The selection of attributes to represent a company's bankruptcy significantly influences the performance of the bankruptcy prediction model. Building a simple model with minimal features is a crucial aspect of developing such a model, focusing on selecting highly relevant attributes as features [7]. Additionally, variations in regulations concerning bankruptcy determination and differences in economic characteristics across company locations, which serve as research subjects, influence the choice of attributes for predicting bankruptcy. For instance, in previous studies [7, 11, 12], varying numbers of features were employed: 110, 64, and 28, respectively. Despite the potential of machine learning algorithms to handle a large number of features [27], prioritizing the control of selected attributes as features remains essential to ensure the cost efficiency of the model.

Imbalanced datasets significantly impact overfitting as the model lacks sufficient input samples from minority classes [8]. Deep learning-based bankruptcy prediction has employed various techniques to address this challenge, including the Synthetic Minority Oversampling Technique (SMOTE), Stacked Autoencoder algorithm, and softmax classifier, resulting in high prediction accuracy even with imbalanced datasets [12]. Additionally, SMOTE was utilized by [28], to mitigate imbalanced data issues, coupled with LSTM for bankruptcy prediction. In a construction industry case, [29] enhanced LSTM bankruptcy prediction by incorporating construction market and macroeconomic variables alongside accounting variables. Furthermore, the study in [11] utilized three non-financial variables for bankruptcy prediction in the restaurant industry, noting their significant contribution to prediction accuracy. Both [11] and [28] underscored the importance of non-financial variables in enhancing prediction accuracy. Moreover, feature selection techniques play a crucial

role in refining bankruptcy prediction models. [30] employed Genetic Algorithm (GA) to select features and control the number of units in the LSTM layers. Addressing outliers is another critical aspect for accurate model development. Outliers in the data can notably impair the performance of bankruptcy prediction models. Two prevalent approaches to handle outliers are omission and winsorization [13]. The research in [21] successfully employed winsorization to tackle outliers, while [5] opted to eliminate variables with over 1000 outliers.

Based on a search for research literature related to the experiments in this research, it can be concluded that outliers and data imbalances are common problems that are the focus of most bankruptcy prediction research using classification techniques, including bankruptcy classification based on the Altman Z-Score model. However, the phenomenon of differences in bankruptcy regulations with varying value parameters causing data anomalies when implemented in the Altman Z-Score model has not received attention and is still an open and challenging gap, that needs to be studied further as explained in this research.

III. METHODOLOGY

The quartile calculation-based data binning technique has been proposed to address imbalanced data and data anomaly issues in bankruptcy prediction using Altman Z-Score and LSTM. This method comprises two primary stages. The initial stage involves data preprocessing, which includes financial dataset preparation, outlier handling, Altman Z-Score calculation, quartile calculation-based data binning, and feature selection. The subsequent stage involves the classification process, which is divided into a four-class classification using LSTM, followed by two-class classification rules to ascertain distress zone and non-distress zone outputs. Fig. 1 illustrates the flow diagram of the proposed prediction model.

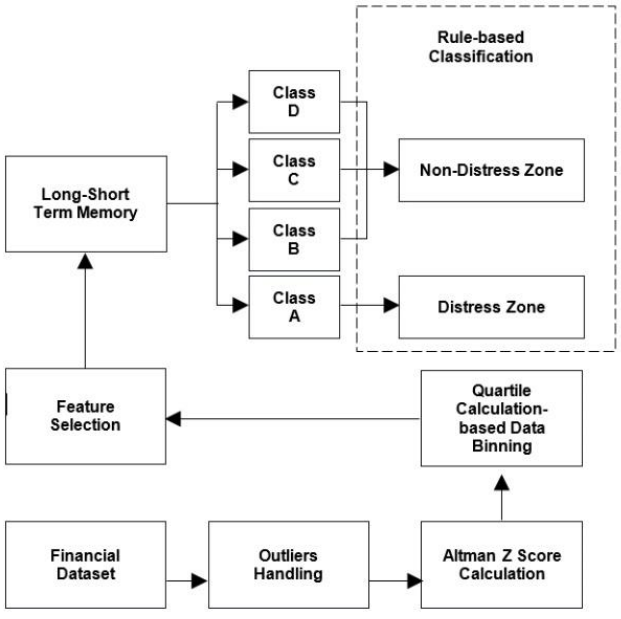

Fig. 1. The proposed bankruptcy prediction model diagram.

A. Data Preprocessing

The data preprocessing phase comprises five stages: financial dataset preparation, outliers handling, Altman Z-Score calculation, quartile calculation-based data binning, and feature selection. The dataset was initially sourced from the Taiwanese Bankruptcy Prediction – UCI machine learning repository, compiled from the Taiwan Economic Journal spanning the years 1999 to 2009 (Taiwanese Bankruptcy Prediction, 2020). Company bankruptcy was determined according to the business regulations of the Taiwan Stock Exchange. The sample consists of 96 financial ratios and 6,819 observations, with 220 representing bankrupt companies and 6,599 representing non-bankrupt companies. While the dataset does not exhibit outlier problems, there was imbalanced data within the distress zone and the non-distress zone classes, with a ratio of 3:95%. However, upon calculating the data using the Altman Z-Score formula, a significant difference in the data volume between the two classes emerged. The calculations reveal that 3,467 companies are in the distress zone, while 3,352 companies are in the non-distress zone, resulting in a revised ratio of 51:49% respectively.

Assumptions derived from the prevalence of imbalanced data, often encountered in bankruptcy prediction problems, serve to reconcile disparities between Taiwan Stock Exchange regulations and the Altman Z-Score framework in classifying companies into distress or non-distress zones. A baseline proportion of 5:95% is adopted to establish assumptions for the distress and non-distress zones, respectively. Following computation via the Altman Z Score formula, the data is arranged in ascending order. Subsequently, the bottom 5% of the data, representing companies with the smallest values, is considered to belong to the distress zone class.

Let $D_N = \{(X_i, Y_i)\}_{i=1}^{N}$ is a dataset of N rows ordered by class Y, where $X = (X_1, X_2, \dots, X_p)$ represents the p attributes of D_N and Y is the class of D_N with $Y = F(X)$. Suppose the dataset D_N contains m rows of distress classes and n rows of non-distress classes, then the dataset D_N can be split into two independent sub-datasets, which are:

$$D_m = \{(X_i, Y_i)\}_{i=1}^{m}$$

$$D_n = \{(X_i, Y_i)\}_{i=1}^{n}$$

$$\text{with splitting ratio: } \gamma = m/N$$

$$\text{where,}$$

$$m + n = N$$

$$D_m \cup D_n = D_N \quad (1)$$

If it is assumed that 5% of the classes are distress, then the sub-datasets are as follows:

$$D_{5\%} = \{(X_i, Y_i)\}_{i=1}^{0.05N}$$

$$D_{0.95} = \{(X_i, Y_i)\}_{i=1}^{0.95N}$$

$$\text{with the splitting ratio of } \gamma = 5\% \quad (2)$$

The splitting results indicate an imbalance in these sub-datasets, posing a challenge for classification purposes. Out of the 6819 data points sorted based on the Altman Z Score calculation, assuming a value of 5%, the distress zone class comprises 349 companies with the smallest Z values. Conversely, the non-distress zone class encompasses the remaining 6,470 companies. Rather than resorting to under-sampling or over-sampling methods to address the data imbalance, an alternative approach could involve segmenting 95% of the non-distress zone data into multiple categories using data binning. Data binning transforms continuous data into categorical data, with each category mirroring the size of the distress zone class. Consequently, the length of each bin would be determined by dividing the amount of data in the non-distress zone category by the size of the distress zone class.

Classes based on the length of bins, which are sub-categories of the non-distress zone, are supposed to have a balanced proportion relative to the size of the distress zone class. However, with an imbalanced data proportion of 5% in distress zone class and 95% in non-distress zone class, the number of subcategories within the non-distress zone becomes less controlled. Binning the non-distress zone class size of 6,470 with a non-distress zone class size of 349 results in 18 subcategories within the non-distress zone. Having 19 classes, comprising 1 distress zone class and 18 classes from the 18 subcategories of the non-distress zone, will complicate the classification process in prediction. The data binning approach will be used to address the imbalance in sub-datasets. This means that the initial supposition of the non-distress sub-dataset will be split into three equal parts restrained by values as follows:

$$Q_j = \left|\frac{j(n+1)}{3}\right|_{j=1}^{2} \quad (3)$$

Let D_1 represent the $D_{95\%}$ of the initial supposition of the non-distress subcategory, comprising $n = 6{,}478$ rows. Subsequently, the data binning approach will produce the subcategories of $(D_{1i})_{i=1}^{3}$, which are D_{11}, D_{12}, and D_{13}, separated by $Q_1 = 2{,}508$, and $Q_2 = 4{,}665$ with a size of 2157 rows for each subcategory. Considering the distress zone category as Class A and the three subcategories of the non-distress zone as Class B, C, and D, Class A comprises 341 rows, indexed from 1 to 349. Meanwhile, Classes B, C, and D encompass 2,157 rows each, indexed from 350 to 2507, 2508 to 4664, and 4665 to 6819, respectively.

At this point, the results still exhibit imbalance issues. Under sampling is conducted to ensure that the sizes of classes B, C, and D are proportional to class A. Some rows within classes B, C, and D are deleted at specific index intervals determined using quartile calculation. The interval value for the calculation is derived by dividing the highest size by the lowest size among the four classes. Thus, the resulting interval value is 2157 divided by 349, which equals six. Consequently, each class B, C, and D comprises 360 rows of data, with index numbers (350, 356, 362, ..., 2504), (2505, 2511, 2517, ..., 4659), and (4660, 4666, 4672, ..., 6814), respectively. Finally, the data preprocessing stage yields class A, B, C, and D with 349, 360, 360, and 360 rows, respectively. Class A represents the distress zone category, while the non-distress zone category is divided into three subcategories: class B, C, and D, representing the non-distress zone to the strong non-distress zone. This technique facilitates the proportional distribution of data across sorted values, ensuring representation from the smallest to the largest values. Fig. 2 illustrates the flow diagram of the data preprocessing stage.

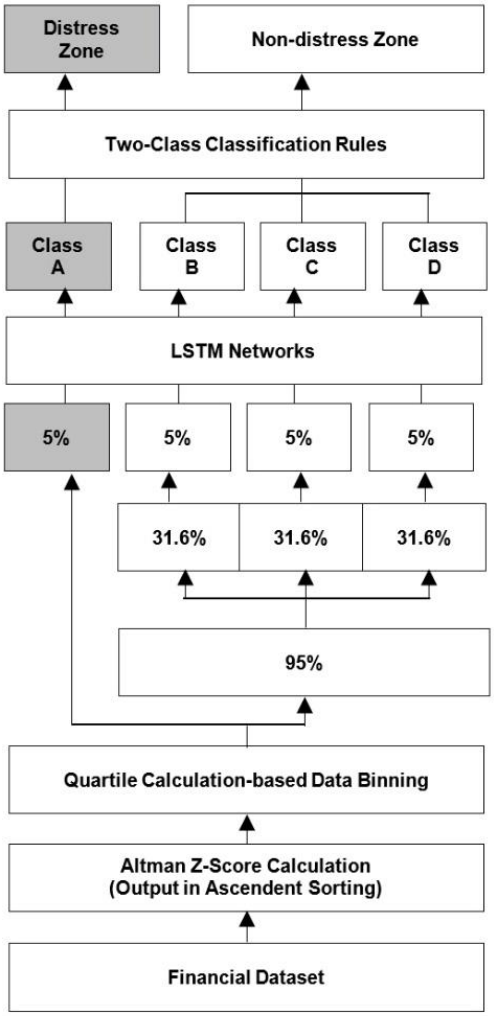

Fig. 2. The data preprocessing diagram.

The new dataset consists of 29 attributes and 1 predicted class of financial ratios. These attributes encompass a range of metrics including Operating Profit Rate, Pre-tax Net Interest Rate, After-tax Net Interest Rate, Net Value Per Share (B), Net Value Per Share (A), Net Value Per Share (C), Revenue Per Share (in Yuan), Operating Profit Per Share (in Yuan), Total Asset Growth Rate, Total Debt/Total Net Worth, Debt Ratio %, Net Worth/Assets, Operating Profit/Paid-in Capital, Net Profit Before Tax/Paid-in Capital, Revenue Per Person, Working Capital to Total Assets, Current Assets/Total Assets, Current Liability to Assets, Inventory/Working Capital, Long-term Liability to Current Assets, Retained Earnings to Total Assets, Total Assets to GNP Price, Gross Profit to Sales, Working Capital, EBIT, Market Value of Equity, Book Value of Total Debt, Sales, and Total Assets.

Fig. 3. The feature selection diagram.

Feature selection is a pivotal step, significantly enhancing model performance, curbing overfitting, and expediting training times. Choosing the most pertinent features is crucial for constructing efficient and interpretable models. In the realm of deep learning, a valuable approach is selecting features based on their weights. The Select Feature by Weight technique was employed for feature selection, prioritizing the weights assigned to each feature during training to pinpoint and preserve the most impactful ones, thereby augmenting model performance. Features with higher absolute weights hold greater influence in the model. Refer to Fig. 3 for the flow diagram illustrating the feature selection process.

The process began with normalizing the values of features within the dataset, followed by assigning weights to the features and ranking them. Normalization methods are preprocessing techniques used to standardize feature values within a dataset, ensuring they are all on the same scale. In this research, Z-transformation methods were applied. Z-score normalization entails transforming variable values to have a mean of 0 and a standard deviation of 1.

Suppose we possess a dataset comprising n subjects. Let X= ⟦{x}⟧ _1,x_2,…,x_j,…,x_m} represent the set of normalized feature values within the chosen data. The formula for Z-transformation is as follows:

$$Z = \frac{x-\mu}{\sigma}, \quad (4)$$

where:

Z is the Z-score,

X is the original data point,

μ is the mean of the dataset,

σ is the standard deviation of the dataset

The feature selection method evaluates the relevance of each feature to both the target feature and the prediction model, deciding whether to include or exclude it from the prediction process. Feature weighting determines the magnitude of influence or importance that each feature has in relation to the target feature and the prediction model. The resulting importance score directs the utilization of the feature's magnitude in prediction, influencing its impact on the overall model.

Consider the following linear regression model: it utilizes normalized feature values available in the selected dataset. The formula for Z-transformation is as follows:

$$\hat{y} = w_0 + w_1 \cdot x_1 + w_2 \cdot x_2 + \ldots + w_n \cdot x_n \quad (5)$$

where:

$\hat{y}$ is the predicted output,

w_0 is the intercept,

$w_1, w_2, \ldots w_n$ are the weights corresponding to features $x_1, x_2, \ldots, x_n$, respectively.

The selected features are determined using the formula: $selected\ features = \{x_i | w_i \geq T\}$, where T is a predetermined threshold value. The correlation matrix of key financial indicators used in the bankruptcy prediction model is displayed in the following heatmap. Fig. 4 shows the heatmap, which represents the correlations between features. All the colored cells indicate the correlation between two features, with the color of the cell denoting the strength of the correlation. A correlation value less than zero indicates a negative correlation, while a zero value indicates no correlation.

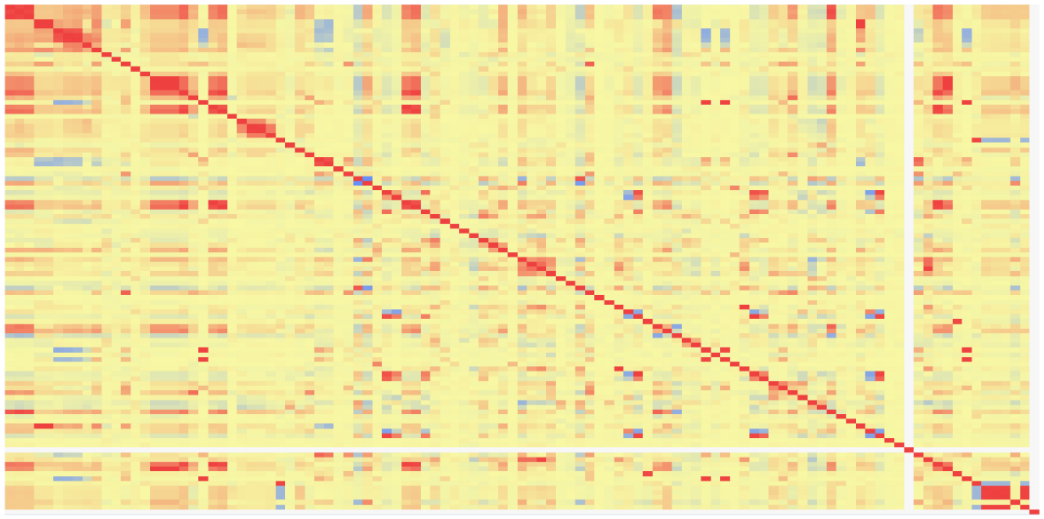

Fig. 4. The heatmap of the correlation matrix of key financial indicators used in the bankruptcy prediction model.

B. Two-Step Classification

Deep learning is a powerful and versatile approach for making predictions across various domains, including bankruptcy prediction. These models are built upon neural networks, which consist of layers of interconnected nodes (neurons). A typical deep neural network includes an input layer, multiple hidden layers, and an output layer. The input layer of the neural network receives raw features or data points related to the prediction task. Each node in the input layer corresponds to a specific feature, and these values are fed into the network. Connections between nodes in different layers are associated with weights. During training, the model adjusts these weights to learn optimal patterns from the input data. Each node in the hidden layers performs a weighted sum of its inputs and passes the result through an activation function. ReLU is commonly used for hidden layers, while Softmax is applied to the output layer.

The flow diagram for bankruptcy prediction begins with learning representations. As data passes through the layers, the network learns hierarchical representations. Lower layers capture simple patterns, while higher layers combine these patterns to form more complex and abstract features. This hierarchical learning enables the model to automatically extract relevant features from the input data without explicit feature engineering. Next is the loss function measurement, where the output of the network is compared to the actual target values using a loss function. The loss quantifies the difference between the predicted and actual values. The goal during training is to minimize this loss by adjusting the weights of the connections through a process called backpropagation. The optimization algorithm stage follows, using methods such as stochastic gradient descent (SGD) to iteratively update the weights based on the calculated gradients of the loss function. This process allows the model to converge towards a set of weights that minimizes the prediction error on the training data. The next stage is data training, where the network is trained on a labeled dataset containing both input features and corresponding target labels. The model iteratively adjusts its parameters to improve its predictive performance. The final stage is testing and evaluation. Once trained, the model is evaluated on a separate test set to assess its generalization performance. Various metrics, depending on the prediction task, are used to measure performance, such as accuracy, precision, recall, and F1-score. Fig. 5 shows the architecture of the LSTM used for the proposed bankruptcy prediction.

The deep learning architecture begins with initializing the weights (W^1, W^2) and biases (b^1, b^2). Next, an input vector X with n features is provided to the input layer, where:

$$X = [x_1, x_2, \dots, x_n]:$$
$$Z^{[1]} = X \cdot W^{[1]} + b^{[1]}$$
$$A^1 = ReLU(Z^1) \quad (6)$$

where:

$Z^{[1]}$ is the weighted sum of inputs, and A^1 is the output after applying the ReLU activation function.

Next is the definition of the relationship between the hidden layer and the output layer. Given A^1, the hidden layer activations:

$$Z^{[2]} = A^1 \cdot W^{[2]} + b^{[2]}$$
$$A^{[2]} = \sigma\left(Z^{[2]}\right), \quad (7)$$

where:

$Z^{[2]}$ represents the weighted sum of the hidden layer activations, and A^2 is the output after applying the softmax activation function (σ).

The softmax activation function (σ) is applied element-wise to the output of the second layer:

$$A_{i,j}^{[2]} = \frac{e^{z_{i,j}^2}}{\sum_{k=1}^{C} e^{z_{i,j}^2}}, \quad (8)$$

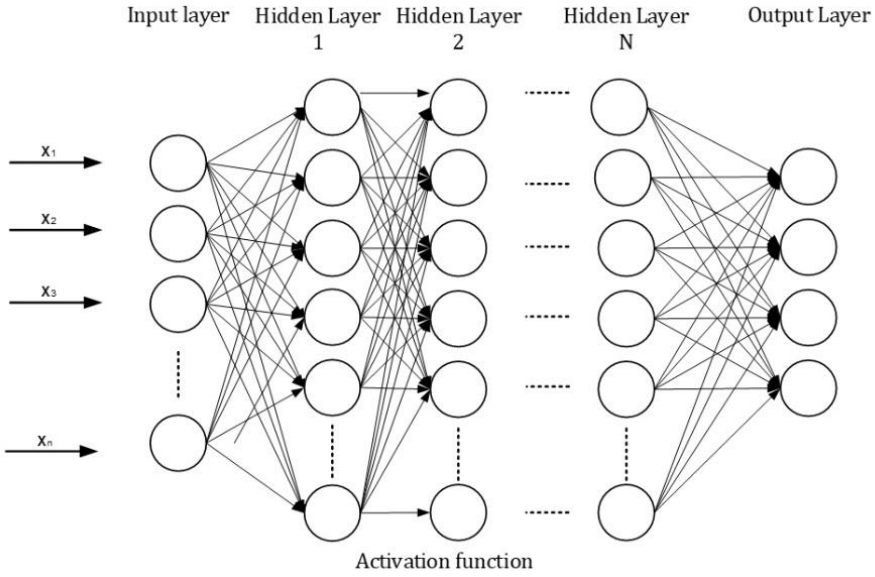

Fig. 5. The architecture of LSTM used for the proposed bankruptcy prediction.

where:

C is the number of classes. Additionally, the loss function is applied using categorical cross-entropy as follows:

$$J = -\frac{1}{m}\sum_{i=1}^{m}\sum_{j=1}^{C} Y_{i,j} \cdot log(A_{i,j}^{[2]})$$

Backpropagation

$$dZ^{[2]} = A^{[2]} - Y$$

$$dW^{[2]} = \frac{1}{m} A^{[1]T} \cdot dZ^{[2]}$$

$$db^{[2]} = \frac{1}{m}\sum_{1=1}^{m} dZ^{[2]}$$

$$dZ^{[1]} = (W^{[2]})^{T} \cdot dZ^{[2]} \odot ReLU'(Z^{[1]})$$

$$dW^{[1]} = \frac{1}{m} X^{T} \cdot dZ^{]1]}$$

$$db^{[1]} = \frac{1}{m}\sum_{i=1}^{m} dZ^{]1]}$$

$\odot$ denotes element-wise multiplication. (9)

Finally, the parameter update using gradient descent is applied to optimize the weights and biases as follows:

$$W^{[2]} = W^{[2]} - \alpha \cdot dW^{[2]}$$

$$b^{[2]} = b^{[2]} - \alpha \cdot db^{[2]}$$

$$W^{[1]} = W^{[1]} - \alpha \cdot dW^{[1]}$$

$$b^{[1]} = b^{[1]} - \alpha \cdot db^{[1]} \ , \quad (10)$$

The final classification output comprises two classes: distress and non-distress categories. The non-distress category undergoes division using data binning techniques, resulting in three classes: B, C, and D. Class A represents the distress category. Consequently, any incorrect predictions among classes B, C, and D are rectified since they fall within the non-distress category. Following the prediction of the four classes, a rule is applied for the final classification. If the prediction outcome is class A, the data is classified into the distress zone category; otherwise, it is classified into the non-distress zone category. The formula for the two-class classification rule, with BP denoting bankruptcy prediction, is as follows:

$$BP = \begin{cases} Distress\ ,\ Class\ A \\ Non-distress, others \end{cases} \quad (11)$$

IV. Results and Discussion

A classification-based bankruptcy prediction model is proposed by utilizing the Altman Z Score on different bankruptcy regulations, and the data binning method is used to overcome the problem of imbalanced data. The extreme data imbalance commonly found in bankruptcy prediction datasets is assumed to define companies falling into the distress zone category. The baseline for companies in the distress zone comprises 5% of the data with the smallest Z Score values in the dataset, with the remainder falling into the non-distress zone category. Of the data in the non-distress zone category, 95% is further divided into three sub-categories using the data binning method to represent varying levels of non-distress, from non-distress to strong non-distress. To address the issue of disproportionate data among the three non-distress zone sub-categories and the distress-zone class, under-sampling and quartile calculation techniques are employed. Data is deleted at specific intervals until the amount of data in each of the three non-distress zone sub-categories is proportional to the amount of data in the distress-zone class. This method ensures the representativeness of Z Score values across classes, maintaining the order from smallest to largest within each class. Instead of balancing the data by selecting 330 of 6599 non-distress zone data randomly as done by [5], binning data into subcategories and then cutting to select a portion of the data within each subcategory is more precise in representing the data by selecting a small portion of a large amount of data.

Data preprocessing yields four classes: one distress zone class (Class A) and three sub-categories of the non-distress zone (Classes B, C, and D). Feature selection, employing feature weighting techniques, identifies 29 features from 96 financial ratios defined by the Taiwan Stock Exchange, along with Classes B, C, and D, each comprising 360 data points. The dataset is split 70:30 for training and testing in the LSTM network, resulting in 1,000 training data points and 429 testing data points. Evaluation of the LSTM network's performance is conducted using precision and recall metrics. Tables I and II present the evaluation results for both training and testing data.

The accuracy achieved in evaluating training data reached 86.3%. Incorrect predictions between class A and class B are the most frequently found. 43 data points that should be included in class A are predicted to be class B. This condition also occurred in 21 instances where data intended for class B was predicted as class A, 30 instances where data meant for class C are predicted to be class B, and 24 instances where data designated for class D are predicted to be class C. This is because the data binning technique, which converts categorical data into ordinal data, makes the distance between successive classes closer. For example, the distance between class A and class B is closer than between classes C and D. Compared with classes A and D, classes B and C are closer to the previous and following classes. However, the incorrect prediction in classes B and C turns out to be stronger in their previous class. Incorrect predictions from class B to class A occur in 21 instances, and there are no incorrect predictions to class C. Incorrect predictions from class C to class B occur in 30 instances, and 10 instances to class D. In terms of recall, the incorrect prediction between classes A and B still dominates among the other classes. The recall evaluation value shows that 21 data points, which should be included in Class A, are predicted by the system as part of class B. Vice versa, 43 data points in class B are predicted as class A. This shows that the system still has difficulty distinguishing the characteristics of classes A and B. There are similar patterns in predicting bankruptcy between training data evaluation and test data evaluation, with incorrect predictions dominated in classes A and B. However, compared with training data evaluation, there is an increase in accuracy in test data evaluation. The accuracy achieved in evaluating test data reached 89.98%, representing an increase of 3.68%.

TABLE I. PRECISION AND RECALL RESULTS FOR THE DATA TRAINING EVALUATION

	True Class A	True Class B	True Class C	True Class D	Class Precision
Class A	219	43	2	3	82.02%
Class B	21	179	0	0	89.5%
Class C	4	30	226	10	83.7%
Class D	0	0	24	239	90.87%
Class Recall	89.75%	71.03%	89.68%	94.84%	

TABLE II. PRECISION AND RECALL RESULTS FOR THE DATA TEST EVALUATION

	True Class A	True Class B	True Class C	True Class D	Class Precision
Class A	97	8	0	0	92.38%
Class B	6	100	5	0	90.09%
Class C	2	0	81	0	97.59%
Class D	0	0	22	108	83.08%
Class Recall	92.38%	92.59%	75%	100%	

At this point, the classification process was still underway, transitioning from a four-class classification to a binary classification, consisting of distress and non-distress categories. This process serves as the cornerstone of the proposed prediction model. The final classification output consists of two categories: distress and non-distress. Class A denotes the distress category, while classes B, C, and D represent the non-distress category. Following the initial four-class classification, additional rules were integrated to facilitate the transition to the two-class classification, which predicts distress and non-distress categories. Misclassifications within classes B, C, and D do not constitute errors as these classes are encompassed within the non-distress category. The proposed bankruptcy prediction model, employing a two-stage classification approach, starting with a four-class classification and proceeding to a two-class classification, demonstrates a notable enhancement in performance. In the four-class classification, the accuracy attained for both training and test data evaluation stood at 86.3% and 89.98%, respectively. Furthermore, the subsequent two-class classification stage yields improved accuracy in both training and test data evaluation, reaching levels of 92.70% and 96.27%, respectively. Tables III and IV present the evaluation outcomes for training and test data during the two-class classification stage. However, in the four-class classification, the system encounters challenges in distinguishing between class B, class A, and class C, resulting in a recall performance of 71.03%. Given that class B and class C fall within the non-distress category, post-two-class classification processing strengthens the overall recall performance within the non-distress category to 93.65%. This trend is mirrored in precision performance metrics within the non-distress category, exhibiting an increase in values up to 96.59%.

There are consistent patterns observed in predicting bankruptcy across both training data evaluation and test data evaluation in both four-class and two-class classifications. Notably, there is an uptick in accuracy during test data evaluation, reaching 96.27%. This marks a 3.57% increase from the accuracy observed during training data evaluation, which stood at 92.7%. By first binning the data to determine 1 distress zone category and three non-distress zone sub-categories and applying four-class classification using an LSTM network followed by two-class classification followed by a two-class classification to summarize predictions into distress and non-distress zone classes, prediction accuracy can be increased to more than 90% and outperform the accuracy achievements of the method proposed by study [5] which is below 90%. Table V illustrates the accuracy comparison between four-class and two-class classifications, while Fig. 6 presents a visual comparison of accuracy across these classifications.

TABLE III. PRECISION AND RECALL RESULTS FOR THE DATA TRAINING EVALUATION IN THE TWO-CLASS CLASSIFICATION

	True Distress Zone	True Non-Distress Zone	Class Precision
Distress Zone (Class A)	219	48	82.02%
Non-Distress Zone (Class B, C, D)	25	708	96.59%
Class Recall	89.75%	93.65%	

TABLE IV. PRECISION AND RECALL RESULTS FOR THE DATA TEST EVALUATION IN THE TWO-CLASS CLASSIFICATION

	True Distress Zone	True Non-Distress Zone	Class Precision
Distress Zone (Class A)	97	8	92.38%
Non-Distress Zone (Class B, C, D)	8	316	97.53%
Class Recall	92.38%	97.53%	

TABLE V. ACCURACY FROM FOUR-CLASS CLASSIFICATION TO TWO-CLASS CLASSIFICATION

	Four-class Classification	Two-class Classification
Training data	86.3%	92.7%
Test data	89.98%	96.27%

Fig. 6. Accuracy from four-class classification to two-class classification.

Experiments demonstrate that the proposed method yields promising results in crafting a bankruptcy prediction model capable of addressing regulatory disparities in assessing a company's bankruptcy risk, as well as tackling imbalanced data issues. In binary classification scenarios, employing data binning techniques can mitigate imbalanced data concerns by partitioning the predominant data category into multiple classes or subcategories via ordinal ranking. Once the data category is segmented into multiple classes, incorporating rules to revert the workflow to binary classification significantly enhances accuracy, precision, and recall performance. Conversely, the application of data binning techniques necessitates a ranking framework, and the Altman Z Score has been validated as a suitable benchmark for ranking data in bankruptcy prediction tasks.

V. CONCLUSION

The bankruptcy prediction model has demonstrated proficiency in addressing challenges related to variations in data value parameters and imbalanced data. Experimental findings bolster the assertion that the Altman Z-Score serves as a robust tool for predicting bankruptcy. Moreover, the proposed method enhances the Altman Z-Score model's ability to handle variations in data value parameters. Segmenting the non-distress zone category into multiple classes through data binning has effectively elucidated the distinguishing characteristics of companies with high Z scores in the non-distress zone, juxtaposed with those in the distress zone.

The proposed method is proven to be reliable as a bridge over different regulations and parameter values with the Altman Z-Score model in determining bankruptcy. The differences produce bankruptcy data anomalies, namely the characteristics of extreme imbalance data in company bankruptcy data which disappear when recalculated using the Altman Z-Score model. This problem can be bridged using the proposed method so that the imbalance data pattern which is an inherent characteristic of company bankruptcy data can be maintained with good accuracy of bankruptcy prediction results. However, the system encounters difficulty in discerning companies within the non-distress zone with rankings proximate to the distress zone. Conversely, while employing an LSTM-based four-class classification for bankruptcy prediction yields promising outcomes, identifying the precise cause of the model's accuracy weakness remains challenging. Current indications suggest that enhancing feature selection performance is imperative to enable the system to differentiate between distress classes and non-distress subcategories with minimal value disparities. Additionally, further investigation is warranted to determine the optimal addition or reduction of financial ratio variables as features.

***Abstract*—Air pollution, which is both environmental and social, is a serious issue that affects people's health as well as ecosystems and the environment. Air pollution currently poses a number of health problems to the ecosystem. The most important factor that has a direct impact on disease occurrence and decreases people's quality of life is city and metropolitan air quality. It is critical to establish real-time air quality monitoring in order to make timely decisions based on measurements and evaluations of environmental factors. Monitoring systems are influential in multiple smart city initiatives for keeping an eye on air quality and reducing pollutant concentrations in metropolitan areas. The Internet of Things (IoT) is becoming increasingly important in a variety of sectors, including air quality monitoring. In this research work, a real-time air quality monitoring model employing fuzzy inference is proposed for monitoring air pollution using multiple parameters such as Sulphur Dioxide (SO2), Nitrogen Dioxide (NO2), Carbon Monoxide (CO), Ozone (O3) and Suspended Particulates (PM10). This proposed research presents a novel technique for improving air quality monitoring. This proposed fuzzy inference system also provides better results in terms of monitoring air quality in a more efficient and effective way.**

Keywords*—IoT; fuzzy inference system; smart city; air quality monitoring

I. Introduction

Beginning the viewpoint of conventional urban policy, there are numerous debates and recommendations on smart cities (cities that have implemented smart services). Technology focused Smart City (SC) initiatives have been criticized for obliterating the various layers of variables that surround SCs. Since smart cities require technological fundamentals and the dynamic fundamentals nearby, governments that fail to recognize multiple factors when implementing smart policies will not offer eminence facilities to people effectually (e.g., the policy ecology and urban substructure). Via an analytic hierarchy process research, this research investigates the causes of smart cities besides their goalmouths.

Smart Cities also appear some obstacles in their operation, but additional Smart City research programs are being funded and implemented regularly. Furthermore, cities worldwide are adopting Smart City structures to boost facilities or residents' superiority of life. We review current Smart City concepts in the literature, assess existing tools and systems, review the different areas of implementations where these techniques and methodologies are being used (e.g., health and education), display cities that have incorporated the Smart City model into their everyday operations, that include a review of the academic literature [1].

The terms IoT and "Smart City (SC)" are often utilized to describe how to deal with the complexities of modern city operations. The key challenges that city operators face are population concentration, resource scarcity, and environmental issues, making ordinary service provisioning less effective. Data in particular domains will be provided by an IoT sensor in the city environment, while control functions will be conducted in the real world by an IoT actuator. Smart IoT systems that operate on IoT or cross-sector elements are interconnected systems which enable useful data and knowledge exchange [2, 3].

There are some factors to remember when planning a smart city. These factors are: social, technological, economic, political and environmental. Finally, the environmental issues that impact smart cities, include water management, food security, infrastructure development, ecosystem services, source reduction, severe weather, Air Pollution (AP), noise, and recycling. Loss of biodiversity, heat stress, sanitation, semi-transportation, land use patterns, sea-level rise, construction use, and transportation motorization are only a few of the issues that need to be addressed. The topic of air pollution is explored in depth here.

With the ongoing growth and increase in population inside metropolitan areas, a number of environmental concerns such as deforestation, uncontrolled hazardous chemicals, solid waste management, pollution, and others have gotten a lot more attention than ever before. Also, the rapid growth in manufacturing and transportation has resulted in increased pollution being a severe issue, which both governments and citizens have given increased attention. According to the World Health Organization (WHO) research, long-term contact with outdoor and indoor particulate matter, an air pollution type, has resulted in around seven million deaths globally, ranking fifth among all hazards [4, 5].

The pollution is known as chemicals under natural settings introducing and giving rise to the damage. Pollution may be caused by chemical compounds or energy, like noise, heat, or light. Pollutants are chemicals or fuels that are either foreign or

*Corresponding Author

naturally occurring and cause pollution. Air pollution is described as contaminants in the atmosphere, harmful to human and living beings' health, or affecting materials or climate. Ammonia, Carbon Dioxide (CO2), SO2, Particulate Matter (PM), methane, and hydrogen cyanide are all forms of air contaminants, particulates (both inorganic), and organic macromolecules. AP may harm humans by causing infections, asthma attacks, and even mortality, as well as animals, food crops, and natural and built ecosystems. All Green-House Gases (GHGs) and geological cycles can pollute the air.

When carbon rise at a certain level in the air, it can be dangerous to us. Individuals are forced to live in places with poor air quality that includes smog, particulate pollution and toxic chemicals hazardous to their health. A high concentration of particular air pollutants can cause:

- Irritation of the nostrils, eyes and throat.
- Breathing issues, which normally include wheezing, coughing, chest pain, and respiratory problems such as asthma and shortness of breath.
- Escalation of chronic respiratory and cardiac illnesses, for instance, asthma.
- Increase in the attack risk of cardiac infarction.

Prolonged exposure to AP can develop into cancer and be harmful to the immune, endocrine, nervous and respiratory systems. A serious tone underlies it because death is a possibility in extreme cases. All living beings of life are impacted by air pollution, in which some people are more sensitive to the typical air pollutants like "particulates and ground-level ozone" than others. Pollution, both land- and airborne (pollutants that are particulates in the air), affects many, with children, the elderly, people who engage in outdoor sports, and people with any cardiac or lung disorders being the most sensitive groups to pollution.

An Air Quality Monitoring (AQM) involves the determination of current air pollution levels about "ambient air quality standards"- that are meant to reduce the levels of pollution and has the target of making clean air. Monitoring helps to prevent emergency cases by warning people and forcing them to take action. It monitors "SO2, NO2, PM10, PM2.5, ozone, arsenic.

Machine learning techniques, integrated within a real-time air quality monitoring model, can enhance predictive capabilities by leveraging fuzzy inference systems to analyze complex environmental data in real time, facilitating proactive measures for pollution control and public health protection [28-32].

Fuzzy Logic (FL) is employed to map human experts' experiences into mathematical languages which govern in areas uncertain. Decision-making with FL can be maximized. The risk of air pollutants can more or less be ranked by FL through a number between 0 and 1. The assignment can be completed by using FL calculations to define each attribute to the set. A fuzzy management system employs analysis of analogue signal values from logical variables that assume either constant values which lay between 0 and 1 or classical/digital logic which operates on discrete values (1 or 0) instead [33-37].

Machine control normally uses FL in computer control. The word "fuzzy" means that in this controversy, the statements will dwell on partial untruths rather than wholly true or untrue opinions. In other cases, there are alternative methods that can perform well as FL like evolutionary algorithms and neural networks, but still, FL has the privilege of "translating" the solution in a throw that the human operator should be able to understand which will add an experience ingredient that could be utilized in the controller design. Now the tasks are humanized, and it is more probable to automatize human activities [6].

Applying fuzzy logic to air quality monitoring can help in making the results more accurate and faster. Fuzzy logic capability of representing data between 0 and 1 helps in improving the analysis of the general data and hence pollution detection. This approach can help in improving the predictions enabling environmental checks, human health, and city designs. Thus, the use of fuzzy logic yields a positive development in improving air quality monitoring systems for enhanced environmental performance.

II. Literature Review

Researchers have been heavily involved with environmental monitoring, detecting pollutants, and figuring out the sources of pollution using sensor networks. As shown by the other researchers [7, 8], the air pollutants which were most dangerous to human health and were discharged into the air when fossil fuels, gasoline, petrol, and diesel were burnt were nitrogen dioxide, hydrocarbon, and particulate matter. The transportation sector, power generation plants, and manufacturing were the primary sources of these contaminants in Erbil. The use of IoT platforms in several fields, like agriculture, nature tracking, human tracking, and "Air Quality Monitoring (AQM)," has increased in recent years.

In study [9, 10], another important factor influencing emission dispersion calculation was the source of pollution. The point, line, field, and volume sources were the most common air pollutant sources. There were two types of sources: stationary and mobile. Stationary sources include flue gas piles, while mobile sources include vehicles. Air quality monitoring has historically relied on network stations and continuous pollution levels at the local and regional levels. The predominant emission sources were used to classify stations (traffic, industrial and background stations). In comparison to in-field observations, air quality modeling was being used for estimating pollution, especially in areas with no measurement stations. Sensor networks, energy consumption reduction, and data transfer to repositories where this knowledge was analyzed have occupied a large portion of research and literature reviews.

Depending on the service area, the low-cost sensors embedded into the network links that make up the network produce better or worse results. One of the regions where low-cost sensors' performance was being tested was air quality sensors [11]. Sensors for "NO2, NO, tropospheric O3, and particle matter (PM2.5, PM5)," etc., were seldom calibrated by the manufacturer. If they were, it was rarely under the conditions

in which they can provide measurement data. This lack of quality control has influenced regulations' negative perceptions of sensors and the scientific community's cautious use of them. Consequently, there was a strong demand for strategies to test or validate sensor data to monitor air pollution [12, 13, 14].

"Multiple Linear Regression (MLR)" [15, 16] "K-Nearest Neighbors (KNN), Support Vector Regression (SVR)" [17, 18], and "Random Forest (RF)" [19] have all seen an increase in interest in comparing and evaluating various calibration algorithms in recent years. Many of these studies utilized nodes to deploy a sensor array. This was because air pollutants were often found to have direct or inverse relationships with other pollutants, such as "ozone being negatively correlated with nitrogen oxide due to titration," or with meteorological conditions like temperature and relative humidity.

Air quality fields that take into account of local variations such as emissions and meteorology were one instrument of the CTMs (Chemical Transport Models) [20, 21, 22]. The Community Multiscale Air Quality (CMAQ) was a model that was state-of-the-art Climate Transmission Model (CTM) to track the motion of air pollutants due to anthropogenic pollution. "CMAQ" not only captures the spatial and temporal variations of the given area but also it might be error prone because of the flaws in meteorological, including the failures in emission-blaming characterization [23]. This study seeks to employ the DF method to develop spatiotemporal concentration maps for PM2.5 mass, five PM species, and three gas concentrations across North Carolina. These maps will be used for a health study focusing on coronary heart disease patients affiliated with the University of North Carolina Chapel Hill. The data fusion system combines information from atmospheric sensors with "CMAQ" to generate ground-level air pollution intensity fields for more accurate exposure estimates on spatial resolution of 12 km. Different techniques were used to provide data withholding and evaluate the stability of the data fusion and it was examined. The effect of total PM2.5 mass concentration was studied for four methods namely: "unadjusted CMAQ pollute Along with examining the effectiveness of various PM2.5 exposure methods, the approaches were being contrasted. The CMAQ and data fusion results were also compared with respect to the exposure fields of five PM entities and three gases.

In study [24], the authors suggested a fresh approach of building an AQM system based on fog computing and IoT" and described an embedded system where air quality data is collected over a time-frame and transferred to fog nodes for processing. Processing will be carried out to the simple information such as regular measurements, and further analyze it in the cloud under long-term storage. The cloud might be a good place to perform global analytics on data acquired from shared equipment over a long period. The infrastructure and model were developed using microprocessors and IoT-cloud platforms. Experimental findings show that this approach was capable of sensing air quality, and long-term air monitoring will help better understand air pollution and find a way to reduce it. This system has no restrictions on where it may be installed. The IoT-cloud was used to estimate air quality data as well as create data visualizations for the end-user.

In study [25], research project on the growth of the "IoT-based Air Pollution Monitoring System (APMS)" was undertaken and it involved an Arduino processor, sensor nodes to detect the existence of hazardous gases in the air, a mobile unit, a temporary memory buffer, and an internet connected web server. At a time, it locates data from many places and organizes the information at a particular instant of the day. A GPS module was connected to the system to precisely depict pollution sources in a given region. The collected data was sent to a computer regularly via a GPRS connection and subsequently displayed on a specific website. This system monitors air quality and will give notification when it is under an agreed limit, e.g., when there's a large amount of poisonous gases in the air, like "CO2, smoke, benzene, as well as NH3." It will display the feature in ppm on LCD and the website so that authorities can know and tackle air pollution in various regions.

The research in [26] introduced a novel evaluation model that incorporates a "FIS and an Analytic Hierarchy Process (AHP)" to create a new "Air Quality Index (AQI)." The toxicological values of environmental parameters ("PM2.5, PM10, O3, CO, NO2, and SO2") were assessed. The primary aim was to give effective evaluation through a "Reasoning Process (RP)" driven by priority weighting. The FIS processes air quality parameters based on their permissible limits in the first phase. Then, using RP, multiple air quality scenarios were modelled. As a result of combining such evaluations, a global score of the air quality situation was generated. FIS analyzes all the contaminants using the same classification system, which could cause complexity when air pollutants can lead to other different health issues. Eventually, in the last step, the system must include weightings derived from the importance of each significant parameter leading to air quality level or Air Quality Index (AQI). Lastly, based on the "Mexico City atmospheric monitoring system" data, the model analyses five score stages: in accordance with "severe, bad, good, regular and dangerous" when we put the weighted measures based on the classification in the pollution air, the results of the experiments discloses that the proposed AQI have better evaluations than the other classical AQI.

The impact of poor indoor air conditions on overall human quality of life is 10 times more damaging than outdoor air pollution where we are dealing with chemical hazards and other toxic substances. The "Environment Indoor Air Quality (EIAQ)" index plays a critical role in establishing the EIAQ that was good for human health by integrating the indoor AQI and "Thermal Comfort (TC) index." [27] introduced an "EIAQ monitoring" and control system that uses "Fuzzy Logic Controller (FLC)" to recognize, categorize, and calculate the EIAQ index value, which was divided into four categories: "'epic , 'ok', 'horrible', and 'worst'" Additionally, there was a selecting of contaminants that were grouped together based on their similar internal characteristics as well as the impact on people's health and environment. This approach uses "rule-based fuzzy logic" to process data obtained from a variety of sensors. The FIS' primary goal was to create an EIAQ index based on fuzzy theory. The EAQI index values served as reference points for the control system, which included fans, inlet-outlet exhaust, a buzzer, and lead components. This system was implemented to enhance indoor air quality and to provide

updates on the status of air TC pollutants. Thus, by and large, these models proved to be of great value in the area of evaluation, classification, of risk analysis, making suggestions, and undertaking actions to raise the well-being level of people.

III. Proposed Air Quality Monitoring Model

Air quality is an integral part of our lives. Smart cities are the main assets that provide their residents with a better quality of life with the provision of a safe and healthy atmosphere. In a smart city, environmental factors must be monitored to detect and mitigate pollution sources. In this research, a model is proposed to predict pollution nodes throughout the region to track pollution and meteorological parameters. By seeing breakdown, the community will take corrective action and enhance its environmental health. People may be warned of a disastrous event by implementing disaster warning devices, e.g., flooding and rainfall forecasting solutions. A holistic perspective can be obtained, allowing authorities to take data-driven infrastructure or policy planning decisions.

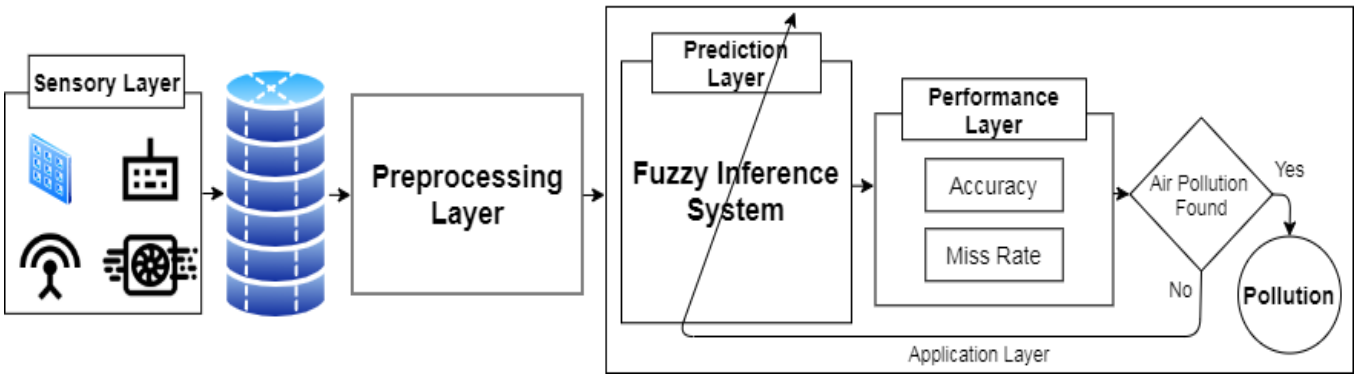

Fig. 1. Proposed model for air quality monitoring.

The following Fig. 1 depicts the waste disposal model. The layer with input values is called the input layer. The proposed methodology depends on three layers: "This layer incorporates Sensory Layer, Preprocessing layer, and Application layer." The Sensory layer deals with parameters input like Sulfur Dioxide (SO2), (NO2), CO, Ozone (O3) and Suspended Particulates (PM10), which get the values from parameters and pass these values through The IoT is the source of raw data because communication is wireless transmission. Maybe it is given some values that it misses or not, but the data may be noisy, too. That's why it's raw data. The top layer of the next layer is the preprocessing layer.

As you can see in Fig. 2, preprocessing involves the extraction of features through normalization and tokenization. Replacing missing data with moving averages and normalization is a crucial preprocessing step aimed at eliminating noise. The processed output from the preprocessing layer is then fed into the application layer, which is further subdivided into the prediction layer and the performance layer.

In Fig. 3, the prediction layer depicts a fuzzy inference engine. When the input parameter is pertinent, it undergoes fuzzification to translate it into fuzzy crisp inputs. This process starts with collecting clear input data, then transforming it into a fuzzy set using fuzzy linguistic variables, fuzzy semantic terms, and membership functions within the fuzzifier. Afterward, the fuzzy enhancements are analyzed through the fuzzy inference engine. Fuzzy inference involves determining an output based on a given input using fuzzy logic, followed by the transformation of fuzzy set values to a precise set in the defuzzifier. This process is commonly utilized in fuzzy control systems. Ultimately, the crisp output value determines whether pollution is predicted. The output from the prediction layer is accelerated to the performance layer for pollution detection, evaluating accuracy and miss rates. If pollution is detected, a message is displayed; otherwise, the fuzzification is adjusted.

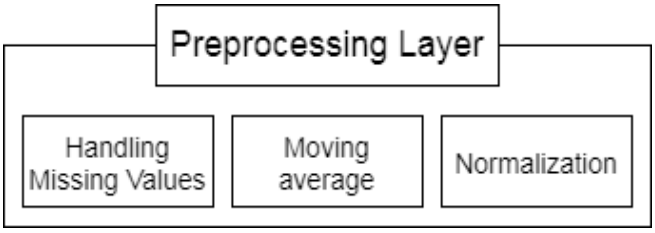

Fig. 2. Framework for preprocessing layer.

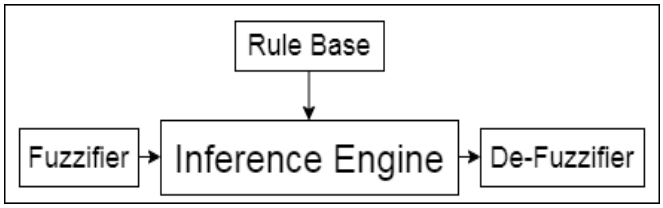

Fig. 3. Fuzzy inference engine.

IV. Membership Functions

A MF gives a statistical overview of input and output variables, showing how input variables are organized to generate membership values ranging from 0 to 1. Table I displays the membership functions of the suggested model's input/output variables for mapping, cluster module, device controller, service controller, and cloud ranking, presented graphically and mathematically.

TABLE I. MEMBERSHIP FUNCTIONS OF AIR QUALITY

Input/Output	Membership Functions	Graphical Representation of MF
Sulphur-Dioxide (SO_2)= $\mu_{SO2}(so2)$	$\mu_{SO2}(so2) = \{\max(\min\left(1, \frac{35 - so2}{15}\right), 0)\}$ $\mu_{SO2}(so2) = \{\max(\min\left(\frac{so2 - 20}{15}, 1, \frac{85 - so2}{15}\right), 0)\}$ $\mu_{SO2}(so2) = \{\max(\min\left(\frac{so2 - 70}{15}, 1\right), 0)\}$	Nitrogen Dioxide (NO_2)=$\mu_{NO2}(no2)$	$\mu_{NO2}(no2) = \{\max(\min\left(1, \frac{40 - no2}{20}\right), 0)\}$ $\mu_{NO2}(no2) = \{\max(\min\left(\frac{no2 - 20}{20}, 1, \frac{70 - no2}{20}\right), 0)\}$ $\mu_{NO2}(no2) = \{\max(\min\left(\frac{no2 - 50}{20}, 1\right), 0)\}$	Carbon mono Oxide (CO)=$\mu_{CO}(co)$	$\mu_{CO}(co) = \{\max(\min\left(1, \frac{50 - co}{10}\right), 0)\}$ $\mu_{CO}(co) = \{\max(\min\left(\frac{co - 40}{10}, 1, \frac{75 - co}{10}\right), 0)\}$ $\mu_{CO}(co) = \{\max(\min\left(\frac{co - 65}{10}, 1\right), 0)\}$	Ozone (O_3) = $\mu_{O3}(o3)$	$\mu_{O3}(o3) = \{\max(\min\left(1, \frac{50 - o3}{15}\right), 0)\}$ $\mu_{O3}(o3) = \{\max(\min\left(\frac{o3 - 35}{15}, 1, \frac{75 - o3}{15}\right), 0)\}$ $\mu_{O3}(o3) = \{\max(\min\left(\frac{o3 - 60}{15}, 1\right), 0)\}$	Suspended Particulates (PM_{10})=$\mu_{PM10}(pm10)$	$\mu_{PM10}(pm10) = \{\max(\min\left(1, \frac{45 - pm10}{15}\right), 0)\}$ $\mu_{PM10}(pm10) = \{\max(\min\left(\frac{pm10 - 30}{15}, 1, \frac{75 - pm10}{15}\right), 0)\}$ $\mu_{PM10}(pm10) = \{\max(\min\left(\frac{pm10 - 60}{10}, 1\right), 0)\}$	Air Quality (AQ)=$\mu_{AQ}(aq)$	$\mu_{AQ}(aq) = \{\max(\min\left(1, \frac{40 - aq}{10}\right), 0)\}$ $\mu_{AQ}(aq) = \{\max(\min\left(\frac{aq - 30}{10}, 1, \frac{70 - aq}{10}\right), 0)\}$ $\mu_{AQ}(aq) = \{\max(\min\left(\frac{aq - 60}{10}, 1\right), 0)\}$	
V. Fuzzy Set Operations

The Union and Compliment are the most vital Fuzzy Set Operations to manage the essence of FL. If there are two fuzzy sets, A and B on the universe X, $x \in X$.

Then the FSO can be written as

Intersection (AND) = $\mu_{A \cap B}(x) = \min(\mu_A(x), \mu_B(x))$

Union (OR) = $\mu_{AUB}(x) = \max(\mu_A(x), \mu_B(x))$,

Additive Complement (NOT) = $\mu_A(x) = 1 - \mu_B(x)$

VI. Fuzzy Propositions

A proposition represents a statement that can be categorized as either true or false. A multi-layered architecture has been proposed to assess cloud automation, structured into two levels of layers.

VII. Layer Level 1

Here, Layer 1 contains 5-factor layers' correspondence with AQ. Every layer has its MF represented by variables.

$$\text{AQ} = \text{t: SO2 x NO2 x CO x O3 x PM10} \rightarrow \text{T1} \quad (1)$$

In the realm of fuzzy expert systems, all qualities of input and output variables are mapped from the real range to probability ranges, given that the system operates within a probability range of 0 to 1. The T-norm function of Layer Level 1 can be expressed as:

$$\text{AQ} = \text{t: [0,1]x [0,1] x [0,1]x [0,1]x [0,1]} \rightarrow \text{T1} \quad (2)$$

Eq. (1) to Eq. (2) convert the MFs of fuzzy sets of simulation, Air Quality as Layer Level 1 is:

From Eq. (1) to (2)

$$t\left[\mu_{SO2}(so2), \mu_{NO2}(no2), \mu_{CO}(co), \mu_{O3}(o3), \mu_{PM10}(pm10) = \min\left(\mu_{SO2}(so2), \mu_{NO2}(no2), \mu_{CO}(co), \mu_{O3}(o3), \mu_{PM10}(pm10)\right)\right] \quad (3)$$

Specify equation (from 3)

$$\mu_{SO2 \cap NO2 \cap CO \cap O3 \cap PM10}(so2, no2, co, o3, pm10) = t[\mu_{SO2}(so2), \mu_{NO2}(no2), \mu_{CO}(co), \mu_{O3}(o3), \mu_{PM10}(pm10)] \quad (4)$$

Specify from Eq. (4)

$$\mu_{SO2 \cap NO2 \cap CO \cap O3 \cap PM10}(so2, no2, co, o3, pm10) = min[\mu_{SO2}(so2), \mu_{NO2}(no2), \mu_{CO}(co), \mu_{O3}(o3), \mu_{PM10}(pm10)] \quad (5)$$

Eq. (5) represents the minimum of intersection all sets.

Here, Layer 2 is containing five member functions respectively M, CM, DC, SC and CR. Every layer has their MF represent by variables.

$$\text{t: AQ} \rightarrow Lt \quad (6)$$

$$\text{t: [0,1]} \rightarrow Lt \quad (7)$$

$$t[\mu_{AQ}(aq) = \min[(\mu_{AQ}(aq))] \quad (8)$$

$$\mu_{AQ}(aq) = \min(\mu_{AQ}(aq))] \quad (9)$$

Eq. (9) specifies the minimum of intersection all sets.

VIII. Fuzzy Inference Engine

The Fuzzy Inference Engine (FIE) is the process of combining the fuzzy "IF-THEN" rules from the Fuzzy Rule Base (FRB) to map a fuzzy input set to a fuzzy output, following fuzzy logic principles. Key components of Fuzzy Inference include MFs, fuzzy logic operators, and if-then rules. All instructions within the FRB are consolidated into a Single Fuzzy Relation (SFR), positioned under the internal item on input universes of discourse, which is then treated as a single fuzzy "IF-THEN" rule. A suitable operator for combining the rules is a union.

Layer 1 IF-THEN fuzzy represent as:

$$R_{N^n} = A^n \times B^n \times C^n \ldots \times N^n$$

$$\mu_{A \cap B \cap C \ldots \cap N}(a, b, c \ldots, n) = \mu_A(a) \cap \mu_B(r) \cap \mu_C(c) \ldots \cap \mu_N(n) \quad (10)$$

Interpreted as SFR defined by

$$R_n = \bigcup_{n=1}^{n} R_N^n$$

Suppose φ, λ and ψ be any three arbitrary fuzzy sets and are also input and output to the FIE, respectively. To view R_n as a single fuzzy "IF-THEN" rule and using the generalized modus ponens.

$$\mu_{Range\ 1 \cap Range\ 2 \cap Range\ 3 \ldots \cap Range\ n}(\varphi) = Sup_{\lambda \in (A,B,C \ldots,N)} t[\mu_\lambda(A, B, C \ldots, N), \mu_{R_n}(A, B, C \ldots, N)] \quad (11)$$

Product Inference Engine format.

$$\mu_\varphi(T) = \max_{0 \le x \le n} \begin{bmatrix} sup_{(a,b,c \ldots,n) \in U} \left(\mu_{A,B,C \ldots,N}(\boldsymbol{a}, \boldsymbol{b}, \boldsymbol{c} \ldots, \boldsymbol{n})\right) \\ \left(\prod_{k=1}^{n} (\mu_{a_k, b_k, c_k \ldots, n_k}(a_k, b_k, c_k \ldots, n_k), \mu_\varphi x(T)\right) \end{bmatrix} \quad (12)$$

Layer 2 IF-THAN fuzzy represent as:

$$R_{\beta^n} = A^n \times B^n \times C^n \ldots, \times N^n$$

$$\mu_{A \cap B \cap C \ldots \cap N}(a, b, c \ldots, n) = \mu_A(a) \cap \mu_B(b) \cap \mu_C(c) \ldots \cap \mu_N(n) \quad (13)$$

Interpreted as SFR for layer 2 is defined by

$$R_n = \bigcup_{n=1}^{n} R_N^n$$

This is layer 2 is interpreted as SFR, defined as R_{α^n}.

IX. Fuzzy IF-Then Rules (Air Quality)

If-then statements are used to construct conditional statements of fuzzy logic. These statements form the basis for building a fuzzy rule base. The following are a few fuzzy inference procedure rules for the mapping.

1) If (SO2) is Poor) and ((NO2) is Poor) and (Carbon mono Oxide (CO) is Poor) and (O3) is Poor) and (Suspended Particulates (PM10) is Poor) then (Air Quality is Poor)

2) If (SO2 is Good) and (NO2 is Poor) and (CO is Poor) and ((O3) is Poor) and (Suspended Particulates (PM10) is Good) then (Air Quality is Good).

3) If (SO2 is Poor) and (NO2 is Moderate) and (CO is Moderate) and ((O3) is Moderate) and (Suspended Particulates (PM10) is Good) then (Air Quality is Moderate).

4) If (SO2) is Good) and ((NO2) is Good) and (Carbon mono Oxide (CO) is Good) and ((O3) is Good) and (Suspended Particulates (PM10) is Good) then (Air Quality is Good).

X. Defuzzifier

The process of defuzzifier derives an outcome in crisp logic by integrating fuzzy sets and evaluating their membership degrees. This makes a fuzzy set to a fresh set. In fuzzy control frameworks, it is expected to be representative. De-Fuzzifiers are available in a wide range of shapes and sizes. A centroid form of a De-Fuzzifier is used in the proposed model. The De-Fuzzifier graphical representation of FIS of mapping, cluster module, device controller, service controller, and cloud ranking is shown in Fig. 4 to Fig. 8.

Fig. 4 illustrates that if Ozone lies between 50-100 and Suspended Particulates between 50-100 then Air Quality is Good (Yellowish). If Ozone lies between 40-50 and Suspended Particulates between 40-50 then Air Quality is Satisfactory (Greenish). If Ozone lies between 0-40 and Suspended Particulates between 0-40 then Air Quality is Bad (Bluish).

Fig. 5 illustrates that if Ozone lies between 50-100 and SO2 Dioxide between 50-100 then Air Quality is Good (Yellowish). If Ozone lies between 40-50 and SO2 between 40-50 then Air Quality is Satisfactory (Greenish). If Ozone lies between 0-40 and SO2 between 0-40 then Air Quality is Bad (Bluish).

Fig. 6 illustrates that if Ozone lies between 70-100 and SO2 between 80-100 then Air Quality is Good (Yellowish). If Ozone lies between 50-70 and SO2 between 30-80 then Air Quality is Satisfactory (Greenish). If Ozone lies between 0-50 and SO2 between 0-30 then Air Quality is Bad (Bluish).

Fig. 7 illustrates that if SO2 lies between 80-100 and Carbon Mono Oxide between 80-100 then Air Quality is Good (Yellowish). If SO2 lies between 70-80 and Carbon Mono Oxide between 70-80 then Air Quality is Satisfactory (Greenish). If SO2 lies between 0-70 and Carbon Mono Oxide between 0-70 then Air Quality is Bad (Bluish).

Fig. 8 illustrates that if Ozone lies between 80-100 and Nitrogen Dioxide between 80-100 then Air Quality is Good (Yellowish). If Ozone lies between 50-80 and Nitrogen Dioxide between 50-80 then Air Quality is Satisfactory (Greenish). If Ozone lies between 0-50 and Nitrogen Dioxide between 0-50 then Air Quality is Bad (Bluish).

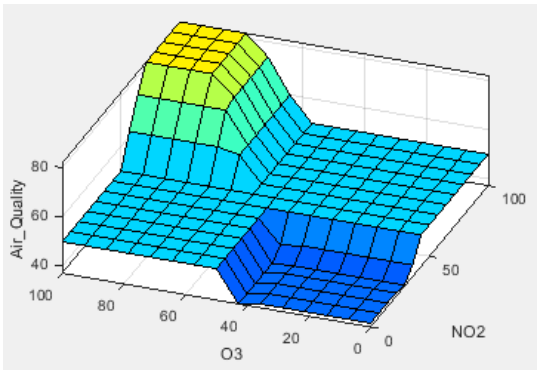

Fig. 8. Rule surface of air quality based on ozone and nitrogen dioxide.

XI. Simulation Results

In fuzzy logic, Boolean logic handles partially true or false values. Boolean values or membership values in fuzzy sets are represented by a number ranging from 0 to 1, where 0 signifies absolute Falseness and 1 represents complete truth. MATLAB is utilized to simulate the Fuzzy system for obtaining simulation results, with the simulated graphs presented in Fig. 9-13. MATLAB finds applications in modeling, simulation, algorithm development, prototyping, and various other domains. To generate the reproduction results, five data sources and one performance factor are employed. The proposed Fuzzy based air quality monitoring model is demonstrated in this article with several outputs such as the proposed system prediction. Based on the lookup rules, a lookup rules diagram is generated using the Fuzzy Logic designer.

Fig. 9 shows that if the values of (SO2) is poor, (NO2) is poor, Carbon Mono Oxide (CO) is poor, (O3) is poor and Suspended Particulates (PM10) is poor then Air Quality is poor.

Fig. 10 shows that if the values of (SO2) is moderate, (NO2) is good, Carbon Mono Oxide (CO) is poor, (O3) is poor and Suspended Particulates (PM10) is poor then Air Quality is poor.

Fig. 11 shows that if the values of (SO2) is moderate, (NO2) is moderate, Carbon Mono Oxide (CO) is moderate, (O3) is moderate and Suspended Particulates (PM10) is moderate then Air Quality is moderate.

Fig. 12 shows that if the values of (SO2) is good, (NO2) is good, Carbon Mono Oxide (CO) is good, (O3) is good and Suspended Particulates (PM10) is good then Air Quality is good.

Fig. 13 shows that if the values of (SO2) is good, (NO2) is poor, Carbon Mono Oxide (CO) is poor, (O3) is poor and Suspended Particulates (PM10) is good then Air Quality is good.

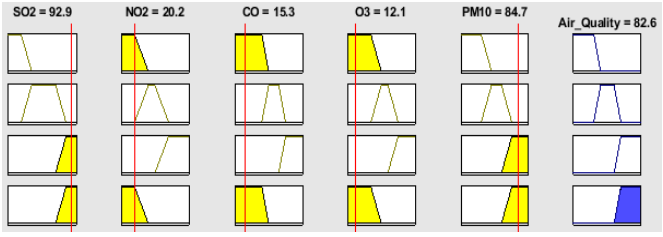

Fig. 13. Lookup diagram of Air Quality (Good) (2).

XII. Conclusion

This research work has introduced a new model based on a fuzzy inference system to monitor air quality status. The focus of this proposed research is to gather values from five atmospheric pollutants, including one particulate matter like Suspended Particulates (PM10) and four gaseous pollutants like SO2, NO2, CO, and O3 to monitor the air quality by using this proposed system. The simulation has shown that the proposed system provides better results in an efficient way to monitor air quality. Depending on the various levels of air quality, individuals can implement corresponding measures to manage and mitigate air pollution. For instance, during periods of good air quality, it indicates that the outdoor air is suitable for activities. Conversely, when the air quality is poor, precautions should be taken to minimize exposure to air pollution.

From Technical Indicators to Trading Decisions: A Deep Learning Model Combining CNN and LSTM

SAHIB Mohamed Rida, ELKINA Hamza, ZAKI Taher
Innovation in Mathematics and Intelligent Systems Research Laboratory, Faculty of Applied Sciences,
Ibn Zohr University, Agadir, Morocco

***Abstract*—Stock market prediction is a highly attractive and popular field within finance, driven by the potential for significant profits that come with substantial risks due to data non-linearity and complex economic principles. Extracting features from trading data is crucial in this domain, and numerous strategies have been developed. Among these, deep learning has achieved impressive results in financial applications because of its robust data processing capabilities. In our study, we propose a hybrid deep learning model, the CNN-LSTM, which combines the 2D Convolutional Neural Network (CNN) for image processing with the Long Short-Term Memory (LSTM) network for managing image sequences and classification. We transformed the top 15 of 21 technical indicators from financial time series into 15x15 images for 21 different day periods. Each image is then categorized as Sell, Hold, or Buy based on the trading data. Our model demonstrates superior performance in stock predictions over other deep learning models.**

***Keywords*—Stock market prediction; CNN-LSTM hybrid model; financial time series; technical indicators; CNN; LSTM**

I. Introduction

The global financial markets are characterized by their dynamic nature, where the profit potential is equally matched by the susceptibility to risk. This duality is largely due to the complex interplay of economic indicators, investor sentiment, and global financial events, making stock market forecasting a highly sophisticated area of study. Forecasting these markets requires an understanding of both macroeconomic trends and the minute fluctuations within trading data [1]. As markets evolve, the tools and techniques employed to forecast these changes must also develop, incorporating new data and adapting to changing conditions.

Traditional financial models, such as the Efficient Market Hypothesis and Fundamental Analysis, have long been used to understand and predict market behaviors. However, these models often fall short in times of increased market volatility and when dealing with large unstructured datasets. In contrast, advanced computational techniques, especially those involving machine learning and deep learning, have shown remarkable success in decoding complex patterns that underlie financial markets [2]. These techniques can process vast amounts of data in real-time, learning from new information as it becomes available, which is a crucial advantage in today's fast-paced markets.

Deep learning, a subset of machine learning, has emerged as a transformative force in financial predictions. The deep neural networks, with their multiple layers of processing, can extract high-level features from raw data, which is pivotal in identifying profitable trading opportunities. Specific architectures like Convolutional Neural Networks (CNNs) and Long Short-Term Memory networks (LSTMs) have been at the forefront of this revolution. CNNs are particularly effective in dealing with spatial data, whereas LSTMs excel in capturing temporal dependencies, addressing two critical dimensions of financial data [3].

The approach of combining CNNs and LSTMs aims to harness the strengths of both architectures to improve the accuracy and reliability of financial predictions. This hybrid model leverages CNN's ability to effectively process and analyze images derived from structured data, such as graphs and charts of market trends, and complements it with LSTM's capability to understand time series data, ensuring that temporal sequences in stock prices are accurately predicted. The synergistic combination of these technologies is designed to handle the multifaceted nature of financial datasets more effectively than models employing a single methodology [4].

Despite significant advancements in machine learning techniques, stock market prediction remains a challenging task due to the inherent volatility and complexity of financial markets. Traditional models often fail to capture the nuanced and multifaceted nature of market data, leading to inaccurate predictions. This research aims to address the gap by developing a hybrid model that combines CNNs and LSTMs to enhance the accuracy and robustness of stock trend predictions. How effective is the CNN-LSTM hybrid model in predicting stock trends compared to traditional financial models?

The objectives of this research are to develop a hybrid CNN-LSTM model for stock trend prediction and to evaluate the performance of the hybrid model against standalone deep learning models.

The significance of this research lies in its potential to revolutionize stock market forecasting by leveraging advanced deep learning techniques. By combining CNNs and LSTMs, the proposed model aims to provide more accurate and reliable predictions, which could significantly benefit investors and financial analysts. This research contributes to the field of financial forecasting by demonstrating the effectiveness of hybrid deep learning models and providing insights into their practical applications in dynamic market environments.

The reminder of this paper is organized into several distinct sections to facilitate a thorough exploration of our research. Section II reviews related works, emphasizing the evolution of

predictive models from traditional to modern deep learning approaches. Section III delves into the technologies underpinning our study, particularly CNNs and LSTMs, elucidating their principles and advantages in financial applications. Section IV details our methodology, including data preprocessing, model development, and algorithmic considerations. The empirical evaluation of our model is presented in Section V, where we discuss its performance against traditional and contemporary benchmarks. We conclude in Section VI, summarizing our contributions and proposing future research directions for enhancing predictive models in finance.

II. Related Works

Stock market prediction has long been a central theme in financial research, with various models being developed to forecast market trends and price movements. Historically, predictive models in finance were largely dominated by linear regression and time-series analysis, focusing on historical data to predict future prices. Seminal works by Fama [5] introduced the Efficient Market Hypothesis, suggesting that stock prices reflect all available information and follow a random walk. However, the hypothesis has been challenged by subsequent studies that recognize patterns and trends in market data, suggesting predictability under certain conditions [6].

Stock market analysis relied heavily on statistical methods and basic machine learning models. Time series forecasting techniques such as ARIMA and exponential smoothing were commonly used due to their simplicity and effectiveness in handling linear trends and seasonality [7]. However, these methods often fall short of capturing the complex, non-linear patterns typically exhibited in financial markets.

With the advent of more advanced computational resources, machine learning techniques have gained prominence. Researchers have explored various algorithms from simple decision trees to complex ensemble methods to predict stock prices. A significant contribution in this area was made by Patel et al. [8], who compared different technical indicators with machine learning algorithms and found that models like Random Forest and SVM outperformed traditional statistical methods.

Deep learning has introduced a paradigm shift in predictive accuracy and data processing capabilities. Among the first to apply deep learning to financial forecasting, Dixon et al. [9] demonstrated that deep neural networks could significantly enhance prediction performance over traditional models. The ability of deep learning models to learn complex, non-linear relationships in data offers unprecedented advantages in the noisy, volatile environment of financial markets.

Convolutional Neural Networks (CNNs) have been primarily utilized in image processing but have found applications in financial markets where pattern recognition in chart analysis plays a crucial role [10]. On the other hand, Long Short-Term Memory networks (LSTMs) are a type of recurrent neural network (RNN) ideal for processing sequences of data, making them suitable for analyzing time series data prevalent in stock market predictions [11].

The innovation of combining CNN and LSTM models is relatively recent, with researchers beginning to explore the synergy between spatial feature extraction and sequential data processing. In one notable study, Zhang et al. [12] developed a hybrid model that utilizes CNNs to interpret visual patterns from stock market charts and LSTMs to analyze the temporal patterns in trading data. Their findings suggest that such hybrid models can outperform models based on a single architecture, particularly in handling the multifaceted nature of financial time series data.

Recognizing the limitations of singular approaches, recent research has shifted towards hybrid models that combine the strengths of CNNs and LSTMs. These models leverage CNNs for robust feature extraction from complex input formats, such as images or transformed time series, and LSTMs to interpret these features over time, enhancing the predictive accuracy for various financial applications [13].

One notable study introduced an attention-based hybrid CNN-LSTM model that incorporates the XGBoost algorithm for feature selection and dimensionality reduction, further refining the model's predictions for stock prices [13]. Similarly, Shang et al. [14] employed a CNN-LSTM hybrid model to enhance signal processing capabilities for damage detection in infrastructure, demonstrating the versatility of hybrid models in diverse applications beyond the financial market.

Khalid et al. presents in his study [15] a convolutional deep neural network model leveraging a 2D-CNN for image processing and classification. The image creation process involves transforming top technical indicators from a financial time series, each calculated over 21 different-day periods, to generate images of specific sizes. These images are then labeled as Sell, Hold, or Buy based on the original trading data. In comparison to the Long Short-Term Memory Model and the one-dimensional Convolutional Neural Network, the proposed model demonstrates superior performance. This research underscores the efficacy of employing a convolutional deep neural network with 2D-CNN for processing and classifying financial time series data. The utilization of top technical indicators in image creation contributes to enhanced predictive capabilities, making the proposed model a promising approach for stock price trend prediction.

III. Background

Deep learning has risen to prominence as a pivotal subset of machine learning, renowned for its efficacy across a broad spectrum of applications from image recognition to natural language processing. This method employs multiple layers of neural networks to interpret vast quantities of data, revealing intricate patterns those traditional techniques could not uncover. Among the most influential architectures within deep learning are Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs).

A. Convolutional Neural Network (CNN)

A Convolutional Neural Network (CNN) is a specialized type of neural network model designed for processing data that has a grid-like topology, such as images. CNNs are particularly powerful for tasks involving image recognition, classification, and analysis, and have been widely adopted in various

applications ranging from medical imaging to autonomous vehicle technology.

A Convolutional Neural Network typically consists of an input layer, multiple hidden layers, and an output layer "Fig. 1". The hidden layers usually include a series of convolutional layers, pooling layers, and fully connected layers at the end:

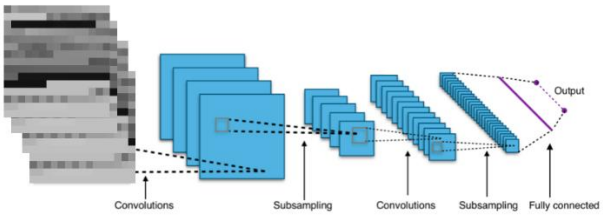

Fig. 1. CNN architecture.

1) Convolutional layers: The core building blocks of a CNN are its convolutional layers, which apply a number of filters to the input. These filters are small matrices used to perform convolution operations that process the data and create feature maps. This process effectively captures spatial hierarchies in data by recognizing patterns such as edges, shapes, and textures within the input images [16]. Mathematically, it is expressed as given in Eq. (1) for a single dimension:

$$(f * g)(t) = \int f(\tau)g(t-\tau)d\tau \tag{1}$$

In the context of CNNs, this is typically simplified to a discrete convolution as shown in Eq. (2), especially for image processing:

$$(f * g)[n] = \sum_{m=-M}^{M} f[m] \times g[n-m] \tag{2}$$

In 2D (for images), it becomes Eq. (3):

$$(I * K)[i,j] = \sum_m \sum_n I[m,n] \times K[i-m, j-n] \tag{3}$$

where:

- I is the input image or feature map.
- K is the kernel or filter.
- m, n index the elements of the kernel.
- i, j index the resulting matrix.

2) Activation function: After a convolution operation, an activation function such as the ReLU (Rectified Linear Unit) as given in Eq. (4) is typically applied to introduce non-linear properties to the system. This helps the network learn complex patterns during training.

$$ReLU(x) = \max(0, x) \tag{4}$$

3) Pooling layers: These layers reduce the spatial size of the convoluted features, helping to decrease the computational load, memory usage, and the number of parameters. Max pooling, which selects the maximum value from the feature region covered by the filter, is a common method used.

4) Fully connected layers: Towards the end of the network, fully connected layers use the features extracted by the convolutional and pooling layers to determine the final output, such as the classification of the image. Each neuron in a fully connected layer has connections to all activations in the previous layer.

5) Output layer: The final layer outputs the prediction of the network using a Softmax or Sigmoid activation function, depending on the task (e.g., multi-class classification or binary classification).

B. Long Short-Term Memory (LSTM)

Long Short-Term Memory (LSTM) networks are a special kind of Recurrent Neural Network (RNN) that are capable of learning long-term dependencies in data sequences. Introduced by Hochreiter and Schmidhuber in 1997, LSTMs were designed to overcome the limitations of traditional RNNs, particularly problems related to learning long-term dependencies and the vanishing gradient problem during training [17]. LSTMs are particularly well-suited for classifying, processing, and predicting sequences where there are lags of unknown duration between important events. This capability makes them ideal for applications such as time series prediction, natural language processing, and speech recognition.

An LSTM unit "Fig.2" typically consists of a cell state and three gates that regulate the flow of information: the input gate (6), forget gate (5), and output gate (9). Here's how each component works mathematically:

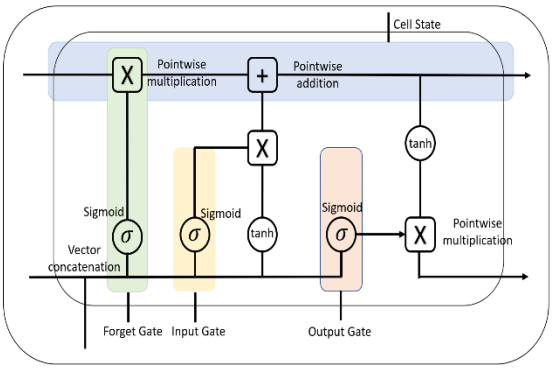

Fig. 2. The structure of LSTM unit.

1) Forget gate: This gate decides what information is discarded from the cell state. σ denotes the sigmoid function, W_f are the weights of the forget gate, h_{t-1} is the previous hidden state, x_t is the input at step t, and b_f is the bias.

$$f_t = \sigma(W_f . [h_{t-1}, x_t] + b_f) \tag{5}$$

2) Input gate: The input gate decides which values will update the cell state. $\tilde{C}$ (7) represents the candidate values for the state update.

$$i_t = \sigma(W_i . [h_{t-1}, x_t] + b_i) \tag{6}$$

$$\tilde{C}_t = \tanh(W_C . [h_{t-1}, x_t] + b_C) \quad (7)$$

3) Cell state update: The cell state C_t (8) is updated by forgetting the old state C_{t-1} as regulated by f_t and adding new candidate values scaled by i_t.

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t \quad (8)$$

4) Output gate: The output gate controls the output of the cell state through the hidden state h_t (10). The actual output $h_t$is filtered by the output gate o_t and then passed through a tanh function to scale the values between -1 and 1.

$$o_t = \sigma(W_o . [h_{t-1}, x_t] + b_o) \quad (9)$$

$$h_t = o_t * \tanh(C_t) \quad (10)$$

C. CNN-LSTM Hybrid Model

The most important and useful deep neural models come from the combining of the different types of networks together into hybrid models. The CNN-LSTM method for the stock market forecasting, composed of a series connection of CNN and LSTM. CNN-LSTM can extract complex features and can store complex irregular trends of stocks market.

In a CNN-LSTM architecture [18], the TimeDistributed layer is used to wrap a convolutional neural network (CNN) so that it can process input data that varies over time, such as frames in a video or a series of images. This layer allows the same CNN model to be applied to each timestep independently and efficiently. Essentially, it acts as a bridge between the CNN and LSTM layers, managing the temporal aspects of the model while preserving spatial feature extraction capabilities of the CNN.

The TimeDistributed layer is a crucial component in neural network architectures where it is necessary to apply the same layer independently to every timestep of input data. This is particularly useful in models that need to maintain temporal order in their inputs, such as CNN-LSTM networks used for sequence prediction tasks that involve spatial data (like videos or time series of images).

1) CNN-LSTM Model with TimeDistributed: In a typical CNN-LSTM setup:

a) Feature Extraction (CNN part): The TimeDistributed wrapper applies the CNN across each timestep. For instance, in video processing [19], each frame (image) of the video passes through the same convolutional layers. This ensures that the spatial features from each frame are extracted in the same way.

b) Temporal Processing (LSTM part): The output from the TimeDistributed-CNN part, now a series of feature vectors (one for each timestep), is then passed to the LSTM layers. The LSTM processes these features over time, capturing dynamic temporal behaviors and interactions between the timesteps, which are crucial for tasks like video classification or predicting sequences of images.

IV. METHODOLOGY

We propose a hybrid analytical model that integrates Convolutional Neural Networks (CNN) and Long Short-Term Memory networks (LSTM) to effectively identify optimal buying and selling points in stock prices. This model employs fifteen selected technical indicators from a set of twenty, each evaluated over various time intervals, to generate representative images. The methodology of our proposed system encompasses five principal stages: data extraction, feature engineering, feature selection, data labeling, and the management of class imbalance, culminating in the creation of images. The primary objective of our research is to accurately determine the most advantageous positions for buy, sell, and hold decisions within the time series data of stock prices.

A. Data Extraction

In our research, the dataset employed comprises several key features that encapsulate the dynamics of the stock market. Specifically, it includes the following attributes: Date, Open Price, Low Price, High Price, Close Price, Adjusted Close Price, and the Trading Volume for each respective date. These features are extracted from the daily stock prices of Apple Inc., sourced from Alpha Vantage, which is known for its comprehensive provision of real-time and historical financial market data. The dataset spans from January 1, 2004, to December 31, 2021, for training purposes, and from January 1, 2022, to December 31, 2023, for testing, allowing a robust assessment of our model's predictive capabilities within the specified periods.

B. Feature Enginnering

Following the extraction of the dataset, our methodology involves calculating 21 technical indicators for each trading day, covering varying intervals ranging from 6 to 27 days. These indicators predominantly fall into two categories: momentum indicators and oscillators. Momentum indicators are used to assess the speed at which stock prices change, providing insights into the strength or weakness of a trend. Oscillators, on the other hand, help determine overbought or oversold conditions by measuring the price momentum and its deviations. This comprehensive analysis of technical indicators enhances our model's ability to accurately predict optimal trading points within the stock market.

1) Moving Average (MA): Shows the average stock price over a specific period of time, smoothing out price data. Eq. (11) shows its calculation.

$$MA = \frac{\sum_{i=1}^{n} P_i}{n} \quad (11)$$

Where P_i is the price at each point and n is the number of points.

2) Exponential Moving Average (EMA): Similar to MA but gives more weight to recent prices, reacting more significantly to recent price changes. Eq. (12) unveils its computational heart.

$$EMA_t = (V_t \times SF) + (EMA_{t-1} \times (1 - SF)) \quad (12)$$

SF is the Smoothing factor is typically $\frac{2}{n+1}$, where n is the number of days.

3) Moving Average Convergence Divergence (MACD) : Indicates the relationship between two moving averages of a stock's price. Eq. (13) and Eq. (14) show the calculations of MACD and Signal Lines:

$$MACD = EMA_{12} - EMA_{26} \tag{13}$$

And the signal line:

$$Signal = EMA_9(MACD) \tag{14}$$

4) Relative Strength Index (RSI): Measures the speed and change of price movements, typically over a 14-day period, to identify overbought or oversold conditions. Eq. (15) provides the calculation of RSI value:

$$RSI = 100 - \frac{100}{1 + RS} \tag{15}$$

where RS (Relative Strength) is:

$$RS = \frac{Average\ Gain}{Average\ Loss} \tag{16}$$

5) Bollinger bands: Consists of a middle band being an N-period simple moving average (SMA) flanked by upper and lower bands at two standard deviations away from the SMA to measure volatility. The inner workings of the Bollinger Bands are detailed in Eq. (17) to Eq. (19):

$$Middle\ Band = MA_{20} \tag{17}$$

$$Upper\ Band = MA_{20} + (2 \times Std_{20}) \tag{18}$$

$$Lower\ Band = MA_{20} - (2 \times Std_{20}) \tag{19}$$

6) Stochastic oscillator: Compares a stock's closing price to its price range over a certain period, indicating momentum and possible trend reversals. Eq. (20) illustrates the specific computation employed by the Stochastic Oscillator:

$$\%K = \frac{C - L_{14}}{H_{14} - L_{14}} \times 100 \tag{20}$$

where, C is the lasted closing price, L_{14} is the low of the 14 previous trading sessions, and H_{14} is the highest price traded during the same 14-day period.

7) On-Balance Volume (OBV): Uses volume flow to predict changes in stock price. Eq. (21) unveils its computational heart:

$$OBV_t = \begin{cases} OBV_{t-1} + Vol_t\ if\ Close_t > Close_{t-1} \\ OBV_{t-1} - Vol_t\ if\ Close_t < Close_{t-1} \\ OBV_{t-1}\ if\ Close_t = Close_{t-1} \end{cases} \tag{21}$$

8) Average Directional Index (ADX): Measures the strength of a trend, regardless of its direction. Eq. (22) illustrates the calculation of ADX:

$$ADX = \frac{SMAoAV(DI^+ - DI^-)}{DI^+ + DI^-} \tag{22}$$

where SMAoAV is the Smoothed Moving Average of the Absolute Value.

9) Accumulation/Distribution Line (A/D Line): Measures the cumulative flow of money into and out of a stock, which can indicate potential price movements. Eq. (23) unveils the A/D's inner workings:

$$A/D = Prev_{A/D} + Vol \times \frac{C - L - (H - C)}{H - L} \tag{23}$$

where Vol is the Volume, C is the close price, L is the Low price, and H is the high price.

10) Ichimoku cloud: Provides more data points, which give a more comprehensive look at resistance and support, as well as momentum and trend direction. One of its components. Eq. (24) shows how Ichimoku Cloud is calculated:

$$Leading\ Span\ A = \frac{ConversionLine + BaseLine}{2} \tag{24}$$

Conversion Line and Base Line involve calculating midpoints of high and low prices over different periods.

11) Standard deviation: Measures the dispersion of a dataset relative to its mean, commonly used to gauge the volatility. Eq. (25) details the SD's calculation:

$$\sigma = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(P_i - \mu)^2} \tag{25}$$

Where P_i is each individual price and μ is the mean price.

12) Volume Weighted Average Price (VWAP): Gives an average price a stock has traded at throughout the day, based on both volume and price. These VWAP, captured in Eq. (26):

$$VWAP = \frac{\sum(Price \times Volume)}{\sum Volume} \tag{26}$$

13) Momentum: Indicates the rate of change or speed of price movement of a stock. Eq. (27) illustrates its calculation:

$$Momentum = Close_{current} - Close_{n\ periods\ ago} \tag{27}$$

14) Commodity Channel Index (CCI): Determines overbought or oversold levels, helping to identify price reversals. Eq. (28) shows the calculation of CCI.

$$CCI = \frac{TypicalPrice - 2OPeriod\ MA\ of\ TP}{0.015 \times Mean\ Deviation} \tag{28}$$

Typical Price (TP) is the average of the high, low, and close prices.

15) Williams %R: Measures the level of the close relative to the highest high for the look-back period, similar to the Stochastic Oscillator. Eq. (29) details the calculation of Williams %R.

$$\%R = \frac{H_n - C}{H_n - L_n} \times -100 \tag{29}$$

16) Chaikin Money Flow (CMF): Combines price and volume to show where the money is flowing, into or out of a stock. Eq. (30) illustrates the specific computation of CMF

$$CMF = \frac{\sum_1^N \left[\frac{((C-L)-(H-C))}{(H-L)} \times Volume\right]}{\sum_1^N Volume} \quad (30)$$

17) Aroon indicator: Measures whether a stock is trending or not and the strength of the trend. For the mathematically inclined, the inner workings of the Aroon indicator are detailed in Eq. (31) to Eq. (32):

$$Aroon\ Up = \frac{(N - Days\ Since\ Nday\ High)}{N} \times 100 \quad (31)$$

$$AroonDown = \frac{(N - Days\ Since\ Nday\ low)}{N} \times 100 \quad (32)$$

18) Keltner channel: Similar to Bollinger Bands, uses envelopes set above and below an exponential moving average, but the bands are based on the Average True Range (ATR). Eq. (33) to Eq. (35) details the mathematical principles behind the Keltner Channel.

$$Middle\ Line = EMA_{20} \quad (33)$$

$$Upper\ Channel\ Line = EMA_{20} + (2 \times ATR) \quad (34)$$

$$Lower\ Channel\ Line = EMA_{20} - (2 \times ATR) \quad (35)$$

19) Elder's Force Index (EFI): Elder's Force Index combines price movement and volume to measure the strength of bulls and bears in the market. It can indicate potential reversals and price corrections. Eq. (36) details the EFI's calculation.

$$EFI = Volume \times (Current\ Close - Prev\ Close) \quad (36)$$

20) Rate of Change (ROC): The Rate of Change indicator measures the percentage change in price between the current price and the price a certain number of periods ago. It's used to identify the momentum behind price movements. Eq. (37) details the ROC's calculation.

$$ROC = \left(\frac{Current\ close - Close\ n\ periods\ ago}{Close\ n\ periods\ ago}\right) 100 \quad (37)$$

21) Average True Range (ATR): The Average True Range is a technical analysis indicator that measures market volatility by decomposing the entire range of an asset price for that period. ATR is not directional and only measures volatility, making it useful for assessing risk. Eq. (38) and (39) unveil the mathematical principles behind this indicator.

$$TrueRange = Max[|H - L|, |H - PreC|, |L - PreC|] \quad (38)$$

$$ATR = MA\ (True\ Range\ over\ n\ period) \quad (39)$$

C. Feature Selection

In the pursuit of enhancing model performance, a rigorous feature selection process was implemented subsequent to the computation of various indicators. The selection involved two established methodologies: the ANOVA F-value [20][21] method (f_classif) and the Chi-Squared test (chi2) [21]. These methods were employed to identify features with the highest statistical significance in relation to the predictive outcome. An intersection of the features identified by both methods was conducted to ensure the inclusion of the most robust features. Furthermore, the features common to both selection results were organized such that indices were sorted, facilitating the clustering of similar types of indicators. This arrangement aims to maintain spatial coherence when these indicators are represented as images, optimizing the model's ability to discern patterns relevant to the predictive tasks at hand.

D. Labeling the Target

To determine the target labels, a computational algorithm is utilized. This algorithm analyzes a sliding window of 11 days at a time, checking the day that falls in the middle of this window. It assigns a "SELL" label if this day has the highest price in the window, a "BUY" if it has the lowest, and a "HOLD" for all other cases. This method can be used to guide trading decisions, suggesting optimal days for buying or selling based on historical price movements within each window [10].

E. Handling Class Imbalance

Upon labeling our target variables, it was observed that the dataset exhibited significant class imbalance. The "Hold" category substantially outnumbered the "Buy" and "Sell" classes. Addressing class imbalance is a pivotal challenge in machine learning, especially in datasets where the frequency of instances across different classes is markedly disproportionate. Such imbalances can detrimentally affect the performance of predictive models by inducing a bias towards the majority class.

To counteract this issue, several methodologies have been developed and are widely recognized within the research community. These include:

- Oversampling the minority class: This involves artificially augmenting the minority class by replicating its instances until the class distribution is more balanced. A popular method is the Synthetic Minority Over-sampling Technique (SMOTE), which synthesizes new examples rather than duplicating existing ones [22].
- Undersampling the majority class: This method reduces the number of samples in the majority class to balance the class distribution. Care must be taken to ensure that this does not lead to the loss of important information.
- Bagging: Using bagging techniques like Random Forest can help by building multiple decision trees on various sub-samples of the dataset and then averaging the results to improve the model's robustness and balance [23].
- Cluster-based Over Sampling: Techniques that involve clustering the minority class and then performing oversampling within each cluster to maintain intra-class diversity [24].

For the purposes of this study, cluster-based oversampling was selected to address the imbalance within the dataset. This choice was predicated on its efficacy in maintaining the diversity and representativeness of the minority class, thereby enhancing the overall predictive accuracy and reliability of the model.

F. Image Generation

Upon completing the aforementioned procedural steps which encompass dataset acquisition, computation of technical indicators, feature selection, target labeling, and data normalization we proceed to organize the daily tabular data, which consists of 225 features, into an image-like format. This transformation facilitates the application of convolutional neural networks, which are adept at processing image data. "Fig. 3" illustrates sample images, each composed of a 15x15 pixel grid, generated during the image creation phase.

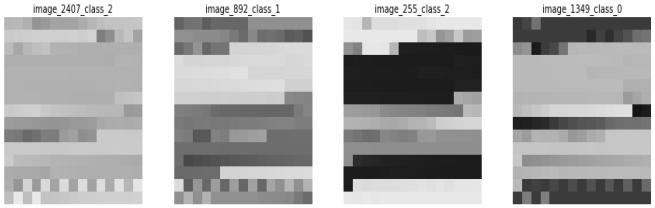

Fig. 3. Sample of images.

In the context of this research, the image dataset comprises a substantial collection of stock price data for Apple Inc. Specifically, the dataset includes approximately 3,481 images designated for training, 1000 images set for testing purposes. This structured division supports a robust framework for evaluating the efficacy of the predictive model under study.

G. CNN-LSTM Architecture

The architecture of the used neural network (see Fig. 4) outlines a hybrid Convolutional Neural Network-Long Short-Term Memory (CNN-LSTM) model, strategically designed to process sequential data that integrates spatial hierarchies. This hybrid model is particularly effective in scenarios where both spatial features and temporal sequences are crucial, such as in video processing, time-series analysis, and complex natural language tasks.

In this model, the data flows through multiple layers, each designed for specific tasks. Initially, spatial features are extracted through time-distributed CNN layers, where each CNN operates independently across different time steps but shares weights. These layers help to capture spatial dependencies within individual time frames of the input data. Subsequent dropout layers are incorporated following each CNN layer to mitigate overfitting by randomly deactivating neurons during training. The outputs are then flattened and sequenced through an LSTM layer, which is adept at understanding and retaining information across time steps, thus capturing the temporal relationships between the extracted features. Finally, the sequential data, now encoded with both spatial and temporal information, is processed through dense layers with another dropout in between to further control overfitting. The last dense layer outputs the final predictions of the model.

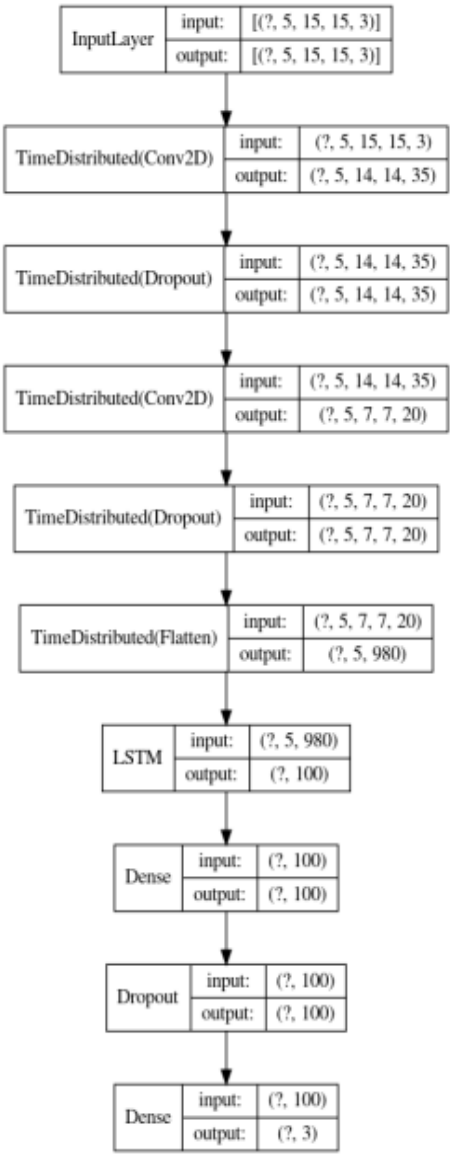

Fig. 4. The architecture of the CNN-LSTM model.

V. Performance and Evaluation

The efficacy of our proposed CNN-LSTM model is assessed primarily through computational evaluation metrics that ascertain how adeptly the classifier distinguishes among the 'Buy', 'Hold', and 'Sell' categories. This assessment involves comparing the labels predicted by the model against the actual stock prices, thereby evaluating the model's practical utility in real-world trading scenarios. The decision to buy, sell, or hold stocks is predicated on these predicted labels, which aim to reflect the optimal trading actions based on the observed data.

Our research employs a sophisticated evaluation methodology for our proposed CNN-LSTM model, utilizing Apple Stock data. The model undergoes rigorous training using the complete dataset, supplemented by cross-validation techniques to ensure generalizability and robustness. The F1 score, a harmonic mean of precision and recall, serves as the primary metric during the training phase, providing a balanced

measure of the model's accuracy in distinguishing between the classes of 'Buy', 'Hold', and 'Sell'.

For the evaluation of test data, we extend our metrics to include a confusion matrix, which offers a detailed visualization of the model's performance across the actual and predicted classifications. This matrix is crucial for understanding the specific types of errors made by the model, such as misclassifications between different trading signals.

Additionally, we utilize the weighted F1 score to account for class imbalance by assigning a weight to each class that reflects its relative importance or frequency. This metric is particularly useful when dealing with skewed class distributions, as it ensures that the performance of the model is not disproportionately influenced by the majority class.

Lastly, the Kappa score, or Cohen's Kappa, is employed to measure the degree of agreement between the actual and predicted classifications, adjusted for the agreement that could occur by chance. This statistical measure provides a more nuanced indication of the model's predictive accuracy and reliability in operational settings.

Together, these metrics furnish a comprehensive framework for evaluating the predictive capabilities of our CNN-LSTM model, ensuring it meets the rigorous standards required for effective stock market trading applications.

On Apple stock data the model gave the following result:

TABLE I. CONFUSION MATRIX OF TEST SET (APPLE)

Actual	**Predicted**		
	Hold	***Buy***	***Sell***
Hold	807	18	12
Buy	32	46	0
Sell	36	0	49

TABLE II. EVALUATION OF TEST SET (APPLE)

	Total Accuracy: 0.86		
	Hold	***Buy***	***Sell***
Recall	0.96	0.59	0.58
Precision	0.92	0.72	0.80
F1-Score	0.94	0.65	0.68
Weighed-F1	0.90		
Kappa score	0.62		

The provided tables elucidate the performance metrics of a classification model dedicated to forecasting stock trading decisions—namely Hold, Buy, and Sell—using Apple stock data. The first table, designated as Table I, presents a confusion matrix that details the accuracy and misclassifications across different trading actions, as predicted by the model. This matrix reveals: For the Hold class, the model achieved substantial accuracy with 807 true positives, while inaccuracies were relatively minor, involving 18 instances predicted as Buy and 12 as Sell. In the Buy category, the model successfully identified 46 instances but incorrectly categorized 32 as Hold, indicating no errors in predicting Buy as Sell. The Sell predictions included 49 correct classifications, but 36 were erroneously predicted as Hold, with no instances misclassified as Buy.

The second table, Table II, provides a comprehensive overview of various evaluation metrics: Total Accuracy stands at 86%, showcasing high overall precision in the model's predictions. The Precision and Recall metrics demonstrate: Exceptional precision (0.92) and recall (0.96) for Hold predictions, indicating the model's efficiency in this category. Moderate precision (0.72) and lower recall (0.59) for Buy predictions, suggesting difficulties in consistently identifying buy transactions. Reasonable precision (0.80) and moderate recall (0.58) for Sell predictions, highlighting some challenges in capturing all actual Sell transactions. F1-Scores further reflect the nuanced performance across categories, with a high of 0.94 for Hold, and lower scores of 0.65 for Buy and 0.68 for Sell, suggesting areas for improvement in balancing precision and recall, particularly for Buy and Sell predictions. The Weighted F1 Score at 0.90% and a Kappa Score of 0.62% suggest a good overall model performance but also room for enhancement, particularly in the precise classification of Buy and Sell actions.

Multi-Layer Perceptron (MLP), Long Short-Term Memory (LSTM), and Convolutional Neural Network (CNN) serve as established methodologies for forecasting stock market movements, and have been selected as baseline models for comparison against our proposed model. The outcomes of these comparisons are detailed in Table III, where the highest Average F1-Score results are highlighted in bold.

TABLE III. THE AVERAGE OF F1-SCORE OF TEST DATA (APPLE) ON DIFFERENT MODELS

Model	***Avg F1-Score***
MLP	0.44
CNN	0.57
LSTM	0.45
CNN-LSTM	**0.76**

VI. CONCLUSION

In this study, we developed and evaluated a hybrid deep learning model combining Convolutional Neural Networks (CNNs) and Long Short-Term Memory networks (LSTMs) for stock market prediction. Our findings demonstrate that this hybrid model outperforms traditional financial models and other deep learning approaches in terms of accuracy and reliability. By effectively processing and analyzing both spatial and temporal dimensions of financial data, the CNN-LSTM model captures complex market patterns and provides robust trading signals.

The superior performance of the hybrid model underscores the potential of integrating advanced machine learning techniques in financial market predictions. This research contributes to the growing body of evidence that deep learning models can significantly enhance the accuracy of financial forecasts, offering valuable insights for investors and traders.

Implications for future research include the exploration of additional hybrid architectures, the incorporation of diverse data sources such as macroeconomic indicators and news sentiment, and the development of real-time analysis capabilities. Additionally, expanding the model's application to other financial markets and improving the interpretability of deep learning models will further enhance their practical utility.

Overall, our study highlights the transformative potential of hybrid deep learning models in financial market analysis, paving the way for more sophisticated and reliable predictive tools in the finance industry.

***Abstract*—Multimodal sentiment analysis extracts sentiments from multiple modalities like text, images, audio, and videos. Most of the current sentiment classifications are based on single modality which is less effective due to simple architecture. This paper studies multimodal sentiment analysis by combining several deep learning text and image processing models. These fusion techniques are RoBERTa with EfficientNet b3, RoBERTa with ResNet50, and BERT with MobileNetV2. This paper focuses on improving sentiment analysis through the combination of text and image data. The performance of each fusion model is carefully analyzed using accuracy, confusion matrices, and ROC curves. The fusion techniques implemented in this study outperformed the previous benchmark models. Notably, the EfficientNet-b3 and RoBERTa combination achieves the highest accuracy (75%) and F1 score (74.9%). This research contributes to the field of sentiment analysis by showing the potential of combining textual and visual data for more accurate sentiment analysis. This will lay the groundwork for researchers in the future to work on multimodal sentiment analysis.**

***Keywords*—Multimodal sentiment analysis; deep learning; transfer learning; natural language processing; image processing; BERT**

I. Introduction

Sentiment analysis is an important part of natural language processing which determines emotions in text [1]. A decade ago, sentiment analysis was performed using text data only, but now advanced technology and programming languages have allowed researchers to combine text with images, audio and video to generate sentiments [2]. Textual data, which contains words, phrases and sentences, provides necessary information about emotions. In visual data (i.e. images and videos) there are facial expressions, body language, and scenes, which can be indicators about sentiments. In Audio Data, a person's voice tone, pitch and intonation carry emotional information. This variation of information modality states the need for multimodal sentiment analysis where information from multiple modalities like textual and visual components are combined. This has inspired researchers to utilize multiple modalities to understand complex emotions.

Multimodal sentiment analysis is inspired from human communication where people use both words and pictures to grasp feelings. Analyzing only one modality i.e text provides a limited view. Focusing solely on text can miss many underlying emotions. By mixing textual and image data, deeper layers of sentiment can be analyzed using facial expressions, scene context, and color tones. Modern AI models are very powerful, and they can combine features of many modalities as well as can handle large datasets. At present almost everyone posts on various social media platforms and these posts contain text, images and emojis. Determining the sentiment of a post requires all these modalities. In healthcare, analyzing the patient's voice, facial expression can assist to diagnose the patient efficiently. Multimodal sentiment analyis can also be applicable in marketing. Researchers believe that combining data of various modalities can reveal deeper layers of sentiment.

The main goal of this paper is to inspect various combinations of different text and image processing models to determine the best fusion technique for multimodal senitment analysis through rigorous comparative analysis. Three model pairings i.e. RoBERTa with EfficientNet, RoBERTa with ResNet50, and BERT with MobileNetV2 are explore in this study. At first, various data preprocessing techniques are explored. Then, different models are combined and trained. Finally, the results are assessed using various evaluation techniques. This includes examining the effectiveness of the chosen model combinations and the preprocessing techniques employed. The main contribution of the study can be outlined as follows:

- Demonstrating how multimodal fusion techniques enhance sentiment classification accuracy.
- Outlining a comprehensive methodology for data preprocessing, model integration, training, and evaluation.
- Developing a framework that future researchers can use and build upon to advance multimodal sentiment analysis.

The rest of the research is arranged in the following manner: Section II discusses related works to this work. Section III concisely presents the datasets used in this investigation. The proposed methodology and the detailed approach, including the use of deep learning models and preprocessing techniques, are also described in this section. The results are presented in Section IV and the discussions are described in Section V. Finally, the paper concludes in Section VI, summarizing the findings and suggesting directions for future research.

II. Literature Review

A. Evolution and Methodological Innovations

Early sentiment analysis used traditional machine learning techniques to detect sentiments from text. Sentiment analysis was first introduced by Pang et al. [3]. In this paper, sentiments of movie reviews were identified using three machine learning

techniques: Naive Bayes, maximum entropy classification, and support vector machine. Turney [4] extended this research by utilizing an unsupervised learning algorithm for classification based on semantic orientation. Kumar et al. mined customer reviews from amazon and used Naive Bayes, Logistic Regression and SentiWordNet to classify the reviews [5]. The introduction of deep learning has significantly changed the sentiment analysis process, producing better sentiment classification and analysis than traditional machine learning models.

B. The Relationship of NLP and Computer Vision

In recent years, significant development in NLP and computer vision has been driven by deep learning. The invention of transformer models has notably improved text analysis, with prominent examples being BERT [6]. There is also an optimized version of BERT and its optimized version, RoBERTa [7]. A decade ago, Word2Vec was widely used for word embedding using a simple neural network [8]. In the realm of computer vision, several powerful architectures, such as ResNet [9] and EfficientNet [10] have been introduced, significantly enhancing image classification and analysis. These advances in deep learning models have laid the groundwork for more sophisticated approaches to understanding and integrating image and text information.

C. Multimodal Sentiment Analysis

Multimodal sentiment analysis was first introduced in 2011. Morency et al. addressed the growing need to harvest relevant information from the vast amount of multimodal data available online, particularly from social websites [11]. The resarch demonstrated that a joint model integrating visual, audio, and textual features could effectively identify sentiment in web videos. A comprehensive survey of multimodal machine learning is provided in [12], presenting a new taxonomy that goes beyond the typical early and late fusion approaches. The authors introduced a novel deep learning architecture for multimodal sentiment analysis, the Gated Multimodal Embedding Long Short-Term Memory (LSTM) with Temporal Attention (GME-LSTM(A)) model, which performs modality fusion at the word level [13]. This model addresses the challenges of noisy modalities by employing gated multimodal embedding and temporal attention mechanisms, achieving good results on the CMU-MOSI dataset. Furthermore, The Attention-based Multimodal Sentiment Analysis and Emotion Recognition (AMSAER) model was developed in study [14], which proposed the hybrid LXGB Model. This model combines the strengths of LSTM and XGBoost classifiers to capture nuanced emotions from diverse data sources like text, images, and audio. It achieved an exceptional accuracy of 97.18% on its dataset. Huang et al. demonstrated a text-centered fusion network with cross-modal attention (TeFNA), which models unaligned multimodal timing information [15]. TeFNA uses text as the primary modality and maximizes mutual information between modality pairs to preserve task-related emotional information. The fusion of ResNet 50 and RoBERTa was utilized in study [16] for multimodal fake news detection, on the FACTIFY dataset. This study combined OCR information and text using models like Bi-directional LSTM and LightGBM for classification, achieving a weighted average F1 score of 0.7428. Peng et al. [17] introduced the Fine-grained Modal Label-based Multi-Stage Network (FmlMSN), which addresses the challenge of handling various sentiments within a video by using seven sentiment labels. This study proposed a discriminative joint multi-task framework (DJMF) to simultaneously perform sentiment prediction and emotion recognition.

Despite significant advancements in natural language processing (NLP) and image processing, there remains a notable gap in the literature concerning the integration of these two modalities through fusion techniques. While some studies have explored multimodal approaches, they predominantly focus on combining text and image data for tasks such as captioning, visual question answering, or sentiment analysis. Our paper aims to address these gaps by developing and implementing advanced fusion techniques for integrating natural language processing (NLP) and image data.

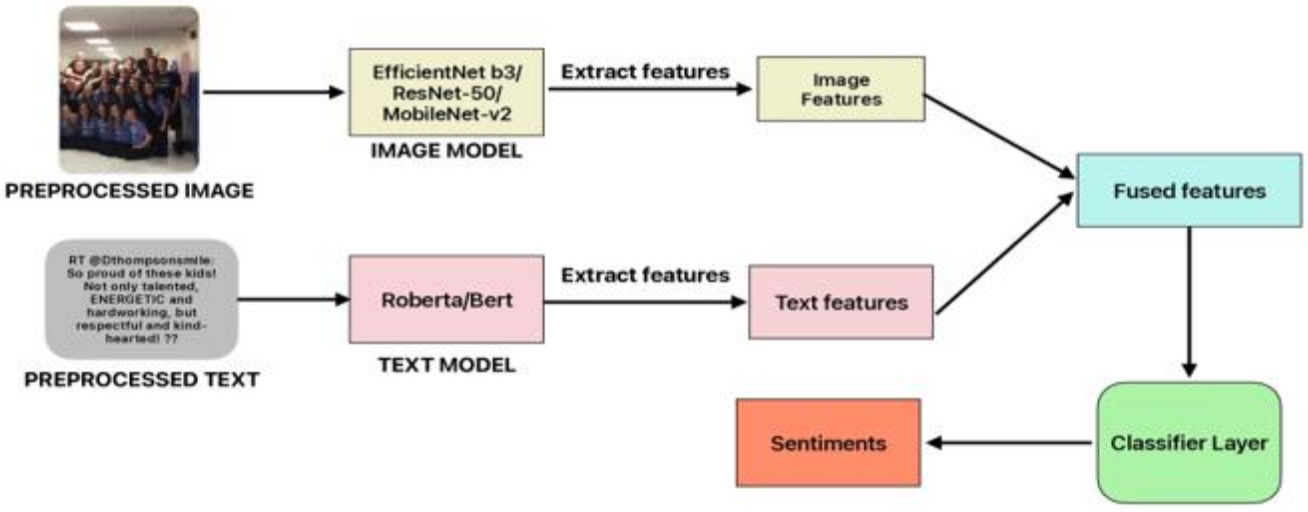

Fig. 1. Block diagram of model.

III. METHODOLOGY

In this study, a comprehensive approach to multimodal sentiment analysis is analyzed by integrating both image and text data using deep learning fusion techniques. The proposed methodology leverages state-of-the-art pre-trained models to extract rich features from both modalities and subsequently combines these features to predict sentiments with high accuracy. Specifically, EfficientNet-B3, ResNet-50, and MobileNet-V2 for image feature extraction, and RoBERTa, and BERT for text feature extraction were utilized. As illustrated in Fig. 1, the preprocessed image and text inputs are fed into their respective models to extract meaningful features. These features are then fused and passed through a classifier layer to generate sentiment predictions. This approach aims to make use of the complementary strengths of visual and textual data, providing a robust framework for sentiment analysis on multimodal datasets. The following sections outline the dataset used, preprocessing steps, and the proposed methodology for feature extraction, fusion, and sentiment classification, along with the techniques used.

A. Dataset

The dataset used in this research is 'MVSA-Single' which was introduced in [18]. A publicly accessible dataset in the field of multimodal sentiment analysis, the MVSA-Single was gathered using Twitter. On the social networking platform Twitter, users can post tweets that include text, photos, hashtags, and other content. Every text-image pair has a unique sentiment label associated with it. The sentiment labels are positive, neutral, and negative. MVSA-Single has 4869 image-text pairs [19]. In case of images there are 2708 positive images, 1223 negative images, and 938 neutral images. In case of texts, there are 1731 positive texts, 1217 negative texts, and 1921 neutral texts.

B. Dataset Preprocessing

All the Images and texts are preprocessed before passing them into the text and image modals. Firstly, the sentiment labels which are initially in text format are converted to numerical labels using dictionary mapping. The positive, neutral, and negative labels were converted to 0,1, and 2 respectively.

Secondly, tokenization is performed on the text using RobertaTokenizer/BertTokenizer depending on the text modal used in the fusion technique. The process of breaking a sentence into smaller pieces (tokens) is called tokenization. These tokens are then converted to numerical identifiers. This process is performed so that each text is converted to a format understood by the machine learning models. The tokenizers add special tokens that are used by the model to understand the structure of the text, such as beginning of sentence and end of sentence markers. To make each text of the same length, tokenizers add padding to tokens. Tokenization is demonstrated in Fig. 2.

The function 'encode_plus' is used to tokenize the text, which also adds special tokens like start or end of sequence markers. This function also pads the sequence to a fixed length with padding tokens if the text is shorter. Attention masks are generated to identify important parts of the sequence. For model compatibility, everything is converted to PyTorch tensors.

In case of images, they are converted to RGB if necessary and then they are resized to a fixed size. Normalization techniques are also applied to images. Images are converted to PyTorch tensors and pixel values are normalized to a specific range for better model performance during training.

These preprocessing techniques ensure the data is in a format suitable for the chosen pre-trained models and the deep learning framework used for training. Train-Test Split has been used in the dataset and 90% is kept for training and 10% is kept for testing.

C. Proposed Methodology

The main goal of this thesis is to use the multimodal dataset and predict the sentiments and get a good accuracy and F1 score using different deep learning fusion techniques. Fig. 1 shows that firstly preprocessed images and text are passed to an image modal and a text modal. This is done to extract features from text and images. The features are fused in the model and then it is classified. Finally, the model generates sentiments as outputs. The entire process can be shown in a few equations.

$$F_T = R(T) \tag{1}$$

$$F_I = E(I) \tag{2}$$

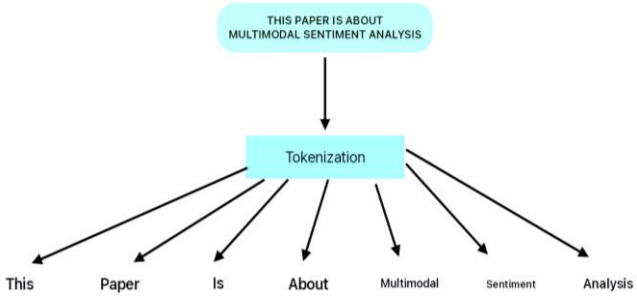

Fig. 2. Tokenization architecture.

In Eq. (1), a text input T is passed into the text model R, which extracts text features F_T. In Eq. (2), an image input I, is passed into the Image model E, which extracts image features F_I. Feature fusion and classification can be represented by a series of equations.

$$F = C(F_T, F_I) \tag{3}$$

$$F' = \sigma(L_I\,(\text{Dropout}(F))) \tag{4}$$

$$S = L_2\,(F') \tag{5}$$

In Eq. (3), the extracted image and text features F_T and F_I are fused (C) into a feature F. In Eq. (4) and Eq. (5), the fused feature F is then passed through linear transformations (L) and activation functions (σ) to produce the final sentiment prediction S. L1 and L2 are layers that convert the feature F to the desired dimensions. The activation function σ is a ReLU that introduces non-linearity.

$$\mathcal{L}(Y, \acute{Y}) = -\sum_i Y_i \log(\acute{Y}) \tag{6}$$

The model is trained on a dataset D using a cross-entropy loss function, $\mathcal{L}$, with the aim to minimize the difference between predicted sentiment labels, $\acute{Y}$, and true labels, Y as shown in Eq. (6). During training, optimisation is performed

using the Adam optimiser. A learning rate scheduler has been used to update the model parameters.

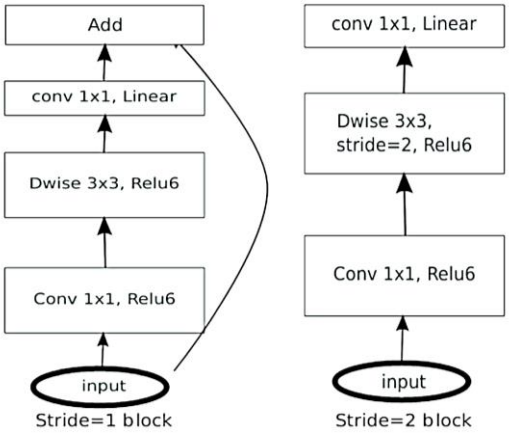

Fig. 3. MobileNet V2 architecture [20].

D. EfficientNet-B3

EfficientNet is a type of convolutional neural network architecture. This architecture was first introduced by a team of researchers at Google AI as a new approach that involves scaling the CNN architectures to achieve high accuracy and efficiency [10]. The EfficientNet-b3 belongs to a family of EfficientNet models. To obtain optimal performance, EfficientNet-B3 uses a new scaling method that scales the dimension of components like depth, width, and resolution. To extract features, it combines pooling layers, activation functions, and convolutional layers. To improve feature representation, it uses squeeze and excitation block technique.

E. MobileNet V2

MobileNetV2 is an improved version of MobileNet. MobileNetV2 was also developed by Google Researchers in 2018. It was specifically designed for mobile and embedded devices. Researchers made this model for image classification & feature extraction tasks [20]. The model is based on an inverted residual structure with shortcut connections in between the thin bottle-neck layers. The intermediate expansion layer filters act as a source of non-linearity using lightweight depth wise convolutions. This model is mainly used for devices which have less resources. Fig. 3 portrays the model architecture.

F. ResNet-50

ResNet-50 and other models of the ResNet family were introduced in 2016 by a group of researchers. ResNet-50 is a deep convolutional neural network architecture. It is known for its depth and effectiveness in image classification tasks. ResNet-50 has 50 layers which help to get high accuracy on image classification tasks [9]. ResNet-50 implements a type of learning called residual learning. This type of learning enables layers to add information to the output of previous layers. Skip connections are used for this task. This helps to solve the vanishing gradient problem. The ResNet-50 architecture is shown in Fig. 4.

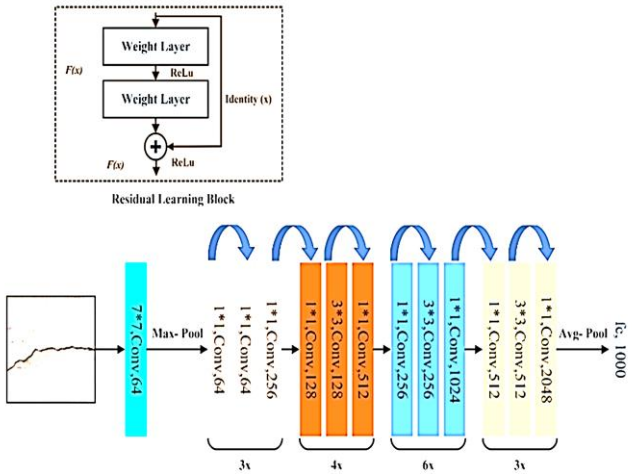

Fig. 4. ResNet-50 architecture [9].

G. BERT

The full form of BERT is 'Bidirectional Encoder Representations from Transformers'. BERT is a powerful pre-trained language model. It was developed by a group of researchers at Google AI in 2018. This model is based on transformers. An encoder only architecture is used by this model [6]. It can work with massive amounts of data. BERT can be fine tuned by adding additional layers. This model also connects all output elements with all input elements.

H. RoBERTa

The full form of Roberta is 'Robustly Optimized BERT Pretraining Approach'. Roberta is a pre-trained language model. It is an improvement to BERT. Roberta was first introduced by a group of researchers at Facebook AI [7]. RoBERTa uses a new training approach where only selective tokens are masked in each training step. The primary difference between BERT and RoBERTa is that there are changes in the main hyperparameters of RoBERTa. Moreover, the next sentence prediction objective that is used in BERT pre-training, is not used in RoBERTa. Larger batch sizes can be used for RoBERTA and this helps to improve training efficiency.

IV. Experimental Results

A. Performance Evaluation

For the three different fusion techniques RoBERTa+EfficientNet b3, MobileNetv2+BERT & ResNet50+RoBERTa, many evaluation measures were used. These measures are Accuracy, F1 score, Confusion matrix, ROC curve and classification report. Evaluation measures were performed on the testing set. There are 487 image-text pairs in the testing set and 4382 image-text pairs in the training set.

B. RoBERTa+EfficientNet b3 Results

RoBERTa+EfficientNet b3 is the first fusion technique that have been applied. In this fusion technique, the best result in accuracy, roc curve, confusion matrix and F1 score were achieved.

The confusion matrix of the RoBERTa+EfficientNet b3 model is shown in Fig. 5. One of the approaches for assessing a classification model's performance is the confusion matrix. The diagonal part of the confusion matrix shows the correctly predicted sentiments by the model. There are 1278 true positives, 1462 true neutrals and 907 true negatives predictions. The other values of the confusion matrix are the incorrect predictions made by the model. From the confusion matrix, it can be inferred that the model was more accurate in predicting neutral class and less accurate in predicting negative class. The classification report in Table I shows precision, recall, f1-score, support & accuracy. The precision indicates the proportion of positive identifications that were correct. For instance, positive class has a precision of 0.77, meaning 77% of predictions were correct. Precision, recall and F1 scores are relatively consistent across all three classes (positive, neutral and negative). This suggests that the model is performing uniformly across different types of data. The recall for the negative class is slightly lower (0.70) compared to the positive and neutral class. The support values indicate the number of instances for each class in the dataset. The 'accuracy' value of 0.75 is the overall accuracy of the model. Plotting the true positive rate (TPR) against the false positive rate (FPR) at each threshold setting creates the ROC curve.

From Fig. 6, it can be inferred that for the positive ROC curve, the model has a slightly better performance in classifying true positives and false positives, as indicated by its higher area under the curve (AUC) of 0.83. Neutral and Negative ROC curves have an AUC of 0.80, which is slightly lower than the positive curve.

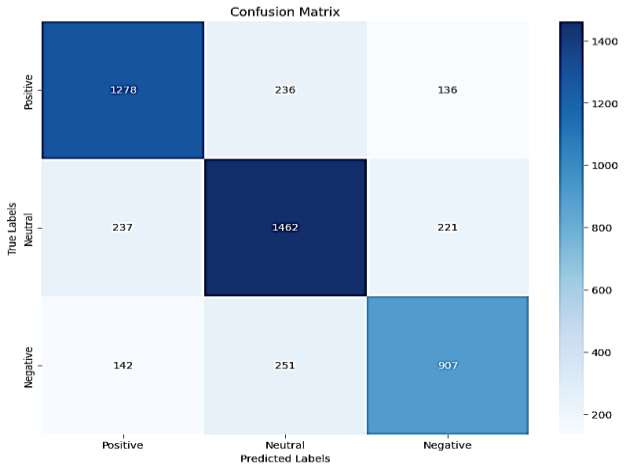

Fig. 5. Confusion matrix of RoBERTa+EfficientNet b3 model.

TABLE I. EFFICIENTNET B3+ROBERTA CLASSIFICATION REPORT

	Precision	Recall	F1-score	Support
Positive	0.77	0.77	0.77	1650
Neutral	0.75	0.76	0.76	1920
Negative	0.72	0.70	0.71	1300
Accuracy			0.75	4870
Macro avg	0.75	0.74	0.75	4870
Weighted Avg	0.75	0.75	0.75	4870

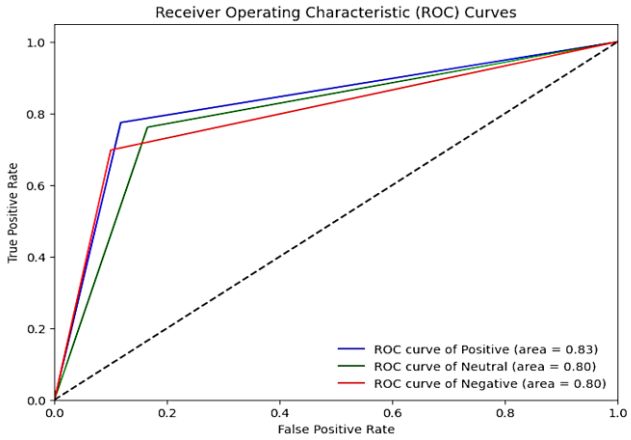

Fig. 6. ROC curve of RoBERTa+EfficientNet b3 model.

C. *MobileNetV2+BERT RESULT*

MobileNetV2+Bert is the second fusion technique implemented. While it achieved good results in accuracy, ROC curve, confusion matrix, and F1 score, the EffcientNet b3 + RoBERTA combination yielded superior performance.

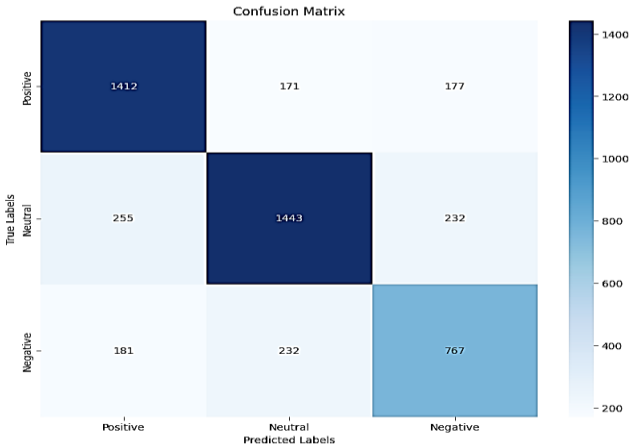

Fig. 7. Confusion matrix of MobileNetV2+BERT model.

From Fig. 7, it can be inferred that the model correctly identified 1412 instances as positive which is true positive. The model correctly identified 1443 instances as neutral which is true neutral. The model correctly identified 767 instances as negative which is true negative. The other values of the confusion matrix are the incorrect predictions made by the model. From this analysis, it appears that the model has a strong performance in identifying neutral sentiments. From Table II, it can be inferred that the model has the best performance with the positive class and the worst performance with the negative class. The model's precision is highest with neutral class, suggesting it is most reliable when predicting this class. The macro and weighted averages being close to the overall accuracy suggests a balanced dataset.

From Fig. 8, it can be inferred that, for the positive ROC curve the model has a good performance in classifying true positives and false positives, as indicated by its higher area under the curve (AUC) of 0.83. This means that the model has 83% chance of correctly distinguishing between positive and

non-positive instances. For the neutral ROC curve, the model has an AUC of 0.81, which is slightly lower than the positive model. This suggests that the model has an 81% chance of correctly distinguishing between neutral and non-neutral instances. For the negative ROC curve, the model has the lowest AUC of 0.77. In summary, the model performs best when predicting positive classes and worst when predicting negative classes.

TABLE II. MOBILENETV2+BERT CLASSIFICATION REPORT

	Precision	Recall	F1-score	Support
Positive	0.76	0.80	0.78	1760
Neutral	0.78	0.75	0.76	1930
Negative	0.65	0.65	0.65	1180
Accuracy			0.74	4870
Macro avg	0.73	0.73	0.73	4870
Weighted Avg	0.74	0.74	0.74	4870

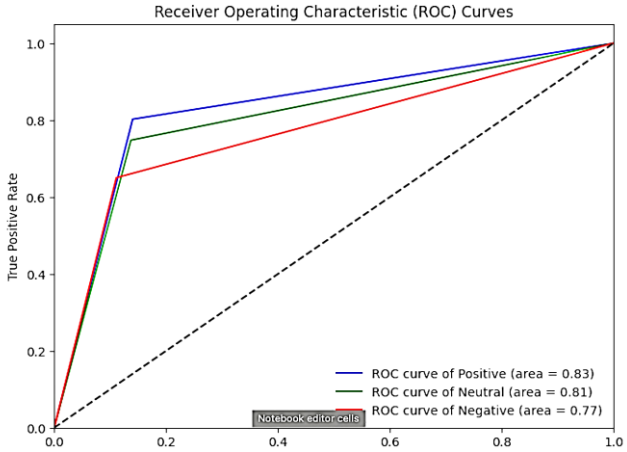

Fig. 8. ROC curve of BERT+MobileNetV2.

D. ResNet-50+RoBERTa Result

ResNet-50+RoBERTa is the final fusion technique that has been applied. The result of this fusion was not as satisfactory as the previous two fusion techniques. From Fig. 9, it can be inferred that the model correctly identified 1244 positive instances, 1272 neutral instances, and 997 negative instances. The other values of the confusion matrix are the incorrect predictions made by the model. From this analysis, it appears that the model has a strong performance in identifying positive sentiments. There are still a significant number of misclassifications, especially for the positive and neutral classes being incorrectly predicted as negative. This suggests that the model struggles with distinguishing between these classes. From Table III, it can be inferred that overall accuracy, macro average, and weighted average are all at 0.72 which means consistent performance across all classes. The model has the best performance with positive class and the worst with negative class. The model's precision is highest with neutral which means that it is most reliable when predicting this class.

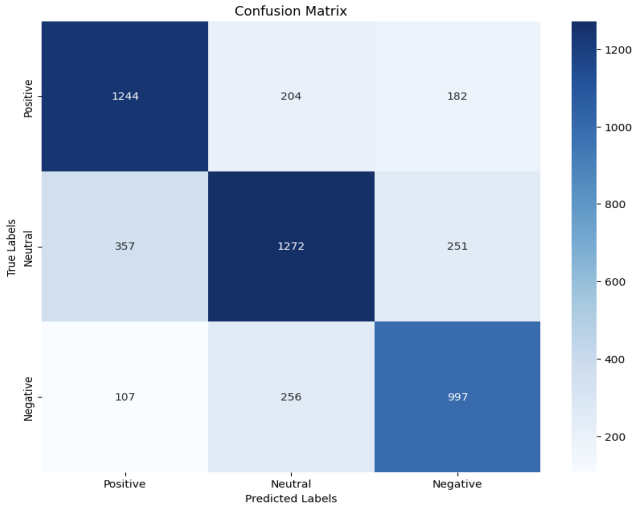

Fig. 9. Confusion matrix of ResNet-50+RoBERTa.

TABLE III. CLASSIFICATION REPORT OF ROBERTA+RESNET-50

	Precision	Recall	F1-score	Support
Positive	0.73	0.76	0.75	1630
Neutral	0.73	0.68	0.70	1880
Negative	0.70	0.73	0.71	1360
Accuracy			0.72	4870
Macro avg	0.72	0.72	0.72	4870
Weighted Avg	0.72	0.72	0.72	4870

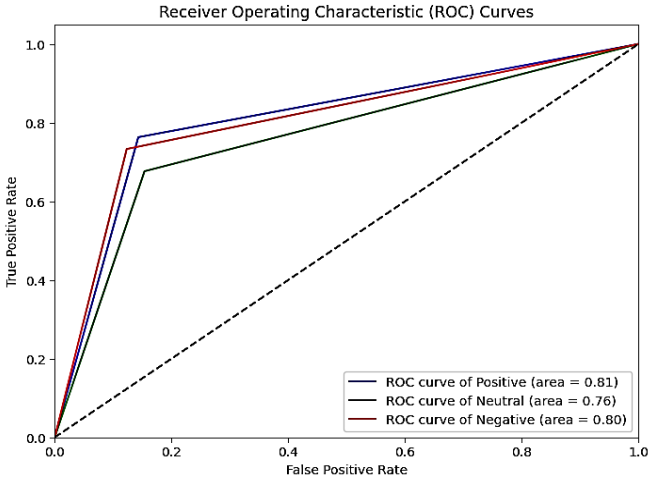

Fig. 10. ROC curve of RoBERTa+ResNet-50.

From Fig. 10, it can be inferred that for the positive ROC curve, the model performs well in classifying true positives and false positives, as indicated by its higher area under the curve (AUC) of 0.81. For the Neutral ROC curve, the model has the lowest AUC of 0.76. In summary, the model performs best when predicting positive classes and worst when predicting neutral classes.

V. DISCUSSION

The study compared the performance of three deep learning fusion techniques for multimodal sentiment analysis: RoBERTa with EfficientNet-b3, MobileNetV2 with BERT, and ResNet-50 with RoBERTa. Among the three techniques, RoBERTa with EfficientNet-b3 achieved the best overall performance, with an accuracy of 75% and an F1 score of 74.9%. This suggests that the combination of EfficientNet-b3 for image feature extraction and RoBERTa for text feature extraction is particularly effective for multimodal sentiment analysis.

Looking deeper into the results for RoBERTa + EfficientNet-b3, it is evident that precision, recall, and F1-scores are relatively consistent across all three classes (positive, neutral, and negative). This indicates that the model performs well on all sentiment categories. The ROC curve analysis further supports this, with AUC values around 0.8 for all classes, suggesting good performance in distinguishing between true positives and false positives. MobileNetV2 with BERT achieved an accuracy of 74%, with the best performance for the positive class and the worst for the negative class. The model's precision is highest for the neutral class, indicating good reliability in predicting neutral sentiment. ResNet-50 with RoBERTa had the lowest accuracy (72%) among the three techniques (see Table III). While it performed well on the positive class, it struggled with distinguishing between positive and neutral classes, as indicated by a significant number of misclassifications in the confusion matrix.

A comparison study with different benchmark models from other papers were conducted. The comparison is presented in Table IV where accuracy and F1 score of all the models are compared. It can be seen that EfficientNet b3+RoBERTa is better than the other fusion techniques as the accuracy of EfficientNet b3+RoBERTa is highest. The F1 scores of all the fusion techniques were almost similar to the accuracy but they are slightly lower than the accuracy. They outperformed the models from other papers.

TABLE IV. ACCURACIES AND F1 SCORES FOR VARIOUS MODELS

Models	Accuracy	F1
CNN-Multi [21]	61.2	58.4
BDMLA [22]	61.7	62.8
DNN-LR [23]	61.4	61.0
LATE-RMNN [24]	67	66.5
CoMN [25]	70.5	70
MultiSentiNet [26]	69.8	69.6
DMAF [27]	70.1	71.7
ResNet-50+RoBERTa	72	72.1
MobileNetV2+BERT	74	73.4
EfficientNet b3+RoBERTa	**75**	**74.9**

VI. CONCLUSION

This paper explores multimodal sentiment analysis through the application of three distinct fusion techniques: EfficientNet b3 + RoBERTa, MobileNetV2 + BERT, and RoBERTa + ResNet-50. This research contributes to the field of sentiment analysis by demonstrating the potential of combining text and image data using deep learning fusion techniques to achieve superior sentiment analysis accuracy compared to traditional methods that rely on a single modality. The approach utilized various convolutional neural networks (CNNs) for image feature extraction, while leveraging two distinct transformers for textual feature extraction. Following feature extraction from text and images through fusion, the model underwent training and testing. The evaluation results showed that EfficientNet-b3 + RoBERTa achieved the best accuracy (75%) and F1 score (74.9%) among the three fusion techniques. This suggests that the combination of EfficientNet-b3 for image analysis and RoBERTa for text analysis is particularly effective for multimodal sentiment analysis.

The primary limitation is the use of a relatively small dataset (MVSA-Single), which might restrict the model's ability to generalize to unseen data. Future work will involve utilizing a new, larger dataset. The creation of a new, expansive multimodal dataset sourced from Facebook is planned for future work. Additionally, the implementation of the latest EfficientNet version is envisioned. The utilization of more powerful computing resources to accommodate larger models is anticipated for future work. Furthermore, advancements in Recurrent Neural Networks (RNNs) are expected to further contribute to the development of multimodal sentiment analysis.

Assessing the Impact of Digitalization on Internal Auditing Function

Khawla Karimallah, Hicham Drissi
Laboratory for Financial Engineering, Governance and Development (LIFGOD), Hassan II University,
National School of Business and Management of Casablanca, Casablanca, Morocco

***Abstract*—Over the past decades, the business environment has become increasingly digitized. Advances in new technologies are driving significant organizational change. Over the years, the internal audit as a governance actor, has adapted to meet the demands of the evolving business environment, and its role in consulting activities has been a significant topic of debate in the literature. This research aims to study the impact of the digitalization of organizations on the internal audit function. The method used to achieve this goal is a survey conducted with 175 internal auditors and managers working for companies in various sectors. The results indicate the existence of a positive relationship between the level of digitalization of the organization and the diversion of risks. This requires greater agility on the part of internal audit, through strengthening the digital skills of auditors, particularly in data analysis, to meet the needs of different stakeholders. The results also indicate that the level of digitalization of the organization has an indirect effect on the level of integration of consulting missions in the internal audit plan, a new role that internal audit is developing to support added value.**

***Keywords*—Digitalization, data analytics; organization; Internal Audit Function (IAF); agility**

I. Introduction

Today's organizational environment is characterized by a multitude of changes that condition the competitiveness of players. These changes take many forms: technological, social, and environmental progress with an ecological dimension, and associate companies with the notion of vulnerability and the use of advantages. Moreover, a company is confronted with new challenges as a dynamic system that interacts with its environment. The study [1] has shown that business problems are constantly evolving. Faced with the difficulties of organization, financing, circulation, and reliability of information linked to the globalization of economies and new information and communication technologies, companies find themselves obliged to adapt their ways of thinking to sustain their profitability and economic growth. One way of doing this is to find ways of strengthening investor confidence, optimizing resources, and defining responsibilities.

With a view to helping companies achieve their objectives effectively and efficiently, by identifying new and emerging risks as effectively as possible, the role of internal auditing is to provide a mechanism for assessing the effectiveness of governance, risk management and control processes, as well as the company's level of resilience and its ability to ensure its business continuity plan in a context of uncertainty marked by crisis.

In such a situation, the internal audit function finds itself obliged to introduce new processes and imbue itself with new procedures that will enable it to pinpoint the key elements of each of these crises as accurately as possible, to provide the most objective and accurate picture possible of the various levels of risk involved.

New technologies for data analysis [2], [3], [4], [5], [6], artificial intelligence [7], [8] and RPA [9], [10] remain an opportunity for the internal audit function to respond to the multitude of expectations by quantifying impacts, predicting and valuing financial stakes, and proposing relevant recommendations. According to several authors [2], [11], auditing is one of the domains affected by the immersion of new technology. As a result, it is undergoing a critical turning point in the wake of advances in information technology and its rapid penetration of companies [11]. As a result, the audit profession is in a period of transition from traditional paper-based auditing to a more digitized audit with automated and dematerialized processes [11].

Recent market developments have removed several barriers to the use of Big Data technologies. These technologies now make it possible to process significant volumes of data and to visualize them, with the deployment of tools such as Qlik and Power BI which have made it easier to handle and share analyses in a synthetic way.

Nonetheless, digitalization has changed risk levels at corporate level. Several observations have been made in this respect:

Firstly, the integration of new technologies can introduce new risks to which the company was not previously exposed. For example, the growing use of ICT's can increase cybersecurity risks, such as hacker attacks, data breaches or online fraud attempts [12].

Secondly, digitalization has led to more complex processes and systems. This can make it more difficult to identify, assess and manage risks. For example, the introduction of interconnected systems or data platforms can make information flows more complex, which can make it difficult to gain an overall understanding of risks and coordinate appropriate control measures [13]. Thirdly, digitalization has impacted on the pace of change within the company, whether in terms of technologies, processes, or business models. This can lead to risks associated with managing change, adapting to new technologies and market developments. Companies need to be

aware of these risks and put in place appropriate mechanisms to manage and adapt quickly to these changes [14].

This study contributes to research on internal function in two ways. First, the derivation of risks following the integration of digital into organizational processes through the evolution of their criticality. Secondly, the level of digitalization of the company has an indirect effect on the internal audit function on several levels. In addition, the internal audit function must be able to adapt to technological developments, new risks, and organizational changes. To achieve this, the function needs to be agile [15]. In other words, internal audit must be able to respond quickly to the following factors demands or priorities within the organization, adjust audit plans accordingly and adapt to changing circumstances.

The article is organized as follows. Firstly, the presentation of the theoretical framework for the digitalization of the internal audit function is given in Section II. Next, the methodological approach used in Section III and present the findings in Section IV. Finally, the paper is concluded in Section V

II. Theoretical Background and Research Questions

A. Risk Diversion in the Age of Digitalization

The adoption of digital technologies has significantly altered the landscape of risks to which companies are exposed. In the same vein, risk derivation refers to the process by which traditional risks are transformed or exacerbated by digital technologies and practices [16]. As digital transformation continues to shape society and the economy, new risks are emerging and existing ones are being amplified.

Several studies have been carried out providing important insights into the impact of digitalization on risk, helping companies, decision-makers, and researchers to better understand the challenges and opportunities associated with this transformation. To illustrate, a few examples are detailed in Table I.

However, it is essential to point out that digitization is not a new phenomenon. It is an old wave that has affected the business world. [17]. Firstly, the integration of computers has had an impact on the way organizations operate, through the gradual replacement of paper. Secondly, the use of the Internet has revolutionized the world. Today, the world is experiencing a new wave of recent technologies such as data analytics, IA, and cloud computing). None of these technologies is a source of problems. However, the confluence of these technologies has changed the way to do business, and what constitutes this digital transformation is as follows [17].

The emergence of digital technologies continues to overwhelm the market every day and continually influence the environment [18] that enable machines and equipment to monitor and analyze their own functioning as well as make autonomous decisions and self-optimize, leading to more efficient production and predictive maintenance. Digitalization is always psychologically linked to instability, complexity, and uncertainty.

Indeed, digitalization are constantly making their presence felt in the corporate environment, forcing organizations to follow this trend progressively to survive in a competitive environment [19].

Digitalization converges the speeds of organizational change, and in turn, implies a series of changes to organizational map [20] leading to more digitized and automated business processes [21]. The persistence of business models is based on proactive strategies that combine regular, gradual modification of the skills map with the structuring of a digital integration model.[22], [23], as well as the search for a sustainable strategic positioning, by focusing on digital technologies and their various technical aspects [24]. In other terms, integrating digital into an organization's strategy remains the cornerstone of digitization, and is a step change that necessitates ongoing organizational evolution [21], [25].

Just as some civilizations were still in the Stone Age and others in the Bronze Age at the same point in history. In the same way, not all companies are at the same level of evolution. As the digital environment rapidly evolves, organizations are also striving to follow the same expansion curve. These actions enable companies to improve their processes and use new technologies to continue their numerical expansion and ensure business continuity [24], [26].

TABLE I. Examples of Previous Studies

Title of study or survey	Organization involved	Year of publication	Objectives
Global Risks Report	World Economic Forum	2023	Examine emerging trends and risks on a global scale.
			Highlight the impact of digitalization on risks, including cybersecurity, data privacy, misinformation, and technological disruptions.
Cost of Cyber Crime Study	The Ponemon Institute	2016	Examine the financial costs and operational impacts of cyber-attacks and data breaches, providing an understanding of the scale of the risks associated with digitalization.
Tech Trends	Deloitte	2023	Present technological trends and their impact on business.
			Investigate technology-related risks, such as security, data confidentiality, ethics, and governance, offering valuable insights into the impact of digitalization.
Digital Transformation and the Risk of Commoditization	Harvard Business Review	2021	Explore the risks involved in the process of digitalization of companies.
Digital Disruption: The Growth Multiplier	McKinsey & Company	2018	Focus on the challenges of increased competition, business model disruption and loss of differentiation in an increasingly digitalized world.

Therefore, there is a semiquinone condition for success. These include the involvement and development of HR capital and the establishment of a flexible organizational culture [27]. Moreover, the implementation of digital strategy will impact the entire organizational value chain. For example, business processes will be impacted first and foremost by the adoption of digital technologies. On the other hand, the digitization of other support processes, such as the internal audit function, can be held up. For example, the integration of data analytics tools into internal audit engagements is not yet standardized. Recent reports indicate that internal audit functions are not exploiting the potential of new technologies and that there is still much to be done. For example, the integration of data analytics tools into internal audit engagements is not yet standardized [28].

Previous research has yet to assess the impact of digitization on the role and activities of the internal audit function [29], [30]. This research aims to examine how the use of digital technologies at the organizational level has affected the internal audit function.

- H1. There is a relationship between the use of technologies at organizational level and the evolution of risks. Consequently, the audit scope is required to cover the resulting risks and measure their impact on the organization.
- H2. New technologies impact the role of the internal audit function.

B. The Digitalization of the Environment

This dynamism and complexity of the corporate environment have been amplified by the omnipresence of digital technology. Today, all companies process their information using digital solutions. What is more, the amount of information processed or stored in this way is growing, even exponentially. This prevalence of digital technology means that auditors must adapt to the specificities of this context.

Nonetheless, the digital transformation of any function aims to improve performance in terms of effectiveness and efficiency [14]. To this end, several authors [14], [21], [27] have confirmed that these technological evolutions offer the auditor the opportunity to use much more advanced techniques, enabling him to achieve his mission in line with standards and creating added value for his stakeholders.

C. Evolution of the Internal Audit Role

Over time, the internal auditing has undergone a remarkable evolution to become a broader, more strategic function within organizations. At the beginning of the 20th century in the United States, large American companies used external auditing firms to certify their annual accounts [1]. The services provided were considered costly and burdensome for these companies. Consequently, the efforts are focused on finding a way to reduce these expenses, by analyzing the nature of the work conducted by the external auditors. Therefore, some of the tasks will be carried out in-house by company employees [31]. The external audit firms agreed, subject to a certain amount of supervision.

It was not until the 1970s and 1980s that the scope of the function's intervention began to expand [32], with objective and independent reviews of operational aspects and internal control systems going beyond financial issues alone [33].

In this regard, internal auditors have begun to play a key role in risk assessment, corporate governance, regulatory compliance, and process management [34]. In the 1990s and 2000s, the internal auditing profession gained in recognition and professionalism. The creation of professional associations and institutes were key to the evolution of the profession, through the development of standards, codes of ethics and qualifications for internal auditors.

Over the past few decades, internal auditing has taken on an increasingly strategic dimension. Internal auditors have become essential partners for senior management and boards of directors, providing independent assurance and helping to improve operations, control systems and risk management. The function has also begun to play a more consultative role, providing advice to management [35]. Internal audit is involved in areas such as enterprise risk management, compliance auditing, IT auditing, sustainable development and corporate social responsibility.

In the wake of financial crises and scandals, the internal audit function has undergone a significant evolution. The repercussions of these crises highlighted the need to strengthen corporate governance, financial transparency, and risk management within organizations [1]. These significant events have underlined the importance of continuous risk assessment and monitoring, with the aim of improving processes, helping the company to identify vulnerabilities and implement appropriate control measure [33].

Analysis of internal auditing research shows that variations in the economic circumstances in which organizations manage seem to have an impact on the evolution of internal auditing [34], [36]. By way of illustration, the concentration of the internal audit function on insurance activities is merely the consequence of the global economic crisis or a financial scandal [1]. In addition, internal audit's commitment to consulting activities stems from changes in the economic and regulatory environment [12]. Today, following the emergence of information technologies and information systems, internal auditing has also had to adapt to manage the risks arising from digitalization and its impact on organizations. It is now time to examine how the integration of digital technologies at a corporate level has shaped the internal audit function. Digitalization can be seen as one of the environmental factors affecting a company's organizational structure [12], [37].

The review of existing literature has shown that previous research focuses much more on the digitalization of external auditing [25], using technologies such as data analysis by external auditors [38], [39].

The theoretical foundations presented prompt to focus on the digitization of the internal audit function, as this is an area of research that has yet to be explored [40], [41]. This research therefore aims to understand how the risks that have been evolving because of the integration of new digital technologies have had an impact on internal auditing.

- H3. Digitalization has pushed the internal audit function to perform functions outside its functional perimeter, through consulting assignments.

III. METHODOLOGY

A. Data Collection

In line with previous research, the paper is based on an online survey. The survey consisted of three sections. In the first section, respondents were asked to answer questions relating to their organization's internal audit function. In the second section, questions were asked about their organization's level of digitalization. The final section included questions related to their organization's sector and the size of the internal audit function. The survey was submitted to a total of three hundred internal audit directors working in various sectors. A total of 175 responses were received, representing a response rate of 58%.

B. Measures

A four-part scale is used to measure the level of digitization of the organization in which the respondents work: the organization's strategy is geared towards digital development, business processes are digitized, the organization prioritizes digital solutions to enhance processes, the organization deploys digital solutions available on the market. These items were measured on five-point Likert scales.

Table II shows two tests that indicate the adequacy of the data for detecting structure. The Kaiser-Meyer-Olkin measure of sampling adequacy is a statistic that indicates the percentage of variance in variables that can be caused by subjacent factors. KMO values of up to 0.776 considered high (close to 1) indicate that factor analysis may be useful for the sample data. The "Bartlett" test of sphericity tests the assumption that the correlation matrix is an identity matrix, which would indicate that the variables are unrelated and therefore inappropriate for detection of structures. In the case of this study, the significance level is below 0.05, indicating that factor analysis is strongly recommended for data reduction.

By using principal component analysis, the variables were clustered under two factors. The Cronbach's alpha of this ad hoc scale was above the critical value of 0.7, and the percentage of variance explained was 83% (see Table III). The eleven items can be grouped under two factors describing "the level of digital integration», called DIGITAL and "the degree of agility of the internal audit function ", called AGILITY calculate this new variable. Tables III, IV and V summarize the results of this analysis.

TABLE II. TEST OF BARTLETTE AND KAISER-MEYER-OLKIN

Kaiser-Meyer-Olkin Index	Bartlett's test	% Explained variance
0,776	Khi 2 : 511,143 ddl : 3 Bartlett(a) : 0,0000	0,83034

TABLE III. SCORE OF ITEMS (1)

Items	1	2	3	4	5	Mean	Min	Max	SD
The ability to quicskly communicate audit results and recommend corrective actions in a digital environment	4	22	0	130	19	3,789	1	5	),88
The use of digital tools and technologies	10	6	0	100	59	4,097	1	5	0,99
The internal audit plan focuses on digital issues	13	12	0	124	26	3,789	1	5	1,02
The internal audit function is successfully anticipating the risks associated with digital transformation	14	12	2	129	18	3,714	1	5	1,01

TABLE IV. SCORE OF ITEMS (2)

Items	1	2	3	4	5	Mean	Min	Max	SD
Integration of digital technologies to manage internal operations	0	6	8	131	30	4,057	1	5	),594
Use of data management and analysis systems (BI, Data Analytics...)	1	10	1	118	45	4,12	1	5	0,729

TABLE V. VARIABLES DESCRIPTION

Variables	Definition	Measurement
DIGITAL	**Organizations level of digitalisation**	Variable with a value between 1 (low level of digitalisation) and 5 (high level of digitalisation)
AGILITY	**Agility of internal audit function**	Variable with a value between 1 (low level of digitalisation) and 5 (high level of digitalisation)
RISKS	**Digital risks**	Variable with a value between 1 (minor risks) and 5 (major risks)
SKILLS	**Digital skills**	Variable with a value between 1 (low qualifications) and 5 (high qualification)
MATURITY	**The level of digital maturity in the organization**	Variable with a value between 1 (low level of maturity) and 5 (high level of maturity)
CONSULTING	**Degree of consulting activities**	Percentage of the internal audit planning dedicated to consulting activities
SECTOR	**Sector of the organization**	Dummy variable with a value of 0 (organization from the non-financial sector) or 1 (organization from the financial sector)

The nature of the sector of activity is included as a variable, as the financial sector is highly regulated compared to the rest of the sectors, which will certainly influence the performance of the internal audit function [42]. Respondents specify the organization's sector of activity. Consequently, a new variable is created (0=> non-financial sector, 1 => financial sector).

IV. RESULTS

A. Test of Hypothesis

For each variable, a two-group T-test was performed, comparing the mean exactly below the median with the mean equal to or above the median.

Tables VI and VII highlight the percentages of digital maturity at organization level, as well as consulting and data analysis activities by sub-group.

T-test results (RISKS: Sig= 0.06 >0.05 and T-test = 2.56), (DIGITAL: Sig= 0.07 >0.05 and T-test = 10.76) and (AGILITY: Sig= 0.06 >0.05 and T-test = 14.81) confirm the null hypothesis of variable equality.

The research results confirmed the research hypotheses cited. Digitalization has a considerable effect on audit risk, changing the nature of the challenges facing internal auditors. Increased complexity makes it difficult to fully understand and audit these systems, increasing the risk of omissions or errors. Business process automation and systems integration can improve efficiency but can also introduce risks associated with algorithmic errors or over-reliance on technology. As a result, the level of digital maturity has a significant impact on risk trends. As a result, the audit scope must cover the resulting risks and measure their impact on the organization [43].

Clearly, the level of digital maturity reflects a clearly defined strategy aligned with the effective use of digital technologies to achieve its objectives [44] Digital transformation is integrated into the company's vision and mission, as is the successful adaptation of digital technologies. In other words, the organization is characterized by the automation of business and support processes and the use of data analytics for decision-making. Moreover, data is collected, managed, and used in an integrated way at all levels of the company. Data analysis is used to make informed decisions and anticipate market trends [45].

What is more, in a digital environment, organizational agility is paramount. As a cross-functional function, the agility of the internal auditing; is key to the success of its day-to-day missions [46]. This quality refers to its ability to adapt quickly and effectively to changes in the business environment, emerging risks, technological advances, and the changing needs of the organization [47].

By integrating advanced new technologies, such as real-time data analysis, artificial intelligence, and automation, to enhance the effectiveness and relevance of audits. Moreover, in an environment characterized by digital maturity, the agile internal audit function will be able to detect and react rapidly to significant changes in the business environment, such as regulatory changes and technological developments. Moreover, this agility manifests itself in its ability to adjust its audit plans in line with the organization's changing priorities, emerging risks and identified opportunities [48]. It also translates into a focus on creating value for the organization [49]. This means aligning with strategic objectives and identifying opportunities for continuous improvement.

Table VII summarizes the T-test results (DIGITAL: Sig= 0.07 >0.05 and T-test = 2.68) and (SKILLS: Sig= 0.06 >0.05 and T-test = 1.03) confirming the null hypothesis of equality of the variables.

In this sense, the results confirm that digitalization can be considered as just one of the environmental issues impacting the scope of action of the internal auditing [25]. Furthermore, the internal audit function can play an important role in providing consulting services to company management, in addition to its traditional audit activities. These consulting activities aim to add value to the company by helping to improve its operations, risk management and internal control. Ipso facto, the function can advise that this may include recommendations on risk management policies, risk assessment processes and the implementation of preventive measures, as well as participation in the development and review of strategic plans, providing an objective view of the risks and benefits associated with the implementation of strategic initiatives [50].

TABLE VI. PERCENTAGE OF MATURITY BY GROUPS

Variables	Groups	N	Mean	SD	T-Test	Sig.
RISKS	**>= median**	159	4,02	**0,74**	2,56	0,06
	< median	16	1,50	**0,52**		
DIGITAL	**>= median**	159	0,20	**0,72**	10,761	0,07
	< median	16	-1,99	**1,21**		
CONSULTING	**>= median**	159	3,96	**0,84**	3,648	0,01
	< median	16	2,56	**1,50**		
AGILITY	**>= median**	159	0,24	**0,69**	14,812	0,06
	< median	16	-2,35	**0,35**		
SKILLS	**>= median**	159	3,03	**1,06**	5,711	0,02
	< median	16	1,50	**0,52**		

TABLE VII. PERCENTAGE OF CONSULTING ASSIGNMENT BY GROUPS

Variables	**Groups**	**N**	**Mean**	**SD**	**T-Test**	**Sig.**
RISKS	**>= median**	150	**3,81**	0,93	1,78	0,06
	< median	25	**3,64**	1,50		
DIGITAL	**>= median**	150	**0,08**	1,01	2,68	0,07
	< median	25	**-0,49**	0,83		
MATURITY	**>= median**	150	**4,35**	0,58	6,79	0,01
	< median	25	**3,40**	0,96		
AGILITY	**>= median**	150	**0,10**	0,90	3,26	0,06
	< median	25	**-0,59**	1,32		

V. Discussion and Conclusion

Today, digitalization is having a profound impact on businesses [12], redefining their operating models, customer interactions and growth strategies. According to [51], digitalization is fundamentally transforming the way businesses operate by automating processes, improving operational efficiency, and creating new opportunities for innovation. Companies that fully embrace digitalization can benefit from greater agility, faster decision-making. However, there is a limited understanding of how digitization is shaping the activities and working practices of the internal audit function [41]. The aim of this research is to understand how internal audit function is changing its activities and practices because of the integration of new technologies. It is a continuation of the research conducted on the digitalization of the internal audit function [41]. In this respect, the internal auditing is reconfiguring its mode of operation by adopting an agile strategy. This agility is defined by the incorporation of technologies like Data Analytics at the level of these missions and the use of agile methodologies.

The literature review and empirical study confirm that there is a significant positive correlation between the digitization of businesses, the integration of new technologies and increased levels of risk. In such a situation, the internal audit function must adopt a nimble approach in response to the diverse demands of stakeholders and reconfirm its role as one of the control measures guaranteeing good corporate governance as result, the more digitized organizations become, the greater the impact on internal auditors' activities [12].

The most widely used digital tool is data analysis. This technology offers internal auditors the ability to raise precise findings, achieve efficiencies in their activities, make sound hypotheses, feedback relevant information and formulate effective recommendations.[52].

What is more, digitalization has enabled the internal audit function to support its added value through the integration of consulting activities with corporate governance bodies. However, it is crucial that the internal audit function retains its independence and objectivity, even when providing consulting services. This ensures that the advice provided is impartial and aligned with the organization's overall objectives.

From a managerial perspective, the findings reveal an increase in the use of data analysis by internal auditors because of digitalization. Consequently, it is becoming essential for the new generation of internal auditors to develop their skills and acquire new knowledge in digital technology, which calls into question their basic training.

While organizations can set up programs to strengthen auditors' digital skills, it is suggested that the internal auditing degree should focus more on digital and IT skills, for a better university/company partnership to reduce the "Expectation gap" in auditing. This approach would enable future internal auditors to develop more advanced digital awareness. Consequently, it is becoming imperative for companies to recruit and retain professionals with advanced digital skills [53].

A Comprehensive Machine Learning Framework for Anomaly Detection in Credit Card Transactions

Fathe Jeribi
Department of Computer Science-Faculty of Engineering and Computer Science, Jazan University, Jazan, Saudi Arabia

***Abstract*—Cybercrimes originate in a variety of forms, and the majority of crimes involve credit cards. Despite various steps taken to prevent credit card fraud, it is crucial to alert customers to unusual attempts at fraudulent transactions. The internet has been largely geared to meet this challenge. Many studies have been published over the years to identify anomalies in credit card transactions, and machine learning (ML) has played a significant role in this. Though various anomaly detection techniques are in place, transaction irregularities remain, especially during banking card transactions. The objective of this proposed work is to bring out an efficient machine learning model for identifying abnormal anomalies in credit card-based transactions by considering the limitations of the existing frameworks. The proposed research employs a ML framework comprising data preprocessing, discovering correlations, outlier removal, feature reduction, and classification with a sampling trade-off. The framework uses classifiers such as logistic regression, kNN, support vector machines, and decision trees. The NearMiss and SMOTE approaches are used to address overfitting and underfitting issues through sampling trade-off, which is the defining feature of this research. Significant improvement was noticed when the machine learning models were evaluated using fresh data after a sampling trade-off.**

***Keywords*—Cybersecurity; anomaly detection; machine learning; optimization; nearmiss; SMOTE**

I. Introduction

According to the Nilson Report, December 2020 [1], a leading business magazine that covers the worldwide payment card industry predicted payment card fraud losses globally will approach $32 billion in 2021, with approximately $12 billion in the United States. In 2021, worldwide losses due to fraud actually rose by 14% from the previous year. Over the course of the next decade, the industry is expected to lose $397 billion globally, with the United States contributing $165 billion. Card fraud cost issuers, merchants, and buyers and debit card transactions a total of $28.58 billion in 2020, or $6.8 every $100 in spending. In United States, as reported by the Federal Trade Commission (FTC), consumers lost over $5.8 billion in fraud in 2021, a 70% increase from the previous year [2]. Fig. 1 shows the 10 years trend on worldwide credit card frauds according to Nilson report 2021. "Credit card fraud is a significant issue for the banking industry and consumers today, and there is no fool-proof measure to thwart fraud" said Brian Quarrie, former managing director of First Data in the Middle East. Roughly 93 percent of financial fraud in Saudi Arabia occurred after the pandemic, confirming how cybercrime activity is rapidly increasing [3].

The prevalence of credit card fraud is increasing as technology develops and the creation of the universal super highway is made possible. In light of this, it is desirable to explore existing infrastructure for dealing with identity theft and credit card fraud. There are several concerns about detecting this sort of fraudulent act. This form of fraud detection is primarily reliant on data analysis, and most of this data is restricted by financial institutions due to privacy. Furthermore, due to the volume of transactions that occur each day, the analysis faces challenges in terms of technology deployment and for researchers exploring the data. The complexity of fraud detection techniques advances along with the fraudsters, who will change their strategies from time to time in order to succeed in their mission.

Machine learning has emerged as a vital part of fraud detection. It is a technology that assists in gathering and interpreting as much data on cardholders as possible in order to identify purchasing trends. Alerts, typing speed information, and fresh phone recognition are sent when fraudsters use card information in a new place. Also, if the transaction occurred at an unusual time, the banking system can flag the transaction in question and notify the cardholder. The black box fraud prevention system is a model that utilizes machine learning and contributes to the prevention of credit card fraud [4]. Such systems are becoming increasingly popular since they provide a credit card risk assessment score quickly and specify which features might result in potentially fraudulent transactions. Know Your Customer (KYC), voice-based biometrics, knowledge-based authentication (KBA), address verification services, adaptive authentication, geolocation alerts, and account takeover tools are the various strategies that financial institutions follow to protect their customers from such fraud.

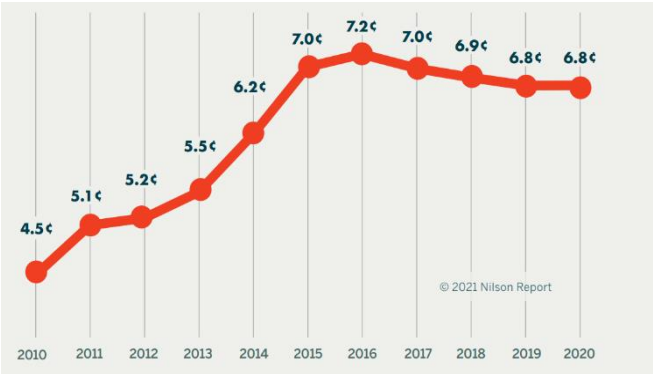

Fig. 1. Card fraud data worldwide.

Proper use of machine learning (ML) algorithms, adoption of systematic approaches for handling the data sets, and efficient use of evaluation methods are important in identifying fraud in credit card based transactions in real time. This is the prime motive behind this research framework. This paper intends to evolve a comprehensive ML-based framework by using several algorithms and a systematic approach. The framework differs from the previous ML-based frameworks in that it handles the data effectively, which is important for bringing enhanced performance in credit card fraud detection. The two main goals of this study are as follows: The first step is to analyze ML and DL-based frameworks for credit card fraud detection, and the second is to create a comprehensive ML-based classification model for fraud detection.

The subsequent sections of the paper are organized as follows: Following the Introduction in Section I, Section II presents the ML-based frameworks that are related to credit card fraud detection, their shortcomings, and the objectives of the proposed work. Section III presents the overall framework and methods of the ML experiments. Section IV presents the results, followed by discussions. The paper ends with a conclusion in Section V.

II. Related Works

As part of the research framework with the objective of identifying the effectiveness of the existing anomaly detection work, several bench-marking studies put forth in recent days are reviewed. Utmost care has been taken in choosing the research literature that reflects the real dilemma in the existing technologies of the financial sector to thwart the security issues of credit card transactions.

Manjeevan Seera et al. [5] address the escalating problem of payment card fraud by employing 13 statistical and machine learning models using both publicly available datasets and real transaction records. The study evaluates these models by comparing results from original transaction features with those derived from aggregated features identified through a genetic algorithm, with statistical tests confirming that aggregated features significantly enhance model performance. The findings highlight the potential of advanced techniques like feature aggregation to improve the accuracy and efficacy of fraud detection models in real-world scenarios. Likewise, a study by Georgios Charizanos et al. [6] introduced a novel real-time fraud detection framework that effectively handles non-stationary changes in fraud patterns and improves model training efficiency with large datasets. The framework employs a robust fuzzy logistic regression model to address class imbalance and separation issues, achieving high specificity and sensitivity, with performance metrics including a Matthew's correlation coefficient exceeding 0.80 and accuracy over 99%. Comparative analysis shows that this methodology outperforms traditional machine learning and other fraud detection methods, promising reduced financial losses and enhanced customer satisfaction.

Alfaiz, N. S., and Fati, S. M. [7] developed a credit card fraud detection model using several machine learning algorithms in two subsequent phases. Though the authors claimed that their model's performance was outstanding, it is evident that the performance of the validation test is considered the overall performance of the model. The researchers used the undersampling technique to obtain the overall performance, which is not always helpful for generalization, especially with nonlinear patterns in the dataset.

Alharbi, A. et al. [8] implemented a deep learning-based model by adopting text-to-image conversion and CNN. The converted images are fed into retrained CNN models. Though the authors claim above 98% accuracy, it is understood that when take into consideration the information loss during text-to-image conversion, the implemented model may not perform well for the new datasets. Hence, the performance of the work is questionable.

A hybrid ML-based algorithm is used in a fraud detection framework implemented by Jovanovic, D., and et al. [9]. They used synthetically oversampled data in addition to the original dataset in order to enhance the detection model. The validation trials were run multiple times, including with the actual unbalanced dataset as well as with a synthetic dataset produced using the SMOTE method. In order to lower the significant discrepancy between classes, more synthetic samples were produced using the SMOTE. According to the authors, the results of the simulations show that the proposed model outperforms rivals in the majority of the test cases. Another hybrid ML architecture was put forth by Malik, et al. [10] in which credit card fraud was first detected using cutting-edge machine learning algorithms, and then hybrid techniques were built using the best algorithm from the initial phase. According to their findings, the hybrid model AdaBoost combined with LGBM exhibits improved performance compared to bench marking works.

A credit card anomaly detection system developed by Stojanovi'c, B., et al. [11] was referred to as benchmarking due to its careful usage of multiple datasets, feature extraction techniques, selected algorithms following a thorough review, and distinctive training methodology. According to the authors, the results indicate that the machine learning techniques contribute to fraud detection with success. Similar to this, Mekterovi'c, I. et al. [12] brought out a much focused framework to solve a unique anomaly with the error "card-not-present" transactions, adopting a data mining technique through systematic feature engineering.

A high-performance ensemble staking method was proposed by Aljasim, M. et al. [13] in order to reveal cyberattacks in IoT edge nodes. Three different datasets were used in the experiments, and it is stated that the proposed classifier performed better than each of the base model classifiers. A game-changing methodology originated by Chaquet-Ulldemolins, J. et al. [14] and is applicable to all classification techniques. It enables the breaching of black-box models, the discarding of dependencies, and ultimately the elimination of unwanted biases. This led to a nonlinear analysis of financial data for fraud detection. It is concluded that it is possible to create an efficient, unique, unbiased, and traceable ML strategy that can handle transaction-level queries from clients and authorities in addition to complying with legal regulations.

To solve the unbalanced data issue, Strelcenia, E. et al. [15] researched a number of data augmentation methods and

presented a brand-new model, K CGAN, for detecting anomalies in credit card transactions. The effectiveness of the augmentation methods is then assessed using a bunch of classifiers. According to the authors, the findings demonstrated that, when compared to other augmentation techniques, B SMOTE, K CGAN, and SMOTE were achieved the best precision and recall. KCGAN stood out among them with an improved F1 performance to win.

A reliable technique of credit card scam identification using ML and blockchain was proposed by Ashfaq, T. et al. [16]. Transactions are classified and transaction patterns are predicted using the XGboost and random forest (RF) algorithms. According to the authors, the simulation results demonstrate that the proposed method accurately locates transaction fraud.

To find abnormalities in credit card-based financial transactions, Moschini, G. et al. [17] developed a semiparametric-based learning model called ARIMA. To understand the customer's normal spending patterns, the proposed model is initially tuned using the daily average of legal money transactions. Using rolling windows and the fitted model, fraud in the testing set is then predicted. They employed a variety of techniques namely, K-means, the box plot, the local outlier factor, and the isolation forest algorithm, to find anomalies. According to the claim, the proposed model performs better using the box plot technique.

Jiang, J. R., et al. [18] proposed a deep learning-based fraud detection methodology by treating transactions as nonlinear and non-stationary. For detecting anomalies, several approaches, including deep learning, are used, and, on comparison, Tri-CAD exceeds the others in terms of precision, recall, and F1-score. Similar to this, G. Zioviris et al. [19] unveiled a deep learning system with the intention of effectively managing inbound transaction patterns and identifying fraudulent ones. They suggested two auto-encoders to carry out feature selection and learn the hidden patterns of data utilizing a nonlinear optimization model. To detect fraud, the selected features are fed into a deep convolutional neural network.

Mehbodniya, A., et al. [20] used several ML techniques, including CNN, in a fraud detection framework centered on the healthcare industry. In comparison to other algorithms, the KNN algorithm performed better. Similarly, Sanober, S. et al. [21] claim that an improved model that combines Spark with deep learning has materialized. For the purpose of finding abnormalities in the transactions, numerous ML classifiers are also used in addition to DL techniques. The suggested model performed exceptionally well when tested using real-world datasets, according to the authors.

Seeja, K. R., et al. [22] likewise propose a customer-centered matching algorithm to look for anomalies in incoming transactions and make intelligent decisions. According to a performance test of the proposed model using an anonymous and unbalanced dataset, it performs significantly better than other commonly used classifiers.

An ensemble learning-based model for recognizing anomalies in card transactions is proposed by Xie, Y., et al. [23]. The model was developed with the intention of dealing with unbalanced data. The experimental findings show that in recognizing the anomalies in the transactions, the proposed model exhibited the most competent performance.

In order to address credit card transaction anomalies, Karthika, J., et al. [24] brought out a convolutional neural network-based deep learning model that learns both spatial and temporal data. The dilated convolutional layer (DCL), which the author developed, enhances the CNN base model. Three datasets are used in the experiments, which are run with different parameters and compared to the existing CNN model. The proposed model, according to the authors, had a 97.39% accuracy rate.

A framework for ML-based anomaly identification in credit card transactions was created by Matthew, T. E. [25]. A set of six parametric classifiers constitutes the proposed model. Both hard and soft voting were used to combine the ensemble. Individual learning approaches were thought to perform worse than group learning techniques. As per the authors' claim, both were demonstrated steady outcomes and the soft voting classifiers were observed to perform better with typical data without feature selection.

Mienye, I. D., et al. [26] proposed a unique deep-learning model that used three learning machines as base learners: long short-term memory (LSTM) and gated recurrent unit (GRU) neural networks. The meta-learner was a multilayer perceptron (MLP). Meanwhile, to equalize the distribution of classes in the class feature of the dataset, the hybrid synthetic minority oversampling method as well as the edited nearest neighbor (SMOTE-ENN) method are used. According to the authors, the results showed that adopting the offered deep learning model demonstrated superior performance, which is far better compared to the performance of benchmarking ML classifiers.

Several weak points were noticed, especially in handling the datasets, while studying recent literature on utilizing deep learning and machine learning to detect credit card fraud. It is a fact that the performance of the overall framework in machine learning is mostly determined by the dataset. By keeping this in mind, the adopted methodology and used datasets of the articles benchmarked are studied. Following are gaps identified from the more recent researches on credit card fraud detection using ML and DL.

- It was noted that the selection of the algorithms for the framework was made without considering the linearity of the dataset.
- Many of the frameworks never addressed overfitting and underfitting issues, and though a few frameworks used undersampling methods for fitting the model, their suitability was not analyzed for the chosen model.
- The trade-off between different values of the hyperparameters used in the models is unknown.

The above key points were kept in mind while developing the method for this proposed research. The objectives of the proposed research include:

- Study and analyze learning-based credit card fraud detection frameworks proposed in the recent past.

- Identify the major flaws in the selected works and devise the mechanism by proposing systematic machine learning-based model.

III. Materials and Methods

A. The Proposed Classification Model

A unique classification model is devised by keeping in mind the limitations of the earlier frameworks for financial fraud detection using machine learning. Several micro level techniques are used in the framework in order to fill all the gaps identified during the literature survey. Fig. 2 shows the overall framework of a credit card fraud detection using several classifiers.

B. Dataset Description

The dataset used for this research framework was obtained from the Kaggle open-source data repository community [27]. To sense the data, one needs to explore the dataset. All features other than the transaction and amount are scaled, and their names are masked out of respect for privacy.

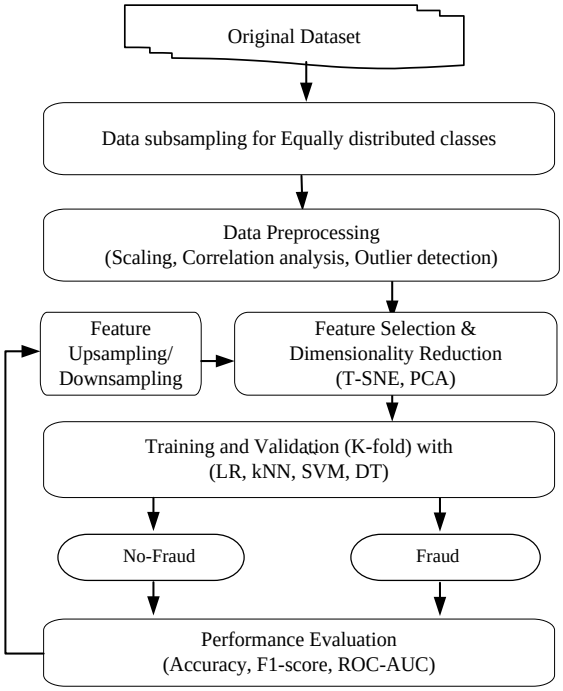

Fig. 2. The proposed CCFD framework.

After analyzing the class feature, it was discovered that there was a serious imbalance that needed to be fixed. Only 1% of transactions are fraudulent, while more than 99% of transactions are normal that needed to be fixed. Only 1% of transactions are fraudulent, while more than 99% of transactions are normal. To ensure a balanced distribution of classes, the samples are then evenly distributed by creating a sub-sample of the data frame, which aids the algorithms in better understanding the patterns that define whether a transaction is fraudulent or not. Fig. 3 shows the distribution of class feature before and after subsampling.

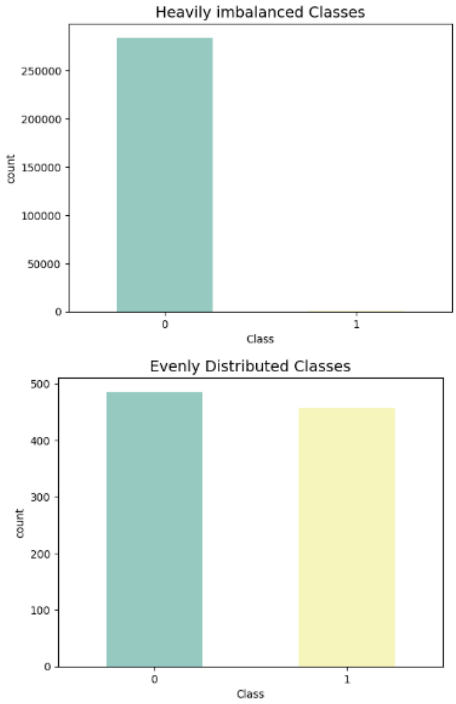

Fig. 3. Class feature before and after subsampling.

C. Data Preprocessing

As a first step in preprocessing, the missing values are filled with the average of the respective columns. The remaining columns, amount and time, should be scaled, as most of the data has already been scaled. The testing set needs to be separated from the original data frame for testing before applying the random undersampling technique. Models must be tested using the original testing set rather than one produced through undersampling or oversampling. To enable pattern detection, models are fitted to under- and over-sampled data sets and then tested on the original testing set.

D. Correlation Analysis

Correlation analysis identifies the most significant features. Negative correlations of the features against the class show that fraud transactions are more likely to occur. Positive correlations of the features against the class show that the likelihood of a fraudulent transaction increases as the feature correlation increases. This is clearly reflected in the heat map which is shown in Fig. 4.

Also, the extreme outliers are removed from the significant features with high correlation, and it is presumed that this will contribute to classification accuracy. A trade-off between different values of threshold in the interquartile range is used to remove outliers. A higher threshold is used to remove only extreme outliers in order to avoid information loss. The histograms shown in Fig. 5 illustrates the density distribution of fraud transactions on selected features with high correlation with class feature namely V10, V12 and V14, before and after outlier removal.

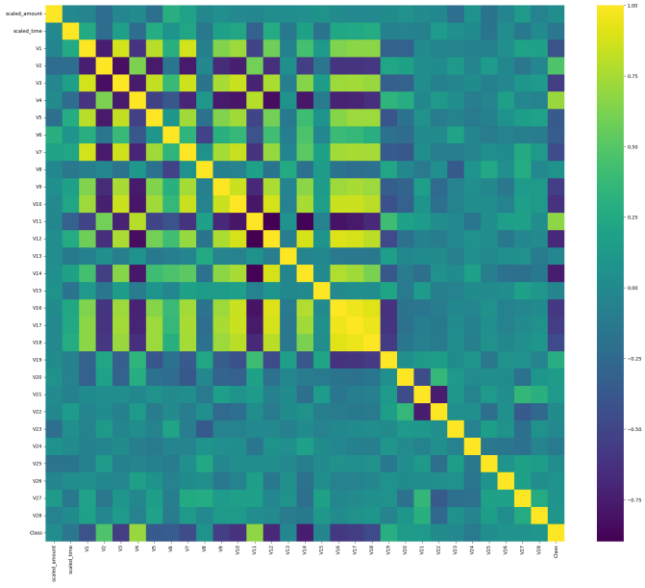

Fig. 4. Heat map showing the correlation matrix of the features.

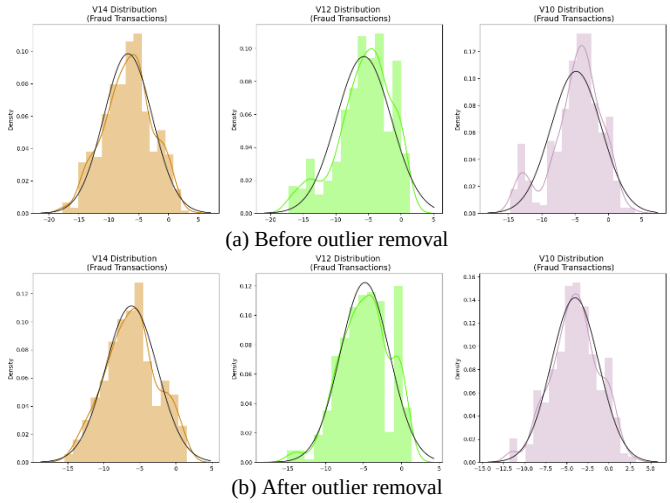


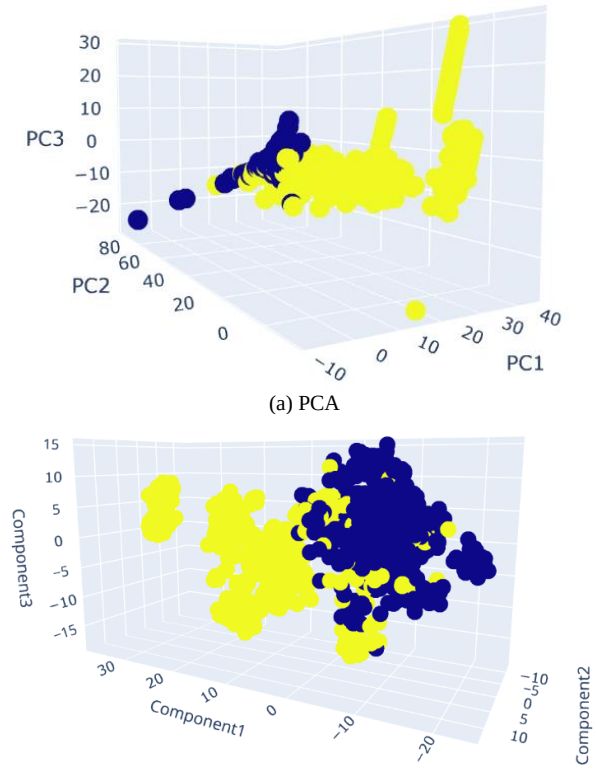
(a) Before outlier removal

(b) After outlier removal

Fig. 5. Density distribution of fraud transactions in V10, V12 and V14.

E. Dimensionality Reduction and Feature Extraction

In machine learning research, dimensionality reduction has a number of benefits, including obtaining a less complex model, a shortened training period, a reduction in space complexity, an enhancement in accuracy, improved visualization, the ability to detect noise, and many more. For feature extraction, two alternative techniques, T-distributed Stochastic Neighbor Embedding (t-SNE) [28] and Principal Component Analysis (PCA) [29], are used. Although both methods are semiparametric, the former is a nonlinear technique, whilst the later is a linear one. If there is a nonlinear relationship in the data, t-SNE will be useful for anomaly detection even though the problem is linear in form and the PCA is sufficient to bring concentrated features as principal components. Both algorithms were employed on the dataset for the proposed problem. PCA's computation time is 0.032 seconds, but t-SNE's computation time is 8.8 seconds for 3 components each. The Fig. 6 exhibits the 3D visualization of the data points after dimension reduction.



(a) PCA

(b) t-SNE

Fig. 6. 3D Visualization of the data points after feature reduction (limited with three components).

F. Classification

Four machine learning classifiers are used to classify the fraud transactions from the normal transactions: logistic regression (LogR), k nearest neighbor (kNN), support vector machine (SVM), and decision tree (DT). Let's look at the brief note on each of the classifiers.

1) Logistic Regression (LogR): A simple linear statistical model widely employed for classification is known as logistic regression (LogR). The objective of using logistic regression is to identify the model that most accurately captures the implied relationship between the dependent and independent variables. It is ideal for binary categorization. In LR, the sigmoid function acts to determine how likely a label is [30]. The sigmoid function is a mathematical function that is used to convert anticipated outcomes into probabilities. The function may transfer any real value into a value between 0 and 1. In a classification, when variables without relationship or with least relationship to the target variable gets eliminated, logistic regression will perform better. Hence, feature engineering is a crucial component of its performance.

2) K Nearest Neighbour (kNN): kNN is a nonlinear and nonparametric supervised algorithm. The concept underlying Nearest Neighbour classifier is straightforward: data objects are classified by their proximate neighbors. Knowing that it is typically useful to take several neighbors into account, this method is generally referred to as k-Nearest Neighbour (kNN) Classification. The parameter k is denoted the number of

labelled points used for classification to identify the classes. It is also known as Memory-based Classification [31] since the training instances are needed at runtime, which means that they must be in memory at runtime. It is known as a Lazy Learning technique since inference gets put off until runtime. It is also known as example-based or a case-based classification since it only uses the training instances to make classification decisions.

3) Support Vector Machine (SVM): When the dataset contains precisely two classifications, then support vector machine is the ideal choice. The support vector machine algorithm (SVM) classifies data by determining the best hyperplane that separates all of the data points in one class from the others. The hyperplane with the biggest margin separating the two classes is the optimum hyperplane for an SVM [32]. The margin is the maximum width of the slab that is perpendicular to the hyperplane but has no internal data points. SVMs use supervised learning method in order to classify unknown data using known classes.

4) Decision Tree (DT): The decision tree is a non-parametric learning technique used in classification and regression applications that is a member of the family of supervised learning algorithms. DT is hierarchical in structure, including a root node, branching nodes, inner nodes, and leaf nodes. It is a rule-based approach to making decisions that is analogous to how people make decisions [33]. An internal node represents a data instances, a branch indicates a decision, and each leaf node shows the outcome in a decision tree, which seems like a flowchart. Decision tree learning employs the divide and conquer strategy by performing a greedy search to discover the optimal partition of data points within a tree. The entire procedure is then repeated from the top down recursively until all or almost all of the items are finally assigned to specific class labels. The complexity of the decision tree influences whether all of the data instances are grouped as homogenous sets.

G. Training, Cross Validation and Sampling Trade-off

Though all the above algorithms are non-parametric, the models are trained using the training set with a trade-off between different sampling methods. Prior to training, data samples are divided into a training set and a test set. Though the training is carried out by fitting the data by importing the predefined classifiers using Python libraries, the training scores using cross validation of the classifiers are recorded at each iteration. By doing this, the best learning parameters are obtained from each classifier and their learning performance is recorded as 'training score'. Five-fold cross-validation is exercised in the experiments, meaning training data is divided into five segments, one of which will be taken out for validation and the other remaining for training. On completing 5 spells, the average score is recorded as the "cross validation score' for analysis.

Model optimization is achieved through oversampling and undersampling trade-off methods. The NearMiss [34] and SMOTE (Synthetic Minority Oversampling Technique) [35] are used to address problems caused by class imbalances during undersampling and oversampling. The NearMiss is initially tried to solve the class imbalances caused by undersampling. SMOTE generates synthetic points from the minority class to achieve a level playing field among the minority and majority classes. It selects a distance between the minority class's nearest neighbors and generates artificially created points that span these distances. In contrary to random undersampling, more data is saved as a result of no rows being discarded. Although SMOTE is more likely to be accurately computed than random undersampling, it will take longer to train because no rows are discarded, as previously indicated.

H. Evaluation Metrics

The dataset is divided into multiple training and validation set pairs solely for the model's optimization. The validation sets effectively become part of the data used because they can optimize the model during training, such as determining when to stop learning. After making all of these assessments, if a specific algorithm is chosen and its error is to be reported, this must be done using a separate test set that was not utilized during the final system's training. For the error estimate to be useful, the dataset must not have been used earlier for training or validation and must be substantial. In light of this, a portion of the dataset should first be set aside as the test set, with the remainder utilized for training and validation. The performance of the binary classification is reflected in the confusion matrix as indicated in Table I.

TABLE I. CONFUSION MATRIX

		Predicted Class	
Actual Class		**Positive**	**Negative**
	Positive	t_p true positive	f_n false negative
	Negative	f_p false positive	t_n true negative

The performance of the models developed using four distinct algorithms is evaluated using multiple types of performance measures. Accuracy is not only sufficient to evaluate the performance of the models especially when using imbalanced datasets. Hence, TPR, FPR, Error rate, F1-Score, AUC-ROC, along with the Accuracy score, were used.

$$Precision = \frac{t_p}{t_p + f_p}$$

$$TPR/Recall = \frac{t_p}{t_p + f_n}$$

$$FPR = \frac{f_p}{f_p + t_n}$$

$$Error\ rate = \frac{f_p + f_n}{N}$$

$$Accuracy = \frac{t_p + t_n}{N}$$

$$Accuracy = \frac{t_p + t_n}{N}$$

$$F1 - score = 2 \times \frac{Precision \times Recall}{Precision + Recall}$$

The projected false events as potential fraud are significant in credit card fraud detection because they are subject to study. The experiments were carried out in the Windows 11 environment using the Python 3.11 (64-bit) programming tool's Scikit Learn on a Jupyter notebook.

IV. Results and Discussions

Fig. 7 depicts the accuracy performance of the four classifiers with different sample sizes, as well as the comparative performance of the 'training score' (classifier training performance with learning parameters on generalization) and the 'cross-validation score' (using 5-fold cross validation of the training set).

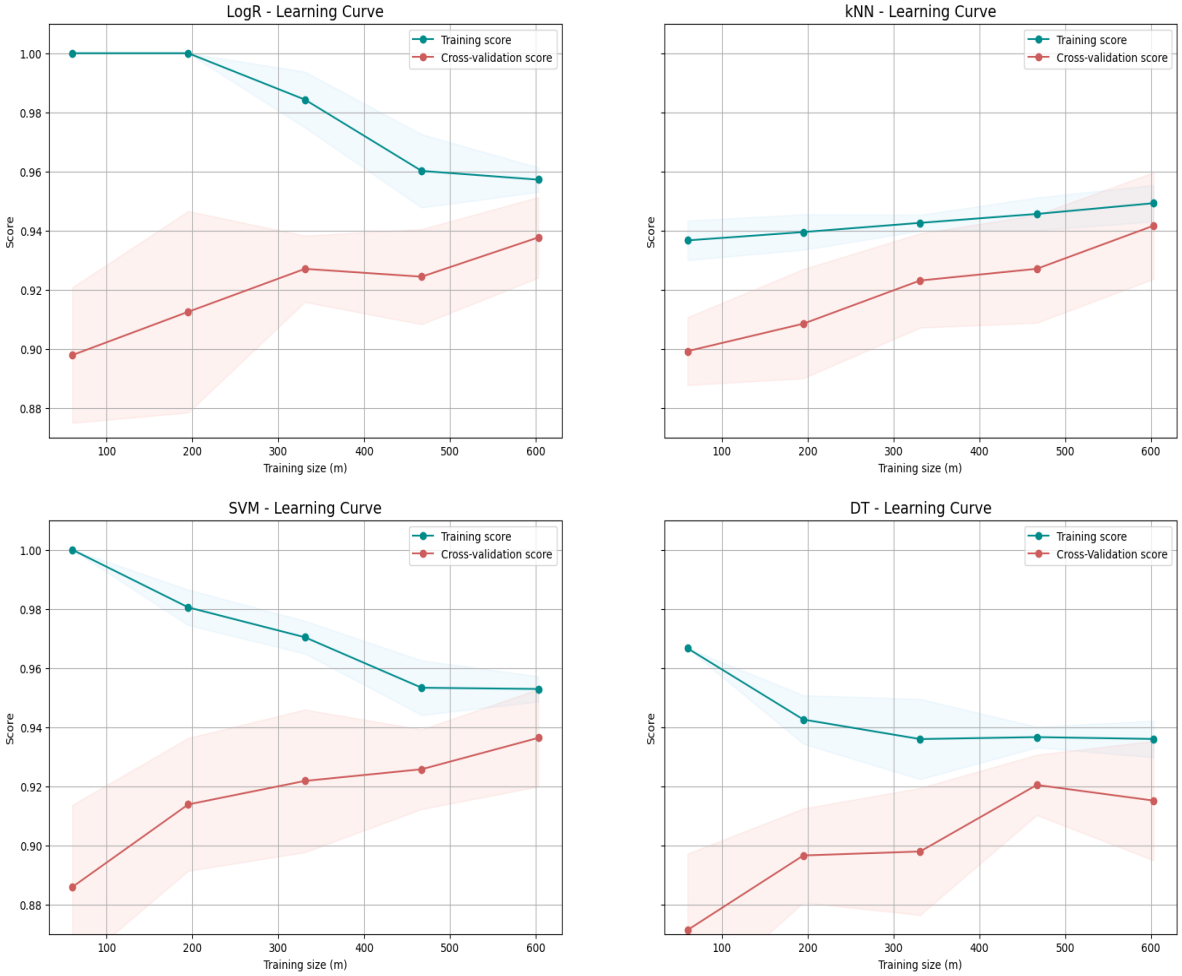


Fig. 7. Learning curves of the classifiers.

TABLE II. Training Performance of Sampling Trade-off before SMOTE

Experiment	Algorithms	Training sample size				
		60	197	333	470	607
Training score (Accuracy)	LogR	0.996666	0.958375	0.951951	0.949787	0.955189
	kNN	0.920000	0.928934	0.948948	0.952765	0.951565
	SVM	1.000000	0.964467	0.965165	0.959148	0.958484
	DT	0.950000	0.938071	0.936336	0.928936	0.930477
5-fold Cross Validation score (Accuracy)	LogR	0.931509	0.940719	0.942044	0.942044	0.944693
	kNN	0.910421	0.919649	0.931483	0.936742	0.928842
	SVM	0.930149	0.907755	0.932816	0.927561	0.939412
	DT	0.851115	0.924904	0.922272	0.920956	0.927535

While experimenting with different sample sizes of the dataset, several interesting observations were made, particularly during training and cross-validation.

The Table II provides insights into the performance of four machine learning algorithms—Logistic Regression (LogR), k-Nearest Neighbors (kNN), Support Vector Machine (SVM), and Decision Tree (DT)—across varying training sample sizes, evaluated through training scores (accuracy) and 5-fold cross-validation scores. From the training score perspective, LogR consistently demonstrated high accuracy across different sample sizes, achieving values ranging from approximately 95% to 99.7%. kNN also performed well, maintaining accuracy levels between 92% and 95%. SVM exhibited near-perfect accuracy (100%) on the smallest training sample and remained consistently high as the sample size increased. DT showed stable performance with accuracy ranging from approximately 93% to 95%.

In terms of 5-fold cross-validation scores, LogR consistently maintained high accuracy, ranging from about 93% to 94.5% across various sample sizes. kNN showed slightly lower but still strong accuracy, ranging from approximately 91% to 93.7%. SVM demonstrated varying accuracy, typically ranging between approximately 90.8% and 93.9%. DT had lower accuracy compared to the other models, with scores ranging from around 85.1% to 92.7%. Overall, the results suggest that SVM and LogR are generally more reliable for this classification task due to their consistently high accuracy across different sample sizes and validation methods. kNN also showed competitive performance but with slight variability, while DT, although effective, exhibited lower accuracy in some cross-validation scenarios. These findings highlight the importance of considering both training and validation scores to assess the robustness and reliability of machine learning models in practical applications.

The performances were studied on various sample sizes in terms of accuracy scores. The average of the AUC-ROC on 5-fold cross-validation is visualized in Fig. 8. LogR and SVM exhibited better performance on cross-validation, irrespective of training sizes.

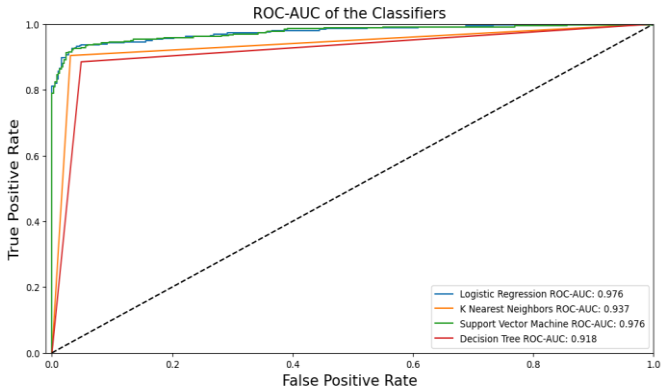

Fig. 8. AUC-ROC of the 5-fold cross validation score before SMOTE.

During this study, underfitting and overfitting issues were observed. Class imbalances are checked and corrected by undersampling. In a few cases, synthetic correction was also experimented with. At each stage of these issues, techniques such as NearMiss and SMOTE are adopted to largely handle them. After upsampling with the SMOTE method, significant improvements were noticed in the testing performance. After this trade-off, the test samples that were never used during training are used to test the performance of the optimized classifiers. The final classification test results in the form of confusion matrix before and after the trade-off are shown in Fig. 9.

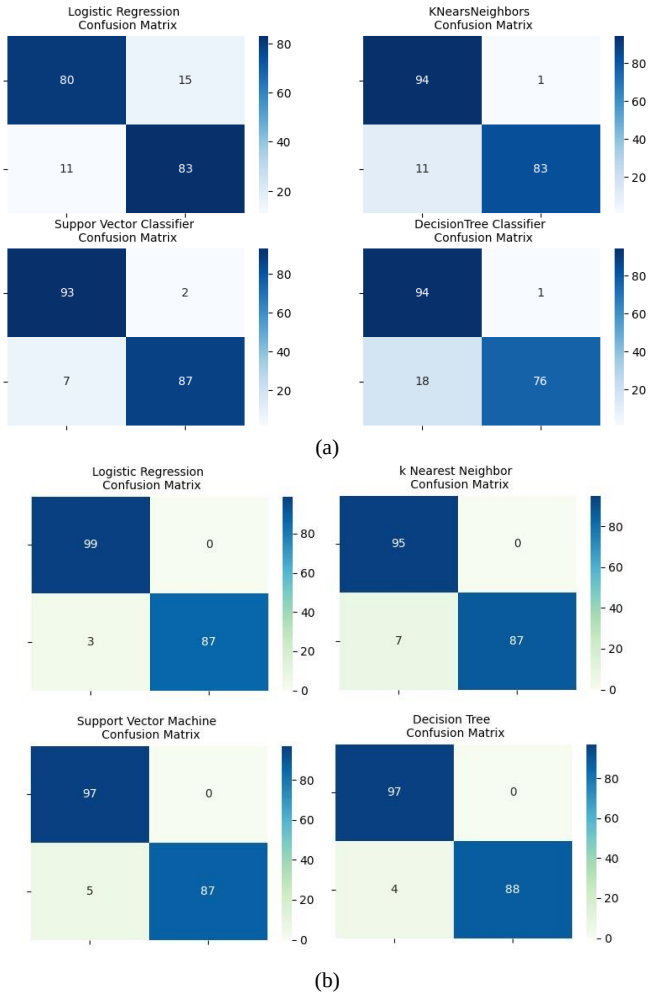

Fig. 9. (a). Performance before NearMiss/SMOTE trade-off using test set, (b). Performance after NearMiss/SMOTE trade-off using test set.

According to the confusion matrix, the sampling trade-off significantly boosted the algorithms' ability to detect fraudulent credit card transactions. The classification accuracy of the methods in detecting credit card fraud is increased as follows: from 0.862 to 0.984 (LogR), from 0.936 to 0.963 (kNN), from 0.952 to 0.974 (SVM) and 0.899 to 0.979 (DT).

V. Conclusion

Anomalies in credit card and other financial transactions are becoming more common as the user base expands. While financial institutions use a variety of methods to detect these irregularities, the fraud rate has not decreased significantly. Financial institutions are strengthening their fraud detection capabilities with the help of AI and other cutting-edge technologies in order to avoid such fraudulent acts and help

users feel comfortable during transactions. Therefore, payment fraud remains a major concern, and taking precautions to safeguard customers and their financial data is critical. Taking advantage of anti-fraud tools, as well as their continuous enhancement and development of new approaches and technologies, is critical to combating payment fraud. The research framework brought out here is one attempt to deal with this issue. In this research, existing ML and DL-based credit card fraud detection methods were reviewed, and a comprehensive ML-based method for detecting credit card fraud was proposed by considering the gaps in the existing literature. Several micro-level approaches were adopted, especially in handling the dataset through sampling trade-offs. While dealing with anomaly detection problems using ML, inefficiencies are usually encountered due to ineffective ways of handling the data. This is smartly addressed in this framework. Significant results were achieved on testing the framework, and it is strongly recommended for the prospective ML of DL-based anomaly detection frameworks.

Despite the promising results achieved by the proposed ML-based credit card fraud detection framework, several limitations remain. One significant limitation is the dependency on the quality and quantity of the dataset. Imbalanced datasets can still pose challenges, potentially leading to biased models that favor the majority class. Additionally, while the framework addresses some inefficiencies in data handling, there remains room for improvement in the preprocessing and feature engineering stages to enhance the detection capabilities further. Future research could explore the integration of more advanced techniques such as ensemble learning and hybrid models that combine both ML and DL approaches to improve detection accuracy. Furthermore, the incorporation of real-time data streams and adaptive learning methods can help in developing more robust and responsive fraud detection systems. Investigating the use of explainable AI (XAI) techniques would also be beneficial to provide transparency and interpretability in fraud detection models, thus increasing trust and adoption by financial institutions.

Defect Prediction of Finite State Machine Models Based on Transfer Learning

Wei Zhang
Experimental Teaching Center, Shandong University of Finance and Economics, Jinan 250014, China

***Abstract*—As software systems become increasingly intricate, predicting cache defects has emerged as a crucial aspect of maintaining software quality. This article introduces a novel approach for predicting cache defects, utilizing a transfer learning (TL) software deterministic finite state machine (DFSM) model. Finite State Machine (DFSM) model defect prediction based on transfer learning is an innovative software defect prediction method. This method combines the advantages of transfer learning (TL) and deterministic finite state machine (DFSM). Intended to improve the effectiveness and accuracy of software cache defect prediction. This innovative method seeks to enhance the effectiveness of predicting cache issues within software. By merging the precision of DFSM with TL's versatility, the proposed technique is transferable to target projects through training and learning from source projects, addressing data scarcity challenges in new or evolving projects. This method utilizes transfer learning (TL) strategy to transfer knowledge from the source project to the target project through learning and training, thereby solving the problem of data scarcity. Experimental findings reveal that as training data grows, the method's test coverage and fault detection rate steadily increase. Additionally, it demonstrates impressive execution efficiency and stability. In comparison to traditional methods, this approach exhibits substantial benefits in elevating software quality and reliability, offering a fresh and efficient tool for ensuring software quality. Thanks to the TL strategy, the method rapidly adapts to the unique environments and requirements of new or evolving projects, thereby enhancing forecasting accuracy and efficiency.**

Keywords*—Transfer learning; DFSM; software defects; defect prediction

I. Introduction

In the intricate ecosystem of software development, maintaining software quality and stability remains a pivotal concern. As software systems grow increasingly vast and complex, the effective prediction and prevention of software flaws have emerged as a significant hurdle in the realm of software engineering [1]. Software flaws can detract from the user experience, potentially causing substantial financial losses and even posing security risks. Despite ongoing practices in software development, predicting such flaws still poses numerous obstacles. Conventional methods for predicting software flaws often rely heavily on extensive historical datasets, limiting their adaptability to novel projects or environments [2]. Furthermore, these approaches frequently overlook the interconnectedness and disparities among software projects, potentially compromising the accuracy of predictions. However, through the lens of transfer learning (TL), we can harness existing knowledge and expertise, bridging the gap between projects and enabling more efficient and precise flaw predictions [3]. TL facilitates the transfer of insights gained from one task to others within the same domain, thereby enhancing learning efficiency and forecast accuracy [4]. In the realm of software flaw prediction, TL holds tremendous promise. By leveraging existing software project data, TL can aid in predicting flaws in new projects, expediting the model's training process and bolstering predictive accuracy [5].

Under the framework of DFSM, software system can be regarded as a process of state transition. By analyzing and modeling the state transition behavior of software system, we can understand its internal logic and operating mechanism more deeply [6]. In software defect prediction, with the help of DFSM model, the state transition paths that may lead to defects can be identified, thus improving the accuracy of prediction [7]. The traditional DFSM model often needs a lot of historical data in the construction process, and its adaptability to new projects is poor [8]. This article aims to study the cache defect prediction model and algorithm of software DFSM model based on TL. By introducing TL strategy, the existing knowledge and experience can be used to assist the DFSM model construction of new projects, thus improving the generalization ability of the model.

The research of this article has important theoretical and practical significance. By combining TL and DFSM models, we can understand the behavior pattern of software system more deeply, and then predict the potential defects more accurately. The research results can provide valuable reference information for software developers and help them identify and prevent software defects more effectively in the actual development process. The research can also provide new ideas for the field of software quality management and promote the sustainable development of the software industry.

The structure of this article is as follows: Firstly, the current situation of software defect prediction is sorted out in the literature review in Section II, and the advantages and disadvantages of existing methods are analyzed. Then, the basic principle of TL and its application prospect in software defect prediction are introduced in Section III. Then, the construction process and experimental design of cache defect prediction model of software DFSM model based on TL are emphasized. Finally, the experimental results are deeply analyzed in Section IV and a conclusion is drawn in Section V.

The research motivation of this article is to explore a more efficient and accurate software defect prediction method,

especially for predicting cache defects. By combining the advantages of transfer learning and DFSM models, we hope to gain a deeper understanding of the behavioral patterns of software systems. Identify potential defect state transition paths and provide valuable reference information for software developers. The potential benefits of this method are mainly reflected in the following aspects:

1) Through transfer learning strategies, we can utilize existing knowledge and experience to assist in the construction of DFSM models for new projects. Thus improving the generalization ability and prediction accuracy of the model.

2) By predicting potential defect state transition paths, developers can detect and fix defects at an early stage, thereby avoiding the high cost of later repairs.

3) This study not only provides new ideas and methods for software defect prediction, but also valuable references for software quality management.

II. Literature Review

Software defect prediction, a pivotal aspect of enhancing software quality, remains a focal point of research in software engineering. Numerous scholars have delved into this domain from diverse perspectives, presenting a range of methodologies and models.

Conventionally, researchers have heavily relied on historical datasets and statistical analyses for software defect prediction. Zhang et al. [9] introduced a model that forecasts future defect patterns by analyzing past defect records. Gong et al. [10], employing statistical techniques, assessed software project quality, revealing notable correlations between factors like project size, complexity, and the occurrence of software defects. Addressing the specifics of distributed software systems, Wang et al. [11] suggested a cloud-based framework tailored for handling extensive software defect data and delivering swift prediction services. Li et al. [12] innovated a method rooted in differential privacy, balancing effective defect prediction with robust data privacy measures. Wang et al. [13] advanced a decision tree-based prediction model, noted for its high predictive accuracy and intuitive explanations.

In recent times, the utilization of machine learning in predicting software defects has been on the rise. Chakraborty et al. [14] employed the Support Vector Machine (SVM) for software defect prediction, yielding impressive results. Wang et al. [15] conducted a comparative analysis of various machine learning techniques in this domain, discovering that algorithms like Random Forest and Gradient Boosting Tree performed admirably on certain datasets. Yu et al. [16] explored the impact of the social network structure within software projects on defect prediction, revealing a notable correlation between project member collaborations and the occurrence of software defects. Florence et al. [17] introduced a deep learning-based model for software defect prediction, capable of automatically extracting features from software codes and predicting defects. Tong et al. [18] suggested a method rooted in oversampling to balance datasets by augmenting the number of defective modules. Song et al. [19] tackled unbalanced data using ensemble learning, enhancing the recognition of minority classes by amalgamating predictions from multiple base classifiers.

TL as an emerging machine learning technique, has also gained traction in software defect prediction. Saifan et al. [20] proposed a TL-based model that leverages knowledge from source projects to aid in defect prediction for target projects. Qu et al. [21] delved deeper into the application of TL in cross-project software defect prediction, affirming its efficacy. Bashir et al. [22] presented a TL-driven method that allows for real-time model updates during software system integrations, adapting to system changes.

In the realm of DFSM modeling, El-Fakih et al. [23] introduced a method for modeling software behavior based on DFSM, precisely capturing the state transition processes within software systems. Hierons [24] integrated the DFSM model with machine learning algorithms, offering a hybrid approach for software defect prediction. This hybrid method takes into account both the dynamic behavior of the software system and the predictive prowess of machine learning.

At present, the research on software defect prediction faces some problems, such as unbalanced data, poor universality of the model, lack of dynamic adaptability and insufficient explanation. The data imbalance leads to the limited ability of the model to identify minority classes, while the lack of universality of the model makes it perform poorly in new projects or environments. In addition, the continuous evolution of software systems challenges the dynamic adaptability of existing models.

This article aims to build a universal and dynamic software defect prediction model by introducing TL strategy and combining DFSM model to solve the problems of data imbalance and model universality. At the same time, it pays attention to the selection of algorithms with good explanatory ability, and improves the dynamic adaptability of the model through online learning, thus comprehensively optimizing the accuracy and practicability of software defect prediction.

III. TL-based Software DFSM Model Cache Defect Prediction Model

Cache defects are common problems in software development, which may lead to data inconsistency, performance degradation, and even system crashes [25]. In order to more effectively predict such defects, this paper proposes a cache defect prediction model based on TL software DFSM model. This model combines the rigor of DFSM with the flexibility of TL, aiming to achieve rapid defect prediction for new or changed projects. The deployment of the data processing platform for the software testing system is shown in Fig. 1.

A. Foundation of Model Construction

1) DFSM: A DFSM is a mathematical model used to describe system behavior. In software system, DFSM can be used to represent the state transition process of software. Each state represents the specific situation of the software at a certain moment, and the transition between states reflects the behavior changes of the software in the process of running.

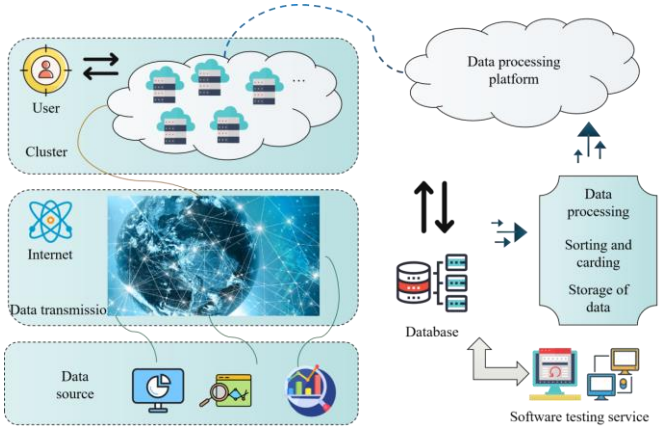

Fig. 1. Deployment of data processing platform of software testing system.

2) TL: TL is a machine learning method, which allows us to transfer what we have learned in one task to other related tasks. In software defect prediction, the application of TL is mainly reflected in two aspects: one is to use the existing software project data to assist the defect prediction of new projects; The second is to transfer the model trained in a software project to other similar projects, to reduce the training cost of new projects and improve the prediction accuracy.

B. Construction of DFSM Model based on TL

1) Data preprocessing and feature extraction: Before building the model, the original data need to be preprocessed and feature extracted. Firstly, the data related to cache is extracted from the source code and log files of software projects. These data include, but are not limited to, the type of cache operation, timestamp, operation result, etc. Then, these data are cleaned and standardized to eliminate the influence of outliers and noise data.

The software distributed parallel computing architecture is shown in Fig. 2.

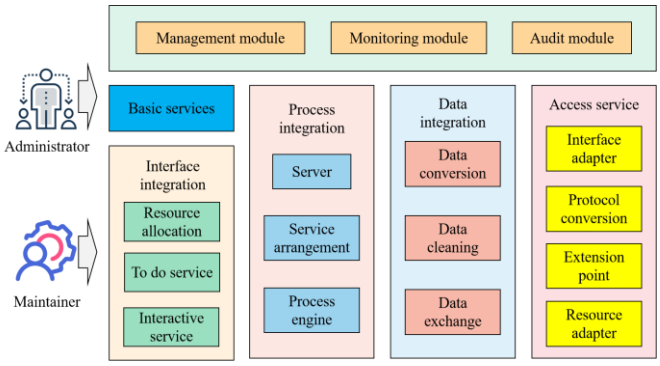

Fig. 2. Distributed parallel computing architecture.

Given that the local data processing capacity is v_i, and considering that the software terminal is capable of processing data locally within the existing resource limitations, it is imperative that the resources allocated for data processing do not surpass its inherent physical resources. In other words, there exist certain constraints:

$$\sum_{i \in N} v_i^{(t)} \le v_{\max}^{(t)} \tag{1}$$

Suppose that the rate at which software test data is migrated to the terminal is:

$$R = W \log_2 \left(1 + \frac{g \cdot P}{N_0 \cdot W} \right) \tag{2}$$

The channel unloading rate R is directly proportional to channel bandwidth W, channel gain g, and transmission power P, while inversely proportional to noise power spectral density N_0. If $a_{ij}^{(t)} = 1$, it signifies that the software testing equipment i is connected to the terminal j, enabling successful data upload to the edge server for processing. Conversely, if the conditions are not met, $a_{ij}^{(t)} = 0$. Additionally, there are specific constraints related to the unloading model of the software test equipment.

$$\sum_{j \in M} a_{ij}^{(t)} \in \{0,1\} \tag{3}$$

$$\sum_{i \in N} a_{ij}^{(t)} \le h_j \tag{4}$$

Eq. (3) represents the maximum number of terminals that a single software testing device can connect to within the same time slot t, which means one software testing device can only be paired with one terminal. Eq. (4) signifies that any given terminal j permits a maximum of h_j software test devices to be simultaneously connected.

In feature extraction, this article mainly focuses on features related to cache defects. These features can include the frequency of cache operations, the proportion of cache hits, and the mode of cache updates. Through in-depth analysis of these characteristics, it is possible to more accurately describe the caching behavior of software systems and provide strong support for subsequent defect prediction.

2) Model migration strategy: In the constructed model, TL is mainly realized by the following steps:

a) Source project selection: First, you need to select one or more source projects similar to the target project. These source projects should have similar cache management mechanisms and defect patterns as the target projects. By selecting similar source projects, we can ensure that the migrated knowledge and experience are instructive to the target projects.

b) Model training and migration: Train a cache defect prediction model based on DFSM on the source project. This model will learn the caching behavior pattern and defect characteristics of the source project. Once the model achieves satisfactory prediction performance on the source project, it can be migrated to the target project.

c) Model adjustment and optimization: During the migration process, some adjustment and optimization are needed to adapt to the specific environment and needs of the target project. For example, fine-tune the parameters of the model according to the data distribution of the target project, or add some features related to the target project to improve the prediction ability of the model.

3) Defect prediction algorithm based on DFSM: After the model migration is completed, the defect prediction algorithm based on DFSM is used to predict the defect of the target project. The algorithm will traverse all the cache operation sequences of the target project, and judge whether there is defect risk in each operation sequence according to the state transition rules of DFSM and the defect characteristics obtained by TL. If there are risks, the algorithm will issue a warning and prompt developers to check and repair. In this section, a model of directly fusing the source syntax tree to the encoder-decoder framework is proposed. The encoder part adopts the cyclic neural network (RNN) of bidirectional gated cyclic unit (GRU), that is, the encoder contains a forward RNN and a reverse RNN (see Fig. 3).

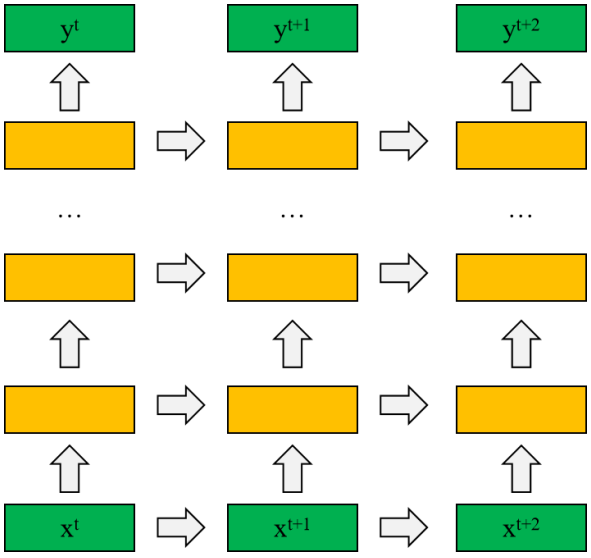

Fig. 3. Example of bidirectional serialization encoder.

Firstly, the original software defect data is preprocessed, including data cleaning, noise and outlier removal, and feature engineering. Define a data preprocessing function P, which transforms the original data set D into a format suitable for model training:

$$D' = P(D) \tag{5}$$

Next, build a TL framework, which allows us to transfer the knowledge learned from other related software projects to the current project. A TL function T is used in the study, which combines the knowledge K_s in the source domain with the knowledge K_t in the target domain:

$$K' = T(K_s, K_t) \tag{6}$$

On the basis of TL, DFSM model is used to represent the behavior of software. Define a DFSM constructor B, which generates the DFSM model M according to the knowledge K' after TL:

$$M = B(K') \tag{7}$$

Based on DFSM model, a defect prediction algorithm A is designed. The algorithm predicts defects according to DFSM model M and current project data D'. Define a prediction function F:

$$P = F(M, D') \tag{8}$$

where, P represents the prediction result, which is a vector containing the defect probability.

In order to train and optimize the defect prediction model, a loss function L is defined. It measures the difference between the predicted result P and the real label Y:

$$L(P,Y) = \sum_{i=1}^{n} (P_i - Y_i)^2 \tag{9}$$

where, n is the number of samples in the data set.

In order to improve the dynamic adaptability of the model, online learning mechanism is introduced. Define an online learning function O, which updates the model parameters according to the newly arrived data D_{new}:

$$M' = O(M, D_{new}) \tag{10}$$

IV. Result Analysis and Discussion

A. Result Analysis

In order to thoroughly evaluate the effectiveness of the software cache defect prediction model based on DFSM and enhanced by transfer learning technology, we designed a series of experiments and selected various software projects of different scales and complexities as experimental objects. Firstly, we collected data related to these software projects, covering software caching behavior, defect records, and other related attributes. By refining and organizing these data, we have constructed a dataset specifically designed for transfer learning.

In the data preparation stage, we ensured the quality and consistency of the data to provide a reliable foundation for model training. Next, we will repeatedly verify according to the pre-defined experimental blueprint. Specifically, we adopted a cross validation approach, dividing the dataset into training, validation, and testing sets. The training set is used to train software DFSM models based on transfer learning, the validation set is used to adjust model parameters and optimize model performance, and the test set is used to evaluate the final performance of the model. The aim of this experiment is to conduct a thorough evaluation of the efficacy of a software cache defect prediction model rooted in DFSM and enhanced by transfer learning technology. The study encompasses a variety of software projects, differing in scale and intricacy, as subjects for examination. Relevant data is gathered, refined,

and organized into a dataset tailored for transfer learning. Through rigorous training and refinement of the model, its performance is gauged across multiple metrics, including test coverage, defect identification rate, algorithmic execution efficiency, and stability. To ensure consistent and dependable outcomes, the entire experimental procedure is executed on a server equipped with ample computational resources.

During the experimental phase, the predefined experiment al blueprint is repeatedly validated. Initially, a prediction model is devised employing the transfer learning-based software DFSM model for cache defect prediction. Crucial data points and assessment criteria are documented throughout. Subsequently, the model undergoes training and optimization, culminating in an enhanced defect prediction model. A detailed breakdown of the experimental findings follows.

As illustrated in Fig. 4, the increase in training data gradually improves the test coverage of the software DFSM model's cache defect prediction method, which relies on TL. This progress indicates that the method is capable of efficiently learning and predicting software cache defects. In comparison to traditional approaches, our method demonstrates notable superiority in test coverage, thereby enhancing the overall quality and dependability of software.

According to the data shown in Fig. 5, the TL-based software DFSM model cache defect prediction method has a high fault detection rate. This means that this method can accurately identify the cache fault in software. Compared with other technologies, this method also has significant advantages in fault detection rate, which is helpful to improve the overall performance of the software and user satisfaction.

Fig. 6 shows the execution time of the algorithm. Although the execution time of the algorithm will increase with the increase of data volume, on the whole, the software DFSM model cache defect prediction method based on TL performs well in execution efficiency. This shows that this method can not only ensure the prediction accuracy, but also maintain efficient operation performance.

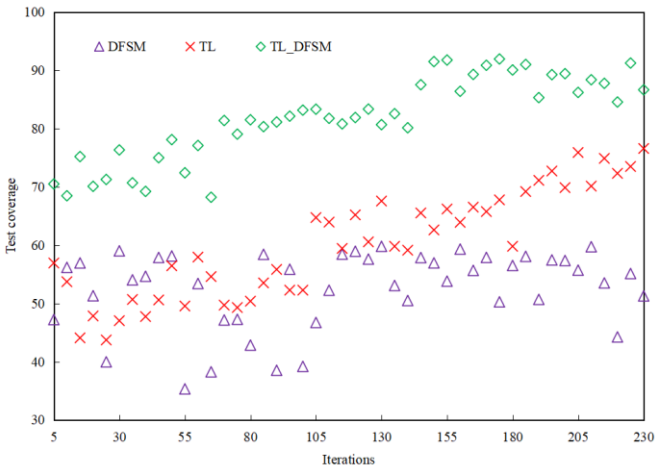

Fig. 4. Test coverage.

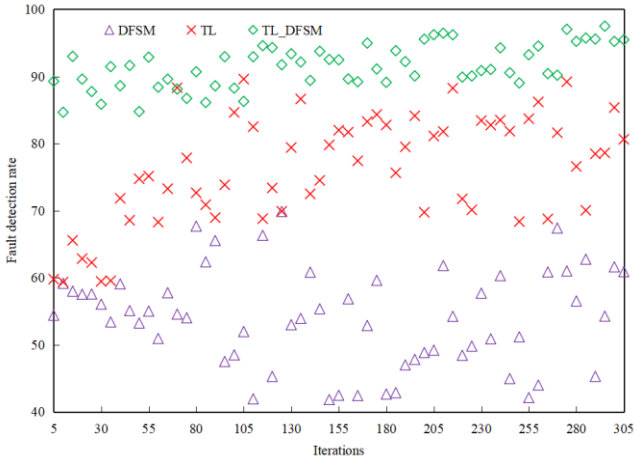

Fig. 5. Fault detection rate.

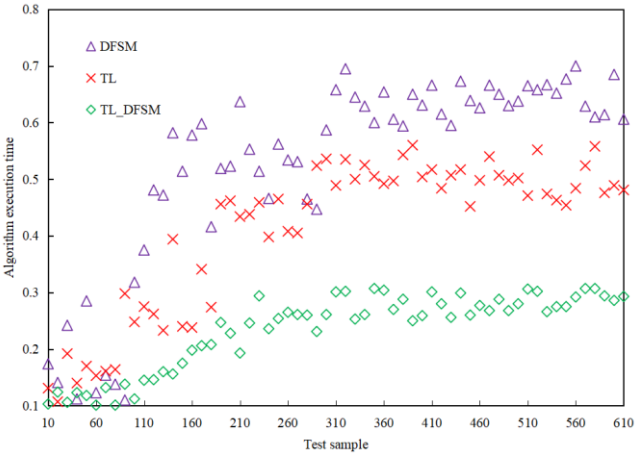

Fig. 6. Algorithm execution time.

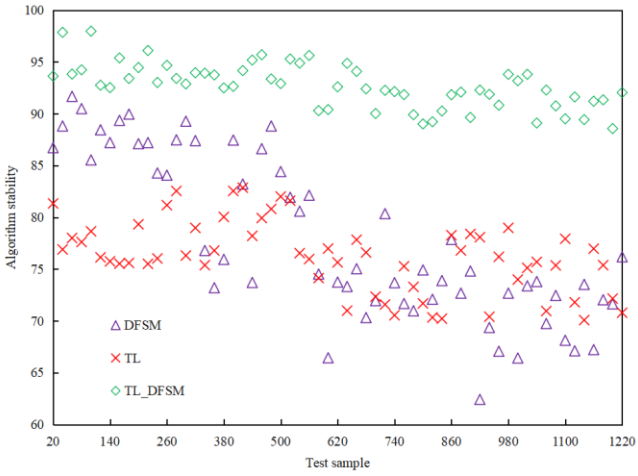

Fig. 7. Stability of algorithm.

As can be seen from Fig. 7, the TL-based software DFSM model cache defect prediction method has excellent stability. Under different experimental conditions, the prediction performance of this method remains stable, and the fluctuation of test coverage and fault detection rate is small. This proves that this method has good robustness and reliability, and is very suitable for practical software defect prediction scenarios.

Through a series of experiments, it is proved that the TL-based software DFSM model cache defect prediction method is excellent in improving test coverage, fault detection rate and maintaining algorithm execution efficiency and stability, which provides a new and effective means for software quality assurance.

B. Discussion

In today's software development field, cache defect prediction is an important and challenging problem. With the increasing complexity and scale of software system, how to effectively predict and identify potential cache defects in order to repair them in time and improve software quality has become the focus of researchers and practitioners. The cache defect prediction model of software DFSM model based on TL proposed in this article provides a new idea for solving this problem.

DFSM provides a clear representation of software systems' dynamic behaviors, including essential operations like cache hits, misses, and updates, by precisely defining states and the transitions between them. This lays a strong theoretical foundation for defect prediction. Additionally, DFSM's interpretability aids developers in intuitively comprehending the system's behavioral patterns, simplifying the identification and resolution of potential issues. TL enables the application of prior knowledge and expertise from one task to related ones, crucial in software defect prediction. Since new or altered projects may lack adequate historical data for training effective prediction models, TL extracts valuable insights from existing projects to bolster new project defect prediction. This approach not only boosts prediction accuracy but also significantly reduces model training time, enhancing overall efficiency.

A series of rigorous experiments have validated the effectiveness of the proposed method. Comprehensive assessments encompassed test coverage, fault detection rate, algorithm execution time, and stability. The results indicate that the TL-based software DFSM model for cache defect prediction excels in all areas, notably surpassing traditional methods. Specifically, this approach demonstrates clear advantages in test coverage and fault detection rate, indicating a more comprehensive exploration of software functional space and precise identification of potential cache defects.

Nonetheless, despite its notable achievements, this method faces certain challenges and limitations. Firstly, constructing a DFSM model demands specific expertise to ensure accurate state definitions and transition relationships. Secondly, TL's effectiveness relies on the similarity between source and target projects; substantial differences may limit TL's impact. Therefore, careful selection and similarity assessment of source and target projects are crucial for ensuring TL's effectiveness in practical applications.

Future research can explore automated DFSM model construction to minimize human intervention. Additionally, investigating advanced TL strategies can enhance knowledge transfer efficiency and accuracy. Furthermore, integrating other machine learning techniques, such as deep learning and reinforcement learning, could further elevate software defect prediction efficacy. The experimental results show that the TL-based cache defect prediction software DFSM model performs well in terms of test coverage and fault detection rate. This demonstrates the comprehensive exploration ability of this method in the software functional space, as well as its accuracy in identifying potential cache defects. Compared with traditional defect prediction methods, this method has achieved significant advantages in multiple indicators.

V. Conclusion

This article introduces a cache defect prediction method utilizing the software DFSM model and TL. This approach targets the challenge of predicting cache defects in fresh or altered projects by integrating DFSM and TL. Initially, DFSM is utilized to model the cache behavior of the software system. Subsequently, TL facilitates the transfer of knowledge and experience from established projects to newer ones, enabling quick and precise cache defect predictions for these new endeavors.

The test results are impressive, demonstrating strong performance in terms of test coverage, fault detection, algorithm execution time, and stability. As the volume of training data expands, test coverage progressively enhances, affirming the method's efficacy. Additionally, the method's high fault detection rate indicates its proficiency in accurately pinpointing cache faults in software, thereby aiding in the enhancement of software quality and reliability. Moreover, the algorithm exhibits commendable execution time and stability, ensuring predictive accuracy while maintaining efficient operation. Importantly, the prediction performance remains consistent across various experimental settings.

To sum up, the cache defect prediction method of software DFSM model based on TL provides a new and effective means for software quality assurance. Although this method has achieved significant results in multiple aspects, there is still room for further improvement and research. The current DFSM model construction process requires a certain amount of professional knowledge and experience. Future research can explore automated DFSM model construction methods to reduce manual intervention and improve the efficiency and accuracy of model construction. In order to further improve the efficiency and accuracy of transfer learning, future research can explore more advanced transfer learning strategies. Such as transfer learning based on deep learning or transfer learning based on graph neural networks.

***Abstract*—This research focuses on Device to Any device (D2A) communication for 6G in unpredictable circumstances where the topology of the D2A network changes over time as a result of the mobility of D2A Devices. Extremely sophisticated applications with demands for ultra-low latency and ultra-high data rate can be made achievable by cellular D2A communications in 6G. The best way to ensure Quality of Service (QoS) is to make the most of the scarce MAC Layer resources. To share information between D2A systems and a variety of devices, spectrum allocation is crucial. In this paper, a novel Fuzzy Based Spectrum Allocation (FBSA) approach is established to efficiently and rational distribute resources for D2A. A system model for D2A transmission has been established for metropolitan regions, common security and non-secure services are implemented in the network to assess the network performance for this feasible technique. Comparing the proposed FBSA approach to its prior works, which could not deliver guaranteed services due to low resource utilization. Riverbed Modeler simulation results show that the proposed approach can significantly enhance resource usage and satisfy the requirements of D2A systems.**

***Keywords*—FBSA; D2A; 6G; spectrum allocation; QoS**

I. INTRODUCTION

The academic and research community have been motivated by the search for new strategies to optimize heterogeneous infrastructure and boost network performance by 6G technical constraints. The emerging sixth-generation (6G) architectures core technology, D2A transmission, promises enhancements to spectral efficiency, overall system capacity and data rates. These network performance enhancements served as the impetus for a considerable amount of D2A research, which revealed important obstacles that must be overcome before these technologies can fully realize their potential in 6G networks and beyond. The sixth-generation (6G) mobile communication networks are anticipated to be a key component of D2A transmission. Due to its ability to support large bit rates and reduce delay, D2A can be used to implement several of the 6G specifications. Throughput, energy efficiency, latency, and accountability may all be improved by D2A communications gains in bandwidth utilization, spectrum reallocation, and noise reduction [1], [2]. Additionally, D2A can provide reduced electrical consumption for the D2A devices interacting due to shorter connection times. Since D2A can enable mobile traffic offloading, it is generally expected that non-D2A cells will also profit from it since they will have access to greater bandwidth for communication with the BS and experience less interference as a result. The use of mmWave communication, non-cooperative subscribers, disruption management, power regulation, privacy, cell expansion and outsourcing, device exploration, method choosing, QoS and trajectory choice as well as transition administration are some of the challenges that must be overcome in order for D2D to be fully realized [3], [4]. The paper analyzes the concept that the D2D communication is an optimization problem that should be independently solved using a fuzzy technique based spectrum allocation rather than being an international challenge that needs to be addressed remotely. The recent [5], [6] article makes a suggestion that the control be handled locally by the device in order to build communication links more quickly. We suggest that in the difficult and dynamic environment of D2A communication, distributed fuzzy technique based spectrum allocation control is most appropriate. To the greatest extent of our understanding, no approaches have been proposed in the literature that encompass every D2A demand. We selected the fuzzy technique because to its capacity to simultaneously answer a number of complicated problems.

In the past few years [7], [8], D2D transmission in 6G heterogeneous networks has received a lot of attention. Ad-hoc, multi-hop, heterogeneous transmission in 5G, in contrast to the D2D communications supported in 6G, offers more complex services. These services carry out more beneficial operations; however, require more effort and have stronger guidelines and they also use a lot of bandwidth and effort. D2D in 6G employs multi-carrier Time-division multiple access (MC-TDMA) at the MAC layer and enables channel widths of 1MHz at the 1THz band. Multiple successive resource channels in the same frame make up a sub-channel. 48 subcarriers with a frequency of 10 KHz each comprise frequency channel, which has a width of 90 KHz. The least amount of spectrum resources each device is capable of receiving. [9], [10] The data link shared channel

is used to send data packets from physical layer channel, while the data link layer control channel is used to send channel state information, which stores the modulation and encoding scheme used for decoding at the receivers. The amount of spectrum that will be used for transmission depends on how much data will be sent.

The preferred distribution of resources strategies can be reviewed in [11], [12]. The first one is a straightforward automatic allocation method, which chooses spectrum and sub-channels at unplanned for each request. A cellular user-aware distribution of resources approach is the alternative. The main goal of this strategy is to minimize the number of simultaneous connections in the network while minimizing beneficiary disruption. When cluster-cell, co channel disruption is not taken into account, these systems can achieve a packet delivery ratio of over 95% since the intra-cell interference is minimized to the utmost level. The previously mentioned methods, however, are unable to ensure excellent service because a sizable fraction of requests have been denied, meaning those users are unable to communicate with others in their network. Due to the size difference between two packets in two consecutive selections, this research [13], [14] identified the inefficiency of the channel sensing system in sub-channel reselection. Based on the research, it was suggested to change the original channel sensing to fully utilize sub-channels. An evolutionary algorithm-based strategy to ensure balanced simultaneous spectrum distribution and power management for fundamental D2D multi-hop communications analyzed in paper [15]. Additionally, in [16], the authors suggested a method for power regulation in two-tier NOMA microcell networks utilizing the swarms approach.

Other sophisticated method is described in study [17], [18], where the authors developed a method for allocating resources approach based on swarm optimization to address the issue of intelligence-based wireless allocation of resources for multi-hop-based D2D communication. As part of the assessment, we will contrast our findings with those of [19]. In order to find companions for bandwidth distributing, the authors in [20] apply a low-complexity method to match connections with cellular users. We will also compare [21], which analyzes the advantage collaborative multichannel transmission offers when utilized to increase the data rate in heterogeneous communication and enable user data distribution through the usage of nodes. which resolves a dual problem of subcarrier assignment and power allocation, none of the techniques listed above address more than one of the numerous problems mentioned. which asserts to provide a remedy for concurrent system admission control, mode and frequency channel assignment, and power distribution in energy-harvesting heterogeneous networks. [22] As far as we are aware, no other research has been done to address 6G D2A communication concerns employing many users and broader machine learning capabilities. In addition to gigantic cells, which offer extensive coverage, heterogeneous networks [23], [24], are among the possible methods for supporting 6G cellular networks.

There are distinct radio interfaces on the 6G D2A. The interface is for direct transmission between D2A, whereas the uU interface is a cellular interface for facilitating D2A infrastructure transmission via uplink. For D2D, the 5G standard specifies eight possible work scenarios. However, due to their various spectrum allocation strategies, only few interfacing modes can provide low-latency communications [25], [26]. Devices often transition to mode 5 and mode 6 choose frequency spectrum resources on their own using a sensing-based device scheduling technique when they are out of coverage. In contrast, device operate in mode 5 when they are inside base station communication range, where there are two choices for spectrum distribution. Base stations either control and periodically allocate the resources or reserve them using the channel sensing approach [27], [28]. The importance of the dynamic resource allocation approach in cellular is underappreciated because a lot of previous research involving physical resource allocation concentrate on transmission scheduling and resource schedule for cellular mode. However, a large proportion of devices are utilized in cities, where several devices exchange a great deal of data. Innovative resource allocation, one of the candidates in cellular mode, also has great potential to exploit resources more effectively and ensure QoS, especially when addressing the strict requirements of the D2A services [29], [30].

However, the device sensing-based scheme exhibits flexibility due to its distributed working manner. In this paper, we investigate the use of fuzzy approach-based channel allocation, one of the key elements, to address issues with resource allocation in cellular mode and to improve network performance in 6G D2A. It is crucial in artificial Intelligence because the fuzzy approach's workings are similar to those of the neurological system. Recent developments demonstrate how artificial intelligence is adopting fuzzier concepts. A methodology for data storage in cellular networks was proposed in the study in [31], [32]. The protocol combines fuzzy learning to assess long-term effectiveness and fuzzy logic to decide which carrier node to use. In paper [33], [34], artificial learning as well as fuzzy analysis are combined to evaluate Network of Everything resources. When defining the appropriate weights for QoS qualities, fuzzy analysis is used to handle uncertainties, and automated instruction is used to categorize resources [35], [36].

The following are the contributions we are making to this article:

1) To completely utilize the MAC layer resources and maximize the reuse of limited resources without explicitly tampering, a novel fuzzy approach-based resource allocation methodology is proposed.

2) The fuzzy approach is an adaptable approach that may proactively modify variables in the process based on analyzing the network's current state, ensuring the optimal performance at all times.

3) Riverbed Modeler is used to analyze a cellular D2A network in metropolitan regions and create a system-level simulation model based on an infrastructure and framework for heterogeneous networks.

4) Standard D2A services are implemented in the network, including both related to security and non-safety services, and the efficiency of the network is determined.

5) We describe a demonstration of concept approach that allows artificial intelligence to be used in the D2A transmission mode selection process while still maintaining good spectrum efficiency and minimal computational load.

6) We analyze this suggested modification in different circumstances and present clarifications of how it works.

The remainder of this paper is organized as follows: System Model on D2A communications and heterogeneous networks is provided in Section II. Section III demonstrates research in FBSA Technique for D2A Heterogeneous 6G Network. Section IV addresses Results and Discussion and the paper is concluded in Section V.

II. System Model

Multiple cellular user smart devices are simultaneously given access to basic safety services, D2A services, and entertainment-related services in 6G heterogeneous networks. Our objective is to assign resources to those consumers in order to fulfill their demands for low latency, data rate, and packet delivery ratio. The system model taken into account in this paper is shown in Fig. 1.

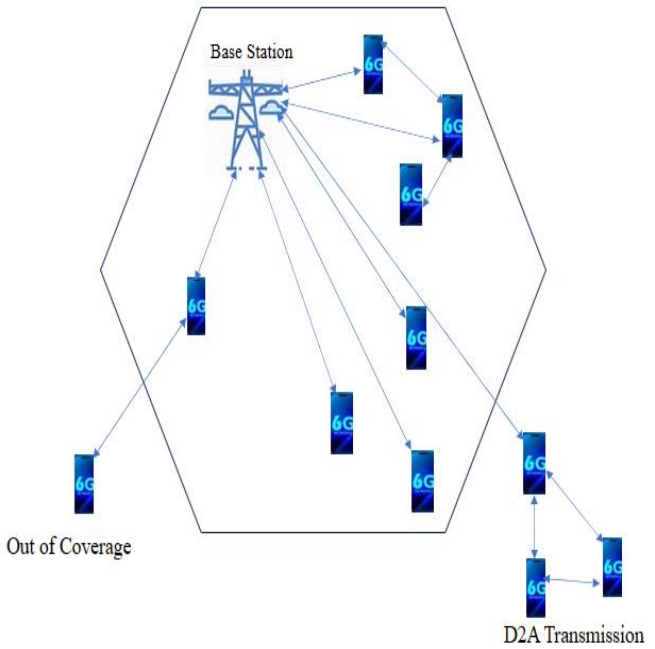

Fig. 1. System model D2A.

In the model, several user types connect to the base station, and they all come together to build a cellular network in an urban setting. A sensing device can be thought of as a static user. The base station's coverage area includes all users. Each sensing unit can communicate with other mobile users within the area it covers. Information sharing between cellular users operating in modes is possible through uplinks. On the other hand, the base station handles the resources in a statistical and dynamic manner. Every time a user distributes a message, it must first send a request to the BS via uplink to request authorization and physical infrastructure. The user can start transmitting depending on the resources allocated by the base station once it receives a response from the base station indicating which actual resources in the reservoir have been reserved for the users via uplink. In contrast, a request will be refused if the BS cannot provide the requested resources and the user will then end the transmission as a result. Additionally, we assume that the uplink radio interface in a semi-duplex mode, which prevents users from simultaneously sending and receiving data via uplink due to heavy interference. We take into account eight typical services in the system model. The chosen services comprise both security-related and non-security-related services, each with unique features, to clearly demonstrate how different applications affect the performance of the D2A heterogeneous network.

The characteristics and criteria are shown in Table I. The Common Attention Notification is a regular message that all devices transmit. Its main objective is to increase mutual awareness amongst devices nearby by exchanging speedy status information. It functions similarly to the basic safety message. Assisted movement is a service for enhanced device coordination, such as computerized grouping together and automated position changes. In comparison to the Common Attention Notification (CAN), a higher data rate and signal frequency are needed since it involves the exchange of information in a fast-moving environment. Simultaneous sensing, which is distinct from CAN and cooperative movement, refers to the extended sensors in D2A. Devices only begin transmitting data produced by sensors mounted inside them when specific triggering events occur. In this scenario, enormous amounts of data are transferred quickly to avoid accidents. Because sophisticated traffic scenarios that can occur at crossings may result in latent risks, we make the plausible assumption in our system model that devices broadcast such forms of data to prevent collisions only when they arrive at an intersection. In order to avoid collisions, a massive amount of data is transferred in this scenario in a brief length of time. Due to the potential for latent risks at an intersection caused by the complex traffic conditions that can occur there, it is fair to assume in our system model that devices broadcast such types of data to prevent crashes only when they reach at a crossover. Sensing units periodically broadcast messages to inform devices of the channel conditions and traffic scenarios as they relate to dynamic traffic control and warning. Regarding both of the last use cases, which both involve services unrelated to safety, it should be noted that real-time content is frequently used in cultural entertainment and media applications like multimedia online chat and streaming films over the Internet, whereas non-real-time information is required by data downloading and uploading activities like transferring and receiving messages and communication. We use Collaborative Sensibility Device (CSD) 1, Collective Action Device (CAD2), Communication in Sensing Device (CoSD3), Adaptive Congestion alert and Management (ACM 4), Safety and Real-time Management (SRM5), Safety and Real time Management (SRM6), Non-safety and Non-real time Management (NNM7), Non-safety and Non-real time Management (NNM8) to signify the eight services that will be deployed in our system model, as indicated in Table I, to make discussion in the following parts easier.

TABLE I. TYPE OF SERVICES AND BROADCAST IMPLEMENTED IN D2A TRANSMISSION

Equipment	D2A Services and Transmission type	Signal Frequency	Latency	Data Rate
Device 1	Collaborative Sensibility Device (CSD 1) with Continuous Transmission Type	50ms	50ms	100-500 Mbps
Device 2	Collective Action Device (CAD2) with Continuous Transmission Type	25ms	25ms	50-250 Gbps
Device 3	Communication in Sensing Device (CoSD3) with Broadcast Transmission Type	20ms	20ms	50-100 Gbps
Device 4	Adaptive Congestion alert and Management (ACM 4) Device with Continuous Transmission Type	100ms	100ms	10-50 Gbps
Device 5	Safety and Real time Management (SRM5) with periodic unidirectional Transmission type	0.5 ms	500-44595 ms	10-20 Gbps
Device 6	Safety and Real time Management (SRM6) with periodic Bidirectional Transmission type	0.5 ms	500-44595 ms	10-20 Gbps
Device 7	Non-safety and Non-real time Management (NNM7) with periodic Unidirectional Transmission type	1 ms	10 ms	20-50 Gbps
Device 8	Non-safety and Non-real time Management (NNM8) with periodic Bidirectional Transmission type	1 ms	15 ms	20-50 Gbps

A. Performance Metrics and Analysis

1) Packet Delivery Ratio (PDR): Packet Delivery Ratio is a ratio between the number of data packets actually delivered over the number of knowledge packets transmitted by way of the source node**.** The BS receives transmission requests from all cellular devices during this time, and based on whether resources can be located using the allocation approach, it either assigns substance assets to the cellular device or rejects the requests. As a result, it shows how many broadcasts the network can support**.**

The packet delivery ratio is defined as follows,

N - The total number of cellular users in the heterogeneous network,

$N_R(j)$ - Total number of requests made by users (j),

$N_T(j)$ - The total number of transmissions from users(j).

$P_T(i)$ -Total number of Packets transmitted from users(i)

$P_R(i)$ - Total number of Packets received from users(i)

The packet delivery ratio is mathematically represented as

$$\text{PDR} = \frac{\sum_{j=1}^{N} N_T(j)\, P_T(i)}{\sum_{j=1}^{N} N_R\,(j) P_R(i)}$$

Within a transmitter's transmission range, packet receiving is typically assured. The PDR, however, could be impacted by adjacent channel interference brought on by co-channel reuse. When a transmission k is connected to a receiving user j,

Let consider,

N_{BC} - broadcast Communication

N_{UC} - Unidirectional Communication,

The packet delivery ratio is defined as

$$PDR = \frac{\sum_{k=1}^{N_{BC}} \sum_{j=1}^{NR(k)} M(j,k) + \sum_{j=1}^{N_{BC}} M(j)}{\sum_{k=1}^{N_{BC}} NR(k) + N_{BC}}$$

Where N_{BC} denotes the number of receivers included in a broadcast transmission's coverage area. For a unidirectional transmission, there is always just only one receiver.

III. A FUZZY BASED SPECTRUM ALLOCATION (FBSA) TECHNIQUE FOR D2A HETEROGENEOUS 6G NETWORK

The optimal selection of resources for uplink transmissions in a heterogeneous network is specified by the proposed fuzzy-logic based spectrum allocation, which also maximizes spectrum reuse and enhances heterogeneous network performance.

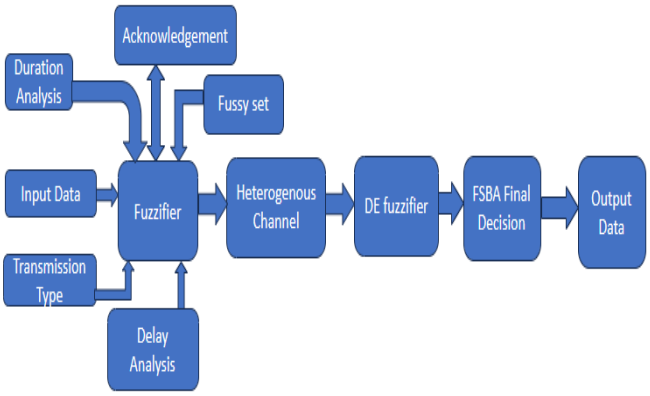

Fig. 2. FBSA technique.

The FBSA algorithm's workflow diagram is shown in Fig. 2. The use of fuzzy logic to solve the problem of understanding approach to get from one input to a desired outcome is known as fuzzy inference. Consulting the following diagrammatic representation may help with decisions. Fuzzy inference techniques have been successfully applied in a number of fields, including data classification, skilled systems, automatic control, evaluation of decisions, and visual analysis. Due to its vast application, the fuzzy inference system is also known as

flexible-rule-based systems, fuzzy experts, fuzzy estimation, fuzzy memories, fuzzy logic control devices, and just fuzzy systems.

The fuzzy circuits at the heart of the FBSA algorithm are responsible for processing incoming data and producing precise results reflecting the availability of particular facilities. The input variables are Processing time, cross-talk, uni-directional, and operation priority will be used to evaluate if the spectrums are appropriate for a broadcaster. The user functions that transform single-valued inputs into the values of an array of fuzzy values will fuzzifier the six related factors in response to a request from a cellular user. The inferential function will evaluate the fuzzy values in accordance with established guidelines. Finally, the assessment that reflects the nature of a result will be defuzzied, and the amounts of data used in decision-making will demonstrate allocation. Additionally, the fuzzing function collects information from the instantaneous form heterogeneous network performance, which also serves as knowledge, and uses it as a key factor in altering the subscription functions' variables. In this research, the joining functions of the influence factor and the semi-duplex factor's values can be influenced in accordance with the properties of the inputs, and the precedence of the amenities that are offered in the network can also be adjusted correspondingly. Notably, the user should provide a training sequence containing information about its present location and packet reception during the previous transmission period before each uplink transmission.

IV. Results and Discussions

Riverbed Modeler is used to simulate the FBSA outcomes. The Fuzzy Logic rules were implemented using a simulation tool. The details of the FBSA rules and simulation parameters are provided in Table II.

TABLE II. Simulation Parameters of FBSA

Simulation Parameter	Value
Maximum Capacity	500 GHz
Front haul Distance	80 KM
Number of Devices	200
Transmission distance of each devices	1m Radius
Medium Access Control Protocol	IEEE 802.11 (1Tbps)
Device Mobility	Grid (500m x 500m)
Packet Size	1024 bytes
Papulation size	50000

We use the proposed FBSA technique to compare heterogeneous networks. The value of the spectrum allocation cost function, which should range between 100 and 600 when the suggested FBSA technique is used, serves as the primary indicator for evaluating the proposed technique. We invested our findings to the test by maximizing the weights of several goals. These goals have a loose connection to five alternative resource allocation scenarios that concentrate on heterogeneous network characteristics. The allocation function variation for the optimized parameters utilizing the FBSA approach is shown in Fig. 3.

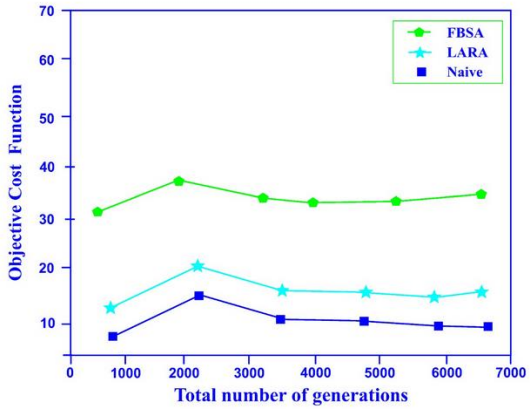

Fig. 3. Variation of objective cost function value for different number of generations.

Each generation has a 600 MHz spectrum allotment size, with an increment of 100 bringing the number of generations from 100 to 600. Beyond 60 generations, it is noticed that the value of the objective function stays mostly unchanged. It is observed that increasing the number of generations maximizes the value of the objective function. Additionally, a statistical analysis is done to evaluate whether the FBSA output is 99% accurate. It has been noted that results with fewer generations are likely to vary more; nevertheless, if the number of generations reaches 100, there is a very strong probability that the result will be optimal because the interval between the data points is fixed.

The 5G-optimized cost function value is optimized to 13.52, which is the multi-objective spectrum allocation function's score. However, the optimal score for the 5-G multi-objective function should fall between 5 and 10. The value of the multi-objective cost function could not be optimized as a result by the 5G heterogeneous network. As a result, we use our proposed

FBSA approach to optimize the weights of the objective function in order to enhance the outcomes of the spectrum allocation function. The outcomes shown in Fig. 3 demonstrate how the proposed FBSA reduces the value of the cost function to an optimal value of 1.8.

Based on the system model, a cellular D2A network is simulated in Riverbed Modeler to determine the performance of the proposed FBSA discussed above. It consists of a single base station, numerous cellular user using cellular handsets, all user devices are covered by the base station's coverage. additionally, taking into account that both intra- and inter-cell interference does indeed are available, as illustrated in Fig. 4, we simulate seven separate cells simultaneously and evaluate the performance of each cell.

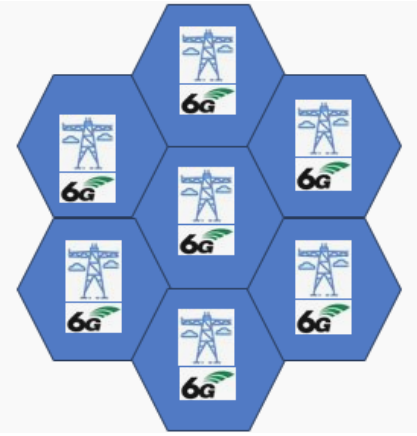

Fig. 4. Seven cells in a cluster in the simulation model.

The coverage region of a cellular network is typically depicted as a hexagon. The hexagon is not representative of the situation. A hexagonal cell, however, indicates that some of the devices may be connected might not be connected. Inter-cell interference and co-channel interference is also taken into account in the simulations that were run. Inter-cell interference typically has a major impact on devices traveling in a high speed near two cells. It is challenging to co-channel interference and show its influence on square cells. Therefore, a hexagonal cell is more suited to expose the actual performance of D2A heterogeneous networks for both realistic and simulational reasons.

TABLE III. SIMULATION SETUP

Parameter	Value
Required Frequency	1 THz
Bandwidth	80 MHz
Number of Cellular users	200
Transmission Range	500m
Number of cells	7
Velocity	100 km/h
Area size	100m x 100m
Noise	AWGN
Channel Model	Rayleigh fading model
Modulation Scheme	128QAM (Quadrature Amplitude Modulation)

Table III shows the key simulation parameters. There are 44 subchannels and 200 subframes in the resource spectrum. If adequate resources can be found, a transmission request should be approved in the following 'T' subframes to prevent significant delays. The value of 'T' is based on various services. The variable 'T' for SRM5 transmissions is 0.5ms. If not, it would be the equivalent of an endless delay. Additionally, within a sender's transmission range, successful packet receipt can be guaranteed; nevertheless, cellular device outside of the range may still have a lesser likelihood of receiving the transmitted data. Different service combinations have been investigated in the simulations to better assess how various D2A services affect the network throughput. We use typical basic safety services, four D2A services, and four entertainment services to evaluate the performance of the suggested allocation mechanism. SRM5 is the most bandwidth-intensive and has the strictest requirements of the eight services. Additionally, a very brief delay of 10 ms or 15 ms is needed for NNM5 and NNM6, respectively. We have chosen these several service kinds to see if the proposed FBSA can meet the needs of various services.

Numerous simulations have been used to compare the FBSA scheme to the naive and LARA schemes in order to assess network performance in terms of packet delivery ratio, successful transmission ratio, and network throughput.

Fig. 5 shows the PDR performance for case 2 for each of the three approaches. The naïve scheme, which is followed by the LARA and the FBSA, has the highest PDR. Because the naive has no intra-cell interference and the LARA has very little intra-cell interference, both have better PDR, and the accompanying curves are extremely close to 100%. Their propensity for avoiding conflicting transmissions in the same cell to the greatest extent determines this. However, in order to accommodate additional demands from cellular users, the FBSA permits as many simultaneous connectivity as is practical. Thus, intra-cell interference will unavoidably manifest and lower the PDR. Additionally, because resource allocation in each of the co-channel cells operates separately and the interference primarily impacts cellular devices that are close to the boundaries, co-channel interference severely affects PDR for all four schemes virtually to the same extent.

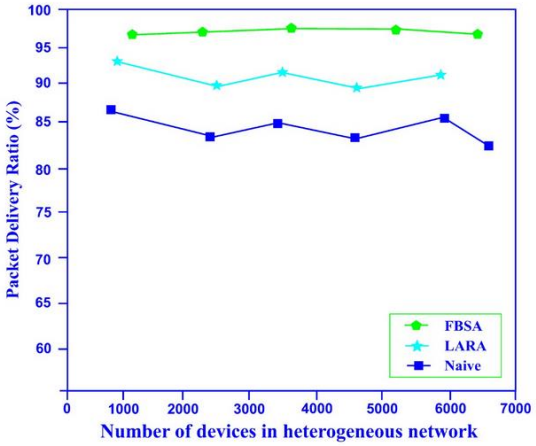

Fig. 5. Packet delivery ratio for various number of devices in heterogeneous network.

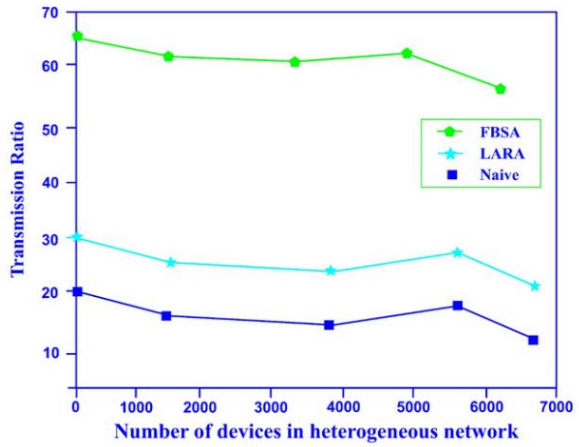

Fig. 6. Transmission Ratio for number of devices in heterogeneous network.

In a D2A network, transmission ratio is plotted versus the number of cellular devices in Fig. 6. Due to increased competition, it is harder for the base station to locate resources for excessive transmission demands when the number of vehicles on a cellular network increases. As can be seen from the figure, the transmission ratio decreases noticeably for both the LARA and naive schemes in any situation when the number of cellular users increases. In addition, in the most extreme case, if all eight services are activated and the naive technique is used, the transmission ratio turns out to be at a fairly low level of 0.5 even if there are just 500 devices dispersed over a 100 km region, not to mention the case with more cellular devices. In other words, more than 90% of requests are turned down, which makes it challenging to meet the needs of many D2A applications. Even while the LARA system, when compared to the naive, can increase the transmission ratio in some way, it is still not adequate. For all four instances and device volumes, the FBSA can keep the transmission ratio at least 99%. When D2A services are enabled or disabled, however, FBSA outperforms the other two techniques in terms of transmission ratio. This is based on the findings that, for a given resource allocation scheme, the gaps between different services for three schemes, with the FBSA having the shortest gaps.

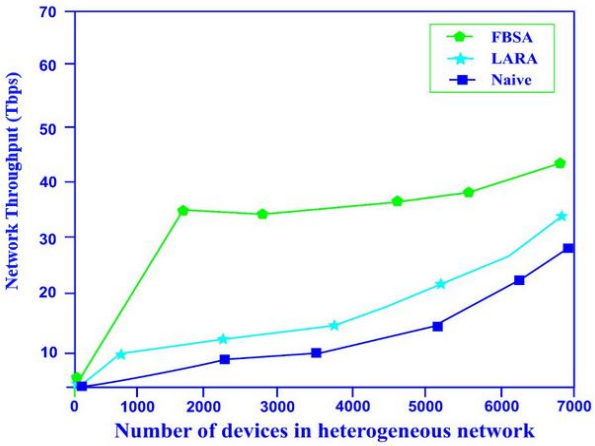

Fig. 7. Network throughput for number of devices in heterogeneous network.

The network throughput is displayed in Fig. 7. Because the network is already congested and cannot allocate any more resources to cellular devices in Fig. 7, the throughput of the naive and the LARA are insensitive to the number of cellular devices. The network speed attained via FBSA approach, however, progressively increases from 100 Gbps to 1 Tbps, exceeding its competitors by a factor of more than 100 times. Because example 1 only comprises six safety D2A services and includes all services, each scheme's relevant curves in Fig. 7 are fairly similar. The likelihood of sending four non-safety services, however, is barely 0.5, and they both have the lowest priority. They cannot significantly increase network throughput.

Contrarily, it can be shown from a comparison of the bottom curves, that the four D2A services have a greater impact on throughput than the FBSA for the naïve and the LARA. The throughput will be reduced from 1000 Mbps to 100 Mbps dramatically if one or more of the D2A services are removed. If FBSA is implemented in the network, these changes in the services offered do not, however, result in such a significant variation in throughput. The advantage comes from the FBSA adaptability, which can dynamically elevate a service's priority to a higher priority by network state. However, the LARA and naive always treat various service types equally and operate in a first-come, first-served manner, which may be impacted by the proportion of requests with various priorities.

V. CONCLUSION

The 6G mobile communication networks are expected to include D2A Communication at its heart. We have researched the unique resource distribution for 6G D2A transmission. We start by outlining the various categories of resource allocation. We concentrate on centralized resource allocation, where the base station controls all dimensional frequency resources because User and cellular devices are within the base station's coverage area. The D2A standard, however, fails to offer for any centralized resource allocation. A flexible logic-based resource allocation mechanism called FBSA is suggested in the paper as a result of this. The FBSA evaluates all available variables as input parameters and uses fuzzy thinking to its ability to consider how to allocate appropriate resources to various users. To ensure optimal resource consumption, it may also centrally modify the fuzzy system's parameters in accordance with the state of the network. Then, using Riverbed Modeler tool, a simulation model is created to simulate D2A communications in heterogeneous cellular networks with co-channel interference. The outcomes of the simulation imply that the FBSA may significantly increase resource usage, enhance information distribution among diverse users, and enhance network throughput when compared to existing methods. The FBSA maintains reasonable complexity while offering an effective resource allocation solution. Future directions could involve applying the suggested technique to newer heterogeneous networks, particularly when it comes to resource allocation and compute offloading in heterogeneous dense networks. Additionally, OpenFlow and Mininet may be used to test the suggested approach.

***Abstract*—This paper outlines a comprehensive AI-driven Quality of Service (QoS) optimization method, presenting a rigorous examination of its effectiveness through extensive experimentation and analysis. By applying real-world datasets to simulate network environments, the study systematically evaluates the proposed method's impact across various QoS metrics. Key findings reveal substantial enhancements in reducing average latency, minimizing packet loss, and boosting bandwidth utilization compared to baseline scenarios, with the Deep Deterministic Policy Gradient (DDPG) model showcasing the most notable improvements. The research demonstrates that AI optimization strategies, particularly those leveraging DQN and DDPG algorithms, significantly improve upon conventional methods. Specifically, post-migration optimizations lead to a recovery and even surpassing of pre-migration QoS levels, with delays dropping to levels below initial readings, packet loss nearly eliminated, and bandwidth utilization markedly improved. The study further illustrates that while lower learning rates necessitate longer convergence times, they ultimately facilitate superior model performance and stability. In-depth case studies within a cloud data center setting underscore the system's proficiency in handling large-scale Virtual Machine (VM) migrations with minimal disruption to network performance. The AI-driven optimization successfully mitigates the typical latency spikes, packet loss increases, and resource utilization dips associated with VM migrations, thereby affirming its practical value in maintaining high network efficiency and stability during such operations. Comparative analyses against traditional traffic engineering methods, rule-based controls, and other machine learning approaches consistently place the AI optimization method ahead, achieving up to an 8% increase in throughput alongside a 2 ms decrease in latency. Furthermore, the technique excels in reducing packet loss by 25% and elevating resource utilization rates, underscoring its prowess in enhancing network efficiency and stability. Robustness and scalability assessments validate the method's applicability across diverse network scales, traffic patterns, and congestion levels, confirming its adaptability and effectiveness in a wide array of operational contexts. Overall, the research conclusively evidences the AI-driven QoS optimization system's capacity to tangibly enhance network performance, positioning it as a highly efficacious solution for contemporary networking challenges.**

I. Introduction

Today's world is undergoing unprecedented digital transformation, and the iterative upgrading of information technology is constantly reshaping the economic structure and social life. From smart homes to smart cities, from distance education to telemedicine, every emerging application puts higher requirements on network service quality. The network is not only a pipeline for data transmission but also a nervous system that supports the operation of society. Therefore, ensuring the efficient, stable and secure operation of the network is directly related to the effectiveness and sustainability of digital transformation [1].

With the commercial deployment of 5G technology and the initial launch of 6G research and development, mobile communications have entered a whole new stage of development. Higher data rates, lower latency, and greater connection density are features that make cutting-edge applications such as autonomous driving, Industry 4.0, and immersive entertainment possible. However, at the same time, these applications demand an unprecedented level of network QoS. How to adjust network resource allocation in real-time and precisely to meet the differentiated demands of various applications in a complex and changing network environment has become a key issue to be solved. Traditional network management relies on preset rules and manual intervention, which is difficult to adapt to the dynamic changes and complexity of the modern network environment. Statically configured policies are often unable to flexibly respond to unexpected traffic, network congestion or failure events, resulting in QoS degradation and impaired user experience [2].

The rise of artificial intelligence, especially machine learning and deep learning, has provided new ideas and tools for network QoS optimization.AI is able to process massive amounts of network data, learn network behavior patterns, predict traffic trends, and automatically optimize network configurations so as to achieve the purpose of improving resource utilization, reducing latency, and enhancing stability. Although AI has great potential in network QoS optimization, the path to its realization is not smooth. How to effectively combine AI algorithms with network engineering practices, how to realize data-driven decision making while safeguarding privacy and security, how to address the interpretive issues of models to enhance trust, and how to harmonize across different network architectures (e.g., cloud, edge, and end) are the main challenges currently faced. Therefore, in-depth research on the

application of AI in QoS optimization is not only a need for technological innovation, but also an inevitable choice to promote a robust digital society [3].

In recent years, the research on network QoS optimization and AI applications in communication networks has made significant progress. Early work focused on the establishment of QoS models and the application of traditional optimization algorithms, e.g., Ghafoor et al. [1] explored the QoS guarantee mechanism based on the DiffServ model, while Babaei et al. [2] analyzed the application and limitations of the IntServ model in multimedia transmission. Subsequently, with the development of AI technology, the research focus has gradually shifted to utilizing AI to enhance network performance [3].

In terms of traffic prediction, Alkanhel et al. [4] proposes a network traffic prediction model based on deep learning, which effectively improves the prediction accuracy and provides a basis for resource scheduling. A breakthrough has also been made in the application of AI in the field of resource allocation, and Malhotra et al. [5] demonstrates a dynamic spectrum allocation scheme based on reinforcement learning, which significantly improves the spectrum utilization. In addition, AI also shows great potential in fault detection and self-healing network construction, e.g., the AI-assisted fault management system developed in the Bendavid et al. [6] is able to realize rapid localization and repair of network problems. Nevertheless, there are still some insufficiently addressed issues in existing research, such as the interpretability of AI models, generalization capabilities, and the challenges of applying them in large-scale heterogeneous network environments. In addition, how to efficiently integrate AI with traditional network management frameworks, as well as to ensure the transparency and security of AI decisions, are also important issues in current research [7]. This research is dedicated to analyzing the potential of Artificial Intelligence (AI) in the field of Quality of Service (QoS) optimization, focusing on three core issues: first, to address the specific challenges of large-scale network environments, the research aims to design and implement an AI-driven QoS optimization framework to ensure that the framework can adapt to the high dynamics and complexity of network environments, and at the same time effectively enhance the deployment of QoS optimization frameworks in large-scale networks, and to improve the efficiency of QoS optimization. Performance in large-scale networks. Second, the study will explore in detail specific applications of deep learning and reinforcement learning models in accurately predicting network behavioral patterns, implementing intelligent resource scheduling, and further optimizing the strategies of these models to maximize the utilization efficiency of network resources and the quality of service delivery.

The strengths of this paper include a comprehensive AI-driven QoS optimization method that is supported by extensive experimentation and analysis using real-world datasets. The research systematically evaluates the method's impact on various QoS metrics and demonstrates significant improvements compared to baseline scenarios. The study also includes in-depth case studies within a cloud data center setting, showcasing the system's ability to handle large-scale VM migrations with minimal disruption to network performance. Comparative analyses consistently show the AI optimization method outperforming traditional traffic engineering methods, rule-based controls, and other machine learning approaches. Additionally, the paper validates the method's robustness and scalability across diverse network scales, traffic patterns, and congestion levels, confirming its adaptability and effectiveness in various operational contexts.

The paper is organized as follows: The literature review in Section II provides an overview of existing research on AI-based QoS optimization, covering the application of machine learning, deep learning, and reinforcement learning techniques. Finally, the current challenges and the future research directions are proposed. The "AI-Driven QoS Optimization Methodology" in Section III details the proposed AI-driven QoS optimization methodology. It is divided into two sections: A. Problem modeling: This section establishes the mathematical model of QoS optimization problem, including the objective function, constraint conditions and symbol definition. B. Method Design: This section describes the design of a framework based on Deep Reinforcement Learning (DRL), including Deep Q-Networks (DQN) and an actor criticism architecture. It covers the algorithm principle, architecture design and parameter adjustment strategy. The experimental design in Section IV describes the simulation setup using real data sets, and compares the QoS metrics before and after optimization to prove the effectiveness of the proposed AI optimization method in Section V. Finally, the paper is concluded in Section VI.

II. Literature Review

A. State of the Artificial Intelligence in QoS Data Optimization

In recent years, the rapid development of Artificial Intelligence (AI) techniques, especially Machine Learning (ML), Deep Learning (DL), and Reinforcement Learning (RL), has opened up new research paths and practice areas for network Quality of Service (QoS) data optimization. The introduction of AI has enabled network management to move toward intelligence and automation, which it helps to build a self-optimizing and self-healing resilient network, and its specific application mode is shown in Fig. 1.

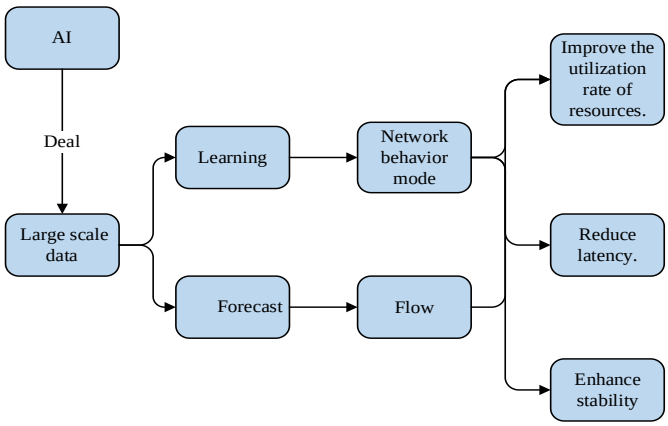

Fig. 1. Application model of AI in QoS optimization.

This section will provide insights into how these techniques can be applied to forecasting, decision making, and dynamic management of network resources with a view to achieving efficient, low-latency, and high-reliability data transmission. Machine learning techniques are able to identify complex network behavior patterns by analyzing historical network data in order to predict future network conditions. Kwon et al. [7] used supervised learning methods to build models that successfully predicted network traffic fluctuations, providing network administrators with a valuable window to adjust resource allocations in advance. In addition, unsupervised learning and semi-supervised learning also show potential in anomaly detection and pattern recognition, which can help to detect and respond to anomalous behaviors in the network in a timely manner and maintain QoS standards [8]. Deep learning, especially Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs), excel in processing sequential data and high-dimensional features, and are widely used for optimization of network data. Wang et al. [9] demonstrated how RNN can effectively predict network congestion, while Arunachalam et al. [10] modeled network traffic by introducing a long short-term memory network (LSTM), which not only improves the prediction accuracy, but also dynamically adapts the data transmission strategy based on the prediction results to reduce delay and packet loss. These deep learning models are able to handle the time series characteristics of network data and provide more refined decision support for QoS optimization. Reinforcement learning has found a place in network resource management and scheduling with its ability to make decisions for optimization in complex environments. Mehraban et al. [11] proposed a dynamic bandwidth allocation algorithm based on reinforcement learning, which is capable of adjusting the policy according to the immediate feedback of the network state and realizing the efficient allocation of resources. In addition, Karasik et al. [12] trained the reinforcement learning model by simulating the environment, enabling the network to adaptively adjust the routing policy under different service demands and network conditions, improving the overall QoS performance. The introduction of reinforcement learning enables the network optimization strategy to adapt more flexibly to changes in the network state, realizing the transition from reactive to proactive optimization. The amount of literature on the application of different techniques in QoS data optimization is specifically shown in Fig. 2.

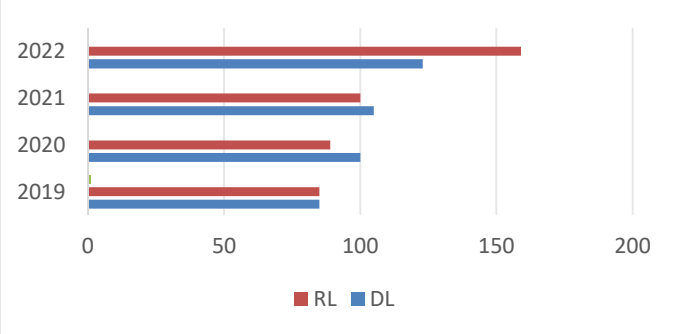

Fig. 2. Number of literature on the application of different techniques in QoS data optimization.

Although AI techniques have made significant achievements in QoS optimization, their practical application still faces a series of challenges, such as model interpretability, acquisition and quality of training data, and computational complexity of algorithms. Rani et al. [13] emphasized the importance of model interpretability in real-world deployments, which is crucial for establishing regulatory trust and troubleshooting. Meanwhile, Can et al. [14] discussed how to effectively collect and utilize network data for model training while protecting user privacy. The specific research findings are shown in Table I.

TABLE I. SUMMARY OF RESEARCH RESULTS

Research Area	Authors and References	Contributions
Traffic Prediction	Alkanhel et al. [4]	Proposes a deep learning-based network traffic prediction model, significantly enhancing prediction accuracy and providing robust support for proactive resource scheduling.
Resource Allocation	Malhotra et al. [5]	Demonstrates a reinforcement learning-driven dynamic spectrum allocation scheme, vastly improving the efficiency of spectrum resource utilization.
QoS Assurance Mechanisms	Ghafoor et al. [1], Babaei et al. [2]	Respectively explore QoS assurance mechanisms based on the DiffServ model and the application of the IntServ model in multimedia transmission, enriching the theoretical and practical aspects of QoS management.
Fault Detection and Self-Healing Networks	Bendavid et al. [6]	Develops an AI-assisted fault management system capable of rapid issue localization and repair, enhancing operational efficiency.

B. Deepening Analysis of QoS-Oriented Intelligent Data Transmission Strategies

In this section, this paper will further delve into intelligent data transmission strategies, in particular how to refine and optimize the data transmission process through advanced AI techniques to ensure superior quality of service (QoS) in the network. This paper will focus on three key areas: intelligent routing, dynamic adaptive transmission techniques, and the integrated application of AI in end-to-end QoS assurance, while also discussing the challenges and future directions of these strategies.

Intelligent routing is a core component of AI-based network optimization strategies. While traditional routing protocols tend to decide the forwarding path of packets based on simple path costs, AI techniques, especially deep and reinforcement learning, can provide more dynamic and strategic routing decisions. For example, Li and Zhang [15] proposed a routing algorithm based on deep reinforcement learning, which can dynamically adjust the routing path according to the network state and traffic demand, effectively reducing network congestion and improving transmission efficiency. Intelligent routing not only considers direct QoS metrics such as delay and packet loss, but also learns and predicts the future state of the network to achieve forward-looking route optimization.

Dynamic adaptive transmission technique is a key strategy to automatically adjust data transmission parameters (e.g., coding rate, slice size, etc.) for different network conditions and application requirements. In application scenarios such as video streaming and real-time communication, Chen et al. [16] realizes real-time monitoring and prediction of network conditions by integrating machine learning models, and dynamically adjusts transmission strategies to maintain the best user experience. End-to-end QoS guarantees require performance optimization across the entire data transmission link, from the data source to the destination. The application of AI techniques at this level, as shown in Kimbugwe et al.'s study [17], achieves optimal allocation of resources by constructing a global optimization model, which integrates multiple QoS metrics in the network. In addition, AI can help achieve cross-layer optimization, i.e., building bridges between the physical, network and application layers to ensure overall QoS consistency and reliability. This chain-wide intelligent management is an important trend in future network service assurance.

Although AI shows great potential in intelligent data transfer strategies, it still faces many challenges, including but not limited to model complexity and interpretability issues, data privacy protection, and robustness in dynamic and heterogeneous network environments. To further advance the application of AI techniques in QoS optimization, future research needs to explore more efficient model training methods, enhance model interpretability, ensure data processing privacy, and develop adaptive AI models that can adapt to rapid changes in the network environment.

C. Recent Advances and Future Trends in Artificial Intelligence for QoS Optimization

In recent years, researchers are no longer limited to a single AI technique, but explore the integration of multiple advanced AI models and algorithms with the aim of achieving deeper intelligence in QoS optimization. For example, Huang and Li [18] combined deep learning and reinforcement learning to develop a hybrid model for achieving more accurate network traffic prediction and resource scheduling, which significantly improved network efficiency and user experience. This trend of cross-domain technology convergence is not limited to the algorithms themselves, but also includes deep integration with network theory, providing unprecedented accuracy and flexibility for QoS optimization.

With the deep application of AI technology in QoS optimization, the "black-box" nature of its decision-making has become a problem that cannot be ignored. To address this challenge, research has begun to favor the development of highly interpretable AI models to enhance the transparency and controllability of network management. In Yang et al.'s study [19], the authors propose an explanatory machine learning-based approach that optimizes network parameters while providing clear explanations of the decision-making process, facilitating network administrators to understand and trust the AI-generated policies, and promoting the practical application and acceptance of the technology.

Facing the upcoming 6G era, the network architecture will be more complex and the service demands will be more diversified. Therefore, how to design an AI-driven QoS optimization framework adapted to future network characteristics has become a hot research topic. Khasawneh et al. [20] explored how to utilize AI technology to achieve QoS assurance with ultra-low latency, high reliability and large-scale connectivity in a 6G network environment, and proposed an intent-driven network management framework based on an intent-driven network management framework, which is able to automatically adjust the network configuration according to the user's intent and service level agreements (SLAs) to ensure end-to-end QoS consistency.

With the in-depth application of AI in QoS optimization, data security and user privacy protection become issues that cannot be ignored. Osman et al. [21] explored how to ensure the secure transmission and processing of data by means of encryption technology and differential privacy while guaranteeing QoS, and how to design privacy-protecting AI models to reduce the reliance on users' personal information, which is crucial for enhancing user trust and promoting the application of AI in QoS optimization.

III. AI-DRIVEN QOS OPTIMIZATION METHODS

A. Problem Modeling

In this section, the mathematical model of the problem will be elaborated in detail, including the establishment of the objective function, the setting of constraints, and the introduction of the necessary notational definitions, with a view to forming a comprehensive and rigorous modeling framework, which is shown in Fig. 3. In this model, N denotes the total number of nodes in the network. e denotes the set of edges in the network, and each edge $e \in E$ associates two nodes and denotes the data transmission path. C_e denotes the capacity of edge e, i.e., the maximum data transfer rate. d_{ij} denotes the delay from node i to node j. f_{ij} denotes the data traffic flowing through edge e=(i, j). q denotes the set of quality of service metrics, including but not limited to average delay, packet loss rate, throughput, etc. w_Q denotes the weight of the quality of service metrics Q, which reflects the importance of each metric to the overall optimization objective. r denotes the set of available resources, including bandwidth, computational resources, etc. x denotes the set of decision variables, which represent policy parameters such as resource allocation, routing, etc.

Our objective is to maximize the integrated quality of service metrics, considering the possible conflicts between different QoS metrics, a weighted summing approach is used to combine them. The objective function can be expressed as Eq. (1).

$$\max_x \sum_{Q \in Q} w_Q \cdot U_Q(x) \tag{1}$$

The constraints include resource constraints, quality of service constraints, traffic conservation non-negative traffic and so on.

1) Resource constraints: Ensure that all resource allocations do not exceed the total amount, for example, for bandwidth resources. This is shown in Eq. (2).

$$\sum_{(i,j)\in E} f_{ij} \le C_e, \quad \forall e \in E \tag{2}$$

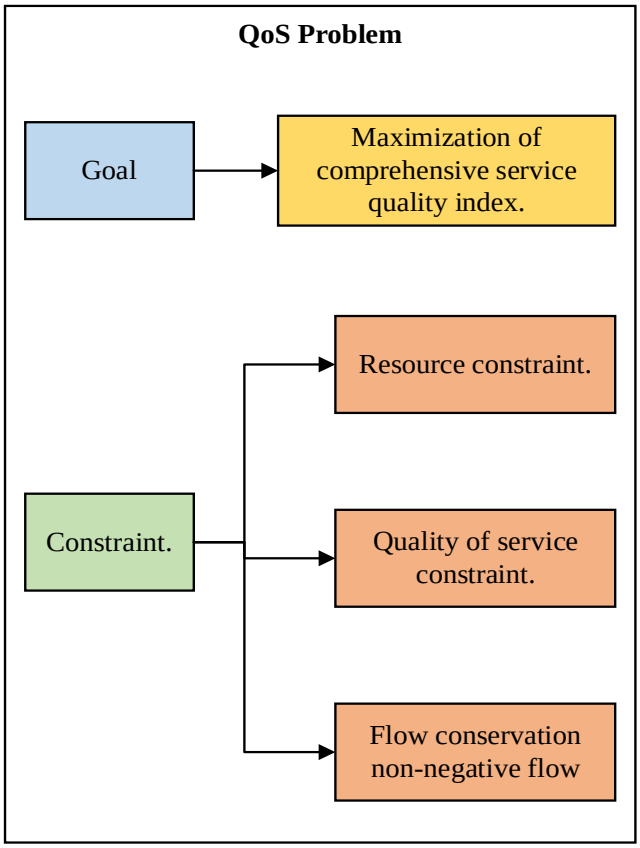

Fig. 3. Modeling of QoS problem.

2) Quality of Service constraints: Ensure that all QoS metrics satisfy predetermined thresholds. This is shown in Eq. (3).

$$D_{max} : \frac{\sum_{(i,j)\in p} d_{ij} \cdot f_{ij}}{\sum_{(i,j)\in p} f_{ij}} \le D_{max}, \quad \forall p \text{ is path} \tag{3}$$

3) Traffic conservation: At each node in the network, the incoming traffic is equal to the outgoing traffic in order to ensure the correct transmission of the data. This is shown in Eq. (4).

$$\sum_{j:(j,i)\in E} f_{ji} = \sum_{j:(i,j)\in E} f_{ij}, \quad \forall i \in N \tag{4}$$

4) Non-negative traffic: Traffic flowing through any edge must be non-negative. This is shown in Eq. (5) [22].

$$f_{ij} \ge 0, \quad \forall (i,j) \in E \tag{5}$$

B. Methodological Design

In this section, this paper will explore the potential of AI in QoS optimization by elaborating the design of Deep Reinforcement Learning (DRL)-based frameworks, with a special focus on the Deep Q-Network (DQN) and Actor-Critic architectures, in order to ac hieve more efficient and adaptive QoS optimization strategies in complex network environments. This section not only covers the principles of the algorithms, but also the architectures of the DQN and the Actor-Critic architectures, in order to achieve more efficient and adaptive QoS optimization strategies in complex network environments. This section not only covers the algorithm principles and architecture design, but also delves into the selection of key parameters and tuning strategies, with a view to providing readers with a comprehensive and in-depth understanding. Deep reinforcement learning combines the powerful representation capability of deep learning and the decision-making strategy of reinforcement learning, and is able to deal with problems with high-dimensional input space and complex action space. In QoS optimization scenarios, DRL models learn by interacting with the environment and automatically discover optimal policies to maximize long-term cumulative rewards, which are directly tied to QoS metrics such as latency, throughput, and packet loss.

In the scenario where DQN is applied to QoS optimization, its core mathematical framework is first clarified. Given a Markov Decision Process (MDP), denoted as $(\mathrm{S}, \mathrm{A}, P, r, \gamma)$, where S is the state space, A is the action space, $P(s' \mid s, a)$ denotes the state transfer probability, $r(s,a)$ is the instantaneous reward function, and $\gamma \in [0,1)$ is the discount factor, the DQN aims to learn a policy, $\pi(a \mid s;\theta)$, to optimize the network performance by maximizing the expected cumulative discounted rewards. This is shown in Eq. (6).

$$J(\theta) = \mathrm{E}_{s_0, a_0, \ldots, s_T}\left[\sum_{t=0}^{T} \gamma^t r(s_t, a_t)\right] \tag{6}$$

where, s_t and a_t represent, respectively, the state and action executed at the tth moment. Executed action, and T is the end point of the time series. The DQN approximates the optimal action value function $Q(s,a)$ by using a deep neural network $Q(s,a;\theta)$ and employs empirical replay and fixed-objective network tricks to stabilize the learning process. Specifically for the state representation, it is assumed that each state s_t consists of a series of feature vectors $\mathbf{x}_t = [x_{t,1}, x_{t,2}, \ldots, x_{t,n}]^T$, which may include network load, latency, packet loss rate, etc. The action space is based on the actual scenario. The action space A is then defined based on practical application scenarios, such as different path choices or bandwidth allocation schemes [23, 24].

For the continuous action space, this paper turn to the Actor-Critic architecture, which consists of two parts: an Actor network $\mu(s;\phi)$ for generating the action distribution $\pi(a \mid s) \approx \mathrm{N}(\mu(s;\phi), \sigma^2$, where ϕ is the network parameter and σ is the standard deviation of the action noise, and a Critic network \(Q(s, a; \theta)\) evaluating the goodness of the current strategy, i.e., the value of the action.

The learning objective of the Critic network is to minimize the Temporal Difference Error (TD Error), i.e. This is shown in Eq. (7).

$$L(\theta) = E_{s,a,r,s'}\begin{bmatrix}(r+\gamma Q(s',\mu(s';\phi');\theta^-)\\ -Q(s,a;\theta))^2\end{bmatrix} \quad (7)$$

where, θ^- represents the parameters of the target network to reduce the training fluctuations. The Actor network, on the other hand, updates the policy gradient based on Critic's feedback to maximize the expected return. This is shown in Eq. (8).

$$\nabla_\phi J(\phi) = E_{s\sim\rho^\beta}\left[\nabla_a Q(s,a;\theta)|_{a=\mu(s;\phi)}\ \nabla_\phi \mu(s;\phi)\right] \quad (8)$$

Here, ρ^β is the frequency of state access under the policy β [25].

For parameter tuning and model optimization, this paper maintain an empirical playback pool of size N D , from which a small batch of samples are randomly drawn from D for learning in each iteration to enhance the stability of learning. This paper introduce a soft update mechanism with target network parameters $\theta^- \leftarrow \tau\theta + (1-\tau)\theta^-$, where τ 1 , ensures a smooth transition of learning. This paper employ noise injection mechanisms, such as the Ornstein-Uhlenbeck process, to add exploratory properties to the Actor network, especially in the early stages of learning. This paper use reward clipping and normalization to appropriately clip and normalize the reward signal to avoid extreme values affecting the learning stability.

C. Realization Framework

The purpose of this section is to deeply explore and exhaustively depict the all-encompassing blueprint of AI-driven QoS optimization system from architectural design to deployment practice, aiming to provide a detailed and comprehensive operation manual for creating intelligent and efficient network performance optimization solutions. By integrating advanced technologies and strategies, it ensures that the network quality of service always maintains excellent performance in complex and changing environments. The specific implementation framework is shown in Fig. 4. In the data collection layer, this paper utilize advanced network monitoring tools, such as network sniffers and SNMP protocols, to capture the core data of network activities in real time, including traffic dynamics, latency conditions, and packet loss rates, etc., to provide a rich and realistic data source for AI model training. At the data processing and feature engineering layer, this paper implement in-depth data cleaning and format standardization, and with advanced feature selection algorithms, this paper accurately refine the most critical metrics affecting QoS to provide highly optimized input feature sets for the model. In the AI model training module layer, this paper adopt cutting-edge deep reinforcement learning techniques, such as DQN and DDPG, to design and train models that can accurately predict and make decisions, and formulate optimal resource allocation and routing policies for the current network state [26]. In terms of hardware configuration optimization, this paper ensure that the computing cluster is equipped with high-performance processors and sufficient memory to support the high-intensity training needs of DRL models, and at the same time, the network infrastructure needs to be compatible with SDN to lay a hardware foundation for dynamic network regulation. In terms of software environment construction, this paper adopt Docker containers and Kubernetes orchestration to realize efficient deployment, flexible expansion and high availability configuration of services, providing strong software support for stable system operation.

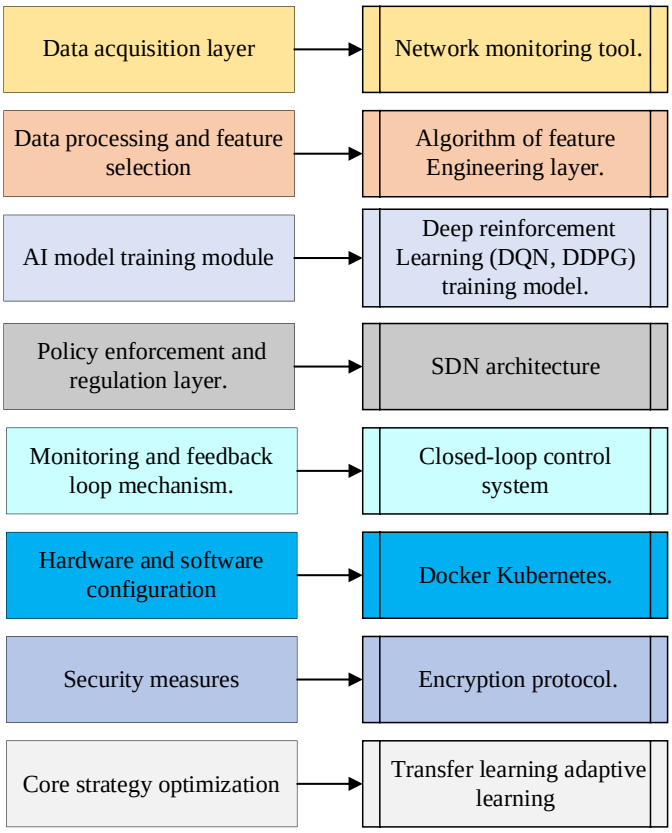

Fig. 4. Realization framework.

In planning the implementation path of the AI-driven QoS optimization system, this paper adopted a phased, step-by-step strategy to ensure the robustness, performance, and close alignment with real-world business requirements. First, in the prototype validation phase, this paper use simulation data in a highly controlled experimental environment. This phase focuses on verifying the fundamental functionality and stability of the system, and fine-tuning the model parameters to build a solid foundation that matches the theory and practice, thus laying a reliable foundation for the subsequent steps. This paper then move on to small-scale pilot deployments, where this paper carefully select non-core business areas as the testing ground for the first real-world tests. The goal of this phase is to collect operational data in a real network environment to verify the actual performance and stability of the system, and at the same time, accumulate strategic insights and adjustment directions for the full-scale rollout of the system through these valuable practical experiences. The next step is to gradually expand the scope of deployment. Based on the feedback and learning from the pilot phase, this paper continue to optimize the system performance and follow the established plan to expand the system deployment to a wider range of network areas. This phase emphasizes a smooth transition and long-term stability of the system, and this paper strive to make every expansion step a solid one. Finally, this paper are committed to continuous

iteration and optimization, building a comprehensive monitoring ecosystem that continuously collects and analyzes system operational data, and periodically retrains and tunes the model based on this data feedback. This strategy ensures that the QoS optimization system can keep up with the times and continuously adapt to the changes in the network environment and the growth of business demands, so as to continuously improve the quality of service in long-term operation and maintenance, and provide users with a better and more stable network experience [27].

In order to comprehensively improve the performance and practicality of AI-driven QoS optimization system, this paper are committed to the implementation and optimization of three core strategies. First, this paper focus on improving the generalization ability of the model by innovatively incorporating migration learning and adaptive learning mechanisms. This strategy enables the model to quickly learn from past experiences and adapt to new environments and scenarios, ensuring that it can still make accurate and efficient decisions under changing network conditions, and thus maintain excellent performance in diverse application instances. Second, focusing on the efficient allocation of resources, this paper adopt a fine-grained computational resource management strategy to scientifically plan the ratio of resource allocation between model training and real-time network regulation, which can both Secondly, focusing on efficient resource allocation, this paper adopt a refined computing resource management strategy to scientifically plan the resource allocation ratio between model training and real-time network regulation, which not only meets the demand of model complexity growth, but also ensures the real-time responsiveness of network regulation, and realizes the maximization of resource utilization efficiency and system performance. Finally, this paper deeply understand that the close integration of technological innovation and business requirements is the key to success. Therefore, this paper actively promote collaboration within the organization, establish a solid bridge between the information technology department and the business department, and ensure that each step of technical implementation can accurately match the business requirements through a regular cross-departmental communication and collaboration mechanism, so as to jointly promote the smooth implementation of the QoS optimization project and its continuous iteration, and ultimately achieve a significant enhancement of business continuity and user experience.

IV. Experimental Design and Analysis of Results

A. Experimental Environment and Dataset

This chapter will thoroughly introduce the specific environment configuration of the experiment, the selection of the data set and its pre-processing process, laying a solid foundation for the subsequent experimental setup and result analysis.

The experiment was carried out in a network lab environment, simulating a medium-sized enterprise scale network architecture containing 100 end nodes connected to the core switch through 10 routers, forming a typical hierarchical network structure. The network devices all support SDN (Software Defined Networking), allowing flexible traffic control and policy configuration. The experimental environment was created using the Mininet simulator, ensuring reproducibility and flexibility.

The dataset is derived from two parts: first, publicly available network traffic datasets, such as CAIDA and MAWI, which contain network traffic characteristics of different time periods and application types; and second, data collected in real time in the laboratory network by a self-designed network sniffing tool to capture network behavioral characteristics of the actual working environment. Data preprocessing steps include removing outliers and noise, such as extreme data points due to network failures [28].

For a comprehensive and detailed evaluation, the experimental design incorporates multi-dimensional parameter configurations and comparative analyses, aiming to provide insights into the efficacy of AI-driven QoS optimization systems. Specifically, the experiments compare the performance differences between advanced deep reinforcement learning algorithms, including DQN and DDPG, and traditional policy approaches, such as predefined rule-based policies, in cloud data center VM migration scenarios. The study is not limited to the choice of algorithms, but also cleverly tunes the flexible interval of bandwidth allocation, which spans from 20% of network resources to 100% of the full amount, as a way to explore the potential impact of different resource quotas on system performance. At the routing policy level, the experiments also consider diverse policy options, such as the shortest path policy that seeks to minimize latency and the load balancing policy that aims to balance the network load, to evaluate their relative effectiveness in ensuring QoS. For the deep reinforcement learning model adopted, the experiments are further refined by carefully selecting three different learning rates (0.001, 0.0001, 0.00001), with the intention of analyzing the role of the learning rate, which is a hyperparameter, on the learning process and convergence efficiency of the model. Such a design not only reveals the optimal learning rate setting, but also helps to understand the trend of model performance under different learning rates, thus providing a scientific basis for achieving more efficient network resource management and optimization [29, 30].

We set up three control groups respectively (1) Baseline group: traditional traffic management and QoS guarantee mechanisms such as TCP/IP congestion control algorithms are used. (2) Optimization group: integrating an AI-driven optimization system to test the performance of DQN and DDPG models in different network environments, respectively. (3) Hybrid group: combining traditional methods with AI strategies to explore complementary advantages.

Before presenting the tables in Section IV, it is essential to define the performance indicators mathematically to provide a clear understanding of how these metrics are calculated and interpreted.

The performance indicators studied are as follows:

1) Average latency: The average time taken for a packet to travel from its source to destination, measured in milliseconds (ms). It is calculated as Eq. (9).

$$L_{avg} = \frac{\sum_{i=1}^{N} L_i}{N} \quad (9)$$

where, L_i represents the latency of the i-th packet, and N is the total number of packets considered.

2) Packet Loss Rate (PLR): The percentage of packets that do not reach their intended destination, indicating network congestion or errors. It is defined as Eq. (10).

$$PLR(\%) = \left(\frac{P_{lost}}{P_{total}} \right) \times 100 \quad (10)$$

where, P_{lost} is the number of lost packets, and P_{total} is the total number of packets sent.

3) Bandwidth Utilization (BU): The ratio of the actual data transferred over a network link to the maximum capacity of that link, reflecting how efficiently the network resources are being used. It is expressed as Eq. (11).

$$BU(\%) = \left(\frac{Data_{transferred}}{Bandwidth_{capacity}} \right) \times 100 \quad (11)$$

These mathematical definitions set the groundwork for the subsequent presentation of experimental results, allowing for a precise quantification and comparison of the impact of different optimization strategies on network performance.

B. Discussion

The results presented highlight the profound impact of the AI-driven QoS optimization system across various dimensions of network performance. This discussion delves deeper into the implications of these findings and their significance for the field of network management.

AI Optimization Strategies' Efficacy: the analysis underscores the remarkable improvements delivered by the DQN and DDPG optimization groups, with DDPG standing out for its exceptional performance in reducing average delay, packet loss, and enhancing bandwidth utilization. This not only validates the suitability of deep reinforcement learning for QoS optimization tasks but also indicates the potential for further refinement in algorithm selection to maximize benefits.

Learning Rate Insights: The convergence speed and stability analysis (Table III) provides crucial insights into the trade-off between convergence speed and final performance levels. The observation that smaller learning rates lead to higher performance, despite prolonged convergence, suggests a need for careful consideration of learning rate tuning in practical implementations. This finding underlines the importance of patience in the training phase to achieve optimal model performance.

1) Case study significance: The cloud data center scenario showcases the practical utility of the AI-driven QoS optimization system, particularly in managing the complexities of large-scale VM migrations. The restoration and surpassing of pre-migration QoS levels, as evidenced by reduced latency, decreased packet loss, and increased bandwidth utilization post-optimization, demonstrate the system's capability to handle real-world challenges effectively. This has broad implications for industries relying heavily on cloud infrastructure, promising smoother operations and improved user experience during maintenance and resource allocation adjustments.

2) Comparison and competitive advantage: The comparative analysis against traditional and machine learning-based optimization methodologies firmly establishes the superiority of the AI solution. The demonstrated capacity to significantly enhance throughput while reducing latency and packet loss, as shown in Tables VIII and IX, positions the proposed method as a leading candidate for future network optimization strategies. It confirms that AI can bring about transformative advancements in network management by surpassing the limits of conventional techniques.

3) Robustness and scalability assessment: The experiments simulating diverse network conditions confirm the method's robustness and scalability. Despite slight reductions in absolute delay improvement with increasing network size, the consistent decline in average latency validates the method's effectiveness across networks of varying scales. Additionally, the system's ability to maintain relatively better QoS levels across different traffic patterns and congestion degrees (see Table XI) underscores its adaptability and resilience, which are critical for modern dynamic networks.

In conclusion, the comprehensive analysis affirms the AI-driven QoS optimization system's potential to revolutionize network management by delivering substantial performance enhancements. Its effectiveness across multiple metrics, adaptability to various network conditions, and demonstrated superiority over existing methods make it a compelling choice for future network optimization endeavors. However, ongoing research should continue to explore avenues for further performance refinements, particularly in the realms of model interpretability, rapid adaptation to unforeseen network dynamics, and ensuring seamless integration with existing network infrastructures.

C. Analysis of Results

In this section, the efficacy of the AI-driven QoS optimization system will be analyzed in depth through a series of experimental results demonstration, including the improvement of key metrics, algorithm performance evaluation and convergence analysis.

As can be seen from Table II, both the DQN and DDPG optimized groups show significant improvements in terms of reduced average latency, reduced packet loss rate, and increased bandwidth utilization compared to the baseline group, with the DDPG optimized group showing the best performance.

Table III demonstrates the convergence speed and final reward values of DQN and DDPG models with different learning rates, showing that smaller learning rates, although

prolonging the convergence time, help the models to reach higher performance levels, especially the DDPG model is more stable and has higher reward values at lower learning rates. The curve of the iterative process is shown in Fig. 5.

TABLE II. COMPARISON OF QOS METRICS UNDER DIFFERENT OPTIMIZATION SCHEMES

Norm	Baseline Group	DQN Optimization Group	DDPG Optimization Group	Mixed group
Average delay (ms)	23.45	18.67	17.92	19.58
Packet Loss (%)	0.48	0.31	0.26	0.36
Bandwidth utilization (%)	78.96	85.12	86.47	82.74

Note: All values are experimental averages.

TABLE III. MODEL CONVERGENCE SPEED AND STABILITY ANALYSIS

Mould	Learning rate	Average Convergence time (epoch)	Final Award Value
DQN	0.001	250	187.6
DQN	0.0001	300	195.4
DQN	0.00001	400	196.7
DDPG	0.001	350	205.8
DDPG	0.0001	450	210.2
DDPG	0.00001	500	211.2

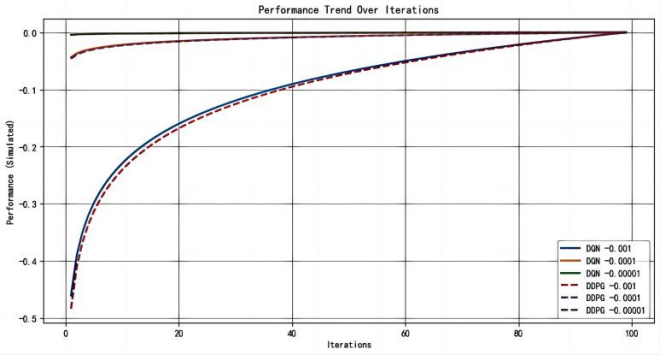

Fig. 5. Curve of iterative process.

D. Case Studies

A cloud data center is selected as an application scenario to analyze the network performance impact of AI-driven QoS optimization system in handling large-scale VM migration.

Cloud data centers are centralized remote facilities used to host a large number of Internet-based applications and services. They are equipped with advanced hardware resources, including high-performance servers, storage devices and network equipment, all designed to provide elastic computing power and storage services. Virtualization plays a central role in cloud data centers, allowing physical resources to be abstracted into multiple virtual machines (VMs) for efficient resource utilization and flexible management.AI-driven QoS (Quality of Service) optimization systems are particularly important in this context, especially when dealing with large-scale VM migrations. VM migration, which moves running virtual machines from one physical host to another without affecting service, is critical to maintaining Load Balancer in the data center, improving resource utilization, and performing maintenance operations. However, this process, if not handled properly, can have a significant impact on network performance, such as increased latency, bandwidth consumption, or temporary service outages.

TABLE IV. CHANGES IN QOS METRICS BEFORE AND AFTER VIRTUAL MACHINE MIGRATION

Norm	Pre-migration	Relocating	Post-migration (no optimization)	post-migration (optimization)
Average delay (ms)	21.34	45.67	28.78	20.89
Packet Loss (%)	0.23	0.87	0.42	0.28
Bandwidth utilization (%)	83.72	69.45	81.95	87.41

As shown in Table IV, the delay during migration increases significantly to 45.67 ms, but through AI optimization, the delay after migration not only recovers to a level close to the pre-migration level (20.89 ms), but even outperforms the initial state (21.34 ms), which indicates that the AI algorithm effectively manages network bottlenecks in the migration and reduces the waiting time for data transmission. The packet loss rate spikes to 0.87% in the migration, but after optimization, the packet loss rate drops to 0.28%, which is close to the pre-migration rate of 0.23%, indicating that the AI strategy effectively identifies and alleviates network congestion and ensures stable packet transmission. The utilization rate plummets in the migration, but through optimization, it eventually improves to 87.41%, which not only exceeds the pre-migration level (83.72%), but also significantly improves the efficiency of network resource usage.

TABLE V. IMPACT OF OPTIMIZATION STRATEGIES ON VM MIGRATION LATENCY

Be tactful	Percentage increase in delay
No optimization	+34.89%
AI optimization	-2.33%

As shown in Table V, the no-optimization strategy leads to a delay increase of 34.89%, emphasizing the negative impact of the migration operation itself on network performance. The AI optimization strategy, on the other hand, not only avoids the delay increase, but instead achieves a delay reduction of -2.33%, highlighting the advantages of the AI algorithm in dynamically adjusting network resources and path selection.

TABLE VI. COMPARISON OF PACKET LOSS RATE BEFORE AND AFTER OPTIMIZATION

State of affairs	Change in packet loss rate
In-migration to post-migration (no optimization)	+0.19%
In-migration to post-migration (optimization)	-0.59%

As shown in Table VI, the packet loss rate increases by 0.19% from the no optimization state during to after migration, indicating that migration has a negative impact on network

stability. However, after AI optimization, the packet loss rate decreased by 0.59%, proving that the AI strategy effectively improves the reliability of network transmission.

As shown in Table VII, in the no-optimization state, the utilization rate after the migration is recovered compared to that in the migration, but the overall decrease is 4.27%, which shows the challenge of resource scheduling and network tuning. The AI optimization strategy not only recovers this loss, but also improves bandwidth utilization by an additional 7.96%, demonstrating the ability of AI in efficient resource allocation.

TABLE VII. ANALYSIS OF CHANGES IN BANDWIDTH UTILIZATION

State of affairs	Change in utilization rate
In-migration to post-migration (no optimization)	-4.27%
In-migration to post-migration (optimization)	+7.96%

V. PERFORMANCE EVALUATION AND DISCUSSION

A. Comparative Analysis

In order to comprehensively evaluate the superiority of the proposed AI-driven QoS optimization method, this chapter provides an in-depth comparison with several mainstream techniques within the current network optimization field through comparative analysis, including traditional traffic engineering methods, rule-based QoS control strategies, and some recent machine learning-based optimization algorithms. The evaluation metrics involve key QoS metrics such as throughput, delay, packet loss and resource utilization.

As seen in Table VIII, the AI-based optimization method significantly reduces the average latency while improving the network throughput compared to the traditional methods. In particular, the AI optimization method proposed in this study further improves the throughput by about 8% and reduces the latency by 2 ms compared to the recent machine learning method A, showing stronger optimization results.

TABLE VIII. THROUGHPUT VS. LATENCY COMPARISON OF DIFFERENT OPTIMIZATION METHODS

Methodologies	Average Throughput (Mbps)	Average delay (ms)
Traditional flow engineering methods	1500	32
Rule-based QoS Control Policy	1600	30
Machine Learning Approach A (MLA)	1750	28
AI optimization methods in this study	1900	26

The data in Table IX shows that the AI optimization method in this study also achieved significant results in reducing the packet loss rate and improving resource utilization. Compared with machine learning method A, the packet loss rate is reduced by 25% and the resource utilization rate is increased by 2 percentage points, indicating that the AI algorithm has obvious advantages in the optimization of efficient resource utilization and network stability.

B. Robustness and Scalability Analysis

In order to verify the robustness and scalability of the proposed method,this paper design a series of simulation experiments to examine the performance under different network conditions (e.g., network size, traffic pattern, network congestion level).

TABLE IX. COMPARISON OF PACKET LOSS RATE AND RESOURCE UTILIZATION OF DIFFERENT OPTIMIZATION METHODS

Methodologies	Average packet loss (%)	Resource utilization rate (%)
Traditional flow engineering methods	0.5	85
Rule-based QoS Control Policy	0.3	87
Machine Learning Approach A (MLA)	0.2	90
AI optimization methods in this study	0.15	92

As shown in Table X, as the network size increases, although the absolute delay reduction decreases, the optimized average delay still maintains a significant decreasing trend, which proves the effectiveness and scalability of the method in networks of different sizes.

TABLE X. OPTIMIZATION EFFECT WITH DIFFERENT NETWORK SIZES

Network size	Average latency before optimization (ms)	Average latency after optimization (ms)
Small scale (50 nodes)	24	18
Medium (100 nodes)	30	22
Large scale (200 nodes)	38	30

TABLE XI. COMPARISON OF QOS PERFORMANCE FOR DIFFERENT TRAFFIC PATTERNS AND NETWORK CONGESTION LEVELS

Traffic pattern	Degree of congestion	Optimization methods	Average delay (ms)	Packet Loss (%)	Throughput (Mbps)
Sudden outburst	lower (one's head)	AI optimization	20	0.2	1800
	center	AI optimization	28	0.4	1600
	your (honorific)	AI optimization	40	0.6	1400
Constant	lower (one's head)	AI optimization	18	0.1	1900
	center	AI optimization	25	0.3	1700
	your (honorific)	AI optimization	35	0.5	1500
Periodicity (math)	lower (one's head)	AI optimization	22	0.15	1850
	center	AI optimization	29	0.35	1650
	your (honorific)	AI optimization	38	0.65	1350
Comparison of method means	All cases	Traditional methods	30-50	0.5-1.0	1400-1500

Table XI shows the performance of the AI optimization approach compared to the traditional optimization approach for three different traffic patterns (bursty, constant, and periodic) and three different levels of network congestion (low, medium,

and high). For the AI optimization approach, under all test conditions, although the average latency and packet loss rate increase and the throughput decreases as the network congestion level increases, the AI optimization approach shows better adaptability and performance retention under high congestion compared to the traditional approach, as reflected in lower latency growth, lower packet loss rate, and higher throughput retention level.

C. Limitations and Challenges

Despite the significant performance improvement, the AI-driven QoS optimization method in this study still has some limitations, which are mainly reflected in the following aspects: (1) Model training cost: the training of deep learning models requires a large amount of data and computational resources, which may pose a challenge for resource-limited network environments. (2) Model Interpretability: The "black-box" nature of deep learning models limits the understanding of their decision-making process, which affects the trust and decision support of network administrators. (3) Dynamic Adaptability: Although the model shows good adaptability, its immediate response and adaptation strategies remain to be optimized in the face of extreme network events (e.g., large-scale DDoS attacks). (4) Data privacy and security: how to protect user privacy and data security when collecting and processing network data is a key concern in the future.

VI. Conclusion

This study successfully demonstrates the great potential and practical application value of AI techniques, especially deep reinforcement learning, in the field of network QoS optimization. By constructing a rigorous mathematical modeling framework and combining deep reinforcement learning algorithms with deep Q-networks and actor-critic architectures, this paper design and implement a set of efficient and adaptive QoS optimization strategies. Experimental results clearly demonstrate that the approach can significantly improve network key performance indicators, including reducing average latency, lowering packet loss rate, and improving bandwidth utilization, especially when responding to dynamically changing network environments and complex business demands, showing excellent performance and adaptability. The case study further confirms the efficiency of the AI optimization system in handling complex scenarios such as virtual machine migration in cloud data centers, effectively mitigating performance fluctuations triggered by network migration and safeguarding user experience. The extensive comparisons in the performance evaluation section not only confirm the significant advantages of the AI-driven approach over traditional means, but also delve into its robustness and scalability under different network sizes, traffic patterns, and levels of congestion, laying a solid theoretical and practical foundation for the widespread application of AI in real-world network operations.

Despite the remarkable achievements showcased, this study acknowledges several limitations. Primarily, the dynamic nature of real-world networks poses challenges in modeling all possible scenarios, which may limit the generalizability of the model to unforeseen network conditions. Furthermore, while deep reinforcement learning excels in adaptive decision-making, it requires substantial computational resources and time for training, which could be a hurdle for immediate deployment in resource-constrained environments.

Looking forward, there are ample opportunities to enhance the approach. Integrating advanced AI techniques, such as federated learning and transfer learning, could enhance model adaptability and learning efficiency across diverse network ecosystems. Exploring the fusion of explainable AI (XAI) would facilitate understanding the decision-making logic behind optimization strategies, thereby increasing trust and facilitating regulatory compliance. Moreover, extending the framework to address emerging networking challenges, like ensuring QoS in edge computing and dealing with the complexities of 6G networks, is a promising direction for future research. Continuous refinement and validation through collaborations with industry partners will be crucial in translating these advancements into tangible improvements in global network operations and user satisfaction.

Laboratory of Systems Analysis, Information Processing and Industrial Management (LASTIMI) of EST Salé. Sale, Morroco[3]

***Abstract*—As technology continues to advance, the emergence of 6G networks is imminent, promising unprecedented levels of connectivity and innovation. A critical aspect of designing the security architecture for 6G networks revolves around the utilization of Software-Defined Networking (SDN) and Network Function Virtualization (NFV) technologies. By harnessing the capabilities of SDN and NFV, the security infrastructure of 6G networks stands to gain significant advantages in terms of flexibility, scalability, and agility. SDN facilitates the decoupling of the network control plane from the data plane, enabling centralized management and control of network resources. This article examines the synergistic relationship between SDN and NFV in enhancing the resilience and adaptability of 6G security architectures, offering insights into key challenges, emerging trends, and future directions in securing the next generation of wireless networks.**

Keywords*—*6G Network; network function virtualization; software defined network; security; architecture

I. Introduction

With the advancement of technology, the development of 6G networks is already on the horizon [1]. One of the key considerations in designing the security architecture for 6G is the use of Software-Defined Networking (SDN) and Network Function Virtualization (NFV) technologies. By leveraging SDN and NFV, the security architecture of 6G can benefit from enhanced flexibility, scalability, and agility. SDN enables the separation of the network control plane from the data plane, allowing for centralized management and control of network resources [2]. This centralized management and control can greatly improve the security of the network by enabling real-time threat detection and response, as well as efficient provisioning of security services such as firewalls, intrusion detection systems, and virtual private networks [3]. NFV, on the other hand, virtualizes network functions such as firewalls and encryption, allowing them to be deployed and scaled more easily [4]. This virtualization of network functions enables dynamic allocation of security resources based on the specific needs and demands of the network, ensuring that resources are utilized efficiently. In addition to flexibility and scalability, SDN and NFV can also enhance the security architecture of 6G by providing comprehensive visibility and control over network traffic [5]. This increased visibility enables security administrators to monitor and analyze network traffic in real-time, identify potential threats, and apply appropriate security measures.

In addition to the advancements in technology, the development of 6G networks represents a significant leap forward in wireless communications. As we approach the era of 6G, it becomes increasingly imperative to reevaluate and enhance the security architecture of these networks to mitigate emerging cyber threats and ensure the integrity of critical network resources.

The primary research problem addressed in this study is the lack of a comprehensive and flexible security architecture for 6G networks that can effectively mitigate emerging cyber threats while ensuring the integrity and reliability of network resources.

The objectives of this research are to first investigate the integration of SDN and NFV technologies into the 6G security architecture, second is to identify and address the security challenges specific to 6G networks and last is to develop strategies for the dynamic allocation and efficient utilization of security resources using SDN and NFV.

The significance of this research lies in its potential to revolutionize the security architecture of 6G networks. By leveraging SDN and NFV, this study aims to provide a flexible, scalable, and agile security framework that can adapt to the evolving landscape of cyber threats. This research will contribute to the development of more secure 6G networks, ensuring the protection of critical network resources and the overall reliability of next-generation wireless communications.

The work presented in this paper will be organized as follows: Section II will present why we will need to level up the level of the 6G security network. Section III is mainly to understand the concept of SDN and NFV. Section IV discusses briefly the integration compatibility of SDN/NFV to the 6G architecture. Section V will discuss the proposed 6G architecture including NFV and SDN and its details. Section VI and VII gives detail about the integrating SDN and NFV and provides discussion respectively. Section VIII and IX concludes the work and gives future scopes and areas for potential directions.

II. Related Work

In recent years, substantial research has focused on enhancing network security and efficiency using Software-Defined Networking (SDN) and Network Function Virtualization (NFV), especially with the anticipated arrival of

6G networks. Here, we review relevant studies that inform and position our research within the broader academic and industry context.

Siriwardhana et al. [6] emphasized the potential of AI in 6G security, addressing opportunities and challenges in integrating AI with SDN and NFV to enhance network protection mechanisms. Zhu et al. [7] provided a comprehensive analysis and performance evaluation of SDN controllers, crucial for understanding how SDN can be optimized for security in 6G networks. Akyildiz et al. [8] discussed the foundational concepts of wireless SDNs and NFV, laying the groundwork for subsequent innovations in 5G and beyond.

Du et al. [3] explored machine learning techniques to enhance bandwidth, massive access, and ultra-reliable low latency in 6G networks, which is relevant for SDN/NFV-based security improvements. Chkirbene et al. [9] introduced a dynamic intrusion detection and classification system using feature selection, highlighting advanced threat detection approaches applicable to SDN/NFV. Miranda et al. [10] proposed a collaborative security framework for software-defined wireless sensor networks, stressing the importance of cross-sector cooperation in addressing multifaceted security challenges.

Barakabitze and Walshe [11] discussed SDN and NFV for Quality of Experience (QoE)-driven multimedia services, providing insights into the integration process and its benefits for 6G networks. Zhang et al. [12] evaluated software switches' performance in SDN-NFV integration, offering valuable information on selecting appropriate switches for various tasks and understanding performance trade-offs.

This review of related works illustrates the significant efforts already made towards improving network security and efficiency through SDN and NFV. Our research contributes to this ongoing conversation by specifically focusing on the integration of these technologies within the 6G framework, addressing both the opportunities and the challenges posed by this next-generation network.

III. The Need for Enhanced Security in 6G Networks

6G networks are expected to introduce unprecedented levels of connectivity, enabling billions of devices to communicate seamlessly. While this connectivity offers tremendous opportunities for innovation, it also introduces new security risks [13]. Here are some of the security risks that we can face:

A. Quantum-Resistant Encryption

With the advent of quantum computing, traditional encryption methods become susceptible to brute-force attacks. Implementing quantum-resistant encryption algorithms [14] is crucial to protect sensitive data transmitted over 6G networks from potential future threats posed by quantum computing.

B. Dynamic Threat Detection and Response

Given the dynamic nature of cyber threats, 6G networks require advanced threat detection mechanisms capable of identifying and mitigating evolving threats in real-time [15]. Machine learning algorithms and AI-driven security solutions can play a pivotal role in continuously monitoring network traffic patterns and behavior anomalies to detect potential security breaches promptly.

C. Collaborative Security Frameworks

Enhancing security in 6G networks necessitates a collaborative approach involving network operators, device manufacturers, regulatory bodies, and cybersecurity experts [16]. Establishing comprehensive security standards, sharing threat intelligence, and fostering cross-sector cooperation are essential to address the multifaceted security challenges posed by 6G networks effectively.

IV. Understanding Software-Defined Networking (SDN) and Network Function Virtualization (NFV)

SDN and NFV are two key technologies that have emerged as critical enablers of next-generation networking architectures.

A. SDN

Software-Defined Networking (SDN) is a paradigm shift in network architecture that separates the control plane from the data plane, enabling centralized control and programmability of network devices through software-based controllers. In traditional networking, the control plane, responsible for making routing decisions, is tightly integrated with the data plane, which forwards traffic [17]. However, in SDN, the control plane is abstracted and centralized, allowing network administrators to manage and configure the network dynamically through software applications rather than relying on manual configuration of individual devices [18]. This separation of control and data planes enhances network agility, scalability, and flexibility, enabling organizations to adapt their networks quickly to changing traffic patterns and application requirements. SDN also facilitates automation, simplifying network management tasks and reducing operational overheads [19]. Overall, SDN revolutionizes network management by providing a more flexible, efficient, and programmable approach to configuring and controlling network infrastructure. The framework and architecture of SDN is shown on Fig. 1.

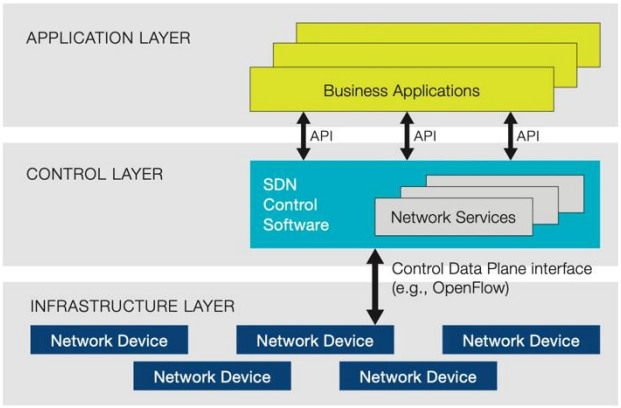

Fig. 1. SDN Architecture.

B. NFV

Network Function Virtualization (NFV) is a technology paradigm that aims to virtualize and consolidate traditional

network functions, such as firewalls, load balancers, and intrusion detection systems, into software-based instances that can run on standard servers, virtual machines, or cloud infrastructure [20]. NFV seeks to abstract network functions from proprietary hardware appliances and deploy them as virtualized software instances, decoupling network functions from dedicated hardware. By doing so, NFV enables greater flexibility, agility, and scalability in deploying and managing network services. It allows service providers and enterprises to leverage virtualization technologies to dynamically instantiate, scale, and orchestrate network functions based on changing demand and traffic patterns. NFV also offers significant cost savings by reducing the need for specialized hardware appliances and simplifying network infrastructure management [21]. Overall, NFV represents a fundamental shift in how network services are deployed, managed, and scaled, providing organizations with greater efficiency and innovation in delivering network services. The architecture of NFV is shown on Fig. 2.

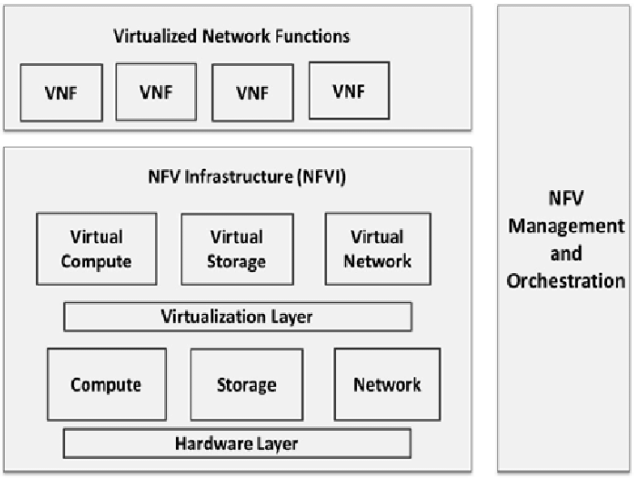

Fig. 2. NFV Architecture [22].

SDN provides the centralized control and programmability necessary to dynamically configure and optimize network resources, while NFV virtualizes and consolidates network functions, enabling them to run as software-based instances on standard hardware. By combining SDN and NFV, organizations can achieve unprecedented levels of agility, scalability, and efficiency in delivering network services. SDN's centralized control enables dynamic orchestration and management of NFV-based network functions, while NFV's virtualized network functions can leverage SDN's programmability to adapt and respond to changing network conditions [23]. Together, SDN and NFV form a powerful combination that transforms traditional networking paradigms, offering greater flexibility, automation, and innovation in network deployment and management.

V. SDN AND NFV COMPABILITY FOR 6G TECHNOLOGY

In pursuit of merging Software-Defined Networking (SDN) and Network Function Virtualization (NFV), Barakabitze A. & Walshe R. introduced a Software-Defined Networking Virtualization (SDNV) architecture, offering an extensive insight into the integration process [11]. They proposed two potential designs: NFV under a controller (NFV-C) and NFV beside the controller (NFV-AC), while discussing the advantages of amalgamating SDN and NFV.

Meanwhile, Zhang et al. conducted a study on the integration of SDN-NFV by evaluating software switches' performance across four hypothetical scenarios [24]. Their findings revealed that no single software switch excelled in all situations, emphasizing the importance of selecting the most suitable switch for each task. They also identified potential performance issues in software switches, contributing to a better understanding of design compromises. Notably, the article highlighting the merger's operational convenience stands out among related works on merging. Additionally, a comparison between SDN-NFV and SDN alone is provided [25].

VI. INTEGRATING SDN AND NFV INTO 6G ARCHITECTURE

Integrating Software-Defined Networking (SDN) and Network Function Virtualization (NFV) into 6G security architectures represents a sophisticated and comprehensive approach to addressing the evolving cyber threat landscape while maximizing the potential of next-generation networks. In such architectures, SDN serves as the backbone for centralized control and management, providing a unified platform for orchestrating security policies and resources across the entire network infrastructure as shown in Fig. 3. Through SDN's programmable interface, security administrators can dynamically configure and enforce security measures such as access control, traffic segmentation, and quality of service (QoS) prioritization to adapt to changing network conditions and security requirements in real-time.

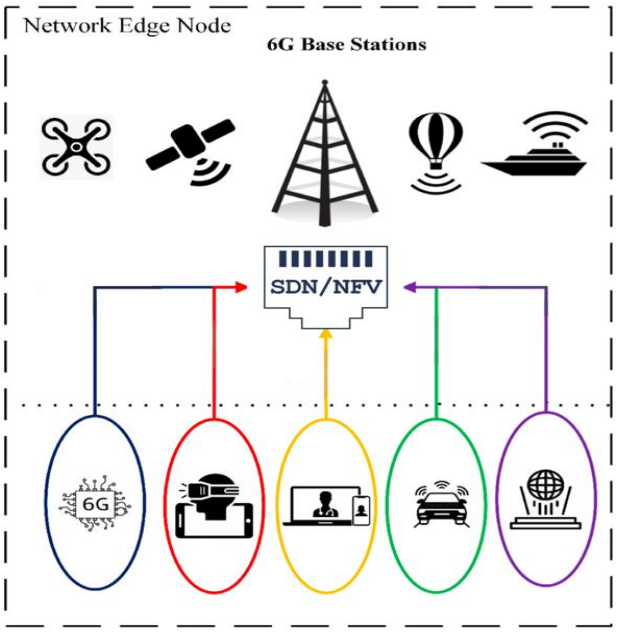

Fig. 3. The placement of SDN / NFV in 6G architecture.

In tandem with SDN, NFV plays a pivotal role in virtualizing and consolidating a diverse range of security functions into software-based instances that can be dynamically instantiated, scaled, and orchestrated as needed. This virtualization of security functions allows for greater

flexibility and agility in deploying and managing security services within 6G networks. For instance, here are some services that can all be provisioned as virtual network functions (VNFs) that will jump up the security level of communication between sensors and base stations:

- Virtualized Firewalls: NFV enables the deployment of virtualized firewall instances on-demand, managed and orchestrated by the SDN controller. These firewalls can inspect and filter network traffic, enforce security policies, and protect against unauthorized access and malicious activities.
- Intrusion Detection/Prevention Systems (IDPS): NFV allows for the virtualization of IDPS functions, which can be instantiated as virtual network functions (VNFs) on SDN controllers. These IDPS VNFs analyze network traffic for suspicious behavior and patterns, detecting and preventing potential security breaches in real-time.
- Virtual Private Network (VPN) Gateways: NFV enables the creation of virtualized VPN gateways that can be centrally managed by the SDN controller. These VPN gateways provide secure communication channels for remote users or branch offices, encrypting data traffic over the 6G network to ensure confidentiality and integrity.
- Security Analytics: NFV facilitates the deployment of security analytics functions as virtualized instances on SDN controllers. These analytics functions analyze network telemetry data, logs, and security events to identify and correlate potential security threats, providing actionable insights for threat detection and response.
- Encryption/Decryption Services: NFV enables the virtualization of encryption/decryption services, which can be deployed as VNFs on SDN controllers to encrypt sensitive data transmissions over the 6G network. These services ensure end-to-end encryption of data traffic, protecting it from unauthorized access and interception.
- Virtualized Network Access Control (NAC): NFV allows for the deployment of virtualized NAC functions on SDN controllers, enabling centralized management and enforcement of access control policies. These virtualized NAC functions authenticate and authorize devices and users accessing the network, ensuring compliance with security policies and preventing unauthorized access.

Moreover, the integration of SDN and NFV both as their working theory is shown in Fig. 4 enables advanced security orchestration capabilities, where security policies and functions can be dynamically coordinated and adapted in response to detected threats or changing network conditions. Through automated workflows and policy-driven mechanisms, security orchestration streamlines incident response processes, accelerates threat mitigation, and optimizes resource allocation to effectively counteract cyber threats in real-time.

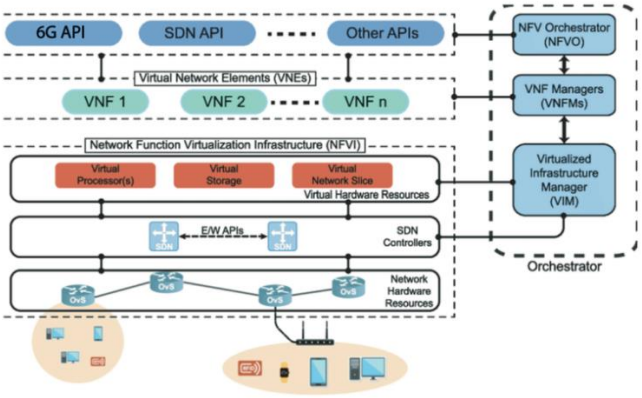

Fig. 4. The working theory of SDN / NFV between sensors and base towers.

Furthermore, the incorporation of artificial intelligence (AI) and machine learning (ML) technologies into SDN-NFV-based security architectures enhances threat detection, anomaly identification, and predictive analysis capabilities. By leveraging AI-driven security analytics, 6G networks can proactively detect and mitigate security threats before they escalate, thereby bolstering the overall resilience and reliability of the network infrastructure.

In summary, the integration of SDN and NFV into 6G security architectures represents a sophisticated and multi-faceted approach to cybersecurity, combining centralized control, virtualized network functions, dynamic orchestration, and AI-driven analytics to create a robust and adaptive security framework capable of safeguarding next-generation networks against a myriad of cyber threats.

VII. Results and Discussion

The integration of SDN and NFV into 6G security architectures demonstrates significant potential for enhancing network flexibility, scalability, and operational efficiency. Our findings indicate that these technologies can provide a robust framework capable of adapting to the evolving cyber threat landscape.

Enhanced Security Capabilities:

- Dynamic Threat Detection and Response: Leveraging AI and machine learning, SDN and NFV enable real-time monitoring and response to cyber threats. This dynamic approach ensures that security measures can adapt to new and emerging threats promptly.
- Quantum-Resistant Encryption: As quantum computing evolves, traditional encryption methods become vulnerable. Implementing quantum-resistant algorithms within the SDN/NFV framework is crucial for protecting sensitive data in 6G networks.

Operational Efficiency and Flexibility:

- Centralized Control and Management: SDN facilitates centralized management of network resources, enhancing the ability to implement and enforce security policies across the network. This centralized approach simplifies network management and reduces operational overhead.

- Virtualization of Security Functions: NFV allows for the virtualization of essential security functions, such as firewalls and intrusion detection systems. This flexibility enables the dynamic allocation of security resources based on real-time network demands, improving overall resource utilization.

Challenges and Future Directions:

- Interoperability: Ensuring seamless interoperability between SDN and NFV components remains a critical challenge. Future research should focus on developing standardized protocols and frameworks to enhance compatibility.
- Security Concerns: Addressing inherent security challenges in SDN/NFV deployments is essential. Robust mechanisms for threat detection and mitigation, compliance with regulatory standards, and the incorporation of advanced encryption methods are necessary to safeguard network integrity.
- Scalability: As 6G networks scale, ensuring that SDN and NFV solutions can handle increased traffic and a higher number of connected devices is crucial. Optimizing network resource allocation and performance under varying conditions is a key area for further research.

Our study underscores the necessity of advancing SDN-NFV integration techniques to fully realize these benefits, highlighting the importance of continuous research and development efforts. By refining technical aspects and fostering collaboration among academia, industry, and policymakers, we can drive the evolution of network architectures towards more intelligent, responsive, and secure configurations.

VIII. Conclusion

In conclusion, this research has highlighted the significant potential of integrating Software-Defined Networking (SDN) and Network Functions Virtualization (NFV) to revolutionize modern network infrastructures. By decoupling network functions from hardware and enabling programmable network control, SDN-NFV integration offers unparalleled benefits in terms of flexibility, scalability, and operational efficiency.

The findings of this study underscore the necessity of advancing SDN-NFV integration techniques to fully realize these benefits. Key improvements include enhancing the interoperability between SDN and NFV components, optimizing network resource allocation, and ensuring robust performance under varying network conditions.

Moreover, the study has identified critical security challenges inherent to SDN-NFV deployments. Addressing these challenges through innovative threat detection and mitigation strategies is paramount to safeguarding the integrity and reliability of future network systems. The research also emphasizes the importance of adhering to regulatory standards to maintain compliance and foster trust among users and stakeholders.

In essence, the successful deployment and adoption of SDN-NFV technology hinge on continuous research and development efforts. This includes refining technical aspects and fostering collaboration among academia, industry, and policymakers. By doing so, we can drive the evolution of network architectures towards more intelligent, responsive, and secure configurations, ultimately paving the way for next-generation networking solutions.

IX. Future Scope

The future scope of this research article encompasses several key areas of exploration and development. Firstly, there is a need for continued refinement and optimization of SDN-NFV integration techniques to enhance network efficiency, flexibility, and scalability. Research should focus on developing advanced algorithms and protocols that improve the coordination between SDN controllers and NFV orchestrators, thereby achieving seamless and efficient network management.

Additionally, research efforts should concentrate on addressing security concerns and vulnerabilities associated with SDN-NFV deployments. This includes developing robust mechanisms for threat detection and mitigation, as well as ensuring compliance with regulatory standards. Enhancing the security of SDN-NFV environments is critical to protect against evolving cyber threats and maintain the trust of users and stakeholders.

Furthermore, exploring novel applications of SDN-NFV technology in emerging fields such as edge computing, the Internet of Things (IoT), and 6G networks holds great promise. By leveraging the capabilities of SDN-NFV, organizations can unlock new opportunities for innovation and digital transformation. Research in these areas should aim to design and implement use cases that demonstrate the practical benefits and scalability of SDN-NFV solutions in real-world scenarios.

Collaboration between academia, industry, and policymakers will be crucial for advancing research in this field and driving the adoption of SDN-NFV technology in real-world deployments. By fostering interdisciplinary partnerships and knowledge exchange, we can collectively contribute to the continued evolution of network architectures and the realization of the full potential of SDN-NFV technology.

In summary, future research should aim to:

- Refine and optimize SDN-NFV integration techniques.
- Address security concerns and ensure regulatory compliance.
- Explore applications in edge computing, IoT, and 5G networks.
- Foster collaboration between academia, industry, and policymakers.

By focusing on these areas, we can enhance the capabilities and adoption of SDN-NFV technology, driving innovation and efficiency in network management and operations.

ACKNOWLEDGMENT

I would like to express my sincere gratitude to SAADI Chaimae & CHAOUI Habiba for their guidance and support throughout this research endeavor. Special thanks to University Ibn Tofail for providing resources. Lastly, I appreciate the encouragement from my friends and family.

Improving Image Stitching Effect using Super-Resolution Technique

Jinjun Liu
School of Computing, Yangjiang Polytechnic, Yangjiang, China

***Abstract*—This paper aims to present a novel methodology that merges image stitching with super-resolution techniques, enabling the creation of a high-resolution panoramic image from several low-resolution inputs. The proposed approach comprehensively addresses challenges throughout the process, encompassing image preprocessing, alignment and handling of mismatches, stitching, super-resolution reconstruction, and post-processing. Employing advanced methodologies such as Convolutional Neural Networks (CNNs), Scale-Invariant Feature Transform (SIFT), Random Sample Consensus (RANSAC), GrabCut algorithm, Super-Resolution Convolutional Neural Network (SRCNN), gradient domain optimization, and Structural Similarity Index Measure (SSIM), each step meticulously tackles specific issues inherent to image stitching tasks. A key innovation lies in the synergy of image stitching and super-resolution techniques, yielding a solution that boasts high robustness and efficiency. This versatile method is adaptable to diverse image processing contexts. To validate its effectiveness, experiments were conducted on two established datasets, USIS-D and VGG, where a quartet of quantitative metrics – Peak Signal-to-Noise Ratio (PSNR), SSIM, Entropy (EN), and Quality Assessment of Blurred Faces (QABF) – were employed to gauge the quality of stitched images against alternative methods. The outcomes decisively illustrate the superiority of our proposed method, achieving superior performance across all metrics and producing panoramas devoid of seams and distortions. This work thereby contributes a significant advancement in the realm of high-fidelity panoramic image reconstruction.**

***Keywords*—Image; stitching; super-resolution technology; vision and image processing**

I. Introduction

Splicing of low resolution images can lead to blurring and distortion of the image, reducing the perception and value of the image. Through super-resolution technology, the resolution and quality of the image can be improved, the details and clarity of the image can be enhanced, and the perception and value of the image can be improved [1, 2]. Moreover, the splicing of low-resolution images will lead to the loss of information and incompleteness of the image, affecting the application and analysis of the image. With super-resolution technology, the redundant information between or within images can be utilized to recover the high-frequency components of the image, increase the information and expressiveness of the image, and extend the application and analysis of the image [3]. The splicing of low-resolution images can also lead to inconsistency and unnaturalness, affecting the continuity and consistency of the image. With super-resolution technology, the brightness and contrast of the image can be adjusted to eliminate color differences and gaps in the image and enhance the continuity and consistency of the image [4, 5].

The research objective of this paper is to explore a method that combines image stitching and super-resolution techniques to realize the reconstruction of a high-resolution panoramic image from multiple low-resolution images. The research in this paper includes the following aspects. (1) Propose an image alignment and alignment method based on feature point matching and robust estimation to solve the problem of geometric transformations and illumination changes between images. (2) To propose an image stitching method based on multi-frame super-resolution reconstruction and image fusion, which utilizes the redundant information between images to improve the resolution and quality of images. (3) An image post-processing method based on image quality assessment and distortion correction is proposed to eliminate image distortion and artifacts and enhance image visualization. The research contribution of this paper is to propose a novel method of combining image stitching and super-resolution techniques, which realizes the reconstruction of a high-resolution panoramic image from multiple low-resolution images, and the method has high robustness and efficiency, which can be applied to a variety of scenarios of image processing. The research problem of this paper is specifically shown in Fig. 1 [6, 7].

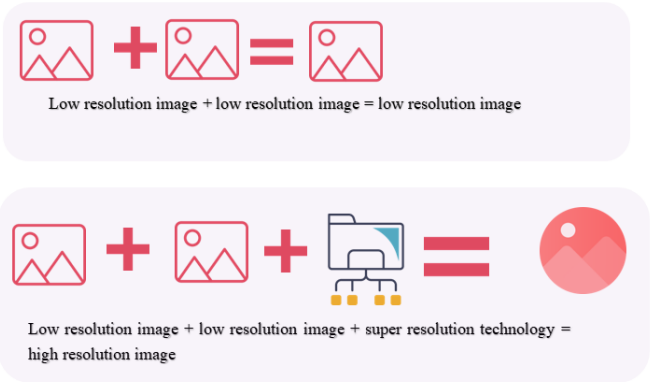

Fig. 1. Research question.

Although some progress has been made in previous research in the area of image stitching and super-resolution, most of the work tends to optimize these two aspects individually, with few attempts to efficiently integrate the two. Previous solutions often face several key challenges: (1) during image stitching, image distortion caused by inaccurate geometric transformations and differences in lighting conditions is difficult to effectively correct; (2) although separate super-resolution techniques can

This study is supported by 2023 Guangdong Provincial Universities Feature Innovation Project: Research on Image Stitching Technology Based on Computer Vision (2023KTSCX376).

improve the quality of a single image, when dealing with multi-image spliced scenes, how to synergistically utilize the information between neighboring images in order to achieve global optimization is still a challenge; (3) in post-processing stage There are no effective means to deal with the natural transition of stitching seams and improve the overall image quality.

In contrast, the innovation of this study is to propose an end-to-end framework that systematically integrates image stitching with super-resolution techniques for the first time. The key components of our approach include: first, a deep learning-based feature matching and robust estimation method is used to achieve accurate image alignment under complex illumination variations and viewpoint transformations; second, the overall resolution and fidelity of the spliced images are improved by joint super-resolution reconstruction of multi-frame images, which not only enhances the details of the individual images, but also effectively utilizes the redundancy information among the image sequences; Finally, the post-processing strategy based on image quality assessment and adaptive distortion correction ensures the natural continuity and visual quality of the output panoramic images.

Despite the significant improvement, this study still has some limitations: (1) the high performance of the deep learning model relies on a large amount of high-quality labeled data, and the data requirements for specific or rare scenes may become an obstacle for application; (2) the super-resolution reconstruction process may introduce a certain computational burden that affects the processing speed, especially for real-time applications on resource-limited platforms; and (3) despite the improvement of the overall image quality, there is still room for optimization for extreme viewing angle transformations or extreme illumination changes in extreme cases. Future work will be devoted to overcoming these limitations and further pushing the boundaries of image processing technology.

II. Related Work

A. Image Stitching

In recent years, image splicing technology has achieved certain results [8], studied the application of a block splicing texture synthesis algorithm in image splicing, which utilizes the principle of block splicing, divides the image into multiple small blocks, and then splices them according to the similarity and priority, realizing seamless splicing, and at the same time processing the splicing seams, which improves the quality and effect of image splicing. However, this method requires meticulous chunking and sorting of the image, which increases the computational complexity and time, and it is not robust enough for image rotation and scaling, which is prone to distortion and deformation [9], proposed a novel image stitching technique based on similarity comparison of document fragments splicing to image stitching by utilizing the features and similarity of document fragments to achieve automatic splicing of document fragments, and then generalized the method of document fragments splicing to image stitching to achieve automatic splicing of image fragments. However, this method requires preprocessing of document fragments and image fragments, such as binarization, denoising, rotation correction, etc., which increases the difficulty and error of preprocessing, and is not sensitive enough to the color and texture of the image, which is prone to inconsistency and unnaturalness. However, this method requires sub-regional processing of images, which increases the complexity and uncertainty of processing, and there is no effective correction and compensation for the distortion and distortion of images, which are prone to deformation and missing. However, this method requires a lot of training and testing of the image, which increases the computational resources and time, and does not preserve enough details and textures of the image, which is prone to blurring and smoothing [10, 11]. In the research [12], an image alignment and collocation method based on feature point matching and robust estimation is proposed, which utilizes local features of the image, which increases the computational complexity and error, and is not robust enough to illumination and occlusion of images, which is prone to mismatching and mismatching [13].

The image processing steps, including processing such as chunking, sorting, preprocessing, and subregioning, although helpful in realizing image stitching, also increase the computational complexity and time overhead, reducing the efficiency and real-time nature of image stitching. At the same time, image stitching techniques do not effectively correct and compensate for image distortion and distortion, which may lead to problems such as distortion, missing or artifacts, affecting the authenticity and integrity of image stitching [14]. Finally, image stitching techniques may not be effective in preserving and enhancing the details and textures of the image, which may result in the image becoming blurred and smoothed, affecting the clarity and contrast of the image stitching. Overall, although significant progress has been made in image stitching techniques, there are still some challenges to overcome [15].

B. Super Resolution Technology

There are three general methods for super resolution technique, first is the interpolation based method, which is used to increase the number of pixels in an image by performing an interpolation operation on a low resolution image. The general formula for interpolation operation is $F(p)=\sum_{i=0}^{n} a_i p^i$, The advantage of the interpolation based method is that it is simple and easy to implement, the disadvantage is that it leads to blurring and jagged effect in the image as it does not consider the high frequency detail information of the image. Next is the reconstruction based method which utilizes some a priori knowledge or constraints to reconstruct a low resolution image to improve the resolution of the image. The general formula for reconstruction is $\hat{x} = \arg\min\{\gamma(x, y) + \lambda R(x)\}$ where $\hat{x}$ is the reconstructed high resolution image, y is the low resolution image, $\gamma(x, y)$ is the data fidelity term which measures the difference between the reconstructed image and the low resolution image, R(x) is the regularization term which measures the complexity or the a priori probability of the reconstructed image, and λ is the equilibrium coefficient. Different reconstruction methods differ only in the form of the choice of data fidelity term and regularization term. The advantage of reconstruction based methods is that they can exploit the a priori knowledge or constraints of the image, the disadvantage is that they require complex computation and optimization processes

and are sensitive to the choice of parameters. The most recent approach is the learning-based approach. This method utilizes some machine learning or deep learning models to learn a mapping function from a large number of low- and high-resolution image pairs to achieve super-resolution in images [16, 17]. The general formula for the mapping function is: $\hat{x} = f(y;\theta)$, $\hat{x}$ is the reconstructed high resolution image, y is the low resolution image, f is the mapping function, and θ is the parameter of the mapping function. Different learning methods differ only in the way they choose the structure of the mapping function and how the parameters are learned. The advantage of the learning-based methods is that they can obtain better results and performance, and the disadvantage is that they require a large amount of training data and parameter tuning, and there may be the risk of overfitting. The trend change of three of these methods is shown in Fig. 2, which shows that learning-based methods have become the mainstream methods for image stitching [18].

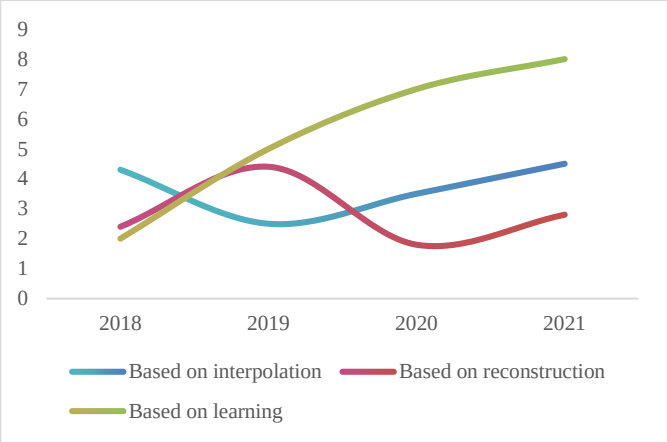

Fig. 2. Changes in trends for the three methods.

III. Image Stitching Model Based on Super-Resolution Technology

This section describes the specific steps of the model proposed in this paper, including image preprocessing, image alignment and misalignment, image stitching and super-resolution reconstruction, image post-processing, etc., which elaborates the image stitching model based on super-resolution technology in detail from multiple steps.

A. Pre-Processing of Images

As the noise of low resolution images reduces the quality and contrast of the image, it affects the feature extraction and matching of the image. Specifically, this paper uses a convolutional neural network model called DnCNN, which consists of multiple convolutional layers and activation layers, which can extract the features of the noise from the low-resolution image and output the denoised high-resolution image with residual learning. The formula for image denoising is shown in Eq. (1) [19]. The minimum loss function of DnCNN is shown in Eq. (2). The forward propagation algorithm of DnCNN model is to pass the noisy observation y through the convolutional and activation layers sequentially to get the residual image R, and then y-R is used to get the denoised image x, as shown in Eq. (3). The back propagation algorithm of the DnCNN model is to use the backpropagation algorithm of DnCNN model utilizes the gradient descent method to update the parameter Θ, so that the loss function L(Θ) gradually decreases. The details are shown in Eq. (4). The flowchart of image de-noising is shown as in Eq. (3) [20]. The image denoising process is specifically shown in Fig. 3.

$$\hat{x} = y - f(y, x) \tag{1}$$

$$L(\Theta) = \frac{1}{2N}\sum_{i=1}^{N} \| R(y_i, \Theta) - (y_i - x_i) \|^2 \tag{2}$$

$$a' = \sigma(z') = \sigma(W'^T a^{l-1} + b') \tag{3}$$

$$\Theta \leftarrow \Theta - \eta \nabla L(\Theta) \tag{4}$$

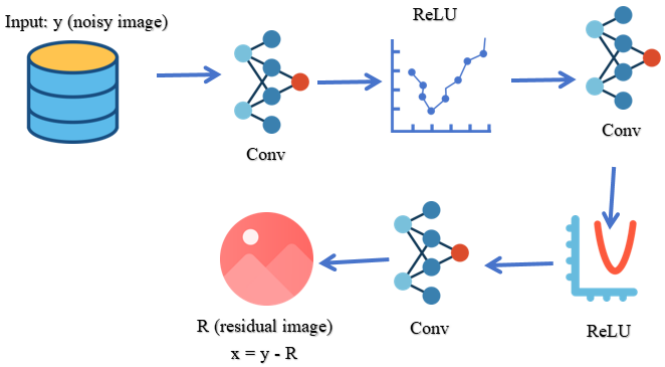

Fig. 3. Image denoising flowchart.

where, $\hat{x}$ is the denoised high resolution image, y is the low resolution image, f is the DnCNN model, and α is the parameter of the DnCNN model.

This paper adopts an image alignment method based on feature point matching and robust estimation, specifically, this paper uses a feature extraction algorithm called SIFT, which can extract feature points with scale invariance and rotational invariance from an image, and compute a descriptor for each feature point, which is used to represent the local information of the feature points. Then, this paper uses a robust estimation algorithm called RANSAC, which can extract some samples randomly from the matched pairs of feature points, calculate the uni-responsive transformation matrix between images, and then use this matrix to transform all feature points, calculate the error between the transformed feature points and the original feature points, and select the matrix with the smallest error as the final uni-responsive transformation Matrix [21]. The principle is to assume that the model parameters this study want to estimate are θ and the dataset is $D = x_i$, where x_i is the input, y_i is the output and N is the total number of data. First, this study randomly select S data points from the dataset D to form the minimum dataset S, where S is the minimum number of data points required to determine the model. The model parameters θ are then calculated using the minimum dataset S, which can be achieved by least squares or other methods. The model parameters θ are then used to make predictions for all datasets D to obtain the prediction output $\hat{y}_i$ and to calculate the prediction

error $e_i = y_i - \hat{y}_i$. If $|e_i|$ is less than some threshold t, then the data point (x_i, y_i) is considered to be an interior point, otherwise it is an exterior point. Noting that the set of interior points is I and the set of exterior points is O, this study have $D = I \cup U$ and $I \cap U = \varnothing$ [22].

If the size of the set of interior points I is larger than a certain threshold value T, a suitable model is considered to be found and the iteration is stopped, otherwise the next iteration is continued. Repeat the above steps K times, record the size of the inner point set obtained in each iteration, and select the model parameter I corresponding to the largest inner point set as the final result. The formula for image alignment is $\hat{y} = Hy$, where $\hat{y}$ is the aligned low-resolution image, y is the low-resolution image, and H is the uni-responsive transformation matrix.

Since low-resolution images may have extraneous backgrounds or edges that interfere with image stitching and fusion, low-resolution images need to be cropped to remove the useless parts and retain the useful parts. In this paper, this study use an image segmentation algorithm called GrabCut, which extracts the foreground and background regions from the image and represents the range of the foreground with a rectangular box, then describes the color distributions of the foreground and background with a Gaussian mixture model, optimizes the segmentation results of the foreground and background with a graph cut algorithm, and finally refines the edges of the foreground with an edge detection algorithm to output the cropped image. The principle of image cropping can be expressed as $\hat{y} = y \Theta m$, $\hat{y}$ is the cropped low-resolution image, y is the low-resolution image, m is the mask of the image, which represents the foreground and background regions of the image, and Θ is the element-by-element multiplication operation. Image noise reduction, image alignment and image cropping are the three steps of image processing and its specific flowchart is shown in Fig. 4 [23].

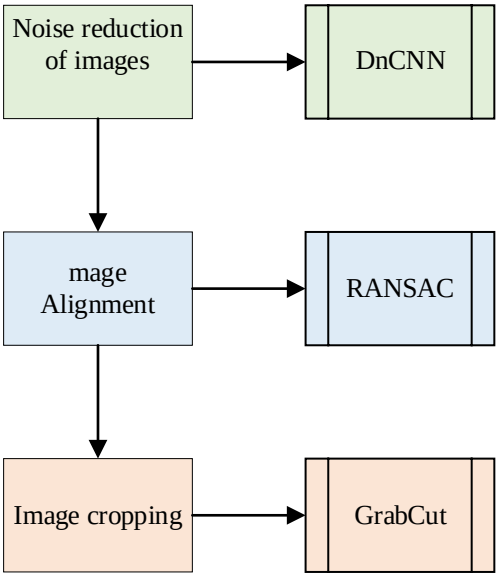

Fig. 4. Flowchart of image processing.

B. Image Alignment and Alignment

The purpose of image alignment and misalignment is to solve the problem of geometric transformations and illumination changes between images using methods based on feature point matching and robust estimation to achieve image alignment and misalignment. The steps of image alignment and misalignment are as follows:

1) Feature point extraction: the feature points are extracted from the cropped low-resolution image to find out the representative and distinguishable local features in the image, which are used for image matching and transformation. The feature point extraction is shown in Eq. (5) [24].

$$k = SIFT(y, \alpha) \tag{5}$$

where, k is the set of feature points, y is a low resolution image, SIFT is the SIFT algorithm and α is a parameter of the SIFT algorithm.

2) Feature point matching: The formula for feature point matching is shown in Eq. (6).

$$m = NNDR(\mathrm{k}; \beta) \tag{6}$$

where, m is the set of matched pairs of feature points, k is the set of feature points, NNDR is the NNDR algorithm, and β is a parameter of the NNDR algorithm [25].

C. Image Stitching and Super-Resolution Reconstruction

The flowchart of image stitching and super-resolution reconstruction is shown in Fig. 5. Firstly, image up-sampling is performed to up-sample the transformed low-resolution image to increase the number of pixels in the image and provide more information for the super-resolution reconstruction of the image. In this paper, this study uses a deep learning-based image up-sampling method, which utilizes convolutional neural networks to map the image in a non-linear way and learn the up-sampling representation of the image to achieve up-sampling reconstruction of the image. Eq. (7) for image up-sampling is shown [26, 27].

$$x = f(\mathrm{y},\ \gamma) \tag{7}$$

Then the image fusion step is performed to fuse the up-sampled high resolution images to eliminate the inconsistencies and unnaturalness between the images, making the transition between the images smoother and more natural, and achieving image fusion. In this paper, an image fusion algorithm called gradient domain optimization is used, which optimizes and fuses the low and high frequency parts of the image according to the weights and gradients of the image to achieve image fusion. The formula for image fusion is shown in Eq. (8), where, $\hat{x}$ is the fused high resolution image, $f(y;\lambda)$ is the up-sampled high resolution image, g is the gradient domain optimization algorithm, and δ is the parameter of the gradient domain optimization algorithm [28, 29].

$$\hat{\mathrm{x}}=\mathrm{g}(\mathrm{f}(\mathrm{y};\gamma);\delta) \tag{8}$$

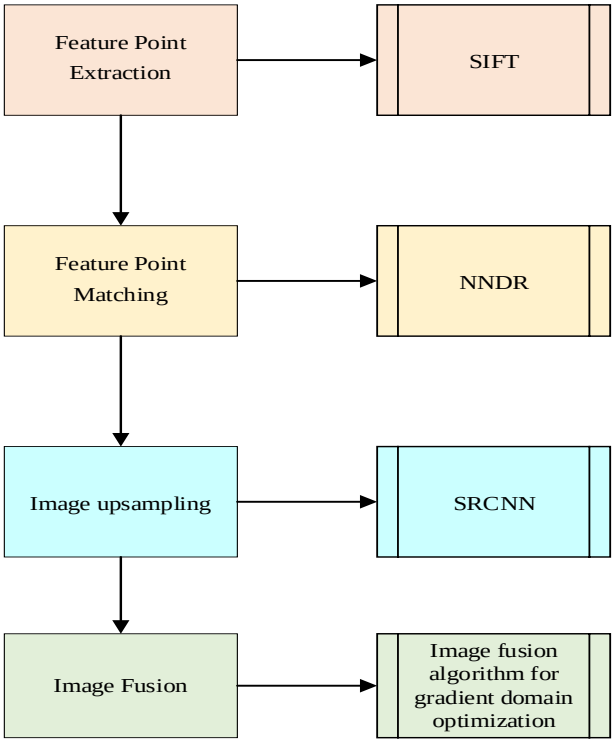

Fig. 5. Flowchart of image stitching and super-resolution reconstruction.

D. Image Post-Processing

The distortion and artifacts of the image are eliminated and the visualization of the image is enhanced using methods based on image quality assessment and distortion correction. This study perform quality assessment of the fused high-resolution images, including evaluating the image clarity, contrast, brightness, color and other metrics, which are used to determine the quality and effectiveness of the image. In this paper, the image quality assessment method based on (SSIM), using three aspects of the image, namely brightness, contrast and structure, calculates the similarity between the image and the reference image as the quality score of the image, and the closer it is to 1 means that the quality of the image is better. This is shown in Eq. (9) [30].

$$Q = SSIM(\hat{x}, x, \varphi) \tag{9}$$

where, Q is the quality score of the image, $\hat{x}$ is the fused high resolution image, x_r is the reference image, SSIM is the SSIM algorithm, and δ is a parameter of the SSIM algorithm.

IV. Experimental Evaluation

A. Experimental Design

In order to verify the effectiveness and robustness of our proposed deep learning-based image stitching method, this study compared it with the following four methods, whose specific information is shown in Table I [31].

This study use two datasets USIS-D and VGG to evaluate our model. USIS-D is an unsupervised image stitching dataset of real scenes constructed by us, containing pairs of images with different scenes, different overlap rates, and different parallaxes, with a total of 10,440 pairs of images in the training set, and 1,106 pairs of images in the test set. VGG is an image stitching dataset provided by VGG Laboratory at the University of Oxford, containing 59 pairs of images from different scenes, viewpoints and lighting. The study uses four metrics to quantitatively assess the quality of image stitching, which are PSNR, SSIM, EN, and QABF, and the formulas for these four metrics are shown in Eq. (10) - (14) [32].

$$PSNR = 10 \cdot \log_{10}\left(\frac{MAX^2}{MSE}\right) \tag{10}$$

$$SSIM(x, y) = \frac{(2\mu_x\mu_y + c_1)(2\sigma_{xy} + c_2)}{(\mu_x^2 + \mu_y^2 + c_1)(\sigma_x^2 + \sigma_y^2 + c_2)} \tag{11}$$

$$EN = -\sum_{i=0}^{L-1} p_i \log_2 p_i \tag{12}$$

$$QABF = \frac{\sum_{l=1}^{L}(\lambda(X'^l)D(X'^l, X''^l) + (1-\lambda(X'^l))D(X'^l, X''^l))}{\sum_{l=1}^{L}(\lambda(X'^l) + \lambda(X''^l))} \tag{13}$$

$$D(X'^l, X''^l) = 20(\sigma(X'^{lf}) / \sigma(X''^{lf}) + c) / (\sigma(X'^{lf}) + \sigma(X'^{lf}) + c) \tag{14}$$

B. Experimental Results

This study performed image stitching for each method on two datasets and calculated the average of the four metrics, and the results are shown in Tables II and III. As can be seen from the tables, our method outperforms the other methods in all metrics, indicating that our method can generate higher quality, more natural and robust spliced images [33].

TABLE I. Information on the Four Models Compared

Method name	Use of technology	Date of submission
SIFT	Manual features + SIFT + RANSAC	1999
APAP	ASIFT + Local Univariate Stress Transform Aligned Images + Multiband Fusion Approach	2014
GSP	Image Stitching with Global Similarity + ORB Feature Point Detection and Matching + Similarity Transform Aligned Images + Multiband Fusion Methods	2022
CI	SIFT + monoattachment transformation + optimal sutures	2022

TABLE II. Image Stitching Results on USIS-D Dataset

Methodologies	PSNR	SSIM	EN	QABF
SIFT	21.34	0.76	6.82	0.67
APAP	22.56	0.79	7.01	0.71
GSP	23.12	0.81	7.15	0.74
CI	23.45	0.83	7.24	0.76
DLIS	24.67	0.87	7.54	0.82

TABLE III. IMAGE STITCHING RESULTS ON VGG DATASET

Methodologies	PSNR	SSIM	EN	QABF
SIFT	19.87	0.72	6.54	0.63
APAP	20.43	0.74	6.68	0.66
GSP	21.01	0.77	6.82	0.69
CI	21.34	0.79	6.91	0.72
DLIS	22.56	0.83	7.24	0.78

In order to demonstrate the effect of image stitching more intuitively, this study selected some typical pairs of images from the two datasets respectively, stitched them with various methods, and visualized the stitched images. Our method can effectively handle image pairs with different scenes, different overlap rates and different parallaxes, and generate seamless, distortion-free and artifact-free spliced maps, whereas other methods suffer from certain alignment errors, unnatural fusion and obvious artifacts [34, 35].

TABLE IV. PERFORMANCE COMPARISON OF IMAGE STITCHING ON USIS-D DATASET

Method	PSNR	SSIM	EN	QABF
SIFT	21.34	0.76	6.82	0.67
APAP	22.56	0.79	7.01	0.71
GSP	23.12	0.81	7.15	0.74
CI	23.45	0.83	7.24	0.76
DLIS	24.67	0.87	7.54	0.82

TABLE V. PERFORMANCE COMPARISON OF IMAGE STITCHING ON VGG DATASET

Method	PSNR	SSIM	EN	QABF
SIFT	19.87	0.72	6.54	0.63
APAP	20.43	0.74	6.68	0.66
GSP	21.01	0.77	6.82	0.69
CI	21.34	0.79	6.91	0.72
DLIS	22.56	0.83	7.24	0.78

PSNR (Peak Signal-to-Noise Ratio): A measure of the ratio of signal to noise in an image, the higher the value, the better the quality of the image and the higher the signal-to-noise ratio. SSIM (Structural Similarity Index Measure): An index that evaluates the structural similarity of two images, close to 1 means that they are very similar. EN (Entropy): The information entropy of an image, reflecting the amount of information in the image, usually higher means that the image contains more information. Entropy): The information entropy of the image, reflecting the amount of information in the image, usually the higher it is, the richer the information contained in the image. QABF (Quality Assessment Based on Feature): A feature-based quality assessment index for evaluating the visual quality of the spliced image, the higher the value represents the better the quality.

As can be seen in Tables IV and V, on two different datasets (USIS-D and VGG), the DLIS (Deep Learning Image Stitching) method achieves the best results in all the assessment metrics, which significantly outperforms the other traditional methods including SIFT, APAP, GSP, and CI. This indicates that DLIS not only generates higher quality spliced images, but also demonstrates superior performance in maintaining the naturalness of the images and reducing the splicing traces, which further validates its advancement and usefulness in the field of image stitching.

V. CONCLUSION

This paper proposes a method that combines image stitching and super-resolution techniques to reconstruct a high-resolution panoramic image from multiple low-resolution images. In this paper, various problems during image stitching such as image distortion, image discontinuity, image blurring, etc. are solved from four aspects such as image preprocessing, image alignment and misalignment, image stitching and super-resolution reconstruction, and image post-processing by using techniques such as Convolutional Neural Networks, SIFT, RANSAC, GrabCut, SRCNN, Gradient Domain Optimization, and SSIM respectively. In this paper, image stitching is performed on two datasets, USIS-D and VGG, and four metrics, PSNR, SSIM, EN, and QABF, are used to quantitatively evaluate the quality of image stitching. The results show that the method in this paper outperforms the other methods in all the metrics, and it can generate seamless, distortion-free, high-resolution panoramic images, which are robust and efficient and can be applied to a variety of image processing scenarios.

Although this study has made remarkable achievements in the combination of image stitching and super-resolution techniques, the following shortcomings still exist, providing potential development space for subsequent research:

Adaptation to variable lighting conditions: despite the adoption of a series of preprocessing and alignment methods, the adaptability and robustness of the existing methods still need to be improved in the face of extreme or rapidly changing lighting conditions, such as strong backlighting and scenes with great contrast between light and dark. Future research can explore more advanced lighting compensation and adaptation strategies to ensure that high-quality image stitching and super-resolution reconstruction can be realized under various lighting environments.

Dynamic scene processing capability: Research has mainly focused on image processing of static scenes, while for scenes containing dynamic objects (e.g., people and vehicles), existing techniques may not be effective enough in dealing with motion blur and object occlusion. Future research can consider incorporating techniques such as motion segmentation and spatio-temporal consistency analysis to enhance support for dynamic scenes.

Model computational efficiency and real-time performance: despite the high accuracy achieved, the introduction of deep learning models inevitably increases the computational cost, limiting their deployment in real-time applications, such as video surveillance and UAV navigation. In the future, model lightweighting, quantization techniques and hardware acceleration solutions can be explored to improve the processing speed and meet the demand for real-time processing.

Although the method proposed in this paper has made significant progress in the field of image stitching and super-resolution, there still some limitations and future directions worth exploring:

Adaptability and generalization ability: The current study mainly validates the algorithm for general scenarios, but the adaptability and generalization ability of the algorithm in special domains, such as medical images, remote sensing images, or images with unique textures and structures, still needs to be examined. Future work should be extended to more diverse datasets and optimize the algorithms to cope with problems specific to different domains.

Real-time processing capability: although the methods in the paper perform well in improving image quality and stitching effects, the use of deep learning models may increase the computational burden, limiting their efficiency in real-time application scenarios. Developing more lightweight or hardware-accelerated models for fast processing in resource-limited environments will be an important direction in the future.

Dynamic scene processing: current approaches focus on image processing for static scenes, while for dynamic scenes containing moving objects or rapid lighting changes, existing alignment and fusion strategies may not be sufficient to cope with the challenges posed by complex motion. In the future, techniques such as combining optical flow estimation and spatio-temporal information analysis can be explored to enhance the performance of algorithms in dynamic scenes.

The Design and Execution of a Multimedia Information Intelligent Processing System Oriented to User Experience

Hongmei Liu
Chengdu College, University of Electronic Science and Technology of China, Chengdu 611745, China

***Abstract*—With the rapid growth of the world economy and the increasing pursuit of culture and entertainment, the integration of multimedia database technology and networks has become crucial. Through extensive research, this integration allows for seamless integration of multimedia information (MI) and promotes accelerated development of cultural exchange on the internet. This article studies and designs a multimedia information (MI) intelligent processing system for user experience (UE). This system integrates multimedia database technology and network technology, aiming to provide seamless integration of multimedia information, accelerate cultural exchange on the network, and enrich the cultural experience of users. In the system design, we propose a UE mode based on context-aware technology and develop an innovative access selection algorithm that can dynamically select the best access path based on network status and user preferences. The experimental results show that the algorithm performs well in terms of throughput, latency, and link load, effectively meeting the QoE (Quality of Experience) requirements of users. In addition, the system has high scalability and can cope with constantly growing data and computing needs without sacrificing performance. The implementation of this system not only provides users with a richer and more personalized cultural experience, but also provides strong support for building a more interconnected global community.**

***Keywords*—User experience; multimedia information; intelligent processing; wireless network**

Nomenclature

MI	Multimedia information	I_{filter}	The result of the weighted average of the last three times
UE	User experience	Max	The maximum value of the corresponding model
QoE	Quality of Experience	k_1, k_2, k_3	The model coefficient
OS	Operating System	p	Path
DDN/FR	Distributed Data Network/File Replication	$jitter$	Jitter
LAN	Local Area Network	$delay$	The time delay
MAN	Metropolitan Area Network	$packet\_loss\_rate$	The packet loss rate
RTP	Real-Time Transport Protocol	CN	The crossing number
SLB	Server Load Balancing	n_k	the eight adjacent points of the current point P
QoS	Quality of Service	n	The number of pixels between the start point and the endpoint
QoE	Quality of experience	d_i	the direction code of each point
IP	Internet Protocol	D_k	Different image
ID	Identification	f_k	The frame image
QoE	Quality of Experience	R_k	Binary image
DSP	Digital Signal Processing	$Q_l(t)$	The backlog of the queue at the current moment of the link
ARM	Advanced RISC Machine	$\{A_l(t)\}_{t=0}^{\infty}$	The packet data quantity of the link time slot t arriving at the link
CPU	Central Processing Unit	c	The number of fuzzy-level values
		x	The number of input parameters
subscript		T	Candidates Network
S	Support		
C	Confidence		
I	The number of packets between the last two packets loses		
σ	Certain threshold		
I_{mprev}	The weighted average packet loss number before the last two packet losses		
I_m	The weighted average packet loss number		

I. INTRODUCTION

As society continues to advance in information technology, networking, and intelligence, the demand for multimedia information (MI) is on the rise, with a specific focus on audio and video content. In the past, a significant amount of time and effort was dedicated to resolving issues related to hardware devices and data formats during video processing. Unfortunately, the work done in this area was not easily transferable or reusable when transitioning to a new hardware platform [1]. In the experience economy, the central feature is the prioritization of humanization, where the user experience takes precedence over the mere functionality of products or services. This shift in focus recognizes the importance of creating memorable and meaningful experiences for customers, rather than solely providing a functional solution to their needs. People's demands for emotion and the realization of self-worth are becoming the focus of attention. Therefore, a more natural and easily accepted management application system based on context awareness has been widely considered and valued by researchers. A priori algorithm typically makes decisions based on historical data or previous experience. In the fields of multimedia information processing and user experience optimization, historical data (such as user preferences, network status, content consumption patterns, etc.) can provide valuable references for predicting future behavior or optimizing system performance. For multimedia applications, real-time response and fast decision-making are crucial. A prior algorithm is usually able to make decisions based on known information in a short period of time, thus meeting real-time requirements. Compared to complex machine learning or deep learning algorithms, prior algorithms often have lower computational complexity and higher efficiency. This is particularly important for processing large amounts of multimedia information and responding in real-time to changes in network status.

The idea of facing UE (user experience) has a long history. At present, there are many professional books about interaction design and UE that deeply explore the relevant interface design methods and criteria. Zhao [2] elaborated on the related knowledge of user interface design, usability design, and testing. Lv et al. [3] put forward that, according to the visual and psychological cognitive characteristics of users of handheld mobile devices, the principles and design methods that should be followed in the design of handheld mobile devices and their graphical interfaces are discussed and summarized. Pei et al. [4], based on the research on the relationship between the target UE and interface design, combined with the related theories of semiotics and product semantics, discussed the method of interface fashion design. Wang et al. [5] proposed that according to the visual and psychological cognitive characteristics of users of handheld mobile devices, the principles and design methods that should be followed in the design of handheld mobile devices and their graphical interfaces were discussed and summarized; Fei et al. [6] provide consulting services for enterprise UE optimization through data analysis. Jin et al. [7]pointed out that the experience of the real world affects users' expectations of the virtual environment displayed by the information system, and there are also differences among users with different cultural and ethnic backgrounds in their expectations of the interface and the ways of understanding the information provided by the interface. Jinkui et al. [8] think that emotional factors include direct and indirect emotional reactions on the one hand and more complex emotional results produced by the cognitive evaluation process on the other hand.

A comprehensive analysis was conducted by Liu et al. [9] on the implementation of an intelligent learning environment that emphasizes experiential learning. This paper focused on the analysis of the main problems, such as teaching-centered classroom settings unsuitable for classroom interaction, public learning spaces with low user experience, and a lack of teaching decisions supported by big data analysis.

Miraz et al. [10] demonstrated through their research that the adoption of dynamic techniques in user experience design can yield significant enhancements in user engagement and enjoyment, surpassing the outcomes achieved with more simplistic approaches. Li et al. [11] undertook a meticulous review of both literature and patents in four closely linked disciplines. Their primary aim was to present a comprehensive overview of the interconnections among these fields and evaluate their potential integration with smart energy management strategies. A study was undertaken to propose a conceptual framework for the development of a real-time self-adaptive user interface using the Android Operating System (OS). The primary focus of this study was to develop the core algorithms for the modules within the proposed framework. Moreover, this study emphasized the value of a customizable interface within the confines of an Android operating system [12].

Capece et al. [13] explored the development of "user experience" in terms of personal enjoyment and interaction with cultural locations by utilizing theoretical frameworks, concepts, and tools in their study. Consequently, this study investigates the restrictions imposed by data management and user privacy on the utilization of these systems. Additionally, it anticipates emerging prospects for augmenting and tailoring the user experience.

MI intelligent processing system is a distributed integrated system that organically combines video, audio, graphics, images, text, animation, and other media information processing. At present, research in this field at home and abroad often isolates the four basic aspects of MI processing technology, which makes it difficult to use various algorithms and tools to form a complex MI intelligent processing system [14]. At the same time, under the influence of service design and sharing economy thinking in the era of the experience economy, the development trend of Internet services has gradually changed from hardware and software construction to centralized cloud services. Looking at the current portable handheld devices, either the MI processing ability is not strong, the resolution is low, and the playback is not smooth enough, or only the video files in a single format can be played and processed, so the applicability is not strong. The system designed in this paper makes full use of Web technology and multimedia technology to obtain the information users need. This system can make users experience faster operation in a more beautiful operation interface and better bring convenience to the network culture and entertainment lives of the majority of netizens. Through this platform, the goal can be achieved and can

effectively meet the various needs of users for multimedia applications.

II. Research Method

A. Demand Analysis

The concept of emotional design is becoming increasingly important in today's competitive market as companies strive to differentiate their products by creating meaningful and memorable experiences for users. Among the three levels of emotional design, the reflective layer corresponds to the strategic layer, the scope layer, and the structure layer in the UE element model, while the behavioral layer and the instinctive layer correspond to the design framework layer and the presentation layer, respectively. Therefore, the emotional design theory has important guiding significance for UE-oriented design methods.

MI intelligent processing system should try its best to meet users' needs, involve data processing at all levels and in all processing links, and focus on the management of meeting users and MI (pictures, videos, and audio). The software design should be modularized, which consists of five modules. The modules are closely related, and each module has its own characteristics. Corresponding configuration modules and usage tools are provided so that the system can be flexibly matched. With the continuous updating and upgrading of the network, the system's security has also been greatly challenged. The design of applied software and database systems should improve their security and prevent the invasion of illegal users. With the rapid development of technology, intelligent service systems have gradually penetrated into every aspect of our lives [15]. From smart homes to online shopping, from health monitoring to education and training, these systems have greatly improved our quality of life by providing convenient and efficient services. However, to make these systems truly effective, the key lies in the design of the human-computer interaction interface [16]. In intelligent service systems, user experience is the core of design. An excellent interface design should be able to visually display the system's functions, guide users to easily complete operations, and provide a pleasant feeling during use. To achieve this goal, we need to have a deep understanding of user needs and habits, as well as their usage scenarios in different scenarios. The interface design should support personalized customization, allowing users to adjust the interface layout, color, font, etc. according to their preferences and needs [17]. This can not only improve user satisfaction, but also enhance the emotional connection between users and the system. The system should provide timely feedback to users on their operations, allowing them to understand the current operational status and results. Reduce user anxiety and frustration through clear prompts and friendly error handling mechanisms [18].

Consistency stands as one of the most prevalent principles in design. Within the realm of design, consistency manifests not only through the uniformity and coherence of the style of every visual element present in the software interface, including icons, buttons, copywriting, and more. Moreover, it encompasses regularity in the application of intangible information architecture, interaction logic, interaction methods, and similar elements. When applications maintain a consistent level of performance, users are more likely to feel comfortable and at ease while using them. This consistency allows users to easily navigate through the content and find the information they need quickly. As a result, users are more likely to have a positive experience and continue using the product in the future.

Users have accumulated some knowledge and skills from their experience using the website, forming habits and expectations. Most of these conventions follow people's cognitive structure and mindset and become conventions because of their effectiveness, which should be paid attention to and fully utilized to reduce users' cognitive burden [19]. People's attention is concentrated and small in a short time, and the user interface based on recognition largely depends on the visibility of the objects that users care about. Displaying too many objects and attributes will make it difficult for users to find interesting objects. A software product with little memory burden is more popular with users. It can enhance user stickiness, improve work efficiency, and improve the success rate of tasks. Interaction designers should pay attention to these aspects when designing products.

B. The General Structure of the MI Intelligent Processing System

The exponential expansion of data in the online realm has rendered the conventional approach of constructing hardware and software infrastructure for data storage and retrieval inadequate to cater to the evolving needs of internet-based businesses [20]. Cloud services are provided to users by seamlessly integrating these flexible and scalable virtual fundamental service resources. By leveraging the services offered by cloud service providers over the Internet, users can achieve their desired functionalities, thereby revolutionizing the conventional approach of investing significant resources in constructing hardware and software infrastructure [21]. Through the implementation of a centralized software and hardware service model, cloud services effectively achieve the functional goals of computing power, speed, performance, and security. Additionally, this model introduces new requirements for creating a comprehensive and user-focused experiential service.

A good information system should have initiative and can actively perceive the information of users' behaviors, and the information push mechanism of commodities is the embodiment of the system's active perception [22]. Most of them push products to consumers according to the similarity of product information, which can only provide the most basic information and can't speculate on the user's commodity preference.

The principle of the Apriori algorithm, based on association rules, is to discover hidden relationships between data sets [23]. In this paper, the support degree is represented by S and the confidence degree is represented by C. The specific definitions of the two are as follows:

$$S = P(A \cup B) \tag{1}$$

$$C = \frac{P(A \cup B)}{P(A)} \tag{2}$$

In this paper, we will integrate, model, plan, and classify all kinds of situation information involved in the system and refer to the characteristics of time situation and user behavior situation in association rules to improve the user preference

model and match it with similar product information in the system.

The congestion control algorithm used in this topic is based on the parameters related to the packet loss rate collected by the server [24]. If the packet loss rate L is greater than a certain threshold σ, the sender will appropriately discard some data frames in the video data. Let I represent the number of packets between the last two packet losses, and I_{mprev} represents the weighted average packet loss number before the last two packet losses. The weighted average packet loss number I_m can be expressed as:

$$I_m = (1-\alpha)I_{mprev} + \alpha I_{filter} \quad (3)$$

$$I_{filter} = \beta_1 I_{mprev-1} + \beta_2 I_{mprev-1} + \beta_3 I \quad (4)$$

Where I_{filter} is the result of the weighted average of the last three I times.

This system adopts a hierarchical and structured design. The multimedia processor with high performance and a built-in hardware codec acceleration engine should be configured. It can complete the real-time coding and decoding of multi-channel video, double-channel 1080P video, or single-channel 4K video. It has an Ethernet interface and a wireless Wi-Fi interface and supports wired and wireless dual-mode transmission of streaming media [25], [26]. At the same time, the system should have a basic intelligent video analysis function and provide basic intrusion detection and abnormal alarms to reduce the large amount of labor cost and workload brought by large-scale monitoring, improve the accuracy rate, and ensure no false alarm or false alarm. The overall architecture of the system is shown in Fig. 1:

It comprises a front-end video coding server, a camera, a tripod head, a tripod head decoder, and various alarm input devices. It can be LAN, MAN, the Internet, or any combination of these networks. We chose the Internet here. Includes a client, an enterprise client, a web client, and a network management client. The client includes central client software and a TV wall system, and the web client is embedded in the web page for ordinary users. The client is responsible for managing and configuring the system.

Data compression is a commonly used expression to improve the efficiency of information transmission and storage in a processing system. By compressing data, the efficiency of information transmission between subsystems and inside can be improved [27]. If the knowledge is well defined, it will make the system a right-hand assistant for researchers and users, and it will be able to advise users to choose appropriate tools, verify the consistency of knowledge, and make decisions. The session control is carried out between the sending and receiving communication terminals through the server. The multimedia stream is transmitted by a real-time transmission protocol, and the solution of audio-video synchronization is also involved in the transmission process.

The multimedia code stream transmission subsystem receives that coded data stream from the miprocess subsystem and carries out RTP packet and transmission through the RTP Server. Clients can access it in B/S and C/S modes according to their needs. The decoder decoding module of the client is responsible for decoding and displaying the decoded code stream, and users can browse real-time images. The application architecture of the multimedia transmission subsystem is shown in Fig. 2.

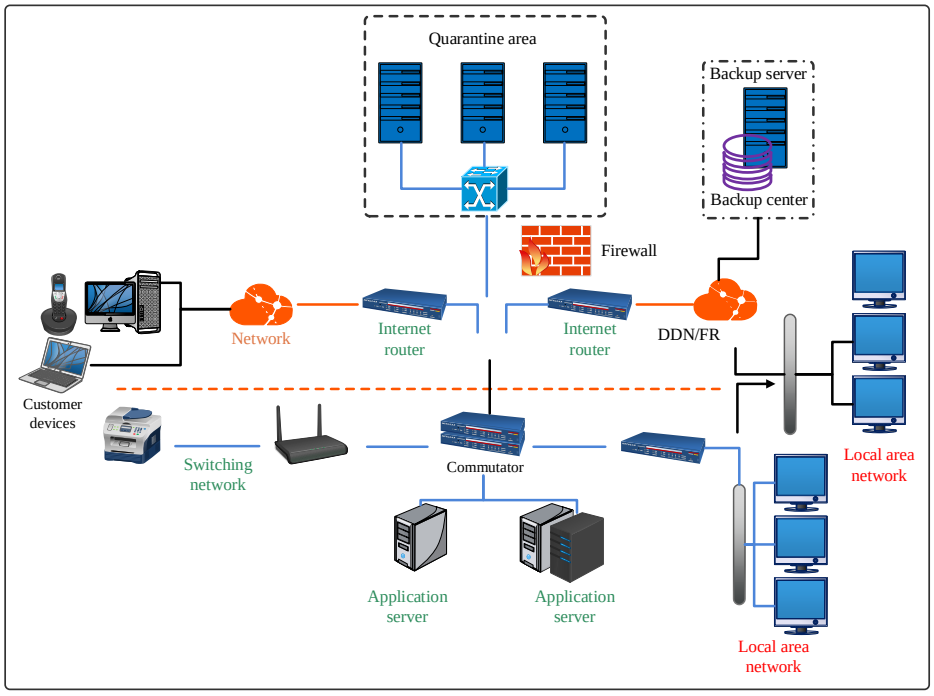

Fig. 1. Overall system framework diagram

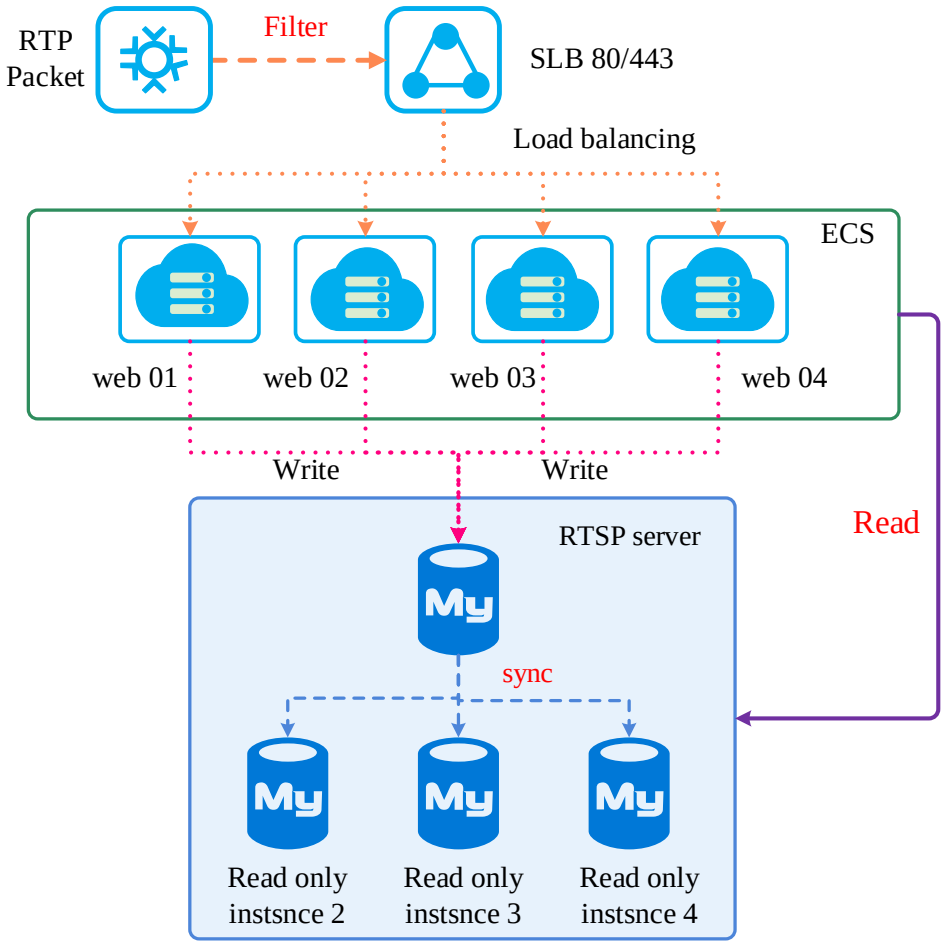

Fig. 2. Multimedia code stream transmission subsystem framework

The user management node realizes the functions of adding, changing, deleting, and querying user information. First, users register on the homepage, then log in, get their desired MI according to their personal preferences and characteristics, and play it to encode and decode MI at will.

According to the conditions set by the user before, the system will display all the found work items in the searched controllable area and show all the qualified documents in the query result list. All the information about the project is included in the content. So that the daily workload and status can be clear at a glance and the management efficiency can be greatly improved.

C. Key Technology Realization of the System

The interaction between users is realized by users' recommendations, evaluations, sharing, and forwarding of digital library information resources. In practice, digital library scientific research establishes its own user interaction platform or uses a third-party embedded user interaction platform to provide technical support for user interaction. The interactive experience evaluation between users and other users of the digital library can be carried out by sharing, recommending, commenting, and forwarding the information provided by the digital library platform. The user's interactive experience with the digital library system will affect the interaction between users and other users. Users will also interact and provide feedback on their experience of the digital library system with their organization, culture, and social background to correct their corresponding cognition.

A mobile terminal is often in the overlapping coverage area of multiple networks. Mobile terminals have different numbers and types of candidate networks in different service areas to access [21]. When a user wants to start a new service or switch, first determine the available network set around the user, and the networks in this set meet the basic QoS (quality of service) requirements of the service being used by the user. Then trigger the UE-based network access selection algorithm. The basic flow of the algorithm proposed in this paper is shown in Fig. 3.

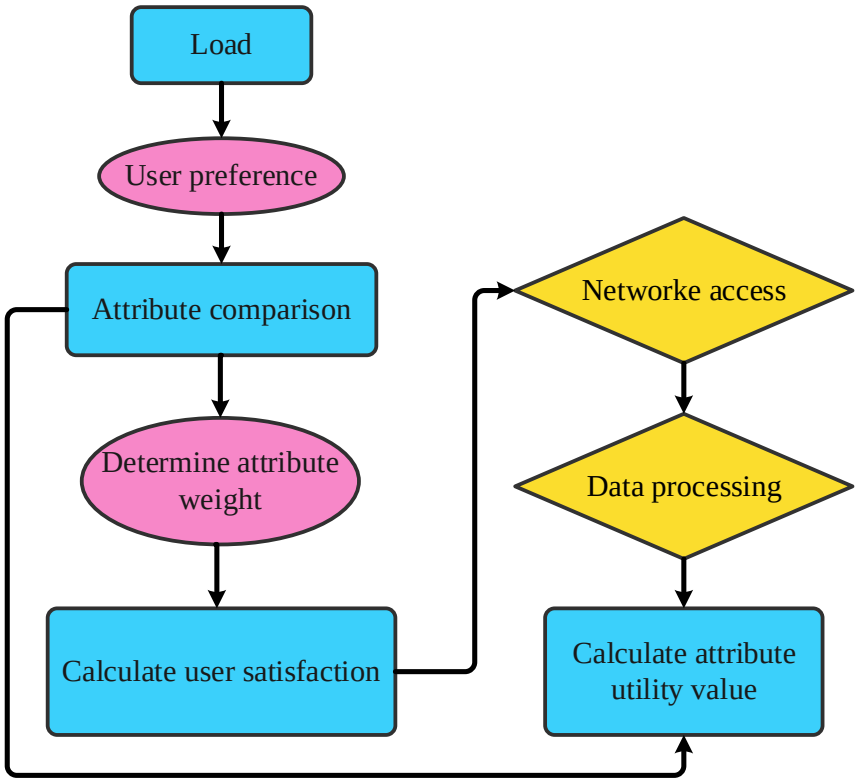

Fig. 3. Flow chart of network access selection algorithm based on UE

Satisfaction with a user's network or business is determined by the application used by the user and the user's preferences [22]. If users prefer to use the cheapest connection when browsing the web, the attributes to be considered will be biased towards the price. The mapping model between QoS and video QoE (quality of experience) is established through regression analysis, and the corresponding model coefficients are determined. On the premise of not losing generality, the following extended form is given:

$$QoE(p) = Max - k_1 * jitter(p) + k_2 * delay(p) + k_3 * packet\_loss\_rate(p) * 100 \quad (5)$$

where Max is the maximum value of the corresponding model; k_1, k_2, k_3 is the model coefficient; p is a given path;$jitter$ is jitter, $delay$ is the time delay, and all single bits are ms; $packet\_loss\_rate$ is the packet loss rate, which is a decimal in the range of 0 ~ 1.

The endpoint can be determined by the number of intersections. The crossing number CN of pixels of (i,j) is defined as:

$$CN = \frac{1}{2}\sum_{k=1}^{8}|n_k - n_{k+1}| \quad (6)$$

in which n_k is the eight adjacent points of the current point P, $n_k \in \{0,1\}$ and $n_9 = n_1$, then $CN = 1$, at that time the pixel(i,j) is an endpoint.

If the next point of P is n_1, the length of the curve track of $d_p = i$ is defined as:

$$L = \sum_{i=1}^{n} 1(d_i) \quad (7)$$

$$1(d_i) = \begin{cases} 1 & if\ d_i = 1,3,5,7 \\ \sqrt{2} & if\ d_i = 2,4,6,8 \end{cases} \quad (8)$$

where n is the number of pixels between the start point and the endpoint and d_i is the direction code of each point. If the ratio is less than a certain value, it is considered that there is no inflection point.

Through morphological filtering and connectivity analysis, the area with the connected area larger than the given threshold is judged as the target.

$$D_k(x,y) = |f_k(x,y) - f_{k-1}(x,y)| \quad (9)$$

$$R_k(x,y) = \begin{cases} 0 & D_k(x,y) \le T \\ 1 & D_k(x,y) > T \end{cases} \quad (10)$$

A difference image D_k is obtained by the gray levels of pixels at the positions corresponding to the k-th frame image f_k and the $k-0$-th frame image f_{k-1}, and then threshold judgment is performed on the difference image to distinguish the foreground and background points, and a binary image R_k is obtained.

The location agent is the bridge between the monitoring center and the broadcast terminal. Because the IP addresses of the monitoring center and the broadcast terminal are both dynamic, a location agent is required for data transmission. The monitoring center can accurately transmit commands and files to the designated playing terminal. The workflow of the agent is shown in Fig. 4.

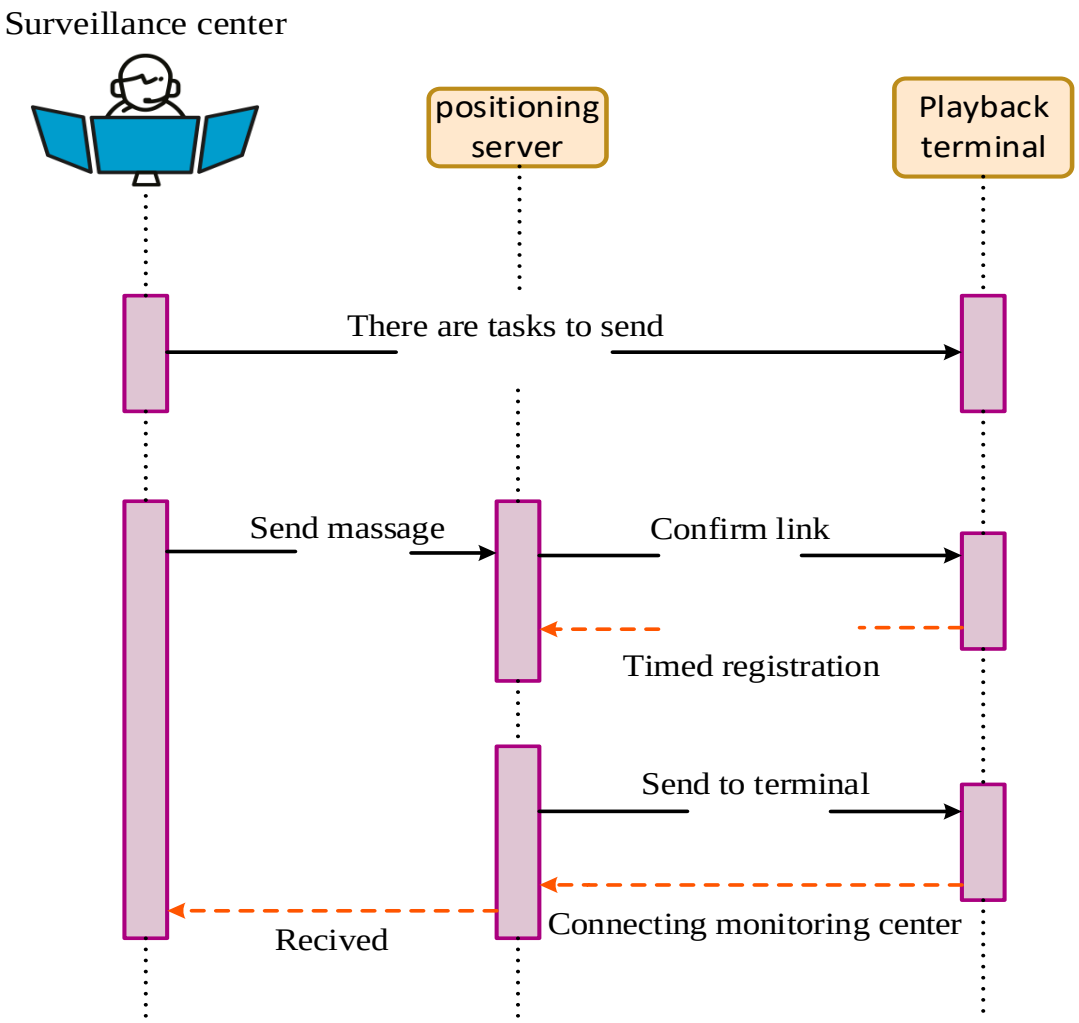

Fig. 4. Location agent workflow chart

When the monitoring center operates the broadcast center, the positioning agent receives the command from the monitoring center, finds the ID of the broadcast terminal to be operated by the monitoring center and the corresponding socket, and rewrites the current time and socket of this test into the data structure of the corresponding ID to ensure that the broadcast terminal is always online. The location agent is ordered to write the received ID into the data structure tasks and wait for the application of the playback terminal.

The development of wireless networks is not limited to the traditional mode of packet forwarding by base stations for access points but can be called IP-based wireless networks. Under the time slot model, data arrival is a discrete process, and the dynamic queue process of each link is described as follows:

$$Q_l(t+1) = \left(Q_l(t) - S_l(t)\right)^+ + A_l(t) \quad (11)$$

$l = 1,2,\cdots,L$, $Q_l(t)$ is the backlog of the queue at the current moment of the link and $\{A_l(t)\}_{t=0}^{\infty}$ is the packet data quantity of the link time slot t arriving at the link l.

If there is a conflict in the broadcast process, the link will give up the transmission opportunity for this time slot:

$$S_l(t) = S_l(t-1) \quad (12)$$

In the fuzzy reasoning module, corresponding rules need to be set according to the number of input parameters and the number of fuzzy grade values. The number of rules l is:

$$l = c^x \quad (13)$$

Where c is the number of fuzzy level values and x is the number of input parameters. When the input parameters increase, the number of rules will increase exponentially, and at the same time, the number of rules will also affect the complexity of deblurring [23].

The two-stage fuzzy logic system obtains the accurate output value F, and the output value set of the candidate network set is $F = \{F_1, F_2, \cdots, F_M\}$, and the candidate network T with the largest output value is selected as the target network to perform switching, that is:

$$T = max\{F_1, F_2, \cdots, F_M\} \quad (14)$$

For any link, if the queue length is expected to be bounded, then the system queue is stable, namely:

$$\lim_{T\to\infty}\frac{1}{T}\sum_{i=1}^{T}E[Q_l(t)]<\infty \quad (15)$$

It is proven whether the system will be overloaded by calculating the expected value of the cache queue length. If it can be proved that the expected value of the queue length is less than infinity, then the system can remain stable.

According to the weighted average method, the total utility value of each attribute provided by users to this candidate network can be obtained; that is, the total satisfaction is:

$$S_i=\sum_j^n u_{ij}w_i \quad (16)$$

Rank the satisfaction of candidate networks, and the network corresponding to the maximum satisfaction is the optimal target network. Users try to access this network, and if the connection is unsuccessful, they try to access the suboptimal network.

III. Result Analysis

System testing plays a crucial role in the overall process of system development. Its primary objective is to evaluate whether the functional and performance benchmarks outlined in the system requirement definition phase have been successfully achieved. By conducting system testing, developers can ensure that the system operates as intended and meets the predetermined criteria. Black-box testing treats the tested system as a black box, inputting data from the outside, and then verifying the output results. White-box testing, on the other hand, involves understanding the structure of the tested object, consulting the content of the tested code to assist in the testing work, understanding the internal design structure of the program and the specific code implementation, and designing test cases based on this knowledge.

The randomly generated topology verifies the computational scalability of the algorithm, while some famous Internet topologies validate the practicality of the algorithm. The famous Internet topologies used in the experiment are ArpaNet, ItalianNet, and AnsNet.

According to the QoE model, the corresponding model coefficient k_1, k_2, k_3 is obtained, and it is tested in ArpaNet, ItalianNet and AnsNet, respectively, and the success rate and running time are recorded, as shown in Tables I to III.

TABLE I. Success Rate and Running Time (ArpaNet)

Model grade	Education		Science and technology	
	Success rate	*Running time /μs*	*Success rate*	*Running time /μs*
1	0.098	209.539	0.134	224.507
2	0.119	213.77	0.243	229.159
3	0.143	212.211	0.239	233.84
4	0.169	214.964	0.186	216.272
5	0.105	214.437	0.172	227.515
6	0.203	205.056	0.12	227.734
7	0.144	206.6	0.216	219.654

TABLE II. Success Rate and Running Time (ItalianNet)

Model grade	Education		Science and technology	
	Success rate	*Running time /μs*	*Success rate*	*Running time /μs*
1	0.181	322.504	0.106	348.499
2	0.143	342.662	0.176	346.928
3	0.229	337.694	0.216	358.174
4	0.151	337.412	0.29	361.18
5	0.213	317.992	0.274	357.943
6	0.262	336.828	0.11	374.232
7	0.289	330.977	0.29	341.311

TABLE III. Success Rate and Running Time (AnsNet)

Model grade	Education		Science and technology	
	Success rate	*Running time /μs*	*Success rate*	*Running time /μs*
1	0.401	761.02	0.318	725.638
2	0.398	747.615	0.318	738.726
3	0.276	737.882	0.318	761.595
4	0.37	722.085	0.213	743.817
5	0.345	751.548	0.304	743.103
6	0.313	740.492	0.293	740.316
7	0.289	724.901	0.391	732.85

It was found that the ArpaNet with the fewest number of nodes and links has the shortest running time and the lowest success rate. ItalianNet, with the largest number of nodes and links, has the longest running time and the highest success rate. The success rate and running time of the optimal routing algorithm based on the QoE evaluation model are very close when the QoE level is 1 ~ 7, which shows that the running time of the algorithm will not increase with the change in QoE demand but only depends on the network topology.

Fig. 5 and 6 count the average satisfaction of all users in different user ratios. When the service arrival rate is high, the comparison algorithm shows slightly higher satisfaction, because users always choose their default optimal network access in the comparison algorithm.

Run H.264 encoding and decoding algorithms on DSP (Digital Signal Processing) respectively, and the load measurement results on DSP are shown in Fig. 7.

The running results can test the load of the H.264 decoding algorithm on the DSP core and the load of video playback on the ARM core. The video decoding frame rate ranges between 20 and 50 frames, with a decoding rate typically around 5 Mbps. The running test load of the codec on the DSP core shows that the CPU load consumed by video coding is higher than that of video decoding.

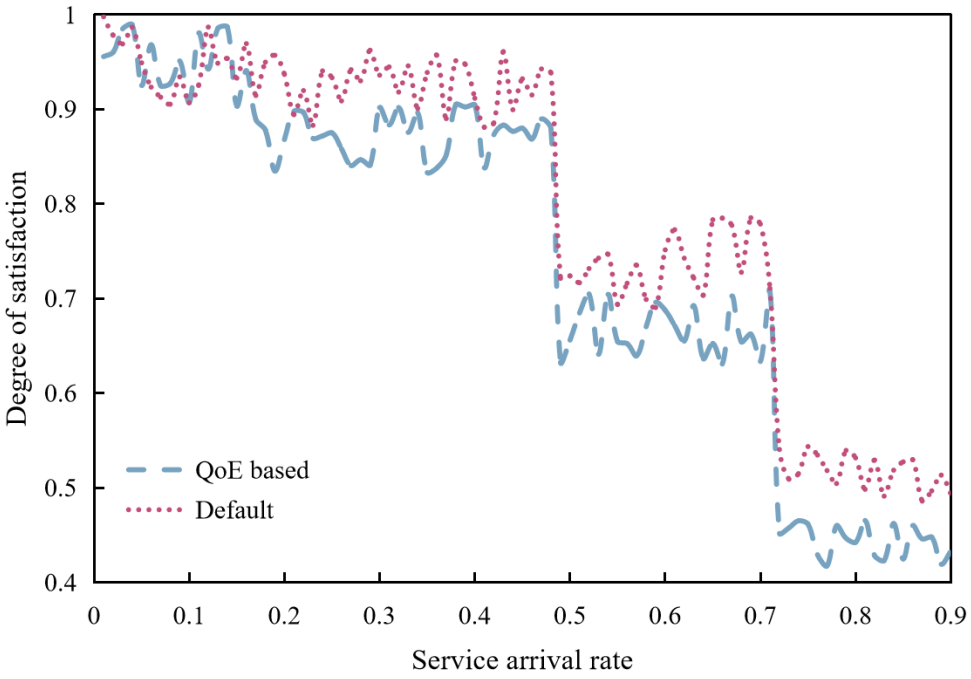

Fig. 5. Average user satisfaction under the user ratio of 1: 1

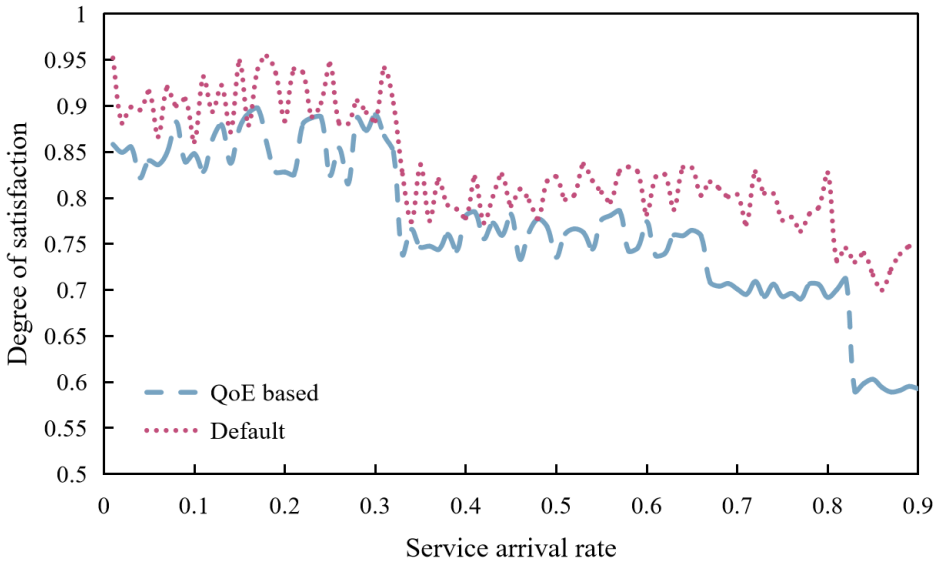

Fig. 6. Average user satisfaction under the user ratio of 2:1

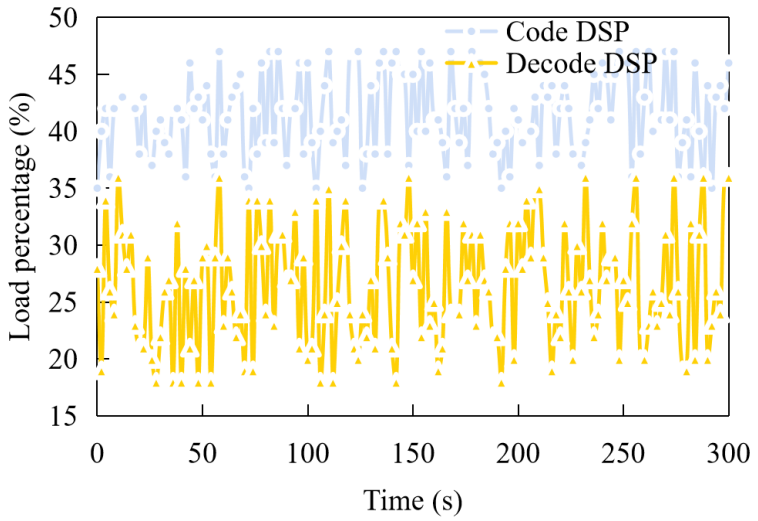

Fig. 7. Load of codec algorithm on DSP

During testing, if the number of test cases is limited, a range of values is also given. Then, choose a few test cases less than the minimum number and a few more than the maximum number to generate test data. When the tester has divided the test case interval, it is more appropriate to select several values near the boundary of the interval when choosing the values. The test results play an absolute guiding role for programmers in debugging programs. However, even if the program has passed the above tests, it doesn't mean that the software has no problems or loopholes.

Fig. 8 compares the handover blocking rate performance of the four algorithms with the trend of increasing the number of users. The blocking rate is defined as the ratio of blocking users to total users during handover.

As can be seen from the figure, when the number of users is 30, the algorithm starts to block. This is because the ref [24] algorithm does not consider the network load, which causes the network to block prematurely. When the number of users is 40, the other three algorithms start to block. With the increase in users, the blocking rates of the four algorithms are increasing. Although the algorithm in this paper considers the load rate of the network, its weight is small, so it has little influence on the network judgment.

Fig. 9 shows the relationship between the total network throughput of the four algorithms and the number of users. The total throughput is the sum of the network throughput occupied by users after handover.

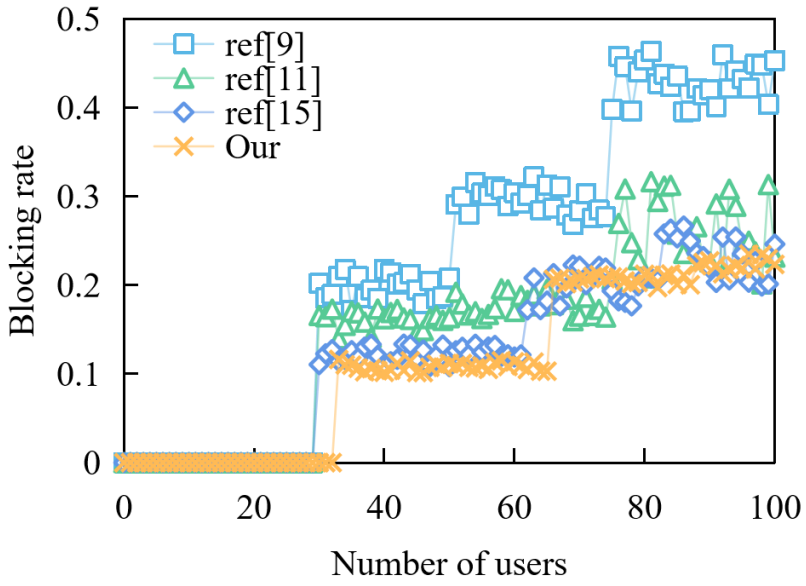

Fig. 8. Handover blocking rate

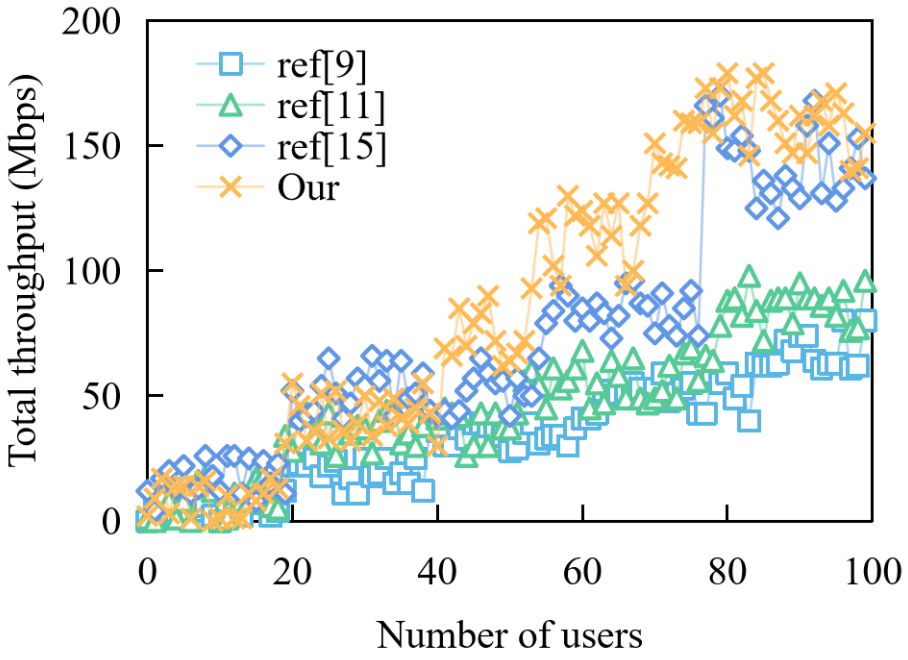

Fig. 9. Total network throughput

As can be seen from the figure, the total throughput increases with the increase in the number of users. When the number of users exceeds 20, the increasing trend of the total throughput of the algorithm gradually slows down. By balancing the load, congestion is reduced, allowing for continuous data transmission. The algorithm referenced in [24] has fewer parameters and does not test the network load, resulting in the highest blocking rate and the lowest network utilization rate, thereby yielding the lowest total throughput.

The most crucial aspect of the UE process is the feedback effect. Feedback is conveyed to users through the corresponding service information prompts on the product interface, aiding users in making choices and judgments. Therefore, a product or service must have a well-designed feedback system to better serve users. The principle of high efficiency forms the foundation for the system to meet UE requirements. To enhance the efficiency of information and data input in the system, many sensor devices can be utilized instead of manual input. This not only increases efficiency but also ensures the accuracy of information extraction to a great extent, significantly reducing labor expenditure.

IV. Conclusion

This paper delves into the intricacies of the MI management system and presents a novel approach in the form of an MI intelligent processing system. The design of this system is the result of a comprehensive investigation and analysis of the current state of MI management, focusing on addressing the practical requirements identified through real-world application scenarios. Analyzing the existing system requires a meticulous examination of its specific characteristics and requirements. This in-depth evaluation will provide valuable insights into the complexities of the system, enabling the development of a comprehensive framework. It is worth mentioning that the system has demonstrated exceptional performance and functionality during rigorous testing, further highlighting its efficiency. Through the running results, the load of the H.264 decoding algorithm on the DSP core and the load of video playback on the ARM core can be tested. The video decoding frame rate typically ranges from 20 to 50 frames, while the decoding rate generally hovers around 5 Mbps. The algorithm's throughput scales proportionally with the increasing user base, ensuring that it can continue to meet the demands of a larger and more diverse audience. When the user population surpasses 20, the gradual slowdown in the increasing trend of the algorithm's total throughput becomes apparent. This results in a reduction in congestion and a more balanced distribution of the load, enabling continuous transmission of data. This study aims to develop and implement an MI intelligent processing system with the objective of fostering mutual learning and knowledge exchange. The primary goal is to create a platform where individuals can share their experiences and gain insights from one another.

The future of multimedia information (MI) management systems holds promise for various advancements and enhancements to elevate their functionality and efficiency. One potential area for improvement is the integration of AI and machine-learning algorithms. Through the utilization of artificial intelligence and machine learning technologies, tasks such as content tagging, classification, and recommendation can be automated, leading to a more intelligent and user-friendly system

Optimized Task Scheduling in Cloud Manufacturing with Multi-level Scheduling Model

Xiaoli ZHU
Wanbo Institute of Science & Technology, Huainan 232251, China

***Abstract*—Cloud Manufacturing (CMfg) utilizes the cloud computing paradigm to provide manufacturing services over the Internet flexibly and cost-effectively, where users only pay for what they use and may access services as needed. The scheduling method directly impacts the overall efficiency of CMfg systems. Manufacturing industries supply services aligned with customer-specific needs recorded in CMfg systems. CMfg managers develop manufacturing strategies based on real-time demand to establish service delivery timing. Many elements influence customer satisfaction, including dependability, timeliness, quality, and pricing. Therefore, CMfg depends on the use of multi-objective and real-time task scheduling. Multi-objective evolutionary algorithms have effectively examined many solutions, such as non-dominant, Pareto-efficient, and Pareto-optimal solutions, using both actual and synthetic workflows. This study introduces a new Multi-level Scheduling Model (MSM) and evaluates its effectiveness by comparing it with other multi-objective algorithms, including the weighted genetic algorithm, the non-dominated genetic sorting Algorithm II, and the starch Pareto evolution algorithm. The primary emphasis is on assessing the efficacy of algorithms and their suitability in commercial multi-cloud setups. The MSM's dynamic nature and adaptive features are emphasized, indicating its ability to effectively handle the complexity and demands of CMfg and resolve the scheduling issue within this environment. Experimental results suggest that MSM outperforms other algorithms by achieving a 20% improvement in makespan.**

Keywords*—Cloud manufacturing; multi-level scheduling model; task scheduling; multi-objective optimization; resource allocation

I. Introduction

Cloud Manufacturing (CMfg) is a new manufacturing paradigm characterized by service-oriented, knowledge-based, and resource-sharing manufacturing. It can virtualize the manufacturing resources into services and realize the control and transmission of virtual manufacturing resources by extending the cloud, ensuring the networked, integrated, and adaptive collaboration of multi-user parties for the entire life cycle of the product [1]. With CMfg, physical resources are conveniently, efficiently shared, and allocated to produce customized products based on consumer demand [2]. Officially launched in 2010, CMfg is widely regarded as a promising direction for the future of manufacturing. Over the past decade, academics and industry have extensively studied and debated this issue [3]. The related topics of CMfg include architectural design, resource virtualization, service selection, service allocation, task scheduling, and service discovery [4]. Despite significant research efforts, the desired concept of CMfg has not yet been realized.

As a result of technological advances in virtualization and commercialization, cloud computing can schedule tasks efficiently on virtual machines [5]. Efficient distribution of resources across each task is a crucial aspect of distributed computing, and scheduling plays an essential role in this [6]. There are currently different scheduling techniques, including cloud service, workflow, static, and dynamic scheduling. Task scheduling is significantly impacted by challenges such as performance, reliability, scalability, load balancing, and dynamic resource reallocation across processing nodes [7]. A robust scheduling method is essential for coordinating work in cloud computing. The CMfg model consists of design, manufacturing, and logistics activities. These tasks are supported by the respective design, manufacturing, and logistics clouds. The suppliers can be individuals or companies, while the customers can be end-users or businesses. A central information store is a hub connecting operators, customers, and suppliers [8]. The sequence of interactions includes the following steps: providers and consumers interact; Consumers submit their requirements to operators; Operators assign tasks to providers based on consumer needs; Providers register their available resources; Operators deliver the resulting output to consumers [9].

In the CMfg operating paradigm, operators act as administrators responsible for monitoring and controlling a CMfg platform. Their debut enables consumers to receive affordable, reliable, and world-class manufacturing services whenever they need them, conveniently via the cloud platform [10]. In addition, the cloud platform offers tools that allow providers to distribute their resources and capabilities efficiently. Under the operator-led unified management, suppliers provide shared-purpose manufacturing resources to the CMfg platform and receive manufacturing tasks from the cloud platform. The customer base comprises corporate customers and individual buyers [11]. Under this centralized management structure, customers submit their requested tasks to the CMfg platform and subsequently receive the performance results of their orders. CMfg uses manufacturing paradigms to develop knowledge that includes rules, concepts, models, protocols, and algorithms [12]. This information is critical in all service lifecycle phases, including service creation, management, and implementation.

Task scheduling represents a significant problem. The efficient organization of work in distributed systems depends to a large extent on precise data about the availability of resources. Resource providers often deliver this information to a central database that planners can access. The exponential growth of cloud providers is obvious [13]. Within a commercial multi-

cloud system, individual providers are primarily motivated to optimize their revenues and may put their interests ahead of the benefit to consumers and other providers. In a multi-cloud enterprise environment where multiple cloud providers are involved and have sensitive information about their resources, application planners must be careful and not rely on the information provided by the providers about the status of their resources. There is a constant risk that providers will misrepresent private data.

This paper follows the following structure. CMfg-related work is reviewed in Section II focusing on scheduling models and optimization techniques. Section III describes our proposed method, emphasizing its adaptive features and effectiveness in addressing CMfg complexities. Section IV provides detailed empirical evaluation results. MSM is compared with existing algorithms, and its practical applications are discussed in section V. Finally, Section VI concludes the paper.

II. Related Work

Scheduling methodologies are one of the most elaborate research areas in CMfg, as the distribution of resources in CMfg poses a series of challenging and intelligent research problems. Several scheduling techniques have been designed for task allocation, resource synchronization, and system optimization. The methods adopted in these papers include multi-objective evolutionary algorithms, Chaos Optimization Algorithm (COA), and creative work that integrates Deep Reinforcement Learning (DRL) with attention mechanisms. Each research corresponds to a different problem, which includes integrated planning, production resource planning, end-to-end solutions, collaborative task planning, logistics integration, and setup time/cost. This section provides a thorough examination and comparative assessment of these studies, revealing their approaches, objectives, and notable results while emphasizing their contribution to addressing complex planning problems in CMfg. Table I provides a comparative analysis of the works, highlighting the diversity of approaches used and their respective contributions to addressing planning challenges in CMfg.

The main goal of the CMfg paradigm is to centralize distributed manufacturing capabilities and businesses, thus enabling enhanced personalized production. Production orders consist of multiple items jointly fulfilled by distributed providers at lower costs. The CMfg platform sets meaningful priorities, identifies acceptable suppliers and production processes for numerous orders, and plans hybrid activities resulting from different orders across manufacturing resources. The goal is to increase production efficiency by managing the trade-offs between orders. Laili, et al. [14] examined the multi-phase integrated scheduling of hybrid jobs in a CMfg context. This included assigning order priorities, selecting suppliers and production processes, and planning production lines. This technique considers five main objectives to evaluate the interrelationships between diverse resources and manufacturing operations. Six exemplary multi-objective evolutionary algorithms were used to address the integrated planning problem. The experiments conducted under six different production conditions indicate that the integrated scheduling method outperforms standard sequential decision-making, resulting in lower production costs and times. In addition, a comprehensive study was carried out to determine the most suitable solution to the integrated planning problem in different situations by comparing the six methods.

Hu, et al. [15] studied the scheduling problem for manufacturers in a CMfg environment. They analyze five factors that impact manufacturer resource planning: task load, task reliability, manufacturing efficiency, availability of manufacturing resources, and Internet of Things (IoT) compatibility. The research creates planning indices and a model with an objective function. The objective function is efficiently resolved using the COA to arrange production orders across several domains. The simulation results validate the comprehensiveness and effectiveness of the proposed planning index. This study integrates all pertinent factors that impact manufacturer planning in the CMfg environment by developing a mathematical model. The scheduling problem is simplified into an arithmetic problem using a linear programming approach. The manufacturer's scheduling algorithm, rooted in chaos theory, effectively addresses the issue of inference and delivers high-quality service in conditional manufacturing to consumers via the CMfg platform.

DRL is increasingly recognized as a viable approach to solving scheduling challenges in CMfg and demonstrates impressive performance in dynamic and unpredictable cloud environments. Nevertheless, the industry needs improved planning algorithms and readily available modeling methods to support the actual use of these advances. Wang, et al. [16] proposed a unique end-to-end scheduling solution to solve job scheduling challenges in CMfg precisely. Their technique utilizes the multi-head attention process to uncover connections between companies and activities. The model is trained using DRL. What is noteworthy is that this concept has a significant reduction in response times compared to heuristic algorithms and allows planning solutions to be created in a matter of seconds. In contrast to previous DRL algorithms, the approach has higher planning performance and uses a more easily understandable modeling method. Significantly, the proposed model only depends on the objective function to ensure continuous training, so there is no need for a reward function based on steps. Combining multi-head attention with DRL for planning problems is a novel approach with promising results. The experimental results of a case study on processing vehicle structural components in CMfg show that the proposed scheduling approach outperforms priority distribution rules, heuristic algorithms, and DRL algorithms in both performance and efficiency.

Chen, et al. [17] studied cloud-edge collaboration manufacturing task scheduling (CETS) to improve customer satisfaction and optimize production balance. CETS aims to increase the efficiency of cloud-based manufacturing services, especially at individual process levels. It coordinates the scheduling of tasks by leveraging current production data at the edge and manufacturing service information in the cloud environment. The study introduces an attention-based DRL algorithm designed for CETS requirements, which are highly dynamic and state-intensive. The DRL method is built on the mathematical model of CETS as a partially observable Markov decision process. It then creates the AV-MPO framework that

uses a Gated Transformer-XL (GTrXL) within an On-Policy Maximum Posterior Policy Optimization (V-MPO) framework. The efficacy, learning progress, generalization, large scale, and robustness of AV-MPO are investigated extensively via experiments. Moreover, AV-MPO is compared with rule-based algorithms and other state-of-the-art DRL methods, such as Proximal Policy Optimization (PPO), Soft Actor-Critic (SAC), and Dueling Deep Q Network (Dueling DQN). The experimental results confirm that AV-MPO successfully handles the inherent difficulties of the CETS problem. Compared to other algorithms, it shows higher efficiency in handling this work.

The CMfg system has undergone significant changes with the advancement of new technologies. Customers can request a wide range of services through a customer-centric framework, gaining access to distributed production resources. Salmasnia and Kiapasha [18] criticize the unreasonable assumption made in previous research that all tasks are immediately available when planning begins. To ensure the model's accuracy in representing reality, two crucial factors are taken into account: (1) the time and cost associated with transferring subtasks between various services offered by companies located in different geographical regions, and (2) the time and cost involved in establishing a service capable of performing multiple subtasks. A thorough model integrates three essential components: the impact of cost on the CMfg system, the duration required to fulfill an order, and the level of service quality. The results underscore the significance of considering the arrival time of tasks and the temporal and financial implications of logistics and setup to achieve more accurate outcomes. The GAMS program solves small and medium-scale problems, while a genetic algorithm is developed to address larger issues. Moreover, a sensitivity analysis is performed to understand better how variables such as time, cost, and user requirements impact the final solution. This comprehensive approach facilitates a more profound comprehension of the intricate interplay of diverse elements within CMfg systems.

Zhang, et al. [19] propose a new approach called Individualized Requirement-Driven CMfg Multi-Task Scheduling (IRCMMS) to address customers' specific needs in demand-driven cloud manufacturing. This strategy attempts to address the particular needs of individual consumers while benefiting the overall system. This technique is primarily designed to obtain an approximation to an optimal Pareto solution set, thereby providing a wider range of possibilities for the CMfg system. The validation process confirmed the applicability and effectiveness of the IRCMMS model, which involved several simulation instances and experimental data. Moreover, these findings emphasize the algorithm's efficacy in effectively addressing the challenges posed by the IRCMMS model.

Wang, et al. [20] presented a novel offline scheduling method for DRL, which aims to overcome the challenges of online trial-and-error methods while maintaining the intrinsic advantages of DRL. A sequential Markov approach was suggested to represent decision-making processes, where each task was defined as an individual agent. Subsequently, a Decision Transformer (DT) framework was presented to convert the decision problem in online planning into a categorization problem in an offline setting. A reference model based on attention was developed and trained offline through the DT architecture to serve as an agent's guide. The experimental results showed that the proposed approach can support online DRL algorithms such as Deep Double Q-Network (DDQN), Deep Recurrent Q-Network (DRQN), PPO, and the offline learning algorithm Behavior Cloning (BC) consistently outperformed, both in terms of planning performance and model generalization. The results highlight the effectiveness of the proposed offline DRL scheduling algorithm in providing excellent scheduling performance while avoiding the difficulties associated with online trial-and-error methods.

TABLE I. SCHEDULING APPROACHES IN CMFG

Reference	Objective	Methodology	Findings
Laili, et al. [14]	Integrated scheduling in CMfg	Multi-objective evolutionary algorithms	More effective and reduced costs/time
Hu, et al. [15]	Manufacturer scheduling factors in CMfg	Chaos Optimization Algorithm	COA efficiently handled scheduling jobs in various conditions
Wang, et al. [16]	End-to-end scheduling solution in CMfg	Multi-head attention with deep reinforcement learning	Outperformed various DRL and heuristic algorithms
Chen, et al. [17]	Cloud-edge collaboration manufacturing task scheduling	AV-MPO, attention-based DRL method	AV-MPO is efficient in handling CETS and outperformed other algorithms
Salmasnia and Kiapasha [18]	Task transfer and setup time consideration in CMfg	Developed a model considering cost implications, job completion time, and service quality	Consideration of logistics setup time is crucial for accurate CMfg solutions
Zhang, et al. [19]	Individualized requirement-driven CMfg multi-task scheduling	Multifactorial evolutionary algorithm	IRCMMS efficiently addressed individual customer requirements
Wang, et al. [20]	Offline DRL scheduling in CMfg	Offline Markov decision process modeling, Decision Transformer framework	Outperformed online DRL algorithms in scheduling performance

III. Proposed Method

The suggested method is divided into three steps. The cloud manager maintains a global queue to handle inbound service requests from clients at the first stage, known as matching, where each request represents one or more tasks. The cloud manager selects the i^{th} task in the global queue and calculates the completion time that this task will use in multiple Virtual Machines under the control of the Content Security Policy (CSP). The entire time includes both scheduling and execution. The manager decides the scheduling process of the k^{th} cloud at the allocation stage to provision service requests to minimize the makespan. Within the cloud, allocation follows a First in First out (FIFO) principle. Additional tasks queued while the manager is allocating are scheduled in FIFO order. The manager selects an alternative VM for the first task that provides the fastest completion time.

When implementing the Continuous Linked Settlement (CLS) strategy, the first task is specifically assigned to VM-2, given that the CLS strategy does not comply with the FIFO order. This stage enables adjustments to tasks depending on the scheduling system. Subsequent scheduling is carried out to complete the calculations. Crucially, every cloud has the potential to carry out several tasks concurrently. The suggested method consolidates service needs worldwide, allowing the manager to choose each job from the queue progressively. The manager evaluates the appropriateness of tasks for all VMs to choose the most suitable VM. Afterward, the manager selects the c^{th} cloud with the most appropriate virtual machine and the necessary state and index. To ascertain the optimal state of the VM, the first step involves invoking the procedure, which examines the scheduling approach used by the cloud *c*. This entails determining whether the cloud uses Round-Robin (RR) or cloud list scheduling.

When RR scheduling is used, the method determines the number of VMs (*VMcount*) in cloud *c*. At first, the value of *VMcount* is set to 1. After assigning the task to the main VM and updating the VM count, the algorithm proceeds with the RR scheduling approach, where the main VM is scheduled first, followed by the other VMs. If the number of VMs equals the index, the task is given to the VM with that index. Otherwise, the task fails. If the CLS technique is selected and neither RR scheduling nor CLS in cloud *c* can handle the task, the algorithm will search for the most suitable VM across all available clouds. Fig. 1 depicts the multi-cloud architecture. The following steps delineate the procedure for scheduling and rescheduling the queues and index. The scheduling process involves initializing cloud settings and implementing the RR scheduling algorithm. It includes identifying VMs, allocating the task to the principal VM, updating the *VMcount*, managing errors, and iterating through the process. Rescheduling entails evaluating unlimited cloud tasks, exploring different values for the index, and adjusting *c* from 1 to *M* (the total number of clouds). This process calls for scheduling that includes the parameters of (*i*, cloud, and index).

Table II depicts the cloud control matrix structure. Two separate clouds are present in this situation, each consisting of two VMs that use different scheduling techniques: RR and cloud list. Given the assumption that tasks are received in a sequential numeric sequence by the cloud manager when the first task (T_0) arrives, the manager determines the VM that can complete the task quickly. As a result, the matching process is ignored, and the cloud control matrix is modified accordingly, indicating that *CCM* (T_0, *VM2*) has an infinite value (∞). Later, the manager identifies another VM (VM3) with the quickest completion time for task T_0.

Consequently, *VM1* is allocated task T_1 since it has a shorter completion time. Afterward, the RR scheduling algorithm is used to schedule T_1 on *VM1*. Subsequently, with the arrival of task T_3, the manager does an assessment and allocates it to *VM4* after scrutinizing the completion durations of T_3 on all accessible VMs. The completion timings are as follows: 6 plus 2, 3 plus 2, 8 plus 3, and 5 plus 0, respectively. Out of these options, the sum of 5 and 0 reflects the shortest time needed to complete the task, resulting in the assignment of T_3 to *VM4*.

The study introduces a multi-level scheduling strategy for dynamic workflow scheduling, abbreviated as *MSM/M2S*. The suggested technique is a list scheduling heuristic that prioritizes activities according to their performance and then organizes them in the setup order. Workflow assignments are prioritized based on their bottom level, described in graph theory as the longest route from each task to the exit task. The ranking is decided by each task by the use of the following recursive function:

$$rank\ (i) = \begin{cases} load\ (i) + \max\{comm\ (i,j) + rank\ (j)\} & if\ i \neq exit \\ load\ (i) & if\ i = exit \end{cases} \quad (1)$$

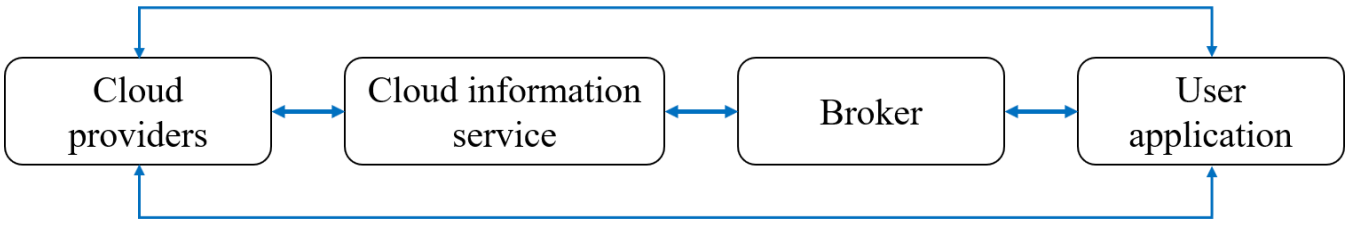

Fig. 1. Multi-cloud architecture.

TABLE II. CLOUD CONTROL MATRIX STRUCTURE

Clouds	VM	T_0	T_1	T_2	T_3	T_4
First cloud (RR scheduling)	VM1	8	1	6	5	3
	VM2	1	4	3	3	6
Second cloud (cloud list scheduling)	VM3	2	9	7	7	4
	VM4	7	5	4	2	2

Eq. (1) defines *load(i)* as the remaining burden of task *i*, and *comm(i,j)* as the communication output between tasks *i* and *j*. The reason for using makespan values to prioritize assignments is based on the structural hierarchical aim that preserves priority linkages in the structured list and substantially influences cost since longer activities take more resources. To organize the task list, we assume a recursive MSM, where n tasks are scheduled one after another using the multi-level scheduling strategy.

The proposed approach for dynamic workflow scheduling consists of a series of steps. These steps include initiating the algorithm and assigning tasks to a list, initializing an empty rank list, starting with the exit task, determining ranks based on a recursive function that takes into account workload and communication output, sorting tasks in descending order of ranks, conducting an auction among tasks using MSM, assigning the winning task to allocated resources, removing completed tasks, and concluding the scheduling strategy by paying the final cost to the task winner. This technique employs a prioritization strategy that considers the performance and execution time of tasks. It aims to optimize the usage of resources in situations that require dynamic workflow scheduling.

While attaining balance in a game is important, the system's usefulness becomes unnecessary if it cannot reach this equilibrium within an acceptable timescale. The technique, which is based on bargaining, also deals with inherent complications in communication. The complexities of the MSM system's algorithms and communication methods are carefully analyzed, calculated, and explained. A comprehensive guide is provided to improve understanding of the suggested method. The presented workflow illustrates that the load of each step indicates its exceptional use for rank estimation. Fig. 2 and Table III depict time and cost as the two essential resources for task execution. The cost considerations are clearly outlined since the suggested solution focuses on a multi-cloud environment. The expense of doing a job on a virtual machine is determined by the execution duration and the cost per unit of time, expressed using a multiplication function, as shown in Eq. (2).

$$cost = \sum_{i=1}^{m} (c_t(t_i) - s_t(t_i)) \times p_j \quad (2)$$

In Eq. (2), s_t represents the beginning time, c_t stands for the completion time, and p_j signifies the price factor. Fig. 2 illustrates the process, accompanied by two matrices that provide specific information on the costs and time required for the resources. The placements of the workflow assignments are calculated based on the first stages. The given tasks are planned by organizing them in decreasing order depending on their rankings. This ordered list, indicated as $A = (T_1; T_2; T_3; T_4)$, is used for scheduling. The first auction begins at time zero, which is assumed to be the start time of task T_1.

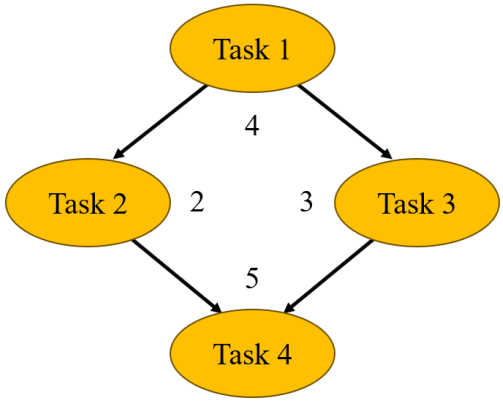

Fig. 2. Task execution process.

TABLE III. TASK DESCRIPTION

	Route 1		Route 2	
Task id	Cost	Time	Cost	Time
1	2	4	4	2
2	6	6	7	4
3	6	6	7	4
4	2	2	3	1

IV. RESULTS

When evaluating balance failure, the main criterion is the cost of disorder, which represents the difference between the highest possible job value of a balance in the game and the desired output. Researchers are focused on multi-level optimization to obtain a collection of better non-dominated solutions known as the Pareto set rather than a single perfect solution. The theoretical evaluation of the cost associated with insurrection is impractical and ignored. Here, some of the findings are shown, while the rest of the results are related to randomly created processes.

The proposed model (MSM) is being evaluated in comparison to numerous other approaches, including Weighted Genetic Algorithm (WGA) [21], Bi-Objective Scheduling Algorithm (BOSA) [22], Non-dominated Sorting Genetic Algorithm-II (NSGA-II) [23], and Strength Pareto Evolutionary Algorithm (SPEA2) [24]. Since MSM deals with multi-objective requirements, other comparable models were considered for comparison purposes. SPEA2 improves SPEA by preserving boundary solutions while offering Pareto-optimum outcomes. NSGA-II offers enhanced capabilities for handling three or more objective functions. This is achieved through reference points to ensure variety in Pareto points. The Bi-objective scheduling technique uses an approximation method to determine the best solutions on the Pareto curve. All strategies use Pareto functions to resolve problems with multiple objectives by assigning weights to objective functions.

V. DISCUSSION

The Pareto set is generated a posteriori, and then an arrangement suitable to the client's needs is selected. The task count and execution sequences of each arrangement are defined by two fitness functions, one for time and one for cost. The algorithms utilized include SPEA2, NSGA-II, BOSS, and WGA. MSM produces non-dominated arrangements compared to Pareto, based on comparative analysis and graphical representation. Table IV summarizes the simulation parameters for the proposed model. A comparison of MSS and Pareto Front arrangements evaluated by multiple evolutionary algorithms is illustrated in Fig. 3 and Fig. 4. Accordingly, Fig. 5 and Fig. 6 present the objective space of randomly generated workflows, providing a comprehensive view of the results of various algorithms.

The study's limitations include the complexity associated with integrating real-time data and fluctuating demand patterns within CMfg systems, which may influence scheduling accuracy and responsiveness. Additionally, while MSM shows promise in improving scheduling efficiency, its applicability to large-scale CMfg operations and the generalizability of findings across different industrial contexts require further validation and refinement. Future research could focus on developing hybrid optimization approaches that integrate machine learning techniques to adaptively optimize scheduling strategies in response to evolving production environments. Moreover, exploring the integration of IoT-enabled sensors for real-time data acquisition and predictive analytics could enhance MSM's performance in anticipating and mitigating disruptions within CMfg workflows. Addressing these limitations and pursuing these avenues of research will advance our understanding and practical application of scheduling models in contemporary manufacturing settings.

TABLE IV. SIMULATION SETTINGS

Parameters	Value
Number of tasks	1000
Energy	200 J
CPU time	160 ms
Number of clouds	5
Number of VMs	20-100
Number of users	100

VI. Conclusion

This study examined the critical area of efficient scheduling within the expansive landscape of cloud computing and CMfg. Global research attention has been captured by the emergence of CMfg, which offers on-demand manufacturing services through the Internet. With real-world and synthetic workflow applications, this research faced numerous challenges associated with effective scheduling within CMfg. The multi-objective evolutionary algorithms evaluated solutions via non-dominant, optimal, efficient, or non-inferior evaluations. The MSS algorithm was compared with popular algorithms like SPEA2, NSGA-II, BOSS, and WSGA. These algorithms are tested against efficiency and applicability in commercial multi-cloud environments. This research demonstrated that MSS can be dynamic and adaptive, navigating the intricacies and demands of manufacturing and scheduling processes. Comparative analysis highlighted MSS's distinct advantages and effectiveness in optimizing scheduling mechanisms, particularly in complex multi-cloud environments. The results of this study offer valuable information on how to improve scheduling efficiency in cloud-based manufacturing paradigms in the future.

Creativity in the Digital Canvas: A Comprehensive Analysis of Art and Design Education Pedagogy

Qian TONG
School of Tourism Management, Chaohu University, Chaohu 238034, China

***Abstract*—Promoting creativity in the dynamic field of education has become a critical goal for educators, aiming to prepare students with the essential abilities for success in various professional and personal situations. As educational institutions globally attempt to promote creative learning outcomes, there is still a notable lack of knowledge regarding efficient techniques for teaching creativity. In this paper, we address the pressing need to bridge the knowledge gap associated with teaching creativity in artistic disciplines. The goal is to offer educators and researchers detailed knowledge of the methods used to promote creativity in art and design education by combining research, historical insights, and modern advancements. We explore the complexities of creative ideas, both classic and current educational methods, as well as the distinct problems and possibilities in art and design education. Finally, the study provides insights into the ongoing debate about creativity with respect to art and design education, offering suggestions for pedagogical innovation in the future to meet the dynamic challenges and potentials within the artistic and design disciplines.**

***Keywords*—Creativity; art and design education; pedagogical practices; learning outcomes; assessment; grounded theory**

I. Introduction

A growing body of research indicates that integrating 21st century skills into education is necessary, such as critical thinking, communication, teamwork, and metacognition [3]. Teachers are expected to excel at 21st century skills and implement them in their teaching. Encouraging student innovation in higher education is essential. Creativity is characterized by innovation, distinctiveness, originality, and practicality. Creativity is a critical skill for driving innovation and business in the 21st century [5]. Creative skills may and should be included in the higher education curriculum. Varying approaches to teaching creativity impact the efficiency of developing creativity [7]. Various studies have tried to improve college students' creativity; however, the effect of different teaching approaches on student creativity is uncertain. More empirical study is required to better comprehend how to improve college students' creativity and identify suitable teaching approaches [9].

Educational creativity involves utilizing diverse teaching techniques, including video, animation, and graphics, to enhance the engagement and interest of learners [10]. Creativity is a teaching approach that strengthens students' innovative thinking and conduct by encouraging the expression of creative concepts [11]. Evidence shows that to foster creative thinking in students, instructors must possess robust creative skills reflected in their teaching methods [12, 13].

Formal education teaching practices are commonly thought to hinder creativity. Traditional approaches, known as instructions, involve lectures, textbook assignments, and standardized examinations to evaluate student memorization [14, 15]. Educators advocate for schools to shift from traditional instructional methods to innovative pedagogies that inspire creativity and global perspectives. Education academics lack a definitive solution to which teaching methods result in creative learning outcomes [16, 17].

There have been numerous proposals for creative learning outcomes, all of which share a similar definition of creativity. In the UK, the Qualifications and Curriculum Authority defined creative learning outcomes as questioning and challenging, making connections and seeing relationships, envisaging possibilities, exploring ideas while keeping options open, and critically reflecting on ideas, actions, and outcomes [18]. According to [19], creativity is characterized by possibility thinking and encompasses seven habits of mind: questioning, playfulness, immersion, invention, risk-taking, imagination, and self-determination. The National Advisory Committee on Creative and Cultural Education [20] from the U.K. stated that teaching for creativity includes promoting beliefs and attitudes, motivation, risk-taking, perseverance, interdisciplinary connections, and supporting experiential and experimental learning.

The study makes significant contributions to the art and design education field by offering a comprehensive analysis of pedagogical approaches aimed at unveiling and nurturing creativity. This paper adopts a structured approach comprising the following sections. It delves into creativity theories to furnish educators and researchers with an insightful comprehension of the cognitive mechanisms underpinning creative ideation. Notably, art and design education undergo a transformative evolution wherein conventional pedagogical methodologies, such as studio-based instruction and mentorship, intersect with modern advancements such as the integration of technology and interdisciplinary cooperation. This investigation elucidates the critical impediments educators face in fostering creativity and provides recommendations to overcome these challenges. Furthermore, the emphasis on inclusivity and diversity underlines the importance of creating inclusive learning environments that empower diverse voices and perspectives. By identifying emerging trends and proposing strategies, the study provides educators with an indispensable resource in order to enhance creativity in their teaching practices, ultimately contributing to the ongoing evolution of pedagogy within the dynamic realms of art and design education.

The rest of the paper is arranged as follows. Section II explores a range of ideas that form the basis of creativity and cognitive techniques. Section III discusses conventional approaches such as studio-based learning and mentoring. Section IV examines innovative techniques such as the integration of technology and the use of multidisciplinary methods. Section V delineates the existing obstacles and potential opportunities in the sector. Section VI provides predictions for future advancements in art and design education. Section VII concludes the topic by summarizing important observations and proposing directions for future study and application.

II. Theoretical Frameworks

In order to cultivate the forthcoming generation of innovative thinkers, a thorough comprehension of the fundamental principles governing creativity within the realm of art and design education is indispensable. This section delves into the theoretical framework that serves as the cornerstone of our inquiry. The initial subsection encompasses a diverse array of viewpoints, spanning from the seminal contributions of Guilford and Wallas to contemporary perspectives elucidating the dynamics of creative processes. Subsequently, the second subsection directs our focus inward, delving into the intricate operations of the mind during acts of creativity. From delineating the cognitive mechanisms underpinning ideation to elucidating the neural substrates governing artistic expression, this segment navigates through the complexities of cognitive paradigms, unveiling the symbiotic interplay between cognition, imagination, and artistic innovation. Collectively, these theoretical strands furnish a comprehensive groundwork for discerning the multifaceted dimensions of creativity within the milieu of art and design education.

Elia, et al. [21] integrated the multiple aspects of digital transformation into a single, unifying framework. They presented a conceptual map for successful digital transformation initiatives based on a synthesis of extensive fragmented literature and feedback from domain experts. Additionally, roles, competencies, behaviors, and enablers were identified in order to lead implementation.

Pavlou and Castro-Varela [22] discussed how teacher educators can use digital technologies to provide quality arts education. They explored teacher educators' perspectives on digital technologies challenges and opportunities when teaching arts courses online. Students' active involvement in the online learning process is one of the key challenges identified as well as converting course content for online delivery and ensuring access to high-quality resources. In contrast, educators adapted arts education by developing new materials and modifying teaching methods through digital technologies.

Hashimi [23] investigated the potential benefits of digital and social media tools for improving creativity among art and design learners, and evaluated how they enhance the creative process. The study examines how educators can use digital media to facilitate students' creativity in an experimental educational context. The results reveal students' and educators' perspectives, desires, and concerns while implementing these technologies.

A. Creativity Theories

Creativity in art and design education is underpinned by a rich range of theoretical frameworks that aim to explain the cognitive processes involved in the generation of new and valuable ideas [24]. As shown in Table I, various theories offer nuanced perspectives on the complexity of creativity. These theoretical frameworks assist educators in evaluating creative aptitude, comprehending the functions of cognitive processes, acknowledging sociocultural impacts, and grasping the dynamic interplay between individual traits and external elements. As we navigate through these theoretical terrains, educators glean invaluable understandings of the foundational principles essential for implementing effective pedagogical strategies aimed at nurturing creativity within the domain of art and design education.

TABLE. I. Creativity Theories and Frameworks

Theory/framework	Key concepts	Educational implications
Psychometric approach [1]	Measurement of creativity through standardized tests; components include divergent thinking, convergent thinking, and fluency.	Assessing and identifying creative potential in students; guiding interventions to enhance specific facets of creativity.
Cognitive approach [2]	Explores mental processes in creative thinking; Sternberg's Triarchic Theory delineates creativity into analytical, practical, and creative components.	Understanding how intelligence and knowledge contribute to creative endeavors; insights into cognitive processes shaping original ideas.
Sociocultural theory [4]	Cultural and social factors influence creativity; emphasizes collaborative learning, peer interactions, and cultural contexts.	Fostering creativity through collaborative environments; recognizing the impact of social dynamics on creative expression and problem-solving.
Systems theory [6]	Views the creative process as a dynamic interaction between individual, field, and domain; Csikszentmihalyi's Systems Model of Creativity.	Considering personal attributes, disciplinary conventions, and societal influences in shaping creative outcomes; a holistic perspective on creativity.
Four Ps framework [8]	Considers creativity as a product of person, process, press, and product; interconnected analysis of individual traits, cognitive processes, external influences, and creative output.	Guiding educators in designing learning environments that foster creativity across interconnected dimensions; a holistic perspective on creativity.

- Psychometric approach: The psychometric approach, notably championed by Guilford, focuses on measuring and quantifying creativity through standardized tests. It separates creativity into various elements, such as divergent thinking, convergent thinking, and fluency

[25]. Educators use this approach frequently to determine creative potential in students, directing interventions to enhance specific facets of creativity.

- Cognitive approach: Rooted in cognitive psychology, this approach explores the mental processes involved in creative thinking. An exemplar within this domain is Sternberg's Triarchic Theory, which delineates creativity into analytical, practical, and creative facets. This theoretical framework underscores the significance of intelligence and accumulated knowledge in fostering creativity, thereby affording educators valuable insights into the ways in which cognitive processes engender the generation of novel ideas [26].
- Sociocultural theory: The sociocultural theory posits that cultural and social factors deeply influence creativity [27]. In an educational scenario, this theory highlights the significance of collaborative learning settings, interactions among peers, and cultural contexts in promoting creativity. Educators leveraging this theory emphasize the social dynamics contributing to creative expression and problem-solving.
- Systems theory: As applied to creativity, systems theory views the creative process as a dynamic interaction between various components. For instance, Csikszentmihalyi's framework defines creativity as the intersection between individuals, fields, and domains [28]. Educators adopting this approach take into account personal characteristics, discipline conventions, and societal influences in shaping creativity.
- Four Ps framework: Rooted in the work of Rhodes, the Four Ps framework considers creativity as a product of person, process, press, and product. Educators adopting this framework analyze how individual traits, cognitive processes, external influences, and the final creative output are interconnected. It provides a holistic perspective, guiding educators in designing learning environments that foster creativity across these interconnected dimensions [29].

B. Cognitive Approaches

Cognitive approaches form a crucial facet of the theoretical framework in understanding and promoting creativity within art and design education. Rooted in cognitive psychology, these approaches delve into the intricacies of mental processes and thinking patterns that underlie creative expression [30]. Table II highlights the importance of various factors in creative thinking, such as intelligence, knowledge, cognitive processes in problem-solving, individual learning styles, and the integration of emotion and cognition. These insights are valuable for educators. An examination of cognitive insights in art and design education will provide educators a clear plan for integrating cognitive insights into their teaching methods.

TABLE. II. COGNITIVE APPROACHES IN ART AND DESIGN EDUCATION

Cognitive approach	Key concepts	Educational implications
Analytical insight into creative thinking	Dissecting creativity into analytical, practical, and creative thinking components, as seen in Sternberg's Triarchic Theory.	Recognizing creativity as a multifaceted construct; guiding educators to balance various cognitive abilities in fostering creativity.
Role of intelligence and knowledge	Underscoring the role of intelligence and accumulated knowledge in the creative process.	Integrating knowledge-building activities into curricula; emphasizing the interconnectedness of creative thinking and cognitive abilities.
Cognitive processes in problem-solving	Shedding light on cognitive processes involved in creative problem-solving, such as divergent thinking and pattern recognition.	Designing tasks that stimulate and enhance creative problem-solving skills among students; fostering a problem-solving mindset in artistic endeavors.
Connection to learning styles	Recognizing individual differences in learning styles and cognitive preferences.	Tailoring instructional methods to resonate with diverse learners; fostering a more inclusive and effective learning environment within art and design education.
Integration of emotion and cognition	Acknowledging the interplay between emotion and cognition in the creative process.	Creating emotionally engaging learning experiences; encouraging students to channel their emotions into their artistic endeavors in art and design education.
Application in art and design pedagogy	Guiding the development of instructional strategies that facilitate critical thinking, problem-solving, and creative expression.	Incorporating activities that stimulate cognitive processes; empowering students to explore, experiment, and innovate within the artistic creation context.

- Analytical insight into creative thinking: Cognitive approaches, such as Sternberg's Triarchic Theory, dissect creativity into distinct components, including analytical, practical, and creative thinking. This analytical understanding enables educators recognize that creativity is not a singular idea, but rather a complex construct that requires a combination of cognitive talents [31].
- Role of intelligence and knowledge: The cognitive approach underscores the role of intelligence and accumulated knowledge in the creative process. The statement indicates that creative thinking is not separate from cognitive abilities, instead being closely linked to them. This understanding leads educators to include knowledge-building activities into art and design courses [32, 33].

- Cognitive processes in problem-solving: Creativity often involves problem-solving, and cognitive approaches shed light on how individuals' approach and solve problems creatively [34]. Understanding these cognitive processes, such as divergent thinking and pattern recognition, enables educators to design tasks that stimulate and enhance creative problem-solving skills among students [35].
- Connection to learning styles: Cognitive approaches recognize individual differences in learning styles and cognitive preferences [36]. Instructors can employ this knowledge to customize teaching techniques that align with the cognitive abilities of a wide range of students, promoting a more inclusive and efficient learning setting [37].
- Integration of emotion and cognition: Artistic expression is inherently linked to emotions, and cognitive approaches acknowledge the interplay between emotion and cognition in the creative process. Teachers may use this knowledge to develop intellectually stimulating educational activities that motivate pupils to express their feelings via their creative pursuits [38].
- Application in art and design pedagogy: In art and design education, cognitive approaches guide the development of instructional strategies that facilitate critical thinking, problem-solving, and creative expression. By integrating activities that engage cognitive processes, educators enable students to investigate, test, and generate new ideas within the realm of creative creativity [39].

III. Traditional Pedagogical Approaches

Conventional teaching methods in art and design education are well-established principles that provide effective tools for nurturing creativity. This section examines widely recognized frameworks that have a long history of artistic instruction. The first subsection puts learners in a studio setting that is designed to fully engage them, with a focus on hands-on exploration and the development of skills. The second subsection reflects the historical origins of artistic education, highlighting the need of individualized assistance and hands-on learning.

A. Studio-based Learning

Studio-based learning is a fundamental aspect of conventional art and design education methods, characterized by an interactive and engaging approach that promotes creativity via practical experiences [40]. Studio-based learning, derived from the atelier model traditionally used in fine arts, has expanded to include several creative disciplines. This approach allows students to immerse themselves in their trade and explore it extensively.

- Hands-on exploration and experimentation: At the core of studio-based learning is hands-on exploration and experimentation [41]. Learners actively participate in the process of production, enabling them to enhance their technical abilities, polish their creative vision, and foster a profound relationship with their chosen medium [42]. The studio becomes a dynamic space where ideas materialize and learning transcends theoretical concepts into tangible expressions.
- Peer collaboration and critique: Studio environments promote peer cooperation, developing a sense of community among budding artists and designers. Collaborative projects and constructive criticisms are essential aspects of the learning process, allowing students to encounter other viewpoints and improve their capacity to provide and accept feedback, a crucial talent in the creative sectors [43].
- Mentorship and apprenticeship dynamics: The studio model often incorporates mentorship and apprenticeship dynamics, where experienced artists guide and inspire emerging talents [44]. This tradition of passing down knowledge and skills from master to apprentice enriches the learning journey, providing students with real-world insights and professional guidance as they navigate the complexities of their chosen artistic discipline [45].
- Integration of theory and practice: Studio-based learning combines academic knowledge with real-world application [46]. As students participate in the creative process, they also acquire knowledge of art history, theory, and cultural contexts, enhancing their work with a sophisticated grasp of the wider artistic environment.
- Freedom for creative expression: The studio setting provides students with the autonomy to take part in imaginative expression and personal exploration [47]. By granting learners liberty, they are able to independently delve into their own artistic expression, developing a strong feeling of ownership and enthusiasm towards their creative endeavors. The studio serves as a conducive environment for the flourishing of creativity and the emergence of individual creative identities [48].
- Preparation for professional practice: Studio-based learning is a robust preparation for the professional art and design world [49]. The challenges and collaborative dynamics within the studio environment mirror real-world scenarios, equipping students with the skills and resilience needed for successful careers in the creative industries [50].

B. Mentorship and Apprenticeship

Mentorship and apprenticeship stand as venerable and time-tested pedagogical approaches in art and design education, embodying a personalized and immersive method of knowledge transfer and skill development [51]. These techniques are based on a long history of creative tradition, focusing on the transmission of knowledge and creating a strong bond between established practitioners and aspiring artists or designers.

- Individualized guidance and support: Mentorship and apprenticeship models prioritize individualized guidance and support, allowing aspiring artists or designers to benefit from the seasoned insights of a mentor. The individualized interaction between mentor and learner creates a dynamic learning setting, in which the mentor customizes education to cater to the apprentice's distinct requirements, strengths, and interests. This approach

enhances the trainee's comprehension of the skill on a deeper level [52].

- Experiential learning through observation: Apprenticeship often entails immersion learning by directly observing and actively participating in the mentor's creative process. This hands-on method surpasses theoretical teaching by offering trainees direct exposure to the practical intricacies of their chosen creative field. By closely observing, apprentices acquire technical expertise as well as the abstract elements of creative intuition and decision-making [53].
- Cultural transmission of artistic traditions: Mentorship and apprenticeship models contribute to the cultural transmission of artistic traditions. Through close collaboration with a mentor, apprentices acquire and preserve technical expertise, as well as the cultural and contextual aspects inherent in the creative process. The transmission of cultural knowledge guarantees the preservation and advancement of creative traditions from one generation to another [54].
- Building a professional network: In addition to acquiring skills, mentoring facilitates the growth of a professional network. Apprentices frequently gain advantages from being exposed to the mentor's network of collaborators, colleagues, and industry experts, which allows them to access opportunities and enhance their comprehension of the wider professional environment [55].
- Cultivation of a strong work ethic: Mentorship and apprenticeship instill a strong work ethic and discipline in aspiring artists and designers. The level of devotion and ongoing growth demanded in a mentor-mentee relationship forms the basis for a resilient and dynamic attitude to creative pursuits [56].
- Preparation for artistic independence: Through mentorship and apprenticeship, aspiring artists or designers are not just recipients of knowledge but are gradually guided toward artistic independence. Mentors facilitate a transition from dependence to autonomy, empowering apprentices to develop their creative voice, make informed decisions, and ultimately emerge as self-assured contributors to the artistic or design field [57].

IV. Contemporary Pedagogical Innovations

Contemporary pedagogical advances in art and design education drive creative learning forward into novel areas. This part explores cutting-edge innovation by examining two unique strands that redefine the limits of conventional teaching methods. The initial portion, as detailed in Table III, delves into the intersection of advanced technology and creative expression, providing students with innovative tools for production, collaboration, and display. The combination of virtual worlds, artificial intelligence, and digital platforms transforms the landscape of artistic discovery. Table IV encapsulates the second subsection, which goes beyond disciplinary boundaries, prompting students to explore the convergence of art, science, and society challenges. Exploring modern teaching methods involves using technology and interdisciplinary studies to help educators prepare students for the complex demands of the creative fields.

TABLE. III. Technology Integration in Art and Design Education

Key components	Description
Digital tools for creative expression	Introduction of graphic design software, virtual reality applications, digital drawing tablets, and multimedia editing platforms.
Virtual and augmented reality experiences	Incorporation of virtual and augmented reality experiences, revolutionizing student engagement through virtual studio spaces and immersive exhibitions.
Global collaboration and cross-cultural learning	Utilization of technology for global collaboration, enabling cross-cultural learning experiences and exposing students to diverse perspectives.
Digital portfolio development	Shaping students' professional identities through digital portfolio development on online platforms and social media.
Adaptive learning platforms and personalized feedback	Implementation of adaptive learning platforms to tailor educational experiences based on individual needs, ensuring personalized instruction and feedback.
Ethical considerations and digital citizenship	Integration of discussions on ethical considerations and digital citizenship, exploring issues of copyright, digital ethics, and responsible technology use.

TABLE. IV. Interdisciplinary Approaches in Art and Design Education

Key components	Description
Breaking down disciplinary silos	Encouragement for students to transcend traditional disciplinary boundaries, drawing inspiration from diverse fields.
Collaborative problem-solving	Strong emphasis on collaborative problem-solving, engaging students in teamwork projects with individuals from diverse backgrounds.
Incorporation of emerging technologies	Integration of emerging technologies into projects, combining traditional principles with technological advancements.
Cross-cultural and global perspectives	Exploration of cross-cultural and global perspectives, allowing students to develop a nuanced understanding of diverse traditions.
Flexible curriculum and personalized learning paths	Flexible curricula empowering students to tailor learning paths based on interests and career goals, fostering agency and ownership.
Real-world application of skills	Emphasis on the real-world application of skills through projects simulating professional scenarios, preparing students for industry challenges.

A. Technology Integration

Technology integration has become a revolutionary and modern teaching innovation in the constantly changing field of art and design education. The incorporation of technology aims to improve creative learning outcomes by using electronic resources and systems, offering students more opportunities for expression, collaboration, and involvement [58].

- Digital tools for creative expression: Technology integration introduces many digital tools that expand the possibilities of creative expression. Graphic design software, virtual reality applications, digital drawing

tablets, and multimedia editing platforms empower students to explore and manipulate various mediums in once-inconceivable ways. This digital toolkit enhances technical skills and encourages experimentation and innovation [59].

- Virtual and augmented reality experiences: Incorporating virtual and augmented reality experiences revolutionizes how students engage with their creative projects [60]. Virtual studio spaces, immersive exhibitions, and interactive simulations offer a dynamic and immersive learning environment. This expands the scope of creative exploration and prepares students for the technological advancements prevalent in contemporary artistic and design practices [61].
- Global collaboration and cross-cultural learning: Technology facilitates global collaboration, enabling students to connect with peers, artists, and designers worldwide [62]. Virtual educational settings, internet forums, and collaborative projects facilitate cross-cultural learning experiences by overcoming geographical limitations. By being networked, students are exposed to a wide range of viewpoints, influences, and creative traditions, which enhances their comprehension of global trends and cultural contexts [63].
- Digital portfolio development: The incorporation of technology is crucial in influencing students' professional identities by supporting the creation of digital portfolios. Online communities and social networks provide avenues for students to exhibit their work, receive feedback, and establish connections with future collaborators and employers. The transition to digital portfolios is in line with current trends in the creative industries, equipping students with the necessary skills for thriving in a digitally focused work environment [64].
- Adaptive learning platforms and personalized feedback: Adaptive learning platforms leverage technology to tailor educational experiences to individual student needs. These systems use algorithms to customize material delivery, guaranteeing that students obtain individualized education and feedback according to their advancement and educational preferences. This tailored method promotes a more efficient and all-encompassing learning atmosphere, supporting the varied requirements of students in art and design education [65].
- Ethical considerations and digital citizenship: Technology integration introduces discussions around ethical considerations and digital citizenship within art and design. Students investigate issues around copyright, digital ethics, and appropriate use of technology in their creative pursuits. This rigorous examination of the moral aspects of technology equips students with the necessary skills to traverse the intricate realm of digital art and design with honesty and consciousness [66].

B. Interdisciplinary Approaches

Contemporary art and design education are using multidisciplinary techniques to meet the ever-evolving demands of the creative field [67]. This progressive educational change motivates students to move beyond conventional disciplinary limits, promoting cooperation and incorporating perspectives from several areas. Interdisciplinary methods in art and design education represent a fundamental change that mirrors the intricate and linked character of modern creative activities.

- Breaking down disciplinary silos: Interdisciplinary approaches break down traditional disciplinary silos, encouraging students to draw inspiration from various disciplines such as science, technology, literature, and social sciences. By eliminating these obstacles, students acquire a more comprehensive outlook and a deeper comprehension of the interrelatedness of concepts, cultivating a mentality that promotes creative thinking [68].
- Collaborative problem-solving: Interdisciplinary education places a strong emphasis on collaborative problem-solving. Students participate in collaborative projects that need the cooperation of persons with a wide range of skills and viewpoints. This collaborative environment replicates real-life situations in the creative industries, where interdisciplinary teamwork is crucial for tackling intricate problems [69].
- Incorporation of emerging technologies: Interdisciplinary approaches often involve integrating emerging technologies into artistic and design projects. By integrating conventional artistic concepts with technology breakthroughs, students acquire a wide range of skills that places them at the forefront of modern creative activities. This integration of technology and creativity equips students with the necessary skills for professions that need proficiency in both fields [70].
- Cross-cultural and global perspectives: Interdisciplinary education encourages students to explore cross-cultural and global perspectives. Students develop a sophisticated comprehension of multiple aesthetic traditions by integrating aspects from different cultures and areas. This exposure enhances their creative output and cultivates a global perspective that is becoming more and more relevant in today's linked society [71].
- Flexible curriculum and personalized learning paths: Interdisciplinary approaches often feature flexible curricula that allow students to tailor their learning paths based on their interests and career goals. Through this customized method, students have the opportunity to delve into many topics and refine abilities that correspond with their own ambitions, promoting a feeling of control and responsibility over their education [72].
- Real-world application of skills: Interdisciplinary education strongly emphasizes the real-world application of skills. Students participate in projects that replicate real-world situations, equipping them with the skills and

experience necessary to tackle the complex and diverse issues they may face in their professional endeavors. The use of information in real-world scenarios improves the student's capacity to negotiate the intricacies of modern creative sectors [73].

V. Result and Discussion

The field of art and design education is marked by a dynamic interaction between challenges and possibilities that influence the experiences of both teachers and students. Comprehending and resolving these complexities are crucial for fostering a flourishing and inventive educational atmosphere.

A. Challenges

- Limited resources and funding: Art and design programs often grapple with limited resources and funding, hindering the implementation of advanced technologies, materials, and facilities. This challenge can restrict the breadth of creative experiences available to students and constrain the development of cutting-edge pedagogical approaches.
- Diversity and inclusivity gaps: Achieving diversity and inclusivity in art and design education remains a persistent challenge. Addressing disparities in representation across demographics and fostering an inclusive environment that welcomes varied perspectives are crucial for nurturing a diverse cohort of creative minds.
- Technological disparities: As technology becomes integral to creative practices, disparities in access to technological resources pose a challenge. Students with limited access to digital tools and software may face barriers to fully realizing their creative potential. Bridging this technological gap is essential for ensuring equitable opportunities for all learners.
- Changing nature of creative industries: The rapid evolution of the creative industries introduces challenges in aligning educational curricula with emerging trends and technologies. Keeping pace with the ever-changing demands of the professional landscape poses a continual challenge for educators striving to prepare students for future career opportunities.
- Balancing tradition and innovation: Striking a balance between traditional artistic principles and innovative approaches is a delicate challenge. While preserving foundational skills and techniques, educators must also integrate emerging technologies and interdisciplinary practices, ensuring students have a versatile skill set.

B. Opportunities

- Advancements in technology: Technological advancements present significant opportunities for enhancing art and design education. Virtual reality, augmented reality, and online collaboration platforms provide new avenues for immersive and interactive learning experiences. Embracing these technologies can enrich the educational journey and prepare students for the tech-driven creative landscape.
- Innovative pedagogical approaches: The challenges of resource limitations and changing industry demands also pave the way for innovative pedagogical approaches. Studio-based learning, mentorship programs, and interdisciplinary curricula offer opportunities for dynamic and experiential education that prepares students for the complexities of the professional realm.
- Cultivating a diverse and inclusive community: While diversity and inclusivity present challenges, they also serve as opportunities to create a vibrant community. Embracing diverse voices and experiences fosters a creative ecosystem where different perspectives converge, leading to a more dynamic and inclusive educational environment.

VI. Future Trends

The future of art and design education is poised for exciting transformations driven by emerging trends that reflect the evolving landscape of creativity and education. Anticipating these trends provides educators, policymakers, and practitioners with insights to adapt and shape the future of art and design pedagogy.

- Integration of Artificial Intelligence (AI) and machine learning: The integration of AI and machine learning is poised to revolutionize art and design education. AI tools can assist students in generating ideas, automating routine tasks, and providing personalized feedback [74, 75]. Incorporating AI into the curriculum enhances technical skills and prepares students for collaborations with intelligent systems in their creative endeavors [76].
- Expansion of Virtual Reality (VR) and Augmented Reality (AR) Experiences: These technologies are expected to play an increasingly prominent role in art and design education. These immersive technologies offer students virtual studio experiences, interactive exhibitions, and collaborative design environments. The expansion of VR and AR in education provides students with novel ways to engage with their creative processes and connect with global artistic communities.
- Continued interdisciplinary integration: Interdisciplinary approaches are expected to evolve further, with a continued emphasis on integrating diverse fields such as science, technology, and humanities into art and design education. This trend acknowledges the interconnected nature of contemporary creative practices and prepares students for collaborative endeavors that transcend traditional disciplinary boundaries.
- Global collaborations and cross-cultural experiences: Advancements in technology facilitate seamless global collaborations, allowing students to engage in cross-cultural experiences without physical limitations. Collaborative projects, joint exhibitions, and shared learning experiences with students worldwide are anticipated to become more prevalent, enriching the educational journey with diverse perspectives.
- Data-driven personalization: The rise of data-driven approaches will enable personalized learning

experiences tailored to individual student needs. Adaptive learning platforms and analytics tools will provide educators with insights into student progress, allowing them to tailor instruction and interventions based on individual strengths and areas for improvement.

- Gamification of learning: Gamification, incorporating game elements into educational activities, will become a prevalent trend. Gamified learning experiences can enhance student engagement, motivation, and skill development. Art and design educators may explore the potential of game-based approaches to make learning more interactive, enjoyable, and conducive to creativity.
- Integration of mindfulness practices: Mindfulness practices, such as meditation and reflection, will find a place in art and design education. Recognizing the importance of mental well-being and its connection to creativity, educators may incorporate mindfulness exercises to help students manage stress, enhance focus, and foster a positive and conducive learning environment.
- Open Educational Resources (OER): The use of OER will increase, offering freely accessible and adaptable learning materials. This trend aligns with the movement towards greater accessibility and inclusivity in education. Educators may leverage OER to provide students with diverse learning materials, reducing financial barriers and enhancing the overall educational experience.
- Design thinking in art education: The integration of design thinking methodologies into art education will become more prominent. This approach encourages students to apply problem-solving techniques commonly used in design fields to artistic challenges. Design thinking fosters a mindset that values empathy, iteration, and user-centric solutions, providing a holistic framework for creative problem-solving.

VII. Conclusion

In the tapestry of art and design education, the threads of innovation, diversity, and adaptability weave a narrative that extends beyond the confines of traditional pedagogies. As we peer into the future, it is evident that the canvas of creative education is undergoing a profound transformation, marked by emerging trends that mirror the dynamic nature of contemporary creative industries. The integration of technology stands as a potent force, propelling art and design education into a realm where artificial intelligence, virtual reality, and digital platforms redefine the boundaries of artistic expression. In this digital atelier, students refine their technical skills and explore novel dimensions of creativity, navigating a landscape where pixels and brushstrokes coalesce in unprecedented ways. Interdisciplinary collaboration emerges as a catalyst for innovation, encouraging students to bridge the chasm between artistic disciplines and other realms of knowledge.

As the silos of traditional education crumble, a new generation of creatives emerges adept at navigating the intersections of art, science, technology, and societal challenges. The future artist is a polymath, a storyteller who draws inspiration from the rich tapestry of human experience. Sustainability and ethical considerations paint a conscientious stroke on the canvas, reminding us that creativity carries a profound responsibility. The future artist is not only a master of form and color but also a steward of environmental consciousness and social impact. In this era of heightened awareness, art and design education become a crucible for nurturing a generation of creatives who forge a path toward a more sustainable and equitable future. As the brushstrokes of innovation paint the landscape, inclusivity becomes the canvas's underlying texture. The future of art and design education is one where diverse voice harmonize and cultural perspectives converge. In classrooms and virtual studios, educators cultivate an environment where creativity knows no bounds, where every student's unique narrative contributes to the rich mosaic of the creative discourse.

Tábata Nakagomi Fernandes Pereira[3], Milena de Oliveira Arantes[4]
Institute of Integrated Engineering, Federal University of Itajuba (Unifei), Itabira, Brazil[1, 2, 3]
National Institute of Telecommunications (Inatel), Santa Rita do Sapucaí, Brazil[4]

***Abstract*—Traditional project management methods are specific, predictable and seek to keep the planning as detailed as possible and, even over time, companies continue to integrate them into their processes. The present study aims to raise the main traditional methods of Project Management, to present them in more detail, through a Systematic Literature Review. In this review, 37 articles were found and analyzed to answer five research questions. The research questions focused on answering: the main traditional project management methods, the most relevant maturity models, trends in the area, and the challenges and future directions for project management. As the main results, PMBOK was pointed out as the main traditional method, followed by PRINCE2, ISO 21500 standard and CTCR methodology. In addition, highlighting the tools, there are Gantt Chart, Earned Value Management, Critical Chain Project Management, and TOC Method as the most relevant. Therefore, it is possible to obtain a broad and detailed view of the main traditional methods of PM and with this, researchers in the area will be able to make better decisions in choosing the appropriate method for their type of project. As for challenges and future directions, the article pointed out that currently, project processes are complex and therefore do not meet their initial deadlines, cost, quality and business goals. Thus, difficulties in PM also stand out: delays in the schedule, lack of clearly defined objectives and support from leadership/company, scope changes, insufficient resources, poor risk management and measurement of project performance and lack of communication.**

***Keywords*—Traditional methods; project management; framework; PMBOK®**

I. Introduction

No matter how successful the organization is, the dynamism of the market requires reinforcements to maintain its capacity for innovation and ensure its competitiveness. Thus, to effectively meet the demand, in an environment characterized by the speed of change, a management model based on priorities and goals has become essential, and that is why project management has developed so quickly all over the world [1].

Therefore, Project Management (PM) corresponds to the applicability of knowledge, skills, tools, and techniques to project activities to fulfill their requirements, allowing organizations to perform their projects effectively and efficiently [2].

Following this direction, the PM is designed to make the best use of resources so that workflows both horizontally and vertically within a company, without eliminating the vertical and bureaucratic workflow, but insisting that the entire company works with easier through horizontal communication between line organizations [3]. The author also presents some characteristics that an adequate project management method needs to have, such as the use of models, indication of the level of detail, standardization of techniques and report format, flexibility for application, rapid improvements and being easy to understand for the customer and the whole company.

Project Management offers several advantages over other forms of management and is effective in achieving the desired results within the time and budget determined by the organization. In this way, the author highlights that the main advantage of the PM is that it is not limited to large, high complexity and cost projects, that is, it can be applied to projects of any complexity, budget, size, and type of business [1].

Besides that, once adopted by an organization, PM can help to better guide and apply scarce resources, direct the organization's focus to goals and objectives, and generate opportunities for development in relation to the skills of teams, through motivation, innovation, learning and construction of multifunctional and multidisciplinary coexistence. In addition, it provides a better understanding of the internal production networks that permeate the different departments and sectors of the organization [4].

This way, the PM has gained a prominent place in the management of organizations through the development of more structured methods, concepts, and techniques to ensure the success of the project. Following this direction, according to [5], the two main methodologies for project management are the traditional approaches, which follow PMBOK® principles, most of the time, and the agile approaches, which are based on the Agile Manifesto that covers the principles and characteristics thereof.

Both traditional and agile methods are widely used [6] and each one has unique characteristics and, consequently, positive, and negative aspects in relation to Project Management. Therefore, their planning and control actions are similar, however, the form of execution of the techniques and tools

employed refers to the main difference between these methodologies [7].

According to [8], agile methods are iterative and incremental, resulting in products developed based on continuous improvement and guaranteeing customer satisfaction, since the same participates fully throughout the project. According to these authors, even though the use of this methodology affects the paradigm of traditional methods, it should not be used as a replacement for these processes, but as a complement or an alternative.

On the other hand, traditional approaches aim at logical sequencing by determining results in advance and evaluating project development based on various resource analyses, so traditional methods are specifiable and predictable, in addition to being built through thorough and extensive planning [9,10].

The implementation of Project Management methods is a strategy increasingly used by companies and the effectiveness, as well as the adequacy, depend on different factors, since organizations differ in organizational structure, size, and sector of activity, among others. Following the idea, the choice of the most suitable method for a company varies according to the purpose it seeks and needs a detailed assessment of all existing approaches [11].

Considering the presented context, the present work has as general objective to identify the main traditional methods of project management and to compare them in a detailed way through a Systematic Literature Review (SLR).

This study is structured in five sections. The first section is the introduction, which contextualizes the entire study and a brief background. Section II introduces the research methodology. Section III refers to the development. Section IV presents the result analysis. Section V presents works related to the topic. Section VI presents the conclusions of the work. Finally, Section VII provides recommendations for future work, followed by the bibliographic references.

II. METHODOLOGY

A. Systematic Literature Review (SLR)

According to Galvão and Ricarte (2019), literature review is a generic expression that includes all published works that provide an analysis of the literature encompassing specific subjects. In this way SLR goes beyond that, as it is a scientific study that consists of its objectives, research questions, methods, results and conclusions. Thus, for this study, the method applied is based on the proposal by [12] which is composed of the following steps to be followed:

- Review planning (preparation phase).
- Conducting the review (operational phase).
- Review documentation (reporting phase).

Fig. 1 visually represents all the steps and sub-steps of the [12] methodology that will be developed in this work.

Fig. 1. Structure of the SLR method. 'Source: [12]'

III. DEVELOPMENT

In order to gather similar materials from various authors, perform a critical analysis and contribute to future investigations on the main traditional methods of Project Management, this SLR will follow the same approach applied in the works of [12], which corresponds to three stages, I) "Planning the review" (preparation phase), II) "Conducting the review" (operational phase) and III) "Documenting the review" (reporting phase), which will be covered in the next sections.

A. Planning the Review (Preparation Stage)

According to study [12], the review planning stage consists of addressing two crucial focuses when preparing the review, which are: the specification of the research question and the development of a research protocol.

Specifying the research question is the first step towards a good systematic review since all work will be guided by it. In this sense, the question must be very well formulated and clear [13], as it will serve as a guide to determine the studies that will be included, in addition to defining search strategies to identify the primary studies and which data need to be extracted.

In this sense, the questions that guide this work were based on the work of [14], to facilitate the subsequent analysis of the results. The questions elaborated are presented as follows:

Q1. What are the main traditional methods of MP?

Q2. What are the main traditional MP tools and/or techniques?

Q3. What are the most relevant traditional project management maturity models?

Q4. What are the trends for the traditional MP area?

Q5. What are the challenges and future directions for the traditional MP area?

Regarding the second sub-step addressed by the authors of the method, which is the development of a research protocol, five databases were initially selected (Scopus, Web of Science, Taylor and Francis, Scielo and Esmerald) to be studied. Thus, after preliminary analyses, the Scopus® database was chosen because it is the main database for citations [15, 16]. It covers the production of files, abstracts, in addition to the quality in the variety of search tools to refine the search.

Once the Scopus® database was defined, the first more diversified search for keywords was started. The defined keywords are presented in Table I.

TABLE I. DEFINED KEYWORDS

	Keyword combinations
1	(TITLE-ABS-KEY (*"traditional methodology"*))
2	(TITLE-ABS-KEY (*"traditional methodology"*) AND TITLE-ABS-KEY (*"project management"*))
3	(TITLE-ABS-KEY (*"traditional methodology"*) AND TITLE-ABS-KEY (*management*))
4	(TITLE-ABS-KEY (*"traditional method"*) AND TITLE-ABS-KEY (*"project management"*))
5	(TITLE-ABS-KEY (*"project management practices"*))
6	(TITLE-ABS-KEY (*"traditional development"*) OR TITLE-ABS-KEY (*"traditional methods"*) OR TITLE-ABS-KEY (*"traditional approach"*) AND TITLE-ABS-KEY (*"project management"*))
7	(TITLE-ABS-KEY (*"project management"*) AND TITLE-ABS-KEY (*waterfall*))
8	(TITLE-ABS-KEY (*"traditional methodology"*) AND TITLE-ABS-KEY (*framework*))

Still with the objective of refining the search results as much as possible and obtaining more assertive results about the work, some filters were applied, which are:

- Open access.
- Article type documents.
- Language in Portuguese and English.

It is worth mentioning that, considering future comparisons, there were no restrictions regarding the year or area of study. Thus, after completing this first phase of initial planning through the definition of research questions and the way of collecting data for the work, the next stage of the SLR method of conducting the research can be continued.

B. Conducting the Review (Operational Stage)

This stage of the method is the operational stage, in which it is proposed to conduct the research through five stages, which are: the identification of relevant research, selection of primary studies, evaluation of the quality of the study, extraction of the necessary data and data synthesis [12].

The first two stages of identifying relevant research and selecting primary studies were presented in the previous step. The result of 4,392 articles was obtained, but to limit the search and focus on the research topic in question, the following filters were applied:

- Documents of the article type.
- Open access only.
- Written in Portuguese or English.
- Studies with the central theme the traditional methods for project management.
- After applying the filters above, it was possible to find 621 articles, of which they were inserted into the Microsoft Excel® software to perform another analysis and remove 97 articles due to duplicity. In addition, it was also possible to discard the keywords "traditional methodology" AND "project management", "traditional methodology" AND management and "traditional methodology" AND "framework", since they only included articles already present in the other groups of keywords.
- Soon after the application of the filters, the evaluation of the quality of the studies began, through the analysis of titles, abstracts, and keywords, to discard articles that do not match the subject of the study search. This way, after the reading, 466 articles were excluded. From this total, it is worth mentioning that 370 (79.4%) are part of the group corresponding to the keyword "traditional methodology", this is because it is a general term and not only directed to project management, as well as articles by several areas of study such as social sciences, agricultural sciences, biochemistry, genetics, molecular biology, medicine, among others. Furthermore, 95 (20.4%) articles were distributed among the other groups of keywords, in which the titles and abstracts were also about other areas or did not address any traditional method of project management, and 1 (0.2 %) article was not found.
- Continuing in one more step, the quality assessment of the study began, 58 articles were downloaded to carry out the analysis through the complete reading and extraction of information relevant to the topic. Therefore, after reading, another 21 articles were discarded for reasons of 14 (66.7%) it is about project management in general, did not mention or focus on traditional methods, 6 articles (28.6%) focused on in agile methodologies and 1 article (4.7%) addressed the traditional methodology, but presented a lot of numerical data instead of theory. Therefore, with the objective of answering the research questions elaborated, this SLR focused on studying 37 articles.

C. Documenting the Review (Information Stage)

The review documentation consists of using the results obtained in the previous stages to answer the questions defined in the first stage and conclude the SLR. To facilitate and speed up the absorption and knowledge of the data by the reader, the results were summarized in graphs and tables with the most relevant perceptions of this SLR. In addition, all this analysis promotes perceptions and gaps for the development of the scientific community around the topic in question. The results will be presented in section four.

IV. ANALYSIS OF RESULTS

The purpose of this section is to portray the observations and studies on the nature of the research. At first, the main traditional methods (Q1) will be presented through the survey of the studies. A total of four traditional methods were identified. The Project Management Body of Knowledge (PMBOK®) was identified as the main traditional method,

since it was reported in 18 studies, followed by the Project IN Controlled Environment (PRINCE2) method, which appears in nine studies. The ISO 21500 standard was reported in two studies and the methodology that combines and simultaneously considers the costs, deadlines, criticality, and risks (CTCR) of project activities, in just one. Both provide guidelines for Project Management.

It is worth mentioning that, from the total of 37 selected articles, 21 reported the four main traditional methods of Project Management presented, and the other articles contemplated answers to the other research questions without reporting any specific traditional method.

According to [17], PMBOK and PRINCE2 are among the several standard PM methodologies that are employed in different areas. Furthermore, the studies by [18] confirm the high percentage of professionals who employ these two Project Management methods, tools, techniques, or standards as a relevant part of project success.

As stated by study [19], initiatives to regularize indispensable knowledge for PM through concepts, information, activities, and documentation, are most often based on the assumption that there are standards from which rules, control, and guidelines for "good practices" can be determined "practices" that are replicable for the PM. Thus, PRINCE2, PMBOK and ISO 21500 were presented by [20] as traditional methodological frameworks of reference because they are effective and necessary in many projects.

Considering question two (Q2) "What are the main traditional MP tools and/or techniques?" it was possible to identify 18 studies that include traditional PM tools and/or techniques. Following the idea, through them, 33 tools and 29 techniques were raised, as shown in Table II. Furthermore, it is observed that in relation to the total number of tools, it is possible to highlight the studies by [21, 22] in which they presented, respectively, eight and seven tools and, in terms of techniques, the article by [7] explained 23 techniques out of the total.

TABLE II. TRADITIONAL PROJECT MANAGEMENT TOOLS AND / OR TECHNIQUES

Tools/Techniques		Authors
Tools	Cost-benefit analysis (C.B.A.)	[21]
	SWOT analysis or matrix	[21]
	Tree of goals	[23]
	Database	[7]
	Brainstorming	[24]
	CCPM - Critical Chain Project Management	[18, 20, 25, 26]
	Checklist	[7]
	Budget control and monitoring and reporting systems	[18]
	Statement of Work (S.O.W.)	[21]
	Earned Value Management (EVM)	
	Structure called 4PTRB	[27]
	Work division structure (W.B.S.)	[21]
	Risk assessment tool based on survival analysis	[28]
	Gantt Chart	[7, 18, 19, 21, 23, 25, 26]
	Activities list	[19]
	Logical framework matrix	[18]
	RACI matrix	[21]
	TOC method	[29, 30]
	SMART methodology	[21]
	Situation Wall Board	[7]
	Software ProjectWise (Electronic document management systems)	[22]
	Software of GP JIRA	[7]
	Software Doc Express	[22]
	Software e-Builder	[22]
	Software Microsoft Project	[7]
	Software PlanGrid	[22]
	Software Primavera P6	[22]
	Software Procore	[22]
	Software AASHTOWare Project	[22]
	Story Boarding	[24]
	Resource Dependency Theory (RDT)	[29, 30]
	Triangular Iron Performance Test	[31]
	Resource-based view (RBV)	[29, 30]
Techniques	Adjusting anticipations and waits	[7]
	Analysis of alternatives	[7]
	Function Point Analysis (FPA)	[24]
	Product analysis	[7]
	Reservation analysis	[7]
	Performance analysis	[7]
	Tree of decision	[7]
	Balanced scorecard	[7]
	Business problem definition	[7]
	Chartering	[7]
	Schedule compression	[7]
	Critical Path Method	[7]
	Delphi Technique	[7]
	Duration and total work effort	[7]
	Earned Value Analysis	[7]
	Similar estimate	[7]
	Estimate based on analogy	[24]
	Parametric estimation	[7]
	Estmation of COst MOdel (COCOMO / COCOMO-II)	[24]
	Point of Use Estimates	[24]
	Event on node diagram	[7]
	Critical current method	[7, 18]
	Expert opinion method	[24]
	Resource leveling	[7]
	Program Evaluation and Review Technique	[7]
	Stoplight reports	[7]
	Meta-network analysis technique (MNA)	[28]
	Three-point estimation technique	[7]
	WBS/ Decomposition	[7]

The most relevant tools raised in this SLR were the Gantt Chart, Earned Value Management (EVM), Critical Chain Project Management (CCPM) and TOC Method, cited seven, five, four and three times respectively in the studies. Thus, the others appeared only once. Regarding the techniques, of the 29 surveyed, only the Critical Current Method was mentioned in two articles. It is worth mentioning that the classification of tools and/or techniques was according to the nomenclature used by the authors.

In this way, it is also observed that studies, mainly related to tools, have been published in recent years, showing that companies are increasingly looking for a more efficient PM using tools and/or techniques. So, to ensure the continuous improvement of processes, facilitating and optimizing planning, in addition to predicting possible difficulties, calculating risks, and identifying which choices are more assertive.

In relation to traditional project management maturity models, next research question (Q3), five studies were analyzed, in which it was possible to raise a total of 15 maturity models. Thus, as shown in Table III below, it is observed that the articles by the authors [32, 33] each presented 8 maturity models, followed by the study of the authors [34] with 6 models portrayed, in addition, these three studies present three similar models.

TABLE III. RELATIONSHIP OF TRADITIONAL PROJECT MANAGEMENT MATURITY MODELS WITH ARTICLES

	Maturity Models	Authors
1	Capability Maturity Model Integration (CMMI®)	[20, 27, 32, 33, 34]
2	Maturity Model	[33]
3	Organizational Project Management Maturity Model (OPM3)	[32, 33, 34]
4	People Capability Maturity Model (P-CMM)	[34]
5	PM Solutions Project Management Maturity Model (PMMM) from the United States Center for Business Practices (CRAWFORD, 2002)	[32]
6	Project FRAMEWORK created by ESI International	[33]
7	Project Management Maturity Model - P3M3	[32]
8	Project Management Maturity Model (PMMM) developed by Kerzner (2001)	[32, 33, 34]
9	Project Management Maturity Model de Knapp & Moore Pty Ltda. (KNAPP & MOORE, 200-)	[33]
10	Project Management Process Maturity Model (PM)2 introduced by Ibbs & Kwak (2000)	[32]
11	Software Process Improvement and Capability determination (SPICE, 2000)	[33]
12	The Berkeley Project management process maturity model	[34]
13	US Federal Aviation Administration Integrated Capability Maturity Model according to Ibrahim, La Bruyere and Wells (2001)	[33]

According to [34], maturity models have been applied and proposed as strategic tools to identify and propose paths for improvement in PM areas. Thus, it is observed that capability Maturity Model Integration (CMMI®), Organizational Project Management Maturity Model (OPM3) and Project Management Maturity Model (PMMM) developed by [3], were the three most relevant maturity models (Q3) in this SLR, reported respectively in 5, 3 and 3 studies.

The Capability Maturity Model Integration (CMMI®) model, which was pointed out as the most relevant for appearing in all studies, is aimed at organizations that develop software and hardware, in addition, it is an evolution of the Capability Maturity Model (CMM), which is used as a basis for several other maturity models and has currently progressed to the model called CMMI for Development, specifically for product, hardware, or software development [33]. This way, it is worth mentioning that, to analyze and respond to Q3, both evolutions were accounted for as Capability Maturity Model Integration (CMMI®).

Regarding the Organizational Project Management Maturity Model (OPM3), it is a project started in 1998 and led by the Project Management Institute (PMI), in which, to examine the organization's competency phase, it proposes a checklist with the relevant steps and in potential capable of leading it to a higher level of maturity, using the best practices in the sector and its internal positive aspects [33].

About the third maturity model, the Project Management Maturity Model (PMMM) developed by [3], according to Viana and Mota (2016), refers to a simple and low-cost application model, since it corresponds in using an evaluation form. In addition, it was developed in line with the PMBOK® principles and has five maturity levels, each with their respective characteristics and recommendations.

Therefore, the three main maturity models raised in this SLR are in line with the study by the authors [33], since they presented several proposals for a maturity model, but highlighted some as the main ones as a result of being the most talked about, discussed and studied in the maturity theory by professionals who manage projects, which are: CMMI, OPM3, PMMM developed by [3], Project Framework and the Maturity Model.

As for the trends for the traditional project management area (Q4), four studies were analyzed that include directions related to adaptive and hybrid methodologies, the exploration of Artificial Intelligence (AI) and sustainability in Project Management.

According to study [23], the adaptive approach aims to solve the difficulties of traditional and agile methodologies, thus, it will use and eliminate the disadvantages of these methods. In addition to maximizing customer satisfaction, different from the traditional PM, in which customer satisfaction is not considered. Still based on these authors, the adaptive approach is based on the planning and budget of the traditional project and implemented according to the market situation.

In this way, the adaptive approach in PM has several benefits for different project members and for this reason, its use is recommended according to [23], as well as generating positive impacts for a more quality and efficient work organization, the professional development of employees and several positive results regarding the possibility of developing future products.

According to the authors [28], the hybrid methodology is usually a combination of agile and traditional, and allows both a flexible structure and different techniques, attributing an excellent project management approach. Although the methodological structure of traditional project planning is very broad, management through the hybrid approach presents a greater possibility of resisting the effects of risk [28].

Therefore, the hybrid methodology provides better and more viable schedules, and from the risk analysis, a more resistant project structure, thus, will take advantage of both flexibility and the selection of completion methods [28]. It is worth mentioning, according to these authors, the appropriate choice of PM methodology is subject to the type of project.

On the other hand, through the results of this SLR, the area of Artificial Intelligence (AI) was also raised as a trend for traditional Project Management, since it will be able to elevate this approach in each of the ten areas of knowledge of according to the definition of the PMBOK®, then AI will be an integral element of the future practice of traditional PM [35].

From this point of view, through the study of the authors [35], a survey was carried out with a group of PM experts regarding the likely effects of AI in the next 10 years. The results showed that of the ten areas of the PMBOK®, the management of project costs, schedule and risks possibly present more benefits from AI. Furthermore, according to these authors, the management of project stakeholders will be less affected by AI, as well as the two processes in relation to the development and management of a team.

In this way, AI will be useful for processes that use data for estimating and planning, as well as controlling schedules, adjusting forecasts, and maintaining baselines, however, the processes and areas that will be less affected need leadership skills human [35]. Thus, these results, according to these authors, will be very useful to help project managers prepare for the future in relation to variations in the traditional PM work environment, skills requirements, and expected competencies.

The latest trend raised in this SLR is the growing study of the link between sustainability and traditional project management. According to [36], the consideration of sustainability in the realization of projects results in better economic performance and greater potential for significant advantages in the short and long term.

Sustainable metrics can be employed in the PM phases or procedures regardless of their goal, thus having a micro-level impact, considering project manager assessments contributions in relation to the decision-making process, individual knowledge, and specific motivation of the project [36].

In addition, sustainability objectives are applied or considered most of the time, when required by law or in line with business purposes, so to overcome this limitation it is necessary to determine critical success conditions, design indicators from diagnostics of problems arising or form guiding methods or structures to include sustainability thoughts in practice [36].

Finally, after surveying the trends for the area of traditional PM mentioned above, it is evident that, although the literature on these subjects is still in the process of evolution, all of them will have a high influence on traditional PM tools, techniques, and methodologies.

Regarding the last question of this RSL (Q5), this is about two aspects, the challenges, and future directions for the PM area. Thus, in relation to the challenges, 17 studies were raised that contemplated results for this question. It was found that traditional PM methods present problems when finding factors of deviations in carrying out the project, and for this reason, they present difficulties in the actual planning of the project [23, 37].

In the traditional approach, according to [24], the accurate estimation of time, effort and budget is the biggest challenge for project managers. In addition, both managers and staff also have difficulties in the lack of knowledge and skills regarding how to use PM methodology tools and the fall in work standards due to the weak project culture [17, 38, 39, 40].

Currently, project processes are complex and for this reason they do not meet their initial deadlines, cost, quality, and business goals [41, 42]. Thus, it also stands out as difficulties in the PM: schedule delays, lack of clearly defined objectives and leadership/company support, scope changes, insufficient resources, poor risk management and project performance measurement and lack of communication [17, 29, 39, 43, 44].

In this way, it is evident that the most frequently reported challenges are related to project delivery on time, uncertain estimates, and scarce resources and, although there is a lot of research related to the PM, poor results in these areas are still frequent, resulting in the need to attention to them [30, 33, 45].

Finally, there is the second part of Question 5 that will bring some future directions within the area of traditional methods that were highlighted by the authors of this SLR. Some of the recommendations for future studies identified in the articles are highlighted, which are:

- Conduct research for future work in relation to the analysis of new possibilities of techniques of various criteria related to the segment of methodologies for the control and monitoring of complex projects. In addition, application of these methodologies that consider and combines costs, deadlines, practicality, and risks of projects in other sectors and areas [37].
- Ponder project characteristics and confront traditional and agile methodologies to identify which project scenarios indicate better adjustments [46].
- Consider renewable, semi-renewable and non-renewable resources as parameters in the PM, in addition to determining a more suitable model based on principles related to the ability to minimize the risks of traditional PM methodologies [28].
- Achieve a greater understanding of how, and to what extent, the technical and social domains of PM knowledge areas will be affected by AI. In addition, continue analyzing the areas of cost, schedule, and risk

management of the projects, raised by the authors as the most impacted by AI, with the objective of signaling more relevant branches in relation to how the PM will ensure itself with automation and increase of machine learners [35].

- Enlarge the sample to deepen other characteristics and differences of small and medium-sized companies in relation to the PM [39].
- Analyze how project managers understand sustainability in traditional PM and how they deal with uncertainty and the discrepancy of sustainability demands in relation to the most common purposes and measures of the project. In addition, deepening the focus on how the individual level of the project manager will help to reduce managers' anxieties when assuming sustainability in traditional PM [36].
- Present PM assessments throughout the life cycle of projects, with the aim of comparing results at different stages, including other managers in the survey, such as product, marketing, and engineering managers, in addition to also considering the point of view of the client. Furthermore, develop a tool capable of analyzing and measuring PM practices in different industry sectors [45].

These were some highlighted future directions cited by the authors of the SLR. In addition, from the synthesis of the studies, there is a diversification of categories related to future studies proposed in the literature, but most of them present the search for possible solutions to the problems raised.

V. Related Work

Project management methods are crucial in ensuring the successful execution of tasks within organizations. These methods provide structured frameworks that help teams plan, execute, and monitor projects effectively, thereby increasing efficiency and minimizing risks. Moreover, the significance of project management extends beyond mere task completion; it encompasses strategic alignment with organizational goals, resource optimization, and stakeholder satisfaction. Numerous studies and literature reviews have explored various aspects of project management, highlighting its multifaceted impact on organizational success and emphasizing continuous improvement in methodologies and practices. As such, understanding and implementing effective project management strategies remain pivotal in achieving sustainable business outcomes.

In order to illustrate some papers related to this article, [47] focused on hybrid project management methods considering the period 2000 to 2020 [47]. The research in [48] proposed a study which seeks to evaluate, synthesize, and present aspects of research on agile methods tailoring including the method tailoring approaches adopted and the criteria used for agile practice selection. The method adopted was a Systematic Literature Review (SLR) of studies published from 2002 to 2014. [49, 50] provided academics and practitioners with a coherent overview of the strategies to introduce agile in traditional project management environment, recommended in literature.

In academic literature, there exists a substantial body of research concerning project management methodologies; however, many of these studies are dated and necessitate contemporary updates. A predominant focus has been on comparisons between agile and traditional project management approaches, or exclusively on agile methodologies, or even hybrid models. Consequently, traditional project management frameworks often receive less attention in current scholarly discourse. There is a growing need for new research that not only updates existing knowledge but also explores the evolving dynamics and integration of both traditional and agile project management practices in contemporary organizational contexts. Such updated insights would provide a more comprehensive understanding and application of project management principles across diverse industries and sectors.

VI. Conclusion

The paper aimed to identify the main traditional methods of Project Management through SLR. In addition, it was intended to discover more relevant evidence in the literature on this topic, such as the main tools and/or techniques, maturity models most relevant and trends and challenges for the area.

In this way, this study was prepared following the SLR structure in which it establishes the realization of the same in three phases: planning the review, conducting the review, and documenting the review.

The first phase consists of two focuses: first is the specification of the research question and the second is the development of the protocol, in which a structure was created to identify the relevant documents to answer the questions elaborated previously.

In the second stage, conducting the review, the determined structure was applied and based on that, the first articles to be studied were obtained. We reached the number of 37 articles for the SLR, in which important information was collected. Then, Excel® was used to facilitate the reading and extraction of the contents that answered the research questions.

Finally, the third step is the documentation of the review and the relevant information extracted in the previous steps was used to obtain answers to the stipulated questions and complete the SLR. Furthermore, attention was paid to synthesizing the results in tables, to facilitate understanding and obtain a more in-depth discussion on the subject. This way, through this analysis, it is possible to identify and ponder knowledge and perceptions in the evolution of the scientific community related to the topic.

Through the results of SLR, the Project Management Body of Knowledge (PMBOK®) was identified as the main traditional method, followed by the Project IN Controlled Environment method (PRINCE2), the ISO 21500 standard and the CTCR methodology.

As for the tools and techniques, a total of 33 tools and 29 Project Management techniques are presented, highlighting the tools: Gantt Chart, Earned Value Management (EVM), Critical

Chain Project Management (CCPM) and TOC Method and technique called Critical Current Method as the most relevant. Still, it was possible to observe that in recent years organizations have increasingly sought a more effective PM using tools and/or techniques to ensure the continuous improvement of processes, facilitate and optimize planning, in addition to predicting potential difficulties, calculate risks, and determine which choices are most reliable.

It was found that the most relevant traditional management maturity models were the Capability Maturity Model Integration (CMMI®), Organizational Project Management Maturity Model (OPM3), and Project Management Maturity Model (PMMM), as they are more discussed and studied by professionals who manage projects in the maturity theory.

By carrying out this work, it can be identified that trends in traditional PM are related to adaptive and hybrid methodologies, in which both aim to combine agile and traditional methods, to resolve their flaws and ensure the success of the project. In addition, another trend observed is how Artificial Intelligence will affect and provide benefits for the areas of cost, schedule, and risk in traditional PM. Finally, the link between sustainability and the PM is presented, as it allows for better performance and potential for the success of the project.

It was also found that the main challenges in the PM area are related to delays, high costs, poor management, uncertain estimates, and scarce resources. And in relation to the future directions of the PM, they lead to studies aimed at searching for other characteristics and differences, possible solutions to problems and analyzes in relation to project management.

In short, it was possible to complete the present work with SLR through a database, to answer the topics defined at the beginning of this present work. Furthermore, the most relevant studies present in the literature on traditional PM methods and their concepts were selected and presented, with the aim of providing contributions on the subject and future research. And therefore, fulfill the last objective of this SLR to provide researchers and professionals with a direct and simple way to obtain knowledge about traditional methods.

In conclusion, this systematic literature review has provided a comprehensive overview of the primary traditional methods of Project Management. It was concluded that this SLR made it possible to obtain a broad and detailed view of the main traditional methods of PM and with this, researchers in the area will be able to make better decisions in choosing the appropriate method for their type of project.

In summary, this SLR has fulfilled its objective of synthesizing current knowledge on traditional PM methods, offering valuable insights for researchers and practitioners alike. By providing a structured framework and detailed analysis, this study equips stakeholders with informed decision-making tools to navigate the complexities of project management effectively. Ultimately, this work contributes to the ongoing discourse on PM methodologies, facilitating informed choices and fostering continuous improvement in project management practices.

VII. Future Work

As a recommendation for future work, it is suggested that studies involving general concepts, structures, advantages and disadvantages, similarities and differences, the contexts used and challenges of implementation of traditional methods of Project Management can be developed.

Another recommendation would be to carry out an SLR of comparison and analysis of traditional and agile methods, to bring the reader the focus of the approach of each of these methodologies. Finally, another recommendation could be a practical study with project management specialists to assess which method is more adherent to the application context.

Acknowledgment

The authors would like to thank FAPEMIG - Fundação de Amparo à Pesquisa do Estado de Minas Gerais, for the support provided in this research and the Study Group on Quality and Productivity.

Intelligent Transport Systems: Analysis of Applications, Security Challenges, and Robust Countermeasures

Mada Alharb, Abdulatif Alabdulatif
Department of Computer Science-College of Computer, Qassim University, Buraydah 51452, Saudi Arabia

***Abstract*—Intelligent Transport Systems (ITS) are instrumental in optimizing transportation networks, enhancing efficiency, and promoting sustainable mobility in smart cities and advanced technological environments. However, the increasing integration of digital technologies in transportation infrastructure introduces cyber-physical risks and privacy concerns. This paper aims to explore the diverse applications of ITS, and its impact on traffic management, vehicle communication, and urban mobility. It examines real-world deployments and emerging trends to illustrate ITS's transformative potential. Furthermore, it critically assesses the security vulnerabilities inherent in intelligent transport systems, including cyber threats targeting communication protocols, data integrity, and network interconnectedness. Privacy issues related to data collection and utilization are also scrutinized. Furthermore, it emphasizes the importance of proactive security measures to mitigate threats and ensure the resilience of ITS. Finally, the research proposes robust security methodologies, such as encryption techniques, anomaly detection systems, and secure communication routes, drawing upon theoretical frameworks and empirical case studies. Legislative recommendations and collaborative initiatives are advocated to foster a trustworthy intelligent transport ecosystem and address security challenges comprehensively.**

***Keywords*—Intelligent Transport Systems (ITS); cybersecurity; urban mobility; anomaly detection systems; privacy concerns**

I. Introduction

Road traffic accidents are now acknowledged as a significant social and public health concern, mainly because the number of cars on the road is expected to surpass two billion by 2050 [1]. At 1.24 million per year, with an additional 20–50 million wounded or incapacitated, the overall number of road traffic fatalities is still unacceptable, according to the World Health Organization (WHO) [2]. By 2030, road traffic injuries are expected to surpass all other causes of mortality by a significant margin. The effects of traffic accidents and wrecks on national economies are substantial. To provide just one example, the American Automobile Association (AAA) has estimated that road accidents cost approximately 166.7 billion USD [3]. Moreover, the World Health Organization estimates that traffic injuries cost middle-income nations about $100 billion annually, or around 2% of their GDP [4]. The aforementioned statistics are expected to significantly influence societies and quality of life, necessitating the implementation of targeted measures to address them in the near future. National strategic programs and targeted awareness campaigns can help reduce traffic accidents by encouraging safe driving practices, enforcing traffic laws, and planning for the construction of safer transportation networks.

ITS uses cutting-edge technology and data solutions to make transportation networks more efficient, safer, and environmentally friendly [5]. Our comprehensive approach includes communication technology, sensing and monitoring devices, safety features, smart parking, traffic management, environmental sustainability, and traveller services [6]. ITS relies on real-time data from sensors and monitoring devices to inform decision-making. Traffic flow, signal regulation, and congestion management may be optimized using the data, which includes road infrastructure insights and traffic conditions. ITS provides adaptive cruise control, lane departure alerts, and collision avoidance to enhance road safety. The system also provides route suggestions and real-time traffic information to enhance passenger satisfaction [7]. It is essential to note that ITS plays an important role in smart parking solutions contributing to environmental sustainability through sustainable mobility and traffic management. The development of autonomous vehicles that transform transportation even faster owing to technology advancements depends on ITS integration integrations [8,9]. ITS provide a technology-based solution to redevelop transport infrastructures for urban and rural areas towards ecological, effective, and safer forms of travel.

Driven by the dynamic nature of transport technology and meeting at the intersection between digital innovation, it is, therefore, crucial to have a deep understanding of the numerous applications and security vulnerabilities that are embedded within ITS [10,11]. The paper focuses on the current state of affairs as a result of integrating digital technology into transport infrastructure, which is very complicated beyond apparent facade existence [12]. It highlights the importance of working out privacy and cybersecurity problems, as well as relevant law consequences. The aim is to provide a broad picture of an increasingly important function that ITS performs in enhancing transportation efficiency without losing sight of the vital importance of preventive security [13]. Also, the research reveals how important it is for public information campaigns to address this knowledge gap and promote these revolutionary technologies [14]. Furthermore, this paper aims to provide valuable knowledge that can inform the design and operationalization of smart transport solutions endowed with security, and efficiency features in favor of urban mobility as well as society at large. This will be achieved through a full-scale study of this investigation.

The significance of this research stems from the imperative to provide a revolutionary avenue for addressing mobility challenges and redesigning the transport landscape. However, the current landscape is marked by a rapid proliferation of technology and smart city initiatives, highlighting the critical importance of comprehending the workings of ITS, as well as addressing its security issues and implementing effective solutions. It is supported by the realization that smarter and more connected design of cities makes transport networks even more complicated to be damaged. Digital technology in transportation infrastructure has numerous benefits, but data privacy, cybersecurity, and system reliability are new problems. The paper examines ITS's many applications, from improving urban mobility to optimizing transport networks. In undertaking this endeavor, it addresses typical security concerns in these systems. Given intelligent transport infrastructure's rising reliance on networked digital systems, security must be addressed. Cyber threats that threaten data integrity, communication protocols, and smart transportation network interconnection need additional study. The aim also involves developing effective countermeasures to increase ITS's resilience in an increasingly interconnected digital environment. The research advocates for strong security procedures based on theoretical frameworks, practical case studies, encryption, anomaly detection systems, and secure communication paths to improve ITS cybersecurity. The initiative also prioritizes ITS data privacy. Threats to data integrity and user privacy from unauthorized access or exploitation of ITS-gathered PII need preemptive security measures and legal advice.

The paper makes several significant contributions to the field:

- Analyze ITS applications and their transformative impact on transport networks and urban mobility, elucidating how ITS enhance efficiency and revolutionizes transportation.
- Identify crucial weaknesses in intelligent transport infrastructure by tackling cyber threats that target communication protocols, data integrity, interconnected networks, and privacy issues.
- Discusses and examines best practices including targeted messaging, ongoing involvement, periodic review, and cross-functional teams. These insights aid security strategy execution.
- Proposes measures to support ITS resilience, encompassing encryption, anomaly detection, secure communication, legislative reforms, and collaborative initiatives. These practical and theoretical approaches effectively target specific security concerns.

The paper reviews the relevant literature and then investigates various ITS use cases. Security threats are explored, such as privacy and communication flaws, and then possible solutions and countermeasures are suggested, such as cryptography and anomaly detection techniques, to overcome ITS security concerns. Findings are grounded in real-world evidence, emphasizing privacy-preserving strategies within Intelligent Transportation Systems (ITS). This discussion explores key considerations for their implementation, ensuring a thoughtful approach to privacy concerns. The conclusion provides a concise yet comprehensive overview of ITS security, integrating critical insights and identifying directions for future research.

II. Literature Review

This paper discusses the security and privacy concerns of ITS applications from different perspectives [16]. First, ITS architecture, features, and important enabling standards and initiatives are examined. Next, ITS security risks and cryptographic countermeasures are categorized. Final analysis and evaluation of a thorough ITS safety application case study using the European ETSI TC ITS standard. ITS safety message signing and verification using different Elliptic Curve Digital Signature Algorithms (ECDSA) is shown in an experimental evaluation. The authors first examine the ETSI ITS security architecture as shown in [17]. They next construct ECC-based digital signature and encryption techniques on an experimental test bed and conduct a comprehensive benchmark analysis to evaluate their performance based on payload size, processor speed, and security. They examine the effects of standard-compliant security processes in dense and realistic smart cities using network simulation models. Results imply that present security solutions significantly impair vehicle application QoS and safety awareness by increasing packet inter-arrival delays, packet, and cryptographic losses, and reducing safety awareness. Finally, we summarize the simulation findings and identify open research problems for efficient security in smart city ITS systems.

Sun et al. examine the current state of security and privacy in the IoV, including the requirements, kinds of attacks, and solutions to these concerns, as well as talk about the concerns that have been solved and what will happen next [18]. van der Heijden et al. cover the limitations of PKI-based security and provide a comprehensive overview of the cITS ecosystem in our study. They provide a comprehensive review of key works on the subject, draw attention to outstanding questions and potential directions for future study, and develop and talk about a categorization for systems that identify inappropriate behavior [19].

Sakiz and Sen provide a literature review of potential assaults of this kind and the detection measures that have been suggested for them [20]. Classification and explanation of the assaults and their consequences are provided, while remedies are offered along with their pros and cons. Additionally, a table summarizing and evaluating the solutions examined is provided.

The objective of Abosata et al. study is to categorize potential threats to the IoT layer architecture and to provide solutions to these problems [21]. As a result, they link each attack to a different architectural layer and then review the literature on the several ways to secure the Internet of Things. In addition, it offers an evaluation of current IoT/IIoT solutions that rely on various security measures, such as protocols for communication, networks, encryption, and intrusion detection systems. A discussion of new simulations and tools for testing and assessing security procedures in IoT applications is also included. This study concludes by outlining several other

important research concerns and obstacles related to the security of the Internet of Things and the Industrial Internet of Things. Also covered are the design aspects, robustness, and dependability of VSN. They also go over some of the important communication technologies and the security issues surrounding them. They draw attention to the most pressing unanswered questions in the literature and provide suggestions on how to address them. The importance of VSNs in creating effective ITS is shown by this investigation. However, for a trustworthy and secure transportation system, the existing security criteria for VSNs need to be enhanced [22]. Bishop covers both general and specialized cars and provides a global overview of the most important intelligent vehicle initiatives and operations [23]. Liu et al. explain the fundamental principles, expose the vulnerabilities of in-vehicle networks, and summarize the attacking tactics [24]. We provide countermeasures for in-vehicle networks, as well as a discussion of obstacles and potential future options.

This study in [25] investigates the possible vulnerabilities of the IVC network as well as the new research that is targeted at mitigating such vulnerabilities. To address these dangers, our project, which is a security architecture that is currently being developed and is dubbed SecCar, provides a potential solution. Security threats to WSNs and the IoT are discussed in depth in [26], along with methods for detecting, preventing, and mitigating such threats. This research primarily divides assaults into two categories: "Passive Attacks" and "Active Attacks." The former covers the vast majority of attacks on WSNs and IoT, while the latter covers the whole spectrum. An informed public and safe expansion of IoT technology may be achieved by studying these threats and the countermeasures that are available to them.

Both centralized and decentralized approaches to Internet of Things (IoT) deployment based on software-defined networking (SDN) are covered extensively in [27], which also provides an overview of SDN. The researchers provided a thorough introduction to software-defined security (SDSec) by expanding on SDN-based IoT security solutions. In addition, research that stresses a network-based security solution for the IoT paradigm is scarce, and the literature highlights key challenges that are the primary obstacles to bringing all IoT stakeholders together on one platform. We conclude by outlining a few potential avenues for further study on SDN-based IoT security solutions. A threat assessment based on risk principles is used in this investigation. An investigation of vulnerabilities is carried out qualitatively in this threat assessment. Turner and Gelles studied VMS-triggered operational, security, reliability, and safety concerns [28]. Critical infrastructure failure may also be avoided with the help of the offered countermeasures. Policymakers and engineers worried about the ITS infrastructure's possible weaknesses are expected to find the results particularly interesting and helpful.

III. Primary Aspects of Attack on Intelligent Transport Systems

A. Communication Protocol Vulnerabilities

The proper operation of ITS is highly dependent on the components' ability to communicate with one another seamlessly. But there are weaknesses that bad actors may take advantage of because of how linked everything is. The opening up of vulnerabilities that may be taken advantage of in the communication protocols can leave them open access to data transmission and system operation thereby putting it at risk. However, the issue of unauthorized access due to compromised communication networks has gained significance in recent years. To get illegal access to ITS networks, malicious actors apply sophisticated techniques that enable the exploitation of communication protocol vulnerabilities. This guarantees document manipulation, traffic control system gaming, and over-linked vehicle theft in addition to data eavesdropping. The extent of this vulnerability is shown by the 30% rise in reported compromised communication cable access. Vulnerabilities need to be fixed since ITS protocol communications are expanding. Hacks of ITS are growing more complex and widespread as evidenced by the 30% increase. These figures show how grave an issue this might become if we do not increase our ability to communicate. Apart from data protection, the consequences influence the reliability and security of transportation systems. One of the key aspects that determine safety in ITS is exposure management through communication protocols. Mechanisms such as robust encryption, continuous monitoring and adaptable security frameworks are needed to fight any form of cunning actions that exploit loopholes in the ITS communication protocol.

B. Data Integrity Breaches in ITS

Integration of ITS with smart city infrastructure requires data integrity protection. These complex systems pose the possibility of data modification or hacking as the main reason for worry. Therefore, transport networks require reliable data to guarantee the security of public life and to encourage confidence in modern technology. A primary concern is the diversity of potential causes of data integrity flaws. Such data, namely traffic light, navigation, and auto data might be the target of malicious attackers. In metropolitan areas, such manipulation of critical information may significantly impact the effective and safe mobility of people hence causing misdirection, disinformation or even compromising safety problems. The rising threat environment is evident from the measurement of this concern. It should be noted that there has been a substantial 40 per cent increase in data integrity breaches within just the past year. Considering the growing frequency in which these occur, it seems that cyber-attacks have become more elaborate since their goal is to deface ITS systems from within. When crucial data about these systems is compromised either deliberately or accidentally, both the organizations that administer such systems as well as individuals depending on timely transportation information will be bothered.

With such rapid growth as 40% in the number of data integrity breaches, a strong determination to protect the information inside ITS is emerging. It, however, casts doubt upon the adequacy of current security strategies and accentuates the need for sophisticated encryption methods as well as 24-hour surveillance to complement proactive threat detection systems. The study also suggests that to strengthen data integrity requirements for intelligent mobility, stakeholders, cybersecurity experts, and legislators should work together. To preserve the integrity and security of intelligent transportation networks and meet technical requirements, data authenticity

vulnerabilities in ITS must be addressed. Proactive and adaptive cybersecurity procedures that may effectively defend ITS from assaults are required given this image's increasing expansion. This is essential to maintain confidence.

C. Interconnected Network Exploitation in ITS

Given their increasing connection with ITS, these advanced smart transport networks might be vulnerable to hacking attacks by malicious actors. They target these networks because they are valuable and because they deteriorate public transit. It is possible to exploit linked networks in addition to these cyber threats. Potential threats include breaking into communication channels or gaining access to sensitive data to impair vehicle functionality or impede traffic flow. Because ITS components are interrelated, a successful attack on one system component might cause disruptions to the yield and safety chains as well as the whole value chain. Remedial action for security breaches degrades the operation of the smart transport network system and results in significant investment losses. This concern is reflected in the 25% increase in attacks aimed at vulnerabilities resulting from highly interconnected ITS components. The dynamic nature of the cyber environment brings to attention the ability of hackers to shrewdly adapt faster than ever before smart transport brains utilize interconnected systems. This result shows the potential enhancement in risks of penetrating a system as well as linked networks using ITS. The fact that there was a sharp increase in occurrences of around 25% suggests an evident need for more proactive and innovative security practices to combat the threat emanating from highly evolved cyberattacks. Since the components of smart transportation get more interconnected, there is a need for cybersecurity evolution. This increase brings to the forefront that in ITS systems it is essential to timely risk assessments, monitoring, and ensuring of installation of powerful intrusion detection systems otherwise such attacks could well compromise the security within Connected Vehicle Networks. Further, the figure acts as a call to action for cybersecurity professionals with lawmakers and industry leaders by calling them on board.

D. Privacy Risks from Data Collection in ITS

With the enhancement of ITS systems, more and more people express concern over potential misuse in violation of privacy due to easy accessing large amounts of data. The data required to perfect transportation networks is personalized since it provides information about destinations, activities, and tastes of people. Data collecting constitutes a dilemma of different dimensions attacking people's privacy. It involves individuals gaining access to a consumer's personal privacy information without the knowledge or consent of that individual so that it will be used in targeted attacks or through fraud, and broader issues associated with people having their rights violated. The significance of data privacy and the ethical manner for handling sensitive information increases as ITS continuously relies on big data-based insights to make decisions.

There has been a discernible pattern in the measurement of this problem; research projects a 35% increase in privacy-related complaints. This rise in complaints is a blatant indication that more and more individuals are concerned about how ITS is handling their personal information. This emphasizes the significance it is to addressing privacy dangers and the need for robust privacy protection techniques in lowering the risks brought about by data collection. The 35% increase indicates that privacy concerns in the setting of smart transportation are evolving. This data may be seen, among other things, as a sign that individuals are starting to realize the risks and weaknesses associated with the vast amounts of individually identifiable data being gathered. Policymakers, corporate stakeholders, and cybersecurity experts should use the increase in complaints as a crucial benchmark to assess how data collection methods affect public opinion and trust.

The privacy of people is threatened by the collection of data; thus a complete solution must be found. Thorough data security protocols, stringent access restrictions (which should include strong encryption technology), and explicit guidelines for handling sensitive data must be implemented. Furthermore, the results reveal that consumers lack the information necessary to protect their right to privacy concerning ITS.

E. Cyber-Physical Attacks in ITS

As worries about cyber-physical assaults in the field of ITS rise, plans to fully integrate digital technology with transport networks are being impeded [29]. The possibility for cyber-manipulation of physical infrastructure is a challenging issue that presents additional risks to the functioning of traffic control systems and automobiles. The interaction between the physical and digital realms gives rise to the problem of cyber-physical attacks in the context of ITS. Hackers may be able to get unauthorized access to physical components by using complex cyber techniques and exploiting weaknesses in digital systems. Changing road signs and traffic lights, as well as actively undermining essential safety precautions to put linked cars in danger, are a few instances of potential activities that may be taken. Other repercussions erode public confidence in intelligent, dependable, and secure transportation networks. These consequences hit other domains in addition to data breaches.

When we quantify this issue, we find that, throughout the last two years, there has been a worrisome trend of a twenty percent increase in the number of cyber-physical assault incidents. The number of incidents has increased, which implies that malevolent actors have become craftier in their attempts to compromise the cybersecurity of public transit networks. Attackers find ITS more alluring because it establishes a link between the digital and real worlds. This result highlights how urgently security measures need to be improved.

With cyber-physical dangers growing at a rate of twenty percent, the ITS must have strong and flexible security procedures. This indicates that cyber dangers are ever-changing and can take advantage of gaps in digital-physical interactions. This data should be noted by all stakeholders, including cybersecurity professionals, legislators, and business leaders, who should work together to strengthen ITS's defenses against new and emerging threats. It will need a comprehensive strategy that incorporates technical improvements and new activities to solve the problem of cyber-physical attacks. Crucial components of an all-encompassing defense plan include secure communication routes, real-time threat monitoring, and enhanced encryption techniques. To further

guarantee the safety and security of intelligent transportation systems, it is essential that all relevant parties work together and that strict laws be put in place.

IV. Overview of Security and Privacy Concerns

The incorporation of cutting-edge technology into ITS gives rise to a multitude of issues about the protection of personal information and general safety. Concerns like these extend to a wide range of ITS applications, embracing not just the digital but also the physical spheres. Among the most important risks to privacy and security are:

A. Communication Security

When it comes to ITS, Communication Security is of the utmost importance. The effectiveness and dependability of the system depend on the safe and smooth transfer of information. This is because there is cause for worry over the security of the communication protocols used by ITS. Such weaknesses put at risk the authorized access rights, interception of confidential data or alteration of important information crossing the transport network. Several elements of the transport system may be affected by compromised communication linkages. As there is a need for exact and reliable real-time transfer of data to make smart decisions, traffic management is one such industry that will be affected. The communication protocols could be hijacked leading to misinformation, longer response times or even re-timing of traffic signals that would start causing cars not to move normally. Possible compromises in communication networks may negatively influence V2V communication of the ITS system. Sending crucial data, such as the position, speed, or status updates of the vehicles constantly needs a reliable connection. In such a case, there is more risk of accidents and modifications regarding the desired traffic flow if this connection is also disrupted. It is not only specific systems that suffer a lapse in communication security, but the whole transport network does also. As all the constituent parts of ITS are interdependent these vulnerabilities can potentially result in significant consequences. A breach that affects traffic control, vehicle communication, and smart elements in transportation systems may lead to severe system failures.

B. Data Privacy and Integrity

IT information management cannot be safe or dependable without data integrity and privacy. ITS systems throw doubt on unauthorized changes and data breaches because of their complexity. Important data breaches or alterations might jeopardize the transport network's efficacy. Data integrity violations have repercussions that go well beyond correctness. The transportation system was put at risk due to the inaccurate data compiled from these violations. Commuter safety and transit efficacy are put at risk by errors in vehicle, traffic, and road statistics. Operating efficiency is increased with ITS data collection, yet privacy concerns arise. The act of collecting data, particularly sensitive data such as individuals' locations, activities, and preferences, increases the risk of illegal access. Inadequate protection might allow for unauthorized access to personal data. Serious consequences result from unauthorized access to personal data. The security of smart transport data is a concern raised by these attacks, which erode public trust. Public trust is crucial to modern transport systems' performance; therefore any violation of an individual's privacy might obstruct advancement.

C. Interconnected Network Exploitation

Because ITS systems have complex interdependencies that make them vulnerable to assaults, interconnected network exploitation has become a major problem in the field [31]. We are very concerned about the prospect of cyberattacks that exploit our internationally interconnected network. These attacks might cause issues if they go beyond isolated instances. In an extreme case, these attacks might compromise the integrity of the system, as well as the linked vehicles and traffic networks. Since connected components have the potential to be abused catastrophically, a proactive and responsive security posture must be maintained. Only the beginning of the problems that such exploitation may bring about for the transport system is the knock-on consequences, which include increasing traffic congestion and less efficient vehicles. The chain reactions of these occurrences provide more proof of the need to maintain ongoing monitoring and implement adaptable safety protocols to protect intelligent transportation networks from any threats.

D. Insufficient Encryption Measures

As a result, inadequate encryption poses a risk to the ITS infrastructure as data security must always be given priority. If the data transmission and storage encryption are not adequate, ITS security may be breached. Its main security threat is poor encryption and unauthorized access to personal data is the biggest issue. This loophole exposes to security breaches vital ITS data. Consequently, malicious actors can gain access to the sophisticated data network for transportation through a weak encryption scheme. Besides granting unauthorized access, these defects have adverse impacts. If there is no encryption, then the sensitive information remains vulnerable to security breaches. Without ITS it is not possible to travel safely and efficiently. Misleading information, system inaccuracies, and public safety threats – such data breaches may result from some. For information safety and to minimize risks ITS must be very secure. This protection should include state-of-the-art encryption to foil even the cleverest hackers, far more than would be provided by merely basic security measures.

E. Lack of Standardized Security Practices

The biggest problem associated with the complex region of ITS is that there are no established safety regulations that guarantee uniformity and best practices in security operations. Nevertheless, the lack of clear security standards for ITS makes all its numerous components not only incompatible but also vulnerable. The main issue is the potential non-uniform implementation of safety measures by ITS modules. Therefore, diversity creates the ideal breeding ground for vulnerabilities and sometimes unconsciously increases security risk with some elements or interfaces. Since there are different security protocols, malicious individuals may enter the system through loopholes present in a transport network. Such differences bring to light the need for standardized security procedures. The ITS region is highly dynamic and cooperative. Hence, the strict controls that ensure maximum performance from component coordination are crucial to building a stable and safe ecosystem. The implementation of security protocols reduces the

vulnerabilities and increases system resilience thus raising a bar for ITS Security architecture.

F. Insider Threats and Unauthorized Access

Due to its dynamism, ITS is prone to conflicts that affect operations, deliberate destruction, and alterations made to the data. The risks here include insider threats and unauthorized access. Confidential information made available from the workplace, or another location can reduce ITS reliability. These risks require a general approach since they affect beyond security matters. This approach, to avoid the occurrence of harmful or inappropriate behavior needs stringent access restrictions. As a precautionary measure, access rights may be used against unauthorized changes and internal attacks on the transport network components. Scrutiny is required and access restrictions should be strict. Such systems detect deviant behavior associated with possible insider attacks or unapproved access that results in the most critical elements. The safety emergencies involving ITS can be addressed in real-time by the current administrators due to developments made in surveillance technology. Significantly, building a complete picture of the risks offered by insiders and unauthorized access needs to be necessary for efficient IT control. To protect against internal and external dangers, ITS should prepare an all-encompassing security plan that will utilize restrictions of access and monitoring. This strategy guarantees the security of the transport network and its capability to adapt with regards to emerging cyber threats. If this accomplishment is achieved, ITS will succeed in achieving its mission of safety and efficiency in urban transportation.

G. Inadequate Public Awareness

ITS has a tremendous awareness challenge. For this reason, public confusion and ITS security concerns should be eliminated. The common use of ITS may be throttled by public unawareness for them. It is knowledge gaps that can lead to suspicion, hostility, and misinformation. Public awareness deficits affect users' willingness and commitment as well as hesitation. Impose ITS and major changes may face resistance or uncertainty due to a lack of information. Inadequate information might create public concern and bias preventing the urban transport business from making good use of ITS. Whenever addressing this issue, knowledge and public awareness shall be the greatest goals. It is societies that are well-informed and beneficial knowledge imbalance must be actively addressed. Such ads clear the myths and give security information to increase people's awareness of the complexity of ITS. Explaining the technology of this approach fosters customer trust and commitment. Public perception is crucial in the development of smart transport. The method encourages community involvement, teaching, and collaboration. These relieve anxiety and promote deliberate assimilation. For effective implementation of modern transport technology in cities, stakeholders are to involve the public in discourses regarding ITS and security requirements. This fosters trust and respect.

H. Data Retention and De-Identification Challenges

Data de-identification and preservation are key challenges to ITS data management. Such issues can lead to privacy violations therefore they are important. The fact that de-identification and data protection procedures would not deliver the desired outcomes might compromise privacy issues of users' anonymity in ITS. The implications from the handling of these topics will be significant as it explains why there is a need for comprehensive and transparent information standard management. It is important to follow correct data retention and de-identification processes to protect privacy. When anonymization is insufficient, ITS users are open to unauthorized monitoring and profiling which threatens their privacy. To address such issues and satisfy safety needs, strong data anonymization methods are necessary. It is therefore compulsory that they adhere to the highest standards of protecting individuals' identities lest privacy breaches occur. By establishing an ethically appropriate structure for data use, ITS can effectively address issues of holding and erasure. This policy, aside from fostering confidence in ITS data usage, also ensures the privacy of personal information.

V. Security Solutions

Reliable defense against weaknesses and assaults is necessary to guarantee the safety and security of ITS systems. To improve the security posture of the ITS, several important actions might be taken, such as the following:

A. Encryption Techniques in ITS

This can be achieved by encrypting data both while in transit movement and stored within ITS. This will ensure that the data is secure and not tampered with. To curtail such illegal access or manipulation one way it must ensure that strong encryption mechanisms have been established. End-to-end encryption has become the de facto in communication channels. This approach guarantees that every communication sent or received between the car, infrastructure component, and command center information is secure. State-of-the-art cryptographic methods such as AES and RSA encrypt data [33] even before it leaves its source. It remains encrypted until it arrives at the destination. Decryption keys possessed by authorized organizations ensure the privacy of the data that is transmitted. Even data that is stored elsewhere, on servers or in databases and even linked cars. With this approach, data security is maintained even in case of both digital and physical breaches. Using secure key management procedures and strong encryption algorithms makes the stored data meaningless to outsiders while retaining its integrity. One of the numerous benefits associated with introducing encryption methods into ITS is data privacy and security. Encryption is a critical element in the protection of user privacy and sensitive information by complying with compliance criteria set out under various data protection regulations and standards. Moreover, it fortifies cyber security by developing a reliable defense mechanism that prevents misuse of the weaknesses associated with ITS infrastructure.

B. Anomaly Detection Systems in ITS

For the ITS, Anomaly Detection Systems [34] play an important role in security. These systems have very advanced algorithms and methodologies that can detect abnormalities in system operation or network traffic. These systems have several elements that collaborate to detect and prevent intrusion attempts, deviations from data-transfer patterns, as well as abnormal operating behavior. Constant network monitoring of

the ITS infrastructure through behavioral analysis, machine learning algorithms, and rule-based methodologies is required by anomaly detection systems to establish what are typical user behaviors. With the use of alarms or automatic replies each time there is a deviation from this benchmark, all potential security vulnerabilities caused by unauthorized access are effectively addressed. Some malicious activities that these systems detect when observing patterns of data transfer within the ITS network include, for instance, exfiltration and unauthorized access. Signature-based detection systems, machine learning models, and statistical methods can detect anomalies such as unexpected performance peaks. It facilitates a reflex action or further investigation of the issue. Besides, anomaly detection systems are excellent at detecting problems within the ITS infrastructure such as unanticipated shifts in device behavior abnormalities of network latency, or system performance that deviates from usual. Heuristic processing, statistical modeling, and machine learning algorithms are used in these systems to set a norm for how the system is usually operated. Any unexpected variations in network traffic or a sharp decline in performance need to be reported and resolved very once. Anomaly Detection Systems provide several advantages to ITS. Their ability to identify security threats early on enables a variety of preventative measures. Machine learning [30] allows these systems to react dynamically and lets them run in real-time mode, which provides continuous monitoring of network activity as well as the behaviors that define their system. They also address safety issues, remove false positives, and enhance security. To perform at their peak and keep up with the always-evolving network, these systems need to be adjusted and calibrated regularly. Problems with security may be resolved efficiently and promptly with a smooth connection. Anomaly Detection Systems increase safety by fortifying ITS security.

C. Secure Communication Routes

To protect data transfers, ITS needs VPNs and certain routes [35]. This method guards against unauthorized access and eavesdropping on V2I and V2V ITS communications [36]. Using V2I communication channels, data transfers between vehicles and infrastructure parts are secure. Communication between vehicles, command centres, roadside devices, and traffic control systems is made possible by this. To protect infrastructure-automotive data, VPNs and encrypted tunnels will be used in the deployment. Secure routes are also required for V2V communication. This enables real-time status, location, and intent sharing and instant communication between cars. This increases the efficiency and safety of travel. To stop third parties from listening in on conversations, vehicle communication channels may be further limited. These connections are safe thanks to the encryption mechanism. The benefits of secure ITS communication routes are many. Their goals are to prevent cyberattacks on crucial communication channels and preserve the confidentiality and integrity of data while it is being sent. Using safe vehicle-to-vehicle communication, this technique increases road safety by improving traffic management. For optimal performance, secure communication channels in the dynamic ITS environment should take latency and bandwidth into account. The current ITS system must work well together to maintain wide interoperability and secure communication. Communication channels become safer and more trustworthy when secured communication techniques are used in the intelligent transportation ecosystem.

D. Legislative Frameworks for Enhanced ITS Security

A legal framework is the solution to the security problems with ITS. To ensure the safety of ITS systems, these theoretical frameworks provide procedures and regulations. It is possible to combat the conundrum of insufficient cybersecurity within ITS systems through legislative changes that impose a clear set of standards on producers, service providers, and government agencies. Such standards may include the need for encryption, secure communication protocols, and succinct guidelines on how to address vulnerabilities. Security can be further enhanced by legislation that requires ITS to have adequate data protection policies. These policies should contain guidelines for de-identifying data [37], how to obtain consent and restrictions on handling sensitive information. The law can also establish ways of reporting events such that data breaches or cybersecurity incidents are reported to the relevant authorities on time. This holistic approach not only ensures a consistent security standard but also protects personal information and enables quick responses to breaches. These legal constructs to function effectively must be able to adapt to changes in new threats and should collaborate among their important parties for standards that are practical yet respected. Regulatory frameworks also play a key role in the development of an intelligent transport system that is safe, and dependable to disruption.

E. Collaborative Initiatives

This will require the undertaking of joint projects that address complex security challenges within ITS. To solve this problem, it is vital to promote networking among cybersecurity professionals; government agencies, and business leaders where they would share information about the potential threats and best practices. For carrying out collaborative projects, it is important for information to be shared among various ITS ecosystem groups and platforms should therefore have been provided. This comprises cybersecurity professionals, government bodies, service providers, and manufacturers. These platforms enable the sharing of threat data in real-time, discussing current security issues, and passing along best practices. The most recent vulnerabilities, attack vectors, and events affecting the ITS ecosystem may be easily understood through information flow promoted by cooperation. Further, they promote the sharing of cybersecurity best practices such as specific security protocols for different sectors and risk mitigation strategies along with successful implementation cases. This application depends greatly on public-private partnership whereby among themselves, the two strata collaborate to work closely in ITS infrastructure activities such as planning, construction, and maintenance. We, therefore, are going to unite our wisdom in handling future threats and sharing it swiftly when they come up. As a result, we will take on cybersecurity directly. Successful implementation requires creating a sense of confidence among the participants, strictly adhering to legal and regulatory frameworks, as well as continuous motivation to develop good information exchange and cooperation. The security resilience of the entire intelligent transportation ecosystem is strengthened by collective action within ITS that brings people together to fight evolving cyber threats.

F. Public Awareness Campaigns for Strengthening ITS Security

A significant step in securing ITS is making people more aware of the problem. These campaigns [38] are intentionally created to inform users and other stakeholders about the benefits and security features that have been integrated into ITS. People can learn about the good security features of the ITS architectural structure through a series of purposeful media information by deliberately educating people with public awareness campaigns. Such a forward-thinking approach eliminates fears, sheds light on confusion, and creates a belief in the abundance of smart transport systems. The application requires the proactive sharing of information about security aspects and benefits that ITS has to offer. These encompass the mechanisms designed to ensure encryption, protection, and incident response. The message is disseminated through public service announcements, websites, informational booklets, and social media It is best for addressing concerns, and dismissing misunderstandings about the safety of ITS using public awareness campaigns. These advertisements aim to make sure that clients and stakeholders have a clear understanding of the strong security measures in place thereby reassuring them. The idea is to promote trust in the adoption of smart transport systems. To draw attention to the ways ITS increases sustainability [15], efficiency, and safety while highlighting security aspects that protect users' data, as well as whole systems, are conducted awareness-raising campaigns. The extension of the application to interactive platforms may facilitate user interaction with information. Questions may be asked during webinars, seminars, and question-and-answer sessions by participants to learn more about the ITS security aspects through direct interaction. On the one hand, such efforts give stakeholders and users enough knowledge they need to make right decisions with regards to ITS technology adoption. Campaigns such as these help to assuage concerns and offer openness, which under positive results leads urban mobility to confidence in the security and reliability of Intelligent Transport Systems. In developing a public awareness campaign, it is important to consider that certain demographics are targeted with appropriate and easily available content. To keep the public informed on changing security measures and new problems, keeping campaigns is important. Regular evaluation of the campaign's efficiency considering users response and adoption rates is necessary to fine-tune and refine communication strategies.

G. Regular Security Audits and Assessments for Robust ITS Security

Secure ITS requires periodic auditing and assessments as they need to be identified with vulnerabilities in the infrastructure. This method implies regular security audits and hardware [39], and software communication inspections of ITS. With a proactive threat management approach, identifying and clearing out security holes fortifies the system. Audits evaluate the entire ITS infrastructure regularly. This covers the process of assessing hardware security systems as well as software integrity and communication network deficiencies. Audit in cybersecurity is for compliance with security standards and best practices. The program covers ITS component assessment. The hardware components including sensors, controllers, and communication systems undergo physical tests for weaknesses as well as manipulation. They are testing software applications using control algorithms and data processing systems for vulnerabilities. Encryption, security, and cyberattack resistance are part of the tested aspects of communication networks. Regular audits and evaluations were undertaken to identify weaknesses in security. Systematic assessing of the ITS infrastructure reveals weaknesses in it before being taken advantage of. Through this proactive approach, quick security enhancements can be achieved. In the application, iterative improvement is used. Security audits are analyzed and suggestions to correct gaps It ensures that the ITS security keeps abreast with cyber threats and technology. Audits performed regularly allow identifying and reducing the risks that may act as tools for opponents before they might be used. Vulnerability discovery and mitigation that are proactive significantly impact cyber threats placed by ITS. Compliance and responsibility are promoted by continuous assessments which guarantee the observance of security standards as well as regulatory compliance. As information technologies presented cyber threats and made other technical innovations, security evaluations were carried out. Working as a team, the cybersecurity specialists and IT professionals along with ITS stakeholders help to improve audits. To ensure the monitoring of progress and records in history, audit outcomes must be recorded with their remedial actions as well as improvements.

H. Privacy-Preserving Techniques for Enhanced ITS Security

First, privacy-sensitive procedures are needed in ITS security. User data that is sensitive to user privacy has been successfully protected by using differential privacy and secure multi-party computing. Privacy-sheltering actions reflect the central position occupied by privacy analysis as it enables data to be used and analyzed in the ITS ecosystem. Data is anonymous and the information that comes from it becomes general to ensure protection, conformity with data-protection regulations, and trust. Differential privacy introduces a purposeful disturbance or noise into the individual data items to essentially diminish every one of that singular reliance on joined information. To ensure that users remain anonymous during the process of extraction insights from collected aggregated data this method makes sure to create an avenue for retrieving useful information. Secure Multiparty Computation (SMPC) enables the calculation of a function on various inputs without revealing and, therefore, greatly simplifies centralized computing. Thus, SMPC fulfills the privacy during computation in ITS when collaborative data analysis must be taken into consideration. The program contains tokenization and encryption which anonymizes the delineated data (PII) as aggregation that protects any information delivered to it. Serial aggregation of data maintains statistical relevance while concealing the names provided by users. It must walk a fine line between privacy and functionality. Through privacy-preserving techniques, user information is protected while aggregated data are available for study. To achieve this equilibrium, a privacy-preserving algorithm is to be designed and configured based on the specifics of ITS. It is the privacy-preserving strategies that enhance the confidence of users because they are assured that their private data remains protected. The regulations they must observe regarding data protection help them meet the requirements too. Such approaches enable secure multi-

partnership cooperation and analysis of diverse data sources while preserving privacy. A successful deployment involves the selection of appropriate privacy preservation techniques considering its operating domain and type of data in ITS ecosystem. Stating about privacy-preserving procedures openly to users ensures system trustworthiness. To solve the privacy problem and keep up with technological advances, these steps should be reviewed and revised regularly.

These cutting-edge security solutions have been developed specifically for ITS and are essential for shielding contemporary transport networks from growing dangers related to cybersecurity. Through the implementation of security solutions tailored to ITS, stakeholders may enhance security and mitigate risks to provide reliable mobility. Urban mobility and ITS networks may prevent cyber-physical threats and data breaches by using encryption, anomaly detection, secure communication channels, legislative frameworks, collaboration, public awareness campaigns, periodic security evaluations, and privacy-preserving solutions. Encryption may be customized for storage and transit to safeguard sensitive data related to transportation infrastructure. By identifying odd patterns or behaviors, anomaly detection solutions enable stakeholders to promptly address security threats. V2I and V2V communication is protected by VPNs and specialized channels [40]. All ITS systems must adhere to strict and uniform cybersecurity standards, as mandated by the Act. Through collaborative projects, government agencies, cybersecurity professionals, and industry partners share best practices and threat intelligence. Reducing fears and increasing trust is achieved via educating users and stakeholders about the security and other benefits of Intelligent Transport Systems. Vulnerabilities in the ITS infrastructure are found via security inspections and assessments, which enable prompt maintenance and security enhancement. Secure multi-party computing and differential confidentiality protect private user data by finding a careful balance between protecting privacy and optimizing the data's analytical value. Through the deliberate implementation of these specific security solutions, intelligent transport participants augment their capacity to recoup their systems from attacks and effectively participate in the development of a dependable and safe mobility milieu. This comprehensive and flexible strategy supports the construction of intelligent and secure urban transport networks while protecting ITS from the ever-present dangers presented by cybersecurity.

The advent of technology in ITS has led to a greater emphasis on addressing privacy and security issues in the optimum of transportation systems. Protocol weaknesses might enable unauthorized parties to view or alter important data, which could deteriorate system performance, which is why security is so important. ITS gathers a lot of data, and data breaches might expose personal information, which undermines public trust. Because connected technologies allow hackers to disrupt vehicle and traffic operations, adaptive security solutions are required. Because inadequate encryption leaves sensitive data open to unauthorized access, encryption is essential. Interoperability is threatened by non-standardized ITS security procedures. Effective security is what we want to achieve. To prevent unauthorized access and internal security breaches, it is necessary to implement efficient monitoring and access restrictions. The importance of public education lies in the fact that any delays in comprehending the hazards and solutions associated with it might result in criticism, mistrust, or dissemination of incorrect information. Clear and comprehensive data management policies are necessary to address issues related to data retention and de-identification to prevent privacy violations. These dangers provoke varied reactions. Communication is safeguarded using anomaly monitoring and encryption that covers the whole transmission process. Communication security safeguards essential channels, as mandated by legislation. Public information campaigns and joint activities rely on the human element that promotes cooperation and security. The idea of privacy implies a fine balance between the importance of information and preserving anonymity. Security assessments spot loopholes and strengthen security procedures. Thus, together these solutions reduce the risks of ITS. It is owing to their adaptability, collaboration, and growth that they have succeeded. The developers of the ITS innovation need to know everything about hazards, have actions focused on hazard minimization, and obey privacy and security laws to create a sustainable mobility system.

VI. Conclusion

The security and privacy challenges come from the dynamic nature of ITS which require more adaptable and pervasive solutions. The significance of ITS is increasing because smart city development and transport innovations alter urban mobility which in turn, changes the features of transportation networks. Protocol communication issues, data integrity breaches, and network attacks are also increasing. Since these risks carry consequences, this is something to keep in mind. However, ITS should also run swiftly and dependably so that it can cover unwanted aspects of safety like cyber threats, privacy risks, and cyber-physical attacks. In some cases, difficulties may occur due to flaws in technology and human limitations including a lack of robust security measures, poor data processing [32], and low public awareness. These problems are addressed by the methods from different perspectives. Modern technology includes various innovative techniques for encrypted communication, anomalous system detection, and encryption. Cooperation between the government and the public ensures efficient communication and control. However, privacy initiatives and awareness promotion help the harmonious cohabitation of technology with humans. To implement these precautions, a comprehensive plan should exploit the specific characteristics of ITS. Regular audits and assessments of security are needed to discover vulnerabilities before a potential application. First and foremost, these security standards should be updated to reduce new threats effectively and improve user education and collaboration with other stakeholders. IT security and privacy stakeholders must learn the relationship between different issues so that working together becomes vital. For the development of ITS, that are reliable, efficient, and safe is needed to take a broader approach to technology while placing human needs into consideration.

ACKNOWLEDGMENT

Spectral Mixture Analysis-based WQI with Convolutional Long Short-Term Memory Techniques

Ika Oktavianti, Yusuf Hartono, Sukemi
Department of Informatics Engineering, Sriwijaya University, Indonesia

***Abstract*—Surface water, including river water, is an important natural resource for human life. However, river water quality in Indonesia often declines due to various factors, such as excessive water consumption, waste pollution, and natural disasters. This study aims to predict the Water Quality Index (WQI) of rivers using Spectral Mixture Analysis with deep learning architecture. The methods used in this study are Spectral Mixture Analysis (SMA) and Convolutional Long Short-Term Memory (ConvLSTM). SMAs are used to decompose the spectral signatures of water quality components and provide insight into the composition of water bodies. ConvLSTM, a deep learning architecture, is used to capture temporal dependencies and spatial patterns in water quality data. The results showed that the percentage of WQI prediction accuracy for 345-band model was better than 234-band model, reaching 34.78%. The visible color spectrum that represents the Meets (M) and Light (R) Pollution Index is Blue (0, 0, 255) and wavelengths ranging from 0.53 µm to 0.88 µm. The test results of the ConvLSTM hybrid model on 8 mandatory parameters of River WQI measurements at 30 watershed monitoring points of North Musi Rawas Regency from 2021 to 2023, the accuracy value reaches 96% or it is considered that the performance of this model is acceptable. This research proves that Spectral Mixture Analysis with hybrid model Convolutional Long Short-Term Memory techniques is effectively capable of predicting and monitoring the WQI of rivers and these results can be used to take appropriate steps in determining policies.**

Keywords*—*Water quality index; Spectral Mixture Analysis; remote sensing; deep learning; convolutional long short-term memory

I. INTRODUCTION

Surface water is water that collects above ground or in springs, rivers, lakes, wetlands, reservoirs or other puddles that do not experience infiltration underground. Surface water classified as river water is widely used for various purposes including drinking, household needs, irrigation, power generation, and industry, as well as supporting all forms of life and affecting health, lifestyle, and human economic well-being [1]. In its utilization, river water quality is influenced by the environment around the river flow and in general the water quality in the upstream part is higher than the downstream. This is caused by industrial, and household waste and all human daily activities that go directly to the river without going through the processing or purification process first.

Currently, the water quality in Indonesia is still relatively low. The low quality of water is due to the influence of contamination of domestic waste, agricultural and livestock industries. The problem of poor water quality is also influenced by excessive water consumption, limited sources of clean water, household waste pollution, and industrial activities. On the other hand, the growing population and the growing industrial expansion require a lot of water supply. The water needed is not only used for household purposes but also industry [2]. South Sumatra as one of the provinces in Indonesia which is fed by nine tributaries of the Musi River has a relatively low level of water pollution compared to the national level. The Water Quality Index (WQI) value for South Sumatra Province in 2017 was 63.81 higher than the National WQI of 53.20. However, in 2022 the WQI value in South Sumatra Province has decreased to 59.85 but the pollution status category is still quite high. Based on observations, it is known that the value of WQI in South Sumatra Province fluctuates from year to year.

Fluctuations in the value of the WQI in South Sumatra are also influenced by natural disasters. Flood natural disasters can have an impact on poor water quality and damage river ecosystems. Floods that deliver poor-quality water to settlements can also adversely affect health. North Musi Rawas Regency is one of the areas in South Sumatra that is often affected by floods. This is because many villages in this district are in the Watershed Area (DAS). In monitoring and controlling watersheds in an area, the availability of comprehensive and accurate data is needed, while the current condition of data related to watershed conditions is still very limited to access. Therefore, identification and inventory of watershed conditions in North Musi Rawas Regency is very necessary. The need for various kinds of data to support research and policy-making carried out by government agencies is very important to allocate budgets effectively and efficiently.

The use of technology in data and information processing can help decision-making and target achievement become more effective and efficient. Based on the phenomena that occur today, data and information related to the river WQI become indispensable in identifying polluted river water. The use of the WQI can facilitate the determination of river water quality and facilitate the provision of information to those in need [3]. Regular monitoring of water quality is an effort to ensure the water used is safe and healthy for humans and the environment.

One of the methods used to determine the value of the WQI is based on Spectral Mixture Analysis with remote sensing. Spectral Mixture Analysis is an analysis method that uses a combination of certain algorithms using values from end members in the spectral library which is usually done to identify an object that is indicated to have mixed pixels. The

advantage of using the SMA method can provide detailed information up to the subpixel level quantitatively from land cover [4]. Furthermore, remote sensing is generally used to examine physical parameters of water quality that have visual characteristics such as water surface temperature, water turbidity, and dissolved solids [5].

Various approaches are used to investigate water quality indices by remote sensing. General methodologies for evaluating concentrations of different variables have evolved from simple linear regression methods and nonlinear multiple regression to principal component analysis (PCA) and neural networks [6–9]. A number of these investigations used tape mathematical algorithms to select correlated single bands and band ratios to map the distribution of spatial indicators [10–11]. However, some conventional regression models may no longer be optimal, especially when there are complex nonlinear relationships between water system behavior and environmental factors.

In recent years, by not changing the classical approach, the use of big data tools and technologies in the water quality sector has become a consensus, although several machine learning-based studies have shown promising results in overcoming low accuracy in time series using simple empirical models [12-13]. However, thoroughly understanding the complex two-way interaction in temporal and spatial contexts is still a challenge [14–16]. Deep learning techniques provide an opportunity to study the characteristics of spatial or temporal correlations [17-20]. Previous studies found that the new artificial intelligence (AI) approach of the Convolutional Long Short-Term Memory (ConvLSTM) model dramatically outperformed classical sequence modeling methods in capturing spatiotemporal correlation data from satellite imagery input. Previous research had been carried out on Lake Small Prespa in Greece, namely predicting water quality variables, namely DO and Chlorophyll-a. The research results show that the Hybrid CNN-LSTM model succeeded in capturing low- and high-level water quality variables, especially for DO concentration. The data used in this research are time series data for water quality parameters such as pH, temperature, DO, Chl-a. The disadvantage of this research is that it uses 3 water measurement parameters and must collect data in the field periodically, so it requires time and money, and is less effective if used as a baseline for predicting water quality in other lakes [26]. However, attempts to apply the ConvLSTM algorithm to water quality extraction are still rare, so special attention is needed in applying WQI modeling.

In this study, we recommend using ConvLSTM quickly by taking data from the results of Landsat 8 OLI/ TIRS spectral standardization at the location of the monitoring point. The initial method used was Spectral Mixture Analysis which was later combined with the Convolutional technique of Long Short-Term Memory to study short-term spatial and temporal characteristics. The Spectral Mixture Analysis method with the Convolutional Long Short-Term Memory technique conducted in this study is believed to make a good combination in measuring WQI in Indonesia in general and in South Sumatra Province in particular. This paper is structured as follows: Section I describes the background and literature review of the various publications related to this study. Data sets and research methods are discussed in Section II. Results and discussion are explained in Section III and Section IV continued with conclusions.

II. Material and Method

SMAs are used to decompose the spectral signatures of water quality components, providing valuable insight into the composition of water bodies. ConvLSTM, a deep learning [21] architecture, is used to capture temporal dependencies and spatial patterns in water quality data. By combining spectral information from SMA with the sequential analysis capabilities of ConvLSTM, our proposed method, called the Spectral Mixture Analysis WQI (SMA-WQI), offers a comprehensive framework for assessing water quality conditions.

The effectiveness of the SMA-WQI model was evaluated using performance metrics such as Mean Absolute Error (MAE) and Correlation Coefficient (r) because previous experimental results showed that the SMA-WQI model outperformed the base model, demonstrating its superiority in water quality assessment. In addition, sensitivity analysis was performed to test the robustness of the SMA-WQI model against variations in input parameters and model configuration. The proposed approach promises to improve water quality monitoring and management practices, providing valuable insights for environmental decision-makers and policymakers.

A. Spectral Mixture Analysis

The data used in this study consisted of in-situ measurements obtained from 30 monitoring points spread across seven sub-districts in North Musi Rawas Regency, representing river conditions in the administrative area of North Musi Rawas Regency. Furthermore, this data will be standardized with spectral data. In-situ data was collected manually, and samples were then taken to the Environmental Laboratory of BLUD UPT Musi Rawas Regency to test the parameters of Chemical Oxygen Demand (COD) and Total Suspended Solids (TSS) according to certified test procedures (Fig. 1). The Environmental Laboratory of BLUD UPT Musi Rawas Regency will then issue a Test Results Report (LHU). Eight parameters are included in the test results, namely pH, Dissolved Oxygen (DO), TSS, COD, Biochemical Oxygen Demand (BOD), Nitrate, Fecal Colliformes (FC), and Phosphate. The study was conducted from 2021 to 2023.

Fig. 1. River water sampling process.

The spectral data used came from the Landsat 8 OLI/TIRS Satellite equipped with 11 bands, which can represent the spectrum of each river monitoring point. Satellite data collection is carried out by the process of spectral down

sampling by determining the location code of each river monitoring point through USGS Earth Explorer, resulting in path code 125 and row 062. Based on this location code, satellite data is taken every semester from 2021 to 2023.

Landsat 8 OLI/TIRS data is then processed using the Software Integrated Land and Water Information System (ILWIS) application. ILWIS is a PC-based Geographic Information System (GIS) and Remote Sensing software developed in 2005. ILWIS provides a wide range of figure processing, spatial analysis, and digital mapping functions. Reasons for using ILWIS include its open-source nature, consistency in the use of georeferenced systems on earth maps, good raster processing capabilities, adherence to topological principles during the editing process, attractive layout display, and the ability to integrate spatial data from various formats as well as tabular data.

The satellite data and in-situ data were then adjusted to the standard using 10 color clusters and analyzed using the Spectral Mixture Analysis method by combining Band 2, Band 3, and Band 4 for the first model, as well as a combination of Band 3, Band 4, and Band 5 for the second model, according to their respective functions. Clustering using 10 colors is done to produce more complete and consistent color differences. Furthermore, the color pixel value is nominated into RGB standards with a color range of 0-255 through a stretching process, resulting in a color combination that matches the RGB combination. The standardized data is then processed using the SMAs method (see Fig. 2).

B. Convolutional Long Short-Term Memory (ConvLSTM)

In this study, using the Convolutional Long Short-Term Memory approach to study long-term spatial and temporal characteristics. ConvLSTM was developed specifically in assisting problems of predicting spatial-temporal sequences and according to previous research, is more effective in extracting spatial and temporal characteristics from feature graphs [22]. This allows ConvLSTM to analyze and predict events in time series, to combine spatial data from a single feature map [23]. To create the ConvLSTM equation [24], the equation is used:

$$it = \sigma(Wpi * Xt + Whi * K(t-1) + Wci \circ C(t-1) + yi) \quad (1)$$

$$ft = \sigma(Wpf * Xt + Whf * K(t-1) + Wcf \circ C(t-1) + yi) \quad (2)$$

$$Ct = ft \circ C(t-1) + it \circ tanh(Whc * K(t-1) + Wxc * Pt + yc) \quad (3)$$

$$Ot = \sigma(Wpo * Pt + Who * K(t-1) + Wco \circ Ct + yo) \quad (4)$$

$$ft = Ot \circ tanh(Ct) \quad (5)$$

The major innovation of LSTM is its memory cell Ct which essentially acts as an accumulator of the state information. The cell is accessed, written and cleared by several self-parameterized controlling gates. Every time a new input comes, its information will be accumulated to the cell if the input gate it is activated (1). Also, the past cell status $C(t-1)$ could be "forgotten" in this process if the forget gate ft is on (2) (3). Whether the latest cell output Ct will be propagated to the final state ht is further controlled by the output gate Ot (4) (5). The it, ft, and Ot gates each represent the 3D tensor of ConvLSTM. The last 2D that is spatial is rows and columns. The operators "$*$" and "$\circ$", respectively, are convolution operators and "Hadamard products". In this case, ConvLSTM is equipped with a batch normalization layer and a dropout layer.

The resulting application of this study is a combination of Statistical Analysis of Temporal Dynamics and Spatial Pattern Identification, namely WQI Spectral Database and Water Period Differences, which can be useful for monitoring water quality in different river areas (see Fig. 3).

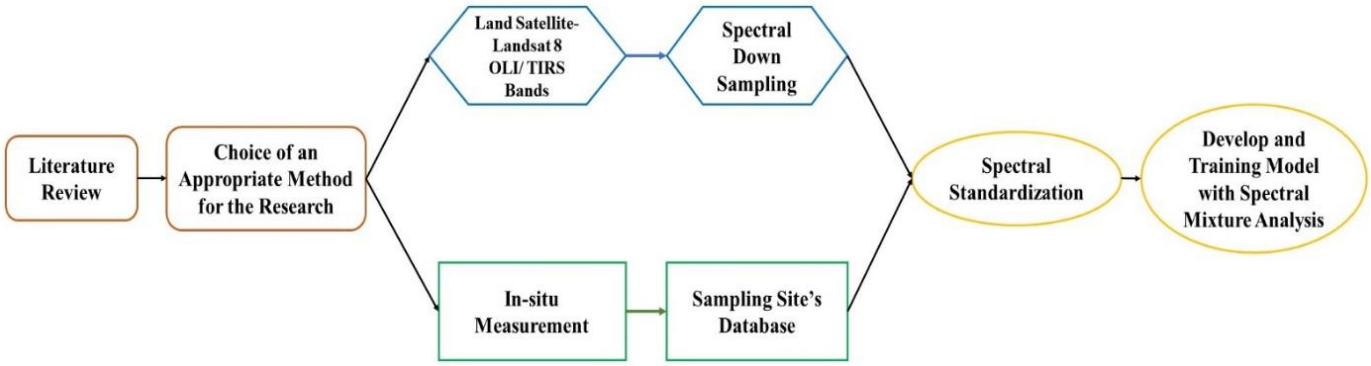

Fig. 2. Research method with SMA.

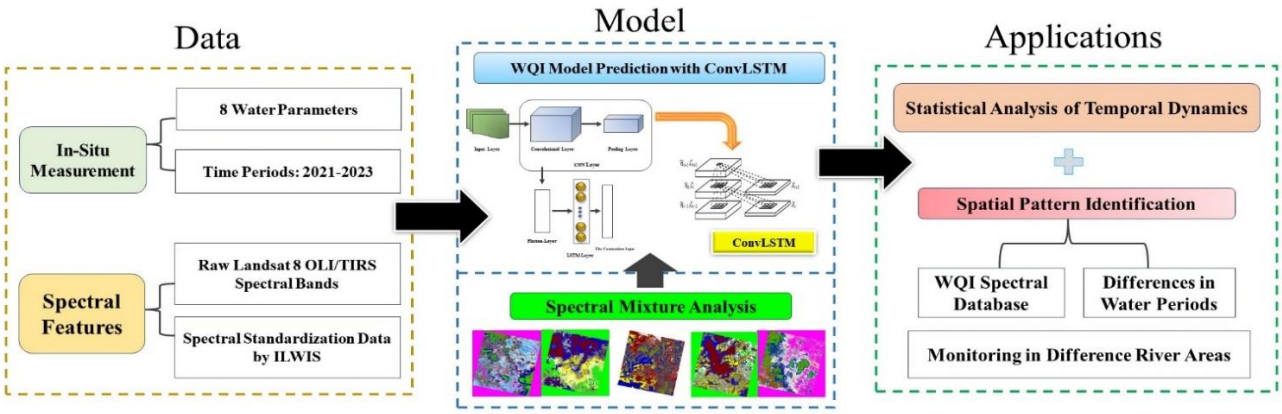

Fig. 3. A Framework of WQI based on SMA and ConvLSTM techniques.

III. Experimental Results and Discussion

A. Experimental Results

The results of this study consist of Pollution Index Score, WQI Score, results of standardization of in-situ data and Landsat 8 OLI/ TIRS data, as well as the results of Spectral Mixture Analysis with a Convolutional Long Short-Term Memory techniques approach.

1) Pollution index and river WQI: The results of monitoring at river monitoring points are separated per category of sample points that meet water quality, so that the Pollution Index (IP) and Index Value per Water Quality are obtained as the basis for calculating the WQI score. Data on the Pollution Index (IP) per semester from 2021 to 2023 can be seen in Fig. 4.

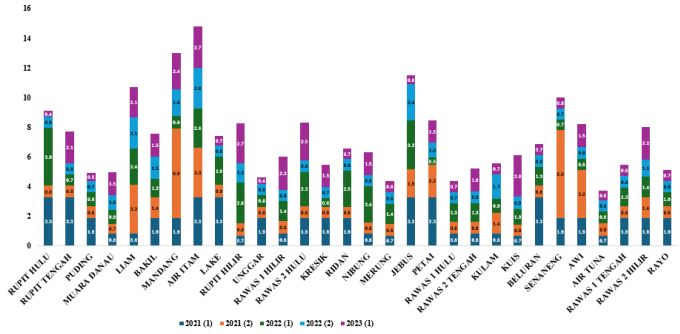

Fig. 4. IP diagram at river monitoring point for 2021 – 2023.

The results of the calculation of the Index value per Water Quality obtained by the WQI Score in 2021 are 59.7; Year 2022 is 61.3 and Year 2023 is 58.7 (Table I). Based on the Canadian Council of Ministers of the Environment (CCME), the higher the WQI River, the better the water quality, it can be concluded that the status of WQI Sungai in Muratara Regency from 2021 to 2023 is monitored poorly. This means water quality is often threatened and compromised, conditions often deviating from naturally desired levels [25].

2) In-Situ data standardization and satellite data of landsat 8 OLI/TIRS: The spectral standardization process produces 8-9 color spectrums with wavelengths from 0.53 µm to 0.88 µm. In the 234-band model, the colors that are not visible from the standardization process are red (255, 0, 0) and magenta (249, 0, 255) with the standardization chart can be seen in Fig. 6 with the highest number of color spectrum, namely blue (0, 0, 255) as many as 39 points and then navy (0, 0, 128) as many as 36 points (Fig. 5). While in the 345-model band, the color that is not visible is aqua color (0, 255, 255) with the standardization chart can be seen in Fig. 6 with the highest number of color spectrum, namely blue (0, 0, 255) as many as 49 points and then navy colors (0, 0, 128) as much as 29 points.

TABLE I. River WQI in North Musi Rawas Region for 2021-2023

(a)

Water Quality	Index Value Weight	Number of Points for Water Quality		
		2021	2022	2023
Good	70	31	34	26
Light	50	27	26	34
Moderate	30	2	0	0
Heavy	10	0	0	0

(b)

Water Quality	Index Value Weight	Percentage of Fulfillment of Quality Standards		
		2021	2022	2023
Good	70	52%	57%	43%
Light	50	45%	43%	57%
Moderate	30	3%	0%	0%
Heavy	10	0%	0%	0%

(c)

Water Quality	Index Value Weight	Index Value for Water Quality		
		2021	2022	2023
Good	70	36,2	39,7	30,3
Light	50	22,5	21,7	28,3
Moderate	30	1	0	0
Heavy	10	0	0	0
WQI = Not Good		59,7	61,3	58,7

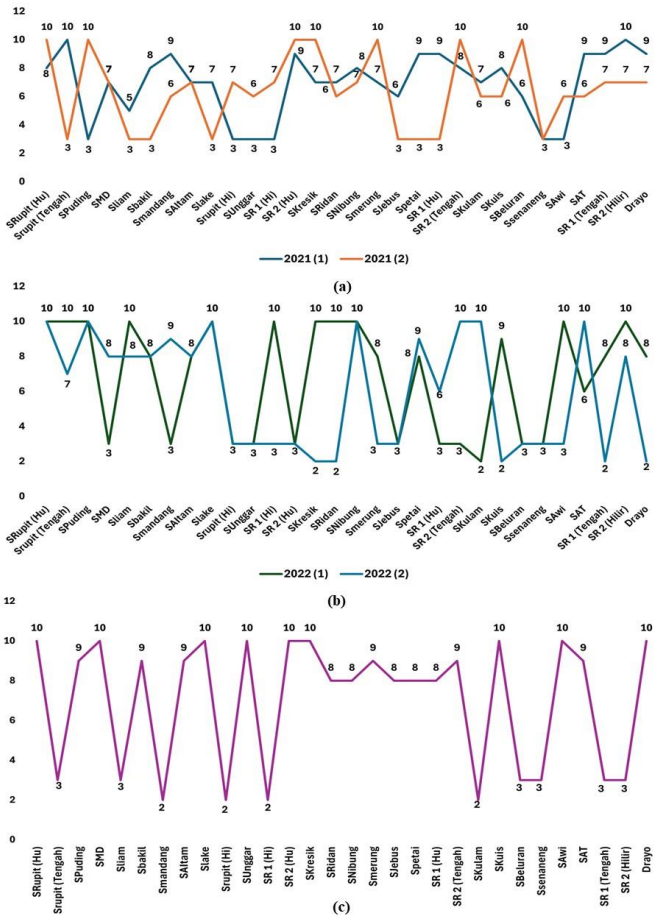

Fig. 5. 234-Band model standardization chart (a) 2021 Semester 1 and 2; (b) 2022 semester 1 and 2; (c) 2023 semester 1.

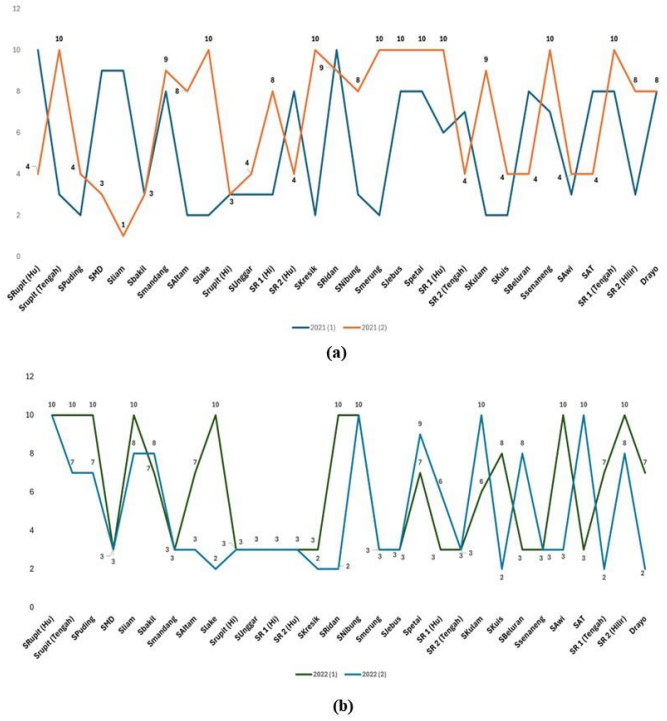

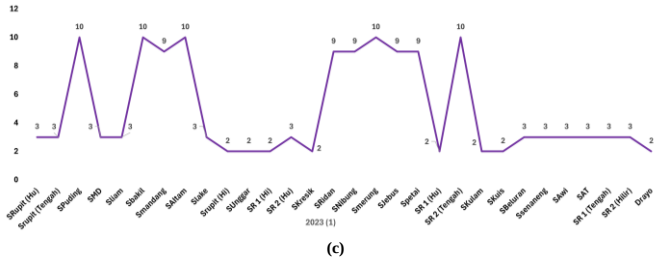

Fig. 6. 345-Band model standardization chart (a) 2021 semester 1 and 2; (b) 2022 semester 1 and 2; (c) 2023 semester 1.

3) Spectral mixture analysis process: The Landsat 8 OLI satellite data process using the ILWIS application remote sensing system produces mixed spectral maps per semester from 2021 - 2023 (Fig. 7).

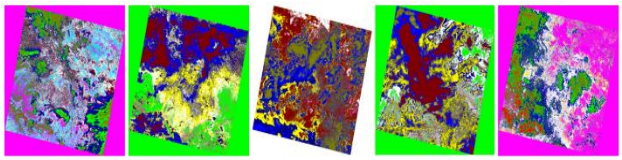

Fig. 7. Mixture spectral map.

The results of standardization produce color combinations that affect two categories of pollution index, namely pollution Meets (M) and Light pollution (R) (Table II).

TABLE II. LEVEL OF ACCURACY WITH SPECTRAL MIXTURE ANALYSIS FOR PREDICTION OF WQI

Band Model	Accuracy Percentage (%)			
	Good Pollution Index (M)	Color Spectrum	Light Pollution Index (R)	Color Spectrum
234	26,58	Blue	27,54	Navy
345	31,65	Blue	34,78	Blue

Based on the observations of Spectral Mixture Analysis, the accuracy rate of the 345-band model is better, reaching 34.78%, compared to the 234-band model which is only 26.58%. Although the accuracy level of the 345-band model is better, the level of accuracy in predicting the WQI is still considered too small. This can be caused by several things, including because: 1) the comparison of wavelengths with the condition of 8 mandatory parameters being measured; and 2) Landsat 8 OLI/TIRS satellite data at two monitoring point locations where cloud cover reached 84%, thus affecting the accuracy of the analysis.

4) Convolutional long short-term memory analysis

a) Selection of eigenvalues: From the number of missing values in each indicator, the dissolved oxygen index value lost in this area is the smallest, and prediction of index using this model has higher accuracy and reliability. Therefore, dissolved oxygen will be the main research to evaluate water quality in this region. The causes of value loss are broadly divided into human factors and natural factors. The natural factor is that in the data collection process, due to machine factors, there are some data collectors that fail, or the

collected data cannot be stored, resulting in some data that cannot be saved. The human factor is caused by human error in the collection process resulting in the loss of some data. If there are enough samples in the data set, the ratio of missing values is relatively small. This small amount of missing value has less impact on the overall situation and can be eliminated directly. Therefore, the missing data value is immediately deleted in this experiment.

b) Handling outliers: In the process of collecting data, there will be abnormal objects due to different types of data sources, data measurements, and collection errors. Abnormal objects are often called outliers. Outlier detection, also known as deviation detection and exclusion mining, is often used as an important part of data mining. The task is to find objects that differ significantly from most data. Therefore, most data mining methods treat this difference in information as noise. Boxplots use the distance between interquartile values as the basis for assessment, so they have objectivity and superiority in identifying outliers. It can be seen from the data set that there is an excessive data between the maximum and minimum dissolved oxygen values, which may be due to the length of the working time of the instrument and the aging of the instrument, resulting in errors in the data at the same time. some point in time. Therefore, such data can be regarded as abnormal values during data analysis.

c) Normalization: In order for the ConvLSTM model to converge faster and have higher stability in the training process, dissolved oxygen data is normalized. To prevent the model from performing well in training sets but generally in test sets, its generalizability is weak. Therefore, this paper takes the resample data of dissolved oxygen concentration data in chronological order by day and divides the data into training sets and verification sets with a proportion of 8:2 in the training process. That is, 732 sample data was used to verify the performance of the model. The results of abnormal data that have not been normalized from the 8 mandatory parameters of WQI measurement are shown in Fig. 8.

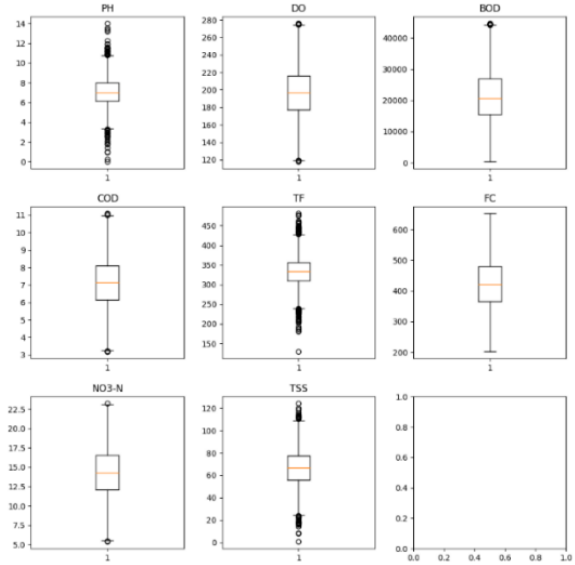

Fig. 8. Abnormal data from 8 parameters with interpolation method.

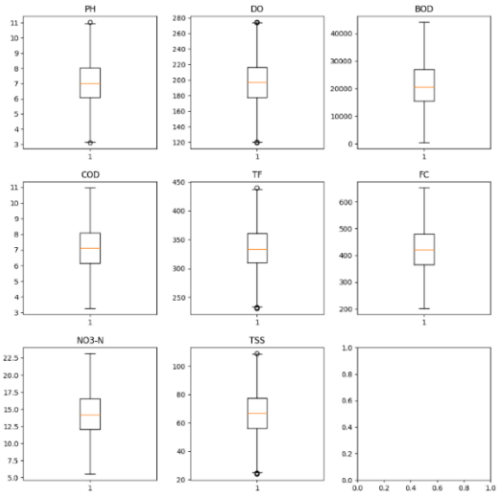

Fig. 9. Normalized data with interpolation method.

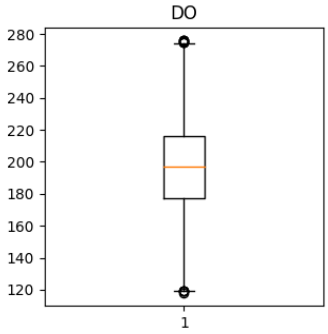

Fig. 10. Data cleaning results from Dissolved Oxygen parameter.

The effect of removing abnormal values in the diagram (Data Cleaning) of the 8 Mandatory Parameters using the interpolation method is shown in Fig. 9, and the comparison diagram after handling abnormal values specific to the dissolved oxygen parameter (Fig. 10). Fig. 11 shows WQI from dissolved oxygen parameter.

d) Data recovery: When evaluating the model after training, to eliminate the impact of normalization on the prediction results, the prediction data needs to be recovered to evaluate the error of the model's prediction values.

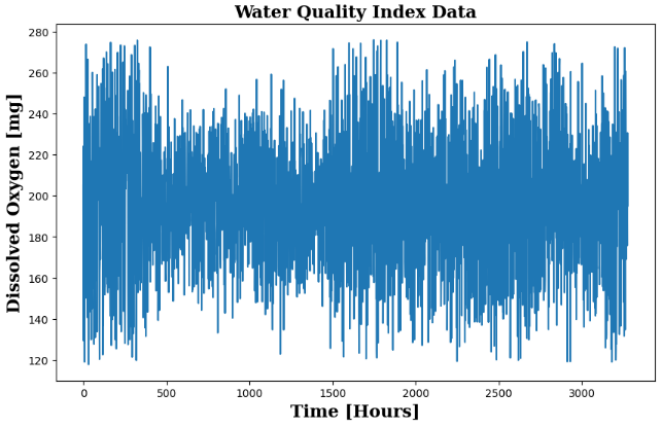

Fig. 11. WQI from dissolved oxygen parameter.

To influence the model's prediction against actual data, this experiment uses the ConvLSTM model to predict the dissolved oxygen concentration in the test sample. At the same time, in order to compare the predictive effects of the two models more clearly, we performed a visual comparative analysis of the data of the first sample, as shown in Fig. 8 and 9. It can be seen that although the ConvLSTM hybrid model can better predict periodic changes in dissolved oxygen, the fit between more significant values and smaller values is relatively poor, resulting in relative deviations. It can be shown that ConvLSTM has stronger prediction performance.

e) Result test of ConvLSTM model: To test the application of the ConvLSTM model in predicting the WQI, commonly used evaluation metrics such as Mean Absolute Error (MAE) and Correlation Coefficient (*r*) were used. Fig. 12 shows the results of processing MAE and r values data from the four ConvLSTM models tested, while Fig. 13 shows the MAE distribution in histogram form.

The test results of the application of the ConvLSTM model with data on 8 mandatory parameters from 2021 to 2023 show an *r* score of 0.96575094 and an RMSE accuracy value of 96% or it is considered that the performance of this model is acceptable or better than the accuracy of applying the model CNN and LSTM separately (range ± 92% - 93%).

B. Analysis Discussion

River WQI monitoring in North Musi Rawas Regency carried out in this research was based on IP values with 4 categories, namely Meet (M), Light (R), Medium (S) and Heavy (B). From the results of in-situ data processing, it was obtained that the number of Sample Meet (M) points was 91, Light (R) was 87 and Medium (S) was 2 data, and there was no heavy pollution category (B). The amount of pollution M and R is not significantly different and is still much greater than the amount of pollution status S and no pollution status B was found. This can mean that in general the condition of the river in the Muratara watershed is still relatively good even though the WQI value is in the Poor category.

In terms of standardization of in-situ data and Landsat 8 OLI/TIRS satellite data, it produces a spectral library which can then be used in the Spectral Mixture Analysis process. In the Landsat 8 OLI spectral image library, endmember values are obtained from the region of interest (roi). Pixels that have been selected using the ROI method can be seen as endmember values using the pixel purity index method. Standardization can be used as a basis for conducting Mixed Spectral Analysis in this research. So that the analysis results are more accurate and the resulting color spectrum to represent pollution status is better.

The Spectral Mixture Analysis carried out in this research first produces a mixed spectral map. The level of accuracy on mixed spectral maps is influenced by the percentage of cloud cover at the location, and the accuracy of the coordinate points and includes 8 mandatory parameters for measuring water quality. The color resulting from the Spectral Mixture Analysis of the 345-band model for the Pollution Index categories M and R is Blue. This means that if the river water is in good condition or there is light pollution, the reflected color that will appear on the 345-band model is blue. The reason is the characteristics of band 5 which measures near infrared, or NIR. This part of the spectrum is critical to ecology because healthy plants reflect water on their leaves, scattering the wavelengths back into the sky. The Pollution Index Category S is not discussed because the number of samples is too small and can bias the analysis results.

IV. CONCLUSION

This research produces a river WQI monitoring model using the SMA method, namely a 345-band model with a visible color spectrum which represents the Met (M) and Light (R) Pollution Index which is Blue and wavelengths (spectrum) ranging from 0.53 µm up to 0.88 µm. The results of testing the application of the hybrid ConvLSTM model with data on 8 mandatory parameters for River WQI measurements at 30 watershed monitoring points in Muratara Regency from 2021 to 2023, produced an accuracy value of 96% or it is considered that the performance of this model is acceptable or better than the accuracy of applying the model CNN and LSTM separately (range ± 92% - 93%). The results of these predictions can be used as a baseline for river monitoring, not only in South

Sumatra Province, but also throughout Indonesia. This research also shows that the results of monitoring with the SMA Model with the ConvLSTM hybrid modeling technique can be used effectively to predict and monitor river WQI, saving time and costs and these results can be used to take appropriate steps in determining policies.

This research can still be developed in the future by continuing to use the SMA model with the ConvLSTM approach, but considering environmental factors, such as rainfall (Rain-ConvLSTM), distance between pollution sources (Distance-ConvLSTM), and connectivity between measurement points (Connectivity- ConvLSTM) is estimated to have better performance in predicting WQI. Accurate rainfall forecasts are very important because they have a big impact on people's social and economic activities. Rainfall data processed using the ConvLSTM model is expected to reduce the RMSE value by up to 23% so that the WQI prediction value is more accurate. This also applies to other environmental considerations.

UAV Path Planning Method Considering Safety and Signal Shielding Risk

Xiaoyong Chen*, Jiajun Fang, Yanjie Zhai
Nanjing Forestry University, Faculty of Mechatronic Engineering, 210037, Nanjing, China

***Abstract*—In order to meet the needs for the safe operation of unmanned aerial vehicles (UAV)s in cities, this paper proposes a multi-objective path planning method based on a particle swarm optimization algorithm. Firstly, a complex urban environment model is constructed by using the grid method. Then, taking the total length of the UAV path and the minimum flight risk as objectives, the multi-objective path optimization problem is established under the condition of taking into account the obstacle avoidance requirements and performance constraints of the UAV. Finally, the optimization problem is solved by a multi-objective particle swarm optimization algorithm and the path curve is smoothed by cubic B-spline. The simulation results show that the multi-objective path planning method proposed in this paper is more reasonable than the method that only considers the lowest security risk or the shortest path.**

Keywords*—Multi-objective particle swarm optimization; path planning; cubic B-splines

I. Introduction

With the continuous development of the electronic economy business, the number of people's online shopping has increased greatly, which also brings problems such as traffic congestion, high labor cost, a more complex service scene and so on. In recent decades, the UAV industry has been growing continuously. UAVs are utilized in urban environments for various purposes, including traffic monitoring [1], photography, and weather forecasting [2]. They are also a core component of Urban Air Mobility (UAM) [3] and future smart city plans [4, 5]. Along with the progress of relevant hardware and software, UAV delivery technology comes into being. At the same time, for the "last kilometer" problem that has plagued the industry for many years, the adoption of UAV delivery is the only feasible plan at present. Drone delivery can alleviate traffic congestion, improve delivery efficiency, and make great contributions to the sustainable development of the express delivery industry. As the premise of delivery, UAV path planning is a top priority issue that we should solve.

According to the classification of algorithms, path planning problems can be divided into traditional classical algorithms and swarm intelligence algorithms. The first kind of algorithms, such as naive Bayes classifier [6], according to Bayes' theorem, based on variable independence hypothesis and maximum likelihood estimation method[7], takes into account stable classification efficiency and insensitive sensitivity to missing data; Or backtracking algorithm [8], which is based on the main theories such as depth-first search [9]and recursion[10], takes into account both systemicity and jumping, and has the advantages of high search efficiency and strong adaptability. Based on this theory, Khan et al. [11] adopted a backtracking optimization algorithm to significantly improve the overlay path smoothing technique. The second type of algorithm, such as the ant colony algorithm [12], adopts the theory of simulating ant foraging, and extracts distributed, global optimization and adaptive features by revealing the selection, renewal and coordination mechanism, taking into account the advantages of fast convergence speed and dynamic path changes in the later period, and improves the planning quality. Based on this theory, Dentler et al. [13] proposed a chaotic ant colony improvement algorithm for path planning in dynamic environments to further shorten the path length. Calik [14] adopted multi-agent structure ant colony optimization algorithm to improve the obstacle avoidance effect for path planning problem in complex multi-obstacle environment.

Or genetic algorithm [15], which adopts the theory of biogenetics to reveal the laws of biological natural selection and genetic mechanism, takes advantage of its global search ability, adaptability, parallelism and other characteristics, takes into account the advantages of wide application range and high flexibility, and improves the quality of planning. Based on this method, Pehlivanoglu et al. [16] adopted a vibration genetic algorithm for path planning in low population environment to speed up the generation cycle.

Although the above methods have achieved beneficial results, they are rarely involved in the consideration of flight safety and signal shielding. Therefore, Banerjee [17] proposed an objective function construction method considering flight safety, using a linear Bayes algorithm to solve the dual-objective optimization problem that takes into account flight safety and shortest path. Ahmed et al. [18] put forward an improved particle swarm optimization algorithm to achieve the best obstacle avoidance effect and the shortest operating path. Levasseur [19] developed a surrogate model (Kriging method and neural networks) that considers wind conditions and various types of uncertainties to calculate the probability of drone impact on the ground. Jin [20] proposed a two-dimensional drone flight safety path planning method based on ground fitting. This method calculates the dynamic density of outdoor pedestrian populations using building volume, residential population, and grid area, thereby designing safe path planning for drones in urban environments.

The aforementioned research works plan routes by considering flight safety factors and constructing safety objective functions based on wind conditions, building volume, population density, and vehicle density. However, these studies do not address issues related to the proximity and avoidance of flight-restricted zones due to signal blocking, and therefore, cannot solve problems such as loss of communication or control

*Corresponding Author.

caused by signal blocking during flight. Signal blocking is a crucial issue in various application scenarios such as wilderness rescue, cave exploration, and military reconnaissance. Consequently, it is necessary to design safety objective functions that account for signal blocking in the path planning process to achieve both the shortest path and the highest safety.

Therefore, based on the practical requirements of designing safety objective functions that consider signal shielding mentioned above, this paper proposes a path planning method for multi-target UAVs based on particle swarm optimization algorithm. The full text is arranged as follows: Section 1 briefly reviews the researches on path planning;

In the second section, a three-dimensional static urban environment model is established based on the three-dimensional raster method under the constraints of the UAV itself, considering the factors such as security risk and signal shielding, and the path optimization problem is described.

In the third section, a new objective function construction method is proposed, which takes into account security risks, signal shielding and shortest path, and uses particle swarm optimization to optimize multiple objective functions, and then smooths the path curve by means of cubic spline curve fitting scatter points.

In the fourth section, a set of Pareto solutions of evenly distributed flight path and safety risk are obtained through simulation examples, and the effectiveness of the proposed method in terms of shortest path and safety optimization is verified by considering safety wind comprehensively.

The fifth section gives the full text conclusion.

II. Environment Modeling and Optimization Problem Description

Environmental modeling is the first problem to be solved in the course of UAV flight path planning. Its purpose is to establish a mathematical model describing the starting point and end point, obstacle position, flight environment information and constraints, and provide an algorithm model for describing the path optimization problem and simulation verification.

A. Establishment of 3D Environment Model

In this paper, it is assumed that the largest external cuboid in the three-dimensional model is the protection area of obstacles, and the UAV track intrusion represents the collision path is not feasible. In this hypothesis, the irregular urban obstacles are regarded as regular columns, so that the planned path reduces the difficulty of the overall path planning and meets the obstacle avoidance requirements. As the input condition of the UAV path planning algorithm, the 3D environment model needs to obtain the flight environment information before the UAV executes the flight task, including the distribution and height of buildings, crowd density, traffic flow density, etc.

In this paper, the three-dimensional histogram shown in Fig. 1 is established to simulate the urban environment. The three-dimensional grid method [21] is adopted to divide the urban environment space into countless independent cells. If the range of the cell does not contain any obstacles, it is called a free grid. In the opposite case, if there are obstacles in the range of the grid, it is called the obstacle grid. The UAV can move freely in the free grid, but it cannot move in the obstacle grid. In order to reduce the calculation amount, no grid is set between each small surface, and the grasp of the granularity is adjusted to the shortest distance of the UAV.

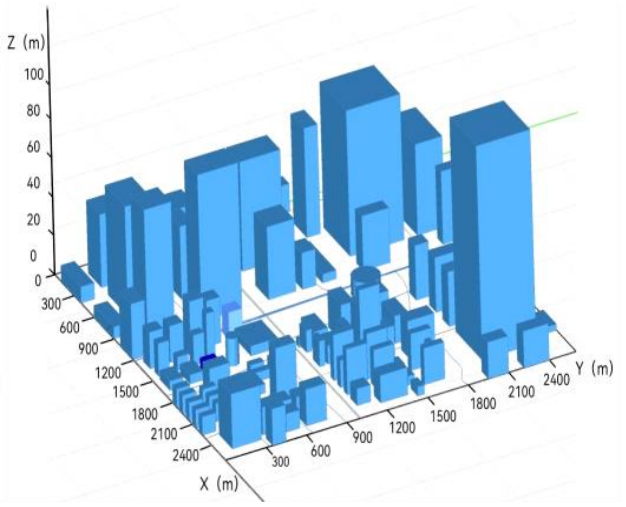

Fig. 1. Histogram of the three-dimensional building group environment.

Fig. 2. Top view.

B. Description of Optimization Problem

In the above environment, planning a path (see Fig. 2) that considers the dual goals of safety and shortest distance, the optimization problem can be described as:

$$\text{Objective function: } \min F = (f_L, f_R)^T \tag{1}$$

Where f_L is the drone track length, which can be converted into the sum of distances of discrete points, the formula is as follows:

$$\min f_L = \sum_{i=1}^{n} \sqrt{(x_i - x_{i-1})^2 + (y_i - y_{i-1})^2 + (z_i - z_{i-1})^2}$$
$$(i = 1, 2..., n) \tag{2}$$

The starting coordinate point of the UAV is (x_0, y_0, z_0), and the coordinates of the middle waypoints are (x_i, y_i, z_i), f_R is a function to consider safety.

$$\min f_R = f_P + f_C + f_S \tag{3}$$

Where, f_P denotes the risk of drone crash for pedestrians, f_C denotes the risk of drone crash for vehicles, f_S denotes and the risk of signal shielding.

C. Constraints of UAV

$$d_{between} > r_{protect} \tag{4}$$

$$\arccos\left(\frac{\mathbf{a}_i^{\mathrm{T}}\mathbf{a}_{i+1}}{\|\mathbf{a}_i\|\|\mathbf{a}_{i+1}\|}\right) \le \theta_{\max} \tag{5}$$

$$\arctan\frac{|z_{i+1}-z_i|}{|a_i|} \le \beta_{\max}\,(i=1,2...,n-1) \tag{6}$$

$$h_{\min} \le z_i \le h_{\max} \tag{7}$$

Where, d_{between} indicates the distance between the UAV and the obstacle, and r_{propect} indicates the radius of the spherical protection area set for the UAV; $\mathbf{a}_i = \begin{pmatrix} x_i - x_{i-1} & y_i - y_{i-1} \end{pmatrix}^{\mathrm{T}}$ is the projection vector of the i section of the voyage on the horizontal ground, $\theta_{\max}$ representing the maximum yaw Angle, $\beta_{\max}$ representing the maximum pitch Angle, $h_{\min}$ and $h_{\max}$ respectively representing the minimum and maximum flight height.

III. Multi Objective Particle Swarm Optimization Algorithm for Solving the UAV Path Planning Problems

A. Construction of Objective Function Considering Safety Risk

As can be seen from formula (3) above, the safety risk objective function in this paper includes three parts: the risk of UAV crash to pedestrians, the risk to vehicles [22] and the risk of entering the signal shielding area during flight. The mathematical models of these three parts will be established as follows:

1) The risk of drone impact on pedestrians on the ground: Due to the differences in the characteristics of different functional areas in the urban environment, such as the population density and shelter [23] coefficient of each functional area, the risk of UAV to pedestrians on the ground should be evaluated according to the different differentiation of the operation area during route planning, as follows:

$$f_R = \lambda QF \tag{8}$$

Where, λ represents the crash probability of UAV per hour, F represents the fatality rate [24] related to the kinetic energy of UAV, and Q represents the number of affected persons. The calculation formula is as follows:

$$Q = A\rho_p \tag{9}$$

Where, A represents the area of the drone and ρ_P represents the population density in the falling area.

The mortality rate F related to unmanned mobility is as follows:

$$F = \frac{1}{1+\sqrt{\frac{\delta}{\varepsilon}}\left(\frac{\varepsilon}{E}\right)^{\frac{1}{4C_V}}} \tag{10}$$

Where, δ is the impact energy required for mortality to reach 50% when c=0.5, and ε is the critical value of impact energy required for death when c=0, C_v is equal to the masking coefficient, when there is no masking, C_v=0; When only trees exist, C_v=0.25; When there are numbers and low buildings, C_v=0.5; When tall buildings exist, C_v=0.75.

In formula (5), E represents the kinetic energy of the drone when it crashes, and the formula is as follows:

$$F_d = \frac{1}{2}R_L A_\rho V_{rel}^2 \tag{11}$$

$$\begin{cases} a = \dfrac{mg-F}{m} = g - \dfrac{R_L A_\rho V_{rel}^2}{2m} \\ = \displaystyle\int_0^t \left(g - \frac{R_L A_\rho V_{rel}^2}{2m}\right)dt = \sqrt{\frac{2mg}{R_L A_{\rho A}}}\left(1 - e^{\frac{\lambda R_L A_\rho A}{M}}\right) \end{cases} \tag{12}$$

$$E = \frac{1}{2}mv^2 \tag{13}$$

Where, F_d represents the resistance of the UAV in falling, R_f represents the falling coefficient, ρA represents the air density, V_{rel} represents the falling speed of the UAV, m represents the mass of the UAV, g represents the acceleration of gravity, h represents the operating height of the UAV, and v represents the operating speed of the UAV.

2) The risk of drone impact on ground vehicles: The risk to the vehicle when the UAV is running is calculated as follows:

$$f_C = \lambda CY \tag{14}$$

Where, C represents the probability of the drone hitting the vehicle after falling, Y is the average death rate of each car accident, and C is determined by the ratio of the area of all vehicles on the road to the total area of the road, as shown in the following formula:

$$c = \frac{\bar{S}_{car}}{S_{road}} \times N_{car} N_{car} \tag{15}$$

Where, $\bar{S}_{car}$ is the projected vehicle area, is the number of vehicles, S_{road} is the road area, L is the road length, K is the

traffic flow density, D_{road} is the width $N_{car} = KL, S_{road} = LD_{road}$

3) The risk of entering the signal shielding area during drone flight

$$f_s = \begin{cases} \frac{d_{in} - d}{d_{in}} & d \le d_{in} \\ 0 & d > d_{in} \end{cases} \quad (16)$$

Where, d_{in} indicates the radius of influence of the signal shielding area, and d indicates the distance between the UAV and the center of the signal shielding area.

B. Multi-Objective Optimization based on Particle Swarm Optimization

The multi-objective optimization problem can generally be expressed as a function

$$\min F(x) = (f_1(x), f_2(x), ..., f_M(x)) \quad (17)$$

$$\text{Among } x \in \Omega, f(x) \in R^M, \forall_i = 1, 2..., M$$

Where R^M is the target space and Ω is the decision space, which maps the decision space to the target space.

Compared with the single objective optimization problem, the most prominent problem of the multi-objective optimization problem is that there is a probability of conflict between different objectives in the multi-objective optimization problem, so it is difficult for the single objective optimization algorithm to have an effect on it.

In the dominance relationship between individuals, p and q are two distinct individuals in the population, which are called p dominate q, if the following conditions must be met:

$$f_k(p) \le f_k(p)(k = 1, 2, \cdots, r) \quad (18)$$

There exists at least one subobjective that makes p better than q, i.e. : $\exists m \in \{1, 2, ...r\}$, so $f_m(p) < f_m(q)$, then p dominates q. Where r is the number of subgoals, then p is said to be non-dominant, or non-inferior or dominant, and q is dominated. Expressed as p $\succ$ q, where '$\succ$'is the dominant relation [25].

The model proposed in this paper includes two factors: the flight path of UAV and the safety risk, in which the safety risk contains three objective functions. Due to the large differences in the order of magnitude and physical meaning of the two objectives of the flight path and security risk in the model, it is difficult to accurately assign weights and convert them into a single objective optimization problem. Meanwhile, for the UAV path planning, a set of Pareto solutions can be obtained to represent multiple optimal solutions, increasing the selectivity of the UAV path. Therefore, based on the multi-objective idea, this paper uses the multi-objective particle swarm optimization algorithm to solve the proposed multi-objective model.

Based on the advantages of PSO (particle swarm), MOPSO (Multi-objective particle swarm Algorithm) [26] uses the idea of external archiving and the principle of Pareto dominance [27] and follows the most basic equation to update its speed and position. When MOPSO deals with multi-objective problems, each iteration will produce a set of non-inferior solutions, which will be optimized through mutual learning among individuals, because the speed and position of each particle in the iterative process of PSO are constantly changing, and the fitness (objective function) will also change. Therefore, it is generally necessary to use an external archive to store the data of pareto optimal solutions and maintain the diversity of solutions. The steps of MOPSO method adopted in this section are as follows.

1) Data initialization, using raster method to generate environment models, initializing their speed and position, and given MOPSO parameters as follows:

$$P_i(x_i, v_i), \ i = 1, 2, \cdots, N \quad (19)$$

Use the generated $P_i(x_i, v_i)$ as the initialization particle and place them in external memory. X_i is the current position of the i^{th} particle and V_i is the current velocity of the i^{th} particle. Includes the inertia weight coefficient ω and learning factors C_1 and C_2, the initial population size N, the number of grids in each dimension D, the maximum increment level M, and the maximum number of iterations G.

2) Comparison: Each particle that is subsequently randomly generated is compared to the particles in memory, updating the particles in memory according to the following rules:

Comparison rule: If all fitness values (path and safety) of a particle in memory are greater than that particle, the particle in memory is deleted from memory; If there is a other particle in the memory, all fitness values are less than the particle, then the particle is not added to the memory, otherwise, the particle is added to the memory. Where, the fitness value is the value of two objective functions, the track path and the safety risk respectively.

3) Update of formulas: Collaboration and information sharing among individuals in the group to find the optimal solution. The particle swarm optimization algorithm only iteratively updates and stores the individual optimal solution and global optimal solution of each iteration through the velocity update formula and the position update formula. All particles adjust their speed and position according to the current individual extreme value found by themselves and the current global optimal solution shared by the whole particle swarm, so as to obtain the overall global optimal solution. Then the velocity and position update formula of particles [28] is as follows:

$$v_i(t+1) = \omega v_i(t) + c_1 r_1 (P_{best}(t) - x_i(t)) + c_2 r_2 (G_{best}(t) - x_i(t)) \quad (20)$$

$$x_i(t+1) = x_i(t) + v_{i+1}(t+1) \quad (21)$$

Where t is the number of update iterations and ω is the inertia weight coefficient. By dynamically changing the inertia of particles in flight, the purpose of global search capability and the purpose of balancing local search capability are achieved. C_1 and C_2 are the learning factors, used to adjust the speed, r_1 and r_2 are the random number on the interval [1,2], so as to increase the randomness of the algorithm. P_{best} is the optimal position of the particle during flight, and G_{best} is the global optimal position in the population. Where, P_{best} is obtained based on the dominant relationship of the current particle, if the current particle dominates, then take P_{best} as the current individual extreme value of the particle; If the two cannot be compared, the number of other particles dominated by the two in the group is calculated, and the number with more domination is taken as the individual extreme value, G_{best} is extracted from the optimal solution of Pareto frontier stored in external memory by roulette method [29].

After updating in the above formula, new particles are generated, the population is sorted by the dominant, the optimal Pareto frontier of the non-dominant solution is stored in the external memory, and the external memory is updated according to the comparison rules in step (2).

4) Repeat step (3) until the termination condition is reached. At this time, the data saved in the external memory is the Pareto frontier obtained by the algorithm. The change value of particle position is set. When the change of all particle positions is less than the threshold value, it is the termination condition, and the optimal Pareto frontier output is the final optimal scheduling result.

The overall framework diagram of the algorithm is shown in Fig. 3.

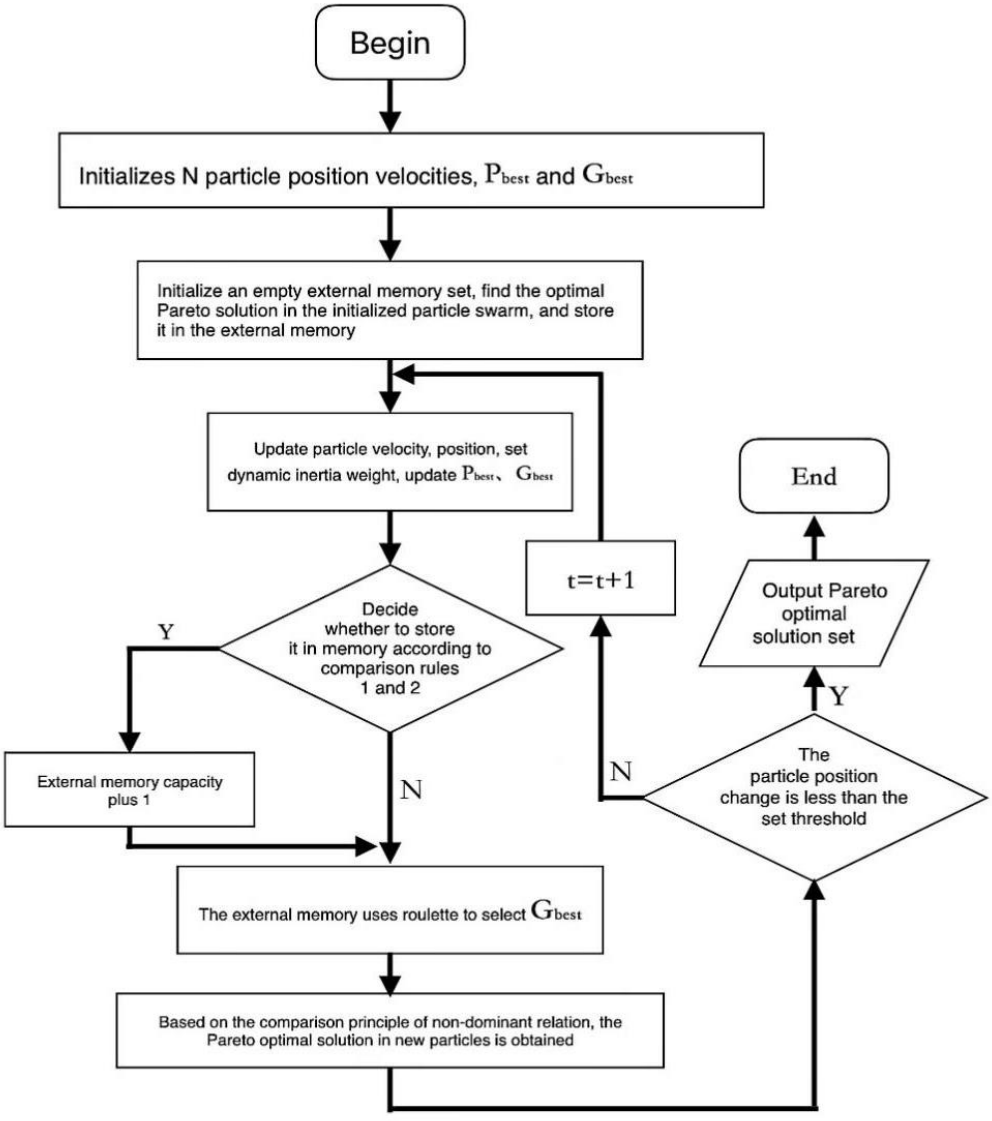

Fig. 3. Algorithm flow chart.

C. 3 Times B-Spline Interpolation Optimization

The planned path is not smooth or even out of reality. In order to keep the stability of the path in order to conform to the operation of the UAV in the city, the cubic spline interpolation is used to smooth the flight path of the UAV.

In this paper, cubic B-spline interpolation [30] is used to smooth the flight path of UAV, and the effect is shown in the figure. The path points that the UAV needs to pass through during flight are $P=(P_1,P_2...,P_n)$, and the coordinate of each point P_k in the three-dimensional coordinate system is (x_k,y_k,z_k). Then perform cubic spline interpolation on $(x_0,x_1...x_n),(y_0,y_1...y_n),(z_0,z_1...z_n)$ separately [31] to form a smooth flight path curve. Fig. 4 shows cubic spline interpolation curve.

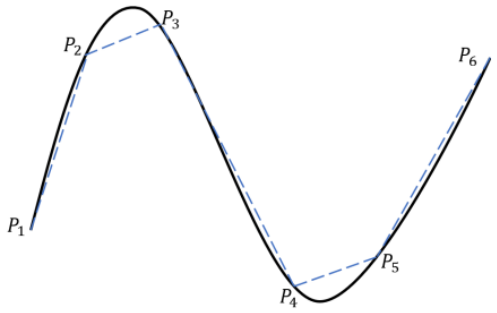

Fig. 4. Cubic spline interpolation curve.

Path smoothing basis function and control point:

Given spatial fixed points $P_i(i=0,1,...,m+n)$, curve segments can be obtained n times:

$$P(t)=\sum_{i=0}^{n}P_iF_{i,k}(t) \tag{22}$$

Where: P_i is the curve equation corresponding to the i^{th} control point, and $F_{i,k}(t)$ is a k-order B-spline basis function. Since the value represents the smoothness of the curve, the higher the value of k, the better the smoothness of the curve, but the greater the degree of calculation. In order to take into account the smoothness and complexity, this paper selects $k=3$ and obtains the basis function of cubic B-spline curve as follows:

$$F_{i,k}(t)=\frac{1}{k!}\sum_{m=0}^{k-i}(-1)^jC_{k+1}^j(t+k-m-j)^k \tag{23}$$

IV. Simulation Analysis and Verification

A. Simulation of Security and Signal Shielding Factors

1) Security: In the course of flight, the UAV should avoid the dense traffic and people as far as possible, reduce the harm caused by the UAV crash to urban roads and pedestrians, and improve the safety of the flight process. The distribution of traffic flow density of each road in the environmental model and the crowd density of the sidewalk is shown in Fig. 5.

The traffic flow density is set to (1,50), and the crowd density is set to (0.02,0.5). The depth of the color in Fig. 5 represents the density. The traffic flow in the intersection area is larger, while the crowd is densely distributed near the complex buildings.

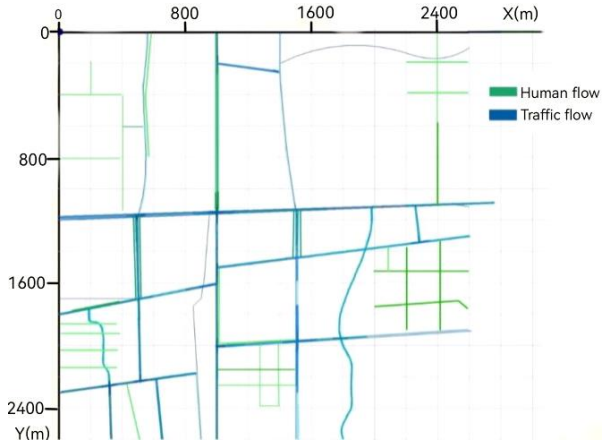

Fig. 5. Distribution of traffic flow density and human flow density.

2) Signal shielding: In the era of modern communication, the consideration of signal shielding area is particularly important. Ensuring that drone paths do not cross these areas reduces communication and navigation risks and improves flight safety. Among them, the signal shielding zones are randomly distributed in urban buildings with different radii, as shown in the Fig. 6.

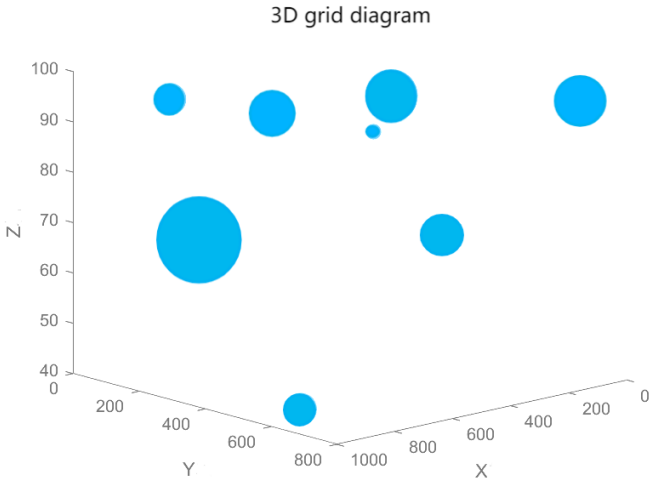

Fig. 6. Signal shielding area.

In summary, these characteristics indicate that MOPSO algorithm plays an important role in urban flight path planning of UAVs, and can fully consider factors such as safety, efficiency and route optimization. Through the analysis of the simulation results, we can further optimize the algorithm and improve the accuracy and reliability of the path planning to deal with various complex situations in the urban environment.

B. Path Planning Simulation

In this paper, the flight is designed to start from (0,0,0) and end from (2500,1560,30). In addition, the path planning also avoids areas with high human and vehicle flow, especially intersections, to reduce the risk of conflict with other traffic participants.

In this paper, the multi-objective model based on MOPSO will finally get a set of Pareto solutions, and Fig. 7 shows the distribution of this set of solutions. The fitness of the model is large because the height of each waypoint is considered in the model's flight path fitness. From the perspective of multi-objective programming, it can be seen that the distribution of this solution has good universality and uniform distribution, so the quality of this group of Parto solutions is good.

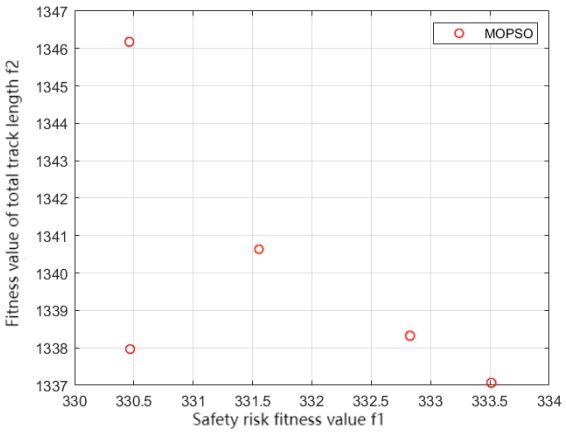

Fig. 7. Fitness distribution map.

Based on multi-objective planning, this method obtains a set of Parto solutions and five path schemes, in which the solution with the lowest security risk is the final path planning solution, as shown in Fig. 8 below, where the red trajectory 1 is the flight path of the UAV. The others can be used as alternative path schemes, providing operators with more path choices, better coping with various emergencies, and excellent adaptability in urban environment.

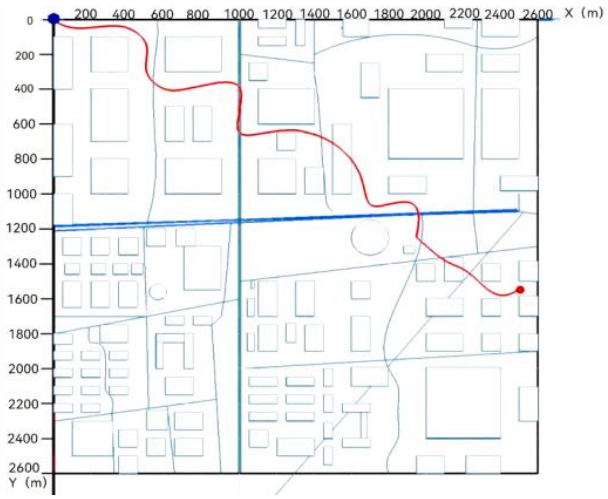

Fig. 8. Top view of path planning.

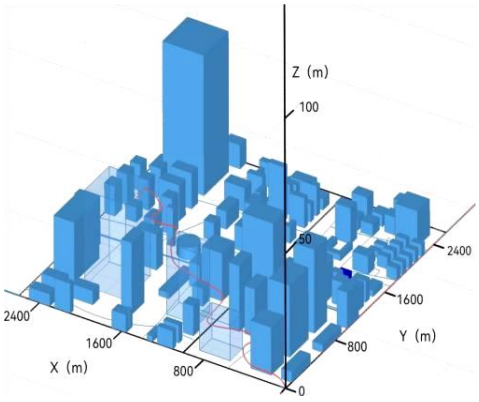

Fig. 9. Three-dimensional diagram of path.

C. Comparison Verification

In order to prove that the path generated in the urban environment model is the shortest and the safest, on this basis, this paper also gives three other comparison paths (see Fig. 9, 10 and 11) under different targets:

Trajectory 2: Only the shortest path is taken as the target, and the signal shielding area is not considered;

Trajectory 3: Only the safety is the goal, but the signal shielding area is not considered;

Track 4: Safety and shortest path is the goal, but the signal shielding area is not considered;

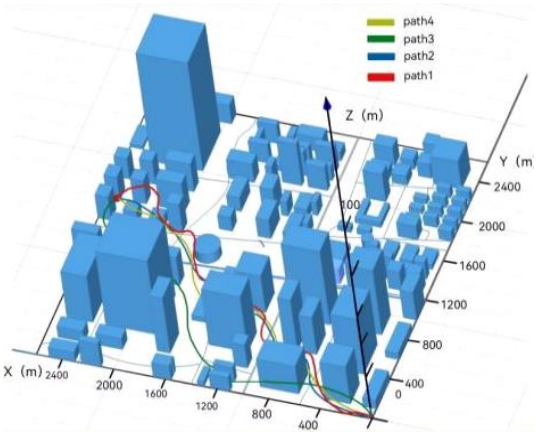

Fig. 10. Three-dimensional diagram of three different paths.

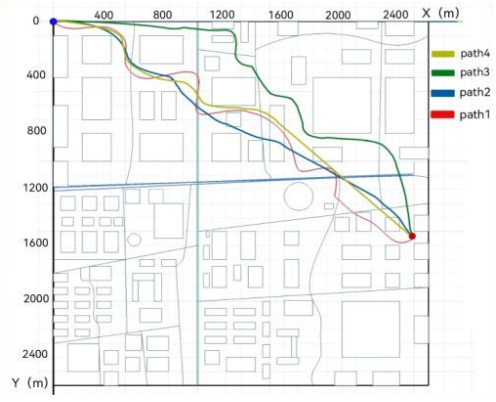

Fig. 11. Top view of three different paths.

D. Expected Result (Analysis)

Although Track 2 is 20.9% shorter than Track 1, it has a 19.5% improvement in fitness for pedestrian hazards and vehicle safety, as well as safety risks in signal-shielded areas.

Trajectory 3: Although aiming at safety, because the trajectory does not consider the distribution of urban signal shielding areas, the safety risk of this trajectory is increased by 6.3% compared with that of trajectory 1, and the total length is increased by 15.6%.

Trajectory 4: The safety risk is increased by 8.1%, but the total path length is shortened by 5.6%

To sum up, the new multi-objective function proposed in this paper comprehensively considers the path length and the security risk with signal shielding, and generates the optimal path when both are taken into account. Table I shows the path length and safety index of each trajectory.

TABLE. I. PATH LENGTH AND SAFETY INDEX OF EACH TRAJECTORY

Verify trajectories	Path length (m)	Safety risk
Track 1	4385.1	330.5
Track 2	3512.5	394.9
Track 3	4661.3	351.3
Track 4	4139.5	357.1

V. CONCLUSION

Aiming at the complex and changeable urban environment model, this paper proposes a multi-objective path planning method which considers the shortest path and the lowest security risk. In this method, the path length and safety risk of UAVs are taken as two major factors to construct the objective function, and the performance and obstacle avoidance requirements of UAVS are taken as constraints. The path optimization problem is established and a set of Parto solutions are obtained by using multi-objective particle swarm optimization algorithm. The simulation analysis results show that the proposed method can effectively reduce the risk by 19.5% or shorten the path by 15.6% compared with the shortest path or the lowest safety risk. The two requirements can be effectively taken into account. In addition, by taking the signal shielding factor into consideration, the security risk can be further reduced by 6.3%. The method proposed in this paper can be used to safely reach the destination in a relatively short path while avoiding the dense area of people and vehicles and the signal shielding area.

***Abstract*—In the times of big data, information security and privacy protection have become important issues facing today's society. To address big data's security and privacy problems, research designs and implements a hybrid encryption method using advanced encryption standard algorithms and standard encryption module 2 algorithms for encryption operations. This method utilizes Advanced Encryption Standard encryption algorithms to encrypt plaintext data without calling any encryption libraries. It improves the key extension method and security analysis of Advanced Encryption Standard algorithms. The experimental results show that by changing one key, the confusion range of the improved Advanced Encryption Standard algorithm is 62 ± 6, while the confusion range of the traditional Advanced Encryption Standard algorithm is 63 ± 7. The encryption time of the RSA algorithm is 16.50ms higher than that of Standard Encryption Module 2. The Advanced Encryption Standard scheme improved by Standard Encryption Module 2+ has the fastest decryption speed, followed by RSA+Advanced Encryption Standard scheme, and finally Standard Encryption Module 2+Advanced Encryption Standard scheme. The hybrid encryption algorithm proposed by the research institute can encrypt sensitive information in big data without leaking plaintext information, effectively protecting sensitive information in big data. This scheme can effectively protect sensitive information in big data and provide new ideas for big data in terms of network security and privacy protection.**

***Keywords*—AES; SM2; privacy protection; encryption algorithm; data security**

I. Introduction

In the past few years, as the quick growth of Internet, the popularity of the network has become widespread, and people's lives are also unknowingly changed by the network. Previous data analysis methods can not satisfy people's growing information needs, and big data, as a new type of data analysis method, has rapidly developed into a critical driving force for social advancement due to its advantages of speed, efficiency, comprehensiveness, and massive amount [1-2]. While big data brings enormous benefits and convenience to society, its privacy and security issues are increasingly prominent. Passwords are the most important part of ensuring information security and privacy protection (SPP), and also one of the most important technical means to guarantee data SPP in the era of big data. The commonly used cryptographic algorithms currently include symmetric cryptographic algorithms, asymmetric cryptographic algorithms, and some new cryptographic algorithms developed with big data [4]. Among them, the Advanced Encryption Standard (AES) data packet length is 128 bits, consisting of 128 message digests. It can resist various known and effective attack methods and is currently one of the most secure data encryption standards. Standard Encryption Module 2 (SM2) is a public key cryptography system composed of 8-bit random integers (RSA). The symmetric encryption algorithm is simple and efficient, but vulnerable to attacks. Asymmetric encryption algorithms are secure and efficient, but their decryption speed is slow [5]. To solve the problems of slow speed and short key length in the SM2 cryptosystem, this study focuses on the private data transmission security in cloud computing environments. An improved mixed encryption method of AES and SM2 is proposed, and the security and effectiveness of the method are studied and analyzed.

II. Literature Review

For the SPP in big data itself, various encryption technologies can be used to achieve the purpose of privacy protection. Kumar AS proposed a hybrid soft computing protection and recovery strategy with big data analysis to address the privacy leakage problem caused by malicious propagation in online social networks. By introducing an improved teaching method for optimizing fish schools, abnormal users in the network were classified, and a strategy with deep belief neural networks was proposed to reduce the number of abnormal users. After evaluation, this method had significant advantages in performance indicators such as detection success rate and detection accuracy [6]. The Wu team classified users based on their reactions to data viruses to prevent large-scale damage and privacy leaks caused by viruses spreading on social networks. To limit virus spread and protect data, the company implemented incentives and developed protection and recovery strategies to minimize infected users and increase immune users. Experiments denoted that the proposed model could better describe the spread of viruses on the Internet, and verify the privacy protection mechanism of big data [7]. To protect privacy and avoid the security crisis of CEC in social Internet of Things (IoT) systems, Zhang put forward a privacy protection method with data interference and adversarial training. Through the application of the adversarial pattern generation method with the firefly algorithm, the time complexity of traditional algorithms was decreased by an order of magnitude. The experiment expressed that the model had good anti-interference ability and helped multiple organizations

achieve data usage and sentence information in accordance with user privacy protection, data security, and government regulations [8]. Zhang and other researchers proposed a privacy-based blockchain industrial IoT data security sharing model to ensure the secure sharing of resources in the industrial IoT. By using authentication techniques to protect user personal information, encrypted shared resources were stored in the off chain database of the blockchain, and blockchain logging technology was used to track and explain illegal access. Through analysis, the model had good performance [9]. Scholars such as Sachi N M developed an efficient lightweight-integrated blockchain model to solve the deficiencies of the IoT. Through the generated coverage network, well-equipped resources could be merged into a public blockchain to verify dedicated security and privacy. Finally, the model was optimized through lightweight consensus algorithms, certificate free encryption, and distributed throughput management solutions. The experimental results indicated that ELIB exhibited the highest performance under multiple evaluation parameters [10].

AES is a type of group encryption, and its variable key length makes the algorithm more flexible in application, which has been studied by many scholars. Velliangiri et al. proposed a secure multimedia big data content protection system for optimizing and maintaining big data storage. By integrating the key values of AES and SHA-256, novel key values were generated, improving the security level. After verification, this scheme only required a small storage space, had high computational efficiency, and had better performance than existing schemes [11]. To raise the encryption speed of XTS-AES, scholars such as An proposed a technology to achieve high-speed GPU encryption by modifying XTS-AES to a form that is conducive to parallel operations. By analyzing the calculation, multiple operations were replaced with a single table reference, and the parts that can be optimized were given. Then, the process that must be sequentially calculated through table reference technology was skipped for calculation. The results indicated that the method performed well [12]. Researchers such as Jin proposed using a small amount of training data to achieve efficient deep learning-based side channel analysis in response to the problem that threat models cannot collect sufficient data. They trained models with different byte median side channel leakage characteristics using multi byte synchronous training methods. The outcomes indicated that this method had good robustness, and the success rate of recovering AES keys could be raised by 250% [13]. Ueno et al. proposed an optimized encryption standard hardware architecture that supports encryption and decryption (ED), which improved hardware efficiency through multiplication offset. Based on shared key scheduling data paths, it could work in real-time in the proposed architecture. This technology performed AES encryption when block parallelism was not available and could be applied to any type of architecture [14]. The Esfahani team introduced the Evict+Reload attack based on T-table AES implementation in response to cache based attacks. In the preprocessing stage, it was used to analyze all temporal features when using known keys to execute AES. During the utilization phase, complete key bytes were obtained through traditional Evict+Reload attacks. After verification, this technology could resist cache based attacks [15].

In summary, with the continuous increase in data volume and diversification of network application scenarios, single type passwords have become inadequate in dealing with complex network security and privacy issues. Therefore, it is particularly critical to study SPS methods based on AES-SM2 hybrid encryption algorithm that are suitable for big data environments.

III. Security and Privacy Protection based on AES-SM2 Hybrid Encryption Scheme

Research conducts corresponding improvements to the AES encryption algorithm and uses programming to encrypt a small amount of data to enhance its security. For large files, an encryption library with guaranteed encryption speed is used to encrypt the randomly generated AES key using the SM2 encryption algorithm, and the encrypted ciphertext is saved on personal storage devices.

A. AES-SM2 Hybrid Encryption Scheme Design

In the times of big data, massive amounts of data come in two types: structured and unstructured. At the same time, the scale of private data is also enormous, so when encrypting it, it is necessary to balance efficiency and ease of use. Traditional data types are relatively single, requiring less data to be encrypted, stored, managed, and analyzed, and can only be achieved through relatively simple encryption mechanisms. Although traditional encryption methods can ensure high security and integrity, they cannot simultaneously satisfy the demands of efficiency and real-time [16]. However, big data has the features of being massive, diverse, fast, and low value density, making traditional encryption techniques unable to meet its encryption requirements. Currently, the encryption processing of private data in big data can usually be divided into two categories. One is to search for privacy information in the data space through data sampling, objectively reducing the size of the ciphertext, making the encryption of the ciphertext more targeted, and thereby improving the bit rate of the ciphertext [17]. However, in some applications, companies only use data sampling techniques to encrypt important data, making it difficult to prevent attackers from mining sensitive information through other information. The second is to use distributed computing, such as MapReduce, to place a large amount of private data on different machines and encrypt it in parallel, thereby greatly improving the ED speed of private data.

From a security perspective, the study uses a random method to generate initial keys, and then uses the SM2 algorithm to encrypt the randomly generated initial keys, and stores the initial keys in personal storage devices. The AES-SM2 hybrid encryption process is indicated in Fig. 1. Firstly, the file to be saved is transmitted to the hardware client via a personal computer. At this time, the data is transmitted via USB and remains in plaintext state. After completing the transmission and user selection functions, the client encrypts the received file plaintext data using the AES encryption algorithm. At this time, the hardware client randomly generates the initial key used by the AES encryption algorithm. After the encryption is completed, the file is converted from the initial plaintext state to ciphertext state and uploaded to the cloud server of the third-party cloud storage service provider selected

by the user. In the previous steps, the randomly generated key was encrypted using the National Secret SM2 encryption algorithm, and the public key used at this time was pre generated and saved on the hardware client. On this basis, using spatial information hiding technology that replaces LSB, the original key is hidden together with the user's photo for future use. In this way, the files that need to be saved will be saved on the cloud server, and the encrypted keywords will be separated from the ciphertext.

In the decryption process, it first downloads the encrypted ciphertext stored on the cloud storage server, then extracts the key to be decrypted from the private storage device. Then the private key stored on the hardware terminal is used to decrypt the SM2 algorithm, and the initial key is obtained. Then the obtained initial key is used to decrypt the data, thereby obtaining plaintext information and restoring the content of the file.

In response to the user's need to encrypt plaintext information, AES-128 with a key length of 128 bits and 10 rounds of encryption is studied for implementation. The implementation is denoted in Fig. 2. In the encryption, the plaintext block and randomly generated sub keys need to be encrypted in one round, and then encrypted through multiple rounds of encryption loops to generate an initial set of keys. The key extension function is utilized to generate 10 sub keys. This method is completed by multiple steps such as byte substitution. The column mixing conversion step does not participate in the last encryption [18].

Fig. 3 is the key extension of the AES encryption algorithm's schematic diagram. The key extension method of AES encryption algorithm is to directly extend the key, and the algorithm itself has high running efficiency. However, if the attacker only obtains the key once, they can infer that all sub keys, that is, sub keys and seed keys have some equivalence, thereby reducing the security. The fundamental reason why the AES algorithm is efficient is that it uses sub keys directly generated from the original key, and then uses the previous key for the next encryption. Generally speaking, the next sub key can be obtained from the previous one, and the previous sub key can also be inferred from the next one, ensuring that the security of the two sub keys is equivalent. The inference from front to back is the operation performed in ordinary password operations, while the inference from back to front is the action performed when password parsing is cracked. If a method that can ensure efficient reasoning while making it difficult to implement backward inference can be found, it can avoid attack methods such as energy and square.

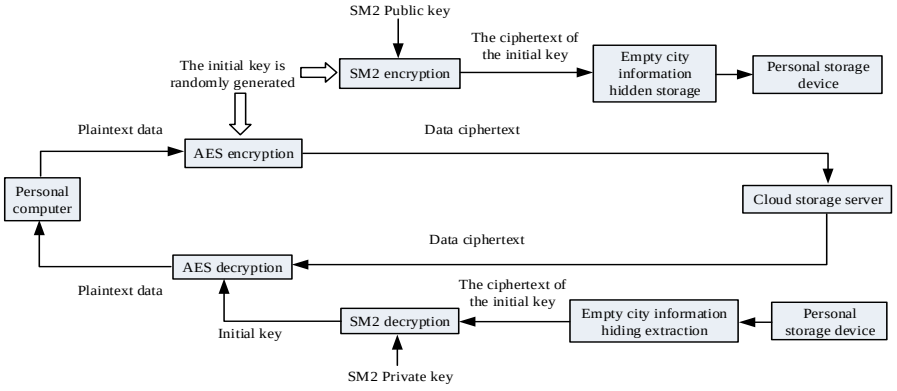

Fig. 1. AES-SM2 hybrid encryption process.

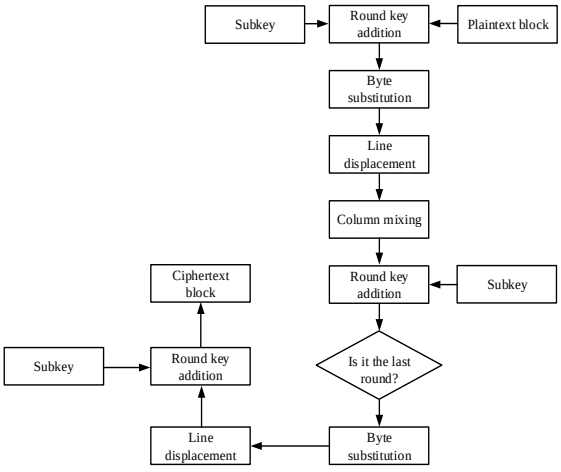

Fig. 2. AES encryption flow chart.

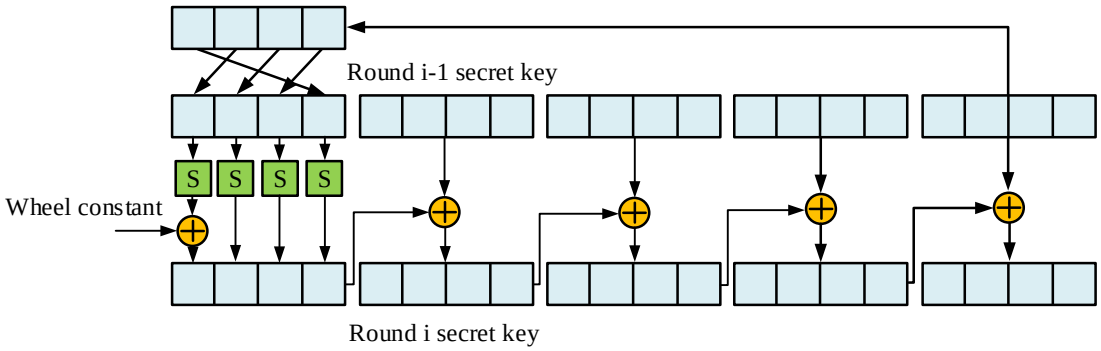

Fig. 3. Schematic diagram of AES key extension.

The round key encryption technique utilizes a mixture of sub keys and columns generated by the system. In the process of generating each round key, the system first randomly generates an initial key, and then uses the key inflation function to calculate each round key. Because both round key encryption and byte replacement transformation perform operations on the state matrix in a column manner, each row shift transformation will break the column configuration and enhance the security of encryption. The encryption operation of AES can be completed through the above steps.

B. Implementation of AES-SM2 Hybrid Encryption Algorithm

The SM2 algorithm is an asymmetric encryption technology based on asymmetric cryptography. When encrypting and decrypting plaintext, two types of keys should be used simultaneously. One is a key that can be made public to the public, and the other is a private key that the decryptor holds and cannot be made public. During data transmission, the encryptor encrypts it with the decryptor's public key, and then decrypts it using their own private key. The encryption communication model of asymmetric encryption technology is shown in Fig. 4. Compared to the AES algorithm, SM2 is more sensitive to key length. Its advantage is that even if it is deciphered, it will not disclose plaintext information [19]. The SM2 cryptosystem has greatly improved security compared to the AES algorithm, but its speed is slower.

Currently, in the big data times, there are many privacy protection methods, among which the advantages of hybrid encryption technology are very obvious. SM4 is a symmetric encryption algorithm with a key length of only 128 bits and poor flexibility. Under the same level of security, AES has faster ED speeds [20]. While meeting security requirements, higher requirements have been raised for the computation and processing of massive data. In view of this, the study combines AES and SM2 elliptic curve encryption methods to achieve big data privacy protection.

The solution of the elliptic curve algorithm mainly relies on the elliptic curve equation, while the SM2 algorithm is built on an elliptic curve over a finite field F_q. When q is an odd prime number, $q = p$, and $p > 2^{191}$ are set, the finite area F_q is called the prime field F_p. When q is a power of 2, which is $q = 2^m$, and m is a prime number larger than 192, the finite region F_q is called the binary extended region F_{2^m}. The expression for SM2 algorithm on prime field F_q is shown in Eq. (1).

$$y^2 = x^3 + ax + b \tag{1}$$

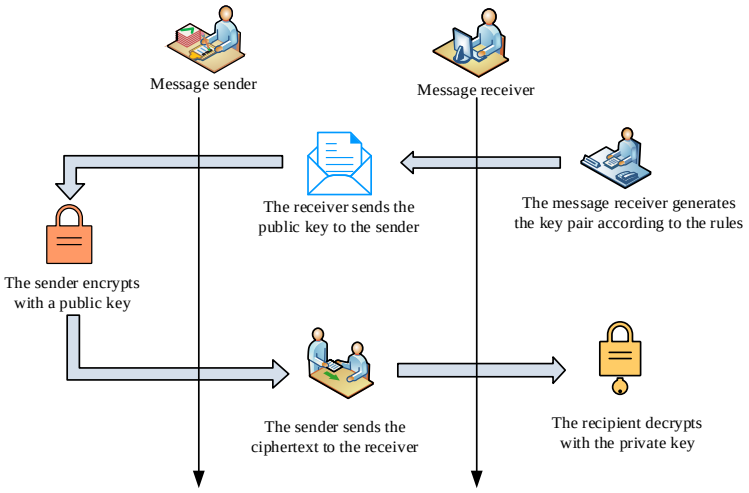

Fig. 4. Encryption communication model of asymmetric encryption technology.

In Eq. (1), $a, b \in F_p$, and a, b satisfy $\left(4a^3 + 27b^2\right) \bmod p \neq 0$. The SM2 algorithm is defined on the binary extended domain F_{2^m} using the Eq. (2).

$$y^2 + xy = x^3 + ax^2 + b \tag{2}$$

In Eq. (2), $a, b \in F_{2^m}$, and $b \neq 0$. Due to the direct relationship between the discrete logarithm problem of elliptic curves and the security of the SM2 algorithm, it is crucial to choose elliptic curves based on finite field F_q security. Assuming the values of the elliptic curve coefficients a and b are given, the unique elliptic curve equation is determined as Eq. (3).

$$y^2 = x^3 - x \tag{3}$$

Fig. 5 shows the affine coordinate graph of Eq. (3), with its base point G set. The parameters involved include the scale q of the finite field F_q and the element $a, b \in F_q$ defined in the elliptic curve $E\left(E_q\right)$. The base point $G = \left(x_G, y_G\right)\left(G \neq 0\right)$ on $E\left(E_q\right)$, where x_G and y_G are the two elements in F_q.

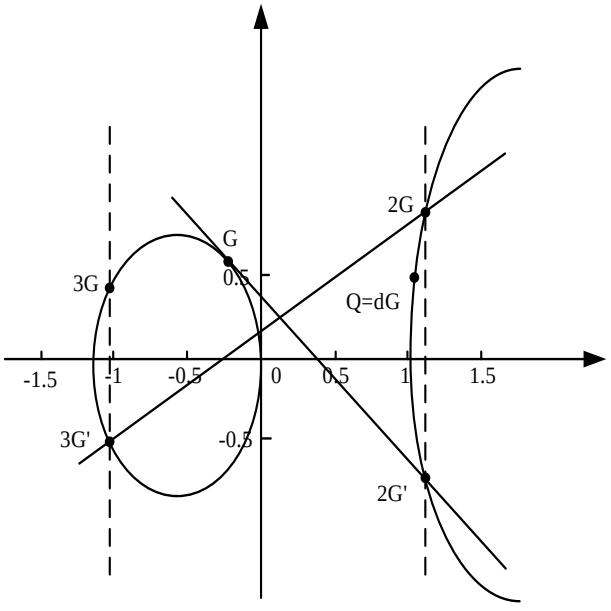

Fig. 5. Affine coordinates of elliptic curves.

An integer d is generated through a random number generator. The integer d is used as the private key, and require d to meet $d \in [1, n-2]$. The d multiplier P of G is calculated using the base point G, as shown in Eq. (4).

$$P = \left(x_p, y_p\right) = [d]G \tag{4}$$

The key pair (d, P) is obtained, where d serves as the algorithm's private key and P serves as the algorithm's public key. Then the point C_1 on the elliptic curve is calculated, as shown in Eq. (5).

$$C_1 = kG = \left(x_1, y_1\right) \tag{5}$$

In Eq. (5), k is a random number, and kG is a multiplication operation. When using elliptic curves for encryption, the main operation is to perform double point operations on the elliptic curve. The point kP_B of the elliptic curve is calculated, as shown in Eq. (6).

$$kP_B = \left(x_2, y_2\right) \tag{6}$$

In Eq. (6), P_B is the public key of user B. And it converts the data types of the horizontal and vertical coordinates x_2 and y_2 into bit strings. When generating the key pair, first is to utilize a random number generator to generate the integer $d \in [1, n-2]$, and calculate Eq. (7).

$$P_B = \left(x_p, y_p\right) = [d]G \tag{7}$$

Because this design uses the SM2 encryption algorithm to encrypt and decrypt the initial key of AES, it is inconvenient for users to generate too many public and private keys for the SM2 algorithm. The study first randomly generates a set of key pairs, and then sets them as a fixed key pair in the subsequent ED process, and stores them on the hardware client for user management and use, as shown in Eq. (8).

$$t = KDF\left(x_2 \| y_2, Mlen\right) \tag{8}$$

In Eq. (8), $Mlen$ is the length of the plaintext bit to be encrypted, $KDF(\ )$ is the key derivation function required for encryption, and the use of the key derivation function is to derive the required key data from the shared secret bit string. The hash algorithm uses the SM3 algorithm. XOR is performed on the corresponding bytes of t and M during the calculation of the intermediate variable t, as shown in Eq. (9).

$$C_2 = M \oplus t \tag{9}$$

In Eq. (9), M represents encrypted plaintext data. The ciphertext is calculated using Eq. (10) again.

$$C_3 = Hash\left(x_2 \| M \| y_2\right) \tag{10}$$

In Eq. (10), $Hash(\ )$ is the password hash function. Finally, the ciphertext is output as shown in Eq. (11).

$$C = C_1 \| C_2 \| C_3 \tag{11}$$

When decrypting the SM2 algorithm, the plaintext C_1 is first extracted from the ciphertext C. And type conversion is performed, then C_2 is extracted and calculated in Eq. (12).

$$dC_1 = (x_2, y_2) \tag{12}$$

Then the data types of the horizontal and vertical coordinates are converted into bit strings, as shown in Eq. (13).

$$t = KDF(x_2 \| y_2, Klen) \tag{13}$$

If the key data bit string t is all 0, it should stop decryption and report an error. It separates the ciphertext C_2 corresponding to the plaintext in the ciphertext information C and decrypts it into plaintext, as shown in Eq. (14).

$$M_1 = C_2 \oplus t \tag{14}$$

In Eq. (14), M_1 is the decrypted message obtained. The hash value of the decrypted plaintext M_1 is calculated using Eq. (14).

$$u = Hash(x_2 \| M_1 \| y_2) \tag{15}$$

Finally, it extracts the C_3 bit string from C and compares it with u to see if it is consistent. If there is any inconsistency between u and C_3, an error will be reported and exit. Finally, plaintext M_1 is output.

Performance Testing of Privacy Protection Algorithms based on Hybrid Encryption

Research was conducted to test the ED speed, signature and verification speed, and memory usage of encryption algorithms. The symmetric encryption algorithm and hash algorithm were compared through multiple tests on the same number of blocks as well as different numbers of blocks, while the signature and verification signature speeds of asymmetric encryption algorithms were compared using block sizes that are equivalent in security.

C. Comparison of ED Time between AES Algorithm and SM2 Algorithm

Based on Windows and Ubuntu, two development tools, VS Code and PyCharm, were adopted. It was developed using front-end and back-end separation under the B/S architecture. The advantage of this approach was that both the front-end and back-end could be independently repaired, reducing system maintenance costs, improving local performance, and reducing backend pressure. Table I shows Algorithm test environment.

TABLE I. ALGORITHM TEST ENVIRONMENT

Hardware/Software	Version/Model
CPU	Intel Core i7-4720HQ
Memory capacity	16G
Operating system	Windows 10 64bit、Ubuntu
IDE	VS Code 、 PyCharm Professional Ed
Blockchain project	Hyperledger Fabri
Front-end development framework	Vue.js v3.0.5+Eleme
Back-end development framework	Flask v1.1.4

The study compared the scalability and obfuscation performance of AES based on 128bit plaintext, and conducted 10 experiments. The outcomes are indicated in Fig. 6. From Fig. 6 (a), by changing one plaintext, the diffusion range of the improved AES was 63 ± 6, while the diffusion range of the conventional AES algorithm was 64 ± 5. From Fig. 6 (b), by changing one key, the confusion range of the improved AES algorithm was 62 ± 6, while the confusion range of the traditional AES algorithm was 63 ± 7. From this, this method had better security without affecting the original scalability and obfuscation of AES.

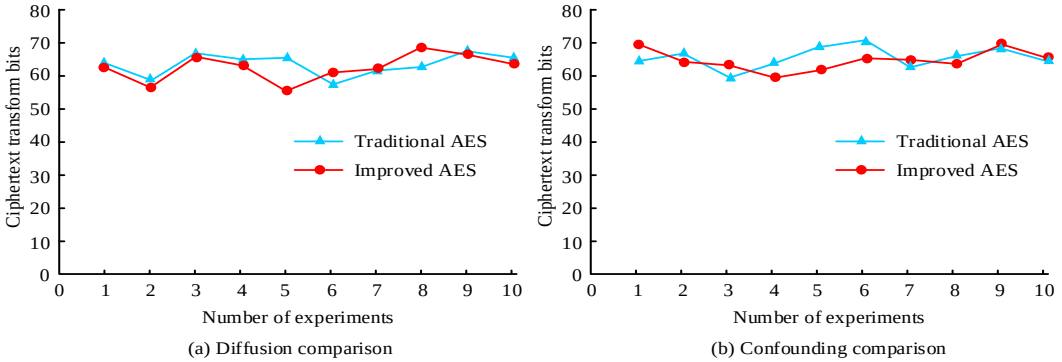

Fig. 6. Diffusion and confounding of traditional and improved AES algorithms confusion comparison.

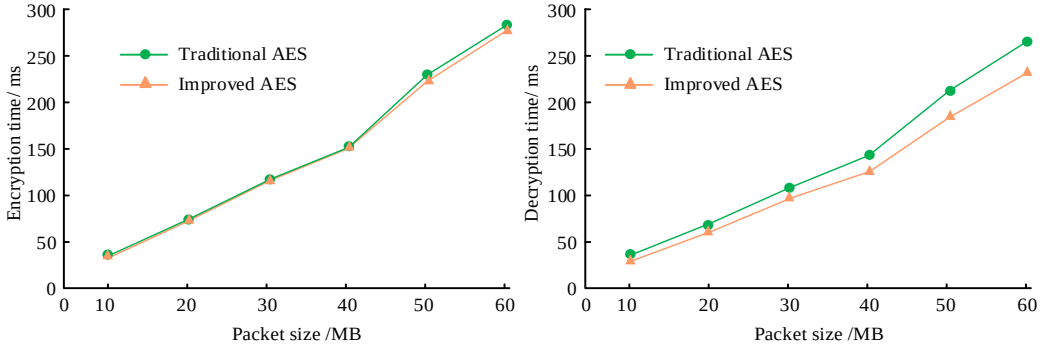
The study also tested the ED time of the AES algorithm. Due to its fast computation and decryption speed, its ED speed was set to around 60MB. The test findings are denoted in Fig. 7. Fig. 7 (a) showcases a comparison of encryption time. From

the figure, the improved AES was basically the same as the traditional AES in terms of encryption time. This is because of the fact that the computational complexity of the AES algorithm does not change during column mixing, and it still involves two multiplication operations and four XOR operations. So, using a double symmetric key could enhance the security of passwords without reducing AES encryption speed. Fig. 7 (b) shows a comparison of encryption time. From the figure, compared to before the improvement, the improved AES encryption time was significantly reduced. Due to the use of the optimal column mixing operation, the computational complexity of the inverse column mixing operation during decryption could be greatly reduced. Therefore, the improved AES algorithm not only enhanced key security, but also enhanced decryption speed.



(a) Encryption time (b) Decryption time

Fig. 7. Comparison of encryption and decryption time of AES algorithm

Performance testing was conducted on SM2, as it was only used for ED of symmetric keys, the data that needs to be encrypted was very small, and a plaintext data length of 128 bits was used as the length of the plaintext data. Table II compared the encryption speeds of SM2 and RSA algorithms under the same security conditions. From the table, under the same security, the encryption time of RSA algorithm was 16.50 milliseconds higher than the encryption speed of SM2. Among them, the RSA algorithm with a length of 3072 bits took about 1204 milliseconds to generate a key pair, while the 256 bit key pair of SM2 took about 360 milliseconds to generate. The RSA algorithm had a higher key generation speed and storage space than SM2. So, overall, it was reasonable to use the SM2 algorithm to encrypt symmetric keys.

TABLE II. COMPARISON OF SM2 ENCRYPTION TIME WITH RSA ENCRYPTION TIME

Class number	SM2	RSA
First group /ms	32.6	14.2
The second group /ms	33.8	13.3
The third group /ms	34.1	15.6
The fourth group /ms	33.5	16.5
The fifth group /ms	33.2	15.1
Average time /ms	33.44	14.94

D. Performance Testing of Hybrid Encryption Algorithms

The study selected blocks of 16, 64, 256, 1024, 8192, 16384 for experiments and compared the differences in memory usage size among these algorithms. The size of memory usage was determined by two factors: average memory size and runtime. The experiment outcomes are denoted in Fig. 8. In the respect of memory utilization, SM4 and AES had similar storage space, while 3DES was larger than other methods. So, in the encryption module, SM4 or AES-128 was chosen as the symmetric encryption algorithm.

The study tested the ED time of SM2 and improved AES, and also compared SM2+AES and RSA+AES. The experiment outcomes are denoted in Fig. 9. From Fig. 9 (a), the RSA+AES algorithm was relatively fast in encryption time, while the SM2+AES algorithm and SM2+AES algorithm had little difference in encryption time. Due to the fact that the key pair generation speed in RSA algorithm is much lower than SM2, and the storage space required by RSA algorithm is also much larger than SM2, RSA+AES did not have significant advantages compared to the other two methods. Compared with the SM2+AES algorithm, the SM2+AES algorithm used a double symmetric key to enhance the security of the key without reducing the encryption speed. From Fig. 9 (b), the decryption speed of the SM2+improved AES scheme was the fastest, followed by the RSA+AES scheme, and finally the SM2+AES scheme. Therefore, the improvement of the AES algorithm was effective. In summary, the hybrid cryptosystem proposed by the research institute had significantly improved security, ED speed, and other aspects.

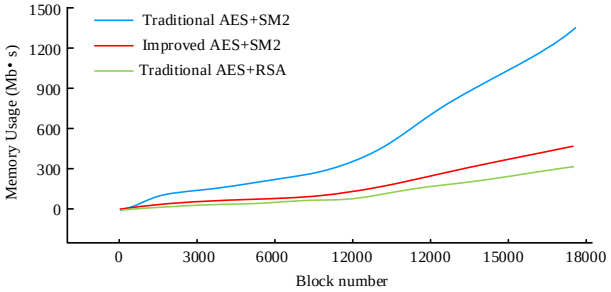


Fig. 8. Memory usage comparison.

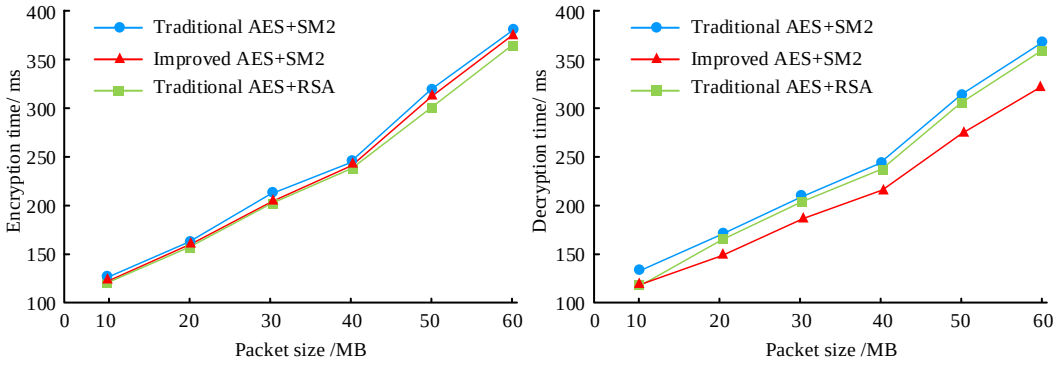

(a) Encryption time (b) Decryption time

Fig. 9. Comparison of encryption and decryption time of hybrid algorithms.

The study tested the throughput of the system within 100 minutes, and the results are shown in Fig. 10. When the overall number of transactions was small, the throughput of the system was only slightly higher than that of the Bitcoin system. When the number of transactions tended to stabilize, the throughput of the system would fluctuate according to probability, about twice that of the Bitcoin system. At the same time, when there was a high demand for practical applications, methods such as reducing sampling values or mining difficulty could be used to improve the average processing speed of the system, but it would also weaken the constraints on high computing nodes. Overall, the system placed greater emphasis on data security and confidentiality, and in terms of performance, it could basically meet practical needs.

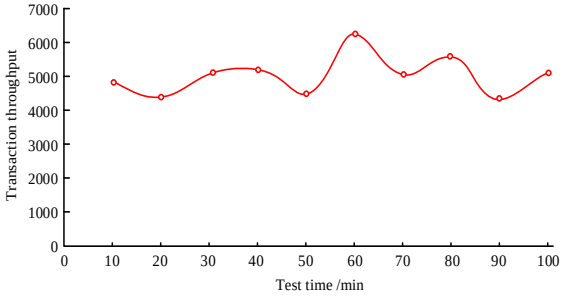

Fig. 10. System throughput.

IV. Conclusion

To guarantee the security and privacy of big data in cloud computing, encryption technology can be applied to ensure the accuracy and confidentiality of data in the cloud. This study focused on the privacy and security issues of big data transmission and storage in the cloud environment, deeply analyzed the merits and demerits of various existing encryption methods. An encryption method that combines an asymmetric encryption algorithm was designed based on the national secret SM2 with an improved AES encryption algorithm. While ensuring the security of big data in the cloud environment, the ED speed was accelerated to ensure the security of data. The outcomes indicated that the diffusion range of the improved AES was 63 ± 6, while the diffusion range of the conventional AES algorithm was 64 ± 5. This method had better security without affecting the original scalability and obfuscation of AES. When the AES algorithm performed column mixing, its computational complexity did not change, and it still performed two multiplication operations and four XOR operations. The encryption time of the RSA algorithm was 16.50ms higher than that of SM2. The AES scheme improved by SM2+ had the fastest decryption speed, followed by the RSA+AES scheme, and finally the SM2+AES scheme. Therefore, the improvement of the AES algorithm was effective. In summary, the hybrid cryptosystem proposed by the research institute has significantly improved security, ED speed, and other aspects. The method proposed by the research institute is only to ensure the transmission of privacy information in the cloud environment. Saving privacy information in ciphertext to the cloud is, in a sense, a security guarantee, but there are also potential risks. Next, it can fully leverage the advantages of cloud computing by combining public and private clouds to ensure the storage security of user privacy data.

***Abstract*—In prosthetics, bionic hand movement recognition is crucial to developing sophisticated systems that can effectively understand and react to human motions. Recent advances in image processing, feature extraction, and deep learning have improved bionic hand movement detection systems' accuracy and flexibility. This study proposes a unified framework called using attention-guided ROI detection and a unique Bionic Fusion-Net architecture to overcome these difficulties which contributes towards Sustainable Development Goal (SDG) Good Health and Well Being. Initially pre-processing undergoes dataset augmentation and image enhancement. The ROI Identification approach uses an attention-guided U-Net with sophisticated convolutional components. Spatial Features, BionicNet-1, and BionicNet-2 learn spatial and temporal features together during feature extraction. Optimized Red Fox Falcon Algorithm (O-RFF) which is a hybrid of Red Fox and Falcon Optimization Algorithms improves the feature selection. The Bionic Fusion-Net Architecture combines Xception, Squeeze-Net, Shuffle-Net, optimized Bi-LSTM, and Huber Loss function application. The recommended technique improves bionic hand movement recognition flexibility that attained an accuracy of about 99% which outperformed other approaches in use for well-being and future health policy.**

Keywords*—Bionic Hand; Optimized Red Fox Falcon Algorithm; Xception; Squeeze-Net; Shuffle-Net; Bi-LSTM; Huber Loss; Sustainable Development Goals (SDG); good health; well-being; health policy

I. Introduction

The human hand is composed of three essential bone groups—phalanges, metacarpals, and carpals—which together contribute to the hand's dexterity and usefulness. The engineering of a 3D hand model seeks to accurately reproduce the complex anatomy of the hand. This is achieved by specifically addressing the distal, middle, and proximal phalanges, and combining the metacarpal and carpal bones into a cohesive unit to enhance overall functioning [1]. This engineering is significant because to its potential application in prosthetics, namely in the evolution of bionic hands. People who have physical impairments, strokes, or damage to their nervous system frequently struggle with a decrease in their capacity to use their hands normally. This affects their ability to adapt to complicated situations and makes it difficult for them to do everyday chores. Prosthetic devices are becoming a viable way to tackle these issues. However, existing choices are often limited in terms of flexibility and the range of gestures they can do. There is a need for increasingly sophisticated prosthetic technology in order to accurately replicate the subtle motions of the human hand. The identification of motions in a bionic hand plays a crucial role in connecting human intention with the reaction of an artificial limb [2, 11]. The control system and interface of the prosthetic hand should be simple and user-friendly [8]. The firms engaged in the development of bionic prostheses are primarily focused on two specific areas of advancement. These prostheses are more affordable. Enhancing the functionality of the prosthesis control system [14]. There are two main sensor control methods. One uses stretch sensor to imitate the motions of a human hand, while the other uses machine learning (AI) and a camera for more advanced control. Electromyography (EMG) pattern recognition algorithms are fundamental for categorizing and regulating hand motions [3].

Surface electromyogram (sEMG) is a method used to gather electrical impulses produced by muscles [12, 13]. It has potential in the field of bionics and is being used in wearable devices for medical and healthcare reasons. Myoelectric pattern-recognition algorithms [10] based on EMG data, aid in the identification of finger motion intents, which is essential for commanding prosthetic robots that imitate known intentions [4, 7, 9]. Hand gesture pattern recognition algorithms may be divided into two categories: traditional approaches and deep learning techniques. These algorithms aim to tackle issues associated with identifying hand poses and trajectories, as well as performing regression of continuous parameters [5]. Robotics, namely in the realm of bionic limbs, is crucial in both engineering and medical fields. It provides mechanically and electrically driven alternatives to replace missing limbs in individuals who have had amputation [6].

The creation of bionic hands is an important achievement, considering the nearly 1.7 million individuals in the United States who have experienced limb loss. The control system and interface of prosthetic hands should be designed to be simple and intuitive, in order to provide broad accessibility and usage. The extensive motion planning algorithms are necessary to provide stable and dexterous grasp control of five-finger bionic

hands, which are characterized by a high number of Degrees of Freedom (DoFs) [8]. Machine learning algorithms play a crucial role in hand gesture detection as corporations prioritize the development of cost-effective prostheses and advancements in control systems. Time and frequency characteristics, which are used as inputs for algorithms like Artificial Neural Networks (ANN), Support Vector Machines (SVM), and k-Nearest Neighbor (k-NN), play a role in classifying hand gestures [15]. The main contribution of this paper is as follows:

- Initially the dataset augmentation and Image enhancement is done.
- ROI are identified by employing a novel apparoch calledAttention guided U-Net with atrous convolution.
- The spatial and temporal features are extracted and the features are selection by employing a novel hybrid approach called Optimized Red Fox Falcon Algorithm (O-RFF).
- Finally, Bionic Fusion-Net Architecture is developed which is a combination of Xception, Squeeze-Net, Shuffle-Net and optimized Bi-LSTM and Huber loss function for the classification.

The remaining section is provided below. Section II discusses the relevant papers, Section III describes the suggested methodology, Section IV shows the results and discussions and finally, Section V concludes the paper.

II. Related Works

Hui Li et al. [16] discussed about the development of human-computer interaction and the use of different devices such as Leap Motion, Gloveone, and Lingzhi. These devices allow users to control computers and perform various operations using gestures. The text highlights the accuracy and speed of the bionic manipulator in accurately interpreting instructions and enabling human-computer interaction in different situations.

Sapto Budi Priyatno et al. [17] provided motor imagery brain wave categorization research for bionic hand control. It created a bionic hand control system using EEG sensors to assess brain bioelectric activity. Alpha and beta waves, associated to motor imagery, are extracted and classified in the research. Features are extracted using the Fast Fourier Transform (FFT) approach and categorized using the Multilayer Perceptron (MLP) method for five bionic hand movement classes. Tests show system accuracy of 77.20% and 84.40% for two situations. The research shows that motor imagery can operate a bionic hand.

Binish Fatimah et al. [18] proposed a Surface Electromyogram (sEMG)-based hand movement recognition method. Entropy and kurtosis are calculated for each Fourier intrinsic band function (FIBF) after the Fourier decomposition method (FDM) decomposes the signals. Train machine learning classifiers using statistically significant features. On two publicly accessible datasets, the suggested technique outperforms current algorithms in accuracy of 93.53% on NinaPro DB5 and 99.49% on the UCI dataset. Its Fourier theory foundation makes it appropriate for real-time implementation with minimal processing cost. The program might help develop efficient and user-friendly prosthetic hands.

Sehyeon Kim et al. [19] suggested a multimodal fusion system for transforearm amputee hand movement detection. The method improves motion categorization by combining EEG and EMG inputs. Use a transfer learning paradigm and convolutional neural network technique to train a model from 2D EEG and EMG input pictures. Comparing the proposed approach to single-model EEG signal trained models demonstrates considerable classification accuracy increase. The research involves five transforearm amputees and nine healthy controls. Both groups show that multimodal fusion works for motion categorization. This method may improve amputee prosthetic arm control.

Shudi Wang et al. [20] emphasized the necessity of building a dexterous hand control system to assist forearm disabled people regain limb functionality. The use of EMG signals for hand control gesture recognition is investigated. Deep learning may improve identification accuracy compared to traditional machine learning. An attention module is added to a multi-stream fusion network using CNNs and GRUs to improve feature extraction. Accuracy is also improved by adding acceleration signals. This strategy may help hand-disabled people in everyday life, according to the paper.

Yang et al. [21] introduced an approach called MResLSTM, which is a multi-stream network that merges the residual model with variant ConvLSTM model to accurately identify and analyse dynamic hand movements. The network attains cutting-edge outcomes and enhances the precision of behavioural action detection. sEMG signals and accelerometer (ACC) signals are gathered to create datasets including various dynamic motions. The research finishes by emphasizing the benefits of deep learning in surpassing the constraints of feature engineering and enhancing the precision of EMG signal detection.

Ricardo. V. Godoy et al. [22] explored the use of EMG based interfaces for the purpose of controlling robotic and bionic systems and suggested using a technique using Temporal Multi-Channel Vision Transformers, a deep learning methodology, to extract intricate characteristics from unprocessed EMG data. The efficacy of this approach is evaluated by comparing its performance with that of other approaches, using the Ninapro dataset. It emphasized the capacity of EMG-based interfaces to attain skilful manipulation of robots and bionic hands.

Dianchun bai et al. [23] investigated a human-computer interaction gesture recognition using sEMG. A multichannel sEMG amplification unit-based feature model creation and optimization approach are employed. A multistate muscle action recognition feature model using CNN and LSTM is produced. The testing findings reveal that this 1 MB model can recognize 91.40% of complicated movements. The CNN+LSTM hybrid framework predicts complicated hand motions better than standard machine learning approaches.

Contemporary studies on the control of bionic hands and the connection between humans and computers demonstrate progress, yet obstacles remain. Research investigates the precision of understanding gestures, the dependability and verification of hand movement detection based on sEMG across various situations. The concerns revolve on the capacity of the suggested systems to handle large-scale operations and be user-friendly, as well as the adaptability of deep learning methods to

different hand movements and human characteristics. To advance the practical usefulness of bionic hand control systems in real-world applications, it is crucial to tackle these obstacles.

III. PROPOSED SYSTEM

Initially, the pre-processing step called dataset augmentation is done by means of rotation, flipping, and scaling and the quality of the augmented image are enhanced using median filtering and Histogram equalization. ROI Identification is done by Attention guided U-Net with atrous convolution followed by that the spatial and temporal features are extracted using Bionic Net-1 and Bionic Net-2. The features are selected by using the novel hybrid algorithm called Optimized Red Fox Falcon Algorithm (O-RFF). Finally, the Bionic Fusion-Net Architecture combines Xception, Squeeze-Net, Shuffle-Net, optimized Bi-LSTM and Huber Loss functions employed for classification. Fig. 1 depicts the recommended methodology.

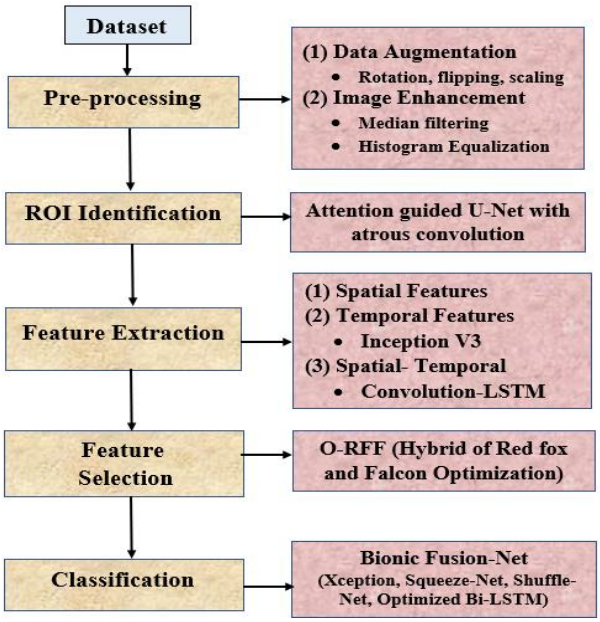

Fig. 1. Recommended methodology.

A. Pre-processing

It is the initial process involved in the model which is a crucial step in converting the unprocessed information into the best format. The data are pre-processed by Data augmentation and image Enhancement.

1) Data augmentation: Despite the quantity of data, finding correct information that matches for our research is difficult. To improve model performance, data must be diverse in measurements, positions, shades, and illumination. To address the limitation of a finite dataset, we employ data augmentation techniques. The data are augmented by the following parameters.

a) Rotation: Image rotation may be done at 90-degree angles or more angles, depending on needs. No background noise is added when an image is rotated 90 degrees. In contrast, rotation at minute angles may cause noise. For black or white backgrounds, the noise may mix, but for various colours, the network treats the noise as a distinguishing feature during learning.

b) Scaling: For the majority of time series data, if we introduce a little alteration to the data in each individual sample, it is probable that the sample will still be assigned the same label as before. Scaling refers to the process of altering the size of the source data by multiplying the sample data by a random scalar. Contrary to the AddNoise approach, Scaling involves the addition of uniform noise to all samples simultaneously, whereas AddNoise introduces distinct noise to each sample. The source data is typically scaled using a normal distribution function with a mean (μ) of 1 and a variance (σ2) of 0.1.

c) Flipping: The images may be flipped either horizontally (HF) or vertically (VF). It generates pictures by rotating the image in increments of 90° degrees. Some frameworks do not have the capability to do VF. To achieve VF, one may rotate the picture by 180° and then apply a HF.

2) Image Enhancement (IE): Enhancement refers to the manipulation of a data to improve its visual quality or adapt it to a certain objective. The following two approaches are used for the purpose of IE which are detailed below.

a) Median filtering (Me-F): Noise cancellation is often achieved using a nonlinear technique called Me-F. The information from both neighbourhoods is selected for sorting based on the window length selected, and each data point to be processed is filtered before the value of the middle size is determined. Enhancing the outcomes of further analysis—such as edge identification on an image, for example—is a routine procedure. Compared to linear filters, it offers a significant advantage in that it completely eliminates the impact of extremely high magnitude input noise levels. They are used as smoothers to eliminate noise from salt and pepper. The Me-F's output y is

$$z(t) = \text{median}\left(y\left(t - {}^{T}/_{2}\right), .., y(t), .., y\left(t + {}^{T}/_{2}\right)\right) \quad (1)$$

where t refers Window size of Me-F

b) Histogram equalization: Image contrast is determined by dynamic range, the ratio of brightest to darkest pixel intensities. Enhancing low-contrast images with contrast enhancement techniques has several uses. Histogram equalization (HE) is a popular approach. The probability distribution of input grey levels is used to map grey levels. Considering image I, the probability density function $P(I_x)$ is given as,

$$P(I_x) = \frac{n_x}{n} \quad (2)$$

Where $x = 0,1,.,L-1$, n_x is the number of times $t$he level $I_x$in input, n represents the overall samples.

The Cumulative Density Function (CDF) is defined as,

$$c(i) = \sum_{j=0}^{x} P(I_j) \quad (3)$$

Where $I_x = i$ for $x = 0,1,.,L-1$, $c(I_{L-1}) = 1$ (constant). The transform function $f(i)$based on CDF is stated as,

$$f(i) = I_0 + (I_{L-1} - I_0)c(i) \quad (4)$$

Output of HE, $S = \{S(q,r)\}$ is given as,

$$S = f(I)=\{f(I(k,j)|\forall I(k,j) \in I\} \quad (5)$$

The high performance of the HE in enhancing the contrast of an image because of the dynamic range expansion.

B. ROI Identification

The quality of the data has a significant impact on how well the model's function. A precise localization of the ROI is vital to avoid biased learning and subpar model performance caused by irrelevant features. Attention guided U-Net with atrous convolution is employed for the ROI Identification.

The U-Net design uses the encoder-decoder structure including compression and expansion path. It consists of three primary components: the left (down-sampling) segment, the center (copy and crop) segment, and the right (up-sampling) segment. During the first stage, the left portion performs four down-sampling procedures to decrease picture size, while extracting characteristics from superficial data. The primary component is performing four concatenation procedures, smoothly merging profound and superficial information to augment feature representation. During the up-sampling step, four processes are performed to retrieve detailed information from the expanded picture. Significantly, the up-sampling procedure entails reducing the number of channels in the picture by half, in contrast to the feature extraction in the left section. During the process of up-sampling, the shallow information on the left is combined and the features are joined together. By include skip connections within the same stage, it guarantees that the reconstructed feature map encompasses a wide range of low-level characteristics and features of different scales. This method enables the prediction of many scales and incorporates deep supervision to enhance the accuracy of segmentation maps by improving details such as edge recovery. The incorporation of a Hybrid Atrous Convolution block, a modified version of a residual block, and a Redesigned skip connection strengthens the U-Net architecture, leading to enhanced performance without any loss of information. Fig. 2 shows the attention guided U-Net with atrous convolution.

1) Hybrid atrous convolution block: The Hybrid Atrous Convolution block utilizes the well-recognized attribute of atrous convolution to greatly increase the receptive field. By using a 3×3 convolution kernel, the combination of 1-dilated and 2-dilated convolutions replicates the effects of a 7×7 convolution kernel. By combining 4-dilated convolution with 1-dilated and 2-dilated convolutions, the resulting receptive field is comparable to that of a 15×15 convolution kernel. This method results in a rapid and significant increase in the receptive field as compared to conventional convolution processes. However, using just stacked convolutions with the same dilation rate creates a discontinuity in the kernel, where not all pixels are included in the computations. The fragmented technique leads to a checkerboard pattern, which undermines continuity and becomes less efficient for little things. The Hybrid Atrous Convolution block is offered as a solution to this problem. It combines several dilation rates to improve the continuity of information and boost performance, particularly when dealing with tiny objects.

$$M_i = \max[M_{i+1} - 2r_i, M_{i+1} - 2(M_{i+1} - r_i), r_i] \quad (6)$$

Where M_i maximum dilation rate at layer i, r_i is the dilation rate of the i^{th}layer.

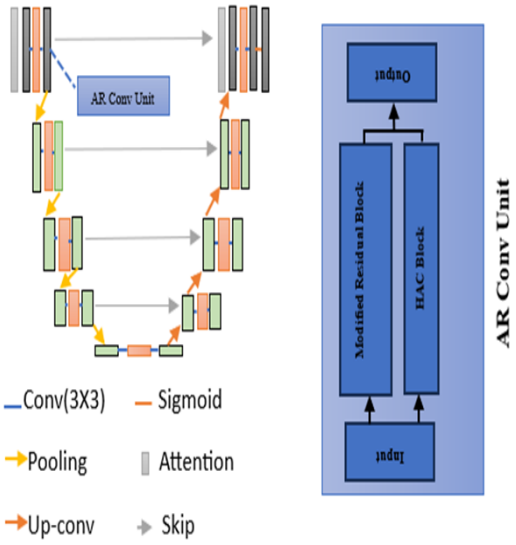

Fig. 2. Attention guided U-Net with atrous convolution.

2) Modified residual block: To improve the performance of the network, a squeeze-and-excitation block has been added to ResNet, which demonstrates variations from the original residual network as seen in Fig. 2. The Squeeze operation, shown by the red box in Fig. 2, is crucial in modifying the spatial dimensions of every input feature map from H×W to a condensed 1×1 format. This conversion is accomplished by means of global average pooling. During the Squeeze process, there is a compression of spatial dimensions, which results in the conversion of each two-dimensional feature channel into a single real number that encompasses the whole field of perception. The output dimension corresponds to the number of feature channels in the input. This technique captures the worldwide dispersion of responses on the characteristic channel, giving the layer near the input a thorough global receptive field. This adjustment is very helpful in a wide range of jobs, enhancing the capabilities of the network.

$$z_c = F_{sq}(u_c) = \frac{1}{H \times W} \sum_{i=1}^{H} \sum_{j=1}^{W} u_c(i,j) \quad (7)$$

z_c represents the channel descriptor for channel c , F_{sq} indicates the represents global average pooling, u_c represents channel c of the input, H, W represent the height and width of the input

In the excitation phase (highlighted in the green box in Fig. 2, the feature dimension undergoes reduction to 1/r of the input. Subsequently, it is elevated back to the original dimension through a fully connected layer following ReLU activation. This approach, characterized by increased nonlinearity, proves

superior in capturing complex correlations between channels compared to the direct utilization of a fully connected layer. Notably, this method significantly diminishes the number of parameters and computational load, offering a more efficient and streamlined computational process.

3) Attention module: The U-Net includes an attention module to estimate the most likely area. This uses a circular bounding box to approximate area coordinates. The feature layer section of the network has an attention module underneath the fully connected layer. The circular bounding box coordinates are acquired by this attention module. Left vertex (x1, y1), right vertex (x2, y2) defines the circular area. Therefore, the attention module's regression component creates an array (x1, y1, x2, y2). The regression results are used to create the loss function, optimizing and training the network. This integration helps the U-Net concentrate and improve its prediction for the area of interest, enhancing task performance.

4) Redesigned skip connection: To use the unique attributes of each level inside the network, a modification to the skip connection has been executed. In contrast to the traditional dense connections that establish connections between every node in the encoder and decoder via intermediary connections, this novel strategy specifically retains skip connections alone between the decoder and each node. The original design's extensive connections led to a large number of model parameters and increased computing complexity. This skip connection, which has been simplified and revamped, successfully decreases the parameter count while retaining all relevant information. This ultimately leads in enhanced segmentation outcomes. This achieves a compromise between computational efficiency and the preservation of crucial information, resulting in a segmentation conclusion that is both more effective and efficient.

$$x^{i,j} = \begin{cases} H(x^{i-1,j}), j = 0 \\ H([x^{i,j-1}, u(x^{i+1,j-1})]), j < 4 - i \\ H\left(\left[[x^{i,k}]_{k=0}^{j-1}, u(x^{i+1,j-1})\right]\right), j = 4 - i \end{cases} \quad (8)$$

C. Feature Extraction

It transforms the preprocessed data into features which is used to categorize the data. The multi-features like spatial and temporal features are extracted using the various approached which are provided below.

1) Spatial features: They include the characteristics of data that relate to the spatial organization or configuration of objects or components within a certain area. These traits are crucial for activities that require comprehension of the geometric connections, locations, and structures of things. Dynamic Filters are used to extract the characteristics. Dynamic filters in CNNs are adjustable or modifiable dependent on the input data, and are used to identify patterns and characteristics. They modify their weights and configurations in order to effectively record changing spatial attributes in real-time. Joint positions refer to the precise locations or coordinates of the joints within a given system. Angles are the quantitative representation of the inclination or relative orientation of lines or surfaces. This encompasses the comparative distances, dimensions, configurations, and characteristics as well.

2) Temporal features: The dependencies delineate the exact timing relations between several components of the motion, governing the seamless progression and precision of the activity. In this Inception V3 is employed for extracting the temporal features.

The selection of InceptionV3, one of the Google Inception Nets, was based on its high accuracy and adaptability. The module's design includes two convolutional layers with a patch size of 3x3 and two unique strides. In order to enhance processing efficiency after the convolutional layers, the Inception model underwent modification by dividing the 5 × 5 layers into several 3 × 3 layers and ReLu levels. The max-pooling methodology is used to extract critical features, namely edges. The average pooling method is used to progressively extract features. Classification is then performed using the SoftMax function in the fully connected layer. The activation function is defined as,

$$j(k) = \frac{1}{1+e^{-k}} \quad (9)$$

The ReLu activation function may be defined as follows:

$$j(k) = \begin{cases} 0; k \leq 0 \\ 1; k > 0 \end{cases} \quad (10)$$

Including one or many pooling layers in the feature maps generated by convolutional layers helps to mitigate computational challenges. To do this, the size of the CL's maps was reduced. The two dominant techniques are average pooling and maximal pooling.

3) Integration of spatial and temporal features: A model called Convolutional-LSTM is employed to integrate the spatial and temporal features. Convolutional Neural Networks (CNNs) include many filter stages and one classification step. In sequence learning, Recurrent Neural Networks (RNNs) are popular. Their efficiency may be limited by the vanishing gradient issue during training backpropagation. Long Short-Term Memory (LSTM) architecture improves data feature long-term dependency. This patch mitigates the vanishing gradient problem, improving the RNN's sequential data handling and long-term pattern learning and retention. Fig. 3 shows the Conv-LSTM.

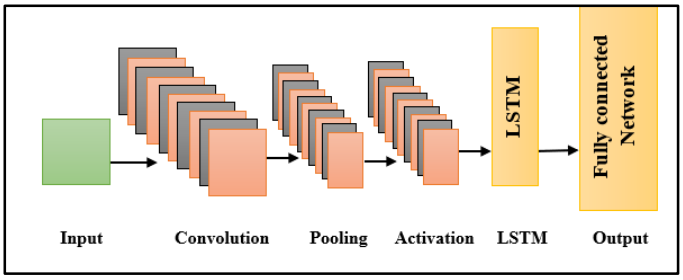

Fig. 3. Conv-LSTM.

a) Input layer: The first layer in CNN is the 'input layer'. Its purpose is to receive data and resize them before forwarding them to subsequent layers for the extraction of features.

b) Convolution layer (conv): This function as image filters. These layers are responsible for identifying features inside images and are also used for determining the matching feature points during testing.

c) Pooling Layer (PL): The feature sets obtained are then sent to the PL. This layer resizes huge photos by reducing their dimensions while retaining the crucial details. It retains the highest value from each window and maintains the most accurate matches of each characteristic inside the window.

d) Activation layer: The inclusion of an activation function layer is crucial in every convolutional block. The network enables a non-linear expression of the input signal, hence improving the representation and increasing the distinguishability of the learnt characteristics. Several activation functions may be used, including ReLU, Identity, Tanh, and Sigmoid, which are often employed.

e) LSTM layer: The purpose of the LSTM is to address the issue of long-term reliance by including the forget gate, which controls the use of information in the cell state.

f)Fully connected Layer (FCL): The final is the FCL which receives the high-level filtered images and converts them into categories with corresponding labels.

D. Feature Selection

The process of choosing a subset of pertinent features from the initial set of features is known as feature selection. Simplifying the model, lowering the complexity of the feature space, and enhancing generalisation performance are the objectives. Utilising the Optimized Red Fox Falcon Algorithm (O-RFF) which is a hybrid of Red Fox and Falcon Optimization Algorithms the features are chosen.

The Red Fox population consists of individuals displaying various habits, with some occupying well defined territories and others adopting a wandering existence. Every territorial group is organized with an alpha pair at the top of the hierarchy. Once the young foxes reach adulthood, they have the option to leave the group and create their own territories, especially if there are favorable chances to win authority over new regions. Alternatively, kids have the option to remain within the family and ultimately inherit the hunting zone from their parents. Red foxes, skilled at capturing tiny animals, whether they are domestic or wild, take advantage of every opportunity to find food as they go across their region. Their hunting style is surreptitiously approaching their victim and slowly reducing the distance before executing a successful assault. The algorithm employs a global search approach by exploring territory in search of food. Next, the second stage entails moving through the environment to approach the prey as closely as feasible before commencing the assault, which is represented as a local search.

Falcons have unique and complex hunting behaviors, using both clear, clearly identifiable techniques and more elaborate, convoluted tactics while chasing and capturing their prey.

During the initial phase, the FOA factors and the governing limits are initialized. Following this, the motion and location of falcons are altered according to the supplied values which is represented as,

$$y = \begin{bmatrix} y_{1,1} & \cdots & y_{1,V} \\ \vdots & \vdots & \vdots \\ y_{A,1} & \cdots & y_{A,D} \end{bmatrix} \quad (11)$$

Where y is the falcon location, regarding the total applicants A every dimension V. The speed is generated randomly within the v_{Max} and v_{Min} limits.

$$v_{Max} = 0.1Up_{li} \quad (12)$$

$$v_{Min} = -v_{Max} \quad (13)$$

Where Up_{li} is the upper limit in every measurement.

Determine the fitness value at each iteration. During that period, the optimal individual is designated as I_b and the optimal position for each falcon is denoted as y_b.

Create two random elements (Q_B, Q_C) with a normal distribution on every bird of attack to study the association between awareness and leap probability. The main probability considered where Q_B is smaller than the falcon is given as,

$$y_t = y_{t-1} + v_{t\text{-}1} + M_t r\left(y_{b,t-1} - y_{t-1}\right) + O_t r\left(I_{b,t-1} - y_{t-1}\right) \quad (14)$$

y_{t-1} , $v_{t\text{-}1}$ are present location and Falcon's motion. $M_t r, O_t r$ are cognitive rate and social

If Q_B exceeds B (Adaptive prob) the jump is compared to Q_C. If Q_C exceeds C (Dive Prob), the falcon selects one prey (y_{ch}) and performs its hunting evolution using logarithmic twisting expressed as,

$$y_n = y_{t-1} + |(y_{ch} - y_{t-1}| \exp(ze)\cos(2\pi e) \quad (15)$$

y_n is the new position, z is accurate observation logarithmic twisting that equates to 1, e is an irregular value in range $[-1, 1]$ indicates how close the falcon is to its actual target.

When Q_B is lower than Q_C, the fitness of the picked prey is compared to the falcon's fitness and this condition is expressed as,

$$y_n = y_{t-1} + v_{t\text{-}1} + f_c r(y_{ch} - y_{t-1}) \quad (16)$$

The constant $f_c r$ describes the falcon's ability to measure its precise position when uncertain. The vision radius from RFO is defined as,

$$r = \begin{cases} a\frac{sin(\emptyset_0)}{\emptyset_0} & ;\emptyset_0 \neq 0 \\ \theta & ;\emptyset_0 \neq 0 \end{cases} \quad (17)$$

θ is a random value in range [0,1], $\emptyset_0 \in [0, 2\pi]$ is chosen for all individuals to simulate falcon observation angle, a is the scaling parameter set once each iteration for all individuals in the population to simulate variable distances from prey during falcon approaches.

Using the O-RFF, the best features are selected based on which the classification is performed.

E. Classification

This is the final step in the process which classifies the final output based on the results from the previous stages. Bionic Fusion-Net Architecture is used for the classification process which is the combination of Xception, Squeeze-Net, Shuffle-Net and optimized Bi-LSTM which results in accurate classification. Fig. 4 depicts the Bionic Fusion-Net Architecture.

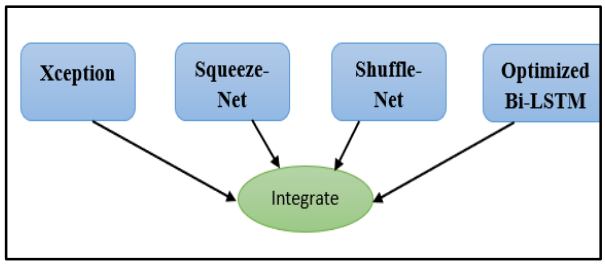

Fig. 4. Bionic fusion-net.

1) Xception: The Xception architecture consists of a total of 36 convolutional layers, which make up the fundamental feature extraction part of the network. Our experimental inquiry only focuses on picture categorization. Thus, the convolutional base is immediately succeeded by a logistic regression layer. Additionally, there is the possibility of including fully-connected layers before to the logistic regression layer. The 36 convolutional layers are arranged in 14 modules, with linear residual connections encompassing them. It is worth mentioning that the initial and final modules lack these linear residual connections. The Xception architecture may be described as a sequential arrangement of depth wise separable convolution layers with residual connections. This specific design decision makes the architecture easily definable and adaptable, providing convenience for modifying and experimenting.

2) Squeeze-Net: With two convolution layers (CL), eight fire layers, three max-pooling levels, one global average pooling layer, one SoftMax output layer, and so on, Squeeze Net is a convolutional network. Squeeze Net has 8 Fire modules (fire2–9) after the 1st CL (conv1). Finally, there is a final convolution layer. From the start of the network to its end, each Fire module has more filters than before. Max-pooling is carried out by Squeeze Net using a two-stride method following layers conv10, fire8, fire4, and conv1.

The RGB channels of the network's input (i//p) measure 227 × 227 pixels. Max pooling is used to further specialize the i//p pictures after convolution. Using 3 × 3 kernels, the convolution layer connects the limited areas and weights in the i//p volumes. Each component is independently activated as the real component by each convolution layer. Each convolution layer performs activation. It utilizes fire layers which squeeze phase (S-p) and Expanded phase (E-p) between the convolution layers. The i//p and output (o/p) tensor scales of the fire are equal. 1 × 1 filters are used in S-p, whereas along with the above filter, 3 × 3 are used in the E-p. The o/p is given as,

$$f(y) = \sum_{fm1=1}^{FM} \sum_{c=1}^{c} W_c^f x_c^{fm1} \quad (18)$$

Where FM, C are feature maps (fm's), channels. The weighted total of the feature maps of each individual tensor is the squeeze results. Max pool down samples along spatial dimensions, whereas the global average pool aggregates the class feature mappings into a single value. Multiclass probability distributions are returned by the SoftMax activation method at the output end.

The improved sliding windowing technique is employed for feature extraction, in contrast to considered whole signal at once, because of its stochastic nature. The procedure is used for segmentation, either adjacent or overlapped [24-25]. The outcomes demonstrate the accuracy of categorization is higher for the overlain windowing strategy compared to the adjacent or disjunct windowing scheme. Data stability during feature extraction is ensured by segmenting the data into brief windows. Each temporal series was divided into ideal segments or sub-frames using the overlapping windowing technique in this investigation.

3) Shuffle-Net (Sh-Nt): A very effective DL architecture called Shuffle-Net was developed using mobile devices. It contains 50 learnable layers, which are comprised of an FC layer, 48 group convolution layers, and 1 convolution layer. To reduce the total computing complexity, pooling layers are used. The output of the convolution layer of the network is given as,

$$s(i,j) = \sum_n \sum_m I(m,n)K(i-m, j-n) \quad (19)$$

K, i are kernel and i//p image. The o/p of size e=((i-k)+2p)/(s+1) is produced after convolution, where p means padding, and s represent steps.

The o/p fm's of the 1st CL is sent to the Sh-Nt unit. Three convolutional procedures make up the Shuffle Net unit: three × three depth wise convolutions and two 1 × 1 pointwise group convolutions. Channel shuffle operation, ReLu activation function, and BN come after the initial pointwise group convolution. ReLu activation is employed due of its simplicity and effectiveness. It is stated as

$$f(y) = \begin{cases} 0; y < 0 \\ 1; y \leq 0 \end{cases} \quad (20)$$

ReLu sets neurons to 0 (deactivates neurons) and activates neurons with positive values. BN comes after the second and third convolution procedures, which are the 3 × 3 depth- wise convolutions and the 1 × 1 pointwise group convolution. A 3-by-3 average pooling on the shortcut paths is included in the model. The model is made up of sixteen sequential Shuffle-Net components. There are fifty layers in the model, and each one offers trainable feature maps. Additionally, these layers extract features. After submitting these feature maps to FC, the final classification layer uses Soft-max activation for classification probability determination.

$$a_i = \sum_{j=o}^{m \times n-1} w_{ij} \times x_i + b_i \quad (21)$$

where i means index of the FC layer's output; n, m, d, and i denote the height, width, depth, and index of FC layers output.).

4) Optimized Bi-LSTM: The forget gate, i/p gate, and o/p gate are the three gated units that make up the majority of the LSTM neural network. Bi- LSTM can processes sequences in

bi-directions. Two LSTM networks are combined, one of which processes the sequence from left to right and the other from right to left. The output of a Bi-LSTM is typically a concatenation of the hidden states from both the left-to-right and right-to-left LSTM networks which provides higher efficiency for the model. This enables it to record each element in the sequence's context from both the past and the future. In order to maintain the interdependence of time series information over long distances and achieve accurate prediction, the sequence data is acquired and stored by specialized gated units. The input data is largely processed by the input gate. The current neuron's capacity to remember prior knowledge is contingent upon the forget gate. The o/p of the neuron is given in the output gate. Assuming that the i/p sequence is x_1,x_(2,..,) x_t, the calculation formula for each LSTM neuron parameter at time t is as follows:

$$i_t = S(W_i * [h_{t-1}, x_t]) \quad (22)$$

$$f_t = S(W_f * [h_{t-1}, x_t]) \quad (23)$$

$$o_t = S(W_o * [c_t, h_{t-1}, x_t]) \quad (24)$$

$$c_t = f_t * C_{t-1} + i_t * \tanh(W_c * [h_{t-1}, x_t]) \quad (25)$$

$$h_t = o_t * \tanh(c_t) \quad (26)$$

The LSTM neural network's weights between nodes are optimized using a predetermined procedure, which can make the weights between neurons more rational and enhance the model's capacity for generalization and prediction. The weights are optimized by using the novel O-RFF Optimization Algorithm.

5) Intergration: All the outputs from the above models are integrated to form a Bionic Fusion-Net model which results in higher classification accuracy than the other models.

F. Huber Loss Function

The Huber loss function is used for regression, especially with outliers. It balances mean squared error and mean absolute error, making it resilient to extreme dataset values. This makes it beneficial when accuracy and robustness must be balanced. Its smooth gradient transition provides robust optimization during training, especially in neural network applications. The Huber loss is adaptable for regression problems with different data properties because the absolute difference between predicted and actual values is a more relevant error statistic than the squared difference.

It is defined as,.

$$L_\delta(x) = \begin{cases} \frac{1}{2}x^2 \ ; \ |a| \le \delta \\ \delta\left[|a| - \frac{1}{2}\delta^2\right]; else \end{cases} \quad (27)$$

IV. Result and Discussion

Using the dataset taken, the results are evaluated using the performance metrices. The results are computed in comparisons of the suggested and the existing methods Xception [24], Squeeze-Net [25], Shuffle-Net and Bi-LSTM which is implemented in the python platform.

A. Dataset Description

The evaluation of the suggested and the current techniques are done using the performance metrics which are explained in detail below and Table I and II provides the values of the Performance metrics for the recommended and methods in use at the rate of 70/30 and 80/20 respectively.

TABLE I. Values of Performance Metrics in the 70/30 Rate

Model	Accuracy	Sen	Spe	Pre	F-measure	FPR	FNR	MCC
Bionic Fusion-Net	0.986	0.987	0.988	0.987	0.984	0.043	0.039	0.988
Bi-LSTM	0.952	0.963	0.966	0.958	0.967	0.073	0.089	0.965
Squeeze-Net	0.930	0.950	0.94	0.933	0.943	0.063	0.079	0.952
Shuffle-Net	0.930	0.951	0.94	0.934	0.945	0.073	0.089	0.953
Xception	0.909	0.949	0.947	0.921	0.930	0.072	0.062	0.953

TABLE II. Values of Performance Metrics in the 80/20 Rate

Model	Accuracy	Sen	Spe	Pre	F-measure	FPR	FNR	MCC
Bionic Fusion-Net	0.986	0.987	0.989	0.991	0.989	0.035	0.0362	0.988
Bi- LSTM	0.990	0.967	0.968	0.963	0.970	0.063	0.079	0.967
Squeeze-Net	0.958	0.952	0.943	0.937	0.949	0.053	0.069	0.953
Shuffle-Net	0.95	0.954	0.952	0.941	0.953	0.063	0.079	0.953
Xception	0.943	0.950	0.948	0.923	0.934	0.061	0.061	0.954

1) Accuracy: It is the proportion of true forecasts to all i/p Observations. It is determined using (28)

$$Accuracy = \frac{Number\ of\ correct\ predictions}{Total\ number\ of\ samples} \quad (28)$$

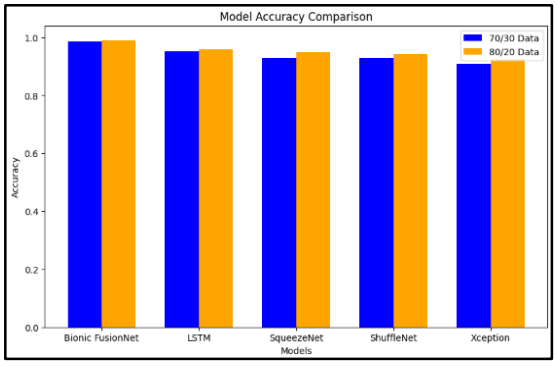

Fig. 5. Examination of suggested and existence approaches in terms of accuracy.

Fig. 5 shows the examination of the recommended and methods in use about Accuracy. From the graphical representation, it is seen that the proposed approach has a higher Accuracy.

2) Sensitivity: The fraction of real positives that are correctly identified is measured by sensitivity. It is given as,

$$Sensitivity = \frac{TP}{TP+FN} \quad (29)$$

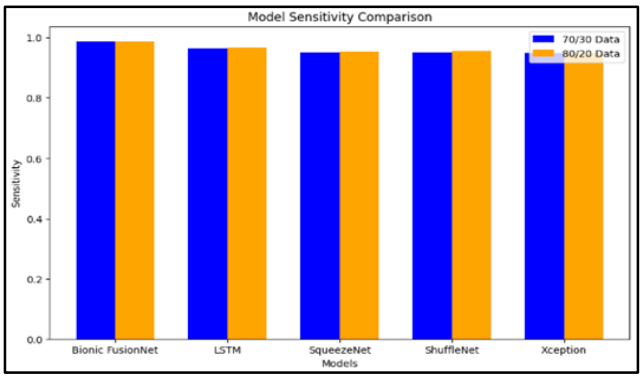

Fig. 6. Examination of suggested and existence approaches in terms of Sensitivity.

Fig. 6 shows the examination of the recommended and methods in use in regard to Sensitivity. From the graphical representation, it is seen that the proposed approach has a higher Sensitivity.

3) Specificity: The percentage of real negatives that are accurately identified is measured by specificity. It is calculated using

$$Specificity = \frac{TN}{TN+FP} \quad (30)$$

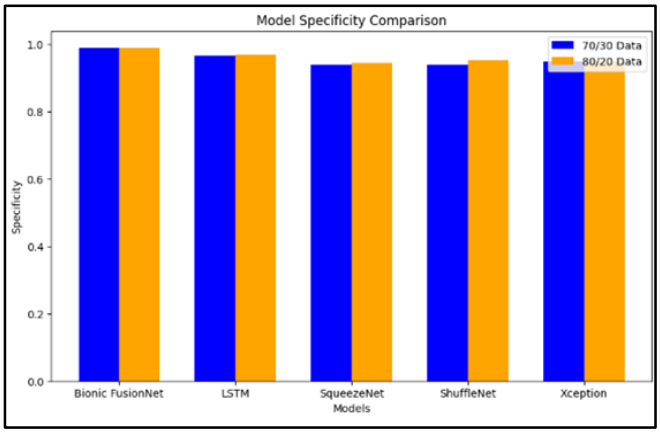

Fig. 7. Examination of suggested and existence approaches in terms of Specificity.

Fig. 7 shows the examination of the recommended and methods in use in regard to Specificity. From the graphical representation, it is seen that the proposed approach has a higher Specificity.

4) Precision: How much of a model's positive predictions are actually right is determined by its precision, which is a performance indicator. In order to assess how well what you detect is actually present, precision is important. It is given as,

$$Precision = \frac{TP}{TP+FP} \quad (31)$$

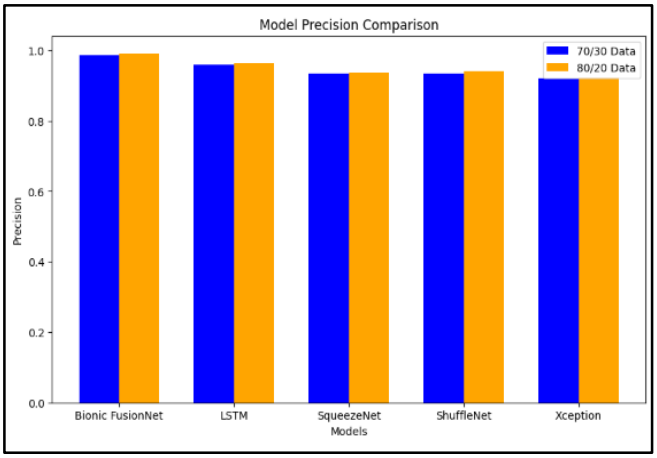

Fig. 8. Examination of suggested and existence approaches in terms of Precision.

Fig. 8 shows the examination of the recommended and methods in use in regard to Precision. From the graphical representation, it is seen that the proposed approach has a higher Precision

5) Precision: A general score for performance evaluation, it is a combination statistic that combines Precision and recall. It is given as,

$$\text{F measure} = 2 * \frac{Precision*Recall}{Precision+Recall} \quad (32)$$

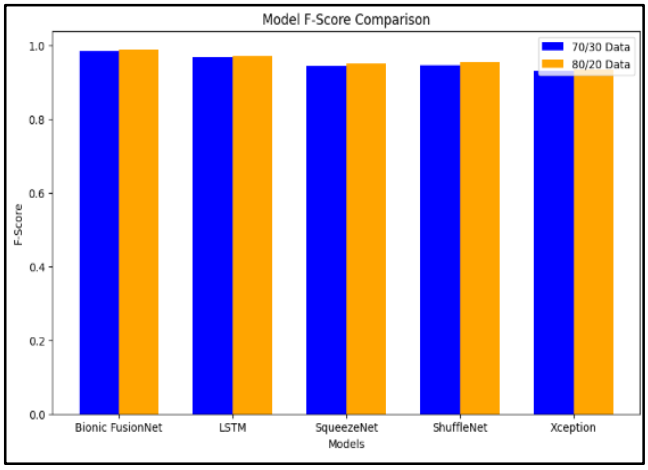

Fig. 9. Examination of suggested and existence approaches in terms of F-measure.

Fig. 9 shows the examination of the recommended and methods in use in regard to F-measure. From the graphical representation, it is seen that the proposed approach has a higher F-measure.

6) FPR: FPR refers to the values that are actually negative but predicted to be positive. It is calculated using the formula,

$$FPR = \frac{FP}{FP+TN} \quad (33)$$

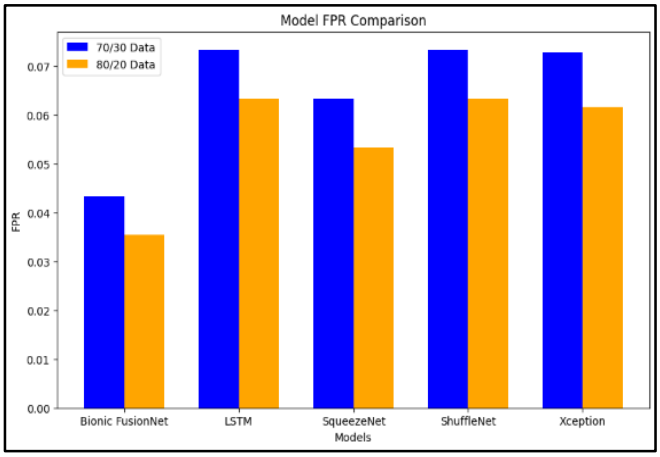

Fig. 10. Examination of suggested and existence approaches in terms of FPR.

Fig. 10 shows the examination of the recommended and methods in use in regard to FPR. From the graphical representation, it is seen that the proposed approach has a lower FPR.

7) FNR: FNR refers to the values that are actually positive but predicted to negative. It is calculated using the formula,

$$FNR = \frac{FN}{FN+TP} \quad (34)$$

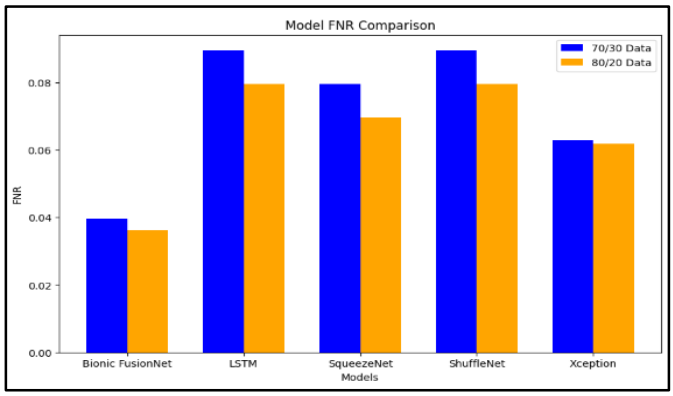

Fig. 11. Examination of suggested and existence approaches in terms of FNR FPR.

Fig. 11 shows the examination of the recommended and methods in use in regard to FNR. From the graphical representation, it is seen that the proposed approach has a lower FNR.

8) Mathew's Correlation Coefficient (MCC): MCC measures the degree of correlation between expected and actual values. It's stated as,

$$MCC = \frac{(TP\times TN)-(FP\times FN)}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \quad (35)$$

Fig. 12 shows the examination of the recommended and methods in use in regard to MCC. From the graphical representation, it is seen that the proposed approach has a lower MCC.

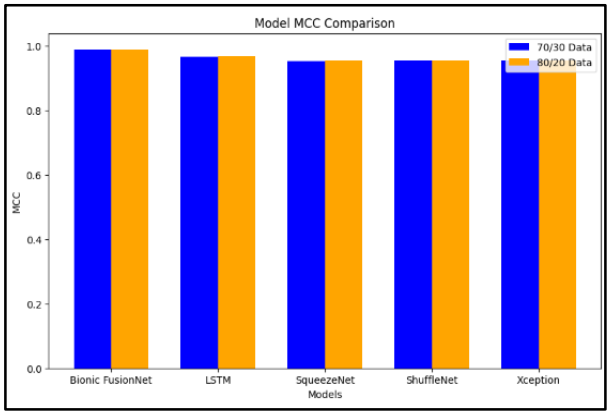

Fig. 12. Examination of suggested and existence approaches in terms of MCC.

V. Conclusion

To create advanced prosthetic devices that recognize and respond to human gestures, bionic hand movement detection is essential. Recent developments in image processing, feature extraction, and deep learning have enhanced bionic hand movement detection accuracy and versatility. This paper presents a unified framework employing attention-guided ROI identification and a novel Bionic Fusion-Net architecture to solve these issues. Initial pre-processing includes dataset and picture improvement. ROI Identification employs an attention-guided U-Net with advanced convolutional components. During feature extraction, BionicNet-1 and BionicNet-2 learn spatial and temporal features jointly. O-RFF, a hybrid Red Fox-Falcon Optimization Algorithm, optimizes feature selection. Xception, Squeeze-Net, Shuffle-Net, optimized Bi-LSTM, and Huber Loss function application form the Bionic Fusion-Net Architecture. The proposed attained a performance of 99% accuracy, 98.7% Sensitivity, 98.9% Specificity, 99.1% Precision, 98.9% F-score, 3.5% FPR, 3.6% FNR and 98.8% MCC. Thus from the results, it is seen that the recommended technique results better in contrast to the methods in use.

***Abstract*—Blockchain technology is known for its decentralized and immutable nature, which makes it highly resistant to hacking and unauthorized access. This would ensure that patients' private health information remains secure and protected from potential breaches. Moreover, the use of blockchain can also enhance data integrity by creating a transparent and tamper-proof record of all health updates, further increasing trust in the systems. The COVID-19 epidemic has made human health one of the most crucial things we should focus on more in our day-to-day lives. Social separation could help contain the COVID-19 pandemic. Humans are therefore urged to avoid physical contact with one another if the condition is permitted. It is suggested that medical professionals use the Internet of Things (IoT)-based Health Monitoring Application to keep an eye on their patients via their mobile devices. With the help of the suggested system, patients can update the system with their daily health status, and medical professionals can use their mobile devices to monitor their patients for future health policy. Because the suggested system is an application that users can access from their mobile devices rather than just using a laptop or computer to browse the website, it is more practical than most of the current system. Patients do not need to visit the hospital for a check-up because they can update the system with their health information. If physicians discover unusual symptoms in a patient's medical record, are they obligated to seek medical attention? Furthermore, private health information is regarded as confidential. Consequently, this would examine the risks associated with the backend system of the suggested solution as well as security threats. Additionally, by utilizing blockchain technology, improvements in security and privacy can be achieved.**

***Keywords*—IoT health monitoring system; security and privacy; and blockchain technology; health policy**

I. Introduction

In reference to the most recent global ailment, the number of patients is fast rising because of the COVID-19 pandemic. According to study [1] telemedicine and other digital tools are becoming more and more important in the fight against the COVID-19 epidemic. According to the study [2], "telehealth is the use of digital information and communication technologies, such as computers and mobile devices, to access health care services remotely and manage your health care." Being a relatively new field of study, telehealth is still expanding. Numerous studies have demonstrated the strategy for leveraging IoT resources to develop telehealth. These studies have shown that integrating IoT devices into telehealth systems can improve patient monitoring, increase access to healthcare services, and enhance overall patient outcomes. Additionally, the use of IoT in telehealth has the potential to reduce healthcare costs and alleviate the burden on traditional healthcare systems. As technology continues to advance, further research and development in this field will likely lead to even more innovative applications of IoT in telehealth. Internet-of-Things (IoT) in healthcare is a system that consists of various sensors or devices to collect data and store it in the cloud online. IoT Healthcare Monitoring system allows many end-users like doctors and patients access to the system. IoT sensors or devices are generating real-time data which the doctors are using to analyze the patient's health condition and create outcomes. The communication between the sensors or devices with the cloud is connected through Internet-Connected Gateways like Wi-Fi or Bluetooth.

Using technology in healthcare has unmatched benefits, such as improving patient health and treatment quality and efficiency [3]. Real-time reporting and monitoring, end-to-end connectivity, tracking, alarms, and other features are advantages of employing technology-based healthcare techniques. Additionally, IoT in telehealth can also improve access to healthcare services, particularly for individuals in remote or underserved areas. This technology enables patients to receive virtual consultations and monitoring, reducing the need for travel and increasing convenience. Furthermore, the integration of IoT devices with electronic health records can enhance data collection and analysis, leading to more personalized and effective treatment plans.

Since the primary issue with telehealth technology is its security and privacy, blockchain technology is utilized to improve the proposed system's security and privacy, even if telehealth research is still relatively young and only offers end-to-end communication. Blockchain technology keeps data in a unique manner that makes it difficult or impossible to alter, hack, or manipulate the system. A blockchain is dispersed throughout the network without the need for outside involvement. As a result, the only people who are permitted to access the network and obtain information are authorized users. This ensures that patient data remains secure and confidential, reducing the risk of unauthorized access or data breaches. Additionally, blockchain technology provides a transparent and

auditable record of all transactions and interactions within the telehealth system, enhancing accountability and trust among users. With the continuous advancements in telehealth and blockchain technology, the future holds great potential for further strengthening the security and privacy of telehealth systems. Blockchain Technology into IoT system helps to enhance security and privacy. It is because Blockchain is a system that stores information in a special way which makes the information hard or impossible to edit, hack, or cheat the system. A Blockchain is distributed across the network that does not require any third party to be involved.

II. Literature Review

"Telehealth is the use of digital information and communication technologies, such as computers and mobile devices, to access health care services remotely and manage your health care. Telehealth is still growing and is relatively new research. Many studies have shown the approach of developing telehealth using IoT resources. Two main problems have been found throughout the research. Firstly, most of the current system is a system that needs to be browsed through a website using laptops or computers. This is inconvenient for the medical staff or doctors if they have outpatient cases. It is inconvenient for them to bring the laptops along during the outpatient cases. Therefore, a web application will be preferable to them, allowing them browsing through the website using their laptops, computers or even mobile devices [3].

Secondly, privacy, data security and data integrity are the challenges of IoT-based systems [4]. An IoT-based system connects the sensors or devices to the system with an internet connection and stores the data in the cloud. In an IoT system, data is moving around to be transmitted, stored, and processed. In between processing the data, a hacker can easily gain access to sensors or devices to change the data. Therefore, a system under a healthcare industry must have integrity and accuracy of the data to make sure the medical staff or doctors are getting the right information.

A permission and private blockchain can help in reducing risks on the front-end and back-end of a system. A permissioned blockchain is a blockchain that requires permission to join or access to the consensus. It supplies an additional level of security over the system. Permissioned blockchain is supplying membership service which allows creating differences in roles or views in the system (Singh, 2020). Membership service requires the users to register themselves to the blockchain and get a private key from the blockchain before they can access the network. This could enhance access control to the system. Besides, a private blockchain network is only allowing a certain company or single organization to take part. It only allows a small group controls to the network [5]. A given participant is only allowed to see the given instance of a smart contract within that network. A private network could enhance the privacy and security of the proposed system

III. Methodology

The waterfall model was applied to the system development process in this study. The waterfall model allows for a systematic and sequential approach to developing the telehealth system, ensuring that each phase is completed before moving on to the next. This methodology also facilitates thorough documentation and clear communication between stakeholders, which is crucial for the successful implementation of a secure and efficient telehealth system. Additionally, by following this model, any potential issues or risks can be identified early in the development process, allowing for timely mitigation strategies to be put in place.

A. Phase 1: Data Collection

As the proposed system is related to the healthcare industry, conducting an interview session with the experienced medical staff to get an in-depth understanding of the healthcare procedure and the features was included in the proposed system. Enhancing the system's efficiencies and making it more accurate or useful would be beneficial to the proposed system and the overall telehealth experience. Incorporating cutting-edge technologies like artificial intelligence and machine learning algorithms can help achieve this by analyzing patient data and offering individualized recommendations or diagnoses. Additionally, continuous feedback from both patients and healthcare providers should be sought to ensure that the system is meeting their needs and addressing any potential limitations or shortcomings in the future.

The methods employed to get the data were background research, questionnaires, and interviews. To gain a deeper understanding of the Internet of Things health monitoring system and analyze the hazards and security issues it raises, numerous publications, articles, and background research were deployed. Additionally, the questionnaires were distributed to healthcare professionals and telehealth system users to gather insights on their experiences and perceptions of security and privacy in telehealth. In addition, expert opinions are obtained, and the research findings are validated through interviews with subject-matter experts. These interviews provided valuable insights into the potential hazards and security vulnerabilities of the Internet of Things health monitoring system. Furthermore, the analysis of existing telehealth platforms helps to identify common security measures and best practices that can be applied to mitigate these risks.

The questions were divided into two sections to study on IoT-based Health Monitoring system and their relation with Privacy and Security. The outcome was to determine whether the experienced medical staff had heard about the IoT-based Health Monitoring system. On the other hand, the Privacy and Security related questions were to determine whether the experienced medical staff had other suggestions or opinions on enhancing the IoT-based Health Monitoring system.

Comprehensive knowledge of the protocols and workings of the healthcare system was acquired through interviews with experienced medical staff. The skilled medical team's recommendations for adding the appropriate new features and functions led to the creation of a system that was also more effective and efficient. The input provided valuable insights from experienced medical staff, which helped in gaining a comprehensive understanding of the protocols and workings of the healthcare system. By incorporating their suggestions, a more effective and efficient IoT-based health monitoring system was developed. However, it is essential to continuously seek

feedback from medical professionals to ensure ongoing improvement and development of the system.

Conversely, a series of questionnaires disseminated via Google Form sought additional data from the intended audience regarding the IoT health monitoring system in order to ascertain whether the intended audience was aware of the risks, security, and privacy concerns associated with the IoT health monitoring system. Additionally, details regarding the target customers' perceptions of how blockchain technology could worsen current security, privacy, and risk issues. The feedback received from medical professionals is crucial in order to address any potential flaws or shortcomings of the system and make necessary improvements. This iterative process ensures that the IoT health monitoring system remains up-to-date and effective in meeting the needs of both medical professionals and patients. Furthermore, gathering insights from the intended audience regarding their awareness of risks, security, and privacy concerns associated with the system helps in designing appropriate measures to mitigate these concerns and build trust among users. Understanding their perceptions of how blockchain technology could exacerbate. These concerns are also crucial in order to address them effectively. Additionally, regularly conducting vulnerability assessments and penetration testing can help identify any potential weaknesses in the system's security measures. By continuously improving and updating the system based on user feedback and emerging technologies, the IoT health monitoring system can ensure that it remains secure, reliable, and trusted by both medical professionals and patients alike.

The analysis shows that respondents agree that blockchain technology may improve an IoT system's security and privacy. The data gathered from all of the aforementioned research projects allowed for the successful development of an IoT health monitoring system using blockchain technology to reduce risks and enhance security and privacy issues. Additionally, the research findings highlighted the importance of user education and awareness about blockchain technology to ensure its effective implementation. This can be achieved through informative campaigns and training programmes to address any misconceptions or fears related to the technology. Ultimately, the successful integration of blockchain in IoT systems can lead to increased user trust and confidence in the overall security and privacy of such systems.

B. Phase 2: System Design

System design is an important step in defining how the system is going to be developed. It is the process of outlining the elements of the system, such as the architecture of the system, components, and system interfaces and data, based on the requirements. Fig. 1 shows the use case diagram of the IoT-Blockchain Network. The use case diagram of the IoT-Blockchain Network provides a visual representation of how different components and actors interact within the system. It helps in identifying the various use cases and scenarios that can be implemented to ensure the seamless integration of blockchain technology in IoT systems. Additionally, this diagram serves as a blueprint for developers and stakeholders to understand the overall functionality and potential benefits of incorporating blockchain into IoT systems.

The component diagram in Fig. 2 was very useful for a complex or huge system. It was used to demonstrate the static implementation view of a system. With a component diagram, it helps to break down the system into smaller components and show how they interact with each other. This allows developers to easily identify the different functionalities and connections within the system, making it easier to design and implement the integration of blockchain technology in IoT systems. Additionally, the use case diagram helps stakeholders understand the specific use cases and scenarios where blockchain can be applied in IoT systems, enabling them to make informed decisions about its implementation and potential benefits.

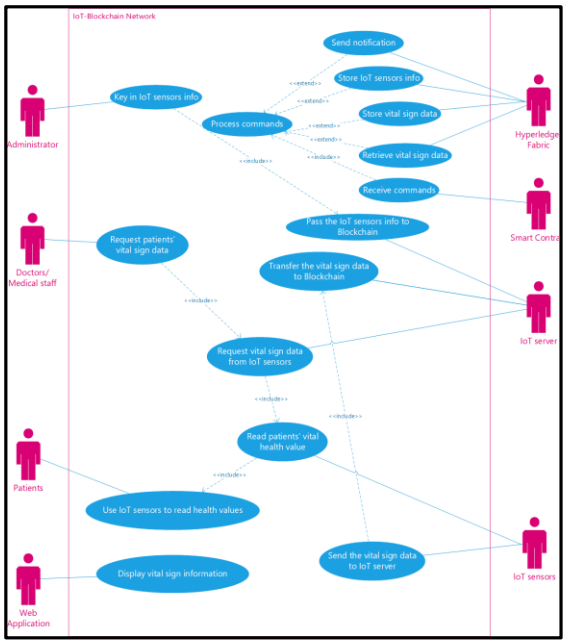

Fig. 1. Use case diagram for the IoT-blockchain network.

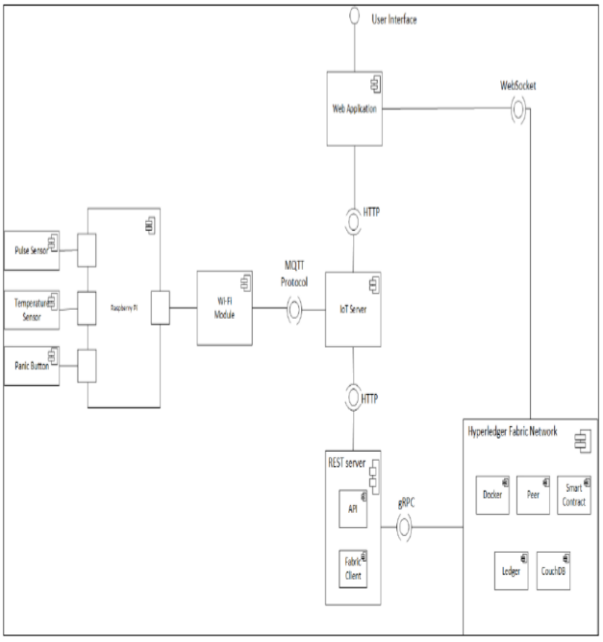

Fig. 2. Component diagram.

C. Phase 3: Implementation

In this development process, Ubuntu Linux has been used to develop and implement the Hyperledger Fabric network. Docker Engine [4-5] is the industry's de facto container runtime that runs on various Linux and Windows operating systems (Docker, 2020a). It does have some tools and a universal packaging approach that wraps up all the dependencies of the application inside a container that will be run on a Docker Engine. 'Docker container image is a lightweight standalone, executable package of software that includes everything needed to run an application' (Docker, 2020b). Having a Docker Engine allows you to easily pull the images with the command provided and start the docker container runtime. It is used to pull the published release fabric images such as fabric-tools, fabric-ca, fabric-peer, ordered, etc. that had been deployed by the Hyperledger Fabric community.

Visual Studio Code was used to develop the chain code, also known as Smart Contract, of the Hyperledger Fabric network using the Node.js programming language. It was also used to develop the web application using Express.js, which is a framework for Node.js, and Pug as the templating engine. Cloud MQTT acts as a broker to receive messages from its publisher client and publish the messages received to its subscriber client. It plays an important role in the MQTT protocol, which is a communication protocol for IoT devices. Without the broker, the messages published could not be successfully sent to the subscribers.

Raspberry Pi [6] is a mini single motherboard that serves as a platform for programming IoT devices. It is used to control the sensors and run the necessary code for the proposed system. The proposed system includes several sensors, such as a temperature sensor, a pulse rate sensor, and a push button. These sensors are used to gather data related to the user's body temperature, heartbeat, and user interaction with the IoT system [7-8]. The temperature sensor is responsible for measuring the body temperature of the user. The pulse rate sensor measures the user's heartbeat in real-time. The push button serves as an input device for users to interact with the IoT system. The sensors collect valuable data, which is then transmitted to the broker using the MQTT protocol [9]. This allows subscribers to receive and process the information for various applications, such as health monitoring or environmental control.

D. Phase: Testing

To guarantee that the testing procedure is carried out efficiently, a test plan is developed. It also serves to guarantee that the methodologies used are appropriate for the proposed system's testing. Unit, integration, and functional testing of the proposed system are all included in the testing. The study examined the connection of Internet of Things (IoT) devices, servers, and brokers, as well as the data integrity between MQTT clients (IoT devices and servers) and brokers. Testing from the Internet of Things system to the web application via the blockchain network was fully included in the scope of the proposed solution. The test plan includes specific test cases for each component of the Internet of Things system, including the MQTT clients, servers, and brokers. Additionally, the testing process ensures that data integrity is maintained throughout the connection between these components. The proposed solution also encompasses comprehensive testing from the Internet of Things system to the web application via the blockchain network to ensure seamless integration and functionality.

At the end, user evaluation is compiled from comments and feedback from users who had never seen the suggested system before. The purpose is to learn about their opinions and reviews of the system, as well as how they feel about it. The author chose to hold a face-to-face meeting to introduce the suggested system to consumers because it is a novel system in comparison to the "traditional" system because it leverages blockchain technology to improve the Internet of Things system. Additionally, the suggested approach requires the network administrator to register the user directly and requires the user to use the offered IoT sensors; as a result, the only method available for evaluating users is in person. This approach ensures that consumers can have a hands-on experience with the system and provide immediate feedback [9-12]. Furthermore, conducting face-to-face meetings allows us to address any concerns or questions that consumers may have, ensuring a better understanding of the system's functionality and benefits.

IV. Results and Discussion

The setup of this proposed system is depicted in Fig. 3. The Raspberry Pi 3 B+ motherboard was selected because it allows wireless connections, which enables to establish a wireless connection with the motherboard. For monitoring a patient's health, two main sensors were utilized: a temperature sensor and a pulse rate sensor. The temperature sensor is designed to accurately measure the patient's body temperature and transmit the data to the Raspberry Pi 3 B+ motherboard. This allows for continuous monitoring and detection of any abnormal fluctuations in temperature. The pulse rate sensor, on the other hand, is responsible for monitoring the patient's heart rate. It uses advanced optical technology to capture the blood flow in the patient's fingertip and convert it into pulse rate data. This information is then transmitted wirelessly to the Raspberry Pi 3 B+ motherboard for real-time analysis and monitoring.

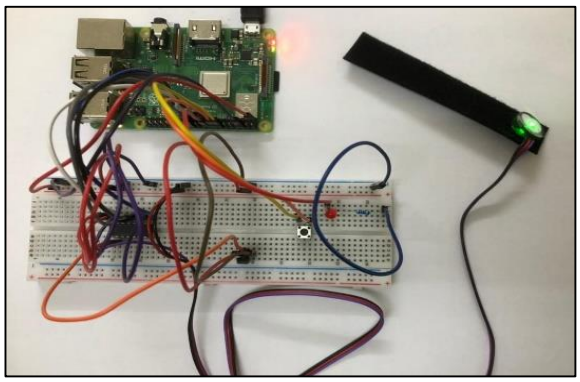

Fig. 3. Setting up the sensors.

One of the key features of the proposed system is the utilization of wireless connections. These wireless connections allow for seamless communication between the sensors and the Raspberry Pi 3 B+ motherboard. By eliminating the need for physical cables, the system becomes more flexible and portable, enabling the patient to move around freely without any constraints. Additionally, wireless connections enable remote

monitoring of the patient's health. This means that healthcare professionals can access and analyze the patient's data from any location, providing timely interventions and reducing response time in critical situations. Furthermore, wireless connections also minimize the risk of tripping or tangling with cables, ensuring the safety and comfort of the patient.

The proposed system includes an emergency push-button sensor, which serves as a vital component for ensuring patient safety. This sensor is strategically placed within reach of the patient, allowing them to hit the button in the event of an emergency. When the button is pressed, a signal is immediately sent to the Raspberry Pi 3 B+ motherboard, triggering an alert. This alert can be programmed to activate various responses, such as notifying healthcare professionals, sending emergency messages to designated contacts, or even initiating an automatic emergency response system. By incorporating this emergency push-button sensor, the proposed system provides an extra layer of safety and reassurance to the patient, enabling immediate response and intervention in critical situations.

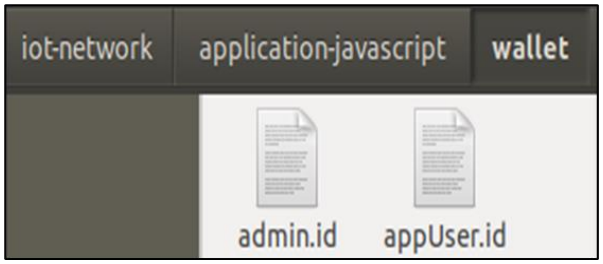

Fig. 4. Wallet of blockchain holding user ID.

The proposed system includes an emergency push-button sensor, which serves as a vital component for ensuring patient safety. This sensor is strategically placed within reach of the patient, allowing them to hit the button in the event of an emergency. When the button is pressed, a signal is immediately sent to the Raspberry Pi 3 B+ motherboard, triggering an alert. This alert can be programmed to activate various responses, such as notifying healthcare professionals, sending emergency messages to designated contacts, or even initiating an automatic emergency response system. By incorporating this emergency push-button sensor, the proposed system provides an extra layer of safety and reassurance to the patient, enabling immediate response and intervention in critical situations. To register an authorized user on the blockchain network, the system administrator follows a specific registration process. This process typically involves verifying the identity of the user and confirming their authorization to access the system. Once the user's identity is verified, the system administrator generates a unique ID for the user, which is then stored in the blockchain network's wallet as in Fig. 4. This ID serves as a digital representation of the user's authorization and allows them to securely access the blockchain network.

By using Hyperledger Fabric technology, the overall security of the system is significantly enhanced. One way this is achieved is using a private blockchain, which ensures that only authorized users have access to the network. This reduces the risk of unauthorized access and potential security breaches. Additionally, Hyperledger Fabric provides a tamper-proof record of all user IDs, meaning that any attempts to modify or manipulate the system can be easily detected and prevented. This transparency further strengthens the integrity of the solution and ensures that the system remains secure.

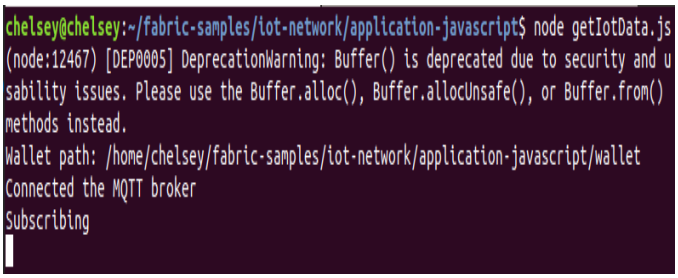

Fig. 5. IoT Server running on a blockchain network.

With reference to Fig, 5, the IoT server is subscribing to the MQTT Broker. MQTT Broker is a lightweight transport protocol that executes messages using a publish or subscribe message queuing scheme (MQTT Documentation, 2021). The MQTT Broker, using a publish or subscribe message queuing scheme, acts as a mediator between the IoT server and the sensors. When the sensors collect personal health data, they publish this data to the MQTT Broker. The IoT server, which is subscribed to the MQTT Broker, receives the published data from the sensors. This mechanism allows for efficient and reliable communication between the IoT server and the sensors, ensuring that the personal health data is transmitted securely and without interference. Blockchain technology enhances the security of the system by providing a decentralized and immutable ledger. When personal health data is collected by the sensors, it is recorded as a transaction on the blockchain. This transaction is then added to a block, which is linked to the previous block in the chain, creating an unbroken record of all data exchanges. The decentralized nature of the blockchain means that there is no single point of failure or vulnerability for hackers to exploit. Additionally, the immutability of the ledger ensures that once data is recorded, it cannot be manipulated or altered, providing an extra layer of security against unauthorized access or tampering.

Fig. 6. A web server running on a blockchain network.

Fig. 6 shows a web server running on a blockchain network. To address privacy and security concerns, the Internet of Things server and a Web server that operate on blockchain technology are only accessible by registered users. As a result, there was a significant decrease in the number of outside attacks on users' personal health data, including those by hackers and attackers.

Blockchain technology is known for its decentralized and immutable nature. As a result, it is less likely that unauthorized access or manipulation will occur to the personal health data stored on the Internet of Things server and Web server. Additionally, the use of cryptographic algorithms in blockchain ensures that the data remains encrypted and secure, further protecting the privacy of the users' personal health information.

Fig. 7. Email sent when the button is pressed.

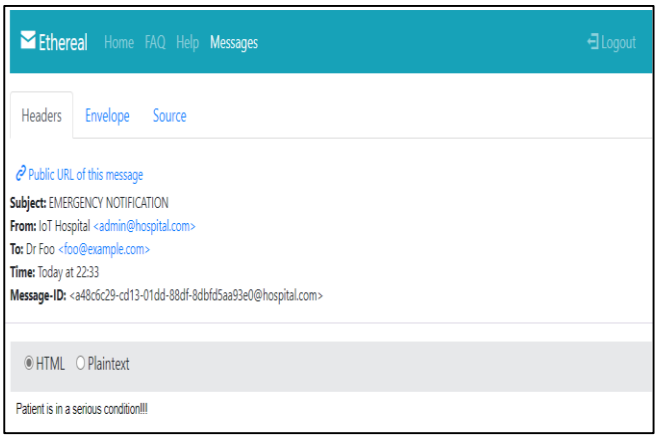

Fig. 8. Example Mailbox sent when user press the button.

Through a secure authentication process that authorized healthcare professionals can quickly complete, the implemented system permits emergency access [13-14]. This ensures that access to personal health data is balanced between privacy and security concerns and the need for timely medical intervention. A sample of notifying medical staff via email when a patient or user clicks the emergency button can be seen in Fig. 7 and Fig. 8. With this feature, the medical team would know that their patient was in critical condition and act accordingly. This feature enhances the response time and effectiveness of the medical team, potentially saving lives in emergency situations. It also ensures that the communication is secure and reliable, as the decentralized and immutable ledger guarantees the authenticity and integrity of the notifications sent to medical staff.

V. Conclusion and Future Enhancement

The system was created and tested to have good efficiency. To lower the possibility of being attacked by hackers or other attackers trying to retrieve user data while it was being transmitted, the Internet of Things server and the Web server were successfully operating on the blockchain network. In addition, the use of the Certificate Authority by the membership service was crucial in granting users access to the Blockchain Network. Finally, data was successfully transferred from the sensors to the blockchain network, enabling registered users to use the sensors to measure their health. The implementation of the blockchain network ensured that all data transmitted from the sensors to the network remained secure and tamper-proof. This provides users with peace of mind, knowing that their sensitive health information was protected from unauthorized access. Additionally, the successful integration of the membership service with the Certificate Authority streamlined the process of granting authorized users access to the Blockchain Network, enhancing overall system efficiency.

Faculty of Data Science and Information Technology, INTI International University, Nilai, Malaysia[5]

***Abstract*—Pneumonia presents a global health challenge, especially in distinguishing bacterial and viral types via chest X-ray diagnostics. This study focuses on deep learning models Convolutional Neural Networks (CNN) and Support Vector Machines (SVM) for pneumonia classification. Our findings highlight CNN's superior performance. It achieves 91% accuracy overall, outperforming SVM's 79% in differentiating normal lungs and pneumonia-affected lungs. Specifically, CNN excels in distinguishing between bacterial and viral pneumonia with 92% accuracy, compared to SVM's 88%. These results underscore deep learning models' potential to enhance diagnostic precision, improve treatment efficacy and reduce pneumonia-related mortality. In the context of Society 5.0, which integrates technology for societal well-being, deep learning in healthcare emerges as transformative. Enabling early and accurate pneumonia detection, this research aligns with the United Nations Sustainable Development Goals (SDGs). It supports Goal 3 (Good Health and Well-being) by advancing healthcare outcomes and Goal 9 (Industry, Innovation, and Infrastructure) through innovative medical diagnostics. Therefore, this study emphasizes deep learning's pivotal role in revolutionizing pneumonia diagnosis, offering efficient healthcare solutions aligned with current global health challenges.**

***Keywords*—Pneumonia; chest X-ray; Support Vector Machine; Convolutional Neural Network; SDGs; Society 5.0**

I. Introduction

Pneumonia is a severe respiratory infection in the lungs and is the leading cause of mortality among children globally [1]. When infected, the alveoli in the lungs fill with fluid and pus, causing painful breathing and restricting oxygen intake [2]. Despite extensive research over recent decades, pneumonia remains one of the primary causes of death worldwide [3]. The Covid-19 pandemic has exacerbated this issue, with pneumonia acting synergistically with the virus to increase mortality rates, particularly among children [4]. In Indonesia, pneumonia was responsible for 15% of toddler deaths, accounting for approximately 922,000 deaths in 2015. From 2015 to 2018, the number of confirmed pneumonia cases in children under five rose by around 500,000 each year [5]. Detecting pneumonia by conventional means is time-consuming and complex [6], resulting in many deaths due to delayed treatment. Therefore, integrating artificial intelligence, especially deep learning, in healthcare, especially for pneumonia detection, might be a novel solution and significantly advance the industry in the Era of Society 5.0 [7]. Deep learning-enhanced and timely pneumonia diagnosis can lead to more effective treatments and improved public health outcomes. This research is crucial because clinical symptoms of pneumonia are often ambiguous and visually similar, particularly in chest X-rays, as illustrated in Fig. 1.

Observing Fig. 1, it is evident that distinguishing between viral and bacterial pneumonia solely from a chest X-ray is challenging [8]. The underlying cause of pneumonia greatly influences the treatment approach. For bacterial pneumonia, prompt antibiotic treatment is essential. Conversely, viral pneumonia requires supportive care, such as rest, Paracetamol, and possibly antiviral medication [9]. This underscores the critical nature of this research, as delays or errors in identifying the pneumonia type can lead to incorrect treatments, with potentially fatal consequences.

Several prior studies have focused on pneumonia classification, including one titled "Classification of Pneumonia in Lung X-Ray Image Augmentation Using Convolution Neural Network Method" [10]. Hipzi's research (2023) achieved a classification accuracy of 95.36%, but it was limited to determining the presence of pneumonia. Another study by Imran et al. (2020) employed various approaches for classifying pneumonia, including logistic regression, SVM, decision tree, and random forest [11]. Although these methods achieved an average accuracy of over 90%, they were restricted to classifying two categories (normal and pneumonia) and were based on numerical data rather than images. Therefore, the novelty of this study lies in developing a model capable of not only identifying pneumonia but also differentiating between bacterial and viral types. Additionally, this research will compare two methods with strong classification capabilities: support vector machine (SVM) and convolutional neural network (CNN).

Fig. 1. Chest X-Rays based on pneumonia status.

In summary, pneumonia remains a major global health challenge, exacerbated by the Covid-19 pandemic and the limitations of current diagnostic methods. Integrating deep learning into healthcare, specifically for pneumonia detection, offers a promising solution. This research aims to develop a model that classify pneumonia types with using of advanced classification methods. By improving diagnostic accuracy and timeliness, this study supports the United Nations Sustainable Development Goals (SDGs), particularly Goal 3 (Good Health and Well-being) and Goal 9 (Industry, Innovation, and Infrastructure). Enhancing healthcare technology through deep learning aligns with these goals by promoting better health outcomes and fostering innovation in medical diagnostics.

II. Related Work and Dataset

A. Related Work

The methods used in this research are Support Vector Machine (SVM) and Convolutional Neural Network (CNN). SVM has been applied in various image classification tasks, such as Setiawan and Putra (2018), who achieved an accuracy rate of 80% in their study for breast cancer classification [12], and Purnajaya (2021), who obtained a 99% accuracy rate in their study for classifying Covid-19 patients using chest X-ray data [13]. Additionally, the CNN method was chosen for comparison because of its advantages in image classification [14]. This is possible because CNN can process data with grid-like patterns and is designed to automatically learn spatial hierarchies [15]. Through this research, it is hoped that the healthcare industry can leverage artificial intelligence-based technologies such as SVM and CNN to enhance efficiency in pneumonia diagnosis. Additionally, this research can contribute to accelerating the achievement of Sustainable Development Goal 3 on Good Health and Well-being by helping improve public health, particularly by reducing pneumonia-related mortality [16].

Through this research, it is hoped that the healthcare industry can leverage artificial intelligence-based technologies such as SVM and CNN to enhance efficiency in pneumonia diagnosis. Additionally, this research can contribute to accelerating the achievement of Sustainable Development Goal 3 on Good Health and Well-being by helping improve public health, particularly by reducing pneumonia-related mortality [17].

B. Dataset

This research is primarily focused on the classification of pneumonia diseases utilizing secondary data obtained from the Kaggle platform [18]. The dataset comprises 6,140 X-ray images of human lungs categorized into three distinct classes namely normal, viral pneumonia patients, and bacterial pneumonia patients. The dataset was collected from a healthcare facility in Guangzhou, China, and has been rigorously verified by three expert radiologists. In the international medical field, there is an independent organization known as the International Commission on Radiological Protection (ICRP), which focuses on providing recommendations and guidelines on all aspects of radiological protection. One of the recommendations from the ICRP that serves as a reference for the entire world pertains to the acquisition and use of X-ray images, as found in the publication "Occupational Radiological Protection in Interventional Procedures" [19]. Therefore, it can be concluded that the techniques for obtaining and interpreting X-ray images are universal and can be applied worldwide. This suggests that the use of X-ray image datasets originating from China can also be applied in Indonesia.

III. Method

To conduct this study, several methodological steps were undertaken, including a literature review, data collection, and data pre-processing. These methods culminated in the creation of a final dataset, which was subsequently split before entering the classification phase. Based on experiments performed by Montesinos-López (2023), the optimal dataset split was determined to be 85% for training data and 15% for testing data. As such, this same split ratio was applied in the present research [20].

A. Data Standardization

The dataset used must go through a standardization process involving pre-processing. In this study, images are read in grayscale, then resized to 150×150 pixels and normalized with Min-Max Normalization with the lower bound of 0 and upper bound of 1, so that pixel values fall within the range of 0 to 1 to ensure efficient training [16]. In the CNN, the data is obtained in the form of a 150×150 array for each image. However, in the SVM, each image is further processed from a 150×150 array into a 1×22,500 array for one image. This is due to the limitation of SVM, which cannot handle multi-dimensional array data.

B. Support Vector Machine

Support Vector Machine (SVM) is a machine learning algorithm that operates based on the principles of Structural Risk Minimization and optimization theory by determining the optimal hyperplane capable of separating specific classes [21]. A hyperplane represents a linear boundary between one class and the others. The best hyperplane is chosen when the distance between the separation line and the nearest feature point (margin) is maximized [22]. Maximizing the margin yields an SVM structure that minimizes the risk of classification errors. The concepts of the hyperplane and margin are visually depicted in Fig. 2.

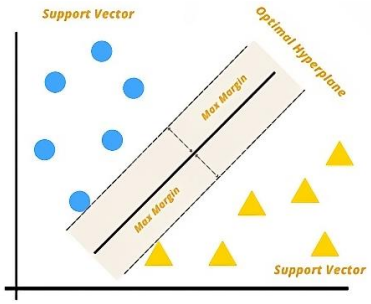

Fig. 2. Hyperplane and margin illustration.

Not all feature data can be straightforwardly separated by a linear boundary. In cases where feature data cannot be linearly separated, SVM hyperplanes employ kernel tricks. Kernel tricks are techniques that transform data into higher-dimensional spaces based on mathematical functions to facilitate linear separation of classes [23]. An illustration of kernel tricks is provided in Fig. 3.

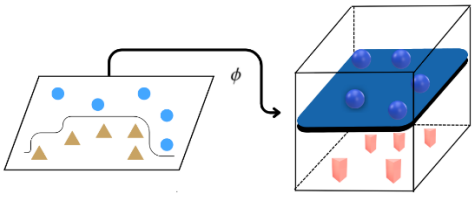

Fig. 3. Kernel tricks illustration.

In Fig. 3, it is evident that what initially could not be represented as a hyperplane can be transformed into a flat, linear hyperplane in a 3-dimensional space. The variable ϕ represents the transformation function variable utilized within the kernel function.

In summary, there are three parameters involved in SVM calculations such as, C value, gamma, and the kernel function. The C value serves as a penalty for errors, and if it is too low, it may lead to misclassifications; conversely, if it is too high, it may result in bias [24]. Therefore, in this research, the iterated C values range from 0.1 to 10. Gamma represents the influence of one data point on another [25]. Generally, the gamma parameter is standardized and frequently used in SVM parameters [26]. As for the last parameter, this study compares three kernel functions: RBF, polynomial, and sigmoid, as all three can be applied to datasets with numerous numerical features [27]. In this research, the classification is divided into two stages: the first model classifies detected pneumonia and normal cases, while the second model differentiates between bacterial and viral pneumonia. This division is made because SVM is particularly suited for binary classification tasks [28].

C. Convolutional Neural Network

With the advancement of technology, CNN models have demonstrated superior performance in image classification when compared to traditional classification methods. CNN leverages spatial structures through convolutional operations to enhance efficiency and effectiveness in the training process. This model has been widely employed in classifying various image types, including pneumonia images [29]. This research also adopts a CNN approach employing two models to classify pneumonia diseases, thereby minimizing classification errors.

Convolutional Neural Networks (CNN) are machine learning models commonly used for image classification. They leverage the concept of Artificial Neural Networks (ANN) to process data with grid-like topologies [30]. For example, time series data can be viewed as a one-dimensional grid by sampling at fixed time intervals, and image data is considered a two-dimensional grid of pixels. CNN makes use of the spatial structure of images through convolution operations to enhance the efficiency and effectiveness of the learning process. Convolution is a specific type of linear operation. CNN consists of several layers, including convolutional layers, pooling layers, and fully connected layers.

The convolutional layers in CNN are responsible for performing convolution operations on input data with specific filters or kernels. These filters extract portions of the input data and generate feature maps that represent features within the input. Each filter in the convolutional layer produces a different feature map, so the more filters you use, the more features can be identified in the input [31].

The pooling layers in CNN are responsible for reducing the dimensions of the feature maps generated by the convolutional layers. This is done to decrease the number of parameters in the model and speed up the training process. Several common types of pooling are used, such as max pooling and average pooling. Max pooling selects the maximum value from a group of values in the feature map, while average pooling calculates the average value from a group of values in the feature map [32].

The fully connected or dense layers in CNN are responsible for connecting the output from the previous layers to the final output. These layers consist of multiple neurons, each of which is connected to all the neurons in the previous layer. The fully connected layers will produce output in the form of probabilities for each class in the data. This output is then used to determine the predicted class of the input data [33].

D. Confusion Matrix

The confusion matrix is an evaluation method used in classification systems to measure the performance of a developed classification model [34]. It contains information comparing actual and predicted values to determine the model's accuracy. The confusion matrix has a size of $n \, x \, n$, where n represents the number of classes to be predicted. In evaluating model performance using a confusion matrix, there are four terms that represent the classification results: TP (true positive) is the number of positive class data correctly predicted as positive, FP (false positive) is the number of negative class data incorrectly predicted as positive, FN (false negative) is the number of positive class data incorrectly predicted as negative, and TN (true negative) is the number of negative class data correctly predicted as negative [35]. The basic structure of a confusion matrix is shown in Fig. 4.

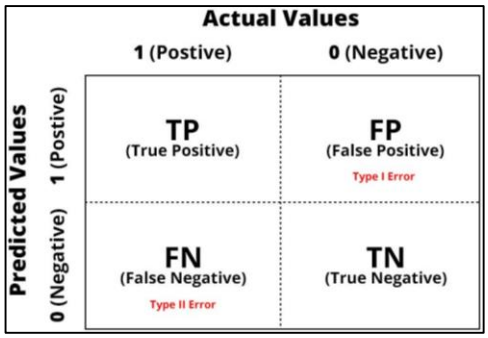

Fig. 4. Confusion matrix structure.

Based on the values obtained from TP, FP, FN, and TN in the confusion matrix, several evaluation metrics such as accuracy, precision, recall, and F1-score can be calculated to assess the model's performance [36]. Accuracy indicates how accurately the model's predictions match the overall data. The accuracy value can be determined using the following Eq. (1).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

Precision measures the accuracy between the given data and the model's predicted results. The precision value can be calculated using Eq. (2).

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

Recall measures the model's success rate in retrieving relevant information. It is the ratio of true positive data to the total positive data. The recall value can be calculated using Eq. (3).

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

Finally, F1-score, or F-measure, is derived from the precision and recall values. The F1-score can be calculated using Eq. (4).

$$F1 = \frac{2 \times recall \times precision}{recall+precision} \quad (4)$$

IV. Experimental Result

A. Experimental Setup

The utilized dataset underwent a standardization process involving pre-processing procedures. In this study, the images were initially read in grayscale, scaled down to 150×150 pixels, and normalized to ensure pixel values fall within the range of 0 to 1, facilitating an efficient training process. In the Convolutional Neural Network (CNN), the input is obtained in the form of an array of dimensions 150×150 for each image. However, in the case of Support Vector Machine (SVM), further data transformation is applied, converting the initial 150×150 input array into a 1×22,500 array for each image. This adaptation is necessitated by the inherent limitation of SVM in processing multidimensional input arrays.

B. Support Vector Machine Training Process

Before performing classification, it is essential to consider the balance of the utilized data. There are 1,341 instances of healthy lung data and 3,875 instances of pneumonia detection. Therefore, balancing needs to be carried out to ensure equilibrium in the training data between healthy lungs and pneumonia cases. The objective of balanced data is to enable the model to recognize data patterns more effectively and avoid anomalies in the dataset [37]. One approach to achieving balance is through the Synthetic Minority Oversampling Technique (SMOTE) algorithm, which generates synthetic data for the minority class based on the nearest distance [38]. Following the application of SMOTE, a total of 3,875 instances of both healthy lungs and pneumonia cases were obtained.

Subsequently, the data will be trained, and the best-performing SVM Model 1 will be applied to a test dataset comprising 624 instances. Table I illustrates the performance of SVM Model 1.

Therefore, the optimal SVM Model 1 utilizes the RBF kernel function with a C value of 0.1. Next, Model 2 will analyze bacterial and viral pneumonia diseases using 2,530 training instances that have undergone the SMOTE process. Subsequently, the best-performing model will be applied to a test dataset consisting of 390 instances. Table II below displays the performance of SVM Model 2.

TABLE I. Classification Performance of SVM Method from Model 1

Kenel Function	Cost (C) Parameter	Accuracy
Radial Basis Function (RBF)	0.1	84%
	1	88%
	10	85%
Polynomial	0.1	87%
	1	86%
	10	83%
Sigmoid	0.1	61%
	1	43%
	10	67%

TABLE II. Classification Performance of SVM Method from Model 2

Kenel Function	Cost (C) Parameter	Accuracy
Radial Basis Function (RBF)	0.1	84%
	1	88%
	10	85%
Polynomial	0.1	87%
	1	86%
	10	83%
Sigmoid	0.1	61%
	1	43%
	10	67%

Based on Table II, the optimal SVM Model 2 is identified, utilizing the RBF kernel function with a C value of 1 for the classification between bacterial and viral pneumonia. In greater detail, the number of classification errors along with metrics from the best performing SVM Models 1 and 2 presented in Table III and Fig. 5.

TABLE III. Evaluation Metrics Between Model 1 and Model 2 with SVM Method

Model	Model 1		Model 2	
Class Classification	Normal	Pneumonia	Viral	Bacterial
Precision	0.91	0.77	0.89	0.88
Recall	0.5	0.97	0.78	0.94
F1	0.65	0.86	0.83	0.91
Accuracy	79.00%		88.00%	

In conclusion, SVM Model 1, with an accuracy of 79%, exhibits numerous classification errors in healthy lung data. On the other hand, Model 2 performs well in predicting bacterial and viral pneumonia data with an accuracy of 88%. Overall, SVM Model 1 proves to be excellent and effective when used to differentiate between bacterial and viral pneumonia. However, in the classification of healthy lungs and pneumonia cases, the performance of SVM Model 2 can be considered satisfactory.

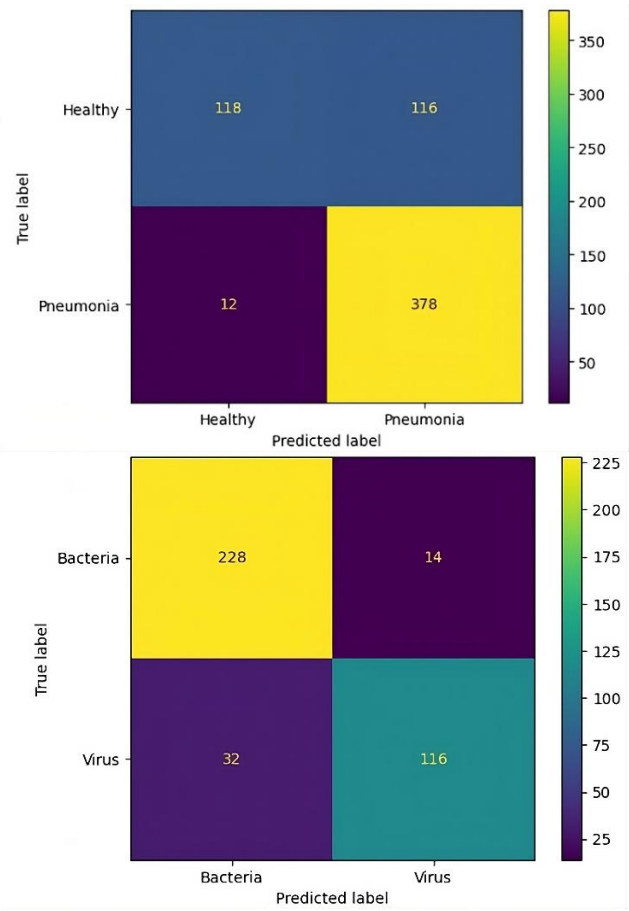

Fig. 5. Confusion matrix for SVM method: (up) Model 1, (below) Model 2.

C. Convolutional Neural Network Training Process

In CNN modeling, data augmentation is performed to address imbalances in the dataset. Data augmentation is carried out by applying random transformations to images, such as rotation, zoom, and shifts, both horizontally and vertically. The purpose of this data augmentation is to expand the variation in the dataset and prevent overfitting [39].

After the images had undergone augmentation, the researchers constructed a CNN model with an architecture consisting of several layers. The first layer is a convolutional layer with 32 filters, followed by a batch normalization layer and a maximum pooling layer. This process is repeated several times with a different number of filters for each convolutional layer. After that, the images are transformed into one-dimensional vectors using a flattened layer before passing through two dense layers. Dropout layers are also used after several convolutional layers and before the dense layers to prevent overfitting. The output layer has one neuron and the goal of the CNN model in this study is binary classification that is, predicting whether X-ray images of the lungs show pneumonia or not [40]. To facilitate understanding of the model architecture, Fig. 6 below is a visualization of the CNN model architecture.

Based on Fig. 6, the Conv2D layer performs convolution to extract image features, while the MaxPooling2D layer reduces data dimensions [41]. Then, the BatchNormalization layer accelerates training and stabilizes the model [42], which is assisted by the Dropout layer to prevent overfitting [43]. After that, the flattened layer transforms the data into a one-dimensional vector, and the Dense layer is used as the output layer in the CNN model.

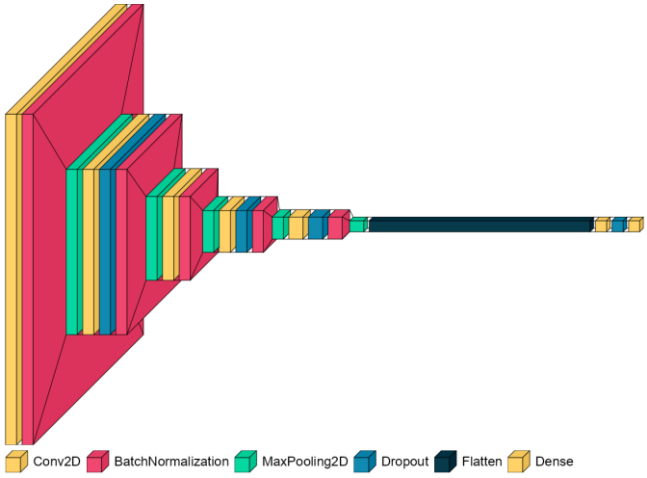

Fig. 6. Architecture of CNN model to classify pneumonia.

To train the model, the researchers used data generated from data augmentation to obtain a greater variation of training data. The researchers used a batch size of 32 and trained the model for 36 epochs, which were chosen based on the model's performance during the learning process. In each epoch, there are evaluation metrics such as accuracy, loss, or other metrics appropriate to the model's objectives as performance indicators. The number of epochs was chosen at the point where the model's performance was stable or there was no significant improvement in evaluation metrics. In addition, to minimize the symptoms of overfitting, the researchers used callbacks to reduce the learning rate if there was no improvement in validation accuracy after several epochs.

In this stage, the researchers conducted model learning on the two CNN models they had previously created. The first model (Model 1) was intended to classify the occurrence of pneumonia, and the second model (Model 2) was intended to classify the type of pneumonia. Thus, the first model was trained using several X-ray images of lungs consisting of healthy lungs and lungs with pneumonia, and the second model was trained using several X-ray images of lungs with pneumonia consisting of viral pneumonia and bacterial pneumonia.

After going through the learning process, a visualization of the results and performance of the model for classifying normal lungs and pneumonia, or CNN Model 1, is provided. This is presented in Fig. 7 as follows:

Then, a visualization and performance results of the CNN model for classifying the type of viral or bacterial pneumonia, or CNN Model 2, is provided. This is presented in Figure 8 as follows:

After obtaining the best weights for the CNN model that has been trained with 36 epochs, the performance of which is represented in Fig. 6 and Fig. 7, and selecting the epoch with the best performance based on the highest accuracy, the classification results are obtained as shown in Table IV:

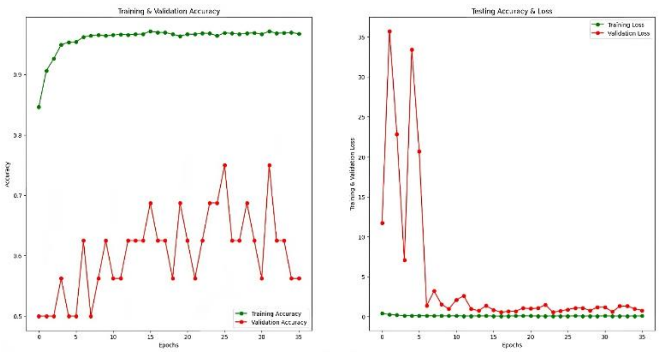

Fig. 7. Training performance of CNN method for Model 1.

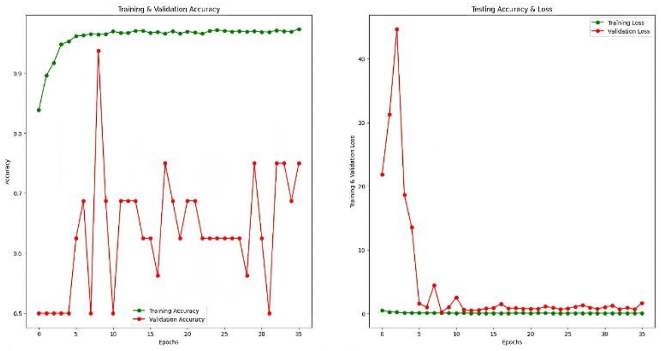

Fig. 8. Training performance of CNN method for Model 2.

TABLE IV. EVALUATION METRICS BETWEEN MODEL 1 AND MODEL 2 WITH CNN METHOD

Model	Model 1		Model 2	
Class Classification	Normal	Pneumonia	Viral	Bacterial
Precision	0.88	0.93	0.88	0.94
Recall	0.88	0.93	0.89	0.93
F1	0.88	0.93	0.93	0.89
Accuracy	91.00%		92.00%	

Based on Table IV, the classification results can be visualized using a confusion matrix, which is presented in Fig. 9 as follows.

Based on Table IV and Fig. 9, the trained CNN model shows good performance in classifying X-ray images. For the pneumonia class, the model achieves a precision of 0.93, recall of 0.93, and F1-score of 0.93. For the normal class, the model achieves a precision of 0.88, recall of 0.88, and F1-score of 0.88. This indicates that the model can identify both classes with almost the same accuracy, with the overall CNN model for detecting pneumonia having an accuracy rate of 91%. The CNN model for detecting the type of pneumonia also shows good performance in classifying the type of pneumonia, with a precision value of 0.94 for bacterial pneumonia and 0.88 for viral pneumonia, overall having an accuracy rate of 92%. Based on the results of these models, it can be concluded that the Convolutional Neural Networks method is an effective method for classifying lung X-ray images to detect pneumonia and the type of pneumonia. With the application of appropriate pre-processing and data augmentation stages, as well as the correct selection of parameters for training the model, CNN can achieve good performance in classification.

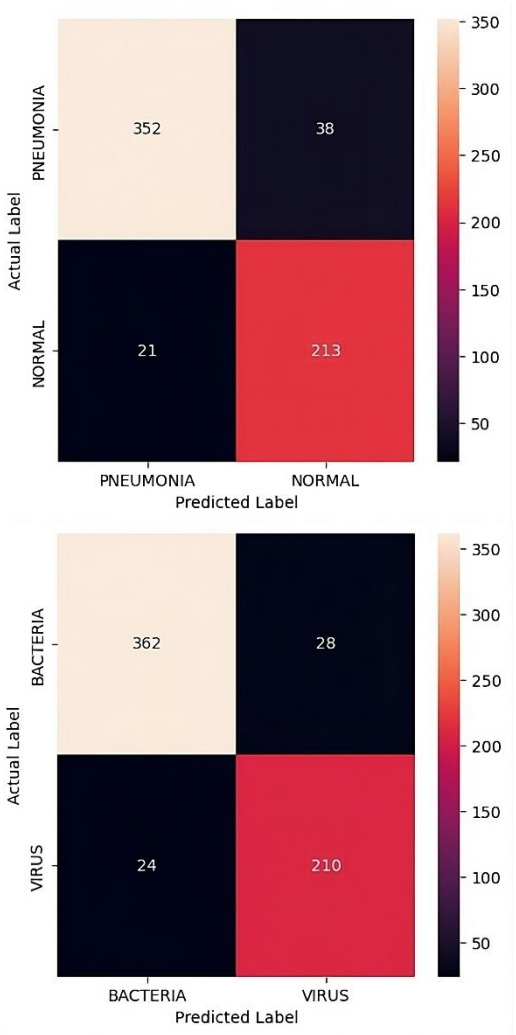

Fig. 9. Confusion matrix for CNN method: (up) Model 1, (below) Model 2.

V. DISCUSSION

Based on the analysis presented, this research has the potential to offer new insights into how pneumonia detection can be performed. By implementing deep learning, the accuracy achieved in detecting normal lungs versus pneumonia, as well as distinguishing between bacterial and viral pneumonia, is very high. A study conducted in 2020 focused on classifying lung diseases [44]. This research used transfer learning with CNN to classify tuberculosis and pneumonia, achieving the highest accuracy of 90% with the ensemble transfer learning method. Another advanced study in 2020 detected normal lungs and Covid-19 infected lungs using a combination of DenseNet121 and SVM models [45]. However, the deep learning model results were implemented through a data pipeline and integrated into a web-based CAD using Flask RESTful. The findings of this current research can also be further implemented by deploying the obtained deep learning model through Flask service to be accessible to a wider audience.

Therefore, the modeling research for detecting normal lungs, bacterial pneumonia, and viral pneumonia holds significant potential for integrating technology with healthcare [46]. It is hoped that this discovery will contribute a leading pneumonia

detection model that can be integrated into digital technology in the future, thereby enhancing public health in the era of Society 5.0 and supporting the global Sustainable Development Goals (SDGs).

VI. CONCLUSION

In this study, demonstrates that the CNN method outperforms the SVM method in accurately classifying pneumonia disease and distinguishing its specific types. The diagnostic challenge of pneumonia, particularly when relying solely on chest X-ray images, underscores the critical need for technology capable of swiftly, cost-effectively, and accurately diagnosing pneumonia. This capability is essential for improving treatment outcomes and reducing pneumonia-related mortality rates.

The integration of deep learning, particularly through CNN methods, holds significant promise in advancing the field of pneumonia classification. Such advancements align with the objectives of Society 5.0, where technological innovation is leveraged to enhance societal well-being through smart and efficient solutions in healthcare. By enabling early detection of pneumonia symptoms, this research not only contributes to Goal 3 (Good Health and Well-being) of the Sustainable Development Goals (SDGs) but also supports Goal 9 (Industry, Innovation, and Infrastructure). Goal 3 aims to ensure healthy lives and promote well-being for all at all ages, while Goal 9 focuses on building resilient infrastructure, promoting inclusive and sustainable industrialization, and fostering innovation.

Multimodal Application of GAN in the Image Recognition of Wheat Diseases and Insect Pests

Bing Li*, Shaoqing Yang, Zeqiang Wang
College of Modern Information Technology, Henan Polytechnic, ZhengZhou 450046, China

***Abstract*—"Food is the most important thing for the people", Food is intricately linked to both the national economy and the livelihood of the people, serving as a vital material for our daily existence. Wheat, standing as one of the three core grain crops, holds paramount importance in safeguarding national food security. However, the wheat planting process remains constantly exposed to a diverse array of environmental factors, ranging from the intensity of light to fluctuations in temperature, soil fertility, fertilizer application methods, and water availability. Occasionally, these variables trigger diseases and insect infestations that can seriously affect wheat yield and quality if not promptly and effectively addressed. Therefore, it is imperative to manage these challenges in a timely and effective manner, ensuring the safety and integrity of wheat production, which in turn guarantees the stability of our national food supply. Traditional methods of manual detection of pests and diseases mainly rely on naked eye observation and manual statistics. Such solutions are highly subjective, have low timeliness, and difficult to unify precision. With the development of computer technology and deep learning, more and more research and applications have been carried out to address the shortcomings of traditional manual detection methods. In this study, deep learning is combined with the application of disease and insect pest recognition. Studying wheat powdery mildew, scab, leaf rust, and midge, convolutional and capsule networks are investigated for pest recognition, establishing an image recognition system for wheat diseases and pests.**

***Keywords*—Deep Learning; Identification of diseases and insect pests; Image classification; System development**

I. Introduction

Wheat, a major food crop, faces challenges from diseases and insect pests triggered by environmental factors [1, 2]. Prompt and accurate identification is crucial to prevent production losses and potential crop failure. Rust, a common menace to wheat crops, can wreak havoc on yields. In epidemic years, it can reduce production by a substantial 20% to 30%. And in extreme cases, the damage can be even more devastating, exceeding 50% and threatening the very existence of wheat production [3, 4]. The figures from the Shandong Plant Protection Research Institute are particularly startling. From 2000 to 2018, the losses attributed to diseases and insect pests in China's prime wheat-growing regions amounted to a staggering 17.67 million tons. That's a loss equivalent to the food supply of nearly 289 million people.

The prevention and prompt diagnosis of wheat diseases and insect pests are imperative for minimizing their detrimental effects on production, yet the unpredictable nature of the agricultural environment poses significant obstacles in the prevention of such threats. Therefore, timely diagnosis and treatment become paramount. Traditionally, disease and pest detection has relied on manual methods, involving naked-eye judgments and manual statistics [5, 6]. The automatic feature extraction function of deep learning enables the automatic classification and recognition of wheat pest images by learning the inherent patterns and characteristics of sample data. This overcomes the limitations of manual recognition in terms of timeliness, subjectivity, and potential damage, offering a novel scientific approach to wheat pest recognition.

A multi-channel network model, CNN-Caps Nets, is established based on convolutional and capsule networks, consisting of multiple conv, pooling, primary capsule, and SoftMax layers. The convolution kernel transmitted by the convolution layer is received by the primary capsule layer, and more image features are extracted for image classification. By comparison, the CNN-Caps Nets model has the best classification effect under the structure of four channels and the number of capsules in the capsule layer is 16. The recognition accuracy of wheat powdery mildew, scab, leaf rust and midge images are 90%, 71%, 91% and 58.3%, respectively. A comprehensive image-sharing database for wheat pests and diseases was established, and a corresponding image recognition system was designed and developed, leveraging the CNN-CapsNet model for effective image classification.

II. Materials and Methods

A. Data Acquisition and Data Set Construction

The quantity and quality of wheat disease and insect pest image samples will directly affect the efficiency and accuracy of subsequent image segmentation and image classification. Due to environmental and regional factors, it is difficult to collect images of wheat diseases and insect pests. This study obtains images with high quality, obvious features, and easy recognition from public data sets (LWDCD, Wheat Leaf Dataset, CGIAR, IDADP, IP102), agricultural databases (National Agricultural Science Data Center, Agricultural Big Data, etc.) and Baidu Gallery the image data is used as the research object, as shown in Table I.

Data sets are essential for training pest classification models. Obtain image data from Wheat-ORL shared database, classify them and collect them in different folders. Using Python, read all pic files in a folder, rename and categorize diseases/insects, then record names and labels in a CSV file as a dataset. The specific data format is shown in Table II.

TABLE I. DATA SOURCES

Wheat Pests and Diseases Image Categories	Number of pictures			Total
	Dataset	Agricultural Databases	Baidu Gallery	
Pest-free	245	0	55	300
Wheat powdery mildew	470	10	20	500
Wheat scab	157	3	30	190
Wheat leaf rust	445	5	100	550
Wheat midge	30	10	20	60

TABLE II. DATASET DATA FORMATS

Image Name	Category	Memo
Heal _ 0. jpg	health	Pest-free
Bfb _ 0. jpg	bfb	Wheat powdery mildew
Cmb _ 0. jpg	cmb	Wheat scab
Yxb _ 0. jpg	yxb	Wheat leaf rust
Xjc _ 0. jpg	xjc	Wheat midge

The 1600-image dataset is divided into training and test sets at a 8:2 ratio for machine learning requirements. The distribution details are shown in Table III.

TABLE III. DATA SET DISTRIBUTION

Categories	Date set	
	Training Set	Testing Set
Pest-free	240	60
Wheat powdery mildew	400	100
Wheat scab	152	38
Wheat leaf rust	440	110
Wheat midge	48	12

B. Graphic Pre-processing

In the process of image generation, it will be affected by noise, insufficient or excessive illumination, inappropriate shooting angle, etc., resulting in a decrease in image quality. In order to improve the accuracy of image feature extraction segmentation and classification smoothing filtering and sharpening of the image can better distinguish the target disease spots pest areas and background in the image.

Smoothing filtering is a low-frequency spatial domain filtering tech to eliminate noise [7]. For different noise characteristics, selecting the corresponding filtering technology can achieve very obvious results. In OpenCV processing library, two kinds of filters are commonly used: Gaussian filter and bilateral filter.

The Gaussian filter is a linear filtering technique that finds extensive application in image smoothing and blurring [8]. When it comes to digital image processing, Gaussian noise is a commonly encountered type of noise. Therefore, Gaussian filtering is extensively utilized in images that are affected by this type of noise. Its basic principle is to achieve image smoothing by weighted averaging the values of each pixel in the image itself and other pixels in the neighborhood. The two-dimensional Gaussian function is the basis for building a Gaussian filter, and the function formula is shown in Eq. (1):

$$G(x,y) = \frac{1}{2\pi\sigma^2} e^{-\frac{(x^2+y^2)}{2\sigma^2}} \quad (1)$$

Bilateral filtering is a nonlinear filter that can simultaneously reduce noise, smooth images and save edges. The filter consists of two functions: two geometrical spaces determine filter coefficients and pixel values determine filter system. In the two-sided filter, the output pixel values are weighted depending on the values of the neighboring pixels, wherein the weighting formula is as follows:

As shown in Eq. (2):

$$g(i,j) = \frac{\sum_{k,l} f(k,l) w(i,j,k,l)}{\sum_{k,l} w(i,j,k,l)} \quad (2)$$

where, the weight coefficients w (i, j, k, D) depend on the product of the domain kernel D (i, j, k, D) and the range kernel r(i, j, k, l), the formulas are shown in Eq. (3), Eq. (4) and Eq. (5).

$$d(i,j,k,l) = \exp\left(-\frac{(i-k)^2+(j-l)^2}{2\sigma_d^2}\right) \quad (3)$$

$$r(i,j,k,l) = \exp\left(-\frac{\|f(i,j)-f(k,l)\|^2}{2\sigma_r^2}\right) \quad (4)$$

$$w(i,j,k,l) = \exp\left(-\frac{(i-k)^2+(j-l)^2}{2\sigma_d^2} - \frac{\|f(i,j)-f(k,l)\|^2}{2\sigma_r^2}\right) \quad (5)$$

Two-sided filtering preserves image edges better by considering both spatial and value domain differences [9]. Therefore, this study will use bilateral filtering method to smooth the image to remove noise and solve the distortion problem in image segmentation.

The purpose of sharpening filter is to highlight the edge of the image and make the image clearer. By adding gradient or finite difference to the high-frequency components in the image, the edges and contours in the image are more obvious. Laplacian operator based on second-order differential is often used to achieve image sharpening.

The Laplace operator calculates pixel grayscale differences within an image neighborhood, an image enhancement technique derived from second-order differential [10]. It computes gradients in four or eight directions of the center pixel, adds these gradients to assess the relationship between the center pixel's grayscale and others, and adjusts pixel grayscale based on the gradient operation's result [11]. Its calculation formula is shown in Eq. (6).

$$\nabla^2 f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} \quad (6)$$

C. Image Segmentation

OpenCV [12] is an open-source computer vision library, which contains rich visual processing algorithms. In terms of image segmentation, there are three classic algorithms: watershed segmentation algorithm, pyramid segmentation algorithm and mean shift segmentation algorithm [13]. Their implementation process is simple, as long as the corresponding

algorithm function can be called to complete the image segmentation according to the edge and other features.

Compared with the other two classical OpenCV algorithms, the watershed algorithm is easier to implement. However, if the input image has no obvious feature edge or is seriously affected by noise, the target area in the image will be difficult to represent, which makes the image over-segmentation phenomenon appear in the watershed algorithm based on gradient image. To compensate for this shortcoming, OpenCV provides an improved watershed algorithm that uses Markers to mark how different regional gradient-guided image segmentation is defined to effectively reduce oversegmentation [14].

OpenCV's GrabCut is a popular image segmentation algorithm. It utilizes image texture and boundary info with minimal user interaction for excellent segmentation. It's a graph-based method where each pixel is a node, and pixel dissimilarity is expressed by weighted edges. Cuts' capacity corresponds to an energy function, with min/max flow algorithms used to cut the graph. The resulting min cut corresponds to the desired boundary [15].

III. Deep Learning

As a subfield of human intelligence, deep learning uses neural networks as the main model. Convolutional neural network and capsule network are two representative network models, which are often used in image processing and image classification.

CNN is a deep feedforward network with local receptive fields, shared weights, and pooling [16]. It mainly consists of convolution, pooling, fully connected layers, and activation functions. Various combination ns of these layers create neural network models with distinct performances [17]. The network model structure is shown in Fig. 1.

A. Convolution Layer

The convolution layer, the heart of CNN, comprises several kernels with pairs of weights and biases [18]. It extracts features from input images, influenced by kernel size. Nodes in the layer receive input from the preceding network, and convolution analyzes each part deeply to yield a more abstract feature set [19].

The convolution kernel is a filter that applies to image parts based on its size, like 3×3 or 5 ×5 grids. Each channel in the convolution layer uses a distinct filter. It convolves RGB images into five feature maps, with different filter values per channel. Filter size and stride (pixels between convolutions) can vary, affecting the learned features. Images may be sampled by pixels based on layer hyperparameters and zero padding. Outputs from multiple channels can be fed into a merging layer.

B. Pool Layer

The pooling layer serves to filter and select the features extracted by the convolutional layer, effectively reducing the matrix size and subsequently diminishing the number of parameters in the fully connected layer. This is achieved by the pooling layer's ability to decrease pixel information in the input image [20]. Usually, the maximum value in each pool is used. The output result is the maximum value in each single block area. In general, the pooling layer will be connected after the convolution layer in CNN networks, because pooling can reduce the space size of volume feature data, reduce the number of parameters and calculation in the network, and suppress the occurrence of over-fitting to a certain extent.

C. Fully Connected Layer

Full connection integrates local features extracted before it into a complete graph via a weight matrix. The fully connected layer, with its multi-layered structure, acts as a “classifier” in CNN. After processing through convolution and pooling layers, extracted features contain high-level image information. Connecting the fully connected layer maps these features to the sample mark space, performs non-linear combinations, and classifies the image using the extracted features. The final classification recognition is obtained through the softmax layer.

In neural networks, receptive field maps the pixel range on the feature map from each conv layer. Traditional neural nets connect each input image pixel to a neuron, leading to a large number of weights and training difficulties. The local receptive field in CNNs depends on the conv kernel size, establishing local connections to form extracted features, reducing weights. By setting conv step size, overlapping areas are avoided, preventing weight increase.

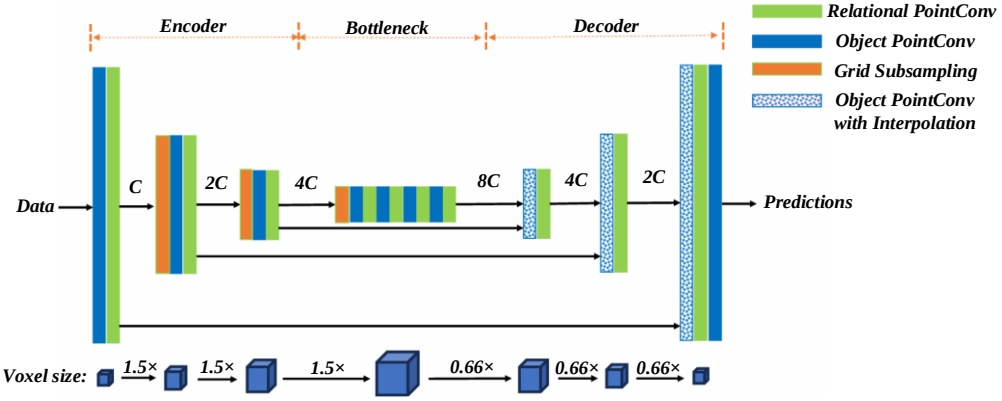

Fig. 1. Structural diagram of the network model.

The convolution kernel's weight is learned and remains constant during convolution. This ensures that the same target in different image positions exhibits similar characteristics. Weight sharing reduces the number of weights in the model. For instance, a 3×3 kernel with nine parameters convolves with different image areas to detect the same features. Different kernels correspond to unique weight parameters for detecting distinct features.

In the convolutional neural network model, the network model with different performance can be obtained by combining different number of convolutional layers and pooling layers into different network structures.

The advantages of the Inception network model are mainly reflected in the control of parameter quantity and calculation amount, while ensuring a higher classification accuracy. The Inception model replaces the full connection layer with global average pooling, reducing overfitting in the classified network. Network performance is enhanced by widening the network. Different-sized convolution kernels enrich layer information in each module. The third edition introduces convolution factorization, decomposing large kernels into smaller ones, saving parameters and reducing model size. The latest version incorporates the residual idea of ResNet for deeper networks.

The main contribution of the ResNet residual network model is the discovery of degenerative phenomena, and the invention of fast connections for degenerative phenomena, and the inclusion of congruent connections, so that gradient propagation can skip the convolution layer, even if the number of network layers reaches a thousand layers can still be trained [21]. The problem that the depth of neural network training is too large is eliminated greatly, and the problem that the learning ability of neurons decreases with the increase of the depth of the network model is solved.

D. Dynamic Routing Algorithm

The dynamic routing algorithm enables the capsule network to achieve superior recognition results. It involves capsules in lower layers predicting and learning instantiation parameters for upper layers via transformation matrices. Consistent predictions from multiple capsules activate upper-layer capsules, outputting feature vectors with expanded receptive fields. This algorithm comprises vector calculations and route selections, detailed in specific computational expressions.

The capsule layer activation output vector Vj is calculated as Eq. (7), Eq. (8) and Eq. (9).

$$S_j = \sum_i c_{ij}\, \widehat{u_{j|i}} \tag{7}$$

$$\widehat{u_{j|i}} = W_{ij} u_i \tag{8}$$

$$v_j = \frac{\|s_j\|^2}{1+\|s_j\|^2} \frac{s_j}{\|s_j\|} \tag{9}$$

Routing parameters, which are used to realize dynamic routing between capsule layers. The specific calculation is shown in Eq. (10) and Eq. (11).

$$b_{ij} \leftarrow \widehat{u_{j|i}} \cdot v_j \tag{10}$$

$$c_{ij} = \frac{\exp b_{ij}}{\sum_k \exp \widehat{b_{ik}}} \tag{11}$$

The loss function can be used to evaluate the implementation effect and performance of the model. The classical capsule network loss function adopts the interval loss function, and the specific calculation is shown in Eq. (12).

$$L_k = T_k max(0, m^+ - \| v_k \|)^2 + \lambda(1 - T_k) max(0, \| v_k \| - m^-)^2 \tag{12}$$

IV. CNN-CapsNets Classification Model

A. Model Structure

By integrating the strengths of two prominent deep learning network models, we have formulated the CNN-CapsNets model specifically for wheat disease and insect pest classification. This model is a fusion of classical convolutional neural networks, ResNet, Inception, and Capsule Networks. The CNN-CapsNets model effectively retains feature information through the utilization of the capsule layer within the Capsule Network architecture. Due to the shallow layer of the capsule network, the ability to obtain features is limited. So, in the model CNN-CapsNets we design multiple channel structures. In each channel we extract more image features through different numbers of convolution layers pooling layers and capsule combinations [22]. To mitigate under-fitting in capsule networks for large-scale images, a pooling layer is employed after convolutional feature extraction to downsize the image, thereby reducing computational parameters. Finally combined with the idea of Inception model to discard the full connection layer and implement classification in the SoftMax layer. The model structure is shown in Fig. 2.

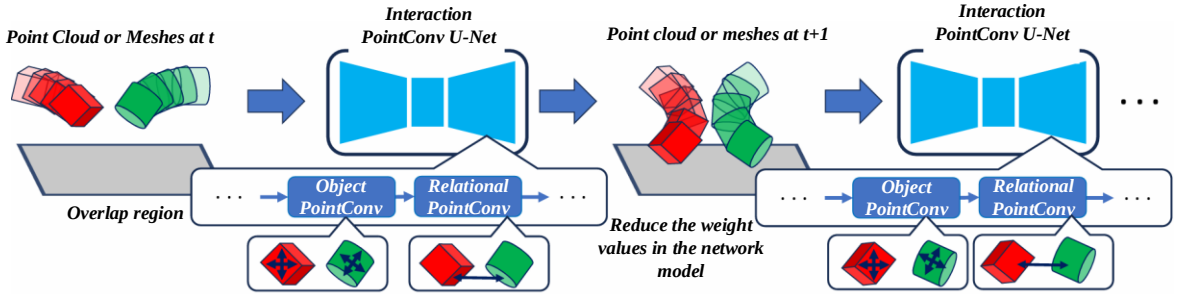

Fig. 2. Structural diagram of the CNN-Caps Nets classification model.

Fig. 2 shows that the CNN-Caps Nets model is multi-channel, dividing the Caps Net's result matrix into several parts. Parallel processing of different channels and lines enhances training efficiency.

B. Optimization Strategy

In the process of establishing the classification model of wheat diseases and insect pests, this paper takes the data set as the input sample information of the network model, and provides the following optimization strategy assumptions on training and optimizing the model. Although both convolutional neural network and capsule network have the ability to automatically extract features, the images of wheat diseases and insect pests taken in the production environment basically have complex backgrounds. If the images are segmented in advance, can the classification recognition degree of the classification model be improved? In this paper, the improved watershed algorithm and GrabCut algorithm are used to segment the image respectively, and the processed images are established respectively. The data set without image segmentation (dataset-no), the improved watershed image segmentation data set (dataset-w), and the GrabCut image segmentation data set (dataset-g). After that, the datasets were used for model training and quizzes, respectively. Finally, the performance and recognition of the classification model are taken as a reference to select the optimal image segmentation scheme.

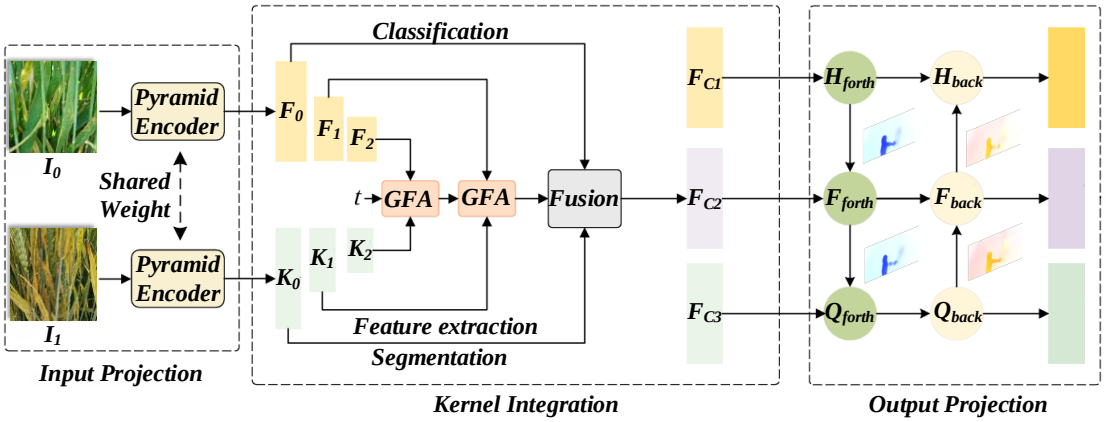

Fig. 3. Multimodal data processing and fusion process.

Fig. 3 shows multimodal data processing and fusion process. The classification model of pests and diseases in this study is designed as a multi-channel structure, which can extract features in different channels to improve the classification accuracy. Although this structure has the characteristic of parallel processing, it has a good effect on improving the efficiency of the model. However, the hardware requirements of parallel processing are also improved, and it is also necessary to consider that when the number of channels increases infinitely, the learned image features will be repeated, which will lead to redundancy in the classification model structure and affect the accuracy and efficiency of the type. Therefore, under the current hardware equipment conditions, the two-channel, four-channel, and eight-channel structure models are designed respectively. To determine the optimal number of channels, various network models with diverse architectures are trained and validated using a uniform dataset. However, it is worth noting that as the number of capsules increases, the computational load of the network model also escalates accordingly. In order to ensure a higher recognition degree and optimize the recognition efficiency of the acquired model, under the optimal number of paths, a model with 4, 8, 10, and 16 capsules in each primary capsule layer is designed. Fig. 4 shows comparison diagram of the multimodal data fusion effect.

C. Cross Validation

Cross-validation is often used as a precision test method, and its main purpose is to verify the stability of the designed network model and whether there is an over-fitting phenomenon [23]. Cross-validation is also called loop estimation. In a given training sample, most of the data is taken out for modeling, and a small part of the data is used to verify the established model. In this way, the suitable optimal network model can be found. Given the limited number of samples in the dataset, this study adopts the leave-one-out cross-validation method, where the original training set is partitioned into a new training set and a validation set in a 9:1 ratio.

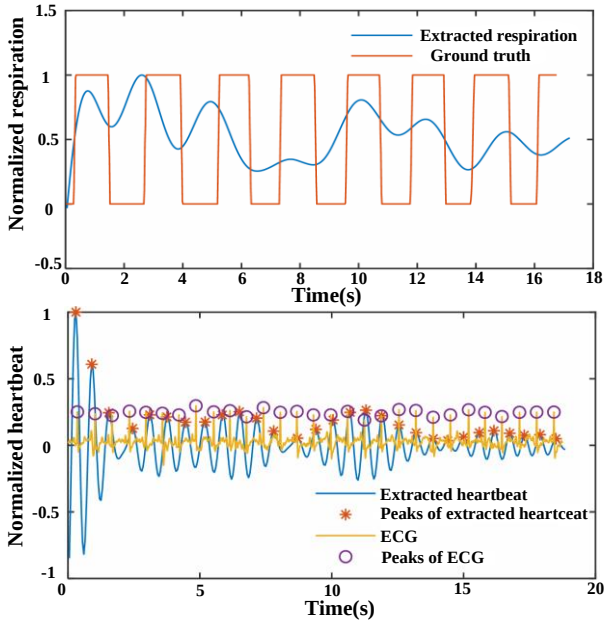

Fig. 4. Comparison diagram of the multimodal data fusion effect.

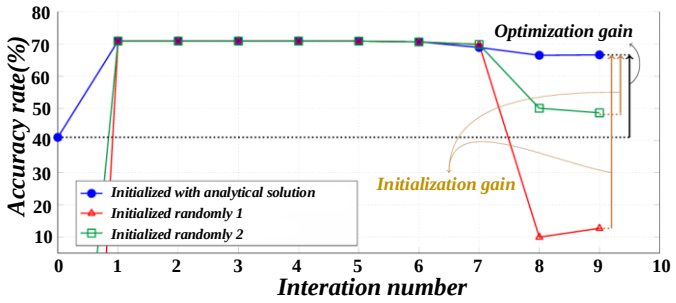

Fig. 5. Curve of image recognition accuracy of wheat disease pests over time.

Fig. 5 shows curve of image recognition accuracy of wheat disease pests over time. The training set trains the classification network, while the verification set checks for overfitting. Performance is assessed by comparing verification accuracy [24].

V. Result Analysis

A. Influence of Image Segmentation Selection on Model

In this study, the accuracy of the test set is used as the judging standard, and the reserved test set is divided into three processing methods: no image segmentation, improved watershed image segmentation, and GrabCut image segmentation to complete the test set establishment, and the data sets of different image segmentation algorithms. The model is trained, and the results are shown in the Fig. 6.

Fig. 6. results of datasets with different image segmentation algorithms. The figure indicates that the enhanced watershed and GrabCut segmentation dataset has minimal impact on enhancing the classification model's accuracy for training. Although GrabCut has a reduction in training time, when GrabCut image segmentation, the segmentation time is too long for large-size images [25]. So finally select the data set that does not segment the image in advance to train the model.

B. Influence of Channel Number on Model

The accuracy of the training set and verification set without image segmentation is used as the evaluation criterion. The training results of the network model with different channels of 2, 4, and 8 are shown in the figure, and the verification results are shown in Fig. 7. Fig. 7 shows training results of the network models for the different channels. Fig. 7 shows that as the number of model channels increases, training accuracy nears 97%, but training time also rises due to the added channels.

Fig. 8 shows distribution of identification accuracy for different wheat disease pest categories. Finally, a classification model with four channels is selected according to the verification accuracy and training time. In comparison to the other two models, the classification model with four channels exhibits the highest verification accuracy, while maintaining a relatively short training time, thus ensuring optimal training efficiency [26].

C. Effect of Capsule Quantity on Model

The training results of the network model with 4, 8, 10, 16 capsules in each primary capsule layer under the 4-channel model are shown. When using the same data set to train the network models with different capsule number structure, the training accuracy has no obvious difference, and the final training accuracy is in the range of 97 +0.45%.

Fig. 9 shows training results of the network model with different numbers of capsules in the main capsule layer. However, when comparing the verification accuracy, it can be seen that after 10 Epoch, the highest verification accuracy is the CNN-CapsNets model with 16 capsules in the primary glue layer [27, 28]. However, through continuous cycle verification, it is found that the accuracy of the four models rises gently and the accuracy begins to approach. Due to the limitation of device memory, when the number of capsules is increased again on the basis of 16, the time required to run the algorithm is too long. Therefore, based on the limitations of the current hardware equipment, considering the time and accuracy, this paper adopts a 4-channel classification model with 16 capsules.

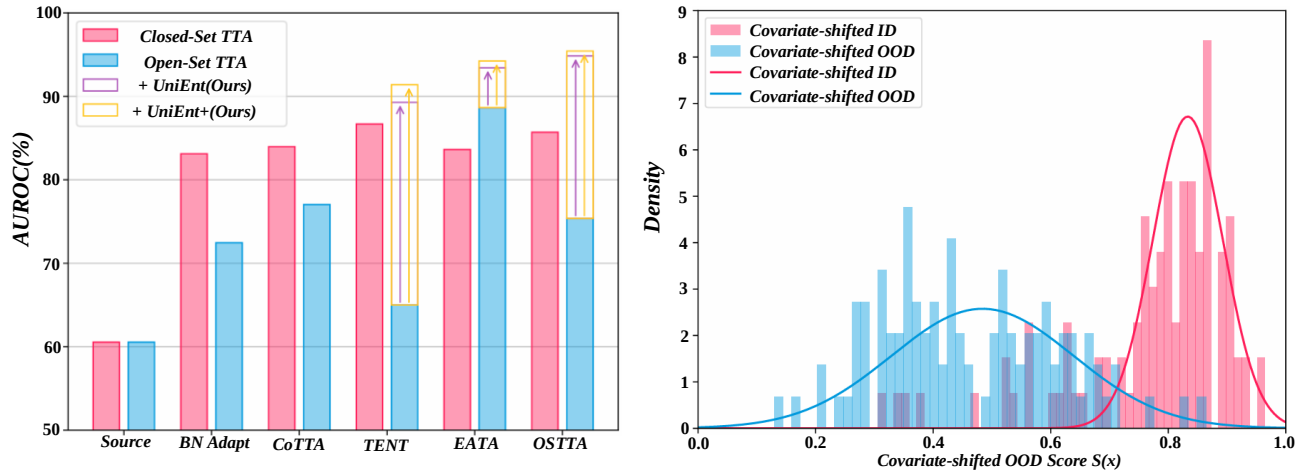

Fig. 6. Results of datasets with different image segmentation algorithms.

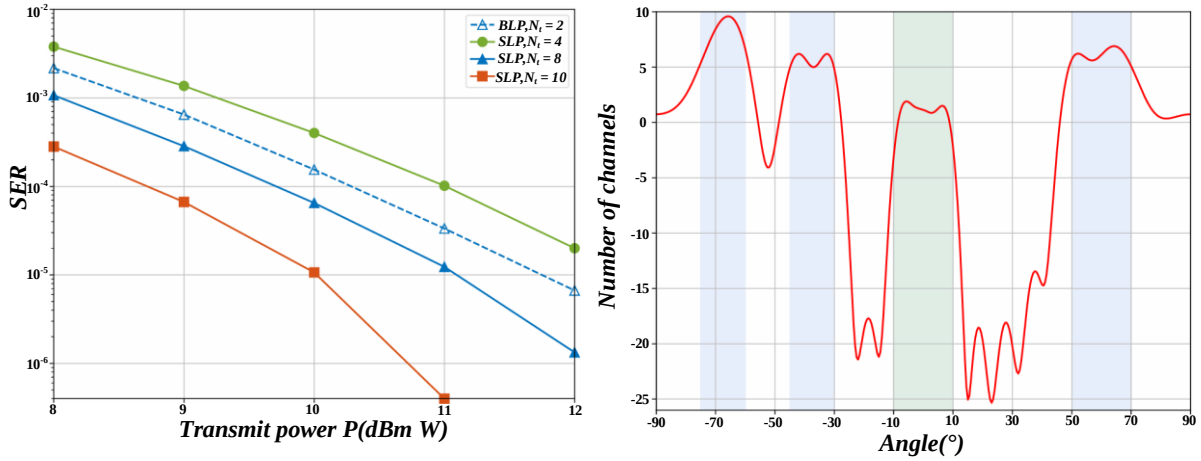

Fig. 7. Training results of the network models for the different channels.

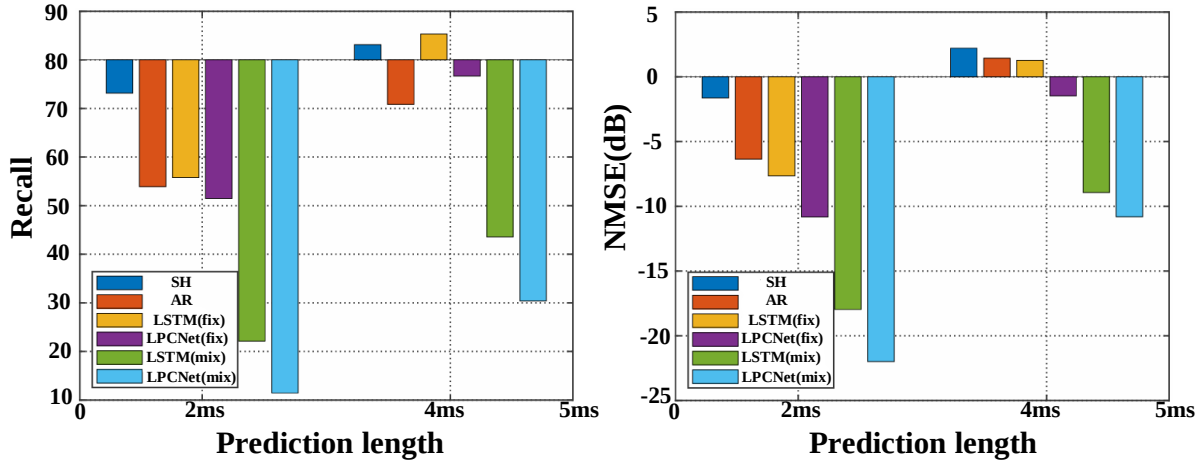

Fig. 8. Distribution of identification accuracy for different wheat disease pest categories.

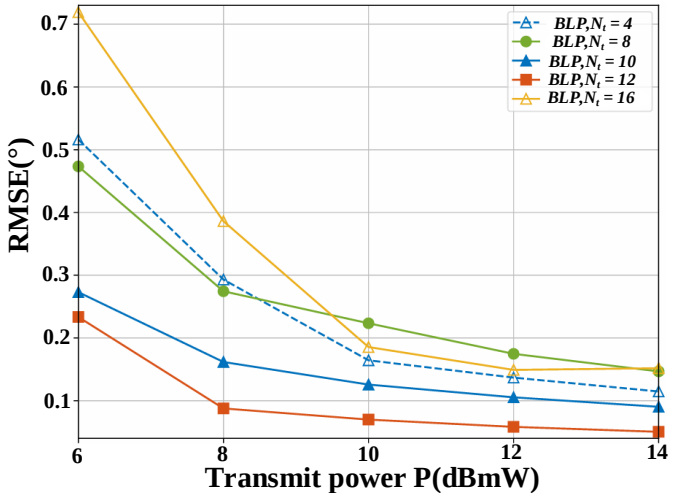

Fig. 9. Training results of the network model with different numbers of capsules in the main capsule layer.

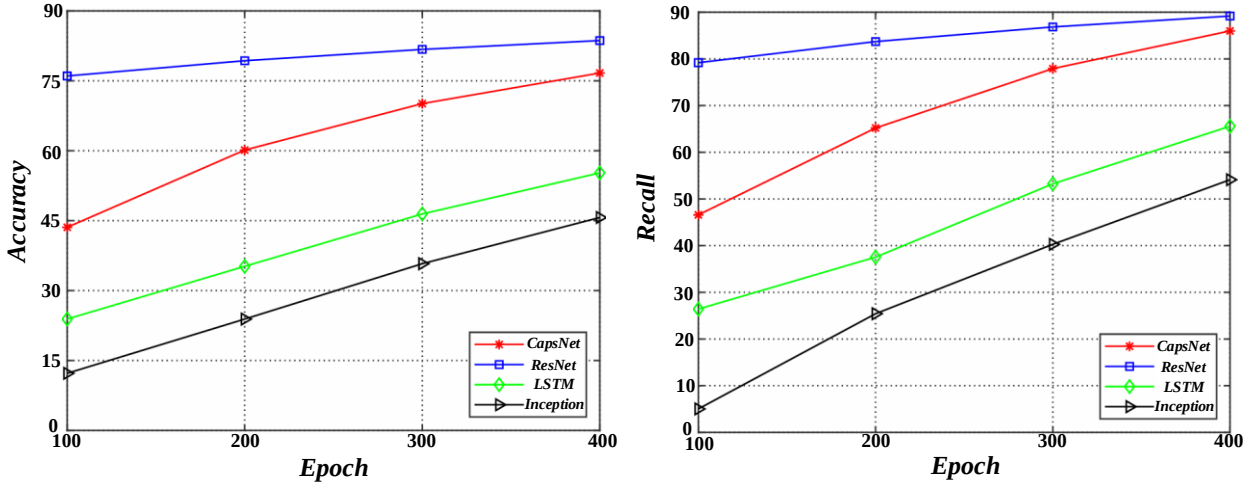

Fig. 10. Effect of multimodal data enhancement on identification performance.

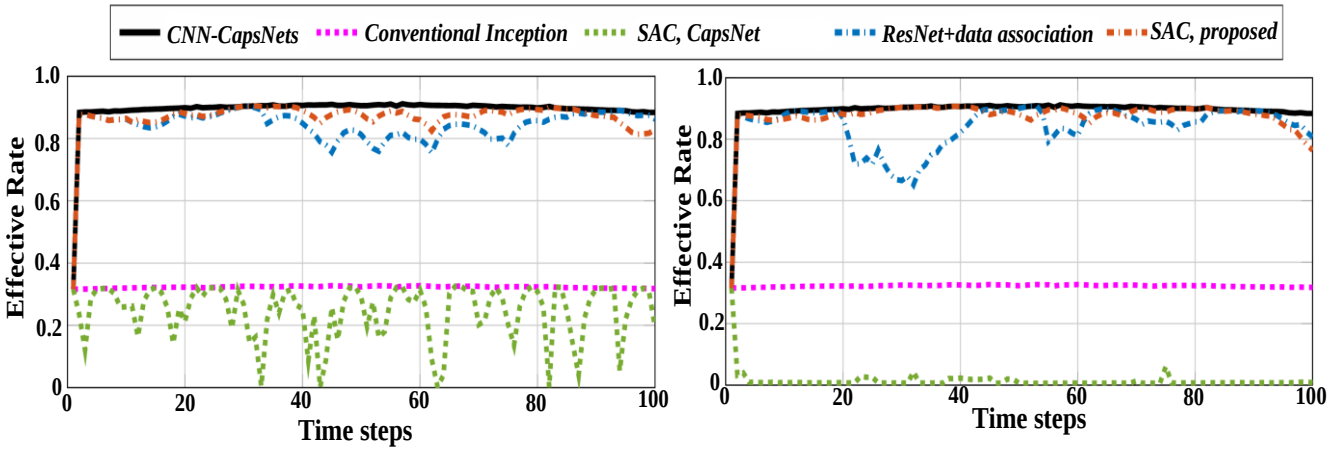

Fig. 11. Comparison of multiple model training results.

Fig. 10 shows the effect of multimodal data enhancement on identification performance. The CNN-CapsNets classification model was compared with classical models such as Inception model, ResNet model, CapsNet model, etc., and the results are shown in the Fig. 11.

As illustrated in the figure, the model employed in this study achieves a significantly superior classification accuracy compared to the Inception, ResNet, and CapsNet models. However, training time is longer than Inception and ResNet but shorter than CapsNet. This is because the CNN-CapsNets model extracts more features through multiple channels, which increases the cost of capsule layer parameter calculation and leads to increased training time. Compared with the CapsNet model, the training practice of the CNN-CapsNets model uses the convolution layer to extract image features, thereby reducing the dynamic routing computational overhead of using capsules to extract features.

The classification model is tested with a pre-dense test set, as shown in the figure. The number of training samples impacts recognition accuracy in deep learning models. More samples enhance the model's generalization and recognition accuracy [29]. Because the images in the training sample and the test sample are not pre-processed in this study, the image quality is different, which reduces the recognition rate to a certain extent. Among the four diseases, powdery mildew and leaf rust have higher recognition accuracy, not only because of the large number of samples, but also because these two diseases have prominent spot characteristics, for example, powdery mildew will appear on the surface of the plant with white powdery mildew. Mildew layer, the image features are obvious, and the network model is easier to extract features, so the classification effect is better [30].

VI. Conclusion

In this paper, four common wheat diseases and insect pests, wheat powdery mildew, wheat leaf rust, wheat scab and wheat midge, are used as research objects, combined with deep learning technology to study the classification and recognition method of pest images, and use Python, Java, and WeChat applet technology to build A wheat pest image recognition system.

To implement the classification of pests and disease images, a classification network model, termed CNN-CapsNets, is established by integrating convolutional neural networks and capsule networks. The model can extract more different features to generate feature maps through multi-channel and multi-level structural characteristics, and then save more image feature

information for classification through the high retention of capsule layer features, so the classification recognition rate is higher. Because the model can complete the internal calculation of the model in parallel in the form of multi-threads, the time required to process features is shortened, so it is faster than the classic capsule network in the same training environment.

Completed the development of the image recognition system of wheat diseases and insect pests. The migration of the pest classification model is realized by Python programming, and the API is developed to realize the call of the small program client, and the development and implementation of the identification system is completed. Finally, the recognition speed of the system is kept within 15s on average.

VII. FUNDING

This study was supported by Science and Technology Project of Henan Province (Project No. 242102111190) and Project Support for Key Scientific Research Projects of Henan Provincial University (Project No. 24B520017).

Improving the Prediction of Student Performance by Integrating a Random Forest Classifier with Meta-Heuristic Optimization Algorithms

Chao Ma
Academic Affairs Office of Jiangsu University, Zhenjiang 223001, Jiangsu Province, China

***Abstract*—Anticipating student performance in higher education is crucial for informed decision-making and the reduction of dropout rates. This study focuses on the intricate analysis of diverse educational datasets using machine learning, particularly emphasizing dimensionality reduction. The aim is to empower educators with data-driven insights, enabling timely interventions for academic improvement. By categorizing individuals based on their inherent aptitudes, the study seeks to mitigate failure rates and enhance the overall educational experience. The integration of predictive modeling, particularly employing the robust Random Forest Classifier (RFC), allows the academic community to proactively address challenges and foster a supportive learning environment, thereby improving student outcomes. To bolster predictive capabilities, the study adopts the RFC model and enhances its efficacy through advanced optimization algorithms, specifically Electric Charged Particles Optimization (ECPO) and Artificial Rabbits Optimization (ARO). These sophisticated algorithms are strategically integrated to refine decision-making processes and enhance predictive precision. Furthermore, the analysis of the input variables has been conducted to assess their individual impact on student performance. This analysis can help institutions identify and address areas for improvement in their management practices. The study's commitment to leveraging state-of-the-art machine learning and bio-inspired algorithms underscores its dedication to achieving precise and resilient predictions of the performance of 4424 students, ultimately contributing to the advancement of educational outcomes. The research outcomes highlight the superiority of the RFEC model, optimized through ECPO for RFC, in aligning with actual measured values, affirming its efficacy in predictive accuracy.**

Keywords*—Classification; student performance; machine learning; Random Forest Classifier; Electric Charged Particles Optimization; Artificial Rabbits Optimization

I. Introduction

Success in higher education is crucial for employment, social equity, and economic development. Addressing dropout rates stands out as a significant challenge for higher education institutions aiming to enhance their success. The definition of dropout lacks universal acceptance, leading to variations in the reported proportion of students leaving, influenced by differing definitions, calculation methods, and data sources [1]. Research often analyzes dropouts by considering the timing of the event, distinguishing between early and late dropouts [2]. Comparing dropout rates across institutions becomes challenging due to discrepancies in reporting practices [3]. Consequently, the diverse definitions and reporting variations contribute to the complexity of understanding and addressing the dropout issue in higher education [4].

In the domain of higher education research, student dropout is precisely defined as a distinctive manifestation of attrition, delineating individuals who disengage from the higher education system without acquiring a (first) degree and fail to complete their academic pursuits after that. This narrow conceptualization has gained prominence in scholarly investigations, as evidenced by studies such as those conducted by Schröder-Gronostay and Daniel, Ziegele, and Heublein, Schmelzer, and Sommer [5–7]. Consequently, alterations in degree programs or fields of study, interruptions in academic pursuits, and changes in institutions are categorized as different forms of attrition. Various methods exist for gauging the frequency of student dropout, with the most effective being statistical tracking of course progression, wherein the investigation status of each student is documented every semester [8–10].

As students' progress through multiple semesters in their academic programs, their evaluation occurs on a semester or term basis. The final academic status, whether at graduation or in a subsequent semester, is inherently influenced by preceding semesters. This pattern allows for the prediction of future semester performance based on historical academic data. Contemporary advancements in this predictive process leverage various Data Mining (DM) tools and techniques, particularly within the domain of Educational Data Mining (EDM) [11–13]. EDM focuses on the prediction of Student Academic Performance (SAP) [14] and often employs predictive models generated by DM tools. These models play a vital part in facilitating SAP prediction, enabling the monitoring of students' academic progress. This, in turn, assists in determining strategic interventions for both students and other education stakeholders [15–17].

II. Literature Review

The exploration, modeling, and prediction of student performance and academic progression have garnered substantial research attention in recent decades, as evidenced by an influx of scholarly contributions [18–20]. While early works in this domain trace back to the '70s and '80s, the contemporary surge in data availability from educational institutions, coupled with the ascent of data science, has ushered in novel research avenues [21–25]. Also, recent research related to this study's target, exemplified by Jayaprakash et al. delved

comprehensively into the intricate factors shaping students' academic accomplishments and their applicability in identifying students at risk. This study innovatively introduced an upgraded Random Forest classifier, striving for heightened accuracy in classification and prediction when juxtaposed with alternative algorithms like Naive Bayes, Bagging, Boosting, and the conventional Random Forest [26]. In alignment with this, Batool et al. employed the Random Forest classification model to anticipate students' final exam outcomes, leveraging publicly available datasets with diverse demographic features. The assessment incorporated meticulous methodologies such as hold-out and cross-validation [27]. Chen and Zhai's investigation took a multifaceted approach, employing three task-oriented educational datasets and implementing seven parameter-optimized machine learning methods for diverse performance prediction tasks [28]. Additionally, Asselmen et al. concentrated on the effectiveness of Ensemble Learning methods, proposing an innovative Predictive Feature Analytics (PFA) approach grounded in various models (Random Forest, XGBoost and AdaBoost,) to augment predictive accuracy in performance of students. The proposed models underwent rigorous evaluation across three distinct datasets [29].

Harnessing the capabilities of machine learning (ML) models to predict student dropout, enrollment, and graduation brings numerous advantages to both students and educational institutions. These models empower educators to accurately identify individuals in danger of dropping out, allowing them to create targeted support strategies that improve the likelihood of a successful post-graduation path. In this research, the recently developed Random Forest Classifier (RFC) method was applied to identify crucial factors influencing dropout, enrollment, and graduation outcomes. The RFC model underwent optimization using two distinct optimizers, Electric Charged Particles, and Artificial Rabbits, aimed at improving its overall performance. A subset of data was utilized from existing scientific articles during the training phase. After training, the model's effectiveness was assessed by testing it with separate data. Ultimately, the model that demonstrated optimal performance, surpassing the predefined benchmark ratio denoted as the actual measured value, was identified as the most adept in predictive capacities.

The research utilizes the RFC for predictive modeling and integrates advanced optimization algorithms, Electric Charged Particles Optimization (ECPO) and Artificial Rabbits Optimization (ARO). ECPO and ARO were chosen for their superior ability to navigate complex search spaces and avoid local optima, ensuring more accurate predictions. Additionally, the analysis of input variables helps identify areas for improvement in management practices. By leveraging state-of-the-art machine learning and bio-inspired algorithms, the study aims to achieve precise predictions for student performance, ultimately advancing educational outcomes.

The paper is structured as follows. Literature review is given in Section II. The detailed explanation of the model is given, and the meta-heuristic techniques employed are covered in Section III. In addition, the description of the dataset and its processing are covered in depth in this section. The created models' performance assesses in Section IV. In Section V and VI, the conclusion and future works shows the summary of paper based on results and description.

III. Materials and Methodology

A. Random Forest Classifier (RFC)

The RF is a supervised ML algorithm tailored for classification and prediction tasks, highlighting its prowess in classification. In this method, the term "forest" denotes a collection of numerous decision trees, and the model's robustness grows as more trees are added. Utilizing diverse data samples, the RFC method constructs individual decision trees. When faced with the challenge of predicting the class for new data points, each tree independently provides its prediction, thereby playing a role in the overall decision-making process. The culmination of this process involves identifying the most effective solution through a voting mechanism, with each decision tree contributing a vote for an input vector (x). The final prediction (C_{rf}^{B}) is determined through a majority vote. Functioning as an ensemble method, this model leverages the power of multiple uncorrelated models (trees) working together to surpass the performance of a single model. By adopting this collaborative approach, errors are mitigated, and overall accuracy is improved, as a range of diverse decision trees collectively contribute to the ultimate prediction.

In shaping decision trees, crucial considerations involve the selection of attributes and pruning techniques. Among these, the Gini Index method holds prominence as a commonly favored approach for attribute selection within RFC [30]. This method gauges the impurity of attributes concerning their respective classes. The assessment involves measuring impurity by randomly selecting a sample case from the training set and predicting its class as C_i. This informed attribute selection is articulated through the following equation, where $(F(C_i,T)/(|T|)$ signifies the probability that a chosen case belongs to the class C_i [31].

$$\sum\sum_{j\neq i}(F(C_i,T)/(|T|)(F(C_j,T)/(|T|) \qquad (1)$$

When establishing a prediction model with RFC, it is imperative to define two key parameters: the number of trees and each tree node's assigned input variables. RFC is composed of N decision trees (with N being user-defined), and these trees collaboratively contribute their votes to ascertain the class of new data points, relying on their predictions [32].

The framework associated with RFC is displayed in Fig. 1.

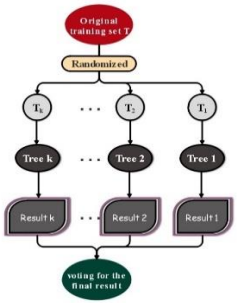

Fig. 1. Flowchart of the RFC.

B. Electric Charged Particles Optimization (ECPO)

Drawing inspiration from the interactions of electric-charged particles (ECPs), the ECPO functions as a population-based algorithm. It incorporates several internal parameters, each serving a specific purpose. The total number of ECPs is denoted as nECP, as well as nECPI represents the number of interacting ECPs. Additionally, naECP denotes the archive pool's size, and MaxITER indicates the maximum number of iterations.

One crucial aspect is nECPI, determining the number of particles engaged in interactions using a unique strategy. During these interactions, when two particles come into contact, a distinctive dynamic unfolds. The worst-performing particle repels the best one, while simultaneously, the best-performing particle attracts the worst one. This interplay within the ECPO framework contributes to its optimization process.

Algorithm 1, encapsulating the pseudo-code of the ECPO algorithm [33]:

ALGORITHM 1. PSEUDO-CODE OF ECPO OPTIMIZER

```

1) Initialization: Commencing with the era of nECP-charged particles in the search space, the ECPO, like other population-based metaheuristics, sees the sorting of these charged particles from the finest to the worst. The charged particles in this ECPO version are generated randomly utilizing an ordinary dispersion method. Nevertheless, the implementation of any other strategy for creating the initial ECPs can be comfortably carried out by the user.

2) Archive pool: Alongside the generated population, an archive pool, denoted as archiveECP and of a predetermined size naECP, is established and populated with the best ECPs. The role of this archive is to retain only the finest ECPs, as will be detailed later. The archive ECP is updated at the conclusion of each cycle.

3) Selection: Selecting the appropriate ECPs is a critical step that significantly influences the algorithm's functionality and the results of subsequent phases. In the ECPO algorithm, a random set of charged particles, denoted as nECPI, is selected from the population. Subsequently, these particles are arranged in order from the worst to the best. The chosen particles undergo the interaction phase in accordance with the specified plan.

4) Interaction: As previously noted, not all ECPs engage in communication with each other; only a selected subset, determined by nECPI, participates in this phase. In this stage, the chosen nECPI particles interact with each other in diverse ways, as specified in the plan. For instance, consider a scenario where nECPI = 3 (this applies to any other value of nECPI as well). These particles are arranged from the best to the worst and denoted as. The particles denoted as ECP_1, ECP_2, and ECP_3 are arranged from the best to the worst. The overall best particle is represented as ECP_{best}.

- Strategy 1

In the initial strategy, communication occurs among the chosen ECP utilizing only the best overall ECP, denoted as ECP_{best}, and one other ECP at a time. In this specific scenario where three ECPs are involved in the interaction, each ECP generates two new particles labeled $ECP_{i\ new\ 1}$ and $ECP_{i\ new\ 2}$ (where i represents the index of the chosen ECP).

- For ECP_1 :

Initially, it is simultaneously influenced by ECP_2 and ECP_{best} to transition to $ECP_{1\ new\ 1}$. Subsequently, ECP_1 is influenced concurrently by ECP_3 and ECP_{best} to transition to $ECP_{1\ new\ 2}$. The consequent force required to move ECP_1 to $ECP_{1\ new\ 1}$ is given by:

$$F = F_{b1} + F_{21} \tag{2}$$

In this context, F_{b1} denotes the force exerted by ECP_{best}, and F_{21} represents the force exerted by ECP_2 on ECP_1.

Here is how these two forces are expressed:

$$F_{b1} = \beta \times (ECP_{best} - ECP_1) \tag{3}$$

$$F_{21} = \beta \times (ECP_1 - ECP_2) \tag{4}$$

The random number β can be generated utilizing various distributions.

The forces can be expressed to indicate that ECP_{best} attracts ECP_1 (since ECP_{best} is superior to ECP_1), while ECP_2 repels ECP_1 (as ECP_2) is inferior to ECP_1).

Therefore, the cumulative force driving ECP_1 to transition to $ECP_{1\ new\ 1}$ is determined by:

$$ECP_{1\ new\ 1} = ECP_1 + F$$

$$= ECP_1 + F_{b1} + F_{21}$$

$$= ECP_1 + \beta \times (ECP_{best} - ECP_1) + \beta \times (ECP_1 - ECP_2) \tag{5}$$

Similarly, the total force propelling ECP_1 to transition to $ECP_{1\ new\ 2}$ can be expressed as:

$$ECP_{1\ new\ 2} = ECP_1 + F$$

$$= ECP_1 + F_{b1} + F_{31}$$

$$= ECP_1 + \beta \times (ECP_{best} - ECP_1) + \beta \times (ECP_1 - ECP_3) \tag{6}$$

- For ECP_2 :

Initially, it is concurrently influenced by ECP_1 and ECP_{best} to transition to $ECP_{2\ new\ 1}$. Following that, ECP_2 is simultaneously influenced by ECP_3 and ECP_{best} to move to $ECP_{2\ new\ 1}$. The forces acting on ECP_2 share the same expressions as Eq. (5) as well as Eq. (6).

- For ECP_3 :

The third particle experiences a dual influence, initially from ECP_1 and ECP_{best}, leading to its transition to $ECP_{3\,new\,1}$. Subsequently, ECP_3 is simultaneously affected by ECP_2 and ECP_{best}, directing its movement to $ECP_{3\,new\,2}$.

- Strategy 2

In the second strategy, ECP_{best} is not connected with the remaining ECPs, and the interaction is carried out on the selected ECP using all the remaining interacting ECPs. Subsequently, in the outlined scenario where there are three interacting ECPs, one new ECP is generated by each ECP, referred to as $ECP_{i\,new}$ (where i denotes the index of the chosen ECP).

- For ECP_1 :

ECP_1 is simultaneously influenced by ECP_2 as well as ECP_3, inducing movement to $ECP_{1\,new}$. The resulting force required to transition ECP_1 to $ECP_{1\,new}$ is expressed by:

$$F = F_{21} + F_{31} \tag{7}$$

F_{31} represents the force exerted by ECP_3 on ECP_1, and F_{21} is the force exerted by ECP_2 on ECP_1. Therefore, the cumulative force propelling ECP_1 to transition to $ECP_{1\,new}$ is determined by:

$$ECP_{1\,new} = ECP_1 + F_1$$
$$= ECP_1 + F_{21} + F_{31}$$
$$= ECP_1 + \beta \times (ECP_1 - ECP_2) + \beta \times (ECP_1 - ECP_3) \tag{8}$$

- For ECP_2 :

The second particle, ECP_2, is concurrently influenced by the first and third particles (ECP_1 and ECP_3), resulting in movement to $ECP_{2\,new}$. The resulting force required to transition ECP_1 to $ECP_{1\,new}$ is expressed by:

$$F = F_{12} + F_{32} \tag{9}$$

F_{12} is the force exerted by ECP_1 on ECP_2, and F_{32} is the force exerted by ECP_3 on ECP_2. The overall force propelling ECP_2 to transition to $ECP_{2\,new}$ is determined by Eq. (8).

- For ECP_3 :

ECP_3 is simultaneously influenced by ECP_1 and ECP_2 with the force expressed as:

$$F = F_{13} + F_{23} \tag{10}$$

F_{13} is the force exerted by ECP_1 on ECP_3, and F_{23} is the force exerted by ECP_2 on ECP_3. The detailed expressions for F_{13} and F_{23} are akin to the expressions in Eq. (9). Consequently, $ECP_{3\,new}$ will transition to $ECP_{3\,new}$.

- Strategy 3

In the third strategy, a combination of the first and second strategies is applied to generate new ECPs. Consequently, for the illustrated scenario where nECPI = 3, nine new ECPs are generated, with 6 resulting from strategy 1 and 3 from strategy 2. The equations previously described are applicable in this context.

At the conclusion of the interaction phase, a set of ECPs is termed new-ECP, and its size remains consistent with the original ECP population. This remains true regardless of the chosen nECPI or the strategy utilized. In simpler terms, if the process begins with 30 particles, the population size remains 30 particles after the interaction phase, irrespective of the strategy or the number of particles involved in the interaction.

In the final phase of ECPO, the newly generated ECPs are subject to bounds checks to ensure they fall within the defined search space. If any ECPs are found to exist outside these bounds, adjustments are made accordingly. Subsequently, a subset of the newly created ECPs undergoes expansion based on the probability of diversification (Pd). The diversity operator, integral to ECPO, incorporates information from both the new ECP population (newECP) and the existing archive pool (archiveECP).

Following the diversification phase, the population is updated by aligning the new population with the previously established archive pool. The best nECP particles, ranked from 1 to nECO, shape the updated population. This refined population then undergoes the same procedure as explained earlier for another cycle.

In terms of termination, the current version of ECPO concludes after iterating MAXIter times, utilizing the various phases described above. However, users retain the flexibility to terminate the process differently if desired.

C. Artificial Rabbits Optimization (ARO)

ARO, or Adaptive Rabbit Optimization, draws its inspiration from the resourceful survival techniques employed by rabbits in their natural surroundings. These techniques, intricately designed to outwit predators and ensure effective evasion, form the foundation of ARO. The algorithm assimilates the foraging and hiding strategies inherent in rabbits, along with their adept energy management, creating a dynamic framework that seamlessly transitions between these strategic modes [34].

1) Detour foraging: During the quest for sustenance, a distinctive detour foraging strategy is observed in rabbits, with a focus on distant food sources and a potential oversight of nearby ones. Within the ARO framework, a community of rabbits is envisioned, each possessing its designated territory comprising burrows and grass. Encounters among these rabbits at each other's foraging sites occur randomly. In this scenario, a mathematical model is presented to articulate the deviation search behavior demonstrated by rabbits.

$$\vec{B}_i(t+1) = x_j(t) + S \times (x_i(t) - x_j(t)) + w(0.5 \times (0.05 + r_1)) \times m_1,$$
$$i, j = 1, \dots, n \text{ and } j \neq 1 \tag{11}$$

$$S = M \times v \tag{12}$$

$$M = (e - e^{\left(\frac{t-1}{I}\right)^2}) \times \sin(2\pi r_2) \tag{13}$$

$$v(y) = \begin{cases} 1 & if \quad y = f(1) \\ 0 & else \end{cases} \quad k = 1, \dots, d \text{ and } l = 1, \dots, \lceil r_3 \times d \rceil \tag{14}$$

$$f = p(d) \quad (15)$$

$$m_1 = N(0,1) \quad (16)$$

In the given framework, n denotes the quantity of rabbits within the population, while d represents the dimension of the problem. The position of the $i-th$ rabbit at time t + 1 is denoted by $\vec{B}_i(t+1)$. The variable n_1 is distributed according to the standard normal distribution. T signifies the maximum number of iterations, and $x_i(t)$ denotes the position of the $i-th$ rabbit at time t. The variable p generates a random rearrangement (permutation) of integers ranging from 1 to d. Additionally, w is a mapping tool within the algorithm, facilitating the random selection of elements from the explorer to introduce variation in the search process. The random numbers r_1, r_2, r_3 fall within the range of (0, 1). Lastly, S is introduced to represent the run length, symbolizing the speed of movement during detour foraging in the algorithm. This comprehensive set of parameters and variables collectively defines the key components and dynamics of the rabbit optimization algorithm.

2) Random hiding: To secure their survival, rabbits demonstrate a proclivity for randomly selecting one of their burrows as a shelter. The mathematical model capturing this stochastic shelter-seeking behavior is articulated through the following equations. The formulation of the $j-th$ burrow of the $i-th$ rabbit is expressed as:

$$\vec{B}_i(t+1) = x_i(t) + N \times f \times \vec{x}_i(t), \;\; i,j = 1,\dots,n \; and \; j \neq 1 \quad (17)$$

$$D = \frac{I-t+1}{I} \times r_4 \quad (18)$$

$$m_2 = N(0,1) \quad (19)$$

$$f(y) = \begin{cases} 1 & if \;\; y = g(1) \\ 0 & else \end{cases} \;\; k = 1,\dots,d \quad (20)$$

$$\vec{R}_{i,r}(t) = \vec{x}_i(t) + N \times f \times \vec{x}_i(t) \quad (21)$$

The parameter of hiding, denoted as N, undergoes linear reduction throughout the iteration process from 1 to $\frac{1}{I}$ with the incorporation of a random perturbation.

In the final stages of implementing either the random hiding or detour foraging strategies, the update to the position of the $i-th$ rabbit adheres to the formula outlined in Eq. (22):

$$\vec{x}_i(t+1) = \begin{cases} \vec{x}_i(t) & g(\vec{x}_i(t)) \leq g\left(\vec{B}_i(t+1)\right) \\ \vec{B}_i(t+1) & g(\vec{x}_i(t)) > g\left(\vec{B}_i(t+1)\right) \end{cases} \quad (22)$$

3) Energy shrinks: Due to the recurrent cycles of detour foraging and random hiding, the energy level of the rabbits gradually diminishes. Therefore, the incorporation of an energy factor becomes crucial within the ARO framework:

$$E(t) = 4\left(1 - \frac{t}{I}\right) ln\frac{1}{r} \quad (23)$$

The algorithmic steps for ARO in Algorithm 2, are displayed as Pseudo-code form as well as Fig. 2 shows the flowchart of ARO.

D. Data Collection

The primary objective of this investigation is to create a robust framework for the precise assessment of student's academic achievements, taking into account contextual nuances. A crucial step in this process involves the thorough preprocessing of the dataset, wherein textual data undergoes conversion into numerical values. This transformation forms the foundation for the application of ML algorithms and advanced statistical methodologies, facilitating a comprehensive analysis of the dataset. The diverse variables within the dataset are systematically categorized, ensuring a structured approach to understanding and predicting academic performance. This strategic approach aims to enhance the accuracy and effectiveness of the assessment, providing valuable insights into the complex landscape of students' academic achievements.

The research incorporates a comprehensive set of inputs to explore various dimensions influencing students' academic performance.

- The Student Demographics category covers details such as Marital Status, Nationality, and Gender, including additional factors like being a Displaced Candidate and the age at enrollment.
- Parental Information delves into the educational qualifications and occupations of both mother and father, providing insights into the familial context.
- Financial and Support Information offers a comprehensive view of students' financial backgrounds, including their academic fee situation, scholarship status, and potential debt.
- Economic Indicators introduce external factors like the Academic Unemployment Rate, Educational Inflation Rate, and GDP, providing contextual economic insights.
- Enrollment Information examines the mode and order of application, as well as the specialized field of study chosen by students.

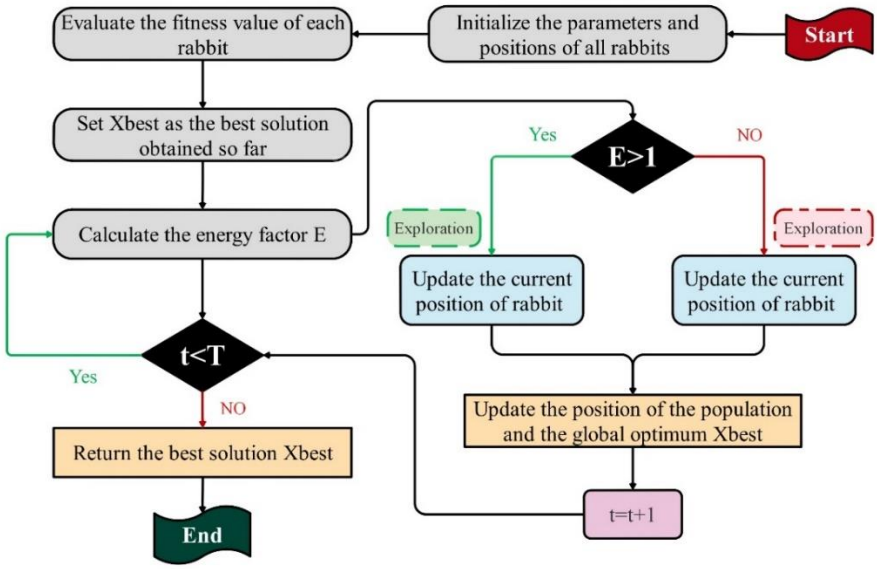

Fig. 2. Flowchart of ARO.

- Finally, Academic Performance metrics include attendance regimes, past educational credentials, and a comprehensive breakdown of curricular units, encompassing enrollment, evaluation, approval, grading, and units without evaluation.

This multifaceted approach ensures a nuanced analysis, considering diverse aspects that collectively contribute to the intricate landscape of student academic performance [17].

In Fig. 3, the visual representation intricately displays the impact of inputs on each other and, crucially, on the target variable. The color spectrum, from white (positive impact) to purple (negative impact), guides the discernment of dynamics at play. Parameters show a self-reinforcing nature, evident from bold white along the main diameter. The final line outlining each input's impact on the target reveals crucial insights. Inputs like Tuition Fees Up to Date, Scholarship Recipient, Curricular Units (evaluations), Curricular Units (approved), and Curricular Units (grade) emerge as influential with substantial positive impact.

Conversely, Debtor, Gender, and Age at Enrollment show predominantly negative impacts. The remaining parameters in pale colors signify minimal influence, underlining limited significance in the predictive context. This visual analysis offers a nuanced perspective on dataset relationships, guiding focus toward the most impactful variables for predictive modeling.

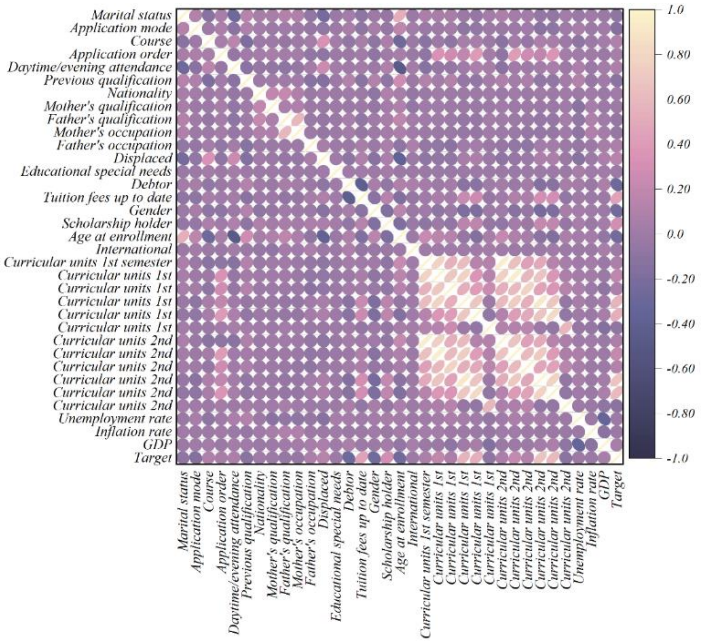

Fig. 3. Correlation matrix for the input and output variables.

E. Hyperparameter

Table I presents the hyperparameters used for the different developed models in this study: RFC, RFAR, and RFEC. These hyperparameters significantly influence the performance and efficiency of each model.

TABLE I. RESULT OF HYPERPARAMETERS FOR THE DEVELOPED MODELS

Models	n_estimators	max_depth	min_samples_split	min_samples_leaf
RFC	20	10	2	1
RFAR	123	1311	2	1
RFEC	56	64	2	1

IV. RESULTS

A. Model Applicability Assessment

In assessing classification problems, Accuracy is a commonly employed metric to gauge a model's overall performance. This metric relies on four essential elements: True Positives (Tp) for accurate positive predictions, True Negatives (Tn) signifying precise negative predictions, False Positives (Fp) representing inaccurate positive predictions, and False Negatives (Fn) indicating incorrect negative predictions. However, the utility of Accuracy diminishes in situations involving imbalanced data, where it tends to favor the majority class, limiting its interpretability. To address this drawback, three additional evaluation metrics—namely Recall, Precision, and F1-Score—are frequently utilized. These metrics provide a more nuanced understanding of a model's performance, particularly in the presence of imbalanced class distributions. Presented through mathematical equations, typically numbered from 24 to 27, these metrics collaboratively contribute to a refined and comprehensive assessment of the effectiveness of a classification model.

$$Accuracy = \frac{Tp+Tn}{Tp+Tn+Fp+Fn} \quad (24)$$

$$Precision = \frac{Tp}{Tp+Fp} \quad (25)$$

$$Recall = TpR = \frac{Tp}{P} = \frac{Tp}{Tp+Fn} \quad (26)$$

$$F1\_score = \frac{2 \times Recall \times Precision}{Recall+Precision} \quad (27)$$

B. Convergence Results

The utilization of a convergence diagram is a prevalent practice in scientific discourse, employed to visually elucidate the progression of convergence or optimization inherent in a model or algorithm across successive iterations. This methodology finds frequent application in diverse domains, including but not limited to machine learning, optimization techniques, and computational science. In the context of this article, the convergence diagram, as illustrated in Fig. 4, functions as a tool for juxtaposing the convergence trajectories of the two optimized iterations of the RFC model, namely RFEC and RFAR. A discerning analysis of the diagram reveals that, during the initial iterations, the RFEC model attains a superior convergence level compared to the RFAR model. Notably, the RFEC model sustains this superiority throughout subsequent iterations, culminating in its establishment as the preeminent model. This visual representation effectively communicates the distinctive convergence dynamics of the two optimized models, substantiating the designation of the RFEC model as the optimal choice within the scope of this study.

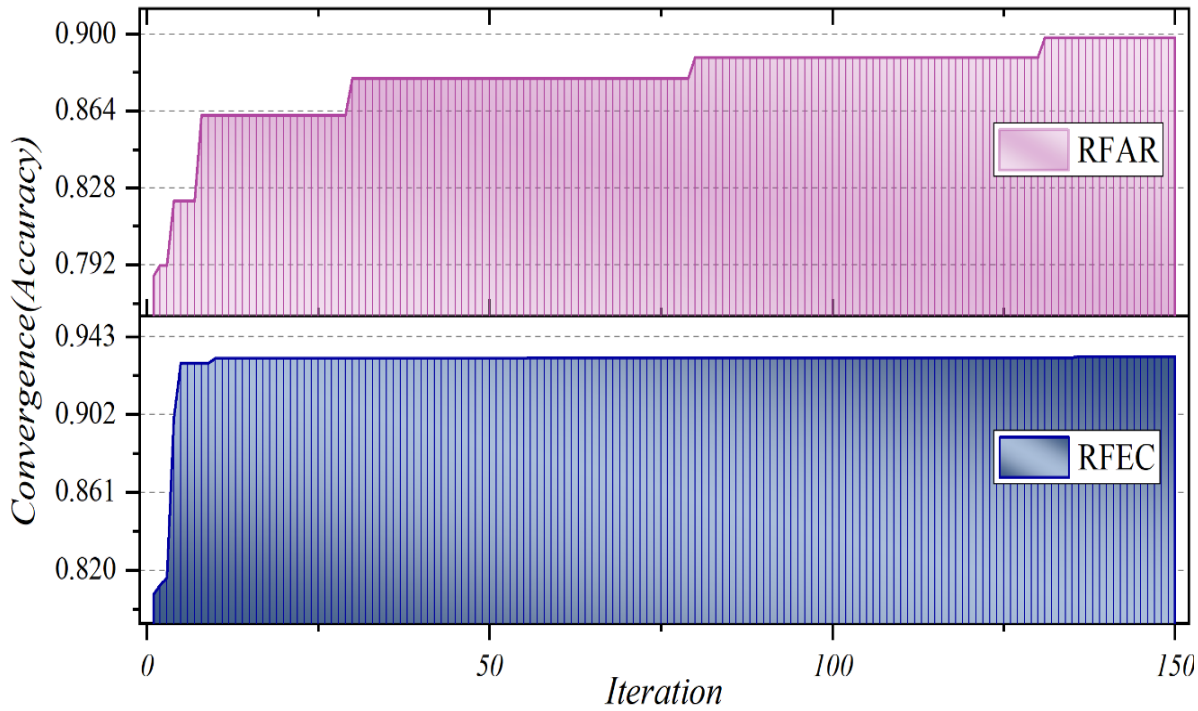

Fig. 4. Line plot for convergence of hybrid models.

C. Hyperparameter

D. Comparing Results of Predictive Models

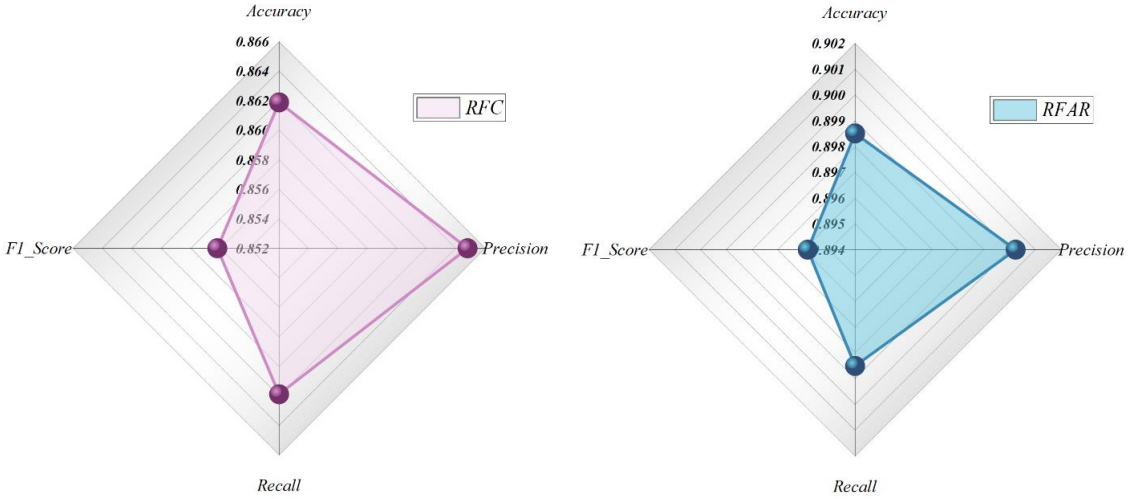
Table II encapsulates a comprehensive compilation of outcomes emanating from the formulated RFC models, facilitating a nuanced comprehension of their performances. Concurrently, Fig. 5 employs a radar plot to present an evaluative comparison among these models. The objective is to discern the model that exhibits the highest precision in predictions when contrasted with real-world outcomes. A substantial proportion of the dataset undergoes rigorous training, and the remaining values are meticulously subjected to testing. The results, spanning the entire dataset, are systematically documented. The pivotal parameter for model assessment lies in all datasets, graphically elucidated in Fig. 5. The evaluation of accuracy is conducted across three distinct phases: Train, Test, and All. In the training phase, the RFEC model emerges as the frontrunner, boasting an accuracy of 0.9997, outpacing the RFC model at 0.9060 and the RFAR model at 0.8949. Transitioning to the testing phase, the RFAR model excels with an accuracy of 0.8985, surpassing the RFC model at 0.7589 and the RFEC model at 0.7566. Remarkably, in the comprehensive all data groups, the RFEC model ascends to the zenith with an accuracy of 0.9326, followed by the RFAR model at 0.8985 and the RFC model at 0.8619. The visual representation encapsulated in Fig. 5 distinctly underscores the discernible superiority of the RFEC model in predictive accuracy, affirming its prominence among the models considered.

E. Classification Outcomes

Table III provides a detailed breakdown of Precision, Recall, and F1-score metrics concerning the classification of 4424 students based on their academic performance. These tabulated metrics offer valuable insights, illuminating the model's precision in positive predictions, ability to accurately identify true positives, and overall effectiveness in classifying students based on their academic achievements. The precision values reflect the accuracy of the model in making positive predictions, while recall signifies the model's ability to capture true positives. Additionally, the F1-score offers a comprehensive measure that balances precision and recall, providing a holistic assessment of the model's performance in classifying students across various academic performance categories. These tables play a pivotal role in the comprehensive evaluation of the model's effectiveness in handling diverse aspects of academic performance prediction.

TABLE II. RESULT OF DEVELOPED MODELS FOR RFC

Phase	Index values	Models		
		RFC	RFAR	RFEC
Train	Accuracy	0.9060	0.8949	0.9997
	Precision	0.9123	0.8971	0.9997
	Recall	0.9060	0.8949	0.9997
	F1-score	0.9031	0.8924	0.9997
Test	Accuracy	0.7589	0.8985	0.7566
	Precision	0.7496	0.8999	0.7495
	Recall	0.7589	0.8985	0.7566
	F1-score	0.7446	0.8963	0.7449
All	Accuracy	0.8619	0.8985	0.9326
	Precision	0.8648	0.9002	0.9258
	Recall	0.8619	0.8985	0.9268
	F1-score	0.8562	0.8958	0.9258



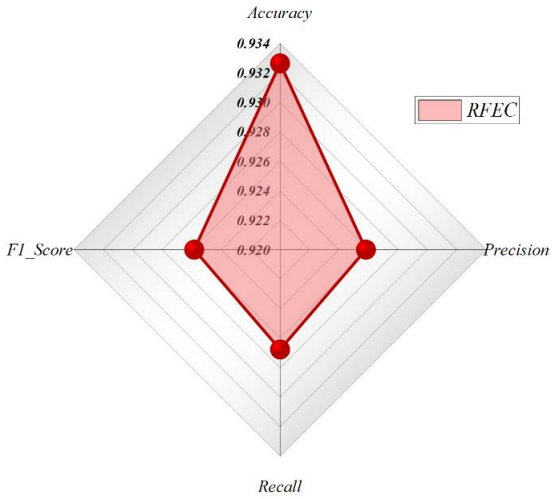


Fig. 5. Radar plot for achievement of developed models based on evaluators.

1) Precision: In this evaluative index, a meticulous examination of each model's performance across distinct categories elucidates the RFEC model's prominence. Notably, its proximity to the numerical value 1 stands out conspicuously, surpassing the comparative performance of other models. This observation underscores the RFEC model's superior precision and effectiveness in positive predictions within the evaluated groupings.

2) Recall: In this evaluation index, uniform performance is observed across all models in the graduate group, registering an identical score of 0.98. Contrarily, within the dropout and enrollment categories, the singular RFC model exhibited inferior performance compared to other models. Further scrutiny reveals notable distinctions between the two optimized models: the RFEC model outperforms the RFAR model by 14.08% in the enrollment group and 4.59% in the dropout group. These discernible variations underscore the efficacy of optimization, particularly emphasizing the superior predictive capabilities of the RFEC model in specific academic performance categories.

3) F1-score: In this performance index, the RFEC model emerges as the most adept, achieving a commendable accuracy rate of 93% in dropout predictions, 85% in enrollment, and 95% in graduation. These results position the RFEC model as the standout performer, showcasing its efficacy in accurately predicting students' academic outcomes across diverse performance categories.

In Fig. 6, a comprehensive examination is conducted, contrasting the predictive performance of models against actual measured values. Notably, within the dropout category, the RFEC model exhibits a superior level, closely aligning with the measured values, indicating accurate predictions. Similarly, in the enrollment grouping, the RFEC model demonstrates predictions that closely resemble reality. However, in the graduate category, the RFAR model outperforms other models. In summary, the RFEC model displays superior performance compared to its counterparts, and while its performance in the graduate group may appear suboptimal, its overall predictive accuracy in other categories warrants commendation.

TABLE III. EVALUATION INDEXES OF THE PERFORMANCE OF DEVELOPED MODELS

Model	Situation	Index values		
		Precision	Recall	F1-score
RFC	Dropout	0.93	0.83	0.88
	Enrolled	0.82	0.59	0.69
	Graduate	0.83	0.98	0.9
RFAR	Dropout	0.95	0.87	0.91
	Enrolled	0.87	0.71	0.78
	Graduate	0.88	0.98	0.93
RFEC	Dropout	0.96	0.91	0.93
	Enrolled	0.89	0.81	0.85
	Graduate	0.92	0.98	0.95

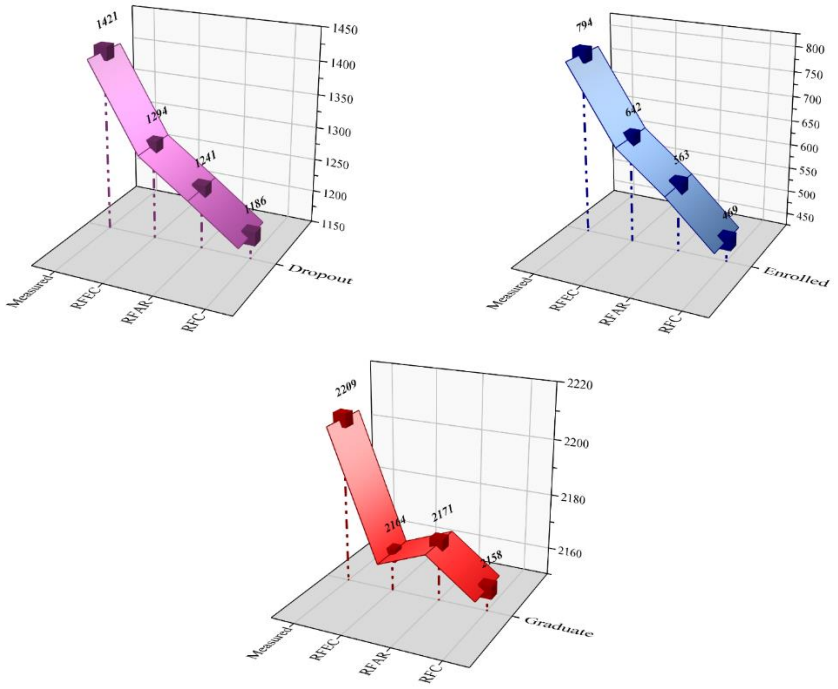

Fig. 6. 3D Ribbon plot for the comparison between the measured and predicted values.

In Fig. 7, a detailed representation of the confusion matrix unveils the accurate classification of students and instances of misclassifications. Within the RFEC model, a meticulous examination reveals the accurate classification of 4100 out of 4424 students across various academic grades. Specifically, within these classifications, 1294 students were accurately identified in the Dropout category, 642 in the Enrolled category, and 2164 in the Graduate category. However, the model exhibited 324 instances of misclassification. In contrast, the RFAR model displayed 449 misclassifications, while the conventional RFC model accurately misclassified 611 students. This comprehensive breakdown provides valuable insights into the models' performance, aiding in a nuanced understanding of their strengths and limitations in accurately categorizing students into their respective classes.

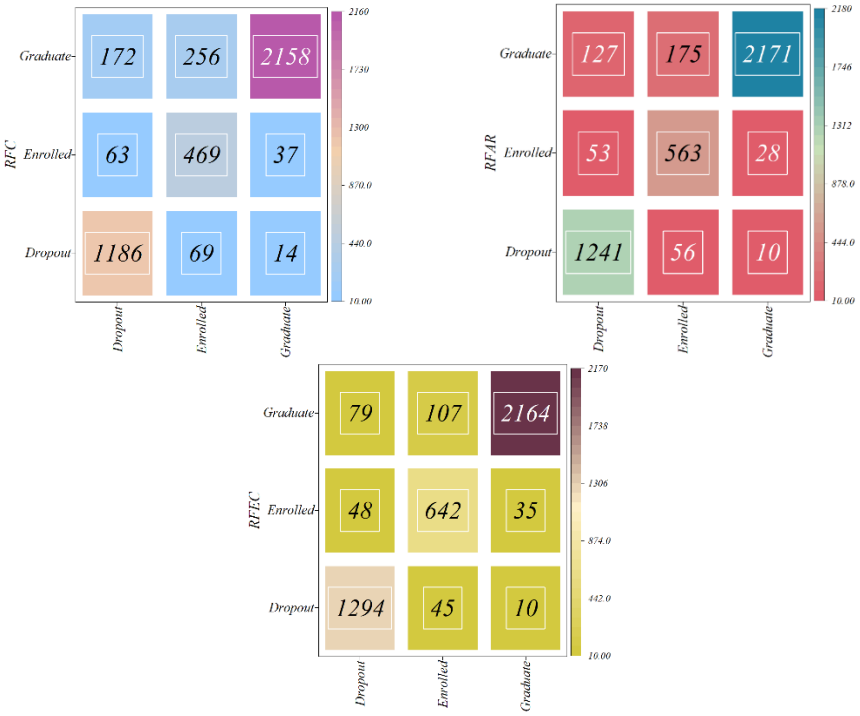

Fig. 7. Confusion matrix for each models' accuracy.

In Fig. 8, a comprehensive analysis of model performance is facilitated through the presentation of two Receiver Operating Characteristic (ROC) charts strategically overlaid for enhanced comparison. The ROC charts visually depict the trade-off between true positive and false positive rates across different classification thresholds. The optimal model in this context is identified by a larger area under the curve (AUC), denoting superior discriminatory power. The meticulous examination of the presented ROC charts leads to the unequivocal identification of the RFEC model as the most efficacious among its counterparts. This determination is substantiated by the model's early attainment of the number 1 true positive rate, signifying its prompt and accurate identification of positive instances. Additionally, a discernible concentration of the ROC curve below the graph further underscores the RFEC model's exceptional performance. These nuanced observations collectively position the RFEC model as the optimal choice, demonstrating a superior ability to balance true positive and false positive rates and thereby affirming its efficacy in classification tasks.

F. Analysing Input Variables

Fig. 9 presents the impact of the presented input variables on the performance of the students. Student success in education is a complex issue with many contributing factors, including the ability to pay tuition fees. Input variables, such as student demographics, home environment, and school resources, play a crucial role in determining student financial well-being and their ability to meet tuition obligations. Understanding how these factors influence tuition fee payment is essential for developing effective interventions to improve student outcomes and promote financial equity in education

Student demographics, such as socioeconomic status, gender, race, and ethnicity, are among the most significant input variables influencing tuition fee payment. Studies have consistently shown that students from low-income families tends to struggle more with tuition payments than their peers from higher-income households. This financial burden is often exacerbated by disparities in access to scholarships and financial aid, leaving students from low-income backgrounds at a greater risk of tuition delinquency or default.

Gender also plays a role in tuition fee payment, with boys generally facing more financial challenges than girls. This disparity may stem from differences in employment opportunities, access to financial resources, and cultural expectations. Race and ethnicity are also associated with variations in tuition fee payment. For instance, African American and Hispanic students tend to have lower rates of tuition payment compliance than White and Asian students. These payment disparities are likely due to a combination of factors, including historical discrimination, unequal access to financial aid, and disparities in parental education.

The home environment is another critical input variable that influences tuition fee payment. Parental involvement in education is particularly important, as it has been shown to positively impact student financial literacy and budgeting skills. Parents who actively support their children's financial education, such as teaching them about saving, budgeting, and the importance of paying bills, can help students make informed decisions about their tuition obligations. Additionally, a supportive and nurturing home environment, free from conflict and stress, can foster a positive financial mindset that promotes responsible fiscal behaviour.

School resources, such as financial aid counseling services and tuition assistance programs, play a crucial role in helping students meet their tuition obligations. Schools that provide comprehensive financial literacy education and accessible financial aid resources can empower students to make informed decisions about their financial aid options and better manage their tuition payments. Additionally, schools with strong partnerships with community organizations and financial institutions can expand access to scholarships, work-study programs, and other forms of financial assistance that can alleviate the burden of tuition payments.

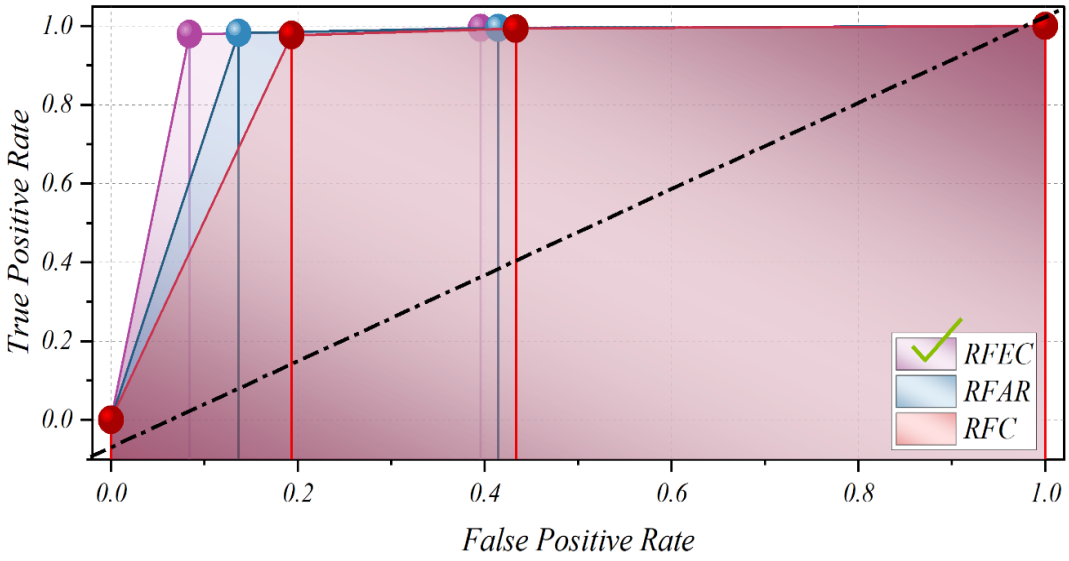

Fig. 8. ROC curve for developed models.

The impact of input variables on tuition fee payment has significant implications for educational practice. It is crucial to recognize that financial well-being is not solely determined by individual effort or ability; it is also shaped by factors beyond a student's control. Educators, policymakers, and community leaders must work together to address the inequities that exist in education and create a more equitable financial environment for all students. This includes providing targeted financial literacy education and support services to students from low-income backgrounds, promoting parental involvement in financial education, and expanding access to scholarships, work-study programs, and other forms of financial assistance.

Input variables, such as student demographics, home environment, and school resources, play a critical role in determining a student's ability to pay tuition fees. By understanding the impact of these variables, educators, policymakers, and community leaders can develop effective interventions to improve student financial well-being, promote financial equity in education, and ensure that all students have the opportunity to reach their full potential.

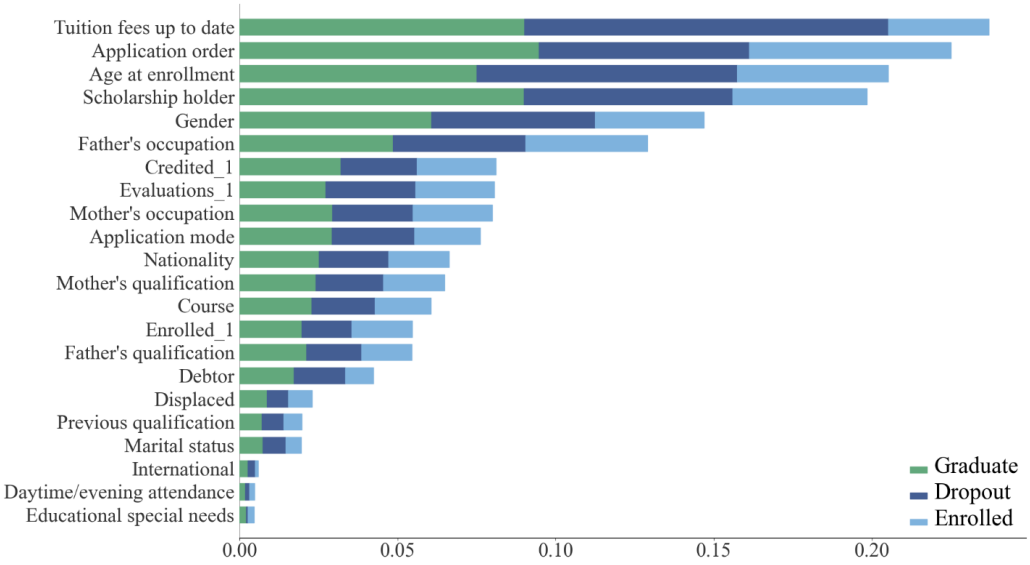

Fig. 9. The SHAP sensitivity analysis of the models.

G. Discussion

Table IV compares the accuracy of the present study's RFEC model with several published models. The RFEC model achieved the highest accuracy at 92.58%, significantly outperforming others. The superior performance of the RFEC model is attributed to the integration of advanced optimization algorithms (ECPO and ARO), which enhance the model's ability to handle complex data. This demonstrates the effectiveness of using sophisticated machine learning techniques and optimization to improve predictive accuracy in educational research.

TABLE IV. PRESENT MODEL EVALUATION WITH PUBLISHED STUDIES

Study	Developed Models	Accuracy
Present study	RFEC	92.58%
Kabakchieva [35]	DTC	72.74%
Bichkar and R. R. Kabra [36]	DTC	69.94%
Nguyen and Peter [37]	DTC	82%
Edin Osmanbegovic et al. [38]	NBC	76.65%

V. CONCLUSION

This research has strategically applied predictive data mining modeling, specifically employing the potent Random Forest Classifier (RFC), to address challenges within the academic domain proactively. The primary aim is to empower educators with the capacity to intervene timely, thereby enhancing academic trajectories, reducing failure rates, elevating the overall educational experience, and fostering an environment conducive to improved student outcomes. The single RFC model exhibited suboptimal performance in predictive modeling. To enhance its efficacy, two optimization algorithms, Electric Charged Particles Optimization (ECPO) and Artificial Rabbits Optimization (ARO), were incorporated. This integration led to the creation of two new optimized models, namely RFEC and RFAR. The utilization of these two optimizers represents a pioneering initiative in the domain of student performance forecasting, signifying a noteworthy advancement for future research and applications in this field. This article conducts an analysis and prediction of information data about 4424 students based on their previous enrollment, graduation, and dropout records. Additionally, a comparative assessment of each model's results against the actual measured values is performed to ascertain the optimal predictive model. The outcomes, accompanied by pertinent tables and figures, indicate that the RFEC model exhibits the smallest deviation, approximately 7.32%, in contrast to the actual measured values. This stands in contrast to the RFAR-optimized model, which demonstrates a higher difference of about 10.14%, and the RFC single model, showcasing a more substantial difference of approximately 13.81% from the measured values.

VI. Future Study

Future research should focus on expanding data sources to include socio-economic backgrounds and extracurricular activities for a comprehensive understanding of student performance. Collaborating with interdisciplinary experts can enrich analyses by considering individual characteristics, social dynamics, and institutional practices. Longitudinal studies are essential for tracking academic trajectories and developing proactive intervention strategies. Validating predictive models across diverse contexts and populations is crucial for ensuring scalability and effectiveness. Ethical guidelines must be prioritized for transparent and accountable deployment of predictive analytics. Exploring emerging technologies like artificial intelligence offers opportunities to enhance personalized learning experiences. By addressing these areas, future studies can contribute to advancing predictive analytics in higher education and fostering a more inclusive learning environment.

***Abstract*—The field of brain computer interface (BCI) is one of the most exciting areas in the field of scientific research, as it can overlap with all fields that need intelligent control, especially the field of the medical industry. In order to deal with the brain and its different signals, there are many ways to collect a dataset of brain signals, the most important of which is the collection of signals using the non-invasive EEG method. This group of data that has been collected must be classified, and the features affecting changes in it must be selected to become useful for use in different control capabilities. Due to the need for some fields used in BCI to have high accuracy and speed in order to comply with the environment's motion sequences, this paper explores the classification of brain signals for their usage as control signals in Brain Computer Interface research, with the aim of integrating them into different control systems. The objective of the study is to investigate the EEG brain signal classification using different techniques such as Long Short-Term Memory (LSTM), Convolutional Neural Networks (CNN), as well as the machine learning approach represented by the Support Vector Machine (SVM). We also present a novel hybrid classification technique called CNN-LSTM which combines CNNs with LSTM networks. This proposed model processes the input data through one or more of the CNN's convolutional layers to identify spatial patterns and the output is fed into the LSTM layers to capture temporal dependencies and sequential patterns. This proposed combination uses CNNs' spatial feature extraction and LSTMs' temporal modelling to achieve high efficacy across domains. A test was done to determine the most effective approach for classifying emotional brain signals that indicate the user's emotional state. The dataset used in this research was generated from a widely available MUSE EEG headgear with four dry extra-cranial electrodes. The comparison came in favor of the proposed hybrid model (CNN-LSTM) in first place with an accuracy of 98.5% and a step speed of 244 milliseconds/step; the CNN model came in the second place with an accuracy of 98.03% and a step speed of 58 milliseconds/step; and in the third place, the LSTM model recorded an accuracy of 97.35% and a step speed of 2 sec/step; finally, in last place, SVM came with 87.5% accuracy and 39 milliseconds/step running speed.**

I. Introduction

Brain Computer Interface (BCI) is a technology that enables direct communication between the brain and an external device using signals generated from the brain. It has been proposed as a potential therapeutic treatment for various neurological disorders and a tool for efficient human-computer interaction. BCI technology can be used to control assistive devices such as wheelchairs, prostheses and communication systems, as well as to monitor brain activity and diagnose neurological diseases. Moreover, BCI technology can be used to provide a more natural form of human-computer interaction, allowing users to control computers with thoughts [1]. BCI technology can be divided into two main categories as shown in Fig.1: invasive and noninvasive. Invasive BCI requires the insertion of electrodes into the brain in order to capture brain signals, which is a risky and complicated process. On the other hand, noninvasive BCI relies on measuring signals from the scalp or other parts of the body to detect brain activities. Noninvasive BCI is more commonly used and includes electroencephalography (EEG), magnetoencephalography (MEG), and functional near-infrared spectroscopy (fNIRS). EEG is the most widely used BCI technique and is based on electrical signals generated by the brain [2].

EEG signals are a type of electrical activity that can be measured from the brain. They are used in a variety of engineering fields, including medical, robotics, and computer engineering. In medical engineering, EEG signals are used to diagnose and monitor neurological conditions. EEGs can be used to detect seizures, diagnose sleep disorders, and monitor brain activity during surgery. EEGs can also be used to measure brain activity during cognitive tasks, such as memory tests. This can help doctors better understand how the brain works and how to treat neurological conditions [3]. In robotics engineering, EEG signals are used to control robotic devices. By measuring the electrical activity of the brain, robots can be programmed to respond to certain commands. This can be used to create robots that can interact with humans in a more natural way. For example, robots can be programmed to respond to facial expressions or voice commands [4]. In computer engineering, EEG signals are used to create brain-computer interfaces. These allow users to control computers with their thoughts. This technology is still in its early stages, but it has the potential to revolutionize the way we interact with computers [5].

The most common EEG signal classification methods as shown in Fig. 2 are supervised learning algorithms, such as Support Vector Machines (SVMs), Artificial Neural Networks (ANNs), and decision trees. These algorithms are used to identify patterns in EEG signals that can be used to diagnose and monitor neurological conditions [6]. For example, SVMs can be used to classify EEG signals into different categories, such as normal or abnormal, or to detect changes in EEG signals

over time. ANNs, which include Convolutional Neural Network (CNN), can be used to identify patterns in EEG signals that can be used to diagnose and monitor neurological conditions. Decision trees can be used to identify patterns in EEG signals that can be used to diagnose and monitor neurological conditions [7].

A. Related Work

Z. -T. Liu et al. (2019) tested a proposed approach on DEAP dataset, classifying Valance and Arousal emotional states using K-nearest neighbor and support vector machine. The experiments compare temporal windows of different lengths and three EEG signal rhythms. The results show that the EEG signal with one temporal window has the highest recognition accuracy of 86.46%. A multimodal emotional communication-based humans-robots interaction system would use the suggested approach for real-time emotion identification [9].

T. Song et al. (2020) to recognize emotions in multichannel EEG data used a dynamical graph convolutional neural network (DGCNN). Our EEG emotion recognition method uses a graph to describe multichannel EEG data and classify emotions using this model. EEG emotion recognition is improved by learning new features from the adjacency matrix. Emotion EEG datasets SEED and DREAMER were extensively studied. The proposed recognition method is more accurate than current methods. On SEED, it averaged 90.4% in subject-dependent experiments and 79.95% in subject-independent cross-validation [10].

In 2020, S. K. Khare and colleagues introduced an adaptive tunable Q wavelet transform for selecting tuning parameters automatically. Grey wolf optimization identifies the best tuning parameters. GWO tuning parameters divide EEG signals into sub bands. Time-domain properties of SB are inputted into a multiclass least-squares support vector machine. Evaluating the classification accuracy of four main emotions - happiness, fear, sadness, and relaxation - compared to current methods. A radial basis function kernel that outperforms prior methods on the same dataset achieves an accuracy of 95.70%. This article presents a nonparametric method for decomposing EEG signals to improve efficiency. This approach can enhance the progress of BCI system development by utilizing machine learning techniques [11].

Chowdary MK, et al., (2022) aim to classify emotions from electroencephalogram signals by utilizing different recurrent neural network structures. Three architectures employed in this study for emotion recognition using EEG signals are RNN (recurrent neural network), LSTM (long short-term memory network), and GRU (gated recurrent unit). Experimental data confirmed the efficiency of these networks in terms of performance measures. The study utilized the EEG Brain Wave Dataset: Feeling Emotions and obtained an average accuracy of 95% for RNN, 97% for LSTM, and 96% for GRU in detecting emotions [12].

EEG capture and emotion categorization in a simulated driving environment is suggested by Chen J. et al. (2024) to study panic emotion and accident-avoidance skills. The program models obstacle avoidance at different risk levels using vehicle speed. The system models the brain's physiological structure for data processing using graph neural networks (GNN) with functional connection and attention mechanisms. Various research compared entropy and power properties. The top single-label F1 score was 76.7%, and the three-class classification was 75.26 % accurate. Binary classification had 91.5% accuracy and the highest F1 score for a single label was 91.86%. Deep learning algorithms can accurately mimic hazardous events, record the driver's EEG data, and quickly track emotional states, according to experiments [13].

This research investigates classifying brain signals for use as control signals in Brain-Computer Interface (BCI) systems designed for various robotic applications. The aim is to compare four methods for multi-class classification: Long Short-Term Memory (LSTM) and Convolutional Neural Networks (CNN) from deep learning, a proposed hybrid CNN-LSTM approach, and Support Vector Machine (SVM) from machine learning. Ultimately, this research seeks to determine the most effective method for classifying emotional brain signals that reflect the user's emotional state.

The rest of this paper is organized as follows: Section II demonstrates the main concepts for signals classification overview; Section III presents the classification models; Section IV describes the dataset; Sections V and VI elaborate the classification results and a discussion of the results generated from the tests; Section VII mentions the applications that can benefit from this research topic; Section VIII concludes the paper and presents the future work.

II. Classification Overview

Dataset classification is a process of organizing data into categories based on certain characteristics. It is a way of organizing data into meaningful groups so that it can be more easily analyzed and understood. Dataset classification is used in a variety of fields, including data mining, machine learning, and artificial intelligence.

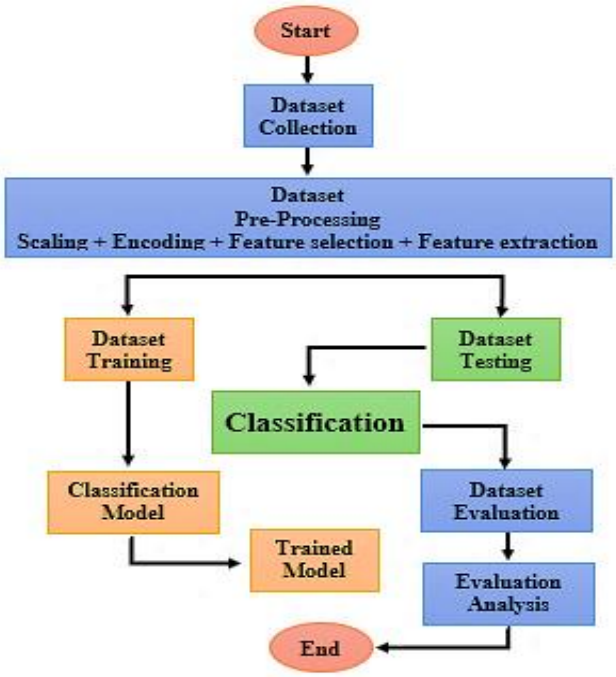

Fig. 3. Dataset classification process overview [14].

The process of dataset classification, as shown in Fig. 3 begins with the identification of the data that needs to be classified. This data can come from a variety of sources, such as databases, text documents, images, and audio files. Once the data has been identified, it is then divided into categories based on certain characteristics. These characteristics can include size, type, content, and other attributes.

Once the data has been divided into categories, it is then analyzed to determine the relationships between the different categories. This analysis can be done using a variety of techniques, such as clustering, decision trees, and neural networks. The goal of this analysis is to identify patterns and trends in the data that can be used to make predictions or decisions. Once the data has been classified and analyzed, it can then be used for a variety of purposes. For example, it can be used to create predictive models, to identify customer segments, or to detect anomalies in the data. It can also be used to create visualizations of the data, such as charts and graphs, which can be used to better understand the data [15].

III. Classification Models

A. Support Vector Machine (SVM)

Support Vector Machines (SVMs) are a powerful and versatile machine learning algorithm used for classification and regression tasks. SVMs are a supervised learning algorithm that can be used to classify data into two or more classes. They are based on the concept of finding a hyperplane that best divides a dataset into two classes. The main advantage of SVMs is that they are very effective in high dimensional spaces. This is because they use a kernel trick to map the data into a higher dimensional space, where it can be separated by a hyperplane. This allows them to capture complex relationships between the data points [16]. SVMs are also very robust to overfitting. This is because they use a regularization parameter which helps to reduce the complexity of the model and prevent overfitting. SVMs are also very efficient in terms of both time and memory. This is because they only need to store a subset of the training data, which makes them very efficient in terms of memory usage. In addition, SVMs are very versatile and can be used for a variety of tasks such as classification, regression, and outlier detection [17].

Building a Support Vector Machine (SVM) algorithm with Python as shown in Algorithm 1 [18], is a relatively straightforward process. The first step is to import the necessary libraries. The most common libraries used for SVM in Python are Scikit-learn, Numpy, and Matplotlib. Once the libraries are imported, the next step is to prepare the data. This involves loading the data into a Pandas Data Frame, cleaning the data, and splitting it into training and testing sets. It is important to ensure that the data is properly scaled and normalized before training the model. The next step is to create the SVM model. This is done by instantiating an SVM classifier object from the Scikit-learn library. The classifier object can then be fitted to the training data using the fit() method. Once the model is trained, it can be used to make predictions on the test data. This is done by calling the predict() method on the classifier object. The predictions can then be evaluated using a variety of metrics such as accuracy, precision, recall, and F1 score [19].

Algorithm 1: SVM model

Input: X (array of input data (features)), Y (array of output data (classes - labels))

Output: performance of model (accuracy – precision – confusion matrix)

```
Training _ SVM
        clf = svm.SVC(kernel='kernal type')
        clf.fit(X_train, y_train)
```

2. Initialize:

```
Learning rate – Number of runs (epoch)
    for i in X array
        if (Y(i) x X(i) x q) > 1
        then
update: q = q + learning rate x ((X(i)*Y(i))*(-2*(1/epoch)*q)
        else
update: q = q + learning rate x (-2*(1/epoch)*q)
        end if
        end
```

In the context of multi-class classification, SVMs can be used to construct a maximum-margin hyperplane that divides the feature space into regions, each corresponding to a particular class. The algorithm then searches for the optimal hyperplane that maximizes the margin between the classes. This hyperplane is then used to classify new data points. The advantage of SVMs is that they can be used to classify data with a large number of features and classes, as well as data with non-linear boundaries. Furthermore, SVMs are robust to outliers and can be used to classify data with a high degree of accuracy [19], [20].

B. Long Short Term Memory (LSTM)

The Long Short-Term Memory (LSTM) classifier is a powerful deep learning algorithm that can be used to classify data. It is a type of recurrent neural network (RNN) that is capable of learning long-term dependencies in data. The LSTM classifier is a powerful tool for predicting and classifying data, and it has been used in a variety of applications, such as natural language processing, speech recognition, time series forecasting, and classifying sequences of data, such as text, audio, and video. As shown in Fig. 4, the LSTM classifier is composed of a series of memory cells, each of which contains a set of weights and biases. The weights and biases are adjusted during the training process to learn the patterns in the data [21]. The memory cells are connected in a chain, and each cell is connected to the next cell in the chain. This allows the network to remember information from previous cells and use it to make predictions [22]. The LSTM classifier is trained using a supervised learning algorithm. During the training process, the network is presented with a set of input data and the desired output. The network then adjusts the weights and biases of the memory cells to learn the patterns in the data. Once the training is complete, the network can be used to make predictions on new data [23].

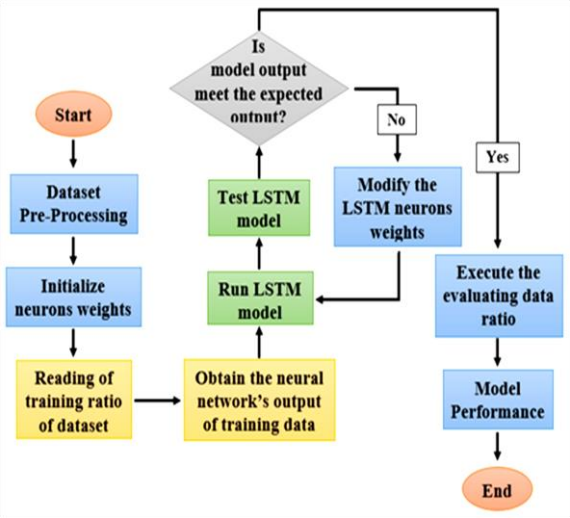

Fig. 4. LSTM classifier model flowchart [21].

Building an LSTM model with Python is a great way to get started with deep learning. The first step in building an LSTM model with Python is to import the necessary libraries. The most popular library for deep learning in Python is TensorFlow, which provides a high-level API for building and training neural networks. Other popular libraries include Keras, PyTorch, and Theano. Once the libraries are imported, the next step is to prepare the data. This involves loading the data, preprocessing it, and splitting it into training and test sets. It is important to ensure that the data is properly normalized and scaled before training the model. The next step is to define the model architecture. This involves specifying the number of layers, the number of neurons in each layer, the type of activation functions, and the type of optimizer. It is also important to specify the input and output shapes of the model. Once the model architecture is defined, the next step is to compile the model. This involves specifying the loss function, the optimizer, and the metrics to be used for evaluating the model. Finally, the model can be trained. This involves specifying the number of epochs, the batch size, and the validation split. It is important to monitor the training process to ensure that the model is not overfitting or underfitting the data [22].

C. Convolutional Neural Network (CNN)

A convolutional neural network (CNN) is a type of artificial neural network used in deep learning that is specifically designed to process data that has a grid-like structure, such as tabular and images datasets. CNNs are composed of multiple layers of neurons that each perform a specific task as shown in Fig. 5. The first layer of neurons is responsible for detecting edges and other basic features in the input image. The second layer of neurons is responsible for detecting more complex features, such as shapes and patterns. The third layer of neurons is responsible for recognizing objects in the image. The fourth layer of neurons is responsible for recognizing more complex objects, such as faces or animals [24].

CNNs are particularly useful in robotics because they are able to process large amounts of data quickly and accurately. For example, a CNN can be used to identify objects in an image or video feed. It can also be used to analyze cognitive data represented in a database that enables robots to understand the surrounding environment and also understand the commands stored within it and classify them according to the event the robot is exposed to. This is useful for robots that need to identify objects in their environment in order to navigate or interact with them. CNNs can also be used to classify objects in a scene, which is useful for robots that need to recognize and interact with objects in their environment [25].

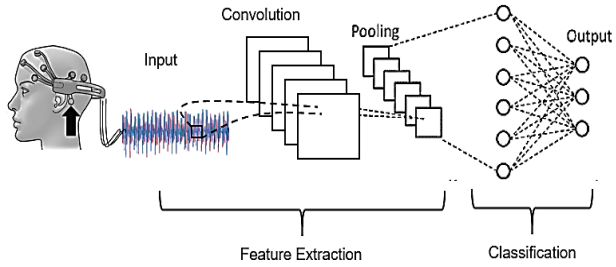

Fig. 5. Convolutional Neural Network (CNN) architecture.

Building a Convolutional Neural Network (CNN) model is a complex process that requires a lot of knowledge and experience. However, with the right guidance, it can be done relatively easily. The following steps outline the process of building a CNN model as described in Algorithm 2 [26]:

- Data Preparation: The first step in building a CNN model is to prepare the data. This includes gathering the data, cleaning it, and formatting it into a suitable format for the model. This step is important as it ensures that the model is trained on the most accurate and up-to-date data.
- Model Architecture: The next step is to decide on the model architecture. This includes deciding on the number of layers, the type of layers, and the number of neurons in each layer. This step is important as it

determines the complexity of the model and how well it will perform.

- Training: Once the model architecture is decided, the next step is to train the model. This involves feeding the data into the model and adjusting the weights and biases of the neurons in order to minimize the error. This step is important as it ensures that the model is able to accurately predict the output given the input.
- Evaluation: After the model is trained, the next step is to evaluate the model. This involves testing the model on unseen data and measuring its performance. This step is important as it allows us to determine how well the model is performing and if it needs to be improved.
- Deployment: The final step is to deploy the model. This involves making the model available to users so that they can use it to make predictions. This step is important as it allows the model to be used in real-world applications.

These are the basic steps for building a CNN model. However, there are many other steps that can be taken to improve the model, such as hyperparameter tuning, regularization, and data augmentation. With the right guidance and experience, building a CNN model can be a relatively straightforward process.

Algorithm 2: CNN model

Input: tabular EEG emotional brain signal dataset
Output: confusion matrix and model testing accuracy

1. Import necessary libraries
(Numpy as np, pandas as pd, tensorflow as tf, Sequential, Dense, Conv1D, MaxPooling1D, and Flatten)
2. Load the emotional dataset
dataset = pd read _ datatype ('dataset . datatype')
3. Analysis the dataset
Input signals = dataset drop (columns = ['target columns'])
Labels = dataset ['last column']
4. Split the dataset into training and testing sets
data train, data test, labels train, labels test = train test split (data, labels, test size = test ratio to complete dataset, random state = no. of states)
5. Build the CNN model
model = Sequential ([
Conv1D parameter definition (filters, kernel size, activation functions)
Input shape = X train shape.
MaxPooling1D size.
Dense (output layer count, output activation function
6. Train the model
Training history = model fit (data train, labels train, epochs number, batch size, validation data (data test, labels test))
7. Evaluate the model
loss accuracy = model evaluate (data test, labels test)
print Test Loss
print Test Accuracy
print confusion matrix

D. CNN-LSTM Hybrid Model

The CNN-LSTM model, which combines Convolutional Neural Networks (CNNs) with Long Short-Term Memory (LSTM) networks, excels at modeling the interdependence of spatial and temporal data. This powerful combination leverages CNNs' ability to extract spatial features and LSTMs' strength in temporal modeling, leading to high effectiveness across various domains.

This hybrid model finds applications in tasks involving complex sequential data. It utilizes CNNs for spatial analysis and LSTMs for understanding temporal sequences. The CNN-LSTM model processes input data through one or more convolutional layers to identify spatial patterns. The output from these layers then feeds into LSTM layers to capture temporal dependencies and sequential patterns. Finally, dense layers are often used for classification or regression tasks. Algorithm 3 lists the whole process of proposed model.

The model's strength lies in the specialized functions of its layers. CNNs excel at extracting features from spatial data, while LSTMs represent complex temporal connections. This combination allows the model to learn both spatial and temporal characteristics simultaneously, enabling a comprehensive interpretation of the data. However, achieving optimal performance requires careful hyperparameter tuning for both CNN and LSTM components, and ensuring compatibility between the input data shape and both layer types. A small code example using the Keras library shows how to sequentially add CNN and LSTM layers for spatiotemporal modelling [27].

Algorithm 3: CNN-LSTM model

Input: tabular EEG emotional brain signal dataset
Output: confusion matrix and model testing accuracy

1. Import necessary libraries
(Numpy as np, pandas as pd, tensorflow as tf, Sequential, Dense, Conv1D, MaxPooling1D, and Flatten)
2. Load the emotional dataset
dataset = pd read _ datatype ('dataset . datatype')
3. Analysis the dataset
Input signals = dataset drop (columns = ['target columns'])
Labels = dataset ['last column']
4. Split the dataset into training and testing sets
data train, data test, labels train, labels test = train test split (data, labels, test size = test ratio to complete dataset, random state = no. of states)
5. Build the CNN-LSTM model
model = Sequential ([
- Conv1D parameters definition (filters, kernel size, activation functions)
Input shape = X train shape.
MaxPooling1D size.
- LSTM parameters definition (units' size, return sequences)
- Dense (output layer count, output activation function)
6. Train the model
Training history = model fit (data train, labels train, epochs number, batch size, validation data (data test, labels test))
7. Evaluate the model
loss accuracy = model evaluate (data test, labels test)
print Test Loss
print Test Accuracy
print confusion matrix

IV. Dataset Description

Datasets can be used to analyze trends, identify patterns, and make predictions. They can also be used to compare

different groups of people or different types of data, store information about people, places, events, and other topics, and create visualizations like charts, graphs, and maps. They can even be used to generate reports and presentations.

Datasets can be used to analyze trends, identify patterns, and make predictions. They can also be used to compare different groups of people or to compare different types of data. They can also be used to store information about people, places, events, and other topics. Datasets can be used to create visualizations, such as charts, graphs, and maps. They can also be used to create reports and presentations. They can also be used to store information about people, places, events, and other topics [28].

The dataset used in this research is a mental emotional sentiment dataset that was collected by other researchers using a commercial MUSE EEG headband which was used with a resolution of four (TP9, AF7, AF8, TP10) electrodes. To collect the data, researchers used a widely available MUSE EEG headgear with four dry extra-cranial electrodes. As can be seen in Fig. 6, micro voltage readings are taken from electrodes TP9, AF7, AF8, and TP10. Two individuals (1 male, 1 female, aged 20-22) each provided 60 seconds of data for each of the 6 film segments, for a total of 12 minutes (720 seconds) of brain activity data (6 minutes for each emotional state). A total of 36 minutes of EEG data was obtained from each individual, including six minutes of "neutral brainwave" data. The brain's waves were captured at a variable frequency and then resampled to 150Hz, yielding a collection of 324,000 data points. The positive and negative valence descriptors were evaluated instead of the emotions themselves to determine which activities were most likely to elicit. For a third category, representing the subject's baseline emotional state, neutral data were also obtained before any data on emotions were gathered (to prevent contamination from the latter). We only gathered data from each participant for three minutes every day to minimize the influence of a baseline emotional state [29].

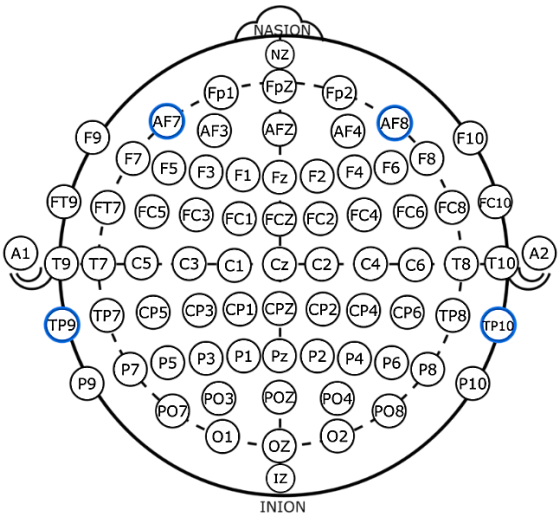

Fig. 6. Position of used EEG electrodes on human skull [29].

V. Classification Results

Classification results are the outcomes of a classification process, which is a type of data mining technique used to identify patterns and relationships in data. Classification results are used to make predictions about future data points, and can be used to make decisions about how to best utilize resources. Classification results are typically presented in the form of a confusion matrix, which is a table that shows the number of true positives, false positives, true negatives, and false negatives [30]. The confusion matrix is used to evaluate the accuracy of the classification model, and can be used to identify areas where the model is performing well or poorly. Classification results can also be used to identify important features in the data that are driving the model's predictions. This can be done by looking at the feature importance scores, which are calculated by the model and indicate how important each feature is in making the prediction. This can be used to identify which features are most important for making accurate predictions, and can be used to inform decisions about which features to focus on when building a model [31], [32].

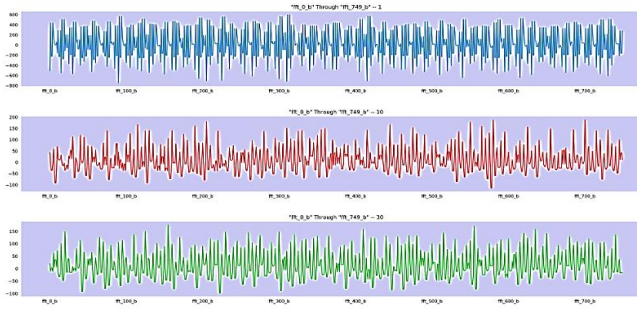

Fig. 7. Classes appearance analysis.

Finally, classification results can be used to compare different models and determine which one is the best for a given task. This can be done by looking at the accuracy scores of each model, as well as other metrics such as precision, recall, and F1 score. Comparing the results of different models can help identify which model is best suited for a given task, and can help inform decisions about which model to use [32].

To classify the dataset, it must first understand its details, the resultant classes from each row of input, and the number of instances of each class over the whole dataset. As the information from the dataset were analyzed, it was discovered that there are three separate classes as a consequence of all the input rows, which are positive, negative, and neutral, as they represent an indicator of the subject's emotional state. After each class was counted, it was discovered that the positive case occurred 708 times, the negative case appeared 708 times, and the neutral case appeared 716 times as shown in Fig. 7. These statistics reveal the dataset's balance, from which the difference in findings may be precisely calculated. As the last stage in studying the dataset, a sample may be obtained for each class using a variety of inputs, as illustrated in Fig. 8.

A. SVM Results

When implementing the SVM algorithm, the tensorflow library was used for deep learning in Python, on the Kaggle coding website. And by classifying the studied dataset, and specifying each of the training data percentage as 50%, the testing data percentage as 25%, the validation data percentage as 25%, and 100 epochs to test the algorithm and conclude the best classification result.

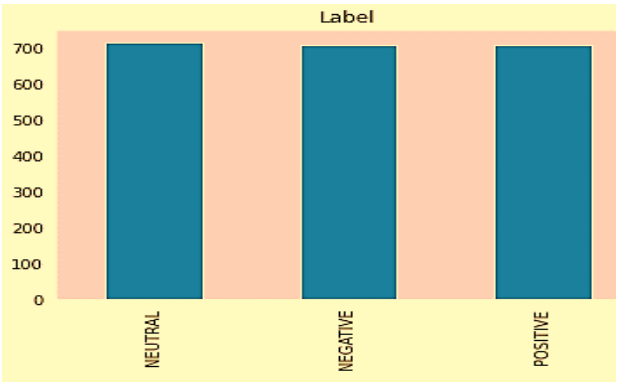

Fig. 8. Classes sample.

The classification results of the algorithm came with an accuracy of 87.5%, after only 15 epochs (early stop), radial basis function (RBF) kernel [33], and 39 ms/step running speed. When viewing the confusion matrix as shown in Fig. 9, which describe matching between actual label and predicted label. It can be seen that the results are not mixed up, or in another sense, the algorithm is not confused between dataset classes when determining the result significantly.

B. LSTM Results

The Long Short-Term Memory (LSTM) model was developed on the Kaggle coding platform using the Python tensorflow deep learning framework. By categorising the examined dataset, designating the percentage of each training data as 50%, the percentage of test data as 25%, and the percentage of validation data as 25%, 100 epochs for model testing, and selecting the best classification result. This model was built to contain the input layer, and the last layer is responsible for the output, and because the dataset contains more than two expected results (3 classes), the Softmax Activation Function is used [34].

The algorithm's classification results showed an accuracy of 97.35% after just 38 epochs (early stopping) and a running speed of 2 s/step, which is an excellent result. This result was reached by setting the learning rate to 0.001 and using Adam as the model's optimization library. In addition, through Fig. 10, it can be noted that the classification model was very sharp in showing the results, as it was not confused with the actual result of implementing the classification except in very simple cases that do not exceed 0.06 for each class confused with other classes.

C. CNN Results

On the Kaggle coding platform, the tensorflow deep learning library in Python was utilized to create the convolutional neural network model. By classifying the investigated data set, defining the percentage of each training data as 50%, the proportion of test data as 25%, and the proportion of validation data as 25%, 100 epochs for model testing, and identifying the best classification result.

This model was built to contain the input layer, five hidden layers all of which contain an activation function of the type Rectified Linear Unit (ReLU) [35], and this function is considered one of the best choices in the selection of the activation. The last layer is responsible for the output, and because the dataset contains more than two expected results (3 classes), the Softmax Activation Function is used.

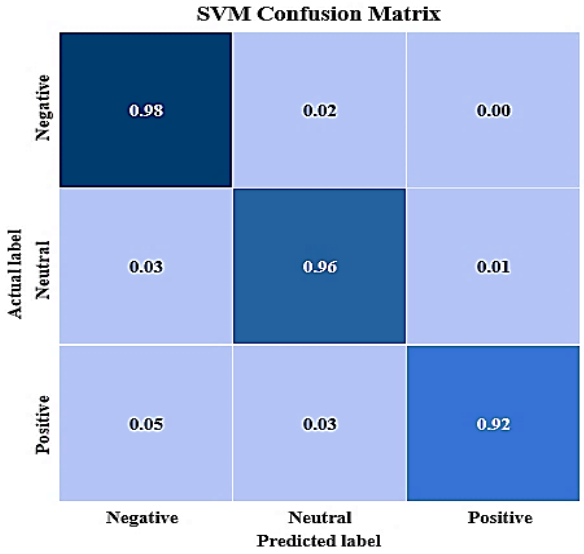

Fig. 9. Confusion Matrix of SVM model result.

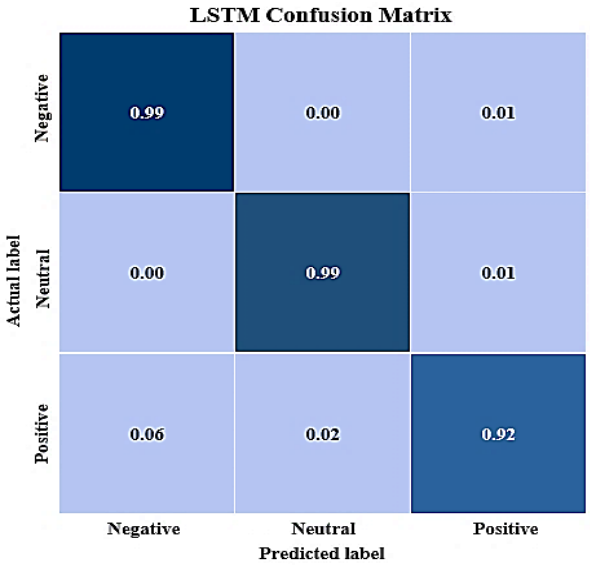

Fig. 10. Confusion matrix for LSTM model results.

The algorithm's classification results came with an accuracy of 98.03 % after only 38 epochs (early stopping) and 58 ms/step running speed, which is a great result. This result was obtained as a result of setting the learning rate to 0.001 and using Adamax as the optimization library on the model. Moreover, it can be shown in Fig. 11 that the classification model was extremely crisp in displaying the results, as it was not confused with the real result of implementing the classification except in very basic examples where 0.03 for each class confused with other classes was not exceeded.

D. CNN-LSTM Results

The CNN-LSTM model was implemented on the Kaggle coding platform using the Python tensorflow deep learning framework. By classifying the dataset, allocating 50% of the data for training, 25% for testing, and 25% for validation,

conducting 50 epochs for model evaluation, and choosing the optimal classification outcome. This model was constructed with an input layer, three CNN layers utilizing the ReLU activation function and progressively increasing filter sizes starting from 64 bits. It also includes LSTM layers and a final output layer. Since the dataset consists of three distinct classes, the Softmax Activation Function is employed.

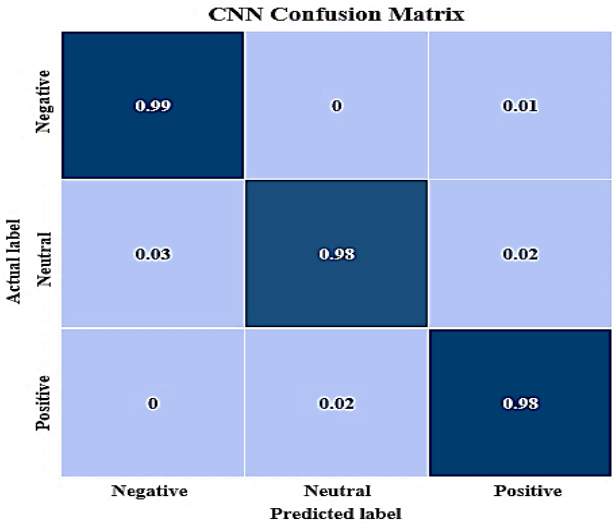

Fig. 11. Confusion matrix for CNN model results.

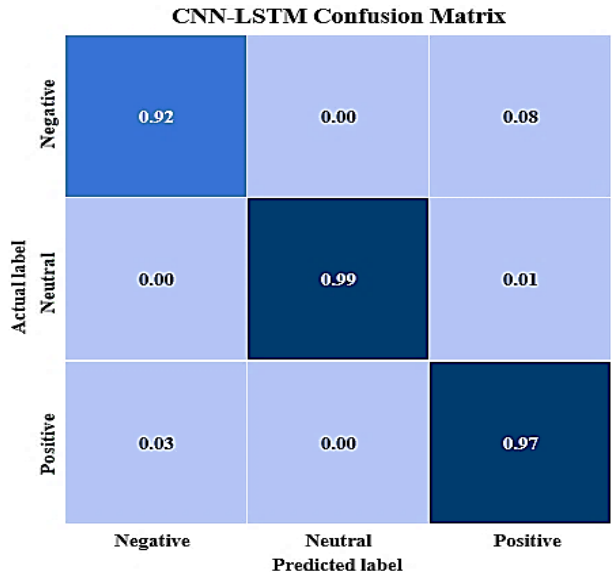

Fig. 12. CNN-LSTM confusion matrix.

The algorithm achieved a classification accuracy of 98.50% after completing 100 epochs without early stopping. Additionally, it demonstrated a running speed of 244 ms/step, which is considered an outstanding outcome. The attainment of this outcome was accomplished by configuring the learning rate to 0.001 and employing Adam as the optimization library for the model. Furthermore, Fig.12 demonstrates that the classification model exhibited a high level of accuracy in presenting the findings, as it only encountered confusion with the actual outcome of the classification in rare instances that did not surpass 0.06 for each misclassified class.

VI. Result and Discussion

When comparing the results of different models to classify the studied dataset (SVM, LSTM, CNN, and CNN-LSTM), more than one aspect can be relied on for comparison, the first and most important of which is the accuracy of the classification when implementing the model, the second is the confusion matrix, which is related in one way or another to the first factor in the comparison, and the third factor that was taken into account when comparing is speed of implementation of the model, as measured by the speed of the test steps and also the speed of early stopping when testing the model. Table I compiles these features for all models utilized in the paper.

TABLE I. Comparision Factor Conclusion

Model	Comparison factors		
	Accuracy	*Test speed*	*Early stop*
SVM	87.5 %	39 ms/step	15 epochs
LSTM	97.35 %	2 sec/step	15 epochs
CNN	98.03 %	58 ms/step	38 epochs
CNN-LSTM	98.50 %	244 ms/step	No

With regard to the first factor in the comparison, which is the accuracy of the model in implementation, it came in the foreground, and it is considered one of the best classification results applied to the studied data set. It is the result of classification using CNN-LSTM with an accuracy of 98.50%. Then it comes in second place, and not by a large difference, is the result of classification using CNN, with an accuracy of 98 %, while in third place was the LSTM model with 97.35 % accuracy, finally SVM where the classification accuracy was not good enough compared to the previous three models with an accuracy of 87.5 %.

As mentioned previously, the confusion matrix is linked to the accuracy of the classification, or in other words, this matrix is a breakdown of the characteristics of the classification result that lead to its accuracy. The order of the models when comparing the results based on the quality of the matrix came in the same order as the models in terms of accuracy.

As for the third factor in the comparison, it is actually divided into two different factors, which are the speed of implementation by step and the speed of implementation in early stopping when testing the model. In view of the speed of execution by step, the SVM model came in first place with a speed of 39 ms/step, and in second place came the CNN model with 58 ms/step, and the CNN-LSTM model came in third place with a large difference from its predecessors with 244 ms/step. and in last place LSTM with extreme test step speed time with 2 sec/step However, when looking at the speed of early stopping, the order can differ relatively, as the SVM model comes in first place equally with the LSTM model by stopping after only 15 epochs out of 100 epochs that were specified for implementation, and the CNN-LSTM model remains in last place with no early stop out of 100 epochs also for implementation.

As a result of this comparison, it can be concluded that although the classification of the CNN-LSTM is the best as a model for classification, it must be taken into account that the

previous results are dependent on the input factors of each model, which were fixed in all cases, so that comparison can be made based on the equality of classification characteristics.

The CNN-LSTM was the best of them, as it has the highest accuracy, which is the most important factor in the comparison. In addition, the execution speed (step speed) was not bad (between the other models), but despite that, it was the most in the number of epochs that the model needed to infer the best classification result (training the model) but this did not significantly affect the outcome of the total execution time of the model.

And if we exclude the factor of execution speed, then CNN-LSTM, CNN and LSTM are very close in the result of classification accuracy, then these models can be equally reliable on the classification of the data set. In contrast, if the accuracy factor is excluded, the SVM model is the fastest in step speed and the least in the number of epochs required to train the model equally with the LSTM model, so SVM can be said that it is the best in the speed factor.

Considering that the CNN-LSTM result is the best model studied in this paper in terms of accuracy, which is the most reliable factor in the comparison. In the end, this model can also be compared with the similar models previously published on a similar database and with the different models. Through the previous literature study during previous years, published research showed limited accuracy of the techniques used, as K-nearest neighbor recorded an accuracy of 86.46% in Z-T. Liu. et al.'s 2019 research. T. Song et al. also recorded in their research published in 2020, an accuracy of 90.4% using DGCNN. Also, it was followed by the accuracy of the research of S.K. Khare et al. 2020, which reached 95.7% using the LSSVM, and then the RNN, LSTM, and GRU models obtained an accuracy of 95%, 97%, and 96% respectively in the research of Chowdary MK et al. 2022. Finally, Chen J. et al. 2024 are achieved 75.26% multi-classification accuracy by using GNN model in their published study. On the other hand, expectations were raised for an impressive result using the studied model (CNN-LSTM), where a classification accuracy was obtained that achieved a gorgeous mark in prediction. A summary of the results of the reviewed researches appears in Table II, where each row indicates the research person, the model used in it, and the model's accuracy result during testing.

TABLE II. LITERATURE RESULTS SUMMARY COMPARED WITH PROPOSED MODEL

Author	Comparison	
	Model	***Accuracy***
Z-T. Liu et al. (2019) [9]	K-NN	86.46 %
T. Song et al. (2020) [10]	DGCNN	90.40 %
S.K. Khare et al. (2020) [11]	LSSVM	95.70 %
Chowdary MK et al. (2022) [12]	RNN	95.00 %
	LSTM	97.00 %
	GRU	96.00 %
Chen J. et al. (2024) [13]	GNN	75.26 %
Proposed model	CNN-LSTM	98.50 %

VII. APPLICATIONS

Brain Computer Interfacing (BCI) is a technology, which enables communication between humans and machines through the direct interpretation of brain activities. This technology has a wide range of potential applications as shown in Fig. 13 and has been explored by researchers in fields such as medical diagnostics, prosthetics, human-machine interaction, and communication aids [36].

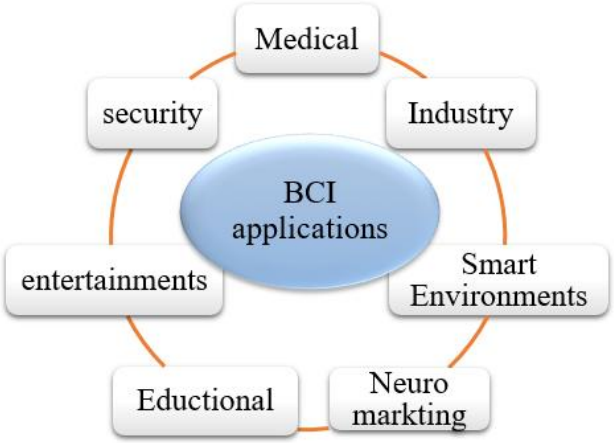

Fig. 13. BCI applications.

After classifying the data set, the classification model may be used to connect the model's inputs, which are brain signals, and any application that can be controlled by the dataset's distinct classifications. When looking at the field of medical industries, it is possible to coordinate between commands to control prosthetic limbs through brain signals directly, through three different commands linked to the three groups of the data set, for patients with paraplegia or total paralysis who are unable to move their natural organs, or move the muscles to control the Industrial limb [37]–[39]. Among the applications is Brain control in industrial robots in smart industries. It is also possible to link the results of classification (one of the classes for the data set) and a set of successive commands that include a path for a complete industrial process, so that the controller has the ability to control the brain in three separate industrial processes [40]. In addition, brain control technology can be used to control laboratory robots, and this can be used in research and scientific projects that allow the formation of innovative systems of intelligent control [41].

One of the most exciting applications of BCI in gaming and entertainment is the ability to control game characters and objects with your thoughts. This could allow players to control their characters in a more natural and intuitive way, as well as allowing for more complex interactions with the game world. For example, a player could use their thoughts to control a character's movements, or to manipulate objects in the game world. This could open up a completely new level of immersion and interaction with games [42].

Brain-Computer Interface (BCI) technology might change how individuals see themselves and their surroundings. BCI technology raises ethical and legal issues. BCI technology may enhance quality of life and give therapeutic advantages, but also

presents privacy, autonomy, and informed consent problems [43].

VIII. Conclusion and Future Work

The domain of Brain-Computer Interface (BCI) stands as an exceptionally captivating realm of scientific inquiry due to its potential intersections with diverse industries, particularly those requiring intelligent control, such as industry and medicine. Various methodologies are employed to assemble datasets of cerebral signals for the comprehensive understanding of the intricate signals emanating from the brain. Among these methodologies, the non-invasive Electroencephalogram (EEG) method holds particular significance. The acquired dataset necessitates meticulous categorization, wherein the identification of influential characteristics responsible for inducing changes becomes imperative for its applicability across diverse control modalities.

Furthermore, the demand for precision and expeditious processing in BCI applications, especially in alignment with dynamic environmental motion sequences, prompted a comparative evaluation of four alternative classification models, namely Support Vector Machine (SVM), Long Short-Term Memory (LSTM), Convolutional Neural Network (CNN), and the hybrid CNN-LSTM model. The findings of this comparative analysis underscore the notable efficacy of the CNN-LSTM model, manifesting an accuracy of 98.5% alongside an operational speed of 244 milliseconds per step. Following suit, the CNN model secured the second position, achieving an accuracy of 98% with a step speed of 58 milliseconds per step. Occupying the third position, the LSTM model demonstrated an accuracy of 97.35%, albeit at a comparatively slower step speed of 2 seconds per step. Conclusively, the SVM model finalized the comparison, registering an accuracy of 87.5% and a step speed of 39 milliseconds per step. These findings accentuate the CNN-LSTM model's prowess in BCI applications, positioning it as the preeminent choice for striking a commendable equilibrium between accuracy and processing speed within dynamic environmental contexts.

Future work can involve two avenues: exploring the accuracy of other classification models and developing entirely new ones to advance the field. Additionally, we can investigate the creation of an integrated system utilizing brain signals for control and evaluate its overall performance in accurately executing commands based on the underlying classification accuracy.

Acknowledgment

We would like to thank Heriot-Watt University for its support to publish this paper. We also thank Horus University (Egypt) for its explicit support throughout this research and for providing access to high featured computer labs for models' implementation.

Kaggle platform was used as a workspace for modeling the studied approaches and implementing the proposed models.

Three-Dimensional Animation Capture Driver Technology for Digital Media

Wanjie Dong
School of Arts and Media, Wuhan Vocational College of Software and Engineering, Wuhan 430000, China

***Abstract*—For the motion capture driving technology of three-dimensional animation, this study combines skeleton extraction methods and human motion pose data to construct the human skeleton of three-dimensional animated characters. Combining matching algorithms and action recognition techniques, the postures of the human three-dimensional model were tested and analyzed. The experimental results showed that the level-set central clustering method extracted shoulder joint position values of 0.26, 0.24, 0.28, and 0.21 in the four models, respectively. The error value was the smallest among the skeleton extraction algorithms, indicating that this skeleton extraction algorithm had high accuracy in extracting human skeleton information. In addition, the depth information of human joint points was compared using the parallax ranging method, and the highest error was 1.57%. This further demonstrated that the coordinate error of the three-dimensional joints was relatively accurate, which also proved the effectiveness of the binocular stereo vision system. The system had an accuracy of over 80% in recognizing joint rotation information and dynamic movements in the human three-dimensional model. Finally, the highest accuracy of inertial sensors in capturing human movements was 97%, indicating the superiority of digital media in capturing three-dimensional animation technology. This also provides a theoretical basis and technical reference for animation production and other aspects.**

***Keywords*—3D animation; computer vision; motion matching algorithm; human 3D skeletal model; motion capture technology**

I. Introduction

With the rapid development of digital media technology and virtual reality technology, animation and film production require increasingly precise character models [1]. However, the three-dimensional (3D) animated character models still requires professional production software and generation systems. Therefore, regarding specific character modeling and motion driving, computer vision and human motion simulation techniques are used to match human 3D skeleton model data, thereby achieving smooth animation effects [3]. Digital media technology mainly processes, stores, and transmits information through computers and digital devices. The application of 3D modeling and rendering functions in digital media in animation production makes it more accurate and realistic, thereby enriching the visual experience [5]. The innovation of digital media technology has also provided new technological platforms and experiential conditions for the cycle and cost of animation production. In addition, regarding the design of motion postures for animated characters, computer vision and computer graphics are used. Combining wearable devices to collect data on human body movements and postures, it has been applied in practical applications such as robot gait rehabilitation, motion analysis, and film and television animation [6]. Finally, based on techniques such as image processing and pattern recognition, human motion analysis is performed on the collected motion data to complete the animation driving of the computer interface. However, for the collection of human motion data, auxiliary tools of wearable devices cannot meet the requirements of 3D animation display and accurate joint position matching. Therefore, the study first combines the skeleton extraction algorithm to build the human 3D skeleton model. Skin technology is used to achieve topology matching of animation models. Secondly, a binocular vision camera system is used to recognize human motion fonts to precisely match human posture movements and joint positions. This research method effectively combines the human 3D skeleton model with posture motion matching, fully utilizing the joint depth information of the skeleton model, and providing accurate data matching for human motion trajectory and 3D animation simulation. Finally, the research combines computer vision and artificial intelligence technology to test and verify motion capture devices, aiming to prove the effectiveness of 3D animation capture driving technology and provide technical means and realistic 3D visual effects for the smooth movements and behavioral postures of character models, thereby promoting the high-quality development of film and television animation production.

The research is mainly divided into six sections. Section II elaborates on the current research results. Section III conducts algorithm analysis on the constructed 3D animated human model to promote skeleton extraction and matching of motion postures. Section IV is to verify and analyze the motion recognition and capture equipment. Results and discussion is given in Section V and finally, Section VI concludes the paper.

II. Literature Review

Due to the advancement of 3D animation and virtual animation technology, motion capture techniques for animation models have been extensively studied. In recent years, domestic and foreign scholars have conducted a lot of research on digital media technologies such as virtual acquisition methods and computer vision in 3D animation production. Jiao L et al. proposed a node encoding classification for graph learning and computer vision applications, focusing on the development of graphic structures and computer vision. The applications of visual tasks based on neural network methods were also summarized [8]. Wang Y et al. used Kinect fusion algorithm and function to evaluate the tracking confidence of virtual reality simulation technology.

Then a prototype system was established to evaluate the

tracking skeleton of moving objects, thereby proving the good fusion performance [9]. Gao P proposed a multi-dimensional data model for video image motion recognition and motion capture based on a deep learning framework. It combined deep learning features and datasets to achieve high recognition accuracy for gesture actions [10]. For the 3D modeling of film and television animation, Xu L combined local binary fitting algorithm and convolutional neural network to construct a single perspective 3D face model. The results showed that it was feasible in film and television animation and human-computer interaction [11]. Wang X P et al. extended the corresponding relationships to functions using the balanced function map algorithm for 3D shape registration. Experimental analysis was conducted on the character animation dataset in function space, demonstrating the superiority of the algorithm [12]. For the application of computer vision and graphic vision, different algorithms have various effectiveness and feasibility in action recognition technology.

Regarding the human 3D skeleton model, researchers from different fields have achieved many results. Bhogal R K et al. used convolutional neural networks to search for optimal features for action recognition in multi-view skeletal 3D data. The long and short-term memory layering was used to achieve model accuracy, thereby proving the high accuracy of the model on the human dataset [13]. Setiawan F et al. used graph convolutional neural networks to simulate human skeleton for action recognition. The Laplace matrix was used to encode graph attributes, thereby achieving high recognition accuracy on human datasets [14]. Mao W S et al. used radio frequency identification technology and bicycle motion networks to label human posture data for 3D human posture tracking, which improved tracking accuracy [15]. Lin Y et al. used velocity threshold correction method to adjust joint data for human 3D posture detection. The camera was used to detect the depth value of posture data, thereby improving the accuracy of human 3D posture detection [16]. Ahad M A R et al. proposed a method for extracting motion posture features based on skeleton data for 3D skeleton joint position recognition. The high accuracy of its method was validated in the benchmark dataset [17].

In summary, researchers have conducted many model constructions and algorithm applications on animation production technology and human motion recognition methods. However, there is a lack of testing for the construction and simulation of internal skeletons in human 3D posture recognition. The research on the application and production effects of 3D animated characters is also limited, resulting in limited research on character simulation and motion posture in film and television animation. Therefore, the study utilizes motion-matching algorithms and skin animation algorithms to construct 3D skeleton models of animated characters. The binocular stereo vision system has high advantages in 3D animation motion capture technology.

III. 3D Animation Human Motion Capture System Construction

This section combines matching algorithms and skin techniques to connect skeleton motion and 3D data to analyze the motion trajectory of the skeleton model. A binocular stereo vision system is used to extract features from human joint points. A binocular local matching algorithm is combined to improve the 3D spatial information of human actions, thereby constructing a human 3D skeleton model and action capture system.

A. Motion Matching Algorithm for 3D Animation Model

3D animation character generation includes extracting skeletons, embedding skeletons, matching actions, and skin binding. The posture model of animated characters identifies joint positions and matches motion data for skeleton extraction to generate 3D animated characters. Therefore, the skeleton discrete embedding is used to identify the positions of key joints. The positions of other joint points are calculated based on the standard proportion relationship, thereby obtaining a complete character skeleton model [18]. However, skeleton motion control in 3D animation requires data that matches with the motion data. The skeleton extraction structure based on the same topology and the motion data structure of the Bio Vision Human Motion Capture (BVH) file are the same. In data matching, the BVH file is scaled to fit the same topology. The data scaling is shown in Eq. (1).

$$A_{dest} = A_{src} * \left(\frac{L_{dest}}{L_{src}} \right) \tag{1}$$

In Eq. (1), A_{dest} represents the motion data of the target skeleton. A_{src} is the motion data of the source animation data file. L_{dest} and L_{src} represent the length of the target joint skeleton and the joint skeleton length of the source skeleton, respectively. The ratio of two skeleton lengths can achieve data scaling. In addition, a hierarchical structure between skeleton joints is established to perform skeleton motion. The motion of the parent node affects the child nodes. Then the joint coordinate system completes the matrix transformation, as shown in Eq. (2).

$$P_a = P_0 E_{m-1}^{m}(t) E_{m-2}^{m-1}(t) ... E_{n-1}^{n}(t) \tag{2}$$

In Eq. (2), a represents the specified joint point. $E_{n-1}^{n}(t)$ is the transformation matrix. P_0 is the reference matrix, which is the initial posture. The transformation formula continuously converts the root node coordinates to the local coordinates of the target node, thereby completing the associated motion between skeletons. The skeleton motion data and 3D model are independent of each other. To achieve the 3D animation effect, the Linear Blending Skinning (LBS) algorithm is used to bind or deform skeleton and skin. The LBS algorithm labels human motion joints to calculate the vertex changes of the model. The vertex is related to the motion state of skeleton. The specific joint transition relationship is shown in Eq. (3).

$$v' = E_i \times A_i^{-1} v \tag{3}$$

In Eq. (3), v represents the coordinate of a vertex in the skeleton. v' is the vertex coordinate that has been converted through coordinate transformation. A_i^{-1} is the local coordinate system that converts the coordinate points in the

global state to joint J_i. E_i is its vertex motion control matrix. A vertex is affected by the joint motion of multiple skeletons, so different vertices are weighted to calculate the motion transformation matrix of the vertex. The weight is shown in Eq. (4).

$$\sum_{i=n}^{n} w_i = 1 \tag{4}$$

In Eq. (4), w_i represents the weight of a vertex. The sum of the weights of its vertices affected by different skeletons is 1. To improve skin technology and animation effects, the motion trajectories of all joints in the skeleton model are calculated, as shown in Eq. (5).

$$v' = \sum_{i=n}^{n} w_i E_{ji} A_{ji}^{-1} v \tag{5}$$

In Eq. (5), v' represents the vertex coordinates converted by coordinates. E_i is its vertex motion control matrix. To make the skin effect smoother and more realistic, as well as avoid collapse, the vertex weight values are kept in the model vertex direction to achieve continuous smooth motion. For the skin deformation problem of 3D animation models, the LBS algorithm is used to calculate the proportion of skeletons and skin at joints, conforming to the same model structure. In addition, the structure of the 3D animation model generation system is divided using the skin technology, as shown in Fig. 1.

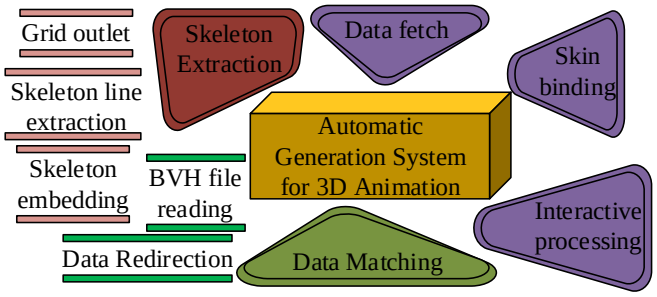

Fig. 1. Schematic diagram of the 3D animation model system structure.

From Fig. 1, the modules of the 3D animation model system mainly include data reading, skeleton extraction, data matching, skin binding, and interaction processing. The skeleton extraction module includes mesh processing, skeleton line extraction, and skeleton embedding. Data matching is the process of reading animation data from a BVH file and redirecting it to an existing model skeleton. In addition, the skin binding module utilizes the LBS skin deformation algorithm to bind skin and skeletons. By calculating the weight relationship between skeletons and model vertices, the motion trajectory of model vertices can be calculated. The final interaction processing of the system implements a visual display window to facilitate data import and parameter settings.

B. *Construction of Human 3D Skeleton and Motion Capture System*

Based on 3D animation motion posture, the human 3D action skeleton is constructed to meet the animation posture needs. The 3D action skeleton requires obtaining joint localization and recognition information. The binocular stereo vision system extracts features from human joints and combines optimization algorithms to obtain 3D information of human movements, thereby constructing a 3D skeleton model [19]. To accurately obtain 3D information of human motion joints, binocular camera calibration and 3D coordinate solution are used to ensure that human posture movements are consistent with joint positions. The visual distance measurement of the binocular camera is obtained by the principle of triangulation. The depth information of the target point is shown in Eq. (6).

$$Z = \frac{J}{X_l - X_r} \times f \tag{6}$$

In Eq. (6), J represents the distance between the center-line of the left and right optical centers of the binocular camera. f is the camera focal length. The mapping abscissa on the left is X_l, and the imaging abscissa on the right is X_r. The disparity value of the left and right mapping points is shown in Eq. (7).

$$d = X_l - X_r \tag{7}$$

In Eq. (7), d represents the disparity value between the left and right image points. Therefore, the depth information conversion of the target point is shown in Eq. (8).

$$Z = \frac{J}{d} \times f \tag{8}$$

In Eq. (8), Z represents the depth value of the target point in the physical world. To accurately obtain the 3D coordinates of human motion joints, this study combines the least squares method and the inner and outer parameter matrices of binocular cameras. Then, combined with the binocular local matching algorithm, the joint depth of human motion skeletons is calculated, as shown in Fig. 2.

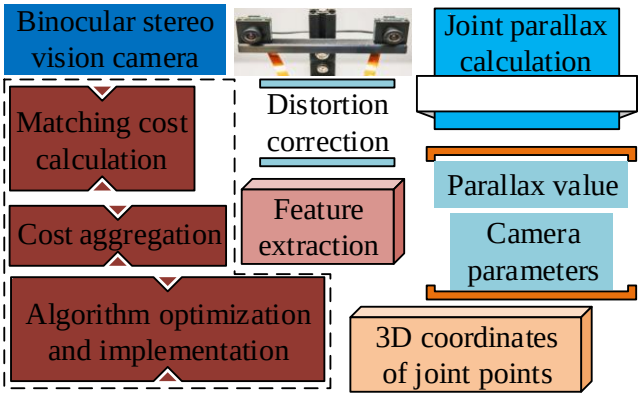

Fig. 2. Structure of binocular stereo matching algorithm.

From Fig. 2, feature constraints are an important step in matching algorithms, which can be used for edge extraction of left and right images, thereby reducing the matching range and obtaining gradient information of the image. In addition, joint disparity mainly includes feature constraints and matching cost calculation, cost aggregation, and algorithm optimization. The disparity value and camera parameters are combined to obtain the 3D coordinates of the joint points. Finally, by calculating the parallax value of human motion joints and accumulating the

relevant state equations, the two-dimensional skeleton joints of human motion can be corrected. Then, based on the coordinate transformation formula, the 3D joint coordinates can be calculated to construct the 3D skeleton of human actions. Based on the constructed 3D skeleton, the model is used to transform the 3D skeleton into a human 3D action that is consistent with the action posture. The motion capture and model error analysis are performed. The structure of the motion capture system is shown in Fig. 3.

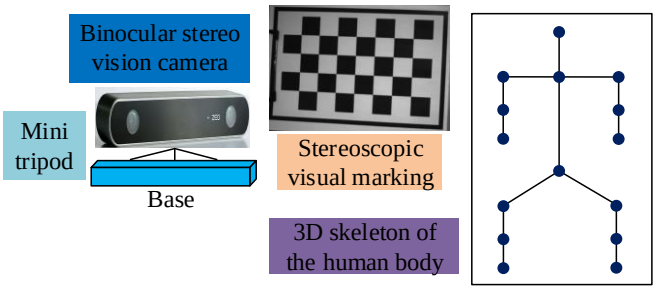

Fig. 3. System structure and model diagram of a 3D motion capture system.

From Fig. 3, the binocular stereo vision camera system used in the study includes a camera, a miniature tripod, and a base for easy portability and camera parameter adjustment. To improve the running speed of the system, platforms such as Windows and Linux are combined with high-performance processors to synchronously obtain images from left and right cameras. Finally, the images are transmitted to the computer through an interface for data processing. Due to the camera system saving data on the 3D skeleton model, the 3D coordinate information of joint points is input into the software to construct the human body skeleton, thereby obtaining action posture spatial information.

C. 3D Animation Model Technology Driven by Action Posture

The human posture and expression behavior unit data of 3D animation are synchronously captured by a dual camera system, which in turn generates the human animation model. The motion posture capture data is mainly controlled through key-frame interpolation and inverse kinematics to control model motion. Key-frame interpolation is generated through interpolation algorithms to generate intermediate transition frames to simulate real motion effects. To ensure that key-frame interpolation methods generate realistic and motion-compliant animations, quaternions are used to represent the rotation information of human joints. The interpolation algorithm is combined to compensate for missing frames in the rotation information. The Spherical Linear Interpolation (SLERP) method in quaternion interpolation can facilitate smooth interpolation of joint information. The ordinary linear interpolation function is shown in Eq. (9).

$$\vec{d} = \vec{d}_0 + t\left(\vec{d}_1 - \vec{d}_0\right) \tag{9}$$

In Eq. (9), $\vec{d}_0$ and $\vec{d}_1$ represent vectors in two directions, and the angle between them is φ. $\vec{d}$ represents the joint rotation information by taking two quaternions from the median vector of two directional vectors, as shown in Eq. (10).

$$\begin{cases} \vec{q}_0 = (x_0, y_0, z_0, w_0) \\ \vec{q}_1 = (x_1, y_1, z_1, w_1) \end{cases} \tag{10}$$

In Eq. (10), $\vec{q}_0$ and $\vec{q}_1$ are the direction vectors of two quaternions, respectively. The surface interpolation between two quaternions is shown in Eq. (11).

$$\begin{cases} \vec{q} = a(t)\vec{q}_0 + b(t)\vec{q}_1 \\ a(t) = \dfrac{\sin\left[(1-t)\varphi\right]}{\sin\varphi} \\ b(t) = \dfrac{\sin t\varphi}{\sin\varphi} \end{cases} \tag{11}$$

In Eq. (11), $(1-t)\varphi$ is the angle between $\vec{d}$ and $\vec{d}_1$. $t\varphi$ is the angle between $\vec{d}$ and $\vec{d}_0$. Therefore, the spherical interpolation is shown in Eq. (12).

$$SLERP(\vec{q}_0, \vec{q}_1, t) = \frac{\sin\left[(1-t)\varphi\right]\vec{q}_0 + \sin t\varphi\vec{q}_1}{\sin\varphi} \tag{12}$$

In Eq. (12), the angle between $\vec{d}$ and $\vec{d}_1$ is $(1-t)\varphi$. The angle between $\vec{d}$ and $\vec{d}_0$ is $t\varphi$. The dot product between two directional vectors is calculated to determine the angle between them, as shown in Eq. (13).

$$\cos\varphi = \vec{q}_0 \square \vec{q}_1 = x_0x_1 + y_0y_1 + z_0z_1 + w_0w_1 \tag{13}$$

In Eq. (13), the angle between the two directional vectors is φ. $(1-t)\varphi$ is the angle between $\vec{d}$ and $\vec{d}_1$. $t\varphi$ is the angle between $\vec{d}$ and $\vec{d}_0$. When the dot product result is negative, the interpolation will move the longest path around the sphere. When the angle between two directional vectors is too small, the denominator results tend to approach 0, and linear interpolation is used to replace the minimum angle. The spherical interpolation method is used to obtain key-frame sequences of uniform motion, but there are still some motion sequences that do not meet the laws of human motion. Therefore, it is necessary to combine the kinematic method to correct parameters and obtain more suitable control parameters for human motion laws. The human motion state is usually based on posture initialization, adding time and parameter changes in kinematics, including forward kinematics and inverse kinematics. In inverse kinematics, the intermediate joint points are calculated based on the position of the end node. The child nodes drive all parent nodes to achieve motion constraints layer by layer, specifically, as shown in Eq. (14).

$$R = f^{-1}(W) \tag{14}$$

In Eq. (14), R represents the joint rotation angle. W represents the end node position. The inverse kinematics analysis method reduces the complexity of node calculation, but it is only suitable for solving nodes with fewer degrees of

freedom. In addition, the inverse kinematics numerical method can solve the nodes with larger degrees of freedom to obtain complex human postures. Finally, combined with the joint limit state of the human skeleton model, the rotation information of all nodes is continuously adjusted. The standard range of human joint angle motion is shown in Fig. 4.

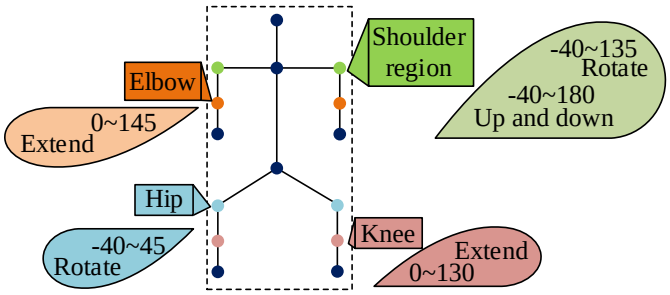

Fig. 4. Schematic diagram of the motion units of some joints in the human body.

From Fig. 4, the range of joint points through extreme motion is maximized when setting the action state of the 3D animation model. According to the constraint conditions, the motion constraint for the rotation angle of the joint point is shown in Eq. (15).

$$\phi_i = \begin{cases} \sum_{n=i-2}^{i} \frac{\phi_n}{n} & if\ (\phi_i < \alpha) \\ \phi_i & if\ (\alpha < \phi_i < \beta) \\ \sum_{n=i-2}^{i} \frac{\phi_n}{n} & if\ (\phi_i > \beta) \end{cases} \quad (15)$$

In Eq. (15), ϕ_i represents the rotation angle of a certain joint point, and its motion range is $[\alpha_{axis}, \beta_{axis}]$. To improve the motion and posture control of the 3D animated human body, a method combining key-frame interpolation and inverse kinematics is used to drive the 3D model, as shown in Fig. 5.

In Fig. 5, the human 3D skeleton model is mapped after importing data. Based on the corresponding skeleton posture data, the structure of the human model is set up to improve the human 3D skeleton model. The key-frame interpolation method involves interpolating the 3D estimation data to ensure smooth, stable, and continuous model motion. Finally, the skeleton data is bound and refreshed at the sent frame rate to obtain 3D animation effects.

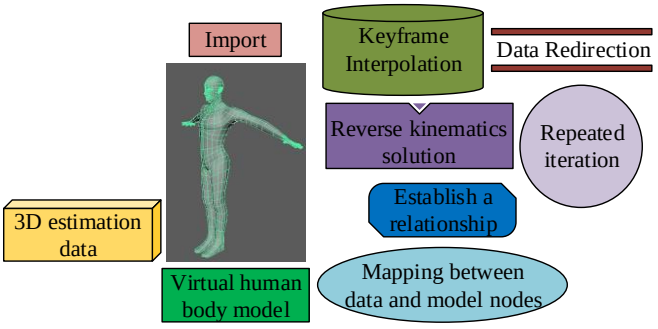

Fig. 5. The action and posture driving process of the 3D animation model.

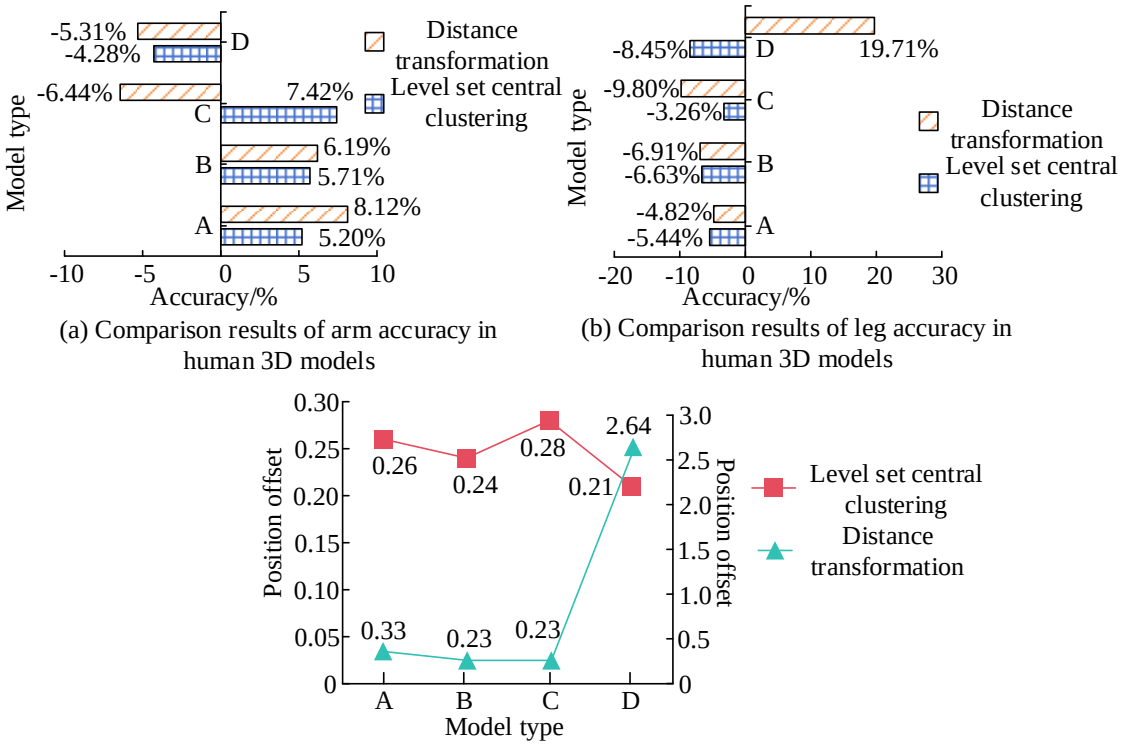
IV. Human Motion Capture and 3D Animation Driving Analysis

The 3D animation generation system and the motion capture system of the human skeleton model are interactively validated on the system platform to compare the motion posture and data errors of the 3D animation. Compared with other motion capture devices, it obtains smoother and more continuous data information in 3D animation information. The interactive 3D animation model is combined with the Microsoft Basic Class Library to establish a system interaction interface for importing BVH files and playback control. The hardware environment of the platform and the software system of the human 3D skeleton are shown in Table I.

In Table I, the interactive interface of the 3D animation model was used to open the BVH file and performed data processing on the 3D model. The motion posture and joint points of the human 3D skeleton were extracted through a camera. Combined with the software platform, image processing and 3D skeleton extraction were completed to construct 3D actions. 3D animation models were combined with skeleton extraction algorithms to conduct comparative experiments on four models. A-D was used to represent them. The number of vertices and polygons in model A was 2541 and 5078, respectively, while the number of information in models B, C, and D was the same, which was 13336 and 26668. The skeleton extraction algorithm adopted the level set central clustering method and distance transformation method. The accuracy of the arms and legs of the four models was compared, as well as the displacement of the shoulder joints, as shown in Fig. 6.

TABLE I. Basic Information of System Hardware Environment and Software Platform

Hardware Environment for 3D Animation Models		Software platform for human 3D skeleton models	
CPU	Intel(R)Core(TM)i5-3230M CPU @2.60GHz	Windows10 system	MATLAB platform
Memory	8G	Binocular camera calibration	Visual Sudio
Graphics card	NVIDIA GeForce GT 750M	Nvidia GeForce GTX1080	16G DDR4 2333MHz
Processing models and analysis results		Image processing and skeleton information extraction	



(a) Comparison results of arm accuracy in human 3D models

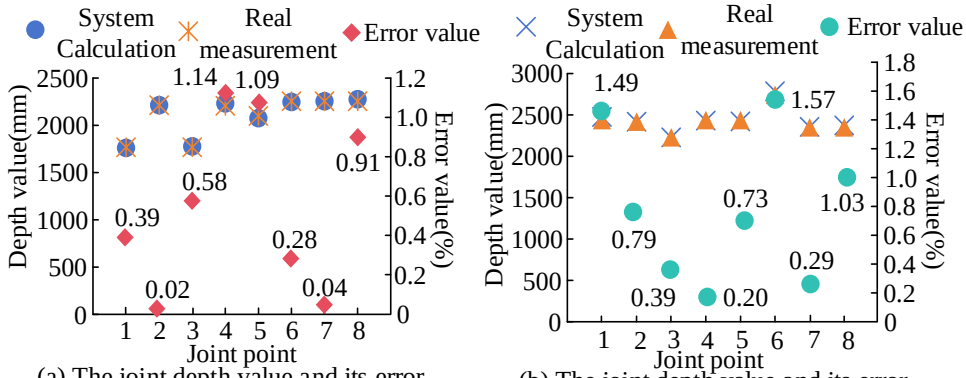
(b) Comparison results of leg accuracy in human 3D models

(c) The displacement results of shoulder joint positions in human 3D models

Fig. 6. Comparison of two skeleton extraction algorithms in human 3D models.

In Fig. 6 (a), the arm accuracy of the four models in the level set central clustering method was 5.20%, 5.71%, 7.42%, and -4.28%, respectively. The values in the distance transformation method were 8.12%, 6.19%, -6.44%, and -5.31%. The overall value of the level set central clustering method was low, with relatively high accuracy. In Fig. 6 (b), the leg accuracy of the human 3D model in the level set central clustering method was -5.44%, -6.63%, -3.26%, and -8.45%, respectively. The values of the distance transformation method were -4.82%, -6.91%, -9.80%, and 19.71%, with an overall difference greater than the former. Fig. 6 (c) shows the shoulder joint displacement in a human model. The level set central clustering method was relatively balanced with small differences, with values of 0.26, 0.24, 0.28, and 0.21, respectively. Therefore, it indicated that the level-set central clustering method had higher accuracy in extracting human skeletons. Afterwards, combining skin binding promoted superior smoothing effects in 3D animation, thereby extracting motion data.

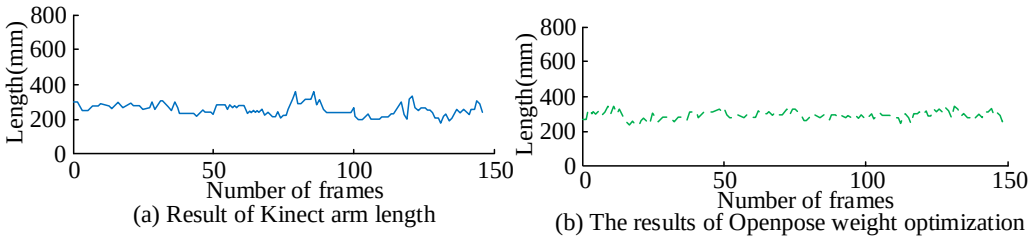
Based on the software platform of the binocular camera system and the constructed human 3D skeleton, the error analysis of joint depth values for human motion posture is carried out to achieve motion capture. The error comparison between the parallax ranging method and the real measurement is conducted using the human skeleton and its joint point model. The results are shown in Fig. 7.



(a) The joint depth value and its error value of the first set of actions

(b) The joint depth value and its error value of the second set of actions

Fig. 7. Results of joint depth values and error values for two groups of actions.



(a) Result of Kinect arm length (b) The results of Openpose weight optimization

Fig. 8. Comparison of results of action capture methods.

The action depth of the human 3D skeleton model is validated. The system calculation and actual measurement values are compared. The highest error was 1.14%, while the lowest was 0.02%. From Fig. 7 (b), the depth information error value for another set of actions was the lowest at 0.20% and the highest at 1.57%. Therefore, the 3D coordinate error of human joints was relatively accurate, which also proved the effectiveness of the binocular stereo vision camera system. Afterwards, joint movements of different human models are compared. Different binocular camera systems are used to capture 3D movements. The measurement length of the motion frame rate is shown in Fig. 8.

In Fig. 8 (a), the length of the limbs captured by the Kinect device remained basically unchanged, which was between 200mm and 400mm. In Fig. 8 (b), the weight optimization of Openpose multi-camera had a lower length fluctuation in the number of frames compared with Kinect devices. Therefore, it indicated the accuracy and superiority of the binocular stereo vision camera system in capturing motion. Finally, regarding the driving system of 3D animation, to simulate real-time human body movements and human-computer interaction movements, the image data of human body movements and postures is captured, as shown in Table II.

According to Table II, the binocular camera system used a Logitech C525 camera with a resolution of 1280×720. The maximum acquisition frame rate was 30fps. The Unity development platform has flexibility and convenience in constructing 3D animation models and their driver programs. It is feasible to solve joint rotation information of human body posture. Therefore, this study selects 3D human postures with static movements to compare the performance of different methods. The results are shown in Fig. 9.

TABLE II. CONFIGURATION OF BINOCULAR STEREOSCOPIC CAMERA SYSTEM PLATFORM

Driving system	Dual camera system

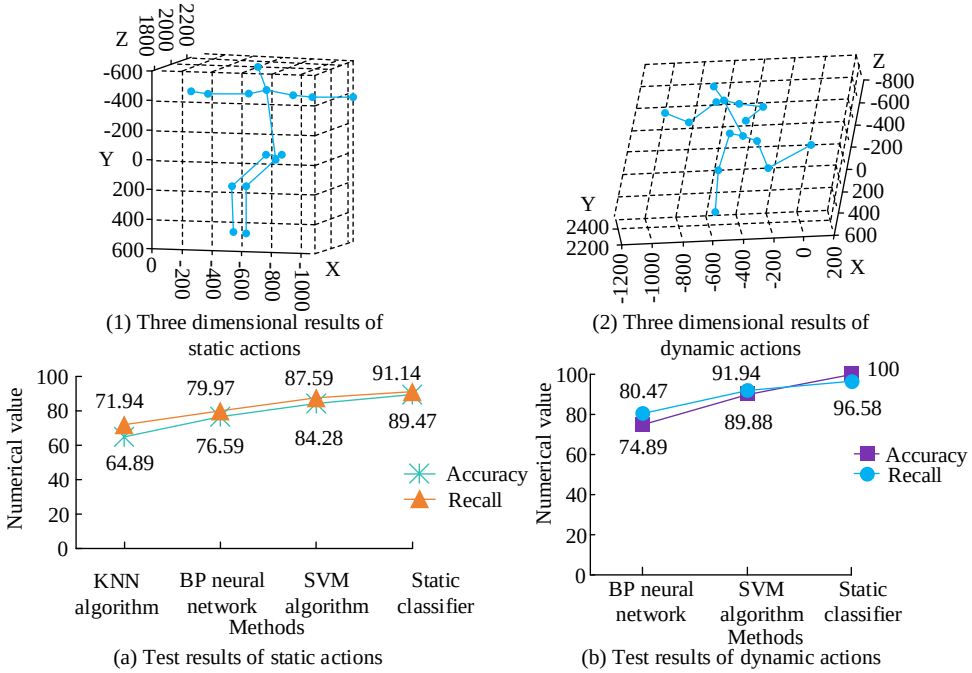
Operating system	Ubuntu 16.04
Development platform	Unity/Visual Studio2017



(1) Three dimensional results of static actions (2) Three dimensional results of dynamic actions

(a) Test results of static actions (b) Test results of dynamic actions

Fig. 9. Action test results of human 3D model.

Fig. 9 (a) displays the static actions of the human 3D model in Fig. 1. Its accuracy was above 70%, and the static classifier was more accurate in recognizing human movements. Fig. 9 (b) shows the recognition accuracy of dynamic movements in Fig. 2. The results were all above 80%, with a recall rate of over 74%, proving that the action testing of human 3D models was superior. Afterwards, the motion capture is performed, as shown in Fig. 10.

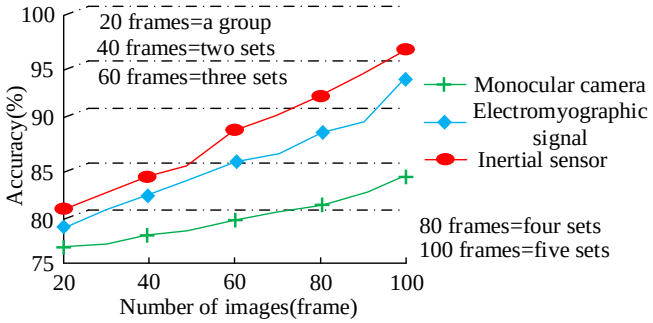


Fig. 10. Test results of different methods for human motion recognition.

In Fig. 10, the accuracy of motion capture improved with the increase in the number of motion images. The monocular camera system method had the lowest accuracy in recognizing human movements, with a maximum value of 84%. The highest accuracy of the action feature extraction method using electromyographic signals was 94%. The action capture accuracy using inertial sensors was as high as 97%. According to the motion capture method, the driving technology of 3D animation is continuously improving, and the motion capture of human 3D models is more accurate, thereby satisfying smooth animation effects.

V. Results and Discussion

As one of the key technologies in 3D animation production, computer vision and human motion simulation technology are important research directions for human 3D models. In the construction of a 3D skeleton model, the skin technology and matching algorithm were used to analyze the trajectory of the 3D data and motion features of the human skeleton. Among them, for the displacement test of the shoulder joints, the difference between the level set center clustering method was small, with specific results of 0.26, 0.24, 0.28, and 0.21. Afterwards, the binocular stereo vision system combined with the binocular matching algorithm to calculate the joint depth of the human action skeleton. The highest error of the skeleton model was 1.57%, which met the accuracy requirements of the 3D skeletal model of human movements. The highest motion capture accuracy for obtaining posture features of the binocular vision camera combined with the 3D skeleton model was 97%.

Based on the above results, it indicates that this study effectively improves the smoothness of 3D animation using matching algorithms and computer vision technologies, while enriching the visual effects and motion smoothness in animation character production. However, the motion recognition and posture data of human joints in this research system are still not complete enough, which affects the detailed effect of animated character models. At the same time, the motion capture driving technology lacks specific parameter moduli for joint points and posture that target the human 3D motion characteristics. In the future, the development and design of motion driving systems for 3D animation still need to continue exploring computer vision and motion capture driving technology to achieve innovative design in film and television animation and game production.

VI. Conclusion

To address the driving technology for 3D animation capture, the motion matching algorithm and human 3D skeleton model were used for data analysis of the 3D animation capture system. Firstly, the generation process of 3D animated characters was used to analyze the motion posture of the skeleton model, and then to match and partition its motion data. The LBS algorithm was used to set up and interact with the skeleton and skin at the joints of the model. Secondly, the human 3D skeleton model was constructed. Combined with a dual camera system to synchronously capture human movements, the depth information of 3D joints was obtained. According to the skeleton extraction algorithm, the accuracy of the arm joints for the four models was 5.20%, 5.71%, 7.42%, and -4.28%, respectively. The depth information verification of the human 3D skeleton movement showed that the lowest error values were 0.02% and 0.20%, respectively, indicating that the binocular stereo-vision camera system had high accuracy in joint recognition of the human 3D skeleton model. Finally, the motion capture system was validated and analyzed based on the captured data of the joint motion posture. The accuracy of human motion recognition was high, all above 80%. Therefore, the capture system platform for 3D animation satisfies the smoothness effect of 3D animation. However, the system's motion recognition animation for human joints is still not complete enough. The impact of additional effects on animation lacks quantitative analysis. Therefore, further research and improvement should be conducted on the development and application of the 3D animation capture driver system.

The Impact of Path Planning Model Based on Improved Ant Colony Optimization Algorithm on Green Traffic Management

Huan Yu
School of Transportation Engineering, Chang'an University, Xi'an, 710064, China
School of Economics and Management, Shaanxi Xueqian Normal University, Xi'an, 710100, China

***Abstract*—In response to the demand for green city construction, low-carbon travel standards have been further implemented. This research focuses on intelligent transportation management and designs path planning algorithms. Firstly, the basic model of the proposed ant colony optimization algorithm was constructed. In response to the poor convergence of traditional algorithms, a rollback strategy was introduced to optimize the model taboo table. Subsequently, in response to the dynamic obstacle avoidance problem in practical applications, the optimized A* algorithm was studied and applied to global path planning. The improved ant colony algorithm was applied to local obstacle avoidance planning, further enhancing the accuracy and practicality of the algorithm. In simulation analysis, facing more complex simulation environments, this research method could better achieve obstacle avoidance path planning. The average number of search nodes decreased by 6, the average search time decreased by 4.11%, and the average path length decreased by 22.07%. In summary, the ant colony optimization algorithm designed through research is more suitable for path planning needs in different scenarios, with the best overall performance. It can plan the shortest driving path while ensuring precise obstacle avoidance, helping to achieve green traffic management.**

***Keywords*—Ant colony optimization; A*; path planning; obstacle avoidance; traffic control**

I. Introduction

With the continuous construction and development of green smart cities, traffic management has gradually become an important factor restricting urban development. Intelligent Transportation System (ITS) integrates advanced technologies such as information, data communication transmission, and electronic control, significantly improving the efficiency of traffic management. While ensuring traffic safety and improving traffic service levels, it also reduces the impact of vehicle driving on the environment. The Path Planning (PP) module is a core component of ITS, responsible for providing users with the optimal driving route based on real-time traffic environment data. PP technology can be divided into two categories: static PP and dynamic PP [1-2]. The former does not consider environmental changes and is simpler and more direct. The latter requires real-time updates of environmental information to achieve dynamic path adjustment, making it more suitable for complex actual traffic environments. Currently, with the iterative updates of sensor technology, cloud computing, and big data, dynamic PP has made significant progress. It can more accurately reflect real-time road conditions, and improve the efficiency and practicality of PP. Dynamic PP can effectively reduce traffic congestion, improve driving efficiency, and guide vehicles to drive reasonably. The reduction of driving route distance naturally helps to establish low-carbon and green cities. This is in line with the current severe environmental problems and energy crisis, and the needs and goals of various regions for green city construction. However, although dynamic PP has made certain progress in both theoretical and technical aspects, it still faces many challenges in practical applications. Firstly, existing PP algorithms have low computational efficiency when dealing with large-scale and highly complex road networks, making it difficult to meet real-time requirements. Secondly, the fusion and processing technology of multi-source heterogeneous traffic data is not yet mature, which affects the accuracy and reliability of dynamic PP [3-4]. Therefore, how to design a dynamic PP algorithm that is both efficient and accurate, while also taking into account multiple practical needs, is the focus of current research in intelligent transportation. A PP model based on Ant Colony Optimization (ACO) algorithm is proposed to address the aforementioned issues. Its purpose is to improve it through rollback strategies and introduce the A* algorithm to optimize obstacle avoidance accuracy. The contributions of the research are as follows: (1) the basic path planning model based on the improved ant colony optimization algorithm is constructed, and the table of the backward strategy optimization algorithm is introduced to improve the convergence performance of the algorithm. (2) The optimized A* algorithm is studied and applied to global path planning, and the improved ant colony algorithm is applied to local obstacle avoidance planning, which further improves the accuracy and practicability of the algorithm.

The study consists of five sections. Literature review given in Section II. Firstly, the research status of PP is introduced in Section III. Secondly, a dynamic obstacle avoidance model based on ACO is designed in Section IV. Then, actual experiments and simulation analyses are conducted on the performance of the design model. Finally, a summary of the experimental results is provided in Section V.

II. Literature Review

The PP algorithm, as a research hotspot in motion planning, has been widely applied in various fields such as robot design, traffic management, and tourism. Li X et al. proposed an improved compression factor particle swarm optimization

method and applied it to the three-dimensional PP of Autonomous Underwater Vehicles (AUVs). In addition, they introduced three-dimensional seabed and Lamb vortex models to optimize navigation costs and ocean current constraints. Their model demonstrated better planning efficiency and path quality [5]. X Wang et al. designed an improved Q-learning algorithm and transformed its learning behavior into a discrete-time Markov chain model. By integrating strategies such as probability calculation tree logic, the effectiveness of PP and the reliability of control systems for mobile agents in uncertain environments were improved in this paper [6]. Y Huang et al. proposed a new underwater robot PP method, which transformed it into a deterministic optimization problem by using whale optimization algorithm and adaptive operator. The introduction of dynamic partitioning and other strategies for virtual individuals improved the search ability of the algorithm. Their method effectively solved the PP problem in complex terrain, improving the model's search ability and robustness [7]. S Zhang et al. proposed a PP model that combined timestamp collision detection and environment improved artificial potential field algorithm. Their model was applicable to the local PP technology of wave gliders, enhancing their obstacle avoidance ability and maneuverability during application [8].

Huo L proposed an improved path selection algorithm and applied it to wireless cloud computing environments to address the characteristics of frequent changes in urban traffic and rich driving paths. And the initial pheromones were non-uniformly dispersed, optimizing urban traffic management planning, improving path search efficiency and user satisfaction [9]. Yang X et al. chose the actor critic algorithm in reinforcement learning to design the PP model and introduced parameter updating and exploration strategies to further optimize it. Finally, it was applied to intelligent ship dynamic obstacle avoidance, improving the performance of the algorithm under complex meteorological conditions [10]. A Zou et al. proposed an innovative robot PP fusion algorithm by combining optimized mayfly algorithm and dynamic window method. The core of the former was the Q-learning algorithm, which could optimize convergence performance through adaptive parameter tuning. Their model reduced the average path length by 6.58% compared to traditional mayfly algorithms in complex environments [11]. Lyridis DV et al. proposed an improved fuzzy ACO for the PP of unmanned surface vehicles. Their method could effectively handle local obstacle avoidance problems and had better PP performance than other algorithms in complex environments [12].

In summary, most PP methods are developed using global or local programming, and their performance needs to be improved. For example, the ability to handle dynamic environments is limited, especially in rapidly changing scenarios, which may cause path failure. The improvement of obstacle avoidance effect may lead to an increase in computational costs, and errors caused by environmental uncertainty may also lead to PP failure. This indicates that it needs to be optimized and improved in multiple aspects such as adaptability, generalization, and security. Therefore, this study achieves a combination of global and local obstacle avoidance through ACO and A* algorithms. This not only improves the obstacle avoidance accuracy of vehicles, but also reduces the computational burden of this model, making it more adaptable in complex operating scenarios.

III. An Intelligent Path Planning Model with Improved Ant Colony Optimization Algorithm and Dynamic Obstacle Avoidance Optimization

To achieve green intelligent traffic management, this study proposes applying ACO to the vehicle PP model. Firstly, the convergence performance of ACO is optimized by building environmental models and other methods. Secondly, to achieve dynamic obstacle avoidance in real-world application scenarios, the A* algorithm is introduced and a dynamic PP model is constructed.

A. Design of Static Path Planning Model Based on Improved Ant Colony Optimization Algorithm

The PP module is an important component of smart transportation systems, aimed at planning an optimal operating path under certain constraints. The study chooses classical heuristic ACO as the basis for the PP model. It assumes that the total number of ants is k, and their individuals represent different paths. Starting from the starting point, individuals continuously update the position of the next node as shown in Formula (1).

$$p_{ij}^{k}=\begin{cases}\dfrac{\left[\tau_{ij}(t)\right]^{\alpha}\left[\eta_{ij}(t)\right]^{\beta}}{\sum_{s\in A}\left[\tau_{is}(t)\right]^{\alpha}\left[\eta_{is}(t)\right]^{\beta}} & if: j\in A\\ 0 & else\end{cases} \tag{1}$$

In Formula (1), p_{ij}^{k} represents the probability of ant k transitioning from position i to position j. t refers to a point in time. τ_{ij} means the concentration of pheromones between nodes at different locations. S is the current location node. A refers to optional location nodes for removing obstacles and other obstacles. α/β means the weights of pheromones and heuristic functions, respectively. η_{ij} represents a heuristic function. The heuristic function is the reciprocal of the distance between two position nodes, expressed by Formula (2) [13-14].

$$\eta_{ij}(t)=\frac{1}{d_{ij}} \tag{2}$$

In Formula (2), d_{ij} represents the distance between two nodes. In addition, each location node will have corresponding pheromones. Whether a node is selected is related to the concentration of pheromones. The more times an individual passes through a node at that location, the higher the corresponding pheromone. However, traditional ACO has excessive computational pressure, poor convergence performance, and is prone to falling into local optima. Therefore, the study addresses the above issues and makes improvements to them. Firstly, the vehicles are simplified as particles, and a two-dimensional grid model is constructed based on the road environment in Fig. 1.

In the two-dimensional grid map of Fig. 1 (a), the black part refers to the obstacle area. Obstacle setting can effectively test the optimization ability of the model. The search path follows the rule of 8-neighborhood representation in Fig. 1 (b). The position of each search point is the center point of the grid. The same initial pheromones in traditional ACO can reduce the accuracy of path search and increase its computational time. Therefore, the study proposes using the starting and ending line as the criterion for pheromone allocation, and the smaller the distance from the line, the greater the pheromone value. This can further improve the efficiency of global search, represented by Formula (3).

$$\begin{cases} \tau = \tau_0 + \vartheta C \\ \vartheta = \mu\varepsilon \end{cases} \tag{3}$$

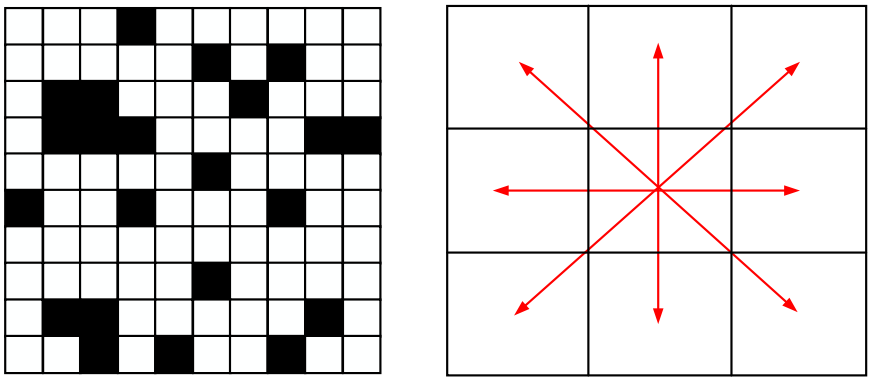
In Formula (3), τ, τ_0 represent the pheromone and basic pheromone of the algorithm, respectively. ϑ is an adaptive parameter. μ means the distance between nodes and connecting lines distributed within (0,1). ε refers to the proportion of obstacles distributed within (0,1). When there are no obstacles on the line, the depth of the grid color is proportional to the pheromone value. When there are obstacles on the connection, the overall pheromones of these other grids will decrease. This uneven initial pheromone concentration distribution is more conducive to the search for the optimal path. In addition, traditional heuristic function calculation methods suffer from low search efficiency and weak heuristic. Therefore, the study introduces a new Manhattan distance to calculate the heuristic function. Compared with Euclidean and diagonal equidistance, the calculation time of Manhattan distance is relatively shorter, expressed by Formula (4).

$$h(n) = D\left[abs\left(x_n - x_{end}\right) + abs\left(y_n - y_{end}\right)\right] \tag{4}$$

In Formula (4), x_n / y_n represents the two-dimensional coordinates of the starting node position. x_{end} / y_{end} is the two-dimensional coordinate of the termination node position. The heuristic function of Manhattan distance is introduced, represented by Formula (5) [15].

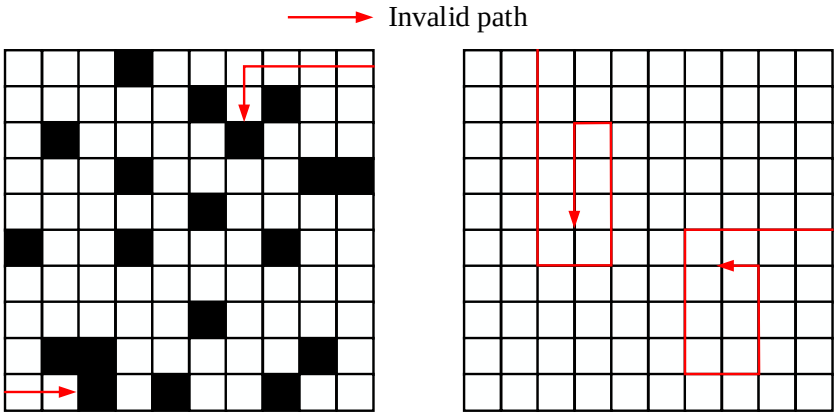
$$\eta_{ij} = \frac{1}{d_{ij} + \left[abs\left(x_j - x_{end}\right) + abs\left(y_i - y_{end}\right)\right]} \tag{5}$$

When an individual encounters obstacles in their search path, which cannot be avoided, or when there are taboo list restrictions, the path will be invalidated. Invalid paths include deadlocks and self-locking in Fig. 2.



(a) Two-dimensional raster map (b) Rules of ant colony pathfinding

Fig. 1. Visual environment modeling.



(a) Deadlock condition (b) Self-locking condition

Fig. 2. Diagram of invalid search path.

The study introduces a rollback strategy to optimize it. And the taboo table is divided into global and local categories, with the former recording deadlock routes and the latter recording self-locking and walking route nodes. Next, the study further introduces a pheromone update strategy to reduce data redundancy, represented by Formula (6).

$$\tau_{ij}(t+n)=(1-\rho)\tau_{ij}(t)+\Delta\tau_{ij}(t,t+n)+h\frac{L-L_n}{L_n} \quad (6)$$

In Formula (6), L, L_n represent the local and global optimal paths. h refers to the adjustable coefficient. ρ means the volatile factor of pheromones. The model only updates the shortest path pheromone. When $L > L_n$, it enhances the pheromone of the latest L. Otherwise, it decreases its pheromone. This method of updating pheromones only for the shortest path improves the convergence performance of the algorithm. In summary, the operational process of ACO has been improved in Fig. 3.

Firstly, it is necessary to build a virtual grid map through a real environment. Next, parameter initialization is carried out, which confirms the starting and ending points. After calculating the heuristic function at the starting node, path search can be performed. Node search needs to consider constraints such as taboo tables. This method iterates continuously until it reaches the endpoint.

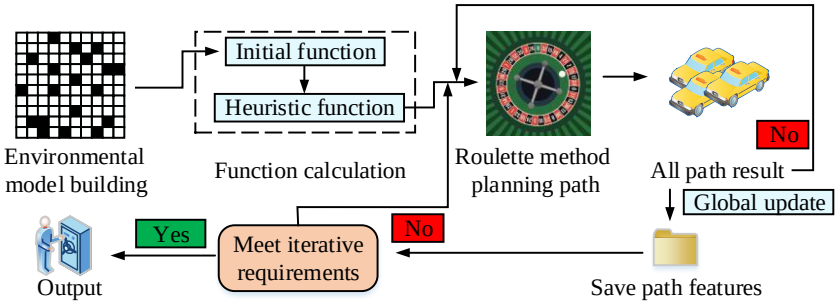


Fig. 3. Operation flow of improved ant colony optimization algorithm.

B. *Dynamic Path Planning Model Integrating A*-ACO Optimization Algorithm*

In practical intelligent traffic management applications, obstacles are often dynamically changing. Therefore, the study introduces the A* algorithm to improve ACO and builds a dynamic obstacle avoidance planning model. The classic A* algorithm updates the path by continuously updating the node cost and selecting the node with the lowest cost. Its performance is highly correlated with the heuristic function. If the heuristic function is too large, it will prioritize width. Otherwise, it is easier to complete the global optimal search. Common heuristic functions include Manhattan distance and Euclidean distance. However, both of these heuristic functions only have four search directions, which is not conducive to the global search of the algorithm and also increases the computational burden, resulting in a more tortuous path. However, to increase the operability of the search path, the path should be made as smooth as possible. Therefore, an improved heuristic function is proposed, which combines two heuristic functions to obtain twice the search direction. The estimated cost $h(n)$ is represented by Formula (7) [16-17].

$$h(n)=\max\left(abs(n_x-g_x),abs(n_y-g_y)\right) \quad (7)$$

In Formula (7), (n_x, n_y) represents the coordinates of the current node n. (g_x, g_y) refers to the coordinates of the target node G. abs means going to absolute values. In addition to smooth paths, this model also needs to implement dynamic obstacle avoidance. The motion model of obstacles is represented by Formula (8).

$$\begin{cases}\dot{x}=v\cos(\theta)\\ \dot{y}=v\sin(\theta)\\ \dot{\theta}=\kappa v\\ \omega=v\kappa\end{cases} \quad (8)$$

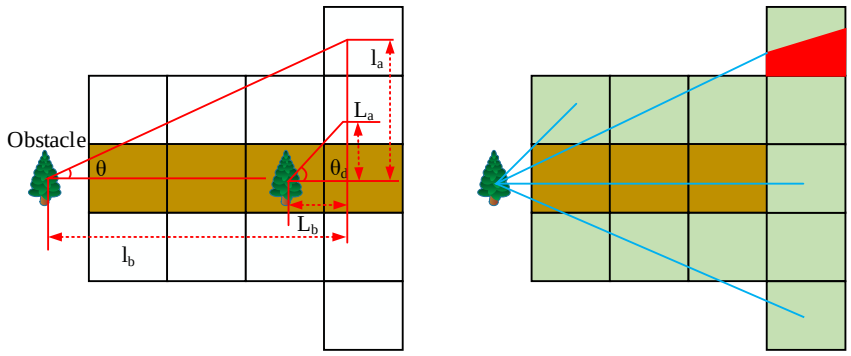
In Formula (8), v, ω represent velocity and angular velocity, respectively. θ is the safe steering prediction angle for speed. κ refers to curvature. Fig. 4 shows a dynamic obstacle model.

In Fig. 4, the angle of the dynamic obstacle also includes an emergency turn prediction angle θ_d, represented by Formula (9).

$$\begin{cases}\theta=\arctan\left(\frac{l_a}{l_b}\right)\\ \theta_d=\arctan\left(\frac{L_a}{L_b}\right)\end{cases} \quad (9)$$

In Formula (9), L_a, L_b represent the vertical and horizontal offset distances during emergency turns, respectively. l_a, l_b refer to the vertical and horizontal distances of slight path offset, respectively. To analyze whether the next node is affected by dynamic obstacles, the ratio of its grid area is calculated using Formula (10) [18].

$$f=\frac{\gamma}{L_i}+m \quad (10)$$



(a) Forecast Angle chart (b) Occupancy prediction chart

Fig. 4. Visual analysis of dynamic obstacles.

In Formula (10), $\gamma = \sin(\theta_i)$ represents the adaptive parameter. θ_i refers to the angle between the center of grid i and the direction of obstacle velocity, representing the proportion of the affected area of the grid to the total area. L_i means the vertical distance between the center of i and the direction of obstacle velocity. When f < 0.5, the corresponding grid is not affected by obstacles and is marked in green. On the contrary, the affected area is marked in red. The motion path of dynamic obstacles may move along the original direction or deviate to varying degrees toward the green area. The probability of deviation is positively correlated with the length of the obstacle's motion path, indicating a safe distance between the vehicle and the obstacle in Fig. 5.

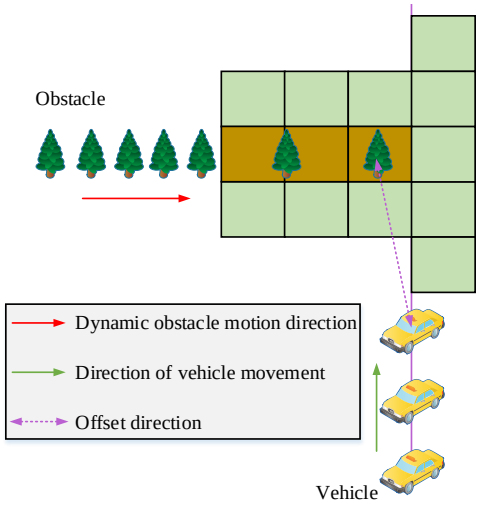


Fig. 5. Location diagram of vehicle and obstacle.

In Fig. 5, the safety distance S is represented by Formula (11).

$$S = \sqrt{(x_a - x_b)^2 + (y_a - y_b)^2} \tag{11}$$

In Formula (12), $(x_a, y_a), (x_b, y_b)$ represent the vehicle position and obstacle position, respectively. The premise for predicting the distance of obstacle movement is that the distance between the vehicle and the obstacle is not greater than the safe distance. The cumulative trajectory length $F(s)$ of the obstacle is represented by Formula (12).

$$F(s) = \sum_{S<S_0} S_b \tag{12}$$

In Formula (12), S_b represents the trajectory length of the obstacle. S_0 refers to the safety distance threshold. Therefore, after detecting and predicting the movement direction of obstacles and potential occupied nodes, they should be added to the temporary taboo list. Subsequently, during ACO runtime, the past taboo nodes are deleted one by one until the temporary taboo table is cleared. When obstacles are detected, local obstacle avoidance is achieved through ACO, and the volume and position of obstacles are uncertain. The obstacle avoidance strategy includes two types. Firstly, the distinction is made based on the angle between the directions of two objects. If the angle is an obtuse angle, it is considered to be an encounter, and vice versa, it is considered a pursuit. Both need to call occupancy prediction after detection to realize obstacle avoidance. In addition, as the distance between the two gradually increases, it is necessary to make another occupancy prediction. To improve the operational efficiency of occupancy prediction, an information inheritance strategy is introduced, represented by Formula (13).

$$\begin{cases} Tua_d = Tua + Tua_s \\ TABU_d = TABU_s \end{cases} \tag{13}$$

In Formula (13), Tua represents the pheromone matrix of the original ant colony. Tua_d, Tua_s refers to the initial pheromone during occupancy prediction and the upper and lower bound optimization pheromone matrices after the call is completed, respectively. $TABU_d$ is the ACO global taboo table for obstacle avoidance. $TABU_s$ represents the ACO global taboo table after the end of the run. In summary, Fig. 6 shows a dynamic obstacle avoidance model that integrates A*-ACO.

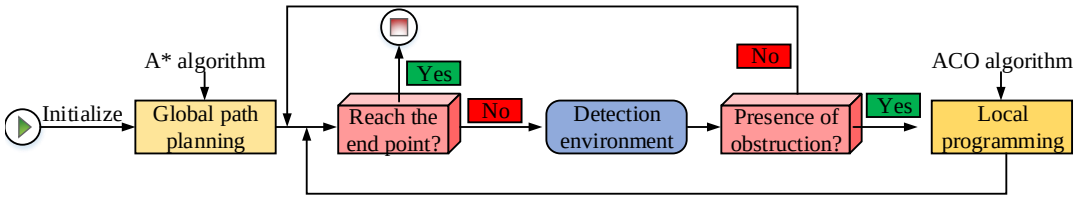

Fig. 6. Dynamic obstacle avoidance path planning process of A*-ACO algorithm.

In Fig. 6, the first step is to build a two-dimensional grid environment model, and then optimize the A* algorithm for static global PP. When conducting obstacle detection, if there are no obstacles, the global path is executed. If there are obstacles, occupancy prediction is made. Optimized ACO is used for local obstacle avoidance PP until reaching the endpoint.

IV. Results and Discussion

In the performance analysis and verification of the PP design algorithm, the study first analyzed the performance of the optimized ACO and the optimized A* algorithm to verify the effectiveness of their improvement strategies. Subsequently, the study applied it to practical simulations to compare the PP performance of various models under different vehicle driving conditions and environmental complexities.

A. Comparison and Analysis of A* and ACO Performance Before and After Optimization

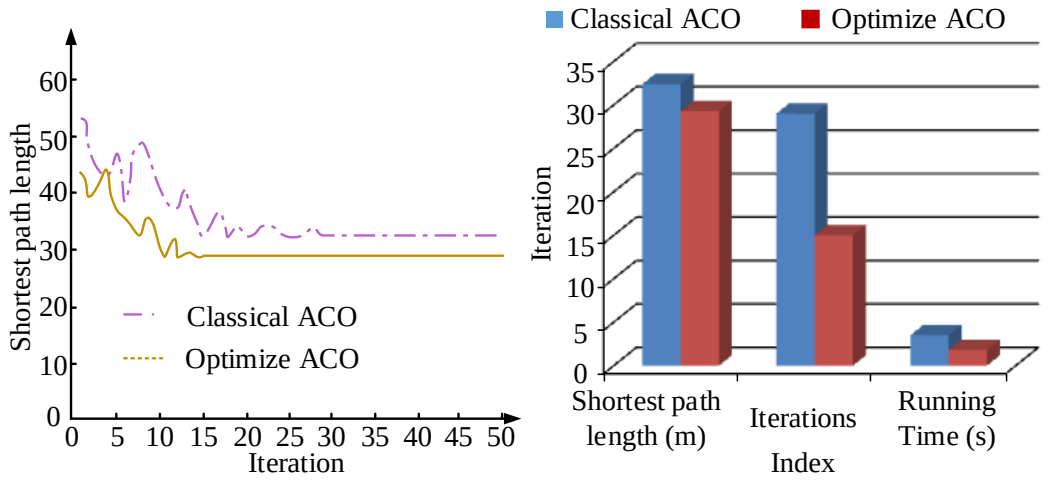
The study first focused on the optimized ACO and A* algorithms. Table I shows the experimental environment and parameter settings.

The study compared the convergence performance before and after ACO optimization in Fig. 7.

From Fig. 7, the optimized ACO showed a significant improvement in convergence performance, which was reflected in both convergence speed and final convergence value. The final convergence value of the optimized ACO, i.e. the output shortest path length, was 29.3 meters. The convergence value of the shortest path length in classical ACO was 32.4 meters, a relative increase of 9.57%. The convergence frequency of the optimized ACO was 15 times, which was a 48.28% decrease compared to the 29 times of the traditional ACO. The runtime of optimized ACO was only 1.8 seconds, while classical ACO took 3.5 seconds to complete the iteration. Therefore, in terms of runtime, this optimization algorithm had relatively decreased by 48.57%. In summary, the performance improvement of optimized ACO was mainly reflected in operational efficiency. In addition, there was also a certain improvement in the output path value. As the PP length increased, the gap between the two algorithms also became larger. The study then compared the performance of A* algorithm before and after optimization in Fig. 8.

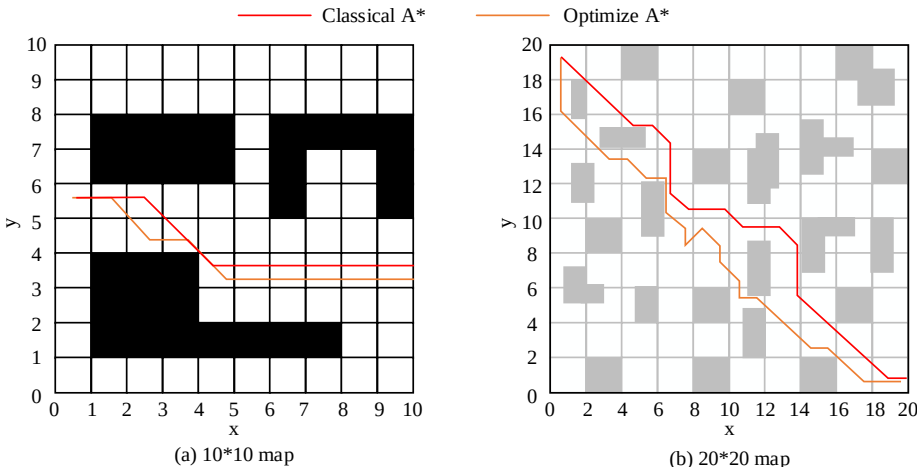
TABLE I. Experimental Environment and Parameter Settings

Name	Settings
Operating system	ThinkPad E440 Ubuntu 16.04
GPU	GTX 2070 Super
Simulation platform	MATLAB
Search individual count	30.0
Pheromone heuristic factor α	1.0
Ideal heuristic factor β	7.0
Number of iterations threshold	50.0
Pheromone volatile factor ρ	0.7
Pheromone enhancement coefficient	1.0



(a) Model convergence graph (b) Model convergence performance

Fig. 7. Comparison of ACO algorithm convergence performance before and after optimization.



(a) 10*10 map (b) 20*20 map

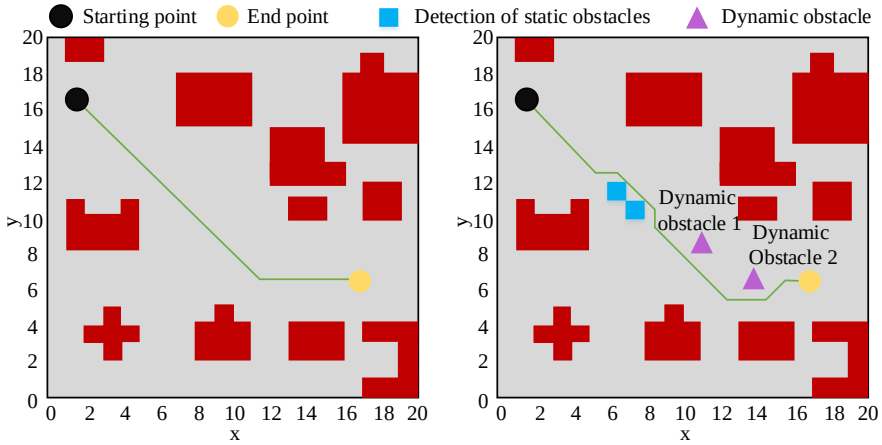
Fig. 8. Comparison of A* algorithm path planning before and after optimization.

The above obstacle avoidance PP experiments were all based on static obstacles. Fig. 8 (a) shows the PP results of the A* algorithm for each model in a 10*10 map before and after optimization. Due to the small size of the map and the concentrated distribution of obstacles, the PP results of each model were not significantly different. But overall, the optimized A* model had a smoother path with only two inflection points. The number of inflection points in traditional A* algorithms was twice that of optimization algorithms. This indicated that even in simple obstacle avoidance environments, the optimized A* algorithm exhibited better PP performance. In Fig. 8 (b), the map size had increased and the distribution of static obstacles was relatively scattered, resulting in smaller sizes. In complex obstacle avoidance scenarios, there was a more significant difference in the PP performance of the A* algorithm before and after optimization. The traditional A* algorithm had 17 inflection points in a 20*20 map, while the optimized A* algorithm had only 11 inflection points in a 20*20 map, a relative reduction of 35.29%. Therefore, the optimized A* algorithm produced smoother paths, shorter path distances, better adaptability in complex scenes, and could better achieve global PP.

B. *Performance Comparison of Dynamic Obstacle Avoidance Path Planning Models Based on A*-ACO*

A simulation obstacle avoidance environment was built on a 20*20 map and its PP process was simulated using A*-ACO in Fig. 9.

Fig. 9 (a) shows the initial global PP results of the improved A* algorithm. In this path, only static obstacles were considered. The optimized A* algorithm had a relatively smooth global planning path with fewer turning points, and overall smoothness, achieving good static obstacle avoidance PP. Then by detecting other obstacles and utilizing the improved ACO, dynamic obstacle avoidance local PP was achieved. Fig. 9 (b) shows the final dynamic obstacle avoidance PP result. It was completed even with the addition of static and dynamic obstacles. There were seven turning points. Compared to static global paths, the path length increased by 23.46%. In summary, the designed dynamic obstacle avoidance PP model based on A*-ACO could cope with the appearance of dynamic obstacles and output a relatively smooth driving planning path. The study continued to analyze the impact of optimization algorithms and classical ACO output paths on the operational performance of driving vehicles in Fig. 10.



(a) Optimize the static obstacle avoidance global planning path of A* algorithm (b) A*-ACO algorithm dynamic obstacle avoidance path output

Fig. 9. Output result of A*-ACO algorithm dynamic obstacle avoidance process path.

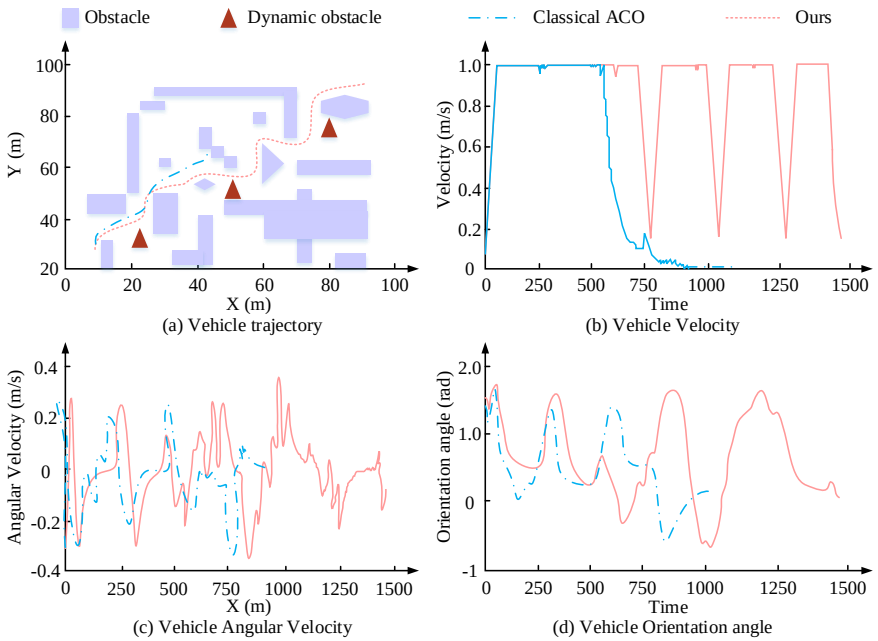


Fig. 10. Vehicle driving simulation results based on path planning model.

The simulated environment for the above experiment was 100m*100m. In Fig. 10 (a), the traditional ACO did not complete the PP, although it successfully avoided the first dynamic obstacle, it collided with the static obstacle at coordinates around (45, 70). Therefore, traditional ACO needed further optimization. The designed hybrid optimization algorithm successfully avoided various static and dynamic obstacles and reached the endpoint. In addition, its output path was smooth, with fewer turning points except for necessary obstacle avoidance turning points. Fig. 10 (b) shows the speed curves of vehicle paths for each model. The linear velocity of the design model always maintained a relatively regular periodic variation, with only small fluctuations of less than 0.1%. After the traditional ACO failed to avoid obstacles, the linear speed dropped sharply and eventually returned to zero. In Fig. 10 (c), the angular velocity of the traditional ACO also returned to zero, and the steering angle in Fig. 10 (d) showed the same change. The linear velocity, angular velocity, and steering angle of the designed algorithm always maintained similar fluctuations without changing the kinematic characteristics. Therefore, this proposed algorithm could better achieve dynamic PP of vehicles. In addition, the study also introduced the Improved Compressed Factor Particle Swarm Optimal Algorithm (ICFPSO) proposed by Li X et al. and the Modified Q-Learning Algorithm (MQL) proposed by X Wang et al. for comparison. Table II shows the experimental results.

In Table II, this design algorithm had the best overall performance. In a 25*25 map, MQL performed the best, with an average decrease of 2.5 search nodes compared to other algorithms. The search time decreased by 10.51%. However, as the complexity of the map increased, this design algorithm gradually demonstrated better PP performance. In a 25*25 map, the average search node decreased by 3.85%, the average search time decreased by 3.62%, and the average path length decreased by 18.20%. In a 100*100 map, the differences between these models were even greater. The average number of search nodes for this design algorithm decreased by 6, the average search time decreased by 4.11%, and the average path length decreased by 22.07%. In summary, this design method was more suitable for PP needs in complex scenarios and had the best overall performance. In order to further confirm the superiority of the research method, the research was compared with the advanced algorithms in the current field, as shown in Table III.

TABLE II. COMPARISON OF PATH PLANNING PERFORMANCE OF DIFFERENT MODELS IN DIFFERENT SCENARIOS

Index	Environmental dimension (m)	Model		
		Ours	***ICFPSO***	***MQL***
Search node mean	25*25	83	82	80
	50*50	234	242	235
	100*100	694	699	701
Search time mean (ms)	25*25	11.21	11.23	10.66
	50*50	88.24	90.37	92.50
	100*100	287.35	288.91	291.47
Mean path length (m)	25*25	28.03	28.55	27.64
	50*50	65.91	65.88	68.96
	100*100	120.74	130.64	134.83

TABLE III. COMPARISON BETWEEN RESEARCH METHODS AND ADVANCED ALGORITHMS

Method	Research method			Li X et al. [5]			X Wang et al. [6]		
Map scale	25*25	50*50	100*100	25*25	50*50	100*100	25*25	50*50	100*100
Average number of search nodes	83	234	694	103	277	793	108	286	834
Average search time (ms)	11.21	88.24	287.35	14.22	107.69	392.48	13.71	121.34	402.95
Average path length (m)	28.03	65.91	120.74	31.02	77.68	143.23	29.97	79.31	142.39

As can be seen from Table III, the research method has certain advantages in terms of the average number of search nodes, average search time and average path length. In order to ensure the accuracy and reliability of the results, the study conducted comprehensive verification. The results show that the convergence frequency of the proposed method is 48.28% higher than that of the traditional algorithm. The generated path has fewer turning points and higher smoothness, and the number of turning points is reduced by 35.29% compared to the traditional algorithm. By analyzing the data of 100 independent simulation runs, the research method is 30% lower in the standard deviation of path length and 25% lower in the standard deviation of search time than the traditional algorithm. The results verify the accuracy and importance of the research method, and clarify its research status and potential application value in the field of intelligent traffic management.

C. Discussion

The proposed path planning model based on improved ant colony optimization algorithm shows good obstacle avoidance path planning ability in simulation analysis. Specifically, compared with the traditional algorithm, the number of search nodes in this algorithm is reduced by 6, the average search time is reduced by 4.11%, and the average path length is reduced by 22.07%. These improvements are mainly due to the following aspects: (1) The convergence performance of the algorithm is effectively improved by introducing a backtracking strategy to optimize the tabu table of the algorithm. (2) Manhattan distance is used instead of the traditional Euclidean distance, which simplifies the calculation of the heuristic function and improves the search efficiency. (3) Combined with the A* algorithm, it achieves effective avoidance of dynamic obstacles and improves the adaptability and practicability of the algorithm in the actual traffic environment. X Wang et al. [6] used an improved Q learning method to translate the learning behavior into a discrete-time Markov chain model. Through the improvement of ant colony algorithm, this study strengthens the heuristic information utilization in path planning, improves the search efficiency and the smoothness of the path. The routing algorithm proposed by Huo L [9] takes into account the characteristics of frequent changes in urban traffic and rich driving paths. This study further improves the adaptability and obstacle avoidance effect in complex dynamic environment through the combination of dynamic obstacle model and A*-ACO algorithm. The method proposed by Lyridis DV et al. [12] performs well in dealing with the local obstacle avoidance problem of unmanned surface vessels. The method in this study also focuses on local obstacle avoidance, but through improved ant colony algorithm and dynamic obstacle avoidance strategy, higher obstacle avoidance accuracy and practicability are achieved. Compared with the improved compression factor particle swarm optimization method proposed by Li X et al. [5], the research method achieves a better balance among multiple objectives. The good performance of the research method in route planning is further explained, which can provide more technical support for traffic development in the future.

V. CONCLUSION

A PP method based on ACO was proposed to address the demand for dynamic obstacle avoidance in ITS. The improved ACO algorithm improves the convergence speed and stability by introducing backtracking strategy and dynamic obstacle avoidance optimization. Combined with A* algorithm, the proposed model can effectively deal with dynamic obstacles in actual traffic and realize real-time path adjustment. The algorithm achieves a good balance among multiple objectives such as search efficiency, path length and smoothness. These results confirmed that the optimized ACO reduced the shortest path length by 9.57% compared to traditional algorithms. The convergence frequency was 15 times, a decrease of 48.28% compared to before. In a 10*10 map, the number of inflection points in the traditional A* algorithm was twice that of the optimization algorithm. In a 20*20 map, the optimized A* algorithm had only 11 inflection points, a relative reduction of 35.29%. Subsequently, simulations were conducted on the practical application of A*-ACO. In a 20*20 map, the optimized A* algorithm's global planning path was relatively smooth and smooth, achieving good static obstacle avoidance PP. On the basis of adding static and dynamic obstacles, the path length increased by 23.46%. Then, on a map of 100m*100m, it was compared with traditional algorithms. These results confirmed that traditional algorithms had failed to complete the path, while the various indicators of this optimized algorithm always maintained similar fluctuation amplitudes and had not changed the kinematic characteristics. In comparison with other models, although the performance of this design algorithm was slightly lower in simple environments, in a 100*100 map, the average search time decreased by 4.11% and the average path length decreased by 22.07%. In summary, these design methods are more suitable for PP requirements in complex scenarios. In future studies, collaborative path planning in multi-vehicle environments will be studied, considering the interaction and collaboration between vehicles to improve the efficiency of the overall traffic flow. And establish a comprehensive evaluation framework to evaluate the performance of intelligent transportation systems in different scenarios, including environmental impact, economic benefits and social benefits.

***Abstract*—Early claims in the life insurance sector can lead to significant financial losses if not properly managed. This paper experiments a number of feature selection such as values regrouping, over or undersampling, and encoding that aim to enhance early claim detection by considering five (5) different machine learning algorithms. Utilizing the built-in feature importance from Random Forest, along with regrouping and correlation techniques, we identify the top seven (7) most significant features from a total 800 feature candidates. Our proposed strategy provides a streamlined and effective way to focus on the most relevant features, thereby improving the accuracy and precision of early claim predictive models for the life insurance domain. The results of this study offer practical insights into reducing fraudulent claims and mitigating financial risk. We used Random Forest besides considering techniques such as LightGBM, XGBoost, Feed Forward Neural Network, and CatBoost to train our model and achieved a maximum accuracy of 0.92 across three samples, indicating that our approach can effectively identify critical features and produce reliable results.**

***Keywords*—Machine learning; feature selection; life insurance; binary classification; Random Forest**

I. Introduction

Early claims in the life insurance industry pose a significant financial loss if the risk of policies sold is high. Life insurance companies, tasked with processing large volumes of claims, are especially vulnerable to early claims that may indicate sophisticated fraud schemes. Without effective detection mechanisms, these organizations may suffer substantial financial loss and reputational harm [1] [2]. Given the complexity and scale of modern insurance operations, efficient early claim detection is more crucial than ever.

One of the critical challenges in early claim detection is dealing with large datasets containing hundreds or even thousands of features. Not all of these features are relevant, and attempting to process all of them can lead to computational inefficiencies and reduced detection accuracy. Therefore, highly reliable feature selection techniques are essential to streamline the process and improve fraud detection outcomes.

In the United States, insurance fraud is thought to cost the country $308.6 billion a year [3]. The average cost of insurance fraud to a customer is estimated to be $900, primarily because the deception raises rates [3]. Health care insurance fraud (including Medicaid and Medicare insurance fraud) is the most expensive category of insurance fraud, costing customers an estimated $105 billion a year. Life insurance fraud comes in second with $74.7 billion, while property and casualty insurance fraud come in third with $45 billion [3].

The impact of insurance fraud activities includes Loss of Personal Income, & Savings, Higher Insurance Premiums, High Personal Costs, Ruined credit, Loss of Jobs, Diverts Government Resources, Loss from Essential Services and Rising cost of Goods & Services [4]. Fraudulent activity in the life insurance industry raises costs and leads to inflated premiums. As a result, having a solid risk management framework is critical for preventing or reducing life insurance fraud [5].

In the following sections, we discuss some past research works and detailed methodology used for data preparation, feature selection and model development. A discussion on the machine learning techniques used in this research and justifications for these techniques will be presented. An experimental setup and analysis and discussion of the results will be presented. We also highlight areas for future research and offer recommendations for implementing our approach in real-world settings.

II. Related Work

In this section, we review past research works on the insurance predictive models building and data preprocessing techniques.

A. Insurance Prediction Model Techniques

The author in study [6] emphasized the significance of the SCOR library for dealing with censored data in the machine learning model family. Various machine learning methods such as XGBoost, CatBoost and LightGBM have been adapted to the specificities of life insurance data, particularly censoring and truncation. On the other hand, [7] introduced data visualization techniques for decision support in the insurance sector. This study proposed that claim analysis can be used to distinguish between fraudulent and genuine claims; it also helped to better understand the customer strata while using the results throughout the underwriting and acceptance/denial stages of insurance enrollment.

The findings in study [8] revealed that ensemble-based approaches (random forest and gradient boosting) and deep neural networks produced the greatest results, outperforming other classifiers, including the widely used logistic regression.

Authors in study [9] aimed to use massive health insurance claims data to predict very high-cost claimants and show that high-performing prediction models may be built using only claims data and publicly available data, even for uncommon high-cost claimants worth more than $250,000. They created a platform with 6,006 variables across all clinical and demographic parameters and built over 100 candidate models. The best model has an area under the receiver operating characteristic curve of 91.2% which indicates that it possesses a high level of accuracy and discriminative power in predicting very high-cost claimants.

On the other hand, research in study [10] constructed and tested an artificial intelligence network-based regression model to forecast health insurance rates. The authors predicted that the health insurance costs experienced by people based on their characteristics and attained an experimental accuracy of 92.72%. In study [11], churn modelling of life insurance policies via statistical and machine learning methods is completed to analyse important features. The authors in the study [12] utilised the Random Forest approach to anticipate policyholders' decisions to lapse life insurance contracts. Even after factoring in feature interactions, the technique beats the logistic model.

The authors in the study [13] examined how car insurance companies employ machine learning into their operations and how ML models might be applied to insurance's large data. They use ML approaches including logistic regression, XGBoost, random forest, decision trees, naïve Bayes, and K-NN to predict claim incidence where the results demonstrated that RF outperformed other approaches. The authors in [14] forecasting motor insurance claims discovered that Random Forest with restricted depth and XGboost, when run on the 15 most relevant variables, outperformed the other models examined.

The study in [15] showed that data imbalance problem contributes significantly to poor model performance in insurance uptake prediction. Learning metrics improved when the data were balanced by either oversampling the minority class (insurance uptake in the instance of the data used) or undersampling the majority class (insurance non-uptake). In [16], the author enhanced the prediction accuracy by adding additional data sets to train and test the model. Features that did not influence the prediction were stripped of their features to examine how different independent factors affected the premium amount. In Table I, a summary of the papers reviewed is tabulated to justify the importance of this research.

The collective insights from the reviewed research paper underscore the significance of advanced machine learning techniques in enhancing insurance claim predictions and identifying fraudulent activities. Our research is distinguished by its comprehensive integration of diverse machine learning algorithms, including Random Forest, CatBoost, LightGBM, XGBoost, and Feedforward Neural Networks, as well as its innovative data preprocessing strategies. Unlike previous studies that focused on individual aspects such as data visualization, dealing with censored data, or specific model comparisons, our research employs a holistic approach. This includes denormalization of complex datasets, handling class imbalance through undersampling, and utilizing placeholder-based imputation for missing values to capture human behavior biases. Additionally, it incorporates quantile-based discretization for simplifying data and iterative feature selection using Random Forest's feature importance, ensuring the most relevant features are retained. The use of a chronological split further validates model performance on future, unseen data, simulating real-world applicability. By combining these methodologies, our research not only builds on the existing body of knowledge but also offers a robust, scalable framework that addresses the nuances of insurance data more effectively, ultimately leading to more accurate and reliable predictions.

TABLE I. SUMMARIZATION OF PASS RESEARCH WORK

Author	Problems	Techniques	Contributions

B. Data Preprocessing Technique

The authors in [17] suggested two strategies to address the issue of numerous majority class examples being disregarded in undersampling. EasyEnsemble selects various subsets from the majority class, trains a learner on each one, and integrates the results. BalanceCascade educates the learners in stages, with the majority of class examples properly identified by the present trained learners being eliminated from consideration at each stage. Experimental data reveal that both approaches have a greater area under the ROC Curve, F-measure, and G-mean values are higher than those of several other class imbalance learning approaches.

Missing data is a systemic issue in real circumstances, resulting in noise and bias when evaluating treatment outcomes. The solution in study [18] is selective imputation, which uses insights from mixed confounded missingness (MCM) to determine which variables should be imputed and which should be excluded. The authors empirically illustrate how selective imputation benefits distinct learners as compared to alternative missing-data methods. In study [19], a Monte Carlo simulation was used to evaluate the influence of the imputation approach on the bias and efficiency of scale-level parameter estimations, such as scale score means, between-scale correlations, and regression coefficients. The empirical data analysis results were consistent with those of the simulation, indicating that researchers should exercise caution when adopting planned missing data designs that require scale-level imputation.

The authors of study [20] presented a quantile-based criterion for the sequential design of trials, similar to the standard anticipated improvement criterion that allows for an elegant treatment of heterogeneous response precision. By analyzing both actual and simulated data, [21] showed that the permutation feature importance metric delivers more precise feature importance rank estimation in the presence of non-additive interactions. The authors of study [22] chose feature selection strategies based on correlation analysis and variance of input characteristics before sending these key features to a classification algorithm. Dimensionality was reduced using correlation and main component analyses.

The study in [23] attempted to identify an ideal strategy to mitigate the negative effects of option overload by assortment classification. This research contends that the number of possibilities under each label is more significant for preventing choice overload than the number of labels. This research discovers that a few labels are useful only when the category ratio falls within the specified ideal range. When categorised with the ideal category ratio, uninformative labels decreased option overload.

The experimental results in study [24] showed that the use of random splits can significantly overestimate predictive performance across all datasets and models. Therefore, the authors suggested that rumour detection models should always be evaluated using chronological splits for minimising topical overlaps. The study in [25] explained the ambiguous terminology, gave explicit principles for distinguishing between measures and metrics for the first time, and presented a new-fully visualised roadmap in a leveled structure for 22 measures and 22 metrics for investigating binary classification performance. In Table II, it tabulates all the papers reviewed in this article and their key contributions.

TABLE II. SUMMARIZATION OF PASS RESEARCH WORK

Author	Problems	Techniques	Contributions
[17]	Exploratory undersampling for class-imbalance learning	EasyEnsemble, BalanceCascade	Address the issue of numerous majority class examples being disregarded in undersampling.
[18]	To impute or not to impute	Mixed confounded missingness	Missing data in treatment effect estimation
[19]	A comparison of item-level and scale-level multiple imputation for questionnaire batteries	Monte Carlo simulation	Evaluate the influence of the imputation approach on the bias and efficiency
[20]	Noisy computer experiments	Quantile-based optimization	Quantile-based optimization of noisy computer experiments with tunable precision
[21]	Genetic association in the presence of non-additive interactions	Random forest models	A comparison of methods for interpreting random forest models of genetic association
[22]	Analysis for accurate breast cancer diagnosis	Correlation analysis, principal component	Feature selection using correlation analysis and principal component
[23]	Search for an optimal solution to reduce choice overload	Category Ratio	Discovers that a few labels are useful only when the category ratio falls within the specified ideal range
[24]	Rethinking evaluation on rumor detection benchmarks using chronological splits	Chronological splits	Evaluation on chronological splits
[25]	Binary classification performance measures/metrics	22 performance metrics	A comprehensive visualized roadmap to gain new insights on performance metrics

The past research paper underscores the multifaceted challenges inherent in data preprocessing and preparation within the realm of machine learning applications, particularly in addressing class imbalance and missing data issues. Our

research endeavors to build upon these insights by implementing a comprehensive approach to data preprocessing and preparation. Inspired by strategies such as EasyEnsemble and BalanceCascade for handling class imbalance, our research employs undersampling techniques while mitigating the potential loss of majority class examples. Additionally, placeholder-based imputation, as suggested in selective imputation, guides the treatment of missing data, ensuring a nuanced approach that minimizes noise and bias in model evaluations. Furthermore, by integrating dimensionality reduction techniques like correlation analysis, our research ensures that only the most relevant and informative features are retained for model training. This approach, validated by empirical and simulated studies, aims to enhance the robustness and efficiency of machine learning models, thereby addressing the challenges highlighted across various studies. Through these meticulously designed data preprocessing and preparation steps, our research aims to contribute to the advancement of predictive modeling in complex domains such as insurance, where data quality and accuracy are paramount.

III. Methodology

In this section, the research flow adopted is explained and justified. A discussion on the resources this research requires and the data to be used in this research is presented.

A. Research Workflow

In Fig. 1, the research flow adopted is presented. Every set of research activities is briefly explained in each stage of the activities.

1) Business understanding: Based on Fig. 1, the business challenge has been identified and the goal of the research is specified. It is important to collaborate extensively with business stakeholders to better understand the challenge and set targets.

2) Study requirement: Next, it is essential to study the information of related areas. This includes conducting an extensive review of the existing literature works related to the research topic. In addition, we identify key theories, concepts, and findings that contribute to the understanding of the research problem.

3) Data acquirement: It is critical to gather a comprehensive dataset that includes historical examples with both input features and corresponding target labels. This dataset will be utilised for training and testing the model. We collaborate with domain experts to ensure the dataset is representative and sufficient for the research objectives.

4) Table denormalization: As illustrated in Fig. 1, the data gathered has been denormalised. To facilitate effective analysis and modeling, we join the relevant tables using the appropriate join keys to denormalize the relational database. This process consolidates the data into a single table, making it easier to manage and analyze.

5) Data cleaning: Data cleaning is a critical step that addresses various issues within the dataset, such as missing values, duplication, and inconsistencies. This process ensures that the data used for modeling is of high quality and reliable. Techniques such as imputation for missing values, statistical methods for outlier detection, and consistency checks are employed to clean the data.

6) Exploratory data analysis (EDA): Exploratory Data Analysis (EDA) involves using data visualization and statistical techniques to understand the dataset's underlying patterns, relationships, and trends. By creating various plots, such as histograms, scatter plots, and correlation matrices, EDA helps in identifying significant variables and detecting anomalies or unusual patterns. Summary statistics provide insights into the distribution and central tendencies of the data, which are crucial for making informed decisions during model development. The findings from EDA guide the feature selection and engineering processes, helping to refine the model and improve its predictive performance.

7) Feature selection: Feature selection is the process of identifying and retaining the most relevant variables that significantly contribute to predicting the target outcome. This step is essential for enhancing the model's performance and reducing its complexity. By analyzing the correlation between features and their importance scores from preliminary models, redundant or highly correlated features are eliminated to avoid issues like multicollinearity. Incorporating domain knowledge helps in understanding the significance of each feature in the business context, ensuring that the selected features are meaningful and valuable for the modelling process.

8) Feature engineering: It is crucial to develop and refine features to more accurately represent the problem. This involves creating new features from existing data and selecting the most relevant ones to enhance model performance. Additionally, employ dimensionality reduction techniques if needed to simplify the model and improve its efficiency.

9) Encoding: Encoding converts categorical variables into a numerical format, which is essential for most machine learning algorithms to process categorical data effectively. For high cardinality features, target encoding or mean encoding may be used to preserve the feature's information without overly increasing the dataset's dimensionality. It's crucial to ensure that the encoding process does not introduce bias or affect the model's interpretability.

10)Train-test split: To evaluate the model's performance, the dataset is split into separate training and test sets. Creating a validation set from the training data is also common to fine-tune model parameters and avoid overfitting. This partitioning allows the model to be trained on one subset of data and tested on another, providing a realistic assessment of how well it generalizes to unseen data.

11)Model training: Then, the dataset is split into training and test sets to evaluate model performance. We choose an appropriate machine learning algorithm to build the predictive model by considering their strengths, weaknesses, and suitability for the business challenge at hand.

12)Model evaluation: The model's performance and its ability to address the business challenge has been thoroughly assessed by accuracy, precision, recall and F1-score. We use a

range of evaluation metrics to gauge the model's effectiveness. Based on the results, refine and optimize the model to ensure it meets the desired accuracy and reliability standards.

13)Deployment: We then implement the final model in a production environment, integrating it seamlessly into existing business processes. Ensure the model operates as intended and delivers the expected results. Ongoing monitoring and maintenance are essential to keep the model effective and responsive to any changes in the business context.

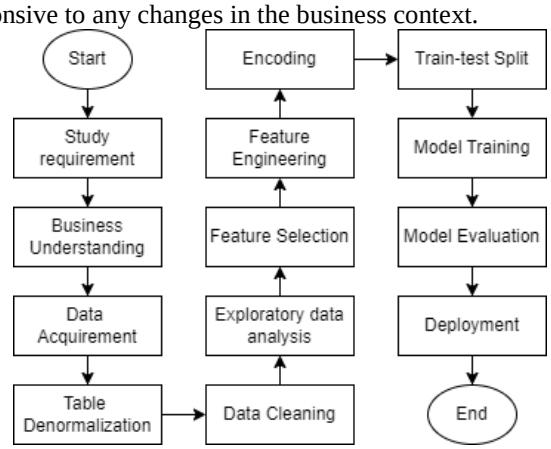

Fig. 1. Research workflow.

B. Resource Used

The hardware resources used in this setup include two servers: a Linux-based workstation and an IBM Power-Server. The Linux workstation offers 144,428.9 MiB (approximately 144.4 GiB) of memory, providing ample capacity for running data-intensive tasks. The IBM Power-Server, with 191,855.6 MiB (approximately 191.9 GiB), is designed for high-performance computing, ensuring that complex computations and large datasets can be processed efficiently. Connectivity between the servers and users is established through a Virtual Private Network (VPN) using FortiClient VPN, which ensures secure and encrypted communication over public networks.

On the software side, the primary integrated development environment (IDE) used is Jupyter Notebook, a versatile platform ideal for data analysis and machine learning tasks. The Python libraries utilised in this environment include PySpark for large-scale data processing, Pandas for data manipulation, Matplotlib for data visualisation, and Scikit-learn (sklearn) for machine learning algorithms. These libraries provide a robust set of tools for analysing, visualising, and modeling data, making the environment suitable for data science and artificial intelligence applications.

C. Data Nature

The data used in this research project is sourced from an insurance information service provider, spanning a comprehensive period of 20 years, from 2003 to 2023. This extensive timespan provides a rich dataset, allowing for in-depth analysis of long-term trends and patterns for this project. The data encompasses a diverse range of information, including policy details, claims history, customer demographics, and financial transactions. Due to data privacy protection regulation, this paper will not reveal other details.

In terms of structure, the data is organised into 12 distinct tables, which collectively contain a total of 7,103,548 rows and 861 columns. This considerable data volume necessitates robust data processing and storage capabilities. The wide variety of columns reflects the intricate nature of insurance-related data, with each table offering specific insights into various aspects of the business. One key aspect of the dataset is the target variable, used for predictive modeling, which has 7,032,993 rows labelled as 0 indicating policyholders have not made any claim whereas 70,555 rows labelled as 1 or 'policyholder have claimed', accounting for approximately 0.01% of the total population of the data. This imbalance data distribution between the two target values suggest that these is a need for advanced techniques to be considered in order to manage the class imbalance prior to the predictive model's development work. In addition, some of the features are found to have a large number of null values and a high number of distinct values. As such, ***strategies*** to manage null values, data binning for features of continuous type and data encoding for categorical features are highly essential for this research. Overall, the data provides a comprehensive foundation for detailed analysis and the development of data-driven strategies within the insurance sector.

IV. Preprocessing and Data Preparation

A. Denormalization

The project used memory-based processing where Python and Spark merge twelve (12) tables into a unified dataset, ensuring scalability and speed. The main method used was the inner join, which retrieves only the rows with matching keys in both datasets. Denormalization reduces field redundancy by joining related tables on common keys. Left joins were used to incorporate information from tables with optional or incomplete relationships, ensuring no key information is lost during the join process. Pivoting was used to transform NBXPROPINS table from long format to wide format (LFKPROPDETINS and LFKPROPDETINS are two columns where they have one one-to-one relationship and if one exists, another will be null), providing a more organised view and simplifying downstream analysis. The process ensured data integrity, handling incomplete data, and transforming complex table structures, providing a robust foundation for further processing and modeling. Fig. 2 depicts the entity relationship of all the tables collected.

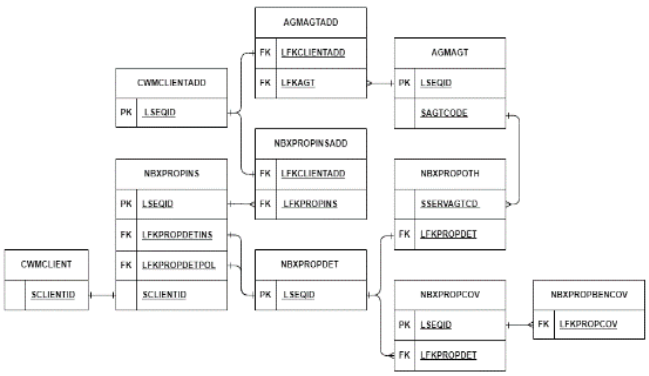

Fig. 2. Entity relationship diagram.

B. Oversampling and Undersampling

Oversampling and undersampling are techniques used to address class imbalance in datasets, which is common in many real-world scenarios [26] [27] [28]. The primary purpose of oversampling is to increase the representation of the minority class by creating synthetic samples or duplicating existing ones, thereby balancing the dataset and improving the model's ability to learn from minority instances [29] [30]. Undersampling, on the other hand, reduces the majority class by removing some of its instances, making the dataset balanced but potentially losing valuable information [31] [32]. Both techniques aim to improve model performance, particularly in classification tasks, by ensuring that the model does not become biased toward the majority class.

In our study, addressing class imbalance was a crucial part of the data preprocessing stage. The target variable exhibited significant skewness, with the majority class value '0' vastly outnumbering the minority class value '1', a common issue in many real-world datasets. To mitigate the imbalance in data distribution, we used an undersampling technique, which involves reducing the number of samples in the class value '0' to create a more balanced dataset. This approach helps to reduce bias and skewness in machine learning model building. While undersampling has the potential drawback of losing information from the majority class values, it effectively combats the tendency of models to overlook the minority class values.

C. Missing Value Handling

In traditional imputation methods, the common approach is to use central tendency statistics like the mean, median, or mode to fill in missing values. [33] Given that human input data can be prone to intentional omission for personal gain, using central tendency-based imputation could lead to misinterpretations and inaccurate predictions. By using placeholder-based imputation, we acknowledge the fact that the data has inherent biases due to human behavior, rather than sensor errors or system malfunctions. This approach can help maintain the context in which the data was originally collected, offering a more accurate representation of missing information [34].

Human input data, unlike automated sensor data, can contain omissions due to personal interests, such as avoiding higher insurance premiums. It's not illegal to leave a field blank, even though it may be against the policy's spirit. For example, someone who smokes might leave the "number of cigarettes per day" field empty to avoid being categorised as a high-risk individual. In such cases, using central tendency for imputation might not truly represent the omitted information, leading to a skewed interpretation of the data. Placeholder-based imputation ensures that the missingness itself is treated as a significant data point, which may suggest a behavioural pattern rather than a random occurrence. This allows the model to better account for intentional data omissions, leading to more robust predictions and insights into potential data-related risks. In this research, we adopt placeholder-based imputation because the context in which the data is collected significantly impacts its interpretation and subsequent analysis. By recognizing that human input data can be intentionally omitted for personal reasons, we address the inherent biases that central tendency-based imputation might overlook.

D. Data Binning using Quantile-based Discretization

Quantile-based discretization is a technique used to transform continuous variables into discrete categories based on their distribution. This approach involves dividing the continuous data into a specified number of intervals, or bins, where each bin contains roughly the same number of data points. This technique is applied to convert all features into categorical data before feature selection.

The advantage of converting continuous variables into categorical is that it simplifies complex data, making it easier for certain machine learning algorithms to process. Additionally, converting continuous variables to categorical can reduce the impact of outliers, which might otherwise skew the analysis. It also enables the use of categorical-specific modeling techniques, such as decision trees, which may perform better with discrete data.

E. Iterative Feature Selection

In this study, we employed an iterative feature selection methodology to identify and select the most appropriate features for our machine learning model. The iterative process allows us to continually refine our feature set until the desired level of model performance is achieved. At this stage, we applied a feature selection technique to identify the most relevant features. We used algorithms with feature importance metrics, such as Random Forests [35][36][37], to rank features based on their contribution to model performance. Features with low importance or high redundancy were removed. After evaluating the model, a decision was made on whether further feature selection was needed. If the results were satisfactory, the process ended. If not, we returned to the feature selection step for further refinement. Fig. 3 illustrates the flow chart of iterative feature selection.

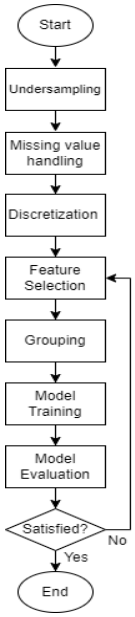

Fig. 3. Flow chart of iterative feature selection.

F. Random Forest's Feature Importance as the Key Selection Indicator

Random forest is adopted as the algorithm produces feature importance scores that are significant as an indicator for the feature selection process in this research. Random forest composed of multiple decision trees, each built from a random subset of features and a random sample of the training data (bootstrapping). As these trees are constructed, each feature is used to split the data, and the quality of these splits is evaluated using metrics such as Gini impurity.

Gini Importance:

$$ni_j = w_j C_j - w_{left(j)} C_{left(j)} - w_{right(j)} C_{right(j)} \quad (1)$$

ni_j = the importance of node j
w_j = weighted number of samples reaching node j
C_j = the impurity value of node j
left(j) = child node from left split on node j
right(j) = child node from right split on node j

G. Correlation Analysis

Correlation analysis is a valuable technique for identifying and dropping features that have high dependency or redundancy. When building a machine learning model, redundant features can lead to overfitting, increased complexity, and reduced interpretability. This research utilises Pearson Correlation Coefficient to measure linear relationships between continuous variables. We select only one feature from each group of highly correlated features. The correlation values range from -1 to 1, where -1 indicates perfect negative correlation, 0 indicates no correlation, and 1 indicates perfect positive correlation.

H. Category Ratio using Target Ratio Grouping

In this research, the challenge of handling categorical features with a high number of unique classes, many of which have limited data and skewed target distributions, is addressed through a method of class grouping based on target ratios. This technique, often referred to as target ratio grouping or data binning, aims to reduce the cardinality of categorical features to improve model robustness and avoid overfitting.

Here, categorical classes are regrouped based on their target ratio, which is calculated as the proportion of one target value within the class. Classes with extreme ratios (such as 1:0 or 0:1) tend to skew the model's performance due to their lack of variability and are prone to overfitting. To mitigate this, classes with similar target ratios are grouped into broader categories according to predefined rules. This approach not only reduces the number of unique classes but also helps ensure the model is not overly sensitive to rarely occurring classes or extreme outliers.

Our grouping rules categorised classes into one of the seven groups based on their target ratio:

- If the target ratio is 0.0 (i.e., the class has no instances of a specific target value), it is assigned to group 1.
- If the target ratio is greater than 0 and less than or equal to 0.2, the class is assigned to group 2.
- A target ratio greater than 0.2 and less than or equal to 0.4 assigns the class to group 3.
- For ratios greater than 0.4 and less than or equal to 0.6, the class falls into group 4.
- Ratios greater than 0.6 and less than or equal to 0.8 are categorised into group 5.
- Ratios greater than 0.8 but less than 1.0 are assigned to group 6.
- Finally, classes with a ratio of 1.0 are grouped into group 7, as they represent a consistent outcome.

By using this method, the cardinality of categorical features is significantly reduced, leading to more manageable datasets and a lower risk of overfitting. This regrouping strategy helps improve model generalisation and efficiency, allowing the model to focus on meaningful patterns without being affected by the noise from rarely occurring or highly skewed classes. This approach has demonstrated benefits in our research, leading to better model performance and reliability.

I. Chronological Split

A chronological split is a method of dividing a dataset into two subsets, typically for training and testing machine learning models. The split is based on a chronological criterion, such as the year or date a policy goes into effect. In this approach, the training set consists of data before year 2020, while the test set includes data from only year 2020. By splitting data in this way, we ensure that the model is trained on earlier information and tested on subsequent, unseen data, reflecting a more realistic scenario. This technique helps evaluate the model's ability to generalize and perform accurately on future data, providing a more robust assessment of its real-world applicability.

Using a time-based split ensures that the machine learning model is evaluated on data from a distinct and future period, which better simulates real-world deployment scenarios. By dividing the dataset according to the year, a policy goes into effect, the model is tested on data that is more representative of future conditions, behaviors, and trends. This approach is particularly useful in time-sensitive domains like insurance, where regulations, customer behavior, and external factors can change over time. It allows the project to assess how well the model can generalize beyond the training data, giving a more realistic indication of its performance in production.

A chronological split provides greater confidence that the model will maintain its accuracy and effectiveness when predicting future data, as it has been validated against a set that follows the temporal sequence of real-world events. This technique also helps identify if a model is overly reliant on historical patterns that may not persist in the future, thereby reducing the risk of overfitting to a particular timeframe or dataset characteristic.

V. Modeling Techniques and Measurement Metrics

In this research, five (5) machine learning algorithms had been evaluated. The following subsections briefly elaborate their theoretical architecture and models.

A. Random Forest

Random Forest is a powerful ensemble learning method that constructs multiple decision trees during training and combines

their predictions through voting or averaging to make final decisions. It excels in handling high-dimensional data and is robust against overfitting, making it well-suited for insurance claim prediction tasks where the dataset may contain numerous input features and a relatively small number of samples. Furthermore, Random Forest provides a measure of feature importance, allowing insurers to identify the most influential variables in predicting claim outcomes. Its ease of implementation and interpretability make it a popular choice for binary classification tasks in the insurance industry, offering a balance between predictive accuracy and model transparency. The architecture of Random Forest is shown in Fig. 4 [38].

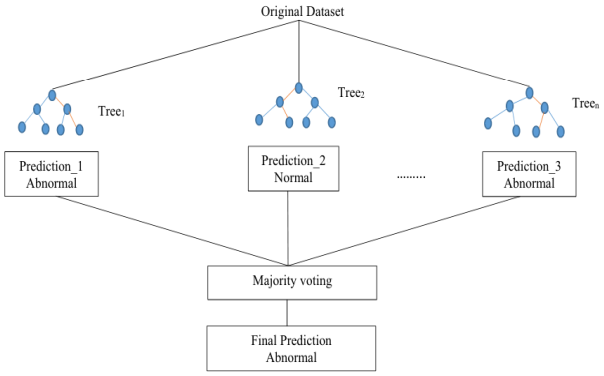

Fig. 4. Architecture of Random Forest.

The diagram in Fig. 4 illustrates a Random Forest classifier, which combines multiple decision trees to improve prediction accuracy. Each tree is built using a different subset of the original dataset and considers a random subset of features for splitting at each node, introducing diversity among the trees. Each tree independently predicts an outcome (e.g., "Abnormal" or "Normal"). The final prediction is determined by majority voting among all the trees' predictions, making the model more robust and reducing the risk of overfitting compared to a single decision tree. In this example, the majority vote results in a final prediction of "Abnormal".

B. CatBoost

CatBoost is a gradient boosting library specifically designed to handle categorical features efficiently, making it an ideal choice for insurance claim prediction tasks where categorical variables play a significant role. It employs gradient boosting techniques to build an ensemble of decision trees, automatically handling categorical features without requiring extensive preprocessing. CatBoost often provides competitive performance out-of-the-box and is less sensitive to hyperparameter tuning compared to other gradient boosting methods. Its ability to handle large datasets and categorical variables effectively makes it a valuable tool for insurers seeking accurate and reliable predictions of claim outcomes while minimizing the need for manual feature engineering. The architecture of Random Forest is shown in Fig. 5 [39].

Fig. 5 illustrates the architecture of CatBoost, a gradient boosting algorithm designed for categorical features. Starting with the UCS (universal concept space) dataset containing *NN* samples and *MM* features, the data is split into bootstrap samples to create multiple training datasets. Each training dataset is used to sequentially build *NN* decision trees (predictors), with each tree improving upon the previous ones. The model incorporates a unique feature called "weight expansion," which adjusts the weights of misclassified samples to emphasize harder-to-classify instances. After training, the individual predictions from each tree are combined through weighted averaging to produce the final prediction, optimizing performance and accuracy by effectively handling categorical variables and reducing overfitting.

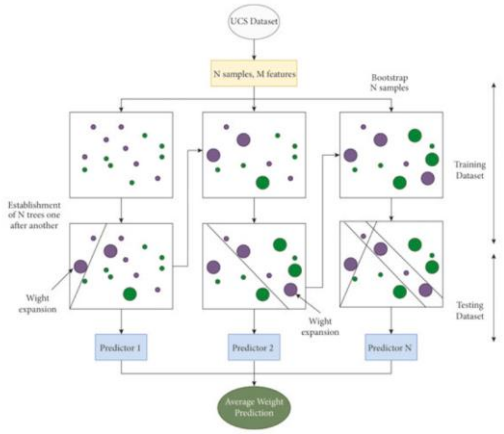

Fig. 5. Architecture of CatBoost.

C. LightGBM

LightGBM is a gradient boosting framework known for its efficiency and speed, making it particularly well-suited for insurance claim prediction tasks involving large volumes of data. It uses a novel tree-based learning algorithm that prioritizes training instances with high gradients, resulting in faster convergence and reduced computational costs. LightGBM is highly scalable and can handle large-scale datasets with millions of samples and features efficiently. Its ability to handle categorical features and missing data effectively further enhances its suitability for insurance claim prediction, where data may be incomplete or heterogeneous. Overall, LightGBM offers a compelling combination of speed, scalability, and predictive accuracy, making it a valuable asset for insurers seeking efficient and reliable models for binary classification tasks. The architecture of Random Forest is shown in Fig. 6 [40].

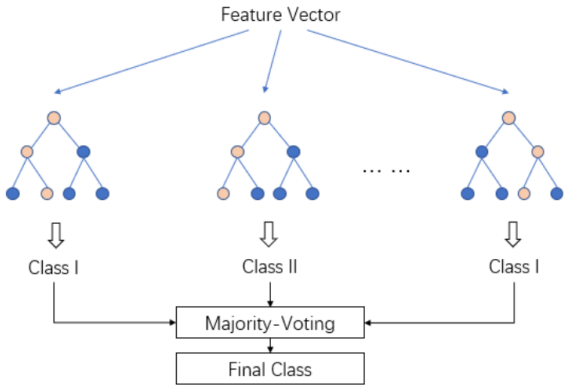

Fig. 6. Architecture of LightGBM.

Fig. 6 illustrates the architecture of a LightGBM (Light Gradient Boosting Machine) ensemble model, which utilizes multiple decision trees to make predictions. Each decision tree receives the same feature vector as input and produces a class prediction. These individual predictions are then aggregated through a majority-voting mechanism to determine the final class. The idea is that by combining the outputs of multiple trees, the model can achieve more accurate and robust predictions, leveraging the collective decision-making of the ensemble rather than relying on a single tree's output. This approach helps reduce overfitting and improves generalization performance.

D. XGBoost

XGBoost, short for eXtreme Gradient Boosting, is a scalable and efficient implementation of gradient boosting. It is widely used in insurance claim prediction tasks due to its exceptional performance and versatility. XGBoost employs a regularized learning objective that combines both gradient descent and second-order gradient descent, allowing it to capture complex patterns in the data while minimizing overfitting. Its ability to handle missing values and categorical features, along with built-in support for parallel computing, makes it well-suited for large-scale datasets common in insurance applications. XGBoost often achieves state-of-the-art results in various machine learning competitions and has become a go-to choice for insurers seeking accurate and robust models for binary classification tasks. Its interpretable nature, feature importance analysis, and ease of use further enhance its appeal, making XGBoost a valuable asset in the insurance industry's quest for reliable predictive models. The architecture of Random Forest is shown in Fig. 7 [41].

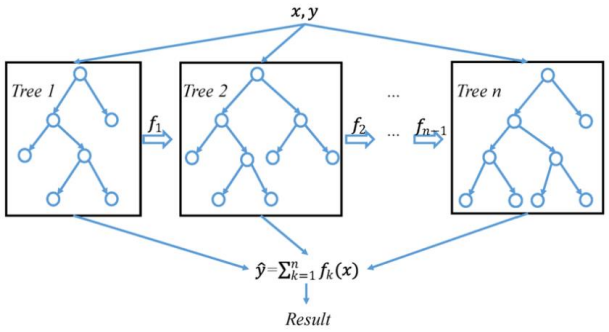

Fig. 7. Architecture of XGBoost.

The diagram in Fig. 7 represents the architecture of the XGBoost (Extreme Gradient Boosting) model, which is an ensemble learning technique that builds multiple decision trees sequentially. Each tree in the sequence is trained to correct the errors made by the previous trees. The input data, consisting of features xx and target yy, is used to train the first tree, $f1f1$. The output from this tree, along with the data, is then used to train the next tree, $f2f2$, and this process continues for all nn trees. The final prediction, $y^y^$, is obtained by summing the outputs of all the trees, expressed as $y^=\sum k=1nfk(x)y^=\sum k=1nfk(x)$. This iterative process allows XGBoost to minimize the overall prediction error, making it a powerful and accurate model for various predictive tasks.

E. Feed Forword Neural Network

A Feed Forward Neural Network implemented using TensorFlow is a deep learning model capable of learning complex patterns in the data through multiple layers of neurons. It offers flexibility in designing and customizing neural network architectures, allowing insurers to adapt the model to the specific characteristics of their data. While neural networks have the potential to outperform traditional machine learning models in certain scenarios, they often require extensive hyperparameter tuning and larger amounts of data to achieve optimal performance. Nevertheless, their ability to learn intricate relationships in the data makes them well-suited for insurance claim prediction tasks where the underlying patterns may be nonlinear or complex. With careful tuning and training, Feed Forward Neural Networks implemented using TensorFlow can offer competitive performance and provide valuable insights into claim outcomes for insurers. The architecture of Random Forest is shown in Fig. 8 [42].

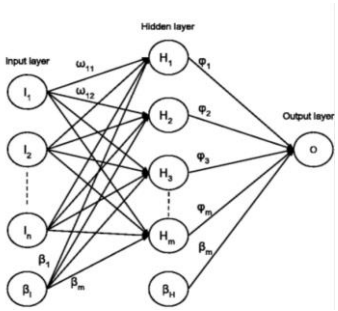

Fig. 8. Architecture of neural network.

The diagram in Fig. 8 illustrates the architecture of a basic feedforward neural network, consisting of three main layers: the input layer, hidden layer, and output layer. The input layer has nodes $I1,2,\ldots,InI1,I2,\ldots,In$, each representing a feature of the input data. These input nodes are connected to nodes in the hidden layer $H1,2,\ldots,HmH1,H2,\ldots,Hm$ through weighted connections $\omega\omega$. Each hidden node applies an activation function $\phi\phi$ to its input, transforming the data in a non-linear manner. The hidden layer nodes are then connected to the output node oo, which combines these inputs to produce the final output. Bias terms $\beta1,\beta H\beta1,\beta H$, etc., are also included in the layers to improve the model's ability to fit the data. This architecture enables the network to learn complex patterns in the data by adjusting the weights and biases through training processes like backpropagation.

F. Performance Metrics

Evaluating the performance of binary classification models is a critical aspect of any machine learning project. This research utilizes accuracy, precision, recall and F1 score as performance metrics.

1) Accuracy: Accuracy measures the proportion of correct predictions (both true positives and true negatives) among the total predictions made by a model. It is calculated as:

$$Accuracy = \frac{True\ Positives + True\ Negatives}{Total\ Predictions} \quad (2)$$

Accuracy is useful when classes are balanced, but it can be misleading when dealing with imbalanced datasets, as it may overstate a model's performance by focusing on the majority class.

2) Precision: Precision measures the proportion of correctly predicted positive outcomes out of all predicted positive outcomes. It is calculated as:

$$Precision = \frac{True\ Positives}{True\ Positives + False\ Positives} \quad (3)$$

Precision is important in scenarios where false positives are costly or undesirable. High precision indicates a low rate of false positives.

3) Recall: Recall, also known as sensitivity or true positive rate, measures the proportion of correctly predicted positive outcomes out of all actual positive outcomes. It is calculated as:

$$Recall = \frac{True\ Positives}{True\ Positives + False\ Negatives} \quad (4)$$

Recall is crucial when false negatives are costly or undesirable. High recall indicates a low rate of false negatives.

4) F1 Score: The F1 score is the harmonic mean of precision and recall, providing a balance between the two metrics. It is useful when you need a single measure to evaluate a model's performance, especially when there's a trade-off between precision and recall. The F1 score is calculated as:

$$F1\ Score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (5)$$

A high F1 score indicates a good balance between precision and recall, making it a robust metric for evaluating models in various scenarios, including imbalanced datasets or cases where both false positives and false negatives have significant consequences.

VI. Experiments and Analysis of Result

We had carried out experimental works using the five (5) machine learning algorithm described in Section V. Out of all the algorithms implemented, Random Forest gives the most consistent and the highest accuracy from model builds. Based on the Random Forest model, the feature that successfully being selected from over 800 features are:

TABLE III. Importance Coefficient in Random Forest

Feature	Sample 1	Sample 2	Sample 3
Benefit Component	0.396595	0.390536	0.390532
Plan Code	0.289045	0.298415	0.325608
Ri Sum At Risk	0.273424	0.270532	0.246030
Installment Premium	0.018618	0.018813	0.016871
Insured Age	0.013365	0.013160	0.013132
Policyholder Occupation	0.004761	0.004536	0.004028
Policyholder Age	0.004191	0.004008	0.003798

Table III shows the feature importance coefficients derived from a Random Forest model across three different samples. These coefficients indicate the relative significance of each feature in making predictions within the model. A higher coefficient suggests that the feature plays a more critical role in determining the outcome. In all three samples, "Benefit Component" emerges as the most important feature, with coefficients consistently near or above 0.39. This implies that variations in this feature are strongly correlated with the model's predictions, suggesting it holds substantial predictive power across multiple datasets.

"Plan Code" and "Ri Sum At Risk" are the next most important features, though their coefficients vary more across the samples. "Plan Code" shows a gradual increase in importance from Sample 1 to Sample 3, indicating its evolving influence in different contexts. "Ri Sum At Risk" has slightly higher importance in the first two samples compared to the third, suggesting its predictive value may vary depending on the data.

The remaining features, such as "Installment Premium," "Insured Age," "Policyholder Occupation," and "Policyholder Age," exhibit significantly lower coefficients, indicating a smaller impact on the model's predictions. Their low importance suggests they may contribute less to the overall predictive accuracy or that their effects are less distinct across the datasets. These insights can guide further feature selection and model optimization by focusing on the most influential features.

Given that the Random Forest model has demonstrated superior performance among all the algorithms, we will focus our discussion on its results in this section. These insights hold particular relevance when derived from a model known for its accuracy and reliability. Our research's primary aim is to pinpoint the most effective machine learning model for the given problem. By showcasing the best model, we directly fulfill this objective, offering findings that are not only pertinent but also actionable. This approach ensures that our analysis is streamlined, emphasizing the significance of the model that has proven to be the most robust and dependable

The performance metrics of each sample is tabulate in Table IV:

TABLE IV. Performance METRIC of Random Forest

Sample	Target	Accuracy	Precision	Recall	F1 Score
1	0	0.92	0.98	0.87	0.92
	1		0.95	0.97	0.91
2	0	0.92	0.98	0.87	0.92
	1		0.96	0.98	0.91
3	0	0.91	0.97	0.87	0.91
	1		0.95	0.96	0.90

The results of the Random Forest model, as presented in the table, illustrate its overall performance across different samples and target classes. The key metrics used to evaluate the model include accuracy, precision, recall, and F1 score, providing a comprehensive view of its effectiveness.

Across all samples, the model demonstrates high accuracy, consistently around 0.91 to 0.92, indicating that a significant proportion of predictions were correct. This high level of accuracy suggests that the model performs well in terms of overall prediction correctness.

When examining precision, which measures the proportion of correct positive predictions out of all predicted positives, the scores range from 0.95 to 0.98 for the majority class (target 0), indicating a very low rate of false positives. Similarly, precision for the minority class (target 1) is also high, with scores between 0.95 and 0.98, demonstrating the model's ability to avoid incorrect positive classifications.

Recall, which represents the proportion of actual positives correctly identified, is slightly lower than precision, particularly for the majority class (target 0), with scores between 0.87 and 0.88. This lower recall indicates that while the model has high precision, it occasionally misses some actual positives. However, the recall for the minority class (target 1) is notably higher, with scores between 0.90 and 0.98, reflecting the model's ability to identify most positive cases in this category.

The F1 score, the harmonic mean of precision and recall, offers a balanced perspective on the model's performance. For the majority class, the F1 score is around 0.91 to 0.92, suggesting a reasonable balance between precision and recall. For the minority class, the F1 score is slightly lower, ranging from 0.90 to 0.91, indicating that while precision is high, recall could be improved for more balanced performance.

Overall, compared to other four (4) algorithms to Random Forest, it was found that the Random Forest model performs more reliably, with high accuracy and precision across all the three (3) samples from the total dataset. The relatively lower recall and F1 scores for some cases point to areas for further tuning and improvement, particularly in identifying a greater proportion of actual positives without compromising precision. This insight can guide future adjustments to the model, focusing on enhancing recall while maintaining high precision.

VII. Discussion

In the context of the insurance industry, each of the features listed can significantly impact the likelihood of an early claim.

The benefit component refers to the type and extent of coverage provided by the insurance policy. Different benefit components have varying risk profiles. Policies offering higher or more comprehensive benefits may attract individuals who anticipate a higher likelihood of claiming soon after policy inception, thus indicating a higher risk of early claims.

Plan Code is an identifier for different insurance plans offered by the company. Certain plans may have been designed for different risk profiles. For example, plans with lower premiums might attract higher-risk customers or those with a higher propensity to claim early. The specific terms and conditions associated with each plan code can also influence early claim likelihood.

Sum Insured is the amount the insurance company would have to pay if a claim is made. Policies with higher sums at risk may be more likely to result in early claims as policyholders might be more motivated to claim early to secure a large payout. Additionally, larger coverage amounts can be indicative of higher risk individuals or those with greater financial needs.

Installment Premium is the periodic payment made by the policyholder to keep the insurance policy active. The premium amount can reflect the risk level assigned to the policyholder. Higher premiums might be associated with higher-risk individuals who are more likely to make early claims. Conversely, lower premiums might attract cost-conscious individuals, potentially leading to different risk profiles.

Insured Age is the age of the person who is covered by the insurance policy. Age is a critical factor in assessing risk. Younger insured individuals might be perceived as lower risk for certain types of policies (e.g., life insurance), but they might claim early for specific reasons like accidents. Conversely, older individuals might be seen as higher risk for health-related claims, including early claims due to pre-existing conditions or health issues.

Policyholder Occupation is the job or profession of the person who holds the insurance policy. Certain occupations are associated with higher risks (e.g., manual labor, construction) and may be more prone to early claims due to accidents or job-related health issues. Occupation can also indicate socioeconomic status, which might correlate with the likelihood of early claims.

Policyholder Age is the age of the person who owns the insurance policy, who may or may not be the same as the insured individual. The policyholder's age can provide insights into their financial planning stage and risk behavior. Younger policyholders might be more cautious and less likely to claim early, whereas older policyholders might have different financial pressures and health concerns that could lead to early claims.

Each feature offers unique information about the risk profile of the policyholder or the insured, helping the model make accurate predictions. These features had reduced variance in the decision trees by creating more homogeneous groups in terms of early claim likelihood. Besides, these features have strong correlations with early claims based on historical data, thus improving the model’s accuracy.

A Random Forest model evaluates the importance of features based on how effectively they split the data to reduce impurity at each node. The features mentioned are likely important because they provide significant information that helps in distinguishing between policyholders who are likely to make early claims and those who are not.

Understanding why these features are important can help insurance companies in risk assessment, pricing strategies, and designing policies that better manage and mitigate risks associated with early claims.

This model's usefulness is confirmed by its effectiveness in the insurance domain, proving its relevance in real-world applications. It has been validated as a beneficial tool to reduce potential financial losses. By mitigating risks, the model offers significant value to stakeholders seeking to safeguard their economic interests.

VIII. Conclusion

The approach outlined in this research offers a practical solution to the challenge of feature selection in the context of early claim detection in the life insurance industry. By focusing on the most relevant features, this approach allows insurance companies to detect and mitigate fraudulent claims more effectively. This, in turn, can lead to significant benefits, including reduced financial risk, enhanced operational performance, and increased customer trust.

Several areas for future research are worth exploring. Given the real-world nature of insurance data, missing data is a common challenge, and advanced imputation techniques could further enhance model performance. Additionally, the significant class imbalance observed in our dataset suggests that advanced methods for handling imbalanced data could improve the robustness and reliability of predictive models. Lastly, as machine learning models become more complex, there's a growing need for approaches that improve model interpretability, allowing insurance professionals to understand and trust the decisions made by these models.

To implement this approach in real-world settings, we recommend beginning with a pilot test to evaluate its impact on existing workflows and claims detection accuracy. Successful integration with existing systems is critical, so it's essential to ensure that the implementation does not disrupt current operations. Additionally, continuous monitoring and adjustment of the model are necessary to maintain optimal performance, as industry trends and regulatory requirements can evolve over time.

In summary, the feature selection approach described in this research has the potential to transform early claim detection in the life insurance industry. By implementing this approach and addressing the challenges outlined, insurance companies can better manage risk, streamline operations, and ultimately deliver a higher level of service to their customers.

Acknowledgment

We would like to convey our heartfelt appreciation to Tunku Abdul Rahman University of Management and Technology for their important assistance and advice during this research effort. We value the insurance partner for their domain knowledge and masked dataset on top of the industry problem statement provided to the research team. We also appreciate the reviewers' critical remarks and the opportunity to present our work. Finally, we are thankful to the individuals and institutions that have helped to promote data science and its uses in the insurance industry.

***Abstract*—The accurate prediction of financial outcomes presents a considerable challenge as a result of the intricate interaction of economic fundamentals, market dynamics, and investor psychology. The task of accurately forecasting stock prices in the securities market is a challenging undertaking owing to the presence of non-stationary, non-linearity, and significant volatility in the time series data of stock prices. The utilization of conventional approaches possesses the potential to enhance the precision of predictive modeling. It is crucial to acknowledge that these methodologies also encompass computational intricacies, hence potentially augmenting the likelihood of prediction inaccuracies. This work introduces a methodology that addresses many issues by integrating support vector regression technology with the Aquila optimizer procedure. The results of this investigation suggest that, when compared to the other models, the hybrid model performed better and had more efficacy. The proposed model performed at an ideal level and demonstrated a significant level of effectiveness, with a low number of errors. The Hang Seng Index data was analyzed in order to assess the predictive model's accuracy in stock price forecasting. The data was accessible for the years 2015 through 2023. The results show that the proposed framework performs well and is reliable when analyzing and predicting the price time series of equities. Empirical data suggests that, in comparison to other methods presently in use, the suggested model forecasts outcomes with a higher degree of accuracy.**

Keywords*—*Efficient market; Hang Seng Index; stock forecasting; support vector regression; Aquila optimizer

I. INTRODUCTION

The field of financial prediction, particularly about the stock market, has garnered significant attention from both researchers and investors in recent years. The objective of stock market prediction research is twofold: to provide forecasts of market prices or directions, to assist investors in making informed investment decisions, and to mitigate the occurrence of stock market upheaval, which can have significant detrimental effects on the overall growth and stability of a capital market [1]. To achieve this objective, a model was developed to examine the correlation between the past performance of stock prices and their subsequent movements. Contemporary methodologies employed in financial prediction can be categorized into two distinct divisions, namely technical analysis and fundamental analysis. The practice of technical analysis involves the examination of historical pricing data and the use of technical indicators to forecast the future movements of financial time series [2]. While the Efficient Market Hypothesis posits that stock prices instantaneously incorporate all available information, proponents of technical analysis maintain that future prices can be forecasted through the examination of past price patterns. Fundamental analysis is predicated upon an evaluation of both internal and external aspects of a given firm. Interest rates and exchange rates [3] are significant external aspects that must be taken into account. The results of the current study suggest that the hybrid model exhibited superior performance and showed greater effectiveness when compared to the alternative models. Machine learning technologies are extensively employed across various areas, including the stock market, electricity consumption, and healthcare, to enhance the efficiency of forecast generation. The selection of an appropriate method is of paramount significance, [4] as it is contingent upon the nature of the dataset and its intended application. There is a possibility of encountering both time-dependent and time-independent datasets and associated challenges. Time series analysis is a widely used technique in the field of stock market analysis, mostly due to its intrinsic temporal aspect, which is defined by frequent price swings that occur at regular intervals. To develop a robust predictive model for future returns, investors must gather a wide array of data and analyze non-parametric, non-linear, and deterministic chaotic systems. Despite the difficulties involved, businesses, investors, and individuals involved in the stock market continue to strive for practical and efficient approaches to forecast future stock prices. The concept postulates that stock prices effectively incorporate the entirety of available information, [5] including exclusive insights. The utilization of neural network approaches has witnessed a surge in popularity compared to traditional techniques when it comes to analyzing time series data that is characterized by instability and nonlinearity [6]. The algorithms have been purposefully designed to address the difficulties presented by intricate and uncertain datasets, hence enabling the attainment of more precise and dependable outcomes. The usage of state-of-the-art technologies and complicated mathematical models in neural networks enables them to efficiently and expeditiously assess large volumes of data. Numerous strategies have been utilized to accomplish this purpose, including the implementation of feed-forward neural network systems. In the realm of conventional neural network models, it is customary to

utilize gradient descent learning as a prevailing approach. However, this technique can be somewhat time-consuming as it necessitates iterative modifications to the model's parameters. Moreover, these models may encounter the occasional obstacle of becoming confined within a local minimum. To tackle this matter, a potential solution has been put out in the form of the support vector regression (SVR) model [7]. By incorporating the SVR algorithm, a complex machine-learning model was created to predict currency exchange rates. Applying the principles of the Support Vector Machine (SVM) to regression problems, [8] SVR is an extension of SVM. Utilizing an analogous algorithmic approach and mathematical framework, this model is customized to forecast continuous numerical values as opposed to class labels. In contrast to SVM, which segments the data into distinct classes, SVR is applied to regression tasks with the objective of locating a hyperplane that fits the data with a satisfactory level of error. SVR is a highly advantageous instrument in the field of financial forecasting, specifically in the domain of stock price prediction [9]. SVR is capable of producing predictions that aid investors in making informed decisions by analyzing the correlation between input variables and the target variable [10] [11].

These methods are founded on probabilistic ideas that are more applicable to sets of solutions than to single ones. Because issue-solving is heavily dependent on the application of predefined rules for decision-making, these people's efforts have had a substantial impact on the field of optimization. These algorithms simulate natural selection to mimic the most effective behavior found in the natural world. This study made use of Particle swarm optimization (PSO) [12], Slime mould algorithm (SMA) [13], and Aquila optimizer (AO) [14]. Among these optimizers, AO made the best results when it was used for the adjusting of the SVR model. The aquila optimizer was initially proposed by Abualigah et al. [14] The AO imitates Aquila's hunting techniques with regard to various species of prey. Four predation strategies afford AO the necessary capability to capture its prey [14]. The impact of supply and demand on the stock market as a barometer of a country's economic health was investigated by Yiming Lu. [15] Biogeography-based Optimization (BBO), the Artificial Bee Colony (ABC) algorithm, and Aquila Optimization with Extreme Gradient Boosting (XGBoost) were all incorporated into the study [15]. The research findings revealed that the integration of AO, a specific optimizer, with XGBoost yielded a substantial enhancement in model performance, establishing the most precise optimization method for forecasting the stock market [15]. Xiaopeng Yang conducted an investigation into the complex realm of stock trading, emphasizing the unpredictable characteristics of stock prices and the continuous pursuit of precise prediction techniques [16]. The study introduced a methodology for forecasting stock prices by integrating the Aquila optimizer with a Gated Recurrent Unit (GRU) [16]. The aforementioned results validated the GRU-Aquila algorithm's exceptional efficacy and precision, showcasing its exceptional capability to predict stock prices and time series data [16].

The current research presents an innovative approach that combines the Aquila optimizer procedure with support vector regression technology, thereby resolving the issues commonly encountered with traditional methods and potentially improving the precision of stock market forecasts. This work assesses the hybrid model's performance by conducting a comparative analysis with employed prediction models, including SVR, SMA-SVR, and PSO-SVR. The results indicate that the hybrid approach consistently demonstrates superior performance compared to alternative methods, underscoring its prominence in terms of accuracy and efficacy. This study can provide practitioners and investors with valuable insights by showcasing the efficacy of the hybrid model as a predictive tool for stock prices. The proposed model has the potential to assist stakeholders in optimizing their portfolios and making informed investment decisions through the provision of precise and dependable forecasts.

The literature review is given in Section II. Methods and materials which contained algorithms, datasets, and assessment metrics, are presented in Section III. The experimental results are provided in Section IV. The discussions and analysis of these results are given in Section V. Lastly, the conclusions, limitations, and future scopes are presented in Section VI.

II. Literature Review

Over the past few years, machine learning algorithms have become increasingly popular for use in stock market forecasting. Shen and Shafiq initiated an investigation with a specific emphasis on the Chinese stock market, wherein they utilized big data and deep learning methodologies to forecast stock market prices and trends [17]. A comprehensive approach was proposed, which incorporated deep learning models and customized feature engineering, based on the collection of two years' worth of data. The solution they developed for forecasting stock market trends comprised dataset preprocessing, numerous feature engineering techniques, and a customized deep learning system [17]. The significance of stock markets in the global financial system and their influence on economic growth and stability were investigated by Kumar et al. [18]. In order to improve the accuracy of stock value forecasting, their research utilized deep learning algorithms, specifically long short-term memory (LSTM) and recurrent neural networks (RNN). Through a comparative analysis of the effectiveness of LSTM and RNN algorithms in stock price estimation, they explored the potential of deep learning to establish a more dependable stock market environment [18]. Utilizing historical market data obtained from the Alpha Vault API, the performance of these models was assessed. The results demonstrated that LSTM exhibited a higher degree of accuracy in forecasting stock prices in comparison to RNN, which faced specific obstacles [18]. Guruprasad and Chandramouli examined the intricacies of stock market modeling within the Indian context, with a specific focus on the era following globalization when market dynamics are influenced by numerous parameters [19]. The authors underscored the fluctuating effects of specific parameters and their cumulative effect over a period of time, suggesting Convolutional Neural Network (CNN) Classifiers as an appropriate modeling instrument. Their objective was to capture the intricacies of the Indian stock market through the utilization of CNNs and the consideration of various parameters that influence stock trends [19]. Hani'ah et al. [20] examined the difficulty that investors encounter when attempting to precisely time stock trades, a factor that may result in financial losses. A novel methodology for forecasting stock prices was put forth,

which utilized machine learning to integrate characteristics extracted from Google Trends data, technical indicators, and stock price data [20]. In order to forecast forthcoming stock prices, three widely used machine learning algorithms were implemented: Support Vector Regression (SVR), Multilayer Perceptron (MLP), and Multiple Linear Regression. With an average Mean Absolute Percentage Error (MAPE) of 0.50%, SVR outperformed MLP and Multiple Linear Regression in predicting the prices of Indonesian stocks, according to the test results. SVR exhibited the capacity to forecast stock prices that were in close proximity to the true values [20]. As an area of increasing interest to investors and researchers, time series forecasting for financial markets was examined by Xia et al. [21]. They put forth a framework for predicting stock market behavior by integrating wavelet coherence, multiscale decomposition, and SVR. Subsequent to extracting valuable information from unprocessed data via preprocessing, they implemented SVR to improve the performance of predictions for multidimensional nonlinear data [21]. Comparative experiments were undertaken to assess the efficacy of the framework by utilizing the Shanghai Composite Index and Dow Jones Index [21]. Pangestu et al. [22] examined the complex issue of forecasting stock prices, placing significant emphasis on the necessity for efficient approaches to acquire precise predictions. The authors suggested utilizing machine learning methods, more precisely the SVR model and linear regression, to forecast Apple Inc. stock prices from 2018 to 2023 using daily historical data [22]. The Grid Search method was employed to optimize hyperparameters, including cost, epsilon, kernel, and intercept fit, with a k-value of 5. The linear regression model with all hyperparameters set to k = 5 performed the best, as indicated by the True intercept fit value [22]. Jayaswara et al. [23] conducted a study on forecasting stock prices in Indonesia's emerging capital market, highlighting the significance of precise predictions for making well-informed investment choices [23]. The researchers employed SVR algorithms with both linear and radial basis function kernels to predict the prices of BCA stocks. The selection of SVR was based on its capacity to deliver accurate forecasts and address overfitting problems [23]. The significance of stock market prediction in furnishing investors with insights into forthcoming stock prospects and optimizing profits was underscored by Ahuja et al. [24]. They predicted stock prices using historical data and three prominent regression techniques: SVR, Random Forest, and Linear Regression. The selection of these machine-learning algorithms was based on their widespread usage and high accuracy of results [24].

The literature review reveals that some studies concentrate on a single machine-learning algorithm or technique for stock price prediction, often overlooking the possible advantages of combining multiple methodologies. Some studies mention optimization techniques, but it's possible that they haven't been thoroughly explored or compared in order to improve the performance of predictive models by using metaheuristic optimization algorithms. In many studies, the accuracy of models is assessed over a brief period of time, which may cause the long-term robustness and reliability of predictions to be disregarded. This study presents the introduction of a hybrid model that integrates the Aquila optimizer procedure and support vector regression method. By capitalizing on the respective strengths of these approaches, this work aims to improve the accuracy of the predictions. Three Aquila optimization, particle swarm optimization, and slime mould algorithm are utilized to optimize the support vector regression model's parameters, thereby mitigating computational complexities and potentially enhancing the accuracy of predictions. This study assesses the performance of the proposed model by utilizing data that covers the period from 2015 to 2023. This evaluation offers valuable insights into the model's reliability and efficacy in predicting stock prices over the long term.

III. Method and Materials

A. Particle Swarm Optimization

The particle swarm optimization algorithm is a computational methodology that simulates the collective behavior of a swarm of avian or aquatic organisms to optimize outcomes. Despite the initial dearth of information regarding the whereabouts of the food source, the swarm has a propensity for adhering to meticulous criteria to proficiently navigate towards it by discerningly selecting the most advantageous route. By employing a strategy of collaborative exploration, the collective of organisms ultimately discovers the precise geographical coordinates at which sustenance can be obtained. Over a temporal duration, it can be observed that both fish and bird aggregations will display coordinated motion toward a solution that is in the near vicinity of the optimal solution. The facilitation of a group of birds' progress toward a solution inside the search area is achieved through their adherence to three fundamental principles [12]: separation, alignment, and cohesiveness. Particles undergo a process of spatial dispersion wherein they disperse from one another as a means of mitigating overpopulation. The particles undergo a phenomenon known as alignment, in which they exhibit movement towards their adjacent particles. This alignment process leads to a modification of their positions, which is controlled by the cohesive forces exerted by the adjoining particles. The PSO methodology was introduced by Kennedy and Eberhart as a method to tackle optimization difficulties. The approach employed in this study is influenced by the emergent behaviour observed in a group of particles forming a swarm [12]. The PSO approach exhibits rapid convergence and requires a minimum number of parameters, hence mitigating computer costs. Additionally, the probability of discovering a suboptimal local solution is diminished because of the extensive investigation carried out by multiple particles in search of an ideal solution. The method exhibits a highly efficient global search mechanism and does not depend on the use of derivatives. Inside the PSO algorithm, each constituent particle inside the swarm partakes in a search process spanning many dimensions. The primary aim of this procedure is to locate a solution that closely approximates the optimal solution. The search process commences by creating initial solutions, often referred to as particles, in a stochastic fashion within the search space. The determination of velocity and fitness values for each particle often entails the utilization of the weighted average of classification accuracy and the number of features in the selected subset. After the initial iteration, this computational procedure allows for the modification of both the velocity and trajectory of their respective paths, and this method is thereafter continued until the predetermined termination

condition is met. The velocity of the particles in the PSO method is updated according to the subsequent equation:

$$\boldsymbol{v_{id}^{t+1}} = \boldsymbol{v_{id}^{t}} + \boldsymbol{C_1 r_1^t}\ (\boldsymbol{Pbest_{id}^t} - \boldsymbol{x_{id}^t}) + \boldsymbol{C_2 r_2^t}\ (\boldsymbol{Gbest_{id}^t} - \boldsymbol{x_{id}^t}) \quad (1)$$

The velocity of the $i-$th particle at a specific time iteration is represented as v_{id}^{k} in a search space characterized by d dimensions. The variables $Pbest_{id}^{t}$ and $Gbest_{id}^{t}$ denote the optimal particle and location for each individual and iteration of the $i-$th function, respectively. The parameters C_1 and C_2 are utilized to adjust the velocity of particles, whereas r_1^t and r_2^t denote random values ranging from 0 to 1. Moreover, the particles within the PSO algorithm can modify their positions, as demonstrated by the equation presented below:

$$\boldsymbol{x_{id}^{t+1}} = \boldsymbol{x_{id}^{t}} + \boldsymbol{v_{id}^{t+1}} \quad (2)$$

The variable x_{id}^{t} denotes the spatial coordinates of the $i-$th particle at iteration t within a search space described by d dimensions. The epoch for PSO is selected to be 200 and the pop size is 20.

B. Slime mould algorithm

The subject matter was introduced by Li et al. [13] at the SMA conference in 2020. The proposed approach is a groundbreaking methodology inspired by the behavior of slime mold in its natural habitat. The slime mould uses olfaction as a means of perceiving and discerning volatile food aromas present in the surrounding atmosphere, hence facilitating its ability to travel toward its prey. This paper provides a complete portrayal of the overall characterization of SMA. The mathematical description of the slime mould's behavior can be represented by the following equation.

$$\overrightarrow{\boldsymbol{X(t+1)}} = \begin{cases} \overrightarrow{\boldsymbol{X_b(t)}} + \overrightarrow{\boldsymbol{v_b}} . \left(. \overrightarrow{\boldsymbol{X_A(t)}} - \overrightarrow{\boldsymbol{X_B(t)}} \right) & \boldsymbol{r < p} \\ \overrightarrow{\boldsymbol{v_c}} . \overrightarrow{\boldsymbol{X(t)}} & \boldsymbol{r \geq p} \end{cases} \quad (3)$$

The variable $X_b(t)$ denotes the precise region of the slime mold that presently displays the greatest concentration of odor. The variables $X(t)$ and $X(t+1)$ represent the spatial coordinates of the slime mold at the $t-$th and $t+1$ -th iterations, respectively. $X_A(t)$ and X_B represent two randomly chosen locations of the slime mold. The variable v_b undergoes temporal changes within the range of $[-a, a]$, where r is a random number between 0 and 1. The parameter p is defined as $a = arctanh(-(\frac{t}{max\_t}) + 1)$, and v_c is a linearly decreasing parameter that ranges from 0 to 1.

$$\mathbf{p = \tanh |S(i) - DF|} \quad \mathbf{i = 1, 2, \ldots, n} \quad (4)$$

The symbol DF denotes the iteration that possesses the utmost fitness value, while $S(i)$ represents the fitness of vector $\overrightarrow{X}$. The equation depicted below provides a formal representation of weight, symbolized as W:

$$\overrightarrow{W(smell\ index(l))} = \begin{cases} 1 + r.log\left(\frac{bF - S(i)}{bF - wF} + 1\right), condition \\ 1 - r.log\left(\frac{bF - S(i)}{bF - wF} + 1\right), others \end{cases} \quad (5)$$

$$smell\ index = sort(S) \quad (6)$$

The variable $S(i)$ denotes the initial half of the population in the provided equation. The symbol bF is used to symbolize the maximum fitness value, whereas wF is used to denote the lowest fitness value. Furthermore, the term "smell index" pertains to the ordered values of fitness. The spatial coordinates of the slime mold are updated by the utilization of the provided formula.

$$\overrightarrow{X^*} = \begin{cases} rand(UB - LB) + LB & rand < z \\ \overrightarrow{X_b(t)} + \overrightarrow{v_b}.\left(\overrightarrow{W} . \overrightarrow{X_A(t)} - \overrightarrow{X_B(t)}\right) & r < p \\ \overrightarrow{v_c}.\overrightarrow{X(t)} & r \geq p \end{cases} \quad (7)$$

Within the given context, the variable z is subject to limitations that confine its values to a specified interval ranging from 0 to 0.1. The terms LB and UB are used to denote the lower and upper boundaries of the search period, respectively. SMA has chosen an epoch of 200 and a pop size of 20.

C. Aquila Optimizer

The proposed approach emulates Aquila's hunting behavior as displayed in Fig. 1 by illustrating the sequential movement during each phase of the hunt [14]. The overall structure of the AO is indicated in Fig. 2. Consequently, the proposed strategy for optimizing the AO algorithm is presented in four distinct approaches: The selection of the search region is determined by the vertical stoop, [14] which involves soaring at high altitudes. The exploration within a divergent search space is conducted through contour flight combined with short hover attacks. Exploitation within a convergent search space is achieved by flying at low altitudes and executing slow descent attacks. Finally, the prey is captured by swooping down, walking, and grabbing [14]. Aquila's behavior was characterized as a mathematical optimization paradigm that seeks to identify the optimal solution within specified constraints. The subsequent representation presents a mathematical model of the AO. The Aquila species has a two-step process for identifying prey and selecting an optimal hunting site. The initial step involves engaging in a high soar, followed by a vertical stoop, in order to accurately pinpoint the prey's location. The AO algorithm conducts a thorough exploration of the search zone at a significant altitude in order to determine the whereabouts of the prey. The aforementioned pattern is quantitatively expressed.

$$\boldsymbol{X_1(t+1)} = \boldsymbol{X_{best}} \times \left(\boldsymbol{1 - \frac{t}{T}}\right) + \boldsymbol{X_M(t)} + \boldsymbol{X_{best}} \times \boldsymbol{rand} \quad (8)$$

where, the outcome of the subsequent iteration of t, which is produced by the first search process x_1, is represented by $x_1(t+1)$. The optimal solution obtained is $x_{best}(t)$ up to the tenth iteration. It depicts the prey's approximate location.

The enlarged search (exploration) is controlled by the number of iterations using this equation $\left(1-\left(\frac{t}{T}\right)\right)$. The $X_M(t)$mean value of the existing solutions linked at the $t-$ th iteration. Furthermore, the variable $rand$ denotes a stochastic value uniformly distributed between 0 and 1. On the other hand, t and T symbolize the present iteration and the upper limit of iterations, correspondingly.

$$\boldsymbol{x_M(t)=\frac{1}{N}\sum_{i=1}^{N} x_i\,(t), \forall j=1,2,\ldots,Dim} \tag{9}$$

The variable Dim represents the dimension size of the problem, whereas N denotes the population size, which refers to the number of alternative solutions. When the prey area is identified from an elevated position during flight, the Aquila species exhibits a hovering behavior directly over the intended prey, initiates the landing procedure, and thereafter executes an attack. This phenomenon is commonly referred to as curved flight with a short gliding attack. During this phase, AO conducts a thorough investigation of the selected habitat of the target prey in preparation for the impending assault. This behavior can be quantified using numerical expressions, as demonstrated in the Equation below.

$$\boldsymbol{X_2(t+1)=X_{bset}(t)\times Levy(D)+X_R(t)+(y-x)\times rand} \tag{10}$$

The variable $x_2(t+1)$ denotes the outcome of the subsequent iteration of t generated by the second search strategy x_2, within the dimension space represented by D. The term $Levy(D)$refers to the dimension level of D. At the $i-$th iteration, $X_R(t)$ is a random solution picked from the range $[1 \ldots N]$.

$$\boldsymbol{Levy(D)=s\times\frac{u\times\sigma}{|v|^{\frac{1}{\beta}}}} \tag{11}$$

Let s be a constant value defined as 0.01, while u and v represent values within the range of 0 and 1. Then, the value of sigma (σ) is determined using the Equation below.

$$\sigma=\left\{\frac{R(1+\beta)\times \sin e(\frac{\pi\beta}{2})}{R(1+\frac{\beta}{2})\times\beta\times 2(\frac{\beta-1}{2}}\right\} \tag{12}$$

Let β be denoted as a constant value, specifically 1.5. The equation presented below represents the relationship between y and x, which correspond to the spiral shape observed in the search space. These variables are calculated using the following method:

$$y=r\times\cos\theta \tag{13}$$

$$x=r\times\sin\theta \tag{14}$$

$$r=r_1+U\times D_1 \tag{15}$$

$$\theta=-\omega\times D_1+\theta_1 \tag{16}$$

$$\theta_1=\frac{3\times\pi}{2} \tag{17}$$

r_1 employs a fixed range of numbers, specifically from 1 to 20, for a specified number of search rounds. In contrast, the set U is characterized by a diminutive value of 0.00565. D_1 is an integer value that is between the range of 1 to the length of the search space, denoted as Dim. In addition, the value of ω is a conservative estimate of 0.005. The third approach is implemented when the specific target area has been accurately determined and the Aquila is prepared to initiate an offensive action. Thus, the Aquila descends vertically, employing an initial strike to assess the response of the prey. This particular method is sometimes referred to as low-altitude flight combined with a steady descent approach to conduct an assault. The AO uses the selected region of the target to approximate its proximity to the prey and initiate an attack. The attack is mathematically represented as follows in Equation:

$$\boldsymbol{X_3(t+1)=\left(X_{best}(t)-X_M(t)\right)\times\alpha-rand+((UB-LB)\times rand+LB)\times\delta} \tag{18}$$

The expression $X_3(t+1)$ denotes the output of the $t-$th iteration generated by the third search strategy X_3. The function $X_{best}(t)$ represents the most optimal solution achieved up to the $t-$ th iteration. Furthermore, $X_M(t)$ represents the average value of the current solution at the $t-$th iteration. The variable r represents a numerical value that spans the interval from 0 to 1. In addition, this study has assigned a low value of 0.1 to the exploitation correction parameters, α and δ. In the given problem, the lower limit is represented by the symbol LB, while the upper bound is represented by the symbol UB. During the fourth approach, when the Aquila nears its target, it employs stochastic movements to strike the prey over the ground. This particular methodology is sometimes referred to as the "stroll and seize" approach. The mathematical formulation of this strategy is expressed as follows in Equation:

$$\boldsymbol{X_4(t+1)=QF\times X_{best}(t)-(G_1\times X(t)\times rand)-G_2\times Levy(D)+rand\times G_1} \tag{19}$$

Consequently, for each iteration of the search, $X_4(t+1)$ represents the outcome of the fourth search method, and QF is a quality function used to balance the search methods. G_1 shows the several AO motions used to track the prey as it elopes. Between 2 and 0, G_2 contains decreasing values that represent the flight slope of the AO that tracked the prey from the initial position (location 1) to the last location (location 0), as determined by Equation:

$$\mathrm{QF(t)}=\mathrm{t}^{\frac{2\times\mathrm{rand}-1}{(1-\mathrm{T})^2}} \tag{20}$$

$$\mathrm{G_1}=2\times\mathrm{rand}-1 \tag{21}$$

In a similar vein, the pop size is 20 and the epoch for ALO is set at 200.

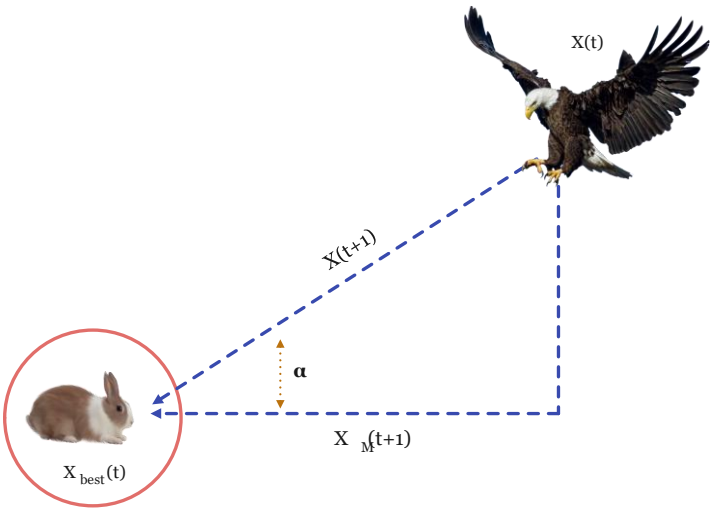

Fig. 1. The illustration of (AO).

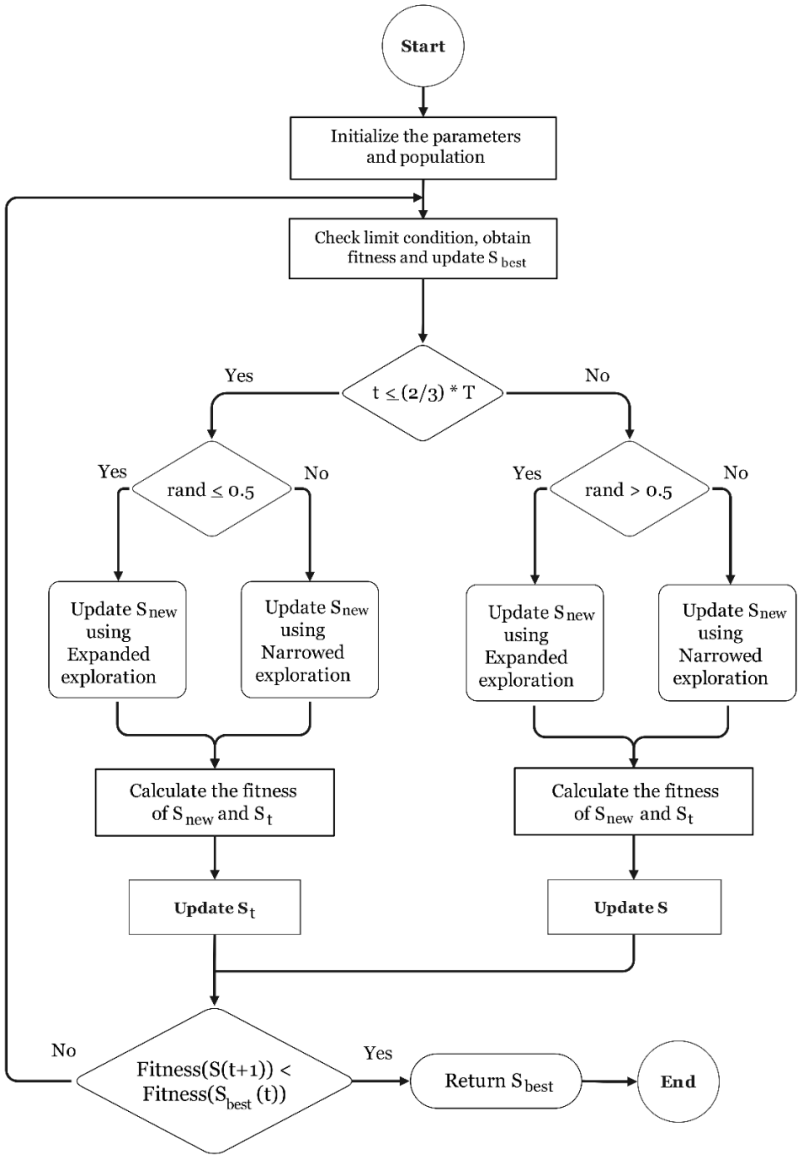

Fig. 2. The framework of (AO).

D. Support Vector Regression

Support Vector Regression (SVR) as demonstrated in Fig. 3 is well recognized as a very dependable approach within the field of machine learning and statistical learning [25]. SVR is an extension of Support Vector Classification (SVC) that is designed to handle continuous response variables. Both SVR and SVC employ the use of kernel functions to accomplish their respective objectives [25][7]. SVR minimizes the ϵ-insensitive loss function, meaning that any loss below the error margin is set to zero and that any loss over that constraint uses the linear loss function as in Equation. In contrast to GPR, which minimizes the squared error (ϵ) loss function and loss for answers, i −th, (quadratic loss).

$$\boldsymbol{I_\epsilon} = \begin{cases} \mathbf{0} \\ |\boldsymbol{y_i} - \boldsymbol{f}(\boldsymbol{x_i})| \end{cases} \tag{22}$$

If the value of $|y_i - f(x_i)|$ is less than ϵ, the loss function of a linear function is displayed as:

$$\mathrm{f(x)} = \beta_o - \mathrm{X_i^t}\beta \tag{23}$$

$$\sum_{i=1}^{n} (\mathrm{y_i} - \mathrm{X_i^t}\beta - \beta_o - \epsilon, 0) \tag{24}$$

where, ϵ is the turning parameter and can be written as a formulation for constraint optimization as seen in Equation:

$$\text{minimize}\frac{1}{2}\|\beta\|^2 \tag{25}$$

$$subject\ to \begin{cases} y_i - X_i^t\beta - \beta_o \le \epsilon, \\ -(y_i - X_i^t\beta - \beta_o) \le \epsilon \end{cases} \tag{26}$$

Table I explains the tunning of the hyperparameters of the SVR model by using three different optimizers where each optimizer found the optimal values. The kind of hyperplane that is utilized to divide the data is decided by the kernel function. A single training example's influence is defined by gamma. Other examples must be closer to being impacted by a greater gamma. The regularization parameter C regulates the trade-off between minimizing the weights' norm and obtaining a low error on the training set. Epsilon describes the epsilon tube when the training loss function has no penalty and the predicted points are within epsilon of the actual value. All of the optimal values found by optimizers for these hyperparameters can be found in Table I.

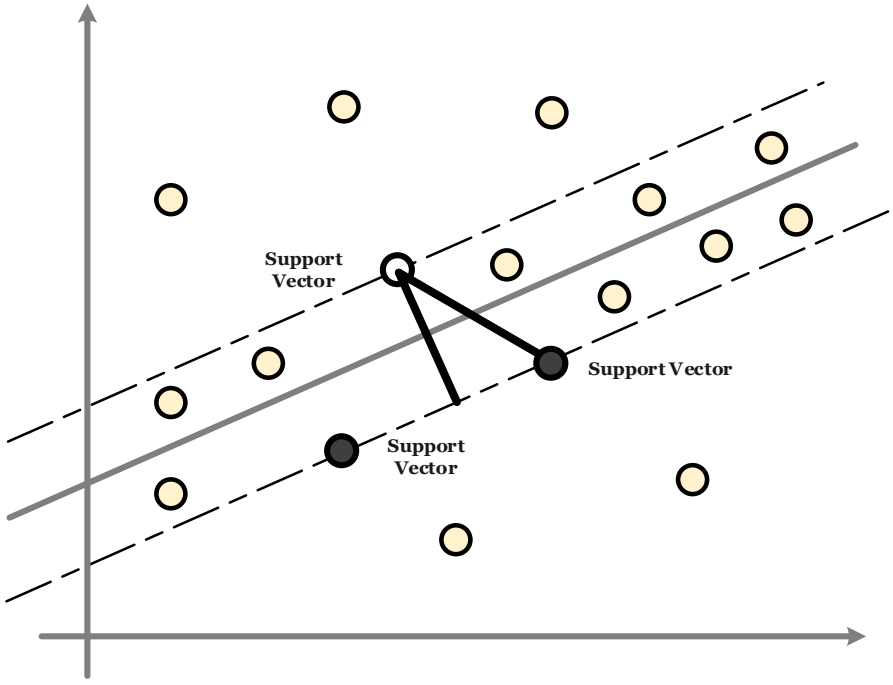

Fig. 3. The illustration of (SVR).

TABLE I. THE SETTING OF THE HYPERPARAMETERS OF THE SVR MODEL BY THREE OPTIMIZERS

SVR		ALO	SMA	PSO
kernal	['linear', 'rbf', 'poly', 'sigmoid']	linear	linear	linear
gamma	[1, 0.5, 0.1, 0.01, 0.001]	0.5	0.1	0.5
C	[0.1, 1, 10, 20, 50, 100]	20	10	50
epsilon	[0.01, 0.05, 0.1, 0.5]	0.05	0.5	0.1

E. Data Collection and Preprocessing

When conducting a thorough analysis of a company, it is imperative to take into account many elements, such as the trading volume and the Open, High, Low, and Close (OHLC) prices during a specific timeframe. The data pertaining to the performance of the HSI index from 2015 to 2023 was obtained solely for the purpose of this specific research. The dataset consisted of information regarding the opening, high, low, and closing prices, as well as the trading volume, for each day within the designated period. An essential component of the preliminary phase involved doing a thorough examination of the data in order to identify any irregularities, exceptional observations, or inconsistencies that could potentially undermine the validity of the results. In order to optimize the performance of the models, two distinct sets of preprocessed data were constructed. The methodology employed in this study utilized a partitioning mechanism, as illustrated in Fig. 4. The study employed a partitioning mechanism in which 80% of the dataset was assigned for training purposes. In contrast, the remaining 20% was allocated for the purposes of validation and testing. The primary goal of this division was to achieve an optimal equilibrium between the requirement for a substantial quantity of data for training the model and the necessity for a substantial and unfamiliar dataset for conducting thorough testing and validation.

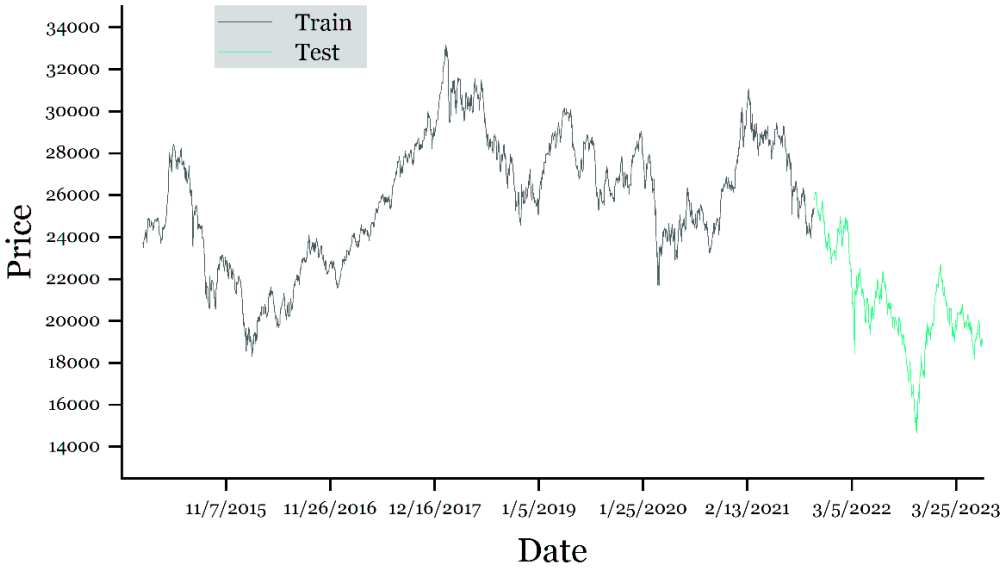

Fig. 4. The process of partitioning the dataset into distinct test and train sets.

F. Evaluation Metrics

The assessment of the precision of the forthcoming forecast was carried out by utilizing multiple performance metrics. The meticulously selected indicators provide a comprehensive assessment of the dependability and accuracy of the forecasts. Numerous parameters were considered during the screening procedure. In the realm of statistical analysis, there are three key metrics that are commonly employed to evaluate the performance and accuracy of a model. These metrics include the mean absolute error (MAE), mean square error (MSE), root mean square error (RMSE), and mean absolute percentage error (MAPE). While RMSE penalizes large errors as well, it does so in the same units as the original data because it is the square root of MSE [26]. By combining the advantages of MAE's interpretability and MSE's sensitivity to large errors, it offers a balanced perspective on model performance [27].

$$\mathrm{RMSE} = \sqrt{\frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{n}} \tag{26}$$

Without taking into account the direction of the errors, MAE calculates the average magnitude of the errors in a set of predictions [27]. It makes it simple to comprehend and convey by offering a clear interpretation of the average prediction error in the same units as the stock prices [28].

$$\mathrm{MAE} = \frac{\sum_{i=1}^{n}|y_i - \hat{y}_i|}{n} \tag{27}$$

Larger errors are given more weight by the MSE metric, which squares the errors before averaging them [27]. It is especially helpful for stock market forecasting since it penalizes large prediction errors, which can have an important impact on financial choices [28].

$$\mathrm{MSE} = \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{n} \tag{28}$$

Prediction accuracy is expressed as a percentage using the MAPE metric, which is useful in financial contexts where relative error is more significant than absolute error [27]. When comparing forecast accuracy across various stock price scales, MAPE is especially helpful [28].

$$\mathrm{MAPE} = \left(\frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right|\right) \times 100 \tag{29}$$

where, $\hat{y}_i$ serves as the predicted value and y_i denotes the actual value [29].

IV. RESULTS

A. Statistic Values

Table II presents a comprehensive overview of the statistical information encompassed within the dataset, playing a vital role in the investigative process. The incorporation of Open, High, Low, and Close (OHLC) price and volume data in the table improves the comprehensibility and transparency of the information. In order to do a comprehensive and accurate examination of the data, it is advisable to utilize statistical measures such as the arithmetic mean, minimum value, maximum value, standard deviation (referred to as Std.), count, 50th percentile, skew, and kurtosis.

B. Comparison and Analyses

The main objective of this study is to determine and evaluate the most effective hybrid algorithm for forecasting stock prices. This study is grounded in the development of predictive models and a thorough understanding of the multiple aspects that influence stock market trends. The main aim is to provide analysts and investors with pertinent information that empowers them to make informed and judicious investment decisions. Table III, Fig. 5, and Fig. 6 provide a comprehensive analysis of the performance demonstrated by each model in the study. This report presents a thorough assessment of the effectiveness of each strategy. Various metrics are utilized to quantify distinct facets of prediction errors. MAPE provides insight into the relative accuracy of predictions, whereas MSE and RMSE emphasize larger errors and MAE provides a direct measure of average error. By employing a blend of these metrics, a more comprehensive assessment is achieved, encompassing multiple facets of model performance.

TABLE II. THE PROVIDED DATASET IS ACCOMPANIED BY A STATISTICAL SUMMARY

	Open	High	Low	Volume	Close

V. DISCUSSION

The data analysis was assessed using the four widely used metrics of RMSE, MAPE, MSE, and MAE. The aforementioned metrics are widely recognized for their ability to provide an extensive assessment of the overall effectiveness, precision, and dependability of the analysis. The performance of the SVR model has been assessed both with and without the assistance of an optimizer using a number of evaluation metrics. Through the application of this approach, one can generate educated opinions and enhance their understanding of the model's operation. Upon analyzing the training and test sets, it was found that the SVR model produced RMSE values of 209.81 and 202.41 for the training and testing sets, respectively, in the absence of the optimizer. When the results were compared, the MAPE values for the training and testing datasets were discovered to be 0.66 and 0.81, respectively. In addition, the training and testing data sets' MSE values were found to be 44018.81 and 40970.18, respectively. Training and testing sets' matching MAE values were 171.34 and 161.84, respectively. The SVR model's efficiency increased significantly when optimizers were used. The results have significantly improved with the use of the PSO optimizer, as seen by the reduction in the RMSE value to 186.22 for the training dataset and 164.12 for the testing dataset. It was found through a comparative analysis that the SMA-SVR model performed better than the PSO-SVR model. Throughout the training and testing stages, the SMA-SVR model consistently displayed RMSE values of 124.12 and 177.89. It is important to note that the training and testing data sets' MSE values decreased, coming in at 15406.07 and 31645.96, respectively. Parallel to this, MAE and MAPE values decreased to 95.46 and 0.37 for the training dataset, and to 137.45 and 0.68 for the testing dataset. The study's findings indicate that the AO-SVR model outperforms the SMA-SVR model in terms of effectiveness. The notable results from training and testing, 56.88 and 156.59, respectively, demonstrate how effective the AO model is. The training MAPE value of 0.16 and testing MAPE value of 0.60 of the AO-SVR model indicate that it performed better than the other models. The previously described results provide empirical evidence supporting the high degree of accuracy and reliability of the AO-SVR model. These results also validate the model's effectiveness as a useful tool for the specific application under investigation.

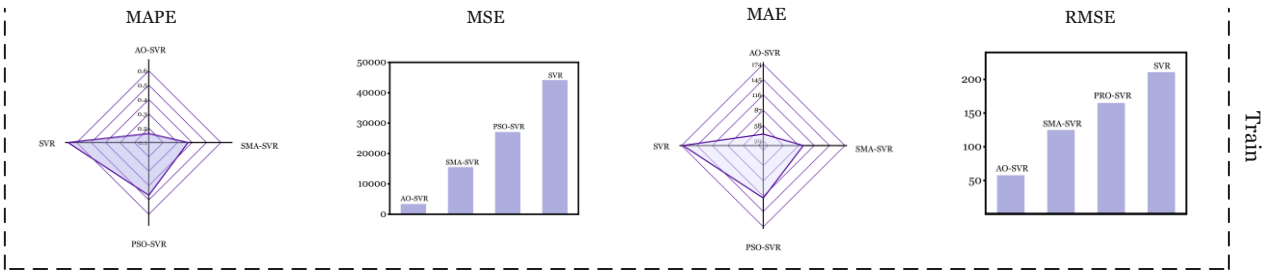

Fig. 5. During the training phase, the model being evaluated produced results for RMSE, MSE, MAE, and MAPE.

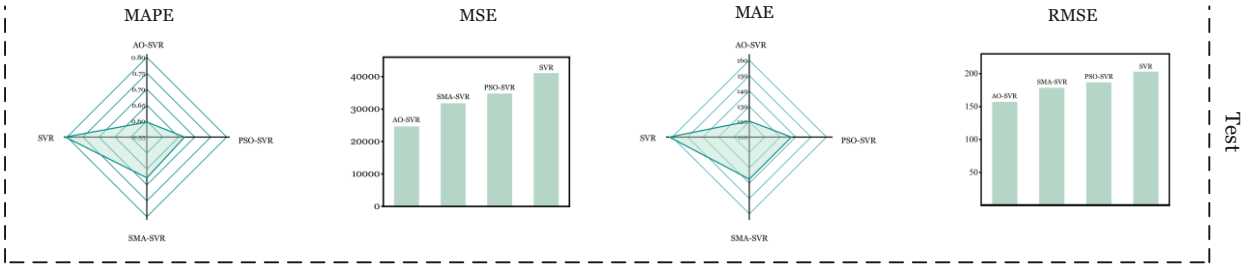

Fig. 6. In the testing phase, the model under consideration generated outcomes for RMSE, MSE, MAE, and MAPE.

Numerous experiments have confirmed the AO-SVR model's effectiveness and shown that it is capable of making accurate stock price predictions. One way to assess the effectiveness of the model is to compare the HSI market curves with the corresponding curves shown in Fig. 7 and Fig. 8. When comparing the AO-SVR model with other models such as SVR, PSO-SVR, and SMA-SVR, it is evident that the AO-SVR model exhibits more accuracy in forecasting stock values. The application of the SVR technique results in a significant enhancement in the quality of the model by reducing the impact of stock price volatility and improving the precision of future trend projections. The AO-SVR model possesses the distinct ability to assimilate knowledge from prior datasets. To attain a satisfactory degree of precision in forecasting stock prices, it is imperative for a model to possess the capacity to adjust to fluctuating market conditions and derive significant insights from historical data. The AO-SVR model has been shown to possess notable levels of accuracy, reliability, and inferential capabilities when applied in conjunction with historical data, hence establishing its efficacy as a strong instrument for forecasting stock prices. The utilization of the SVR method and AO optimizer is favored due to their capacity to dynamically adjust to fluctuations in market conditions, making them highly sought-after by individuals seeking to execute lucrative transactions inside the stock market.

The distinct qualities and characteristics of each dataset account for the variability in the performance of the proposed algorithms across them. Using an analysis of multiple datasets, including Hang Seng Index data spanning the years 2015 to 2023, this research identified variations in error metrics and prediction accuracy. Strong seasonal patterns or long-term trends may be present in particular datasets, which may have an impact on the precision of predictions [30]. The proposed model's capability to detect these patterns may differ based on the frequency and prominence of these trends within the dataset. For example, datasets containing distinct seasonal patterns may enable the model to operate more efficiently as a result of the predictability of these trends [27]. In determining performance, the quality and applicability of the features utilized in the prediction models are also critical factors. Predictions may be enhanced when datasets contain precisely defined and pertinent characteristics that capture the fundamental dynamics of the market, as opposed to datasets that contain noisy or irrelevant features [31].

The results of the analysis suggest that the algorithms that were suggested exhibit robust performance on a diverse range of datasets, with a particular emphasis on datasets that contain intricate patterns and non-linear associations. In conjunction with the optimization functionalities of the Aquila optimizer, the adaptability and resilience of the SVR empower the model to efficiently accommodate diverse categories of data. Traditional linear models may struggle to handle non-linear and complex datasets, but the proposed model excels at handling such data [32]. This characteristic renders it highly suitable for stock market data, which frequently demonstrates such attributes. The integration of SVR and the Aquila optimizer in a hybrid framework demonstrates high efficacy in accommodating dynamic and non-stationary data, thereby delivering resilient forecasts amidst abrupt market fluctuations or trends.

Table IV and Fig. 9 provide a comparative analysis of different methodologies employed in the prediction of stock market prices. Every method enumerated in this table utilized the HSI market dataset to forecast the stock market. Although traditional RNN-based methods produced greater error rates, advanced models that incorporated attention mechanisms, hybrid architectures, and optimizations outperformed their predecessors. The AO-SVR method utilized in this study exhibited superior performance compared to all other methods, as evidenced by its lowest MAE. This indicates that the method effectively predicted stock market prices using the HSI dataset.

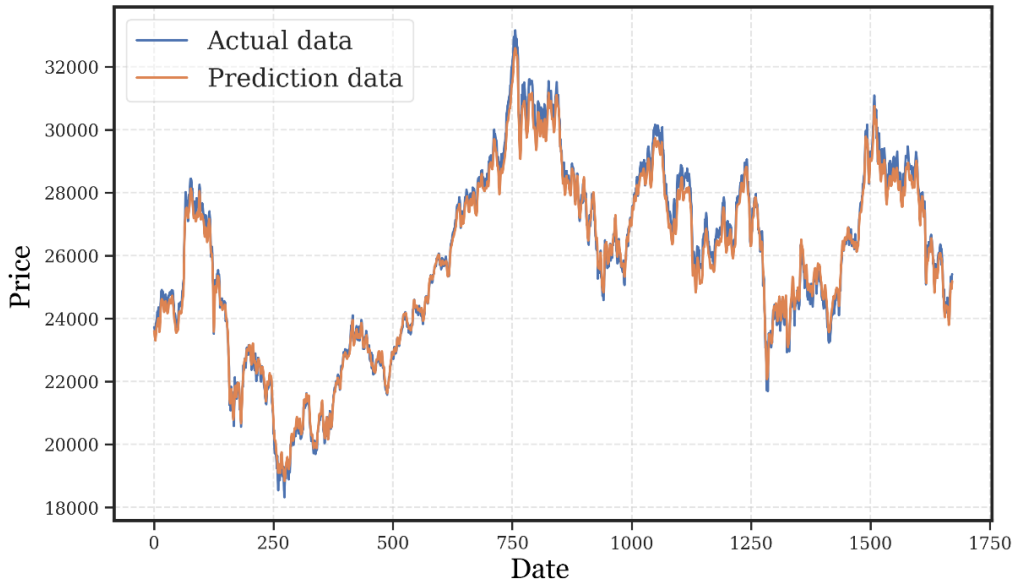

Fig. 7. The application of the AO-SVR approach was employed in the training procedure to build the forecasting curve.

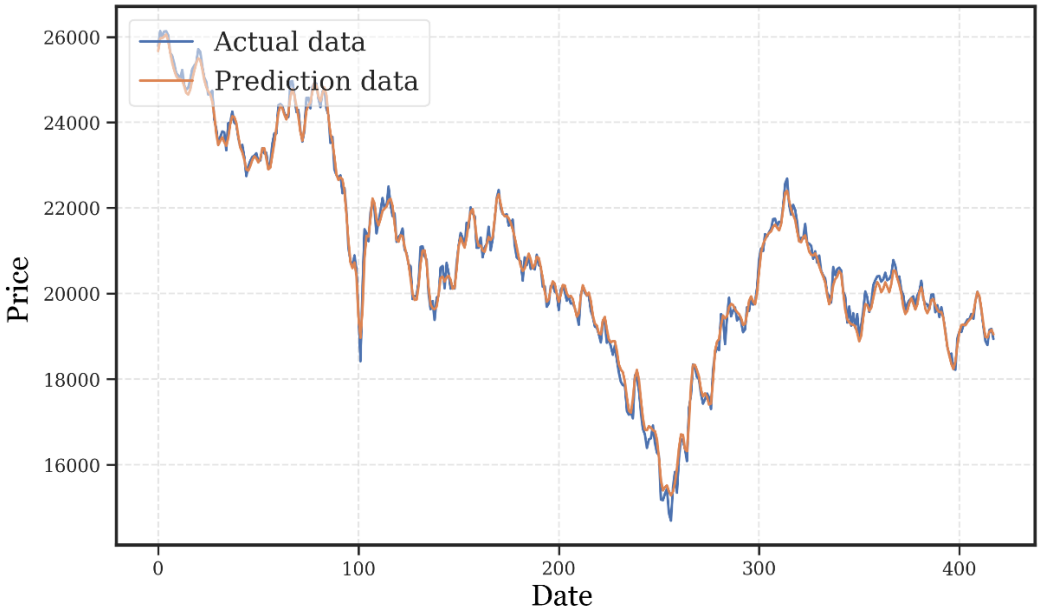

Fig. 8. The application of the AO-SVR approach was employed in the testing procedure to build the forecasting curve.

TABLE IV. THE COMPARISONS OF THE METHOD IN LITERATURE WITH THE CURRENT STUDY

Authors	Methods	MAE
Siami-Namini et al. [33]	RNN	259.94
	LSTM	258.70
	BiLSTM	259.21
Lu et al. [34]	CNN-LSTM	258.68
Lu et al. [35]	CNN-BiLSTM	258.02
	CNN-BiLSTM-AM	257.80

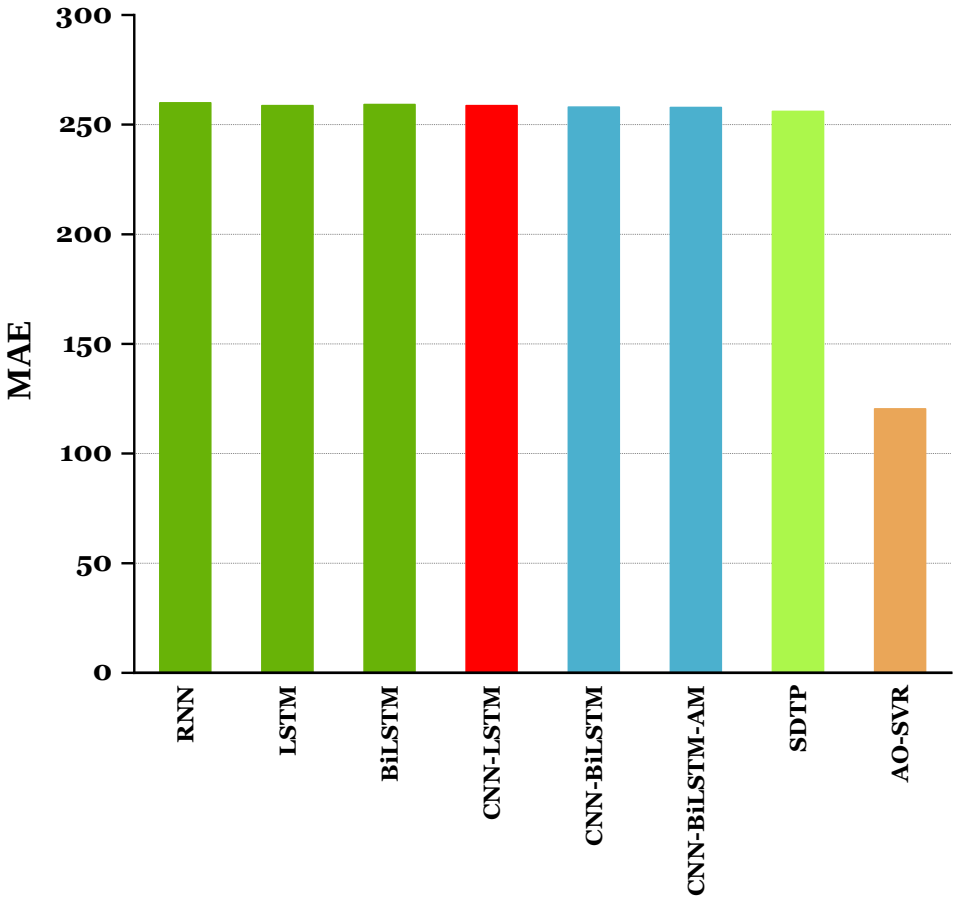

Fig. 9. A Comparison between the present study and the method as depicted in the literature.

A precise forecast of stock prices holds significant importance for investors aiming to maximize the efficiency of their investment portfolios. By utilizing a hybrid predictive model, investors can gain significant insights regarding forthcoming stock valuations. This empowers them to make informed investment decisions, potentially optimizing returns while mitigating risks. The predictive model can be employed by financial institutions and investment firms to evaluate and control the level of risk associated with their portfolios. The identification of potential market fluctuations and the implementation of risk mitigation strategies to safeguard assets can be achieved through the more precise prediction of stock prices. By integrating the hybrid model into algorithmic trading systems, the buying and selling of stocks in response to predictive signals can be automated. By utilizing the model's real-time predictions, algorithmic traders can optimize trade execution and take advantage of favorable market conditions. Both individuals and wealth management firms have the ability to employ the predictive model in order to formulate individualized investment strategies and financial plans. The predictive model can be employed by policymakers, economists, and researchers to estimate the potential impact of economic policies and external factors on financial markets and to forecast stock market trends.

VI. Conclusion

The endeavor of predicting stock prices is a multifaceted endeavor that necessitates a comprehensive comprehension of numerous interrelated aspects. The stock market is susceptible to several influences, encompassing political, sociological, and economic factors. The aforementioned system has a dynamic characteristic and possesses inherent complexity. In order to provide precise forecasts regarding future stock valuations, it is imperative to take into account an extensive array of financial literature, earnings statements, market patterns, and pertinent information. Furthermore, it is imperative to acknowledge that macroeconomic indices, like inflation, interest rates, and global economic conditions, exert a substantial impact on the dynamics of the stock market. The development of precise and reliable prediction models might provide challenges due to the many elements involved in forecasting stock values. In order to attain precise predictions, it is important to develop a comprehensive comprehension of the complex and uncertain characteristics inherent in the field. In addition to providing a workable solution to these problems, the AO-SVR model has proven to be extremely accurate and reliable. The goal of the current study was to evaluate the performance of several stock price prediction models, such as SVR, SMA-SVR, and PSO-SVR. SMA, PSO, and AO were the hyperparameter optimization techniques used to optimize the SVR's parameters. Nevertheless, the AO optimizer approach showed better outcomes when used in

conjunction with the SVR strategy. The study utilized OHLC price and volume data for the HSI index, spanning the years 2015 through 2023, as the dataset. The experimental findings illustrate the notable accuracy and reliability exhibited by the AO-SVR model in forecasting stock prices. As an integral part of the research process, a comparative analysis was performed to evaluate the accuracy and predictive capacities of the AO-SVR model in relation to various other models. Based on the obtained data, it can be inferred that the AO-SVR model consistently exhibited superior performance when compared to the other models. The attained MAE score of 120.40 suggests that the prediction models exhibit a notable degree of precision. The model's predictive accuracy was validated by the testing phase, which yielded an RMSE score of 156.59 and an MSE value of 120.40. The model's MAPE score of 0.60 indicates that it has a consistent ability to produce correct predictions. It was shown that the AO-SVR model performed better in terms of accuracy and efficacy than the other models that were being studied. The AO-SVR model is an effective instrument for stock price prediction and provides investors with insightful information to help them make well-informed investment decisions.

The research is predicated upon historical Hang Seng index data spanning the years 2015 to 2023. Although the dataset offers significant insights regarding the predictive model's performance, it might not comprehensively encompass the wide array of market conditions and events that have the potential to impact stock prices. Subsequent investigations may profit from augmenting the strength and variety of the datasets utilized in order to bolster the analysis. The study presents a hybrid predictive model that integrates the Aquila optimizer procedure with support vector regression technology. This integration potentially results in heightened computational demands and longer training and evaluation periods for the model. One possible approach to address these challenges while maintaining accurate predictions is to investigate alternative optimization techniques or simplify the model architecture. The research centers on the Hang Seng index, an indicator of a particular stock market. Although the results illustrate the efficacy of the suggested model within this particular framework, its applicability to alternative stock markets or financial instruments is still ambiguous. Subsequent investigations might delve into the versatility of the hybrid model by examining its suitability across diverse asset classes and markets.

Additional optimization techniques may be investigated in subsequent research endeavors with the aim of further augmenting the predictive model's performance. It is possible to conduct experiments utilizing various optimization algorithms or parameter tuning strategies in order to determine the most effective configurations that simultaneously enhance prediction accuracy and reduce computational burden. Further data sources, including social media activity, economic indicators, and sentiment analysis of news articles, might be integrated to enhance the predictive model and offer a more holistic comprehension of market dynamics. By integrating disparate datasets, it may be possible to capture a more comprehensive array of factors that impact stock prices, thereby improving the accuracy of predictions. To evaluate the predictive model's long-term performance and dependability, a longitudinal study could be undertaken, providing significant insights into its enduring stability and resilience. An examination of its performance throughout various market cycles and economic conditions could substantiate its efficacy and pinpoint possible avenues for enhancement. Incorporating live validation tests and real-time deployment of the predictive model in trading environments could yield valuable practical insights regarding its usability and performance in real-world scenarios. Ongoing assessment of its performance in ever-changing market conditions and modification of model parameters have the potential to enhance its precision and practicality in real-life situations.

***Abstract*—Controlling the spread of Coronavirus Disease 2019 (COVID-19) and reducing its impact on public health need prompt identification and treatment. To improve diagnostic accuracy, this study attempts to create and assess a Multi-Modality COVID-19 Diagnosis System that integrates X-ray, Electrocardiogram (ECG), and Computed Tomography (CT) images utilizing Convolutional Neural Network (CNN) algorithms. To increase the accuracy of COVID-19 diagnosis, the suggested system incorporates data from many imaging modalities in a novel way, including cardiac symptoms identified by ECG data. This approach has not been thoroughly studied in the literature to date. The system analyses CT, ECG, and X-ray images using CNN algorithms, including Visual Geometry Group 19 (VGG19) and Deep Convolutional Networks (DCNN). While ECG data helps detect related cardiac symptoms, CT and X-ray images offer precise insights into lung abnormalities indicative of COVID-19 pneumonia. Noise reduction and image smoothing are accomplished through the implementation of Gaussian filtering algorithms. After extracting characteristics suggestive of either bacterial or viral pneumonia, a deep neural network refines them for accurate COVID-19 identification. Python software is employed throughout the system's implementation. A thorough evaluation of the trained CNN model using separate datasets revealed an amazing 99.12% accuracy rate in COVID-19 detection from chest imaging data. The diagnostic accuracy of the suggested DCNN model was much higher than that of the current models, including Random Forest and Linear Ridge. The Multi-Modality COVID-19 Diagnosis System uses cutting-edge CNN algorithms to seamlessly combine ECG, X-ray, and CT imaging data to provide a highly accurate diagnosis tool. With the implementation of this approach, medical personnel could potentially be able to diagnose COVID-19 more quickly and accurately, which would improve the disease's treatment and control.**

Keywords*—COVID-19 Diagnosis; Multi-Modality Imaging; Convolutional Neural Networks (CNN); CT imaging; Gaussian filtering

I. Introduction

COVID 19 has led to an advancement, in technologies, for the prompt and precise detection of the virus. One notable development is the emergence of faceted diagnostic systems, which offer a comprehensive understanding of the illness [1]. In the world of medical research, the application of CNNs to analyze CT and MRI images has demonstrated tremendous promise for COVID-19 identification [2]. These sophisticated machine learning algorithms are very adept at interpreting complex patterns and traits seen in medical imaging data, which makes it easier to identify critical markers of COVID-19 infection in patients [3]. An imaging method for respiratory disorders, computed tomography (CT) scans provide precise three-dimensional pictures of the lungs, which are essential for determining the kind of pulmonary abnormalities [4]. These images may be precisely examined to determine certain characteristics linked to COVID-19, including the existence of ground-glass transparency, by employing CNN technology. Additionally, magnetic resonance imaging (MRI) has shown to be a useful diagnostic and evaluation technique for pathology due to COVID-19 [5]. An understanding of pulmonary and cardiovascular health—both of which are greatly influenced by COVID-19 infection—can be gained through magnetic resonance imaging (MRI), which is well-known for its capacity to provide high-resolution images of soft tissues and organs. When CNNs are used on MRI scans, they can detect certain signs of COVID-19-related pathology, such as cardiac damage, lung inflammation, and vascular alterations. This helps with the thorough assessment of individuals who are impacted [6].

To analyze CT and MRI images for COVID-19 identification by CNN has great potential for enhancing diagnostic accuracy and speed in clinical practice [7]. Healthcare professionals can quickly and reliably detect COVID-19 patients based on imaging results by utilizing deep learning algorithms [8]. It is imperative to acknowledge that the efficacious utilization of CNNs for COVID-19 identification is contingent upon many aspects, such as the quality and amount of accessible imaging data, the resilience of deep learning algorithms, and the validation of outcomes via meticulous clinical investigations [9]. To guarantee the accuracy and applicability of CNN-based techniques in actual healthcare settings, issues including data fluctuation, imaging artifacts, and model understanding must also be resolved. Notwithstanding these obstacles, there are many intriguing prospects for more innovation and enhancement in COVID-19 diagnosis and patient care because of the continuous developments in medical imaging technology and machine learning algorithms [10]. CNNs with their ability to automatically learn and extract intricate patterns from images, have been employed to interpret these CT images for the presence of COVID-19-related features. By training on datasets of CT images from both COVID-19 positive and negative cases, CNNs can distinguish between healthy and infected individuals, aiding in rapid and accurate diagnosis [11], [12].

The integration of CNNs in COVID-19 detection through CT and MRI images brings several potential advantages. These

algorithms can assist healthcare professionals in identifying COVID-19 cases swiftly, facilitating timely interventions and patient management. Moreover, the automated nature of CNNs can help alleviate the burden on radiologists and healthcare systems, especially during surges in COVID-19 cases [13]. MRI, another sophisticated imaging modality, offers a different perspective on pulmonary and cardiovascular health. The utilization of CNN algorithms across the Multi-Modality COVID-19 Diagnosis System to leverage the unique strengths of each imaging technique. The paper presents Multi-Modality COVID 19 Diagnosis System that utilizes CNN algorithms to analyze information from three perspectives; ECG, X ray and CT images.

The proposed method is chosen for its ability to integrate multi-modal data such as chest X-ray (CXR), CT scans, and clinical data, enhancing COVID-19 diagnosis and prognosis accuracy. Leveraging the deep learning capabilities of CNNs and RNNs, it effectively learns intricate patterns from large-scale medical datasets. Feature fusion techniques combine radiomic and clinical features to provide robust predictions, while rigorous data augmentation and preprocessing mitigate dataset challenges. Model interpretability through explainable AI ensures transparency in predictions, fostering clinical trust. Designed for scalability and seamless integration into healthcare workflows, the method continuously adapts to evolving COVID-19 trends, ensuring ongoing efficacy and relevance in clinical settings.

The key contributions are as follows:

- This work provides an innovative method of diagnosing COVID-19 by combining CT, X-ray, and ECG data. A comprehensive evaluation of the condition is made possible by this multi-modal integration, which records its symptoms from several angles and offers a full picture of the patient's health.
- The study effectively analyses a variety of data types by utilising the capabilities of sophisticated Convolutional Neural Network (CNN) algorithms, such as VGG19 and Deep Convolutional Networks (DCNN). This advanced technique improves the system's diagnostic capabilities by enabling the discovery of complex patterns that are essential for an effective diagnosis.
- The suggested diagnosis approach significantly improves the accuracy of recognising COVID-19 instances by utilizing cutting-edge CNN algorithms and merging data from many imaging modalities. Enhancing patient outcomes, this increased accuracy helps medical practitioners make prompt accurate decisions.
- With its capacity to smooth and reduce noise, Gaussian filtering improves picture quality. This helps the diagnostic system get clear and accurate input data, which increases dependability and overall performance.
- The multi-modality COVID-19 diagnosis system is a ground-breaking development in medical diagnostics that combines a variety of imaging modalities with state-of-the-art CNN algorithms to provide a reliable, accurate, and efficient diagnostic tool that aids medical professionals in fighting the pandemic.

Structure of the study is given as follows: Existing literature reviews and its challenges are given in Section II. Identified problem from the related studies are given in Section III. Section IV presents the proposed method to overcome the challenges in the existing study. Findings derived from the proposed work is given in Section V. Conclusion of the study and future directions are given in Section VI.

II. Related Works

Wu et al. [14] present DeepCOVID-Fuse, a unique neural network fused model intended to forecast risk categories for COVID-19 patients. DeepCOVID-Fuse attempts to deliver more precise risk evaluations by combining medical data obtained at the period of beginning hospital admission with chest radiographs (CXRs). To ascertain risk levels, the study made use of information gathered from February to April 2020, which included CXRs, clinical factors, and outcomes including death, the intubation procedure hospitalized duration of the stay, and admission to the ICU. The fusion model was evaluated on 439 individuals from distinct holdout healthcare and examined on 428 individuals from the local healthcare system. The training dataset for the fusion model included 1657 individuals Using the DeLong and McNemar examinations, performance comparisons were made between DeepCOVID-Fuse and systems training on CT scans or medical parameters. Results showed that DeepCOVID-Fuse, with an accuracy around 0.650 and a region according to the ROC curve (AUC) of 0.842, performed significantly better than these separate models. The research highlights the potential benefits of fusion algorithms for hospital triage facilities and highlights their effectiveness in improving risk estimation for COVID-19 patients. Still, several restrictions should be noted. Firstly, model robustness could have been damaged by incomplete or missing medical information in the training dataset. The investigation failed to establish a direct comparison between DeepCOVID-Fuse's efficiency and radiologist' since risk prediction is a difficult and subjective process that depends on expert evaluation of both clinical and radiological information.

Fathima et al. [15] uses deep neural networks to provide a unique multimodality-based and featured fusion-based (MMFF) COVID-19 identification method. There are several essential phases in the building of the MMFF method. In the beginning, a multi-modality dataset is used to detect COVID-19. After that, non-discriminative information is removed from audio signals using a variety of speech preparation techniques. The process then proceeds to extract discriminative features from each medium, resulting in the master featured vector (MFV) being created. The LSTM (Long Short-Term Memory) recurrent neural networks approach is then used to classify COVID-19 cases using MFV. Due to the dataset's imbalance, audio augmentation methods are used to rectify the class imbalance. MMFF uses multi-modality audio samples taken from the COSWARA database to efficiently discriminate between healthy persons and COVID-19 sufferers. Utilizing LSTM classifiers to combine information from nine distinct approaches, the suggested method outperforms baseline approaches by 17 to 20% and achieves an impressive 96%

accuracy. Additionally, using audio augmenting approaches improves performance on datasets that are unbalanced as well as those that are balanced. In addition to helping with COVID-19 diagnosis without working against social distancing protocols, the suggested approach has potential applications in sentiment evaluation, sexuality categorization, and identification of speakers, among other audio analysis and classification issues. Subsequent efforts will be directed at developing an automated COVID-19 diagnostic tool with spectrogram data and methods like the CycleGAN system and Transfer Learning will be employed.

Abdar et al. [16] framed UncertaintyFuseNet, a deep neural fusion of features network accurately detect COVID-19 utilizing CT scan and X-ray data. The Ensemble Monte Carlo (MC) Dropout (EMCD) approach is integrated to evaluate uncertainty, highlighting the necessity of taking uncertainty about predictions during the learning process. The two fundamental deep learning models are presented in which Deep 1 consists of three feature extraction layers that are layers of convolution with MC failure, followed by three classification-focused layers that are dense. On the other hand, Deep 2 is made up of three primary units that operate as features extraction methods, each of which is followed by a layer for classification and a fusion layer. A comprehensive view from the third convolutional block, in-depth data from the last and final blocks of data, and the characteristics of the VGG16 transferred learning network are all combined in the suggested feature combination architecture. It also contains ROC plots for model assessment and graphical illustrations of the X-ray and CT imaging datasets. UncertaintyFuseNet's performance is compared to other methods using a thorough simulation analysis, with a focus on the terms precision, recall, the F measure, accuracy, and ROC curves. the model addresses uncertainty quantification through techniques like Ensemble Monte Carlo Dropout (EMCD), there may still be scenarios where uncertainty estimation is not sufficiently accurate or reliable.

Alazab et al. [17] work uses data from the real world, mainly X-ray chest images, to offer an AI-driven method for COVID-19 diagnosis and forecasting. Using an enhanced dataset, a Deep CNN, namely the VGG16 model is used for diagnosis in order to quickly and accurately discover COVID-19 patients, with an excellent the F-value of 99%. Also, the number of COVID-19 confirmations, recovery efforts, and mortality over the following week are predicted using three forecasting techniques: the prophetic algorithms (PA), the ARIMA method, and LSTM. With forecasting accuracy levels that vary from 79.3% to 99.9%, PA outperforms other models in the task of predicting these parameters for Australia and Jordan. Additionally, this research analyzes the worldwide geographically distribution for COVID-19 dissemination, emphasizing the features of severely affected places being comparable to one another and the much more widespread in coastal regions relative to non-coastal parts. These results highlight the significance of preventative actions, particularly in coastal areas, such as routine examinations and focused therapies. The report also suggests more research be done to determine how environmental variables like humidity and temperature affect the transmission of COVID-19. All things considered, this study advances AI-based methods for COVID-19 identification and forecasting and offers insightful information for successfully containing the pandemic. The model's performance may be limited by the specificity and sensitivity of chest X-ray imaging in detecting COVID-19.

Jian et al. [18] proposed an alternate diagnosis method that applies the latest algorithms in deep learning to chest X-ray scans in order to identify COVID-19 instances. The preprocessing phase data augmentation, and two stages of deep neural network modelling comprise the technique's four major phases. The study uses 1215 imagery at first, increased to 1832 images to improve model generalization and avoid overfitting by utilizing web resources. Based on chest X-ray images, the two-phase deep network structure seeks to distinguish COVID-19-induced influenza with pneumonia caused by bacteria, pneumonia caused by viral infections, and normal people. The two-stage approach performs well; the initial stage can discriminate between various forms of the illness and healthy persons, and the second step is particularly effective at accurately identifying COVID-19. For accurate identification of COVID-19 pneumonia, which is the suggested strategy provides efficiency, accuracy, and dependability while demanding the least amount of computing resources. According to the method, employing this strategy for parallel testing might reduce the risk of infection for frontline staff members and speed up initial diagnosis.

Hussain et al. [19] introduced CoroDet, a unique CNN-based technique that uses unprocessed chest X-ray and CT imaging data to automatically identify COVID-19. CoroDet outperforms 11 other methods in the context of a comparison, with accuracy in classification of 99%, 94%, and 91% for the second, third and fourth classes categorizations respectively. CoroDet's consistency is further enhanced by the fact that the dataset used for assessment is among the most comprehensive datasets accessible to COVID identification. The dataset prepared for evaluating CoroDet constitutes one of the largest datasets for COVID detection. Deep learning models like CoroDet typically require substantial computational resources for training and inference, which may pose challenges for deployment in resource-constrained healthcare settings, especially in low- and middle-income countries. The COVID-19 pandemic is characterized by evolving epidemiological trends, including the emergence of new variants and changing clinical presentations. It does not provide external validation of CoroDet's performance on independent datasets from different institutions or geographic regions. Without validation on diverse datasets, the robustness and applicability of the model to different healthcare settings remain uncertain.

DeGrave et al. [20] demonstrate that AI models trained on datasets synthesized from separate COVID-19-positive and negative images may learn spurious 'shortcuts' to achieve high accuracy, posing challenges for generalization to new hospitals. AI systems are trained offers a nearly perfect environment for picking up these fictitious 'shortcuts'. Through the synthesis of training data from distinct datasets including images either positive or negative for COVID-19, these algorithms could unintentionally pick up features irrelevant to the pathophysiology of the disease. As a result, these models could perform well in assessment but have trouble generalizing to other hospitals or datasets. Also, dependence on medically relevant disease may not be ensured by evaluating these AI

models only on external data. Unwanted short cuts that these models take out might not always affect performance on fresh datasets, which makes it difficult to identify problematic behaviour using only external validation. In addition, relying just on assessments of other information may not be sufficient for these AI systems to be evaluated in terms of clinically applicable disease. It can be difficult to identify bad behaviour alone through external validation since unwanted short cuts that these models develop may not always affect performance on fresh datasets. Deep learning models may rely on confusing features rather than medically relevant pathology, leading to inaccurate or unreliable predictions.

Ismael and Sengur [21] demonstrated techniques which include complete training of models using CNN, deep extraction of features, and pre-trained CNN fine-tuning. The collected characteristics were then classified using Support Vector Machine processors with different kernel features. A new CNN model was created and trained entirety in addition to the pretrained CNN models undergoing fine-tuning. The accuracy of 94% was obtained by combining deep features taken from the ResNet50 algorithm with an SVM classifier that used a linear kernel. An accuracy of 92% was obtained by fine-tuning the ResNet50 model, whereas an accuracy of 91.6% was obtained by the end-to-end trained CNN model. Moreover, contrasts using SVM classifications and local texture descriptors demonstrated how much better deep learning techniques performed than conventional techniques for COVID-19 identification from chest CT images.

The relevant studies cover approaches, to using learning in diagnosing and predicting COVID 19 from chest X ray and CT scans. A fusion network for COVID-19 detection using CT and X-ray data, incorporating uncertainty quantification techniques, was also developed. Additionally, a CNN-based technique for automatic COVID-19 detection from CT and chest X-ray imaging data, achieving high classification accuracy, was introduced. These research findings demonstrate that deep learning algorithms can effectively detect COVID 19 cases and track the progression of the disease. By integrating data and chest CT scans through a fusion technique, the proposed method enhances approaches providing more precise risk assessments for COVID 19 patients. Through evaluations the method surpasses techniques achieving high accuracy in classification and demonstrating efficacy in accurately identifying COVID 19 cases.

III. Problem Statement

While some studies focus on analyzing CT scans and chest X-rays individually for COVID-19 diagnosis, there is a lack of research that effectively integrates multimodal data, such as ECG signals, to improve diagnostic accuracy [22]. It trains and evaluates their models on specific datasets, which may limit the robustness and generalization of the proposed methods to diverse patient populations and healthcare settings. The Existing methods has limitations, such as handling diverse and unbalanced datasets in clinical settings, relying on traditional machine learning algorithms without deep learning advancements, and lacking robust uncertainty quantification methods. Scalability concerns and deployment in resource-limited healthcare environments also pose practical challenges. Addressing these issues is crucial for improving the method's utility and reliability in clinical practice. Thus, the proposed Multi-Modality COVID-19 Diagnosis System, which integrates information from ECG, X-ray, and CT images using advanced CNN algorithms. The proposed system uses multi-modality diagnosis, integrating data form-ray, ECG, and CT images, to improve COVID-19 diagnosis accuracy. It uses CNN algorithms like VGG19 and Deep Convolutional Networks to analyze complex data. The developed COVID-19 detection system is evaluated on independent datasets to assess its real-world performance.

IV. Proposed Multi-Modality Covid-19 Detection System using Deep CNN Algorithm

The Proposed Multi-Modality COVID-19 Diagnosis System analyzes data from ECG, X-ray, and CT images for improved COVID-19 identification using CNN algorithms, such as VGG19 and Deep Convolutional Networks. In order to extract valuable details from each modality and enable thorough analysis of medical data, CNN algorithms are used. The system analyzes ECG data to identify relevant features that are suggestive of cardiac symptoms linked to COVID-19. Chest X-rays are evaluated to find typical patterns associated with COVID-19 pneumonia. In between, CT scans provide fine-grained depicts of lung tissue, making it possible to identify minute anomalies that might indicate COVID-19 infection. CNN methods, such as VGG19 and Deep Convolutional Networks, play an essential part in the analysis of these various types of data. Large datasets of tagged COVID-19 patients and unaffected controls are used to train these algorithms so they can recognize intricate patterns and correlations in the data. By means of extraction and classification of features, the CNN algorithms are able to discriminate between COVID-19 instances and non-COVID-19 diseases, therefore offering healthcare providers invaluable diagnostic support. Fig 1 depicts the illustration of the proposed multi-modality COVID-19 detection system using CNN Algorithms.

A. Data Collection

The Kaggle dataset titled Extensive COVID-19 X-Ray and CT Chest Images Dataset contains a large collection of X-ray and CT images of the chest from patients [23]. The dataset consists of both Non-COVID and COVID cases represented in X-ray and CT images. With the aid of various augmentation techniques, the dataset has been expanded to encompass approximately 17,099 CT images and X-ray. Within the database, there are two primary files, one designated for X-ray images and the other for CT images. COVID-19 X-ray images typically show bilateral ground-glass opacities (hazy areas) and consolidations (dense areas) in the lungs, which are indicative of viral pneumonia. X-ray images are widely used for initial screening and diagnosis of COVID-19 due to their accessibility, simplicity, and lower cost compared to CT scans. CT (Computed Tomography) scans use a series of X-ray images taken from different angles to create cross-sectional images of the body. COVID-19 CT images typically reveal bilateral and peripheral ground-glass opacities, consolidations, and crazy paving patterns in the lungs, often involving multiple lobes. ECG data for COVID-19 detection can be collected from patients who have been diagnosed with the virus or suspected cases. The

dataset may include ECG recordings obtained during routine clinical assessments [24]. Table I shows the sample of the dataset.

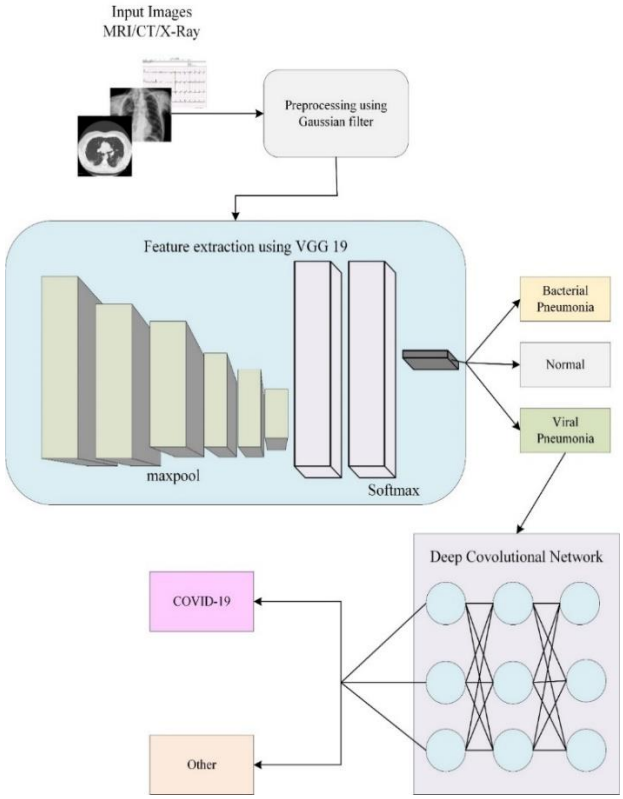

Fig. 1. Conceptual framework of multi-modality COVID-19 detection system using deep CNN algorithms.

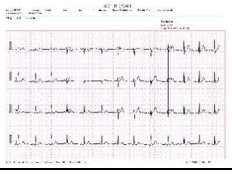
TABLE I. SAMPLE DATASET

ECG	X-Ray	CT Images
		
		
		
		



B. Pre-Processing using Gaussian Filter

X-ray and CT images may come in varying sizes, so resizing them to a standard resolution can facilitate consistency and reduce computational complexity. Intensity Normalization is done by adjusting the intensity levels of the images to a standard scale helps in reducing variability between images captured using different devices or settings. Enhancing image contrast can improve the visibility of important features, making it easier for medical professionals to interpret the images accurately. Removing baseline wander or low-frequency noise from ECG signals helps in isolating the cardiac waveform and improves signal quality. Segmenting ECG signals into individual heartbeats or cardiac cycles facilitates the analysis of specific features such as the P-wave, QRS complex, and T-wave.

Pre-Processing using a Gaussian filter is a widely used method for smoothing and noise reduction in images and signals. The Gaussian function, a bell-shaped curve representing the distribution of values, is generated based on two parameters: the σ and μ. The Gaussian kernel is convolved with the input image or signal, multiplying neighboring values at each pixel or data point and summed to produce the output value. This process is repeated for all pixels or data points in the image or signal. Smaller kernel sizes and lower standard deviations result in less smoothing, while larger values produce more pronounced blurring. After the convolution operation is performed, the output is generated, representing the pre-processed version of the input. The Gaussian filter is defined by the Gaussian function, which is given by the following Eq. (1),

$$G(a,b) = \frac{1}{2\pi\sigma^2} e^{\frac{a^2+b^2}{2\sigma^2}} \quad (1)$$

where, G(a, b) is the Gaussian function at coordinates (a, b),σ is the standard deviation of the Gaussian distribution.

C. Feature Extraction and Pneumonia Detection using VGG 19

Initially, relevant structures are extracted from the data images using techniques like CNNs. These structures may include the presence of specific patterns, densities, or shapes indicative of different respiratory conditions. For viral pneumonia detection, characteristic features may include bilateral lung involvement, ground-glass opacities, and peripheral distribution of lesions. Bacterial pneumonia, on the other hand, may exhibit lobar consolidation, air bronchograms, and pleural effusions. Normal cases are characterized by clear lung fields without any abnormal opacities or consolidations. Once features are extracted, a classification algorithm is employed to categorize the cases into viral pneumonia, bacterial pneumonia, or normal. This algorithm could be a deep learning model trained on labelled datasets containing examples of each condition.

Fig. 2 shows the architecture of VGG 19 model. In the context of pneumonia classification using deep learning techniques like VGG-19, distinguishing between viral and bacterial pneumonia involves training the model to recognize patterns and features specific to each type of infection.

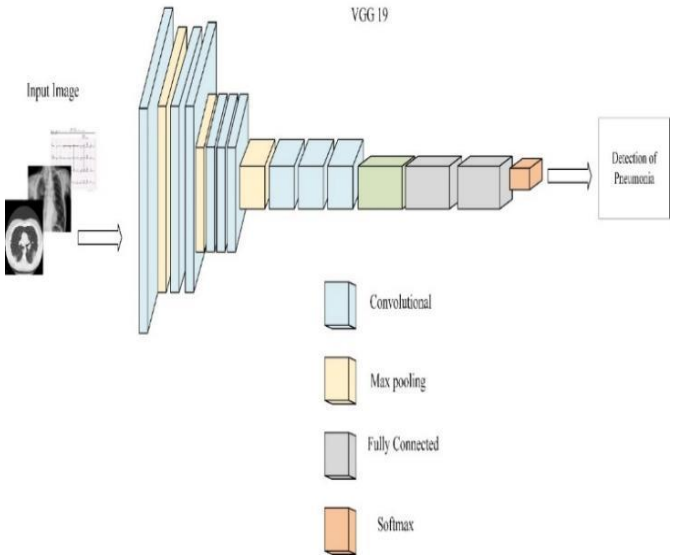


Fig. 2. VGG 19 architecture.

D. Prediction of COVID-19 using Deep CNN

The recognition of COVID-19 using deep CNNs following the classification of pneumonia by VGG-19 involves a sequential order. Initially, the VGG-19 architecture is employed to categorize chest X-ray or CT images into different pneumonia categories, such as bacterial pneumonia, viral pneumonia and normal lungs. This step involves optimizing the pre-trained VGG-19 model on a database containing labelled images of various pneumonia types. Initially, the VGG-19 architecture is employed to classify chest X-ray or CT images into different pneumonia categories, such as viral pneumonia, bacterial pneumonia, and normal lungs. This step involves fine-tuning the pre-trained VGG-19 model on a dataset containing labelled images of various pneumonia types. The extracted features from the VGG-19 model are then fed into a deep CNN specifically designed for recognizing COVID-19. This network is trained on a dataset comprising chest imaging data from individuals diagnosed with COVID-19 and those without the virus. The COVID-19 detection CNN undergoes training and fine-tuning using the extracted features as input. During this process, the model learns to distinguish between COVID-19 cases and non-COVID-19 based on the learned features from the VGG-19 architecture. Once trained, the concert of the disease detection CNN is assessed using a separate test dataset containing chest images from individuals with known COVID-19 status. Fig. 3 shows the COVID-19 prediction using Deep CNN.

Specifically, the system utilizes average pooling layers (La), which compute the average activation within each pooling region. This can be expressed mathematically in Eq. (2),

$$PL = da/|da| \quad (2)$$

where, da represents the activation set in the pooling region a, and |da| denotes the cardinal number of the set. It employs soft max and fully connected layers to facilitate classification. The fully connected layer establishes connections with all neurons, multiplying its input with a weight matrix to produce the multiplicative result. It is represented by Eq. (3),

$$SL = \frac{e^{\beta^{Ps}}}{\sum_{A-1}^{P} \cdot e^{\beta^{Ps}}} \quad (3)$$

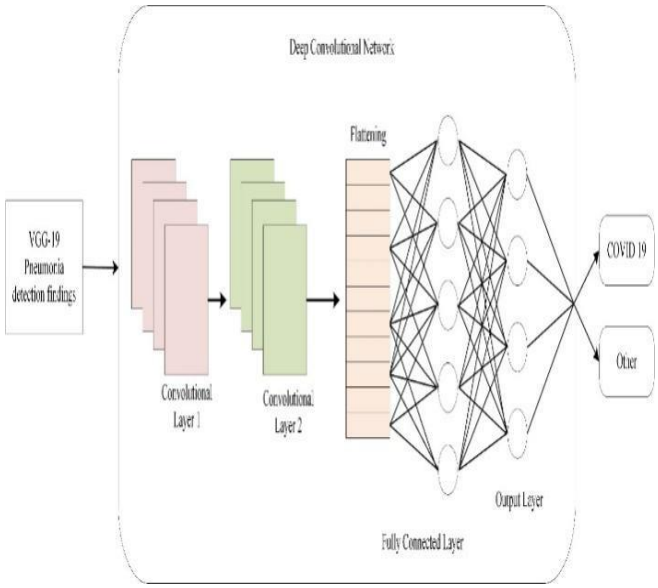

Fig. 3. Detection of COVID-19 using deep CNN.

where, β^{Ps} represents the value of the output neuron for class P and sample s. P represents the total number of classes. A represents the Index variable used for summation over all classes. e represents the Euler's number, approximatelyequalto2.71828. To prevent overfitting, we incorporate dropout layers, which randomly deactivate neurons during model training, and rectified linear units (ReLU) to efficiently handle gradient-based training. It is given by the Eq. (4).

$$Relu\ Function = max(0, \alpha) \quad (4)$$

where, α represents the Input value to the ReLU function. The ReLU function outputs the maximum of either 0 or the input value α. If α is negative, the ReLU function outputs 0; otherwise, its outputs α.

This process involves the expansion and training of a specialized CNN architecture tailored specifically for detecting COVID-19 from chest imaging data. The CNN architecture is trained using the labelled training dataset to learn the patterns and features associated with COVID-19 in chest imaging data. As the CNN trains on the chest imaging data, it automatically learns to extract relevant features and patterns from the input images. These features capture important characteristics indicative of COVID-19 infection, such as ground glass opacities, consolidation, and other abnormalities typically observed in chest imaging of COVID-19 patients. Once training is complete, the CNN is evaluated on the database to evaluate its concert and recognize latent problems such as underfitting. Finally, the trained CNN is tested on an independent dataset (the testing set) to evaluate its real-world performance.

Algorithm for the Proposed Multi-Modality COVID-19 Diagnosis System

Input: ECG data, X-ray images, CT images

Output: COVID-19 diagnosis

Start

Load the Input Images

Pre-Processing using Gaussian Filter

Resize CT images and X-ray to a standard resolution

Normalize intensity levels of images

Enhance image contrast

Apply Gaussian filtering for image smoothing and noise reduction

Feature Extraction and Pneumonia Detection using VGG19

Load pre-trained VGG19 model

Extract features from input images using VGG19

Classify features into pneumonia categories (viral, bacterial, normal)

Prediction of COVID-19 using Deep CNN

Optimizing pre-trained VGG19 model for COVID-19 detection

Train specialized CNN architecture for COVID-19 identification

Evaluate trained CNN on independent datasets

Output

COVID-19 diagnosis based on analysis of ECG, X-ray, and CT data

End

V. Results and Discussion

The Multi-Modality COVID-19 Diagnosis System, integrating ECG, X-ray, and CT data, demonstrated robust performance in enhancing COVID-19 diagnosis. The study's approach of implementing each dataset separately underscores its meticulous and thorough methodology in evaluating the performance of the proposed multi-modality COVID-19 diagnosis system. By analysing each dataset independently, the study ensures a comprehensive understanding of the system's effectiveness across various medical imaging modalities, including ECG, CT scans, and X-rays. Feature extraction and pneumonia detection using VGG19 facilitated the recognition of specific patterns indicative of viral or bacterial pneumonia, further enhancing COVID-19 diagnosis accuracy. The deep CNN, fine-tuned on extracted features from VGG19, effectively detected COVID-19 cases. Employing various neural layers ensured robust classification and regularization of the model. During training, the COVID-19 detection CNN iteratively adjusted parameters based on error, learning to extract relevant features suggestive of disease infection from input data. Implemented in Python software, the COVID-19 detection system achieved an impressive accuracy of 99% when evaluated on dataset. Implemented in Python software, the COVID-19 detection system achieved an impressive accuracy of 99.12% when evaluated on the Extensive COVID-19 X-Ray and CT Chest Images Dataset. Through iterative parameter adjustments based on error during Deep CNN training, the system learns to extract relevant features indicative of COVID-19 infection from chest imaging data. The evaluation on independent datasets, including the dataset, showcases anotable accuracy of 99.12% in detecting disease.

A. Dataset Comparison

Table II shows that the ECG abnormalities in Covid-19 patients could be attributed to myocardial damage, inflammation, or arrhythmias. A typical chest X-ray reveals clean lung fields, well-defined lung structures, and no evidence of infection or consolidation. It acts as a benchmark for comparison. Covid-19 pneumonia is often characterized by bilateral ground-glass opacities or consolidations on chest X-rays. A typical CT scan of the chest shows clear lung tissue and blood arteries, with no evidence of infection or inflammation. Covid-19 CT findings include bilateral GGOs, crazy-paving patterns, and consolidations.

TABLE II. Comparison of Dataset

ECG	X-Ray	CT Images
COVID-19 	**COVID-19** 	**COVID-19** Normal 	**Normal** 	**Normal** 
B. Evaluation of Performance for VGG 19 in Pneumonia Detection

Table III and Fig. 4 gives the comparison of VGG 19 with other existing models. The proposed VGG-19's precision is 99.4%. This indicates that the technique correctly predicts pneumonia 99.4% of the time. The proposed VGG-19 has a recall of 98.7%, which means it properly detects 98.7% of all cases of pneumonia. The proposed VGG-19 has an excellent F1 score of 99.32%. The proposed VGG-19 has an accuracy of 99%, demonstrating a high level of accuracy in pneumonia diagnosis. The proposed VGG-19 has superior precision, recall, F1-score, and accuracy in identifying pneumonia. Its outstanding performance makes it an attractive contender for use in clinical settings.

TABLE III. EVALUATION OF PERFORMANCE

Methods	Precision (%)	Recall (%)	F1-Score (%)	Accuracy (%)
Res Net 50[25]	95	95.3	96	95.6
Image Net[25]	98.2	97	97.4	97.68
Proposed VGG 19	99.4	98.7	99.32	99

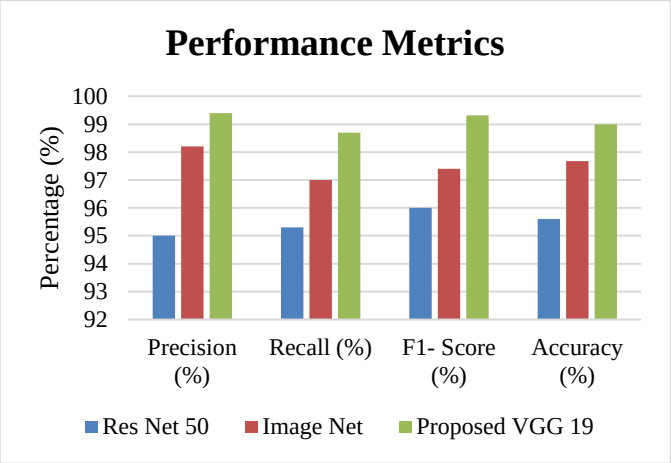

Fig. 4. Comparison of VGG performance with existing methods.

TABLE IV. COMPARISON OF THE PROPOSED VGG 19'S PERFORMANCE IN ECG,CTS AND X-RAY IMAGES

Proposed VGG 19	Accuracy (%)	Recall (%)	Precision (%)	F1 Score (%)
ECG	99.1	98.4	98	98.9
CTs	99	98.9	99.23	98.34
X-Ray	99.12	99.34	99.02	98.07

Fig. 5 and Table IV shows the accuracy of the proposed VGG 19 model. The suggested VGG-19 has an amazing 99.1% accuracy in categorizing ECG images. This high level of precision suggests that the model is good in detecting aberrant heart beats and patterns in ECG data. The proposed VGG-19 retains a high accuracy of 99% when identifying CT images. CT scans are critical for identifying a variety of illnesses, and the accuracy of the model provides repeatable findings. The Proposed VGG-19 obtains 99.12% accuracy on X-ray images.

This precision is critical in diagnosing lung abnormalities, fractures, and other disorders evident on X-rays. The proposed VGG-19 performs consistently and robustly across multiple medical imaging modalities, making it an important tool for correct diagnosis and treatment of patients.

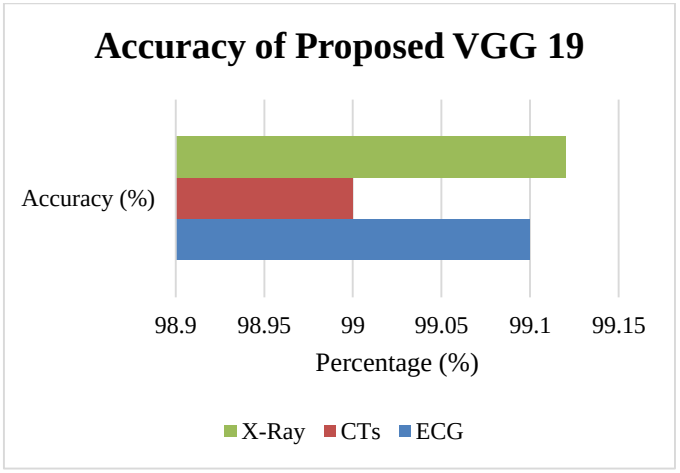

Fig. 5. Accuracy of proposed VGG 19.

C. Training and Validation Accuracy

As shown in Fig. 6, the training accuracy measures the efficiency with which the trained model responds to training data for every epoch. Training precision increases substantially with an increasing number of epochs. In the beginning, after 10 epochs, the model obtains a training accuracy of 0.41, indicating underfitting.

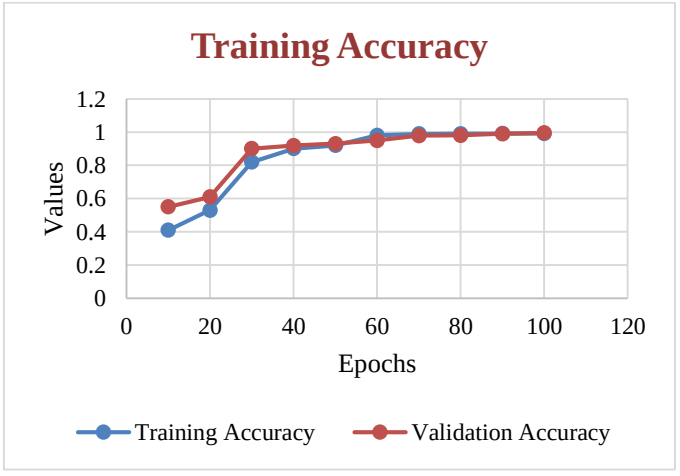

Fig. 6. Training accuracy of deep CNN.

But as training goes on, accuracy gradually improves. At 60 epochs, the training accuracy is 0.98. At 100 epochs, it has improved to 0.992. This pattern indicates that a model is acquiring information from the training information and getting more effective. Validation accuracy assesses how effectively the model extends to new data (validation set). Validation accuracy, like training accuracy, increases as epochs increase. The validation accuracy at ten epochs is 0.55. By the 100th epoch, it has reached an amazing 0.995, showing that the framework operates effectively with new information. The growing validation accuracy indicates that the prediction model has

minimal overfitting and may generalize successfully. As the algorithm trains, the accuracies of both training and validation improve regularly. The model's performance maintains at roughly 100 epochs, indicating that more training could not considerably increase accuracy. It is critical to establish a balance between training for sufficient time to understand patterns while minimizing overfitting.

D. Training and Validation Loss

The training loss is the difference between both model's predicted and real desired outcomes at each epoch. As shown in Fig. 7, reduced training loss implies that the model is well fitted to the training data. In the supplied data, the training loss is 0.98 after 10 epochs. The training loss lowers continuously as the epochs advance, reaching 0.36 after 60 epochs. At 100 epochs, it drops to an excellent 0.16. This pattern indicates that the algorithm is absorbing information from training data and increasing its forecasting abilities. The validation loss indicates how effectively the model applies to previously unidentified information (validation set). Like training loss, smaller validation loss suggests higher adaptation. In the presented data, the validation loss is 0.89 after 10 epochs. By 100 epochs, it has dropped significantly to 0.11. The reduction in validation loss indicates that the algorithm has limited overfitting and will function well with new data. As the model learns, both training and validation losses gradually reduce. The gradual reduction of training and validation losses indicates that the algorithm is learning efficiently and without overfitting from occurring. The right quantity of epochs for training can be determined through observation of the loss curve. The Deep CNN has a positive loss curve, suggesting excellent learning and adaptation. Model training requires improving hyperparameters and ending quickly due to validation loss.

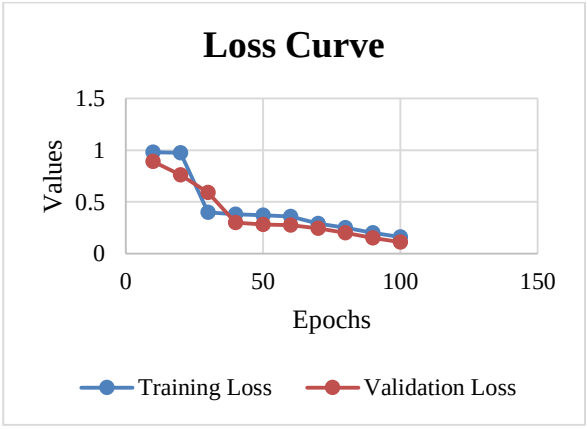

Fig. 7. Loss curve of deep CNN.

E. ROC Curve

Fig. 8 shows the Receiver Operating Characteristic Curve for the Deep CNN based on the provided True Positive Rate and False Positive Rate data. The ROC curve is an illustration of a classifier's efficiency at various classification levels. It compares the TPR (sensitivity or recall) to the FPR (1-specificity) when the value of the threshold for identifying positive and negative examples changes. The information being given demonstrates the TPR and FPR at different thresholds (0 to 0.6). At the lowest possible threshold (0), both TPR and FPR are zero, indicating that the model forecasts no positive events (either true or false positives). As the value of the threshold is raised, TPR gradually rises, showing that the model correctly recognizes more positive events. PR also rises, but at lower rates, implying that the model has produced certain false positive forecasts. At 0.6, the TPR is 0.991, indicating that the model accurately identifies 99.1% of positive cases. The FPR is also 0.991, meaning that the model mistakenly labels 99.1% of negative instances as positive.

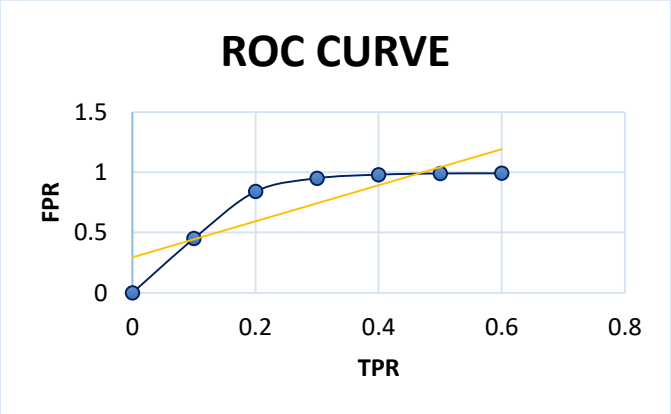

Fig. 8. ROC curve of DCNN.

F. Comparison of the Proposed Deep CNNs Performance with Existing Methods

The Deep CNN performed successfully, exceeding both Random Forest and Linear Ridge techniques. As shown in Fig. 9 and Table V, its high precision (99%), recall (99.1%), and F1-score (98.8%) suggest appropriate Covid-19 classification. The proposed CNN utilizes transferable learning and pre-trained structures, making it useful for medical imaging despite the low availability of information. The proposed Model achieves a high accuracy of 99.12%, which is comparably high with RF and Linear ridge methods.

G. Discussion

The results from the multi-modality COVID-19 diagnosis system, integrating ECG, X-ray, and CT scan data, enhancing the accuracy and performance of COVID-19 analysis. By leveraging VGG19 for feature extraction and pneumonia detection, the machine demonstrates robust performance in figuring out specific patterns indicative of viral or bacterial pneumonia, thereby augmenting the accuracy of COVID-19 prognosis [25]. The best-tuning of deep CNNs on extracted functions in addition complements the system's capability in detecting COVID-19 instances, making sure a complete method to disease identity.

TABLE V. COMPARISON OF PERFORMANCE IN COVID-19 CLASSIFICATION USING DEEP CNN

Methods	Precision (%)	Recall (%)	F1- Score (%)	Accuracy (%)
Random Forest [26]	58.8	56.3	57.3	56
Linear Ridge [26]	54.4	53.3	53.6	53.6
Proposed Deep CNN	99	99.1	98.8	99.12

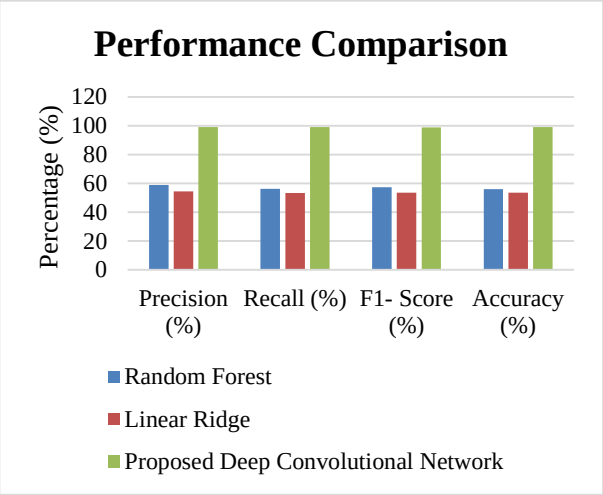

Fig. 9. Comparison of performance in COVID-19 classification using deep CNN.

The evaluation of the proposed VGG19 version's performance against present techniques highlights its superiority in precision, recall, F1-score, and accuracy in figuring out pneumonia throughout distinct imaging modalities. With precision achieving 99.4% and an accuracy of 99%, the proposed VGG19 version showcases good performance in pneumonia diagnosis, underscoring its ability for medical application [26]. Additionally, the version's constant and strong performance across numerous clinical imaging modalities, which include ECG, CT scans, and X-rays, emphasizes its versatility and reliability in helping accurate diagnosis and treatment selection-making.

The training and validation processes of the deep CNN elucidate the model's dynamics and generalization competencies. The determined patterns of growing training and validation accuracies imply the model's effective learning from the data at the same time as minimizing overfitting. The integration of training and validation losses similarly validates the model's efficient mastering method without conceding its capability to simplify to new data. The ROC curve evaluation affords insights into the version's sensitivity and specificity, showcasing its efficiency in categorizing positive instances while minimizing false-fine predictions. Overall, the contrast of the proposed deep CNNs overall performance with existing strategies underscores its efficacy in COVID-19 type, signifying its capacity as a valuable tool in clinical settings for correct disease diagnosis.

VI. Conclusion and Future Work

The multi-modality COVID-19 diagnosis system created in this work uses deep Convolutional Neural Network (CNN) algorithms to analyse CT, X-ray, and ECG images, which is a major breakthrough in medical diagnostics. The extraction of complementary information is made possible by the integration of many imaging modalities, which improves the overall efficiency and accuracy of diagnosis. Capturing the different patterns linked to COVID-19 in medical images, the CNN algorithms employed in this system are skilled in feature extraction and classification. Additionally, the ability to detect cardiac abnormalities—which are commonly seen in COVID-19 patients—enhances the diagnosis procedure when ECG data is included. Healthcare workers' diagnostic load is lessened by this automated, quick analysis capabilities, which makes processing massive amounts of medical data more effectively possible. The outcome of the study show that this technology has the potential to greatly enhance patient outcomes and diagnostic accuracy. However, further actions are required before its potential could be realized in clinical practice. To guarantee the system's dependability and efficacy across a range of patient demographics and healthcare contexts, validation via comprehensive clinical studies and real-world application is essential. Subsequent investigations have to concentrate on many crucial domains to augment the system's relevance and influence. Primarily, broadening the dataset to encompass a more diverse array of patient demographics and imaging modalities would enhance the system's resilience and generalizability. Through the implementation of cutting-edge machine learning techniques, the multi-modality COVID-19 diagnosis system shows great promise for revolutionizing COVID-19 diagnoses by increasing accuracy and efficiency. The problem identified in this paper include the complexity of integrating multi-modality data, the computational demands of training deep neural networks, and the need for extensive and diverse datasets to ensure the robustness of the system. Additionally, addressing potential biases in the training data and ensuring the generalizability of the model across different populations are critical challenges that need to be addressed in future research. This approach has the potential to be a vital weapon in the global fight against COVID-19, improving patient outcomes and healthcare delivery around the globe, if the previously indicated future research directions are addressed.

***Abstract*—Early illness diagnosis, treatment monitoring, and healthcare administration all depend heavily on the identification of abnormalities in medical data. This paper proposes a unique way to improve healthcare anomaly detection through the integration of attention mechanisms and Generative Adversarial Networks (GANs) for improved performance. By integrating GANs, artificial data that closely mimics the distributions of actual healthcare data may be produced, so, it is important to supplementing the dataset and strengthening the resilience of anomaly detection algorithms. Simultaneously, the Convolutional Block Attention Module (CBAM) facilitates the model's concentration on useful characteristics present in the data, thereby augmenting its capacity to identify minute deviations from the norm. The suggested method is assessed using a large dataset from healthcare settings that includes both typical and unusual cases. When compared to current techniques, the results show notable gains in anomaly detection performance. The model also shows resilience to noise, small abnormalities, and class imbalance, indicating its potential for practical clinical applications. The suggested strategy has the potential to improve clinical decision-making and patient care by giving doctors faster, more precise insights into anomalous health states. With an accuracy of around 99.12%, the suggested GAN-CBAM is implemented in Python software and outperforms other current techniques such as Gaussian Distribution Anomaly detection (GDA), Augmented Time Regularized (ATR-GAN), and Convolutional Long Short-Term Memory (ConvLSTM) by 2.97%. With potential benefits for bettering patient outcomes and the effectiveness of the healthcare system, the suggested strategy is a major step forward in the improvement of anomaly identification in the field of medicine.**

Keywords*—Generative Adversarial Networks (GANs); Convolutional Block Attention Module (CBAM); anomaly detection; attention mechanism; healthcare

I. Introduction

Advancements in anomaly detection methodologies hold significant promise for enhancing healthcare outcomes by enabling early identification of abnormal patterns or deviations in medical data [1]. Anomaly detection plays a pivotal role in various healthcare applications, including disease diagnosis, treatment monitoring, and patient management [2]. However, the complexity and heterogeneity of healthcare data pose significant challenges for traditional anomaly detection techniques. In recent years, the integration of advanced machine learning techniques has emerged as a promising approach to address these challenges and improve the accuracy and reliability of anomaly detection in healthcare settings [3]. In this context, this paper proposes a novel framework for advancing healthcare anomaly detection by integrating GANs with attention mechanisms to achieve enhanced performance [4].

GANs have garnered considerable attention in the ML community for their ability to generate synthetic data that closely resembles real-world data distributions [5]. By leveraging the adversarial training paradigm, GANs learn to generate high-fidelity samples that capture the underlying structure and complexity of the original data [6]. In the context of healthcare anomaly detection, GANs offer a promising avenue for data augmentation, enabling the generation of diverse and representative synthetic samples to augment limited or imbalanced datasets [7]. Furthermore, attention mechanisms have gained prominence for their ability to focus on relevant features or regions within the data, thereby enhancing the model's ability to capture salient information for anomaly detection. By integrating attention mechanisms into the anomaly detection framework, the proposed approach aims to improve the model's discriminative power and robustness to subtle deviations or anomalies in healthcare data [8].

The integration of GANs and attention mechanisms represents a novel and synergistic approach to advancing healthcare anomaly detection [9]. By harnessing the complementary strengths of these techniques, the proposed framework aims to overcome limitations associated with

traditional anomaly detection methods, such as reliance on handcrafted features or susceptibility to class imbalance and noisy data [10]. Moreover, the proposed approach holds promise for facilitating interpretability and explainability in anomaly detection, enabling clinicians to better understand and trust the model's outputs. Overall, this paper contributes to the ongoing efforts in leveraging advanced machine learning techniques to enhance anomaly detection in healthcare, with potential applications in improving patient outcomes, clinical decision-making, and healthcare system efficiency [11].

Healthcare anomaly detection, a critical aspect of healthcare informatics, involves the identification of abnormal patterns, deviations, or outliers within healthcare data. This field plays a pivotal role in various healthcare applications, including disease diagnosis, treatment monitoring, patient safety, fraud detection, and resource optimization. Anomalies in healthcare data can manifest in diverse forms, such as unusual physiological measurements, unexpected variations in medical imaging findings, irregularities in billing records, or atypical patterns in patient health records. Detecting these anomalies is essential for ensuring early disease diagnosis, timely intervention, and effective healthcare management, ultimately leading to improved patient outcomes and healthcare system efficiency [12].

One of the primary objectives of healthcare anomaly detection is to enhance early disease diagnosis and treatment monitoring. By analyzing patient health records, medical imaging data, and physiological measurements, anomaly detection algorithms can identify subtle deviations from normal patterns that may indicate the presence of underlying health conditions [13]. For example, anomalies in ECG signals could signify cardiac arrhythmias or abnormalities, while anomalies in medical imaging scans such as CT or MRI could indicate the presence of tumors, lesions, or other pathological findings. Early detection of these anomalies enables healthcare practitioners to initiate timely interventions, implement appropriate treatment strategies, and monitor patient progress more effectively.

Furthermore, healthcare anomaly detection plays a crucial role in patient safety and quality of care. By flagging unusual medication prescriptions, treatment orders, or adverse drug reactions, anomaly detection systems help prevent medication errors, adverse events, and patient harm. Similarly, anomaly detection algorithms can identify anomalies in hospital admission records, discharge summaries, or surgical procedures, enabling healthcare providers to ensure compliance with clinical protocols, minimize risks, and enhance patient safety standards [14].

In addition to improving patient care and safety, healthcare anomaly detection contributes to healthcare system efficiency by optimizing resource allocation, streamlining administrative processes, and reducing operational costs. By identifying anomalies in healthcare supply chain data, inventory management systems, or staffing schedules, healthcare organizations can optimize resource utilization, mitigate supply chain disruptions, and improve workflow efficiency [15]. Moreover, anomaly detection algorithms can identify inefficiencies, bottlenecks, or deviations from established performance metrics within healthcare operations, enabling administrators to implement targeted interventions, process improvements, and quality assurance initiatives to enhance overall system performance.

The key contributions of the article are,

- The paper suggests a unique method to improve healthcare anomaly detection that combines GANs with attention processes, notably the CBAM. The model can now produce synthetic data that closely resembles actual healthcare distributions while concentrating on useful aspects seen in the data, which enhances the algorithm's capacity to spot minute departures from the norm.
- The work efficiently increases the dataset and improves the resilience of anomaly detection models by utilizing GANs for data augmentation. This augmentation leads to more dependable detection outcomes by addressing the restrictions caused by incomplete or unbalanced datasets that are frequently found in healthcare settings.
- The suggested methodology is assessed using an extensive dataset that includes both typical and unusual cases from medical environments.
- The study demonstrates how resilient the suggested paradigm is to problems like noise, class imbalance, and minute abnormalities seen in healthcare data. Because of its resilience, the model may be applied more effectively in actual clinical situations and gives doctors faster, more precise insights into diseases that deviate from the norm.

The remainder of the article includes related works, problem statement, methodology and results in Section II, III, IV and V. The paper and future scope are concluded in Section VI and Section VII respectively.

II. Related Works

Oluwasanmi et al. [16] explain that due to their involvement in several crucial and vital situations, computerized anomaly detection and detection have grown increasingly important in the modern age. It suggests three AI systems that use DL techniques to examine and identify abnormalities in human electrical impulses in order to achieve these objectives. Two of the three suggested methods are a restoration decoder with minimal remodeling losses and an attention automatic encoder that transfers the input information to a lower-dimensional latent representations with optimal features persistence. To identify the prominent responses in the encoded dispersion, the auto encoder incorporates a focus component at the bottlenecks. Furthermore, time-series sequencing data analysis and generating reconstructions have been developed for learning a Gaussian distribution through the use of a VAE and a network with LSTM. When identifying normal beating hearts from individuals suffering from acute congestive cardiac failure, the three suggested models shown exceptional capacity to identify abnormalities on the assessed ECG5000 data with an accuracy of 99% and 99.3% precise value.

Vaccari et al. [17] explains that AI and ML techniques are increasingly being used in the medical field for a variety of

reasons, including systems for clinical decision-making, tracking patients, and the detection and prognosis of potential illnesses. In addition, because autonomous medical devices which fall under the IoMT umbrella allow ongoing surveillance and immediate utilization of data by medical professionals, their widespread adoption has made it easier to get information about patients. Nevertheless, the data gathered may not be accurate enough to apply accurate methods because of potential problems in real-world contexts, like connectivity failure, inconsistent use, abuse, or lax compliance to a surveillance programmed. To build artificial datasets big enough to train ML models, hence, methods to augment data can be applied. In this study, it uses the notion of GANs to supplement patient data collected by IoMT devices for the purpose of tracking COPD. By contrasting the artificial information with the actual data captured by the detectors, also use an understandable AI system to show how accurate the simulated information is. As confirmed using a unique ML-based technique, the outcomes show that data sets generated by an organized GAN are similar with a real database.

In the United States, heart disease is the primary cause of mortality. In order to preserve the lives of individuals, prompt medical attention is essential for the accurate identification of cardiac disease. The ECG is an extremely widely used tool used by doctors to evaluate heart electrical activity and identify potential abnormalities. Creating efficient mathematical models is necessary to fully utilize the ECG data for trustworthy heart disease diagnosis. Zekai Wang et al. [18] present a GAN-based two-level hierarchy structure to support ECG signal interpretation. A Made GAN makes up the first-level demonstrate, that attempts to distinguish anomalous signals from regular ECGs in order recognize anomalies. By combining the TL learning method used to on information from the first-level acquiring with the multi-branching design to deal with the data-lacking and unbalanced information problems, the second-level training aims at strong multi-class categorization for various arrhythmia recognition. It assesses how well the suggested architecture performs using actual ECG readings obtained from the MIT-BIH cardiac dataset. According to results from experiments, suggested model works better than the approaches that are already in widespread use in fact.

Said et al. [19] explains that False alarms have several detrimental consequences in important IoT application areas including the Defense Industry and Healthcare, including anxiety, interruption of emergency services, and wasted resources. As a result, an alert should only be delivered when the right thing happens. However, the accuracy of identifying events is impacted by intrusions into connected devices. In this study, an ADS is presented for a connected device in a smart healthcare facility to identify occurrences of interest related to the surroundings and health of patients while also looking for hacking attempts. It was demonstrated that supplying one platform for e-health assessment and network infrastructure supervision helps to optimize capabilities and uphold system dependability. As a result, choices about patient treatment and environmental modification are made with more accuracy. Because of an edge installation that enables processing near to data sources, minimal latency is guaranteed. The suggested ADS is put into practice and assessed utilizing the Contiki Cooja simulator, and an examination of an actual data set serves as the foundation for the e-health detection of events. The findings demonstrate a high rate of detection for both IoT network breaches and e-health-related incidents.

Li et al. [20] explains that Modern manufacturing has made extensive use of supervised ML approaches, like categorization models, for web-based anomaly detection. Since anomalous process states are uncommon in typical industrial environments, there's a chance that the data used to train the model is excessively unbalanced. This might lead to a large amount of training biases in supervised learning that would further reduce the accuracy of anomaly detection. It makes sense to use methods for data enhancement to provide useful fake data samples for the anomalous process states in order to lessen training bias. Unfortunately, the majority of data enhancement algorithms now in use do not adequately account for the temporal arrangement of the signal generated by sensors, and in need to achieve appropriate augmentation achievement, a significant number of real samples are often needed. This research created a unique data-driven approach called augmented temporal regularized ATR-GAN to overcome these constraints. ATR-GAN can provide simulated samples for models of supervised learning that are more successful by including a suggested enhanced generator. Three factors sum up this enhanced generator's originality in the suggested technique: 1) To recognize high-quality manufactured samples, an enhanced filter layer is added to the augmented the generator; 2) A new separation metric called TRH distance was created in the enhanced filter layer to accurately assess the similarities within accomplished artificial instances and actual instances. However, and 3) to make the most of the comparatively small amount of training data and better diversify the generated data, batching methods have been included in the suggested enhanced generator. Furthermore, cases from the real-world in additive production and computational modelling are used to verify the efficacy of the suggested ATR-GAN.

Ziyu Wang et al. [21] explains that EMR progress has been hampered by the dichotomy between the years of administrative oversight and the enormous rise in the need for health information privacy. This invention has the potential to encourage patient data independence at this historical juncture. In this work, researchers suggest a decentralized, effective, and secure Ethereum platform for sharing and protecting data privacy called Guard Health. When working with sensitive data, Guard Health oversees data exchange, security, authorization, and preservation. In order to ensure safe information preservation and transmission which forbids transmission of information without authorization it makes use of the Blockchain and smart contracts. The latest GNN for harmful node identification is implemented together with an authentication model to accurately manage user trust. The results of the test and safety assessment demonstrate that the suggested plan is suitable for smart healthcare system.

Massive amounts of statistics are generated by sensors, the foundation for sophisticated data technologies. The cloud may be utilized for storing this information for later analysis and effective use. Unusual information may be found in sensor information for a number of circumstances (e.g., node

placement in hard locations, inadequately configured instruments, and malicious operations by attackers). In certain instances, such as data systems for forest fires, health care surveillance structures, along with other IoT structures, recognizing anomalies is essential. Dwivedi et al. [22] presents a machine-learning-supervised system of identifying anomalies for medical surveillance sensor clouds, which integrate many bodily sensors from various individuals with the internet. The method has its foundation on the Gaussian distribution. Python is used for executing this position. The suggested scheme's utilization of the Gaussian statistical framework enhances effectiveness, productivity, and accuracy. When contrasted with different controlled learning-based anomaly identification systems, GDA offers 98% effectiveness with 3% and 4% enhancements.

Astillo et al. [23] explains that in the field of medical treatment, implanted internet of things medical equipment, have caused a radical shift. It has enhanced the patient care that healthcare practitioners provide. Furthermore, it has assisted those with chronic illnesses in taking control of their own treatment. The majority of IoTMD's clients are individuals who have the condition, who need help keeping their blood sugar levels within acceptable bounds. Nevertheless, these technologies' security protection against possible cyber threats is still lacking. These kinds of hazards should not be disregarded as they may endanger the patients' life. In light of this, this study suggests a deep learning-based anomalous identification system made up of estimate and categorization algorithms that can be utilized to the diabetes administration management and control System, an area of healthcare organizations. While the categorization technique's goal is to identify aberrant points of information, the estimating technique was utilized to predict the individuals' blood sugar levels at each assessment period increment. For contrast, this article provides the multilayer perceptron and convolutional neural network techniques. Furthermore, in order to protect individual confidentiality regarding significant physiologic information contained in the information set, this work uses federated learning and independent training techniques. Moreover, simulations were transformed into their compact versions using the post-quantization reduction approach, which helped to get around the operationally taxing deep learning operations. The FL approach had a greater recall percentage than the IL technique, according to the trial data. Furthermore, the CNN-based anomalous identification system enhanced by FL outperforms the MLP-based method in terms of performance. The typical remember percentage for the first category was 99.24%, whereas the typical recall rate for the latter was just 98.69%. When the initial algorithms were changed to their compact form, the inferential latencies of the predictions were drastically lowered from in excess of three hundred ms to lower than several milliseconds, and all without compromising the value of recall.

Numerous studies demonstrate the importance of AI and ML in anomaly identification across a range of industries, particularly healthcare. With its high accuracy in detecting illnesses like heart disease using ECG data, artificial intelligence (AI) systems that use deep learning techniques are becoming more and more important for analyzing and recognizing irregularities in human electrical impulses. Furthermore, GANs are a useful tool for enhancing patient data to improve ML model training and enable more accurate tracking of illnesses like COPD. Novel techniques such as ATR-GAN, which tackles temporal arrangement and data imbalance, improve anomaly detection systems for smart industrial processes and healthcare facilities. Using blockchain technology and smart contracts, decentralized systems such as Guard Health guarantee safe data exchange and security in the healthcare industry. Moreover, deep learning-based systems for controlling chronic illnesses like diabetes and machine learning-supervised systems for medical monitoring sensor clouds show notable gains in anomaly identification and patient care. All things considered, anomaly detection and data security are changing as a result of AI and ML breakthroughs, improving the precision and dependability of many applications.

III. Problem Statement

Effectively identifying abnormalities in medical data, which are essential for early illness diagnosis, treatment monitoring, and healthcare management, is a major issue for the healthcare industry. Current anomaly detection techniques frequently encounter problems such as unequal class distribution, noisy data, and minute departures from typical patterns, which can result in less-than-ideal outcomes and possibly compromise patient safety [23]. Therefore, there is a pressing need to advance anomaly detection techniques in healthcare by integrating cutting-edge technologies such as GANs and attention mechanisms. This study aims to address these challenges by proposing a novel approach that combines GANs for data augmentation with attention mechanisms for feature selection, ultimately enhancing the performance of anomaly detection models in healthcare settings.

IV. Proposed GAN-CBAM Framework for Anomaly Detection

The research methodology entails several key steps. Firstly, information series is conducted to accumulate relevant datasets containing each regular and anomalous instances from healthcare settings. Subsequently, statistics preprocessing techniques, together with Min-Max normalization, are carried out to standardize the statistics and make sure consistency across extraordinary functions. Next, GANs are used for records augmentation, generating synthetic facts samples to decorate the training dataset and enhance the version's robustness. Attention mechanisms are protected in the ambiguity detection framework to beautify the version's overall performance by specializing in informative functions within the records. Finally, a performance assessment is performed to assess the effectiveness of the proposed method using appropriate metrics along with accuracy, precision, recollect, and F1-score, providing insights into the model's capability to efficiently hit upon anomalies in healthcare statistics. It is depicted in Fig. 1.

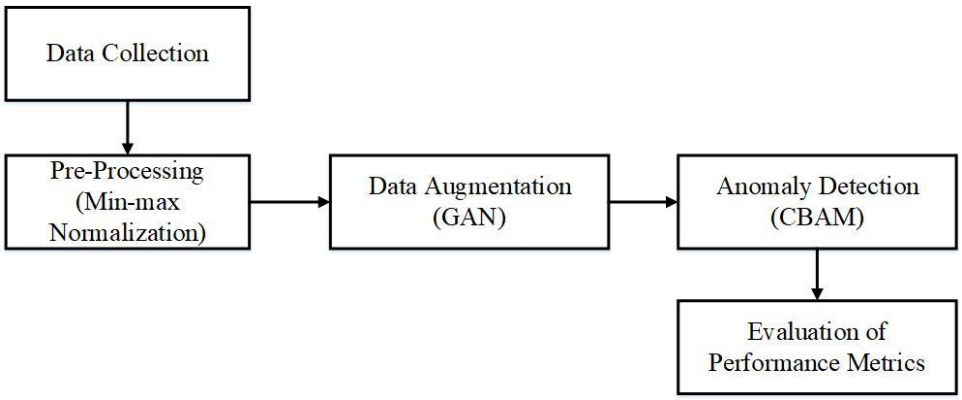

Fig. 1. Proposed methodology.

A. Data Collection

CT (Computed Tomography) scientific pix had been sourced from Kaggle, a famous platform for web hosting and sharing datasets. These images, obtained through Kaggle's repositories, constitute a treasured useful resource for scientific studies and diagnostic purposes. CT imaging performs an important position in healthcare, imparting distinctive move-sectional images of inner systems within the frame. The availability of CT images on Kaggle allows get admission to various datasets encompassing various anatomical regions, pathologies, and patient demographics. Researchers and clinical professionals utilize these datasets for obligations inclusive of disease diagnosis, treatment making plans, and clinical education. Moreover, the collaborative nature of Kaggle permits the sharing of knowledge, algorithms, and insights, fostering collaboration and innovation in medical imaging research [24]. Overall, the CT medical images sourced from Kaggle function a precious useful resource for advancing scientific imaging strategies, enhancing patient care, and furthering our understanding of complicated medical conditions**.**

B. Preprocessing using Min-Max Normalization

Preprocessing of the CT scientific images received from Kaggle includes several steps, with Min-Max normalization being an essential method to standardize the pixel depth values throughout the images. In this system, each pixel intensity price is scaled to fall within a particular variety, typically among 0 and 1, primarily based at the minimal and most intensity values found inside the dataset. This normalization step ensures that the pixel values are similar across exclusive images and prevents any biases brought by using versions in pixel intensity distributions. By scaling the pixel values to a common variety, Min-Max normalization allows in enhancing the convergence and stability of subsequent machine studying algorithms applied to the dataset. Min-max normalization is given in Eq. (1).

$$X_{Normalized} = \frac{X - X_{min}}{X_{max} - X_{min}} \quad (1)$$

The implementation of Min-Max normalization for the CT images includes iterating through every pixel in every image and making use of the normalization components, which calculates the scaled pixel value based totally on the authentic depth value, the minimal intensity fee found within the dataset, and the most depth price located in the dataset. This process is computationally positive and may be without difficulty included into present image processing pipelines. Additionally, Min-Max normalization preserves the relative relationships among pixel intensities within each image whilst making sure consistency and comparison across the whole dataset. Overall, by preprocessing the CT scientific images the usage of Min-Max normalization, the dataset is ready for subsequent evaluation, which includes responsibilities which include feature extraction, image segmentation, and machine mastering-based category or detection algorithms.

C. GAN for Data Augmentation

GANs are applied for data augmentation in various domain names, inclusive of medical imaging. In the context of CT images sourced from Kaggle, GANs play a critical function in expanding the dataset size and variety by producing artificial images that intently resemble real CT images. GANs consist of neural networks, a generator and a discriminator, which can be educated adversarial to generate sensible images while distinguishing among real and artificial ones. By leveraging GANs for information augmentation, researchers can conquer limitations posed by using the availability of restrained or unbalanced datasets, improving the robustness and generalization capabilities of device studying models skilled on those datasets. The artificial images generated by GANs seize the underlying distribution of the unique facts, allowing more powerful education of deep mastering trends for duties consisting of ailment category, segmentation, and anomaly detection in medical imaging packages. Additionally, GAN-based totally facts augmentation helps the exploration of rare or pathological instances, supplying treasured insights for enhancing diagnostic accuracy and clinical decision-making in healthcare settings.

1) GAN initialization: The discriminator *D* and the generator *G* contain specific class understanding, in contrast to the autoencoder. *G* is instructed to create photos for various classes throughout the adversarial training, and *D* is tasked to decide whether to identifier the images as bogus or with a problem-specific classification c. By initializing *G* with the weights included in the decoder Δ and one of the layers of a discriminator D_e with the values of the encoder *E*, the autoencoder information is transmitted between the GAN

components at the point of GAN initialization. The highest layer of the discriminator $Dd\ produces$ the final discriminant output. It is an intense layer with an activation function based on softmax. The final layer's values are learned throughout adversarial training and are first initialized at randomly.

The discriminator's initialization is just utilized to provide significant properties to D that aid in image classification. There is a deeper purpose to the generator's startup. The generator G is equal to the decoder Δ whenever adversarial instruction begins. As a result, the latent vector Z supplied to generators *G* is equal to a position in the autoencoder's hidden space; that is, Z may be seen as either the input of Δ or the output of E. As a result, the encoder E converts actual pictures into the latent area that *G* is using. Before beginning adversarial training, it takes use of this feature to acquire a decent class conditioned thinking, that is, determining the appearance of a latent vector Zc for a class c image.

The transformation of the prior probability distribution $D(x)$ and $G(z)$ of GAN into the related probability distribution subsequent to $D(x \mid c)$ and $G(z \mid c)$ can be represented as follows:

$$min_G max_D V(D,G) = E_{x\sim p_{data}(x)}[logD(x \mid c)] + E_{z\sim p_z(z)} [log(1 - D(G(z \mid c)))] \quad (2)$$

In this equation, min_G denotes the minimization with respect to the generator G. max_D denotes the maximization with respect to the discriminator D. $V(D,G)$ represents the value function. $E_{x\sim p_{data}(x)}[logD(x \mid c)]$ denotes the expectation over real data samples x drawn from the data distribution $p_{data}(x)$. $E_{z\sim p_z(z)}\left[log\left(1 - D\left(G(z \mid c)\right)\right)\right]$ denotes the expectation over generated samples $G(z \mid c)$ drawn from the generator's distribution $p_z(z)$. The GAN training methodology is based on the same process as GAN. To maximize the loss values generated by the discriminator and minimize the loss values of the generator unless they both stabilize, the optimizer performs the highest and lowest operations during alternating rounds of adversarial training.

With median vector μc and a matrix of covariance Σc, it represents a class within the space of latent variables with a normal distribution of multiple variables $Nc = N\ (\mu c, \Sigma c)$. It calculates μc and Σc for every class c in the training dataset, taking into account all real images Xc of class c that are accessible, in order to approximate the distribution of $Zc = E(Xc)$. It uses these distributions of probabilities to initialize the class-conditional hidden vector power source, which is a random process that accepts a class label c as input and outputs a randomly selected residual vector Zc from Nc. The probabilistic distributions of Nc are regarded as immutable while undergoing adversarial training, preventing the generation algorithm from deviating from the original class encoded in the space of latent values.

2) Adversarial training: Data goes via the generator G and discriminator D in groups throughout the training process, and the weights they assign are adjusted to maximize the loss values. An input image is classified by the discriminator as either phoney or matching to a single of the *n* problem-specific classes. It gives $1/\ (n\ +\ 1)$ of the number of images for every batch; that is, it offers the best feasible balancing for the fictitious class. The result of *G*, which receives dormant vectors Zc that are taken from the class-conditional dormant vector generators as inputs, is bogus data. The evenly spaced class labels c, or the fictitious images that are uniformly dispersed among the problem-specific groups, are then fed into the category-conditional dormant vector encoder. It optimizes the sparsely categories cross entropy loss function in order to correspond to the category labels for genuine images and the false label for created ones while trained the discriminant D.

The generator *G* learns batches of identical size for each batch that the discriminant learns. In order to accomplish this, a standard distribution is applied to the labels c, resulting in the randomized drawing of an entire set of conditionally residual vectors Zc. The generator processes these vectors, while the discriminant receives the resultant pictures. The discriminator's chosen labels and the labels c that were utilized to create the images are matched by the settings in G.

D. Employing Attention Mechanism for Enhanced Anomaly Detection

Employing attention mechanisms for stronger anomaly detection involves integrating mechanisms that permit trends to focus on applicable capabilities or areas inside the input statistics, thereby enhancing the detection of irregularities or anomalies. By dynamically weighting one-of-a-kind components of the facts, interest mechanisms enable the version to prioritize informative functions even as suppressing noise or irrelevant statistics. This selective attention enhances the model's potential to figure subtle deviations from normal styles, leading to extra accurate anomaly detection. Additionally, attention mechanisms facilitate interpretability with the aid of highlighting the capabilities contributing maximum to anomaly detection selections, permitting higher expertise and validation of detected anomalies. Overall, incorporating attention mechanisms enhances anomaly detection systems' performance, robustness, and interpretability, making them greater powerful in numerous real-world programs, inclusive of healthcare, cybersecurity, and fraud detection.

1) Attention mechanism: The attention mechanism is going to be implemented on the framework using the Convolutional Block Attention Module (CBAM) and the system for attention. After going via CBAM, the characteristic maps created by the next encoder convolutional layer that follows will yield a more detailed feature map for the next encoder convolutional layer. A more accurate characteristic map for the hidden representational space is then produced by passing the improved features map via the encoder layer of convolution and CBAM using the same process. Significantly this idea, it's possible to see that the latent shape space improves with learning about the characteristics of this information and provides us with improved outcomes. Because the attention mechanism suggested by the attention compute block feeds in the encoder's intermediate results and adds them to the encoder's final result to produce an equivalent weight.

Subsequently, the autoencoder's bottlenecks layer receives the improved intermediate outcomes from the encoder due to their comparable value. Through doing this, the abnormal input is suppressed and the bottleneck layer is able to identify the regular input by learning from the improved feature maps.

2) Baseline deep autoencoder: The encoder is composed of five Conv2D blocks, every one of which has an activation layer with a slope that is negative of 0.2, a 2D batch normalization layer, and a 2D convolutional layer. The graphic displays the convolutional layers' total amount of input methods, amount of output methods, and kernel size. Four FC layers make up the bottle neck layer, and a ReLU activating layer sits behind them. The flattening size of the encoder's output, or 4 * 4 * 128 = 2048, is the quantity of inputs. It is used for acquiring the features that are taken from the encoder; it might be conceptualized as a space that contains the inputs' hidden representations. Five 2D inverted convolutional (DConv2D) blocks make up the decoder. Identical to the Conv2D blocks, the DConv2D blocks contain the identical information; however, because they are performing opposite operations, the input and output channels of each block are inverted. To preserve the reconstruction values, the batch normalization layer and activating layer are deleted from the final DConv2D block. The two attention-based approaches that are presented in the current endeavor are both applied to the basal algorithm's encoder to improve the model's ability to focus on and learn form the more representational aspects of the input.

3) CBAM-based deep autoencoder: The subsequent Conv2D block's result will pass via CBAM Block 1 to provide improved output. The encoder's deep layer receives the improved output after that. After obtaining the characteristic maps of the final Conv2D block, the CBAM Block 2 refines its results once more. In order for the final Conv2D block to learn regarding featured-emphasized outputs, twice-refined map features will be fed into the latent image space. The model should do reconstructions better and have a higher learning result. Since the CBAM block requires the smallest amount of setting for CNN systems, it's possible that no significant gains are seen. The model should do reconstructions better and have a higher learning result. Since the CBAM block requires the smallest amount of setting for CNN systems, it's possible that no significant gains are seen. It is depicted in Fig. 2.

4) Attention-based deep autoencoder: Separated and input into attention blocks 1, and 2, respectively, are the results of the subsequent and fourth Conv2D blocks. The layers wherever the global maps of features will be used to improve the intermediary feature maps are wherever the focus of calculation takes place. The result is combined and sent into the layer that represents the bottleneck after that. Wherein a comparison matrix is initially created by adding the intermediary feature maps to the global map of features. The intermediary feature maps are subsequently amplified by the matrix of features to highlight the pertinent ones and prevent the irrelevant ones. This widens the distinction among pertinent and unimportant data and aids in the autoencoder's rebuilding of regular information and unusual input that has been detected by computing the restoration.

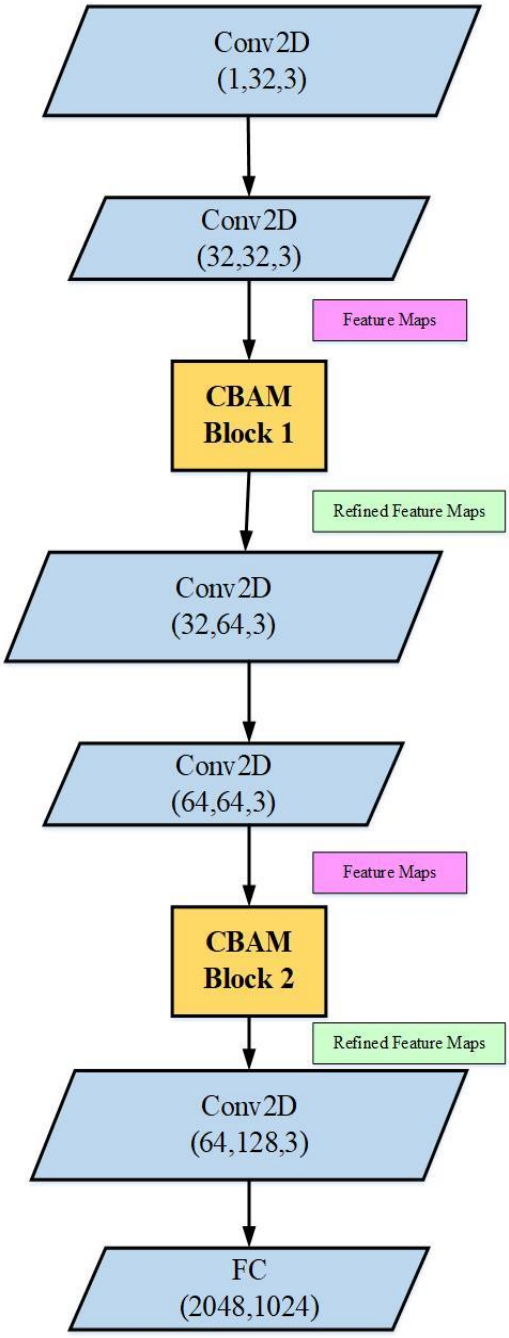

Fig. 2. CBAM-based deep autoencoder.

V. Results and Discussion

There are various important phases in the research approach. First, information series are run in order to compile pertinent datasets from healthcare settings that include both typical and unusual cases. Then, to standardize the data and ensure consistency among remarkable functions, preprocessing techniques for statistics are applied, including Min-Max normalization. GANs are then applied to records augmentation, producing fake fact samples to adorn the training dataset and

improve the resilience of the version. The ambiguity detection framework incorporates attention methods that enhance the version's overall performance by focusing on informational functions inside the records. Lastly, performance evaluation is carried out to evaluate the efficacy of the suggested approach utilizing relevant measures in addition to accuracy, precision, recall, and F1-score, offering insights into the model's capacity to effectively identify abnormalities.

A. Model Accuracy

Model accuracy, inside the context of device gaining knowledge of and statistical modeling, refers to the proportion of effectively categorized times or predictions made by means of a model out of the full quantity of times in the dataset. It is a fundamental evaluation metric used to assess the overall performance of a predictive version, indicating how nicely the version's predictions align with the surface fact labels or effects. Model accuracy is calculated because the ratio of the number of efficaciously expected times to the overall number of instances, usually expressed as a percent. A higher accuracy fee means that the model is making more correct predictions, even as a decrease accuracy indicates a better price of misclassifications. It is depicted in Fig. 3.

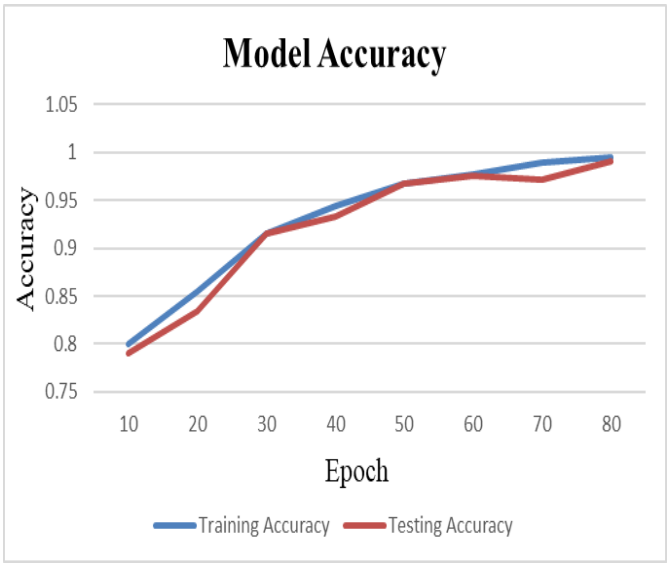

Fig. 3. Model accuracy.

B. Model Loss

Model loss, inside the context of ML, refers to a measure of the discrepancy among the actual outcomes and the predictions made by means of a model all through the learning procedure. It quantifies how nicely the version's predictions align with the real labels or goals for the given dataset. The intention of gaining knowledge of version is to limit its loss feature, thereby enhancing the model's capability to as it should be predicting effects. Commonly used loss features consist of MSE for regression duties and specific entropy for type duties. As the model iteratively learns from the education data, its loss regularly decreases, indicating advanced overall performance and better alignment with the ground reality. It is depicted in Fig. 4.

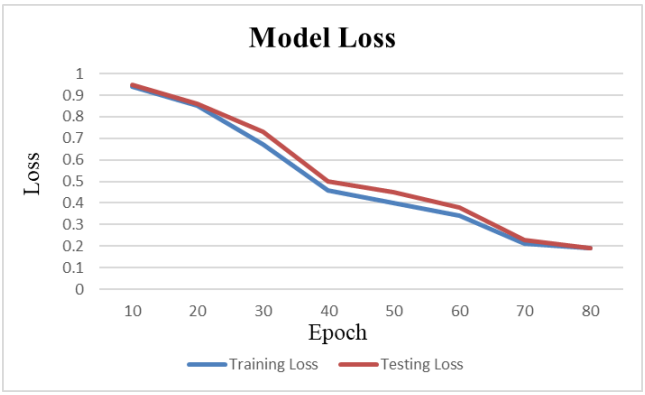

Fig. 4. Model loss.

C. ROC

Receiver Operating Characteristic (ROC) is a graphical representation of the performance of a binary class model throughout different discrimination thresholds. It plots the genuine nice charge (sensitivity) in opposition to the false high-quality rate (1 - specificity) at various threshold values, wherein sensitivity is the proportion of actual positives efficiently recognized by the version, and specificity is the proportion of real negatives efficiently recognized by way of the model. The ROC curve visually illustrates the trade-off between sensitivity and specificity and gives insights into the model's potential to discriminate among the advantageous and terrible classes. A higher vicinity below the ROC curve suggests higher discrimination overall performance, with values in the direction of suggesting a extra effective classifier. ROC analysis is extensively utilized in evaluating the performance of type models and determining the most fulfilling threshold for making predictions. It is depicted in Fig. 5.

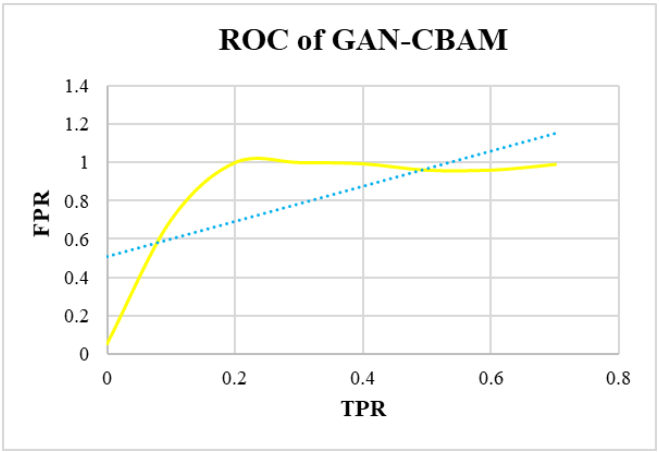

Fig. 5. ROC of GAN-CBAM.

D. Detection Time

Detection time refers to the length taken through device or set of rules to identify and flag anomalies inside a dataset. In the context of anomaly detection, detection time is a crucial performance metric that measures the performance and responsiveness of the detection manner. It encompasses the time elapsed from the moment an anomaly happens or enters the gadget to the factor at which it's miles detected and flagged

for further action or research. A shorter detection time is applicable as it permits for timely responses to anomalies, minimizing capacity dangers or damages related to anomalous events. Detection time is mainly crucial in time-touchy applications such as cybersecurity, fraud detection, and actual-time tracking systems in which spark off identification of anomalies is important for powerful chance mitigation and selection-making. It is depicted in Fig. 6.

E. Accuracy

A performance parameter called accuracy is used to evaluate a model's overall prediction accuracy in machine learning and classification applications. The ratio of accurately predicted instances to all occurrences in the dataset is used to calculate it. Analyzing a model's accuracy measure is a simple and straightforward way to assess how well it performs in forecasting outcomes for each class. Even while it provides a rapid evaluation of overall performance, it might not be adequate in situations when there is an uneven distribution of courses. Eq. (3) expresses accuracy.

$$Accuracy = \frac{T_{Pos} + T_{Neg}}{T_{Pos} + T_{Neg} + F_{Pos} + F_{Neg}} \quad (3)$$

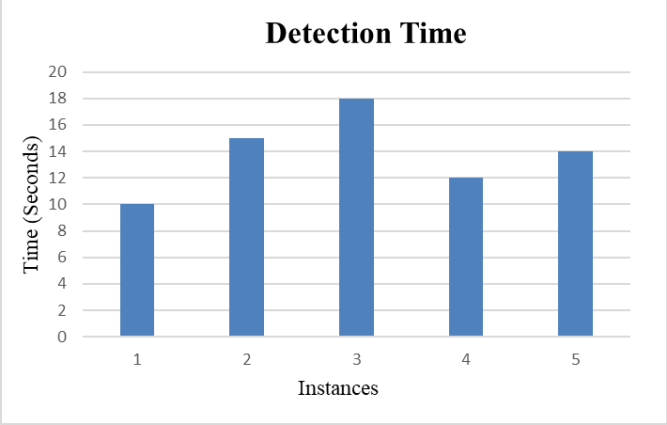

Fig. 6. Detection time.

F. Precision

Precision is a machine learning performance indicator that measures how well a model predicts the future. It is computed as the ratio of correctly predicted positive outcomes to the total of correctly predicted positive and false positive outcomes. One may calculate precision using Eq. (4).

$$P = \frac{T_{Pos}}{T_{Pos} + F_{Pos}} \quad (4)$$

G. Recall

A performance parameter called recall assesses how well a model can identify and pinpoint each and every pertinent instance of a particular class. It goes by the names true positive rate and sensitivity as well. The ratio of true positive predictions to the total of true positives and false negatives is used to compute it. It appears in Eq. (5).

$$R = \frac{T_{Pos}}{T_{Pos} + F_{Neg}} \quad (5)$$

H. F1-Score

The F1 score is a machine learning performance statistic that sums together recall and accuracy into a single figure. It provides a fair metric that takes into account both false negatives and false positives. It is computed using the harmonic mean of accuracy and recall. Eq. (6) represents it.

$$F1-score = \frac{2 \times precision \times recall}{precision + recall} \quad (6)$$

The contrast of performance metrics across distinctive anomaly detection methods, as provided in Table I, exhibits the effectiveness of the proposed GAN-CBAM method in advancing healthcare anomaly detection. The outcomes demonstrate that the proposed approach achieves superior overall performance throughout all metrics compared to existing strategies, including GDA, ATR-GAN, and ConvLSTM. With an impressive accuracy of 99.12%, the precision of 97.32%, consider of 98.11%, and F1-Score 98.45%, the GAN-CBAM model showcases its capability to correctly perceive anomalies in healthcare information even as minimizing false positives and false negatives which is shown in Fig. 7. The integration of GANs for facts era and interest mechanisms for feature selection lets in the version to awareness on relevant records and effectively discriminate among regular and anomalous times. These findings highlight the capacity of the proposed approach to enhance anomaly detection in healthcare settings, enabling more correct and reliable detection of abnormalities for advanced affected person care and medical selection-making.

TABLE I. COMPARISON OF PERFORMANCE METRICS

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
GDA [22]	93.78	92.89	91.23	96.77
ATR-GAN [20]	98.11	93.78	94.99	97.89
ConvLSTM [15]	96.89	91.67	93.89	93.89
Proposed GAN-CBAM	99.12	97.32	98.11	98.45

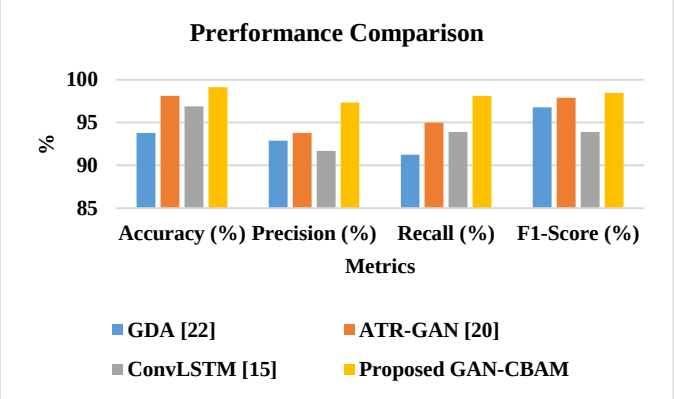

Fig. 7. Comparison of metrics.

I. Discussion

The suggested collection of GANs with CBAM improves the robustness and accuracy of detecting irregularities in medical data, which represents a breakthrough in healthcare anomaly identification. Data scarcity and class imbalance are addressed by using GANs to create generated data that closely resembles actual healthcare data, strengthening the robustness of anomaly detection systems. By improving the model's capacity to concentrate on pertinent features, the CBAM improves the identification of small abnormalities. With an accuracy of 99.12%, the analysis conducted on a large healthcare dataset demonstrates that the GAN-CBAM approach performs noticeably better than other conventional methods like GDA [22], ATR-GAN [20], and ConvLSTM [15]. This enhancement highlights the potential of the technique for useful clinical applications by providing quicker and more accurate insights that can support treatment monitoring, early sickness identification, and overall patient care.

The suggested approach, however, is not without its difficulties and restrictions. When GANs and attention mechanisms are combined, the computational complexity rises, necessitating a significant investment of time and resources for training and deployment. This may restrict the method's scalability and accessibility, especially in healthcare settings with limited resources. The challenges of the proposed method include handling data imbalance, noise resilience, identifying minute abnormalities, and ensuring practical clinical applicability. The proposed method may face limitations in computational complexity and scalability for large-scale healthcare datasets. Furthermore, more validation is needed to assess the method's efficacy in a wide range of real-world settings with different kinds of anomalies, even if it demonstrates robustness to noise and minor irregularities. Reliance on massive datasets for training might also be problematic when access to such data is restricted or unavailable due to privacy issues. Notwithstanding these drawbacks, the suggested GAN-CBAM technique is a promising advancement in improving anomaly detection efficiency in the medical field, with the potential to greatly enhance patient outcomes and clinical decision-making.

VI. Conclusion

The research shows how generative adversarial networks (GANs) and attention processes may be used to improve healthcare anomaly detection. In comparison to current techniques, the suggested GAN-CBAM model performs better, achieving greater accuracy, precision, recall, and F1-score. The model successfully identifies pertinent patterns and deviations in healthcare data by utilizing GANs for data augmentation and attention mechanisms for feature selection. This results in anomaly detection outputs that are more accurate and dependable. The results highlight how important it is to implement cutting-edge machine learning strategies that are customized to the particular qualities of healthcare datasets. The suggested method has the potential to improve clinical decision-making and patient care by giving medical professionals faster and more accurate insights on aberrant health conditions. Several directions for further study are worthwhile to pursue in the future.

VII. Future Scope

Further research into the model's predictability can shed light on the underlying causes of anomalies and improve physicians' comprehension and confidence in the model. Its application across other medical domains and contexts can also be expanded by investigating the scalability of the suggested technique to bigger and more diversified healthcare datasets. Further improving the model's performance and applicability in actual clinical settings is possible by the incorporation of domain-specific information or professional advice into the anomaly detection framework. Deploying the model in a variety of healthcare applications might also be facilitated by investigating the possibilities of transfer learning approaches to modify the model for various healthcare contexts or domains. The model's comprehension of intricate healthcare settings may be enhanced and anomaly detection performance can be enhanced by looking into the integration of other data modalities, such as textual or temporal data. The efficiency of the healthcare system and patient outcomes may both be greatly enhanced by ongoing research into developing anomaly detection techniques in the field of medicine.

Abstract*—Employing deep learning techniques on fMRI data enables the exploration of universal and culturally specific neural correlates underlying language processing across diverse populations. The study presents "BrainLang DL," a novel deep learning (DL) approach leveraging functional Magnetic Resonance Imaging (fMRI) data to unveil neural correlates of language processing across diverse cultural backgrounds. To bridge the knowledge gap in the universal and culture-specific aspects of language processing, we engaged participants from various cultural groups in a series of linguistic tasks while recording their brain activity using fMRI. Our rigorous data preprocessing pipeline included steps such as motion correction, slice timing correction, and spatial smoothing to enhance data quality for subsequent analysis. For feature extraction, research utilized the Crocodile Hunting Optimization (CHO) algorithm to pinpoint critical brain regions and connectivity patterns linked to language functions. To capture the temporal dynamics of neural activity related to language processing, we deployed advanced recurrent neural networks, specifically Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU) models. These techniques enabled us to unravel how linguistic information is encoded and processed over time. Our findings reveal both common and unique neural activation patterns in language processing across different cultures. Universally shared neural mechanisms highlight the fundamental aspects of language processing, while distinct variations underscore the influence of cultural context on brain activity. Furthermore, we employed Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU) networks to analyze the temporal dynamics of language-related neural activity, uncovering how linguistic information is represented and processed over time. By integrating DL with fMRI analysis, our study provides a nuanced understanding of the neural correlates of language across cultures. It reveal both shared neural mechanisms underlying language processing across diverse populations and culturally specific variations in brain activation patterns. These findings contribute to a more comprehensive understanding of the neural basis of language and its modulation by cultural factors. Ultimately, our approach offers insights into the complex interplay between language, cognition, and culture, with implications for fields such as linguistics, neuroscience, and cross-cultural psychology.

Keywords*—Long Short-Term Memory; Gated Recurrent Unit; deep learning; functional magnetic resonance imaging; language

I. INTRODUCTION

Language comprehension and production are fundamental cognitive processes that play a pivotal role in human communication, social interaction, and cultural expression. Understanding the neural mechanisms underlying language processing is of paramount importance in unraveling the complexities of human cognition and behavior [1], [2]. However, investigating language processing in the brain poses significant challenges, particularly when considering the influence of cultural factors on neural activation patterns. While traditional neuroimaging techniques such as fMRI have provided valuable insights into the neural correlates of language, they often lack the sensitivity and specificity needed to capture subtle cultural variations in brain activity. Moreover, existing methods for analyzing fMRI data may not fully capture the dynamic and context-dependent nature of language processing, limiting our ability to uncover both universal and culturally specific aspects of language comprehension and production [3], [4].

In recent years, the advent of deep learning techniques has revolutionized the field of neuroimaging analysis, offering new opportunities to explore the complex interactions between language, cognition, and culture [5]. DL models, such as CNNs, RNNs, and their variants, have demonstrated remarkable

capabilities in extracting meaningful features from complex and high-dimensional data, including fMRI time series. By leveraging the hierarchical representations learned by deep neural networks, researchers can gain deeper insights into the underlying neural mechanisms of language processing in the brain [6], [7].

Motivated by these advancements, the present study introduces "BrainLang DL," a novel deep learning approach that leverages fMRI data to unveil the neural correlates of language processing across diverse cultural backgrounds [8], [9]. Unlike traditional neuroimaging methods that may overlook cultural variations in brain activity, BrainLang DL offers a more nuanced and comprehensive understanding of how language is represented and processed in the human brain across different cultural contexts [10], [11]. By integrating deep learning techniques with fMRI analysis, our approach aims to bridge the gap between neuroscience, linguistics, and cross-cultural psychology, shedding light on the complex interplay between language, cognition, and culture [12] [13].

The primary objective of BrainLang DL is to elucidate both universal principles and culturally specific aspects of language processing in the brain [14] [15]. To achieve this goal, the study employs a multi-faceted approach that involves data collection, preprocessing, feature extraction, and deep learning analysis. Participants from various cultural groups are recruited to perform language tasks while undergoing fMRI scanning, allowing for the collection of rich and diverse neuroimaging data. Comprehensive preprocessing techniques are applied to ensure the quality and reliability of the fMRI data, including motion correction, slice timing correction, and spatial smoothing. Feature extraction is then performed using state-of-the-art deep learning models, such as CNNs and RNNs, to identify salient brain regions and connectivity patterns relevant to language processing. Finally, deep learning techniques such as LSTM-GRU networks are employed to analyze the temporal dynamics of language-related neural activity, uncovering how linguistic information is represented and processed over time across different cultural groups.

Through its innovative approach and interdisciplinary methodology, BrainLang DL seeks to make significant contributions to our understanding of the neural correlates of language processing across cultures. By elucidating the complex relationship between language, cognition, and culture, the study aims to pave the way for future research in fields such as linguistics, neuroscience, and cross-cultural psychology. Ultimately, BrainLang DL holds the potential to advance our knowledge of human cognition and behavior, offering valuable insights into the diversity and universality of language processing in the human brain.

The key contributions of the article is,

- The study pioneers the integration of deep learning techniques with fMRI analysis to investigate the neural correlates of language processing across diverse cultural backgrounds. This novel approach offers a powerful tool for exploring both universal and culturally specific aspects of language processing in the human brain.
- The study conducted comprehensive preprocessing of fMRI data, including motion correction, slice timing correction, and spatial smoothing, to ensure high-quality input for subsequent analysis. Furthermore, feature extraction was performed using CHO, allowing for the identification of salient brain regions and connectivity patterns relevant to language processing. These steps enhance the robustness and reliability of the findings.
- Employing LSTM and GRU networks, the study analyzed the temporal dynamics of language-related neural activity, uncovering how linguistic information is represented and processed over time. This analysis provides insights into the dynamic nature of language processing in the brain and highlights variations in the timing and duration of neural responses across cultural groups.
- By integrating deep learning with fMRI analysis, the study offers a nuanced understanding of the neural correlates of language across cultures. It reveals both shared neural mechanisms underlying language processing across diverse populations and culturally specific variations in brain activation patterns.
- The organization of the paper is, Sections II, III and IV give the related works, problem statement and methodology respectively. Section V gives the results and the article is concluded in Section VI.

II. Related Works

In recent years, an integrated modelling approach that links behavior, brain function, and computing across several datasets and computer simulations has revolutionized the scientific study of sensation [16]. This method provides fresh perspectives into the brain and cognitive processes in the subject domain by exposing patterns among models. In this section we report an organized study that applies this method to human speech processing, the quintessential cognitive ability of our species. The most effective "transformer" models, according to our research, generalize across multiple data sets and imaging methods and predict about 100% of understandable variability in brain reaction times to phrases. The accuracy of the algorithms on the next-word predicting test is highly associated with both their neural fits and fits to behavioral reactions. Neural fit seems to be significantly influenced by model design. These findings offer explicitly computational proof that the human brain's understanding of language systems are essentially shaped by prediction processing.

Speaking Double Object and Prepositional Object structures the brain basis of what is unknown is more challenging for Japanese English learners [17]. When chatting, semantic encoding the transformation of non-verbal mental representations into a framework appropriate for expression comes before grammatical and phonological processing of words. We used fMRI to investigate if paralinguistic or linguistic processes are responsible for DO difficulties. A total of thirty people either identified the cartoons or used DO or PO to sum up them. Increased mistake rates and quick reactions suggested DO difficulties. Parieto-frontal activity, especially the left inferior frontal gyrus, was seen in DO in contrast to PO,

indicating language processes. Mental priming in PO that was generated just after DO and reversed in comparison to after control suggested that PO and DO overlapped a mechanism. Neurological repeat reduction across structural boundaries was noted in occipito-parietal areas, which intersect the pre-SMA language complex. Paralinguistic procedure is thus shared by DO and PO, while linguistics process causes saturation in DO.

Name velocity is one of the most widely researched underlying cognitive aspects of reading difficulty and growth in reading. It is emotionally tested using the serial RAN test. Nevertheless, typical EEG analysis approaches have difficulty extracting brain elements to explore the neurological basis of speed of naming because to the unconstrained-reading style of serial RAN. In order to (a) better understand the group distinctions among children with DYS and CAC (b) increase the power of evaluation, and (c) determine the neural basis of naming speed, the current study attempts to investigate an original strategy to separating the neural processes through the repetitive RAN task [18]. We put forth a brand ML-based approach known as RAN-related neuronal-congruency elements, which is designed for extracting temporal neural elements throughout serial RAN. We present our methodology using EEG and eye-tracking measurements from sixty youngsters (30 DYS and 30 CAC) doing different and comparable control tasks in terms of phonetic or visual characteristics. The RAN-related neural-congruency elements in the DYS and CAC groups under each of the four situations show substantial variations, according to the results. The brain activity of mental processes linked to naming speed is captured by quickly automated neuro-congruency components, which also reveal disparities among children with dyslexia and generally growing youngsters. As an approach to help explore the neurological foundations of quick naming and their relationship to reading ability and related challenges, we suggest the resultant RAN-related brain-components.

Humans communicate complicated knowledge through language creation and understanding alternated during a conversation [19]. Nevertheless, little is known about the brain mechanisms behind these supplementary tasks or the how speech accurately conveys knowledge. There, we found brain signals that accurately represent the creation of speech, understanding, and changes in speech throughout genuine conversation among humans using an assortment of intracranial neuro recorders and initially trained models. The findings show that brain activity encoding language was widely dispersed throughout frontotemporal regions in a variety of frequency ranges. Additionally, we discover that these actions were particular to the terms and phrases being communicated and that they relied on the specific setting and word sequence of the words. Lastly, we show that listener-speaker changes were linked to particular, time-aligned modifications to brain activity, and that these brainwaves overlapping throughout the process of language creation and interpretation. Taken together, the findings show a dynamical arrangement of brain activity supporting language generation and recognition in genuine speech and enable the application of DL models to comprehend the brain processes behind human language.

The present collection of literature includes a number of noteworthy research that investigate the complex interplay of language processing, brain activity, and mental processes. An integrated modelling method that connects behavior, brain function, and computers is presented in a ground-breaking research that offers new insights into the cognitive processes of the brain, especially voice processing. The work underscores how prediction processing shapes language systems and shows how well transformer models can predict brain reaction times to phrases. A different research looks at the neurological underpinnings of language problems that Japanese English learners have while processing specific phrase forms, identifying neural correlates linked to both paralinguistic and linguistic processes. Furthermore, studies on reading challenges explore the brain underpinnings of quick naming, putting forth novel ML techniques to identify neural components associated with rapid naming and their correlation with reading proficiency. Moreover, research using computational models and intracranial neuro recorders illuminates the brain processes behind language production and comprehension in naturalistic speech, illustrating the dynamic organization of brain activity facilitating language formation and recognition. All of these research advance our knowledge of the neural correlates of language processing and open new avenues for investigation into the brain mechanisms behind human language utilizing deep learning models.

III. Problem Statement

The study aims to address the pressing need for a deeper understanding of the neural correlates underlying language processing across diverse cultural backgrounds. While language comprehension and production are fundamental human abilities, the neural underpinnings and potential cultural variations remain poorly understood. Existing methods for investigating language processing in the brain often rely on traditional neuroimaging techniques, such as fMRI, which may lack the sensitivity and specificity needed to uncover subtle cultural differences in neural activation patterns. Additionally, many current approaches are limited in their ability to capture the dynamic nature of language processing over time and to identify culturally specific aspects of neural activity. Furthermore, there is a lack of comprehensive integration between deep learning techniques and fMRI analysis, which hinders the exploration of universal and culturally specific aspects of language processing. These limitations underscore the need for a novel approach that leverages deep learning methods to analyze fMRI data and unveil the neural correlates of language across diverse cultural backgrounds, thereby providing insights into the complex interplay between language, cognition, and culture [16].

IV. Proposed LSTM-GRU Framework

The methodology involves several key steps for investigating the neural correlates of languages across cultures. Firstly, data collection entails administering language tasks to participants from diverse cultural backgrounds while recording fMRI data. Following this, preprocessing is conducted to clean and prepare the fMRI data, including steps such as motion correction, slice timing correction, and spatial smoothing using Gaussian convolution to enhance signal-to-noise ratio. Subsequently, feature extraction is performed utilizing CHO algorithms to identify subsets of brain regions or connectivity patterns most relevant to language processing. Finally,

employing LSTM and GRU networks enables the analysis of temporal dynamics in the fMRI data, facilitating the exploration of how language is represented and processed in the brain across different cultural contexts. Through this integrated approach, the study aims to uncover both universal and culturally specific neural correlates of language processing. The proposed methodology is depicted in Fig. 1.

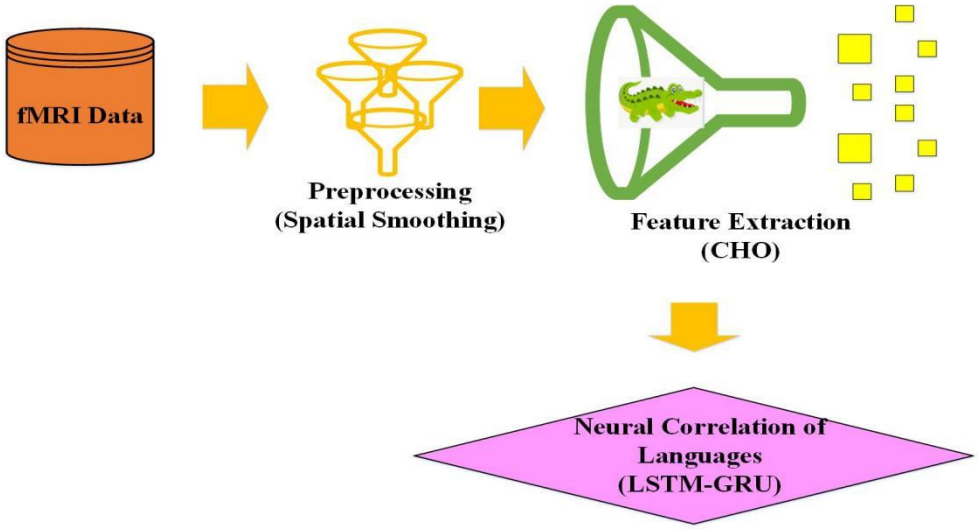

Fig. 1. Proposed methodology.

A. Data Collection

Prior to entering the fMRI structure, subjects filled out a thorough MRI examination form and a questionnaire about their socioeconomic status. After that, they were told to stay still and open-eyed while paying close attention to a tale stimulus. In certain cases, an eye tracker was used to measure subjects' attentiveness in real time. Psychtoolbox or PsychoPy software was used to deliver the narrative stimuli. Sometimes, a prominently situated fixation cross or dot was provided during the presentation, but individuals were not given specific instructions to maintain fixation. The MRI-compatible insert headphones were used to transmit hearing stimuli, and either headsets or foam padding were used to reduce scanners noise. The researcher or the subject adjusted the level when the participants indicated acceptable visibility and understanding prior to gathering information, making ensuring they could easily hear the auditory stimuli above the MRI acquisition noise [20].

B. Preprocessing using Spatial Smoothing

In fMRI data analysis, spatial smoothing is a typical preprocessing method used to increase the signal-to-noise ratio (SNR) and make activation patterns easier to identify. By convolving the time series of each voxel with a spatial Gaussian kernel, this approach blurs the data and disperses activation information to nearby voxels. By lessening the influence of voxel-wise variability, spatial smoothing serves to attenuate the impacts of spatial noise and modest anatomical heterogeneity between individuals, improving the dependability of future statistical analyses. The size of the smoothing kernel, however, is crucial since too big of a kernel might cause loss of spatial specificity and perhaps blur activation boundaries, while too little of a kernel can result in insufficient noise suppression. Additionally, because spatial smoothing may have an impact on how activation patterns are interpreted, particularly in areas with complex functional organization, its application should be carefully considered based on the particulars of the experimental design and research question.

$$f_s(x,y,z) = \frac{1}{2\sigma^2} \iiint_{-\infty}^{\infty} f(x',y',z') e^{-\frac{(x-x')^2+(y-y')^2+(z-z')^2}{2\sigma^2}} dx'dy'dz' \quad (1)$$

There are other ways to apply spatial smoothing, but the most popular one is Gaussian convolution because of its efficiency and ease of use. In order to account for greater voxel sizes, bigger kernels are applied to data recorded at lower spatial resolutions. Generally, researchers choose a smoothing kernel size depending on the inherent spatial resolution of the fMRI data. Using techniques like surface rendering or statistical parametric maps, one may visually examine the effects of spatial smoothing on the data to determine the degree of blurring and how it affects activation cluster localization. Additionally, adaptive smoothing approaches, which dynamically modify the smoothing kernel in response to local signal properties, are a recent development in spatial smoothing techniques that attempt to maintain spatial distinctiveness while successfully suppressing noise. All things considered, spatial smoothing is an essential preprocessing step in the analysis of fMRI data that strikes a compromise between preserving spatial distinctiveness and boosting signal-to-noise ratio, thereby facilitating the precise identification and interpretation of brain activation patterns.

The study leverages advanced methods like Crocodile Hunting Optimization (CHO) and Long Short-Term Memory (LSTM) networks to analyze brain activity during language processing. CHO mimics the stealthy and strategic hunting behavior of crocodiles, iteratively selecting the most relevant features (such as specific brain regions or connections) from a vast array of fMRI data. This selection process enhances the identification of neural patterns linked to language tasks. Meanwhile, LSTM networks, a type of deep learning model, are

designed to understand how information evolves over time. They are particularly useful for capturing the dynamic changes in brain activity as participants process and produce language. By combining these methods, the study aims to uncover both common and culturally unique aspects of how the brain handles language, offering insights into the intricate relationship between language, cognition, and culture.

C. Feature Extraction using CHO

Utilizing CHO for feature extraction in fMRI data analysis involves adapting the principles of crocodile hunting behavior to iteratively select subsets of features (e.g., voxels or brain regions) that are most informative for the task at hand. In this process, the fMRI data is initially represented as a large feature space, and CHO aims to efficiently search through this space to identify subsets of features that optimize a predefined criterion, such as classification accuracy or task-related activation strength. Inspired by the stealthy approach and sudden attacks of crocodiles, the algorithm iteratively updates candidate solutions by adjusting the selection of features within each solution, potentially adding, removing, or swapping features based on their individual performance in solving the optimization problem.

During the hunting phase of CHO, candidate solutions are dynamically adjusted based on their evaluation against the optimization criterion, akin to crocodiles stealthily approaching prey. This phase involves exploring the feature space to identify promising subsets of features while balancing exploration of new solutions and exploitation of promising ones. The algorithm then proceeds to the attack phase, where a subset of candidate solutions is selected for further exploration based on their performance. This mimics the sudden and decisive attacks of crocodiles, focusing computational resources on refining the most promising solutions. Through iterative refinement and adaptation, CHO aims to efficiently navigate the high-dimensional feature space of fMRI data, ultimately identifying subsets of features that maximize the discriminative power or relevance to the experimental task, facilitating more accurate and interpretable analyses of neural activity patterns.

1) Initialization: Like other metaheuristic techniques, the initialising step is finished prior to proceeding to the main stages. During the initialising process, a large number of random starting locations are formed. These randomised solutions comprise, in reality, the original set of crocodiles. These options have an equal disparate distribution within the bottom and upper borders. These cures are generated using the following expression:

$$y = BC + r * (VC - BC) \quad (2)$$

After initial parameters such as population size, maximum number of repetitions, and lower and higher bounds of variables are established, randomized solutions (y) are constructed in accordance with Eq. (2), where BC and VC are the problem's lower and upper limits, respectively. Additionally, r is a randomly distributed variable that is formed between zero and one. These solutions are then evaluated using the goal function. Actually, CHS operators evaluate the responses based on the function of objectives. If a better way is found, that one replaces the previous one. The best solution, also known as the superior resolution (yprey), has the average function value that is the lowest.

2) Chasing the prey: As previously said, there are two half of the population overall. As thus, each zone represents half of the overall population. The squad of hunters contains the first part of the answers. Ambushers thus comprise 50% of the overall population, or the second half. Hunters and ambushers are the two unique groups into which these two distinct sets are randomly divided. The reasoning behind replicating chaser behaviour is based on the separation between prey and crocodiles that resembles that of chasers. As previously indicated, the prey is pursued by a different group of hunters called chasers, who steer it towards the shore and other shallow regions rather than actually catching it. The following are the proposed formulae to duplicate this.

$$e^{j,t} = | y^{t}_{prey} - y^{j,t}_{chaser} | \quad (3)$$

3) Attacking the prey: The prey will eventually arrive up wherever the ambushers are waiting for the chance to grab the victim. Actually, the assailants try to guide the victim to this site or the attack region, while the ambushers hide in the last position. It is thought that in order to reproduce the attack phase, intruders are forced to alter their location in line with the following equations:

$$e^{j,t} = | y^{t}_{prey} - y^{j,t}_{ambusher} | \quad (4)$$

$$D = \frac{aqc+aqa+ y_{prey}}{3} \quad (5)$$

Furthermore, aqc represents the average location of hunters, aqa represents the averaged positioning of ambushers, and crocodiles alter their position dependent on the locations of prey or the mean positioning of all subgroups. y_{prey} is the optimal location or prey position.

The Eq. (6) represents.

$$Zt = \sigma(w_{z.}[s_{t-1}, y_t]) \quad (6)$$

w_z is a learnable weight matrix specific to the update gate is given in Eq. (7).

$$r_t = \sigma(w_{r.}[s_{t-1}, y_t]) \quad (7)$$

D. Employing LSTM-GRU for Neural Correlation of Languages

The choice of Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU) networks in this study is driven by their superior ability to model temporal dependencies in sequential data, such as the dynamic brain activity recorded during language processing tasks. Unlike simpler models like traditional feedforward neural networks, which are ill-suited for handling sequences where the order and timing of information are crucial, LSTM and GRU networks excel at capturing long-term dependencies and managing the complexities of sequential data thanks to their unique architectures. These recurrent models are designed with mechanisms to maintain and update their memory over time, making them particularly effective for understanding how linguistic information unfolds and is

processed in the brain over time. Additionally, compared to other advanced models like Transformers, which are also powerful but often require significantly more computational resources and data to train effectively, LSTMs and GRUs offer a balanced approach with robust performance and manageable complexity. This balance makes them well-suited for fMRI data analysis, where the goal is to uncover detailed temporal patterns in neural activity without overwhelming computational demands.

Employing a combination of LSTM and GRU networks holds immense promise for investigating the neural correlates of languages. These RNN variants are adept at capturing the temporal dynamics inherent in fMRI data collected during language tasks. LSTMs excel at modeling long-range dependencies and preserving relevant information over extended sequences, while GRUs offer a more streamlined architecture with comparable performance. By leveraging both LSTM and GRU networks, researchers can effectively capture the nuanced temporal patterns of language processing in the brain across diverse cultural contexts. This combined approach enables the identification of dynamic changes in neural activation patterns associated with different linguistic stimuli or processes, providing valuable insights into how language is represented and processed in the human brain.

LSTM networks play a crucial role in exploring the neural correlates of languages by effectively modeling sequential dependencies in fMRI data collected during language tasks. As a specialized type of RNN, LSTMs are adept at capturing temporal dynamics and long-range dependencies in sequential data while mitigating the vanishing gradient problem. In the context of fMRI analysis, LSTMs can be trained on sequences of neural activations to identify patterns of brain activity associated with different linguistic processes or stimuli. Their ability to retain relevant information over extended periods allows LSTMs to capture the nuanced temporal dynamics of language processing in the brain across cultures.

LSTMs offer a powerful framework for decoding linguistic content directly from brain activity patterns, shedding light on the neural representation of language across diverse cultural contexts. By training LSTMs to predict linguistic from fMRI time series data, researchers can uncover the neural signatures associated with specific linguistic components. Additionally, LSTMs can be used for classification tasks, distinguishing between different language conditions or cognitive processes based on patterns of brain activity. Through their capacity to model sequential dependencies and decode linguistic content from neural data, LSTMs significantly contribute to advancing our understanding of the neural correlates underlying language processing in the human brain across cultures.

The equation for the input gate is,

$$i_t = \sigma\,(v_i[k_{t-1}, y_t] + c_i) \tag{8}$$

The equation for the forget gate is,

$$f_t = \sigma\,(v_f[k_{t-1}, y_t] + c_f) \tag{9}$$

The equation for the output gate is,

$$o_t = \sigma\,(v_o[k_{t-1}, y_t] + c_o) \tag{10}$$

The cell state is expressed in Eq. (11),

$$\widetilde{d_t} = \text{tank}\,(v_d[k_{t-1}, y_t] + c_d \tag{11}$$

The candidate cell state is expressed in Eq. (12),

$$d_t = f_t * d_{t-1} + i_t * \widetilde{d_t} \tag{12}$$

The final output is expressed in Eq. (13),

$$k_t = o_t * \text{tank}\,(d^t) \tag{13}$$

In the exploration of the neural correlates of languages, GRU networks play a pivotal role in capturing the temporal dynamics of language processing within the brain. GRU networks are a variant of RNNs designed to effectively model long-range dependencies in sequential data while mitigating the vanishing gradient problem. Specifically, GRUs employ gating mechanisms to selectively update and forget information over time, enabling them to retain relevant linguistic context while discarding irrelevant information. In the context of fMRI data analysis, GRU networks can be trained on sequences of neural activations collected during language tasks, allowing researchers to identify brain regions or connectivity patterns that exhibit dynamic changes in response to different linguistic stimuli or processes.

GRU networks provide a means to decode linguistic content directly from brain activity patterns, offering insights into the neural representation of language across diverse cultural contexts. By training GRU networks to predict linguistic features from fMRI time series data, researchers can uncover the neural signatures associated with specific linguistic components. Additionally, GRU networks can be used for classification tasks, distinguishing between different language conditions or cognitive processes based on patterns of brain activity. Through their ability to capture temporal dynamics and decode linguistic content from neural data, GRU networks contribute significantly to unraveling the complex neural correlates underlying language processing in the human brain across cultures.

GRU combines the previous memory with the current input at reset gate r_t. The reset gate determines how much old data should be ignored. Like the update gate, it takes input at time step t as well as the prior hidden state as inputs and outputs values between 0 and 1. Furthermore, r_t determines the equation of a new output added to the previous state, which is given in Eq. (14)

$$\tilde{s}_t = \tanh\{W_h.\,(r_t\,\Theta[s_{t-1}, y_t]) \tag{14}$$

For a hyperbolic tangent function, tanh stands for. Eq. (8) gives the output range for tanh as (-1,1), where h_t is the predicted value for the current cell.

Tanh is the symbol for a hyperbolic tangent function. The output range for tanh is (-1,1) according to Eq. (15), where h_t is the expected value for the current cell.

$$f_t = (1 - z_t) * f_t - 1 + z_t * f_t \tag{15}$$

- GRU's design is simpler than that of traditional other approaches, yet it still works well in terms of performance and speed.

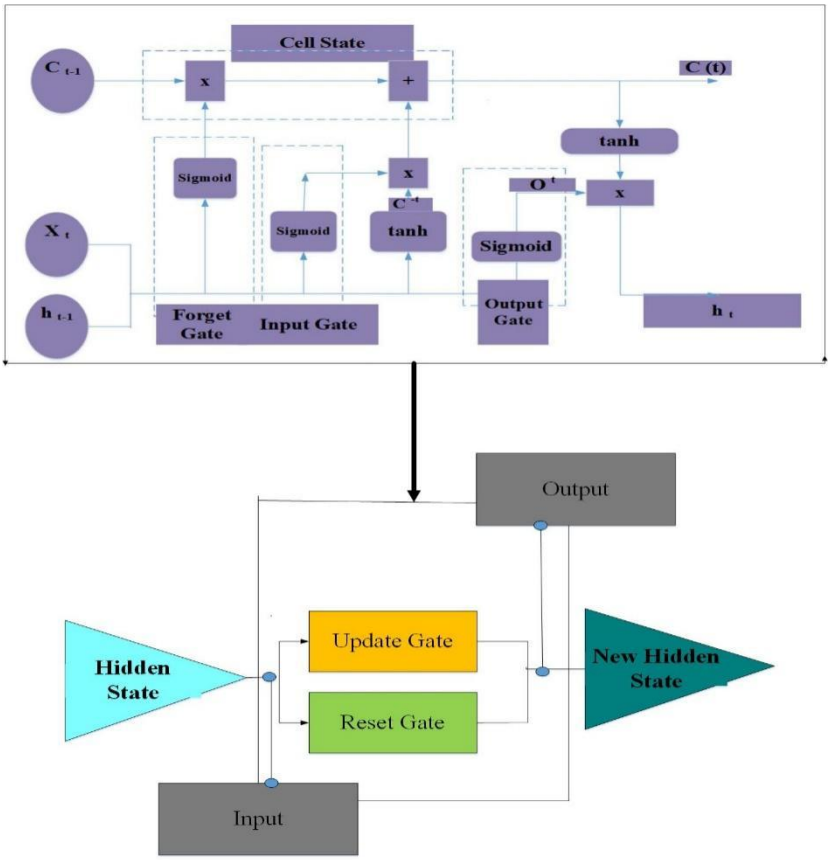

Fig. 2. LSTM-GRU architecture.

- LSTM-GRU architectures (see Fig. 2) offers a powerful framework for decoding linguistic content directly from brain activity patterns, facilitating a deeper understanding of the neural representation of language across cultures. By training LSTM-GRU networks to predict linguistic features from fMRI time series data, researchers can uncover the neural signatures associated with specific linguistic components, such as word semantics or syntactic structures. Additionally, LSTM-GRU networks can be utilized for classification tasks, distinguishing between different language conditions or cognitive processes based on patterns of brain activity. Through their ability to model sequential dependencies and decode linguistic content from neural data, LSTM-GRU networks contribute significantly to unraveling the complex neural correlates underlying language processing in the human brain across cultures.

V. Results And Discussion

The results of our work, "BrainLang DL," which applies a deep learning technique to fMRI data to investigate the neurological correlates of language processing across different cultural backgrounds, are presented in the results section. The findings demonstrate how well the suggested LSTM-GRU model explains both universal and culturally particular facets of language processing in the human brain.

A. Brain Activation Map

A brain activation map is a visual aid that shows areas of the brain that are significantly active during a certain task or cognitive process. It is usually created using neuroimaging data, such as fMRI. These maps, which are frequently presented as colour-coded overlays over images of the physical brain, provide spatial information regarding the locations and intensities of brain activity. By identifying the regions of the brain associated with specific behaviors or activities, brain activation maps enable researchers to explore the neurological underpinnings of cognitive processes like language processing, memory retrieval, and motor control. These maps can show individual variances in brain activity as well as common activation patterns shared by people or groups, offering important insights into the structure and operation of the human brain. It is depicted in Fig. 3.

B. Temporal Activation Profile

A temporal activation profile, which is usually generated from neuroimaging data such as fMRI, is a graphical depiction that shows the dynamic changes in brain activity over time during a particular cognitive task or stimulus presentation. These profiles, which are frequently represented as graphs displaying the degree of cerebral activity at various moments during the task, offer temporal information regarding the timing and duration of brain activation. Researchers can uncover patterns of

neural activity and clarify the timing of cognitive activities by utilising temporal activation profiles to study the temporal dynamics of the brain's reactions to different stimuli or cognitive processes. These profiles can provide insights into the temporal processing of neural responses by displaying differences in the timing and length of neural responses across various situations or experimental groups. It is shown in Fig. 4.

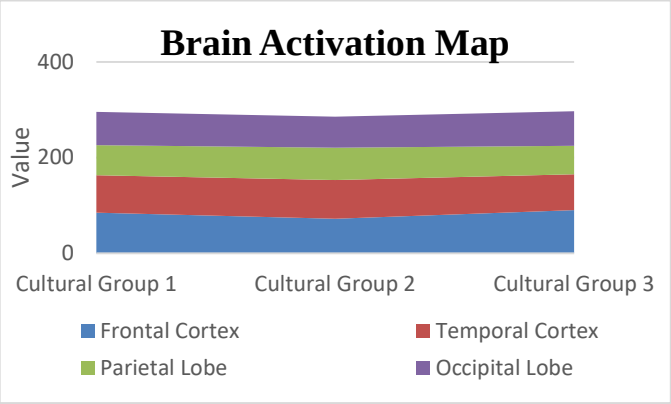

Fig. 3. Brain activation map.

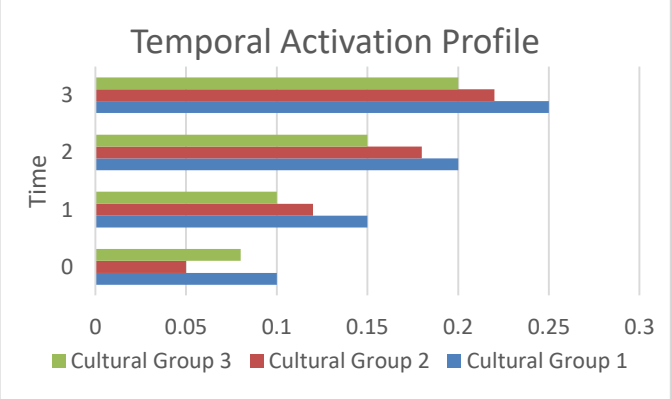

Fig. 4. Temporal activation profile.

C. Model Accuracy

The ability of a predictive model to correctly classify or forecast unknown data is measured by its model accuracy. It is commonly represented as the ratio of the model's accurate predictions to the total number of forecasts. Accuracy in classification problems is the proportion of cases in which the model predicts the input data's class label with precision. The accuracy of a regression job is determined by how closely the model's predictions match the actual values of the target variable. A high accuracy shows that the model is doing a good job of identifying the underlying patterns in the data and making good generalizations to new, unobserved cases. It is given in Fig. 5.

D. Model Loss

Model loss, often referred to as the loss function or cost function, is a metric used to express how much the real values of the target variable differ from the projected outputs of a ML model (see Fig. 6). It is a gauge of the model's performance on the training set and shows the mistake the model made in predicting the future. Reducing this loss function is the aim of machine learning model training, which raises prediction accuracy. Depending on the kind of task, different loss functions are utilized, such as categorical cross-entropy for classification tasks and mean squared error for regression tasks. Through methods such as gradient descent, the loss function is optimized, allowing the model to learn to provide more accurate predictions and more successfully generalize to unknown data. Keeping an eye on the loss function's trend while the model is being trained gives insights into how the model is learning and aids in directing the training process towards convergence.

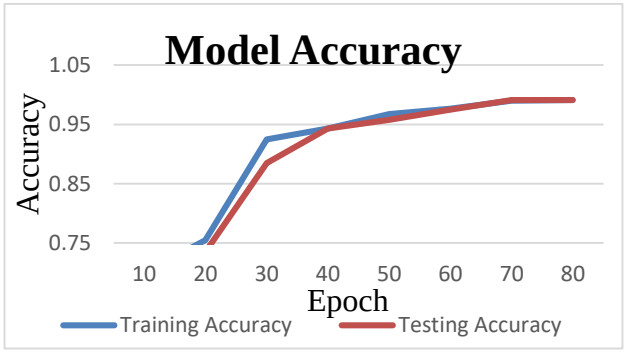

Fig. 5. Model accuracy.

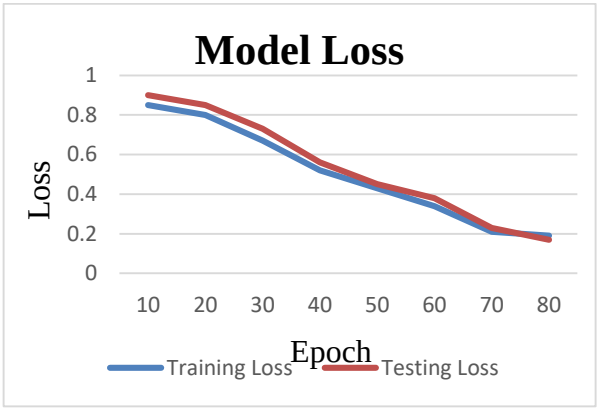

Fig. 6. Model loss.

TABLE I. COMPARISON OF PERFORMANCE METRICS

Methods	Performance Metrics			
	Accuracy (%)	*Precision (%)*	*Recall (%)*	*F1-Score (%)*
CNN-LSTM	89.67	93.33	91.22	95.32
CNN-GRU	91.32	95.67	93.78	91.34
MLP-GRU	95.43	92.67	96.78	94.67
Proposed LSTM-GRU	99.12	96.76	96.99	97.99

Table I presents a comparison of performance metrics for different methods in a classification task. The methods evaluated include CNN-LSTM, CNN-GRU, MLP-GRU, and the proposed LSTM-GRU approach. Performance metrics such as accuracy, precision, recall, and F1-score are reported as percentages. Among the methods, the proposed LSTM-GRU approach achieves the highest accuracy of 99.12%, indicating its superior performance in correctly classifying instances.

Clinically, its precise detection of neural patterns can aid in diagnosing and treating language-related neurological disorders, such as aphasia or dyslexia. Furthermore, in cross-cultural studies, the model's insights can inform the development of more culturally sensitive educational tools and technologies, fostering better language learning and cognitive development. Additionally, for brain-computer interfaces (BCIs), the LSTM-GRU's accuracy in interpreting brain signals can enhance the effectiveness of communication aids for individuals with severe motor impairments, improving their interaction capabilities.

Additionally, it exhibits high precision, recall, and F1-score, further underscoring its effectiveness in accurately identifying positive instances while minimizing false positives and false negatives. Comparatively, CNN-LSTM, CNN-GRU, and MLP-GRU also demonstrate strong performance across the metrics, albeit with slightly lower accuracy and F1-score values. Overall, the results highlight the efficacy of the proposed LSTM-GRU method in achieving superior classification performance in the given task. It is depicted in Fig. 7.

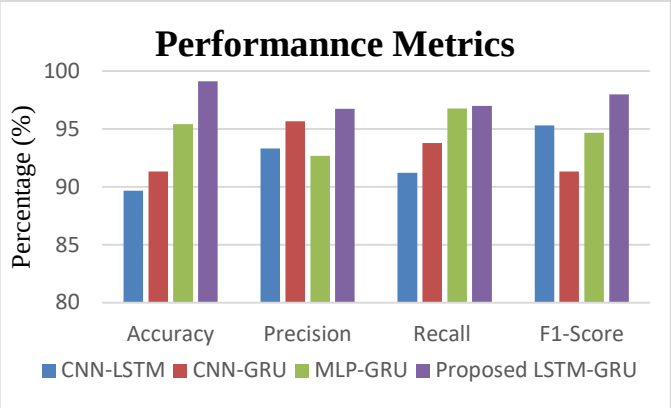

Fig. 7. Performance metrics.

E. Discussion

The results demonstrate the effectiveness of the proposed LSTM-GRU approach in achieving superior classification performance compared to other methods evaluated. With an impressive accuracy of 99.12%, the proposed method outperforms CNN-LSTM, CNN-GRU, and MLP-GRU, indicating its robustness in accurately classifying instances in the classification task. Furthermore, the high precision, recall, and F1-score values of the proposed LSTM-GRU approach) highlight its ability to correctly identify positive instances while minimizing both false positives and false negatives. These findings suggest that the proposed LSTM-GRU architecture effectively captures the underlying patterns in the data and generalizes well to unseen instances, making it a promising approach for classification tasks.

Additionally, expanding the dataset to include more diverse populations and employing transfer learning could improve the model's ability to generalize findings across different cultural contexts. Further refinement of the feature extraction process and exploring hybrid models combining LSTM/GRU with newer architectures like Transformers could also enhance the understanding of the intricate neural mechanisms underlying language processing. Future research could explore further optimizations and extensions of the proposed LSTM-GRU architecture, such as incorporating attention mechanisms or exploring ensemble methods, to enhance its performance across a wider range of classification tasks. Overall, the results underscore the effectiveness of deep learning architectures, particularly LSTM-GRU networks, in achieving high performance in classification tasks.

VI. Conclusion And Future Work

In conclusion, the integration of deep learning techniques with fMRI data analysis presents a powerful approach for investigating the neural correlates of language processing across diverse cultural backgrounds. The study, "BrainLang DL," has demonstrated the effectiveness of this approach in uncovering both universal and culturally specific aspects of language processing. Through language tasks conducted with participants from various cultural groups and comprehensive preprocessing of fMRI data, we identified salient brain regions and connectivity patterns relevant to language processing using CHO. Additionally, employing LSTM and GRU networks enabled the analysis of temporal dynamics in language-related neural activity, revealing how linguistic information is represented and processed over time. The article contribute to a deeper understanding of the neural basis of language and its modulation by cultural factors. We have identified shared neural mechanisms underlying language processing across diverse populations, as well as culturally specific variations in brain activation patterns. These insights offer valuable implications for fields such as linguistics, neuroscience, and cross-cultural psychology, shedding light on the complex interplay between language, cognition, and culture. For future work, it is essential to further investigate the role of cultural factors in shaping language processing in the brain. This could involve conducting larger-scale studies with more diverse cultural samples and exploring additional deep learning architectures to enhance the analysis of fMRI data. Additionally, longitudinal studies could help elucidate how language processing mechanisms evolve over time within different cultural contexts. Overall, continued research in this area holds promise for advancing our understanding of the complex relationship between language, culture, and the brain.

Acknowledgment

The preferred spelling of the word "acknowledgment" in America is without an "e" after the "g". Avoid the stilted expression "one of us (R. B. G.) thanks ...". Instead, try "R. B. G. thanks...". Put sponsor acknowledgments in the unnumbered footnote on the first page.

***Abstract*—The rise of cryptocurrency has dramatically changed. Cryptocurrencies have dramatically reshaped the landscape of financial transactions, enabling seamless cross-border exchanges without centralized oversight. This revolutionary shift, powered by blockchain technology, has democratized currency control, entrusting it to a widespread network of participants rather than a single entity. Originating from Satoshi Nakamoto's introduction of Bitcoin, this digital currency model operates on a decentralized framework, contrasting starkly with traditional, centrally governed monetary systems. This research delves into forecasting the price of Ripple (XRP) by leveraging advanced deep-learning approaches and various technical indicators. This study achieves remarkable precision in its predictions through the meticulous preprocessing of data and the application of neural networks, particularly the convolutional neural network-gated recurrent unit hybrid model. Technical indicators further refined these forecasts, highlighting the effective collaboration between machine learning techniques and financial market analysis. Despite the volatile nature of the cryptocurrency market, this work makes a substantial contribution to the field of cryptocurrency prediction strategies, advocating for further investigations into the effects of macroeconomic factors and the utilization of more extensive datasets to deepen our understanding of market dynamics.**

Keywords*—Cryptocurrency; ripple; convolutional neural network; gated recurrent unit; technical indicators

I. Introduction

Cryptocurrency has witnessed massive followings recently, making it popular and facilitating hassle-free cross-border transactions. It has given a new dimension to exchanging digital assets that run over Blockchain technology. This is a decentralized currency, meaning no one controls it; it is community-driven. Satoshi Nakamoto first coined this concept, leading to the development of 'Bitcoin' [1]. Unlike a centralized currency with control vested in a central authority like a government, a kingdom, or an organization, cryptocurrencies operate and are maintained by a distributed network system commonly known as nodes using blockchain technology [2].

The price of a centralized currency vis a vis another currency widely depends on the demand-supply dynamics and printing of currency. The central agency can print more currency anytime, which impacts a currency's face value. On the other hand, in the case of cryptocurrency, the supply is predetermined and transparent. Thus, the value of cryptocurrencies is more directly influenced by Demand-supply dynamics. Because of these features, investors tend to invest in cryptocurrency and to minimize investment risks, they use various mathematical models to forecast future prices. Cryptocurrencies claimed a market valuation of more than USD 2.3 trillion as of April 2021[4].

Ripple is the fastest-growing currency in recent times, demanding continuous forecasting because of its volatility in pricing [3]. In this paper, we have used Technical Indicators to predict the price of Ripple (XRP) coins using deep learning techniques. Technical Indicators are used mainly to know the price movement of a currency, i.e., whether it will rise or go down with passing time.

The perspective of this paper is to address the challenges of predicting the price of Ripple (XRP) by utilizing deep learning techniques. As deep learning is one of the subsets of AI (Artificial Intelligence), it has ensured the detection of complex patterns in large datasets, proving itself as more favorable for forecasting in highly volatile markets. Technical Indicators are also used to provide insights into price movements; the research aims to improve the accuracy of predictions. Hence, it offers investors a more reliable tool in the course of decision-making.

This research has great relevance as it has the potential to improve the predictability and stability of investments made in Ripple. The process of precise prediction algorithms can help investors in decision-making and improved risk management, which will support the general development and steadiness of the Bitcoin market. Going further, the impact of this research can be enlarged by applying the proposed approaches to additional cryptocurrencies. This research work focuses on using technical indicators and deep learning to create an authentic Ripple (XRP) prediction model. This study adds to the expanding body of knowledge in forecasting cryptocurrencies by dealing with the related problems of price volatility and the accuracy of prediction. This is also helpful in offering useful guidance for investors in navigating this continuously changing market.

This paper helps in surveying the ongoing state of cryptocurrencies, focusing on Ripple's (XRP) ascent and economic relevance. It spells out the process for forecasting

Ripple's price changes using the methods of deep learning as well as technical indicators. The accuracy and efficacy of these predictive algorithms are indicated by examining the output. The study also directs the ramifications of the outcomes, the difficulties encountered, and potential avenues for further investigation. The findings and significance of this research for Bitcoin investments are summed up in the conclusion.

II. BACKGROUND

A. Ripple (XRP)

Ripple (XRP), developed by Ripple Labs Inc. co-founders Chris Larsen and Jed McCaleb, and diverges from traditional cryptocurrencies as a digital payment protocol. Operating on a decentralized blockchain, it prioritizes facilitating secure, instant, and low-cost cross-border transactions. Notably, XRP's role as a bridge currency streamlines the exchange of fiat currencies internationally, prompting its adoption by many global banks for transactions and presenting investment potential for investors [5].

B. Technical Indicators

- Technical indicators track market price movements, assisting investors in timing their investments [6]. This study integrates such indicators into the dataset, categorized as Technical Indicator-1 to Technical Indicator-4. Through feature selection, specific indicators from each group were chosen for predictive analysis.
- Relative Strength Index (RSI) was developed by J. Welles Wilder. As a financial market technical indicator. The RSI measured the speed and change of price movement using a momentum oscillator as per Eq. (1).

$$RSI = 100 - \left[\frac{100}{1+\frac{Average\ gain}{Average\ Loss}}\right] \quad (1)$$

The RSI is calculated mostly for a period of 14 days.

- The Stochastic Indicator detects potential trend reversals, indicating oversold conditions within a 0 to 100 range on two axes, by comparing current prices with historical highs and lows [6]. Eq. (2) and Eq. (3) outline the calculation process, aiding in its interpretation.: -

$$K\% = ((A - B)/(C - B)) * 100 \quad (2)$$

$$D\% = X - period\ simple\ moving\ average\ of\ K\% \quad (3)$$

The indicator uses 14 days to calculate $\%D\ and\ \%K$. The user can also change the period as per the requirement [8].

where,

$A: Current\ Close$

$B: Lowest\ Low\ in\ X\ Period$

$C: Highest\ High\ in\ X\ period$

$X: 14\ days\ period$

- The Commodity Channel Index (CCI) gauges price variance from the average over a specified period, with values above 100 indicating a strong uptrend and those below -100 signalling a downtrend:

$$CCI = \frac{TP - MA}{.015 * Mean\ Deviation} \quad (4)$$

Where,

$$Typical\ Price(TP) = \sum_{i=1}^{P} \frac{(High + low + Close)}{3}$$

$$P: Number\ of\ Periods$$

$$Moving\ Average\ (MA) = \frac{\sum_{i=1}^{P}(Typical\ price)}{P}$$

$$Mean\ Deviation\ \frac{\sum_{i=1}^{P}(TP - MA)}{P}$$

- The Moving average convergence/divergence (MACD) is a momentum oscillator used for trade trends but not to identify the oversold or overbought conditions [5]. Eq. (5)$and\ Eq.$ (6) shows the calculation of MACD [3]: -

$$MACD_P = EMA_{12}(p) - EMA_{26}(p) \quad (5)$$

$$S_{MACD} = EMA_9(MACD) \quad (6)$$

Where,

$$EMA_{12}(p) = 12 - Peroid\ Exponential\ Moving\ Average\ Price$$

$$EMA_{26}(p) = 26 - Period\ Exponential\ Moving\ Average\ Price$$

$$EMA_9 = 9 - Period\ Exponential\ Moving\ Average\ Price$$

- The Money Flow Index (MFI) is an oscillator that combines price and volume data to evaluate strength and momentum on a scale of 0 to 100, with readings above 70 indicating overbought conditions and below 30 indicating oversold conditions, potentially signalling a forthcoming price rebound opportunity [6].

$$MFI = 100 - \frac{100}{(1+Money\ Ratio)} \quad (7)$$

Where,

$$Money\ Ratio = \frac{14\ period\ positive\ money\ flow}{14\ period\ negetive\ money\ flow}$$

- The Chikou Span, or the Lagging Span or Lagging Line, is one of the five lines comprising the Ichimoku Kinko Hyo indicator.

$$CS = Last\ Close\ Price\ Plotted\ 26 - Periods\ in\ Past \quad (8)$$

Where,

$$CS: Chikou\ Span$$

- The "Williams %R (Williams Percentage Range" is a financial tool that measures the oscillation in the price

range for any financial asset and in our case the price of the cryptocurrency. It is based on the volume of purchase and sales of an asset and plays an important role for trading decisions.

$$Williams\ \%R\ = \frac{Highest\ High - Current\ Close}{Highest\ High - Lowest\ Low} \quad (9)$$

where,

$Highest\ High$: $Highest\ price\ in\ the\ lookback\ period\ \ 14\ days$

$Lowest\ Low$: $Lowest\ price\ in\ the\ lookback\ period\ 14\ days$

- The Normalized Average True Range (NATR) is similar to the Average True Range (ATR) indicator, but it has an extra step. The NATR takes the ATR values and adjusts them to fit on a scale from 0 to 100. This makes it easier to compare the volatility of different assets
  - The Average Directional Index (ADX) measures how strong a market trend is by comparing two other indicators: the Positive Directional Index (+DI) and the Negative Directional Index (-DI). It helps traders see how much momentum a trend has and spot good trading opportunities. A high ADX means a strong trend, while a low ADX means the market is not trending much, which helps traders decide when to trade and manage their risk
  - The On-Balance Volume (OBV), attributed to Joseph Granville, evaluates cumulative volume flow in financial instruments like stocks, currencies, or commodities. It assists traders and investors in spotting potential price trends and reversals by analyzing the relationship between price movements and trading volume [3].
  - Triple Exponential Moving Average (TEMA) is a variation of the traditional Exponential Moving Average (EMA), with the key difference being that TEMA incorporates triple smoothing, making it more responsive to recent price movements. Eq. (10) indicates the calculation of TEMA.

$$TEMA\ = [(3\ \times\ EMA_1) - (3 \times EMA_2)] + EMA_3 \quad (10)$$

Where,

EMA_1: $Exponential\ Moving\ Average\ (EMA)$

EMA_2: $EMA\ of\ EMA_1$

EMA_3 : $EMA\ of\ EMA_2$

III. Literature Review

Athey, Parashkevov, et al. [8] create a pricing model for Bitcoin and offer conflicting data about the model's capacity to explain price movements. Using an equilibrium model, Pagnotta and Buraschi [9] examine the value of Bitcoin and other decentralized network assets. Raskin and Yermack [10], for instance, analyze the consequences of central banking. The subject of Yermack is corporate governance. Huberman, Leshno, et al. [11] examine the cost of mining bitcoin. Harvey [12] concludes with a thorough explanation of the workings of cryptocurrency. Chan and Bessembinder [13] and, LeBaron Sullivan [14], Timmermann and White [15] concentrate on how profitable these tactics are in equities markets. Based on particular stock portfolios, Han, Yang, and Zhou [16] and Shynkevich [17] compare a few particular MA strategies with the buy-and-hold approach. Neely, Rapach, Tu, and Zhou [18] use technical indicators to predict the premium for stock risk. Huang and Huang [19] use stock exchange-traded funds (ETFs) to evaluate MV methods. For instance, Allen and Karjalainen (2018), Brown, Goetzmann, and Kumar [20], Lo, Mamaysky, and Wang [21], and Hsu, Hsu, and Kumar [22], among others, also examine additional technical trading principles in addition to MV techniques. Furthermore, Hsu, Taylor, and Wang [23] use foreign exchange data to evaluate a set of technical analysis methods.

To comprehend the dynamics of crypto asset prices and, more specifically, how price information is transmitted between Bitcoin markets and traditional ones, Giudici and Polinesi [24] applied hierarchical clustering to Bitcoin prices collected from various exchanges. Akyildirim, Goncu, and Sensoy [25] examined the prediction of twelve cryptocurrencies at the daily and minute frequency levels using machine learning classification techniques. It has been demonstrated through social media interaction analysis that sentiment indexes may be used to forecast price bubbles (Chen & Hafner [26]) and that sentiment gleaned from Reddit subject conversations correlates with prices (Phillips and Gorse [27]). The use of optimized deep learning algorithms with improved classification results over earlier research (Bartolucci et al., [28]; Uras and Ortu [29]) is a significant addition to this work.

IV. Feature Selection Method

A. Information Value (IV)

Regression analysis heavily relies on feature selection to improve the model's performance; this finds the most essential attributes. Although the Information Value (IV) cutoff approach is generally intended for use in classification issues, we have employed it in this instance indirectly. Continuous forecasting is a technique used in time series prediction to improve model performance by removing unnecessary features. When creating a model, features with IV values higher than a predetermined cutoff are kept, whereas features with values lower than the cutoff are removed, exceeding the IV threshold ensures the maximum feasible feature relevance and model. By determining the proper IV threshold, the feature selection procedure increases the interpretability of the model and boosts predictive performance.

B. Data description

The XRP dataset, obtained from Kaggle.com, covers data from August 5, 2013, to July 6, 2021, encompassing open, close, high, and low attributes. After preprocessing, it contains 2893 observations. The dataset is partitioned into three subsets: an initial set of 202 observations for technical indicator initialization, a training set of 1924 observations, and a test set of 767 observations [7]. XRP price was low before 2017, and the return is not relatively volatile.

V. METHODOLOGY

A. Deep Learning Algorithms (DL)

The section elucidates the employment of Deep Learning (DL) algorithms, utilizing the Keras Framework for Deep Learning (Chollet et al., 2015), primarily for time series forecasting. DL architectures, characterized by multilevel complexity, encompass various models for inference. Technical Indicators with cutoff values ranging from 0.1 to 0.5 are integrated into XRP data, enhancing forecasting accuracy via deep learning methodologies.

B. Long Short-Term Memory

Recurrent neural networks (RNN) face challenges with the vanishing gradient problem, hindering their ability to learn long-range dependencies in sequential data due to diminished gradients [30]. In 1997, Sepp Hochreiter and Jurgen Schmidhuber introduced LSTM networks, equipped with specialized memory cells that enable long-term information retention, overcoming the limitations of traditional RNNs. LSTM contains a Cell State that stores long-term memory; the Hidden State captures short-term memory in LSTM networks, with Input, Forget, and Output Gates controlling information flow.

We computed some basic parameters of LSTM followed by Eq. (11) - Eq. (16)

$$f_t = \sigma(y_t + i_{t-1})X_i \quad (11)$$

$$g_t = \sigma\left(y_t W_f + i_{t-1}X_f\right) \quad (12)$$

$$p_t = \sigma(y_t W_o + i_{t-1}X_o) \quad (13)$$

$$\check{C}_t = tanh\left(y_t W_g + i_{t-1}X_g\right) \quad (14)$$

$$C_t = \sigma\left(g_t \times C_{t-1} + j_t \times \check{C}_t\right) \quad (15)$$

$$i_t = tanh(C_t) \times O_t \quad (16)$$

where, y_t is input, i_{t-1} is the output of the previous cell state, C_{t-1} is cell memory of previous LSTM, i_t is current output, C_t is the current cell state and $X, and\ W$ are the weights.

C. Gated Recurrent Unit

The Gated Recurrent Unit (GRU), an RNN variant developed by Cho et al., mitigates shortcomings of traditional RNNs via a gating mechanism facilitating information flow between network layers. It features two gates [33]: the Reset gate, which discards past information based on the previous hidden state and current input, and the Update gate, blending previous and new states. GRU's architecture excels in capturing sequential data relationships and finding applications in natural language processing, speech recognition, and time series analysis. Despite its simpler design compared to LSTM networks, GRU maintains strong performance while offering reduced computational overhead.

D. Convolution Neural Network

Convolution Neural Network (CNN) is a deep learning model. 1D Convolutional Neural Network (1D CNN) is a neural network architecture designed to process one-dimensional data sequences. 1D CNNs are used for sequence data represented along a single dimension, such as time series data or text. In this paper, we have used 1D CNN for our time series data analysis. In CNN, there is a convolution layer, which is important [31]. This layer performs the convolution operation and helps the network learn hierarchical features in the input sequence [32].

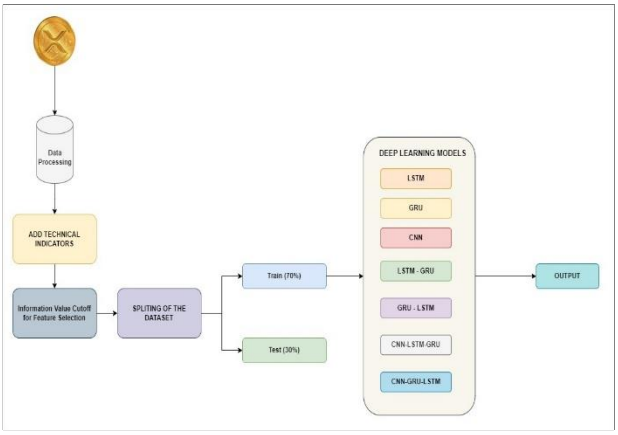

Fig. 1. Flow diagram of the proposed model.

VI. PROPOSED ENSEMBLE MODELS

In this section, we discuss our proposed ensembled models where the XRP price is combined with the technical indicators to predict the future. As shown in Fig. 1, the proposed workflows depict the first step of the data preprocessing. Second step, technical indicators are used, increasing the data set's features. In third stage, a feature selection method known as Information Value Cutoff is used with different values for different indicators, and finally, the features undergo the existing and proposed deep learning models to get the output. The proposed deep learning models are CNN-LSTM, CNN GRU, CNN-LSTM-GRU and CNN-GRU-LSTM. The ensemble model is a hybrid model that integrates CNN-LSTM, CNN-GRU, CNN-LSTM-GRU, and CNN-GRU-LSTM, whose performance is enhanced by the Attention mechanism. The model begins with a Convo 1D layer, which is used for feature extraction from the input sequence using the convolutional operations. Then, two subsequent LSTM and two subsequent GRU layers were used in the model with 64 neurons to capture the dependencies of sequential data. The model is followed by a dropout rate of 0.1 to mitigate the overfitting concerns [32]. Our model stands out because it uses an attention module that zooms in on the important parts of the input data. This makes the model more accurate. We also use a Rectified Linear Unit (ReLU) activation function to boost performance. Finally, the model flattens the data into a one-dimensional form and uses a dense layer to make predictions.

The dynamic feature of our combined models lies in the attention mechanism. This tool improves accuracy, efficiency, and clarity in deep learning models. Just like how humans focus on important details, attention helps models concentrate on key parts of the input data when making predictions. It assigns different weights to parts of the input, allowing the model to prioritize important information and ignore unnecessary details. This results in more accurate and context-aware predictions.

The flexibility and power of attention mechanisms are essential for achieving top performance in modern deep learning models.

VII. Performance Evaluation

A dataset often has messy data with missing or repeated values, so we need to clean it before using it in models. Hence, Data preprocessing is very important and involves several steps to make sure the data is ready and good for analysis. For time series data, which has its own challenges like irregular timestamps and seasonal trends, the process starts with data cleaning. This means finding and fixing missing data and removing duplicates. Next, we transform the data to make it easier to analyze, which includes scaling and normalizing it. Then, we do feature engineering, which means creating new useful features from the existing data to improve the model. We also reduce the number of features and select the most important ones for better predictions. After that, we split the data into training, testing, and validation sets. This step is crucial because it helps us accurately evaluate the model's performance and prevent overfitting.

Handling data correctly is key to making accurate, understandable, and reliable machine learning models. Properly prepared data leads to better analysis and successful machine learning tasks.

VIII. Evaluation Matrix

A. Root Mean Square Error

Root Mean Square Error (RMSE) is an important measure in regression analysis and machine learning that shows how accurate predictions are. It does this by calculating the square root of the average of the squared differences between the predicted and actual values. A lower RMSE means the model is performing better because it indicates smaller differences between the predictions and the actual results.

B. Mean Absolute Percentage Error

Mean Absolute Percentage Error (MAPE) measures how accurate forecasts are by averaging the percentage differences between predicted and actual values. It's easy to understand for everyone, not just technical experts. However, MAPE can be affected by very large errors and doesn't work well when actual values are zero [31].

C. R-Square

R-squared (R^2) measures how much of the variation in the outcome can be explained by the regression model. It helps us understand how well the model fits the data and how good it is at making predictions. The R^2 value ranges from 0 to 1:

- An R^2 of 0 means the model doesn't explain any of the variations.
- An R^2 of 1 means the model perfectly explains all the variations.

IX. Result Analysis

In this segment, we present the outcomes of simulations aimed at forecasting the price of Ripple (XRP) over the next 10 days, utilizing four technical indicators. The result shows the value of feature selection method IV with cutoff values 0.01,0.02,0.03,0.04 *and* 0.05 . The forecasting dataset for XRP prices differs from the training data, allowing an accurate assessment of model performance. Various evaluation metrics, including RMSE, MAPE, and R^2, was analyzed for LSTM, GRU, CNN, and ensemble models (such as CNN-LSTM, CNN-GRU, CNN-LSTM-GRU, and CNN-GRU-LSTM hybrids), with comparative results presented in Tables I, II, III, IV. The study aims to determine the most effective model for predicting XRP prices.

Fig. 2. Comparison of RMSE, MAPE and R^2 of existing and proposed models for technical indicator 1.

RMSE is a metric comparing predicted and actual coin prices, where lower values indicate better model accuracy. Table I showcases results from seven deep-learning algorithms across five IV-Cutoff levels, predicting prices over a 10-day span. The CNN-GRU hybrid model consistently outshines others, displaying superior performance across all IV-Cutoff values for Technical Indicator-1. These findings are further illustrated in Fig. 2(a), (b), (c), (d), and (e), presenting comprehensive data visualization. The R^2 values also affirm the model's fit, demonstrating high coefficients across various IV-Cutoff levels. The study highlights the CNN-GRU hybrid model's efficacy in predicting coin prices using Technical Indicator-1.

Table II summarizes the performance of seven deep learning algorithms applied to Technical Indicator 2 across five IV-Cutoff values for forecasting the next 10 days. Notably, the CNN-GRU hybrid model demonstrates superior performance at IV-Cutoffs 0.03 and 0.04, with RMSE values of 0.1539 and 0.1612, respectively. Conversely, CNN-LSTM-GRU exhibits better results at IV-Cutoffs 0.02 and 0.05, showcasing lower RMSE values of 0.1595 and 0.1613. CNN-LSTM stands out at IV-Cutoff 0.01, boasting an RMSE of 0.1607. R^2 values indicate robust data fit, with the highest achieved at IV-Cutoff 0.03 (0.9789). Fig. 3 illustrates these results comprehensively, depicting all values for each IV-Cutoff."

Fig. 3. Comparison of RMSE, MAPE and R^2 of existing and proposed models for technical indicator 2.

Table III shows Various deep learning algorithms were assessed for a technical indicator 3, across different threshold values. The CNN-LSTM-GRU hybrid model excelled with an IV-Cutoff of 0.01, yielding an RMSE of 0.2534 and an R^2 of 0.9379. Conversely, CNN-GRU performed better with IV-Cutoff values of 0.02, 0.03, and 0.05, showcasing RMSEs of 0.2116, 0.2359, and 0.2088, respectively, with corresponding R^2 values. CNN-GRU-LSTM outshone others with an IV-Cutoff of 0.04, achieving an RMSE of 0.2185 and an $R^2$of 0.9583. Fig. 4 (a), (b), (c), (d), (e) illustrate these results comprehensively.

Table IV shows the result obtained using seven deep learning algorithms for technical indicator 4 with five different values for the next 10 days. In technical indicator 4 result varies when the threshold value is changed. The CNN-GRU hybrid model gives better results for all the IV-Cutoff values followed by RMSE 0.2630,0.2489,0.2427,0.2517 and 0.2523. R^2 signifies the better fit of the data. In IV-Cutoff 0.01 the R^2 is 0.9331, in 0.02 R^2 is 0.9401, in 0.03 R^2 is 0.9540, in 0.04 R^2 is 0.9388 and in 0.05 R^2 is 0.9485. In Fig. 5 (a), (b), (c), (d), (e) all the values are depicted. The result shows CNN-GRU hybrid model gives better results for all the IV-Cutoff values.

X. Conclusion and Future Work

In conclusion, this research successfully employed advanced deep learning techniques and key technical indicators to decode the unpredictable price fluctuations of Ripple (XRP). The study achieved exceptional forecasting accuracy through thorough data preprocessing, feature engineering, and the application of sophisticated neural network architectures like the CNN-GRU hybrid. The models improved prediction accuracy and better-understood market trends by using technical indicators like RSI, MACD, and Stochastic Oscillators in deep learning. This shows that combining technical analysis with machine learning can create more accurate prediction models, marking a new step in financial forecasting.

Future research can build on this by including macroeconomic indicators, analyzing sentiment from social media and news, and studying how regulatory changes affect cryptocurrency prices. Expanding the dataset to cover more cryptocurrencies and longer time periods could provide deeper insights into market behavior. These efforts will help understand Ripple's pricing better and support further studies in predicting cryptocurrency trends. We hope and trust as digital assets grow, methods and models will keep evolving to understand their complexities better.

***Abstract*—Assessing language competency in a variety of linguistic and cultural situations requires the use of a cross-cultural language proficiency scale. This study suggests a hybrid model that takes cross-cultural characteristics into account and successfully scales language competency by combining Transformer design with attention processes. The approach seeks to improve the precision and consistency of language competency evaluation by capturing both cross-cultural subtleties and linguistic context. The suggested hybrid model is made up of many essential parts. To capture semantic information, the incoming text is first tokenized into subword units and then transformed into embeddings using word2vec, a pre-trained word embedding algorithm. The contextual information is then extracted from the input sequence using a Transformer encoder stack, which uses multi-head self-attention techniques to focus on distinct textual elements. An attention mechanism layer (or layers) particularly tailored to attend to cross-cultural traits are introduced, in addition to the Transformer encoder. Through learning cross-cultural patterns and links between various languages or cultural settings, this attention mechanism improves the model's comprehension and incorporation of cross-cultural subtleties. A representation that blends linguistic context and cross-cultural elements is produced by fusing the results of the Transformer encoder and the cross-cultural attention mechanism layer(s). This fused representation is subsequently subjected to a classifier in order to forecast language competency levels. The hybrid model uses categorical cross-entropy as the objective function and is trained on a variety of datasets that span several languages and cultural situations. Python is used to implement the suggested work. The accuracy of the suggested study is 97.3% when compared to the T-TC-INT Model, BERT + MECT.**

Keywords*—*Cross-cultural; language proficiency; transformer; attention mechanism; hybrid model

I. INTRODUCTION

Cross-cultural and cross-linguistic communication skills are becoming more and more important in a society that is becoming more and more globalized. It is impossible to overestimate the value of cross-cultural language competency in corporate negotiations, diplomatic missions, educational exchanges, or even day-to-day encounters [1]. It serves as a link between disparate groups, promoting empathy, understanding, and collaboration in the face of diversity. Language proficiency is only one aspect of cross-cultural language competency [2]. It necessitates a thorough comprehension of the subtle cultural differences that influence social conventions, communication styles, and behavioural expectations in other nations. Beyond only words and syntax, it explores the subtleties of body language, tone, and context, all of which have a big influence on perception and meaning [3]. Fundamentally, the goal of cross-cultural language competency is to remove obstacles, such as those resulting from misinterpretation, bias, and poor communication [4]. It is about creating deep connections that go beyond language and cultural barriers, cultivating respect for one another and a tolerance for other viewpoints [5]. Assessment of language competency is essential in many areas, such as work, education, and international communication. A person looking for work placement, education, or immigration to a country where a foreign language is spoken must be able to test language proficiency effectively. However, in cross-cultural circumstances, where linguistic variety and cultural subtleties greatly impact language usage and comprehension, evaluating language ability becomes more difficult [6].

Finding cross-cultural language competency entails using a variety of techniques to evaluate people's capacities for engagement and communication in a variety of linguistic and cultural contexts [7]. In addition to assessing linguistic abilities, standardized language proficiency exams like the "TOEFL, IELTS, and DELF" also include activities that gauge cross-cultural communication, such recognizing and reacting to cultural quirks [8]. Questionnaires on cultural awareness assess people's knowledge of variations in culture and their capacity to modify their communication style accordingly. Role-playing games test participants' intercultural sensitivity, empathy, and flexibility by simulating real-life cross-cultural situations. Study abroad opportunities and other cultural immersion

programs expose people to many cultures and languages, which naturally promotes the growth of abilities to communicate across cultures. Individuals' capacity to modify their communication styles to fit various cultural situations is assessed through the use of content and discourse analysis, which looks at language elements and conversational techniques [9]. Through qualitative analysis, assessors can learn more about participants' cultural origins, experiences, and opinions of communication achievements and obstacles through focus groups and interviews. Through the recreation of cross-cultural scenarios in simulation exercises, participants may hone and showcase their abilities in authentic environments while being evaluated by assessors for decision-making, communication tactics, and cultural adaptability. A thorough assessment of a person's cross-cultural language competency may be obtained by combining interactive techniques with standardized tests. This combination takes into account the speaker's linguistic competence, cultural sensitivity, and ability to communicate effectively in a variety of situations [10].

Conventional methods of evaluating language competency frequently depend on subjective assessments or standardized exams, which may not be appropriate in a variety of linguistic and cultural circumstances. Furthermore, these methods may fall short of capturing the nuanced interactions between linguistic proficiency and cultural variables. Innovative approaches that may successfully scale language competency across various linguistic and cultural contexts are therefore becoming more and more necessary. NLP has advanced recently, resulting in the creation of complex models that can learn language representations on a large scale and capture contextual information [11]. One of the most effective frameworks for a variety of NLP activities is the Transformer architecture, which provides excellent results in tasks like sentiment analysis, text production, and machine translation. The Transformer is an excellent choice for modelling language sequences because of its self-attention mechanism, which allows it to capture contextual information and long-range relationships. Apart from the Transformer architecture, attention methods have been extensively utilized to enhance the functionality of NLP models by enabling them to concentrate on pertinent segments of the input sequence. When a model has to pay attention to certain details in the input data in order to provide correct predictions, such as in tasks requiring cross-modal or cross-domain knowledge, attention methods have proven very useful [12].

The proposed study integrates attention processes with the Transformer design, presenting a unique strategy for scaling language competency across cultures. This hybrid approach uses modern NLP methods to identify both contextual linguistic and cross-cultural elements, aiming to alleviate the shortcomings of standard language competency assessment methods. This technique is new because it can model language sequences well and especially takes cross-cultural subtleties into account. This improves the resilience and accuracy of language competency assessments in a variety of linguistic and cultural situations. The rising need for precise and flexible language competency evaluation instruments across a range of fields, such as education, work, and international communication, is the driving force behind this study. The flexibility required to account for the linguistic variety and cultural quirks inherent in cross-cultural contexts is sometimes lacking in traditional approaches to language competency testing. In order to address the difficulties associated with scaling cross-cultural language competency, this research attempts to create a more complete and context-aware hybrid model by fusing the advantages of the Transformer design with attention processes. Because it allows for more precise and culturally sensitive language ability evaluation, the suggested approach has the potential to have a substantial influence on language learning, career growth, and worldwide interaction.

The key objectives of the proposed work are as follows:

- The suggested hybrid approach combines attention mechanisms made expressly to pick up on cross-cultural cues with Transformer architecture.
- In contrast to earlier approaches, this results in a more thorough and precise assessment of language proficiency in a range of cultural and linguistic contexts.
- The model provides emotional salient characteristics to the classification layer by refining feature representation at different levels through the application of transformer encoder layers and attention processes.
- The design and training methods of the hybrid model enable generalization in a variety of language and cultural situations.
- The approach may thus be applied in a variety of real-world contexts, including education, as it can scale language competency across languages and cultural contexts with effectiveness.

In the subsequent sections of this paper. In the portions of this paper that follow. An introduction is given in Section 1. Related works are covered in Section II. Section III discusses the shortcomings of the current system. In Section IV, a thorough synopsis of the suggested hybrid model is given. Experiments showing the model's efficacy are presented in Section V. Section VI concludes with implications of the results and suggests future options for this field of study.

II. Related Works

Zaidi et al., [13] suggested that emotion identification in cross-language speech. An approach to improve cross-language Speech Emotion Recognition effectiveness is presented in this paper: the Multimodal Dual Attention Transformer (MDAT) model. In addition to including a dual attention mechanism consisting of graph attention and co-attention, the model includes previously trained multimodal extraction of features algorithms. With less target language data, this strategy facilitates superior Speech Emotion Recognition results by capturing complex relationships across several modalities. To improve the accuracy of emotion categorization, MDAT also uses a transformer encoder layer for improved feature representation. The model produces emotionally compelling characteristics for the categorizing layer by refining features at several stages. This novel method promotes cross-modality and

cross-linguistic interactions while maintaining modality-specific emotional information. The model's greater efficacy over baseline models and contemporary methods is demonstrated through assessments of performance on four openly available Speech Emotion Recognition datasets.

Zhu et al., [14] offer a solution in this paper for the Multimodal Sentiment Analyse Challenge's Cross-Cultural Humor Detection sub-challenge. The goal of the MuSe humor challenge is to identify comedy in multimodal data—text, audio, and video—in a cross-cultural setting. German recordings make up the training data, and English recordings make up the test data. As a way to address this sub-task, they suggest a technique known as MMT-GD, which makes use of a multimodal transformer model in order to effectively incorporate the multimodal data. In order to assure ensuring the combination process captures discriminative information from each modality and avoid over-reliance on any one modality, they also include graph distillation. The method's efficacy is confirmed by the experimental findings, which yielded an AUC score of 0.8704 for the test set and allowed us to place third in the challenge. The model's efficacy in real-world applications beyond the MuSe-Humor sub-challenge may be impacted by limitations such as potential bias resulting from the reliance on pretrained models, limited generalization to languages other than German and English, and difficulties guaranteeing an efficient incorporation of multiple types of information across diverse cultural contexts.

Kastrati et al., [15] states that social media sites had been one of the venues via which individuals have shared their ideas, views, and feelings about the pandemic crisis while they were compelled to physically withdraw themselves. The analysis of sentiment of thoughts posted on Facebook in languages with limited resources on the present pandemic scenario is the main goal of this research project. In order to accomplish this, they have compiled a sizable dataset of 10,742 hand categorized Albanian comments. Additionally, they describe in this paper the research on the creation and implementation of a DL-based sentiment analyser. Therefore, employing several models of classifiers using "static and contextualized word embeddings—fastText and BERT", for example—trained and validated on the gathered and curated dataset, and describe the experimental results derived from the suggested sentiment analyser. Considering an F1 score of 72.09%, the results show that the combination of the BiLSTM and an attention mechanism performed the best on their analysis of sentiment test.

Liu et al., [16] research states that contextual comprehension in complicated discussion contexts has proven to be a difficult problem, and most existing approaches have fallen short in this regard. This work develops a unique composite big language model to study this problem in order to close the gap. Consequently, this study proposes an autonomous conversation model based on Transformer-BERT integrated model, using the English context as the scene. First, the attention method is introduced to enhance the unidirectional BERT-based automated conversation model. By connecting context to recognize lengthy, challenging phrases, it is anticipated to improve feature representation for conversation texts. In addition, the input layer preceding the BERT encoder is a bidirectional Transformer encoder. To construct the automated conversation model, adaptive instruction in languages centered on English situational talks may be finished using the two modules. The conversation performance of the suggested conversation framework is further evaluated in a large-scale real-world English language environment. The experimental findings demonstrate that the proposal has greatly enhanced answer quality and speed in an English environment when compared with conventional rule-based or ML approaches. It is more adept at capturing minute semantic variations, comprehending context more precisely, and producing more cogent replies.

Bethel et al., [17] suggested that cross-cultural shifts are difficult and can have negative effects on one's psychological health. This is especially true for foreign students attending postsecondary institutions, who are transferring not just between school and university education but also between radically dissimilar educational systems. Using foreign students, this study evaluates a psychological adaptation prediction model in which the impacts of environmental and personal resources on adaptive outcomes are mediated by host nation connections. Indicators of psychological adaptability, inclusivity, cultural distance, host nation connectivity, and English language competency were evaluated in a survey of 1527 foreign postsecondary students in New Zealand. Path analysis revealed that host national connectedness partially controlled the impact of "language proficiency, cultural distance, and inclusion in the classroom on psychological symptoms and life satisfaction", while entirely controlling the impacts of English language proficiency on mental health issues. The results underscore the significance of the connections that foreign students have with their host countrymen, and they are examined in light of potential tactics to improve the connectivity between students and hosts during cross-cultural exchanges.

The associated research encompasses several areas, such as "automated conversation modelling, multimodal sentiment analysis, sentiment analysis in low resource languages, and psychological adjustment of overseas students. Every work offers novel approaches to solve certain problems in their specialized fields. In the same way, the MMT-GD model handles the MuSe-Humor challenge by combining graph distillation to capture discriminative characteristics and successfully integrating multimodal input. Also, a sentiment analyser that uses contextualized word embeddings and deep learning techniques is being developed to handle analysis of sentiment in low resource languages. A Transformer-BERT [18] combined model is presented to improve contextual comprehension in intricate conversation circumstances within the field of autonomous conversation modelling. The last study examines the mediating function of host nation connectivity in the impacts of environmental and personal resources on adaptive outcomes. It concerns the psychological adaptation of foreign students. These works show notable advances in their respective professions, yet they also have certain drawbacks. Dependence on already present datasets, a lack of generalization across various language and cultural settings, and difficulties with scalability and interpretability are common drawbacks. It may also be challenging to compare

results adequately since the assessment measures utilized in these works might not always accurately capture the whole range of model outcomes or may not be consistent across research.

III. Problem Statement

The approaches currently in use for scaling cross-cultural language proficiency have a number of drawbacks, such as a weak ability to capture cross-cultural subtleties, an excessive dependence on target language data, and difficulties maintaining modality-specific emotional information while improving cross-modality interactions. Also, these approaches could have trouble generalizing to other linguistic and cultural settings and might not adequately satisfy the requirement for flexibility and adaptation in language competence testing. The suggested work presents a unique hybrid model that combines attention processes with the Transformer design in order to get over these drawbacks [19]. Through including both cross-cultural characteristics and linguistic context, this model particularly tackles the difficulties in scaling cross-cultural language competency. The hybrid model incorporates to capture complicated relationships across several modalities and uses models that have been trained for multimodal feature extraction. The suggested model seeks to produce better performance in cross-language scenarios with little target language data while keeping modality-specific emotional information by utilizing the advantages of both the Transformer architecture and attention processes. Transformer encoder layers also make it easier to express high-level features, which improves the accuracy of emotion classification and guarantees that the model may be used to a variety of language and cultural situations.

IV. Cross-Cultural Language Proficiency Assessment Using Transformer- Attention Mechanism

The process for creating a methodical approach starts with precisely defining the issue and conducting a comprehensive analysis of pertinent literature. After that, a heterogeneous dataset comprising language competency evaluations from various cultural contexts is gathered and subjected to preprocessing, which includes operations like cleaning, tokenization, normalization, and maybe translation. The architecture of the hybrid model, which incorporates Transformer and attention processes, is carefully crafted to account for differences in language skills between cultures. To guarantee that the model performs consistently and impartially across a wide range of cultural groups, cross-cultural validation is essential. The architecture, training plans, and data preparation methods of the model are adjusted in light of the validation's findings. Fig. 1 proposed Cross-Cultural Language Proficiency workflow.

A. Data Collection

The dataset utilized in this study comprises an extensive rubric designed for the thorough assessment of essays that include both independent and source-based writing. This rubric evaluates a comprehensive range of factors, ensuring a detailed analysis of each essay. Key areas of assessment include the writer's point of view, critical thinking, the use of evidence and examples, organization, coherence, language proficiency, vocabulary, sentence structure, syntax, usage, and mechanics. Scores are assigned on a scale from 1 to 6, with each section of the rubric outlining specific requirements for each score level. For source-based writing, the rubric details the desired mastery levels, highlighting strengths and weaknesses for each criterion. Similarly, it provides matching descriptions for autonomous writing, ensuring that all aspects of an essay are thoroughly evaluated.

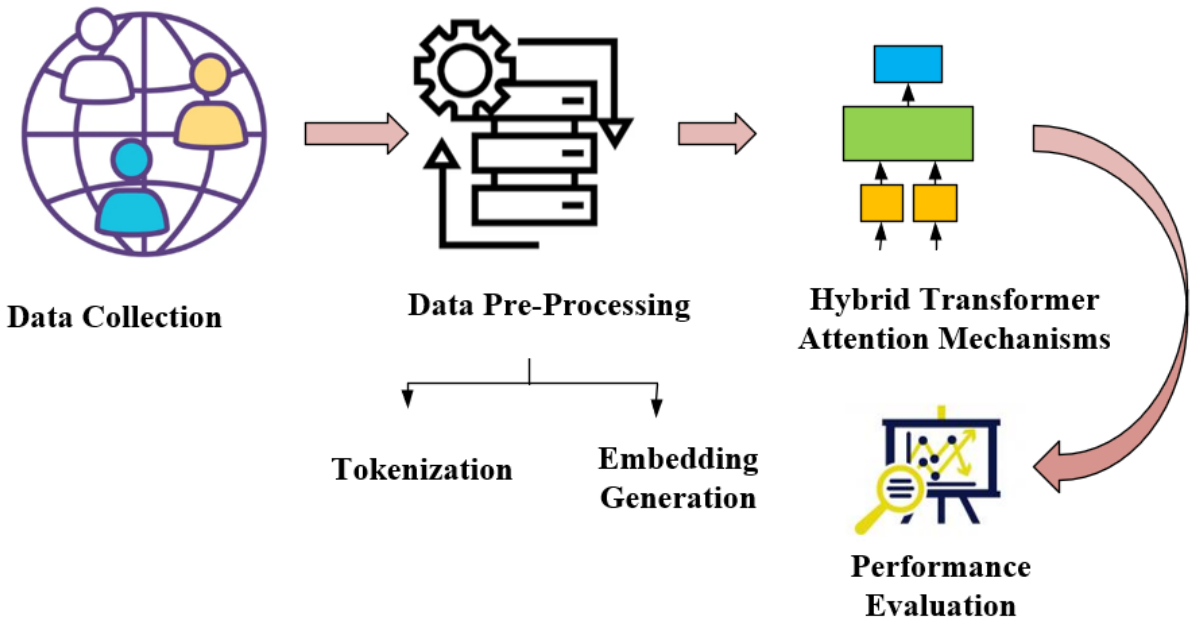

Fig. 1. Cross-cultural language proficiency workflow.

The dataset's detailed rubric makes it a valuable resource for researchers, educators, and organizations involved in automated scoring systems, essay evaluation, and natural language processing activities related to writing assessment. By providing explicit criteria for scoring across multiple dimensions of writing, the dataset allows for a nuanced analysis of writing competency. This, in turn, can enhance the development and evaluation of automated scoring models. The comprehensive nature of the rubric ensures that the assessment captures the multifaceted nature of writing proficiency, making it an essential tool for improving the accuracy and reliability of essay evaluations in diverse educational and research contexts. Including detailed information about this dataset in the paper will significantly enhance its quality, providing clear insights into the robust framework used for essay assessment and the potential applications of the dataset in various domains.

The comprehensive scoring guidelines make it easier to train human raters to score essays consistently, develop and assess automated essay scoring models, analyze the traits of writing proficiency, create synthetic essay datasets for testing and training models, and investigate the connections between different writing competencies [20]. Table I describes the dataset.

TABLE I. DATASET DESCRIPTION

Language Used	Language Proficiency	Score
English	Advanced	6
Spanish	Intermediate	4
French	Beginner	2
German	Proficient	5
Mandarin	Advanced	6
Italian	Intermediate	3
Japanese	Beginner	1

B. Data Pre-processing

For data preprocessing, the rubric text is tokenized, and each token is converted into pre-trained word embeddings like Word2Vec to capture semantic information.

1) Tokenization: Tokenization is employed in the proposed work to handle the text data from the rubric in order to score essays holistically. To enable additional analysis and modelling, tokenization entails dividing the text into smaller pieces, such as words or subwords. To evaluate essays, the rubric text is tokenized in this instance to extract specific criteria like "point of view, critical thinking, using examples or evidence, organization, coherence, language use, vocabulary, sentence structure, syntax, use, and mechanics". Because each criterion is handled as a distinct token, writing competence levels may be thoroughly analyzed and evaluated. The hybrid model may encode and analyze the rubric's criteria once they have been tokenized. This model combines attention mechanisms with Transformer architecture.

2) Embedding generation: Following tokenization, the suggested approach generates embeddings utilizing word embeddings that have already been trained, such as Word2Vec. Through this approach, the semantic information contained in the text is extracted from each tokenized word and represented as a dense vector representation. Using word co-occurrence patterns from a large text corpus, Word2Vec, a well-known word embedding approach, develops distributed representations of words. The matching pre-trained Word2Vec embedding is extracted for every tokenized word in the rubric criteria. This produces a high-dimensional vector that captures the semantic meaning and contextual usage of the term. The hybrid model uses these embeddings as input characteristics to comprehend the interactions between words and their context in the rubric text. The suggested approach takes advantage of the semantic information included in the embeddings, which have been learnt from large amounts of textual data, by utilizing pre-trained embeddings. This enhances the accuracy and resilience of language competence scaling across various linguistic and cultural settings by making it easier for the model to capture the complex linguistic context and cross-cultural characteristics included in the rubric criteria. Pre-trained embeddings also save computing resources by reducing the requirement for the model to learn word representations from start, allowing for more effective training. In general, the creation of embeddings utilizing word embeddings that have already been trained, such as Word2Vec, is essential to enabling the hybrid model to process and comprehend the tokenized rubric text in an efficient manner, which advances the objectives of the suggested work in scaling cross-cultural language competency.

C. Transformers and Attention Mechanisms

A turning point in the development of deep learning models has been reached with the transformer model. Unlike traditional sequence transduction models that make use of recurrent or convolutional layers, the transformer model only utilizes attention processes, creating a new standard in applications like NLP and machine translation. The attention mechanism, which is the main element of a transformer model, is available in two varieties: multi-head attention and self-attention (also known as intra-attention). The primary purpose of the attention mechanism is to simulate how various items interact with one another in a sequence, capturing the interdependence between them independent of where they are in the sequence. Essentially, it establishes how much attention to give certain input components when generating a specific result. Self-attention mechanisms work by imbuing each element in a set with a representation that encompasses the significance of every other piece in the sequence. To do this, a softmax function is used for each pair of elements to calculate a score. These weights are then used to create a weighted sum of the initial element representations. As a result, it enables every member in the sequence to communicate with every other element, giving rise to a more comprehensive image of the sequence as a whole.

On the other hand, several self-attention mechanisms, or heads, working in tandem make up the multi-head attention mechanism. The final output is produced by concatenating and

linearly transforming each heads independently computed learned linear transformation of the input. This makes it possible for the model to represent many kinds of dependencies and interactions in the data. Positional encoding is another essential component of the transformer design, in addition to the self-attention process. There must be a way to include information about the elements' positions within the sequence since the model is permutation-invariant, meaning it has no intrinsic idea of the order of the input components. For this, positional encoding is useful [21].

The input embeddings at the base of the encoder and decoder stacks are supplemented with positional encodings. The goal of these learnt or fixed embeddings is to introduce information about the absolute or relative placements of the words in the sequence. The model can now utilize the sequence's order thanks to the inclusion of positional encodings, which is essential for comprehending structured data like language. The use of sine and cosine functions at various frequencies is a popular method for positional encoding. This method assigns a sine or cosine function for every dimension of the positional encoding. The wavelength of these functions is a geometrical progression from 2π to $10{,}000 \times 2\pi$.

Because of its sequential structure, the transformer model has several benefits over standard RNNs and CNNs, one of which is its ability to manage long-term dependencies in the data. Transformers provide an alternative to condensing all data into a fixed-size hidden state that frequently results in information loss in lengthy sequences, by enabling all parts to interact concurrently. To address the lack of intrinsic positional information in attention systems, transformers also provide the idea of position encoding. This is important, particularly for activities where the pieces' arrangement conveys important information.

Three essential parts make up the transformer's self-attention mechanism: the value (V), the key (K), and the query (Q). These elements are obtained by multiplying the input by the corresponding learned weight matrices, which are derived from the input representations. Every one of these elements has a distinct role in the attention system. The element for which are attempting to construct the context-dependent representation is precisely matched by the query. The items against which are comparing the query to ascertain the weights are related to the key. To produce the final output, the value is the last component that is weighted by the attention score obtained from comparing the query and the key.

For the self-attention mechanism to function, a pair of queries and keys must first be given an attention score. To guarantee that the weights lie between zero and one and add up to one, it achieves this by taking their dot product and applying a softmax function. This gives each element a normalized measure of attention or relevance that the model allocates while encoding that specific piece. The model determines the weighted sum of the value vectors, where the weights are determined by the attention scores, once the attention scores have been calculated. Each element is then encoded in a context-sensitive manner, where the context is contingent upon every other element in the sequence.

These encodings are then sent into the transformer model's subsequent layer. The model may learn to concentrate on distinct elements of the input data and identify which details are crucial for encoding a certain element by using the Q, K, and V matrices. As a result, the attention mechanism of the transformer gives the model a great deal of flexibility and power, enabling it to manage a wide range of activities effectively and efficiently. Fig. 2 and Fig. 3 show the structures of the attention mechanism and the transformer design.

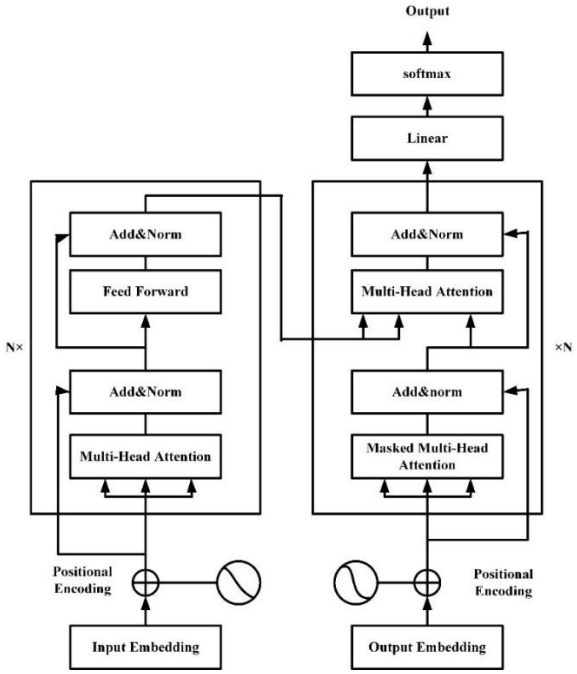

Fig. 2. Transformer model structure.

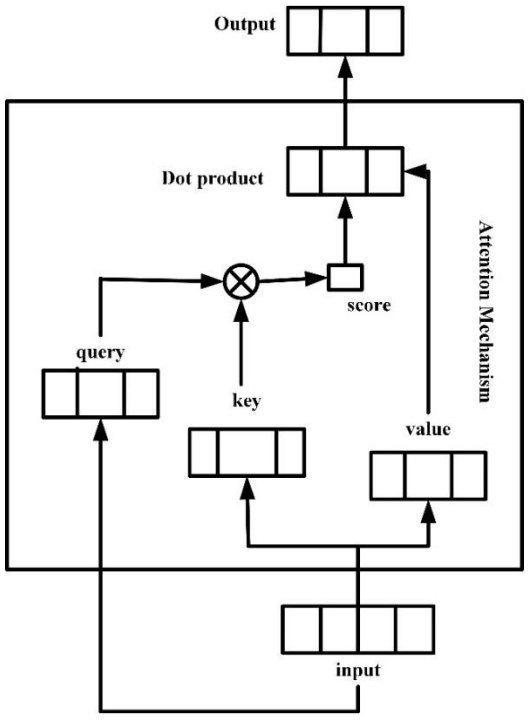

Fig. 3. Structure of attention mechanism.

An architecture for a hybrid model was developed, which combined Transformer and attention mechanisms to account for differences in language competence between cultures. The model effectively extracts semantic information from a variety of linguistic settings by capturing word dependencies in input sequences through the use of a multi-head self-attention mechanism within the Transformer framework. Extra attention mechanisms were added to handle cross-cultural subtleties by dynamically adapting to differences in language use and understanding. The combined representation is supplied into a classifier following processing through the Transformer and attention mechanism layers. To predict language competency levels, the proposed approach adds a classifier on top of the fused representation after processing the tokenized and embedded input using the transformer encoder and attention methods. The outcomes of the transformer encoder and the attention processes are combined in the fused representation, which captures cross-cultural and language properties. The model may produce good predictions by learning to map the fused representation to language competency levels with the addition of a classifier layer. Effective language proficiency scaling is facilitated by the classifier's ability to adapt to various linguistic and cultural settings by training on a variety of datasets and adjusting on task-specific data. The model's ability to acquire and encode culturally unique information during training is enhanced by this adaptive strategy, which helps the model predict language competence levels across a range of cultural backgrounds. The suggested hybrid model provides a stable and flexible structure for cross-cultural language proficiency scaling by combining the benefits of Transformer and attention processes, and it promises notable improvements in the precision and fairness of language assessment techniques.

V. Results and Discussion

The proposed hybrid model, which integrates Transformer and attention mechanisms, demonstrated promising outcomes in predicting language competency across diverse cultural backgrounds. After training and evaluating the model on a comprehensive dataset of language competency tests from various ethnic groups, the model exhibited excellent accuracy in predicting competency levels. Furthermore, the model achieved balanced performance metrics, including accuracy, recall, and F1-score, across different competence levels. These results indicate that the hybrid approach effectively addresses the challenges associated with evaluating linguistic competency across cultural boundaries, showcasing its potential to deliver precise and reliable assessments in multicultural contexts.

The range of skill levels is seen in Fig. 4. The chart is divided into eight sections, each of which represents a distinct skill-level score. Advanced has the highest scores of all the ability levels, with segments indicating scores of 3, 5, and 6. Beginner and Proficient each have one segment with a score of 4 and 6, respectively, while Intermediate is represented by two segments with scores of 1 and 2. This graphic offers a concise summary of the distribution of skill levels and associated scores throughout the dataset. The dataset used in the proposed work is from Kaggle.

A. Performance Evaluation

Performance of the proposed work is evaluated using several metrics. Metrics like accuracy, precision, recall, and F1-score are represented in Eq. (1), Eq. (2), Eq. (3) and Eq. (4). It is used to assess how well the suggested Cross-Cultural Language Competence Scalability Utilizing Transformer and Attention Mechanism Hybrid Model performs. Analyzing it against current methods allows for an accurate assessment of how well it scales language competency in various linguistic and cultural situations.

$$Accuracy = \frac{\text{Tpos+Tneg}}{\text{Tpos+Tneg+Fpos+Fneg}} \quad (1)$$

$$Precision = \frac{Tpos}{Tpos+Fpos} \quad (2)$$

$$Recall = \frac{Tpos}{Tpos+Fneg} \quad (3)$$

$$F1-Score = \frac{2\times precision \times recall}{precision \times recall} \quad (4)$$

The suggested Transformer and Attention Mechanisms model's performance metrics are depicted in the Fig. 5. The algorithm forecasts language competency levels with a 97.3% accuracy rate. With a precision of 96.8%, it is the percentage of accurately categorized positive cases out of all positive instances that were classified. With a recall of 95.6%, the model can reliably distinguish positive cases from all real positive instances. With a harmonic mean of 96.4%, the F1-Score strikes a balance between recall and accuracy, indicating the overall performance of the model. These impressive results show how well the model scales language competency in a variety of linguistic and cultural situations.

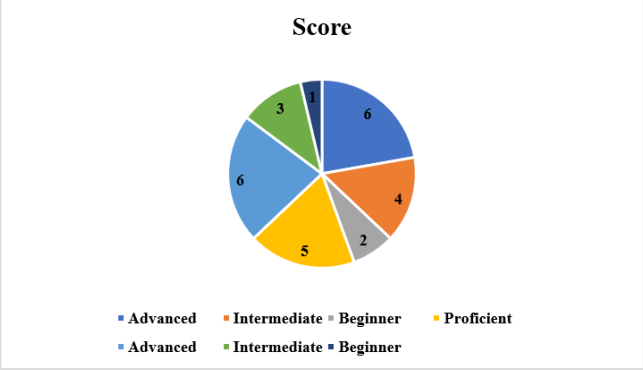

Fig. 4. Language proficiency score.

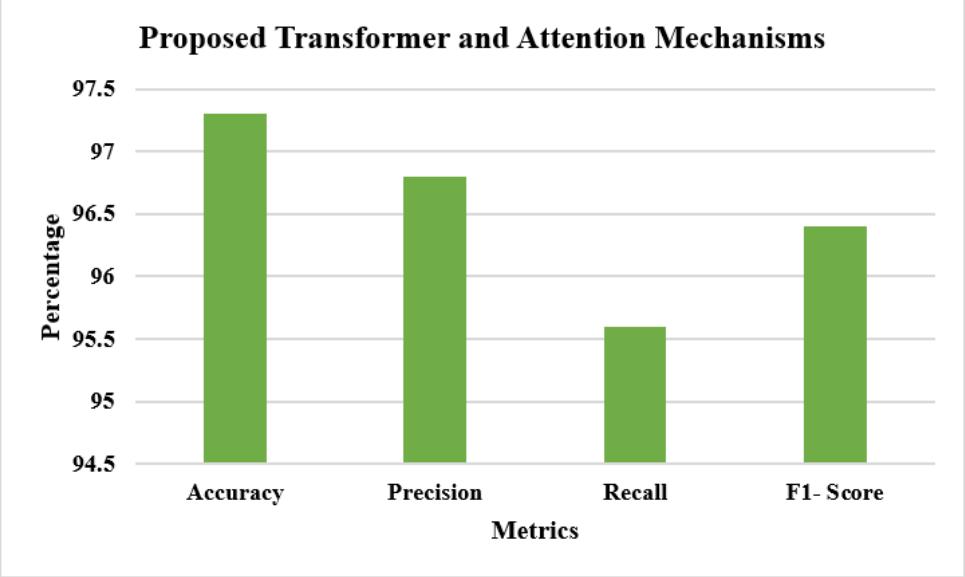

Fig. 5. Performance of proposed method.

TABLE II. PERFORMANCE COMPARISON OF VARIOUS METHOD WITH PROPOSED METHOD

Method	Accuracy	Precision	Recall	F1- Score
T-TC-INT Model [22]	81.83	80.1	77.2	80.91
BERT + MECT [23]	95.98	91.5	88.8	90.2
Proposed Transformer and Attention Mechanisms	97.3	96.8	95.6	96.4

Three distinct models' performance metrics are compared in this Table II for a cross cultural language proficiency. With accuracy of 81.83%, precision, recall, and F-score values of 80.1%, 77.2%, and 80.91%, respectively, the "T-TC-INT Model" performs well. The "BERT + MECT" model performs better than the T-TC-INT Model, with slightly better precision, recall, and F-score values, as well as greater accuracy (95.98%). The suggested Transformer and Attention Mechanisms model, on the other hand, outperforms the two earlier models, with a 97.3% accuracy rate and better precision, recall, and F-score values of 96.8%, 95.6%, and 96.4%, respectively. These findings demonstrate the efficacy of the suggested model in the assessed task by showing a notable improvement over previous models using Transformer architecture and attention processes.

The efficiency parameters of three distinct models for a competence in languages across cultural boundaries are compared in the Fig. 6. With accuracy of 81.83%, the T-TC-INT model also has recall, precision, and F-score values of 77.2%, 80.1%, and 80.91%, respectively. With an accuracy of 95.98% and greater precision, recall, and F-score values, the BERT + MECT model performs better. In contrast, the suggested Transformer and Attention Mechanisms model performs better than the other two, attaining an accuracy of 97.3% and showing improved precision, recall, and F-score values. These outcomes show that the suggested model is successful in producing precise and well-rounded predictions for the task.

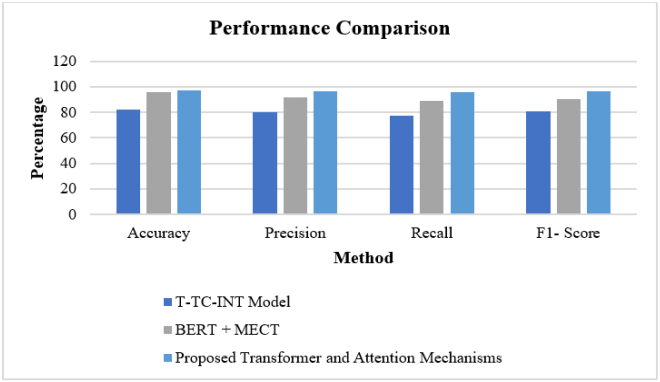

Fig. 6. Performance comparison.

B. Discussion

The evaluation results of the proposed Transformer and Attention Mechanisms model demonstrate its superiority in language competency assessment compared to existing models. With an accuracy of 97.3%, precision of 96.8%, recall of 95.6%, and F1-score of 96.4%, the proposed model outperforms both the T-TC-INT [22] Model and the BERT + MECT [23] model, which exhibit lower performance metrics (T-TC-INT Model: 81.83% accuracy, 80.1% precision, 77.2% recall, 80.91% F1-score; BERT + MECT: 95.98% accuracy, 91.5% precision, 88.8% recall, 90.2% F1-score). These results indicate that the hybrid approach not only excels in predicting language competency levels with high accuracy but also maintains a balanced performance across precision, recall, and F1-score, ensuring reliable and consistent evaluations. The superior metrics highlight the model's capability to effectively capture subtle language patterns and cultural nuances, making it a robust tool for multicultural language assessments. However, further validation on diverse datasets is necessary to confirm its scalability and mitigate any potential biases, ensuring its applicability in various linguistic and cultural contexts.

The suggested method raises several important concerns for consideration. First and foremost, the model represents a breakthrough in the area of language evaluation since it can reliably predict language competency levels across a range of cultural backgrounds. Current methods for enhancing language proficiency across cultures have limitations such as inability to capture cross-cultural subtleties, over-reliance on language-specific data, and challenges in preserving emotional information [24]. The model can capture subtle language patterns and cultural differences by utilizing the strength of Transformer models and attention mechanisms. This results in more accurate and consistent competency ratings. The suggested method has the benefit of being flexible enough to work in many cultural settings. In contrast to conventional techniques of evaluating language competency that could exhibit bias towards certain cultural norms or linguistic conventions, the hybrid model is capable of properly accounting for variations in language usage and comprehension among diverse cultural groups. This flexibility improves the model's suitability in multicultural contexts, where standardized evaluation instruments could not adequately capture the nuances of linguistic competency. But there are a few disadvantages to the suggested strategy as well that should be taken into account. The training data may have biases that disproportionately reflect particular language or cultural groups, which is one of its limitations. Data biases may lead to distorted forecasts and imprecise evaluations, especially for marginalized or underrepresented groups. Furthermore, Transformer models' computational complexity may provide issues with training time and resource needs, especially for large-scale datasets or applications in real time. Notwithstanding these drawbacks, the suggested hybrid approach is a major advancement in the evaluation of cross-cultural language competency. The concept might transform language evaluation procedures with more development and validation, enabling more inclusive and fair assessment approaches in a range of linguistic and cultural contexts.

The proposed model marks a significant advancement in language evaluation by effectively predicting language competency across various cultural contexts, addressing limitations in current methods that often fail to capture cross-cultural nuances and overly depend on language-specific data. Leveraging the strengths of Transformer models and attention mechanisms, the hybrid approach excels in identifying subtle language patterns and cultural differences, resulting in more accurate and consistent competency ratings. Its adaptability to different cultural settings ensures that the model can account for variations in language use and comprehension, making it a valuable tool for multicultural assessments. However, some limitations must be acknowledged, including potential biases in the training data that could skew predictions and evaluations, particularly for underrepresented groups. Additionally, the computational complexity of Transformer models poses challenges in terms of training time and resource requirements, especially for large-scale datasets or real-time applications. Despite these drawbacks, the hybrid model represents a significant step forward in cross-cultural language competency evaluation, with the potential to revolutionize assessment practices and promote more inclusive and equitable evaluation methods across diverse linguistic and cultural landscapes. Further research and validation using different datasets are necessary to fully establish the scalability and robustness of this approach.

However, to fully validate the scalability and robustness of this hybrid model, additional research is required. Specifically, evaluating the model on diverse datasets beyond the initial Kaggle dataset is crucial to ensuring its generalizability across various linguistic and cultural contexts. This further evaluation would help identify any potential biases in the training data and assess the model's performance in different real-world scenarios. Moreover, it is essential to explore the model's computational efficiency, particularly in handling large-scale datasets and real-time applications, to ensure its practical viability. Addressing these aspects through comprehensive testing and validation will provide a more robust foundation for the model's application in diverse educational and assessment settings, ultimately supporting its role in creating more inclusive and equitable language competency evaluations.

VI. Conclusion and Future Work

The hybrid model that integrates attention processes and Transformer is a viable method for extending language competency across cultural boundaries. The model has proven to be successful in predicting language proficiency levels across a range of cultural backgrounds through rigorous training and evaluation on a broad dataset of proficiency examinations. Although the model exhibits significant improvements in resilience and adaptability, it is not without flaws, especially when it comes to possible biases in the training set and computational complexity. However, this study offers a more comprehensive and sophisticated method of evaluating competency in multicultural contexts, which is a substantial improvement in the field of language assessment. The successful integration of pre-trained word embeddings further enhances the model's ability to understand semantic information and contextual usage, contributing to its superior performance.

Subsequent research endeavors in this domain can concentrate on mitigating the detected constraints and augmenting the model's functionality and relevance. The development of strategies to reduce biases in training data, such as algorithmic fairness measures or data augmentation approaches, is one direction that future research should go. Additionally, the model may be more useful for real-world applications if efforts are made to maximize its computing efficiency, maybe through parallel processing or model compression. Also, investigating methods for integrating multimodal input, including auditory or visual signals, might improve the model's comprehension of linguistic ability and cultural background. Additionally, longitudinal studies that monitor a person's language growth over time may offer insightful information on the dynamic nature of language competency and help to improve assessment techniques.

***Abstract*—This research paper delves into the intricate domain of cyberbullying detection on social media, addressing the pressing issue of online harassment and its implications. The study encompasses a comprehensive exploration of key aspects, including data collection and preprocessing, feature engineering, machine learning model selection and training, and the application of robust evaluation metrics. The paper underscores the pivotal role of feature engineering in enhancing model performance by extracting relevant information from raw data and constructing meaningful features. It highlights the versatility of supervised machine learning techniques such as Support Vector Machines, Naïve Bayes, Decision Trees, and others in the context of cyberbullying detection, emphasizing their ability to learn patterns and classify instances based on labeled data. Furthermore, it elucidates the significance of evaluation metrics like accuracy, precision, recall, F1-score, and AUC-ROC in quantitatively assessing model effectiveness, providing a comprehensive understanding of the model's performance across different classification tasks. By providing valuable insights and methodologies, this research contributes to the ongoing efforts to combat cyberbullying, ultimately promoting safer online environments and safeguarding individuals from the pernicious effects of online harassment.**

***Keywords*—Machine learning; cyberbullying; feature engineering; feature extraction; feature selection**

I. Introduction

Cyberbullying has emerged as a significant concern in the digital age, posing threats to the mental and emotional well-being of individuals, particularly adolescents and young adults. With the proliferation of social media platforms and online communication channels, the avenues for perpetrating cyberbullying have expanded, making it imperative to develop effective detection and mitigation strategies. This paper presents a comprehensive review of machine learning models employed in addressing the cyberbullying detection problem.

Recent studies have emphasized the escalating prevalence of cyberbullying incidents [1], highlighting its diverse manifestations across online platforms [2]. The multifaceted nature of cyberbullying, ranging from textual abuse to image-based harassment, necessitates innovative and adaptive detection mechanisms. Machine learning, with its capacity for processing vast amounts of data and identifying intricate patterns, has gained prominence in addressing this pressing issue.

In this review, we delve into the extensive body of literature on machine learning-based cyberbullying detection. We examine the evolution of techniques and methodologies, from early rule-based approaches [3] to the more sophisticated deep learning algorithms [4]. By harnessing natural language processing (NLP) techniques, these models enable the analysis of textual content to identify hate speech, offensive language, and threatening messages [5]. Additionally, image analysis and sentiment analysis have been integrated into the detection process to capture the nuances of cyberbullying [6].

One of the pivotal challenges in cyberbullying detection is the class imbalance problem, wherein instances of cyberbullying are often significantly outnumbered by benign content [7]. Addressing this issue requires the development of balanced datasets and the implementation of advanced sampling techniques, which we explore in this review.

This comprehensive examination aims to provide researchers, practitioners, and policymakers with a holistic understanding of the evolving landscape of machine learning models in cyberbullying detection. By synthesizing insights from diverse studies and methodologies, we seek to contribute to the ongoing efforts to mitigate the harmful effects of cyberbullying and create safer digital environments for all. In the subsequent sections, we delve into the various machine learning approaches and their effectiveness in addressing this pressing societal concern.

II. Classification of Cyberbullying Types

Cyberbullying encompasses a diverse range of behaviors that manifest in digital spaces, each posing distinct challenges for detection and intervention. In this section, we categorize cyberbullying into eight primary types, drawing insights from seminal research in the field. Understanding these categories is essential for developing effective machine learning models that can identify and mitigate cyberbullying incidents with precision. Fig. 1 demonstrates types of cyberbullying.

Harassment: Harassment involves repeated and unwanted online interactions that intend to harm, annoy, or intimidate the victim. This may include sending threatening messages,

spreading rumors, or engaging in persistent stalking behaviors [8].

Denigration: Denigration refers to acts of tarnishing a person's reputation by posting derogatory or defamatory content online. This often involves sharing embarrassing or false information about the victim, causing emotional distress [9-10].

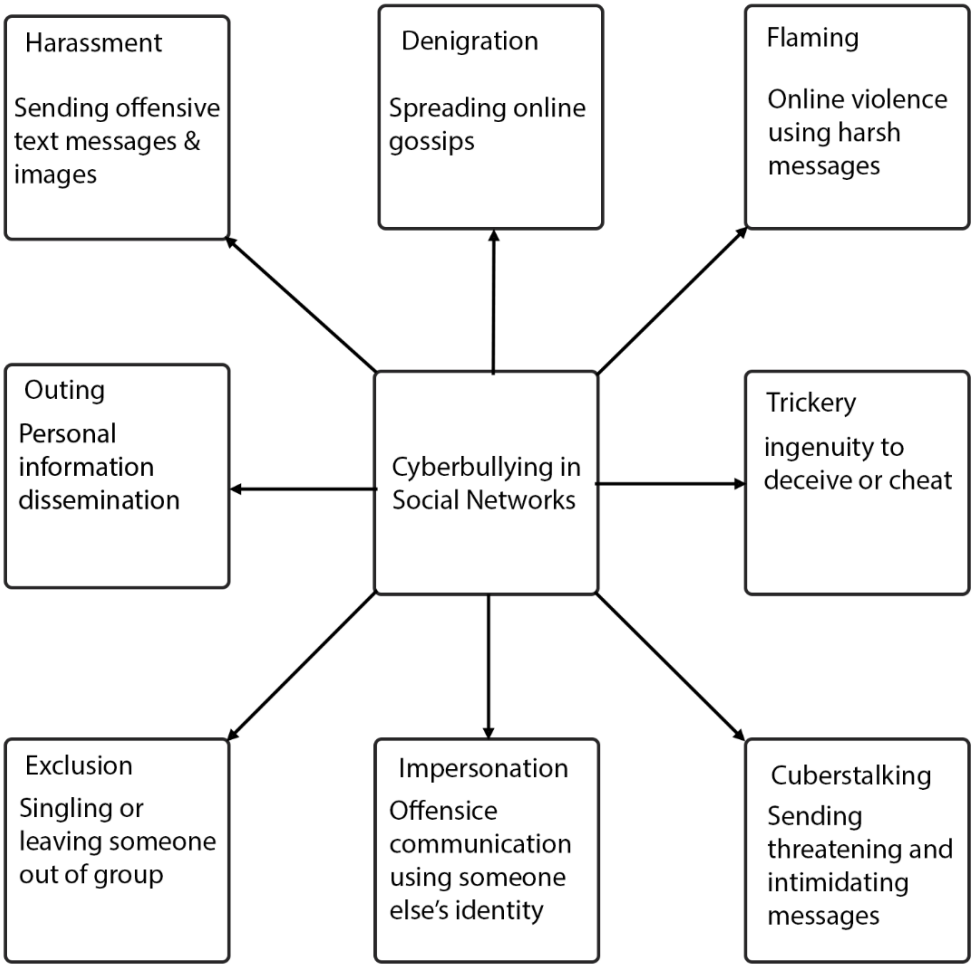

Fig. 1. Types of Cyberbullying.

Flaming: Flaming entails the use of highly inflammatory and provocative language in online discussions or forums. It aims to provoke emotional reactions and incite conflicts among participants, fostering a hostile online environment [11-12].

Outing: Outing involves the unauthorized disclosure of someone's private or sensitive information, such as personal photos or confidential messages, with the intent to harm or embarrass the victim. This type of cyberbullying can lead to severe emotional and psychological distress [13].

Trickery: Cyberbullying through trickery relies on deception and manipulation to victimize individuals [14-15].

Exclusion: Exclusion is a form of indirect cyberbullying, where individuals are deliberately left out or ignored in online groups or social circles. It can lead to feelings of isolation and social exclusion, causing emotional harm [16].

Impersonation: Impersonation involves creating fake online profiles or accounts to impersonate the victim, leading to false communications or actions attributed to them [17]. This type of cyberbullying can harm the victim's reputation and relationships [18].

Cyberstalking: Cyberstalking is characterized by persistent, unwanted online attention, which may include tracking the victim's activities, sending unsolicited messages, and engaging in obsessive online monitoring [19].

Understanding these distinct categories of cyberbullying is crucial for the development of machine learning models that can accurately identify and classify such behaviors. By categorizing cyberbullying types, researchers and practitioners can better tailor their detection algorithms to target specific threats, thereby enhancing the effectiveness of cyberbullying prevention and intervention efforts.

III. Machine Learning in Cyberbullying Detection Problem

A. Data Collection

This section explores each of these critical steps in detail, shedding light on the intricacies of data collection, feature

extraction, model development, and evaluation, all of which contribute to the ongoing battle against cyberbullying in the digital realm. Fig. 2 demonstrates data collection and cyberbullying detection process using machine learning.

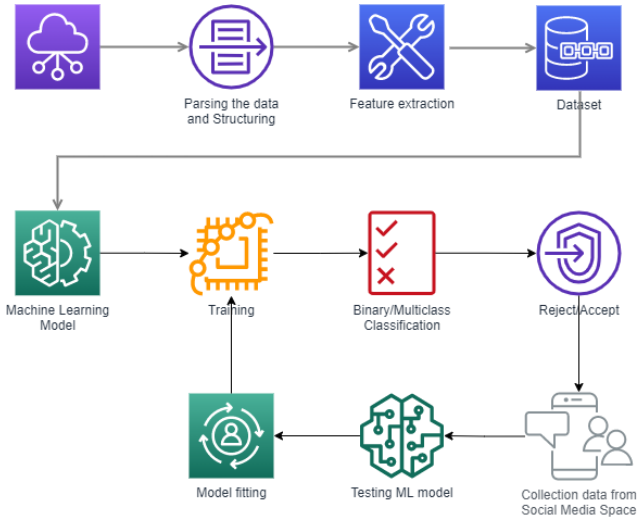

Fig. 2. Data collection and applying machine learning for cyberbullying detection.

1) Data collection: To develop an effective cyberbullying detection model, the first step involves collecting data from various online sources, such as social media platforms, forums, and messaging apps [20]. This data often includes text and multimedia content, user interactions, and metadata associated with online posts. The process of data collection also entails web scraping, API integration, or acquiring datasets through partnerships with social media platforms.

2) Parsing the data and structuring: Raw data collected from online sources is typically unstructured. It needs to be parsed and organized into a structured format for analysis [21]. This step involves text preprocessing, where text is cleaned, tokenized, and organized into a structured dataset, ensuring consistency and uniformity.

3) Feature extraction: Feature extraction is a crucial step in preparing the data for machine learning [22-25]. It involves converting the structured data into numerical features that the model can process.

4) Dataset creation: The structured and feature-engineered data is divided into training, validation, and testing datasets [26-28]. This separation ensures that the model is trained on one set of data, validated for hyperparameter tuning, and tested on unseen data to evaluate its generalization performance.

5) Binary/Multiclass classification: Cyberbullying detection can be framed as both binary (e.g., identifying whether a post is cyberbullying or not) and multiclass (e.g., classifying different types of cyberbullying) [29-30]. The choice depends on the research or application's specific objectives.

6) Reject/Accept decisions: After model training, it is essential to set a threshold or decision boundary for classifying new, unseen data. Depending on the desired trade-off between precision and recall, the model can be configured to make accept or reject decisions regarding potentially harmful content.

7) Collecting data from social media space: Continuous data collection is crucial in the dynamic online environment. Regular updates to the dataset ensure that the model remains effective in identifying emerging cyberbullying trends and adapting to evolving language and behavior patterns.

8) Model fitting and iteration: Based on the testing results, the model may require further fine-tuning and optimization. Model parameters, hyperparameters, and features can be adjusted iteratively to enhance performance and adapt to evolving cyberbullying dynamics.

In summary, developing a cyberbullying detection model involves a series of steps, from data collection and preprocessing to model training and evaluation. Continuous monitoring and updates to the model and data collection methods are essential to ensure its effectiveness in addressing the evolving challenges of cyberbullying in the social media space.

B. Feature Engineering

In the realm of machine learning-based cyberbullying detection, the foundational building blocks lie in the creation and utilization of feature vectors. Features, quantifiable attributes of observed tasks [31], serve as the bedrock upon which machine learning algorithms rely to differentiate between various classes [32]. The efficacy of most machine learning models hinges significantly on the process of feature engineering [33–34], a pivotal phase where the success or failure of a predictive model is greatly influenced [35-38].

In many applications, the initial stride towards constructing a potent classifier involves the proposition of a collection of discriminative features. These features, which may encompass textual and contextual information, are instrumental in enabling machine learning classifiers to distinguish between instances of cyberbullying and neutral content [32–34]. Recent studies have illuminated the relationship between various features, such as gender, age, user character, and the prevalence of cyberbullying [32–34]. Such insights are instrumental in crafting feature vectors that enhance a classifier's discriminatory power [35–36].

To bolster the accuracy of cyberbullying prediction models, novel features have been introduced through cutting-edge research. For instance, lexical syntactic features have been proposed for predicting offensive language, proving to be more accurate than traditional learning-based techniques [38]. Some studies have utilized demographic features, like gender, to augment a classifier's discriminatory abilities [38]. Profane phrases have also been employed as features to signify cyberbullying instances, substantially improving the model's performance [35, 39–41]. The quantity and density of "bad" words, as well as the expansion of a list of pre-defined obscene terms with varying weights, have been considered as valuable features [32–34].

The choice of constructing the feature vector can greatly impact a classifier's performance. Context-based methods often outperform list-based methods [37], although the inherent diversity and complexity of cyberbullying may necessitate a nuanced approach. Sentiment analysis has been explored as a means to discriminate between cyberbullying and non-cyberbullying messages [33, 39, 41], as sentiment traits are hypothesized to be indicative of cyberbullying occurrences. Additionally, researchers have proposed models that leverage various features, including content-based, profile-based, and network-based characteristics, to improve authorship identification and troll profile detection [38, 39].

In summary, the creation and selection of features constitute a critical phase in the development of machine learning models for cyberbullying detection. A well-designed feature space that encompasses a diverse range of relevant aspects associated with cyberbullying behavior is essential for the successful learning process. Nevertheless, the process should also include feature selection techniques to evaluate the relevance of the chosen features, ensuring that they contribute effectively to the classification task. The richness and relevance of the features ultimately determine the model's ability to distinguish between cyberbullying and non-cyberbullying content, making feature engineering a cornerstone of effective cyberbullying detection systems.

C. Machine Learning in Cyberbullying Detection

In the realm of machine learning (ML) for cyberbullying detection, supervised ML stands out as the most prominent and widely employed technique [31-36]. The success of an ML model hinges on its ability to accurately transform past observations or task-specific information into actionable insights. Therefore, selecting the appropriate ML algorithm is paramount, and there is no one-size-fits-all solution for all problems [37–41]. As a result, researchers typically explore and evaluate various supervised classifiers to determine the best fit for their specific task. The choice of classifiers often depends on the most commonly used predictors in the field and the available data attributes for experimentation. The most frequently employed machine learning techniques for constructing cyberbullying prediction models include Support Vector Machines (SVM), Naïve Bayes (NB), Random Forest (RF), Decision Tree (DT), k-Nearest Neighbors (KNN), Logistic Regression (LR), and Radial Based Method (RB) [37].

Cyberbullying, a pervasive issue involving various forms of online harassment, such as offensive emails, explicit content, or threats, presents a substantial challenge in today's digital landscape [30]. To address this problem, supervised machine learning has been applied [30–31]. One study [32] contrasts machine learning approaches with lexical methods, highlighting the lexical approach's limitation in identifying verbally expressed emotions. To overcome this limitation, various techniques have been proposed, including rule-based approaches, supervised machine learning, deep machine learning with neural networks, and hierarchical models [32].

Content-based approaches have also been explored in cyberbullying detection on social networks. For instance, Sarna and Bhatia [33] utilized four ML models (SVM, NB, DT, KNN) to classify texts as bullying or non-bullying, incorporating features like bad words, emotions, links, proper nouns, and pronouns. Similarly, another study introduced two feature sets tailored for cyberbullying early detection: text similarities and time features. They modified machine learning models and found that the dual model consistently provided the best performance for early detection of cyberbullying [31].

In the pursuit of robust cyberbullying detection, researchers have examined various feature sets, encompassing content-based and profile-based features, as well as mobile applications for identifying cyberbullying on social media [34, 40]. The development of machine learning models has also ventured into assessing the tonality of texts, using markers such as pre-typologized emoticons to differentiate power and expanding the range of identifiable emotions [34, 36, 42–44, 37].

Furthermore, ML techniques have been instrumental in studying different forms and manifestations of online aggression, including trolling, verbal hostility, cyberbullying through mobile applications, manipulation, inciting discord, and mass protest in the digital realm [38-39]. Cybermetric analysis, a complex methodology, has been employed to segment information flows based on search queries and marker dictionaries, aiding in the assessment of real mass protests and the identification of factors that trigger them [42].

In summary, the application of ML techniques in cyberbullying detection encompasses a wide array of approaches, classifiers, and feature sets tailored to the task. These techniques play a crucial role in identifying and mitigating the diverse forms of online aggression, ultimately contributing to a safer and more inclusive digital environment.

D. Evaluation Metrics

The performance evaluation of cyberbullying detection models is pivotal to assess their effectiveness in distinguishing between cyberbullying and non-cyberbullying instances. In this section, we present a comprehensive overview of the key evaluation metrics employed in this research. These metrics provide a quantitative assessment of model performance and guide the selection of the most suitable models.

$$accuracy = \frac{TP + TN}{P + N} \tag{1}$$

$$preision = \frac{TP}{TP + FP} \tag{2}$$

$$recall = \frac{TP}{TP + FN} \tag{3}$$

$$F1 = \frac{2 \times precision \times recall}{precision + recall} \tag{4}$$

IV. Experimental Setup and Results

The problem of identifying cyberbullying at an early stage on social media platforms may be fundamentally different from the task of categorizing various forms of cyberbullying. In the situation described here, we pinpoint a group of social media exchanges referred to as S. It's reasonable to consider that

some of these exchanges may constitute instances of cyberbullying. The evolution of these interactions on a specific social network can be summarized using the Eq. (1).

$$S = \{s_1, s_2, ..., s_{|S|}\} \tag{5}$$

In this study, the term S represents the total number of sessions, and "i" denotes the current session being examined. It's important to highlight that the sequence in which submissions occur within a session may change at different points in time, influenced by various complex factors.

$$P_s = \left(\left\langle P_1^S, t_1^S \right\rangle, \left\langle P_2^S, t_2^S \right\rangle, ..., \left\langle P_n^S, t_n^S \right\rangle\right) \tag{6}$$

In this study, the tuple represented by "P" stands for the kth post within the social network session, with "s" indicating the timestamp marking the exact moment when post P was distributed. Additionally, a unique set of attributes is utilized to unmistakably identify each post.

$$P_k^S = \left[f_{k_1}^S, f_{k_2}^S, ..., f_{k_n}^S\right], k \in [1, n] \tag{7}$$

Therefore, the main objective of this undertaking is to gather the necessary insights, facilitating the creation of a function labeled as "f," which is capable of identifying the relationship between a particular text and the existence of hate speech.

Evaluation metrics play a pivotal role in assessing the efficacy of algorithms in classifying instances within the cyberbullying classification dataset. Confusion matrices, as depicted in Fig. 3, serve as essential tools for visualizing the outcomes of these classification techniques, providing a clear representation of the distribution of classification results across different classes. Through the utilization of confusion matrices, researchers can discern true positive, true negative, false positive, and false negative predictions, facilitating a comprehensive understanding of the model's performance in distinguishing between cyberbullying and non-cyberbullying instances. These evaluations are crucial for refining and optimizing cyberbullying detection algorithms to improve their accuracy and reliability in addressing the critical issue of online harassment and bullying. By employing rigorous evaluation measures such as confusion matrices, researchers can enhance the effectiveness of cyberbullying detection systems, thereby contributing to the development of more robust solutions for mitigating online abuse and fostering safer online environments.

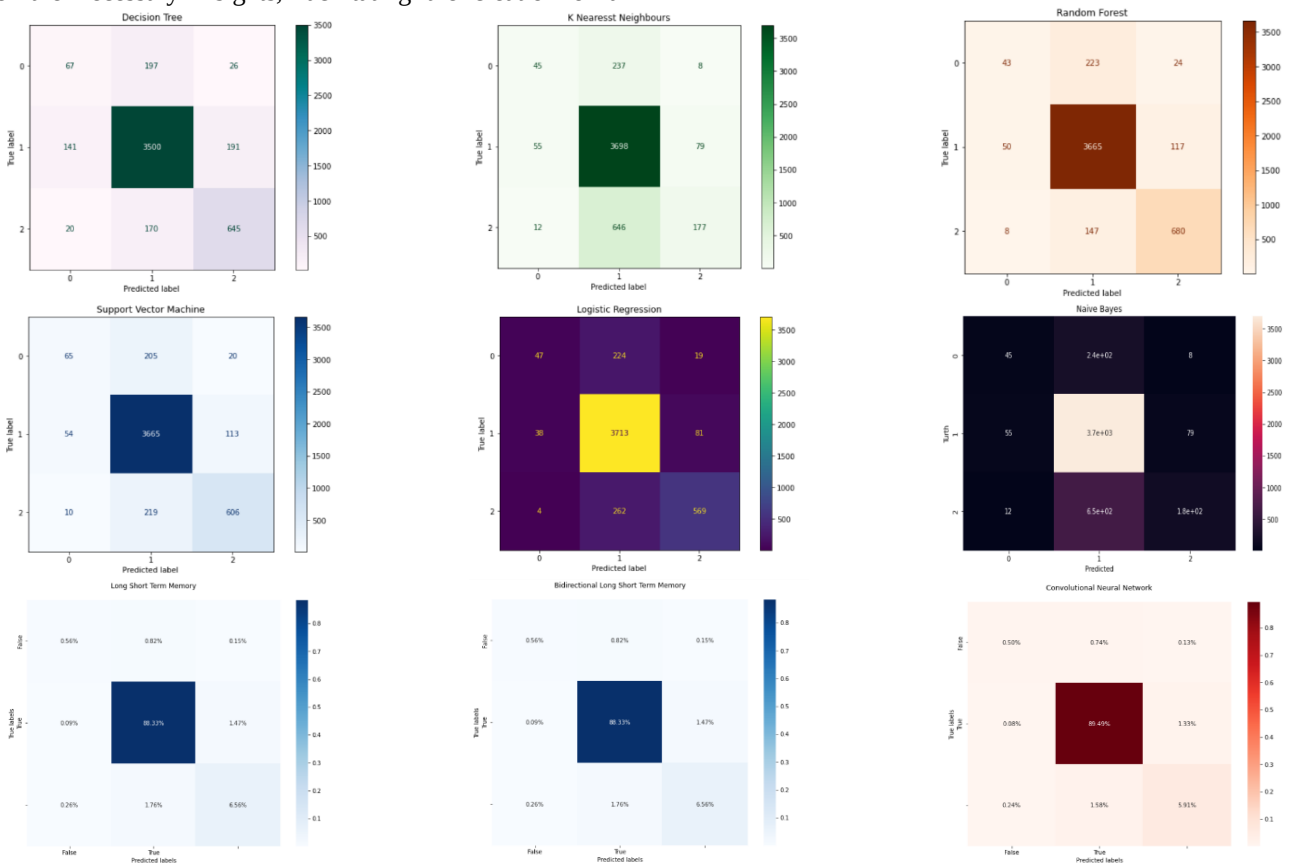

Fig. 3. Confusion matrix for cyberbullying detection.

Fig. 4 presents a comparative analysis between the proposed model and a spectrum of machine learning and deep learning models employed in this study. Performance evaluation in each classification scenario is conducted through computation of the Area Under the Receiver Operating Characteristic Curve (AUC-ROC), incorporating all extracted features. This method facilitates a comprehensive assessment of the discriminative capability and effectiveness of the

proposed model in comparison to alternative methodologies, thereby providing valuable insights into its performance across various classification tasks. The utilization of AUC-ROC as an evaluation metric ensures a robust examination of the model's ability to discriminate between classes and its overall effectiveness in classification tasks. These findings contribute to the growing body of knowledge on the efficacy of deep learning paradigms in enhancing classification performance, emphasizing the significance of rigorous evaluation methods in assessing the suitability and reliability of models in real-world applications.

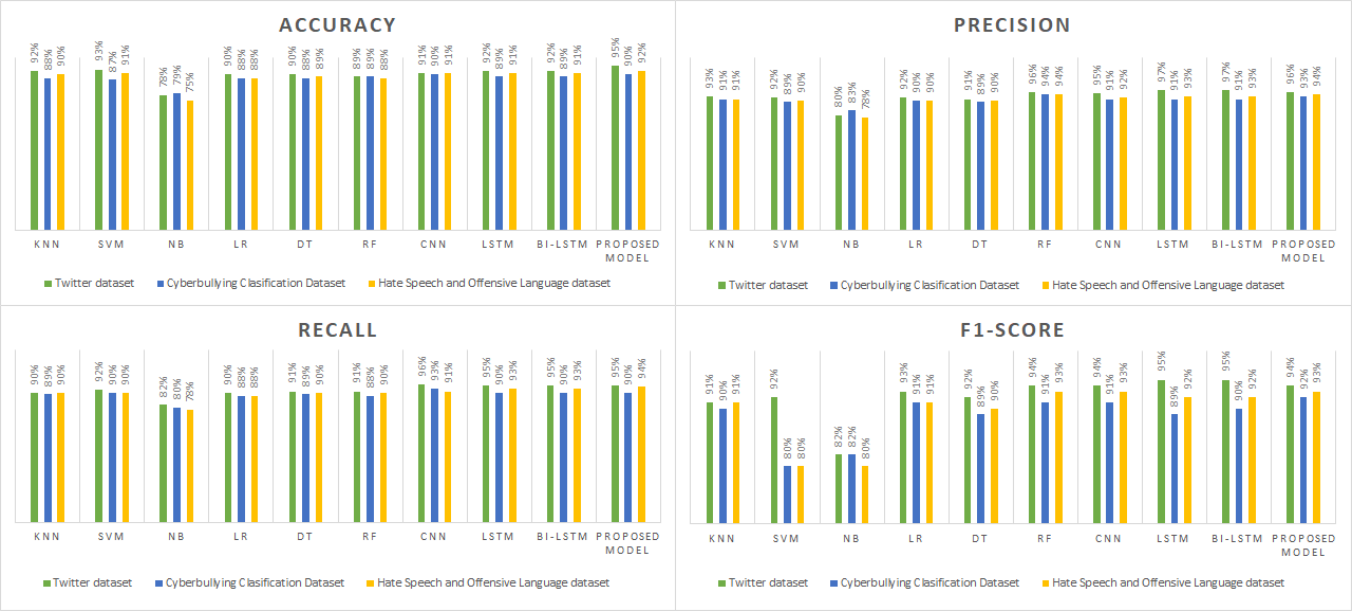

Fig. 4. Results in cyberbullying detection.

These results emphasize the effectiveness and strength of the BiLSTM-based model in accurately distinguishing and categorizing the target classes, further validating the value of deep learning approaches within the scope of the research.

V. Discussion

The emergence of social networking platforms has facilitated unprecedented levels of communication and interaction among individuals worldwide. However, alongside the benefits of these platforms come challenges, particularly concerning the prevalence of cyberbullying—a phenomenon characterized by the use of electronic communication to intimidate, harass, or harm others. As cyberbullying continues to pose significant risks to individuals' mental health and well-being, there is an urgent need for effective detection and mitigation strategies. This research paper explores the application of machine learning and deep learning techniques in addressing the cyberbullying detection problem, aiming to enhance the accuracy and efficiency of detection methods.

The findings of this study highlight the efficacy of machine learning and deep learning approaches in identifying instances of cyberbullying within social networking platforms. By employing various algorithms such as Support Vector Machines (SVMs), Random Forests, Convolutional Neural Networks (CNNs), and Bidirectional Long Short-Term Memory Networks (BiLSTMs), the researchers demonstrate the potential of these techniques in discriminating between cyberbullying and non-cyberbullying content. The comparative analysis presented in this paper showcases the performance of these models across different classification scenarios, with the Area Under the Receiver Operating Characteristic Curve (AUC-ROC) serving as the evaluation metric.

One of the key insights derived from this study is the significance of evaluation measures, particularly confusion matrices, in assessing the effectiveness of cyberbullying detection algorithms. As depicted in Fig. 3, confusion matrices provide valuable insights into the distribution of classification results, enabling researchers to identify true positive, true negative, false positive, and false negative predictions. This comprehensive understanding of the model's performance is essential for refining and optimizing detection algorithms, ultimately enhancing their accuracy and reliability in addressing the critical issue of online harassment and bullying.

Furthermore, the results indicate that deep learning models, such as BiLSTMs, exhibit superior performance compared to traditional machine learning algorithms in cyberbullying detection tasks. The ability of BiLSTMs to capture temporal dependencies in textual data makes them well-suited for analyzing social media interactions, where the context and dynamics of communication play a crucial role. By leveraging the sequential nature of text data, BiLSTMs demonstrate enhanced discriminatory power and effectiveness in distinguishing between cyberbullying and non-cyberbullying content.

It is important to acknowledge the limitations and challenges associated with cyberbullying detection, despite the promising results obtained in this study. The dynamic and evolving nature of online interactions presents complexities in accurately identifying instances of cyberbullying, particularly given the nuanced and context-dependent nature of language.

Additionally, the prevalence of adversarial behaviors and disguised forms of cyberbullying further complicates detection efforts, necessitating ongoing research and development of robust detection mechanisms.

Moreover, the ethical considerations surrounding cyberbullying detection algorithms warrant careful attention. While the primary goal is to mitigate harm and promote safety in online environments, there is a risk of infringing on individuals' privacy and freedom of expression. It is imperative for researchers and practitioners to strike a balance between effective detection and protection of users' rights and liberties. Transparent and accountable decision-making processes, along with mechanisms for user consent and data protection, are essential aspects of ethical cyberbullying detection practices.

Looking ahead, future research directions in cyberbullying detection could focus on incorporating multimodal data sources and advanced natural language processing techniques. By integrating information from text, images, and videos, detection systems can gain a more comprehensive understanding of online interactions and detect cyberbullying across diverse media formats. Additionally, exploring techniques for explainable AI and interpretability in machine learning models can enhance the transparency and trustworthiness of detection systems, enabling users to understand and interpret the decisions made by these algorithms.

In conclusion, this research contributes to the growing body of knowledge on cyberbullying detection by leveraging machine learning and deep learning techniques. The findings underscore the potential of these approaches in effectively identifying instances of cyberbullying within social networking platforms, while also highlighting the importance of rigorous evaluation measures and ethical considerations in the development and deployment of detection systems. Moving forward, continued research and innovation in this field are essential for addressing the complex challenges posed by cyberbullying and promoting a safer online environment for all users.

VI. Conclusion

In conclusion, this research paper has navigated the multifaceted landscape of cyberbullying detection on social media, addressing the persistent challenge of online harassment. Through a comprehensive exploration of data collection, feature engineering, machine learning model selection, and evaluation metrics, we have provided valuable insights into the development and assessment of effective cyberbullying detection systems. The critical role of feature engineering and the selection of discriminative features has been emphasized, underscoring their impact on model performance. The versatility of supervised machine learning techniques, including Support Vector Machines, Naïve Bayes, Decision Trees, and others, has been showcased, exemplifying their relevance in the realm of cyberbullying detection. Furthermore, the significance of robust evaluation metrics such as accuracy, precision, recall, F1-score, and AUC-ROC has been elucidated, offering a quantitative framework for assessing model effectiveness. This research contributes to the ongoing efforts to mitigate cyberbullying, providing a foundation for the development of more reliable and efficient detection mechanisms that foster safer online environments.

Quantum-Enhanced Security Advances for Cloud Computing Environments

Devulapally Swetha[1], Dr.Shaik Khaja Mohiddin[2]
Research Scholar, Department of Computer Science & Engineering, Koneru Lakshmaiah Education Foundation, Vaddeswaram, Guntur, Andhra Pradesh, India[1]
Associate Professor, Department of CSE, Koneru Lakshmaiah Education Foundation, Vaddeswaram, Guntur, Andhra Pradesh, India[2]

***Abstract*—Recent developments in quantum-enhanced security have demonstrated encouraging promise for enhancing cloud computing environments' security. Utilizing quantum physics, in particular Quantum Key Distribution (QKD), provides a new method for generating cryptographic keys and improves cloud data transport security. The present study offers a thorough investigation of the integration of QKD with conventional encryption techniques, including Advanced Encryption Standard (AES), in order to tackle the dynamic cyber security scenario in cloud computing. The approach entails combining AES for encryption and decryption procedures and establishing a QKD layer within the cloud architecture to produce true quantum keys utilizing Quantum in Cloud technology. Data transmission security is greatly improved by the smooth integration of AES with QKD-generated keys, guaranteeing confidentiality, integrity, and authenticity. In addition, strong key management practices are put in place to handle cryptographic keys safely at every stage of their lifespan, reducing the possibility of unwanted access or interception. The suggested approach successfully addresses the difficulties presented by cyber threats by offering a robust and flexible means of enhancing security in cloud-based systems. Using both traditional and quantum encryption methods, this strategy provides a strong barrier against cyber-attacks, data leaks, and other security flaws. After 70 simulation rounds, the suggested strategy, which is implemented using the QKD-AES framework in Python software, achieved a data access rate of 820 MB/s. In addition to providing an accurate and quantitative assessment of the performance, this also exhibits a high data access rate attained under simulated conditions. At 15 milliseconds, the key generation time was achieved with efficiency, guaranteeing the quick creation of secure cryptographic keys in cloud environments. Overall, there is a lot of potential in using quantum-enhanced security techniques to protect sensitive data and guarantee the integrity of cloud computing infrastructures.**

Keywords*—Quantum-enhanced security; cloud computing; quantum key distribution; advanced encryption standard; key management

I. INTRODUCTION

The process that organizations and people access and manage computer resources has been completely transformed by cloud computing. Essentially, it is the provision of computer services via the internet, enabling customers to access storage, processing power, and applications without requiring equipment to be located on-site. Platform as a Service (PaaS), Software as a Service (SaaS), and Infrastructure as a Service (IaaS) are just a few of the services that cloud environments offer to meet different requirements and preferences when it comes to computing. Because of cloud computing's scalability, flexibility, and affordability, it is becoming a popular option for businesses looking to innovate and streamline their IT operations [1]. Cloud computing offers on-demand self-service, wide network connectivity, and resource pooling, enabling economies of scale and productivity gains by allowing multiple individuals to access and utilize computer resources from various devices and locations [2]. Rapid elasticity also makes it possible to scale cloud resources up or down fast in response to shifting needs, guaranteeing peak performance and economical effectiveness. Finally, through pay-per-use payment methods, metered services enable customers to monitor and regulate their resource utilization, therefore promoting accountability and transparency [3].

Cloud computing systems may be set up in a variety of ways to suit users' unique requirements and preferences. Third-party service providers own and run public clouds, which make computer resources available to anyone who wants to use them over the internet. On the other side, private clouds are more expensive but provide more control, individualization, and security because they are exclusive to a particular business. Hybrid clouds allow companies to benefit from the scalability and cost of public clouds while maintaining encryption and private cloud settings for sensitive data and apps [4]. In order to minimize risks associated with depending on a single cloud provider, avoid vendor lock-in, and enhance performance, multi-cloud methods employ many cloud providers. Numerous advantages of cloud computing have led to its broad acceptance in a variety of sectors. The main factor is cost savings since cloud services offer pay-as-you-go pricing structures that match costs to real usage, negating the need for upfront capital expenditures in hardware and infrastructure [5]. Organizations can quickly adjust their IT resources to accommodate changing demands, such as seasonal swings or unexpected increases in traffic, thanks to scalability and flexibility. Furthermore, by giving developers and companies access to state-of-the-art tools and technologies, cloud computing fosters creativity and cooperation by enabling them to test ideas and make adjustments faster. Through the use of globally distributed data centers and redundant infrastructure, enhanced dependability and disaster recovery abilities guarantee business continuity by reducing the effect of outages and interruptions[6].

Cloud computing has many advantages, but it also poses special security risks that need to be resolved in order to

guarantee the privacy, availability, and integrity of information and applications. Clear rules and processes are required to successfully manage security threats, since shared responsibility models outline the security duties of cloud service providers and their clients [7]. Cloud computing security issues involve data loss, illegal access, and breaches, particularly in multi-tenant setups. Compliance with industry rules and data protection legislation complicates security operations. Encryption is crucial for securing sensitive information in transit [8]. By limiting user involvement in resources in accordance with pre-established regulations, access control techniques reduce the possibility of insider threats and illegal access. Frequent audits and vulnerability evaluations assist in locating and fixing security flaws before malevolent actors may take advantage of them. Furthermore, strong authentication systems, such multi-factor authentication, increase access restrictions and lower the possibility of unwanted access and credential theft.

New methods and technologies are being developed to improve security in cloud computing systems as the threat landscape changes[9]. Continuous threat mitigation and incident response are made possible by the real-time detection and reaction to security risks made possible by artificial intelligence and machine learning. Cloud-native apps benefit from increased isolation and security provided by containerization and micro services designs, which lessen the effect of security lapses and vulnerabilities. Furthermore, by including security into the software development lifecycle, DevSecOps methods encourage cooperation and security awareness among the development, operations, and security teams [10]. Cloud computing is well-positioned to keep developing to satisfy customers' ever-changing demands. By bringing computer resources closer to end users, edge computing claims to lower latency and boost performance for applications that are sensitive to latency. With server less computing, infrastructure administration is abstracted away, freeing developers to concentrate on developing code rather than setting up or maintaining servers [11]. Furthermore, the use of quantum computing has the potential to completely transform cloud computing by making it possible to do intricate computations and cryptographic jobs that are not possible with traditional computing. In order to be competitive and safe in an increasingly digital environment, it will be imperative for enterprises to stay up to date with new developments and innovations as cloud computing continues to develop.

The proposed framework is chosen to address critical security flaws in cloud computing environments, specifically focusing on securing data processing, transmission, and storage while preventing unauthorized intrusions. Traditional cryptography methods, though widely used, are increasingly vulnerable to quantum computing attacks. Thus, there is a pressing need to explore innovative solutions that harness quantum-enhanced security measures. Integrating Quantum Key Distribution (QKD) with conventional encryption techniques like AES establishes a layered defense mechanism. This approach utilizes quantum mechanics to generate robust cryptographic keys, significantly bolstering encryption against potential breaches and ensuring the confidentiality, integrity, and authenticity of cloud-stored and transmitted data. However, existing frameworks have encountered substantial challenges, including high computational overhead and scalability limitations. These limitations hinder the efficient implementation of quantum-enhanced security measures in cloud systems. Therefore, the research aims to overcome these obstacles by refining the integration of QKD with AES to achieve optimal performance and scalability in real-world cloud computing environments.

The suggested method's principal contributions are as follows:

- Designing and implementing a robust framework that seamlessly integrates QKD protocols into cloud infrastructures. This entails researching and developing novel methods to overcome existing challenges such as scalability, efficiency, and practical deployment issues.
- During the development phase, QKD algorithms will be modified to meet the specific needs and limitations of cloud computing environments. This will guarantee compatibility with current cloud infrastructures while upholding strong security standards. Comprehensive testing and validation will also be a part of the integration process to confirm the dependability and efficacy of the QKD-based secure data transmission solution in cloud settings.
- Ultimately, the goal is to establish a resilient and scalable system capable of providing end-to-end encryption for data transmission in cloud computing environments, bolstering security and confidentiality against potential threats.
- Integrating QKD with AES to ensure secure data transmission within cloud computing environments, addressing concerns of secrecy, integrity, and authenticity.

The subsequent portions of the study are organized as follows: In Section II, a comprehensive review of prior studies is presented. Section III looks at the suggested course of action, while Section IV provides a comprehensive analysis of the issue description. The results and a thorough discussion of the conclusions are presented in Section V. The paper's concluding concepts are summarized in Section VI.

II. Related Works

In order to deal with the risks brought about by the combination of block chain technology, cloud computing, and the approaching age of quantum computing, the research suggests a thorough security architecture for block chain systems that are based in the cloud. The framework strengthens data against quantum attacks and improves privacy and verification procedures by integrating QKD, CRYSTALS-Kyber lattice-based encryption, and Zero-Knowledge Proofs. The framework proves its practicality in practical applications cloud environments through a thorough assessment of performance that includes studies of encryption procedures, quantum key generation inflation and system effectiveness. Though the suggested system provides a great deal of progress toward quantum-safe security for block chain storage in the cloud, it is not without drawbacks. To completely fulfill the system's prospective in tackling increasing security risks in cloud computing settings, more research and improvement are

needed to address feasible scaling, integration complexities, and efficiency decisions [12].

In order to solve the urgent issues with data security and secrecy in cloud computing settings, the paper presents a cloud security model based on quantum cryptography. The model enhances the security of data kept and exchanged in the cloud by facilitating the safe distribution of secret keys between parties through the utilization of the Quantum Key Distribution Protocol. By guaranteeing that only authorized users possessing the proper decryption keys may access the data via a secure quantum channel, attribute-based encryption helps data owners feel safer about the security of their shared information. The findings show that the suggested paradigm outperforms current methods in terms of security and efficiency, allowing private data exchange between organizations in cloud frameworks with the least amount of delay. It is imperative to acknowledge that although the QC-CSM exhibits potential for augmenting cloud security, practical implementation obstacles may arise, such as the intricacy of quantum cryptography protocols and possible scalability concerns. Therefore, additional exploration and improvement are necessary to fully actualize the efficacy of the QC-CSM in authentic cloud environments [13].

In order to solve issues with scalability and security in cloud computing settings, the article provides a revolutionary Scalable and Secure Cloud Architecture that incorporates IoT devices with cryptographic algorithms. In order to effectively manage user requests, the design takes a decentralized approach, leveraging many cloud nodes. The Multicast and Broadcast Rekeying Algorithm is incorporated to maintain anonymity and secrecy. By utilizing a hybrid cryptosystem that blends block chain, post-quantum cryptography, and MBRA, the SSCA hopes to create reliable and scalable cloud systems that can support many users' access to cloud resources. The architecture guarantees the security of information gathered by utilizing strong encryption techniques and distributed IoT sensing resources, while the block chain assures that the information is stored in distributed and unchangeable records. The SSCA may encounter challenges in real-world application despite its intriguing methodology and proven efficacy in decreasing response time and enhancing metrics including AUC values in comparison to current models. These restrictions could include difficulties with the intricacy of combining cryptography methods with Internet of Things devices, as well as possible scalability problems when implementing the architecture in large-scale cloud systems. To overcome these obstacles and effectively utilize the SSCA in practical cloud computing applications, more research and development are required[14].

The paper suggests a lattice-based authentication system for public cloud computing in order to mitigate the risks presented by both conventional security assaults and the developments in quantum computing. In the era of quantum computing, conventional authentication systems that depend on factorization or discrete logarithm issues become susceptible. The suggested strategy seeks to thwart known conventional security risks while withstanding quantum assaults. The Real-Or-Random model's provably secure authentication procedure is based on the lattice approach. Comparing the protocol to other lattice-based authentication protocols, experimental findings show that it is lightweight, indicating that it might be used in real-world quantum contexts. Though the protocol appears promising, practical implementation may encounter obstacles such compatibility problems with current systems, scalability problems, and possible compromises in performance. To overcome these obstacles and guarantee the efficacy and workability of the suggested authentication protocol in various cloud computing contexts, more investigation and verification are required [15].

The goal of the project is to improve the security and performance of cloud computing systems by addressing the urgent issues related to intrusion detection. Although cloud computing systems have many advantages, they are vulnerable to a number of security risks, such as invasions and privacy violations. These worries are made worse by the emergence of quantum computing assaults, which makes the installation of efficient intrusion detection systems necessary. The study aims to accomplish two goals: an analysis of the current IDS constraints and the presentation of an accuracy enhancement approach. Experiments comparing the efficacy of EICDL with state-of-the-art machine learning techniques and current intrusion detection systems reveal an important enhancement in intrusion detection accuracy. Challenges may include issues with scalability, real-world implementation, and adaptation to changing threats, despite its encouraging findings. To overcome these obstacles and guarantee the viability and efficacy of the suggested intrusion detection technique across a range of cloud computing contexts, more investigation and verification are required [16].

III. Problem Statement

The current issue revolves around the pressing need to resolve security flaws in cloud computing environments, particularly with regard to data protection during processing, transmission, and storage as well as the identification and prevention of illegal intrusions. Despite being widely used, traditional cryptography techniques are vulnerable to attacks from quantum computing. It is critical to investigate novel approaches that make use of quantum-enhanced security measures in order to mitigate these dangers. Through the integration of QKD with conventional encryption techniques such as AES, the research can create a multi-tiered defensive framework that secures data transfer in cloud computing settings. This approach leverages the unique properties of quantum mechanics to generate secure cryptographic keys, thereby fortifying the encryption process against potential breaches and ensuring the confidentiality, integrity, and authenticity of data stored and transmitted within cloud infrastructures. Nevertheless, previous endeavours have encountered significant hurdles, such as excessive computational overhead and scalability limitations[17]. Therefore, more research is needed to overcome these obstacles and implement quantum-enhanced security measures in cloud systems in an efficient manner. The proposed framework addresses these limitations by leveraging quantum-enhanced security measures, thus offering a promising avenue for securing cloud computing infrastructures against current and future cybersecurity threats.

IV. Proposed Quantum Key Distribution (QKD) Integration for Secure Data Transmission in Cloud Computing Environments

The methodology for integrating QKD with AES in cloud computing environments involves several key steps to ensure the seamless and secure transmission of data. Firstly, the implementation of the QKD protocol is essential for generating secure cryptographic keys using quantum principles. This involves setting up a QKD layer within the cloud infrastructure, employing Quantum in Cloud technology to generate genuine quantum keys utilizing quantum devices. The keys produced are then managed by key servers situated in the key management layer, ensuring their security and integrity throughout their lifespan. Simultaneously, the traditional encryption method AES is integrated into the system. AES serves as a symmetric encryption technique renowned for its effectiveness and strength in cryptography. The secure keys generated by the QKD protocol are utilized alongside AES for data encryption and decryption processes. The integration process involves encrypting the data using AES with the secure keys generated by QKD before transmission. This ensures that even if an adversary manages to intercept the data, they would be unable to decrypt it without the corresponding decryption key. Overall, the integration of QKD with AES provides a comprehensive solution for enhancing security in cloud-based environments. By leveraging both quantum and conventional encryption techniques, the system addresses the challenges of secrecy, integrity, and authenticity in data transmission within cloud infrastructures and the overall concept is depicted in Fig. 1.

A. Dataset Collection

The dataset presented above is derived from the Cloud Computing Workloads Dataset available on Kaggle [18]. It has been modified and adapted for the purpose of this study on evaluating the performance of an integrated Quantum Key Distribution (QKD) with the Advanced Encryption Standard (AES) framework in a cloud computing environment. The dataset provides insights into the performance of your integrated QKD-AES framework in terms of encryption and decryption times, quantum key characteristics, storage utilization, and security enhancements achieved. Utilize this information to assess how well your strategy works to improve cloud computing environments' data transmission security. Adjust the content and parameters according to the specific details and findings of the study. It is illustrated in the Table I.

B. Quantum Key Distribution (QKD) and BB84 Protocol

Using the ideas of quantum physics, QKD is a novel approach to cryptography that creates safe cryptographic keys between participants in communication. In contrast to traditional cryptography techniques that depend on mathematical intricacy to provide security, QKD leverages the intrinsic characteristics of quantum systems to attain absolute security. Heisenberg's uncertainty principle, which captures the idea of quantum indeterminacy, is the fundamental idea of QKD. According to this concept, it is impossible to measure two physical attributes at the same time with arbitrary accuracy, such as a particle's location and momentum. QKD enables two parties to generate cryptographic keys whose security is ensured by quantum mechanics by encoding information onto quantum states and measuring these features.

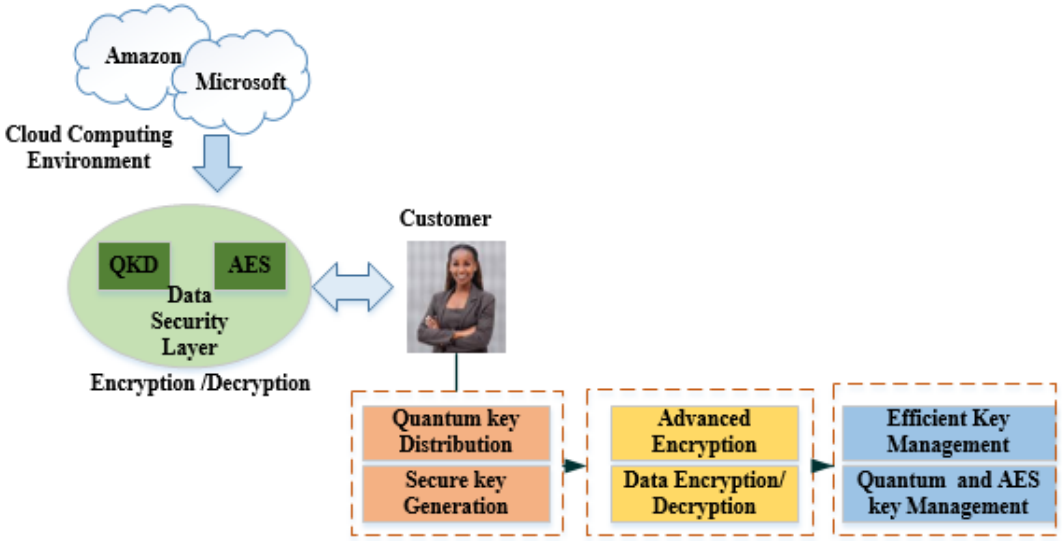

Fig. 1. The conceptual diagram of the proposed model.

TABLE I. Dataset

File Type	File Size (MB)	Encryption Algorithm	Encryption Time (ms)	Decryption Time (ms)	Quantum Key Size (bits)	Quantum Key Generation Time (ms)	Storage Utilization (%)	Security Enhancement
Text	10	AES-256	50	60	256	100	70	Yes
Image	5	AES-128	30	40	128	80	65	Yes
Video	100	AES-256	120	150	256	200	75	Yes

Based on quantum physics, quantum cryptography ensures that the qubit used to distribute keys cannot be changed without potentially changing its initial state. Two parties, like Alice and Bob, utilize a quantum channel to exchange bits at random in order to secure their one-time pad communication. The likelihood of detecting an eavesdropping effort by an opponent like Eve is great. The BB84 protocol, so named for its creators, Charles Bennett and Gilles Brassard, who presented it in 1984, is one of the first protocols in QKD.

Quantum states (usually photons) encoded with data in one of two mutually orthogonal bases (rectilinear (Z) basis or diagonal (X) basis) are sent using the BB84 protocol. Every bit is encoded using a basis selected at random by the transmitter, and each measurement basis is selected at random by the recipient. By use of this quantum state communication and measurement procedure, the sender and recipient can build a mutual secret key that is only known to them. The no-cloning theorem, which asserts that an unidentified quantum state can't be precisely replicated, is one of the fundamental principles of quantum mechanics that accounts for the key's security.

The security of the key is maintained because any effort by a third party to intercept or analyze the data being transmitted quantum states will unavoidably cause disruptions that may be identified by authorized parties. Quantum cryptography is made possible via the BB84 protocol, which allows qubits to be transferred across a quantum channel between two parties. However, they also use the risky traditional channel. Polarizations can be used to depict distinct quantum states. The BB84 protocol facilitates secure interaction among Alice and Bob in this way.

- Bob receives an encoded version of the random bit sequence that Alice sent him.
- Bob's job is to receive photons and arbitrarily decode them.
- Everybody compares a few pieces that have the same foundation. If the projected error rate is lower, the test is deemed successful in the procedure.
- After applying mistake correction and privacy amplification to additional bits, Alice and Bob are ultimately able to derive a secret key using those bits.

Table II shows the communication method for safe key distribution using the BB84 protocol. Cloud services are supplied by the cloud layer. Using both conventional and quantum cryptography, the encryption and decryption processes are handled by the cloud data security layer. While quantum cryptography distributes keys in a safe manner, classical cryptography is used to secure data. The generation of quantum keys is handled by the QKD layer. Key servers, which are situated in the key management layer, are responsible for maintaining the created keys. The paradigm of cloud data security is displayed in Fig. 2.

TABLE II. COMMUNICATION METHOD FOR SAFE KEY DISTRIBUTION USING BB84 PROTOCOL

String of Alice	1	1	0	1	0	0	1	0	1	1	1	1	0	0
Alice's basis	+	+	+	x	x	+	x	x	x	x	+	+	+	+
Alice sends	-	-	|	\	/	|	\	/	\	\	-	-	|	|
Bob's basis	+	x	+	+	x	+	x	+	x	x	+	+	+	+
string of Bob	1	0	0	1	0	0	1	1	1	1	1	1	0	0
Similar basis?	Y	N	Y	N	Y	Y	Y	N	Y	Y	Y	Y	Y	Y
Bits to hold	1		0		0	0	1		1	1	1	1	0	0
Test	Y		N		N	Y	N		N	N	N	Y	Y	N
Key			0		0		1		1	1	1			0

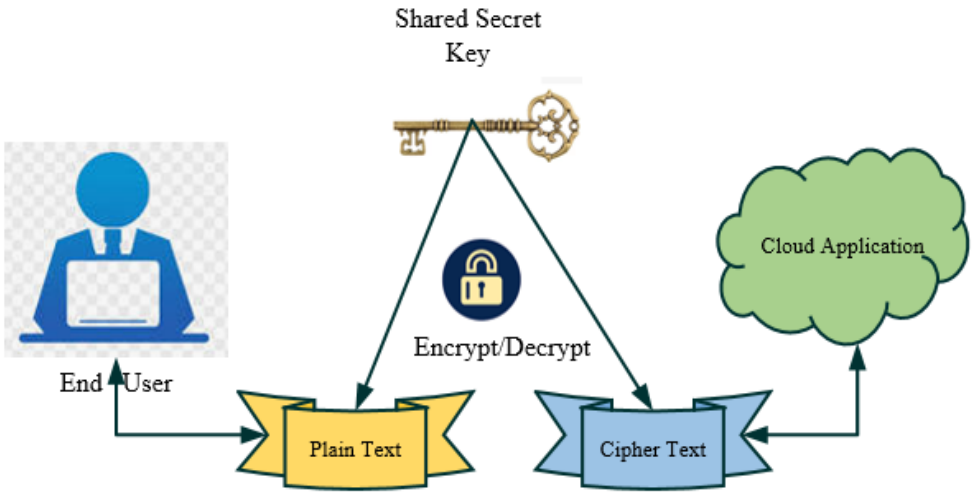

Fig. 2. Model of cloud data security.

C. Integration of Quantum Key Distribution (QKD) with Advanced Encryption Standard (AES)

For data encryption and decryption, the secure key created by the QKD protocol may be used with traditional encryption methods like the AES. Because of its effectiveness and strength in cryptography, AES is a symmetrical encryption method that is often used. A strong and safe solution for data transfer in a variety of programs, including cloud computing settings, is provided by the resultant encryption method, which combines the computing power of AES with the uncompromising security of QKD.

Data transmission security is greatly enhanced by AES after a secure key is created using the QKD technique. Symmetric encryption algorithms like AES are widely recognized for their strong cryptography and computing efficiency. AES offers key sizes of 128 bits, 192 bits, and 256 bits and operates on fixed-size data blocks, which are commonly 128 bits. AES-256 is the most secure option available, making it the first choice for applications that need strong encryption. Multiple iterations of substitution and permutation operations are used in the substitution-permutation network (SPN) structure used by AES-256 [19]. AES-256 performs a number of modifications on data blocks during encryption, such as adding round keys, moving rows, combining columns, and substituting bytes. The key expansion procedure in AES-256 takes the original encryption key and creates a collection of round keys. In order to determine round keys for every encryption round, a key schedule method must be used recursively. The key scheduling technique improves security against cryptographic attacks by creating round keys with no relevance to the original key using a mix of substitution and permutation operations. Because of its complicated encryption algorithm and big key size, AES-256 provides an excellent degree of security. Because of the large key space provided by the 256-bit key length, brute-force assaults are computationally impractical with present technology.

Furthermore, AES-256's resilience to thorough cryptanalysis and examination by security professionals confirms its potency as a cryptographic primitive. AES-256 encryption can also be used to reduce the dangers of illegal access and interception in data storage systems, secure communication routes, and authentication systems. After the cryptographic keys are safely dispersed by QKD, the data is encrypted before to transmission and decrypted upon arrival using AES. By doing this, the communication route is further secured, making it impossible for an opponent to decode the data even if they managed to intercept it and get the matching decryption key. QKD's smooth integration with AES fits very well with the cloud computing environment, where privacy of information is critical. In conjunction with the QKD protocol, AES is the encryption technique that makes it possible for data to be sent securely inside cloud infrastructures. The merging of quantum and conventional encryption techniques improves security while guaranteeing compatibility with current cloud systems and protocols. Our framework offers a strong and adaptable way to secure data transfer in cloud-based environments by utilizing both QKD and AES.

To keep the systems cryptographic keys secure and intact, effective key management procedures are necessary. The AES keys used for encrypting information and the quantum keys produced by QKD are both managed by the key managing layer in our architecture. This covers operations like generating, distributing, storing, and revoking keys. We guarantee that cryptographic keys are safely handled throughout their lifespan by putting into practice effective key management procedures, which makes secure data transfer possible in cloud computing settings.

$$\text{Encrypted Data} = AES_{K_{QKD}}(\text{Data})$$

K_{QKD} This represents the secure key generated using the QKD protocol. QKD ensures that the key is distributed securely between the sender and receiver, leveraging the principles of quantum mechanics to detect any eavesdropping attempts, $AES_{K_{QKD}}$ This denotes the AES encryption algorithm using the key K_{QKD}The subscript indicates that the specific key used for AES encryption is the one generated by the QKD protocol. This is the plaintext data that needs to be securely transmitted. This is the output of the AES encryption process, where the data has been encrypted using the AES algorithm and the secure key provided by QKD.

The process involves:

- Key Generation: The QKD protocol is used to generate and distribute a symmetric key securely between the sender and receiver.
- Encryption: The sender encrypts the plaintext data using the AES algorithm with the QKD-generated key K_{QKD}.
- Transmission: The encrypted data is transmitted over the communication channel.
- Decryption: Upon receiving the encrypted data, the receiver uses the same QKD-generated key K_{QKD} with the AES algorithm to decrypt the data back into plaintext.

The suggested approach provides a complete answer for improving safety in cloud-based environments by fusing AES and QKD. The integration of quantum and conventional encryption techniques offers a resilient and expandable solution for ensuring safe data transfer, effectively tackling the issues of secrecy, integrity, and legitimacy in cloud computing settings. This technique uses the computing power of AES and the unique properties of quantum mechanics provided by QKD to secure the confidentiality and integrity of data sent inside cloud infrastructures.

D. Analysis of AES-256 and AES-128 Encryption Algorithms Across Various File Types

The methodology involves a comprehensive performance analysis of AES-256 and AES-128 encryption algorithms across different file types, namely text, image, and video. The study evaluates key parameters such as encryption time, decryption time, quantum key generation time, and storage utilization. For each file type, the encryption and decryption processes were timed, and the storage utilization was measured to determine the efficiency of each algorithm. Additionally, the time required for quantum key generation was recorded to assess its impact on the

overall performance. The results were systematically compared, revealing that AES-128 consistently provides faster encryption and decryption times, quicker quantum key generation, and lower storage utilization compared to AES-256. This analysis highlights the trade-offs between the stronger security offered by AES-256, due to its larger key size, and the superior speed and resource efficiency of AES-128. These findings guide the selection of the appropriate encryption algorithm based on specific application requirements, emphasizing a balance between security, processing speed, and resource management.

V. Results and Discussion

The results section begins by offering a comprehensive understanding of network operational dynamics and the comparative efficacy of encryption algorithms. This is achieved through an in-depth analysis of empirical findings and conclusions derived from the examination of key performance indicators. Employing a device equipped with the Windows 10 operating system and utilizing Python programming language facilitates the exploration of these aspects within the study. The findings of the study underscore the efficacy of integrating Quantum Key Distribution (QKD) with the Advanced Encryption Standard (AES) to bolster security in cloud computing environments. Through comprehensive simulations and empirical analysis, the research demonstrates significant enhancements in data transmission security, achieving a high data access rate of 820 MB/s under simulated conditions. Key findings highlight the efficient generation of cryptographic keys in just 15 milliseconds, validating the practicality and speed of QKD-AES integration. This approach effectively addresses cybersecurity challenges by leveraging both traditional and quantum encryption methods to safeguard against cyber threats and ensure data integrity within cloud infrastructures.

A. Performance Metrics

1) Encryption time: Encryption time is the duration needed to convert plaintext into cipher text using an encryption algorithm. It's influenced by algorithm complexity, data size, and available computational resources. In cloud computing, effective and safe data transfer and storage are ensured by minimizing encryption time. It is represented in Eq. (1) as,

$$ET = t_{encrypt} \quad (1)$$

2) Decryption time: The amount of time needed to use a decryption algorithm to convert cipher text back into plaintext is known as the decryption time. It is affected by variables like the amount of the data, the difficulty of the method, and the processing power available. The decryption time equation is represented in Eq. (2) as

$$DT = t_{decrypt} \quad (2)$$

3) Key generation time: The amount of time required to produce cryptographic keys using a certain cryptographic method or protocol is referred to as key generation time. It is a critical metric in cryptography as it directly impacts the efficiency and performance of cryptographic operations such as encryption and decryption. The Eq. (3) for calculating key generation time can be represented as,

$$Key\ Generation\ Time = \frac{t}{n} \quad (3)$$

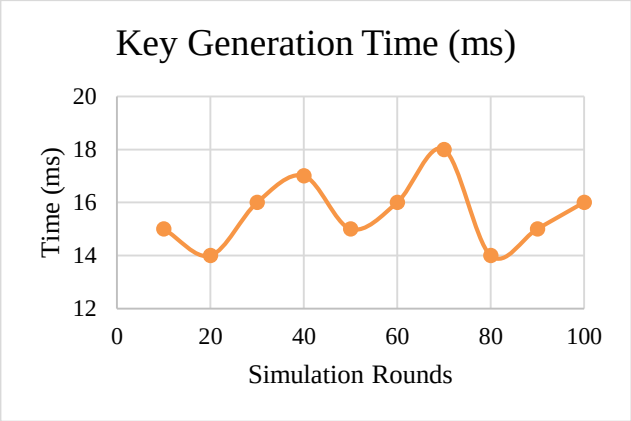

Fig. 3. Key generation time.

Fig. 3 illustrates the key generation time performance of the proposed QKD-AES framework across different simulation rounds. As depicted in the graph, the key generation time remains relatively stable throughout the simulation rounds, with minor fluctuations observed. The average key generation time recorded during the simulations is approximately 15 milliseconds, indicating consistent and efficient key establishment within the cloud infrastructure. This result demonstrates the capability of the QKD-AES framework to generate cryptographic keys promptly, facilitating secure data transmission and encryption processes.

4) Data access rate: The data access rate is the amount of data that is sent and retrieved for each user. This includes the time needed to encrypt, decrypt, and confirm their legitimacy. When such procedures are faster and incorporate more data, they will yield a high access rate. This illustrates the protocol's reliability and stability in the face of high data use. A greater access rate is indicative of efficient processing, meaning that activities are finished quickly and cover a bigger amount of data. This effectiveness highlights the protocol's robustness and dependability even in settings with high data use. Strong data access rates demonstrate the system's capacity to manage large data loads without sacrificing security or performance, in addition to guaranteeing timely access to information.

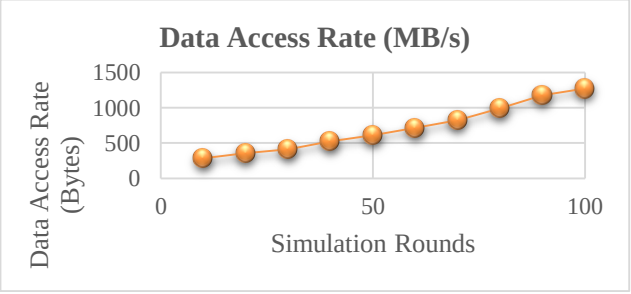

Fig. 4. Data access rate.

The relationship between the Simulation Rounds and the Data Access Rate (Bytes) is seen in Fig. 4. This specific type of graph is used to show how one variable affects another, in this

case, the number of simulation rounds and its effect on the data access rate. If the pattern that has been shown continues, this graph may be used to anticipate data access rates for more simulation rounds than the ones that are shown in a more general analytical setting. It also offers a clear and aesthetically pleasing way to illustrate changes or patterns over a series of occasions or time frames, which makes it appropriate for use in reports or presentations that call for the display of dynamic data linkages.

TABLE III. COMPARISON OF ENCRYPTION METHODS FOR SECURITY IN CLOUD COMPUTING ENVIRONMENTS

Method	Encryption Algorithm	Key Generation	Encryption Time (ms)	Decryption Time (ms)	Storage Utilization (%)	Security Enhancement
RSA[20]	RSA	RSA	50-200	60-250	70-80	No
DES[21]	DES	Manual	40-150	50-200	60-70	No
Proposed (QKD-AES)	AES-256	QKD	30-120	40-150	65-75	Yes

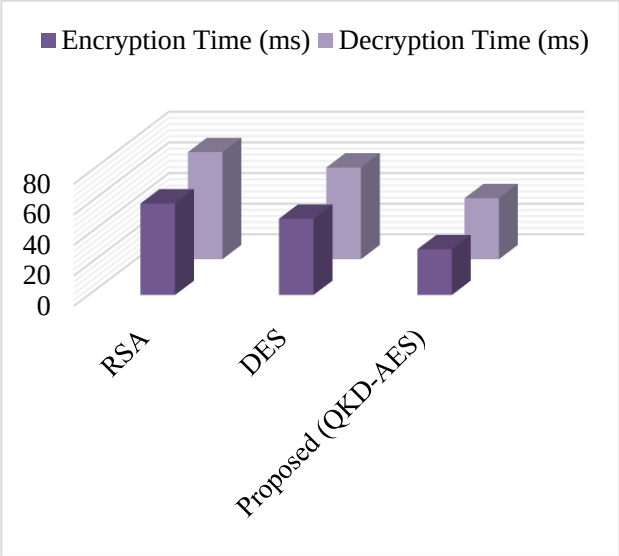

Fig. 5. Comparison of encryption methods with the proposed method.

Table III compares three encryption methods: RSA, DES, and the proposed QKD-AES. While RSA and DES rely on traditional algorithms for key generation, QKD-AES leverages Quantum Key Distribution for enhanced security. The proposed method demonstrates faster encryption and decryption times compared to RSA and DES, with lower storage utilization. Additionally, QKD-AES offers a significant security enhancement, making it a promising solution for safeguarding data in cloud computing environments. It is depicted in Fig. 5.

Table IV show performance metrics analysis .this evaluates encryption and decryption times, quantum key generation times, and storage utilization across different file types encrypted with AES-256 and AES-128 algorithms. AES-128 demonstrates faster encryption and decryption times compared to AES-256 across both text and image files, while AES-256 exhibits longer times, particularly noticeable in video files. AES-128 also shows quicker quantum key generation and lower storage utilization, highlighting its efficiency and suitability for applications prioritizing speed and resource efficiency. AES-256, although potentially offering stronger encryption due to its larger key size, requires more time and storage space, which may impact performance in environments with stringent processing and storage limitations. This analysis underscores the trade-offs between speed, security, and resource utilization in selecting the appropriate encryption algorithm for specific application needs.

TABLE IV. PERFORMANCE METRICS COMPARISON OF ENCRYPTION ALGORITHMS

File Type	Encryption Algorithm	Encryption Time (ms)	Decryption Time (ms)	Quantum Key Generation Time (ms)	Storage Utilization (%)
Text	**AES-256**	**50**	**60**	**100**	**70**
Image	**AES-128**	**30**	**40**	**80**	**65**
Video	**AES-256**	**120**	**150**	**200**	**75**

TABLE V. PERFORMANCE METRICS COMPARISON BETWEEN AES-256 AND AES-128 ENCRYPTION ALGORITHMS

Metric	AES-256	AES-128
Encryption Time (ms)	50, 120	30
Decryption Time (ms)	60, 150	40
Quantum Key Generation Time (ms)	100, 200	80
Storage Utilization (%)	70, 75	65

Table V demonstrates the analysis compares AES-256 and AES-128 encryption algorithms across various metrics crucial for data security and performance in different file types. AES-128 shows superior encryption and decryption speeds, advantageous quantum key generation times, and lower storage utilization, making it favorable for applications prioritizing efficiency and resource conservation. AES-256, while potentially offering stronger encryption due to its larger key size, requires more processing time and storage space, which could impact performance in environments with stringent speed and storage requirements. This comparison underscores the nuanced considerations between AES-256 and AES-128 in choosing the appropriate encryption strategy based on specific application needs, balancing between security, efficiency, and resource management.

B. Discussion

The performance metrics provide valuable insights into the efficiency and effectiveness of the proposed QKD-AES framework. The consistent and efficient key generation time, averaging approximately 15 milliseconds, highlights the framework's capability to swiftly establish cryptographic keys within the cloud infrastructure, thereby facilitating secure data transmission and encryption processes. Moreover, the comparison of encryption methods reveals the superior performance of QKD-AES in terms of encryption and

decryption times emphasizing its potential as a robust solution for enhancing security in cloud computing environments. In addition, the comparison of encryption methods, including RSA, DES, and the proposed QKD-AES framework, highlights the advantages of leveraging Quantum Key Distribution for enhanced security in cloud computing environments. While RSA and DES exhibit certain limitations in terms of key generation time, encryption and decryption times, and storage utilization, the QKD-AES framework demonstrates superior performance across these metrics. These findings underscore the significance of integrating Quantum Key Distribution with Advanced Encryption Standard to achieve a balance between security and efficiency in data protection.

Research plays a pivotal role in impacting communities by advancing knowledge, solving pressing issues, and driving innovation across various fields. It contributes to societal development through the discovery of new technologies, improvement of existing practices, and formulation of evidence-based policies. Research outcomes often lead to practical applications that enhance quality of life, address environmental challenges, and promote economic growth. Moreover, research fosters critical thinking, educates the public, and inspires future generations of scientists and innovators. By bridging gaps in knowledge and promoting collaboration, research positively influences community well-being and helps tackle global challenges in a sustainable manner. To further enhance the security and performance of cloud computing environments, it is recommended to: 1) optimize the integration of QKD with AES for improved scalability; 2) explore post-quantum cryptography methods to counter quantum computing threats; 3) continuously refine key management strategies; and 4) ensure adaptive measures to address evolving cyber threats.

VI. Conclusion and Future Scope

In conclusion, a potential development in enhancing cloud computing environments' security is the combination of QKD with the AES. This comprehensive architecture uses both conventional and quantum encryption techniques to provide a multi-layered security strategy against cyber-attacks. Using AES for encryption and decryption procedures, the technique integrates a QKD layer for safe key generation into the cloud architecture. The suggested technique protects the confidentiality, integrity, and legitimacy of data sent and stored in cloud settings by using efficient key management techniques. Performance metrics such as encryption and decryption time, storage utilization, and security enhancement demonstrate the effectiveness and efficiency of the proposed model. The study's findings emphasize key considerations in integrating Quantum Key Distribution (QKD) with the Advanced Encryption Standard (AES) for enhancing security in cloud computing. Specifically, the research highlights the seamless integration of AES with QKD-generated keys, ensuring confidentiality, integrity, and authenticity in data transmission. By employing robust key management practices, the study addresses vulnerabilities posed by cyber threats, ensuring secure cryptographic key handling throughout their lifecycle. The achieved data access rate of 820 MB/s and efficient key generation time of 15 milliseconds underscore the practicality and efficiency of the QKD-AES framework in real-world cloud environments, demonstrating its potential to significantly elevate cybersecurity standards and protect sensitive data effectively. Looking ahead, the future scope lies in further optimizing the integration of QKD with AES to enhance performance and scalability. Furthermore, studies might investigate the application of post-quantum cryptography methods to strengthen security against any dangers from quantum computing. To reduce risks and adjust to changing cyber threats in cloud computing, it will also be essential to continuously improve critical management strategies and processes. With plenty of room for future development and improvement, the suggested architecture, taken as a whole, provides a strong basis for guaranteeing the security and integrity of data in cloud settings.

Harnessing Machine Learning and Meta-Heuristic Algorithms for Accurate Cooling Load Prediction

Yanfang Zhang
Hebi Institute of Engineering and Technology, Henan Polytechnic University; Hebi Henan, 458000, China

***Abstract*—Precisely calculating the cooling load is essential to improving the energy efficiency of cooling systems, as well as maximizing the performance of chillers and air conditioning controls. Machine learning (ML) has better capabilities in this area than conventional techniques and regression analysis, which are lacking. ML models are capable of automatically recognizing complex patterns that are influenced by various factors, including occupancy, building materials, and weather. They enable responsive predictions that enhance energy optimization and efficient building management because they scale well with data and adapt to changing scenarios. This research acknowledges the difficulties presented by the intricacies of energy optimization while exploring the intricate world of cooling load systems. To solve these issues, in-depth research and creative approaches to problem-solving are needed. The Weevil Damage Optimization Algorithm (WDOA) and the Improved Manta-Ray Foraging Optimizer (IMRFO) are two meta-heuristic algorithms that are seamlessly combined with the Gaussian Process Regression (GPR) model in this study to increase accuracy. Previous stability tests have provided extensive validation for the cooling load data used in these algorithms. The research presents three different models, each of which offers important insights for precise cooling load prediction: GPWD, GPIM, and an independent GPR model. With an RMSE value of 1.004 and an impressive R^2 value of 0.990, the GPWD model stands out as the best performer among these models. The remarkable outcomes demonstrate the outstanding precision of the GPWD model in forecasting the cooling load, highlighting its applicability to actual building management situations.**

Keywords*—Building energy; cooling load; machine learning; Gaussian Process Regression; Improved Manta-Ray Foraging Optimizer; Weevil Damage Optimization Algorithm

I. Introduction

The imperative for energy conservation has garnered significant attention from scholars, given the staggering volumes of energy consumed across diverse applications. A substantial proportion of this energy is attributable to the global building sector, where the effective management of a crucial parameter, cooling load (CL), assumes pivotal importance. The Ventilation and Air Conditioning (HVAC) systems wield the responsibility of regulating these loads, a task heavily reliant on a multifaceted interplay of variables, including building characteristics, utilization patterns, and prevailing climatic conditions [1], [2]. HVAC systems, in addition to managing loads, are engineered to enhance indoor air quality and comfort. Achieving sustainable energy consumption hinges on adopting a judicious approach, such as the rigorous evaluation of energy performance through building energy testing (EPB) and the deployment of sophisticated HVAC models [3].

Presently, global energy consumption levels are alarmingly high, with projections suggesting a continued upward trajectory. This surge is often attributed to humanity's ever-increasing aspirations for improved living standards [4], [5]. Notably, Europe alone accounts for almost 40% of total energy consumption within buildings, underscoring the magnitude of the challenge [6]. In 2013, global energy consumption reached a staggering 12,928.4 million tonnes, with the lion's share supplied by fossil fuels. Just five years prior, in 2008, the world consumed a colossal 474 Exajoules (EJ) of energy, with fossil fuels remaining the primary source [7]. Global electricity consumption experienced a substantial surge of 70% between 1990 and 2008, underscoring the mounting energy demands. Building sector figures are particularly significant, as they constitute approximately 40% of global energy consumption and contribute to 30% of global CO_2 emissions [8].

Due to the severe challenge posed by cooling loads, HVAC systems come to the fore. Typically, sensors and automation technology are harnessed to compute these loads. However, even advanced commercial Building Management Systems (BMS) at times struggle to predict cooling loads with the requisite accuracy. The complexity of this forecasting task is attributable to a web of interconnected factors, including a vast array of appliances and the need for building customization to meet the evolving demands of the population. This confluence of challenges underscores the pressing need for more robust and accurate load forecasting models that can empower engineers and scientists to better evaluate sustainability concerns during the construction phase of buildings [9], [10].

A. Literature Review

Research into HVAC regulations and best practices has brought organizations like ASHRAE to the fore. ASHRAE's core mission revolves around advancing the knowledge and practice of cooling, ventilation, air conditioning, refrigeration, and associated human factors to meet the ever-expanding needs of the public [11]. The HVAC systems, in particular, play a transformative role in regulating the indoor environment, wielding significant influence over a building's overall energy consumption. Thus, the accurate prediction of cooling loads is pivotal in the quest to preserve energy. Researchers have embarked on substantial efforts to forecast the cooling loads of buildings. Their pursuit has culminated in the deployment of diverse machine learning (ML) algorithms that have proven to be effective in predicting these loads. For instance, Deb et al. [12] successfully employed artificial neural networks (ANN), which are particularly useful when dealing with nonlinear patterns that elude conventional analysis. Similarly, Khayatian et al. [13] harnessed ANN to forecast energy performance,

exemplifying the versatility and adaptability of this approach. In tandem, Moradzadeh et al. [14] contribute to the field by predicting heating and cooling loads with Support Vector Regression (SVR) and Multilayer Perceptron (MLP) models. Notably, the MLP method achieves an outstanding R-value of 0.9993 in predicting Heating Load. This research introduces an advanced methodology that utilizes artificial neural networks and ML applications, specifically MLP and SVR techniques, for forecasting heat and cool loads and optimizing the consumption of energy in residential buildings. These technological strides collectively affirm the transformative potential of advanced computational methods in elevating the precision and efficiency of predictions the energy consumption of residential building.

The application of ML in predicting cooling loads has opened up a realm of possibilities for enhancing energy efficiency in the building sector [15]. ML can sift through vast datasets, identify intricate patterns, and optimize HVAC system operations [16]. Through continuous learning and adaptation, these algorithms can adapt to changing building dynamics, further enhancing energy conservation efforts [17]. One notable advantage of ML is its ability to account for nonlinear relationships and complex interactions among variables. Traditional methods of load prediction often struggle with these complexities, leading to less accurate results [18].

Furthermore, ML models can continually refine their predictions as new data becomes available. This adaptability ensures that the HVAC system's performance remains optimized over time, even as building usage patterns and climate conditions evolve [19], [20]. The use of ML, such as artificial neural networks, offers a sophisticated approach to optimizing HVAC system operations, ultimately reducing energy consumption and environmental impact. As global energy consumption continues to rise, innovative solutions like ML must be embraced to mitigate the environmental footprint of the building sector and ensure a more sustainable future [21].

The primary aim is to forecast the cooling load of buildings utilization real-world dataset accurately that demonstrates energy usage patterns. Gaussian Process Regression (GPR) is employed as a simulation method to achieve this objective. To improve the efficiency of the GPR model, the Improved Manta-Ray Foraging Optimizer (IMRFO) and Weevil Damage Optimization Algorithm (WDOA) are chosen as hybrid models due to their unique advantages. These meta-heuristic algorithms are designed to optimize the GPR hyperparameters. Also, a perfect statistical analysis is carried out to assess the accuracy and reliability of each optimizer. The main goal of this research is to anticipate the cooling load demand of buildings precisely by combining sophisticated optimization algorithms with GPR. The selection of IMRFO and WDOA further enhances the effectiveness of the model as optimizers. Through a robust statistical analysis and the use of diverse performance metrics, this study aims to provide accurate and reliable predictions while enabling a comprehensive evaluation of the chosen optimizers' performance.

The research examines how integrating machine learning methods like GPR, IMRFO, and WDOA improves HVAC system performance. Key findings and methodologies are summarized in a Table I, demonstrating continuous improvement of predictions with new data. Advanced algorithms enhance GPR effectiveness through rigorous optimization. Statistical analysis confirms accuracy and reliability, supporting energy efficiency and sustainability in buildings.

TABLE I. THE EFFICIENCY AND WORK DONE SUMMARY

Aspect	Description
Machine Learning Benefits	Continuous refinement of predictions with new data
	Optimization of HVAC system operations with artificial neural networks
	Reduction of energy consumption and environmental impact
Research Methodology	Use of Gaussian Process Regression (GPR) for accurate cooling load forecasts
	Integration of Improved Manta-Ray Foraging Optimizer (IMRFO) and Weevil Damage Optimization Algorithm (WDOA) as hybrid models for GPR optimization
Performance Evaluation	Comprehensive statistical analysis to assess accuracy and reliability
	Evaluation of optimization algorithms (IMRFO and WDOA) effectiveness

II. MATERIALS AND METHODOLOGY

A. Data Gathering

This study focuses on the importance of reliable data for the successful implementation of strategies to predict cooling load requirements in buildings. The research utilizes a dataset consisting of 768 samples sourced from the study available at https://www.sciencedirect.com/science/article/abs/pii/S2352710223020351, which is crucial for training sophisticated models and evaluating the proposed strategies. The study utilizes a GPR model and considers eight key input variables related to cooling load production. These variables include relative compactness, surface area, roof area, wall area, orientation, overall height, glazing area, and glazing area distribution. Each variable has an impact on cooling requirements and is represented in a correlation plot (Fig. 1). Statistical values of these input parameters are provided in Table II. The study emphasizes the significance of these variables in understanding the dynamics of cooling load in buildings. It highlights the need for high-quality data and emphasizes the importance of intelligent model training and data analysis techniques to achieve research objectives [22], [23].

B. Gaussian Process Regression (GPR)

The framework for probabilistic regression used by GPR starts with a training dataset as its input $D = \{(y_w, x_w)\ ,\ w = 1,2,3, \dots, W\}$ of W couples of vector input $x_w IR^L$ and based on a dataset of training phase with output values (yn), GPR builds a model that can successfully generalize to the output distribution at new input locations. It is assumed that the output noise uncertainty is extremely, zero-mean, stationary, and normally distributed and is brought on by outside variables like truncation or observation errors [24].

$$y = f(x) + \delta, \quad \delta\ "W(0, s^2_{noise}) \tag{1}$$

TABLE II. THE STATISTICAL PROPERTIES OF THE INPUT VARIABLE OF COOLING

Variables		Indicators			
	Category	***Min***	***Max***	***Avg***	***St. Dev.***
Relative Compactness	Input	0.62	0.98	0.764	0.106
Surface Area	Input	514.5	808.5	671.7	88.09
Wall Area	Input	245	416.5	318.5	43.63
Roof Area	Input	110.25	220.5	176.6	45.17
Overall Height	Input	3.5	7	5.25	1.751
Orientation	Input	2	5	3.5	1.119
Glazing Area	Input	0	0.4	0.234	0.133
Glazing Area Distribution	Input	0	5	2.813	1.551
Cooling	Output	10.9	48.03	24.59	9.513

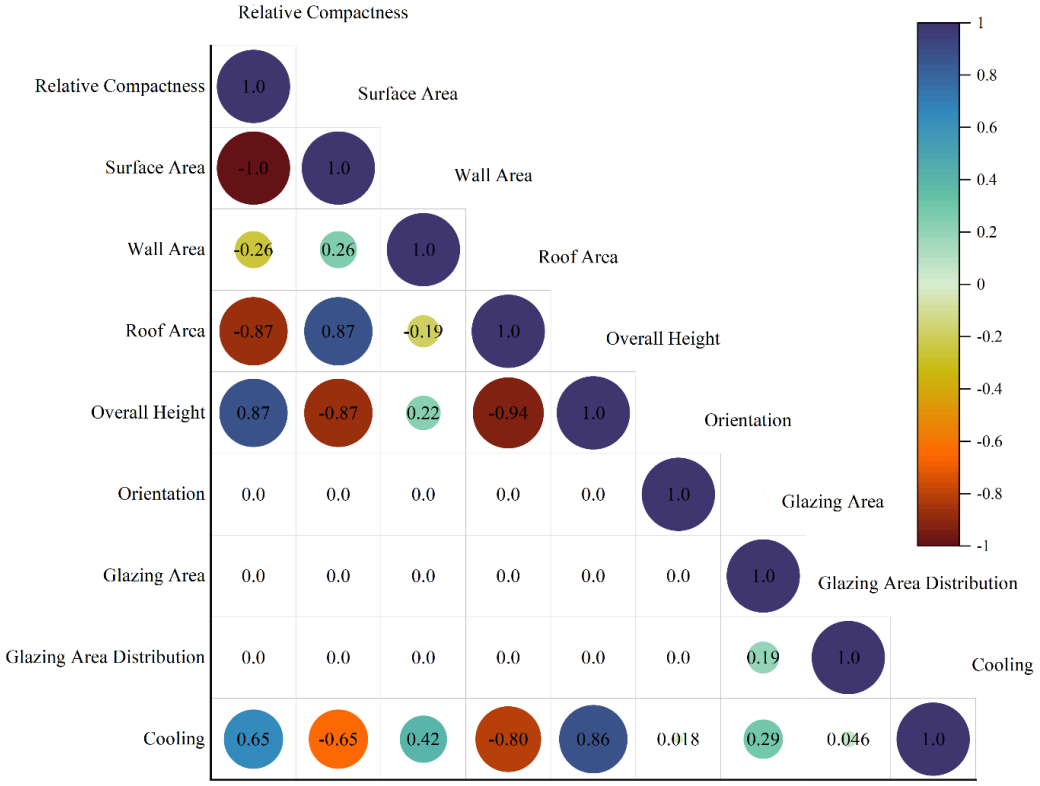

Fig. 1. The plot of correlation for the input and output variables.

GPR utilizes a Gaussian Process (GP) to represent the hidden parameters of f, with x serving as an index for these parameters. The goal is to limit the analysis to functions whose values are correlated in a Gaussian manner, which is achieved by using a Fixed Gaussian distribution for any limited set of $\{f(x_1), \dots, f(x_k)\}$ with unique indices. In a Bayesian framework, this is akin to setting a GP prior over functions. By specifying the mean function $v(x)$ and the function of covariance $k(x, x')$, can conveniently define functions. This technique makes it simple to determine the function values of new inputs with a small amount of training data. The variance of the s^2_{noise}, is used to represent the noise in the model.

$$v(x) = E[f(x)], \quad k(x, x') = E[(f(x) - v(x))(f(x') - w(x'))] \tag{2}$$

The $E[.]$ denote expectation. Only the unseen region of the input space is relevant for the mean function selection, which is typically set to 0. The covariance function, which is regular and positive indeterminate by definition when assessed for any couple of points in input space, is the only factor that influences how the process behaves [25]. The function of covariance usually includes several hyperparameters, determining the earlier distribution of $f(x)$. The squared exponential of covariance function is commonly used in [26].

$$k(x, x') = q_1 \exp\left(\frac{\|x - x'\|}{2q_2}\right) \tag{3}$$

Here, k denotes a norm that is defined on the input space. It is worth noting that the covariance function decays rapidly as the distance of input pairs x and x' rises, indicating weak correlations between $f(x)$ and $f(x')$. There are three hyperparameters involved: q_1 specifies the $maximum$ allowable covariance, the correlation decay rate as points become farther apart is characterized by a positive hyperparameter, q_2, and q_3 is a hyperparameter that represents the variance s^2_{noise} in Eq. (1), although it has not specifically been expressed in Eq. (2). A vector (q) is formed by grouping these hyperparameters, which are then considered as realization of random vector (Q). Based on the training data, the realization that offers the most appropriate for the dataset is chosen to make predictions. The inference procedure is easy if this assumes that the hyperparameters are already known. Denoting the vector of training latent variables as f and the vector of test latent variables as f^*, can obtain the following joint Gaussian distribution:

$$p(f, f^*) = W\left(0, \begin{bmatrix} k_{f,f} & k_{*,f} \\ k_{f,*} & k_{*,*} \end{bmatrix}\right) \quad (4)$$

The covariance matrix K is formed by calculating the covariance of the $i-th$ parameter in the group represented by the first subscript and the j_th parameter in the group represented by the second subscript ($*$ is used in place of f^* for short), using the function of covariance $k(.,.)$ in Eq. (4) and the related hyperparameters [27]. The prediction framework is illustrated in Fig. 2.

C. Improved Manta-Ray Foraging Optimizer (IMRFO)

One of the effective metaheuristic methods for resolving optimization issues is the Manta Ray Foraging Optimisation Algorithm. Premature convergence, however, occasionally acts as a constraint. Two changes have been made to the Manta Ray Foraging Optimisation Algorithm to maximize its potential. The first entails integrating the algorithm with the widely recognized opposition-based learning (OBL) technique. Sometimes, the primary solution is in the opposite direction of the optimal solution, and the solution deviates from it. This may result in unsuccessful attempts at problem-solving or in more optimization efforts [28]. It is crucial to think about the worst-case scenario in such circumstances. As a result, the OBL technique was applied to the algorithm to produce more effective results, as follows:

$$\bar{x}_i^d = x_i^{max} + x_i^{min} - x_i^d \quad (5)$$

In this approach, $\bar{x}_i^d$ represents the opposite location of x_i^d, while x_i^{max} and x_i^{min} represent the maximum and minimum constraints, respectively. If $\bar{x}_i^d$ has better performance than its opposite location, which is denoted as x_i^d, then $\bar{x}_i^d$ is utilized instead of x_i^d.

The second change entails applying the self-adaptive technique, which permits the individual to adjust their size through variable adaptation. Optimizing for individual size is a critical component. First, this transformation is applied to update the primary individual size:

$$x_i^d(t) = 10 \times N \quad (6)$$

N, in this case, stands for the number of parameters. Then, the following formula determines the updated individual size for the next iteration:

$$\bar{x}_i^{d+} = round(x_i^d \times (1 + \delta)) \quad (7)$$

The adjustable parameter δ, which represents a random in range of -0.5 to 0.5, is used to modify the individual size in this context.

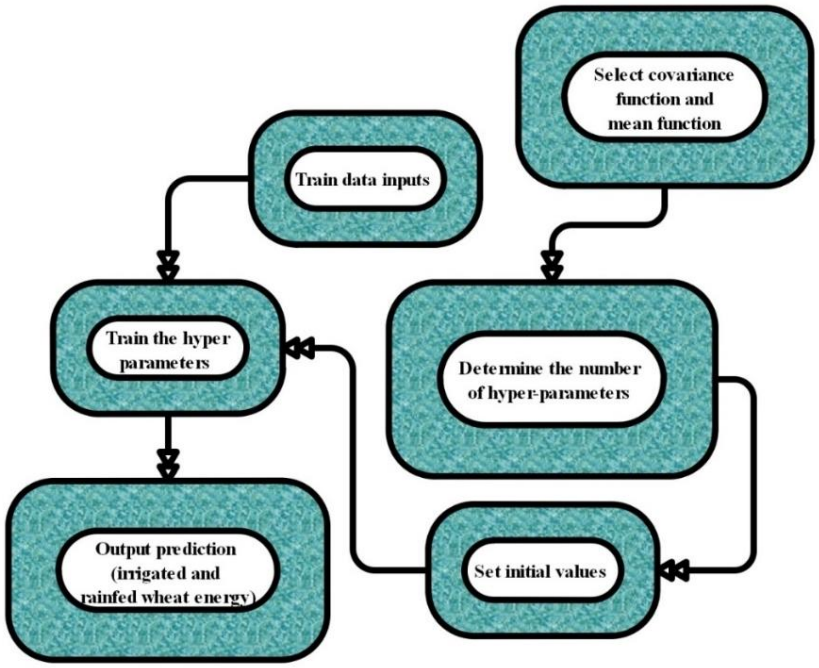

Fig. 2. Estimation framework of the GPR model.

Based on whether δ is positive or negative, the individual size either increases or decreases. If the updated individual size ($\bar{x}_i^{d+}$) is larger than the previous size ($\bar{x}_{i-1}^{d+}$), the current populations proceed to the subsequent iteration. In such cases, the remaining individuals are selected based on elitism. On the other hand, when $\bar{x}_i^{d+}$ is less than $\bar{x}_{i-1}^{d+}$, only the best individuals from the current population are carried forward to the subsequent iteration, and the remaining populations are discarded. It is set to the number of problem parameters if the updated individual size is less than the problem size.

D. Weevil Damage Optimization Algorithm (WDOA)

The Curculionidae superfamily of insects includes the large and diverse group of insects known as weevils. Their prominent snouts help to identify them. An estimated 97,000 species, they constitute one of the largest groups of organisms on the planet. While most weevil species are considered environmental nuisances, some, such as the boll, wheat, and maize weevils, are well known for seriously harming crops.. Weevils, despite their unfavourable image, are crucial components of many ecosystems as pollinators, decomposers, and animal prey [29]. The populations of weevils are generated randomly, resulting in n populations represented as $(W_1, W_2, \dots W_n)$. It is well known that weevils actively seek out the ideal conditions for breeding, which is frequently represented as a cost function. The following actions are taken until the condition for termination is satisfied [30].

- Take the strongest applicant out of the pool of applicants as a first step. Doing this, the best weevil is kept and can be utilized to create new weevil populations.
- Distribute the Fly Power Rate (ψ) and Snout Power Rate (φ) for each weevil to promote population diversity. This step involves assigning a value of φ and ψ to each weevil, representing their relative power levels. It is possible to diversify the weevil population and prevent any one individual from taking over by dispersing these values.
- Implement these tactics to increase the number of weevils. Retaining the best candidate and promoting population diversity by assigning values can both enhance the general quality and diversity of the weevil population.

Adopting measures such as distributing (φ) and (ψ) for each weevil provides a comprehensive understanding of their power levels. Each weevil's level of harm is determined by the Damage Decision Variable (DDV), where greater damage increases the weevil's chance of surviving. Performance and the mutation rate parameter, μ, in the Reproduction Environment Rate (RIR) are inversely correlated. Evolutionary algorithms typically sort the population and pass on the best individuals to the next generation to increase population diversity and quality [31].

$$WDOA = CF \sum_{i=1}^{n} \sum_{DDV=1}^{n} (W_i[\varphi, \psi] \times RIR\ of\ \mu \quad (8)$$

CF refers to the cost function. The pseudo-code for the $WDOA$ is presented as follows.

Algorithm 1. The pseudo-code of WDOA.

Creat a random set of Weevils: $(W_1, W_2, \dots W_n)$
Calculate CF value (Cost function and sort best to worst)
While the termination criterion is not met
Continue the best individuals
Calculate Fly Power Rate ψ and Snout power Rate φ for each Weevils according to CF
Seeking for an environment with more food source
Choose W_i by probability with φ
Choose Wj by probability with ψ
Randomly choose a DDV from W_j
Change out random DDV W_j with W_i

Begin Mutation μ
Choose a DDV in W_i with the probability of mutation rate (RIR)
If W_i DDV is selected
Change out Wi (DDV) with a randomly developed DDV
End if
End Mutation
Calculate the ESI value of new Weevils
Sort population ($best\ to\ worst$ ($cost$))
Change out the worst with the preview development's best
Sort population ($best\ to\ worst$ ($cost$))
End while

E. Efficiency Assessment Methods

This article uses a variety of metrics to assess the models, including the previously mentioned Fractional bias (FB), Correlation Coefficient (R^2), Mean Square Error (MSE), Index of agreement (IOA), and Root Mean Square Error ($RMSE$).

- Fractional Bias (FB): Fractional Bias calculates the average bias, the variation of predicted and observed values, relative to their average. An FB value close to 0 indicates that the predictions are unbiased, while a positive or negative value indicates overestimation or underestimation, respectively.
- Correlation Coefficient (R^2): The Correlation Coefficient, also known as the coefficient of determination, quantifies how well the predicted values correlate with the observed values. An R^2 value close to 1 demonstrates a great positive correlation, meaning the model explains most of the variability in the observed data. A value close to 0 indicates little to no correlation.
- Mean Square Error (MSE): Mean Square Error is the average of the squared differences between predicted and observed values. Lower MSE values indicate better model performance, as they show that the predictions are closer to the actual values. It is sensitive to outliers due to the squaring of errors.
- Index of Agreement (IOA): The Index of Agreement is a standardized measure of the degree of model prediction error, taking into account the range of observed values. IOA values range between 0 and 1, which 1 represent perfect agreement between the model predictions and the observed values.
- Root Mean Square Error (RMSE): The square root of the average of the squared discrepancies between the predicted and observed values is known as the root

mean square error. Similar to MSE, lower RMSE values indicate better model performance. RMSE is useful because it provides an error metric in the same units as the original data, making it easier to interpret.

During the training, validation, and testing phases, a high R^2 value determines that the algorithm performed suitable. Conversely, smaller MSE and RMSE values are better since they indicate less model error. These metrics are computed using Eq. (9–13).

$$R^2 = \left(\frac{\sum_{i=1}^{N}(h_i-\bar{h})(q_i-\bar{q})}{\sqrt{[\sum_{i=1}^{N}(h_i-h)^2][\sum_{i=1}^{N}(q_i-\bar{q})^2]}} \right)^2 \quad (9)$$

$$RMSE = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(q_i - h_i)^2} \quad (10)$$

$$MSE = \frac{1}{N}\sum_{i=1}^{N} q_i^2 \quad (11)$$

$$FB = \frac{1}{N}\sum_{i=1}^{N} \frac{2\times(q_i-h_i)}{q_i+h_i} \quad (12)$$

$$IOA = 1 - \frac{\sum_{i=1}^{N}(x_{i,q}-x_{i,h})^2}{\sum_{i=1}^{N}(|x_{i,h}-\overline{x_q}|+|x_{i,q}-\overline{x_q}|)^2} \quad (13)$$

Here, h_i and q_i refer to the predicted and experimental values, respectively. The mean values of the experimental samples and predicted are represented by $\bar{h}$ and $\bar{q}$, alternatively, and N demonstrates the number of samples being considered.

III. Results

A. Hyperparameter

Table III presents the results of the hyperparameter tuning for two models: GPWD and GPIM. Hyperparameters are critical settings that influence the training process and performance of machine learning models. For the GPWD model, the hyperparameters include 120 restarts, a length scale of 685.0302031, and an alpha value of 0.896335693. These values suggest a robust optimization process aimed at fine-tuning the model for high precision in cooling load prediction. On the other hand, the GPIM model is configured with 55 restarts, a length scale of 112, and an alpha value of 1.4. This set of hyperparameters indicates a different optimization strategy, potentially focusing on balancing computational efficiency and prediction accuracy.

The number of restarts in both models indicates multiple attempts to find the optimal solution, enhancing the reliability and stability of the models. The length scale parameter influences the model efficiency in generalizing across various scales of data, while the alpha parameter affects the model's noise tolerance, contributing to its robustness in varying conditions. The distinct hyperparameter values reflect the tailored approaches of each model to achieve optimal performance in forecasting cooling loads.

B. Evaluation of Models

The objective of this study was the prediction of cooling loud using three distinct models: GPR, GPWD, and GPIM. Model performance was assessed against experimental data, which was divided into training (70%), validation (15%), and testing (15%) phases. This division ensured an unbiased evaluation of the models. To comprehensively compare the algorithms employed five statistical metrics: R^2, RMSE, FB, IOA, and MSE.

During the training phase, the GPWD model exhibited exceptional predictive accuracy. It achieved the highest R^2 (0.990) and IOA (0.997) values, surpassing the other models. In comparison, the GPR model had slightly lower R^2 (0.971) and IOA (0.993) values. The GPWD model's superior performance was further highlighted by additional error indicators, such as the RMSE values ranging from 1.004 to 2.208, indicating lower errors compared to the GPR model. When considering the FB values during training, the GPWD model demonstrated the lowest value (-0.007), while the GPR model had the highest value (0.002). This suggests that the GPWD model provided a better fit to the data than the GPR model. Furthermore, in terms of MSE, the GPWD model excelled with a training value of 1.007, while the GPR model exhibited the highest value (2.658).

Overall, the results underscored the superiority of the GPWD model over the GPR and GPIM models, particularly during the training phase. Its high R^2 and IOA values indicate a strong ability to explain the variance in the dependent variable. Additionally, the lower RMSE and FB values, along with the lower MSE value, further support the GPWD model's superior performance. It is important to note that these findings are specific to the training phase and may vary across different phases or datasets. Further analysis and evaluation are necessary to validate the models' performance in real-world scenarios.

Nonetheless, the results obtained from this study highlight the potential of the GPWD model for accurate cooling load prediction. The developed models' results for GPR are represented in Table IV, and Fig. 3 displays the line plot for each metric.

This study compares how well hybrid models perform in the training, validation, and testing stages utilization the scatter plot shown in Fig. 4. Overall, the GPWD model shows minimal variation of predicted and observed values, indicating good accuracy. The performance of the GPR and GPIM models is similar, with slightly lower precision and higher inaccuracy, even though their data points are farther from the centreline. A wider dispersion of the data points suggests a slightly higher inaccuracy and lower precision when compared to the GPWD model.

TABLE III. Result of the Hyperparameter

Models	Hyperparameter		
	n_restarts	length_scale	alpha
GPWD	120	685.0302031	0.896335693
GPIM	55	112	1.4

TABLE IV. RESULT OF DEVELOPED MODELS FOR GPR

Model	Phase	Index values				
		RMSE	R^2	MSE	FB	IOA
GPR	Train	1.630	0.971	2.658	0.002	0.993
	Validation	2.208	0.955	4.874	0.024	0.988
	Test	1.782	0.970	3.177	0.032	0.991
	All	1.751	0.967	3.067	0.010	0.992
GPWD	Train	1.004	0.990	1.007	-0.007	0.997
	Validation	1.402	0.984	1.965	-0.003	0.995
	Test	1.443	0.980	2.081	-0.008	0.994
	All	1.145	0.988	1.311	-0.006	0.996
GPIM	Train	1.332	0.981	1.774	-0.006	0.995
	Validation	1.659	0.975	2.753	-0.005	0.993
	Test	1.839	0.966	3.384	-0.010	0.990
	All	1.470	0.978	2.162	-0.006	0.994

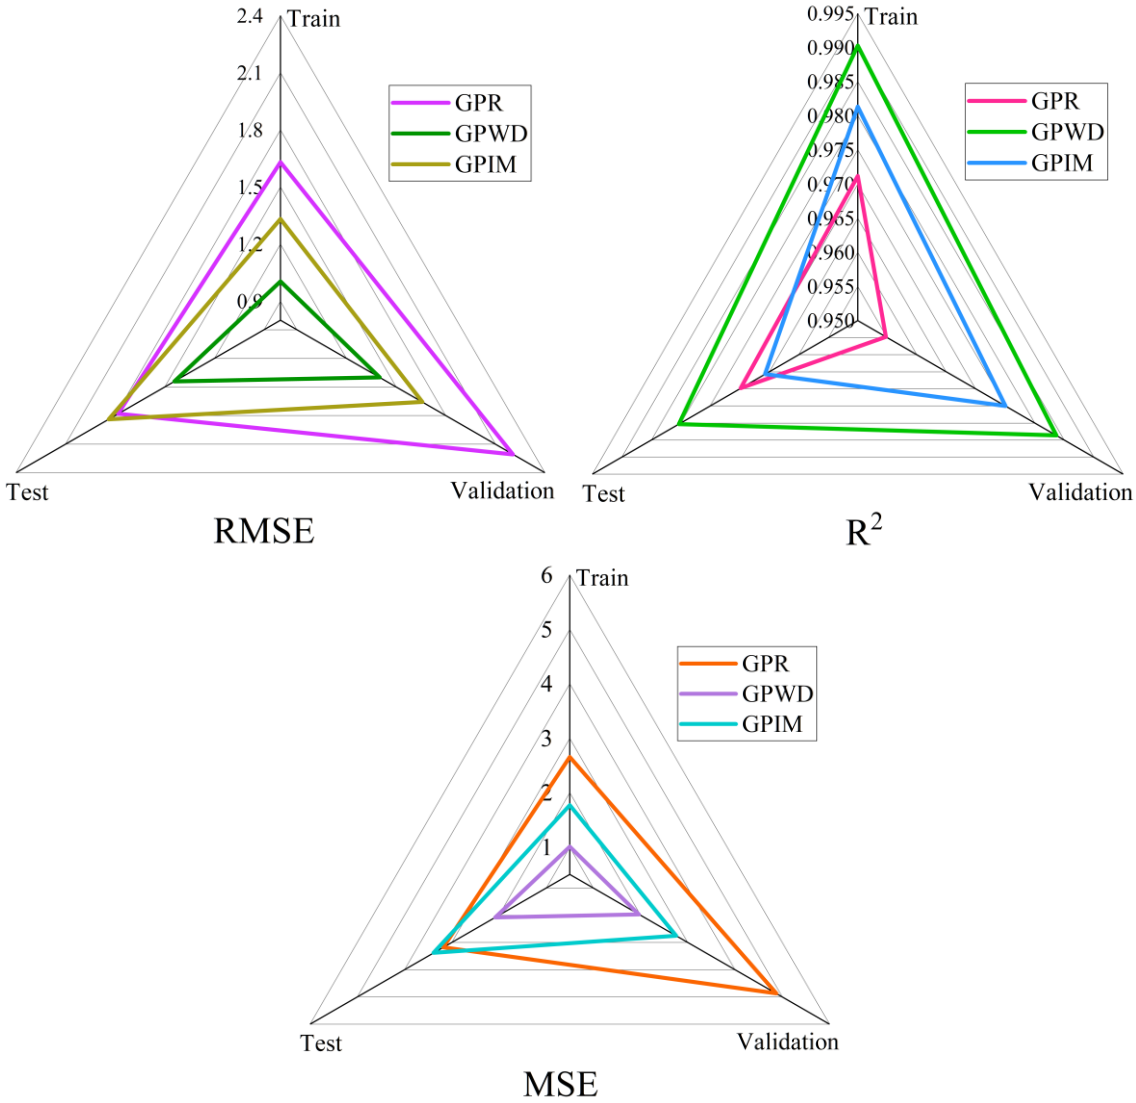

Fig. 3. The line plot for developed models' comparison according to metrics.

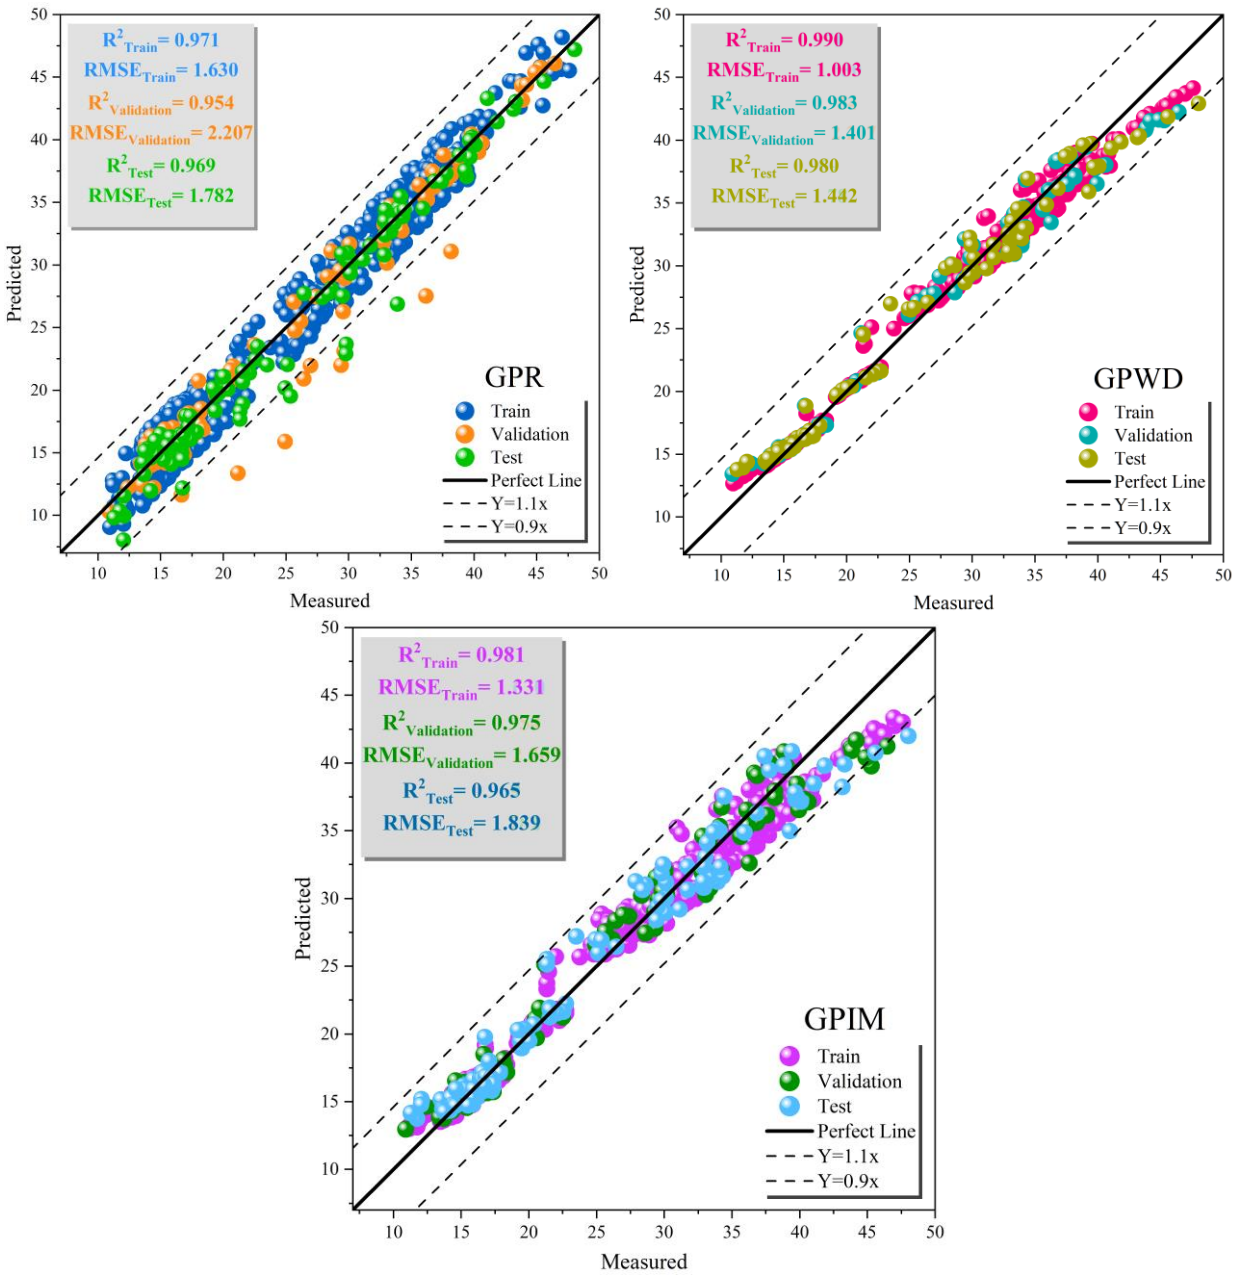

Fig. 4. Plotting the dispersion of evolved hybrid models.

In Fig. 5, a vertical drop line graph illustrates the percentages of error related with the created models. Notably, the GPWD model stands out with the lowest error of 23.18%. The graph indicates that the majority of values for GPWD are clustered around the 10% range. In contrast, the error percentages for GPR and GPIM exhibit a broader distribution, with a significant concentration of values higher than 36.85% and 25.79%, respectively. It is noteworthy that both the GPR and GPIM distributions are right-skewed, indicating a significant number of data points which increased rates of error. This results highlights the great accuracy of GPWD and effectively showcases the percentage of error distributions in developed models, as depicted in the plot.

The study shows the respective error percentages for the three models in Fig. 6, which is a box normal plot. The GPWD model showed remarkable performance, with errors under 10% and little dispersion. The GPR model's dispersion had a monotonous distribution with a topmost value of 20% and was constant across all phases. The GPIM model had the most significant differences between the models during the assessment stage, with one outlier data point accounting for more than 15% of the data.

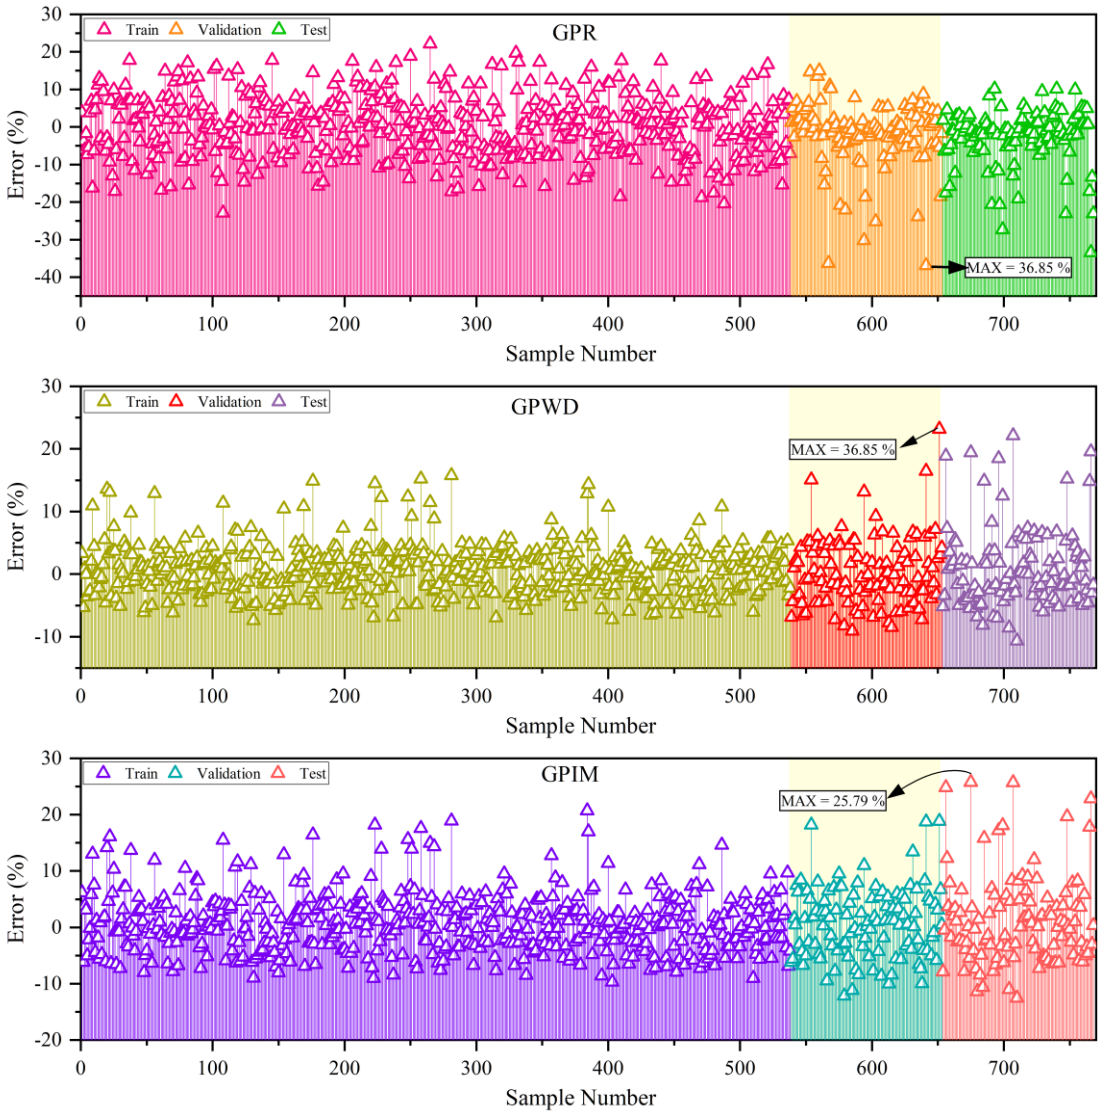

Fig. 5. The error percentage of the models is based on the vertical drop line plot.

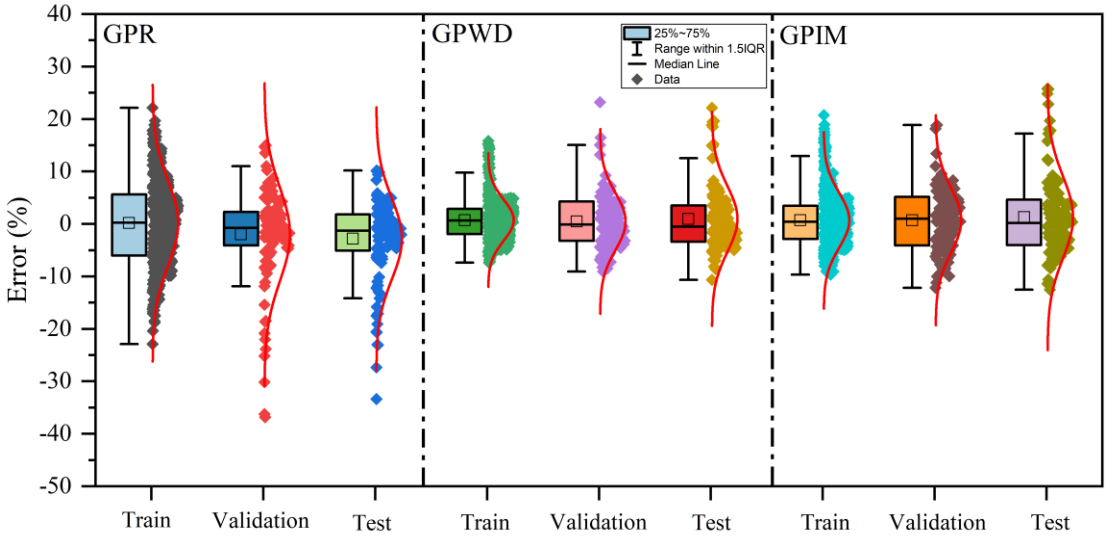

Fig. 6. The box normal plot errors of proposed models.

IV. DISCUSSION

A. Comparison

Table V compares the best-performing models from the present study with those from related literature, highlighting their RMSE and R^2 values. The study by Moradzadeh et al. using the Support Vector Regression (SVR) model achieved an RMSE of 0.9887 and an R^2 of 1.7389. Roy et al. employed the Multivariate Polynomial Multiple Regression (MPMR) model, which resulted in an RMSE of 0.0791 and an R^2 of 0.99. Afzal et al. utilized the Particle Swarm Optimization with Grey Wolf Optimization (PSOGWO) model, attaining an RMSE of 1.9275 and an R^2 of 0.9590. In the present study, the GPWD model demonstrated an RMSE of 1.004 and an R^2 of 0.990. Despite the GPWD model not having the lowest RMSE, its high R^2 value signifies strong predictive accuracy and robustness. Comparing these results illustrates the competitive performance of the GPWD model against other advanced techniques in the literature, confirming its efficacy in forecasting cooling loads. The comparison underscores the potential of the GPWD model in achieving reliable predictions, essential for energy-efficient building management.

TABLE V. THE STUDY COMPARES THE BEST-PERFORMING MODELS RESULTS WITH RELATED LITERATURE

Articles	Index values		
	Models	*RMSE*	R^2
Moradzadeh et al. [14]	SVR	0.9887	1.7389
Roy et al. [32]	MPMR	0.0791	0.99
Afzal et al. [33]	PSOGWO	1.9275	0.9590
Present Study	GPWD	1.004	0.990

B. Limitation

Despite the promising results, this study has several limitations. First, a particular dataset was used to train and validate the models, potentially limiting their generalizability to other contexts or buildings with different characteristics. The dataset's scope and quality may influence the models' performance, necessitating further testing on diverse datasets. Second, the study focused primarily on a controlled environment, which might not capture the variability of real-world conditions, such as unexpected occupancy changes or extreme weather events. Additionally, while the integration of meta-heuristic algorithms with the Gaussian Process Regression model enhanced prediction accuracy, it also increased computational complexity, potentially posing challenges for real-time applications. Lastly, the study did not consider the economic aspects of implementing these advanced ML models in existing systems, which could impact their practical feasibility and adoption. Further research is needed to address these limitations and validate the models in various real-world scenarios.

V. CONCLUSION

To sum up, precise cooling load prediction is critical to enhancing the energy efficiency of cooling systems and maximizing the functionality of air conditioning controls and chillers. Within this field, machine learning (ML) models have become extremely powerful instruments, outperforming traditional methods and regression analysis because of their ability to identify complex patterns impacted by a variety of variables, including occupancy, construction materials, and meteorological conditions. Machine learning models provide dynamic forecasts that improve energy efficiency and enable effective building administration; they are data-scalable and scenario-adaptive. This research has shed light on the intricacies of cooling load systems, and the challenges entailed in energy optimization. To address these challenges, the study employed a comprehensive research methodology and innovative problem-solving approaches. The integration of the Weevil Damage Optimization Algorithm (WDOA) and the Improved Manta-Ray Foraging Optimizer (IMRFO), both meta-heuristic algorithms, with the Gaussian Process Regression (GPR) model was seamlessly executed to augment prediction accuracy. Rigorous validation, including stability tests, was performed on the cooling load data employed in these algorithms to certify the reliability of the outcomes obtained.

The study presented three distinct models: GPWD, GPIM, and an independent GPR model. Each model provided valuable intuitions for the exact prediction of cooling load. Among these models, the GPWD model exhibited exceptional performance, surpassing the others in terms of accuracy. Boasting an RMSE value of 1.004 and an impressive R^2 value of 0.990, the GPWD model demonstrated its prowess in forecasting cooling loads with remarkable precision, thereby indicating its practical applicability in real-world building management scenarios. The findings of this research underscore the superiority of ML models, particularly the GPWD model, in the prediction of cooling load. By harnessing complex algorithms and incorporating diverse factors, these models offer insights that contribute to energy optimization and efficient building management.

Nevertheless, it is essential to acknowledge that the results obtained in this study are specific to the dataset and training phase. Further analysis and evaluation are imperative to validate the performance of these models across different contexts and real-world scenarios. In conclusion, the study underscores the potential of ML models, particularly the GPWD model, in accurately predicting cooling load. This research contributes to the expanding body of information in the discipline of energy optimization and emphasizes the significance of leveraging advanced techniques to enhance the efficiency of cooling systems. Ongoing research and development efforts in this area are critical for advancing energy optimization and sustainable building management.

***Abstract*—Respiration monitoring is essential for diagnosing and managing a variety of diseases. It is a non-invasive, convenient and effective method to derive breathing from ECG signals. This paper proposes a new complementary ensemble empirical mode decomposition (NCEEMD) method for respiration extraction. By additional ensemble empirical mode decomposition (EEMD) of the auxiliary white gaussian noise, the noise residue of the corresponding respiratory band after the EEMD decomposition of original ECG signal is subtracted. The new IMF was selected for correlation analysis with the measured respiratory signal, and the optimal amplitude noise coefficient was determined adaptively by the principle of maximum correlation increment. Then IMF in the respiratory band is selected to reconstruct the respiratory signal which is ECG-derived respiration (EDR). A comparative experiment of respiration extraction was conducted using the data of the MIT-BIH Polysomnographic database. The experimental results show that compared with the complementary ensemble empirical mode decomposition (CEEMD) method, the proposed EDR extraction method reduces the average MSE by 3.95%, RMSE by 2.74%, and MAE by 2.52% and the physical significance of the IMF component is more explicit. This method has good accuracy, robustness and adaptability, and provides a new solution idea for the extraction of respiratory signals.**

Keywords*—ECG; white gaussian noise; complementary ensemble empirical mode decomposition; ECG-derived respiration (EDR)

I. Introduction

Breathing is an important physiological parameter in the human body and is commonly associated with heart disease, sleep apnea syndrome and anxiety [16, 19], and a coupling between breathing and heart rate has been demonstrated [17, 20]. However, monitoring breathing requires bulky equipment that may interfere with natural breathing. ECG-derived respiratory (EDR) from ECG signals can effectively reduce the cost of monitoring, improve user comfort, and be more suitable for outpatient and home monitoring.

Scholars at home and abroad have carried out a lot of explorations and researches on the extraction of EDR based on ECG signals. EDR is extracted from the slope and angle of QRS complex wave of ECG signal, but this method only be used to estimate the respiratory rate, and can not obtain the respiratory waveform [2]. Millimeter wave radar technology is used to obtain ECG and respiratory signals in a non-contact manner, which is capable of real-time monitoring, but the signal quality can be affected by environmental factors, human movement and other interferences, and the scope of application is limited [1, 22]. Linear principal component analysis (PCA) was used to extract EDR signals from ECG signals and extracted the main components by calculating eigenvectors and eigenvalues, but PCA could not capture the nonlinear relationship between ECG and respiratory signals, which resulted in distorted downscaling results [6]. Literature proposed kernel-based principal component analysis to introduce nonlinear feature extraction into PCA by introducing kernel tricks, but the optimization process of kernel parameters is complicated [28]. Researchers have found that the EDR extraction technique based on the principle of empirical mode decomposition (EMD) out-performs the method based on the discrete wavelet transform, and it can be a better alternative method for indirect extraction of respiration [4, 13], but it causes severe mode aliasing in time-frequency distributions, which blurs the physical significance of the individual intrinsic modal functions [11, 14]. Wu and Huang proposed an ensemble empirical mode decomposition (EEMD) method [25], which overcomes the mode mixing problem of EMD, but the superimposed white noise amplitude and the overall average number of iterations of this method rely on human empirical choices [3, 29], and the effect of the residual white noise after signal reconstruction is not negligible [15].

A complementary ensemble empirical mode decomposition (CEEMD) method is mainly used to add a pair of opposite white noise signals to the source signal and performing EMD decomposition. CEEMD reduces the reconstruction error caused by white noise compared to EEMD method [26], but disadvantage is that the operation is doubled, and if the white noise amplitude and the number of iterations are not appropriate, more pseudo-components will be decomposed, which need to be recombined or processed subsequently for the IMF components.

For improved EMD methods, the addition of auxiliary white noise may lead to energy shift and spectrum distortion in the decomposition results, reducing the accuracy and reliability of the decomposition results. For how to eliminate the added auxiliary white noise effect, it is necessary to find an effective method to distinguish and suppress the noise components in order to retain the useful information of the signal. Inappropriate noise amplitude parameters may mask or change the features in the original signal, making the accuracy and interpretability of IMFs decreased [5, 24]. The statistical and distribution characteristics of white noise make the estimation of auxiliary noise level subjective and uncertain [25]. Based on the resonance characteristics of the signal in the time-frequency plane, the noise residue in the corresponding frequency band can be eliminated during the original signal decomposition by leveraging the decomposition characteristics of white Gaussian noise itself, thereby reducing the mutual interference and

aliasing of energy dispersed between different Intrinsic Mode Functions [8, 12].

This paper proposes a new complementary empirical ensemble mode decomposition (NCEEMD) method for breath extraction. By additional EEMD decomposition of the auxiliary white noise, the noise residue of the corresponding respiratory band after the original ECG decomposition is subtracted. And the optimal amplitude noise factor is selected adaptively.

The structure of this paper is as follows: Section II proposes the EDR method based on NCEEMD and its evaluation performance index. It also introduces the data set. Experimental results in Section III. Finally, the discussion and conclusion are given in Section IV and in Section V respectively.

II. Materials and Methods

A. Datasets

The MIT-BIH Polysomnographic Database (MBPD) includes 18 consecutive records from 16 male subjects diagnosed with sleep apnea syndrome [10]. Slp01a and slp01b are polysomnographic segments of the same patient, slp02a and slp02b are polysomnographic segments of another patient, and the remaining 14 data records belong to 14 different patients. Individual recordings in the database are between two and seven hours in length and are digitized at 250Hz and 12-bit resolution. The recorded physiological signals include electrocardiogram, electromyogram, electrooculogram, arterial blood pressure, respiration, and arterial oxygen saturation.

In this study, we used ECG and respiratory signals measured synchronously by the MBPD. ECG signals measure and record the electrical activity of the heart via electrodes attached to the patient's chest and are used to detect heart abnormalities and assess heart function. Respiratory signals are recorded by an inductive plethysmograph or nasal thermistor, which records the amplitude of abdominal motion and changes in nasal airflow, thereby providing information about respiratory activity. The sampling frequency of the above physiological signals is 250Hz, and the sleep phase is marked every 30s. Fig. 1 is an example of time domain waveform of 60s ECG signal and respiratory signal recorded by slp01a in the database.

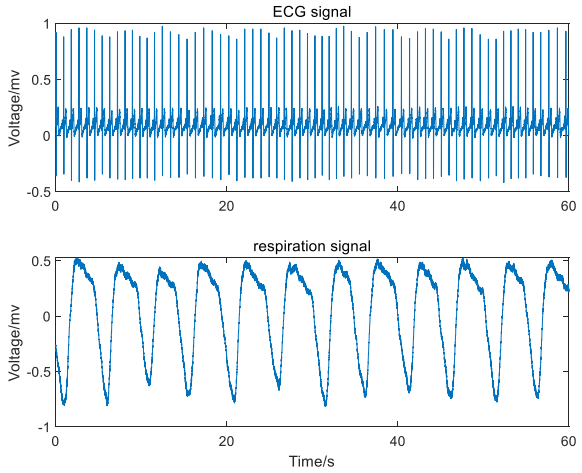

Fig. 1. Examples of waveforms of ECG and respiratory signals recorded by slp01a.

B. The Proposed NCEEMD Method

The EMD method can be used to analyze nonlinear and non-stationary signal sequences, which have a high signal-to-noise ratio and well time-frequency focus [9]. However, the defects of the method make the physical meaning of a single intrinsic mode function ambiguous, which will cause severe mode aliasing in the time-frequency dis-tribution. Compared with the original EMD, CEEMD has been greatly improved [26]. By superimposing multiple EMD decomposition of positive and negative white noise which are negative to each other, the problem of pattern aliasing is effectively solved by using the statistical property of Gaussian white noise with uniform frequency distribution. However, in the CEEMD decomposition method, the setting of the noise amplitude coefficient still depends on the human experience. Although the impact of noise on the results decreases with the increase of the overall average number of iterations, the time cost of the method also increases correspondingly, and the residue of white noise added cannot be ignored. Based on this, an NCEEMD method is proposed in this paper. In order to eliminate the residual white noise in the reconstructed signal to a certain extent, the EEMD decomposition of Gaussian white noise is first subtracted from the EEMD decomposition result of the original signal, and the noise residue in the signal decomposition is diluted or eliminated by using the characteristics of Gaussian white noise to improve the accuracy of the method.

1) Suppose the original signal is $y(t)$, gaussian white noise signal is $g(t)$, the overall average number is preset to m, the noise amplitude coefficient is α;

2) The white noise sequence with standard normal distribution added for the ith time is $n_i(t)$, then the noisy signal of the ith experiment is $y_i(t)$, $g_i(t)$;

$$y_i(t) = y(t) + \alpha n_i(t) \quad i = 1,2,\dots,m \qquad (1)$$

$$g_i(t) = g(t) + \alpha n_i(t) \quad i = 1,2,\dots,m \qquad (2)$$

3) The i th EMD process is conducted to $y_i(t)$, $g_i(t)$. The obtained multi-resolution features of the original signal can reflect more detailed scale information. Observing the detailed characteristics of gaussian white noise in each frequency band, which is used to simulate the error residue of white noise added by EEMD in reconstruction;

$$y_i(t) = \sum_{j=1}^{n} x_{ij}(t) + r_i(t) \quad j = 1,2,\dots,n \quad g_i(t) \qquad (3)$$

$$= \sum_{j=1}^{n} k_{ij}(t) + l_i(t) \quad j = 1,2,\dots,n \qquad (4)$$

where, $x_{ij}(t)$ is the average value of the jth IMF component obtained from the EMD decomposition of the original signal. $r_i(t)$ is the average value of the residual item. It is the average value of the j th IMF component obtained by EMD decomposition of gaussian white noise. $l_i(t)$ is the average value of the residual item.

4) Subtract the IMF components obtained in Eq. (3) and Eq. (4) in the corresponding frequency band to obtain a new IMF component $W_{ij}(t)$, which is used to eliminate the white noise residue in the EEMD decomposition of the original signal.

$$W_{ij}(t) = x_{ij}(t) - k_{ij}(t) \quad (5)$$

$$T_{ij}(t) = r_i(t) - l_i(t) \quad (6)$$

where, $W_{ij}(t)$ is the newly obtained average value of the jth IMF component. $T_{ij}(t)$ is the average value of the new residual item.

5) Repeat the process of 3) and 4) until $i = m$, the average value of the jth IMF component and the average value of the residual item obtained after the mth EMD decomposition are calculated, the functions are as follows.

$$A_j(t) = \frac{1}{n}\sum_{i=1}^{n} W_{ij}(t) \quad (7)$$

$$B_n(t) = \frac{1}{n}\sum_{i=1}^{n} T_{ij}(t) \quad (8)$$

6) The final result $C(t)$ after compound noise reduction with gaussian white noise is:

$$C(t) = \sum_{j=1}^{n} A_j(t) + B_n(t) \quad (9)$$

C. NCEEMD-based EDR Extraction Method

To solve the defects of the noise amplitude coefficient in the CEEMD method that need to be set by human experience and reduce the introduced noise interference, considering that the correlation between signals will gradually increase with the decrease of the noise residue in the original signal decomposition, this paper proposes an EDR method based on NCEEMD in Fig. 2. By presetting different noise coefficients, the correlation between the IMF component obtained from CEEMD decomposition and NCEEMD decomposition and the original respiration was compared. The optimal amplitude noise coefficient α in the method was determined by the principle of maximum increment of the correlation coefficient, which was used to reconstruct respiratory signals and automatically adjust parameters according to data characteristics to improve the adaptability of the method.

Selection of the IMF frequency range to reconstruct the respiration. Since respiration and heartbeat are in different frequency bands, respiration can be separated from the ECG signal by filtering or decomposition. Typically, the human respiratory rate ranges from 0.1 to 0.5 Hz, while the heart rate ranges from 0.8 to 2 Hz [7]. Considering that the patient has shortness of respiration or apnea, the respiratory frequency range selected in this paper is 0.07-0.75 Hz [3], and the IMF component in the frequency band is used as the component of reconstructed respiration.

Calculation of the correlation between the IMF and the measured respiration signal. Multiple IMF components are obtained by decomposing the original signal by NCEEMD. In this paper, the Pearson correlation coefficient index is used to measure the correlation between the IMF component and the measured respiration. The size of the correlation coefficient reflects the degree of correlation between two signals. P is a test value, which is used to test whether the two variables have the same correlation as the sample in the population from which the sample comes. If P is less than 0.05, it is considered statistically significant, and the correlation R is considered significant.

$$R(X,Y) = \frac{Cov(X \cdot Y)}{\sqrt{Var[X]Var[Y]}} \quad (10)$$

where, $Cov(X \cdot Y)$ is the covariance of X and Y, $Var[X]$ is the variance of X, $Var[Y]$ is the variance of Y.

Determination of the optimal magnitude noise coefficients. The increment of the correlation coefficient between the CEEMD decomposition component $x_{ij}(t)$, the NCEEMD decomposition component $W_{ij}(t)$, and the measured respiratory signal are compared respectively. The optimal amplitude noise coefficient α is determined by the principle of the maximum increment of the correlation coefficient, which is used to reconstruct the respiratory signal.

D. Evaluation Metrics

To quantify the error between EDR and original respiration, this paper evaluates the method by calculating mean square error (MSE), root mean square error (RMSE), and mean absolute error (MAE) accuracy.

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(\hat{y}_i - y_i)^2 \quad (11)$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(\hat{y}_i - y_i)^2} \quad (12)$$

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|\hat{y}_i - y_i| \quad (13)$$

where, $\hat{y}_i$ is the predicted value and y_i is the actual measured value.

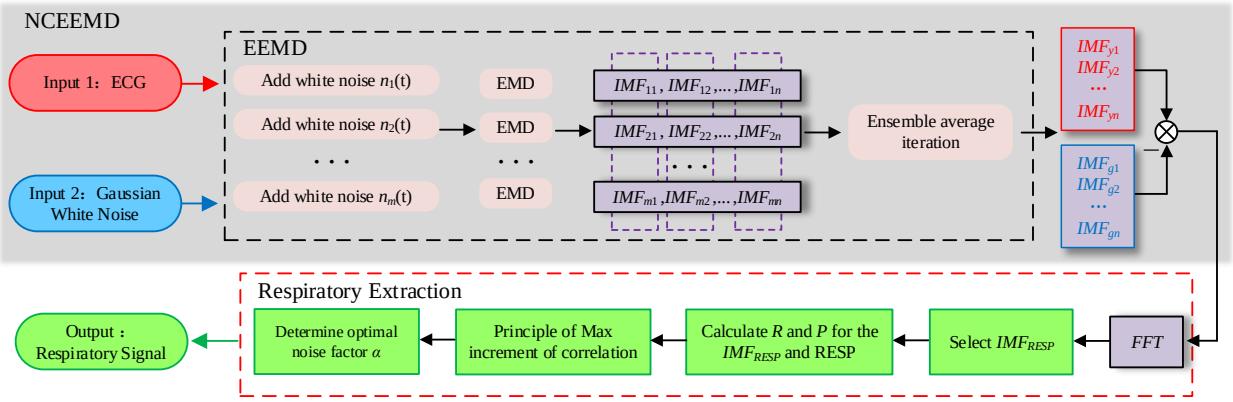

Fig. 2. Overview of the proposed NCEEMD method for respiratory extraction.

III. RESULTS

A. NCEEMD Method for ECG Signal

Taking the first 60 seconds of slp01a data in MBPD as an example, NCEEMD decomposition of the raw ECG signal was done to obtain different IMF components, as shown in Fig. 3.

Gaussian white noise is a kind of noise with zero mean in time domain and uniform distribution of power spectral density in frequency domain [5]. Each sample is independent from each other and exhibits Gaussian distribution characteristics. EEMD decomposition of Gaussian white noise is performed below, as shown in Fig. 4.

Subtract the IMF components obtained in EEMD decomposition of ECG signals and Gaussian white noise signal in the corresponding frequency band to obtain a new IMF component, which is used to eliminate the white noise residue in the EEMD decomposition of the original signal, as shown in Fig. 5.

B. Respiratory Extraction Method

The original ECG signals were decomposed by EMD, EEMD, CEEMD and NCEEMD methods to obtain different IMF components, and the IMF components in the respiratory band (0.07 ~ 0.75 Hz) were calculated by FFT technology as shown in Fig. 6 and Table I below. In the NCEEMD decomposition results, the maximum centre frequency of IMF8~IMF10 is within the range of 0.07-0.75Hz in the respiratory band.

As can be seen from Table I, the components in the respiratory band obtained by EMD decomposition are: IMF5~ IMF 8; The components in the respiratory band obtained by EEMD/CEEMD/NCEEMD decomposition are IMF8~IMF 10.

The P and R values of IMF and measured respiratory signals in the respiratory band were calculated in Table II and Table III. The increment of the correlation coefficient between the CEEMD decomposition component, the NCEEMD decomposition component and the measured respiratory signal are compared respectively. The optimal amplitude noise coefficient α is determined by the principle of the maximum increment of the correlation coefficient, the optimal amplitude coefficient is used for the final reconstruction of the respiratory signal.

NCEEMD	3.3	1.125	1.125	**0.325**	**0.2**	**0.1**

TABLE II. COMPARISON OF P VALUES BETWEEN DIFFERENT IMF COMPONENTS AND ORIGINAL RESPIRATION

Method	Significance *P* value					
	IMF5	IMF6	IMF7	IMF8	IMF9	IMF10
EMD	0.2033	0	0	0	0.5684	/
EEMD	0.5411	0.4435	0.0252	0	0	0
CEEMD	0.4646	0.1196	0.6107	0	0	0
NCEEMD	0.5412	0.4385	0.0234	0	0	0

TABLE III. COMPARISON OF R VALUES BETWEEN DIFFERENT IMF COMPONENTS AND ORIGINAL RESPIRATION

Method	Correlation coefficient *R* value					
	IMF5	IMF6	IMF7	IMF8	IMF9	IMF10
EMD	**0.0127**	**0.0826**	0.0889	0.0416	0.0057	/
EEMD	-0.0061	-0.0077	-0.0067	0.1628	0.2198	0.0787
CEEMD	0.0073	0.0156	-0.0051	0.1413	0.1945	-0.174
NCEEMD	0.0111	-0.0136	**-0.1635**	**0.2261**	**0.2338**	**0.0876**

With a statistically significant P-value<0.05, the correlation coefficient R-value of NCEEMD with original respiration was the largest among components IMF7 to IMF10 (see the bolded portion in Table III), indicating that the IMF component decomposed by this method had the strongest correlation with original respiration. The changes in the incremental correlation coefficients of NCEEMD-IMF with original respiration were calculated comparing the CEEMD decomposition method under different amplitude noise factor α, as shown in Fig. 7 below.

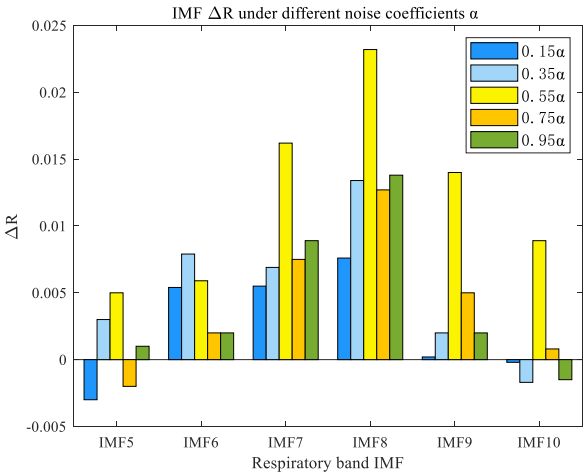

Fig. 7. IMF correlation coefficient increment at different noise coefficient α.

As shown in Fig. 7, under the noise amplitude coefficient $\alpha = 0.55$, the correlation coefficient of each component is increased and the correlation coefficient of IMF8 component has the largest increment. The frequency of IMF8 component is 0.4Hz, which is also the closest to the original respiratory frequency of 0.3Hz, indicating that the decomposed component of this method highlights the respiratory feature information more. Under other different noise coefficients, the correlation between IMF5 and IMF10 decreases, which may be since the IMF5 component carries the characteristic information of the ECG signal, and the IMF10 component carries part of the characteristic information of the baseline drift, which makes its correlation with the respiration weakened, which is manifested in the decreasing increment of the correlation coefficient [23]. The method proposed in this paper has good adaptability in determining the noise amplitude coefficient.

C. Compare EDR Extraction with Other Methods

As can be seen from Table I, the components in the respiratory band obtained by EMD decomposition are: IMF5~ IMF 8; The components in the respiratory band obtained by EEMD/CEEMD/NCEEMD decomposition are IMF8~ IMF 10. Based on the above determination of the optimal noise amplitude coefficient, slp01a data in the first 60 seconds of MBPD is taken as an example to compare EDR signals obtained by EMD, EEMD, CEEMD, and NCEEMD decomposition methods, respectively, and compare them with the measured raw respiration in the database in Fig. 8.

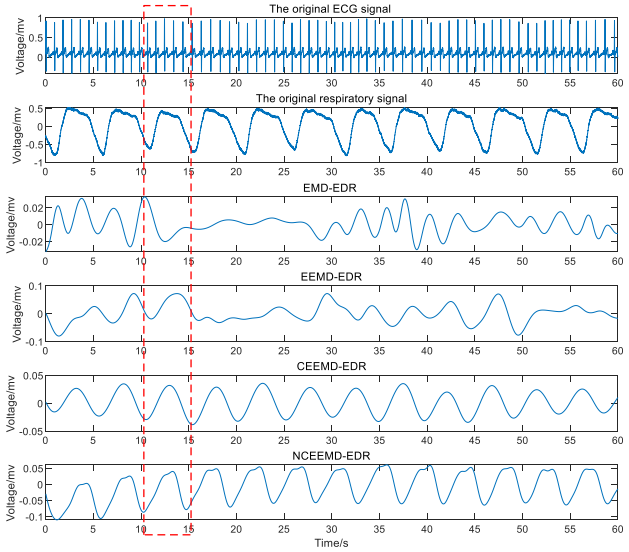

Fig. 8. Example of a comparison of the different EDRs recorded by slp01a with the original respiration.

Fig. 8 shows an example of an abdominal respiration fragment recorded using slp01a over a period of 60 seconds. Each of the above EDR techniques provides information on the peaks and valleys of inhalation and exhalation, as well as respiration rates. In the red box in the figure above, firstly, the respiratory peaks and trills of EMD-EDR and EEMD-EDR are inconsistent with the original respiratory signals, and the respiratory waveforms of the whole minute are incomplete, resulting in poor respiratory extraction effect. Second, although CEEMD-EDR retains part of the characteristics of the respiratory cycle, the overall waveform is too smooth, and the detailed information between the crest and the trough is covered, and the characteristic information of the respiratory rhythm cannot be highlighted. The respiration extracted based on the NCEEMD-EDR method is more morphologically like the original respiration. This means that the NCEEMD algorithm can retain the morphological characteristics of the original breathing signal more accurately when extracting EDR. The NCEEMD method significantly reduces noise residue by incorporating additional EEMD decomposition of white noise, which effectively separates signal and noise, reducing mode mixing. Compared to traditional techniques like low-pass filtering or wavelet transform, NCEEMD excels in handling non-stationary and nonlinear signals, preserving the physical significance of the signal more accurately. Our experimental results indicate that NCEEMD maintains high signal extraction accuracy even in noisy environments.(Q3: Can you elaborate on the advantages of the noise residue removal process in the NCEEMD method compared to other noise removal techniques? Specifically, how does this method compare with other recent noise removal techniques?)

After the ECG derived respiratory EDR is obtained by different decomposition methods, Hilbert-Huang transform is applied to the original time-domain sequential signal in Fig. 9, and the obtained Hilbert spectrum represents the distribution and characteristics of the signal in time-frequency domain [9]. In the Hilbert spectrum, the main frequency variation is restricted to a narrow range of about 0 to 1.5Hz. By analysing the Hilbert spectrum, the characteristics and variation modes of the signal in the time-frequency domain can be obtained. It can help reveal features such as frequency components, frequency jumps, harmonics, nonlinear vibrations, and resonances in the signal.

In Fig. 10, EMD-EDR has the sparsest Hilbert spectrum, meaning that the breathing related waveforms in the signal have fewer discrete frequency components in a specific frequency range. The frequency of the Hilbert spectrum of EEMD-EDR and CEEMD-EDR is within the range of 0 to 1.5Hz, but the signal amplitude remains constant throughout the period, there is no significant amplitude modulation, and the energy distribution in the frequency space is weaker. The Hilbert spectrum energy of NCEEMD-EDR has a good locality in both frequency domain and time domain, and the extracted EDR signal has a similar instantaneous frequency change to the original breathing signal, reflecting the local characteristics of important events and sudden activities of the signal.

Compared with other algorithms, NCEEMD is more accurate and effective in extracting respiratory features from ECG signals.

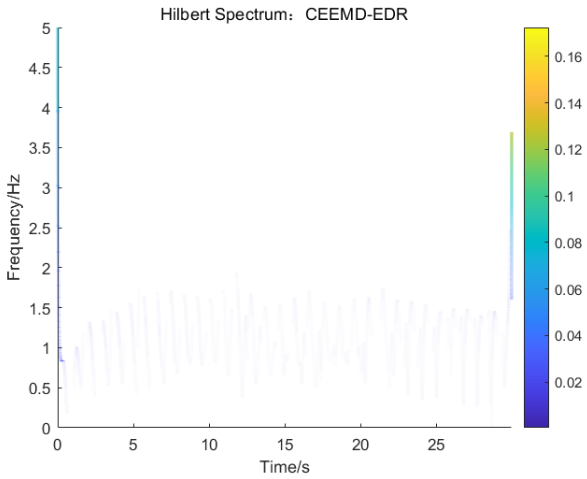
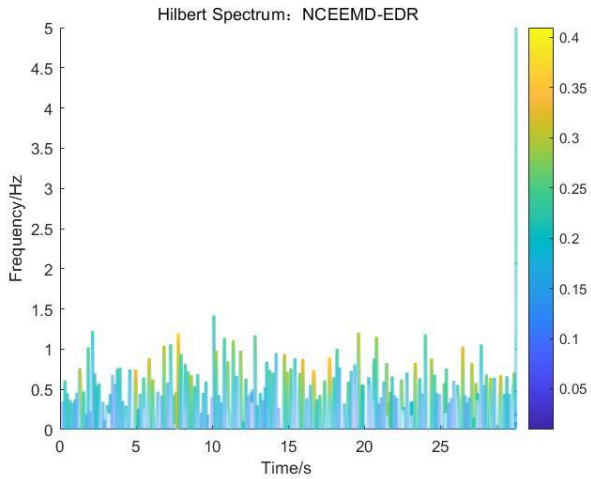
(b) Hilbert Spectrum of EEMD-EDR



(c) Hilbert Spectrum of CEEMD-EDR



(d) Hilbert Spectrum of NEEMD-EDR

Fig. 10. Compare the Hilbert Spectrum of different EDR extraction methods.

The error comparison of all records is listed below in Table IV. In Table IV, taking the slp01a record in MBPD as an example, the EDR extracted by this method has the smallest error in MSE, RMSE, and MAE of the original breath, and compared with CEEMD method, the average MSE is reduced by 3.95%, the average RMSE is reduced by 2.74%, and the average MAE is reduced by 2.52%. In most cases, the EDR extracted by the NCEEMD method minimizes all kinds of errors with respect to the original respiration (see the bolded part in Table IV), and the NCEEMD-based EDR method has a higher accuracy.

TABLE V. COMPARISON OF EEMD, CEEMD AND NEEMD INDICES RECORDED BY SLP01A

Method	Added noise amplitude：α	Number of added noises：Ne	Method computation time /s	Orthogonality index [27]
EEMD	0.2	100	**21.01**	0.21
CEEMD	0.2	100（50×2）	40.23	0.26
NCEEMD	0.2	100	25.14	**0.01**

The methods were run on a computer with a CPU model i7-11800H, 16GB of memory, and an RTX3050Ti graphics card. In Table V, under the same noise amplitude coefficient and number of noises, the computation time of this method is 25.14s, which is 37.5% faster than the CEEMD method. The orthogonality index of this method is only 0.01, and its decomposition components have higher independence, which can effectively extract the independent features or components in the data, and the physical meaning of IMF components is more explicit.

IV. Discussion

A. Significance Test of IMFs of White Noise

"Significance test of IMFs of white noise" aims to determine if the IMFs extracted from a given signal exhibit characteristics that can be attributed to random white noise or if there is a significant departure from randomness [24]. The IMF significance test for white noise has several purposes:

1) Verify the IMF extraction method: By resolving the IMF from white noise, it is possible to assess whether the chosen method can accurately decompose the signal into its inherent components.

2) Assess the randomness of the IMF: White noise is a random signal of equal intensity across all frequencies. If the IMF of white noise is found to be statistically significant, it indicates that the extracted components have some characteristics that deviate from random behaviour. This could indicate a non-random pattern or underlying structure in the signal. If the significance test shows that the IMF of white noise is not statistically significant, this means that the extracted components are likely random and do not contain any meaningful patterns or structures. Despite the increased computational complexity of the proposed NCEEMD method compared to existing EEMD and CEEMD methods, optimizations such as parallel computing and efficient programming techniques can significantly reduce computation time. Our experiments indicate that while the complexity is higher, the NCEEMD method remains manageable in terms of computational resources and offers significant advantages in accuracy and robustness, which are crucial for practical applications.(Q1: The proposed NCEEMD method adds complexity compared to existing EEMD and CEEMD methods. How do you address the increased computational cost and practical applicability of this method?)

The relationship between energy density and average period of Gaussian white noise. The horizontal coordinate is the natural logarithm of the mean period of IMFs, the curve is the natural logarithm of the mean energy of the significance line, and the red dot is the natural logarithm of the mean energy of all IMFs.

As can be seen from the figure, the natural pair value of the average energy of all IMF (the midpoint in the Fig. 11) is near the natural logarithm of the average energy of the significance lines (95% and 99% confidence intervals), and the IMF is statistically significant, that is, it is not produced by pure randomness. This shows that IMFs derived from Gaussian white noise decomposition contain some non-random patterns or structures. The residual of auxiliary white noise added to the original signal affects the decomposition results and physical significance of different IMFs. Based on the above analysis, the same decomposition of Gaussian white noise and the elimination in the frequency band of the IMFs corresponding to the original signal can eliminate or reduce the influence of noise residue on the reconstructed EDR.

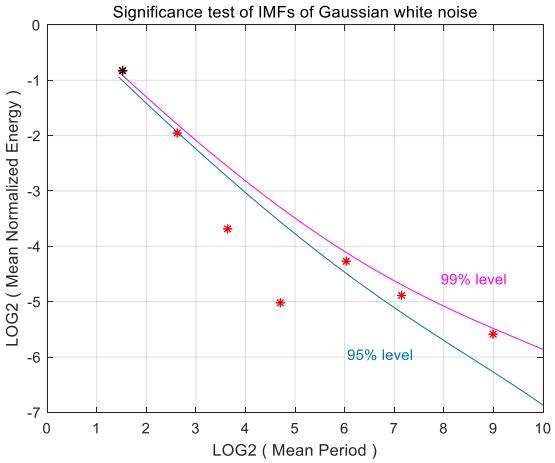

Fig. 11. Significance test of IMFs of white noise.

B. Cycle Comparison of NCEEMD-EDR and Original Respiration

The time of breath detected in the EDR signal is compared with the time of the corresponding reference breath signal in Fig. 12. The time window for determining the reference breath corresponding to the EDR is two seconds. Each breathing peak or trough is labelled to define the breathing beat.

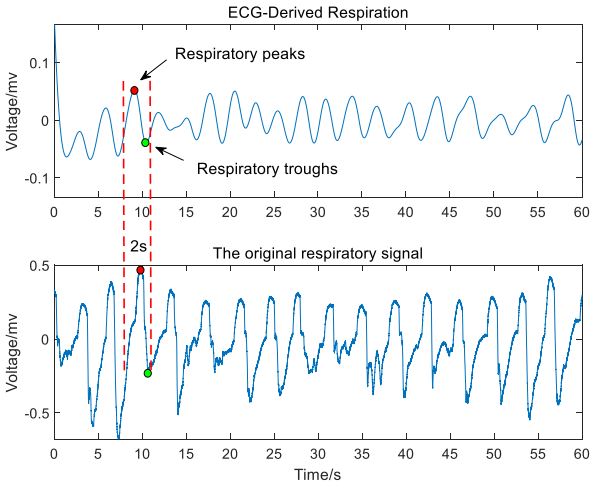

Fig. 12. Comparison of NCEEMD-EDR recorded by Slp03 with original respiration.

Based on the NCEEMD-EDR method, the number of respirations was extracted and compared with the measured number of respirations in the database in Table VI.

TABLE VI. CYCLE COMPARISON OF NCEEMD-EDR AND ORIGINAL RESPIRATION

Record	Age	Gender	This method respiration times/min	Measured respiration times/min	Errors/min
Slp01a	44	M	13	12	1
Slp01b	44	M	11	10	1
Slp02a	38	M	20	21	-1
slp02b	38	M	19	21	-2
Slp03	51	M	17	16	1
Slp04	40	M	9	10	-1
Slp14	37	M	13	15	-2
Slp16	**35**	**M**	**22**	**21**	**1**
Slp32	**54**	**M**	**7**	**7**	**0**
Slp37	39	M	18	18	0
Slp45	42	M	12	12	0
Slp48	56	M	13	11	2
Slp60	49	M	13	13	0
Slp61	32	M	17	18	-1
Slp66	33	M	15	18	-3
Slp67x	/	M	14	15	-1
Average error					-0.3125

As can be seen from Table VI, compared with the respiration cycle of NCEEMD-EDR and the original measured respiration, the error times were all less than two times/min, except for some data with large deviations. For patients with shortness of respiration (Slp16 record: 21 times/min) and slow respiration (Slp32 record: 7 times/min), the error times were 1 time/min and 0 times/min, and the total average error was about ±0.31 times/min. The EDR method based on NCEEMD had stronger robustness.

The respiratory signals extracted based on the method in this paper can be used in respiratory-related research and clinical applications. The analysis of respiratory signals can reveal respiratory rhythm and variability, help evaluate respiratory function and abnormalities, and monitor the progress and treatment effects of respiratory diseases. The NCEEMD-EDR method was applied to the extraction of ECG-derived breathing signals, and the accuracy and reliability of the method were evaluated by comparing the error accuracy and breathing period with the real breathing signals. The effectiveness of this method for measuring respiratory cycles has been proven and does not hinder its use in patient populations. In addition, it is an easy method to implement. The method proposed in this paper is feasible and effective in extracting respiratory rate and detecting respiratory activity during sleep, but the limitation is that this method cannot distinguish between obstructive apnea and central apnea, and can only provide reference guidance such as AHI index. A significant decrease in EDR signalling during apnea events is a sensitive feature for identifying obstructive apnea [18, 21]. The use of EDR technology to distinguish obstructive apnea from central apnea needs further research in the future.

The NCEEMD method offers several advantages in practical medical applications, including non-contact monitoring, which enhances patient comfort and compliance, and its robustness in detecting respiratory abnormalities such as sleep apnea. However, the method's higher computational complexity requires high-performance computing resources, potentially increasing costs. Implementing this method in hospital or home settings requires consideration of real-time data processing capabilities and system portability. Additionally, training medical personnel is essential to ensure accurate usage and interpretation of results. （Q4: What are the benefits and limitations of applying the proposed method in real-world medical environments? For instance, what additional considerations are needed when implementing this method in hospitals or homes?)

V. CONCLUSION

We compared four different methods to calculate EDR and found that they lead to different results. In this paper, a new complementary empirical ensemble mode decomposition respiration extraction method for deriving respiration signals from ECG signals is proposed, which does not require preprocessing of ECG data to obtain good EDR signals. As analyzed by experimental comparison, the NCEEMD decomposition yields more detail scales than the EMD decomposition and less residual noise in the IMF component than the EEMD and CEEMD decompositions. The NCEEMD-based breath extraction method proposed in this paper reduces the average MSE by 3.95%, the average RMSE by 2.74%, and the average MAE by 2.52%, while the computational time consumed is reduced by 37.5%, and the orthogonality of the obtained IMF decomposition components is better when compared with the CEEMD method. The EDR signal obtained by this method has a high similarity to the respiratory signal synchronously recorded by commercial instruments, which can be used for different applications such as sleep apnea detection and home-based respiratory monitoring.

Currently, our research is primarily based on the MIT-BIH database. However, we acknowledge the necessity of validating the method across various datasets to ensure its broad applicability and generalization. Future work will include testing the NCEEMD method on different physiological signal

datasets to further evaluate its performance under diverse conditions. In the initial phase of our research, we focused primarily on comparing the NCEEMD method with the most commonly used EEMD and CEEMD methods to validate its effectiveness. However, we plan to extend the scope of comparisons to include other recent respiration signal extraction methods, such as those based on machine learning and deep learning techniques, in future studies. This will help establish the relative superiority of the NCEEMD method in various scenarios and applications. (Q2: Have you validated the performance of the proposed method on datasets other than the MIT-BIH database? If not, do you think it is necessary to validate it across a variety of datasets? Q5: Why did you not include additional performance comparisons with other recent respiration signal extraction methods? Do you have any plans to provide more comparisons to better establish the relative superiority of the proposed method?)

***Abstract*—Sleep apnea is a prevalent sleep problem marked by interruptions in breathing or superficial breaths while asleep. This frequently results in disrupted sleep patterns and can pose significant health risks such as cardiovascular issues and daytime exhaustion Rapid Eye Movement (REM) sleep stage is easily identifiable due to rapid eye movements, intense dreaming, and muscle immobility. This stage is vital for cognitive processes, the strengthening of memories, and the regulation of emotions. Detection of REM sleep is essential for understanding sleep architecture and diagnosing various sleep disorders. This paper proposes two machine learning models to detect these disorders from physiological signals. The study employs the Apnea-ECG dataset from PhysioNet for sleep apnea detection and the Sleep-EDF dataset for REM detection. For sleep apnea, a ResNet-50 deep learning model is adapted to process ECG signals, treating them as image-like representations. ResNet-50 is trained on the Apnea-ECG dataset, which provides annotated electrocardiogram recordings for supervised learning. For REM detection, Gradient Boosting, an ensemble machine learning technique, is applied to EEG signals from the Sleep-EDF dataset. Relevant features associated with REM sleep phases are extracted from EEG signals and used to train the model. This paper contributes to automated sleep disorder diagnosis by presenting tailored machine learning models for detecting sleep apnea and REM from physiological signals.**

***Keywords*—Sleep Apnea; Rapid Eye movement; ResNet-50; Gradient boost; sleep stage; sleep disorders**

I. Introduction

Sleep disorders, can alternatively be referred to as sleep-wake disorders, encompass a range of issues related to sleep's timing, quality, and duration resulting in daytime impaired functioning and distress. Disorders like these often coincide with medical conditions or various mental health or medical conditions issues like anxiety, depression or cognitive disorders. They encompass various types, with insomnia being the most frequent, along with parasomnias, obstructive sleep apnea, restless leg syndrome, and narcolepsy.

Challenges with sleep impact both physical and emotional well-being, exacerbating existing mental health conditions and potentially indicating other mental health disorders. Insomnia is prevalent, affecting about a third of adults, with 6-10 percent crossing the scale for insomnia disorder. Sleep is essential for overall health, occurring in cycles throughout the night with REM sleep, related with dreaming, and Non-REM sleep, including deeper stages. The sleep timing is regulated by a 24-hour circadian rhythm.

Sleep needs vary by age and individual, with recommendations suggesting seven to nine hours of sleep per night for most adults. However, a significant portion of the population falls short of these guidelines, with many adults sleeping lower than six hours per night and only a minority of high school students achieving adequate sleep. Many Americans rate their sleep quality as poor, and millions struggle with chronic sleep disorders.

Sleep apnea is a problem which creates interruptions in breathing during sleep, categorized into Central Sleep Apnea (CSA) and Obstructive Sleep apnea (OSA). Symptoms include loud snoring, abrupt awakenings, and daytime sleepiness, potentially leading to serious health issues if untreated. Diagnosis involves sleep studies, and treatments range from lifestyle adjustments to surgical interventions for severe cases.

REM sleep is a distinct phase marked by increased brain activity, vivid dreaming, and rapid eye movement. It is essential for emotional regulation, learning, and memory consolidation, with disruptions affecting cognitive function and emotional well-being. Monitoring REM patterns is crucial for understanding sleep disorders and overall sleep health.

While sleep apnea and REM sleep are interconnected aspects of sleep physiology, they represent distinct phenomena. Sleep apnea involves breathing interruptions during sleep, disrupting the sleep cycle, while REM sleep is a specific stage crucial for cognitive and emotional processes.

With respect to REM sleep, individuals with sleep apnea often experience disruptions in this specific sleep stage. During REM sleep, the muscles become temporarily paralyzed (atonia) to prevent the acting out of dreams. In individuals with sleep apnea, the relaxation of throat muscles and partial or complete airway obstruction can lead to brief awakenings to resume normal breathing. These interruptions can fragment REM sleep, affecting the overall sleep architecture and potentially contributing to daytime sleepiness and other symptoms associated with sleep apnea. Monitoring REM patterns in sleep studies is essential for understanding the impact of sleep apnea on different sleep stages.

II. Background

Sleep apnea is a common sleep condition which entails constant interruptions in breathing throughout sleep, varying from partial to full obstructions of the airway. Central sleep apnea (brain signaling issue), obstructive sleep apnea (muscle-related), and complex sleep apnea syndrome are main types in sleep apnea. Factors that increase the likelihood of risk

encompass age, sex, obesity, and familial medical background. Symptoms encompass snoring, daytime sleepiness, and concentration difficulties. Left untreated, sleep apnea poses risks like cardiovascular disease. Treatment options range from lifestyle changes to medical interventions, emphasizing the importance of professional diagnosis and intervention. Sleep apnea and rapid eye movement (REM) are critical aspects of sleep monitoring, impacting over-all health and well-being. Sleep apnea is identified by interruptions in breathing or superficial breaths while asleep, resulting in disturbances to typical sleep rhythms. REM sleep is a phase where vivid dreaming occurs and is crucial for cognitive function and emotional wellbeing.

Conventional approaches to identifying sleep disorders typically depend on physiological indicators like electromyogram (EMG), electroencephalogram (EEG) and electrooculogram (EOG). These signals provide valuable information, but the complex interactions between different physiological factors can be challenging to capture effectively.

Sleep Apnea and Rapid Eye Movement (REM) are linked because episodes of sleep apnea can happen both during REM sleep and other sleep phases. In the course of REM sleep phase, the body enters a phase where muscles experience a natural state of paralysis or atonia, believed to prevent individuals from physically acting out their dreams. This muscle relaxation during REM sleep can contribute to the occurrence of sleep apnea episodes. The muscles in the throat may become overly relaxed, leading to an increased likelihood of airway obstruction.

III. Literature Review

In their study, Soler A. et al. [1] aimed to automatically Identify when rapid eye movements (REM) commence within REM sleep from EEG data by utilizing EEG signals, electrooculogram (EOG), and sub-mental electromyograms (EMG) collected from eight participants. The researchers introduced an algorithm focused on three key EOG parameters associated with REM: amplitude, duration, and slope. They utilized a process of resampling the data to 80Hz, followed by employing a double derivative method to detect peaks within the data. In their research, Seongju Lee et al. [2] introduced a sleep scoring approach utilizing EEG signals. Their model endeavors to categorize successive single-channel EEG segments into different sleep stages, paying special attention to classifying the EEG segment marked as the target, denoted as the L-th input EEG segment. Díaz, C. H et al. [3] in their paper proposed a system which detects Rapid Eye Movement using Support Vector Machine using EOG signals which were recorded by placing electrodes placed at the right and left canthus. The recorded signals were first marked by an expert who marked which candidate corresponds to REM (Rapid eye movement) and then using SVM the signals were classified whether they correspond to REM or not. The results obtained from SVM were later compared to results marked by the expert. In their study, Bahrami, M et al. [4] conduct a thorough examination of neural network-based learning and computational learning algorithms applied to the PhysioNet ECG Sleep Apnea dataset. They begin by preprocessing and segmenting electrocardiogram (ECG) signals. Then, they employ a variety of conventional machine learning as well as deep learning architectures for detecting sleep apnea. The dataset is divided into training, validation, and testing subsets to refine model parameters, hyperparameters, and evaluate model effectiveness. Through 5-fold cross-validation, the research reveals that hybrid deep learning models exhibit the most effective detection performance, achieving notable accuracy, sensitivity, and specificity. In their paper, Bernardini, A et al. [5] examine the significance of polysomnography (PSG) in diagnosing Obstructive Sleep Apnea Syndrome (OSAS), especially in individuals who have experienced a stroke. Traditionally, physicians manually identify OSAS episodes in PSG recordings, which is crucial due to the link between OSAS and increased mortality and neurological deficits in stroke patients. However, the limited availability of polysomnographs and healthcare professionals creates challenges in diagnosing OSAS, particularly in stroke patients. This research concentrates on data collected from 30 stroke patients treated at Udine University Hospital in Italy, with few exclusion criteria applied. The dataset comprises overnight vital signs from ECG, photoplethysmography, and PSG, along with expert annotations for OSAS. Despite the presence of noise and concurrent medical conditions within the data, the study endeavors to aid the creation of automated techniques for detecting Obstructive Sleep Apnea Syndrome (OSAS) using regularly monitored vital signs, applicable for practical use in real-world scenarios. Yoo, Y. et al. [6] in their paper presented an unsupervised method utilizing 61 GHz FMCW radar to detect three sleep stages which are wake sleep stage, REM sleep stage, and non-REM sleep stage by extracting characteristic breathing and movement information. Experimental results using clinical data show a 68% average similarity to polysomnography (PSG)-observed sleep stages, indicating the potential of Frequency Modulated Continuous Wave (FMCW) radar as a substitute for polysomnography (PSG) for sleep-stage detection. In their research. Gulyani, Majumdar, et al. [7] offer a comprehensive review concentrating on rapid eye movement (REM) sleep and the importance of investigating its deprivation. They delve into the historical context of REM sleep research along with its physiological attributes. The review underscores the importance of studies involving REM sleep deprivation in comprehending its functional importance and emphasizes the necessity for additional research in this domain. Yetton et al. [8] introduce a novel machine-learning strategy aimed at automatically identifying rapid eye movements (REMs). Their method, designed to enhance REM detection in sleep research, presents promising prospects for refining REM identification processes using advanced computational techniques. Hong et al. [9] investigate the importance of quick and vivid eye movements during sleep as a distinct marker of consciousness. They posit that REM sleep presents a special avenue for scrutinizing consciousness, providing valuable insights into its neural mechanisms and operations. The study elaborates on how delving into REM sleep can enhance comprehension of consciousness and associated phenomena. Vallat et al. [10] present a publicly available tool for automated sleep staging, created to effectively analyze sleep EEG data. The tool is intended to deliver superior performance and precision in categorizing sleep stages, thereby aiding both research and clinical endeavors. It serves as a beneficial asset for individuals in the scientific and medical communities who require

dependable approaches for automated sleep staging. Abbasi et al. (2021) [11] present a comprehensive review of obstructive sleep apnea (OSA), covering its epidemiology, pathophysiology, clinical manifestations, diagnosis, and treatment options. The paper provides an overview of the current under-standing of OSA, highlighting its prevalence, risk factors, and associated health consequences. It serves as a valuable resource for healthcare professionals and researchers interested in OSA management and advancements in the field. Osman et al. [12] provide contemporary viewpoints on obstructive sleep apnea (OSA), covering its prevalence, underlying mechanisms, symptoms, diagnostic approaches, and treatment options. The article offers perspectives on recent progress in OSA research and therapeutic interventions, acknowledging the complex nature of the condition. It stands as a valuable asset for healthcare practitioners and researchers aiming to gain a thorough grasp of OSA. Hirani et al. (2023) [13] conduct a scoping review to assess the current status of knowledge regarding sleep apnea. They explore various aspects of the disorder, including its prevalence, risk factors, diagnostic methods, treatment options, and associated comorbidities. The review provides an overview of the existing literature on sleep apnea, highlighting areas of consensus, gaps in knowledge, and avenues for future research. Levy et al. [14] introduce a study utilizing deep learning methods to diagnose obstructive sleep apnea (OSA) by analyzing single-channel oximetry data. Their investigation centers on harnessing sophisticated computational techniques to create a precise and effective diagnostic solution for OSA. The study showcases the promise of employing deep learning methodologies to enhance the detection and treatment of disorders in sleep, notably OSA, using oximetry data. Djonlagic et al. [15] examine how OSA specifically associated to REM sleep influences motor memory consolidation and emotional well-being. Their investigation seeks to determine if REM-related OSA impacts the consolidation of motor memories differently compared to emotional health. By delving into these areas, they aim to clarify the importance of REM-related OSA in both behavioral and mental functioning when you sleep. Chen et al. [16] presented a model with the help of single-lead ECG signals, on spatio-temporal learning for identifying sleep apnea. Their study concentrates on employing sophisticated computational methods to devise a reliable technique for recognizing sleep apnea occurrences. The research adds to the field by presenting an innovative method that utilizes spatio-temporal patterns in ECG signals to achieve precise sleep apnea detection, potentially enhancing diagnostic accuracy. Mukherjee et al. [17] carry out an experimental investigation centered on employing various deep learning models to identify and detect the apneas. Their study evaluates the efficacy of integrating various deep learning techniques to enhance the precision of sleep apnea detection. The research adds value to the field by showcasing the capability of ensemble methods in boosting the effectiveness of automated sleep apnea detection systems, offering significant insights for both future research endeavors and clinical implementations. Chang et al. [18] design a detection system for sleep apnea employing a single-lead ECG with a one-dimensional deep neural network model (CNN) architecture. Their study endeavors to devise an efficient technique for recognizing sleep apnea occurrences utilizing ECG data. The research adds to the field by offering a fresh approach that harnesses automation of apnea detection using deep learning techniques, utilizing readily available ECG signals. Gabryelska et al. [19] investigated the relationship between REM phenotype, excessive daytime sleepiness (EDS), and the severity of obstructive sleep apnea (OSA). Their investigation investigates whether there exists a link be-tween the severity of OSA and the occurrence of EDS, with a particular focus on analyzing the REM phenotype as a potential influencing factor. The study aims to clarify the interaction among these variables, offering understanding into the clinical consequences of REM-related sleep disruptions in OSA patients.

IV. Proposed System

The proposed system aims to detect sleep apnea and REM (Rapid Eye Movement) sleep using machine learning models trained on physiological signals. Two separate models will be developed: one for detecting sleep apnea from ECG signals and another for detecting REM from EEG signals.

For detecting Sleep Apnea ResNet-50 algorithm is used which is a deep learning model. The dataset used is Apnea-ECG dataset from physionet. The dataset comprising of ECG recordings collected for 7-10 hours. The R-R interval from ECG recordings is extracted and saved as images. From this R-R interval heart rate is calculated and the plots are saved as images. To this image data ResNet-50 algorithm is employed and the data is classified into two categories: sleep apnea, non-sleep apnea and the result is displayed in terms of accuracy.

For detecting REM (Rapid Eye Movement) Gradient Boost is used which is a ma-chine learning algorithm. The dataset used is Sleep-EDF dataset from physionet. The dataset comprises of polysomnographic data which includes EMG, EEG and EOG signals. EEG (electroencephalogram) Fpz-Cz is extracted from the data and stored in npz file format. These recordings are 8 to 10 hours long which are later divided into 30 seconds interval. The data is stored in array format in npz file from which da-ta(frequency) and label (sleep stage) is given as input for Gradient boost algorithm. Data is split into 70 percent training data and 30 percent testing data. The data is classified into two categories: REM and Non-REM sleep stage. The metrics used is displayed in terms of accuracy. Fig. 1 shows different phases and modules of the proposed system explained above.

A. Modules

1) Data acquisition and pre-processing: To change the default, adjust the template as follows.

a) Sleep apnea: The Apnea-ECG dataset, sourced from PhysioNet, is utilized for sleep apnea detec-tion, focusing on ECG signals. It includes 70 entries divided into a training set of 35 records namely (a01 to a20, b01to b05, and c01 to c10) and a test set of 35 records (x01 to x35). Each record includes continuous digitized ECG signals, human-expert-generated apnea annotations based on simultaneous respiration signals, and QRS annotations generated by machine. Eight recordings (file of a01 to a04, b01, and c01 to c03) also feature additional signals such as respiratory effort (Resp C and Resp A), oral-nasal airflow (Resp N), and oxygen level (SpO2). Multiple files are associ-ated with each recording, with specific data formats

detailed in corresponding .hea text header files. Binary annotation files (.apn) indicate the occurrence or ab-sence of apnea per minute in the training set recordings., while machine-generated QRS annotation files (.qrs) offer convenience for those not using their own QRS detectors. The dataset encompasses three subjects (a, b, c) and includes ECG signals classified into severe sleep apnea (Class A), moderate sleep apnea (Class B), and normal sleep (Class C). The model initially plots ECG signals and stores results in pkl file format, subsequently extracting heart rates from the recordings. Fig. 2, 3, and 4 depict plots of ECG signals from patients in Class A, B, and C, respectively.

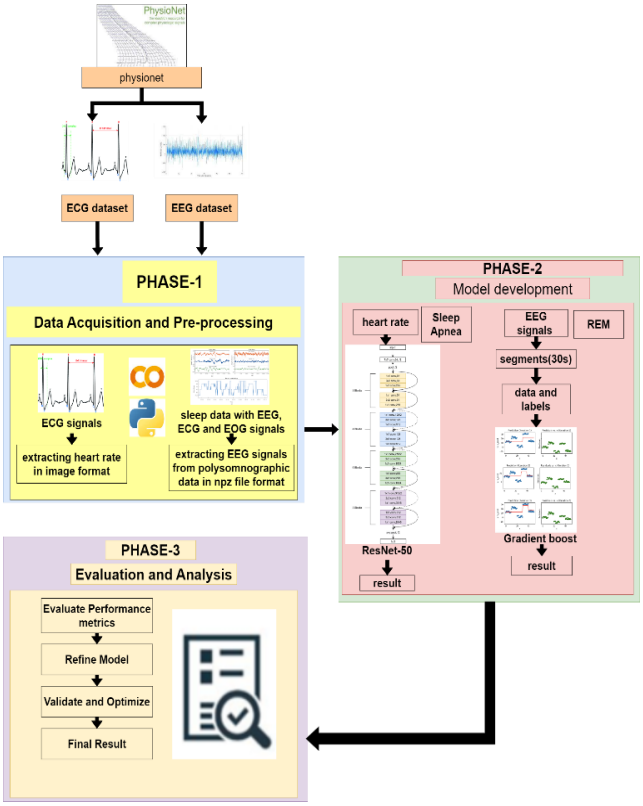

Fig. 1. System diagram.

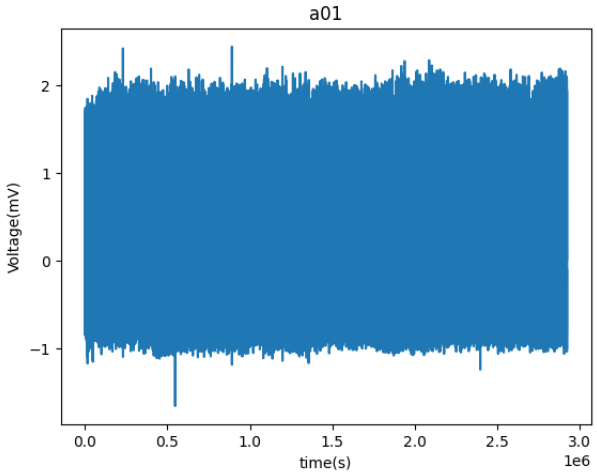

Fig. 2. Class A patient ECG signal plot.

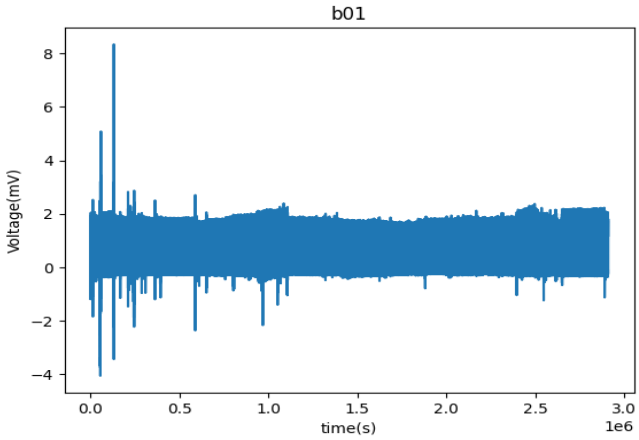

Fig. 3. Class B patient ECG signal plot.

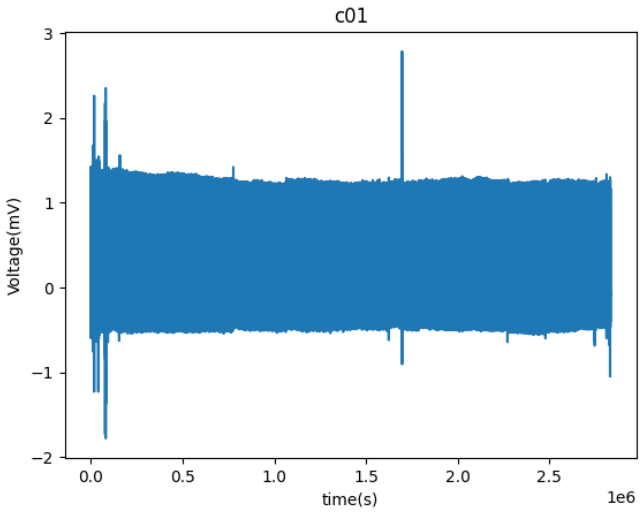

Fig. 4. Class C patient ECG signal plot.

ECG signals will have three waveforms which is P, QRS complex and T waves. The P waveform is depolarization of atria which is contraction of myocardial muscle. The QRS complex is depolarization of ventricles. The Q wave succeeds the P wave and begins with a slight downward deviation. The R wave follows Q wave and it is a sharp peak in the wave which is then followed by S wave which is small deflection downwards. If the QRS complex is 80-120ms then the heart is functioning properly. The t wave is repolarization of ventricles. The model will calculate heart rate from R-R interval. R-R interval is time lapse between two R waves. By dividing R-R interval from 60 it will get heart rate.

From the pkl files which were created the model will be extracting r-r interval and calculate the heart rate from it. It will extract the heart rate signal images and store them in a folder. Biosppy library in python is used to extract R-R inter-vals from ECG signal recordings. The biosppy library is a toolbox used for bio signal processing in python. The model will calculate heart rate by dividing r-r interval from 60. The heart rate is stored in mage format. Fig. 5, 6 and 7 shows heart rate plots of different patients belonging to A, B and C classes respectively where heart rate is in beats per second (BPS) and time is in seconds.

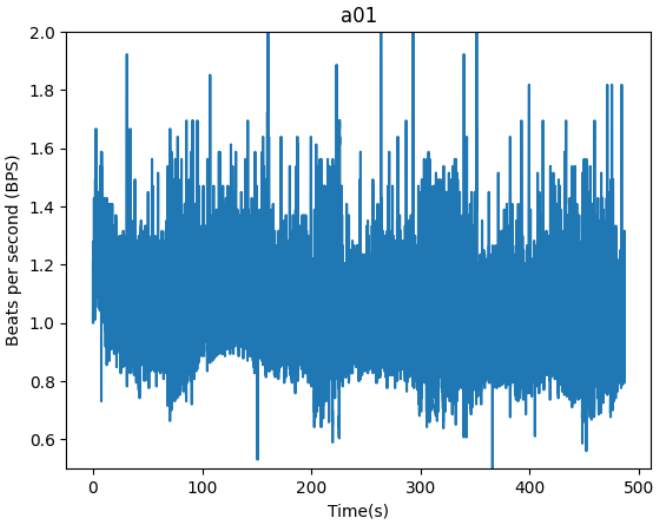

Fig. 5. Class A patient heart rate plot.

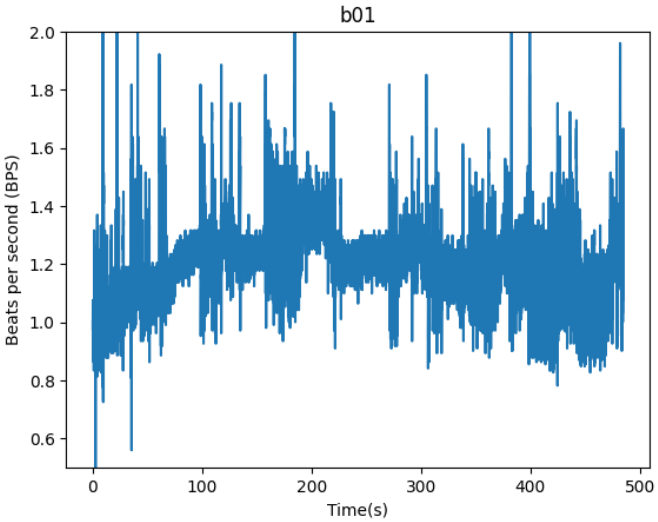

Fig. 6. Class B patient heart rate plot.

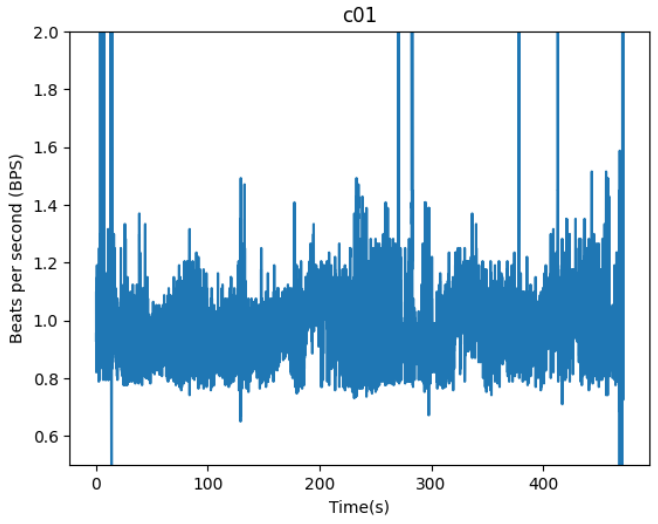

Fig. 7. Class C patient heart rate plot.

b) Rapid eye movement: The Sleep-EDF dataset sourced from PhysioNet includes 197 full-night polysomnographic sleep recordings, including event markers, EEG, chin EMG, and EOG. Data on body temperature and respiration are also included in certain record-ings. Trained technicians manually scored hypnograms corresponding to these re-cordings, detailing sleep patterns based on the Rechtschaffen and Kales manual. These annotated hypnograms are available within the database. From the Sleep-EDF data, the model extracts EEG Fpz-Cz signals and stores them in array format in npz files. A total of 39 recordings, each lasting 8 to 10 hours, are extracted. This data is then segmented into 30-second intervals, and the frequency and labels, stored in array format, are extracted and utilized as input data. This input data is divided into testing and training sets in a 30:70 ratio. Fig. 8 shows plots of EOG, EMG, and EEG signals from the data of Sleep-EDF procured from PhysioNet.

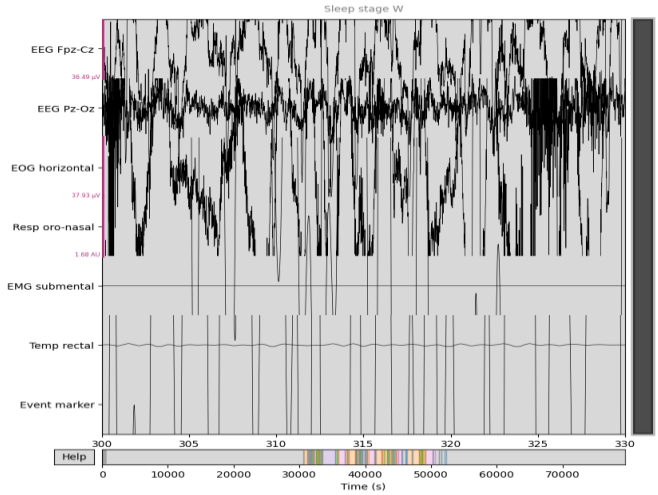

Fig. 8. EEG, EOG and EMG signals.

2) Implementation:

a) ResNet-50 for sleep apnea detection: The model will utilize the ResNet-50 architecture for sleep apnea detection, employing transfer learning. Transfer learning involves repurposing a model trained on one task (the source task) for another related task (the target task). Usually, this involves adjusting the pre-existing model using a smaller set of data tailored to the particular task at hand. This approach leverages the insights acquired from the original task to improve performance on the new task, particularly in situations where there is limited labeled data available for training. The model will be using pre-trained ResNet-50 model. ResNet-50 algorithm is employed to detect sleep apnea from heart rate images. ResNet-50 operates by incorporating residual connections into the architecture, which serves to maintain continuous information flow and mitigate gradient vanishing issues. The residual connection, functioning as a shortcut, allows information to bypass one or more layers, reaching the output directly. By learning residual functions, the network can efficiently make incremental parameter updates, facilitating faster convergence and enhanced performance. This approach is grounded in the concept that learning the residual function,

which maps inputs to desired outputs, is more straightforward than mastering the intricate mapping between inputs and outputs. ResNet-50 is organized as a series of residual blocks, each comprising layers of convolution, activation using ReLU, batch normalization, and incorporating skip connections. ResNet-50 model is built on following layers to detect Sleep Apnea. Let x_i be the input to the model where i indexes the elements in the input vector (features). The ResNet-50 model generates an output labeled as x, which undergoes processing through a Global Average Pooling layer, denoted as $GAP(x)$. The result of this pooling layer is a fixed-length vector, termed as g. The subsequent layers consist of fully connected (dense) layers followed by dropout layers:

$$h\_i = \sigma(w\_i.g + b\_i) \quad (1)$$

where, w_i represents the weight matrix, denotes the bias vector, σ stands for the activation function which is ReLu for ResNet-50 and g is output of previous layer.

First fully connected layer: $h\_1 = \sigma(w\_1.g + b\_1)$

First Dropout layer: $h\_2 = Dropout(h\_1)$ where h_2 is the output after applying dropout to h_1

Second fully connected layer: $h\_3 = \sigma(w\_2.h\_2 + b\_2)$

Second Dropout layer: $h\_4 = Dropout(h\_3)$

Third fully connected layer: $h\_5 = \sigma(w\_3.h\_4 + b\_3)$

Third Dropout layer: $h\_6 = Dropout(h\_5)$

Fourth fully connected layer: $h\_7 = \sigma(w\_4.h\_6 + b\_4)$

Fourth Dropout layer: $h\_8 = Dropout(h\_7)$

Output layer (softmax): $\hat{y} = softmax(w\_5.h\_8 + b\_5)$, where $\hat{y}$ is the predicted output vector.

The softmax function calculates the probability distribution across the output classes. The ReLU activation function brings non-linearity to neural networks, enabling them to capture intricate patterns within the data. It is a commonly employed component in deep learning models because of its straightforwardness and efficacy in mitigating the vanishing gradient issue during training.

$$f(x) = (0, x) \quad (2)$$

The sparse categorical cross entropy loss function is used to compute loss. Rather than using one-hot encoded vectors, this function is frequently employed in classification problems when the target labels are integers. It is suitable when the classes are mutually exclusive (each sample belongs to exactly one class).

b) Gradient boost for REM detection: For REM detection, Gradient Boosting is utilized to identify the sleep stage. Gradi-ent Boosting functions through iterative steps: it starts with a simple base model, typically a decision tree or a constant prediction, and sequentially fits fresh models to the prior models' residuals. A fresh weak learner is taught to reduce the mistakes produced by the collection of models that have already been built in each epoch. Residuals, indicating the differences between the actual and predicted values, are computed and utilized as the target for subsequent models. The predic-tions of each new model are integrated with those of the previous ones, gradually refining the ensemble's predictions. Techniques like regularization, includ-ing shrinkage and tree constraints, are applied to prevent overfitting and improve generalization. Through this iterative process, Gradient Boosting maximizes a given loss function, such cross-entropy in classification or mean squared error in regres-sion., ultimately generating a robust predictive model capable of accurately capturing intricate patterns in the data.

3) Model evaluation and final result: After the models are built and they are trained with the training data created in the data pre-processing module. The performance of the models is checked using accuracy as the performance metrics. The hyperparameters of models are refined based on the accuracy achieved. The best accuracy is considered as the final result.

Accuracy is a commonly used measure in machine learning to evaluate how well a classification machine learning or deep learning model performs. It quantifies the ratio of accurately classified instances to the total instances.

Mathematically, it is calculated as:

$$accuracy = \frac{no\ of\ correct\ predictions}{total\ no\ of\ predictions} * 100 \quad (3)$$

The count of correct predictions refers to instances where the model's prediction aligns with the actual target label. The total number of predictions denotes the overall count of instances present in the dataset.

V. Experimental Setup

The proposed system is deployed on a DELL laptop of Inspiron 5490 model equipped with an Intel(R) Core (TM) i5-10210U processor. The CPU boasts a base clock speed of 1.60GHz, indicating its capability to execute tasks at a consistent rate. Furthermore, it features a maximum clock speed of 2.11GHz, which suggests enhanced performance potential, particularly during more demanding computational tasks. The device is efficient enough and has the ability to handle more intensive workloads, making it suitable for running the computational models for sleep apnea and REM detection effectively.

The proposed system was developed and executed using Google Colaboratory, a no-cost, cloud-based platform created by Google. It offers a collaborative environment based on Jupyter notebooks for coding in Python. Google Colaboratory pro-vides access to GPUs and TPUs for performing high-performance computing tasks and train machine learning models efficiently. Integrated with Google Drive, Colab allows seamless saving and sharing of notebooks and for storage of extracted data. Google Colaboratory is pre-installed with popular libraries like TensorFlow and NumPy. It supports data analysis and machine learning workflows. Further-more, Colab offers access to various Google services such as Cloud Storage and BigQuery, enhancing its versatility and integration capabilities for a wide range of projects and applications.

A. Dataset Size

For sleep apnea the heart rate images are extracted from ECG signals. The R-R intervals of ECG signals which are

recorded for 7 to 10 hours have been divided in 60 seconds intervals to calculate heart rate. These heart rate images are stored as training, validation and testing data. Fig. 9, 10 and 11 shows the training data, validation data and testing data sizes respectively which are used to train and test the model developed.

20099 images from both classes belong to training data.

```
[ ]  train_generator = datagen.flow_from_directory(
        directory="/content/gdrive/MyDrive/capstone/cnn/Apnea_train/train",
        classes = class_names,
        target_size=(224, 224),
        batch_size=32,
        class_mode="binary",
    )

     Found 20099 images belonging to 2 classes.
```

Fig. 9. Training data size for sleep apnea.

The validation data consists of 6741 images in both classes.

```
[ ]  # validation data
     valid_generator = datagen.flow_from_directory(
         directory="/content/gdrive/MyDrive/capstone/cnn/Apnea_train/val",
         classes = class_names,
         target_size=(224, 224),
         batch_size=32,
         class_mode="binary",
     )

     Found 6741 images belonging to 2 classes.
```

Fig. 10. Validation data for sleep apnea.

Testing data consists of 6291 images in both classes.

```
[ ]  # test data
     test_generator1 = datagen.flow_from_directory(
         directory="/content/gdrive/MyDrive/capstone/cnn/testing_final1",
         classes = class_names,
         target_size=(224, 224),
         batch_size=32,
         class_mode="binary",
     )

     Found 6291 images belonging to 2 classes.
```

Fig. 11. Testing data for sleep apnea.

For REM the dataset size consists of X and Y. X consists of data and Y consists of labels which is shown in Fig. 12.

```
[3]  # Load npz files

     # Change variable 'path' with own path

     path = '/content/gdrive/MyDrive/rem/data' #the path where the npz files were saved in the first notebook.

     files = os.listdir(path)
     filespath = []
     for i in files:
       filespath.append(os.path.join(path,i))

     X, Y = _load_npz_list_files(filespath)

     X = X.reshape((X.shape[0], X.shape[1]))
     print(X.shape, Y.shape)

     (42308, 3000) (42308,)
```

VI. Result and Discussion

ResNet-50 and Gradient boost algorithms were used to detect sleep apnea and REM (Rapid eye Movement) respectively. Accuracy is the metric employed to assess and contrast the outcomes of the proposed model with those of other models. ResNet-50 model classified heart rate images and detected the presence of sleep apnea. The model demonstrated validation accuracy of 90.21 and test accuracy of 90.001.

To visualize the performance of the model, few graphs were plotted.

Fig. 13 shows loss curve which depicts the change in the loss function's value over time (epochs or iterations) during the training of a machine learning model. The loss function evaluates the difference in variability between the predicted values and the actual target values, acting as an indicator of the model's effectiveness. Training loss and validation loss of each epoch is plotted using line graph.

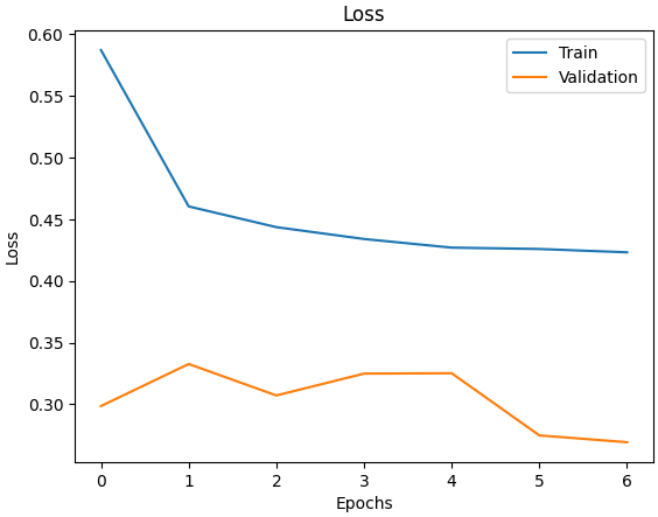

Fig. 13. Loss curve.

Fig. 14 shows accuracy curve. The testing and validation accuracy of each epoch is plotted using a line graph.

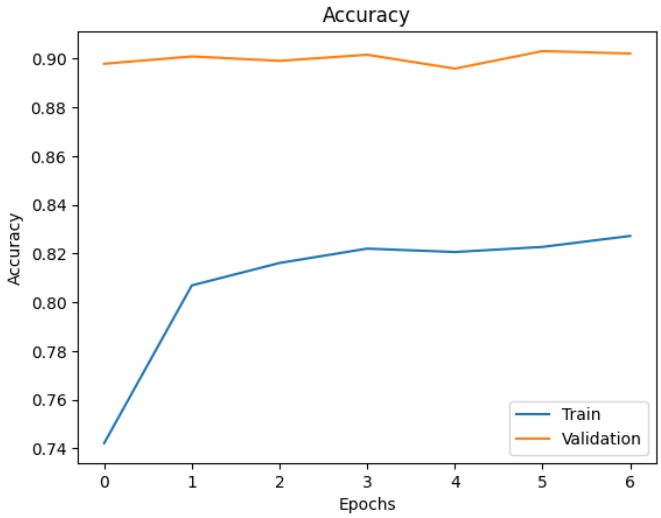

Fig. 14. Accuracy curve.

Fig. 15 and Fig. 16 shows the bar graph plot of duration in minutes where each patient doesn't experience Sleep Apnea and duration in minutes where each patient experiences Sleep Apnea.

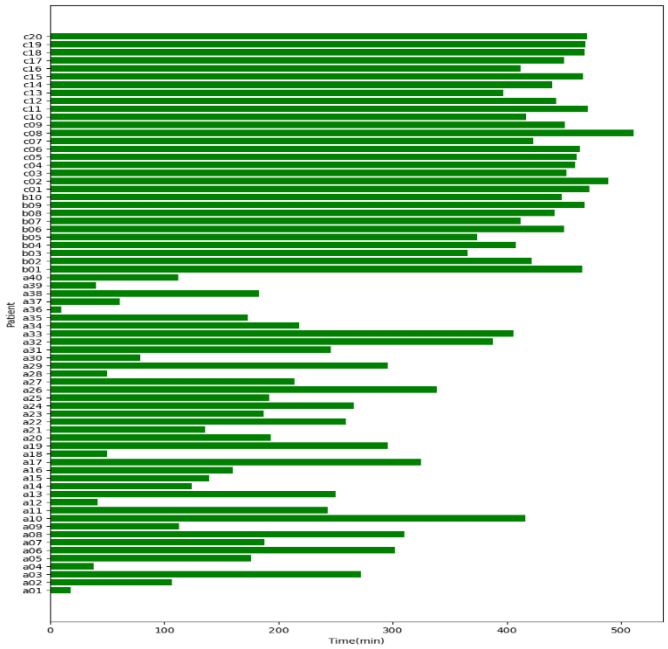

Fig. 15. Non-Apnea duration for each patient.

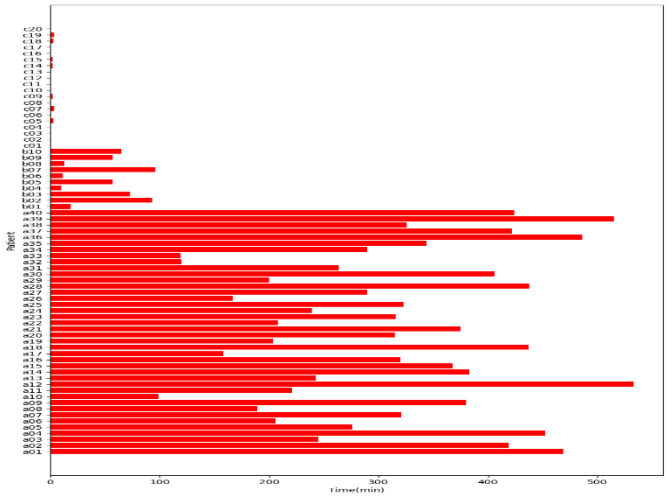

Fig. 16. Apnea duration for each patient.

Fig. 17 shows overall duration in minutes from all the recording of patients where sleep apnea was detected and duration in minutes when sleep apnea is not present in the recordings. This plot shows the sum of duration in minutes of sleep apnea and duration when patients didn't experience sleep apnea from each ECG signal recording.

Feature correlation for each feature in the dataset has been calculated to find out which features are more important. Fig. 18 shows a bar graph where each feature of the data along with its importance according to the feature correlation calculated is plotted.

Table I gives an insight into other machine learning and deep learning models and the accuracies of each model compared with the ResNet-50 model. The accuracies have been referred from Bahrami, M et al. [4].

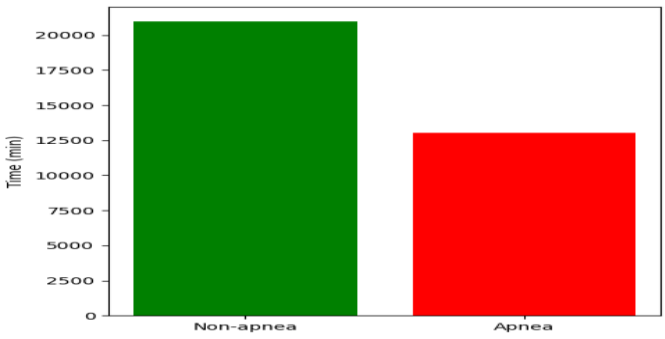

Fig. 17. Total Apnea and non-Apnea duration.

TABLE I. COMPARING THE ACCURACY PERFORMANCE OF THE RESNET-50 MODEL WITH THAT OF OTHER MODELS. THE MODEL ACCURACIES HAVE BEEN REFERRED FROM [4]

Model	Accuracy (%)
ResNet-50	**90.001**
LSTM (Long Short-term memory)	82.52
BiLSTM	82.45
GRU (Gated Recurrent Unit)	82.93
ZFNet	87.36
AlexNet	87.09
VGG16	87.26
VGG19	86.75
VGG16-LSTM	88.02
VGG16- GRU	87.78
VGG16- BiLSTM	88.01
VGG19- LSTM	87.06
VGG19- GRU	86.62
VGG19- BiLSTM	86.92
AlexNet- LSTM	87.32
AlexNet- GRU	87.11
AlexNet- BiLSTM	87.43
ZFNet- LSTM	87.84
ZFNet- GRU	87.43
ZFNet- BiLSTM	88.13
LDA (Linear Discriminant Analysis)	76.77
QDA (Quantitative Descriptive Analysis)	75.54
LR (Logistic Regression)	76.91
GNB (Gaussian Naïve Bayes)	75.96
GP (Gaussian Process)	77.26
SVM (Support Vector Machine)	78.44
KNN (K-nearest neighbours)	77.85
DT (Decision Tree)	74.47
RF (Random Forest)	77.79
ET (Extra Tree)	78.33
AB (AdaBoost)	77.09
GB (Gradient Boosting)	77.52
MLP (Multi-Layer perceptron)	78.52
MV (Majority Vote)	79.39

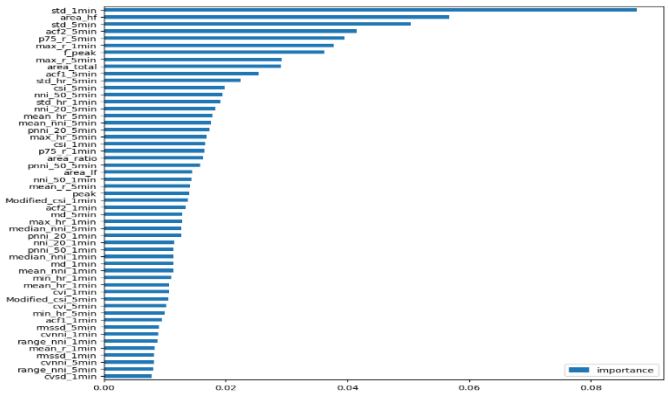

Fig. 18. Feature importance plot (max_r_5min, max_hr_1min, min_hr_5min etc.).

For REM the model used Gradient Boosting algorithm. The gradient boost algorithm has classified the sleep dataset into two stages: Non-REM and REM. The metrics used to validate the model is accuracy. The model has demonstrated an accuracy of 81.65% and precision of 50.77%, area under ROC curve is 54.39% recall score is 1.0.

The Receiver Operating Characteristic (ROC) curve visually represents the diagnostic effectiveness of a binary classifier system as it adjusts its discrimination threshold.

To visualize the model performance, ROC curve has been shown in Fig. 19.

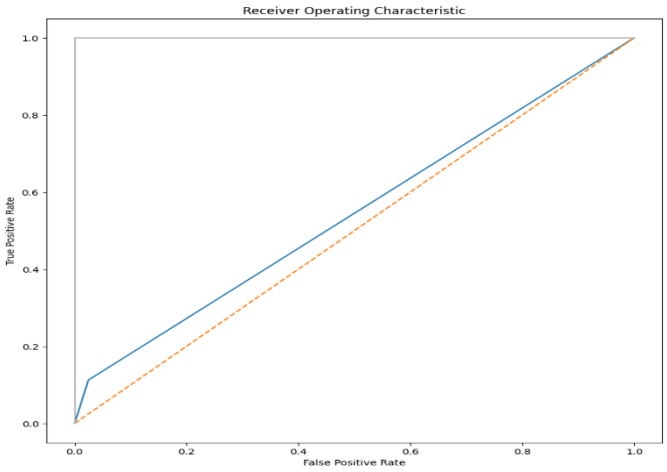

Fig. 19. ROC curve for REM detection using Gradient Boost.

The SHAP (SHapley Additive exPlanations) plot is a visual tool utilized for interpreting the results of machine learning models, particularly those with intricate decision making mechanisms such as tree-based models or deep neural networks. SHAP plots aid in comprehending the significance and impact of various features in the prediction process. SHAP values were plotted for all instances of the dataset. Fig. 20 shows shap plot where each feature of the data is plotted against its calculated SHAP value.

To visualize precision and recall scores, precision-recall curve was plotted. Fig. 21 shows precision score on y-axis and recalls core on x-axis.

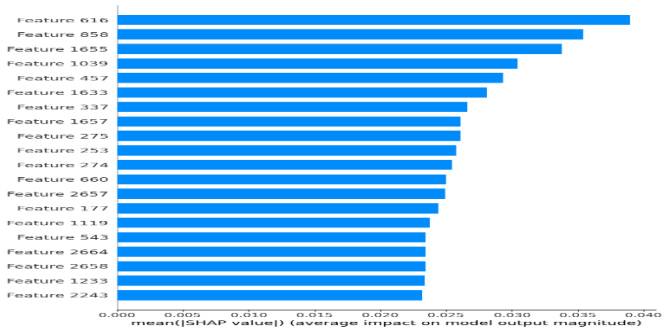

Fig. 20. SHAP plot for REM.

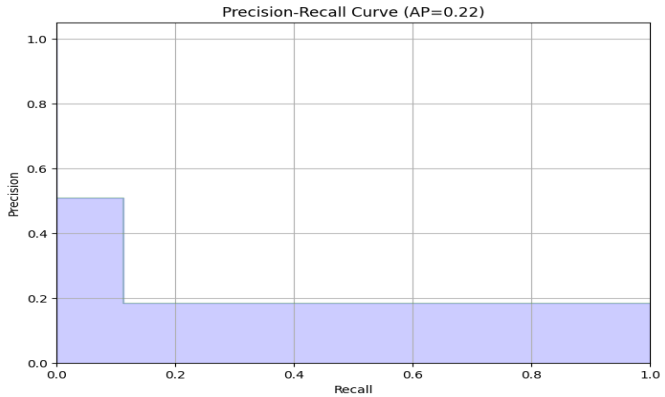

Fig. 21. Precision-recall curve REM.

VII. Conclusion and Future Work

In conclusion, this paper aimed at developing a comprehensive system to detect Sleep Apnea and Rapid Eye Movement (REM) using a multi model approach using ECG signals dataset from Apnea-ECG dataset from physionet and EEG signals data from Sleep-EDF data from physionet.

This provides a complete sleep analysis as the system is detecting sleep stage which is REM and sleep disorder Sleep apnea. For sleep apnea detection heart rate was extracted from ECG signals and ResNet-50 model was employed to detect Sleep apnea. Loss and accuracy curve was plotted to visualize the model performance. For REM EEG signals have been extracted from polysomnographic data which is Sleep-EDF data and Gradient Boost model was employed to detect the REM sleep stage. ROC curve, SHAP plot and precision-recall curves have been plotted to visually assess the model's effectiveness. Both the models have been validated using accuracy as the main performance metric.

Sleep apnea, both obstructive and central, can occur during REM sleep. During REM sleep, the muscles of the upper airway, including those in the throat, tend to relax more, which can exacerbate breathing difficulties in individuals with sleep apnea disorder. With reference to REM sleep, individuals suffering with sleep apnea often experience disruptions in this specific sleep stage. During REM sleep stage, the muscles become temporarily paralyzed (atonia) to prevent the acting out of dreams. In individuals with sleep apnea, the relaxation of throat muscles and partial or complete airway obstruction can lead to brief awakenings to resume normal breathing. These interruptions can fragment REM sleep, affecting the overall

sleep architecture and potentially contributing to daytime sleepiness and other symptoms associated with sleep apnea.

Future work could involve further investigation and validation to improve the system, facilitating its integration into clinical practice and enhancing the detection and treatment of sleep apnea and REM disorders, ultimately improving patient care. One promising direction is to develop a real-time implementation of the model that can run on edge devices, enabling the detection of sleep apnea and REM in home environments. This can be complemented by creating a mobile application that utilizes the trained models to provide immediate feedback and alerts to users, making sleep health monitoring more convenient. To ensure accessibility and user satisfaction, it is essential to design an intuitive, user-friendly interface suitable for non-technical users. Additionally, incorporating educational materials into the app can help users better understand their sleep patterns.

***Abstract*—PCOS is a common endocrine disorder that impacts women in their reproductive years characterized by irregular menstrual cycles, hyperandrogenism, and polycystic ovaries. Polycystic Ovary Syndrome (PCOS) presents significant challenges in diagnosis due to its heterogeneous nature and varied clinical manifestations. This project aimed to develop a comprehensive system for PCOS detection, integrating ultrasound images and clinical data through advanced machine learning techniques, using Rotterdam criteria for diagnostic decisions. Feature extraction from ultrasound images was conducted using the ResNet-50 deep learning model, while clinical data underwent correlation-based feature selection. Three classification algorithms - Support Vector Machine (SVM), Random Forest and Logistic Regression - were used to categorize the extracted features from ultrasound images. The integration of image-based and clinical-based features was explored and evaluated to have better accuracy revealing the potential for enhancing PCOS diagnosis accuracy. The developed system holds promise for assisting doctors in PCOS diagnosis, offering a holistic approach that leverages both imaging and clinical information.**

***Keywords*—PCOS; ultrasound images; clinical data; feature extraction; classification; Rotterdam criteria**

I. Introduction

Polycystic Ovarian Syndrome (PCOS) is a prevalent hormonal condition affecting individuals in their reproductive years, with a global prevalence estimated to be between 8% and 13%. This multifaceted condition is characterized by a range of symptoms, including irregular menstrual cycles, elevated levels of androgens (hyperandrogenism), and the appearance of multiple cysts on the ovaries as seen on ultrasound. Despite its widespread impact, PCOS diagnosis remains challenging, often requiring a multidimensional assessment of clinical, biochemical, and imaging data. However, current diagnostic approaches often rely on the interpretation of disparate data sources, leading to variability and potential delays in diagnosis. Current systems often lack clarity on the criteria used for diagnosis, leading to inconsistencies and potential misdiagnoses.

In response to these challenges, this research aims to introduce an intelligent PCOS diagnostic system that leverages machine learning to integrate health records and ultrasound imaging. The integration of health records provides a rich source of clinical and biochemical data, encompassing information on menstrual patterns, hormonal levels, and other relevant patient history. Complementing this, the inclusion of ultrasound imaging allows for the examination of ovarian morphology, particularly the presence of multiple small follicles. By combining these diverse data modalities, the proposed system seeks to create a more comprehensive and accurate diagnostic framework.

The main objective of this research is to enhance PCOS diagnosis, facilitating early identification and intervention. By harnessing machine learning algorithms, this study aims to develop a model that can identify nuanced patterns in the data, thus improving the accuracy and effectiveness of PCOS diagnosis. The integration of health records and ultrasound imaging serves as a strategic foundation, recognizing the importance of a holistic approach to reproductive health. Additionally, this research employs the Rotterdam criteria, a widely accepted standard in PCOS diagnosis, to ensure that the decision-making process is grounded in established clinical guidelines. The outcome of this research offers potential not just for reproductive health but also for the wider realm of personalized medicine and data-driven healthcare innovations.

II. Background

PCOS is a multifaceted hormonal disorder impacting women during their reproductive years, noted for its varied clinical presentations and effects on metabolic health. The diagnosis of PCOS involves a multifaceted assessment of various criteria, reflecting the heterogeneity of the syndrome. The Rotterdam criteria, [1] frequently embraced in clinical practice, require the presence of a minimum of two out of three primary features for diagnosis: irregular menstrual cycles (oligo-anovulation), clinical or biochemical indicators of elevated androgens (hyperandrogenism), and the observation of multiple cysts on the ovaries during ultrasound examination.

- Oligo-anovulation refers to irregular menstrual cycles or the absence of menstruation. This criterion acknowledges the hormonal dysregulation that often underlies PCOS and is crucial for diagnosis.
- Hyperandrogenism manifests as elevated levels of androgens, leading to clinical symptoms such as acne, hirsutism (excessive hair growth), and male-pattern baldness. Biochemical evidence, including increased testosterone levels, supports this criterion.

- Ultrasound imaging plays a crucial role in the diagnosis of PCOS by providing a visual representation of the ovaries. The typical findings include the presence of 12 or more small follicles (2-9 mm in diameter) in each ovary and/or an enlarged ovarian volume.

Despite these established criteria, PCOS diagnosis remains challenging due to variations in symptom presentation and the potential overlap with other conditions. The reliance on clinical judgment, often subjective, underscores the need for objective and data-driven diagnostic approaches. This study aims to address this need by proposing an intelligent diagnostic system that leverages machine learning to integrate health records and ultrasound imaging, contributing to a more precise, timely, and personalized approach to PCOS diagnosis. The subsequent sections will delve into the methodology, data integration processes, and potential implications of this novel diagnostic framework.

III. Related Works

Many research papers focusing on PCOS detection predominantly center on the identification of cysts within ultrasound images through a variety of methodologies. The paper by M. Sumathi et al. [2] demonstrates the effectiveness of utilizing image processing techniques and classification algorithms such as DarkNet-19, AlexNet, SqueezeNet, and SVM for automated PCOS diagnosis. Gray Level Co-Occurrence Matrix was used for extracting features from the images and classification with DarkNet-19 achieved 99% accuracy, thus improving performance metrics. PCO follicle detection through preprocessing, feature extraction, and classification phases proposed by Bedy Purnama et al. utilizes techniques like Gabor wavelets for feature extraction, [3] it employs SVM-RBF Kernel for classification, achieving 82.55% accuracy for Dataset A and 78.81% for Dataset B, demonstrating its potential for enhancing PCOS diagnosis accuracy. Yinhui Deng et al. proposed object-growing algorithm [4] initially identifies multiple objects, likely follicles, with high probabilities from ultrasound images. It utilizes a cost map to differentiate the ovary from external regions and dynamically updates potential follicles based on their cost functions. This approach achieved an 89.4% recognition rate and a 7.45% misidentification rate on 31 actual PCOS ultrasound images, demonstrating superior performance compared to other methods. The method by Sharvari S Deshpande et al. uses ovarian ultrasound image processing, feature extraction, segmentation, and classification through Support Vector Machine (SVM), achieving a high accuracy of 95%. [5] The research employs preprocessing techniques, including contrast enhancement and filtering, on ovarian ultrasound images. Feature extraction involves Multiscale morphological approach and Top-hat transform, while segmentation uses Canny edge detection. The approach proposed by SaymaAlma Suham et al. involves employing a CNN with transfer learning for feature extraction and a stacking ensemble machine learning model with XGBoost [6] as the meta-learner for classification. The proposed technique achieves accuracy improvement, reaching 99.89%, with reduced execution time compared to existing machine learning methods. The optimal performance is achieved by integrating the "VGGNet16" pre-trained model with CNN for feature extraction and utilizing "XGBoost" as the meta-learner for classification. An innovative machine learning approach was proposed by Pradeep Bedi et al., the Attention Residual UNet (AResUNet) Model, [7] for detecting PCOS. The model incorporates adaptive bilateral filter-based image pre-processing with attention-guided residual UNet allowing it to effectively handle both 2D and multi-modal images. The results demonstrate that the AResUNet Model achieves high accuracy of 98%. The method proposed by Asma' Amirah Nazarudin et al. combines Otsu's thresholding with the Chan–Vese method [8] to create a binary mask and define follicle boundaries. Compared to the classical Chan–Vese method, the proposed approach demonstrated superior performance with an average sensitivity of 0.74, which was significantly higher than the sensitivity of 0.54 for the classical Chan–Vese method.

Certain papers utilize clinical data, comprising information from manually recorded ultrasound images by radiologists, alongside other parameters crucial for PCOS detection. A balanced dataset was achieved Ejay Nsugbe by using synthetic sample generation software to mitigate bias in training prediction models. [9] Ten machine learning models were explored, revealing high-order SVM with a nonlinear decision boundary as the optimal classifier demonstrating superior performance. The research by Satish C. R Nandipati et al. aims to identify the most effective classification model and significant features for predicting PCOS, utilizing Python-Scikit Learn and RapidMiner tools. The results in [10] indicate that Random Forest achieves the highest accuracy (93.12%, RapidMiner) with the complete dataset, KNN and SVM exhibit similar accuracy (90.83%, RapidMiner) with 10 selected features. ML is employed to construct a stacking ensemble model by Hela Elmannai et al. combining LR, RF, DT, NB, SVM, KNN, Xgboost, and Adaboost [11] at the base learner level, with RF at the meta-learner level, aiming to enhance single ML performance. The resulting Stacking ML, particularly with REF feature selection, achieved notable performance recording high accuracy 98.87%. The application of ensemble classifiers, including Ensemble Random Forest, Extra Tree, Adaptive Boosting (AdaBoost), and Multi-Layer Perceptron (MLP) for diagnosing PCOS is explored [12] by Homay Danaei Mehr et al. Subrato Bharati et al.'s study compares classifiers using holdout and cross-validation methods. Their results show that ensemble Random Forest, with feature subset selection [13], achieves the highest accuracy of 98.89% and sensitivity of 100%. RFLR demonstrates the highest testing accuracy of 91.01% and a recall value of 90% when using 40-fold cross-validation on these 10 most important features. A novel feature selection method proposed by Shazia Nasim et al., optimized chi-squared (CS-PCOS) [14] to select required features for detecting PCOS. Among ten hyper-parameterized machine learning models, Gaussian Naive Bayes (GNB) excelled, achieving 100%. Employing MATLAB and a dataset from Kaggle, paper by Dana Hdain et al. [15] utilized seven classifiers, with Linear Discriminant exhibiting the highest accuracy and K-Nearest Neighbor showing the best sensitivity for detection of PCOS. The paper by Manjunathan Alagarsamy et al. employs preprocessing techniques, such as a heat map for feature correlation, and utilizes Support Vector Machine, K-Nearest Neighbors, Naive Bayes, and a Hybrid Algorithm [16] for classification. The proposed approach

demonstrates superior performance compared to other methods achieving high accuracies (97% for Ensemble, 95% for SVM, and 93% for Naive Bayes) in identifying PCOS-affected ovaries. The research by Amsy Denny et al. utilizes machine learning techniques, including Logistic regression, Naïve Bayes, and Random Forest Classifier (RFC), and identifies RFC [17] as the most accurate method with 89.02% accuracy. The machine learning models were implemented in Spyder Python IDE, and the system employed RFC after optimizing features with Principal Component Analysis (PCA). The article by Sayma Alam Suha et al. introduces a unique stacked ensemble approach [18]which combines weak traditional ML classifiers and boosting or bagging models, achieving 95.7% accuracy. It also explores feature selection techniques, with PCA identifying the top 25 features for effective forecasting.

The paper by Jay Jojo Cheng et al. aimed to develop ML algorithms for classifying polycystic ovary morphology in pelvic ultrasounds, [19] utilizing electronic medical records. Pelvic ultrasound reports from 39,093 patients were analyzed. The classifiers Gradient Boosted Tree text classifier and rule-based text classifier achieved high accuracy, with rates of 97.6% and 96.1% on the evaluation set of 1000 ultrasound reports. The paper by Victor Castro et al. aims to enhance the accuracy of identifying PCOS subjects [20] by utilizing electronic medical records text and data, compared to the conventional use of International Classification of Diseases 9 codes. A natural language processing approach was employed to identify PCOS subjects in electronic medical records, and an algorithm was developed using 32 terms to categorize definite PCOS cases based on Rotterdam criteria. The algorithm demonstrated a 64% confirmation rate for definite PCOS cases with a 9% false positive rate, comparable to the 66% confirmation rate using ICD-9 codes with an 8.5% false positive rate.

The work by Alamoudi et al. utilized [21] fine-tuned Inception architecture to classify ultrasound images, achieving 84.81% accuracy. Additionally, a study combining image and clinical features through deep learning showed promising results, with joint fusion type I outperforming, highlighting the significance of clinical data in PCOS diagnosis.

The above studies utilizes either ultrasound or clinical data to predict PCOS and lacks a standardized prediction basis. In contrast, this research employs a hybrid dataset and utilizes the Rotterdam criteria, endorsed by the NIH and widely used by medical professionals for diagnosing PCOS. This approach integrates both clinical and ultrasound data, providing a more comprehensive and validated method for PCOS prediction.

IV. Proposed System

The proposed PCOS detection system strategically combines deep learning and traditional machine learning methodologies for a thorough examination of ultrasound images and clinical data as shown in Fig. 1 below. The initial phase involves the application of a ResNet50 deep learning model to meticulously extract intricate features from ultrasound images leveraging the model's prowess in intricate pattern recognition.

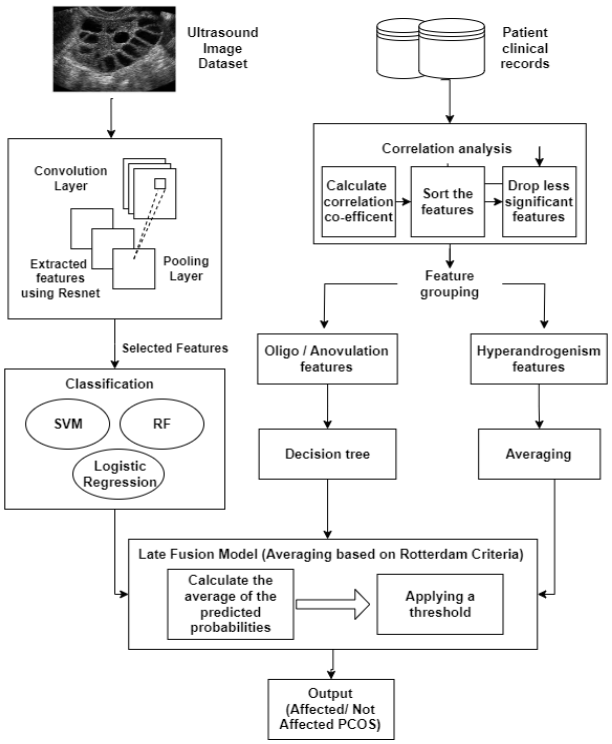

Fig. 1. System architecture to detect PCOS through ML and MMI.

These extracted features are pivotal for subsequent image classification, a crucial step in discerning whether the ultrasound images exhibit the characteristic traits of polycystic ovaries. Various classification models such as Support Vector Machines, Random Forest, and Logistic Regression are compared to find the best suited model.

Simultaneously, the clinical dataset undergoes meticulous curation through the selection of significant features, a process driven by correlation coefficients. This ensures that the subsequent analyses are streamlined, focusing on the most relevant clinical indicators. The chosen features are then segregated into two distinct categories: Oligo/anovulation features and hyperandrogenism features. For anovulation or oligo features, a decision tree model is deployed, bringing a level of interpretability to the assessment of irregular ovulation patterns. Concurrently, hyperandrogenism features undergo a nuanced analysis, with an averaging mechanism applied to gauge the extent of androgen excess.

The culmination of these diverse analyses leads to three distinct outputs, each providing a critical aspect of the PCOS diagnosis. The late fusion model, a mechanism that assigns weighted averages to the outputs, orchestrates the integration of these results. This step is pivotal, allowing for a nuanced combination of image-based evidence and clinically derived insights. The result of this intricate fusion process is the ultimate determination of whether the patient is affected with PCOS.

A. Ultrasound Feature Extraction

In the feature extraction process using the ResNet-50 model for ultrasound images, the aim is to capture and distill complex hierarchical features that are essential for subsequent

classification tasks. The ResNet-50 model, pre-trained on the ImageNet dataset, is employed as a feature extractor due to its proficiency in discerning intricate patterns and representations within images. The model, consisting of 50 layers, is well-suited for this task as it possesses a deep architecture that allows for the extraction of high-level features. The dataset consists of 3200 ultrasound images for training and 1468 images for testing. Each ultrasound image is loaded and resized to a standard size of 224x224 pixels. It is then converted into a numerical array and preprocessed to meet the ResNet-50 model's specifications. The pre-trained ResNet-50 model is then utilized to predict the features present in the image. ResNet-50 operates by passing the input image through a series of convolutional layers, pooling layers, and activation functions. The convolutional layers within ResNet-50 are designed to learn hierarchical features of increasing complexity. Lower layers of the network learn simple patterns like edges and textures, while deeper layers gradually extract more complex and distinctive features relevant to the task.

In each convolutional layer, the operation can be represented mathematically as a convolution operation followed by a non-linear activation function. Let us denote the output of the convolutional layer as H_l where l is the layer index. The mathematical operation for a single convolutional layer can be represented in Eq. (1):

$$H_l = \sigma(W_l * H_{l-1} + b_l) \quad (1)$$

where, W_l is the set of learnable weights (filters for layer l, H_{l-1} is the input feature map from the previous layer, b_l is the bias term, σ is the activation function (commonly ReLU). Throughout the network, the Rectified Linear Unit (ReLU) activation function is frequently employed to add non-linearity following each convolutional layer. ReLU function is defined as shown in Eq. (2).

$$f(x) = \max(0, x) \quad (2)$$

ResNet-50 makes use of residual blocks, which alleviate the vanishing gradient issue and facilitate the training of deep networks by introducing skip connections. Each residual block within the network contains a shortcut connection, allowing the input to bypass certain layers and directly propagate to deeper layers. Residual block is mathematically represented as shown in Eq. (3)

$$H_l = F(H_{l-1}, \{W_{l,i}\}) + H_{l-1} \quad (3)$$

where F represents the residual function $\{W_{l,i}\}$ denotes the set of learnable weights specific to the residual block and H_{l-1} is the input to the block. Global average pooling is used to transform the spatial data into a vector representation at the end of the convolutional layers. It is indicated mathematically through Eq. (4).

$$v = \frac{1}{N}\sum_{i=1}^{N} H_i \quad (4)$$

where v is the vector representation of the image features, N is the number of elements in the feature map and H_i represents the individual elements of feature map. For ultrasound images, these features might include distinctive patterns related to ovarian structures, cysts, or other relevant characteristics indicative of polycystic ovaries. The resulting feature vector is flattened to create a one-dimensional array, capturing the essence of the image's intricate characteristics. The features are then saved in a NumPy (.npy) file format, creating a reusable and compact representation that can be easily utilized in subsequent stages of the PCOS detection system, such as model training and classification.

B. Ultrasound Image Classification

The objective extends beyond a binary determination of the presence or absence of polycystic ovaries. Specifically, the classification system aims to discern nuances within the ultrasound images, including the identification of minimal and small-sized cysts, which are categorized as healthy and unhealthy ovaries are denoted with a greater number of cysts which are bigger in size. Three distinct classification models, namely Support Vector Machines (SVM), Random Forest, and Logistic Regression, are employed to discern patterns within these features and make predictions based on the labeled training data.

SVM, Random Forest, and Logistic Regression all analyze ResNet-50 features extracted from ultrasound images. SVM finds an optimal separation line, Random Forest combines multiple decision trees for complex patterns, and Logistic Regression estimates the likelihood of PCOS. Comparing their performance helps identify the best model for accurate PCOS classification, improving your overall detection framework.

C. Clinical Feature Selection and Analysis

A systematic and data-driven approach is employed to distill relevant information from a dataset comprising 39 features. The initial step involves a careful consideration of feature correlation coefficients, allowing for the identification and subsequent removal of features with less impact on the overall analysis. Correlation coefficients are statistical measures that quantify the direction and strength of the relationship between two variables. This curation process is crucial as it optimizes the dataset, focusing on attributes that exhibit stronger relationships with the outcomes of interest. The Pearson correlation coefficient is the default approach used by Python's corr() method to determine the correlation between columns in a Data Frame containing numerical data. The linear relationship between two continuous variables is measured by the Pearson correlation coefficient. Given two variables X and Y, with observations (x_i, y_i) for I =1, 2, 3, ……n, the Pearson coefficient r, is calculated as shown in Eq (5).

$$r = \frac{\Sigma(x_i-\bar{x})(y_i-\bar{y})}{\sqrt{\Sigma(x_i-\bar{x})^2}\sqrt{\Sigma(y_i-\bar{y})^2}} \quad (5)$$

The features that survive this correlation-based filtering are then categorized into two distinct sets: those features contributing to oligo/anovulation and those features associated with hyperandrogenism.

1) Ovarian dysfunction: The irregular menstrual cycles that characterize oligo/anovulation can be attributed to either infrequent periods (oligomenorrhea) or the total lack of ovulation and menstruation (anovulatory cycles). The main feature is the irregularity in cycle duration, which differs from the normal range of 21 to 35 days for menstrual periods. From the selected features after correlation analysis, features related

to menstrual cycle like cycle length(days), irregular cycles etc are grouped together into this category. For the set of features contributing to oligo/anovulation, a decision tree model is utilized. Decision trees are particularly effective in scenarios where complex decision-making processes depend on multiple factors. In the context of PCOS detection system, the decision tree scrutinizes the features relevant to oligo/anovulation, aiming to create a clear and interpretable decision path. The flow of decisions that decide if the person has ovarian dysfunction is shown in Fig. 2. This model facilitates the determination of whether an individual has a likelihood of PCOS based on the presence of oligo or anovulation, providing valuable insights into menstrual irregularities that are characteristic of the syndrome.

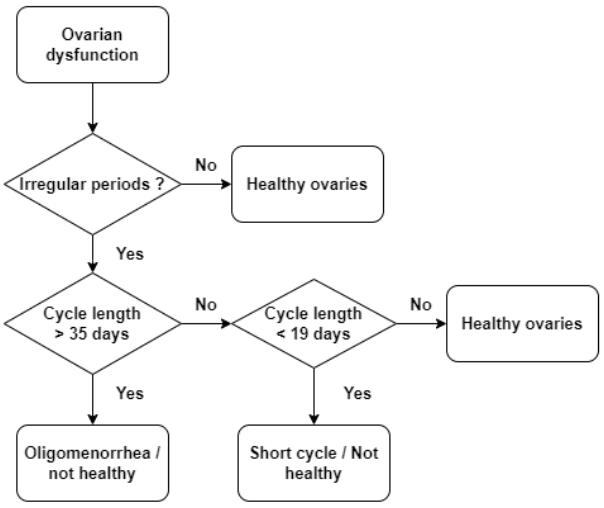

Fig. 2. Flow of decisions for features grouped into oligo/anovulation.

2) Hyperandrogenism features: Simultaneously, the features associated with hyperandrogenism undergo a distinct analytical process determined by averaging out the contributing factors. Features related to hyperandrogenism is grouped into this category after correlation analysis like skin darkening, pimples, hair loss etc. This approach acknowledges the multifactorial nature of hyperandrogenism, where diverse clinical indicators collectively contribute to the assessment of androgen excess. Averaging allows for a comprehensive and nuanced evaluation, providing a more accurate representation of the overall hyperandrogenic status. The integration of these clinical insights with the earlier image-based classification results in the final determination of PCOS presence, contributing to a holistic and robust diagnostic framework.

D. Data Integration and Final Prediction

In the data integration and final prediction stage of your PCOS detection system, the diverse outputs obtained from the ultrasound image SVM classifier, the oligo/anovulation decision tree, and the hyperandrogenism assessment are harmonized to yield a comprehensive and conclusive diagnosis. The distinct sources of information are treated as complementary dimensions contributing to the overall understanding of PCOS.

The SVM classifier, trained on the extracted features from ultrasound images, provides a binary classification output, discerning between individuals with and without polycystic ovaries. This classification serves as a foundational element in the final prediction, capturing crucial insights derived from the imaging data. Simultaneously, the decision tree model for oligo/anovulation offers a nuanced perspective on menstrual irregularities, helping identify individuals who exhibit characteristics associated with PCOS. This element enriches the diagnostic process by incorporating clinical indicators related to reproductive health aligning with the multifaceted nature of the syndrome. The hyperandrogenism assessment, determined through averaging clinical features, contributes a continuous and graded evaluation of androgen excess. This dimension acknowledges the spectrum of androgenic manifestations, offering a more refined understanding of the hormonal aspects of PCOS. The integration of these three outputs is orchestrated through a late fusion model, specifically a weighted average. The late fusion model allows for the consideration of the diverse nature of the inputs, assigning appropriate weights to each source based on their relative significance in the diagnostic process. But in this scenario as per Rotterdam criteria, equal weights have been assigned to the different inputs. Upon applying the weighted average, a continuous score is generated, reflecting the amalgamated insights from the image-based classification, reproductive health assessment, and hormonal evaluation. To finalize the prediction, a threshold is established, delineating the boundary between a positive and negative diagnosis for PCOS. This threshold serves as a decision criterion, guiding the system to categorize individuals based on the combined evidence from ultrasound images and clinical data.

The different phenotypes of PCOS are based on the presence or absence of these three features.

- Type A: This phenotype is the most prevalent and is distinguished by the presence of all three features: excess androgen levels, ovarian dysfunction, and polycystic ovarian morphology.
- Type B: This phenotype is defined by elevated androgen levels and ovarian dysfunction, although the ovaries do not exhibit the typical morphology associated with PCOS.
- Type C: This phenotype is marked by elevated androgen levels and the presence of polycystic ovarian morphology, despite normal ovarian function.
- Type D: This phenotype is distinguished by ovarian dysfunction and polycystic ovarian morphology, without the presence of elevated androgen levels.

These are just four of the many possible phenotypes of PCOS. The condition can vary greatly from woman to woman, and some women may have symptoms that do not fit neatly into any one category. The number of people affected with each phenotype is calculated to understand the diversity of the syndrome.

V. Results and Discussion

ResNet-50 extracted features from both training and testing datasets, yielding arrays of 100352 dimensions (224,224,2). Subsequently, three classification models – Support Vector Machine (SVM), Random Forest and Logistic Regression - were utilized to categorize the extracted features. Evaluation metrics were computed for each model to gauge their effectiveness. For SVM, the results demonstrated high accuracy (0.99), precision (0.99), and F1-score (0.98), along with a respectable AUC-ROC value of 0.98. Random Forest exhibited slightly lower accuracy (0.95) and AUC-ROC (0.89), but still showed strong precision (0.97) and F1-score (0.87). Logistic Regression performed consistently well across metrics, with accuracy at 0.97, precision at 0.92, recall at 0.92, F1-score at 0.92, and AUC-ROC at 0.95.

TABLE I. Comparison of Evaluation Metrics for Different Classification Models

Evaluation Metrics	SVM	Random Forest	Logistic Regression
Accuracy	99	95	97
Precision	99	97	92
Recall	96	79	92
F1 - score	98	87	92

Furthermore, Receiver Operating Characteristic (ROC) curves were plotted for all three models, providing visual insights into their performance. The ROC curve illustrates the true positive rate (TPR) on the y-axis against the false positive rate (FPR) on the x-axis, as depicted in Fig. 3. The area under the ROC curve (AUC) is a metric indicating the model's ability to differentiate between positive and negative cases. A perfect model would have an AUC of 1. In the provided ROC curve, the SVM model has the highest AUC (0.98), followed by the Logistic Regression model (0.95) and the Random Forest model (0.89). This suggests that the SVM model is the most effective at distinguishing between positive and negative cases in this scenario. The summarized results are mentioned in Table I.

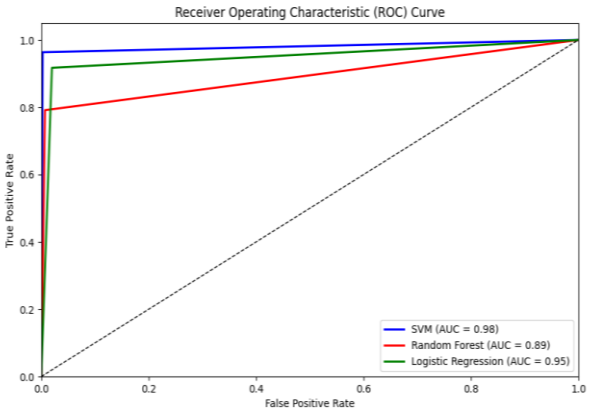

Fig. 3. ROC curve for three classification models.

The analysis also included SHAP interpretability plots for each model, enhancing the understanding of feature importance and contribution to classification decisions. Fig. 4, Fig. 5 and Fig. 6 displays the mean magnitude of SHAP values for each feature, showing both the direction and strength of the impact. Each dot represents a specific instance, and the color indicates the feature value (red for high values, blue for low values). Features are ordered by their importance based on the mean absolute SHAP values across all instances. The most influential features are located at the top. The horizontal position of each dot reflects the impact of the corresponding feature on the model's prediction for a specific instance. Dots positioned to the left contribute negatively, while those on the right contribute positively. The summary plot helps you understand the contribution of each feature to the model's predictions across different instances in your dataset.

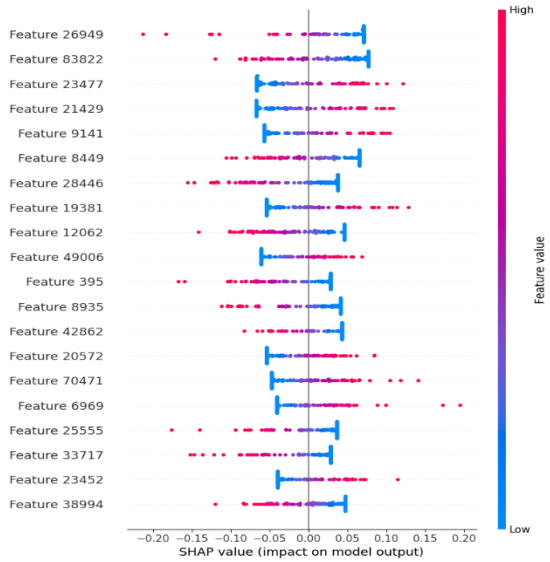

Fig. 4. SHAP interpretability of SVM classifier.

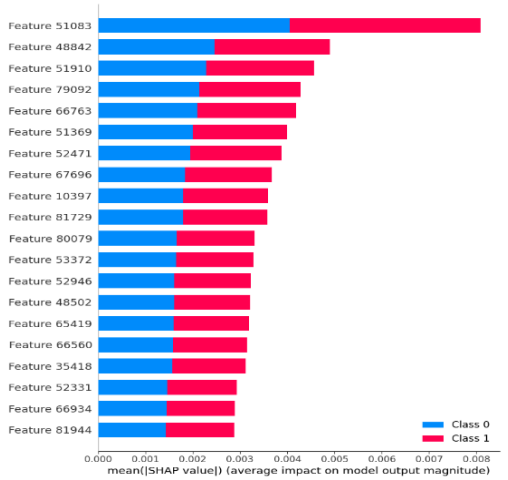

Fig. 5. SHAP interpretability of Random Forest classifier.

In the feature extraction process for clinical data, correlation coefficients were computed for various features, including Age (yrs), Weight (Kg), Height (Cm), BMI, Blood Group, Pulse rate (bpm), and others, which is plotted in x-axis. The y-axis shows the correlation coefficient, which is a measure of how strong the relationship is between a particular feature and PCOS. It can range from -1 to 1, where -1 indicates a perfect negative

correlation, 0 indicates no correlation, and 1 indicates a perfect positive correlation. Features with correlation coefficients above 17% were considered significant and selected for further analysis. The selected features include Weight (Kg), BMI, Cycle (R/I), Cycle length (days), Weight gain (Y/N), Skin darkening (Y/N), hair growth (Y/N), Hair loss (Y/N), Pimples (Y/N) and Fast food (Y/N). These features exhibit substantial correlations with the target variable or are deemed clinically relevant for PCOS diagnosis, thereby enhancing the effectiveness of subsequent analysis and modeling efforts.

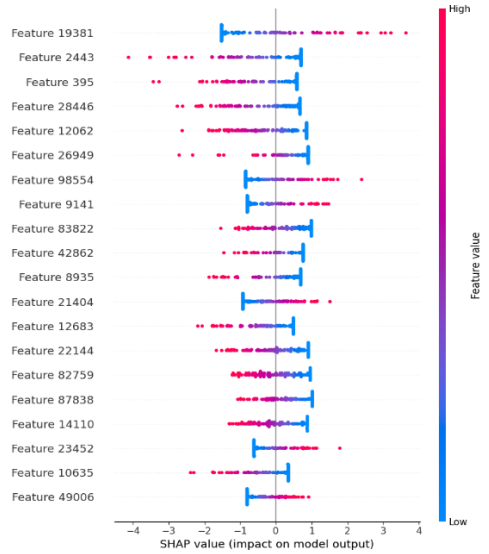

Fig. 6. SHAP interpretability of Logistic regression classifier.

The selected features are grouped into two categories, features contributing to hyperandrogenism and oligo/anovulation as shown below in Fig. 7. A decision tree helps assess irregular periods and Rotterdam criteria. Irregular periods with abnormal cycle length (less than 19 or more than 35 days) suggest oligomenorrhea, while normal cycle length (19-35 days) indicates healthy ovaries. Regular periods also suggest healthy ovaries. In the hyperandrogenism assessment, the features skin darkening, pimples, hair growth, hair loss, and fast-food consumption are collectively evaluated. Averaging these features provides a holistic perspective on the presence of hyperandrogenism, a common manifestation of PCOS. By combining these indicators, the analysis aims to capture the overall pattern of hyperandrogenic symptoms, offering a simplified yet comprehensive approach to assessing this aspect of PCOS.

The late fusion model integrates outputs from three distinct features- polycystic ovaries, hyperandrogenism, and oligo/anovulation to provide a unified assessment of PCOS diagnosis. Utilizing weighted averaging, each feature is assigned equal importance based on Rotterdam criteria, ensuring a balanced consideration of all contributing factors. If more than two inputs indicate the presence of PCOS, the individual is classified as having the condition, thereby delineating four distinct phenotypes. This approach facilitates a comprehensive evaluation of PCOS status, accounting for the multifaceted nature of the syndrome and enabling tailored treatment strategies based on identified phenotypes.

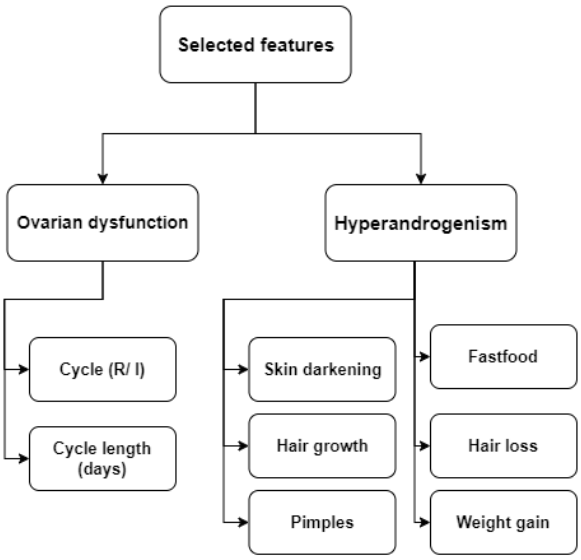

Fig. 7. Correlation analysis of clinical features.

The late fusion model uses weighted averaging and determines whether the patient is affected by PCOS or not. Fig. 8 shows the result of the fusion model in which out of the 1468 patients, 464 patients have PCOS whereas 1004 patients are not affected with PCOS.

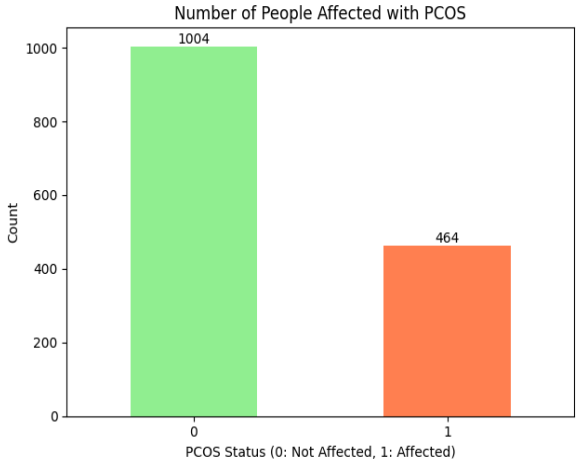

Fig. 8. Number of people affected vs. number of people not affected in total of 1468 patients.

The bar graph in Fig. 9 shows the distribution of people with and without polycystic ovary syndrome (PCOS) across three features that are commonly used to diagnose the condition according to Rotterdam criteria. There is fair share of affected and not affected for each feature which shows that each of the feature is important to accurately diagnose if the person has PCOS or not. It is important to note that not all women with PCOS will exhibit all these characteristics. Diagnosis typically involves a combination of symptoms, physical signs, and diagnostic tests such as blood tests and ultrasound imaging.

The affected patients (464 people) can be further categorized into 4 phenotypes to see the different possible combinations of features. The presence of all three features in a

patient gives Type A and the presence of two out of three features gives the rest of the phenotypes. (Type B, Type C, Type D). The number of people in different phenotypes are calculated and shown in Fig. 10. Type B is the phenotype with highest number of patients which shows that hyperandrogenism and ovarian dysfunction is equally important as polycystic ovaries for diagnosis of PCOS.

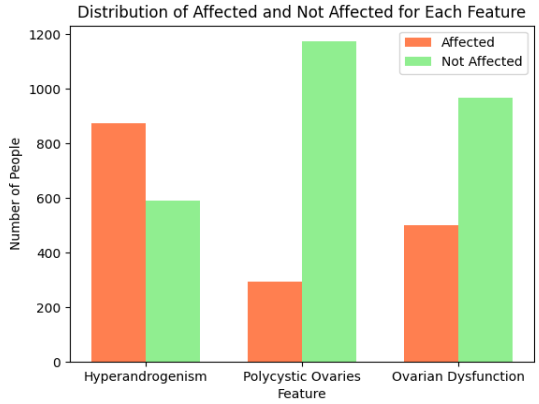

Fig. 9. Distribution of patients over three features mentioned as per Rotterdam criteria.

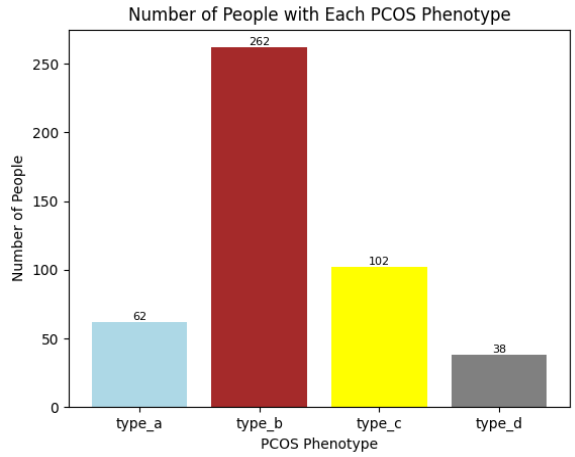

Fig. 10. Distribution of PCOS affected patients over different phenotypes.

The heatmap in Fig 11 appears to show the feature correlations between three features related to PCOS diagnosis: ovarian polycystic status, ovarian dysfunction, and hyperandrogenism. Each square in the heatmap illustrates the correlation coefficient between two features, varying from -1 (perfect negative correlation) to 1 (perfect positive correlation), with 0 indicating no correlation. The color intensity indicates the strength of the correlation, with darker shades denoting stronger correlations.

- Ovarian polycystic status: This feature has a strong positive correlation with both ovarian dysfunction (0.73) and hyperandrogenism (0.6). This suggests that patients with polycystic ovaries are more likely to also have ovarian dysfunction and hyperandrogenism, which are all characteristics of PCOS.
- Ovarian dysfunction: This feature has a moderate positive correlation with hyperandrogenism (0.4). This indicates that there is a positive association between these two features, but the relationship is not as strong as the one between ovarian polycystic status and the other two features.
- Hyperandrogenism: This feature has a weak positive correlation with ovarian polycystic status (0.6) and a moderate positive correlation with ovarian dysfunction (0.4). This suggests that hyperandrogenism is associated with both PCOS risk factors, but the strength of the association varies.

Overall, the heatmap confirms that there are positive correlations between all three features, which is consistent with the established risk factors for PCOS.

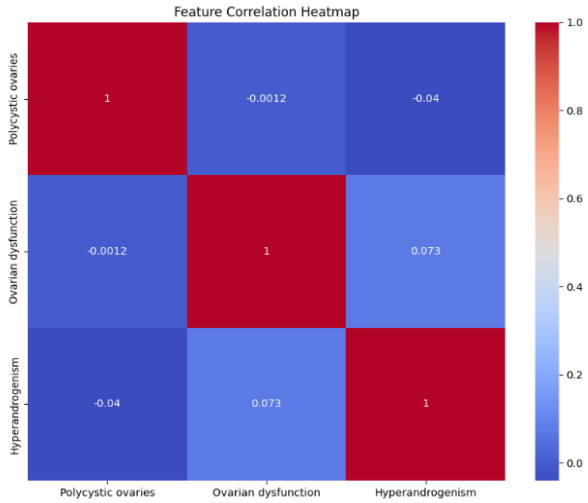

Fig. 11. Heatmap of feature correlation.

A. Validation of Results

The proposed system is evaluated on different evaluation metrics. The predictions are evaluated against the patient's actual health which is validated by a medical expert. The proposed system achieved promising performance metrics in the evaluation. Accuracy is the ratio of correctly classified instances to the total number of instances. It serves as a metric for assessing the overall performance of a model.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (6)$$

In Eq. (6), Eq. (7), Eq. (8), Eq. (9) TP stands for True Positive, TN stands for True Negative, FP stands for False Positive, and FN stands for False Negative. The proposed system attained an accuracy of 94%, indicating the overall correctness of the system's predictions. Precision is the ratio of true positive predictions (correctly predicted positive instances) to the total number of positive predictions made by the model. It gauges the accuracy of positive predictions.

$$Precision = \frac{TP}{TP + FP} \quad (7)$$

The precision of 96% indicates the proportion of correctly identified positive cases out of all predicted positives,

demonstrating the system's capacity to minimize false positives. Recall, on the other hand, is the ratio of true positive predictions to the total number of actual positive instances. It assesses the model's ability to identify all relevant instances.

$$Recall = \frac{TP}{TP+FN} \quad (8)$$

The recall rate of 87% signifies the system's capability to correctly identify most actual positive cases. F1-score, as the harmonic mean of precision and recall, offers a balanced measure between precision and recall, particularly useful when dealing with imbalanced classes.

$$F1score = \frac{2\ X\ Precision\ X\ Recall}{Precision+Recall} \quad (9)$$

The F1-score, reflecting a balance between precision and recall, was computed at 91 indicating a harmonious blend of the two metrics. Furthermore, the area under the receiver operating characteristic curve (AUC-ROC) was determined to be 93% as shown in Fig. 12.

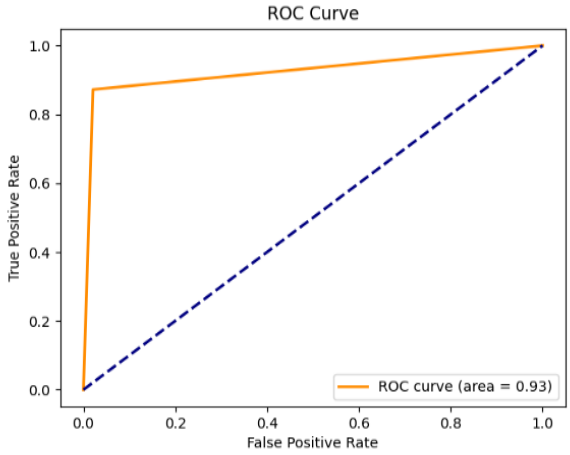

Fig. 12. ROC curve for the proposed system.

VI. Conclusion and Future Work

The project aimed to develop a comprehensive system for the detection of Polycystic Ovary Syndrome (PCOS) using a multi-modal approach, integrating both ultrasound images and clinical data. Feature extraction from ultrasound images was performed using the ResNet-50 deep learning model, achieving promising results. Three classification models-Support Vector Machine (SVM), Random Forest and Logistic Regression - were applied to classify the extracted features, with SVM demonstrating superior performance with 99% accuracy, 99% precision, 96% recall, and 98% F1 score. Furthermore, ROC curves and SHAP interpretability plots provided insights into model performance and feature importance.

In parallel, clinical data were analyzed, and feature extraction was conducted based on correlation coefficients, identifying key features relevant to PCOS diagnosis. The selected features from correlational analysis of clinical dataset were grouped into two categories of Rotterdam criteria: hyperandrogenism and Ovarian dysfunction. Decision tree was used to find if the patient has ovarian dysfunction based on the cycle length measure in days and irregularity of the cycle. Hyperandrogenism was determined by averaging different features contributing to it. Late fusion model is used to combine the results of all three deciding factors of PCOS as per Rotterdam criteria. The proposed system achieved 94% accuracy, 96% precision, 87% recall, 91% F1 score when evaluated against patients' actual health status. Thus, using two models of dataset, ultrasound images and clinical data of the patient is necessary for an accurate prediction of the syndrome. This study proves deep learning can analyze ultrasound images and clinical data for PCOS diagnosis. Enhancing the PCOS prediction through the utilization of larger, more diverse datasets containing extensive patient records encompassing various manifestations of PCOS. Incorporating additional etiological factors contributing to PCOS onset into predictive models for better forecast. Additionally, developing better methods to predict hyperandrogenism will be necessary as more features will be added to facilitate early and accurate diagnosis.

***Abstract*—In the contemporary educational landscape, proactively engaging in predictive assessment has become indispensable for academic institutions. This strategic imperative involves evaluating students based on their innate aptitude, preparing them adequately for impending examinations, and fostering both academic and personal development. Alarming statistics underscore a notable failure rate among students, particularly in courses. This article aims to employ predictive methodologies to assess and anticipate the academic performance of students in language courses during the G2 and G3 academic exams. The study utilizes the Gaussian Process Classification (GPC) model in conjunction with two optimization algorithms, the Population-based Vortex Search Algorithm (PVS) and the COOT Optimization Algorithm (COA), resulting in the creation of GPPV and GPCO models. The classification of students into distinct performance categories based on their language scores reveals that the GPPV model exhibits the highest concordance between measured and predicted outcomes. In G2, the GPPV model demonstrated the notable 51.1% correct categorization of students as Poor, followed by 25.57% in the Acceptable category, 14.17% in the good category, and 7.7% in the Excellent category. This performance surpasses both the optimized GPCO model and the singular GPC model, signifying its efficacy in predictive analysis and educational advancement.**

Keywords*—Academic performance; language; hybrid algorithms; Gaussian Process Classification; population-based Vortex Search Algorithm; COOT Optimization Algorithm

I. INTRODUCTION

Artificial Intelligence (AI) has significantly contributed to the growth and productivity of various industries, including transportation, communication, commerce, and finance. However, its impact on the education sector requires further refinement, particularly in the enhancement of AI-based learning systems designed to support students in both classroom and remote settings, as well as individuals with special needs [1], [2]. In software development, there is a notable emergence of instructional software tailored to individual learning needs. These innovative tools not only foster connectivity among learners but also provide access to a vast array of digital materials. Furthermore, they support decentralized learning tools, creating a dynamic and engaging learning environment that caters to diverse educational requirements [1].

In educational contexts, traditional machine learning approaches have been extensively employed, including support vector machine (SVM) [3], [4], decision tree [5], and matrix factorization (MF) [6], [7], along with their respective extensions [8], [9]. The SVM algorithm, in particular, is a frequently applied method known for its superior performance [3], [10]. However, its original design for binary classification poses limitations, as it does not inherently account for the relative importance of feature vector elements. While extensions for multiple classification problems exist, they may not consistently yield optimal results. The advent of deep learning [11], [12], [13], [14], [15] has brought about notable advancements in the educational domain. Despite its promising performance, the issue of overtraining looms large, especially when the dataset size is not sufficiently large. Recent studies propose that a moderately deep Artificial Neural Network (ANN) [16] can offer comparable accuracy without succumbing to overtraining, making it a viable alternative in educational applications. This nuanced understanding of traditional and contemporary machine learning methods provides valuable insights for selecting appropriate models tailored to specific educational contexts and datasets.

Analyzing and mitigating factors influencing student performance is a paramount concern for educational institutions aiming to reduce student failure rates. Educational data mining (EDM) emerges as a pivotal technique in this endeavour [17]. EDM encompasses the development of methodologies tailored to handle diverse data types within educational systems, ultimately enhancing students' learning outcomes [18]. Through the amalgamation of statistical, machine learning, and data mining approaches, EDM endeavours to extract and modify information from educational data, facilitating informed decision-making in the educational domain. The primary objective of EDM is to glean valuable insights from educational data, enabling effective decision-making to enhance educational outcomes [18]. By harnessing the power of predictive modelling, EDM can forecast students' academic achievement at an early stage [19]. This multifaceted approach encompasses various strategies to analyze and interpret educational data, offering institutions valuable tools for proactive intervention and support to improve overall student success.

The data mining project, initiated in 2013, constitutes a comprehensive effort aimed at extracting valuable insights from existing datasets to inform university management strategies, particularly in understanding student dynamics and refining university marketing policies. A thorough review of the literature indicates a sustained interest in these issues, with 63 researchers exploring various facets in recent years. Luan [20] delves into the potential applications of data mining in higher education, emphasizing resource efficiency and academic effectiveness. Several papers [20], [21], [22], [23] scrutinize student typology and targeted marketing through data mining

models. Similarly, DeLong et al. [24] and Nandeshwar and Chaudhari [25] focus on student types, marketing strategies, and enrollment prediction models based on admissions data, utilizing diverse data mining methods. Dekker et al. [26] concentrate on predicting student dropouts, contributing to the broader discourse on enhancing university management and decision-making through data-driven approaches in higher education.

In this comprehensive investigation, we utilize the Gaussian Process model along with two advanced optimization algorithms—the Population-based Vortex Search Algorithm (PVS) and the COOT Optimization Algorithm (COA)—to enhance the model and develop distinct versions (GPPV and GPCO). The primary objective is to categorize students' performance in language courses based on G2 and G3 exam results into four performance grades: poor, acceptable, good, and excellent. We rigorously evaluate and compare the predictive performance of these models using key classification metrics such as Accuracy, Precision, Recall, and F1-score.

This study aims to provide a thorough understanding of the research findings, with subsequent sections delving into the impact of carefully selected input data on model outcomes. Beyond categorizing students, the analysis extends to examining the models' predictive capabilities, highlighting their strengths and limitations. Furthermore, the article offers detailed explanations of the Gaussian Process model, the Population-based Vortex Search Algorithm, and the COOT Optimization Algorithm, providing readers with a comprehensive perspective on the methodologies employed in this study.

II. Data Selection and Preparation

Data mining, known as database knowledge discovery, involves the systematic extraction of valuable insights and patterns from large datasets. This process employs various techniques and algorithms to uncover hidden knowledge, contributing to informed decision-making and meaningful analysis. This study relies on an extensive dataset from previous research covering various variables. These include school, sex (female or male), age, residence, family size (famsize), parental cohabitation status (Pstatus), and details about the mother's and father's education and occupations (Medu, Fedu, Mjob, Fjob). The dataset also explores reasons influencing school choice, such as proximity, reputation, and course preferences. Additionally, it delves into aspects like the student's guardian (whether it is the father, mother, or another guardian), travel time to school (traveltime), weekly study hours (studytime), past failures, participation in educational support programs (schoolsup), family educational support (famsup), engagement in paid classes and extracurricular activities, attendance at nursery school, aspirations for higher education, internet access at home, romantic relationships, family relationships (famrel), free time, going out with friends, alcohol consumption in weekdays (Dalc) and weekends(Walc), health status, and school absences.

In Fig. 1, a visual representation illustrates the influence of each specified parameter on the outcomes of both G2 and G3 tests. The visualization employs a color-coded scheme, with red denoting the most positive impact (+1) and blue representing the most negative influence (-1). As the colours gradually fade, approaching zero, the corresponding influence diminishes. The shapes depicted tend towards circular, with a tendency towards elongation (oval) when nearing the maximum or minimum values. Examining the graph's details, it is evident that the most substantial positive effect is associated with the impact of each parameter on itself, visually depicted by the diameter of the shape. Following this, the influence of G2 on G3 emerges as particularly significant. In the final two lines of the figure, portraying the impact of each parameter on G2 and G3, it becomes apparent that failures exert the most pronounced negative impact, aligning with logical expectations. Furthermore, aspirations for higher education exhibit the most positive influence on these tests. Notably, the majority of effects are proximal to zero, signifying a circular and faint representation.

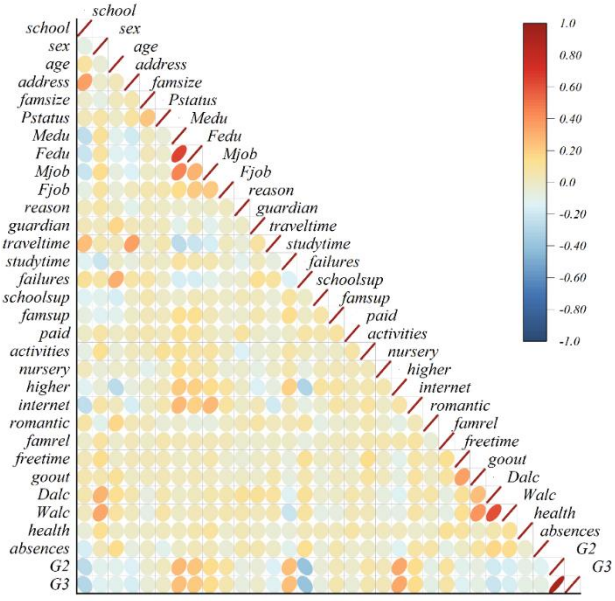

Fig. 1. Correlation matrix for the input and output variables.

III. GAUSSIAN PROCESS CLASSIFIER (GPC)

A nonparametric probabilistic classification model based on Gaussian procedure regression is the GPC [27]. Here, the value of an underlying latent function connected to the input data exhibits a monotonic correlation with the probability that the incoming data falls into a certain class. Initially establishing a prior for this latent function, the available information aids in deducing the values of hyperparameters that control various aspects of the function as well as the latent function's posterior distribution.

Consider a dataset comprising observations denoted as $x = (x_1, x_2, \ldots\ldots, x_N)$ and $y = (y_1, y_2, \ldots\ldots, y_n)$. Here, $x_t = \left(x_{t,1}, x_{t,2}, \ldots, x_{t,P}\right)^T$ represents the vector of p inputs at time t, and y_t corresponds to the associated binary response, i.e., $y_t \in \{1, -1\}$ for $t = 1, \cdots, n$. To streamline the representation of the response distribution y_t, it is expedient to introduce the concept of an unobserved "latent function," denoted as f_t.

$$p(y_t = 1) = Lf(f_t) \tag{1}$$

In the given context, Lf serves as the link function, and $f_t = X_t'\beta$, where β denotes the coefficient vector. This implies that the likelihood of $y_t = 1$ is contingent on a nonlinear function, specifically the result of the linear combination of the input data X_t. To illustrate, a logistic model for a binary target can be conceptualized as follows:

$$p(y_t = 1) = [1 = \exp(-X_t'\beta)]^{-1} \tag{2}$$

The link function is defined as $Lf(z) = (1 + exp(-z))^{-1}$.

Given inputs $X_1, X_2, \cdots, X_n$, let the latent functions $f = [f(X_1), \cdots, f(X_n)]$ follow a multivariate Gaussian distribution. Its mean and covariance functions entirely specify a Gaussian process. In simpler terms:

$$f\,|X \sim GP\,(\mu(X), V(X, X')) \tag{3}$$

Here, the mean vector $\mu(X)$ is represented as $[\mu(X_1), \cdots, \mu(X_n)]$, while $V(X, X')$ signifies the $n \times n$ covariance matrix of f, where the (i, j)-th element $V_{i,j}$ is expressed as $V(\mathrm{X}_i, \mathrm{X}_j)$. It is pertinent to note that for this article, $\mu(X)$ is considered to be zero, specifically $\mu(X) = 0$.

$$f\,|X \sim GP\,(0, V(X, X')) \tag{4}$$

The covariance function, $V(X, X')$, is pivotal in defining the relationship between latent variables, determining the response at a single input, X_i, is influenced by responses at another input, X_j. Different kernel functions, such as the Automatic Relevance Determination (ARD) exponential kernel function outlined in Eq. (5), can be utilized to define the covariance function $V(\cdot, \cdot)$. These kernel functions introduce varying levels of smoothness and structural characteristics, offering flexibility to tailor the covariance function to capture the intricate relationships between latent variables more effectively.

$$V\left(X_i, X_j\right) = \sigma_0^2 exp\left(-\frac{1}{2}\sum_{l=1}^{n}\frac{\left(X_{i,l} - X_{j,l}\right)^2}{\lambda_l^2}\right) \tag{5}$$

The hyper-parameters λ_l's represent the characteristic length scales and the scale parameter σ_0^2 signifies the relevance of different regions. In essence, the characteristic length scale provides a concise measure of the distance between input values X_i, indicating the range within which response values become uncorrelated.

Let X^* represent the input data in the testing or prediction dataset. The latent value corresponding to the testing data is denoted as f^* and expressed as $X^{*\prime}\beta$, can be derived. The posterior probabilistic prediction of the probability $\pi^* = p(y^* = 1)$ can be calculated using Eq. (6).

$$p(y^* = 1 \mid X, Y, X^*) = \int Lf(f^*)p(f^* \mid X, Y, X^*)df^*, \tag{6}$$

Where

$$p(f^* \mid X, Y, X^*) = \int p(f^* \mid X, X^*, f)p(f \mid X, Y)df \tag{7}$$

The probability $p(f\,|X, Y)$ can be computed using the formula presented in Eq. (8).

$$p(f\,|X, Y) = \frac{1}{Z}\,p(f\,|X)\prod_{i=1}^{n} p(y_i|f_i) \tag{8}$$

Here, $p(f\,|X)$ denotes the Gaussian prior distribution of f, $GP\,(0, V(X, X')$. The normalization term Z corresponds to the marginal likelihood, expressed as $Z = \int p(f\,|X)\prod_{i=1}^{n} p(y_i|f_i)$. For binary classification, a probit likelihood is employed, where $p(y_i|f_i)$ represents the density function of a standard normal distribution.

The computational complexity of Gaussian process methods is typically $O(n^3)$ due to the inversion of the covariance matrix. However, various sparse approximation techniques, including Markov Chain Monte Carlo (MCMC), Laplace approximation (LA), expectation propagation (EP), and variational inference (VI), have been introduced to mitigate this complexity. For a detailed exploration of these approximation methods in the context of Gaussian Process Classification (GPC), refer to [28]. Additionally, [29] provides a comprehensive review of various sparse approximation methods.

In the investigation conducted, the Expectation Propagation (EP) algorithm from [30] is employed to approximate the Gaussian posterior distribution specified in Eq. (6). Eq. (8), representing the posterior probability function $p(f\,|X, Y)$, can be approximated using Eq. (9).

$$\begin{aligned} p(f\,|X, Y) &= \frac{1}{Z}\,p(f\,|X)\prod_{i=1}^{n} t_i\left(f_i|\tilde{Z}_i, \tilde{\mu}_i, \tilde{\sigma}_2^2\right) \\ &= \mathcal{N}(\mu, \sum) \end{aligned} \tag{9}$$

The site parameters, expressed as $\tilde{\mu}_i$ and $\tilde{\sigma}_i^2$, are integral components within the normalized Gaussian distribution denoted by the notation $\mathcal{N}$.

$$\mu = \sum \tilde{\sum}^{-1}\tilde{\mu} \tag{10}$$

And

$$\sum = (V^{-1} + \tilde{\sum}^{-1})^{-1} \tag{11}$$

Matrix $\widetilde{\sum}$ is a diagonal matrix characterized by the elements $\widetilde{\sum}_{ii} = \tilde{\sigma}_i^2$, and $\tilde{\mu} = (\tilde{\mu}_i, \dots, \tilde{\mu}_N)$.

In accordance with Eq. (7) and (9), Eq. (12) presents the Gaussian approximation to the posterior distribution outlined in Eq. (6).

$$P(y^* = 1 \mid X, Y, X^*) = \Phi\left(\frac{V^{*\prime}\left(K + \widetilde{\sum}\right)^{-1}\tilde{\mu}}{\sqrt{1 + V(X^*, X^*) - V^{*\prime}\left(V + \widetilde{\sum}\right)^{-1}V^{*\prime}}}\right) \quad (12)$$

Here $V^* = V(X, X^*)$.

IV. Optimization Algorithms

A. Coot Optimization Algorithm (COA)

The Coot Optimization Algorithm (COA) draws inspiration from the collective behaviours of Coots. Water birds are known for various movements on the water, including random, chain, leader-driven, and leader-adjusted behaviours. In its metaheuristic optimization approach, COA initializes a population randomly based on Eq. (13) [31]:

$$CP(i) = rand\ (1, N) \times (Ub - Lb) + Lb \quad (13)$$

$CP(i)$ represents the positions of an individual coot, where N is the problem's dimensionality or the number of variables. Ub and Lb indicate the upper and lower limits of the exploration space for the search.

$$Ub = [Ub_1, Ub_2, \dots, Ub_N], Lb = [Lb_1, Lb_2, \dots, Lb_N] \quad (14)$$

Following the initial population setup, the positions of the coots are then modified using four distinct movement patterns.

1) Random movement: The position S for this particular movement is initially randomized according to the equation outlined in Eq. (15):

$$S = rand(1, N) \times (Ub - Lb) + Lb \quad (15)$$

To avoid entrapment in local optima, the position is updated following the procedure defined in Eq. (16):

$$CP(i) = CP(i) + A \times R_2 \times (S - CP(i)) \quad (16)$$

The variable R_2 is a randomly generated number falling within the interval [0,1], while A is computed using the equation specified in Eq. (17):

$$A = 1 - W \times \left(\frac{1}{Iter}\right) \quad (17)$$

$Iter$ denotes the maximum allowable number of iterations, and W represents the current iteration count.

2) Chain movement: To perform the chain movement, the average position of two coot birds can be computed using the formula provided in Eq. (18):

$$CP(i) = \frac{CP(i-1) + CP(i)}{2} \quad (18)$$

where, $CP(i-1)$ represents the position of the second coot in the sequence.

3) Adjusting position according to the leader: In each subgroup, the position of a coot bird is modified in alignment with the leader's position, resulting in the follower moving closer to the leader. The leader is chosen based on the equation specified in Eq. (19).

$$q = 1 + (i\ MOD\ NW) \quad (19)$$

where, q denotes the index of the leader, i represents the number of the follower coot bird, and NW signifies the overall count of leaders in the group.

In this specific movement, the position of a coot is adjusted following the formula provided in Eq. (20):

$$CP(i) = LP(q) + 2 \times R_1 \times Cos(2R\pi) \times (LP(q) - CP(i)) \quad (20)$$

The notation $CP(i)$ represents the current position of the coot bird, and $LP(q)$ stands for the position of the selected leader. The parameters R_1, a random number within [0, 1], and R, a random number within [-1, 1], play a role in the position update computation outlined in Eq. (20).

4) Leader movement: The positions of leaders undergo updates according to Eq. (21), which are aimed at transitioning from local optimal positions to global optimal positions.

$$LP(i) = \begin{cases} B \times B_3 \times Cos(2\pi R) \times \left(gBst - LP(i)\right) + gBst & B_4 < 0.5 \\ B \times B_3 \times Cos(2\pi R) \times \left(gBst - LP(i)\right) - gBst & B_4 \geq 0.5 \end{cases} \quad (21)$$

In this scenario, $gBst$ represents the optimal position, and B_3 and B_4 are random numbers within the interval [0, 1]. The value B is determined through the calculation outlined in Eq. (22):

$$B = 2 - L \times \left(\frac{1}{Iter}\right) \quad (22)$$

B. Population-based Vortex Search Algorithm (PVSA)

The Vortex Search algorithm, a metaheuristic known for its efficient exploitation capabilities, revolves around a single solution [32]. It swiftly generates new candidate solutions using a Gaussian distribution, clustering them around a central point. However, this approach may face premature convergence issues in specific situations despite efforts to maintain diversity in the search space. Population-based approaches, particularly effective in exploration phases, excel in investigating unexplored positions by generating fresh coordinates based on accumulated knowledge from previous iterations [33].

1) Initializing: In the algorithm's setup phase, crucial control parameters such as population size (psize), vortex size (vsize), termination criteria, and mutation probability (η_m) are defined. The psize parameter determines the total candidate solutions generated in one iteration, with $vsize$ being half of $psize$. Initially, the candidate solutions (CS) count equals $vsize$, extending subsequently to $psize$. The algorithm halts upon reaching the predetermined maximum number of function evaluations ($maxFEs$). In the second phase, the polynomial

mutation operation is contingent on the probability parameter η_m. Furthermore, μ_0 and q_0 are computed sequentially using Eq. (23) and Eq. (24).

$$\mu_0^i = \frac{up_i + low_i}{2} \tag{23}$$

$$q_0^i = \sigma_0^i = \frac{\max(up_i) - \min(low_i)}{2} \tag{24}$$

up means upper, and low means lower.

2) First phase: In the initial iteration of this stage, a population of $psize$ individuals is randomly generated. Subsequent iterations limit random generation to only half of the population, denoted as $vsize$. The stage concludes with the update of the central point (μ), achieved by replacing it with the best-discovered solution. This update employs a Gaussian distribution to generate half of the population, following the principles outlined in Eq. (25) of the original VS algorithm. While one-half of the population undergoes exploitation focused on the best centre, the other half is updated using a population-based approach with selection pressure. Solutions exceeding a specified limit are adjusted to fall within the designated range.

$$s_i^t(x_i^t \Big| \mu_t, v) = ((2\pi)^d |v|)^{-\left(\frac{1}{2}\right)} e^{(-1/2\left(x_i^t - \mu_t\right)^T v^{-1}(x_i^t - \mu_t)} \tag{25}$$

$$\begin{aligned} s_i(low_i \vee s_i) up_i \rightarrow s_i \\ = rand \times (up_i - low_i) + low_i \end{aligned} \tag{26}$$

The original VS algorithm utilizes the initial centre point (μ_0) to generate the initial population, though it is not directly part of that population. A modification to the VS algorithm has given rise to PVSA algorithm variants. In $PVSA_a$, μ_0 is included in the initial population, while $PVSA_b$ excludes it. In the first iteration of $PVSA_a$, μ_0 serves as the initial candidate solution ($POP(1)$) in the population, with the remaining $psize - 1$ candidate solutions ($POP(2{:}psize)$) generated randomly. In contrast, the initial population of $PVSA_b$ is formed by randomly generating $psize$ candidate solutions ($POP(1{:}psize)$).

3) Second phase: Population-based algorithms, distinct from single-solution counterparts, leverage interactions among candidate solutions across iterations to adapt their positions in the search process. These algorithms encapsulate the experiences of candidates collectively or individually in vector form, fostering effective information exchange. Take the PVSA algorithm as an example, employing a proportional selection approach amalgamated from the observer bee phase of the ABC algorithm with tailored adjustments for problem minimization. Eq. (27) computes the selection probability vector (pb) for each candidate solution.

$$pb_i = csum_i / csum_{psize} \tag{27}$$

$$csum_i = \sum_{j=1}^{i} normp_i \ \ and$$

$$normp_i = p_i / \sum_{i=1}^{psize} p_i \ \ and$$

$$p_i = 0.9 \times \left(max\{\vec{f}\} - f_i\right) + 0.1$$

The variable f symbolizes the fitness metric linked to the $i-th$ solution, while $max\{\vec{f}\}$ signifies the maximum fitness value within the existing population. p_i represents the rescaled fitness measure of the $i-th$ solution concerning minimization. The probabilities derived from the normalization of p values are denoted as $normp$, ensuring their confinement within the range of $[0.5-1]$.

In the latter segment of the population, encompassing solutions identified as CS_i where i lies within the range of $vsize + 1\ to\ psize$, a neighbouring solution is randomly chosen from the entire population. The selection is influenced by the $prob$ vector. Employing Eq. (28), the value of a randomly selected dimension is altered to generate a novel solution designated as CS_{new}. Following this modification, the adjusted dimension's value is scrutinized to determine if it surpasses predefined limits, as specified in Eq. (29).

$$\begin{aligned} CS_{new} = CS_{cur}\ then\ CS_{new}^i = CS_{cur}^i + \\ (CS_{cur}^i - CS_{neigbour}^i) \times (r - 0.5) \times 2 \end{aligned} \tag{28}$$

$$CS_{new} = \begin{cases} low_i, & CS_{new}^i < low_i \\ CS_{new}^i, & lower_i \le CS_{new}^i \le up_i \\ up_i, & CS_{new}^i > up_i \end{cases} \tag{29}$$

The evaluation of the newly generated solution, denoted as CS_{new}, involves incorporating a randomly chosen number r from the range of 0.5 to 1. Subsequently, the newly computed fitness is juxtaposed with the fitness of the current solution, CS_{cur}. If CS_{new} demonstrates a superior fitness compared to CS_{cur}, it supplants the latter.

However, in cases where CS_{new} falls short of surpassing CS_{cur}, a mutant solution designated as $\mathrm{CS_{mut}}$, is crafted using polynomial mutation. This mutation process adheres to the procedural steps expounded in Eq. (30).

$$CS_{mut} = CS_{cur} + \delta_q \times (up - low)$$

$$\delta_q = \begin{cases} \left[\begin{smallmatrix} 2r + (1-2r) \\ (1-\delta_1)^{\eta_m+1} \end{smallmatrix}\right]^{\frac{1}{\eta_m+1}}, & if\ \ r \le 0.5 \\ 1 - \left[\begin{smallmatrix} 2(1-r) + 2(r-0.5) \\ (1-\delta_2)^{\eta_m+1} \end{smallmatrix}\right]^{\frac{1}{\eta_m+1}}, & otherwise \end{cases} \tag{30}$$

$$\delta_1 = \frac{CS_{cur} - low}{up - low}$$

$$\delta_2 = \frac{up - CS_{cur}}{up - low}$$

In these situations, a random number rnd is generated for each dimension between 0.5 and 1. The polynomial mutation operator, known for overcoming local optima in metaheuristics, introduces perturbations into the solution. A selection process favours the superior solution between CS_{cur} and CS_{mut}. After this step, the central point μ is updated with the best solution.

After assessing Eq. (31), the radius size for the subsequent generation diminishes at the conclusion of the ongoing generation. The PVS algorithm persists until it reaches the maximum number of function evaluations. Initially, $vsize$ solutions within the reduced radius are duplicated, and in the subsequent phase, random data is incorporated into the solutions constituting the remaining population.

$$r_t = \sigma_0 \times \frac{1}{x} \times \Gamma(x, a_t)$$
$$where\ \ a_t = \frac{(MaxFEs - Fes)}{MaxFEs} \quad (31)$$
$$then\ \ if\ \ (a_t \leq 0) a_t = 0.1$$

V. Performance Evaluation Metrics

The evaluation of the classification performance of the developed models is delineated through the presentation of statistical metrics, as detailed in Eq. (32) – Eq. (35):

$$A = \frac{Tp + Tn}{Tp + Tn + Fp + Fn} \quad (32)$$

$$P = \frac{Tp}{Tp + Fp} \quad (33)$$

$$R = TpR = \frac{Tp}{P} = \frac{Tp}{Tp + Fn} \quad (34)$$

$$F1\_score\ = \frac{2 \times R \times P}{R + P} \quad (35)$$

where A, P , and R represent Accuracy, Precision, and Recall, Tp (True positives) denotes the occurrences where the model accurately predicted the outcome. Conversely, Fp (False positives) represents instances where the model's forecasts were incorrect. Tn (True negatives) refers to situations where the model made accurate predictions, while Fn (False negatives) pertains to instances where the model inaccurately predicted the outcome.

VI. Clustering

Clustering is a fundamental technique in data analysis and machine learning, utilized to identify and group similar data points within a dataset. This process involves partitioning data into clusters, where items in the same cluster share common characteristics, while those in different clusters are distinct from each other. The primary goal of clustering is to uncover inherent structures in data without prior knowledge of category labels, making it an unsupervised learning method. Various clustering algorithms have been developed, each with its unique approach to grouping data. K-means clustering, one of the most widely used methods, partitions data into K distinct clusters by minimizing the variance within each cluster. It is particularly effective for datasets where clusters are spherical and of similar size. Hierarchical clustering, another popular technique, builds a tree-like structure of nested clusters, offering a visual representation of data organization. This method is advantageous when the number of clusters is not predetermined. In the context of educational assessment, clustering can be a powerful tool. By applying clustering algorithms to student performance data, educators can identify distinct groups of students with similar learning behaviors and academic outcomes. For instance, clustering students based on their scores during the G2 and G3 exams can reveal patterns that are not immediately apparent through traditional grading methods. These insights can inform targeted interventions, tailored support, and personalized learning plans, ultimately enhancing the educational experience. Moreover, clustering combined with predictive models, like the Gaussian Process Classification (GPC) discussed earlier, can further refine the categorization of student performance. By integrating clustering techniques with optimization algorithms such as the Population-based Vortex Search Algorithm (PVS) and the COOT Optimization Algorithm (COA), educators can achieve more accurate and actionable predictions. This hybrid approach not only improves the precision of student assessments but also supports strategic decision-making in educational institutions.

VII. Convergence Assessment

In this study, the GPC underwent optimization through the application of metaheuristic optimization algorithms, specifically PVS and CO. The integration of these algorithms with GPC led to the development of hybrid models, termed GPPV and GPCO. To assess the convergence of these optimized models, a robust evaluation method was employed, which involved generating a convergence curve, exemplified in Fig. 2. This curve illustrates the trajectory of Accuracy measurements across 200 iterations. Upon comparative analysis of line plots for G2 and G3 in Fig. 2, a distinct observation emerges. Notably, both the GPPV and GPCO models stabilize before the 150th iteration. Further examination reveals that throughout this convergence process, the GPPV consistently outperforms its GPCO counterpart in both G2 and G3 scenarios.

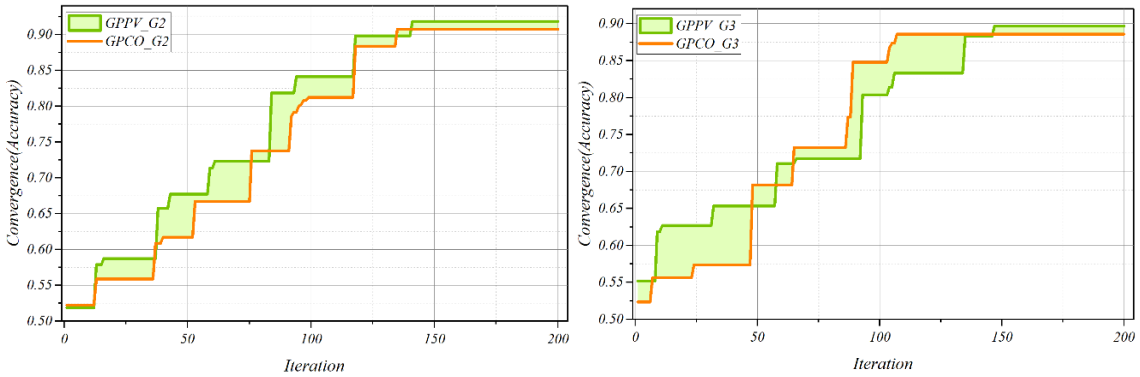

Fig. 2. Line plot for convergence of hybrid models.

VIII. Significance of Model

The significance of the models developed in this study lies in their potential to revolutionize educational assessment and intervention strategies. The choice of the Gaussian Process Classification (GPC) model, enhanced with the Population-based Vortex Search Algorithm (PVS) and the COOT Optimization Algorithm (COA), was driven by several key factors that make these methods particularly suitable for addressing the complexities of educational evaluation. Firstly, the GPC model is renowned for its robustness and flexibility in handling non-linear relationships, which are often present in educational data. This makes it highly effective in capturing the nuanced patterns of student performance. Secondly, the integration of PVS and COA enhances the GPC model's predictive accuracy and reliability. These optimization algorithms are designed to efficiently search large solution spaces and find optimal parameter settings, which is crucial for developing precise predictive models in complex domains like education. Furthermore, these advanced methodologies offer more than mere categorization—they provide a comprehensive framework for educational institutions to identify students who may need additional support or resources early on. By accurately predicting which students are likely to struggle, educators can implement targeted interventions to address specific needs, thereby improving overall educational outcomes. This proactive approach can help reduce the alarming failure rates, particularly in language courses, and promote both academic and personal development among students. Moreover, the use of PVS and COA exemplifies the integration of cutting-edge computational techniques in educational research. This not only enhances the predictive power of the models but also paves the way for future studies to explore and implement similar methodologies in different educational contexts. In summary, the models developed in this study are significant for their ability to provide accurate, early predictions of student performance, enabling targeted interventions and fostering improved educational outcomes. The innovative use of optimization algorithms further underscores the potential of advanced computational techniques in enhancing educational assessment and intervention strategies.

IX. Results and Discussion

The primary objective of this study was to introduce and evaluate three predictive models employing a classification methodology, to forecast students' academic performance in language courses and strategically enhance subsequent grades. Among these models, one utilized a Gaussian Process Classifier (GPC), while the remaining two were derived through the optimization of GPC via the Population-based Vortex Search Algorithm (PVS) and COOT Optimization Algorithm (CO). The dataset underwent partitioning into 70% for training and 30% for model testing. Evaluation metrics, including Accuracy, Precision, Recall, and F1-score, were computed and presented for both the training and testing phases of all models in Tables I and II. It is noteworthy that metric values during the training phase exceeded those observed in the testing phase across all models. The GPPV model exhibited superior performance, recording the highest values across all metrics for G2 and G3 (Accuracy G2 = 0.918, Accuracy G3 = 0.897, Precision G2 = 0.925, Precision G3 = 0.900, Recall G2 = 0.918, Recall G3 = 0.897, F1-score G2 = 0.916, and F1-score G3 = 0.896).

These input variables encompass a diverse array of data types, including nominal, numeric, and binary, thereby providing a comprehensive and informative dataset for the study. Moreover, the academic year comprises three final exams, with a focus on predicting the last two exams, specifically G3 and G2. These grades, ranging from zero (indicating the lowest score) to 20 (representing the highest attainable score), are reported by the school. To further classify the reported scores, students are segmented into four distinct categories based on their G3 and G2 performance: Poor (0-12 range), Acceptable (12-14 range), Good (14-16 range), and Excellent (16-20 range). According to Fig. 3, the examination of the G2 distribution for the GPPV model unveils a dominant majority of students (51.1%) falling within the Poor category. Subsequently, 25.57% are classified as Acceptable, 14.17% as Good, and 7.7% as Excellent. Transitioning to the G3 analysis for the GPPV model, 46.37% of students are categorized as Poor, followed by 23.72% in the Acceptable range, 17.25% in the good category, and 12.63% in the Excellent category. These distribution patterns in Fig. 3 delineate the varying proportions of students across performance categories, providing insights into the effectiveness of the GPPV model in predicting academic outcomes in both G2 and G3 assessments.

TABLE I. RESULT OF PRESENTED MODEL FOR G2

Model	phase	Index values			
		Accuracy	*Precision*	*Recall*	*F1_score*
GPC	Train	0.894	0.909	0.894	0.885
	Test	0.887	0.904	0.887	0.881

Table III presents a comparative analysis of the accuracy results from existing studies alongside the findings of the present work. The focus of this comparison is to highlight the advancements in predictive modeling accuracy achieved in the current study compared to previous research. In previous studies, various predictive models were employed, including Decision Tree Classification (DTC) and Naive Bayes Classification (NBC). Kabakchieva [34] utilized DTC, achieving an accuracy of 72.74%. Similarly, Bichkar and R. R. Kabra [35] employed DTC and reported an accuracy of 69.94%. Nguyen and Peter [36] also used DTC, but with a significantly higher accuracy of 82%. On the other hand, Edin Osmanbegovic et al. [37] implemented NBC, achieving an accuracy of 76.65%. The present study introduces a novel approach using the Gaussian Process Classification model optimized with the Population-based Vortex Search Algorithm (GPPV) to predict student performance in language courses during the G2 and G3 exams. The results demonstrate a substantial improvement in predictive accuracy. For G2, the GPPV model achieved an accuracy of 91.8%, while for G3, the accuracy was 89.7%. These findings indicate a significant enhancement in prediction accuracy compared to the models used in prior studies. The GPPV model's superior performance can be attributed to the advanced optimization techniques incorporated, which likely contribute to its higher precision in categorizing students' performance levels. In summary, the present study's use of the GPPV model represents a notable advancement in the field of educational predictive analytics. The increased accuracy rates for both G2 and G3 exams underscore the model's potential to more effectively assess and anticipate student performance, thus providing valuable insights for educational institutions aiming to improve academic outcomes.

TABLE III. COMPARING RESULTS OF EXISTING STUDIES AND PRESENT WORK

Author (s)	Models	Accuracy
Kabakchieva [34]	DTC	72.74%
Bichkar and R. R. Kabra [35]	DTC	69.94%
Nguyen and Peter [36]	DTC	82%
Edin Osmanbegovic et al. [37]	NBC	76.65%
Present study for G2	GPPV	0.918
Present study for G3	GPPV	0.897

Tables IV and V comprehensively present the values corresponding to Precision, Recall, and F1-score indices, serving as evaluative metrics for the classification performance of the developed models concerning distinct student categories in both G2 and G3 assessments. In the ensuing analysis, a

meticulous examination of Precision values elucidates nuanced distinctions among the models across performance categories. In the Excellent group of G2, GPCO and GPC models exhibit comparable performances, whereas the GPPV model surpasses both, achieving a Precision value of 0.91. Conversely, in the Good and Poor groups, the GPC model demonstrates superior performance. Notably, in the Acceptable group, GPCO and GPPV, with a Precision of 0.78, outperform the singular GPC model. In the context of the G3 test, all three models demonstrate optimal Precision in the Good group with a maximum value of 1, while their performances converge at 0.84 in the Excellent group.

Furthermore, discerning comparisons between Acceptable and Poor categories reveal the GPPV model's superior performance. Upon evaluating Recall and F1-score, the GPPV model consistently outperforms its counterparts in both G2 and G3 predictions. Moreover, a comprehensive comparison involving Recall, F1-score, and Precision collectively substantiates the superior performance of the GPPV model across G2 and G3 assessments in contrast to other models.

The crux of the confusion matrix lies in its fundamental principle: accurately predicted instances align along the main diagonal, while misclassifications diverge from this central axis. In Fig. 4, particularly within the context of G2, a meticulous examination reveals misclassifications in the GPPV model, totaling 53 instances, compared to 60 in the GPCO model and a relatively higher count of 67 in the single GPC model. Acknowledged as the superior performer, the GPPV model exhibits the fewest misclassifications, thus boasting superior predictive accuracy. Likewise, in G3, the GPPV model excels with 67 misclassifications, surpassing the GPCO model with 74 and the single GPC model with 80 misclassifications. This consistent pattern underscores the efficacy of the GPPV model, validating its superior performance in minimizing misclassifications and enhancing predictive accuracy across both G2 and G3 scenarios. Fig. 5 provides a visual representation of the confusion matrix, offering a clear portrayal of the accuracy of each model. Through meticulous analysis and comparison, the GPPV model emerges as the frontrunner, demonstrating its reliability and efficacy in predictive modeling tasks.

TABLE IV. EVALUATION INDEXES OF THE DEVELOPED MODELS' PERFORMANCE BASED ON GRADES IN G2

Model	**Grade**	**Index values**		
		Precision	***Recall***	***F1_score***
GPC	Excellent	0.86	0.94	0.90
	Good	1.00	0.37	0.54
	Acceptable	0.69	0.88	0.78
	Poor	0.97	0.97	0.97
GPCO	Excellent	0.85	0.95	0.89
	Good	0.97	0.57	0.72
	Acceptable	0.78	0.85	0.81
	Poor	0.97	0.97	0.97
GPPV	Excellent	0.91	0.91	0.91
	Good	1.00	0.62	0.76
	Acceptable	0.78	0.92	0.85
	Poor	0.96	0.98	0.97

TABLE V. EVALUATION INDEXES OF THE DEVELOPED MODELS' PERFORMANCE BASED ON GRADES IN G3

Model	**Grade**	**Index values**		
		Precision	***Recall***	***F1_score***
GPC	Excellent	0.84	0.84	0.84
	Good	1.00	0.66	0.79
	Acceptable	0.74	0.77	0.75
	Poor	0.93	0.99	0.96
GPCO	Excellent	0.84	0.83	0.83
	Good	1.00	0.73	0.85
	Acceptable	0.79	0.79	0.79
	Poor	0.92	0.99	0.96
GPPV	Excellent	0.84	88.96	0.86
	Good	1.00	0.73	0.85
	Acceptable	0.79	0.79	0.79
	Poor	0.95	0.99	0.97

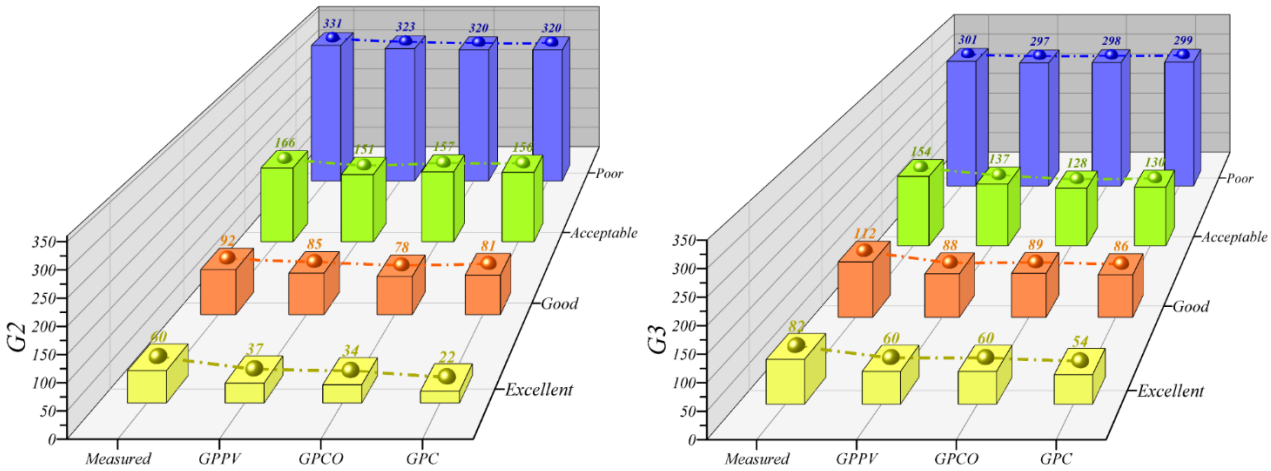

Fig. 3. 3D Bar plot for the comparison between the measured and predicted values.

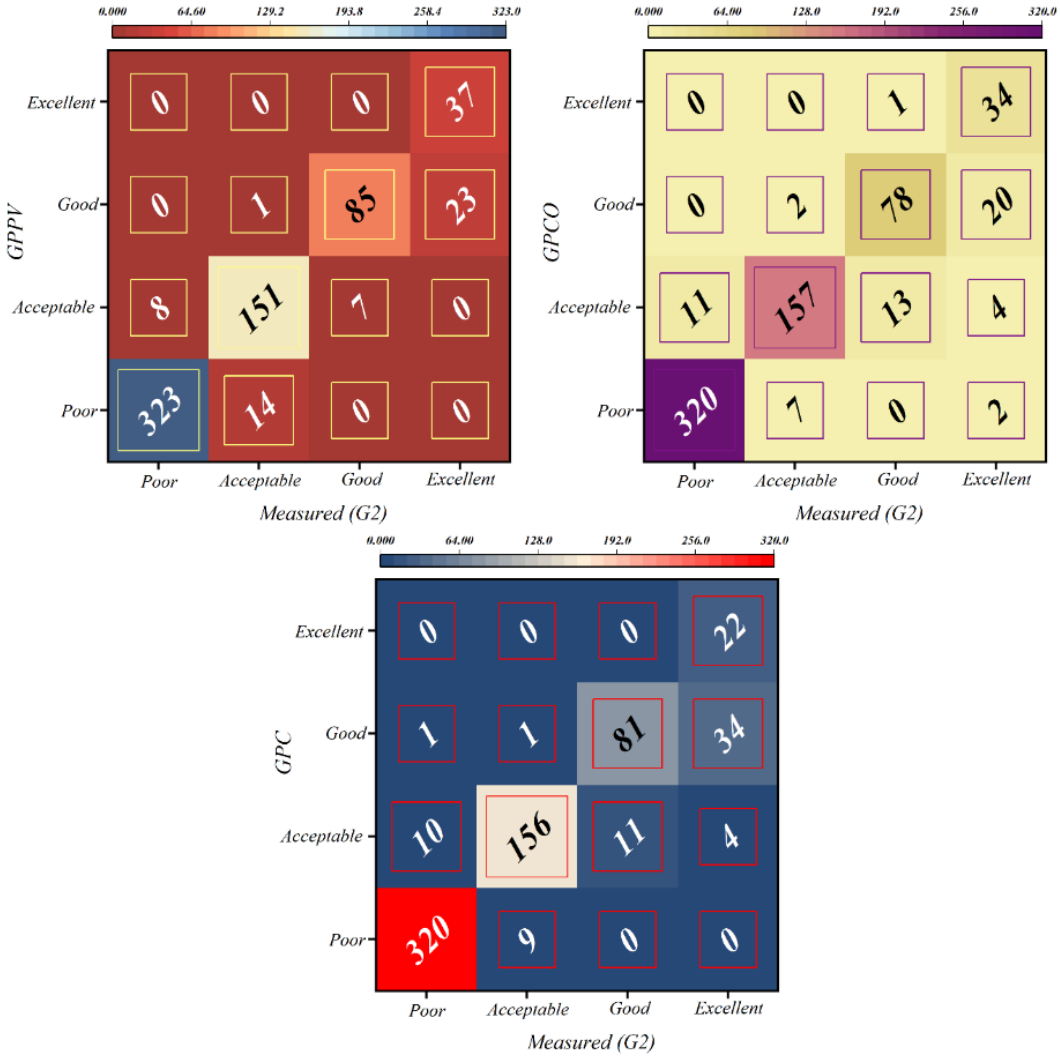

Fig. 4. Confusion matrix for each model's accuracy.

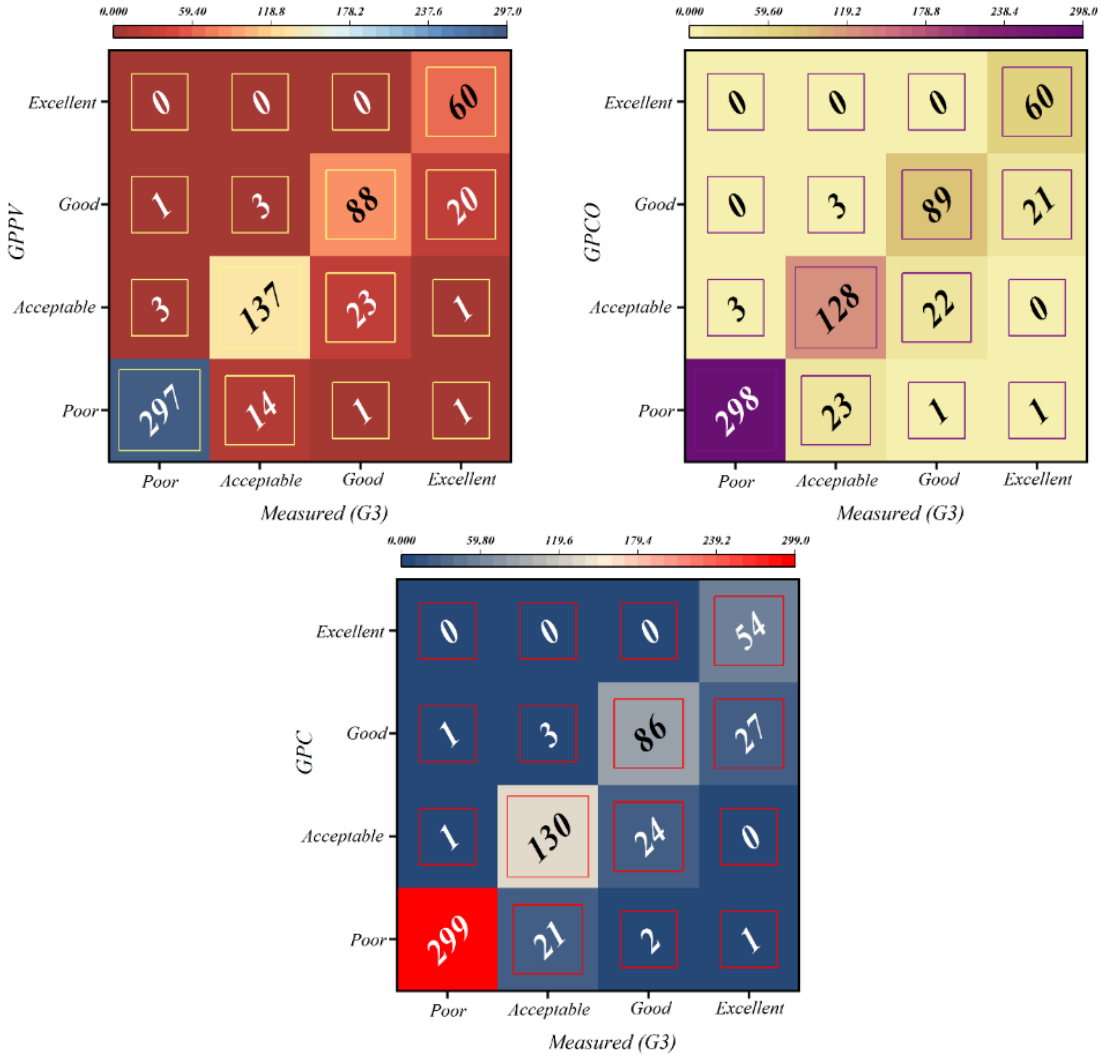

Fig. 5. Confusion matrix for each model's accuracy.

The depiction of model performance in Fig. 6, presented as a 3D Scatter plot mapping achievement percentages based on evaluative metrics, offers a nuanced understanding of the developed models. Through its volumetric representation, where higher cube numbers correspond to superior model performance, it underscores the thoroughness of the assessment. When comparing G2 and G3, the discernible prominence of the GPPV model above others signifies its superior performance. This superiority is further evidenced by the GPPV model's achievement of the highest precision predictions in both G2 (0.9245) and G3 (0.9002). The visual insights gleaned from the 3D Scatter plot not only accentuate the consistent prominence of the GPPV model but also affirm its superior Precision, thereby cementing its position as the optimal model for attaining accurate and reliable predictions across a spectrum of evaluation metrics and academic contexts. In essence, the 3D Scatter plot serves as a powerful tool for visually dissecting and comprehending the intricate nuances of model performance. Its depiction of achievement percentages based on evaluative metrics provides researchers with a holistic view, enabling them to discern patterns and trends that may not be immediately apparent through other means. This aids in making informed decisions regarding the selection and refinement of models, ultimately contributing to the advancement of predictive modeling in academic and research domains.

Fig. 7 showcases the Receiver Operating Characteristic (ROC) curve, a pivotal tool meticulously delineated to evaluate the superior GPPV model with clarity. This visually immersive representation enables a nuanced comprehension of the model's performance across various thresholds. The Area Under the ROC Curve (AUC), a widely recognized metric, serves as a comprehensive gauge of predictive accuracy and classification efficacy for the GPPV model, with a perfect test achieving an AUC of 1. Upon comparing G2 and G3, the Excellent group dominates both predictions, achieving an AUC of 1 and boasting the largest area under the curve. Following closely, the Poor group exhibits a slightly smaller difference in G3 and a marginally larger gap in G2. In G2, subsequent rankings feature the Good model followed by the Acceptable model, whereas in G3, the positions of the Acceptable and Good models interchange, with the former claiming the third rank and the latter securing the fourth position.The ROC curve's depiction elucidates the model's discriminative ability across varying

thresholds, offering valuable insights into its performance characteristics. By analyzing the AUC metric, researchers can assess the model's overall predictive power and its ability to distinguish between classes. This comprehensive evaluation aids in informed decision-making regarding model selection and refinement, contributing to enhanced predictive modeling outcomes in diverse applications and research endeavors.

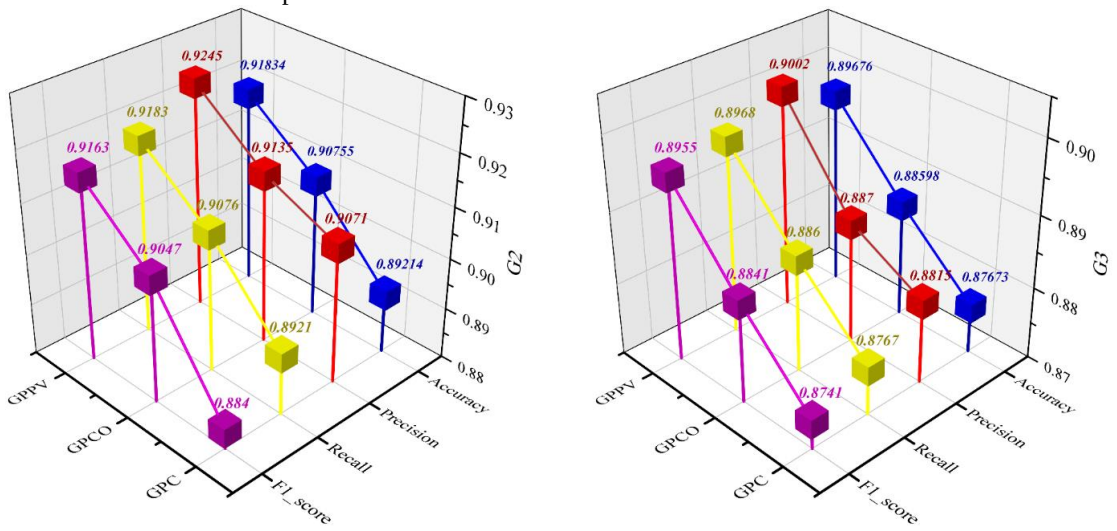

Fig. 6. 3D Scatter plots the percentage of achievement for developed models based on evaluators.

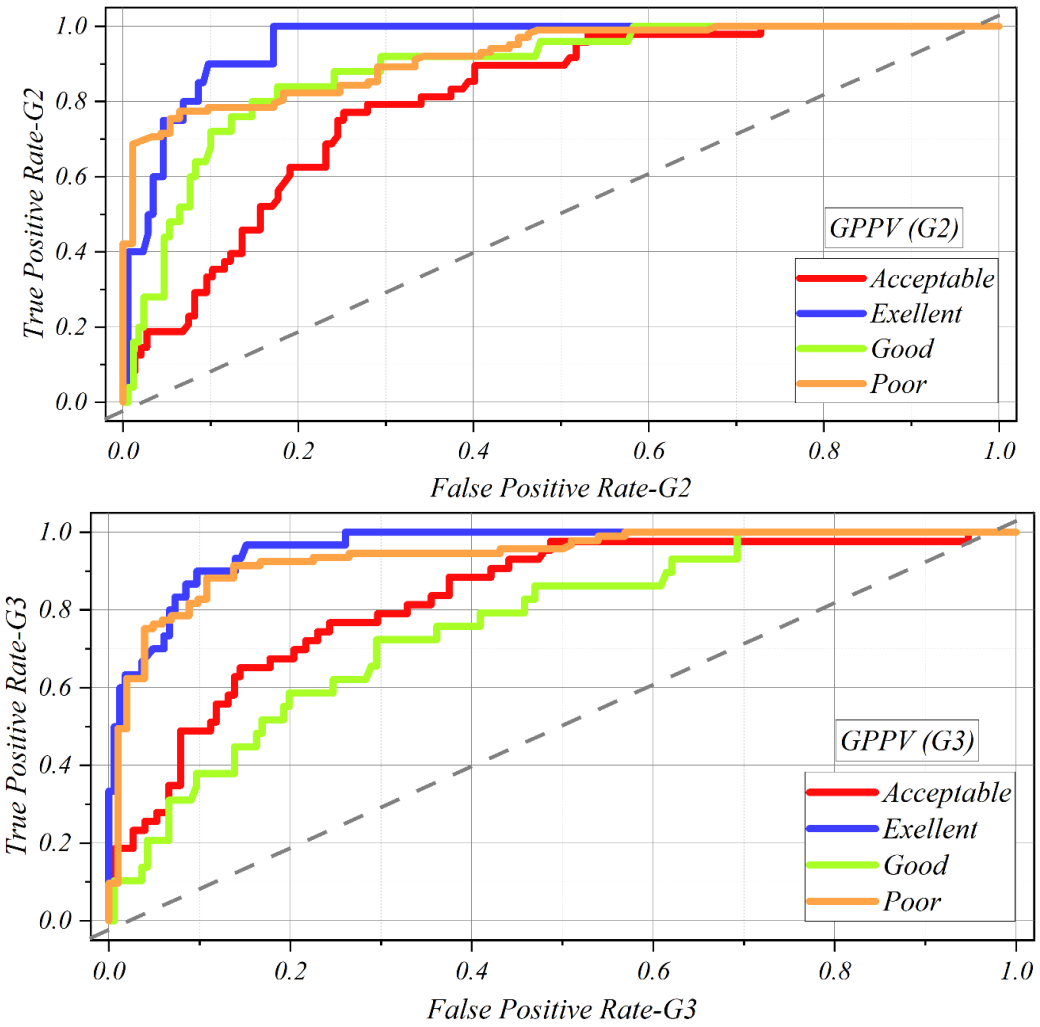

Fig. 7. The result of the ROC curve validation.

The validation of this study represents a pivotal step forward in affirming the efficacy and applicability of advanced predictive models within the realm of educational assessment and intervention. At the core of this validation process lies a meticulous examination of the methodologies employed. The deliberate integration of the Gaussian Process Classification (GPC) model with the Population-based Vortex Search Algorithm (PVS) and the COOT Optimization Algorithm (COA) was predicated on their demonstrated capabilities in handling non-linear relationships and navigating complex parameter spaces. This methodological selection was not arbitrary but grounded in empirical evidence and theoretical underpinnings, ensuring that the models were robustly equipped to address the multifaceted nature of educational data. The validation extends beyond the theoretical realm into practical implementation. Through rigorous testing and evaluation, the study demonstrated the tangible impact of these models in real-world educational settings. By accurately identifying students in need of additional support and facilitating targeted interventions, the integrated approach showcased its ability to significantly enhance educational outcomes. Furthermore, the proactive nature of these interventions, particularly in addressing elevated failure rates, underscores the practical relevance and urgency of this research. By actively mitigating academic challenges and fostering holistic student development, the study exemplifies a paradigm shift towards more personalized and effective educational practices. Moreover, the incorporation of advanced optimization algorithms such as PVS and COA not only enhances the predictive power of the GPC model but also highlights the potential of cutting-edge computational methodologies in driving innovation within the educational landscape.

In conclusion, the validation of this study serves as a testament to the transformative potential of advanced predictive models in shaping the future of educational assessment and intervention, paving the way for continued exploration and advancement in this vital field.

X. Conclusion

In the pursuit of advancing academic excellence and refining educational practices, this research emphasizes the instrumental role played by data mining and classification algorithms, specifically focusing on Gaussian Process models, in deciphering and foreseeing student performance in language courses. Diverging from conventional methodologies, this study introduces an inventive approach that integrates meta-heuristic optimization algorithms, notably the Population-based Vortex Search and COOT Optimization Algorithms (PVS and COA). These optimizers led to elevating the Precision and accuracy of student performance models, contributing a novel dimension to the existing body of literature.

The extensive evaluation, encompassing vital metrics such as Accuracy, Precision, Recall, and F1-score, illuminates the considerable potential of these meta-heuristic algorithms in refining classification outcomes. Moreover, the stratification of 649 students based on their final grades exposes the superior performance of the GPPV model, showcasing a remarkable capacity to accurately categorize the majority of students (596 correct in G2 and 582 in G3), in contrast to the comparatively lower correct classifications by GPCO and GPC. Beyond contributing to the existing knowledge base, this study offers valuable insights for educators and institutions striving to optimize educational processes, foster academic success, and thereby advance societal development and progress.

Despite its innovative approach, this study has several limitations. It focuses solely on language courses, which may limit the generalizability of its findings to other subjects. The dataset, while extensive, may not fully represent the diversity of student populations, potentially affecting the model's applicability in different educational contexts. Additionally, the reliance on historical data means the models may not adapt well to future changes in curricula or teaching methodologies. The meta-heuristic algorithms, although improving accuracy and precision, still leave room for errors, as not all student performance variability can be captured. Furthermore, external factors such as socio-economic conditions, psychological well-being, and classroom dynamics, which can significantly impact student performance, are not accounted for in the models. Finally, the computational complexity of the optimization algorithms may pose practical challenges for their implementation in real-world educational settings.
