firstly, they can directly request a download of their data via their profile. Following some processing time, Spotify packages this data and dispatches it to the user's account via email. However, for projects requiring real-time data, tapping into Spotify's web API proves more fitting [12]. Spotify employs an approximate scoring system, assigning nine "audio features" to songs, with scores ranging from 0.0 to 1.0. These features gauge different facets of an audio track's composition. The audio features are as listed below: -

- Acousticness
  - Represents if a track has high confidence in being acoustic.
- Danceability
  - Describes suitability to dance in terms of tempo, rhythm, beat, strength.
- Energy
  - Represents track intensity.
  - Higher scores are tracks that are fast, loud, and noisy.
- Instrumentalness
  - Predicts degree of vocal presence in a track
  - Sounds like “ooh” and “aah” are not vocal content.
  - A higher score represents a higher likelihood of having no vocal content.
- Liveness
  - Detects audience presence if the track artist performed live.
  - A value more than 0.8 has a strong likelihood of live performance.
- Speechiness
  - Detects the presence of spoken words.
  - Values above 0.66 have a high likelihood of the track being made of spoken words such as podcasts or audio books.
  - The value between 0.33 and 0.66 may contain both spoken words and music.
  - Values below 0.33 may be music or other non-speech audio.
- Tempo
  - Estimates the beats per minute (BPM).
  - Represents the pace (speed) of the track.
- Valence
  - Represents musical positiveness.
  - High values represent positive emotions such as happiness and cheerfulness.
  - Low values represent negativity such as sadness and anger.

In instances where Spotify has assigned pre-labelled scores to its track data, the methodology behind the determination of these scores remains ambiguous. A comment in a blog post by Shanahan (2016) indicated that this information is proprietary, with Spotify deriving these scores through their internal algorithms. It was mentioned that these algorithms appear to be aligned with the principles of Echonest's algorithm [11].

D. Spotify Wrapped Campaign

The inception of the "Spotify Wrapped" campaign in December 2017 ignited a social media phenomenon, capturing the enthusiasm of users who eagerly shared their listening statistics across various platforms. With its organic growth fueled by word-of-mouth promotion, the campaign swiftly gained traction, serving as a communal celebration of beloved artists [7]. Its resonance reverberated through the digital landscape, spawning a proliferation of news articles and blog posts dedicated to extolling its virtues.

Evolved into an annual tradition, each iteration of the campaign sought to introduce novel features, fostering heightened user engagement with every passing year. Notably, in 2022, the campaign unveiled 16 distinct listening personality archetypes for individual users, alongside a strategic foray into the burgeoning metaverse landscape via Roblox [13]. However, Adenuga (2022) raised poignant ethical concerns regarding the extensive collection and dissemination of users' data, prompting reflection on the justification and inherent value of such surveillance practices.

While businesses often approach data through a macroeconomic lens, emphasizing its monetary utility, users derive personal value from the insights gleaned, facilitating a deeper understanding of their emotions and preferences. Thus, amidst the ethical discourse surrounding data privacy, users find solace in the self-awareness afforded by these analytics.

E. Similar Systems

Table I elucidates three contemporary systems available at the time of the study, designed to furnish user listening analytics leveraging Spotify data.

TABLE I. COMPARISON OF SIMILAR SYSTEMS

Features	Systems		
	Spotilyze	Stats For Spotify	Stats.fm (Spotistats)
Desktop Resolution	Yes	Yes	Yes
Mobile Resolution	No	Yes	Yes
Stores Data	No	No	Yes
Has Time Range Filter	No	Yes	Yes
Analysis Infographics and Platform Features	Playlist mood radar chart. Top artists in the playlist. Top genres of the playlist. Track the popularity of songs within the playlist. Distribution of track information within the playlist.	User's top tracks User's top artists User's top genres Recently played activity	A user profile that links to Spotify Integrated "friend" system that allows users to add friends. User's top tracks User's top artists User's top genres Recently played tracks activity. Genre analysis Track content analysis
Pros	Clean and simple user interface design Easily digestible visualization and metrics	Time filter available Mobile responsive	Time filter available with custom time range Mobile responsive Simple user interface
Cons	Not mobile friendly Restricted only to analysis of playlists. No time filter available	Has no visualization and only uses lists. Have limited features	Has limited variations of visualization. Paywalls restrict most of the features. Collects and stores user data which creates privacy risk.

Although existing systems boast robust and dynamic functionalities, they fall short of adequately addressing the specific problem of correlating emotions with individual music preferences. The prevailing limitations of these systems primarily revolve around leveraging the features offered by platforms like Spotify, rather than focusing on solving the fundamental issue while harnessing the data provided by such platforms. Consequently, the rationale behind selecting the proposed research and implementation methods lies in their adaptability and effectiveness in addressing the inherent challenge of connecting emotions with music preferences.

III. TECHNICAL STACK

Table II outlines the chosen technical stacks designated for system development. GitHub, coupled with Git, emerges as a pivotal quality-of-life tool for version control among developers. JavaScript, renowned as the prevailing industrial standard for contemporary web development, stands as the unequivocal choice for system development, owing to its expansive capabilities and user-friendly nature. Given the plethora of community libraries and frameworks available for JavaScript, incorporating additional features or addressing potential compatibility issues within the project's scope and deliverables can be seamlessly adapted, ensuring scalability and flexibility to accommodate evolving requirements.

TABLE II. TECHNICAL STACK

Category	Name
Programming Language (Framework)	ReactJS on NextJS (JavaScript)
Styling Library	MantineUI, ChakraUI
Data Visualizations Library	Recharts
Developer Tools	NodeJS + NPM (Package Manager) GitHub + Git (Version Control)
Design Tool	Figma
Deployment Service	Vercel
Database	None

IV. METHODOLOGY

A. Introduction

The proposed project embodies dual facets, intertwining both software development and data science methodologies, owing to its nature spanning across these two domains. Fundamentally reliant on data to catalyze its initiation, the project necessitates a data science methodology (see Fig. 3). Conversely, the deployment of the platform within a web application necessitates a software development methodology. These complementary methodologies will converge within a hybrid framework, fostering a synergistic workflow and structured project plan. Initiating the project involves delving into data comprehension and domain understanding, for which the CRISP-DM methodology serves as the cornerstone. Transitioning to the data preparation stage, elements borrowed from the waterfall model will be seamlessly integrated into the hybrid methodology. This strategic amalgamation promises to enhance both the understanding of data intricacies and the efficacy of software development within the project. Tables III and IV delineates the phases of these comprehensive approaches.

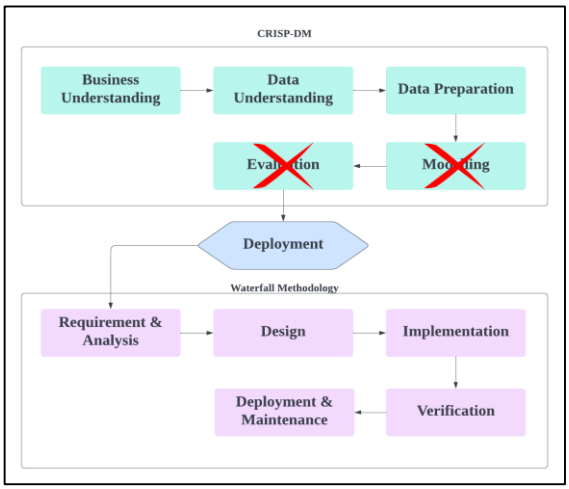

Fig. 3. Proposed mixed methodology framework.

B. Phases of Data Mining Methodology (CRISP-DM)

TABLE III. CRISP-DM PHASES

Phase	Purpose & Outcomes
Business Understanding	Assessing and understanding the current business objectives of Spotify while aligning the project outcomes.
Data Understanding	Explore the capabilities, limitations, and intended use of Spotify data through their Web API.
Data Preparation	This phase is not needed as Spotify has already cleaned their data for usage.
Modelling	N/A – Irrelevant for this project
Evaluation	N/A – Irrelevant for this project
Deployment	This entire phase will be conducted in accordance with the waterfall methodology as listed in the next subsection.

C. Phases of Data Mining Methodology (Waterfall)

TABLE IV. WATERFALL METHODOLOGY PHASES

Phase	Purpose & Outcomes
Requirements & Analysis	Conduct a zero-party data approach of collecting personal opinions of platform features through a questionnaire distributed online. Results of questionnaire are used to validate useful features for the design phase.
Design	Convert the analysis of requirements into low-level visual components through Figma.
Implementation	Develop the designed system with the technical stack proposed. Test plans are also developed within this phase.
Verification	Conduct unit testing and system integration testing with Spotify data.
Deployment & Maintenance	Deploy the system for public usage. Apply for Spotify's extended quota mode to enable all Spotify users to connect to the platform.

V. RESEARCH METHODS

The selected research methodology involved the utilization of an online survey, a strategic means of gathering quantitative data [17] to glean valuable insights from participants regarding the research topic at hand. Leveraging surveys proves advantageous due to its cost-effectiveness and capacity to swiftly engage a sizable cohort of target users [14]. This methodology aligns seamlessly with the envisaged waterfall methodology employed during the requirements phase, facilitating the efficient collection and analysis of project requisites. Streamlining the process further, platforms like Google Forms, Microsoft Forms, and Survey Monkey offer integrated solutions for data collection and analysis, thus optimizing time utilization. Conversely, a qualitative approach is deemed impractical due to its inherent time intensiveness, requisite expertise, and inability to furnish generalizable insights for the target demographic.

Given the nature of the proposed project, which does not necessitate the inclusion of personal viewpoints from participants, the qualitative research methodology is deemed unsuitable for attaining the research objectives. The author faces constraints in conducting qualitative research due to the requisite presence of a skilled moderator, which is currently lacking. Conversely, surveys offer a means to uphold participant anonymity, thereby fostering greater engagement, particularly given concerns regarding data privacy [15].

In the context of system testing, qualitative methodologies present a justifiable approach for gathering opinions and feedback, particularly in instances where quantitative data may not adequately capture user experiences. This phase of research entails soliciting verbal feedback to ascertain the impact of the system on users and any perceived benefits derived from its usage. However, at the onset of research, particularly during the requirements gathering stage, a combined qualitative and quantitative approach may not be appropriate. Qualitative inquiries may inadvertently encroach upon individuals' privacy, particularly concerning sensitive aspects such as emotional states. Thus, initiating with a quantitative focus allows for the establishment of user trust and willingness to engage with the system. Subsequently transitioning to qualitative assessments becomes less intrusive, as users become more receptive to providing nuanced feedback. This progression is rationalized by the integration of emotions and moods into a composite score, which can be presented to users for comparative analysis, rather than intrusively assigning a numerical value to represent their mood.

Unlike qualitative approaches, such as interviews, surveys afford participants a higher degree of privacy, crucial for eliciting candid responses while safeguarding sensitive information. Presented below are tables and figures illustrating the outcomes of primary research conducted among 53 respondents drawn from Malaysian adolescents? The questionnaire encompassed four distinct sections, featuring nominal, linear scale, checkbox, and multiple-choice grid inquiries as shown in Table V, Table VI, Fig. 4 and 5.

TABLE V. SECTION 1: PARTICIPANT DEMOGRAPHIC

Question	Results
Gender	52.8% - Male 45.3% - Female 1.9% - Prefer Not to Say
Age	**86.8% - 18 to 25 years old** 5.7% - 26 to 30 years old 3.8% - <18 years old 1.9% - 31 to 35 years old 1.9% - 36 to 40 years old
Occupation	77.4% - Student 22.6% - Working

TABLE VI. SECTION 2: MUSIC STREAMING PLATFORMS

Question	Results
What music streaming platforms that have you used?	84.9% - Spotify 84.9% - YouTube Music 35.8% - Download mp3 files locally 24.5% - Apple Music 22.6% - SoundCloud 9.4% - Tidal 3.8% - Tencent Music 1.9% - Amazon Music

Question	Results
Does your emotional state influence the type of music consumed?	Likert Scale (Multiple Choice) 5 – 26.4% **4 – 47.2%** 3 – 13.2% 2 – 9.4% 1 – 3.8%
Does the type of music consumed influence your emotional state?	Likert Scale (Multiple Choice) 5 – 17% **4 – 49.1%** 3 – 22.6% 2 – 7.5% 1 – 3.8%

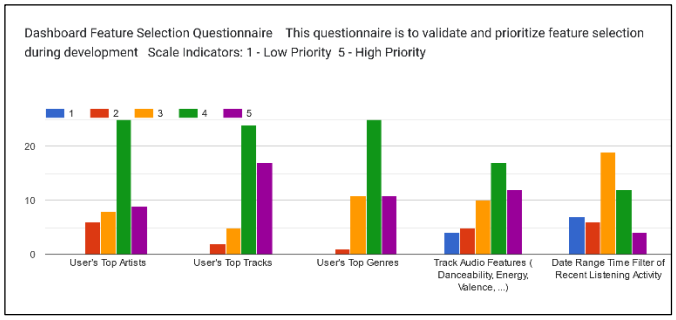

Fig. 4. Dashboard Feature Selection.

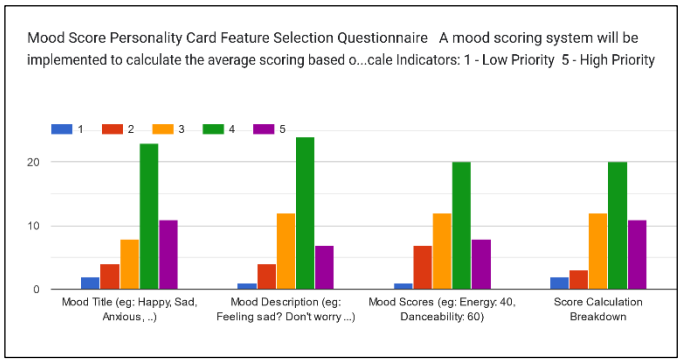

Fig. 5. Mood card content preference.

VI. Data Understanding

The initial exploration of Spotify's Web API delved into its capabilities, potential uses, and inherent limitations regarding the data it provides. Spotify's Web API offers external applications the ability to interact with Spotify's extensive data, encompassing tasks such as retrieving content metadata and accessing account information [16]. Nonetheless, leveraging Spotify's Web API entails adhering to a specific sequence of steps to enable users to access data from their platform. This necessitates the creation of an application within Spotify's developer dashboard to acquire the requisite client credentials. Armed with these credentials, the application gains the ability to initiate Web API calls to Spotify's servers. Within the scope of the proposed project, Natsukashii, integration of a login feature via Spotify facilitates user authorization and seamless data retrieval.

A. Relevant Endpoints

- v1/me
  - Fetch user's account name, display image, and external URL link
- v1/me/top/{type}
  - Fetch user's top tracks and top artists
  - Time range parameters of 1 month, 6 months, and several years
  - Images and metadata must comply with Spotify's design guidelines to obtain approval for Spotify Quota Extension
- v1/audio-features
  - Fetch track's audio features such as valence and energy score
  - Used to build own API endpoint that calculates a mood profile based on Russell's Circumplex Model
- v1/me/player/recently played
  - Fetch the recently played unique tracks with a limit of 50 each API call
  - After and before parameters available to call specific tracks played in a timeframe

B. Data Limitations and Workarounds

It sounds like you're discussing an issue with the Spotify Web API, specifically regarding the before and after parameters for fetching recently played tracks within a certain time frame, such as a week. Despite these parameters being documented, it appears that they are not currently supported based on your research and personal exploration. Additionally, you've found that other developers in the community forum have encountered similar difficulties, specifically with being unable to retrieve more than the initial 50 responses. This limitation might pose challenges for developers who need to access a larger dataset of recently played tracks. If you're looking to address this issue, you might consider reaching out to Spotify's developer support or checking for any updates or announcements regarding changes to the API's functionality. Alternatively, exploring workarounds or alternative methods for accessing the desired data could also be worth investigating.

The issue arises when attempting to use the "before" or "after" cursors in the second response, hindering the retrieval of subsequent responses. Consequently, developers are constrained to fetching no more than 50 responses, thus restricting the available data to only the most recent 50 listened songs [4].

Owing to constraints imposed by Spotify, the component will presently only draw data from the latest 50 tracks played. As a result, the inclusion of a date filter is currently redundant, pending future enhancements from Spotify. Consequently, the initially proposed date picker filter will be replaced with pre-defined time range options, ensuring seamless integration with the bar chart, area chart, and sentiment mood card.

The sentiment mood card and the recently played area chart components retain full functionality, albeit restricted to the fifty most recently played tracks. Notably, these components are no longer influenced by the time range filter located at the top of the page. While this may be perceived as a limitation, it enhances granularity while reducing flexibility in track selection. From a business perspective, this feature encourages frequent visits to the platform, thereby bolstering user engagement. It's worth noting that aside from the recently played tracks endpoint, all other data endpoints are accessible and can be utilized without any constraints or impediments.

C. Data Driven Implementations

The data under examination will undergo meticulous processing and refinement to align with the intended component implementations. This preparatory phase entails server-side processing within the cloud server, leveraging the project's bespoke API. By employing the Natsukashii application's API for executing the processing logic, the burden on client-side machines is mitigated, ensuring a smoother experience for platform users.

The track audio features data provided by Spotify do not inherently convey the emotional state of a listener. To discern emotions, developers typically employ data preparation techniques, often leveraging models such as Russell's Circumplex Model. This model allows developers to interpret emotions based on metrics like average energy and valence scores. Implementing this approach, developers devise calculations to delineate the boundaries of energy and valence scores. Consequently, they can categorize emotional states into nine distinct profiles. Fig. 6 and Fig. 7 are the diagram and the code snippet accompanying this process.

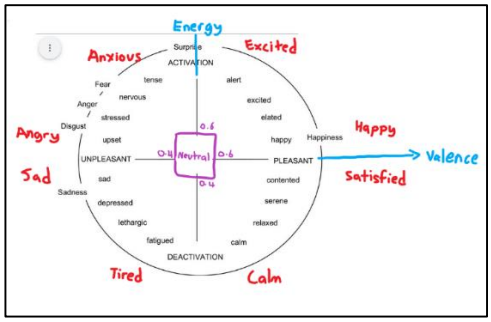

Fig. 6. Russel's Circumplex Model Decimal Point Boundaries.

```
export function getMood({ valence: valence, energy: energy }) {
  // assuming 0.5 is the value of 0,0 on the russell's circumplex model
  // values between 0.4 and 0.6 for both values are considered neutral

  let mood = "neutral";

  if (valence >= 0.6) {
    // positive
    if (energy >= 0.65) mood = "excited";
    if (energy >= 0.5 && energy < 0.65) mood = "happy";
    if (energy > 0.35 && energy < 0.5) mood = "satisfied";
    if (energy <= 0.35) mood = "calm";
  } else if (valence < 0.4) {
    // negative
    if (energy >= 0.65) mood = "anxious";
    if (energy >= 0.5 && energy < 0.65) mood = "angry";
    if (energy > 0.35 && energy < 0.5) mood = "sad";
    if (energy <= 0.35) mood = "tired";
  } else {
    // close to x-axis origin
    if (valence > 0.5) {
      if (energy >= 0.65) mood = "excited";
      if (energy <= 0.35) mood = "calm";
    } else if (valence < 0.5) {
      if (energy >= 0.65) mood = "anxious";
      if (energy <= 0.35) mood = "tired";
    }
  }

  return profiles[mood];
}
```

Fig. 7. Code snippet of mood score calculation.

VII. System Architecture

After careful examination, it was determined that the project solely requires frontend frameworks, with minimal integration with Spotify's Web API through RESTful connections. Recognizing the paramount importance of data security in accordance with Spotify's developer guidelines, it was decided that no data collection or storage would be undertaken within this project. Instead, real-time data would be continuously retrieved from Spotify's Web API, rendering the necessity for a database redundant within this system.

Upon thorough examination of the system's core functionalities and deliverables, it was determined that a monolithic application, devoid of a database, stands as the optimal choice for the proposed project, tailored for a solitary user. A monolithic architecture encapsulates the entire application within its ecosystem, operating as a cohesive entity with its distinct services and APIs. Conversely, microservices distribute autonomous services to support the application. Given the project's modest scale and the requirement for only a singular communicative service for the user interface, the microservice architecture is deemed unsuitable [5].

In this section, we delve into the high-level architecture of the proposed system, a guiding blueprint empowering developers to seamlessly transition into the developmental phase of our methodology. The design phase emerges as a pivotal precursor to venturing into development within the chosen waterfall methodology. Crafting a user journey and system architecture entails meticulous planning, ensuring developers grasp the fluidity and comprehensive scope of the project. Moreover, a preliminary wireframe design for the user interface has been meticulously sketched to visually illustrate the arrangement of component locations as illustrated in Fig. 8 – Fig. 12.

D. Abstract Architecture

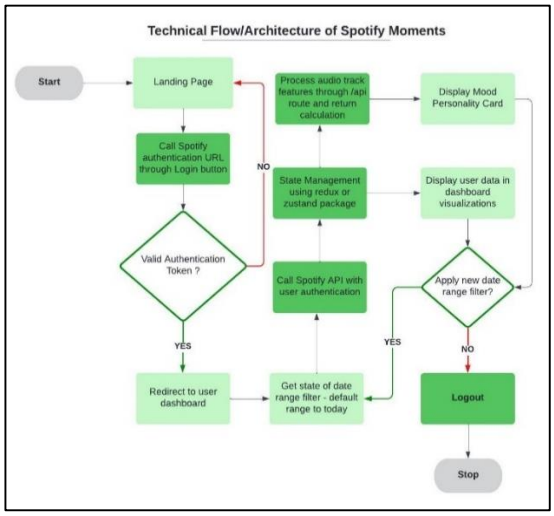

Fig. 10. Natsukashii server-side flow.

E. User Interface Design

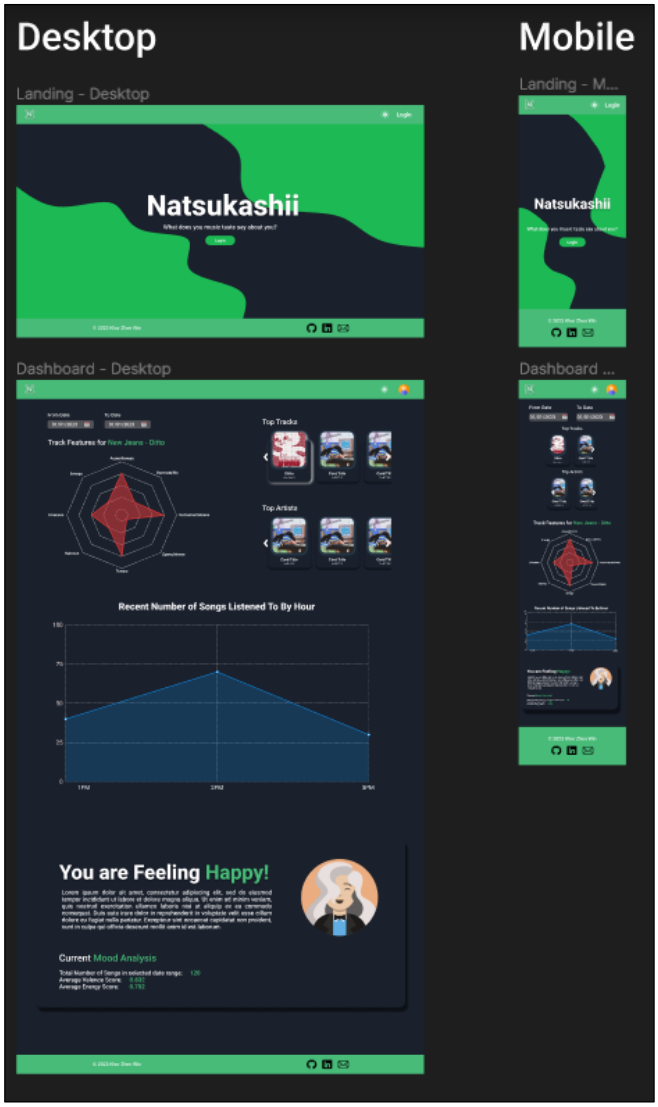

Fig. 11. Natsukashii overall design.

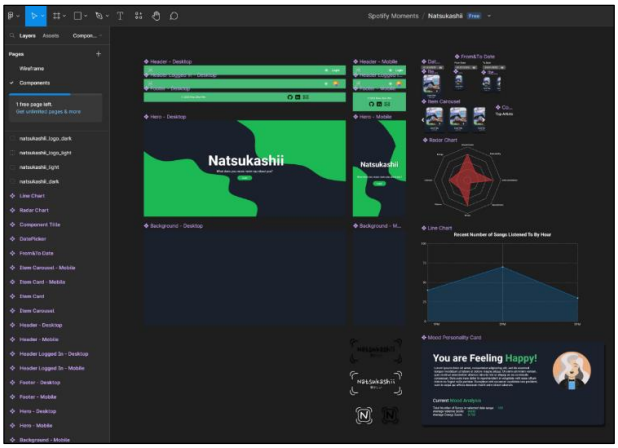

Fig. 12. Natsukashii component level design.

VIII. Implementation

The project Natsukashii has been deployed (see Fig. 13) on https://natsukashii-kzw.vercel.app/ and is freely hosted by Vercel. The application is both available on desktop and mobile browsers alongside light and dark theme modes.

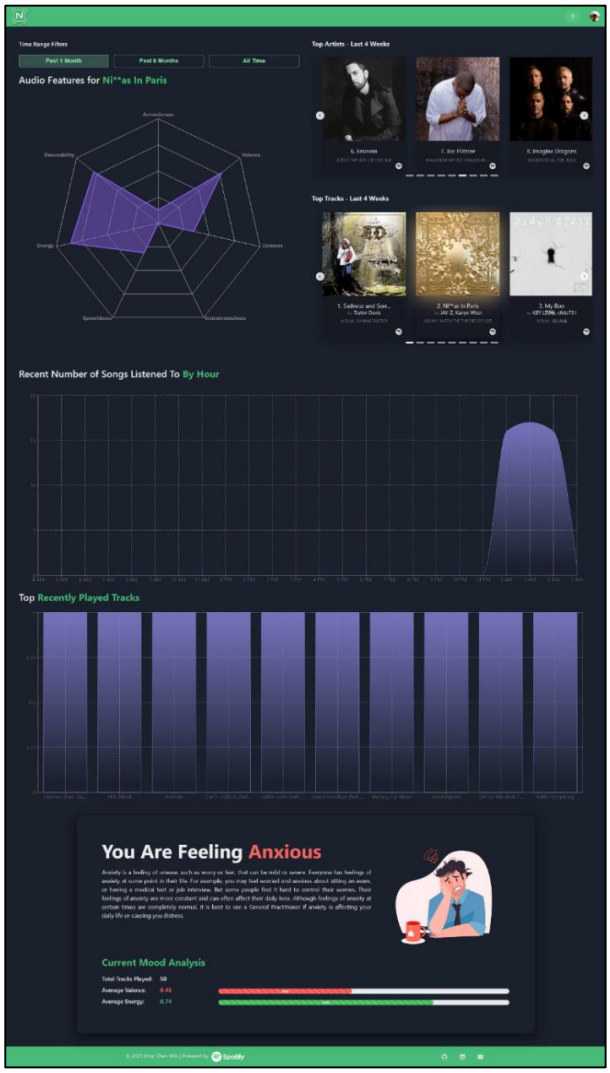

Fig. 13. Natsukashii final system.

IX. System Validation

The testing conducted aimed to ensure the seamless operation of the system both at a granular component level and from the perspective of end users. Unit testing was meticulously performed to assess the functionality and design of each discrete component. Gratifyingly, all unit tests yielded successful outcomes, aligning precisely with the predefined test cases as shown in Table VII. Moreover, a comprehensive system integration testing, serving dually as a user acceptance test, was executed to gauge the platform's efficacy in facilitating the onboarding process for new users. Three proficient testers were enlisted to provide comprehensive feedback and evaluation across four distinct criteria. The culmination of their assessments is encapsulated in the tabulated average score above, wherein all feedback was meticulously addressed, and recommended enhancements were promptly implemented to enrich the overall user experience.

TABLE VII. System Integration Testing Results

Results From System Integration Testing				
Tests	User Interface	User Friendliness	Analytics Insights	Bug-free
Tester 1	4	5	5	5
Tester 2	5	5	5	5
Tester 3	5	5	5	5
Average	4.67	5	5	5

One recommendation remained unfulfilled, namely, the integration of mood with genre types within the sentiment mood profile. This oversight stems from the constraints of Spotify's API, which lacks track genre integration, thereby limiting the ability to analyze diverse song genres effectively.

X. Discussion and Analysis

Throughout the developmental stages of the system, the author conducted comprehensive testing to explore its potential benefits within the scope of personal interests. During data collection, distinct emotional responses were observed across various music genres; for instance, heavy metal music tended to evoke predominantly negative emotions, particularly anger, while classical piano melodies conveyed a sense of calmness. These nuanced insights offer a fresh perspective on how individuals may experience emotions based on their musical preferences. However, it is important to acknowledge the complexity of human emotions, as this correlation may not always hold true universally. Indeed, discussions arose regarding the possibility that certain music genres could simply be a personal favorite without directly influencing one's mood. Nonetheless, such preferences may still provide insights into individuals' personalities, potentially hinting at broader traits such as a tendency towards short-temperedness. This discourse underscores the multifaceted nature of music's impact on human emotions and behaviors, stimulating further investigation into the interplay between musical preferences and personality traits.

XI. Conclusion

Personalized data analytics remains uncommon, largely due to its primary beneficiaries being top-level management. Consequently, research on end-user analytics has been sparse. Exploring the correlation between music and emotional states presents its own challenges, as it's often discussed casually but lacks academic inquiry. However, identifying this gap, the researchers justified the project's significance by drawing upon existing implementations with subtle differences from the proposed system. This process provided the author with insights into bridging industrial contexts with academic research frameworks.

Emotional sentiment analysis through music listening history represents a burgeoning area with promising implications for the medical and psychotherapy domains. By delving into individuals' music consumption patterns,

healthcare professionals can access nuanced insights into emotional states, preferences, and potential triggers. This rich reservoir of data empowers the development of tailored treatment plans, thereby enhancing the management of various mental health conditions. In the realm of psychotherapy, leveraging knowledge about patients' musical preferences fosters deeper therapeutic rapport and enables the customization of interventions to align with their unique needs. Furthermore, the longitudinal analysis of emotional trends derived from music listening histories offers clinicians invaluable tools for tracking progress and fine-tuning therapeutic approaches over time. Ultimately, the integration of music listening histories into medical and psychotherapeutic frameworks promises a comprehensive strategy for comprehending and addressing emotional well-being.

Spotify's current web API support, while functional, is not as comprehensive as one might desire, as outlined in their documentation. Nevertheless, ingenious workarounds were implemented to ensure the timely completion of the project. During its development, the author encountered challenges stemming from limitations within Spotify's developer account, particularly concerning the necessity to whitelist testers for system trials. Consequently, seeking a quota extension to increase API call rates and eliminate the need for user whitelisting became imperative to facilitate the platform's successful launch.

In forthcoming system enhancements, we aim to amplify the adaptability of the dual graphs and sentiment mood profile card, leveraging Spotify's [18] Web API upgrades. This enhancement will empower users with the ability to select flexible time ranges, spanning days, weeks, and months, enabling them to gain insights into their mood over broader durations. Moreover, we plan to introduce a comprehensive FAQ page to enrich the platform's usability. This resource will guide users through site navigation and illuminate the platform's purpose, ensuring a seamless and fulfilling experience for all. These enhancements will seamlessly integrate within the maintenance and support phase of our methodology, ensuring continuous refinement and adaptability, particularly in response to any changes in Spotify API endpoints in the future.

***Abstract*—Hard-constrained controllable text generation aims to forcefully generate texts that contain specified constrained vocabulary, fulfilling the demands of more specialized application scenarios in comparison to soft constraint controllable text generation. However, in the presence of multiple weak correlation constraints in the constraint set, soft-constrained controllable models aggravate the constraint loss phenomenon, while the hard-constrained controllable models significantly suffer from quality degradation. To address this problem, a method for hard-constrained controllable text generation based on latent variables improving on weak correlations is proposed. The method utilizes latent variables to capture both global and local constraint correlation information to guide the language model to generate hard-constrained controllable text at the macro and micro levels, respectively. The introduction of latent variables not only reveals the latent correlation between constraints, but also helps the model to precisely satisfy these constraints while maintaining semantic coherence and logical correctness. Experiment findings reveal that under conditions of weak correlation hard constraints, the quality of text generation by the method proposed exceeds that of the currently established strong baseline models.**

***Keywords*—Latent variables; controllable text generation; weak correlation; hard constraint**

I. INTRODUCTION

Pre-trained Language Models (PLMs) [1] [2] [3] achieve high-quality text generation through learning from massive corpora and modelling the distribution of natural language. To meet the requirements of specific tasks or scenarios, such as simulating conversations, describing data, editing stories, or auto-generating reports, researchers introduce control mechanisms to ensure that the generated text satisfies given constraints. These constraints can encompass aspects such as sentiment, tone, topic, style, and content.

Constrained controllable text generation can be divided into three rudimentary strategies. The first method [4] [5] [6] [7] usually encompasses constraint controllability during the decoding phase. For example, within each Beam in Beam Search, scores are jointly computed based on the constraints and predicted words, eventually selecting the text route that is both highest scoring and meets the constraints. This method comes with a high decoding cost.

The second method applies a non-autoregressive language model (NAR) [8] [9] based on an Insertion-Transformer. During the text generation process, NAR initially generates words that are bound by constraints, gradually refining the text through insertion operations. These hard-constrained methods require multiple rounds of optimization to generate high-quality text, leading to no significant advantage in terms of generation efficiency and text quality compared to autoregressive models.

The third method is a prompt-based approach [10]. It inputs prompts or a piece of text into the model to guide the model in generating text in line with the prompts. This method offers the advantages of low decoding overheads and high generation quality. However, during the initial phase of generation, the model usually focuses on information that is highly related to the prompt, leaning towards generating text skewed away from prompts with weak correlation.

Fig. 1 delineates the process of generating text from four specific cue words: “Apple”, “Mouse”, “Table”, and “Doll”. The relationship among these words is portrayed through a spectrum of colours where darker shades imply stronger connections, as deduced through Euclidean distance. The diagram reveals a hierarchy change from deep hues in the top-left corner to paler ones in the bottom-right, with the confluence of “Apple” and “Mouse” appearing the most intense, indicating their high correlation. Conversely, the link between “Table” and the rest of the cue words is comparatively weaker, with “Doll” exhibiting the lowest correlation. An in-depth analysis of the generated text content reveals that the model gives precedence to “Apple” and “Mouse” during the composition, demonstrates reduced attention towards “Table”, and entirely excludes “Doll”.

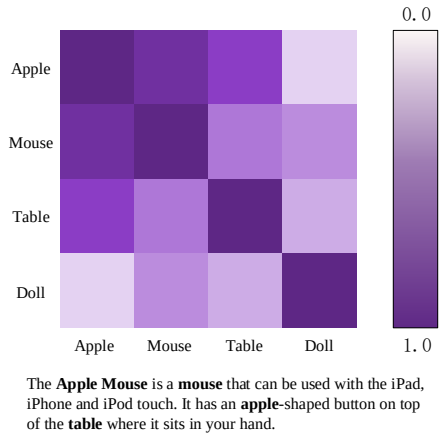

Fig. 1. Example of the constrained controllable text generation problem.

*Corresponding Author.

This case demonstrates that during the initial stages of generation, language models tend to focus more on constraints with stronger relevance. This results in the model deviating from weaker constraints as the generation progresses, moving towards directions less associated with these weaker constraints.

To address this problem, we propose a method that latent variables improve hard-constrained controllable text generation method on weak correlation. This method introduces a latent variable constraint correlation module which initially captures the semantic context related to constraints and decodes to generate ambiguous text as a global constraint correlation. Subsequently, the module integrates the global constraint correlation text with individual constraint using latent variables to acquire localized constraint correlation text. Ultimately, the model combines both global and local constraint information with the context, steering the text generation towards the constraints. Compared to robust baseline models, our model enhances the connection between weak correlation constraints and the context, generating high-quality text that complies with hard constraints.

The sections that follow are organized as follows: Section II provides an introduction and summary of the works on controllable text generation and latent Transformers. Section III elaborates on the methodology of the model. Section IV gives a concise description of the experimental framework. In Section V, we present an array of experimental outcomes and provide an analysis of these results. Finally, Section VI summarizes the study with a thoughtful conclusion.

II. Related Works

This section chiefly summarizes related works on controllable text generation and latent Transformers. Our mission is to guide the model to generate high-quality text in alignment with constraints, which emphasis is strengthening the correlation information of weak correlation constraints.

A. Controllable Text Generation

Controllable text generation represents a pivotal and challenging branch within the field of Natural Language Processing (NLP), giving rise to a diversity of solutions. Initially, Keskar et al. introduced a novel method by appending a control code (domain, style, theme, etc.) at the beginning of the text corpus, training a language model, CTRL, based on various control codes. Subsequently, Dathathri et al. [11] developed the PPLM model, leveraging an attribute discriminator model to guide the PLM in generating text. Building upon the works of CTRL and PPLM, Chan et al.[12] introduced a conditional control module that facilitates precise control over text generation at the level of words and phrases. Krause et al. [13] employed class-conditional language models as generative discriminators (GeDis) to direct the language generation towards the desired attributes. Yang and Klein [14] proposed the flexible and modular Fudge model, which adds an attribute predictor on top of the original PLM to adjust the probability distribution, achieving improved performance in tasks such as poetry generation, thematic text generation, and machine translation. Pascual et al. [4] introduced a straightforward, efficient, and discriminator-free plug-and-play decoding method, K2T. Other researchers have advanced upon NAR, such as Zhang et al.[8], who proposed Pointer, an insertion-based method for constrained text generation. Miao et al. [15] developed a method known as CGMH, which facilitates the generation of constrained sentences through Metropolis-Hastings sampling. He [9] improved upon CGMH by enabling the model to autonomously learn where to insert, replace, and duplicate content.

To address the escalating costs associated with model training, researchers have proposed the use of Prompts. Li et al. [16] applied Prompts to the domain of controllable text generation, introducing prefixes that guide and constrain the output of generative models to yield desired results. Similarly, Lester et al. [17] employed the model to learn "soft prompts" to adjust a frozen language model for performing specific downstream tasks. Han et al. [18] defined a set of logical rules and used Prompts embedded with these rules as input to generate text related to specified categories as the output. Zou et al. [19] suggested a method known as reverse prompt, which employs candidate texts generated by a PLM to inversely predict prompts. Yang et al. [20] introduced a soft prompt-based method for multi-attribute controllable text generation, which diminishes the impact of prompt placement on text quality. Carlsson et al. [10] presented the use of non-residual prompts for fine-grained control of text generation, addressing the trade-off between fine-grained control and the capability for more expressive advanced instructions.

B. Latent Transformers

Compared to the conventional Transformer models, the latent variable-based Transformer introduces an extra latent variable to capture the semantic information of the input sequence, followed by NAR prediction. The approach of using latent variables in Transformer models was initially proposed by Kaiser et al. [21], who incorporated the concept of discrete latent variables to expedite the decoding process. Expanding on this concept, Shu et al. [22] introduced a NAR neural machine translation et al. [24] proposed a method for non-autoregressive translation by learning target category codes, and later introduced a technique for parallel text generation [25] using method utilizing discrete latent variables. Ma et al. [23] combined generative flows with conditional variational autoencoders to efficiently generate conditional sequences. Based on latent variables, Bao discrete latent variables to capture lexical category information, thus mitigating multimodal issues.

This study makes the following three main contributions to hard-constrained controllable text generation, Specifically, as follows:

1) A novel latent variable constraint controllable strategy is proposed to improve the issue of constraint bias in existing language models.

2) Utilizing latent variables to reveal potential connections among constraints, assisting language models in accurately fulfilling given hard constraints while maintaining semantic coherence and logical correctness.

3) Confirming the effectiveness of this latent variable constraint controllable strategy through experimental results. It demonstrates that this method can effectively satisfy weakly

related hard constraint conditions while ensuring the quality of generated text, meeting practical application requirements.

III. METHODOLOGY

Humans form sentences based on constraints through rational combinations and skilful utilization. In other words, the intrinsic message contained in a sentence reveals the latent and profound connections among constraints. Present controllable text generation models mainly focus on learning the probability distribution that coexists with text and constraints, while neglecting the correlated information between the constraints. This limitation often leads the model to favour constraints with stronger correlations when faced with weak correlation constraints. Hence, we guide text generation with constraint correlation information, a method more in line with human thinking. By introducing latent variables, we more effectively unearth the latent correlation within sentences, thereby strengthening their generalization capabilities, especially in managing weak correlation constraints. Beyond that, using latent variables to model target sentences helps to reduce the multimodality problem of sentences. Additionally, learning discrete latent variables directly through a Transformer greatly improves the model's overall operational efficiency.

This section is structured into five main components: Part A illustrates the generation of latent constraint correlations. Part B details the embedding of constraints, Part C describes the framework of model, Part D explains the model training process, and finally, Part E summarizes the model inference.

A. Latent Constraint Correlation Generation

To enhance the capacity of model in handling weak correlation constraints and controllable text generation, we introduce a Latent Constraint Correlation Generation (LCCG) module inspired by the concept of VQ-VAE[26]. This module utilizes latent variables to separately process all constraints and individual constraint, thereby obtaining both global and local constraint correlation information. As shown in Fig. 2, based on the foundation of the Vanilla Encoder of Transformers (VET), we add a Constraint Embedding module and a Target Length Prediction (TLP) module. Moreover, the Multi-head Attention layer (MHA) in the Decoder module is employed as the Decoder for LCCG.

The LCCG is responsible for processing an input X of length m, initially transforming it into embedded vectors through the CE layer, and then feeding these vectors into the TLP layer to predict the target sentence length l, akin to a typical classification task. Its prediction loss is as follows:

$$\mathrm{L}_{len} = -\log p_\theta(y_{len} \mid X) \tag{1}$$

where, θ represents the model parameters.

After obtaining the length value l, the module adopts the Softcopy mechanism proposed by Wei et al. [27] to match the target sentence length. The hidden layer state $H = \{h_1, h_2, ..., h_j\}$, obtained after the process, is then fed into VET to acquire the continuous latent variable $Z = \{z_1, z_2, ..., z_j\}$. To discretize these continuous latent variables, our study employs the Vector Quantised technique. First, define an embedding space $Q \in \mathbb{R}^{K \times D}$ and denote K is the number of vectors e in the embedding space Q. Then, discrete latent variables are assigned to each continuous latent variable through nearest neighbour lookup. The formula is as follows:

$$\begin{aligned} z_{q,i}^{(k)} &= e_k, \\ k &= \arg\min_{t \in [K]} \left\| z_i - e_t \right\|_2 \end{aligned} \tag{2}$$

where, $i \in \{1, 2, ..., m\}$.

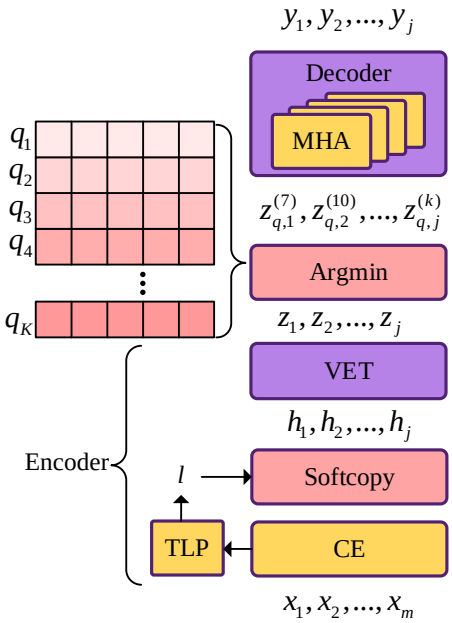

Fig. 2. Latent constraint correlation generation module.

Vector Quantization employs the $\arg\min$ function during forward propagation to obtain discrete latent variables Z_q. As the $\arg\min$ function is non-differentiable, a Straight-Through Estimator is utilized to design the loss, thus the loss for LCCG is as follows:

$$\begin{aligned} \mathrm{L}_{LCCG} &= -\log p_\theta(Y \mid Z_q, X) + \alpha \| z - sg[z_q] \|_2^2 + \beta \mathrm{L}_{len}, \\ sg(\square) &= \begin{cases} x & forward\ pass \\ 0 & backward\ pass \end{cases} \end{aligned} \tag{3}$$

where, $\alpha = 2.5$, $\beta = 2.5$. LCCG updates the embedding space $q_j \in Q$ vectors with an Exponential Moving Average over a small batch of target labels $\{y_1, ..., y_i, ...\}$, which is defined as follows:

$$\begin{aligned} v_j &\leftarrow \lambda v_j + (1-\lambda) \sum_i \mathbb{1}[z_{qi} = j], \\ q_j &\leftarrow \lambda q_j + (1-\lambda) \sum_i \frac{\mathbb{1}[z_{qi} = j] y_i}{v_j} \end{aligned} \tag{4}$$

where, v_j represents the count for the group j, $1[\square]$ is the indicator function, and the decay parameter λ is set to 0.9999 following prior work.

B. Constraint Embedding

To deepen our comprehension of constraints and textual characteristics, we integrate a Constraint Embedding layer positioned between the conventional Token Embedding and Position Embedding layers. The specific framework is illustrated in Fig. 3.

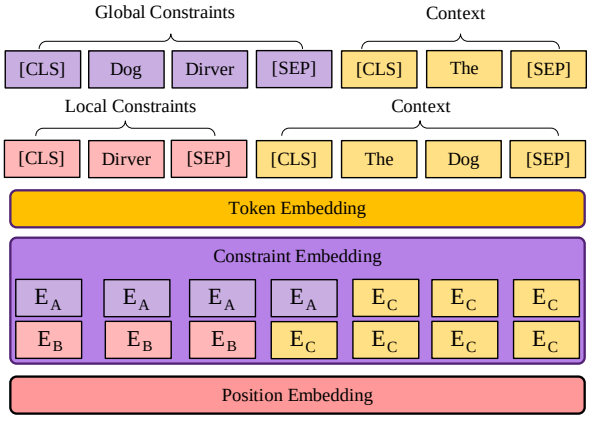

Fig. 3. Constraint embedding layer.

The newly added Constraint Embedding layer embeds three types of input sequences: Global Constraints Sequence, Local Constraints Sequence, and Context Sequence, into three different embedding vectors, namely E_A, E_B, and E_C. In our practical experiments, E_A, E_B, and E_C were set to vectors entirely composed of 0, 1, and 2, respectively. This embedding approach effectively captures the latent information within global constraints, as well as the latent information between local constraints and sentences, thus enhancing the ability of model to understand constraints.

C. Model Framework

Our model adopts an encoder-decoder Transformer architecture similar to BART. As depicted in Fig. 4, the primary function of the encoder is to transform constraints into latent variables. In the decoder section, we have refined the attention mechanism for each layer. The Masked Multi-Head Attention (MMHA) is used exclusively to obscure future information of each token in the context, while the MHA is used for cross-attention between the context and constraint-related information and also as a part of the latent variable decoder.

The Fully Connected layer (FC) is utilized to fine-tune the constraint correlation information and text generation. The given constraints $C=\{c_1,c_2,...c_m\}$ and the context X, let the constraints c_i denote unmet constraints within the context, where $i\in\{1,2,...,m\}$. The satisfaction of fine-grained, controllable text generation requires the following steps:

1) Global constraints text generation: Constraints C are input into the encoder to obtain discrete latent variables Z_G, which then bypass the MMHA module and are passed to the MHA in the decoder, thereby generating global constraint correlation text Y_G:

$$p(Y_G \mid \mathrm{C}) = \prod_{j=1}^{J} p(y_j \mid Z_G, C) \square p(Z_G \mid C) \tag{5}$$

2) Local constraints text generation: This step is different from the first one in that it uses Y_G as the context, which is input along with the constraints c_i. The model generates local constraint correlation text Y_L that is relevant to the constraints based on the input information:

$$p(Y_L \mid c_i, Y_G) = \prod_{h=1}^{H} p_\theta(y_h \mid Z_L, c_i, Y_G) \square p(Z_L \mid c_i, Y_G) \tag{6}$$

3) Constraint-guided text generation: This step entails applying Global Average Pooling (GAP) to Y_G, to obtain P_G. The context X, after embedding, is fed into the MMHA of the decoder while masking future information of the token. Thereafter, X, as the Query, engages in cross-attention calculations with both P_G and Y_L to predict the subsequent token.

$$p(y \mid X, C) = \prod_{n=1}^{N} p_\theta(y \mid X < n, P_g, Y_L) \tag{7}$$

4) Incorporate the predicted token into the context X and reselect constraint c_i. Repeat the operations of the second and third steps until the generated text meets all the given constraint conditions.

Global constraint correlation text provides a macroscopic guiding direction for the language model, while local constraint correlation text serves to refine the relevant constraint text. Considering that the quality requirements for these texts are not high, a non-autoregressive approach is adopted for generation to improve efficiency.

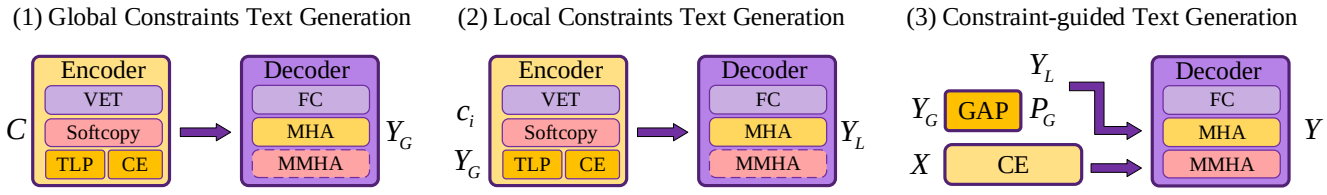

Fig. 4. Procedure for hard-constrained text generation.

D. Model Training

The model training consists of two stages. The first stage is the training of latent variables, where the task is to enable the model to generate both global and local constraint correlation text given the provided constraints and contextual conditions. During this stage, the MMHA layer is frozen. When the input consists of all constraints, the text is used as the training target. When the input consists of a single constraint or global constraint correlation text, the target text is selected from the beginning of the original text or the position after the previous constraint to the end of the original text or the position before the next constraint.

The second stage is the fine-tuning stage, where the encoder, MHA, and MMHA layers of the model are frozen, and only the FC layer of the decoder is fine-tuned. The specific loss function is as follows:

$$\begin{aligned} \mathrm{L} = &-\log p_\theta(y \mid X, P_G, Y_L) - \mu \log p_\theta(Y_G \mid C) - \\ &\eta \log p_\theta(Y_L \mid c_i, Y_G) \end{aligned} \tag{8}$$

where $\mu = 0.4$, $\eta = 0.6$.

E. Inference

Cross-attention between constraints and context is an effective soft constraint method for language models. However, it is challenging to train a model to generate text that fully incorporates constraints, often requiring additional processing. Therefore, in the inference stage, we draw inspiration from the work of Pascual et al. [4] and make some improvements to ensure that the model's output meets the constraints.

In concrete terms, we involve treating a subset of words from the correlated text as a set of guiding words, denoted as set W, while disregarding the order of these guiding words. At each decoding step t, a new subset of guiding words, denoted as set W_t, is selected from set W, consisting of guiding words that have not appeared before the current time step. The top-k algorithm is then employed to select the k most likely predicted words from the predicted word set. Subsequently, the similarity between each predicted word y_t and guiding word w is computed, $w \in W_t$. This similarity is then weighted with the probability distribution of each predicted word, resulting in a reweighted probability distribution for the current word. The formula is as follows:

$$\begin{aligned} score(\cdot \mid y_{1\cdots t-1}) &= \log p(\cdot \mid y_{1\cdots t-1}) \\ score'(y_t, W_t \mid y_{1\cdots t-1}) &= score(y_t \mid y_{1\cdots t-1}) + \\ &\lambda \max\left\{0, \max_{w \in W_t}\left[\cos(y_t, w)\right]\right\} \end{aligned} \tag{9}$$

where, $score(\cdot \mid y_{1\cdots t-1})$ is the scoring function, and scores are used for sampling. $score'(y_t, W_t \mid y_{1\cdots t-1})$ is the overloaded scoring function, which takes the guiding word set W_t as input. Parameter λ adjusts the transition of tokens generated by the model from being unconstrained to becoming the next guiding word. The calculation for λ is as follows:

$$\lambda_t = \begin{cases} \lambda_0 \exp\left\{\dfrac{c(t-t_n)}{T-|W_t|-t_n}\right\} & t < T-|W_t| \\ \infty & t \geq T-|W_t| \end{cases} \tag{10}$$

where, T represents the length of the text under local constraints, t_n denotes the position where the last guiding word appeared. The hyperparameters λ_0 and c are used to control the initial value and increment of λ. In this context, they are set to 10 and 100, respectively. When $\lambda \to \infty$, the predicted word is forced to be a constrained guiding word, and the current local constraint is terminated. Then, the model enters the next local constraint while updating the guiding word set W.

IV. Experimental Setup

In this section, we list the datasets suitable for the text generation method used in our study, then outline the metrics for both automatic and human evaluations, and finally provide a description of the experimental details.

A. Datasets and Evaluation Metrics

1) Datasets: The experiments consist of two tasks, starting with the model pre-trained on the Wikitext-103-raw-v1 dataset. The first task is focused on constraint-driven controllable text generation, with the objective to evaluate and ascertain if this approach enhances the model's competency in excavating and understanding the latent connections among constraints, as well as if it elevates the quality of text production. The data for the experiments include CommonGen [28], Yelp Reviews [29], and E2ENLG [30], with detailed information presented in Table I.

TABLE I. The Comparison Statistics of Datasets

Datasets	Train	Valid	Test	Total
Wikitext-3-raw-v1	1801.35k	3.76k	4.35k	1805.7k
CommonGen	67.39k	4k	1.5k	68.89k
Yelp Reviews	650k	46.5k	50k	700k
E2ENLG	42.1k	4.67k	4.69k	4.79k

Table I compares the parameters of the training sets, validation sets, and test sets for the Wikitext-103-raw-v1, CommonGen, Yelp Reviews, and E2ENLG datasets.

CommonGen dataset is used for model training in commonsense reasoning benchmark tasks, where the goal is to generate a coherent and commonsense sentence given a set of common concept words. The training, validation, and test sets of CommonGen dataset comprise 67,389, 4,018, and 6,042 sentences respectively. Each sample features has three to five key concepts with an average sentence length of 11 words.

Yelp Reviews dataset contains over fifty million reviews. Our study builds upon the data processing work of He [10] on the Yelp Reviews dataset, who chose a keyword set from a thousand sentences that could not cover the entire text extensively. This work constructs a keyword set based on word frequency, eliminating Stopwords and selecting the top 5,000 most frequent words to assure the quality of the set. Exclusions are made for samples without the keywords. For each case, the

corresponding target word is a term from the keyword collection, supplemented by additional words randomly chosen from the sample to enhance the target word's diversity.

E2ENLG dataset is an end-to-end text generation dataset for the restaurant industry, with tasks requiring the generation of descriptions based on multiple key-value pairs. E2ENLG dataset provides a crowdsourced corpus of 50k instances, each with a Meaning Representation (MR) shaped by dialogue acts and accompanied by up to 16 natural language references.

2) Evaluation metrics: We employ both automatic and manual evaluations to demonstrate the enhanced generative performance of our model in universal text generation. For automatic evaluation of generation quality, the paper employs Perplexity (PPL), BLEU [31], NIST [32], and DIST [33] as indicators to measure the similarity between the generated text and human references. Higher scores in BLEU and NIST denote that the model is capable of crafting sentences closely resembling those made by humans.

a) PPL low value often indicates better linguistic fluency. c, degraded repetition can also result in a reduced perplexity score. Hence, one should not rely solely on perplexity, but should combine it with other metrics and qualitative analysis.

b) BLEU Lower-order assesses word-level accuracy, whereas higher-order BLEUs can gauge sentence fluency. We adopt both BLEU-2 and BLEU-4 for evaluation.

c) NIST is an improvement over the BLEU method. It introduces the concept of the information quantity of each n-gram. The NIST score is derived by accumulating the information quantity and then dividing by the total number of n-grams in the translation, effectively placing more weight on less frequent words.

d) DIST measures diversity by dividing the number of unique n-grams by the total number of n-grams; a higher value indicates greater diversity in the text.

For the human evaluation component, this study expands upon the framework established by He [10], incorporating an additional dimension, semantic consistency. The comparative performance of the models is assessed across three criteria: semantic consistency, the smoothness of the sentences, and the richness of information conveyed. In pursuit of impartiality, a set of 50 sentences is chosen at random, and five evaluators are enlisted to review the sentences produced by varying models. These evaluators are tasked with delivering their assessments premised on the consistency in meaning, the fluidity of the text, and the depth of information presented. In instances where the evaluators find themselves unable to discern a clear winner, the outcome is declared a draw. Prior to the annotation process, the sequence of sentences is shuffled to eliminate any potential for prejudice.

B. Experimental Details

In terms of model parameters, this study adopts the pre-trained parameters from BART to serve as the model's initial parameters for fine-tuning tasks. For the first two rounds of training, the learning rate is set at 1e-3, and it is reduced by 3e-4 in each successive round until it reaches the threshold of 1e-5. The experiments utilize an Nvidia RTX A5000 GPU, and taking into account the experimental hardware and training efficiency, the batch size is determined to be 64. The study sets the character length limit to 128. In addition, the paper introduces a regularization parameter to curb overfitting during the training phase. The regularization parameter is established at 0.04, informed by the training performance. Across all tasks, the AdamW algorithm is employed for model optimization.

V. Results and Discussion

This section comprehensively discusses the experimental and analysis work we have undertaken, divided into six parts: automatic evaluation, human evaluations, weak correlation constraint analysis, ablation study, hyperparameter analysis, and generating instances. The principal aim of both part A and part B, automatic and human evaluations, is the appraisal of our model's text generation calibre. Analysis touching on weak correlation constraint investigates how the quality of text is influenced when this study's model, as well as benchmark models, face several weakly related constraints. Part D, Ablation study, validates whether the integration of a latent constraint-association generation module in our model enhances the handling of weak correlation constraints. Part E is hyperparameter exploration segment, which discusses the model's performance under varying parameter configurations. Part F, the exemplification analysis showcases instances of text generated by our model.

The model proposed is compared with three of the latest strong baseline fine-grained text generation models (Keyword2Text (K2T) [4], NRP [10], CBART [9]) and one traditional baseline (Pointer[8]).

The Pointer utilizes the Insertion Transformer architecture for hard constraint text generation, which still has room for improvement regarding the quality of output. The CBART, using an Encoder-Decoder structure for non-autoregressive hard constraint generation, has enhanced the quality, yet it struggles with quality reduction under weak correlation constraint conditions, similar to the plug-and-play controlled decoding approach of K2T. The NRP, utilizing a non-residual attention mechanism, betters text generation but risks constraint loss within contexts of weak correlation constraints. Our model is capable of generating text that meets weak correlation constraints, thereby enhancing the quality of generation.

A. Automatic Evaluation Results and Analysis

This experiment evaluates the text generation quality of the improved model versus the baseline models on three test sets: CommonGen, Yelp Reviews, and E2ENLG.

As shown in Table II, on the Common Gen test set, our model is slightly inferior to the K2T model in terms of NIST scores, but demonstrates a distinct advantage in BLEU and DIST scores. This is due to the fixed mapping from keywords to text in the K2T model, which thus offers relatively poor text diversity. The performance of our model on DIST-4 is comparable to that of NRP, but slightly superior to NRP on DIST-2. This suggests that the improved model can exhibit more granular controllability when generating high-quality sentences.

TABLE II. AUTOMATIC EVALUATION EXPERIMENTS SCORES COMPARISON

Datasets	Models	BELU↑		NIST↑		DIST↑		PPL↓	Len
		B-2	B-4	N-2	N-4	D-2	D-4		
CommonGen	K2T	19.5	4.25	7.52	7.63	0.72	0.95	25.27	7.1
	CBART	17.44	5.34	5.01	3.15	0.71	0.98	32.62	5.7
	NRP	20.15	7.28	7.43	7.59	0.74	0.99	24.01	6.3
	Pointer	10.18	1.77	2.23	2.4	0.45	0.9	72.82	7.2
	Ours	22.92	9.21	7.22	7.36	0.78	0.99	22.73	6.8
Yelp Reviews	K2T	25.6	8.25	7.53	7.61	0.69	0.89	31.19	17.2
	CBART	18.41	7.4	2.54	2.63	0.48	0.94	50.61	15.7
	NRP	23.52	9.11	8.47	8.66	0.74	0.91	35.78	20.3
	Pointer	11.48	2.46	2.14	2.16	0.35	0.68	101.8	27.2
	Ours	26.25	9.52	8.42	8.51	0.82	0.95	40.23	16.8
E2ENLG	K2T	27.1	9.1	8.44	8.65	0.78	0.92	25.79	12.4
	CBART	20.22	8.06	3.46	3.67	0.82	0.91	34.21	13.4
	NRP	26.33	9.23	8.42	8.7	0.81	0.98	20.18	15.3
	Pointer	12.65	2.98	2.39	2.43	0.55	0.83	60.84	14.2
	Ours	29.01	9.78	8.65	8.81	0.86	0.99	19.86	16.1

[a.] Note: Bold numbers indicate the optimal values under this dataset and evaluation method. B-2, B-4 represent the BLEU evaluation method using 2-gram, 4-gram, respectively, with NIST and DIST following a similar pattern.

Our study further evaluated the performance of our model on the Yelp Reviews test set. The results indicated that our model is comparable to the highly-rated NRP model in terms of NIST score, while it also achieves the highest scores in BELU and DIST metrics. This reflects our model deals with the constraints on latent variables, as well as its inclusion of some extraneous noise in the prompt transformation process, impacting its understanding and generation capabilities. Owing to the learning ability of latent variables, our model still surpasses baseline models in terms of generation quality.

On the E2ENLG test set, our model scored the highest across all evaluation metrics. It exceeded the CBART model by 0.04 points in DIST score and the K2T model by 0.2 points in NIST-2 score. This suggests that the model also slightly outperforms baseline models in terms of text diversity and coherence. According to the assessment data from CBART and Pointer, it can be observed that the quality of non-autoregressive generation is slightly lower than that of autoregressive generation.

B. Human Evaluation Analysis

Table III shows that our model outperforms the baselines in terms of semantic consistency, fluency, and informativeness, which is even comparable to human levels in sentence fluency and semantic consistency. In text fluency, our model slightly exceeds the baseline models, and considerably surpasses the baselines in both semantic consistency and sentence informativeness. However, our model still falls behind humans in terms of sentence informativeness, this is attributed to the model's excessive focus on text fluency, leading to the generation of sentences that are shorter and less informative than those referenced by humans.

In summary, the evaluations demonstrate that the improved model excels in text generation quality, surpassing other baseline models. This also validates the superior performance and generalization capability of our model in the domain of controlled text generation.

C. Weak Correlation Constraint Analysis

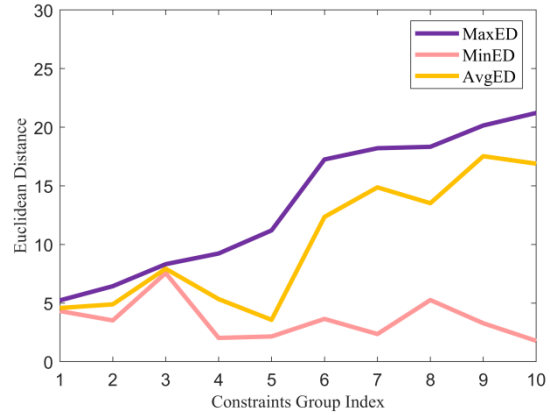
This section is dedicated to analyzing the impact of weak correlation constraints on the model. Existing pre-trained language model is black-box model, and the features they learn from constraints lack interpretability. Therefore, we assess the strengths and weaknesses of the relationships between constraints based on their Euclidean distance, allowing for a more precise measurement of the constraints' impact on the model. Compared to simply measuring the strength of relationships between constraints based on co-occurrence frequency, Euclidean distance can more effectively evaluate the similarity of features among constraints, making this method more comprehensive and accurate.

TABLE III. HUMAN EVALUATION SCORES COMPARISON: %

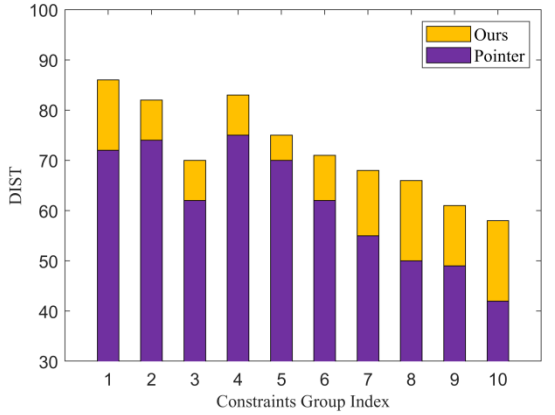
Metrics	**Model A won**		**Tied**	**Model B won**	
Semantic Consistency	Ours	63.5	15.2	21.3	K2T
	Ours	55.6	10.3	34.1	NRP
	Ours	32.6	21.4	46	Human
Sentence Fluency	Ours	47.5	20.3	32.2	K2T
	Ours	42.7	14.8	42.5	NRP
	Ours	30.1	29.7	40.2	Human
Sentence Informativeness	Ours	71.6	10.4	18	K2T
	Ours	64.3	7.5	28.2	NRP
	Ours	23.5	12.9	63.6	Human

[b.] Note: “Consistency” represents which sentence is more consistent; “Fluency” stands for which sentence is more fluent; “Informativeness” indicates which sentence is more informative?

Within an individual sample, for a given set of constraints $C = \{c_m, m \in \square_+\}$, $((m-1)*m)/2$ Euclidean distances can be computed. To better evaluate the model under the influence of constraints, we examined the maximum Euclidean distance (MaxED), the minimum Euclidean distance (MinED), and the average Euclidean distance (AvgED) separately. MaxED can assess the model's capability to handle weak correlation constraints, while MinED can evaluate its ability to deal with strong constraints. These two values also provide insights into the dispersion among the constraints within the set. AvgED offers a more comprehensive metric, presenting an overview of the overall distribution of the constraint set.



(a) Euclidean Distance Line Graph of Constraints Group



(b) DIST Score Bar Chart

Fig. 5. Weak correlation constraint analysis chart.

Subfigure (a) of Fig. 5 reveals an inverse relationship between MaxED among constraints and the quality of sentence generation, indicating that the weaker the relevance of the constraints, the more challenging it is for the model to generate high-quality sentences. Furthermore, if MinED is close to AvgED, it suggests that the constraints are generally weakly correlated, and the quality of the sentences generated by the model is primarily influenced by AvgED. However, when MinED greatly differs from both MaxED and AvgED, strongly related constraints have a minor impact on the quality of sentence generation by the model. According to subfigure (b) of Fig. 5, when the constraints are weaker in correlation, our improved model consistently outperforms the comparison model Pointer in terms of generation quality, and its rate of decline is also slower than that of Pointer. The analysis verifies that the model ensures quality generation when facing weakly related constraints and that the improvement method can effectively handle weak correlation constraints.

D. Ablation Study

Reflecting on the analysis of weak correlation constraints from the, it's evident that these constraints largely influence the quality of the model's output. To substantiate the preceding section advancements of our model in managing weak correlation constraints, we conducted an ablation study. The study was structured such that each set of constraints included two strongly related constraints, with a progressive addition of weak correlation constraints to discern the disparity in output quality between models applying the LCCG module and those without it, referred to as Non-LCCG.

According to the data presented in Table IV, the assessments indicate enhancements in models incorporating the LCCG module compared to those which do not include it. More specifically, the inclusion of LCCG led to an increase of 4 to 7 percentage points in BLEU-2 scores, a rise of 2 to 3 points in NIST-2, and a significant enhancement of 15 to 20 percentage points in DIST-2. The evidence suggests that with the addition of weak correlation constraints, the gap in generative quality between the two approaches diminishes.

TABLE IV. ABLATION STUDY SCORES COMPARISON

Count	Models	Automatic Evaluation Metrics		
		BLEU	NIST	DIST
0	Non-LCCG	18.47	4.32	0.76
	LCCG	35.46	7.13	0.98
1	NON-LCCG	12.25	3.67	0.69
	LCCG	26..16	6.21	0.87
2	NON-LCCG	10.07	2.93	0.53
	LCCG	15.24	5.21	0.75
3	NON-LCCG	4.16	2.05	0.41
	LCCG	8.2	4.33	0.56

[c.] Note: The count refers to the number of newly added weak correlation constraints. BLUE, NIST, and DIST indicate that the evaluation method uses 2-grams.

The experimental outcomes emphatically confirm the noteworthy efficacy and superiority of our proposed technique in handling weak correlation constraints. The research, underscored by its experimental design and data interpretation, verifies the method's precision and robustness when confronting issues related to weak correlation constraints.

E. Hyperparameter Analysis

Hyperparameters are significantly influential in both the performance and training process of the model. After completing training in the initial phase, the model has adeptly learned the art of autoregressive text generation and the ability to infer text that adheres to latent variable constraints.

Therefore, in the second phase, we also fine-tuned the loss weight associated with the latent variable constraints. Excessively high loss from latent variable constraints may hinder the language model's ability to find the optimal solution

for incorporating latent variable constraints, while too low a loss might fail to ensure that the generated text complies with the constraints. As depicted in Fig. 6, based on feedback from experimental results and our experience, we adjusted the latent variable constraint loss weight μ to 0.4 and η to 0.6 to strike a better balance.

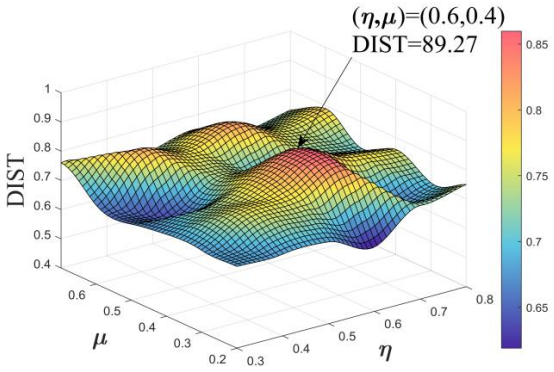


Fig. 6. Hyperparameter analysis.

F. Instance Analysis

In Table V, Case 1, "Basketball" "Forest" and "Paper" are weak correlation constraints. The K2T model generates semantically inconsistent sentences, while the NRP model focuses on the constraints of "Forest" and "Paper" which are Constraints with a strong correlation, neglecting "Basketball" However, our model using latent variables, finds the potential connections between these three constraints. It interprets "Forest" as the venue and "Paper" as paper packaging, and uses "Basketball" to link them together.

TABLE V. GENERATING INSTANCES WITH WEAK CORRELATION CONSTRAINTS

Constraint Case	Models	Instance Output
Basketball, Forest, Paper	K2T	When playing basketball in the forest, I use paper to achieve floating flight.
	NRP	In the forest, I found a paper airplane, which made me feel the flying green leaves and fresh air.
	Ours	We were playing basketball in the forest when we accidentally spilled our paper wrapped lunch.
Phone, Rocket, Eat, Floor	K2T	Eating rocket shaped mobile phones on the floor feels really delicious.
	NRP	The floor of the Rockets is very smooth, and the players are eating cake while making phone calls
	Ours	While I was eating, my phone suddenly slipped from my hand like a rocket and fell onto the floor.
Apple, Mouse, Table, Doll	K2T	I placed a mouse and a doll next to the apple, hoping that they could entertain each other.
	NRP	The Apple Mouse is a mouse that can be used with the iPad, iPhone and iPod touch. It has an apple-shaped button on top of the table where it sits in your hand.
	Ours	The doll was sitting on the table with an apple beside it, while a mouse scurried across the floor.

[d] Note: In the output sentence, words that are constraints are highlighted in bold.

Similarly, in Case 2 of Table V, the four constraints have a weak correlation. The K2T model poorly handles the constraints, resulting in sentences with illogical constructions. The NRP model still focuses on the more related constraints, leading to sentences with less information. However, our model did not encounter such issues, instead, it makes a reasonable arrangement based on the latent characteristics of these four constraints, forming a semantically coherent sentence.

In Case 3 of Table V, NRP primarily focuses on "Apple" and "Mouse" generating a sentence related to the technology field, consequently overlooking "Doll." K2T considers constraints more comprehensively than NRP but also experiences issues with constraint loss. In contrast, our proposed model didn't lose any constraints and didn't simply interpret "Apple" and "Mouse" as the company brand and technology product, respectively. By thoroughly considering the potential relationships between these four constraints, an optimal solution was found, and a high-quality sentence was successfully generated while satisfying all the constraints.

VI. CONCLUSION

In our study, we conduct an extensive study on the problem of hard-constrained controllable text generation, and propose a novel latent variable constraint-controllable strategy. The strategy effectively deals with the existence of multiple weak correlation constraints in the text generation process from the language model. Through a series of experiments, the results confirm that the strategy significantly improves the quality of controllable text generation and satisfies the weak correlation constraints.

This study makes significant progress in the direction of hard-constrained controlled text generation, there are still many areas to be explored and deepened, such as the excessive decoding time. In our future work, we intend to further optimize the latent variable constraint-controllable strategy and endeavor to adjust the initialization and capture of latent variables to more accurately reveal the relations between constraints and generate constraint-compliant text more quickly and efficiently.

Foliar Nitrogen Estimation with Artificial Intelligence and Technological Tools: State of the Art and Future Challenges

Ángeles Gallegos, Mayra E. Gavito*, Heberto Ferreira-Medina
Instituto de Investigaciones en Ecosistemas y Sustentabilidad, Universidad Nacional Autónoma de México
Antigua Carretera a Pátzcuaro No. 8701, Col. San José de la Huerta, C.P. 58190. Morelia, Michoacán, México

***Abstract*—Nitrogen plays a fundamental role in plant growth, but its high application has significant negative impacts for the farmers and the environment. This nutrient is often provided in excess to prevent plant growth limitations when it ought to be administered in the exact quantities because many farmers do not have access to technology or affordable soil and plant chemical analyses. Precision agriculture through monitoring of crop nutrition may be possible with quantitative, non-destructive methods and technological tools that allow farmers to conduct a rapid and representative verification of their fertilizer applications. In this sense, we carried out a systematic review and bibliometric analysis of recent scientific research to answer the questions: 1) Can artificial intelligence-based, non-destructive analysis of plant nutrition provide relevant information for decision-making in agricultural systems?, 2) Have recent studies reached the stage of developing technological tools to be applied in agricultural systems and field conditions?, and 3) What is the way forward to achieve popularization of the application and development of technological tools in agricultural systems? We found that non-destructive analyses of foliar nutrition need to provide more supportive information for decision-making given the challenge of interpreting and replicating results in agricultural systems operating under uncontrolled conditions, such as field conditions. To address this issue, we propose developing accessible technological tools, such as mobile applications, tailored to farmers' needs. However, most studies had not yet considered developing a technological tool as part of their objectives. Therefore, it is critical to develop accessible and affordable technologies and monitoring systems that approach precision agriculture since the conservation and sustainable management of natural resources demands translating scientific knowledge into supporting tools that reach farmers and decision-makers worldwide. The way forward is innovation through technological developments that enhance current agricultural systems.**

Keywords*—Digital images; spectral data; estimation models; technological tools; nitrogen

I. Introduction

Deficiencies of macro and micronutrients essential for plant growth can limit crop yields. As a result, farmers increase the use of chemical fertilizers to prevent nutrient limitations [1]. Unfortunately, the excessive use of fertilizers to ensure good production is popular today, despite the high costs involved and the fact that it is one of the most influencing factors in the degradation of soils and aquifers [2].

Ensuring effective fertilizer management is one of the main paradigms of precision agriculture. Precision agriculture is a strategy that seeks to increase productivity in agricultural fields by improving crop yields and assisting farmers in management decisions using high-tech analysis tools [3]. This type of agriculture requires the intensive collection and processing of spatio-temporal data on crops [4].

The most widespread method to obtain crop nutrient data to verify that fertilization is adequate fertilization was achieved is by carrying out destructive analyses of plant tissue and soils using laboratory chemical procedures, given that fertilization should complement soil available nutrients and the requirements of each crop. However, the periodic and systematic achievement of this type of analysis is time-consuming and costly, and the results are sometimes difficult for farmers to interpret. As a result, these activities are never performed at all or, in the best case, on a rare basis as a routine check of fertilization efficiency, and "panic" over-fertilization prevails.

There are also non-destructive methods for diagnosing the nutritional status of plants, which are fast but less accurate. These methods include the use of color charts for visual evaluation of plant leaves [5], sensors for chlorophyll measurement [6], and the use of digital information, such as images, for plant color analysis [7], all of which can support the implementing of precision agriculture. For example, on the one hand, [8] reviewed the available information for determining plant nitrogen through remote sensing. They found that there is still a need to generate more knowledge, especially in the agricultural domain, even though their research has identified guidelines to help selecting the appropriate sensor based on the specific objective of each study.. On the other hand, [9] also explored the usefulness of remote sensing. They focused on evaluating nitrogen in cereals, concluding that accurate and timely field monitoring is essential to guarantee crop performance and protect the environment by adjusting applications of fertilizers. However, while these methods can save resources, they are not always within the reach of farmers. This may be due to the cost of acquisition (in the case of sensors), the impossibility of applying them (image analysis requires computational algorithms), or the difficulty in understanding the results (chlorophyll measurements are not interpretative).

*Corresponding author

In this sense, the scientific community has made significant efforts to develop non-destructive methods and technologies to reduce the negative impacts of over-fertilization on the environment. Artificial intelligence (AI) branches, such as Machine Learning (ML) and computer vision with Deep Learning (DL), have been used to provide consistent assessments of the nutritional level of distinct types of crops in a fast, economical, and reliable way [10], [11]. However, farmers apply AI-generated models for estimating the nutritional status of plants in uncontrolled conditions within agricultural systems in a very sparse manner. In addition, these automated systems hardly evolve to the innovation of a technological tool, such as software, web systems, or mobile applications, to support farmers in non-destructive and cost-effective field determinations.

One of the most significant nutrients studied with AI models is nitrogen (N) due to its fundamental role in plant growth through cell division, protein synthesis, and enzyme production [12]. However, there is evidence that excessive N addition has led to significant negative impacts on the environment, such as aquifer contamination [13], [14], harmful accumulation of nitrates and nitrogen dioxide (carcinogenic substances) in cultivated plants [15], and the acceleration of soil acidification and salinization through N transformation processes [16]. Therefore, N must be administered only in the precise amount needed to satisfy the nutritional goals.

The fact that N concentration is related to leaf color in many plants makes color a valuable parameter that serves as a basis for estimating foliar nitrogen levels [17]. For example, [18] presents the results of a conducted review of non-destructive techniques for determining foliar N, based primarily on color analysis parameters. They found that digital image processing attracts agricultural scientists due to its promising results and moderate cost.

Quantitative chemical or biochemical analyses and color measurements made on the same plant tissue, and critical foliar nutrient concentration values, are required as references to establish color values and build color charts that accurately reflect measured nutrient levels [19]. Several color guides have been produced and printed on paper for the main cereals, given that nutritional deficiencies are evident in grasses [20]. Mobile applications have also been developed in recent years [21], [22].

This work aimed to carry out a systematic review and bibliometric analysis of the current state of scientific knowledge on the evaluation of the nutritional status of plants using a quantitative, AI non-destructive approach, to provide relevant information for decision-making in agricultural systems under field conditions. This review's contribution is to present recent knowledge and identify its potential for the generation of accessible technological tools that might serve as low-cost support for promoting the rational and adequate use of fertilizers within the framework of sustainable precision agriculture.

II. Materials and Methods

The traditional methodology “Preferred Reporting Items for Systematic Review and Meta-Analysis” (PRISMA) [23] was followed to conduct a systematic review of current scientific knowledge. This review mainly focuses on nitrogen content, as color characteristics can conveniently detect nitrogen deficiencies and excessive concentrations for adequate fertilization of crops.

The PRISMA methodology was complemented with the PSALSAR methodology [24]. In addition, a bibliometric analysis was carried out to evaluate the production, visibility, and impact of the scientific literature related to the topic of study (see Fig. 1).

The research questions posed for this review were: 1) Can artificial intelligence-based non-destructive analysis of plant nutrition provide relevant information for decision-making in agricultural systems?, 2) Do studies reach the stage of developing technological tools for application in agricultural systems under field conditions?, and 3) What is the way forward for the popularization of the development and application of technological tools in agricultural systems?

Relevant platforms were used to search for information. The selected databases were Scopus[1], Science Direct[2], and Web of Science[3]. Initially, the search terms were specific, including "nitrogen" and "color", however, the results were limited; so, the search was broadened to include the keywords "machine learning" and "deep learning" (see Table I). The search was restricted to publications from the last ten years, as this work aims to gather information on the most recent technologies and processing methods.

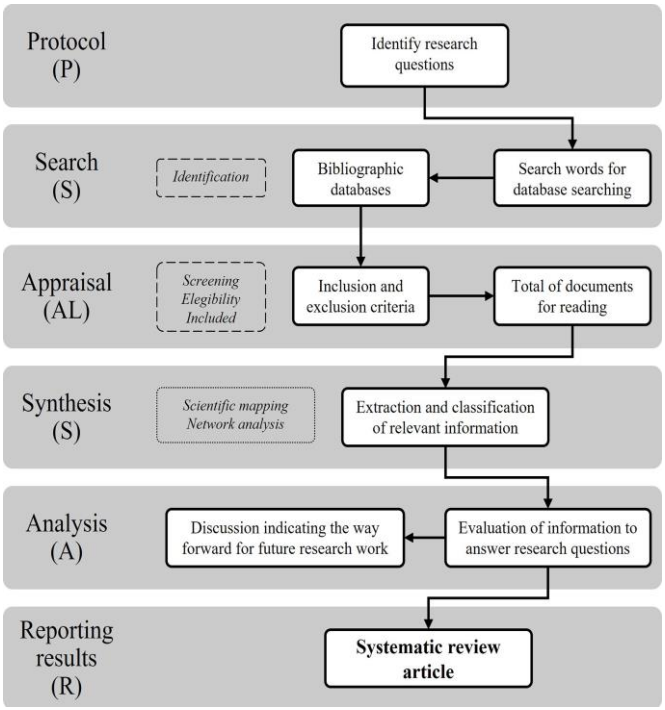

Fig. 1. Phases of the psalsar methodology applied in this systematic review. Scientific mapping and network analysis were performed as part of the bibliometric analysis.

TABLE I. SEARCH TERMS FOR COMPILING SCIENTIFIC ARTICLES ON PROCESSING DIGITAL PLANT LEAF IMAGES TO EVALUATE THEIR NUTRITION

Data bases	Searching string		No. of articles *	Consultation date
Scopus	Article title, abstract, keywords	"nitrogen" AND "color" AND "plant leaf" AND "image processing"	15	September 19, 2023
		"plant leaf" AND "deep learning" AND "nitrogen"	10	
		plant leaf AND machine learning AND nitrogen	22	
Science Direct	Advanced Search Find articles with these terms	"nitrogen" AND "color" AND "plant leaf" AND "image processing"	104	September 19, 2023
		"plant leaf" AND "deep learning" AND "nitrogen"	80	
		"plant leaf" AND "machine learning" AND "nitrogen"	152	
Web of Science	Search in: Collection Editions: All	nitrogen (All Fields) and color (All Fields) and plant leaf (All Fields) and image processing (All Fields)	74	September 19, 2023
		plant leaf (All Fields) and deep learning (All Fields) and nitrogen	48	
		plant leaf (All Fields) and machine learning (All Fields) and nitrogen	222	

[a.] The documents considered include review and research articles written in English from 2013 onwards.

The collected articles were evaluated using inclusion and exclusion criteria based on the objective of the review work. The inclusion criteria were a) search words exist in the title, keywords, or summary, b) the article must be written in English, c) the article's publication date is less than ten years, d) ML or DL models were used, e) the precision or uncertainty of the predictive models was calculated, and f) relevant gray literature documents (not conference proceedings) are acceptable. The exclusion criteria did not consider duplicate articles and documents not accessible.

After omitting inaccessible or duplicate articles and checking that the search words existed in the title or keyword section, 174 documents were left for initial review, which were downloaded from the search platforms and stored locally. Subsequently, the abstract of all articles was read and classified into two groups: 1) studies focused on the identification of nutrient levels, and 2) studies for the detection of pests and diseases in plant leaves, which were discarded. In total, 111 articles were collected using images and data from the leaves of different plants for the study of nutrient levels. A second search was carried out from the references cited in those articles to obtain 123 articles for full reading.

The relevant information of the selected articles was extracted and classified. This phase was complemented by scientific mapping and network analysis with the bibliometric method to identify the relationships between different research areas in the context of producing scientific papers [25]. Conducting a meta-analysis was not possible due to the wide heterogeneity of the studies reviewed.

Through scientific mapping it is possible to recognize the most influential works based on the classification and visualization of studies without the subjective bias of non-systematic literature reviews [26]. Network analysis uses graph theory to calculate the number of times that a) a document has been referenced by others (indegree), b) a particular node cites others (outdegree) [27], and c) the degree of intermediation of each element within the network (betweenness) [28].

Analysis of citations, co-citations, bibliographic coupling, co-authorship, and co-occurrence of words was applied in 117 studies of this review. In addition, 105 documents were synthesized in the supplementary material, 11 studies were not included because their methodology was unclear, and seven were review documents.

The tools used for scientific mapping and network analysis were VOSviewer[4] and biblioshiny by bibliometrix [29]. The analysis and graphical representation of the science tree were performed with Tree of Science (Core of Science, 2020), and word clouds with text mining were generated using Voyant[5]. An evaluation of the synthesized information was carried out to answer the research questions. The analysis includes narrating the results, discussing the way forward for future research work, and the conclusion [24].

III. RESULTS AND DISCUSSION

A. Bibliometric Analysis

An increasing publication trend was found, with an annual growth rate of 20.89%. China has the most publications, followed by Brazil, USA, India, and Australia. This is probably associated with the current existence of accessible devices, with better hardware and software features for data collection and the availability of free software tools that allow the processing of large amounts of information with a quantitative approach and known precision. Research from China is the most cited, followed by research from Brazil, Germany, Korea, and Iran.

Scientific mapping and network analysis with tree of science allowed identification of the most influential research on the topic of study, some of which was not considered during the information search phase. The metaphor of the tree of science to perform network analysis facilitated the recognition of connections and hierarchies based on the frequency of appearance of specific terms or concepts together in the scientific literature addressed in this review.

Given their theoretical dominance in derivative studies, the tree of science roots showed the classic documents of fundamental relevance in the subject. Twenty articles were considered the pillars of subsequent knowledge, they focused mainly on proposing and comparing the performance of different vegetation indices. Some of the early indices, which at the time were considered novel, are still in use today, such as the Soil-Adjusted Vegetation Index (SAVI), Transformed Soil-

[4] Web link: https://www.vosviewer.com/
[5] https://voyant-tools.org/, 2023

Adjusted Vegetation Index (SAVIT), Modified Soil-Adjusted Vegetation Index (MSAVI), among others [30].

The trunk of the tree of science includes 20 articles from authors that first discovered the applicability of this type of research. These documents are the central pillar of collective knowledge on the subject, and the proposal of new indices is a topic of interest. The most relevant studies explored the potential of the RGB color system through the relationship of its channels, mainly green and red, to the nitrogen content of different types of crops [31]. Other studies explored the use of spectral data [32], [33].

Three branches were identified based on underlying citations, each integrating 15 trending studies. The tree leaves represented the most recent and innovative papers citing each other, showcasing current trends framing emerging research.

The analysis of citations through scientific mapping showed that 103 of the studies considered in this review were connected, forming 12 clusters, which can be considered subfields of the central theme of the review. With the cocitations analysis, a thematic affinity was found among the documents reviewed; these studies are closely related to the extent that they have a greater number of bibliographic references in common. With the co-occurrence analysis, the most frequent keywords detected were: "vegetation indexes", "reflectance", "chlorophyll content", "regression" and "spectral reflectance".

Other reviews have been written on estimating plant nutrition with non-destructive methods. Reference [12] describes the techniques available to estimate nitrogen content, finding that several factors influence their suitability and applicability; for example, the accuracy of leaf color tables is not guaranteed since they are based on visual color inspection.

The work in [7] reviewed the use of RGB digital images for foliar nutrition estimation, finding that existing processing technology can support the development of agricultural automation by achieving low price, high efficiency, and high precision. Reference [10] studied proximal image capture with different types of sensors, concluding that studies of this type are becoming less and more dispersed, making it difficult to draw a complete picture of the state of the art of this type of research. On the other hand, [8], [34], [35] focus their reviews on obtaining and analyzing spectral information. Although these reviews give a comprehensive view of the advances in scientific literature, they do not focus on the progress of technological tools, which is the contribution of this review.

B. Can Artificial Intelligence-based Analysis of Plant Nutrition Provide Relevant Information for Decision-Making in Agricultural Systems?

The methodology for obtaining and analyzing information in non-destructive plant nutrition studies varies according to the types of data available and the estimation models selected. However, the overall process could be standardized into four phases commonly used for analyzing digital information with artificial intelligence (see Fig. 2). The most used measuring devices for data acquisition are conventional [36], spectral [37], [38], or modified digital cameras [39], and sensors that enable the collection of continuous and discrete numerical values [40], [41]. Some of these sensors and digital cameras can be installed on unmanned aerial vehicles (drones) to conduct canopy-level surveys [42], [43].

The data types obtained are RGB digital images [44], spectral data and images [35], and measurements with SPAD sensors [45] or color sensors [46]. In addition, it is common to calculate vegetation indices from distinct color models and spectral channels [47]. For example, the green channel is the one that has been most frequently used on its own or as part of indices for diagnosing plant nutrition levels [48], [49], [50].

Studies published after 2018 mainly use multi and/or hyperspectral data, probably because researchers have ventured into developing reliable and inexpensive sensors [49] and because of the increase in available computational capacity. Spectral information requires greater computational processing since it presents several bands of information across the entire electromagnetic spectrum [50]. This large amount of information can be used to produce maps of precise biophysical indicators throughout the different crop development cycles, which would allow better decision-making and the implementation of precise agriculture [3].

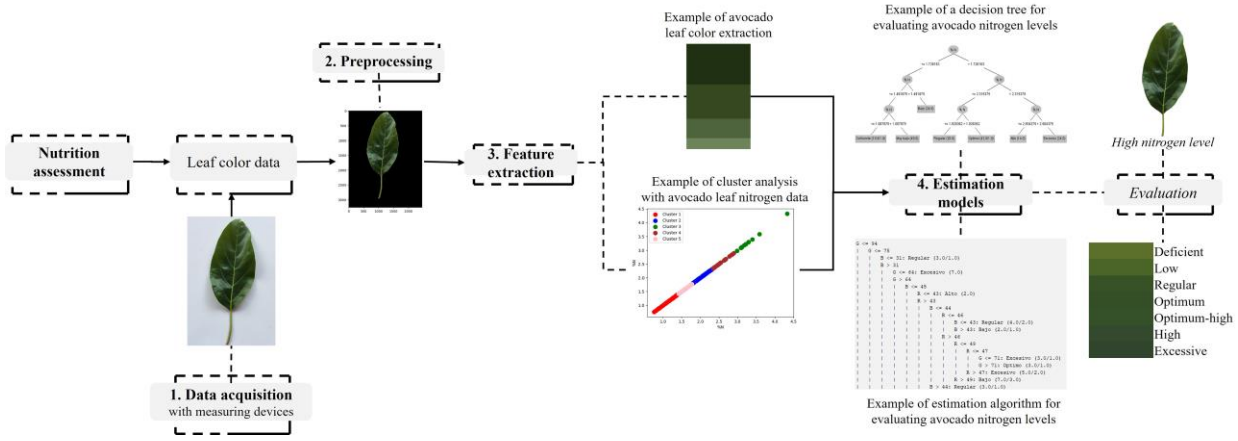

Fig. 2. Phases of data processing for the evaluation of the nutritional level of plants. Example of an assessment of the nitrogen level of an avocado leaf from the color in RGB.

Obtaining spectral information through sensors can be proximal in the field, or aerial. Satellite is the best option for the measurement of the entire field or plot quickly and free of charge. Unmanned aerial vehicles are the most advantageous option to measure quickly with high resolution and high level of detail. Leaf-based sensors are very accurate to measure at a specific point [8].

On the other hand, each data type has its limitations, for example, one of the main challenges associated with digital imaging for plant nutrition diagnostics is the illumination of the environment, as it can have a significant impact on the performance of estimation model algorithms [31]. Light variations in field conditions can severely hinder the ability of models to provide reliable estimates as, for most imaging devices, the same part of a plant may have different color attributes depending on whether the capture conditions are under sunny or cloudy conditions, also changing depending on the time of day, and even if some correction or calibration is applied [51]. In some studies, light conditions have been resolved through controlled environments, such as laboratory conditions, the creation of structures that block the passage of natural light or contact techniques [52].

The massive amounts of information are the most important limitations of using spectral data and images. Redundancy, collinearity, and noise do not favor data processing, therefore, extracting characteristic wavelengths (reducing dimensionality) is necessary for training of estimation models [53]. It should be noted that wavelengths vary, so they must be calibrated and selected according to the type and variety of plant being studied.

Another limitation for the use of spectral data is associated with the type of measurement that is performed, as this can be at the canopy level, which means that reflectance is scanned from the top layer of the leaf and the vertical distribution of nutrients in the crop is difficult to infer. Unlike leaf-level measurements, that are performed only on young leaves that better reflect the current nutritional status of the plants [54], spectral data at the canopy level create uncertainty in crop monitoring and limit the practical value of estimates at the plot and plant levels, given such heterogeneity.

Sensor differences between devices should also be considered, as they can have significant variations [55]. Technical characteristics, such as optical quality and pixel sensor type (CMOS or CCD), change between models and manufacturers [10]; therefore, proper calibration is necessary to compensate for these effects. In addition, the interpretation of measurement results may require expert knowledge and may not be accessible, given the excessive cost of some of these devices.

On the other side, preprocessing is necessary to improve and select information that will be used for training estimation models of crop nutrition levels. In the case of RGB images, the preprocessing can include reducing intensity variations between neighboring pixels (smoothing), modifying pixels whose intensity level is quite different from their neighbors (noise removal), increasing intensity variations between pixels (detail enhancement), detecting pixels with abrupt changes in intensity (edge detection), and adjusting brightness [56]. Different filters can also be applied to enhance RGB images, such as mean, median, and Gaussian [57].

Segmentation is used in RGB images for background extraction, the main challenge is capturing information under field conditions since image backgrounds can be diverse [58]. It is common to use unsupervised analysis to perform feature extraction and find patterns in the data without any prior knowledge of classes or groups, as it allows having an overview of the main sources of variation in the data. Cluster analysis and principal component analysis are among the most used algorithms.

Preprocessing of spectral information is carried out to select important bands to reduce data dimensionality and improve the robustness and interpretability of the estimation models [40]. These preprocessing methods include a) first derivation to overcome band shifting and overlap problems, b) light scattering reduction, and c) reflectance to absorbance conversion to linearize the spectrometer response [59]. First-order derivatives have been the most used, with better results [60], [61]. On the other hand, feature extraction refers to calculating new information from the data. In the case of digital images, it is possible to obtain numerical values of color, texture, shape, and geometry. The final phase of the process consists of estimating and classifying plant nutrient levels through the application of trained mathematical models. Studies published before 2018 mainly used linear regression models, given their simplicity and the possibility of generating approximation functions. More recently, ML and DL models have been used, such as convolutional neural networks, which refer to a class of feedback networks applied to the analysis of digital images [62].

The regression models for estimating plant nutritional levels represent suitable solutions to complex problems thanks to the evolution of ML and DL techniques. Many of these algorithms are freely available on various platforms so that they can be easily applied by anyone with a basic understanding of their concepts [63]. However, one of the main limitations of this models is that, in many cases, users do not have enough knowledge about the algorithms they are applying. Hence, the experimental design is not always appropriate. In addition, it may not be possible to validate the congruence of models with expert knowledge, as some models are so complex that they can function as black boxes, making unfeasible to fully understand the decision process. A summary of the regression and validation models applied in the research with technological tool development considered in this review can be found in the Table II.

In conclusion, artificial intelligence-based analyses of plant nutrition are a good source of information for decision-making in agricultural systems, since its allows monitoring the state of crops by measuring and analyzing different variables. However, using this information implies expert knowledge, high computational processing capabilities, memory spaces, and, in some cases, the acquisition of expensive sensors. Therefore, at this point, its implementation in agricultural fields is not viable; so, the development of technological tools that are easy to use and accessible to decision-makers is necessary.

TABLE II. SYNTHESIS OF THE STUDIES THAT LED TO THE DEVELOPMENT OF A TECHNOLOGICAL TOOL

Reference	Tool or technology development	Branch of artificial intelligence	Input data types	Regression models	Crops	Database size	Validation methods	Models accuracy (best model)
2013 [36]	Software	Machine learning	RGB images	Stepwise multiple linear regression (shoot dry weight showed better performance)	Rice	166 observations for model calibration and 161 observations for model validation	Determination coefficient Root mean square error in prediction	0.87 0.52
2013 [64]	Four-wheel mobile structure	Machine learning	RGB images	Linear regression	Rice	140 samples to develop the prediction model and 80 samples to validate the model	Determination coefficient	0.95
2015 [44]	Smartphone application (PocketN)	Machine learning	RGB images	Linear regression (Dualex was the best method)	Rice	864 determinations for prediction, 54 for determining trueness	Determination coefficient	0.96 in leaves nitrogen content
2015 [52]	Smartphone application	Machine learning and deep learning	RGB images	Linear regression and Neural Network model (NN). The best model was NN	Maize	480 contact images	Determination coefficient Root mean square error	0.82 5.10
2020 [65]	Multispectral sensor	Machine learning	Numerical data	Rational quadratic gaussian process regression. Best model was for Soybean	Canola, maize, soybean, and wheat	Spectral data were collected from 307 leaves (121 for N)	Determination coefficient Root mean squared error	82.29 0.21
2020 [66]	Smartphone application	Computer vision	RGB images	Color difference calculated by the CIEDE2000 formula	Rice	180 leaves	Manual inspections	0.95
2021 [21]	Smartphone application	Machine learning	RGB images	Simple linear regression (carotenoid concentration was the best model)	Spinach	A total of fifty upright leaves were visually selected	Determination coefficient	0.95
2021 [67]	SPAD type portable device (SPAD-Cap) and a web GUI for data control and visualization	Machine learning and deep learning	RGB images	Partial least square regression and convolutional neural network for regression	Rape leaves and some other plant leaves of cotton, sugarcane, citrus, brassica, and bamboo	Totally 120 rape leaves and 50 others were collected and tested	Determination Coefficient Root mean square error	0.97 for rape leaf 2.5 for rape leaf
2022 [68]	Structure for taking photographs	Machine learning and deep learning	Hyperspectral images	Random forest, Support Vector Regression (SVR), partial least square regression, and artificial neuron network. Best model was SVR.	Oil palm	A training set with 50 samples was used to be modeled for each target, and a test set with 15 samples was employed to evaluate model performance	Determination coefficient for prediction Root mean square error of calibration Standard error of prediction	0.655 0.17 0.18
2022 [33]	Hardware device with a spectral camera	Machine learning	Multispectral images	Partial least squares regression	Wheat	144 samples in the calibration set and 72 samples in the validation	Determination coefficient Root mean squared error	0.79 3.94
2022 [69]	Sensor to acquire and analyze a color image	Machine learning	RGB images	Simple linear model	Winter rapeseed	In total 100 rapeseed leaves were examined	Determination coefficient	0.81
2022 [39]	Image acquisition device	Machine learning	RGB images	Random forest sequential backward selection and support vector regression were combined	Aquilaria sinensis	The original dataset contains 48 samples with 108-dimensional image features.	Determination coefficient	0.87

C. Do Studies Reach the Stage of Developing Technological Tools for Application in Agricultural Systems under Field Conditions?

Most of the studies reviewed (86%) did not consider developing a technological tool as part of their objectives. They were limited to applying regression and classification estimation models with different levels of complexity and evaluating their accuracy. Therefore, this knowledge is mainly aimed at specialists, who are usually not the decision-makers in agricultural fields. The few technological developments in the studies reviewed include software [36], mobile applications [21], [52], [66], and hardware devices, such as sensors [33], [65], [69], structures [64], and intelligent robots [70].

The development of mobile applications dates to studies published in 2015 and is resumed in works from 2017, 2020, and 2021. Only one software tool was presented in a study from 2013 [36], and the hardware appeared in documents published in different time intervals (2013-2015, 2017 and 2018, and 2020-2022) (see Fig. 3).

Most of the studies, in which the development and testing of these tools have been published, report satisfactory results in their application. Mobile apps and software were searched on the web for installation and testing but are unavailable. This is probably because they are not open access, their download is blocked in some countries, or the devices used do not meet the requirements for their installation. On the other hand, mobile and robot structures have not been commercialized to the public, their construction and use are limited to experts, so it would be difficult for decision-makers to replicate these structures.

Some tools have not been developed with a scientific approach and have not been published as research but are commercialized and available to farmers. If their accuracy is proven adequate through rigorous testing, they could be valuable options for decision-making in agricultural systems. Examples of such tools are FieldScout GreenIndex+ Nitrogen App, which is a paid application developed to manage the nitrogen needs of maize crops, and Yara ImageIT, created to calculate nitrogen uptake from foliage cover, leaf color, and the estimated brown-leaf fraction.

The limitations that hinder the transfer of knowledge and technology to farmers should also be considered. One limitation is the lack of environmental regulation, which can be lax, especially in poor and developing countries, with no restrictions on fertilizer use and no accompaniment during the production process or incentives to reduce over-fertilization, that makes the optimization of fertilization practices irrelevant. Another limitation is that technology implementation for smart agriculture can involve high costs, making it inaccessible to small and medium-sized farmers.

The rocketing price of chemical fertilizers in recent years may nonetheless change this perception and increase the interest of farmers worldwide in such fertilizer optimization tools, if not for environmental reasons, for economic concerns. Given that such scenario is unlikely to change soon, it is worth to continue developing tools that are economically accessible, with easy-to-interpret and scientific-evidence-based results. Mobile and robot technology is becoming affordable and ubiquitous and should become available to farmers at no or minimum cost to promote sustainable and precision agricultural practices.

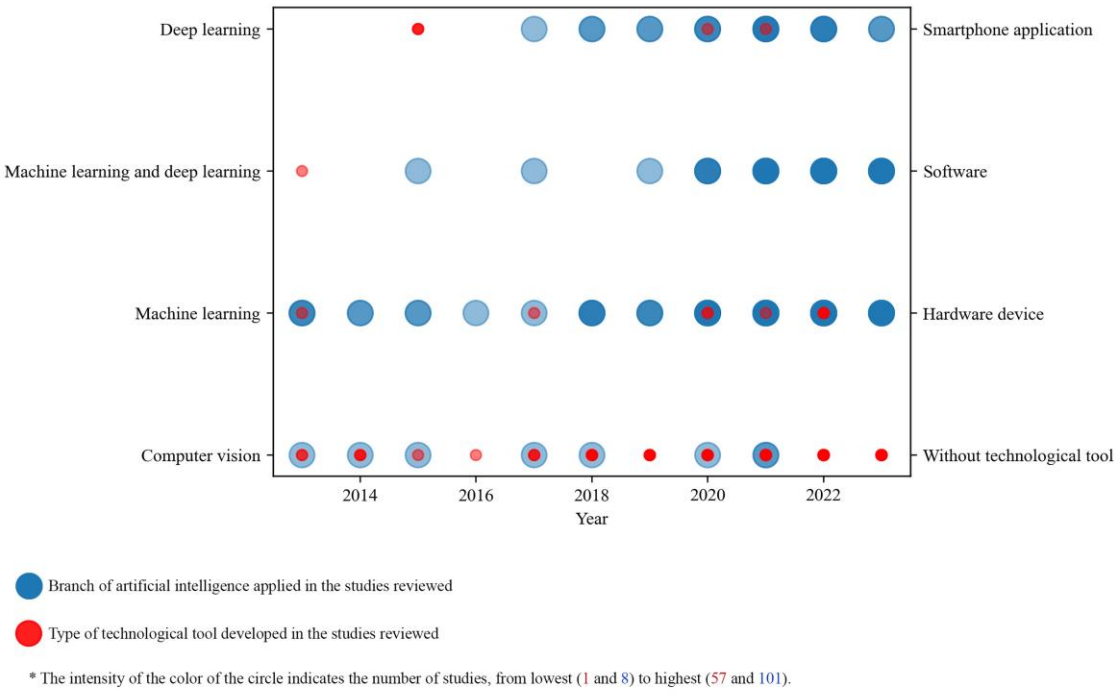

Fig. 3. Types of technological tools created, and branches of artificial intelligence applied in the studies over time.

D. What is the Way Forward for the Popularization of the Development and Application of Technological Tools in Agricultural Systems?

There is still much to be done in intelligence-based nutritional diagnostics for different crops, as most studies have focused on cereals, especially rice, maize, and wheat. In addition, varieties of the same crop may possess specific canopy architectures [36], different rates of coloration and leaf development, and different responses to nutritional deficiency [71]. Nutrient estimation models generated for a given crop may become less effective when applied to other varieties of the same crop, which means that it is necessary to develop a specific estimation model for each type of crop [31], [72], [73].

Similarly, the plant developmental stage must be considered, as it may affect the behavior of the variables used by the estimation models given that as plants and leaves mature, leaf color changes [74] and, as a consequence, also their spectral responses [75]. The same plant often contains leaves at different stages of development, so studies should consider conducting experiments with other varieties of the same crop at various critical stages of their growth [72], [73]. It may be more efficient to develop nutritional diagnostic tools for perennial crops, whose varieties do not change as rapidly as annual crops and whose nutritional requirements are more difficult to estimate because plantation areas are usually very heterogeneous and tree responses to fertilization are slow and less evident.

In general, the main weaknesses of current knowledge about intelligence-based nutritional diagnostics are: 1) given that the research has been developed mainly by and for experts, the estimation models and the few technological tools developed are complex, so decision-makers do not use them; b) training estimation models with deep learning requires a large amount of information and computational resources, which can imply a high economic investment if there are no free repositories with the necessary information or adequate computing equipment; and c) its application in agricultural systems is a challenge since most of the knowledge generated has been tested under controlled conditions, without demonstrating promising results in field conditions.

The threats lie in the limitations of the data, estimation models, and tools, which may turn them not robust enough to be applied with acceptable reliability in agricultural fields, producing deficiencies in crop performance. Estimation models require data that can be used as predictor variables of foliar nutrition. Although color has proven to be a good predictor variable for some crops [66], finding the correct variables is a challenge in other cases. Other aspects of the crop, such as leaf shape, size, age, etc., may need to be considered.

The strengths focus on the valuable theoretical knowledge generated to date, which has made possible to establish methodologies for continuing studies of new crops or varieties and different growth stages of crops that have already been studied. Given the high cost of destructive nutrition analyses, farmers use them on a limited number of samples (of leaves or soils, for example), therefore their view of nutrition status at the plot level is limited. However, using estimation models or technological tools would allow multiple estimates to be made quickly and economically to monitor crops at the plot level. So far, most studies have only estimated macronutrient deficiencies [7], [76], so there is an opportunity to generate knowledge from micronutrients.

Furthermore, in 49% of the review studies, ML has been used to generate predictive models, 16% use DL, and 28% compare the performance of algorithms from both subfields. Therefore, there is an opportunity for developing new research in which predictive models are generated using DL to estimate the foliar nutrition of different crops.

The way forward for the popularization of the development and application of technological tools in agricultural systems is the innovation. Innovation can be defined as “invention plus exploitation” [77], and the innovation process considers 1) the production of knowledge and, according to this review, there are currently sufficient advances in the scientific literature; 2) the transformation of knowledge into artifacts, which has had little progress with a scientific basis; and 3) the continuous adaptation of these artifacts, according to the needs and demands of the market. Based on the documents reviewed, we can infer that it has only been achieved by commercial tools, whose developments have yet to be published in the scientific field. Although the innovation process can follow different paths, depending on the type of product, in Fig. 4, we propose a path forward focused on generating technological tools with a scientific basis.

In the future, we glimpse a precision agriculture achieved through technological innovation, using monitoring systems and the Internet of Things for the acquisition of crop information [78]. Also, soil and climate information could be included in the estimating models, representing an improvement in their capacity and the possibility of including fertilization recommendations besides nutritional diagnosis. A monitoring system would not only identify plant nutritional deficiencies, but could calculate and provide optimal solutions, informing the user of the required nutrient supply and focusing not only on one type of nutrient but several. Also, Mobile smartphones and similar devices will soon be accessible (sensu lato, in terms of costs, operation, language, connectivity, etc.) even in the most remote areas, and developing free/low-cost applications to support farmers is becoming easier and cheaper (see Fig. 5).

Therefore, the popularization of the development and application of technological tools in agricultural systems represents a valuable opportunity to translate the scientific knowledge generated into accessible tools that bring together the recent boom of technological advances and put them in the hands of people to facilitate and promote a sustainable management of natural resources. In this regard, it is crucial to form multidisciplinary working groups that bring together experts in agronomy, sustainability, programming, robotics, electrical systems, data analysis, among others. Finally, research information should be shared in free repositories to increase the amount and variety of data available to improve the training and validation of estimation models and technologies.

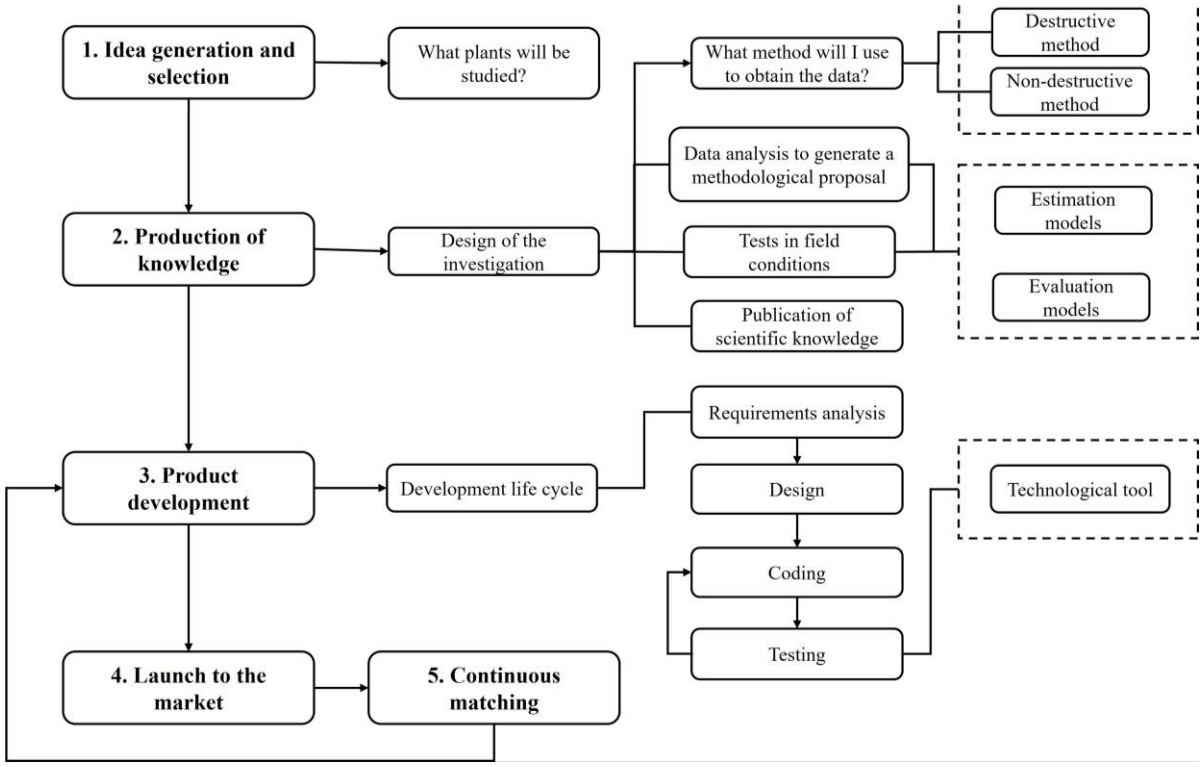

Fig. 4. Process proposal for the generation of technological tools from scientific information considering the phases of innovation and the development cycle of software or mobile applications.

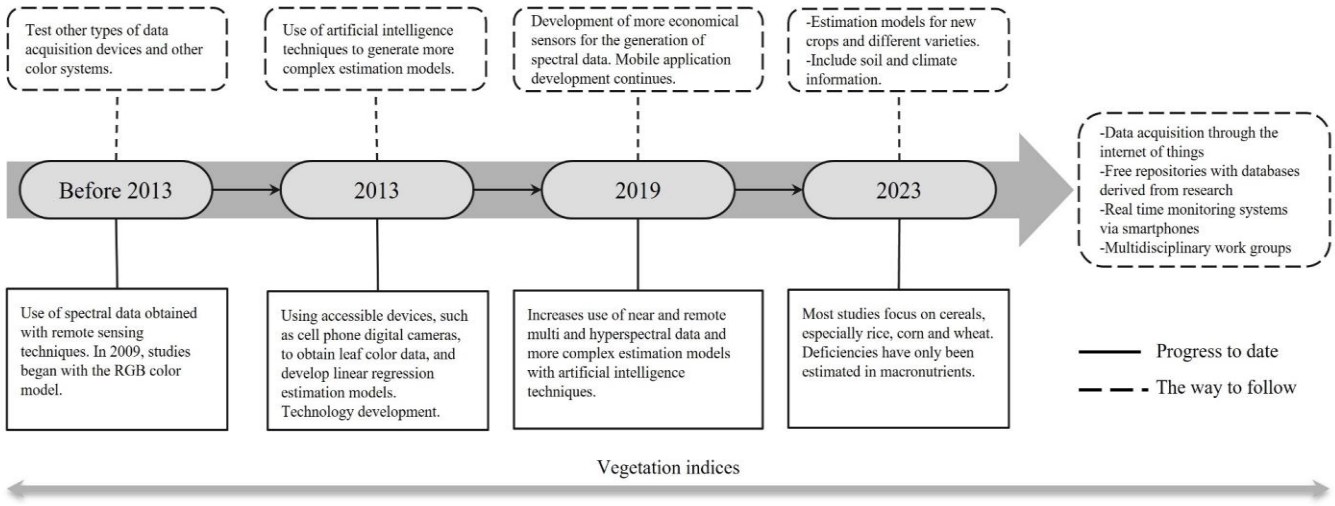

Fig. 5. Advances in assessing the nutritional status of plants with non-destructive methods and the gaps in their study, which become future opportunities, and the way forward.

IV. Conclusions

In a promising future, theoretical scientific knowledge will evolve towards technological innovation to achieve precision and sustainable agricultural systems. The estimation of foliar nutrients with AI non-destructive methods will be carried out also using more technological tools, with information acquisition achieved through the Internet of Things and with all this information stored in free repositories for use in training robust estimation models. As a direct result, real-time monitoring systems will be developed based on these models, which will integrate hardware and special software built for the particular characteristics of each crop type by interdisciplinary and scientifically based work groups, approaching alternative agriculture and seeking environmental conservation.

Nowadays, it is possible to estimate the nutritional status of crops through quick, economical, and non-destructive measurements thanks to current technological advances. These characteristics are of the utmost relevance to support farmers and advance environmental conservation. This paper presented an overview of the current state of scientific research to

identify its scope to generate accessible technological diagnostic and planning tools that support farmers.

It is possible to conclude that digital image processing has evolved to allow the detection of slight visual alterations in plant color and morphology using appropriate technology. At the same time, through predictive models, it is possible to solve problems of approximation and classification of values with acceptable precisions, with sufficient, representative available data. However, the main limitation lies in the limited development of technological tools accessible to all types of farmers and other non-expert users. These tools should include robotic systems, specialized software, and mobile applications for decision-makers that can be used and tested in practical field environments.

The scientific community must prioritize advancing science and technology that improves the quality of life, especially those that help produce healthy and safe crops in a healthy environment. The skills required to achieve these goals are within our reach, as can be inferred from the research presented in this review. Although there are still challenges and constraints to overcome, progress is being made in the right direction to achieve a brighter future in agriculture that focuses on preserving natural resources and biodiversity while enabling the production of high-quality food.

ACKNOWLEDGMENTS

This work was financed by Dirección General de Asuntos del Personal Académico (DGAPA) from the National Autonomous University of Mexico (UNAM) through projects PAPIIT-IN223824 granted to M.E.G., PAPIME PE106021 granted to H.F.M., and a postdoctoral fellowship granted to Á.G. Thanks to the National Laboratory of Ecotechnological Innovation for Sustainability (LANIES-UNAM) for hosting and supporting this work and to Sergio. R. Tinoco M. for his comments on this work.

Image Technology Investigation Based on Fingerprint Devices and Artificial Intelligence

Xuemei Zhao
School of Information Engineering, Yancheng Institute of Technology, Yancheng, 224000, China

***Abstract*—In response to the inaccurate visual positioning of fingerprint data images in investigative techniques, a new method based on wireless networks and artificial intelligence is proposed. The new method integrates wireless networks and image vision, while enhancing fingerprint data and images using cross temporal generative networks and channel state information. The research results indicated that the maximum positioning error value of the new model was 1.3m, which was 0.7m, 0.2m, and 0.4m lower than other models. The minimum positioning error value in indoor environments was 0.9m, which was lower compared with the 1.0m, 1.4m, and 1.6m of other models. The model used in the study had higher localization performance and recognition accuracy. The average accuracy was improved by about 4.5% compared with the TDF method with the lowest accuracy. The average root mean square error value was relatively low, with a minimum of 2.15. Compared with the highest SDF model, it was 4.43 lower. Therefore, the proposed method has better fingerprint recognition localization and investigation techniques, which has a better research guidance role for fingerprint localization and image recognition localization.**

***Keywords*—Investigation technology; fingerprint devices; image vision; fingerprint localization; image recognition**

I. Introduction

In the digital age, crime investigation technology is rapidly developing, especially in terms of fingerprint recognition accuracy and efficiency [1]. With the advancement of technology, traditional fingerprint recognition technology has been combined with new artificial intelligence technologies, making it more widely applied [2]. Fingerprint recognition technology is currently one of the most widely used identification methods. Its uniqueness and invariance make it an indispensable tool in criminal investigation [3]. However, with the increasing complexity and high technology of criminal methods, relying solely on traditional fingerprint recognition technology cannot meet the needs of modern investigation [4]. Therefore, artificial intelligence has been introduced into fingerprint recognition, especially in image processing and fingerprint localization analysis. It can not only greatly improve the speed and accuracy of recognition, but also identify and analyze complex fingerprint samples that are previously difficult to process. Therefore, the study combines wireless networks with fingerprint localization. Visual images are fused to expand the localization effect of current fingerprint data, and improve the accuracy of fingerprint localization. Secondly, Cross Temporal Generative Network (CTGN) and Channel State Information (CSI) are used to enhance fingerprint data to ensure that the current model can locate and investigate different environments and improve the effectiveness. The main purpose of the research is to explore how to improve the efficiency and accuracy of criminal investigation work by combining advanced fingerprint recognition equipment and artificial intelligence image technology. The study is divided into five sections. Section II reviews domestic and foreign research. Section III is about design research methods. Section IV analyzes the effectiveness of the model. Section V is a summary of the paper.

II. Related Works

In the current digital age, fingerprint recognition, as a highly reliable and accurate identity authentication technology, has been widely applied in the legal enforcement and personal security. Zhu et al. found that current fingerprint localization techniques became increasingly widespread, but there was still limited offline training for noise anti-interference. Therefore, a new indoor positioning method was proposed in the study using generalized learning systems. The new method could locate and analyze indoor fingerprint data through offline data training, while using principal component analysis to analyze data to reduce complexity. The research results indicated that the proposed method significantly shortened model training time and improved model accuracy [5]. Labinghisa et al. found that fingerprint authentication indoors required a significant amount of time. Meanwhile, there were more data issues with access points in the environment. Therefore, a new neural network fingerprint recognition method was proposed, which could improve the efficiency of model training and data collection. The research results indicated that the new method could improve the effectiveness and efficiency of indoor fingerprint localization [6]. The existing indoor positioning methods cannot effectively achieve high-precision positioning. Therefore, Zhang et al. proposed a beam antenna to enhance fingerprint localization method. The new method used beam antennas to locate fingerprint information, which was equipped with multiple antennas to improve positioning accuracy. The research results showed that the new method could accept fingerprint signals and improve the positioning effect of the model [7]. Traditional transfer learning algorithms have various problems and cannot effectively locate fingerprint information in space. Therefore, Li et al. proposed a new framework model for fingerprint localization. The new model could perform localization analysis on the spatial domain by removing redundant data information, improving the localization effect on fingerprint images. The research results indicated that the new method significantly enhanced the positioning accuracy of the model [8].

In indoor fingerprint localization, fingerprint integration can achieve better fingerprint information localization, but the limitations of improving fingerprint localization performance through this method are also obvious. Therefore, Zhou et al. proposed a fingerprint localization method based on deep learning. The new method mixed the received signals and fingerprint channel states to locate and analyze fingerprints. The research results indicated that the new method had better localization performance than traditional methods [9]. Li et al. proposed a new method based on Siamese convolutional neural network learning to achieve high-precision localization of fingerprint signal data. The new method improved the effectiveness of fingerprint localization by locating CSI within the same time interval. The research results indicated that the new method could effectively reduce fingerprint localization errors and improve localization performance compared with existing methods [10]. In the localization of fingerprint signals, frequency and geomagnetic signals can effectively locate fingerprints. Meanwhile, traditional signal acquisition may be affected by signal bias, resulting in labeling errors. Therefore, Tan et al. proposed a new method that combines frequency and geomagnetic signals. The new method could correlate spatial signals without artificial interference. The research results indicated that the new method could effectively improve the accuracy of fingerprint localization [11]. Li et al. found that most studies on fingerprint localization have been put on hold due to the large workload of offline data collection. Therefore, a new method based on Markov state iteration was proposed to address this issue, which utilized storage sources to solve the signal reception strength. The research results indicated that the new method could reduce the workload of offline data collection and improve positioning accuracy [12].

In summary, most of the current research on fingerprint localization and recognition mainly focuses on offline data collection and localization accuracy of fingerprint localization. Meanwhile, there are still some problems in current research, such as weak signal reception data, poor fingerprint positioning effect, and insufficient data processing accuracy. Therefore, a new model combining image technology and time-domain spatial algorithm is proposed. The new model accurately locates fingerprint data information through intelligent networks and CSI. Afterwards, time-domain spatial algorithms are used to integrate fingerprint images with data processing, thereby improving the accuracy and data processing performance of the model.

III. Design of Fingerprint Device and Artificial Intelligence Image Localization and Investigation Technology

This section mainly elaborates on the positioning methods of currently used fingerprint devices and the fusion technology of image vision. How to improve the accuracy of fingerprint localization and image recognition using current models has been analyzed, and data augmentation methods and localization models have been introduced.

A. Visual Efficient Image Investigation Fusion Technology

Wireless networks and biological vision signals have interoperability in locating location information. Integrating these two methods can achieve efficient localization of fingerprint devices. However, there are still many issues with the current methods used. CSI in wireless networks often fails to consider the relative position of the wireless network when performing data feature localization, resulting in inaccurate data information obtained [13]. Secondly, in the fusion of wireless networks and visual images, the position signal connection between the two is not sufficient, which leads to poor utilization of data information between the two. Finally, in the fused model, the two parts of data feature extraction and image fusion are independent of each other, making the processing process more complex and resulting in inaccurate positioning of fingerprint devices. Therefore, a new fingerprint device and image fusion model is designed, as shown in Fig. 1.

From Fig. 1, the model consists of three modules: location information collection module, data fusion module, and location detection module. The location information collection module mainly incorporates two data collection networks. Network channels collect feature data of the current visual image. A low orbit parameter fusion method is used in the data fusion module, which enables the model to maintain efficient vector fusion even with low computational complexity. The location detection module mainly classifies and predicts location information. The loss function is calculated to achieve end learning of the model. The network structure in the location information collection module is shown in Fig. 2.

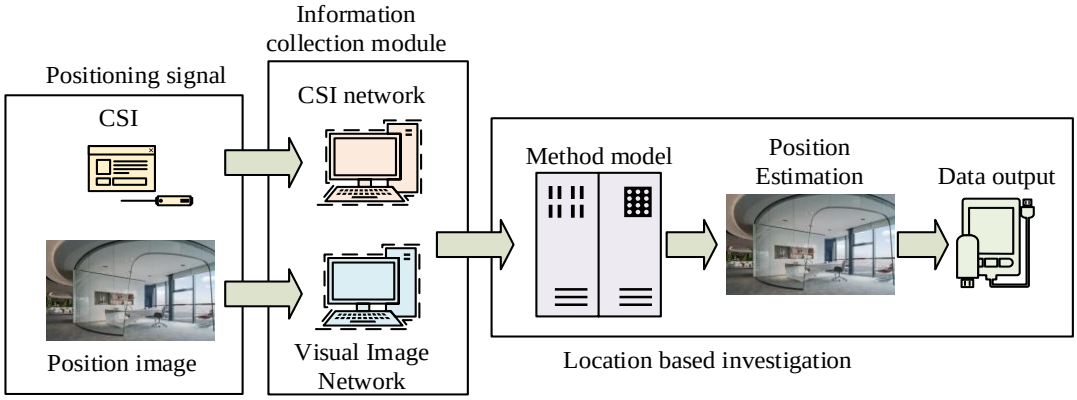

Fig. 1. Fingerprint device and image fusion model.

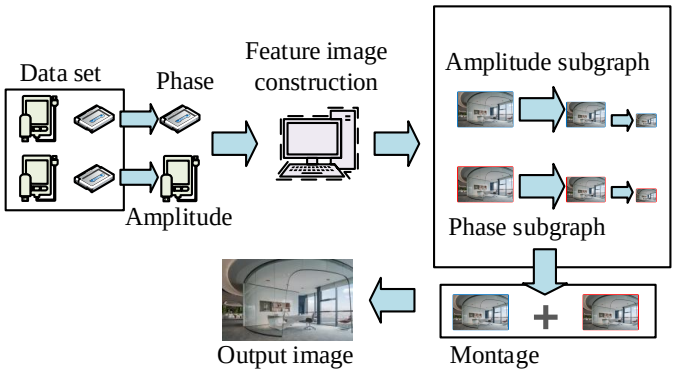

Fig. 2. Network structure of the location information collection module.

From Fig. 2, the CSI feature data image mainly collects position correction and amplitude of visual space images. Afterwards, the collected data is divided into amplitude sub-graphs and phase sub-graphs. The amplitude sub-graph expands and shrinks the image data, organizing it into a small data image. The same phase sub-graph also reduces or enlarges the features of the image data. The data features obtained from both are concatenated and fused to obtain usable data vector images. The process of building CSI involves collecting and using data. The carrier size of the wireless network is shown in Eq. (1) [14].

$$CSI_{m,n} = \left|CSI_{m,n}\right| \exp(j \angle CSI_{m,n}) \tag{1}$$

In Eq. (1), $\left|CSI_{m,n}\right|$ represents the amplitude value of the n-th wave in the m vectors. $\angle CSI_{m,n}$ represents the phase value of the n-th wave in m vectors. $1 \le m \le M, 1 \le n \le N$. Different wireless network lines are sorted by amplitude values to obtain the amplitude value matrix, as shown in Eq. (2).

$$AMP = \begin{bmatrix} \left|CSI_{1,1}\right| & \cdots & \left|CSI_{1,N}\right| \\ \vdots & \ddots & \vdots \\ \left|CSI_{M,1}\right| & \cdots & \left|CSI_{M,N}\right| \end{bmatrix} \tag{2}$$

In Eq. (2), AMP represents the amplitude matrix. The initial data collected may experience offset and delay. Therefore, the position information is corrected. Eq. (3) shows the size of the phase correction matrix [15].

$$PHA = \begin{bmatrix} \angle CSI_{1,1} & \cdots & \angle CSI_{1,N} \\ \vdots & \ddots & \vdots \\ \angle CSI_{M,1} & \cdots & \angle CSI_{M,N} \end{bmatrix} \tag{3}$$

In Eq. (3), PHA represents the size of the phase matrix. Through matrix size data analysis, the obtained matrices are fused to obtain the network input data. Meanwhile, to make feature data extraction more unified in the model, a new feature data extraction network is built based on network shared data, as shown in Fig. 3.

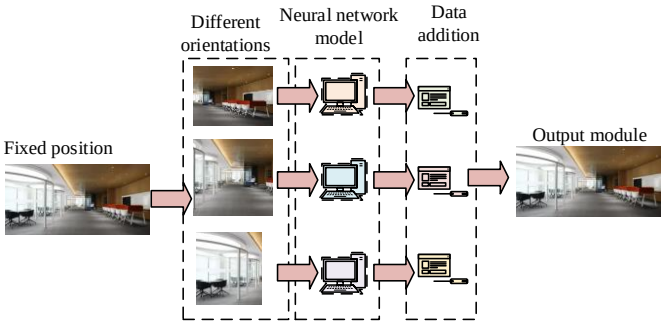

Fig. 3. Feature data extraction network.

From Fig. 3, after obtaining image data of a scene, visual information from different orientations of the image is first collected. Secondly, the collected image data is input into a convolutional neural network, where each convolutional layer can share the same network data. The images are added according to their positions to output feature data. The orientation information of the image is difficult to determine. Therefore, when extracting feature data, the direction information of the current data needs to be determined. Eq. (4) shows the image structure processed by the convolutional network [16].

$$h_{IMA}^{i} = shared_{CNN(image_i)} \tag{4}$$

In Eq. (4), $shared_{CNN}$ represents the shared convolutional neural network. $image_i$ represents the image information at the i-th position in the network. h_{IMA}^{i} represents the feature information of the image. Afterwards, the image scene information is fused and processed. Finally, all image data information is connected through the connection layer of the convolutional neural network, as shown in Eq. (5).

$$h_{CSI} = FC\_layer(\bar{h}_{IMA}) \tag{5}$$

In Eq. (5), h_{CSI} represents the size of the feature extraction vector for the visual image. $FC\_layer(\bar{h}_{IMA})$ represents the feature vector of the connection layer.

B. Fingerprint Device Image Recognition and Positioning Method

Visual image extraction and data sharing can achieve feature extraction of visual images in space, but there are still positioning deviations and unstable data collection in the model. The second problem of fingerprint collection and recognition in reconnaissance still needs to be solved. CTGN can collect data from different image information and perform localization, recognition, and analysis on fingerprint images in changing indoor environments. CTGN can convert image information of different styles without data matching and preserve the data information of the images. Fig. 4 displays its network structure.

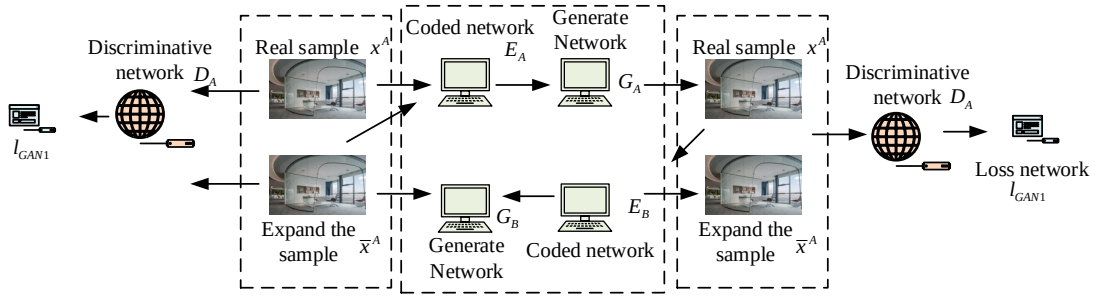

Fig. 4. Cross temporal generative network structure.

From Fig. 4, the network structure includes a judgment structure for image data. The information in the judgment structure is obtained through the loss of positional information in the encoding network and the generative network. Among them, network information will be obtained for sample judgment, which is divided into real samples and expanded samples. The dataset under indoor spatial conditions is divided into A and B. The upper layer network structure is a mapping from A to B, and the output data sample is x_a. The output data sample from the mapping from B to A is x_b. Encoding network and generative network are added to the structure. The encoding network encodes the positional information of samples. The generative network generates corresponding expanded data samples. The judgment network judges whether the input data sample is a real sample or an expanded sample. The loss function in the network model consists of two parts: adversarial loss function and localization information loss function. Eq. (6) displays the network structure adversarial loss function [17].

In Eq. (6), G_A represents the sample of A in the generative network. G_B represents the sample of B in the generative network. D_A represents the judgment network of A. D_B represents the judgment network of B. $E_{x^A \in S_R^A}$ represents the training set of dataset A. $E_{x^B \in S_R^B}$ represents the training set of the dataset B. $l_1(G_A, D_B, A, B)$ represents a set of loss functions. $D_b(x^b)$ represents the judgment network parameters of the real sample A. $D_B((G_A(E_A(x^A))))$ represents the judgment network parameters of the real sample B. Some similar sample sets are existed in the expanded samples. Therefore, the adversarial loss function of the judgment network is shown in Eq. (7).

$$l_1(G_A, D_B, A, B) = E_{x^B \in S_R^B}[\log D_B(x^B)] + E_{x^A \in S_R^A}[\log(1 - D_B((G_A(E_A(x^A)))))] \quad (6)$$

$$l_2(G_B, D_A, B, A) = E_{x^A \in S_R^A}[\log D_A(x^A)] + E_{x^B \in S_R^B}[\log(1 - D_A((G_B(E_B(x^B)))))] \quad (7)$$

At this point, the data objectives that need to be optimized in the network model are shown in Eq. (8).

$$\min_{G_B} \max_{D_A} l_2(G_B, D_A, B, A) \quad (8)$$

Calculating the adversarial loss function can perform image style analysis between two spatiotemporal regions. However, for the positioning of fingerprint devices, it is necessary to expand the data and constrain the data information. For the real sample data in space, it can be mapped into the same position space. Eq. (9) displays the current generated mapping feature vector size.

$$E_B(\bar{x}^B) = E_B(G_A(E_A(x^A))) \approx E_A(x^A) \quad (9)$$

In Eq. (9), $\bar{x}^B$ represents the expanded sample data. Similarly, for sample data A, the above formula conditions are also applicable. The main purpose of network structure is to map the maximum and minimum data of the network parameters generated by the entire data, as shown in Eq. (10) [18].

$$G_A^*, G_A^* = \arg \min_{G_A, G_B} \max_{D_A, G_B} l_{CSGN}(G_B, G_A, D_A, D_B) \quad (10)$$

In Eq. (10), G_A^*, G_A^* represents the mapping effect of network parameters generated through data. The judgment network generates parameters and fixes the generative network parameters. Then, the generative network parameters are replaced and recalculated, which achieves the maximum and minimum judgment of the model mapping relationship. When locating spatial positions, it is necessary to locate and judge a fingerprint signal at a specific time and state. Eq. (11) represents the size of the fingerprint signal dataset.

$$D_m = \{(x_i^m, y_i^m)\}_{i=1}^{Nm} \sim p^m(X, Y) \quad (11)$$

In Eq. (11), D_m represents the dataset in the spatiotemporal domain. X represents sample spatiotemporal. Y represents the spatiotemporal position of the sample. x_i^m represents the i-th signal sample in spatial region m. y_i^m represents the G-th signal sample in the spatial position region m. $p^m(X, Y)$ represents the data distribution in the m-th spatial and spatial location area. A new network model structure is obtained by analyzing the spatial location of the network model and fingerprint, as shown in Fig. 5.

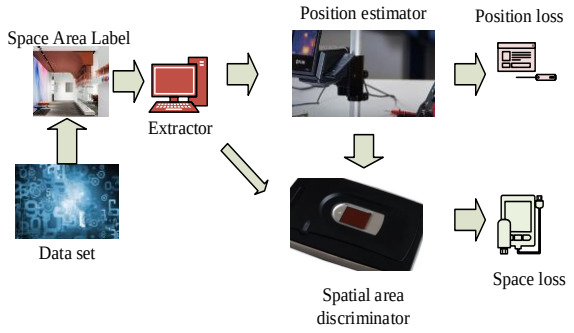

Fig. 5. Structure of fingerprint spatial network model for localization analysis.

From Fig. 5, during the training of network data, image data, coordinate data, label data, and CSI data are extracted from the data. Then, the fingerprint signal is extracted using a fingerprint data extractor to obtain the fused fingerprint signal. The spatial position calculation formula mentioned above is used to calculate the fingerprint position. The feature data of the fingerprint also needs to be identified and analyzed through a discriminator. The adversarial loss function and spatial position loss function are obtained. Finally, the integration of fingerprint data and network structure is completed. The fingerprint adversarial loss function in the network is shown in Eq. (12).

$$l_y(\theta_f,\theta_y)=-\sum_{m=1}^{M}\frac{1}{N_m}[\sum_{i=1}^{Nm}\sum_{j=1}^{N_{RPs}} y_i^m(i)\log(\hat{y}_i^m(j))] \quad (12)$$

In Eq. (12), y_i^m represents the position data obtained from the training samples in the data. N_{RPs} represents the number of reference points for fingerprints, which is the total number of fingerprint positions. θ_f represents a spatial discriminator. θ_y represents a position discriminator. $l_y(\theta_f,\theta_y)$ represents the adversarial loss function value. $\hat{y}_i^m$ represents the probability distribution of the data estimator position. The spatial position loss function of the network is shown in Eq. (13) [19].

$$l_d(\theta_f,\theta_d)=-\sum_{m=1}^{M}\frac{1}{N_m}[\sum_{i=1}^{Nm}\sum_{j=1}^{N_{RPs}} d_i^m(i)\log(\hat{d}_i^m(j))] \quad (13)$$

In Eq. (13), $l_d(\theta_f,\theta_d)$ represents the loss function of spatial position. θ_d represents a region discriminator. d_i^m represents the spatial data information obtained from training samples in the data. d_i^m represents the probability distribution of the region discriminator location. Finally, to achieve precise positioning of fingerprint devices and image recognition in indoor spaces, a new fingerprint positioning framework model is built on the basis of the network model, as shown in Fig. 6.

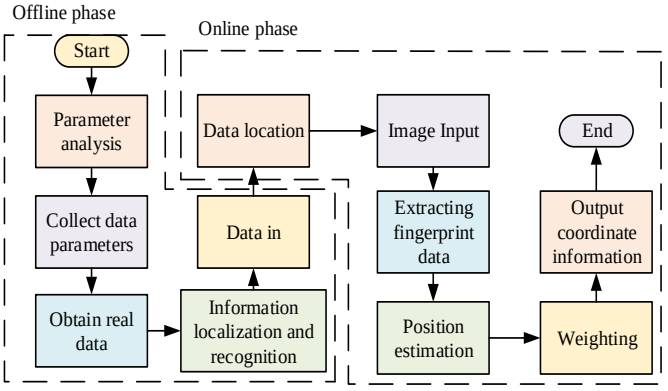

Fig. 6. Fingerprint localization framework model.

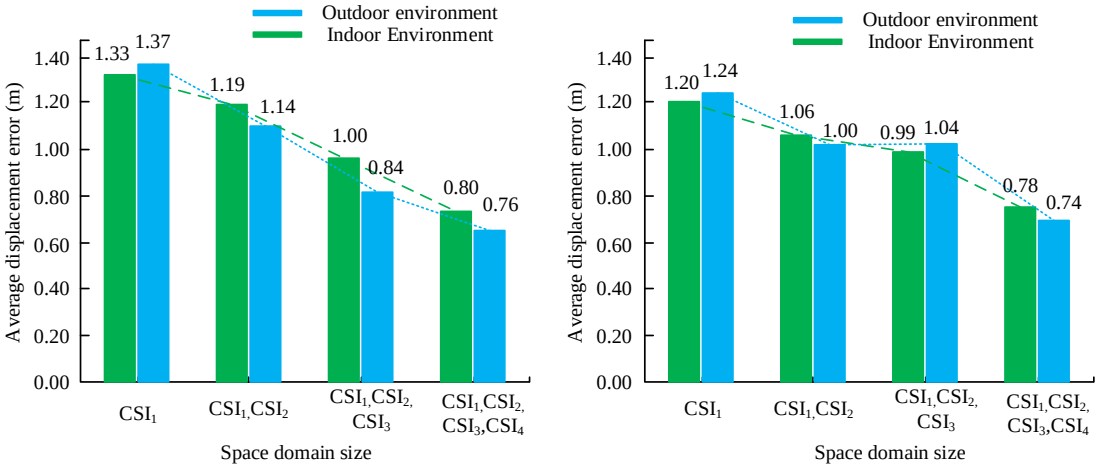
From Fig. 6, the framework is mainly divided into two stages: offline and online. Offline state analyses data parameters for coordinate images and CSI of reference point positions in space. Simultaneously collecting data parameter information from these aspects can yield more authentic and effective data. Afterwards, unknown information is located and identified through the above network structure. The obtained data information is transmitted to the network structure. It is input into the online stage through the network structure. In the online stage, real-time image input is completed by locating the data. The spatial fingerprint extractor is used to extract the fingerprint data. Then the fingerprint position is estimated and analyzed through the position estimator. The network model is weighted and processed. Finally, the coordinate information of the position is output.

IV. Analysis of Fingerprint Device and Artificial Intelligence Image Fusion Method

This section mainly analyzes the effectiveness of the current model parameters used to explore their practical application effects under different parameters. Secondly, the recognition and fingerprint localization performance of the model are compared with traditional methods through experiments.

A. Model Performance Parameter Testing and Analysis

To study the performance of the model, the multi-directional signal data of the image data is collected. The wireless network device used is Intel5300. The network data received signal size is 20MHz. The wireless network signal received is placed in the corner for signal data collection in four directions. The experiment uses different spaces for fingerprint recognition research. The collected data includes indoor and outdoor environments. To test the training effect of the current model on different spatial domains, fingerprint localization errors are compared in different spatial domains. The spatial domain sizes calculated in the previous section are denoted as CSI_1 and CSI_1, CSI_2. CSI_1, CSI_2, CSI_3 and $CSI_1, CSI_2, CSI_3, CSI_4$ are used as spatial domain size comparison parameters, as shown in Fig. 7.



(a) Comparison of different spatial domains in Data 1 (b) Comparison of different spatial domains in Data 2

Fig. 7. Comparison of positioning errors in different spatial domain sizes.

From Fig. 7 (a), the average positioning error of the model varied in different space domains. In the $CSI_1, CSI_2, CSI_3, CSI_4$ space domain, its average positioning error value was the smallest. Compared with the highest error value, its outdoor average error was 0.53m smaller and the indoor average error was 0.61m smaller. In Fig. 7 (b), the minimum average positioning error still appeared in the $CSI_1, CSI_2, CSI_3, CSI_4$ space domain. The minimum error values for outdoor and indoor environments were 0.78m and 0.74m, respectively. Compared with CSI_1 with the highest average error value, its error value distribution was 0.42m and 0.50m lower. When the space domain was $CSI_1, CSI_2, CSI_3, CSI_4$, the model had the best positioning effect and the lowest positioning error. The commonly used image fusion methods, including Stage Data Fusion (SDF), Threshold Data Fusion (TDF), and Tensor Fusion (TF), are compared to obtain the required parameter data for localization, as shown in Table I. A smaller cosine distance indicates better performance of the model.

From Table I, in the indoor cosine distance comparison of the model, the shortest cosine distance of the proposed model was only 0.076. Compared with the highest SDF model, it was 0.208 lower. The proposed model used in outdoor environments was 0.206 lower than the highest model. In the comparison of the average running time, the running time of the proposed model was shorter, indicating that the running speed and efficiency of the model used in the study were faster and higher. The model had better model performance compared with traditional models.

B. Analysis of Fingerprint Localization Effect

Comparative tests are conducted on different data localization methods, such as Received Signal Strength Indicator (SSI), Time Difference of Arrival (TDOA), and Angle of Arrival (AOA), to obtain the positioning error. Fig. 8 displays the results.

TABLE I. COMPARISON OF MODEL FINGERPRINT LOCALIZATION PARAMETERS

Environment	Cosine distance of fingerprint features in different spatial domains	Average cosine distance	Training frequency	Average positioning time (s)
Indoor Environment	SDF	0.284	100	0.054
	TDF	0.265	100	0.056
	TF	0.245	100	0.064
	CTGN	0.156	100	0.026
	Research model	0.076	100	0.012
Outdoor environment	SDF	0.282	100	0.058
	TDF	0.263	100	0.064
	TF	0.241	100	0.034
	CTGN	0.157	100	0.022
	Research model	0.076	100	0.013

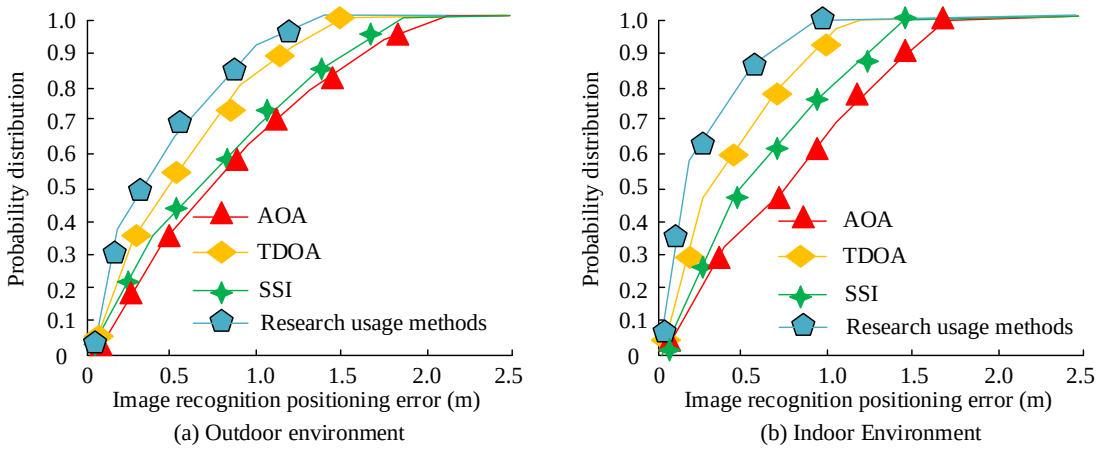


Fig. 8. Comparison of positioning errors of different models.

From Fig. 8 (a), in the outdoor environment, the error values of the four models increased with the increase of the positioning point probability distribution, and then tended to stabilize. When the probability distribution is 100%, the positioning error value of the positioning model reached its maximum. The maximum positioning error value of the research model was 1.3m, while the maximum positioning error values of the AOA, TDOA, and SSI were 2.0m, 1.5m, and 1.7m, respectively. The positioning error value of the model used in the study was smaller, which was 0.7m, 0.2m, and 0.4m lower than the three models, respectively. From Fig. 8 (b), in indoor environments, the minimum positioning error value of the model used in the study was 0.9m. Compared with the 1.0m, 1.4m, and 1.6m of the other three models, the model used in the study had a lower positioning error value. The model used in the study performed better in data image localization. From the figure, the indoor positioning error value was smaller, which may be due to the smaller indoor environment space and fewer measured position points. The fusion network used in the study is a CTGN. Therefore, to test the effectiveness of the current fusion network in image position information localization, different fusion methods are compared. The test results are shown in Fig. 9.

From Fig. 9 (a), in indoor environments, the positioning error value based on the spatiotemporal fusion method was even smaller, only 1.6m. The positioning error values of SDF, TDF, and TF for other fusion methods were 4.1m, 3.4m, and 2.4m, respectively. Compared with the spatiotemporal fusion method, other methods had larger positioning error values, which were 2.5m, 1.8m, and 0.8m higher than the methods used in the study, respectively. The spatiotemporal fusion method used in the study showed better performance in locating indoor environments. From Fig. 9 (b), in the outdoor environment, the fusion method used in the study has a positioning error of 2.1m, which is also significantly smaller than other fusion methods. However, from the comparison of indoor and outdoor environments in the above figure, the positioning error value of the outdoor environment should be greater than that of the indoor environment. From the figure, except for the method used in the study, the positioning error values of the other three fusion methods were relatively small, but the difference was not significant. This may be due to the low requirements of other fusion methods for spatial position positioning, resulting in little difference in the error data values between indoor and outdoor. To test the fingerprint recognition accuracy of the research model, it is compared with the other fusion methods mentioned above. The results are shown in Fig. 10.

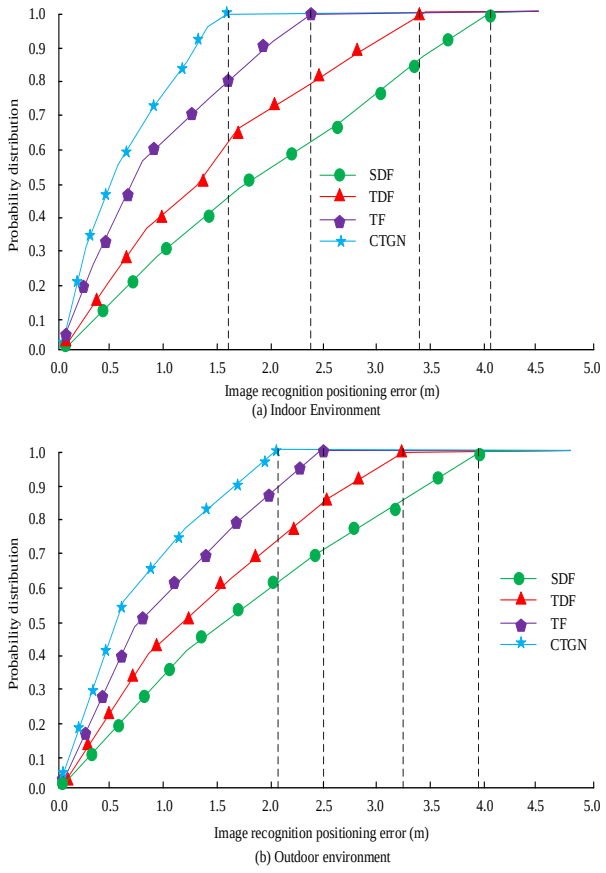

Fig. 9. Comparison of positioning errors between different fusion methods.

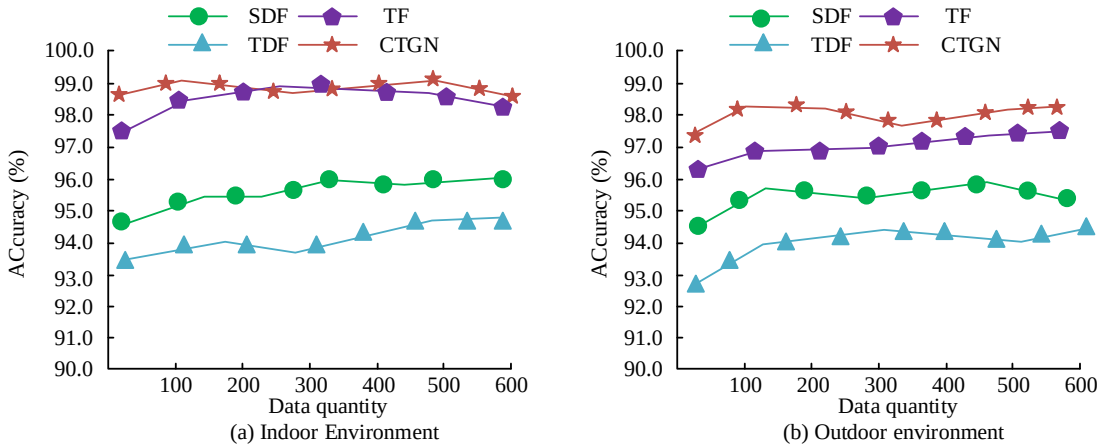

Fig. 10. Comparison of accuracy of different fusion methods.

From Fig. 10 (a), the fingerprint recognition accuracy of the four methods increased with the increase of data, and then tended to a relatively stable state. However, the overall curve changes showed fluctuations. This may be due to the fact that when fingerprint data is used for localization and recognition, the accuracy of the model is lower due to the larger dataset. However, the accuracy of the research method was higher, with an average accuracy of about 98.6%, which was about 4.5% higher than the TDF fusion method with the lowest accuracy of 94.1%. From Fig. 9 (b), the accuracy of the research method was higher than other methods, with an average accuracy of about 97.8%, which was about 3.6% higher than TDF model with the lowest accuracy of 94.2%. The research method had a higher accuracy in fingerprint recognition. To test the application effectiveness of the current research model in several traditional models, the recall rate, F1 value, and recognition error in fingerprint recognition positioning data are compared. The analysis results are shown in Table II.

TABLE II. PERFORMANCE COMPARISON OF DIFFERENT MODELS

Model	Recall (%)	F1	Average percentage error	Root mean square error
SDF	88.62	0.53	6.53	6.58
TDF	89.65	0.68	7.65	6.35
TF	90.15	0.96	5.32	5.78
CTGN	92.35	0.75	5.96	5.48
SSI	88.68	0.64	4.36	5.62
TDOA	91.25	0.88	5.87	4.35
AOA	90.64	0.92	3.56	4.36
Research model	96.35	0.99	2.35	2.15

In Table II, in terms of recall rate, the highest recall rate of the research method was 96.35%. The average percentage error value was the smallest among several models, with a median of 2.35. Compared with the TDF with the highest recall rate, it was 5.30 lower. The root mean square error value of the research method was also the smallest, at 2.15, which was 4.43 lower than the SDF model with the highest recall rate. From this, the research method showed good model performance in fingerprint recognition and localization.

V. CONCLUSION

A fusion algorithm model combining artificial intelligence and spatiotemporal domain algorithms is proposed to address the insufficient accuracy in fingerprint image extraction and localization in different investigation environments, as well as difficulties in collecting fingerprint localization data. The research results indicated that the optimal space domain size for the model was $CSI_1, CSI_2, CSI_3, CSI_4$. The minimum error values for outdoor and indoor environments were 0.78m and 0.74m, respectively. The cosine distance of the research model was the shortest, only at 0.076. Compared with the highest SDF model, it was 0.208 lower. The maximum positioning error value of the model used in the study was 1.3m, which was 0.7m, 0.2m, and 0.4m lower than other models, respectively. The minimum positioning error value for the proposed model in indoor environments was 0.9m. Compared with other models at 1.0m, 1.4m, and 1.6m, the positioning error value of the research model was lower. Compared with the spatiotemporal fusion method, other methods had larger positioning error values, which were 2.5m, 1.8m, and 0.8m higher than the methods used in the study. The accuracy of the research method was higher, with an average accuracy of about 98.6%, which was about 4.5% higher than the TDF fusion method with the lowest accuracy. The root mean square error value of the research method was also the lowest, only at 2.15, which was 4.43 lower than the highest SDF model. The performance of the research model is significantly better than traditional methods. It has better results in data processing. Although some achievements have been made in the research, there are still some problems, such as the small amount of data used in the study. Therefore, more and larger data will be used for analysis and research in the future.

***Abstract*—Now-a-days, traditional color matching methods cannot meet the current market demand. Meanwhile, there are many factors to consider in the design, which affect the design efficiency. Therefore, it is necessary to seek more efficient design methods. So, this study proposed an improved K-Means based on silhouette coefficients and designed an image main color adaptive extraction model. Subsequently, an evaluation method for artistic color matching schemes based on visual perception and similarity measurement was introduced. Finally, Pix2Pix based on visual aesthetics was designed to develop color matching schemes. These results confirmed that in the objective evaluation of the main color extraction results, the structural similarity of the main color images generated using the silhouette coefficient was superior to other methods. The maximum structural similarity of this method was 0.675, with an average of 0.663. Meanwhile, the peak signal-to-noise ratio of the main color image generated by this method reached a maximum of 21.49 dB, with an average of 21.05 dB. In the validation of Pix2Pix based on visual aesthetics, the average color palette similarity of Pix2Pix's design scheme based on visual aesthetics was 0.807. Meanwhile, the average comprehensive evaluation index of this method was 0.798, which was better than Pix2Pix without integrating visual aesthetics. In the experimental verification of computational efficiency, the average color matching time of the Pix2Pix network model based on visual aesthetics is only 13.75ms. The average time consumption of the K-Means clustering algorithm model is as high as 135.67ms. Overall, the designed image main color adaptive extraction model and color matching model have strong practical applicability. These methods provide effective auxiliary design solutions for the design and development of artistic products, which helps to improve design efficiency.**

I. Introduction

Due to the rapid development of industrial technology, significant achievements are made in the application of color science in engineering. Color plays a very important role in interior design, cultural and creative industries, printing and packaging, dyeing and finishing chemistry, and textile and clothing [1-2]. Colors are usually presented in groups of multiple forms in the application field, namely color matching schemes. Human Visual Perception (VP) has an impact on color, so there are certain patterns in color matching schemes under sensory recognition. VP also has advantages and disadvantages in human perception. How to design excellent color matching schemes is a key issue faced by designers and related industry personnel [3]. In response to the challenges encountered in design, computer-aided design patterns based on image processing and computer vision increasingly emerge and become a research focus in intelligent design. Through image processing technology and artificial intelligence algorithms, color processing and digital representation can be achieved, while intelligent design, matching, and recommendation can be achieved based on the attribute elements of color. However, color matching is influenced by physical, physiological, and psychological factors, which increases the complexity of implementing intelligent color matching design algorithms [4-5]. Currently, the evaluation of color matching schemes mainly relies on subjective methods such as sensory engineering. Although these methods can reflect user preferences, the evaluation is often cumbersome and easily influenced by subjective factors [6].

At present, domestic and foreign researchers mainly introduce the application research of color matching algorithms in the field of color science from three aspects: image main color extraction, color matching method research, and color matching evaluation methods. The main color of an image is the representative color of the image. Generally speaking, the number of main colors in an image is much smaller than the total number of colors in the source image. Meanwhile, the main color of the image is the color description that best fits the visual perception of the source image. In the research of color matching algorithms, the extraction of image main colors plays a crucial role in stimulating designers' design inspiration and obtaining high-quality color matching schemes. Due to the different color information in each image in nature, the corresponding number of main colors should have certain differences. Therefore, how to perform adaptive main color extraction on images is an important research topic in this field. In the research of color matching methods, due to the various attributes related to the human visual perception system such as psychology, physics, and physiology, how to combine human visual perception to generate color matching schemes in the field of computer-aided design is an important issue in this field of research. In addition, in the field of intelligent design, the intelligent matching and design of colors is a subjective design requirement. However, subjective evaluation methods are often more complex, which significantly affects product design efficiency. Therefore, using a combination of subjective and objective evaluation methods to evaluate color matching schemes is of great significance. How to conduct a comprehensive and multidimensional analysis of color matching schemes is currently a research focus and difficulty. Therefore, an image main color adaptive extraction method based on Silhouette Coefficient (SC) was adopted in this study, and a visual aesthetics based Pix2Pix was designed to formulate

color matching schemes. Meanwhile, a multi-dimensional color matching evaluation method combining VP and similarity measurement was proposed. The contribution of this study lies in proposing an intelligent computer-aided design method for artistic color matching, which fully integrates VP and intelligent algorithms, helping to design color matching schemes that are more in line with the human eye VP.

The research content mainly includes six sections. Firstly, a review is conducted on K-Means based on SC and color image processing techniques. Secondly, an improved K-Means based on SC is introduced, and an image main color adaptive extraction model is designed. Meanwhile, a method for evaluating artistic color matching schemes and a model for developing color matching schemes are designed in Section III. In Section IV, the proposed method is experimentally validated. Finally, Section VI is summarized and future prospects are proposed.

II. Related Works

SC can effectively improve clustering performance, which is widely used in the improvement of K-Means. Regarding the clustering problem of student data, A. Yudistira et al. proposed using K-Means to analyze student datasets. These results confirmed that a total of 3 clusters were obtained, including 59, 94, and 1 student, respectively. The elbow method was used to determine a good classification number of 3, with an SC of 0.489, indicating that the clustering results of this study were superior [7]. Xiang et al. introduced K-Means and SC to address the low quality of answering questions in Brainly and segmented users by tracking the records of answering mathematical topic questions. These results confirmed that K-Means performed better in silhouette score, with a score of 0.9081 [8]. Ben Marzouk et al. proposed a K-Means-based energy consumption structure analysis method to address the large and chaotic data in analyzing energy consumption structures in different regions. Meanwhile, this team analyzed energy consumption using the elbow method and SC. These results confirmed that this algorithm efficiently conducted data mining, greatly improving the convenience of energy consumption structure analysis [9]. Qu et al. proposed the Bert-CK mode to address the instability of traditional K-Means. This pattern combined Bert to extract semantic, syntactic features, and SC, improved the CK mean+algorithm, and solved the instability of K value and initial centroid selection. These results confirmed that the Bert-CK model outperformed the baseline model, improving the accuracy of user classification and topic features [10]. To address the instability and local optima of traditional K-Means, Agustino et al. proposed a relative mass algorithm based on data fields. This algorithm selected high-quality points as the initial clustering centroids and used SC to improve K-Means to improve the analysis performance. These results confirmed that the acceleration ratio of the improved algorithm increased to 1.91, and the computational efficiency increased by 33.03% [11].

Currently, color plays an important role in image processing. Tabatabaian et al. proposed an algorithm based on a combination of color and shape features to address the insufficient image retrieval efficiency. Cumulative histograms were used to calculate color features, 7 Hu invariant moments were used to calculate shape features, and weights were combined to measure similarity using Euclidean distance. These results confirmed that this algorithm effectively improved the accuracy of image retrieval [12]. In response to the poor performance and resource consumption of traditional photo enhancement methods on high-resolution images, Zeng et al. proposed a learning-based image adaptive 3D lookup table method. By learning 3D lookup tables and small convolutional neural networks, fast and flexible photo enhancement was achieved, with model parameters less than 600,000 and processing 4K images in less than two milliseconds. The PSNR, SSIM, and color difference metrics of this method were superior to state-of-the-art photo enhancement methods, demonstrating efficient and superior performance [13]. Berman et al. found that color distorting et al. happened in underwater images, and their study considered different water types' spectral profiles. By assessing only the blue-red and blue-green color channels' attenuation ratio, this challenge was simplified. These results confirmed that this dataset achieved strict quantitative evaluation of natural image restoration algorithms for the first time [14]. To address underwater images' color deviation and low contrast, Li et al. proposed a multi-color space embedding underwater image enhancement network called Ucolor guided by medium transmission. This network was combined with attention mechanisms to adaptively integrate and highlight the most discriminative features extracted from multiple color spaces. These results confirmed that the network outperformed other methods in both visual quality and quantitative metrics [15]. Zhang et al. found that the traditional color perception and recognition methods for Cantonese embroidery images had poor three-dimensional color restoration. They introduced a discrete mathematical model to design a new color perception and recognition method for Cantonese embroidery images. These results confirmed that the color pixel image curve of this method had 800 pixels for each color, and the color pixel image curve distribution was the most dense, with a high color restoration degree [16]. To deal with the encryption of RGB color images, MA Tahiri et al. used 3D fractional order modified Henon mapping and discrete fractional order Krawtchuk moments. Meanwhile, this team put forward a new method to optimize the proposed Henon map's parameters. These outcomes indicated this mixed algorithm's optimization efficiency compared to other metaheuristic methods [17].

In summary, numerous scholars have conducted extensive research on the application of SC-based improved K-Means and color image processing. On this basis, the improved K-Means based on SC is applied to the extraction of main colors in images for future development and evaluation of artistic color matching schemes. This paper hopes to provide effective color matching design for the field of art and design.

III. Artistic Color Matching Technology based on Silhouette Coefficient and Visual Perception

To deal with the problem that traditional algorithms cannot adaptively extract the main color of images, an improved K-Means based on SC is proposed, and a corresponding image main color adaptive extraction model is designed. Next, a color matching evaluation scheme combining VP and similarity measurement is introduced. Finally, a Pix2Pix based on visual

aesthetics is designed to achieve intelligent color matching scheme formulation.

A. Adaptive Extraction and Evaluation of Image Main Colors based on Silhouette Coefficients

Adaptive extraction of image main colors is crucial in artistic color matching, which affects the normal operation of the entire color matching. In image processing, using K-Means for image main color extraction can efficiently separate the main colors of images in complex color spaces. The core of this algorithm is to minimize the sum of squared distances between each pixel in the class and its corresponding Cluster Center (CC) [18]. K-Means is a clustering algorithm based on Euclidean distance. The closer the Euclidean distance between two data points, the greater the similarity between these two. Given a sample set, this algorithm first randomly selects k initial CC and then measures their Euclidean distance from the remaining data. Subsequently, the CC with the closest Euclidean distance was determined and the target object was assigned to the corresponding cluster. Next, the average value of data within each cluster is calculated and used as the new CC. Finally, the running is iterated to the maximum to end [19-20]. The calculation of spatial Euclidean distance is represented by Eq. (1).

$$d(v,C_i)=\sqrt{\sum_{j=1}^{n}(v_l-C_{il})^2} \tag{1}$$

In Eq. (1), C_i refers to the i th CC. v refers to the target data. n refers to the data dimension. x_l refers to the l th attribute value of the target data. C_{il} refers to the l th attribute value of CC. The objective function used by K-Means for image main color extraction is represented by Eq. (2).

$$J=\sum_{n=1}^{M}\sum_{k=1}^{K}r_{nk}\left\|C(m)-\mu_k\right\|^2 \tag{2}$$

In Eq. (2), N refers to the total distance of all classification categories. M refers to the quantity of sample colors. K refers to the quantity of color classification. m is the pixel index of the image. k refers to the k th class color. r_{nk} refers to two components. μ_k refers to CC for the k th class color. Given the unique color information of each image, the dominant colors and their quantities also vary. Traditional K-Means cannot adaptively extract the main color, which has certain limitations. Therefore, the study proposes SC to improve K-Means [21]. Fig. 1 shows an improved K-Means based on SC.

In this improved algorithm, each cluster corresponds to an SC value. The clusters corresponding to the maximum SC value are the optimal clusters for the sample. The distance within the cluster is represented by Eq. (3).

$$a(i)=\frac{1}{\left|C_i-1\right|}\sum_{j\in C_i,i\neq j}d(i,j) \tag{3}$$

In Eq. (3), $a(i)$ refers to the intra cluster distance, which is the average Euclidean distance between the current pixel and all pixels in the cluster. $d(i,j)$ refers to the spatial Euclidean distance between the targets i and j. The distance between clusters is represented by Eq. (4).

$$b(i)=\min_{k\neq i}\frac{1}{\left|C_k\right|}\sum_{j\in C_k}d(i,j) \tag{4}$$

The SC value of the target sample i is calculated using Eq. (5).

$$s(i)=\begin{cases}1-\dfrac{a(i)}{b(i)}, & a(i)<b(i)\\ 0, & a(i)=b(i)\\ \dfrac{b(i)}{a(i)}-1, & a(i)>b(i)\end{cases} \tag{5}$$

In Eq. (5), $s(i)$ refers to the SC value, with a range of [-1, 1], representing the best and worst clustering effects, respectively. The overall SC value of the cluster is represented by Eq. (6).

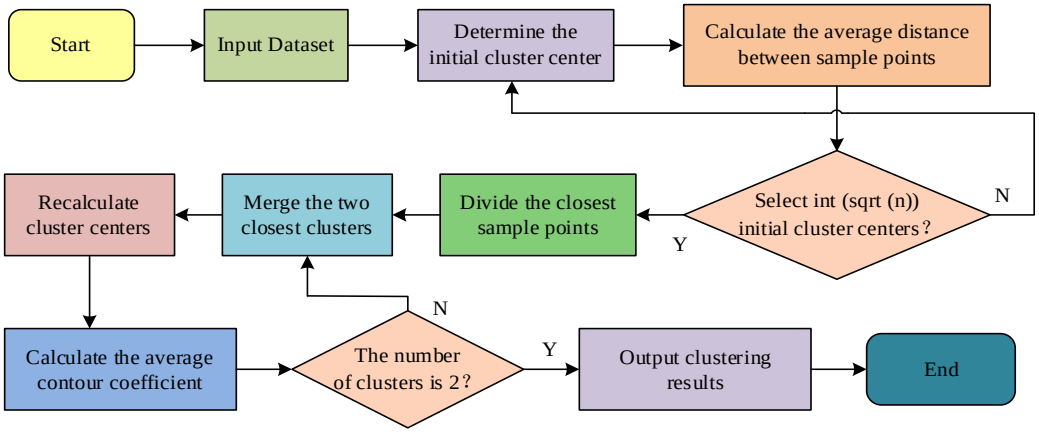

Fig. 1. The process of improving K-Means algorithm based on silhouette coefficients.

$$s = \frac{\sum_{i=1}^{N} s(i)}{N} \tag{6}$$

In Eq. (6), N represents the total target sample. At present, the evaluation methods for main color extraction mainly include questionnaire survey or manual visual inspection, which can effectively combine VP to evaluate the results of main color extraction, but often require a lot of user time. To address these shortcomings, a comprehensive evaluation method is proposed, which utilizes the main color image features and pairwise image similarity to evaluate the effectiveness of main color extraction. The main color image refers to the image obtained by replacing the color of each pixel in the source image with the target main color. To construct a main color image, the first step is to convert the image from the RGB color space to the Lab color space. Next, each pixel of the image was traversed and the extracted main color Lab values are input. Then, the Lab color difference between each pixel's color and all target main colors is calculated separately. The Lab value corresponding to the minimum color difference is used to replace the Lab value of the current pixel. Finally, the main color images are output. After obtaining the main color images corresponding to each sample, the Peak Signal-to-Noise Ratio (PSNR) and structural similarity between paired images are calculated using similarity measurement method. This method is mainly used to characterize the effectiveness of main color extraction [22]. The objective quantitative evaluation indicators are represented by Eq. (7).

$$\begin{cases} E_1 = PSNR(I_0, I_1) \\ E_2 = SSIM(I_0, I_1) \end{cases} \tag{7}$$

In Eq. (7), E refers to the quantitative evaluation indicator. I_0 refers to the source image. I_1 is the main color image. On this basis, qualitative analysis of the main color results extracted by various methods is conducted by combining subjective sensory engineering experiments. Table I shows the five-point scale of perceptual engineering.

TABLE I. FIVE-POINT SCALE OF PERCEPTUAL ENGINEERING

Number	Effect description	Rating range
I	Extremely poor	0-1
II	Poor	1-2
III	General	2-3
IV	Better	3-4
V	Perfect	4-5

Fig. 2 shows the adaptive extraction of image main colors based on SC.

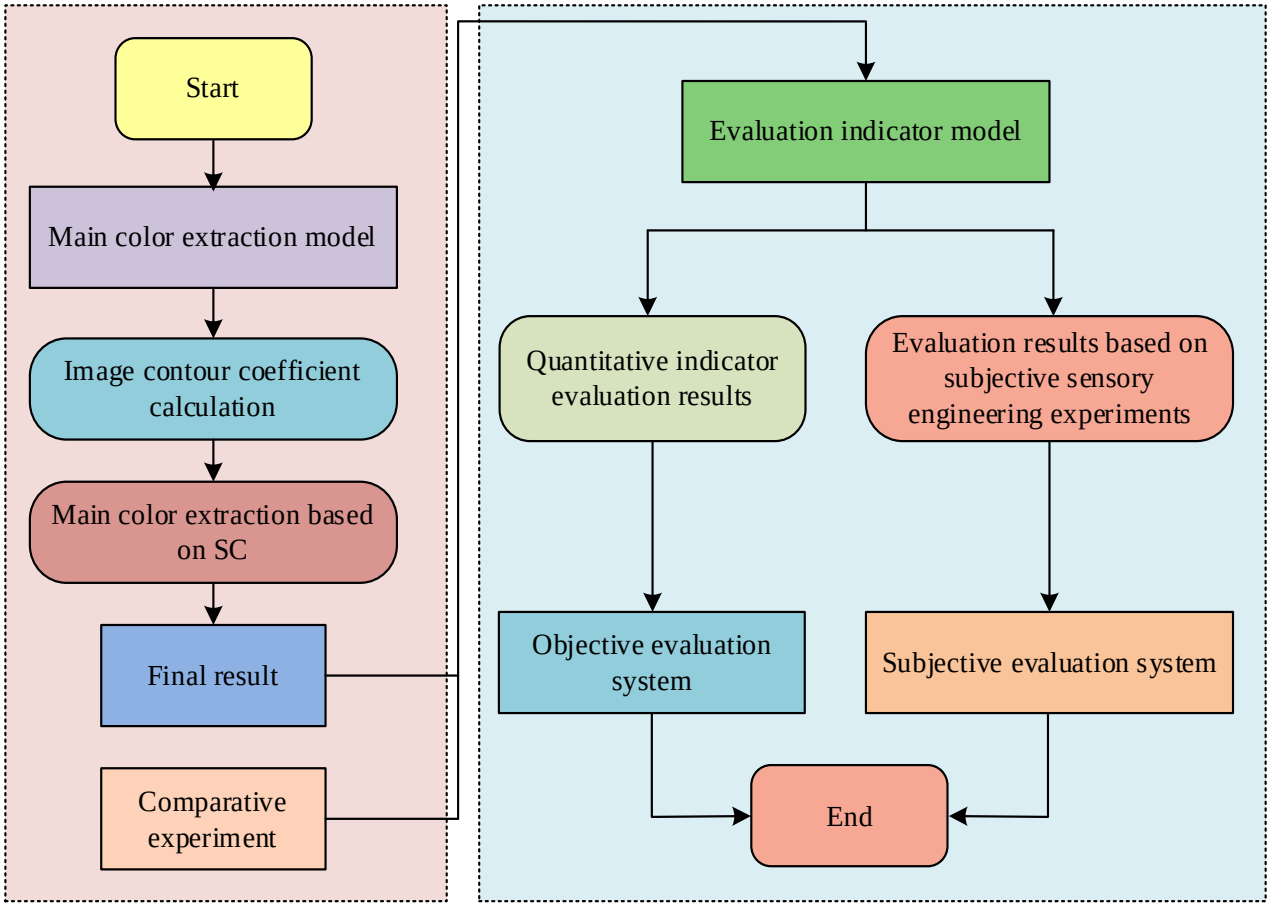

Fig. 2. Adaptive extraction process of image main color based on silhouette coefficients.

B. Color Matching Evaluation Based on Similarity Measurement and Visual Perception

Traditional methods for measuring the similarity of color matching schemes fail to take into account the different orientations of each color block in the palette, resulting in inaccurate color difference calculation for paired palettes [23]. To scientifically and effectively describe the similarity between color palettes composed of multiple color combinations, a minimum color difference model combining position information is proposed. This method mainly adopts the middle color palette strategy to avoid changes in the calculation results caused by differences in position information. The specific calculation steps include six steps. Firstly, it is assumed that the number of main colors in both the source and target palettes is u. The source palette is labeled as P1, and all colors in P1 are traversed and their Lab values are calculated. The target color palette is marked as P2, and all colors in P2 are traversed and their Lab values are calculated. In the second step, the color difference is calculated for the first color of the source palette P1 using all the colors in the target palette P2, and the results are recorded with the corresponding color in P2. The color block corresponding to the minimum value of the calculation result is set as the first color of the middle palette P3. In the third step, the first two stages are repeated, using all colors of P2 to calculate the color difference for the remaining u-1 colors of P1 one by one. Based on the first step, the remaining colors of the middle palette P3 are determined, and the complete middle palette P3 is ultimately obtained. In the fourth step, the average color difference between the source palette P1 and the middle palette P3 is calculated. Fig. 3 shows the specific calculation.

In the fifth step, for the u colors in the source palette P1, the color difference is calculated for each color in the target palette P2, and then a new intermediate auxiliary palette is obtained according to the processing method in the second step, denoted as P4. In the sixth step, the average color difference between P2 and P4 is calculated using the method in the third step. Fig. 4 shows the specific calculation.

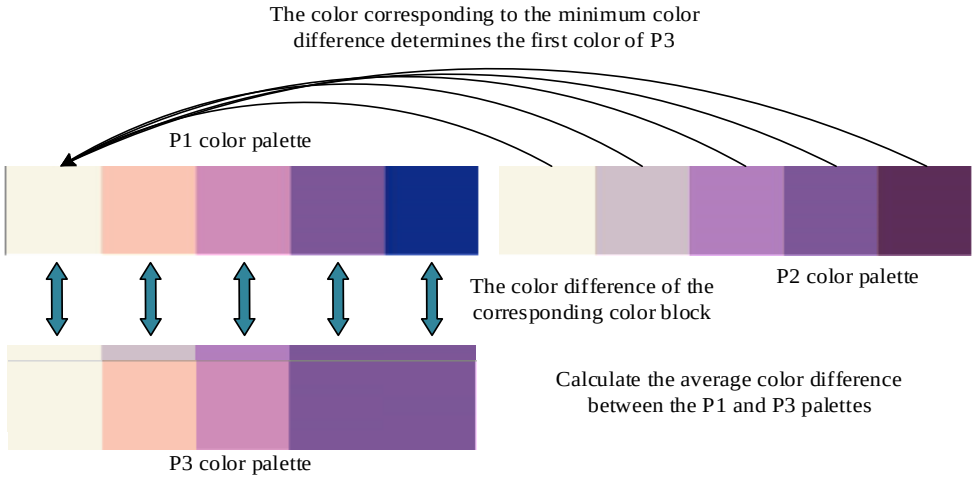

Fig. 3. Calculation method for middle auxiliary color palette P3.

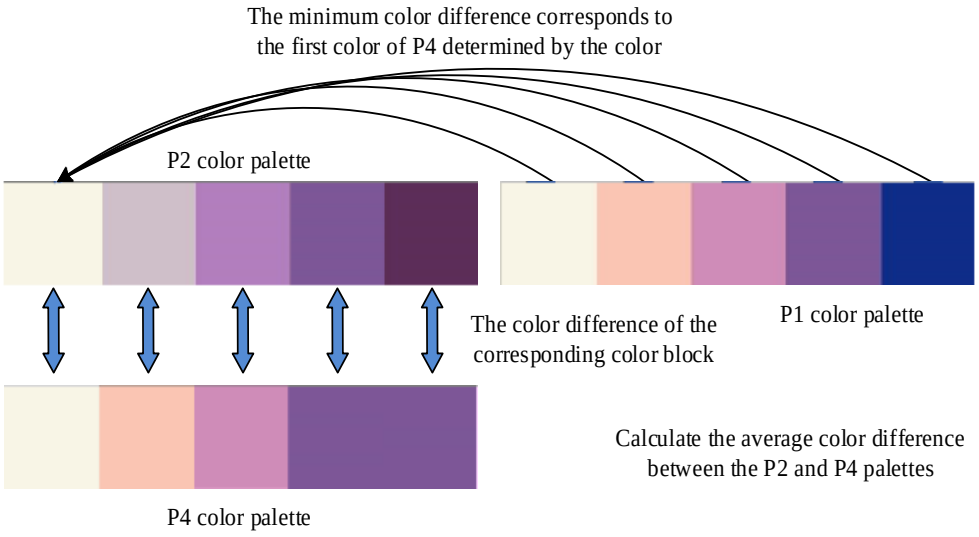

Fig. 4. Calculation method for intermediate auxiliary color palette P4.

Color is a comprehensive effect of the complex physiological and psychological reactions produced by the human visual system under the influence of light. The evaluation of different color schemes should take into account both physical properties and physiological and psychological reactions [24-25]. Therefore, eye tracking technology is used in this study to compare the color matching scheme generated by this intelligent color recommendation system with the original scheme. Based on computational aesthetics and experimental aesthetics, an aesthetic dimension evaluation is conducted on the color matching scheme. Firstly, eye tracking stimulation materials are constructed using the original sample images and the re-colored images. Subsequently, an eye tracking experiment is conducted, recording the basic information of the subjects and each participant's eye movement behavior measure for each group of image. Then the mean first fixed time, mean number of fixed points, and mean fixed time for each sample are calculated. Subsequently, the eye movement behavior indicators of each sample are normalized and these three indicators are weighted and fused. The longer the first fixed time, the lower the attractiveness. Therefore, it is necessary to use the normalized theoretical maximum value minus the normalized first fixed time. Finally, the VP data of the heavily colored image are calculated in proportion to its corresponding source image, which is the VP measure.

C. Intelligent Artistic Color Matching based on Visual Aesthetics

Due to the susceptibility of the human visual system to more visually attractive objects, eye movement behavior measurement is considered an important technical means in the field of quantitative visual aesthetics [26]. In quantifying visual aesthetics using eye movement behavior measurement, the three most critical eye movement behavior indicators include first fixed time, mean number of fixed points, and mean fixed time. These indicators reveal the characteristics of test images or videos from three aspects: visual comfort, attractiveness, and impact. The calculation of mean fixed time in eye tracking experiments is represented by Eq. (8).

$$T = \frac{\sum_{q=1}^{Q} T(AOI)}{Q} \tag{8}$$

In Eq. (8), Q refers to the number of test images. $T(AOI)$ refers to the testing time for dividing regions of interest in eye movement experiments. In visual search, more emphasis is usually placed on targets that have visual aesthetic appeal. The corresponding eye movement behavior indicators include first fixed time, mean number of fixed points, and mean fixed time. Eye movement behavior indicators are utilized to construct a visual aesthetic data stream, and three eye movement behavior indicators are subjected to normalization preprocessing. The mean number of fixed points and mean fixed time are positively correlated with the level of visual aesthetic preference [27-28]. The processing method for mean fixed time is represented by Eq. (9).

$$h' = \frac{h - h_{\min}}{h_{\max} - h_{\min}} \tag{9}$$

In Eq. (9), h refers to the mean fixed time data that currently requires normalization preprocessing. h and $h_{\max}$ refer to the mean fixed time's maximum and minimum values, respectively. The first fixed time measurement index is negatively correlated with the visual aesthetic preference in interactive tasks, represented by Eq. (10).

$$g' = 1 - \frac{g - g_{\min}}{g_{\max} - g_{\min}} \tag{10}$$

In Eq. (10), g refers to the first fixed time data that currently requires normalization preprocessing. $g_{\max}$ and $g_{\min}$ represent the first fixed time's maximum and minimum values, respectively. The visual aesthetic parameter is represented by Eq. (11).

$$W = 10 \cdot (\alpha h' + \beta q' + \gamma g') \tag{11}$$

In Eq. (11), W refers to the visual aesthetic parameter that integrates three different eye movement behavior data, with a range of values between [0, 10]. α, β, and γ represent the weights of mean fixed time, mean number of fixed points, and first fixed time, respectively. The image translation model Pix2Pix is a representation of conditional generative adversarial networks in image translation tasks. This model consists of U-Net and Markov discriminator as conditional generative adversarial networks for generator and discriminator, respectively [29]. This generator's input is a real sample image, and the output is a generated image. The discriminator needs to determine the authenticity of the output image of the generator, so its input is a paired image composed of the generated and real images. Fig. 5 shows the structure of Pix2Pix.

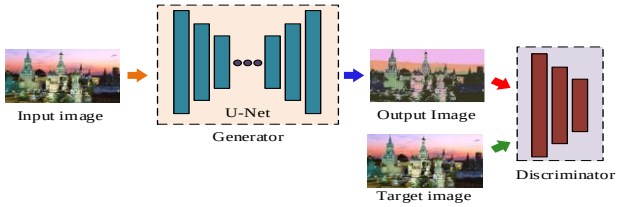

Fig. 5. The network structure of Pix2Pix.

Pix2Pix introduces $L_1 Loss$ to judge the global image based on the conditional generative adversarial network, represented by Eq. (12).

$$G^* = \arg\min_G \max_D L_{CGAN}(G, D) + \lambda L_{L_1}(G) \tag{12}$$

In Eq. (12), G refers to the generator. D refers to the discriminator. $L_{L_1}(G)$ refers to $L_1 Loss$. λ refers to the weight of $L_1 Loss$. $L_1 Loss$ is represented by Eq. (13).

$$L_{L_1}(G) = E_{x,y,z}\left[\left\| y - G(x, z) \right\|_1\right] \tag{13}$$

In Eq. (13), x refers to the true sample. y refers to conditional probability. z refers to random noise. A visual aesthetic evaluation model for color palettes is constructed using visual aesthetic parameters and image main color palettes.

This evaluation model mainly scores the input color palette and optimizes the loss function of the Pix2Pix backbone network using the score values [30]. The network model used is SE Inception V3, which compresses image features through global average pooling and scores the probability distribution of image aesthetic quality. This model mainly uses the real visual aesthetic parameters of the palette as the corresponding palette labels to train the rating model. Fig. 6 is a visual aesthetic evaluation model for color palettes based on SE-Concept V3.

In updating the loss function of the backbone network Pix2Pix, the aesthetic loss function is effectively optimized by introducing a palette aesthetic score, represented by Eq. (14).

$$S(G) = 10 - Score \tag{14}$$

In Eq. (14), $Score$ refers to the rating of the visual aesthetic rating model for the color palette, with 10 points being the maximum rating. Fig. 7 is an intelligent color matching algorithm based on visual aesthetics.

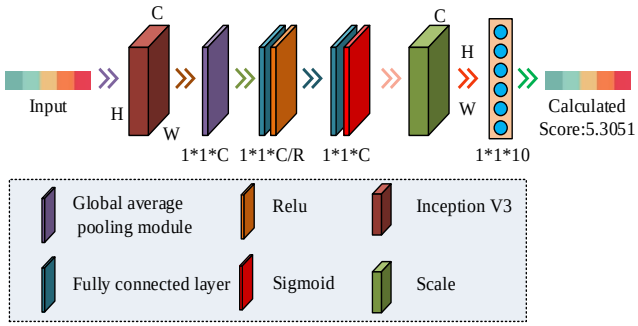

Fig. 6. A visual aesthetic evaluation model for color palettes based on SE-Concept V3.

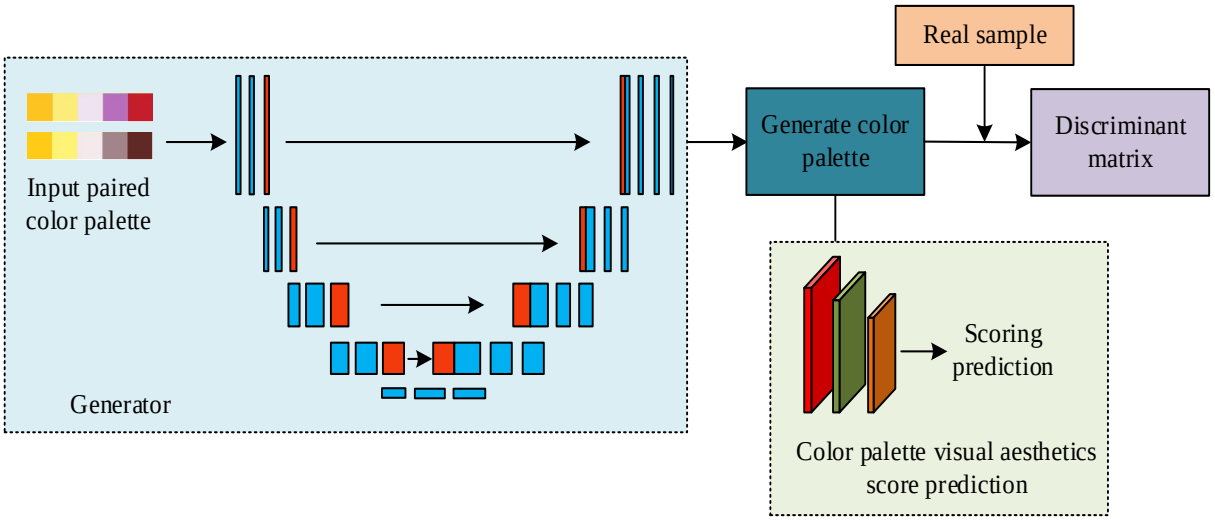

Fig. 7. A network model of intelligent color matching algorithm based on visual aesthetics.

IV. Experimental Analysis of Artistic Color Matching Based on Silhouette Coefficients and Visual Perception

Firstly, the study validated the effectiveness of the SC-based adaptive extraction method for image main colors and evaluated the main color extraction method from both subjective and objective perspectives. Subsequently, the effectiveness of the aesthetic evaluation model for color palettes was verified. Finally, experimental analysis was conducted on Pix2Pix based on visual aesthetics.

A. Adaptive Extraction and Analysis of Image Main Colors based on Silhouette Coefficients

To validate the SC based image main color adaptive extraction method's effectiveness, traditional K-Means, Median cut, and Octree algorithms were selected for comparison in main color extraction. To ensure the scientific and stable nature of the experiment, 58 sample images were collected from three types of samples: complex natural scenes, animal and human images. Table II shows the relevant parameters.

TABLE II. Relevant Parameters

Equipment and environment	Model number
Operating system	Windows10
Processor	ntel(R)Xeon(R)E5-2678V3
Graphics calculation card	NVIDIA GeForce GTX 1080 Ti
Develop compilation tools	Visual Studio Code
Server	Ultrascopic 7048 GR-TR
Algorithm framework dependencies	Numpy、OpenCV
Memory	Samsung 32G 2RX4 2400T
Algorithm development environment	Python 3.7

Firstly, the study evaluated the main color extraction methods from a subjective visual perspective, selecting natural scenes, animal and human images for main color extraction. Meanwhile, corresponding main color images were constructed based on the extracted results. Fig. 8 shows the main color extraction and image generation results of some natural scenes. In Fig. 8 (a), among the main color extraction results of natural landscapes, the image based on SC had the best main color extraction result. This method only characterized the color

scheme of the entire lake with three main colors. In Fig. 8 (b), the image main color extraction method based on SC only characterized the color scheme of the entire scene with four main colors. Meanwhile, the main color extracted by SC matched better with the source image, and Octree had the lowest matching degree. In summary, compared to other methods, SC was more effective in extracting representative colors.

Fig. 9 shows the main color extraction and image generation results of some animals and characters. In Fig. 9 (a), in the main color extraction of animal scenes, the image main color extraction method based on SC extracted the three most representative colors of the source image. In Fig. 9 (b), the image main color extraction method based on SC only characterized the color scheme of the entire character scene with four main colors. Compared with other methods, the proposed method extracted colors that matched better with the source image. Octree had the worst extraction performance.

The study continued to objectively evaluate the main color extraction results of various methods. The evaluation indicators include the structural similarity and PSNR between the main color and source images. Fig. 10 shows the structural similarity and PSNR measured by various methods for 58 images. In Fig. 10 (a), the structural similarity of the main color image generated by SC was better than other methods. The maximum structural similarity of this method was 0.675, with an average of 0.663. The main color images generated by Octree had the lowest structural similarity, with an average of only 0.617. In Fig. 10 (b), the PSNR of the main color image generated by SC was also optimal. The PSNR of this method reached a maximum of 21.49 dB, with an average of 21.05 dB. The PSNR of K-Means ranks second, with an average of 20.54 dB. Therefore, the main color extraction method based on SC was optimal, and the generated main color image had a higher similarity with the source image.

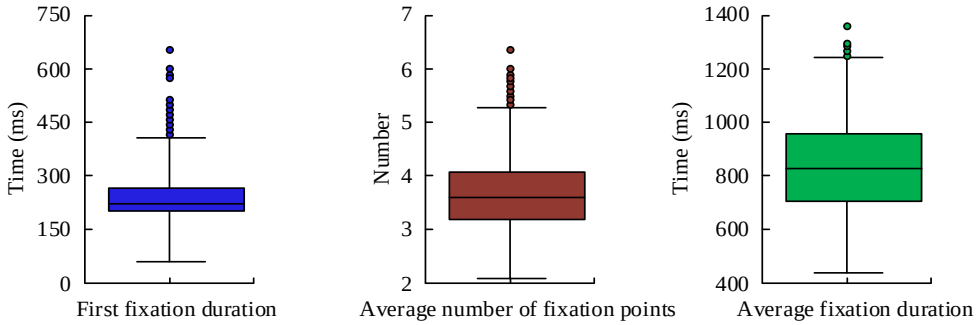
B. *Analysis of Intelligent Art Color Matching Evaluation Based on Visual Aesthetics*

To verify the effectiveness of the aesthetic evaluation model for color palettes, a dataset of 2800 color palettes was collected in Adobe Color CC. The study conducted eye tracking experiments on each dataset to obtain its visual aesthetic parameters. These samples were randomly divided into 700 groups of eye tracking stimuli as experimental data for eye tracking. The study invited 50 undergraduate students to participate in eye tracking experiments. All participants had good vision, no color blindness, weak color, and other physical effects that affected their vision. The playback time of each group of stimulating materials on the screen was 5,000 milliseconds. After the experiment, the average eye movement data of each designated area of interest was obtained based on the eye tracking data of the subjects. Fig. 11 is a box plot of the first fixed time, mean fixed time, and mean number of fixed points. In Fig. 11 (a), the mean first fixed time of the experimenter was 182.58 ms. In Fig. 11 (b), the mean number of fixeds of the subjects was 3.5. In Fig. 11 (c), the mean fixed time of the subjects was 826.36 ms. There were outliers in the upper limits of the first fixed time, mean fixed time, and mean number of fixed points. This is due to the influence of psychological and physical factors on eye movement behavior, resulting in fluctuation.



(a) Box plot of first fixation time (b) Box plot of average number of fixation points (c) Box plot of average fixation duration

Fig. 11. Box plots of three eye movement fixed indicators.

The study continued to use a color palette visual aesthetic evaluation model to evaluate the visual aesthetics of sample images. To reduce the interference of outliers on the results, the upper and lower limits of these data were used as the maximum and minimum values for normalization processing. Fig. 12 shows the true values of visual aesthetic parameters and the visual aesthetic evaluation model scores of the color palette for 20 samples. The data predicted by the color palette visual aesthetic evaluation model were relatively close to the actual values. The predicted data of sample 8's model only differed by 0.05 from the actual value, indicating that the designed color palette visual aesthetic evaluation model had good predictive performance.

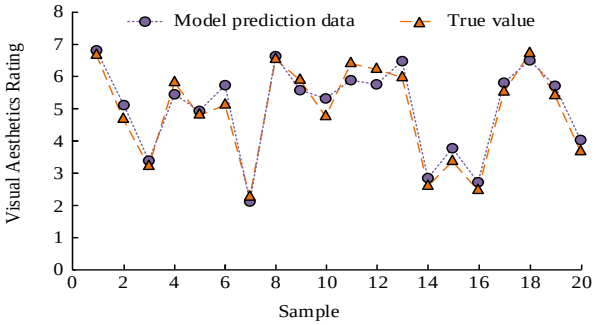


Fig. 12. Color palette visual aesthetic evaluation model rating results.

To verify the effectiveness of Pix2Pix based on visual aesthetics, this study selected art and design designers with matching schemes and Pix2Pix without integrating visual aesthetics for experimental comparison. 1680 sample images were extracted in the experiment, and the main color palette was obtained by extracting the main color from the sample set. Due to Pix2Pix requiring input into paired color palettes, the main color palette was fragmented to construct a paired color palette. To ensure consistent size of the paired color palettes, black replaced the missing color blocks, which were the colors that needed to be matched. The palette samples were divided into training and testing sets in an 8:2 ratio, with a total of 1344 training samples and 336 testing samples. In addition, the Adam optimizer was used for training, with an initial learning rate of 0.0002, an initial momentum term of 0.5, a network epoch count of 200, Batch_Size of 8, an initial parameter training weight of 100 for $L_1 Loss$, and an initial weight of 0.1 for $S(G)$. Fig. 13 shows the results of some color matching tests. Fig. 13 (a) means the incomplete palette, and Fig. 13 (b) refers to the source palette. In Fig. 13 (c), the complete color palette matched by the designer exhibited high harmony in color attributes and superior visual effects, but its design took a long time. In Fig. 13 (d), the color palette of Pix2Pix without incorporating visual aesthetics was vivid, but the visual effect was relatively cluttered. The reason is that Pix2Pix, which does not integrate visual aesthetics, mainly focuses on the sample distribution of all training images, but fails to effectively combine human eye VP, resulting in poor harmony in the generated color matching scheme. In Fig. 13 (e), the designed model had a visual effect similar to that of the source palette and a professional designer in terms of color matching. For the real-time performance of color matching, due to the sample size of color matching images being 32×1, the computational complexity of the designed model basically met the real-time requirements.

(e) Pix2Pix network model based on visual aesthetics

Fig. 13. Partial color matching test results.

Further research is conducted to verify the computational efficiency of the Pix2Pix network model based on visual aesthetics. Compare with K-means clustering algorithm, Gaussian Mixture Model (GMM), and Generative Adversarial Networks (GANs). The experiment measures CPU time, which includes the time required for palette generation and pixel mapping stages. The efficiency of color matching generation for sample images by each model is shown in Fig. 14. As shown in Fig. 14, the average color matching time of the Pix2Pix network model based on visual aesthetics proposed in the study is only 13.75ms. The average time consumption of K-means clustering algorithm model, GMM model, and GANs model is as high as 135.67ms, 90.36ms, and 54.69ms, respectively, which is significantly higher than the algorithm proposed in the study. The color matching scheme of the Pix2Pix network model based on visual aesthetics can complete tasks at a faster speed and has efficient computational performance.

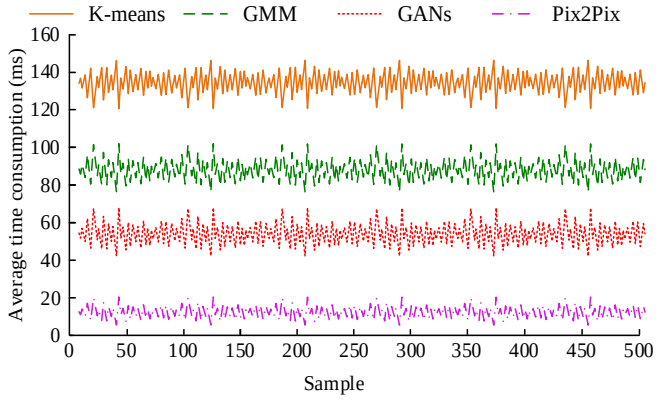

Fig. 14. The color matching time of each model for sample images.

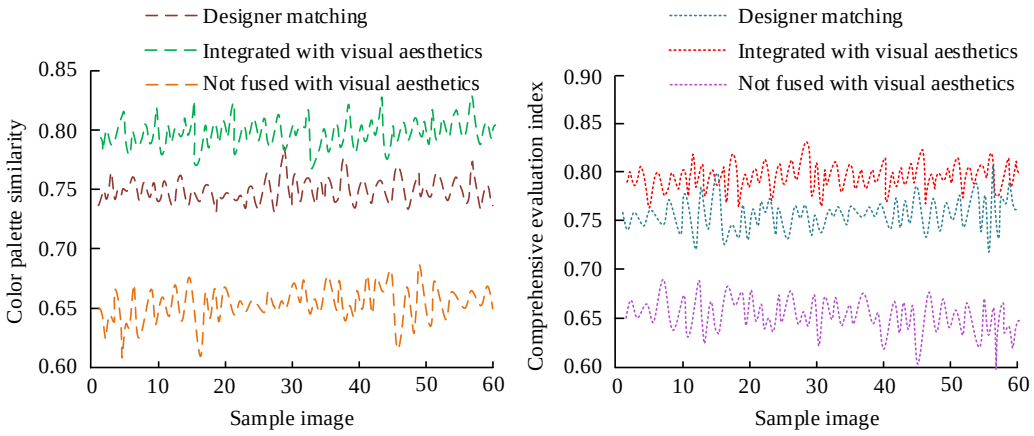
To scientifically analyze and compare the experimental results, the color matching evaluation method was used to evaluate the color matching effects of each method. 60 samples were selected for color matching effect analysis, with evaluation indicators including similarity of color palettes and comprehensive evaluation index. Fig. 15 shows the evaluation indicators for three methods. In Fig. 15 (a), the average color palette similarity of the Pix2Pix design scheme based on visual aesthetics was 0.807, which was 0.043 higher than the scheme designed by the designer. In Fig. 15 (b), the average comprehensive evaluation index of the proposed method was 0.798, which was 0.158 higher than the Pix2Pix without integrating visual aesthetics. Pix2Pix based on visual aesthetics had a more significant color matching effect.



(a) Color palette similarity across different methods (b) Comprehensive evaluation index of different methods

Fig. 15. Color palette similarity and comprehensive evaluation index of three methods.

The study then combined perceptual engineering experiments to conduct psychological and physical analysis on the effect of color matching. Twenty sample sets were selected for the experiment, and 10 participants were invited to subjectively evaluate the test results. The average score was taken as the final result. Fig. 16 shows the average scores of all participants on the four color matching schemes. The subjective score of the color palette generated by the proposed method reached a maximum of 4.25, with an average of 3.81, which is 027 and 0.39 higher than the Pix2Pix without integrating visual aesthetics, respectively. Meanwhile, the matching effect of this method was closer to the matching scheme designed by professional designers and the color matching effect of the source palette. The proposed method also performed well in subjective evaluation.

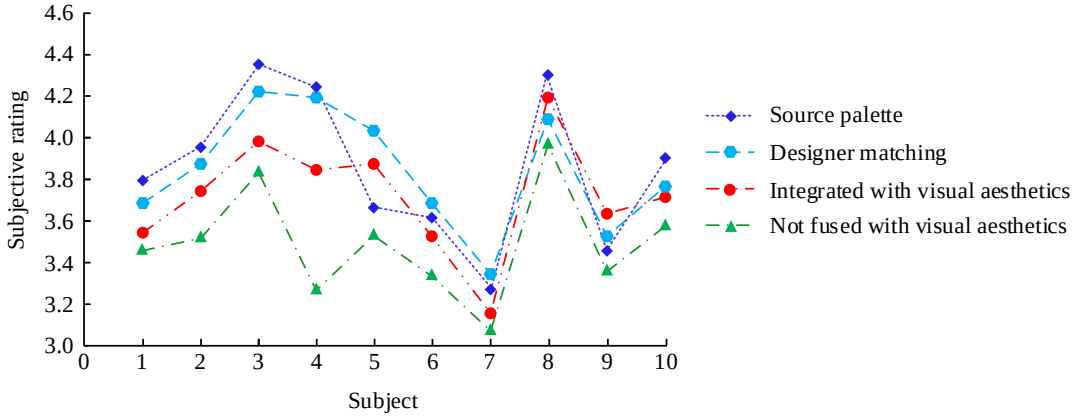


Fig. 16. The average rating results of four color matching schemes.

V. Discussion

Currently, in the field of color science, issues related to color matching include image main color extraction, color matching methods, and the selection of color matching evaluation methods. The purpose of the study is to achieve effective adaptive color extraction, combine human visual perception to generate the best color matching scheme, and conduct a more comprehensive and multidimensional analysis of the color matching scheme. For this purpose, research has successively proposed a SC based adaptive extraction method for image main colors, a Pix2Pix network model based on visual aesthetics, and a multi-dimensional color matching evaluation method combining visual perception and similarity measurement. The results showed that in the main color extraction results of natural landscapes, the image main color extraction based on SC was the best, and this method only represented the color system of the entire lake with three main colors. Meanwhile, this method only characterizes the color

scheme of animal and human image scenes with four main colors. At the same time, it can be seen that the main color extracted by SC matches better with the source image. Related studies have shown that the image main color extraction method based on SC can represent the color scheme of the entire image with the most concise colors, which is concise and efficient [31]. In the effectiveness verification of the Pix2Pix network model based on visual aesthetics, the complete color palette matched by the designer showed high harmony in color attributes and superior visual effects, but the design process was time-consuming. The Pix2Pix network model, which does not integrate visual aesthetics, is paired with a palette of bright colors, but the visual effect is relatively messy. The model designed for research has a visual effect similar to that of the source color palette and professional designers in terms of color matching. The experimental results of K. Qiu et al. show that integrating visual aesthetics can effectively improve the color matching effect of network models, and has lower computational complexity [32]. In addition, in the experimental analysis of color matching effect evaluation, the subjective score of the color palette generated by the proposed method reached the highest of 4.25, with an average of 3.81. Compared with the Pix2Pix network model without integrating visual aesthetics, it improved by 027 and 0.39, respectively. Meanwhile, the matching effect of this method is closer to the matching scheme designed by professional designers and the color matching effect of the source palette. The method proposed by the research institute also performs well in subjective evaluation. And the data predicted by the color palette visual aesthetic evaluation model is relatively close to the actual values. Among them, the predicted data of sample 8's model only differs by 0.05 from the true value, indicating that the color palette visual aesthetic evaluation model designed in the study has good predictive performance.

VI. Conclusion

Currently, there are challenges in color matching, such as cumbersome design processes and severe homogenization. To achieve intelligent color matching scheme design and development, a computer-aided design method based on image processing and VP was introduced. For image main color extraction, a SC-based image main color adaptive extraction model was introduced. Meanwhile, a color matching evaluation method combining VP and similarity measurement was introduced. In addition, a color matching model based on visual aesthetics was designed. These results confirmed that in the main color extraction of natural landscapes, animals, and people, the image main color extraction based on SC had the best results. Meanwhile, the main color extracted by this method was more closely matched with the source image, which more effectively extracted representative colors. In the validation of the color palette aesthetic evaluation model, the data predicted by the color palette visual aesthetic evaluation model were relatively close to the actual values. The model prediction data of sample 8 only differ by 0.05 from the true value. In the validation of Pix2Pix based on visual aesthetics, the designed model achieved visual effects similar to those of the source color palette and professional designers in color matching. Moreover, its computational complexity basically met the real-time requirements. In addition, the subjective score of the color palette generated by the proposed method reached a maximum of 4.25, with a mean of 3.81, which was 027 and 0.39 higher than the Pix2Pix without integrating visual aesthetics, respectively. The average similarity of color palettes in the design scheme of the Pix2Pix network model based on visual aesthetics is as high as 0.807, which is 0.043 higher than the scheme designed by the designer. And the average comprehensive evaluation index of the method proposed by the research institute is as high as 0.798, which is 0.158 higher than the Pix2Pix network model without integrating visual aesthetics. Meanwhile, the matching effect of this method was closer to the matching scheme designed by professional designers and the color matching effect of the source palette. Overall, the proposed color matching computer-aided design method achieved significant results and had significant practical application value. However, the designed SC-based image main color adaptive extraction model has a high time complexity. Subsequent research can further improve algorithm efficiency while ensuring adaptive conditions are met.

Virtual Second Life Affects the Existence of Arab Residents

Galal eldin Abbas Eltayeb*
Department of Management Information Systems, College of Business and Economics,
Qassim University, Buraydah, Saudi Arabia

***Abstract*—The 3D virtual community known as Second Life (SL) which is available on the Internet (www.secondlife.com) represents the latest online services for business, learning, training, and entertainment. People, regional and ethnic groups, business organizations, social activities, and various societal environments populate this world. People who live in this virtual world, known as residents, use personal avatars to declare themselves. People from the Arab region also exist in this world, and they practice their activities as human beings, emotions, and actions. For the Arab residents, there is no escape from living in these communities, like others, using this unlimited space and time. The SL Societies honour their own traditions, ethics, and behaviors as personal values. And since Arab society, in particular, has its own values, traditions, and ethics, could there be a significant reflection of these values in the Second Life Society? This paper aims to pinpoint the possible consequences that certain ethical attitudes attribute to Arab residents, while also posing the crucial question of whether these values and ethics align with the diverse societies within the SL realm. The paper identifies the possibility of a decline in the popularity and population of SL with the reluctance of Arab societies, although, a large number of Arabs have access to Internet services as enriched with technical issues and Internet provision in most Arab countries.**

***Keywords*—Internet; second life; virtual worlds; Arab; values; ethics**

I. Introduction

Linden Research, Inc. owns Second Life (SL). In 2003, it was opened to the public; in 2013, there were more than one million monthly residents; in 2017, there were at least 600,000 active residents; in 2018, that number dropped to around half a million active monthly residents; in 2019. As of August 7, 2020, at 14:20:03 SLT, the total number of residents stands at 64,167,367, with an additional 47,696 residents accessing the site online [1] [32]. After 20 years, and close to the 21st birthday of the second life, from 21st June 2024 through until 21st July 2024 Rachel Douglass reported on July 28, 2023 [34], that there are still about 74.7 million active residents in SL (https://gridsurvey.com/), with an average of 200000 daily access, but Second Life Grid Statistics on June 20, 2024 Update [35] listed a decrease in residents concurrency levels in SL Life regions, now statistics account a total of 67,862,439 residents.. Linden owns intellectual property rights, forms requirements, terms of service in this world directives, and licenses virtual lands. SL residents can interact with others through their avatars to socialize and participate in the live components that exist in this world: conversations, trading, simulation sex, rape, or even marriage and divorce, as well as having fun and sharing their knowledge. So it's fully a pseudo-reality of the real world, but with a high level of privacy in creating what you desire, including potentials, resources, and behaviors, starting with selecting your personality, identifying your features, and choosing to communicate and visit as many places as you want. Hence, social virtual worlds in SL represent the real world digitally, so it is necessary to meet legal and ethical situations as in real life. In this paper, we perform an extensive analysis of the existence of Arab avatars in SL and how their ethics and values affect these worlds negatively or positively, Also, this noticeable decrease in the number of Second Life residents, are they part of it?

II. Objective and Method

This paper follows the investigative approach to ensure the existence of Arab content, personalities, and sciences in SL environment that does not revolve around the barrier of language or moral legacies, customs, and beliefs, so that this environment is an uncomfortable place and does not continue to accept and be in it, this was done by examining the Arab presence in the SL environment actually, and through the publications of Arab and non-Arab residents in it related to these axes, and the paper tried to summarize this with all transparency in the quest to try to understand the Arab presence, investigating the withdrawal of a large number of them from this virtual world, and whether this is their own or it is a general issue that affected all other nationalities. Taking into account the noticeable decrease in resident numbers, we cannot deny that Arabs are part of this decrease. The paper also seeks to confirm that Arabs are an indispensable nationality that has a share of this decrease.

A. The Arab Identity

Arab identity as a reality, not a choice, depending on state of birth, lineage, legacies, and place of birth, and upbringing and coexistence with family and peers have linked it to the culture of the surrounding environment. In virtual worlds such as SL, the origins of this identity, its legacies, and its behaviors are very far from reality. Rather, it is a natural reflection in which a resident's practice differs according to his origin, or he seeks to escape from the real world, which causes him some complications that are not commensurate with what he is expect. Arab identity is the people who exist within the Arab region, which includes the 22 countries spreading from the Atlantic to the Arabian Gulf, and the predominant language in it is Arabic in both speech and writing. Interestingly, they have different ethnic, religious, and cultural backgrounds [2] [3]. Otherwise, they may exist outside the Arab region while

maintaining an attachment (stuck) to their culture and heritage. Fig. 1.

Google Trends (https://trends.google.com/trends/) reveals that the interest in SL among Arab individuals in the Arab region over the past five years, across four states or more in each country, has resulted in the numbers shown in Table I. These numbers indicate the rate of interest in the web search for "Second Life" term specifically, and we calculate this rate by comparing it to the highest point in the graph for the specific region and period, i.e. the value "100" represents the peak popularity of the search term compared to other search words in the same region, while the value "50" represents half the popularity of this phrase. For absent countries, there is not enough data available for this search term.

Fig. 1. Arab region map. Source: League of Arab States (LAS) [4].

TABLE I. INTEREST IN SL TERMS AMONG ARAB COUNTRIES, LISTED ON TUESDAY, MAY 14, 2024

Country	*Number of sub-regions*	*Level of interest by sub-region (mean)*
Algeria	4	91.50
Bahrain	4	92.50
Egypt	4	56.25
Iraq	4	79.00
Jordan	4	65.00
Kuwait	4	78.25
Lebanon	3	79.30
Libya	3	96.67
Mauritania	1	100.00
Morocco	4	70.50
Qatar	4	75.25
Saudi Arabia	4	53.75
Somalia	1	100.00
Syria	2	100.00
Tunisia	4	81.25
United Arab Emirates	4	93.75
Yemen	1	100.00

B. Second Life's Terms

Residents are expected to adhere to a set of community standards as part of their agreement with Second Life's Terms of Service (ToS). The Terms of Service (ToS) outline the actions that can restrict your access to the service, including the possibility of terminating your membership. These actions can include racism, intolerance, harassment, abuse, intimidation, disrespect for space and privacy, sharing inappropriate content, doing suspicious things, being in places that are allowed for people of a certain age and status, like adult areas, as well as keeping data private and not sharing information in harmful or other ways that bother other residents, or being hostile or acting in a subversive way [5]. The ethics in Second Life's Terms cover social and commercial activities, property rights, and their legal review [6]. As a result, forms of virtual crime, such as murder, theft, and harassment, have emerged as a likely sign of moral disorder in virtual life similar to real life. For instance, a woman in Japan faced arrest after her husband killed her Avatar in a virtual environment [7], while a woman in Delaware faced accusations of plotting to kidnap a real life from a loved one she had met through an SL [8]. In SL, morality presents a vast, large, and complex landscape, which is interesting in many ways. Second-life science of personality and its ills often links these moral issues to real-life practices. This is especially true in a world that fails to meet all control standards, including restrictions on access to pornography and inappropriate content, online gambling, and the promotion of violence, harassment, and bullying.

C. Arab Ethics and Values

Ethics is the noble characteristic of the human being that makes him appreciated and respected, and the people of the Arab region derived some characteristics from their environment. Cultural and religious beliefs often deeply root these ethics, shaping how people interact, make decisions, and approach various aspects of life. Some key elements of Arab ethics and values are sincerity; they tend to adhere to the teachings, which are characterized as divine, comprehensive, and stable; the mind accepts them and stimulates responsibility and public interest; they watch the person inwardly and outwardly; and they seek to control their instincts and passions. Therefore, they are characterized by good hospitality, honoring the guest, forgiving when able, providing relief to the needy, relief of the distressed, acumen, and inspiration. In terms of chastity, the characteristics of the Arabs include generosity, kindness, modesty, help, piety, lack of greed [9], respect for elders, respect for parents, caring for children and relatives, and maintaining family unity, all of which are considered important values. It may clash with a virtual reality in which there are all types of people and morals, as well as a lot of ethnic, creedal, and customary variations, such as the Second Life society. Furthermore, the majority of Arab societies maintain a conservative view of women, which varies significantly depending on the culture, traditions, and values of each Arab country. Even within each country, there may be differences between urban and rural societies, as well as between different generations. Women's rights and opportunities to participate in public life, including education, work, politics, decision-making, and mingling with men, reflect ancient traditions and inherited concepts. In a global space like SL, these boundaries

and separations may be absent, which is reflected in the behavior of the Arab individual before or after the rejection of certain stances and behaviors, which directly affects his presence or non-existence within this society.

III. PREVIOUS STUDIES

Second Life Grid Statistics for June 2024 show that the grid has remained above the 30,000 region mark since May 2024, with private estates increasing slightly. Linden regions have remained the same for the past month, indicating no significant developments on the Bellisseria continent. The development work for Linden regions has slowed down due to the upcoming opening of SL21B to the public. Second Life daily user concurrency has risen slightly in recent weeks, with daily concurrency levels bouncing back. The monthly maximum concurrency trend started higher during the first three months of 2024 but has declined since April 2024. The trend might improve in late 2024/early 2025. Maximum peaks for Second Life during 2023 were higher at the start of the year but decreased slightly with a slight increase at the end of the year. The overall trend for max peaks in 2023 is similar to last year, with the highest peak occurring in January 2023 [38].

Hassan Hamidoui [10] noted that over 25,000 avatars have visited the Kingdom of Saudi Arabia island in Second Life, while another 25,500 avatars have journeyed to the Middle East, the most favored among the thirty-six Arab islands in Second Life. Also, he mentioned that these avatars can engage in activities they might not be able to do in real life, like celebrating Western holidays such as Valentine's Day, receiving gifts from the opposite genders, and even dancing to DJ music. To prevent illicit relationships or indecent clothes according to its religion and values, this island posted an ethical logo.

Güzel and Aydin [11], studying the effect of second life on speaking achievement, concluded that if avatars joined speaking classes, they could increase their speaking achievement in one of these ways: traditional speaking activities, speaking proficiency levels, or appropriate responses to situations that indicate improvement.

Smith and Berge [12] concluded in social learning theory in SL that people live in multiple interconnected worlds, similar to hyperlinks. In those worlds, in the future, we can expect to smell and feel things. Therefore, educators must reconsider their approaches to guiding learners; additionally, Bandura's social learning theory suggests that we can only relinquish our attitudes and emotional behaviors in these worlds, while accomplishing all other tasks.

When Kusumo and Endriastuti [7] studied the mental synthesis identity in Second Life, they came to the conclusion that, because SL residents feel free to create new identities with specific appearances and life goals, the attraction between the cyberghetto and cybertopia paradigms is never inevitable.

A study by Abdallah and Douglas [8] involved questioning a group of 45 mature undergraduate students at one of the universities in the United Arab Emirates. Abdallah and Doudlas asked the students to freely explore this environment over a period of several days. Students' engagement with Second Life averaged 4 hours, with some students clocking 15 hours. 34% of students identified the 'socializing' aspect of Second Life as their primary attraction, while 11% acknowledged the educational benefits of using it. However, 4% expressed dissatisfaction with SL's features and expressed negative sentiments about the appearance of naked women and men. The cultural, technical, and complexity barriers prevent students from returning to Second Life.

Pohlke's master thesis [13] discusses Second Life's (SL) language, citing nine different languages on the SL platform and approximately 38 languages spoken by residents (http://secondlife.com/corporate/sysreqs.php). This diversity allows residents to communicate and respond positively to the challenges posed by a multicultural society. The thesis concluded that the SL is not only a meeting space for people with different cultural backgrounds but also a social space where cultures of their own have evolved and may or may not offer a suitable test case for real-life cultures [31].

A. Avatars Talks

There was a lot of talk about the Arabic language, and Arab residents in the second life, MH [14], wondered about the presence of Arabs and the disappearance of the Arab Forum in Kuwait Virtual City and the other 100 region estates, which are inhabited by more than 50,000 active daily people. Kuwait City boasts 190,000 daily active users. What's happened to this? Erica Jameson [15] conveyed her fascination with the Arab lifestyle, particularly the marriage between a white girl and an Arab resident, and questioned if this could be considered a form of enslavement. Meanwhile, Aura [15] concentrated on gathering authentic feedback from the Second Life community regarding the issue of Arabs and Arabic in particular, the issues raised about it, the subsequent ban or closure of accounts, the potential bias against those who don't speak Arabic, and whether the language barrier is a contributing factor. Blocking and closing accounts? Sammantha Koppel [15] expressed his skepticism about bans based solely on English language proficiency. Mansour Riler [15] questioned why Linden Labs does not recognize the Arabic language. However, Linden Labs recognizes most other major languages. Void Singer responds, "Is this because more than one Arabic nation blocks access to SL, thereby reducing the number of people who speak it?" In contrast, Void Singer [16] asserted that the issue facing Arab residents stems from a significant volume of content theft in certain Arab societies, leading to user bans, often without their knowledge. On the other hand, the observers in the LL are not as numerous as to ascertain the Arabic writings and their significance, and this has been compared to other foreign language societies, such as Brazilian society, with little such a problem in French, German, and Italian societies. Muhammad Ahmad posted on Tuesday, June 23, 2015, at 02:21 AM [17]. Of all the communities, it was the most ignored by the SL owners. For years, other residents faced severe discrimination against most Arabs due to their limited English proficiency. People think it's simple to learn English when many are in nations that frown on western culture and ideas, so when one starts typing or speaking English, the censors take notice of you and your family. That's why they chose not to learn or speak about it on unprotected channels. Indeed, the absence of translation among viewers and the stricter regulations over the past three years have led them

to explore alternative online content. Even the owners of Second Life (SL) desired our departure, prompting the largest communities to convene a large meeting where elders cast votes to determine the winner. We asked SL's staff to attend the meeting, but we received a phone call informing us that no one was available. They expressed concern that others might perceive them as barbaric and doubt their humanity based on linguistic and religious differences rather than their character. Despite this, they continue to spend more money and lease more land than any other community. On Tuesday, June 23, 2015, at 06:04 AM, Rin posted that the marked decline in Arabic-speaking and regional participation in SL is a result of various developments in the Arab world. Sadly, almost all authoritarian regimes have leaped on any sign of uncontrollable online freedom of speech or service that may allow the dissemination—for them—of dangerous material and ideas. We wouldn't be surprised if SL followed suit, given its current state, although the exact extent of this decline remains unclear, as evidenced by the numerous comments in the SL community and New World Notes [17].

B. Arab Communities on SL

In the Arab region as a whole or the Middle East region, there are some Arab communities and gatherings that are popular and frequented by a significant number of residents. Here, we will examine some Arab Sims and societies that accurately portray the Arab individual and their activities, as evidenced by their message and behavior, and provide commentary on how these align with moral values and expected behaviors, such as:

Arabian Nights: Inspired by the tales of "One Thousand and One Nights," its themes encompass a large tent, featuring fictional or mythical elements such as magic jinn, flying carpets, beautiful palaces, bustling bazaars, and exotic landscapes like deserts and oases. Residents share activities that promote this, centered on Arab folklore or indigenous figures with a reputation and inherited history, such as adventurers, kings, merchants, and Sufis, and are full of events, concerts, and cultural performances. These events provide opportunities for socializing, creative expression, and immersive experiences in the Arabian Nights. Fig. 2(a) shows inside the buildings and aesthetic sites described in the tales of "One Thousand and One Nights" [18].

Dubai Event: This is a monthly shopping event that starts on the 20th of each month. It refers to a virtual event or series of events hosted within the platform that revolve around Dubai, the city known for the UAE, with its modernity, luxury, and cultural vitality, and reviews futuristic architecture, luxurious lifestyles, desert landscapes, traditional Arab culture, popular activities and attractions such as the Burj Khalifa, cultural performances such as music and dance performances, and interactive experiences related to Dubai's industries such as aviation, finance, and tourism. [19]. Fig. 2(b).

Habibi: Habibi Club is a Middle Eastern oasis on SL, a place or community where people interested in Arab culture gather. This oasis is characterized by Arab-style landscapes, buildings, and activities that reflect the richness of Arab heritage and aesthetics. This oasis provides a variety of activities, including listening to exotic music, watching belly dancers, listening to Arabic music such as traditional oud or contemporary pop, participating in storytelling sessions, and engaging in language exchange activities where participants can learn or practice Arabic [20] as shown in Fig 2(c).

Middle East: It reviews the art of Arab architecture and authentic Arabian horses to indicate equestrianism with Arab costume (jilbab and shemagh) as well as displays religion through the prayer of Muslims, and then displays Arab art, especially for the Levant region, which is famous for Dabke, and does not miss the scene of modern architecture high such as Burj Al Arab and Burj Al Faydaliya in Saudi Arabia, Burj Khalifa, Kuwait Towers, Sheikh Zayed Mosque, palms, and the sea, all of which came together in a painting that shows the beauty of the Middle East. As for personal values, modesty is observed for men and a reduction of nudity for women, such as very rare tattoos, chains, belongings, and attachment to liquor. As for fashion design, in the construction and empty design of the houses, it is noted that tents, the Bedouin environment, beauty, desert backgrounds, and sand are shown on the one hand, and the other hand, buildings with arches and long columns appear [23] as shown in Fig 2(d).

Sami (samiq8) created the Arab Market, a virtual marketplace or area within Second Life that specifically caters to Arab culture, products, and experiences. It includes virtual representations of traditional Arab markets where users can interact, trade, and engage in cultural activities [22], Fig. 2(e).

Antara Ansar founded the Arabesque group for artists and creators of Arabic aims intending to unite all lovers of Arabic and Islamic art and calligraphy [21] as shown in Fig. 2(f).

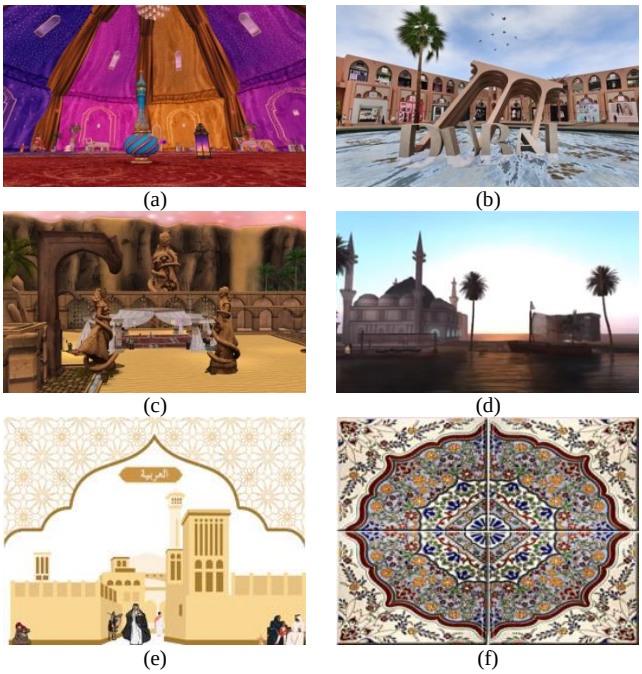

Fig. 2. Various images of Arab communities on SL: (a) Arabian Nights tent, (b) Dubai Event, (c) Habibi Club, (d) Middle East, (e) Arab Market and (f) Arabesque.

IV. DISCUSSION

Arab values manifest in the virtual cyber society through a complex interplay of offline culture being enacted online, counteracted online, and online culture being enacted offline. The digital transformation has impacted Arab and Islamic societies, blurring distinctions between traditional values and modern influences [24] and [25]. Arab youth, with their progressive civic outlook and digital engagement, show promise for better governance, embracing diversity, co-existence, women's empowerment, and innovation [26]. Arab women have used cyberspace to advocate for women's rights, fostering collective identity and solidarity through cyberfeminism [27]. The Internet-influenced Arab media landscape strikes a balance between preserving cultural norms and modern influences, catering to diverse audiences, and engaging in both conformity and resistance to traditional authorities [28]. This dynamic interaction reflects the evolving nature of Arab values in the virtual realm.

SL is a virtual Cyber Society community that provides users (residents) with a vast array of material for creation, modification, and reuse. Hence, the residents can program different communication routines, verbal and non-verbal, to engage with others. According to Bandura's social learning theory, avatars have the power to influence their learning in new situations by controlling the environment around them (Bandura, 1999). (Hathaway, Muse, and Althoff, 2007, p. 3) anticipates Arab avatars to scrutinize the actions of others, initiating the learning process through assimilation and imitation. However, the question arises: to what degree does this behavior align with their values? Or add positive experiences for them? To answer these questions, we must remember that the Arab avatar typically refers back to his family's education and traditions for guidance before deciding whether or not to imitate the observed behavior. Also, we cannot ignore the sight of his emotional response and his whims.

SL terms formed many rules to prevent the unauthorized use of protected content and avatars from violating each other or harming them psychologically. Therefore, Arab avatars must adhere to these rules and avoid expulsion due to their transgressions, particularly those involving extremely violent and sexual content.

If we assume that the behaviours, values, and morals of the avatars in Second Life mirror their real-life values, then we expect them to act in accordance with their legacies and education. Then, if we concede that the Arab avatar in SL is meager compared to other ethnicities, taking into consideration their total ability to buy and own lands, including the wealth and emptiness among some, then why is this meager presence? Even though it may be an open window to a freer life for those who live with many restrictions because of laws, traditions, and religious values, why not make this spacious space the safest haven and a spacious chest for them? In this paper, we made some assumptions to analyze Arab avatar actions:

- We can attribute this to Second Life's lack of language translators or the cancellation of the free Google Translate service. Arab avatars faced significant discrimination from other residents due to their limited English proficiency. On the other hand, people often perceive Arabs as savages based solely on their language and faith, rather than their character. As a result, Arabs have suffered significant financial losses, with land rental costs exceeding those of any other community. In addition, the wide range of freedom in SL makes it dangerous for many Arab cultures that survive on fear and guilt! According to religious regulations.
- Some land creators, like Abu Fahd al-Jassem, creator of the Middle East, seek a world that captures the real lives of people in the Middle East to be a meeting point for them [10]. So in the context of the speech, he talked about the difference in values between Arab reality and the created world on SL, where females feel spatially that they are somehow free [33].
- SL enabled users to do most real-life activities, including sexual activities with other avatars, since each avatar represents a real human being, but it prevented users from touching in general except the users of the SexGen bed, so SL encroached on real-life for many avatars, including Arab ones.
- SL is not free of technical, legal, or ethical criticisms, including all activities done by residents as undesirable content in adult activities that may interfere with Arab values.
- By understanding that SL is a new world synonymous with reality, the Arabs, most of whom are Muslims, return all their activities in this world to the Islamic values and teachings that they have received from their educational institutions and their environment.
- There are many interesting areas in SL that touch on many ethical problems that are also often associated with real life, like access to pornography and inappropriate content, online gambling, the promotion of violence, and online harassment. These activities motivate Arab avatars, especially those who coexisted in reality with a closed environment and a blockade with issues of religion and demerit culture, to try these activities.
- Katherine Smith: Our project does not support the Arabic language at the moment, but earlier this month, the Linden Lab introduced the source code for the SL program, which allows users to modify and develop it to suit their needs, including the introduction of new languages. Certainly, the Arabic language will undoubtedly have a clear imprint given the technological boom that the Arab region is currently experiencing. I am almost certain that there are Arab developers who can introduce many modifications and other options in addition to the language element https://aitnews.com/2007/01/25/3882/.
- Last Thursday, at 8:00 PM, 2024, Oberwolf Linden posted the following: We are committed to creating a richer, more immersive, and safer environment for everyone, and we are sharing many important updates

and developments that not only aim to improve SL, but updates include mobile and desktop fronts to make SL safer. We will enhance the protection of society in a safe environment while preserving the freedom of expression that makes our virtual world so special, and we also feel that it is crucial to reinforce our stance that sexualized ageplay is strictly prohibited. One of the consequences of auditing and improving is to review the Child Avatar Policy to ensure a clear separation and to safeguard all community members [29].

- Second Life has officially launched Physically Based Rendering (PBR) Materials after November 29, 2023, a new feature that allows users to use PBR Materials in the Second Life viewer. This project aims to increase visual realism, keep up with industry standards, and bring GLTF content into Second Life. PBR Materials mimic how our eyes learn to identify surfaces, providing a step up in the appearance of the Second Life world. These new features may be an incentive for new residents to join the Second Life world, including Arab citizens [36]. Furthermore, Second Life is launching the Second Life Community Exhibition (SLCE) to connect newcomers with active in-world communities. The exhibition will feature a diverse range of communities during the earliest moments of the new resident journey, with 11 initial participants in phase one. The exhibition will be updated regularly with a mix of community showcases [37].

V. CONCLUSION

The entire Arab community has vanished! Does this imply that they failed to coexist with other societies, that the environment did not meet their needs, or that the manufacturing of SL components was weak? According to the aforementioned narrative, the actual presence of Arab residents and their worlds in SL has decreased. Our observations, follow-ups, and comments from the Avatars reveal that, despite the beauty, creativity, and diversity of this sphere space, the Arab resident did not find SL a comfortable place to coexist and perceive himself as an authentic citizen. This conclusion is based on a few statements and observations:

- They consider it a world that is only an alternative to their reality, in which they find only what is different from their daily lives.
- They did not find what they could create in terms of interaction, behavior, and alternative virtual living due to the limited options in light of the morals and values that restrict them.
- They only considered it an escape—a place where there is fun and reality that has no place in their real lives, and no physical gender spacing [30].
- They did not find enough time to live in it because they must interact with behaviors and personalities that those around them find out of the ordinary, which puts them in a state of hiding from the eyes of their parents and guardians.
- They expect a sense of guilt and a violation of recognized values and ideals when they go to clubs, discos, and bars.
- Commercial practices, land ownership, sale, and trade exchange take place in an environment where there is no solution for halal and haram according to their beliefs, resulting in a reluctance to interact well with them.
- The SL environment needs technical equipment because of the speed of the Internet and because the quality of the display cards is not available to most people in the region.

Multi-Class Flower Counting Model with Zha-KNN Labelled Images Using Ma-Yolov9

Multi-Class Flower Counting Model

***Abstract*—The flowering period is a critical time for the growth of plants. Counting flowers can help farmers predict the corresponding fields' yield information. As there are several works proposed for flower counting purposes, they lack the prediction of different flowers with counts. Hence, a novel model has been proposed in this study. Initially, this model is fed with different flower images as input, then these images undergo pre-processing. In pre-processing, the images are converted to grayscale for improved accuracy, and then the image's noise is removed using bilateral filters. Noise-removed images are then given for edge detection, using GI-CED. Edge-detected images are then augmented to improve the learning rate of the model. Augmented images are labeled using ZHA-KNN. Labeled images feature extracted and are given to MA-YoloV9, which is pre-trained to detect flowers in the image count and obtained as output. Overall, the proposed model was implemented and obtained an accuracy value of about 98.8% and F1-Score obtained 92.2% which is far better than the previous counting models.**

Keywords*—Flower counting; bilateral filter; Zhang Shasha Algorithm distance measured-K-Nearest Neighbor (ZSA-KNN); Gradient Intensity-Canny Edge Detection (GI-CED); mish-activated YoloV9
