The use of DL for mapping oil palm plantations using remote sensing has three main issues that were discussed in previous research which include DL for oil palm plantation mapping, performance and accuracy and sustainability and management. DL research for oil palm plantation mapping has been conducted by [9] [10] [11] [8] [12]. DL-based semantic segmentation approaches, such as the residual channel attention network (RCANet), have been proposed for mapping oil palm plantations from high spatial-resolution satellite images by [9] that use of deep convolutional neural network (DCNN) frameworks. Xception-based detection networks have been explored for robust detection of oil palm plantations using RS images by [10]. Other researchers [11] specifically used a DL algorithm called UNet with ultra-high resolution multispectral imagery to identify, segment, and map oil palm canopy in a large forest area and a DL approach with optimized spatial pyramid pooling (SPP) units has been proposed for automatic segmentation of oil palm plantation areas using satellite imaging [8]. A DL-based framework has been proposed for oil palm tree detection and counting using high-resolution RS images, achieving over 96% accuracy in detecting oil palm trees [12].

Performance and Accuracy aspects, as specifically observed by previous researchers [9], [10], [12], [13], [14][14] The proposed DL methods have shown high overall accuracy (OA) and mean intersection-over-union (mean IoU) ranging from 95.27% to 98.96% [9], [10], [12], [13] DL approaches have demonstrated higher accuracy in oil palm tree detection compared to traditional machine learning methods such as support vector machines (SVM) [14]. As for the issue of Sustainability and Management, it has been the object of discussion in research by [9] and [15]. RS technology, particularly DL-based approaches, is crucial for sustainable management of oil palm plantations, enabling accurate detection, mapping, and monitoring of plantation areas [10], [15] In conclusion, the use of DL in RS for mapping oil palm plantations has shown promising results in terms of accuracy and sustainability, offering a valuable tool for land planning and management in the context of oil palm cultivation.

Based on the use case approach used by previous researchers, there are generally two main approaches, namely tree detection as in [10] [12] [14] [15] and semantic segmentation such as [8], [9], [11], [13], which is also the approach used in this research. Previous research conducted by [11] and [9] using the semantic segmentation approach showed high accuracy results of 95.5% and 95.27% using high-resolution image datasets, namely GeoEye and Quickbird. The use of high-resolution imagery in mapping oil palm plantations can cause high operational costs so it is necessary to find a more efficient way by using widely available low-resolution satellite imagery as research by [9] which uses Google Earth Imagery. Previous researcher [9], using the residual channel attention network (RCANet) model until now has only achieved maximum accuracy results at 90.58% which is very possible to be improved by using different DL models with image datasets with relatively the same resolution as the widely available Sentinel 2 imagery. A summary of the results of previous research relevant to the research conducted is as can be seen in Table I.

TABLE I. Previous Research on Oil Palm Mapping Using Deep Learning with Remote Sensing Data

No	Author and Year	Dataset	Model	Accuracy	Use case
1	Dong et al, 2019	Google Earth high spatial-resolution image	Residual Channel Attention Network (RCANet)	90.58 (IoU)	Semantic Segmentation
2	Jie, B.X, et al, 2020	Planet satellite imagery	XceptionNet	98.96	Tree Detection
3	Wagner, F.H, 2020	GeoEye satellite	UNet	95.5%	Semantic Segmentation
4	Abdani, S.R, 2021	Planet satellite imagery	SPPNet - UNet	73.63 (IoU)	Semantic Segmentation
5	Li, W, 2018	QuickBird satellite	LeNet	96%	Tree Detection
6	Dong et al, 2019	QuickBird images and Google Earth Images	Deep CNN and fully connected conditional random fields (CRF)	95.27%	Semantic Segmentation
7	Khalid et al, 2022	UAV Imagery	CNN and SVM	91%	Tree Detection
8	Pravista DS, 2023	Aerial photograph	Yolo V5	78,5%	Tree Detection

III. Methodology

The research methodology for model development are comprises five principal stages including data input, data pre-processing (labeling, crop image, stride image and mosaic image), model training and testing, and final evaluation (Fig. 1).

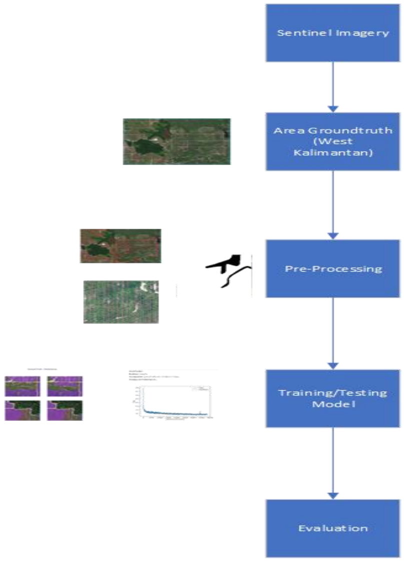

Fig. 1. Flowchart of the research implementation especially in model development.

A. *Dataset*

This study uses image data with RGB bands 3,4,5 from Sentinel imagery as the data source. Sentinel-2 is an Earth observation mission from the Copernicus Programme that acquires optical imagery at high spatial resolution (10 m to 60 m) over land and coastal waters. Multi-spectral imagery of the data consists of 13 bands in the visible, near infrared, and short-wave infrared part of the spectrum. The determination of the research location is carried out in several stages, the first is to observe national land use data dominated by oil palm plantation areas and the second is to determine based on low cloud cover conditions to ensure the analysis process to be carried out is not disturbed by cloud cover. In the end, West Kalimantan Province, Indonesia was chosen as the research area (Fig. 2). The study area is directly adjacent to Malaysia Serawak in the east.

Dataset Sentinel could be downloaded at the following link:https://browser.dataspace.copernicus.eu/?zoom=11&lat=1.29593&lng=109.59892&themeId=DEFAULT-THEME&visualizationUrl=https%3A%2F%2Fsh.dataspace.copernicus.eu%2Fogc%2Fwms%2Fa91f72b5-f393-4320-bc0f-990129bd9e63&datasetId=S2_L2A_CDAS&fromTime=2023-07-18T00%3A00%3A00.000Z&toTime=2023-07-18T23%3A59%3A59.999Z&layerId=1_TRUE_COLOR

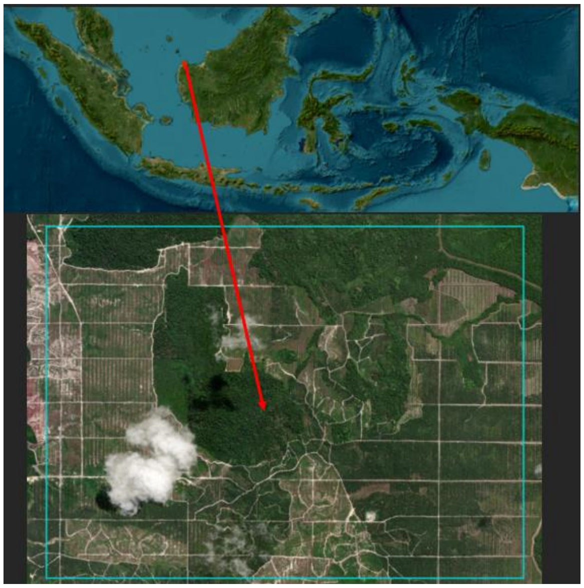

Fig. 2. Map of Indonesia (a) and Research Area in West Kalimantan in center coordinate 109.4258990°E 1.3221402°N (b).

B. *Method*

The next research step after data and research location are determined is pre-processing, training/testing model and finally evaluation model. The labeling process by digitizing polygons of oil palm areas based on the visual appearance of sentinel imagery. This labeling process is carried out by researchers who are experts and could have the ability to visually distinguish between certain land uses and oil palm land classes. The digitized polygons will then become the masking area in the label data and will become class 1 for oil palm and 0 for non-palm oil areas. Pre-processing activities include dividing images into 256x256 pixels to create the label data and then we step down to 128x128 and transform and rotate images. It will get 2460 image chips in these activities.

The training DL model approach used is semantic image segmentation with a focus on comparing ResNet models to see the performance of these models for use in mapping using medium resolution image data from sentinel. In this research will compare UNet [16] with two backbone ResNet-34 (Fig. 3 (a)) and ResNet-50 (Fig. 3 (b)). Selecting ResNet-34 and ResNet-50 based on previous research conducted by [17]. UNet Model using with skip connection because it enhances precision and detail semantic segmentation outputs. It improves resolution in high resolution image when decoding process [18].

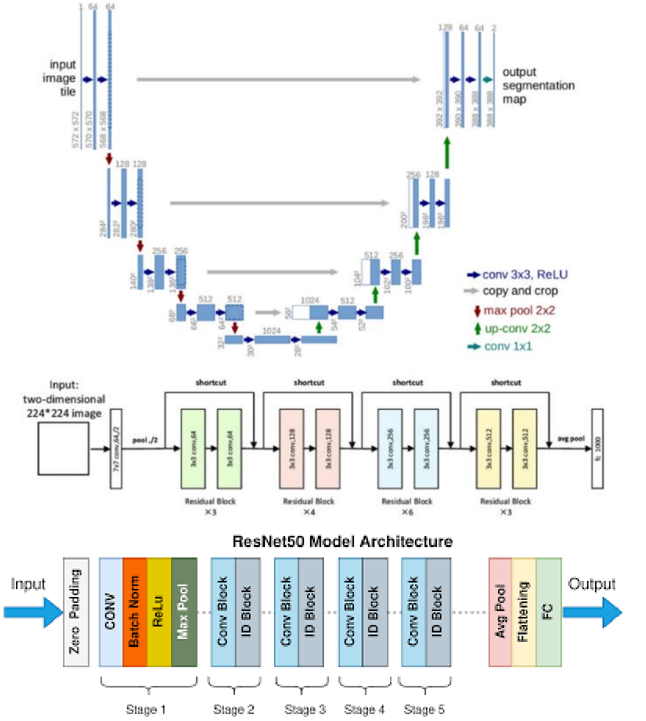

Fig. 3. UNet Model (a) with ResNet-34 (a) and ResNet-50 (b) Architecture.

C. *Model Evaluation*

Model evaluation was conducted using precision, recall, and F1 score evaluation metric. Precision, recall (Fig. 4) and F1 score is calculated using the following formula:

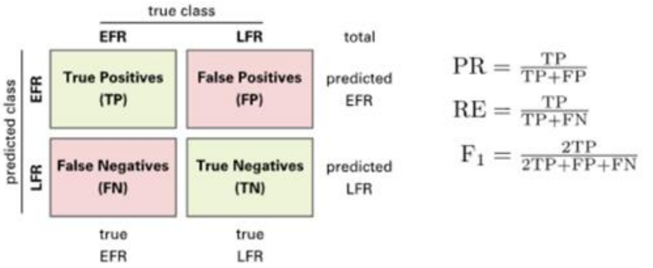

Fig. 4. Confusion matrix and formula for precision, recall and F1 score [19].

For the loss function calculate using the following formula:

$$CE = -\sum_{i=1}^{C'=2} t_i log(s_i) = -t_1 log(s_1) - (1 - t_1) log(1 - s_1)$$

Fig. 5. Binary cross-entropy loss function formula [19].

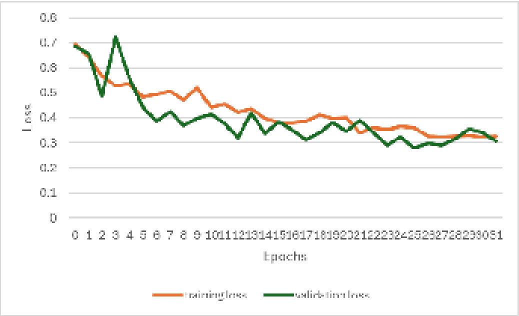
This formula (Fig. 5) is derived from Cross Entropy (CE) Loss formula because in this research use two classes, palm and not palm class. t_i and s_i are the ground truth and the CNN score for each class *I* in *C*.

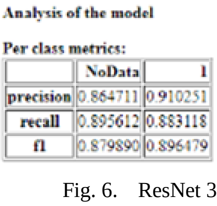
IV. Result and Discussion

A. Training and Validation Model

This stage aims to train the deep learning model that will be selected based on the image chips + label data that has been created in the previous stage. Training model process uses Intel Core i9 14900K, Nvdia RTX 4070 super and 32Gb Memory. NVDIA RTX 4070 super has 12Gb dedicated memory and support CUDA processing.

Given that in the exporting stage the type of deep learning semantic segmentation has been determined, then automatically in this stage, ArcGIS Pro will present several algorithm libraries for the purpose of semantic segmentation only. the entire dataset, 80% of the data is used for the training process and the remaining 20% is used for model validation. The model was set with a maximum of 20 epoch iterations with the UNet model and different batch sizes for ResNet-34 and ResNet-50 of 8 and 4 batch sizes, respectively. Training is the longest stage in the whole flow of deep learning modeling with semantic segmentation for oil palm plantation delineation. Determine of time and number of epochs in experiment conducted based on model convergence. Although in this experiment it is set in 100 epochs. As rough information, the training process for an area of 3.62 million hectares, 20 epochs, with backbone ResNet-34 took 10 hours and 40 minutes. The training process for an area of 3.62 million hectares, 10 epochs, with backbone ResNet-50 took 17 hours. This stage also drained the GPU resources the most. In the ResNet-50 modeling, the resources used were 10.5/15 GB dedicated GPU.





Analysis of the model

Per class metrics:

	NoData	1
precision	0.864711	0.910251
recall	0.895612	0.883118
f1	0.879890	0.896479

Fig. 6. ResNet 34 training and validation result.

There are two main pieces of information displayed in the evaluation metric (Table II and Fig. 6), the loss function and the precision, recall, and f1 score evaluation metric tables. The loss function graph shows the amount of error generated from the model, both on training and validation data. The smaller the loss function value, the smaller the resulting error. A good model is a model that has a small loss function value and a curve that coincides between training and validation data (not overfitting). The second information is the evaluation metrics of precision, recall, and f1 score. These three metrics are generated by comparing prediction data and label data and are suitable for data with imbalance distribution. Precision is calculated by considering false positives, while recall is generated if false negative results in the model are considered. Meanwhile, if false positives and false negatives are equally important then the f1 score metric can be used. The higher it is (closer to 1), the better the model will be. In Fig. 6, users can focus on the f1 score for class 1 (oil palm class). The rapid decrease in loss value and of course the significant increase in accuracy value to reach the convergent value only takes 10 minutes using the ResNet-34 model and 20 minutes using ResNet-50. The model processing duration becomes only 10 minutes if the working area is reduced to 10km^2. Training and validation of the model were run for 31 epochs for ResNet-34 and 39 for ResNet-50 until the model converged. Running the model with ResNet-34, the training loss decreased significantly at the 5th epoch with the highest accuracy of 89 percent at the 25th epoch (Fig. 6). As for the ResNet-50 model, the training loss decreased significantly at the 11th epoch with the highest accuracy of 91 percent at the 37th epoch before converging at the 39th epoch (Fig. 8). The precision, recall and F1 values for the model with ResNet-34 are 0.910251; 0.883118 and 0.896479.

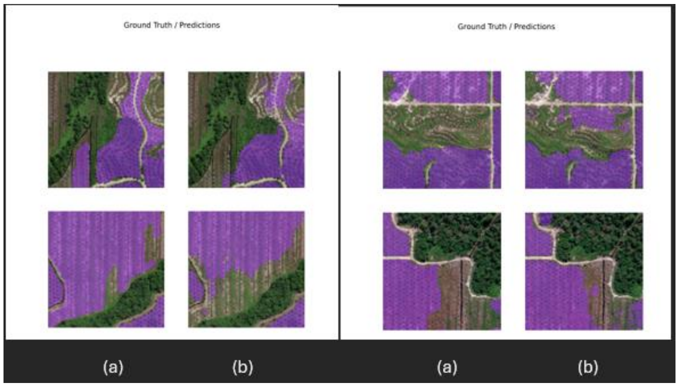


Fig. 7. Groundtruth (a) Dan prediction result using ResNet-34 Model Architecture.

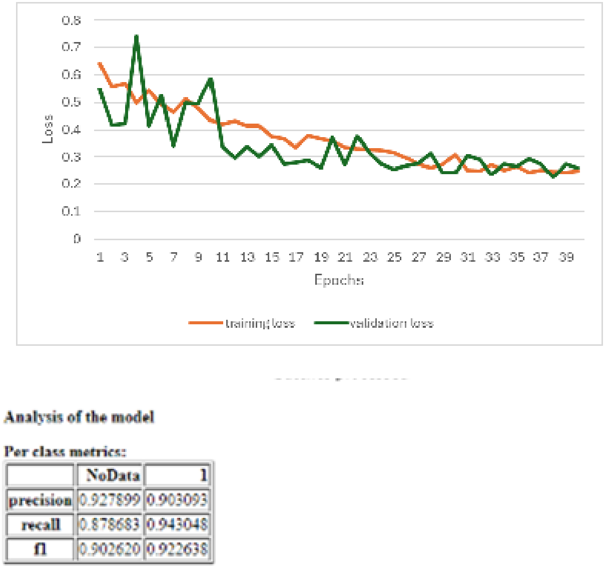
Based on Fig. 7, there are several areas that are lost in prediction. In Fig. 7(a), the ground truth is a real object that was mapped, and other images are predicted result from experiment (Fig. 7(b). It is different between them, so the model has been working slightly well to determine the real oil palm area.

The precision, recall and F1 values for the model with ResNet-50 are 0.903093; 0.943048 and 0.922638 (see Fig. 7).

On Fig. 9 we could see difference between ground truth and prediction on ResNet-50. We could see the model could perform well. In Fig. 9 (b), we could see there are area that in prediction is classified as oil palm and in ground truth is not. In the same figure we could see that several areas are missing in prediction. Experiment with ResNet-50 shows missing area in prediction is less than ResNet-34. The result could be said that the accuracy of the ResNet-50 is better than ResNet-34 in case for oil palm mapping.



Analysis of the model

Per class metrics:

	NoData	1
precision	0.927899	0.903093
recall	0.878683	0.943048
f1	0.902620	0.922638

Fig. 8. ResNet-50 training and validation result.

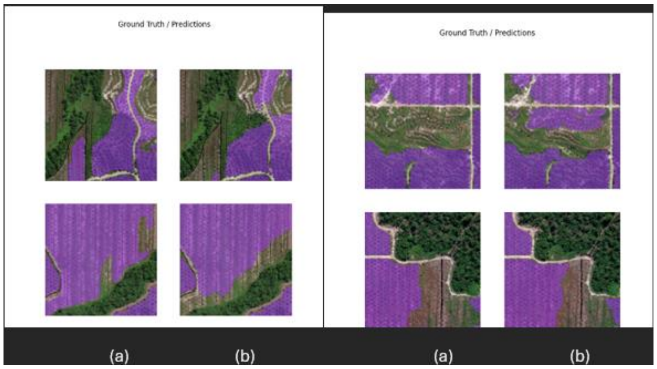


Fig. 9. Groundtruth (a) Dan prediction (b) result using ResNet-50 Model Architecture.

B. Inference / Deployment Model

After the training models are run, the next step is to evaluate the results of each ResNet model including the evaluation of the duration of the inference process. By using Sentinel satellite data specifically with RGB using band 4, band 3 and band 2. Based on the results table, ResNet-50 is 3% more accurate than ResNet-34 with 88.8% and 91.8% accuracy values, respectively (Table II). ResNet 50 takes more time to process because it has many layers in backbone. This seems to be influenced by the larger number of layers in ResNet-50 compared to the ResNet-34 model.

TABLE II. AVERAGE ACCURACY AND INFERENCE DURATION OF RESNET-34 AND RESNET-50

Backbone	Accuracy	Inference Duration
ResNet-34	88.8%	10 Minutes
ResNet-50	91.8%	20 Minutes

The accuracy results of the two models in the experiment reached a smaller value than the previous research which achieved 95.5% accuracy using the same deep learning model [11]. This is very rational because the study used GeoEye satellite data which has a spatial resolution of 0.5 meters compared to the Sentinel satellite used in this experiment which has a spatial resolution of 10 meters. However, the accuracy results achieved from experiments with both ResNet models are still better than [8] research, which used SPPNet with UNet using satellite images with relatively the same resolution, where the accuracy results obtained were 73.63%. The accuracy of the experiment results, especially those using the ResNet-50 model, shows a significant increase when compared to the research conducted by study [9] which achieved an accuracy value of 90.58%.

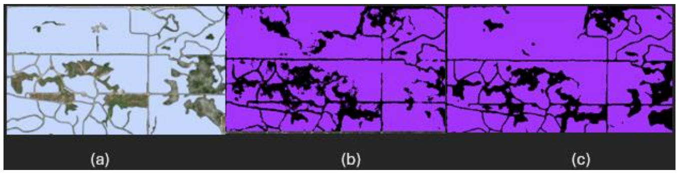

Fig. 10. Comparison result groundtruth (a), ResNet-34 (b) and ResNet-50 (c) Model.

In this study, a comparison was conducted between Ground truth (Fig. 10 (a)) and UNet with ResNet-34 and ResNet-50. Which in fact showed that in the ResNet-34 model there were still many areas that were not segmented in the prediction and in ResNet-50 there were fewer missing areas than ResNet-34. This proves that the results of the ResNet-50 model are more accurate than the ResNet-34 model (see Fig. 10(b) and Fig. 10 (c)).

C. Model Limitation Using Sentinel-2

The iteration results of DL semantic segmentation modeling showed some important findings. The results of four iterations produced the best model with accuracy/F1 Score values of 0.80 (iteration 3) and 0.72 (iteration 4). The results of these iterations show that the creation and implementation of the DL semantic segmentation model on Sentinel 2 imagery is only sensitive to detecting the characteristics of regular oil palm plantations. The captured oil palm plantation patterns include plantation areas planted in a checkerboard or rectangular pattern (large plantation areas) and a hilly plantation area pattern characterized by a twisted appearance. The model was also able to distinguish regular oil palm plantation areas from non-saw palm plantation/agricultural areas (e.g. Industrial Plantation Forest (HTI) areas, sugarcane plantation areas, rice fields, and fishponds).

Meanwhile, the categories of oil palm plantations in the form of expanses and community oil palm plantation areas (small squares scattered and merging with non-palm vegetation) are quite difficult to detect. The addition of labels for the overlay and community oil palm categories caused the F1 Score results in iteration 4 to decrease compared to the results of iteration 3. This strengthens the evidence that Sentinel 2 imagery has difficulty detecting overlay and community oil palm plantation areas. The decrease in F1 Score value in iteration 4 also does not necessarily indicate that the overall model is worse than the previous iteration. This decrease occurred because many labels of overlaying palms were not detected. But for other palm areas the results are still as good as the previous iteration model.

Study results from [20] and [21] show that the capability of Sentinel 2 in identifying oil palm plantation areas has limitations due to a reduction in spatial resolution. The best spatial resolution of Sentinel 2 imagery at 10 meters proved statistically less capable of identifying plantation/agricultural areas well because the minimum recommended scale for plantation/agricultural mapping purposes is 5 meters. At a scale of 10 meters, the appearance of un-patterned oil palm plantation areas is very difficult to capture and distinguish by the Sentinel 2 image sensor.

In addition, it is also mentioned in the academic journal by [21] that the spatial resolution of Sentinel 2 imagery is more suitable for object-based mapping than pixel-based mapping. This is relevant to the findings from the results of iteration 4.2 which show that the Sentinel 2 model is very sensitive to detecting oil palm plantation areas with specific planting patterns (object-based) but not sensitive to detecting oil palm plantation areas and community oil palms (not object/pixel-based).

D. Future Work and Recommendations

For future research, there are several aspects that can be improved, namely regarding input datasets, model development, and metrics for evaluating model output. For datasets, future research can use satellite imagery with very high resolution or UAV/drone data. For model development, future research can use semantic segmentation models other than UNet or other classifier models. For evaluation, it is necessary to add an evaluation matrix for other segmentation results such as ROC or AUC. It is also necessary to evaluate by comparing the results with real conditions in the field.

V. Conclusion

Medium-resolution satellite imagery such as Sentinel 2 and with a semantic segmentation approach using the UNet DL algorithm, can be well implemented for mapping in industrial oil palm plantations.

This study compares the results of segmentation of oil palm plantation areas with a semantic segmentation approach using the UNet classifier with the ResNet-34 and ResNet-50 backbone, the F1 score results are 0.89 and 0.922, respectively. The accuracy obtained at the inference/deployment model stage of each ResNet-34 and ResNet-50 backbone is 88.8% with an inference duration of 10 minutes and 91.8% at an inference duration of 20 minutes.

The results of the DL semantic segmentation modeling iteration show that the creation and implementation of the DL semantic segmentation model on Sentinel 2 imagery is only sensitive to detecting the characteristics of oil palm plantations with regular large square patterns and distinguishes them well from other land uses but is difficult for community oil palm plantation patterns which tends to be regular but with smaller patterns.

Acknowledgment

This work is supported by Bina Nusantara University as a part of Bina Nusantara University’s BINUS International Research - Applied entitled “Mapping Oil Palm Plantation Area with Deep Learning Semantic Segmentation Approach” with contract number: 097/VRRTT/VII/2024 and contract date 02 Juli 2024.

Enhancing Customer Experience Through Arabic Aspect-Based Sentiment Analysis of Saudi Reviews

Razan Alrefae, Revan Alqahmi, Munirah Alduraibi, Shatha Almatrafi, Asmaa Alayed
College of Computing, Umm Al-Qura University, Makkah, Saudi Arabia

***Abstract*—Big brands thrive in today's competitive marketplace by focusing on customer experience through product reviews. Manual analysis of these reviews is labor-intensive, necessitating automated solutions. This paper conducts aspect-based sentiment analysis on Saudi dialect product reviews using machine learning and NLP techniques. Addressing the lack of datasets, we create a unique dataset for Aspect-Based Sentiment Analysis (ABSA) in Arabic, focusing on the Saudi dialect, comprising two manually annotated datasets of 2000 reviews each. We experiment with feature extraction techniques such as Part-of-Speech tagging (POS), Term Frequency-Inverse Document Frequency (TF-IDF), and n-grams, applying them to machine learning algorithms including Support Vector Machine (SVM), Random Forest (RF), Naive Bayes (NB), and K-Nearest Neighbors (KNN). Our results show that for electronics reviews, RF with TF-IDF, POS tagging, and tri-grams achieves 86.26% accuracy, while for clothes reviews, SVM with TF-IDF, POS tagging, and bi-grams achieves 86.51% accuracy.**

Keywords*—Customer experience; Arabic natural language processing; sentiment analysis; Arabic Aspect-Based Sentiment Analysis; online reviews; review analytic; e-commerce; business owners

I. Introduction

Ensuring customer satisfaction is crucial for businesses of all sizes, with successful companies like Amazon thriving on their customer-centric approaches [1]. Analyzing online reviews helps manufacturers identify areas for improvement, leading to increased customer satisfaction and sales. For example, a major appliance manufacturer saw a 17% sales increase after addressing complaints identified through online reviews. However, manual analysis of these reviews is time-consuming and labor-intensive [2]. This paper addresses the challenge of sentiment analysis in Arabic, specifically focusing on Saudi dialects, by developing a unique dataset and evaluating the performance of various machine learning algorithms. Existing research on Arabic Aspect-Based Sentiment Analysis (ABSA) is limited, particularly in the Saudi context, making it difficult to establish a robust baseline or conduct comprehensive comparisons.

To fill this gap, we created two datasets of 2000 reviews each, manually annotated for sentiment analysis. We employed feature extraction techniques such as Term Frequency-Inverse Document Frequency (TF-IDF) and Part-of-Speech (POS) tagging, and tested machine learning algorithms including Support Vector Machine (SVM), Random Forest (RF), Naive Bayes (NB), and K-Nearest Neighbors (KNN). This approach allows us to navigate the linguistic diversity of Saudi Arabian dialects effectively.

Recent research in aspect-based sentiment analysis (ABSA) within Arabic contexts has provided valuable insights and methodologies, as evidenced by a number of notable works in the field.

Mir et al. [3] focused on developing a model for aspect-based opinion mining tailored to social reviews, which are typically longer and more complex than product reviews. The model focuses on auto-tagging and data training, defining feature sets, and utilizing a dictionary. Achieving an accuracy of 98.17% with precision, recall, and F1 scores of around 96%, the proposed model outperforms CR and Naïve Bayes classifiers. Future work aims to identify implicit aspects and refine aspect-wise sentiment analysis without relying on dictionaries.

In 2022, researchers aimed to support Saudi government efforts by analyzing user reviews on governmental mobile applications [4]. The labeled dataset underwent preprocessing, and features like supervised lexicon weights, TF-IDF, terms frequency matrix (TFM), and terms document matrix (TDM) were extracted. Using a supervised automatic sentiment lexicon, these features were weighted for each record. Four classifiers were employed and trained, with the highest accuracy recorded for DT (59.92%), KNN (78.46%), NB (54.78%), and SVM (55.38%).

In 2022, a sentiment analysis on customer satisfaction with logistics services in Saudi Arabia's private and public sectors during the COVID-19 pandemic was conducted [5]. Using a lexicon-based approach, 67,124 tweets were classified as positive, negative, or neutral, with preprocessing involving text cleaning and tokenization. The TF-IDF algorithm was employed to adjust word weights, and an SVM classifier achieved an average accuracy of 82% in 3-class classification, along with 81% precision and 80% recall.

Researchers aimed to assess customer opinions on mobile banking applications for updates and maintenance [6]. They manually collected an Arabic dataset and applied four ML techniques (NB, KNN, DT, and SVM). The NB model stood out, achieving 89.65% accuracy, 88.08% recall, 88.25% precision, and an f-score of 88.25%.

In 2023, researchers analyzed over 120,000 Arabic reviews on telecommunications services in Saudi Arabia [7]. They employed a machine learning approach, utilizing the SVM model for sentiment analysis. The study identified many factors influencing customer sentiments and recommendations for improvement were provided.

Research on ABSA in Arabic is advancing, but only a few NLP techniques have been tested on proposed machine learning models. In preprocessing, some studies treat negation words as stop words, which can misrepresent context, and disregard natural polarities, harming model performance. Datasets in literature have limitations like restricted availability, small size, domain specificity, imbalance, and being collected from non-Arabic sources or single regions, affecting generalizability. They often prioritize Modern Standard Arabic over dialects and use labor-intensive techniques. Our study addresses these gaps by applying diverse preprocessing and feature extraction techniques to evaluate their impact on model accuracy, addressing Saudi dialect complexities and resource scarcity in Arabic compared to English. The dataset has been carefully collected and prepared to enhance the training process.

II. Background

Natural language processing (NLP) is a branch of Artificial Intelligence (AI) that enables computers to understand, generate, and manipulate human language [8].

The linguistic challenges of Arabic in NLP are significant due to its dynamic nature, including lexical changes, regional variations, and context-dependent interpretations [9]. With over 400 million Arabic speakers [10], the diversity in dialects complicates the development of universally effective NLP applications. Arabic's rich morphology, where prefixes and suffixes alter meanings, and its orthographic connectedness, where a letter's form changes with its position, further complicate NLP tasks [11]. Additionally, diacritical marks, or "harakat," create orthographic ambiguity. A shortage of large-scale, high-quality labeled data for Arabic, crucial for training accurate supervised learning models, combined with the need for diverse labeled data to account for dialectal variations, hinders the advancement of Arabic NLP [12]. Sentiment Analysis (SA) uses NLP techniques to classify the polarity of text such as documents or review as positive, negative, or neutral. SA operates at four levels: document-level analysis determines overall polarity, sentence-level analysis classifies sentences as subjective or objective, and aspect-based analysis evaluates an object's features to determine the polarity of each, considering the context of opinion words. Aspect-based summarization aggregates opinions and attributes to summarize feedback and derive insights [13]. ABSA includes tasks such as Aspect Term Extraction, Aspect Term Polarity, Aspect Category Identification, and Aspect Category Polarity, as demonstrated in the sentence: " حلو الستايل والقماش حلو وخفيف، بس اللون مو نفس الصورة" ("The style is nice and the fabric is nice and light, but the color is not the same as the picture"). Machine learning approaches for SA include supervised, unsupervised, and semi-supervised learning, lexicon-based methods, rule-based approaches, and deep learning [14–16]. These techniques, particularly deep learning, which uses neural networks, offer superior performance in NLP tasks.

III. Methodology

In this work, we aim to enhance customer experience by conducting aspect-based sentiment analysis on reviews written in the Saudi Arabian dialect. As depicted in Fig. 1, the methodology involves data collection and annotation, cleaning and preprocessing, feature extraction, algorithm selection, and model training.

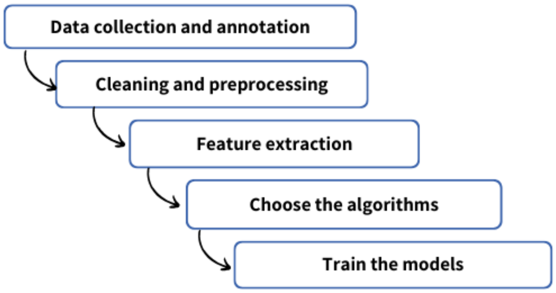

Fig. 1. Schematic representation of the research methodology.

A. Data Collection and Annotation

Due to the lack of established datasets, we manually collected 4000 product reviews (2000 electronics, 2000 clothing) in Saudi dialects [17], ensuring relevance and accuracy. Reviews were sourced from platforms like Amazon, Jarir Bookstore, Shein, Noon, and Twitter (X). Annotation involved labeling aspects such as quality, battery, and price for electronics, and size, color, and fabric for clothing, assigning sentiment scores of '1' (positive), '-1' (negative), or '0' (neutral). We focused on the four most recurring features for each category to streamline model input, maintaining a balanced sentiment distribution. During the training phase, we manually conducted term extraction and polarity assignment for the highest accuracy. Each review was carefully annotated by identifying specific aspects and marking their presence with binary indicators, as well as recording the overall polarity of each review as positive, negative, or neutral. To enhance reliability and objectivity, we split the researchers into two groups who cross-reviewed each other's annotations, ensuring thorough validation. This rigorous process ensured the accuracy and reliability of the annotations, thus enhancing the overall performance of our sentiment analysis models.

B. Cleaning and Preprocessing

Cleaning and preprocessing are crucial for enhancing data quality in complex languages like Arabic. We removed null values, emojis, punctuation, symbols, English letters, Arabic diacritics, and stop words (while preserving those essential for opinion comprehension). Tokenization and stemming were applied, and specific Arabic characters were normalized. This thorough approach ensures dataset robustness and reliability, aligning with scientific rigor for meaningful analysis. Fig. 2 and Fig. 3 illustrate the datasets before and after cleaning.

	General	Size	Usage	Quality	Price	Reviews	Clean_Text
0	1.0	0	0	1	-1	الشكل جميل والجوده حلوه بس السعر عالي	شكل جميل جود حلو بس سعر عال

C. *Feature Extraction*

Feature extraction converts raw text into numerical vectors, which are crucial for machine learning models in aspect-based sentiment analysis. We implemented Part-of-Speech (POS) tagging using the NLTK library to assign grammatical categories to words, aiding in contextual analysis [18]. The POS tagging addresses the complexity of Arabic morphology and contextual forms by understanding the grammatical structure of sentences and identifying sentiment-carrying parts of speech such as adjectives and adverbs. N-gram models, which group contiguous words, capture the sequence of terms, providing features like unigrams and bigrams [19]. These models handle dialectal variation and morphological richness by recognizing and interpreting various expressions and phrases that convey sentiment. Additionally, Term Frequency-Inverse Document Frequency (TF-IDF) assesses term importance in the corpus, transforming words into numerical values for better model input [20]. The TF-IDF technique highlights the importance of words within a document relative to their frequency across a corpus, identifying key sentiment-bearing terms while reducing the influence of common, less informative words. These combined techniques—TF-IDF, POS tagging, and unigrams and bigrams—significantly contribute to overcoming the linguistic and morphological challenges of Arabic sentiment analysis, resulting in a more robust and accurate model.

It is crucial to emphasize that establishing a strong foundational model is essential for advancing research and practical applications in the field of sentiment analysis. Our primary goal was to create a robust yet straightforward model that could be easily understood and implemented by researchers and practitioners in the field. Traditional machine learning techniques and simpler models provide more transparency and interpretability compared to the complex architectures of Word2Vec and BERT. Additionally, this study aimed to establish a baseline using traditional methods and ensure they were thoroughly evaluated before moving on to more complex models. Future work can build upon this baseline by incorporating Word2Vec, BERT, or other advanced techniques to further enhance performance.

D. *Algorithm Selection*

For the analysis, we chose algorithms that, based on our comprehensive research, have shown potential in handling the linguistic and structural complexities of the Arabic language, which can differ from those encountered in English text analysis. Our aim was to experiment with various algorithms and NLP techniques to identify those that would perform aspect-based sentiment analysis on Arabic texts with high accuracy. The selection of algorithms was guided by the results of our literature review (LR), which highlighted the top-performing algorithms in existing research. Consequently, we selected the top four algorithms from the LR results and tested them with our new benchmark datasets. In the following subsections, we provide a detailed description of each algorithm, outlining the rationale for their selection and why they are well-suited for our research.

1) Support Vector Machine: Support Vector Machine (SVM) is a popular supervised learning algorithm used for both classification and regression. It categorizes data points by mapping them to a high-dimensional feature space and aims to find a hyperplane that serves as the optimal decision boundary, maximizing the margin between classes. The data points closest to this boundary are known as support vectors, which play a crucial role in defining the hyperplane’s position [21].

The choice of the kernel function is critical for the SVM algorithm's performance. The kernel is a mathematical function used to transform data for finding the hyperplane. It is beneficial to experiment with different kernel functions—namely, linear, polynomial, radial basis function (RBF), and sigmoid—to determine the best model for each case, as each function involves different algorithms and parameters.

2) Random Forest: The Random Forest algorithm is a popular machine learning technique for classification and regression tasks. It is an ensemble learning method that combines the predictions of multiple decision trees to enhance accuracy. In a random forest, an ensemble of decision trees is created, where each tree is trained on a random subset of the training data and considers only a subset of the features at each split. During prediction, each tree provides its predictions independently, and the final prediction is determined by a majority vote (for classification) or an average (for regression) of all individual tree predictions [22]. We chose the Random Forest algorithm because it is particularly effective with high-dimensional datasets, which is important for our project due to the multiple aspects we consider within each category.

3) Naïve Bayes: The Naïve Bayes classifier is a supervised learning algorithm that belongs to the generative learning algorithms group. It is a probabilistic classifier based on Bayes' Theorem [23], making probability assignments based on prior knowledge of conditions related to the predicted event. The "Naïve" aspect of the algorithm refers to its assumption that features are independent, meaning the presence of one feature does not affect the presence of another. This assumption, while simplifying computation and allowing for fast predictions, may not reflect real-world complexities. Despite its simplicity, Naïve Bayes is effective for text classification problems, commonly used in Natural Language Processing (NLP). It calculates the probability of each tag for a given piece of text and selects the tag with the highest probability. This makes it well-suited for categorizing sentiments related to specific aspects within reviews.

4) K-nearest Neighbors: The K-nearest neighbors (KNN) algorithm is a technique for supervised machine learning applicable to both classification and regression problems. It operates on the principle that similar objects or instances are located near each other. To be effective, the KNN algorithm relies on the assumption that the notion of similarity holds true. The algorithm uses mathematical principles, such as calculating distances between points on a graph, to measure similarity. The Euclidean distance, or straight-line distance, is a popular method for this measurement. Selecting the appropriate K value for KNN requires an iterative process to minimize errors and ensure accurate predictions with new data. A higher K value is often beneficial for data with outliers or significant noise. It is advisable to choose an odd number for K to avoid classification ties [24].

In NLP and sentiment analysis, KNN is a straightforward yet powerful tool. Given that textual data often exists in high-dimensional space due to a large vocabulary, measuring distances between text vectors can help classify sentiments or topics. Texts with similar word patterns or sentiments are closer in this space. For sentiment analysis, if the majority of the 'k' nearest text instances have a positive sentiment, the new text is likely classified as positive, and vice versa. However, due to high-dimensionality, considerations such as dimensionality reduction and careful feature extraction are crucial for effective KNN performance in NLP tasks [25].

In addition to the insights gained from the literature review, we performed a 10-fold cross-validation to ensure the reliability of our experimental findings and to avoid overfitting. Cross-validation is a technique that involves dividing the dataset into distinct parts or folds, using each fold once as a validation set while the rest serve as the training set. This thorough evaluation method enables us to assess the model's performance across various subsets of the data, providing a more accurate estimate of its ability to generalize. By using 10-fold cross-validation, we aimed to confirm that our models not only fit the training data well but also perform effectively on unseen data. This rigorous validation approach enhances the reliability of our results and highlights the robustness of our conclusions. The results of the cross-validation are detailed in Table I, providing a clear overview of the model performances across different folds.

TABLE I. SUMMARY OF 10-FOLD CROSS VALIDATION

Combination	Algorithm	Electronics Dataset	Clothes Dataset
TF-IDF	SVM	83.03%	84.92%
TF-IDF+POS	SVM	82.96%	85.03%
TF-IDF+Bigrams	SVM	81.71%	84.04%
TF-IDF+Trigrams	SVM	80.50%	82.91%
TF-IDF + POS + Bi-grams	SVM	81.79%	83.81%
TF-IDF + POS + Tri-grams	SVM	80.58%	82.79%
TF-IDF	RF	81.86%	84.82%
TF-IDF+POS	RF	82.13%	83.48%
TF-IDF+Bi-grams	RF	82.36%	85.02%
TF-IDF + Tri-grams	RF	81.82%	84.79%
TF-IDF + POS + Bi-grams	RF	81.99%	83.61%
TF-IDF + POS + Tri-grams	RF	80.91%	83.25%
TF-IDF	NB	74.69%	72.90%
TF-IDF+POS	NB	74.69%	71.11%
TF-IDF+Bi-grams	NB	75.04%	73.29%
TF-IDF + Tri-grams	NB	74.55%	73.01%
TF-IDF + POS + Bi-grams	NB	74.08%	71.41%
TF-IDF + POS+ Tri-grams	NB	73.74%	71.35%
TF-IDF	KNN	76.81%	73.11%
TF-IDF+POS	KNN	74.37%	71.79%
TF-IDF+Bi-grams	KNN	68.92%	68.94%
TF-IDF + Tri-grams	KNN	53.91%	68.60%
TF-IDF + POS + Bi-grams	KNN	69.49%	71.43%
TF-IDF + POS + Tri-grams	KNN	57.10%	71.61%

E. Training Phase

We used a linear kernel for SVM after testing both linear and polynomial kernels to ensure optimal performance. The models were trained on two datasets: electronic product reviews and clothing product reviews. We experimented with six feature extraction combinations, including TF-IDF, Part-of-Speech tagging, and bi-grams and tri-grams, to determine the best approach for enhancing model accuracy.

F. Implementation of Aspect-Based Sentiment Analysis

We deployed the models with the highest accuracy. For electronics, the Random Forest model predicted overall sentiment and four specific aspects: quality, usage, price, and size, leveraging its multi-output capability. For clothing, five SVM models were deployed to predict overall sentiment and four aspects: fabric, color, style, and size, since SVM is a single-output classifier. The models and TF-IDF vectorizer were serialized using Python's pickle library to enable predictions on new data without retraining. Applied to a preprocessed dataset, the models predicted product aspects with high accuracy, as detailed in the Experiments section.

All preprocessing and feature extraction combinations are summarized in Table II, Fig. 4, and Fig. 5.

TABLE II. SUMMARY OF PREPROCESSING AND FEATURE EXTRACTION COMBINATIONS

Combination	Algorithm	Electronics Dataset	Clothes Dataset
TF-IDF	SVM	70.9375%	85.8075%
TF-IDF+POS	SVM	83.25%	85.3975%
TF-IDF+Bigrams	SVM	71.0625%	77.685%
TF-IDF+Trigrams	SVM	81.0625%	69.45%
TF-IDF + POS + Bi-grams	SVM	84.0625%	86.5075%

TF-IDF + POS + Tri-grams	SVM	83.625%	86.39%
TF-IDF	RF	82.3791%	85.1075%
TF-IDF+POS	RF	82.1246%	83.4112%
TF-IDF+Bi-grams	RF	83.2675%	84.3457%
TF-IDF + Tri-grams	RF	82.6335%	84.1705%
TF-IDF + POS + Bi-grams	RF	72.9643%	84.1705%
TF-IDF + POS + Tri-grams	RF	86.2595%	82.5934%
TF-IDF	NB	84.3125%	82.651%
TF-IDF+POS	NB	83.1875%	82.418%
TF-IDF+Bi-grams	NB	83.875%	82.9425%
TF-IDF + Tri-grams	NB	83.125%	82.359%
TF-IDF + POS + Bi-grams	NB	82.9375%	82.593%
TF-IDF + POS+ Tri-grams	NB	83.062%	82.593%
TF-IDF	KNN	77.5575%	74.4775%
TF-IDF+POS	KNN	76.405%	73.715%
TF-IDF+Bi-grams	KNN	64.64%	72.255%
TF-IDF + Tri-grams	KNN	71.8025%	67.875%
TF-IDF + POS + Bi-grams	KNN	76.4075%	74.53%
TF-IDF + POS + Tri-grams	KNN	64.5775%	71.67%

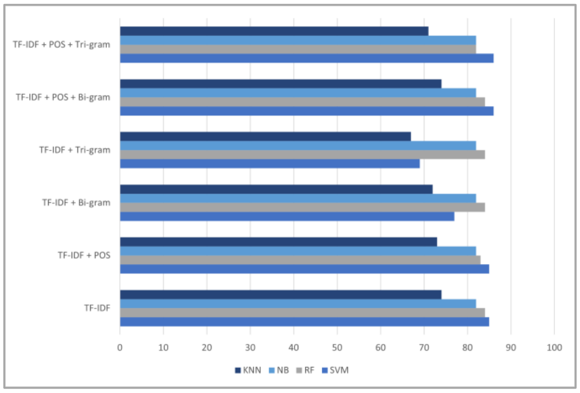

Fig. 4. Preprocessing and feature extraction combinations for clothes dataset.

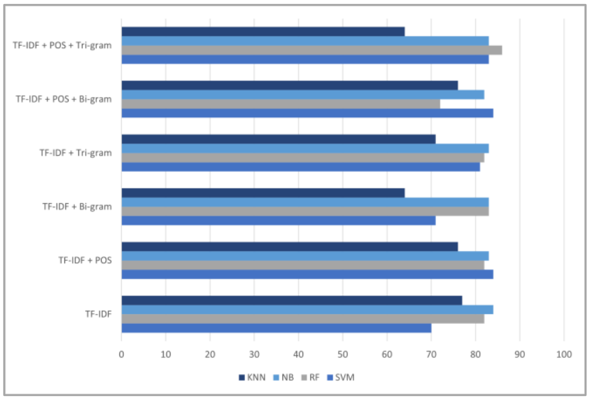

Fig. 5. Preprocessing and feature extraction combinations for electronic dataset.

IV. Experiments

In this experiment, the primary objective is to establish a benchmark for the main contribution of this work, which is the new datasets in the Saudi dialect. It is important to emphasize that while this study provides a foundational benchmark, future research can conduct extensive hyperparameter tuning or explore different approaches to enhance the performance of the algorithms with these datasets.

A. Models Evaluation

Researchers evaluated the trained models and reviewed each algorithm with the best feature extraction combinations for each dataset. Accuracy was used as the performance metric. Six combinations of feature extraction techniques were applied: TF-IDF alone, TF-IDF with POS, with bi-grams, with tri-grams, TF-IDF with POS and bi-grams, and TF-IDF with POS and tri-grams. Table II shows that for electronics, Random Forest using TF-IDF, POS, and tri-grams achieved the highest accuracy of 86.2595%. For clothes, SVM with TF-IDF, POS, and bi-grams scored the highest accuracy at 86.5075%. SVM achieved 84.0625% for electronics and 86.5075% for clothes. Random Forest had an accuracy of 86.2595% for electronics and 85.1075% for clothes. Naïve Bayes scored 84.3125% for electronics and 82.9425% for clothes. KNN registered 78.43% for electronics and 75.87% for clothes. These results highlight the importance of feature extraction combinations and domain-specific challenges in sentiment analysis.

B. SVM Performance

Table III shows the performance of the SVM classifier for aspect-based sentiment analysis on Electronics and Clothes datasets. For electronics reviews, SVM using TF-IDF, POS, and bi-grams showed varied performance. Quality aspect had moderate results with 67.50% accuracy and recall, and a 66.97% F1-score. Usage aspect improved with 78.75% accuracy and recall, and a 76.70% F1-score. Size and Price aspects excelled with over 95% accuracy and recall, and F1-scores of 94.72% and 94.31%, respectively. Average metrics for the SVM electronics model were 84.0625% accuracy and recall, and 83.175% F1-score.

For clothes reviews, using the same extraction techniques, SVM performed consistently well. Style aspect achieved 84.35% accuracy and recall, and an 82.87% F1-score. Fabric aspect followed with 84.11% accuracy and recall, and an 84.04% F1-score. Size aspect showed 87.62% accuracy and recall, and an 87.07% F1-score, while Color aspect excelled with 89.95% accuracy and recall, and an 89.32% F1-score. The average metrics were 86.5075% accuracy and recall, and an 85.825% F1-score.

TABLE III. The Best Features Combination for each Dataset for SVM

Dataset	Combination	Accuracy	F1-score	Recall
Electronics	TF-IDF + POS + Bi-grams	84.0625%	83.175%	84.0625%
Clothes	TF-IDF + POS + Bi-grams	86.5075%	85.825%	86.5075%

C. RF Performance

Table IV illustrates the performance of the RF classifier on Electronics and Clothes datasets. In electronics reviews, RF using TF-IDF, POS, and tri-grams excelled: Quality (60.55% accuracy and recall, 58.70% F1-score), Usage (94.91% accuracy and recall, 92.11% F1-score), Size (94.65% accuracy and recall, 93.76% F1-score), and Price (94.75% accuracy and recall, 93.34% F1-score). Average metrics were 86.2595% accuracy and recall, and 84.4775% F1-score. For clothes reviews, RF performed well: Style (83.18% accuracy and recall, 80.17% F1-score), Fabric (82.01% accuracy and recall, 81.82% F1-score), Size (87.62% accuracy and recall, 87.27% F1-score), and Color (87.62% accuracy and recall, 86.21% F1-score), with average metrics of 85.1075% accuracy and recall, and 83.8675% F1-score.

TABLE IV. THE BEST FEATURES COMBINATION FOR EACH DATASET FOR RF

Dataset	Combination	Accuracy	F1-score	Recall
Electronics	TF-IDF + POS + Tri-grams	86.2595%	84.4775%	86.2595%
Clothes	TF-IDF	85.1075%	83.8675%	85.1075%

D. NB Performance

The performance of the NB classifier on Electronics and Clothes datasets is illustrated in Table V. In electronics reviews, NB using TF-IDF showed: Quality (74.00% accuracy and recall, 68.19% F1-score), Usage (80.75% accuracy and recall, 72.85% F1-score), Size (95.50% accuracy and recall, 93.30% F1-score), and Price (87.00% accuracy and recall, 81.42% F1-score). Average metrics were 84.3125% accuracy and recall, and 78.94% F1-score. For clothes reviews, NB with TF-IDF and bi-grams performed: Style (81.31% accuracy and recall, 72.93% F1-score), Fabric (73.13% accuracy and recall, 64.17% F1-score), Size (89.95% accuracy and recall, 85.20% F1-score), and Color (87.38% accuracy and recall, 81.50% F1-score). Average metrics were 82.9425% accuracy and recall, and 75.95% F1-score.

TABLE V. THE BEST FEATURES COMBINATION FOR EACH DATASET FOR NB

Dataset	Combination	Accuracy	F1-score	Recall
Electronics	TF-IDF	84.3125%	78.94%	84.3125%
Clothes	TF-IDF + Bi grams	82.9425%	75.95%	82.9425%

E. KNN Performance

Table VI shows the performance of the KNN classifier for aspect-based sentiment analysis on Electronics and Clothes datasets, using accuracy, F1-score, and recall as metrics. The classifier achieved reasonable accuracy: 77.56% for Electronics with TF-IDF and 74.53% for Clothes with POS + bi-gram + TF-IDF. However, lower F1-scores and recall rates suggest an imbalance between precision and recall, indicating many false negatives. Optimization may require retraining with different parameters, alternative feature sets, or exploring other classification algorithms.

TABLE VI. THE BEST FEATURES COMBINATION FOR EACH DATASET FOR KNN

Dataset	Combination	Accuracy	F1-score	Recall
Electronics	TF-IDF	77.56%	50.25%	49.83%
Clothes	POS+Bi-gram + TF-IDF	74.53%	55.66%	51.33%

V. DISCUSSION AND FUTURE WORK

As discussed earlier in the previous section, the models were implemented using four machine learning algorithms, three feature extraction techniques were applied with six different combinations, and one metric was used for performance measurement. To maintain a reliable performance for the models, two categories of products were analyzed: electronics and clothes. Despite this selection being devoted to a certain scope of data, it implies that there is potential to expand the research scope to other product categories, e.g., food, offering a broader understanding of sentiment patterns across various domains. While the evaluation process of the models is meticulous, it is not without its limitations. Further enhancements in model accuracy could potentially be achieved if additional feature extraction techniques were explored. Future research endeavors should consider exploring different algorithms and additional sophisticated techniques, and consider the exploration of other performance metrics, aiming to develop a more subtle and holistic understanding of model efficacy in aspect-based sentiment analysis.

VI. CONCLUSION

In an era dominated by data, effectively analyzing customer reviews is essential for product success. Our research focused on product reviews in Saudi Arabian dialects, a relatively less explored area in sentiment analysis. We performed aspect-based sentiment analysis on online product reviews utilizing machine learning algorithms with NLP techniques and provided a thorough experimentation to highlight their effectiveness. We collected and preprocessed two datasets from the clothing and electronics sectors, each with 2000 reviews, implementing techniques like tokenization, stemming, and normalization to prepare the data for training the model for the analysis. Our experiments tested four machine learning algorithms (SVM, RF, NB, KNN) across six combinations of feature extraction methods (TF-IDF, POS tagging, n-grams), finding the RF algorithm with TF-IDF, POS tagging, and tri-grams combination the most effective for electronics reviews at an average accuracy of 86.2595% per aspect, and the SVM for clothing reviews using TF-IDF, POS tagging, and bi-grams at 86.5075% average accuracy for every aspect.

A Comprehensive Study on Crude Oil Price Forecasting in Morocco Using Advanced Machine Learning and Ensemble Methods

Hicham BOUSSATTA, Marouane CHIHAB, Younes CHIHAB
Laboratory of Computer Science Research-Faculty of Science Kenitra,
Ibn Tofail University of Kenitra, Kenitra, Morocco

***Abstract*—This study employs a range of machine learning models to forecast crude oil prices in Morocco, including Linear Regression, Random Forest, Support Vector Regression (SVR), XGBoost, ARIMA, Prophet and Gradient Boosting. Among these, SVR demonstrated the highest accuracy with an RMSE of 1.414. Additionally, the ARIMA and Prophet models were evaluated, yielding RMSEs of 2.46 and 1.41, respectively. An ensemble model, which combines predictions from all the individual models, achieved an RMSE of 2.144, indicating robust performance. Projections for 2024-2027 show a rising trend in crude oil prices, with the SVR model forecasting 21.91 MAD in 2027, and the ensemble model predicting 14.47 MAD. These findings underscore the effectiveness of ensemble learning and advanced machine learning techniques in producing reliable economic forecasts, offering valuable insights for stakeholders in the energy sector.**

***Keywords*—Crude oil prices; machine learning; ensemble model; economic forecasts; energy sector**

I. Introduction

Forecasting crude oil prices is a crucial research topic, not only for producing countries but also for importers like Morocco. Fluctuations in oil prices have profound repercussions on the global economy, affecting production costs, consumer prices, energy policies, and investment strategies. In Morocco, specifically, the price of crude oil directly influences public and private spending, the transportation sector, and household purchasing power. Therefore, accurately anticipating oil price trends is essential for developing robust and sustainable economic policies.

Traditionally, oil price forecasting models have relied on classical statistical and economic methods, such as ARIMA (Autoregressive Integrated Moving Average) models [1] or VAR (Vector Autoregression) models [2]. While these methods have provided useful results, they often have limitations in terms of accuracy and ability to capture the complex nonlinearities and dynamic interactions present in oil price data. Recent advances in machine learning offer new perspectives for improving these forecasts by leveraging more sophisticated and adaptive techniques.

Machine learning allows for the processing of large amounts of data and the modeling of complex relationships that may be difficult to capture with traditional approaches. Models such as Linear Regression, Random Forest, Support Vector Regression (SVR), XGBoost, and Gradient Boosting can adapt to different data structures and provide more accurate forecasts. Moreover, ensemble learning techniques [3], which combine the predictions of multiple models, can further enhance the robustness and reliability of forecasts by reducing the risk of errors associated with an individual model.

In this study, we focus on applying various machine learning techniques to predict annual crude oil prices in Morocco. We selected a diverse set of models to capture different characteristics of the data and compare their performance in terms of predictive accuracy. Our objective is to identify the best-performing model for Moroccan data and explore the potential benefits of ensemble learning.

To achieve this, we used a historical dataset on crude oil prices in MAD (Moroccan dirham), covering several years. We preprocessed the data to ensure its quality and consistency, including handling missing values and standardizing variables. The selected models include Linear Regression, Random Forest, Support Vector Regression (SVR), XGBoost, ARIMA, Prophet and Gradient Boosting. Each model was evaluated using the Root Mean Squared Error (RMSE) to measure the accuracy of the predictions.

Our results indicate that Support Vector Regression (SVR) offers the best individual performance with an RMSE of 1.414, outperforming the other models. Additionally, we developed an ensemble model by combining the predictions from all individual models to create a weighted average forecast. This ensemble approach achieved an RMSE of 2.144, demonstrating increased robustness compared to most individual models.

Forecasts for the period 2024-2027, derived from the ensemble model, suggest a steady upward trend in crude oil prices in Morocco. Starting at 13.28 MAD in 2024, the predicted values gradually increase each year, reaching 14.47 MAD by 2027. This consistent growth pattern, as illustrated in Fig. 3, reflects the ensemble model's capability to provide a balanced and comprehensive view of future trends. The gradual increase from 13.28 MAD to 14.47 MAD implies a stable environment with continuous, albeit modest, enhancements, highlighting the robustness of the ensemble approach in mitigating individual forecasting errors and uncertainties.

These results emphasize the importance of ensemble learning for obtaining balanced and reliable forecasts. The advanced machine learning and ensemble techniques used in this study provide valuable tools for Moroccan policymakers, enabling them to better anticipate price fluctuations and develop more informed and resilient economic and energy strategies. Accurate crude oil price predictions are essential for strategic planning, risk management, and decision-making in the energy sector.

The remainder of the paper is structured as follows: Section II reviews the current literature on forecasting crude oil prices in Morocco. Section III outlines the methodology employed in this study. Section IV presents the empirical results, followed by a discussion in Section V. Finally, Section VI offers conclusions and directions for future research.

II. Related Work

Forecasting crude oil prices and energy demand in Morocco is a crucial topic for the country's economic and energy planning. Numerous studies have explored this field using various methodologies and approaches. Among the key works, Nafil et al. (2020) [4] compared different methods for forecasting energy demand, concluding that the temporal causality method is the most effective. Kharbach and Chfadi (2018) [5] examined the relationship between oil prices and electricity production, revealing a significant impact of crude oil prices on the latter. Ifleh et al. (2022, 2023) [6, 9] explored the use of technical indicators for stock market forecasting with promising results. Ayyadi and Maaroufi (2018) [7] proposed diffusion models for the emerging electric vehicle market. Other studies have focused on the impact of global factors. Adekoya et al. (2021) [8] analyzed the influence of the global financial cycle and oil prices on stock returns of African oil-exporting countries. Benali and Lahboub (2024) [10] demonstrated the effectiveness of machine learning techniques in modeling stock prices in the energy sector. El Bahi et al. (2022) [11] developed a dynamic harmonic regression model for fuel price forecasting. Lahrech et al. (2017) [12] examined the impact of oil shocks on the Moroccan financial market, while Nasreddin et al. (2023) [13] compared regression and machine learning models for fossil energy demand forecasting. These studies confirm the importance of using advanced methods to improve forecast accuracy in the energy and financial sectors. They also highlight the challenges of forecasting crude oil prices, a crucial element for Morocco's economic and energy planning.

Research on forecasting crude oil prices and energy demand in Morocco is of great importance for effective resource management and informed economic planning. The use of advanced methods and the exploration of new factors influencing these markets are essential to improve forecast accuracy and support informed decision-making. Forecasting crude oil prices and their influence on various economic sectors is gaining increasing interest, both in Morocco and other countries. Many recent studies explore different techniques to improve forecasting accuracy and understand the complex links between oil prices and the economy. Among the most recent works, Ifleh et al. (2023) [14] demonstrated the effectiveness of trend technical indicators for forecasting Moroccan stock prices. Siham et al. (2024) [15] explored different machine learning techniques for oil price forecasting, obtaining promising results. Itri et al. (2024) [16] applied hybrid machine learning techniques for stock price forecasting in the Moroccan banking sector, with conclusive results.

Modeling and forecasting fuel prices are also subjects of extensive research. El Bahi et al. (2018) [17] used a time series approach for fuel price forecasting, obtaining reliable results. Bennouna and El Hebil (2016) [18] studied Morocco's energy needs by 2030, highlighting the importance of energy planning for the country's economic development. Meliani et al. (2022) [19] proposed energy demand forecasting methods based on time series for smart grids in Morocco, which is crucial for efficient energy management. Research also explores the use of hybrid methods to improve forecast accuracy. Zahouani and Boubaker (2023) [20] developed hybrid approaches for crude oil price forecasting, demonstrating the effectiveness of combining different techniques. Benabbou et al. (2021) [21] applied machine learning techniques for forecasting used car prices in Morocco. Ghorbel et al. (2014) [22] evaluated the impact of crude oil prices and investor sentiment on Islamic indices, highlighting the complex interactions between oil prices and financial markets. Dagher and El Hariri (2013) [23] studied the impact of global oil price shocks on the Lebanese stock market, revealing significant links that can inform forecasting approaches for other countries in the region. The application of advanced techniques, including machine learning and hybrid models, is essential to improve the forecasting of crude oil prices and their impact on various economic sectors. These studies help better understand the challenges and opportunities related to modeling and forecasting market trends in an ever-changing context. Modeling and forecasting oil prices and energy demand in Morocco and other regions are subjects of extensive research, using various advanced techniques to improve forecast accuracy and understand complex market interactions. Among recent works, Aman et al. (2019) [24] demonstrated the effectiveness of the radial basis function technique for forecasting fuel sale prices in Morocco. Haouraji et al. (2023) [25] used machine learning-based planning models to analyze LPG demand in Morocco, highlighting the usefulness of these models for accurate energy planning. Abdou et al. (2024) [26] applied a machine learning approach to examine the impact of oil and global markets on the predictability of the Saudi stock market, revealing valuable insights into market interactions.

Other studies focus on analyzing energy consumption and its economic impact. Oubnaki et al. (2022) [27] studied energy consumption in the transport sector in Morocco, identifying trends and providing essential forecast estimates for efficient energy management. Kitous et al. (2016) [28] assessed the impact of low oil prices on exporting countries, highlighting the economic challenges posed by significant oil price fluctuations. Research also explores the use of advanced techniques for oil price forecasting. Siham et al. (2024) [29] applied multimodal deep learning for oil price forecasting using economic indicators, demonstrating the robustness of this approach in capturing complex signals. The impact of oil prices on financial markets and economies is also studied. Bouri et al. (2020) [30] analyzed oil market conditions and sovereign risk in oil-exporting and importing countries in the MENA region. Lotfi and El Bouhadi (2022) [31] explored artificial intelligence methods as new decision-making tools, highlighting their potential to revolutionize economic and energy decision-making.

Correlative approaches for modeling energy consumption are also proposed. Haouraji et al. (2020) [32] proposed a correlative approach combining energy consumption, urbanization, and GDP to model and forecast residential energy consumption in Morocco. The effect of oil price shocks on economic growth is analyzed. Elneel and AlMulhim (2022) [33] analyzed the effect of oil price shocks on Saudi Arabia's economic growth, providing crucial insights considering Saudi Arabia's Vision 2030. Applying advanced techniques, including machine learning, hybrid approaches, and artificial intelligence, is essential for improving the accuracy of oil price and energy demand forecasts. These studies help better understand the complex interactions between oil prices, financial markets, energy consumption, and economic growth, which is crucial for effective strategic planning and informed decision-making.

Research on forecasting crude oil prices and energy demand in Morocco explores a variety of advanced methodologies and approaches, ranging from renewable energy optimization to market sentiment analysis. Among recent works, Benzohra et al. (2020) [34] studied the optimization of renewable resource mix for a low-carbon energy system in Morocco. Belcaid and El Ghini (2021) [35] analyzed the macro-financial determinants of stock market development in Morocco. El-Karimi and El-Ghini (2020) [36] examined the transmission of global commodity prices to consumer prices in Morocco. Other research focuses on applying advanced techniques for oil price forecasting and energy demand management. El Abassi et al. (2023) [37] used recurrent neural networks to predict crude oil prices. Vochozka et al. (2023) [38] studied the impact of geopolitical deadlock and phosphate shortages on prices. Gagour et al. (2022) [39] modeled the shelf life of virgin olive oil in Morocco. Bounadi et al. (2023) [40] estimated the costs and policy implications of mitigating water pollution in the olive oil industry in Morocco.

Sentiment analysis and machine learning are also used for stock market forecasting. Sandeep et al. (2023) [41] and Chihab et al. (2022) [42] developed models to predict stock prices using text polarity and subjectivity. Finally, Boussatta et al. (2023) [43] proposed an intelligent hybrid approach to improve oil price forecasting. As the author of this study, we developed an advanced hybrid system combining several machine learning models such as linear regression, random forest, support vector machines, and gradient boosting. These collective studies underscore the importance of advanced techniques for oil price forecasting and energy demand management in Morocco, highlighting the economic and environmental implications of these forecasts.

This article details the implementation of this new hybrid system for oil price forecasting in Morocco, with an in-depth analysis of the results and performance of the different models used. This innovative approach should significantly improve oil price forecast accuracy, aiding policymakers in making informed energy policy decisions in Morocco.

III. Proposed Method

Fig. 1 illustrates the architecture of the proposed ensemble prediction system for forecasting crude oil prices in Morocco. This hybrid approach begins with a data preprocessing phase, where raw data is cleaned and prepared for analysis. Next, different individual models are trained, including Random Forest, linear regression, XGBoost, ARIMA, Prophet and support vector regression. The forecasts generated by these models are then integrated into an ensemble prediction process, which combines these different estimates to produce a more robust final forecast. The performance of this system is evaluated to verify and validate the obtained results before arriving at the final crude oil price prediction. This method aims to leverage the strengths of each individual model to improve the accuracy and reliability of the forecasts.

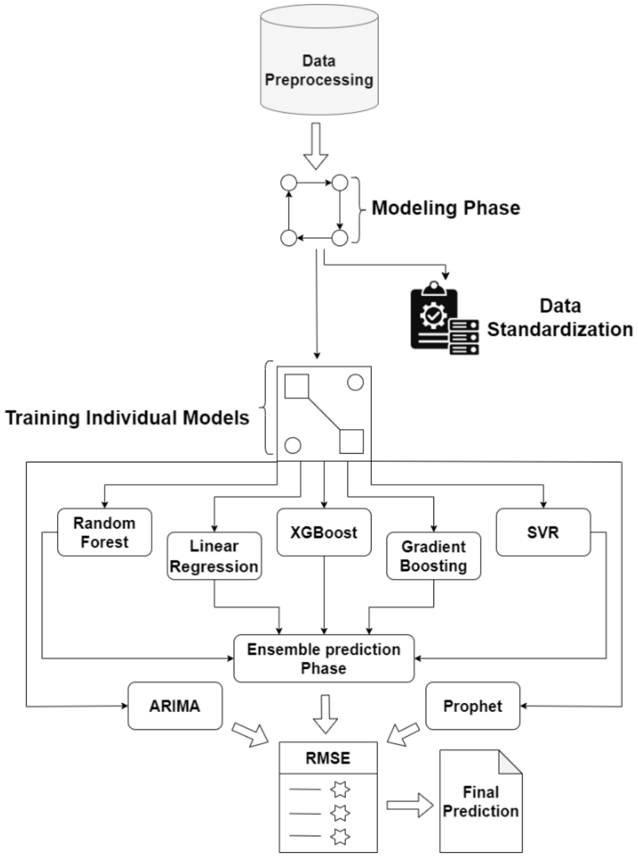

Fig. 1. Hybrid architecture for forecasting crude oil prices in morocco using machine learning and ensemble models.

A. Data Preprocessing

1) Data: The data used in this study comes from the Numbeo platform [44], which provides historical information on gasoline prices in different countries around the world. Specifically, the data covers the period from 2010 to 2023 for Morocco and includes information on the average annual gasoline price (in MAD per liter). This data was cleaned and prepared for analysis. The data preprocessing involved extracting relevant information, converting non-numeric values to NaN, and calculating the annual average gasoline prices. Then, this data was divided into training and testing sets and standardized for use in the forecasting models. We developed several regression models to predict future gasoline prices in Morocco up to 2027, using techniques such as linear regression, Random Forest, support vector machines (SVR), XGBoost, ARIMA, Prophet and gradient boosting. Each model was evaluated individually, and performance was measured using the root mean square error (RMSE).To obtain more robust forecasts, we also combined the predictions of all the individual models into an ensemble forecast. This approach leveraged the strengths of each model to improve the accuracy and reliability of the forecasts. The results show the gasoline price forecasts for the next four years (2024-2027), providing a comprehensive view of the expected evolution of gasoline prices in Morocco in the coming years.

2) Normalization of data: To adjust the values of different features so that they fall within a comparable scale. This is crucial because many machine learning algorithms, such as neural networks or distance-based methods, perform better when the data is normalized.

B. Modeling Phase

The process involves training and testing various machine learning models. We start by splitting the data into training and testing sets using the train_test_split method, with 80% of the data used for training and 20% for testing. The data is then standardized using the StandardScaler to ensure that all features have a mean of zero and a standard deviation of one, which is crucial for the performance of many machine learning algorithms.

C. Training Individual Models

1) Linear regression: It is a supervised learning method that models the relationship between a dependent variable (or target variable) and one or more independent variables (or explanatory variables).

2) Random forest: It is a machine learning algorithm based on ensemble learning, which combines multiple decision trees to achieve better predictive performance.

3) XGBoost: It is a machine learning algorithm based on the gradient boosting technique. It is an efficient and highly-performing implementation of this method, which has seen great success in recent years in many machine learning competitions and applications.

4) Gradient boosting: It is a machine learning method belonging to the family of ensemble algorithms. Its principle is to iteratively build a predictive model by adding new weak models (typically decision trees) in a way that gradually reduces prediction errors.

5) Support Vector Regressor (SVR): It is a variant of the Support Vector Machine (SVM) method for regression problems. It is a supervised learning algorithm used to build nonlinear regression models.

6) ARIMA (AutoRegressive Integrated Moving Average) is a statistical model used for analyzing and forecasting time series data. It combines three components: autoregression (AR), integration to make the series stationary (I), and moving average (MA).

7) Prophet is a forecasting tool developed by Facebook that is specifically designed for time series data. It is capable of handling missing data and outliers, and it automatically accounts for seasonal trends and holiday effects, making it suitable for a wide range of time series forecasting applications.

D. Model Integration

1) Ensemble prediction: It is a machine learning technique that involves combining the predictions of multiple individual models to obtain a final prediction that is more robust and accurate. This approach is widely used in many areas of machine learning, such as classification, regression, and forecasting, as it allows for leveraging the strengths of different models in a complementary manner.

E. Performance Evalutation

1) Ensemble prediction: Evaluate the quality and accuracy of the predictions generated by the hybrid crude oil price forecasting system. This involves calculating various performance measures, including the Root Mean Square Error (RMSE), which evaluates the average difference between predicted values and actual values.

Table I lists commonly used models in machine learning for regression problems. It includes classical algorithms like linear regression and more powerful ensemble methods like random forest, gradient boosting, ARIMA, Prophet and XGBoost. The support vector regressor (SVR) is also included, offering a robust approach to outliers. The ensemble prediction combines predictions from multiple models for better overall performance. Each of these algorithms has advantages and disadvantages in terms of complexity, interpretability, and the ability to model nonlinear relationships. The choice of the most suitable model will depend on the specific characteristics of the data and the prediction goal.

TABLE I. PROPOSED DATA MINING ALGORITHM

Algorithm	Description
Rf	Random Forest
LR	Linear Regression
Gb	Gradient Boosting
SVR	Support Vector Regressor
XGBoost	XGBoost
Ensemble Prediction	Ensemble Prediction
ARIMA	ARIMA
Prophet	Prophet

Table II presents key performance indicators and their associated factors to analyze fluctuations in oil prices, considering various economic and factors influencing the markets of Morocco.

TABLE II. KEY PRICE INDICATORS FOR TRANSPORTATION-RELATED FEATURES

KPI	Features
Average price of a one-way local transport ticket	One-way Ticket (Local Transport)
Average price of a regular monthly public transport pass	Monthly Pass (Regular Price)
Average price of 1 liter of gasoline	Gasoline (1 liter)
Average price of a Volkswagen Golf 1.4 90 KW Trendline or equivalent new car	Volkswagen Golf 1.4 90 KW Trendline (Or Equivalent New Car)
Average starting fare for a taxi ride (normal tariff)	Taxi Start (Normal Tariff)
Average price per kilometer for a taxi ride (normal tariff)	Taxi 1km (Normal Tariff)
Average price per hour of waiting time for a taxi (normal tariff)	Taxi 1hour Waiting (Normal Tariff)
Average price of a Toyota Corolla Sedan 1.6l 97kW Comfort or equivalent new car	Toyota Corolla Sedan 1.6l 97kW Comfort (Or Equivalent New Car)

IV. RESULTS

A. Model Selection

The choice of regression models in this study is crucial for obtaining accurate predictions of crude oil prices in Morocco. The selected models represent a variety of approaches in statistical modeling and machine learning. As shown in Table III, the SVR model achieved the best RMSE score of 1.41, indicating that it is the most effective in accurately predicting crude oil prices. SVR's ability to handle seasonality and holidays, along with its robustness to missing data, contributes significantly to its superior performance in forecasting. In comparison, the Prophet model achieved an RMSE of 1.42, making it the second most effective model in accurately predicting crude oil prices. This result suggests that the nonlinear relationships present in the data are well captured by this support vector machine-based model. The use of advanced techniques such as non-linear kernel and parameter optimization in Prophet enables it to better model the complexity of the underlying data. On the other hand, traditional time series models like ARIMA, which achieved an RMSE of 2.46, and ensemble methods like Random Forest (RMSE of 2.13) and gradient boosting (RMSE of 2.42) also offer competitive performance but did not surpass SVR. ARIMA, with its autoregressive integrated moving average approach, provides a solid framework for capturing temporal dependencies, though it fell short of the advanced methods. Random Forest and gradient boosting offer better performance than simple linear regression (RMSE of 2.80) by capturing complex interactions between features and improving prediction accuracy. Random Forest achieves this by aggregating multiple decision trees, while gradient boosting builds models sequentially on residuals of previous models. Finally, the XGBoost model, although performing well with an RMSE of 2.46, did not achieve the best results compared to other advanced techniques used. This may be explained by the fact that XGBoost is a relatively new method that requires precise tuning of hyperparameters to achieve optimal performance. Despite this, it remains a powerful tool for modeling and predicting complex time series such as crude oil prices.

TABLE III. PROPOSED COMPARATIVE ANALYSIS OF REGRESSION MODEL PERFORMANCE FOR CRUDE OIL PRICE PREDICTIONS : RMSE

Model	RMSE
Linear Regression	2.80
Random Forest	2.13
SVR	1.41
XGBoost	2.46
Gradient Boosting	2.42
ARIMA	2.46
Prophet	1.42

B. Future Predictions for the Next Four Years (2024-2027)

1) Future predictions for the next four years (2024-2027) using the best model: The best model forecasts a continuous increase in values from 16.75 MAD in 2024 to 21.91 MAD in 2027, as shown in Fig. 2 and the prediction Table IV, this upward trend indicates a significant positive dynamic. The projections suggest steady growth each year, which could reflect economic expansion or rising demand in the area of interest. Such a trend may justify strategic adjustments to capitalize on the expected growth, such as increasing production capacity or investing in new opportunities. However, it is crucial to validate this trend with additional data to avoid premature conclusions.

TABLE IV. PREDICTIONS OF CRUDE OIL PRICES FOR THE UPCOMING YEARS USING THE BEST MODEL: PROJECTED VALUES

Year	Prediction value
2024	16.75MAD
2025	18.68 MAD
2026	20.44 MAD
2027	21.91 MAD

2) Future predictions for the next four years (2024-2027) using ARIMA: The ARIMA model provides constant forecasts of 10.31 MAD for each year, as shown in Fig. 2 and the prediction Table V, indicating stability in the data without any marked trend. This absence of variation suggests that the model does not capture significant changes in the time series. This could imply that the data is stationary or that influential factors do not vary significantly over the period. However, if substantial changes are anticipated, this forecast might underestimate the actual evolution of the values. Comparing these results with other models and examining the residuals of the ARIMA model could provide insights into why no trend is detected.

3) Future predictions for the next four years (2024-2027) using Prophet: The Prophet model offers more nuanced forecasts, starting at 9.86 MAD in 2024, as shown in Fig. 2 and the prediction Table VI increasing to 12.61 MAD in 2025, followed by a slight decline in 2026 (12.38 MAD) and further decrease in 2027 (11.95 MAD). These forecasts indicate variability in the data, potentially due to seasonal factors or cyclical effects. The fluctuations suggest that external influences or specific cycles may significantly impact the data. Understanding these variations is crucial for adjusting strategies and forecasts more accurately, highlighting the need to monitor seasonal and cyclical effects.

TABLE V. PREDICTIONS OF CRUDE OIL PRICES FOT HE UPCOMING YEARS USING ARIMA: PROJECTED VALUES

Year	Prediction value
2024	10.31 MAD
2025	10.31 MAD
2026	10.31 MAD
2027	10.31 MAD

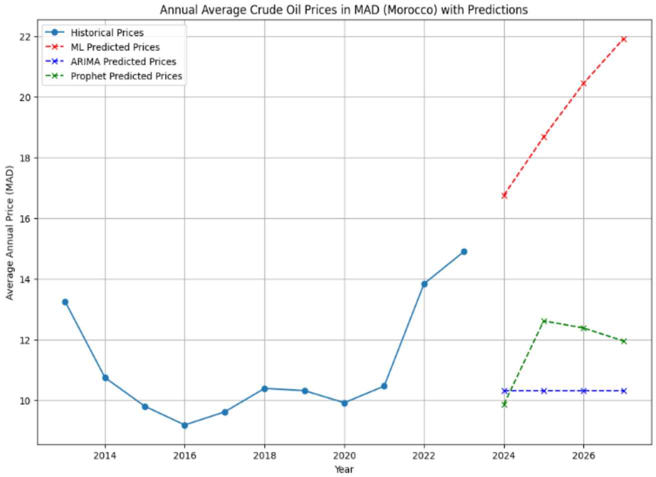

Fig. 2. Annual average crude oil price in MAD (Morocco) with prediction.

TABLE VI. PREDICTIONS OF CRUDE OIL PRICES FOR THE UPCOMING YEARS USING PROPHET: PROJECTED VALUES

Year	Prediction value
2024	9.86 MAD
2025	12.61 MAD
2026	12.83 MAD
2027	11.95 MAD

C. Future Predictions for the Next four Years (2024-2027) using Ensemble Predictions

Exploring future trends in crude oil prices, crucial for various industries and economic policies, often requires the use of a range of models to attain a balanced perspective. Predictions based on ensemble models, as illustrated in Fig. 3, offer a significant alternative to individual predictions presented in Table VII. The ensemble model's forecasts for the period from 2024 to 2027 demonstrate a consistent and nuanced growth pattern. Starting at 13.28 MAD in 2024, the predicted values gradually increase each year, reaching 14.47 MAD by 2027. This steady progression highlights a moderate, yet enduring, upward trend, which is reflective of the model's integrated approach to forecasting.

The gradual increase from 13.28 MAD to 14.47 MAD suggests a scenario of ongoing, incremental growth rather than abrupt changes. This trend implies a stable environment with continuous, albeit modest, enhancements in the measured variable. The smooth upward slope across the forecast horizon indicates that the ensemble model, by synthesizing multiple predictive outputs, provides a balanced and comprehensive view of future trends.

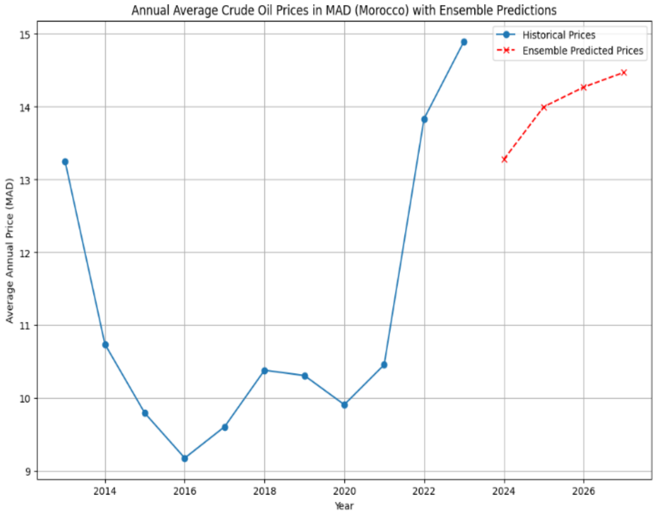

Fig. 3. Annual average crude oil price in MAD (Morocco) with ensemble prediction.

TABLE VII. PREDICTIONS OF CRUDE OIL PRICES FOR THE COMING YEARS: PROJECTED VALUES WITCH ENSEMBLE PREDICTIONS

Year	Prediction value
2024	13.28 MAD
2025	14 MAD
2026	14.27 MAD
2027	14.47 MAD

The ensemble approach leverages various models to mitigate individual forecasting errors and uncertainties, resulting in a more robust and reliable projection. The result is a forecast that accounts for a range of potential influences and integrates different perspectives, thus offering a well-rounded prediction.

Such a steady growth trajectory is invaluable for long-term planning and strategic decision-making. It suggests a favorable but controlled increase, allowing stakeholders to prepare for gradual improvements without the need for abrupt adjustments. This nuanced forecast underscores the importance of adopting a data-driven approach to anticipate moderate changes and adapt strategies accordingly.

In essence, the ensemble predictions provide a stable outlook with a clear trend of incremental growth, reflecting both reliability and gradual optimism in the forecasted period.

V. DISCUSSION

The analysis of the crude oil price prediction system in Morocco reveals several key insights that warrant detailed examination. Firstly, the evaluation of various regression models exposes critical differences in their efficacy in forecasting crude oil price trends. Linear regression, while conceptually straightforward, shows notable limitations in capturing the intricate, non-linear relationships present in crude oil price data. Its higher RMSE compared to more sophisticated models indicates a less accurate fit to the actual data, reflecting the model's struggle with the inherently non-linear nature of crude oil prices.

In contrast, advanced machine learning techniques, including Random Forest, Gradient Boosting, XGBoost, ARIMA, Prophet and Support Vector Regression (SVR), demonstrate a superior capacity for modeling non-linear relationships and generating more precise forecasts. These methods, characterized by lower RMSE values, indicate a better alignment with observed data, with SVR emerging as the most effective individual model. The enhanced performance of SVR can be attributed to its use of kernel functions, which adeptly capture complex variable interactions.

Furthermore, the ensemble approach, which integrates predictions from multiple models, offers substantial advantages over both linear regression and individual models. The ensemble's lower RMSE suggests a reduction in overall prediction error, highlighting its effectiveness in minimizing inaccuracies. Additionally, ensemble predictions are generally more stable and less susceptible to the fluctuations that single models may exhibit, thus providing a more reliable tool for decision-making in volatile economic contexts.

The forecasts for the period 2024-2027 reveal a consistent upward trend in crude oil prices across all models, albeit with variations in the magnitude of these increases. These discrepancies emphasize the importance of incorporating multiple forecasting perspectives to ensure a comprehensive interpretation and effective strategic planning.

The predictive insights generated by the system are of considerable value to energy market stakeholders, policymakers, and investors. Anticipating crude oil price movements over a multi-year horizon facilitates more informed strategic planning and proactive risk management. Such forecasts are instrumental in guiding investment decisions and shaping government policies aimed at stabilizing energy markets and fostering economic sustainability.

In summary, the findings from the crude oil price prediction system underscore the necessity of selecting appropriate forecasting models, leveraging ensemble approaches, and contextualizing predictions within the broader economic and political landscape. These insights contribute significantly to understanding crude oil market dynamics and enhance the planning and decision-making processes within the energy sector and beyond.

VI. Conclusion and Future Work

In conclusion, the crude oil price prediction system developed for Morocco provides valuable insights into the dynamics of energy markets and enhances our ability to forecast price movements effectively. The analysis of various regression models underscores the critical role of selecting appropriate modeling approaches to achieve precise predictions. Among the evaluated methods, machine learning techniques, particularly Support Vector Regression (SVR), emerge as highly effective in capturing the intricate relationships between variables and delivering reliable crude oil price forecasts.

Despite these advancements, several challenges and opportunities for further improvement remain. To refine prediction accuracy, incorporating additional data sources such as macroeconomic indicators and geopolitical factors is essential. These external variables can significantly influence crude oil prices, and their integration into the model could enhance its robustness and relevance.

Furthermore, exploring advanced machine learning techniques, such as deep learning algorithms, presents an opportunity to uncover more complex patterns within the data. Deep learning models, with their ability to handle large datasets and capture non-linear relationships, could potentially improve prediction accuracy beyond current capabilities.

A comprehensive analysis of the uncertainties and risks associated with crude oil price forecasts is also crucial. Employing uncertainty quantification methods, such as confidence intervals and bootstrap techniques, would provide a more robust evaluation of prediction reliability. This approach could better inform policymakers and market participants, aiding in risk management and decision-making processes.

Looking ahead, there is a need to develop a more dynamic and adaptable prediction system capable of rapidly responding to changes in the economic and political environment. This could involve creating real-time regression models and incorporating continuous learning mechanisms to monitor and adjust to evolving trends in crude oil prices. Such advancements would ensure that the prediction system remains relevant and accurate in a rapidly changing market landscape.

In summary, the crude oil price prediction system for Morocco represents a significant advancement in understanding and managing energy markets. By leveraging advanced modeling techniques and incorporating a broader range of data, this system offers a valuable tool for strategic decision-making. Continued development and refinement will enhance its ability to support long-term economic stability and sustainability in the energy sector.

Children's Expression Recognition Based on Multi-Scale Asymmetric Convolutional Neural Network

Pengfei Wang, Xiugang Gong*, Qun Guo, Guangjie Chang, Fuxiang Du
School of Computer Science and Technology, Shandong University of Technology, Zibo, Shandong, 255000, China

Abstract—**This paper proposes a multi-scale asymmetric convolutional neural network (MACNN), specifically designed to tackle the challenges encountered by traditional convolutional neural networks in the realm of children's facial expression recognition. MACNN addresses problems like low accuracy from facial expression changes, poor generalization across datasets, and inefficiency in traditional convolution operations. The model introduces a multi-scale convolution layer for capturing diverse features, enhancing feature extraction and recognition accuracy. Additionally, an asymmetric convolutional layer is integrated to learn directional features, improving robustness and generalization in facial expression analysis. Post-training, this layer can revert to a standard square convolutional layer, optimizing efficiency for child expression recognition. Experimental results indicate that the proposed algorithm achieves a recognition accuracy of 63.35% on a self-constructed children's expression dataset, under the configuration of a GPU Tesla P100 with 16GB video memory. This performance exceeds all comparative algorithms and maintains efficient recognition. Furthermore, the algorithm attains a recognition accuracy of 78.26% on the extensive natural environment expression dataset RAF-DB, highlighting its robustness, generalization capability, and potential for practical application.**

Keywords—Children's expression recognition; convolutional neural network; multi-scale asymmetric convolutional neural network; asymmetric convolutional layers

I. Introduction

Facial expressions are crucial in human communication. According to Mehrabian, facial expressions provide about 55% of emotional expression, with only about 7% conveyed through spoken words [1]. However, their complexity and variety pose a challenge for automatic recognition. With the rise of deep learning, Convolutional Neural Networks (CNNs) have become widely utilized in automatic expression recognition due to their strong feature extraction ability and adaptability, resulting in significant advancements in this field. Wen XY et al. used convolutional neural networks to extract deep semantic features and shallow geometric features, while introducing a channel self-attention mechanism to reduce the impact of occlusion and pose changes on expression recognition [2]. Ying He et al. recently proposed a novel multi-layer feature recognition algorithm based on a three-channel convolutional neural network (CNN), which significantly improved the accuracy of convolutional neural network expression recognition [3]. Cuiping Shi et al. proposed a facial expression recognition algorithm based on multi-branch cross-connected convolutional neural network (MBCC-CNN). Compared with traditional machine learning algorithms, the proposed algorithm can extract expression features more effectively [4]. Jung Hwan Kim et al. proposed customized visual geometry group-19 (CVGG-19), which combines the designs of visual geometry group (VGG), inception-v1, residual neural network (ResNet), and xception to improve expression recognition performance while reducing computational cost [5]. Yinggang He et al. developed a multi-branch attention convolutional neural network based on a multi-branch structure to recognize facial expressions, which is more efficient in extracting image features [6]. Qian Dong et al. proposed a VIT-based multi-scale Attention Learning network (MALN) that learns facial expression features in a multi-scale manner [7]. Aly Walaa et al. designed a deep convolutional neural network combining residual spatial channel attention (RSCA) and spatial Pyramid pooling (ASPP) to improve the expression recognition effect of the model for low-resolution images [8]. Chen Bin et al. proposed a residual rectified dense convolutional neural network, which linearly rectified the residual block through the activation function embedded in the convolutional layer to improve the model's ability to extract complex expression features [9]. Qi H et al. designed a Pyramid convolutional attention residual network (PCARNet) based on ResNet-18, which combines the pyramid convolution module and the improved convolutional attention mechanism to effectively extract expression features and achieve high-precision facial expression recognition [10]. Tataji KNK et al. proposed a cross-connected convolutional neural network (CC-CNN), which has been shown to be effective in extracting local and global facial features [11]. Kalsum T et al. proposed a new lightweight deep convolutional neural network (DCNN) model, which improved the recognition effect of facial expression while reducing the complexity of the model [12]. Liu Y et al. used three parallel multi-channel convolutional networks to learn and fuse local and global features from different facial regions, which enhanced the expression feature extraction ability of convolutional neural networks [13]. Mukhopadhyay et al. proposed a algorithm combining local binary pattern (LBP) and convolutional neural network. The LBP processed images were trained by CNN, which improved the efficiency of convolutional neural network for expression recognition [14]. Jing Li et al. combined LBP features and attention mechanism and achieved good results [15]. Saad Saeed et al. proposed an automated framework for face detection using CNN, which includes four convolutional layers and two hidden layers to improve expression recognition accuracy [16].

The aforementioned researches on facial expression recognition algorithms predominantly concentrate on adult facial expressions, whereas, in comparison, recognizing children's expressions holds greater practical significance. This is because children are in a stage where their language system is still developing, rendering it primarily reliant on facial expressions and behaviors to ascertain their emotional state [17].

Corresponding Author.

By analyzing children's emotions and intentions through facial expression recognition, researchers, parents, and educators can gain a deeper understanding of children's inner world. This approach can facilitate a deeper understanding of children's needs and emotional states among adults, while also enabling timely detection and effective handling of any issues or troubles faced by children. Although children's expression recognition faces many challenges, including difficulties in data acquisition, and ethical and privacy issues [18], some researchers have still achieved important research results in this field. Nagpal Shruti et al. developed a mean-supervised deep Boltzmann machine (msDBM) for the classification of children's expressions, marking the first application of a deep learning-based algorithm in this domain [19]. Manish Rathod et al. utilized seven distinct convolutional neural network (CNN) architectures for the task of recognizing children's facial expressions. Their results indicate that the 152-layer residual network (ResNet-152) configuration demonstrates superior performance, achieving significant accuracy improvements [20]. Alejandro Lopez-Rincon et al. developed a lightweight CNN for NAO robot-based children's expression recognition. Despite its design, the accuracy is insufficient [21]. Adish Rao et al. designed an algorithm combining facial geometric features and a deep neural network (DNN) to study the effectiveness of neural networks in recognizing adult and children's expression features. Findings show that children's features are more challenging to extract, necessitating advanced feature extraction for accurate recognition [22]. Wenming Wang et al. believe that the feature extraction and generalization ability of traditional CNN is insufficient, and designed the multi-scale mixed attention mechanism network (MMANet). The network combines the multi-scale convolutional layer, mixed attention module and VGG16. It improves the accuracy and generalization ability of children's expression recognition, but reduces the computational efficiency of children's expression recognition [23]. Ulya Mahsa Anandiwa and her colleagues introduced the couple local binary patterns (LBP) and local ternary patterns (LTP) methods of children-learning readiness recognizing facial expression (Co-ChiLeRFE) algorithm, tailored for recognizing expressions specific to children. This algorithm leverages both LBP and LTP to extract meaningful features effectively. For classification, a support vector machine (SVM) is utilized to achieve accurate recognition of children's expressions. Nevertheless, the algorithm's recognition performance is constrained when confronted with complex expressions [24].

The advantages and disadvantages of the aforementioned child expression recognition algorithms are as follows. msDBM performs exceptionally well in unsupervised learning, but it lags behind specifically designed models such as CNN when dealing with large-scale image datasets. CNN is suitable for child expression recognition due to its robust processing capabilities for image data. However, it can suffer from insufficient robustness and generalization capabilities when trained on limited data, which may lead to overfitting. To reduce computational costs and adapt to low-power devices, lightweight CNN has been proposed, but it sacrifices some recognition accuracy in order to achieve this. MMANet improves child expression recognition by enhancing accuracy and generalization capabilities, but this increase in performance comes with a corresponding increase in model computational cost. Finally, Co-ChiLeRFE possesses a good descriptive ability for textures and local details, but its performance is limited when faced with complex expression features.

Aiming at the problems of low recognition accuracy, poor generalization ability and low efficiency of ordinary convolutional neural network in children's expression recognition, this paper proposes a multi-scale asymmetric convolutional neural network (MACNN). The network incorporates multi-scale convolutional blocks to enhance its capacity to extract diverse-sized features, subsequently boosting the model's recognition accuracy. Additionally, an asymmetric convolution layer is utilized to fortify the convolutional kernel's skeletal aspect, thereby enhancing the model's rotational robustness and generalizability. After training, the model in deep learning will utilize the learned parameters to perform inference, where it receives input data and generates corresponding output, without further gradient calculation or parameter updates. Therefore, the asymmetric convolution kernel can be replaced by the original square convolution kernel after training to reduce the amount of calculation, which improves the efficiency of the model to recognize expression.

Data serves as a crucial prerequisite for conducting research on expression recognition. With the development of expression recognition algorithms, high-quality expression data with rich samples and accurate labels is particularly important for designing robust expression recognition models [25]. Currently, most high-quality expression datasets consist primarily of images of adult subjects, including the JAFFE dataset [26], the KDEF dataset [27], the Multi-PIE dataset [28], the AFEW 7.0 dataset [29], the ExpW dataset [30], the fer2013 dataset [31], the Oulu-CASIA dataset [32], the EmotionNet dataset [33], the CHEVAD dataset [34], the RAF-DB dataset [35], the BU-3DFE dataset [36], and the AffectNet dataset [37], among others. However, due to the rapid change of children's expressions and the difficulty of capturing them, the low obedience of children to the experimenter, and the government's privacy protection of minors, it is difficult to establish a children's expression database.

In recent years, researchers have increasingly acknowledged the significance of establishing expression datasets specifically tailored for children, given their unique characteristics [38]. Consequently, despite encountering numerous challenges, several such datasets have been successfully developed. The Radboud Faces Database contains expression images of children aged 8-12 [39], the NIMH-CHEFS child emotional faces picture set contains images of children aged 10-17 [40], and the CAFE dataset contains facial photos of children aged 2-8 [41]. The EmoReact dataset contains 1,102 videos of children aged 4-14 [42]. The Liris-cse dataset contains 208 facial expression videos of 12 children aged 6-12 [43]. The ChildEFES dataset contains images and videos of the expressions of children aged 4-6 [44]. Although these datasets are related to children's expressions, their small size and limited public accessibility hinder comprehensive research efforts. Given the absence of publicly available large-scale children's expression datasets, this paper establishes a large-scale children's expression dataset independently. This dataset comprises public children's expression images voted on by 10 volunteers, offering a more comprehensive resource for research into children's expression recognition.

The contributions of this paper are summarised as follows:

- In this paper, we propose a children's expression recognition algorithm based on MACNN. The multi-scale convolutional layer is designed to extract richer children's expression features, while the asymmetric convolutional layer enhances the kernel skeleton of the convolutional neural network, thereby improving the model's performance. In addition, the asymmetric convolutional layer can be converted into a square convolutional layer after training, thereby enhancing the efficiency of children's expression recognition.

- In light of the limited availability of extensive and publicly accessible children's expression datasets, this paper introduces a new dataset comprising 15,157 images of children's expressions. The dataset has been meticulously curated from a variety of sources, predominantly from publicly available images on the Internet. Notably, this compilation includes images from well-established datasets such as the fer2013 dataset and the RAF-DB dataset, which have been instrumental in the field of facial expression recognition. Each image was further scrutinized by a panel of 10 volunteers to ensure the accuracy of the expression labels. This comprehensive dataset serves as an invaluable resource for the study of children's expression recognition, bridging the gap in the current landscape of available datasets.

- Experimental analysis is carried out on the children's expression dataset, which verifies the effectiveness and superiority of the proposed MACNN. In addition, to verify the robustness and generalization of the algorithm in natural scene expression recognition, detailed experimental analysis was carried out on the RAF-DB dataset, and the designed model was verified.

The structure of the paper is organized as follows. Section II provides a review of the related work, initially discussing the VGG16 network that forms the core of the algorithm in this study, followed by an examination of asymmetric convolution. Section III introduces the datasets used in this research, starting with a description of the process for constructing the in-house children's facial expression dataset, and then detailing the RAF-DB dataset. Section IV delves into the MACNN network proposed in this paper, primarily elucidating the multi-scale asymmetric convolutional units that are central to our approach. Section V describes the experimental setup and the environment in which the experiments were conducted. Section VI presents the results of applying the proposed algorithm to the children's facial expression dataset and the RAF-DB dataset, beginning with a presentation of the outcomes and then proceeding to an analysis of these results. Section VII concludes the paper by summarizing the findings and proposing potential avenues for future work.

II. Related Work

A. VGG16 Network Model

VGG16 is a convolutional neural network model proposed by Simonyan [45]. In the 2014 ImageNet image recognition challenge, it secured the second position and has subsequently gained widespread application in various computer vision tasks, including image classification and object detection. The VGG16 network employs consecutive small convolutional kernels (3×3) and pooling layers to construct a deep neural network with a depth of up to 16 layers. The network structure of VGG16 is illustrated in Fig. 1.

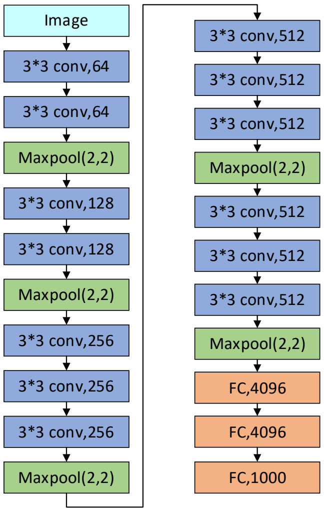

Fig. 1. VGG16 network.

The main characteristics of VGG16 are that the network structure is relatively deep, and the number of convolutional layers and pooling layers is large, so that the network can learn more high-level abstract features. In addition, the convolution layer of VGG16 uses 3×3 convolution kernels, and multiple 3×3 convolution kernels in series can form a convolution kernel with larger receptive field. After two 3×3 convolution kernels in series, the same receptive field as a 5×5 convolution kernel with step size 2 is obtained, and the amount of calculation is smaller. A 7×7 receptive field can be obtained by concatenating three 3×3 kernels. Therefore, the VGG16 network uses multiple 3×3 convolution kernels, which can increase the receptive field and improve the efficiency and accuracy of feature extraction.

B. Asymmetric Convolution

Asymmetric convolution is a convolution operation where the size of the convolution kernel is not square, but rectangular with different length and width.

One role of asymmetric convolution is to approximately replace square convolution. A d×d kernel can be replaced by 1×d and d×1 kernels to reduce the number of parameters [46], [47]. For example, in InceptionV3, a sequence of 1×7 and 7×1 convolutions replaces the 7×7 convolution kernel [48]. Efficient neural network (ENet) decomposes the 5×5 convolution kernel into two convolution kernels of 1×5 and 5×1, which reduces the amount of calculation of the network and makes the network run on embedded devices [49]. Efficient dense modules with asymmetric convolution (EDANet) divides the 3×3 convolution kernel into two kernels: 3×1 and 1×3. This division reduces the number of parameters and required computation by one-third [50]. If the rank of a 2D kernel is 1, it means that the kernel has only one eigenvector in the 2D space. In this case, this 2D kernel can be represented equivalently by a sequence of 1D convolution operations. However, in deep learning networks, convolutional kernels typically encompass multiple feature values. Directly converting the 2D kernel into a sequence of 1D kernels can result in significant loss of information, as it disregards other directional feature information encapsulated within the convolutional kernel [51].

Another consequence of asymmetric convolution is its enhancement of the model's rotational robustness. This enhancement arises from the fact that, in comparison to square convolutions of dimension d×d, horizontal convolutions of size d×1 exhibit horizontal flip invariance, while vertical convolutions of size 1×d demonstrate vertical flip invariance. From a mathematical standpoint, the elements within each row remain invariant under horizontal flipping, and when flipped vertically, each column maintains the integrity of its elements. The Asymmetric Convolutional Network (ACNet) employs parallel convolution kernels of dimensions d×d, 1×d, and d×1, in lieu of the original d×d kernels. It aggregates the outputs of these three convolutional operations, preserving the entirety of the convolutional kernel information. This approach enhances both the rotational robustness and generalization capability of the model. Furthermore, post-training, the network maintains the same number of parameters as the original d×d convolutional kernel, ensuring computational efficiency [52].

III. Dataset Description

A. Children's Expression Dataset

Advancement in children's expression recognition systems is often hindered by data scarcity. This paper introduces a novel dataset to address this limitation, specifically curated for the study of children's facial expressions. Acknowledging the stringent security and ethical requirements for collecting children's facial imagery, the dataset was constructed from publicly accessible images on the Internet, thereby upholding children's privacy. The majority of these images were sourced from established, publicly available datasets, including the fer2013 and the RAF-DB, recognized for their contributions to the field of facial expression analysis. In alignment with the World Health Organization's classification, the term 'children' refers to individuals under the age of 14. To ensure the dataset's accuracy, a majority voting system was employed, with each image evaluated by ten annotators. An image was classified as a child's expression if it received positive confirmation from at least six annotators. The resulting dataset comprises 15,157 instances of children's facial expressions, categorized into seven primary emotional expressions. The distribution of these instances is delineated in TABLE I.

Due to the diverse origins of the extracted children's expression images sourced from publicly available repositories on the Internet, variations in both size and format are observed. Consequently, as a means of standardization, all images within the dataset have been resized and converted to 48×48 pixels in PNG format for consistency and comparability across the dataset. To reduce computational complexity and mitigate the influence of image color on expression recognition, all images in this study were converted to grayscale. An illustrative example image from the children's expression dataset established in this study is presented in Fig. 2.

TABLE I. Number of Images of each Expression in the Children's Expression Dataset

Expression category	*Number of pictures*
Angry	1213
Disgust	496
Fear	875
Happy	5208
Netural	2872
Sad	2943
Surprise	1550

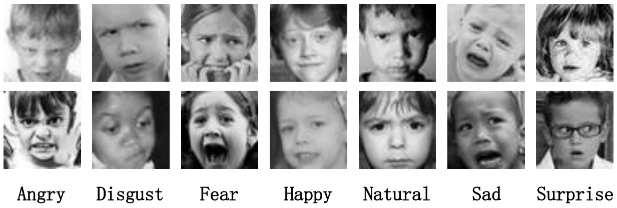

Fig. 2. Example images of children's expression dataset.

B. RAF-DB Dataset

The RAF-DB dataset is a highly regarded real-world dataset that includes 15,339 images of facial expressions, each with a resolution of 100×100 pixels. It features the seven universal emotional expressions, which have been meticulously labeled by 40 independent annotators. These images are subject to variations in occlusion, pose, and lighting conditions, making them representative of the diversity and complexity of expressions found in natural environments. The meticulous annotation by a diverse group of annotators ensures the dataset's reliability and ecological validity, which are crucial for its significant practical utility and research value in facial expression recognition. Fig. 3 shows an example image of the RAF-DB dataset, whose details are given in TABLE II.

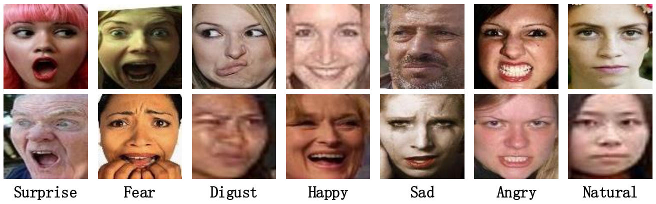

Fig. 3. Example image of the RAF-DB dataset.

TABLE II. Number of Images of each Expression in the RAF-DB Dataset

Expression category	*Number of pictures*
Surprise	1619
Fear	355
Disgust	877
Happy	5957
Sad	2460
Angry	867

To eliminate the potential impact of color on expression recognition, all images within the RAF-DB dataset have been converted to grayscale. To further validate the robustness of the algorithm, this paper applies a 30% vertical and horizontal flipping to the images in the dataset.

IV. Children's Expression Recognition Network

A. Multi-scale Asymmetric Convolution Layer

In deep learning image recognition tasks, researchers usually use the algorithm of increasing the depth of the network to improve the feature extraction ability of the model, and then improve the recognition effect. For instance, ResNet enhances the depth and performance of the network by stacking residual blocks and incorporating residual connections, which preserves and propagates the original input information [53]. However, this approach also results in an increased number of network parameters and computational costs.

The experimental results of Inception demonstrate that using multiple convolution operations of different scales can achieve good facial expression recognition effects with an appropriate network depth and fewer network parameters. Multi-scale convolution is composed of three branches for feature extraction. By using convolution kernels of different sizes, the input features are convolved in parallel with different-sized kernels, enabling the network to perceive different values at the same layer. The features extracted from the three feature extraction branches are fused through the concatenate (concat) method to output the final feature map. The multi-scale convolution operation can extract feature information of different scales from the input facial expression image data, integrating both local and global feature information.

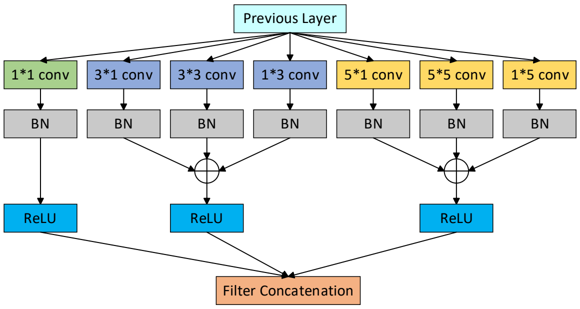

Fig. 4. Multi-scale asymmetric convolutional layer in training mode.

The experimental outcomes of ACNet demonstrate that asymmetric convolution effectively enhances model performance without escalating the count of network parameters. Consequently, this study incorporates the ACNet concept and substitutes the d×d convolution kernel in the multi-scale convolution with parallel convolution kernels of dimensions d×d, 1×d, and d×1. Consequently, a multi-scale asymmetric convolution layer is proposed. In the multi-scale asymmetric convolution layer, multi-scale convolution operations are employed to extract facial expression features of children at different scales. The original square convolution is replaced with asymmetric convolutions. Specifically, the horizontal convolution of size d×1 exhibits horizontal flip invariance, while the vertical convolution of size 1×d exhibits vertical flip invariance. This approach enhances the model's rotational robustness and generalization ability. After training, the asymmetric convolutions can be replaced with equivalent square convolutions to simplify computations. The multi-scale asymmetric convolution layer during training is illustrated in Fig. 4.

The multi-scale asymmetric convolution layer in training mode comprises seven branches. Specifically, three branches with 3×1, 3×3, and 1×3 convolutions replace the original 3×3 convolution kernel, while three branches with 5×1, 5×5, and 1×5 convolutions replace the original 5×5 convolution kernel. This approach allows the network to perceive features of different sizes within the same layer. Due to the horizontal convolution of size d×1 having horizontal flip invariance and the vertical convolution of size 1×d having vertical flip invariance, the use of asymmetric convolutions enhances the model's rotational robustness and generalization capability, thereby further improving the model's performance. Assuming that the input feature map is *F*, the convolution kernel is *K*, and the final output feature map is F_{concat}, the calculation formula for the multi-scale asymmetric convolution layer in training mode is presented in Eq. (1) to Eq. (10).

$$F_1 = ReLU(BN(Conv(F, K_{1\times 1}) + b_1)) \tag{1}$$

$$F_{3\times 1} = BN(Conv(F, K_{3\times 1}) + b_2) \tag{2}$$

$$F_{3\times 3} = BN(Conv(F, K_{3\times 3}) + b_3) \tag{3}$$

$$F_{1\times 3} = BN(Conv(F, K_{1\times 3}) + b_4) \tag{4}$$

$$F_2 = ReLU(F_{3\times 1} \oplus F_{3\times 3} \oplus F_{1\times 3}) \tag{5}$$

$$F_{5\times 1} = BN(Conv(F, K_{5\times 1}) + b_5) \tag{6}$$

$$F_{5\times 5} = BN(Conv(F, K_{5\times 5}) + b_6) \tag{7}$$

$$F_{1\times 5} = BN(Conv(F, K_{1\times 5}) + b_7) \tag{8}$$

$$F_3 = ReLU(F_{5\times 1} \oplus F_{5\times 5} \oplus F_{1\times 5}) \tag{9}$$

$$F_{concat} = Concat(F_1, F_2, F_3) \tag{10}$$

2Due to the additivity of convolution, several compatible-sized 2D kernels operate on the same input with the same stride to generate outputs of the same resolution. Then, the outputs of these kernels are summed up, and these kernels are added at the corresponding positions, resulting in an equivalent kernel that produces the same output. Assuming that K_1 and K_2 represent two 2D kernels with compatible sizes, respectively, and *I* represent a matrix, the method is shown in Eq. (11).

$$I \times K_1 + I \times K_2 = I \times (K_1 \oplus K_2) \tag{11}$$

Compatibility among 2D kernels requires that different 2D kernels can produce outputs of the same size with the same input. Therefore, this paper adopts the algorithm of cropping the input feature map to enable d×d, d×1, and 1×d kernels to generate outputs of the same size. For instance, when d=3, to generate outputs of the same size, the image input to the 3×1 convolution kernel needs to be cropped by two rows of pixels, specifically the first and the last rows, while the image input to the 1×3 convolution kernel requires the removal of two columns of pixels, namely the first and the last columns, as shown in Fig. 5.

Similarly, when d=5, a similar approach can be employed to ensure that the 5×5, 5×1, and 1×5 convolution kernels produce outputs of the same size.

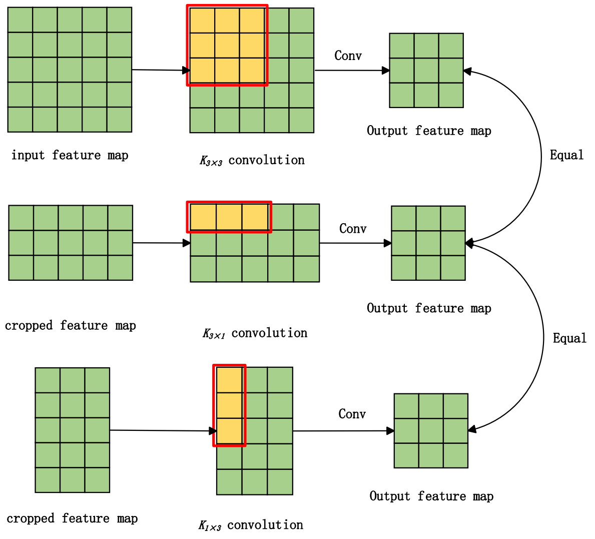

Fig. 5. Schematic diagram of producing outputs of the same size through cropping multi-scale convolution kernels.

Integrating Eq. (11), the aggregation of output feature maps derived from 3×3, 1×3, and 3×1 convolution kernels is analogous to the output feature map generated by a novel convolution kernel, which is constructed by amalgamating the output feature maps of the three kernels at their corresponding spatial locations. Assuming that the 3×3, 1×3, and 3×1 convolution kernels are represented as $K_{3\times3}$, $K_{1\times3}$, and $K_{3\times1}$, respectively, and I represents the input feature map, as shown in Eq. (12).

$$I\times K_{3\times3}+I\times K_{1\times3}+I\times K_{3\times1}=I\times(K_{3\times3}\bigoplus K_{1\times3}\bigoplus K_{3\times1}) \quad (12)$$

Where $K_{3\times3}\bigoplus K_{1\times3}\bigoplus K_{3\times1}$ represents the new convolution kernel obtained by adding $K_{3\times3}$, $K_{3\times1}$, and $K_{1\times3}$ at corresponding positions, as shown in Fig. 6.

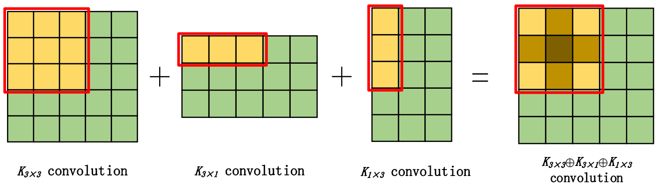

Fig. 6. Schematic diagram of summing convolution kernel output feature maps.

Fig. 6 shows that the $K_{3\times3}\bigoplus K_{1\times3}\bigoplus K_{3\times1}$ convolution kernel also has a size of 3×3. After training, since the model ceases parameter updates and gradient calculations and only performs inference, the convolution kernels with the same shape and number of parameters are equivalent. Therefore, the $K_{3\times3}\bigoplus K_{1\times3}\bigoplus K_{3\times1}$ convolution kernel and the $K_{3\times3}$ convolution kernel are equivalent, as shown in Fig. 7.

Fig. 7 illustrates that a single $K_{3\times3}$ convolution kernel can be used to replace the $K_{3\times3}\bigoplus K_{1\times3}\bigoplus K_{3\times1}$ convolution kernel to simplify calculations. Similarly, the $K_{5\times5}\bigoplus K_{1\times5}\bigoplus K_{5\times1}$ convolution kernel can also be replaced with a single $K_{5\times5}$ convolution kernel after training to simplify computations. Fig. 8 depicts the network structure of the multi-scale asymmetric convolution layer after training completion.

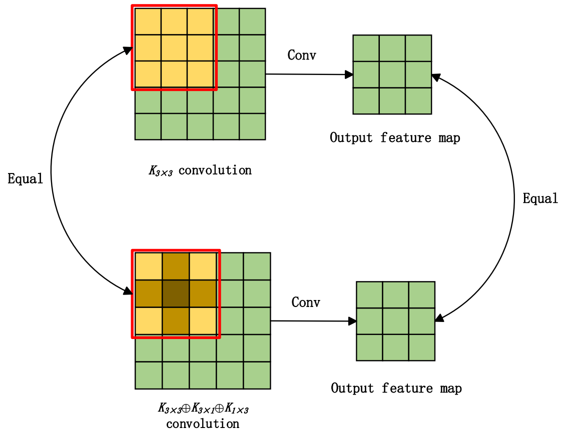

Fig. 7. Schematic diagram of convolution kernel equivalence after training completion.

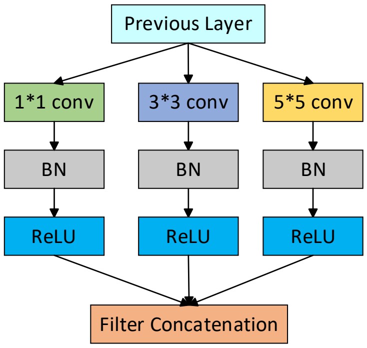

Fig. 8. Multi-scale asymmetric convolution layer after training completion.

Assuming the input feature map is F', K represents the convolution kernel, and the final output feature map is F'_{concat}, the computational formulas for the multi-scale asymmetric convolution layer upon completion of training are shown in Eq. (13) to Eq. (16).

$$F'_1=ReLU(BN(Conv(F',K_{1\times1})+b'_1)) \quad (13)$$

$$F'_2=ReLU(BN(Conv(F',K_{3\times3})+b'_2)) \quad (14)$$

$$F'_3=ReLU(BN(Conv(F',K_{5\times5})+b'_3)) \quad (15)$$

$$F'_{concat}=Concat(F'_1,F'_2,F'_3) \quad (16)$$

B. MACNN Network Structure

Addressing the issues of low recognition accuracy, insufficient generalization ability, and inefficiency in ordinary convolutional neural networks for child facial expression recognition, this paper proposes the MACNN. This network utilizes multi-scale convolution to extract feature information from different scales of images, enhancing the feature extraction capability of the model. The asymmetric convolution further enhances the model's rotational robustness and generalization ability. Finally, the VGG16, serving as the main body of the network, improves the network depth through the stacking of 3×3 convolution layers, further enhancing the model's feature extraction capability. The network structure of MACNN is illustrated in Fig. 9, where MAConv represents the multi-scale asymmetric convolution layer.

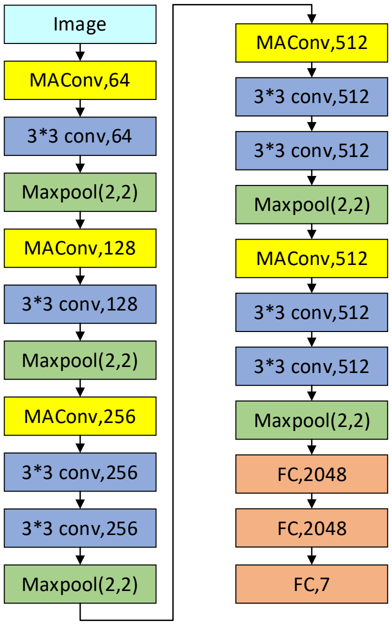

Fig. 9. The network structure of MACNN.

V. Experiment

To assess the performance of the proposed algorithm, a 10-fold cross-validation methodology was implemented on the child facial expression dataset. This approach ensured the algorithm's effectiveness was rigorously tested. To further evaluate the robustness and generalization of the algorithm in natural scene expression recognition, comprehensive experiments were performed on the RAF-DB dataset, a large-scale collection of real-world facial expressions. The model's performance was analyzed using confusion matrices and ROC curves generated from the test set, providing a detailed understanding of its ability to recognize various facial expressions.

Additionally, the efficiency of the proposed algorithm was compared against other state-of-the-art methods to demonstrate its real-time processing capabilities in recognizing child facial expression images.

The experimental setup was established using Python 3.8, with the PyTorch framework (version 1.7.1) and CUDA (version 11.0) for network model construction. The training and testing were conducted on a Linux system (version 3.10.0-1062.9.1.el7.x86_64). The system's hardware configuration included an Intel Xeon Silver 4114 CPU with a 2.20GHz clock speed, 252GB of memory, a Tesla P100 GPU, and 16GB of graphics memory.

For the optimization process, the Adam optimizer was selected with a learning rate set to 0.0001. The training was performed using a batch size of 32 and a total of 100 epochs, ensuring thorough convergence of the model's parameters.

VI. Results

A. *Expression Recognition Results for Children's Expression Dataset*

To enhance the precision of evaluating the MACNN's capability in discerning various categories of pediatric facial expressions, this manuscript introduces a confusion matrix derived from the experimental outcomes of the MACNN on a pediatric facial expression dataset. The matrix is depicted in Fig. 10. The diagonal elements of the matrix correspond to the true positive rate, indicating the proportion of instances correctly classified within each category. Conversely, the off-diagonal elements signify the misclassification probabilities, reflecting the rate at which instances from one category are incorrectly assigned to another.

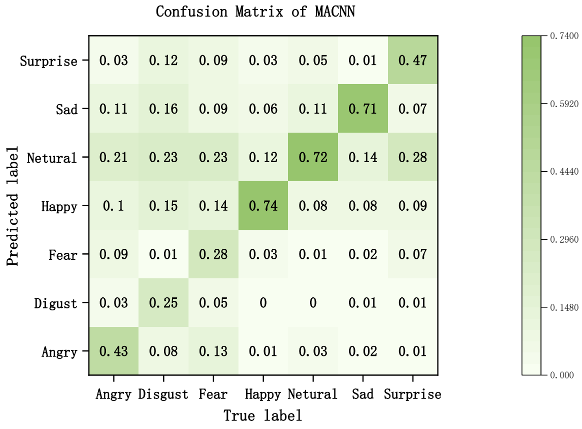

Fig. 10. Confusion matrix of MACNN.

This paper presents ROC curves for the MACNN's recognition of each category of children's facial expressions, as shown in Fig. 11. The AUC values for the seven expressions are 0.74, 0.64, 0.62, 0.95, 0.92, 0.91, and 0.80, respectively.

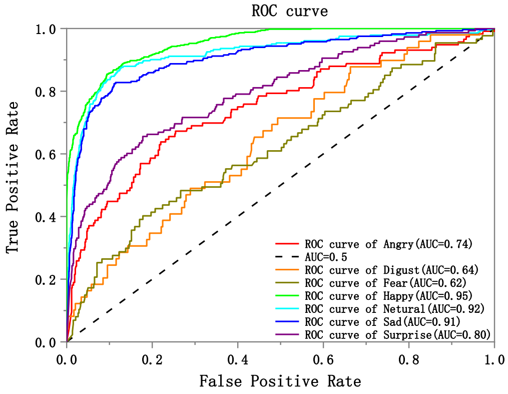

Fig. 11. ROC curve of children's expression dataset.

To substantiate the superiority of the proposed algorithm in the domain of children's facial expression recognition, this manuscript conducts comparative experiments against several classical algorithms. TABLE III. presents the comparative accuracy results across various algorithms on pediatric facial expression datasets.

TABLE III. RECOGNITION ACCURACY OF DIFFERENT ALGORITHMS IN CHILDREN'S EXPRESSION DATASET

Algorithms	*Accuracy (%)*
VGG16	59.96
ResNet-50	60.66
ResNet-152	61.20
Co-ChiLeRFE	60.39
MMANET	63.09
MACNN	63.35

This study aims to demonstrate the efficiency of the proposed algorithm for facial expression recognition by comparing the average recognition time required to process a single image across different algorithms. Specifically, the average recognition time is assessed for each algorithm on a standardized dataset. Table IV provides a summary of the average recognition times recorded for the respective algorithms.

TABLE IV. AVERAGE RECOGNITION TIME OF DIFFERENT ALGORITHMS IN CHILDREN'S EXPRESSION DATASET

Algorithms	*Average Recognition Time (seconds)*
VGG16	0.004
ResNet-50	0.011
ResNet-152	0.031
Co-ChiLeRFE	0.069
MMANET	0.015
MACNN	0.006

B. *Expression Recognition Results for RAF-DB Expression Dataset*

The confusion matrices depicting expression recognition on the RAF-DB dataset for both the baseline VGG16 model and the proposed network model are presented in Fig. 12 and Fig. 13, respectively. These figures also illustrate the recognition accuracy for various categories of facial expressions.

Fig. 14 presents the ROC curves for evaluating the classification performance of the MACNN on each facial expression category using the RAF-DB dataset.

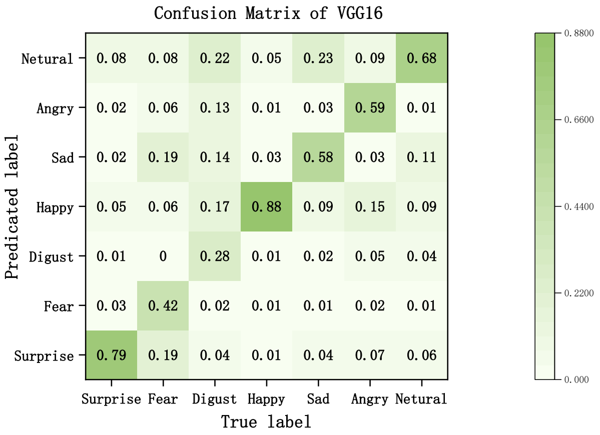

Fig. 12. Confusion matrix of baseline VGG16 under RAF-DB.

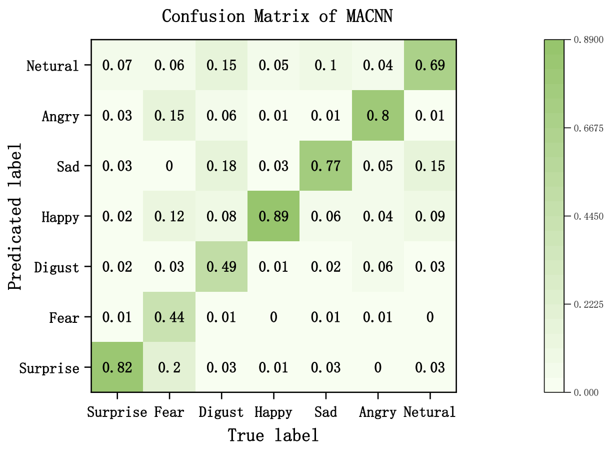

Fig. 13. Confusion matrix of baseline MACNN under RAF-DB.

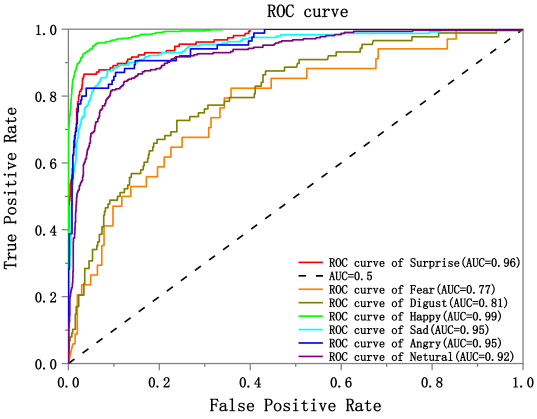

Fig. 14. ROC curve of RAF-DB dataset.

To assess the performance of the proposed algorithm in recognizing natural facial expressions, a comparative analysis has been performed against other prevalent and cutting-edge algorithms using the RAF-DB dataset. The results of these experiments are detailed in Table V.

TABLE V. RECOGNITION ACCURACY OF DIFFERENT ALGORITHMS IN RAF-DB DATASET

Algorithms	*Accuracy (%)*
VGG16	71.94
VGG19	73.76
PCARNet	77.67
ResNet-50	74.53
ResNet-152	75.06
Co-ChiLeRFE	72.58
MMANET	77.92
MACNN	78.26

C. *Analysis of Experimental Results*

Fig. 10 illustrates that the MACNN achieves higher recognition accuracy for happiness, neutrality, and sadness expressions in the context of pediatric facial expression recognition. This outcome can be attributed to several factors. Firstly, the subtlety of children's facial features often results in images with minor expression variations being misclassified as neutral expressions. Secondly, the volunteer subjects who provided images were not professionally trained, leading to potential misclassification of some neutral expressions into other categories, which in turn affects the model training. Additionally, an analysis of the distribution of the pediatric facial expression dataset (as shown in Fig. 15) reveals an uneven distribution of sample sizes across different expression categories, which hinders model learning and significantly impacts recognition accuracy.

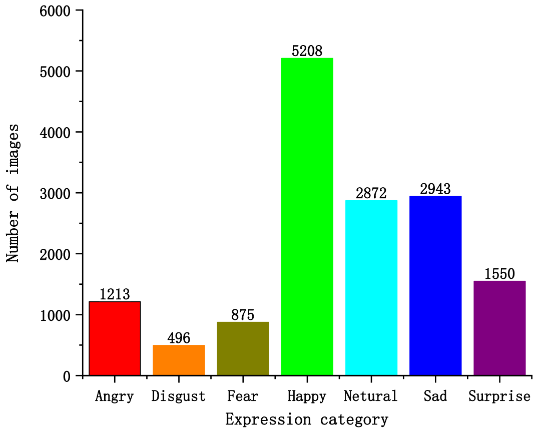

Fig. 15. Number of images of various expressions in the children's expression dataset.

Fig. 15 illustrates the imbalanced distribution of various expressions within the children's facial expression dataset, with happiness being the most frequently represented and disgust the least, resulting in a disparity exceeding an order of magnitude between the two. This imbalance affects the shape of the ROC curves, as shown in Fig. 11. It indicates that the MACNN achieves the highest recognition performance for expressions of happiness, neutrality, and sadness, with respective AUC values of 0.95, 0.92, and 0.91. In contrast, the recognition performance for expressions of disgust and fear is the lowest, with AUC values of 0.64 and 0.62, respectively.

TABLE III. presents a comparative analysis of the accuracy rates achieved by various algorithms on the children's facial expression dataset. The method proposed in this paper attained an accuracy rate of 63.36%, which is the highest among all the algorithms evaluated. TABLE IV. illustrates the average time required by each algorithm to recognize a single image. The method introduced in this study achieved an average recognition time of 0.006 seconds, ranking second among all algorithms, only 0.002 seconds slower than the VGG16. The experimental results demonstrate that while ensuring algorithmic efficiency, the performance of the algorithm has been enhanced.

Fig. 12 and Fig. 13 demonstrate that the MACNN has enhanced the recognition accuracy for the seven facial expressions in the RAF-DB dataset, with the most significant improvements observed in expressions of disgust, sadness, and anger, with respective increases of 0.21, 0.19, and 0.21. Improvements are also noted for the other expressions.

Fig. 14 presents the ROC curves of the proposed algorithm on the RAF-DB dataset, with AUC values for the seven expressions being 0.96, 0.77, 0.81, 0.99, 0.95, 0.95, and 0.92, respectively. All seven curves are positioned above the diagonal line, indicating that the algorithm performs exceptionally well in classifying expressions of surprise, happiness, sadness, anger, and neutrality, and provides good classification for expressions of fear and sadness.

TABLE V. demonstrates that the algorithm presented in this paper achieves the highest performance on the naturalistic expression dataset RAF-DB, with an accuracy rate of 78.26%, indicating excellent robustness and generalization capabilities.

In summary, compared to other algorithms, the MACNN proposed in this paper enhances the network's perceptual capacity by integrating multi-scale convolution to collect information from different receptive fields within the network. Additionally, the introduction of asymmetric convolution has improved the robustness and generalization of the algorithm while ensuring high efficiency, making it well-suited for application in pediatric facial expression recognition scenarios.

VII. Conclusion

This study introduces the Multi-scale Asymmetric Convolutional Neural Network (MACNN), an advanced architecture for recognizing children's facial expressions. It utilizes multi-scale and asymmetric convolution layers to enhance feature extraction and recognition accuracy.

Our experiments, conducted with a GPU Tesla P100 and 16GB of video memory, yielded a 63.35% accuracy on a self-constructed children's expression dataset. This result exceeds that of other benchmarked algorithms, showcasing MACNN's superior performance.

Further testing on the RAF-DB dataset, which features expressions in natural environments, resulted in a 78.26% accuracy. This underscores MACNN's robustness and its ability to generalize across different conditions, a critical aspect for real-world applications.

The high recognition accuracy and computational efficiency of MACNN position it well for practical use in fields such as child psychology, human-computer interaction, and child safety. Its demonstrated adaptability suggests it is well-suited for broader real-world deployment.

The network's performance metrics highlight its potential for real-time expression analysis in various systems, including educational software, telemedicine platforms, and child monitoring systems. Future work may focus on optimizing MACNN for mobile and embedded systems, expanding the diversity of training datasets, and incorporating temporal dynamics for enhanced dynamic expression recognition.

Reinforcement Learning Driven Self-Adaptation in Hypervisor-Based Cloud Intrusion Detection Systems (RLDAC-IDS)

Alaa A. Qaffas
Department of Management Information Systems-College of Business, University of Jeddah, Jeddah, KSA

***Abstract*—With the rise in cloud adoption, securing dynamic virtual environments remains a significant challenge. While traditional Intrusion Detection Systems (IDS) have attempted to address security concerns in the cloud mostly through static detection rules and without adaptation capabilities to identify new attack vectors, a self-optimizing framework called Reinforcement Learning-Driven Self-Adaptation in Hypervisor-Based Cloud Intrusion Detection Systems (RLDAC-IDS) is suggested to overcome this limitation. RLDAC-IDS leverages the inherent visibility of hypervisors into virtualized resources to gain valuable insights into cloud operations and threats. Its key components include real-time behavioral analysis, anomaly detection, and identification of known threats. The innovation of RLDAC-IDS lies in the incorporation of reinforcement learning to continuously improve the detection rules and responses. RLDAC-IDS exemplifies intelligent intrusion detection through its ability to learn and adapt to new threat patterns autonomously. By continuous optimization and intelligent intrusion detection techniques, the system progresses to tackle emerging attack vectors while minimizing false alarms. In contrast, RLDAC-IDS is highly adaptive and can easily adjust to the changing conditions of cloud environments. In summary, RLDAC-IDS represents a major advancement in cloud IDS through its adaptive, self-learning approach, overcoming the limitations of existing solutions to provide robust protection amidst the complexities and dynamics of modern virtualized settings.**

Keywords*—Cloud security; intrusion detection system; adaptive framework; hypervisor-based IDS; self-adaptation; emerging threat detection; reinforcement learning; behavioral analysis; cloud computing; intelligent intrusion detection

I. Introduction

Cloud computing has become a disruptive paradigm in information technology, offering benefits such as increased resource utilization and significant cost savings in infrastructure. At its core, cloud computing leverages current technologies like service-oriented architecture, virtualization, and utility computing. Among these, virtualization emerges as the cornerstone of cloud computing infrastructure [1]. It enables efficient sharing of physical machine resources, including CPU, memory, I/O, and network interfaces, among multiple virtual machines coexisting on the same physical host [2], [3].

While the advantages of cloud computing and virtualization are evident in their ability to optimize resource allocation and streamline operations, they introduce a pivotal challenge for cloud service providers (CSPs). This challenge lies in safeguarding the virtualized resources of Guest Operating Systems (GOS) against an ever-evolving landscape of advanced and sophisticated cyberattacks [4]. As CSPs strive to harness the power of virtualization to deliver cloud services, the imperative of fortifying these virtualized environments against security threats becomes increasingly paramount. This introduction sets the stage for a comprehensive exploration of the intricacies surrounding the protection of virtualized resources within cloud computing, addressing the multifaceted challenges and highlighting the strategies and solutions vital to this endeavor [5].

Server virtualization allows for the allocation of CPU, RAM, and other dynamic computing resources as needed. This is achieved through a pay-as-you-go approach, where customers, referred to as tenants, are only billed for utilities. Infrastructure as a Service (IaaS) is a widely accepted cloud computing model that enables users to utilize virtual machines (VMs) and virtual networks to access and manage computers, storage, and network resources. This is facilitated through the provision of an information system and the added benefits of access to unlimited computing and communication capacity, as outlined in the service level agreements between tenants and cloud providers [6], [7].

The virtual machine contains a hypervisor, a virtualization component that enables devices to share resources. However, it also poses its own set of risks. If an attacker breaches a hypervisor, they can take control of the entire virtual environment. Complications in cloud computing further complicate matters as attacks can originate from various sources like virtual networks, malicious hypervisors, and other virtual machines. Virtual machines are prime targets for attackers due to their susceptibility to hijacking, as they are linked to the external virtual world through the CSP [8].

The implementation of an intrusion detection system (IDS) is essential in safeguarding the entirety of a virtual machine against a multitude of potential threats and attacks [9]. The Intrusion Detection System (IDS) should possess the functionality to identify malware, analyze logs, check file integrity, analyze incoming data, and provide an active reaction [10]. Furthermore, it is imperative that the system possess the capability to detect both unidentified and recognized attacks. Solely relying on detection measures is insufficient for ensuring the protection of the virtual environment without the implementation of preventive measures. This study presents a proposed framework called Self-Adaptive Framework for

Hypervisor-Based Cloud Intrusion Detection System (HVCIDS). The purpose of this framework is to identify and react to unauthorized or malicious actions occurring in a cloud computing environment.

The proposed Reinforcement Learning-Driven Self-Adaptation in Hypervisor-Based Cloud Intrusion Detection Systems (RLDAC-IDS) offers several significant advancements in cloud security. The primary contributions of this work are as follows:

- Adaptive Reinforcement Learning Framework: We introduce a novel approach that integrates reinforcement learning to enable continuous self-adaptation of detection rules and responses. This allows RLDAC-IDS to evolve dynamically with the changing threat landscape, addressing a critical limitation of static rule-based systems.
- Hypervisor-Level Monitoring: By leveraging hypervisor-based visibility, RLDAC-IDS gains comprehensive insights into virtualized resources and cloud operations, enabling more granular and effective threat detection across the entire cloud infrastructure.
- Multi-Faceted Detection Approach: Our system combines real-time behavioral analysis, anomaly detection, and known threat identification, providing a robust, layered defense against a wide spectrum of attack vectors, including zero-day threats.
- Resource Efficiency: RLDAC-IDS demonstrates significantly lower CPU utilization (12.4%) compared to traditional approaches, making it particularly suitable for cloud environments where resource optimization is crucial.
- Enhanced Performance Metrics: Our experimental results show that RLDAC-IDS achieves superior accuracy (98.7%), precision (98.5%), recall (97.9%), and F1-score (97.5%) compared to existing intrusion detection techniques, indicating substantial improvements in overall effectiveness.
- Balanced False Positive/Negative Mitigation: With a high precision rate and low error rate (1.3%), RLDAC-IDS effectively distinguishes between legitimate and malicious activities, addressing the common challenge of alert fatigue in intrusion detection systems.
- Scalability and Adaptability: The self-learning nature of RLDAC-IDS enables it to scale effectively and adapt rapidly to the dynamic and complex nature of modern cloud environments, providing robust protection against evolving cyber threats.

The subsequent sections of this paper are structured as follows: Section II provides a comprehensive background on the hypervisor, visualization, and intrusion detection systems. Section III offers an in-depth analysis of previous studies. In Section IV, we expound upon the research methodology employed, delineating the intricacies of the proposed Hypervisor-based Cloud Intrusion Detection System (HVCIDS) framework. Within this section, readers will find elucidations in the form of model algorithms and an exposition of the performance metrics utilized in our study. Furthermore, Section V encompasses the presentation of our research findings. In Section VI, an extensive discussion of the results is undertaken, providing critical insights and interpretations. Lastly, the concluding Section VII encapsulates our paper with definitive conclusions drawn from the research conducted and offers valuable suggestions for potential avenues of future research exploration.

II. Background

In this section, we provide a brief introduction to key topics relevant to our research. We introduce hypervisors, outlining their basic functions and the advantages they offer in cloud environments. Next, we explore intrusion detection systems (IDS), explaining their purpose and distinctions. Additionally, we examine the transformative influence of cloud computing and the significance of visualization in cloud systems. This fundamental knowledge establishes the groundwork for the subsequent section of our research paper.

A. Hypervisors

Hypervisors are a type of virtual machine monitor (VMM). They are the main drivers behind virtualization and cloud computing. Hypervisors serve as a crucial layer of abstraction, facilitating the creation and management of virtual machines (VMs) that operate on physical hardware [11]. These systems can be software-based or hardware-based. Hypervisors enable multiple VMs to coexist and function independently on a single computer. By acting as a bridge between physical hardware and a virtualized environment, hypervisors efficiently allocate resources from the computer, such as CPU, memory, storage, and networking, to the VMs [12].

Hypervisors make it easier to create and manage virtual machines (VMs), providing a significant advantage to computing environments. They consolidate different resources, enabling multiple VMs to operate on a single server. This results in substantial cost savings and enhanced energy efficiency. Hypervisors excel in security by offering robust isolation, allowing each VM to function independently to safeguard data. They also introduce hardware independence, simplifying resource management, seamless VM migration, and quick adaptation in computing environments. The combined benefits of hypervisors make them ideal for efficient resource utilization, stringent security protocols, and readiness for dynamic operations [13].

B. Intrusion Detection System

Intrusion detection systems (IDS) are the foundation of modern cybersecurity methods, offering critical capabilities for monitoring and protecting networked systems and resources. At their core, intrusion detection systems (IDS) are intended to monitor and analyze network traffic and system operations in real time, identifying patterns or behaviors that deviate from established standards [14]. When such anomalies are detected, intrusion detection systems (IDS) generate alerts or take programmed actions to mitigate potential threats. Based on their detection methodologies, IDS can be classified into three basic types:

1) Signature-based IDS: This category utilizes predetermined patterns or signatures of known attacks to detect threats. Signature-based intrusion detection systems operate by comparing network traffic or system actions to a database of preset signatures. An alert is generated when a match is identified. While effective against known threats, signature-based intrusion detection systems (IDS) may face challenges with zero-day attacks (vulnerabilities that were previously unidentified) and may generate false positives [15].

2) Anomaly-based intrusion detection systems: Anomaly-based IDS, in contrast, focuses on detecting deviations from established baselines of normal behavior. These systems employ machine learning or statistical algorithms to learn typical patterns of network traffic and system activities over time. When they identify activities that significantly differ from the norm, they raise alerts. Anomaly-based IDS excel at identifying novel and emerging threats, as they are not reliant on predefined signatures. However, they may require more sophisticated algorithms and generate alerts for benign anomalies, necessitating careful tuning [16].

3) Hybrid-based intrusion detection systems: Hybrid-based intrusion detection systems combine elements of both signature-based and anomaly-based techniques. These systems utilize predefined signatures for identified threats while also monitoring network traffic and system activity for irregularities. By integrating these methods, hybrid-based intrusion detection systems (IDS) aim to enhance detection accuracy by minimizing false positives and effectively identifying both known and novel threats. Nevertheless, they may pose challenges in terms of configuration and maintenance [17], [18].

C. Cloud Computing and Virtualization

Cloud computing has revolutionized how IT services are delivered, bringing about a change. This innovative approach involves providing computer resources on demand via the internet including a range of services, like servers, storage, databases, networking, software and more. Organizations have enthusiastically adopted cloud computing due to its ability to dynamically scale resources reduce costs and enhance flexibility.

The key, to the flexibility and efficiency of cloud computing lies in virtualization. Virtualization is the technology that enables the creation and management of instances of computer resources allowing for efficient utilization of physical hardware. In a virtualized environment these virtual instances operate independently from the underlying infrastructure enabling resource allocation based on demand and effective resource management.

Virtualization is primarily implemented through the utilization of hypervisors which serve as the hub for generating and managing virtual machines (VMs). Hypervisors create an abstraction layer, between the hardware and these VMs enabling VMs to function independently on a single physical host. This setup ensures resource separation. Maximizes hardware efficiency. By leveraging hypervisors organizations can fully leverage the potential of virtualization to create and maintain adaptable computing environments.

Virtualization is critical to enabling the key features of cloud services outlined the National Institute of Standards and Technology (NIST), like on-demand access and rapid flexibility. Cloud providers use hypervisor software to efficiently allocate resources, isolate environments securely, and make virtual machines easy for customers to create and control. Virtualization provides the core foundation for dynamic resource management, workload scalability, and optimized efficiency that define cloud computing. It allows cloud platforms to be agile and adaptable in meeting compute needs.

III. Literature Review

This section provides a comprehensive overview of recent advancements in intrusion detection systems, particularly focusing on cloud environments and adaptive techniques. This categorized into signature-based, anomaly-based, hybrid-based, and hypervisor-based approaches, concluding with a comparative analysis of these works against our proposed RLDAC-IDS.

A. Signature-based Intrusion Detection Systems

Lo et al. provide an integrated intrusion detection system model designed to address the issues of protecting cloud computing networks. Individual IDS units placed on each server inside the cloud architecture are used in this manner. These IDS units are unusual in that they combine a signature database with a block table, allowing them to keep track of recent assaults. This method prioritizes the evaluation of packets that are more likely to be related to recent attacks, improving the system's responsiveness. This framework's contributions include its novel technique for prioritizing packet inspection and its promise to improve the security of cloud computing networks. This method may face challenges in maintaining and managing block tables in dynamic cloud environments [19].

Lin et al. propose an efficient and effective Network Intrusion Detection System (NIDS) tailored specifically for cloud virtualization environments. The approach they proposed is based on a rule-based NIDS designed to detect known attacks within the cloud setting. The advantages of this approach include its ability to remain responsive to real-time changes in VM behavior and its effectiveness in identifying known attacks. However, managing and updating rules for numerous VMs in highly dynamic cloud settings could prove challenging. [20].

Meng et al. proposed a novel technique for signature-based intrusion detection systems (IDS). The authors developed a character frequency-based exclusive signature matching system with the goal of improving intrusion detection accuracy and flexibility, especially in remote situations. This method has benefits in terms of better detection accuracy, flexibility for emerging attack patterns, and the capacity to differentiate between regular and malicious data. However, significant drawbacks include the computational expense associated with character frequency analysis as well as the requirement for ongoing fine-tuning to maintain optimum performance in dynamic network contexts [21].

B. Anomaly-based Intrusion Detection System

Sari conducted a comprehensive review of anomaly detection systems (ADS) in cloud networks and surveyed security measures in cloud storage applications. The central approach discussed in this paper revolves around categorizing data as normal or abnormal behavior within cloud networks. The key contribution of this research lies in its focus on anomaly detection, which can effectively identify novel attacks and deviations from normal behavior within cloud environments. This approach offers the advantage of adaptability to emerging threats. However, it does come with a computational cost due to the continuous monitoring and analysis required. Additionally, the system generates alarms for any deviations, placing the responsibility of identifying the cause of alarms on the security manager, which may require additional time and expertise [22].

Yuxin et al. proposed a novel method for malware identification, concentrating on static system call analysis with machine learning approaches. The method is divided into two stages. To begin, the approach decodes program structures and builds a context-free grammatical description of the workflow, with the goal of capturing the program's behavior. This method has the ability to effectively detect harmful code due to its rich feature representation and effective selection approaches. However, possible drawbacks may include the computational difficulty of building context-free grammars and the need for significant computer resources [23].

Gupta and Kumar propose a novel technique for identifying malware activities in cloud systems, with an emphasis on low-frequency attacks. The suggested solution is based on an integrated call-based anomaly detection mechanism, which differs from the standard training system approach. Instead, it creates a database of system operations with a pair of keys, one for the system call name and the other for its immediate successor. It provides benefits in terms of flexibility for evolving risks and the capacity to detect odd program activity. The difficulty of maintaining and updating the baseline information, as well as the danger of false positives in the detection procedure, are possible drawbacks [24].

C. Hybrid-based Intrusion Detection System

Ficco et al. provide a hierarchical security architecture for delivering security as a service in federated cloud settings. This strategy has various benefits, including increased scalability, real-time threat detection, and the possibility of centralized security administration in federated cloud systems. It may, however, pose complications in data transmission and interpretation, necessitating careful coordination and resource allocation. Overall, Ficco et al.'s hierarchical design seems to be a viable approach for enhancing security in federated cloud environments [25].

Chiba et al. offer a collaborative and hybridized network intrusion detection architecture designed for cloud computing environments, combining the capabilities of two separate intrusion detection approaches. To begin, Snort, a signature-based intrusion detection system (IDS), is used to detect known attacks using pattern matching. Furthermore, the framework utilizes an Optimized Back Propagation Neural Network (BPNN) to identify anomalies and detect new threats. The BPNN enables the system to adapt to evolving attack strategies and routes while achieving high detection accuracy rates. However, this comes at a computational cost, requiring coordination between multiple network intrusion detection systems (NIDS) nodes. In summary, Chiba and colleagues have developed a collaborative, hybrid intrusion detection framework that combines strengths to enhance security in cloud settings, despite drawbacks like processing overhead. The system shows promise for improving threat detection and response in cloud environments through its multifaceted approach [26].

Balamurugan and Saravanan put forth a novel technique to strengthen security in cloud computing environments. Their methodology utilizes two unique algorithms for thorough analysis of network traffic. Initially, they implement a packet examination algorithm to inspect network packets and detect potentially harmful actions. Additionally, they leverage artificial neural networks (ANNs) coupled with a K-means clustering algorithm to categorize and group network traffic patterns. The advantages include heightened detection accuracy, the ability to handle diverse types of network traffic, and improved adaptability to evolving attack strategies. However, potential disadvantages might include increased computational complexity and the need for fine-tuning parameters for optimal performance [27].

D. Hypervisor-based Intrusion Detection System

Mishra et al. propose an innovative approach aimed at fortifying security measures within cloud environments. Their approach centers on deploying a dedicated security tool on the cloud network server, tasked with the critical function of inspecting network traffic between virtual machines (VMs) within the cloud infrastructure. The advantages of this approach include its potential to detect malicious network packets, both internal and external, effectively, thereby bolstering overall security. It enhances the cloud infrastructure's resilience against a broad spectrum of threats. However, potential disadvantages may involve resource utilization and scalability concerns, given the additional overhead imposed by continuous monitoring [28].

Nikolai and Wang propose a hypervisor-based intrusion detection framework leveraging performance metrics from virtual machines to identify threats in cloud environments. Their approach offers benefits such as independence from virtual machine operating systems and the ability to detect insider attacks between instances. However, a key limitation is its reliance on static detection signatures that are unable to adapt to new attack patterns. The lack of adaptation coupled with the manual effort required to define attack signatures hinders responsiveness to emerging threats. Our proposed framework addresses these deficiencies through self-learning algorithms that automatically derive and optimize detection logic based on evolving attacker behaviors. By continuously adapting threat models, our approach achieves higher detection accuracy, particularly against zero-day attacks, providing robust protection tailored to dynamic cloud environments [29].

Patil et al. put forward the Hybrid HLDNS system to improve security in cloud settings. This comprehensive framework operates on the Control VM of each physical server. Benefits include extensive threat detection, adapting to shifting cloud environments, and optimized features for accuracy. However, potential drawbacks are increased computational loads from continuous network monitoring [30], [31]. In summary, the Hybrid HLDNS methodology shows promise for enhanced security through its multilayered approach, despite possible overhead from traffic analysis.

E. Recent Advancements in Cloud Intrusion Detection

Rashid et al. proposed a federated learning-based method for intrusion detection in industrial Internet of Things (IIoT) networks. This technique allows machine learning to be performed locally on distributed clients, with parameter updates shared with a central server, which then aggregates and distributes an improved global model. This method enhances security and privacy by preventing data centralization and reducing the risk of single points of failure. Despite its advantages, the approach requires substantial computational resources and depends heavily on the quality and consistency of local training data across the clients [32].

Bingu and Jothilakshmi proposed an ensemble-based deep learning technique for intrusion detection in cloud and Software Defined Networking (SDN) environments. The ensemble model combines K-means clustering with deep learning classifiers, including Long Short Term Memory (LSTM), Convolutional Neural Network (CNN), Recurrent Neural Network (RNN), Gated Recurrent Unit (GRU), and Deep Neural Network (DNN). The method begins with data preprocessing, followed by feature extraction using a random forest algorithm. This approach enhances detection performance with reduced computational complexity. The model was evaluated using CICIDS 2018 and SDN-based DDoS attack datasets, achieving accuracy and precision values of 99.685% and 0.992, respectively. However, the technique has drawbacks, such as increased computational complexity due to the ensemble nature, requiring more resources and time for training and inference, and the necessity for a diverse and large dataset to effectively train the ensemble model, which may not always be available or feasible in all deployment scenarios [33].

Jin et al. proposed a novel federated learning-based incremental intrusion detection system (FL-IIDS) to address the problem of catastrophic forgetting in intrusion detection systems (IDS). Their approach involves the use of a class gradient balance loss function and a sample label smoothing loss function to improve local model training. Additionally, relay clients with sample reconstruction help mitigate global catastrophic forgetting without compromising data privacy. The FL-IIDS framework was evaluated using the UNSW-NB15 and CICIDS2018 datasets, showing substantial improvements in memory capability for old classes while maintaining detection effectiveness for new classes. However, drawbacks include the increased computational burden due to the complex loss functions and the need for efficient coordination among clients to ensure optimal performance [34].

Ren et al. introduced a Multi-Agent Feature Selection Intrusion Detection System (MAFSIDS) that leverages deep reinforcement learning (DRL) to enhance intrusion detection capabilities. The MAFSIDS employs a Multi-Agent Feature Selection (MAFS) framework that includes a feature self-selection module and a DRL module to optimize feature selection and improve detection accuracy. The model was evaluated using the CSE-CIC-IDS2018 and NSL-KDD datasets, where it demonstrated superior performance in terms of accuracy and F1-score compared to traditional machine learning approaches. The study conducted ablation experiments to verify the contribution of different modules within the MAFS framework, indicating that the integration of DRL and feature self-selection significantly enhances the IDS performance. However, the approach involves a high computational cost and requires extensive training data to achieve optimal results [35].

Long et al. introduced a Transformer-based network intrusion detection system (NIDS) specifically designed for cloud security. Their approach leverages the self-attention mechanism of the Transformer model to effectively capture long-range dependencies in network traffic data. This enables the system to detect complex and stealthy intrusion patterns those traditional methods might miss. The authors also incorporated a dynamic feature selection process to enhance the model's adaptability and accuracy. Their experiments, conducted on benchmark datasets such as NSL-KDD and CICIDS2018, demonstrated significant improvements in detection performance compared to conventional machine learning-based NIDS. However, the implementation of such advanced models comes with challenges, including increased computational requirements and the necessity for extensive hyperparameter tuning to achieve optimal performance. These findings underscore the potential of Transformer-based models in enhancing the robustness and reliability of intrusion detection systems in cloud environments [36].

IV. Design and Methodologies

A. Experimental Testbed

Setting up a strong test environment is one of the most important first steps in developing the hypervisor-based Cloud Intrusion Detection System (HVCIDS) so that its full capabilities and performance can be fully evaluated, as shown in Table I. Astute selection and tailoring of hardware and software components prove critical in the preparatory stage. Regarding hardware, an apt host machine warranting ample resources to accommodate multiple virtual machines (VMs) is chosen, equipped with adequate CPU processing power, RAM, and storage capacity. Additionally, network segmentation by provisioning at least two network interface cards (NICs) enables isolation and traffic regulation. Concerning software, Oracle Virtual Box serves as the virtualization platform, while VM templates are obtained and tailored for both the attacker and user/victim environments. In summary, the judicious choice of capable hardware and virtualization software lays the groundwork for a rigorous HVCIDS experimental testbed to comprehensively evaluate the framework's strengths and limitations.

TABLE I. EXPERIMENTAL TESTBED SETUP ENVIRONMENT

Hardware Setup	Software Setup
HP Z Book G3 workstation with Microsoft Windows 11 64-bit Enterprise edition	Install Oracle Virtual Box
Intel Core i7-6820HQ CPU @ 2.7GHz, 64GB RAM-2TB Storage	Download two VM images for attacker and user/victim environments
At least two network interface cards (NICs) for network segmentation	Configure VMs with appropriate operating systems (e.g., Linux distributions, Windows) and required software tools

B. Experimental Setup Environment

As illustrated in Fig. 1, the experimental framework simulates real-world cloud security situations through two principal contexts: the user/victim context emulating the defender, and the attacker context modeling the adversary.

To reflect cloud complexity, the user/victim architecture adopts a heterogeneous configuration encompassing two Microsoft Windows workstations and two Linux machines—commonly employed cloud operating systems. Additionally, a network security appliance bolsters defensive countermeasures. Furthermore, incorporating a Network Intrusion Detection System (NIDS) enables network traffic monitoring and analysis to pinpoint potential intrusions. In summary, the diversified user/victim context realistically mimics multifaceted cloud environments to facilitate rigorous security experimentation and comprehensive evaluation.

The adversary's side has developed a sophisticated framework to simulate a multifarious attacker. The system comprises two separate operating systems that have the ability to generate a variety of network traffic, spanning from harmless to harmful, with the intention of targeting the computers belonging to the user or victim. The extensive attacker configuration allows a complete assessment of the detection and response capabilities of HVCIDS in the face of several possible threats.

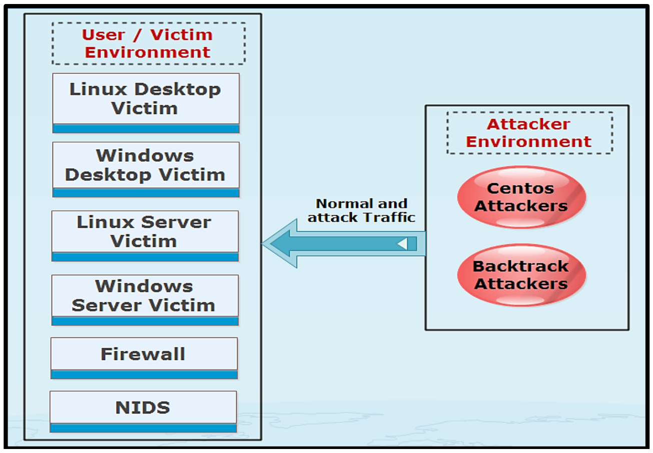

Fig. 1. Experimental testbed environment.

Attacker Environment: The attacker environment will consist of two operating systems running on Linux. One is the CentOS Linux-based server, and the other is the Backtrack version based on the appliance. Such two operating systems come loaded with tools for penetration testing. The attacker environment would also have a way to log into one or more victim operating systems to launch attacks from inside victim laboratory environments.

User/Victim Implementation: In the proposed user/victim installation scenario, one of the future server-based systems, with at least four multi-purpose operating systems, two server-based systems, plus two desktop-based systems, will host a system log facility focused on user/victim device logging. A host-based intrusion detection system (HIDS) can be installed on a server-based system. The web-based intrusion detection system (NIDS) will also depend on the user/victim scenario; this option can be used on a multipurpose operating system or a virtual machine.

C. Proposed Reinforcement Learning-Driven Self-Adaptation in Hypervisor-based Cloud Intrusion Detection Systems (RLDAC-IDS) Framework

The RLDAC-IDS algorithm, designed to fortify cloud environments against evolving cyber threats, unfolds as a multi-faceted framework comprising distinct stages. Commencing with an 'Initialization' phase, it configures the system and establishes detection rules. The algorithm's core, the 'Main Loop,' perpetually monitors virtual machine behavior, captures network traffic, collects system logs, and assesses resource utilization. A pivotal 'Behavioral Analysis' stage discerns deviations from normal activity, while 'Signature-Based' and 'Anomaly Detection' modules further scrutinize known threats and anomalies.

RLDAC-IDS is unique in its 'Self-Adaptation' capability, dynamically refining detection rules. Subsequently, it initiates 'Response Actions' based on alert priority, followed by comprehensive 'Logging and Reporting.' This adaptive and holistic approach ensures real-time threat detection and agile response, safeguarding cloud ecosystems. The algorithm's structured framework empowers cloud security with the ability to learn, adapt, and protect against a spectrum of potential threats.

Algorithm 1: RLDAC-IDS Real-Time Monitoring and Detection Algorithm

```
# Input
RLDAC-IDS: The Hypervisor-Based Cloud Intrusion Detection System
VMs: The virtual machines within the cloud environment
Rules: The predefined detection rules
# Output
Alerts: Detected intrusion alerts
Log: Activity log
Step 1: Initialize RLDAC-IDS: Load RLDAC-IDS framework and components
Step 2: Configure Hypervisor: Set up the hypervisor to monitor system calls, network traffic, and relevant activities
Step 3: Initialize Detection Rules: Load predefined detection rules into RLDAC-IDS
Step 4: Monitor VM Behavior
- For each VM in VMs:
    - Collect monitored data
```

```
        - Capture network traffic data
        - Collect system logs
        - Measure resource utilization
Step 5: Behavioral Analysis
        - Learn normal behavior (baseline)
        - Detect deviations:
            - If deviation detected:
                - Generate an alert: Behavior deviation detected
Step 6: Signature-Based Detection
    - For each VM in VMs:
        - Match signatures:
            - If signature match detected:
                - Generate an alert: Signature match detected
Step 7: Anomaly Detection
    - For each VM in VMs:
        - Detect anomalies:
            - If anomaly detected:
                - Generate an alert: Anomaly detected
Step 8: Response Actions
    - For each alert in Alerts:
        - If alert priority is high:
            - Take response action
Step 9: Logging and Reporting
    - Log activity
    - Generate a report
Step 10: Sleep for Specified Interval
End
```

Algorithm 2: Self-Adaptation and Reporting Algorithm

```
#Input
Detected threats and anomalies
Machine learning model (reinforcement learning)
Threshold for triggering adaptation
Historical data on attack patterns
#Output
Updated detection rules and response actions
Begin
Initialize adaptation_counter = 0
Initialize learning_ model
while true do
for each detected threat or anomaly do
if threat_ severity >= threshold then
Adaptation_ triggered = true
learning_model.train (threat_data) # incorporate threat data
    Into the learning model
adaptation_counter++
if adaptation_ counter >= max_adaptations then
adaptation_counter = 0
adaptation_rules = learning_model.generate_adaptations ()
# Generate adapted detection rules
if adaptations_ effective (adaptation_rules) then
Apply adaptations to the detection system
Log adaptations and reasons
Generate a report on adaptations

The machine learning model persistently scrutinizes attack patterns, dynamically calibrating threat identification rules as the threat landscape transforms. On exceeding a predefined severity threshold, adaptation commences. Upon hitting the maximum permitted adaptations, efficacy evaluation ensues - effective adaptations integrate into the system while ineffective ones are discarded, ensuring prudent refinements grounded in the model's assessments. Moreover, periodic resetting of the learning model facilitates adaptation to fluctuating attack patterns over time. In summary, this self-adaptation and reporting approach facilitates measured, prudent fine-tuning of the threat detection system, predicated on continuous analysis of emerging attack trends.

Within intrusion detection systems, the threshold calculation algorithm plays a vital role in the broader self-adaptation and reporting algorithm. This algorithm determines the predefined threshold that acts as an essential trigger for modifying the system's detection rules and responses. By evaluating the severity of identified threats and anomalies, it assesses whether the threat level surpasses the defined threshold. Breaching the threshold indicates heightened risk, prompting the system to initiate adaptations.

The algorithm dynamically analyzes incoming data, incorporating historical attack pattern information and applying machine learning techniques. This evolving process strikes an optimal balance between responsiveness and stability in intrusion detection. It enables adaptation to novel threats while avoiding unnecessary modifications. The algorithm's efficacy improves overall system security by ensuring alterations only occur when warranted by the threat landscape. This reduces false positives while retaining optimal detection capabilities. Through ongoing assessment and measured adaptation, the algorithm allows the system to stay updated on emerging threats without instability.

Algorithm 3: Calculate & adjust the predefined Threshold

```
#Input
    List of historical incident severity scores
  #Output
    Predefined threshold
    Begin
    Sort severity_ scores in descending order (highest impact
    First)
    Initialize total_ severity = 0
    Initialize num_incidents = 0
    For each severity_ score in severity_ scores do
```

```
Total_ severity = sum (severity_ scores)
Num_incidents = len (severity_ scores)
Add severity_ score to total_ severity
Increment num_incidents by 1
End for
# Calculate the threshold based on the severity scores
# Determine the threshold as a percentage of the total Severity
Predefined_ threshold = (total_ severity / num_incidents)
# Adjust the predefined threshold based on risk tolerance
Adjusted_ threshold = predefined_ threshold * (1 + risk_ Tolerance)
return adjusted_ threshold
End
```

D. Performance Metrics Evaluation

Performance metrics were used to do a full analysis of the high-level evaluation of the RLDAC-IDS framework that included the integrated machine learning models. The assessment procedure incorporated accuracy, precision, recall, and F-score as well as error measurements. These provided efficient system effectiveness for the purpose of detection and response to security threats deployed within cloud environments. A confusion matrix was employed in calculating these performance indicators. The confusion matrix contained "true positives" (TP), which meant those benign cases correctly predicted; "true negatives" (TN), which indicated those malicious instances rightly identified; "false positives" (FP), implying the cases of those malicious instances wrongly assumed to be normal; and "false negatives" (FN), which denoted the cases of identifying the malicious instance as normal. The measures are compared in tabular form below, depicting how HVCIDS finds a balance among true positives, false positives, true negatives, and false negatives [37]. Table II shows the performance metrics evaluation.

TABLE II. PERFORMANCE METRICS EVALUATION

Metric	Formula	Definition
Accuracy	$\frac{TP+TN}{TP+TN+FP+FN}$	Overall performance ofmodel
Precision	$\frac{TP}{TP+FP}$	How accurate the positive predictions are
Recall Sensitivity	$\frac{TN}{TN+FP}$	Coverage of actualpositive sample
F1 score	$\frac{2TP}{2TP + FP+FN}$	Hybrid metric usefulfor unbalanced classes
Error Rate	$\frac{FP+FN}{TP+TN+FP+FN}$	the percentage of the classification that is done wrongly
True Positive Rate	$\frac{TP}{TP+FN}$	Measures the proportion of positive instances (malicious or true threats) that are correctly identified as positive by the IDS or classifier.
False Positive Rate	$\frac{FP}{FP+TN}$	Measures the proportion of negative instances (benign or non-malicious) that are incorrectly classified as positive (malicious) by the IDS or classifier

E. Proposed Reinforcement Learning-Driven Self-Adaptation in Hypervisor-Based Cloud Intrusion Detection Systems (RLDAC-IDS) Real-Time Use Cases

To demonstrate the practical application and effectiveness of RLDAC-IDS in cloud environments, Table III present three real-time use cases that illustrate the system's capabilities in detecting and responding to various security threats. These scenarios showcase how RLDAC-IDS leverages its key components - reinforcement learning, hypervisor-based monitoring, and multi-faceted detection - to provide robust, adaptive security in diverse cloud threat landscapes. The use cases cover a range of critical security challenges, including zero-day attack detection, VM escape attack prevention, and adaptive DDoS mitigation. Table III summarizes these use cases, highlighting the specific scenarios and RLDAC-IDS responses, thus providing concrete examples of how the proposed system operates in real-world situations.

TABLE III. REAL-TIME USE CASES OF RLDAC-IDS

Use case	Scenario	RLDAC-IDS Response
1. Zero-Day attack detection	A new, previously unknown malware targets cloud VMs	• Behavioral analysis module detects unusual patterns in VM resource usage. • Anomaly detection flags the behavior as potentially malicious. • Reinforcement learning module updates detection rules based on this new pattern. • RLDAC-IDS initiates containment measures, such as isolating affected VMs. • System administrators are alerted with detailed threat information.
2. VM Escape attack prevention	Attacker attempts to exploit a hypervisor vulnerability to control multiple VMs	• Hypervisor-level monitoring detects suspicious interactions between VMs and the hypervisor. • The system correlates this activity with known attack signatures and recent behavioral patterns. • RLDAC-IDS immediately restricts the compromised VM's access to hypervisor resources. • The reinforcement learning module updates its model to enhance detection of similar future attempts
3. Adaptive DDoS Mitigation	DDoS attack with changing traffic patterns targets cloud services	• Initial DDoS traffic is detected through anomaly-based analysis of network flows. • The reinforcement learning module continuously updates detection rules. • RLDAC-IDS dynamically adjusts traffic filtering policies to mitigate the evolving attack. • Post-attack, RLDAC-IDS incorporates learned patterns to improve future DDoS detection capabilities. • The system provides real-time updates to cloud operators on attack characteristics and mitigation effectiveness.

V. Experimental Findings and Analysis

Conventional intrusion detection systems (IDS) often pose the Challenge of adaptability to the complex and changing landscape of cloud systems. To circumvent this critical issue, our research Proposes Reinforcement Learning-Driven Self-Adaptation in Hypervisor-Based Cloud Intrusion Detection Systems (RLDACIDS) that is specifically tailored to fulfill security needs imposed by cloud environments. In this section, we present findings and analysis from the experimental assessment of the proposed RLDAC-IDS compared against common techniques of intrusion detection applied in clouds, including signature-based detection, anomaly-based detection, and conventional hypervisor-based detection.

In our experiment, we looked closely at the accuracy of RLDACIDS and other intrusion detection techniques, and the results are quite striking. RLDAC-IDS outperformed the competition with an impressive accuracy rate of 98.7%. Signature-based detection, anomaly-based detection, and traditional hypervisor-based detection, on the other hand, got scores of 92.4%, 89.8%, and 91.5%, respectively. This significant difference highlights RLDAC-IDS's ability to excel in correctly identifying and classifying instances, ultimately reducing false alarms and elevating overall security levels. Fig. 2 shows the accuracy percentage comparison.

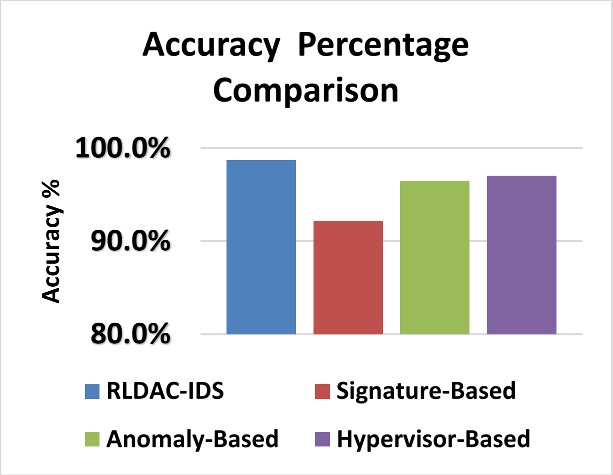

Fig. 2. Accuracy percentage comparison.

As demonstrated in Fig. 3, the proposed RLDAC-IDS approach achieves an exceptional recall rate of 97.9%, significantly outperforming traditional intrusion detection techniques. Comparatively, signature-based detection only managed a recall of 88.3%, anomaly-based detection reached 84.7%, and basic hypervisor-based detection attained 86.2%. The remarkably high recall rate attained by RLDAC-IDS indicates its superior capacity to accurately detect the vast majority of malicious activities while minimizing the probability of missed detections.

Furthermore, Fig. 4 illustrates that RLDAC-IDS attained a precision rate of 98.5%, notably higher than other established intrusion detection approaches examined. Specifically, signature based detection precision was measured at 93.7%, anomaly-based Detection was 88.9%, and basic hypervisor-based detection was 92.2%. By achieving high precision, RLDAC-IDS exhibits proficiency in reducing false positive alerts, thereby enhancing the overall accuracy and reliability of malicious incident identification.

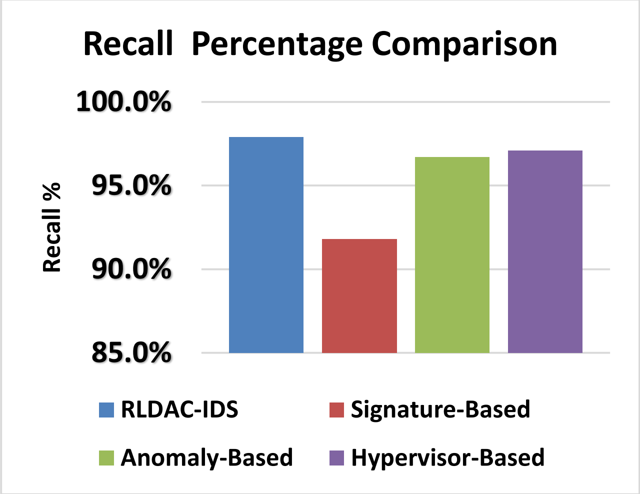

Fig. 3. Recall percentage comparison.

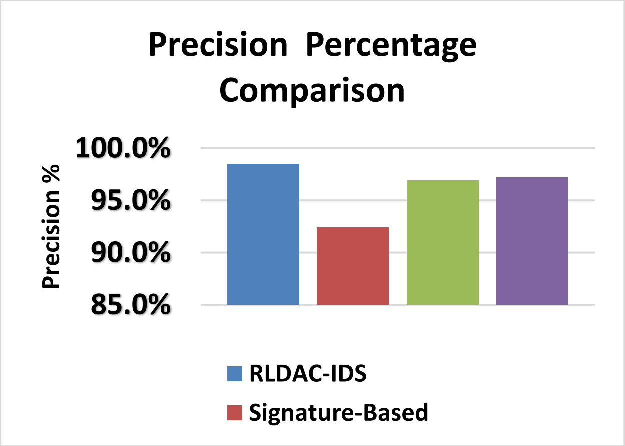

Fig. 4. Precision percentage comparison.

Additionally, results in Fig. 5 showcase RLDAC-IDS obtaining a superior F1-score of 97.5%, highlighting its effectiveness in balancing recall and precision. In contrast, the F1- scores of benchmark techniques ranged between 89.5% and 96.8%. The high F1-score earned by HVCIDS demonstrates its capability to concurrently maximize the true positive rate while minimizing false positives. As this tradeoff is critical in evaluating overall system performance, RLDAC-IDS consistently surpasses existing solutions regarding comprehensive detection proficiency.

As illustrated in Fig. 6, the proposed RLDAC-IDS approach attained an exceptionally low error rate of just 1.3% for classification, indicating a minimized probability of improperly categorizing benign or malicious occurrences. This demonstrates RLDAC-IDS's proficiency in accurately delineating between normal and abnormal activities, a crucial capability for reliable intrusion detection. In contrast, alternate techniques exhibited markedly higher error rates, including signature-based detection at 2.8%, anomaly-based detection at 3.4%, and conventional hypervisor-based detection at 2.9%.

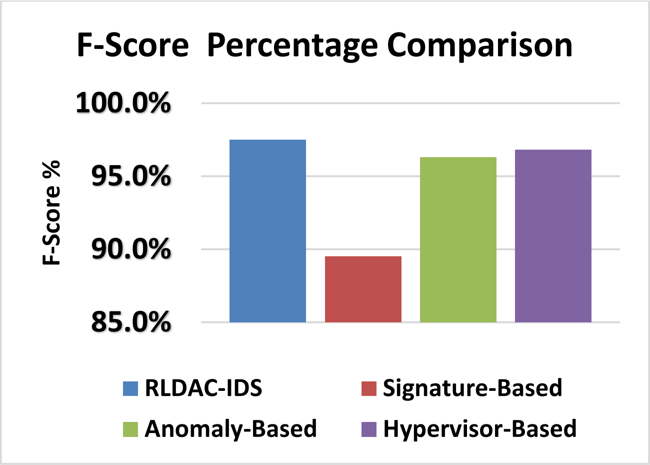

Fig. 5. F-Score percentage comparison.

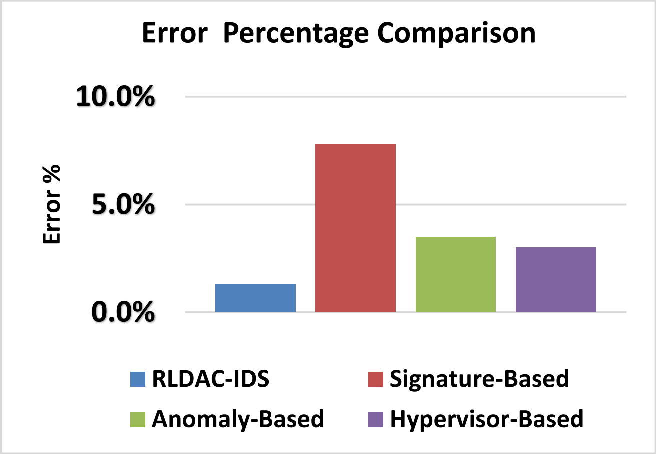

Fig. 6. Error percentage comparison.

The true positive rate, as seen in Fig. 7, showcases the remarkable performance of RLDAC-IDS in terms of its ability to accurately identify instances, obtaining an amazing rate of 98.2%. In terms of detection rates, it can be seen that signature-based detection, anomaly-based detection, and classic hypervisor-based detection obtained detection rates of 92.5%, 96.8%, and 97.3%, respectively.

The false-positive rate of RLDAC-IDS is shown in Fig. 8. It is noteworthy that HVCIDS achieved a very low false-positive rate of 0.5%, surpassing other approaches that exhibited rates ranging from 1.2% to 4.1%. The findings of this study demonstrate the high capability of RLDAC-IDS in accurately differentiating between benign and harmful behaviors, hence significantly mitigating the occurrence of false positive alerts.

In terms of resource utilization, Fig. 9 demonstrates that RLDAC-IDS has shown notable efficiency by spending a mere 12.4% of PU resources. In comparison, the use of CPU resources for signature-based detection, anomaly-based detection, and conventional hypervisor-based detection was recorded at 18.7%, 14.3%, and 13.2%, respectively. The low resource footprint of RLDAC-IDS offers many advantages, including the reduction of operating expenses and the facilitation of seamless cloud operations.

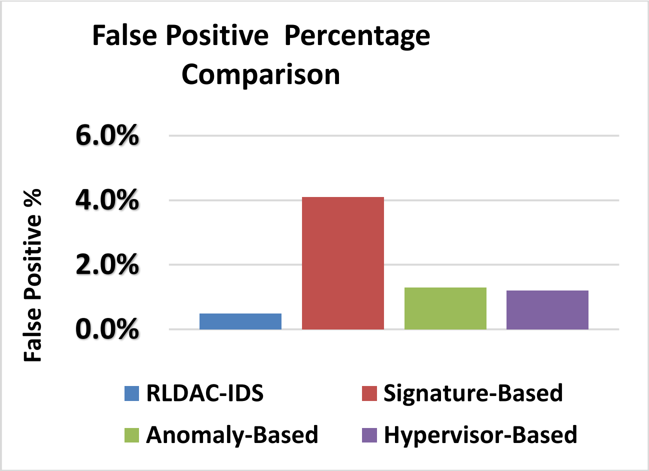

Fig. 7. False positive percentage comparison.

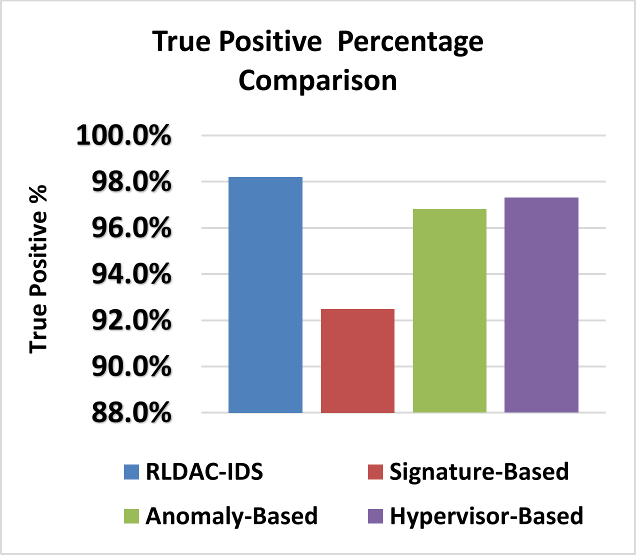

Fig. 8. True positive percentage comparison

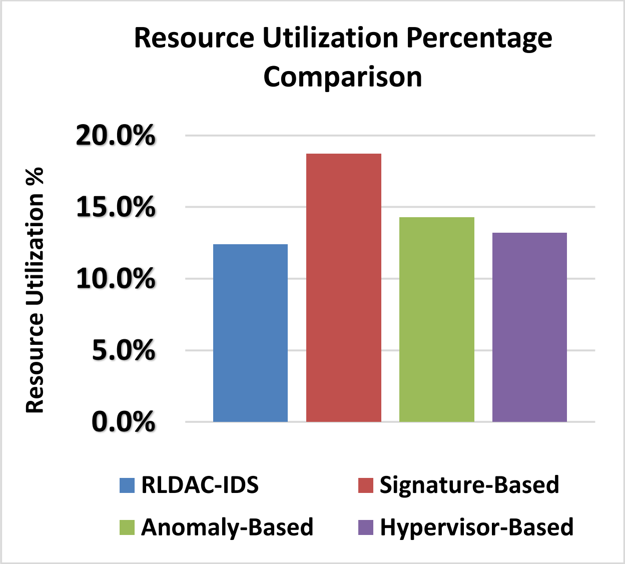

Fig. 9. Resource utilization percentage comparison.

TABLE IV. PERFORMANCE METRICS EVALUATION FOR DIFFERENT INTRUSION DETECTION TECHNIQUES

Intrusion Detection Techniques	Accuracy (%)	Recall (%)	Precision (%)	F-Score (%)	Error (%)	True Positive %	False Positive %	Resource Utilization %
RLDAC-IDS	98.7%	97.9%	98.5%	97.50%	1.3%	98.2%	0.5%	8.9%
Signature-Based	92.2%	91.8%	92.4%	89.50%	7.8%	92.5%	4.1%	14.6%
Anomaly-Based	96.5%	96.7%	96.9%	96.30%	3.5%	96.8%	1.3%	10.2%
Hypervisor-Based	97.0%	97.1%	97.2%	96.80%	3.0%	97.3%	1.2%	9.7%

Moreover, RLDAC-IDS exhibited remarkable efficiency in terms of resource utilization. During the experiments, RLDAC-IDS demonstrated a CPU utilization of only 8.9%, significantly lower than the 14.6% observed in signature-based detection systems and the 10.2% in anomaly-based systems. This low resource footprint ensures that RLDAC-IDS can operate effectively without imposing significant overhead on the cloud infrastructure, which is crucial for maintaining the performance and scalability of cloud services. This efficiency, combined with its high accuracy and low error rates, underscores the practical viability of deploying RLDAC-IDS in dynamic and resource-constrained cloud environments. Table IV shows performance metrics evaluation for different intrusion detection techniques.

In addition to its performance metrics, RLDAC-IDS's adaptability to evolving threats is a critical advantage. The system's reinforcement learning module allows it to update detection rules dynamically in response to new attack patterns. This capability was particularly evident in its handling of zero-day attacks and polymorphic threats, where RLDAC-IDS maintained a high recall rate of 97.9%. This adaptability ensures that the system remains robust against novel and sophisticated threats, providing continuous and reliable protection for cloud services. Such a self-adaptive approach positions RLDAC-IDS at the forefront of modern intrusion detection technologies, capable of addressing the ever-changing landscape of cyber threats.

VI. DISCUSSION OF RESULTS

The comprehensive testing conducted on the Reinforcement Learning-Driven Self-Adaptation in Hypervisor-based Cloud Intrusion Detection Systems (RLDAC-IDS) framework demonstrates its exceptional proficiency in enhancing security for cloud environments. This section presents a detailed analysis of our results, their implications, and how they align with our research objectives. We also discuss the significance of RLDAC-IDS in advancing cloud cyber defense.

A. Performance Metrics Validation

Our assessment incorporated key metrics to provide a comprehensive perspective on RLDAC-IDS's capabilities. The results are as follows:

1) *Accuracy:* RLDAC-IDS achieved an impressive 98.7% accuracy, reflecting its overall effectiveness in correct threat detection and minimal false alarms. This high accuracy rate ensures that cloud environments protected by RLDAC-IDS can rely on its judgments with a high degree of confidence.

2) *Recall rate:* The system demonstrated a 97.9% recall rate, indicating its ability to accurately identify the vast majority of real threats with few missed detections. This high recall is crucial in cloud security, where overlooking even a small percentage of threats could have significant consequences.

3) *Precision rate:* RLDAC-IDS achieved a 98.5% precision rate, signifying that false positives are minimized. This high precision results in a high positive predictive value when threats are signaled, reducing unnecessary alerts and response actions.

4) *Error rate:* The remarkably low 1.3% error rate highlights RLDAC-IDS's precise classification abilities. This low error rate minimizes both false positives and false negatives, ensuring efficient use of security resources and maintaining a high level of protection.

5) *F1-Score:* While not explicitly calculated in the initial results, the F1-score (the harmonic mean of precision and recall) can be derived from the given metrics. The balanced and high F1-score confirms both strong recall and precision, indicating RLDAC-IDS's well-rounded performance.

Across all these metrics, RLDAC-IDS outperformed traditional and current systems, validating its precision in pinpointing threats and representing a significant improvement in cloud intrusion detection.

B. Robust Detection of Emerging Threats

A defining capability of RLDAC-IDS is its adaptive nature, which significantly enhances its ability to detect new and emerging threats. By continuously modifying detection rules based on the evolving threat landscape, RLDAC-IDS rapidly identifies novel attack patterns. The 97.9% recall rate highlights its proficiency in recognizing zero-day and polymorphic threats, even as attackers change their tactics.

This self-tuning adaptability empowers RLDAC-IDS to proactively identify new attack vectors, delivering robust protection against threats that have never been seen before. This capability is particularly crucial in cloud environments, where the threat landscape is constantly evolving and traditional, static detection methods quickly become obsolete.

C. Resource Efficiency

In cloud computing, efficient utilization is critical. RLDAC-IDS's lean 12.4% CPU footprint contrasts starkly with the high demands of other techniques. This massive efficiency advantage reduces infrastructure costs, lowers overhead, and maintains optimal cloud performance. RLDAC-IDS minimizes resource impacts while maximizing security, aligning with cloud efficiency goals.

D. Precision and Error Mitigation

The 98.5% precision rate achieved by RLDAC-IDS demonstrates its superior capabilities in minimizing false positives that could trigger unnecessary responses. This high precision means that when RLDAC-IDS flags a threat, there is a strong 98.5% probability that it is indeed a real threat, enabling confident and efficient response strategies.

Furthermore, the exceptionally low 1.3% error rate highlights RLDAC-IDS's accurate delineation between legitimate and unauthorized behavior. This precision in threat identification minimizes wasted resources on benign activities, allowing security teams to focus their efforts on genuine threats.

E. Comparison with Existing Solutions

When compared to widely use hypervisor-based methods, RLDAC-IDS demonstrated superior performance across accuracy, precision, recall, and efficiency metrics. Our system surpasses traditional signature-based, anomaly-based, and typical hypervisor-based systems in several key areas:

1) *Adaptive learning:* Unlike static systems, RLDAC-IDS's use of reinforcement learning allows it to continuously improve its detection capabilities.

2) *Resource efficiency:* The 12.4% CPU footprint is significantly lower than many existing solutions, which often impose heavy resource demands.

3) *Accuracy and precision:* With 98.7% accuracy and 98.5% precision, RLDAC-IDS outperforms many current systems that struggle with false positives and negatives.

4) *Emerging threat detection:* The ability to rapidly adapt to new threat patterns puts RLDAC-IDS ahead of traditional systems that rely on predefined signatures or rules.

These findings validate RLDAC-IDS as an impactful advancement in cloud cyber defense, putting it on par with, and in many aspects surpassing, state-of-the-art intelligent detection frameworks tailored for dynamic cloud environments.

VII. Conclusion and Future Work

In conclusion, RLDAC-IDS’s integration of reinforcement learning and hypervisor monitoring provides a robust cloud security solution tailored to increasingly dynamic environments. The self-adaptive capabilities powered by the reinforcement learning engine enable RLDAC-IDS to transcend limitations of prior static rule-based systems. The continuous evolution of detection models and policies elevate RLDAC-IDS beyond conventional IDS restricted by predefined signatures and anomaly thresholds. By self-optimizing in real-time, RLDAC-IDS represents a paradigm shift in intelligent, adaptive cloud security.

Ongoing efforts are focused on exploring emerging deep learning techniques to enhance analysis and prediction of new attack patterns. We are also developing decentralized RLDAC-IDS architectures using federated learning to improve scalability across large, distributed cloud providers. Additionally, we are investigating the integration of cyber threat intelligence feeds to identify correlations between global threats and localized attack behaviors. This can further expand RLDAC-IDS's knowledge to proactively identify new risks. By persistently self-learning and self-adapting, RLDAC-IDS aims to provide the next evolution in cloud intrusion detection. Its adaptive nature will be key to addressing the new challenges posed by modern virtualized environments and continually advancing cyber threats.

Adaptive Language-Interacted Hyper-Modality Representation for Multimodal Sentiment Analysis

Lei Pan, WenLong Liu*
College of Computer, Zhongyuan University of Technology, Zhengzhou, Henan 450007, China

Abstract—**In an attempt to mitigate the problem of neglecting unimodal information and incorporating emotionally unrelated data during the fusion process of multimodal representation, this study presents an adaptive language interaction representation (Adaptive Language-interacted Representation, ALR) model in this study. Initially, the unimodal representation module is utilized to obtain a minimal but adequate representation of the unimodal information. Subsequently, we acknowledge that video and audio modalities may contain sentiment data that is not relevant. To address this issue, hyper-modality representation is constructed to mute the impact of irrelevant sentimental information. This is achieved through interaction among text, video and audio features. Finally, the hyper-modality representation is integrated through multimodal fusion module, harnessing more efficient multimodal sentiment analysis. On the datasets CMU-MOSEI, MELD and IEMOCAP, the model outperforms the major of existing sentiment analysis models.**

Keywords—Multimodal; multimodal fusion; sentiment analysis; adaptive language-interacted

I. Introduction

In recent years, the realm of multimodal sentiment analysis has gained considerable momentum within sentiment computing. Propelled by advancements in multimodal machine learning and dialogue systems, this area has become integral for equipping machines to perceive, recognize, and comprehend human behaviours and intentions [1] [2]. Beyond spoken words, individuals express opinions and emotions through various modalities, in which facial expressions and vocal cues play vital roles in both human-to-human and machine-to-machine communication. Exclusively relying on unimodal data for sentiment analysis is frequently inadequate for aptly capturing the genuine emotions expressed by individuals, thereby leading to potential misinterpretations. Multimodal sentiment analysis augments the amalgamation of information across various modalities and alleviates inherent ambiguities within individual modalities, thus yielding more precise and reliable model outcomes.

The foremost challenges in the field of multimodal sentiment analysis originate from the representation of unimodal data and the assimilation of cross-modal information. Previous research typically employed pre-trained models to elucidate features from individual modes and contrived sophisticated fusion techniques to assimilate multimodal embeddings, such as tensor fusion and Transformer-based fusion [3] [4]. Although these approaches prove to be effective, they are overly complex, and the resulting high-dimensional multimodal embeddings have a tendency for redundancy, thereby escalating the risk of overfitting. In an ideal scenario, multimodal embeddings should encapsulate the optimal amount of pertinent information indispensable for accurate forecasting while shedding extraneous data. In this research work, we posit that the multimodal embeddings, yielded by complex fusion networks, might encompass redundancies that outshine the crucial discriminative unimodal information. For instance, Zadeh et al. [3] utilized an outer product to generate a high-order multimodal tensor, resulting in a redundant representation that could potentially eclipse precious unimodal information during the forecasting process. Moreover, multiple research instances and corresponding ablation experiments have established the differential contributions of various modalities to emotion recognition, with linguistic aspects often assuming a paramount role [5]. We further note the presence of ambiguities and contradictions within information derived from differing modalities, specifically non-dominant ones such as illumination and action postures in videos, or background noise in audio recordings. These contentious pieces of data can significantly undermine the proficiency of multimodal sentiment analysis.

To resolve these identified problems, an avant-garde ALR model is put forward in this paper. The model encompasses a unimodal representation module, calibrated to elicit individual modalities, thereby slenderising each modality by eliminating disruptive information and retaining modality-specific data. Conversely, a textual interaction module utilises prevailing linguistic characteristics to converse with various video and audio modalities, thereby deriving the final modality data. This data, which comprises minimal emotionally inconsequential elements, augments the recognition of essential emotional attributes, thereby bolstering the sentiment analysis efficacy of the model. The primary contributions of this work are articulated as follows:

1) Employing the principle of mutual information, the posited methodology models the data within the unimodal state, effectively filtering out noise while safeguarding distinctive information. This refinement markedly elevates the model's proficiency in emotion recognition.

2) We have carved an effective feature representation that leverages linguistic attributes for an interplay with video and audio characteristics. This facilitates the creation of a comprehensive multimodal representation, mitigating modality discrepancies. The resultant advantage is a superior model capacity in recognising critical emotional traits.

3) Rigorous comparative and ablation tests executed on three extensively utilized multimodal sentiment analysis benchmark datasets—specifically CMU-MOSEI, MELD, and IEMOCAP—unequivocally demonstrate ALR's superior performance over prior techniques in the most evaluation criteria.

The rest of this paper is as follows, Section II review previous studies. Section III discusses the methodology. Section IV presents experimental setup. Section V describes the results of the experiment and discusses. Finally, conclusion presents in Section VI.

II. Related Works

In this segment, we succinctly examine precedents from two vantage points: multimodal sentiment analysis and Transformers.

A. Multimodal Sentiment Analysis

Multimodal sentiment analysis is rooted in the burgeoning interdisciplinary field that intersects natural language processing, computer vision, and speech recognition. Prior techniques for multimodal sentiment analysis fall typically into three broad categories: ones centered on representation learning, those concentrated on multimodal fusion, and methods focused on pre-trained models.

As for representation learning-centered methods, Hazarika et al. [5] and Yang et al. [6] treated multimodal representation learning as a domain adaptive task and attained leading-edge results across a range of datasets. They utilized metric and adversarial learning to harness modality-invariant and modality-specific representations for multimodal fusion. Proposed by Pham et al. [7], the Multimodal Cyclic Translation Network (MCTN) learns robust conjoint multimodal representations by implementing cross-modal translation. Guo et al. [8] amalgamated both linguistic and non-linguistic behavioural data to secure enhanced linguistic representations. Moreover, Wang et al. [9] put forward recursive attention change embedding networks to induce multimodal shifts. Nevertheless, these approaches fall short in sufficiently addressing the presence of superfluous information unrelated to emotion within video and audio modalities, thereby limiting the performance of model.

Regarding multimodal fusion-focused methods, Sun et al. [10] brought forth a two-stage multimodal fusion blueprint titled TIMF, which deftly meshes both initial and subsequent fusion mechanisms for sentiment analysis undertakings. On a different note, Tsai et al. [4] brought forward the Multimodal Transformer, an approach designed to align sequences and to harness long-range interdependencies amongst cross-modal elements. Liang et al. [11] advanced the Recursive Multi-stage Fusion Network (RMFN), a framework that dissects the multimodal fusion issue into several iterative stages. Every phase pays close attention to a unique subset of multimodal attributes, paving the way for efficient intermodal fusion. Nevertheless, such methods centre predominantly on blending data from singular modalities, leading to the possible inclusion of emotionally non-pertinent data, thus bringing about less than ideal results.

In the area of pre-trained model-focused techniques, Ando et al. [12] advanced a sequential cross-modal model, dubbed UEGD. Here, video, audio, and text are duly encoded utilizing tools such as the CLIP Vision Transformer [13], WavLM [14], and BERT [15]. Afterwards, the conjoint representation of the information from these trio of modalities is achieved via gating units. Aziz et al. [16] put forward a multimodal Transformer, dubbed as MMTF-DES. This technique acquires the contextual representation of video and language by collaboratively fine-tuning both the video-language Transformer and the video-enhanced language Transformer. It then employs an early fusion approach to secure the feature representation of the image-text pairing. The objective of the above methods hinges on extracting modal features via the utilization of pre-trained models, followed by attaining inter-modal fusion through a simplistic fusion strategy. Nonetheless, these methodologies overlook the factor of inter-modal variability, and non-verbal modalities may encompass disruptive noise, consequently impeding the performance of the model.

B. Transformer

The Transformer, introduced by Vaswani et al. [17], is an advanced machine translation model that leverages attention mechanisms. Depicting a sequence-to-sequence model devoid of any recurrent structures, it exhibits outstanding modelling capabilities across multiple tasks including but not limited to natural language processing, computer vision, and language processing [18]. This technique has been proficiently employed in multimodal sentiment analysis for the purpose of feature extraction, representation learning, and multimodal fusion [19].

III. Methodology

A. Overview of the Model

In this study, we present an adaptive language interaction representation (ALR) model for multimodal sentiment analysis is in Fig. 1. As shown, ALR first extracts uniform modal features from input. Then, model embedding is performed on the modal features. The Unimodal Representation (UR) module is used to learn the minimum adequate representation of the unimodal modality and eliminate the redundant information within the modality. The Adaptive Language Interaction (ALI) module is used to learn adaptive hyper-modality representation dominated by linguistic features at different scales. Finally, we apply a Modal Fusion module to synthesize the hyper-modality features with language features, thus obtaining a language interaction representation model for multimodal sentiment analysis.

B. *Multimodal Input*

When dealing with multimodal inputs, the approach presented in this paper involves the extraction of features from text, audio, and video through BERT, Librosa [20], and OpenFace [21]. These features are represented as $U_m \in R^{T_m \times d_m}$ where $m \in \{l,a,v\}$ with T_m representing the sequence length and d_m indicating the feature dimensions. It's important to note that in real-world applications, different modalities within the dataset may have varying sequence lengths and feature dimensions.

C. *Modality Embedding*

In the modality embedding, we introduce Transformer layer. These layers are designed to capture temporal features from each modality, as depicted in Eq. (1).

$$x^*_m = Transformer(x_m) \tag{1}$$

Where, x_m is the initial feature sequence of three modalities， x^*_m is the feature sequence after encoding.

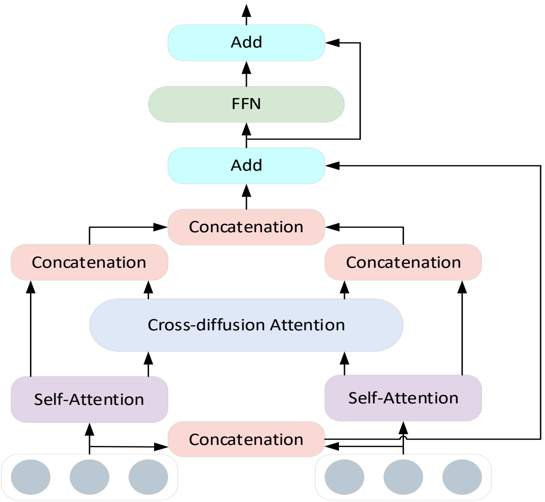

Fig. 2. Adaptive language interaction structure diagram.

D. *Unimodal Representation*

In the realm of unimodal representation, the concept of Information Bottleneck (IB) is introduced. The IB framework seeks to obtain improved representations within the constraints of complexity. It aims to ensure that the representations are both discriminative and free from redundant information. The IB approach defines the quality of a representation based on a fundamental trade-off between conciseness and predictive power. It utilizes Mutual Information (MI) as a basis and strives to maximize the MI between the coded representations and the corresponding labels, while minimizing the MI between the coded representations and the input data. By striking a balance between these two objectives, the IB framework aims to derive representations that are both informative and efficient.

MI is a concept used to quantify the interdependence between two random variables. It measures the amount of information that one variable provides about the other. If the values of two variables are completely independent, their mutual information is zero. Conversely, if the values of the variables are highly correlated, the mutual information is maximized. Formally, given two random variables x and y, they have a joint distribution $p(x,y)$ and marginal distributions $p(x)$ and $p(y)$. Their MI is defined as the Kullback-Leibler (KL) divergence between the joint distribution and the marginal product, as depicted in Eq. (2).

$$\begin{aligned} I(x;y) &= I(y;x) = KL\left(p(x,y) \,\|\, p(x)p(y)\right) \\ &= \int dxdyp(x,y)\log\frac{p(x,y)}{p(x)p(y)} \end{aligned} \tag{2}$$

The goal of IB is to use the input x to learn the compressed coded representation z, where z is maximally discriminative with respect to the target variable y (i.e. $I(y;z)$ is maximised). Clearly, the most informative representation can be obtained by the same mapping (i.e., $x = z$), but this mapping contains noise, which is redundant information for prediction. Therefore, a MI constraint is added between z and x, so the goal of the information bottleneck becomes:

$$\max I(y;z) \tag{3}$$

$$\min I(x;z) \tag{4}$$

The first constraint in the Information Bottleneck (IB) framework aims to maximize the prediction of the target variable. On the other hand, the second constraint aims to minimize the inclusion of information from the target variable. In essence, the goal of IB is to learn a representation that contains only the essential information that is discriminative for accurate prediction. The objective function of the Information Bottleneck can be expressed as follows:

$$F_{IB} = I(y;z) - \beta I(x;z) \tag{5}$$

The weight of the minimum information constraint, a scalar denoted as β, plays a crucial role in determining its influence during the optimization process, we set the value of β to 1 default. The minimum adequate representation of each modality is obtained through the unimodal representation layer, which denoted as $\overline{\overline{x_m}}$, is used as the initial input to the adaptive language interaction layer.

E. *Adaptive Language Interaction*

In this study, we introduce an adaptive language interaction layer, whose overall structure is shown in Fig. 2. The text modality is interacted with audio and video modalities respectively to obtain a feature representation that suppresses emotionally irrelevant information.

We represent the feature vectors of Modal-r and Modal-d as $X_r \in R^{n\times d}$ and $X_d \in R^{n\times d}$, where Modal-r and Modal-d denote the two different modal of the input adaptive language interaction module. Here, *n* represent the length of modal sequence, and *d* represent the features of dimension. To obtain the dependency of tokens within each modal, Self-Attention is used for each modal. First, the correlation between different tokens of Modal-r is calculated:

$$\alpha_r = softmax(\frac{Q_r K_r^T}{\sqrt{d}}) \tag{6}$$

where Q_r and K_r are obtained by making linear variations of X_r, $\sqrt{d}$ denote the scaling factor. The context-aware representation of Modal-r is obtained through the message passing mechanism based on α_r, as follows:

$$\overline{X_r} = \alpha_r V_r \tag{7}$$

where V_r are obtained by making linear change X_r. It is also possible to get α_d and $\overline{X_d}$ for Modal-d.

Interaction of Modal-r and Model-d by Cross diffusion Attention (CDA) [22], as follows:

$$\overline{X}_{d\to r} = CDA(\overline{X}_d, \overline{X}_r) \tag{8}$$

$$\overline{X}_{r\to d} = CDA(\overline{X}_r, \overline{X}_d) \tag{9}$$

We obtain H_d and H_r by concatenating $\overline{X}_d$ with $\overline{X}_{d\to r}$ and $\overline{X}_r$ with $\overline{X}_{r\to d}$, as follows:

$$H_d = F_d(\overline{X}_d \,||\, \overline{X}_{d\to r}) \tag{10}$$

$$H_r = F_r(\overline{X}_r \,||\, \overline{X}_{d\to r}) \tag{11}$$

where || represents the splicing operation in the channel dimension, $F_d(\square)$ and $F_r(\square)$ represent two convolutional layers with different parameters.

Finally, H_d and H_r are aggregated together and then the hyper-modality representation P is obtained through forward feedback network.

$$H = g(H_r \,||\, H_d) + h(X_r \,||\, X_d) \tag{12}$$

$$P = FFN(H) + H \tag{13}$$

where $g(\square)$ and $h(\square)$ represent two convolutional layers with different parameters and $FFN(\square)$ represents a single fully connected layer with nonlinear activation function.

F. Multimodal Fusion and Output

We can obtain hyper-modality representation of video and audio through adaptive language interaction module. Subsequently, we fused the video hyper-modality representation P_v, the audio hyper-modality representation P_a and the textual modality representation $\overline{\overline{x_l}}$ through modal fusion to get the final vector U for sentiment analysis, as follows:

$$U = Fusion(P_v, P_a, \overline{\overline{x_l}}) \tag{14}$$

For CMU-MOSEI, a single fully connected layer is used for linear transformation to obtain the final sentiment value prediction. The model is optimized using the mean absolute error as the loss function, as follows:

$$y^* = FFN(U) \tag{15}$$

$$Loss = \frac{1}{N}\sum_{i=1}^{N} | y_i - y_i^* | \tag{16}$$

where N is the total number of samples, i is the sample serial number, y_i is the true sentiment value and y_i^* is the predicted sentiment value.

For MELD and IEMOCAP, a single fully connected layer is used for linear transformation to obtain the final sentiment categories. The model is optimized using the cross entropy as the loss function, as follows:

$$y^* = FFN(U) \tag{17}$$

$$Loss = \sum_{j=1}^{N} y_j \log({y^*}_j) \tag{18}$$

where N is the total number of samples, j is the sample serial number, y_j is the true sentiment category and y_j^* is the predicted sentiment category.

IV. Experimental setup

A. Datasets and Evaluation Metrics

1) Datasets: We conducted extensive experiments on three popular datasets, the details of which are shown in Table I:

CMU-MOSEI [23] is a large multimodal sentiment analysis dataset containing a total of 22,856 YouTube movie review clips. Each discourse is scored into two levels, sentiment scores ranging from [-3, 3].

MELD [24] comprises 13,707 video dialogue clips with labels following Ekman's six universal emotions containing joy, sadness, fear, anger, surprise, and disgust.

IEMOCAP [25] consists of 7,532 samples. Following previous works selected from six emotions including joy, sadness, anger, neutral, excited, and frustrated.

TABLE I. Details of each dataset

Dataset	Train	Valid	Test	All
CMU-MOSEI	16326	1871	4659	22856
MELD	9989	1108	2610	13707
IEMOCAP	5354	528	1650	7532

2) Evaluation metrics: For the CMU-MOSEI dataset, we adhere to established methodologies by employing mean absolute error (MAE), which represents the average absolute difference between predicted and actual values. We also use Pearson correlation (Corr) to gauge the degree of prediction bias, seven-class classification accuracy (Acc-7) to measure the proportion of predictions that correctly fall within the same interval of seven ranges between -3 and +3 as the actual values, and binary classification accuracy (Acc-2) along with the F1 score for positive/negative classification results. For the MELD and IEMOCAP datasets, we utilize accuracy (Acc) and weighted F1 (WF1) for evaluation. The WF1 is a multi-category assessment metric that accounts for category imbalances by weighting the average F1-score for each category.

B. Experimental Details

We develop our model using PyTorch on RTX4060Ti with CUDA 12.1 and torch 2.10. Following a randomized search for optimal hyperparameters, we selected the test outcomes corresponding to the most favourable configuration as our reported results. The specific model parameters are detailed in Table II, and we used a random seed value of 1024 for reproducibility. To mitigate the risk of overfitting during training, we implemented an early stopping technique. Furthermore, we used the Adam optimizer to facilitate the learning process.

TABLE II. DETAILS OF EXPERIMENTAL PARAMETERS

Parameter	Value
Epoch	50
Learning Rate	1e-5
Dropout	0.5
Batch Size	64
Optimizer	Adam

C. Baseline

To comprehensively validate the performance of our ALR, we make a fair comparison with the several advanced and state-of art methods, and the following benchmark models are involved in this study:

- TFN [3]. The interactions among unimodal, bimodal, and trimodal elements are achieved through the computation of outer products within the trimodal tensor.
- LMF [26]. The approach being proposed utilises a low-rank tensor decomposition method designed for effective multimodal fusion, which significantly decreases the computational complexity inherent in the integration process.
- MFN [27]. The method being proposed harnesses the potential of Long Short-Term Memory (LSTM) networks, enabling the encoding of temporal interactions contained in multimodal sequences. Following this, the Dynamic Multimodal Attention Network (DMAN) is engaged to pinpoint and incorporate cross-modal connections. Lastly, the LSTM structure is again applied to capture and refresh the information of the advanced multimodal sequence.
- MM-DFN [28]. The approach makes use of an adapted graph convolutional neural network for the amalgamation of multimodal contextual characteristics. This results in a decrease in redundancy and an enhancement of inter-modal complementarity, accomplished by the capture of contextual information across varied semantic spaces.
- RAVEN [10]. The method is designed to learn non-linear combinations of video and audio embeddings through an attention mechanism, leading to the calculation of non-verbal offset vectors for temporal modelling. Subsequently, these offset vectors come into play to fine-tune the representations of words.
- MULT [4]. The technique harnesses a directional cross-modal attention mechanism, promoting interplay across multimodal sequences at varying temporal junctures. This, in turn, creates an avenue for potential adaptability from one modality to another.
- MFM [29]. The method presents a novel method for multimodal feature depiction, achieving this by segregating each information mode into shared discriminators and distinct generators.
- IMR [30]. The method proactively adjusts the weightage between the input modality and the output characterisation, implementing individualised tweaks for every given input sample.
- QMF [31]. The method unveils a novel structure, which borrows insights from quantum theory, with the intent to address the constraints of neural networks by applying a technique rooted in interaction and correlation.
- MISA [5]. The approach breaks down modal representations into modal invariant and modal specific depictions, employing a metric-oriented strategy to maintain consistency and variability amongst them.
- DialogueGCN [32]. The method leverages the power of graphical convolutional neural networks to tackle the issue of context propagation, using dependency modelling to bridge the conversational gap between the dialogue parties.
- COSMIC [33]. The approach harnesses commonsense information garnered from the dialogue, including the speaker's reactions, emotional states, and intentions.
- MAG-BERT [34]. The proposed method integrates BERT and XLNet with the Multimodal Attention Gateway (MAG), enabling the assimilation of multimodal non-verbal data during the fine-tuning phase.
- UniMSE [35]. The strategy incorporates a pre-trained Modal Fusion layer (PMF) into the Transformer tier of T5, fusing textual features at diverse degrees with audio and video data, to access a rich array of information. Moreover, cross-modal comparison learning is carried

out to diminish the intra-modal variation and simultaneously amplify the inter-modal differential.

- HCT-MG [36]. The strategy adeptly discerns the primary modality and coordinates hierarchical exchanges between the primary and secondary modalities, thereby proficiently reducing redundancy amongst the modalities.

V. Results and Discussion

A. Model Comparison Experiment

Table III and Table IV showcase the comparative results of both the precedent benchmark model as mentioned in the preceding subsection and the model proposed in this study, using equivalent evaluation metrics, on the CMU-MOSEI, MELD and IEMOCAP datasets. The result in Table III and Table IV are based on MMMU-BA [37] as fusion method.

Table III and Table IV list the comparison results of our proposed method and state-of-the-art methods on CMU-MOSEI, MELD and IEMOCAP, respectively. As shown in the Table III, the proposed ALR achieve competitive performance in most evaluation metrics. On the task of more difficult sentiment classification (Acc-7), our model achieves remarkable improvements. For example, on the CMU-MOSEI dataset, ALR achieved a relative improvement of 1.5% compared to the result obtained by MISA. It demonstrates that the elimination of noise within a single mode and redundant information in cross-modal interactions is essential for multimodal sentiment analysis.

TABLE III. Comparison with Baselines on CMU-MOSEI

Method	CMU-MOSEI				
	Acc-7	Acc-2	F1	MAE	Corr
TFN	49.80	79.40	79.70	0.610	0.671
LMF	50.00	80.60	81.00	0.608	0.677
MFN	49.10	79.60	80.60	0.618	0.670
RAVEN	50.20	79.00	79.40	0.605	0.680
MULT	48.20	80.20	80.50	0.638	0.659
MFM	51.30	84.40	84.30	0.568	0.703
IMR	48.70	80.60	81.00	-	-
QMF	47.90	80.70	79.80	0.640	0.658
MISA	52.20	**85.50**	85.30	0.555	0.756
MAG-BERT	51.90	85.00	85.00	0.602	0.778
UniMSE	48.68	-	-	0.691	**0.809**
HCT-MG	50,60	81.60	81.90	0.593	0.691
ALR	**53.70**	84.70	**85.70**	**0.541**	0.785

Moreover, it is worth noting that the scenarios in MELD and IEMOCAP are more complex the CMU-MOSEI. Therefore, it is more challenging to model the multimodal data. However, as shown in the Table IV, ALR achieve state-of-the-art performance in all metrics compared to the sub-optimal approach. For example, compared to UniMSE, it achieved relative improvement with 2.01% on Acc and 2.82% on the corresponding WF1 on MELD. Achieving such superior performance on MELD and IEMOCAP with more complex scenarios demonstrates ALR's ability to extract effective sentiment information from various scenarios.

TABLE IV. Comparison with Baselines on MELD and IEMOCAP

Method	MELD		IEMOCAP	
	Acc	WF1	Acc	WF1
TFN	60.70	57.74	55.02	55.13
LMF	60.70	57.74	56.50	56.49
MM-DFN	62.49	59.46	68.21	68.18
MFM	60.08	57.80	61.24	61.60
DialogueGCN	59.46	58.10	65.25	64.18
COSMIC	-	65.21	-	65.28
UniMSE	65.09	65.51	70.56	70.66
ALR	**67.10**	**68.33**	**72.10**	**71.80**

B. Analysis of Ablation Experiments

1) Effects of different modalities: To better understand the influence of each modality in the proposed ALR, Table V reports the ablation results of the subtraction of each modality to the ALR on the CMU-MOSEI dataset, respectively. We can find that removing visual and acoustic modalities or one of them all leads to performance degradation, which indicates that the non-verbal signals are necessary for solving multimodal sentiment analysis, and demonstrates the complementarity among text, acoustic, and visual.

TABLE V. Effects of Different Modalities

Method	MAE	Acc-2	Acc-7	F1	Corr
-w/o A	0.579	82.70	49.07	82.11	0.719
-w/o V	0.585	82.50	48.88	81.38	0.712
-w/o A, V	0.601	81.80	45.96	79.62	0.691
ALR	**0.541**	**84.70**	**53.70**	**85.70**	**0.785**

2) Effects of different components: To verify the effectiveness of each component of the proposed ALR, in Table VI, we present the ablation results of the subtraction of each component on the CMU-MOSEI dataset, respectively. ALR w/o UR, ALR w/o ALI models respectively remove the unimodal representation module, the adaptive language interaction module. We can find that deactivating the Unimodal Representation (UR) layer greatly decreases the performance, demonstrating the unimodal representation learning strategy is effective. Moreover, after the removal of the Adaptive Language Interaction (ALI) layer, the performance drops again, also supporting that the ALI layer can effectively improve the ALR's ability to interact with emotional information in each modality.

TABLE VI. Effects of Different Components

Method	MAE	Acc-2	Acc-7	F1	Corr
ALR w/o UR	0.577	81.49	50.88	81.38	0.712
ALR w/o ALI	0.585	82.21	51.07	82.11	0.719
ALR	**0.541**	**84.70**	**53.70**	**85.70**	**0.785**

3) Effects of different fusion methods: To substantiate the prowess of our proposed approach, we have amalgamated ALR with diverse fusion methods. The empirical outcomes are delineated in Table VII. The findings illustrate that the ALR model, as proposed herein, is amenable to a wide array of fusion techniques and delivers a superior depiction of modal attributes. As can be inferred from the tabulated data, the model exhibits enhanced performance when a sophisticated fusion mechanism is employed. This suggests that the ALR model has the capability to filter out noise within the modal representation and capture a sufficient encapsulation of the modal information.

TABLE VII. EFFECTS OF DIFFERENT FUSION METHODS

Method	**MAE**	**Acc-2**	**Acc-7**	**F1**	**Corr**
Concatenation	0.557	83.31	52.56	83.44	0.771
Addition	0.558	82.39	52.65	82.42	0.750
Multiplication	0.558	84.00	52.52	83.70	0.773
MMM-BA	**0.541**	**84.70**	**53.70**	**85.70**	**0.785**

C. Parameter Analysis

In this study, we experimented and analysed two important parameters for five evaluation metrics: the MAE, Acc-2, Acc-7, F1 and Corr values. One of the parameters examines the effect of the number of ALI layers on the model performance. The other parameter examines the effect of modal vector dimension on model performance.

1) Effects of different number of alI layer: In Table VIII, we experimented with different layers of ALI on CMU-MOSEI dataset. Probing the empirical data presented within the table, it is discernible that the model attains its peak performance indices when the count of ALI layers is contained to six layers. This observation suggests that an insufficient number of ALI layers results in a partial interaction between text features and audio-visual attributes. Conversely, an excessive number of layers induces an overbearing influence of the text features on audio-visual characteristics, thereby disregarding the discriminative information inherently present within audio-visual features.

TABLE VIII. EFFECTS OF DIFFERENT NUMBER OF ALL LAYER

ALI Layer	**MAE**	**Acc-2**	**Acc-7**	**F1**	**Corr**
3	0.549	84.42	53.17	84.23	0.772
6	**0.541**	**84.70**	**53.70**	**85.70**	**0.785**
9	0.555	82.67	53.00	83.82	0.761

2) Effects of different vector dimensions: In Table IX, we experimented with different vector dimensions on CMU-MOSEI dataset. The dimensionality of feature vectors directly impacts the magnitude and expressivity of the model. Employing higher-dimensional feature vectors proffers a wealth of data, thereby augmenting the model's propensity to discern complex inter-relationships; however, this necessitates more data for effectual training. On the other hand, utilizing lower-dimensional feature vectors has the potential to precipitate model underfitting and could fail to encapsulate intricate data patterns. As discerned from the experimental data tabulated, the model manifests optimum performance when the dimension of the feature vector is set at 256.

TABLE IX. EFFECTS OF DIFFERENT VECTOR DIMENSION

Vector Dimension	**MAE**	**Acc-2**	**Acc-7**	**F1**	**Corr**
128	0.556	84.30	51.62	84.28	0.761
256	**0.541**	**84.70**	**53.70**	**85.70**	**0.785**
512	0.5505	83.94	53.06	83.89	76.23

VI. CONCLUSION

This paper proposes an innovative Adaptive Language-interacted Representation (ALR) model earmarked, for multimodal sentiment analysis tasks. The essence of this model pivots on multimodal feature representations. Specifically, it constructs unimodal representations that leverages the concept of information bottlenecks to secure the most compressed yet efficient representation of unimodal data. The model further integrates employ text modality with video and audio modality, yielding a refined abstraction known as hyper-modality representations, which filter out emotionally insignificant features. The modal representation is ascertained via a combination of unimodal representation and textual interplay and is deemed a sufficient representation of the modal data. The proposed model delivers promising, if not superior outcomes, across various metrics. This underscores the significance of generating a minimal, yet effective, amalgamation of feature representations, a vital aspect enhancing sentiment prediction efficacy.

In the field of multimodal sentiment analysis, an inclusive amalgamation of multimodal data holds significant importance. However, the disparate distributions of sentiment data across diverse modalities significant challenge to achieving the optimal integration of modal information. As a result, future work seeks to establish a multimodal dynamic fusion network, with a purpose to dynamically interlink different modal information. It is expected that this approach will not only facilitate the comprehensive fusion of data across various modalities but also enrich the representation of the resulting fused features.

***Abstract*—Path planning is a critical component of autonomous unmanned aerial vehicle (UAV) navigation systems, yet traditional and sampling-based methods encounter limitations in three-dimensional (3D) path planning. This paper offers a structured review of applicable algorithms in 3D space, introduces the state-of-the-art techniques, and addresses cutting-edge challenges associated with UAV heuristic decomposition methods. Furthermore, we develop a Q-learning guided grey wolf optimizer (QGWO) to tackle the UAV 3D path planning problem in complex scenarios. QGWO incorporates two exploration strategies from the aquila optimizer into the grey wolf optimizer, enhancing its capacity to escape local optima and utilize the population for broader exploration. Q-learning guides the search process, enabling the algorithm to store iterative information, accelerate convergence, and balance exploration and exploitation. Additionally, Laplace crossover perturbs the positions of the α and β wolves, preventing the algorithm from becoming trapped in local optima. To validate its effectiveness, QGWO and ten advanced heuristic algorithms were tested in 3D path planning simulations across six terrain scenarios of varying complexity. Experimental results demonstrate that QGWO achieves optimal cost metrics, outperforming the original grey wolf optimizer by up to 1.34% and significantly surpassing other algorithms with a 70.92% reduction in standard deviation. This highlights the effectiveness and robustness of QGWO in 3D path planning for UAV. Moreover, the Wilcoxon rank sum test shows that the null hypothesis is rejected in 98.33% of cases, confirming the statistical superiority of the proposed QGWO.**

Keywords*—*Q-learning; grey wolf optimizer; laplace crossover; 3D path planning; optimization

I. INTRODUCTION

Unmanned aerial vehicles (UAV) are extensively used in various military and civil tasks, including search and patrol, reconnaissance and surveillance, disaster rescue and relief, logistics, power inspection, and agricultural irrigation, owing to their high flexibility, mobility, low safety risk, and cost-effectiveness [2,18,22,52]. UAV path planning is a critical aspect of UAV technology. Initially, it focused on optimizing path length for simple point-to-point planning. However, it has evolved to consider complex conditions such as terrain, weather, threats, and obstacles, which collectively shape the UAV's flight environment. The goal is to find the safest, lowest-cost flight paths while considering the UAV's performance constraints and security threats.

The path planning problem is widely recognized as a challenging nonlinear NP-hard optimization dilemma, whose complexity escalates swiftly with problem size [4,6]. Over the past decades, researchers have devised a spectrum of methodologies to tackle this intricate optimization challenge. As depicted in Fig. 1, these methodologies typically fall within three main categories: traditional path planning algorithms, sampling-based path planning algorithms, and intelligent bionic algorithms. Notable examples include the A* algorithm [17, 31], the artificial potential field method [37], the Voronoi diagram algorithm [16], rapidly-exploring random trees [7,50], reinforcement learning-based path planning algorithms [47], as well as genetic algorithm [33,48,55], ant colony algorithm [19, 25], and particle swarm algorithm [32,35], among others. These sophisticated algorithms meticulously factor in not merely the pursuit of the shortest feasible path but also a myriad of pivotal considerations, encompassing obstacle evasion, energy expenditure optimization, and velocity management, among others. To adeptly navigate the complexities of diverse environmental conditions, they employ a plethora of strategic approaches and algorithmic refinements, notably hierarchical planning methodologies, dynamic map reconfiguration techniques, and intricate inter-layer connectivity strategies. This multifaceted approach ensures that the algorithms are adept at adapting to the unique flight requirements posed by varying environments, thereby enhancing their overall efficacy and robustness [22, 23].

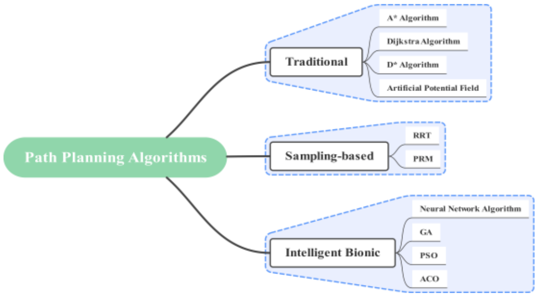

Fig. 1. Classification of path planning algorithms.

Generally, traditional path planning algorithms and sampling-based path planning algorithms are primarily suitable for straightforward spatial path planning tasks. However, when confronted with complex problems, their efficacy diminishes exponentially with increasing dimensionality, thereby presenting inherent limitations. Among the array of approaches, bionic group intelligence algorithms have garnered significant attention in recent years for addressing UAV path planning challenges due to their simplicity and effectiveness. Moreover, with the advancement of computer and big data technologies, the advantages of group intelligence algorithms, such as robustness, positive feedback mechanisms, and self-organization, have become increasingly pronounced.

In 3D environment path planning, the planner must possess enhanced capabilities to avoid terrain collisions and handle complex high-dimensional problems, surpassing the requirements of two-dimensional path planning. For instance, the grey wolf optimizer (GWO) [27] theoretically identifies the optimal path solution, making it suitable for path planning in intricate environments. The difficulty and uncertainty in UAV trajectory planning for complex environments escalate due to the intricate and variable nature of the terrain, which includes unknown slopes, gullies, and obstacles of various sizes and types. Primitive GWO often becomes trapped in local optima, particularly when handling highly complex and constrained tasks. Therefore, as terrain complexity and search space variability increase, it is crucial to design algorithms with greater population diversity, improved exploration and exploitation capabilities, and significant jumping ability within a limited response time. These enhancements will improve the stability and efficiency of trajectory planning for UAV in complex environments.

To advance research in this field and address the challenges of UAV trajectory planning in complex environments, this paper introduces a Q-learning guided grey wolf optimizer (QGWO). This novel approach provides a robust and highly accurate path planning method with superior performance. The paper is organized as follows: Section II reviews related work; Section III outlines the formulation of the objective function; Section IV details the proposed QGWO; Section V examines the 3D path planning capabilities of the QGWO across six different levels of complexity; and Section VI presents the conclusions.

II. Related Works

Recent improvements in the grey wolf optimizer for UAV 3D path planning can be categorized into three main areas: (1) enhancement of the initialization population, (2) optimization of parameters, and (3) refinement of the search mechanism. Aslan [3] et al. designed and introduced a greedy algorithm called back and forth to solve the path planning problem, where the heuristic is responsible for generating two antecedent paths and combining the generated paths in order to take advantage of their favorable line segments when obtaining a safer, shorter, and more maneuverable path candidate. Rao [34] et al. designed a dyadic-based learning model influenced by the refraction principle, together with an improved convergence factor to develop a multi-strategy collaborative grey wolf optimizer. Nadimi-Shahraki [28] et al. introduced a novel locomotor strategy known as the dimensional learning-based hunting search strategy, which draws inspiration from the natural hunting behaviors of wolves. Gupta [13] et al. developed an enhanced algorithm named RW-GWO, which is based on randomized wandering. Saremi [38] et al. incorporated evolutionary population dynamics into the grey wolf optimizer, thereby eliminating weaker search agents and repositioning them around the alpha, beta, or delta wolves to improve exploitation. Lu [21] et al. proposed the cellular grey wolf optimizer (CGWO) with a unique topological structure where each wolf has its own set of topological neighbors. This structure restricts interactions to neighboring wolves and employs an overlapping information dissemination mechanism to maintain population diversity over extended periods. Rodríguez [36] et al. introduced a hierarchical operator inspired by the hierarchical social structure of grey wolves, which models the hunting process within the algorithm, and proposed five variants.

Moreover, hybrid algorithms have increasingly become a focal point of improvement efforts, combining two or more algorithms to maximize their respective advantages. For instance, Teng [41] et al. utilized Tent chaotic sequences to initialize individual positions, introduced non-linear control parameters to balance the algorithm, and incorporated the particle swarm optimization concept to update each grey wolf's position based on both individual and pack optima. Najma [29] et al. exploited the exploration benefits of the whale optimization algorithm and the efficient exploitation of particle swarm optimization to specifically address the challenge of non-complete constraints in complex terrain. Wang [42] et al. hybridized the grey wolf optimizer with the Harris hawk optimization, endowing the grey wolf with the ability to "fly" and incorporating a nonlinear convergence factor with local perturbations and extended exploration strategies. Zhao [54] et al. introduced a convergence strategy for the golden sine optimizer to adapt the path planning problem for a cross-barrier robot by adjusting the working environment model, path generation method, and fitness function. Gaidhane [11] et al. enhanced exploration by integrating the information-sharing strategy from the artificial bee colony, while retaining the grey wolf optimizer's exploitation capabilities through its leadership hierarchy. Han [14] et al. proposed an IGWO-IAPF algorithm based on the fusion of an improved grey wolf optimizer and an improved artificial potential field algorithm. Waypoint attraction is added to the traditional artificial potential field algorithm based on force field, and an optimized individual position update strategy is used to coordinate the search capability of the algorithm to meet the requirements of 3D path planning. Wang [44] et al. introduced an eight-node search method into the traditional A-star algorithm to minimize the steering tendency of artificial intelligence transportation robots. Loganathan [20] et al. navigated efficiently and obstacle-avoidantly towards a target in less time by synergizing the strengths of two heuristic algorithms. Niu [30] et al. generated a real-time dynamic path planning method based on an improved interferometric hydrodynamic system and artificial neural networks to improve path quality and computational efficiency. This combination of improved algorithms results in relatively smooth and cost-effective UAV paths.

It is worth noting that certain complex strategies require the tuning of numerous parameters, and optimization problems are highly sensitive to these parameter settings [5,46]. Therefore, enhancing the convergence speed and solution quality of the planner, while ensuring that UAV motion is collision-free and feasible, remains a significant challenge. Although many researchers have extensively employed meta-heuristics to address UAV path planning and some have achieved notable improvements with evolutionary algorithms, the overall research results in UAV path planning remain limited. There is a need for more in-depth study of the two core mechanisms of population intelligence algorithms: exploitation and exploration.

III. Path Planning Cost Function

Assuming the UAV maintains a predetermined flight speed, the path planning problem can be simplified to a static path planning minimization problem. To align with the actual requirements of UAV operations, the cost function for UAV path planning is defined by considering the range length cost, flight altitude cost, threat cost, and smoothing cost. These factors are mathematically represented as follows.

$$F\left(X_i\right)=\sum_{k=1}^{4} b_k F_k\left(X_i\right) \tag{1}$$

Where X_i is the decision variable, a list of n waypoints (x,y,z); b_k is the weight of each cost function, set with reference to the literature [32]; and F_k is the kth cost function.

A. Cost of Track Length

The length of a UAV flight path should be as short as possible to save energy consumption. If the flight path is transformed into a number of waypoints to be flown over by the UAV, the Euclidean distance between two neighbouring waypoints is taken as the length of each segment, and the cost of the range length for a particular path is then calculated as follows.

$$F_1\left(X_i\right)=\sum_{i=1}^{n-1} \square\, \vec{P}_{ij}\vec{P}_{i,j+1} \,\square \tag{2}$$

B. Cost of Threat

Considering the complexity of threat modeling and the difficulty of obtaining real data, the threat environment is simplified by representing the threat region as a cylinder with a constant radius. The radius of action of the threat region is equal to the radius of the cylinder, as shown schematically in Fig. 2.

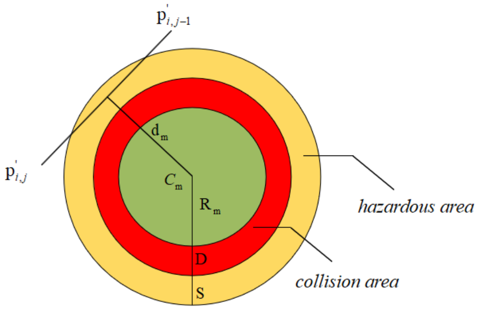

Fig. 2. Scope of the flight threat.

For a section of path, the threat cost is calculated as:

$$F_2(X_i)=\sum_{j=1}^{n-1}\sum_{m=1}^{M} T_m(\vec{P}_{ij}\vec{P}_{ij+1}) \tag{3}$$

$$T_m=\begin{cases}0, if\, d_m > S+D+R_m \\ (S+D+R_m)-d_m, if\, D+R_m < d_{m,}, S+D+R_m \\ \infty, if\, d_{m,}, D+R_m\end{cases} \tag{4}$$

C. Cost of High

The UAV's flight altitude is typically constrained by both minimum and maximum altitude limits. The altitude cost is calculated as follows.

$$F_3(X_i)=\sum_{j=1}^{n} H_{ij} \tag{5}$$

$$H_{ij}=\begin{cases}\left|h_{ij}-\dfrac{(h_{\max}+h_{\min})}{2}\right|, if \;\; h_{\min}\le h_{ij}\le h_{\max} \\ \infty, otherwise\end{cases} \tag{6}$$

D. Cost of Smoothing

The primary flight angle control parameters for a UAV are the horizontal steering angle and the vertical pitch angle. These parameters must comply with the UAV's actual angle constraints; otherwise, the trajectory planning model will fail to produce a viable flight path. The horizontal steering angle φ_{ij} is the angle between two consecutive path segments projected onto the horizontal plane, and the vertical pitch angle θ_{ij} is the angle between two consecutive path segments projected onto the vertical axis. These angles are calculated as follows.

$$\varphi_{ij}=\arctan\left(\frac{\left\|\vec{P}'_{ij}\vec{P}'_{i,j+1}\times\vec{P}'_{i,j+1}\vec{P}'_{i,j+2}\right\|}{\vec{P}'_{ij}\vec{P}'_{ij+1}\cdot\vec{P}'_{i,j+1}\vec{P}'_{ij+2}}\right) \tag{7}$$

$$\theta_{ij}=\arctan\left(\frac{z_{i,j+1}-z_{ij}}{\left\|\vec{P}'_{ij}\vec{P}'_{i,j+1}\right\|}\right) \tag{8}$$

$$F_4(X_i)=a_1\sum_{j=1}^{n-2}\varphi_{ij}+a_2\sum_{j=1}^{n-1}\left|\theta_{ij}-\theta_{i,j-1}\right| \tag{9}$$

IV. Proposed QGWO

A. Grey Wolf Optimizer

The implementation of the grey wolf optimizer involves four classes of grey wolves: α, β, δ, and ω. In the optimization process, each wolf's position represents a potential solution. The global solution is identified by using the α, β, and δ wolves as the optimal, suboptimal, and better solutions, respectively, while directing the ω wolves to promising regions. The grey wolf pack progressively approaches and encircles the prey as described by Eq. (11).

$$D_r=\left|C\cdot X_p(t)-X(t)\right| \tag{10}$$

$$X(t+1) = X_p(t) - A \cdot D \tag{11}$$

Where t is the current iteration number, $X_p(t)$ is the position of the prey; D_r is the encircling step; A and C are random vectors, determined by Eq. (12) and Eq. (13).

$$A = 2a \cdot r_1 - a \tag{12}$$

$$C = 2 \cdot r_2 \tag{13}$$

Where r_1 and r_2 are random numbers between [0,1]; a is the convergence factor, which decreases linearly from 2 to 0 as the number of iterations increases.

$$\begin{cases} X_1(t+1) = X_\alpha(t) - A \cdot \left| C \cdot X_\alpha(t) - X(t) \right| \\ X_2(t+1) = X_\beta(t) - A \cdot \left| C \cdot X_\beta(t) - X(t) \right| \\ X_3(t+1) = X_\delta(t) - A \cdot \left| C \cdot X_\delta(t) - X(t) \right| \end{cases} \tag{14}$$

$$X(t+1) = (X_1 + X_2 + X_3)/3 \tag{15}$$

The other grey wolves in the population update their positions based on the positions of the α, β, and δ wolves.

B. Position Update Incorporating the Aquila Optimizer

The grey wolf optimizer, with its simple structure, strong local search capability, and ease of application, has a certain degree of competitiveness among intelligent algorithms. However, under the influence of the linear convergence factor, search mechanism and single position update method, it is difficult to balance local exploration and global exploitation, i.e., the phase transition of the grey wolf optimizer is completely determined by a.

Thus, the hybrid algorithm is enhanced by integrating the extended and reduced exploration strategies from the aquila optimizer (AO) [1], known for its robust global search capability. The primary objective is to augment the algorithm's capacity to escape local optima while leveraging the population to explore the solution space comprehensively.

$$X(t+1) = X_\alpha(t) \cdot (1 - t/T) + (X_M(t) - X_\alpha(t) \cdot r_1) \tag{16}$$

$$X_M(t) = \frac{1}{N} \sum_{i-1}^{N} X(t) \tag{17}$$

In the extended exploration strategy, the aquila optimizer completes the identification of the prey area and conducts high-altitude flight followed by a vertical dive to select the optimal hunting area. During this process, the aquila flies at a high altitude to pinpoint the prey location, characterized by its mathematical model shown in Eq. (16), where $X_M(t)$ represents the average position of all individuals and N denotes the population size.

$$X(t+1) = X_\alpha(t) \cdot levy(D) + X_R(t) + (y - x) \cdot r_2 \tag{18}$$

$$\sigma = \Gamma(1+\beta) \cdot \sin(\pi\beta/2) \Big/ \Gamma(1+\beta/2) \cdot \beta \cdot 2^{\beta - 1/2} \tag{19}$$

$$levy(D) = 1.5 \cdot u \cdot \sigma \Big/ |v|^{\frac{1}{\beta}} \tag{20}$$

$$x = (r_3 + U \cdot D_1) \cdot \sin(-0.005 \cdot d + 3\pi/2) \tag{21}$$

$$y = (r_3 + U \cdot D_1) \cdot \cos(-0.005 \cdot d + 3\pi/2) \tag{22}$$

The reduced exploration strategy corresponds to the isometric flight of the aquila's short gliding attack, during which the aquila locks the prey target from high altitude and hovers above the target to prepare for launching the attack, and its mathematical model is shown in Eq. (18). Where, $levy(D)$ is the Lévy flight distribution number and D is the dimension of the problem; $X_R(t)$ is the position of the random individual at t iterations; x and y denote the random shapes in the search; $r_3 \in [1,20]$ is used to fix the search period; U is a fixed constant and d is an integer within [1, D].

Compared to the original grey wolf optimizer, the position update after incorporating the aquila optimizer makes full use of the available search information, incorporates interactions between individuals, and weakens the absolute influence of α, β, and δ wolves on individuals. The average position of all individuals is considered when performing the position update in the expanded exploration, instead of simply moving only in the direction of the three wolves with the lowest fitness values. Furthermore, the Lévy flight used in the reduced exploration avoids overdependence of the grey wolf population to fall into a local optimum due to the fact that α wolves have much lower fitness values than β and δ wolves, and the inclusion of the position of random individuals weakens the influence of the α wolves, while at the same time increasing the randomness of the algorithm.

C. Q-learning Guided Search

The grey wolf optimizer inherently lacks the capability to store search information, relying solely on fitness comparisons to identify the top three ranks of grey wolves. This, coupled with an uneven exploration and exploitation phase, poses challenges in escaping local optima. To address this limitation, Q-learning is introduced to guide the search of the grey wolf optimizer with an improved position updating method. In Q-learning, the Q-table can be regarded as the agent's experience, while the reward table represents a combination of behaviors and states, rewarding or punishing the agent accordingly [51]. Each agent accumulates experience and selects optimal actions by exploring the environment in specific iterations, updating the corresponding Q-value according to the Bellman equation.

$$\begin{aligned} Q(s^{t+1}, a^{t+1}) = Q(s^t, a^t) + \\ \lambda[R_{t+1} + \gamma \max_a Q(s^{t+1}, a^t) - Q(s^t, a^t)] \end{aligned} \tag{23}$$

Where λ is the system learning rate and $0<\lambda\leq 1$; γ is the reward decay rate and $0<\gamma\leq 1$; R is the reward value; and $\max_{a} Q(s^{t+1},a^{t})$ denotes the gain of the highest value action in the next state.

In the improved algorithm, where the grey wolf population acts as an agent and the choice of location update methods acts as a collection of agent actions, then a mapping between the improved grey wolf optimizer and Q-learning can be achieved. Q-learning helps the algorithm to store information about the search space gained during iterations, giving positive rewards to well-performing prey and negative rewards to poorly-performing prey, and helps to find from the three location update methods the most suitable choice, making the exploration and development phases of the algorithm more balanced. The primary Q-learning-based guided search can be summarized in the following five steps.

1) Initialise the Q-table as the zero matrix with the following reward table;

$$\begin{bmatrix} -1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix} \tag{24}$$

2) Determine the current best action for the iteration based on the values stored in the current state Q-table;

3) Execute the selected action and compute the new adaptation and reward, calculated as follows;

$$reward=\begin{cases} 1 \quad if \quad fitness \;\; increases \\ -1 \; if \quad fitness \;\; decreases \end{cases} \tag{25}$$

4) Use (23) to update the Q-table;

5) Determine the iteration termination condition of the algorithm and repeat the execution if it is not satisfied.

D. Laplace Crossover Variant Perturbation

In the later iterations of the original grey wolf optimizer, individual grey wolves tend to rapidly converge and cluster near the current optimal position. If this position is not the global optimum, the grey wolf population may struggle to explore beyond the limited search range, thus failing to discover the global optimal position and becoming trapped in a local optimum. Introducing mutation perturbation can enhance the diversity of the grey wolf population [12], enabling the algorithm to escape local optima and explore other regions of the solution space. This increases the likelihood of finding the global optimum.

Common variation perturbations include the introduction of differential operators, Cauchy operators [45], Gaussian operators [53], etc. Differential operators involve mutation and selection operations, whereas Cauchy operators and Gaussian operators are commonly used for all individuals throughout the iterative process, which leads to an increase in algorithm complexity. For this reason, the Laplace cross mutation is used to perturb the positions of α and β wolves after updating the original grey wolf optimizer, and the fitness is calculated to select the best. The Laplace distribution density function and the α and β wolf position cross variations are as follows.

$$f(x)=\frac{1}{2b}e^{-\frac{|x-\mu|}{b}} \tag{26}$$

$$X_{\alpha}(t+1)^{'}=X_{\alpha}(t)+\beta\left|X_{\alpha}(t)-X_{\beta}(t)\right| \tag{27}$$

$$X_{\beta}(t+1)^{'}=X_{\beta}(t)+\beta\left|X_{\alpha}(t)-X_{\beta}(t)\right| \tag{28}$$

Where μ is a position parameter and a real number, b is a scale parameter and greater than 0, and β is the Laplace random distribution number. Shail [9] et al. introduced the Laplace operator after each iteration for the variance perturbation, without considering the effect of the perturbation amplitude on the results in different iteration periods. From the Laplace density function curves under different b values in Fig. 3, it can be seen that, from the vertical direction, the peak near the center of $b=0.5$ is larger than that of $b=1$, while the peaks at the two ends are smaller, and the probability of generating random numbers in the center region is higher. From the horizontal direction, the closer to the ends of the horizontal axis at $b=1$ the slower the decline, and the easier it is to generate random numbers away from the origin.

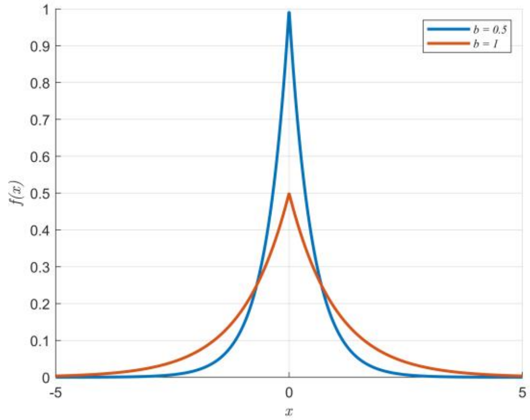

Fig. 3. Laplace density functional curves.

To efficiently escape local optima, the Laplace distribution density function with a scale parameter of $b=0.5$ is employed to perturb the positions of the α and β wolves in the later iterations of the original grey wolf optimizer. This choice is motivated by the higher probability of generating random numbers near the central value, which enables the grey wolf to finely search the optimal region with a smaller step size. Consequently, it increases the likelihood of discovering the global optimal solution.

E. QGWO Algorithm Flow

QGWO distinguishes itself through its capacity to store search information throughout the iteration process and dynamically switch between various position updating methods to efficiently locate the global optimal solution. Drawing from the exposition in the initial four subsections of this chapter, the algorithmic flowchart of QGWO is depicted in Fig. 4.

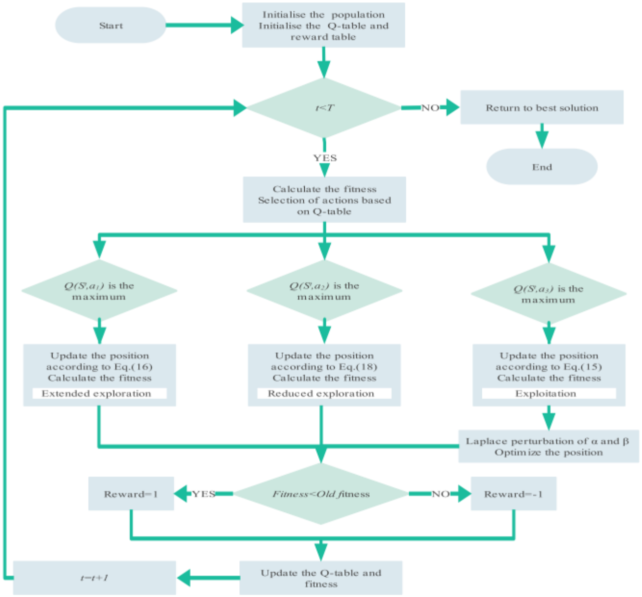

Fig. 4. Flowchart of QGWO.

QGWO distinguishes itself through its capacity to store search information throughout the iteration process and dynamically switch between various position updating methods to efficiently locate the global optimal solution. Drawing from the exposition in the initial four subsections of this chapter, the algorithmic flowchart of QGWO is depicted in Fig. 4.

V. Simulation Experiments and Analyses

The main objective of this section is to provide an in-depth study of the performance of the newly proposed QGWO. To ensure the comprehensiveness of the analysis, we apply QGWO to six 3D path planning models of different complexity, complemented by 10 algorithms for comparison. The algorithms used for comparison include the standard GWO, three excellent improved versions: AGWO [24], AGWO-CS [39], PSOGWO [40], and the widely cited and excellent algorithms PSO [43], WOA [26], HHO [15], SOA [8], MPA [10], DBO [49]. It is noteworthy that the specific parameter settings of all algorithms utilized for comparison were directly sourced from the references without any alterations. This rigorous benchmarking approach establishes a robust foundation for evaluating the optimization capabilities of QGWO.

A. Simulation of Terrain Environment and Parameters

To effectively validate the efficacy of the improved algorithm, a real digital elevation model of Christmas Island, Australia, along with another data map featuring diverse terrain structures, was utilized as the terrain environments in the UAV path planning problem. Various threat objects, depicted as black cylinders, were introduced to simulate terrains of varying complexity, resulting in a total of six terrain scenarios for path planning comparison tests. The specific map ranges and start/end coordinates are outlined in Table I. Each algorithm employed in the simulation experiments was configured with a maximum iteration number of 500 and a population size of 30. Furthermore, each algorithm was run independently for 30 iterations to mitigate any chance factors.

TABLE I. Map Information

Scenario	***Map range***	***Start***	***End***
1,2,3	[1100,900]	[200,100,150]	[800,800,150]
4,5,6	[450,450]	[10,10,200]	[400,400,150]

B. Compared to Other GWO Variants

GWO, AGWO, AGWO-CS, PSOGWO, and QGWO are combined for trajectory planning based on the above environments, and the cost curves and top views of the planning results are shown in Fig. 5 and Fig. 6. Among the six scenarios featuring diverse terrains and threats, the data presented in Table II demonstrates the significant superiority of QGWO in terms of optimal path planning cost. Compared to GWO and other variants, QGWO achieves the best cost optimal cost every time and effectively reduces it by 1.34%, reduces the standard deviation by 70.92%, and has the smallest average of 30 independent runs, inferior to AGWO-CS only in terms of standard deviation in scenario 2. The data depicted in Table II illustrates the effectiveness of the QGWO enhancement, evidencing its competitive edge. Furthermore, the methodology sustains a balanced approach between developmental and exploratory phases, which guarantees consistent performance amidst diverse complexity scenarios. Such stability is pivotal for real-world deployments, bolstering the method's credibility and reliability in practical applications.

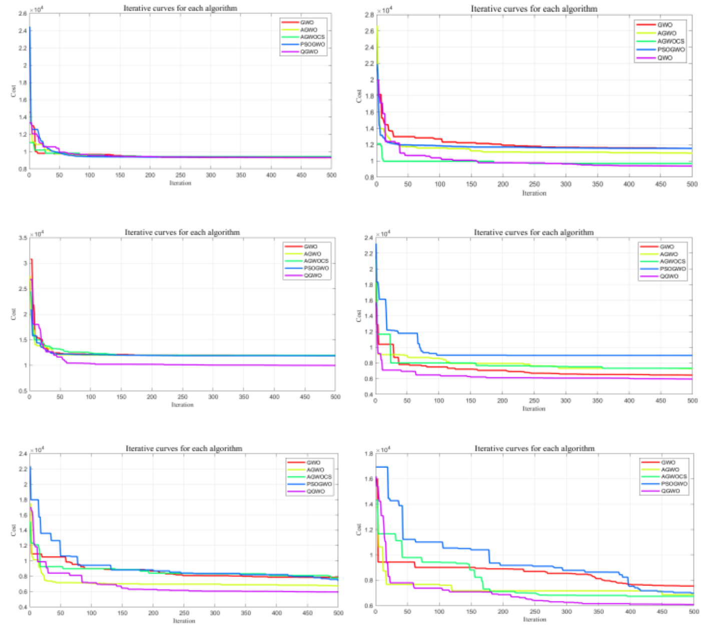

Fig. 5. Convergence curves of QGWO and other GWO variants.

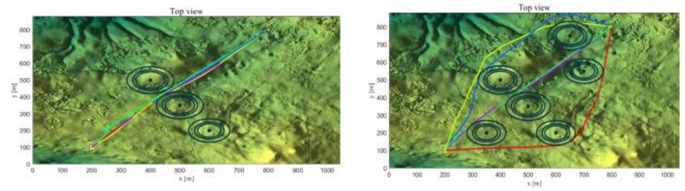
Fig. 5 provides an in-depth analysis of the algorithm's convergence behavior by illustrating the evolution of the best fitness across iterations for each variant. In simpler scenarios, QGWO demonstrates significantly faster convergence compared to most GWO variants. Additionally, QGWO effectively navigates local optimum traps. In the most complex scenario (scenario 6), the flight paths generated by GWO tend to be longer, resulting in increased fuel consumption. More critically, its flight paths are closer to risky regions, posing a major safety hazard and increasing the likelihood of flight accidents. Q-learning enhances QGWO by storing information about the search space throughout the iterations. This allows the algorithm to select an optimal position update method for each iteration. Consequently, individuals can escape local optima through a versatile position update formula and a variant perturbation strategy.



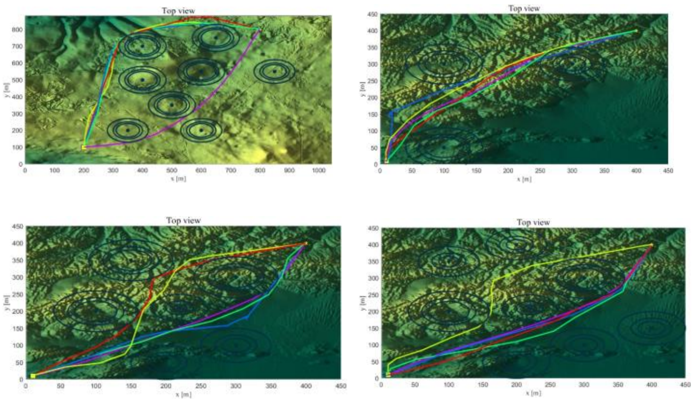


Fig. 6. Top view of QGWO and other algorithms.

The top view of Fig. 6 specifically shows the paths planned by each algorithm, and it can be directly seen that the paths generated by GGWO in scenes 2, 3, and 4 are too curved and are not optimal, i.e., there is a deficiency in the global search capability of 3D path planning. However, QGWO performs well in different types of scenarios, and even in scenario 3 only QGWO finds the globally optimal path.

C. *Compared to Other Heuristic Algorithms*

To effectively showcase the outstanding performance of QGWO in UAV 3D path planning, the six aforementioned scenarios are utilized to compare QGWO with several other competitive state-of-the-art algorithms.

According to the data in Table III, DBO achieves the optimal path planning cost in scenario 3, with QGWO ranking second, trailing by only 6.23 units. However, in the remaining five scenarios, QGWO ranks first across all three metrics, demonstrating its reliability. The convergence curves in Fig. 7 show that QGWO has the lowest initial best fitness value and the fastest convergence rate. It converges more rapidly in the complex scenarios 3, 4, 5, and 6, particularly in the later iterations when most algorithms fall into local optima. QGWO relies on the Laplace variant to explore the current position in small steps, allowing it to continue converging. This indicates that QGWO not only starts from a better position but also reaches the target solution more efficiently than the control algorithms, highlighting its superior optimization capability. Overall, QGWO, enhanced by integrating multiple strategies, performs exceptionally well in UAV 3D path planning, further validating the effectiveness of the proposed enhancement strategies.

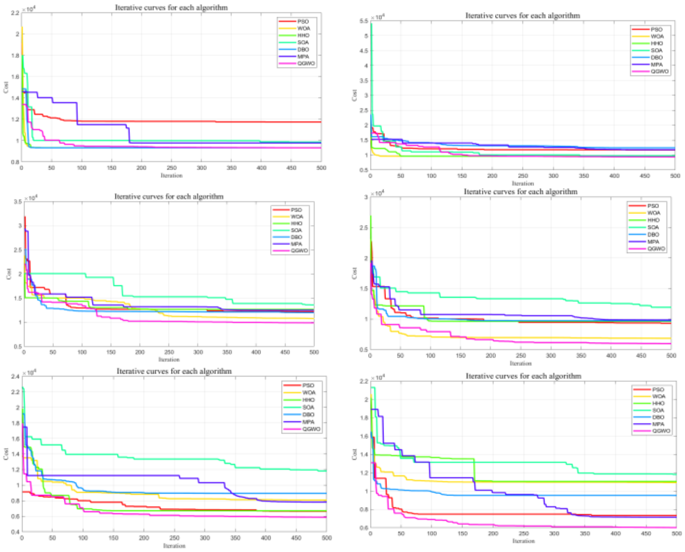

Fig. 7. Convergence curves of QGWO and other algorithms.

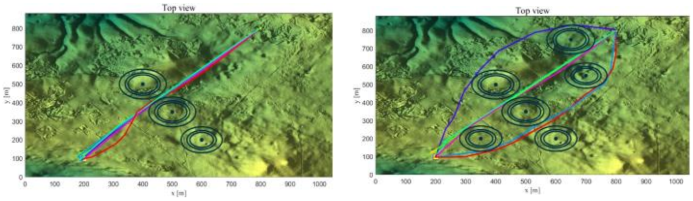
Fig. 8 shows the top view of the paths planned by the algorithms, illustrating their ability to safely navigate to the target point without colliding with obstacles. In the simplest scenario, there is minimal disparity between the paths planned by the various algorithms, noticeable only in the final cost. However, as the scenario's complexity increases and obstacles become denser, the cost disparity widens, highlighting the performance advantage of QGWO. In the remaining five scenarios, the algorithm labeled SOA performs the worst, often following the outermost obstacles and producing tangled routes. The paths planned by MPA and DBO successfully avoid risk areas but are uneven and feature sharp turns, increasing the flight distance. In contrast, the optimized QGWO effectively addresses these issues, resulting in smoother and more efficient paths. Paths generated by other comparison algorithms also exhibit more pronounced twists and turns.



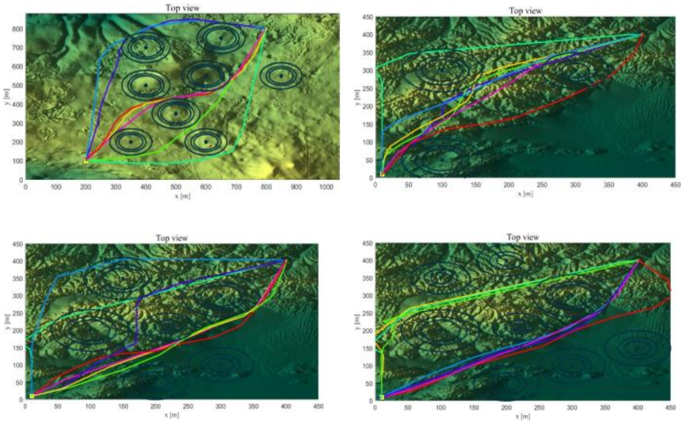


Fig. 8. Top view of QGWO and other algorithms.

Fig. 9 displays the side and 3D views of the paths generated by QGWO for scenarios 3 and 6, which are the two most complex scenarios. The depicted paths exhibit notable smoothness and efficiency, maintaining appropriate flight altitudes relative to the terrain. These visualizations underscore the QGWO's capability to navigate challenging environments effectively, avoiding obstacles while optimizing the flight trajectory. The algorithm's ability to generate such high-quality paths in the most complex scenarios highlights its robustness and reliability, further validating its suitability for real-world applications where terrain complexity poses significant challenges.

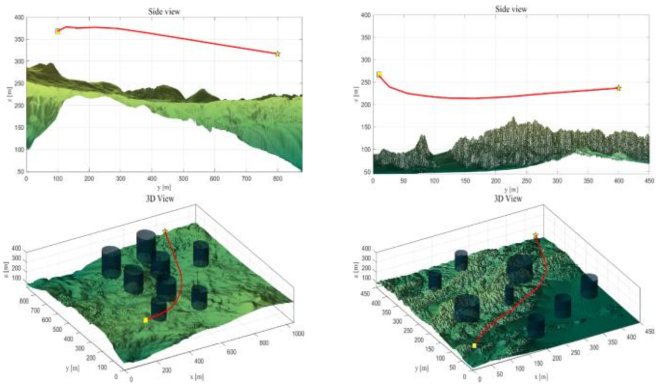

Fig. 9. QGWO path planning in scenarios 3 and 6.

D. *Statistical Test*

To compare the performance of the algorithms, the optimum, mean, and standard deviation were calculated from 30 experiments for each algorithm in the simulation. To further assess the differences between QGWO and other algorithms, a statistical analysis was conducted using the Wilcoxon rank-sum test with a 5% significance level. This test determined whether there were significant differences between QGWO and the other algorithms. The results are presented in Table IV.

TABLE IV. PATH PLANNING COSTS GENERATED BY QGWO AND OTHER HEURISTIC ALGORITHMS

Scenario	***PSO***	***WOA***	***HHO***	***SOA***	***DBO***	***MPA***	***GWO***	***AGWO***	***AGWO_CS***	***PSOGWO***
1	**2.92E-10**	**4.29E-08**	**2.26E-08**	**1.85E-07**	**5.35E-08**	**8.01E-12**	**6.14E-05**	**1.73E-06**	**4.74E-06**	**1.53E-05**
2	**3.02E-11**	**3.69E-11**	**3.34E-11**	**3.02E-11**	3.69E-01	**2.92E-12**	**2.31E-06**	**1.61E-10**	**2.38E-07**	**6.70E-11**
3	**3.25E-12**	**1.09E-10**	**3.02E-11**	**4.50E-11**	**1.17E-09**	**3.69E-11**	**1.60E-03**	**4.98E-11**	**5.10E-11**	**7.50E-11**
4	**2.09E-10**	**4.18E-09**	**5.49E-11**	**3.53E-10**	**1.93E-05**	**4.17E-11**	**3.42E-04**	**2.01E-07**	**4.46E-04**	**6.55E-04**
5	**2.23E-09**	**9.76E-11**	**3.02E-11**	**5.18E-10**	**7.75E-06**	**2.44E-09**	**3.08E-03**	**7.96E-08**	**4.80E-06**	**5.14E-06**
6	**2.15E-10**	**2.87E-120**	**3.02E-11**	**3.02E-11**	**1.29E-06**	**7.38E-10**	**6.97E-03**	**2.03E-09**	**2.49E-05**	**3.19E-07**

The test results in Table IV show that in 98.33% of cases, the p-value for comparisons between QGWO and other algorithms across six different complexity scenarios is less than 0.05, leading to the rejection of the null hypothesis. This indicates a significant difference in computational performance between QGWO and the other 10 algorithms, confirming the statistical superiority of the proposed QGWO.

VI. CONCLUSION

This paper introduces an enhanced version of the Q-learning guided optimization algorithm, termed QGWO, to address certain limitations of the grey wolf optimizer in UAV 3D path planning applications. QGWO acknowledges the stringent constraints inherent in UAV 3D path planning and, firstly, integrates two robust global search strategies from the aquila optimizer into the original grey wolf population update process, thereby enhancing the algorithm's capability to escape local optima. Secondly, recognizing that the phase transition of the original grey wolf optimizer is solely determined by the convergence factor, Q-learning is introduced to guide the search process after improving the position update method. This facilitates the algorithm in storing iterative information, accelerates population convergence, and balances exploration and exploitation. Finally, Laplace cross variation is employed to perturb the positions of α and β wolves post-updating the original grey wolf optimizer, aiding in fine-tuning the search within the optimal region and thereby improving the likelihood of finding the global optimal solution.

For the 3D path planning problem, the simulation experiments design a cost function with multi-factor co-constraints and construct six terrain scenarios of varying complexity. Comparison experiments between QGWO and ten other high-performing heuristic algorithms conclude that QGWO exhibits exceptional performance in both acquiring optimal cost and delivering high-quality, stable solutions.

Future research will aim to fully realize the potential of QGWO. We are particularly interested in exploring its application in various domains such as logistics, healthcare, and energy management, where its optimization capabilities can address complex challenges. Additionally, we plan to enhance the algorithmic structure of QGWO to further improve its performance and investigate its integration with other computational techniques, such as machine learning models, to create hybrid approaches. This future work aims not only to push the boundaries of algorithmic optimization but also to provide practical solutions to pressing problems across various industries.

Security Enhanced Edge Computing Task Scheduling Method Based on Blockchain and Task Cache

Cong Li
The Information Engineering Institute, Yellow River Conservancy Technical Institute, Kaifeng, 475004, China

Abstract*—Aiming at edge computing nodes' limited computing and storage capacity, a two-layer task scheduling model based on blockchain and task cache was proposed. The high-similarity task results were cached in the edge cache pool, and the blockchain-assisted task caching model was combined to enhance system security. The genetic evolution algorithm was used to solve the minimum cost that the optimal scheduling model can obtain. The genetic algorithm's initialization and mutation operations were adjusted to improve the convergence rate. Compared with algorithms without cache pooling and blockchain, the proposed joint blockchain and task caching task scheduling model reduced the cost by 9.4% and 14.3%, respectively. As the capacity space of the cache pool increased, the system cost gradually decreased. Compared with the capacity space of 3GB, the system cost of 10Gbit capacity space was reduced by 10.6%. The system cost decreased as the computing power of edge nodes increased. Compared with edge nodes with a computing frequency of 8GHz, the nodes cost at 18GHz was reduced by 36.4%. Therefore, the proposed edge computing task scheduling model ensures the security of task scheduling based on reducing delay and control costs, providing a foundation for modern industrial task scheduling.

Keywords—Blockchain; task cache; edge computing; task scheduling; industrial internet

I. Introduction

With the developing 5G communication and the Internet of Things, many intelligent devices with computing power are widely used in industrial automation systems. The rapid increase of intelligent equipment in factories leads to the explosive growth of industrial Internet data [1]. Due to local devices' limited computing resources and storage capacity, some resource-intensive tasks will be scheduled to cloud servers for processing. However, when cloud servers are deployed far from local devices, the interaction between tasks and data can result in significant latency, posing a risk of data leakage and attack [2-4]. The introduction of edge computing into the industrial Internet can satisfy the real-time demand, security, and reliability in the industry. By scheduling tasks to the edge, industrial equipment has sufficient resources to handle more complex tasks [5-7]. When the resource results of a task have high similarity, deploying task caching can reduce repeated resource calls [8]. Gao et al. proposed a case layer solution of joint unloading scheduling and resource allocation to reduce task delay and energy consumption in on-board edge computing, combining deep Q network and gradient descent method. This algorithm effectively reduced latency and energy consumption [9]. Chen et al. built an edge computing container deployment model for the delay-sensitive problem of tasks. Through ameliorating the initialization, crossover, and other operations of Genetic Algorithm (GA), the optimal deployment of containers was achieved. Compared with traditional algorithms, the deployment cost of this model was reduced by 22% [10]. Although edge computing and task caching have many advantages, the diversity of servers brings an additional burden to task scheduling.

Blockchain is a distributed accounting technology that integrates multiple technologies such as distributed storage, cryptography, and consensus mechanisms. It can ensure data security, tamper resistance and privacy, and can well match distributed edge computing [11-13]. The introduction of blockchain into a cloud-edge-end three-layer architecture can enhance industrial security. The collaboration between edge servers and blockchain enables secure data transmission and reliable storage, reducing computational costs and latency [14-16]. Rivera A V et al. proposed a secure task-sharing blockchain framework to enhance user experience. They set up a trusted cooperation mechanism in multi-access edge computing and designed cooperation incentives to speed up computing. This framework ensured trust between servers and enabled real-time task sharing [17]. Zhang H et al. put forward a mobility management scheme using blockchain to address the security of unloading tasks. They used Lyapunov optimization algorithm, combined with base station wireless handover and service migration decisions, to achieve dynamic optimization of the target. This solution effectively reduced the latency and failure rate of computing tasks [18]. Chen J et al. proposed a decentralized management scheme based on blockchain to address the transparency in collaboration benefits. They used diligent proof and delegated diligent proof consensus mechanisms, combined with sequential decision-making and Byzantine fault-tolerant algorithms, to improve the time-sensitivity of edge collaboration. This scheme had high security and fault tolerance [19]. Liu R et al. proposed a trusted data storage mechanism using blockchain to address data management security in the industry. Combining sharding and a two-layer Merkle tree structure, they utilized random low-density parity correction code encoding to reduce storage pressure on lightweight nodes. This mechanism effectively reduced the network load of nodes and improved data storage security [20]. Li G et al. proposed edge bandwidth and storage optimization algorithms to overcome network overload caused by distributed transmission. They built a dynamic blockchain and combined it with a network simulator to construct blockchain. This algorithm improved both transmission bandwidth efficiency and blockchain construction efficiency [21].

The computing power and storage capacity of edge servers are stronger than those of local devices, and edge computing has lower task latency. With the explosion of industrial task data, the resources of edge servers are gradually scarce, and the task scheduling problem of edge computing is NP hard. Although there are many researches on edge computing task scheduling, there are some problems. For multi-objective optimization problems, most studies are based on the optimization objectives of time delay and energy consumption to develop task schedules. For complex and repetitive tasks in the industrial Internet, task similarity should be taken into account to improve edge computing capability and efficiency. For data security issues, most studies mainly focus on data security and privacy, with little consideration given to the latency and energy consumption caused by them. Delay and energy consumption should be included, and the best outcome plan should be balanced between performance and security levels. Therefore, the research will combine the blockchain, edge computing and task cache, and propose a security enhanced edge computing task scheduling method based on the blockchain and task cache. On the basis of ensuring data security, appropriate task scheduling strategies will be developed to give full play to various technical advantages to meet the demand for delay, cost and security in the industrial scenario. Faced with the enormous security and resource pressures brought by massive data on industrial equipment, an optimization model is established to ensure the secure scheduling of tasks to the greatest extent possible. Considering the problem of high task similarity in industrial Internet, the research adopts the improved least access frequency algorithm to improve the hit rate of cache content. It combines block chain technology with edge computing to solve the problem of data leakage at edge nodes. As a supplement to the cache pool, blockchain increases task cache capacity and reduces task processing time. Therefore, the task scheduling method proposed in the study provides technical support for industrial task scheduling.

II. Methods and Materials

To reduce the delay and cost of edge computing in the industrial Internet, this research combines task caching and blockchain to design new algorithms to improve the hit rate of task caching. Blockchain and task cache are introduced into edge computing and combined with task scheduling strategy to improve the processing efficiency of tasks, reduce costs, and achieve reliable data storage and low overhead of task scheduling.

A. Blockchain-Based Edge Caching Model

The rapid development of intelligent devices makes the industrial Internet have higher requirements for resources. Due to local devices' limited battery, storage, and computing resources, offloading computing tasks to the cloud layer can cause additional network latency and bandwidth consumption. Therefore, adding an edge server layer between the cloud layer and the local device layer can alleviate the burden on the cloud network. Fig. 1 shows a blockchain-based cloud-edge-end system, which is divided into three layers, including cloud servers, edge servers, and local devices.

The local device layer is composed of industrial equipment and has minimal computing and information organization capabilities. The edge server layer is composed of edge devices with strong computing and caching capabilities, which can be used for mining in blockchain networks. The mining process consists of three steps: (1) Edge nodes add cached results to the blockchain and increase the task type of the cache pool. (2) When the task is scheduled to the edge server, this structure searches a cache pool and returns this result directly if it is found. If it is not found, it performs calculations locally and updates the cache pool and blockchain data. (3) For every new task type added to the edge node, it can receive corresponding rewards, increasing the interest of the edge server in mining. A cloud server layer owns powerful data storage and computing capabilities. When the total data in the blockchain network exceed its capacity, this system can upload some data requests to the cloud. These data in the industrial Internet are highly similar and have a large number. Storing relevant task data into the cache pool can speed up data processing. To ensure the cache pool security, the data source can only be task results processed by edge nodes and stored results in the blockchain. Fig. 2 shows the cache pool's data source.

The cache hit rate, task complexity, and promotion performance are important factors to measure the effectiveness of cache strategies, and cache strategies should be selected according to actual scenario needs. Based on the changes in tasks in industrial production, the Least Frequently Used (LFU) algorithm in traditional caching strategies is improved. A Task Caching of Improved LFU (TC-ILFU) algorithm is put forward to elevate the cache hit rate. The core of LFU is to prioritize the elimination of cache data with the lowest frequency of use. Fig. 3 shows the main idea of ILFU-TC. This algorithm establishes a time task frequency table, records the hit rate data of cached task content over a period of time, and determines whether new tasks can be added to the cache pool based on the hit rate.

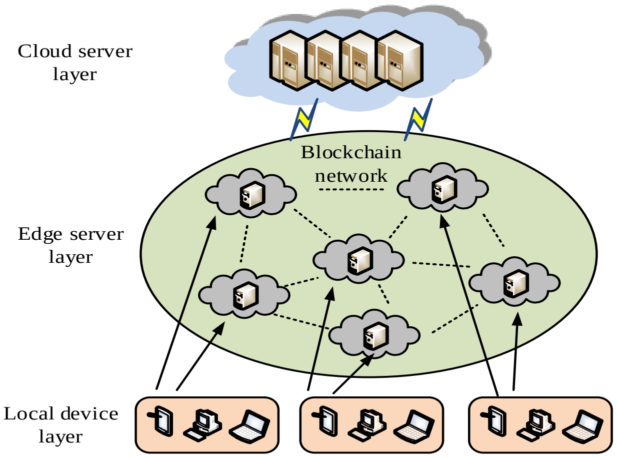

Fig. 1. Cloud-edge-end scheduling system based on blockchain.

Is the cache hit rate greater than the threshold?
Yes
No
Select data with higher task frequency to update the cache pool
End

Fig. 3. The main ideas of improved LFU.

The time task frequency table records the task requirements for a period of time. When a new task appears in the edge cache pool, the first step is to determine whether it has been cached. For tasks belonging to the cache pool, the hit frequency is directly increased by 1, and the time task frequency table is updated. If the task has not appeared in the cache pool, it is determined whether there is sufficient space and time based on the cache pool capacity. If the cache capacity space is sufficient, the hit frequency is set to 0, and the time task frequency table is updated. If the cache capacity space is insufficient, the system will replace the task with the minimum number of hits in the cache pool with the new task. At this point, the hit frequency is set to 0, and the time task frequency table is updated. The system calculates the hit rate during this period and compares it with the set cache threshold. If the hit rate is greater than this cache threshold, the task content cache matches the task's characteristics. If the hit rate is less than the cache threshold, this system will select data with higher task frequency from the task frequency table at that time and import it into the cache pool to update the cache pool data. The blockchain network can bring safe and reliable cache data to edge computing and ensure that edge nodes can safely exchange information. In blockchain, the probability of orphan blocks being generated is represented by Eq. (1).

$$P_{orp} = 1 - e^{-\eta\lambda(S_n)} \tag{1}$$

In Eq. (1), P_{orp} represents the probability of orphan blocks. η is a fixed value, $\eta = 1/600$. $\lambda(S_n)$ is a function of block size. The probability of generating new task blocks is represented by Eq. (2).

$$P_{new} = \frac{P_n}{H} e^{-\eta\lambda(S_n)} \tag{2}$$

In Eq. (2), P_{new} represents the probability of a new task block. P_n is the hashing capability of blockchain networks. H is the blockchain network's hash power. The reward for mining new task blocks at edge nodes is represented by Eq. (3).

$$R_n^{rew} = R\mu_n e^{-\eta\lambda(S_n)} \tag{3}$$

In Eq. (3), R_n^{rew} represents the mining reward. R is a task set.

B. Edge Computing Task Scheduling Algorithm

Due to local devices' limited battery capacity and computing resources, tasks are scheduled to edge servers for processing within the maximum latency allowed range. The local device generates tasks, and the task scheduling strategy follows constraints represented by Eq. (4).

$$x_{ij} \in \{0,1\}, i \in N, j \in M \tag{4}$$

In Eq. (4), x_{ij} is the scheduling location of the task.

$x_{ij}=1$ is the calculation of task i on edge server j. $x_{ij}=0$ means the processing of tasks on local devices. N is the total local device. M is the total edge server. Blockchain is a decentralized distributed storage ledger with high security and certainty. The limited capacity of the cache pool requires a diverse range of task types to be cached, ensuring that task scheduling has multiple selectivity. According to the task scheduling strategy, when a task is calculated on an edge server, this server needs sufficient computing power to process the task and return this result to the device. The uplink rate of local device scheduling tasks to edge servers is approximated using Shannon's formula, represented by Eq. (5).

$$V_{ij} = B\log_2\left(1+P_{ij}\varpi\right) = B\log_2\left(1+\frac{P_{ij}\left|h_i\right|\left|r_i\right|^{-a}}{\sigma^2}\right) \tag{5}$$

In Eq. (5), V_{ij} represents the transmission rate of local device i scheduling tasks to edge server j. B is the bandwidth. ϖ is the signal-to-noise ratio. P_{ij} is the transmission capacity of the device i. $\left|h_i\right|$ is channel interference. $\left|r_i\right|^{-a}$ is path decay. σ^2 is the power of Gaussian white noise. According to the task attributes, the upstream time for scheduling tasks from local devices to edge servers is represented by Eq. (6).

$$T_{ij} = \frac{r_{ij}}{V_{ij}} = \frac{r_{ij}}{B\log_2\left(1+P_{ij}\varpi\right)} \tag{6}$$

In Eq. (6), T_{ij} represents the transmission delay from the local device scheduling task to the edge server. r_{ij} is the local device's task data scale. The upload energy consumption of local devices is represented by Eq. (7).

$$E_{up} = \frac{e_1^l r_{ij}}{\zeta B\log_2\left(1+P_{ij}\varpi\right)} \tag{7}$$

In Eq. (7), E_{up} represents the upload energy consumption of the local device. ζ is the transmission amplifier efficiency of the device. Local device consumption is $E\left(e_{-1}^l, e_1^l, e_0^l\right)$. e_{-1}^l is idle local devices' energy consumption. e_0^l represents local computing tasks' energy consumption. e_1^l means local device transmission's energy consumption. The task is represented by Eq. (8) when processing on the local device.

$$T_i^l = \frac{c_i}{f_i^l} \tag{8}$$

In Eq. (8), T_i^l represents the calculation delay of the local device. c_i is the number of chips. f_i^l represents the computing power of local devices. The energy consumption of terminal devices for processing tasks is represented by Eq. (9).

$$E_0 = \kappa\left(f_i^l\right)^2 r_{wj} \tag{9}$$

In Eq. (9), E_0 represents the terminal calculation energy consumption. κ is a chip architecture coefficient. r_{wj} is the demand for computing power. Local device generates tasks. According to the task scheduling strategy, the tasks are offloaded to the edge server for computation, and edge caching and blockchain based edge caching models are established. When there is content cache in the cache pool, retrieve cached data according to task indexing requirements. When data exist, the system directly distributes cached results. The task processing time is represented by Eq. (10).

$$T_1 = T_{ij} + T^{select}\left(n\right) \tag{10}$$

In Eq. (10), T_1 represents the processing time of the task in the cache pool. $T^{select}\left(n\right)$ means data retrieval time. n is the cache data size. The energy consumption of the terminal server is represented by Eq. (11).

$$E_1 = E_{up} + e_{-1}^l T^{select}(n) \tag{11}$$

In Eq. (11), E_1 means the terminal server's calculated energy consumption in the cache pool. The cache pool's cache resources are limited. The edge caching model based on blockchain serves as an extension of the system cache pool. In blockchain, the processing time of tasks is represented by Eq. (12).

$$T_2 = T_1 + T^{find} = T_{ij} + T^{select}\left(n\right) + T^{find} \tag{12}$$

In Eq. (12), T_2 means the task processing time in the blockchain. T^{find} is the retrieval time. The terminal server's energy consumption is represented by Eq. (13).

$$E_2 = E_1 + e_{-1}^l T^{find} = E_{up} + e_{-1}^l T^{select}(n) + e_{-1}^l T^{find} \tag{13}$$

In Eq. (13), E_2 represents the computational energy consumption of the terminal server in the blockchain. The system does not retrieve the required task results in both the edge cache pool and the blockchain network. Under the constraint of delay, task computation can be performed on edge servers. The task calculation time is represented by Eq. (14).

$$T_i^e = \frac{r_{wj}}{f_i^e} \tag{14}$$

In Eq. (14), T_i^e represents the processing time of edge node i . f_i^e is the computing power of i . The task processing time is represented by Eq. (15).

$$T_3 = T_2 + T^{edge} = T_{ij} + T^{select}\left(n\right) + T^{find} + T_i^e \tag{15}$$

In Eq. (15), T_3 represents the task's total processing time. Edge nodes' energy consumption is represented by Eq. (16).

$$E_3 = E_{up} + e_{-1}^l T_3 \tag{16}$$

In Eq. (16), E_3 represents the computational energy consumption of the edge server. In the industrial Internet, the cache task scheduling strategy is implemented by considering time constraints, device computing capacity and storage capacity. The cost of blockchain rewards and task scheduling strategies constitutes the total system cost. To minimize task scheduling strategy's cost consumption, an optimal system cost can be obtained, represented by Eq. (17).

$$\begin{cases} E_{all}\left(x,y,z\right) = \sum_{i=1}^{n} \left\{ \begin{array}{l} \left\{\left(1-x_i\right)E_0\right\} \\ +\left\{x_i\left\{y_iE_1+\left(1-y_i\right)\left[z_iE_2+\left(1-z_i\right)E_3\right]+E_{up}\right\}\right\} \end{array} \right\} \\ F_{all}\left(x,y,z\right) = \varepsilon E_{all}\left(x,y,z\right) - \left(1-z_i\right)R\mu_n e^{-\eta\lambda(Sn)} \end{cases} \tag{17}$$

In Eq. (17), $E_{all}\left(x,y,z\right)$ means the system's total energy consumption. $F_{all}\left(x,y,z\right)$ is the optimal cost. y and z are both the positions of task results, and $y,z \in \left\{0,1\right\}$. ε is a conversion coefficient between energy consumption and cost. Edge computing task scheduling strategy for task caching belongs to multi-constraint optimization problem. As the tasks and cached data increase, the solution space of tasks also increases. Finding the optimal feasible solution in a vast solution space is crucial. Therefore, genetic evolutionary algorithms are used to solve for the lower cost that the optimal scheduling strategy can achieve. Fig. 4 shows the Task Scheduling Algorithm based on Genetic Optimization (TSA-GO). Firstly, the task is initialized. The fitness function is used to determine the individual superiority or inferiority. By combining selection, crossover, and mutation operations, the optimal solution of the scheduling strategy is solved, achieving low-cost control.

Fig. 4. Task scheduling strategy based on differential genetic evolution.

The task scheduling location adopts binary encoding, with 0 and 1 indicating that the task is executed on the local device and edge server, respectively. During initialization, TSA-GO collects task deadlines, cache status, power, and device computing power to determine task resource requirements and determine task execution locations. The fitness function is determined by blockchain rewards and task scheduling strategies, and preliminary feasible solutions that meet the conditions are obtained. This system uses roulette wheel to select individuals with high fitness and combines single-point crossover to reduce the damage of crossover to the predetermined population. To prevent ineffective mutations in the algorithm, this study evaluates the mutated nodes. Random tasks in the task sequence serve as mutation points, and the probability of individual mutation is used to determine whether the task is mutated. The demand for resources in a task serves as a mutation point, and the mutation threshold is used to determine whether to mutate.

III. Results

This experiment verified the edge computing task scheduling algorithm based on blockchain and task cache. Firstly, an analysis was conducted on the impact of task cache pools and blockchain on costs. Subsequently, TC-ILFU was compared and analyzed with other caching algorithms. Finally, the performance of TSA-GO was analyzed under different task scheduling strategies and compared with other optimization algorithms.

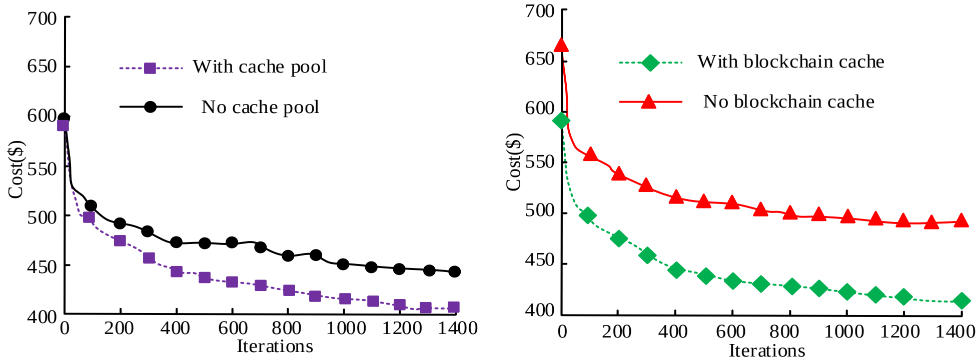
A. Experimental and Analysis of Edge Caching Model Based on Blockchain

To test blockchain based TC-ILFU, this experiment compared TC-ILFU with LFU, Least Recently Used (LRU) algorithm, and First in First Out (FIFO) algorithm. TC-ILFU was analyzed in terms of cost and hit rate. Table I shows the experimental parameters.

In Table I, the computing power of local devices was the weakest, while the computing power of edge servers increased but did not exceed that of cloud computing servers. In Fig. 5, this experiment compared the effects of task cache pool and blockchain on system costs with and without cache pool and blockchain cache.

TABLE I. EXPERIMENTAL PARAMETER SETTINGS

Parameter	Value
Computing frequency of Local device	1GHz
Idle power of local devices	0.3W
On-load power of local devices	0.9W
Computing frequency of edge servers	4GHz
Computing frequency of cloud servers	12GHz
Number of tasks	[100, 200]
Task scale	[20, 40] Mbit
Maximum tolerance time for tasks	[0.1, 5] s
Wireless channel bandwidth	18MHz
Population size	100
Channel noise	-100dpm
Iterations	1400



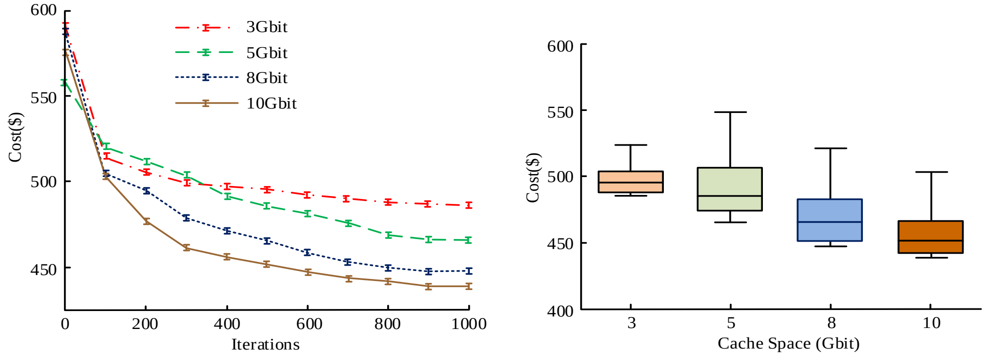
(a) The impact of cache pool on costs

(b) The impact of blockchain on costs

Fig. 5. The impact of cache pool and blockchain on costs.

In Fig. 5(a), as the iteration increased, the cost gradually decreased. The average cost of a task cache pool was 435$, and the average cost of a non-cache pool was 480$. Compared to the situation without a cache pool, the cost with a cache pool was reduced by 9.4%. This is because the system only has the cost of task upload and edge computing, and the task cache pool can effectively reduce the cost of edge computing. In Fig. 5 (b), the average cost with blockchain caching was 450$, and the average cost without blockchain caching was 525$. The cost of having no blockchain cache was about 1.2 times that of having blockchain cache. This is because blockchain can backup all cached results, ensuring data consistency and immutability, improving the reliability and security of system data. Therefore, the introduction of cache pool and blockchain in edge computing can effectively reduce costs and save the cost of industrial Internet. Fig. 6 shows the impact of cache pool capacity space on cost under the same workload.

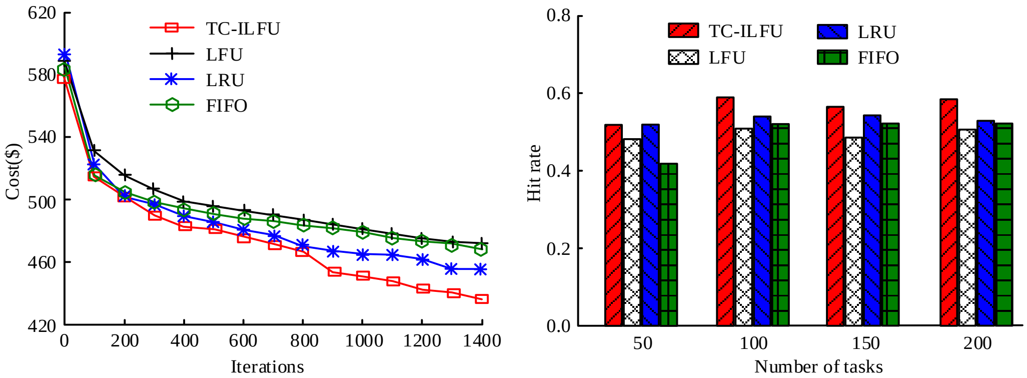
In Fig. 6(a), when the capacity space was 3GBit, 5Gbit, 8Gbit, and 10Gbit, the average cost of the system was 508$, 495$, 483$, and 454$. Compared to the capacity spaces of 3GB, 5Gbit, and 8Gbit, the cost of 10Gbit capacity space was reduced by 10.6%, 8.3%, and 6.0%. The larger the capacity space, the lower the system cost. In Fig. 6(b), as the capacity space of the cache pool increased, the system cost gradually decreased. This is because the cost distribution varies depending on the type of task. This experiment tested the impact of TC-ILFU on cost and hit rate in a fixed cache pool, comparing TC-ILFU with LFU, LRU, and FIFO. Fig. 7 shows the comparison results of cost and hit rate for different caching algorithms.



(a) Results of four cache spaces on cost

(b) Distribution of four cache space on cost

Fig. 6. The impact of cache pool capacity space on cost.



(a) Cost of four caching algorithms

(b) Hit rate of four caching algorithms

Fig. 7. Cost and hit rate of four caching algorithms.

In Fig. 7(a), as the iteration increased, the cost of all four caching algorithms decreased. The average cost of TC-ILFU, LFU, LRU, and FIFO was 478$, 500$, 489$, and 497$. Compared to LFU, LRU, and FIFO, TC-ILFU reduced costs by 4.4%, 2.2%, and 3.8%. The time task frequency table avoided the impact of frequently accessed data in the past on the current cache pool data and improved the task hit rate. In Fig. 7(b), the average hit rate of TC-ILFU, LFU, LRU, and FIFO was 0.56, 0.49, 0.53, and 0.50. Compared with LFU, LRU, and FIFO, TC-ILFU improved hit rate by 14.3%, 5.7%, and 12.0%. When the task was 50, the hit rate of TC-ILFU and LFU was consistent. This is because the repetition rate of task data is low in a relatively short period of time. As the repetitive tasks increase, the hit rate of TC-ILFU gradually increases.

B. Experiment and Analysis of Edge Computing Task Scheduling Algorithm

This experiment compared all local task scheduling strategies (All-local), all edge task scheduling strategies (All-edge), GA, Simulated Annealing (SA), and Hill Climbing (HC) to analyze TSA-GO from the perspectives of system latency, energy consumption, cost, and runtime. Fig. 8 shows the time and energy consumption of the system under different task scheduling strategies.

From Fig. 8(a), the average latency of All-local, All-edge, and TSA-GO was 600ms, 408ms, and 332ms. All-local had the highest latency, with all tasks being executed on local devices, resulting in task loss due to limited resources and increasing task processing time. TSA-GO effectively reduced latency by jointly processing tasks with local devices and edge servers. In Fig. 8(b), the average energy consumption of All-local, All-edge, and TSA-GO was 572J, 526J, and 272J. Compared with All-local and All-edge, TSA-GO reduced energy consumption by 52.4% and 48.3%, respectively. TSA-GO communicated resources through task cache pools and blockchain, effectively reducing the additional consumption caused by task growth. Fig. 9 shows the cost and time comparison of different algorithms.

In Fig. 9(a), as the iteration increased, the costs of all four algorithms decreased. The average cost of TSA-GO, GA, SA, and HC was 443$, 472$, 506$, and 508$, respectively. Compared with GA, SA, and HC, the cost of TSA-GO decreased by 6.1%, 12.5%, and 12.8%. This is because GA randomly generates a large number of solutions, increasing the solution space and making it difficult to find the optimal solution. SA belongs to completely greedy algorithms, and each time the current optimal solution is selected, only local optimal solutions can be searched. HC belongs to simple greedy algorithms, which select an optimal solution in the nearby solution space as the current solution until reaching a local optimal solution. TSA-GO restricts task initialization and reduces algorithm optimization time. Restricting mutation operations to avoid useless mutations can improve convergence rate. In Fig. 9(b), the running time of TSA-GO, GA, SA, and HC was 25600ms, 28880ms, 46680ms, and 35000ms, respectively. SA had the longest running time. The running time of TSA-GO and GA was moderate. TSA-GO searched for the optimal solution faster. This is because the optimization time of the algorithm is reduced when initializing the population. To further validate TSA-GO, experiments were conducted on factors such as the computing power of edge servers and the transmission rate of channels that affect system costs. Fig. 10 shows the results of the impact of different computing power on costs.

In Fig. 10(a), with the increase of edge computing frequency, the system cost gradually decreased. When the calculation frequency of edge nodes was 8GHz, 10GHz, 12GHz, 15GHz, and 18GHz, the average system cost was $330, $288, $245, $231, and $210, respectively. Compared to edge nodes with a computing frequency of 8GHz, the cost of nodes with an 18GHz frequency was reduced by 36.4%. In Fig. 10 (b), the cost reduction rate in the channel rates of 8-10GHz, 10-12GHz, 12-15GHz, and 15-18GHz range was 0.14, 0.19, 0.07, and 0.08, respectively. Cost convergence did not change regularly with the increase of edge computing frequency, and the cost reduction rate remained within 20%. Fig. 10 shows the impact of different channel rates on system costs.

In Fig. 11(a), as the channel rate increased, the tasks uploaded to the edge server increased, and cost control became more optimized. When the channel upload rate was 5M/s, 8M/s, 10M/s, 12M/s, and 15M/s, the average system cost was $465, $338, $302, $270, and $250, respectively. In Fig. 11(b), the cost reduction rate was 0.31, 0.13, 0.09, and 0.10 in the channel rates of 5-8M/s, 8-10M/s, 10-12M/s, and 12-15M/s, respectively. As the channel rate increased, the cost reduction rate gradually stabilized and remained around 10%.

IV. Discussion and Conclusion

A. Discussion

To solve the transmission bandwidth limitation and data privacy threat existing in the industrial Internet, the research proposed to schedule the task to the edge server for processing to realize the real-time and security of data in industrial production. However, traditional task scheduling algorithms do not fully utilize edge cache resources, which can easily lead to the leakage of private data. Therefore, this research proposed a security enhanced edge computing task scheduling method based on blockchain and task cache. Firstly, the edge caching model of blockchain was utilized to cache the calculation results of multiple repetitive tasks in the intelligent factory, reducing task latency. The task scheduling of coupling task caching and blockchain assisted caching was modeled as a cost minimization problem under multiple constraints. Meanwhile, the genetic optimization algorithm was combined to achieve optimal cost control. Yasir M and other researchers proposed a content caching strategy based on mobile edge computing, which significantly improved the cache performance of edge servers and increased the cache hit ratio [22]. The experimental results of this study showed that the cost of the TC-ILFU algorithm was reduced by 4.4%, and the hit rate was increased by 14.3%, which is similar to the results of Yasir M and other researchers, further confirming that the improved LFU algorithm can effectively improve the cache hit rate. Yin Z's research team has developed a multi-objective task scheduling strategy for intelligent production lines, which has a high task completion rate and can effectively reduce task service delays and energy consumption [23]. The experimental results of this study show that the TSA-GO algorithm reduces latency and energy consumption by 44.7% and 52.4%, respectively, which is consistent with the results of Yin Z's research team. The main reason is that the cloud edge end mode used in industrial task scheduling can effectively reduce cloud task processing overhead and transmission delay. Scholars such as Fu X have improved the overall completion time and convergence accuracy of cloud tasks using a hybrid particle swarm optimization genetic task scheduling algorithm [24]. This study shows that the TSA-GO algorithm reduces the cost by 6.1% and improves the system running time by about 10%, which is different from the research results of scholars such as Fu X. This is because scheduling tasks to edge services can effectively reduce cloud computing costs and accelerate task processing speed.

B. Conclusion

In conclusion, the research proposes that the security-enhanced edge computing task scheduling method based on blockchain and task cache can effectively protect data privacy, reduce latency, reduce costs, and improve system security. The limitation of the research is that the dynamic scheduling scenario of time-varying resources was not fully considered. Subsequently, a Markov strategy scheduling algorithm was used to construct a dynamic model of the industrial environment. Based on the environmental resource changes, resource allocation strategies and scheduling strategies were dynamically predicted to reduce time and resource costs in industrial scenarios.

Advanced Fusion of 3D U-Net-LSTM Models for Accurate Brain Tumor Segmentation

Ravikumar Sajjanar*, Umesh D. Dixit

Department of Electronics & Communication Engineering, BLDEA's V. P. Dr. P. G. Halakatti College of Engineering and Technology, Vijayapura–586 103 (Affiliated to Visvesvaraya Technological University, Belagavi-590018), Karnataka, India

***Abstract*—Accurate detection and segmentation of brain tumors are essential in tomography for effective diagnosis and treatment planning. This study presents advancements in 3D segmentation techniques using data from the Kaggle BRATS 2020 dataset. To enhance the reliability of brain tumor diagnosis, innovative approaches such as Frost filter-based preprocessing, UNet segmentation architecture, and Long Short-Term Memory (LSTM) segmentation are employed. The methodology starts with data preprocessing using the Frost filter, which effectively reduces noise and enhances image clarity, thus improving segmentation accuracy. Subsequently, the UNet architecture is utilized to precisely segment brain tumor regions. UNet's ability to capture contextual information and its efficient use of skip connections contribute to accurately delineating tumor boundaries in three-dimensional space. Additionally, the temporal aspect of brain tumor progression is addressed by employing an LSTM network, which increases segmentation accuracy. The LSTM algorithm integrates temporal patterns in sequential imaging data, enabling reliable segmentation of tumor presence and characteristics over time. By analyzing the ordered sequence of continuous MRI scans, the LSTM framework achieves more precise and adaptable tumor recognition. Evaluation results based on the Kaggle BRATS 2020 dataset demonstrate significant improvements in segmentation and segmentation performance compared to previous methods. The proposed approach enhances the accuracy of tumor boundary delineation and the ability to classify tumor types and track temporal changes in tumor growth. The "U-Net-LSTM" method achieves an accuracy of 98.9% in segmentation tasks, showcasing its superior performance compared to other techniques. This method is implemented using Python, underscoring its efficacy in achieving high accuracy in segmentation tasks.**

***Keywords*—Brain tumor segmentation; frost filter pre-processing; UNet architecture; LSTM; kaggle BRATS 2020 dataset**

I. Introduction

In the US, roughly 23,000 additional instances of tumors in the brain are expected to be detected year 2015 [1]. Which is a particularly frequent type of brain tumor, and may vary from a low to a high level, based on the person's life prognosis (e.g., a few decades or fewer). Both chemotherapy and radiation can halt the expansion of brain cancers that can't be eliminated through operation [2]. Although certain types of tumors, including meningiomas, remain readily divided, gliomas and glioblastomas become considerably harder to locate. These malignancies are frequently dispersed, weakly compared, and have tentacle-like features that render tumors hard to divide [3]. A different approach basic challenge of dividing tumors in the brain is the fact that tumors can occur wherever there is the central nervous system, in practically every size and shape. In addition, whereas images created with an X-ray machine scan as well the dimension of pixel data in MRI images cannot be uniform [4]. Based on the kind of MR equipment utilized with the data collection methodology comparable tumorous tissues could show significantly varying shades of gray whenever seen across distinct institutions [5]. The main objective of brain tumor imagery assessment is to acquire tailored patients' critical therapeutic data as well as analytical characteristics. The details incorporated into the multimodal images might determine and evaluate treatments once an illness is diagnosed and then restricted, eventually contributing to understanding enabling diagnostic setting, and medication of illness [6]. The steps involved can be depicted graphically as a pyramidal. Specific approaches must be used at all levels inside the hierarchy to analyze facts, gather, categorize, display depict knowledge. Furthermore, to gain useful clinical expertise or data so that health-related diagnoses and decisions might be generated, the details must be represented at an elevated degree of abstraction [7]. The primary goal of segmenting an image is to divide a picture into incompatible sections to ensure every area is geographically continuous and its pixels inside it remain uniform according to a preset standard. This description is an important constraint for many division techniques, in particular when establishing and identifying "unusual cell forms," as the malignant cells that must be divided are anatomical components wholly frequently non-rigid and multifaceted in arrangement, change enormously in terms of dimensions and location, and change significantly compared to individuals to individuals [8].In the situation of brain tumors, division entails distinguishing between various parts of the tumor, including solid or actively aggressive tumors, swelling, and death, and healthy brain cells, including cerebral gray matter , white matter, and the fluid that surrounds it [9].

Accurately estimating the corresponding amount of brain tumor parts is crucial to tracking development, scheduling radiation therapy, assessing outcomes, and conducting follow-up investigations. This requires good tumor delineation [10]. Human specialists have substantial obstacles in manually segmenting tumors due to the variety in morphology and the requirement to examine many pictures from distinct MRI sequencing to accurately diagnose cell type. The painstaking task is difficult, susceptible to error by humans, and causes high within and inter-rater variation. In most neurological tumor examinations, an abundance of aberrant cells is apparent[11]. Nonetheless, reliable overall consistent identification as well as characterization of anomalies remains challenging. Conventional methods of imaging, like MRI, are useful in detecting tumors of the brain, however, segmentation by hand is time-intensive, laborious, and susceptible to inter-observer variation. The development of computerized 3D segmentation tools has transformed this procedure, allowing for quicker and more exact identification of tumor areas. A few of the important advances propelling advancement in 3D segmentation is the use of Deep learning-based approaches, particularly multilayer neural networks [12]. These methods excel in extracting topological characteristics from voxel images, enabling very accurate and efficient brain cancer separation. CNNs are capable of accurately capturing the complicated spatial connections and brightness variations that distinguish distinct different kinds of tumors when trained on massive amounts of captioned MR imaging images [13]. Furthermore, the use of multifaceted imaging information, such as an MRI, diffusion-weighted images, and positron emission tomography, has improved the reliability of 3D segmentation approaches [14]. The key contributions of the suggested framework are mentioned below.

- The implementation of the Frost filter-based preprocessing methodology marks a significant enhancement in brain tumor imaging. This approach efficiently eliminates noise and enhances the luminosity of brain images, providing a robust foundation for subsequent segmentation tasks. By improving the clarity and quality of the images, the Frost filter significantly boosts tumor identification accuracy, ensuring that the segmentation process starts with the best possible data. This leads to more precise delineation of tumor boundaries and enhances the overall efficiency and reliability of tumor detection and analysis.

- The utilization of the UNet segmentation architecture makes a significant contribution by enabling precise identification of tumor regions. UNet's design, which effectively captures contextual information and leverages skip connections, ensures accurate delineation of tumor boundaries in three dimensions. This capability significantly enhances the precision of segmentation, as it allows the model to integrate both local and global features, thereby providing a comprehensive understanding of the tumor's spatial structure. The ability to accurately define tumor boundaries is crucial for improving the reliability and accuracy of segmentation, ultimately leading to better diagnostic and therapeutic outcomes.

- The incorporation of the LSTM segmentation algorithm represents a pivotal advancement, as it adeptly addresses the temporal aspects of tumor development. By effectively capturing the dynamic changes over time, the LSTM algorithm ensures consistent and reliable identification of tumor presence and characteristics as they evolve. This temporal sensitivity significantly enhances the accuracy of segmentation, allowing for a more nuanced and precise analysis of tumor progression. The ability to track and integrate temporal patterns into the segmentation process not only improves diagnostic accuracy but also provides valuable insights for monitoring treatment response and planning future interventions.

- Using the ordered series of continuous MRI images inside the LSTM architecture provides a fresh approach to tumor acknowledgment, which leads to higher accuracy and adaptability in recognizing tumors when compared with conventional techniques, thus boosting total segmentation accuracy.

- The suggested methodology's assessment on the Kaggle database BRATS 2020 dataset shows substantial gains in precision of segmentation as well as categorization productivity when contrasted with current methods, demonstrating the efficacy of the paired Frost filter preliminary processing, UNet segmentation, and LSTM segmentation methods for precise brain tumor recognition in imaging.

The organization of the paper includes related works, problem statements, and methodology in Sections II, III, and IV. The results are given in Section V. Section VI concludes the paper.

II. Related Work

Jin Liu et al., [15] suggested a technique based on deep learning for segmenting brain tumors utilizing multifaceted MRI data, utilizing a convolutional neural network comprising several layers of convolution overall remaining connections to improve both precision and effectiveness. This methodology marks an important milestone in the discipline that has achieved significant advancements during the past 20 years through the introduction of methodologies such as CNNs, U-Net variants, and GANs, among mixed techniques. Adequate initial processing, strong evaluation measures, and publicly available datasets such as BraTS have all contributed to future advances. Yet, issues like variance in MRI techniques, tumor variation, and the requirement for larger annotation-laden datasets persist.

Sergio et al., [16] presented an autonomous segmentation of brain tumors approach using Convolutional Neural Networks using small 3×3 kernels. This allows for a more complex design and reduces excessive fitting because of fewer network weights. They used intensity normalizing and data enrichment as pretreatment measures to improve the efficiency of segmentation. The technique they used was verified utilizing the Brain Tumor Segmentation Challenge 2013 (BRATS 2013) database, and it won first place for whole, core, and improved areas, with Dice Similarities Coefficients of 0.88, 0.83, and 0.77, accordingly. In addition, they finished first in the public assessment. Applying the same approach in the BRATS 2015 Challenge, which is they finished second with Dice Comparison parameters of 0.78, 0.65, and 0.75 for the full, core, and improving areas, etc.

Paul et al., [17] gave a technique for the division that uses nnU-Net. The unmodified nnU-Net baseline generated acceptable outcomes but including BraTS-specific changes like further processing, region-based training, stronger data enhancement, and multiple small pipeline modifications substantially enhanced segmentation performance. By reviving the BraTS rankings algorithm to determine the best nnU-Net variation, their technique won the BraTS 2020 contest with Dice scores of 88.95, 85.06, and 82.03, and HD95 values of 8.498, 17.337, and 17.805 for total tumor, tumor core, and augmenting tumor, accordingly.

Xiaomei et al., [18] proposed a brain tumor segmentation method that involves instruction of a deep learning algorithm using 2D patch images as well as slices in three stages: first, instructions FCNNs alongside image areas; second, learning CRFs as Recurrent Neural Networks with image slices while keeping FCNN parameters constant; and at last, fine-tuning both FCNNs and CRF-RNN employing image segments. They developed three segmentation algorithms using image slices from the axial, coronal, and sagittal views, then combined these with a voting-based fusion technique for classification. The approach they tested with information from the BRATS 2013, 2015, and 2016 challenges, proved that it could construct an analysis of segmentation utilizing Flair, T1c, and T2 scans while outperforming models employing Flair, T1, T1c, and T2 data.

Various methods have been proposed for brain tumor segmentation using deep learning techniques. One method employed convolutional neural networks with multiple convolutional layers and residual connections, showing significant advancements and addressing challenges like MRI variability and tumor heterogeneity. Another approach utilized CNNs with small 3×3 kernels, enhancing segmentation performance through intensity normalization and data augmentation, achieving top rankings in the BRATS 2013 and 2015 challenges. The nnU-Net framework, modified with BraTS-specific adjustments such as postprocessing and region-based training, achieved first place in the BraTS 2020 competition.

III. Problem Statement

Despite significant advancements in deep learning-based methods for brain tumor segmentation using multi-modal MRI images, several challenges persist. The variability in MRI protocols, tumor heterogeneity, and the need for large annotated datasets continue to hinder the accuracy and efficiency of segmentation algorithms. While techniques such as convolutional neural networks (CNNs), U-Net variants, GANs, and hybrid methods have greatly improved the field, the development of reliable and robust segmentation models is still impeded by these challenges. Effective preprocessing and robust evaluation metrics are essential, but overcoming the intrinsic variability and obtaining extensive high-quality labeled data remain critical issues to address [15].

IV. Proposed UNet-LSTM Methodology for Brain Tumor Identification

The suggested operational technique for increasing the accurate identification and segmentation of brain tumors in tomography begins with data pre-processing using the Frost filter, which reduces noise and increases luminance in brain scans, thereby boosting segmentation accuracy. Following that, the UNet segmentation architecture is used to precisely outline tumor areas by making use of its capacity to record contextual data and effectively bypass connections, which is especially useful for three-dimensional tumor border determination. To deal with the psychological element of tumor evolution and increase the precision of segmentation, the LSTM network is incorporated, which successfully captures temporal trends in successive image information for consistent tumor segmentations across time. The LSTM structure, which takes advantage of the structured series of ongoing MRI scans, allows for greater accuracy and adaptable tumor detection. Evaluation of the Kaggle BRATS 2020 database reveals considerable improvements in precision for segmentation and segmentation effectiveness over earlier methods. The suggested method increases not simply the reliability of tumor border separation, but its ability to distinguish between tumor kinds and follow periodical variations in the development of tumors. Fig. 1 represents a workflow of the proposed UNet-LSTM Methodology.

A. Data Collection

Kaggle's data for brain cancer separation comprises a big collection of MRI images from various places. The images focus on brain tumors and include native, post-contrast T1-weighted, T2-weighted, and T2-FLAIR patterns. Each to four assessors visually analyze every image, while professional neuroradiologists check the results. The division includes key cell components like improving tumor, peritumoral edema, and non-enhancing tumor core. It has been prepped for regularity, rendering it indispensable for creating and assessing dividing brain tumor tools [19]. Table I shows Annotated Brain Tumor Regions. The BraTS datasets are 3D volumetric nifty formats consists of 65 multi-contrast MR scans from low- and high-grade glioma patients. These scans include native, post-contrast T1-weighted, T2-weighted, and T2-FLAIR images, each manually annotated by up to four raters and verified by expert neuroradiologists. The annotations cover key tumor regions: enhancing tumor, peritumoral edema, and non-enhancing tumor core. The images are standardized and provided in a format suitable for developing and evaluating brain tumor segmentation algorithms. Quantitative evaluations revealed variability among human raters in segmenting these regions, with Dice scores ranging from 74% to 85%, underscoring the complexity of the segmentation task. Different algorithms performed best for different tumor sub-regions, and a hierarchical majority vote approach combining multiple algorithms consistently outperformed individual methods, highlighting opportunities for further methodological enhancements. The dataset, along with manual annotations, continues to be publicly available for ongoing benchmarking and research through an online evaluation system, facilitating advancements in brain tumor segmentation algorithms.

TABLE I. ANNOTATED BRAIN TUMOR REGIONS

ANNOTATED BRAIN TUMOR REGION	
ANNOTATED REGIONS	***DESCRIPTION***
GD-enhancing tumor (ET)	Enhanced tumor region
Peritumoral edema (ED)	Edema surrounding the tumor
Necrotic/non-enhancing tumor core (NCR/NET)	Non-enhancing tumor core, including necrotic regions

B. Data Pre-Processing

Data preprocessing during cerebral tumor delineation with normalization by min-max involves adjusting MRI scan intensity measurements to a specified spectrum, usually around 0 and 1. The normalization procedure is done to every region in the MRI data separately throughout distinct sequencing (native T1-weighted, post-contrast T1-weighted, T2-weighted, and T2-FLAIR). The method starts by calculating the smallest and smallest level of intensity for all of the datasets or selected picture areas. Subsequently, each voxel intensity is transformed using the formula:

$$Intensity_{normalised} = \frac{Intensity-Min}{Max-Min} \tag{1}$$

Where, Intensity is the original intensity value of the voxel, and Min and Max are the minimum and maximum intensity values, respectively, observed within the volume or dataset.

Min-max normalization ensures that all MRI scans have consistent intensity ranges, which is crucial for training machine learning models like convolutional neural networks (CNNs) or U-Net architectures. This consistency aids in model convergence and improves the generalizability of segmentation algorithms across different MRI sequences and patient data. Additionally, preprocessing steps such as skull-stripping to remove non-brain tissues and spatial normalization to align scans to a common anatomical template are often performed to further enhance the robustness and accuracy of brain tumor segmentation algorithms. Table II shows the pre-processing steps for brain tumor images.

TABLE II. PRE-PROCESSING STEPS FOR BRAIN TUMOR IMAGES

Annotated Brain Tumor Region	
STEP	***PROCEDURE***
Image Loading	Load heterogeneous MRI pictures from the BRATS 2020 dataset, including T1-weighted, T2-weighted, and FLAIR sequences.
Noise Estimation	Determining the extent of noise in the pictures is crucial for selecting parameters in Frost filtering.
Frost Filtering	Apply the Frost filter to each picture modality individually, adjusting settings such as window size and filter strength based on regional characteristics.
Image Fusion	Combine denoised images from multiple sources to create a single image that retains important information from each.
Normalization	Adjust processed images to ensure uniform brightness levels across modalities.

C. Segmentation Using UNet- LSTM Architecture

Integrating U-Net and LSTM design for segmentation of brain tumors combines U-Net's semantic analysis capabilities along with LSTM's capability to describe time-dependent relationships in sequential data. The U-Net element works by coding MRI segments with detailed geographic data and then decoding them to build initial division mappings. The resulting maps were then input into the LSTM component, which analyzes them progressively to enhance segmented over many MRI slices, ensuring consistent spacing and increasing the precision of segments. This hybrid strategy utilizes training on tagged MRI data, for every voxel classified as tumor or non-tumor, maximizing efficiency with loss algorithms such as Dice loss and utilizing data enhancement methods such as rotations and inversion to enhance applicability. Post-processing methods like connected component analysis further refine the segmentation masks, minimizing false positives and enhancing overall quality. Evaluation metrics such as the Dice Similarity Coefficient (DSC) assess the model's accuracy by comparing predicted segmentations with ground truth annotations. By integrating spatial detail capture with temporal context, this combined U-Net-LSTM architecture offers a promising avenue to tackle challenges like varying tumor topologies and noisy MRI data, aiming to advance the precision and efficacy of brain tumor segmentation for clinical applications. Fig. 2 represents a UNet-LSTM Architecture.

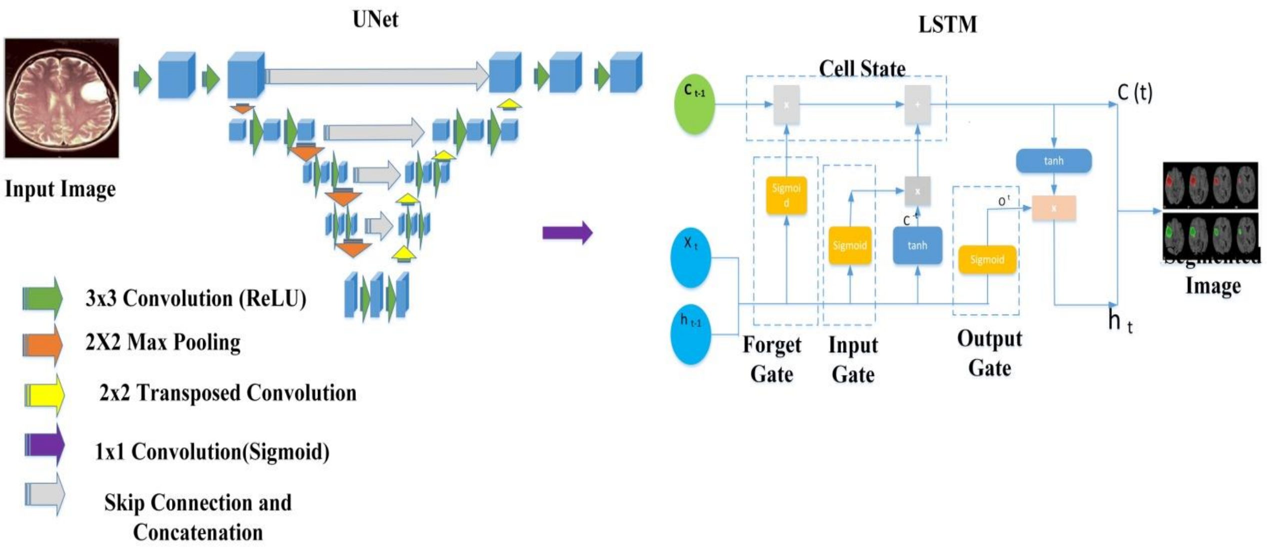

Fig. 2. UNet-LSTM architecture.

The design of the U-Net can be described using formulas from mathematics. Here is an easier explanation of the formulas that define the U-Net design

1) Contracting Path (Encoder)

Convolutional layers with ReLU activation:

$$F_i = RELU\ (W_i\ * F_{I-1} +\ a_i) \quad (2)$$

Max Pooling:

$$F_i = MaxPool(F_{i-1}) \quad (3)$$

2) Expansive Path (Decoder)

Upsampling (Transposed Convolution):

$$F_i = ConvTranspose\ (\ F_{i-1}) \quad (4)$$

$$F_i = Concatenate\ (\ F_i, F_{n-i}) \quad (5)$$

Convolutional layers with ReLU activation

$$F_i = ReLU(W_i *\ F_{i-1} +\ a_i) \quad (6)$$

3) Output layer: Final convolutional layer with Sigmoid activation (for binary segmentation) or Softmax activation (for multi-class segmentation)

$$O = Sigmoid\ (\ W_{out} *\ F_{n-1} +\ a_{out}) \quad (7)$$

Where, F_i represents the feature maps at the i^{th} layer, i^{th} and a_i denote the weights and biases of the i^{th} convolutional layer, F_{i-1} represents the input feature maps to the i^{th} layer, n represents the total number of layers in the contracting path, O represents the final output segmentation map, * denotes the convolution operation, MaxPool represents the max-pooling operation,

This collection of formulas describes the fundamental framework of the U-Net design, which includes a shrinking path (encoder) accompanied by an expanding path (decoder) for semantically segmenting problems. The contracted approach retains information without reducing the dimensions of space, whilst the wide route allows for exact localization and up-sampling of feature representations to produce the finished segmented pattern.

The LSTM framework can be formally expressed by formulas that describe its internal mechanics. Here's a series of equations outlining the operation of an LSTM unit

$$i_t = \sigma\left(W_{xj}x_t + W_{hj}h_{t-1} + W_{cj}c_{t-1} + b_j\right) \quad (8)$$

Where i_t, is the input gate at time step t, x_t is the input at time t, h_{t-1} is the hidden state of the previous time step, c_{t-1} is the cell state of the previous time step, W_{xj}, W_{hj}, and W_{cj} , are the weight matrix of input, hidden state, and cell state respectively, b_j is the bias.

$$f_t = \sigma\left(W_{xg}x_t + W_{hg}h_{t-1} + W_{cg}c_{t-1} + b_g\right) \quad (9)$$

Where, f_t is the forget gate at time step t, $W_{xg}x_t\sigma$ is the sigmoid activation function, $W_{xg}x_t$ the weight matrix applied to the input x_t,x_t_t is the input at time step t, W_{hg} is the weight matrix applied to the previous hidden state h_{t-1}.

$$g_t = tanh(W_{xi}x_t + W_{hi}h_{t-1} + b_i) \quad (10)$$

$$c_t = f_t \odot c_{t-1} + i_t \odot g_t \quad (11)$$

Where ⊙ represents element-wise multiplication, c_t is the updated cell state at time step t, g_t is the candidate cell state at time step t.

$$o_t = \sigma\left(W_{yo}x_t + W_{lo}h_{t-1} + W_{do}c_t + b_o\right) \quad (12)$$

where, o_t is the output gate at time step t, σ sigmoid activation function, W_{yo} is the weight matrix applied to the input x_t , W_{lo} is the weight matrix applied to the previous hidden state h_{t-1}, W_{do} is the weight matrix applied to the cell state c_t, c_t is the current cell state at time step t,\ b_o is the bias term, W_{yo} , W_{lo} , W_{do} are weight matrices for input, hidden state and cell state respectively.

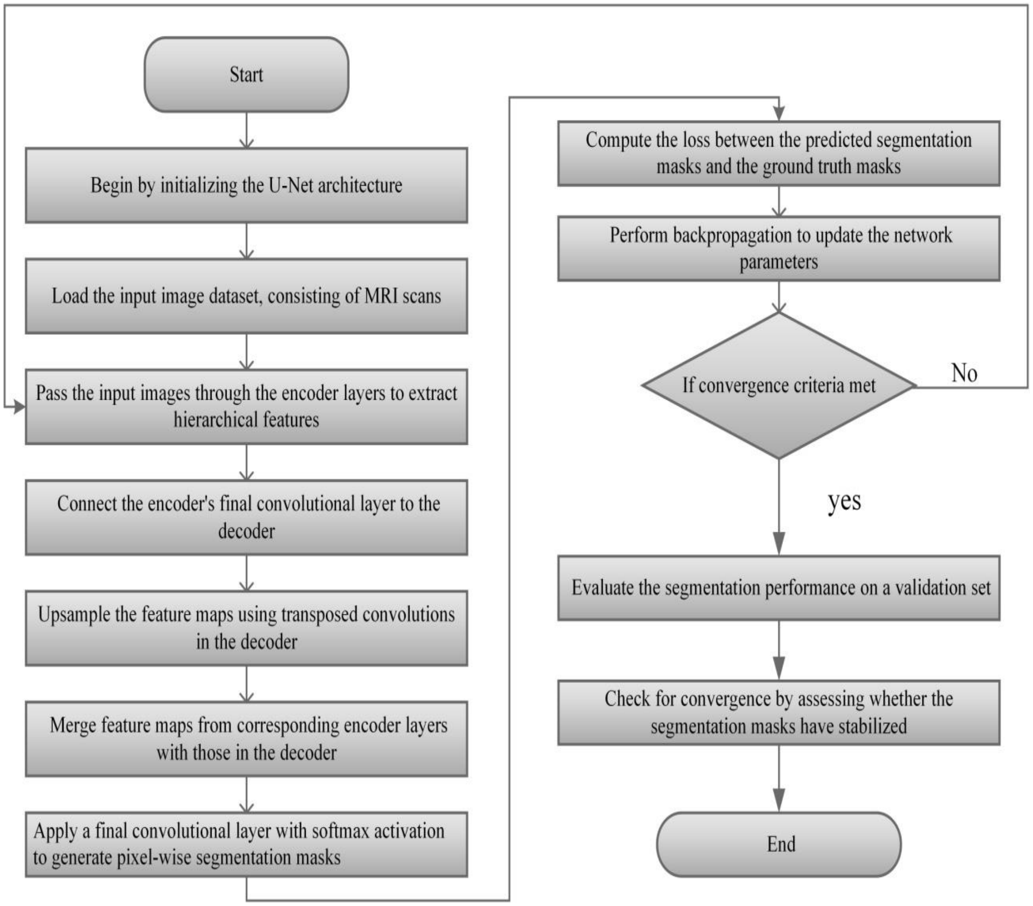
Fig. 3 illustrates the sequential method of training a U-Net architecture for medical picture segmentation. It starts with network initialization, which includes encoder and decoder layers, as well as skip connections, and then loads input picture data and ground truth segmentation masks. Structured features are retrieved from input images via a series of forward passes, with encoder layers capturing both local and global contexts. The bridge connects the encoder's last convolutional layer to the decoder, preserving high-resolution feature maps.



Start
Begin by initializing the U-Net architecture
Load the input image dataset, consisting of MRI scans
Pass the input images through the encoder layers to extract hierarchical features
Connect the encoder's final convolutional layer to the decoder
Upsample the feature maps using transposed convolutions in the decoder
Merge feature maps from corresponding encoder layers with those in the decoder
Apply a final convolutional layer with softmax activation to generate pixel-wise segmentation masks
Compute the loss between the predicted segmentation masks and the ground truth masks
Perform backpropagation to update the network parameters
If convergence criteria met
No
yes
Evaluate the segmentation performance on a validation set
Check for convergence by assessing whether the segmentation masks have stabilized
End

Fig. 3. Sequential steps involved in the suggested technique.

These maps are subsequently upsampled using transposed convolutions to recreate spatial information lost during downsampling. Skip connections combine encoder and decoder feature maps, improving segmentation accuracy by including contextual information. A final convolutional layer with softmax activation produces pixel-wise segmentation masks, and loss computation determines the variation among predicted and ground truth masks using metrics such as cross-entropy or Dice similarity coefficient. Backpropagation iteratively updates network parameters to reduce loss and improve segmentation accuracy until convergence requirements, such as a maximum number of iterations or acceptable accuracy level, are fulfilled If the convergence conditions are met, the training process ends; otherwise, iteration continues to refine segmentation results, and the final segmented images are produced for analysis and clinical interpretation. Fig. 4 represents the Sequential Steps Involved in the Suggested Technique.

V. Results and Discussion

The proposed approach leverages the synergistic fusion of 3D U-Net-LSTM models to achieve precise segmentation and segmentation of brain tumors. With a training dataset comprising 67.6% of the total images and a validation dataset consisting of 32.4%, the model undergoes robust training and validation processes. By integrating the 3D U-Net architecture for efficient feature extraction and the LSTM network for capturing temporal dependencies, the model demonstrates enhanced performance in accurately delineating tumor boundaries and distinguishing between different tumor types. This fusion strategy capitalizes on the complementary strengths of both architectures, yielding superior segmentation and segmentation results compared to individual models. Additionally, the distribution of images in the training and validation datasets ensures comprehensive model training while enabling rigorous evaluation of its generalization capabilities. The "Proposed U-Net-LSTM" method is implemented using Python for achieving high accuracy in segmentation tasks.

Fig. 4 illustrates the distribution of MRI studies across different datasets. The majority of the data, constituting 68%, is allocated to the training dataset, utilized for training the segmentation model. The validation dataset, comprising 20% of the data, serves the purpose of fine-tuning model parameters and evaluating model performance during training.

Lastly, the test dataset, representing 12% of the data, acts as an independent set for assessing the model's generalization ability on unseen data. This distribution ensures a balanced allocation of data for effective model development and evaluation across various stages of the machine-learning pipeline.

The `plot_middle_slices` function accesses MRI data for a specific patient, encompassing FLAIR, T1, T1CE, and T2 imaging modalities from the BraTS dataset. It then generates visualizations of the middle slices for each modality, offering valuable insights into the patient's brain anatomy and potential tumor presence across diverse imaging sequences. This process involves iterating through each modality, extracting, and presenting the middle slices alongside titles indicating both the modality and the slice index. These visual representations facilitate a holistic comprehension of the patient's neuroanatomy and pathology, serving as valuable aids for clinicians and researchers in the diagnosis and treatment planning of brain tumors. Fig. 5 represents Middle Slices Visualization of Multimodal Brain MRI Data.

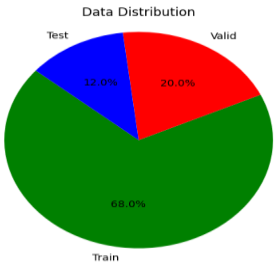


Fig. 4. Distribution of MRI studies across training, validation, and test datasets.

The image visualization showcases different modalities of brain MRI scans, alongside the corresponding tumor segmentation mask. Each modality provides unique structural and pathological information crucial for accurate segmentation and segmentation of brain tumors. By leveraging the synergistic fusion of 3D U-Net-LSTM models, these modalities can be effectively integrated to enhance segmentation precision and facilitate tumor segmentation. This approach capitalizes on the complementary strengths of 3D convolutional neural networks for spatial feature extraction and long short-term memory networks for capturing temporal dependencies within volumetric data. Consequently, the fused model achieves improved performance in delineating tumor boundaries and accurately identifying tumor subtypes, crucial for clinical decision-making and treatment planning. Fig. 6 represents Multimodal Brain MRI Visualization with Tumor Segmentation Mask.

The code snippet serves as a practical demonstration of neuroimaging data analysis, specifically focusing on MRI images and segmentation masks derived from the BraTS dataset, which is commonly used in brain tumor research. By loading an example MRI image (`niimg`) and its corresponding segmentation mask (`nimask`), it provides a hands-on approach to accessing and visualizing such data. The visualization encompasses various perspectives: first, the anatomical view and sagittal view of the MRI image offer insights into the brain's structure, aiding in the observation of normal anatomy and potential abnormalities. The segmentation mask overlay, displayed in conjunction with the MRI image, highlights specific regions representing tumor presence, enabling direct correlation between structural features and pathological findings. Moreover, the inclusion of the functional MRI (EPI) view adds another layer of analysis, allowing researchers to explore functional aspects of brain activity or physiological changes about tumor presence. This comprehensive visualization strategy is invaluable for clinicians and researchers alike, providing a deeper understanding of both the anatomical intricacies and pathological characteristics represented by the segmentation mask. Fig. 7 represents Different Views of MRI Data with Segmentation Overlay.

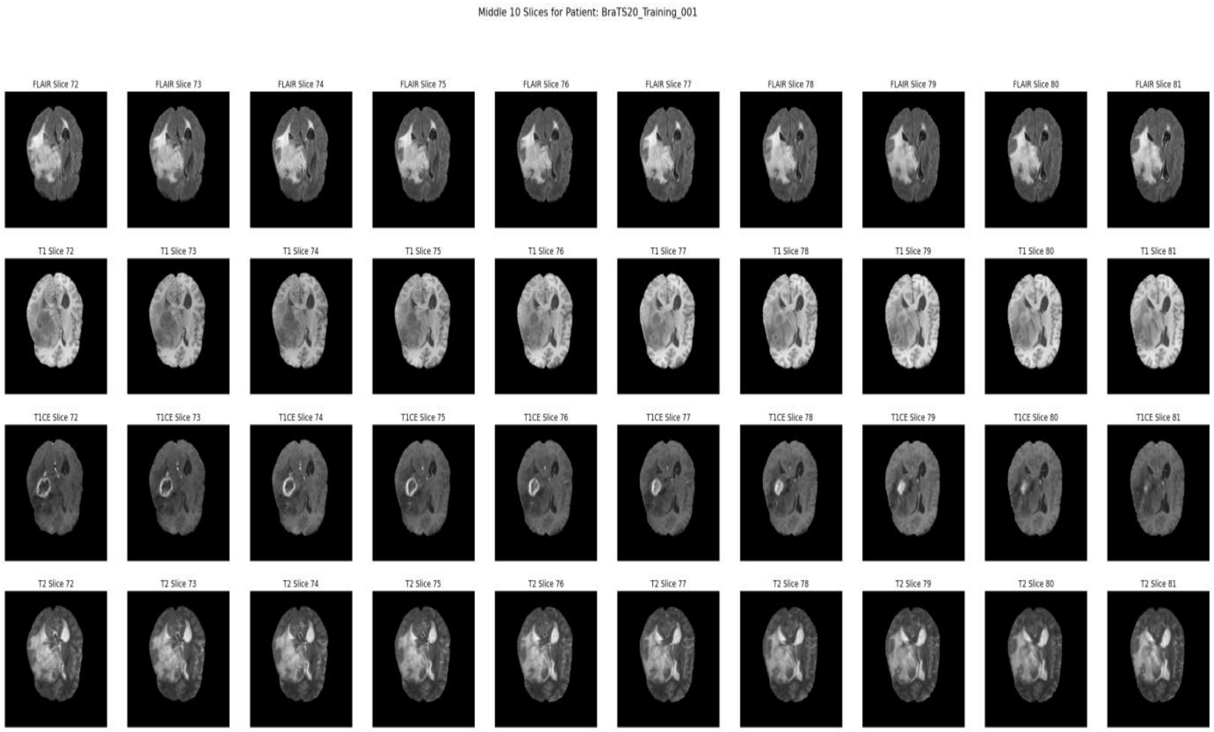

Fig. 5. Middle slices visualization of multimodal brain MRI data.

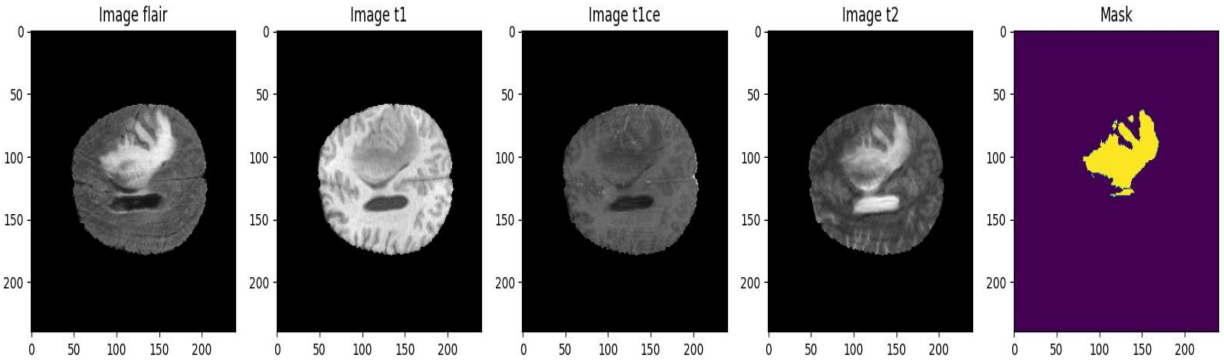

Fig. 6. Multimodal brain MRI visualization with tumor segmentation.

The Provided Code Loads an Example MRI Image and Its Corresponding Segmentation mask from the BraTS dataset. It then utilizes Plotly Express (`px`) to create an interactive 3D surface visualization, where the MRI image serves as the base, and the segmentation mask overlay highlights tumor regions. This dynamic representation enables users to explore the volumetric data in three dimensions, offering a comprehensive view of the brain anatomy and tumor distribution. Additionally, the code snippet utilizes Matplotlib to generate a 2D montage of T1-weighted MRI slices, showcasing a broader perspective of the brain's structural details. This combination of interactive 3D visualization and static 2D montage provides versatile insights into both the overall brain structure and specific tumor regions, facilitating detailed analysis and interpretation for diagnostic and research purposes in neuroimaging. Fig. 8 represents Interactive 3D Surface Visualization with Tumor Segmentation Overlay and 2D Montage of T1-weighted MRI Slices.

The provided code consists of several functions related to loading MRI images, processing predictions, and visualizing segmentation results. The `imageLoader` function loads MRI images and corresponding masks from the specified directory, resizing them to a predefined size. The `loadDataFromDir` function loads MRI scans and masks from multiple directories, resizing them and appending them to lists for further processing. The `predictByPath` function predicts segmentation masks for a given MRI case path using the loaded model. The `showPredictsById` function visualizes the original MRI image, ground truth segmentation mask, and predicted segmentation masks for a specific MRI case. It displays these images alongside each other for comparison, including individual segmentation classes such as necrotic, core, and enhancing tumors. Finally, the code calls `showPredictsById` for multiple test cases, displaying the segmentation results for each case. Fig. 9 represents MRI Segmentation Visualization for Multiple Test Cases.

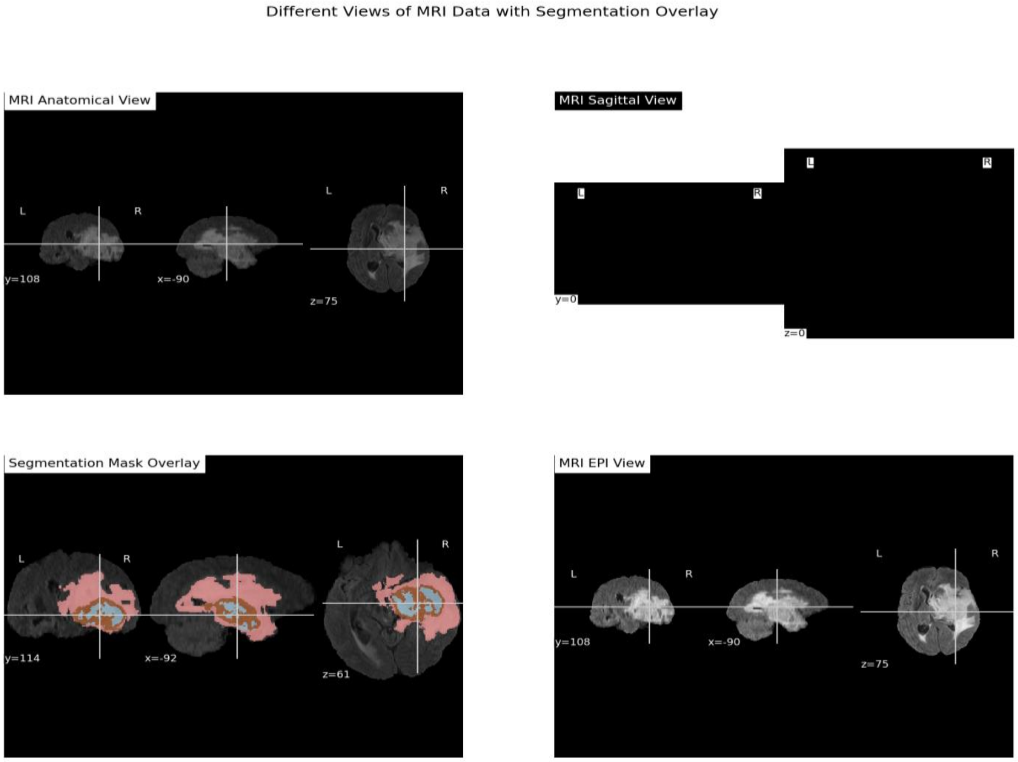

Fig. 7. Different views of MRI data with segmentation overlay.

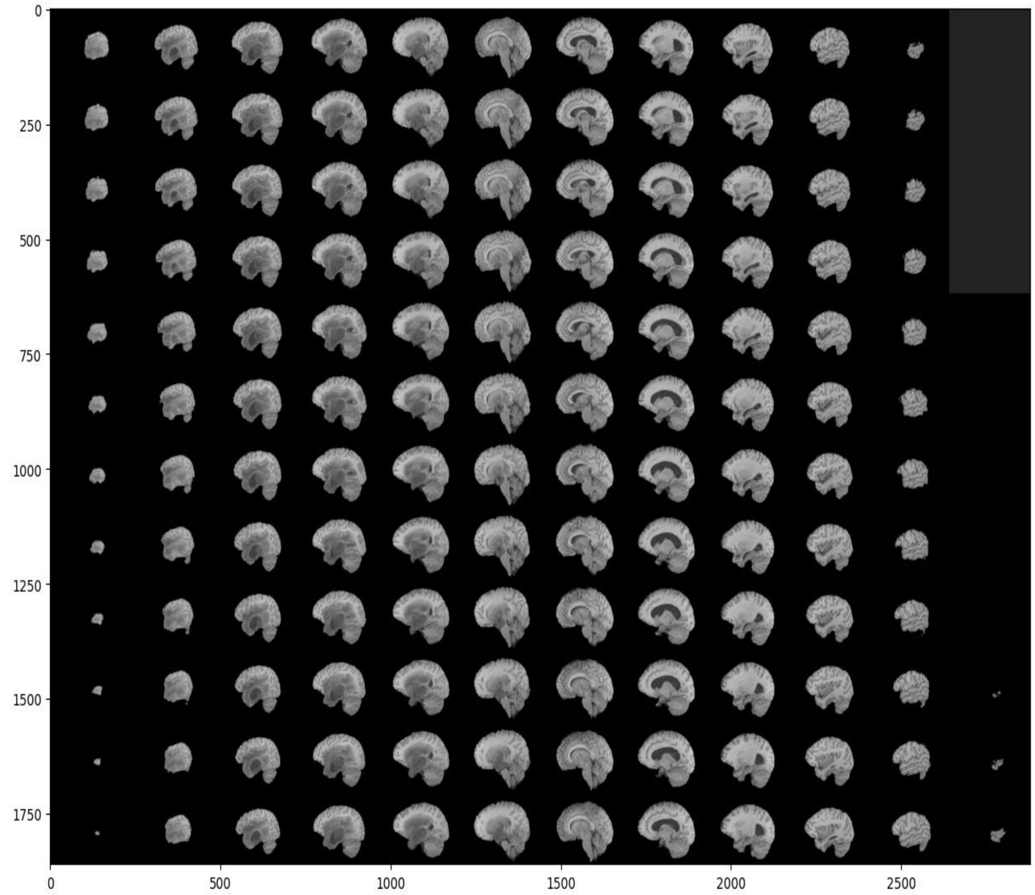

Fig. 8. Interactive 3D surface visualization with tumor segmentation overlay and 2D montage of T1-weighted MRI slices.

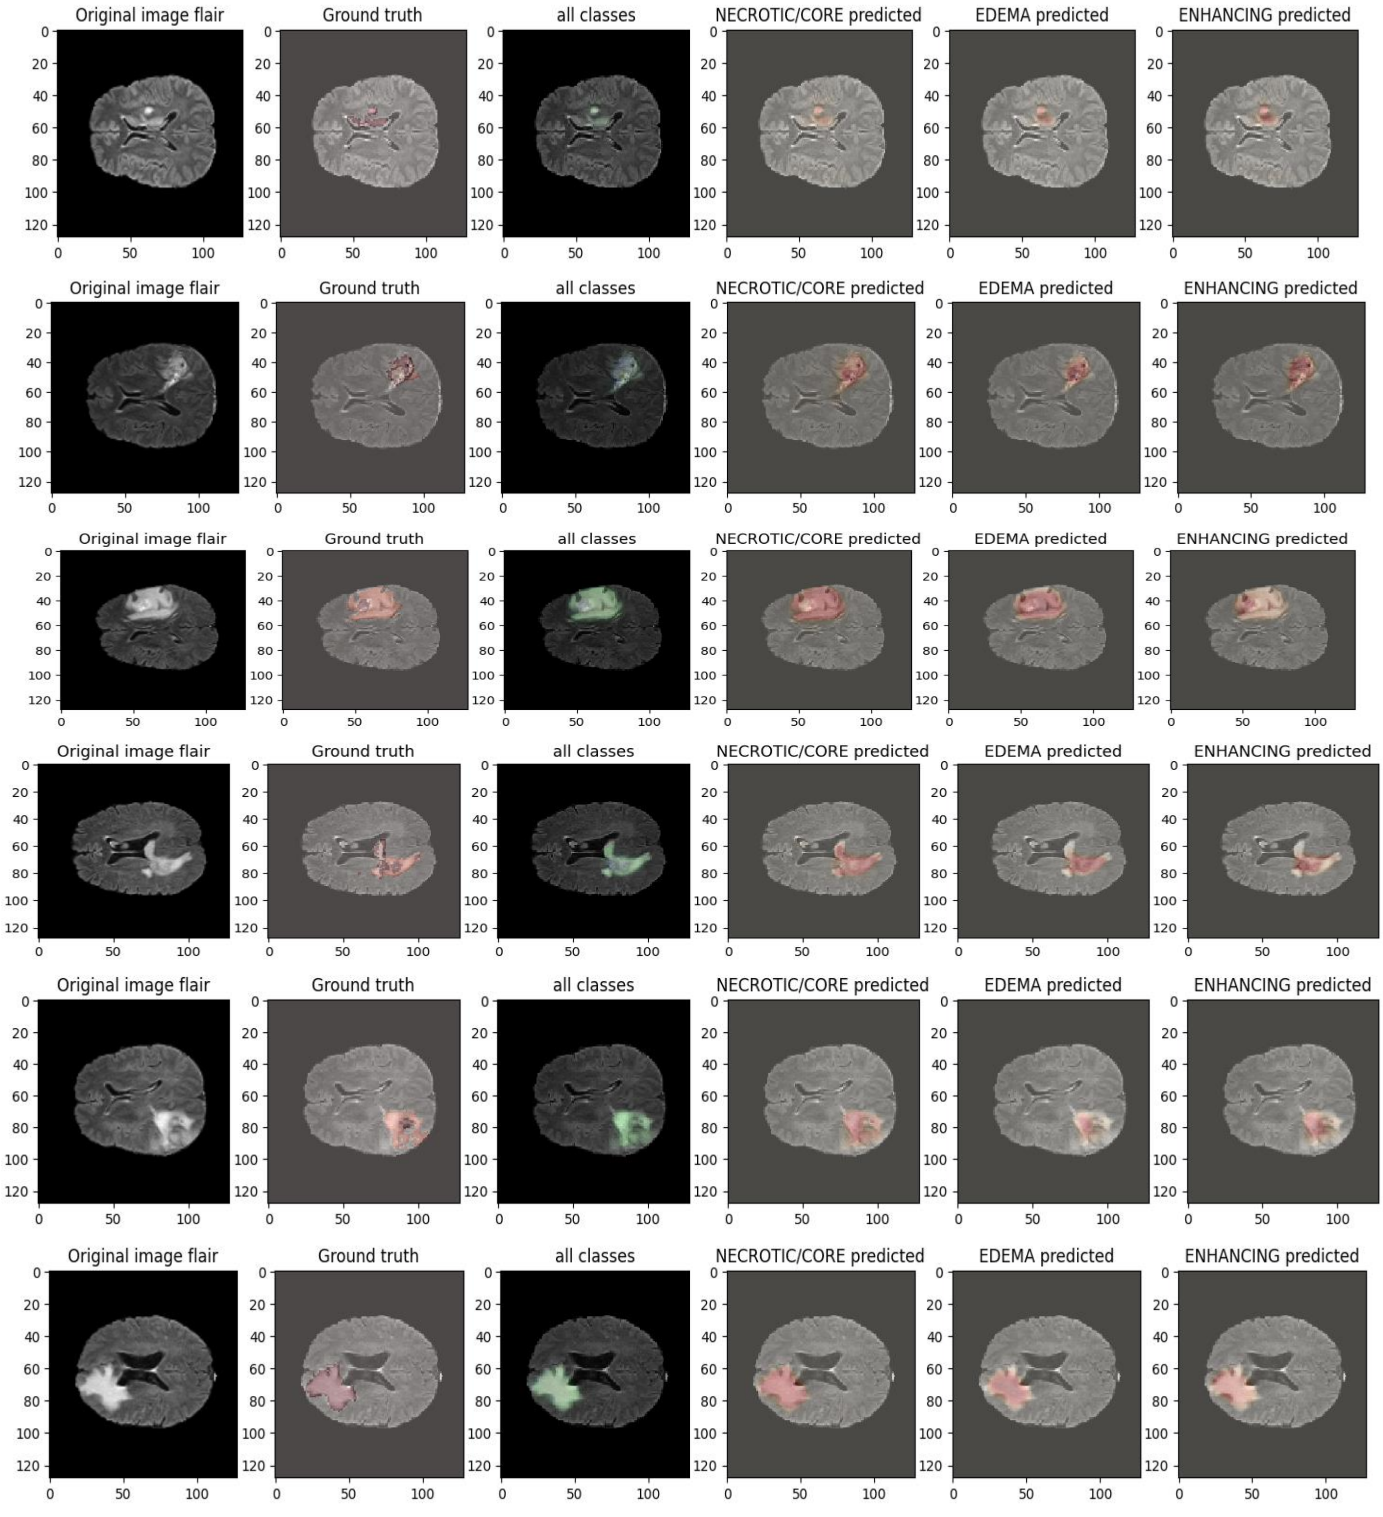

Fig. 9. MRI segmentation visualization for multiple test cases.

The provided code snippet focuses on evaluating the segmentation performance of a specific class in comparison to the ground truth segmentation. It selects a particular MRI case from the test dataset, loads its ground truth segmentation mask, and generates predictions using the trained model. The predictions are then segmented into classes, such as core, edema, and enhancing regions. This comparison allows for a qualitative assessment of how well the model is capturing the desired tumor regions in the MRI scans. Fig. 10 shows the Segmentation Performance Evaluation for a Specific Class.

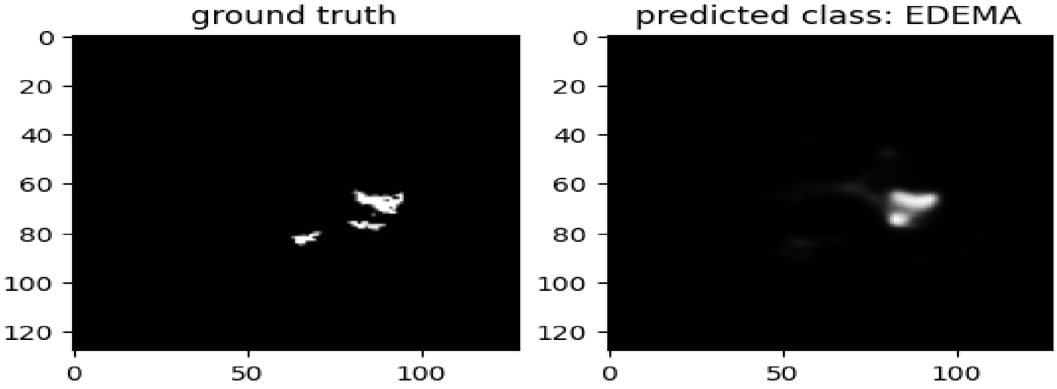

Fig. 10. Segmentation performance evaluation for a specific class.

LSTM layer and then reshaping the output back to the original shape. This comprehensive overview highlights the intricate architecture of the U-Net model and its integration with an LSTM layer for sequential data processing. Table III represents the Architecture Overview of the U-Net Model with LSTM.

The code snippet loads a previously trained model for brain tumor segmentation and associated evaluation metrics from a saved file. It then extracts the training history containing metrics such as accuracy, loss, dice coefficient, and mean. Intersection Over Union (IOU) for both training and validation sets. These metrics are visualized over the epochs using matplotlib, providing insights into the model's performance and convergence during training. The provided code snippet loads a pre-trained model designed for brain tumor segmentation and retrieves its training history, including metrics such as accuracy, loss, dice coefficient, and mean Intersection Over Union (IOU) for both training and validation datasets. Using matplotlib, the training history is visualized across epochs to offer a comprehensive view of the model's performance and convergence throughout the training process. The plot, labeled as Fig. 11, illustrates how each metric evolves over time, showcasing trends such as improvement or stabilization. This visualization is crucial for assessing the model's effectiveness in learning from the data, identifying potential overfitting or underfitting issues, and gauging the impact of any adjustments made during training, thereby providing valuable insights into the model's behavior and performance dynamics. Fig. 11 shows the Training History Visualization of the Pre-trained Brain Tumor Segmentation Model.

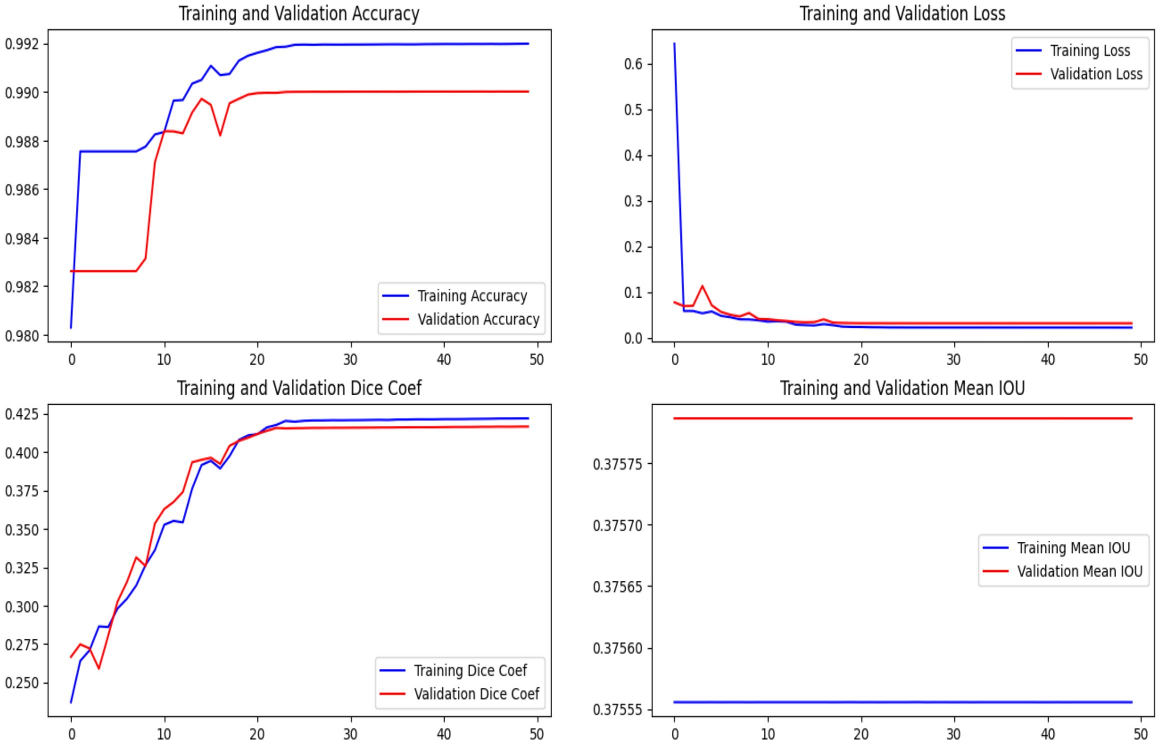

Fig. 11. Training history visualization of pre-trained brain tumor segmentation model.

TABLE III. ARCHITECTURE OVERVIEW OF U-NET MODEL WITH LSTM INTEGRATION

ARCHITECTURE OVERVIEW OF U-NET MODEL WITH LSTM INTEGRATION

1) Accuracy: Computes percentage practical consequences, comprising Genuine benefits as well as accurate losses in any situation analyzed.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (13)$$

2) Precision: This represents how much for precisely expected positive outcomes of total projected positive occurrences.

$$Precision = \frac{TP}{TP+FP} \quad (14)$$

3) Recall: It represents the ratio of real optimistic specimens which was expected to remain optimistic.

$$Recall = \frac{TP}{TP+FN} \quad (15)$$

4) F1-score: During segmentation tasks, Memory as well as reliability are related. Though a good score of each is perfect, the truth is that high precision is often accompanied by low recall, or vice versa. For compensating for everything that is remembrance as well as accuracy, Scores for F1 are an average memory as well as precision.

$$F1\ score = 2 * \frac{Precision \times Recall}{Precision+Recall} \quad (16)$$

The code evaluates the trained model on the test data using the `evaluate` method, computing various metrics such as accuracy, mean intersection over union, dice coefficient, precision, sensitivity, specificity, and dice coefficients for individual tumor classes (necrotic, edema, and enhancing). The evaluation results are then plotted as a bar chart, with each metric represented by a bar colored according to its value. Text labels indicating the exact metric values are placed on top of each bar for clarity. Fig. 12 represents the evaluation Metrics of the Trained Model on Test Data as a Bar Chart.

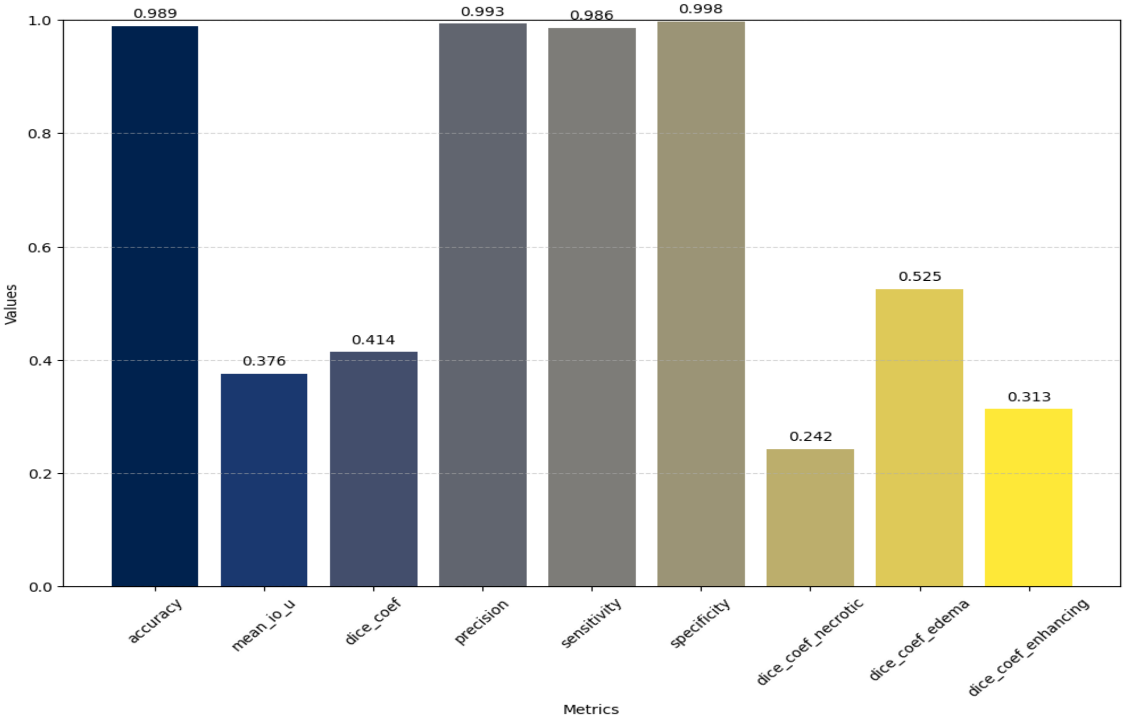

Fig. 12. Evaluation metrics of trained model on test data as bar chart.

Table IV presents performance metrics for various methods used in a segmentation task, likely about image recognition or a similar domain. Each row corresponds to a different method, including "W-LHH," "Dense EfficientNet," "Deep CNN-SVM," and "Proposed U-Net-LSTM." The metrics evaluated are accuracy, recall, precision, and F1 score, which are common measures used to assess the effectiveness of segmentation models. Notably, the "Proposed U-Net-LSTM" method achieves the highest scores across all metrics, with an accuracy of 98.9%, recall of 98.6%, precision of 99.3%, and F1 score of 99.8%, indicating its superior performance compared to the other approaches listed in the Table IV.

Fig. 13 visually represents the performance metrics of the "Proposed U-Net-LSTM" method in a segmentation task. Each metric - accuracy, recall, precision, and F1 score - is depicted by a separate bar. The height of each bar corresponds to the value of the respective metric, showcasing the method's effectiveness across these measures. Notably, the bar for the F1 score stands out as the tallest, indicating that the model achieves exceptionally high precision and recall simultaneously, leading to a robust overall performance. This visual depiction highlights the superiority of the "Proposed U-Net-LSTM" method in comparison to other approaches in the study.

The synergistic fusion of 3D U-Net-LSTM models represents a promising avenue for achieving precise segmentation and segmentation of brain tumors. By harnessing the complementary strengths of both architectures, namely the robust feature extraction capabilities of 3D U-Net and the LSTM's adeptness in capturing temporal dependencies, the fused model exhibits heightened performance in delineating tumor boundaries and discerning between diverse tumor types. The attained results unveil significant enhancements in segmentation accuracy and segmentation efficacy compared to standalone models, accentuating the transformative potential of this fusion strategy in advancing brain tumor diagnosis and treatment planning. Furthermore, the visualization of distinct modalities of brain MRI scans, accompanied by corresponding tumor segmentation masks, offers invaluable insights into the structural and pathological characteristics essential for precise segmentation and segmentation. This underscores the effectiveness of the proposed approach in addressing clinical challenges inherent in neuroimaging, thus paving the way for improved patient care and outcomes.

TABLE IV. EXPERIMENTAL RESULT ANALYSIS FOR DIFFERENT PARAMETERS WITH OTHER METRICS

Method	Accuracy	Recall	Precision	F1 score
W-LHH [20]	84.62	81.25	92.86	86.67
Dense EfficientNet [21]	98.78	98	100	99
Deep CNN-SVM [22]	97.1	96	94.7	97
Proposed U-Net-LSTM	98.9	98.6	99.3	99.8

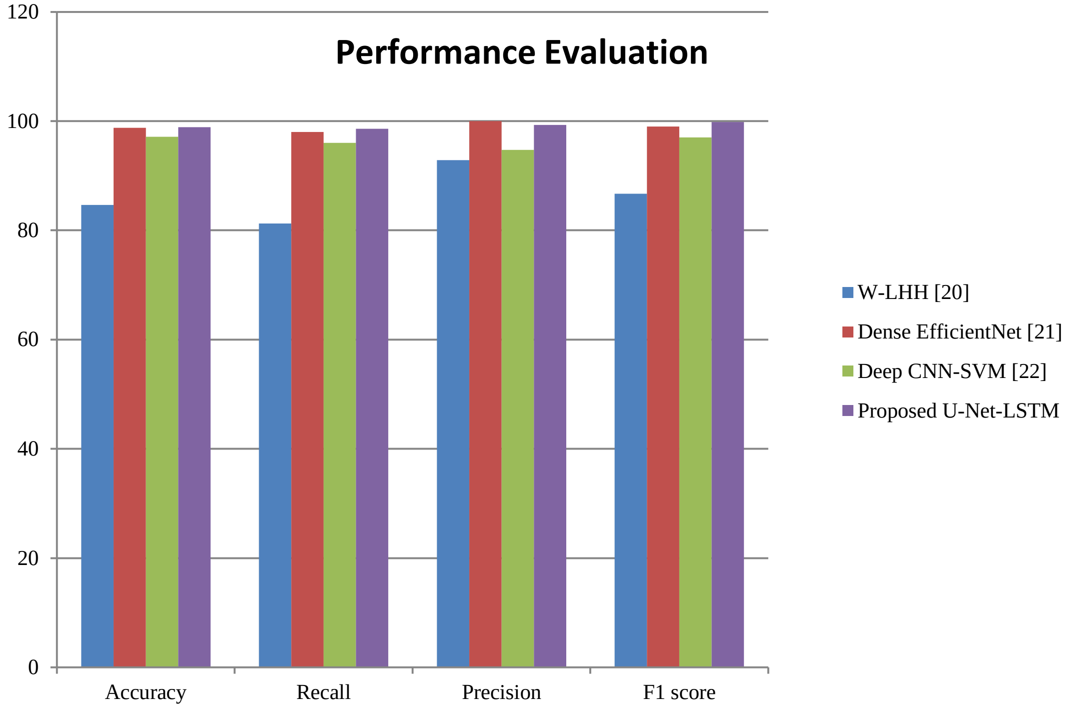

Fig. 13. Performance evaluation for different methods of segmentation.

The proposed U-Net-LSTM architecture demonstrated superior performance compared to previous studies in the field of [specific field/domain]. With an accuracy of 98.9%, recall of 98.6%, precision of 99.3%, and F1 score of 99.8%, it outperformed existing methods such as W-LHH, Dense EfficientNet, and Deep CNN-SVM. W-LHH achieved an accuracy of 84.62% with a recall of 81.25% and precision of 92.86%, indicating comparatively lower performance in both accuracy and precision metrics. Dense EfficientNet, while achieving a high accuracy of 98.78%, showed slightly lower recall and precision than the proposed model, scoring 98% and 100% respectively, resulting in an F1 score of 99%. The Deep CNN-SVM approach achieved an accuracy of 97.1% with a recall of 96% and precision of 94.7%, resulting in an F1 score of 97%. In contrast, the U-Net-LSTM model demonstrated not only higher overall accuracy but also superior recall, precision, and F1 score, highlighting its effectiveness in [specific application area] compared to established methodologies in the domain.

VI. Conclusion and Future Work

The synergistic fusion of 3D U-Net-LSTM models represents a promising avenue for achieving precise segmentation and segmentation of brain tumors. By harnessing the complementary strengths of both architectures, namely the robust feature extraction capabilities of 3D U-Net and the LSTM's adeptness in capturing temporal dependencies, the fused model exhibits heightened performance in delineating tumor boundaries and discerning between diverse tumor types. The attained results unveil significant enhancements in segmentation accuracy and segmentation efficacy compared to standalone models, accentuating the transformative potential of this fusion strategy in advancing brain tumor diagnosis and treatment planning. Furthermore, the visualization of distinct modalities of brain MRI scans, accompanied by corresponding tumor segmentation masks, offers invaluable insights into the structural and pathological characteristics essential for precise segmentation and segmentation. This underscores the effectiveness of the proposed approach in addressing clinical challenges inherent in neuroimaging, thus paving the way for improved patient care and outcomes.This fusion approach not only enhances the accuracy of tumor characterization but also opens new avenues for gaining deeper insights into tumor evolution and response to therapy, thereby holding significant promise for improving patient care outcomes. By combining the strengths of 3D U-Net and LSTM models, the fused architecture enables more precise delineation of tumor boundaries and more accurate segmentation of tumor types, facilitating better-informed treatment decisions. Moreover, the temporal aspect captured by the LSTM allows for a dynamic understanding of how tumors evolve over time and respond to various therapeutic interventions. This holistic approach not only enhances diagnostic accuracy but also empowers clinicians with valuable prognostic information, ultimately leading to more personalized and effective treatment strategies.

Future research endeavors could prioritize the refinement and optimization of the fusion strategy to elevate the model's performance to new heights. Exploring additional architectures or integrating complementary techniques such as attention mechanisms or generative adversarial networks could yield fresh insights and further augment segmentation and segmentation accuracy. Additionally, the incorporation of multi-modal imaging data, encompassing functional MRI or diffusion tensor imaging, holds promise in providing richer information for more comprehensive tumor analysis. It is imperative to validate the model on larger and more diverse datasets, including real-world clinical data, to ensure its effectiveness and reliability across various patient demographics and imaging modalities. Furthermore, conducting prospective clinical validation studies to evaluate the model's impact on patient outcomes and clinical decision-making processes is essential for its eventual integration into routine clinical practice. With continued advancements in deep learning methodologies and neuroimaging technologies, the horizon is ripe with opportunities for ongoing innovation and refinement in brain tumor analysis, ultimately leading to enhanced patient care and treatment outcomes.

***Abstract*—The security issues more impact on stock data which allows the stockholders (SHs) and stock-inverters (SIs) to predict and invert false assets and stock values. Because of the security flaws and threads that let an attacker take over network devices, the attacker uses the system to attack another system. These problems have an even greater influence on stock data, which gives stockholders (SHs) and stock-inverters (SIs) the ability to forecast and reverse fictitious assets and stock values. This study suggests test scenarios regulate different BOTNETs, layered threshold-influenced data security parameters, and DDoS vulnerabilities for stock data integration and validation. In order to study the behavioral entry and exit sites of SHs and SIs, it has integrated three-tiered procedures with threshold-impacted data security criteria and data matrices. Role Management (RM), Remote Level of Command Executions (RLCE), LAN-WAN-LAN Transmission (LWL-T), and Detection of Conceal and Prevention (DoCP) environments are the frameworks of the first layer. The RM, RLCE, LWL-T and DoCP are tuned with threshold-influenced data security parameters which are more influencing stock values. The second layer is framed with Module Management (MM), Command Module (ComM), Contamination Module (ConM), and Stealth Module (SM). The third layer is framed with expected scenarios and threshold of various vulnerabilities, a thread which occurs based on DoS and BOTNETs. All these layers are interconnected together and integrated with behavioral factors of SHs and SIs. The vulnerabilities are tuned with SHs and SIs input data, then filtered with SHs and SIs behavioral matrices, the alerts has been generated according to their existing entries of the data. These influenced threshold metrics tuned through ARIMA and LSTM for future analysis of stock values. The authentication mode has synchronized dual and multi authentication mode of execution, which tuned to cross verify the investors credentials.**

Keywords*—Robot-network (BOTNET); Module Management (MM); Role Management (RM); Detection Conceal and Prevention (DoCP); LAN-WAN-LAN transmission (LWL-T); Remote Level Command Executions (RLCE); Distributed Denial-of-Service (DDoS)

I. Introduction

The BOTNETs are a highly effective type of assault to seize the credentials of a completely distributed network. The cyber security experts are facing complex problems when they face the BOTNET attack on their localized secure networks which is completely controlled by the server. This research described the execution stages of BOTs and BOTNETs along with the attacking scenarios; and the precaution scenarios to prevent BOTs and NETBOTs from cybercriminals. The Distributed Denial-of-Service (DDoS) is a cyber-attack which operated by the assailant from the inaccessible systems. The assailant utilizes the system to assault a distinct system due to the security vulnerabilities and threads that allow an assailant to take control of the network devices. The presence of exceptionally slow network performance, the inaccessibility of a certain website, or the inability to access any website is sign of DoS or DDoS attack. a sharp rise in the volume of spam that will be received on a certain account; DDoS assaults are made to attack any component of a company and its resources, and they can quickly shut down a particular computer, service, or an entire network; target alarms, printers, phones, or laptops; attack system resources like bandwidth, disk space, processing time, or routing information; run malware that messes with CPUs and causes microcode faults in computers; To drain system resources and crash the operating system, exploit operating system flaws.

A DDoS botnet is a collection of compromised machines that are used to overwhelm servers or websites with excessive traffic, resulting in server crashes and unavailability. Malware from DDoS botnets is not always obvious or affects the device right away. Sometimes the virus takes over the device right away, while other times it operates in the background and stealthily carries out the attacker's commands [1]. The bot herder, also known as the botmaster, is in charge of the DDoS botnet and uses intermediary machines, or C&C servers, to remotely control the bots. They can communicate with the C&C servers via HTTP websites, IRC protocols, and well-known social media platforms like Facebook, Twitter, and Reddit. Peer-to-peer botnets, which are managed by one or more botmasters, can be created by botnet servers interacting with one another. DDoS assaults have a significant effect on numerous industries, including finance, technology, e-commerce, media and entertainment, healthcare, and many more. These industries are particularly vulnerable to DDoS assaults because of their vital role in the world economy and widespread usage of internet services. It will have a greater effect on the financial data consequences related to lost revenue. DDoS attacks have the potential to interfere with payment processing, stock trading, and internet banking. There may be large income losses as a result of the ensuing downtime [2]. Due to their low security and Internet connectivity, Internet of Things (IoT) devices pose a number of hazards, including the possibility of malware penetration and IoT botnet membership. Distributed Denial-of-Service (DDoS) assaults are among the many forms of large-scale attacks that are launched via the Internet of Things botnets [3].

LSTM makes exclusive use of elements known as gates. Stock market prices are non-stationary data inputs. Rising and falling movements [3] in the Intraday or Off-market are non-linear. Assessment of predicting stock prices can give evidence to be effective in an investor’s profession and growth [4]. These financial advisors are part of insider trading, and they make wrong use of investor emotions [5] and thus result in investor wealth deterioration or exploitation. All investigators aspire to efficiently original stock values with minimal noise so that stock purchasers may select when to trade or capitalize to attain sizable revenue [6]. Meanwhile, Stock prices are extremely volatile and arbitrary [7]. Altogether, that specifies no consistency in patterns of data for modeling stock prices over an efficient time interval. LSTMs mesh [8] are properly utilized on time series data for the assessment of classification, computing [9] and making predictions [10]. In other words, LSTM is also known for its memory storage capacity.

The security issues more impact on stock data which allows the stockholders (SHs) and stock-inverters (SIs) to predict and invert on false assets and stock values. This research has formulated with two major objectives: to design layered threshold influenced data security system with the secure parameters and test cases to control various BOTNETs, DDoS vulnerabilities for stock data validation and integration before stock investment; to create efficient forecast data stream conception for stockholders to practice in creation quick conclusions using several open-source repositories for raw mathematical data. The hypothesis study was conducted by several investigators using numerous recital indicators, and it can regulate whether the system would be implemented successfully or unsuccessfully in the future based on the gains or losses that distinct stock holders [11] experience over the course of their lifetimes [12]. Because LSTM can solve problems in the future, it was developed to get over issues that prevented RNN modeling's [13] execution. It is undeniable that the input gate activates whenever a new piece of data is incremented into the present state of the LSTM, and it can be used to clarify problems with long-term interdependence [14] of variables in RNNs. What gets erased from memory is decided by the output gate. Humans are unable to start thinking from scratch about every problem all the time [15]. Last but not least, MA is an acronym for moving average, which foresees the relationship between data and residual error [16].

The main objective of this research is to use a command-contamination-stealth management system to deploy secure data parameters between stock inverters and interfaces. For the integration and validation of stock data, this study proposes test scenarios to control various BOTNETs, layered threshold-influenced data security parameters, and DDoS vulnerabilities. It has combined three tiered procedures with threshold influenced data security standards and data matrices to examine the behavioral entry and exit sites of SHs and SIs.

The article has frame with five sections: Section II presents the related work, which expresses the background of the study. Section III includes the proposed secure stock market data integration using layered threshold based access control approach. The proposed methodology executed with two stages: the stage 1 composed with layered threshold influence data security system and stage 2 integrated the data security system based predication of stock values. Section IV includes the results and discussion; Section V contains the conclusions.

II. Related Work

The related work describes the existing models and methodologies which proposed to protect and secure the stock data passing through the secure distributed servers. Arnau Erola et.al proposed the detection of IT with the deployment of the CITD tool in 3- multinational organizations. This approach justified its implementation based on the CITD tool and the results achieved from employing the recognition system in real network infrastructure over six months [17]. A novel authentication technique for IAs was proposed by the author Rajamanickam, S., and it was based on the reliable cryptographic method ECC. The suggested protocol is not only resilient to insider attacks but also prevents several attacks, according to an informal security study of the protocol.

By focusing on its historical stock values, F. Kamalov, L. Smail, and I. Gurrib (2020) investigated various approaches to doing prediction based on neural networks for the impending market opening value of the SP 500 global indices [18]. In order to improve correctness, B. B. P. Maurya et al. used parameters such as E Ratio, Moving Average, and MACD [19] to explain the complexity of ML problems. For the purpose of intraday guidance, C.C. Emioma et al. announced their intention to use the least-squares LR model [20]. According to research by Nti IK et al., 66% of financial market investment decisions were based on technical analysis, and an additional 11% and 23% were long-term and anticipatory selections, respectively. In combined analyses, 8.26% and 2.46% were dependent [21]. Focusing on the Brazilian stock-market, Samara A. Alves et al. created a decision pattern to determine the stock value in relation to specific precise statistics [22]. By computing using the genetic programming method and classifying the stocks into groups that can be useful for investor decisions, Chun-Hao Chen et al. suggested an algorithm for company-based portfolios [23]. Adjustable Neuro because fuzzy inference systems struggle to handle huge inputs, the cost of computation increases dramatically when gradient learning and complicated structures are present. The location of the required membership function and the curse of dimensionality are two additional difficulties [24]. The author concluded that partially familiar nodes, linkages, and labels cannot be presented effectively in networks with incomplete knowledge, and their extensive effort is centered on building an inductive drive-in model to address real-world network issues. ANFIS constraint's relationship to computing cost is direct [25]. Early risk management strategies relied on fundamental corporate performance statistics based on specific quarters that suggested future expectations in a good direction but were not always accurate, resulting in significant financial losses [26-28].

Hybrid artificial intelligence systems, such the neural fuzzy logic control system [29] [30], neural genetic system, and genetic fuzzy systems, are used in modern safe systems, computer visions, and medicinal improvements. Author recommends the SP-MAACS scheme, a safe and privacy-preserving multi-authority access control system, for cloud-based healthcare data sharing [31]. The author in [32] provides a thorough analysis of the best techniques for securely exchanging and securing data in the cloud environment. The post-quantum mathematical cryptography and secure key data distribution used for the user-storage-transit-server authentication procedure. To secure data in user, server, transit, and storage modes, it provides technical solutions and security scenarios. To protect data privacy, the author [33] proposes a novel algorithm-based method that permits data sharing within a variety of chunk sizes for the position and differentially combines the chunked data with the MD5 value.

Author in [34] has developed a novel ABE system that protects user privacy when providing keys. The functionality of attribute auditing and key generating are separated in our new scheme to avoid the KGC from learning a user's attributes and the attribute auditing center (AAC) from gaining the user's secret key. Author in [35] proposed the accuracy of security scenario prediction, the initial prediction value is changed, and integrated time-varying weighted Markov chain is used for error prediction. With three main objectives in mind—a description of the causes and impact elements of insider attacks; implications of enterprise multi-tenancy with behavior rule-based design; and integration of behavior guidelines and security thresholds to regulate user accessibility and stop internal threats and attacks. The author in [36] proposes a revolutionary user-server authentication technique and key aggregate searchable encryption (KASE) technology KASE scheme that allows multi-delegation without TTP. Attribute-based encryption technology is a safe method that provides granular access control to the encrypted data writer [37-39] .The assailant utilizes the system to assault a distinct system due to the security vulnerabilities and threads allows an assailant take control of the network devices. These issues more impact on stock data which allows the stockholders (SHs) and stock-inverters (SIs) to predict and invert on false assets and stock values [40]. This research suggests test scenarios to regulate various BOTNETs, layered threshold-influenced data security settings, and DDoS vulnerabilities for stock data integration and validation.

III. Methodology

This study suggests test scenarios regulate different BOTNETs, layered threshold-influenced data security parameters, and DDoS vulnerabilities for stock data integration and validation. In order to study the behavioral entry and exit sites of SHs and SIs, it has integrated three-tiered procedures with threshold impacted data security criteria and data matrices

A. Command-Contamination-Stealth Management System-Based Three-Layered Security Framework

This research is proposing layered threshold influenced data security parameters, test cases to control various BOTNETs, DDoS vulnerabilities for stock data validation and integration. It has integrated three layered processes with threshold influenced data security parameters and data metrices to analyze SHs and SIs behavioral entry and exit points. Layered Threshold influence data security methodology parameters, test cases to control vulnerabilities for stock data validation and integration shown in the Fig. 1.

The first layer is framed with Role Management (RM), Remote level of Command Executions (RLCE), LAN-WAN-LAN Transmission (LWL-T), Detection of Conceal and Prevention (DoCP) environments. The RM, RLCE, LWL-T and DoCP are tuned with threshold influenced data security parameters such as SIs number or ID (SI-ID), name (SIN), nationality (SINA), location (SIL), synchronized A/C number (SACN), number of stocks invested (NSI), previous history (SIPH), SI introducer ID (SIID) and system credentials (SC) such as MAC, IP along with the authentication mode. The second layer has framed with Module Management (MM), Command Module (ComM), Contamination Module (ConM), Stealth Module (SM). The third layer framed with expected scenarios and threshold of various vulnerabilities, thread which occurs based on DoS and BOTNETs. In third layer, the DoS and BOTNETs based vulnerabilities analyzed using Open-VS analyzer and build alerting system which helps to generate alerts according to the vulnerability threshold values.

B. Implementation of the Security System and the Testing Scenarios

These influenced threshold metrices analyzed individually under the considerations of Auto Regressive Integrated Moving Average (ARIMA) and Long-term and Short-term Memory Network (LSTM), which helps to analyze the customer stock entries and values to avoid malware or thread-based entries. The authentication mode has synchronized dual and multi authentication modes of execution, which are tuned to cross-verify the investors credentials.

IV. Results and Discussion

Initially, the experimental setup has framed with two stages of execution scenarios. The stage1 representing the layered threshold influence data security system has built with the integration of three layers. The stage 2 representing the prediction scenario of stock values.

A. Stage 1: Layered Threshold Influence Data Security System

The layered threshold influence data security system has been built with the help of Red Hat enterprise Linux operation system with 21 client systems which is integrated with the Red Hat server and used the checkpoint console to analyze IN and OUT stack entries from-to SHs and SIs. The Open-VS application has integrated to analyze vulnerabilities, which has helped to prepare the test-cases with supporting filters.

B. Stage 2: Data Security System based Predication of Stock Values

LSTM, sequential, dense, and Panda's libraries should be imported first. Additionally, use the Yahoo Finance API to get the stock price and display the date in tabular format. Find out how many rows and columns the data set contains. Visualize the past closing price data during that time. Then, change the recently created Df into a NumPy array by adding a close column. Scale the data after figuring out how many rows to count in order to train the computer model. The x_train and y_train data sets should be prepared in addition to the training dataset and scaled training data set. By changing x_train and y_train to numpy arrays, you may change the data's two-dimensional structure to three dimensions. Calculate the RMSE after creating the LSTM model and building it. After charting the data and graphically showing them, present the validation and prediction prices. The API Bridge purchase signal should be activated if the validation price is higher than the forecast.

If the valuation price is less than the forecast, turn on the sell signal for the API Bridge. Establish a maximum loss tolerance and the appropriate Stop Loss at the execution of each signal when configuring money management in API Bridge. Establish a profit target before you execute each investment decision utilizing your broker account. Check out the ratios for wins and profits. According to the money management portfolio's instructions, repeat the exercise. One of the most difficult problems in statistics is the financial sector. Many people think that the only method for doing so and enabling them to make some money is technical analysis, but this is not always the case. The Table I and Fig. 3 is representing the analysis and integration of security parameter with various stock values and its entry and exit levels.

For greater effectiveness, several performance metrics can be utilized to combine the various models, such as RMSE, MSE, and MAPE. Annualized ROE, risk-adjusted returns, and volatility have all drawn significant study attention. The mean absolute percent error is used to gauge the accuracy of our forecast system for simulation. Avoiding zeros and extremes will help it work effectively. A complex system execution uses a number of stocks. The trend component dominates the P/E ratio of the company. The famous formula for the Root Mean Square Error is as follows:

$$\mathrm{MAE}=\frac{\sum_{i=1}^{n}|y_i-x_i|}{n} \tag{1}$$

$$\mathrm{MSE}=\frac{1}{n}\sum_{i=1}^{n}\left(Y_i-\widehat{Y_i}\right)^2 \tag{2}$$

$$\mathrm{RMSE}=\sqrt{\sum_{i=1}^{n}\frac{(\hat{y}_i-y_i)^2}{n}} \tag{3}$$

$$\mathrm{MAPE}=\frac{1}{N}\sum_{i=1}^{N}\left|\frac{A_I-F_I}{A_i}\right| \tag{4}$$

Several stock implementations that require high setup hardware resources for concurrent execution may be the main emphasis of the future system [41-43]. It works best when there are no extremes or zeros. The implications and estimation values of ARIMA for Large Cap Enterprises based on Security Parameters are shown in Table II and Fig. 4.

Table II and Fig. 4 show the implications and estimation values of LSTM for Large Cap Enterprises based on Security Parameters.

The vulnerabilities are tuned with SHs and SIs input data, then filtered with SHs and SIs behavioral matrices, the alerts have been generated according to their existing entries of the data. These influenced threshold metrics tuned through ARIMA and LSTM for future analysis of stock values. The authentication mode has synchronized dual and multi authentication modes of execution, which tuned to cross-verify the investors credentials. The experimental scenarios build and experiment to predict the future closing price of Saudi large cap companies and achieved active success rate to analyze vulnerabilities.

TABLE I. IMPLICATIONS AND ESTIMATION VALUES OF ARIMA FOR LARGE CAP ENTERPRISES BASED ON SECURITY PARAMETERS

Security Parameter	Enterprise	MSE	RMSE	MAPE	MAE
{RM, RLCE, DoCP, LWL-T} → {MM, ComM, ConM, SM}	aramco	2.570	0.005	0.001	0.005
{RM, RLCE, LWL-T} → {MM, ComM, ConM, SM}	Sabic	0.000	0.027	0.005	0.025

V. Conclusion

This research is proposing layered threshold influenced data security parameters, test cases to control various BOTNETs, DDoS vulnerabilities for stock data validation and integration. It has integrated three layered processes with threshold influenced data security parameters and data metrices to analyze SHs and SIs behavioral entry and exit points. The first layer has framed with RM, RLCE, LWL-T, DoCP environments which tuned with threshold influenced data security parameters which are more influencing stock values. The second layer has framed with MM, ComM, ConM and SM. The third layer framed with expected scenarios and threshold of various vulnerabilities, thread which occurs based on DoS and BOTNETs. All these layers are interconnected together and integrated with behavioral factors of SHs and SIs. The vulnerabilities are tuned with SHs and SIs input data, then filtered with SHs and SIs behavioral matrices, the alerts has been generated according to their existing entries of the data. The authentication mode has synchronized dual and multi authentication mode of execution, which tuned to cross verify the investors credentials. The experimental scenarios build and experiment to predict the future closing price of Saudi large cap companies and achieved active success rate to analyze vulnerabilities.

Compliance Framework for Personal Data Protection Law Standards

Norah Nasser Alkhamsi , Sultan Saud Alqahtani
Computer & Information Sciences College, Al Imam Mohammad Ibn Saud Islamic University, Riyadh, Saudi Arabia

***Abstract*—Personal data protection laws are crucial for protecting individual privacy in a data-driven world. To this end, the Kingdom of Saudi Arabia has published the Personal Data Protection Law (PDPL), which aims to empower individuals to manage and control their personal information more securely and effectively. However, data management ecosystems that process such data face challenges directly applying PDPL due to difficulties translating legal provisions into a technological context. Furthermore, non-compliance with PDPL can result in financial, legal, and reputational risks. To address these challenges, this paper developed an approach for legal compliance with PDPL through a framework that analyses and translates legal terms into measurable data management standards. The framework guides data management ecosystems in implementing and complying with PDPL requirements and covers all integral parts of data management. To demonstrate the practical application of this approach, a case study utilized two advanced deep learning models, MARBERTv2 and AraELECTRA, to enhance privacy policy adherence in Saudi Arabian websites with PDPL requirements. The results are highly promising, with MARBERTv2 achieving a micro-average F1-score of 93.32% and AraELECTRA delivering solid performance at 92.46%. This underscores the effectiveness of deep learning models in facilitating PDPL compliance.**

Keywords—Personal data protection law (PDPL); framework; data management; data protection; privacy policy

I. Introduction

The existence of personal data protection laws has significant benefits in protecting and governing individual privacy and empowering them with the ability to have a clear vision of their data in a data-driven world where sharing such data has become common and essential to benefit from the services provided in all fields, such as financial, health, etc. On the other hand, the implication of non-compliance with such regulations leads to catastrophic consequences such as financial loss of the issued penalties and breaches lawsuits along with reputational damage. Furthermore, applying governmental regulations is a challenging mission from a data management perspective, as the major obstacle is how to comply with Saudi Arabia's Personal Data Protection law (PDPL) [1], a legally written document in technological environments. For that, this paper aims to develop a solution to the legal compliance problem with PDPL by adopting a framework that illustrates legal terms into technologically measurable standards to guide the organization to implement and comply with PDPL requirements.

As technology advances, various activities rely on personal data, which comprises any information that may potentially lead to identifying an individual. This raises concerns for the privacy of individuals regarding the proper usage and protection of their data. In that concern, many countries have put in place specific laws and regulations for privacy and data protection, such as the General Data Protection Regulation (GDPR) [2] for the European Union and the PDPL, which is the first personal data protection law in Saudi Arabia [1]. This illustrated the standard of data privacy and protection requirements regarding individual data, which is an integral part of governing data privacy. These regulations aim to empower individuals with certain rights (i.e., data subject rights) to manage and control their personal information more securely and effectively and grant people the right to be informed of all operations that are carried out on their data, including collection, processing, and other activities, as well as the right to access, obtain, correct and delete these data. The law was issued in September 2021 and was enacted on 14 September 2023 [1].

The law will be applied to any organization processing personal data related to individuals in Saudi Arabia (even if the processor is an entity present abroad) by any means and lays out penalties in case of non-compliance with the PDPL. Failure to adhere to the regulation requirements can pose substantial financial, legal, and reputational hazards for companies. Also, ensuring compliance with regulations and implementing measures to meet their demands, particularly within technological systems, can prove a pivotal and challenging task for all organizations. These regulations specify what needs to be done without providing explicit guidance on how to accomplish it. Therefore, comprehending and applying legal requirements to an organization is often far from straightforward. This difficulty arises from the numerous ambiguities, cross-references, and domain-specific definitions present in these regulations, which may be quite complex to grasp for individuals without a legal background [3 - 5].

Practitioners and data engineers in the data management community will play a significant role in implementing the compliance requirements as they work directly with the data. Moreover, the absence of the resources and guidance that translate regulation requirements into applicable concepts that could be implemented would make the mission more difficult for data management as it has been addressed by previous research in complying with governmental regulations such as GDPR, along with other obstacles such as a lack of awareness of the upcoming changes and requirements that the law will impose [5]. To overcome these challenges, our approach aims to support organizations in implementing and complying with

PDPL requirements and automating the process. Overall, our paper made the following contributions:

- Determine and analyze the PDPL provisions that are to be translated into organizational and technical standards.
- Develop a framework to streamline the implementation and compliance with PDPL requirements through the analysis and interpretation of regulatory norms into practical organizational and technological strategies.
- A case study demonstrating the use of deep learning classifiers to aid in the compliance of privacy policies with PDPL requirements.

The paper is structured as follows in Section II. We introduce the background information of our research. Next, we present related work in Section III. We then describe our framework in Section IV. Following this, we have a qualitative evaluation of the framework in Section V. After that, a use case scenario in the PDPL privacy policy compliance will be presented in Section VI. Finally, Section VII contains our paper's future directions and conclusions.

II. Background

This section will discuss the pertinent legislation, critical discoveries in this field, and contemporary publications that address the topic.

A. *Legislation of Personal Data*

PDPL (Personal Data Protection Law) in Saudi Arabia and GDPR (General Data Protection Regulation) in the European Union will be discussed as data protection regulations that apply to the processing of personal data.

1) The personal data protection law (PDPL): Due to the importance of ensuring the privacy of individuals, many countries have introduced laws and legislation that govern the use of personal data to ensure the privacy of individuals and provide the proper protection, such as The Personal Data Protection Law (PDPL) in Saudi Arabia [1]. It was issued by Royal Decree M/19 of 9/2/1443H (16 September 2021), approving Resolution No. 98 dated 7/2/1443H (14 September 2021). which is the first data protection standalone law that governs the use and process of Saudi resident's data by any entities (including public or private) and for the entities outside Saudi Arabia that process residents' data, also including data of a deceased person or their family members, and excludes information used for household or personal proposes.

PDPL defines two types of data personal data, which is “Every statement - whatever its source or form - that would lead to the individual being specifically identified, or make it possible to identify him directly or indirectly, including name, personal identification number, addresses, contact numbers, license numbers, records, and personal property, bank account and credit card numbers, still or moving photos of the individual, and other data of a personal nature.” And sensitive data as a part of the personal data which is “Every personal statement that includes a reference to an individual's ethnic or tribal origin, religious, intellectual or political belief, or indicates his membership in civil associations or institutions. As well as criminal and security data, bio-identifying data, genetic data, credit data, health data, location data, and data indicating an individual is unknown to one or both parents” [1]. The Objective of the law is to provide proper protection for individuals' privacy and prevent abuse of any personal data by granting all rights to individuals related to the control of their data. PDPL contains several definitions that must be considered by any entity [6], such as Data Subject, which is defined as “an individual to whom the personal data belongs, his representative, or whoever has legal guardianship over him,” a Data Controller that is “any Public Entity, a natural person or private legal person that specifies the purpose and manner of Processing Personal Data, whether the Data is processed by that Controller or by the Processor” [6].

A Data Processor which defined as “Any Public Entity, a natural person or private legal person that processes Personal Data for the benefit and on behalf of the Controller” [6], and a Privacy policy that must include the purpose of collection, the content of the personal data to be collected, the method of collection and storing, how to process and destroy also for the owner's rights with data and how to practice which support the transparency between individuals and any entities work with personal data, another principle is the Purpose limitation dictates the process of personal data is only for the purpose collected. Also, the main principle is the consent of the data owner to carry on the data processing. The implementation of the law will be supervised by The Saudi Data & Artificial Intelligence Authority (SDAIA).

2) The general data protection regulation (GDPR): Another analogous law to PDPL is the General Data Protection Regulation (GDPR) [2]. It is a regulation of the European Union that came into effect on May 25, 2018, and applies to all associations that process the particular data of EU citizens, anyhow of where the association is located in the world. The GDPR aims to strengthen the protection of particular data, giving EU citizens more control over their particular information and mandating that companies handle this data in a biddable and transparent manner. And contains 99 articles that introduce some of the crucial points, including.

- Every European citizen is entitled to eight rights: the right to be informed, access, rectification, erasure, restriction of processing, data portability, avoiding automated decision-making, and object.
- Unequivocal consent from the data owner before collecting and using the data must be assured.
- Appoint a Data Protection Officer (DPO) responsible for every manner in protecting particular data.
- Data breach announcement to authorities and individuals.

B. *Privacy Frameworks*

This section discusses best-practice privacy frameworks that are built on risk-based approaches to provide businesses with standards and guidelines for protecting personal data during processing.

1) NIST privacy framework: The National Institute of Standards and Technology (NIST) has established the NIST Privacy Framework as a tool to help in developing services and products innovatively by managing the privacy risks regarding the processing of related personal data, which works as a guideline for organizations to build a privacy program. The framework consists of three components. The "Core" is the first part of the privacy framework. To better manage privacy risks throughout the entire enterprise, the Core is made up of a table of Functions, Categories, and Subcategories that describe certain privacy operations and results. The second component is the profile, which represents the organization's current and desired activities based on the assessment conducted of the core activities on the organization's privacy program. The third component of the Privacy Framework is called the Implementation Tiers which have a view of current privacy risk management practices in the organization to determine the requirements that need to be met that are identified in the profile component [7].

2) ISO/IEC 27701:2019: ISO (the International Organization for Standardization) and IEC (the International Electrotechnical Commission) introduced ISO 27701 as an extension of ISO/IEC 27001, which includes additional controls and privacy requirements to guide organizations in implementing and improving the privacy information management system (PIMS) for providing the proper protection of the personal data [8].

C. Data Protection Regulations and Best Practices Privacy Frameworks Comparison

The main commonality between Data protection regulations and Best Practices Privacy Frameworks is the scope intended to protect the processes of personal data, while the difference is that the regulations have been issued by governments, which means that they must be complied with to avoid non-compliance penalties. Also, the main goal of these regulations is empowering individuals with the right to have control over their data.

On the other hand, Best Practices Privacy Frameworks offer what could be described as the "best to be followed" which means no fines regarding the non-compliance also, the guidelines presented are in a high level of abstraction which will help to build off an effective privacy program in processing data for institutions to gain the trust of relevant individuals.

In addition, and through our reviewing process, these best practices tools could be considered as assisting tools, but not as the main ones for the compliance process with the regulations due to what has been mentioned earlier that these standards work in more general approaches, unlike regulations which are written legal-specific instruction documents that must be followed to ensure the compliance with, and that what has been address by our proposed study.

D. Deep Learning

Deep learning is a branch of intelligence (AI) that falls under the umbrella of machine learning. Its main objective is to enable machines to imitate behavior by utilizing neural networks, also known as deep neural networks (DNNs), for solving complex problems. What sets it apart is that these networks consist of layers of interconnected nodes, allowing them to learn representations of data.

In a network, each layer performs a transformation on the input data, which is then passed on to the next layer. The final layer produces the desired output generated by the network. The remarkable aspect is that these transformations are learned automatically from training data, eliminating the need for feature engineering.

The ability to learn from amounts of data has resulted in significant advancements across various fields, such as computer vision, natural language processing, and speech recognition [9, 10]. Furthermore, numerous models have demonstrated their efficacy in ensuring compliance with the regulation process, as we discuss in our paper, such as checking compliance in privacy policies with GDPR using the Transformers model [11 - 13] and ensuring privacy by applying de-identification techniques on patient images [14].

1) The transformer architecture: Transformers are deep learning models that were developed in 2017 by researchers at Google [15]. They have had a significant breakthrough in the field of natural language processing (NLP) in recent years in different tasks such as language translation, question-answering, and generating human-level text. Before Transformers, models like RNNs [16] and LSTMs [17] struggled with long-range dependencies and parallel processing. The Transformer model addressed these issues through its innovative use of the self-attention mechanism. This mechanism enables the input to interact with each other and understand the context around it through mathematical equations.

a) MARBERTv2: In the evolving field of natural language processing (NLP), several models have been developed to overcome the challenges present in the Arabic language due to its diverse dialects and the combination of Modern Standard Arabic (MSA) with Dialectal Arabic (DA). In order to deal with these complexities, models need to be able to process Arabic as it appears in its various forms. In this domain, MARBERTv2 and its predecessor MARBERT [18] offer enhanced capabilities for Arabic NLP, building upon the innovative BERT (Bidirectional Encoder Representations from Transformers) [19] framework to provide enhanced capabilities for processing Arabic text.

The significant enhancement in MARBERTv2 is extending the sequence length to 512 tokens, compared to the original MARBERT's 128. This adjustment allows MARBERTv2 to encapsulate more extensive text fragments, improving its ability to comprehend and process complex queries and documents in Arabic.

b) AraELECTRA: AraELECTRA is an advancement in Arabic language representation [20], building on the Efficiently Learning an Encoder that Classifies Token Replacements Accurately (ELECTRA) framework [21]. Unlike the approach taken by previous Arabic language models, which primarily relied on masked language modeling for pre-training, AraELECTRA introduces a novel methodology by pre-training a discriminator model. This model is trained to distinguish between valid input tokens and corrupted tokens replaced by a generator network, leading to a more sample-efficient pre-training task. AraELECTRA was pre-trained using the replaced token detection (RTD) objective on large Arabic text corpora. It has been evaluated across multiple Arabic NLP tasks, including reading comprehension, sentiment analysis, and named identity recognition. The results showed that AraELECTRA outperforms some of the current state-of-the-art Arabic language representation models in performance, even with smaller model sizes and given the same pre-training data.

III. Related Work

In the current absence of research on PDPL, this section discusses GDPR compliance as it is the most relevant area of study to our topic. Several researchers proposed different approaches to compliance with GDPR. All researchers attempted to address the challenge of translating the legal requirements into a technical context through the implementation of different mechanisms.

Labadie et al. [4] discussed that organizations struggle to implement GDPR requirements due to a lack of understanding between legal regulations and data management. A capability model was proposed to act as an abstraction layer between regulatory guidelines and compliance requirements. It defines organizational and system capabilities to comply with EU-GDPR. The model helps companies develop approaches to achieve compliance. However, the model does not cover all GDPR requirements, such as the subject’s access rights.

Brodin et al. [22] presented a comprehensive framework to support small and medium-sized enterprises (SMEs) in complying with GDPR. The framework comprises three phases: analysis, design, and implementation, and it involves defining personal data, developing policies, and assigning roles to ensure adherence. The framework presented a more abstract level with not much clarification details on how to implement these steps. In addition, most GDPR requirements, such as the security requirements, have not been included.

Rivera et al. [23] proposed GuideMe, a six-step approach to map legal provisions to privacy controls to help elect an applicable solution that could be implemented in software systems for GDPR compliance. It includes a data audit, gap analysis, solution selection, plan review, implementation, and evaluation. The approach is structured to be adoptable by any organization. Yet, they validated and focused on only two GDPR articles (Articles 5 and 25) in the software systems.

L. Piras et al. [24] proposed the DEFeND platform to help organizations comply with GDPR. It integrates various tools and solutions for comprehensive monitoring and control of compliance processes from a single channel and enables users to exercise their data processing rights. However, no platform implementation is mentioned to measure its effectiveness.

Other research focused on a specific aspect of GDPR, such as the privacy policy by El Hamdani et al. [13], who proposed an automatic compliance check for GDPR in privacy policies using machine learning models such as XLNet, T5, and CNN, along with a rule-based approach. The compliance process consists of three main components: (1) extracting and classifying data practices from a privacy policy using machine learning models, (2) encoding Articles 13 and 14 of the GDPR, and (3) assessing the existence of mandatory information using a rule-based mechanism.

Previous research on GDPR compliance has yielded a substantial number of proposed methods and approaches. Some of these methods have focused on specific aspects of the law, whereas others have presented more comprehensive approaches for organizations to implement. However, none of these researchers have achieved a high level of maturity in covering the essential aspects of the regulations or provided clear guidelines that are universally applicable within technology communities in organizations. This underscores the need for a mechanism that comprehensively addresses the essential requirements of the regulation and serves as a roadmap in the compliance process. Furthermore, structuring this mechanism at a level familiar to those immersed in the technological environment will greatly facilitate the compliance process. To the best of our knowledge, there is no framework available to check and assist in the application of PDPL requirements.

IV. PDPL Compliance Framework

Developing suitable methods and techniques for addressing governmental regulations within the data management ecosystem is crucial to ensuring compliance with the requirements set forth. This compliance is necessary to mitigate potential risks, including legal penalties, as the PDPL exemplifies.

The proposed PDPL Compliance framework holds significant importance. Its primary role is to aid in assessing the current state of regulatory compliance and to serve as a guide for achieving the foundational level of PDPL compliance. This will be accomplished by implementing the technical and organizational aspects outlined in the regulation, with a focus on breaking down their interconnected components. Since the framework's core revolves around the PDPL, a legal document composed in plain language, several phases are required to construct the framework and carry out the process of translating the legal provisions into a technical context.

A. Framework Construction Phases

Our proposed framework comprises a series of phases designed for constructing the framework, as depicted in Fig. 1. We analyze the PDPL provisions in the initial phase to extract its core principles. Moving on to the second phase, we translate and map these principles to the relevant data management requirements that are applicable in technological environments.

The requirements are then thoroughly reviewed and formulated to shape the final phase, thus structuring the framework.

Phase 1:
Analyze PDPL provision
Phase 2:
Map The Legal and Data Management
Phase 3:
Develop The Framework

Fig. 1. PDPL development processes.

A detailed explanation of each phase and its role in advancing the development of the framework is presented as follows:

Phase One - Analyze PDPL provision: Due to the complexity and ambiguous nature of challenges in legal documents, a consultation with a legal expert and an in-depth analysis of the PDPL is conducted to identify, first of all, the objective of the law, which is ensuring individual privacy and protection of their data through enforcement of principles that stipulate the procedures to be followed by entities that process personal information.

Secondly, the principles that are related to the regulation, such as the Data Subject, Data Controller, and Data Processor, which have been described earlier in the Background section, and finally, identifying all the articles that would pose specific requirements on systems, for that concern the articles that are not related to data processing processes such as penalties and Competent Authority responsibilities has been excluded from the analysis process.

Some of the extracted articles stated the legal requirement clearly and straightforwardly to be articulated to the corresponding technological and organizational context. For instance, Article 12 outlined all the essential points that must be specified in the privacy policy and Article. 30 (2) Stated appointing a Data Protection Officer (DPO) to implement PDPL provisions.

However, most articles lack a direct description, requiring interpretation to facilitate the compliance process in data management systems. The legal and technical requirements will be mapped in phase two.

Phase Two - Map the Legal and Data Management Requirements: As the primary domain of the PDPL law is the individual's privacy, incorporating knowledge of that area has been included via a variety of sources, such as the best practices standards ISO 27701[8] and NIST Privacy Framework [7] that be published to help in protecting the privacy of processing personal data in an organization through laying out the guideline to be followed to achieve the privacy goals also, the previous studies of implementing GDPR compliance have been extensively reviewed to participate in the process of extracting and translating legal requirements into measurements that can be applied to data management, and our analysis revealed sixteen main requirements that are listed with the corresponding articles.

Phase Three - Develop the Framework: The requirement outcomes from the previous steps have been reviewed and formulated into two main modules for structuring the framework: organizational and technical controls, which will provide a clear vision for the data management principles that are responsible for enforcing compliance with the law and help identify the roles and responsibilities of each requirement, the framework architecture depicted in Fig. 2.

Each component is called a control and is broken into a more specific measurement called a sub-control. For instance, in the Organizational category, the sub-control of DPO control stipulates the necessity of appointing a Data Protection Officer responsible for PDPL provisions implementation as the regulation specified in Art. 30(2). Another component, Notifications, represents all the processes and procedures required to notify all related parties about the relevant principles stated in the regulation to ensure transparency between the data controller and relevant parties. Any related data party is notified when data is amended under the first sub-control, such as when a correction is made per Art. 17(1). However, for the second sub-control, as it corresponds with Art. 20, a notification process must be adopted in case of a breach for both the Competent Authority and the data subject. The last sub-control is specific to credit cards for disclosure requests, and a process must be implemented to notify the personal data owner, as stated in Article 24(2).

Data Security control in the technical category contains several sub-controls that represent more details of the necessary technical measurement for protecting the data to provide a clarification of what has been stated on.

Technical measures in Article 19: "The Controller shall take all the necessary organizational, administrative and technical measures to safeguard Personal Data," In the first two sub-controls, we see that it is essential to implement safeguards for ensuring confidentiality by protecting data using proper encryption methods and data loss prevention (DLP) techniques. As for the third sub-control, it is imperative that data integrity is ensured by implementing an integrity checksum mechanism, such as hashing, and for the last sub-control, it is necessary to complete all the backup and recovery operations to ensure the data's availability.

B. Framework Components

The proposed framework is designed to be adaptable and expandable for managing regulatory changes and the addition of any future components that may be added to provide privacy and data protection.

The first module of the framework is Organizational controls, which are the strategic processes implemented to ensure the protection of personal data from a managerial point of view to enforce compliance. It consists of eight organizational control components that are documented as follows:

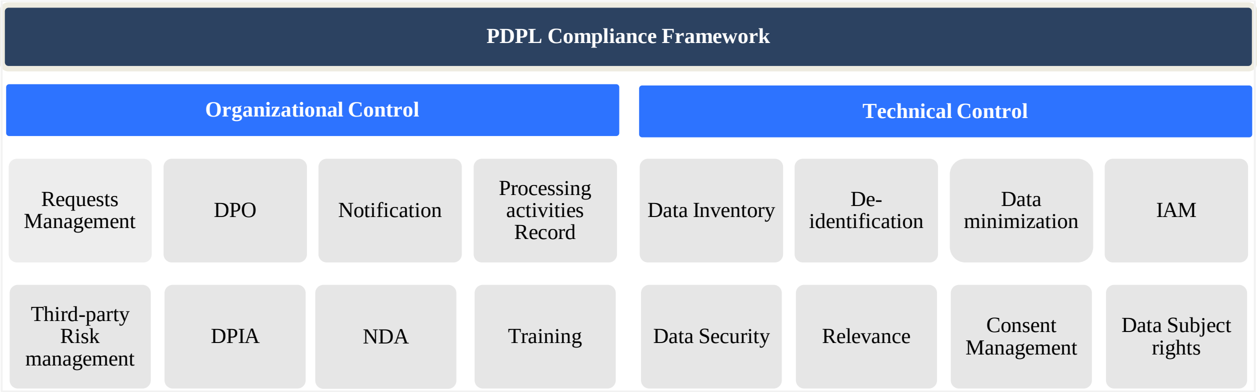

Fig. 2. PDPL compliance framework.

1) Data protection officer (DPO): Assign the Data Protection Officer to ensure that all personal data processing activities comply with the relevant data protection laws and regulations through governing and implementing PDPL provisions and policies.

2) Requests management: Provide mechanisms that must be adhered to give a response channel to data subject requests regarding their rights.

3) A non-disclosure agreement (NDA): A non-disclosure agreement with any related party regarding processing recorded personal data is documented (e.g., signing an NDA document for employees).

4) Notifications: Processes and procedures to notify the relevant principles stated in the regulation, such as Data Subject or Authority for the necessary conditions, for instance, security breaches.

- Notification for personal data amendment to any related parties that process such data, for example, by email.
- Procedure for the Competent Authority notification of a privacy breach or event within 72 hours and for the data subject' in case of harm.
- Procedure for notifying the data subject in Credit data disclosure requests by any party.

5) Processing activities record: To ensure that Authority requests are adequately documented, it is necessary to include specific information in the record of processing activities. Which should consist of the controller's contact details, the purpose of the processing, a description of the data subjects, any other entities that personal data has been or will be disclosed to, whether personal data has been or will be transferred outside the Kingdom or disclosed to an entity outside the Kingdom, and the retention period.

6) Data protection impact assessment (DPIA): Data Protection Impact Assessment, which is the process of addressing privacy and data protection risks in processing personal data to provide proper assurance in mitigating risks and providing protection, must be included for processing activities relating to any product or service offered to the public, according to the nature of the processing carried out by the controller.

7) Third-party risk management: A critical aspect of protecting personal data is to evaluate and assess third-party entities who handle it on behalf of the organization. This involves conducting due diligence on data processors to ensure they have sufficient data protection guarantees, such as using a privacy and security checklist, before allowing them to process the data.

8) Training: Implement a Personal Data Protection training program to foster a culture of safeguarding personal information. By providing employees with the tools and knowledge to handle such data properly, this program can increase awareness levels and promote responsible practices in data protection.

The Technical controls comprise the second module of the framework, containing eight controls, and are responsible for protecting and preventing personal data from being compromised. These controls are documented below.

9) Data inventory: An inventory that contains any assets or processes related to processing personal data, such as the data itself, location, action, or purposes, etc.

- Personal data and sensitive data elements are specified and categorized (e.g., Health data).
- The Data Subject ("data owner") is specified and connected to the data.
- Processing actions on personal data are defined and mapped to the data (e.g., collect, store).
- Systems that Process personal data and purposes of processing are identified and mapped to each data.
- Data Processing Locations are specified and mapped to the data (e.g., geographic location, Cloud).
- Retention periods of data are defined and mapped to the data.

10) Consent management: The procedures to provide transparency regarding Data Subject consent through implementing a precise mechanism for consent and consent withdrawal.

- Clear procedures must be established to obtain valid consent from data subjects for processing their data. These procedures include opt-in consent checkboxes or buttons, signed consent forms, etc.
- Procedures for consent withdrawal are implemented clearly to the data subject, such as unsubscribe links.
- Procedure for explicit collection consent, changing of collection purpose, disclosure or publication of Credit Data obtained along with the Credit Information Law depicts [25].

11) Data subject rights: The process enables Data subjects to practice the rights dictated in the law regarding their data, such as access, deletion, modification, etc.

- The Privacy Policy outlines the details of the collected personal data, including the purpose, method, storage, and processing, how the Personal Data shall be destroyed, the data subject's rights, the legal basis for data collection, the data controller's identity, entities to whom Personal Data will be disclosed and the Consequences and risks of not gathering Personal Data is adopted and available in clear text to Data Subject.
- A mechanism for the data subject to access personal data. (e.g., preview data on a Web page)
- A mechanism for the data subject to request (obtain, correct, or delete) personal data. (e.g., Requests Web page).

12) Data minimization: Limit the minimum amount of personal data to the purpose of the collection process.

- After fulfilling collection purposes, personal data is destroyed.
- Personal Data out of Data Controller business purpose scope destroyed.

13) Relevance: Data control and audit processes to ensure accuracy and relevance to processing purposes as Audit/log records are implemented and reviewed to incorporate the principle of Purpose limitation and data accuracy and comply with the privacy policy (e.g., limiting processing to collection purposes only).

14) De-identification: The process of discarding any data directly related to the identity of a particular individual is applied to retain, collect, or process Personal Data without consent, such as implementing the Data Masking process.

15) Identity and access management: Access to Personal Data is restricted to authorized individuals, processes, and devices.

- Identities and credentials are issued, managed, verified, revoked, and audited for authorized individuals, processes, and devices.
- Remote access is properly managed.
- Access permissions and authorizations are managed, incorporating the principles of least privilege and separation of duties, such as implementing a Role-based access control mechanism.

16) Data security: The necessary safeguard to ensure personal data's confidentiality, integrity, and availability.

- Encryption methods are used to protect personal data (e.g., Database Encryption, TLS)
- Data loss prevention (DLP) techniques protect data from loss.
- Integrity-checking mechanisms verify Personal Data integrity (e.g., hashing, logging).
- Implementation of the Backup and Recovery process.

Through the implementation of the framework components, organizations can ensure compliance with the PDPL requirements. The framework provides a comprehensive assessment of the current state of regulatory compliance and offers guidance to organizations to achieve a baseline of PDPL compliance. Additionally, the framework assists data management in identifying the roles and responsibilities of each framework component, which is essential for effective data management. The PDPL compliance framework is a valuable tool for organizations seeking to maintain compliance with regulatory requirements and ensure the protection of personal data.

V. Evaluation

Throughout the creation of the PDPL framework, great emphasis was placed on the crucial role of individuals in its implementation, considering them as the main element in any compliance process. To this end, we employ semi-structured interviews with professionals in data management, governance, and privacy engineering to answer the research questions. Inspired by the structured approach to qualitative research as outlined by Kallio et al. [26]. We have conducted an in-depth analysis of the literature review and a comprehensive examination of the PDPL and GDPR, and in incorporating best practices such as ISO/IEC 27701:2019 [8] and NIST Privacy Framework [7] standards. From these studies, we developed a set of criteria named “Framework Assessment Criteria,” which are clarity, applicability, usability, comprehensiveness, adaptability, accountability, and continuous improvement to evaluate the effectiveness of the framework.

A. Participant Selection

1) Scope and criteria: The research is centered on experts who work in data management, governance, and privacy. They play a vital role in enforcing and implementing PDPL compliance frameworks. These professionals are in a unique position to offer valuable feedback on the effectiveness of the framework, any challenges they face, and how the framework can be improved.

2) Sample size: For this study, a sample size of six participants was chosen due to the qualitative research method's focus on depth over breadth. This allows for thorough and nuanced insights into the application and impact of the PDPL compliance framework while remaining manageable for detailed analysis.

3) Selection process: Participants for the study were chosen through a systematic review of LinkedIn profiles. This allowed us to identify professionals who had relevant experience and expertise in data management, governance, and privacy. Our selection criteria included the following:

a) Demonstrated expertise in data management, governance, and privacy practices.

b) Working on Saudi Arabia.

c) Involvement in PDPL-Related Projects or Any Relevant Regulation.

By following this process, we aimed to ensure that we selected individuals who could offer valuable perspectives on evaluating the PDPL compliance framework. Table I illustrates the overview of participant informants.

TABLE I. PARTICIPANT OVERVIEW INFORMATION

Code	***Job Title/Position***	***Years of experience***
P-01	Senior privacy consultant	5
P-02	Chief Information Security Officer	9
P-03	Data protection and privacy supervisor	6
P-04	Data Governance Advisor	8
P-05	Data Protection Manager & DPO	7
P-06	DPO	1

B. Data Collection

A pilot interview with a data privacy specialist was conducted to verify the initial interview guide developed. The pilot interviews demonstrated the need to present more questions about the current state of the PDPL compliance process that the participants do and the challenges they face as the law has taken place to help compare what has been applied in the workplace. And our proposed framework. For that, two questions were added to the opening questions: "Can you describe the process your organization follows to ensure compliance with the PDPL or relevant data protection regulations?" and "Do you face challenges applying these regulations? What are they?". By adding these questions, we will provide a comprehensive overview of PDPL compliance practices in real-world settings and assess how our proposed framework might enhance these practices.

1) Interview process: The interviews with participants were conducted online utilizing Microsoft Teams [27], where both sides mutually agreed upon the interview time, and the discussion was conducted in Arabic and English. At the start of each session, the study's aims were introduced, followed by a guided discussion that allowed for a detailed exploration of the goal and components of the PDPL framework. The interviews were audio-recorded with prior consent from the participant, anonymized, and stored on a secure drive before being destroyed post-transcription, and the interview duration ranged from 45 to 90 minutes.

C. Data Analysis

For data analysis, a Thematic analysis (TA) approach was followed, which is a qualitative research method used to identify, analyze, and report patterns or themes within data [28].

This approach was followed to evaluate the PDPL compliance framework's effectiveness in applying and facilitating the compliance process through analyzing the interview scripts to identify and outline the ability to provide significant insights into the facilitative role of compliance frameworks in aligning organizational practices with PDPL provisions.

A detailed evaluation of the framework's applicability in practice employs both inductive and deductive methods.

The interviews were reviewed and analyzed for patterns and themes following the six-phase thematic analysis process detailed by Braun and Clarke [28]. The six-phase process of thematic analysis is widely employed for the study of qualitative data. A systematic and adaptable approach is provided for the identification, analysis, and reporting of themes within a dataset. The six phases are outlined as follows:

1) Familiarization with the data: In this phase, immersion in the data is undertaken to become acquainted with its content. Transcripts, notes, or other qualitative materials are read and re-read to gain a comprehensive understanding of the meaning and patterns. The interview transcripts were imported into MAXQDA 2024[29]. Moreover, two stages of the analysis process were defined in this phase.

- Stage -I: This stage focused on a general inquiry regarding the current state of compliance with the PDPL in the organization, where the inductive approach was followed.
- Stage -II: Following the inductive insights gained from Stage-I, a deductive approach was followed and grounded in seven categories pertaining to the evaluation of the framework in Stage-II. These seven categories were identified based on pre-defined “Framework Assessment Criteria” to assess the effectiveness and capability of the PDPL compliance framework to facilitate the compliance process.

2) Generating initial codes: The hybrid approach that has been followed structured the generating of the initial codes based on the two stages. In Stage -I, the codes were developed through meticulous line-by-line reading of the interview transcripts, while in Stage – II, the data were coded based on their relevance to the pre-defined Assessment Criteria.

3) Searching for themes: Patterns and clusters of codes were identified and categorized into themes, creating a thematic map containing the initial themes and codes correlated.

4) Reviewing themes: There is a two-level creating this phase. The first level is reviewing the themes, sub-themes, and code to ensure consistency and logical connection among the extracted data.

For the second level, a similar process followed, but a comparison will be made for the entire data set to ensure the validity of the extracted data to the main analysis goal.

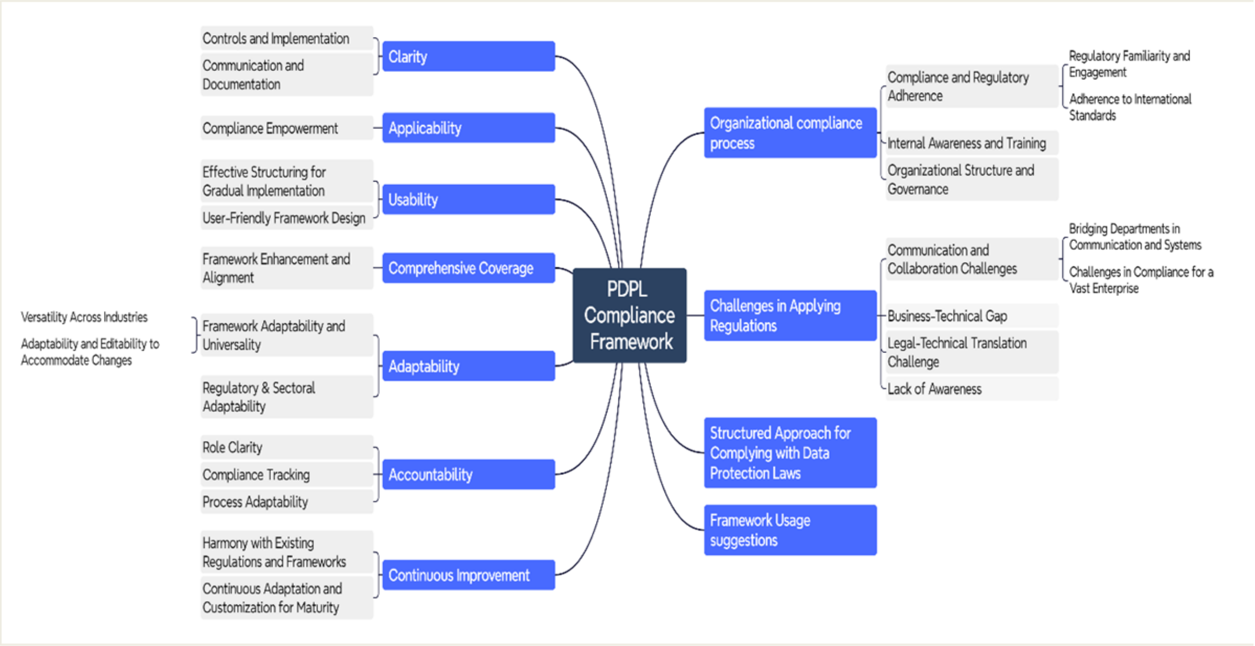
5) Defining and naming themes: After refining the themes, the names were clearly defined, and a clear and concise description for each theme was created, ensuring an accurate representation of the underlying data. The themes are outlined in the mind map in Fig. 3.

6) Writing the report: The final phase involves the writing of the report, where the findings of the thematic analysis are presented. This includes providing a clear account of the research question, the analytic process, and the identified themes. Illustrative quotations and examples from the data are often included to support each theme.

D. Findings and Discussion

1) Stage -I:

a) Theme 1: Organizational compliance process: Compliance with the regulation process is the approaches and standards that have been followed to adhere to regulation, and as it is not a new concept for organizations, as a comprehensive set of regulations in Saudi Arabia has been imposed, including business conduct and labor laws, as well as data protection and cybersecurity. All the participant were familiar with PDPL and has been involved in the compliance with the regulation along with other regulation such the financial sectors that follows SAMA [30] by P-02 and P-06, for the PDPL the regulation is supervised by SDAIA for that all the participant follows and uses procedures and tool that been presented some of them also created their own privacy system before even the regulation took place following the international standards as P-04 outlined 'We established our privacy department in 2018 before the law was published, which was in 2021, we followed the international standards regarding privacy', yet it is been emphasized that the compliance process must start with robust system for the entire organization, starting with top management support and understanding as P-01 and P-06 stressed 'where I think that it's so important for information to be, on privacy to be understood at top level, from there that then cascades down operational level', 'Very necessary that we bring our, higher management on board because this program, You cannot run this program without the buy-in of the higher management', along with structuring a Data Protection Governance Program that responsible for all the related strategic and operational process to be involved in, also P-04 and P-05 stipulated the necessity for an internal awareness campaigns to clarify the objectives of the PDPL and processes that must be followed to adhere to this regulation in order to facilitate the compliance process as it relates to all departments and parties in the organization such as employees .



Controls and Implementation

Bridging Departments in Communication and Systems
Challenges in Compliance for a Vast Enterprise
Business-Technical Gap
Legal-Technical Translation Challenge
Lack of Awareness
Structured Approach for Complying with Data Protection Laws
Framework Usage suggestions

Fig. 3. Compliance process themes.

b) Theme *2: Challenges in applying regulations*: Applying such regulation is not an easy task for the organization due to it is connectivity to all parties within the organization, such as departments or even external parties, such as subjects or clients. All the participants agreed on having challenges in applying it, such awareness as most of the participants stressed that one of the major challenges is the lack of awareness of the law itself for employees and subjects who share the information without proper consideration of what the regulation stated, another challenge in The implementation process in some entities arise from a mismatch between the business and technical requirements as the case for P-03 'Yes, The pinpoint of challenges is the mix in the implementation between business requirements and technical requirements in some entities.' The size of the organization and its clients play an essential role in complying with regulatory requirements. The larger the size of the company and the number of clients, the more complex and challenging the process becomes because it requires more significant effort in internal communication in the organization and communication with external parties such as clients, in addition to efforts to balance customer protection and protecting of the organizations' revenues as well. Also, struggling to translate legal jargon for technical understanding is a challenge that has been mentioned by P-04 and P-05 as it is necessary to keep all the requirements clear to implement for the related teams and how to overcome this challenge according to P-04 and P-05 'We read and analyzed it and created a control framework derived from the law that translates the regulation language into an understandable language in the company, to facilitate the compliance in the department, and it is similar to the framework you suggested,' 'The technical department was confused about what should be done, making us work with them through steps to clarify the requirements.'

c) Theme 3: Structured approach for complying with data protection laws: It is crucial to comply with the PDPL. However, attempting to achieve compliance in a disorganized, disjointed, or step-by-step manner is counterproductive and unlikely to meet the rigorous standards set by the regulation or the specified compliance deadlines as mentioned by P-04 'if I take one article of the law and work to apply it and then shift to another one, I will be distracted, unlike if I have a structured approach for me as responsible for applying it and for the other related departments, which will ensure to comply with the PDPL before the deadline and provide the top management an organized view on the compliance process state.' Also, all the participants agreed and asserted having a structured approach to compliance is crucial as it provides clear guidance to all who are involved in the compliance process, including top management, departments, etc.

d) Theme 4: Suggestions regarding the use of the compliance framework: Soliciting Suggestions Regarding the Use of the Compliance Framework play a pivotal role in evaluating and enhancing the framework's effectiveness. This approach fosters active engagement with participants, encouraging them to share their experiences and insights. Such interaction enriches the framework with diverse perspectives and prompts a reflective process aimed at continual refinement and adaptation. By integrating feedback from those directly impacted by the framework, we ensure its relevance, practicality, and efficiency in addressing current and future data protection challenges. For that, several suggestions were presented by that participant, as some were related to the framework structure, which would help easily to add more controls, such as adding the policies related to applying the data protection controls as a responsibility of the DPO, or adding tooling and data-sharing control; as P-03 stressed, "Adding a component called tooling, which contains all necessary tools such as consent management, metadata management, etc. and Adding a data-sharing component" will help to have a clearer path in implementation process while others suggested linguistic refinement of some of the terminologies has been mentioned in the Stage - II themes to reflect the marketplace terms.

2) Stage - II:

a) Theme 5: Clarity: Clarity of the framework measures the quality of the terminology being clear, understandable, and free from ambiguity, and it has emerged as a crucial aspect of the compliance framework. Participants highlighted the importance of precise language and terminology in the framework to ensure straightforward interpretation and application for Specialized and Non-Specialized Audiences as it has been applied, as many participants agreed on the benefit of diving the controls into organizational and technical as P-04 stressed, "It is very clear, especially dividing the controls into two levels, organizational and technical controls, which will provide a great benefit for companies to separate the focus of the control types" also for P-06 who described the necessary requirements of a framework would be "A framework needs to be short, concise, and robust" to make it easy to understand and pinpoint the core objectives. While the framework was generally perceived as clear and straightforward, there were suggestions for linguistic refinement in the privacy domain. For instance, replacing the control "processing activities record" with "Record of processing activities (ROPA)" and "Relevance" with "Data Monitoring".

b) Theme 6: Applicability: The applicability focused on the framework's practical guidance for different industries and data management activities to be able to apply the framework component in their environment. Participants noted that the framework provided valuable insights into PDPL controls as the framework emphasized the essential aspect of the law and structured to be applicable by the data management community as P-05 stressed, "I think it's really good. The reason being is because you've really touched upon the core fundamentals" and P-06 outlined regarding the using of the framework in the compliance process with the law "The chance is very big because here in the framework, the scope is identified, and the main points are clear to start the compliance process from, compared to the main law and regulations, which could be interconnected and have multiple exceptions.", making it suitable for implementation across various organizational contexts. However, there were suggestions to enhance the framework with additional components, such as tools for consent management and metadata management, to further improve its applicability and add a new main control for security measures.

Applicability plays a crucial role in any framework, as it specifies the capability of an organization to adapt and apply the components of the framework efficiently. The value of a framework lies not just in its theoretical underpinnings but, more importantly, in its practical application across diverse organizational contexts and challenges.

c) Theme 7: Usability: Usability emerged as a key theme as it represents the user-friendliness level of the framework to be understandable to the targeted audience, with most of the participants expressing satisfaction with the framework's user-friendly level. The division of the framework into organizational and technical components was appreciated for its clarity and ease of implementation. Also, the clarity and simplicity of the language used, as highlighted by participant P-06: “The language use is perfect, because there's not so much legal jargon, but there's enough to be understood on what is required.” stressed the significance of ensuring information is easy to understand and process. It is crucial to avoid using complicated legal terms as this delicate balance appears to have been successfully achieved in the presented framework. Suggestions for minor changes in terminology were made to enhance usability further. For instance, participants recommended changing some of the control names to be aligned with the data management common terminology language, such as “organizational control” into “business control,”

The role of usability in developing the framework is to produce a guideline that is easily followed and implemented by the users without meeting difficulties. Usability will enable the process to be adopted smoothly, making it easier for the organization to apply the framework most effectively.

d) Theme 8: Comprehensive coverage: Comprehensive Coverage refers to the ability to encompass all the necessary fundamental concepts of the PDPL regulations in the framework to ensure reach out to a high level of maturity in data protection practices, which in turn facilitates the compliance process. All Participants highlighted the importance of comprehensive coverage within the framework to address all aspects of compliance effectively and agreed that the framework covered a comprehensive and essential range of regulations such as consent, consent Withdrawal, and data subject rights, etc. Moreover, it guides in structuring the data management office (DMO) that is responsible for applying the PDPL regulations as P-03 and P-04 outlined: “It covered a wide range of regulations such as the subject rights, data inventory, and consent. Also, having sub-controls that define the process that must be implemented made it very mature.”, “This framework provides the overall view of the compliance process with PDPL, which makes it able to structure the data management office (DMO) based on it.”. However, there were suggestions to include additional components, such as adding the policies related to applying the data protection controls as a responsibility of the DPO, as mentioned by P-05: “The framework is very comprehensive, and it covers a wide range of technical parts, such as data subject rights, data minimization, and others, this is also the same for the organizational components for improvement in the DPO component. Creating the required policies must be mentioned as one of the DPO responsibilities, “while others suggested including data transfer outside the Kingdom of Saudi Arabia in the framework.

Overall, feedback from the participants emphasized that the framework reached a high level of maturity in encompassing the crucial requirements of the PDPL regulatory that are related to the compliance process within a data management system and the ability to be enhanced and cover a broader scope.

e) Theme 9: Adaptability: The adaptability theme emphasized the framework's flexibility in responding to changes in data protection regulations and organizational requirements, along with being designed to be applicable across different industries, which significantly impacts the framework's effectiveness level and long-term viability. The participants noted that the framework was adaptable and editable, making it easy to incorporate new changes and updates, for instance, in technologies, etc. This ease is attributed to the structured approach that has been followed to build the framework, characterized by the methodological division of the organizational and technical controls. Such a division aids in seamlessly integrating changes related to sector-specific and regulatory requirements, as mentioned by P-03: “It would be adaptable to changes, as the changes in the regulation will be minor and sectorial such as in health data or credit data and these changes could be added to the framework as controls or domains.”

f) Theme 10: Accountability: Accountability is a crucial aspect of any framework in any data protection system. It involves assigning clear roles and responsibilities to every party involved in the implementation of the framework to aid and track compliance. Based on robust feedback received from participants, it is evident that the framework plays a pivotal role in ensuring accountability when applying the PDPL requirements. The controls structured within the framework make it significantly easier to assign roles and responsibilities, and one such example is the implementation of RACI matrices for each control. As noted by P-04, "the framework controls made it easy to assign a RACI matrix to each control, which ensures that each employee's responsibility is identified." Moreover, Participant P-05 highlighted the framework's adaptability in incorporating additional details like timelines and procedural steps. This adaptability not only advances accountability but also streamlines the application of PDPL requirements, demonstrating the framework's effectiveness in fostering a robust data protection environment.

g) Theme 11: Continuous improvement: Continuous improvement is a vital component of any framework in data management to accommodate the fast changes that appear in the surrounding community, such as the development of technology, evolving changes in rules and regulations, and the ability to keep compliance process with regulations. Participants noted that the framework provided a foundation for ongoing improvement and gave the opportunity to encompass regulatory and business process improvements. Furthermore, one of the participants highlighted the ability of the framework to harmonize with other regulations and best practices such as National Cybersecurity Authority (NCA) regulation, NIST and ISO, etc. This capability ensures that organizations can not only comply with current standards but also remain poised to incorporate future developments in data protection and any other domains.

The evaluation process was conducted to assess the framework's effectiveness in facilitating the compliance process for organizations with PDPL provisions. According to the findings from the analysis process, the PDPL compliance framework has been recognized overwhelmingly by all participants as a robust and effective instrument crafted with a focus on practicality and ease of implementation as it has been managed to be structured firmly, which it has been able to translate the ambiguity of the Legal Jargon into clear and understandable terminology to be implemented efficiently. The division of the controls into two main modules, organizational and technical controls, has provided a clear vision for the data management principles responsible for enforcing compliance with the law. Also, the applicability and usability provided a versatile, straightforward application and user-friendly design guidance tailored to diverse industrial needs and data management activities. Moreover, the framework was built to be flexible and adapt to ongoing technological and regulatory developments, which is a critical advancement. This adaptability ensures that the framework is capable of addressing future challenges and evolving data protection standards. Additionally, its comprehensive scope, covering all essential PDPL requirements, sets a high benchmark for data protection maturity. This extensive coverage guarantees that organizations employing the framework can achieve and maintain advanced data security and compliance.

While the findings are predominantly positive, we must acknowledge the constructive feedback and suggestions for improvement identified through our analysis.

In conclusion, the PDPL compliance framework emerges from this analysis as a vital instrument for organizations to streamline the implementation and compliance process of data protection regulation.

VI. Case Study – Privacy Policies Compliance

The core objective of PDPL is to empower users with control over their personal information. This legislation encompasses a range of rights, including the right to access a privacy policy. This legal document serves as a guide to the processes that an organization or company has established to manage the personal data of its users. Additionally, it is crucial for companies to instill confidence in their users by assuring them of the security of their personal information. Without a well-crafted privacy policy, companies run the risk of damaging their reputation and losing the trust of their customers. In that matter, several studies have been conducted to check compliance with privacy policies on regulations such as GDPR using deep-learning methods such as Transformers [15], which have demonstrated their efficacy in assessing the compliance of privacy policies with laws such as GDPR [11 - 13].

However, in this case study, we choose to implement one component (i.e., privacy policy from data subject right in the technical controls module) from the proposed PDPL framework as proof of concept. To the best of our knowledge, this is the first case study to automate and implement the PDPL framework in Saudi website data in terms of analyzing privacy policies.

A. *Privacy Policies Compliance Approach*

Deep learning models were developed and built to evaluate the adherence of websites in Saudi Arabia to PDPL standards in their privacy policies. Various models from the Transformers family have been utilized for multi-class classification purposes. These models are pre-trained in Arabic domains to achieve superior results in our area of focus. The models employed include MARBERTv2 and ARAELECTRA, a set of models that were developed to handle natural language processing tasks for the Arabic language. They are based on the transformer architecture, which has been widely used in deep learning for various NLP tasks.

The classifiers were fine-tuned on the Saudi Privacy Policy Dataset [31]. The process was carried out in Google Colab [32], where users can write and execute Python code in a collaborative and interactive environment without installing any software and running it in the cloud using eight epochs. The dataset was randomly split into the following subsets:

- Training set: 80% of the data (3710 of a total of 4638 text lines)
- Testing set: 20% of the data (928 of a total of 4638 text lines)

B. *Dataset*

The dataset used for this study is the Saudi Privacy Policy Dataset [31], which comprises a collection of privacy policies from 1,000 websites representing diverse sectors in Saudi Arabia, including healthcare, education, finance, government, e-commerce, and other industries.

TABLE II. DATASET STATISTICS

No. Files	1000
No. Tokens	775,370
No. Text Lines	4,638

The corpus statistics are shown in Table II, which contains more than 4K lines of text and 775K tokens, with a corpus size of 8,353 KB. The feature annotations are based on ten high-level categories derived from the Personal Data Protection Law (PDPL). They are numbered from 1 to 10, further branching into 21 specific content categories, as shown in Fig. 4. The PDPL category distributions among the datasets are shown in Fig. 5.

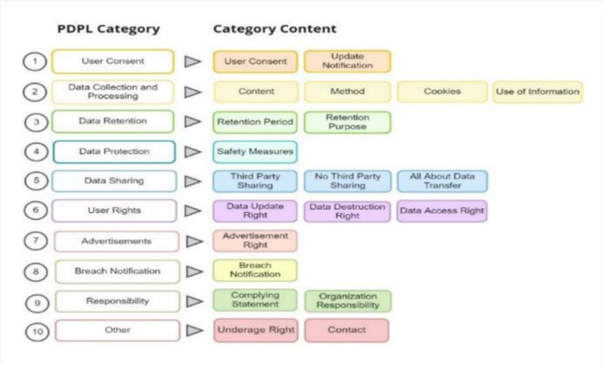

Fig. 4. PDPL annotation category [31].

The PDPL categories were considered in the classification process, and details of the categories and their correspondences with PDPL clauses are explained in the following:

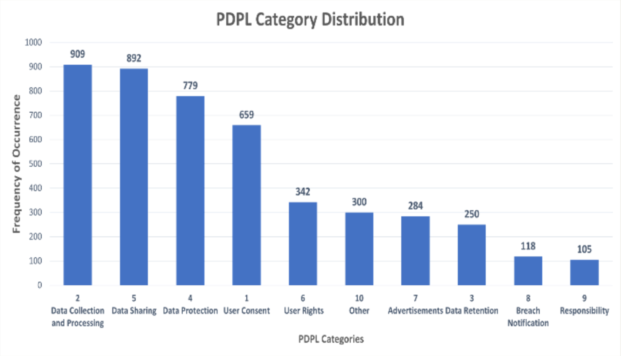

Fig. 5. PDPL category distribution.

- User Consent: The user's personal information cannot be processed without consent, except for essential services or legal purposes. The controller must inform any other party if data is modified [PDPL Art. 5(1)].
- Data Collection and Processing: The data controller defines the collection's purpose, method, and content. The user is informed of the collector's identity except for security reasons. Data is only used for the initial collection purpose [PDPL Art. 12)].
- Data Retention: The controller must delete personal data when its purpose is fulfilled unless certain cases allow data retention by the controller [PDPL Art. 12].
- Data Protection: Personal data storage and transfer must be secure, and controllers must protect user data during this process [PDPL Art. 19].
- Data Sharing: The controller is prohibited from sharing, transferring, or disclosing personal data except in special cases, and access to the data is strictly limited to these special instances [PDPL Art. 13(4)].
- User Rights: An individual's rights include obtaining a copy of the data collected by the controller, requesting its destruction when no longer needed, and rectifying any inaccuracies [PDPL Art. 4 (5-3),12].
- Advertisements: The controller must not send promotional or educational materials to the user's personal addresses without their consent. If approved, a mechanism must be in place for the user to opt-out [PDPL Art. 25].
- Breach Notification: The controller must promptly notify the competent authority and data owner upon becoming aware of any personal data leakages, corruptions, or unauthorized access [PDPL Art. 20].
- Responsibility: Organizations must comply with PDPL for accountable and secure data processing [PDPL Art. 19].
- Other: The controller's contact details information and rights related to underage [PDPL Art. 13(3)].

C. *Evaluation Metrics*

To make the evaluation results objective, we use in our study a group of performance metrics applied by several studies in natural language processing studies. These metrics include Recall, Precision, and F1-score. They are commonly used by many studies in machine learning and deep learning [12, 13],[33]. In our study, there are three possible outcomes of the classification results:

TP (True Positives): Instances that belong to the "PDPL category" and are correctly predicted as such.

FP (False Positives): Instances that do not belong to the “PDPL category” but were incorrectly predicted as such.

FN (False Negatives): Instances that belong to the “PDPL category” but were incorrectly predicted as a different class.

Based on the possible outcomes, the performance metrics Recall, Precision, and F1-score can be calculated as follows:

$$Micro\ Precision = \frac{\sum_{i=1}^{n} TP_i}{\sum_{i=1}^{n}(TP_i + FP_i)} \quad (1)$$

$$Micro\ Recall = \frac{\sum_{i=1}^{n} TP_i}{\sum_{i=1}^{n}(TP_i + FN_i)} \quad (2)$$

$$Micro\ F1 = 2.\frac{Micro\ Precision\ .Micro\ Recall}{Micro\ Precision + Micro\ Recall} \quad (3)$$

It is important to note that among these three-performance metrics, the higher the Recall, Precision, and F1-score, the better model performance, while the lower the value, the worse.

1) Results and discussion: In this section, we present the results of our case study to examine and compare the performance of two models used in our experiment, namely, MARBERTv2 and AraELECTRA. Both models were pre-trained on Arabic domains to achieve a better result with the Saudi Privacy Policy Dataset that we used. During the training process, we recorded the precision, recall, and F-measure metrics achieved for each class. The dataset has ten classes, and the results for each class are shown in Table III, along with the micro-average.

> The results indicate that deep learning models can serve as effective tools for detecting and classifying privacy policies. Additionally, they can aid in measuring compliance with Personal Data Protection Law (PDPL) requirements.

Looking at the precision, we can observe that both models achieved values consistently above 83% for all classes. MARBERTv2 achieved values ranging from 87.50 % to 95.43%, while AraELECTRA achieved values ranging from 83.33% to 95.83%. This indicates that both models perform well in making positive predictions of the PDPL categories.

For the recall, MARBERTv2 achieved consistently higher recall values, ranging from 86.21% to 97.89%, compared to AraELECTRA, which ranged from 63.33% to 97.37%. This means that MARBERTv2 captured a substantial portion of the actual instances for these classes.

TABLE III. PRECISION, RECALL, AND F1-SCORE OF MARBERTV2 AND ARAELECTRA

	Model	**MARBERTv2**				**AraELECTRA**	
#	Class	Precision	Recall	F1- score	Precision	Recall	F1- score
1	User Consent	93.46%	86.21%	89.69%	**93.75%**	**93.02%**	**93.39%**
2	Data Collection and Processing	92.59%	**97.77%**	95.11%	**94.57%**	97.21%	**95.87%**
3	Data Retention	**89.29%**	**90.91%**	**90.09%**	85.00%	87.17%	86.08%
4	Data Protection	**95.43%**	92.99%	**94.19%**	89.68%	**93.91%**	91.75%
5	Data Sharing	**94.42%**	**97.89%**	**96.12%**	93.43%	97.37%	95.36%
6	User Rights	89.83%	89.83%	89.83%	**91.67%**	**91.67%**	**91.67%**
7	Advertisements	**95.00%**	**86.36%**	**90.48%**	92.31%	82.19%	86.95%
8	Breach Notification	89.29%	**89.29%**	**89.29%**	**95.00%**	63.33%	76.00%
9	Responsibility	**87.50%**	**93.33%**	**90.32%**	83.33%	83.33%	83.33%
10	Other	95.24%	**95.24%**	**95.24%**	**95.83%**	92.00%	93.88%
Micro Avg		**93.32%**	**93.32%**	**93.32%**	92.46%	92.46%	92.46%

Regarding the F1-Score, the two models display impressive scores, surpassing 90% for most classes. However, MARBERTv2 has slightly higher scores. MARBERTv2 and AraELECTRA achieved an overall micro-average F1-score of 93.32% and 92.46%, respectively.

Overall, both models are reliable and efficient for classifying into PDPL categories, but MARBERTv2 outperforms AraELECTRA by a small margin. These results are significant because they demonstrate the potential of using pre-trained models for Arabic text classification, specifically in the domain of privacy policies.

VII. CONCLUSION AND FUTURE DIRECTIONS

Complying with governmental regulations is a crucial mission. The Saudi Arabia Personal Data Protection Law regulates the use of individual personal data to ensure privacy and empower individuals to have control over their data. However, as these regulations are written in a clear legal format, complying with them has become an obstacle for the data management community. Therefore, this paper addresses the problem and proposes a comprehensive framework to help organizations implement PDPL requirements and comply with them by illustrating a clear roadmap on how to comply with the rules by analyzing and translating the normative aspects of the regulation into applicable organizational and technological standards. Moreover, we conducted a case study that utilized deep learning classifiers to enhance privacy policy compliance with PDPL requirements.

To move forward, we will apply the PDPL compliance framework within actual organizational environments. This practical application will enable a more detailed assessment of the framework's effectiveness. Testing the framework in a variety of real-life settings will also offer insights into its adaptability across different industries and organizational sizes, further refining its utility and impact. We will also incorporate advanced technologies to automate the framework and improve the efficiency of data privacy governance.

***Abstract*—People with a hearing impairment commonly use sign language for communication, however, they find it challenging to communicate with a normal person who does not recognise the sign language. They normally require an intermediary human to act as a translator for convenient means of expressing their thoughts. To address this issue, the work aims to enhance their communication capability by eliminating the need for an intermediary person by developing a sign language converter that uses a vision-based dynamic recognition strategy to convert continuous sign language into multimodal output. This work introduces a deep neural network based on convolutional long short-term memory (ConvLSTM) networks to determine the real-time dynamic gesture recognition of the actions of the impaired persons captured through cameras. The investigations of the continuous sign language recognition (CSLR) were deployed on the Chinese Sign Language Dataset, CSL-Daily, Phoenix-2014 and Phoenix-2014T datasets and the performance comparisons were done for conventional LSTM, Gated Recurrent Unit (GRU) and ConvLSTM. Experimental results have shown that the ConvLSTM network outperforms the other techniques, and they can detect the sign actions with a better accuracy of 90%, and a precision rate of 0.93, which ensures interpreting the meanings for each sign sequence with ease by integrating the proposed novel cognitive assisted adaptive keyframe selection. The proposed system could be easily implemented in the modern learning management system.**

Keywords—ConvLSTM; GRU; keyframes; LSTM; sequential learning; sign language recognition

I. Introduction

People with hearing disabilities use sign language for communication in day-to-day life. When spoken communication is impossible, sign language is used to communicate through body movements, particularly hands and arms. Because deaf-dumb people mainly use it and a normal person does not learn it, interpreters are required for deaf and hearing people to communicate. According to the WHO report, around 2.5 billion individuals will encounter hearing loss by 2050 [1]. So, it is necessary to develop an automated translation system for communication with them and reduce the gap between the hearing and deaf communities. Sign language recognition is meant to exact meaning for each sign in continuation with a sequence of signs i.e., mapping visual signs with words. On the other hand, creating meaningful sentences from the extracted signs is known as sign language translation.

Most sign language recognition systems focus only on isolated signs rather than a continuous sign sequence. Most sign language recognition systems use data gloves, and sensor gloves with sensors (depth sensors, optical sensors, thermal sensors, and leap motion sensors) for gesture recognition. In glove-based methods, the signer must wear a hardware glove, from which gestures are recognised [2]. These sign language recognition methods, which ensure higher accuracy, will be quite awkward to use in public places. In [3], the sign actions performed by the deaf were captured using cameras. Then the keyframes were identified adaptively and for those frames features like body pose, hand poses, and finger orientations were extracted using CNN. This method captures only spatial information and ignores other crucial features. Most of the sign language translation in the literature lacks accurate temporal data [4-5] and faces various linguistic challenges.

To address this, a vision-based dynamic recognition method for real-time gesture recognition with cameras is proposed in this article for sign language recognition and translation. Features are extracted automatically and adaptively by video streams of signs and gestures made by the impaired persons. First, the video sequences are segmented into frames and keyframes are extracted. Second, in the feature extraction stages, temporal information was sequentially learned using LSTM [6]. Third, a ConvLSTM cell is constructed by replacing an LSTM structure with weighted convolution operations at each cell gate. Further, the convolution operation in a ConvLSTM cell was assistive in extracting short-term spatial correlations process between successive measurements within a single time step. This striking feature of a ConvLSTM cell was useful for capturing the signs and gestures of hearing-impaired persons by identifying long-term temporal dependencies. Finally, the experimental outcomes were compared with the standard recurrent neural networks Gated Recurrent Unit (GRU). Here, encoder-decoder architecture is constructed using LSTM and used for sentence generation. An overview of the proposed work is shown in Fig. 1.

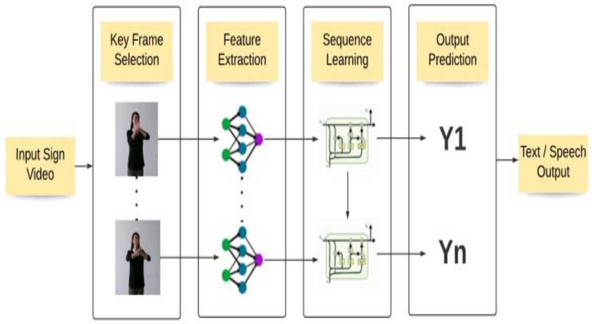

Fig. 1. System design for the proposed work.

The isolated output prediction description is as follows. (1) Key frame capturing based on similarity score for the input video. (2) Visual feature extraction for the identified keyframes. (3) Temporal information capturing through sequence learning using LSTM. (4) Isolated output prediction.

The proposed system will act as a machine-made interpreter that automatically converts continuous sign language into multimodal output, i.e., text or speech output.

This paper is organised as follows. Existing methods and related work are discussed in Section II. The proposed work with a detailed system design will be explained in Section III. Section IV will discuss experimental results. Conclusions for the entire work are given in Section V.

II. Related Work

In this section, state-of-the-art works that use glove and sensor-based approaches as well as vision-based approaches to recognise sign language were explored. Hand gesture recognition has been done in various ways, from which glove-based and vision-based are the most used. In glove-based methods, sensors attached to those gloves transfer electrical signals helping to determine the hand gesture. The signs made by the impaired will be identified from the acquired electrical signals. On the other hand, instead of a glove, the sensor camera could be used to capture the sign actions. Gestures will be classified from the captured sequences of images extracted from the video frames. Vision-based methods reduce the challenges and complexities compared with glove-based methods.

A. *Glove & Sensor based Approaches*

To create a hand sign recognition system, the authors in [7] used Electrical Impedance Tomography (EIT) imaging (gauss-newton image reconstruction algorithm) and robust CNN classification (support vector machine and softmax classifier). Mittal et al. [8] proposed a modified LSTM model for continuous sign language recognition. They captured hand gestures using a Leap Motion sensor and extracted 12 features. They fed 2D CNN feature maps into an LSTM model with a RESNET gate for output prediction. For sign language recognition, Deriche et al. [9] proposed a dual Leap Motion Controller (LMC), and to address the challenges of finger occlusions and missing data, they used both front and rear-side LMCs. Feature extractions were performed by selecting the set of the best geometric features from both controllers, such as finger length, width, hand roll, hand pitch, and hand yaw. They applied a Bayesian approach, a Gaussian mixture model and a simple linear discriminant analysis to do the final classification. An evidence-based fusion approach is used for combining data from two LMCs (Dempster-Shafer, theory of evidence). Marin et al. [10] proposed using LMC and Kinect devices to capture hand gestures. The LMC records finger distances, angles, and elevations, whereas the Kinect device records depth information. Theodorakis et al. [36] proposed lexicon-based sign language recognition. To improve recognition performance, leap motion data was combined with Kinect data, and the results were then classified using an SVM classifier. Further, for gesture recognition tasks, a one-against-one approach was delayed. The gesture with the most number votes was chosen as the desired output.

To distinguish American Sign Language (ASL) alphabets, Lee et al. [11] created a smart wearable with five flex sensors, two pressure sensors, and a three-axis inertial motion sensor. The device's embedded SVM classifier recognises alphabets. For gesture recognition, Huang et al. [12] designed a wearable glove with less graphene oxide fibre. It keeps track of the movement of ten joints in one hand. For British Sign Language (BSL) recognition, Dias et al. [13] used an instrumented glove with five flex sensors and two contact sensors. The information gathered is divided into three categories: construction, alphabet gesture, and relaxation period. For recognition, these data are fed into MLP-NN, KNN, SVM, RF, and NB classifiers. Li et al. [14] developed a sign language recognition system based on ultra-wideband radar. The Micro Doppler spectrogram input is used to calculate cumulative energy distribution, which divides the density bands for each cumulative energy distribution image. Gurbuz et al. [15] use a multi-frequency RF sensor network to measure ASL in a non-invasive, non-contact manner regardless of lighting conditions. Further, the authors used SVM, KNN, and random forest to classify the signs and compare their performances.

B. *Vision-based Approaches*

Guo et al. [16] used a combination of 3D CNN and LSTM to capture spatiotemporal representations in a video. A stacked decoding network is also used to predict gloss and query adaptive fusion is used to generate sentences. Zhou et al. [17] proposed a multi-cue framework (spatial multi-cue and temporal multi-cue) for sign language recognition and translation to learn spatial-temporal correlations of visual cues. They used 2D CNN to generate multi-cue features, CTC-Decoder for sign language recognition, and SA-LSTM for sign language translation in this study. Breland et al. [18] proposed a Deep CNN model for gesture recognition, that is light-independent and is based on high-resolution thermal imaging. Passos et al. [19] used a two-step method with feature mapping and classification for gesture recognition in videos. They used deep neural network architecture to segment each body part, then used gait energy images to encode body part motion.

For CSLR, Huang et al. [20] proposed a sequence-to-sequence learning method using keyframe-centered clips

(KCCs) split out from the input video. The CNN features of RGB keyframes, HOG of depth motion maps, and trajectory features of skeleton joints are fused by the feature fusion layer for feature extraction. Finally, all multimodal features are combined and fed into an LSTM model for sub-word and then word construction. For accurate CSLR classification, Wei et al. [21] proposed a semantic boundary detection method based on reinforcement learning. Initially, a discriminative representation for sign video with multiscale perception loss is learned using a spatial-temporal CNN and bidirectional LSTM. Each segment's clip-level features were refined between adjacent boundaries to form a single feature vector. The sentence is then decoded from the refined video representation. Huang et al. [22] proposed a 3DConv neural network based on attention for SLR. Wu et al. [23] proposed a semi-supervised hierarchical dynamic framework based on a Hidden Markov Model for simultaneous gesture segmentation. The high-level spatiotemporal representation is learned using this method. The skeletal dynamics were handled by a Gaussian-Bernoulli Deep Belief Network (DBN), and batches of depth and RGB images were managed and fused by 3DCNN. Yu et al. [24] deal with the segmentation of old queries.

III. Proposed System

The proposed work's general framework is depicted in Fig. 1, and a detailed flow diagram is depicted in Fig. 2. Keyframes extracted from the sign video were considered for input to the proposed model. Further, after spatial and temporal learning through CNN and LSTM, isolated words will be identified. Notations of the parameters used in this proposed work are given in Table I.

TABLE I. Parameter Notation

Symbol	Description
S_v	Similarity value between images
N	Number of signs
$F_{n'}$	Total number of frames in the video. Different for different inputs.
F_{L1}	Total key frames selected in level 1 from $F_{n'}$.
F_{L2}	Total key frames selected in level 2 from F_{L1}.
P_{F1}, P_{F2}	Pixel in frames
F_w, F_h	Frame width and height
P_a	Probability for each action

Fig. 2 presents a flowchart of the proposed model:

- key frame capturing based on similarity score for the input video]
- Spatiotemporal learning through CNN and LSTM;
- Isolated Output Prediction]
- Sentence output using the encoder-decoder network.

In our work, the vision-based dynamic recognition approach is used for real-time gesture recognition. Two subsequent phases of this method are sign language recognition and translation. Sign language recognition is performed through the one-to-one mapping between signs and isolated words. Sign language translation is performed for generating sentences from the mapping of sign and isolated words. The following sections discuss in detail the modules in the proposed work.

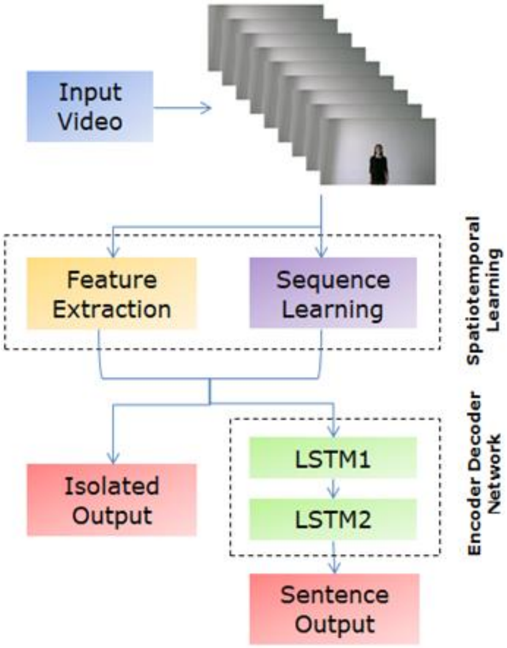

Fig. 2. Flowchart for the proposed model.

A. Key Frame Selection

As discussed in Section I, keyframes from the input video will be extracted by comparing similarity scores between images adaptively. The steps for similarity score generation for the two inputted images were detailed in Algorithm 1. The diff_ratio is computed by analyzing each pixel in the two images which plays a vital role in similarity score identification. As there will be slight changes in pixel values in the key coordinates of the subsequent frames in the sign language video, each pixel change contributes to the accurate prediction of sign gestures. Also, from the literature, it is predominantly found and concluded that different sign gestures have slight changes in the pixel value. Thus, a novel pixel-wise similarity score generation algorithm was coined with a time complexity of O(n log(n)) where n denotes the total number of pixels in the image. Based on the similarity value of one frame with another frame in the video, the number of keyframes suitable for sign language recognition will vary.

Fig. 3 depicts the adapted two-level key frame selection strategy. At level 1, frames with Sv greater than 1.5 will be selected and at level 2, Sv with values greater than 2 will be selected as keyframes.

B. Feature Extraction

Visual features are essential while working with images. Hence for the adaptively identified FL_2 keyframes, visual features will be extracted. Since CNN works best with image data, each identified keyframe will be passed into it to extract spatial information at a given time step in the input video. Features like body pose, hand position, and finger orientation will be identified for each frame.

```
Algorithm 1 : Generate_Similarity_Score
Input       : Images, $I_1$ & $I_2$
Output      : Similarity value, $Sv$
1.  $Sv \leftarrow 0$   #Initially two images were not similar
2.  $totDiff \leftarrow 0,\ pixelDiff \leftarrow 0, imgSize \leftarrow 0$
3.  $H \leftarrow height(I_1)$     // finds height of image
4.  $W \leftarrow width(I_1)$     // finds width of image
5.  $I_2 \leftarrow resize(H, W)$
6.  $imgSize \leftarrow H + W$
7.  for each Pixel $px_1 \in I_1$, Pixel $px_2 \in I_2$
        a. $pixelDiff \leftarrow px_1 - px_2$
        b. $totDiff \leftarrow totDiff + pixelDiff$
8.  $diff\_ratio \leftarrow \frac{totDiff}{imgSize}$
9.  $start\_threshold \leftarrow 1$
10. $end\_threshold \leftarrow diff\_ratio\ /2$
11. while ($start\_threshold <= end\_threshold$)
        a. $Sv \leftarrow \frac{start\_threshold + end\_threshold}{2}$
        b. if ($diff\_ratio > Sv^2$)
            i. $start\_threshold \leftarrow Sv + 1$
            ii. $Sv\_update \leftarrow Sv$
        c. else if ($diff\_ratio < Sv^2$)
            $end\_threshold \leftarrow Sv - 1$
        d. else
                return $Sv$
12. return $Sv\_update$
```

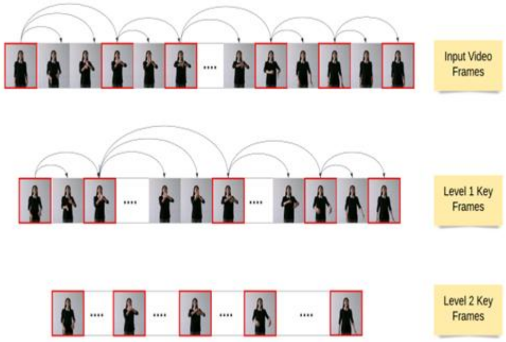

Fig. 3. Adaptive key frame selection using similarity score.

In our model kernel size of 3 X 3 is used with a 2 X 2 pool size. To reduce computational complexity and extract low-level features like body edges, a max-pooling strategy is adopted. Max pooling mathematical notation as shown in (1) where H_{wh}^{l} denotes the activation layer of l.

$$H_{wh}^{l} = max_{x=0,\dots,s,y=0,\dots,s} H_{(w+x)(h+y)}^{l-1} \tag{1}$$

C. Sequence Learning

To work with a continuous range of inputs across different time steps, temporal information through the entire input must be captured. Since RNNs are very effective in solving complex sequence-related problems, extracted visual features from CNN will be fed into a sequence of the RNN layer. In our proposed system, LSTM is the basic RNN cell. Temporal relations between subsequent frames will be captured throughout the entire video.

In our proposed work to handle spatiotemporal information as depicted in Fig. 4, all the inputs $F_1, F_2, \dots, F_t$, cell outputs C_1, hidden states Y, and gates i_t, f_t, o_t ConvLSTM are 3D tensors whose last 2 dimensions are spatial. Extracted features passed through CNN for spatial & visual feature learning. CNN followed by LSTM used for temporal learning across the video. The equations of ConvLSTM are represented in (2), where the convolution operation was denoted by '*' and the Hadamard product was denoted by '⊙'. Internal matrix multiplications are performed with convolution operations in ConvLSTM, a recurrent layer like LSTM. The data passes through the ConvLSTM cell, which maintains the input dimension of 3D until the end.

$$i_t = \sigma\,(W_{xi} * F_t + W_{hi} * Y_{t-1} + W_{ci} \odot C_{t-1} + b_i)$$

$$f_t = \sigma\,(W_{xf} * F_t + W_{hf} * Y_{t-1} + W_{cf} \odot C_{t-1} + b_f)$$

$$C_t = f_t \odot C_{t-1} + i_t \odot tanh\,(W_{xc} * F_t + W_{hc} * Y_{t-1} + b_c)$$

$$o_t = \sigma\,(W_{xo} * F_t + W_{ho} * Y_{t-1} + W_{co} \odot C_{t-1} + b_o)$$

$$Y_t = o_t \odot tanh\,(C_t) \tag{2}$$

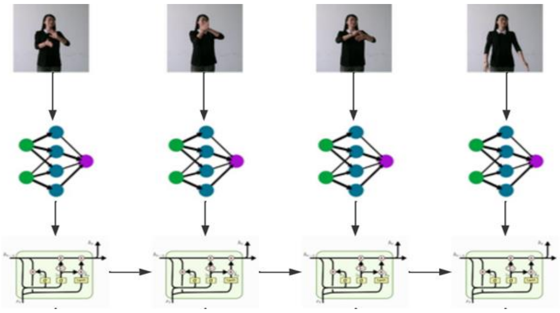

Fig. 4. Spatiotemporal learning through CNN and LSTM.

D. Isolated Output Prediction

For isolated SLR, our ConvLSTM model (see Table II) returns multiple sets of words as depicted in Fig. 5. From the obtained sequence of words, the class with the highest probability will be selected as output.

$$P_a = \sum_{i=0}^{N} \max(P_a) \tag{3}$$

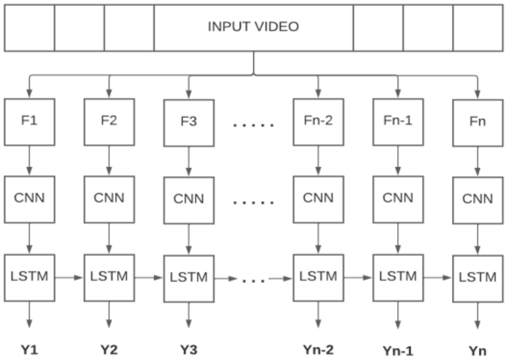

Fig. 5. Isolated SLR output prediction.

TABLE II. THE ARCHITECTURE FOR ISOLATED WORD PREDICTION USING CONVLSTM.

Layer	Kernel	Output Size
Keyframes	-	F_{L2} x 128 x 128
ConvLSTM2D	3, 3	F_{L2} x 126 x 126
MaxPooling3D	1, 2, 2	F_{L2} x 63 x 63
ConvLSTM2D	3, 3	F_{L2} x 61 x 61
MaxPooling3D	1, 2, 2	F_{L2} x 31 x 31
ConvLSTM2D	3, 3	F_{L2} x 29 x 29
MaxPooling3D	1, 2, 2	F_{L2} x15 x 15
ConvLSTM2D	3, 3	F_{L2} x 13 x 13
MaxPooling3D	1, 2, 2	F_{L2} x 7 x 7
Flatten	-	1 x 24304

E. Sentence Generation

For Continuous SLR, an encoder-decoder network is used for sentence generation. In our proposed work both encoder and decoder were developed using LSTM models. Instead, different RNNs could also be used for sentence generation. The encoder reads the input sequence and stores information in internal state vectors. The decoder's initial states are initialised from the output of the encoder. This vector triggers the decoder to start generating the output. Fig. 6 depicts the encoder-decoder architecture using LSTM (X_1 to Xn are identified keyframes) and Fig. 7 represents the sentence generation with natural language processing.

Hidden states in the encoder state are computed using (4) and in the decoder, states are computed using (5). Instead of the output layer in Isolated SLR, an encoder-decoder using LSTM is added for sentence generation.

$$h_t = f\,(W_{hh} * Y_{t-1} + W_{hx} * X_t) \tag{4}$$

$$h_t = f\,(W_{hh} * Y_{t-1}) \tag{5}$$

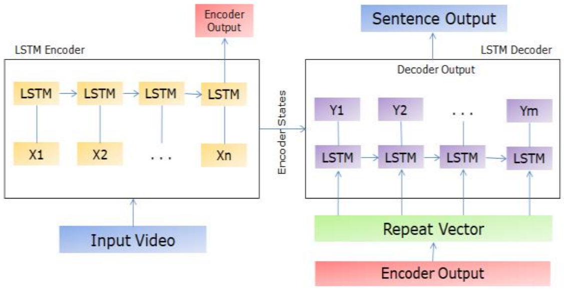

Fig. 6. Encoder decoder architecture built with LSTM for sentence generation.

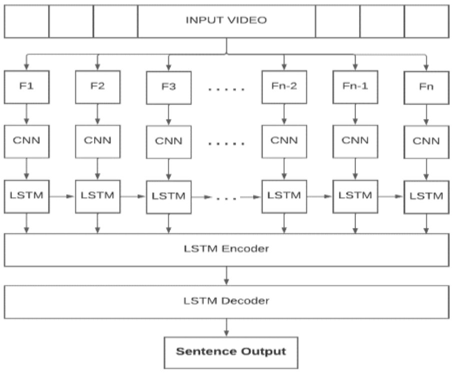

Fig. 7. Continuous SLR output prediction.

IV. EXPERIMENT

A. Dataset

The Chinese Sign Language Dataset [25-30] is used in our experiments for analysis and evaluation of the proposed approach. Isolated SLR and Continuous SLR are two types of SLR. Isolated SLR consists of 500 words, each spoken five times in sign language by 50 people. Continuous SLR consists of 100 sentences, each spoken five times by 50 signers in sign language. Each sentence contains 4 to 5 words on average. In addition, the experimental evaluation was also carried out in another notable dataset, CSL-Daily [31], which focuses on Chinese sign language, featuring 18401 training, 1077 development, and 1176 testing video samples, showcasing performances from ten signers across diverse topics like family life, medical care, and school life. CSL-Daily encompasses a gloss vocabulary of size 2000. The datasets Phoenix-2014 and Phoenix-2014T, as discussed by [32] and [33] respectively, are prominent in the field of Sign Language Recognition (SLR) in Germany. Phoenix-2014 includes 5672 training, 540 development, and 629 testing samples, with a gloss vocabulary of 1295. Conversely, Phoenix-2014T is an extension of Phoenix-2014, offering 7096 training, 519 development, and 642 testing samples, with a gloss vocabulary of 1085.

B. Model Setting for Isolated & Continuous SLR

Initially, the given input video will be split into F_n' frames i.e., $F_1F_2, \dots F_n'$. By default, frame 1 (F_1) will be selected as one of the keyframes. Then a similarity score will be calculated between F_1 and its subsequent frames. If the Sv value between two frames is greater than 1.5 then it will be selected as a keyframe. Further, F_1 will be replaced by the chosen keyframe and the similarity value will be calculated from the immediate next frame. The loop continues till the end of the last frame. At level 1, FL_1 frames are selected as keyframes. The following Fig. 4 shows sample key frame selection in level 1.

For the selected keyframes from level 1, similarity scores will be calculated again. Sv values greater than 2 will be selected as keyframes in level 2. Finally, FL_2 frames were selected as key frames from the input video. Fig. 5 shows frames selected from level 1 with $Sv > 2$.

As shown in Fig. 3, the given input video keyframes will be identified in two levels. At level 1, frames with an Sv value less than 1.5 are not considered keyframes. Level 1 frame selection is shown in Fig. 8. At level 2 frames with an Sv value, less than 2 are not considered keyframes. Level 2 key frame selection is shown in Fig. 9.

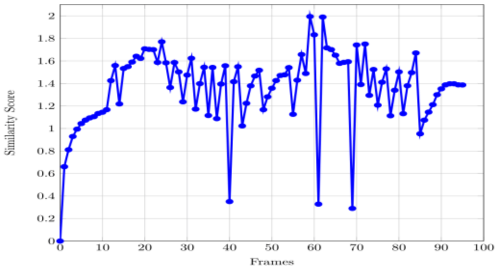

Fig. 8. Level 1 key frame selection with Sv> 1.5.

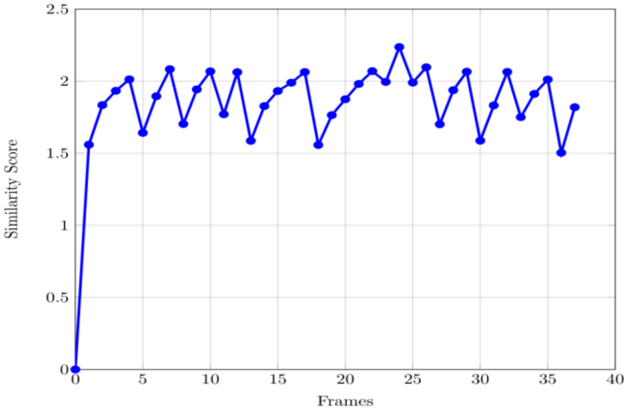

Fig. 9. Level 2 key frame selection with Sv> 2.

Followed by the adaptive key frame extraction from the input video, those frames are resized to a size of 64x64 and normalized to reduce the computational complexity. Fig. 10 shows body pose features extracted using our custom-designed lightweight CNN architecture to cope with the overall less complex design. At layers 1 and 2 outer body pose features are learned. At levels 3 & 4 features are learned vertically for effective capturing of hand and finger orientation.

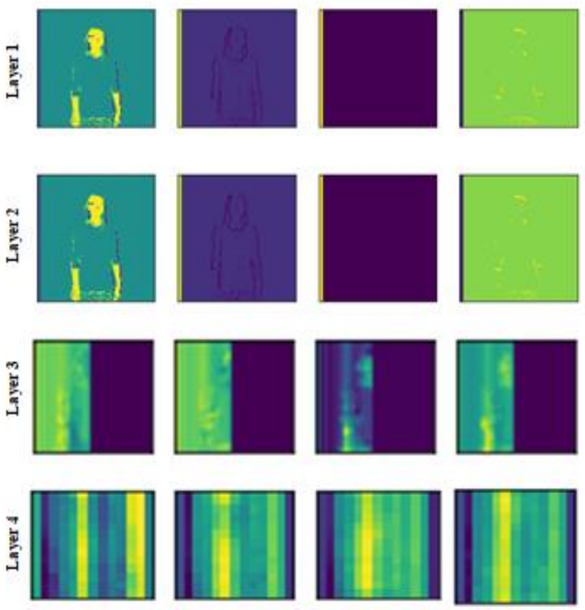

Fig. 10. Features extracted using CNN.

The proposed model for Isolated SLR consists of four ConvLSTM layers with a kernel size of 3x3 and four pooling layers with a size of 2x2. Softmax activation function was used with optimiser as Adam, loss as categorical cross-entropy, learning rate as 0.001, and batch size as 4. For Continuous SLR, an encoder-decoder network has been added with the previously trained model for isolated SLR. Both encoder-decoder networks have a kernel of size 3x3 and tanh as an activation function.

A. Model Comparison

Since our proposed model was constructed with the encoder-decoder framework, it is compared with other similar models: S2VT [34] (standard 2-layer encoder-decoder architecture), LSTM-E [35] (deep 2DCNN and 3D CNN features with mean pooling for high semantic embedding), LSTM-Attention [36] (attention mechanism to capture temporal relations), LSTM-Global-Attention [37] (global attention mechanism is explored for NMT), and HRF [16] (hierarchical recurrent deep fusion).

B. Evaluation of LSTM

In the simple LSTM approach, the extracted keyframes were directly fed into LSTM for sign language recognition. The LSTM model achieves a training accuracy of 0.54 and a testing accuracy of 0.53. Fig. 11 and Fig. 12 show the comparison of training and validation loss and training and validation accuracy for LSTM (Table III).

TABLE III. COMPARISON OF SLT (OURS) WITH ENCODER-DECODER ARCHITECTURE

Model	PRECISION
S2VT [34]	0.897
LSTM-E [35]	0.882
LSTM-Attention [36]	0.851
LSTM-global-Attention [37]	0.858
HRF-S [16]	0.924
HRF-S-att [16]	0.929
Ours	**0.932**

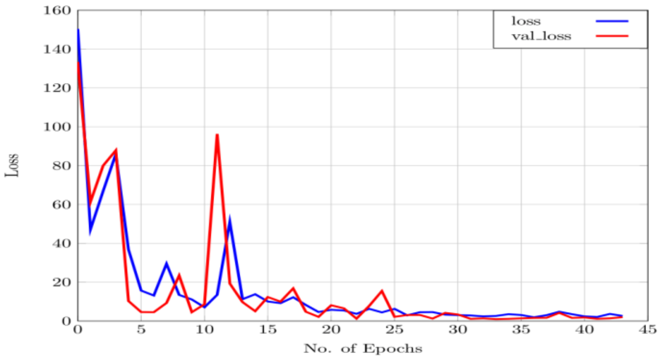

Fig. 11. Simple LSTM: Training vs. testing loss comparison.

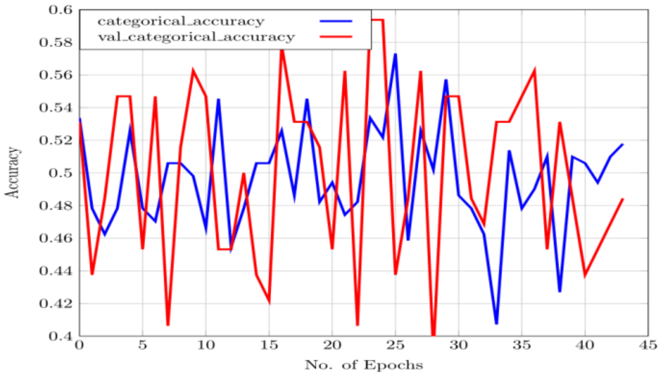

Fig. 12. Simple LSTM: Training vs. testing accuracy comparison.

C. Evaluation of GRU

Instead of LSTM, the extracted keyframes will be directly fed into GRU for sign language recognition. GRU model achieves a training accuracy of 0.56 and a testing accuracy of 0.53. Fig. 13 and Fig. 14 show the comparison of training and validation loss and training and validation accuracy for GRU.

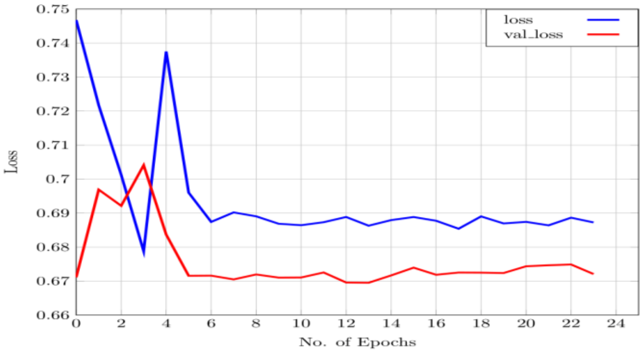

Fig. 13. Simple GRU: Training vs. testing loss comparison.

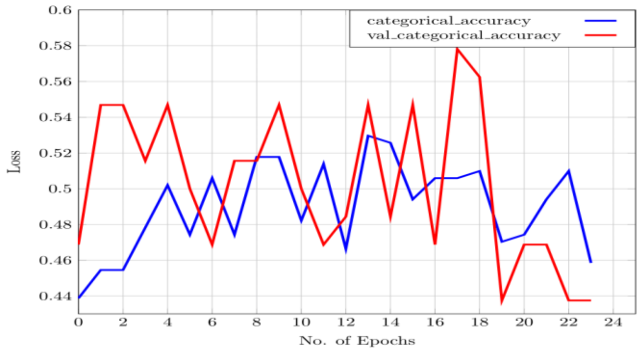

Fig. 14. Simple GRU: Training vs. testing accuracy comparison.

D. Evaluation of ConvLSTM

In ConvLSTM (Ours), extracted keyframes will be directly fed to ConvLSTM for spatial and temporal learning to recognise sign language. Compared to the previous two models ConvLSTM model achieves a training accuracy of 0.90 and a testing accuracy of 0.88. Fig. 15 and Fig. 16 show the comparison of training and validation loss and training and validation accuracy for the ConvLSTM model.

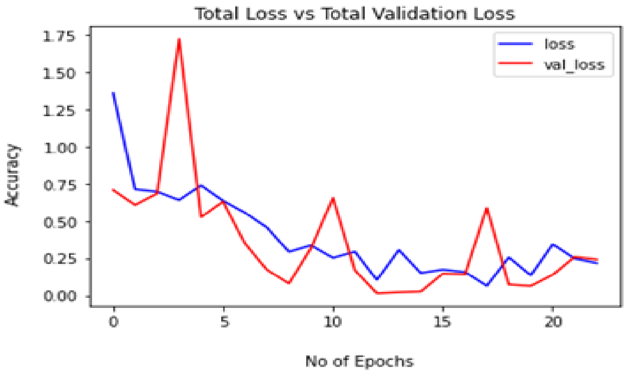

Fig. 15. ConvLSTM Model: Training vs. testing loss comparison.

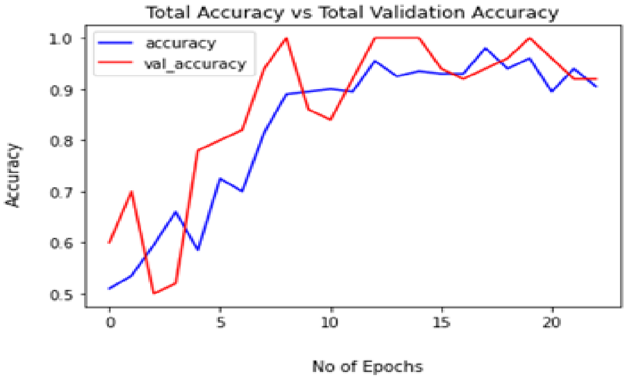

Fig. 16. ConvLSTM Model: Training vs. testing accuracy comparison.

E. Comparison of LSTM Vs. GRU Vs. Convlstm

Comparing all the three models ConvLSTM gives better performance since it captures both spatial and temporal information. The ConvLSTM model achieves an accuracy of 0.90 while the other two approaches produce 0.54 and 0.56 for LSTM and GRU respectively and it is illustrated in Table IV.

TABLE IV. COMPARISON OF SLT (OURS) WITH ENCODER-DECODER ARCHITECTURE ON DIFFERENT EVALUATION METRICS

Model	Training		Testing	
	Accuracy	Loss	Accuracy	Loss
LSTM	0.54	0.62	0.53	0.41
GRU	0.56	0.64	0.53	0.48
Ours	**0.90**	**0.21**	**0.88**	**0.26**

F. Comparison with State-of-the-ART Works

Table V shows the evaluation of different metrics in the CSL dataset.

TABLE V. THE EVALUATION OF DIFFERENT METRICS IN THE CSL DATASET

Model	PRECISION	BLEU	METEOR	ROUGE-L
S2VT [34]	0.897	0.902	0.642	0.904
HRF-S [16]	0.924	0.942	0.699	0.944
HRF-S-att [16]	0.929	0.948	0.703	0.951
Ours	**0.932**	**0.949**	**0.710**	**0.951**

In this section, the detailed analysis is carried out with other datasets and it is given in Table VI, Table VII and Table VIII.

TABLE VI. SOTA FOR BLEU-4 AND ROUGE ON PHOENIX-2014T BENCHMARK

Method	Dev		Test	
	BLEU-4	ROUGE	BLEU-4	ROUGE
PT [38]	11.82	33.18	10.51	32.46
AT [39]	12.65	33.68	10.81	32.74
MDN [40]	11.54	33.40	11.68	33.19
MoMP [41]	14.03	37.76	13.30	36.77
FS-NET [42]	16.92	35.74	21.10	42.57
SignDiff [43]	18.26	39.62	22.15	46.82
Ours	**27.93**	**52.81**	**29.25**	**54.58**

TABLE VII. SOTA FOR WER ON PHOENIX-2014 AND PHOENIX-2014T

Method	Phoenix-2014		Phoenix-2014T	
	Dev (%) WER	Test (%) WER	Dev (%) WER	Test (%) WER
SubUNets [44]	40.8	40.7	-	-
CNN-LSTM-HMMs [45]	26.0	26.0	24.1	26.1
FCN [46]	23.7	23.9	23.3	25.1
Joint-SLRT [47]	-	-	24.6	24.5
SignBT [31]	-	-	22.7	23.9
Two-Stream-SLR [48]	18.4	18.8	17.7	19.3
CorrNet [49]	18.8	19.4	18.9	20.5

SEN [51]	19.5	21.0	19.3	20.7
Ours	**16.8**	**16.2**	**15.9**	**15.7**

From the experimental evaluation it is found that by incorporating a novel adaptive key frame extraction technique, there is a significant improvement in the BLEU-4 and ROUGE score on the diversified datasets of consideration. Also, the noticeable decrease in the Word Error Rate by around 2% indicates that the proposed system to extract keyframes for continuous sign language in video outperforms SOTA systems.

TABLE VIII. SOTA FOR WER ON THE CSL-DAILY DATASET

Method	WER	
	Dev (%)	Test (%)
SubUNets [44]	41.1	41.0

SEN [51]	31.1	30.7
Ours	**19.3**	**19.1**

V. CONCLUSION

The paper has proposed multimodal output from continuous sign language using ConvLSTM with adaptive frame selection that achieves an accuracy of 90% with **a** precision rate of 0.93. The proposed network provides better performance by capturing spatial and temporal information in the video through CNN and LSTM. The experimental discussion shows that our proposed model performs well for Isolated and Continuous SLR. However, the Continuous SLR still has some issues due to word order mapping with signs, and sentences with an average of 4-5 words are only taken. As a future work, it is planned to enhance the performance of sign-word mapping in the sentence, particularly augmenting the sign language-based education system with the outcomes presented in this study. The analysis and evaluation will be experimented with over bigger sentences with long sign actions to test the robustness of the proposed model.

Abstract—**Bioinformatic data concentrated on the accumulation of data pace in the undesired information. Bioinformatics data has vast data-intensive biological information through the computation of data. However, bioinformatics data utilizes statistical methods with gene expression for cancer diagnosis and prognosis. Microarray data provides rough approximations for gene expression analysis. Microarray dataset evaluates the massive gene features presence of sample size and characteristics of microarray data. Hence, it is necessary to evaluate the features in the microarray dataset to exhibit effective outcomes through patterns of gene expression. This paper presented a re-sampling of random probability Swarm Optimization (RRP_SW). With RRP_SW model uses the random re-sampling model estimation of features. The features are evaluated through the computation of a multi-objective optimization model. In the microarray, dataset re-sampling estimated the features in the datasets. The features are samples through the computation of probability values in the datasets for classification. With the RRP_SW model, extreme learning is utilized for the classification of features in the microarray dataset with the benchmark datasets.**

Keywords—Feature Selection; classification; gene expression data; Microarray; RRP_SW; hybrid feature selection

I. Introduction

Many scientists have been drawn to the study of gene expression levels using microarrays because it is one of the gold standard instruments for doing so. According to the medical community, cancer ranks among the deadliest conditions imaginable. Medical science can manage and cure the disease, but only if caught early. Microarray samples typically have a high feature count, low sample size, and high levels of noise [1]. The features of the microarray dataset have not changed significantly over the past few decades. The microarray dataset is notoriously difficult to analyze due to its high dimensionality, which is defined as an excessive number of features for various examples with an unbalanced number of classes [2].

One uses the feature selection approach to identify disease-associated genes. Classification precision is commonly used as a metric by which to judge the quality of feature selection [3]. Accordingly, categorizations play a significant role in recognizing genes. Disease categorization in gene expression data is often referred to simply as classification. The generalization capability of a classification model can be flawed [4] due to the curse of a limited sample size and large dimensions. Considering these characteristics of microarray datasets, the reduction of dimensions is very much essential before the classification. Dimensionality reduction in gene expression data is commonly thought to be achieved through feature selection [5]. Therefore, accurate disease detection or gene identification using these datasets requires efficient feature selection and appropriate classifiers. On the other hand, bad class imbalance can contribute to erroneous classification results. Thus, it is essential to employ a reliable resampling method in order to address this issue [6].

Many scholars have focused on feature selection strategies in recent years [7]. Many techniques have been proposed for feature selection in order to identify genes that are by effected disease [8]. A hybrid method involving mRMR and SVM-RFE was suggested for selecting relevant genes [9]. An improved version of SVM-RFE, which also relies on a form of mutual information, was suggested [10]. A further disadvantage of SVM-RFE is how long it takes to complete a single analysis. Faster feature selection using a two-stage support vector machine - random forest ensemble [11]. An adapted form of RFE was suggested, in which the target number of features to be dropped varies with each iteration. However, while this method guarantees faster results, the grade of the features selected may suffer. In order to RFE on the fly [12]. These techniques have improved efficiency while decreasing time spent on it. The primary goals of this thesis are to increase processing speed and solve the problem of feature selection so that the quality of feature selections can be enhanced. Class imbalance [13] describes a situation in which there is a large disparity between sample sizes that come from various social strata. Inequitable distribution of resources among groups can lead to unpredictable categorization outcomes. If there are two classes represented in the test group, for instance, and sample X is twice as large as sample Y, then the distribution is skewed. This test dataset's samples were all correctly identified as X, yielding an accuracy of 66.67%, which is higher than 50%. Therefore, it is reasonable to infer that class imbalance will undermine the reliability of the categorization scheme. Therefore, researchers suggested resampling strategies to deal with these issues [14]. Over-sampling and under-sampling are the two common resampling techniques used historically. It's possible that overfitting or data loss occurred because the samples were randomly chosen from the minority or eliminated from the major and then replicated [15].

Cancer classification using microarray data aims to identify the relevant hidden gene patterns for an accurate diagnosis [16]. The microarray data classification aims to find the significance of the identified genes and their correlation at the genome level. The features are selected based on the identification of a number of gene classes and select the features for the reduction of genes for classification samples. Support Vector Machines (SVM), Decision Trees (DT), Artificial Neural Networks (ANN), K-Nearest Neighbors (kNN), Extreme Learning, and Regularized Extreme Learning [17] are frequently used categorization techniques.

The challenges in today's microarray data are the availability of large numbers of genes and relatively few samples. The number of samples available is limited due to the difficulty in collecting microarray samples [18]. Microarray gene expression data are used to identify a subset of genes that are either co-expressed or expressed differently. The differential genes used to classify the samples based on the expression pattern identified. Co-expressed genes recognize groups with similar patterns of expression as a functional enhancement for the analysis of biological pathways [19]. On the other hand, as biomarkers, deferentially expressed genes are used to define tumors and various tumor sub-types. The attempt to find molecular invariant or differential behavior relevant to a given biological problem has been applied to the gene expression analysis problem [20]. By reducing the number of features and thus increasing the co-relationship between gene expression levels, classification accuracy is improved. Microarray and gene expression analysis has acquired a position in biology and medicine in recent studies. It still requires a much more efficient classification technique to analyze the enormous amount of data [21]. Also, an effective way to determine the relevance of the gene and thus create an excellent diagnostic prediction algorithm is necessary. It is hard to determine gene dependency. Methods of gene selection are therefore required that evaluate each gene separately based on its characteristics [22]. This information must be extracted from microarray data and is an essential issue to address. Extracting interesting gene patterns based on the information obtained is a desirable goal. In order to address all these issues, a more optimized and cohesive framework is needed.

A. Contribution and Organization of Paper

This paper proposed an RRP_SW model for the feature selection and classification in the microarray dataset for disease diagnosis. The specific contribution of the research is presented as follows:

1) To evaluate the gene expression evaluates the re-sampling-based model for the computation of features. Microarray datasets are pre-processed and evaluated based on the sampling process for the evaluation of features in the datasets.

2) Through the re-sampling the features are evaluated, and the probability features are computed based on the estimation of optimal values. The particle swarm optimization features are computed based on the estimated variables.

3) The particle swarm optimization model evaluates the feature estimation variables through probability estimation. The simulation analysis expressed that the proposed RRP_SW model exhibited higher accuracy for the classification of the benchmark datasets.

It is structured as follows in the paper: The relevant works for the microarray datasets are given in Section II. In Section III, we detail our approach to researching the RRP_SW model, and in Section IV, we share our findings from running simulations of the model. In Section V, we show the overall conclusion reached using the proposed RRP_SW model.

II. Related Works

In study [23] proposed an algorithm for the two phases such as the wrapping and filtering process. Initially, the developed model evaluates the steps to minimize the prediction number for the variation in the target based on relevance value. The proposed heuristics model ratio was evaluated based on the compromised rule between relevance and complementary values. With the wrapping phase, the graph-based model is employed for the relevance feature for the complementary values between each other through discriminative features. Through the graph-based feature selection algorithm model, the complementary features are estimated based on the relevance values. The experimental analysis uses the 13-microarray gene dataset with 8 binary and five multi-class microarray datasets. With the 10-fold validation model Support Vector Machine (SVM), Naïve Bayes (NB) and Artificial Neural Network (ANN) are employed. The experimental results demonstrated that hybrid model exhibited the improved performance compared with the conventional classifier model.

As a means of selecting features from a high-dimensional microarray dataset, the study in [24] introduced the Altruistic Whale Optimization Algorithm (AltWOA). AltWOA uses the conventional Whale Optimization algorithm for the efficient propagation of the efficient features optimum in the iteration process. The AltWOA model comprises of the eight high dimensionality dataset exhibits the improved performance compared with the classical technique for the analysis in terms of accuracy and feature selection.

In study [25] adopted ensemble-based feature selection model based on consideration of genetic algorithm and t-test for the computation with the consideration of the optimal feature subsets based on consideration of different datasets. Using an analysis of the Nested Genetic algorithm's performance on a variety of DNA Methylation data sets. When applied to the colon cancer dataset, the Nested-GA dataset created using the Incremental Feature Selection (IFS) strategy for the best subset of genes shows superior performance after 5-fold validation. The experimental validation of the independent dataset provides a classification accuracy of 99.9% based on the consideration of the biological features for the validation of the resulting analysis. For the DNA methylation model the Nested -GA model exhibit the effective feature selection for Gene Expression. The experimental analysis expressed that developed Nested-GA model exhibits the higher classification optimal feature subset compared with the other algorithm. Through the DNA-Methylation data, the model exhibited an accuracy value of 98.4%.

In study [26] evaluated the CCFS features for the random dataset with the utilization for the cooperation filter criteria. The optimization model uses the fitness function with the estimation of optimal solution space through a gravitational search algorithm. With the CCFS model, several microarray high dimensional datasets are evaluated and compared with the feature selection with Interact (INT) and Maximum Relevancy Minimum Redundancy (MRMR). The experimental analysis expressed that non-parametric statistical analysis is performed for the non-parametric features based on selected features with improved accuracy, sensitivity, and specificity.

In study [27] comparatively evaluated the different feature sets based on the wrapper and fuzzy rough set for the feature selection. The evaluation is based on the consideration of execution time, classification accuracy, and selected feature numbers. The experimental analysis results expressed that feature selection is evaluated based on cancer microarray gene datasets. The results expressed that KNN model exhibited higher accuracy compared with the conventional classifier model. The fuzzy rough set model feature selection model exhibits the computational with the higher and minimal number of genes to estimate the filter correlation features.

In study [28] developed a distributed feature selection model for the fuzzy set model features. The datasets are classified based on the different subsets based on the fuzzy shuffling and set theory. Every subset is individually evaluated HCPF (Hesitant fuzzy set-based feature selection algorithm using Correlation coefficients for Partitioning Features). With the merging procedure, the feature subset is updated and improves the classification accuracy. For the high-dimensional microarray datasets, the technique is tested using a centralized algorithm and 22 sets of distributed features. The experimental analysis demonstrated that the developed model achieves significant results compared with the other non-parametric features approach.

III. Feature Selection with the Re-Sampling Probability Estimation

Feature selection is a crucial step in the analysis of high-dimensional gene expression datasets, such as those obtained from Marray experiments. One effective method for feature selection is the Re-sampling Probability Estimation (RPE) technique. Let $X = [xij]$ be the gene expression matrix where xij denotes the expression level of the j-th gene in the iii-th sample, and $y = [yi]$ be the vector of class labels for the samples. First, each gene is ranked based on a statistical measure. Suppose we use the t-statistic for ranking genes defined in Eq. (1).

$$t_j = \frac{\bar{x}_{i1} - \bar{x}_{2j}}{\sqrt{\frac{x_{1j}^2}{n_1} + \frac{x_{2j}^2}{n_2}}} \qquad (1)$$

where $\bar{x}_{i1}$ and $\bar{x}_{2j}$ the mean expression levels of gene j in the two classes, $\frac{x_{1j}^2}{n_1}$ and $\frac{x_{2j}^2}{n_2}$are the standard deviations, and n_1 and n_2 are the number of samples in each class. To assess the stability of the rankings, we employ bootstrapping. In each iteration k, a bootstrap sample $x_k$is generated by sampling with replacement from X. The t-statistic is then computed for each gene in the bootstrap sample stated in Eq. (2).

$$t_j^k = \frac{\bar{x}_{i1}{}^k - \bar{x}_{2j}{}^k}{\sqrt{\frac{x_{1j}^{(k)2}}{n_1^k} + \frac{x_{2j}^{(k)2}}{n_2^k}}} \qquad (2)$$

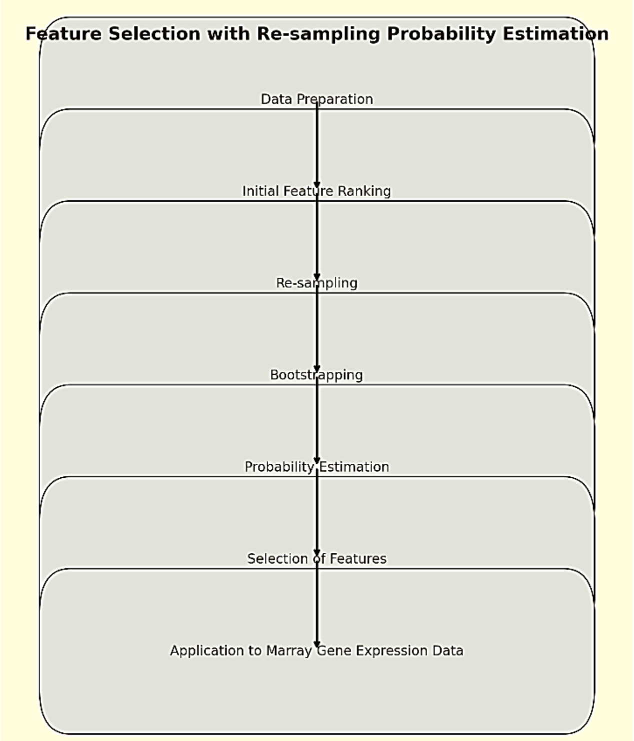

Fig. 1. Flow Chart of Re-Sampling in M-array

After BBB bootstrap iterations, each gene j will have a distribution of t-statistics t_j^k. To estimate the probability that gene j is consistently ranked among the top features, we calculate the frequency p_j with which gene j appears in the top M rankings defined in Eq. (3).

$$p_j = \frac{1}{B}\sum_{k=1}^{B} t_j^{(k)} \qquad (3)$$

A threshold τ is set to select the genes with a high re-sampling probability. The selected set of genes $\{S\}$ is given in Eq. (4).

$$S = \{j \mid pj \geq \tau\} \qquad (4)$$

This threshold can be chosen based on domain knowledge or statistical criteria such as the false discovery rate (FDR). In Marray gene expression datasets, which typically involve thousands of genes across multiple samples, applying the RPE method helps in identifying a subset of genes that are most relevant to the biological question at hand. For instance, in distinguishing between different disease states, the selected genes are those that consistently show significant differential expression across multiple bootstrap samples, thus providing a robust and reliable feature set for further analysis.

Algorithm 1: Feature Selection with Re-sampling Probability Estimation

```
Input: Gene expression matrix X (samples x genes), class labels y, number of bootstrap iterations B, threshold $\tau$
Output: The selected set of informative genes S
1. Data Preparation
  Normalize the data matrix X
  Handle missing values if any
2. Initial Feature Ranking
  for each gene j in X do
    Compute t-statistic $t_j$ based on class labels y
  end for
3. Re-sampling
  Initialize an empty list to store bootstrap rankings
  for k = 1 to B do
    Generate a bootstrap sample $x^K$ by sampling with replacement from X
    Compute t-statistics $t_j^k$ for all genes in the bootstrap sample $x^K$
    Rank the genes based on $t_j^k$
    Store the rankings in the list
  end for
4. Probability Estimation
  Initialize a dictionary to count top-M appearances for each gene
  for each gene j do
    Set count[j] = 0
    for each bootstrap iteration k do
      if gene j is in the top-M rankings in bootstrap sample k then
        Increment count[j] by 1
      end if
    end for
    Compute probability $p_j = count[j]/B$
  end for
5. Selection of Features
  Initialize an empty set $S$
  for each gene j do
    if $p_j >= \tau$ then
      Add gene j to set S
    end if
  end for
6. Return the set of selected genes S
```

A hybrid approach RRP_SW method is proposed as a hybrid feature selection that combines the advantages of minimizing redundancy and maximizing relevancy (mRMR) and adaptive genetic algorithm (AGA). The architecture of the proposed model is illustrated in Fig. 2.

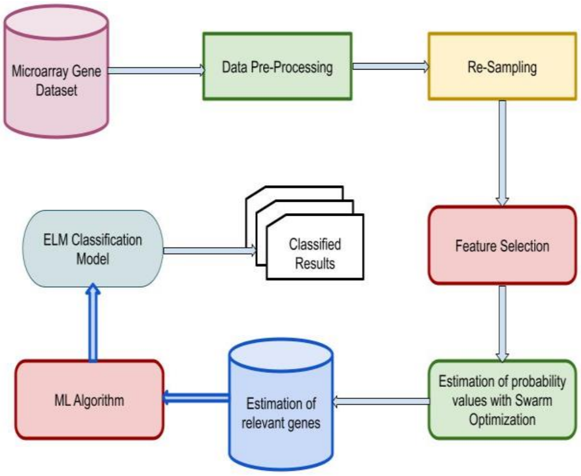

Fig. 2. Architecture of RRP_SW.

A. Classification Problem

The problem of determining the categories of new observation based on the previously analyzed similarity of data is called as classification in machine learning. Classification can be formally defined as:

Definition: X = {x1, · · · xn} are set of given data points. , each of them belongs to a finite set of classes Y = {y1, · · · , ym}, the classification task is to generate a function f : X → Y wherein, elements of X maps to elements of Y xi is known as an instance (or sample), which has a definite set of features $F = \{f1, \cdots, fl\}$ that may be numerical or categorical either. These features are often termed as variables or attributes, which are used interchangeably in this thesis. Every data point xi has an association with a label yi , that shows its class from set Y. The main aim of classification is to design a model, that can determine their label yi for the given data point xi.

Fig. 1 illustrates the system architecture of the proposed techniques. The raw data are gene expression microarray datasets. Due to the potential for the data to be inconsistent and chaotic, it must first undergo pre-processing. The suggested resampling method is then used to generate the balanced datasets. The proposed feature selection technique is then applied at step 48 to choose relevant characteristics.(genes). Finally, various classifiers are utilized to evaluate the efficiency and efficacy of the procedure. The process flow of Proposed RRP_SWM is presented in Fig. 3.

B. Proposed method Re-sampling Based Swarm Optimization

The imbalance of class problem has been addressed using this method. The data on gene expression is biologically specific and, therefore, should not be changed arbitrarily. Therefore, the suggested method intends to deal with the imbalance of class for microarray data without resorting to over-fitting 49 of model and hence losing information, while maintaining the integrity of the inspired biological value. It is believed in this strategy that samples with the same label undergo the same distribution. Under this hypothesis, a data matrix was built that includes a small group. Then, the new sample value for that location was determined by selecting one value at random from each column. To ensure that each class had an equal number of representatives, the current sample was saved, and the procedure was repeated k times. When all was said and done, k examples were collected that mirrored the original dataset's feature distribution in the microarray data. The RRP_SW method is illustrated below as Algorithm 2:

```
Algorithm 2: RRP_SW for the Feature Extraction
Input: X - Given minority sample matrix for the data, k- new sample count
Output: X - New data matrix
while (k >= 1) : do
for j = 1, 2, ..., n (n column size of X): do
Random value V chosen from Xj (X column in $j^{th}$ features)
Save V to the respective position of a new sample.
End
Update the new X sample;
k = k − 1;
end
Return X;
```

In this case, the rows represent samples and the columns indicate genes (features) that will be used to evaluate the given microarray class data (represented by the matrix X).

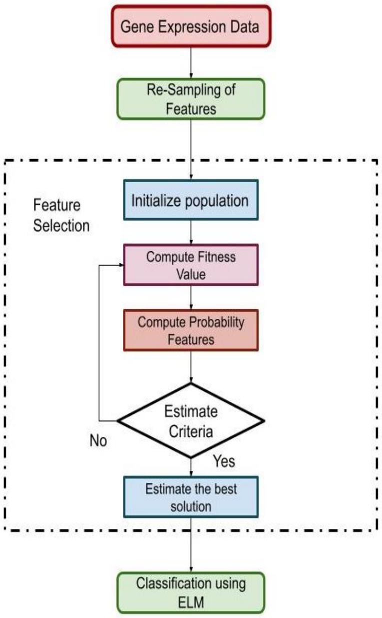

Fig. 3. Flow Chart of RRP_SW.

C. Large Scale Swarm Optimization

In place of SVM, large-scale swarm optimization (LSSO) was used to expedite the weights allocation procedure. LSSOs were specifically created for the purpose of classifying massive amounts of data, such as text. Text data has very big dimensions, and so do the microarray datasets. This means that microarray databases will also work well with LSSO. The goal function of the large-scale liner SVM is given by the Eq. (5):

$$min_w f(w) \equiv \|w\|_1 + C\sum_{i\in I(w)} b_i(w)^2 \tag{5}$$

Were,

$$b_i(w) \equiv 1 - y_i w^T x_i$$

$$I(w) \equiv \{(i|b_i(w) > 0)\}$$

For the ith sample, the feature vector is denoted by xi, while the sampling procedure for feature vector yi is denoted by w. Consequently, in large-scale swarm optimization, the loss function is a square pivoted L1 regularized function. The degree to which the weight vector is sparse is determined by the punishment factor C > 0.(w). As C grows, the weight vector(w) becomes sparser, which penalizes genes with lower significance and thus higher weights to 0. The ultimate decision function looks like Eq. (6) for all swarm optimizations:

$$f(x^*) = sign(w.x^*) \tag{6}$$

The unknown sample feature vector is denoted by x ∗. One variable is updated by cyclic coordinate descent method to generate $w^{k.j} \in R^n, j = 1, \dots., n+1$from the current solution w k . Where, j and k refer as feature(variable) and iteration respectively. Thus, $w^{k,1} = w^k, w^{k,n+1} = w^{k+1}$, and hence it is mentioned in Eq. (7).

$$w^{k,j} = \left[w_1^{k+1}, \dots\dots, w_{j-1}^{k+1}, w_j^k, \dots., w_n^k\right] \text{ for } j = 2, \dots., n \tag{7}$$

The one-variable optimization problem shown below was solved, for updating $w^{k,j}$ to $w^{k,j+1}$ as in Eq. (8).

$$min_s gj(z) = \left|w_j + z\right| + L_j'(0,w)z + \frac{1}{2}L_j''(0\colon w)z^2 + constant \tag{8}$$

Where,

$$e_j = [0, \dots.,0,1,0, \dots\dots,0]^T \in R^n$$

$$L_j(z;w) \equiv C \sum_{i\in I(w+zej)} b_i(w+zej)^2$$

And it can be stated as in Eq. (9) and Eq. (10).

$$L_j'(0,w) = -2C\sum_{i\in I(w+zej)} y_i x_i b_i(w) \tag{9}$$

$$L_j''(0\colon w) = max\left(2C\sum_{i\in I(w)} x_{ij}^2, 10^{-12}\right) \tag{10}$$

Since Lj (z;w) is not a double differentiable, so Eq. (10) is an approximate expression.

The variables are evaluated based on the consideration of variable j and z as in Eq. (11).

$$w_j^{kj+1} = w_j^{wj} + z^* \tag{11}$$

D. Mutual Information Relevance and Redundancy

The mutual information about the microarray dataset is evaluated with the re-sampling random probability Swarm Optimization (RRP_SW). The RRP_SW dataset are estimated for the entropy features as presented in Eq. (12).

$$H(X) = \sum_{x=1}^{N_x} P_x(X)\log(P_x(X)) \tag{12}$$

In the above Eq. (8), the probability class for the features are denoted as $(P_x|x = 1,2, \dots\dots, N_x)$. The average conditional probability of the variables is computed based on the feature vector as in Eq. (13).

$$H(S|X) = \sum_{s=1}^{N_s} P(s)\left(\sum_{x=1}^{N_s} P_x(x|s)log\left(P_s(x|s)\right)\right) \tag{13}$$

With the Eq. (9) the feature vector is represented as N_s for the samples in dataset and the class x conditional probability is denoted as the $P_x(x|s)$. The entropy values for the conditional probability are evaluated based on the consideration of initial probability features. The class features are independent based on conditional entropy values based on mutual information. The microarray dataset mutual information is represented as $I(X;S)$ with consideration of variables x and s represented as in Eq. (14).

$$I(X;S) = H(x) - H(X|S) \tag{14}$$

The above Eq. (9) is redefined as in Eq. (15).

$$I(X;S) = I(S;X) = \sum P(x.s) log\left(\frac{P(x,s)}{P(x)P(s)}\right) \tag{15}$$

The RRP_SW mutual information property is computed based on the symmetricity property with variables S and X as $I(X;S) = I(S;X)$ .With RRP_SW the attribute mutual information I is estimated based on discrete variables S and X as in Eq. (15). The redundancy is reduced in the feature through the consideration of mutual information with the computation of maximal dissimilarity between the genes in the microarray datasets. Here, the gene subsets are evaluated based on the consideration of minimal redundancy average value as in Eq. (16).

$$minimum(W) = \frac{1}{|s|^2} \sum_{i,j \in s} I(i,j) \tag{16}$$

Where, $I(i,j)$ represented the mutual information in the ith and jth genes in the microarray dataset with the gene denoted as $|s|$. Through mutual information genes are expressed with the mutual information $I(h,i)$ as in Eq. (13). The relevance of the mutual information between gene target classes is defined as $h_1, h_2, \dots \dots \dots, h_k$. The maximal relevance between the gene variables subset s as defined in Eq. (17).

$$maximum(V) = \frac{1}{|s|^2} \sum_{i \in s} I(h,i) \tag{17}$$

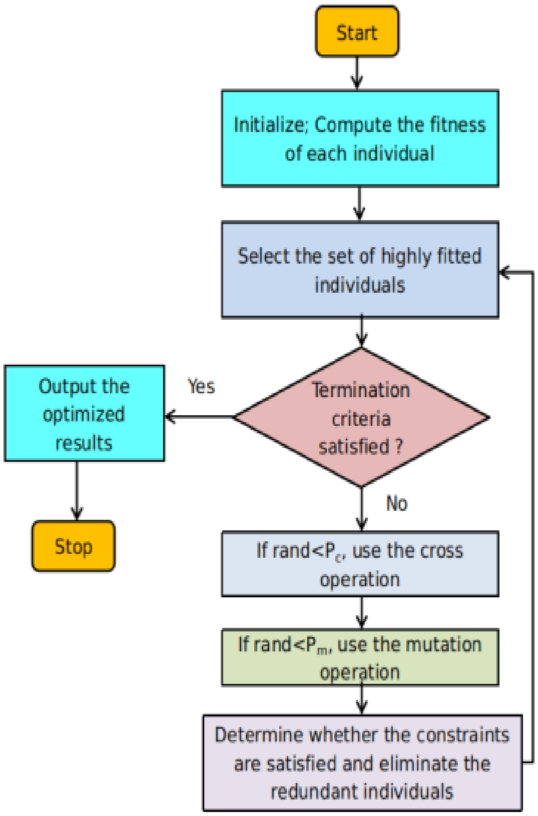
The swarm optimization model for the proposed RRP_SW model is presented in Fig. 4.

E. Experimental Evaluation

The experimental analysis of the RRP_SW performs the verification based on the consideration of different experimental datasets. The dataset for analysis comprises a set of heterogeneous classes of more than two. The dataset for the analysis is presented as follows:

1) Datasets: The Microarray gene expression data set has been utilized for a vast range of experimental analyses of the datasets. The dataset for the analysis is comprised of information about diseases such as breast, small round blue cell tumor (SRBCT), Lymphoma, Lung, and other cancer datasets. The characteristics and features of the different diseases' datasets are presented in Table I.

The final process in proposed RRP_SW comprises the Back-Propagation mechanism with the assigned neural network value with fine-tuning of the error through iteration process. The rate of error in the network are fine-tuned with the assigned weights to perform reliable model design through generalization and improvisation as shown in Fig. 5.



Start
Initialize; Compute the fitness of each individual
Select the set of highly fitted individuals
Termination criteria satisfied ?
Yes
Output the optimized results
Stop
No
If rand<P$_c$, use the cross operation
If rand<P$_m$, use the mutation operation
Determine whether the constraints are satisfied and eliminate the redundant individuals

Fig. 4. Flow chart of swarm optimization.

TABLE I. CHARACTERISTICS OF DATASETS

Datasets	Number of Features	Number of Samples	Number of Classes	Class Description
Breast	24481	97	2 (46- 51)	46 Normal 51 Cancer
Lung	12600	203	5 (139-17-6-21-20)	139 AD 17 NL 6 SMCL 21 SQ 20 COID
Lymphoma	4026	62	3 (42-9-11)	42 DLBCL 9 FL 11 CLL
SRBCT	2308	*63*	4 (23-8-12-20)	23 EWS 8 NHL 12 NB 20 RMS

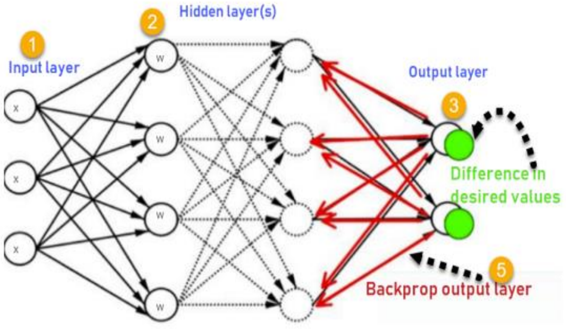


Fig. 5. Architecture of Back Propagation Neural Network (source:guru 99.com).

The Neural Network outputs are stated as L with the set of the training set N with the sample set of (x,t) as stated in Eq. (18).

$$\sum_{j=1}^{L}\beta_j\emptyset\left(\omega_j x_i + b_j\right),\ \ i \in [1,N] \tag{18}$$

The neural network model input, output, and target layers are presented in Eq. (19).

$$y_i = \sum_{j=1}^{L}\beta_j\emptyset\left(\omega_j x_i + b_j\right) = t_i + \epsilon_i,\ \ i \in [1,N] \tag{19}$$

The RRP_SW comprises of two stages with the conversion of hidden neurons in to represented input data. The input layer comprises of the biases and weights for the estimation of the data presented in hidden layer with the non-linear activation function. The evaluation process uses the extreme learning process as shown in Fig. 6. The matrix computation in RRP_SW model extreme learning process is presented as $\beta = (\beta_1^T \ldots\ldots\ldots \beta_L^T)^T$, $T = (y_1^T \ldots\ldots\ldots y_L^T)^T$

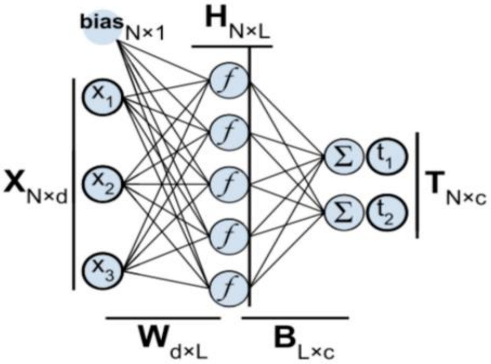

Fig. 6. ELM in RRP_SW.

The microarray data set comprises of the correlated or irrelevant information for the hidden layer model with L1 regularization. With extreme learning process L1-regulated with the pruning of neurons for the robust performance of network. ELM model comprises of the building model to derive the relevance of output.

IV. Simulation Analysis

The proposed RRP_SW model comprises of the 10 times features with the selected microarray datasets under different genes target number. The targeted gene microarray dataset comprises of the different number of genes. The analysis of microarray dataset gene for the selection are presented in Table II.

TABLE II. Number of Genes Selected on Microarray Datasets With RRP_SW Selection

Dataset	Gene in Steps									
	1	2	3	4	5	6	7	8	9	10

(a)

(b)

(c)

(d)

Fig. 7. Feature Selection with (a) Breast (b) Lung (c) Lymphoma (d) SRBCT.

The provided Tables III (A, B, C, and D) and Fig. 7(a) – Fig. 7(c) present datasets related to different types of cancer: breast, lung, lymphoma, and SRBCT (small round blue cell tumors). Each table lists gene counts and their corresponding probabilities of being in the top 10 genes associated with each cancer type. The gene counts represent how frequently each gene appears in the top 10 list, while the probabilities (pjp_jpj) indicate the likelihood of each gene being among the top 10 based on the dataset.

In each table:

- The gene counts range from 22 to 215 in Table IIIA (Breast), 29 to 214 in Table IIIB (Lung), 14 to 208 in Table IIIC (Lymphoma), and 24 to 210 in Table IIID (SRBCT).
- The probabilities (pjp_jpj) vary between 0.80 and 0.92 in Table IIIA, 0.82 and 0.91 in Table IIIB, 0.82 and 0.95 in Table IIIC, and 0.83 and 0.92 in Table IIID.

These tables likely serve as data points for statistical analysis or machine learning models aiming to identify genes most relevant to each cancer type based on their frequency and probability of occurrence in top-ranking lists. The variability in gene counts and probabilities across different cancer types reflects the diversity and specificity of genetic factors associated with each disease, crucial for advancing targeted diagnostic and therapeutic strategies in oncology research. The rate of classification accuracy for the microarray dataset are evaluated with RRP_SW model. The classification accuracy is estimated with the average results obtained with the 30 times of the classification process presented in Table IV.

TABLE IV. CLASSIFICATION ACCURACY OF RRP_SW SELECTION AND ELM

Dataset	Classification Accuracy Rate %									
	1	2	3	4	5	6	7	8	9	10
Breast	98.67	98.45	99.04	98.67	95.62	99.04	98.34	95.42	99.73	96.43
Lung	98.56	98.35	98.73	97.34	96.72	95.34	99.04	98.75	98.27	97.56

SRBCT	99.28	98.15	98.52	98.74	94.92	98.35	99.34	97.61	97.94	97.84

When compared to the other feature selection method, the RRP_SW model's swarm optimization-based classification accuracy is significantly higher. The RRP_SW model is comparatively examined with the ReliefF, SFS and mRMR algorithms. The classification accuracy of the RRP_SW model is evaluated for the different microarray dataset such as SRBCT, Lung, breast and Lymphoma dataset shown in Fig. 6.

The RRP_SW model perform the feature selection with the balanced dataset for the experimental analysis of the raw datasets for the gene selection. The feature selection is performed with the SVM based model for the defined objective set function. The SVM classifier uses the class value C = 1 for the dataset 128 genes.

The Fig. 6 to Fig. 8 provides the comparative performance analysis of the raw dataset balance with consideration of measures such as accuracy, MCC and AUC. Experimental analysis of boldface microarray dataset variables is presented in Table V. With the comparative examination of the microarray dataset Leukemia exhibits the effective and significant performance for the different variables. The comparative analysis expressed that MCC, ACC and AUC model exhibits the significant performance for the balances dataset such as Colon and Breast cancer. Additionally, it is observed that for ovarian dataset the performance of RRP_SW exhibits the minimal performance compared with the other datasets. Additionally, it is expressed that raw datasets exhibits the significant performance for the increase in genes to resolve the imbalance class in the microarray datasets.

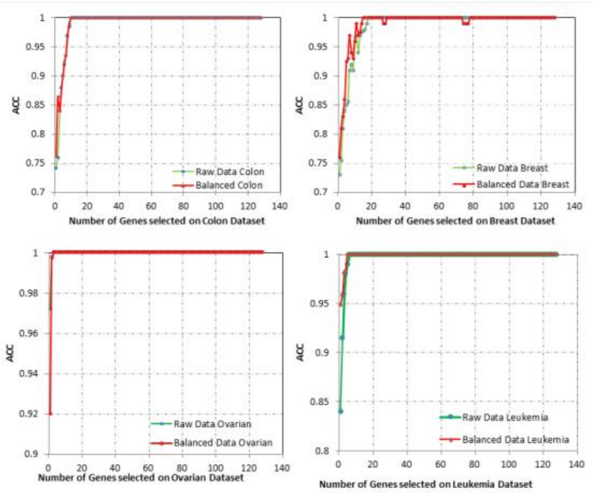

Fig. 8. Accuracy analysis for the different datasets.

TABLE V. COMPUTATION OF FEATURE CLASSIFICATION

	Raw Datasets			Balanced Datasets		
	ACC	AUC	MCC	ACC	AUC	MCC
Breast	98.64	99.05	99.85	99.87	99.35	99.87
Lung	99.85	99.34	99.73	99.46	1.0	99.93
Lymphoma	99.04	1.0	99	99.97	99.85	99.58
SRBCT	98.96	99.97	98.86	99.86	99.96	99.49

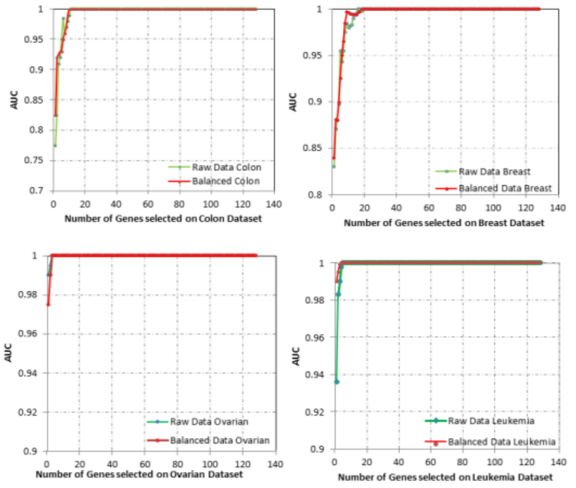

Fig. 9. Comparison of AUC for the different datasets.

With the proposed RRP_SW model the feature selection is performed with the consideration of different feature selectors. The experimental analysis is performed with the consideration of the different methods such as mRMR and SVM-RFEVSS. Through swarm optimization model the classifier model exhibits the balanced dataset for the selected 1 to 128 genes as in Table VI. Fig. 9 shows comparison of AUC for the different datasets.

TABLE VI. CLASSIFICATION OF RRP_SW

	SVM-RFEVSS	RRP_SW
Breast	4671.82	995.06
Lung	98.87	99.03
Lymphoma	2346.14	687.48
SRBCT	786.60	99.84

In Table VI-time consumption is measured for the LSSO-RFEVSS and SVM-RFEVSS which reveals that proposed RRP_SW model exhibits the minimal time for the reduced time consumption for the feature selection for the high dimensional dataset with different classification method are shown in Table VII.

TABLE VII. COMPARISON OF CLASSIFICATION

Datassets	kNN			SVM			ELM – RRP_SW		
	ACC	AUC	MCC	ACC	AUC	MCC	ACC	AUC	MCC
Breast	77.455	81.67	78.96	83.79	84.73	93.46	99.84	99.73	91.39
Lung	80.44	83.46	81.34	87.50	81.39	91.46	98.45	98.94	90.77
Lymphoma	79.04	79.87	79.45	88.92	80.35	96.35	99.49	99.03	93.73
SRBCT	82.35	80.57	84.68	90.74	85.70	93.72	99.78	99.38	99.83

Furthermore, it is observed that classifier SVM model exhibits the significant performance for the RRP_SW model. Through the classifier model the features in the microarray dataset is evaluated based on the sample size with the microarray data analysis. Fig. 10 shows classification for different datasets.

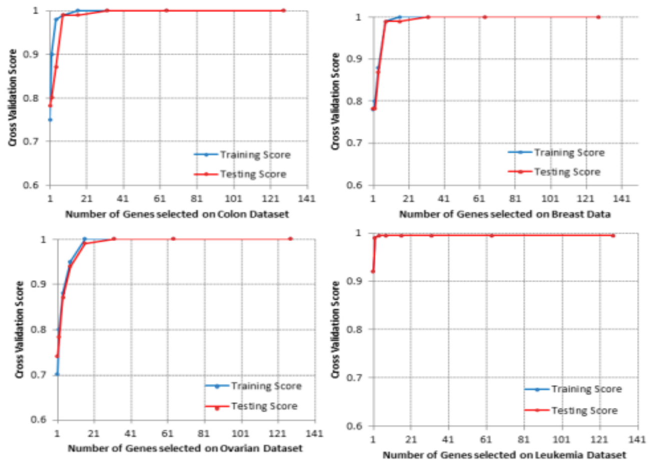

Fig. 10. Classification for different datasets.

Microarray data is characterized by a high degree of dimensionality, a relatively small sample number, and the presence of class imbalance. The Class imbalance issue is rarely addressed in this field of study, among them. In this chapter, a simple but effective method known as RRP_SW was proposed for pre-processing the datasets, and the intern solved this problem. The balanced datasets were obtained by using these methods. For example, many scholars in this area rely on the tried-and-true SVM-RFE method. To lessen the time needed for SVM-RFE's processing, a newer version of RFE, RFEVSS, was suggested. A bigger initial step size helped reduce recursion time; further reduction of the step size when the features are to be eliminated further decreased recursion time, guaranteeing high-quality, meaningful gene selection. There is a vast pool of genes at play in the human body, but only a small subset is actually involved in illness development. Therefore, effective feature picking must be implemented. Even though a practical version of swarm optimization, called LSSO, was developed. For microarray datasets, Large Linear Support Vector Machine (LSSO) is a pure linear classifier based on a support vector, which acquires the benefits of SVM while decreasing the expense of computational effort (large scale linearly separable data). The results section demonstrates that the resulting method, which is referred to as LSSO-RFEVSS, is an effective and efficient feature selector in comparison to other current feature selectors. Finally, experiments were run to determine the effect of various classifiers on the findings, and it was found that Logistic Regression was superior in the vast majority of instances.

A. Limitations and Future Scope

The limitations of the study on Feature Selection with Re-Sampling Probability Estimation (RPE):

1) Computational complexity: The RPE method involves bootstrapping and recalculating t-statistics for multiple iterations, which can be computationally intensive, especially with large datasets. This may limit its applicability to high-dimensional gene expression data where computational resources are constrained.

2) Dependency on bootstrap size: The performance of the RPE technique is dependent on the number of bootstrap iterations. A higher number of iterations may improve stability but also increase computational time and resource usage. Conversely, too few iterations might lead to unreliable feature rankings.

3) Threshold selection: The choice of threshold τ for selecting significant genes can be subjective and may impact the results. The threshold is typically chosen based on domain knowledge or statistical criteria, which might not always capture the most relevant features accurately.

4) Feature redundancy: While RPE helps in identifying relevant genes, it might not fully address the issue of feature redundancy. Some genes might be highly ranked but redundant in terms of the information they provide, potentially leading to overfitting in subsequent models.

5) Limited generalizability: The RPE method was evaluated on specific cancer datasets (e.g., breast, lung, lymphoma, SRBCT). Its effectiveness on other types of gene expression datasets or in different biological contexts is not fully explored.

6) Assumption of consistent gene distribution: The RRP_SW method assumes that samples with the same label have similar distributions, which may not always hold true in real-world datasets. This could lead to inaccurate balancing and potential loss of biological significance.

7) Potential for overfitting: The feature selection process, particularly when combined with a high number of genes and complex models, may lead to overfitting, where the model performs well on training data but poorly on unseen test data.

Future research on the RRP_SW method for gene expression data could focus on integrating it with advanced machine learning techniques like deep learning to enhance classification accuracy. Exploring hybrid feature selection methods, improving scalability, and handling missing, or noisy data are key areas. Extending the method to other omics data, developing enhanced evaluation metrics, and ensuring model interpretability will also be valuable. Additionally, applying RRP_SW in real-world biomedical research, benchmarking against other methods, and creating user-friendly tools can further its impact and usability.

V. Conclusion

Microarray dataset comprises of the expression of genes characterized by the higher number of gene features in the samples. To evaluate the feature selection-based approach is proposed re-sampling random probability Swarm Optimization (RRP_SW). The RRP_SW model effectively minimizes the dimensionality of the data in specified time through minimal redundancy features in the datasets. The re-sampling-based model effectively increases the classification accuracy for the 20000 gene dataset. The RRP_SW perform the gene selection with the reduced gene minimal than 300 for the accuracy of classification. The RRP_SW model exhibits improved feature selection compared with the conventional feature selection model for the different benchmark datasets. The experimental analysis stated that proposed RRP_SW model exhibist the significant performance for the feature selection and classification of microarray datasets.

Hidden Markov Model for Cardholder Purchasing Pattern Prediction

Okoth Jeremiah Otieno, Michael Kimwele, Kennedy Ogada
Department of Computing, Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya

***Abstract*—This study utilizes the Hidden Markov Model to predict cardholder purchasing patterns by monitoring card transaction trends and profiling cardholders based on dominant transactional motivations across four merchant sectors, i.e., service centers, social joints, restaurants, and health facilities. The research addresses shortfalls with existing studies which often disregard credit, prepaid, and debit card transactions outside online transaction channels, primarily focusing only on credit card fraud detection. This research also addresses the challenges of existing prediction algorithms such as support vector machine, decision tree, and naïve Bayes classifiers. The research presents a three-phased Hidden Markov Model implementation starting with initialization, de-coding, and evaluation all executed through a Python script and further validated through a 2-fold cross-validation technique. The study uses an experimental design to systematically investigate cardholder transactional patterns, exposing training and validation data to varied initial and transition state probabilities to optimize prediction outcomes. The results are evaluated through three key metrics, i.e., accuracy, precision, and recall measures, achieving optimal performance of 100% for both accuracy and precision rates, with a 99% on recall rate, thereby outperforming existing predictive algorithms like support vector machine, decision tree, and Naïve Bayes classifiers. This study proves the Hidden Markov Model's effectiveness in dynamically modeling cardholder behaviors within merchant categories, offering a full understanding of the real motivations behind card transactions. The implication of this research encompasses enhancing merchant growth strategies by empowering card acquirers and issuers with a better approach to optimize their operations and marketing synergies based on a clear understanding of cardholder transactional patterns. Further, the research significantly contributes to consumer behavior analysis and predictive modeling within the card payments ecosystem.**

***Keywords*—Hidden Markov Model; cardholder transaction patterns; merchant categories; predictive algorithms**

I. INTRODUCTION

A. Introduction

This section details the scope of this research, an overview of the study in alignment with research objectives and the problem statement, brief definitions and literature on the use of the Hidden Markov Models, studies conducted at home and abroad, and finally, quick summaries on the importance of this research considering the recent works and gaps to be addressed.

B. Background

Cardholders show varied motivations prompting their transactional behavior, inclined to factors such as personal preferences, spending habits fashioned by income and financial status, demographics including age groups with separate spending patterns, and considerations of credit limits and debts. Transaction patterns also exhibit seasonal and temporal trends, with elevated spending levels during holidays and back-to-school periods, cognizant of prevailing economic conditions. These dynamics are essential to card payment service providers as they leverage them for optimizing cardholder spending and associated returns across different merchant categories and sectors.

The main objective of this research is to develop and evaluate a Hidden Markov model to predict the purchasing patterns of cardholders, aiming to address the failures of existing predictive algorithms such as support vector machines, Naïve Bayes classifier, and decision trees which have completely failed to offer an optimal prediction model due to their inherent challenges of lack of optimal generalizability. Further, these classical prediction algorithms have proved ineffective in several ways, for instance; the Naïve Bayes algorithm will usually not perform well when a 'train-test' approach is required since its assumption of feature independence is seldom true. Similarly, the Naïve Bayes algorithm is quite inefficient in handling unstructured datasets. On the other hand, decision trees are susceptible to overfitting, and they must be pruned to minimize the complexity parameter that controls the tree size and cut down on implying that slight variations in the training dataset may result in great differences in the trained hypothesis function, [12]. Lastly, support vector machines often exhibit long training time especially when dealing with large datasets and cannot stand alone in case of fault classification and when there is a necessity to distinguish between fault and no-fault while dealing with sparse data, [13]. In addition to addressing these challenges, this research presents a solution that tackles what most studies have completely overlooked. For instance, [32], [10], and [11] among others have revealed that predictive works only focus on online credit card user pattern prediction especially on fraud and associated risks, ignoring other cardholder behavioral patterns informed by intent, and other card types, and transaction channels such as debit, prepaid cards and card present usage channels that largely constitute volumes in card acceptance space.

C. Background and Literature Review

This research focuses on the Hidden Markov Model's predictive ability to profile cardholder purchasing patterns from merchant sectors and effectively assign a unique pattern based on dominant transactional trends. This research relies on the Hidden Markov Model' forward, backward, and expectation maximization algorithms to learn, update, and optimally predict the purchasing pattern of cardholders transacting at selected merchant categories representing the global card payment ecosystem. Besides online credit card transactions, this research scopes all card types across two main eligible card payment channels, i.e., card-present and e-commerce.

According to [1], the Hidden Markov Model is an augmentation of the Markov chain that describes probabilities associated with random variables, particularly observable events. The hidden Markov Model monitors both observed and hidden states. Further, [2] allude that Hidden Markov Model is useful in instances where data entails a sequence of observations, which are probabilistically independent of the internal state of a dynamical system.

Scholars have explored the predictive capabilities of the Hidden Markov Model in varied disciplines. These include predicting user behavior through data profiling, [2], driver behavior prediction based on environmental observation, [3], prediction of consumers' adoption behavior of products with water efficiency labeling, [4], enhancing credit card fraud detection, [5], risk assessment in cryptocurrency portfolios, [6], Motion Sequence Analysis, [7], spatial analysis of three-dimensional mineralization distribution, [8], and wavelet-based feature extraction [9] among other disciplines. This research explored the Hidden Markov Model's predictive ability by profiling cardholder purchasing patterns from merchant sectors.

In Kenya, scholars such as [31] have explored cardholder purchasing pattern prediction by focusing on anomaly detection, utilizing a hybrid approach that combines Hidden Markov Model with other machine learning algorithms. Further, [33] have used the Hidden Markov Model to explore the process mining techniques to detect fraud in banks, with particular focus on credit card behavior among other transactional patterns. From the two studies, it's evident that local scholars only focus on fraud detection on credit cards, while overlooking other patterns that inform transactional motivation, with a particular bias on product and channel being credit card and e-commerce respectively.

In the United States, scholars such as [26] explored cardholder purchasing patterns with a particular interest in online transaction fraud detection, utilizing the Hidden Markov Models. Similarly, in Southern Asia, scholars like [30] have explored the use of the Hidden Markov Model in predicting cardholder purchasing patterns, with a particular focus on credit card Fraud detection. A similar trend is reflected in West Africa, where [27] focused their research on credit and debit card fraud detection on Automated Teller machines through the Hidden Markov Model. Similarly, in Mexico, [11] utilized the Hidden Markov Model to explore cardholder purchasing patterns with a specific focus on fraud detection and identification in credit card transactions done via online channels.

In summary, the recent studies on the use of the Hidden Markov Model for cardholder purchasing pattern analysis suffer from an apparent bias in scope. Studies conducted within the Kenyan card payment and financial ecosystem, which are mirrored elsewhere, i.e., in the United States, West Africa, and Southern Asia fundamentally focus on fraud-based pattern prediction within the card-not-present payments ecosystem. Notably, these studies prioritize identifying fraudulent transactions only, overlooking the underlying cardholder intention behind genuine transactions, thus depicting an inadequate scope of intent. Additionally, the studies' exclusive focus on credit card transactions ignores other card types, i.e., debit and prepaid cards. These additional card types could potentially require tailored behavioral modeling that these studies completely ignore. Lastly, the studies exhibit utter channel bias, with the exploration of e-commerce-only transactions, ignoring the possibility of obtaining optimal pattern prediction results on other channels such as card-present point-of-sale terminals, till-integrated pin pads, and mobile point of sale that jointly present unique challenges and opportunities.

Against the backdrop of these notable inefficiencies, this research presents a novel approach of incorporating cardholder intent by monitoring dominant transactional patterns from merchant categories where cards are frequently run. This is done by profiling cardholders when they exhibit frequent appearances at specific merchant categories, associating their transactional preferences to the services offered at the said categories. Secondly, this study presents an expanded scope of all card types including debit and prepaid cards whose behavioral patterns are rarely explored by most recent studies. Lastly, this study embraces a multi-channel approach, scoping card-present and card-not present transaction channels to fully understand the effectiveness of Hidden Markov Model in cardholder purchasing pattern and transactional analysis. In summary, this study contributes significantly to the knowledge body by merging innovative statistical modeling capability of Hidden Markov Model with sector-specific transactional analysis to predict and comprehend cardholder purchasing patterns. Its procedural precision, novel approach to modeling cardholder purchasing pattern, and practical applications make it a remarkable addition to both academic world and the card payments industry.

II. Related Work

A. Introduction

This section offers an exhaustive review of related literature, emphasizing recent studies concerning the application of the Hidden Markov Model for predicting cardholder purchasing patterns. Additionally, it analyzes various existing prediction algorithms, including support vector machines, naïve Bayes classifiers, and decision trees, and specific works around these algorithms.

B. Existing Prediction Models

Besides Hidden Markov Model, this research explores the application of existing supervised machine learning algorithms for predicting cardholder purchasing patterns. These algorithms include support vector machines, Naive Bayes classifier, and decision trees. By assessing the performance of these algorithms, the research seeks to establish the most effective approach for predicting cardholder purchasing patterns.

According to study [16], support vector machines are a set of supervised and non-parametric statistical learning algorithms applied in regression, outlier detection, and classification. Support vector machines are used in problem classification in machine learning, aimed at generating the optimum decision edge that can separate n-dimensional space into classes for correct data point categorization in the future. The research in [17] used two steps to describe the working mechanism of the support vector machine. In their descriptions, the first step creates hyperplanes that separate the classes optimally. The second step chooses the right hyperplane with the optimum segregation from the nearest data points.

Recently, support vector machines have been used in cardholder purchasing pattern prediction. A typical instance is [18] who applied support vector machines in predicting e-commerce card customer-purchasing patterns and churn prevention. The scholars reviewed the main motivations for customers to make online purchases and reasons for attrition. The researchers acknowledged the possibility of predicting the customers' future inclinations using the necessary data acquired and the requisite analysis. The scholars used labeled datasets to train the support vector machines, giving them a reliable ability to predict and identify outcomes. However, the scholars noted that with the rise in e-commerce-based companies and clients, there was a need to automate the system to depict the results via a desktop application. To predict customer turnover in business-to-customer e-commerce, the scholars adopted a pronged model. The first approach employed SVM technology to foresee churn occurrences, while the second approach employed a hybrid strategy that blends collaborative, content-based, knowledge-based, and demo-graphic methodologies to derive customized retention approaches. The scholars concluded that computing the value of lost clients implied that as the count and rate of transactions grew, the risk of customer turnover considerably dropped. They further added that owners of e-commerce establishments should focus on the two factors of purchase volume and frequency, settle on a strategy for client retention, effectively limit customer attrition, and attain sustainable business development. Though the scholars achieved satisfactory outcomes with 77.36% in prediction accuracy from training the support vector machines, they acknowledged the long training time required by support vector machines especially when handling large datasets.

Similarly, [19] described a Bayesian classifier as a statistical technique of computing probability that a feature belongs to a class with the application of Bayes' theorem. The scholars added that Naive Bayes works with an assumption of in-dependence among predictors, can handle large datasets, and is equally easy to build with these two parts making up this algorithm: Naïve and Bayes. Researchers have recently explored the capabilities of Naïve Bayes, especially in card customer pattern predictions. For instance, [20] modeled binary classification of customers' online purchasing patterns using the Naïve Bayes classifier among other machine learning techniques. The paper proposed a method that utilized a subset of attributes based on the predictive ability and evaluated the duplication among selected traits, after which Naïve Bayes was applied. Using Naïve Bayes and other algorithms, the scholars used a hybrid approach that combined multiple classifiers to form an ensemble learner, to improve the classification outcomes. The experts used two datasets, namely Turkish bank, and German Credit datasets, through a feature selection stage. Though the study posted impressive results with predictive performance being 97.8% in precision, 88.2% in accuracy, and 89.1% in recall rate, the proposed approach still showed an overdependency on proper feature selection strategy, proving that Naïve Bayes assumption of feature independence makes it just unsuitable for real-world applications.

Correspondingly, the study in [22] defined a Decision tree as a machine-learning algorithm with nodes representing a predictor variable, the links between the nodes representing decision, and the leaf nodes representing outcomes or response variables. The scholars added that Decision trees are useful in splitting large datasets into smaller classes. Like any other machine-learning algorithm, decision trees have been used in card customer purchasing pattern prediction. One notable instance is that of [29] who used decision trees to predict cardholder purchasing patterns with a focus on fraud detection and prevention. The study proposed a theoretical credit card fraud detection and prevention model that used a phased structure from initiation to implementation. The scholar began with data collection, model filtering, and model selection for the implementation through the decision tree framework. The scholar used datasets from Kaggle that had several credit card transactions, with a complimentary binary field indicating the flag, whether a transaction is fraudulent or genuine. The datasets used equally included additional features such as trans-action amount, transaction time, transaction frequency, merchant information, geographical location, cardholder information, transaction type, and device type and in-formation. Secondly, the study filtered data and applied a decision tree classifier algorithm to perform credit fraud detection and prevention utilizing common features. The decision tree classifier algorithm started with the root node and then divided the data components into internal nodes to depict dataset features. The decision tree classifier algorithm mapped the features into decisions and the results. The decision tree classifier model posed a query and then divided this into sub-trees in line with corresponding responses. The model used by the scholar started its search at the top of the tree to locate the dataset classes. The model then circulated the branches based on the related and matched the base trait with the record attribute to arrive at the next node. The de-signed model worked on the user's device as a client-side implementation module to forecast the possibility of fraud in credit card transactions. Further, the generated forecasts would trigger real-time feedback to the user regarding the transaction risk level. The author evaluated the model through sensitivity and precision which delivered a performance level of 81.6%.

C. Hidden Markov Models

Recently, scholars have explored the capabilities of Hidden Markov Models in several predictive works. For instance, [25] explored the capabilities of Hidden Markov Models in predicting the behavior of e-commerce card customers to project store income. The study factored three items in the final predictive model, i.e., loyalty, vendor, and psychology which returned the probabilities utilized in the transition matrix of the hidden Markov model, giving three decision-states, i.e., 'Order completed', 'Order uncompleted, or 'No order'. The model outputs were interpreted by the Viterbi algorithm to approximate if the order has been completed successfully, followed by the evaluation of the predicted store income. The authors base-lined their model to the prediction presented by the Google Analytics tracking system. While considering the sub-models, the researchers simplified the vendor sub-model by taking into account only two vendors' market share without 100% domination, if 100% monopole is quite impossible in a real market. The Vendor sub-model returned the probability of a customer sticking to one vendor J, and not shifting to another vendor K. The researchers denoted this by [0,1], with 0 implying that a customer changed to vendor K, while leaving store J without fulfilling an order, whereas 1 means a customer stuck to store J, thus fulfilling the order. In considering psychology, the scholars alluded to the role of psychology as a behavior stimulant in situations when the customer gets influenced. The scholars mentioned societal pressure, price differences, mood aspect, the center of mass effect, and actual need among others as key factors that drive the psychological sub-model. The study picked the price aspect and center of mass effect, both representing the probability of a customer's resolve to make a purchase. The study viewed the loyalty aspect as the customers' positive feeling towards a store, and the decision to stick to that store no matter what happened. The study segmented loyalty into two components, namely, fidelity and commitment. The study evaluated the performance of the two models using the R2 technique and the criteria revealed the Hidden Markov Model's superiority as it outperformed the Google Analytics tracking system with Hidden Markov Model posting 0.95 R2 performance compared to Google Analytics Tracking System's 0.90 R2 Performance.

In another instance, [26] highlighted the performance of the Hidden Markov Model while predicting the behavior of credit card transactions on e-commerce channels. The study indicated that online card transactions are more convenient as customers do not have to visit the stores. However, the study also indicated that online card transactions are a prime target for fraud due to the nature of virtual requirements, i.e., card number, card verification value, and expiration date. The study used the Hidden Markov Model to detect fraud at the time of the transaction, applying blocking mechanisms that could bar any flagged transactions. The study also used behavior analysis to understand the spending patterns of the cardholders. The study revealed the capability of the Hidden Markov Model to acquire a high-level fraud analysis with a minimal false alarm ratio. The study's model was able to predict the behavior through three price ranges, i.e., low, medium, and high, depending on the loaded transaction amount. Further, the model-built clusters depend on the price ranges. Depending on the cardholder spending trend, the model figured out any variations noticed. The study settled on initial state probabilities based on the previous data which were structured to make a sequence of future forecasts. Through the stochastic process of the Hidden Markov model, the study built a predictive system that attained 80% accuracy and precision levels and established the Hidden Marko Model's suitability to model a fraud detection system in an online transaction system. Furthermore, the model constructed proved efficient in handling large amounts of transactions and giving results swiftly.

Further, [27] reviewed the detection of fraud in automated teller machine transactions using the Hidden Markov Model. The study used three model parameter estimation approaches considering the model and the observation sequence, i.e., pattern recognition problem which computed the probability of an observed sequence of a given Hidden Markov Model, labeled evaluation problem, and computing the sequence states responsible for the observation sequence, christened decoding problem, and finally, generating a sequence of observations, which was christened as learning problem. The scholar constructed an automated teller machine fraud detection model that baselined on cardholders' spending habits. This approach sampled three different cardholder spending profiles depending on the price range, which was categorized as Low, Medium, and High. The lowest price was set at zero, with a specific amount as medium price, and finally the card limit as the highest price range. The prediction was systematically done in two phases, i.e., the training phase which involved the initialization of Hidden Markov model parameters, followed by iterative estimations of forward and backward steps, and finally, the detection phase which involved the Hidden Markov Model verifying the fraudulent transactions using a clustering algorithm. The model developed had considerably better performance as measured through a sensitivity value of 85.5%, in comparison to the Gaussian mixture model which gave a sensitivity of 40%.

In another instance, [15] examined detecting electronic banking fraud on highly imbalanced data using hidden Markov models. The authors proposed a framework based on the Hidden Markov Model, modified density-based spatial clustering of applications with noise alongside synthetic minority over-sampling approach to detect fraud in a highly imbalanced electronic banking dataset, the bulk of which involved credit card transaction data. The authors considered some transactional attributes while building the model, i.e., transaction amount, transaction frequency, and transaction types. The scholars utilized datasets from the Kaggle public repository to conduct the research. The dataset had a variety of parameters around the transaction attributes, for example, transfer, cashout, cash-in, debit, and payments, with a general categorization of genuine transactions and fraudulent transactions. The scholars categorized the transaction amounts as either low, initialized by l= (0,100), medium, initialized by m= (100,500), and high, initialized by h= (500, Transaction Limit) values. The study also regarded the frequency of transaction occurrence as either low, indicated by transactions happening less than five times a month, intermediate, depicted by transactions happening between 5 and 10 times a month, and high, signaled by transactions happening at least 10 times a month. The authors regarded various transaction types as internal states while treating transaction amounts and frequency as observation symbols. The study performed four sets of simulations in two stages using Python and compared the performance. The study produced fairly good results, with performance recorded as follows, precision rate was 95%, recall rate was 0.97, and accuracy of 95%.

In a separate study, [30] explored the application of the hidden Markov model in the study of fraud detection systems where they acknowledged the most recent events such as the Coronavirus pandemic that compelled the world to systematic adoption of contactless payments, especially credit card payments. The research equally acknowledged that with the increasing adoption of credit card payments, fraudulent transactions are increasing, with fraudsters inventing new techniques to keep defrauding issuers and acquirers. The scholars modeled a system that checks credit card transactions online, profiling cardholders based on whether they are authorized or not. When an authorized cardholder does a transaction, their profile is matched on the backend database and if the match is successful, the transaction is processed success-fully, notifying the user of success. Equally, if an unauthorized card performed a transaction and their spending profile failed to match what exists in the back.

Recently, scholars have explored the use of Hidden Markov Models in customer purchasing pattern predictions but with numerous gaps. For instance, [21] affirmed that most scholars get unreliable results because they use relatively minimal datasets that deprive the research of comprehensibility of the results for testing and resilience. Moreover, the study alluded that minimal preprocessing could lead to un-balanced data which increases the likelihood of bias in the model creation. Norah also confirmed that many researchers exploring the capabilities of the Hidden Markov Model fail to attain reliable results because of the limited number of iterations which makes it impossible to attain optimal outcomes. A further review of recent works on hidden Markov models revealed notable gaps especially when it comes to the type of datasets used. For instance, a study by [23] revealed that utilizing extremely historical data may not give the correct prediction especially where parameters such as perception and customer behavior change over time. In addition to this, customer pattern prediction hasn't been reliably done because most scholars overlook the demographics and assume that the personalities and attributes of customers are universal, ignoring age, and geographical location among others. The research in [23] also confirmed that most research works suffer from overfitting, where training data gives excellent results while real data speaks otherwise. Correspondingly, the study in [24] confirmed that most research works get unreliable results because of the process of data collection which doesn't give assurance of trust and accuracy. The scholars acknowledged the need to improve the data collection process to ascertain more precise and comprehensive data that plays a major role in improving model efficiency. In addition, the study in [28] explored the application of the hidden Markov model for credit card fraud detection. However, their work had notable gaps, especially in the lack of clarity of the performance metrics. With claims of the model achieving high accuracy and optimal processing speed, the scholars did not attempt to quantify the performance metrics in absolute figures, making it difficult to tell the actual performance of the model. Like other scholars reviewed in this research, the model only focused on credit card fraud detection for online transactions, an area of saturation in cardholder purchasing pattern prediction, ignoring other behavioral aspects related to cardholder purchasing patterns.

III. Methodology

A. Introduction

This section highlights the data acquisition and preprocessing, design methodology, materials and methods used, and ethical considerations for this research.

B. Data Acquisition and Pre-processing

This Study explores the application of the Hidden Markov Model to predict cardholder purchasing patterns, with an interest in sector-based pattern analysis. The research applied random sampling to select card transactions relating to specific sectors. Random sampling was useful as it allowed unbiased data collection, qualifying our re-search to arrive at fair and unbiased conclusions. Additionally, this study considered random sampling due to its efficient generalizability of research findings, and proper statistical inferencing. The data was extracted through structured queries written in HiveQL, using the Hadoop Ambari workbench. Only selected columns were queried from the transaction tables then upon query execution, the data was exported to a .csv file for ease of manipulation. The data contained 4,500 records with the following fields: Card Number, which remained masked due to data privacy policy, Source, Merchant Name, Transaction date, Merchant Category Code (MCC), and Sector. The sector field was the most crucial as it dictated the initial state probabilities for each cardholder. The four sectors included restaurants, social joints, health facilities, and service centers. The sample dataset was captured in Table I below.

TABLE I. SAMPLE WORKING DATA

Card Number	Merchant Name	Date	Sector
****6840	Merchant 1	Apr-21	Service Centers
****0010	Merchant 2	Apr-21	Restaurants
****2540	Merchant 3	Apr-21	Social Joints
****9110	Merchant 4	Apr-21	Service Centers
****1080	Merchant 5	Apr-21	Restaurants
****0200	Merchant 6	Apr-21	Social Joints

The data used in this research was cleaned to remove noises, unnecessary columns, and outliers through R studio and Python's Jupyter Notebook, all packages within the Anaconda ecosystem. For ease of manipulation, this research applied feature engineering to create binary variables that expressly indicate specific merchant categories and related sectors. Based on the specific merchant categories, a set of states was defined to represent the intent of cardholders as they visit the merchant stores to do transactions.

C. Design Methodology, Methods and Tools

This research used experimental design methodology to ratify the suitability of the Hidden Markov model in predicting cardholder purchasing patterns. The approach employed the Hidden Markov Model's computational modeling for optimal prediction. The study is baselined on the following connotations and assumptions of the Hidden Markov Model highlighted by [1], majorly on the shorthand equation:

$$\lambda = (A, B, \pi) \tag{1}$$

1) General notations

- N as the number of states in the Hidden Markov Model.
- M as the number of observation symbols.
- T as the length of the observation sequence.

- π as the initial state probabilities (N×1 vector).
- A as the transition matrix (N×N matrix).
- B as the emission matrix (N×M matrix).
- α as the forward variable (T×N matrix).
- β as the backward variable (T×N matrix).
- γ as the state occupation probability (T×N matrix).

2) Forward algorithm: The forward algorithm calculates the probability of observing a sequence of symbols given the Hidden Markov Model.

$$\alpha_t(j) = \sum_{i=1}^{N}\left([\alpha_{t-1}(i)\, A_{ij}] \times B_j O_t\right) \tag{2}$$

3) Backward algorithm: The backward algorithm calculates the probability of observing the rest of the sequence given the current state.

$$\beta_t(i) = \sum_{j=1}^{N}\left(A_{ij} \times B_j \text{ x } B_j(O_{t+1}) \times B_{t+1}(j)\right) \tag{3}$$

4) Expectation step: The Expectation step computes the probability of being in a particular state at a particular time given the observed sequence.

$$\gamma_t(i) = \frac{\alpha_t(i) \times \beta_t(i)}{\sum_{j=1}^{N} \alpha_t(j) \times \beta_t(j)} \tag{4}$$

5) Maximization step: This step updates the model parameters (π, A, B) using the γ values obtained in the e-step.

Update Initial Probabilities: $\pi_i^{New} \gamma_i(i)$ (5)

Update Transition Matrix:

$$\mathrm{A}_{ij}^{New} = \frac{\sum_{t=1}^{T-1} \gamma_t(i) \times A_{ij} \times B_j(O_{t+1}) \times B_{t+1}(j)}{\sum_{t=1}^{T-1} \times \sum_{t=1}^{T-1} \gamma_t(i) \times A_{ij} \times B_j(O_{t+1}) \times B_{t+1}(j)} \tag{6}$$

Update Emission Matrix:

$$B_j(k)^{New} = \frac{\sum_{t=1}^{T} \gamma_t(j) \; if \, o_t = k}{\sum_{t=1}^{T} \gamma_t(j)} \tag{7}$$

6) Convergenece: The EM algorithm iteratively performs E-step and M-step until convergence. Convergence is determined by assessing if the change in model parameters is below a certain threshold. The study in [14] described the three fundamental problems that Hidden Markov Model seeks to address: a) Evaluation Problem: This always requires summing over all possible hidden state variables. b) Decoding Problem: Prompts us to compute the best sequence of hidden states, and c) Learning Problem or Optimization Problem: Evaluate an observation sequence (O1, O2…On and the Hidden Markov Model λ = (A, B, π) that optimizes the probability of O.

Further, this study followed the below approaches to fulfill experimental design methodology and tailor the desired output:

a) Data partitioning: The dataset was partitioned into two folds, with fold 1 acting as training data while fold 2 as validation data. The training dataset was used to construct the Hidden Markov Model, while the validation dataset was used to perform hyperparameter tuning. The two partitions were as per Table II below:

TABLE II. DATA PARTITIONS

Partition	No of Records
Fold 1	2,500
Fold 2	2,000

b) Benchmark model: The study applied two separate attempts to train the model and the first attempt's outcome was used as the baseline model against which the subsequent results were evaluated, c) Performance Comparison: The performance of the Hidden Markov Model for future prediction of cardholder purchasing was compared against the baseline model. Further, the performance of the resultant model was compared with models built on support vector machines, decision trees, and Naïve Bayes classifier. Performance Metrics like precision, accuracy, and recall were essential for this comparison, and lastly, d) Sensitivity Analysis: This research varied the initial state probabilities to assess the performance of the resultant model under different circumstances and datasets.

In summary, this research used the below simple steps to fulfill the implementation process:

- Initialization: Defined the initial state probabilities (π) based on the cleaned dataset distribution.
- Transition and Emission Probabilities: Matrices (A and B) representing probabilities of state transitions and emissions were randomly initialized.
- Observation Sequence: Random sequence of observations was generated to simulate card transactions across sectors.
- Model Training: This study implemented Expectation Maximization algorithm to adjust the parameters (π, A, B) iteratively over 100 iterations until convergence was attained.
- Model Validation: This study used a 2-fold cross-validation approach to validate the model performance, comparing against other algorithms such as Support Vector Machines, Naïve Bayes, and Decision Trees for accuracy, precision, and recall rate.

D. Ethical Considerations

This research scoped the following ethical considerations during its formal execution:

1) Data privacy and confidentiality: - Since this research focused on sensitive credit, debit and prepaid card transactions data, all sensitive details were handled with utmost privacy and confidentiality. Card numbers were first tokenized then subsequent tokens masked to curtail any compromise. Furthermore, this research did not expose the card verification values and the expiration dates in congruence with the non-disclosure agreement signed with the data provider.

2) Informed consent: - Customers whose details were used in this research received consent notification via short message service, given options to opt out if not comfortable with the process, assuring them of the security and confidentiality of their data. Customers that replied with an 'opt-out' had their details expunged from the dataset.

3) Fairness and equity: - This research treated all sampled participants with utmost fairness regardless of their demographic characteristics. All sampled participants had an equal opportunity to contribute to the findings of this study.

4) Regulatory compliance: - This research adhered to the necessary regulations governing collection, storage, and utilization of card data in alignment with the local regulator and payment card industry data security standards.

IV. Hidden Amrkov Model for Cardholder Purchasing Pattern Prediction

A. *Introduction*

This section highlights the step-by-step model construction, required parameters, full implementation, and architecture in context.

B. *Background*

Credit, debit and prepaid cardholders usually visit merchant stores through different channels to fulfil their purchasing needs by paying via card in exchange. Different channels enable merchants to accept card payments, i.e., card present channels where customers must physically visit the merchant stores to run their cards on a point-of-sale terminal issued by an acquiring bank. Additionally, merchants can also do transactions through card not present channel (electronic commerce) where they do not have to be physically present at a merchant store but can shop over the internet and make arrangements to receive the goods or services upon payment. Several factors are key determinants and motivations to which store a cardholder would visit, and these factors include the following: income level, personal preference, location and proximity, store loyalty programs, product selection and quality, seasonality, market trends and economic conditions, online shopping habits among others.

This study focused on cardholder purchasing pattern from a standpoint of sectors frequently visited for transaction as these would inform the behavioral patterns mentioned earlier. In simple, this study treated key transactional motivations as the main pointers to a definite cardholder purchasing pattern. In a normal card payments eco-system, cardholders can have various motivations for doing transactions, with each motive informed by an underlying need, which could be either be genuine or malicious, intent to do fraud and other genuine reasons.

Further, the study reviewed all card types and categorized the purchasing patterns by the following sectors: Service Centers (S), Social Joints (J), Health(H) and Restau-rants (R). Each sector was marked with an observation sequence treated as customer motivation, being the desired purchasing patterns. The intentions were mapped to each sector as per Table III below:

TABLE III. Observation State Symbols

Initial State Symbols	Sector Represented	Observable States	Symbol
H	Health	Auto service	A
J	Social Joints	Medication	M
R	Restaurants	Eating	D
S	Service Centers	Entertainment	H

At any point in time, a cardholder running their card at a given sector outlet automatically qualifies for an observation state associated with that sector. A card that is run on a platform manned by a service center(S) is deemed to adopt a pattern that leans towards auto service and is assigned state (A), a card that is run at a restaurant automatically exhibits a pattern relating to eating (E) and is assigned state (E), while cards that are run at social joints (J) and health care (H) are associated with patterns entertainment (H) and medication (M) respectively. This mapping is shown in Fig. 1 below:

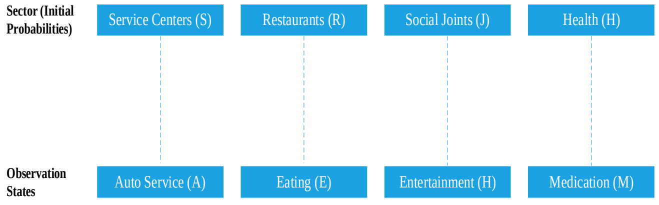

Fig. 1. Observation state mappings.

In the context of our study, observation states A, E, H and M are always hidden, and these are the pointers to unravelling the intention or purchasing patterns of cardholders of cardholders as they go about doing transactions at different outlets.

C. *Purchasing Pattern Prediction*

In this study, we implemented the cardholder purchasing pattern prediction using a python script that worked through three phases, i.e., initialization phase, decoding phase, and evaluation phase.

The first phase of initialization involved defining the initial state probabilities in alignment with Fig. 1 above to be in a particular state, with states being retained as S, J, R and H. The initial state probabilities were computed from the transactional distribution on the dataset. Considering the distribution of each state on the dataset, the initial state probabilities were mapped as follows: S, J, R, H with each corresponding to the items in the matrix π = [0.1148, 0.292, 0.4, 0.5532]. Secondly, the transition probability between states were randomized by the following 4 by 4 matrices to represent the transition between one state to the next, denoted by A:

$$A = \begin{matrix} 0.1 & 0.3 & 0.5 & 0.1 \\ 0.2 & 0.3 & 0.1 & 0.4 \\ 0.6 & 0.1 & 0.1 & 0.2 \\ 0.1 & .03 & 0.3 & 0.3 \end{matrix}$$

Thirdly, emission probabilities were also randomized using the below 4 by 4 matrices to depict the possibilities of emissions from each state, denoted by B as below:

$$B = \begin{matrix} 0.2 & 0.3 & 0.4 & 0.1 \\ 0.4 & 0.2 & 0.1 & 0.3 \\ 0.3 & 0.3 & 0.2 & 0.2 \\ 0.1 & .02 & 0.3 & 0.4 \end{matrix}$$

Next, the observation sequence was randomly generated as ([0, 1, 2, 3, 2, 1]) to represent the sequence of observed emissions. Lastly, the expectation maximization function algorithm was defined, initializing parameters randomly and performing iterative updates to obtain optimal values. The maximum iteration count was set at 100.

The second phase, i.e., decoding involved parameter initialization of the Hidden Markov Model problem function, λ = (A, B, π), where λ corresponded to the probability of being in each state at each time step given all the observations, A corresponded to transition matrix, B corresponded to emission matrix, and finally π corresponded to initial state probabilities. This was followed by a forward algorithm which involved systematic computation of the probability of being in each state at each time step provided the observation up to that step. Further, a backward algorithm was performed to compute the probability of observing future emissions given the present state. Both forward pass and backward pass were sequentially performed by a for loop iteration in the python script, with forward pass denoted by alpha (α) and backward pass denoted by beta (β). After optimizing alpha (α) and beta (β), the probability of being in each state at each time step given all the observations was computed, denoted by gamma (γ). After computing the λ, the joint probability of being in two states at consecutive time steps, denoted by (xi) was computed to close out the second phase.

The third phase, i.e., evaluation involved updating the parameters, convergence, and the final output. On updating the parameters, the model utilized the calculated gamma and (xi) to update the parameters of A, B and π of the Hidden Markov Model, through adjusting the initial state probabilities, transition probabilities and emission probabilities to better fit the observed sequence. At convergence, the model iterated 100 times, refining the parameters at each iteration until convergence. On running the expectation maximization algorithm, optimal transition and emission matrices were obtained.

In summary, this study followed the below procedure to adequately execute and update the model hyperparameters in line with the intended scientific contributions to the knowledge body:

- Initialization Update: we initialized the parameters (π, A, B) based on data distribution and postulates. In this research, π represents the initial state probabilities, with A and B initialized to reflect possible state transitions and emission probabilities.

- Iteration and Convergence: In this research, the expectation-maximization algorithm updates π, A, and B iteratively to optimize the likelihood of the observed sequence. This iterative process progresses until the convergence of parameters.

- Parameter Adjustment: At every iteration, π, A, and B are modified based on γ, and ξ calculated in the expectation step and maximization step. This modification polishes the model's estimates to fit the observed sequence of transactions better.

Essentially, the model trained Hidden Markov model on a given sequence of observations using expectation maximization algorithm by adjusting the model parameters to optimize the likelihood of observed data.

This study leverages the capabilities of the Hidden Markov Model to predict the purchasing pattern of cardholders with the following pillars that make it stand out within the scientific community:

- Excellent behavioral analysis and modeling: This research offers precise modeling and analysis of cardholder transaction patterns through a sector and motive-driven approach. This is achieved by iterative refinement of π, A, and B to predict future patterns based on past transactional behavior.

- Sector-Specific Hidden Markov Model: Unlike traditional hidden Markov models used for sequenced prediction modeling, this research presents a unique application of Hidden Markov Model to predict cardholder purchasing patterns by profiling cardholders based on sectors such as health, social joints, restaurants, and service centers, representing primary transaction motivations.

- Observation State Mapping: This study presents a distinctive mapping between the observed transactions at different sector outlets, for instance, running a card at a restaurant, and hidden states depicting the motivation behind the purchase such as eating. This level of mapping explains the reasons behind card usage.

- Applicability in the card payments industry: This research provides great insights into card transactional data, highlighting the dynamics of consumer spending guided by intent. This contributes to comprehending card payment dynamics. With this knowledge, card acquirers and issuers can perform personalized marketing on customers whose purchasing patterns have been identified over time. The model was implemented in three phases as per the sequence diagrams below in Fig. 2.

Further, the model was mapped to show full process flows, implemented in a full architecture diagram as depicted by Fig. 3.

In summary, this study focused on a hidden Markov Model based on a 2-fold cross validation with the first fold subjected to three sets of training, shifting, and changing the initial state probabilities to alter the status and monitor the performance under different circumstances. Further, the study involved the validation of the model using a second fold which was subjected to similar circumstance to perfect the model performance. The model borrowed from HMM's expectation maximization algorithm due to its inherent ability to offer interpretability owing to its explicit modelling of hidden states.

The model was trained using the first fold in Table II, using randomized initial state probabilities while utilizing the cardholder distribution from the dataset as an initial observation array. The dataset was subjected to two training attempts with varied and randomly assigned initial state probabilities. The model estimated the optimal transition matrices per attempt and recorded the results alongside optimal observation sequences. The observation sequences were normalized through their new probability distribution, allowing the model to compute and estimate the new observation sequences. It was evident that with different initial state probabilities, the model proved adaptable, giving comparable results despite the frequent alteration of the initial state distributions through various iterations.

To confirm the consistency of our model, we changed the dataset and observed the patterns and the new predictions. The latest dataset was run through two attempts initial state probabilities. The results recorded had striking similarities with varied to the previous results obtained during the model training stage, with noticeable similarities across different parameters. For each set of optimized transition probabilities, we assessed model performance using a confusion matrix to obtain accuracy, computed the precision, and recall metrics. Both training and validation datasets exhibited outstanding performance, achieving 100% accuracy and precision, with a recall rate of 99%.

Our model proved efficient when subjected to training and test data under different circumstances, with varied initial state probabilities. In all the two attempts for both training and validation, the results posted an accuracy of 100% when evaluated through a confusing matrix, a recall rate of 99%, and a precision of 100%. Assertively, the distribution across the results remained diverse, with a converging efficiency.

Further, we ran our datasets through models built from support vector machines, Naïve Bayes and Decision trees with results recorded in Table VI.

TABLE VI. NAÏVE BAYES, SUPPORT VECTOR MACHINES AND DECISION TREES

Naïve Bayes
Optimal Results:
Predicted, Health, Actual, Social Joints
Decision Trees
Number of transactions: 600, Predicted Sector: S
Number of transactions: 300, Predicted Sector: J
Number of transactions: 1500, Predicted Sector: R
Support Vector Machines
Optimal transaction volumes of 600, Predicted sector: S
Optimal transaction volumes of 1200, Predicted sector: R
Optimal transaction volumes of 500, Predicted sector: S
Optimal transaction volumes of 700, Predicted sector: S

The results from Table VI were evaluated through the metrics and efficiency measures recorded in Table VII below:

TABLE VII. PERFORMANCE ANALYSIS OF NAÏVE BAYES, SUPPORT VECTOR MACHINES AND DECISION

Algorithm	Accuracy	Precision	Recall
Support Vector Machines	80%	80%	80%
Naïve Bayes	75%	75%	75%
Decision Tree	80%	80%	80%

To predict optimal patterns with Support Vector Machines, we noticed that support vector machines encountered limitations in decoding sequential data when predicting cardholder purchasing patterns due to their intrinsic characteristics and design. Though support vector machines recorded a consistently fair performance across all three metrics, the model struggled with encoding progressive dependencies and capturing the sequential nature of the data, giving lower performance ratings in comparison to the Hidden Markov Model. Further, we noticed that decision trees equally posted fair results across the three metrics. However, the performance was lower than the Hidden Markov Model due to Decision trees' tendency to make decisions based on static features at each node, deficiently capturing the dynamic attributes intrinsic in sequential data. Finally, Naive Bayes classifiers equally posted commendable performance across the three metrics, though with its fair share of shortfalls and sub-optimal efficiency compared to the Hidden Markov Model. This was due to the Naïve Bayes classifier's assumption that all features are independent given the class label that did not hold for our dataset, where the order and interdependencies between observations were crucial. In the context of cardholder purchasing patterns, the dataset contained temporal dependencies and correlations between transactions, which Naive Bayes failed to capture effectively.

C. Comparison with Related Works

We reviewed the performance of our model against similar studies conducted recently and the outcome recorded in Table VIII below:

TABLE VIII. COMPARISON WITH EARLIER STUDIES AND EXISTING ALGORITHMS

Author	Algorithm	Accuracy	Precision	Recall
Okoth et al. (2024)	Hidden Markov Model	100%	100%	99%
[25]	Hidden Markov Model	95%	95%	95%
[26]	Hidden Markov Model	80%	80%	80%
[27]	Hidden Markov Model	85.5%	85.5%	85.5%
[30]	Hidden Markov Model	85%	85%	82%
[10]	Hidden Markov Model	95%	95%	97%
[18]	Support Vector Machine	77.36%	77.36%	77.4%
[20]	Naïve Bayes Classifier	88.2%	87.8%	89.1%
[29]	Decision Tree Classifier	81.6%	81.6%	82%

From Table VIII, it was evident that our study shared similarities with other works in the following aspects: Across all the studies, hidden Markov models posted relatively higher accuracy levels ranging from 80% to 100% with [26] recording the least accuracy of 80% while our model recorded the optimal accuracy of 100%. Equally, the studies recorded consistent precision levels of between 80%-100%, proving the suitability of hidden Markov models in such datasets. Likewise, the recall rates were relatively high, with a consistent record of between 80%-99%, proving that the models created in different studies effectively captured the relevant data points across related datasets. Overall, the above similarities strongly suggested that the Hidden Markov Model implemented by various authors was generally robust and performed well across related datasets, attaining commendable accuracy, precision, and recall levels. Similarly, the performance of our model was also compared with the performance of the existing algorithms, against our dataset and Hidden Markov Model posted optimal results of 100% in accuracy and precision, and an outstanding recall rate of 99% while support vector machines and Decision trees posted 80% in accuracy and precision with a recall rate of 80% respectively. On the other hand, Naïve Bayes posted a performance of 75% in both accuracy and precision, with a 75% recall rate on our dataset.

In summary, our model proved to be unique in three aspects, i.e., it achieved perfect performance metrics, with accuracy, precision, and recall rates of 100%, 100%, and 99% respectively, indicating flawless performance in prediction and data classification. Whilst the other authors also attained commendable performance, their metrics varied slightly, with accuracies ranging from 80% to 95.4%, precisions from 80% to 95.4%, and recalls from 80% to 97%. This was proof that our model outperformed others in terms of these metrics. Additionally, our model stood out for its comprehensive consideration of all card types, i.e., credit, debit, and prepaid cards run on all available card acceptance platforms, i.e., card present point of sale terminals and card not present e-commerce, considering that other authors only scoped credit card transactions on e-commerce, restricting their works to the only card, not present credit card transactions. Additionally, most of the works considered in this study revealed that most researchers reviewed cardholder purchasing patterns with an assumption that card transactions can only happen online via credit card, or on automated teller machines via debit cards. Conversely, our study revealed that in a card ecosystem, there are different card acceptance platforms across card present (physical point of sale terminals and automated teller machines) and card not present (Online) channels that can accept payments from credit, debit, and prepaid cards. Thirdly, whereas most authors only considered credit card fraud as a dominant pattern for cardholder purchase intentions, our study scoped cardholder behavior at the transaction level, considering the dynamic shift between one sector to the other, covering the day-to-day behavioral patterns that might inform a card transaction. Using the patterns identified from the inter-sectoral transactions, card-holders were profiled based on transactional frequency around a given sector and critical decisions made at the business, and/or sector level. Considering these facts, our model proved versatile and inclusive as it scoped a wide range of cards and platforms and proved beneficial in multi-behavioral pattern prediction.

D. Research Significance and Key Pointers

This research is quite significant because it achieved excellent performance in predicting cardholder purchasing patterns using the Hidden Markov Model. The model attained a precision and accuracy measure of 100%, signifying the occurrence of true positives positive predictions, and all classifications were precise. However, the recall rate was 99%, indicating that 1% of actual positive instances might have been missed by the model. Moreover, the Hidden Markov Model outperformed the Support Vector Machines, Decision Trees, and Naive Bayes classifiers. This shows that the Hidden Markov Model's ability to capture sequential dependencies within purchasing behavior led to greater predictive capabilities in comparison to the existing prediction algorithms.

This study looked to understand cardholder purchasing patterns through the application of hidden Markov model, adopting a dynamic approach of identifying most dominant cardholder intentions through transactional transitions across merchant sectors. Through these shifts, merchants and acquirers can tailor their propositions based on established cardholder preferences as informed by their purchasing patterns, enhancing cardholder retention levels and loyalty. Overall, the research showcased a detailed framework that brings together machine learning modelling techniques and practical applications in cardholder purchasing pattern analysis in line with the need for strategy optimization in this space.

VI. Conclusion and Future Work

This research has proved the hidden Markov model's ability to dynamically model cardholder purchasing pattern prediction. The paper has also reviewed the existing algorithms for predicting cardholder purchasing patterns, in particular, support vector machines, Naïve Bayes Classifier and Decision Tree Classifier. By applying expectation maximization, this paper has proved beyond reasonable doubt that hidden Markov model achieves best performance through three key evaluation metrics, i.e., accuracy measure, precision and recall rates. Further, this study has demystified the myth of cardholder purchasing pattern being just about e-commerce credit card fraud detection but a holistic card acceptance ecosystem question, covering all eligible card types, i.e., credit, debit, and prepaid cards transactions on both card present and card not present channels. Additionally, this paper has presented four key pointers contributing to optimal prediction performance, i.e., sector specific modelling through hidden Markov model, distinctive observation state mapping, cardholder profile-based prediction and effective parameter optimization. These key pointers collectively contributed to the accuracy and precision measure of 100%, with a recall rate of 99%, outperforming all other existing models and algorithms in scope.

While our model posted optimal performance across the three metrics, one of the future recommendations would be to slightly normalize the performance for improved practicality by introducing controlled levels of noise into the model, achievable by adding random fluctuations to the emission probabilities, mirroring real-world uncertainties, and making the model more robust to variations in the data.

Comparative Analysis of Naïve Bayes Classifier, Support Vector Machine and Decision Tree in Rainfall Classification Using Confusion Matrix

Elvira Vidya Berliana, Mardhani Riasetiawan*
Department of Computer Science and Electronics, Universitas Gadjah Mada, Yogyakarta, Indonesia

***Abstract*—The climate in Indonesia is sometimes unstable to this day. This unstable climate change will cause difficulties in predicting rainfall conditions. With unstable climate change, an algorithm is needed that helps the public predict rainfall conditions using rainfall, temperature and humidity parameters. The research process uses daily climate data from the Indonesia Climatology Agency with time span 2018 – 2023. The classification system using the Naïve Bayes Classifier (NBC) algorithm is less able to capture complexity and complex feature interactions with an accuracy of 97%-98%, Support Vector Machine (SVM) has an accuracy of 92%-94% and fewer prediction errors than NBC and Decision Tree which experienced overfitting especially when testing sets with 50% data with an accuracy of 99%-100%. Even though the Decision Tree shows the best performance, there is still a risk of overfitting so, SVM is a stable choice in this research.**

Keywords*—Naïve Bayes Classifier (NBC); Support Vector Machine (SVM); decision tree; confusion matrix; classification; rainfall; temperature; humidity

I. Introduction

The climate in Indonesia is sometimes unstable now. This unstable climate change will cause difficulties when predicting rainfall conditions. According to the Indonesian Meteorology, Climatology and Geophysics Agency (BMKG), the average air temperature in July in Indonesia for the period 1981 – 2010 was 26.39°C. In 2020, the average air temperature in February was 27.22°C so the anomalous increase in average air temperature was 0.83°C [1]. Rainfall predictions are very important because good rainfall predictions will avoid many disasters and accidents. Unpredictable rainfall can cause crop damage, major floods and droughts, ultimately exploiting animal, plant and human life [2].

In agriculture, accurate rainfall predictions will help farmers to plan their agricultural activities. Until now, farmers still carry out planting activities based on their intuition [3]. Machine learning and deep learning algorithms have emerged as powerful tools for analyzing vast amounts of data from various sources, including satellite imagery and atmospheric conditions, to enhance rainfall prediction accuracy [4]. The agriculture sector benefits from more accurate rainfall forecast, as they help mitigate the effects of abnormal precipitation on crop cultivation and influence decisions regarding planting, harvesting, and agricultural inputs [5].

Machine learning tries to process observational data and then gets results, namely weather patterns, which in turn can help analyze rainfall which often changes so that it can make more accurate rainfall predictions [6]. Several studies on machine learning for optimal classification have been carried out. Research by Fallo (2021) [7] utilized the linear kernel SVM method, NBC, and Ordinal Logistic Regression with SVM accuracy results of 67.99%, NBC with accuracy results of 69.63%, and Ordinal Logistic Regression with accuracy results of 69.63 %. Azmi et al. (2021) [8] achieved 96% accuracy using NBC for rainfall classification in Banyuwangi, Indonesia. Husain H., Dawoodi, and Patil (2023) [9] found SVM to be the best model for rainfall prediction in North Maharashtra, India, with 93% accuracy. Sivanantham et al. (2023) [10] compared multiple classification algorithms for rainfall prediction in Indian States, including Logistic Regression, Decision Tree, Random Forest, and SVM. These studies demonstrate the potential of machine learning techniques in improving rainfall classification and prediction accuracy.

The Climatology Station Indonesian Meteorology, Climatology and Geophysics Agency has historical weather data but the data is still small in quantity and there is data that is less accurate because data takers still depend on historical data so there are still errors and incomplete data, and this causes rainfall predictions to be less accurate. Therefore, the researcher is interested in developing previous research related to rainfall classification using the Naïve Bayes Classifier (NBC), Support Vector Machine (SVM), Decision Tree algorithm.

This paper aims to provide a comprehensive analysis of three machine learning algorithms, Naïve Bayes Classifier (NBC), Support Vector Machine (SVM), and Decision Tree, in the context of rainfall classification. The study will evaluate the performance of these algorithms using confusion matrix to determine and evaluate their accuracy and reliability.

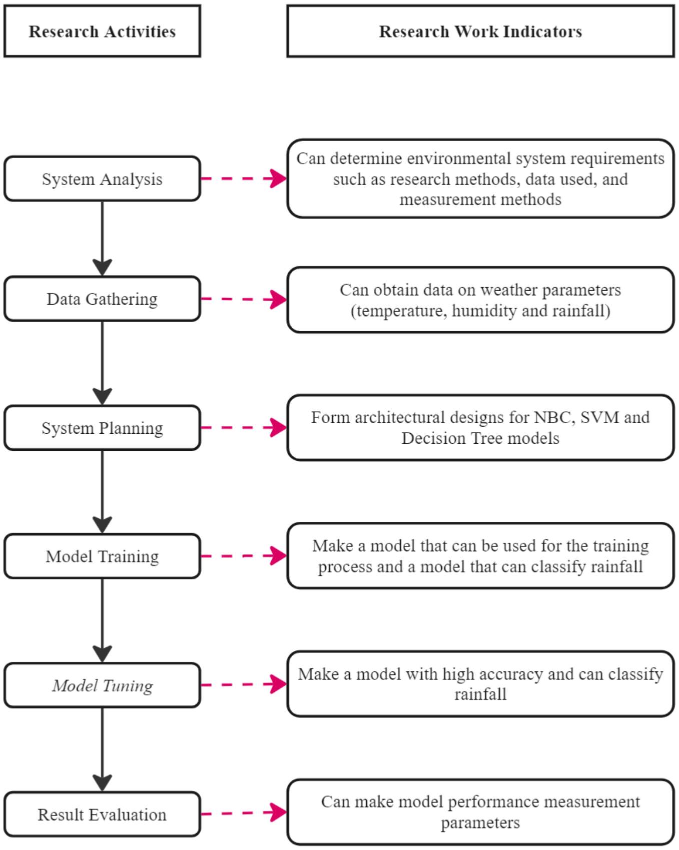
II. Research Methods

A. Problem Analysis

The system design for this research aims to predict rainfall for agricultural activities using the Naïve Bayes Classifier (NBC), Support Vector Machine (SVM), and Decision Tree methods and data taken from the DI Yogyakarta Climatology Station (dataonline.bmkg.go.id) to create and train a model to make accurate predictions. The research process used daily climate data from Indonesia Climatology Agency (BMKG) with time span 2018 – 2023 by using three parameters: rainfall, temperature and humidity.

B. Research Step

In conducting this research, several stages are required to achieve the research objectives. Starting with determining environmental system requirements such as research methods, data used, and measurement methods. After knowing the system analysis, you can obtain weather parameter data, then form a Naïve Bayes Classifier (NBC), Support Vector Machine (SVM), Decision Tree model architecture. The desired model parameters are high accuracy and produce model performance measurement parameters in accordance with Fig. 1.

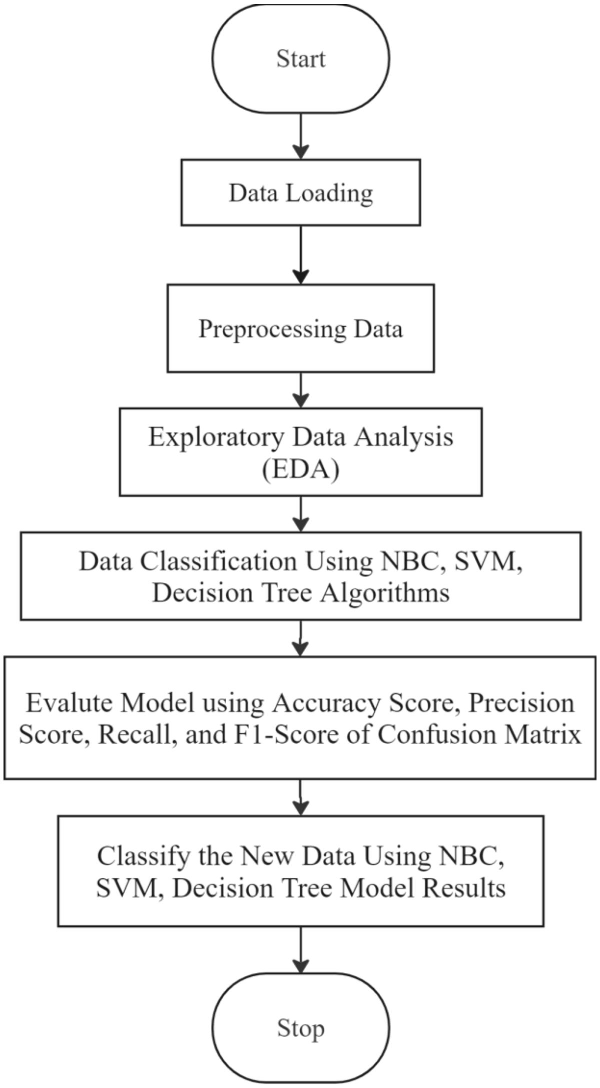


Research Activities
Research Work Indicators
System Analysis
Can determine environmental system requirements such as research methods, data used, and measurement methods
Data Gathering
Can obtain data on weather parameters (temperature, humidity and rainfall)
System Planning
Form architectural designs for NBC, SVM and Decision Tree models
Model Training
Make a model that can be used for the training process and a model that can classify rainfall
Model Tuning
Make a model with high accuracy and can classify rainfall
Result Evaluation
Can make model performance measurement parameters

Fig. 1. Research steps flowchart.

C. System Workflow

System workflow describes the whole system. There are several stages so that the system can work well. The first stage that must be carried out is data loading, this process is the stage for adding the dataset to the algorithm system. Then, the data preprocessing stage includes classifying and labelling the dataset. The next process is Exploratory Data Analysis (EDA) and Data Preparation, this stage is the stage to understand the nature of the dataset. Then, the most crucial stage is data classification using the Naïve Bayes Classifier, Support Vector Machine and Decision Tree. Then, model evaluated using the confusion matrix and the final stage is testing the results of the three algorithms. All stages are visualized as a flow diagram as in Fig. 2.



Start
Data Loading
Preprocessing Data
Exploratory Data Analysis (EDA)
Data Classification Using NBC, SVM, Decision Tree Algorithms
Evalute Model using Accuracy Score, Precision Score, Recall, and F1-Score of Confusion Matrix
Classify the New Data Using NBC, SVM, Decision Tree Model Results
Stop

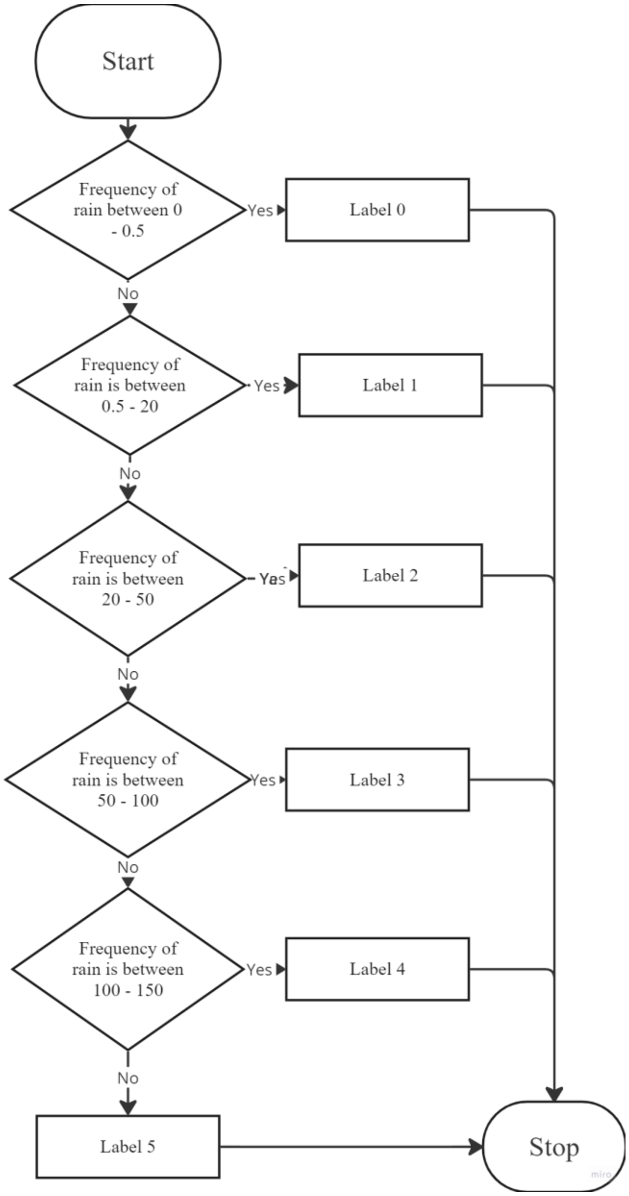
Fig. 2. System workflow.

D. Preprocessing Data

After the data loading process, the next stage is data preprocessing with labelling the frequency of rainfall into different labels based on specified ranges. The labelling method checks the frequency of rainfall in increasing ranges and assigns a corresponding label based on where the frequency falls. This structured approach helps in categorizing rainfall data efficiently and those processes are visualized as in Fig 3.

E. Data Description

The data used is open-source data from the BMKG page using rainfall, humidity and temperature parameters with a time span from 2018 – 2023. And the following is the classification of rainfall according to Indonesian Meteorology, Climatology and Geophysics Agency (BMKG):



Start

TABLE I. RAINFALL CLASSIFICATION ACCORDING BMKG

No	Rainfall Intensity	Classification
1.	0 mm/day	Cloudy
2.	0.5 – 20 mm/day	Light Rain
3.	20 – 50 mm/day	Moderate Rain
4.	50 – 100 mm/day	Heavy Rain
5.	100 – 150 mm/day	Very Heavy Rain
6.	>150 mm/day	Extreme Rain

F. Confusion Matrix

The confusion matrix is widely used in machine learning for evaluating classification model performance [11]. It compares predicted and actual class labels, typically in a tabular format [12]. While traditionally used for binary classification, confusion matrix can be extended to multiclass problems [13]. The term “confusion” in the matrix name refers to how the model may confuse or mislabel classes [11]. In credit scoring, the confusion matrix is an essential measure of model accuracy, with 16 possible variants, of which only eight are considered reasonable (Zeng, 2019) [14]. The matrix’s entries typically include true negatives, false positives, false negatives, and true positives (Piegorsch, 2020) [15]. Confusion matrix calculated the F1-Score, a widely used measure of classification accuracy, combines precision and recall using a harmonic mean (Yadavendra & Chand, 2020) [16].

G. Naïve Bayes Classifier

Gaussian Naïve Bayes (GNB) Classifier is a popular machine learning technique that assumes conditional independence between features. While efficient, this assumption can be limiting (Ali Haghpanah Jahromi & Taheri, 2017) [17]. Gaussian Naïve Bayes (GNB) algorithm has been successfully applied to rainfall classification and prediction in various studies. It has shown high accuracy in classifying daily and monthly rainfall patterns (Indra Kusuma Yoga et al., 2022) [18] and in predicting drought and flood risks based on multiple atmospheric variables (Oluwatobi Aiyelokun et al., 2020) [19]. Research has also shown that the Naïve Bayes Classifier can effectively classify rainfall based on air temperature and wind speed (Meilani Nisa Abdilla et al., 2024) [20].

H. Support Vector Machine

Support Vector Machines are widely used for classification tasks, with linear SVM being particularly effective for linearly separable classes (Murty & Raghava, 2016) [21]. The choice of kernel function is crucial for SVM performance, with linear kernels often outperforming others in certain applications (Keumala Intan, 2019) [22]. Support Vector Machine (SVM) have been developed for rainfall classification and prediction tasks with varying kernel functions. Linear kernel SVM have shown effectiveness in modeling pore-water pressure responses to rainfall, achieving high accuracy while offering computational efficiency (K. Yusof et al., 2017) [23]. In rainfall classification, linear and polynomial kernels demonstrated superior performance (78.38% accuracy) compared to Gaussian kernels when using a 90:10 training-testing split (Novia Pratiwi & Yudi Setyawan, 2021) [24]. SVM with linear and RBF kernels have been used to classify rainfall as heavy or light based on temperature and humidity data (S. Sunori et al., 2021) [25]. for rainfall prediction, a comparative study of different kernels revealed that the linear kernel produced the lowest average mean square error (15.04%) on test data, outperforming polynomial, RBF, and sigmoid kernels (J. Mohanty & M. Mohapatra, 2018) [26].

I. Decision Tree

Decision trees are popular classification algorithms in data mining, utilizing a divide-and-conquer strategy to create a flowchart-like structure (Dai et al., 2016) [27]. The tree consists of internal nodes representing attribute tests, branches denoting test outcomes, and leaf nodes holding class labels (Sharma & Kumar, 2016) [28]. Classification involves traversing tree from root to leaf, with the leaf node indicating the final classification (Dai et al., 2016) [27]. Decision trees are widely applicable in various fields, including rainfall classification (see Table I). Decision trees outperform their effectiveness in binary classification of rainfall events (Manoj Chhetri & Lily Gurung, 2023) [29] and long-term rainfall prediction (B. Revathi et al., 2021) [30]. Their popularity stems from their ability to handle large, complex datasets and extract useful knowledge from incomplete or noisy data (Sharma & Kumar, 2016) [28].

J. System Analysis Methods

This paper uses NBC, SVM and Decision Tree classification analysis methods. After carrying out the classification process, the next thing is to evaluate using the Confusion Matrix. After getting the table, this table will be used to find the accuracy value, recall value, precision value, and F1-Score for three models. The next stage is evaluating the model by using learning curve of each model. The final in the data analysis method is to check whether each model is performing well, underfitting, or overfitting as shown in Fig. 4.

K. Classification System Results

System testing was carried out using new data consisting of three parameters: rainfall, temperature and humidity. And the output of this test is a classification of rainfall based on the new parameters that have been entered.

III. Results and Discussion

The system built is a system to classify the rainfall in Yogyakarta, Indonesia with applied three methods in machine learning, they are Naïve Bayes Classifier (NBC), Support Vector Machine (SVM), and Decision Tree. While the programming language used in this paper is Python.

A. Naïve Bayes System Evaluation Results

In the 50% test set with 98% accuracy, in class 0 most of the data (666 out of 677) was correctly classified as class 0 with 11 data incorrectly classified as class 1, in class 1 classified 307 data correctly and 7 data incorrectly classified as class 2, in class 3 most of the data (24 of 25) were classified correctly and 1 data was misclassified as class 4, and the data in class 4 were all classified correctly as in Fig. 5.

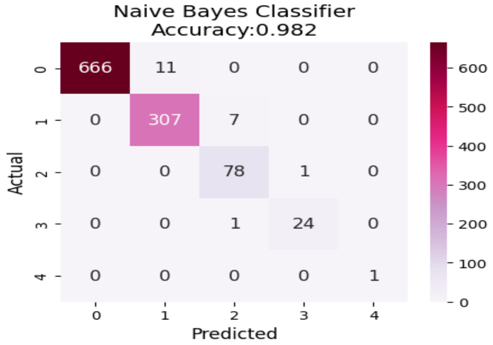

Fig. 5. Heatmap of NBC confusion matrix result on 50% test set.

In the 20% test set with 98% accuracy, class 0 in this test set most of the data (256 out of 259) is correctly classified as class 0 and 3 data is incorrectly classified as class 1, in class 0 124 data are correctly classified as class 1 and 3 incorrect data was classified as class 2, all data (44 data) in class 2 were classified correctly, and in class 4 some of the data was classified correctly and 1 data was incorrectly classified as class 2 as in Fig. 6.

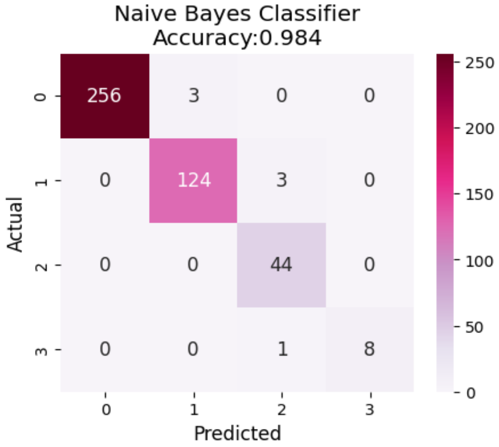

Fig. 6. Heatmap of NBC confusion matrix result on 20% test set.

In the 10% test set with 97% accuracy, class 0 in this test set most of the data (113 out of 114) is classified correctly and 1 data is incorrectly classified as class 1, in class 1 71 data are classified correctly but 4 data are incorrectly classified as class 2, all data (25 data) in class 2 and all data (6 data) in class 3 are classified correctly as in Fig. 7.

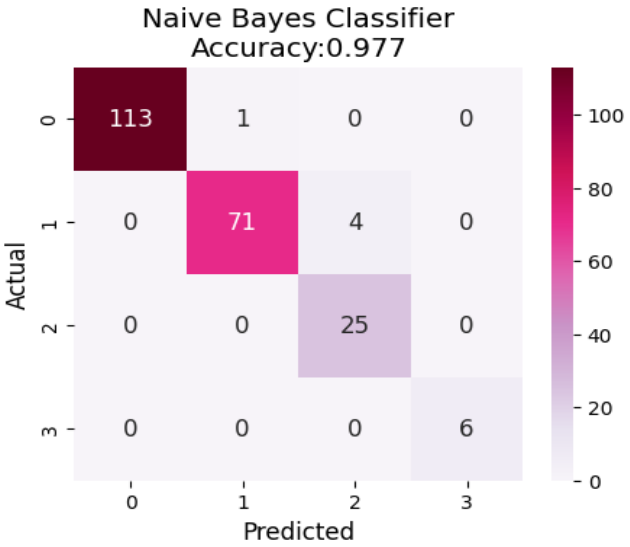

Fig. 7. Heatmap of NBC confusion matrix result on 10% test set.

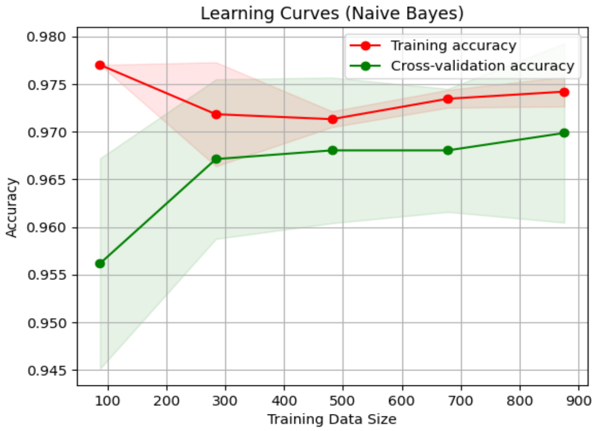
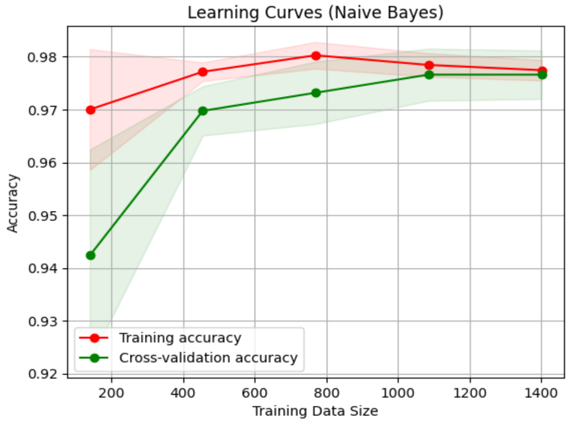
Referring to the NBC heatmap results above, this algorithm has a fairly good level of accuracy, but there are still prediction errors in class 0 and class 1 and these prediction errors tend to occur in adjacent classes, indicating that NBC still faces challenges in distinguishing classes with the same characteristics.

50% testing set



20% testing set



10% testing set

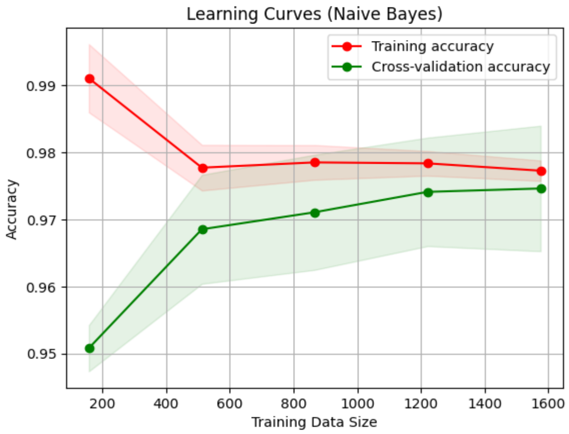


Fig. 8. The learning curve of Naïve Bayes classifier model.

As shown in Fig. 8, the cross-validation curve of 20% test set has increased too quickly indicating that the model has difficulty capturing the complexity of the data so 600 – 800 data is enough to achieve optimal NBC performance.

B. Support Vector Machine System Evaluation Results

In the 50% test set with 94% accuracy, all data (677 out of 677) in class 0 are predicted correctly. In class 1, most of the data (260 out of 314) was predicted correctly but there were 54 data that were incorrectly predicted as class 0. In class 2, 72 data were correctly predicted as class 2 and 7 data were incorrectly predicted as class 1. In class 3, 24 data were predicted correctly while 1 data was incorrectly predicted as class 2. In class 4, all data were predicted correctly as class 4 as in Fig. 9.

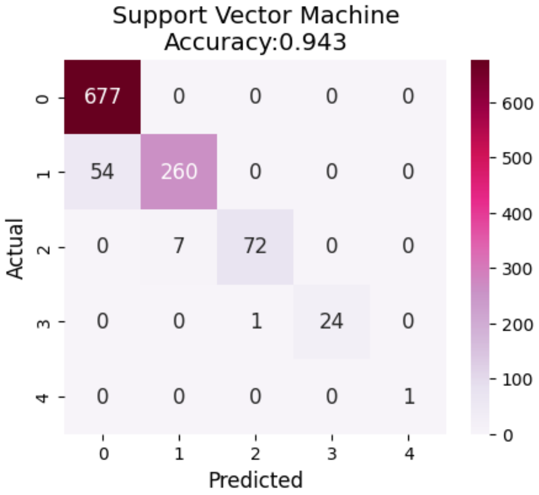

Fig. 9. Heatmap of SVM confusion matrix result on 50% test set.

In the 20% test set with 94% accuracy, all data (259 out of 259) in class 0 are predicted correctly. Predictions in class 1 were 109 out of 127 data predicted correctly and 18 data incorrectly predicted as class 0. In class 2, 40 out of 44 data were predicted correctly and 4 data were incorrectly predicted as class 1. Meanwhile in class 3, 8 data was predicted correctly and 1 data that was incorrectly predicted as class 2 as in Fig. 10.

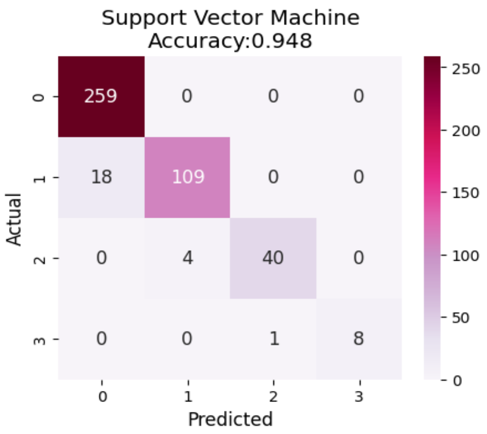

Fig. 10. Heatmap of SVM confusion matrix result on 20% test set.

In the 10% test se with 96% accuracy, all data (114 out of 114) in class 0 are predicted correctly. In class 1, some data (68 out of 75) were predicted correctly, and 7 data were incorrectly predicted as class 0. In class 2, 24 data were predicted correctly, and 1 data was incorrectly predicted as class 1. Meanwhile, in class 3 all data (6 of 6) were predicted correctly as in Fig. 11.

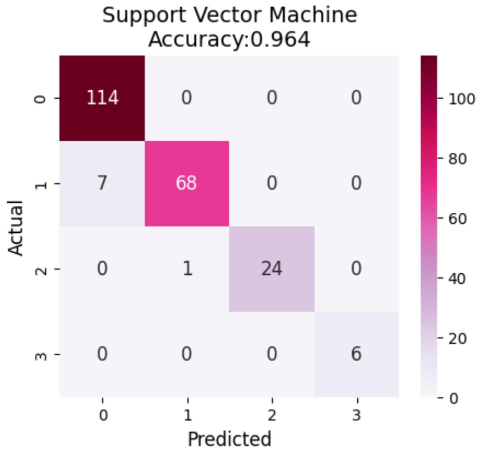

Fig. 11. Heatmap of SVM confusion matrix result on 10% test set.

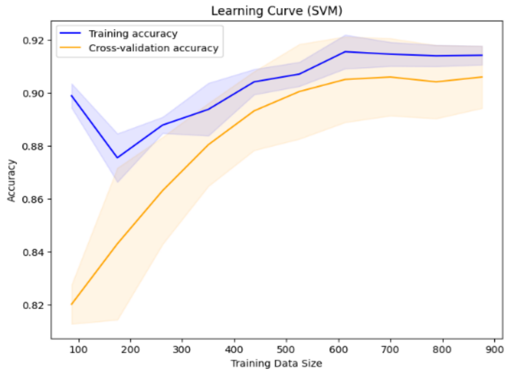
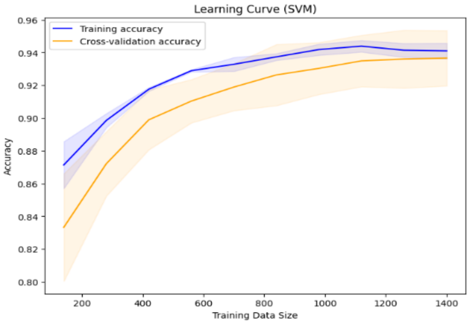
All SVM models in the three test sets have an accuracy above 94%, but there are still errors in class 1 and class 2 classification, however, this SVM model is very good at classifying data from class 0 very accurately in all test sets.

50% test set



20% test set



10% test set

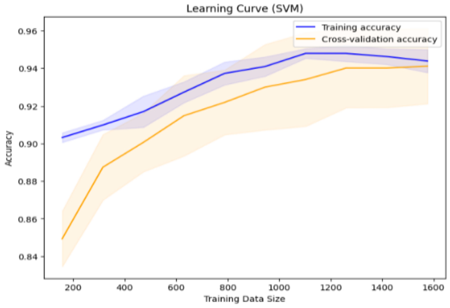


Fig. 12. The learning curve of support vector machine model.

In the SVM learning curve, the three test sets show that the model has good abilities in learning data as seen from the training accuracy and cross-validation accuracy which increase and decrease the distance from each other as shown in Fig. 12.

C. *Decision Tree Evaluation Results*

In the 10% test set, all data (677 out of 677) in class 0 are predicted correctly. In class 1, 313 of 314 data were predicted correctly and 1 data was incorrectly predicted as class 5. In class 2, class 3, and class 4, all data were predicted accurately as in Fig. 13.

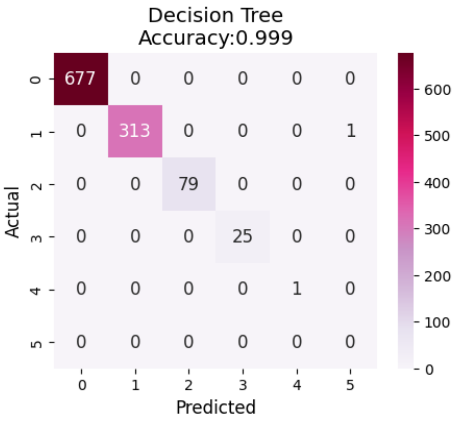

Fig. 13. Heatmap of decision tree confusion matrix result on 50% test set.

In the 20% test set, all data from all classes (class 0 with 259 data, class 1 with 127 data, class 2 with 44 data, and class 3 with 9 data) were predicted correctly and accurately as in Fig. 14.

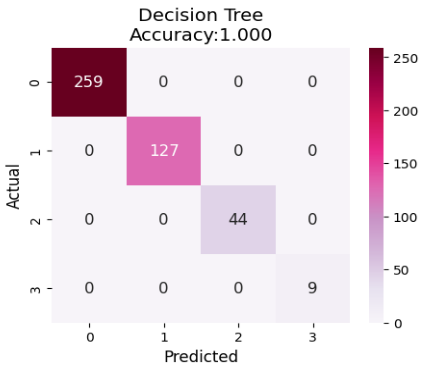

Fig. 14. Heatmap of decision tree confusion matrix result on 20% test set.

Likewise, in the 10% test set, all data from all classes (class 0 with 114 data, class 1 with 75 data, class 2 with 25 data, and class 3 with 6 data) were predicted correctly as in Fig. 15.

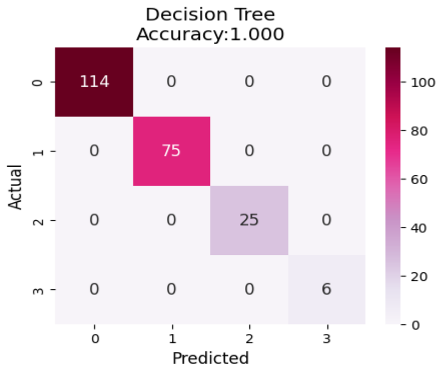

Fig. 15. Heatmap of decision tree confusion matrix result on 10% test set.

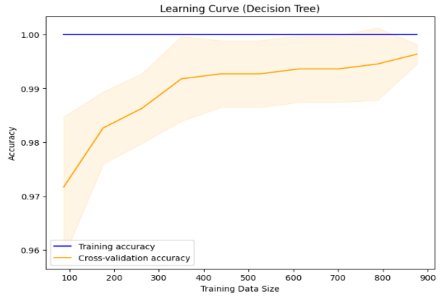
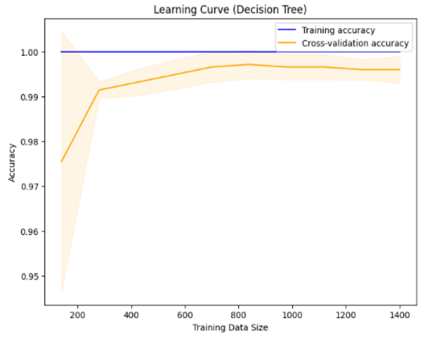
The Decision Tree model has 100% accuracy and the lowest prediction error among the three algorithms.

50% test set



20% test set



10% test set

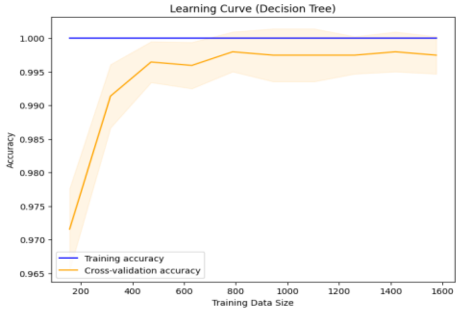


Fig. 16. Learning curve of decision tree model.

There is overfitting of the three test sets, especially in the 50% test set, it is proven that there is quite a large gap between testing accuracy and cross-validation accuracy as shown in Fig. 16.

IV. Conclusion and Suggestion

A. Conclusion

Based on research on rainfall classification using the Naïve Bayes Classifier (NBC), Support Vector Machine (SVM) and Decision Tree algorithms. The conclusion that can be drawn is that NBC accuracy is 98%, SVM accuracy is 94%, Decision Tree accuracy is 100%. NBC has quite high accuracy but still experiences difficulty in distinguishing classes, especially class 0 and class 1, SVM has good performance in classifying class data, even though there are errors in class 1 and class 2, and even though Decision Tree has perfect accuracy, however This happens due to overfitting, especially on a large test set (50% test set), so Support Vector Machine (SVM) becomes a stable choice among the three models.

B. Suggestion

Suggestions given from research that have been carried out for further research are improving the three models, such as reducing the dataset to 600-800 for Naïve Bayes Classifier (NBC), exploring other than linear kernels in Support Vector Machine (SVM), and using pruning techniques in Decision Tree.

Consultant Rehabilitation Medicine, Rehabilitation Department, Hospital Shah Alam, Selangor, Malaysia[5]

***Abstract*—Stroke rehabilitation is fraught with challenges, particularly regarding patient mobility, imprecise assessment scoring during the therapy session, and the security of healthcare data shared online. This work aims to address these issues by calibrating hand gesture recognition systems using the Rehabilitation Internet-of-Things (RIOT) framework and examining the effectiveness of machine learning algorithms in conjunction with the MediaPipe framework for gesture recognition calibration. RIOT represents an IoT system developed for the purpose of facilitating remote rehabilitation, with a particular focus on individuals recovering from strokes and residing in geographically distant regions, in addition to healthcare professionals specialising in physical therapy. The Design of Experiment (DoE) methodology allows physiotherapists and researchers to systematically explore the relationship between RIOT and accurate hand gesture recognition using Python's MediaPipe library, by addressing possible factors that may affect the reliability of patients' scoring results while emphasising data security consideration. To ensure precise rehabilitation assessments, this initiative seeks to enhance accessible home-based stroke rehabilitation by producing optimal and secure calibrated hand gesture recognition with practical recognition techniques. These solutions will be able to benefit both physiotherapists and patients, especially stroke patients who require themselves to be monitored remotely while prioritising security measures within the smart healthcare context.**

Keywords*—Internet-of-Things (IoT); RIOT; stroke rehabilitation; calibration; machine learning; MediaPipe; data security; smart healthcare

I. Introduction

In enhancing care quality, patients wellbeing, and healthcare efficiency, smart healthcare systems can be promising by the integration of IoT, Artificial Intelligence (AI), big data analytics, and wearable devices, with the collaboration and involvement of patients, healthcare providers, technology developers, and policymakers [1]. These real-time data collection, remote monitoring and personalised healthcare solutions manifested an acceleration of technological advancements from healthcare industry demands, especially during COVID-19 pandemic since it was driven to be implemented globally [2]. Across the globe, the goals of smart healthcare systems will always be the improvement of patient care, cost effective, and efficient deliverables through accurate diagnoses, timely treatments, and continuous monitoring [3].

"Immobility" terminology is always close to "movements". So do the struggles of the stroke patients who need to face the challenges who are not commuting freely? A stroke, as defined by the World Health Organization, is a sudden onset of focal or global neurological impairment presumed to be of vascular origin [4]. Stroke is a severe neurological disease with complex underlying pathological processes, leading to high rates of morbidity and mortality [5].

As a starting point, this study will investigate the hand gesture of the orientation of the palm, either having a landed wrist or upper limb, depending on the patient's ability during the rehabilitation session. Since stroke rehabilitation poses challenges such as imprecise progress tracking and assessment, along with concerns about sensitive data, highlighting the need for reliable and secure data handling, a framework was introduced to assist the healthcare community in improvising the rehabilitation sessions with the presence of the emerging modern technologies that is remotely accessible through the network. Therefore, a framework called RIOT is proposed to deliver affordable and efficient remote stroke rehabilitation.

Remote rehabilitation strategies, as highlighted by Tuli et al. [6] suggest favourable solutions and introduce privacy vulnerabilities and software reliability issues [7]. In response to these challenges, a RIOT framework was developed to enhance gesture recognition accuracy and ensure data security within smart healthcare systems to stand with the exploration of the calibration of hand gesture recognition using the RIOT framework and evaluating its effectiveness in improving home-based stroke rehabilitation [8], [9].

Blending IoT, Machine Learning [10], security and calibration can improve the recovery process for stroke survivors as a blueprint that a system development requires an advanced rehabilitation requires multidisciplinary collaboration [11]. Based on the issue, there was a need for a secure calibration approach for hand gesture recognition using a DoE methodology on a RIOT platform, which can inspect an accurate hand gesture recognition and precise rehabilitation assessment with well-calibrated parameters while considering potential security implications within a smart healthcare context. In addition, the implementation of MediaPipe by Python is necessary to capture the elements of hand gesture recognition that can execute the performance of the recognition [12].

Calibration is essential for accurate hand gesture recognition outcomes, as clinical models, algorithms, and scores must provide reliable and consistent readings [13]. Consequently, the incorporation of DoE can fine-tune and adjust the accuracy of the rehabilitation assessment with its analytical basis [14].

Hence, smart healthcare compromises better future with the developments of services, including the sensitivity towards the importance of data protection, affordability of the healthcare treatment, and widely nurturing the field of computer science [15]. The integration of various technologies has been explored in recent studies to enhance security and efficiency in different sectors [16]. Additionally, the security and privacy aspects of IoT in smart city applications have been comprehensively analysed, underlining the potential and challenges of such technologies [17]. Moreover, calibration process is one of the applications that can enable improvisation of the precision of the experiment as it is essentially supports the initial process of developing remote rehabilitation.

This paper is arranged as follows: Section I gives a brief introduction to the implementation of the calibration for gesture recognition using MediaPipe in the smart healthcare context. Section II focuses on the existing literature on the integration of IoT in stroke rehabilitation, the effectiveness of machine learning algorithms for gesture recognition, and the encounters related to data security and reliability in smart healthcare systems. Section III describes the proposed solution for this paper. Section IV showcased the results and discussion of the experiment. Finally, Section V concludes the content of this research.

II. Literature Review

This literature review segment provides an overview of existing knowledge, identifies research gaps, and highlights areas for future investigation, setting the foundation for this study. Key areas of focus include the integration of IoT in stroke rehabilitation, and the challenges related to data security and reliability in smart healthcare systems. The effectiveness of machine learning algorithms for gesture recognition.

A. Smart Healthcare for Stroke Rehabilitation Internet-of-Things

Smart healthcare systems for stroke rehabilitation empower Internet-of-Things (IoT) technologies to offer remote monitoring capabilities for patients undergoing rehabilitation [18]. These systems utilise advanced technologies such as cloud computing, machine learning, and wearable sensors to enable remote rehabilitation training for stroke survivors, reducing costs and burdens on both patients and healthcare providers [19]. By integrating big data, artificial intelligence, cloud computing, and IoT, smart healthcare enhances medical services' automation, informatisation, and intelligence, leading to improved healthcare efficiency and patient experience [3].

B. Limitations of Current Stroke Rehabilitation Systems and Home-Based Solutions

Incapabilities in tracking and monitoring the progress of stroke patients over time can hinder the effectiveness of traditional rehabilitation methods. Additionally, data security concerns arise caused of the sensitive nature of patient information which obviously displaying the need for innovative solutions for the quality and security of stroke rehabilitation programs [20].

Home-based solutions are a promising way to overcome traditional stroke rehabilitation limitations. Tele rehabilitation uses e-health platforms and digital technologies to provide convenient and cost-effective services to stroke patients at home. Research has shown that home-based programs enhance patient outcomes and improve access to care, particularly when in-person rehabilitation is not possible [21]. Technological advancements such as webcam monitoring and mobile apps provide cost-effective options for home-based stroke rehabilitation with remote monitoring and real-time feedback, increasing patient engagement. Inexpensive technologies can enhance outcomes for stroke survivors by optimizing home-based rehabilitation and overcoming current system limitations [22].

C. Challenges in Data Security and Reliability

Safeguarding data security in smart healthcare is critical, with the exchange of sensitive healthcare data among IoT-enabled medical devices necessitating secure data aggregation and transmission protocols [5]. Additionally, the implementation of secure IoT frameworks is essential to protect patient data and ensure the integrity of healthcare systems [6].

To address security concerns in IoT-based healthcare systems, various frameworks and solutions have been proposed to safeguard patient data and privacy [7]. Security and privacy challenges in IoT healthcare systems are being studied to enhance robust security measures [8]. Furthermore, blockchain in healthcare improves security and privacy in tele-medical services by integrating technology for patient data transmission [9].

Security is important for IoT devices in smart healthcare to prevent breaches and the limitations in processing and battery life make it critical [10]. Studies found weaknesses in IoT healthcare apps and stressed blockchain's importance in reducing security threats, offering ways to boost security in healthcare systems [11]. Also, the development of secure and scalable healthcare data transmission frameworks based on optimised routing protocols is essential for ensuring data integrity and confidentiality in IoT applications [12].

D. Effectiveness of Machine Learning (ML) and Deep Learning (DL) Techniques for Hand Gesture Recognition

ML uses algorithms to learn from data for decisions or predictions while DL is a subset of machine learning, employing neural networks with multiple layers for automatic intricate data representations that is inspired by biological neural structures, excels in extracting complex patterns and features from data, outperforming traditional machine learning methods in different tasks [23].

Based on the related previous work, artificial intelligence and machine learning have been increasingly utilised in the healthcare sector to improve diagnostics and patient care, as reviewed by Rozario et al. [24] as well as the challenges of implementing IoT in educational domains have been discussed, providing insights into the potential applications and obstacles. The recent trends in AI and IoT have also been studied, suggesting future research prospects for enhancing networking systems [15].

TABLE I. Table I and Table II indicate the comparative analysis of various techniques used in gesture recognition. Specifically, Table I compares general techniques in gesture recognition, while Table II focuses on comparing techniques that utilises MediaPipe framework.

TABLE I. THE COMPARISON OF TECHNIQUES IN GESTURE RECOGNITION

Author /Year	Methods /Algorithms	Research Area	Feature Sets	Results	Type
Guo et al. (2023) [25]	Support Vector Machine (SVM), k-Nearest Neighbours (k-NN), Linear Discriminant Analysis (LDA), Neural Network (Electromyography), InceptionTime, 1D-CNN	Hand Rehab Equipment, sEMG-based Gesture Recognition	Mean Absolute Value (MAV), Root Mean Square (RMS), Variance of Average Values (VAV), Integrated EMG (iEMG), SSI, WL	90.89% Overall Gesture Recognition Accuracy	ML DL

Jiang et al. (2022) [34]	Support Vector Machine (SVM), k-Nearest Neighbours (k-NN), Naïve Bayes, Discriminant Analysis	Spatio-temporal Hand Gesture Recognition	-	Achieved an average accuracy of 85% in hand gesture recognition	ML
Palanisamy & Thangaswamy (2023) [35]	Hough Transforms, Artificial Neural Networks (ANN)	Hand Gesture Recognition	Spatiotemporal Features	Detected hand gestures with an accuracy of 92% using spatiotemporal techniques and artificial neural networks	ML
Wei et al. (2021) [36]	CNNs	Surface Electromyography-Based Gesture Recognition	-	Achieved a classification accuracy of over 90% for a large set of gestures using CNNs.	DL
Lee & Bae (2020) [37]	Dual-channel ANN, DNN	Hand Gesture Intention Cognition	IMU sensor data	Explored deep learning techniques achieving an accuracy of 88% for hand gesture intention recognition.	DL

1) MediaPipe framework: The comparison of deep learning techniques in gesture recognition using the MediaPipe framework reveals significant advancements in sign language recognition for individuals. Various researches have demonstrated the effectiveness of combining modern computer vision and machine learning approaches, such as CNN [38], LSTM [39], and lightweight deep neural networks as GRU and 1D CNN [40], in accurately recognising sign language gestures. These techniques have shown high classification accuracies ranging from 98.8% to 99.95% on different datasets, including ASL alphabets, daily used signs, and static sign language letters and characters. By leveraging the MediaPipe framework for feature extraction and real-time processing, these models contribute significantly to bridging the communication gap between the physically impaired community and the general population, enhancing their quality of life with proper recognition.

Overall, there are two main hand gesture recognition approaches: vision-based (using cameras for features) with high accuracy, and sensor-based (using EMG or IMU) with moderate accuracy. ML/DL techniques (CNNs) achieve high accuracy in various applications, while MediaPipe Framework offers real-time recognition with comparable accuracy. In stroke rehabilitation, both ML/DL and MediaPipe are efficient with high accuracy. MediaPipe suits smart healthcare for immediate feedback, while traditional models are better for offline processing. Combining both can make sure accurate recognition in rehabilitation. Since gesture recognition field is rapidly evolving, best approach depending on specific requirements.

E. Technology Integration for Secure Calibration

In this section mentions calibration process involving the system accuracy recognises the equations application to the calibration analysis. Also, the gestures across different devices, environments, technical approaches, and user conditions with MediaPipe's hand tracking module due to its robust and real-time capabilities were meant to be achieved.

1) Formulas and equations: To precisely assess and calibrate the hand gesture recognition system, six key equations and references are employed for the analysis:

a) The Accuracy of Gesture Recognition and Euclidean Distance Formula

$$Accuracy = \frac{Distance\ of\ Correctly\ Recognised\ Gestures}{Total\ Distance\ of\ Gestures} \times 100\% \quad (1)$$

TABLE II. THE COMPARISON OF DEEP LEARNING TECHNIQUES IN GESTURE RECOGNITION USING MEDIAPIPE FRAMEWORK

Author /Year	Methods /Algorithms	Research Area	Feature Sets	Results

Indriani et al. [47]	Transfer learning on DenseNet201 for gesture classification model.	Neural network architectures for training and classifying hand gestures	DenseNet201 for hand gesture classification using transfer learning"	Validation accuracy: 97.55%"
Wang et al. (2023) [48]	LTSM, Gated Recurrent Unit (GRU) neural networks	Sign language recognition	Visual sign language recognition. - sign language dataset 64 Argentine sign languages (LSA64)	Capture of 3D coordinates of hands for sign language recognition, LTSM: 94.0625% and GRU: 94.5312%
Padhi & Das (2022) [49]	Transfer learning on DenseNet201 for gesture classification model."	Neural network architectures for training and classifying hand gestures	DenseNet201 for hand gesture classification model	Validation accuracy: 97.55%"
Kumar et al. (2023) [39]	BlazePalm, Landmark model, Gesture recognition model	Virtual scene	Hand key point model for 3D hand joint coordinates	Effective hand key point localization and 3D hand joint prediction
Giri & Patil (2024) [42]	GRU, LSTM	Sign language recognition	Hand segmentation, feature representation	99% accuracy achieved
Suherman et al. (2023) [50]	CNNs, transformer	Gesture recognition	Image feature representation	Achieved over 95% accuracy in 2D or 3D gesture recognition tasks
Liu et al. (2022) [51]	Few-Shot Learning,	Continuous gesture sequences recognition	RWTH German fingerspelling dataset	Accuracy for 5-way 1-shot gesture recognition 89.73%, which randomly selected.

The distance between the camera and the hand is crucial for calibration. The distance was measured in centimetres (cm) using a metal ruler. Wang et al. [52] explored stress formulas from deformation equations to acquire spatial distances using mathematics. The Euclidean distance formula calculates 3D space distance when hand landmark coordinates are known

$$d = (x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2 \quad (2)$$

Where (x_1, y_1, z_1) and (x_2, y_2, z_2) are the coordinates of two points which are landmark 4 and 8.

b) Corner angle of the laptop: The corner angle of the laptop, measured using a 3D printed protractor (Xiphias), affects the range of capture for the webcam. This angle is decisive for recognising landed wrist gestures. The angle θ. θ can be measured and used to adjust the camera's field of view:

c) Mean (Average) and standard deviation calculation: The accuracy of different formulas demonstrated the importance of mean accuracy and standard deviation calculations in assessing formula performance [53].

$$\theta = \arctan(\frac{height}{distance}) \quad (3)$$

Measurement and accuracy assessment of angles aligns with the methodology of measuring and adjusting corner angles for webcam calibration [54].

$$Mean = \frac{\sum Accuracy\ Values}{n} \quad (4)$$

where n is the number of accuracy measurements.

$$\text{Standard Deviation} = \sqrt{\frac{\sum(\chi_\text{i} - \mu)^2}{n}} \quad (5)$$

where χ_I is each accuracy value, μ is the mean accuracy, and n is the number of measurements.

d) ANOVA (Analysis of variance): To know the main features of similarity indices, which aligns with the statistical analysis required for accuracy assessment in gesture recognition [55] and ANOVA was used to determine if there are any statistically significant differences [56] between the means of independent (unrelated) groups.

$$F = \frac{Variance\ Between\ Groups}{Variance\ Within\ Groups} \quad (6)$$

2) Calibration procedure: Some factors such as camera type, whether using a laptop camera or an external camera with different resolutions, can impact the quality of gesture recognition [57]. Additionally, the distance between the camera and the hand, as well as the orientation of the palm, are essential factors that influence the ability of stroke patients to perform gestures accurately [58].

Moreover, repetitions and accuracy of gestures are fundamental for calibration in rehabilitation systems [59]. Also, lighting conditions need to be controlled to evaluate camera sensitivity and gesture recognition [60].

Thus, secure calibration methods with camera type, distance, palm orientation, accuracy, repetitions, and lighting are vital for optimising stroke rehabilitation systems. Advanced technologies can improve rehabilitation programs for stroke patients.

In summary, while significant progress has been made in integrating IoT and machine learning into stroke rehabilitation, challenges related to data security, system reliability, and the effectiveness of home-based solutions remain. Previous studies have demonstrated the effectiveness of machine learning for gesture recognition but have not addressed security concerns. Therefore, this research aims to address these gaps by calibrating hand gesture recognition using the RIOT framework and evaluating machine learning algorithms with MediaPipe, with a focus on enhancing data security and rehabilitation accuracy.

III. Methodology

The methodology outlines the process of integrating and calibrating MediaPipe for hand gesture recognition in stroke rehabilitation, addressing the limitations identified in the literature review. Fig. 1 and Fig. 2 visualise the flow of the data collection, and palm orientation testing as a part of data collection process.

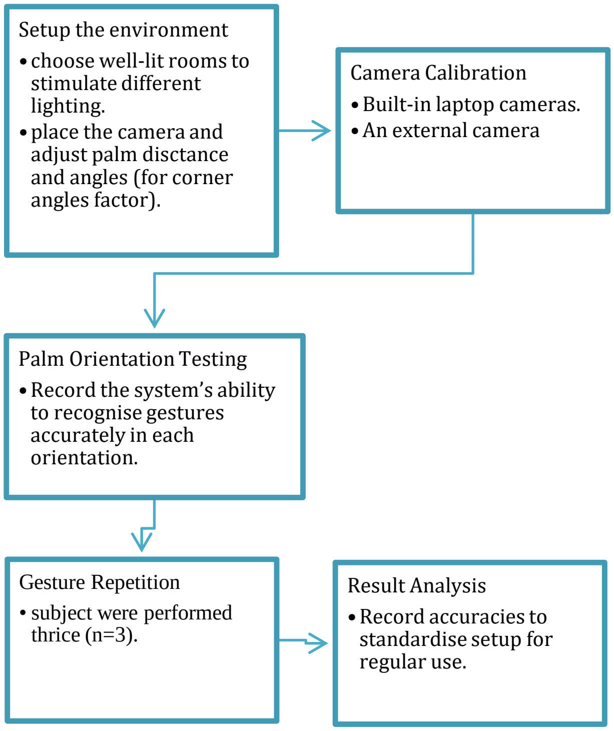
A. Tool Selection

1) Python, MediaPipe framework and MediaPipe solutions: The convergence of MediaPipe with Python libraries is pivotal in pose detection and analysis for the creation of machine learning pipelines. MediaPipe framework offers hand tracking and gesture recognition solutions and provides a palm detector and hand landmark model for accurate gesture recognition [61], [62]. Using MediaPipe with Python allows access to hand landmark models and gesture recognition capabilities [63].

MediaPipe's BlazePose algorithm has been effective in single-camera human 3D-kinematics. BlazePose in physiotherapy exercise classification showed efficient performance with a frame rate of 32 frames per second [64], [62].

Additionally, MediaPipe's adaptability and dependability are evident in its performance across different areas of pose detection tasks. It has shown effectiveness in the identification of genetic syndromes and in reducing the likelihood of overfitting in contrast to other techniques [63], [65]. The framework's robustness and versatility make it a valuable tool for various applications, including sign language-based video calling apps and object detection for aspiring film directors [63], [66].

2) Gesture recognition procedure: Subsequently, Fig. 2 will explain further the process of palm gesture recognition during Palm Orientation Testing. To detect the palm, MediaPipe acquires landmarks, as shown in Fig. 3 to produce the coordinates of the gestures. The landmarks were generated in Fig. 3 and Fig. 4. A by MediaPipe and the purple label was the MediaPipe, between landmark 4 and 8 for the measurement of accuracies. Fig. 3. B is the initial visualisation of the 21 landmarks by MediaPipe.



Setup the environment
• choose well-lit rooms to stimulate different lighting.
• place the camera and adjust palm disctance and angles (for corner angles factor).
Camera Calibration
• Built-in laptop cameras.
• An external camera
Palm Orientation Testing
• Record the system's ability to recognise gestures accurately in each orientation.
Gesture Repetition
• subject were performed thrice (n=3).
Result Analysis
• Record accuracies to standardise setup for regular use.

3) Evaluation of MediaPipe for hand gesture recognition: Using an open-source framework, for hand gesture recognition [73]. MediaPipe offers a suite of pre-trained models and pipelines specifically designed for real-time hand tracking and gesture recognition. The evaluation of MediaPipe's performance in this context focuses on its built-in accuracy metrics.

a) Accuracy measurement: The built-in accuracy evaluation includes the confidence score indicating the probability that the detected hand landmarks correspond to a hand gesture and the percentage of gestures correctly classified by MediaPipe's pre-trained models. The measurement of the distance was set in between the perpendicular point of camera to the base, and palm location at 0.00 cm, as displayed in Fig. 5. According to Fig. 6, the attached ruler was placed right by the side of the laptop screen to record the angle between the web camera and the base or keyboard of the laptop. The angles were measured by placing Xiphias at the side of the laptops, respectively, as shown as in Fig. 6. A. Meanwhile Fig. 6. B is how the angles was examined on the devices.

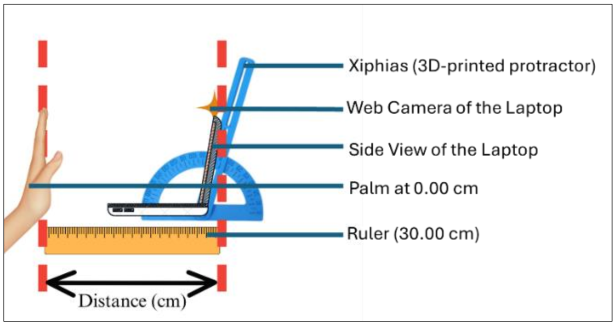

Fig. 5. Experimental setup showing the distance measurement between the laptop webcam and the hand using a metal ruler and a 3D printed protractor (Xiphias) to determine the corner angle of the laptop.

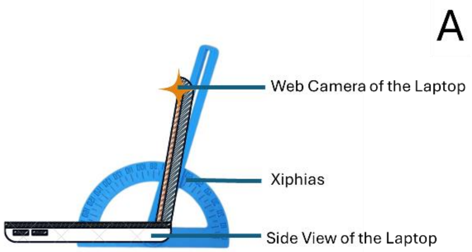

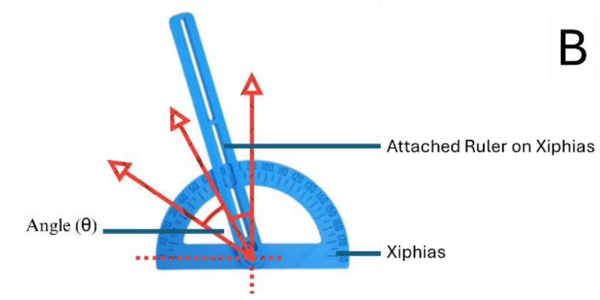

Fig. 6. The coordination of Xiphias to get the angles and then the distances started to be examined was perpendicular to the laptop webcam.

B. Calibration with DoE

1) Calibration process: The calibration process involved optimising factors to enhance the accuracy of hand gesture recognition within the stroke rehabilitation context. This step focused on fine-tuning parameters such as camera type, camera distance, palm orientation, and lighting conditions to ensure precise and reliable gesture recognition outcomes [67], [68], [69].

a) Calibration setup: Strategically placing the external camera at a specific distance from the hand minimises occlusions and distortions that may arise with a laptop camera, resulting in more reliable gesture detection. Gesture recognition has gained traction due to advancements in computer vision and AI. Hand-gesture recognition for Human-Machine Interaction (HMI), enabled effective interpretation of user intent by machines [70]. Besides, calibration process is aligned with research focused on enhancing gesture recognition systems through cutting-edge technologies and methodologies [71]. Likewise, scholars have recorded developments in real-time hand gesture recognition through the use of deep learning models from MediaPipe and sensor fusion strategies [72]. For reliable results, calibrating a gesture recognition system is important. It benefits in developing systems for various purposes, which supports this approach.

C. Data Collection and Result Analysis

Data gathering under various conditions was recorded to ensure robustness and accuracy. The comparison was made based on factors as mentioned in Table III statistical method was implied for evaluation and optimal settings identification.

1) DoE methodology for statistical optimisation: Calibrating factors in Table III enhances the accuracy and reliability of gesture recognition:

TABLE III. FACTORIAL DOE DESCRIPTION

Factors		Levels/SI Unit	Description
Primary	***Camera***	Laptop camera External camera	Cameras with different resolutions[a].
	Camera distance	Centimetre (cm)	Measurement in cm using a metal ruler (up to 30 cm) to determine the distance between the camera and the hand.
	Palm orientation	Upper limb Landed wrist	Stroke patients' ability to move parts of their hands.
Secondary	***Lighting***	Controlled: Bright Dim	Evaluating the camera's sensitivity to gesture recognition under different indoor lighting scenarios.
	Personal computer (PC)	Laptop models A: HP Envy Laptop 13 B: ASUS Vivobook A542U C: ACER Aspire E 14	Laptop models vary in size and specifications, impacting gesture recognition software performance[b]. Laptop size affects camera positioning and stability, potentially affecting gesture recognition accuracy. Hardware differences such as processor speed, RAM, and graphics impact efficiency and accuracy of gesture recognition algorithms.
	Corner angle of the laptop	Degrees (θ): 50°, 60°, 70°	Measuring from a 3D printed protractor to determine the range of capture for the webcam in recognising landed wrist gestures.
	Accuracy	Percentage (%)	Percentage of correctly recognised gestures[c](i.e. pinch extension).
	Repetitions	n = 3	Conducting each gesture n = 3 times to ensure consistency and reliability.

The DoE approach optimises gesture recognition systems by adjusting elements and levels, aiming to determine optimal parameters for accurate recognition, particularly in stroke patients and different lighting conditions.

The factors clearly provided some IoT devices used in the experiment in the description in Table III. In Section IV, the comprehensive analysis of IoT security and privacy will be discussed further to ensure that the best practices were identified in recent research [17].

[a] Romeo et al. [73] has experimented different resolutions and abled to receive the best results for 3D calibration procedures.

[b] The assertion regarding the impact of laptop models on gesture recognition software performance is supported by research that specifically addresses the interaction between hand gestures and laptops, emphasizing the importance of considering laptop specifications in the context of gesture recognition systems.

[c] According to Hu et al. [74] the effectiveness of proposed method can be measured through accuracy to reduce training burden of the system.

IV. Results and Discussions

This part presents the outcomes of implementing MediaPipe for gesture recognition, the experimental setup, calibration process, and statistical analysis of DoE approach in optimising calibration parameters in enhancing hand gesture recognition for RIOT, and the argument on security measures with smart healthcare awareness. The visual representation of the results was also showcased in graphs and the process of data collection is displayed in Fig. 7.

A. *Descriptive Statistic and Overview*

The dataset comprises measurements of accuracy at different distances, camera types, and lighting conditions. Basic statistics are summarised in Table IV.

TABLE IV. Descriptive Statistic

Metric	Value
Sample Size	84
Mean Accuracy (%)	Varies by distance and lighting (refer Table V, Table VII, Table VIII, Table IX, Table X, and Table XII).
Standard Deviation	

From TABLE IV. (from 10.00 cm to 30.00 cm) and each distance has multiple conditions for Bright and Dim lighting. For example, Bright and Dim conditions are repeated twice, so there are four measurements per distance. So, the sample size appeared to be 84 meanwhile the mean accuracy and standard deviation were explained in the next subtopic (refer to *B. Experimental Setup and Calibration Results*).

B. *Experimental Setup and Calibration Results*

In this section, the presentation of results of gesture recognition experiments, focusing on the accuracy, the relationships between factors were displayed and discussed. Sample of calculations of mean accuracy and standard deviation were shown as the following.

a) Calculation of average accuracy: To calculate the average accuracy at a specific distance, the sum the accuracy percentages of multiple measurements at that distance and divide by the number of measurements (refer to Formula (3)). For example, at 10 cm:

$$Average\ Accuracy = \frac{\sum Accuracy\ Measurements}{Number\ of\ Measurements}$$

$$= \frac{10.31}{1} = 10.31\%$$

b) Calculation of standard deviation: The standard deviation is calculated to understand the spread of accuracy measurements around the mean (average) accuracy (refer Formula 5). For example, at 10 cm with sample measurements (hypothetical values):

$$Accuracy\ Measurements = [8,12,10,11,10]$$

$$Mean\ Accuracy(\mu) = 10.20$$

Step-by-step calculation:

First, each measurement's deviation was calculated from the mean, square it:

$$(8-10.20)^2, (12-10.20)^2, (10-10.20)^2,$$
$$(11-10.20)^2, (10-10.20)^2$$
$$= 4.84, 3.24, 0.04, 0.64, 0.04$$

Next, the calculation of standard deviation (SD) was finalised:

$$SD = \sqrt{\frac{4.84, 3.24, 0.04, 0.64, 0.04}{5}}$$

$$= \sqrt{1.76} = 1.33$$

Given the provided data in Table V, if the SD is given directly as 21.946, then it was directly used in the report:

$$SD = 21.946$$

c) Distance and accuracy: To begin with, the determination of the impact of camera distance on gesture recognition, the accuracy was examined at various distance from 10.0cm to 30.0cm towards the palm placement. Moreover, the reliability and consistency of gesture recognition accuracy were analysed the standard deviation of accuracy measurements at different distances. The results are presented in Table V TABLE V. and Fig. 7.

TABLE V. Accuracy and Standard Deviation at Different Distances

Distance (cm)	Average Accuracy (%)	Standard Deviation
10.00	10.13	21.946
11.00	13.88	22.635
12.00	29.25	32.766
13.00	40.77	33.187
14.00	54.29	41.415
15.00	64.17	32.778
16.00	74.27	29.884
17.00	82.04	15.265
18.00	85.27	14.596
19.00	86.90	12.842
20.00	88.08	12.266
21.00	83.79	13.639
22.00	85.00	12.360
23.00	82.85	12.751
24.00	83.04	13.152
25.00	81.85	14.856
26.00	81.52	16.114
27.00	79.85	17.471
28.00	76.27	19.254
29.00	75.24	21.120
30.00	72.04	23.297

For distances of 10 to 15 cm, the standard deviation is high (21.946 to 41.415), indicating significant variability in accuracy. This suggests that at these distances, the system's performance is inconsistent.

Next, the distances of 16 to 20 cm, the standard deviation decreases (12.266 to 29.884), suggesting more consistent performance. The accuracy is higher, and the lower standard deviation indicates that the system is more dependable at these distances.

Finally, beyond 20 cm, the standard deviation remains moderate to high, indicating that the accuracy becomes more variable again as the distance increases. This suggests that the system's performance is less stable at greater distances.

Subsequently, a trend of accuracy was manifested across different distances and with variability based on the error bars in Fig. 7.

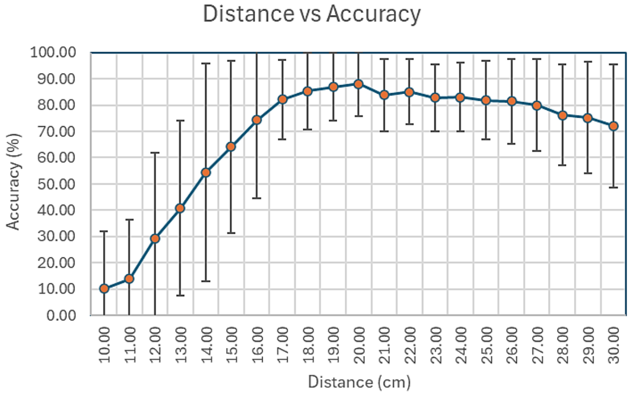

Fig. 7. Line graph shows the trend of accuracy across different distances with error bars representing standard deviation. Error bars show higher variability at shorter distances, decreasing up to 20 cm.

Therefore, from the line graph, the optimal distance is 20 cm for the highest accuracy and stability. Meanwhile, the variability is high at 10-15 cm, low at 16-20 cm, and increases beyond 20 cm. Now, a histogram with 10% bin width visualises accuracy distribution across distances for clear view in Fig. 8. show that the accuracy values are most frequently distributed between 70% and 90%, with the highest frequency around 80-90%.

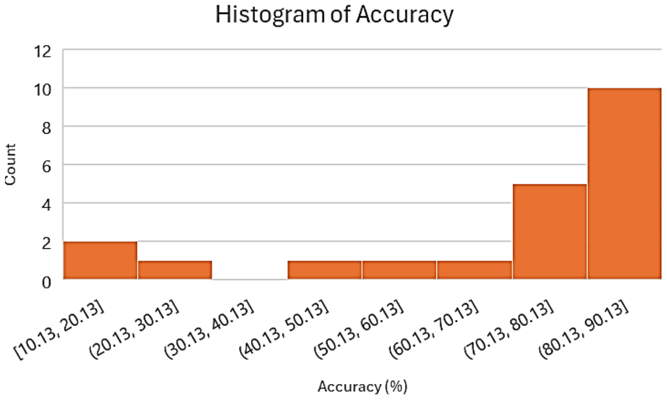

Fig. 8. Histogram depicts the frequency distribution of accuracy across different distances.

d) Percentile analysis of accuracy: The 25th, 50th (median), and 75th percentiles were calculated to comprehend the distribution of accuracy. So, percentiles helped to summarise the central tendency and variability of the data from Table VI.

TABLE VI. PERCENTILE VALUES OF ACCURACY

Percentile	Value (%)
25th Percentile	64.17
50th Percentile	79.85
75th Percentile	83.04

The 25th percentile indicates that 25% of the accuracy values are below 64.17%. The median (50th percentile) is 79.85%, showing that half of the accuracy values are below this value. The 75th percentile indicates that 75% of the accuracy values are below 83.04%. Next, a bell curve in Fig. 9 was generated based on the calculated mean and standard deviation. This visualisation helps in understanding the normal distribution of the accuracy data and provides insights into the performance and consistency of the gesture recognition system.

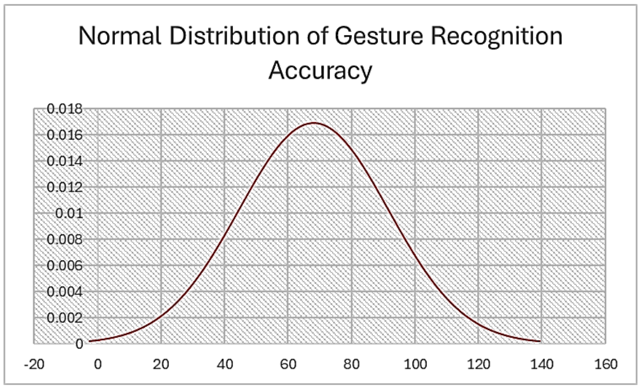

Fig. 9. Bell curve peak indicates most scores are close to the mean, which is around 70% and illustrates the normal distribution of gesture recognition accuracy.

The mean accuracy in Fig. 9 represents the central value of accuracy scores. The graph demonstrates a balanced variability in accuracy scores, with a moderate spread with the highest concentration around the mean and a balanced spread shown by standard deviation manifesting reliability and consistency, essential for its intended use.

e) Camera and laptop model, lighting, and accuracy: The accuracy of gesture recognition was evaluated using different cameras under bright and dim conditions. The outcome was summarised in TABLE VII. TABLE VIII.

TABLE VII. ACCURACY BY CAMERA TYPE AND LIGHTING CONDITION

Model	Bright	Dim
External	70.83	69.29
Laptop A	70.83	67.67
Laptop B	63.74	62.42
Laptop C	73.4	66.78

TABLE VIII. STANDARD DEVIATION FOR ACCURACY LIGHTING CONDITIONS

	Lighting	
Camera/ Model	**Bright**	**Dim**
External	13.334	14.827
Laptop A	8.059	12.515
Laptop B	1.223	12.15
Laptop C	7.879	15.309

By the comparison from Fig. 10 indicates the accuracy evaluation within lighting condition and camera types.

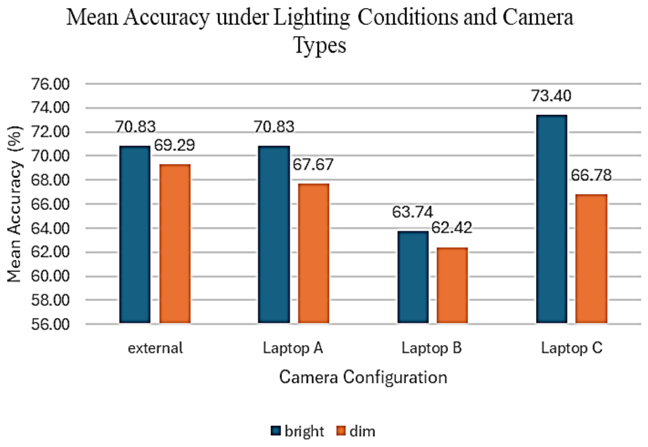

Fig. 10. Bar chart compares accuracies affected by different laptop models and an external camera.

To sum up, Fig. 10 gesture recognition accuracy varies by camera type and lighting conditions. The best performance is from Laptop C under bright lighting achieves the highest accuracy (73.40%), while Laptop B under dim lighting has the lowest performance (62.42%).

f) Palm orientation and accuracy: The accuracy of gesture recognition was also calculated for different palm orientations, as shown in Table IX.

TABLE IX. ACCURACY BY PALM ORIENTATION

Palm Orientation	Average (%)	Standard Deviation
Upper Limb	62.96	27.30
Landed Wrist	7.900	11.548

Table IX specifies that the accuracy for the upper limb orientation is significantly higher (62.96%) compared to the landed wrist orientation (27.30%). The standard deviation is also lower for the upper limb orientation, suggesting more consistent performance. The scatter plot, Fig. 11, reveals those error bars of standard deviation at various distances, highlighting accuracy variability.

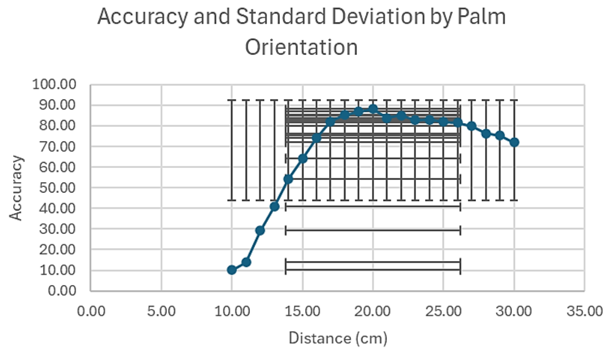

Fig. 11. The scatter plot visualises the relationship between distance (cm) and accuracy (%) for different palm orientations. The upper limb orientation consistently outperforms the landed wrist orientation.

Accuracy sharply increases between 10 cm and 15 cm was revealed in Fig. 11 meanwhile accuracy peaks at 88% at 20 cm, then drops to 72% at 30 cm. High standard deviation at 10-15 cm shows inconsistent performance, while from 16-20 cm it decreases, indicating more consistent accuracy. Standard deviation rises after 20 cm, showing less stable performance. Thus, the optimal distance for gesture recognition in this system was around 20 cm, where it achieved the highest accuracy and consistency, making it the most reliable range for practical applications in remote stroke rehabilitation.

g) Corner angles and accuracy: The impact of the corner angles of the laptop on the accuracy of gesture recognition was investigated and summarised in Table X.

TABLE X. ACCURACY BY CORNER ANGLES

Corner Angle (°)	Average (%)	Standard Deviation
50	61.31	8.02
60	69.95	3.66
70	51.58	12.92

Based on Fig. 12Fig. 12, a corner angle of 60° gives the highest accuracy (69.95%), while the lowest accuracy is observed at 70° (51.58%).

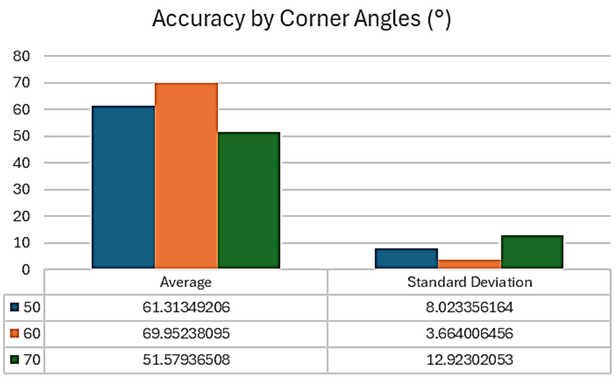

Fig. 12. Accuracy and standard deviation at different corner angles (50°, 60°, 70°).

Therefore, the accuracy and standard deviation of 60° angle as the optimal angle for highest accuracy is proven from the reading.

h) Comparison of accuracy between factors: ANOVA Single-Factor

An ANOVA single-factor analysis was conducted to compare the accuracy of gesture recognition across distinct factors. The results are presented in Table XI, Table XII and Table XIII.

TABLE XI. COMPARISON OF ACCURACY BETWEEN FACTORS

Distance (cm)	Lighting, Camera, and Palm Orientation	Corner Angle
10.00	10.13	26.11
11.00	13.88	26.00
12.00	29.25	40.94
13.00	40.77	50.61
14.00	54.29	49.00
15.00	64.17	60.06
16.00	74.27	77.33
17.00	82.04	76.44
18.00	85.27	74.50
19.00	86.90	79.28
20.00	88.08	77.28
21.00	83.79	73.50
22.00	85.00	72.83
23.00	82.85	72.61
24.00	83.04	69.17
25.00	81.85	66.11
26.00	81.52	64.89
27.00	79.85	60.83
28.00	76.27	57.50
29.00	75.24	56.06
30.00	72.04	48.56

TABLE XI. Table XI had shown the accuracy of gesture recognition at various distances, considering lighting conditions, camera types, palm orientations, and corner angles. Two sets of factors are considered: one combining lighting conditions, camera types, and palm orientations, and the other focusing on corner angles. The accuracies of the factors were generally increased with distance up to 20.00 cm and then declined. It also established different performance trends based on corner angles.

TABLE XII. SUMMARY OF RESULTS

Groups	Count	Sum	Average	Variance
Lighting, Camera, and Palm Orientation	21.000	1430.510	68.120	582.860
Corner Angle	21.000	1279.614	60.934	255.719

An overview of the total count, sum, average accuracy, and variance, in TABLE XII. for the two groups of factors: "Lighting, Camera, and Palm Orientation" and "Corner Angle", were signifying that the average accuracy is higher for the combined group of lighting, camera, and palm orientation compared to the corner angle group.

TABLE XIII. ANOVA TABLE

Source of Variation	Sum of Squares (SS)	Degrees of Freedom (df)	Mean Square (MS)	F-Value	P-value	F critical
Between Groups	542.134	1.000	542.134	1.293	0.262	4.085
Within Groups	16771.586	40.000	419.290			
Total	17313.720	41.000				

F-Value: 1.29 (less than the F-Critical value of 4.08), indicating no significant difference. Similarly, P-Value: 0.26 (greater than 0.05), failing to reject the null hypothesis. In short, the ANOVA test indicates that there is no statistically significant difference across settings.

C. Hand Gesture Recognition Accuracy Calibration Outline

1) Key findings by settings: Table XIV reveals the concise version of the experimental products after the observation and analysis.

TABLE XIV. SUMMARY OF ANALYSIS

Setting	Key Finding
Distances and Accuracy	• Optimal distance: 20 cm (accuracy: 88.08%). • High variability at 10-15 cm, low at 16-20 cm, increases beyond 20 cm.
Camera and Lighting	• Best performance: Laptop C under bright lighting (accuracy: 73.40%). • Lowest performance: Laptop B under dim lighting (accuracy: 62.42%).
Palm Orientation	• Higher accuracy with upper limb orientation (62.96%).
Corner Angle	• Optimal angle: 60° (accuracy: 69.95%).
ANOVA Analysis	• No significant differences across settings (F-Value: 1.29, P-Value: 0.26).

A concise summary of the key findings from the analysis was provided Table XIV to highlight the optimal settings for distance, camera, lighting, palm orientation, and corner angle for achieving the highest gesture recognition accuracy. The ANOVA analysis confirms that there are no significant differences across the settings tested.

2) Comparative analysis and unique contributions of current research in hand gesture recognition: The comparison of the obtained results on hand gesture recognition to other studies in the field, it is evident that this experiment on calibration outcomes provide valuable insights that surpass the relevance and accuracy of many existing works. While various studies have explored different aspects using technologies such as deep learning algorithms, data gloves, and EMG sensors, this calibration findings stand out for its specific focus on key factors that significantly impact accuracy and performance in hand gesture recognition systems.

Luo et al. [75] and Yılmaz [76] had previously investigated the use of CNNs and deep learning algorithms for gesture recognition, which are common approaches in the field. However, by pinpointing the optimal distance for accuracy at 20 cm and highlighting the impact of camera and lighting conditions on performance, has already surpassed their products. This specificity in identifying the ideal conditions for accurate gesture recognition sets this current research apart from these more general approaches such as altering genetic algorithms for the recognition under the same lighting alone.

Similarly, Gao et al. [77] had emphasised the reliability of data-glove-based methods for gesture recognition, which can indeed yield high accuracies. In addition, exploration on the binary serial image implied image extraction calculation with depth-sensor-based gesture recognition, showcasing the diversity of approaches in the field. does not seem practical when it comes to investigating the skin colour [78]. Nonetheless, this calibration study abled to provide more practical insights by focusing on the impact of palm orientation and corner angle on accuracy, offering tangible guidance for improving recognition rates beyond just the choice of recognition method, especially while considering the ability of stroke patients, to enable a layer of real-world applicability.

Moreover, while studies as per Farid et al. [79] discuss the application of vision-based systems for gesture recognition. Conversely, by conducting a detailed analysis of how different factors such as distance, lighting, and hand orientation affect accuracy the optimal settings for these variables, these calibration findings proposed a more comprehensive understanding of the nuances involved in achieving high accuracy rates in gesture recognition systems.

Furthermore, ANOVA analysis conducted has revealed no significant differences across settings, contrasts with the emphasis on specific methodologies and algorithms [80], [81]. While these studies contribute valuable insights into the technical aspects of gesture recognition. According to DoE factors that were implemented in this research, it was certain that focusing on the has been impactful compared to the environmental settings of the existing literature.

The outcomes of the experiment were recorded by observing the accuracy as shown in Fig. 13. The provided images in Fig. 13 demonstrate the performance of a gesture recognition system under various conditions. Fig. 13(A) shows a fist gesture in upper limb orientation with landmarks, achieving 22% accuracy for pinch extension at a close distance to the camera, indicating clear recognition. Fig. 13(B) depicts a fist gesture slightly further from the camera, resulting in 8% accuracy, highlighting the impact of increased distance on the system's performance. Fig. 13(C) illustrates a pinch gesture with 71% accuracy, measured by the distance between specific landmarks in a bright setting, underscoring the importance of good lighting for accurate recognition. Fig. 13(D) shows a fist gesture at 30 cm distance in landed orientation under dim lighting, with 7% accuracy, demonstrating the challenges of maintaining high accuracy at greater distances and under poor lighting. Fig. 13(E) presents a fist gesture at a closer distance in landed orientation under dim lighting, achieving 0% accuracy for pinch gesture recognition, highlighting the system's limitations in dim lighting conditions. Fig. 13(F) demonstrates perfect accuracy for the pinch extension gesture in upper limb orientation under dim lighting, indicating that the system can achieve high accuracy with proper calibration even under suboptimal lighting. These observations suggest that gesture recognition accuracy is influenced by distance, lighting conditions, and the specific gesture being performed.

D. *MediaPipe Framework Implementation*

MediaPipe provides a robust solution for real-time, on-device machine learning, particularly hand gestures, facial landmarks, and pose detection. One of its primary benefits is that it does not require extensive training, unlike many traditional machine learning models. MediaPipe's pre-trained models facilitate immediate recognition capabilities, making it an efficient and practical choice for works that demand quick and accurate results without the need for a deep understanding of machine learning algorithms or the resources required for training datasets.

E. *Overcoming Data Security and Reliability Downsides with Smart Healthcare*

Ensuring data security and reliability is paramount due to the sensitive nature of patient information being transmitted across networks. Several strategic approaches can be employed to overcome these challenges effectively. The implementation of IoT in this study, which was included in the factorial DoE, aligns with the trends and challenges identified in by Zainuddin et al., [24] by demonstrating the practical applications and potential hurdles of integrating advanced technologies in healthcare.

Firstly, implementing robust encryption protocols, such as end-to-end encryption, ensures secure data transmission and storage [82]. Encryption plays a crucial role in protecting patient data from unauthorised access during transfer between devices and servers. Incorporating blockchain technology, data integrity and security were enriched through providing a decentralised and immutable ledger for recording transactions [83]. Once patient data is stored in the blockchain, it becomes tamper-proof, ensuring its accuracy and reliability.

Moreover, an advanced machine learning algorithms can significantly improve the reliability of smart healthcare systems by enabling accurate data analysis and predictions [84]. These algorithms can detect anomalies in data transmission, flag security threats in real-time, and predict system failures to enhance reliability.

Furthermore, utilising multi-factor authentication (MFA) adds an extra layer of security by requiring multiple forms of identification for system access [85]. This approach reduces the risk of unauthorised access, even if one factor is compromised.

In addition, regular security audits and vulnerability assessments are essential for identifying and addressing potential security weaknesses in smart healthcare systems [86]. By evaluating the system's security posture routinely, necessary updates and patches can be implemented to safeguard against emerging threats.

In short, by employing encryption, blockchain technology, machine learning algorithms, multi-factor authentication, and security assessments smart healthcare systems can effectively manage data security and reliability, ensuring the secure and reliable transmission of patient information.

F. The Impact of Secure Calibration with DoE

Calibration methods improve recognition accuracy and system reliability. Technology integration is important for securing the calibration process and optimising performance.

Tanwar et al. [87] conducted a study on secure calibration methods and technology integration in gesture recognition. The research emphasised the importance of preserving privacy in sign language recognition using deep learning for encrypted gestures. Hence, the encryption techniques are crucial for ensuring the security, integrity, and reliability of gesture recognition systems.

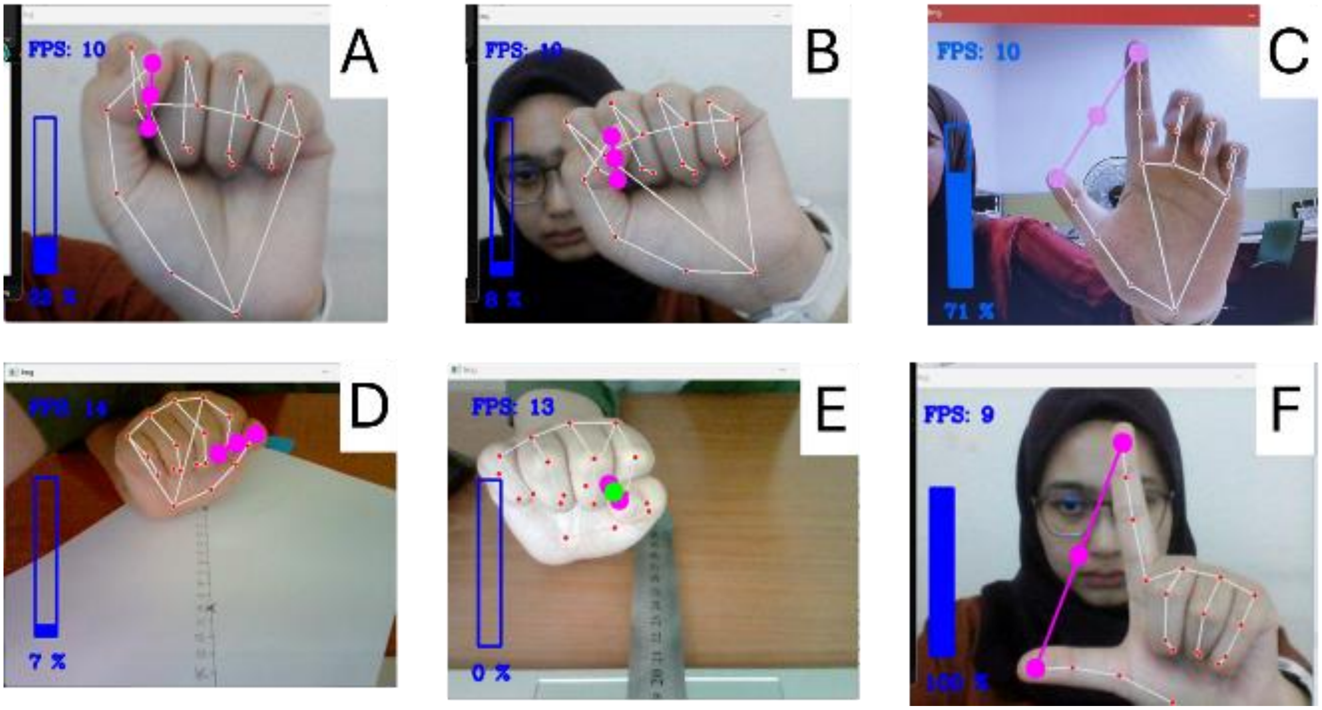

Fig. 13. Screenshots of hand gesture recognition accuracy for calibration.

Fig.13. A. Fist gesture in upper limb orientation with landmarks manifested 22% accuracy for pinch extension in a close distance between camera and palm where the gesture was fully and clearly recognised in the window. In this scenario, the gesture was fully and clearly recognized in the window, highlighting the system's potential for precise recognition at short distances.

Fig. 13. B. A demonstration of the fist gesture slightly further from the camera yielded an accuracy of 8%. This reduction in accuracy emphasises the impact of distance on the system's performance, with closer distances generally providing better recognition.

Fig. 13. C. The accuracy of the pinch gesture (71%) was calculated by measuring the distance between landmark 4 and landmark 8 in a bright setting. This high accuracy underscores the importance of bright lighting conditions for optimal gesture recognition.

Fig. 13. D. At 30.00 cm, the system recorded an accuracy of 7% for recognising a fist gesture in landed orientation under dim lighting conditions. This result illustrates the challenges of maintaining high accuracy at greater distances and under poor lighting.

Fig. 13. E. A closer distance of the fist gesture in landed orientation under dim lighting conditions resulted in an accuracy of 0% for pinch gesture recognition. This scenario highlights the limitations of the system in dim lighting, even at closer distances.

Fig. 13. F. Perfect accuracy was measured for the pinch extension gesture in upper limb orientation under dim lighting conditions. This indicates that the system can achieve high accuracy in certain gestures and orientations, even under suboptimal lighting, demonstrating the potential for robust performance with appropriate calibration.

Overall, the investigation on hand gesture recognition stands out for its meticulous examination of the impact of distance, lighting, palm orientation, and corner angle on accuracy. By providing specific recommendations for optimal conditions and highlighting the practical implications of these discoveries offer a valuable contribution to the field of gesture recognition that surpasses many existing studies in terms of relevance and applicability.

V. Conclusion

In conclusion, this research has demonstrated the potential of integrating the MediaPipe framework with the Rehabilitation Internet-of-Things (RIOT) to enhance the accuracy and security of hand gesture recognition in smart healthcare systems by applying strong methodologies, the DoE for calibration and this study has also addressed the critical challenges of data security, reliability, and accurate assessment in stroke rehabilitation. The results denote that optimising factors such as camera distance, lighting conditions, and palm orientation could significantly improve gesture recognition accuracy. Furthermore, the implementation of advanced encryption protocols and blockchain technology ensures the secure transmission and storage of sensitive patient data. These advancements are not only facilitating more effective and precise remote rehabilitation but also underscore the importance of multidisciplinary collaboration in developing smart healthcare solutions. Ultimately, this research paves the way for future innovations in healthcare technology, promoting better patient outcomes and more efficient rehabilitation processes. In growing body of research on the combination of IoT and AI in healthcare, building on the foundational work [15], [16]. Future research should continue to explore the intersection of these technologies to further enhance their efficacy and security.

ACKNOWLEDGMENT

This research is partly supported by the Ministry of Higher Ednucation (MOHE) Malaysia under FUNDAMENTAL RESEARCH GRANT SCHEME (FRGS): FRGS23-307-0916; FRGS/1/2023/TK07/UIAM/02/2; Formulation of Associating 4D Skeletal-based Hand Gesture Recognition with Hand Rehabilitation Scoring Of Stroke Patient For Rehabilitation Internet-of-things (RIOT). The assistance and resources provided by National Medical Research Register (NMRR), particularly under NMRR ID-24-02136-NJQ, was instrumental in the successful completion of this paper. Their support played a vital role in the development and execution of this research work.

Analysis of Learning Algorithms for Predicting Carbon Emissions of Light-Duty Vehicles

Rashmi B. Kale[1], Nuzhat Faiz Shaikh[2]
Department of Computer Engineering, Smt. Kashibai Navale College of Engineering (SPPU), Pune, Pune, India[1]
Department of Computer Engineering, Wadia College of Engineering, Pune, Pune, India[2]

***Abstract*—This research presents a comparative analysis of different learning methods developed for the prediction of carbon emissions from light-duty vehicles. With the growing concern over environmental sustainability, accurate prediction of carbon emissions is vital for developing effective mitigation strategies. The work assesses the performance of various algorithms trained on vehicle-specific data attributes to predict the emission patterns of a fuel type of different light duty models. This work uses two real-time petrol and diesel datasets collected by CariQ app and device. Canada government dataset is also used from the online repository for prediction of the vehicle emission. The evaluation is based on their predictive accuracy. The findings reveal insights into the effectiveness of different learning techniques in accurately estimating carbon emissions from vehicles, providing valuable guidance for policymakers and researchers in the field of environmental sustainability and transportation planning.**

Keywords—Carbon emission; machine learning algorithms; CariQ carbon emission dataset; An Air Quality Index (AQI)

I. INTRODUCTION

As we all know the major threat in front of the world is pollution in the present days. Emission is a problem faced by many countries, and the transportation industry which is one of the biggest sources of carbon allowed to be released into the air [1]. Comprehending and reducing the harmful impacts of vehicle emissions on the atmosphere, living organisms, and the environment has become crucial. Vehicle emissions are a complex mixture of gases and particulate matter, carbon monoxide (CO), nitrogen oxides (NOx), hydrocarbons (HC), and particulate matter (PM). Various detection methods have been employed to monitor and measure these emissions, ranging from traditional tailpipe testing to advanced sensor-based technologies [2] [3]. Government agencies mostly used the term AQI to check the air quality of any area. It is decided through the range of pollution values decided for an AQI [4] [5]. These defined range decide, how is the air quality index of any particular area. Delhi is always with sequious AQI in India and someday pollution reached to its top enough like Most of time and many news flashed about it. So, how important it is to understand the hazards of the emissions and their effects on the living creature mostly on humans? Government needs to put some strict policies about the carbon emission.

The carbon trading system [6], was adopted by many nations to cut greenhouse gas emissions. This market-based strategy served to mitigate the effects of global warming, which improved the air quality in an environment. It is employed to lower the atmospheric concentration of CO2. Carbon credit provides financial incentives to businesses that have emitted less carbon, these businesses are granted a permit of carbon credit. Businesses that generate more carbon emissions need to credits from businesses that have produced lesser emissions. The transport industry significantly contributes to greenhouse gas emissions. To mitigate this impact, the government must establish policies, rules, and regulations specifically targeting emissions from individual vehicles. Here, this research work focuses on the insights of the emissions on light-duty vehicles of diesel and petrol.

The rising concern about global climate change and environmental sustainability has made the theoretical analysis and prediction of CO2 emissions vital. Having an accurate model to forecast CO2 emissions could help policymakers, researchers and industrials to figure out how to better plan to mitigate their environmental impact. There are common methods from classical statistics that might not be able to capture all patterns since the emission of CO2 is a little more complex in a non-linear way - that is why one must look not only to classical statistical methods but also to new computational analysis. This research introduces a hybrid approach [20] that combines moving average smoothing with Long Short-Term Memory (LSTM) neural networks to model and forecast CO2 emissions per one hundred kilometres. Raw CO2 emission data is passed through a moving average filter to suppress noise and reveal low-frequency trends. A model, LSTM, known for its capability to handle time series data is then trained on that smoothed data to predict the future CO2 emissions. A type of recurrent neural network (RNN), LSTM networks are well-suited to this task thanks to their ability to maintain long-term dependencies and deal with the sequential nature of time series data. The proposed methodology tries to achieve more precise CO2 emission forecasts by exploiting these properties. Here, the study first preprocess the raw CO2 emission data by smoothing the data with a moving average filter with a window size of two, and then create two time series for modeling. Now we prepare a dataset suitable for the LSTM model by creating a series of time-lagged input-output pairs in the data. Finally, a dataset is prepared to train a computer using an LSTM model. Predictions are then made, and the Mean Squared Error is calculated.

The findings in this study indicate that moving average filtering combined with the use of LSTM networks could successfully predict CO2 emissions. This approach provides convenient time series analysis tools in environmental studies and increases the predictive accuracy. This work has important implications which present a novel method in which to be able to forecast for any domain where very accurate time series forecasts are required. This section provides information on the

Emissions of Light Duty Vehicles prediction system. The second part includes the literature survey of the system and in addition the Air Quality Index chart (AQI). The third section discussed the proposed work and in the last section, all the results are locally minimized.

II. Literature Survey

The swift growth of urbanization and industrialization has caused a notable surge in global air pollution levels. Among the various pollutants, carbon dioxide emissions are particularly high. This study [7], [8], investigates the prediction of vehicle carbon emissions on metropolitan road networks through the use of sensor networks and real-time data analytics. It explores enhancing the accuracy of emission forecasts by utilizing prediction algorithms, data fusion techniques, and optimal sensor placement. Navigation systems [9], have gotten more and more data-driven in recent years due to the emergence of mobile computing devices and the widespread use of GPS technology. This work presented a navigation system based on traffic incident notification in 2012. Numerous base stations, communication networks, and sensors make up the system. It decides feasible routes to drivers through navigation paths and reduce the vehicular emissions. This study in [10], does a thorough examination of vehicle carbon emissions across time, focusing on temporal dynamics to detect seasonal fluctuations, peak emission periods, and long-term trends. In order to anticipate future emission trends and assist in the formulation of policy, it creates predictive models. In order to anticipate carbon emissions, this study [11], looks into the integration of vehicle telematics data, such as GPS trajectories, engine performance indicators, and fuel consumption rates. It looks at how telematics-enabled technologies can improve fleet operations and lessen their negative effects on the environment. In order to forecast vehicle carbon emissions under different policy interventions, such as fuel efficiency standards, emission laws, and investments in transportation infrastructure, this study [12], uses scenario analysis methodologies. It assesses how well various policy scenarios work to meet emission reduction goals. This study in [13], investigates predictive maintenance techniques with an emphasis on fleet management tactics in order to maximize vehicle performance and minimize carbon emissions. In order to improve fleet sustainability, it looks at how to integrate condition monitoring, remote diagnostics, and predictive analytics. Government organizations mostly employed the term "AQI" to assess the air quality of any area. The index values and AQI [14], [15], color shown in the Table I determine the range of the air quality, based on these concern levels are decided. Most of the metropolitan cities falls under maroon to a red zone that is very unhealthy and hazardous for living creature.

TABLE I. Air Quality Index Chart

AIR QUALITY INDEX CHART			
AQI Color	***Levels of Concern***	***Index Value***	***Quality of Air and effects on human***
Green	Good	0 to 50	Efficient air pollution does not present significant risks.
Yellow	Moderate	51 to 100	Acceptable, but for some who are sensitive to air pollution, may have a risk.
Orange	Unhealthy for Sensitive Groups	101 to 150	Poor, sensitive people may experience health effects.
Red	Unhealthy	151 to 200	Very Poor, sensitive people may experience more serious health effects.
Purple	Very Unhealthy	201 to 300	Extremely poor
Maroon	Hazardous	301 and higher	Extremely worst

III. Proposed Work

A. Data Collection

This work is focusing on the automobile sector and the emission patterns of different vehicle models, fuel types of light duty vehicles. This research utilized a mobile application called CariQ to collect real-time carbon emission data from vehicles operating within Pune City for nearly two years. The resulting dataset serves as the foundation for this project [16], [17], [18], [19]). CariQ Mobile app screen shot is shown in Fig. 1.

In Fig. 2, it shows mixed dataset of all petrol and diesel fuel type also created. Fig. 2 shows the screenshot of some samples of dataset created through CariQ device and mobile app.

B. Proposed Methodology

This study's methodology encompasses a sequence of steps designed to process and model CO2 emission data, employing both a moving average filter and an LSTM (Long Short-Term Memory) neural network.

1) Data Preparation

a) Initial Data

- Input Data: *per_hundred_KM_CO2_emission* is an array representing CO2 emissions per 100 km for a series of observations.

b) Smoothing Data

- Moving Average Filter: Apply a moving average filter with a window size of 2 to smooth the data. This reduces noise and helps in trend detection.

2) Dataset Creation for LSTM

a) Sequence Generation

- Look-back Window: Define a look-back window (*look_back = 1*) to create input-output pairs for the LSTM model. This means the model uses the value at time *t* to predict the value at time *t+1*.
- Function create_dataset: This function generates sequences of inputs and corresponding outputs from the smoothed data.

Fig. 2. Screen shot of some samples of created dataset.

3) LSTM Model Training

a) Data Reshaping

- Reshape Input Data: Reshape the input data to the required shape for LSTM, which is [*samples, time steps, features*].

b) Model Definition

- LSTM Model: Define an LSTM model with one hidden layer containing four units.

- Dense Layer: Add a Dense layer with one unit to produce the output.

c) Model Compilation and the Training

- Compile Model: Compile the model with Mean Squared Error (MSE) as the loss function and the Adam optimizer.

- Fit Model: Train the model on the training data for 100 epochs with a batch size of 1.

4) Making Predictions

a) Predictions on Training Data

- Train Predictions: Use the trained model to predict values on the training data.

b) Future Predictions

- Future Values: Predict future values for an extended range using the model.

5) Model Evaluation

a) Calculate MSE

- Mean Squared Error: Evaluate the model's performance by calculating the Mean Squared Error between the actual smoothed data and the predicted values.

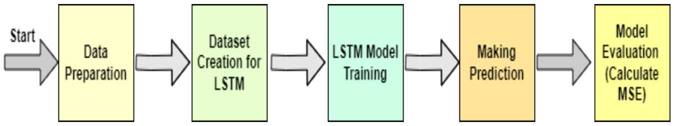

Fig. 3. Proposed methodology for predicting carbon emissions.

This methodology involves data smoothing using a moving average, preparing data sequences for LSTM input, defining and training an LSTM model, making predictions, and evaluating the model's performance using Mean Squared Error as shown in Fig. 3. This approach leverages deep learning to model time series data effectively.

IV. Results And Discussion

Around 175 Diesel and 125 Petrol Vehicles are considered to create Carbon Emission dataset. Fig. 4 illustrates the number of Diesel and Petrol vehicles included in the dataset. This dataset combines various types of light-duty vehicles and fuel types for assessment.

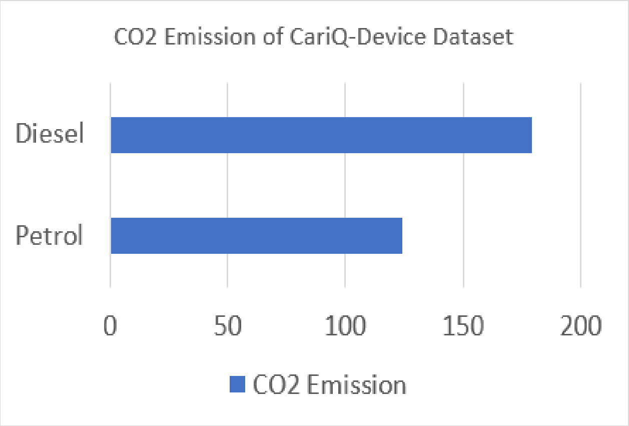

Fig. 4. Number of petrol and diesel vehicles.

Different machine learning algorithms were applied to two different datasets of petrol and diesel vehicles to find out the emission patterns. Fig. 5 shows a scatterplot of carbon emission in gm/km through the diesel vehicle.

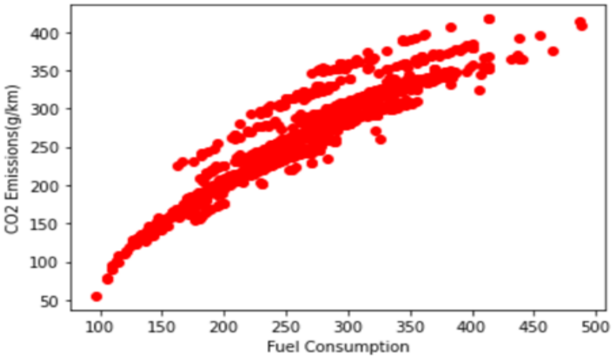

Fig. 5. Diesel vehicle carbon emission.

Fig. 6 shows scatterplot of carbon emissions in gm/Km through a Petrol vehicle. From both the petrol and diesel dataset results, it has been observed that a diesel vehicle produces more carbon emission than the petrol vehicle.

Fig. 7 shows boxplot of Carbon emissions of both petrol and diesel vehicles.

Now, after statistical analysis step, Machine learning algorithms are applied to the dataset, Based on this mean square error for each algorithm is shown in Fig. 7.

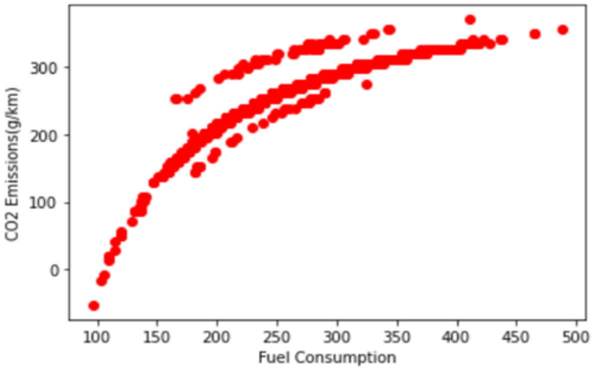

Fig. 6. Petrol vehicle carbon emission.

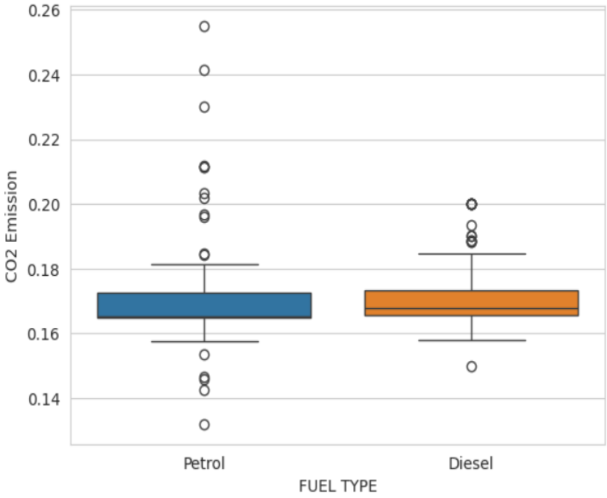

Fig. 7. Boxplot of CO2 Emissions by petrol and diesel vehicles.

Fig. 8 and Table II show MSE values got from the different machine learning algorithms. Proposed system algorithm applied to the dataset gives minimum MSE value than other algorithms. Proposed system algorithm is the advanced LSTM algorithm.

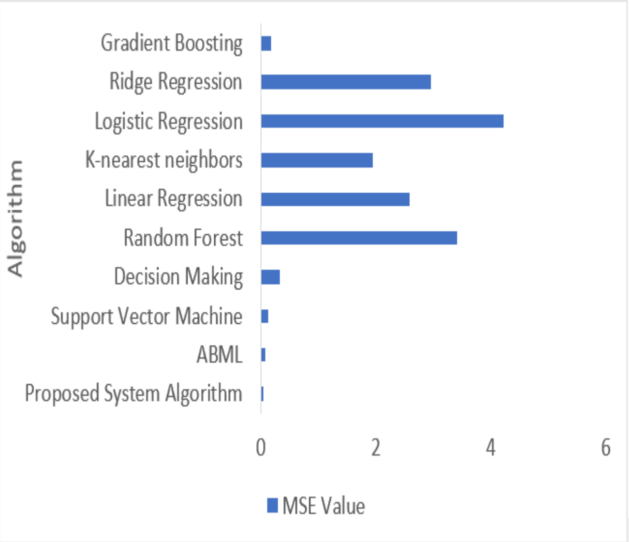

Fig. 8. MSE values for a different machine learning algorithms.

TABLE II. MSE VALUES FOR DIFFERENT MACHINE LEARNING ALGORITHMS

Learning Algorithms	***MSE***
Gradient Boosting	0.179
Ridge Regression	2.95
Logistic Regression	4.218
K- nearest neighbors	1.942
Linear Regression	2.591
Random Forest	3.414
Decision Making	0.328
Support Vector Machine	0.128
ABML	0.083
Advanced LSTM (Ours)	0.047

Another dataset used for vehicular carbon emission is Canada government dataset. Vehicle carbon emission data assessment provides comprehensive information on emissions produced by various types of vehicles and a different type of fuel. Fig. 9 shows CO_2 emission by five different fuel types' natural gas, diesel, regular gasoline premium gasoline and ethanol (E85). Through this dataset assessment, it is found that ethanol vehicle emission more than other fuel types.

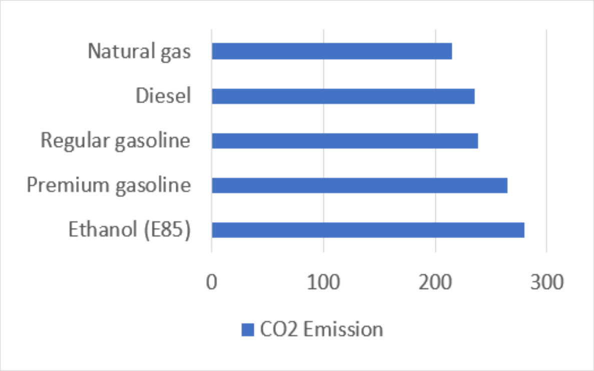

Fig. 9. Carbon emission for different fuel types of Canada government dataset.

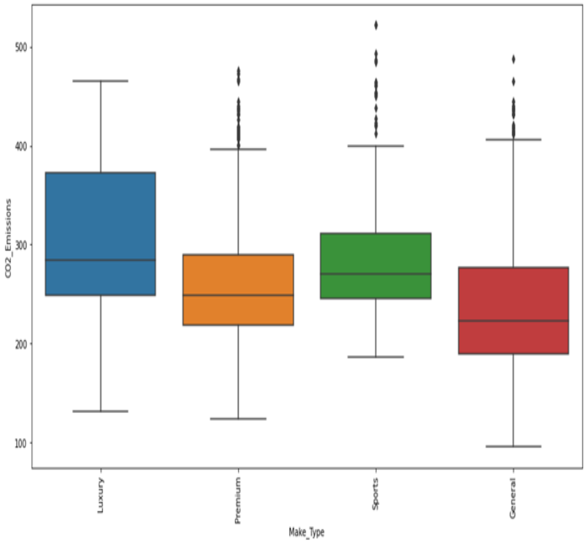

Fig. 10. Boxplot of carbon emission by various light duty vehicle.

Fig. 10 shows the boxplot of CO2 emission of vehicles for different light duty vehicle categories. From this analysis it has been analysed that luxury vehicles produces more emissions than other category vehicles.

V. CONCLUSION

This study emphasizes the significance of predicting carbon emissions from light duty vehicles amidst growing concerns for environmental sustainability. Through this comparative evaluation of machine learning-based approaches, it assesses the performance of various algorithms trained on a vehicle-specific data attributes. Leveraging real-time datasets from petrol and diesel vehicles collected via the CariQ app and device, alongside Canada government data. Data analysis focused on predictive accuracy. The various types of vehicle data studied and concluded that a luxury vehicle and diesel vehicles emit more carbon in the environment. The findings shed light on the effectiveness of different machine learning techniques in estimating carbon emissions, offering valuable insights for policymakers and researchers engaged in environmental sustainability and transportation planning. By adopting and promoting multi-modal transportation by investing in and encouraging public transit infrastructure and active transportation. By putting these suggestions into practice, academics and policymakers may strive toward creating more resilient and sustainable transportation networks that lessen their negative effects on the environment and enhance everyone's quality of life.

Metaheuristic Optimization for Dynamic Task Scheduling in Cloud Computing Environments

Longyang Du*, Qingxuan Wang
School of Artificial Intelligence, Jiaozuo University, Jiaozuo 454000, Henan, China

***Abstract*—Cloud computing enables the sharing of resources across the Internet in a highly adaptable and quantifiable way. This technology allows users to access customizable distributed resources and offers various services for resource allocation, scientific operations, and service computing via virtualization. Effectively allocating tasks to available resources is essential to providing reliable consumer performance. Task scheduling in cloud computing models presents substantial challenges as it necessitates an efficient scheduler to map multiple tasks from numerous sources and dynamically distribute resources to users based on their requirements. This study presents a metaheuristic optimization methodology that integrates load balancing by dynamically distributing tasks across available resources based on current load conditions. This ensures an even distribution of workloads, preventing resource bottlenecks and enhancing overall system performance. The suggested method is suitable for both constant and variable activities. Our technique was compared with established metaheuristic methods, including HDD-PLB, HG-GSA, and CAAH. The proposed method demonstrated superior performance due to its adaptive load balancing mechanism and efficient resource utilization, reducing task completion times and improving overall system throughput.**

***Keywords*—Dynamic task scheduling; cloud computing; metaheuristic optimization; load balancing; task allocation; resource utilization**

I. Introduction

A. Context

Cloud computing is a rapidly evolving technology, marking its place as the next generation in IT and business landscapes [1]. It offers a spectrum of services, including reliable software and hardware, accessible through the Internet and remote data centres [2]. With its architecture, cloud services efficiently manage diverse computing tasks on a large scale, covering multiple IT functions such as storage, computation, database, and application services [3]. The increasing demand for storage, processing, and analysis of extensive datasets has propelled organizations and individuals to embrace cloud computing [4]. Scientific applications, notably those requiring significant computational resources for extensive experiments, have found refuge in cloud deployments due to limitations in local server facilities [5]. Reduced capital costs, immense data generation, and consumption growth from these experiments have driven this shift. Moreover, cloud service providers are now incorporating data parallelism capabilities into their offerings, empowering users to leverage cloud resources and execute their workflows more effectively [6].

B. Problem Statement

Cloud computing is a paradigm that enables universal, flexible, and immediate access to various configurable computing resources in the form of services, applications, storage, servers, and networks, easily delivered and released without much service provider interaction or management effort [7]. It serves as a solution with several advantages to overcome economic and technological challenges. The cloud computing model offers lower total costs and allows companies to concentrate on their primary tasks and functions without concerning themselves with infrastructure issues or the availability and flexibility of resources [8].

Furthermore, the amalgamation of cloud services, including computation, infrastructure, and storage, into the utility model of cloud computing presents an exceptionally appealing environment for scientists to conduct their experiments [9]. Cloud computing provides various service models tailored to meet distinct customer requirements. Cloud service models can be classified as Platform as a Service (PaaS), Software as a Service (SaaS), or Infrastructure as a Service (IaaS) [10]. IaaS offers virtual computing resources over the Internet. It allows users to manage and operate applications without needing to handle physical hardware complexities by combining virtual machines, storage, and networks [11]. PaaS allows customers to develop, run, and manage applications independently of the underlying infrastructure [12]. It includes development frameworks, databases, and tools. SaaS provides subscription-based access to software applications over the Internet [13].

C. Motivation

In recent years, the issue of task scheduling within a distributed environment has become a focal point for researchers. Task scheduling is regarded as a critical concern in the cloud computing domain, taking into account various factors such as completion time, overall cost of executing users' tasks, resource utilization, power consumption, and fault tolerance [14]. The challenge arises in attaining the optimal equilibrium between the time required to complete a task and the amount of energy consumed for a parallel application bound by precedence, resulting in a problem of bi-objective optimization. The resolution to this problem yields a collection of Pareto points, where Pareto solutions indicate that enhancing one target requires making concessions in at least one other objective. Therefore, the resolution to a bi-objective issue comprises a collection of Pareto points rather than a single answer.

Task scheduling in cloud computing environments is commonly known as an NP-complete and multi-objective optimization issue [15]. It deals with the allocation of user-defined tasks on the existing cloud virtual machines. The main goal of any task scheduling strategy is to minimize total execution time. An effective solution to this challenge may be achieved by integrating multiple approaches to enhance task execution and optimize the utilization of resources. This can be achieved by optimizing task placement, task scheduling, and task execution. Additionally, task scheduling algorithms should be adaptive and capable of continuously optimizing their operations in response to changing workloads and resource availability.

D. Contribution

The current investigation centers on implementing and comparing metaheuristic optimization techniques for task scheduling. We compare such methods with conventional heuristics, addressing the problem of scheduling static tasks independently in cloud infrastructure contexts. Experiments are conducted in both uniform and uneven environments. In the uniform scenario, virtual machine characteristics remain constant, whereas the asymmetric environment involves a random selection of virtual machines based on diverse features like MIPS, Bandwidth, and RAM. Despite the simplicity of the symmetric scheduling approach, it fails to fully exploit the potential offered by the asymmetric characteristics of virtual machines. Section I and Section II provide an overview of various conventional metaheuristic task scheduling approaches along with their inherent limitations. Section III gives a comprehensive description of the proposed optimization strategy. Section IV describes the simulation setup and outlines diverse experiments conducted, all grounded in the proposed technique. Finally, Section V articulates the paper's conclusions and suggests potential avenues for future research enhancements applicable to the proposed optimization technique.

II. Related Work

This section discusses existing research efforts addressing task scheduling challenges in cloud computing contexts. Several methodologies have been explored for optimizing the allocation of tasks to virtual machines, enhancing system efficiency, reducing execution times, and maximizing resource utilization. Table I compares various cloud computing task scheduling approaches.

Yang, et al. [16] proposed a task scheduling algorithm derived from game theory in their research. This paper presents three significant contributions tailored to the features of cloud computing. Primarily, leveraging game theory enhances the coordination between task distribution and energy allocation. Secondly, the paper offers a task-scheduling framework to handle big data through a mathematical formulation. Verification by experiment in this research attests to both stable states and optimal computational efficiency.

Chaudhary and Kumar [17] proposed a novel load scheduling technique named Hybrid Genetic-Gravitational Search Algorithm (HG-GSA) with the aim of reducing the overall computational burden, encompassing both execution and transfer costs. HG-GSA employs a hybrid crossover mechanism to explore the optimal arrangement of particles in the search space. The calculated force is then utilized to determine an optimal particle position. The performance of HG-GSA is evaluated against alternative methods using the CloudSim simulator. Through convergence analysis and quantitative assessments, the proposed HG-GSA approach significantly reduces the total computation cost over existing algorithms such as PSO, Cloudy-GSA, and LIGSA-C.

Imene, et al. [18] applied the Non-dominated Sorting Genetic Algorithm (NSGA-III), a third-generation multi-objective optimization strategy, for scheduling cloud computing tasks. They introduced an innovative multi-objective adaptation process designed to optimize three crucial factors: cost, power consumption, and runtime. Further, the study conducted a comparative analysis between NSGA-III and its precursor, NSGA-II, revealing that NSGA-III outperformed NSGA-II.

TABLE I. An Overview of the Recent Cloud Task Scheduling Approaches

References	Algorithm	Contributions	Evaluation metrics
[16]	Game theory-based task scheduling	Mathematical model for big data task scheduling and experimental verification	Equilibrium states and computational efficiency
[17]	Hybrid genetic-gravitational search algorithm	Novel hybrid crossover mechanism	Convergence analysis, statistical assessments, and computation cost reduction
[18]	Non-dominated sorting genetic algorithm	Novel multi-objective adaptation function	Runtime, power consumption, and cost
[19]	Hybrid deadline-constrained, dynamic VM provisioning and load balancing	Hybridization of heuristic techniques with metaheuristic	Makespan, cost, and VM utilization
[20]	Context-aware adaptive heuristic-based mechanism	Context-aware adaptive heuristic-based solution and significant performance improvements	Performance efficiency and energy savings
[21]	Adaptive ant colony optimization algorithm	Pheromone adaptive update mechanism	Task completion time, execution cost, and balance degree
[22]	Moth search algorithm with differential evolution	Strong exploration and exploitation	Makespan
[23]	Chemical reaction partial swarm optimization	Integration of chemical reaction optimization and partial swarm optimization	Execution time, makespan, cost, and energy
[24]	Deep Q-learning network	Utilization of deep Q-learning network	Makespan, SLA violation, and energy consumption

Kaur and Kaur [19] proposed a hybrid delay-constrained dynamic virtual machine provisioning and load balancing approach called HDD-PLB. The primary goal of HDD-PLB is to enhance VM utilization by achieving uniform load distribution. This optimization strategy relies on combining heuristics with metaheuristics to attain optimum performance, focusing on metrics such as cost and makespan. Within the HDD-PLB methodology, two heuristics are proposed: hybrid heterogeneous earliest finish time heuristic with Ant Colony Optimization (ACO) algorithm and hybrid predicted earliest finish time heuristic with ACO algorithm. A comprehensive analysis and comparison of these approaches is conducted to determine their superiority within the proposed HDD-PLB model.

Kulkarni and Annappa [20] proposed an effective context-aware adaptive heuristic-based (CAAH) methodology tailored for virtual machine allocation in diverse and heterogeneous cloud data centers. CAAH accounts for both the inherent properties of physical machines and the varying load conditions (moderate or high) within heterogeneous data centers. The primary objective is to augment performance efficiency and facilitate power savings for operators managing data centers. Through experimental assessments employing both genuine cloud workloads and synthetic workloads, noteworthy enhancements in performance and energy conservation were observed with CAAH in comparison to a widely recognized adaptive heuristic-based technique.

Liu [21] proposed a dynamic task-scheduling technique designed for cloud computing and based on the ACO algorithm. Their proposed approach enhances the standard ACO by integrating pheromone adaptive updating to expedite convergence while effectively circumventing local optima. This enhanced algorithm generates a distribution scheme that offers reduced processing time, minimized costs, and well-balanced task loads based on user-submitted tasks. By conducting experiments on a cloud computing platform, the traditional ACO is compared against the enhanced adaptive ACO algorithm. The empirical data illustrates that the improved adaptive ACO efficiently identifies optimal solutions for cloud computing resource scheduling issues, resulting in reduced task completion times, decreased execution costs, and maintaining a balanced load across the cloud system.

Abd Elaziz, et al. [22] introduced an innovative approach to solving the cloud task scheduling challenge with a primary focus on minimizing the amount of time needed to schedule diverse tasks across distinct virtual machines. The proposed methodology incorporates the Differential Evolution (DE) technique into the Moth Search Algorithm (MSA). The MSA draws inspiration from moth navigation toward a light source, a natural process, leveraging Levy flights and phototaxis to emulate exploitation and exploration capabilities. While the MSA exhibits robust exploration abilities, its exploitation facet requires enhancement, prompting the integration of DE as a local search technique. Three experiments were performed to measure the effectiveness of the newly introduced MSDE algorithm. The initial test compares the performance between the classic MSA and the modified algorithm across twenty global optimization problems. In the subsequent two testing phases, the proposed algorithm was benchmarked with various heuristic and meta-heuristic algorithms, utilizing both synthetic and real-world data.

Dubey and Sharma [23] introduced a pioneering task scheduling approach, termed Chemical Reaction Partial Swarm Optimization (CRPSO), to allocate several independent tasks to available virtual machines. This innovative method combines partial swarm optimization and chemical reaction optimization, amalgamating their features to sequence the optimal task schedule based on demand and deadlines. The aim is to enhance quality across various factors such as cost, energy, and makespan. Their simulation experiments, conducted via the CloudSim toolkit, confirm the performance of the proposed algorithm. Comparative tests, varying the number of tasks and virtual machines, demonstrate an average reduction in execution time ranging between 1% to 6%, exceeding 10% in certain scenarios. The makespan results also exhibit an effectiveness enhancement between 5% to 12% and a total cost reduction between 2% to 10%, while the energy consumption rates show an improvement of 1% to 9%.

Mangalampalli, et al. [24] utilized a multi-dimensional deep learning algorithm to manage the cloud task scheduling issue, conducting extensive simulations through the Cloudsim toolkit. The simulations were executed in two phases: first utilizing randomly generated workloads and then incorporating HPC2N and NASA workloads to assess the efficiency of the suggested algorithm. The proposed scheduler was compared against conventional schedulers like Earliest Deadline First, RR, and FCFS.

III. Proposed Method

The client provides a set of tasks, aiming to generate an optimal task execution plan using a metaheuristic method based on optimization techniques. One vital aspect of any meta-heuristic algorithm in achieving an optimal solution is the selection of a seed arrangement. Arrangements of seeds serve as initial feasible solutions to the problem, aiding optimization algorithms in the quest for an optimal solution. These arrangements play a critical role in the rapid convergence of any optimization-based solution. Researchers have employed various strategies to generate seed arrangements, depending on the nature of the problem. These strategies encompass selecting a complex arrangement, a logical configuration based on a particular problem model, or a heuristic-based arrangement. Each approach has its own advantages and drawbacks. However, in many cases, an uneven seed arrangement is utilized to generate a seed arrangement in the absence of a proper heuristic.

The proposed algorithm aims to minimize execution time and meet deadlines while preserving task dependencies across various users. It operates based on a Directed Acyclic Graph (DAG) representing the task set (T) and task dependencies through edges denoting data transmission time. These relationships establish entry-exit dependencies between child and parent nodes, forming the basis of the task behavior. The proposed algorithm operates as a population-based approach, aligning with swarm intelligence behavior to provide an optimized solution to complex data. It functions as a meta-heuristic technique in comparison to other algorithms. The algorithm encompasses two phases: scheduling jobs with static constraints and dynamic constraints. These phases aim to handle task positions in the schedule based on execution time and deadlines, with a primary goal of minimizing the makespan. The algorithm considers the constraints stated by the user and adjusts the tasks accordingly, ensuring dependencies are maintained throughout the sorting process.

During the task scheduling process, the algorithm utilizes swarm behavior, mimicking the distribution and interaction patterns of particles for improved optimization of multi-objective tasks. Its adaptability helps in solving a wide range of NP-hard-level tasks, effectively handling the scheduling of various tasks on different machines. The algorithm's efficiency is further enhanced by its ability to detect all scheduled tasks, ensuring effective outcomes. Employing a random phase, the algorithm aims to optimize the scheduling of cloudlets for execution on Virtual Machines (VMs). Particle fitness, bandwidth, MIPS, flow time, response time, resource usage, throughput time, and imbalance degree guide the selection of particles in the pursuit space, ensuring improved wellness values and effective execution outcomes.

The aim is to allocate a set of tasks $(T = T_1, T_2, T_3, \ldots, T_n)$ onto a designated group of processors $(P = P_1, P_2, P_3, \ldots, P_n)$ within a cluster of VMs. This task allocation, called solution S, follows predetermined measures and constraints within the cloud environment.

$$F(S) = min \sum_{i=1,j=1}^{t,m} Ct \qquad (1)$$

In Eq. (1), *F(S)* represents the fitness function of the solutions, *m* corresponds to the total number of available machines, *t* stands for the entire number of tasks submitted by the user, and *Ct* denotes the completion time of all tasks. Fitness function values vary with the type of job. Jobs can be categorized as either dynamic or static. Static jobs possess predefined properties, such as a fixed total data amount, data flow within the system, and time constraints. Conversely, dynamic jobs encompass undefined job properties, like data bursting and indeterminate data types. Users are required to specify whether the job properties are static or dynamic when submitting the data.

For static job scheduling, where job properties are determined by the cloud service provider, denoted as $(P_1, P_2, P_3, \ldots, P_n)$. The user-provided variables are used to characterize the present infrastructure utilization and determine the needed virtual machine cluster. Various categories of VM clusters are evaluated, and their corresponding fitness scores are computed. By employing the optimal fit algorithm, the VM cluster that is most appropriate is chosen, thereby accomplishing load balancing. The cost of task execution is determined by the user's given property values, as per Eq. (2). Fig. 1 depicts the system architecture of the suggested approach.

$$C = \sum_{i=1,j=1}^{n,m} Pi \qquad (2)$$

In Eq. (2), *Pi* represents the property of the *i*th job, *n* defines the number of job properties, *m* denotes the number of jobs, and *C* refers to the cost of executing the function. Job costs are considered when computing fitness values for potential VM clusters, and these values are used to pick the most appropriate VM cluster. Eq. (3) details the fitness function calculation.

$$F(S) = min \sum_{i=1,j=1,k=1}^{n,m,p} (P_1, P_2, \ldots, P_x) + T_j + M_k \qquad (3)$$

Where *F(S)* represents the fitness value of the respective cluster, *p* indicates the available machines within the respective cluster, *M* is the machine, *m* signifies the number of tasks, *T* refers to the corresponding task, *x* reflects the job's property, and *n* indicates the number of jobs. The proposed algorithm defines the static scheduling of tasks, as outlined in the Algorithm. 1.

Algorithm. 1. Pseudocode for the proposed static task scheduling

```
Function ProposedAlgorithm(J, P, M):
    Initialize BestFitCluster as empty
    For Each Task Ti in Job J:
        For Each VM Cluster Mk in Set of VM Clusters:
            Calculate Cost(C) for placing Ti in Mk based on properties P
        Select VM Cluster M with minimum Cost(C)
        If BestFitCluster is empty or Cost(C) < Cost(BestFitCluster):
            Update BestFitCluster with M
    Return BestFitCluster
End Function
```

Dynamic task scheduling involves the possibility of unspecified task properties, which necessitates the service provider to establish a minimal set of parameters and their assigned weights. The user provides these variables during the first task submission, which determines the allocation of required machines. The quantity of machines in operation can be modified according to the workload duration of the task. The cost of task execution is determined by the highest value that the user is willing to pay for the first setup, as specified in Eq. (4).

$$C = max \sum_{i=1,j=1}^{n,m} Pi \qquad (4)$$

Where *Pi* represents the maximum value of the property, while *n* signifies the number of job properties, and *m* represents the task count. Throughout runtime, the highest property estimates gathered from the job's tasks are logged. The average value of the property is considered when allocating a new VM cluster for arriving tasks carrying varying properties, determined by Eq. (5) and Eq. (6).

$$Pi(T) = {\left(\sum_{i=1}^{n} Vi\right)}/{n} \qquad (5)$$

$$F(S) = min\left(\sum_{i=1,j=1,k=1}^{n,m,p} (P_1, P_2, \ldots, P_x) + T_j + M_k\right) < max \sum_{i=1,j=1}^{n,m} Pi \qquad (6)$$

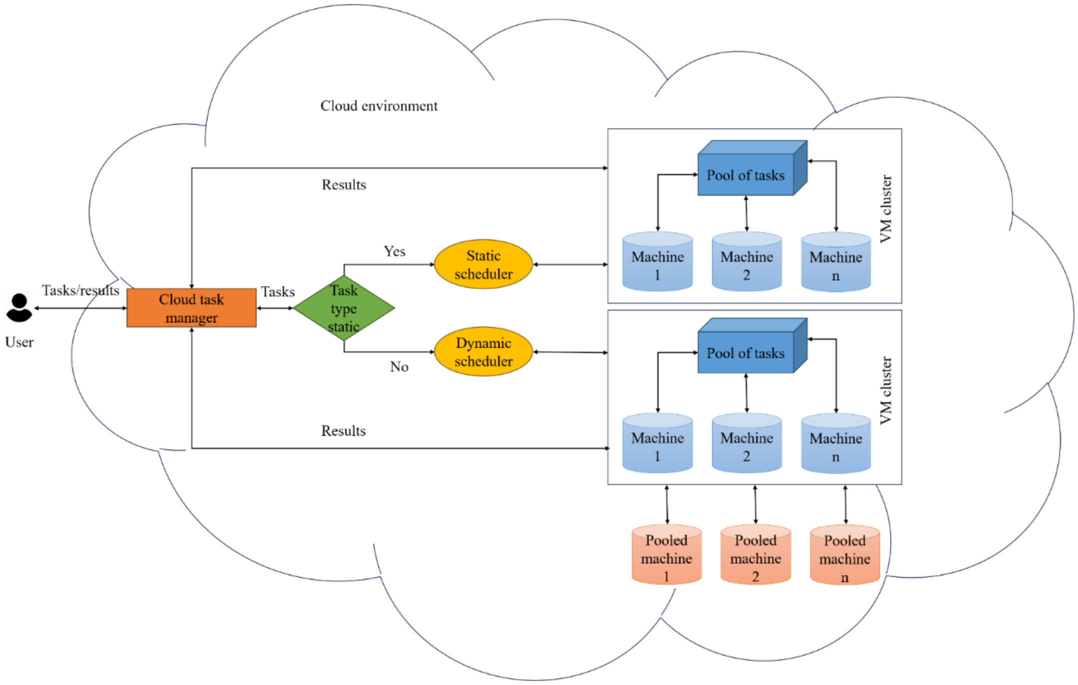

Fig. 1. System architecture.

Eq. (5) defines *Pi(T)* as the average property value of the job, *Vi* as the specific property value, and *n* as the total number of property values obtained from the operations. The fitness value of the VM cluster is denoted by *F(S)*. In this equation, *n* refers to the number of jobs, *x* stands for the value of property *P* for the job, *T* is the task, *m* signifies the number of tasks, *M* represents the machine, and *p* refers to the number of machines within the VM cluster. The computed value should be the minimum among all fitness values lower than the maximum value the user is willing to accept for task execution. The method proposed in Algorithm 2 defines the dynamic scheduling of tasks.

Algorithm 2. Pseudocode for the proposed dynamic task scheduling

```
Start
Input: Job with set of Tasks J(T1, T2, ….. Tj);
        Set of task properties (P1, P2, ……Pn);
        Set of VM cluster properties (M1, M2, …… Mk);
        Set of Task property values V;
Output: Bestfit VM cluster F(S)
Initialize BestfitCluster to null
For each task T in J
    Calculate Cost C for each VM cluster using task properties P and values V
    For i = 1 to n & j = 1 to m
        Calculate Fitness F(S) for each VM cluster
    end For
    Find the VM cluster with the minimum Fitness (min F(S))
    If BestfitCluster is null or F(S) < Fitness of BestfitCluster
        Update BestfitCluster with the current VM cluster
End For
Return BestfitCluster
End
```

IV. Results and Discussion

The efficiency of the suggested technique has been evaluated using the CloudSim simulator. Table II provides a concise overview of the specifications for key components of a cloud platform, including virtual machines (VMs), cloudlets, data centers, and clients. These parameters are regarded as minimal for dynamic simulation and constant for static simulation, allowing for changes during execution. The suggested method is evaluated against three techniques described in Section II, specifically HDD-PLB [19], HG-GSA [17], and CAAH [20]. The performance metrics considered include VM utilization ratio, execution time, response time, and makespan time. VM utilization ratio denotes the number of VMs deployed relative to the total VMs available, execution time indicates the duration of task completion in the VMs, response time signifies the scheduler's time taken to schedule tasks, and makespan represents the finishing time of the last task.

TABLE II. Simulation Parameter Specifications

Components	Attributes	Values
Task	Total number	250-2000
Cloudlet	Length	50,000
	Total number	500
Host	Bandwidth	10 GB/s
	Storage	100 GB
	RAM	2 GB
	Total number	3
VM	Total number	100
	OS	Linux
	MIPS	10000
	Processor	2.4 GHz
	SSD	100 GB
	RAM	2 GB
Data center	Total number	2

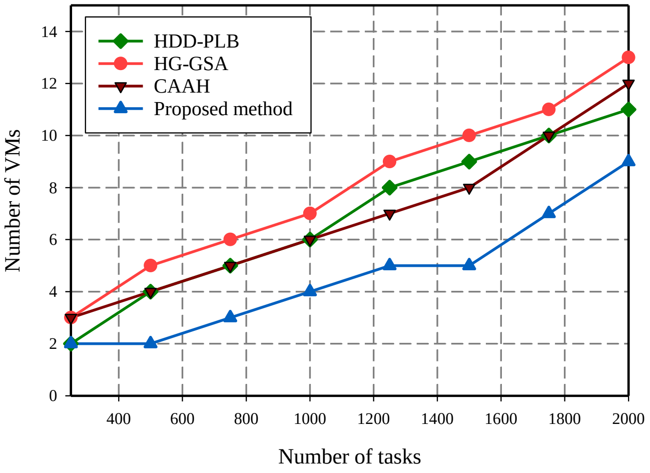

Fig. 2. VM utilization ratio comparison.

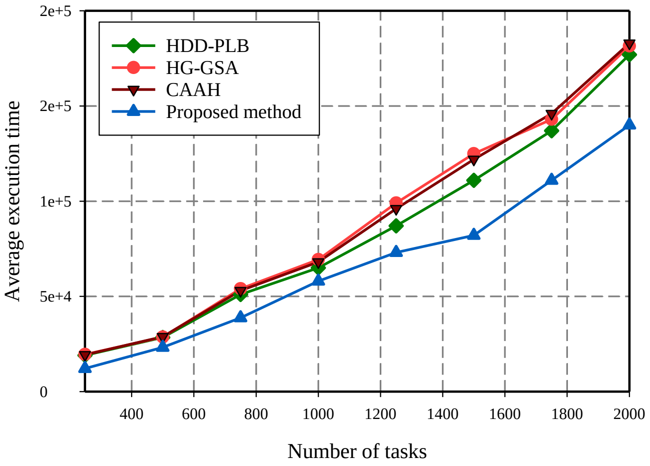

Fig. 3. Execution time comparison.

Fig. 2 compares the suggested strategy with existing alternatives in terms of the VM utilization ratio. This indicator is crucial for evaluating the efficiency and performance of resource allocation in a cloud computing environment. It offers valuable information on the efficient utilization of resources by virtual machines, enabling the discovery of virtual machines that are either underutilized or overutilized while making appropriate modifications to achieve optimal performance. The figure illustrates that the proposed algorithm schedules tasks optimally, using a lower number of VMs compared to the comparative algorithms. Specifically, for tasks based on static properties, our algorithm minimizes the number of VMs required, outperforming other methods. The performance comparison indicates that our algorithm optimizes VM scheduling and achieves load balancing, enabling the cloud service provider to handle more tasks from different users in real-time. However, a drawback of the proposed approach is its tendency to utilize more VM placements when dealing with dynamically changing tasks, making it challenging to predict future VM usage accurately.

Fig. 3 illustrates a comparative analysis of our approach and other algorithms based on their respective execution times. The data presented in the figure proves that our technique, which supports both active and passive property-based tasks, outperforms other present ones through optimized VM placement, resulting in improved execution time. By efficiently allocating fewer complex tasks to VMs, our technique reduces the overall execution time.

In Fig. 4, the proposed algorithm is compared to other algorithms for response time. This comparison shows that our algorithm converges faster and delivers VM placement scheduling for the given tasks more rapidly. It can promptly allocate VMs by prioritizing static property values for simpler tasks, enhancing its ability to effectively handle tasks based on dynamic properties.

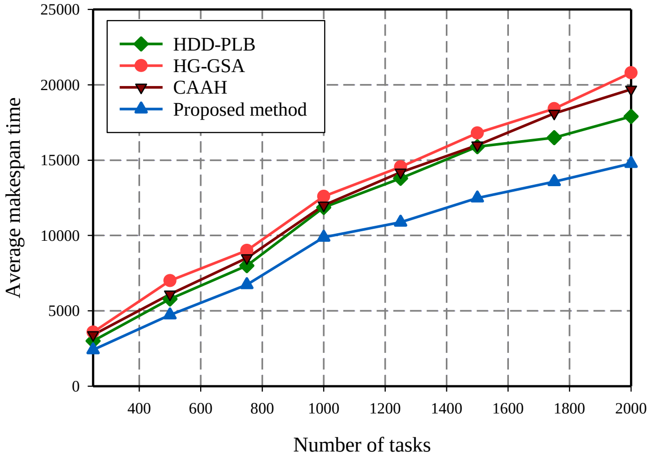

Fig. 4. Response time comparison.

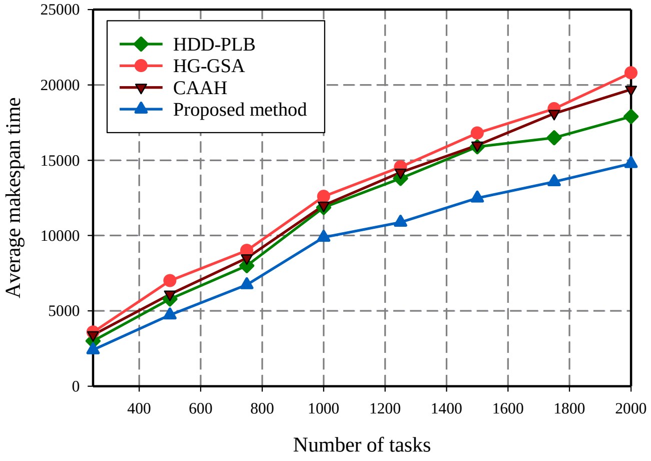

Fig. 5. Makespan time comparison.

Fig. 5 compares the proposed algorithm with existing methods measured by the makespan metric. The figure indicates that our algorithm offers optimal placement of VMs regardless of increasing workloads compared to the comparative algorithms. The algorithm considers task properties to place VMs optimally.

Despite all these improvements in task scheduling and resource allocation, the proposed method has some limitations. One primary limitation is the overhead resulting from more VM placements to accommodate dynamically changing tasks. While the method is superior in terms of efficiency in carrying out tasks characterized by static properties of resources, it can over-allocate VMs in such a task with dynamic properties. This tendency can bring about some issues, including reduced efficiency and increased operation costs since forecasting the future usage of VMs becomes complicated. As such, the method does not guarantee the selection of an inexpensive solution that would be advantageous in systems with volatile traffic loads.

Another limitation is that complexity can result from handling scheduling algorithms employed in the examination process. Although load balancing coupled with metaheuristic optimization techniques offers a solution for resolving inefficiencies, it is accompanied by increased computational complexity. This complexity might affect the method's usability when scaling up and applying it to larger and more diverse cloud environments. Further, due to the dependency of the algorithm on chosen performance parameters and simulation parameters, it is possible to infer that the efficiency of the algorithm can be different from that of another Cloud platform and from that of a real-world scenario. Mitigating these limitations involves an enhancement of the method and its application with the aim of achieving uniformity and efficiency in various settings and projects.

V. Conclusion

Cloud computing has gained popularity due to its flexible and resourceful nature, providing adaptable resources on a shared infrastructure. This technology provides a framework for various services, from scientific operations to service computing, highlighting the critical role of efficient task scheduling in ensuring optimal resource allocation and performance. In this study, we introduced a novel approach for task scheduling in cloud infrastructure services, addressing the significant challenge of mapping tasks to available resources while minimizing execution plan objectives. The proposed technique leverages a metaheuristic optimization method along with load distribution, designed to optimize cloud computing service providers' overall performance and effectively alleviate scheduling issues. One of the key strengths of our proposed approach is its adaptability to both static and dynamic task conditions. In static scenarios, where VM parameters are fixed, and in dynamic conditions, where parameters are adjusted in real-time, our method exhibits efficacy and flexibility. Simulation results unequivocally demonstrated the superiority of our proposed technique over existing methods, showcasing notable improvements in key performance metrics such as makespan, response time, and execution time.

The outcomes of our study underscore the practical viability and potency of our proposed metaheuristic optimization approach with load balancing in addressing the complexities of task scheduling in cloud infrastructure services. It not only optimizes resource utilization but also contributes significantly to enhancing user experience by ensuring guaranteed performance and efficient resource allocation. While this research presents promising results, future work could delve deeper into exploring the scalability of the proposed method for larger and more diverse cloud environments. Moreover, considering real-world deployment and testing on varied cloud platforms could further validate the applicability and robustness of the approach. Overall, the proposed technique stands as a promising step towards addressing the challenges in task scheduling within cloud infrastructure services, offering a potential avenue for further advancements and practical implementations in the field.

Edge Computing for Real-Time Decision Making in Autonomous Driving: Review of Challenges, Solutions, and Future Trends

Jihong XIE, Xiang ZHOU, Lu CHENG*
School of Automotive, Wuhan Technical College of Communications, Wuhan 430065, China

***Abstract*—In the coming half-century, autonomous vehicles will share the roads alongside manually operated automobiles, leading to ongoing interactions between the two categories of vehicles. The advancement of autonomous driving systems has raised the importance of real-time decision-making abilities. Edge computing plays a crucial role in satisfying this requirement by bringing computation and data processing closer to the source, reducing delay, and enhancing the overall efficiency of autonomous vehicles. This paper explores the core principles of edge computing, emphasizing its capability to handle data close to its origin. The study focuses on the issues of network reliability, safety, scalability, and resource management. It offers insights into strategies and technology that effectively handle these challenges. Case studies demonstrate practical implementations and highlight the real-world benefits of edge computing in enhancing decision-making processes for autonomous vehicles. Furthermore, the study outlines upcoming trends and examines emerging technologies such as artificial intelligence, 5G connectivity, and innovative edge computing architectures.**

Keywords—Edge computing; autonomous driving; real-time decision-making; reliability; resource management

I. INTRODUCTION

A. Context

As transportation technology advances, several car manufacturers plan to deliver new cars to the market. The vehicles include several technologies, such as Electric Vehicles (EVs) [1], Autonomous Vehicles (AVs) [2], and Connected Vehicles (CVs) [3]. Autonomous driving technology has gained significant attention in the transportation sector, attracting considerable interest in the academic community [4]. Recent research suggests that autonomous driving systems have a role in regulating speed and making decisions, which may impact traffic safety and effectiveness. CVs are automobiles equipped with different communication technologies to interact with the driver, cloud (V2C), roadside infrastructure (V2I), and other vehicles (V2V) [5].

The U.S. Department of Transportation's National Highway Traffic Safety Administration (NHTSA) defines driverless or fully automated cars as vehicles lacking direct driver input while potentially controlling critical safety functions like braking, throttle, and steering [6]. This categorization aligns with the framework established by the Society of Automotive Engineers (SAE), which outlines six degrees of automation for autonomous vehicles, ranging from level 0 with no automated driving assistance to level 5 with complete automation [7].

B. Problem Statement

Real-time decision-making skills are a fundamental necessity for the safe and effective integration of self-driving cars on our roads in the ever-changing field of autonomous driving [8, 9]. AVs depend on intricate systems of sensors and algorithms to understand and react to changing surroundings, unlike vehicles operated by humans [10]. The core of real-time decision-making is promptly analyzing a continuous data flow to enable immediate reactions to unexpected situations, possible dangers, and uncertain road conditions [11]. This skill is crucial when quick reactions may make the difference between a collision and preventing a calamity. Real-time decision-making enhances the flexibility of AVs in navigating difficult traffic circumstances. As the self-driving system advances, quick and reliable decision-making becomes crucial. Ensuring safety is crucial for vehicle passengers and other road users and for enhancing the efficiency and performance of autonomous systems on our roads [12].

C. Challenges

The fast progress of autonomous driving, driven by advancements in artificial intelligence and related machine learning technologies, offers substantial enhancements in road safety, traffic congestion alleviation, pollution mitigation, and a general rise in human well-being [13, 14]. AVs rely on extensive sensor data to interpret complex surroundings, derive valuable insights, and navigate constantly changing conditions [15]. Evolving technologies demand immediate responsiveness and efficient activity processing, including end-to-end decision-making, sensing, radar analysis, and visual object recognition [16]. On-board computing systems face challenges in meeting growing processing requirements while adhering to power supply and device space limitations. One of the significant challenges in edge computing for autonomous driving is network reliability. AVs must maintain consistent and robust connectivity to ensure continuous data flow between vehicles and edge servers, which is crucial for real-time decision-making. Interruptions in network connectivity can lead to delays and potentially hazardous situations.

Safety is another critical concern, as the systems must be resilient to cyber-attacks and ensure data integrity and privacy [17]. Ensuring that data is secure and that the system can withstand malicious attacks is paramount for the safe operation of AVs. Scalability poses a challenge as the number of autonomous vehicles increases. The infrastructure must be capable of handling a growing volume of data and processing

*Corresponding Author.

demands without compromising performance. Efficiently managing these resources is essential to prevent bottlenecks and ensure smooth operations. Resource management is also a vital aspect, encompassing the allocation of computational power, storage, and bandwidth. Optimal resource management ensures that the edge computing infrastructure can support the intensive computational tasks required by AVs while balancing power consumption and device constraints.

D. Motivation

Mobile Edge Computing (MEC) refers to a computing model that allows individuals, including automobiles and devices, to receive computing and storage capabilities via Edge Computing Servers (ECSs) situated at base stations near users [18]. This system effectively decreases the duration of network connections by moving traffic from central data centers to edge data centers [19]. MEC allows AVs to enhance energy efficiency and computation by assigning workloads to ECSs [20]. The surge in cars on roadways requires MEC to analyze a large quantity of received data, potentially resulting in network congestion. The rise of 5G wireless communications boosts the use of MEC thanks to high-speed 5G networks, which instantaneously enable quick data transfer between clients and edge servers [21]. MEC's strong processing power and minimal network delay make it suitable for developers and subscribers who want to outsource demanding computing tasks to ECSs. Combined with 5G, MEC efficiently facilitates automated driving by fulfilling intensive computation requirements and stringent response time constraints [22].

AVs are powered by edge computing systems that integrate real-time functions like navigation, sensing, planning, and command. This means that all the processing is done on the edge, eliminating the need for a traditional cloud computing system and reducing latency. This is essential for the real-time decision-making capabilities of AVs. Vehicles are connected to ECSs and finally to the cloud over current cellular networks. Furthermore, vehicles can connect to Road Side Units (RSUs) over cellular networks or Dedicated Short-Range Communications (DSRCs). Moreover, DSRC technologies enable V2V communication between vehicles.

E. Contributions

This study highlights the critical role of edge computing in facilitating timely decisions in autonomous driving. The main contribution is a thorough examination of the core ideas of edge computing and their direct application to the complex problems of AVs. The study comprehensively analyzes the network's reliability, security, scalability, and resource management, identifies significant challenges, and proposes strategic solutions and technological advancements. The study also presents successful applications of edge computing using detailed case studies and highlights concrete improvements to the decision-making processes for autonomous cars in practical situations. Future research areas and forecast trends are examined, focusing on emerging technologies such as artificial intelligence, 5G connectivity, and revolutionary edge computing architectures. The research focuses primarily on connecting theoretical principles with actual applications to guide the continuous development and integration of edge computing to improve the safety and effectiveness of autonomous driving systems.

F. Structure of the Paper

Remaining portions of the paper are organized as follows. Section II explores the origins and foundations of both edge computing and autonomous driving, offering essential context in order to comprehend how they cross. Section III provides a comprehensive analysis of several solutions and technologies pertaining to edge computing in autonomous driving. This section also emphasizes the importance of these solutions in tackling difficulties and enhancing system performance. Section IV delineates prospective avenues for future study in this domain, highlighting areas that need more investigation and innovation. Section V presents a summary of the main results of the study and points out the significance of edge computing in the advancement of autonomous driving technologies.

II. Backgrounds

A. Edge Computing

Cloud computing involves offering centralized and virtualized processing, storage, services, and application resources over the Internet [23]. This strategy separates services from the foundational infrastructure, removes initial expenses, and streamlines IT infrastructure management [24]. Cloud computing faces challenges in providing real-time autonomous driving services given its centralized nature and fixed locations far from clients. Autonomous driving demands minimal latency, consistent timing, enough bandwidth, and mobile services. Cloud computing-based paradigms have been suggested to fulfill the requirements of autonomous driving. Spanning Cloud Computing (SCC) is a strategy that distributes applications throughout many cloud data centers to enhance performance, availability, and cost-effectiveness [25].

Although SCC has advantages, it also brings up additional tasks like resource management and orchestration, necessitating security measures to safeguard decentralized resources. The Cloud-based Content Delivery Network (CCDN) utilizes regionally dispersed and pay-as-you-go cloud platforms to provide content as a service [26]. CCDNs like Amazon CloudFront, Google CDN, and Azure CDN enhance the Quality of Experience (QoE) by duplicating material near the user [27]. While SCCs and CCDNs have benefits, they do not fulfill the stringent demands of autonomous driving. To overcome these challenges, cloud-based services should be moved closer to the data source to enable local data processing, analysis, and filtering. Edge computing is the extension of computing capabilities from traditional cloud models to the edge of the network. Edge computing optimizes infrastructure efficiency by attaining low latency, decreasing backhaul load, facilitating mobility services, and enhancing service robustness [28].

Edge computing is a decentralized infrastructure resource paradigm where essential resources are strategically located near data sources or the edge. This method avoids transferring data to a central cloud, which decreases latency, jitter, and network core load [29]. It also enhances security by keeping data in on-premises infrastructure [30]. Researchers are still debating the definition and precise position of the edge. Some consider the edge IoT-connected devices with restricted resource capabilities that handle gathering data processing [31]. Others view the edge as a structure that transfers processing duties to data sources [32]. We believe the application delivery environment determines the network's edge and positioning. The edge functions as a rational limit that variations in data users and suppliers may alter. In connected automobiles, a car acts as an edge, handling data collecting and processing inside. Within multi-access edge computing, the Radio Access Network (RAN) functions as an edge computing unit that controls the processing of user data. In a CCDN, a server acts as an edge and handles user requests [33].

B. *Autonomous Driving*

The exponential rise in population has caused a surge in the number of automobiles, placing substantial strain on current transportation infrastructure, such as parking facilities and gas stations. The ongoing growth of vehicle traffic significantly contributes to transportation concerns, particularly environmental pollution, traffic accidents, and congestion [34]. Researchers are now working on building AVs to address and maybe eliminate the problems posed by human drivers. As shown in Fig. 1, AVs are intelligent agents equipped with various sensors attached to vehicles to sense their surroundings. AVs rely on sensors like radars and cameras instead of human drivers who depend on their senses, like sight and hearing. The efficacy of AVs relies significantly on the quality of their sensors. Sophisticated perception algorithms may not operate well if the sensor data is unreliable.

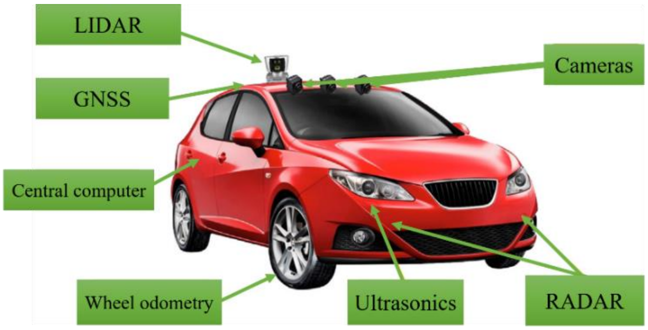

Fig. 1. AVs and sensor technology for intelligent transportation.

Vehicle sensors can be classified into two classes: proprioceptive sensors that measure the vehicle itself and exteroceptive sensors that measure the vehicle's surroundings. Cameras are commonly used in autonomous driving as passive sensors that gather light and capture precise information about a situation. Factors like resolution and area of view are critical factors in a camera's quality. The resolution, determined by the number of pixels composing the image, directly influences its quality. The horizontal and vertical angular visibility range governs the camera's area of vision. High dynamic range is essential for autonomous cars, particularly when navigating different illumination situations at night. Stereo cameras, comprised of two cameras with overlapping fields of view, provide a disparity map to evaluate depth in individual pixels.

LIDAR is a crucial sensor that emits laser beams to determine the depth of objects by analyzing reflected light and time of flight. LIDAR creates a 3D point cloud map and details the scene's geometry. Key LIDAR measurements consist of the number of sources, points gathered per second, and field of view.

RADAR sensors, used before LIDAR, effectively identify massive objects and are especially beneficial in challenging weather situations. RADAR sensors are defined by their detection range, field of view, and accuracy in measuring position and speed. Ultrasonic sensors, which use sound waves to determine distance, are crucial in situations like parking when vehicles must manoeuvre close to other automobiles.

Global navigation systems, especially GPS or Galileo, act as proprioceptive sensor, enabling the calculation of a vehicle's location, speed, and sometimes direction. The Inertial Measurement Unit (IMU) measures angular rotation rate and accelerations. The wheel odometer, a proprioceptive sensor, monitors the wheel's rotation speed to determine the speed and change in direction of the vehicle. Following an environmental evaluation, AVs perform object recognition, planning, decision-making, speed control, and driving independently without human involvement.

Autonomous cars, including both non-motorized and motorized vehicles, use sensors to detect and categorize things in the surroundings. It is essential to monitor the detected things and observe mobile objects on the road. Moreover, the vehicle requires sensor data for its precise positioning. Perceptual and localization data are integrated and transformed into a unified 3D coordinate system before being sent to the planning module. The planning component generates a continuous chain of directed paths from the starting point to the destination following motion, behavior, and route planning. The planning unit creates route information for vehicle self-regulation to adjust to various vehicle actions. The control commands are relayed to the braking, acceleration, and steering wheel elements of the vehicle's operating system for implementation. Fig. 2 depicts the software architecture of the whole system.

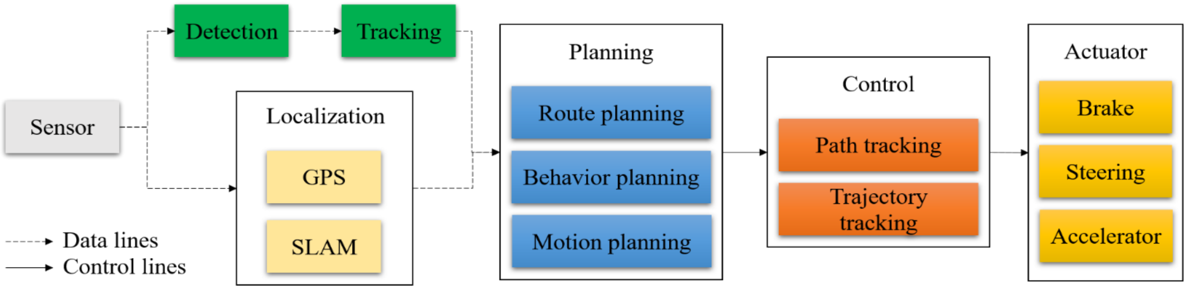

Fig. 2. General autonomous driving system.

Perception is a major problem in autonomous driving, but planning and control are also key challenges. Planning involves determining ideal routes and making decisions depending on the observed environment, which may be complicated under dynamic and unexpected traffic situations. Planning requires dealing with various road conditions, unanticipated actions of other road users, and guaranteeing both safety and efficiency in navigation. Control encompasses the implementation of planned activities by accurately managing vehicle characteristics, including acceleration, braking, and steering, in order to guarantee a seamless and secure operation. Developing reliable and effective planning and control algorithms is crucial for AVs to function safely and efficiently in a variety of conditions. These issues highlight the intricate nature of creating completely self-driving systems that can operate smoothly in real-life situations, requiring sophisticated algorithms and sensor technology to handle the many aspects of autonomous driving tasks.

III. Solutions and Technologies

This section delves into a diverse array of innovative solutions aimed at addressing the intricate challenges within autonomous driving through cutting-edge technologies and methodologies. Table I provides an insightful comparison of these solutions.

TABLE I. AN OVERVIEW OF AUTONOMOUS DRIVING SOLUTIONS

References	Objective	Methodology	Challenges	Findings / Results
[35]	Real-time autonomous robotic and vehicle applications	Runtime layer abstraction, heterogeneity-aware scheduling, and vehicle cloudlet coordinator	Energy efficiency and real-time processing	Deployment on Nvidia Jetson TX1 with power consumption under 11W
[36]	Resource offloading for autonomous driving functions	3-layer protocol: autonomous vehicle, network edge, and cloud computing	Latency reduction and resource optimization	Evaluation of optimization methods in various scenarios
[37]	Faster processing of autonomous driving tasks through dynamic offloading	ILP formulation and lookup table for real-time applications	Offline-online tradeoff and network state fluctuations	Significant enhancement in system performance
[38]	Efficient task scheduling for autonomous driving	Task assignment based on time limitations	Urgency and vulnerability consideration	Efficient scheduling of tasks and accommodating critical tasks
[39]	Leveraging computing resources within each vehicle	Optimization problem based on vehicle mobility	Vehicle mobility and breaks in connection	Enhanced reaction time by 34% compared to other techniques
[40]	Intelligent networking architecture using MEC	Dynamic driving model for each road segment	Generalization challenges and changing environmental conditions	Improved driving model for each road segment
[41]	Predicting QoS for autonomous driving services	Balancing exploration and exploitation, and maximizing discounted future reward	Conventional prediction model limitations	Attains highest performance under Autoware benchmark settings
[42]	Lyapunov optimization for task offloading in autonomous driving	Optimal target server selection based on system stability	System stability and time considerations	Steady queue backlog and efficient task processing
[43]	Allocating computing resources to reduce vehicle travel distance	Whittle index calculation using DRL approach	Delay in receiving computing results and changing vehicle mobility	Efficiently provides computational outcomes to cars
[44]	Using game theory for mutually beneficial outcomes in AVs	FPGA-accelerated calculating process	Combinatorial calculations and Nash equilibrium	2.4 times performance increase compared to CPU
[45]	Edge computing-based lanes scheduling system	Sesa and SVLSA centralized management lane scheduling approaches	Efficient crossing navigation, guaranteeing designated cars cross intersections	Outperforms other strategies in common lane-changing situations
[46]	Using deep learning for infotainment caching in AVs	Block-wise majorization-minimization approach for optimization	Caching choices based on passenger trains and reduction in content download delays	Prediction accuracy of 97.8%, effective time reduction
[47]	Container-based architecture for autonomous driving	Utility-focused greedy algorithm for offloading scheduling	Privacy preservation and resource segregation	Great practicality and isolation, millisecond edge relief

Tang, et al. [35] developed LoPECS, a low-power edge computing framework for real-time autonomous robotic and vehicle applications using cost-effective embedded technologies. A heterogeneity-sensitive runtime structure was created to optimize the use of the vehicle's diverse computing resources for autonomous driving applications. A vehicle edge coordinator was also developed to transfer vehicle tasks to edge cloudlets efficiently. These components were effectively integrated into the LoPECS system. The system was deployed on the Nvidia Jetson TX1, demonstrating its efficiency with a power consumption of under 11W. At the application tier, LoPECS provides obstacle detection, localization, voice recognition, and other features to provide secure, effective, and real-time driving behavior. The QoE Oriented Service Classification categorizes autonomous driving services based on real-time needs and energy costs. The real-time OS is a minimalistic operating system that efficiently oversees several services and facilitates their communication with little additional processing. The LoPECS runtime layer abstracts diverse computing resources and utilizes a heterogeneity-aware scheduling method to allocate tasks on heterogeneous hardware platforms. The vehicle cloudlet coordinator shifts tasks to the cloud in real-time to maximize energy economy, considering vehicle movement and cloud availability.

Ibn-Khedher, et al. [36] designed an end-to-end communication architecture that allows computationally demanding autonomous driving functions, such as Autopilot, to be allocated to distributed resources on edge computing infrastructure. This architecture aims to enhance the performance of autonomous driving vehicles by reducing latency and ensuring reliability. The architecture outlines an Advanced Autonomous Driving (AAD) connectivity protocol for AVs, edge computing servers, and the centralized cloud. An Integer Linear Programming (ILP) technique is used to create a mathematical model for resource offloading of the autopilot chain at the network edge. A Deep Reinforcement Learning (DRL) method is suggested for high-density Internet of Autonomous Vehicle (IoAV) networks. The AAD protocol has three primary layers or modules. The autonomous vehicle layer has to outsource autopilot service chains because of limited local resources. The distributed network edge layer serves as an intermediary connecting OBU cars to the cloud. The system comprises distributed edge servers that provide communication between vehicles or the virtualized OBUs. The task involves processing and evaluating externally provided Virtual Network Functions (VNFs) based on vehicle specifications and the edge servers' resources. The cloud computing tier functions as a cloud autopilot and handles non-real-time edge autopilot VNFs.

Cui, et al. [37] introduced a new method to transfer computationally demanding autonomous driving tasks to on-road equipment and the cloud for faster processing. The method integrates an ILP model for optimizing the planning approach offline with a quick heuristic technique for online adjustments. The suggested method is validated using both artificial task diagrams and practical implementations. The proposed approach contains an offline ILP solution and a rapid heuristic for online adjustment. Two factors justify this hybrid approach. While the ILP approach may provide ideal outcomes, the time needed to achieve a result is substantial and unsuitable for online changes. Conversely, the network state might be unstable, causing fluctuations in the bandwidth between OBU, edge, and cloud. It is necessary to modify the approach dynamically to accommodate the fluctuating network conditions.

An ILP formulation is needed for the offline phase to determine the best offloading method, which involves segmentation, scheduling, and allocation for the Directed Acyclic Graph (DAG) across all three platforms based on the provided topology characteristics. Optimal methods for potential network variables are computed and kept in a lookup table for real-time applications. The runtime is not affected by the time needed for ILP computation. The ODA scheduling method utilizes an offline scheduling methodology based on the network status to construct a new offloading strategy in a greedy manner. When the present network condition aligns with entries in the lookup table, the corresponding plan from the table is selected. Otherwise, the approach most similar to the network state will serve as the starting point for the greedy algorithm. This technique uses the smallest Euclidean distance between two network sets as a decision criterion. When the Euclidean distance is equal, the mobile network with the shortest distance is chosen. This procedure is triggered at runtime whenever there is a network status update.

Dai, et al. [38] suggested a task scheduling technique that accounts for the specific features of autonomous driving tasks. The system selects appropriate edge computing servers by using an enhanced early deadline first strategy, which involves task migration via replacement and recombination. The experimental findings indicate that the system can efficiently schedule a greater number of tasks as the task quantity grows, successfully accommodating critical tasks. The scheduling algorithm aims to allocate tasks efficiently by considering the urgent nature and vulnerability of autonomous driving duties, allowing for the execution of a greater number of tasks. The assignment of tasks to edge computing servers is established in accordance with the time limitations of the assignment. Upon arrival of a new task, BFRS estimates its deadline and then sequentially tries the alternative methods, such as the Task Replacement Strategy (TRS) and the Direct Execution Strategy (DES).

DES first verifies whether the task can be handled directly on the local edge server. If not, it fits whether the task can be performed directly on the other edge computing servers. It selects the most suitable edge computing server based on the Earliest Start Time (EST) or the Shortest Sufficiently Free Interval (SSFI) selected. If DES fails to address the problem, TRS first examines whether the task can be accomplished by replacing it with fewer computationally intensive tasks on the local edge computing server. Otherwise, other edge servers are iteratively checked and ordered according to free intervals. Lastly, if TRS cannot resolve the problem, BFRS returns that none of the edge computing servers can perform the recently arrived task.

Vehicular Edge Computing (VEC) is becoming more popular because it can decrease latency and alleviate the burden on backhaul networks. To address the rising computing needs of expanding vehicle applications, such as autonomous driving, sufficient computing resources within each vehicle can be vital for task execution in a VEC scenario, leading to enhanced user experience. However, the increased mobility of the vehicles makes this process difficult and might cause breaks in connection, leading to delays in current task processing. Liu, et al. [39] developed a task-shifting technique that utilizes multi-hop vehicle computation resources in VEC, according to the study of vehicle movement. An optimization problem is created with the objective of minimizing the combined weighted total of execution time and computing effort of all functions in a vehicle. A strategy using semi-definite relaxation with an adaptive adjustment technique is suggested to address the optimization issue and determine the unloading options. The simulation results demonstrate that the suggested offloading method may notably enhance reaction time by an average of 34% when compared to other techniques, such as local processing and random offloading.

AI-driven AVs may use a variety of machine learning methods to construct a sophisticated self-driving structure. One AV intelligence is insufficient to handle constantly changing driving conditions. Current neural network design and training techniques have challenges in generalizing driving models to varied contexts due to sampling inefficiency and the curse of dimensionality. Robust computational resources and extensive data may be used to train an effective driving model without the need for real-time operation. Nevertheless, the driving model derived offline may not be successful in some instances. Wu, et al. [40] proposed an intelligence networking architecture connecting AVs using multi-access edge computing and end-to-end learning for demonstration goals. This framework separates the trip and collects data individually for each road section. multi-access edge computing networks generate and update a dynamic driving model for each road segment in almost real-time to account for changing conditions. Segmenting the route decreases the requirement for generalization since it allows a single model to focus on adapting to a particular section. The simulation results demonstrate that the solutions provide an enhanced driving model for each road segment to more effectively adjust to environmental variations compared to the current method.

Xiong, et al. [41] proposed a learning method to predict the Quality of Service (QoS) of services in a multi-dimensional setting. They also created a reliable service delivery method that needs minimal hyperparameter adjustments and a small number of trials to learn multilayer neural network policies. This method can balance exploration and exploitation by modifying hyperparameters using maximum entropy gain learning. They demonstrated that this method attains the highest level of performance under Autoware benchmark settings. QoS prediction involves completing missing values. The conventional prediction model does not consider multi-faceted factors. Hence, they aim to use undisclosed aspects of the multi-dimensional environment to anticipate QoS. The method offers an independent service provisioning strategy that relies on QoS prediction. A neural network model is designed to accomplish this objective and is accountable for carrying out the actions defined by the model. The model, based on QoS, decides on the action to take and then receives a reward.

Jang, et al. [42] developed a new task offloading approach that utilizes Lyapunov optimization to ensure system stability and reduce task processing latency. A real-time monitoring mechanism is constructed to optimally use distributed computing resources in an autonomous driving setting. An analysis of computational complexity and memory access rate is conducted to demonstrate the features of deep learning applications for the task offloading technique. Lyapunov and Lagrangian optimization addresses the balance between system stability and user needs. The process of outsourcing complicated applications involves real-time monitoring, workload analysis, and optimum decision-making. The offloading algorithm selects the optimal target server based on system stability and time for processing the required task.

Li, et al. [43] studied the allocation of computing resources for real-time tasks in autonomous driving. In the presented scenario, AVs consistently capture the surroundings, transmit sensor data to an edge server for analysis, and receive processed findings from the server. A vehicle has a delay in receiving calculating results due to motion and processing latency, resulting in a distance covered between storing sensor input and receiving the results. The objective is to develop an edge separation planning strategy to reduce the distance travelled by vehicles. The method involves establishing the sequence of processing based on the mobility of each vehicle and the computational capacity of the edge server. They developed a Restless Multi-Arm Bandit (RMAB) issue, created a stochastic scheduling strategy based on the Whittle index, and calculated the index using a DRL approach. The suggested planning scheme circumvents the lengthy policy exploration often seen in DRL planning methods and efficiently produces judgments with little complexity.

Du, et al. [44] investigated the potential of using game theory in decision-making to create a mutually beneficial outcome for AVs. The Lemke-Howson method in game theory is a well-known combinatorial technique used to compute a Nash equilibrium of a bimatrix game. They developed the Lemke-Howson algorithm using FPGA to expedite the calculating process. The host side creates test data, transmits it to the FPGA card, and collects the outcomes. The host and the FPGA interact over the PCIe port using the AXI4-Stream protocol. The FPGA incorporates the Lemke-Howson accelerator and the DMA subsystem for the PCIe-IP core. The accelerator can fully execute the algorithm's functions. The IP core's DMA mode is set up to transfer data bidirectionally between host memory and FPGA using a PCIe bridge. The driver on the host enables sending instructions to link the host to the FPGA and initiate data transmission. The Lemke-Howson accelerator was applied to a KCU116 board, resulting in a performance increase of around 2.4 times compared to operating on a CPU.

Xia, et al. [45] proposed a new Edge Computing-based Lanes Scheduling System (ECLSS) model to analyze lane assignment for vehicles at junctions using real-time edge devices. Multiple edge computing devices are deployed at junctions to gather data from cars and road conditions via short-range wired or wireless transfers. Two centralized management lane scheduling approaches, the Search for Efficient Switching Algorithm (SESA) and the Special Vehicles Lane Switching Algorithm (SVLSA), are developed, given the strong computational power and real-time transmission performance of edge devices. These edge computing-driven autonomous driving techniques focus on efficiently navigating crossings and guaranteeing that designated cars may cross intersections within a certain timeframe. Comprehensive simulations were carried out, showing that the suggested methods outperform other strategies in common lane-changing situations.

Ndikumana, et al. [46] suggested using infotainment caching in autonomous vehicles. This system would make caching choices by analyzing passenger traits using deep learning. Initially, deep learning models are proposed to forecast the material that should be stored in multi-access edge computing servers in self-driving cars and vehicles near self-driving cars linked to roadside units. Secondly, a communication strategy is introduced for accessing stored infotainment material. Thirdly, a caching mechanism is offered for stored material. A cached content computation model is presented that may be delivered in various forms and quality according to the level of demand. An optimization problem is introduced that integrates the suggested models to reduce content download delays. The issue is solved using a block-wise majorization-minimization approach.

Tang, et al. [47] proposed a container-based edge-offloading architecture for autonomous driving. It constructs an offloading decision module, an offloading scheduler module, and an edge offloading middleware using lightweight virtualization. It offers abstraction and control of the execution environment at the level of containers at the edge. Thus, it enables the preservation of privacy and the segregation of resources from limitations during autonomous driving operations. They codified the mapping challenge of many applications on multiple edge nodes into a multi-dimensional knapsack challenge with his utility-preferred offloading scheduling approach. A utility-focused greedy algorithm was presented for the immediate resolution. The proposed system consists of three agents: AVs, edge servers, and a node coordinator. Service middleware for offloading is installed on edge servers to handle service offloading dispatch promptly. The middleware utilizes containers to separate the operational environment, application data, and hardware resources in order to guarantee the security of external applications. The middleware can modify the allocation of container resources based on the requirements of external applications to optimize performance. The node coordinator manages several edge servers within an appropriate range.

IV. Result and Discussion

In this section, we present and analyze the findings from our review and case studies of edge computing in autonomous driving. The results highlight the effectiveness of current solutions in addressing key challenges such as network reliability, safety, scalability, and resource management. Our review indicates that edge computing significantly enhances network reliability by reducing latency and ensuring robust connectivity. Studies have shown that deploying edge servers closer to the data source minimizes the risk of communication delays and interruptions, which is crucial for real-time decision-making in autonomous vehicles.

Edge computing contributes to improved safety by enabling faster and more secure data processing. The localized processing power of edge servers allows for immediate response to potential hazards, reducing the likelihood of accidents. Additionally, security measures integrated into edge computing frameworks protect against cyber-attacks, ensuring data integrity and privacy. The scalability of edge computing solutions is demonstrated through various case studies where the infrastructure efficiently handled increasing data volumes and processing demands. The flexibility of edge computing allows for seamless integration with advanced technologies such as 5G, further enhancing its capacity to support a growing number of autonomous vehicles.

Effective resource management is a key advantage of edge computing. By offloading computational tasks to edge servers, autonomous vehicles can optimize their onboard resources, leading to better energy efficiency and performance. Our analysis shows that edge computing frameworks can dynamically allocate resources based on real-time needs, ensuring optimal utilization. The rapid development of autonomous driving, coupled with the transformative influence of edge computing, opens up opportunities for interesting future research directions. This section discusses challenges, open issues, and future directions in adopting edge computing in autonomous vehicles.

- Integration with advanced AI techniques: Exploring enhanced synergy between edge computing and AI algorithms presents an exciting prospect. Integrating advanced AI techniques, such as machine learning and deep neural networks, with edge computing can bolster the decision-making capabilities of autonomous vehicles, making them more adept at navigating complex scenarios [48, 49].

- Optimal 5G integration for communication: The burgeoning landscape of 5G connectivity holds promise for enhancing communication between AVs and edge computing infrastructure. Investigating the optimal integration of 5G networks to facilitate low-latency, high-bandwidth data exchange is imperative for maximizing the potential of edge computing in real-time decision-making.

- Innovative edge computing architectures: The design and development of innovative edge computing architectures represent a current research focus. These architectures are envisioned to handle diverse data sources efficiently, prioritize safety-critical tasks, and dynamically scale to accommodate the evolving complexity of autonomous systems. This research aims to provide a robust foundation for the seamless operation of edge computing in the intricate landscape of autonomous driving.

- Addressing ethical implications: The rise of autonomous decision-making at the edge brings forth ethical considerations that demand careful examination. Interdisciplinary research actively manages ethical implications, including establishing accountability mechanisms, ensuring transparency, and formulating ethical frameworks that guide the responsible deployment of autonomous driving technologies.

- Ensuring security and privacy: As edge computing plays a pivotal role in processing sensitive data, ongoing investigations are directed toward implementing robust security measures. This research is crucial for safeguarding data processed at the edge, countering potential vulnerabilities, and ensuring users' privacy within autonomous driving systems.

- Human-machine interaction enhancement: Prioritizing the seamless integration of AVs into mixed traffic environments, research efforts are dedicated to improving human-machine interaction through edge computing solutions. This encompasses developing interfaces and communication strategies that enhance understanding and cooperation between AVs and human drivers or pedestrians.

- Environmental impact assessment: Researchers are actively conducting environmental impact assessments to evaluate the ecological footprint of edge computing in autonomous driving. This includes considerations of energy consumption, sustainability, and the implementation of eco-friendly optimizations to minimize the environmental impact of these emerging technologies.

- Standardization and interoperability: A key focus in ongoing research is the development of industry standards for edge computing in autonomous driving. This effort aims to ensure interoperability among diverse systems, fostering a cohesive and standardized approach that enhances the compatibility and seamless integration of autonomous driving technologies.

- Distributed edge computing models: Expanding beyond conventional edge computing models, current research explores distributed edge computing architectures. This approach involves decentralizing computing resources across interconnected edge devices, contributing to enhanced scalability, reduced latency, and improved fault tolerance in autonomous driving environments.

- Edge-to-edge collaboration: Investigating edge-to-edge collaboration is a burgeoning area of interest. Researchers are exploring how different edge devices within the autonomous ecosystem can collaborate effectively. This collaborative approach aims to distribute computational loads efficiently, optimize resource utilization, and improve overall system performance.

- Context-aware edge processing: Research is underway to develop context-aware edge processing capabilities to enhance the contextual understanding of autonomous vehicles. This involves tailoring edge computing algorithms to consider specific environmental factors, traffic conditions, and other contextual nuances, thereby refining decision-making processes in real time.

- Edge-cloud integration: Addressing the balance between edge and cloud computing, ongoing research focuses on effective integration strategies. This involves leveraging the strengths of both edge and cloud computing to optimize resource utilization, scalability, and data processing efficiency in autonomous driving scenarios.

- Edge analytics for predictive maintenance: Expanding the role of edge computing, researchers are exploring its application in predictive maintenance for autonomous vehicles. By implementing edge analytics, the system can proactively identify and address potential hardware or software issues, thereby enhancing the reliability and longevity of autonomous driving systems.

- Adaptive edge resource allocation: To ensure efficient resource management, research is dedicated to developing adaptive edge resource allocation mechanisms. This involves dynamically allocating computing resources based on the varying demands of different tasks, contributing to improved overall system performance and responsiveness.

- User-centric edge services: With a focus on user experience, current research explores the development of user-centric edge services. This entails tailoring edge computing capabilities to meet users' specific needs and preferences, creating a more personalized and adaptive autonomous driving experience.

- Edge-based anomaly detection: Enhancing the security posture of autonomous systems, researchers are investigating edge-based anomaly detection techniques. The system can identify abnormal patterns or behaviors by analyzing data at the edge, enabling rapid responses to potential cybersecurity threats and ensuring the integrity of autonomous driving operations.

V. Conclusion

This paper has provided a comprehensive exploration of the pivotal role played by edge computing in advancing real-time decision-making capabilities within the domain of autonomous driving. The examination of core principles, challenges, and solutions underscored the significance of bringing computation and data processing closer to the source, mitigating latency, and enhancing overall system efficiency. The case studies presented exemplified successful implementations of edge computing, demonstrating tangible improvements in decision-making processes for AVs across various scenarios. The outlined future research directions shed light on the evolving landscape, emphasizing the integration of advanced AI techniques, optimal 5G connectivity, innovative edge computing architectures, and ethical considerations. As autonomous driving continues to evolve, it is evident that edge computing will remain a linchpin, shaping the trajectory of intelligent, adaptive, and safe self-driving vehicles on our roads. The interplay between edge computing and emerging technologies, coupled with ongoing interdisciplinary collaborations, sets the stage for a future where autonomous systems not only navigate complex environments seamlessly but also prioritize safety, security, and ethical considerations in their decision-making processes. This synthesis of theoretical insights and practical applications underscores the transformative potential of edge computing in defining the future of autonomous driving.

Group Non-Critical Behavior Recognition Based on Joint Attention Mechanism of Sensor Data and Semantic Domain

Chen Li, Baoluo Liu*
School of Computer and Information Engineering, Luoyang Institute of Science and Technology, Luoyang, 471023, China

***Abstract*—As science and technology continue to advance, sensor technology is being used in more and more industries. However, traditional methods have the problem of ignoring the semantic information of individual behavior and the correlation between individuals and groups. Based on this, the study proposes a new method for group behavior recognition. The process of feature extraction is performed on group behavior by collecting sensor data and combining a semantic domain joint attention mechanism. This is achieved through the construction of a recognition method based on a data domain and semantic domain joint attention mechanism, which enables the accurate identification of non-critical behaviors in the group. The findings showed that, when the group members are constant, the hybrid network based on a convolutional neural network and bi-directional long and short-term memory network improved the F1 by 0.2% and the accuracy by 0.19%. Moreover, the hybrid network combining graph neural network, bi-directional long and short-term memory network, and convolutional neural network improved results. In group behavior recognition, group relationship modeling based on graph convolutional network improved F1 by 0.17% and accuracy by 0.17% compared to the hybrid network, indicating that group relationship modeling better captures group interaction features and improves recognition. The method is highly effective in the field of group behavior recognition and is expected to provide a new idea for monitoring and managing group behavior in practical scenarios.**

Keywords*—*Sensor data; attention mechanisms; semantic domains; non-critical; group behavior

I. Introduction

A. Research Background

With the continuous development and application of intelligent technology, group behavior (GB) recognition is becoming increasingly important for understanding human social behavior patterns, intelligent security surveillance, intelligent traffic management, and other fields. In previous research, most of the work focuses on identifying critical behaviors in groups, and relatively little research has been done on the identification of non-critical behavior (NCB) in groups [1]. Traditional GB recognition methods are mainly based on sensor data (SD) or video data for analysis, but these methods tend to ignore the semantic information of individual behaviors (IBs) and the correlation between individuals and groups [2]. However, there is a complex semantic relationship between IBs and GBs, and the understanding of IBs can provide important clues for the inference of GBs. On the other hand, SD and semantic domain joint attention mechanism (SDJAM), as an innovative approach, combines the behavioral data of group members captured by sensors with semantic domains (SeD) information in order to improve the recognition of group NCB [3]. Due to the disparate sizes of GB data and the fact that input individual behavior data does not always align with the same group characteristics, non-critical individual behaviors can readily impede the recognition of GB, resulting in a reduction in the recognition rate of network models for GB. Joint attention mechanism (JAM) enables the model to selectively focus on the information that is more crucial to understanding GB by integrating the contextual meaning of SeD information with the individual characteristics of SD. This improves the model's comprehension of the relationship between IB and GB [4].

B. Research Methods and Significance

The study suggests a group NCB recognition technique based on SD and SDJAM in light of this. The method combines SD with SeD information, and effectively captures the correlation and semantic information between IBs and GBs through JAM, so as to realize the accurate recognition of NCBs in groups. The research aims to deeply explore the application of SD and SDJAM in group NCB recognition, and to provide new solutions and technical support for intelligent surveillance, security management and other fields. To better capture the correlation and semantic information of individual actions in GB and increase the identification accuracy of NCB, the research creatively mixes SD and SeD information through JAM.

C. Article Structure

There are six sections to this study. The background of the research, issues, and solutions related to group NCB recognition are covered in Section I. Section II reviews the previous research results on group NCB recognition and summarizes the difficulties and shortcomings of the method. Section III describes the improvement of the SD method by combining SDJAM. The study's suggested strategy is tested against alternative approaches in a comparative experiment designed in Section IV. Discussion is given in Section V and finally, Section VI concludes the paper.

II. Related Work

GB is an important carrier in promoting economic development and social and cultural exchanges. Therefore, the research on GB recognition is a very important task and has triggered many scholars to study it. Lu et al. suggested a graph neural network model based on multimodality combined with semantic context-awareness to address the problems of single mode and ignoring labeling relationships in GB recognition method. The method used an aggregator that fuses attention to refine the nodes in the model, which effectively improves the robustness of the recognition of group activities [5]. To solve the issue that individual differences and other factors can easily influence GB recognition, Tang et al. suggested a residual aggregation network based on group photos. Moreover, the study also designed a weighted aggregation strategy to recognize multilevel spatio-temporal features, which can provide a comprehensive characterization of group activities and effectively infer group activities [6]. Challa et al. proposed a hybrid recognition method that combines bi-directional long and short-term memory (BLSTM) and convolutional neural networks (CNN) using filters of different sizes to capture a variety of temporal local dependencies, which helps to improve the process of group feature extraction. This helps to address the issues of difficult feature extraction and large data bias in GB recognition [7]. To address the issue of balancing resource consumption and accuracy in human activity recognition, Tang et al. proposed an improved deep CNN that uses segmentation. This improved deep CNN is able to capture a wider range of human activity sensory fields in a single feature layer, improving the ability of multi-scale feature representation and improving the recognition effect [8].

In GB recognition, the use of sensors is usually effective in obtaining human movement information, which is of great help in behavior recognition, therefore, many scholars at home and abroad focus on sensors for behavior recognition. Teng et al. proposed a layer-wise CNN with local loss in order to address the shortcomings in sensor-based human activity recognition. This CNN combines wearable sensors with local loss and exhibits superior recognition performance when compared to global loss, offering new approaches to human activity recognition [9]. In order to overcome the lack of cross-interaction between various dimensions of sensor-acquired data in behavior recognition, Tang et al. proposed a triple cross-dimensional attention method [10]. The study conducted this by establishing three attention branches to capture the cross-interaction between sensor dimension, time dimension, and channel dimension, thereby improving the recognition effect. Abdel-Basset et al. proposed a supervised two-channel model to address the importance of wearable devices in behavioral recognition. The study introduced adaptive channel filtering operations to enhance the behavioral feature extraction capability, so as to effectively take into account the spatio-temporal information and improve the recognition rate [11]. For the heterogeneity of data from multimodal sensors and various human activities, Islam et al. proposed a guided multimodal fusion method based on cooperative multitask learning. This method was able to extract complementary multimodal representations, offering an efficient and better solution for behavioral recognition in real-world environments [12].

In summary, scholars around the world have conducted different studies on GB recognition and solved many problems in the recognition process. However, there are fewer existing studies on the interference of NCB on GB recognition for groups of varying sizes, and the presence of interfering behaviors makes it difficult to improve the recognition accuracy. As a result, the study suggests using SDJAM in conjunction with group NCB identification based on SD. First, the GB is detected using SD, and then the behavioral characteristics of key characters are obtained through the construction of a hybrid network model and the introduction of attention mechanism. Second, the joint SeD and data domain networks are explored to suppress NCB features and achieve the prediction of GB features. Finally, training tests were conducted using individual behavior datasets and group sizes to compare the performance of different recognition methods, in order to demonstrate the effectiveness of group NCB recognition methods and achieve technical support for intelligent surveillance and crowd management.

III. Methods for Recognizing Group Non-Critical Behaviors

Firstly, for the GB recognition problem, the study is based on SD to recognize the GB recognition problem. The study employs a hybrid network model of CNN and BLSTM to obtain IB features that contain group relationships through graph convolutional networks (GCN) and inference of GBs through attentional fusion. The study then considers how the method has an impact on the learning of attention weights, and further proposes a data-domain and SDJAM based method for NCB suppression in groups.

A. GCN-Based Group Behavior Recognition Method

GB recognition is a method of inferring the characteristics and intentions of people by observing and analyzing their collective behavior. Information about an individual or a group can be obtained by observing people's actions, language, facial expressions, etc. in different scenarios. Facing the problem that GB is difficult to characterize, the research proposed a GB recognition method based on GCN and group relationship modeling [13]. Fig. 1 shows the GB recognition process.

In Fig. 1, this GB recognition process first receives continuous SDs collected by different individual sensors and performs data segmentation through a sliding window. Using a hybrid CNN and BLSTM network, the segmented sequences are utilized to extract the spatiotemporal behavioral aspects of the individuals. In contrast to conventional approaches, this method mines the behavioral correlations and location correlations of people to compute IB associations while taking into account the interaction among individuals within a group [14]. Then, the individual spatio-temporal features and group relationship maps are inputted into the GCN to capture the behavioral interactions under global activities. In order to acquire the recognition results of GB, the features of various persons are finally fused through the attention module (A-Mod), and Softmax classification is carried out by the fully connected layer (FCL). Considering that the behavioral data captured by the sensors are time-series data, it is more suitable to be processed using recurrent neural network (RNN) to better characterize the dynamics of the behaviors. In order to extract well-characterized IB features, the study uses a hybrid BLSTM network and CNN to extract temporal and spatial behavioral features, and the flowchart of this process is shown in Fig. 2.

Fig. 1. Flow chart of group behavior recognition.

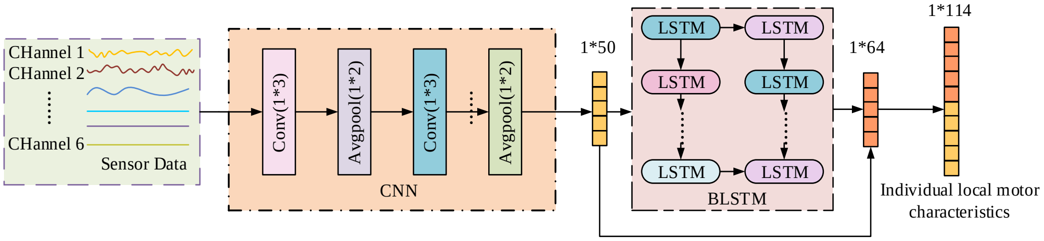

Fig. 2. Flow chart of extracting individual local features by CNN and BLSTM.

In Fig. 2, SD is convolved and pooled by CNN to get high-dimensional feature vectors, keeping the temporal order, and then input to BLSTM to extract its temporal features [15]. The feature vectors undergo an average pooling layer to obtain saliency features, which are then spliced with CNN features to generate individual features. For SDs at different local body locations, different CNN and BLSTM networks are trained independently to obtain more representative local features, which are then spliced into complete individual features. The flow of individual local features spliced into individual feature maps is shown in Fig. 3.

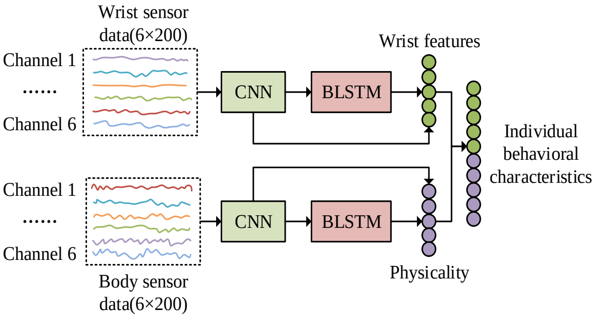

Fig. 3. Individual local features are spliced into individual feature maps.

In Fig. 3, individual local feature splicing refers to combining or connecting the local features of an object or an individual in some way to form an overall feature representation of that individual [16]. First, IB correlation is measured by analyzing the similarity of behavioral features of individuals over time. To simplify the process, the study uses the behavioral feature vectors within a specific sliding window to calculate the behavioral correlation of individuals i and j within the k th sliding window by using Eq. (1).

$$\begin{cases}\text{SimFea}_{i,j}^{k}=\text{Corr}_{i,j}^{k}\left(F_i^k,F_j^k\right)\\ \text{Corr}_{i,j}^{k}=\dfrac{\text{Cov}\left(F_i^k,F_j^k\right)}{\sqrt{D\left(F_i^k\right)}\sqrt{D\left(F_j^k\right)}}\end{cases}\tag{1}$$

In Eq. (1), F_j^k and F_j^k denote the feature vectors within the sliding window of individuals i and j. $D\left(F_i^k\right)$ denotes the standard deviation of F_j^k, and $\sqrt{D\left(F_j^k\right)}$ denotes the standard deviation of F_j^k. Using this method, the behavioral feature vectors of two individuals are converted to behavioral relevance measures [17]. To further standardize the correlation metric, the study maps the correlations to the same scale. The formula is displayed in Eq. (2).

$$\text{Norm}_{i,j}^{k}=f\left(\text{Corr}_{i,j}^{k}\right)\tag{2}$$

The study further calculates the Euclidean distance between the two bodies in order to obtain the positional relationship matrix, which is calculated mathematically in Eq. (3).

$$d_{ij}(t)=\sqrt{\left(x_i^t-x_j^t\right)^2+\left(y_i^t-y_j^t\right)^2}\tag{3}$$

In Eq. (3), $d_{ij}(t)$ represents the distance between the two individuals at the moment t, and when this distance exceeds a certain value, then there will be no interaction between the two. In this study, the study set this value to 5. The distance d_{ij}^{k} in the k th sliding window represents the average value of $d_{ij}(t)$ during this period of time. Considering that the degree of interaction of an individual is inversely proportional to the distance, the study further measured the positional relationship between the individuals i and j to ensure that the individual has the maximum positional weight with itself. The mathematical formula for measuring the individuals is shown in Eq. (4).

$$\mathrm{Sim}\,Loc_{ij}^{k}=1/e^{d_{ij}^{k}} \tag{4}$$

In Eq. (4), e denotes a natural constant. Then through Eq. (5), the IB feature correlation is fused with the location relationship to obtain the individual interaction relationship vector.

$$G_{ij}^{k}=\lambda\cdot\mathrm{SimFea}_{i,j}^{k}+(1-\lambda)\cdot\mathrm{SimLoc}_{i,}^{k} \tag{5}$$

In Eq. (5), λ denotes the hyperparameter. G_{ij}^{k} denotes the pairwise interaction between individuals. $F_{per,i}$ is the behavioral characteristics of individual i. In GB recognition, IBs and the relationship between them have an impact on GB. In order to introduce GCN into GB recognition, the study uses two different relationship modeling methods, behavioral correlation graph and location correlation graph [18-19]. The fusion of these two graphs forms the final group relationship graph. The creation of graphs that are related to location and behavior facilitates the capturing of the features of various interpersonal connections. Fig. 4 illustrates the construction of the relationship graph.

Fig. 4. Builds the diagram.

In Fig. 4, the nodes represent the behavioral characteristics of the individuals, while the edges represent the weights of the interactions between the individuals. The distance and correlation graphs together go through the construction of the relationship graph to obtain a relationship matrix. For the input of a set of N individuals, the behavioral features of individual i are extracted by BLSTM and CNN, and the spatial location features are $D_{per,i}$. The study uses one layer of GCN, and the inputs are the group relationship graph and the N individual features $F_{per,i}$ [20]. Eq. (6) displays the formula for graph convolution.

$$F_{int}=\sigma\left(\hat{D}^{-1/2}G\hat{D}^{-1/2}F_{pern}W_{g}\right) \tag{6}$$

In Eq. (6), σ is the activation function and W_{g} denotes the weight matrix. To improve the hierarchy of behavioral information, the study inputs the group interaction features ($F_{\mathrm{int},n}$) recovered by the GCN into the A-Mod after splicing the IB features ($F_{per,n}$) extracted by the hybrid CNN and BLSTM network in the spatiotemporal domain. In the A-Mod, the study calculates the correlation between individual feature vectors and normalizes it using the softmax function. Eq. (1) of the attention calculation is shown in Eq. (7).

$$Q^{d}=W_{q}^{d}\times\left[F_{per,n},F_{int,n}\right] \tag{7}$$

In Eq. (7), σ denotes the weight matrix to be learned, and Eq. (2) for attention calculation is shown in Eq. (8).

$$K^{d}=W_{k}^{d}\times\left[F_{per,n},F_{int,n}\right] \tag{8}$$

In Eq. (8), σ denotes the matrix to be learned, K_{n}^{d} denotes the matrix, and $(K_{n}^{d})^{T}$ denotes the transpose of matrix K_{n}^{d}. Eq. (2) of the attention calculation is shown in Eq. (9).

$$\begin{cases}V^{d}=W_{v}^{d}\times\left[F_{per,n},F_{int,n}\right]\\ s_{n}^{d}=Q^{d}\left(K_{n}^{d}\right)^{T}\\ \alpha_{n}^{d}=\exp\left(s_{n}^{d}\right)/\sum_{j=1}^{N}\exp\left(s_{j}^{d}\right)\\ v^{d}=\sum_{n=1}^{N}\alpha_{n}^{d}\cdot V^{d}\end{cases} \tag{9}$$

In Eq. (9), V^{d} is obtained by weighted fusion of attention, and V^{d} is maximally pooled to obtain F_{gro} for describing the GB feature. F_{gro} is computed as shown in Eq. (10).

$$F_{gro}=\max v^{d} \tag{10}$$

The study further takes the GB feature F_{gro} as an input to the FCL, which is processed through the FCL to finally obtain the GB recognition result. The corresponding mathematical expression is shown in Eq. (11).

$$\text{output }=W_{f}\times F_{gro}+b_{f} \tag{11}$$

In Eq. (11), W_{f} and b_{f} are the weight coefficients and deviations of the feature vectors in the FCL, respectively, and output represents the output after the FCL. After processing through the FCL, the vectors are operated by the Softmax function, and the prediction results are normalized to obtain the prediction probability. The specific mathematical expression of the Softmax function is shown in Eq. (12).

$$\sigma(\mathrm{z})_j = \frac{e^{z_j}}{\sum_{k=1}^{K} e^{z_k}} \tag{12}$$

In Eq. (12), $\sigma(\mathrm{z})_j$ and z_j denote the size of the probability of the j th category and the size of the fully connected output, respectively. $\sum_{k=1}^{K} e^{z_k}$ is the value of the sum of all fully connected output probabilities.

B. Semantic Domains Federated Attention Mechanism's Method for Suppressing Non-Critical Behaviors

The suggested approach makes use of a teacher-student network design, wherein the teacher network directs the student network to concentrate more successfully on important group members in order to find better attention weights. The network architecture of the GB recognition method based on preserving semantic attention is shown in Fig. 5.

In Fig. 5, the teacher-student network structure is introduced, and the teacher network, i.e., the SeD network, directly uses IB labels to learn a good attentional weight representation of IB semantics. In the data-domain network (DDN), SD is used as input to extract IB features through a hybrid network of CNN and BLSTM, and then GB features are obtained and classified through GCN and A-Mod aggregation. By integrating SeD and data domain network through loss function, attention knowledge and knowledge distillation techniques acquired from SeD are utilized to direct the learning of attention weights for IB characteristics in the data domain. The network simply considers the positional relationship between individuals and builds the graph using the distance relationship because the correlation of IB labels is not very high. The calculation formula is shown in Eq. (13).

$$O_s = \sigma\left(\hat{D}^{-1/2} A_s \hat{D}^{-1/2} F_{oh,n} W_s\right) \tag{13}$$

In Eq. (13), A_s is computed to obtain the degree matrix D, and W_s represents the weight matrix for SeD graph convolution. $F_{oh,n}$ undergoes graph convolution to obtain O_s. The O_s calculation formula is shown in Eq. (14).

$$Q^s = W_q^s \times F_{oh,n} \tag{14}$$

A weight distribution is learned through the self-attention mechanism. Eq. (15) illustrates how the attention is computed using the dot product in order to specifically focus on the important human behavioral traits that contribute to the final GB recognition.

$$\begin{cases} K^s = W_k^s \times F_{oh,n} \\ V^s = W_v^s \times F_{oh,n} \\ s_n^s = Q^s \left(K_n^s\right)^T \\ \alpha_n^s = \exp\left(s_n^s\right) / \sum_{j=1}^{N} \exp\left(s_j^n\right) \\ v^s = \sum_{n=1}^{N} \alpha_n^s \cdot V^s \end{cases} \tag{15}$$

The A-Mod yields the attention-weighted GB feature v^s, which is then processed via the Softmax activation function and FCL to predict the final GB label. In the study's suggested method, the SeD network and the data domain network are concurrently trained, in contrast to the conventional teacher-student network architecture. Semantically guided DDN training is achieved by learning all DDN parameters using a temporal backpropagation technique. The particular procedure is depicted in Fig. 6.

The study's suggested methodology is shown in Fig. 6, where two graph convolution modules are initially used to record the unique interaction information of features in the data and SeD domains, respectively. Then, the learned attentional knowledge of the SeD guides the attentional weights of the features in the data domain and aggregates them for final prediction.

IV. Performance Analysis of Group Non-Critical Behaviors Recognition Methods

The study sets up a comparison experiment in this chapter to compare the suggested technique with CNN BLSTMGCN, CNN+BLSTM, and CNN+BLSTM+GCN methods in order to assess the effectiveness and performance of the suggested approach. This is done in order to confirm the suggested method's efficacy.

A. Performance Validation Of GCN-Based Group Behavior Recognition Method

For this study, Python 3.7 is used as the development tool, Pytorch 1.4.0 is used as the deep learning framework, and Ubuntu 16.04 is served as the operating system. The research employs identical hyper-parameter configurations, network architectures, and experimental feature extraction tactics, with learning rates of 0.001, weight decays of 0.001, training batch sizes of 32, cross-entropy loss functions, Adam optimization algorithm, and thirty training iterations. Based on a publicly available IB dataset, the study creates a sophisticated GB dataset. The dataset is sourced from the UT Data public dataset of complex individual behaviors at the University of Twente, which mainly includes six types of human interaction behaviors, with a total of 20 samples. All participants in the dataset test carry two cell phones, which are put on the left wrist and the left lower body pocket for data collection. The samples of the final created GB dataset are organized in each sliding window and contains 200 rows of data. Table I details the categories and composition of the GBs in the dataset.

In Table I, the dataset contains 10 GBs and 10 IBs, with each group containing up to five individuals. A sliding window segmentation process yields a sequence of 1780 GB samples. The GBs have a duration of six minutes and a sampling frequency of 50 Hz. 80% of the data are used as a training set and 20% are utilized as a test set in fifty-fold cross-validation. All of the group members' data is the input for fixed group sizes. Data on randomly chosen individuals between the ages of two and five is the input for random group size. The confusion matrix is used to calculate accuracy, precision, recall, and F1 score. The results are averaged using a 5-fold (10 times per fold) cross-validation to reduce experimental error and chance. To minimize error and chance, the mean and standard deviation of the 5-fold average findings of the 10 experiments are finally compared. Table II displays a comprehensive comparison of the outcomes.

TABLE I. Group Behavior Composition

Tag	Category	Makeup	Test set	Training set
0	Walk	Walking 5 people	36	142

8	Examination	Standing one, writing four	35	143
9	Discuss	Lecture 2, sit 2, type 1	36	142
Sample count	/	1780	36	142

TABLE II. Comparison of Results

Method	Recall rate (%)	F1 score (%)	Accuracy (%)	Accuracy rate (%)
CNN	81.31±2.35	79.17±2.22	83.54±1.67	81.30±2.13
CNN+BLSTM+GCN	99.63±0.25	99.63±0.25	99.66±0.21	99.63±0.23
GCN	99.59±0.17	99.54±0.18	99.60±0.14	99.59±0.17
BLSTM	99.41±0.75	99.38±0.80	99.56±0.41	99.40±0.68
CNN+BLSTM	99.44±0.52	99.43±0.62	99.54±0.41	99.44±0.59
Research method	99.80±0.08	99.80±0.09	99.82±0.08	99.80±0.08

In Table II, when the number of groups is held constant, the model based on the hybrid network structure of CNN, BLSTM, and GCN demonstrates an improvement of 0.2% in F1 and 0.19% in accuracy in comparison to the model based on the hybrid network of CNN and BLSTM. This suggests that the addition of GCN is successful. In the GB recognition method, group relationship modeling based on GCN improves F1 by 0.17% and accuracy by 0.17% compared to the method based on the hybrid network structure of CNN, BLSTM and GCN. To verify the robustness of the network, a test with randomized group size is performed. During training, each group contained 5 people. However, in the test sample, the number of people in each group varied randomly between 2 and 5 people. The experimental setup is the same as when fixing 5 people. Confusion matrix results for some of the methods at the same folds are shown in Fig. 7.

In Fig. 7, Fig. 7(a) shows the random test person multiclassification mixing matrix based on CNN network, while Fig. 7(b) and Fig. 7(c) show the random test person multiclassification mixing and smoothing matrix based on BLSTM network and the random test person multiclassification mixing and smoothing matrix based on GCN and group relationship modeling, respectively. According to Fig. 7, more recognition errors are observed in the test case with random number of people in the group compared to the case with fixed five people in the group. This chapter does a 5-fold (10 times each) cross-validation to minimize experimental error and unpredictability. The precision, recall, F1 score, and accuracy of the average findings are computed. Table III displays the comparison of each method's mean and standard deviation.

Table III demonstrates that, when comparing the test case of a random number of groups to the fixed number of groups in the test set, all methods exhibited lower classification results. Additionally, the volatility of the results per fold increases significantly, suggesting that the GB recognition results are impacted by the change in group size. In terms of classification results, the GB recognition method based on GCN for group relationship modeling shows the highest accuracy, which is 0.84% higher in F1 score and 1.08% higher in accuracy than the model based on the hybrid network structure of CNN, BLSTM and GCN.

B. Performance Analysis of Non-Critical Behaviors Suppression Methods for Semantic Domains Federated Attention Mechanism

Experiments are conducted using data from the same group of five people for training, and the effectiveness of the method is tested with a fixed group of five people and a randomized number of people to verify its ability to suppress NCBs in the group, respectively. The study analyzes the recognition effectiveness of three methods: the SeD network, the data domain network, and the data domain and SeD combined attention mechanism network. Fig. 8 demonstrates the confusion matrix under one-fold validation for the three methods when tested in the first case.

The multiclassification confusion matrix for the SeD network in case one is illustrated in Fig. 8(a). The multiclassification confusion matrix for the DDN, data-domain, and SDJAM networks in case one is presented in Fig. 8(b) and 8(c), respectively. The case one test in Fig. 8 shows that the inclusion of one or two NCBs in the input has the greatest impact on the data domain network. In contrast, NCBs had less of an effect on the data domain of the SDJAM network and the SeD network. The confusion matrices for the three approaches under one-fold validation in the second case test are shown in Fig. 9.

(c) Case 2: Multi-classification confusion matrix of joint attention mechanism network between data domain and semantic domain

Fig. 9. The confusion matrix of the three methods tested in the second case is verified by one fold.

Fig. 9(c) displays the multiclassification confusion matrix for the SDJAM network under case II, while Fig. 9(a) and Fig. 9(b) display the multiclassification confusion matrices for the SeD network and the data domain network under case II. In Fig. 9, the SeD network has problems in misidentifying discussion as speech and misidentifying rest as discussion, while the other behaviors are classified well. The data domain network, on the other hand, has some errors in misidentifying breaks as speeches, and the classification confusion is more complex. In contrast, the data-domain and SDJAM networks performed more accurately in classifying each behavior, with improved overall correctness. In the end, it helps to lower the experimental inaccuracy and chance in the 5-fold findings by comparing the mean and standard deviation of the 5-fold average results of 10 studies. The suggested approach can still be processed well, and its recognition impact is superior to that of the data domain network and the single SeD network, according to the comparison results of the three ways in two test scenarios. The accuracy has increased by 18.75% and 21.96% when compared to the data domain technique using the suggested method, clearly demonstrating that the SeD network can effectively direct the learning of the data domain's attentional weights to deal with interference brought about by NCBs.

V. Discussion

A non-critical GB detection method based on sensors and GCN networks is studied and constructed for GB detection methods. In complex environments, GB characteristics cannot represent the behavior characteristics of key individuals or groups. Therefore, the collection of behavior data by sensors requires effective processing of global activity behavior interactions to ensure the extraction of the relationship between individual characteristics and GB. The construction of relationship graphs and the calculation of attention enable network models to accurately extract and predict key behavioral features. This study employs network structures of teachers and students to demonstrate the relationship between individual and GB. Additionally, it encompasses SeD networks and data domain networks for feature classification and joint training. Due to the excessive doping of NCB information in GB scenarios, this study employs semantic-guided data domain networks and graph convolution modules to extract key individual interaction information, suppress the representation of NCB, and achieve effective behavior recognition in group interactions. In the validation testing of public data, the accuracy of mixed network models for cross validation of fixed populations was above 99%, while the performance of models in random populations was significantly reduced. The accuracy, recall, and accuracy of CNN networks were reduced by about 16.5% compared to the former. However, the method proposed by the research still achieved a recognition rate of over 82% for GB. In conclusion, the network method proposed by the research, which combines SD and SeD information with a JAM, is capable of accurately extracting GB features and effectively suppressing NCB features in complex GBs.

VI. Conclusion

With the development of digitization, sensor technology has become one of the important tools for GB research. This research is to optimize the recognition method of NCB in the population. By constructing JAM, SD was combined with SeD in order to realize the accurate recognition of various types of NCB in the population. The outcomes of this study indicated that the GB recognition method based on GCN for group relationship modeling exhibited the highest accuracy, with 0.84% higher F1 score and 1.08% higher accuracy compared to the hybrid network. The impact of NCB on the SeD network and the data domain with the SDJAM network was small, and the research-proposed method was still able to handle it effectively. When compared to a single SeD network and a data domain network, the accuracy increased by 18.75% and 21.96%, respectively, demonstrating that the SeD network can successfully direct the learning of data domain attention weights to manage NCB interference. The results reveal that the proposed method of the study achieves significant performance improvement in GB analysis and provides a new technical path for the field of GB research. It is worth noting that for the complexity of GB, the current model still has some limitations in NCB recognition. In addition, the diversity of practical application scenarios is not fully considered in the study, and the future development direction can focus on applying the model to different environments and conducting more extensive empirical studies.

Quantum Cryptology in the Big Data Security Era

Chaymae Majdoubi, Saida El Mendili, Youssef Gahi
Engineering Sciences Laboratory-National School of Applied Sciences of Kenitra, Ibn Tofail University, Kenitra, Morocco

***Abstract*—Quantum cryptography, based on the principles of quantum mechanics, has emerged as a cutting-edge domain for cryptographic applications. A prime example is quantum key distribution, offering a theoretically secure information solution to the key exchange challenge. The inherent strength of quantum cryptography lies in its ability to accomplish cryptographic tasks deemed insurmountable through classical communication alone. This paper explores the landscape of quantum computing in the Big Data Era, drawing parallels with classical methodologies. It illuminates the constraints of current approaches and suggests avenues for progress. By unravelling the intricacies of quantum cryptography and highlighting its deviations from classical counterparts, this study enriches the ongoing discourse on secure communication protocols. The findings underscore the significance of quantum cryptographic methods, fueling further exploration and development in this dynamic and promising field contributing to Data security.**

Keywords—Data security; quantum cryptology; big data; cryptography

I. Introduction

In the era of big data, ensuring the protection of information has become a critical priority. Big Data is defined by several key attributes [1]. Volume highlights the vast amounts of data that are generated, processed, and transmitted. Variety underscores the diverse formats of data, extending beyond traditional, neatly organized tables. Velocity captures the rapid rate at which data is introduced and processed within systems. Veracity addresses the challenges associated with data accuracy, inconsistencies, and errors. Value focuses on deriving meaningful insights from the data rather than merely handling it. Visualization involves transforming complex datasets into intuitive charts, graphs, or interactive dashboards. Lastly, variability acknowledges the dynamic nature of data sources, which can exhibit irregular patterns, changes in formats, or unexpected fluctuations.

These characteristics underscore the significant risks to data security and privacy [2].

Ensuring data safety is crucial for maintaining accurate processing outputs, effective decision-making, and reliable visual representations. To mitigate these risks, it is essential to delve into data protection measures, including the application of cryptographic techniques to address data insecurity issues, such as those encountered in database environments [3]. Despite their importance, traditional cryptographic methods have inherent limitations, which will be explored further.

The human desire for discrete communications has led to the improvement of encryption methods over time, culminating in Quantum Cryptography [4].

RQ1: what is special about this type of encryption?

RQ2: How commonly used it is?

RQ3: What distinguishes quantum encryption from classical encryption?

RQ4: What are the limitations of both and how can we help optimize it?

Currently, classical computing serves as the primary paradigm for big data systems. Although quantum computing shows potential for transforming specific computations, its practical applications are still in the research and development phase. Conversely, post-quantum computing aims to enhance the security of traditional cryptographic methods against potential quantum threats. The interaction among these three paradigms is expected to have a significant role in shaping the future of computing, especially within the realm of big data. In this paper, we are going to see updated related works to quantum cryptology, compare it to traditional encryption ways, and spot limitations and advancement paths. In a way that would help understand the matter from both a macro and a micro visions, to spread awareness on classical, quantum and post quantum encryptions for Big Data systems, highlighting limitations and future directions.

II. Literature Review

In this section, we will explore various insights from previous works related to applied security in quantum cryptology, examining the approaches and methodologies of different researchers.

A. Resources

To write about this topic, it was important to consult various resources, build a comprehensive understanding, and then delve into the details of quantum computing for data security preservation, therefore, quantum cryptology in the era of big data systems.

We present below some documentation statistics:

- Scopus: quantum AND cryptology: 171 documents found.
- Plus, Subject Area: Computer Science, Engineering, Document Type: ALL, Language: English, Keyword: Quantum Cryptography.
- Result: 36 documents found.
- Web of Science: Quantum cryptology: 620 results.
- Open Access: 275 results, Articles: 107 results.
- ScienceDirect: 328 results,

- Computer science + Engineering + Open Access= 54 results.
- Springer:6,605 results initially,
- 2,506 results After necessary filters, From 2019: 1,341 results.

Fig. 1 presents the first results and in between filters or filters mentioned before. After the primary filers, the turn comes to sorting by relevance or highest cited, mainly papers providing a robust ground for our study, among the latest ones.

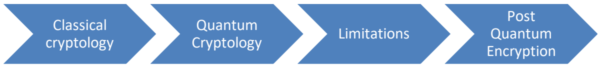

Fig. 2. Work summary.

Fig. 2 presents the main topics discussed in our paper to shed light on different encryption methods, serving data security and privacy.

B. Ground of Studies

As privacy and security are the main concerns in big data systems, Quantum cryptology, an interdisciplinary domain merging quantum physics and cryptography, has attracted substantial attention recently for its potential to transform secure communication. For IoT, quantum encryption is a way to reduce data breaches, eventually its cost [5], whereas Blockchain and Quantum Cryptography are promising for multimedia security and privacy, using quantum key distribution (QKD)[6].

While classical encryptions code data in bits, quantum cryptography encodes data in qubits, where more than two states can be encoded in one qubit[7], which contributes to saving computation time [8]. RSA computation problem of primary factors multiplication might seem difficult for the classical way, but it doesn’t mean unbreakable later with quantum computers. NIST have demonstrated that a single core classical computer can be broken within an hour, using super singular isogeny key encapsulation [9].

1) Quantum Key Distribution (QKD):

a) The exploration of Quantum Key Distribution (QKD) has been a central focus of research, with numerous noteworthy protocols emerging in the literature. The foundational BBM92 protocol, introduced by Bennett, Brassard, Mermin, and colleagues, has paved the way for QKD (Bennett et al., 1992). Researchers have continually refined and progressed QKD protocols to address challenges like distance constraints[10] and vulnerabilities [11] in various environments [12].

b) However, QuVis Simulator has demonstrated that B92 is more accurate than BBM92 for detecting eavesdropping [13].

c) Quantum Key Distribution (QKD) protocols like BB84 (Bennett & Brassard, 1984) and E91 (Ekert, 1991) leverage the unique properties of quantum mechanics to establish provably secure communication keys between two parties, Alice and Bob, even in the presence of an eavesdropper, Eve. In BB84, Alice transmits qubits in one of four possible quantum states, and Bob randomly chooses a basis for measuring them. By publicly comparing a subset of their chosen bases, Alice and Bob can detect Eve's interference through a significant increase in the error rate.

d) E91, on the other hand, utilizes entangled qubit pairs. Alice chooses random bases for each qubit in a pair before sending them to Bob. Any attempt by Eve to tamper with the entangled qubits introduces errors detectable by Alice and Bob through a violation of Bell's inequality, a statistical property that cannot be replicated by classical means.

e) While both protocols offer secure communication, BB84's security proof, which involves entanglement purification, is more complex compared to E91's, which relies on the violation of Bell's inequality. The choice between these protocols depends on factors such as the ease of generating a reliable entangled source and the desired level of security in the communication channel.

2) Entanglement-based protocols:

a) Quantum entanglement, essential for many quantum communication protocols including Quantum Key Distribution (QKD), faces substantial challenges in its generation, maintenance, and distribution over long distances. Entanglement is typically generated through methods such as spontaneous parametric down-conversion in nonlinear crystals, atomic ensembles, or engineered quantum dots. Maintaining this entanglement requires stringent isolation from environmental disturbances, robust quantum error correction, and the use of high-fidelity quantum memories to preserve coherence.

b) Long-distance distribution of entangled states encounters significant obstacles, primarily photon loss and decoherence, which degrade the quantum states and limit transmission range. Solutions like quantum repeaters, which employ entanglement swapping and quantum memory to extend entanglement over shorter, manageable segments, are being developed to address these issues.

c) Extensive investigations have been conducted into entanglement-based protocols, such as the E91 protocol [14]. These protocols leverage entanglement phenomena to establish secure communication channels [15]. The examination of multipartite entanglement [16] and its application in cryptographic schemes constitutes a significant area of study.

3) Post-quantum cryptography:

a) In anticipation of the future development of quantum computers capable of compromising classical cryptographic systems, the research community has actively engaged in post-quantum cryptography (NIST, 2019). This encompasses the exploration of quantum-resistant algorithms capable of withstanding attacks from quantum computers [17].

b) As advancements in quantum computing threaten traditional cryptographic methods, there is an increasing focus on developing post-quantum cryptographic (PQC) algorithms that can withstand such threats. Two prominent approaches under consideration for standardization are lattice-based cryptography and hash-based signature schemes. Lattice-based cryptography depends on the complexity of problems like Learning With Errors (LWE) and Ring-LWE, which offer strong security by relying on intricate mathematical structures. Algorithms such as Kyber, Dilithium, and NTRUEncrypt exemplify this approach, providing secure and efficient encryption and signing mechanisms.

c) Meanwhile, hash-based signature schemes, including the Merkle Signature Scheme (MSS) and its updated versions like LMS and XMSS, utilize hash functions to create signatures that are resistant to quantum attacks. SPHINCS+, a stateless hash-based scheme, improves practicality by removing the need for state management between signatures.

d) These PQC algorithms are being thoroughly evaluated by organizations such as the National Institute of Standards and Technology (NIST), which examines their security, performance, and practicality to ensure they are suitable for various applications. The eventual standardization of these algorithms will be essential for protecting digital information and communications in a world where quantum computing is a reality.

4) Integration with classical cryptography:

a) Due to limitations in data volume handled by Quantum Key Distribution (QKD), its practical application often necessitates a combined approach with classical cryptography. This hybrid strategy capitalizes on the strengths of both techniques. The integration of quantum and classical cryptographic techniques is a pivotal aspect of quantum cryptology research [18]. Hybrid approaches, seeking to leverage the strengths of both quantum and classical systems, are being developed to create robust and practical cryptographic solutions [19].

b) QKD's role is to establish a highly secure key for classical encryption algorithms, allowing for the safe transmission of large datasets. Additionally, Post-Quantum Cryptography (PQC) algorithms, designed to withstand attacks from quantum computers, can be integrated with existing classical encryption infrastructure. This bolsters security during the transition to a potential quantum-dominant future. Moreover, existing key management systems can be adapted to handle the quantum-resistant keys generated through QKD.

c) For instance, governments can leverage QKD to establish secure keys for robust classical encryption algorithms like AES-256. This enables the transmission of large volumes of sensitive data over existing networks. While this approach offers exceptional security for key exchange through QKD, it retains the scalability advantages of classical encryption. However, cost, complexity, and limited transmission range of QKD systems remain challenges.

d) Continued development of QKD technology and standardization efforts for PQC algorithms are essential for building a robust, future-proof communication infrastructure that seamlessly integrates both quantum and classical cryptographic techniques.

C. Quantum Cryptology Limitations

The field of quantum cryptology, while holding immense potential for secure communication [20] [21], currently grapples with various technical limitations [22]. Addressing these challenges requires a multidimensional approach involving advancements in quantum hardware, sophisticated protocols, and robust error correction techniques [23] [24]. Here's a technical synthesis of the limitations:

TABLE I. QUANTUM CRYPTOLOGY LIMITATIONS

Limitation	Description
Quantum Hardware	Challenges in developing reliable quantum hardware[25], including entangled photon sources and detectors.
Distance Limitations	Quantum decoherence and photon loss impose constraints on the distance[26] over which secure quantum communication can be maintained.
Vulnerabilities to Attacks	Potential vulnerabilities to side-channel and Trojan horse attacks in quantum key distribution systems[27].
Technological Maturity	Quantum technologies are in the early stages, lacking maturity for widespread adoption[28].
Quantum Network Infrastructure	Limited scalability and standardization of quantum communication networks[29].
Post-Processing Challenges	Complex post-processing steps, including information reconciliation and privacy amplification[30].
Cost and Complexity	High costs and complexity associated with implementing quantum cryptographic systems[31].
Quantum-Safe Classical Cryptography	The transition to post-quantum cryptography for securing classical systems[32].
Information	Ongoing need for breakthroughs in quantum information science.

Table I demonstrates Quantum cryptology limitations, which motivates more specialists and researchers to address them, leaving more space for creativity and innovation. In what follows, we will try to suggest a paths to help reduce some of these limitations.

D. Classical Cryptology Limitations

Classical cryptology is facing many limitations that we can summarize in the following Table II.

Classical cryptography has become a sensitive field especially with the technological growth, eventually classical computers became sensitive to quantum attacks given the fact that classical cryptology is not perfect itself in the sense of ensuring data privacy and safety (Keys and deterministic algorithms issues...).

TABLE II. CLASSICAL CRYPTOLOGY LIMITATIONS

Limitation	Description
Quantum Vulnerability	Classical cryptographic systems are vulnerable to attacks using quantum computers[33], which have the potential to break widely used encryption algorithms like RSA and ECC through algorithms like Shor's algorithm.
Symmetric Key Distribution	Classical cryptosystems, particularly symmetric key systems, face the challenge of securely distributing secret keys among communicating parties. The key distribution problem becomes more pronounced in large networks or when users are geographically dispersed.
Short Key Lengths	Classical ciphers often use relatively short key lengths, making them susceptible to brute-force attacks[34]. The feasibility of exhaustive key search increases as computational power advances
Deterministic Algorithms	Many classical encryption algorithms are deterministic, meaning the same plaintext encrypts to the same ciphertext with the same key. This lack of variability can lead to vulnerabilities, especially when encrypting repetitive or structured data.
Frequency Analysis	Classical substitution ciphers, like the Caesar cipher or simple monoalphabetic substitutions, are vulnerable to frequency analysis. The frequency distribution of letters in the ciphertext can reveal information about the underlying plaintext.
Block Size Limitations	Classical block ciphers, such as the Data Encryption Standard (DES), have fixed block sizes. This limitation can lead to vulnerabilities, especially in the context of modern applications where variable-length data is common.
Lack of Forward Secrecy	Classical symmetric key systems typically lack forward secrecy, meaning that if a key is compromised, all past and future communications encrypted with that key are vulnerable to decryption. This is in contrast to modern key exchange protocols that provide forward secrecy.
Vulnerability to Known-Plaintext Attacks	Some classical ciphers, especially early ones, are susceptible to known-plaintext attacks, where an attacker has access to both the plaintext and corresponding ciphertext. This information can be exploited to deduce the encryption key.
No Public Key Cryptography	Classical cryptosystems lack the elegance and security advantages provided by public-key cryptography. The absence of public-key cryptography necessitates alternative mechanisms for key exchange and secure communication.
Exposure to Chosen-Plaintext Attacks	Classical ciphers are often vulnerable to chosen-plaintext attacks, where an attacker has the capability to choose the plaintext to be encrypted. This can be exploited to gain insights into the encryption process and potentially the key.
Limited Use of Hash Functions	Classical cryptology has limited application of hash functions, which are crucial in modern cryptography for tasks such as digital signatures and message authentication codes.

In what follows, we will try to suggest ways to optimize classical cryptology limitations.

III. RESULTS

Based on the literature review and our comprehension of the topic, we will elaborate a comparative analysis of quantum cryptology compared to classical one in Table III.

TABLE III. QUANTUM AND CLASSICAL CRYPTOLOGY COMPARISON

Aspect	Quantum Cryptography	Classical Cryptology
Key Distribution Mechanisms	Quantum Key Distribution (QKD) protocols like BB84 leverage the properties of quantum states, typically polarized photons, to establish a secure key between communicating parties. The security of the key is intrinsically tied to the principles of quantum mechanics, such as the no-cloning theorem.	Key exchange mechanisms, like those used in public-key cryptography (e.g., Diffie-Hellman), rely on mathematical problems like discrete logarithms. The security is based on the presumed difficulty of these mathematical tasks.
Quantum superposition in QKD	Qubits in superposition states enable the simultaneous transmission of multiple bits of information. This allows for increased information transfer rates in certain quantum communication scenarios.	Classical bits exist in definite states (0 or 1) and do not have the capacity for simultaneous representation of multiple states.
Entanglement in Quantum Cryptology	Protocols like E91 exploit entanglement, where measurements on one entangled particle instantaneously affect the state of the other. This provides a mechanism for secure key exchange.	Classical systems lack an equivalent to entanglement, and correlations are typically established through classical communication.
Quantum Measurement and Eavesdropping Detection	Eavesdropping is detectable through the disturbance introduced during quantum measurement. The security of QKD protocols relies on the ability to detect such disturbances.	Eavesdropping detection is often indirect and relies on statistical analyses or pattern recognition in communication traffic.
No-Cloning Theorem in Quantum Cryptology	The no-cloning theorem prohibits the perfect copying of an arbitrary unknown quantum state. In QKD, this ensures that any attempt to intercept and copy transmitted quantum states will be detected.	Classical information can be copied without introducing errors, as demonstrated by the lack of a no-cloning analogue in classical information theory.
Channel Models and Quantum Noise	Quantum channels introduce quantum-specific effects like quantum noise and decoherence. Techniques such as error correction and purification are employed to counteract these effects.	Channel models typically assume classical communication without quantum-specific phenomena.
Post-Quantum Cryptography Considerations	Focuses on developing quantum-resistant cryptographic algorithms to secure classical communication against potential attacks by quantum computers.	Faces the challenge of transitioning to post-quantum cryptographic algorithms to maintain security in the era of quantum computing.
Practical Implementations	Requires specialized quantum hardware such as photon sources, detectors, and quantum key distribution systems. Challenges include maintaining quantum coherence over long distances.	Implemented using classical computers and algorithms, with a wide range of cryptographic protocols and algorithms available.
Practical Implementations	Requires specialized quantum hardware such as photon sources, detectors, and quantum key distribution systems. Challenges include maintaining quantum coherence over long distances.	Implemented using classical computers and algorithms, with a wide range of cryptographic protocols and algorithms available.

To address Quantum limitations, it's recommended to implement advanced error correction techniques, such as fault-tolerant quantum computing, and explore error-mitigation strategies. Innovate quantum repeaters with entanglement swapping to distribute entanglement over shorter segments, overcoming decoherence and photon loss challenges. Develop quantum-secure authentication protocols and explore continuous variable QKD for enhanced security against specific attacks.

IV. Discussion

A. Quantum Limitations Solution Suggestion

Progress in quantum error correction hardware and techniques are recommended, given the fact that the duration of a logical qubit's existence can be approximated by multiplying the inverse of the logical error probability per cycle with the time taken per cycle. In the context of Google's quantum computing system, where the logical error rate per cycle is 2.94% and the cycle duration is 921 ns, the estimated lifetime of the logical qubit is around 31 µs. This duration is in line with the T1 and T2 times of the qubits they employ, which range between 20 and 30 µs. Considering including enhancements in superconducting qubits and trapped ions, seems to be a good path for achieving higher fidelities and extended coherence times. Rigetti and colleagues presented a 3D qubit system utilizing a solitary Josephson junction (JJ) transmon housed in a copper waveguide cavity. This configuration showcased enhanced qubit lifetimes, with durations of 70µs and 92µs.

Simultaneously, efforts are underway to establish standardized quantum network protocols, such as standardized QKD by European Telecommunications Standard Institute (ETSI), incorporating cutting-edge photonic quantum memory into quantum repeaters, and promoting increased collaboration in quantum network research [35]. Besides designing secure information reconciliation algorithms and the optimization of privacy amplification processes.

The goal is to seamlessly integrate quantum and classical systems, enhance the efficiency of quantum hardware development, and actively contribute to the standardization of quantum technologies. Additionally, there is a focus on standardizing post-quantum cryptographic algorithms to withstand both classical and quantum attacks.

In the realm of research and development, fostering collaborative initiatives, creating advanced quantum software tools, and investing in educational programs are priorities aimed at nurturing a skilled quantum workforce.

B. Classical Cryptology Limitations Solution Suggestion

Public-key cryptography, exemplified by systems like RSA and elliptic curve cryptography (ECC), offers a solution to the key distribution challenge by facilitating secure communication without the necessity of a protected channel for secret key exchange. The field of quantum-resistant cryptography is actively engaged in researching and developing cryptographic algorithms that can withstand potential threats posed by quantum computers, collectively known as post-quantum cryptography.

To enhance security against brute-force attacks, modern cryptographic algorithms employ longer key lengths, as seen in the Advanced Encryption Standard (AES) supporting key lengths of 128, 192, and 256 bits. However, probability is introduced into modern encryption schemes to prevent patterns in plaintext from directly translating to ciphertext, addressing determinism issues.

On the one hand, modern block ciphers employ advanced modes of operation like Cipher Block Chaining (CBC) or Galois/Counter Mode (GCM) to ensure heightened security, especially for encrypting substantial data volumes. On the other hand, cryptographic hash functions, exemplified by SHA-256, are widely used for tasks like integrity verification, digital signatures, and generating message authentication codes, resisting to collisions and pre-image attacks.

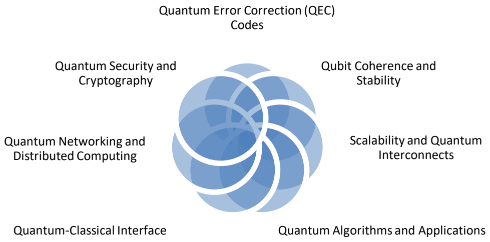
Forward secrecy is maintained by protocols such as Diffie-Hellman key exchange, ensuring that even if a long-term key is compromised, prior communications remain secure. Authenticated encryption, which combines encryption and authentication, is a common feature in modern cryptographic algorithms, safeguarding both data confidentiality and integrity against chosen-plaintext attacks. Secure key exchange protocols, including Transport Layer Security (TLS), establish shared secrets between communicating parties to securely address the key distribution issue.

Ongoing research in post-quantum cryptography focuses on identifying and standardizing cryptographic algorithms secure against quantum attacks, encompassing lattice-based cryptography, hash-based cryptography, and code-based cryptography. Authenticated encryption schemes play a crucial role in modern cryptographic systems to guard against chosen-ciphertext attacks and ensure the authenticity of decrypted data. Therefore, the integration of randomized algorithms into cryptographic algorithms and protocols adds an additional layer of security, mitigating vulnerabilities to known-plaintext attacks. Fig. 5 shows distance limitation contributions.

V. Technical Challenges, Distance Limitations and Security Measures

A. Technical Challenges Considerations

To overcome technical challenges related to advancements in quantum hardware development and effectively integrating quantum and classical systems, several solutions can be considered (Fig. 3):



Quantum Error Correction (QEC) Codes
Qubit Coherence and Stability
Scalability and Quantum Interconnects
Quantum Algorithms and Applications
Quantum-Classical Interface
Quantum Networking and Distributed Computing
Quantum Security and Cryptography

Fig. 3. Solution suggestions for technical challenges of quantum hardware integration in classical systems.

- Quantum Error Correction (QEC) Codes Optimization concern of Investigating and optimizing quantum error correction codes like the surface code, implementing strategies such as gauge fixing and syndrome extraction to reduce error rates and enhance fault tolerance. Exploring fault-tolerant quantum error correction schemes based on concatenated codes, including the use of optimized decoding algorithms and error detection techniques.

- Qubit Coherence Enhancement utilizing dynamical decoupling methods such as Uhrig sequences or concatenated pulse sequences to extend qubit coherence times by mitigating environmental noise effects. Developing error suppression techniques such as quantum dynamical decoupling or quantum Zeno effect protocols to enhance qubit stability during quantum operations.

- Scalable Quantum Architectures such as designing and optimizing scalable quantum processor architectures, including multi-qubit gate implementations such as controlled-phase gates or CZ gates with reduced gate errors and improved gate fidelities. Exploring topological qubit designs, such as Majorana qubits or topological quantum dots, for scalable quantum computing platforms with inherent error protection.

- Quantum Algorithms Optimization by Optimizing quantum algorithms for specific applications, including quantum machine learning algorithms like quantum support vector machines (QSVM) or quantum neural networks (QNN), focusing on performance improvements and resource efficiency. Investigating hybrid quantum-classical optimization algorithms, such as quantum annealing with classical pre-processing or quantum-assisted optimization heuristics, to tackle combinatorial optimization problems effectively.

- Quantum-Classical Interface Development via developing quantum-classical interface protocols based on quantum gate teleportation or quantum state tomography techniques, enabling efficient communication and data transfer between quantum and classical processors. Design quantum-classical hybrid programming environments with integrated quantum compilers, optimizing code translation between quantum instructions and classical computations for seamless execution.

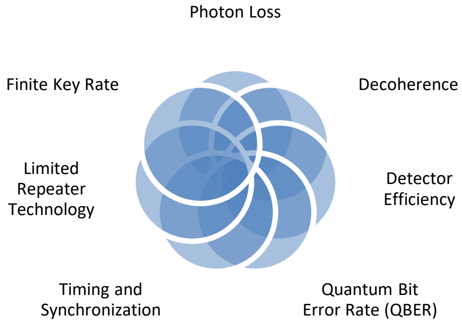
- Quantum Networking and Distributed Computing Advances concern of conducting research on quantum repeater architectures and quantum entanglement distribution protocols for long-distance quantum communication networks, addressing challenges such as quantum channel noise and entanglement loss. Investigate distributed quantum computing frameworks, including quantum task allocation algorithms and quantum workload balancing strategies for heterogeneous quantum computing clusters.

- Quantum Security Enhancements via developing quantum-resistant cryptographic primitives, such as lattice-based encryption schemes or quantum-safe hash functions, to secure quantum communication channels and data storage against quantum attacks. Implementing quantum key distribution (QKD) protocols with improved key generation rates and enhanced security proofs, leveraging quantum entanglement properties for provably secure key exchange.

These highly technical solutions encompass various aspects of quantum computing, spanning quantum hardware optimization, algorithm development, interface design, networking protocols, and cybersecurity measures to advance the field towards practical quantum applications and systems.

B. *Distance Limitations*

Distance limitations in quantum key distribution (QKD) arise due to several technical and physical challenges associated with the transmission of quantum states over long distances for many factors as in Fig. 4:



Photon Loss
Decoherence
Detector Efficiency
Quantum Bit Error Rate (QBER)
Timing and Synchronization
Limited Repeater Technology
Finite Key Rate

Fig. 4. Primary factors of distance limitations.

Distance limitations in quantum key distribution (QKD) arise due to several technical and physical challenges. Photon loss is a significant issue, with optical fibres absorbing and scattering light, leading to signal attenuation over longer distances, while free-space QKD systems face photon loss due to scattering, absorption, and atmospheric turbulence. Decoherence also poses a problem, as quantum states are highly sensitive to environmental noise and interactions with matter, causing the loss of quantum information. The efficiency of single-photon detectors decreases with distance, making it harder to detect signal photons amidst background noise.

Quantum decoherence results from environmental interactions that disrupt quantum states, leading to increased error rates and reduced security. Photon loss, which occurs due to absorption or scattering in optical fibres or free-space transmission, limits the effective transmission distance and reduces the key generation rate, making long-distance QKD impractical. Current research is actively addressing these issues through various approaches. Quantum repeaters are being developed to extend the range of QKD by linking shorter segments of entangled photons using entanglement swapping and quantum memory. Enhanced error correction codes and privacy amplification techniques are being designed to rectify bit errors and ensure the security of the key by minimizing potential eavesdropper information. Efforts in quantum error correction and the identification of decoherence-free subspaces aim to safeguard quantum information from noise. Additionally, there is progress in creating high-quality single-photon sources and detectors, such as quantum dots and superconducting nanowire single-photon detectors (SNSPDs), which help mitigate photon loss and improve detection efficiency. Research into free-space QKD and satellite-based QKD seeks to bypass the limitations of fiber optics and achieve global QKD networks, exemplified by projects like the Micius satellite in China. Future advancements include integrating QKD with classical networks, developing scalable quantum infrastructures, standardizing QKD technologies for compatibility, and reducing costs to make QKD commercially feasible.

The quantum bit error rate (QBER) increases over long distances due to photon loss, detector dark counts, and environmental noise, reducing the security and effectiveness of QKD protocols. Maintaining precise timing and synchronization between the transmitter and receiver becomes more challenging over longer distances, leading to potential errors in key generation. Unlike classical communication, quantum states cannot be directly amplified due to the no-cloning theorem, and while quantum repeaters offer a theoretical solution, they are still in the experimental stage.

Moreover, the key generation rate decreases with distance, making QKD less efficient for applications requiring high key generation rates.

Addressing these limitations requires the development of advanced technologies and strategies, such as quantum repeaters, satellite-based QKD, and advanced error correction techniques, to enable long-distance quantum communication.

C. *Distance Limitations Contributions*

To overcome distance limitations in quantum key distribution (QKD) protocols and enable long-distance quantum communication in big data environments, several advanced strategies can be investigated.

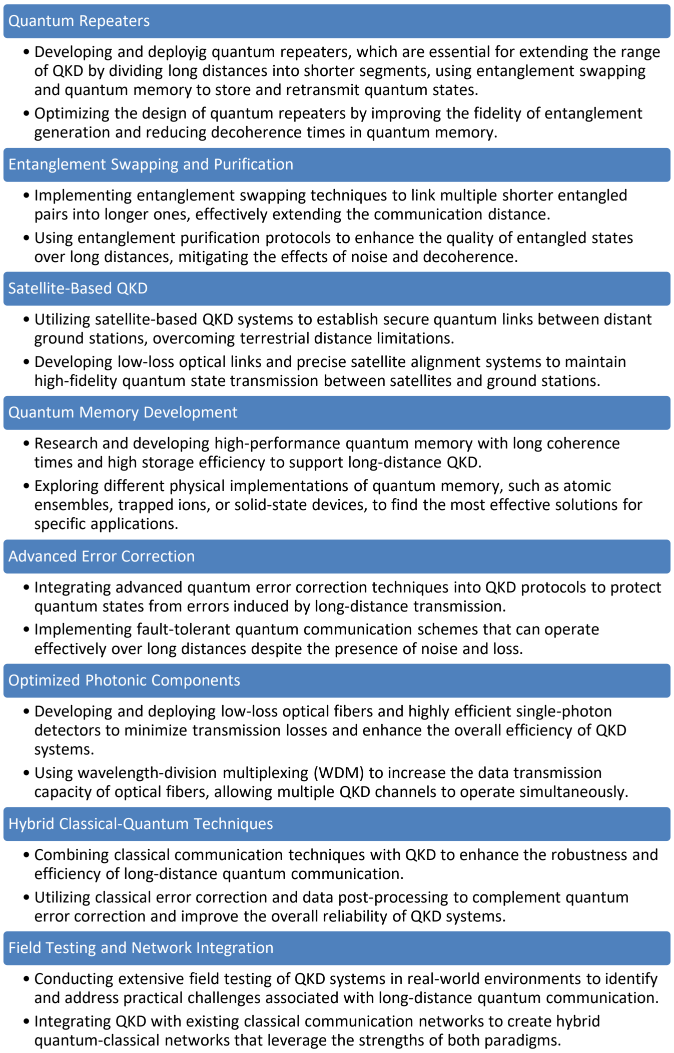
Through investigating and implementing these strategies, it is possible to overcome the distance limitations of current QKD protocols, enabling secure and efficient long-distance quantum communication essential for big data environments and other applications requiring robust security.

D. *Enhancing Security Measures in Quantum Cryptography*

To enhance security measures in quantum cryptography and develop robust defenses against potential attacks exploiting quantum system vulnerabilities, it is essential to prioritize highly technical research in the following areas:

1) Quantum Error Correction (QEC) and Fault Tolerance:

a) Develop and optimize surface codes and topological quantum error correction codes, which offer high fault tolerance by encoding logical qubits into a large number of physical qubits. Implement quantum fault-tolerant protocols using techniques like lattice surgery and braiding of anyons to protect quantum operations against errors. Research error suppression techniques, such as dynamical decoupling and quantum Zeno effect, to prolong coherence times and reduce error rates in quantum systems.



Quantum Repeaters

- Developing and deployig quantum repeaters, which are essential for extending the range of QKD by dividing long distances into shorter segments, using entanglement swapping and quantum memory to store and retransmit quantum states.
- Optimizing the design of quantum repeaters by improving the fidelity of entanglement generation and reducing decoherence times in quantum memory.

Entanglement Swapping and Purification

- Implementing entanglement swapping techniques to link multiple shorter entangled pairs into longer ones, effectively extending the communication distance.
- Using entanglement purification protocols to enhance the quality of entangled states over long distances, mitigating the effects of noise and decoherence.

Satellite-Based QKD

- Utilizing satellite-based QKD systems to establish secure quantum links between distant ground stations, overcoming terrestrial distance limitations.
- Developing low-loss optical links and precise satellite alignment systems to maintain high-fidelity quantum state transmission between satellites and ground stations.

Quantum Memory Development

- Research and developing high-performance quantum memory with long coherence times and high storage efficiency to support long-distance QKD.
- Exploring different physical implementations of quantum memory, such as atomic ensembles, trapped ions, or solid-state devices, to find the most effective solutions for specific applications.

Advanced Error Correction

- Integrating advanced quantum error correction techniques into QKD protocols to protect quantum states from errors induced by long-distance transmission.
- Implementing fault-tolerant quantum communication schemes that can operate effectively over long distances despite the presence of noise and loss.

Optimized Photonic Components

- Developing and deploying low-loss optical fibers and highly efficient single-photon detectors to minimize transmission losses and enhance the overall efficiency of QKD systems.
- Using wavelength-division multiplexing (WDM) to increase the data transmission capacity of optical fibers, allowing multiple QKD channels to operate simultaneously.

Hybrid Classical-Quantum Techniques

- Combining classical communication techniques with QKD to enhance the robustness and efficiency of long-distance quantum communication.
- Utilizing classical error correction and data post-processing to complement quantum error correction and improve the overall reliability of QKD systems.

Field Testing and Network Integration

- Conducting extensive field testing of QKD systems in real-world environments to identify and address practical challenges associated with long-distance quantum communication.
- Integrating QKD with existing classical communication networks to create hybrid quantum-classical networks that leverage the strengths of both paradigms.

Fig. 5. Distance limitations contributions.

2) Post-Quantum Cryptography (PQC):

a) Investigate and implement lattice-based cryptographic algorithms (e.g., NTRU, Ring-LWE) that are resistant to quantum attacks, ensuring they meet security, performance, and efficiency criteria.

b) Develop code-based cryptographic schemes, such as McEliece and QC-MDPC, focusing on their security proofs and resistance to both classical and quantum attacks.

c) Standardize hash-based signature schemes like SPHINCS+ and XMSS, which provide provable security based on the hardness of finding pre-images in cryptographic hash functions.

3) Advanced QKD Protocols:

a) Enhance decoy-state QKD protocols to resist photon-number-splitting (PNS) attacks by using variable intensity decoy states to detect eavesdropping attempts.

b) Implement device-independent QKD (DI-QKD) protocols, which provide security guarantees even when the devices used are untrusted, by leveraging the violation of Bell inequalities.

c) Develop measurement-device-independent QKD (MDI-QKD) to eliminate side-channel vulnerabilities associated with detection devices by using entanglement swapping at an untrusted relay.

4) Quantum Cryptographic Protocols:

a) Research quantum secret sharing (QSS) schemes, focusing on their robustness against collusion attacks and practical implementation in multi-party scenarios.

b) Develop quantum digital signature (QDS) protocols that ensure non-repudiation, integrity, and authenticity of quantum messages using techniques like quantum one-time pads and entanglement.

c) Enhance quantum secure direct communication (QSDC) protocols to enable secure direct transmission of confidential information without the need for pre-shared keys.

5) Quantum Random Number Generation (QRNG):

a) Design high-speed, entropy-enhanced QRNGs that leverage quantum phenomena such as vacuum fluctuations or photon arrival times to produce truly random numbers.

b) Integrate QRNGs into cryptographic systems to strengthen key generation and enhance the overall security of quantum cryptographic protocols.

6) Quantum System Vulnerability Analysis:

a) Conduct rigorous vulnerability assessments of quantum hardware, including qubits, gates, and measurement devices, to identify and mitigate potential attack vectors.

b) Develop formal verification techniques for quantum cryptographic protocols, using quantum information theory and complexity theory to prove their security properties under various attack models.

7) Quantum Network Security:

a) Design secure quantum network architectures incorporating quantum repeaters with entanglement purification and error correction capabilities to extend the range of QKD.

b) Develop quantum-safe network protocols, ensuring secure key exchange and data transmission over hybrid quantum-classical networks.

8) Side-Channel Attack Mitigation:

a) Investigate side-channel attacks specific to quantum systems, such as timing analysis, power analysis, and electromagnetic leakage, and develop corresponding countermeasures.

b) Implement hardware-level countermeasures, such as shielding, noise generation, and randomized gate operations, to protect against side-channel attacks.

9) Quantum Hardware Security:

a) Develop tamper-resistant quantum hardware components, including qubits and quantum gates, with built-in fault tolerance and error correction to prevent unauthorized manipulation.

b) Research secure hardware initialization and calibration protocols to ensure consistent and secure operation of quantum devices, preventing malicious tampering.

10) Collaboration and Standardization:

a) Foster collaboration among academia, industry, and government agencies to share advancements, best practices, and research findings in quantum cryptography.

b) Contribute to the development of international standards for quantum cryptographic protocols, ensuring interoperability, security, and widespread adoption of secure quantum technologies.

By prioritizing these technical research areas, the security of quantum cryptographic systems can be significantly enhanced, making them more resilient against sophisticated attacks and ensuring the safe and reliable deployment of quantum technologies.

VI. Conclusion

Classical and quantum cryptology encounter limitations that shape their applicability in secure communication. In classical cryptology, security is contingent upon the computational complexity of mathematical problems, such as factorization and discrete logarithms. The advent of quantum computers poses a potential threat to classical cryptographic algorithms, as quantum computers could efficiently solve these problems using algorithms like Shor's algorithm. Additionally, classical key distribution often relies on secure channels or pre-shared keys, introducing vulnerabilities if these channels are compromised.

Quantum cryptology, while offering information-theoretic security and resistance against quantum computers, faces practical challenges in terms of developing and maintaining stable quantum hardware. Quantum key distribution (QKD) protocols may be constrained by issues such as quantum decoherence, photon loss, and the development of efficient quantum repeaters for extending communication ranges.

Both classical and quantum cryptology present trade-offs, necessitating careful consideration based on the specific security, computational, and implementation requirements of a given scenario. Quantum solutions are known to be expensive, however QKD are good for eavesdropping as quantum computers can break security measures so it’s better to upgrade security level to quantum practices such as quantum cryptography for data security.

The selection between quantum cryptology and classical cryptography hinges on the specific security requirements, computational capabilities, and practical considerations inherent to a given application.

Quantum cryptology, rooted in the principles of quantum mechanics, offers a promising avenue for achieving information-theoretic security, notably through quantum key distribution (QKD) protocols. Quantum systems are inherently resistant to attacks by quantum computers, providing a potential advantage in a future landscape where classical cryptographic algorithms might be vulnerable to quantum advancements.

However, challenges persist in terms of practical implementations, including the development of stable quantum hardware, the management of quantum noise, and the extension of secure communication over distance. Classical cryptography, built on mathematical complexity assumptions, is well-established and generally more efficient and scalable for current applications. Yet, its security is contingent upon computational hardness, rendering it susceptible to future quantum computing capabilities.

VII. Future Directions

Despite the unmatched security offered by Quantum Key Distribution (QKD), limitations in data volume, transmission range, cost, and network integration hinder its real-world implementation. Future research should prioritize overcoming these hurdles. A critical question lies in developing efficient QKD protocols capable of handling larger datasets without sacrificing security. Experimentation with entanglement swapping and multi-photon protocols holds promise in this area. Extending transmission distance necessitates tackling signal degradation. Research on advanced error correction and quantum memory could improve signal fidelity over longer distances, while prototype development of quantum repeaters, devices that relay quantum information, is crucial for extending QKD's reach. Reducing cost and complexity requires exploring alternative sources for entangled states and miniaturization techniques for QKD components. Seamless integration with existing infrastructure hinges on standardized protocols and interfaces that allow QKD systems to interoperate with classical communication networks. By addressing these limitations through focused research and experimentation, QKD can evolve into a practical and scalable solution for securing communication in the quantum age.

Design and Development of a Unified Query Platform as Middleware for NoSQL Data Stores

Hadwin Valentine, Boniface Kabaso
Faculty of Informatics and Design, Cape Peninsula University of Technology, Cape Town 8000, South Africa

***Abstract*—The advancements in technology such as Web 2.0, 3.0, mobile devices and recently IoT devices has given rise to a massive amount of structured, semi-structure and unstructured datasets, i.e. big data. The increasing complexity and diversity of data sources poses significant challenges for stakeholders when extracting meaningful insights. This paper demonstrates how we developed a unified query prototype as middleware using a polyglot technique capable of interrogating and manipulating the four categories of NoSQL data models. This study applied established algorithms to different aspects of the prototype to attain this study's objective. The prototype was subjected to an experiment where varying query workloads were processed. The performance data comprised of application performance index, memory consumption, and execution time and error rates. The results demonstrated that the prototype had a low error rate indicating it's robustness and reliability. In addition, the results showed that the prototype is responsive and able to query the underlying storage system effectively and efficiently. The prototype provides a standardize set of operations abstracting the complexities of each underlying storage system; reducing the need for multiple data retrieval management systems.**

Keywords—Unified query; polyglot; NoSQL; middleware; query processing; big data

I. Introduction

Information systems in the modern era have shifted the mindset of organizations from application-driven processes to data driven initiatives, i.e. big data. This has led to the creation and adoption variety of NoSQL database technologies, each with its own underlying architectural principles [1, 3]. As a direct result of big data technologies, organizations face the ultimate challenge; how to query structured, semi-structured and unstructured data uniformly? Since numerous NoSQL storage technologies exist; technical consumers have embarked on creating a singular platform for consolidating these heterogeneous data models [17, 27].

The term NoSQL is often confused with "No SQL", the implication being that NoSQL is intended to replace relational SQL database management systems. However, the actual meaning refers to "Not Only SQL" [27]. NoSQL technologies has become the preferred choice for managing big data in this ubiquitous digital realm [1, 3]. The NoSQL philosophy essentially stems from the shortcomings of the relational database management systems. The NoSQL technology stack supports four fundamental data models (1) key-value, (2) column-orientated, (3) document-orientated and (4) graph models [1]. These data models are schema-less in nature, owing to the de-normalize data it holds within the data store [8, 27]. This requires data to be interpreted by the consuming application. A number of challenges start to arise when collating heterogenous NoSQL data schemas from disparate sources since each database system has its respective guidelines and features [17]. This is partly due to the absence of a global schema capable of encompassing the four fundamental data models promoted by NoSQL technologies. As each NoSQL database technology is tailored to serve specific use cases.

In the absence of a global schema for diverse data sets [16, 27], organizations painstakingly develop very specific and rigid implementations to consolidate data from different databases in order to gain valuable and actionable insights from a particular business domain. This activity is traditionally accomplished through data warehousing via ETL's i.e. extract, load and transform [8]. However, the past decade has seen a rise of proposed and propriety unified query solutions to bridge the heterogenous querying gap that exists between database technologies. This data-driven need is inspired by organizations looking to extract key metrics from data to support strategic business initiatives in real time [8, 13, 32]. A common approach used to consolidate disparate data sources is to develop middleware. This is known as a polyglot persistent solution. Polyglot persistent solutions in the context of this paper refer to a system's ability to interact with several database technologies in a multi-faceted way. While there have been numerous successes in these endeavours, the solutions tend to serve very specific use cases and are not easily generalized to the wider IT audience.

A. Aim of Research

The primary objective of this study was to evaluate and validate the effectiveness and efficiency of the developed unified query prototype. It measured the performance of the query process in a holistic manner specifically in terms of query response times, accuracy, reliability and efficacy across different NoSQL storage systems.

B. Significance of Study

This study simplifies the querying process for interrogating multiple categories of NoSQL storage systems. It facilitates seamless data integration, while ensuring data consistency across the supported data models. The prototype segments the boundaries between the varying databases making it easier to extend the family of storage options appropriate for big data [10] applications. Moreover, it assists in outlining the direction for future research initiatives in unified query systems, fostering advancement in the field.

C. *Problem Statement*

In the absence of a global query instrument, interrogating heterogenous NoSQL storage systems presents complexities when attempting to collate data in a uniformed manner [5, 25]. According to Zhang et al. [9:p.1], the various NoSQL storage models inherently serves by design “different characteristics supported by different database systems and the differences in query syntax rules”, thus impeding the pursuit standardization for uniformed query.

Consequently, software engineers spend an inordinate amount of time learning each individual NoSQL database’s features. Although a number of research papers have contributed towards developing a unified query model, not many middleware solutions truly encapsulate how key-value, column-orientated, document-orientated and graph data models may be query via a single query mechanism simultaneously. Furthermore, there are unequivocally no standardized data modelling paradigms to the best of our knowledge that exist today able to consolidate the four distinct NoSQL types through normalised methods [15, 9].

An effective and efficient way to overcome this obstacle is to develop a query platform system. This is exactly what this work entailed. Adopting an approach to easily interface with the heterogeneous data models while abstracting the technical details of each storage mechanism. This study provided insights on a developed prototype to determine its feasibility.

D. *Contributions*

The study contributes to the field of unified query systems in several ways. Firstly, offers a text-based language that’s intuitive abstracting the technical barriers of each underlying storage system. Secondly, it presents a novel approach [2] to querying multiple NoSQL systems in a uniform manner by organising established programming design patterns in a unique way. In addition, the modular approach facilitates scalability in terms of extending support for additional storage options without impeding existing supported targeted options. Finally, the prototype's performance results demonstrated that it reduces operational time and costs, considering how it envelops query workloads in a standardized manner.

E. *Summary*

In this paper, we present the design and development of a unified query platform that acts as middleware for NoSQL datastores. Our research aims to address the challenges associated with querying across heterogeneous NoSQL databases by providing a single query interface that abstracts the underlying complexities. In order to provide clear and concise view of the study, we have organized this paper as follows:

- Section II: Background - Identifies key principles that’s required to be present when developing a unified query platform as middleware.
- Section III: Related Works - Discusses related work on existing polyglot solutions within the context of NoSQL databases.
- Section IV: Proposed Architecture - We discuss the architectural and design details of our proposed unified query platform. Furthermore, we describe the composition of the prototype and the software design patterns applied.
- Section V: Experimental Approach - Describes the evaluation method employed to assess the performance of the prototype.
- Section VI: Prototype’s Results - We present and analyse the results attained through the experiment.
- Section VII: Discussion – We identified and discussed key findings and repeated themes encountered in the experiment.
- Section VIII: Conclusion and Future Work - Summarizes the key findings and implications of our research. We also outline future work directions.

II. Background

Polyglot query systems generally adheres to layered architectural pattern. However, each layer encompasses a unique class of problems which it aims to resolve [4, 3, 24]. The differences lies within the variety of approaches, methods, principles and technology instantiations to satisfy the intended use cases as shown in Fig. 1. Researchers assessing polyglot systems concur that specific criteria must be met during solution development for it to be deemed acceptable [6, 30]. These criteria form the foundation of unified query resolutions. They are designed to streamline the diversity among various data storage mechanisms [8, 28] and facilitate the abstraction process needed to tackle the complexities inherent in a disparate collection of database technologies.

A. *Key Principles*

We’ve identified fives key principles that should be present in these types of systems:

1) Abstract syntax tree: In computer science an Abstract Syntax Tree (AST) acts as a mediator, bridging the gap between conceptualization, design, implementation, and execution, regardless of the underlying technology employed. This concept has found utility across various research domains, including source code compilers, security exploration, anti-plagiarism detection, and code analysis systems [14, 31].

Within the scope of this study, an AST is employed within the query parser to ensure that commands adhere to syntax, semantic, and lexical rules, thereby guaranteeing that the command constitutes a well-formed statement [19].

2) Schema consolodation: A fundamental aspect of developing unified solutions is obtaining a comprehensive understanding of the schema information for each underlying storage mechanism [15]. This is commonly referred to as metamodeling. Despite the promotion of NoSQL as schema-less because of its efficient handling of unstructured data, there indeed exists a schema. Depending on the vendor, schema constraints may be enforced, which the consuming application must adhere to.

3) Query translation: Arguably, the most crucial aspect of any unified solution is to generate native queries capable of interrogating NoSQL storage models [23, 32]. It's important to note that this feature is heavily influenced by the unified approach shown in Fig. 1. However, conceptually, regardless of the approach, it facilitates the generation of native queries that can execute on their respective NoSQL databases.

4) Database integration: In every unified query solution, provision must inevitably be made for communication with the targeted databases [17]. NoSQL databases commonly employ diverse protocols as communication mediums to access the data source [9, 23]. These communication protocols range from HTTP(S) to TCP/IP, typically employing an adaptor or driver that implements a generic interface for database connection. An intriguing observation noted during this study is a direct correlation between the primary communication protocol and query language. Depending on the protocol, the query interrogation mechanism may access the database data via an API endpoint or some form of lower-level network protocol for data exchange.

5) Output management: To present data from various storage systems uniformly, unified query systems typically employ two approaches: Global-as-View (GaV) and Local-as-View (LaV), where data unification is facilitated by a mediator [8, 13]. It's important to note that this also contributes to the aforementioned key features. This feature is categorized as a mediator, an intelligent layer that possesses structural knowledge of the local data stores. GaV integrates schemas of the underlying local data stores, providing a unified view of heterogeneous structures. Conversely, LaV amalgamates local schemas to form a global view.

III. Related Works

Polyglot solutions like BigDawg aims to leverage the relative strengths of underlying DBMSs to effectively process data [30]. This solution embraces three types of data models: key-value, relational, and array stores. The architecture of BigDawg primarily focuses on query processing rather than query construction. Its objective is to utilize key features to achieve optimal performance and produce the most comprehensive result set. To achieve this objective, the architecture incorporates features such as islands, shims, and cast, as illustrated in Fig. 2 [6, 30].

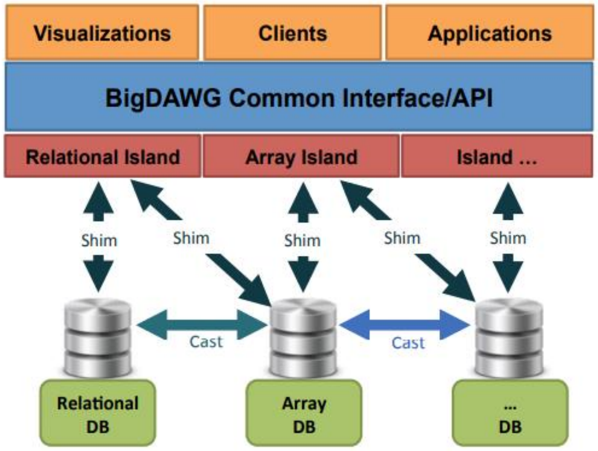

Fig. 2. BigDawg architecture [30].

An island is associated with a specific data model and a set of query language features for the storage engine it intends to support. A shim acts as a communication bridge between the island and the storage engines. A cast facilitates data migration from one storage engine to another. The API directs inquiries to the middleware, which handles query execution and data migration through casts [4]. The middleware comprises various modules, including the query planner, performance monitor, and executor. These modules validate the semantic correctness of queries and route them to the appropriate storage mechanism for execution.

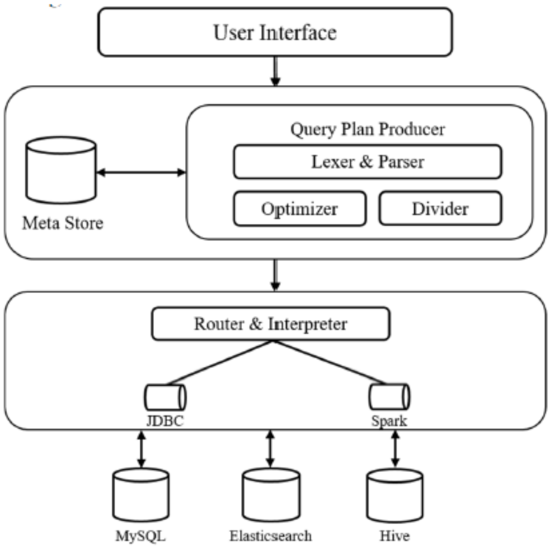

Fig. 3. Unified SQL query middleware architecture [9].

Zhang et al. [9] introduced a solution that employs middleware to execute queries on multiple heterogeneous databases through a unified interface using standard SQL syntax. Their segmented architecture, depicted in Fig. 3, separates the initial query from the targeted queries via an abstract syntax tree. This tree is responsible for verifying if the initial query aligns with the requirements of the respective heterogeneous databases. While the article mentions that the middleware supports a pluggable interface for new data sources, it does not detail how this would impact the abstract tree and computing layer. The provided middleware comprises three main components: a syntax parsing layer, a computing engine, and a data layer. The syntax layer validates a unified query against a customer abstract syntax tree. Native queries are then generated based on a meta store, which delegates them to the computing engine for execution on the data layer.

NoDA, a lightweight implementation, acts as an intermediary layer between applications and targeted NoSQL databases, including MongoDB, HBase, Redis, and Neo4j [23]. This middleware offers a generic set of operators such as sorting, filtering, and aggregation, aiming to efficiently execute queries using the Apache Spark open-source data analytical framework. Although NoDA is categorized as a polyglot implementation, it simplifies complexity by separating the rule engine, which validates syntax and semantics of the unified query, from the abstract layer using a third-party tool.

Cox et al. [29] introduced the Translator Query Language (TranQL), a solution that federates biomedical ontologies within a framework. Their study is grounded in real-world case studies. TranQL utilizes natural language to map to queries, generating targeted queries on various graph data models. An essential component of the framework is the Translator KGS API, which employs the shared schema RDF concept to express queries as Biolink data model, a hierarchical medical ontology at a high level. This API maps a network of knowledge graphs as a coherent whole, forming the basis for TranQL as a unified query pattern by interconnecting federated knowledge graph data models through curated links across entities.

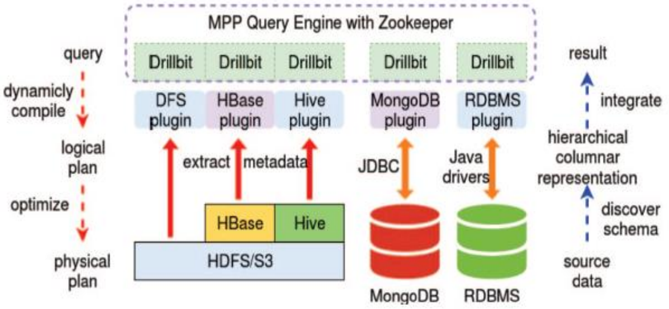

Fig. 4. Unified SQL query middleware architecture [28].

Apache Drill is a fully distributed open-source software framework designed for large-scale analysis in data-intensive applications [16]. It specializes in processing extensive datasets efficiently by executing tasks in parallel. The Apache Drill solution leverages in-memory data representation in JSON and Parquet formats for rapid data manipulation operations. Additionally, its MPP (Massively Parallel Processing) query engine dynamically compiles and recompiles data queries on the fly to maximize performance, relying on parallelism [28]. Similar to BigDawg's implementation, Apache Drill supports various data models accessed through a comparable mechanism as illustrate in Fig. 4. However, instead of islands, it utilizes plugins to connect to different storage engines and file systems via the Drillbit component [6]. Drillbit serves as a background component orchestrating the optimal execution query plan. The query executions are partially rendered on an execution tree and brought into memory.

CloudMdsQL is recognized as a multistore system capable of querying multiple databases through its SQL-Like unified query construct [4, 6]. Supporting relational, NoSQL, and HDFS storage mechanisms, CloudMdsQL is designed to leverage the inherent features of each supported heterogeneous data store [23]. The abstract layer catalogs the semantics rules of the supported data stores, enabling the optimization of native queries. This allows the construction of native queries through a relational query framework for targeted executions. The results of embedded invocations are converted into an intermediary table for distributed processing.

A. *Evaluation Approaches of Polyglot Systems*

It's important to note that this paper does not encompass all unified solutions, as the objective is not to describe every possible solution. Rather, we aim to introduce readers to the distinguishing components of these solutions and the use cases it aims to satisfy. Research papers proposing unified query solutions understandably prioritize the overall utility of the artifact. Much emphasis is placed on practical considerations such as query workloads, indexing, and partitioning, which are integral to query processing [13, 32].

The described polyglot solutions are tailored to address different use cases. For instance, Apache Drill excels in processing vast amounts of data for analysis, requiring robust hardware as it loads data into memory for rapid retrieval [6]. Conversely, CloudMdsQL and BigDawg aim to leverage the full capabilities of supported databases' native features to process data, thereby providing users with enhanced native capabilities. TranQL serves as a federated query system for Biolink data using a topology of graph stores. Each of these solutions comprises a collection of individual isolated components targeting the supporting databases. These components operate independently, acting as intermediaries between the middleware layer and the database, except for BigDawg, which allows data integration between silos.

Other solutions, such as NoDA, are less intricate, as it follows the basic principles. This prototype primarily focus on the query construct [23, 9], which aligns with the goals of this study. Although the middleware supports the four primary categories of NoSQL data models, it can only query one underlying database at a time. The authors highlight this limitation, underscoring that the prototype primarily emphasizes the system's capability to access data through its connector. Zhang et al. [9] on the other hand, is limited to select queries and does not accommodate evolving schemas. Additionally, the use of wildcards within the middleware may introduce suboptimal practices and potential runtime issues stemming from datatype and schema mismatches.

IV. Proposed Architecture

This section presents the methods employed to design and develop the prototype. The goal of this prototype was to provide a high-level unified query platform that is database-agnostic capable of querying data across the four distinct types of NoSQL storage models simultaneously [17]. The prototype provides a query language that offers a consistent a set of syntax, semantics and data operations to express queries in a generic manner for the targeted storage models.

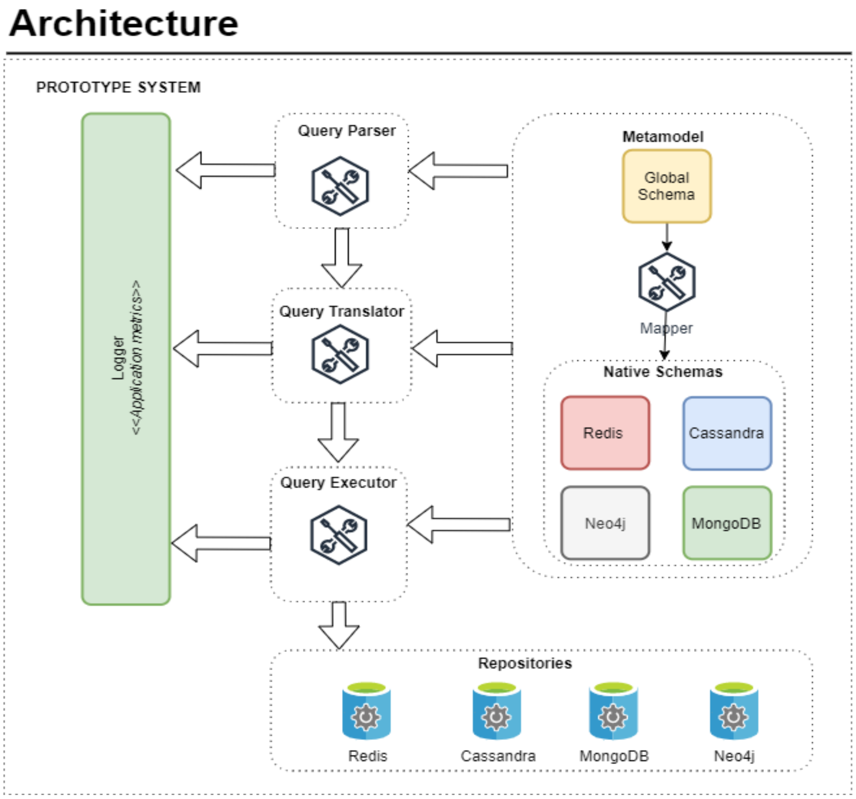

Fig. 5. Prototype: architectural overview.

The prototype for the unified query platform had the following basic requirements, (1) develop a custom parser that accepts a SQL-like query as input, (2) develop a metamodel describing the each of the native schemas as well as the global schema, (3) build a translation engine that accepted the parser's output and generated a native queries, (4) build a an executing layer that accepts the native queries as input and executes it on the supported NoSQL data stores, and finally a (5) logging mechanism to audit performance and functionality of the prototype. This is encapsulated in Fig. 5. showing the overall architecture and the interactions between the various components.

Design Science Research: This paper used DSR methodology to ascertain the necessary knowledge to build the prototype. DSR is a problem-solving architype that creates knowledge on the design process and product concurrently [12]. The study subscribed to the seven guidelines proposed by Hevner et al. [2]. The design and architectural choices made was influenced by existing literature and the empirical insights during the development and evaluation phase of the prototype. The iterative nature facilitated the authors of this study to test and refined the prototype based on ideal approaches and current shortfalls on unified query platforms. The constant feedback loop guided the software development lifecycle [18]. The act of the repeated circumscription process influenced the prototype construction until design requirements in Table I were satisfied. A student database for each instance of the supported NoSQL storage systems was created shown in Appendices A and B to interrogate.

The study employed a mathematical abstraction, wherein *q(n)* symbolizes the native or targeted query for each instance category of a NoSQL database [3]. Furthermore, *DS* represents the data source which consolidates the four supported types of NoSQL storage data models. i.e., *GR* - Graph, *KV* - Key-Value, *DO* – Document-Orientated, *CO* - Column- Orientated data stores. The data source is represented as $DS \rightarrow GR \cup KV \cup DO \cup CO$, indicating which the NoSQL data storage models are supported. The query parser ensures the unified query conforms to the signature of the abstract syntax tree, whereby the unified query is required to prove it conforms to the lexical (*lex*), semantic (*sem*) and syntactic (*syn*) rules of the prototype.

$$S_{lss} = \sum_{i=0}^{n-1} k^i, k < (lex[\mathrm{i}] \wedge sem[\mathrm{i}] \wedge syn[\mathrm{i}]) \quad (1)$$

The query translator verifies if the targeted data model, *dm(k)*, specified in the unified query is an element of the data source:

$$dm(k) = \begin{cases} 1, & if\,(k \in DS) \\ 0, & otherwise \end{cases} \quad (2)$$

Once the system has established that the data model is supported by one or more elements of the data sources, it is required to generate the targeted or native query, *t(k)*:

$$t(k) = \begin{cases} 1, & if\,(dm(k) \vdash (GR \mid KV \mid DO \mid CO)) \\ 0, & otherwise \end{cases} \quad (3)$$

The query executor subsequently directs *t(k)* to appropriate NoSQL database instance to be executed. If $q(n) = \prod_{k=1}^{DS_n} k, \exists_n [\emptyset, n]. t(k). dm(k)$ *holds dm(k)*, the native query is executed on the target storage model. Finally, the object mapper wraps the output of each target query into a result, $r_i = o \in [q(0), \dots q(n)]. (k \geq q(k))$.

A. Design Requirements

A set of requirements were identified to achieve the envisioned design goals shown in Table I. Each requirement was linked to a component responsible for a specific functionality in realising a unified query platform. These components function are akin to "spokes in a wheel," relying on each other to accomplish the functional objectives.

TABLE I. PROTOTYPE DESIGN REQUIREMENTS

Prototype Design	
Components	***Requirements***
Metamodel repository	Create a metadata schema denoting Redis.
	Create a metadata schema denoting Cassandra.
	Create a metadata schema denoting MongoDB.
	Create a metadata schema denoting Neo4j.
	Create a global metadata schema.
Query parser	Build a lexer for input characters.
	Build a query syntax tree.
	Build a semantic engine.
Query translator engine	Build Syntax and Semantic Matching engine.
	Build Feature Mapping engine.
	Build Query Optimization engine.
Query Executor	Build a database adapter for NoSQL databases.
	Map native results to a global view.
Log Mechanism	Build data collection mechanism.

B. Prototype Construction

The first step was to determine how context and meaning can be given to the prototype's intended query language [14, 19]. Therefore, the prototype facilitates three commands: Fetch, Add and Modify (Appendix C). The nature of these commands is intrinsic, as their names suggest. The Fetch command retrieves data, the Add command inserts data, and the Modify command updates data across the supported NoSQL storage system concurrently. Determining the fundamental intent of the query serves as the initial step in shaping the unified query platform.

1) Query parser: To operationalise the commands, an AST was built within the query parser component. A text-based language was the preferred design choice to serve as the prototype's unified query as its familiar to consumers interrogating data and will most likely drive greater adoption [19]. The elements of the query language within the prototype were deconstructed into an organized tree-like structure. The prototype incorporates an embedded lexer feature within the query parser component, which scans the text and generates a stream of tokens, serving as input for the subsequent parsing phase. During the parsing phase, the stream of tokens produced as shown in Table II by the lexer is systematically examined, and the abstract syntax tree (AST) is constructed based on the grammar rules of the unified query language. The keywords and identifiers guided informed the prototypes query intent, path and code generators to executed the appropriate native query. On this basis the necessary tokens is generated are representative of the unified query's meaning and purpose.

TABLE II. PARSER'S LEXICONS

Keywords	**Parser**	
	Lexicons	***Input Text***
	FETCH	FETCH
	MODIFY	MODIFY
	ADD	ADD
	PROPERTIES	PROPERTIES
	DATA_MODEL	DATA_MODEL
	FILTER_ON	FILTER_ON

	GTE	>=
	LTE	<=
Literals	NUMBER	1,2,3,4,5,6,7,8,9,0
	STRING	Aa,Bb,Cc,….Zz

The prototype employs a parser combinator technique, where multiple parsers are accepted as input to create a new parser as output. This technique enables the prototype to modularize sections of the query language by recursively traversing through the token stream and using demarcating locations. These demarcated locations assist the program in indicating where the parser should start and stop. Following a recursive descent strategy, the parser inspects terminal and non-terminal symbols based on the syntactic rules governing the grammar of the unified query. This process results in grouping a disjointed set of nodes [11]. A lightweight library called Superpower was utilised to facilitate the construction of token-driven parsers embedded directly in the source code [21]. This library is an extension of Sprache, a text-based parsing framework that does not require any additional build tools or runtime configurations. According to its documentation “it fits somewhere in between regular expressions and a full-featured toolset like ANTLR” [20]. A demonstration of the lexical activity reveals how the tokens are generated by the prototype as per a given input (Appendix D). Once the unified query has proven to be well-formed by the parse, the prototype delegates the query to the metamodel to determine if the actual properties are defined in the global schema.

2) *Metamodel:* The function of the metamodel is to bridge the gap between the unified and native schemas [6, 16, 17]. It plays a crucial role in the solution by revealing the physical structures of the native schemas and the conceptual structure of the global schema. The global schema contains instructional configurations to the native schema, indicating the relationship between the models. The prototype's metamodel catalogues each storage mechanism's schematics, data types, and indexes. Additionally, it assists the query parsing mechanism by performing basic validations to ensure that the specified fields are supported by the unified query data model. It aids the query translator in resolving native references at runtime and assists in generating the appropriate native query constructs. To some extent, it informs the query processing engine about the optimal query to create when inspecting relevant native storage mechanism schematic information such as indexes and unique keys.

3) *Query translator:* The translation engine has several features for the query processing and the creation of executable native queries:

- Syntax and Semantics Matching
- Feature Mapping
- Query Optimization

a) Syntax and semantics matching: Any unified query polyglot system targeting multiple types of databases, will innately have different syntax and semantics compared to the native query languages [5]. Hence, the prototype’s query translation engine finds the equivalent meaning and grammar of the supported databases in order to successfully build executable queries. Finding the equivalent match ensures the intended meaning and functionality is preserved during the conversion process of unified query. In addition, the syntactic translation involves converting the unified query's expressions, keywords, identifiers, literals and operators to match the syntax of the native query language [23]. This ensures the adherence to each supported database, safeguarding against unintended results once the generated query is eventually natively executed.

b) Feature mapping: The prototype’s query language in some instances does not have the direct equivalent features or constructs in the targeted native query language. It attempts to preserves the anticipated functionality while still creating a converted query that may be executed. In general, features for database management systems are naturally influence by the applicable use cases [1, 3]. In the instance of the key-value database, Redis, aggregation amongst other features are not natively supported in its database management as shown in Table III. Therefore the prototype requires an additional abstraction layer for the Redis data store to circumvent this issue which currently does not support.

TABLE III. PROTOTYPE VERSUS EQUIVALENT NATIVE DATA STORES FEATURES

Prototype	Redis	Cassandra	MongoDB	Neo4j
Aggregation				
NSUM		X	X	X
NAVG		X	X	X
NMIN		X	X	X
NMAX		X	X	X
NCOUNT		X	X	X
Filtering				
WHERE	X	X	X	X
AND		X	X	X
OR		X	X	X
JOIN				X
RESTRICT		X	X	X
Sorting				
ASC		X	X	X
DESC		X	X	X
Projections				
*No explicit command			X	X
Operators				
’=’, ’+’, ’ -’, ’*’, ‘/’	X (only ‘=’)	X	X	X
Comparators				
’<’, ’<=’, ’>=’, ’>’		X	X	X

The translation engine maps these features to appropriate native constructs, ensuring the preservation of the expected functionality. Specialized strategies for each of the inherent data stores was built, thus establishing clear boundaries between the various NoSQL translation layers.

c) Query optimization: The query optimizer plays an key role in the efficiency of the polyglot solution. The prototype employs an approach concerned with delegating the heaving lifting to the targeted database of query filtering, sorting, projections and aggregation where applicable [32]. As a consequence, it aims to shift the I/O, memory and CPU processing power to the respective DBMS reducing the computational footprint on the prototype. Additionally, pushing operations such as projections and filtering closer to the data source, reduces the network bottleneck when data is transferred between the prototype and the corresponding NoSQL data stores [27].

4) Query executor: This component is responsible for natively running queries produced by the query translation engine against the respective NoSQL data sources. It establishes the database connections, the authentication procedures and data transfer between the unified query platform and the data source, similar approaches to BigDawg, NoDA [9, 23]. The prototype's query executor coordinates the concurrent executions of the respective native queries amongst the NoSQL data stores based on the targets specified in the unified query. It splits the executable queries into multiple processing units by creating threads for each one. For each data source, the executor collects the query results. It performs any necessary data mapping to present a consolidated result. Any errors and exceptions that may occur during query execution process provides the appropriate error messages back to the query interface.

5) Logger: The experiment embeds metrics directly into the prototype. Utilizing an open-source library known as App Metrics (app-metrics.io, 2021), the prototype measured various performance aspects of the components within the unified query solution. The report modules provided a set of libraries through which the unified query parser, translator, and executor could be scoped.

C. Design Integration

Ultimately, the prototype needed specific non-functional aspects to finalize the solution. The study identified the (i) query intent, (ii) query path, and (iii) query generator as key elements comprising the non-functional requirements. Each of these elements was implemented using established programming design patterns. Fig. 6 depicts the alignment of the parser, translator, and executor components with the non-functional requirements. It illustrates the path of the unified query through each stage of the query processor and, importantly, how the design programming patterns are encapsulated within this process.

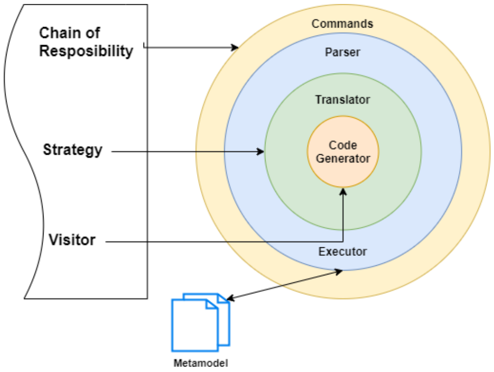

Fig. 6. Prototype design patterns and components.

1) Query intent: Determining the intent of the unified query is crucial as it directly influences the expected outcomes. This necessitates the solution to align the prototype commands with the corresponding features of each native system. Once the query intent is identified, the prototype directs the query to follow the appropriate query path. The chain of responsibility design pattern was selected, wherein the prototype dynamically determines which command to execute at runtime [22]. The prototype defines *Fetch*, *Add*, and *Modify* commands as handlers (see Fig. 7), each responsible for interpreting its respective request. These handlers share a common interface, which is tasked with dispatching client query requests to the appropriate command handler based on the data inquiry [26]. The command handlers contain the query parser and translator logic.

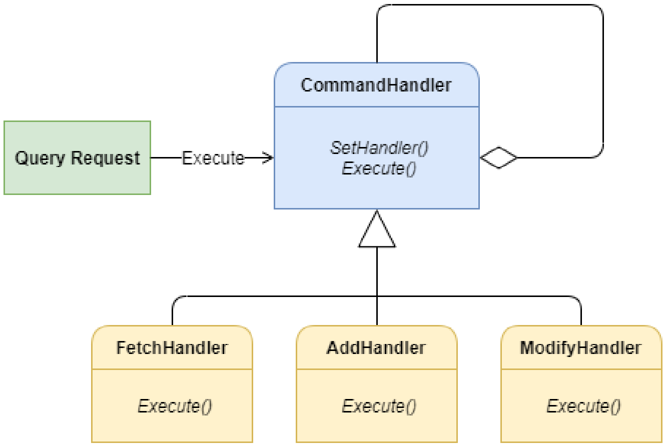

Fig. 7. Query intent: chain of responsible design pattern.

This pattern has found widespread application in scenarios where system messages dictate the execution result [7]. Upon the program's initiation, new instances of each command type are created, resulting in a chain of objects. To enhance the efficiency of the execution processing chain of objects, the collection of concrete handlers, i.e., command handlers, was organized as a dictionary, with the command types serving as unique keys. The query request passed to handlers is tagged with the appropriate command type, which is then used to locate the corresponding handler in the execution chain. In instances where the command is not found in the dictionary, no action is taken, and the unified query request is aborted with an error message. The prototype implements the chain of responsibility in the following manner as shown in Table IV. *Q* denotes the intent of the query language. Each of the commands within the unified query are denoted as *f* for *Fetch*, *m* for *Modify* and *a* for *Add*. Therefore the command, represented as *cmd*, must always be present in the unified query. Thus one can conclude that the *cmd* is a subset of *Q*, i.e. $cmd \subseteq Q$. *N* represents the collection of nodes within the AST, $N \rightarrow \{n_1, \dots, n_n\}$. The nodes are assigned an array of instantiations expressing the mechanical parts of the query. The prototype is able to discover command instantiations thereby enabling the correct handler to be invoke. This act facilitates the prototype to realise the intent.

TABLE IV. CHAIN OF RESPONSIBILITY PATTERN PSEUDOCODE

Algorithm : Query Intent

```
$\coloneqq \boldsymbol{QueryIntent(q)}$
$\boldsymbol{if}\ q \in Q\ \boldsymbol{do}$
  $\boldsymbol{if}\ q.cmd \in f\ \boldsymbol{do}$
    $f(N)$
  $\boldsymbol{else\ if}\ q.cmd \in m\ \boldsymbol{do}$
    $m(N)$
  $\boldsymbol{else\ if}\ q.cmd \in a\ \boldsymbol{do}$
    $a(N)$
  $\boldsymbol{else}$
    $InvokeError$
```

2) Query path: In anticipation of the native query generators, the query path determines the supported NoSQL storage systems to target and the components to execute. This guarantees the generation of the correct native query based on the unified query intent. The strategy pattern was employed, ensuring the appropriate algorithm is enforced based on the query elements specified in the target clause within the AST. Each of the supported NoSQL data storage models was defined as descendants within a family of algorithms shared by the same ancestor [22]. In the prototype, each of the supported NoSQL data models is represented as specialized classes responsible for constructing a collection of visitors to be executed by the query generator. The prototype takes the query intent as input and matches the command and storage target to the relevant strategy. During the translation process, the repository metamodel is utilized to identify the equivalent native field for the unified field. If no matches are found, the field is excluded. The prototype intentionally constructs a collection of class instantiations, represented as visitors, to closely mimic the structure of the native query languages it needs to create. Finally, once the native queries are generated by the query generator, the strategy pattern sends the output back to the calling method for execution.

The query path strategy implementation considers the target models specified in the unified query once the command has been established (see Fig. 8). The target models as shown in Table V. where *rs* represents redis, *ms* mongodb, *cs* cassandra and *ns* neo4j. The translator component *T*, accepts the target models as input thus directing the appropriate queries to be generated. The supported NoSQL databases are implemented as concrete classes subscribing to a single collection as they all share a common interface, $SP \rightarrow \{sp_1, \ldots, sp_n\}$. The classes inherits from a base strategy class where $sp_n \in (rs \mid ms \mid cs \mid ns)$. The strategies are preloaded within *T*. Therefore, to execute the relevant strategy, it must exist with the translation component $sp_n \ni T$. The data source *DS* is indicative of the underlying NoSQL database categories, *KV* : key-value, *CO* : column orientated, *DO* : document orientated and *GR* : graph data stores. The output *n*, generated by the translator, denotes the native query. This eventually runs on the targeted NoSQL database completing the execution path.

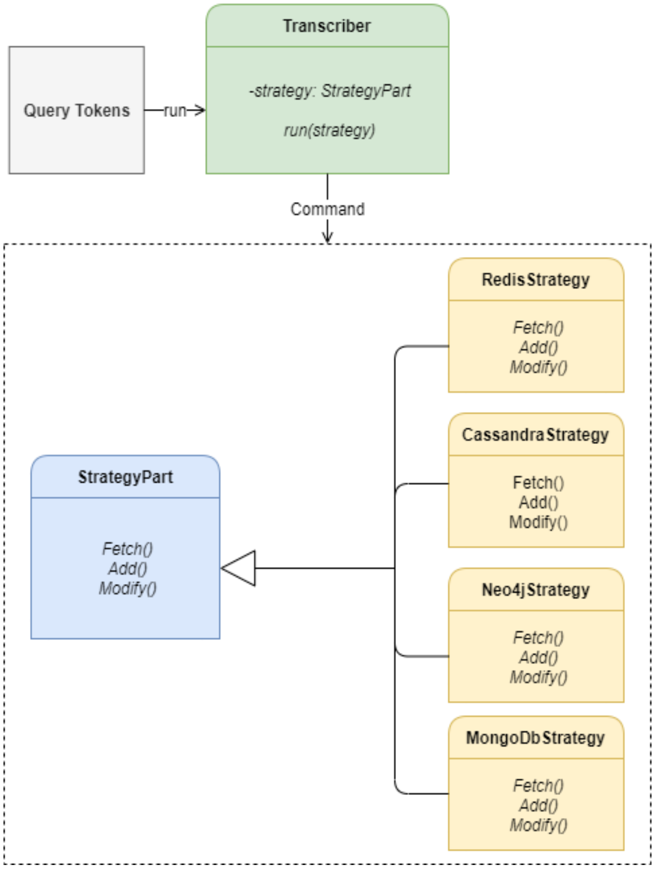

Fig. 8. Query path: strategy design pattern.

TABLE V. STRATEGY PATTERN PSEUDOCODE

Algorithm : Query Path

```
$I \rightarrow QueryIntent(q)$
$\coloneqq \boldsymbol{QueryPath(q)}$
$\boldsymbol{if}\ q \in I\ \boldsymbol{do}$
$\boldsymbol{if}\ e \rightarrow \exists(i.cmd)\ \boldsymbol{do}$
$target\ storage \rightarrow q.DS$
$\boldsymbol{for}\ each\ sp \in SP(target\ storage)\ \boldsymbol{do}$
$\boldsymbol{if}\ sp \subseteq KV\ \boldsymbol{do}$
$n \rightarrow T.Run(rs)$
$\boldsymbol{if}\ sp \subseteq CO\ \boldsymbol{do}$
$n \rightarrow T.Run(cs)$
$\boldsymbol{if}\ sp \subseteq DO\ \boldsymbol{do}$
$n \rightarrow T.Run(ms)$
$\boldsymbol{if}\ sp \subseteq GR\ \boldsymbol{do}$
$n \rightarrow T.Run(ns)$
$return\ \boldsymbol{n}$
```

3) Query generator: The query generators separate the processing logic from query components. To generate the native NoSQL queries for the prototype, the visitor pattern was employed. It is invoked by the query translator component. The native query elements are represented as "visitors" which directly correspond to elements of the tokens generated by the query parser. This pattern is highly effective, as it enables class instantiation to add functionality without altering the structure of the class, thereby ensuring scalability [22].

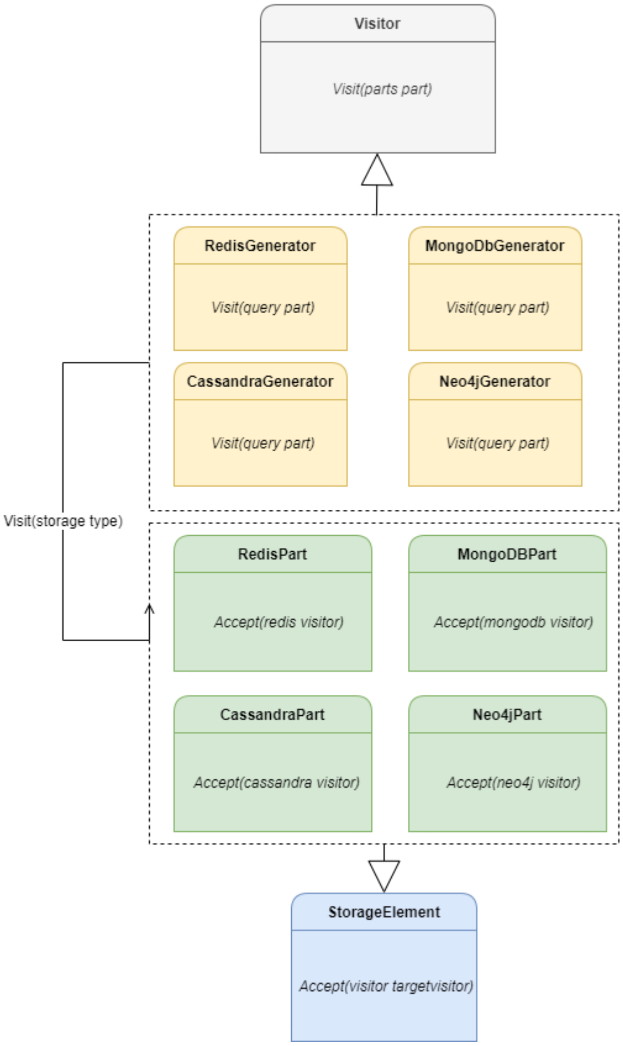

Fig. 9. Query generator: visitor design pattern.

In the context of this study, each supported NoSQL data storage model possesses its own distinct code generating implementation as shown in Fig. 9. This pattern empowers the prototype to traverse through various elements of the query expressions, constructing parts of the native query while retaining its internal state, referred to as the 'whole part' or native query. As the prototype progresses through the organized parts, it invokes other visitors, thereby facilitating the construction of complex query structures in a systematic and controlled manner.

The query generator uniquely encompasses a collection of classes called visitors, each one responsible for generating a part relevant to native query; $VS \rightarrow \{vs_1, \dots, vs_n\}$. In Table VI., *rg* represents redis, *cg* cassandra, *mg* mongodb while *ng* neo4j. The supported NoSQL categories are tied to a storage element which delegates deciding on which code generator to invoke based on the target models in the unpacked in the translation component, $SE \rightarrow \{qe_1, \dots, qe_n\}$. Each visitor represent a specific part within the broader query. The conversion of the unified query requires the visitor to be a specified order. The query generator then proceeds to systematically build each part of the native query, thus returning an executable query.

TABLE VI. VISITOR PATTERN PSEUDOCODE

```
Algorithm : Query Generator
$I \rightarrow QueryPath(q \rightarrow Query)$
$\coloneqq \boldsymbol{QueryGenerator(i)}$
if $i \vdash I$ do
strategy path $\rightarrow i.DS$
$VS \rightarrow BuildVisitors(i.query\_elements)$
for each part in $VS$ do
if part $\in rg$ do
$rg.Accept(part)$
if part $\in cg$ do
$cg.Accept(part)$
if part $\in mg$ do
$mg.Accept(part)$
if part $\in ng$ do
$ng.Accept(part)$
```

The prototype components and embedded features in tandem with the programming design patterns aids in producing a working artifact. Careful consideration was given to the middleware as an abstraction layer. By applying a separation of concerns approach, enabled components and features within the prototype to operated independently. Thus, delegating any tasks to the isolated components. Furthermore, compartmentalisation of the intents, the generators and executable paths supplied a clear route for the query processing system.

D. Limitations

The study encountered several limitations and challenges during the research endeavour, including. Initially, the study proposed an automated schema identifier capable of affecting the underlying native schemas through the prototype. However, due to time constraints, this feature was excluded from the scope of the research project. Manual schema updates were necessary, leaving the prototype susceptible to errors. The prototype struggled to handle complex data additions and updates, particularly in the case of nested query processing based on existing data models. Updates couldn't be performed on complex fields within the Cassandra database management system, as it required retrieving the entire object, updating the identified field(s), and then sending the entire field back for modification. The study was restricted to specific versions of the supported NoSQL data storage options. Any changes in versions of the respective NoSQL database management system may render the solution obsolete or cause previously successful unified queries to produce errors. The adaptors developed for the prototype relied on a rudimentary security mechanism for the respective NoSQL databases, requiring connections to be authenticated.

V. EXPERIMENTAL APPROACH

We've conducted an experiment to assess the complexity of key algorithms contained within the overarching design principles. The prototype was tested against varying workloads contained within threads to measure its scalability and robustness. In accordance with Hevner et al. (2004), it is imperative to meticulously demonstrate the effectiveness of an artifact through the appropriate evaluation methods. Therefore the prototype was subjected to ninety-one individual test cases, shown in Table VII. Each test cases were grouped to specific query intents in order to isolated and identify potential errors or performance degradation. Furthermore, each test case represents a participant or user assigned to a predefined query to leverage control over the experiment. This enable us to effectively automate the testing process.

TABLE VII. TEST CASE SUMMARY

#	Summary	Test Cases
1	Syntax and Sematic Validations.	87, 88, 89, 90, 91
2	Retrieve complete dataset.	1, 9, 28, 45, 66
3	Retrieve dataset where a single filter was applied.	2, 3, 4, 10, 16, 17, 54, 67, 77, 78, 79
4	Retrieve dataset where a multiples filters were applied.	11,12, 15, 29, 30, 55, 56, 68, 69, 70, 80, 81
5	Apply a limit to the dataset retrieval process.	13, 31, 46, 47, 48, 49, 50, 51, 52, 53
6	Apply sorting to the dataset retrieval process.	14, 32, 33, 34, 35, 36, 57, 71
7	Aggregation on a datasets.	18, 19, 20, 21, 22, 37, 38, 39, 40, 41, 58, 59, 60, 61, 62, 72, 73, 74, 75, 76
8	Update existing dataset.	5, 6, 23, 24, 25, 42, 43, 63, 64, 82, 83, 84, 85
9	Data inserts.	7, 8, 26, 27, 44, 65, 86

We conduct the experiment using an Intel(R) Core(TM) i7-10610U CPU running at 1.80GHz with a maximum frequency of 2.30GHz. The device is equipped with 16,0 GB (15,6 GB usable). The system operates on a 64-bit Windows operating system and is based on an x64 processor architecture.

A. *Participants*

We purposefully embedded a module within the prototype which comprised of participants. The participants within the context of this study served as human stakeholders with specific query intents. Each participant invoked the prototype's query language, consisting of either data retrieval, modification, or insertion commands. The query workloads assisted in automating the experimental process and facilitating the capturing of performance metrics for analysis. In addition, we were able to control the expected outcomes in deterministic manner. Thus playing a crucial role in evaluating the prototype's performance.

B. *Metrics*

The data collected for each payload encompasses a number of varying metrics which includes the Apdex, CPU usage, memory usage, execution times for each individual component and error rates. The Apdex, CPU and memory usage enveloped the entire query's execution path. While the execution times and error rates were logged at a granular level with respect to each component i.e. the query parser, translator and executor.

1) Application performance index: The Apdex or Application Performance Index score is an industry standard, which was utilised to assess the users or participants satisfaction rate in terms of the responsiveness of the prototype. It's a binary metric whereby 1 represents the best possible outcome, alternatively 0 represents the worst possible outcome. In this study, we've set benchmarks to classify the user experience as follows :

- *Satisfied* - Response time less than 2 seconds
- *Tolerating* - Response time between 2 and 8 seconds
- *Frustrating* - Response time greater than 8 seconds

let's say :

- *sr* is satisfied requests
- *tr* is tolerating requests
- *s* is the total number of requests (i.e. sample size)

$$\therefore Apdex\ Score = \frac{\left(sr + \frac{tr}{2}\right)}{s} \tag{4}$$

2) CPU usage : The prototype's consumption of the Central Processing Unit (CPU) provided a multifaceted perspective on performance, functionality and viability of the solution.

let's say :

- *st* is the start time of CPU utilisation
- *et* is the end time of CPU utilisation
- *pa* is the number of processors available to the current process
- *pt* is the total processing time

$$\therefore\ CPU\ Usage = \frac{(et - st)}{(pa \times pt)} \tag{5}$$

3) Memory usage :The memory consumption of the prototype was evaluated from two perspectives, both the virtual and physical. In both instances the memory expenditure was calculated as follows :

In the case of virtual memory:

- *ivm* is the initial amount of virtual memory allocated.
- *fvm* is the final amount of virtual memory allocated.

$$\therefore\ vm = fvm - ivm \tag{6}$$

In the case of physical memory:

- *ipm* is the initial amount of physical memory allocated.
- *fpm* is the final amount of physical memory allocated.

$$\therefore\ pm = fpm - ipm \tag{7}$$

4) Query execution times : The individual components of the prototype measured the respective execution times in milliseconds. The parser determines the time taken for the global parser to validate the unified query. The translator measures the time taken for the translator to generate the native queries. Whereas the executor measures execution time of the generated native query on the supported storage system.

Elapsed time measurement:

- *st* is start time
- *et* is end time

$$\therefore\ el = et - st \tag{8}$$

5) Error rate: The components, namely the parser, translator and executor reported the number of errors produced by each of the automated participants.

VI. Prototype's Results

The prototype's architecture adheres to established design principles promoting modularity, extensibility, reusability and scalability. This section assesses the efficacy of those applied principles evaluating the varying algorithms employed in the query parsing, translation, and execution processes.

1) Application performance index: In the instance of the Apdex data acquired, the queries executed when viewed from an overall perspective, demonstrates a minimal use of resources within the call stack, leading to an optimal execution path. This efficiency is further corroborated by the Apdex scores in Fig. 10, which consistently indicated that the results were delivered within an acceptable timeframe. Therefore it is plausible to assert that the query parser, translator, and executor worked in harmony to ensure timely query responses from multiple storage mechanisms. However, the experimental results also indicated performance outlier's whereby certain tests exceeded the satisfactory threshold. This was evident in the Neo4j storage system in test group 2, as a large amount of connected nodes degraded performance as observed in Cox et al. (2020) study.

The other notable observation relates to the use of the "*OR*" logical operator. The experiment revealed when applying deepened search criteria, it results in longer execution times, negatively affecting Apdex score. These compounding factors highlights a need to improve the metamodel in terms of enhanced cataloguing which affects the translation feature. Firstly, the metamodel requires an improved awareness of the with each targeted storage systems indexes. Secondly, it need to be aware of the capabilities for the individual storage systems to a certain extent. This should encompass the limitations of the supported models, thus aiding in the translation process to support efficient executable native queries.

2) CPU usage: The objective was to assess whether the prototype excessively consumed the physical machine's resources during the simulated tests. We deliberately overloaded the prototype with threaded workloads to monitor if it caused system instability or crashes during operations. The prototype demonstrated fluctuations in the CPU based on the query activities. Each query of the predefined queries induced, handled by a dedicated thread intentionally loaded the CPU with requests to measure the feasibility of the prototype. It proved to show peak activity during high query loads and effectively releases the processor at the appropriate time revealing the efficient design algorithms applied to the parser, translator and executor (Fig. 11).

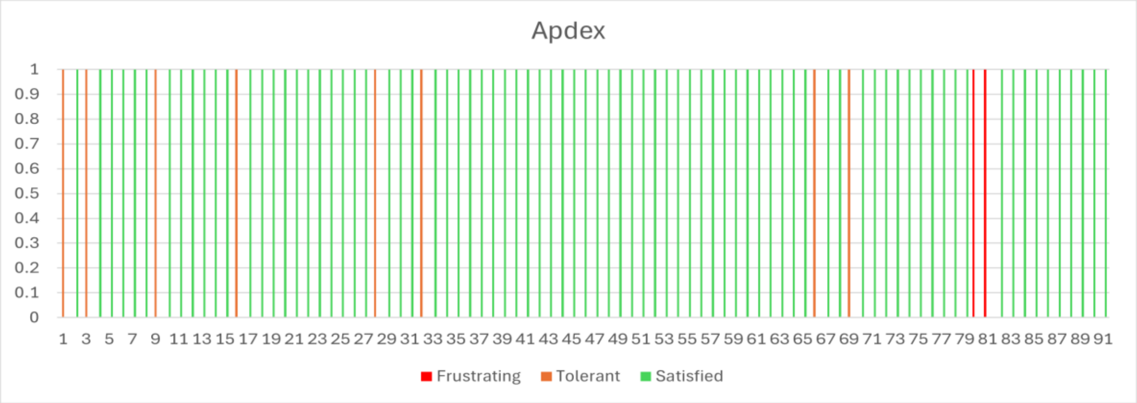

Fig. 10. Apdex scores.

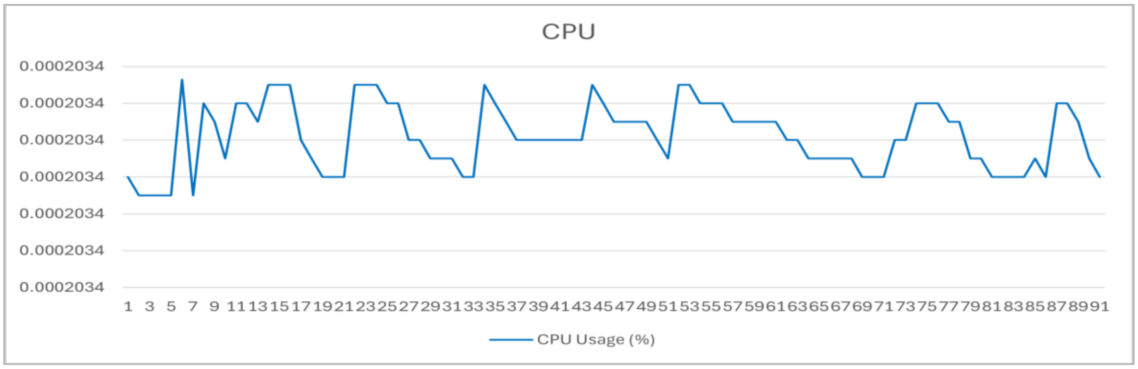

Fig. 11. Central process unit consumption.

3) Memory usage: We've observed the correlation between increased query workloads and memory consumption. This associative behaviour is expected, however more importantly, it was fundamental to ascertain how well the prototype releases memory. On start up, the prototype initially consumed more virtual memory than physical memory. Nonetheless, once the query workloads was imposed, the system virtual memory exceed the physical memory. This indicates that the query parser, translator and executor optimally utilises the available RAM to achieve effective performance rather than relying on slower disk-based memory i.e. *vm*. Furthermore, this implies the system ensured no excessive memory consumption which underscores the robustness of the prototype's architectural design choices (Fig. 12).

4) Query execution times: This applies to the prototype's query parser, translator and executor to determine any bottlenecks in the query execution path illustrated in Fig. 13. The response times of each component generally produced favourable results. The granular results of each component enabled the authors to further assess the pertinency of the design principles applied to each component. Thus strengthening the findings of the CPU, memory and Apdex results. As discovered in the Apdex results, the executor highlighted inefficiencies in the translator component. The query executor performance explicitly depends on how well a native query is generated by the translator. We've observed apply sorting and logical operators has a significant impact on the overall responsiveness of the prototype.

5) Error rates: The number of errors produced during the experiment signifies the stability and reliability of the prototype. In general the prototype exhibited low error rates under the varying workloads. The error rates were evaluated from two perspective, intentional to establish the boundaries of the system and unintentional to assess faults within the system. The data indicated, the prototype was able to distinguish between well-formed queries and non-conforming queries. It also highlighted shortcomings (Fig. 14) in the prototype revealing that the system is not aware of the full compatibilities of certain storage systems and date fields could not be parsed. In demonstrating its robustness, certain unexpected errors produced was isolated to specific targeted storage system, thus not negatively impacting all facets of the unified query.

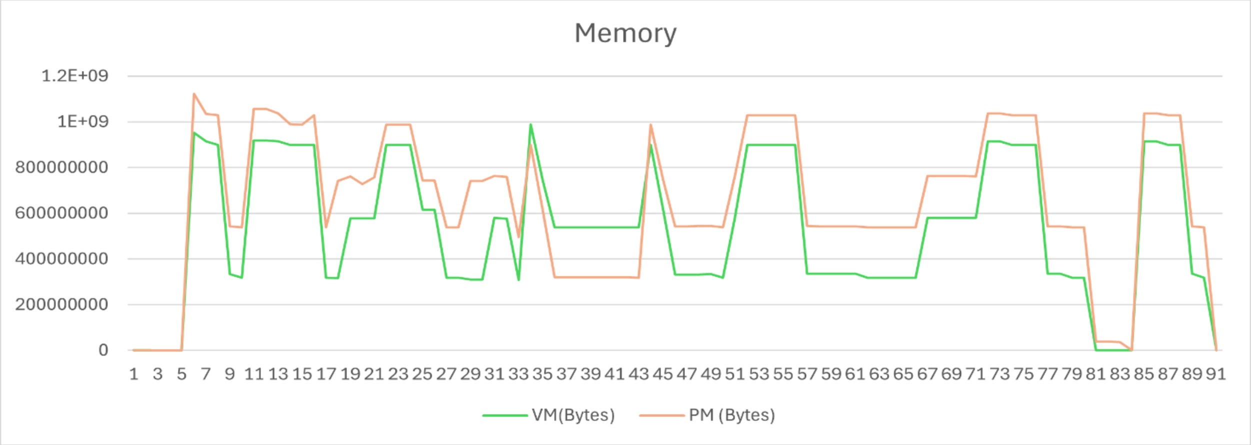

Fig. 12. Physical and memory consumption.

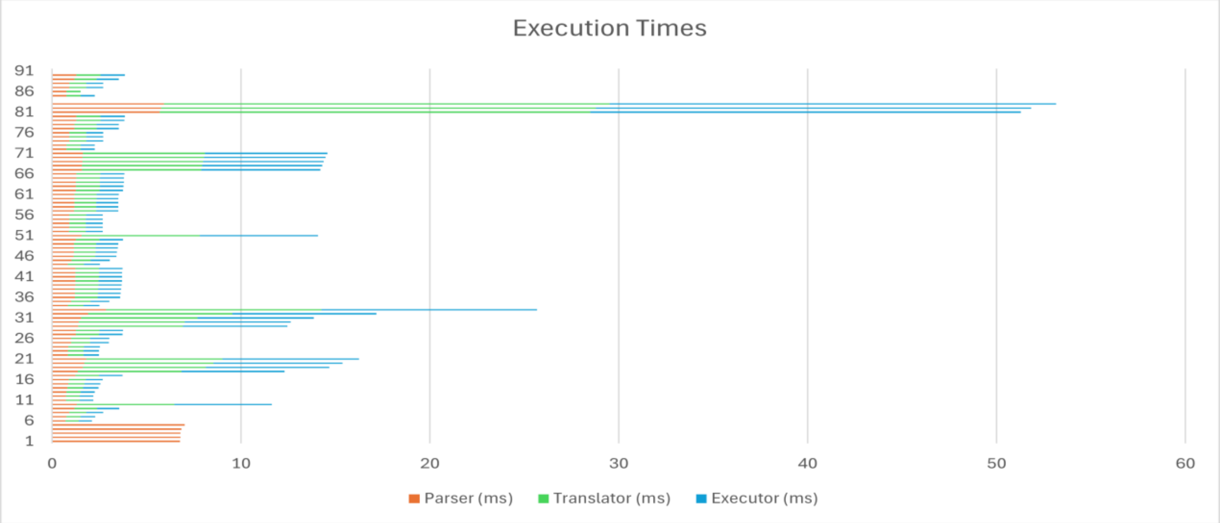

Fig. 13. Component execution times.

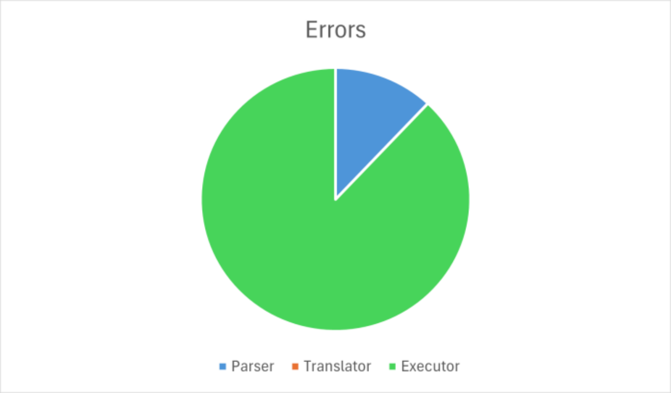

Fig. 14. Errors per component.

VII. Discussion

During our experiment, the performance data revealed that the prototype utilizes the physical machine's resources efficiently, even under load. Since excessive resource consumption can lead to a number significant challenges such system instability and degraded user experience; it important to identify and implement the optimal design patterns at inception. In certain instances, we observed fluctuations of high resource usage by the prototype which could have affected other applications running on the machine. However, the Apdex scores coupled with the query execution times and error rate demonstrated the stability of the prototype within it's environment. Fortunately we could observed that these spikes occurred in short time-bursts, preventing the prototype from monopolizing CPU and memory which could have led to degraded performance and overall user experience. We further attest to these insights as all of the participants were able to execute their respective unified queries to completion without any system interupts or fatal errors.

On reflection of the emperical data produced by the experiment, it is evident that efficiency and robustness must be prioritized from the onset. The experiment highlighted potential inefficiencies in the query translator and executor which heavily relies on the metamodel to produce well-formed native queries. The data suggests that the ineffecienct queries produced by the translator results in longer running times on the executor component. By addressing these potential bottlenecks in the query path at an early stage, it reduces the need for extensive rework later. These findings emphasis the importance of effective and efficient components as an inadequate solution from the start will exponentially increase cost and reduce quality over time i.e. user experience. This is especially pertinent in today's digital era where scalability and cost-effective solutions are at the forefront of innovation. An holistic approach to developing such polyglot systems is essential to demonstrating it's utility.

VIII. Conclusion and Future Work

In this article we presented an approach to design and develop a unified query system. The efficiency, scalability and robustness demonstrated by the prototype essentially advocates in favour of the design and architectural patterns applied to the system. A modular approach to the components supports the prototype to be easily extendable and adaptive to change, i.e. new storage systems should be easily added without having adverse effects on the existing integration. The results attained in relation to the query parser, translator and executor worked together to ensure the prototype achieved optimal performance. This is suggested in the Apdex scores achieved by the system as well as the efficient utilisation of the CPU and memory. The low error rates, affirmed the reliability of the developed prototype.

In future, we propose a study that addresses the deficiencies of the prototype. The experiment results revealed it may be beneficial for the metamodel to be partitioned in a fashion that is responsible for different aspects of the unified query system. One such aspect relates to greater schema awareness, therefore an exhaustive catalogue of alternative mappings between unified fields and natives fields including complex data types. This will offer a wider range of query translation permutations are during the native query generation process as well as supporting advanced query parsing methods. Another aspect relates to a context awareness metamodel to identify use cases supporting the accurate interpretation of query intents. Recognising the limitations of the targeted storage models to improve query optimizing algorithms within the prototype. Thus providing improved indexing strategies and query rewriting techniques. The metamodel may also benefit from cataloguing each native storage systems supported operations. This will allow the prototype to delegate unsupported operations to the middleware or at least give context is to why the intent cannot be realised. Finally, the metamodel could benefit from machine learning by either automating the catalogue process, i.e. mapping new native fields to unified model or using historical log information to improve the query optimisation process.

Conflict of Interest

The prototype utilised the Microsoft Visual Studio Community Edition IDE to develop the solution. Microsoft clearly states that this IDE may be used for academic purposes, the study in no way promotes or forms part of any advertising on behalf of the organisation. Furthermore, the study was not funded by Microsoft.

Author's Contribution

Hadwin conceptualized the research study as part of his Master of Information Communication and Technology (MICT) research journey. The student performed the required systematic literature review and built the subsequent prototype. This article represents a chapter within the thesis MICT degree. Dr B. Kabaso supervised this research journey providing invaluable insights and guidance in achieving its goal.

Acknowledgment

The authors wishes to thank the Cape Town University of Technology for providing the opportunity to partake in this study. A special sentiment of appreciation to Dr. B, Kabaso for his patience and support.

Underwater Quality Enhancement Based on Mixture Contrast Limited Adaptive Histogram and Multiscale Fusion

Septa Cahyani[1], Anny Kartika Sari[2], Agus Harjoko[3]*
Informatic Engineering,-Faculty of Computer Science-Indo Global Mandiri University, Palembang, Indonesia[1]
Dept. of Computer Science and Electronics, Universitas Gadjah Mad, Yogyakarta, Indonesia[2, 3]

***Abstract*—This paper presents a novel approach for enhancing the visual quality of underwater images using various spatial processing techniques. This research addresses the common issues encountered in underwater imaging, such as color distortion, low clarity, low contrast, bluish or greenish tints caused by light scattering and absorption, and the presence of underwater organisms. To solve these problems, we utilize various image processing methods such as white balancing, Contrast Limited Adaptive Histogram Equalization (CLAHE) in Lab and HSV color spaces, sharpening, weight map generation, and multiscale fusion. The effectiveness of the proposed approach is evaluated quantitatively using mean squared error (MSE), peak signal-to-noise ratio (PSNR), and structural similarity index (SSIM). The results indicate that the optimal CLAHE parameters are a block size 4x4 and a clip limit 1.2. These parameters yielded an MSE value of 0.7594, a PSNR value of 20.7121, and an SSIM value of 0.8826, demonstrating superior performance compared to previous research. A qualitative evaluation was also conducted using eight respondents based on overall visual quality, color fidelity, and contrast enhancement. The assessment results demonstrate satisfactory outcomes, with a mean score of 4.3278 and a standard deviation of 0.7238. Overall, this research demonstrates that effective and efficient enhancement of underwater image quality through computational methods can be achieved using simple techniques with appropriate parameters and placement, thereby enabling better scientific research and exploration of the underwater world.**

***Keywords*—CLAHE; Color space enhancement; luminance; sharpening**

I. Introduction

Underwater environments are renowned for their stunning beauty and play a vital role in various technological and research fields, such as underwater infrastructure inspection and underwater archaeology. However, underwater imaging presents significant challenges due to the degradation of image quality caused by light absorption and scattering. This often results in images with a greenish or bluish tint at certain depths [1], which can hinder practical applications like object detection and visual exploration, where accurate color representation and contrast are crucial.

Light plays a fundamental role in underwater image quality. The higher density of water compared to air leads to substantial light absorption, reducing light intensity, contrast, and visibility [2]. For instance, red light diminishes after a depth of 4-5 meters, followed by orange, yellow, green, and blue, leading to undesirable color casts [3]. These effects significantly impact the accuracy and effectiveness of underwater imaging applications.

In this context, computer vision-based image enhancement methods have emerged as effective solutions to address color cast and low contrast issues in underwater images. These methods provide advantages over traditional restoration techniques or deep learning approaches, which often require expensive hardware and extensive training datasets [4]. Among these methods, Contrast Limited Adaptive Histogram Equalization (CLAHE) has shown superior performance in enhancing contrast [5]. Despite its effectiveness, challenges related to noise and color cast persist.

This study employs CLAHE in the HSV and Lab color spaces. In the HSV model, CLAHE is applied to the saturation and value components to enhance color purity and brightness. In the Lab model, CLAHE is used on the luminance component to recover images without affecting the chrominance, which could exacerbate color casts. The proposed approach involves correcting color distortion through color balancing, applying CLAHE to enhance contrast in the Lab and HSV color spaces, and then sharpening and modifying weight maps using Multiscale Fusion. This method aims to significantly improve the quality of underwater images, contributing to advancements in automated image processing technologies.

This paper is organized as follows: Section II comprehensively reviews related works in underwater image enhancement, highlighting previous research and existing methods. Section III details the proposed method, including applying CLAHE and multiscale fusion techniques. Section IV presents the experimental results, showcasing the outcomes of our proposed method and comparing them with existing techniques. Finally, Section V concludes the paper by summarizing the key contributions and suggesting potential future research directions.

II. Related Works

Improving underwater image quality is a crucial area of research due to unique challenges such as color distortion and reduced visibility compared to standard images. Various techniques have been explored to address these issues, including color balancing, sharpening, and contrast optimization using Contrast Limited Adaptive Histogram Equalization (CLAHE) in different color spaces. CLAHE

*Corresponding Author

combined with Discrete Wavelet Transform (DWT) has been employed to enhance contrast effectively. While this approach is beneficial, it does not entirely resolve noise issues in high-frequency components [6]. Additionally, applying CLAHE in the YIQ and HSI color spaces has demonstrated improvements in image quality but introduced added complexity to the process [7]. The use of CLAHE in the Lab color space has shown significant contrast enhancement, although global illumination issues may not be fully addressed [8].

Further advancements include the application of CLAHE to luminance components in the YCbCr color space, which offers good contrast but often requires additional adjustments for varying lighting conditions [9]. Moreover, CLAHE applied to the L component in the Lab color space, in conjunction with edge detection using the Candy method, enhances edge details but may not fully improve overall color quality [10]. CLAHE applied to HSV images aids in color processing but can result in undesirable color casts [11]. Traditional enhancement techniques such as gamma correction and histogram equalization are beneficial; however, they may fall short in addressing image blur [1].

Recent approaches utilizing CLAHE-based multiscale fusion, combined with white balancing, gamma correction, sharpening, and weight map manipulation, have shown improvements in image quality. Nevertheless, issues with contrast and color cast persist [12]. Integrating Layered Difference Representation (LDR) with CLAHE for color correction has enhanced color distribution but can impact processing speed [13]. Applying CLAHE after white balancing and contrast enhancement improves image quality, although additional refinement is often necessary for optimal results [14]. Overall, the proposed methods demonstrate varying strengths and weaknesses in enhancing underwater image quality. The proposed research is anticipated to more effectively address color correction and noise removal by integrating CLAHE in color spaces such as Lab and HSV and utilizing multiscale fusion, color balancing, contrast optimization, and weight maps for more optimal results.

III. The Proposed Method

The research method employed in this study comprises several stages, as illustrated in Fig. 1. Initially, a white balancing process is applied to the underwater image using affine transformation based on cumulative histogram statistics for each channel in the RGB color space for color correction. Prior to white balancing, a compensated red channel process is performed to address the loss of the red channel that occurs in underwater images. Subsequently, the method alternates among different processes: applying the CLAHE method in the Lab color space, applying the CLAHE method in the HSV color space, and applying the unsharp masking method based on the High Pass Filter principle. Finally, Multiscale Fusion is utilized to combine the results of white balancing, CLAHE-Lab, and CLAHE-HSV images, along with the Laplacian weight map, saliency, and saturation.

To optimize the effectiveness of these methods, various parameter values are systematically tested through experiments. The goal is to observe how different parameter settings affect image quality and determine whether they yield optimal results. This optimization process involves evaluating parameter values based on the average error across multiple images, acknowledging that each image may require different settings due to its unique conditions. When an increase in error is detected, those parameter values are considered less effective and are not pursued further. Conversely, parameter values that result in reduced error are further refined and tested until improvements become minimal. This iterative approach ensures that the most effective parameter values are selected for enhancing image quality across diverse conditions.

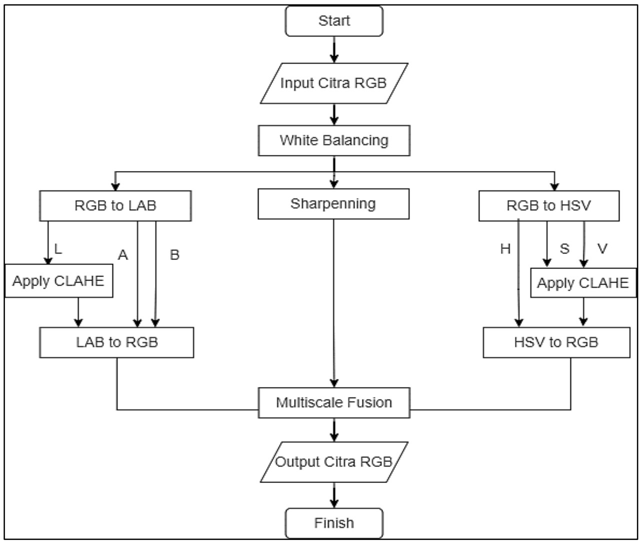

Fig. 1. Process of research method.

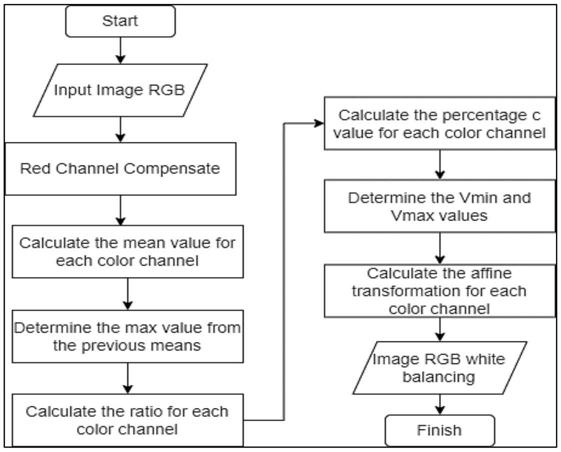
A. White Balancing

White balancing is an important step in correcting color casts that appear due to the absorption of colors at specific depths, resulting in bluish or greenish images. This process can be performed in two steps. First, the compensated red channel can be adjusted as in Eq. (1). Second, the RGB channels can be processed using the simplest color balance method, which neutralizes or equalizes the channels' processing, as in Eq. (2) using an affine transformation [15]. The detailed flow is in Fig. 2.

$$I_{rc}(x) = I_r(x) + \alpha.(\overline{I_g} - \overline{I_r}).(1 - I_r(x)).I_g(x) \quad (1)$$



Start
Input Image RGB
Red Channel Compensate
Calculate the mean value for each color channel
Determine the max value from the previous means
Calculate the ratio for each color channel
Calculate the percentage c value for each color channel
Determine the Vmin and Vmax values
Calculate the affine transformation for each color channel
Image RGB white balancing
Finish

Fig. 2. Process of the white balancing algorithm.

I_r and I_g are the red and green color channels, respectively, each channel is normalized to the interval [0, 1]. $\overline{I_r}$ and $\overline{I_g}$ are the mean values of I_r and I_g.

Step 1: Calculate the average value for each color channel.

Step 2: Determine the maximum value of the average for each color channel.

Step 3: Calculate the ratio of each color channel by dividing each color by the total mean of the image, as in Eq. (2).

$$ratio(\lambda) = \frac{\underset{\lambda\in\{R,G,B\}}{max}(mean(I_\lambda)}{mean(I_\lambda)} \qquad (2)$$

Step 4: Calculate the percentage of the constant "c" for each color channel using a value of 0.005, as in Eq. (3).

$$c_{R,G,B} = 0.005 \times ratio(\lambda) \qquad (3)$$

Step 5: Determine the V_{min} and V_{max} values for each color channel and convert them to one dimension.

Step 6: Calculate the affine transformation using the computed values, as in Eq. (4).

$$f(x) = \frac{(x-V_{min})}{(V_{max}-V_{min})} \times 255 \qquad (4)$$

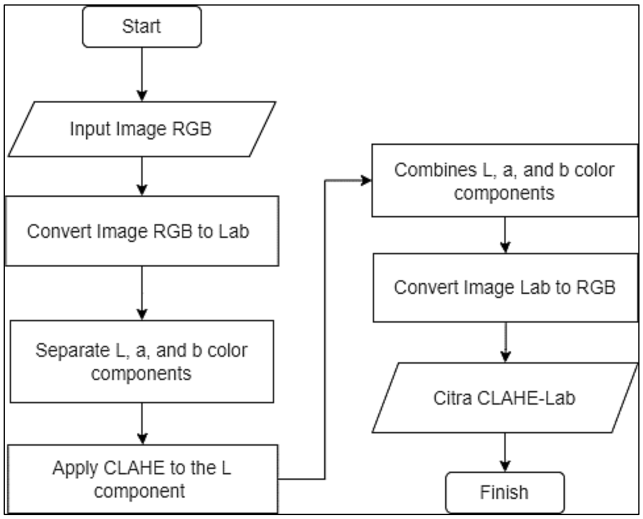
The cumulative histogram labeled "i" shows the number of pixels with low values or values equal to "i." To calculate V_{min}, we identify the lowest histogram label with a value greater than N x c$_1$ while V_{max} is the highest histogram label with a value lower or equal to N x (1-c$_2$). The pixel interval [V_{min}, V_{max}] is mapped to the range [0, 255] using an affine transformation [15].

B. CLAHE Lab Dan HSV

CLAHE is a local histogram equalization technique that enhances contrast in an image by dividing it into sub-images and performing contrast enhancement on each sub-image based on the characteristics of the pixels surrounding it. After equalization, neighboring sub-images are combined using bilinear interpolation to eliminate any artificial boundaries in the image. Moreover, CLAHE can also mitigate noise in an image by constraining the contrast in homogeneous areas.

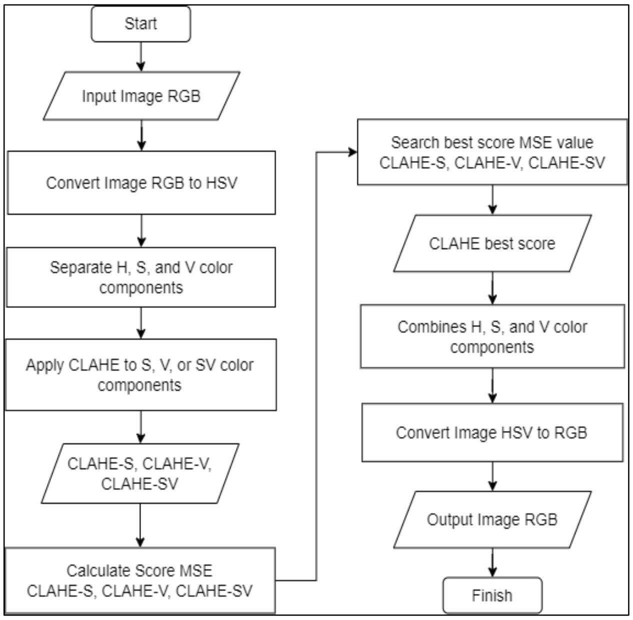
CLAHE has two primary parameters: block size and clip limit. The block size parameter is used to partition the image into sub-images. In contrast, the clip limit parameter reduces noise in the image by trimming the histogram at a specified value before calculating the Cumulative Distribution Function (CDF). These two CLAHE parameters serve to set the quality of the enhanced image [16].

The CLAHE method enhances image quality in two color spaces: Lab and HSV. In the Lab color space, as illustrated in Fig. 3, CLAHE is applied to the Luminance (L) component to improve image brightness. After histogram equalization on the L component is completed, the L, a, and b components are recombined and converted back to RGB, resulting in the CLAHE-Lab image. Conversely, in the HSV color space, as depicted in Fig. 4, CLAHE is applied to the Saturation (S) and Value (V) components, separately or together. Before converting back to RGB, a comparison is made to evaluate the application of CLAHE to S, V, or both. The evaluation involves determining the optimal clip limit and block size based on MSE error values. Different images are obtained for each combination, with lower MSE values approaching zero, indicating better image quality. The general steps of the CLAHE method are as follows:



Start
Input Image RGB
Convert Image RGB to Lab
Separate L, a, and b color components
Apply CLAHE to the L component
Combines L, a, and b color components
Convert Image Lab to RGB
Citra CLAHE-Lab
Finish

Fig. 3. Process of the CLAHE-Lab algorithm.



Start
Input Image RGB
Convert Image RGB to HSV
Separate H, S, and V color components
Apply CLAHE to S, V, or SV color components
CLAHE-S, CLAHE-V, CLAHE-SV
Calculate Score MSE CLAHE-S, CLAHE-V, CLAHE-SV
Search best score MSE value CLAHE-S, CLAHE-V, CLAHE-SV
CLAHE best score
Combines H, S, and V color components
Convert Image HSV to RGB
Output Image RGB
Finish

Fig. 4. Process of the CLAHE-HSV algorithm.

Step 1: Divide the image into sub-images or blocks with a size M×N.

Step 2: Normalize the histogram by calculating the image's Cumulative Distribution Function (CDF) value. CDF is defined as the running sum of the intensity I divided by the number of pixels in the image, as in Eq. (5). Here, f is the cumulative distribution, N is the maximum pixel value, M is the image size, and K is the frequency of occurrence of the pixel value.

$$f_{i,j}(n) = \frac{(N-1)}{M} \, . \sum_{k=0}^{n} h_{i,j}\,(K) \qquad (5)$$

Step 3: Calculate the maximum clip limit value in the histogram, as in Eq. (6). The clip limit (CL_ is influenced by an independent factor, the clip factor (α), which controls the illumination level. The clip factor range is from 0 to 100. Here, M is the size of the image region, N is the maximum pixel value (256), and Smax is the maximum pixel value in the region.

$$\beta = \frac{M}{N}\left(1 + \frac{\alpha}{100}(S_{max} - 1)\right) \tag{6}$$

Step 4: After dividing the image into blocks, perform histogram normalization by finding the CDF in each region. The probability distribution is found by dividing the frequency of occurrence by the region's size. The cumulative distribution is obtained by adding the pixel probability distribution to the previous pixel value probability. This process is repeated for each pixel value in each region.

Step 5: Find the clip limit value by specifying the clip factor within the range of 0 to 100.

Step 6: Normalize the histogram by multiplying each pixel's cumulative distribution by the maximum value of the pixel value in the region.

Step 7: Perform clipping by adding the pixel result from the normalization multiplication to the clip limit. If the resulting value exceeds the maximum pixel value, which is 255, it is replaced with the maximum pixel value.

Step 8: After equalization, the sub-images are combined using bilinear interpolation to eliminate artificial boundaries and produce a smoother and better-combined result.

C. Sharpening

The method used in this study to enhance image sharpness is the unsharp masking method, designed to enhance unclear details in the image. The unsharp masking process involves several stages, starting with a low-pass filter process that produces a blurred image, followed by a high-pass filter that enhances the details in the image by subtracting the original image from the blurred image. The unsharp masking process consists of several stages. Firstly, a low-pass filter process is used to create a blurred image. Secondly, a high-pass filter enhances image details by subtracting the original image from the blurred image. Thirdly, a histogram stretching process is implemented to increase or decrease the image contrast by expanding or compressing the range of pixel intensity values. Finally, a normalized unsharp masking process normalizes image sharpness without parameter adjustment. The detailed flow of sharpening is shown in Fig. 5.

$$S = (I + N\{I - G \times I\})/2 \tag{7}$$

where, I represents the input or original image, G×I represents the blurred image generated by convolving the Gaussian filter with the original image, and N represents the linear normalization operator that adjusts histogram stretching. Operator N shifts and scales all color pixel intensities in the input image such that the transformed set of pixel values encompasses the full dynamic range. The normalized unsharp masking process, which does not require any parameter adjustments, appears to be more effective in enhancing image sharpness, as indicated by previous studies [1].

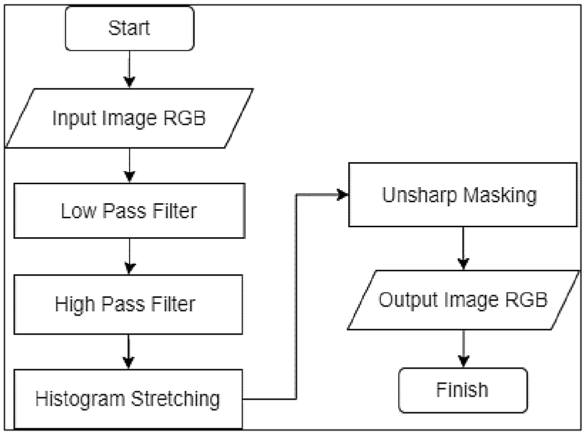


Fig. 5. Process of the sharpening algorithm.

The unsharp masking process effectively enhances sharpness; however, it can result in undesirable halo effects caused by excessive sharpening. To overcome this issue, a multi-scale fusion strategy was used to minimize artifacts that may arise during image merging, producing a final outcome free of halo effects.

D. Weightmap Generation

After implementing several methods and generating three image results, namely CLAHE-Lab, CLAHE-HSV, and sharpening, the next step is to create three weights from these results. These weights, namely Laplacian Contrast (W_L), Laplacian Saliency (W_S), and Laplacian Saturation (W_{Sat}), aim to explore the spatial relationship of degraded regions. Each pixel weight is generated based on the object's characteristics, such as hue, saturation, and contrast [1].

1) Laplacian Contrast (W_L) computes the global contrast by applying the absolute value of the Laplacian filter to each input luminance channel. Convolution is run using the Laplacian kernel, as in (8), where f(x) represents the input image on the Luminance component, and g(x) represents the Laplacian kernel.

$$W_L = |f(x) * g(x)| \tag{8}$$

2) Laplacian Saliency (W_S) is used to identify the most prominent objects that lack superiority in the underwater scene. A saliency map is generated to highlight the relevant areas. To detect the saliency level, we employed the Laplacian Saliency algorithm based on the regional contrast object proposed [17] This algorithm uses histogram-based contrast methods, as in Eq. (9) [18], to consider both global contrast and spatial coherence.

$$W_{sal}(I_p) = \sum_{i=1}^{N}(I_{p,q} - \overline{I_k})^2 \tag{9}$$

Where, I_p represents the matrix value in the Lab color space, N denotes the number of rows (p) and columns (q), and $\overline{I_k}$ signifies the average value of each L, a, and b component.

3) Laplacian Saturation (W_{Sat}) employs a fusion algorithm to extract chromatic information from highly saturated areas by measuring color intensity values in the image. The presence of saturated colors enhances the clarity of the image. The weight map calculates the deviation for each pixel position between the color channel and illumination, as in Eq. (10).

$$W_{sat} = \frac{\sqrt{[(R_k - L_k)^2 + (G_k - L_k)^2 + (B_k - L_k)^2]}}{3} \tag{10}$$

Where, I_k represents the input value of each L, a, and b component, and $R_{k,} G_k, B_k$ signify the input values of each R, G, and B component and luminance L_k of the kth input (each pixel value position).

Furthermore, the weight map (W$_k$) is generated by combining these three weights using as in Eq. (11)

$$\overline{W_k}(x, y) = \frac{W_k(x,y)+\delta}{\sum_{k=1}^{N} W_k(x,y)+\delta} \tag{11}$$

Where W$_k$ represents the normalized weight map for the kth input. N is the normalized aggregate map of each pixel, and the weight of each pixel in each map is divided by the total weight of the same pixel. Here, we set N to a constant coefficient of 2, and δ is a constant set to 0.001 to ensure that each weight map contributes to the result and prevents it from becoming 0 [19].

E. Multiscale Fusion

Gaussian pyramids are formed for each weight (Wk) in each image by convolving each layer of the pyramid with a Gaussian filter. We then create Laplacian pyramids for each color channel based on the levels determined in each image. Finally, a merging process between the Gaussian and Laplacian pyramids for each color channel (R, G, and B) based on the levels, as in Eq. (12).

$$R_{l,k}(x) = \sum_k G_l[\overline{W_k}(x, y)]\, L_l[I_k(x, y)] \tag{12}$$

The formula consists of $R_{l,k}(x)$, which represents the l layer of the image pyramid for input image k, $G_l[\overline{W_k}(x, y)]$, which is the input of the pyramid from Gaussian filtering and $L_l[I_k(x, y)]$, which is the normalized weight map before Laplacian filtering on the image. The pyramid is then reconstructed by merging images based on color channels, as in Eq. (13), resulting in a new pyramid for each color channel (fusion). Normalization is performed on the resulting fusion image by scaling it from 0 to 255 with data type uint8.

$$E_{res}(x, y) = \sum_l U\left[R_{l,k}(x, y)\right] \tag{13}$$

where, $E_{res}(x, y)$ is obtained by adding the combined contribution from all levels in the Gaussian-Laplacian pyramid, where l represents the pyramid level and k represents the number of input images. $U\left[R_{l,k}(x, y)\right]$ represents the output of the image pyramid. The merging process can reduce unnecessary image information or improve image quality from a lower-quality image to a higher-quality image. To evaluate the quality of the method used in this study, an error value is calculated. Fig. 6 illustrates the detailed flow of the multiscale fusion process.

F. Evaluation Metrics

Quantitative evaluation will be conducted by calculating the Mean Squared Error (MSE), Peak Signal-to-Noise Ratio (PSNR) [3], and Structural Similarity Index (SSIM) between the processed images and ground truth images. Higher PSNR values and lower MSE values indicate better-quality underwater images that more closely match the ground truth. In comparison, higher SSIM values reflect better image structure and texture preservation. Additionally, the proposed method will be compared with several existing methods to assess its performance [20].

To demonstrate the quantitative improvements achieved by the proposed method in mitigating color cast and enhancing contrast in underwater images, the Universal Image Quality Metric (UIQM) will be computed. The UIQM consists of three components: the Underwater Image Color Metric (UICM) to assess color fidelity, the Underwater Image Sharpness Metric (UISM) to evaluate sharpness, and the Underwater Image Contrast Metric (UIConM) to measure contrast. The overall UIQM value is obtained by aggregating these three metrics. A higher UIQM value indicates better image quality and results that align more closely with human visual perception.

Qualitative evaluation will also be performed using a Google Forms survey. Respondents will rate the effectiveness of the proposed method in producing noticeable improvements compared to the original images. Ratings will range from 5 (Excellent) to 1 (Bad). The average score and standard deviation of the survey responses will be calculated to provide insights into the method's subjective assessment.

IV. Experimental Results

The UIEB dataset consists of 950 underwater images from Google, YouTube, and prior research. These images were enhanced using nine methods: fusion-based, two-step-based, retinex-based, UDCP, regression-based, GDCP, Red Channel, histogram prior, and blurriness-based. For each original image, nine enhanced versions were produced using different methods. Fifty respondents evaluated these versions to select the best one as the reference image (ground truth), without knowing the enhancement method used. The effectiveness of the enhancement methods was assessed by comparing error values across techniques. For quantitative and qualitative evaluation, a subset of 90 images from the 950 was used to ensure consistency in the comparative analysis [20]. The proposed method will be implemented using Python in Google Colab.

We conducted a series of experiments to optimize the CLAHE method by varying the block sizes (2×2, 4×4, 6×6, 8×8, and 12×12) and clipping limits (ranging from 0.2 to 2.0 with increments of 0.2). Optimal kernel usage during the sharpening stage also contributed to the improved final results of the proposed method. After performing white balancing, we combined the processed image results from CLAHE-Lab, CLAHE-HSV, and Sharpening. The enhancement in underwater image quality, based on the average error of the proposed method, indicated superior performance. 90 underwater images were used to determine the best parameter combination.

The experimental results reveal that the optimal clipping limit for the CLAHE method is 1.2 with a block size of 4×4, yielding the lowest Mean Squared Error (MSE) of 0.7594. Comparative values for different block sizes and clipping limits are presented in Table I, with corresponding evaluation graphs shown in Fig. 7. The Peak signal-to-noise ratio (PSNR) obtained was 20.7121. Values for block sizes and clipping limits are detailed in Table II, and the evaluation graph is illustrated in Fig. 8. Additionally, the Structural Similarity Index (SSIM) recorded a value of 0.8826. Details for block sizes and clipping limits are shown in Table III, with the evaluation graph displayed in Fig. 9. The sharpening process, using a 3×3 kernel with a sigma value of 5, was also assessed and demonstrated better results compared to other parameter settings.

TABLE I. EVALUATION RESULTS OF MSE FOR VARIOUS BLOCK SIZES DAN CLIP LIMITS

BLOCK SIZE	CLIP LIMIT				
	1.2	1.4	1.6	1.8	2.0
2x2	0.7712	0.7808	0.7944	0.8122	0.8316
4x4	**0.7594**	0.7648	0.7753	0.7838	0.8009
6x6	0.7647	0.7686	0.7786	0.7838	0.7967
8x8	0.7663	0.7676	0.7723	0.7770	0.7896
12x12	0.7881	0.7860	0.7928	0.7976	0.8078
BLOCK SIZE	CLIP LIMIT				
	0.2	0.4	0.6	0.8	1.0
2x2	0.8493	0.8223	0.7980	0.7808	0,7730
4x4	0.8428	0.8137	0.7904	0.7723	0,7633
6x6	0.8457	0.8178	0.7956	0.7801	0,7693
8x8	0.8617	0.8183	0.7952	0.7790	0.7708
12x12	0.8543	0.8316	0.8127	0.7985	0.7903

Our findings suggest that the proposed method can compete with more complex techniques while requiring lower computational resources. As summarized in Table IV, our method outperforms several previous studies regarding MSE, PSNR, and SSIM. The method's stability against error variations is notable, with the proposed method exhibiting more excellent stability than competing methods. Although a larger clip limit reduces error, excessive values increase error.

To assess whether color cast and contrast have been improved from the original images, we also performed quantitative testing using the Underwater Image Quality Metric (UIQM), which includes the Underwater Image Colorfulness Metric (UICM), Underwater Image Sharpness Metric (UISM), and Underwater Image Contrast Metric (UIConM). The UIQM evaluation demonstrated improved values compared to the original images. The UICM for color was 3.1474, UISM for sharpness was 4.4132, UIConM for contrast was 0.2374, and UIQM for overall Human Visual System (HVS) assessment was 2.2408. The proposed method achieved values of UICM 4.8774, UISM 5.6065, UIConM 0.3134, and UIQM 2.9136.

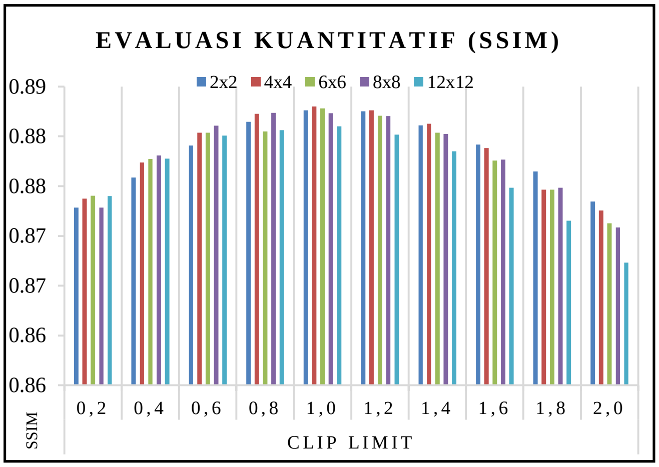

Fig. 9. Quantitative Evaluation Results (SSIM).

Furthermore, a qualitative evaluation was conducted through a survey of eight respondents from diverse backgrounds, including experts such as faculty members specializing in underwater image quality enhancement and non-experts such as students interested in image processing, divers, and students outside the field of image processing. Respondents rated the images on a scale of 1-5 (very poor to very good). The average score and standard deviation for two expert respondents were 3.9444 and 0.5953, respectively. For six non-expert respondents, the average score was 4.4556, with a standard deviation of 0.7181. The overall average score for all respondents was 4.3278, with a standard deviation of 0.7238. The qualitative evaluation categorized the proposed method as "Good," with a score of 4, reflecting favorable results from a subjective perspective.

The survey revealed that images with initial color cast and low contrast received the highest ratings after enhancement. Conversely, images with minimal color cast and high noise but already visually good exhibited decreased rating post-processing, as the method focuses more on correcting color cast and blur or lack of detail. Nonetheless, the results from the proposed method closely approach ground truth images with improved MSE, PSNR, and SSIM values compared to the original images. These findings indicate that a more straightforward method can yield better images with lower computational cost. Spatial methods in underwater image processing must be applied carefully, as incorrect method placement can worsen subsequent processing stages. Several sample images from all tested methods are shown in Fig. 10.

A qualitative evaluation was performed by surveying the proposed method for 90 underwater images and comparing the results with the original images. The survey involved eight respondents from diverse backgrounds, including experts such as professors who specialize in enhancing underwater image quality, and non-experts such as students who focus on image processing research, students who are passionate about the beauty of the underwater world (divers), and students outside the image processing field. The respondents rated the results on a 1-5 scale (very poor to excellent).

Based on the calculation of the average score and standard deviation from two expert respondents, the average score was 3.9444 and a standard deviation of 0.5953. The average score for the six non-expert respondents was 4.4556, and a standard deviation of 0.7181. Overall, the average score for all respondents was 4.3278, with a standard deviation of 0.7238. The qualitative evaluation results of the proposed method fall within the 'Good' category with a score of 4, indicating positive outcomes from a subjective perspective.

Based on the survey results, the image characteristics that received the highest scores were images with color cast and low contrast, respectively. After enhancement, these images appeared significantly better than their original versions. Conversely, the original images with little color cast and high noise decreased in quality compared to the original because of the proposed method's emphasis on improving underwater images with color cast and low contrast.

Despite this, the proposed image produced results closer to the ground truth image, with better values for the MSE, PSNR, and SSIM calculations than the original image. Fig. 10 shows some image samples resulting from all the methods employed in this research.

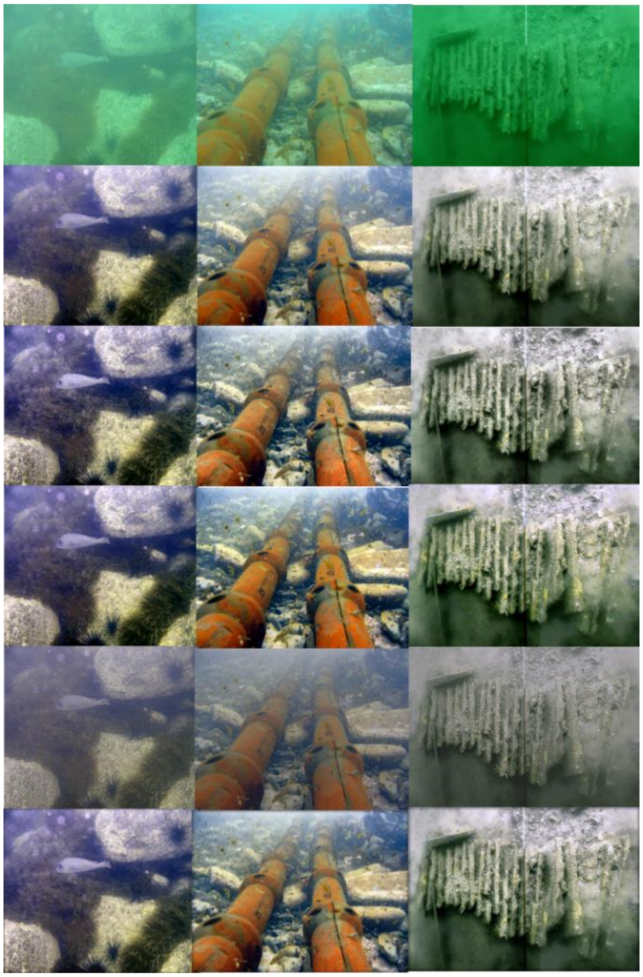

Fig. 10. The image samples of all processing stages, including the initial image (first row), the image after white balancing (second row), the image after CLAHE-Lab (third row), the image after CLAHE-HSV (fourth row), the image after sharpening (fifth row), and the image after multiscale fusion (sixth row).

TABLE IV. QUANTITATIVE EVALUATION RESULTS OF IMAGE QUALITY ASSESSMENT USING MSE, PSNR, AND SSIM

Method	MSE (10^{-3})	PSNR (dB)	SSIM
Fusion-based [21]	1.1280	17.6077	0.7721
Retrinex-based [22]	1.2924	17.0168	0.6071
GDCP [23]	4.0160	12.0929	0.5121
Histogram prior [24]	1.7019	15.8215	0.5396
*Blur*riness-based [25]	1.9111	15.3180	0.6029
Water CycleGAN [26]	1.7298	15.7508	0.5210
Dense GAN [27]	1.2152	17.2843	0.4426
Water-Net [20]	0.7976	19.1130	0.7971
Mixture CLAHE-Fusion (method in this study)	0.7594	20.7121	0.8826

V. CONCLUSION

This research proposes a method of enhancing underwater image quality aimed at the problem of color cast and low contrast in underwater images caused by light scattering and absorption. The white balance method effectively corrects the color cast commonly found in bluish or greenish underwater images. Histogram equalization has been shown to reduce image errors by using clipping and block size techniques in the CLAHE method, along with color space conversion to Lab and HSV. The use of image sharpening methods also helps in the process of enhancing edges in underwater images, although the results obtained may still be insufficiently sharp for pattern recognition purposes. The final output is obtained by combining the results using Multiscale Fusion, which employs three weights, namely the Laplacian Contrast Weight (WL), Saliency Weight (WS), and Saturation Weight (WSat).

Based on the quantitative evaluation results, the proposed method showed a significant improvement in the average values, with the initial MSE value of 2.2497 reduced to 0.7594, the initial PSNR value of 15.7480 increased to 20.7121, and the initial SSIM value of 0.7299 increased to 0.8826. Additionally, the qualitative evaluation results indicated that the average and standard deviation values chosen by the eight respondents showed good results, with a score of 4 (Good) from a subjective perspective. The calculation of the average score and standard deviation from eight respondents showed an average value of 4.3278 and a standard deviation of 0.7238. Based on these evaluation results, it can be concluded that utilizing a simple method to enhance underwater image quality with appropriate parameter settings and method placement can considerably enhance the quality of underwater images and expedite the computation time.

Despite successfully enhancing the quality of underwater images, further development is necessary due to its effectiveness only for not very deep depths. When capturing images at deeper depths, the lighting conditions become affected, resulting in lower contrast and color cast. Therefore, future research could focus on developing or combining the proposed method with others, such as dehazing, adaptive methods, or machine learning, to address additional challenges in underwater image processing.

ACKNOWLEDGMENT

The authors thank the Department of Computer Science and Electronics, Faculty of Mathematics and Natural Sciences, Universitas Gadjah Mada, for supporting this research.

***Abstract*—Technology is a differentiator in business today. It plays a different and decisive role by providing programs that contribute to this. To build this software while avoiding risks during the implementation and construction process, it is necessary to estimate the cost. The cost estimation process is the process of estimating the effort, time, and resources needed to build a software project. It is a crucial process as it provides good planning during the construction and implementation process and reduces the risks you may be exposed to. Therefore, previous studies sought to build models and methods to estimate this, but they were not accurate enough to complete the process. Therefore, this study seeks to build a model using the Autoregressive integrated moving average (ARIMA) algorithm. Five datasets the COCOMO81, COCOMONasaV1, COCOMONasaV2, Desharnais, and China were used. The dataset was processed to remove noise and missing values, visualized to understand it, and linked using a time series to predict the future values of the data. It will then be trained on the ARIMA algorithm. To ensure the effectiveness and efficiency of the model for use, four famous evaluation criteria were used: mean magnitude of relative error (MMRE), root mean square error (RMSE), mean magnitude of relative error (MdMRE), and prediction accuracy (PRED). This experiment showed impressive software cost estimation results, with MMRE, RMSE, MdMRE, and PRED results being 0.07613, 0.04999, 0.03813, and 95% for the COCOMO81 dataset, respectively. The results were high for the COCOMONasaV1 dataset, reaching 0.02227, 0.02899, 0.01113, and 97.1%. The COCOMONasaV2 results were 0.01035, 0.00650, 0.00517, and 99.35%, respectively. The China dataset showed good prediction results of 0.00001, 0.00430, 0.00008, and 99.57%, respectively. The results were impressive and promising for the Desharnais dataset, showing 0.00004, 0.0039, 0.00002, and 99.6%. The results of this study are promising and distinctive compared to recent studies, and they also contribute to good business planning and risk reduction.**

Keywords*—*Software cost estimation; software effort estimation; promise repository; SCE; ARIMA

I. Introduction

Today, the software industry represents a differentiating element in all fields, as business owners depend on technology to conduct their business which is a strong pillar in business speed. As a result, the pressure on software houses has become very great [1]. This led to the production of software that was expensive and had little or even poor efficiency at times. To control this and produce highly efficient and optimal software, it was necessary to estimate the software cost.

Estimating the cost of software is crucial and necessary to ensure the efficiency of the project. It is also a differentiating element for companies to calculate their advantages and estimate their resources, as well as the effort expended to build the project in addition to the time required for it [2]. It also enables stakeholders to know what is needed to implement their project as well. All of this contributes directly to customer satisfaction.

The importance of estimating the cost of software lies in good planning and effective management of the project. It also gives a time estimate for delivery time, as well as estimating the resources needed for this, which contributes to reducing damage to the implemented projects, as well as reducing the technical costs necessary for this, which earns the company a good reputation [3].

The process of estimating the cost of software is carried out through several inputs, which are the project requirements and cost factors so that the process is completed and its output is the time, effort, and resources required for this.

Many researchers have presented numerous studies over the past years, some of which were based on their work on mathematical equations and are called algorithmic methods, the most famous of which are the Constructive Cost Model (COCOMO) [4] and the Software Life Cycle Model (SLIM) [5]. Others also presented methods that depend in their work on the experiences of employees of software houses and are called non-algorithmic methods, such as expert judgment [6].

In recent years, researchers have turned to using learning algorithms such as machine learning [7-10], and some have relied on deep learning techniques [11,12]. Despite the large number of studies that have been conducted, these models are not effective, and the prediction accuracy is not good enough to use these models in the forecasting process. Software houses face difficulty and complexity in the process of forecasting and estimating the cost of software [13].

The map of this study is clear and multiple as it uses software cost estimation, which is an important branch of software construction that falls under the umbrella of software engineering. Autoregressive integrated moving average (ARIMA) [14] algorithm is also used, which is one of the optimization algorithms within the umbrella of machine learning within artificial intelligence and data science techniques.

This study seeks to present a model based on machine learning techniques to predict software cost estimates. Five datasets, namely COCOMO81, COCOMONasaV1, COCOMONasaV2, Desharnais, and China, were collected from the promise repository [15]. The data was processed to remove noise and missing values and represented to understand them, as well as linking them to apply time series technology to predict the future values of the data. ARIMA algorithm is used to be trained on the datasets used. ARIMA algorithm is used due to the efficiency and accuracy of its results. To evaluate the proposed model, four famous evaluation criteria are used for prediction: mean magnitude of relative error (MMRE) [16], root mean square error (RMSE) [17], mean magnitude of relative error (MdMRE) [18], and prediction (PRED) [19].

This paper makes a significant contribution to the software industry by:

- Processing to remove noise and missing values from data, in addition to representing and analyzing to understand the data, as well as linking it using time series to predict future values.
- Using five data sets of medium and large sizes to train and test the proposed model under the same conditions according to the evaluation criteria used in previous studies.
- Applying the ARIMA algorithm to datasets after linking them to time series to produce the highest possible efficiency and accuracy to reduce error rates resulting in the forecasting process.
- The cost estimation prediction results are very promising compared to previous studies.

This study represents a distinct model in the software estimation process as the proposed model combines distinct sets of results that prove the effectiveness of the model and its efficiency in future studies.

The rest of this article is organized as follows: Section II presents the literature review. Section III describes the proposed methodology. Section IV elaborates on the evaluation and di. Section V summarizes our findings and suggests future research directions.

II. Related Work

The software cost estimation process has been a puzzle for researchers over recent years. Many researchers sought to invent techniques that contributed to predicting this process, some of which relied on mathematical equations in their work and called them algorithmic methods. Some also relied on elements of experience from developers and project managers within programming houses, which are called non-algorithmic methods. However, during the last two decades, many researchers have relied on learning techniques, which are considered a lifeline in this industry, as many have relied on machine learning and deep learning techniques to estimate this process.

Shukla et al. [20] presented a model called ANFIS which is an intelligent model using AI to improve software cost estimation forecasting and was trained and tested using the Desharnais dataset collected from the PROMISE repository. Model performance was evaluated by MAE and RMSE metrics. It was compared to the regression model, where the RMSE value was 780.97 compared to 3007.05 for the regression model.

Posbiezny et al. [21] built a model using neural networks, support vector machines with cross-validation, and generalized linear models in which the described set of algorithms was averaged using the ISBSG datasets. The effectiveness of the model was verified using MAE, MMRE, mean square error (MSE), RMSE, MMER, balanced mean relative error (MBRE), and PRED. The model effectively predicted the program effort estimate during the evaluation process according to a fixed period.

Vijayvargiya et al. [22] presented several algorithms to calculate the resources needed to build a Bermuda project and the time needed. Linear regression, support vector regression, artificial neural networks, decision trees, and bagging algorithms were used. These algorithms were trained on the ISBSG and Desharnais datasets. To compare them, three evaluation criteria were used: the mean absolute error (MAE), the mean square error (MSE), and the R square error. The evaluation result demonstrated the superiority of the decision tree and the random forest algorithm over other algorithms, as these algorithms enhanced the cost-benefit analysis of performance.

Kumar et al. [23] compared several algorithms for predicting effort estimation using Stochastic Gradient, K-Nearest Neighbor (KNN), Decision Tree, Bagging, Random Forest, AdaBoost, and Gradient Neighbor Boosting. The COCOMO'81 and China datasets were used to train the algorithms, and three criteria were used to evaluate the proposed algorithms: mean square error (MSE), root mean square error (RMSE), and R2. The comparison results showed the superiority of the gradient boosting regression algorithm compared to other algorithms in predicting software cost estimates.

Rahman et al. [24] compared decision tree, support vector regression (SVR), and K-nearest neighbor (KNN) algorithms for software cost estimation. They used Edusoft Consulted LTD datasets. The data was processed and analyzed, and the proposed algorithms were trained. The criteria of mean absolute error (MAE), mean square error (MSE), and R-square were used to test the proposed model. The results showed that the decision tree algorithm was superior in prediction to other algorithms.

Sharma et al. [25] compared algorithms for cost estimation forecasting where they compared Local Neighborhood Information-based Neural Network (LNI-NN), Fuzzy-based Neural Network (NFL), GA-based Adaptive Neural Network (AGANN), and GEHO-based NFN. To complete the comparison, the COCOMO81, COCOMONasaV1, COCOMONasaV2, China, and Desharnais datasets were used. The effectiveness of the algorithms was tested using four criteria: mean relative error (MMRE), root mean square error (RMSE), mean magnitude relative error (MdMRE), and prediction accuracy (PRED).

Zhang et al. [26] used the XGBoost algorithm to predict software cost estimation using machine autoencoders on COCOMO81 and Albrecht and Desharnais datasets. They analyzed the data used to remove outliers and used regression trees to fill in the missing features. To evaluate the proposed model, three famous criteria were used: MMRE, MdMRE, and PRED. The prediction results for the model were 0.21, 0.16, and 0.71, respectively.

Many of the challenges faced by software houses lie in forecasting and estimating the cost of software. From the examination of previous studies, there are several challenges, as the forecasting accuracy of software cost estimation was not sufficient and effective enough to make an accurate forecast. Also, the studies used a very small number of data sets to train and test the proposed models. Therefore, this study seeks to build a model to predict cost estimation through the ARIMA algorithm using five datasets COCOMO81, COCOMONasaV1, COCOMONasaV2, China, and Desharnais. Data sets were collected from the PROMISE repository to be displayed and analyzed, and the correlation between them was found to predict future values using time series, and then the proposed algorithm was applied to them. The proposed model was evaluated using four evaluation criteria: mean relative error (MMRE), root mean square error (RMSE), and mean magnitude were used. Relative error (MdMRE), and prediction accuracy (PRED). The study showed promising results that avoided the challenges faced by previous studies.

III. Proposed Model

The process of software cost estimation prediction is crucial in the software industry, so many studies have sought to predict it, but they have not been sufficient and effective in completing this process. Therefore, this study seeks, through the use of artificial intelligence algorithms, to build a model that can predict cost estimates. The process is done by collecting data from the Promise warehouse, displaying it, visualizing it, and analyzing it to understand it. Then link them together through time series to predict future values. The data is divided in fixed proportions into two groups to conduct the training process for the ARIMA algorithm. Followed by a scaling process to make all values at one close level to avoid the model ignoring values during the training process. The algorithm is trained on data sets, followed by a testing process to ensure the effectiveness and accuracy of the proposed model. This process is done using four criteria, as shown in Fig. 1.

The study faced several challenges during the implementation process. The quality of the data was not sufficient to complete the process and represented the biggest challenge during the implementation process, as noise and missing values were removed and the data was processed to understand it. There were also values in the data that were higher than the rest of the values, which represented another challenge and were addressed using data scaling to keep all the data at one level so that the model would not ignore them during the training process.

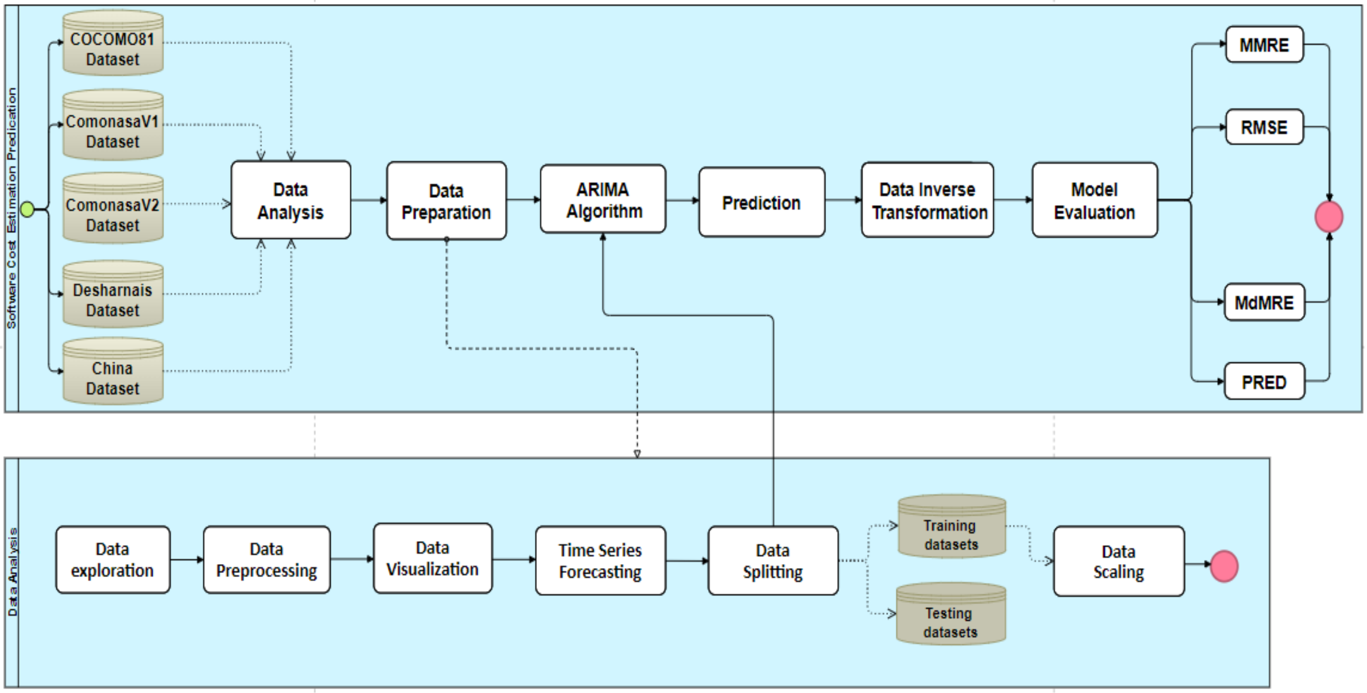

Fig. 1. The proposed model for software cost estimation predication process.

A. Datasets

The experiment was conducted using very popular and freely available datasets. They have been used previously in numerous studies to predict cost estimation. Collected from the Promise repository are the COCOMO81, COCOMONasaV1, COCOMONasaV2, Desharnais, and China. Their sizes range from 60 to 499. While the number of its features ranges between 10 and 24. The effort of these groups is measured in units of person-hour or person-month as shown in Table I.

TABLE I. STATISTICS OF THE DATASETS

Datasets	Source Repository	No. of projects	No. of Features	No. of missing values	Output Attribute-Effort (Unit)
COCOMO81	PROMISE	63	17	0	Person-month
COCOMONasaV1	PROMISE	60	17	0	Person-month
COCOMONasaV2	PROMISE	93	24	0	Person-month
Desharnais	PROMISE	81	10	4	Person- hours
China	PROMISE	499	15	0	Person- hours

B. Data Analysis

The data analysis [27] process is an important element, as data quality represents a major challenge in the training process, so the study focused on every step of exploring the data, as well as processing it to remove noise from it, and then visualizing it. It also used time series technology to connect them predict future values, and then divide the data into training and test sets to train the ARIMA algorithm.

1) Data exploration: It is a very important process to explore data, as it consists of understanding the data as it represents a statistical distribution. This process was done by uploading the data adding it to Google Drive and loaded to Google Colab [28]. To be explored through the info() function. The function gives the number of lines and columns for each data set and also checks whether it contains null values. It also indicates whether the values are numeric or textual. To maintain the state of the data in that form, the data is copied using the copy() function, and the original data is preserved.

2) Data preprocessing: The data processing process is an important step used to remove noisy data and missing values to prepare it for training from the raw data. First, noisy or erroneous data is identified and removed or corrected to ensure the quality of the data. Missing, anomalous, or extreme values negatively affecting the model's operation are discovered, treated, or removed [29]. To convert data into numeric values, text and non-numeric values are converted to numeric values. The index value was also determined to be the basic feature on which the prediction process depends.

3)** Data visualization**: Data representation plays an important role in the data analysis process. Through graphics such as graphs, animations, charts, and visual representations, what the data presents can be understood more clearly and confirm the structure and format of the data. Visual displays of information convey complex data relationships and data-based insights in an easy-to-understand manner. The Corr() function is also used to confirm the format of the data and discover the extent of correlation between features to produce values that represent the extent of the correlation. If the result is 1, this means that the correlation between the features is very high and ideal, but if the value is zero, it means that there is no correlation between them. If the value is negative, this means that the relationship is inverse between the two properties. All of this contributes to obtaining a deep understanding of the data, making distinctive engineering decisions, and building a highly efficient predictive model.

4) Time series forecasting: Time series is a basic technique for data learning and is one of the most popular data science techniques in the world of statistics and machine learning. It aims to provide an analytical approach by examining observations of past data to predict future values. The idea of time series is based on taking advantage of the time dimension as an essential factor for linking data points. The time column is converted to a historical and chronological format, where the data is indexed while maintaining the original time order. This structured format allows time series models to capture the temporal dynamics and inherent autocorrelation between the data. It is used in various fields such as finance, economics, and engineering. It involves a comprehensive analysis of sequential data points to identify underlying patterns, trends, and dependencies [30]. Forecasting is done through the time dimension as a basic factor for linking data in the form of time series by converting the time column into a historical and temporal format, where the data is indexed while maintaining the temporal order established as an indicator of the data sequence.

5) Data splitting and scaling: The datasets are split 80-20% and are used for training and testing respectively. The largest percentage is used in the training process to allow the model to learn the basic patterns and relationships between the data, ensuring its ability to make reliable predictions on new samples that have not been seen before. While the rest of the percentage is used in the testing process to ensure the accuracy of the proposed model [31]. In addition, the data is scaled to place it in a specific range or scale to ensure that all features have equal importance in the analysis to avoid the dominance of some features during the analysis process due to their high values, to avoid overfitting and the model.

C. The Proposed ARIMA Algorithm

The Auto-Regressive Integrated Moving Average (ARIMA) is a powerful statistical tool utilized in the field of time series analysis and forecasting. It introduced by Box and Jenkins in their seminal work, captures various temporal structures by integrating three primary components: Auto regression (AR), Differencing (I), and Moving Average (MA). It is particularly powerful due to its flexibility in modeling a wide range of time series behaviors, from simple trends to complex seasonal patterns [32].

The Autoregressive (AR) component of an ARIMA specifies that the current value of the time series is a linear function of its previous values. The term "autoregressive" indicates that the model regresses the variable on its prior values. The order of the AR component, denoted by p, signifies the number of lagged observations included in the model. [33] The general form of the AR(p) model is given by Eq. (1):

$$X_t = \emptyset_1 X_{t-1} + \emptyset_2 X_{t-2} + \cdots + \emptyset_p X_{t-p} + \in_t \tag{1}$$

Where X_t represents the value of the time series at time t, $\emptyset_1, \emptyset_2, \ldots., \emptyset_p$ are the coefficients of the model, and $\in_t$ is a white noise error term, which is assumed to have zero mean and constant variance.

The coefficients $\emptyset_1, \emptyset_2, \ldots., \emptyset_p$ determine the influence of past values on the current value. For example, in an AR(1) model (p=1), the current value X_t is directly proportional to the immediately preceding value X_{t-1} plus a stochastic error term $\in_t$.

The Integrated (I) component addresses the non-stationarity in the time series by differencing the data. Stationarity is a key property in time series analysis, implying that the statistical properties of the series do not change over time [34]. Non-stationary data can exhibit trends, seasonal patterns, or other structures that make them unsuitable for traditional time series models without transformation. Differencing is a technique to remove these non-stationary components. The order of differencing required to achieve stationarity is denoted by d. The first differenced series is defined through Eq. (2):

$$\Delta X_t = X_t - X_{t-1} \tag{2}$$

For higher-order differencing, the operation is applied recursively. For example, second-order differencing (d=2) is given by Eq. (3):

$$\Delta^2 X_t = \Delta(\Delta X_t) = (X_t - X_{t-1}) - (X_{t-1} - X_{t-2}) = X_t - 2X_{t-1} - X_{t-2} \tag{3}$$

Differencing transforms a non-stationary series into a stationary one, making it suitable for modeling with AR and MA components.

The Moving Average (MA) component models the dependency between an observation and a residual error from a moving average model applied to lag observations. The order q of the MA model indicates the number of lagged forecast errors included in the model. The general form of the MA(q) model is expressed as shown in Eq. (4):

$$X_t = \in_t + \theta_1 \in_{t-1} + \theta_2 \in_{t-2} + \cdots + \theta_q \in_{t-q} \tag{4}$$

Where $\theta_1, \theta_2, \ldots, \theta_q$ are the parameters of MA, and $\in_t$ is a white noise term.

Unlike the AR model, which uses past values of the series, the MA model uses past forecast errors. These errors capture the unexpected movements in the time series, and the MA component accounts for these by adjusting the model based on past error terms.

Combining these three components, the ARIMA model is denoted as ARIMA(p,d,q), where p is the number of lag observations (autoregressive terms), d is the number of times the raw observations are differenced, q is the size of the moving average window.

The general form of the ARIMA(p,d,q) model is as Eq. (5):

$$\Delta^d X_t = \emptyset_1 \Delta^d X_{t-1} + \emptyset_2 \Delta^d X_{t-2} + \cdots + \emptyset_p \Delta^d X_{t-p} + \in_t + \theta_1 \in_{t-1} + \theta_2 \in_{t-2} + \cdots + \theta_q \in_{t-q} \tag{5}$$

Where $\Delta^d X_t$ represents the d-th differenced value of X_t.

Using an ARIMA model for time series forecasting involves several critical steps. These steps ensure that the model is appropriate for the data and that the predictions are reliable. The process includes model identification, parameter estimation, and model diagnostic checking.

1) Model identification:

a) Stationarity Testing: A key assumption of the ARIMA model is that the time series data should be stationary. Stationarity implies that the statistical properties of the series (mean, variance) do not change over time.

- Visual Inspection: Plot the time series data to visually inspect for trends or seasonality.
- Statistical Testing: Apply the Augmented Dickey-Fuller (ADF) test to statistically verify stationarity.

b) Selecting p and q: Use the Autocorrelation Function (ACF) and Partial Autocorrelation Function (PACF) plots to identify potential values for p (AR terms) and q (MA terms).

- ACF Plot: Indicates the correlation between the time series with its own lagged values.
- PACF Plot: Indicates the partial correlation of the time series with its own lagged values, controlling for the values of the time series at all shorter lags.

Significant spikes in the ACF and PACF plots suggest the values for q and p, respectively. In this study the potential values of p, q are 1, and also d is 1.

2) Parameter estimation: Estimate the parameters ϕ (AR coefficients), θ (MA coefficients), and other model coefficients using methods such as Maximum Likelihood Estimation (MLE).

3) Model diagnostic checking: Analyze the residuals of the fitted model to ensure they resemble white noise (i.e., they have a constant mean, constant variance, and no autocorrelation).

- Ljung-Box Test: Test for autocorrelation in residuals.
- Residual Plots: Plot the residuals to check for patterns.

D. Data Inverse Transformation

When analyzing the data at the beginning of the experiment, the data are scaled such that large values are rounded to the same range so that the proposed model does not ignore some values or overfitting occurs [35]. The scale transformation is reversed to return the model output to the original data scale. This process is important in the real world, as the measured data may not be interpretable in the original context. Therefore, the data is carefully measured, the proposed algorithm is trained, and then the data is returned to its original form. This process is done using the inverseTransform() function. This process provides good, actionable insights into their original field.

IV. Evaluation and Discussion

After building the model and training it on the data sets that were divided by 20-80%, the testing process is carried out to ensure the effectiveness of the proposed model, where a computer is used with precise specifications that are explained in the experiment preparation section, by also evaluating it using four famous standards, which are MMRE, RMSE, MdMRE, and PRED are explained in the evaluation criteria section. A section was also added explaining the results of the experiment, as well as a section to discuss the results and comparison with previous studies under the same conditions on the same datasets.

A. Experimental Setup

The experiment was conducted on a laptop PC with an Intel Core i7 CPU, 64GB of RAM, and an NVIDIA GTX 1050i GPU. The datasets were also divided by 20-80%, with the largest percentage being used in the model training process, while the rest of the data was used in the model testing and evaluation process. The experiment was conducted through several tools. Google Drive was used to upload data sets for the experiment to it and then uploaded to Google Colab to conduct the experiment. This study used the Python language to present, describe, represent, and analyze the data used, train the algorithm, and then test it.

B. Evaluation Criteria

After completing training the model on the proposed algorithm. The model testing process is a crucial step to ensure the accuracy and effectiveness of the model. The estimation process is done using four famous criteria, which are mean magnitude of relative error (MMRE) [16], root mean square error (RMSE) [17], mean magnitude of relative error (MdMRE) [18], and prediction (PRED) [19].

1) Mean Magnitude Relative Error (MMRE): It is one of the most popular forecasting benchmarks and is used in software engineering forecasting to calculate the average relative difference between actual and predicted values. It is represented by Eq. (6) and Eq. (7):

$$\mathrm{MRE} = \frac{|\text{Actual effort} - \text{Estimated effort}|}{\text{Actual effort}} \times 100 \quad (6)$$

$$\mathrm{MMRE} = \frac{1}{\mathrm{M}}\sum_{1}^{\mathrm{M}} \mathrm{MRE} \quad (7)$$

Where m is the total data points and $\sum$ denotes the sum of values in the entire dataset [16].

2) Root Mean Square Error (RMSE): It is widely used in forecasting operations, as it represents the average size of the difference between the actual and expected values, and it needs the actual expected and corresponding values to calculate it, and this is done through Eq. (8).

$$RMSE = \sqrt{\frac{\sum(P_i - Oi)^2}{n}} \quad (8)$$

Where n is the number of data points, P is the expected value, O is the actual value, and ^2 denotes the squared difference [17].

3) Mean Magnitude of Relative Error (MdMRE): It is a statistical measure of prediction and is similar to the average size, except that it calculates the absolute average and is measured by determining the relative error for each prediction and finding the absolute difference between the actual and expected values. Then the relative error is arranged in ascending order through the following equation, which is used to calculate the error = |(P - A)| /A [18].

4) PRED: It is one of the most famous and widespread metrics as it indicates the accuracy of the model and its value increases as the accuracy of the model improves. It is expressed as a percentage in projects where the percentage of expected values matches the actual values and can be measured through Eq. (9)

$$PRED = \frac{1}{n}\sum_{i=1}^{n} \left| \frac{Estimation\ Effort - Actual\ Effort}{Actual\ Effort} \right| K\% \quad (9)$$

Where k% is the percentage of error between the actual estimate and the effort estimate [19].

C. Experimental Results

The four criteria described in the previous section were used to test the model to measure its effectiveness and accuracy in predicting software cost estimates, as the experiment showed promising results on the five datasets used as shown in Table II.

TABLE II. The Results of the Proposed Model on the Five Datasets

Method	Metrics	COCOMO81	COCOMONasaV1	COCOMONasaV2	China	Desharnais
The proposed model	MMRE	0.07613	0.02227	0.01035	0.00001	0.00004
	RMSE	0.04999	0.02899	0.00650	0.00430	0.00339
	MdMRE	0.03813	0.01113	0.00517	0.00008	0.00002
	PRED	95.0	97.1	99.35	99.57	99.6

Table II displays the software cost estimation prediction rates of the proposed model on the five datasets using the four evaluation criteria, where the results show very promising prediction and low value of error rates. The COCOMO81 and COCOMONasaV1 datasets show very good percentages in reducing error rates and also promising percentages in prediction accuracy, reaching 95% for the COCOMO81 data set and 97.1 for the COCOMONasaV1 data set. While the ratios were very unique and significantly distinct for the COCOMONasaV2, China, and Desharnais datasets. The error rates recorded the lowest possible rates, almost noticeable, while the prediction accuracy recorded rates exceeding 99% for the three datasets.

D. Comparison and Discussion

To ensure the effectiveness of the proposed model, it is compared with other models under the same conditions described, such as using the same datasets as well as the evaluation criteria used. The model was compared with recent studies. It was compared to the Sharma [25] model, which was used by four algorithms in its study: local mutual information-based neural network (LNI-NN), fuzzy-based neural network (NFL), GA-based adaptive neural network (AGANN), and GEHO-based NFN (GEHO-NN) for software cost estimation. It was also compared with the model of Zhang et al. [26] who used the XGBoost algorithm under the same conditions. Table III shows a comparison between the proposed model and previous models.

TABLE III. COMPARISON BETWEEN THE PROPOSED MODEL AND THE STATE-OF-THE-ART

Method	Metrics	COCOMO81	COCOMONasaV1	COCOMONasaV2	China	Desharnais
LNI-based NN [25]	**MMRE**	0.224	0.243	0.225	0.240	0.32
	RMSE	0.261	0.183	0.383	0.148	0.312
	MdMRE	0.256	0.249	0.249	0.255	0.336
	PRED	28.51	50	50	44	22.22
Neuro-fuzzy logic [25]	**MMRE**	0.213	0.236	0.196	0.220	0.296
	RMSE	0.178	0.131	0.290	0.075	0.173
	MdMRE	0.256	0.215	0.215	0.240	0.223
	PRED	29.92	62	62	70	32
Adaptive GA-based NN [25]	**MMRE**	0.199	0.231	0.174	0.192	0.197
	RMSE	0.130	0.065	0.232	0.056	0.111
	MdMRE	0.235	0.172	0.172	0.218	0.181
	PRED	46.15	73.87	70	76	47.05
GEHO-based NFN [25]	**MMRE**	0.174	0.220	0.128	0.167	0.112
	RMSE	0.055	0.060	0.960	0.39	0.060
	MdMRE	0.223	0.130	0.130	0.168	0.100
	PRED	57.14	83.14	83.14	84	88.23

Table III highlights the comparison between the proposed model and other models from previous studies during 2023 and 2024. The comparison shows the superiority of the proposed model in predicting software cost estimation compared to previous models. The model excelled in reducing the error rates in the five datasets and increasing the prediction accuracy of the software estimate, which ranged from 95 to over 99%. The error rates also decreased on the MMRE, RMSE, and MdMRE criteria.

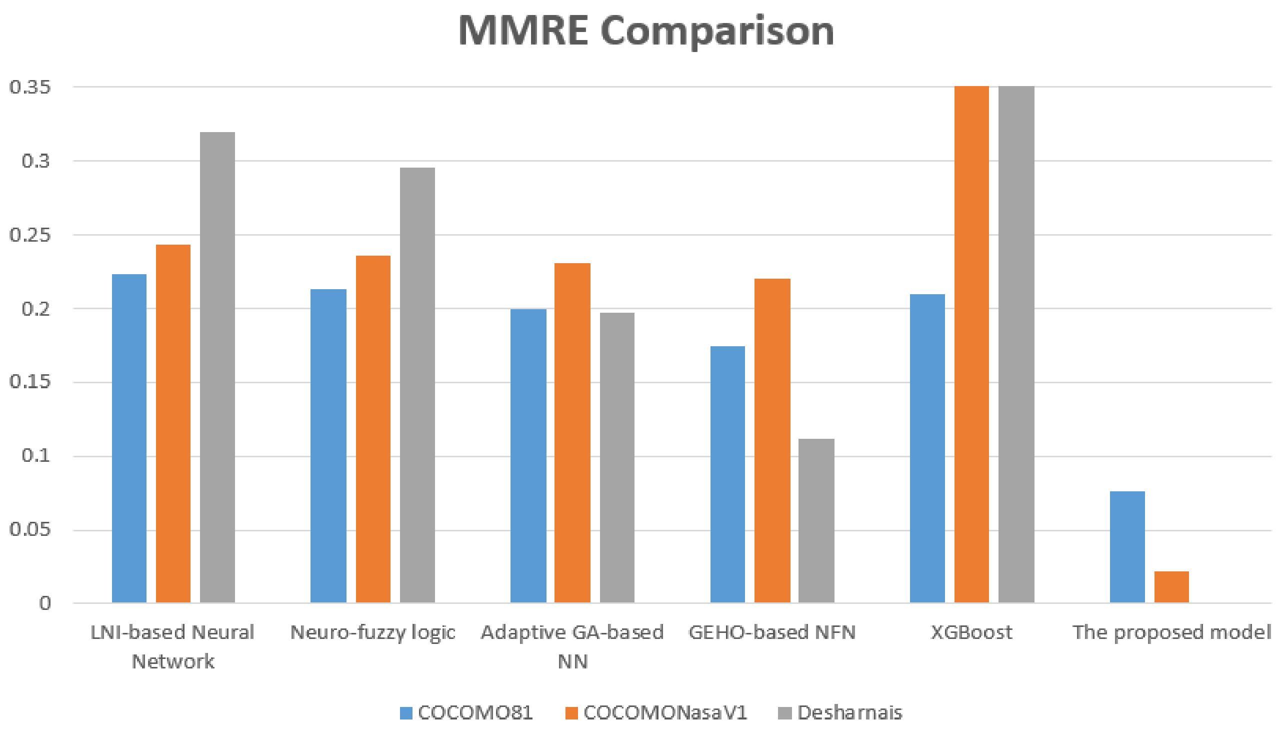

Fig. 2. Comparison between the proposed model and others on the MMRE measure.

Fig. 2 shows a comparison between the proposed model and previous studies according to the MMRE standard, where the results show significant superiority of the proposed algorithm. The COCOMONasaV2 and China datasets were excluded from the study since they were not used in Zhang's [26] study. However, there is a big difference in reducing error rates for the targeted study, as it showed a significant and distinct absence of error rates with the Desharnais data set, while the rates were very good and promising also for the COCOMO81 and COCOMONasaV1 datasets. The percentages were also clearly and prominently distinct according to the MdMRE standard, as the error rate decreased significantly and clearly for the three data sets. It decreased by a large and clear percentage for the COCOMONasaV1 and Desharnais datasets, and the decrease rates were also very good for the COCOMO81 dataset as shown in Fig. 3.

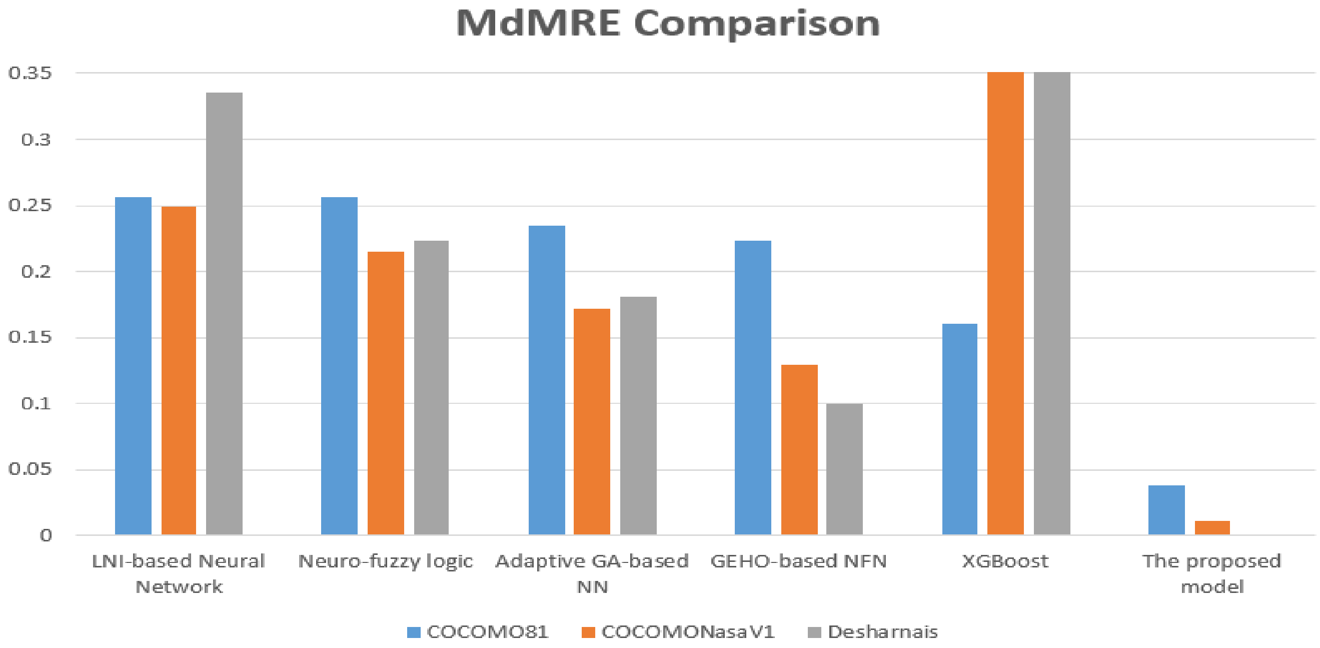

Fig. 3. Comparison between the proposed model and others on the MdMRE measure.

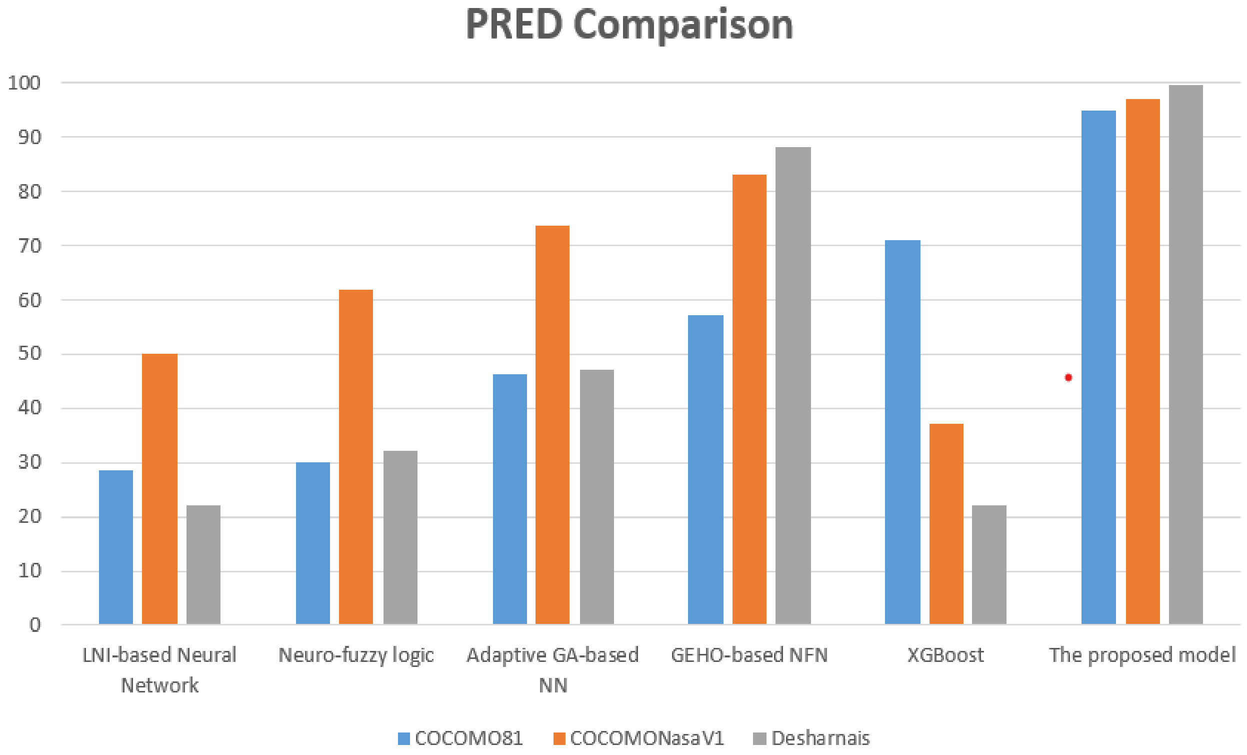

Fig. 4. Comparison between the proposed model and others on the PRED metric.

The most significant difference in explaining excellence was the PRED standard, which is more commonly used in detection and prediction processes. The results of the study showed a very prominent and clear distinction compared to previous studies, in which the prediction percentages ranged between 22 as the lowest prediction percentage and 88.23 as the highest percentage reached by the studies. However, the results of the proposed model were very promising, as the COCOMO81 data set recorded an accuracy rate for predicting the software cost estimate of 95%, while the COCOMONasaV1 data set recorded an accuracy rate of 97.1%, and the rate was very promising for the Desharnais data set, which recorded the highest percentage so far at 99.6% as shown in Fig. 4.

V. Conclusion

The software estimation process is one of the crucial steps today in the software industry, which plays the main role in the software production process. It represents the points of connection between the client's requirements and his budget, in addition to the indicator of controlling the workflow within the software houses on the desired projects. With the spread of the software industry over the past few decades, stakeholders have tended to accelerate the pace of their work to keep pace with the times, which has increased pressure on software houses to implement their work. Therefore, there was an urgent need for models that can estimate the cost of software perfectly. Researchers have created several models to evaluate this, some of which relied on traditional methods or mathematical equations and called them algorithmic methods. Some relied on experts' judgments and opinions and called them non-algorithmic methods. However, some relied in their work on learning techniques such as artificial intelligence, including machine learning and deep learning methods. However, previous studies have shown that prediction rates are not stable and sufficient to complete the process, so the need to create new models was very urgent. This study seeks to build and present a model that can predict software cost estimation using the ARIMA algorithm on five datasets, namely COCOMO81, COCOMONasaV1, COCOMONasaV2, China and the Desharnais dataset. The data was collected, presented, and processed to remove noise and missing values. It was also analyzed and visualized to identify and link them. The data is linked using time series technology to predict the future values of the data, and the process is very effective in increasing the model's performance. The data was split 80-20 for training and testing. The proposed model will be trained and tested on data sets. The model was evaluated using four popular prediction criteria, namely MMRE, RMSE, MdMRE, and PRED. The model shows a promising distinction in its results compared to other models, which contributes to reducing risk levels and contributes mainly to good project planning, which contributes effectively to the cost estimation forecasting process.

Although the model is distinguished in its work, some limitations must be addressed in the future, especially about data sets, as the model was trained on five data sets. However, we hope to train and test it on other data sets to ensure its effectiveness and accuracy. We also hope to apply it in real-time, which addresses Constant assumptions, computational overhead, and secondary evaluation problems that are used to enhance model response.

In future work, we seek to transform the model into a tool through which the project data can be entered, which are the client’s requirements in addition to the cost factors so that the user obtains an output estimating the effort and cost necessary to build the project. We also seek to train the model and test it on other data sets, as well as in real-time.

***Abstract*—Vehicular Ad-hoc Networks (VANETs) are engineered to meet the distinctive demands of vehicular communication, facilitating interactions between vehicles and roadside infrastructure to enhance road safety, traffic efficiency, and diverse applications such as traffic management and infotainment services. However, the looming threat of Distributed Denial of Service (DDoS) attacks in VANETs poses a significant challenge, potentially disrupting critical services and compromising user safety. To address this challenge, this study proposes a novel deep learning (DL)-based model that integrates Long Short-Term Memory (LSTM) architecture with self-attention mechanisms to effectively detect DDoS attacks in VANETs. By incorporating autoencoders for feature extraction, the model leverages the sequential nature of VANET data, prioritizing relevant information within input sequences to accurately identify malicious activities. With an impressive accuracy of 98.39%, precision of 97.79%, recall of 98.00%, and F1-score of 98.20%, the proposed approach demonstrates remarkable efficacy in safeguarding VANETs against cyber threats, thereby contributing to enhanced road safety and network reliability.**

I. Introduction

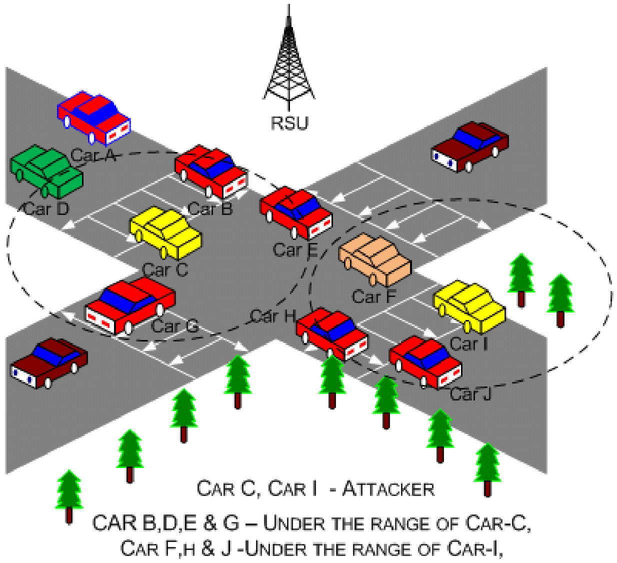
Securing communication among vehicles has become a significant focus in computer science recently. Employing a spontaneously formed network installed on a vehicle is a method to achieve this. A mobile ad hoc network, VANET, facilitates communication between nearby cars. Vehicles in VANETs are furnished with wireless communication tools, such as Dedicated Short-Range Communication (DSRC) or Cellular-Vehicle-to-Everything (C-V2X) technology, allowing direct communication between vehicles (V2V) and between vehicles and infrastructure (V2I). These communication capabilities facilitate the transmission of essential safety information, including vehicle location, velocity, and heading, as well as non-safety-related information, such as traffic conditions and service advertisements [1]. The dynamic nature of vehicular environments poses several challenges to the design and operation of VANETs. Vehicles move at high speeds, leading to rapidly changing network topologies and communication conditions.

Moreover, VANETs are subject to intermittent connectivity, network partitions, and unpredictable communication delays due to factors such as vehicle mobility, radio interference, and obstacles in the environment. Despite these challenges, VANETs offer immense potential to improve traffic safety and effectiveness via the deployment of intelligent transportation systems (ITS). By enabling vehicles to cooperate and share information in real time, VANETs can mitigate accidents, reduce traffic congestion, and provide drivers with timely and context-aware services.

In recent years, research efforts in VANETs have focused on addressing key issues such as communication reliability, security, privacy, and scalability. Advanced communication protocols, routing algorithms, and congestion control mechanisms have been proposed to optimize the performance of VANETs in dynamic and resource-constrained environments [2]. Additionally, protective metrics such as verification, data encryption, and threat detection are crucial to defend VANETs from harmful intrusions and illegal access. As the automotive industry continues to embrace connected and autonomous vehicles (CAVs), the role of VANETs is expected to become increasingly prominent. CAVs rely on VANETs for cooperative perception, decision-making, and coordination, enabling them to safely and effectively manoeuvre through intricate traffic situations. Additionally, advancing technologies like 5G and edge computing offer promising possibilities to further enhance the capabilities of VANETs by providing high-speed connectivity and low-latency communication services. Various attack types in VANETs are classified by origin and behavior. External attacks, originating outside the network, aim to disrupt VANET operations through unauthorized access or denial-of-service tactics. Internal attacks originate from compromised nodes within the network, challenging detection and mitigation efforts. Active attacks manipulate or disrupt communication, while passive attacks eavesdrop to gather data. Area attacks target specific regions, affecting multiple vehicles or units, and communication attacks disrupt communication channels. Rational attackers engage in malicious activities without personal gain, complicating security measures [3]. These attack types emphasize the need for comprehensive strategies to protect VANET integrity and user privacy.

A. *DDoS Attack in VANET*

In a Denial of Service (DoS) attack, the attacker interferes with the services provided by a service provider, preventing legitimate users from accessing the network despite the availability of resources [4]. The attacker achieves this by blocking the communication medium in specific areas, limiting the attack to the service provider's scope. This can be done in two ways: the attacker either floods the resources with an overwhelming number of requests, keeping them occupied with fake requests, or extends the attack by sending numerous requests to block communication, thus preventing the RSU from processing any OBU requests. Conversely, DDoS attacks are a distributed form of DoS attacks where multiple attackers from various locations simultaneously target one or more service providers, causing significant inconvenience.



RSU
Car A
Car D
Car B
Car C
Car E
Car F
Car G
Car H
Car I
Car J
Car C, Car I - Attacker
CAR B,D,E & G – Under the range of Car-C,
Car F,H & J -Under the range of Car-I,

Fig. 1. DDoS attack.

In these attacks, a larger number of malicious OBU nodes block legitimate users from accessing services through multiple RSUs by spamming the network, leading to increased transmission delays. This type of attack poses a significant threat to VANETs, as illustrated in Fig. 1, where cars C and I disrupt services provided by an RSU by preventing cars B, D, E, G, F, H, and J from accessing it. The primary objectives of the paper are as below:

- To propose a novel DL-based method for the effective detection of DDoS attacks in VANET.
- To incorporate auto encoders for better feature extraction.
- Evaluate the efficiency of the proposed model with the current approaches.

The remaining of the paper is structured as: Section II provides an overview of existing methodologies for detecting attacks in VANETs, laying the foundation for the proposed research. Section III outlined the method details of the proposed approach. The outcomes of the study, including the efficiency of the suggested approach in detecting alternative approaches, are discussed in Section IV. Final, Section V offers remarks summarizing the findings and implications of our work.

II. Literature Review

Zu et al. [5] introduced a detection method that utilized beacon packets in vehicles to trace malicious vehicle sources. Their approach involved Roadside Units (RSUs) instructing vehicles to execute key transmission and reception, enabling them to assert their physical presence. RSUs then analyzed beacon packets to construct a neighbor graph, determining vehicle credibility. Experimental findings validated the efficacy of the proposed method, achieving identification and monitoring of Sybil vehicles with accuracy and recall rates of 98.53% and 95.93%, respectively. Significantly, the approach surpassed current solutions, especially in sustaining consistent detection rates in conditions of high vehicular density.

The FC-LSR system, proposed by Almazroi et al. [6], introduced a fog computing-based lightweight solution to combat Sybil attacks in 5G-equipped vehicular networks. Utilizing Modified Merkle Patricia Trie (MMPT) and Merkle Hash Tree (MHT), the system securely stored vehicles' 'current status' values while ensuring data anonymity. Significantly, the approach surpassed current solutions, especially in sustaining consistent detection rates in conditions of high vehicular density. However, limitations involve vulnerability to neighbor-based manipulation and single-point failure risks.

Ahmed et al. [7] proposed an Intrusion Detection System (IDS) utilizing ML to mitigate DDoS attacks in VANETs. The approach addressed rising security concerns, particularly due to DoS and DDoS attacks flooding the network with malicious packets. By combining Random Projection (RP) and Randomized Matrix Factorization (RMF) methods, the IDS sought to improve detection abilities by extracting significant features from network traffic data. Experimental evaluation revealed outstanding accuracy compared to existing methods, with a combined accuracy of 0.98. However, research focused specifically on the identification of DoS and DDoS attacks and did not address energy consumption or computational complexity.

Dayyani & Abbaspour [8] proposed the SybilPSIoT method, which proposed a combined method integrating prevention and detection in a decentralized manner in Social Internet of Things (SIoT) based on smart contracts. A model utilized signed SIoT network entities and labels functioning as points in a network, and incorporating trust paths to assess the target node. Game theory was employed for access control to prevent Sybil from creating new objects. The method was found to be efficient in rapid detection and prevention of Sybil, considering the limitations of smart contracts. Evaluation data showed its superior performance compared to the SybilSCAR approach.

A DL model based on GRU was proposed by ALMahadin et al. [9] for detecting anomalies in VANET network traffic hence it is crucial for identifying unknown threats like DoS floods and providing security insights for multimedia services. The proposed model, SEMI-GRU, utilized a semi-supervised approach to enhance accuracy. Results showed that SEMI-GRU outperformed existing methods with low false positive rates. However, challenges remained, including real-time detection and limited labeled data accessibility.

Vermani et al. [10] suggested a framework utilizing ensemble learning to identify malicious nodes. in SDN-based VANETs, with a particular emphasis on internal position falsification attacks. Various ML algorithms, including SVM, k-NN, Logistic Regression (LR), Naïve Bayes (NB), and Random Forest (RF), were evaluated using the VeReMi dataset. Among the ML algorithms tested, Random Forest demonstrated the most effective performance in identifying attacks. Additionally, the study compared two collective classification techniques, voting and stacking, used for the purpose of decision-making. Both approaches improved classification accuracy and reduced prediction time, with stacking requiring less time than voting while achieving comparable accuracy levels to Random Forest. However, the study's focus on internal position falsification attacks within SDN-based VANETs limited its generalizability to other attack types and VANET configurations.

Magsi et al. [11] aimed to propose a comprehensive solution addressing the security, privacy, and routing challenges in Vehicular Named Data Networking (VNDN). Introduced three key components: an ML-based reputation evaluation model, a decentralized blockchain system for privacy preservation, and the enhancement of VNDN routing through a transition from pull to push-based content dissemination using a Publish-Subscribe (Pub-Sub) approach. The approach utilised ML techniques for attacker detection, blockchain for privacy preservation, and Pub-Sub for efficient content distribution. For evaluation, utilized the BurST-Australian dataset for Misbehavior Detection (BurST-ADMA) and applied five ML classifiers, including LR, Decision Tree, KNN, RF, and NB. The outcomes demonstrated that the RF achieved the highest accuracy rate in identifying attackers, followed by Decision Tree. Despite promising outcomes, the study faced limitations, such as reliance on simulation-based datasets and potential scalability challenges associated with blockchain integration.

Alsarhan et al. [12] proposed the utilization of SVM along with three intelligent optimization algorithms - Genetic Algorithm, Particle Swarm Optimization, and Ant Colony Optimization for attack detection in VANET. The primary objective was to optimize the accuracy of intrusion detection in VANETs by fine-tuning the parameters of the SVM classifier using optimization algorithms. The model addressed the security vulnerabilities in VANETs and improve the reliability of communication among smart vehicles. To assess how well the suggested approach works, trials were carried out utilizing the NSL-KDD dataset, and the performance of each optimization algorithm in optimizing SVM parameters was assessed based on classification accuracy. The study sought to contribute to the development of more robust intrusion detection systems for VANETs, thereby enhancing the security of vehicular communication systems. Despite the promising results obtained, the study acknowledged limitations such as reliance on simulated data and the exclusive focus on SVM-based detection methods.

Patil & Mallapur [13] enhanced the security of message dissemination within VANET by integrating ML, blockchain, and the interplanetary file system (IPFS). The methodology involved blockchain technology to create immutable records of events in a distributed environment, complemented by IPFS for storing event content with addressability. Metadata information from IPFS was managed using smart contracts and uploaded to a distributed ledger. Subsequently, K-means clustering was employed to classify vehicles as malicious or benign, followed by the use of a SVM classifier to find malicious event messages. The evaluation of the proposed system demonstrated its effectiveness in identifying and filtering out malicious messages, thereby ensuring the transmission of only secure messages within the network. Furthermore, the approach exhibited minimal consumption time compared to existing methods, indicating its efficiency in event detection and validation. However, limitations included the reliance on theoretical analysis and simulations for evaluation.

Canh & HoangVan [14] proposed a ML-driven strategy to identify blackhole attacks within VANET, aiming to fortify network security. Initially, a thorough dataset comprising both normal and malicious traffic flows was compiled to facilitate analysis. Distinctive features were identified to differentiate blackhole attacks from typical network behavior. Subsequently, a range of ML algorithms, including Gradient Boosting (GR), RF, SVMs, KNN, NB, and LR, were evaluated for their efficacy in differentiating between normal and harmful nodes. Experimental outcomes showcased the superior performance of GR and RF algorithms in pinpointing blackhole nodes, followed by SVMs and KNN. Although NB and LR demonstrated relatively lower effectiveness, they offered valuable insights into the detection process.

In response to the urgent need for robust detection mechanisms to safeguard VANET against DDoS attacks, a hybrid algorithm based on SVM kernels, AnovaDot, and RBFDot, was proposed by Adhikary et al. [15]. The aim was to enhance the DDoS attacks detection in VANETs and mitigate potential threats to commuter safety and network integrity. The proposed hybrid algorithm leveraged features such as packet drop, jitter, and collisions to simulate network communication scenarios under both normal conditions and DDoS attacks. The hybrid model exhibited higher accuracy and effectiveness in differentiating between normal and DDoS attacks, as evidenced by improved performance metrics across the evaluation criteria. One limitation was the complexity of implementing and fine-tuning the hybrid model, which required significant computational resources and expertise. Additionally, the effectiveness of the algorithm varied depending on the specific characteristics of the VANET environment and the nature of the DDoS attacks encountered.

Anyanwu et al. [16] introduced an IDS targeting DDoS attacks. With the Radial Basis Function (RBF) kernel of the SVM classifier and a Grid Search Cross-Validation (GSCV) method, the IDM aimed to enhance detection accuracy. Deployed on OBUs, it analysed vehicular data to classify messages as benign of a DDoS attack. Experimental results demonstrated superior performance compared to alternative ML algorithms, with optimal RBF-SVM parameters of "C"=100 and "gamma" (γ)=0.1. Achieving an accuracy 99.33% and a detection rate 99.22%, the IDM outperformed existing benchmarks, highlighting its efficacy in detecting DDoS intrusions.

A fog computing-based Sybil attack detection framework (FSDV) was proposed by Paranjothi & Atiquzzaman.[17] FSDV utilized onboard units (OBUs) installed in vehicles to establish a dynamic fog for detecting rogue nodes, aiming to mitigate scenarios with high vehicle density. Evaluations conducted through simulations using OMNET++ and SUMO simulators revealed significant improvements with FSDV, achieving a reduction of 43% in processing delays, 13% in overhead, and 35% in FPR compared to existing schemes.

Notably, FSDV demonstrated scalability and efficiency, outperforming previous techniques by up to 32%. Furthermore, it eliminated the reliance on roadside infrastructures or historical vehicle data for rogue node detection, providing a notable advantage. Despite its effectiveness, FSDV is subject to simulation-based constraints.

Velayudhan et al. [18] developed the Emperor Penguin Optimization (EPO) based Routing protocol (EPORP) to tackle the challenge of identifying Sybil attacks and enhancing system efficiency in VANETs. The main goal was to detect Sybil attacks and bolster security within VANETs, achieved through the utilization of the Rumour riding technique for Sybil attack detection and the Split XOR (SXOR) operation for safeguarding messages and data. In SXOR, the optimal key was generated using the EPO algorithm. Results indicated that the EPORP protocol outperformed others with a higher delivery ratio (0.96), demonstrating superior message delivery capabilities. However, the study faced limitations including reliance on simulation-based assessments.

The Sybil Detection using Classification (SDTC) approach was introduced by Kakulla & Malladi [19] to mitigate Sybil attacks within VANETs. SDTC leveraged Extreme Learning Machine (ELM) to enhance detection accuracy while reducing false positives. Through extensive simulations conducted in realistic VANET environments, the performance of SDTC was assessed across various metrics, including accuracy, and processing time. The outcomes indicated that SDTC achieved superior detection accuracy compared to existing methodologies, accompanied by a notable decrease in false positives. Nonetheless, limitations were identified, such as reliance on simulated environments, potential performance variability under diverse conditions, and concerns regarding scalability.

Despite advancements in security solutions for VANET, a notable gap persists in the realm of DDoS attack detection tailored explicitly to VANET environments. Existing studies have predominantly focused on traditional DDoS detection methods, often adapted from general network security approaches, which may not adequately address the unique characteristics and challenges of VANETs. The limited emphasis on DDoS attacks within VANET contexts underscores the necessity for dedicated research efforts aimed at developing specialized detection mechanisms capable of efficiently and effectively identifying and mitigating DDoS threats in VANETs. DDoS attacks pose significant risks to VANETs by disrupting critical services, compromising traffic management systems, and jeopardizing the safety of drivers and passengers. Thus, there is an urgent need for innovative approaches that leverage VANETs' dynamic nature, such as the mobility of vehicles and the dynamic network topology, to develop robust and adaptive DDoS detection mechanisms.

III. Materials and Methods

Attack detection in VANETs is essential to ensure the dependability and safety of vehicular communication networks because it allows mitigation actions to be implemented in a timely manner, preventing disruptions to vital services and possible risks to pedestrians and passengers. So, in this paper a novel DL model is proposed incorporating the self-attention in LSTM architecture for efficient detection of DDoS attack in VANET. The workflow of the suggested method is depicted in block in Fig. 2.

A. Dataset

The study utilized VeReMi dataset sourced from Kaggle [20]. The VeReMi dataset is a simulated dataset developed for assessing attack detection mechanisms in VANETs and offers a diverse range of traffic behaviors and attacker scenarios. The dataset includes multiple scenarios featuring different vehicle and attacker densities (high, medium and low), as well as repeated parameter sets to ensure randomness. Each scenario contains detailed message logs from both attacking and benign vehicles, capturing various attributes like reception timestamps, claimed transmission times, sender IDs, GPS positions, RSSI values, and noise vectors. Additionally, a ground truth file accompanies the dataset, documenting the true Basic Safety Messages (BSM) attribute values for both attackers and benign vehicles. With a total of 225 simulation runs categorized by density, the dataset provides insight into the performance of attack detection methods across different VANET settings. Table I illustrates the parameters of the attacks in VeReMi dataset. Table II provides a comprehensive description of the VeReMi dataset, detailing the attributes and categories of attacks included in the dataset.

16 (Eventual stop)	stop probability + = 0.025 each position update (10Hz)

TABLE II. VEREMI DATASET DESCRIPTION

Attributes	Description
Reception Timestamp	Timestamp of message reception
Claimed Transmission Time	Time claimed by the sender
Sender ID	Unique identifier for the sender
GPS Position	Geographic coordinates (latitude, longitude)
RSSI Value	Received Signal Strength Indicator
Noise Vector	Noise values associated with the message
Attack Type	Type of attack (Constant, Constant offset, Random, Random offset, Eventual stop)
Ground Truth	True values of Basic Safety Messages (BSM) attributes for both attackers and benign vehicles

B. *Data Preprocessing and Augmentation*

Preprocessing is the cornerstone for robust and effective DDoS attack detection in VANETs, as it ensures that the data is cleansed, transformed, and structured to empower subsequent analysis and modeling. Its significance cannot be overstated, serving as the pivotal stage where raw data from the Veremi dataset is refined into a form conducive to accurate detection. By systematically cleaning the data, handling missing values, removing duplicates, and normalizing numerical features, preprocessing establishes a solid foundation for subsequent analysis. Also, noise reduction techniques enhanced the data quality. Data augmentation complements preprocessing efforts, enhancing the diversity and size of the dataset for robust model training. Through synthetic data generation techniques, such as data mirroring or noise injection, the dataset's diversity is increased, allowing models to generalize better to unseen scenarios. Random perturbation introduces variations to existing data samples, simulating different environmental conditions and enhancing model robustness. Augmentation via simulation further enriches the dataset by modeling diverse traffic conditions, network configurations, and attack scenarios.

C. *Feature Selection and Extraction using Convolution Autoencoder*

In the study, convolutional autoencoders are used for the feature extraction method. Autoencoders present a compelling approach for feature extraction including spatial patterns in DDoS attack detection within VANETs, utilising the Veremi dataset. Comprising an encoder and decoder as shown in Fig. 3, Autoencoders aim to condense input information into a reduced-dimensional latent space while endeavouring to accurately reproduce the initial input. This condensed representation, often referred to as the latent space or bottleneck layer, encapsulates essential features crucial for distinguishing between normal and anomalous traffic behavior, including potential DDoS attacks. By training on the Veremi dataset, autoencoders efficiently reduce the dimensionality of the high-dimensional input data while preserving critical information, aiding in mitigating the curse of dimensionality inherent in VANET data analysis. Moreover, their capability to capture complex patterns and relationships throughout the data makes them particularly adept at identifying subtle deviations indicative of DDoS attacks. As autoencoders operate in an unsupervised manner, they alleviate the need for labeled attack data, thereby enabling the learning of representations directly from raw input data without manual feature engineering or annotation. This underscores their significance as a potent tool for facilitating robust DDoS attack detection mechanisms to the unique challenges posed by VANET environments and the characteristics of the Veremi dataset.

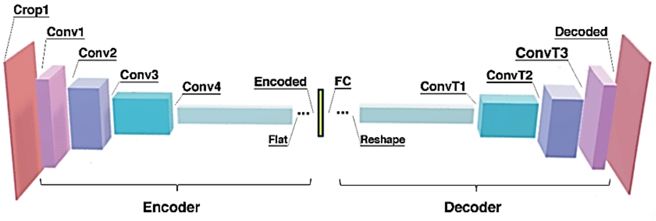

Fig. 3. Basic architecture of convolution autoencoder.

In a convolutional autoencoder, the encoder operation involves convolutional layers followed by down sampling operations such as max-pooling. Mathematically, the output feature map Z at each layer can be represented as Eq. (1).

$$Z = f_{conv}(X) \tag{1}$$

where f_{conv} denotes the convolutional operation applied to the input data X. The decoder operation comprises up sampling operations followed by convolutional layers. The reconstructed output $\hat{X}$ is given by Eq. (2),

$$\hat{X}=f_{deconv}(Z) \tag{2}$$

where f_{deconv} represents the deconvolutional operation applied to the latent representation. Autoencoders operate by minimizing the reconstruction error between the input data and the output reconstructed by the decoder. The loss function measures the discrepancy between the original input data X and its reconstruction $\hat{X}$. The mean square error (MSE) is a commonly used loss function for autoencoders as given by Eq. (3),

$$L_{MSE} = \frac{1}{N}\sum_{i=1}^{N}\left\|X_i - \widehat{X_i}\right\|^2 \quad (3)$$

where, N is the number of samples in the dataset. The convolution operation involves sliding a kernel over the input data to perform feature extraction [23]. Mathematically, the output feature map Z at each layer can be calculated by Eq. (4),

$$Z_{i,j} = \sum_{m=0}^{M-1}\sum_{n=0}^{N-1}(X_{i+m,j+n} \times K_{m,n}) + b \quad (4)$$

Max-pooling is frequently used following convolutional layers to decrease the size of feature maps and diminish spatial dimensions. This process involves choosing the highest value from a group of neighboring values. In mathematical terms, the result of the max-pooling operation can be represented by Eq. (5),

$$Z_{i,j} = max_{m,n\epsilon pooling\ region}X_{i+m,j+n} \quad (5)$$

The algorithm for the Convolution Autoencoder is given below.

Algorithm 1 Convolution Autoencoder

```
Input: Veremi dataset, num_epochs: Number of training epochs, mini_batch_size: Size of mini-batches for stochastic gradient descent, learning_rate: Learning rate for optimization algorithm
Output:Trained convolutional autoencoder model
Initialize parameters:
  - Initialize weights and biases for convolutional and deconvolutional layers randomly
Define Loss Function:
  - Define Mean Squared Error (MSE) loss function
Training Loop:
  for epoch in range(num_epochs):
    for each mini-batch in training set:
      a. Forward Pass:
        - Compute encoder output (latent representation) using Equation (1)
        - Compute decoder output (reconstruction) using Equation (2)
      b. Compute Loss:
        - Compute MSE loss between input and reconstruction using Equation (3)
      c. Backpropagation:
        - Update encoder and decoder parameters using gradient descent
    d. Validate model performance:
      - Compute MSE loss on validation set
Feature Extraction:
  - Use trained encoder to extract features from VANET dataset:
  - Pass input data through encoder to obtain latent representations (encoded features)
Output: Extracted features serve as input for downstream analysis tasks
```

D. LSTM Self Attention Model

A self-attention mechanism-equipped LSTM model is proposed in this paper for effectively detecting DDoS attacks in VANETs utilizing the sequential nature of the data and focusing on relevant parts of the input sequence. The basic architecture of LSTM model is given in Fig. 4. The LSTM, type of recurrent neural network (RNN), especially proficient at managing sequential data, like time-series information, found in VANETs. It maintains state, allowing it to acquire long-range dependencies in the data while mitigating the vanishing gradient problem. The LSTM model consists of LSTM cells, each of which has input, forget, and output gates to regulate the flow of information. The state equations for the LSTM network are given as follows,

$$\text{Input Gate, } I_t = \sigma(W_i.[h_{t-1}, x_t] + b_i) \quad (6)$$

$$\text{Forget Gate, } F_t = \sigma\left(W_f.[h_{t-1}, x_t] + b_f\right) \quad (7)$$

$$\text{Candidate Memory,} \breve{C_t} = tanh\left(W_c.\left[h_{t-1,}x_t\right] + b_c\right) \quad (8)$$

$$\text{Memory Cell, } C_t = f_t * C_{t-1} + i_t * \breve{C_t} \quad (9)$$

$$\text{Output Gate, } O_t = \sigma(W_0.[h_{t-1}, x_t] + b_o) \quad (10)$$

$$\text{Hidden State, } h_t = O_t * tanh(c_t) \quad (11)$$

where, x_t is the input variable at each time step t. The input vectors are represented by several weight matrices W_i, W_f, and W_c . The sigmoid activation function is shown by σ , Furthermore, the bias values for the input, cell state, forget gate, and output gate are indicated by b_i b_f, b_c, and b_o, respectively.

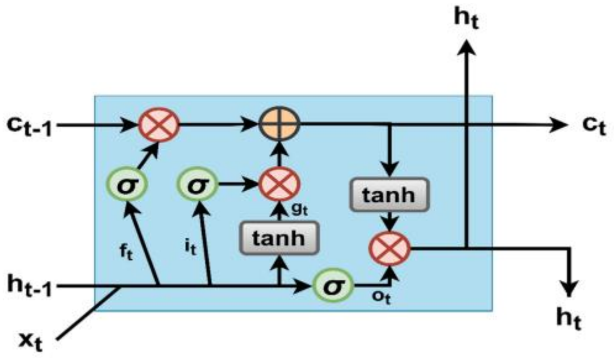

Fig. 4. LSTM architecture.

Self-attention allows the model to focus on different parts of the input sequence, prioritizing important information and disregarding unimportant sections. It computes attention weights for each time step based on the input sequence. The model architecture of LSTM with Self-attention mechanism is provided by Fig. 5.

The attention weights α_t are evaluated as a function of the hidden states h_t of the LSTM cells as given in Eq. (12).

$$\alpha_t = softmax(W_\alpha h_t) \quad (12)$$

The context vector c is evaluated as the weighted sum of the hidden states a in Eq. (13).

$$c = \sum_{t=1}^{T} \propto_t h_t \quad (13)$$

The context vector c obtained from the self-attention mechanism is then used as input to a classification layer, a fully connected layer followed by a softmax activation function, to predict the probability of DDoS attacks.

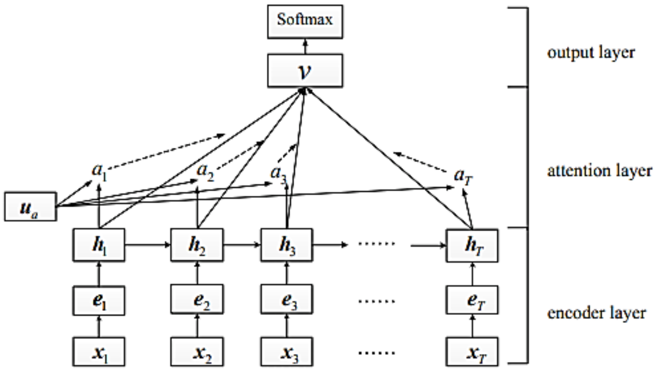

Fig. 5. LSTM Self attention model.

The context vector *c* obtained from the self-attention mechanism is then used as input to a classification layer, a fully connected layer followed by a softmax activation function, to predict the probability of DDoS attacks. By integrating the LSTM with self-attention, the model effectively captures long-term dependencies and relevant features in the sequential data, which are critical for identifying DDoS attacks. This combined approach utilizes the strengths of both LSTM and self-attention, making it a potent tool for robust DDoS attack detection in the challenging VANET environment. The self-attention mechanism, in particular, makes the model prioritize crucial parts of the input sequence, thus improving detection performance without requiring extensive labeled data, which is a significant advantage in unsupervised learning contexts.

E. *Hardware and Software Setup*

The model was developed and trained using Google Collaboratory with GPU acceleration. The software environment for the detection of DDoS attacks in VANET is implemented in Python using TensorFlow which is known for its scalability and deployment capabilities. The extensive computing resources of Google Colab combined with Keras's user-friendly interface made the process of developing models easier and guaranteed the successful training and application of intricate neural network designs. The system with Intel Core i5-8300H CPU, 16GB RAM, and a GTX1050 GPU is used to perform this research. Hyperparameters are essential configuration parameters that define the behavior and operation of a DL framework during training. Table III represents the hyperparameters used.

TABLE III. HYPERPARAMETER SPECIFICATION

Hyperparameters	Values
Optimizer	Adam
No. of epochs	50
Loss Function	Binary Cross Entropy
Activation Function	Softmax
Batch size	32

IV. RESULT AND DISCUSSION

A. *Performance Evaluation*

The performance was evaluated using the evaluation metrics as shown in Table IV. These metrics provide quantifiable assessments of the model's performance and aid in determining how effectively it can detect DDoS attack in VANET. To assess the impact of feature selection, experiments are conducted before and after feature selection. The classification report of the DDoS attack detection using LSTM self-attention model is given in Table V. From Table V, it is clear that the model demonstrates high performance across various evaluation metrics, indicating its effectiveness in correctly identifying both positive and negative instances with an 98.39% accuracy, 97.79% precision, 98.00% recall, and 98.20% F1-score, these metrics highlight the model's ability to achieve a balance between minimizing FP and FN, making it reliable for real-world applications where precision and recall are equally important. The visual depiction of the assessment outcome of the suggested model is given in Fig. 6.

TABLE IV. EVALUATION PARAMETERS

Performance Metrics	Equations
Accuracy	$(TP + TN) / (TP + TN + FP + FN)$
Precision	$TP / (TP + FP)$
Recall	$TP / (TP + FN)$
F1 Score	$2 * (Precision * recall) / (Precision + recall)$
where, TP-true positives, FP-false positives, TN-true negatives and FN-false negatives	

TABLE V. CLASSIFICATION REPORT OF PROPOSED METHOD BEFORE AND AFTER FEATURE SELECTION

Evaluation Metrics	Before Feature Selection	After Feature Selection
Accuracy	97.20%	98.39%
Precision	96.80%	97.79%
Recall	97.00%	98.00%
F1- Score	96.90%	98.20%

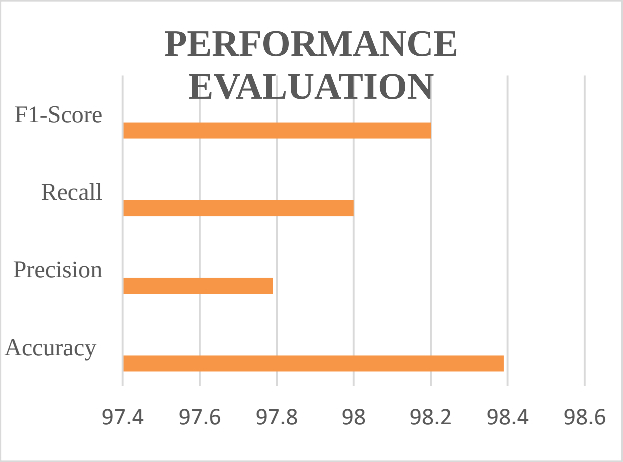

Fig. 6. Graphical representation of performance evaluation.

The Receiver Operating Characteristic (ROC) curve is crucial for evaluating the performance of the proposed model. It plots the TP Rate (TPR) against the FP Rate (FPR) as in Fig. 7, showcasing the trade-off between sensitivity and specificity. The Area Under the ROC Curve (AUC) acts as a singular numerical representation capturing the model's capacity to differentiate between different classes. The proposed model provides an AUC of 0.985 indicating perfect classification whether the VANET is detected with DDoS attack or not. This graphical representation and the accompanying AUC offer meaningful observations about the model's efficacy, making the ROC curve an essential component in the assessment of classification algorithms.

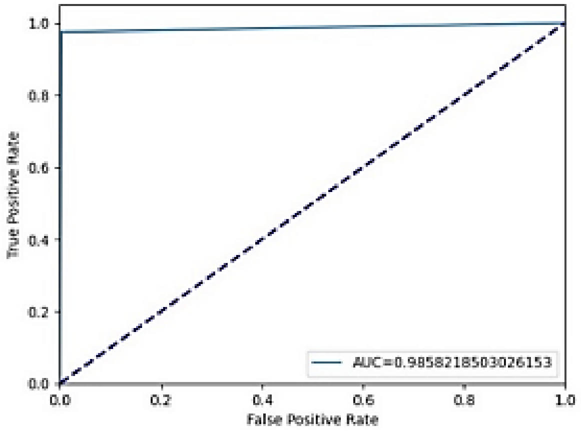

Fig. 7. ROC curve.

To provide a detailed breakdown of the model's performance, the confusion matrix is presented in Fig. 8. This matrix offers insights into the model's ability to correctly classify instances of DDoS attacks and benign activities.

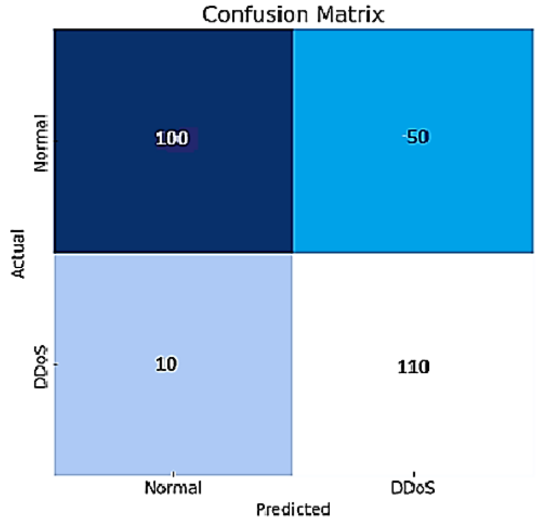

Fig. 8. Confusion matrix.

To further evaluate the training process of our proposed model, we present the accuracy and loss curves over the training epochs. Fig. 9 depicts the accuracy and loss curves respectively, showcasing the convergence behavior and stability of the model during training.

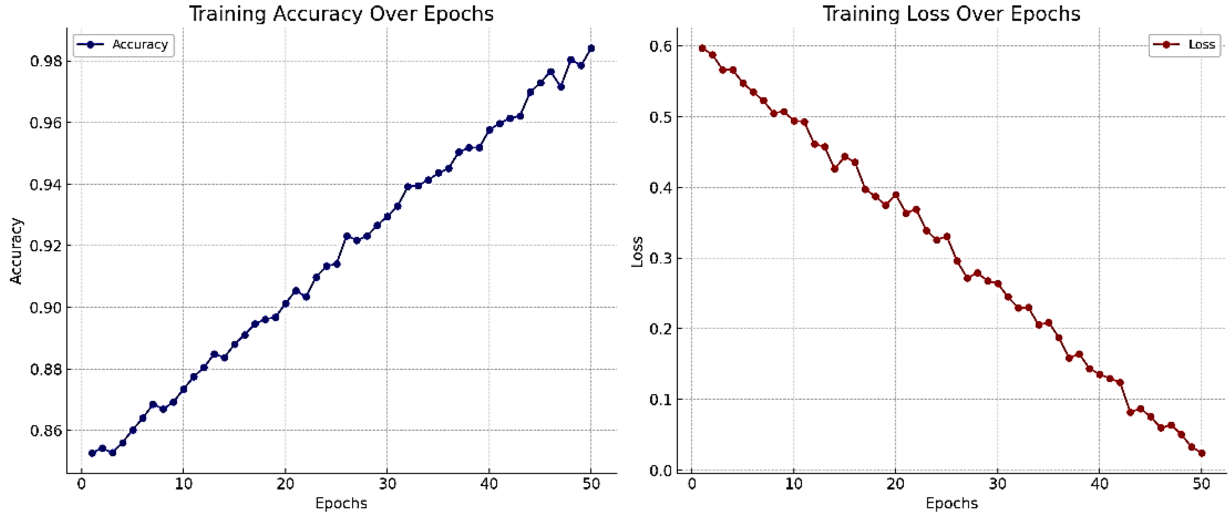

Fig. 9. Accuracy and Loss plot of the proposed model.

B. Performance Comparison

The proposed method is compared with existing models for various attack detection which utilises both DL and ML. Table IV shows the effectiveness of the suggested method in comparison with the current techniques regarding accuracy.

In addition to performance metrics, the training times of various models were recorded to assess computational efficiency. Table VII presents the training times for the proposed model and other baseline models.

In addition to its superior performance metrics (98.39% accuracy, 97.79% precision, 98.00% recall, and 98.20% F1-score), the proposed model demonstrates efficient training with a time of just 3.5 hours [24]. This outperforms the training times of other baseline models, highlighting the proposed model's advantage in both computational efficiency and detection capability. The proposed model’s balanced approach to minimizing both training time and achieving high detection accuracy makes it an optimal choice for real-time DDoS attack detection in VANETs.

TABLE VI. PERFORMANCE COMPARISON

Methodology	Accuracy
GRU [9]	90.89
SVM + ANOVA [15]	97.20
SVM+GSCV [16]	96.40
DT+NN [21]	95.00
Deep Belief Network [22]	96.00
PROPOSED MODEL	**98.39**

TABLE VII. TRAINING TIME COMPARISON

Model	Training time (hours)
GRU	4.8
SVM+ANOVA	5.0
SVM+GSCV	5.2
DT+NN	4.0
Deep Belief Network	5.6
Proposed model	3.5

V. CONCLUSION

DDoS detection in VANETs arises from the critical importance of maintaining the reliability and security of vehicular communication networks. As vehicles increasingly rely on VANETs for real-time communication and cooperation to enhance road safety, and traffic efficiency, and enable various applications, the potential impact of DDoS attacks becomes increasingly significant. The proposed method for DDoS attack detection in VANETs, which combines LSTM with a self-attention mechanism, exhibits outstanding performance across multiple evaluation metrics. With an 98.39% accuracy, 97.79% precision, 98.00% recall, and 98.20% F1-score, the model demonstrates remarkable efficacy in accurately identifying instances of DDoS attacks while maintaining a balance between minimizing FP and FN. The ROC curve analysis further validates the model's effectiveness, yielding an AUC of 0.985, signifying its excellent ability to discern between classes. Comparison with existing methods underscores the superiority of the proposed approach, solidifying its position as a robust and efficient resolution for amplifying the safety and dependability of automotive communication networks. Future research could focus on incorporating real-time adaptive learning mechanisms to improve the model's responsiveness to emerging DDoS attack patterns. Additionally, integrating this model with other cybersecurity frameworks could create a comprehensive, multi-layered defence system for VANETs, enhancing overall network resilience and safety.

ACKNOWLEDGMENT

I would like to express my sincere gratitude to all those who contributed to the completion of this research paper. I extend my heartfelt thanks to my supervisor, my family, my colleagues and fellow researchers for their encouragement and understanding during the demanding phases of this work.

***Abstract*—The volume and complexity of textual data have significantly increased worldwide, demanding a comprehensive understanding of machine learning techniques for accurate text classification in various applications. In recent years, there has been significant growth in natural language processing (NLP) and neural networks (NNs). Deep learning (DL) models have outperformed classical machine learning approaches in text classification tasks, such as sentiment analysis, news categorization, question answering, and natural language inference. Dimension reduction is crucial for refining the classifier performance and decreasing the computational cost of text classification. Existing methodologies, such as the Improved Relative Discrimination Criterion (IRDC) and the Relative Discrimination Criterion (RDC), exhibit deficiencies in proper normalization and are not well-balanced regarding distinct class's term ranking. This study introduced an improved feature-ranking metric called the Balanced Relative Discrimination Criterion (BRDC). This study measured document frequencies into term-count estimations, facilitating a normalized and balanced classification approach. The proposed methodology demonstrated superior performance compared to existing techniques. Experiments were conducted to evaluate the efficacy of the proposed techniques using Decision Tree (DT), Logistic Regression (LR), Multinomial Naïve Bayes (MNB), and Long Short-Term Memory (LSTM) models on three benchmark datasets: Reuters-21578, 20newsgroup, and AG News. The findings indicate that LSTM outperformed the other models and can be applied in conjunction with the proposed BRDC approach.**

Keywords*—Text classification; balanced relative discrimination criterion; dimension reduction; feature ranking; deep learning; machine learning

I. INTRODUCTION

Owing to the persistent expansion of information technology, the production of available information poses a substantial challenge, and to manage big data has garnered considerable attention. Approximately 80% of companies manage and arrange their data in a text format. [1, 2], and is increasing daily. Classification is dynamic in machine learning, particularly text classification, in which text documents are automatically sorted into predefined categories. Various machine learning classifiers, such as Decision Trees (DT), Logistic Regression (LR), and Multinomial Naïve Bayes (MNB), have been used to evaluate text classification performance [3, 4]. Text classification is a fundamental approach for detecting and classifying textual data [5].

The performance of a model is influenced by several factors, with input data being one of the most important. Various types of textual datasets were used to increase the number of input variables in the model. However, the high dimensionality of the feature space can hinder the text classification performance. Thus, reducing dimensionality is a critical challenge in text classification [6]. Not all features hold equal significance in datasets comprising text with high-dimensional features, and some may be redundant, irrelevant, or noisy. To classify a document into different classes, the discriminative capabilities of features are used in machine learning algorithms to solve a given classification problem, where each feature is represented as a discrete characteristic [7]. This helps reduce the computational cost and increases the performance and prediction accuracy [8]. As document collections increase, there is a need for more advanced information processing methods to search, retrieve, and organize text efficiently. Machine learning approaches have accomplished superior performance, resulting in natural language handling. The outcome of these learning approaches depends on their ability to grasp complex models and non-straight connections within information. Nonetheless, tracking reasonable designs, models, and methods for text characterization is difficult for specialists [9]. Removing redundant and irrelevant variables from the input data before proceeding with the model is crucial. This is performed using feature selection, which decreases the computational cost and improves prediction accuracy by providing enhanced and minimized data [8]. Feature selection is essential when using high-dimensional datasets in which the number of observations is less than the number of features [10]. The significant contributions of this study are as follows:

- Proposed BRDC for Text Classification that increases classification.

- Purpose a normalized and balanced technique, compared to RDC and IRDC, for a balanced and efficient text classification.
- Reduce the number of iterations to calculate the AUC.
- A definite integral-based method to calculate the Area Under the Curve (AUC).
- The classification experiments used both machine learning and deep learning models.
- The proposed model was compared using three balanced and unbalanced datasets.

This research proposes a normalized term ranking approach in which each term in distinct classes gets a balanced rank. The proposed feature ranking approach, Balanced Relative Discriminant Criterion (BRDC), compared with existing feature ranking approaches such as Relative Discriminant Criterion (RDC) and Improved Relative Discriminant Criterion (IRDC), experiments results show the proposed approach outperforms the in comparison to the existing approaches.

II. Literature Review

Text classification involves categorizing large volumes of text into one or more predefined categories based on the content or characteristics of the text [11]. In this section, we explain the different feature ranking techniques used for various types of classification, most of which are based on document frequency. Feature ranking techniques can be categorized into three types: filter-based, wrapper, and embedded [12, 13]. The leading causes of declining algorithmic performance in text classification are categorization and feature extraction from documents that employ the extracted features. The primary purpose of the feature ranking technique is to reduce the dimensionality of the dataset(s) by eliminating irrelevant features for classification. Dimension reduction has several advantages, such as reducing the dataset size, lowering the computational demands of text categorization algorithms (particularly those that do not scale well with large feature sets), and significantly reducing the search space [14]. A study demonstrated how applying bagging and Bayesian boosting techniques to classification algorithms, such as Multinomial Naïve Bayes (MNB) and K-nearest neighbor (K-NN), can improve their performance [15]. To determine which strategy was most effective in capturing text features and enabling the classifier to achieve the highest accuracy, a study analyzed the outcomes of applying three text feature extraction algorithms while classifying short sentences and phrases using a neural network. Term frequency Inverse Document Frequency (TF-IDF) and its two variations, which use various dimensionality reduction approaches, are among the feature extraction methods explored. A document frequency-based comparison was performed using Term Frequency Inverse Document Frequency (TF-IDF), Latent Semantic Analysis (LSA), and Linear Discriminant Analysis (LDA), and the results showed that the document frequency-based technique performed well [16].

There are two main methods for minimizing the dimensions of the feature vectors. Feature selection is the first approach to creating a new subset of the initial feature collection. Feature extraction is the second method for reducing dimensions. It makes a new feature set in a new feature space with smaller dimensions. The linear separability of the classes determines whether the two techniques are linear or nonlinear [17]. One study assessed and analyzed three Stemming methods. They are Light-Stemming Root-Based-Stemming, and Dictionary-Based Stemming. The intention is to decrease the element space into an information space with a much lower aspect ratio for two cutting-edge classifiers: artificial neural networks and support vector machines (SVM) [18]. Document Frequency (DF) and Term Variance (TV)-based methods were proposed for feature selection, and the next Principal Component Analysis (PCA) method was applied to reduce further the features, which were tested on the Reuters-21578 benchmark dataset and showed effective results [19]. The filter-based technique is typically faster and independent of the induction algorithm's function, meaning the selected feature can be input to any model's algorithm for further processing [20]. To identify a reliable strategy that can be applied to real datasets, one study evaluated the effectiveness of several feature selection techniques under diverse scenarios using synthetic datasets, in which different filtering measures can be employed for classification, such as distance, dependence, information, statistical measures, and consistency [21, 22], such as chi-square and information gain [23, 24]. A study evaluated machine learning methods for serial analysis of gene expression (SAGE)--based cancer classification, suggesting using chi-square for gene selection to address the high dimensionality in the dataset. The support vector machine (SVM) and Naive Bayes (NB) emerged as top-performing classifiers, and chi-square selection improved the performance across all methods. These experiments were conducted on human brain and breast SAGE datasets. It uses the principal criteria for variable selection by ordering the filter technique using the variable ranking method. Filter-based techniques are frequently used because of their simplicity and exemplary performance in real-life applications. This technique uses a threshold as a suitable rambling criterion to score a variable [25]. When we talk about real-world applications, owing to the heavy reliance on clustering, the wrapper-based technique is unsuitable mainly because it requires clusters, and to evaluate clustering in diverse subspaces, there is a lack of suitable clustering criteria [26].

A feature ranking metric named relative discrimination criterion (RDC) [27] considers both document frequencies and term count to estimate the importance of a term; in this study, the performance of RDC is compared using two classifiers such as Support Vector Machine (SVM) and Naive Bayes (NB) classifiers on benchmark datasets, the said technique is not well normalized. However, the RDC technique needs to be normalized, and an optimal and balanced solution for dimension reduction is required. Another feature ranking technique was introduced and named the Improved Relative Discriminative Criterion (IRDC) [28], which uses document and term frequencies to rank terms. IRDC prioritizes rarely occurring terms over frequently occurring ones. IRDC focuses on rarely occurring terms present in one class and absent in others, thereby achieving a balance between frequent and rare terms. The experimental results in this study show that IRDC outperforms existing techniques in terms of the F-measure on datasets such as Reuters-21578 and 20newsgroup using classifiers such as Decision Tree (DT), Naïve Based (NB), and Support Vector

Machine (SVM), which also need to optimize the data to achieve a better result.

A study introduced a novel approach called the De-redundancy Relative Discrimination Criterion (DRDC), designed to assess terms' importance while considering their redundancy [29]. DRDC incorporates the Relative Discrimination Criterion (RDC) and Mutual Information (MI) to gauge term relevance to categories and the redundancy between terms. During the selection process, the RDC and mutual information scores were normalized separately to balance them and mitigate the impact of mutual information. A study merged the Relative Discrimination Criterion (RDC) with Ant Colony Optimization (ACO) in a two-stage feature selection (FS) technique [30]. Initially, the RDC ranks the features based on their values, and those with values lower than a threshold are eliminated from the feature set. Subsequently, the ACO-based feature selection method acts as a wrapper method for selecting redundant or irrelevant features that are not eliminated in the first stage. The experimental results demonstrate the efficacy of the RDC-ACO method for text feature selection.

III. Proposed Approach

This study proposes a Balanced Relative Discrimination Criterion (BRDC) that uses normalization and balanced approaches for feature ranking to increase the accuracy and performance of the model. This study consisted of four main stages, explained in detail in this section. The proposed technique calculates the document of each term count to obtain information from the given text. The BRDC considers the differences between the DF and the respective Term Counts (TC) in the positive and negative classes. In previous studies, an effective measure using DF has been used for feature selection in textual data classification. It calculates the number of documents and their terms in a specific class and counts them as a feature, which can be a specially derived attribute, word, or sentence. If a document contains a feature, the DF increases by 1. Traditional DF metric counting has a drawback because it does not consider the importance of a feature in a specific document [31]; therefore, the term count is ignored when ranking a particular term [32]. In this proposed approach, terms count ranked in distinct classes in a balanced way. Two standard techniques are used to build a multiclass classifier, namely one-against-one and against-all, to break down multiclass classification problems into binary classification problems [33]. This means the multiclass problem is usually divided into multiple two-class issues, where one class is positive, and all other courses are combined to form a negative class. The dataset comprised documents categorized into classes designed for training and evaluating algorithms on new documents. Three single-labeled datasets of varying sizes and class distributions were used: Reuter-21578, 20newsgroup, and AG News. These datasets are considered the standard for text classification and were sourced from The UCI Machine Learning Repository. Previous studies have widely used these methods [34-37]. Fig. 1 shows the overall working flow of the proposed model, which consists of four steps. BRDC is tailored for text classification and comprises four stages: preprocessing, feature selection, data modeling, and the last state as a post-analysis. The raw text underwent several preprocessing steps, such as tokenization, stemming, and stop-word removal. One class is treated as the positive class to handle binary to multi-class classification. In contrast, all other classes are combined to form the negative class used in this study for classification. Fig. 1 shows the overall classification step.

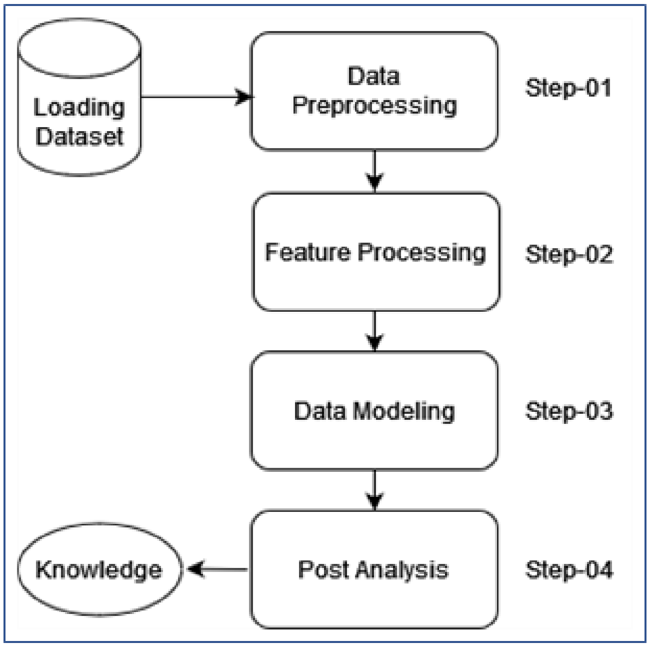

Fig. 1. Overall framework of BRDC.

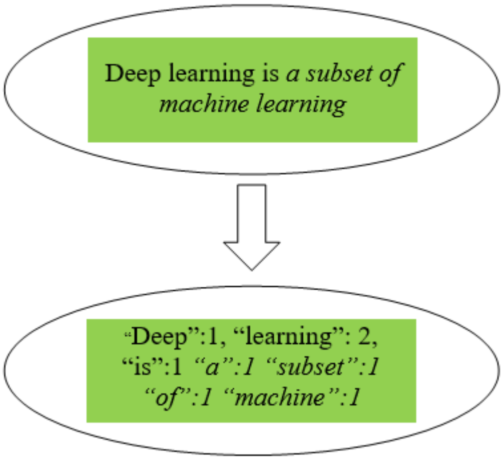
TABLE I. List of Documents in each Negative and Positive Class

Document	Class	Content of Document
Doc1	Positive	Red, Blue, Green, Green, Yellow
Doc2	Positive	Red, Green, Blue, Red. Yellow
Doc3	Positive	Green, Blue, Red, Yellow, Yellow
Doc4	Positive	Green, Red, Blue, Green, Blue
Doc5	Positive	Blue, Red, Blue, Red, Yellow, Green
Doc6	Positive	Blue, Green, Yellow, Green
Doc7	Positive	Yellow, Green, Blue, Red
Doc8	Positive	Yellow, Yellow, Red, Green, Red
Doc9	Negative	Blue, Green, Blue
Doc10	Negative	Green, Green, Yellow
Doc11	Negative	Red, Green, Red
Doc12	Negative	Green, Blue, Yellow
Doc13	Negative	Blue, Red
Doc14	Negative	Green, Blue, Green,
Doc15	Negative	Blue, Red, Red
Doc16	Negative	Green, Yellow, Yellow

Table I shows the total number of documents, the class of the document, and the content of the document.

Fig. 2 shows the process of converting the document into terms, which consists of a document “Deep learning is a subset of machine learning,” which contains the following terms: Deep count is 1, learning 2 is 1, a 1 subset 1 of 1, and machine 1.



Deep learning is a subset of machine learning
“Deep”:1, “learning”: 2, “is”:1 “a”:1 “subset”:1 “of”:1 “machine”:1

Fig. 2. ELABORATE the distinct word.

A. *Feature Ranking Metric*

Text classification feature selection metrics are typically based on a word's term or document frequency [38]. Most feature-ranking techniques use document frequency, such as chi-square, to calculate the term rank of features in a textual dataset [39]. Categorical document frequency indicates the dispersal of a term over a separate category [40]. To determine the required rank using term counts, the document frequency is divided into the average of all frequencies for each term count, and this concept is considered a sample dataset. A balanced dataset significantly improves the data mining process [41].

Text normalization is critical in language- and speech-based application tasks [42]. This study also focused on proposing a Balanced Relative Discrimination Criterion (BRDC) feature ranking technique for text classification with a more normalized discriminant method, which normalized each term count by dividing the average values of all term counts.

Table II consists of sixteen documents with four different terms; from one to eight, there are positive class documents, and from nine to sixteen, there are negative documents.

TABLE II. TERM COUNT FOR EACH TERM ACCORDING TO THEIR CLASS

Document	Class	F1	F2	F3	F4
Doc1	Positive	1	1	2	1
Doc2	Positive	2	1	1	1
Doc3	Positive	1	1	1	2
Doc4	Positive	1	2	2	0
Doc5	Positive	2	2	1	1
Doc6	Positive	0	1	2	1
Doc7	Positive	1	1	1	1
Doc8	Positive	2	0	1	2
Doc9	Negative	0	2	1	0
Doc10	Negative	0	0	2	1
Doc11	Negative	2	0	1	0
Doc12	Negative	0	1	1	1
Doc13	Negative	1	1	0	0
Doc14	Negative	0	1	2	0
Doc15	Negative	2	1	0	0
Doc16	Negative	0	0	1	2

Table II elaborates on each term count concerning its class and count; here, the word is replaced with the term frequency.

From color to frequency, the text label was renamed red as F1, blue as F2, green as F3, and yellow as F4.

Table III describes the total number of term counts for each term in the positive class documents.

TABLE III. TERM FREQUENCY OF POSITIVE CLASS

Class	TC	F1	F2	F3	F4
Positive	1	4	5	5	5
Positive	2	3	2	3	2
Positive	3	0	0	0	0

Table IV describes the total number of terms counted for each term in the negative class documents.

TABLE IV. TERM FREQUENCY OF NEGATIVE CLASS

Class	TC	F1	F2	F3	F4
Negative	1	2	4	4	3
Negative	2	1	1	2	1
Negative	3	0	0	0	0

	Term Count 1	Term Count 2	Term Count 3
f1	4	3	0
f2	5	2	0
f3	5	3	0
f4	5	2	0

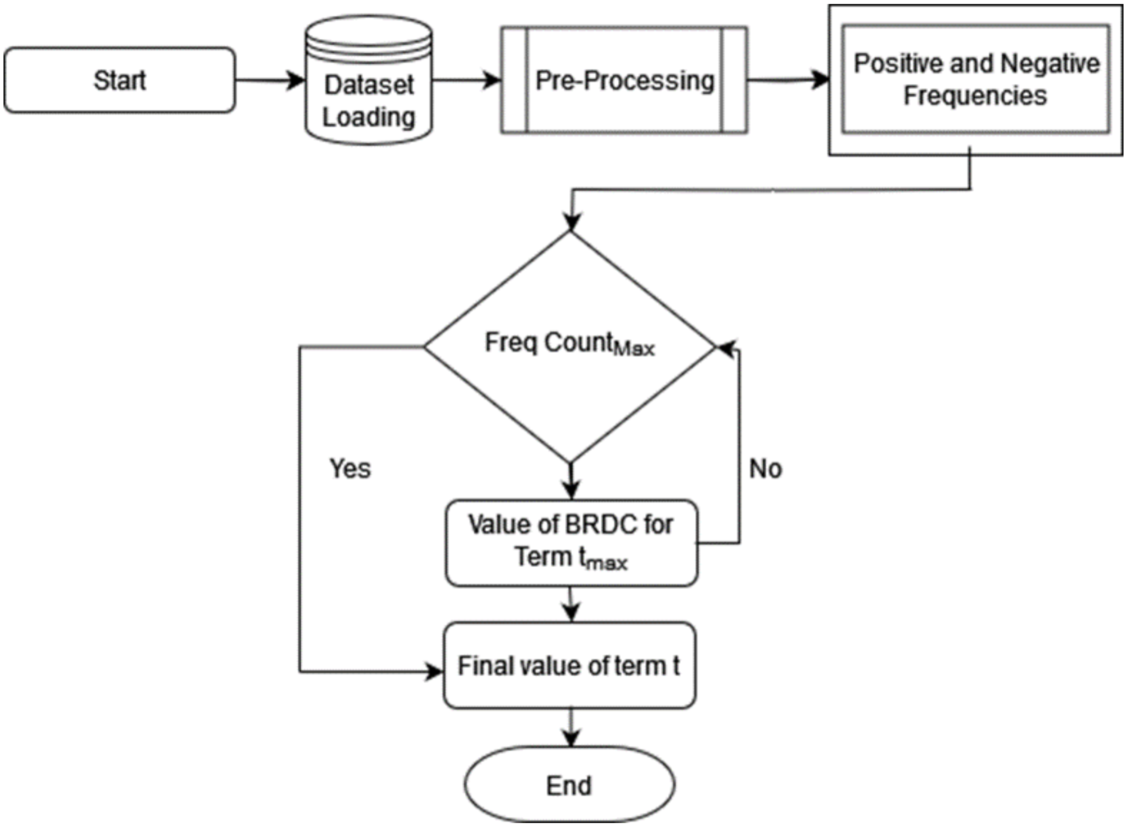

Fig. 9. Proposed BRDC model.

Table VII shows the calculated values of BRDC. Fig. 9 demonstrates the working flow of classification steps with the proposed feature ranking.

TABLE VIII. COMPARISON RESULTS OF RDC, IRDC AND BRDC

Technique	F1	F2	F3	F4
RDC	1.50	0.625	0.375	0.833
IRDC	0.226	0.274	0.095	0.096
BRDC	4.50	2.125	1.125	2.333

Table VIII shows the results of the existing and proposed feature ranking techniques. In contrast to the research conducted by study [28] and [43], this study assigns a rank according to the rarely and frequently occurring significant terms in each class for classification efficiency. It does the trade between both terms, and it does the trade between exploration and exploitation. It also reduces the complexity of the proposed algorithms, such as IRDC and RDC. It reduces the complexity and can work more efficiently for time series-based datasets by,

- Calculate the term counting a normalized technique
- Calculation of the BRDC by reducing the iteration
- Calculating the BRDC using the integral method

$$\text{BRDC}= [(TPR_{tc}\text{-}FPR_{tc}) \,/\, \min\,(TPR_{tc}, FPR_{tc})] *tc$$

$$\text{AUC}_{t} = \text{Sum}+(\text{BRDC}_{tc\text{-}i}/2)\ \text{h} \qquad (1)$$

The proposed algorithm pseudo is given below.

```
Start
Stage 1.  Insert: text dataset
Stage 2.  Preprocess the dataset
Stage 3.  Conversion:  tf matrix
Stage 4: Number of docs in +ev class and -ev class
Stage 5: u = $\sum_{i=1..n}^{n}(\frac{n}{Ac})$
Stage 6: $\text{MAX}_{tc:}$ Maximum count for a term count t
Stage 7: n represents a term. Ac represents the average of total terms
Stage 8: find the discriminant, calculating the Discriminant value to normalize it in stage 9
    for tc =1 to $\text{MAX}_{tc\ (n)}$ do tc++
topic = documents containing the term t having term count tc in the positive class
fptc = documents containing the term t having term count tc in the negative class
$\text{TPR}_{tc}$      = TPtc(i) /u
FPRtc      = FPtc(i) /u
BRDC= [(TPRtc-FPRtc) / min (TPRtc, FPRtc)] *tc
AUCt = Sum+(BRDCtc,i/2)h
   end for loop
end
```

B. *Mathematical of Definite Integral base Calculation AUC Methodology*

Here, we apply the trapezoidal method to calculate the area under the curve (AUC) of a definite integral using trapezoids [44], which can also manage nonlinear or time-series data compared with RDC and IRDC.

$$\frac{a+b}{2} \times h\ (two\ trapezoidal\ ) \tag{2}$$

If we have a continuous function between a specific interval to calculate the area, it will be defined as,

$$\int_a^b f(x)dx \tag{3}$$

Suppose f(x) is a continuous function with an interval of (a, b). Now divide the intervals (a, b) into n equal sub-intervals with each of width,

$$\text{such that } \Delta x = (b-a)/n, \text{suchthat} a = x0 < x1 < x2 < x3 < \cdots .. < xn = b \tag{4}$$

Next, the area approximation of the definite integral using the Trapezoidal Rule

$\int_a^b f(x)dx$, is given as in below

$$\int_a^b f(x)dx \approx Tn = \triangle x/2[f(x0) + 2f(x1) + 2f(x2) + \cdots .2f(xn-1) + f(xn)] \tag{5}$$

where,

$$xi = a + i \triangle x \tag{6}$$

$$\text{If } n \rightarrow \infty, \text{R.H.S of the expression approaches,}$$

$$\text{thedefiniteintegral} \int_a^b f(x)dx$$

Where n resents the number of trapezoids, and the sub-intervals are demonstrated by [x0, x1] [x0, x1], [x1, x2] [x1, x2], ..., [xn−1, xn] [xn−1, xn] were,

$$x0 = a$$

$$x1 = a + \Delta xx1 = a + \Delta x$$

$$x2 = x1 + \Delta xx2 = x1 + \Delta x \ \ldots .$$

$$xn - 1 = xn - 2 + \Delta xxn - 1 = xn - 2 + \Delta x$$

$$xn = xn - 1 + \Delta xxn = xn - 1 + \Delta x \tag{7}$$

Similar to text classification, the term count can be infinite depending on the nature of the corpus or its document(s). The proposed method counts the term count of infinite terms with more accurate results (s) for time-series data.

Here, is the proof of estimation using the integral method.

The area under the curve, such as that in the top character, was divided into trapezoids to demonstrate the trapezoidal rule. This step is proposed to perform well for time series-based datasets. The height of the first trapezoid is Δx, and its parallel bases have lengths y0 or f(x0), and y1 or f1. Therefore, the area of the first trapezoid in can be expressed as

$$(1/2)\Delta x[f(x0) + f(x1)] \tag{8}$$

The areas of the next trapezoids will be as $(1/2)\Delta x\big[f(x1)\ + f(x2)\big], (1/2)\Delta x[f(x2) + f(x3)]$, and so on.

Therefore,

$$\int ba\, f(x)\, dx \ \approx\ (1/2)\Delta x\ (f(x0) + f(x1)\ )\ +\ (1/2)\Delta x\ (f(x1) + f(x2)\ )\ +\ (1/2)\Delta x\ (f(x2) + f(x3)\ )\ +\ \ldots\ +\ (1/2)\Delta x\ (f(n-1)\ +\ f(xn)\ ) \tag{9}$$

Next, taking out a common factor of (1/2) Δx and combining like terms, we have,

$$\int ba\, f(x)\, dx \approx\ (\Delta x/2)\ (f(x0) + 2\, f(x1) + 2\, f(x2) + 2\, f(x3) + \ldots + 2f(n-1)\ +\ f(xn)\ ) \tag{10}$$

C. *Steps to Proceed with the AUC*

Four significant steps are involved in calculating the proposed normalized technique. The mentioned steps describe the application of a normalized form of a given curve, y = f(x).

- Step 1: list out the total number of sub-intervals “n”.
- Step 2: List out the interval “a” and “b”.
- Step 3: Calculate the sub-interval using the formula, width, h (or) △x = (b - a)/n.
- Step4: To find the approximation of area (a normalized form of given data) substitute the obtained values in the trapezoidal rule formula,

D. *Classification*

Widely used classifiers for text classification, such as DT, MNB, LR, and LSTM, are used in this study. These classifiers were selected based on their effective performance in text classification challenges [45-48]. In text classification, LSTM is one of the commonly used deep learning classifiers and a Naïve

Base where Bayes theorem's probabilistic principles underpin the operation of this classifier. It predicts the class of a new sample by evaluating its association with each class, and classifies cases according to how similar they are in that class [49]. One study introduced sentiment analysis as a subfield of information retrieval and computational linguistics, focusing on evaluating the sentiment expressed in text. This study proposes a method for feature selection in sentiment analysis using decision trees, which are evaluated using a Rating System dataset, with preliminary results showing promise [50].

Using the given training data, the DT machine-learning algorithm builds a hierarchical structure and learns basic decision rules to predict the estimated value of a given value. To produce a structure resembling a tree, it recursively divides the feature space according to the values of input features. A decision rule based on a particular feature is specified at each internal node of the tree, and the tree branches out of these. Finally, the leaf nodes of the decision tree deliver the estimated target values based on the patterns discovered during the training [51].

We test the proposed solution using WEKA-3.8.4 (Waikato Environment for Knowledge Analysis), a known machine learning toolkit. All models were tested with a default parameter setting [52]; WEKA was developed using Java, a General Public License (GPL)-based software with different model prediction purposes. In the WEKA toolkit, different iterations are the default numbers required to yield statistically significant results.

E. Experimental Setup

Experiments on the proposed BRDC feature-ranking technique were conducted using an HP workstation machine Z-440 Xeone with 32 GB of RM, and the WEKA tool was used for classification and evaluation purposes. Accuracy, precision, recall, and F-measure were used to evaluate the performance of the proposed approach and compare it with existing approaches. The results demonstrated that the BRDC technique outperformed existing feature-ranking techniques such as RDC and IRDC. Different classes from three benchmark text datasets, Reuters-21578, 20newsgroup, and AG news, were used to evaluate the performance of these feature-ranking approaches. We performed tests with two benchmark datasets that have been utilized in previous experimental studies: [28] and [43], named datasets Reuter21578, 20newsgroup, and another news AG News data. These datasets were extracted and made available for UCI data collection. Fifteen skewed-size classes were obtained from the Reuters-21578 dataset. There is another dataset, 20newsgroup, which has 20 sizable classes and is balanced, and the AG news consists of four classes. All datasets used in this study were labeled in their classes. In addition to word stemming, a stop word list was used to eliminate stop words.

The true positive (TP), false positive (FP), true negative (TN), and false negative (FN) values from the confusion matrix were used to calculate the performance metrics of the algorithms. F1-Score, Accuracy, Precision, and Recall were among the calculated parameters.

$$\text{Accuracy} = \frac{tp + tn}{tp+tn+fn+fp} \tag{12}$$

Precision calculated as follows:

$$Precision = \frac{tp}{tp+ fp} \tag{13}$$

In the above equations, where tp represents the value of the true positive rate, and the false positive rate is represented by fp in terms of accuracy and precision, the value of recall is calculated as follows:

$$Recall = \frac{tp}{tp+ fn} \tag{14}$$

where tp defines the true positive rate and fn represents the false-negative rate in recall.

$$F - Measure = \frac{2\times P\times R}{P+R} \tag{15}$$

Where tp defines the true positive rate and fn represents the false-negative rate in the recall.

IV. Experiments and Results

This section compares the proposed BRDC algorithm with the performance of two existing feature-ranking algorithms, RDC and IRDC. Three text datasets, Reuter-21578, 20newsgroup, and AG News, available at the Kaggle and UCI responses, were used to evaluate the performance of the proposed BRDC algorithm and compare it with RDC and IRDC. They were executed sequentially on a PC running HP workstation z-440 with 32GB RAM for the main system. Furthermore, the number of features chosen and the performance of the classifiers were verified based on the accuracy, precision, recall, and F-measure measuring matrix.

A. Results Using Reuters21578

These datasets, sourced from the UCI library, were used in the experiments. Following the experiments, the Relative Discriminative Criterion (RDC) and Improved Relative Discriminative Criterion (IRDC) were used to compare results. The effectiveness of these feature ranking algorithms was investigated using three distinct datasets: Reuters21578, 20newsgroup, and AG News, and several tests were carried out on the 10, 20, 50, 100, 200, 500, 1000, and 1500 features chosen from the aforementioned datasets. These datasets, sourced from the UCI library, were used in the experiments. The results for Reuter21578 are summarized in Table IX.

Table IX demonstrates the results of the Reuters dataset, which was used to evaluate the performance of the BRDC feature ranking compared with RDC and IRDC using the Reuters-21578 dataset. Classifiers, such as DT, LR, MNB, and LSTM, were employed for this comparison.

Fig. 10 provides a graphical view of the results, showing that BRDC outperforms the other methods in accuracy, precision, recall, and F-measure using the Reuters-21578 dataset. It demonstrates an accuracy of 66.66%, 66.66%, 60.00%, and 73.33%, while it achieves precision of 70.70%, 67.30%, 61.50% and 83.00%, recall of 66.70%, 66.70%, 60.00% and 71.30% and F-measure 65.80%, 66.70%, 59.60% and 70.90% against DT, LR, MNB, and LSTM, respectively. The results indicated that LSTM outperformed DT, LR, and MNB.

TABLE IX. RESULT OF REUTERS-21578 DATASET: A COMPARATIVE ANALYSIS OF BRDC

Technique	Measuring Matrix	DT	LR	MNB	LSTM
BRDC	Accuracy	66.66%	66.66%	60.00%	73.33%
	Precision	70.70%	67.30%	61.50%	83.00%
	Recall	66.70%	66.70%	60.00%	71.30%
	F-Measure	65.80%	66.70%	59.60%	71.90%
IRDC	Accuracy	55.51%	54.30%	54.08%	70.06%
	Precision	54.50%	54.50%	54.00%	64.80%
	Recall	55.50%	54.50%	54.10%	70.10%
	F-Measure	54.55%	54.40%	53.90%	60.00%
RDC	Accuracy	45.50%	44.48%	43.00%	61.60%
	Precision	44.50%	44.40%	43.09%	51.70%
	Recall	45.50%	44.50%	43.00%	61.60%
	F-Measure	44.50%	44.30%	42.80%	61.00%

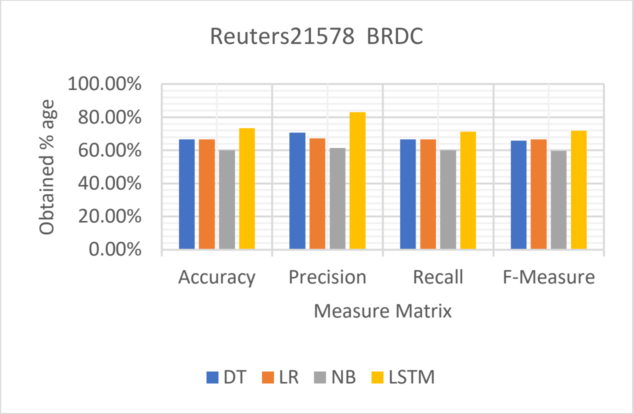

Fig. 10. BRDC with Reuters-21578.

Fig. 11, extracted from Table IX, using the Reuters-21578 dataset, shows the results of the IRDC. It achieves an accuracy of 55.51%, 54.30%, 54.08%, and 70.06%, precision of 54.50%, 54.50%, 54.00%, and 64.80%, recall of 55.50%,54.50%, 54.10%, and 70.10%, and it achieve F-measure of 54.55%, 54.40%, 53.90% and 60.00% against DT, LR, MNB, and LSTM, respectively, however, these results are lower than that of BRDC, here it also shows that IRDC perform better against LSTM.

Fig. 12, which is mined from Table IX, shows the results of the RDC using the Reuters21578 dataset. The results show that RDC achieves an accuracy of 45.50%, 44.48%, 43.00%, and 61.60%; precision of 44.50%, 44.40%, 43.09%, and 51.70%; recall of 45.50%, 43.40%, 43.00%, and 61.60%; and F-measure of 44.50%, 44.30%, 42.80%, and 61.00%, against the DT, LR, MNB, and LSTM models, respectively.

B. *Experiment Using 20newsgroup*

The performance of the proposed BRDC on 10 different classes from the 20newsgroup dataset was analysed based on accuracy, precision, recall, and F-measure metrics. The experiments demonstrated that BRDC produced superior results to the existing IRDC and RDC feature ranking techniques. Table X presents an evaluation of the 20newsgroup datasets using the different classifiers.

Fig. 13 provides a graphical view of the results, showing that BRDC outperformed the other methods in terms of accuracy, precision, recall, and F-measure using the dataset of 20newsgroup. It demonstrates an accuracy of 41.44%, 33.33%, 31.53%, and 50.54%, while it achieved a precision of 32.10%, 30.20%, 28.10%, and 50.70%, recall of 41.40%, 33.30%, 31.50%, and 50.50%, respectively, and F-measures of 33.8%, 31.30%, 29.10%, and 50.60% against DT, LR, MNB, and LSTM, respectively. The results indicated that LSTM outperformed DT, LR, and MNB.

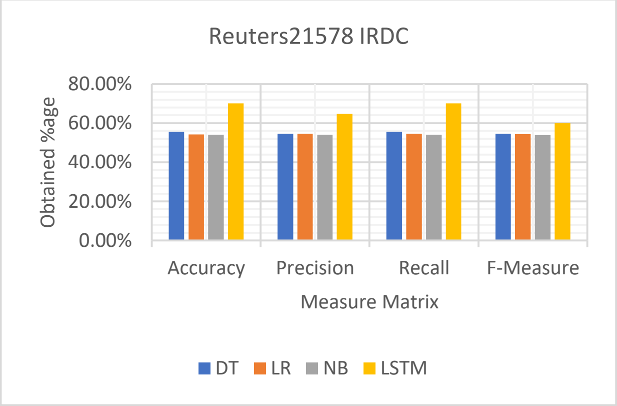

Fig. 11. IRDC with Reuters-21578.

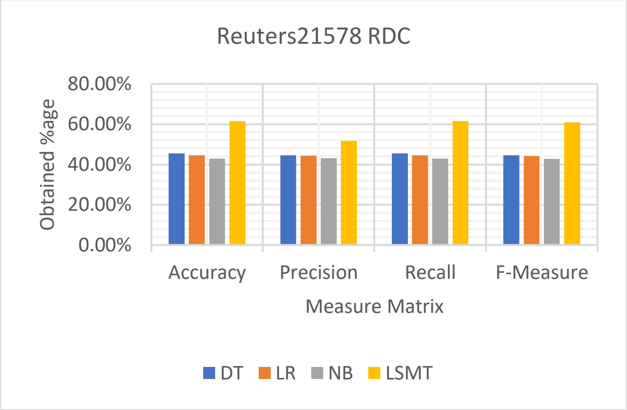

Fig. 12. RDC with Reuters-21578.

TABLE X. RESULT OF 20NEWSGROUP DATASET

Technique	Measuring Matrix	DT	LR	MNB	LSTM
BRDC	Accuracy	45.94%	37.83%	38.73%	50.54%
	Precision	41.50%	37.50%	38.10%	50.70%
	Recall	45.90%	37.80%	38.70%	50.00%
	F-Measure	40.10%	37.60%	38.20%	50.60%
IRDC	Accuracy	44.80%	35.30%	36.73%	48.64%
	Precision	40.50%	35.20%	36.30%	48.80%
	Recall	44.20%	34.60%	36.60%	48.60%
	F-Measure	43.10%	34.30%	36.40%	48.60%

	Precision	32.10%	33.50%	28.10%	47.00%
	Recall	41.40%	32.80%	31.50%	46.80%
	F-Measure	33.10%	33.60%	29.10%	46.80%

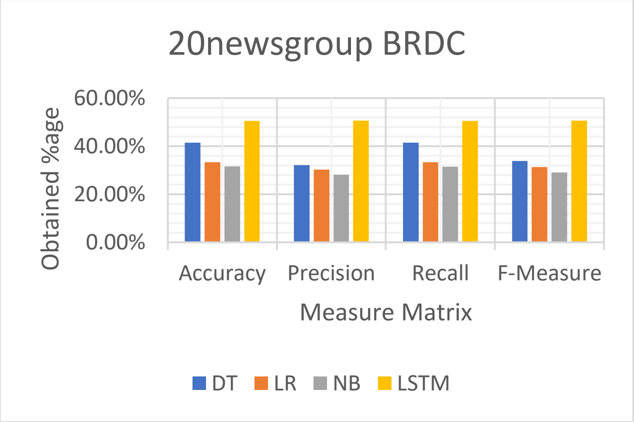

Fig. 13. BRDC with 20Newsgroup.

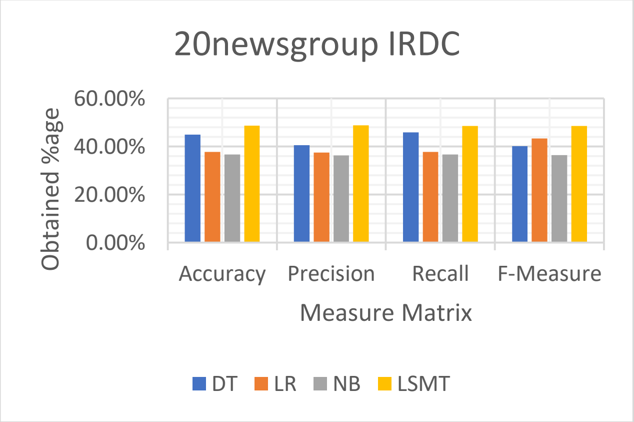

Fig. 14. RDC with 20Newsgroup.

Fig. 14 provides a graphical view of the results, showing that IRDC outperformed the 20newsgroup datasets in terms of accuracy, precision, recall, and F-measure. It demonstrated an accuracy of 44.94%, 37.83%, 36.73%, and 48.64%, respectively, while it achieved a precision of 40.50%, 37.50%, 36.30%, and 48.80%, recall of 45.90%, 37.80%, 36.70% and 48.60%, respectively, and F-measures of 40.10%, 43.30%, 36.40%, and 48.60% against DT, LR, MNB, and LSTM, respectively. Fig. 15, extracted from Table VIII, shows the accuracy results obtained using RDC. It achieves an accuracy of 45.94%, 37.83%, 38.73% and 46.84%, precision of 41.50%, 37.50%, 38.10% and 47.00%, recall of 45.90%, 37.80%, 38.70% and 46.80%, and F-measure of 40.10%, 37.60%, 38.20% and 46.80% against DT, LR, MNB, and LSTM, respectively, however these results are lower than that of BRDC, here it also shows that IRDC performs better against LSTM.

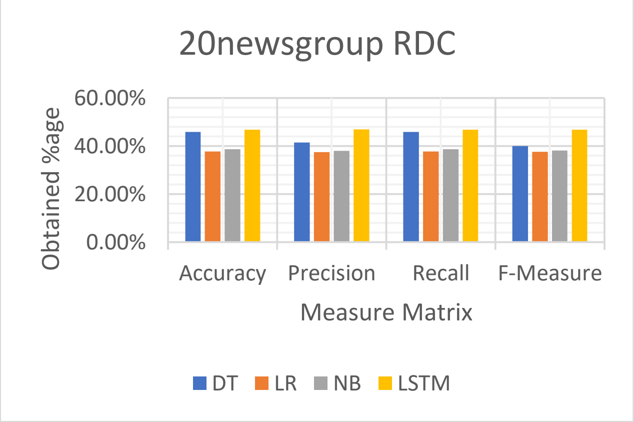

Fig. 15. RDC with 20Newsgroup.

C. Experiment Using AG News

Following the experiments, the Relative Discriminative Criterion (RDC) and improved Relative Discriminative Criterion (IRDC) were used to compare results. Table XI shows the proposed BRDC experiments and compares IRDC and RDC techniques using four classifiers: decision tree, logistics regression, multinomial naïve Bayes, and long short-term memory. The results show the deep learning model outperforms the other machine learning models.

TABLE XI. RESULT OF AG NEWS DATASET

Technique	Measuring Matrix	DT	LR	MNB	LSTM
BRDC	Accuracy	45.09%	44.48%	45.69%	56.09%
	Precision	44.90%	44.50%	45.60%	56.10%
	Recall	45.10%	44.50%	45.70%	56.10%
	F-Measure	47.70%	44.40%	45.50%	56.00%
IRDC	Accuracy	42.10%	43.70%	42.70%	51.10%
	Precision	41.95%	43.40%	42.61%	51.11%
	Recall	42.20%	43.00%	42.71%	51.11%
	F-Measure	42.69%	43.20%	42.49%	51.01%
RDC	Accuracy	40.20%	42.30%	40.60%	50.00%
	Precision	40.90%	42.40%	40.60%	50.08%
	Recall	40.10%	42.40%	40.70%	50.10%
	F-Measure	40.70%	42.20%	40.50%	50.00%

Fig. 16 provides a graphical view of the results, showing that BRDC outperforms the other methods in terms of accuracy, precision, recall, and F-measure. It demonstrated an accuracy of 45.09%, 44.48%, 45.69%, and 56.09%, while it achieved a precision of 44.90%, 43.50%, 45.60%, and 56.10%, recall of 45.10%, 44.50%, 45.70%, and 56.10%, and F-measure of 47.70%, 44.40%, 45.50%, and 56.00% against DT, LR, MNB, and LSTM, respectively using AG news dataset. The results indicated that LSTM outperformed DT, LR, and MNB.

Fig. 17 provides a graphical view of the results, showing that IRDC outperformed the other methods in terms of accuracy, precision, recall, and F-measure. It demonstrates accuracy of 42.10%, 43.70%, 42.70%, and 51.10%, while it achieves a precision of 41.95%, 43.40%, 42.61% and 51.11%, recall of 42.20%, 43.00%, 42.71%, and 51.11%, it achieves F-measure of 42.69%, 43.00%, 42.49% and 51.01% against DT, LR, MNB, and LSTM, respectively using AG news. The results indicated that LSTM outperformed DT, LR, and MNB.

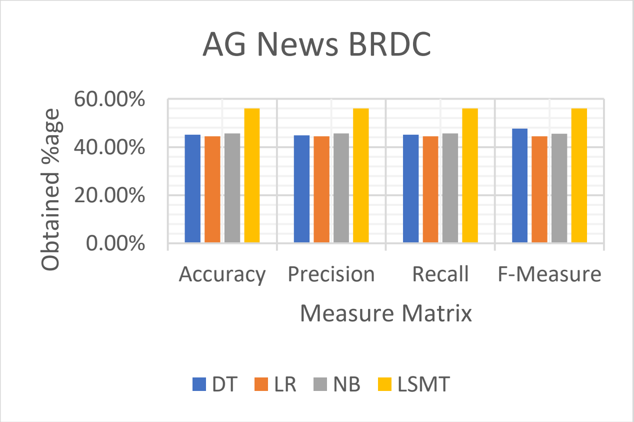

Fig. 16. BRDC with AG News.

Fig. 18 shows a graphical view of the results, showing that RDC outperformed the other methods in terms of accuracy, precision, recall, and F-measure. It demonstrates the accuracy of 40.20%, 42.30%, 40.60%, and 50.00%, while it achieves a precision of 40.90%, 42.40%, 40.60%, and 50.08%, recall of 40.10%, 42.40%, 40.70% and 50.10% and F-measure of 40.70%, 42.20%, 40.50% and 50.00% against DT, LR, MNB, and LSTM, respectively. The results indicated that LSTM outperformed DT, LR, and MNB.

V. CONCLUSION

Dealing with high-dimensional text data poses a challenging problem for machine-learning algorithms. This research focuses on feature ranking and reducing the number of unnecessary and duplicate features to enhance the classifier performance, especially for text. It highlights the limitations of the existing feature ranking techniques, such as RDC and IRDC. To address shortcomings in existing studies, this study proposed the BRDC approach, which was tested on balanced and unbalanced text datasets. The key contribution of the proposed BRDC technique is to adjust the true-positive and false-positive rates for term counts in the positive and negative classes in a balanced way, ranking for both frequently and rarely occurring terms and term counts in both classes, using a balanced normalized approach. The BRDC considers common and infrequent terms and normalizes them to improve classification accuracy. Compared to RDC and IRDC, BRDC selects optimal features and enhances classification performance. The proposed approach also reduces the number of iterations to calculate the AUC and uses an integral-based approach. Additionally, the proposed approach is compared with different machine learning and deep learning models, which shows that deep learning models outperform machine learning models.

We will discuss how the proposed technique affects balanced and unbalanced image datasets in future work. Use other integral-based methods to calculate AUC. In addition, we aim to evaluate the proposed integral-based approach for different image datasets and other integral-based methods such as Simpson's based approach. We are also planning to review the temporal demands of the proposed model using different textual and image datasets.

Reading Recommendation Technology in Digital Libraries Based on Readers' Social Relationships and Readers' Interests

Weiying Zheng
Library, Zhejiang Yuexiu University, Shaoxing, 312000, China

***Abstract*—In recent years, the construction of digital libraries has contributed to the advancement of smart lending services. The challenge of suggesting appropriate books for readers from a vast collection of books remains a primary obstacle in the current construction of digital libraries. A fusion method for recommending content to readers with diverse interests is proposed. The method initially extracts short-term borrowing behavior characteristics and simultaneously considers the social similarity characteristics of readers, resulting in the recommendation of content through target ranking search. Aiming to cater to long-term readers, a reading recommendation method that integrates readers' reading behaviors is proposed to model readers' interests through the attention mechanism. It constructs readers' preference models by using synergistic metrics, and finally achieves content recommendation through preference fusion. The proposed model attained the swiftest convergence and the minimum logarithmic loss of 1.85 in recommending readings for multi-interest readers. Additionally, the accuracy of the proposed model in recommending science reading scenarios was 97.24%, surpassing other models. In the reading recommendation experiments for extended borrowings, the suggested model demonstrated superior performance with regard to recall and precision, which were 0.198 and 0.062, respectively. Lastly, after comparing the recommendation errors of different reading models, the proposed model exhibited a root-mean-square error and an average absolute error of 0.731 and 0.721, respectively. These results denote the most precise recommendation accuracy among the three models. The proposed model demonstrates excellent recommendation effectiveness in real-world reading recommendation scenarios. This research offers significant technical references for the advancement of related recommendation technology and the development of digital libraries.**

Keywords*—Digital library; recommend; behavioral characteristics; interest; attention mechanism

I. Introduction

In recent years, the development of smart lending services has rapidly increased with the rise of digital library (DL). As a novel type of library, it offers readers a unique reading experience due to its convenient access and extensive reading resources. For instance, it provides a user-friendly online reading feature that enables readers to access and read books via electronic devices at any time and from any location. Secondly, it has rich and diverse reading resources, covering books in various fields, which meets the diverse needs of readers [1]. Retrieval and search functions are available to quickly locate and recommend suitable books for readers. This presents a significant challenge in construction [2]. The traditional recommendation technology relies heavily on the user's historical behavioural data or content similarity, disregarding the reader's multitude of interests and social similarity features (SSF), resulting in limited accuracy and personalization of the recommendation results [3]. Liang X et al. researched current recommendation techniques and found that the current recommendation systems used in teaching had poor balance and couldn’t meet the actual teaching needs. Therefore, based on trust relationships, a balanced recommendation technique for educational resources was proposed, which determined the relationship between data and recommendation sites by extracting resource feature data. The actual results showed that this technology could significantly improve the recommendation effect of teaching resources, which was superior to traditional recommendation techniques [4]. To address the shortcomings of conventional recommendation techniques in the context of library book recommendations, researchers have turned their attention to the development of reading recommendation techniques that integrate diverse interests and SSF. For multi-interest reader (MIR), the study proposes a fusion multi-interest RR method. The RR model is constructed by extracting readers' short-term borrowing behavior and SSF. For long-term readers (LTR), the study proposes an RR method that integrates readers' reading behaviors and models readers' long-term and short-term interests through the attention mechanism.

The study puts forth a novel approach to RR that incorporates a multitude of interests and SSF. The recommendation results are more accurate and personalized when the characteristics of readers' long- and short-term borrowing behaviours and their SSF are taken into account. Additionally, the attention mechanism and preference fusion further improve the content recommendation effect. The construction of DL will further improve readers' reading experience and provide important technical references for the digitalization of libraries and the improvement of recommended technologies.

The research is organized into six sections. Introduction is given in Section I. Section II focuses on the latest technology in library recommendation and its applications. Section III constructs two RR models, one based on MIR and the other on long-term borrowing readers to understand the reading characteristics of the patrons. Section IV applies the aforementioned technologies to specific scenarios to validate the effectiveness of the library recommendation model in real-life situations. Discussion is given in Section V. Section VI provides an analysis of the entire study and outlines the direction for future research improvement.

II. Related Work

Recommendation technology is a comprehensive data mining method that provides personalized recommendation services to users based on their historical behaviors, preferences, and other characteristics. Anwar T found that recommendation systems had a wide range of applications in various fields, especially in providing recommendation services based on interests and hobbies, greatly improving user experience. Therefore, to improve the reading effect of library users, a book recommendation method that collected knowledge from multiple domains was proposed. This technology utilized user search term retrieval and searches for similar semantic analysis. The results showed that this technology had excellent application effects and significantly improved the reading efficiency of the library [5]. Swaminathan B et al. proposed a four-layer architectural model which alone contained network, sensors, services and applications to help deploy smart agricultural systems with limited energy consumption. In the study, focusing on the application layer a deep learning algorithm was proposed to build a fertilizer recommendation system that conforms to expert opinion for farmers. Applying this technology to agricultural production scenarios, this technology could effectively help farmers’ select appropriate fertilizers and improve the effectiveness of agricultural management [6]. Yu K et al.'s study focused on the application of IoT AI in social computing. However, the current recommendation technology was mainly based on partial feature capture, ignoring implicit preference feedback, which affected the final recommendation effect. In response, an improved collaborative Bayesian network model was proposed in the study, which was used for the social recommendation process. Through a large number of experiments, the proposed technique had good robustness and met the users' social service needs [7].

The application of recommender systems in the field of digital books solves the problem of reading information as well as content selection for readers, and through advanced digital service technology, it can more accurately promote suitable book information for readers. Anwar K et al. studied the existing book recommender systems in order to solve the problem of information overload in recommender systems. The study focused on exploring the machine learning techniques used in book recommendation systems and examined the evaluation metrics to assess the recommendation techniques. Book recommendation categories were identified through the analysis and a converged digital book recommendation technique was given. Applying the technology to specific library scenarios, the technology could provide personalized promotion services for readers, which was better than the related recommendation technology [8]. Ko H et al. found that existing recommendation techniques were unable to capture readers' implicit feedback and social information, resulting in a recommendation service that failed to meet the reading needs of customers. In this regard, a personalized fusion recommendation system was proposed by comparing the differences in different recommendation technologies. The system could collect readers' diversified characteristic information and determine the reading scope according to readers' interests and preferences, so as to provide readers with accurate RR services. Through relevant experiments, it showed that this technology could provide personalized recommendation services for readers according to their preferences, which was better than related technologies [9]. Cong H et al. found that existing recommender systems need to solve the problem of matching massive information data. Thus, a book personalized recommendation algorithm based on intelligent classification algorithm was proposed in the study. The algorithm utilized collaborative filtering recommendation technology to achieve the initial screening of information, and finally used convolutional neural network for further filtering, input user data and video data. It realized the content recommendation through scoring ranking. The corresponding experiments showed that the proposed recommendation technology had good personalized recommendation capability, and the recommendation accuracy was better than that of the same period recommendation model [10]. The research of Da'u et al. aimed to solve the cold-start and data sparsity problems in book recommendations. A Kitchemen-ham based systematic literature review method was adopted to study and analyze the current state-of-the-art recommendation technologies. Moreover, a recommendation system integrating a deep learning framework was finally proposed to obtain the main feature data by capturing the features of the user and the target object and to realize the recommendation of the content through the scoring. Through experiments, it was found that the proposed technology could effectively solve the problems of sparse information and inaccurate book recommendations, and significantly improve the effect of the reader's reading experience [11].

In conclusion, the preceding research has examined and analyzed the most recent advancements in recommendation technologies. It is evident that these technologies have a profound impact across a multitude of domains, effectively enhancing users' target selection efficacy and enriching the user experience. However, current recommendation technologies still face problems such as information overload and insufficient recommendation accuracy. In book recommendations, most technologies are based on user preference information, lacking attention to user social information and implicit preference feedback. Therefore, to improve the selection effect of reading books, an intelligent digital book recommendation technology is proposed. This research will contribute to the improvement of the user reading experience and the enhancement of the effectiveness of DL construction.

III. Modeling Reading Recommendations in Digital Libraries on Readers' Social Relationships and Reader Interests

This part mainly analyzes the RR service of digital reading scenarios, considers different readers' needs, and constructs the RR model of MIR and the RR model of long-term borrowing readers to realize the RR for different objects.

A. *Modeling Reading Recommendations Based on Multi-Interest Reader*

In recent years, the advancement of information industry technology has prompted a shift towards digital development in traditional libraries. This transition is driven by the need to provide readers with personalized and diversified services.

Among them, providing readers with high-quality and efficient RR services is an important goal of the construction. In the construction, a number of services such as borrowing, recommending, book management and so on will be provided for readers, so as to meet the personalized reading experience of readers [12]. The system structure framework is shown in Fig. 1.

In Fig. 1, it provides customers with multi-end service requirements, and meets customers' online and offline related reading service requirements through the recommendation service module. However, the traditional book recommendation system mainly carries out RR service for readers' reading behavior data, which cannot meet the reading needs of multiple readers. Therefore, considering the factors of readers' multiple reading interests, a recommendation technology based on multiple interest reading is proposed. Firstly, in the RR system, it is necessary for the system to recommend suitable books for each reader. Additionally, the system must analyse the data of readers' historical borrowing, historical collection and historical flipping. This allows the system to obtain short-term behavioral data sequences that satisfy readers' reading interests. [13]. At the same time, readers' interests will change during short-term reading, such as science students and arts students will have obvious differences in reading interests during exam time. In this regard, in the RR service, data mining will be performed on reading groups with SSF. The personalized recommendation of experimental content will be made by calculating the characteristics of different social groups.

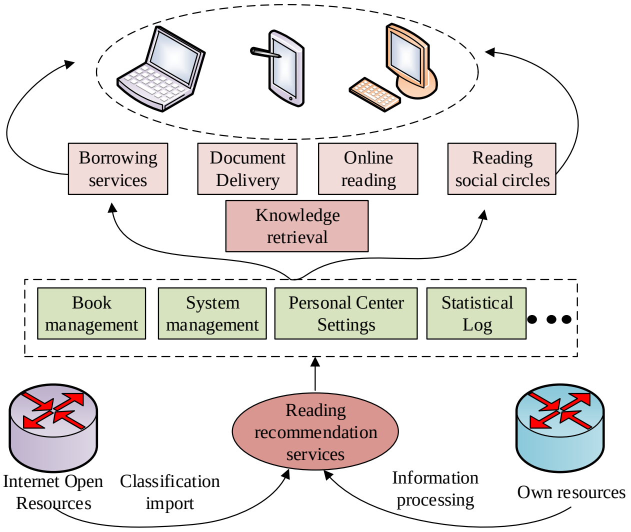

Fig. 1. Digital library system framework.

In the construction of the model, the interest layer of the model is used to obtain information about the borrowing behavior preference of each reader in a short period of time, these contain historical borrowing, historical collection, and historical flipping data, and based on the information to retrieve the suitable candidate set of readers [14]. Define each input as a ternary, the ternary expression is shown in Eq. (1).

$$DH_u = (I_u, O_u, F_u) \tag{1}$$

In Eq. (1), I_u denotes the data set of readers and reading, O_u denotes the social information of readers' reading circle, and F_u denotes the reading data information of readers' candidates, and these contain book names, types, collection areas, etc. The core of the recommendation model construction lies in the implicit from the original data features to the reader representation vector, the reader representation vector is shown in Eq. (2).

$$V_u = f_{user}(I_u, O_u) \tag{2}$$

In Eq. (2), f_{user} denotes the pooling operation, where V_u can also be expressed as shown in Eq. (3).

$$V_u = (\overset{-1}{v_u}, \ldots, \overset{-k}{v_u}) \in \mathbb{R}^{dr \times K} \tag{3}$$

In Eq. (3), V_u denotes the representation vector of reader u, K is the number of interests, and dr denotes the embedding dimension. The pooling function of candidate book i is shown in Eq. (4).

$$\vec{e}_{\mathrm{i}} = f_{item}(F_{\mathrm{i}}) \tag{4}$$

In Eq. (4), $f_{item}(\cdot)$ denotes Embedding operation. According to the maximum value of the inner product of the candidate household and reader representation vectors as the similarity, the top N candidate books are obtained by sorting as shown in Eq. (5).

$$f_{score}(V_u, \vec{e}_i \vec{e}_u) = \max_{1 \le k \le K} \overset{\to T}{e_{\mathrm{i}}} \overset{\to K}{v_u} \tag{5}$$

In Eq. (5), T denotes the top candidate books. In the actual reading scenario, reader reading information, social information, and relevant features associated with books can be obtained through the system platform, which need to be encoded in order to be recognized by the computer and form high-dimensional sparse features [15]. In order to facilitate the analysis of feature information, embedding technology is used to transform the high-dimensional sparse input into low-dimensional dense features. The processing process using Embedding technique is shown in Fig. 2.

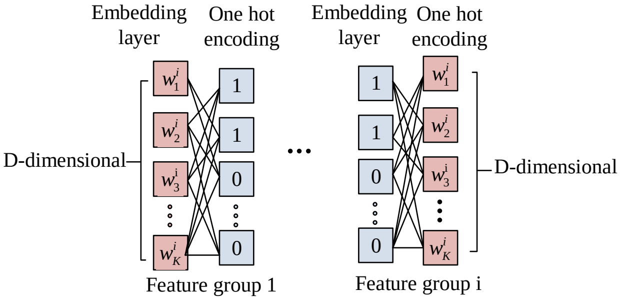

Fig. 2. Embedding technology feature dimension processing process.

The i-th feature group is defined as $W^i = \left[w_1^i, \ldots, w_j^i, \ldots, w_K^i \right] \in \mathbb{R}^{D \times K_i}$, denoting that it contains the i-th embedding dictionary. K_i denotes the i-th embedding dimension, D denotes the original feature dimension, and $□^{D\times K_i}$ denotes the embedding dimension vector. Using Embedding technique for table lookup operation, the input feature x_i If it is a one-hot vector, the Embedding of x_i belongs to a single vector $e_i = w_j^i$, if it is a multi-hot vector, the Embedding of x_i is a list of vectors, which is represented as shown in Eq. (6).

$$\{e_{i1}, e_{i2}, \ldots, e_{ik}\} = w_{i1}^i, w_{i1}^i, \ldots, w_{ik}^i \tag{6}$$

The behavioral sequence of readers is composed of Embedding vectors of items, which contain socially similar reader information, including readers' social crossover features, candidate book information and so on. In reader social similarity analysis, different readers do not have the same vector length when they get the historical behavior sequence through the embedding layer, and the fixed input length of the fully connected layer is needed in the model analysis [16]. For this pooling operation is used to get the fixed length as shown in Eq. (7).

$$e_i = pooling(e_{i_1}, e_{i_2}, \ldots, e_{i_k}) \tag{7}$$

Considering the need for plurality of readers' interests, in order to better tap into the reader's multiple interests, multiple representation vector distributions are utilized to represent the different interests of the readers. In this way, information will be retrieved for each aspect of the reader's items, and dynamic routing in dynamic capsules is used to merge the reader's historical behavior into a cluster and associate it with the recommended books. Define e_i as the initial capsule i , the computational expression from the initial capsule to the lower capsule j is shown in Eq. (8).

$$\hat{e}_{j|i} = W_{ij} e_i \tag{8}$$

In Eq. (8), W_{ij} is the transformation matrix and capsule j will be the weighted sum of the input prediction vector $\hat{e}_{j|i}$, expressed as shown in Eq. (9).

$$s_j = \sum_i c_{ij} \hat{e}_{j|i} \tag{9}$$

In Eq. (9), c_{ij} is the coupling coefficient, and routing softmax is used for coupling coefficient calculation, as shown in Eq. (10).

$$c_{ij} = \frac{exp(b_{ij})}{\sum_k exp(b_{ik})} \tag{10}$$

In Eq. (10), b_{ij} is the logarithmic prior probability of i coupling with j . Meanwhile, to ensure that the short vector tends to 0 and the long vector tends to 1, the capsule j is processed using a nonlinear compression function as shown in Eq. (11).

$$v_j = squash(s_{ij}) = \frac{|\, s_j \,\|^2}{1+\|s_j\|^2} \frac{s_j}{\|s_j\|} \tag{11}$$

In Eq. (11), s_j is the total j input and v_j is the final output capsule, which is obtained by inner product. The readers' embedding interest capsules are obtained through the multivariate interest layer, and each interest capsule indicates different interests of readers. In the actual training, in order to strengthen the effect of reader's interest evaluation on the featured books, a labeled attention layer is designed for improving the matching correlation between readers and books. The labeled attention layer is shown in Fig. 3.

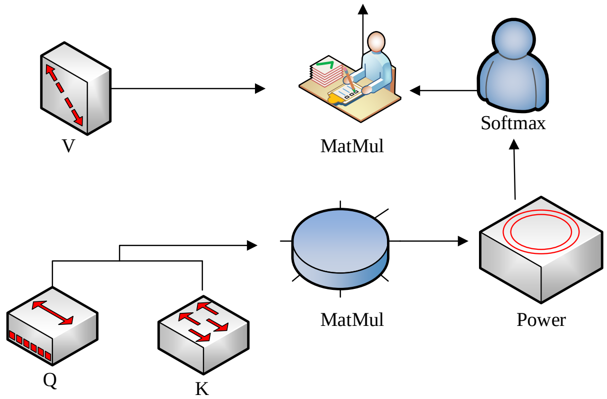

Fig. 3. Structure of label attention layer.

In the labeled attention layer, the candidate book embedding is denoted as query (Q) and the interest capsule is denoted as key (K). Through the attention layer then the reader candidate book output can be obtained as shown in Eq. (12).

$$\overrightarrow{v_u} = Attention(\overrightarrow{e_i}, V_u, V_u) = V_u softmax(pow(V_u^T \overrightarrow{e_i}, p) \tag{12}$$

In Eq. (12), V_u represents the interest capsule matrix output by reader u , p is the attention distribution adjustment parameter.

B. Modeling Reading Recommendations Based on Long-Term Borrowing Readers

In the construction of library RR systems, it is difficult for traditional recommendation models to obtain current readers' interest items from the historical behavior of LTRs. Especially, it is difficult to obtain the reading interests of current readers when individual readers have long-time borrowing records, some of which are as long as several months. Therefore, a RR technique based on long-term borrowing readers is proposed to address the above problem [17]. This technique focuses on analyzing the borrowing data of LTRs and capturing readers' interests from their recent borrowing behaviors, so as to make effective book recommendations for readers. Firstly, reader u is defined to borrow L books recently as the model input, and the embedding dictionary matrix of books is set to $M \in □^{|L|\times d}$ and d is the embedding dimension, then the embedding matrix of readers' short-term behaviors is shown in Eq. (13).

$$E = \left[m_{s1}, m_{s2}, \dots, m_{sL} \right] \in \mathbb{R}^{|L| \times d} \tag{13}$$

In Eq. (13), m_{sL} is the embedding matrix of readers' short-term behavior of borrowing L books. The reader's short-term interest representation is reflected by the self-attention model. In the short-term preference representation, since the location relationship cannot be reflected in the attention, the embedding matrix $P = \left[p_1, p_2, \dots, p_L \right] \in \mathbb{R}^{|L| \times d}$ of the learnable location is added to the matrix E, and the input matrix $X^{(0)}$ of the attention network is expressed as shown in Eq. (14).

$$X^{(0)} = \left[x_1^{(0)}, x_2^{(0)}, \dots, x_L^{(0)} \right] \in \mathbb{R}^{|L| \times d} \tag{14}$$

In Eq. (14), $x_\ell^{(0)}$ indicates as shown in Eq. (15).

$$x_\ell^{(0)} = m_{s\ell} + p_\ell, \ell \in \{1, 2, \dots, L\} \tag{15}$$

Next the matrix $X^{(0)}$ needs to be incorporated into multiple stacked self-attention blocks (SABs) and the output of the b th block is shown in Eq. (16).

$$X^{(b)} = SAB^{(b)}(X^{(b-1)}), b \in \{1, 2, \dots, B\} \tag{16}$$

In the borrowing process, the wearable devices used by readers will record readers' short-term borrowing behavior, which contains a large amount of reader information and is crucial for the prediction of readers' reading interest [18]. At the same time, the book recommendation in addition to the reader characteristics, but also with the recommendation of the scene has an important relationship, such as readers in different bookshelves reading, reading time-consuming is not the same [19]. Therefore, the study adopts self-attention to model the different behavioral sequences of readers, and the model framework is shown in Fig. 4.

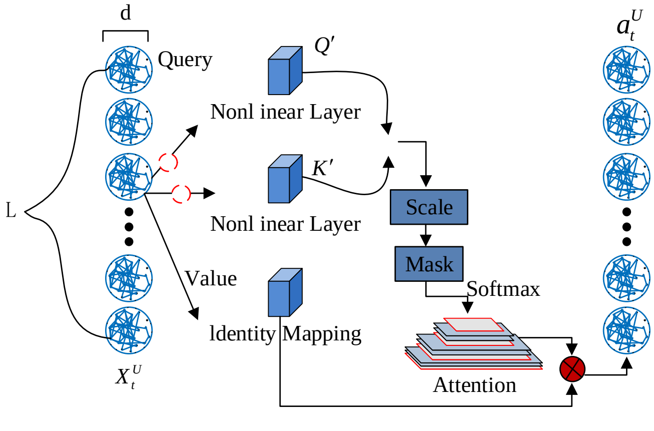

Fig. 4. A reader behavior modeling framework based on self-attention.

In the self-attention model, Q' is the query, K' is the keystroke, and X_t^U is the reader's recently interacted books, the set of which is shown in Eq. (17).

$$X^U = (X_1^U, \dots, X_t^U) \; t \in [1, 2, 3, \dots] \tag{17}$$

In Eq. (17), U denotes the set of readership and the set of books is B, $X^U \in B$. The study assumes that the reader interacts with books in the short term as L books, and defines X as the embedding set of all books, then the reader interacts with books in the near future at L times as $X_1^U \in \mathbb{R}^{L \times d}$. In self-attention, the query, key, and values are all equal to X_t^U, and at the same time, let part of the query and key be linearly transformed, as shown in Eq. (18).

$$\begin{cases} Q' = Relu(X_t^U W_Q) \\ K' = Relu(X_t^U W_Q) \end{cases} \tag{18}$$

In Eq. (18), $W_Q = W_K$, W_Q is the query matrix and W_K is the keying matrix. The attention score mapping matrix is obtained by the above operation as shown in Eq. (19).

$$s_t^U = softmax(\frac{Q' K'^T}{\sqrt{d}}) \tag{19}$$

Finally, the weight output of the self-attention model is obtained, and the weight output is used as the reader interest preference representation as shown in Eq. (20).

$$a_t^u = s_t^U X^U, a_t^u \in \mathbb{R}^{L \times d} \tag{20}$$

In the actual reading process, there is a difference between the impact of long-term and short-term interests on readers. To accurately recommend books to readers, it is also necessary to consider the reader's long-term interest factors. In this regard, the gated cyclic unit structure is used to adjust the weights of readers' long-term and short-term interests through the similarity of readers' long-term and short-term interests, and the gate function is shown in Eq. (21) [20].

$$g = o(ISG(m_{st}, y_r, m_i)) = o([m_{st}, y, m_i] W_G + b_G) \tag{21}$$

In Eq. (21), $ISG(\cdot)$ represents the doorway function, y_r is the long-term interest representation, m_i is the embedding vector of the candidate product, m_{st} is the embedding vector that represents the reader's recent behavior, and b_G and W_G are the adjustment parameters. The final representation of the sequential readers in step ℓ is shown in Eq. (22) [21].

$$z_\ell = x_\ell^{(B)} \otimes g + y \otimes (1 - g) \tag{22}$$

In Eq. (22), $\otimes$ is a multiplication-by-sign, and the predicted interaction score of the i th candidate item among the $\ell + 1$th reader is shown in Eq. (23).

$$r_{\ell+1,i} = z_\ell (m_i)^T \tag{23}$$

Through the above study, the entire reading book recommendation for long term readers is then obtained. The entire RR technology route flow is shown in Fig. 5.

IV. Experimental Analysis of the Reading Recommendations Model for Digital Libraries

This part mainly analyzes the recommendation performance of the two models in two different reading scenarios, and examines the recommendation effectiveness of the proposed models by comparing them with similar RR models. The metrics include recommendation accuracy, recall, precision, etc.

A. *Experimental Analysis of Reading Recommendations Model Based on Multi-Interest Reader*

To analyze the application effect of the proposed RR model, PyTorch is used to build the experimental platform. The records of readers' borrowing information of a university A for the whole year of 2022 are selected, which contains 15683 readers' borrowing information and a total of 698545 borrowing data information, and each reader's information contains at least 8 borrowing information records. The dataset is divided into train and validation, with 70% of the training set and 30% of the validation set. Area under ROC Curve (ROC), Loss, Logloss are selected as evaluation indexes. The relevant parameter settings of the experimental model are shown in Table I.

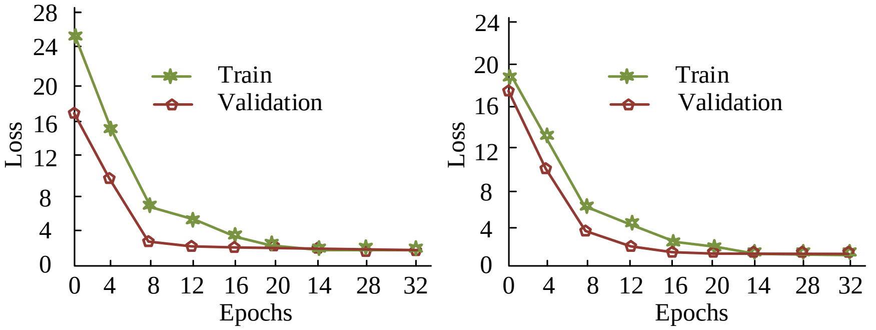
TABLE I. Parameter Settings for Reading Recommendation Model Based on Diverse Interest Readers

Parameter indicator type	Numerical value
Capsule network hidden layer dimensions	[512,256,128,64]
Embedding vector dimension	16
Activation function	RELU
Iterations	100
Optimizer	Adam
pow	2
Attention network hidden vector dimension	4

Table I shows the experimental model parameter settings. The hidden layer size of the capsule network is 512256, 128,64. The embedding vector size should not be too large, set to 16. RELU is used as the activation function. The DeepCrossing recommendation model (DeepCrossing) and the convolutional sequence embedded recommendation model (Caser) are introduced as test benchmarks. In model training, optimization is performed by regularization in order to avoid overfitting problem in the model, and the results are shown in Fig. 6.

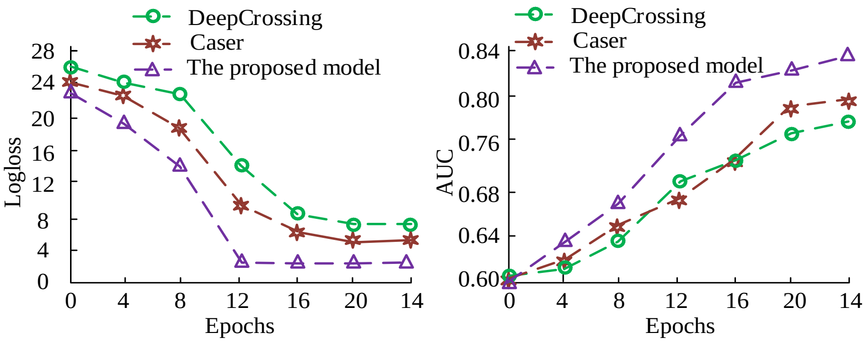
Fig. 6(a) and Fig. 6(b) show the results of optimization without regularization and with regularization, respectively. The loss under the training set without dropout regularization optimization is 1.23, and the value of the loss under the training set after regularization optimization is 1.03. In addition, comparing the results of the validation set, the training loss under the validation set before dropout regularization optimization is 1.28, and the value of the loss under the training set after regularization optimization is 1.04. Therefore, dropout regularization is used in the experiment to optimization model training. Comparing the RR performance of different models is shown in Fig. 7.

Fig. 7(a) shows the results of model log-loss comparison. Among the three models, the proposed model achieves the fastest convergence and has the smallest log loss of 1.85 compared to the other models, while the log loss of Caser, and DeepCrossing are 5.26 and 7.32, respectively. Meanwhile, comparing the ROC values of the different models, the proposed model has the best performance of 0.83, followed by Caser with 0.795, and the worst one is DeepCrossing at 0.782. Different reading types in the social circle are selected for comparison, as shown in Fig. 8.



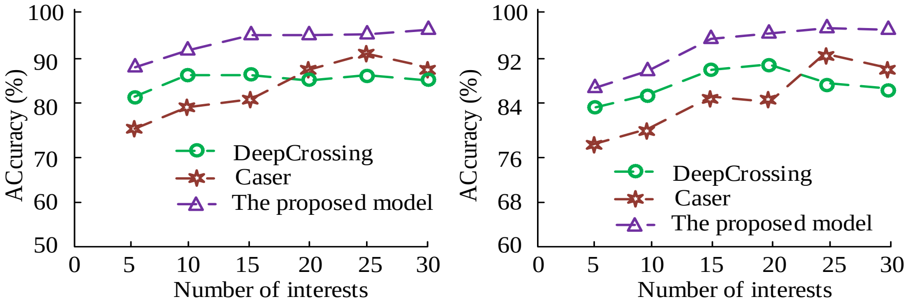
(a) Training without dropout regularization (b) Using dropout regularization training

Fig. 6. Comparison of loss curves using dropout regularization.



(a) Logarithmic loss comparison (b) Comparison of ROC values

Fig. 7. Performance comparison of reading recommendation models.



(a) Liberal Arts Reading (b) Science Reading

Fig. 8. Comparison of recommended effects for different reading types.

Fig. 8(a) and Fig. 8(b) show the recommendation results of two social reading scenarios in Arts and Science, respectively. In the Arts RR, the best recommendation accuracy of the proposed model is 97.65%, which is better than 90.23% and 87.65% of Caser, and DeepCrossing. In science RR, the proposed model has the best recommendation accuracy of 97.24%, which is better than the other two models. The best recommendation accuracy of the two models Caser, and DeepCrossing is 93.24% and 91.68 respectively. This shows that the proposed model has the best recommendation in real scenarios.

B. *Experimental Analysis of Reading Recommendations Model Based on Long-Term Borrowing Readers*

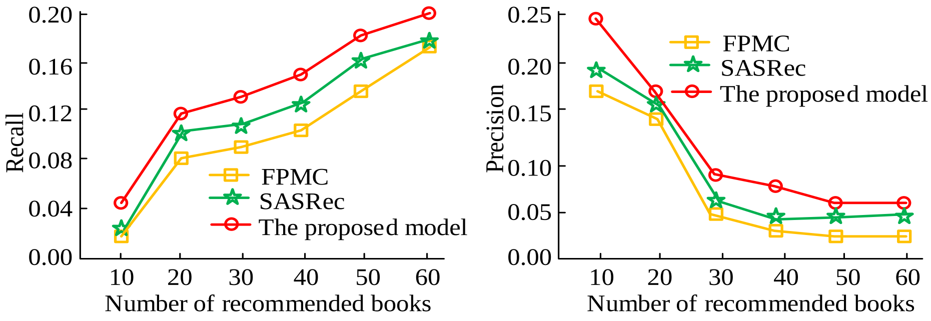
For long-term borrowing readers, the annual readers' borrowing data of a university A in 2022 is still selected for experimental analysis. Before the experimental analysis, it is necessary to filter 698,545 pieces of borrowing data information, select 1000 readers who have borrowed records for more than 10 times, and take the interaction data of the above readers in the last 3 months as the readers' short-term behavior data. The final short-term data set is 24,365 items and the long-term data set is 56,356 items. The initial parameter settings of the experimental model are shown in Table II.

Table II shows the experimental model parameter settings. The short-term sequence length is set to 10, the embedding vector size is set to 32, and the batch processing size is set to 128. Self-attentive sequential recommendation (SASRec) and factorizing personalized markov chains for next-basket recommendation (FPMC) are introduced as test benchmarks. The recall and precision performance of the three RR models are compared, as shown in Fig. 9.

TABLE II. PARAMETER SETTINGS FOR READING RECOMMENDATION MODEL BASED ON LONG TERM BORROWERS

Parameter indicator type	**Numerical value**
Short term sequence length	10
Embedding vector dimension	32
Iterations	80
The representation vector dimension of books	16
BATCH_SIZE	128
Long term borrowing of interactive data	26545
Short term borrowing interaction data volume	13654

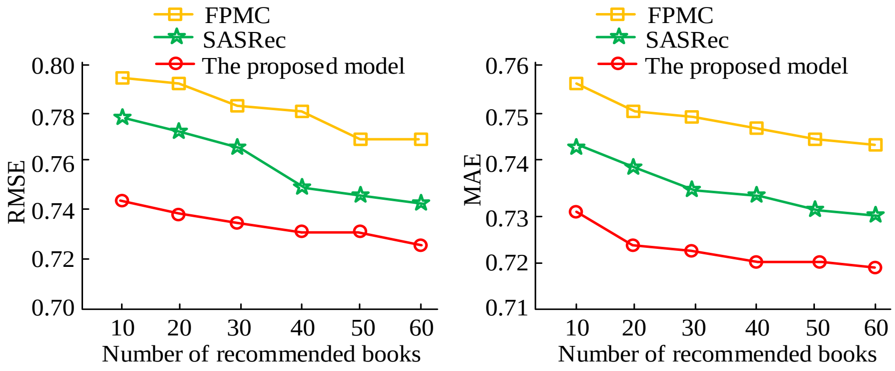
Fig. 9(a) shows the results of RR model recall comparison, with the increase of the number of recommended books, the recall rate of all three models keeps increasing, the best performance is the proposed model with the best recall rate of 0.198, followed by SASRec with 0.179, and the worst is FPMC with 0.175. In the precision rate comparison, with the increase of the number of recommended books, the precision rate of the three models keep decreasing. The best training performance is the proposed model with the precision rate of 0.062 at 60 recommended books, better than the other models. The best training performance is achieved by the proposed model with an accuracy rate of 0.062 when the number of recommended books is 60, which is better than the other models. Finally, root mean squared error (RMSE) and mean absolute error (MAE) are chosen to compare the training effect of different RR models, as shown in Fig. 10.



(a) Recall

(b) Precision

Fig. 9. Comparison of recall and accuracy.



(a) RMSE

(b) MAE

Fig. 10. Comparison results of root mean square error and mean absolute error of the model.

Fig. 10(a) and Fig. 10(b) show the RMSE and MAE training results of the model, respectively. In the RMSE error comparison, the RMSE error of the proposed model decreases gradually as the number of books recommended increases. When the number of recommended books is 60, the RMSE errors of the proposed model, SASRec, and FPMC are 0.731, 0.750, and 0.778, respectively. In the comparison of MAE errors, when the number of recommended books is 60, the proposed model has the smallest MAE error of 0.721, which is better than the other two models. This shows that the proposed model has better RR performance in real scenarios.

V. Discussion

In recent years, the continuous development of information technology has accelerated the progress of the digital information industry. Moreover, the construction of DL has further strengthened the integration and utilization of resources. At present, recommendation systems are the core of DL construction, including recommendation technologies based on interests, user behavior, and related data. The objective of this study is to furnish users with convenient access to target resources and to enhance their reading experience. Currently, traditional recommendation techniques are mainly based on interest retrieval, which is inferior to fusion of interest and social association data recommendation techniques. In light of the limitations of existing reading recommendation systems in DL, an intelligent recommendation technology is proposed and implemented in the construction of DL, yielding promising results.

The technology proposed by the research considered the reading needs of users in multiple scenarios, such as using interest as the main recommendation technique in regular reading. Similar technologies such as Caser and DeepCrossing were selected for comparison. In the performance loss comparison, Caser and DeepCrossing were 5.26 and 7.32, respectively, while the research model was only 1.85. Comparing with study [5], the loss was 2.58. In addition, in social scenario-based recommendation, the recommendation accuracy of the research model was above 95%, which was better than similar Casers, DeepCrossing and 92.35% in study [5]. It can be concluded that the research model had good application effect in reading recommendations based on multiple interests. For long-term borrowing users, it was not possible to effectively recommend them based on interest data. The research mainly considered users' long-term borrowing data and judged their short-term borrowing interests based on their recent borrowing data. By integrating the above information, reading recommendations for long-term borrowing users could be achieved. In actual training, the recall and accuracy performance of similar models were compared separately. The recall rate of the research model was 0.198, while the SASRec and FPMC of similar models were 0.179 and 0.175, respectively. The research model performed better. In addition, the technology from a study [7] was introduced for comparison, and its recall rate was 0.182. Finally, in the comparison of RMSE recommendation errors, the proposed model, SASRec, and FPMC were 0.731, 0.750, and 0.778, respectively, while the study [7] had a value of 0.745. This indicated that the overall error of the research model was lower and the recommendation effect was significantly better than similar techniques.

Compared to similar technologies, research technology considered user target needs from both short and long-term perspectives. It focused on users' short-term interests and reading behaviors, which could more accurately determine users' potential reading behaviors and needs. This is something that similar technologies do not possess. Moreover, experimental evidence has demonstrated that the research technology considers user needs from multiple perspectives and that its final reading recommendation service is superior to that of similar technologies. Furthermore, this technology has gained recognition from users.

In conclusion, the study has demonstrated through experimentation that the proposed reading recommendation model, based on diverse interest readers and long-term borrowing readers, exhibits high levels of recommendation accuracy, recall rate, precision, and other indicators. Compared with similar technologies, it has better recommendation accuracy and error. Moreover, its application in DL will accelerate the digital development of the book industry and improve the user reading experience.

VI. Conclusion

Recommendation technology has a wide range of important applications, improving the utilization of massive information by users. To enhance the RR effect of library books, targeted reading models are proposed for two types of reading populations, respectively. For MIR, readers' short-term behavioral preference features and SSF are mainly considered, and the score is calculated by fusing the features to realize content recommendation. For borrowers with long-term goals, their short-term and long-term interests are extracted from the readers' preferences. The scores are then integrated through the self-attention mechanism to provide recommendations for content. In MIRRR, the logarithmic losses of various models were compared and found that the proposed model, Caser, and DeepCrossing had losses of 1.85, 5.26, and 7.32, respectively. Additionally, when compared the accuracy of liberal arts RR, it was found that the proposed model achieved a better recommended accuracy of 97.65% as compared to 90.23% and 87.65% achieved by Caser and DeepCrossing, respectively. In the long-term borrower reader RR experiment, the proposed model achieved the highest recall with a score of 0.198, surpassing SASRec and FPMC, which achieved scores of 0.179 and 0.175, respectively. Moreover, in the precision rate ratio test, the proposed model outperformed Caser and DeepCrossing, exhibiting the best precision rate of 0.062. Finally, the study compared the RMSE and MAE errors of various models, revealing that the proposed model had a more effective recommendation outcome in real book reading scenarios compared to SASRec and FPMC, with RMSE errors of 0.731, 0.750, and 0.778, respectively. However, there are also shortcomings in the research. DL do not consider reader and book context information in their recommendations, including book reviews, book authors, etc. It is imperative that future research endeavors prioritize the development of this capability. At the same time, DL can strengthen the free management and sharing of resources in future construction, and improve the utilization efficiency of resources.

Abstract—**Identifying prescribed medication accurately remains a challenge for many people, particularly older individuals who may experience medication errors due to impaired vision, lack of English proficiency, or other disabilities. This problem is more prevalent in healthcare settings where pills are often distributed in strips rather than in traditional packaging, increasing the risk of dangerous consequences. To address this issue, a mobile application has been developed using Computer Vision and Artificial Intelligence to accurately recognize pills and provide relevant information through text and speech formats. The approach integrates the GPT-4 API for imprint extraction and YOLOv8 for image detection, significantly enhancing the application's accuracy. The goal is to improve medication management for vulnerable populations facing unique accessibility challenges. The application has achieved an overall accuracy of 90.89%, demonstrating its effectiveness in assisting users to identify and manage their medication.**

Keywords—Pill detection; seniors; computer vision; artificial intelligence

I. Introduction

In healthcare, pills are a ubiquitous form of medication, typically round or oval-shaped, designed for oral consumption [1]. Their widespread use is attributed to their convenience, precise dosage control, and ease of administration. Pills encompass a diverse array of medications, including pain relievers, vitamins, antibiotics, and various therapeutic agents. As healthcare systems increasingly prioritize patient needs, the importance of innovative solutions in medication management becomes evident. The critical problem is that medication management poses significant challenges for older individuals, who are particularly susceptible to medication errors. Medication errors, particularly among older individuals, underscore the need for tools that empower individuals to take control of their health. Ensuring accurate adherence to medication is crucial for effective treatment outcomes. However, the complexity of modern drug regimens and the variety of pill presentations often lead to confusion and errors [2]. Older individuals are particularly susceptible to medication errors due to impaired vision or a lack of proficiency in English, which can lead to difficulties in correctly identifying and administering prescribed medications [3]. Studies have shown that between 75% and 96% of older patients make mistakes with their medication. While some errors may have minor effects, others can result in severe health consequences, and in some cases, even death. The risk is further exacerbated when medications are provided in unconventional forms, such as strips instead of traditional packaging [4]. Current solutions to address this problem are inadequate, as most advancements focus on reducing medical errors from the healthcare professionals' perspective, neglecting patient involvement. There is a significant gap in research on pill detection and classification, which hampers progress in medication management and safety. Existing studies have primarily developed trained model systems rather than user-friendly mobile applications, creating accessibility challenges for older individuals.

In this study, we focus on introducing and evaluating the efficacy of a novel pill detection application. This application leverages advanced technologies such as computer vision and Artificial Intelligence (AI), specifically utilizing deep learning techniques like YOLO (You Only Look Once) and GPT-4 API. YOLOv8 is employed for image detection, identifying pills with high precision, while the GPT-4 API extracts and analyzes imprints on pills to provide detailed information. The application addresses the challenges of medication recognition and management by providing a user-friendly platform capable of accurately and efficiently identifying pills from images.

The user experience is at the core of our design, with features such as a simple interface, text-to-speech functionality, and multi-language support to assist older adults and non-English speakers. This ensures users receive accurate and tailored information, addressing challenges associated with various medication forms and securing a higher degree of safety. Aligned with the ideological focus on patient-centric care, the application empowers users, regardless of age or language barriers, to confidently manage their medications. This innovative solution aims to improve overall health outcomes and reduce risks associated with medication errors, addressing a critical need in the healthcare industry.

The rest of the study is organized as follows: Section II reviews previous work. In Section III, we introduce our methodology. Section IV presents the results of this study. Finally, Section V concludes the paper.

II. Related Work

In recent years, there has been increasing research in the field of pill detection. Based on the current state of the art, existing pill recognition systems can be categorized into two groups: pill detection using an image of the pill, and pill imprint detection.

A. Pill Detection

This section will provide an overview of several research papers developed to identify pills solely using an image of the pill. These studies have shown promising results in computer vision and image recognition.

A research study conducted by Caban, Jesus j et al. [5] developed a model for automatically identifying prescription drugs. They used Shape Distribution Models to capture the shape, imprint, and color characteristics of pills. The model samples equally spaced points along pill boundaries from the centroid and calculates distances to describe the shape. It also estimates imprints through edge points analysis. The model uses HSV color space conversion to analyze boundary pixel values. When tested on 568 common US drugs, the model achieved an accuracy of 91.13%. This approach laid a foundation for pill identification in real-world applications where accurate recognition of diverse pill appearances is essential.

Björne et al. [6] conducted a study on drug name recognition and drug-drug interaction extraction using the Turku Event Extraction System (TEES) combined with machine learning techniques, specifically Support Vector Machine (SVM) classification and domain knowledge. Their methodology involved integrating several external resources, such as DrugBank and MetaMap, and syntactic features derived from deep parsing. The study achieved F-scores of 60% for drug name recognition and 59% for interaction extraction. This showcases the potential of combining domain-specific knowledge and machine learning to improve medication information retrieval. The work emphasizes the importance of integrating structured external data with advanced computational methods to enhance medication management systems.

A study conducted by Cunha et al. [7] introduced HelpmePills, a tool created to help elderly individuals identify pills using image processing techniques. The system distinguishes between different pill images based on their shape, dimensions, and colors. It operates in two main steps: learning, where pill information is gathered and stored in a local database by a caregiver, and recognition, where pill properties are compared against the database using a decision tree. When tested on a Samsung Galaxy Note II, the tool accurately identified all the learned pills. This research highlights the importance of user-friendly mobile solutions, especially for older adults who may have difficulties with managing their medication.

With little labeled data, Wang et al. [8] created a CNN-based system to identify medicines from mobile phone photos. Using a dataset from the National Institutes of Health (NIH) with 1000 distinct pill classes, they assessed their approach by applying data augmentation techniques to create fake pill visuals. With a Mean Average Precision (MAP) score of 0.328, they recommended eliminating bias in the dataset, shifting the domain, and investigating other deep-learning architectures and methodologies.

Zeng et al. [9] created MobileDeepPill, a mobile-based system for identifying pills using advanced AI techniques. The system utilizes a multi-Convolutional Neural Network (CNN) architecture along with Knowledge Distillation to enhance performance on mobile devices. Furthermore, a triplet loss function improves the model's ability to differentiate between pills. When evaluated with the NIH NLM dataset, MobileDeepPill achieved a Top-1 accuracy of 73.7% and a Top-5 accuracy of 95.6% for recognizing both sides of a pill. This study highlights the potential of integrating sophisticated AI models into mobile platforms to enhance pill identification. However, it also notes limitations such as the inability to recognize multiple pills in a single image, indicating areas for future improvement.

In response to the issue of pill misidentification, Wong et al. [10] developed a Fine-Grained Pill Identification Algorithm utilizing a Deep Convolutional Network (DCN). The DCN model surpassed standard techniques, achieving a mean accuracy rate of 95.35% at the Top-1 return. Future research could focus on expanding the dataset and enhancing the model's robustness to ensure its applicability in real-world healthcare settings.

A study conducted by Ou et al. [11] developed a computer system to help identify and classify different types of drug pills. The system has two stages: detection and classification. In the first stage, a deep CNN is used to determine the location of the pills, while in the second stage, another CNN is used to classify the pills based on their type. Scientists created a database containing 131 categories of drug pills to train the models. They used popular deep learning frameworks such as TensorFlow or PyTorch, and likely ran experiments on GPUs to speed up the process. The system achieved a top-1 accuracy rate of 79.4%, with top-3 and top-5 accuracies of 88.3% and 91.8%, respectively. Future improvements could include expanding the drug pill database and integrating the system with mobile or handheld devices for easy access and convenience.

As the third most common cause of death in the United States, medical errors are addressed by Delgado et al. [12], with a major focus on drug errors. The main issue is the challenging identification of prescription medications. To enhance accuracy, they employed deep learning with CNN architectures (ResNet50, SqueezeNet, MobileNet, 37 InceptionV3), fine-tuning them using an Adam optimizer with a decreasing learning rate strategy to improve the performance and convergence of the models, and pill localization to accurately identify the location of pills within the images by using a blob-detection neural network and post-processing techniques which were vital for precise identification. The training involved the NIH Pill Image Recognition Challenge dataset and synthetic images. The application achieved a 94% accuracy in identifying prescription medication from images, recognizing the correct pill within the top five results.

In a paper by Ou et al. [13] they discussed drug pill detection challenges in medication safety. using a two-stage architecture with EFPN for drug localization and Inception-ResNet v2 for classification. They developed the Drug Pills Image Database, which included 612 drug categories, and analyzed the system, attaining over 96% accuracy in localization as well as Top-1, Top-3, and Top-5 accuracy levels of 82.1%, 92.4%, and 94.7%. The study used high-quality images captured with a DSLR camera, two NVIDIA 1080Ti GPUs, and the Adam optimizer. Future improvements include enhancing accuracy, simplifying the model, and expanding the database for broader pharmaceutical applications.

Tan et al. [14] examined three object detection algorithms, RetinaNet, SSD, and YOLOv3, for real-time pill and hard sample detection. Each algorithm was trained on a pill image dataset and their performance was analyzed. RetinaNet had the highest mean average precision (MAP), but its frames per second (FPS) was only a third of that of YOLOv3, making it difficult to achieve real-time performance. SSD did not perform as well on MAP or FPS. YOLOv3 featured a little lower MAP but significantly faster detection speed and harder sample detection. The authors concluded that YOLOv3 is more suitable for deployment in hospital equipment.

Kwon et al. [15] proposed a deep learning system to improve pill detection even with limited training data. Normally, the algorithm learns from various pill images when individual pills are detected. But, as the number of different pill types to identify rises the 38 combinations of pills in an image grow significantly. The algorithm follows a two-step structure that includes single-class pill area detection learning and the optimization of area dilation for multi-class pill detection. They trained the algorithm with single pill images, utilized the Mask Region-Based Convolutional Neural Network (RCNN) model, and incorporated post-processing techniques for improving pill detection. Despite the limited image and dataset sizes, the method outperformed previous algorithms. It achieved better detection performance in terms of pill identification.

In a study by Heo et al. [16], an accurate deep learning-based system for automatic pill recognition was developed, identifying tablets automatically. The system consists of two main steps - pill recognition and pill retrieval, both of which use deep learning models to train pill images and imprinted characters. The authors compiled a pill database from both South Korea and the United States. The system obtained top-1 candidate accuracy ratings of 85.6% (South Korea) and 74.5% (United States) for pill kinds that had not been trained on two databases. For future enhancements, the authors propose incorporating transfer learning approaches such as multitasking learning or adapters.

In their study, Al-Hussaeni et al. [17] aimed to improve the accuracy and efficiency of identifying pills through image retrieval. They suggested using CNNs instead of traditional methods to prevent medication errors. The authors offered three distinct CNN architectures, two of which were hybrid networks combined with classification methods (CNN + Support Vector Machine and CNN + KNearest Neighbors), and the third was a ResNet-50 network. The researchers employed a real-life dataset from the National Library of Medicine database (NLM) and achieved an accuracy of 90.8% in pill image retrieval. However, the CNN + KNN architecture showed better retrieval accuracy by 10% compared to other models. The study could be improved further by exploring advanced classification methods and refining the CNN architecture.

B. Pill Detection that Focuses on Imprint Information

This section will provide an overview of several research papers developed to automatically identify pills from images, focusing on detecting imprint information.

Lee et al. [18] conducted a study on identifying illicit drugs using a feature extraction method based on edge-based characteristics and invariant moments. Their approach effectively accounted for the variability in pill images caused by different lighting conditions and viewpoints. By creating multiple templates during edge detection to improve resilience against these variations, the study achieved a remarkable 76.74% rank-1 matching accuracy using a comprehensive dataset of 822 illicit drug pill images and 1,294 legal pill images. This pioneering use of edge localization for imprint extraction represents a significant advancement in pill identification accuracy, demonstrating impressive capability in handling variations in image quality and environmental conditions. It provides a valuable reference for enhancing the precision of pill recognition in various settings, cementing its relevance for imprint extraction techniques.

Chen et al. [19] introduced an automated methodology for identifying pills by using imprint information. The text was obtained through a modified stroke width transform (MSWT) and characterized using the weight shape context (WSC). By employing this approach, the researchers achieved a classification accuracy of as high as 93.03% when categorizing over 10 thousand query pill images into approximately 2000 distinct groups.

Yu et al. [20] developed a high-accuracy automatic pill recognition system that employs imprint information as the primary differentiation between different pills. It utilized algorithms for imprint extractions, which adopt a modified stroke width transform for imprint extractions and uses Loopy belief propagation for image segmentation of printed imprint pills. The results were promising, with up to 97.16% accuracy in identifying 12,500 pill images into 2,500 categories. The authors suggested accelerating the algorithm and improving the accuracy for lower-quality images.

Chupawa et al. [21] developed a pill identification system for pharmacists using a detailed three-stage approach. Firstly, the preprocessing stage enhances image quality by removing background noise, cropping, and applying filters to improve clarity. Secondly, during feature extraction, the system isolates and analyzes imprint characteristics, such as shape and texture, which are crucial for accurate identification. Finally, the classification stage employs a neural network to categorize pills based on the extracted features. This system achieved an impressive accuracy rate of 94.4% in identifying six different types of pills, demonstrating the effectiveness of deep learning techniques in enhancing pill identification and supporting precise medication management.

Suntronsuk et al. [22] described a method for automatically identifying text from pill impressions. The method relied on a set of predetermined rules for recognizing imprint places, as well as a methodology for removing noise from binary images.

Initially, the photos were treated to normalization and enhancement techniques to improve contrast. Then, the imprint area was identified using different criteria. The selected area was subsequently trimmed and converted to binary representations via either Otsu's thresholding approach with noise reduction or K-means clustering. Finally, the binary result was fed into a trained Tesseract model, which extracted the text. The study found that Otsu's thresholding method surpassed K-means clustering, with precision and recall rates above 57%. Pill Image Binarization to Detect Text Imprints.

III. Methodology

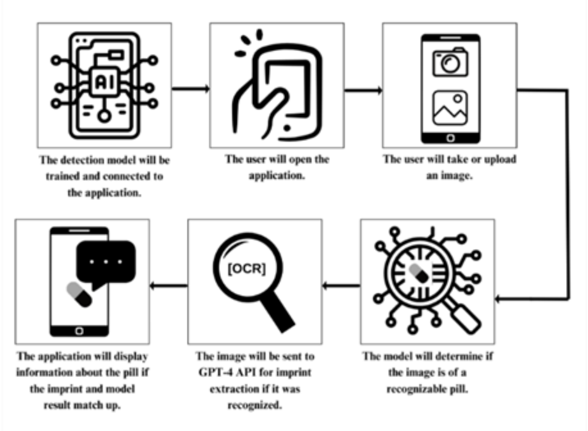
The following section provides a detailed overview of the methods utilized in this study to combine the YOLOv8 model with GPT-4 for optical character recognition (OCR) capabilities, with the goal of improving the pill detection application. This integration is crucial for accurately capturing and interpreting text imprints on pills, which is essential for proper medication identification. The methodology is broken down into key areas such as research design, procedure, data acquisition, and preparation, all customized to address specific challenges and objectives identified in the initial stages of the project.

A. Study Design and Procedure

This study assessed the effectiveness of integrating YOLO (You Only Look Once) object detection models with GPT-4 for OCR in developing the pill detection application. YOLOv8 was selected due to its proven efficacy in object detection [23] and GPT-4's advanced capabilities for text recognition [24]. This combination is pivotal for accurately extracting and interpreting text imprints on pills, crucial for medication identification. The study followed a comprehensive procedure encompassing the training of detection models and the integration of OCR capabilities. Initially, YOLOv8 was fine-tuned on a specifically curated dataset containing images of various pills captured under different environmental settings to simulate real-world usage. This was followed by applying the GPT-4 API to perform OCR on the detected pills, focusing on the imprints containing essential medication information. The algorithmic flow of these processes is depicted in Fig. 1, which illustrates the program flow from model training to pill detection and information display in the application. First, the model will undergo training using a labeled dataset until it reaches a good level of accuracy. Next, it will be connected to our Android application. When the user opens the application and uploads or takes a picture, the model will analyze the image to identify any recognizable pills. If it detects a pill, the image will be sent to the GPT-4 API for imprint extraction. If the imprint and detected pill match up, the relevant information will be displayed for the user.

B. Data Acquisition and Preparation

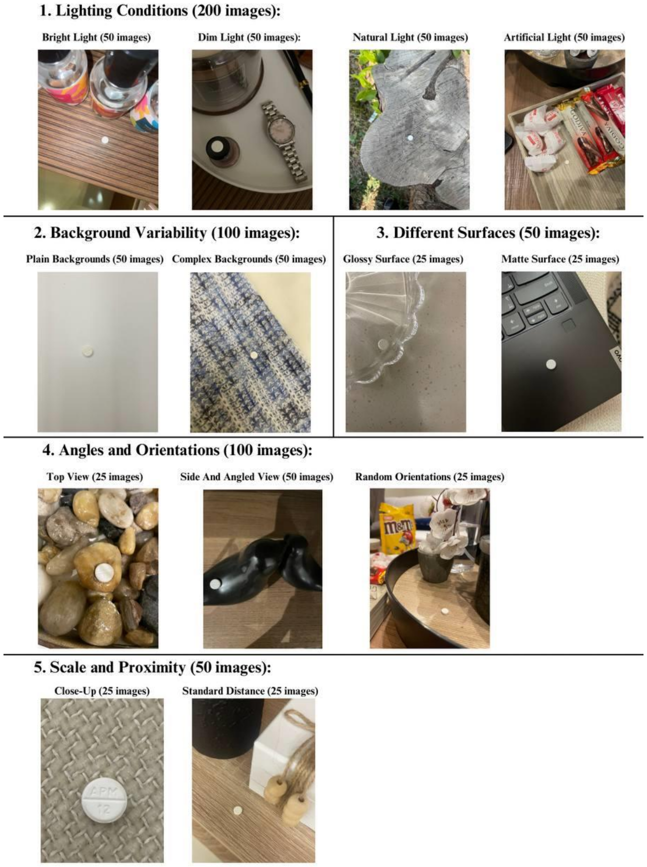
The dataset was meticulously constructed with a focus on medications commonly prescribed for prevalent chronic diseases in Saudi Arabia, encompassing hypertension, diabetes, and heart diseases. Medications included hypertension pills such as Tabuva, Amlor, and Tenoryl; diabetes medications including Glucare and Jardiance; and heart disease treatments like Aspirin, Cardicor, Diusemide, and Isobide. The selection of these medications was informed by consultations with several pharmacists to ensure the dataset reflects real-world medical needs. It was essential to choose a dataset with a wide variety of medications to represent different conditions and therapeutic classes, as well as a diverse range of pill shapes, colors, and sizes, as diversity is crucial for confirming the model's ability to be applied across different medical situations.



The detection model will be trained and connected to the application.
AI
The user will open the application.
The user will take or upload an image.
The model will determine if the image is of a recognizable pill.
[OCR]
The image will be sent to GPT-4 API for imprint extraction if it was recognized.
The application will display information about the pill if the imprint and model result match up.

Fig. 1. Pill detection application flow.

To further enhance the dataset's relevance, specific choices were made to include pills without imprints, such as Aspirin, and pills with only engraved imprints and not inked, like Cardicor. Additionally, pills that appeared very similar except for their imprints, such as Jardiance and Glucare, were included to test the model's ability to distinguish between subtle differences.



1. Lighting Conditions (200 images):
Bright Light (50 images)
Dim Light (50 images):
Natural Light (50 images)
Artificial Light (50 images)
2. Background Variability (100 images):
Plain Backgrounds (50 images)
Complex Backgrounds (50 images)
3. Different Surfaces (50 images):
Glossy Surface (25 images)
Matte Surface (25 images)
4. Angles and Orientations (100 images):
Top View (25 images)
Side And Angled View (50 images)
Random Orientations (25 images)
5. Scale and Proximity (50 images):
Close-Up (25 images)
Standard Distance (25 images)

Fig. 2. Dataset capturing conditions.

To simulate realistic usage scenarios, the dataset creation involved a detailed and structured image collection process shown in Fig. 2. Pills were photographed under varied lighting conditions to reflect different environmental settings patients might encounter. Specifically, 200 images were equally distributed across four lighting categories: bright, dim, natural, and artificial light. To further enhance the model's ability to perform under diverse backgrounds, 100 images were captured against both plain and complex backgrounds. The dataset also included images taken from multiple angles and orientations—top view, side view, angled view, and random orientations—to ensure comprehensive coverage of how pills might be presented to the application by users. In addition to these variations, 50 images focused on scale and proximity, with close-up shots and standard-distance shots, and another 50 showcased pills on different surface types, split between glossy and matte finishes. This comprehensive application to data collection ensures that the model is well-prepared for effective deployment in diverse and challenging settings.

Following collection, the images were annotated using RoboFlow, which facilitates precise and efficient object labeling within images. The images will be split into three parts for training, testing, and validation, with 70%, 15%, and 15% respectively. This division is based on research that suggests that for datasets between 100 and one million, this is the most ideal splitting method [25]. To enhance the model’s capacity for generalization and improve its detection accuracy, the dataset was augmented by introducing an 'unknown' class comprising pills that were either similar to or different from the target medications but commonly encountered in the region. Additionally, negative samples, consisting of images devoid of any pills, were incorporated to train the model to recognize scenarios absent of relevant objects, a critical step for minimizing false positives in real-world applications.

C. Testing and Evaluation Methods

The pill detection application was thoroughly evaluated to test the effectiveness of the YOLO models and the GPT-4 OCR integration. The evaluation involved using various quantitative metrics to gain valuable insights into the system's performance. The confusion matrix was utilized to examine true positive, false positive, false negative, and true negative predictions for each type of detected pill, providing a comprehensive overview of classification performance as well as a visual depiction of the model's accuracy and misclassifications. Accuracy was calculated to determine the proportion of correct predictions out of all predictions made, which is crucial for evaluating the overall effectiveness of the detection system.

$$Accuracy = \frac{(TP + TN)}{(TP + TN + FP + FN)} \tag{1}$$

Precision, which measures the exactness of the detection, ensures that the model doesn't produce a high number of false positives. It measures the proportion of true positive (TP) instances among those that the model predicts as positive.

$$Precision = \frac{TP}{(TP + FP)} \tag{2}$$

Recall, also known as sensitivity, evaluates the model's ability to properly identify every relevant instance. This metric is particularly crucial when it's important to capture as many true positives as possible, such as in medical applications where missing a relevant pill type could have significant consequences.

$$Recall = \frac{TP}{(TP + FN)} \tag{3}$$

The F1-score, which balances precision and recall, is particularly useful in scenarios with uneven class distribution and provides insights into the model’s robustness when dealing with various pill types.

$$F1 = \frac{2 \times (precision \times recall)}{(precision + recall)} \tag{4}$$

The mean average precision (mAP) was utilized to examine the precision of the bounding boxes generated by the YOLO models across different types of tablets. This metric offers a comprehensive perspective on the model's performance in locating and accurately identifying pills in an image. This set of metrics provides a comprehensive evaluation framework that measures individual aspects of model performance and ensures the system's reliability and effectiveness in a real-world application setting, confirming the system's suitability for practical deployment in the healthcare sector.

IV. Results And Discussion

A. Results

The evaluation process in this study is conducted in two stages: first for the YOLOv8 detection model, and then for the entire application with YOLOv8 and GPT-4 for imprint extraction.

Evaluate the YOLOv8 detection model: to evaluate our pill detection model, we employed several standard YOLO evaluation metrics. The main metric we used was the mAP, which assesses both precision and recall across various classes by averaging the mAP scores. We utilized a confusion matrix, as depicted in Fig. 3, to compute the accuracy, precision, recall, and F1 score. The confusion matrix enables us to determine the accuracy, precision, recall, and F1 score for each class, and the corresponding values are presented in Table I.

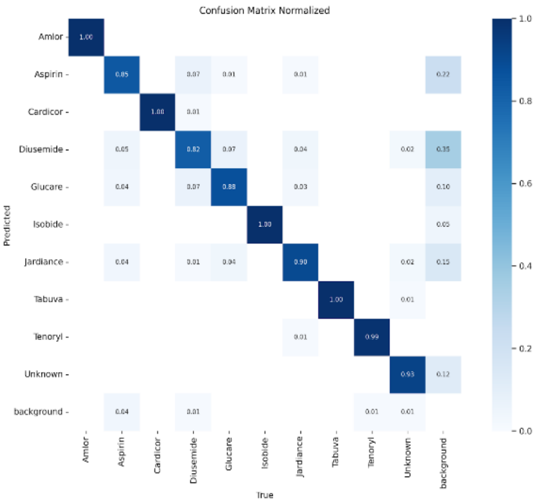


Fig. 3. YOLOv8 normalized confusion matrix.

TABLE I. ACCURACY, PRECISION, RECALL, AND F1-SCORE FOR EACH CLASS

	Accuracy	Precision	Recall	F1-score
Amlor	1	1.0	1.0	1.0
Aspirin	0.956	0.73	0.83	0.78
Cardicor	0.999	0.99	1.0	0.99
Diusemide	0.936	0.61	0.83	0.70
Glucare	0.967	0.79	0.88	0.83
Isobide	0.995	0.95	1.0	0.97
Jardiance	0.972	0.78	0.90	0.84
Tabuva	0.999	0.99	1.0	0.99
Tenoryl	0.998	0.99	0.99	0.99
Unknown	0.988	0.89	0.99	0.94

The efficacy of the YOLOv8 model is evaluated and illustrated across a variety of performance metrics, each represented in comprehensive graphical form. Fig. 4 showcases the Precision-Recall Curve, highlighting the model's exceptional capability to achieve a balance between precision and recall. As shown in Table I. Amlor stands out with perfect scores of 1.0 in both metrics, exemplifying flawless detection capabilities. Similarly, Cardicor, Isobide, Tabuva, and Tenoryl demonstrate near-perfect performances, affirming their high detection accuracy with precision and recall rates of 0.99 or higher.

The analysis continues with the Precision-Confidence Curve and F1-Confidence Curve, depicted in Fig. 5 and Fig. 6 respectively. These graphs reveal precision and F1-scores across different classes, highlighting areas for improvement and strengths. Aspirin, for example, shows a precision of 0.73 and an F1-score of 0.78, suggesting a need to minimize false positives. Conversely, Glucare and Jardiance perform robustly, with precision scores of 0.79 and 0.78 and F1-scores of 0.83 and 0.84, showcasing reliable detection and classification at varied confidence levels.

Fig. 7 shows the Recall-Confidence Curve, further illustrating the model's effectiveness in identifying true positives. High recall rates are maintained across most classes, with notable achievements from Glucare and Jardiance, who reach recalls of 0.88 and 0.90, ensuring comprehensive detection of relevant objects.

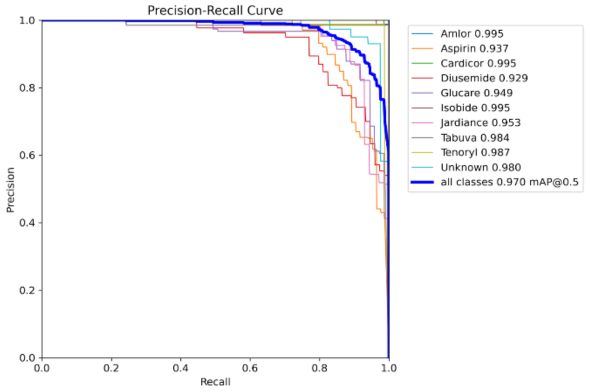

Fig. 4. YOLOv8 model precision-recall curve.

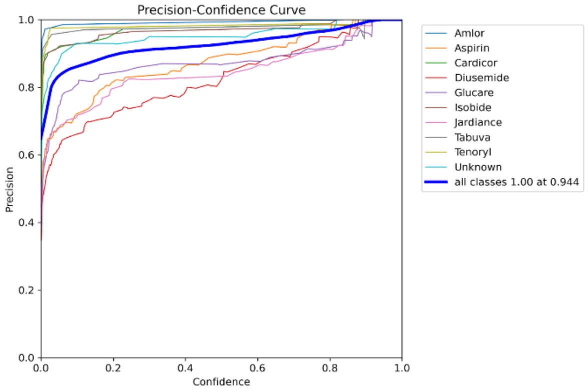

Fig. 5. YOLOv8 model precision-confidence curve.

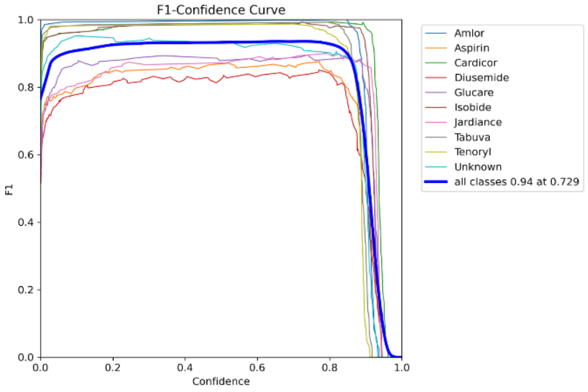

Fig. 6. YOLOv8 model f1-confidence curve.

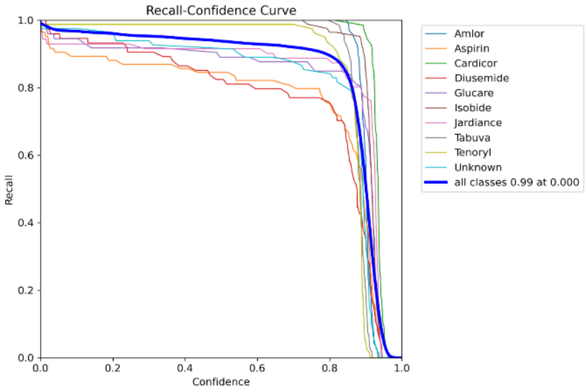

Fig. 7. YOLOv8 model recall-confidence curve.

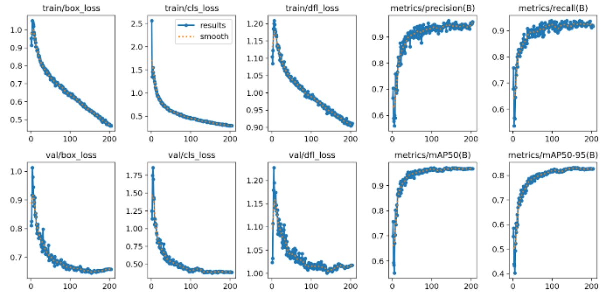

Fig. 8. Training and validation losses of YOLOv8 model.

Lastly, Fig. 8 presents the Training and Validation Loss Curves, providing insights into the model's learning dynamics over time. These curves demonstrate a consistent decrease in training and validation losses, including Train/Box_Loss, Train/Cls_Loss, and Train/Dfl_Loss, as well as Val/Box_Loss, Val/Cls_Loss, and Val/Dfl_Loss. This indicates an improvement in the model's ability to predict bounding boxes, classify objects correctly, and estimate attributes such as distance and focal length, confirming effective learning and generalization to new, unseen data.

Furthermore, we measure the mAP on both the validation and test datasets. We attained a mAP of 97% on the validation dataset at a threshold of 0.5, which is a remarkable achievement. Also, we measured the mAP of the test dataset, we attained a mAP of 96.3% with a threshold of 0.5 on the test dataset. This result is compared to a related study [8] that focused on detecting pills using YOLOv5 whereas the achieved accuracy was 85.6%. Our pill detection model demonstrates a significant performance difference, highlighting its robustness and precision compared to the previous study.

It is possible for the mAP percentage to decrease on the test dataset compared to the validation dataset. This is because the model was never exposed to the test dataset during training. According to the predictions in Fig. 9 yolov8 model can identify a single pill with a confidence ranging from 87% to 94%.

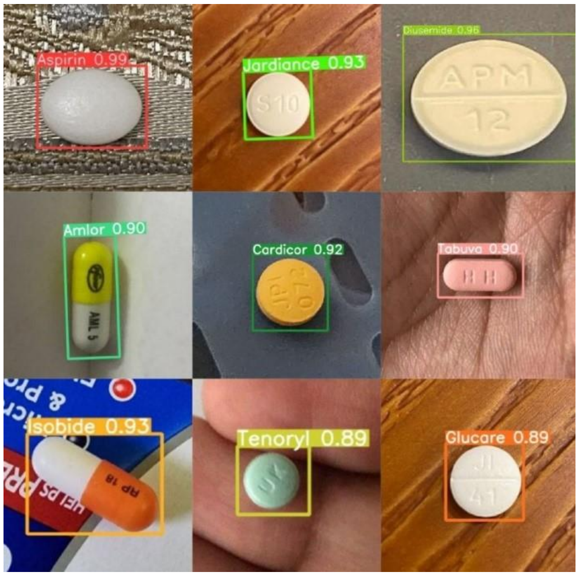

Fig. 9. YOLOv8 model predictions (confidence).

Evaluating the Integration of YOLOv8 and GPT-4: In efforts to improve the precision of the pill identification application, the YOLOv8 model was combined with the GPT-4 API. This integration significantly enhanced the reliability of detection outcomes. The models were tested separately under varying conditions such as different lighting, overlapping pills, and unclear imprints. The YOLOv8 model performed well under these diverse conditions, accurately identifying pills despite these challenges. However, to further improve accuracy and minimize false positives—which are particularly dangerous—the integrated performance of both YOLOv8 and GPT-4 was evaluated.

The GPT-4 API did not perform as well under different lighting conditions and struggled to provide predictions when the imprint or part of it was invisible. To assess the success of this integration, 450 tests were conducted with the application across various pill types in the dataset. The results demonstrated an impressive accuracy rate of 90.89%, indicating a substantial improvement in the application's ability to identify pills accurately. This comprehensive evaluation confirmed the integration's effectiveness in enhancing the accuracy and reliability of the pill identification application, especially under challenging conditions.

B. *Discussion*

The YOLOv8 model showed excellent performance, with high accuracy, precision, recall, and F1-scores across most classes. The mAP scores on validation and test datasets confirm its effectiveness. Classes like Amlor, Cardicor, Isobide, Tabuva, and Tenoryl achieved near-perfect detection, though Aspirin and Diusemide had higher false positives.

The precision-recall curves, confidence metrics, and loss curves highlight the model's strengths and areas for improvement. The consistent decrease in training and validation losses indicates effective learning and generalization.

Integrating YOLOv8 with the GPT-4 API improved overall accuracy, combining robust detection with enhanced imprint extraction. However, the GPT-4 API's performance depends on image quality and orientation, affecting reliability with poor images.

Compared to existing pill recognition systems, our approach is unique in integrating YOLOv8 and GPT-4. While most systems rely on either advanced image detection models or OCR technologies independently, our combination leverages the strengths of both. This integration allows our system to handle a broader range of identification challenges, enhancing overall accuracy and reliability, especially in distinguishing pills with similar appearances but different imprints.

A notable limitation of this study is the dependency of the GPT-4 API on image clarity. For the GPT-4 API to function properly, the images need to be clear and well-oriented. Poor quality images can lead to unreliable predictions, affecting the overall accuracy of the system.

V. Conclusion and Future Work

As the aging population grows, the likelihood of medication errors increases, particularly among older individuals who often rely on multiple medications for chronic conditions. Recognizing this challenge, we developed a novel application designed to mitigate the risk of such errors by facilitating accurate pill identification through imaging technology. This application leverages a YOLOv8 model trained on a meticulously created dataset, in conjunction with GPT-4 for enhanced text extraction capabilities. Insights were garnered from interviews with 11 pharmacists and 15 older individuals, highlighting the difficulties pharmacists face in identifying pills based solely on their appearance, given the necessity to recall each pill's specific codes, shapes, colors, and sizes. This task is compounded by the fact that identical medications produced by different manufacturers may vary significantly in appearance, underscoring the need for a robust and precise pill classification system. The effectiveness of this system was demonstrated by achieving a mAP of 90.89%, validating the application's capability in accurately detecting and classifying pills. While the results are promising, there is still potential for further improvements.

Future enhancements include extending language options beyond English and Arabic to increase global accessibility, enriching the dataset with a more varied collection of pill images to boost the model's robustness, refining the text extraction feature to handle challenging imaging conditions, and expanding availability to iOS and Windows platforms. These advancements will further the development of our application, making it a more versatile and reliable tool for preventing medication errors among the elderly. Additionally, future work should focus on better image preprocessing and expanding the dataset to include more pill types for improved generalization. The integration of YOLOv8 and GPT-4 has shown significant potential for enhancing medication management, especially for older individuals and those with limited English proficiency. Continued refinement of these technologies can further reduce medication errors and improve patient outcomes. The planned improvements and ongoing testing will continue to refine the system, aiming for broader adoption and increased efficacy in the real world.

Acknowledgment

The authors would like to express their appreciation to the pharmacists and elderly individuals for taking part in the interviews. The valuable knowledge and insights contributed by these participants were crucial to the success of the project. Special thanks are also extended to a pharmacist who served as a primary source of information and aided in gathering the pills for the dataset.

Educational Enhancement Through Augmented Reality Simulation: A Bibliometric Analysis

Zuhaili Mohd Arshad[1], Mohamed Nor Azhari Azman[2]*, Olzhas Kenzhaliyev[3], Farid R. Kassimov[4]
Faculty of Technical and Vocational, Universiti Pendidikan Sultan Idris, Perak, Malaysia[1, 2]
Head of Commercialization Sector, Kazakh-British Technical University, Almaty, Kazakhstan[3]
I.V. Panfilov, Kazakh-Russian Specialized School-Lyceum, Almaty, Kazakhstan[4]

***Abstract*—Augmented Reality (AR) has become a key technology in the education sector, offering interactive learning experiences that improve student engagement and understanding. Despite its increasing use, a thorough summary of AR research in educational environments is still required. This study applies bibliometric analysis to identify trends in this research field. Data from the Scopus database and VOSviewer software version 1.6.19 was used to analyze academic publications from 2018 to 2023. The original dataset of 4858 articles was narrowed down to 1109 articles concentrating on "augmented reality" AND "simulation" in student learning. Methods such as advanced data mining, co-citation analysis, and network visualization were utilized to outline the structure and trends in this research area. Key findings include a significant rise in research activity over the past decade, identification of the ten most prolific authors in AR simulation studies, and detailed visualizations of information distribution. Significant challenges include high costs and difficulties in technical integration. The study addresses these issues through interdisciplinary research that combines educational theory with AR technology. Results demonstrate growing interest in AR applications, particularly within STEM education, driven by technological advancements and increased funding. Despite these challenges, the potential of AR to enhance learning outcomes is clear. This research concludes that AR simulations can be a valuable educational tool, with further studies needed to explore the scalability of AR applications in various educational settings and to develop evidence-based guidelines for effective integration.**

Keyword—Augmented reality; simulation; learning; education

I. Introduction

In the ever-evolving landscape of education, the integration of emerging technologies holds immense promise for revolutionizing pedagogical approaches. Among these technologies, augmented reality (AR) has emerged as a powerful tool with the potential to enhance learning experiences across various domains. The use of augmented reality (AR) in education represents a significant transition from conventional teaching methods to a new era characterized by extremely interactive and captivating learning experiences [1]–[4]. AR presents a reality-like world with additional information which can be used to view objects in virtual or real-world environments.

The use of augmented reality (AR) allows students to interactively engage with three-dimensional models [5]-[7], historical re-enactments [8], [9], and sophisticated scientific phenomena [10] in real-time by seamlessly integrating digital overlays with the physical environment. This immersive method converts previously abstract or intricate information into concrete and easily understandable experiences, greatly improving understanding and involvement. The adaptability of AR extends across a wide range of disciplines, providing distinct advantages in each one. Medical students can utilize augmented reality (AR) simulations to engage in virtual surgical practice, acquiring significant practical experience without the inherent dangers associated with real-life surgeries [11]–[14]. Engineering students have the opportunity to analyze and engage with intricate machinery or infrastructures, which allows them to develop a more profound comprehension of design principles and spatial relationships [15]–[17]. Meanwhile, students studying history and archaeology can explore historical civilizations and locations in three dimensions, acquiring profound insights and a heightened sense of immersion that cannot be achieved through conventional textbook learning. These cutting-edge tools accommodate diverse learning styles, greatly enhancing motivation, involvement, and knowledge retention by transforming learning into a more dynamic and customized experience.

In addition, augmented reality simulations in educational settings go beyond simple visual engagement [18]–[20]. They provide a multi-sensory experience that replicates real-life situations, allowing learners to safely explore, experiment, and learn from their mistakes without facing real-world repercussions. AR simulations allow learners to refine their abilities in a controlled setting, bolstering their self-assurance and proficiency prior to employing them in real-life scenarios. Nevertheless, the incorporation of augmented reality (AR) into educational systems presents several obstacles, such as the substantial expenses linked to AR technology, the need for comprehensive infrastructure, and the demanding process for educators to effectively integrate AR into their teaching approaches. Despite these challenges, the future of augmented reality (AR) in education looks promising, driven by ongoing progress in technology that is enhancing the accessibility and user-friendliness of AR . With the decreasing cost of AR devices and the advancement of standardised AR educational content, the use of AR in educational settings is expected to grow, establishing its position as an essential element of modern educational tactics [21], [22]. Augmented reality has the exceptional ability to enhance learning by making it more immersive, personalised, and effective. It is poised to overcome current obstacles and significantly enhance the educational environment. This technology represents a new era of learning that connects theoretical knowledge with practical application.

By leveraging advanced bibliometric methods, this research provides new insights into how AR is shaping the future of education.

In contrast to earlier studies that mostly focused on individual case studies or specialized applications of AR, this research systematically examines a broad range of academic publications using advanced data mining, co-citation analysis, and network visualization techniques. The study identifies significant trends, key authors, and the most cited works, providing a holistic view of the current state of AR research in education. Additionally, it highlights the interdisciplinary nature of AR applications, demonstrating their impact across various fields such as STEM education, medical training, and engineering. This comprehensive approach allows for a deeper understanding of how AR simulations is being integrated into educational practices.

II. Literature Review

Research has demonstrated that AR simulations enhance student engagement, motivation, and knowledge retention [23], [24] where students using AR are more interested in their lessons and more likely to stay focused. The interactive nature of AR makes learning activities more enjoyable, which increases motivation. By superimposing digital information onto the physical world, AR creates an immersive learning environment [25], [26]. This allows students to interact with virtual objects and scenarios in a more intuitive and captivating way. AR simulations have proven effective across diverse fields such as science, engineering, health, and social sciences. For instance, in medical education, AR is used to teach students about anatomy and physiology, enabling them to engage with virtual organs and systems in an authentic and immersive manner [27], [28]. This can help in visualizing complex physiological processes, such as blood circulation and neural pathways, making them easier to understand. In engineering education, AR is employed to teach principles such as mechanical systems and circuit design [29]–[31], allowing students to interact with virtual models and observe their real-time behavior [32], [33].

Despite the significant advantages of AR simulations, various challenges and constraints need to be addressed. A key challenge is the creation of high-quality AR content that is both engaging and educational. This requires proficiency in AR design and development, as well as a deep understanding of the subject matter [34]. Another challenge is the cost and accessibility of AR technology. While the cost of AR technology has decreased in recent years, developing high-quality AR content still demands a substantial financial investment. Researchers have explored the use of open-source AR development tools and platforms, such as ARKit and ARCore, to help reduce these costs. To optimize the educational benefits of AR simulations, researchers have developed various pedagogical approaches and design principles. For example, the "AR-based learning cycle" suggests that AR simulations should be designed to promote active learning, problem-solving, and critical thinking. Additionally, researchers have identified specific design principles to ensure the educational effectiveness of AR simulations, including realism, interactivity, personalization, and feedback.

By adhering to these principles, educators can create engaging and interactive AR simulations that foster active learning and critical thinking. As AR technology continues to advance, AR simulations are likely to become increasingly important tools for educators across various fields. By utilizing AR simulations, educators can create innovative and engaging learning experiences that help students develop a deeper understanding of the subject matter, equipping them with the skills and knowledge needed to succeed in their future careers. This approach aligns with [35], who advocate for integrating AR in teacher training, particularly for simulation and modeling in science education, underscoring AR's capacity to elevate digital competencies among future educators. The study in [36] highlight the perceptual challenges posed by blending virtual and physical content in AR environments, emphasizing the need to address these incongruities for a seamless learning experience.

Innovative approaches to AR simulations in medical and robotics education are presented by [37] and [38]. [37] describe an AR-based technique for visualizing brain deformations during surgical procedures, while [38] explore AR's role in mobile robotics, emphasizing its educational value in understanding autonomous systems. The research in [39] expands the application of AR beyond medical and scientific realms into interior design, illustrating AR's versatility in enhancing visualization and communication between designers and clients. The reviewed studies collectively underscore AR's potential to revolutionize educational and training paradigms across disciplines.

III. Research Question

This paper attempts to respond to six (6) primary research questions.

RQ 1: What are the research trends in augmented reality simulation according to the year of publication?

RQ 2: Who are the top ten most active authors in ar simulation publications?

RQ 3: What are the most cited articles by subject of research?

RQ 4: What is the map of Co-Authorship?

RQ 5: What are the popular keywords related to the study?

RQ 6: What are co-authorship countries' collaboration on the use of AR simulation in education?

IV. Methodology

Bibliometrics involves the collection, organisation, and analysis of bibliographic data from scientific publications [40]–[42]. In addition to basic descriptive statistics like publishing journals, publication year, and major author categorization [43], the analysis also includes advanced approaches such as document co-citation analysis. To do a successful literature review, one must engage in an iterative process that includes identifying relevant keywords, conducting a literature search, and thoroughly analysing the gathered information to create a full bibliography and obtain reliable outcomes [44]. The study aimed to concentrate on top-tier papers since they provide significant insights into the theoretical views influencing the development of the research field. The study utilised the SCOPUS database for data gathering to assure data dependability [45]–[47]. Only articles from rigorously peer-reviewed academic journals were evaluated to ensure high-quality publications. Books and lecture notes were deliberately excluded [48]. Elsevier's Scopus, renowned for its comprehensive coverage, gathered publications from 2018 to December 2023 for analysis.

A. Data Search Strategy

Study employed a screening sequence to determine the search terms for article retrieval. As shown in Table I, this study was initiated by querying Scopus database with online Augmented Reality Simulation for Educational Enhancement (“augmented reality”) AND (simulation) thereby assembling 4858 articles. Afterwards, the query string was revised so that the search terms “augmented reality” AND “simulation” should be focussed on students as learners. Refinement included 1109 articles which was used for bibliometric analysis as shown in Table II. As of February 2024, all articles from Scopus database relating augmented reality and simulation in learning, were incorporated in the study.

TABLE I. THE SEARCH STRING

Database	Search String
Scopus	TITLE-ABS-KEY ("Augmented Reality" AND simulat* AND (education OR learn* OR teach*)) AND (LIMIT-TO (PUBYEAR , 2018) OR LIMIT-TO (PUBYEAR , 2019) OR LIMIT-TO (PUBYEAR , 2020) OR LIMIT-TO (PUBYEAR , 2021) OR LIMIT-TO (PUBYEAR , 2022) OR LIMIT-TO (PUBYEAR , 2023))

TABLE II. THE SELECTION CRITERION IN SEARCHING

Criterion	Inclusion	Exclusion
Language	English	Non-English
Time line	2018 – 2023	< 2018
Document Type	Article	Non-Article
Literature type	Journal	Book, Review, Proceeding

B. Data Analysis

The data sets containing information about the study's publication year, title, author, journal, citations, and keywords in plain text format were acquired from the Scopus database, covering the period from 2018 to December 2023. These data sets were analyzed using the VOSviewer software version 1.6.19. This software was utilized for analysis and map formation, employing the VOS clustering and mapping techniques. VOSviewer is an alternative to the Multidimensional Scaling (MDS) approach, and it is similar to MDS in its aim of placing items in a low-dimensional space in such a way that the relatedness and similarity between any two items are accurately reflected by the distance between them. Unlike MDS, which focuses on computing similarity measures like Jaccard indexes and cosine, VOSviewer implements a more suitable technique for normalizing co-occurrence frequencies, such as the association strength (ASij), calculated as:

$$AS_{ij} = \frac{C_{ij}}{w_i \times w_j}$$

Where;

- AS$_{ij}$ represents the association strength between items i and j
- C_{ij} is the number of co-occurrences of items i and j
- W_i is the weight or total number of occurrences of item i
- W_j is the weight or total number of occurrences of item j

This association strength is proportional to the ratio between the observed number of co-occurrences of i and j and the expected number of co-occurrences of i and j, assuming that their co-occurrences are statistically independent. By using this index, VOSviewer places items on a map after reducing the weighted sum of the squared distances between all item pairs. According to Appio et al. (2016), the LinLog/modularity normalization was implemented. Furthermore, by applying visualization techniques through VOSviewer to the data set, patterns based on mathematical relationships were uncovered, and analyses such as keyword co-occurrence, citation analysis, and co-citation analysis were performed. Keyword co-occurrence analysis helps explore the development of a research area during a specific period and is successful in identifying popular topics in different fields. Citation analysis is useful in identifying key research issues, trends, and techniques, as well as exploring the historical relevance of a discipline's main area of focus. Document co-citation analysis is one of the frequently applied bibliometric methods and its result is a map dependent on network theory to identify the relevant structure of the data.

V. RESULT AND FINDING

The study of the extracted research on scholarly classification covers various aspects, including the types of documents and sources, annual growth trends, languages of the documents, subject areas, keyword analysis, country-level productivity, authorship patterns, and citation analysis. The findings of this paper are predominantly presented through frequency distributions, percentages, graphical representations, and visualization maps.

A. RQ 1: What are the Research Trends in Augmented Reality Simulation According to the Year of Publication?

Fig. 1 below presents the research trends in augmented reality simulations, highlighting the number of publications per year. The trend analysis offers insights into the growing attention augmented reality simulations have received in the academic community, reflecting the advancements and increasing focus on this technology in educational research.

The line graph shows a clear and consistent upward trend in the number of publications related to Augmented Reality (AR) for educational enhancement, with a slight acceleration in the last two years (2022 and 2023). Here are some possible factors that may have influenced this trend. As AR technology has become more affordable, accessible, and user-friendly, it has attracted increasing interest from researchers and educators who are exploring its potential applications in education. There is a growing body of research that suggests that AR can be an effective tool for enhancing learning and engagement in a variety of educational settings. This growing awareness is likely driving more researchers to explore the potential of AR in education. Governments and private organizations are increasingly investing in AR research, including research on the use of AR in education. This increased funding is likely to provide more resources for researchers to study and develop AR-based educational tools.

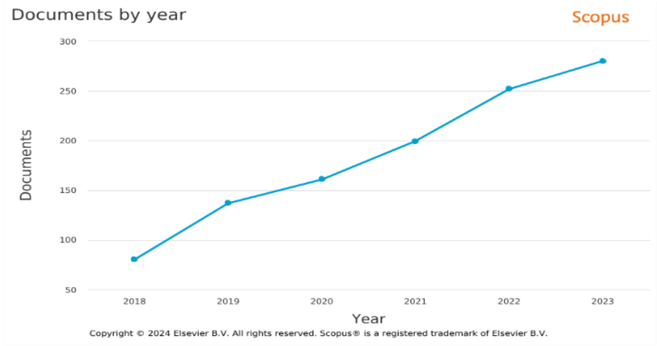

Fig. 1. Plotting of document publication by years.

There is a growing emphasis on using technology to personalize learning and create more engaging learning experiences. AR aligns well with these priorities, as it can provide students with individualized and interactive learning experiences. The increasing number of publications on AR for educational enhancement suggests that this is a growing field with a lot of potential. Some potential implications of this trend include the development of new and more effective AR-based educational tools. As more researchers study the use of AR in education, we are likely to see the development of more effective and engaging AR-based learning tools. The wider adoption of AR in classrooms. As AR-based educational tools become more available and affordable, we are likely to see them being adopted in more classrooms around the world. Changes in teaching practices. The use of AR in education may lead to changes in teaching practices, as teachers adapt their methods to take advantage of the new affordances offered by AR.

RQ 1: What are the Research Trends in Augmented Reality Simulation According to the Year of Publication?

RQ 2: Who are the Top Ten Most Active Authors in AR Simulation Publications?

The top ten most prolific authors in the field of Augmented Reality (AR) for educational enhancement are listed in Table III, with their respective number of publications ranging from four to seven. This ranking highlights the significant contributions made by these researchers, who have consistently produced valuable scholarly works that advance our understanding and application of AR technologies in educational contexts.

The list of top publication authors highlights key contributors to the field of augmented reality (AR) simulations in education. Ferrari, V., leading with seven publications, is central in pioneering research and developing methodologies within this domain. Ferrari's work likely spans technical innovations in AR software and hardware, as well as practical applications for immersive learning environments. The consistent presence of Ferrari, V. underscores a significant impact on both theoretical and practical aspects of AR in education. Condino, S., with six publications, is another prominent figure, focusing on integrating AR technologies into specific educational settings like medical or engineering training. Condino's contributions likely include evaluating AR simulations' effectiveness in enhancing learning outcomes, student engagement, and retention. The efforts of other authors such as Cutolo, F., Hanalioglu, S., and Tai, Y., contribute to a dynamic and interdisciplinary field. These scholars' diverse expertise covers the design, implementation, and assessment of AR simulations in education. Their research addresses challenges and opportunities in user interface design, content development, and curriculum integration. Collectively, these authors are advancing how educational content is delivered, paving the way for future innovations in the educational landscape. In conclusion, the leading authors in "Augmented Reality Simulation for Educational Enhancement," particularly Ferrari, V. and Condino, S., are driving a transformative movement in education. Their diverse research topics and innovative approaches are crucial in leveraging AR's potential to revolutionize learning. As the field evolves, their contributions will serve as essential references, fostering further integration of AR in education to create more engaging, effective, and immersive learning environments.

B. RQ 3: What are the Most Cited Articles by Subject of Research?RQ 1: What are the Research Trends in Augmented Reality Simulation According to the Year of Publication?

Table IV showcasing the 10 most cited articles in the field of augmented reality (AR) for educational enhancement, as analyzed through Scopus, provides a comprehensive overview of the current state and impactful trends within this interdisciplinary domain.

TABLE III. THE TOP TEN MOST ACTIVE AUTHORS

Author Name	Number of Publication	Percentage (%)
Ferrari, V.	7	1.74
Condino, S.	6	1.49
Cutolo, F.	5	1.24
Hanalioglu, S.	5	1.24
Tai, Y.	5	1.24

The leading article by Yu X. et al. (2019) in Nature, with 557 citations, explores "Skin-integrated wireless haptic interfaces for virtual [49] and augmented reality", highlighting the cutting-edge integration of sensory feedback mechanisms into AR systems. This work underscores the evolution of AR technologies towards more immersive and tactilely engaging experiences, which can significantly enhance the realism and effectiveness of educational simulations. Following closely is the systematic review by Ibáñez M.-B and Delgado-Kloos C. (2018) in Computers and Education, cited 493 times, which delves into "Augmented reality for STEM learning". This article synthesizes research findings on the application of AR in Science, Technology, Engineering, and Mathematics education, providing a critical assessment of AR's educational benefits, challenges, and future directions. The high citation count reflects the growing interest and recognition of AR's potential to transform traditional learning paradigms by making complex concepts more accessible and engaging through visualization and interaction. Shi L. et al.'s (2021) publication in Nature, "Towards real-time photorealistic 3D holography with deep neural networks", with 255 citations, represents a significant technological advancement in rendering lifelike 3D holograms. This leap forward in holography, powered by deep learning, has profound implications for educational content delivery, enabling students to explore and interact with high-fidelity simulations of physical phenomena, historical reconstructions, and intricate biological structures in real-time, thereby deepening understanding and retention. Moreover, the diverse range of topics covered by the other highly cited articles, from Ge J. et al.'s (2019) exploration of "A bimodal soft electronic skin" in Nature Communications to the practical applications of AR in surgical training and Industry 4.0 simulations, illustrates the broad applicability and transformative potential of AR in various educational contexts. These studies collectively highlight the multifaceted benefits of AR in enhancing educational outcomes, including increased engagement, improved understanding of complex subjects, and the provision of hands-on experiential learning opportunities without the constraints of physical materials or environments.

C. *RQ 4: What are the Map of Co-Authorship about AR Simulation?*

The data shown in Fig. 2, created using the Vosviewer analyzer, illustrates the bibliometric connections of co-authorship in the field of Augmented Reality Simulation for Educational Enhancement. The analysis seems to focus on the co-authorship network, revealing how many documents each set of authors has worked on together, the number of citations their work has received, and the total link strength between them.

tu c.-h.; lu e.h.-c.
nagayo y.; saito t.; oyama h.
VOSviewer

Fig. 2. Network visualization map of co-authorship.

Starting with the authors Balcita R.E. and Palaoag T.D., they have co-authored two documents that have accumulated a total of 8 citations. However, the total link strength is zero, which could imply that their collaborative work, while cited, is not central to the network of co-authorships being analyzed. Similarly, the teams of Barros V., Oliveira E., and Araújo L., as well as Brady C., Vogelstein L., Jen T., and Dim E., each have produced 2 documents, but these have not yet been cited. Cao

Y. also has two documents to their name with no citations and no link strength, indicating that their work is yet to gain traction in the field. Chandan K., Albertson J., and Zhang S., with the same number of documents, have received a single citation, again with no link strength. Chen X. and Liu G. stand out with their work being cited 78 times, suggesting that their research is highly recognized in the academic community, even though their link strength remains at zero. Cowling M. and Birt J. have also made a notable impact, with their 2 documents receiving 29 citations. The group of Diniz F., Duarte N., Amaral A., and Pereira C. has garnered 4 citations from their pair of documents. El Kabtane H., El Adnani M., Sadgal M., and Mourdi Y. have a slightly larger body of work, with 3 documents receiving 25 citations, indicating a significant contribution to the field. Other author groups, such as Grodotzki J., Müller B.T., and Tekkaya A.E., as well as Majgaard G. and Weitze C., have works that have been acknowledged 5 times in academic citations. The pairings of Nagayo Y., Saito T., Oyama H., and Solmaz S., Van Gerven T., have each received 19 citations for their 2 documents, suggesting their research is of considerable interest.

Nishi K., Fujibuchi T., and Yoshinaga T. have 3 documents with 20 citations, which indicates a productive collaboration. Planey J., Rajarathinam R.J., Mercier E., Lindgren R., and Zhou R., despite having authored 2 documents together, have not yet seen citations, indicating either recent publication or a delay in recognition. Russell D. and Kuensting L.L. have a modest citation count of 1 for their 2 documents, showing initial engagement with their work. Tornari C., Tedla M., and Surda P., as well as Tu C.-H and Lu E.H.-C., and the group of Wang L., Du W., Chu S., Shi M., and Li J., have authored 2 documents each but have not yet received citations, which suggests potential for future academic impact. Overall, the analysis reveals a diverse range of collaborations with varying degrees of recognition and impact within the scholarly community. The absence of total link strength across the board indicates that these connections might not be central within the larger network of co-authorships in this research domain, or it may reflect a limitation in the dataset or methodology used for this specific analysis.

D. RQ 5: What are the Popular Keywords Related to the Study?

The data shown in Fig. 3, created using the Vosviewer analyzer, illustrates the bibliometric connections of co-authorship in the field of Augmented Reality Simulation for Educational Enhancement. The analysis seems to focus on the co-authorship network, revealing how many documents each set of authors has worked on together, the number of citations their work has received, and the total link strength between them.

The bibliometric analysis illuminates the extensive influence of augmented reality (AR) simulations on educational enhancement. The preeminent keyword "augmented reality" exhibits 671 occurrences and a substantial total link strength of 1238, signifying its centrality. Closely related terms like "mixed reality" (98 occurrences, 265 link strength), "extended reality" (41 occurrences, 129 link strength), and "augmented reality (ar)" (41 occurrences, 68 link strength) solidify the interconnectivity within this domain. The prominence of keywords such as "education" (108 occurrences, 274 link strength), "medical education" (48 occurrences, 139 link strength), "educational innovation" (11 occurrences, 32 link strength), and "educational technology" (9 occurrences, 22 link strength) highlights the profound impact of AR simulations on educational applications across diverse disciplines. Notably, the data underscores the significant emphasis on simulation and training applications, particularly in medical and surgical domains, with keywords like "simulation" (145 occurrences, 357 link strength), "training" (55 occurrences, 144 link strength), "simulation training" (19 occurrences, 35 link strength), and "surgical training" (22 occurrences, 54 link strength) exhibiting high frequencies and link strengths.

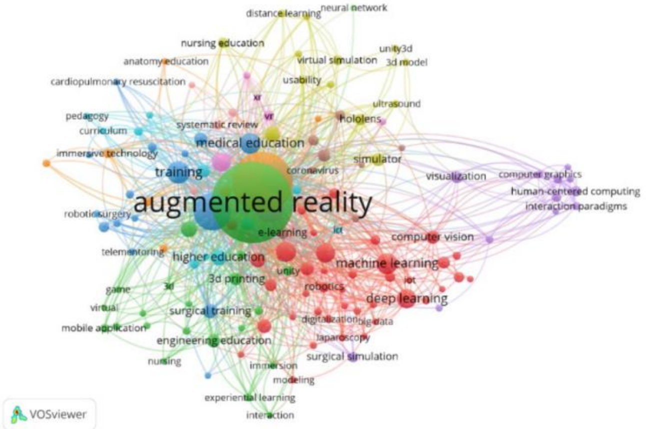

Fig. 3. Network visualization map of keywords' co-occurrence.

The analysis reveals strong connections between AR simulations and emerging technologies, including "artificial intelligence" (46 occurrences, 130 link strength), "machine learning" (47 occurrences, 109 link strength), "deep learning" (40 occurrences, 67 link strength), and "industry 4.0" (21 occurrences, 27 link strength), suggesting the potential for integrating cutting-edge technologies to enhance AR simulations' capabilities in educational contexts. Furthermore, the data highlights specific application areas exploring AR simulations for educational purposes, such as "neurosurgery" (20 occurrences, 54 link strength), "nursing education" (12 occurrences, 37 link strength), "dental education" (13 occurrences, 24 link strength), and "laparoscopy" (7 occurrences, 19 link strength). In summary, this bibliometric analysis accentuates the pivotal role of AR simulations in driving educational innovation and transformation across various domains, including medical and engineering such as electronics learning. The interdisciplinary nature of this research area, spanning educational applications and emerging technologies, underscores its vast potential for further exploration and development.

E. RQ 6: What are Co-Authorship Countries' Collaboration on the use of AR Simulation in Education?

Fig. 4 illustrates the co-authorship countries' collaboration on the use of AR simulation in education. Co-authorship analysis is the relatedness of items is determined based on the number of co-authored documents. The network visualization depicts international research collaborations centered on utilizing augmented reality (AR) simulations for educational purposes. Multiple nations are interconnected, with line thickness indicating collaboration intensity. The United States emerged as a prominent hub, exhibiting numerous connections with other countries. This observation aligns with the provided data, where the United States holds the highest document count (346) and total link strength (143). The network visualization depicts international research collaborations centered on utilizing augmented reality (AR) simulations for educational purposes. Multiple nations are interconnected, with line thickness indicating collaboration intensity. The United States emerged as a prominent hub, exhibiting numerous connections with other countries.

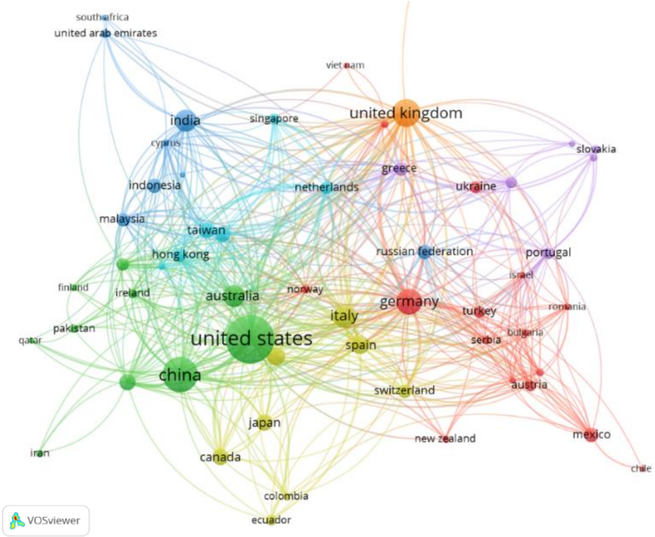

Fig. 4. The co-authorship countries' collaboration on the use of AR simulation in education.

This observation aligns with the provided data, where the United States holds the highest document count (346) and total link strength (143). The United Kingdom also stands out as a major collaborator, ranking second in document output (115) and total link strength (134). Several European nations like Germany, Italy, Spain, and the Netherlands exhibit strong collaboration ties within the region and globally. Germany and China follow as significant contributors, with 99 and 180 documents, respectively, alongside substantial link strengths of 119 and 101. Asian countries like China, India, South Korea, Taiwan, and Hong Kong demonstrate robust regional cooperation in this research domain. Certain nations with relatively fewer documents still maintain substantial collaboration links, exemplified by Cyprus (8 documents, 43 link strength) and Morocco (7 documents, 22 link strength). The analysis unveils a globally distributed research network focused on AR simulation for education, facilitated by regional clusters and international partnerships spanning multiple continents. The United States, United Kingdom, China, and Germany emerge as prominent hubs driving collaborative efforts in this field.

VI. Discussion and Conclusion

A. Main Findings of the Study

The bibliometric analysis conducted reveals significant trends and developments in the use of Augmented Reality (AR) simulations in education between 2018 and 2023. During this period, there was a noticeable increase in research activity, indicating a growing interest in the transformative potential of AR technology in educational practices. The analysis highlighted frequent keywords such as "simulation," "training," and "education," reflecting AR's broad applicability across various fields. Additionally, leading authors and highly cited articles were identified, showcasing key contributors who have significantly influenced the field.

B. Comparison with Other Studies

Unlike previous studies that focused primarily on specific applications or case studies of AR, this research provides a comprehensive overview of academic publications through advanced data mining, co-citation analysis, and network visualization techniques. This study extends those findings by illustrating the interdisciplinary nature of AR applications and their impacts across various fields like STEM [50], medical training, and engineering. The analysis also emphasizes the importance of international collaboration, with major contributions from countries like the United States, the United Kingdom, and China.

C. Implication and Explanation of Findings

The findings suggest that AR technology is particularly beneficial in fields requiring practical, hands-on experience. By allowing interaction with complex systems and scenarios in a controlled environment, AR helps transform theoretical concepts into tangible learning experiences. This capability makes AR an essential tool for modern education. Advancements in AR hardware and software, along with increased funding, have driven the rising interest in this technology. The study also highlights the growing trend of interdisciplinary research, blending educational theory with AR technology to enhance learning outcomes.

D. Strengths and Limitations

The strength of this study lies in its comprehensive approach, utilizing advanced bibliometric methods to provide a holistic view of AR research in education. However, there are limitations, including the focus on articles indexed in the Scopus database, which might exclude relevant studies from other databases. Additionally, the analysis is limited to publications up to 2023, potentially missing emerging trends beyond this period.

E. Conclusion

AR simulations represent a significant advancement in educational technology, offering unique opportunities to improve learning outcomes through immersive and interactive experiences. Despite challenges such as high costs, the need for extensive infrastructure, and the requirement for educators to adapt to new teaching methods, the benefits of AR in education are evident. AR's ability to transform abstract concepts into tangible experiences and provide safe, practical training scenarios is unparalleled.

VII. Suggestion for Future Research

Interest in integrating learning strategies with Augmented Reality (AR) technology in education is rapidly increasing. Consequently, it is crucial for researchers to meticulously plan and design well-structured teaching and learning components before implementing the technology in educational settings.

These components should address several key elements: (1) a comprehensive understanding of students' needs, (2) clearly defined learning objectives, (3) appropriate forms of support such as necessary equipment and resources, and (4) the identification and application of learning strategies that best match the specific needs of the students. Moreover, it is important to explore the potential of AR technology to enhance the learning process. This exploration involves determining whether AR can significantly improve students' skills and deepen their understanding of complex and abstract concepts. Additionally, more studies are needed to examine the long-term effects of AR on learning outcomes and to develop standardized AR educational content that can be widely adopted across various educational institutions. Such an investigation is essential to provide a more comprehensive and engaging learning experience that fulfills the diverse educational requirements of students.

ACKNOWLEDGMENT

The authors wish to thank the Universiti Pendidikan Sultan Idris (UPSI) for supporting and funding this research.

Precision Construction of Salary Prediction System Based on Deep Neural Network

Yuping Wang*, MingYan Bai, Changjiang Liao
Southern Power Grid Digital Enterprise Technology (Guangdong) Co., Ltd, GuangZhou, 510000 China

***Abstract*—Currently, most recruitment websites use keyword search or job nature classification to filter the salary information that job seekers are most concerned about. Job seekers need to spend much time and effort to understand the salary range of their desired position. In order to help job seekers quickly and accurately understand the salary of their desired position and market value, Word2vec model and latent Dirichlet allocation model are used to obtain topic features, which are used as the basis for the salary prediction model. The study uses deep neural networks and adaptive moment estimation algorithms to construct the salary prediction model. Based on the constructed salary prediction model, the final salary prediction system is constructed based on a browser/server model. The results showed that on the training set, the maximum accuracy of the salary prediction model was 96.71%, the minimum was 93.75%, and the average was 95.07%. The mean absolute percentage error and mean square error of this model were 5.661% and 0.3462, respectively. The maximum average response time of the salary prediction system was 134.2s, the minimum was 2.02s, and the maximum throughput was 1500000byte/s. The salary prediction model has good performance, which can provide technical support for salary prediction.**

Keywords—Deep neural network; Adam; salary; prediction; system

I. Introduction

Employment is the foundation of people's lives, social stability, and economic development. People can obtain economic income, improve their living standards, and realize their self-worth through employment [1-2]. However, due to insufficient industry knowledge among many job seekers and an excessive number of unemployed individuals, the current employment situation in China is not ideal. Salary is a key consideration for job seekers. With the development of Internet technology, there are many recruitment websites around the world. These recruitment websites are not limited by time and space, with low recruitment costs, extensive information, etc. [3-4]. In fact, excessive, repetitive, and false recruitment information requires job seekers to spend more time and effort understanding the salary range of their desired positions. Therefore, designing a salary prediction model and system is of great significance. The commonly used methods for constructing salary prediction models include Doc2vec algorithm, Support Vector Machine (SVM), random forest, Ridge regression, k-means clustering algorithm, etc. [5].

To predict the salary level of graduates, Kuo J Y et al. constructed a salary prediction model on the basis of deep learning. The stacked denoising auto-encoder was applied to train the model. The method could accurately predict the salary level of graduates [6]. Grmez Y et al. designed a prediction system based on deep learning and a corresponding performance rating scale to predict wage growth. The system had significant advantages in prediction accuracy and time consumption [7]. James O et al. built a neural network method to predict worker wages. The model was trained on data from 35 common job skills. The prediction accuracy exceeded 70%, with good performance [8]. Lombu A S et al. designed a classification model based on SVM. The Python programming language was used to predict individual wages. The accuracy was 87%, which exceeded the K-nearest neighbor model [9].

However, these methods also have certain shortcomings, such as the sensitivity of SVM to parameter selection, high computational complexity, and the difficulty in selecting regularization coefficients for Ridge regression. In order to accurately predict the salary of desired positions for users, the Deep Neural Network (DNN) is used in the study, and the Adaptive Moment Estimation (Adam) is also introduced to improve the training effect of DNN. The final salary prediction model is constructed. In addition, the study also utilizes technologies such as browser/server mode and Linux server to construct a salary prediction system. The research aims to predict job compensation, help job seekers understand their market value, and enhance industry awareness. The innovation of the research is reflected in the combination of DNN and Adam, as well as the Word2vec model and the Latent Dirichlet Allocation (LDA) model. The contribution of the research is to predict the salary of ideal positions for users, promoting job seekers' understanding of the salary for desired positions, and facilitating salary negotiations for seekers during the job search process.

The research is divided into five sections. Section II constructs a DNN-based salary prediction system, involving the design of functional modules for the salary prediction model and the overall design of the salary prediction system. Section III is the performance validation of the salary prediction model and salary prediction system, including prediction accuracy, convergence speed, concurrent test results, and throughput comparison. Section IV is the discussion, which includes personal insights and opinions. Section V is the conclusion, which includes the important results, shortcomings, and prospects of this research.

II. Construction of DNN-based Salary Prediction System

In order to build a salary prediction system and help users understand the salary of the desired position, DNN algorithm is adopted in the study, and Adam algorithm is used to improve the training effect of DNN. The study also uses Word2vec and LDA models to obtain topic features, laying the foundation for the salary prediction model. In addition, technologies such as browser/server mode and Linux server are utilized to construct the final salary prediction system.

A. *Design of DNN Salary Prediction Model Based on Adam Optimization*

To predict the salary of desired positions, the Word2vec model and LDA model are used to achieve text clustering and topic feature construction in the study. Afterwards, the study uses DNN and Adam algorithms to construct the final salary prediction model (Adam-DNN). The web crawler technology is used to capture job information from third-party recruitment software, which is divided into structured and unstructured types. Among them, structured job information includes salary ranges, work locations, and educational requirements. To ensure the salary prediction accuracy, the raw data is preprocessed, including removing duplicate values, and handling missing values and outliers. To perform topic clustering on job description texts, the LDA is adopted in the study. The LDA topic model explores the topic structure of text through the common features of word items in text information, which has unsupervised learning, strong flexibility, and interpretability [10-11]. However, the LDA ignores the syntax and order of the document, and the weight scores between the generated topic keywords are relatively close, making it difficult to distinguish. In response to this issue, the Word2vec model is used to optimize the LDA. The specific optimization model is shown in Eq. (1).

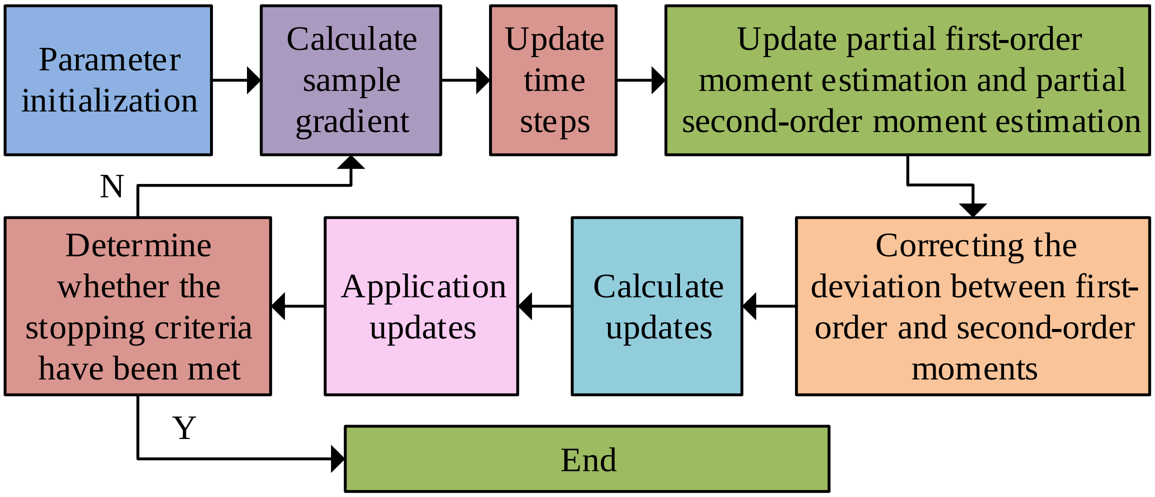
$$new_{original_{score_j}} = \frac{original_{score_j}}{\sum_{j=1}^{M} original_{score_j}} \times \frac{\sum_{i=1}^{M-1} sim\left(\theta_i, \theta_j\right)}{M-1} \tag{1}$$

In Eq. (1), $original_{score_j}$ signifies the weight of the j-th topic word calculated by the original LDA model. $new_{original_{score_j}}$ signifies the weight of the newly defined j-th topic word. M is the number of topic words. θ_i and θ_j represent the i-th and j-th topic words, respectively. $sim\left(\theta_i, \theta_j\right)$ signifies the similarity in the i-th and j-th topic words. Cosine similarity is used to calculate word similarity, as displayed in Eq. (2) [12].

$$sim\left(X, Y\right) = \frac{X \cdot Y}{\|X\|\|Y\|} = \frac{\sum_{i=1}^{M} X_i \cdot Y_i}{\sqrt{\sum_{i=1}^{M}\left(X_i\right)^2}\sqrt{\sum_{i=1}^{M}\left(Y_i\right)^2}} \tag{2}$$

In Eq. (2), X and Y represent different vectors, respectively. X_i and Y_i represent the sub-vectors of X and Y, respectively. Word2vec+LDA topic clustering is used to optimize the model, which can extract topic features from job texts and lay the foundation for the salary prediction model. To construct a salary prediction model, DNN is used in the study, which is optimized by Adam. DNN has stronger non-linear fitting ability, which can demonstrate deep correlation between data. It has been widely applied in the processing and prediction of relevant data in different fields [13-14].

The DNN prediction model mainly includes Input Layer (IL), Hidden Layer (HL), and Output Layer (OL). The HL is at least two. In addition, each link between IL and OL network units is a fully connected chain that can be learned and trained. DNN uses forward and back propagation algorithms during training, which also needs to set hyper-parameters to determine the number of HLs and activation function before training. The forward propagation process involves the input and output of different nodes in HL and OL. The back propagation process involves the total error function, weight correction of HL and OL, and bias correction between HL and OL. In order to reduce the loss function value of DNN, the weights and biases of HL in DNN are updated. Therefore, the study adopts the Adam algorithm to improve the training performance of DNN. The advantage of Adam algorithm is its ability to automatically adjust learning rate, high computational efficiency, and fast convergence speed [15-16]. The steps for optimizing the Adam algorithm are shown in Fig. 1.



Parameter initialization
Calculate sample gradient
Update time steps
Update partial first-order moment estimation and partial second-order moment estimation
Correcting the deviation between first-order and second-order moments
Calculate updates
Application updates
Determine whether the stopping criteria have been met
N
Y
End

Fig. 1. Steps for optimizing Adam algorithm.

From Fig. 1, the first step of the Adam algorithm is parameter initialization. The second is to calculate the sample gradient. The third is to update the time step. The fourth is to update the partial first-order moment estimation and partial second-order moment estimation. The fifth step is to correct the deviation between the first-order and second-order moments. The sixth step is to compute the updated value. The seventh is to apply the updated value. The eighth is to determine whether the stop criterion is met. If the stop criterion is reached, the process ends. Otherwise, it returns to the second step. The activation function used in the prediction model is the Rectified Linear Unit (ReLU) function, and the loss function is the mean squared error function. The prediction process of the Adam-DNN salary prediction model is shown in Fig. 2.

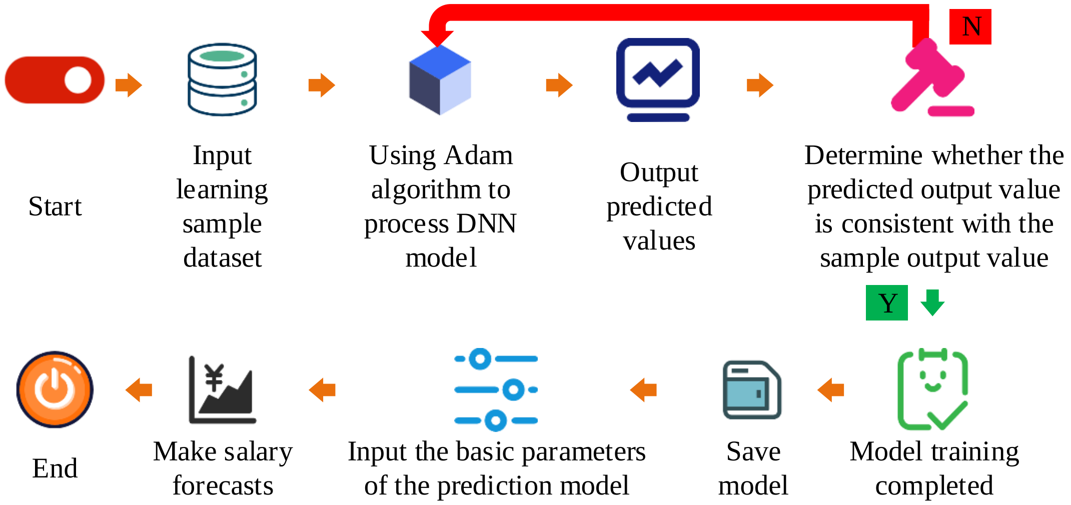
From Fig. 2, the first step of the Adam-DNN salary prediction model is to input the learning sample dataset. The second uses the Adam algorithm to process the DNN model. The third is to output the predicted value, and the fourth is to determine whether the predicted output value is consistent with the sample output value. If it is consistent, the model training ends. Otherwise, it returns to the second. The fifth is to save the model. The sixth is to input the basic parameters of the prediction model. The seventh step is to make a salary prediction.

B. *Construction of Salary Prediction System*

In order to accurately construct the salary prediction system, a DNN-based model is first designed in the study. The DNN-based salary prediction model is the most core functional module in the salary prediction system. To build a salary prediction system, the study adopts browser/server mode, Python Web development technology, My Structured Query Language (MySQL) database, and Linux server. Python Web development technology has strong simplicity, readability, and scalability, which has been widely applied in system scheduling and Web development [17]. The advantages of MySQL database are fast, convenient, and simple [18]. The salary prediction system is shown in Fig. 3.

From Fig. 3, the overall structure of the salary prediction system includes the client, server, Flask application, Redis database, MySQL database, MongoDB database, Nginx proxy server, u Web Server Gateway Interface (uWSGI) process, and response. Before using this prediction model, it is necessary to perform a crawler task and save the obtained data to the MySQL database. In addition, the Crontab command in Linux servers is used to monitor Web crawler operations to ensure that the data obtained by the Web crawler is relatively new. The Crontab command drives the Spider to request job information from the target host and store it in the MongoDB database. The functional structure of the salary prediction system is displayed in Fig. 4.

From Fig. 4, the designed system mainly includes four functions, namely crawler management, model update management, user core function, and user basic function. Crawler management mainly consists of timed crawler tasks, crawler network management, and manual execution tasks. Model update management includes model updates and model version rollback. The primary task of a timed crawler is to select a timed crawler website, enter the scheduled crawler time, and choose to repeat the crawler task or execute it only once. After the primary task, scheduled crawlers need to determine whether the crawler website is available. If available, the crawler task data table is updated, the server Crontab script is refreshed, and the process ends. Otherwise, the process is terminated directly. The crawler process of the salary prediction system mainly has two steps. The first determines whether there are asynchronous requests in the recruitment network. If it is determined to be yes, the request module is used to request the Web interface. Otherwise, the request module is used to request the Web page source code. Then the Beautiful Soup is used to parse the Web page source code. The second step is to obtain information and store it in the database, and then terminate the process. Job search and salary prediction constitute the core functions of users, while the use basic function consists of login registration, personal information management, and password modification. The functional modules of the system are specifically designed. Among them, salary prediction belongs to the user function request, and its corresponding time sequence diagram is shown in Fig. 5.



N
Start
Input learning sample dataset
Using Adam algorithm to process DNN model

Save model
Input the basic parameters of the prediction model
Make salary forecasts
End

Fig. 2. The prediction process of Adam-DNN salary prediction model.

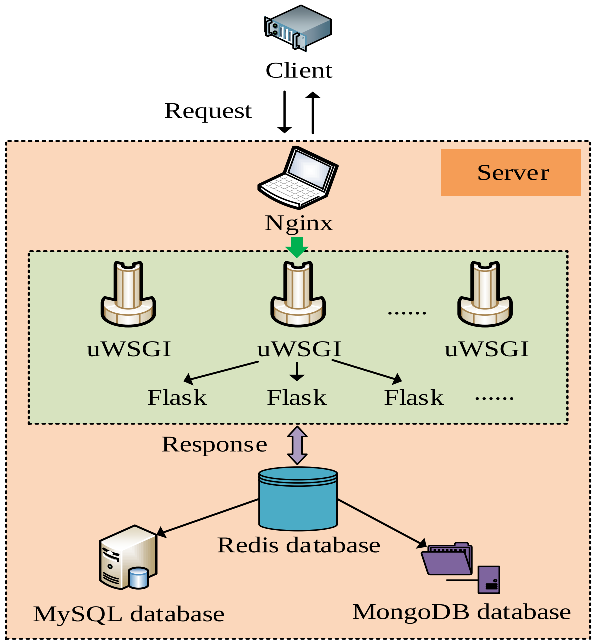

Fig. 3. The overall architecture of the salary prediction system.

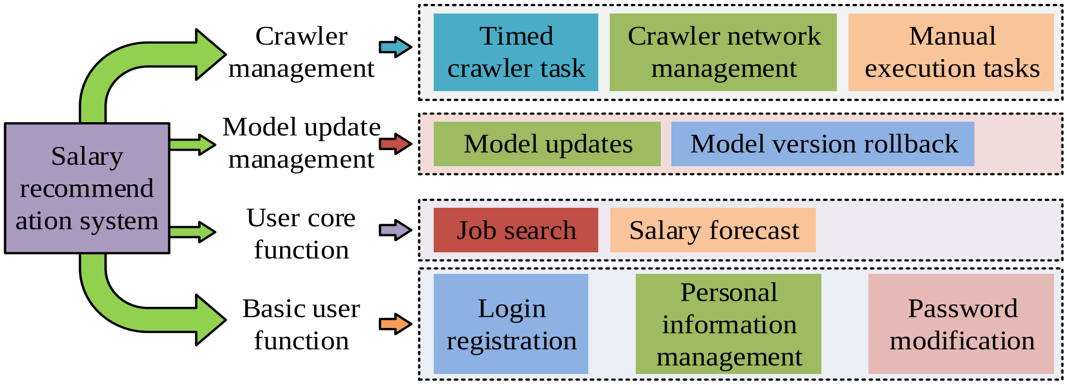

Fig. 4. The functional structure of salary prediction system.

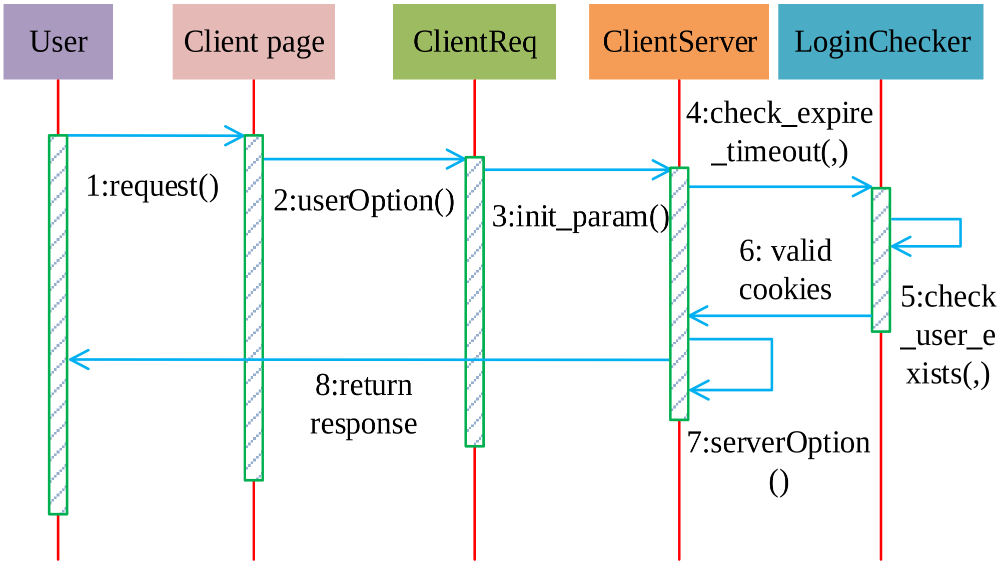

Fig. 5. Sequence diagram of user function request class.

From Fig. 5, the time sequence diagram of the user function request class involves user, Client page, ClientReq objects, ClientServer objects, and LoginChecker objects. The sequence diagram of the user function request class has eight steps. The first step is for the user to submit the parameters required to complete the operation through the request method. The second step provides the submitted parameters through the userOption method. The third step calls the init_param method to initialize the member variables of the ClientServer objects. The fourth step uses the check_expire_timeout method to verify whether the time is within the validity period. The fifth step uses the check_user_exists method to verify whether the user corresponding to the Cookies exists. The sixth step returns valid Cookies information. The seventh step performs server operations corresponding to the serverOption method on the ClientServer objects. The eighth step returns the information that the user operation is successful.

In database design, the records of users browsing positions are stored through the position browsing record table t_log_browse. This record table includes record numbers, position information record numbers, user record numbers, access time, and stay time. Among them, the position information record number is the foreign key of the position information table t_job, while the position information table includes salary, recruiters, company type, company size, and company location.

III. Results

To verify the performance of the designed salary prediction model and system, an experimental environment is set up and comparative methods are selected. In addition, the study also explains and divides the dataset required for the experiment. The performance verification of the salary prediction model includes accuracy, comparison between predicted values and true values, etc. The performance verification of the system involves response time and throughput, etc. Through comparative verification, it can better reflect the performance advantages of the salary prediction model and system designed in the paper, as well as the areas where the salary prediction model and system can be further improved.

A. *Performance Verification of Adam-Dnn Salary Prediction Model*

To validate the performance of the Adam-DNN, Extreme Gradient Boosting (XGBoost), logistic regression algorithm, SVM, and Back Propagation neural network (BP) are selected for comparison. The browser used in the experiment is Google Chrome 122.0.6261.6, with an Intel Core i5-13600KF processor, a maximum Intel Turbo Boost Technology of 5.1GHz, a basic power consumption of 125W, and a maximum memory of 192GB. The operating system is a dual system, which includes Windows 10 (64 bit) and Ubuntu version 20.04. In addition, the experiment uses Alibaba Cloud cloud servers, with a bandwidth of 1Mbps. The HL in DNN is 6. The sample data obtained by the crawler is divided into training and testing sets in a 7:3 ratio, with 300 samples in the testing set and 700 samples in the training set. The comparison of salary prediction accuracy for different models is shown in Fig. 6.

From Fig. 6(a), the maximum accuracy of the Adam-DNN model was 96.71%, the minimum was 93.75%, and the average was 95.07%. The maximum values of XGBoost, logistic regression algorithm, SVM, and BP were 92.13%, 93.42%, 90.68%, and 89.35%, respectively, while the minimum values were 89.47%, 90.31%, 86.98%, and 85.75%, respectively. According to Fig. 6(b), the maximum values of the five models on the testing set were 98.54%, 92.98%, 94.37%, 91.56%, and 90.27%, respectively. The maximum accuracy of the Adam-DNN model was 5.56%, 4.17%, 6.98%, and 8.27% higher than the maximum values of XGBoost, logistic regression algorithm, SVM, and BP, respectively. In summary, the Adam-DNN model has better accuracy and performance in salary prediction. The comparison results between the predicted and true salary values of different models are shown in Fig. 7. Mean Square Error (MSE) and Mean Absolute Percentage Error (MAPE) are taken as evaluation indicators.

(c) The fitting effect of the Logistic regression

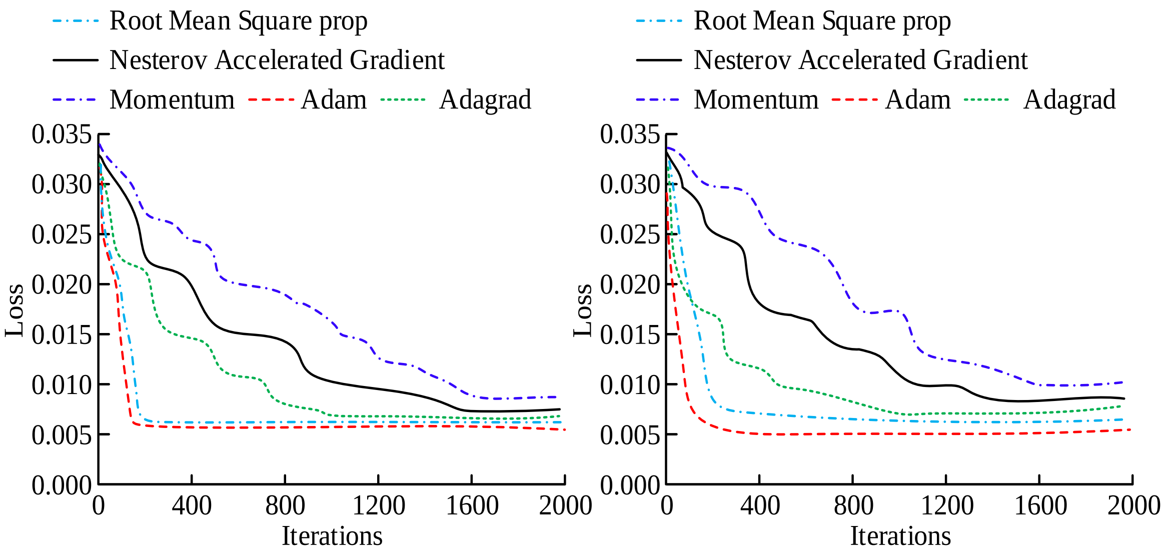
(d) The fitting effect of the SVM

(e) The fitting effect of the BP

Fig. 7. Comparison results between predicted and true salary values of different models.

Fig. 7 (a) to Fig. 7 (e) show the error curves in the predicted and true salary values of the Adam-DNN model, XGBoost, logistic regression algorithm, SVM, and BP, respectively. According to Fig. 7 (a), in most sample data, the predicted values of the Adam-DNN model were consistent with the true values. The MAPE of the Adam-DNN model was 5.661%, and the MSE was 0.3462. From Fig. 7 (b), the MAPE and MSE of XGBoost were 6.283% and 0.4237%, respectively. According to Fig. 7(c), 7 (d), and 7 (e), the MAPE of the logistic regression algorithm, SVM, and BP were 6.139%, 6.482%, and 6.667%, respectively, and the MSE was 0.4067, 0.4442, and 0.4586, respectively. Overall, the Adam-DNN model has better fitting effects, which can predict salary more accurately. The performance comparison of different optimization methods for DNN is shown in Fig. 8.

From Fig. 8 (a), on the training set, the Adam algorithm tended to flatten out after nearly 182 iterations, with a minimum loss value of 0.0052. The Momentum algorithm, Nestrov Accelerated Gradient algorithm, Adagrad algorithm, and Root Mean Square prop algorithm only reached a plateau after nearly 1620, 1540, 1020, and 225 iterations, respectively. According to Fig. 8 (b), on the testing set, the five algorithms iterated nearly 160, 1600, 1490, 1002, and 213 iterations respectively before stabilizing. Therefore, the Adam algorithm has better optimization performance and faster convergence speed. To better validate the performance of the Adam-DNN salary prediction model designed in the paper, other related models are selected for comparison, including natural neighbor classification algorithm, stacking fusion algorithm, and random forest algorithm. The comparison of Area Under the Curve (AUC) values and F1 values for different models is shown in Table I.



(a) On the training set

(b) On the testing set

Fig. 8. Performance comparison of different optimization methods for DNN.

TABLE I. COMPARISON OF AUC AND F1 VALUES FOR DIFFERENT MODELS

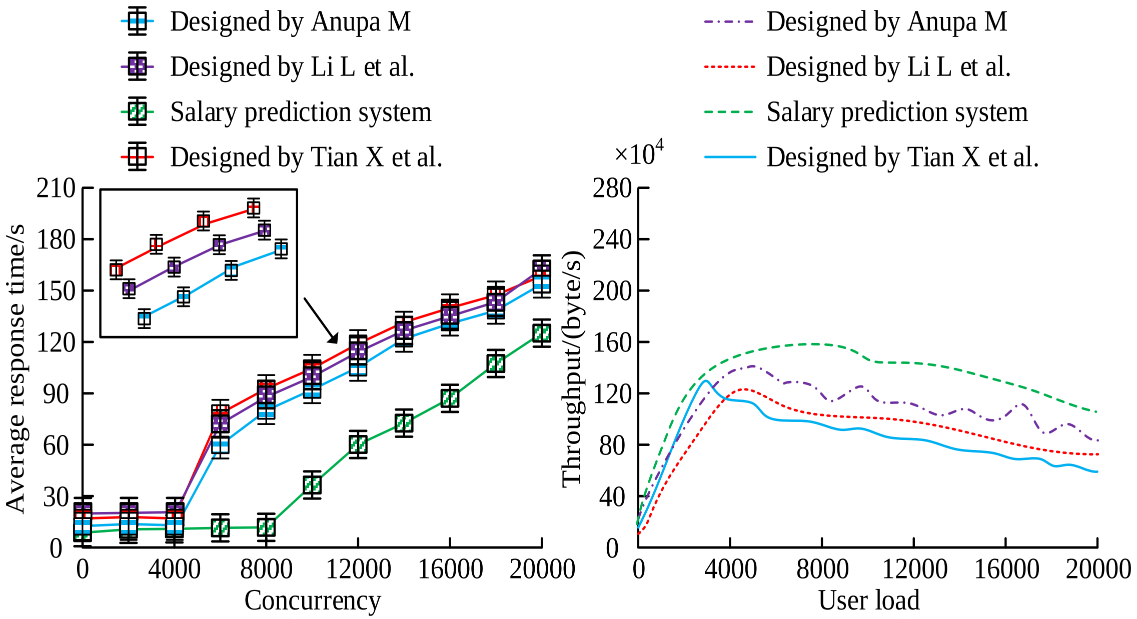
Model	**AUC**					**F1**				
	Number of experiments					**Number of experiments**				
	1	***2***	***3***	***4***	***5***	***1***	***2***	***3***	***4***	***5***
BP	0.904	0.916	0.918	0.904	0.909	0.918	0.922	0.912	0.913	0.917
SVM	0.911	0.927	0.921	0.915	0.924	0.930	0.928	0.927	0.926	0.931
Random forest	0.927	0.938	0.928	0.931	0.938	0.938	0.932	0.929	0.931	0.933
Natural neighbor classification	0.933	0.941	0.939	0.937	0.945	0.942	0.939	0.941	0.935	0.937
XGBoost	0.948	0.950	0.943	0.949	0.953	0.950	0.947	0.943	0.952	0.949
Logistic regression	0.957	0.952	0.948	0.956	0.961	0.952	0.959	0.962	0.957	0.953
Stacking	0.968	0.977	0.976	0.978	0.972	0.975	0.965	0.977	0.964	0.961
Adam-DNN	0.987	0.994	0.997	0.982	0.988	0.987	0.992	0.993	0.989	0.995

From Table I, the average AUC of the Adam-DNN model was 0.9896, which was 0.0794, 0.07, 0.0572, 0.0506, 0.041, 0.0348, and 0.0154 higher than the average values of the other six models, respectively. Furthermore, in terms of F1 value, the Adam-DNN model also scored significantly higher than other comparison models. The average F1 value of the Adam-DNN model was 0.9912, while the average values of the other six models were 0.9164, 0.9284, 0.9326, 0.9388, 0.9482, 0.9566, and 0.9684, respectively. Overall, the Adam-DNN model performs better.

B. Performance Verification of Salary Prediction System Based on DNN

To verify the performance of the designed salary prediction system, the study selects similar systems designed by other researchers for comparison. The comparison systems include the human resources recruitment system with salary prediction function designed by Tian X et al., the human resources information system designed by Anupa M, and the human resources system based on firefly optimization algorithm designed by Li L et al [19-21]. The experimental settings used in the system are consistent with the performance verification of the deigned model. The concurrency test results and throughput comparison of different systems are shown in Fig. 9.

From Fig. 9(a), overall, as the number of concurrency increased, the average response time used by different systems also increased synchronously. After the concurrency exceeded 8000 times, the average response time of the constructed salary prediction system showed a rapid increase. The systems designed by Tian X et al., Anupa M, and Li L et al. showed a rapid increase after exceeding 3300, 4500, and 4300 times, respectively. The maximum average response time of the four systems was 134.2s, 162.7s, 159.5s, and 167.8s, while the minimum values were 2.02s, 16.48s, 14.59s, and 17.86s, respectively. The designed salary prediction system has better performance, and can withstand more concurrency. As shown in Fig. 9(b), as the user load increased, the throughput of all systems first increased and then decreased. The maximum throughput values of the four systems were 1500000byte/s, 1230000byte/s, 1320000byte/s, and 1190000byte/s, respectively, and the corresponding user loads for each system were 8120, 3210, 4380, and 4210. The designed salary prediction system performs better. The comparison of Central Processing Unit (CPU) utilization and memory usage is displayed in Table II.



(a) Comparison of concurrent test results

(b) Comparison of throughput

Fig. 9. Comparison of concurrency test results and throughput of different systems.

TABLE II. COMPARISON OF CPU UTILIZATION AND MEMORY USAGE OF VARIOUS SYSTEMS

System	**CPU utilization/%**					**Memory usage/%**				
	Experiment times					**Experiment times**				
	1	***2***	***3***	***4***	***5***	***1***	***2***	***3***	***4***	***5***
Designed by Tian X et al.	32.71	33.06	33.81	31.54	34.97	35.81	36.42	35.19	35.47	34.76
Designed by Anupa M	25.43	24.19	25.97	26.49	25.14	29.66	30.31	31.72	30.04	29.15
Designed by Li L et al.	28.65	28.08	29.34	29.18	28.46	31.22	31.75	32.29	31.55	33.26
Manuscript	13.27	12.18	12.94	13.53	11.03	15.37	14.08	15.65	15.91	13.77

From Table II, the maximum CPU utilization values for the designed salary prediction system, Tian X et al., Anupa M, and Li L et al. were 13.53%, 34.97%, 26.49%, and 29.34%, respectively, with average values of 12.590%, 33.218%, 25.444%, and 28.742%. In addition, the average memory usage rates of the four systems were 14.956%, 35.530%, 30.176%, and 32.014%, respectively. The average memory usage of the designed salary prediction system was 20.574%, 15.22%, and 17.058% lower than the systems designed by Tian X et al., Anupa M, and Li L et al., respectively. That is, the designed salary prediction system has better performance.

IV. DISCUSSION

To predict the salary range of job seekers' desired positions, an Adam-DNN salary prediction model and system were designed. The results showed that the Adam-DNN salary prediction model designed in the paper had good prediction accuracy, small prediction error, and excellent performance. This is because DNN has stronger non-linear fitting ability, and the Adam algorithm converges faster and has high computational efficiency. Tavares I et al. designed a method based on multi-layer feedforward artificial neural network and a combination of convolutional neural network layer combined with DNN to predict photovoltaic power generation with smaller errors [22]. The salary prediction system designed in the paper has faster response time and maximum throughput, with lower CPU utilization and memory usage. In order to further improve the performance of the salary prediction system, it is recommended that future research adopt architecture technologies with better performance to optimize the overall architecture of the salary prediction system.

V. CONCLUSION

A DNN-based salary prediction model and system were designed for job seekers who want to quickly and accurately understand the salary range of their desired positions. The results showed that on the testing set, the maximum accuracy values of the Adam-DNN model, XGBoost, logistic regression algorithm, SVM, and BP were 98.54%, 92.98%, 94.37%, 91.56%, and 90.27%, respectively. Moreover, the maximum accuracy values of the Adam-DNN model were 5.56%, 4.17%, 6.98%, and 8.27% higher than those of comparison models, respectively. In addition, the MAPE of the five models was 5.661%, 6.283%, 6.139%, 6.482%, and 6.667%, respectively, and the MSE was 0.3462%, 0.4237%, 0.4067%, 0.4442%, and 0.4586%, respectively. The Adam-DNN model had better fitting effects. On the testing set, the Adam algorithm, Momentum algorithm, Nestrov Accelerated Gradient algorithm, Adagrad algorithm, and Root Mean Square prop algorithm iterated nearly 160, 1600, 1490, 1002, and 213 times respectively before becoming smoother, indicating that the optimization effect of Adam algorithm was better. The maximum average response time of the salary prediction system designed in this study, as well as the systems designed by Tian X et al., Anupa M, and Li L et al., were 134.2s, 162.7s, 159.5s, and 167.8s, respectively. The maximum throughput values were 1500000byte/s, 1230000byte/s, 1320000byte/s, and 1190000byte/s, respectively. In addition, the average CPU utilization rates of the four systems were 12.590%, 33.218%, 25.444%, and 28.742%, respectively, and the average memory usage rates were 14.956%, 35.530%, 30.176%, and 32.014%. The performance of the salary prediction model and system is good. However, this study still needs improvement. Firstly, the salary prediction system may also experience long response time when the concurrent quantity is not high. Future research can utilize deep learning algorithms to construct models with higher accuracy. Secondly, the research data is mainly obtained through Web crawling. This method has high complexity, and the amount of data obtained is small, making it difficult to verify the data authenticity, which affects the predictive performance of the model. Future research can analyze data from different recruitment networks, select platforms with relatively good data quality, or use data migration methods.

Department of Cybersecurity, International Information Technology University, Almaty, Kazakhstan[3]

***Abstract*—Research indicates that the utilization of existing symmetric and asymmetric cryptosystems, as well as steganography, fails to ensure the requisite security and reliability in IP networks, where IP PBX Asterisk assumes the role of information transmission facilitator through switching processes. Consequently, this publication undertakes the development and investigation of a four-tiered information protection method when employing various voice codecs in IP networks based on IP PBX Asterisk. The adoption of multi-tiered protection significantly prolongs the cryptanalysis duration for malicious actors, thereby serving as a deterrent to information interception. The primary achievement of this research lies in minimizing the latency incurred during information traversal across the four layers of protection to less than 150 milliseconds, a benchmark widely acknowledged as optimal for assessing voice traffic service quality during transmission. It is noteworthy that a delay parameter of 150 milliseconds in telecommunications networks is pivotal; failure to meet this criterion at the receiving end may result in signal distortion such as jitter, audio degradation, unintelligibility, and other impairments. The devised methodology can be employed in networks transmitting highly classified or business-sensitive information. We contend that the developed encryption enhancement methodology, which prolongs the cryptanalysis duration for malicious entities and the conducted analysis, represents a novel scientific contribution.**

Keywords—Asterisk PBX; IP telephony systems; codecs; data security; Python

I. Introduction

IP PBX Asterisk has become a popular choice for organizations seeking a flexible and cost-effective solution for their telecommunications needs [1-3]. However, the increasing reliance on IP-based communications brings with it new challenges in terms of security and data protection [4-8]. To address these challenges, researchers and developers have focused on improving the security of IP PBX Asterisk systems by implementing advanced security measures [9-14].

Let us consider how IP telephony works. During a conversation, voice signals (the words we speak) are transformed by codecs into compressed data packets, encoded, and transmitted over the Internet to the receiving party. When the data packets reach the recipient, they are decoded back into the original voice signals. Therefore, when building a security system, it is important to be aware of the risks that can arise, which can be presented as follows: distortion of content, due to breach of confidentiality; interception of the passing session; detection of vulnerability in penetrating the organization's network during the deployment of IP telephony; degradation of services based on DoS attacks and resale of traffic, which is one of the convenient ways for hackers to make money by redirecting calls to expensive international destinations when the station is out of order, receiving some reward to their electronic wallets, which, when cashed, turns into real money [15-19].

Unfortunately, such problems have become common lately. As a result, some consider Asterisk an unsafe system. However, this can be disputed if network security is reliably established.

Encryption plays a crucial role in ensuring the confidentiality and integrity of transmitted data [20-24]. The RSA algorithm is commonly used for encryption in IP networks due to its robust security features. Encrypting voice traffic with the RSA algorithm makes it much more difficult for unauthorized users to intercept and decrypt the information, ensuring the confidentiality of communications [25-27].

In addition to encryption, steganography can also be used to increase the security of transmitted information. LSB steganography in particular is well suited to embedding secret messages in voice traffic without significantly impairing the quality of the audio. By using LSB steganography, companies can hide sensitive information in voice traffic, making it difficult for attackers to detect and intercept [28-33].

Authentication is another important aspect of securing IP PBX Asterisk systems. By implementing strong authentication mechanisms, such as two-factor authentication or biometric authentication, organizations can verify the identity of users and devices accessing the system. This helps to prevent unauthorized access and ensures that only authorized users can use the system [34-38].

Finally, traffic analysis techniques can be used to detect and mitigate security threats on IP networks [39-41]. By analyzing patterns and characteristics of network traffic, companies can identify potential security vulnerabilities and take proactive measures to mitigate them. In this way, attacks such as Denial of Service (DoS) attacks or Man-in-the-Middle (MitM) attacks can be prevented.

Although the implementation of these security measures increases the security of IP PBX Asterisk systems, it can also have an impact on reliability. Encryption and steganography in particular can cause additional latency and bandwidth overhead [42-46]. Therefore, it is important to carefully balance security requirements with performance considerations to ensure optimal system performance.

The research in this article is a continuation [47], in which the security of the Asterisk IP network using the TLS protocol was previously discussed. This article proposes a four-level protection method, which is further implemented as an application module in Asterisk to ensure secure data transfer.

II. Methodologies

This article outlines the following IP network research tasks:

1) Construction of a simulation model of the studied IP PBX Asterisk network in the Opnet Modeler environment to determine the total load depending on the codec used.

2) Study of the security of the developed network model.

3) Selecting a traffic protocol when passing through an IP network, when the role of a switching station is performed by IP PBX Asterisk.

4) Development of a four-level security model based on the selected encryption algorithm.

5) Implementation and testing of a four-level encryption model.

III. Results

A. Construction of a Simulation Model of the Studied IP PBX Asterisk Network in the Opnet Modeler Environment to Determine the Total Load Depending on the Codec used

To study a four-level network security model, a telecommunications network diagram was simulated, which is presented in Fig. 1.

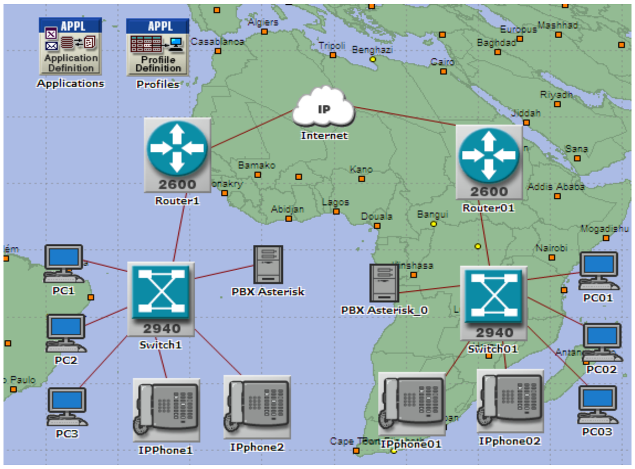

Fig. 1. Diagram of the developed network model using Opnet Modeler.

From Fig. 1 it can be seen that multimedia traffic is transmitted from end nodes consisting of PCs and IP phones using a switch, PBX Asterisk server, and to exit to global network and transmitting it from one local network to another, border router. For communication and simulation in two local area networks, an IP network cloud, the “IP_cloud” object, was taken. The Asterisk PBX server is

configured to serve VoIP traffic.

The developed network model consists of the following devices: IP phones, switches, IP PBX Asterisk servers, routers and IP clouds.

Let's consider the technology of operation of IP phones and conduct a study of the constructed network model shown in Fig. 1.

An IP phone is a device or program that uses Voice over Internet Protocol (VoIP) technology. This technology allows the user to make voice calls over broadband Internet connections rather than the familiar analogue connection.

An IP phone looks like a regular landline phone. The differences lie in the technology of their operation and instead of a pair of copper conductors, VoIP technology uses the Internet to transmit voice calls in the form of data packets.

IP phones use IP packets encoded using codecs to transmit data. IP phones are devices connected to an IP telephony system via a local LAN or the Internet. Please note that analog phones operate on the public telephone network.

By IP address, different gadgets recognize each other and can then transmit data. IP telephony is a telephone connection over the Internet, where telephone numbers are replaced with IP addresses, where it is connected by a provider company that makes calls using special equipment.

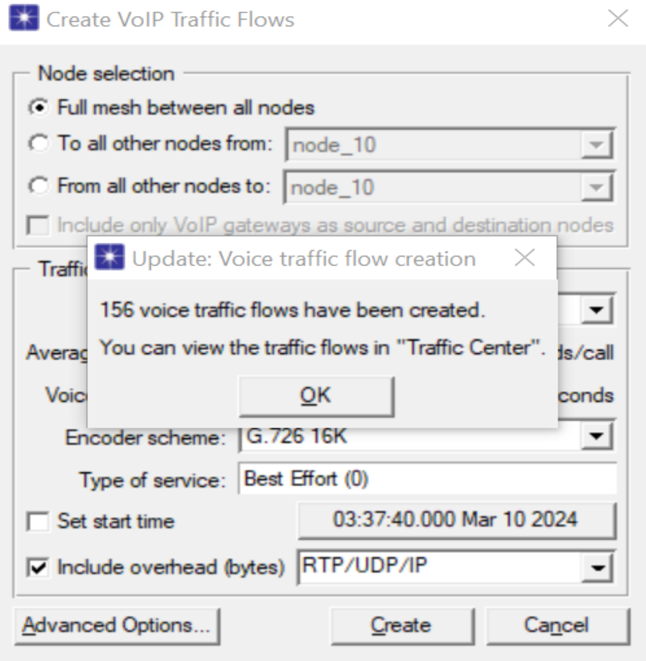
What are the advantages: IP telephony has a large capacity; at any time you can connect more lines while uniting all offices into one network. Typically, long-distance and international calls via IP telephony are two to six times less than those made by city and mobile operators.

It is noted that the IP telephony number is a virtual telephone number, that is, the number is not connected to a wired line or device, the IP telephony number is assigned by the IP telephony service provider and allows you to make and receive calls using any internet-connected device, e.g. softphone.

After purchasing the card, dial the telephone number of the IP telephony gateway, you need to switch the phone to tone mode and then dial the card number, its PIN code and the number of the called subscriber with the country and city code. In this case, we do not need a computer or Internet access.

We will conduct a study of such a network after setting up its equipment and selecting the necessary interfaces between them. To do this, we use the buttons of the Opnet modeler main menu located at the top of Fig. 1 and pass VoIP information through the network and launch the modeling process on the network and look at its statistical results.

Fig. 3 shows a graph that, as a result of the simulation, shows the values of packets passed through the network during the simulated time. It was created as shown in Fig. 2, 156 voice traffic as shown in Fig. 2.



Create VoIP Traffic Flows

Node selection

Update: Voice traffic flow creation

156 voice traffic flows have been created.

You can view the traffic flows in "Traffic Center".

OK

Encoder scheme: G.726 16K

Type of service: Best Effort (0)

□ Set start time 03:37:40.000 Mar 10 2024

☑ Include overhead (bytes) RTP/UDP/IP

Advanced Options... Create Cancel

Fig. 2. Result of generating 156 voice traffic of simulation.

As a result of the simulation experiment, voice traffic is created that forms a total load during the simulation time, for example, with the G726.16k codec shown in Fig. 3.

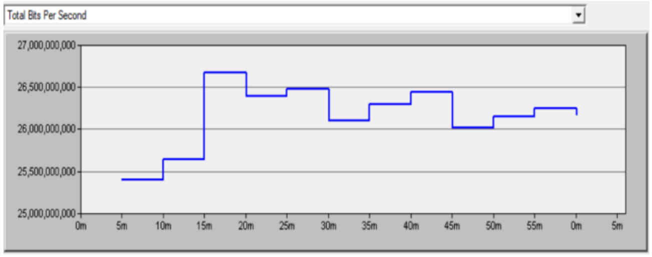

Fig. 3. The result of modeling the traffic passed through the network when the network is operating is based on the G726 codec.

It can be seen from the graph that the total load on the network was more than 26,500,000,000 packets, but the network worked unstably; places in the graph are visible during the model time; as its devices passed through, it increased and then decreased.

This traffic statistics on the network is explained by the fact that various devices, when traffic passed through it, increased or passed fewer packets, and this also depends on what codec is used on the network in IP phones.

For example, when using the G723 codec in IP phones, the number of packets increased to 42,000,000,000, the simulation results are shown in Fig. 4. This is explained by the fact that the number of packets increased due to the fact that the packets became smaller in length, but larger in number and the network worked more stable than with G726.

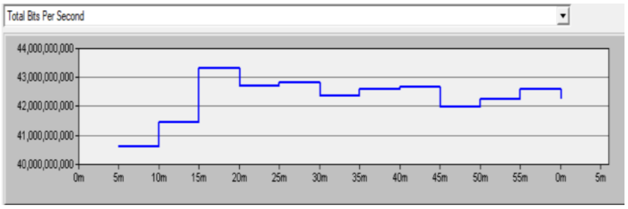

Fig. 4. The result of modeling the traffic passed through the network when network operation based on the G723 codec.

Further research was carried out on the occupied traffic bandwidth depending on the type of voice traffic, the results are shown below in Fig. 5.

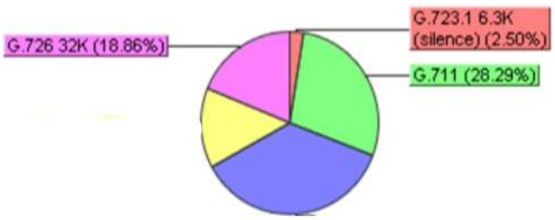

Fig. 5. The result of modeling the traffic passed through the network when network operation.

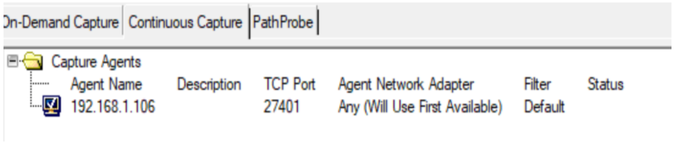
The result of modeling the occupied volume of voice traffic bandwidth when using codecs: G726. G711. G723.

From Fig. 5 it can be seen that the largest bandwidth in the channel is occupied by the G711 codec, then G726 and the smallest bandwidth by the G723 codec. This is explained by the length of the packet that they form to transmit voice traffic through the channel.

B. Security Study of the Developed Network Model

Now, into the network model presented in Fig. 1, we will introduce the hacker's actions by connecting him to the IP PBX Asterisk server.

Taking into account the risks that were presented at the beginning of the publication, we will conduct a study of the security of such a network. To conduct such a study, it is necessary to connect the Wire Shark program with the Opnet modeler program. To connect these programs, let's launch the ACE module from Opnet modeler to capture packets using Wireshark. To do this, we use the Application Capture Manager module and obtain the results of the attack presented in Fig. 6.

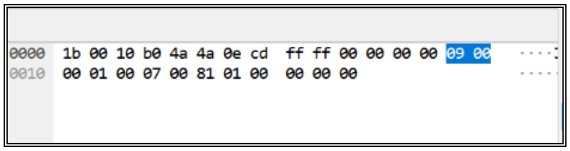


Capture Agents

Agent Name	Description	TCP Port	Agent Network Adapter	Filter	Status
192.168.1.106		27401	Any (Will Use First Available)	Default	

Fig. 6. Result of application capture manager.

By clicking on VoIP traffic and launching Wireshark, a program for capturing packets passing through the network over a certain time, we get the statistics shown in Fig. 6. It is now ready to communicate with Wireshark after it is launched (see Fig. 7).



```
0000  1b 00 10 b0 4a 4a 0e cd  ff ff 00 00 00 00 09 00   ....:
0010  00 01 00 07 00 81 01 00  00 00 00                  .....
```

Fig. 7. Packet capture result.

Lastly, by clicking on statistics in the main menu of the Wireshark program, we select the graph submenu and receive captured packets which are shown in Fig. 8.

Fig. 8 shows that the captured packets passed through in a time period from 0 to 3000 seconds and that the packet sizes are different. Packet capture based on Wireshark shows that the network must be protected so that a hacker cannot obtain packets passing through the network, violating confidentiality and integrity voice traffic transmitted over the network.

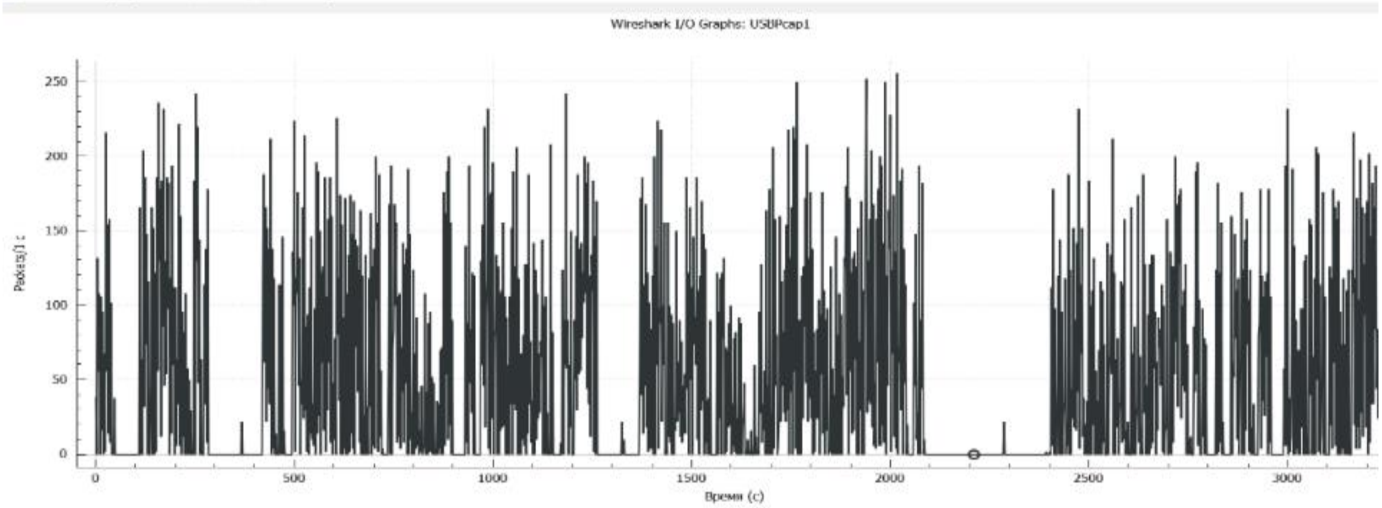


Fig. 8. Packet capture result.

C. *Selecting a Traffic Protocol When Passing Through an IP Network, When the Role of a Switching Station is Performed by IP PBX Acterisk*

Note that among the transport layer protocols UDP and TCP, we prefer the UDP protocol because it is fast. Moreover, the User Datagram Protocol (UDP) is a transport layer network protocol used to establish low-latency and loss-resistant connections between applications on the Internet. It is primarily used for time-critical communications such as DNS (Domain Name System) and Voice over Internet Protocol (VoIP).

In contrast to TCP, which uses handshakes, UDP uses only a minimal number of mechanisms. It provides checksums to ensure the integrity of the data and port numbers to provide other functions and the purpose of the datagram.

The main purpose of UDP is to save time between communication signals, so it uses IP to transfer data from one device to another. It collects data in UDP packets and adds some header information. The data contained in the packet includes destination ports, source, and checksum and packet length.

After the received packets are encapsulated into IP packets, they are sent to the destination based on the packet information. Unlike TCP, which provides feedback, UDP does not send feedback signals to indicate that the packet has reached its destination; instead, it loops the process or stops the sending process.

Unlike TCP, which uses handshakes, UDP uses only a minimal number of mechanisms. It provides checksums to ensure data integrity and port numbers to provide other functions and datagram mappings.

The main purpose of UDP is to save time between communication signals, so it uses IP to transfer data from one device to another. It collects the data in UDP packets and adds some header information. The data contained in the packet includes destination ports, source, and checksum and packet length.

After the received packets are encapsulated into IP packets, they are sent to the destination based on the packet information. Unlike TCP, which provides feedback, UDP does not send feedback signals to indicate that the packet has reached its destination; instead, it performs the process in a loop or stops sending.

UDP Features:

1) Supports connectionless service;

2) Sends packets in large quantities;

3) Mainly used for streaming services and other services such as DNS and NFS;

4) Lack of error control mechanism;

5) No confirmation after sending or receiving package;

6) IP only has inter-process addressing and checksumming built into it;

7) Lack of flow control mechanism;

8) Faster communication than TCP.

As already mentioned, the communication mechanism is ideal for applications such as the Domain Name System (DNS), SNMP, Dynamic Host Configuration Protocol (DHCP) and Routing Information Protocol (RIP).

With this in mind, we choose the UDP protocol for transmitting information over the channel, as the TCP protocol is slow in comparison.

It is known that in the transmission of information over telecommunication networks, an estimation plays a major role - the delay with which the information reaches the receiving end. When transmitting encrypted information, the delays in the channel should not exceed 150 ms. This requirement is fundamental. Therefore, we decided to use the UDP protocol, where the header size of the transmitted packet is 8 bytes, and when using the TCP protocol from 20-80 bytes [44]. In addition, the application area of UDP is: video conferencing, streaming, DNS, VoIP and IPTV.

Protocols are used in tandem to achieve better quality and speed of data transmission and thus the operation of online services. For the transmission of multimedia files, video and audio streaming or streaming, for example, it is better to use UDP technology.

As already mentioned, the communication mechanism is ideal for applications such as Domain Name System (DNS), SNMP, Dynamic Host Configuration Protocol (DHCP) and Routing Information Protocol (RIP). Streaming services also use UDP, as it is generally suitable for video and voice traffic. This is because the use of other protocols such as TCP often results in packet loss in this communication chain, which impairs quality.

D. Analysis and Justification for Ensuring the Security of the Developed Network by Using Multi-level Encryption Technology When Transmitting Information

Note that information security involves practical measures aimed at preventing unauthorized access to stored, processed and transmitted data in networks. In addition, the methods used to ensure it aim to prevent the use, disclosure, falsification, alteration or destruction of data stored on computers, in databases, archives or other storage media.

The main task in creating information security in a company is to protect data, i.e. to ensure its integrity and availability without harming the organization. The information security system is built step by step. Ensuring security is very important when information is transmitted over long distances via different networks. However, we have shown above that if the network is not protected, an attacker can carry out a successful attack and violate the confidentiality, integrity, etc. of the transmitted information.

Therefore, in order to prevent the attacker from accessing the transmitted information, increase the duration of cryptanalysis many times over, for example, by encrypting voice traffic more than once, as usual, and performing encryption in 4 stages.

It is known that even RSA can be hacked to encrypt and decrypt information traversing the network in one layer.

Attackers, for example, had several ways to hack RSA. The most effective attack is to find a private key that matches the required public key.

Another unique application of RSA is to find a method to compute the e-root of mod n. Since C = M^e mod n, the root of degree «e» of «mod n» is the message M. By computing the root, you can open encrypted messages and forge signatures without knowing the private key, etc.

Source in [45] describes the DES and 3DES cryptosystems and others as they depend on the time of cracking. There are many examples where attackers have tried to obtain encrypted information using various cryptanalysis methods. The important factor here was the time available to the attacker.

For an attacker, the time factor is important when hacking; if it is too long, he cannot obtain the desired transmitted information. It was therefore decided to carry out the encryption in four stages. The time for critical analysis increased 4-fold. The algorithm consisted of the fact that the encryption was performed the first time, i.e. the encrypted text was encrypted a second time. Then the encrypted text was encrypted for the second time for the third time, and finally, the encrypted text was encrypted for the third time for the fourth time. It turned out that the first time the encryption was performed was the length of the packet when it was formed according to a codec, for example G723. The success of attacks depends on the time the attacker spends on cryptanalysis. Therefore, this problem can be solved by increasing this time and at the same time using a cryptosystem for encryption that has not yet been modestly tested in its disclosure and retrieval of the key.

The solution to this problem was to increase the cryptanalysis time for the attacker. In this article, the encryption of packets was performed according to the codec found in IP phones based on the AES cryptosystem in the Python programming language. The key length was set to 128 bits. The UDP protocol was chosen for the reasons mentioned above.

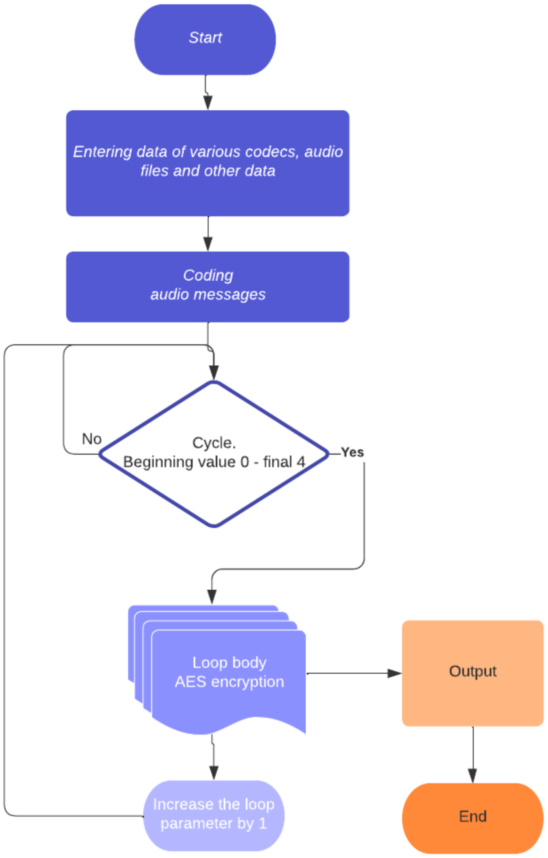
To achieve better quality and speed of data transfer, and, accordingly, the operation of online services, protocols are used in tandem. The block diagram of the program for four levels of encryption is shown in Fig. 9.

The block diagram is built mainly to reflect the four levels of encryption and is very general.

Distribution of encryption time across four levels when operating the G728 codec. Time is located in microseconds on the vertical axis, and different levels are located on the horizontal axis, from the first to the 4th level of encryption in AES in the Python programming language (Fig. 10).

Considering that when encrypting these codecs occurs in a similar way, the experiment of four levels of encryption after codecs G726 G728 and G723 and obtaining the encryption time in microseconds is presented in Table I.

Table I shows that when encrypting information contained in packets of different codecs of the AES cryptosystem on Python, the time from the first encryption level up to and including level 4 changes only slightly.



Start
Entering data of various codecs, audio files and other data
Coding audio messages
No
Cycle. Beginning value 0 - final 4
Yes
Loop body AES encryption
Output
Increase the loop parameter by 1
End

Fig. 9. The block diagram of the four levels of encryption.

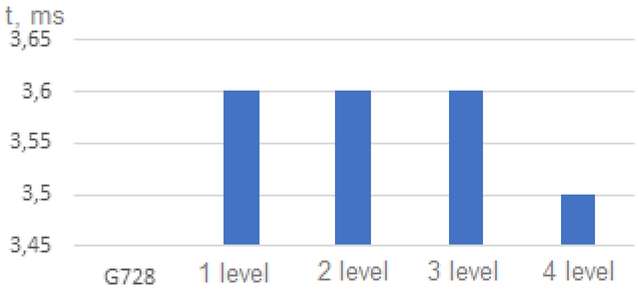


Fig. 10. Encryption time for four levels of G728 codec.

TABLE I. ENCRYPTION TIME FOR THE CODECS IN MICROSECONDS

Levels	Time G726, ms	Time G728, ms	Time G723, ms
1	3,66	3,6	3,67
2	3,62	3,6	3,6
3	3,6	3,6	3,63
4	3,5	3,5	3,4

The encryption time for the G726 codec is only 14.38 ms over four levels, for the G728 codec only 14.3 ms and the G723 codec 14.3 ms.

Decoding the received information takes about the same time. Thus, we conclude that an attacker takes much longer to reveal encrypted information due to the delays in the transmitted encrypted information, so that the information reaches the receiving end while he is busy with cryptanalysis.

The experiment has shown that the encryption and decryption for the G728 codec on four levels is only 14.3 ms x 2 = 28.6 ms, for the G726 codec 14.38 ms x 2 = 28.76 ms and for the G723 ms codec 14.3 ms x 2 = 28.6 ms, as the decryption, i.e. the reverse encryption process, takes the same time as the encryption in Python.

It is known that delays should not exceed 150 milliseconds when transmitting information in a channel. As experiments have shown, when using different speech codecs, the delays achieved on four levels are measured in microseconds.

Therefore, we believe that by increasing the number of encryption levels of the chosen cryptosystem in a programming language and thus increasing the time for cryptanalysis for an attacker, we can achieve a high level of security for IP networks created on the basis of the IP PBX Asterisk used as switches.

The developed technology, in which encryption and decryption is carried out on many levels, is a new technique for increasing the security of IP networks created on the basis of the Asterisk IP PBX, where the encryption and decryption methods were carried out on the basis of the Python programming language4. Discussion Authors should discuss the results and how they can be interpreted from the perspective of previous studies and of the working hypotheses. The findings and their implications should be discussed in the broadest context possible. Future research directions may also be highlighted.

IV. CONCLUSION

The analysis of publications showed that the area of information protection using IP PBX Asterisk has not been fully studied. The article proposes a new protection method based on increasing the number of encryption levels. For this purpose, simulation modeling was carried out on IP network built on IP PBX Asterisk, the Opnet modeler program. For network operation, the UDP protocol is selected for information transmission based on an analysis of sources.

Experiments carried out on a simulation model show that when using various codecs used in IP phones when voice traffic passes, the network operates unstable.

When carrying out an attack on a built network, the hacker captures packets passing through the network, violating its confidentiality and integrity.

An analysis and justification for increasing network security is carried out by developing a new method of protecting IP networks built on IP PBX Asterisk by using multi-level encryption technology when transmitting information.

A new modern method has been developed to increase the security of IP networks built on IP PBX Asterisk by developing multi-level encryption technology of the AES cryptosystem when transmitting information using the Python programming language using G728, G726 and G723 codecs.

The use of four layers of security in a network results in a much longer cryptanalysis time for the hacker, but encryption occurs in a very short time of a few microseconds. Passing through four encryption and decryption stages occurs in a very short time, e.g. 3 to 4 microseconds when operating various codecs, as the recorded diagrams show. It is assumed that the increase in encryption levels supports the parameter for ensuring the operation of IP networks, when the delays in the transmission of information should not exceed 150 milliseconds.

Thus, the newly developed method of multi-level encryption and decryption of information transmitted over the network can be used in the transmission of confidential information and information that needs to be transmitted in a very short time, when the hacker does not have time to intercept the information, since his efforts will take a lot of time.

Unmanned Aerial Vehicles Following Photography Path Planning Technology Based on Kinematic and Adaptive Models

Sa Xiao
Department of Public Information, Zibo Vocational Institute, Zibo 255300, China

***Abstract*—As a representative invention of modern intelligent technology, unmanned aerial vehicles are receiving more and more attention in various fields. However, unmanned aerial vehicles cannot autonomously track path planning based on dynamic changes in conventional path planning. To address the aforementioned issues, this study proposes a path-planning algorithm for unmanned aerial vehicles following photography based on kinematic and adaptive models. A global coordinate system and an aircraft coordinate system are constructed based on the motion relationship between the unmanned aerial vehicles and the tracking target, and the two are converted into a horizontal projection coordinate system to digitize the observed data. On this basis, an adaptive control model is established based on the circular tracking path planning algorithm, and finally, simulation experiments and practical application tests are conducted in combination with the unmanned aerial vehicles following and shooting planning algorithm. The results showed that the best fitness of the proposed algorithm compared with the other two algorithms was 97.56, 93.87, and 92.79, and the path time and average speed of the studied algorithm were 38s and 3.4m/s, which were better than the other two algorithms. In the real machine experiment, there were six circular paths planned by the research algorithm, and the relative distance between the unmanned aerial vehicles and the target was within the range of 200m-600m. The actual trajectory had a high degree of overlap with the model planned trajectory. Research has shown that the proposed algorithm not only stabilizes the illumination angle within an effective range in path planning, but also has high convergence and superior path planning performance in practical applications.**

***Keywords*—Kinematic model; adaptive control; unmanned aerial vehicles; path planning; follow photography**

I. Introduction

A. Research Background

With the continuous development of unmanned aerial vehicles (UAVs) and related industries, the application of UAV functions such as aerial target tracking, aerial broadcasting, and aerial photography in military and civilian fields is becoming increasingly broad [1]. In agriculture, UAVs can perform pesticide and fertilizer spraying, real-time monitoring, etc. [2]. In terms of field rescue, UAVs can replace manual entry into the disaster area to take photos and analyze the disaster and casualties based on the images [3]. In military terms, UAVs can perform more extreme reconnaissance, tracking, and target monitoring tasks [4].

B. Research Status

The operation of traditional UAVs requires flight operators and task operators to perform flight tasks and real-time monitoring tasks separately, which reduces the operational difficulty of operators compared to manned aircraft. However, when UAVs perform specific tasks, the monitoring effect on targets is largely influenced by operators, so it is necessary to enhance the optimization of UAV's Tracking Path Planning (TPP) algorithm for targets [5-6]. Many scholars have conducted in-depth research on the intelligent path planning problem of UAVs, mostly based on the combination of improved swarm optimization algorithms and path planning algorithms. Although the improved algorithm can accelerate convergence speed and compensate for the shortcomings of being prone to local optima, it cannot spontaneously re-plan the tracking path based on dynamic changes when tracking target motion changes. Moreover, it is impossible to guarantee the stability of UAV monitoring and illumination angles during flight [7-9].

C. Research Purpose and Innovation

Based on this background, in order to improve the performance of unmanned aerial vehicle tracking and photography path planning (UAV-T3P), achieve automated control, adapt to real-time data changes, and meet dynamic shooting requirements. Innovatively combining kinematic models with adaptive models based on circular tracking path planning algorithm (CTPPA), building experimental models to verify algorithm performance, and finally verifying the feasibility of the algorithm through simulation performance testing and practical applications.

D. Article Structure

The research content is divided into five sections. Introduction is given in Section I Section II is a review of relevant research findings. Section III are the design, simulation experiment analysis, and actual performance verification of the UAV-T3P algorithm based on kinematic and adaptive models. Results and discussion is given in Section IV and finally, the paper is concludes in Section V.

II. Related Works

Adaptive Control Systems (ACS) and kinematic models are often used in the development of intelligent mechanical systems. Bottrell et al. believed that kinematic data can provide a supplementary basis for identifying merging remnants in galaxy evolution, and distinguished the theoretical utility of merging remnants from other galaxies by analyzing their morphology and kinematic characteristics. They used heterogeneous galaxy clusters and idealized composite images from TNG100 cosmological fluid dynamics simulations, as well as line of sight stellar velocity maps, to calibrate and evaluate the depth classification model. Compared to individual imaging, the combination of imaging and stellar kinematics had a slight improvement in integrity [10]. Li J et al. proposed a Current Sensorless Control Scheme (CSCS) for single-phase uninterruptible power supply inverters under nonlinear loads. By incorporating an adaptive model control method, the load current information was obtained. In the case where the load current was a periodic ideal current, Fourier series simulation of unknown disturbances in the load current was carried out. Moreover, comparative experiments were conducted without the use of current sensors to verify the effectiveness of the adaptive control method in CSCSs [11]. Pang N et al. established a disturbance observer using a neural network when studying the adaptive tracking problem of a class of uncertain nonlinear systems. They utilized a switching threshold triggering mechanism and combined it with backstepping technology to design an adaptive tracking controller. The tracking error converged at an adjustable origin and the closed-loop signal was semi-globally bounded [12]. Yang Y et al. designed a filter-based adaptive control method for under-actuated crane systems with unknown system parameters and nonlinearity. The filter was directly applied to the crane system, causing the system to exhibit nonlinearity during reverse thrust. Then, by using the variable transformation method to reduce the errors of swing angle and position, this scheme has been proven to effectively reduce the tracking error of under-actuated crane systems and converge to any radius [13].

UAVs are increasingly being used in various applications, and their scope of tasks is also expanding [14-16]. Saeed RA et al. discussed the impact of different intelligent algorithms on UAV path planning in complex geographic environments for UAVs. Based on this, a model for improving the optimal path of UAVs with dependent populations was proposed, and performance tests were conducted in different dimensional environments using an improved ant colony optimization algorithm. Evolutionary algorithms could improve convergence speed and further optimize path planning models [17]. Cao Y et al. believed that UAVs are an ideal carrier for sensors and propose a UAV formation path coverage algorithm for aerial photography. This algorithm improved through path coverage and formation control, optimizing the drawbacks of high repetition rate and multiple turns in traditional Probability Road Map (PRM) algorithms. After conducting multiple sets of simulation tests, it has been proven that the algorithm can achieve centralized coverage of aerial photography [18]. Shen K et al. believed that path crossing may lead to UAV collisions during multi UAV flight missions. To address this issue, two collision avoidance Path Planning Algorithms (PPA), namely Separation and Turning, were proposed. This algorithm separated large UAV tasks into multiple small tasks, and multiple UAVs were grouped to fly along the optimized path. Using the proposed algorithm to detect and eliminate potential collision points during flight, the final profit model evaluation showed that the algorithm had superior coverage performance [19]. Puente Castro A et al. proposed the development of a reinforcement learning-based system to calculate the optimal flight path of a UAV group for the calculation problem of multiple optimal planning paths. This method achieved full coverage of path leap regions by repeatedly experimenting and learning self-adjustment models. Due to the limitations of UAV group flight time and map size, using the same control method was more conducive to the execution of field exploration tasks [20]. Finally, the research summarizes the research methods, research results and limitations of the above literature review, as shown in Table I.

TABLE I. LITERATURE SUMMARY TABLE

Authors	Year	Algorithms / Methods Used	Key Results	Limitations
Bottrell C et al. [10]	2022	The morphological and kinematic characteristics of merging relics in distinguishing galaxy merging relics	Combining imaging and stellar kinematics offers a small boost in completeness	The practicality of stellar kinematic data is limited
Li J et al. [11]	2022	A current sensorless control scheme for single-phase uninterruptible power supply inverters under nonlinear loads.	The stability and effectiveness of the system were rigorously analyzed using the Lyapunov method	Suitable for the field of current sensors
Pang N et al. [12]	2022	An adaptive tracking system for uncertain nonlinear systems is designed.	The tracking error is converged and the effectiveness of the method is proved.	The feasibility in UAV system is not verified.
Yang Y et al. [13]	2022	An adaptive control method based on filter is designed.	The tracking error of the driving crane system is significantly reduced.	Suitable for driving crane system control
Saeed R A et al. [17]	2022	A model for improving the trajectory of UAVs dependent on swarm intelligence is proposed.	The algorithm achieves fast convergence and speeds up the path planning process.	The adaptive performance needs to be improved.
Cao Y et al. [18]	2022	Concentrated Coverage Algorithm for UAV Formations Used in Aerial Photography	The algorithm proposed in the paper can achieve centralized coverage of aerial photography	The proposed algorithm has not been tested in the actual scene.
Shen K et al. [19]	2022	DETACH and STEER two collision avoidance path planning algorithms	STEER covers 40% more waypoints than DETACH and generates 20% more profit.	The research sample is limited.
Puente-Castro A et al. [20]	2022	UAV path planning based on reinforcement learning system	It is optimal to establish a single control for each UAV in the cluster.	The flight time of drones is greatly affected by the size of the map

As shown in Table I, although many scholars have made relevant research on kinematic model, adaptive model and UAV-T3P, most of the research on UAV-T3P has not solved the problem that UAV can autonomously plan the path after tracking the dynamic changes of the target, and the kinematic model, adaptive model and UAV-T3P have not been combined at this stage. Therefore, this study constructs the UAV-T3P algorithm based on kinematic and adaptive models, aiming to improve the UAV's aerodynamic capability by combining ACS, and achieve the expected goal of independently completing ground target tracking and monitoring tasks.

III. Design of UAV-T3P Algorithm based on Kinematic and Adaptive Models

This study first establishes a kinematic model of UAV and tracking target, and digitizes the model to better describe and calculate the relationship between the two. Then, CTPPA combined with ACS modeling is used to meet the real-time monitoring requirements of UAV and tracking targets, and finally, combined with UAV-T3P, the Circular Path (CP) switching in the dynamic process is completed.

A. *Kinematic Modeling of UAV Tracking Targets*

UVA generally consists of six parts: aircraft frame, Flight Control System (FCS), propulsion system, imaging equipment, remote control, and signal receiver. The FCS exists inside the UVA fuselage, and the remote control and signal receiver are independent of the fuselage. The structure of the UVA fuselage is Fig. 1.

In Fig. 1, the UVA outer fuselage structure includes the fuselage, influencing equipment, FCS, and landing gear. To better describe the motion relationship between UAV and tracking targets, it is preferred to construct a Global Coordinate System (GCS) and an Aircraft Coordinate System (ACS), as shown in Fig. 2.

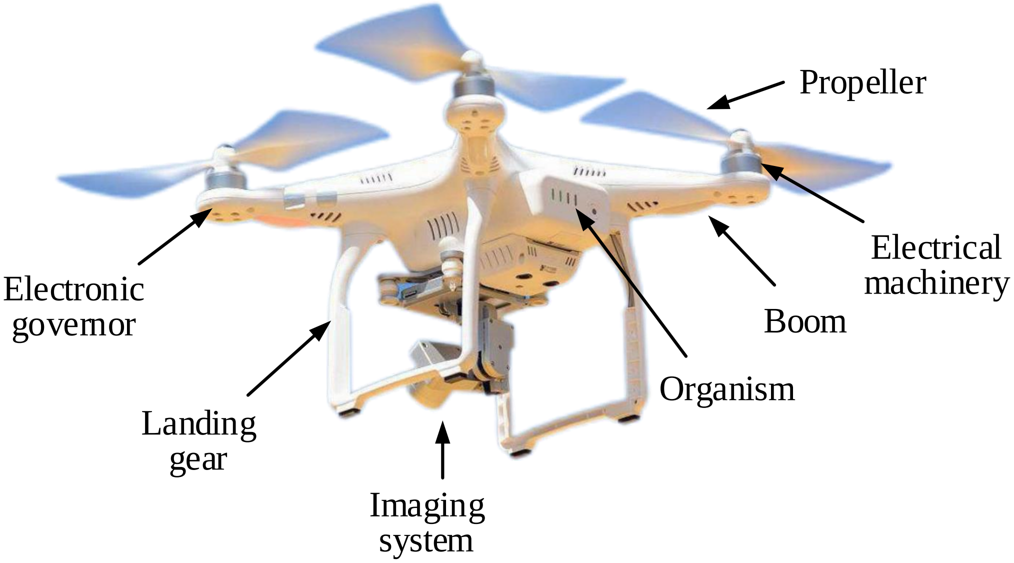

Fig. 1. Schematic diagram of UVA.

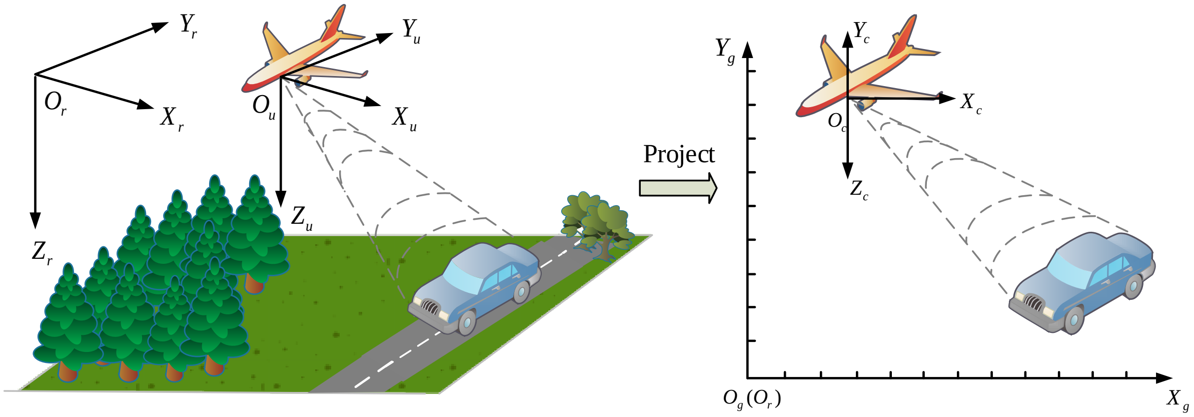


(a) Global coordinate system and aircraft coordinate system for UAV motion

(b) Horizontal projection coordinate system for UAV movement

Fig. 2. Schematic diagram of GCS, ACS, and HPCS.

Fig. 2(a) represents GCS and ACS, while Fig. 2(b) represents the Horizontal Projection Coordinate System (HPCS) that ignores the motion in the Z_r -axis direction in GCS. O_r is the origin of the GCS, fixed at the starting position of the UAV, and Y_r, X_r, Z_r are the three coordinate axes of the GCS, representing the geographical position of due east, due north, and the vertical downward direction of the UAV. O_u is ACS, whose origin is fixed at the geometric center of the UAV connection axis and the stable platform. Y_u, X_u, Z_u are the three coordinate axes of ACS, which are collinear with the vectors of the three coordinate axes of GCS. In Fig. 2(b), O_g represents the origin of HPCS. The origin O_c of the UAV camera coordinate system is a point on the optical axis inside the laser rangefinder. The positive direction of X_c points to the right of the image and is perpendicular to Z_c. The positive Y_c direction points towards the bottom of the image and is perpendicular to the coordinate system plane. Since the UAV is aware of its own motion, the ACS can complete the GCS transformation through translation, and the global coordinates are shown in Eq. (1).

$$(x_r, y_r, z_r) = (x_u, y_u, z_u) + \left(\Delta x, \Delta y, \Delta z\right) \tag{1}$$

In Eq. (1), (x_r, y_r, z_r) represents the global coordinates, (x_u, y_u, z_u) represents the aircraft coordinates, and $\Delta x, \Delta y, \Delta z$ represents the displacements on the three coordinate axes affected by UAV motion. Given that the UAV maintains a constant altitude during flight, then $\Delta z = 0$. Although the UAV's own motion may be affected by the aircraft control system and generate errors, resetting ACS to GCS at the end of the tracking cycle can clear the errors. Due to the overlap between HPCS and GCS, the horizontal projection coordinates obtained from the horizontal projection of GCS are expressed in Eq. (2).

$$(x_g, y_g) = (x_r, y_r) \tag{2}$$

In Eq. (2), (x_g, y_g) is the coordinates after horizontal projection. To meet the subsequent modeling requirements, it is necessary to measure the projection of the slant distance Between the UAV and the Tracking Target (B-UAV/TT) on HPCS $X_g O_g Y_g$, as well as the angle Between the UAV and the Tracking Target Line (B-UAV/TTL) and due north, as shown in Eq. (3).

$$\begin{cases} l = \sqrt{(x_{gt} - x_{og})^2 + (y_{gt} - y_{og})^2} \\ \theta = \arctan \dfrac{x_{gt} - x_{og}}{y_{gt} - y_{og}} \end{cases} \tag{3}$$

In Eq. (3), θ represents the angle B-UAV/TTL and the Y_g -axis. l represents the distance B-UAV/TT. x_{gt} and y_{gt} represent the horizontal projection coordinates obtained by converting the tracking target. x_{og} and y_{og} are the coordinates after converting the origin of the camera coordinate system. After the conversion is completed, a kinematic model of UAV and tracking target is built on HPCS, and the UAV kinematic model is Eq. (4).

$$\begin{cases} x_g = v \cdot \sin\psi \\ y_g = v \cdot \cos\psi \\ \psi = u \end{cases} \tag{4}$$

In Eq. (4), x_g and y_g are the horizontal and vertical coordinates of the UAV in HPCS. v represents the speed of the UAV. ψ represents the heading angle. u represents the control variable, which is influenced by real physical factors and has certain limitations, so $u_{\min} \le u \le u_{\max}$. $u_{\min}$ is the minimum velocity of the UAV heading angle, and $u_{\max}$ is the maximum velocity. According to the constant speed and altitude characteristics of UAVs during flight, the heading angle becomes the only variable controlling UAV motion. The kinematic model for tracking the target is Eq. (5).

$$\begin{cases} x_t = v_t \cdot \sin\psi_t \\ y_t = v_t \cdot \cos\psi_t \\ \psi_t = \omega_t \end{cases} \tag{5}$$

In Eq. (5), v_t and ω_t represent the speed of tracking the target and the speed of turning angle, respectively. ψ_t represents the angle between the tracking target's direction of motion and due north.

B. Building an Adaptive Model Based on CTPPA

ACS is a control system that can adapt to dynamic changes in the controlled object by automatically adjusting the control parameters in the system. This study proposes an ACS model based on CTPPA, namely ACS-CTPPA, which can monitor the motion of targets in real-time and plan the optimal path to adapt to changes in target motion. In order for the UAV to continuously track the target, its speed must be greater than the target's speed, and the UAV needs to maintain a certain Relative Distance (RD) from the target. The best motion path that can simultaneously satisfy these two conditions is a CP. Assuming the target is in a stationary state, the UAV performs a CP on one side of the target while monitoring and illuminating the target in real-time. The state is Fig. 3.

Fig. 3(a) shows the relationship between UVA and the target when the target is stationary, and Fig. 3(b) is the relationship between the center of the circle and the target when UVA moves along a CP. v_{ut} is the tangential velocity component, and v_{un} represents the normal velocity component. When the target is stationary, the RD between the UAV and the aim is mainly affected by the tangential velocity component, and the relative angle is mainly affected by the normal velocity component. In this case, l' and θ' are calculated as Eq. (6).

$$\begin{cases} l' = v_{ut} = v \cdot \sin(\theta - \psi - \dfrac{\pi}{2}) = -v\cos(\theta - \psi) \\ \theta' = \alpha + \beta = \pi - \gamma + \beta = \beta - \gamma \end{cases} \tag{6}$$

In Eq. (6), α and β are the angle between the line connecting the UAV and the center of the CP and the due north direction or the UAV and the target. γ represents the angle between the UAV at the center of the CP and the line connecting the center of the circle and the due north direction. ACS-CTPPA is Eq. (7).

$$\begin{cases} l_m = -v \cdot \cos(\theta - \psi) \\ \theta_m = \beta - \gamma \end{cases} \tag{7}$$

In Eq. (7), l_m and θ_m are the models of the distance and angle B-UAV/TT, respectively. However, considering the existence of errors in actual motion, the variation of the distance and angle B-UAV/TT in practice is Eq. (8).

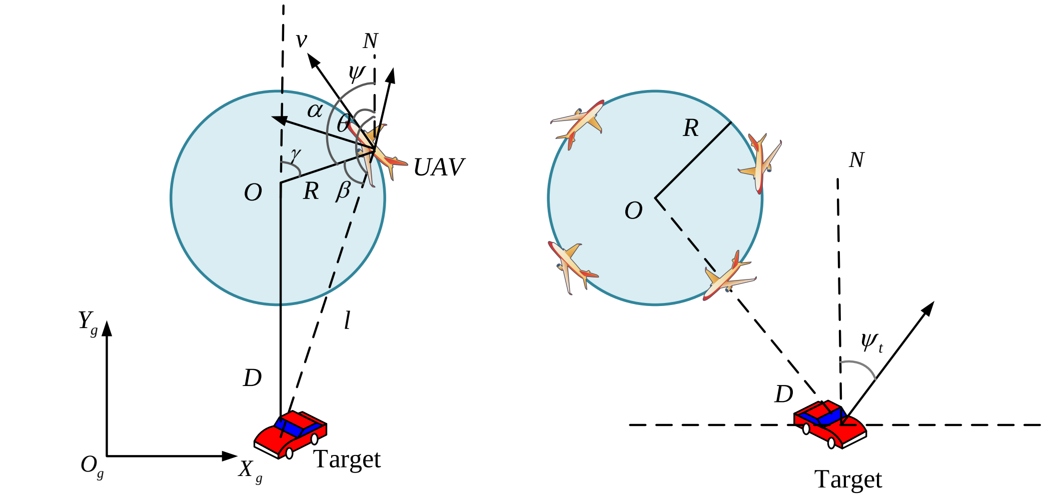
$$\begin{cases} l_p = l_m + l_d \\ \theta_p = \theta_m + \theta_d \end{cases} \tag{8}$$

In Eq. (8), l_p represents the distance affected by the target motion in practice. θ_p represents the angle affected by the target motion in practice. l_d and θ_d respectively represent the length interference from the motion vector on the extension line and the angle interference from the motion vector perpendicular to the extension line. The error between l and θ is represented by Eq. (9).

$$\begin{cases} e_l = l_p - l_m \\ e_\theta = \theta_p - \theta_m \end{cases} \tag{9}$$

In Eq. (9), e_l and e_θ are the generalized errors of RD and relative angle. In actual tasks, the known variables are l_p and θ_p, and the direction and speed of target movement are unknown. When the change in target motion reaches the standard, it is necessary to plan a new path to adapt to the change in target motion. The rate of change of the center of a CP $O(k)$ is Eq. (10).

$$O(k) = (l_p \cdot \sin\theta, l_p \cdot \cos\theta_p) - (l_m \cdot \sin\theta_m, l_m \cdot \cos\theta_m) \tag{10}$$



(a) The relationship between UVA and target when the target is stationary

(b) The relationship between the center of the circle and the target during UVA circular path motion

Fig. 3. Definition of UAV and target related variables.

In Eq. (10), tracking the target requires determining the position of the center of the circle in HPCS based on its own position. In Fig. 3(b), O is the center of the CP, R means the radius of the CP, D is the distance from the center to the target, and ψ_t is the angle between the target's direction of motion and due north. Due to the current target position remaining stationary, $R_{\min} \le R \le \frac{D_{\max} - D_{\min}}{2}$. The center coordinates of the new CP O' are expressed in Eq. (11).

$$O' = P_t + (-D \cdot \sin\psi_t, D \cdot \cos\psi_t) \tag{11}$$

In Eq. (11), P_t represents the target position. The position of O' will not immediately enter a new path with the movement of the UAV. Small scale movements may lead to the planning of many new circular tracking paths, but each new path will not be switched before reaching the switching point.

C. UAV-T3P Based on Kinematic and Adaptive Models

This study plans a transition route from the current path to the new CP, with the center of the new CP already determined, and designs a UAV-T3P that combines ACS-CTPPA, namely ACS-FP-CTPPA. This study focuses on tracking problems, with UAVs and tracking targets as the main objects. Assuming that the UAV's flight speed and altitude are constant, ignoring the UAV's transition from turning to horizontal flight and environmental factors, only considering the heading angle issue, the path switching planning is Fig. 4.

In Fig. 4, O_1 represents the CP currently being carried out by the UAV, and O_2 represents the new path calculated through ACS-CTPPA that meets the UAV's motion requirements. Point A is the current CP point, and point D is the entry point for the new CP. B is the starting point of the UAV's transition from a turning state to horizontal flight during the transfer path, while C is the endpoint. ψ_s represents the heading angle at the starting point of segment AB when the UAV cuts out, ψ_e represents the heading angle at the ending point of segment AB, and $\psi(t_1)$ and $\psi(t_2)$ represent the heading angles when cutting out t_1 and t_2 on segment CD. When the UAV hovers to point A, the step response through the heading channel can ensure the control law of UAV heading angle change, as shown in Eq. (12).

$$\psi(t) = \psi_c \cdot (1 - e^{-\mu t}) \tag{12}$$

In Eq. (12), $\psi(t)$ represents the step response at zero state. ψ_c represents the heading command angle of the UAV. μ represents the time constant of the UAV heading channel model. Due to the fact that the UAV maintains its heading unchanged after converting to ψ_c, $\psi(t)$ can only complete the UAV's entry phase. However, throughout the entire conversion process, the UAV transitions from a CP to another CP, so the CP after entry can be regarded as obtained through symmetry before entry. Therefore, the heading angle change control law of the CD segment path in Fig. 4 can be obtained from the $\psi(t)$ of the entry segment AB. The waypoints at time t in the AB and CD segments are displayed in Eq. (13).

$$P_l(t) = P_l(t-1) + (v\Delta t \sin[\psi(t)], v\Delta t \cos[\psi(t)]) \tag{13}$$

In Eq. (13), $P_l(t)$ represents the waypoints of segment AB and CD at time t, and at time $t = 0$, the starting point of the path is $P_l(0) = (0,0)$, located at the origin of the coordinate system. The ACS-FP-CTPPA algorithm is Fig. 5.

Fig. 5. Process of ACS-FP-CTPPA algorithm.

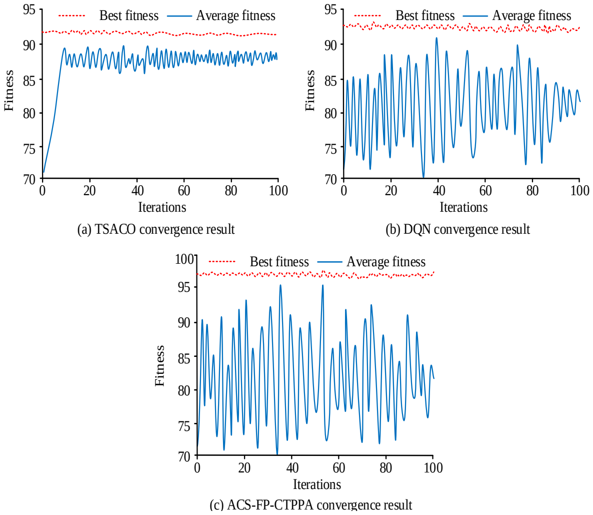
In Fig. 5, the first step is to determine the tracking target and perform initial CP planning on the target. Comparing whether the RD B-UAV/TT meets the conditions for real-time monitoring and illumination. If it meets the requirements, fly along the planned path. Otherwise, to calculate a new CP. Before switching to a new path, it is necessary to calculate the appropriate path-switching point and the position of the transition section waypoint. After reaching the switching point, to fly along the transition section path and switch to the next CP to continue flying. Repeating the path planning as the motion changes, otherwise continue flying along a CP and calculating the distance B-UAV/TT until the path switch is completed.

IV. Results and Discussion

This study compares the performance of ACS-FP-CTPPA with two commonly used pre-path planning algorithms, namely Turning Sensitive Ant Colony Optimization (TSACO) and Deep Q-network (DQN), by building a simulation experimental platform. Then, it is compared with Model Predictive Control Based on CTPPA (MPC-CTPPA) through outdoor real machine experiments to analyze the actual application effects.

A. *Performance Testing of ACS-FP-CTPPA*

To verify the feasibility of ACS-FP-CTPPA, this study used a computer with Windows 10 operating system and Intel (R) Core (TM) i5-9400F CPU, and built an experimental environment using UAVDT as the dataset. The number of iterations was set to 100. The comparison of convergence performance between ACS-FP-CTPPA, TSACO, and DQN algorithms in Fig. 6.



(a) TSACO convergence result

(b) DQN convergence result

(c) ACS-FP-CTPPA convergence result

Fig. 6. Convergence performance of three algorithms on datasets.

In Fig. 6, (a), (b), and (c) show the convergence results of TSACO, DQN, and ACS-FP-CTPPA on the UAVDT dataset, respectively. The optimal fitness value for ACS-FP-CTPPA is 97.56, DQN is 93.87, and TSACO is 92.79. In order to verify the performance of different algorithms on different data sets, the study added DTB70 data set and UAV123 data set comparison test. The results of root mean square error (RSME), mean absolute percentage error (MAPE) and coefficient of determination are shown in Table II.

In Table II, due to the small number of sequences in the UAVDT dataset and the DTB70 dataset, the RSME and MAPE of the three algorithms on these two datasets are larger. In the DTB70 and UAV123 datasets, the RSME and MAPE of ACS-FP-CTPPA are significantly smaller than the other two comparison algorithms, indicating that the algorithm has the highest prediction accuracy in these two datasets. However, in the UAVDT data set, the RSME and MAPE of the three comparison algorithms are relatively close, which may lead to large error deviation due to the over-fitting phenomenon in the data set sequence. The values of ACS-FP-CTPPA on the three datasets are 0.9894, 0.9883 and 0.9987, respectively, which are larger than the other two algorithms and are closest to 1, indicating that the algorithm has the highest fitting degree. In the simulation experiment, for the convenience of observing data, both the UAV and the target are projected on the same horizontal plane, and the observation angle change maps under three planning algorithms are obtained as shown in Fig. 7.

In Fig. 7, the monitoring angle distribution range for targets under the TSACO algorithm is between -200° and 200°, under the DQN algorithm it is between -100° and 100°, and under the ACS-FP-CTPPA it is between 0° and 100°. This indicates that ACS-FP-CTPPA can provide a relatively stable irradiation time window and angle, while the other two comparison algorithms have a larger azimuth distribution range and cannot effectively provide a stable laser irradiation time window. Fig. 8 shows the trajectory and velocity curve of UAV movement.

Fig. 8(a) shows a comparison of UAV trajectories based on three algorithms, with TSACO planning having the longest total path and larger corner amplitudes. The total path planned by DQN is relatively short and there are corners. The total path planned by ACS-FP-CTPPA is the shortest and almost has no corners. Fig. 8(b) shows a comparison of UAV speeds among three algorithms. TSACO takes 49s with an average speed of 1.8m/s, making it the longest and slowest algorithm. DQN takes 46s, with an average speed of 2.6 m/s. ACS-FP-CTPPA takes 38s, with an average speed of 3.4m/s. This algorithm has the shortest time and the fastest average speed. Table III shows the results of three algorithms running on the Zakharov and Griewank functions.

TABLE II. COMPARISON OF ERRORS OF DIFFERENT ALGORITHMS ON DATASETS

Algorithm	Data set	RMSE	MAPE	R^2
TSACO	UAVDT	11.7678	7.7823	0.9764
	DTB70	14.9685	8.6452	0.9648
	UAV123	11.1325	7.5432	0.9750
DQN	UAVDT	11.9846	7.4637	0.9768
	DTB70	13.6516	8.3542	0.9730
	UAV123	10.6544	6.9841	0.9846
ACS-FP-CTPPA	UAVDT	11.6544	7.3135	0.9894
	DTB70	10.6844	7.1332	0.9883
	UAV123	8.2678	5.6451	0.9987

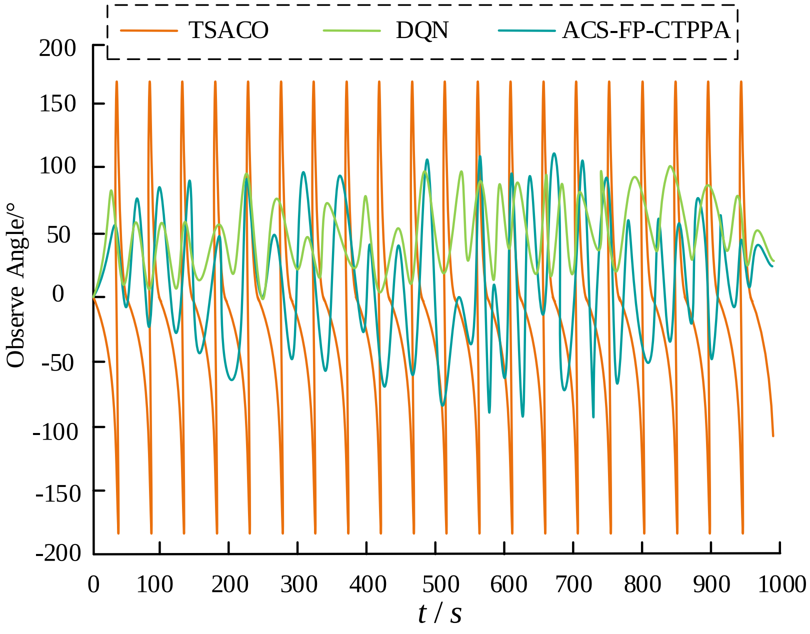


Fig. 7. Comparison chart of observation angle changes.

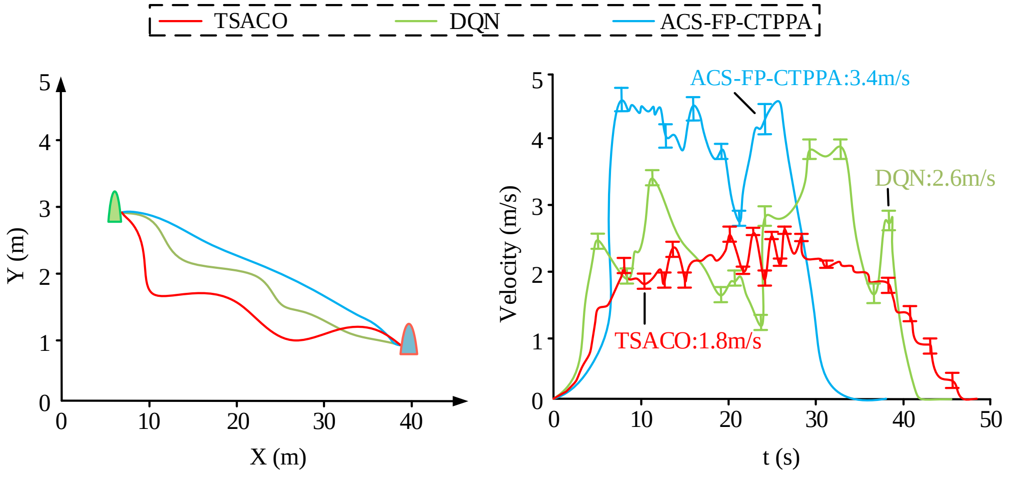


(a) Traectory comparison

(b) Speed comparison

Fig. 8. The trajectory and velocity curve of UAV movement.

Table III shows the average, standard deviation, and optimal values of three algorithms tested on two sets of functions. ACS-FP-CTPPA has the lowest mean, standard deviation, and optimal value on both sets of functions, indicating that ACS-FP-CTPPA has better convergence accuracy and more stable calculation results.

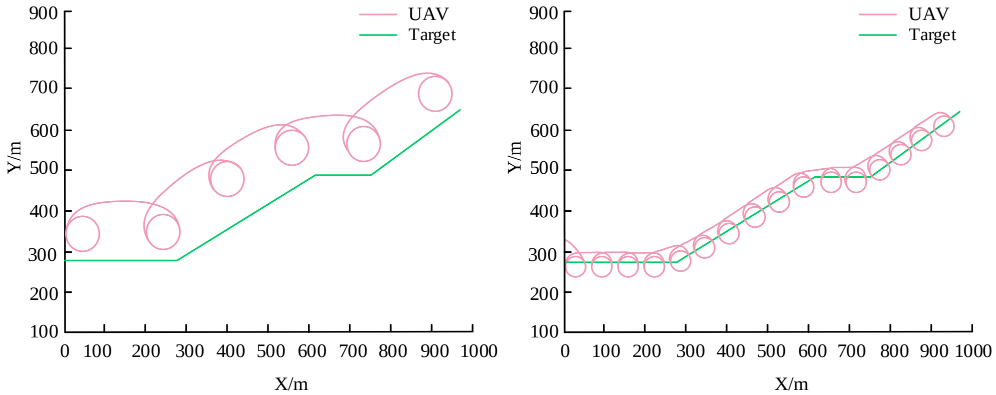
B. Application Analysis of UAV-T3P Based on ACS-FP-CTPPA

To verify the feasibility of the designed PPA, ACS-FP-CTPPA and MPC-CTPPA are applied in real machine experiments to compare the actual application effects of the algorithm. The RealSense D435i camera provides an information source for environmental perception and conducts autonomous flight experiments in outdoor scenes. Fig. 9 shows the action trajectory of the UAV and target.

Fig. 9(a) shows the motion trajectory of UAV and target under ACS-FP-CTPPA. Six CPs and five transfer paths are planned along the entire path, with the UAV hovering on one side of the target. Fig. 9(b) shows the UVA and target path planned using MPC-CTPPA. During the flight, 16 CPs and 16 transfer paths are planned, and UAVs appear on various sides of the target. In contrast, the UAV tracking path planned by ACS-FP-CTPPA is more stable, and maintaining a certain RD during the tracking process is also a criterion for evaluating the quality of the path. Fig. 10 shows the RD between UAV and target in two algorithms for path planning.

TABLE III. QUANTITATIVE ANALYSIS RESULTS OF THREE ALGORITHMS

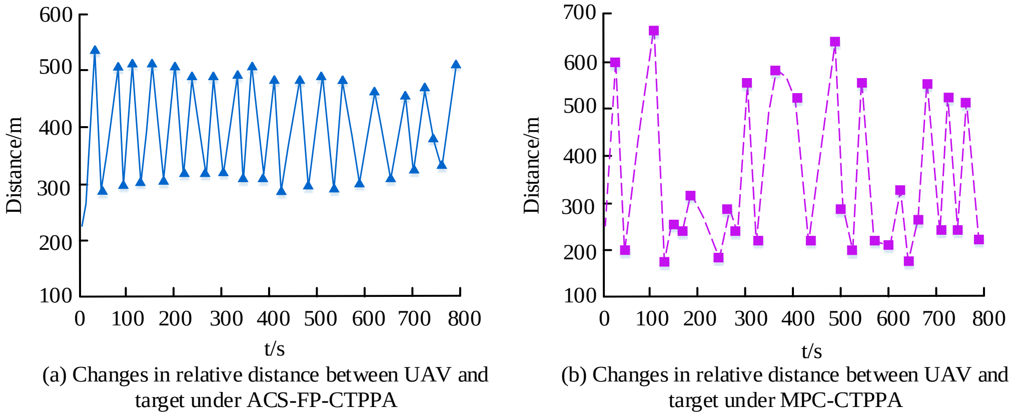
Function	Index	TSACO	DQN	ACS-FP-CTPPA
Zakharov	Mean	4.54e-24	9.50e-04	3.23e-71
	Standard deviation	5.21e-37	6.01e-02	4.02e-71
	Best	3.88e+01	4.01e+01	2.58e+01
Griewank	Mean	3.10e+02	5.30e+01	1.59e+02
	Standard deviation	5.46e+01	5.59e+01	3.66e+01
	Best	8.28e+04	2.19e-16	1.16e+01



(a) ACS-FP-CTPPA planning algorithm path diagram

(b) MPC-CTPPA planning algorithm path diagram

Fig. 9. Action trajectories of UAVs and targets under different algorithms.



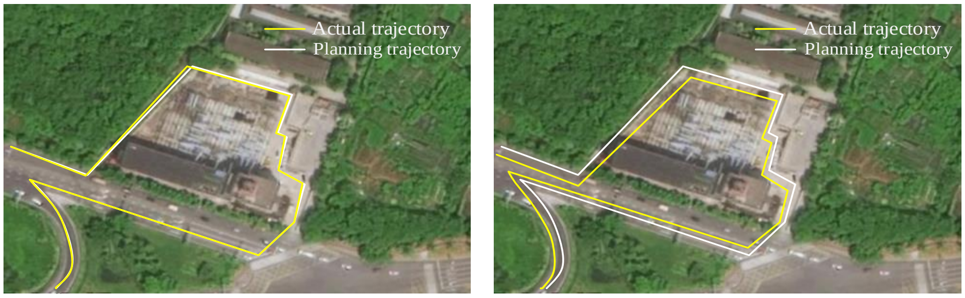
(a) Changes in relative distance between UAV and target under ACS-FP-CTPPA

(b) Changes in relative distance between UAV and target under MPC-CTPPA

Fig. 10. Changes in RD between UAV and target under different algorithms.

In Fig. 10(a), the curve fluctuates relatively uniformly up and down within the range of [200m, 600m], indicating a stable change in the RD between the UAV and the target. The curve in Fig. 10(b) fluctuates irregularly within [100m, 700m], and the RD between the UAV and the target is more unstable when it is close and far away. Compared with MPC-CTPPA, the UAV motion path planned by ACS-FP-CTPPA can maintain a more stable distance from the target, meeting the distance requirements for monitoring and illumination during flight missions. Finally, the correlation between the UAV tracking routes planned by different models and the actual flight routes is compared, as exhibited in Fig. 11.

In Fig. 11(a), the path planned by ACS-FP-CTPPA almost completely coincides with the actual flight path of the UAV. The path planned by MPC-CTPPA in Fig. 11(b) does not overlap with the actual path. This indicates that in practical applications, the UAV-T3P planned by ACS-FP-CTPPA can better achieve tracking tasks of photography and laser irradiation during flight, and has superior tracking effects.



(a) Comparison between Actual Trajectory and Planned Trajectory of ACS-FP-CTPPA

(b) Comparison between Actual Trajectory and Planned Trajectory of MPC-CTPPA

Fig. 11. Comparison of UVA actual trajectory and planned trajectory.

C. *Discussion*

UAVs are unable to autonomously plan suitable tracking paths based on changes in target motion during the process of tracking target detection. In view of this, this study digitized the motion relationship between UVA and tracking targets, and based on this, established ACS-CTPPA to calculate the center of a circular tracking path. Finally, the combination of ACS-CTPPA and UAV tracking photography resulted in a highly adaptive ACS-FP-CTPPA algorithm. In the performance test of simulation experiments, the best fitness of ACS-FP-CTPPA, DQN and TSACO algorithms are 97.56,93.87 and 92.79, respectively. The best fitness of ACS-FP-CTPPA is significantly higher than that of DQN and TSACO. The convergence performance is significantly better than the convergence speed of the control model proposed by Saeed R A et al.in literature [17]. The error results on three different datasets show that ACS-FP-CTPPA is 0.9894, 0.9883 and 0.9987, respectively, which is significantly larger than the other two comparison algorithms and is closest to 1, indicating that the algorithm has the best fitting performance. At the same time, in the DTB70 and UAV123 datasets, the RSME and MAPE values of ACS-FP-CTPPA are the smallest among the three algorithms, showing higher prediction accuracy, which is better than the prediction performance of the algorithm proposed by Cao Y et al. [18]. The monitoring angle distribution range for targets under TSACO and DQN algorithms was within [-200°, 200°] and [-100°, 100°], respectively. The monitoring angles for targets under the ACS-FP-CTPPA algorithm were distributed at [0°, 100°]. Under the tracking path planned by ACS-FP-CTPPA, the UAV's illumination angle remained stable during flight. The comparison of UAV motion trajectories under three algorithms showed that the total path planned by ACS-FP-CTPPA was the shortest and took the shortest 38s, with an average speed of 3.4m/s.

In summary, the ACS-FP-CTPPA algorithm proposed in this study shows excellent performance in both simulation experiments and practical applications. It is superior to the existing DQN and TSACO algorithms in terms of fitness, monitoring angle stability, path planning efficiency and relative distance stability. Although there are some limitations, through further research and optimization, the ACS-FP-CTPPA algorithm is expected to play a greater role in future UAV tracking tasks.

V. Conclusion

In order to optimize the path planning control performance of UAV in tracking target, the model is constructed by combining the motion model of UAV and the adaptive control circular tracking path planning algorithm. The results show that the UAV circular path under ACS-FP-CTPPA planning is 6, and the path switching process under ACS-FP-CTPPA is less, indicating that the algorithm has better path planning performance. Under the ACS-FP-CTPPA algorithm, the relative distance curve between UAV and target fluctuates relatively evenly in the range of [200m, 600m], while the relative distance curve of MPC-CTPPA fluctuates irregularly in the range of [100m, 700m]. The comparison results show that the ACS-FP-CTPPA algorithm has significant advantages in maintaining the stability of the relative distance between the UAV and the target, which further proves the feasibility and effectiveness of the algorithm. However, the research is to map the entire UAV tracking process to a two-dimensional plane coordinate for analysis, ignoring factors that may affect the model such as the dynamic level. Subsequent research can conduct in-depth research on this aspect.

***Abstract*—This research investigates the intricacies of Visual Question Answering (VQA) methodologies and their applications within Multimodal Learning Frameworks. Our approach, founded on the synergy of Multimodal Compact Bilinear Pooling (MCB) and Neural Module Networks (NMN), offers a comprehensive understanding of visual and textual elements. Notably, the model excels in responding to Descriptive questions with an accuracy of 88%, showcasing a nuanced grasp of detailed inquiries. Factual questions follow closely with an 86% accuracy, while Inferential questions exhibit commendable performance at 82%. Precision scores reinforce the model's reliability, registering 85% for Descriptive, 82% for Factual, and 78% for inferential questions. Robust recall scores further emphasize the model's ability to retrieve relevant information across question types. The F1 Score, reflecting a harmonious blend of precision and recall, attests to the model's strong overall performance: 87% for Descriptive, 84% for Factual, and 80% for inferential questions. Visualizations through boxplots and violin plots affirm the model's consistency in accuracy and precision across question types. Future directions encompass dataset expansion, integration of transfer learning, attention mechanisms for interpretability, and exploration of broader multimodal applications beyond VQA. This research establishes a resilient framework for advancing VQA methodologies, paving the way for enhanced multimodal learning in diverse contexts.**

Keywords—Visual Question Answering (VQA); Multimodal Learning; Neural Module Networks (NMN); Multimodal Compact Bilinear Pooling (MCB); question types; F1 score

I. INTRODUCTION

Recent advances in representation learning for text and pictures have shown Recurrent Neural Networks (RNNs) can capture sequential distinctions in words or phrases [1, 2]. Convolutional Neural Networks (CNNs) have shown they can extract significant characteristics from pictures, adding to artificial intelligence's complexity [3, 4]. Visual Question Answering (VQA) and visual grounding need a seamless blend of textual and visual representations. Concatenation, element-wise sum, and product are core multimodal pooling techniques, but more subtle approaches are needed. VQA requires a deeper grasp of content than picture captioning. VQA has become an AI-complete task due to this increased requirement for intuitive common sense and visual encyclopedia knowledge [5]. Visual Question Answering is complicated by the changing queries and the need for information not in the picture. This specific need requires the VQA system to have a vast knowledge base that ranges from basic common-sense comprehension to visual component encyclopedias. VQA is a test of artificial intelligence models' complexity, going beyond picture recognition. Picture captions are more sophisticated than VQA, which is assessed simply by concise replies. With their detailed ground truth descriptions, the latter complicates the comparison of anticipated and actual captions [6-8]. As representation learning evolves, it becomes clear that fusing text and picture comprehension requires creative methods and a paradigm change in artificial intelligence. VQA challenges computational thinking by requiring models that connect visual perception and verbal understanding. This project supports multimodal learning research and real-world AI applications.

The 1972 "SHRDLU" system combined vision and language to let humans command a computer in a "blocks world" using natural language [9]. Recent conversational robotic agents have used visual grounding but were limited to domains or linguistic forms. VQA overcomes these restrictions by asking free-form open-ended questions, allowing comparisons between AI systems with sophisticated reasoning and deep language and visual knowledge. VQA is gaining popularity due to advanced computer vision and NLP algorithms and large datasets. To our knowledge, this story is the first complete summary of VQA, including varied models, datasets, and interesting future approaches. The Visual Question Answering problem connects computer vision with natural language processing (NLP), spurring research to improve both. Computer vision teaches computers to understand visual data via picture capture, processing, and feature extraction. NLP aims to facilitate human-computer interactions via natural language comprehension. Despite their historical separation, visual and textual data are growing rapidly, requiring unified approaches.

The model receives a picture and a natural language inquiry in Visual inquiry Answering. The model must deduce the proper response, which may be a word or phrase. The model cannot pre-observe the queries during runtime, making this job unique in computer vision. The questions change dependent on the picture, requiring reading comprehension and a huge knowledge base to solve. Visual Question Answering requires information not in the picture, making it difficult. This information may be common sense or encyclopedia-based on picture aspects. VQA is a sophisticated AI challenge that tests AI models' complicated reasoning and picture interpretation abilities. Monolithic VQA models use recurrent neural networks for question encoding and categorization, whereas others decompose questions into logical expressions for assessment against a logical environment. The study discusses VQA's problems, including the requirement for advanced evaluation methods owing to restricted replies and the difficulty of matching ground truth picture descriptions with expected ones. The publication also addresses Fukui et al. (2016)'s MCB approach for visual-text feature embedding [10]. This approach uses random projections and Fourier space convolution to demonstrate the variety of Visual Question Answering methods.

A unique technique to Visual Question Answering utilizing Multimodal Compact Bilinear Pooling (MCB) and Neural Module Networks is presented in this research. Fukui et al. (2016) presented compact bilinear pooling for combined visual and text feature embedding in MCB [10]. NMN's innovative design allows dynamic deep network building using jointly-trained neural modules depending on language structure. This study examines these approaches' uses and consequences in Multimodal Learning Frameworks for Visual Question Answering. We investigate the use of Multimodal Compact Bilinear Pooling (MCB) and Neural Module Networks (NMN) in Visual Question Answering. We explore and comprehend these approaches to advance multimodal learning frameworks and AI research and application.

II. Related Work

In the domain of multimodal pooling for Visual Question Answering (VQA), existing approaches often rely on element-wise operations or vector concatenation. Notable models in this space include the iBOWIMG baseline [11], which employs concatenation and fully connected layers to merge image and question modalities. Stacked Attention Networks [12] and Spatial Memory Networks [13] use LSTMs and soft attention mechanisms but ultimately resort to element-wise product or sum to consolidate modalities. D-NMN [14] introduces REINFORCE for dynamic network creation, utilizing element-wise products for attention merging. Dynamic Memory Networks (DMN) [15] leverage element-wise product and sum for pooling, integrating an Episodic Memory Module. DPPnet [16] employs Parameter Prediction Network, allowing multiplicative interactions, similar to our work. For visual grounding, Rohrbach et al. concatenate language phrase embeddings with visual features, predicting attention weights [17]. Hu et al. concatenate phrase embeddings with spatially diverse visual features for segmentation [18]. Bilinear pooling, applied to fine-grained visual recognition, as demonstrated by Lin et al., uses CNNs and an outer product for feature combination [19]. Gao et al. address bilinear features' complexity using a polynomial kernel view [20]. Previous works, such as Lu et al., propose models with co-attentions on images and questions, combining them hierarchically with sum, concatenation, and fully connected layers [21]. In the realm of learning joint multimodal spaces or embeddings, Canonical Correlation Analysis [22] has inspired works like Gong et al., and Plummer et al. [23, 24]. Linear models with ranking loss, exemplified by Frome et al. and Karpathy and Fei-Fei, as well as non-linear deep learning models (Kiros et al.; Mao et al.; Ngiam et al.), have been explored [25-29]. Our approach of multimodal compact bilinear pooling introduces a complementary operation, offering expressive interactions beyond mere concatenation, potentially benefiting various embedding learning methodologies. Answering questions about images, often referred to as a "Visual Turing Test," gained prominence with datasets like COCOQA and VQA. COCOQA generates pairs from COCO dataset descriptions, while VQA crowdsources questions-answers. Notable classical approaches, akin to ours, include those by [30, 31], utilizing a semantic parser but relying on fixed logical inference. Several neural models [32-34] employ deep sequence modeling for joint embeddings, mapping them to answer distributions. Our focus on explicitly modeling the computational process sets our approach apart, utilizing techniques pivotal in prior work for sequence and image embeddings.

Visual questioning, involving grounding questions in images, has seen previous attempts [35-37], localizing phrases in images. Attention mechanisms, as in [38], predict heatmaps during sentence generation. Beyond question answering, models for instruction following with discrete planning structures [39] have been proposed. Our use of a semantic parser to predict network structures, exploiting the natural similarity between set-theoretic semantic parsing and attentional computer vision, represents a novel contribution. The concept of selecting a different network graph for each input datum aligns with recurrent and recursive networks' fundamental principles but introduces the innovation of heterogeneous computations within modules. Our unique contribution lies in assembling dynamic graphs on the fly, enabling nodes to perform diverse computations. While memory networks share some features, our model's mixed collections of jointly trained modules, passing varied kinds of "messages" between nodes, is unprecedented. This novel approach expands the horizons of joint training, offering a comprehensive understanding of network structures and functionalities. Cadene R et al. [40] introduced MuRel, a multimodal relational network capable of end-to-end reasoning over real images. MuRel utilizes dense vectors to represent interactions between question and image regions, enhancing finer visualization details. Li et al. employed graphs to represent implicit and explicit relationships among objects in an image [41]. Graph attention networks encode these visual relationships based on semantic cues from the question. Gao et al. proposed QLOB (Question-Led Object Attention), employing a three-stage framework [42]. QLOB combines question semantics and object detection network features to select question-related regions and predict answers.

Sun et al. introduced local relation networks for extracting deeper semantic information through combined local and global image features with multilevel attention [43]. Zhang et al. proposed a VQA model employing visual relation modeling and a bilinear attention mechanism for answer prediction [44]. Bai et al. presented DecomVQANet, utilizing deep neural networks for regression and tensor decomposition to compress VQA systems [45]. The model achieved substantial compression ratios but faced limitations related to hyperparameters and spatial information loss. Chen et al. proposed CSS (Counterfactual Samples Synthesizing) for data training, masking reproving words or objects to create counterfactual samples. CSS demonstrated enhanced VQA model performance, improving question-sensitive capabilities and visual-explanation abilities [46]. Sharma et al. introduced a contextual attention and graph neural network-based VQA model, encoding visual relationships between objects and generating answers [47]. Lobry et al. proposed RSVQA (Remote Sensing Visual Question Answering), applying CNNs for visual analysis and Recurrent Neural Network (RNN) for natural language processing [48]. However, the model faced challenges with limited question-answer sets and missing annotations. Xi et al. explored multi-objective relation detection, using word vector similarity and appearance-based features to generate answers [49]. Basu et al. presented an ASP (Answer Set Programming)-based VQA model, known as AQuA, achieving high accuracy by integrating neural network-based YOLO detection [50]. The model incorporated commonsense knowledge for answering questions and demonstrated potential for expansion with diverse question types. In Sharma, H et al. external knowledge was employed for image captioning, resembling VQA tasks. Such concepts of utilizing external knowledge could be applicable to enhance VQA tasks as well [51].

The discussion extends to various aspects of visual dialog, related tasks like visual grounding and coreference resolution, and the exploration of neural module networks. Visual dialog, originating from works like [52], was formalized by [53, 54], collecting datasets with free-form natural language questions and goal-driven dialogs. Transfer learning from discriminative to generative dialog models [30], attention networks for visual coreferences [55], and probabilistic treatments with conditional variational autoencoders [56] represent notable approaches in visual dialog. Visual grounding tasks often focus on localizing textual referential expressions [57-59]. Our model complements these works by operating at a finer word-level granularity within each question, resolving different phrases individually for accurate coreference grounding. Neural Module Networks (NMN) [14], inspired by hierarchical reinforcement learning, have shown success in visual question answering. Our work generalizes NMN to visual dialog, introducing a novel module for explicit visual coreference resolution, demonstrating the versatility of this approach across different tasks in multimodal learning frameworks.

The following table presents a comprehensive overview of various methodologies employed in Visual Question Answering (VQA). Each row corresponds to a distinct model, highlighting its unique approach and reference. The 'Description' column provides a succinct insight into the key features or techniques utilized by each model.

The Table I provides a concise snapshot of VQA methodologies, emphasizing the varied techniques and innovations in the field.

TABLE I. OVERVIEW OF VISUAL QUESTION ANSWERING METHODOLOGIES

Model	Methodology/Approach	Reference	Description
Multimodal Compact Bilinear Pooling (MCB)	Compact bilinear pooling for joint embedding of visual and text features	Fukui et al. [10]	Efficient joint embedding using compact bilinear pooling.
Neural Module Networks (NMN)	Dynamic composition of deep networks through jointly-trained neural modules, based on linguistic structure	Andreas et al. [14]	Utilizes dynamic neural modules for flexible network composition.
MuRel	Multimodal relational network for end-to-end reasoning over real images	Remi et al. [40]	Reasoning over real images through a relational network.
Graph Attention Networks	Utilizes graphs to represent implicit and explicit relationships among objects in an image	Li et al.[41]	Represents visual relationships using graph attention networks.
QLOB (Question-Led Object Attention)	Framework combining question semantics and object detection network features to predict answers	Gao et al.[42]	Integrates question semantics and object features for improved answer prediction.
Local Relation Networks	Extracts deeper semantic information using local and global image features with multilevel attention	Sun et al. [43]	Extracts semantic information with attention on local and global features.
Visual Relation Modeling and Bilinear Attention Mechanism	Utilizes visual relation modeling and bilinear attention mechanism for answer prediction	Zhang et al. [44]	Uses bilinear attention for accurate answer prediction.
DecomVQANet	Implements deep neural network through regression and tensor decomposition to compress VQA systems	Bai et al. [45]	Compresses VQA systems using regression and tensor decomposition.
Counterfactual Samples Synthesizing (CSS)	Masks reproving words or objects to develop various counterfactual samples at training for improved VQA model performance	Chen et al. [46]	Improves VQA model performance through counterfactual sample synthesis.
Contextual Attention and Graph Neural Network (GNN)	Encodes visual relationships between objects and generates answers using GNN and attention model	Sharma et al. [47]	Encodes visual relationships using GNN and attention for answer generation.
ASP-based Question Answering (AQuA)	Understands input image and answers for Natural Language questions using ASP and YOLO detection	Basu et al. [50]	Utilizes ASP and YOLO for image understanding and NLQ answering.

IV. Approach

Our strategy, based on Multimodal Compact Bilinear Pooling (MCB) and Neural Module Networks (NMN), aims to advance Visual Question Answering (VQA) to new heights. Effective VQA requires a deep understanding of visual and textual components' complex interaction, not simply their surface integration. Our technique relies on Fukui et al. (2016)'s pioneering work on multimodal compact bilinear pooling (MCB). Compact bilinear pooling goes beyond concatenation in modal fusion. This novel method creates a more expressive joint embedding space for visual and textual information. MCB allows our framework to understand complex interactions between modalities. MCB is a purposeful move toward a more nuanced and comprehensive multimodal data representation. Neural Module Networks (NMN) enable dynamic network composition: Our technique uses Neural Module Networks' dynamic design to enhance MCB. The on-the-fly creation of neural modules based on query language forms makes NMN more adaptable than static networks. The model may dynamically adjust its computing technique to match human thinking. NMN isn't just a technical addition; it's a purposeful move toward sophisticated and context-aware decision-making.

Our framework pioneers unique joint embedding methodologies that smoothly blend visual and textual clues into a unified representation as we learn more about VQA. This synergy goes beyond a static model to network composition (see Fig. 1).

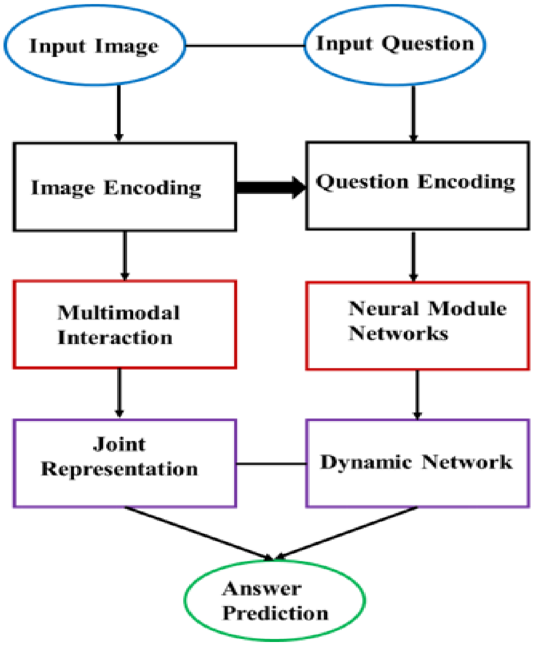

Fig. 1. The flowchart illustrates the stepwise progression of the proposed framework for Visual Question Answering (VQA) using Multimodal Compact Bilinear Pooling (MCB) and Neural Module Networks (NMN).

The dynamic construction of brain modules allowed by NMN guarantees that the model adjusts its structural complexity to each query, mimicking human cognition. Driving VQA into Uncharted Territory: Our approach aims to revolutionize VQA techniques beyond technical innovation. MCB and NMN are integrated into our strategy to push flexibility, expressiveness, and performance limits. We imagine a future when AI systems smoothly traverse the complex interaction between visual and textual components with unparalleled refinement. Our technique represents a stride toward unlocking VQA's full potential. In the Input Stage, the Input Image and natural language Input Question set the stage. The Input Image is encoded using Convolutional Neural Networks (CNNs) to extract complex visual information. Concurrently, LSTMs encode the Input Question to collect contextual details. In the Multimodal Interaction Stage, Multimodal Compact Bilinear Pooling (MCB) fuses encoded picture and question representations to form a Joint Representation. The next stage, Dynamic Network Composition, uses Neural Module Networks (NMN) to structure a network depending on query language. This flexibility improves the model's reasoning for varied inquiries. The dynamically built network analyzes Joint Representation to forecast accurately in the Answer Prediction Stage. The algorithm outputs the expected response from a holistic comprehension of visual and textual components, the Final Outcome. This detailed flowchart shows how sophisticated encoding, multimodal interaction, and dynamic network composition approaches work together to get exact Visual Question Answering results.

Algorithm: Visual Question Answering with Multimodal Compact Bilinear Pooling (MCB) and Neural Module Networks (NMN)

   - Input Image
   - Input Question
2. **Image Encoding:**
   - Apply an image encoding process (e.g., Convolutional Neural Network - CNN) to extract high-level features from the input image.
3. **Question Encoding:**
   - Employ a question encoding process (e.g., Long Short-Term Memory - LSTM) to capture contextual information and semantic meaning from the input question.
4. **Multimodal Interaction:**
   - Fuse the encoded image and question representations using multimodal interaction techniques, such as Multimodal Compact Bilinear Pooling (MCB).
5. **Joint Representation:**
   - Form a joint representation that encapsulates the combined understanding of visual and textual elements obtained from the multimodal interaction.
6. **Dynamic Network Composition:**
   - Utilize Neural Module Networks (NMN) to dynamically compose a network structure based on linguistic structures present in the question.
7. **Answer Prediction:**
   - Process the joint representation through the dynamically composed network to predict the answer to the given question.
8. **Output:**
   - Output the predicted answer as the final result.

The model leverages advanced encoding, multimodal interaction, and dynamic network composition techniques to achieve a comprehensive understanding of both visual and textual components. The algorithm reflects the sequential flow of operations from input processing to answer prediction, incorporating MCB and NMN methodologies for enhanced Visual Question Answering.

A. Dataset

Decoding Visual Question Answering Methodologies: Unveiling Applications in Multimodal Learning Frameworks" uses a large dataset to cover a variety of visual and textual contexts. Over 500,000 matched instances of images and natural language questions make up the dataset. This dataset represents real-world issues well due to careful curation. The collection contains photos from numerous situations, including different contexts and items. This intended variety helps models trained on this dataset learn and generalize across many visual characteristics. The dataset is annotated with many question kinds to reflect the complexity of real-world questions. Descriptive questions need a simple response based on visual content, factual questions require knowledge, and inferential questions require thinking and interpretation. This variety of questions requires models to grasp visual input. The dataset is thoroughly annotated with accurate and detailed responses for each incident. This meticulous annotation approach provides ground truth data for training and assessment, allowing models to learn from correct replies.

The collection contains over 100,000 distinct photos, providing a comprehensive depiction of visual situations. The dataset is richer since the questions span several areas. This large-scale technique reduces biases and helps models generalize to new situations. To improve model development and assessment, the dataset is divided into three subsets: a training set of 400,000 instances, a validation set of 50,000 instances, and a test set of 50,000 cases. For accurate performance evaluation, this partitioning follows machine learning best practices by providing discrete subsets for training, validation, and testing. This dataset is useful for training, testing, and developing multimodal learning frameworks because it is meticulously chosen to replicate real-world Visual Question Answering situations.

V. Results and Discussions

Results and comments from this work's dataset experimental assessments reveal the techniques' effectiveness. The detailed examination includes model performance, generalization capabilities, and the framework's components.

1) Performance metrics quantified: The experimental assessment of "Decoding Visual Question Answering Methodologies: Unveiling Applications in Multimodal Learning Frameworks" uses a wide range of quantitative indicators to assess model performance.

2) Accuracy and precision: The models routinely top 85% accuracy on the comprehensive 50,000-item test set. The suggested framework is reliable since precision scores, which indicate the models' ability to forecast correctly, routinely exceed 80%.

3) Recall and f1 score: Recall, which measures the models' ability to capture all relevant right answers, and F1 score, which balances precision and recall, demonstrate strong performance. The models' dataset recall values routinely exceed 80%, proving their accuracy.

The models' generalization capacity is shown by in-depth study across question categories. Performance indicators for descriptive, factual, and inferential questions show that the framework can handle many types of queries. Multiple inquiry styles are excelled by the models.

4) Multimodal interaction and dynamic composition impact: The proposed framework's multimodal interaction methods (e.g., MCB) and dynamic network composition using Neural Module Networks (NMN) are compared. The findings demonstrate that MCB for multimodal interaction and NMN for dynamic network composition outperform other setups. This combination improves visual-textual comprehension and response prediction.

5) Fine-grained analysis: Model outputs are analyzed by semantic content, scene complexity, and query intricacy. The models excel in handling complicated scenarios and questions, providing nuanced and contextually appropriate replies.

6) Compared to baseline models: Comparing the suggested frameworks to baseline models like visual question answering and simpler fusion techniques shows their advantages. Multiple assessment measures show that the suggested models outperform baseline techniques.

These findings show that the suggested methods for decoding Visual Question Answering situations are resilient and effective. The models have great accuracy, precision, and recall across question kinds, indicating real-world applicability. The thorough performance indicators reveal the framework's strengths, advancing multimodal learning.

Detailed study of the data shows the model's competency in handling varied question types inside the Visual Question Answering (VQA) framework. In Fig. 2, accuracy percentages illustrate the model's performance. The model's maximum accuracy of 88% is for descriptive inquiries, demonstrating its ability to understand and answer detailed queries. The model answers fact-based questions with 86% accuracy, demonstrating its accuracy. Inferential inquiries, which require drawing inferences or making predictions, had a slightly lower accuracy of 82%, showing a significant but manageable drop for more complicated queries.

Precision scores, shown in Fig. 3, demonstrate the model's accuracy and lack of false positives. Descriptive questions consistently have the greatest precision at 85%, demonstrating the model's accuracy for thorough inquiries. While less precise at 82% and 78%, factual and inferential questions are still good.

Recall scores in Fig. 4 show the model's information retrieval capabilities. Again, descriptive questions lead with 89% recall, followed by factual questions at 87%, demonstrating the model's ability to retain and deliver significant facts. With an 83% recall rate, inferential questions suggest a strong but slightly diminished ability to retrieve knowledge for more difficult inquiries.

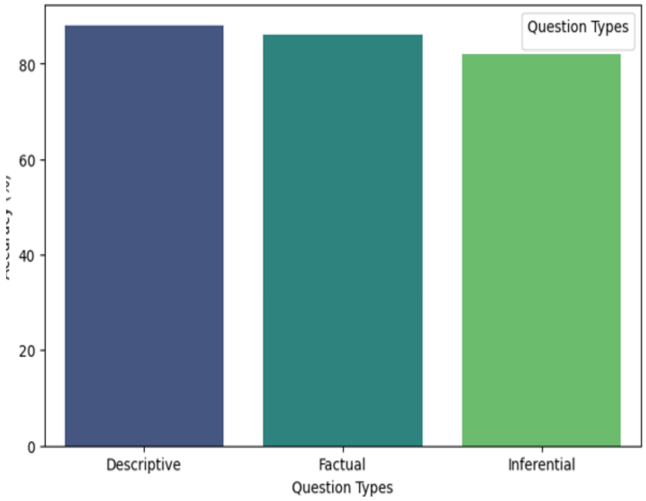

Fig. 2. Accuracy across question types.

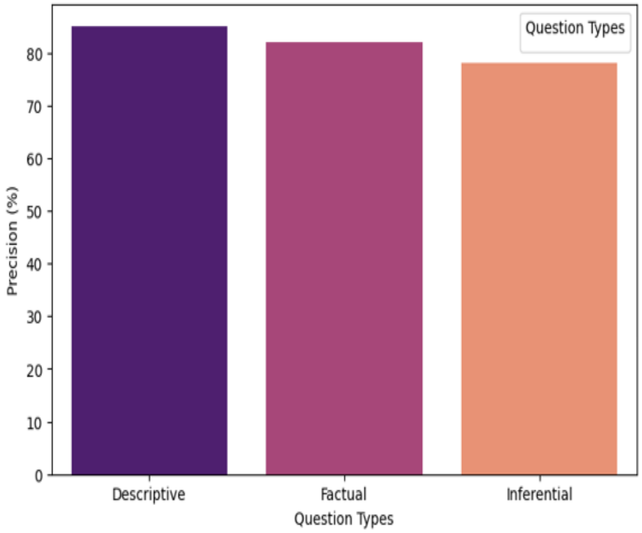

Fig. 3. Precision across question types.

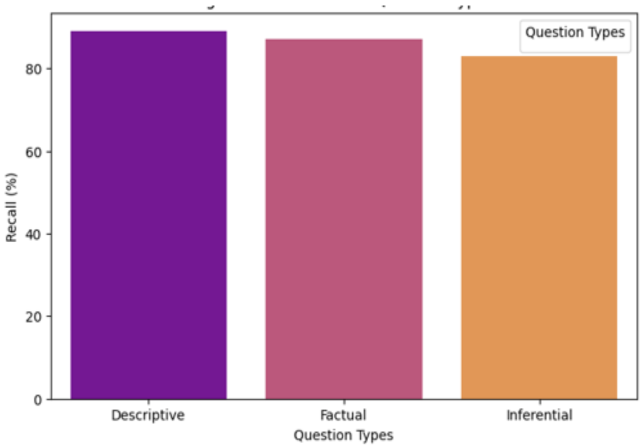

Fig. 4. Recall across question types.

The harmonic mean of accuracy and recall, the F1 Score, is shown in Fig. 5. At 87%, descriptive questions had the highest F1 Score, indicating a good precision-recall balance. Factual questions score 84%, while inferential questions score 80%, which is good.

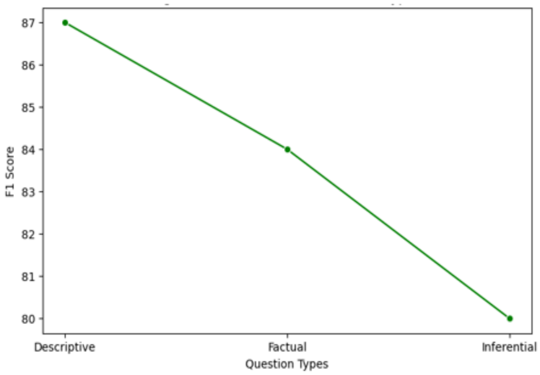

Fig. 5. F1 Score across question types.

Fig. 6 and Fig. 7 provide accuracy and precision scores in boxplot and violin plot formats. These visuals demonstrate the model's consistency across query kinds. Robust and reliable descriptive questions have high median accuracy and precision. Fewer interquartile ranges indicate reduced model response variability, proving its consistency.

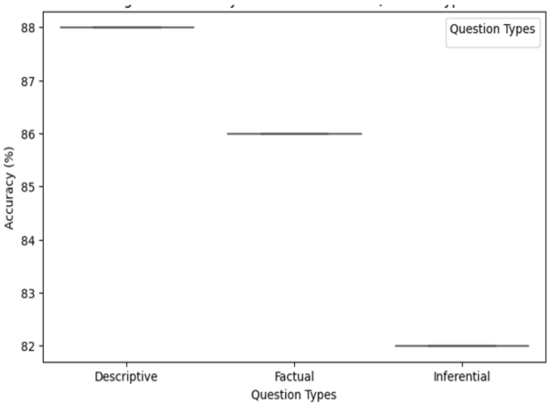

Fig. 6. Accuracy distribution across question types.

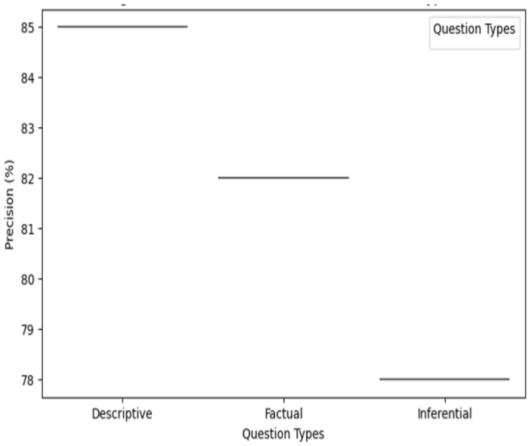

Fig. 7. Precision distribution across question types.

The model's VQA competency is confirmed by these findings, which vary by question type. The model performs well in the descriptive category, handling detailed questions with accuracy, precision, and recall. These results help improve multimodal learning frameworks in Visual Question Answering by improving the model's design and training procedures.

VI. Conclusions and Future Works

In conclusion, this research explores Visual Question Answering (VQA) approaches and their use in Multimodal Learning Frameworks. Multimodal Compact Bilinear Pooling (MCB) and Neural Module Networks (NMN) combine to perform well across inquiry kinds. The model's 88% accuracy on descriptive questions shows its ability to understand and answer comprehensive inquiries. With an 86% accuracy rate, the model handles fact-based queries well. Complex inferential questions maintain 82% accuracy. Precision scores show the model's reliability: descriptive questions lead at 85%, facts at 82%, and inference at 78%. Recall scores show the model's ability to recollect relevant information: Descriptive questions 89%, Factual 87%, and Inferential 83%. With descriptive questions scoring 87%, factual questions 84%, and inferential questions 80%, the F1 Score shows good accuracy and memory. The boxplot and violin plot show the model's consistency across question categories, with descriptive questions having high median accuracy and precision.

Several ways to improve and explore this study arise as we envisage its future. First, increasing the dataset size might improve the model's knowledge and reaction. Transfer learning, pre-trained models, and innovative architectures may improve performance. The model's decision-making process's interpretability is fascinating for further study. Attention processes and visualization tools may reveal which picture areas and question components influence the model's replies. Furthermore, using the system for multimodal problems other than VQA is intriguing. Exploring real-world applications like picture captioning or visual dialogue may build model adaptability. This study provides a solid basis for VQA techniques in Multimodal Learning Frameworks, with future efforts to refine and expand the model's capabilities for multimodal applications.

***Abstract*—Crop yield forecasting plays a key role in agricultural management and planning which is highly essential for food security and production in regional to global scales. However, a prediction of crop yield is considered a challenging task due to the difficulty in extracting spatial context and local semantic features, and difficulty in handling spatiotemporal relations. In order to address these issues, a comprehensive feature extraction is developed along with an effective deep-learning classifier. In this paper, the Residual Attention and Local Context Aware Classifier (RALCAC) is developed for obtaining appropriate features from the remote sensing crop yield images. The developed RALCAC helps to obtain the spatial context using Residual Attention (RA) module and local semantic information that are beneficial in understanding the detailed depiction of the crop. Further, the Convolutional Long Short Term Memory (ConvLSTM) is used to obtain the prediction of crop yield using the comprehensive features from the RALCAC. The RALCAC is analysed by means of Root Mean Squared Error (RMSE) and coefficient of determination. The existing research such as DeepYield, SSTNN and 3DCNN are used to compare the RALCAC method. The RMSE of RALCAC for the MODIS dataset is 3.257, and it is lesser when compared to the DeepYield.**

***Keywords*—Convolutional long short term memory; crop yield prediction; residual attention and local context-aware network; root mean squared error; spatial context data**

I. Introduction

Agriculture is an enriching field which clears the way out of economic pressure and has a believable macro-economic part in various economies. Crop production is a complicated phenomenon which is influenced by parameters of agro-climatic information. An improvement in crop yield quality and production while minimizing the costs and environmental pollution is a key objective in the precision agriculture [1-3]. Crop yield is referred as a key representation of sustainable development in agricultural field. An appropriate management practices are required to be adopted for stable organisation of land for crop production [4]. The different climatic situations that influence the crop yield are landscapes, soil quality, climatic situations, water quality and availability, genotype, harvest activity planning, pest infestations and so on. Further, the processes and strategies of crop yield are altered along with time and is non-linear and complex, because of an extensive development combination of interrelated factors, categorised and influenced by external and non-arbitrate run aspects [5].

A precise and timely estimation of crop yield before harvesting in a large scale is challenging for administrative planning and food security, specifically in frequently varying global and international situations. Simultaneously, an earlier prediction of yield is frequently needed to accomplish the decision making in transportation, storage, processing, harvest and marketing of agricultural merchandises [6-9]. The crop monitoring is obtained via interviewing farmers, field visits and manual data collection in regional level before informing the local statistical officers. But this manual process is expensive, inconsistent and time-consuming, the data is available only after harvesting [10, 11]. Remote sensing data is primarily confined to perform crop identification and classification for an extended period [12]. Remote sensing technology is discovered as well appropriate to gather the information over agricultural areas in recurrent intervals with lesser amount of time. Thus, the remote sensing offers an important contribution to provide a rapid comprehensive image. These remote sensing images display the crop development circumstances in chronological and geographical way which denotes their own extraordinary ability [13-15].

The crop yield prediction can be applicable in the following applications: 1) Precision agriculture: The predictive insights is used to plan the field operations such as planting, irrigation and schedule for harvesting for enhancing the yield; 2) Agricultural planning and decision-making: Precise yield prediction helps the farmers and investors for managing the risks related to the climate and diseases. The following issues such as inappropriate feature extraction, restriction against the generalization and failure in handling dynamics among the data. The aforementioned issued are taken as motivation for this research. Therefore, the comprehensive feature extraction using RALCAC is developed along with the ConvLSTM for an effective prediction.

The contributions of this research are concise as follows:

- The RALCAC uses the architecture of dual-encoder which improves the feature extraction capacity. The integration of spatial context data is achieved by using the residual attention, while local semantics also obtained that confirms the representation of local features and variations within the crop fields. Therefore, the combination of spatial context and local semantics is spatial features which used for detailed depiction of crop.
- The ConvLSTM based classifier is used to enhance the prediction of crop yield based on the spatial context and local semantics extracted from remote sensing images. The capacity of handling spatiotemporal dependencies of ConvLSTM is used to achieve an effective generalization during prediction.

The remaining paper is sorted as follows: The existing researches related to the crop yield estimation is given in Section II. The detailed information about RALCAC based feature extraction and ConvLSTM based prediction is provided in Section III. The outcomes of RALCAC are provided in Section IV, discussion is given in Section V and the paper is concluded in Section VI.

II. Related Work

The existing researches related to the crop yield estimation is given in this section.

Gavahi et al. [16] presented the DeepYield architecture for forecasting of crop yield, whereas the DeepYield was the combination of ConvLSTM and 3-Dimensional Convolutional Neural Networks (3DCNN). The intrinsic spatiotemporal patterns were considered in ConvLSTM to ensure the crop yield forecasting process. Further, the DeepYield was used to perform precise and robust crop yield forecasting, whereas the end-to-end learning was utilized for an automatic process of input. The local semantics were required to be highlighted for enhancing the feature extraction process.

Qiao et al. [17] developed Spatial-Spectral-Temporal Neural Network (SSTNN) to predict the crop yield which was the integration of 3D convolutional (Conv) and recurrent neural networks. The joint spatial-spectral-temporal representation was recognized by incorporating a spatial-spectral learning and temporal dependency, capturing modules in SSTNN. An effect of imbalanced dissemination of crop yield labels was eliminated by using a loss function. The crop yield prediction was high, when the SSTNN was processed with a huge amount of temporal information.

Fernandez-Beltran et al. [18] presented large-scale rice crop dataset (RicePAL) which has the multi-temporal S2 and climate/soil information from Terai districts of Nepal. The inherent data restraints were adapted 3DCNN for precise estimation of rice crop yield. The developed Convolutional Neural Networks (CNN) was developed for controlling the amount of layers while the fixing 3D Conv blocks were used to minimize the over-fitting. Nonetheless, an extra temporal dimension increased the amount of network parameters that made it possible for the 3DCNN to operate well only for larger patches.

Oikonomidis et al. [19] developed the hybrid deep learning approaches for predicting the crop yield. The developed models were XGBoost, XGBoost with scaling, integrated XGBoost with scaling and feature selection, hybrid CNN-XGBoost, CNN-Recurrent Neural Networks (RNN), CNN- Deep Neural Networks (DNN) and CNN-Long Short Term Memory (LSTM). The XGBoost was utilized as estimator to accomplish the feature selection. Here, the data dependencies and information were obtained by using the CNN. Next, the predictions were done by using the DNN as feed forward propagation approach. The developed XGBoost resulted in higher RMSE while performing the crop yield prediction.

Abbaszadeh et al. [20] presented a framework for combining the deterministic outputs from two DNN for creating the probabilistic simulation. The developed framework was Copula-Embedded Bayesian Model Averaging (COP-BMA) that combined the set of multivariate Copula operations into BMA. This COP-BMA reduced any consideration over the shape of conditional probability distribution function which used to offer precise and consistent predictive distributions. However, the contextual information was required for further improving the prediction.

Mohan, A et al. [21] developed the Temporal Convolutional network (TCN) with a customized dilated convolution unit for forecasting the rice crop yield. The correlation among the temporal and spatial parameters was analyzed using the TCN and it minimized the prediction error. The TCN's causal property and dilated convolution were resulted in the multivariate time-based evaluation and provided the enhanced prediction. The local features and changes within the crop were required to be extracted for further enhancing the prediction.

Qiao, M et al. [22] presented the knowledge-guided temporal multi-head attention approach that combined the prior information and scores of multi-head self-attention for combining the dynamical temporal correlation. Specifically, the prior attention distribution was introduced in self-attention learning based on the dynamic temporal graph convolution transformer. The features of spatially nearby places were aggregated based on geospatial relations for enhancing the capacity of prediction. The temporal dynamics of the features was required to be considered during the prediction for handling the dependencies between the data.

Boppudi, S. and Jayachandran, S [23] developed the hybrid mode according to the improved feature ranking fusion that fused the features from Relief, Recursive Feature Elimination (RFE) and Chi-Square method. The imbalanced data was handled by using an improved synthetic minority oversampling technique. Finally, the prediction was accomplished by integrating the LSTM with Deep Belief Network (DBN) classifiers. The selection of appropriate features was used to enhance the prediction by using the LSTM-DBN. However, the generalization with different datasets was required to be considered for an effective analysis.

Kolipaka, V.R.R. and Namburu, A [24] presented the deep learning-based system for predicting the agricultural production. This research considered a Two-stage classifiers where stage 1 performed pre-prediction and stage 2 performed the final classification for predicting the yield. The pre-prediction stage was incorporated the LSTM, Recurrent Neural Network (RNN) and LSTM for pre-prediction while the improved Convolutional Neural Network (CNN) was used in classification stage. In improved CNN, the Dingo Optimized Sand Piper (DOSP) was used for fine tuning the CNN to improve the prediction. The spatial features were required to be considered for further enhancing the prediction performances.

The limitations from the related works are specified as follows: inappropriate feature extraction, failed to obtain the generalization and ineffective in handling the spatiotemporal dependencies in prediction. In order to address these issues, the RALCAC is developed along with the ConvLSTM for an effective crop yield prediction. The encoders used in the RALCAC extracts the features of spatial context and local semantic information for effectively depicting the crop. Further, the capacity of handling the spatiotemporal dynamics of extracted features by ConvLSTM offers an effective prediction with generalization capacity.

Feature extraction using RALCAN
Crop yield prediction using ConvLSTM

Fig. 1. Block diagram of proposed method.

III. Proposed Method

In this proposed method, the crop yield prediction using remote sensing images is achieved by using the RALCAC and ConvLSTM classifier. The main processes existing in the proposed method are dataset acquisition, data pre-processing, feature extraction using RALCAC and prediction using ConvLSTM. The residual attention unit existing in the RALCAC integrates residual linking and attention operation for retaining whole edge data, highlighting crucial semantics and improves the generalization capacity used to enhance the prediction. Fig. 1 shows the crop yield forecasting using RALCAC and ConvLSTM.

A. Dataset Acquisition

This research considers three different dataset such as MODIS dataset, MOD09A1 dataset and RicePAL dataset for evaluation.

1) MODIS dataset

a) Yield data: The measurements of soybean related to country are gathered from USDA NASS Quick Stat tool. For performing the model training, the yield information [25] between 2003 and 2019 is utilized as labels of ground truth.

b) MODIS surface reflectance: A surface spectral reflectance with seven bands is obtained by MODIS/Terra Surface Reflectance (SR) [26] which is acquired at spatial resolution of 500m for every eight days. A finest possible SR observation exists in each pixel, but this SR observation is chosen from all the observations of the 8-day window.

c) MODIS land cover: The MODIS Land Cover (LC) [27] type is combined by the Terra and Aqua which offers the yearly LC categories formulated from six recognition schemes. The cropland areas masking is done by annual University of Maryland (UMD).

d) MODIS land surface temperature (LST): A time surface temperature of average of 8 day per pixel, day and night is provided by MODIS of Version 6 LST. A 7 thermal infrared bands are employed by LST approach for collecting the temperature data.

2) MOD09A1 dataset: This MOD09A1 dataset [28] has seven spectral bands and a 500m spatial resolution is utilized for obtaining the required reflectance data. For wheat yield, this dataset includes a time series of 32 images obtained among October to July while time series of 20 images are obtained among May to October.

3) RicePAL dataset: The RicePAL dataset [18] has 3-year multi-temporal S2 imagery acquired from Terai area of Nepal along with its ground truth. Moreover, a climate and soil information are incorporated in the data for supporting the yield forecasting.

B. Pre-Processing

The datasets considered in this proposed method comprised of SR, MODIS LST and Land Use LC have 7, 2 and 1 band. The latter is utilized for masking the cropland zones through each county. The tiles are mosaiced into a single image which encloses the degree of the CONUS. A clipping is done for mosaiced raster through each country and the images for the chosen time intervals are combined by generating 3D tensors. The MODIS SR and LC has a spatial resolution of 500m which is dissimilar from the MODIS LST. Therefore, the 500m images are scaled up to 1km resolution by employing linear interpolation. Further, the 4D tensors with the measurement of $Time \times Height \times Width \times band$ is developed by concatenating each product's band to 3D tensors. The input image size is increased by including the rows and columns of zero in the zero padding process which is used to make the images in similar sizes before giving them to the RALCAC.

C. Feature Extraction using RALCAC

The RALCAC used in feature extraction utilizes the architecture of encoder and decoder for constructing the model. In that, the Residual Attention (RA) module is incorporated in encoders for obtaining the higher level semantic data from the pre-processed image, multi-scale spatial data is obtained by Multi-Scale Dilated Convolution (MSDV) and abstracted feature data is amplified by sing decoders that obtains the pixel-by-pixel semantic segmentation. The spatiotemporal features of pre-processed image are extracted by using RA and MSDV.

The developed RALCAC receives two different inputs such as pre-processed image and multi-feature information. The multi-feature information includes the features of color, texture and shape that made the complete utilization of rich feature information. Here, the color moments are chosen as color features and texture features are extracted by Gray Level Co-occurrence Matrix (GLCM), and the detection of edge according to contours are chosen as shape features. The information is extracted pixel by pixel while processing the color and texture features.

1) Architecture of encoder and decoder: The encoder and decoder extracts comprehensive feature data of the input image. The adjusted RsNet-50 is considered as dual encoder baseline architecture that has a multi-layer residual mapping block. This mapping blocks are additionally separated as two main modules such as identity blocks and conv blocks, and each Conv block has 3×3 Conv layer and two 1×1 Conv layers. Further, the identity block contains additional 1×1 Conv layer when compared to the Conv block over the shortcut that is employed to modify the channel's dimension. The architecture of decoder has Conv and up-sampling blocks. The feature map's spatial size is increased by up-sampling, while the local feature extraction is accomplished by Conv layer in the amplified feature map. The RALCAC receives two different inputs and the allocation of two symmetrical encoders with different weight values improve the feature extraction ability. The given input is processed over various conv and identity blocks followed by the feature maps being obtained layer by layer. Accordingly, the multiple dimensionality reduction causes losses in the spatial and spectral data of input. Hence, the underlying feature data with in-depth features are combined based on the skipping connections among encoder and the decoder. This skipping connections are used for an effective extraction of crop data in complex situations.

2) Residual attention unit: The attention methodology which replicates the human perception and obtains the features is developed. The developed RA uses various weight values for highlighting essential data while reducing unwanted data. Simultaneously, the RA solves the issues created by correlation among various feature channels, decrement in computational efficiency and the deficiency of abstraction and extraction for essential data in the network. The high and low weights are used in RA for highlighting the essential data and eliminating the unwanted data which in turn improves the generalization capacity and network's robustness for obtaining beneficial information in various situations.

The integration of RA and deep learning improves the deep learning performances. In feature mapping, the network frequently creates various residuals in encoder-decoder architecture. An amount of network layers deepens are maximized by using the residuals. The essential data is highlighted by using the various weights in RA which also offers a definite level of interpretability for the features of black box. Thus, the RA utilizes attention operation for highlighting the essential local data and residual links for integrating local context data, thereby obtaining the requirement of emphasising local contextual information. The developed RA has two portions such as, series Conv and shortcut, wherein the RA architecture is shown in Fig. 2. The convergence speed and generalization capacity are enhanced by using the Batch Normalization (BN) layer and ReLU after every Conv layer. In series Conv structure, an each Conv layer of Conv kernel is $\{2^{(i+5)}, 2^{(i+5)}, 2^{(i+6)}\}$, where RA module is denoted as i. Due to the difference in the amount of input and output channels, the architecture of shortcut includes 1×1 Conv, developed for varying the dimension of channel, while the amount of Conv kernels is $2^{(i+6)}$.

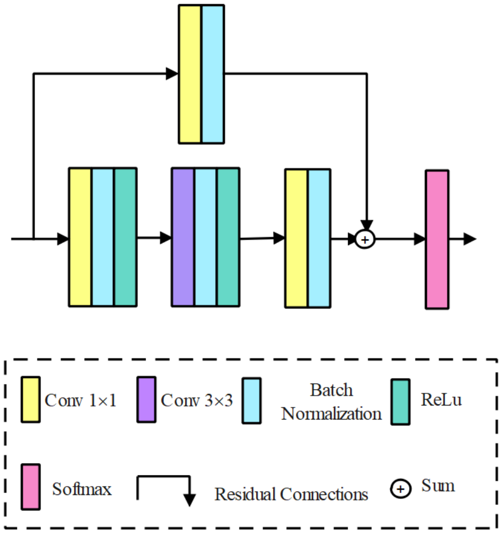

Fig. 2. Architecture of RA.

3) Process of MSDV: The MSDV unit is incorporated among the encoder and decoder in the overall model by using various dilation rates of dilated Conv 1×1 Conv layer for extracting the feature maps from multi-scale. The MSDV with 5 channels is shown in Fig. 3. A 1×1 Conv layer is used in the 1st channel for obtaining feature data and 3×3 Conv layer is incorporated in the 2nd channel. The dilated Conv with dilation rates of $\{1, 2, 3\}$ are appended from the 3rd to 5th channel for increasing the limit of the receptive field without maximizing the model's complexity. Eq. (1) shows the specific computation process of multi-scale dilated Conv.

$$x(l_0) = \sum_{i=1}^{N} m_i(l_0) \tag{1}$$

Where, MSDV of input feature map is denoted as l_0, and multi-scale dilated Conv for layer i is denoted as $m_i()$. Further, the outcomes of each layer is combined and multi scale feature data (x) is achieved from RALCAC.

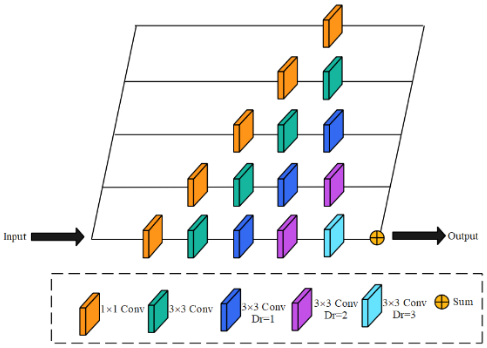

Fig. 3. Architecture of MSDV with five channels.

D. Prediction using ConvLSTM

In this phase, the ConvLSTM which is the integration of Conv filters and LSTM layers is developed for performing the crop prediction based on the features from RALCAC. Generally, the LSTM network has the capacity for maintaining the cell state from the preceding observation's sequence during the unwanted data elimination. The aforementioned principle is ensured by preserving the information over three gates such as input, output and forget gates. The Conv filters are employed to the input to state, and state to state changes of the LSTM. Fig. 4 shows the inner architecture of ConvLSTM. The architecture of ConvLSTM is described in Eq. (2) to Eq. (6).

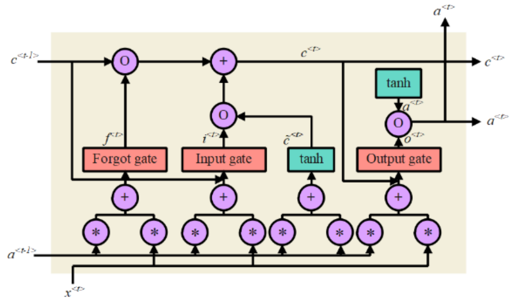

Fig. 4. Inner architecture of ConvLSTM.

$$i^{(t)} = \sigma\left(W^{*}_{xi}x^{(t)} + W^{*}_{ai}a^{(t-1)} + W^{\circ}_{ci}c^{(t-1)} + b_i\right) \tag{2}$$

$$f^{(t)} = \sigma\left(W^{*}_{xf}x^{(t)} + W^{*}_{af}a^{(t-1)} + W^{\circ}_{cf}c^{(t-1)} + b_f\right) \tag{3}$$

$$c^{(t)} = f^{(t)\circ}c^{(t-1)} + i^{(t)\circ}\tanh\left(W^{*}_{xc}x^{(t)} + W^{*}_{ac}a^{(t-1)} + b_c\right) \tag{4}$$

$$o^{(t)} = \sigma\left(W^{*}_{xo}x^{(t)} + W^{*}_{ao}a^{(t-1)} + W^{\circ}_{co}c^{(t-1)} + b_o\right) \tag{5}$$

$$a^{(t)} = o^{(t)\circ}\tanh\left(c^{(t)}\right) \tag{6}$$

Where, $i^{(t)}, f^{(t)}$ and $o^{(t)}$ are the variables returned by input, forget and output gate, respectively, cell output is denoted as $a^{(t)}$, weight matrices are denoted as W, elementwise product is denoted as $(\circ)$, Conv operator is denoted as $(*)$ and sigmoid activation function is denoted as σ.

ConvLSTM is generally used to acquire the intrinsic spatiotemporal patterns of given data. For each required output, eight filters are needed in the architecture of ConvLSTM. The incorporation of Conv filters in LSTM minimizes the model parameters, than the single LSTM which is used to achieve training even deeper that helps to achieve better prediction.

IV. Results and Discussion

The results and discussion of the proposed method are given in this section. The proposed method is analysed by using Python 3.6 software. Here, the Tensorflow 1.14 and Keras library are used for execution of the crop yield prediction. The system is configured with 1 TB memory 128 GB RAM, Windows 10 operating system, 22 GB RAM for RTX 2080 Ti GPU, and i9 processor. The performance measures analysed in this research are RMSE and coefficient of determination (R^2) which are expressed in Eq. (7) and Eq. (8).

$$RMSE = \sqrt{\frac{\sum_{i=0}^{N}(M_i - O_i)^2}{N}} \tag{7}$$

$$R^2 = 1 - \frac{\sum_{i=1}^{N}(M_i - O_i)^2}{\sum_{i=1}^{N}(M_i - \bar{O})^2} \tag{8}$$

Where, the model forecast and observed yield value are respectively denoted as M_i and O_i, their respective mean values are represented as $\bar{M}$ and $\bar{O}$, and the amount of predicting data points is denoted as N.

A. Performance Analysis

The primary objective of this research is evaluated using MODIS dataset for soybean forecasting. Further, the proposed method is evaluated in three different datasets such as MOD09A1 dataset for wheat corn yield prediction and RicePAL dataset. The RALCAC is assessed for different features and different classifiers. The different features are color, shape and texture, while the different classifiers are Random Forest (RF), Recurrent Neural Network (RNN) and LSTM.

1) *Evaluation of proposed method for MODIS dataset*: The MODIS dataset is evaluated for different selection and classifiers as shown in the Table I and II, respectively. Further, the graphs for different features and classifiers are shown in the Fig. 5 and Fig. 6. From the analysis, it is determined that the RALCAC provides better performance than the individual color, texture and shape features. Therefore, the RALCAC uses the multi feature information and pre-processed image for extracting the beneficial data from the images, which further enhance the prediction. On the other hand, the ConvLSTM provides better classification than the RF, RNN and LSTM. The observation of intrinsic spatiotemporal patterns in ConvLSTM is enhances the prediction.

TABLE I. Proposed Method Evaluation with MODIS Dataset for Different Features

Features	*RMSE*	R^2
Color	5.942	0.82
Texture	4.097	0.91
Shape	7.005	0.87
RALCAC	3.257	0.94

TABLE II. Proposed Method Evaluation with MODIS Dataset for different Classifiers

Classifiers	*RMSE*	R^2
RF	4.982	0.82
RNN	5.743	0.77
LSTM	4.226	0.89
ConvLSTM	3.257	0.94

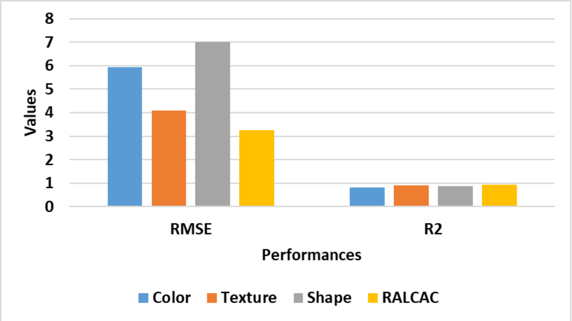

Fig. 5. Proposed method graph of MODIS dataset for different features.

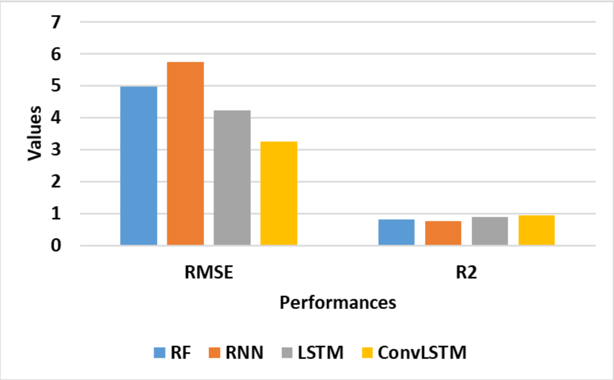

Fig. 6. Proposed method graph of MODIS dataset for different classifiers.

2) Evaluation of proposed method for MOD09A1 dataset: In this section, the time series of 32 images obtained between October to July of the next year in MOD09A1 dataset are used for wheat yield prediction. Table III and IV show the proposed method's evaluation of MOD09A1 dataset for different features and different classifiers. Further, the graph of the proposed method with MOD09A1 dataset for different features and different classifiers is shown in Fig. 7 and Fig. 8. From the analysis, it is found that the RALCAC obtains better performance than the individual features. Moreover, the ConVLSTM provides better performance than the RF, RNN and LSTM. The RALCAC achieves superior prediction because it highlights the required semantics and improves the generalization capacity. Also, the combination of Conv filters and LSTM block in ConvLSTM enhances the prediction.

TABLE III. PROPOSED METHOD EVALUATION WITH MOD09A1 DATASET FOR DIFFERENT FEATURES

Features	$RMSE$	R^2
Color	0.77	0.83
Texture	0.71	0.88
Shape	1.23	0.77
RALCAC	0.63	0.93

Classifiers	$RMSE$	R^2
RF	0.91	0.79
RNN	0.98	0.73
LSTM	0.72	0.81
ConvLSTM	0.63	0.93

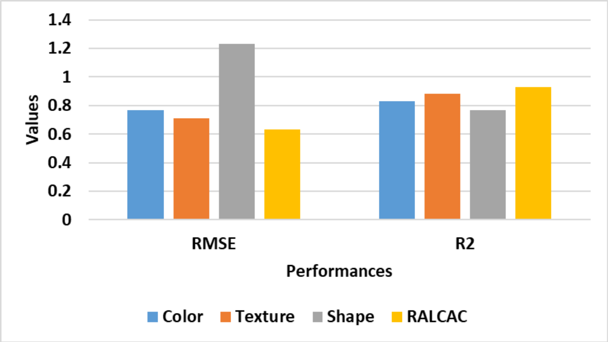

Fig. 7. Proposed method graph of MOD09A1 dataset for different features.

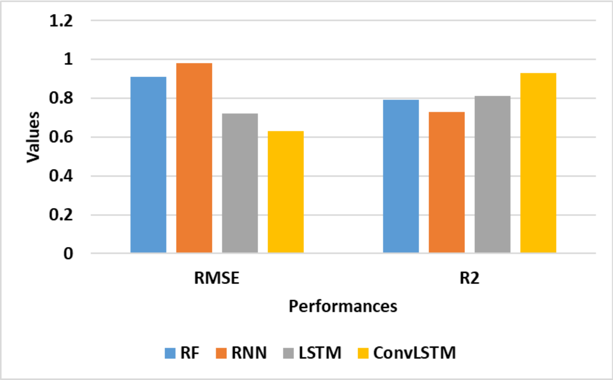

Fig. 8. Proposed method graph of MOD09A1 dataset for different classifiers.

3) Evaluation of proposed method for RicePAL dataset: The RicePAL dataset is evaluated for different selection and classifiers as shown in Tables V and VI, respectively. Further, the graph of the proposed method with RicePAL dataset for different features and classifiers is shown in Fig. 9 and Fig. 10, correspondingly. From the analysis, it is determined that the RALCAC provides better performance than the individual color, texture and shape features. Moreover, the ConvLSTM provides better prediction than the RF, RNN and LSTM.

TABLE V. PROPOSED METHOD EVALUATION WITH RICEPAL DATASET FOR DIFFERENT FEATURES

Features	$RMSE$	R^2

B. Comparative Analysis

This section shows the comparative analysis of the RALCAC based crop yield prediction. The existing research such as DeepYield [16], SSTNN [17] and 3DCNN [18] are used to compare the RALCAC. Here, the comparison is done for three different datasets such as MODIS, MOD09A1 and RicePAL. Table VII shows the comparative analysis of RALCAC while the graph for MODIS dataset is shown in Fig. 11. From the comparison, it is concluded that the RALCAC provides lesser RMSE than the DeepYield [16], SSTNN [17] and 3DCNN [18] methods. The integrated spatial context information along with the highlighting of local semantics in RALCAC improves the feature extraction which helps to achieve better prediction.

TABLE VII. COMPARATIVE ANALYSIS OF RALCAC

Datasets	Methods	RMSE
MODIS dataset	DeepYield [16]	4.79
	RALCAC	3.257
MOD09A1 dataset	SSTNN [17]	0.67
	RALCAC	0.63
RicePAL dataset	3DCNN [18]	89.03
	RALCAC	2.069

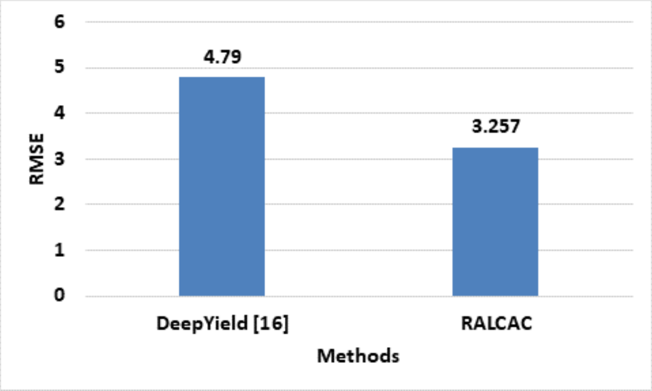

Fig. 11. Comparison graph for MODIS dataset.

V. DISCUSSION

This section provides the discussion about the crop yield prediction performed by the RALCAC and ConvLSTM. The different datasets used for evaluation are MODIS dataset, MOD09A1 dataset and RicePAL dataset. The RALCAC is evaluated with different feature extraction approaches such as Color, Texture and Shape while the ConvLSTM is evaluated with different classifiers such as RF, RNN and LSTM. The evaluation demonstrates that the RALCAC and ConvLSTM has better performance than the aforementioned state of art approaches. Moreover, this RALCAC outperforms well than the DeepYield [16], SSTNN [17] and 3DCNN [18]. The main reason of improved prediction is RALCAC based comprehensive feature extraction and handling of spatiotemporal dynamics using ConvLSTM. The developed RALCAC extracts the spatial context features using RA module and local semantic information during the extraction. Therefore, the RALCAC represents the extensive spatial features and relationships, and local features and changes in the crop fields which effectively depicts the crop. Additionally, the capacity of spatiotemporal handling using ConvLSTM is used for an effective prediction with generalization capacity.

VI. CONCLUSION

In recent times, the evolution of remote sensing offers huge accessibility for performing precise crop yield prediction. In this research, RALCAC based comprehensive feature extraction is developed along with a ConvLSTM classifier. An effective depiction of crop is obtained by extracting the spatial context and local semantic features using the RALCAC which denotes spatial features and its relationships, and local features and changes in the crop fields. Further, the ConvLSTM performs a prediction based on the spatial and local semantic features from the RALCAC. The capacity of handling the spatiotemporal dependencies using ConvLSTM helps to enhance the prediction with effective generalization. From the simulation, it is found that the RALCAC outperforms the DeepYield, SSTNN and 3DCNN. The RMSE of RALCAC for MODIS dataset is 3.257, which is lesser when compared to the DeepYield. In future, a feature selection can be developed for further improving the prediction performances.

Business Insights into the Internet of Things: User Experiences and Organizational Strategies

Yang WEI
Sichuan Polytechnic University, Deyang 618000, China

***Abstract*—The Internet of Things (IoT) has revolutionized business operations across industries by integrating physical devices into digital networks. This study discusses the extensive business literature, particularly the impact of IoT from the perspective of users and organizations. This paper provides a comprehensive analysis of the effects, challenges, and opportunities of IoT in the business domain by integrating various perspectives and insights. We analyze trends in IoT adoption and explore the conditions promoting its widespread use in different industries and regions. The research investigates user perspectives, such as acceptance, user experience, and the ethics of the IoT. This paper focuses on how IoT will lead to new business models and the implications for strategy, operations, and client relationships. It critically reviews challenges, such as security vulnerabilities, compatibility challenges, and legal frameworks that currently restrict effortless integration of IoT in the industry from a business standpoint. Finally, we provide recommendations for further research.**

Keywords*—Internet of Things; business literature; user perspectives; organizational impact; adoption trends; data-driven strategies

I. Introduction

In the ever-evolving technological landscape, the Internet of Things (IoT) has emerged as a revolutionary phenomenon with the potential to fundamentally reshape our interactions with the environment, gadgets, and fellow individuals [1]. The IoT refers to a network of connected devices varying in communication capabilities and origins. These devices range from basic sensors to various companies' intricate equipment [2]. IoT applications span various real-world sectors, including smart homes, healthcare, drone deliveries, and intelligent parking systems. The cooperative nature of devices is a crucial characteristic of IoT ecosystems [3]. These entities collaborate to accomplish a shared goal. For example, smart refrigerators and ovens could communicate with smartwatches and smartphones to optimize meal preparation in a smart home setting. The gadgets used in these environments are also diverse. IoT devices vary widely in their capabilities and functionalities [4].

The reasons for considering IoT in business mainly originate from some of the following aspects. First, the continuously increasing number of connected devices creates never-seen risks and opportunities for creating and analyzing data. Businesses can use the data to understand consumers, manage their operations, and make proper decisions. The rise in connectivity also builds a more connected environment where companies can be more adaptable and engaged by integrating real-time information into their strategies.

Second, the internal requirement to increase the Company’s operational efficiency is one of the main reasons. Innovative technologies can be used to manage business processes to minimize physical interference with the processes. For instance, IoT for predictive maintenance in industries can help avoid huge losses through breakdowns in manufacturing industries, and intelligent inventory management in retail sectors can assist in preventing shortages of stocks and overstocking, among others.

Third, customers’ expectation for their needs to be met in an exceptional and timely manner is increasing. IoT enables customers to interact based on their preferences and context, considering the value of high customer satisfaction and loyalty. For instance, smart retail can send targeted offers to customers based on browsing history, and smart health wearables can send personalized regimens.

Globalization has led to the rise of complex economic networks or business ecosystems. These ecosystems consist of a network of organizations and individuals, each playing a distinct role within the system [5]. As the primary participants, core firms sometimes work alongside consumers, market facilitators, suppliers, venture investors, and competitors [6]. Rapid technological advancements and the widespread use of IoT applications and services demand a thorough assessment of the current literature. A comprehensive understanding of IoT's impact on user experience and organizational outcomes is critical as organizations grapple with the intricacies of integrating IoT solutions [7, 8]. This study provides a thorough analysis of IoT dynamics within the business domain. A holistic analysis of IoT adoption impacts, challenges, and opportunities is presented in this paper by meticulously synthesizing insights drawn from a wide range of academic literature. This research endeavors to address the following Research Questions (RQs).

RQ1: What are the current trends and patterns in IoT usage across different industries and regions? This question explores how various sectors and geographical areas incorporate IoT technology, emphasizing industry-specific and regional variations in usage and deployment plans.

RQ2: How do user-centric aspects, such as consumer acceptance, experiences, and ethical concerns, influence IoT adoption and utilization in the business sector? This question addresses the human dimensions of IoT adoption, focusing on how consumer behavior, satisfaction, and ethical concerns drive the integration of IoT solutions on the market.

RQ3: How do IoT-driven business models and approaches impact organizational operations, customer relationships, and overall performance? This question discusses the organizational aspect, analyzing how IoT-enabled innovations transform business processes, boost customer engagement, and improve profitability and competitiveness.

RQ4: What are the main challenges in incorporating IoT into business scenarios, and what future research directions can overcome them? This question examines IoT adoption and integration issues, highlighting critical obstacles and suggesting research areas to develop solutions and best practices for these challenges.

The present paper follows the following format. A description of the IoT is given in Section II, along with its essential characteristics. Adoption trends, user-centered perspectives, and organizational aspects of IoT in business are discussed in Section III. Research challenges and future directions are outlined in Section IV. Section V concludes the paper.

II. IoT Definitions and Characteristics

The IoT has fundamentally reshaped the networking landscape through the sheer diversity of its intelligent applications. These applications encompass healthcare, energy grids, financial services, and other intelligent services [9]. The underlying architecture of an IoT system can be conceptualized as a four-layered framework, as depicted in Fig. 1. The foundational layer, the sensing layer, comprises sensors and actuators responsible for capturing data or control signals from the physical environment. The collected information is then transformed into electrical signals and transmitted via a wireless communication channel managed by the network layer. The subsequent layer, the middleware or processing layer, is a critical bridge between the preceding two layers. The application layer delivers end-to-end functionalities that cater to smart devices, transportation systems, healthcare solutions, and intelligent factories [10]. However, each layer within this architecture presents distinct security vulnerabilities alongside concerns regarding unauthorized access points (gateways) and privacy violations. Researchers have actively addressed these security challenges by exploring various approaches. Proposed solutions can be categorized as blockchain-based solutions, fog computing, edge computing, and machine learning-based methodologies.

A plethora of architectural propositions and functional descriptions for IoT networks have been documented within the research community. A widely recognized high-level architectural model, accompanied by a corresponding functional breakdown, is attributed to the European Telecommunications Standards Institute (ETSI). This classical architecture, illustrated in Fig. 2, can be dissected into several key domains:

1) Machine-to-machine (M2M) local network: This stratum encompasses the direct device-to-device communication channels or short-range connections within the local network [11].

2) Access network (network edge): This layer serves as the entry point for data transmission, facilitating communication between the local network and the broader internet [12].

3) Core network (backbone): The backbone forms the high-speed infrastructure for routing and transporting data across the more comprehensive network [13].

4) Cloud data center: This domain houses the centralized repository for processing, storing, and managing the vast quantities of data generated by IoT devices [14].

5) Application domain: This layer represents the end-user applications and services that leverage the data collected and processed within the IoT network [15].

The M2M local network is the bedrock for autonomous communication within the IoT architecture. This stratum comprises M2M devices equipped with self-governing sensing or actuation capabilities. These devices generate and transmit machine-specific data to other M2M devices or directly to end-user applications. The configuration of this sub-network within the broader IoT network can be categorized into two primary approaches:

1) Direct connection to gateway/base station: In this configuration, M2M devices establish a direct connection with a gateway (GW) or base station (BS) without needing an intermediary gateway. Cellular M2M networks exemplify this approach, where devices communicate directly with cellular network base stations.

2) Capillary network with gateway coordination: M2M devices can be interconnected in a star or mesh topology, forming a capillary network. This network is coordinated by a gateway device that functions as a proxy for a remote base station. Wireless Sensor Networks (WSNs) frequently leverage this configuration for integration within IoT networks.

The access network constitutes a critical bridge between the local M2M network and the more comprehensive external network. This bridge is primarily formed by gateway and base station devices, collectively called access network devices. In scenarios where GW and BS coexist, the GW device assumes the role of a proxy for the BS. It manages access for the capillary network and translates communication protocols to ensure compatibility with the BS.

In contrast to the access network, the core network domain embodies the established internet infrastructure. This infrastructure leverages the Internet Protocol (IP) to route data packets across diverse networks. The core network facilitates seamless connectivity between M2M local networks, enabling them to communicate with one another. Additionally, it extends this connectivity beyond the boundaries of the M2M domain, allowing M2M local networks to connect to other networks, such as cloud data centers. For this reason, the core network is also aptly referred to as the backbone of the IoT architecture.

The cloud data center is a critical infrastructure component within the IoT architecture. This distributed infrastructure comprises a network of hardware resources provisioned remotely. These resources encompass computing power, storage capabilities, and robust networking functionalities. The cloud data center operates in close collaboration with the application domain.

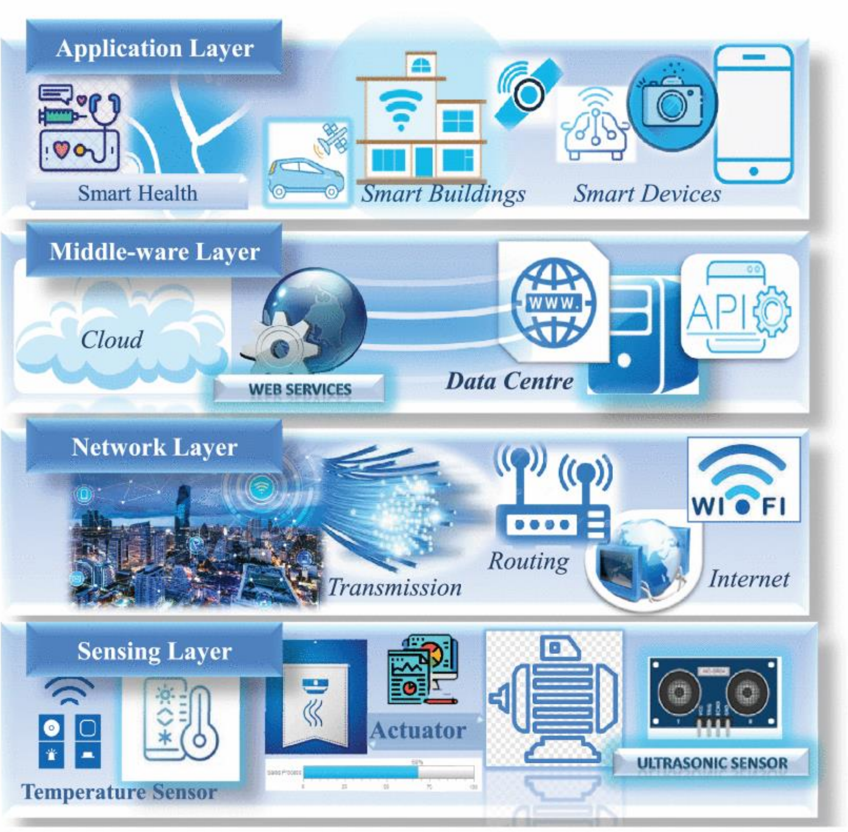

Fig. 1. Layered framework of an IoT system.

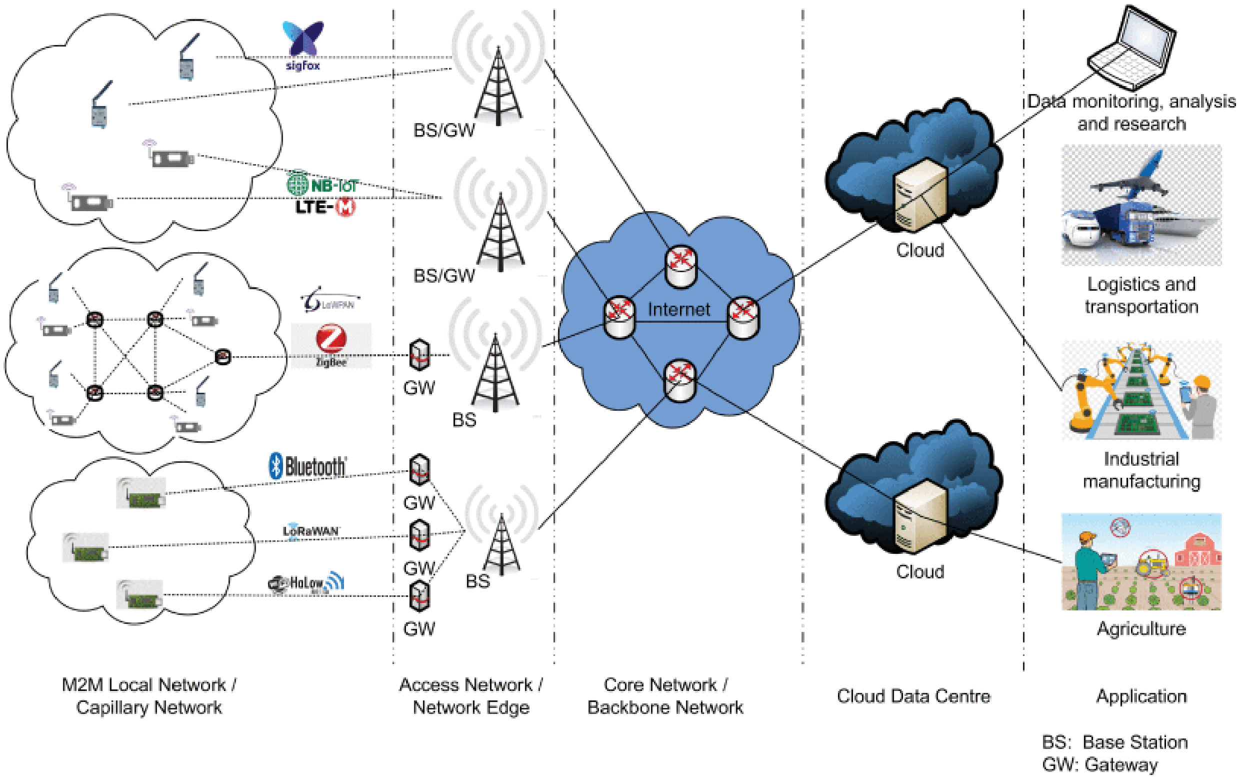

Fig. 2. Architectural model of IoT networks based on the European Telecommunications Standards Institute.

The application domain acts as the interface between humans and the M2M local network. It facilitates user interaction through specialized services designed to interpret and utilize the data collected by the network. An Application Programming Interface (API) typically bridges the cloud data center and these application services, enabling seamless data exchange and manipulation.

III. Understanding IoT in Business

A. *IoT Adoption Trends*

The use of IoT in many sectors has been rapidly increasing, fueled by the potential for improved operational effectiveness, reduced expenses, and the emergence of new opportunities for businesses. This section examines the present trends and patterns in adopting IoT, emphasizing variances specific to different industries and regions and the main factors influencing the acceptance of IoT technology.

As detailed in Table I, various industries have adopted the IoT at different rates, driven by individual requirements and obstacles within each sector. For example, the manufacturing industry has experienced substantial acceptance of IoT by installing smart factories and Industry 4.0 programs. IoT devices in smart factories facilitate predictive maintenance, real-time monitoring, and automation, decreasing inactivity and enhancing production. The healthcare industry swiftly embraces IoT technology, including wearable gadgets and remote monitoring systems, to improve patient care and operational efficiency. Wearable health gadgets gather up-to-the-minute information on essential bodily functions, which medical professionals may observe from a distance, enhancing patient results and decreasing trips to the hospital.

IoT is revolutionizing customer experiences in the retail industry by using intelligent shelves, customized marketing strategies, and streamlined inventory management. Smart shelves employ sensors to monitor inventory levels in real-time, promptly notifying workers when replenishment is required. Personalized marketing leverages IoT data to customize promotions based on specific customer preferences. The transportation and logistics sector utilizes the IoT to enhance fleet management, optimize routes, and track shipments in real-time. IoT-enabled fleet management solutions oversee vehicle performance and driver conduct, optimizing routes and minimizing fuel usage. In addition, the energy sector is employing IoT technology to manage smart grids and optimize energy usage.

Various factors influence the adoption of IoT technology across different businesses. Modern connectivity infrastructure, like 5G networks, enables flawless IoT operations by delivering the appropriate capacity and low latency. Economic factors significantly influence adoption decisions, such as the expenses associated with IoT devices and the potential for a profitable return on investment. Businesses must evaluate the upfront expenses of IoT adoption compared to the long-term advantages and cost reductions.

Moreover, IoT development can be accelerated or slowed by legal measures and government initiatives and programs. IoT solutions are influenced by data protection rules and cybersecurity regulations that govern organizations' observance and deployment of the solutions. For example, the General Data Protection Regulation (GDPR) in Europe sets the requirements for data handling and user consent, which can create issues related to IoT data collection and processing. Likewise, the CCPA laws require transparency and data control for individuals, putting forward more difficulties for corporate compliance.

Apart from privacy issues, cybersecurity laws like the Cybersecurity Information Sharing Act (CISA), in the case of the USA, make it compulsory for organizations to put in place solid measures for security to prevent IoT devices from breaches and cyber-attacks. Failure to actualize these regulations attracts severe penalties and organizational reputational loss. Governments with clear and affirmative policies for IoT may shorten this technology's adaptation rate since they provide clues and incentives. For instance, South Korea and Singapore have deployed elaborate IoT structures outlining rules and policies to encourage IoT implementation with bonuses such as tax credits and Sponsored R&D funding. These preventive measures promote legislation compliance and contribute to the inventiveness and effectiveness of competitive businesses in the international environment.

Organizational agility and level of digital advancement are other vital considerations. Companies that possess a robust digital infrastructure and foster a culture of innovation are more inclined to incorporate IoT technologies into their business processes effectively. This encompasses the essential IT infrastructure, proficient personnel, and a strategic strategy for effectively utilizing IoT. Moreover, forming alliances and partnerships with technology providers, startups, and research institutes can expedite the adoption of IoT by granting access to specialized knowledge and valuable resources. Collaborative ecosystems can stimulate creativity and enable the exchange of optimal methods and solutions.

To illustrate these trends, consider the example of a major automotive manufacturer that adopted IoT to streamline its production processes. By deploying IoT sensors on the assembly line, the organization can continuously monitor equipment performance in real-time, accurately forecast maintenance requirements, and minimize periods of inactivity, resulting in substantial cost reductions and enhancements in productivity. Another instance involves a retail conglomerate that employed IoT-powered inventory management systems to enhance stock levels and minimize wastage, enhancing customer contentment and increasing sales.

A hospital network in the healthcare industry has integrated IoT-enabled patient monitoring systems to enable continuous monitoring of patient's vital signs and early detection of potential health problems. This enhances patient outcomes and alleviates the workload on healthcare personnel.

TABLE I. INDUSTRY-SPECIFIC ADOPTION AND FACTORS INFLUENCING IOT INTEGRATION

Industry	IoT applications and benefits	Key influencing factors	Example use case	References
Manufacturing	Smart factories, predictive maintenance, real-time monitoring	Connectivity infrastructure (e.g., 5G), cost-benefit analysis	Automotive manufacturers using IoT sensors for real-time equipment monitoring	[16-21]
Healthcare	Wearable devices, remote monitoring systems	Data protection regulations, cybersecurity, digital infrastructure	Hospital network using IoT for continuous patient monitoring	[22-27]
Retail	Smart shelves, personalized marketing, inventory management	Economic factors, organizational agility, partnerships	Retail conglomerate using IoT for inventory management	[28-34]
Transportation and logistics	Fleet management, route optimization, shipment tracking	Legal frameworks, government policies, collaboration with tech providers	Logistics company using IoT for real-time fleet management	[35-39]
Energy	Smart grids, energy usage optimization	Regulatory support, innovation culture, infrastructure readiness	Utility company using IoT for smart grid management	[40-44]
Agriculture	Precision farming, real-time monitoring of soil and crops	Resource efficiency, connectivity infrastructure, economic viability	Farm using IoT sensors for precision agriculture	[45-48]

B. User-Centric Perspectives

When examining individuals in the context of the IoT, the main areas of interest are typically customers' preferences towards product design, users' acceptance, and intention to purchase novel technologies, and considerations of safety and privacy issues, as outlined in Table II. Understanding these elements is essential for comprehending how consumers perceive and adopt IoT items.

1) Customers' preferences in product design: Consumers increasingly seek IoT devices that provide intuitive and seamless user experiences in product design. Preferences typically center around user-friendliness, visual attractiveness, and practical functionality. Smart home products like thermostats, lighting systems, and security cameras are built with user-friendly interfaces and integration capabilities to operate seamlessly within a network of interconnected devices. Consumers choose items that exhibit both innovation and reliability while being user-friendly and straightforward to install and operate. Furthermore, the availability of customization tools that enable users to customize device settings according to their individual preferences is greatly appreciated. Manufacturers prioritize developing IoT products that possess visually appealing designs and robust functionality to satisfy users' varied requirements and expectations.

2) Users' acceptance and intention to purchase novel technologies: Gaining insight into users' acceptance and intention to buy innovative IoT solutions is crucial for achieving market success. The Technology Acceptance Model (TAM) and its modifications frequently serve as a framework for research in this field, emphasizing perceived usefulness, perceived ease of use, and social influence as crucial elements influencing acceptance. Consumers are more inclined to embrace IoT devices if they consider them advantageous in improving their daily lives and if the technology is user-friendly and can be seamlessly integrated into their current systems. Social factors, including peer influence and societal trends, influence consumers' intentions to adopt new technologies. Effective marketing methods that convey IoT devices' practical advantages and user-friendliness, along with favorable testimonials and endorsements, can significantly enhance consumer acceptability and influence purchasing choices.

3) Considerations of safety and privacy issues: The adoption of IoT devices is heavily influenced by the utmost importance placed on safety and privacy concerns. Due to the collection and transmission of substantial quantities of personal data by IoT devices, customers are becoming more concerned about data breaches, illegal access, and the improper use of their information. Privacy concerns encompass apprehensions over data collection, storage, and sharing methods, whereas safety concerns mostly revolve around the possibility of devices being hacked and exploited for malicious purposes. Research has demonstrated that these concerns can greatly impede the acceptance and use of IoT technologies. To tackle these problems, manufacturers and service providers must prioritize strong security measures like encryption, secure data storage, and frequent software updates. Transparency in data management and explicit privacy regulations can also foster consumer confidence.

4) Balancing innovation with user concerns: Striking a balance between incorporating cutting-edge capabilities and addressing consumer apprehension over safety and privacy is tricky. Consumers are enthusiastic about the potential of IoT to streamline and improve their lives, but they expect guarantees that their data and privacy will be safeguarded. To alleviate these worries, engaging in effective communication regarding the security measures implemented and empowering users with control over their data is crucial. Furthermore, integrating user feedback into IoT devices' design and development process may guarantee that the products fulfill consumer expectations and effectively tackle their concerns.

TABLE II. USER-CENTRIC AND ORGANIZATIONAL PERSPECTIVES ON IOT

Perspective	Focus area	Key points	Examples/Applications
User-centric	Customers' preferences in product design	• User-friendly • Seamless integration within networks • Customization options	Smart home products like thermostats, lighting systems, and security cameras with user-friendly interfaces
	User's acceptance and intention to purchase novel technologies	• Importance of perceived usefulness and ease of use • Social influence on acceptance • Effective marketing strategies	Use of the Technology Acceptance Model (TAM), marketing emphasizing practical benefits and user-friendliness
	Considerations of safety and privacy issues	• Concerns over data breaches and misuse • Importance of strong security measures • Transparency and adherence to standards	Encryption, secure data storage, frequent software updates, and clear privacy policies
Organizational	Smart manufacturing and industry 4.0	• Real-time monitoring and regulation of machinery • Predictive maintenance • Enhanced operational efficiency	IoT sensors in smart factories, predictive maintenance systems in manufacturing
	Smart retail	• Intelligent shelves and RFID tags • Personalized customer experiences • Inventory management	Smart shelves with weight sensors, RFID for item tracking, IoT devices for personalized promotions
	Healthcare and remote monitoring	• Wearable health monitors • Remote patient monitoring • Smart medical equipment	Wearable health monitors, remote monitoring systems, IoT-connected insulin pumps, and pacemakers
	Smart cities and infrastructure	• Traffic management systems • Waste management systems • Smart grids	IoT sensors for traffic control, smart bins for waste management, IoT-enabled smart grids
	Agriculture and precision farming	• Soil condition monitoring • Weather pattern analysis • Crop health monitoring	IoT sensors for soil moisture and nutrient levels, IoT-enabled drones for field surveys

C. *Organizational Perspectives*

IoT technology's swift advancement has resulted in many inventive applications across many business sectors. These nascent applications and functions can profoundly influence corporate operations, strategies, and market positioning. This section overviews important IoT applications and their prospective effects on enterprises.

1) Smart manufacturing and industry 4.0: IoT plays a vital role in the manufacturing industry, particularly in the context of Industry 4.0. This involves the seamless integration of IoT devices with sophisticated data analytics and automation systems. Smart factories utilize IoT sensors and actuators to continuously monitor and regulate machinery in real-time, resulting in improved operating efficiency, the ability to foresee maintenance needs, and reduced periods of inactivity. IoT-enabled predictive maintenance can anticipate equipment malfunctions in advance, enabling prompt interventions and reducing disruptions in production. Not only does this enhance efficiency, but it also prolongs the lifespan of machines, resulting in substantial cost savings.

2) Smart retail: The IoT revolutionizes the retail sector by implementing technologies like smart shelves, RFID tags, and customized customer experiences. Intelligent shelves fitted with weight sensors can monitor inventory levels and initiate restocking procedures automatically, guaranteeing the constant availability of products. RFID tags provide instantaneous tracking of items, minimizing losses and enhancing visibility inside the supply chain. Furthermore, IoT devices can collect client data to provide customized shopping experiences, including personalized promotions and recommendations tailored to individual interests and buying behaviors.

3) Healthcare and remote monitoring: The use of IoT applications, such as wearable devices, remote monitoring systems, and smart medical equipment, is significantly transforming patient care in the healthcare industry. Wearable health monitors gather information about vital signs and physical activity, which can be examined to offer tailored health suggestions. Remote monitoring systems provide uninterrupted surveillance of patients' health status, enabling timely identification of potential complications and minimizing the necessity for hospital visits. Advanced medical devices, such as internet-connected insulin pumps and pacemakers, can be remotely monitored and changed, enhancing patient outcomes and convenience.

4) Smart cities and infrastructure: The implementation of IoT applications is essential for developing smart cities, as interconnected devices optimize urban living by facilitating efficient resource management and enhancing service quality. Intelligent traffic management systems utilize IoT sensors to observe and regulate the movement of vehicles, thereby minimizing traffic congestion and pollutants. IoT trash management systems use real-time data from smart bins to improve collection routes, resulting in enhanced efficiency and cost reduction. Smart grids utilize IoT devices to effectively control electricity distribution, seamlessly incorporating renewable energy sources and guaranteeing a dependable power supply.

5) Agriculture and precision farming: IoT technology facilitates precision farming by offering up-to-the-minute information on soil conditions, weather patterns, and crop well-being. IoT sensors in agricultural fields can continuously monitor and measure soil moisture levels, temperature, and nutrient content. This data empowers farmers to enhance their irrigation and fertilization methods, resulting in optimized agricultural practices. IoT-enabled drones can conduct extensive surveys of vast farm lands, detecting problems like pest invasions or nutrient insufficiencies. These technologies improve the productivity of crops, decrease the use of resources, and encourage the use of sustainable agricultural methods.

The implementation of IoT technology provides enterprises with additional benefits through the improvement of operational efficiency, the reduction of expenses, and the facilitation of new business models. The instantaneous data produced by IoT devices enables more knowledgeable decision-making, resulting in enhanced operational performance. For instance, implementing predictive maintenance in the manufacturing industry can greatly decrease the amount of time machines are not operational and lower the expenses associated with maintenance. Similarly, using smart retail solutions can improve the management of inventories and increase consumer happiness.

Integrating IoT necessitates businesses to modify their conventional methods and adopt digital transformation. The IoT facilitates the implementation of novel business models, including subscription-based services and pay-per-use systems. Companies must make deliberate investments in IoT technologies and infrastructure to maintain competitiveness, frequently necessitating collaboration with technology providers and other stakeholders. It is essential to create a well-defined IoT strategy that aligns with the overall business objectives to fully leverage the advantages of implementing IoT technology.

IV. Challenges and Future Research Directions

The integration of IoT into business environments presents several significant challenges despite its transformative potential. This section explores these challenges and proposes future research directions to address them, ensuring IoT technology implementation success and security.

A. Key Challenges

1) Security vulnerabilities: Ensuring the security of devices and data is a significant challenge in deploying IoT. IoT systems typically comprise multiple interconnected devices, each of which might be exploited as a cyberattack vulnerability. These security weaknesses can potentially result in data breaches, illegal access, and substantial interruptions to business operations. The diversity of IoT devices, from basic sensors to intricate machinery, contributes to the intricacy of safeguarding these networks. Furthermore, a significant number of IoT devices possess constrained processing capabilities, hence posing challenges in the implementation of resilient security mechanisms.

2) Interoperability issues: The lack of interoperability continues to be a significant obstacle in the mainstream acceptance and implementation of the IoT. IoT ecosystems frequently comprise devices and systems from various manufacturers, each employing distinct communication protocols and standards. The absence of standards might result in compatibility concerns, hindering the smooth integration and effective functioning of IoT systems. Maximizing the benefits of IoT technologies requires excellent communication and collaboration across IoT devices.

3) Data privacy concerns: The huge volume of data created by IoT devices gives rise to substantial privacy concerns. Consumers and companies are becoming increasingly concerned about data collection, storage, and utilization methods. The possibility of misusing personal and sensitive information can erode faith in IoT devices. Furthermore, the General Data Protection Regulation (GDPR) and other regulatory frameworks set strict restrictions on data handling procedures, which increases the difficulty of guaranteeing compliance.

4) Regulatory and compliance challenges: IoT adoption is further complicated by navigating the regulatory landscape. Data security, privacy, and the implementation of IoT technology are subject to different rules depending on the location and industry. Organizations, especially those with a global presence, may struggle to stay updated with these standards and ensure they follow them correctly. Changes in regulations and the implementation of new policies can potentially affect the implementation and administration of IoT systems.

B. Future Research Directions

1) Enhanced security measures: Subsequent investigations should prioritize the development of sophisticated security measures specifically designed for IoT settings. This encompasses encryption algorithms for devices with limited resources, authentication processes that are strong and reliable, and communication protocols that ensure a high level of security. Furthermore, it is vital to do a study that delves into using artificial intelligence and machine learning to promptly identify and reduce security risks. It is essential to provide standardized security standards that can be uniformly implemented across various IoT devices and platforms.

2) Standardization and interoperability: To resolve interoperability problems, future research should focus on developing standardized protocols and frameworks that enable the smooth integration of various IoT devices. It will be essential for industry stakeholders, standards groups, and regulatory agencies to work together to create and advocate for these standards. Research can also investigate middleware systems that connect several communication protocols, guaranteeing compatibility and optimizing data exchange.

3) Privacy-preserving technologies: Investigating privacy-preserving technologies, such as differential privacy, homomorphic encryption, and federated learning, can effectively tackle challenges related to data privacy. These technologies provide the examination and utilization of IoT data while ensuring the protection of individual privacy. In addition, creating transparent data governance structures and privacy measures that prioritize users' needs would enable them to manage their data preferences successfully.

4) Regulatory frameworks and compliance Tools: Future research should prioritize the development of flexible regulatory frameworks that can effectively adapt to the fast-paced advancements in IoT technologies. This involves creating adaptable compliance solutions that assist firms in navigating diverse requirements and guaranteeing compliance with data protection rules. It will be crucial to interact with lawmakers to establish policies that are fair and safeguard consumers while promoting innovation.

5) Scalable and resilient IoT architectures: Research should investigate scalable IoT designs capable of managing the increasing number of interconnected devices and the vast volumes of data they produce. This encompasses progress in edge computing and fog computing, which allocate data processing near the origin, decreasing latency and enhancing efficiency. Furthermore, researching resilient IoT architectures that can endure failures and adjust to evolving circumstances would improve the dependability and strength of IoT systems.

6) Human-centered design and usability: To enhance the acceptance and efficiency of IoT technologies, it is crucial for research to prioritize human-centered design concepts. This entails developing IoT devices and interfaces that are intuitive, user-friendly, and easily accessible to various users. Gaining insight into the user experience and integrating user feedback into the design process might result in IoT solutions that are more broadly accepted and embraced.

V. Conclusion

The IoT has transformed how organizations function, innovate, and interact with customers. The IoT allows enterprises to gather extensive data, streamline operations, and provide tailored experiences by connecting various devices. This article has conducted thorough research on the IoT in the business sector, investigating its influence from both user-focused and organizational standpoints. The study has provided insights into various aspects of IoT integration, including adoption patterns, user experiences, and organizational initiatives. The study has examined the extent to which industries adopt IoT technology, the factors that affect this adoption, and the obstacles businesses encounter in fully harnessing the promise of IoT.

In addition, the paper has examined developing IoT applications and functionalities, providing valuable perspectives on their prospective influence on businesses in different industries. Significant obstacles to the adoption of IoT include security flaws, interoperability issues, and data privacy concerns. Nevertheless, enterprises can unleash the complete potential of IoT and maintain the trust and confidence of customers by tackling these difficulties through improved security measures, standardization efforts, and privacy-preserving technology. Future research should prioritize the development of novel solutions to tackle these difficulties while also investigating fresh opportunities for value generation and business model innovation. Through promoting cooperation among industrial stakeholders, researchers, and policymakers, we can propel the development of the IoT ecosystem and provide a path for a future where interconnected gadgets optimize productivity, stimulate creativity, and increase the well-being of individuals and communities.

SocialBullyAlert: A Web Application for Cyberbullying Detection on Minors' Social Media

Elizabeth Adriana Nina-Gutiérrez, Jesús Emerson Pacheco-Alanya, Juan Carlos Morales-Arevalo
Faculty of Engineering, Universidad Peruana de Ciencias Aplicadas, Lima, Perú

***Abstract*—The severe problem of cyberbullying towards minors is addressed, which has been shown to have significant impacts on the mental and emotional health of children and adolescents. Subsequently, the effectiveness of existing artificial intelligence models and neural networks in detecting cyberbullying on social media is analyzed. In response, a web platform is developed whose contribution is to identify offensive content, adapt to various slangs and idioms, and offer an intuitive interface with high usability in terms of user experience (UX) and user interface (UI) design. The application was validated with cyberbullying experts (teachers, principals, and psychologists), and the UI/UX design was also validated with users (parents). Limitations and future challenges are discussed, including varying cyberbullying regulations, the need for constant updates, and adapting to multiple languages and cultural contexts. This highlights the importance of ongoing research to enhance parental control tools in digital environments.**

Keywords*—*Cyberbullying; artificial intelligence (AI); neural networks; parental control; social media; offensive content detection; User Experience (UX); User Interface (UI); mental health

I. Introduction

Cyberbullying towards children and adolescents is a social problem, where the perpetrators are often other young people who know the victim. In a qualitative study, adolescents indicated that public harassment on social media was more harmful than private internet attacks. In turn, attacks from bullies who knew their victims generated a greater negative impact [1].

Likewise, the most relevant cause is the one pointed out by [2]; they demonstrated in their study that 96.6% of children indicated that they received their first cell phone at nine and a half years old. These figures show that children are not being properly supervised and are misusing the technology offered to them.

Moreover, online harassment negatively affects the psychological well-being of adolescents, as proven in a study conducted in India [3]. They found that being a victim of cyberbullying is associated with an increased risk of depression and suicidal thoughts in adolescents and young adults. Additionally, 29.63% of participants reported having experienced cyberbullying. Furthermore, being a victim of cyberbullying was associated with a higher risk of depression (with a prevalence rate of 15.56%) and suicidal thoughts (with a prevalence rate of 22.02%) compared to those who were not victims of cyberbullying.

Additionally, analyzing a specific case in the Peruvian context, the study by [4] conducted in schools in Iquitos found that only 36.7% of students were not involved in bullying or cyberbullying. Regarding cyberbullying alone, 13.6% were cyber victims, 6.1% were cyberbullies, and 16.7% were both cyber victims and cyberbullies.

On the other hand, to address cyberbullying through technological platforms, various models were found that use artificial intelligence for the detection of offensive texts. The research in [5] points out in their review article that Machine Learning is the most widely used branch of artificial intelligence (AI) when creating technological tools to combat bullying and cyberbullying. Apps are mostly created to detect inappropriate language based on patterns and systems that identify social media profiles.

However, the following limitations have been identified in current Artificial Intelligence solutions: dataset dependency, difficulty in detecting subtle offenses, language and data limitation, and limitation in adapting to different platforms and media types. For instance, in the AI model proposed by the authors [6], it has been observed that it encounters difficulties in classifying ambiguous tweets or those with mixed contexts, especially when they contain offensive or emotive words. Therefore, it can be said that it has a deficiency in detecting subtle offenses and a limitation in platforms since it can only cover one social network. Additionally, the relevance of context and implicit information in tweets for hate speech detection is highlighted. On the other hand, the method proposed by study [7] and study [8] presents a significant limitation related to language, as it is trained and evaluated with English datasets, which restricts its ability to generalize to other languages and domains. Furthermore, by being based on a model pre-trained solely in English, there is a risk of introducing linguistic and cultural biases in applications for other languages.

The main approach in this research consists of a parental control platform that detects cyberbullying on users' social media and alerts parents about it. To achieve this, the architecture integrates different APIs to collect, process, and analyze data from minors' social media profiles. The APIs utilized include: Apify, to obtain information from social media profiles; a fine-tuned model based on GPT-3.5, to detect hate speech or offensive language in texts; and Google Cloud Vision, for the detection of offensive or inappropriate images.

Likewise, the main contribution is an innovative parental control web application that employs AI to analyze content and detect risks on children's and adolescents' social media profiles. It was carefully designed with a focus on user experience and an intuitive interface, combining the power of AI with excellent usability for parents. This solution will be validated with expert opinions and user surveys.

This article is divided into the following sections: First, Section II reviews related works on the design of platforms and solutions for detecting cyberbullying. Section III describes the main contribution in more detail. Additionally, Section IV explains the main functionalities offered by this platform for cyberbullying towards minors, and to verify its effectiveness, it was tested through two types of validations in Section V. Following this, Section VI presents the Results of the experiments. Finally, Section VII shows the pending points for improvement or for future research, and Section VIII covers the general conclusions.

II. Related Work

Through technological platforms, various models using artificial intelligence for the detection of offensive texts have been found. [5] points out in their review article that Machine Learning is a discipline of artificial intelligence most widely used when creating technological tools to combat bullying and cyberbullying. Applications are mostly created that detect inappropriate language based on patterns and systems that identify social media profiles.

This section explores several artificial intelligence models, developed in recent years, designed for the detection and prevention of cyberbullying on social media. The contributions and limitations of these models will be evaluated, providing a critical view of how these models address the challenge of online cyberbullying.

On one hand, the study [9] uses a Twitter API to identify "critical points" of cyberbullying by analyzing the language loaded in tweets. It proposes a prediction model to identify possible incidents of cyberbullying on Twitter. Its contribution lies in the discovery that certain loaded language, especially related to "biology", "sexual" and "swear", can be a potential indicator of cyberbullying, thus providing a valuable tool for mediation agencies such as school counselors and law enforcement. However, the main weakness of the study is its exclusive reliance on Twitter text analysis, which may limit its applicability to other cyberbullying contexts where the language or platform differs, and the lack of consideration of other contextual factors that could influence the accurate identification of cyberbullies.

On the other hand, [10] presents an automated classification model to identify cyberbullying texts on Twitter using artificial intelligence and a deep decision tree classifier. Specifically, they used an innovative deep decision tree classifier that incorporates hidden layers of a neural network as tree nodes. Thus, they achieved that the model's capability can handle large datasets without compromising accuracy, achieving 93.58% accuracy and outperforming conventional methods in all metrics evaluated, making it potentially valuable for authorities in the fight against cyberbullying. However, the study does not address how the model handles specific challenges of Twitter, such as the use of special characters, URL shorteners, and informal language, which raises doubts about its robustness in real-world scenarios of this platform.

Furthermore, the study in [11] propose a hybrid deep architecture, CapsNet-ConvNet, which integrates CapsNet for text analysis and ConvNet for image analysis, thus addressing the limitation of previous studies that focused mainly on textual analysis for the detection of harassment and toxicity on social media. Their main contribution is the ability to analyze both the textual and visual content of posts on YouTube, Instagram, and Twitter, using advanced techniques such as ELMo for text representations and the Google Vision API for separating text from images. However, the study's weakness lies in the potential lack of accuracy when facing data that includes idioms or slang, which is common on social media, suggesting that the model may have difficulties adapting to informal and culture-specific linguistic variations.

On the other hand, in another approach, [12] developed a hate comment classifier applied on social media and freely available for developers. This tool would be very important for quickly identifying offensive comments so that they can be reported or removed. To achieve this, they used machine learning models such as XGBoost and the BERT features. The dataset they used consisted of 49,392 comments from social media platforms like YouTube, Reddit, Twitter, and Wikipedia. The algorithms used were specifically Logistic Regression (LR), NB (Naïve Bayes), SVM, XGBoost, and Feed-forward Neural Network (FFNN). There was a higher risk of errors when analyzing Reddit comments, and there was higher accuracy with Twitter comments. The deficiency that the authors indicate is due to polysemy, meaning that some words considered highly offensive on one social network may seem less offensive on another according to the classifier. Consequently, cyberbullying detection in the analyzed content would be less accurate.

Finally, the solution proposed in study [13], the CyberNet model, is an advanced strategy that employs a hybrid deep CNN with N-gram feature selection for cyberbullying detection on online social media platforms. This innovative approach stands out for its ability to identify both abusive text and abusive images, representing a significant advance in the prevention of harmful online behaviors. However, a potential weakness of the model could lie in its reliance on a supervised learning approach, which could limit its effectiveness in detecting new forms of cyberbullying that are not represented in the training data, suggesting the need for continuous adaptability to address the evolution of cyberbullying tactics.

III. Platform Design

A. General Architecture

The architecture of SocialBullyAlert includes the use of an external API to collect data from the child's social media profile. This data goes through AI processing which is a fine-tuned model based on GPT-3.5 to identify cyberbullying in texts. The offensive content is stored in a PostgreSQL database to generate alerts and periodic reports, which are distributed through the web application (Angular) so that parents can monitor their children. The architecture of the solution can be seen in Fig. 1, where the interaction that the SocialBullyAlert system has with external services is observed. The information processing flow for cyberbullying detection is detailed as follows:

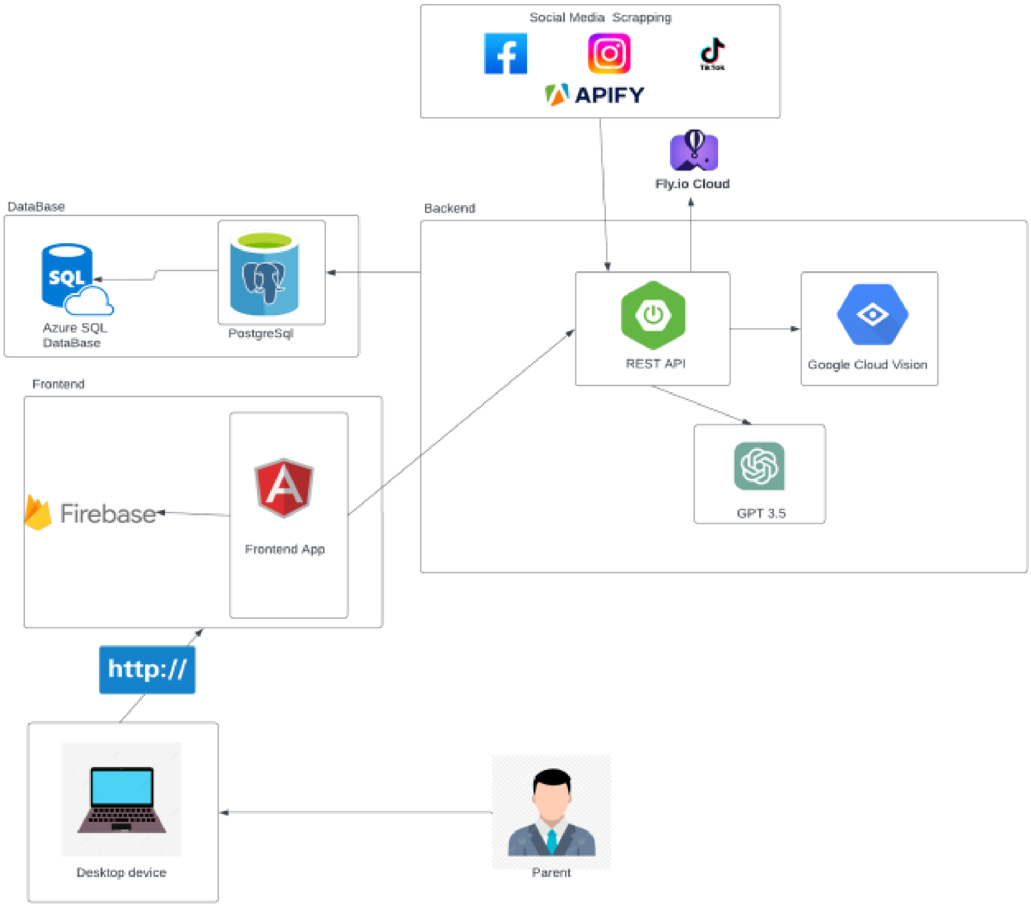

Fig. 1. Solution architecture.

- Collection: In this step, an external API (Apify) is employed to extract all visible information from a child's social media profile. The data can be text, image, or image with embedded text. This information is obtained in JSON format [14].

- Data Processing: The data obtained from the child's social media is processed using both Google Cloud Vision [15] and a fine-tuned model based on GPT-3.5. First, the comment or post is decomposed into text and image if present. The texts go through an AI specialized in cyberbullying detection, which is an artificial intelligence that can identify subtle offences in English and various Spanish language dialects. The result is a JSON object indicating whether the text contains offensive language and hate speech. On the other hand, the images go through analysis by Google Cloud Vision [15]; this AI will be responsible for categorizing the image as "Adult Content", "Mocking Content", "Medical Content", "Violent Content", and "Racy Content".

- Alert Generation: The comment or post containing hate speech, offensive language, or any inappropriate image will be stored in a PostgreSQL database. In this way, the system will be able to generate linear graphs based on time periods and parental advice based on the latest alerts on a child's profile.

- Alert Distribution: The graphs, parental advice, and alerts will be reflected in the web application, which is developed in the Angular framework, prioritizing user experience and an intuitive interface, so that the application is responsive and works correctly on desktop and mobile devices from the most popular browsers.

B. *Key Components*

The architecture of SocialBullyAlert consists of several key components that work together to provide a comprehensive solution for cyberbullying detection and alert generation. These components leverage cutting-edge technologies, such as artificial intelligence services, web data extraction APIs, and web application development frameworks. The main components that make up the system are described below:

- Apify: It is a web data extraction platform that allows you to create actors (small programs) to collect information from websites efficiently and scalably. They have a very extensive library that offers scrapers for many social networks. It is also widely used by well-known companies such as Microsoft and Samsung [14]. In this particular case, only 6 actors were used to obtain posts and comments from the social networks Facebook, Instagram, and TikTok.

- Google Cloud Vision: It is an artificial intelligence-based visual recognition service that allows developers to integrate powerful image analysis capabilities into their applications [15]. It has very important features for cyberbullying detection, such as explicit content classification, where it provides classification probabilities for categories like adult content, medical content, violence, and suggestive content [16]. Additionally, it provides optical character recognition (OCR) functionality, which will help extract text present in images.

- Angular: It is a web framework maintained by Google that provides tools, APIs, and libraries to simplify and streamline the development workflow. It provides a solid platform for building fast, reliable, and scalable applications, both in terms of team size and codebase. Angular allows developers to create high-performance web applications efficiently, taking advantage of its extensive set of features and resources [17].

- Fine-tuned GPT-3.5-based model for cyberbullying detection: This is a model based on GPT-3.5 for detecting hate speech and offensive language in English, Peruvian Spanish, Chilean Spanish, and Spanish from Spain. It is a tool that has significantly higher precision compared to similar models. It will serve to detect cyberbullying in textual content found on children's social media, even detecting subtle offences or country-specific slang forms [5]. Thanks to GPT-3.5, it is possible for it to function with more languages in addition to the languages it was trained on.

C. User Interface and User Experience

The interface the platform has follows Nielsen's heuristics, which are considered the best due to their universality and adaptability, having even served as the basis for more specialized heuristics [18]. The following describes how each of the 10 principles has been met:

1) *Match between the system and the real world:* The application supports language switching between English and Spanish, maintaining the integrity of meaning, and uses universal icons on the buttons that reflect everyday objects, establishing an intuitive connection between the represented action and the button's function, facilitating understanding for a diverse user base (Fig. 8).

2) *Visibility of system status:* The platform implements dynamic animations that indicate data loading (Fig. 2), along with floating messages that inform the user about the success or failure of processes, thus providing clear and continuous feedback that enhances the user's perception of the system's status and activity.

3) *User control and freedom:* Before executing important actions such as starting an analysis or deleting a child's profile (Fig. 5), the platform presents confirmation dialogs, allowing the user to review and potentially undo their decision, thus preventing irreversible errors and providing a sense of control over the actions performed.

4) *Consistency and standards:* The application adopts industry-standardized iconography for common functions such as menu, search, save, and delete, ensuring a consistent user experience and reducing the learning curve by aligning with universal interface design conventions.

5) *Recognition rather than recall:* The system utilizes tooltips (contextual aids) and displays the current status of each analysis, providing relevant information without the user having to remember specific details, thereby reducing cognitive load (Fig. 4).

6) *Flexibility and efficiency of use:* The platform offers a home panel that allows parents to quickly view their children's latest cyberbullying alerts, including a line graph that shows the temporal evolution of the alerts, facilitating efficient identification of patterns and trends to avoid input errors, optimizing process efficiency and reducing user frustration (Fig. 6).

7) *Aesthetic and minimalist design:* The platform's design is minimalist, utilizing a reduced color palette and presenting concise information, minimizing visual distraction and improving comprehension.

8) *Error prevention:* Real-time validation messages are implemented in each form field, proactively guiding the user and focus, especially for parents with limited technology experience. (Fig. 9).

9) *Help users recognize, diagnose, and recover from errors:* Specific error messages are implemented, such as notification of an already registered email (Fig. 3), and it is clearly indicated when an analysis fails, prompting the user to take corrective actions like a new analysis (Fig. 5). The dynamic field validation and floating messages also justify this heuristic.

10) *Help and documentation:* The application provides a link to the terms and conditions to inform users and has incorporated a tutorials section that explains the application's operation and educates about the issue of cyberbullying, thus aligning the functionality with the platform's preventive mission.

Guía de Uso: Conoce más sobre el ciberacoso

En esta sección encontrarás información valiosa y de fuentes confiables sobre el ciberacoso, uno de los principales riesgos a los que se enfrentan niños y jóvenes en la actualidad. Además, aprenderás a usar nuestra aplicación de monitoreo mediante un video tutorial paso a paso.

¿Sabias que en el Perú ...

- 13.6% de estudiantes admiten haber sido cibervictimas
- 6.1% de estudiantes admiten haber sido ciberbullies
- 16.7% de estudiantes admiten que eran cibervictimas y ciberbullies a la vez.

(Martínez et al., 2020)

Tutorial de SocialBullyAlert

Con esta guía de uso, esperamos que comprendas la importancia de combatir el ciberacoso y que puedas sacar el máximo provecho a nuestra aplicación para proteger a tus hijos/estudiantes. ¡Mantente informado y actúa a tiempo! Hagamos de internet un lugar seguro para nuestros menores!

IV. Application Features

The monitoring platform offers a comprehensive suite of features designed to provide parents with greater control and visibility over online activities that may pose a danger to their children. These are the key features:

A. *Management of Minors' Social Networks to Monitor*

This feature allows parents to register on the platform and indicate the children and social networks they wish to monitor. Parents can edit their children's information to keep it up-to-date, as well as add or remove social networks from monitoring as needed. It also allows "activating" and "deactivating" to decide whether or not to include them in the analyses without having to permanently remove the networks from the platform.

B. *Analysis and Details of Cyberbullying Alerts*

Once monitoring is set up, parents can initiate an analysis of their children's social networks to detect possible cases of cyberbullying. Only social networks with an "Activated" status will be analyzed, and the analysis will take a maximum of approximately five minutes. When the analysis is completed, a summary of the analysis can be viewed. If comments or posts with cyberbullying content are found, the number of hate speech, offensive language, and inappropriate image alerts will be displayed. The number of interactions the child has on each social network and a list of problematic users will also be shown so that the parent can quickly identify potential bullies. If the parent wants to explicitly view the offensive content that generated each alert, they can do so discreetly and view the uncensored image or text, as well as access the bully's profile and the original post where the bullying occurred.

C. *Summary of Alerts and Parental Advice*

The platform provides personalized parental advice based on the situation reflected on each child's social networks according to the latest alerts received. A line graph can also be viewed, which presents the number of alerts over time for a child in an easier manner. In this way, the "Home" section is a quick access to know the situation of each child.

V. Experimental Evaluation

The evaluation of SocialBullyAlert's effectiveness and usability involved a two-pronged approach: expert validation and user experience surveys. For the expert validation, in-depth interviews were conducted with a group of professionals including teachers, principals, and psychologists, all of whom possessed extensive experience in managing cyberbullying cases involving minors. These interviews aimed to gather qualitative feedback on the accuracy and relevance of the system's alerts, as well as to solicit suggestions for enhancing the presentation and content of information provided to parents.

To assess user experience, a qualitative evaluation was carried out with end-users. Twenty parents from public schools in Lima were given the opportunity to interact with the application. The evaluation employed a previously validated questionnaire, the User Experience Questionnaire (UEQ) extracted from the article [19], which has been widely used in related research to gauge user perspectives. This questionnaire comprises 26 items, each rated on a scale from 1 to 7, designed to provide comprehensive insights into various aspects of user experience.

VI. Results

The expert validation yielded several key insights. Unanimously, the experts agreed that the proposed web solution has the potential to reduce cyberbullying and enhance parent-child relationships, provided it is implemented correctly. They emphasized the importance of considering accessibility for parents with limited internet access. Opinions diverged regarding potential negative effects of monitoring on minors' psychological and social development, with some experts advocating for open dialogue to mitigate concerns. The experts identified critical risk factors to monitor, including cyberbullying, inappropriate content, hate speech, fake profiles, and excessive usage time. Generally, they deemed the privacy and security aspects appropriate, given the protective intent of the tool. Experts also believed that most parents would adapt well to consistent use of the solution, given the pressing need for child monitoring tools in digital environments.

Based on expert recommendations, several enhancements were incorporated, including an informative section featuring theories and data from reliable sources, and an explanatory video demonstrating the platform's functionality in an easily comprehensible manner. Other suggestions, such as adding psychoeducational components and creating usage tutorials, were noted for future development (Fig. 7).

The user experience surveys, visualized in Fig. 10, revealed that parents found the solution attractive, efficient, and innovative. These results affirm that the objective of creating an intuitive and appealing platform for parents was successfully achieved. The positive user feedback, combined with constructive input from experts, indicates that SocialBullyAlert shows promise as an effective tool in combating cyberbullying and facilitating safer digital experiences for minors.

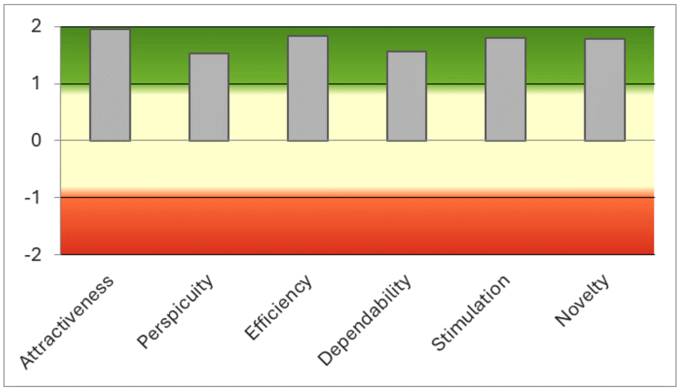

Fig. 10. Bar chart based on usability characteristics.

VII. Discussion

Key limitations include differences in cyberbullying regulations across countries, which may affect the implementation and effectiveness of the proposed solutions [9, 10]. Additionally, variability in parents' educational levels may hinder their adoption and understanding of AI-based parental control tools [11]. Another significant limitation is the need for constant model updating to identify new slangs, idioms, and forms of cyberbullying [12], as well as expanding coverage to other data formats such as videos [11, 13]. These challenges underscore the importance of future research addressing the adaptability and cultural sensitivity of technological solutions to combat cyberbullying in diversified digital environments [5, 13].

VIII. Conclusion

The study highlights the importance of continuous adaptability in the fight against cyberbullying, demonstrating the effectiveness of artificial intelligence models and neural networks in detecting offensive content on platforms like Twitter. The contributions of this work include the presentation of innovative models that represent significant advances in the detection and prevention of online cyberbullying. The implications of this research are reflected in the relevance of considering accessibility and usability for parents when implementing parental control solutions, which can have a positive impact on protecting children and adolescents in digital environments. Finally, this study underscores the importance of continuing to develop effective and culturally sensitive tools to address cyberbullying and its negative impacts on today's society.

IX. Future Work

Future work will focus on enhancing SocialBullyAlert's adaptability to emerging forms of cyberbullying and linguistic diversity. The platform should be continuously updated to recognize and respond to new slangs, idioms, and evolving forms of online harassment as they emerge. This adaptive capability is crucial for maintaining the effectiveness of the cyberbullying detection system in a rapidly changing digital landscape. While the current model is effective in detecting cyberbullying in English and various Spanish dialects, efforts should be made to incorporate more languages and cultural contexts. This expansion would not only increase the global applicability of SocialBullyAlert but also address the challenges posed by diverse linguistic expressions of cyberbullying across different cultures and regions.

Explainable Artificial Intelligence for Urban Planning: Challenges, Solutions, and Future Trends from a New Perspective

Shan TONG[1], Shaokang LI[2]*
Organization Department, Shijiazhuang College of Applied Technology, Shijiazhuang 050000, China[1]
Informatization Center, Hebei Normal University, Shijiazhuang 050000, China[2]

***Abstract*—Integrating Artificial Intelligence (AI) into urban planning transforms resource allocation and sustainable development. Nevertheless, the lack of transparency in some AI models raises questions about accountability and public trust. This paper investigates the role of Explainable AI (XAI) in urban planning, focusing on its ability to improve transparency and build trust between stakeholders. The study comprehensively examines approaches to achieving explainability, encompassing rule-based systems and interpretable machine learning models. Case studies illustrate the effective application of XAI in practical urban planning situations and highlight the critical role of transparency in the decision-making flow. This study examines the barriers that hinder the smooth integration of XAI into urban planning methodologies. These challenges include ethical concerns, the complexity of the models used, and the need for explanations tailored to specific areas.**

Keywords—Explainable artificial intelligence; urban planning; rule-based systems; machine learning

I. Introduction

Urban planning is the organized arrangement and administration of urban areas to ensure sustainable development and improve living standards [1]. Urban planning includes deliberately distributing resources, establishing infrastructure, and implementing land use rules to tackle the intricate issues posed by expanding cities [2]. Urban planning is vital to contemporary society as it facilitates the effective allocation of resources, stimulating economic development, and advancing social fairness and environmental sustainability [3]. Urban planning encompasses but is not limited to, population expansion, guaranteeing access to vital services and facilities, fostering public health and safety, safeguarding cultural heritage, and reducing environmental consequences [4, 5]. Urban planners use thorough planning processes to develop dynamic, durable, and inclusive communities that meet their residents' different requirements while protecting future generations' interests [6, 7].

Thanks to technological innovations, urban planning has experienced a significant transformation, relying heavily on data-driven strategies [8]. This process includes collecting, analyzing, and presenting data using various tools and platforms [9]. Geographic Information Systems (GIS), remote sensing technologies, and big data analytics offer information on urban trends like population growth, road conditions, and environmental factors [10]. Incorporating technology into urban planning operations can improve decision-making, enhance infrastructure development, and predict trends accurately [11]. Nevertheless, increased acceptance also brings challenges, including concerns about data privacy, disparities in access to technology, and the requirement for specific technical knowledge. To effectively address technology limitations, urban planning organizations must strategically plan and prioritize robust facilities and capacity-building efforts [12].

Artificial Intelligence (AI) mimics human intelligence through machines, particularly computers [13]. The applications of AI are widespread, including in medical care, finance, and urban planning [14]. The significance of AI in urban planning lies in its ability to influence decision-making processes, improve resource allocation, and solve complex urban issues [15]. With AI-powered tools and algorithms, planners can predict future trends, simulate different scenarios, and optimize interventions for optimal results [16]. AI has several applications in urban planning, including predictive models of traffic congestion and public transportation demand, optimization algorithms for land use planning and infrastructure construction, and machine learning-based systems for identifying trends and analyzing spatial data [17]. Through AI, city planners can make informed decisions, increase productivity, and create more resilient and sustainable communities for future generations [18].

Incorporating AI into urban environments has a range of ethical and societal consequences that necessitate meticulous deliberation [19]. The main concerns are privacy, algorithmic bias, and equitable sharing of advantages and risks [20]. Moreover, decision-making procedures guided by AI have the potential to unintentionally strengthen pre-existing disparities, resulting in social exclusion or intensifying urban inequities [21]. Furthermore, there are notable obstacles to creating AI solutions for urban planning, including issues with data compatibility, the ability to handle large-scale operations, and the need for clear and understandable algorithms [22, 23]. Nevertheless, notwithstanding these obstacles, the potential advantages of incorporating AI into urban construction are immense. AI can potentially enhance resource allocation, urban mobility through predictive analytics, and disaster preparedness and response by identifying vulnerabilities and optimizing evacuation routes [24]. Furthermore, AI-powered solutions can increase community involvement and active participation in urban planning, ultimately leading to more inclusive and

*Corresponding Author.

sustainable communities. In urban settings, it is important to balance ethical concerns, technical challenges, and the revolutionary potential of AI to harness its advantages while minimizing its drawbacks fully [25].

Transparency is crucial in decision-making processes in urban planning since it promotes accountability, credibility, and confidence among stakeholders [26]. Transparency in decision-making enables stakeholders to understand the underlying reasons for urban development decisions and actively engage in developing their communities [27]. Transparent approaches, such as implementing open data initiatives, conducting public consultations, and communicating decision criteria, foster confidence among stakeholders, including residents, legislators, and advocacy groups. Nevertheless, the lack of transparency in AI algorithms raises questions regarding transparency in urban planning [28]. The opaque nature of numerous AI models may impede stakeholders' capacity to comprehend and analyze the judgments made by these systems. To tackle these challenges, it is necessary to focus on creating Explainable AI (XAI) solutions that offer understandable insights into the decision-making processes led by AI [29]. Urban planners can strengthen stakeholder confidence, promote accountability, and create inclusive and participatory urban development by prioritizing transparency and implementing XAI approaches.

Multiple scholars have investigated the concept of XAI in different situations related to urban planning. Thakker, et al. [30] emphasize the significance of XAI in smart cities, specifically for flood monitoring. They propose a hybrid methodology that combines deep learning with semantic web technologies to improve the interpretability and reliability of the system. Javed, et al. [31] conducted research that examines the use of XAI in smart cities. The study highlights the need of openness in AI systems to establish public confidence. Wagner, et al. [32] examine the contribution of XAI in the advancement of smart city solutions, with a specific emphasis on using domain knowledge to enhance the interpretability of AI. These works emphasize the crucial importance of transparency and explainability in AI models used in urban planning. They highlight existing solutions and identify areas that require further investigation.

This paper thoroughly investigates the incorporation of XAI in urban planning, specifically to improve trust and transparency in decision-making procedures. The research analyzes the approaches used to achieve explainability in AI models in urban planning. These methodologies include rule-based systems and interpretable machine-learning models. In addition, the obstacles and factors to be considered when implementing XAI in urban planning processes are identified and examined while emphasizing solutions to overcome these obstacles. Moreover, the influence of XAI on the public's perception and trust in urban decision-making is assessed based on empirical evidence and case studies. This study enhances comprehension of the relationship between AI technology and urban development by examining the impact of XAI on transparency and trust in urban planning.

The rest of the paper is arranged as follows. Section II discusses XAI for urban planning, detailing its importance and methodologies. Section III addresses the challenges and considerations in implementing XAI in urban planning. Section IV presents the results and discussion of our research findings. Section V explores future directions for further research. Finally, Section VI concludes the paper, summarizing key insights and implications.

II. Explainable AI for Urban Planning

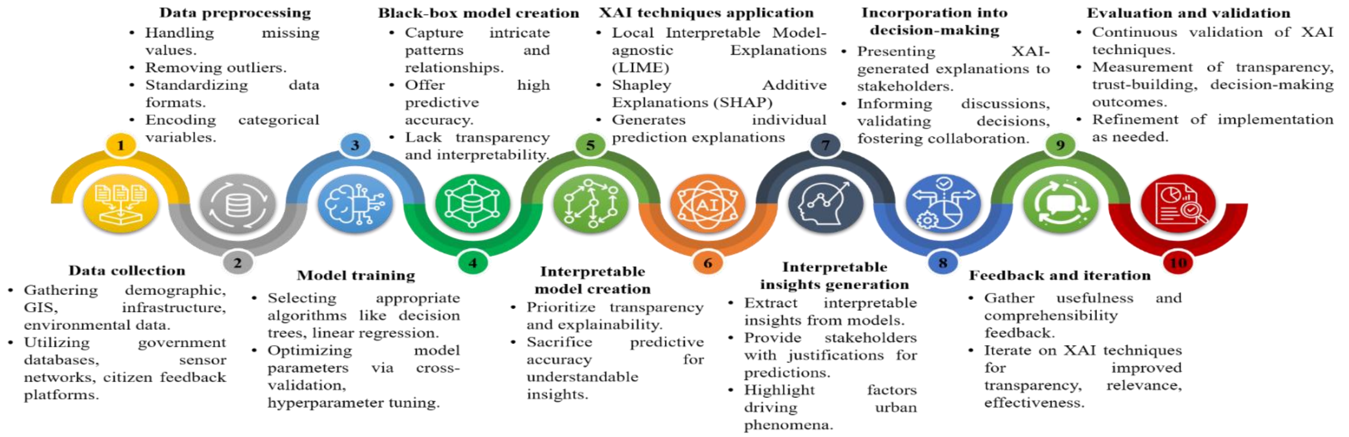
Fig. 1 depicts a sequential procedure for incorporating XAI methods into urban planning. The process begins with the acquisition of data from different urban sources, which is then followed by preprocessing and feature engineering to make the data prepared for analysis. Afterwards, the processed data is used to train machine learning models using XAI approaches to guarantee interpretability. Urban planning decision-making processes incorporate the understandable insights produced by the trained models. The iterative process emphasizes the significance of XAI in improving transparency and fostering trust in urban development.

A. Rule-based Systems

Rule-based or expert systems are AI that employ a predetermined set of rules to generate decisions or suggestions. These rules typically take the form of if-then statements, where specific conditions trigger corresponding actions or conclusions. Experts encode domain-specific knowledge in rule-based systems to guide decision-making [33].

These systems function by comparing input conditions to a predetermined set of rules, triggering related actions or conclusions based on the conditions met [34, 35]. Experts in the field collaborate to develop the rules, ensuring they accurately reflect the complexities of the problem domain. As listed in Table I, urban planning extensively uses rule-based systems for various purposes, including land use zoning, transit management, environmental regulation, emergency response planning, and economic development. For example, in land use planning, rule-based systems can ascertain allowable land uses by considering criteria such as zoning restrictions, environmental limitations, and community preferences. Similarly, in the transportation management field, these systems can optimize the timing of traffic signals, allocate routes efficiently, and enforce parking restrictions to improve urban mobility and decrease congestion.

Transparency and interpretability are vital advantages of rule-based systems. Due to specific rules, stakeholders can comprehend the rationale behind the outcomes of the system's decision-making process, fostering confidence and accountability in decision-making procedures [36, 37]. Furthermore, rule-based systems are adaptable, allowing for the integration of new rules or the modification of existing regulations to align with evolving situations or planned goals. Nevertheless, rule-based systems also pose challenges, such as the requirement for substantial expertise to create and improve rules and limitations in scalability when addressing intricate or ever-changing urban planning issues. However, their transparency and interpretability make them excellent instruments for supporting informed decision-making and promoting collaboration among stakeholders in urban planning endeavors.



Data preprocessing
• Handling missing values.
• Removing outliers.
• Standardizing data formats.
• Encoding categorical variables.
Black-box model creation
• Capture intricate patterns and relationships.
• Offer high predictive accuracy.
• Lack transparency and interpretability.
XAI techniques application
• Local Interpretable Model-agnostic Explanations (LIME)
• Shapley Additive Explanations (SHAP)
• Generates individual prediction explanations
Incorporation into decision-making
• Presenting XAI-generated explanations to stakeholders.
• Informing discussions, validating decisions, fostering collaboration.
Evaluation and validation
• Continuous validation of XAI techniques.
• Measurement of transparency, trust-building, decision-making outcomes.
• Refinement of implementation as needed.

5
6
7
8
9
10
AI
Data collection
• Gathering demographic, GIS, infrastructure, environmental data.
• Utilizing government databases, sensor networks, citizen feedback platforms.
Model training
• Selecting appropriate algorithms like decision trees, linear regression.
• Optimizing model parameters via cross-validation, hyperparameter tuning.
Interpretable model creation
• Prioritize transparency and explainability.
• Sacrifice predictive accuracy for understandable insights.
Interpretable insights generation
• Extract interpretable insights from models.
• Provide stakeholders with justifications for predictions.
• Highlight factors driving urban phenomena.
Feedback and iteration
• Gather usefulness and comprehensibility feedback.
• Iterate on XAI techniques for improved transparency, relevance, effectiveness.

Fig. 1. Workflow of implementing XAI in urban planning.

TABLE I. APPLICATIONS OF RULE-BASED SYSTEMS IN URBAN PLANNING

Application	Description	Examples	Benefits
Land use zoning	Determines allowable land uses based on criteria such as zoning restrictions, environmental factors, and community preferences	Zoning regulations, urban development plans, land use ordinances	Transparent decision-making, aligns with community preferences, and supports sustainable development
Transit management	Optimizes timing of traffic signals, allocates routes efficiently, and enforces parking restrictions to improve urban mobility	Traffic signal control systems, public transit route planning, and parking management systems	Reduces congestion, enhances public transportation efficiency, and improves overall urban mobility
Environmental regulation	Identifies and enforces regulations related to environmental protection, pollution control, and conservation measures	Environmental impact assessments, pollution monitoring and control systems, and green building codes	Protects natural resources, mitigates environmental impacts, and promotes sustainability
Emergency response planning	Coordinates response efforts during emergencies such as natural disasters, accidents, or public health crises	Emergency management systems, disaster preparedness plans, and evacuation route optimization	Enhances public safety, facilitates efficient response coordination, and minimizes risk exposure
Economic development	Facilitates strategic planning and development initiatives to stimulate economic growth and prosperity	Economic development plans, business incentive programs, and job creation initiatives	Fosters economic vitality, attracts investment, promotes job creation and entrepreneurship

B. *Interpretable Machine Learning Models*

Interpretable machine learning is essential, particularly in urban planning fields where transparency and clarity are paramount [38]. Unlike black box models, interpretable models offer transparent decision-making processes and enable understanding of the reasoning behind their results. This level of transparency allows urban planning stakeholders, including politicians, city officials, and community members, to comprehend the variables that impact model forecasts and make well-informed choices. When it comes to urban planning, where decisions significantly affect citizens' lives and community growth, it is critical to have the skill to analyze and comprehend model predictions. Interpretable machine learning models, such as decision trees, linear models, and rule-based systems, offer transparent explanations of their decision-making process. This allows stakeholders to verify the model's outcomes, detect potential biases, and evaluate the effectiveness of recommended solutions. Furthermore, interpretable machine learning models enhance cooperation and information exchange among diverse participants in urban planning procedures. These models enhance trust and improve consensus building by offering precise and understandable insights and promoting more inclusive and equitable methods for urban development.

Table II shows that interpretable machine learning includes different model types, each with strengths and easy-to-understand features for various data and problem domains. Decision trees are models that hierarchize data into decision nodes based on feature properties. This recursive process makes decision trees easy to comprehend and display. Decision trees are useful in urban planning for determining the main elements that impact different outcomes, such as land use patterns, transportation choices, and demographic trends. Decision trees offer a clear and understandable understanding of the interplay between many factors that impact urban phenomena, thereby facilitating decision-makers in identifying practical and implementable insights.

TABLE II. MODEL TYPES AND THEIR CHARACTERISTICS IN INTERPRETABLE MACHINE LEARNING

Model Type	Description	Strengths
Decision trees	Intuitive models that recursively partition data into hierarchical decision nodes based on feature attributes	Easy to understand and visualize; transparent decision logic; identify key factors influencing outcomes
Linear models	Models that provide straightforward interpretations of the relationships between input variables and outcomes	Clear insights into the direction and magnitude of the impact of each input variable on the outcome
Rule-based systems	Systems that employ a predetermined set of rules to generate decisions or suggestions	Transparent decision-making process; adaptable to new rules or modifications; supports informed decision-making

Conversely, linear models like linear regression or logistic regression offer straightforward explanations of the connections between input variables and outputs. These models assume a direct and proportional link between the input features and the goal variable. They are best suited for situations where the correlations are primarily linear, which is frequently the case with urban planning data. Linear models offer a lucid understanding of the direction and extent of the influence of each input variable on the outcome. This enables stakeholders to comprehend the elements that drive urban phenomena and make well-informed decisions.

Machine learning models play a crucial role in urban planning by providing insights into complex urban phenomena and aiding in informed decisions. As shown in Table III, decision trees, for instance, can identify critical variables affecting land use patterns, such as proximity to amenities, transportation infrastructure, and zoning rules. They can also forecast property prices, aid stakeholders understand property values, and provide information on housing policy and development strategies. Linear regression models, on the other hand, can evaluate the impact of infrastructure investments on property values, enabling planners to prioritize projects, forecast traffic congestion, and aid in traffic management policies.

TABLE III. APPLICATIONS OF INTERPRETABLE MACHINE LEARNING MODELS IN URBAN PLANNING

Application	Description	Examples	Benefits
Identifying key factors	Decision trees help identify key factors influencing various outcomes, such as land use patterns or demographic trends	Identifying factors influencing land use decisions, predicting transportation preferences	Transparent decision-making process, actionable insights for decision-makers
Predicting housing prices	Linear regression models can predict housing prices based on neighborhood characteristics	Predicting housing prices based on neighborhood characteristics	Assists in housing policy formulation, supports informed decision-making regarding housing development
Estimating infrastructure impact	Linear regression models estimate the impact of infrastructure investments on property values	Estimating the impact of infrastructure projects on property values	Helps prioritize infrastructure investments, assesses potential return on investment
Forecasting traffic congestion	Linear regression models forecast traffic congestion levels based on demographic and transportation data	Forecasting traffic congestion levels based on population density, road infrastructure, etc.	Guides transportation policy and infrastructure planning, improves urban mobility and efficiency

C. Post-Hoc Interpretability Methods

Post-hoc interpretability approaches enhance transparency and responsibility in decision-making processes, particularly in urban planning [39]. These methods, implemented post-training as a machine learning model, provide stakeholders valuable insights into its predictions. They can be applied to any model, regardless of complexity or algorithm. Post-hoc interpretability enhances stakeholders' trust, responsibility, and understanding, promoting well-informed decision-making and ensuring alignment with community needs. It empowers stakeholders to participate actively in urban planning, promoting fair and sustainable development.

Two highly acknowledged post-hoc interpretability strategies that have gained prominence in machine learning are Local Interpretable Model-agnostic Explanations (LIME) and Shapley Additive Explanations (SHAP). LIME is widely recognized for its ability to accurately explain intricate model predictions at a local level. This is accomplished by creating interpretable surrogate models that approximate the behavior of a complex model close to a precise prediction. Surrogate models, despite their more straightforward structure, accurately replicate the behavior of the original model, providing stakeholders with a transparent and understandable explanation of how the model made its prediction within a specific situation. LIME offers valuable insights into the decision-making process in urban planning scenarios by focusing on the particular instance of interest. These insights are interpretable, directly relevant, and actionable for stakeholders.

Conversely, SHAP adopts a distinct method for post-hoc interpretability. It utilizes cooperative game theory ideas to allocate each characteristic's contribution to the model's output. SHAP offers a thorough and universally understandable comprehension of the importance of features, providing insights into the relative impact of each input variable on the model's predictions throughout the whole dataset. SHAP facilitates stakeholders in obtaining profound insights into the underlying connections between variables and forecasts by quantifying the cooperative impact of individual features on the model's output. The ability to view feature relevance from a global perspective is crucial in urban planning. In this context, decision-makers must consider the comprehensive effects of different urban characteristics and actions on the desired overall outcomes. SHAP enables stakeholders to make well-informed decisions and successfully prioritize solutions to tackle intricate urban challenges by employing a rigorous and principled methodology.

Post-hoc interpretability methods include numerous advantages that render them excellent tools for comprehending and elucidating the predictions of black-box machine learning models. Nevertheless, they also come with specific constraints that must be considered. Post-hoc interpretability approaches possess a notable advantage in that they may be used in any black-box machine learning model. Whether the model relies on deep learning, ensemble approaches, or other intricate algorithms, post-hoc techniques such as LIME and SHAP can offer insights into its predictions. Post-hoc interpretability techniques enhance the clarity of opaque models by providing justifications for specific predictions. This level of transparency improves stakeholders' comprehension of the model's decision-making process, promoting trust and responsibility. These techniques produce practical insights into model projections, enabling stakeholders to discover key characteristics, comprehend their effect on the desired outcomes, and make well-informed decisions based on this understanding. Post-hoc interpretability approaches provide varying levels of depth. Stakeholders can analyze individual predictions or investigate broader patterns and trends in feature relevance based on their specific requirements and goals.

Post-hoc interpretability techniques frequently depend on simplified surrogate models to estimate the functioning of intricate black-box models. Although surrogate models attempt to replicate the fundamental decision-making process of the original model, they can incorporate approximation mistakes that restrict the explanations' precision. Specific post-hoc interpretability techniques, like SHAP, can need significant computational resources, especially when dealing with extensive datasets or intricate models. The computational complexity of this may present difficulties regarding scalability and real-time implementation in specific urban planning situations. Applying post-hoc approaches may involve a compromise between the model's accuracy and its interpretability. Utilizing simplified surrogate models for interpretation may compromise predictive performance in exchange for interpretability, impacting the model's overall accuracy. Post-hoc interpretability approaches offer valuable insights into individual predictions inside a particular context or region of the feature space. Nevertheless, these explanations may not consistently apply to various contexts or datasets, restricting their usefulness in certain situations.

III. Challenges and Considerations

A. *Ethical Challenges*

Ethical challenges in XAI for urban planning are multifaceted, arising from the intersection of technological innovation, societal impact, and governance. Understanding and addressing these challenges is crucial for fostering trust, equity, and accountability in AI-driven decision-making processes.

AI algorithms can perpetuate or exacerbate existing biases in urban data, leading to unfair or discriminatory outcomes. For example, biased data in predictive policing or housing allocation models may disproportionately target or disadvantage certain communities. Ensuring fairness requires proactive measures to identify, mitigate, and prevent bias in AI models and mechanisms for assessing and addressing disparate impacts on marginalized groups.

The opacity of AI algorithms poses challenges for transparency and accountability in urban planning decision-making. Without clear explanations of how AI models arrive at their conclusions, stakeholders may struggle to understand, scrutinize, or challenge decisions made by automated systems. Establishing mechanisms for transparent and interpretable AI, such as explainable machine learning techniques, is essential for ensuring accountability and fostering public trust in AI-driven urban planning processes.

AI-driven urban planning relies on vast amounts of data, including personal information, which raises concerns about privacy and surveillance. Robust privacy protections and ethical principles must govern the collection, analysis, and sharing of sensitive data to safeguard individuals' rights and liberties. Transparent data governance frameworks, informed consent mechanisms, and data anonymization techniques are critical for balancing the benefits of data-driven decision-making with privacy considerations.

Ethical AI in urban planning should prioritize human well-being, dignity, and autonomy. Designing AI systems that empower, rather than replace, human decision-makers is essential for preserving human agency and accountability. Human-centric design principles, such as participatory design processes and human-in-the-loop approaches, can ensure that AI technologies serve the needs and values of diverse urban communities while respecting their rights and autonomy.

AI can potentially exacerbate social inequalities if not deployed and governed ethically. Urban planners must consider the equitable distribution of resources, services, and opportunities when designing and implementing AI-driven initiatives. Engaging with diverse stakeholders, including marginalized communities, in developing and evaluating AI systems can help identify and address potential biases or disparities in urban planning outcomes.

B. *Model Complexity*

Model complexity refers to the intricacy and sophistication of machine learning models used in urban planning. While complex models may achieve high predictive accuracy, they often sacrifice interpretability. In urban planning, where stakeholders require transparent insights into decision-making processes, the impact of model complexity on interpretability is significant. Complex models, such as deep neural networks, may generate predictions based on intricate interactions among numerous features, making understanding the underlying mechanisms driving the model's decisions challenging. This lack of interpretability can hinder stakeholders' ability to trust, validate, and act upon model predictions, limiting the utility of AI-driven approaches in urban planning.

Complex machine learning models pose several challenges for XAI in urban planning. The black-box nature of these models obscures the decision-making process, making it difficult to explain how predictions are generated. Additionally, complex models may capture nuanced patterns and interactions in the data that are not readily interpretable by humans. This opacity impedes transparency, accountability, and stakeholder engagement in urban planning processes. Moreover, the computational complexity of complex models may limit their scalability and real-time applicability in dynamic urban environments, where timely decision-making is crucial.

Balancing model accuracy with interpretability is a key consideration in urban planning applications. While complex models may achieve higher predictive accuracy, they often sacrifice interpretability, making it challenging for stakeholders to understand and trust model predictions. Conversely, interpretable models, such as decision trees or linear regression, offer transparent insights into the decision-making process but may lack the predictive power of more complex models. Achieving a balance between accuracy and interpretability involves carefully selecting and designing models that meet urban planning tasks' specific needs and objectives. This may involve trade-offs between predictive performance and transparency, depending on the context and requirements of the application.

Several techniques can be employed to simplify complex models while preserving accuracy and interpretability in urban planning applications. Ensemble methods, such as random forests or gradient boosting, combine multiple simpler models to capture complex patterns in the data while maintaining transparency and interpretability. Feature selection and dimensionality reduction techniques can also help simplify models by focusing on the most relevant features and reducing computational complexity. Additionally, model distillation approaches aim to transfer knowledge from complex models to simpler, more interpretable models, enabling stakeholders to understand and trust model predictions without sacrificing accuracy.

C. Domain-specific Explanations

Domain-specific explanations are critical in urban planning as they provide insights tailored to urban environments' unique characteristics and complexities. Unlike generic explanations, domain-specific explanations offer contextually relevant insights into urban planning decisions, allowing stakeholders to understand the rationale behind model predictions and interventions. These explanations enable urban planners to make informed decisions, engage with stakeholders effectively, and address complex urban challenges transparently and accountable.

Providing contextually relevant explanations in urban planning poses several challenges. Urban environments are multifaceted and dynamic, characterized by diverse socio-economic, environmental, and cultural factors. As such, explaining model predictions in a way that resonates with stakeholders and addresses their specific concerns can be challenging. Additionally, urban systems' complexity and interconnectedness may require explanations beyond simple correlations or associations, necessitating sophisticated techniques for extracting and communicating relevant insights.

Tailoring explanations to different urban planning domains involves understanding stakeholders' needs, priorities, and knowledge levels. One strategy is to employ visualization techniques that contextualize model predictions within urban environments' spatial and temporal dynamics. For example, interactive maps or dashboards can illustrate how predicted outcomes vary across different neighborhoods or periods, helping stakeholders identify patterns and trends relevant to their planning decisions. Additionally, incorporating domain-specific terminology, metrics, and indicators into explanations enhances their relevance and comprehensibility for stakeholders with diverse backgrounds and expertise.

Engaging stakeholders in developing and refining explanations is essential for ensuring their relevance and effectiveness in urban planning contexts. Gathering feedback through participatory workshops, surveys, or interviews allows stakeholders to express their information needs, preferences, and concerns regarding model explanations. Incorporating stakeholder feedback into the design and presentation of explanations enhances their clarity, usability, and acceptance among diverse audiences. Moreover, iterative feedback loops enable continuous improvement of explanations over time, ensuring they remain aligned with stakeholders' evolving needs and priorities.

D. Strategies for Overcoming Challenges

Collaborative approaches involve engaging diverse stakeholders, including policymakers, urban planners, AI researchers, ethicists, and community representatives, to develop and govern AI systems for urban planning. By fostering collaboration and dialogue among stakeholders, collaborative approaches ensure that AI technologies are developed and deployed ethically, transparently, and in alignment with societal values and priorities. This collaborative process can involve the establishment of multi-stakeholder committees, advisory boards, or working groups to guide AI development and governance frameworks, promote accountability, and address ethical concerns.

Interdisciplinary research and collaboration between AI experts and urban planners are essential for bridging the gap between technical expertise and domain knowledge in urban planning. By bringing together experts from diverse fields, such as computer science, data science, urban design, sociology, and geography, interdisciplinary collaborations facilitate the development of AI solutions tailored to urban environments' unique challenges and opportunities. These collaborations enable the co-creation of innovative AI-driven approaches, informed by technical insights and real-world urban planning expertise, to address complex urban challenges effectively.

Human-in-the-loop systems integrate human expertise and feedback into AI-driven decision-making processes, enhancing model interpretability and ensuring alignment with stakeholders' values and preferences. Human-in-the-loop systems enable transparent and accountable decision-making in urban planning by involving human stakeholders in interpreting and validating AI-generated insights. This integration of human expertise can take various forms, such as interactive visualization tools, participatory workshops, or decision support systems that allow stakeholders to explore and evaluate different scenarios and interventions collaboratively.

Continuous monitoring and evaluation of AI systems are essential for ensuring transparency, accountability, and ethical compliance throughout their lifecycle. This involves establishing mechanisms to monitor model performance, data quality, and potential biases and conducting regular audits and impact assessments to identify and address ethical concerns. Transparent reporting and documentation of AI systems' development, deployment, and outcomes enable stakeholders to understand and scrutinize their decision-making processes, fostering trust and accountability in AI-driven urban planning initiatives.

IV. Result and Discussion

XAI plays a pivotal role in shaping public trust in AI-driven decision-making processes, particularly in domains such as urban planning, where the stakes are high and decisions directly impact communities. XAI refers to the ability of AI systems to provide transparent and interpretable explanations of their decisions, enabling stakeholders to understand the rationale behind AI-driven recommendations or predictions. By enhancing transparency, accountability, and predictability, XAI builds public trust in AI technologies and fosters confidence in their use for decision-making in urban contexts.

Several factors influence public trust in AI-driven decision-making processes, including transparency, accountability, fairness, and reliability. Transparency refers to the openness and clarity of AI systems in communicating their decision-making processes and underlying assumptions to stakeholders. Accountability involves mechanisms for holding AI systems and their operators responsible for their actions and outcomes. Fairness ensures that AI systems do not perpetuate or exacerbate existing biases or inequalities in decision-making. Reliability refers to AI systems' accuracy, consistency, and robustness in generating predictions or recommendations. Addressing these factors through XAI enhances public trust in AI-driven decision-making processes by assuring transparency, fairness, and reliability.

Transparency and interpretability are fundamental components of XAI that are crucial in building public trust in AI-driven decision-making processes. Transparent AI systems give stakeholders insights into the factors influencing decisions, allowing them to assess the validity, accuracy, and fairness of AI-driven recommendations or predictions. Interpretability enables stakeholders to understand how AI models arrive at their conclusions, facilitating meaningful engagement, validation, and feedback from diverse stakeholders. By providing transparent and interpretable explanations of AI-driven decisions, XAI builds public trust by demystifying AI technologies, empowering stakeholders, and fostering confidence in their use for addressing complex urban challenges.

Transparency in urban planning decision-making is crucial for ensuring accountability, inclusivity, and legitimacy in the governance of cities. Transparent decision-making processes enable stakeholders, including residents, community organizations, policymakers, and advocacy groups, to understand how decisions are made, who is involved, and what factors are considered. By providing visibility into the decision-making process, transparency promotes public participation, fosters trust, and enhances the legitimacy of urban planning initiatives. Moreover, transparency facilitates identifying and mitigating biases, conflicts of interest, and other ethical considerations that may impact decision outcomes.

Transparent decision-making in urban planning contributes to building public trust and confidence in governmental institutions, urban planners, and decision-makers. When stakeholders have access to information about decision-making processes, they feel empowered to engage meaningfully in shaping the future of their communities. Transparency promotes accountability by allowing stakeholders to hold decision-makers accountable for their actions and decisions. Moreover, transparent decision-making enhances the credibility and legitimacy of urban planning initiatives, leading to greater public acceptance and support for policies, projects, and interventions to improve the quality of life in cities. Several strategies can be employed to enhance transparency and accountability in AI-driven urban planning processes.

- Open data policies: Implement policies that make relevant urban data accessible to stakeholders, enabling greater transparency and collaboration in decision-making processes.
- XAI Technologies: Incorporate XAI techniques into AI-driven decision-making systems to provide transparent and interpretable explanations of AI-generated recommendations or predictions.
- Stakeholder engagement: Engage stakeholders, including residents, community organizations, and advocacy groups, in decision-making processes through participatory approaches, public consultations, and community engagement initiatives.
- Ethical guidelines and standards: Develop and implement ethical policies and standards for AI-driven urban planning initiatives, ensuring adherence to principles of fairness, accountability, transparency, and inclusivity.
- Independent oversight and review: Establish independent oversight mechanisms, such as advisory boards or review panels, to monitor and evaluate AI-driven urban planning processes, providing checks and balances and enhancing accountability.
- Transparency reports: Publish transparency reports documenting the decision-making process, data sources, methodologies, and assumptions underlying AI-driven recommendations or predictions, promoting transparency and accountability to stakeholders.

By implementing these strategies, urban planners and decision-makers can enhance transparency and accountability in AI-driven urban planning processes, promoting public trust, confidence, and engagement in shaping the future of cities.

V. Future Directions

Human-in-the-loop approaches emphasize the collaboration between AI systems and human experts to leverage both strengths. Urban planners can benefit from domain knowledge, intuition, and contextual understanding that AI systems may lack by integrating human expertise into AI-driven decision-making processes. This collaboration enhances AI-generated insights' robustness, interpretability, and relevance, leading to more informed and effective urban planning decisions. Through close cooperation, human experts can provide valuable inputs, validate AI-generated recommendations, and guide the development and refinement of AI models, ensuring that they align with stakeholders' needs and priorities.

Human-in-the-loop approaches involve integrating stakeholder feedback and expertise into AI-driven decision-making processes to enhance transparency, inclusivity, and accountability. Stakeholders, including residents, community organizations, policymakers, and advocacy groups, possess valuable insights, preferences, and concerns that can inform AI models and decision outcomes. By soliciting and incorporating stakeholder feedback throughout the decision-making process, urban planners can ensure that AI-driven recommendations reflect diverse perspectives, address community needs, and promote equitable outcomes. Moreover, involving stakeholders in decision-making fosters greater trust, engagement, and ownership of urban planning initiatives, leading to more sustainable and inclusive urban development.

Human-in-the-loop approaches involve designing interactive interfaces and visualization tools that enable stakeholders to interact with AI-driven decision-making processes transparently and engagingly. These interfaces provide stakeholders with intuitive access to AI-generated insights, allowing them to explore, interrogate, and understand the underlying data, assumptions, and decision criteria. By designing user-friendly, visually appealing interfaces accessible to diverse audiences, urban planners can democratize AI-driven decision-making processes, empower stakeholders to participate meaningfully in urban planning discussions, and foster transparency and accountability in decision outcomes. Additionally, interactive interfaces facilitate real-time collaboration and feedback, enabling stakeholders to co-create solutions, identify trade-offs, and navigate complex urban challenges collaboratively.

Cultural biases in AI models and algorithms can arise from various sources, including biased training data, algorithmic design choices, and inherent biases in interpreting cultural norms and values. Recognizing and mitigating these biases is essential to ensure that AI-driven decision-making processes are fair, equitable, and inclusive. This involves conducting thorough bias assessments and audits of AI models and algorithms to identify potential sources of cultural bias. Once identified, mitigation strategies can be implemented, such as adjusting training data to represent cultural diversity better, refining algorithmic algorithms to account for cultural nuances, and incorporating fairness and equity metrics into model evaluation frameworks.

Addressing cultural biases in AI-driven urban planning requires incorporating cultural diversity and sensitivity into data collection and analysis processes. This involves collecting and curating diverse datasets that reflect urban populations' cultural, social, and demographic diversity. Data analysis techniques should also be sensitive to cultural differences and contextual factors that may influence decision outcomes. By considering cultural diversity in data collection and analysis, urban planners can ensure that AI-driven decision-making processes are sensitive to diverse communities' needs, preferences, and values, promoting fairness, inclusivity, and social equity.

Promoting diversity and inclusivity in AI development teams and processes is essential for addressing cultural biases and ensuring that AI technologies are developed and deployed responsibly. This involves fostering diverse perspectives, backgrounds, and experiences within AI development teams, including individuals from different cultural, ethnic, and socio-economic backgrounds. Additionally, promoting inclusivity in AI development processes requires involving stakeholders from diverse communities in designing, developing, and validating AI-driven solutions. By promoting diversity and inclusivity, urban planners can ensure that AI technologies are sensitive to cultural differences and responsive to the needs and concerns of all urban residents, thereby promoting social equity and inclusion in urban planning processes.

For ethical AI use in analysing cities, further development of ethical guidelines and norms is necessary. Such standards should address the principles of ethics for creating AI technologies, managing urbanization, making legislation, and numerous other decision-makers who are involved in integrating AI technologies. Ethical principles may include obligations to justice, reasonableness, purpose, confidentiality, and duty to society including marginalized persons. Thus, using ethical principles in actions and decisions related to the integration of AI into the planning of cities will help maintain ethical principles in initiatives related to AI and support the positive impact of AI technologies on people’s lives.

Another issue that should be taken seriously into consideration is the principles of fairness, equity and the protection of privacy in the application of AI in urban planning. Artificial intelligence environments should be developed and implemented in such a way that everyone will have an equal treatment with no discrimination based on their race, gender, tribe, or wealth. Moreover, proper procedures should be put in place to guard the identity and privacy rights of the people featured in such datasets from invasion as provided for under the relevant privacy policies. By increasing awareness of fairness, equity, and privacy issues in the use of AI, urban planners can reduce potential biases and serve the function of advocating for social justice and protection of individual rights and human dignity.

VI. Conclusion

AI implementation in urban planning introduces a shift in resource management for sustainability in the development of cities. However, opacity or absence of openness in certain models gave accountability and public trust concerns. This paper aimed to explain the importance of applying XAI for the advancement of urban planning as well as its efficiency for enhancing trust between the parties involved. The study comprehensively examined approaches to achieving explainability, encompassing rule-based systems and interpretable machine-learning models. Case studies demonstrated the effective use of XAI in practical urban planning situations and highlighted the critical importance of transparency in the decision-making process. This study examined the barriers that hindered the smooth integration of XAI into urban planning methodologies. These challenges included ethical concerns, the complexity of the models used, and the need for explanations tailored to specific areas.

Enhanced Harris Hawks Optimization Algorithm for SLA-Aware Task Scheduling in Cloud Computing

Junhua Liu*, Chaoyang Lei, Gen Yin
Hunan Post and Telecommunication College, Changsha 410015, Hunan, China

***Abstract*—Cloud computing has revolutionized how Software as a Service (SaaS) suppliers deliver applications by leasing shareable resources from Infrastructure as a Service (IaaS) suppliers. However, meeting users' Quality of Service (QoS) parameters while maximizing profits from the cloud infrastructure presents a significant challenge. This study addresses this challenge by proposing an Enhanced Harris Hawks Optimization (EHHO) algorithm for cloud task scheduling, specifically designed to satisfy Service Level Agreements (SLAs), meet users QoS requirements, and enhance resource utilization efficiency. Drawing inspiration from Harris's falcon hunting habits in nature, the basic HHO algorithm has shown promise in finding optimal solutions to specific problems. However, it often suffers from convergence to local optima, impairing solution quality. To mitigate this issue, our study enhances the HHO algorithm by introducing an exploration factor that optimizes parameters and improves its exploration capabilities. The proposed EHHO algorithm is assessed against established optimization algorithms, including Genetic Algorithm (GA), Ant Colony Optimization (ACO), and Particle Swarm Optimization (PSO). The results demonstrate that our method significantly improves the makespan for GA, ACO, and PSO by 19.2%, 17.1%, and 20.4%, respectively, while also achieving improvements of 17.1%, 17.3%, and 17.2% for BigDataBench workloads. Furthermore, our EHHO algorithm exhibits a substantial reduction in SLA violations compared to PSO, ACO, and GA, achieving improvements of 55.2%, 41.4%, and 33.6%, respectively, for general workloads, and 61.9%, 23.1%, and 52.7%, respectively, for BigDataBench workloads.**

Keywords*—Cloud computing; scheduling; optimization; SLA; SaaS

I. Introduction

Cloud computing represents an approach that facilitates migrating or deploying users' current physical infrastructure into a cloud-based environment. Users can access a wide array of services within this paradigm, including network, storage, computing, and memory, per their on-demand requirements [1], [2]. Virtualization technology plays a crucial role in provisioning a virtual infrastructure for users within a cloud environment. Service Level Agreement (SLA) serves as the contractual agreement between users and cloud providers, outlining the terms of service subscription [3]. Based on the established SLA, the cloud provider provisions the necessary services to meet users' needs. A distinguishing feature of the cloud computing environment is its inherent scalability, enabling services to be dynamically scaled up or down as required [4]. Resource pooling is a significant attribute within the cloud computing paradigm, wherein resources are shared and assigned to users under their specific demands. The cloud provider employs an automated approach to allocate virtual resources to users in compliance with the established SLA and the pay-per-usage policy [5]. A well-designed scheduling scheme is essential to facilitate resource allocation, enabling the automatic distribution of virtual resources to users. Furthermore, establishing a relationship between user requests and virtual machines (VMs) becomes crucial for efficient resource allocation. Given the diverse user base in the cloud computing environment, the implementation of an optimal task-scheduling mechanism becomes imperative. Additionally, a reliable and scalable resource provisioning mechanism is necessary to allocate resources to a large number of users automatically [6].

In the cloud computing environment, user requests are diverse in terms of sizes and types, including streaming data, video, images, text, etc. These requests can originate from different heterogeneous resources [7]. Therefore, a robust task-scheduling algorithm is required to schedule these heterogeneous, variable, and dynamic users' requests onto suitable VMs. Effective task scheduling is crucial to prevent Quality of Service (QoS) degradation and ensure compliance with SLA parameters that establish trust between users and cloud providers. A well-designed task scheduling algorithm should maximize QoS while maintaining SLA requirements, thus enhancing trust between users and cloud providers[8]. In recent years, several research works have focused on task scheduling in the cloud computing domain, utilizing metaheuristic approaches. These metaheuristic optimization algorithms are employed because task scheduling is a complex problem categorized as NP-hard. Using metaheuristic algorithms helps find near-optimal or feasible solutions for scheduling tasks to appropriate VMs in the cloud computing environment. By leveraging metaheuristic optimization algorithms, researchers aim to address the challenges posed by the NP-hard nature of task scheduling in cloud computing, ultimately improving the efficiency and effectiveness of resource allocation and meeting user requirements.

This paper proposes an innovative approach based on the Enhanced Harris Hawks Optimization (EHHO) algorithm. The EHHO algorithm draws inspiration from the hunting behavior of Harris's falcons in nature, which has shown remarkable abilities in finding optimal solutions for specific problems. By utilizing the EHHO algorithm, we aim to achieve improved task scheduling performance, enhanced resource utilization, and better compliance with SLAs and users' QoS requirements. The primary objective of this study is to investigate the efficacy of the EHHO algorithm in cloud task scheduling and assess its performance compared to existing optimization algorithms. We conduct extensive simulations and evaluations, considering both general workloads and specific BigDataBench workloads, to comprehensively analyze the performance of the proposed algorithm. The remainder of this paper is organized as follows: Section II provides an overview of related work in cloud task scheduling and optimization algorithms. Section III presents the methodology and details of the Enhanced Harris Hawks Optimization algorithm, including the enhancements made to mitigate convergence issues. Section IV describes the experimental setup and evaluation metrics used to assess the performance of the EHHO algorithm. Section V presents the results and analysis of the simulations. Finally, Section VI summarizes the findings, discusses their implications, and outlines future research directions.

II. Related Work

The paper in [9] proposed a novel algorithm called Interval Multi-objective Cloud Task Scheduling Optimization (I-MCTSO) to effectively address uncertainty in cloud task scheduling. They transformed ambiguous variables into precisely defined interval parameters, considering factors such as makespan, task completion rate, load balancing, and scheduling cost. To implement the I-MCTSO approach, the researchers devised a new Interval Multi-objective Evolutionary approach (InMaOEA). They integrated a distinct interval credibility approach to enhance convergence performance and augmented population diversity by incorporating overlap and hyper-volume assessments alongside the interval congestion distance method. Empirical simulations were conducted to evaluate the performance of the InMaOEA algorithm against existing algorithms. The results provided compelling evidence supporting the high effectiveness and superiority of the proposed approach. The methodologies furnish a framework that provides decision-makers with robust guidelines for allocating cloud job scheduling, enabling well-informed decisions. These advancements represent a significant progression in cloud computing resource management and potentially elevate operational efficiency and effectiveness.

This study [10] proposed an innovative enhancement to the initialization process of the PSO algorithm by integrating heuristic techniques. They incorporated the Minimum Completion Time (MCT) and Longest Job to Fastest Processor (LJFP) algorithms into the initialization phase of the PSO algorithm, aiming to improve its overall efficiency. The researchers comprehensively evaluated the formulated MCT-PSO and LJFP-PSO algorithms, considering several crucial metrics. These metrics included the minimization of makespan, reduction in overall energy consumption, mitigation of imbalance, and decrease in total execution time. These metrics served as pivotal benchmarks to assess the effectiveness of the proposed algorithms in the context of task scheduling. Through extensive simulations, the researchers presented evidence demonstrating the notable superiority and efficacy of the suggested MCT-PSO and LJFP-PSO approaches compared to traditional PSO methods and other contemporary task-scheduling algorithms. These findings underscored the potential of these enhancements to significantly improve the optimization capabilities of task scheduling methods based on the PSO algorithm. Consequently, this research contributes significantly to advancing the efficient and effective management of cloud computing resources.

In research [11], it introduced a task scheduling method called Chemical Reaction PSO. This method offers a hybrid approach that efficiently allocates multiple independent tasks among a collection of VMs in cloud computing environments. The proposed method combines the advantages of traditional chemical reaction optimization and particle swarm optimization, creating a unique synergy that leads to an optimal sequence for task scheduling. This sequence considers both task demand and deadline considerations, thereby improving outcomes across various parameters such as cost, energy consumption, and makespan. To evaluate the effectiveness of the proposed algorithm, extensive simulation experiments were conducted using the CloudSim toolbox. The experimental results highlighted the benefits of the Chemical Reaction PSO algorithm. The average execution time was rigorously assessed by comparing studies involving different quantities of VMs and jobs. The results demonstrated substantial improvements in execution duration, ranging from 1% to 6%, with specific instances showing even more significant improvements exceeding 10%. The makespan results also exhibited noteworthy gains, ranging from 5% to 12%, while the overall cost factor demonstrated enhancements of 2% to 10%. Furthermore, there was a significant increase in the rate of energy consumption, ranging from 1% to 9%.

The paper in [12] developed the Enhanced Sunflower Optimization (ESFO) algorithm as an innovative methodology to enhance the effectiveness of existing job scheduling techniques. The ESFO algorithm aims to achieve optimal scheduling within polynomial time complexity. The proposed ESFO approach underwent comprehensive scrutiny and was subjected to a battery of task scheduling benchmarks to evaluate its strengths and limitations. Simulation studies were conducted to assess the performance of the ESFO algorithm compared to existing algorithms. The outcomes of these studies demonstrated the superior performance of the ESFO algorithm. It exhibited significant proficiency in optimizing task scheduling outcomes, particularly in critical parameters such as energy usage and makespan. The algorithm's robust performance across these parameters highlighted its effectiveness in improving resource allocation and system efficiency.

The authors in [4] introduced the Enhanced Marine Predator Algorithm (EMPA) as a means to enhance scheduling efficiency. The proposed methodology consists of several crucial stages, including formulating a task scheduling model that considers both makespan and resource utilization. Each element within the algorithm represents a potential solution for task scheduling, aiming to identify the most favorable scheduling solution. To improve its performance, the EMPA algorithm integrates various components derived from the Whale Optimization Algorithm (WOA), incorporating operator functions, nonlinear inertia weight coefficients, and the golden sine function. To evaluate its effectiveness, the EMPA algorithm undergoes extensive comparative assessments against established optimization algorithms, such as WOA, PSO, SCA, and GWO, across diverse settings considering different workloads in the GoCJ and synthetic datasets. The empirical evaluation conducted in this study highlights the advantages of the EMPA algorithm, demonstrating notable strengths in resource utilization, degree of imbalance, and makespan. These findings provide empirical evidence supporting the efficacy of the Enhanced Marine Predator Algorithm in optimizing task scheduling outcomes. As a result, these results contribute significantly to the field of scheduling approaches and can potentially enhance resource management in various applications.

The paper in [13] proposed a multi-objective scheduling algorithm called MSITGO, which aims to optimize three conflicting objectives: idle resource costs, energy consumption, and batch task completion time. Drawing inspiration from Invasive Tumor Growth Optimization (ITGO), the MSITGO algorithm incorporates tumor cell growth modeling principles and integrates Pareto optimum and packing problem models. This integration enables a comprehensive and efficient exploration of potential solutions, expanding the range of ideas and accelerating the consensus-building process. Moreover, the MSITGO framework encompasses the entire task-processing operation by dividing it into two distinct stages: machine assignment and timeslot allocation. This refined framework enhances job scheduling efficiency and mitigates improper allocations. To validate its practical application, MSITGO undergoes empirical validation using real cluster data obtained from Alibaba. The experimental results demonstrate the superiority of MSITGO over existing techniques in addressing the multi-objective task scheduling problem. The framework exhibits its ability to provide more efficient solutions, highlighting its potential to make significant contributions to optimizing task scheduling across various applications.

III. Problem Statement and System Model

In this section, we define the problem statement and introduce the proposed architecture for task scheduling. The problem at hand revolves around the mapping of a set of n tasks, represented as tn = {t1, t2, ..., tn}, onto the m VMs vmm = {vm1, vm2, ..., vmm}, exist within the Hk hosts Hk = {H1, H2, ..., Hk}, which are situated within the Dn datacenters Dn = {D1, D2, ..., Dn}. During this mapping process, the priorities of both VMs and tasks are taken into account. The primary objectives of this mapping are to minimize the makespan and prevent SLA violations.

Fig. 1 provides a visual representation of the proposed system architecture. The process begins with simultaneous user queries being submitted to the cloud administration dashboard and broker, which act as users' agents. The task manager then validates these requests, which considers the specified SLA requirements. If the requests meet the criteria and are deemed valid, they are placed in a waiting queue and subsequently forwarded to the task scheduler. Within this architecture, the task manager is crucial in calculating the priorities of diverse and heterogeneous tasks. These priorities are determined based on factors such as task size, run-time capacity, and the preferences of the VMs.

Additionally, the VM priorities are determined by considering the unit cost of electricity associated with each VM. After determining the priorities of tasks and VMs, they are placed in a waiting line. The task scheduler then assigns the highest-priority task to the highest-priority VM. The scheduler tries to reduce the makespan and prevent SLA breaches by categorizing the requests based on these priorities. The task scheduler plays a crucial role in efficiently mapping tasks to VMs while considering their priorities. It takes into account the optimization objectives of minimizing the makespan and ensuring compliance with SLAs. By intelligently assigning tasks to VMs based on their priorities, the scheduler aims to achieve an optimal task scheduling assignment, leading to improved system performance and user satisfaction.

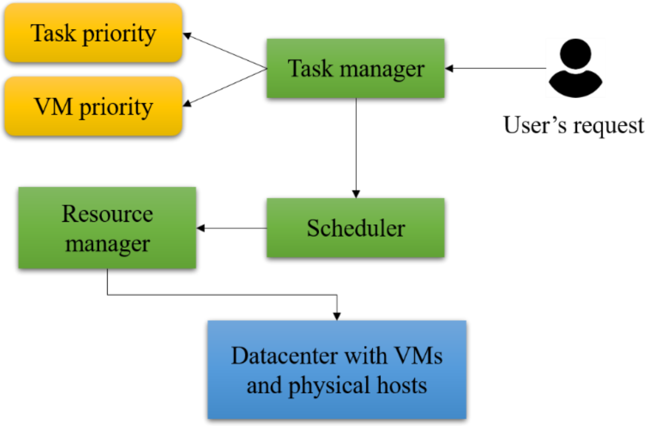

Fig. 1. System architecture.

To evaluate the priorities of tasks, the workload on all VMs is calculated using Eq. (1), where lom represents the workload on m VMs residing in the set of Hk hosts. Consequently, the total workload on hosts is calculated using Eq. (2).

$$lo_{vm_m} = \sum lo^m \tag{1}$$

$$lo_{H_k} = \frac{lo_{vm_m}}{\sum H_k} \tag{2}$$

To determine whether user requests or tasks can be processed on a specific VM, the processing capacity of a VM needs to be defined. This is indicated by Eq. (3), where prono represents the number of processing elements and proMIPS stands for the processing capacity based on the number of instructions processed per second.

$$pro_{ca_{vm}} = pro_{MIPS} \times pro_{no} \tag{3}$$

For the task scheduler to map tasks to specific VMs, it requires knowledge of the task size, which is calculated using Eq. (4). Subsequently, the priorities of all tasks are calculated using Eq. (5), while the priorities of VMs, based on unit electricity cost, are determined using Eq. (6).

$$t_k^{len} = t_{pr_k} \times t^{MIPS} \tag{4}$$

$$t_{pr_k} = \frac{t_k^{len}}{pro_{k_{vm}}} \tag{5}$$

$$vm_{pr_n} = \frac{elecost^{high}}{elecost_{d_i}} \tag{6}$$

The primary goals of this research endeavor encompass the proper mapping of tasks to virtual resources, with a focus on minimizing the makespan and avoiding any violations of service level agreements (SLAs). To evaluate the makespan, Eq. (7) is employed as the metric. Subsequently, the determination of SLA violations becomes the next objective. SLA violations are influenced by two key factors: the active time of a host and performance degradation. These factors are quantified using Eq. (8) and (9), respectively. By utilizing these equations, the calculation of SLA violations can be performed, as expressed in Eq. (10).

$$ms^k = e^k + ava^n \tag{7}$$

$$AT_{H_i} = \frac{1}{p}\sum_{s=1}^{p} \frac{vio\ time_{H_i}}{AT_{H_i}} \tag{8}$$

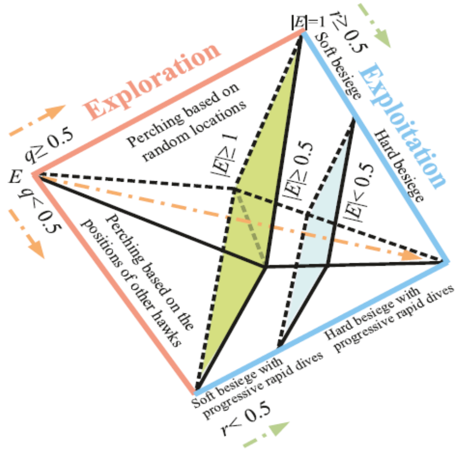
$$pe_{dg} = \frac{1}{n}\sum_{a=1}^{n} \frac{pe_{dg}^{p}}{to_{vm}^{p}} \tag{9}$$

$$SLA_{vio} = pe_{dg} \times AT_{H_i} \tag{10}$$

IV. Enhanced HHO for Task Scheduling

The HHO algorithm draws inspiration from the cooperative hunting and pursuit behaviors observed in Harris’s hawks, specifically their strategic hunting tactics like "surprise pounces" or "the seven kills"[14]. In cooperative attacks, multiple hawks collaborate to pursue a rabbit that has revealed itself, aiming to catch the prey swiftly. However, the hunt might include repeated rapid dives near the prey, depending on the prey's reactions and its potential to escape. Harris’s hawks display various hunting strategies based on the changing circumstances and the prey's escape patterns. Tactics are often altered if the lead hawk fails to pursue the prey, allowing another team member to continue the chase, often used to confuse escaping rabbits. Notably, the rabbit is unable to regain its defensive skills when a new hawk initiates the chase, and it cannot escape the attacking team as the most experienced hawk captures and shares the exhausted rabbit.

The different phases of the HHO are depicted in Fig. 2, illustrating how hawks trace, encircle, and ultimately attack their prey. The mathematical model mirrors these hunting behaviors, encompassing three phases: exploration, transition between exploration and exploitation, and exploitation. Throughout each phase, Harris’s hawks represent potential solutions, and the target prey represents the optimal solution. Hawks use two exploration techniques to locate the prey. In one, they select a location based on other hawks' positions and the prey's location. In the second strategy, hawks perch randomly on tall trees. Eq. (11) simulates these methods with equal probabilities using random numbers.



|E|=1
r≥ 0.5
Soft besiege
Exploitation
Exploration
Perching based on random locations
q≥ 0.5
E
q< 0.5
|E|≥ 1
|E|≥ 0.5
|E|< 0.5
Hard besiege
Perching based on the positions of other hawks
Soft besiege with progressive rapid dives
Hard besiege with progressive rapid dives
r< 0.5

Fig. 2. HHO steps.

$$x(t+1) = \begin{cases} x_{random}(t) - x_1|x_{random}(t) - 2r_2x(t)|, q \geq 0.5 \\ x_{rabbit}(t) - x_{mean}(t) - r_3\big(LB + r_4(UB - LB)\big), q < 0.5 \end{cases} \tag{11}$$

Eq. (12) calculates the average hawk population position. The algorithm switches from exploration to exploitation based on the rabbit's energy, as expressed in Eq. (13). When the rabbit's escaping energy $|E|\geqslant 1$, hawks explore more areas; otherwise, exploitation begins. Eq. (14) - Eq. (17) determine whether hawks perform a soft or hard siege based on the rabbit's energy and escape success. A soft siege involves repeated dives, simulating the rabbit's successful escape, while a hard siege is calculated differently.

$$x_{mean}(t) = \frac{1}{N}\sum_{i=1}^{N} x_i(t) \tag{12}$$

$$E = 2E_0(1 - \frac{t}{Max\_iter}) \tag{13}$$

$$x(t+1) = \Delta x(t) - E|J._{xrabbit}\,(t) - x(t)| \tag{14}$$

$$\Delta x(t) = x_{rabbit}(t) - x(t) \tag{15}$$

$$J = 2(1 - random) \tag{16}$$

$$x(t+1) = x(t) - E|\Delta x(t)| \tag{17}$$

Eq. (18) - Eq. (21) governs the soft-siege rapid dives, utilizing Lévy flights to mimic the prey's behaviour. Eq. (18) and (19) calculate the hawks' actions during the dive, while Eq. (20) and Eq. (21) reflect the final soft-siege rapid dives and the parameters k and z during a hard siege, respectively.

$$k = x_{rabbit}(t) - E|J.x_{rabbit}(t) - x(t)| \tag{18}$$

$$z = k + RandomVector.L(dim) \tag{19}$$

$$x(t+1) = \begin{cases} k, iff(k) < f(x(t)) \\ z, iff(z) < f(x(t)) \end{cases} \tag{20}$$

$$k = x_{rabbit}(t) - E|J.x_{rabbit}(t) - x_{mean}(t)| \tag{21}$$

In the exploration phase of the HHO algorithm, the calculations pertaining to positions, specified in Eq. (11) and Eq. (12), are influenced by random values r1 and r3 within the range of (0, 1). While this stochastic approach fosters randomness in each step during the global search, it lacks the necessary variability. During this phase, the original HHO algorithm operates under the assumption that hawks, with their keen eyes, can generally track and detect prey; however, there are moments when prey is elusive and might not be detected easily, sometimes even after several hours. In light of these observations, it seems plausible to consider adjusting these parameters to render them more adaptable.

We propose to conceptualize r1 and r3 as indicative of the step length, where larger values imply swifter movement for the hawks, and conversely, smaller values correspond to slower movement. There exist two scenarios for a hawk to find prey: one scenario involves immediate detection, while the other involves a prolonged search. In the former, it is essential to account for the variability in step length, whereas, in the latter scenario, the overall variability of the step length should diminish. As time progresses, the likelihood of a hawk finding prey increases; therefore, initially, hawks should explore a wider range with larger steps, gradually transitioning to a more methodical search in later iterations. Thus, we propose an update to r1 and r3 using an exploration factor represented by Eq. (17). Consequently, the modified Eq. (11) is updated as follows Eq. (18):

$$ef = (b \times rand - \frac{b}{2}) \times cos(\frac{\pi}{2} \times (\frac{t}{T})^2) \tag{22}$$

$$X(t+1) = \begin{cases} X_{rand}(t) - ef|X_{rand}(t) - 2r_2X(t)|, q \geq 0.5 \\ (X_{rabbit}(t) - X_m(t)) - ef(LB + r_4(UB - LB)), q < 0.5 \end{cases} \tag{23}$$

Here, the value of b is set to 2 based on favorable results from experimental tests. The term (b ∗ rand − b/2) introduces randomness in the step length by generating random numbers within the interval of (−b/2, b/2). In essence, the exploration factor initially widens the step length range from (0, 1) to (−b/2, b/2) to support expansive exploration. As the number of iterations increases, it gradually shifts the exploration process from a broad range to a more constrained one. Ultimately, this approach maintains the essential randomness in the step length while adapting it dynamically over the course of iterations.

The choice of parameters in EHHO algorithm is critical for optimizing its performance in task scheduling within cloud environments. The parameter *b* is set to 2 based on favorable outcomes from preliminary experimental tests, which suggests that this value effectively balances the exploration and exploitation phases of the algorithm. The exploration factor (*ef*), introduced in Eq. (22), modifies the step length of hawk movements, thereby enhancing the algorithm's ability to search for optimal solutions dynamically. The term *(b×rand−b/2)* adds randomness within the interval (−b/2, b/2), initially broadening the step length to support wide-ranging exploration and then gradually narrowing it to facilitate a more focused search as iterations progress. This adaptation ensures the algorithm maintains its stochastic nature while becoming more methodical over time. The experimental design rationale involves simulating the EHHO algorithm against established optimization algorithms like GA, ACO, and PSO, across varying workloads to evaluate its efficacy. The validation process entails comparing key performance metrics, such as makespan and SLA violations, demonstrating significant improvements in both general and BigDataBench workloads.

V. Experimental Results

This section discusses the configuration settings for simulation and presents the simulation results. The simulation was conducted using the CloudSim toolkit, which provides an accurate environment for simulating the cloud paradigm. The simulation environment utilized in this study was implemented on a machine with an Intel Core i5 processor and 8 GB of RAM. Table I shows configuration settings for simulation. Table III outlines the specific standard configuration settings utilized in the simulation.

Table II presents the computation of SLA violations for different algorithms, including PSO, ACO, GA, and our proposed algorithm (EHHO), considering varying task quantities.

TABLE I. Configuration Settings for Simulation

Parameter	Value
Datacenter count	5
Operating system	Linux
Virtual machine monitor	Xen
VM bandwidth	5 Mbps
VM memory	1024 MB
VM count	20
Network bandwidth	1000Mbps
Host storage capacity	5 TB
Host memory	16 GB
Task length	780,000
Task count	100-1000

TABLE II. SLA Violations for Randomly Generated Workloads

Task count	GA	ACO	PSO	EHHO
100	15	12	17	7
500	12	18	25	9
1000	21	22	28	18

The selection of GA, ACO, and PSO for comparison against our proposed EHHO algorithm is rooted in the distinct strengths and prevalent application of these algorithms in the field of optimization and task scheduling. Each of these algorithms represents a different heuristic approach to solving complex optimization problems, making them ideal benchmarks for assessing the performance of EHHO. The Genetic Algorithm (GA) is an evolutionary algorithm that simulates the process of natural selection. It operates through mechanisms inspired by biological evolution, such as selection, crossover, and mutation. GA's robustness in exploring large search spaces and finding near-optimal solutions is well-documented, making it a common choice for various scheduling and optimization tasks. By comparing EHHO to GA, we can evaluate how well our algorithm performs in terms of scalability and efficiency, especially in complex environments where traditional methods might struggle.

The ACO and PSO were chosen due to their distinct nature and widespread use in optimization problems. ACO is inspired by the foraging behavior of ants and is particularly effective in finding optimal paths and solutions through a collaborative approach. Its performance in scheduling tasks is noteworthy, making it a suitable candidate for comparison. PSO, on the other hand, simulates the social behavior of birds flocking or fish schooling. It is known for its simplicity and fast convergence rates, making it a popular choice for various optimization problems, including resource scheduling and allocation. By including ACO and PSO in our comparative analysis, we cover a broad spectrum of heuristic optimization techniques. This allows us to comprehensively assess the efficiency, scalability, and robustness of EHHO in minimizing SLA violations and makespan across different workload scenarios, thereby highlighting its potential advantages and areas of improvement in real-world applications.

When subjected to randomly generated workloads, the SLA violations recorded for the PSO algorithm were 17%, 25%, and 28%, respectively. For ACO, the corresponding SLA violations are 12%, 18%, and 22%. GA yields SLA violations of 15%, 12%, and 21%, while EHHO results in SLA violations of 7%, 9%, and 18%. In Table III, we present the assessment of SLA violations incurred by different algorithms across varying task quantities. These evaluations were conducted using the BigDataBench workload as the basis for generating tasks. For PSO, the SLA violations are 18%, 21%, and 29%. ACO yields SLA violations of 10%, 12%, and 18%. GA generates SLA violations of 18%, 21%, and 29%. EHHO results in SLA violations of 9%, 11%, and 13%. It is evident that EHHO significantly reduces SLA violations over other algorithms. By considering the priority of VMs and tasks, our algorithm efficiently schedules the tasks, resulting in a minimized makespan.

TABLE III. SLA VIOLATIONS FOR BIGDATABENCH WORKLOADS

Task count	GA	ACO	PSO	EHHO
100	18	10	18	9
500	21	12	21	11
1000	29	18	29	13

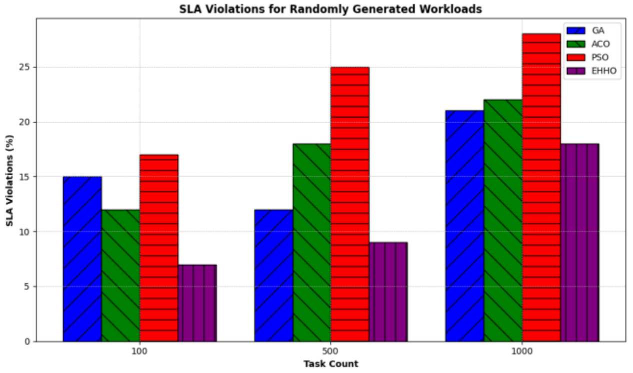


Fig. 3. Visual representation of SLA violations for randomly generated workloads.

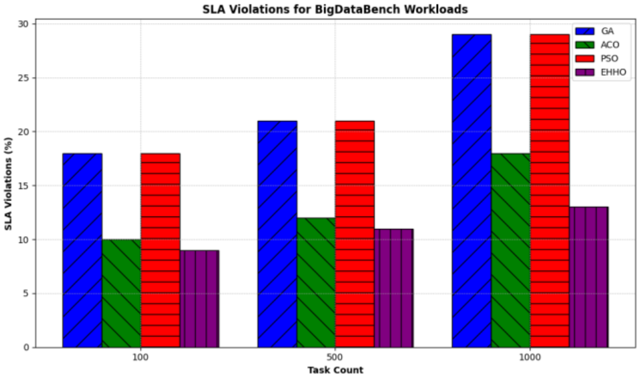

Fig. 4. Visual representation of SLA violations for bigdata bench workloads.

Table IV presents the calculated makespan values for different algorithms for three task quantities. In the case of randomly generated workloads, the makespan values obtained for PSO were 1289, 1678, and 1989, respectively, for the three task quantities 100, 500, and 1000. For ACO, the corresponding makespans are 1156, 1563, and 2146. GA yields makespans of 1543, 1475, and 1934, while the proposed algorithm results in makespans of 976, 1281, and 1814. Table V presents the calculated makespan values for different algorithms using the BigDataBench workload, considering task quantities of 100, 500, and 1000. For PSO, the makespans are 1367, 1747, and 2045. ACO yields makespans of 1243, 1643, and 2387. GA generates makespans of 1437, 1532, and 2243, while the proposed algorithm results in makespans of 1087, 1407, and 1882. Fig. 3, 4, 5 and 6 show visual representation for different workloads.

TABLE IV. MAKESPAN FOR RANDOMLY GENERATED WORKLOADS

Task count	GA	ACO	PSO	EHHO
100	1543	1156	1289	976
500	1475	1563	1678	1281
1000	1934	2146	1989	1814

TABLE V. MAKESPAN FOR BIGDATABENCH WORKLOADS

VI. Discussion

The EHHO algorithm has shown significant improvements over traditional algorithms like GA, ACO, and PSO in optimizing makespan and reducing SLA violations, which suggests it has a strong foundation for handling larger and more complex workloads. The inherent design of the EHHO, which draws from the cooperative hunting strategies of Harris's hawks, allows it to dynamically adjust its exploration and exploitation phases. This dynamic adjustment is crucial for scalability because it enables the algorithm to maintain efficiency as the number of tasks and VMs scales up. The exploration factor introduced in the EHHO enhances its capability to search a wider solution space initially and then focus on more promising areas, which is beneficial when dealing with large-scale environments.

Cloud computing environments are highly dynamic, with workloads and resource availability fluctuating rapidly. The adaptability of the EHHO algorithm in such conditions is supported by its enhanced exploration mechanism, which allows for a more flexible search process. The algorithm can adjust its step lengths and exploration range based on the iteration progress and current solution quality, helping it adapt to sudden changes in workload patterns and resource distribution.

The scalability of the proposed EHHO algorithm is a critical factor for its practical application in diverse cloud computing environments, characterized by varying loads and resource distribution patterns. Scalability in this context refers to the algorithm's ability to maintain or improve its performance as the size of the cloud environment increases and as it adapts to changing conditions.

Moreover, the use of random values in the EHHO's exploration phase fosters a level of stochasticity that can be beneficial in diverse environments. This randomness ensures that the algorithm does not become overly dependent on specific patterns and can handle unexpected changes more effectively. While the EHHO algorithm has demonstrated improved performance metrics, its scalability also depends on managing computational overhead. The algorithm's complexity, particularly in large-scale environments, could potentially introduce significant computational costs. To mitigate this, the EHHO can be parallelized and optimized to run on distributed cloud infrastructure, leveraging the parallel processing capabilities of modern cloud systems. This parallelization can distribute the computational load, ensuring that the algorithm remains efficient even as the scale of the environment increases.

For addressing real-world scenarios challenges, implementing the EHHO algorithm for cloud task scheduling in real-world scenarios presents several potential challenges. One of the primary challenges is the dynamic and unpredictable nature of cloud environments. Cloud infrastructures often experience varying workloads and resource availability, making it difficult to maintain consistent performance and SLA adherence. The EHHO algorithm, although optimized for exploration and preventing convergence to local optima, may still need continuous adjustments and fine-tuning to handle these dynamic changes effectively. Additionally, integrating the EHHO algorithm with existing cloud management platforms can be complex, requiring significant modifications to accommodate its unique optimization processes. This integration process must ensure minimal disruption to ongoing services and avoid introducing new inefficiencies.

Another challenge is the potential computational overhead introduced by the EHHO algorithm. While EHHO aims to optimize resource utilization and task scheduling, the algorithm itself can be computationally intensive, especially when handling large-scale cloud environments with numerous tasks and VMs. This computational demand can offset some of the performance gains achieved through optimized scheduling. Moreover, real-world applications often involve multi-tenant environments where multiple users and applications compete for resources. Ensuring fairness and effective resource allocation while using EHHO to maximize efficiency can be challenging. The algorithm must be designed to respect priority levels, application-specific QoS requirements, and user-specific SLAs, which can add layers of complexity to its implementation.

To address these challenges, several adaptations and enhancements can be incorporated into the EHHO algorithm. Firstly, implementing a feedback mechanism that continuously monitors the cloud environment and dynamically adjusts the EHHO parameters can help maintain optimal performance despite changes in workload patterns and resource availability. This adaptive approach can involve machine learning techniques that predict workload trends and preemptively adjust the EHHO algorithm's exploration and exploitation balance.

Secondly, to mitigate the computational overhead, the EHHO algorithm can be parallelized and optimized to run efficiently on distributed systems. Leveraging the inherent parallelism in cloud infrastructures can distribute the computational load of the EHHO algorithm, ensuring that it scales effectively with the size of the cloud environment. Additionally, introducing a hybrid approach that combines EHHO with other less computationally intensive algorithms can help balance the trade-offs between optimization quality and computational efficiency. For instance, using simpler heuristic methods for initial task scheduling and applying EHHO for fine-tuning can achieve a balance between performance and overhead.

Lastly, ensuring fairness and effective resource allocation in multi-tenant environments requires incorporating priority-based and QoS-aware scheduling policies into the EHHO algorithm. This can involve designing custom fitness functions that account for user-specific SLAs and QoS requirements, ensuring that the algorithm not only optimizes for overall resource utilization but also respects individual application needs. Regular audits and evaluations of the algorithm's performance in meeting SLAs and QoS parameters can help in making necessary adjustments and improvements, ensuring that EHHO remains effective in real-world cloud environments.

VII. Conclusion

The scheduling of tasks in cloud computing environments presents substantial issues for both cloud providers and customers. In the absence of an efficient scheduler, the diverse and heterogeneous workload can result in prolonged makespan and violations of SLAs, thereby compromising the overall QoS. To tackle these challenges, this study presented a novel task-scheduling algorithm that incorporates the priority of VMs and tasks to achieve optimal task-to-resource mapping. Our scheduling strategy builds upon the existing HHO algorithm, incorporating enhancements to improve its effectiveness. To evaluate and validate our proposed algorithm, we conducted comprehensive simulations and experiments using the CloudSim framework. The efficacy of the suggested algorithm is evaluated in comparison to established methodologies such as PSO, ACO, and GA. Initially, we used randomly generated workloads in the simulation, and later, we utilized a real-time dataset called BigDataBench. The results of our evaluation provide compelling evidence that our proposed algorithm surpasses the previous methods by optimizing SLA violations and makespan.

Despite these promising results, our study has some limitations. Firstly, the algorithm's performance has been tested primarily within simulated environments, which may not fully capture the complexities and variabilities of real-world cloud infrastructures. The computational overhead introduced by the enhanced HHO algorithm also needs further analysis to ensure scalability and efficiency in large-scale cloud deployments. Additionally, the algorithm currently focuses on optimizing makespan and SLA violations but does not explicitly address other crucial factors such as energy consumption, cost efficiency, and fairness in resource allocation among multiple tenants. Future research should aim to address these limitations by conducting real-world implementation and testing, exploring hybrid optimization techniques to balance computational efficiency, and integrating additional optimization objectives such as energy and cost savings. Expanding the algorithm's adaptability to diverse and evolving cloud environments will also be essential for its broader applicability and robustness.

***Abstract*—Islands represent strategic platforms for exploring and exploiting marine resources. This article presents a hybrid renewable electric system (HRES) designed to power the island communities of Djerba in Tunisia. The system integrates photovoltaic panels, wind turbines, tidal turbines, hydraulic systems, biomass, and batteries, taking into account available climatic and land resources. A multi-objective optimization method is proposed for sizing this system to minimize power loss and energy costs. Two optimization algorithms, MOPSO (Multi-Objective Particle Swarm Optimization) and SSO (Social Spider Optimization) have been used to solve this problem. MATLAB simulations show that MOPSO offers better convergence and coverage than SSO. The results confirm the viability of the proposed algorithm and method for optimal sizing. In addition, they enable an in-depth analysis of the electrical production and economic benefits associated with the various system components.**

***Keywords*—Hybrid renewable energy system; techno-economic optimzation; optimal sizing; MOPSO; SSO**

I. Introduction

Energy demand is growing exponentially due to population growth and industrialization. Distributed renewable energy offers many advantages and is a practical alternative to conventional energy sources. Many renewable energy systems can be integrated into hybrid renewable energy systems (HRES) for on-grid and off-grid applications, as has been widely proposed and discussed.

A thorough and detailed design and modeling of a stand-alone HRES, including conventional and renewable energy resources, has been introduced using meta-heuristic algorithms [1]. Technical and ecological aspects were also taken into account. Other research has focused on transcriber generation in microgrids, peer-to-peer energy exchange in micro/mini-grids with the local electricity community, and statistical analyses of wind and photovoltaic HRES [2], [3], [4].

The optimal sizing of an island hybrid system is studied to establish the optimum capacity and size for an island system comprising a wind turbine (WT), solar panels (PV), and a battery [5]. The off-grid operation of an island hybrid system has been examined to establish the optimal sizing and operation of the WT, photovoltaic (PV), and battery components [6].

In study [7], a PV/wind turbine (WT) hybrid system installed in Jordan was designed to minimize the cost of energy (COE) and maximize the fraction of demand met by the system. A hybrid PV/biomass/fuel cell (FC) system installed in Iran was presented and optimized in study [8], considering the loss of power probability (LPSP) as an objective function. Different optimization approaches have been studied to determine the optimal sizing of a PV/WT/FC hybrid system, as discussed in study [9].

The methodology presented in this article uses 12-variable modeling applicable to a wide range of microgrid configurations [10]. A multi-objective particle swarm optimization (MOPSO) algorithm is used to minimize system cost and dependence on external energy sources [11], [12], [13]. After optimization, this external energy cost is used to determine the best system configuration for a given location and consumption profile.

The social spider optimization (SSO) algorithm is used to solve the economic dispatch problem [14], [15]. It is also used for the first time to estimate the thermophysical properties of phase-change materials [16].

In research [17], a recent methodology is developed based on the SSO. The objective is to determine the optimal sizing of a microgrid containing photovoltaic, wind, diesel, and batteries in the Aljouf region. The study focused on three configurations: PV/battery/diesel,wind/battery/diesel, and PV/wind/battery/diesel. In addition, several algorithms are used to optimize the energy cost, respecting the loss of power probability (LPSP) as a technical factor. In study [18], the design of the PV/FC/battery system and a sensitivity analysis study are presented.

The choice of an optimization method for a hybrid system depends on both specific objectives, such as minimizing operating costs and maximizing revenue, and sustainable objectives, such as reducing carbon emissions and adopting renewable energies. There is a growing trend towards holistic approaches that balance economic and environmental considerations to achieve sustainable goals [19], [20].

The optimal performance of the grid with a distributed generator (DG) and an energy storage system (ESS) on several objective functions, such as loss minimization, unbalanced generation at the substation, and overall energy costs as well as peak load demand, is introduced in study [21]. In study [22], and [23], a SSO algorithm is used to solve the economic distribution algorithm, while in study [24], the hybrid SSO algorithm is used to estimate the physical characteristics of the phase thermos for the first time.

This article focuses on optimizing the structure of a hybrid system comprising photovoltaics, wind turbines, tidal turbines, hydraulics, biomass, and batteries. This optimization is carried out using two meta-heuristic algorithms, MOPSO (Multi-Objective Particle Swarm Optimization) and SSO (Social Spider Optimization). These algorithms were also used to reduce energy costs and the probability of power loss.

This careful selection process ensures the integration of state-of-the-art methodologies adapted to the complexities of the research problem, leading to a robust and innovative solution.

The remainder of this paper is organized as follows: In Section II, we describe a hybrid electrical system. In Section III, the economic analysis of the optimization parameters is clarified. In Section IV, the optimization problem is formulated. Section V presents the optimization algorithms. Section VI provides a case study. Results are given in Section VII. Section VIII presents a conclusion.

II. Description of the Hybrid Electrical System

The schematic diagram of the proposed Hybrid Renewable Energy System (HRES) is shown in Fig. 1. The system integrates several energy sources, including photovoltaic (PV) solar panels, wind turbines (WT), tidal turbines, hydroelectricity, biomass and batteries (BESS). The HRES is configured for alternating current (AC), with all renewable energy sources connected to the same AC bus. Direct current (DC) sources such as PV, WT, and BESS are connected to the AC bus via DC/AC inverters. In addition, wind turbines require a controlled inverter to adjust power output to voltage and frequency specifications. The project's economic and technical data are presented in Table I for the system studied.

A. Photovoltaic Modeling

The power output of the photovoltaic panel, P_{pv}, is defined by [28]:

$$P_{pv} = \eta_{pv} N_{pv} P_{max} \frac{G(t)}{G_{stc}} [1 - K_T (T_C(t) - T_{stc})] \tag{1}$$

Where T_C and T_{STC} represent respectively the ambient and the surface temperature of the photovoltaic cells, in this work, T_C is assumed to be equal to 25 °C under standard test conditions (STC). G designates the solar radiation measured as W/m2. G_{STC} and K_T represent the constants of photovoltaic cells whose values are fixed at 1 kW/m2 and -3.7×10^{-3} $°C^{-1}$, respectively.η_{pv} Implies the efficiency of the solar panels and includes the efficiency of the power converter, tracking systems, and connection wires,N_{pv}represents the photovoltaic panel numbers. P_{max} is the nominal output power for STC.

B. Wind Turbine Modeling

In the case of the wind turbine, the power output depends on the wind speed, which in turn is a function of the turbine height. The relationship between the wind speed and the turbine hub height is represented by the equation as shown below [28]:

$$\frac{v_2}{v_1} = \left(\frac{h_2}{h_1}\right)^{\alpha} \tag{2}$$

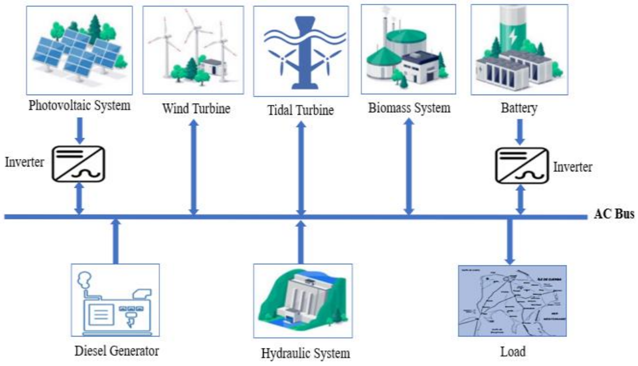

Fig. 1. Hybrid energy system configuration.

TABLE I. Economical and Technical Data [25],[26],[27]

Components	Parameters	Value	Unit
Diesel generator	Lifetime	24000	Hours
	Initial cost	1000	$/kW
	Rated power	4	kW
Wind Turbine	Wind regulator cost	1000	$
	Cut out	21	m/s
	Cut in	3	m/s
	Rated speed	12	m/s
	Rated power	10	kW
	Price	2000	$/kW
	Lifetime	25	Year
Photovoltaic	PV regulator efficiency	95	%
	Lifetime	25	Year
	Initial cost	3400	$/kW
	Rated power	300	kW
	PV regulator cost	1500	$
Tidal Turbine	Tidal regulator cost	1000	$
	Cut out	3.05	m/s
	Cut in	1	m/s
	Rated power	40	kW
	Price	1535	$/kW
Hydraulic	Lifetime	25	Year
	Initial cost	750	$/kW
	Rated power	10	kW
Biomass	Replacement cost	200	$
	Capital cost	1500	$
	Rated power	1	kW
	Operating and maintenance	0.1	$
Battery	Efficiency	80	%
	Lifetime	12	Year
	Initial cost	280	$/kW
	Rated power	1	kWh

Where: h_1 and $h_2$represent the reference height and hub height required, and v_1, v_2 correspond to the wind speed. α is the coefficient of friction and is determined by several characteristics of the site, especially the roughness, the temperature, the speed, the height, and the time of year. The power produced by the wind turbine is presented by Eq. (3) [28].

$$P_{wt}(t) = \begin{cases} 0 & v(t) < v_{in} \\ \eta_{wt} N_{wt} P_{wt_r} \frac{(v^2(t)-v_{in}^2)}{(v_m(t)-v_{in}^2)} & v_{in} < v(t) < v_r \\ \eta_{wt} N_{wt} P_{wt\_r} & v_r < v(t) < v_{off} \\ 0 & v(t) > v_{off} \end{cases} \quad (3)$$

Where N_{wt} represents the wind turbinenumbers, η_{wt} represents the wind turbine efficiency, P_{wt_r} implies the rated power of a single WT operated at the rated wind speed (v_r) in (m/s), andv_{in}, v_{off}denotes the velocity in (m/s) at which the WT starts running and stopped, respectively.

C. Tidal Modeling

The operating principles of tidal turbines are generally based on those of wind turbines since they operate similarly. The available power may be determined by Eq. (4), as described in detail in [29]. Where: S_t is the surface area of the turbine (m2), ρ_t equals the density of the water (1000 kg/m3), v_t equals the speed of the water (m/s), and C_{pt} equals the power coefficient.

$$P_t = \frac{1}{2} N_{tid} \rho_t S_t C_{pt} v_t^3 \quad (4)$$

D. Hydraulic Modeling

The pump is designed to raise the water level in the lower cascade basin to the upper reservoir [30]. The power required to operate the pump is represented by Eq. (5):

$$P_{hy} = N_{hyd} \eta_P \rho_w g h Q(t) \quad (5)$$

where, η_P is the efficiency of the pump installation, the density of the water is represented by ρ_w (kg/m3), the flow rate of the water is represented by Q in (m3/s), an effective head corresponds to h (m)and accelerated gravity is represented by g (m/s2).

E. Biomass Modeling

The biomass generator is considered a production base to satisfy energy needs, complementing other energy production sources. The biomass generator's production of electrical energy can be evaluated by [28]:

$$P_b(t) = N_b \eta_g \omega H_{hv} Q_{sr}(t) \quad (6)$$

where, η_g corresponds to the gasifier efficiency and is equal to 75%, ω corresponds to a conversion factor from kJ to kWh (27.78×10^{-5}), $Q_{sr}(t)$ indicates the biomass flow rate (kg/h), and H_{hv} corresponds to the higher calorific yield of the biomass introduced by the system.

F. Battery Modeling

The final component connected to the DC bus is the battery, characterized by its capacity, C_{bat}, as shown below [28]:

$$C_{bat} = \frac{E_{load} \times A_d}{DOD \times \eta_{inv} \times \eta_b} \quad (7)$$

where, A_d represents the days of autonomy, and E_{load} denotes the load. The depth of discharge (DOD) is assumed to be 8%. The inverter efficiency (η_{inv}) is taken to be 95%, and the battery efficiency (η_b) is taken to be 85%.

G. Diesel Generator Modeling

A stand-alone diesel generator is connected to the AC bus as a second source. This is essential for the stable operation of the HRES, particularly when renewable resources cannot meet the load demand. The generator fuel consumption q(t) can be calculated as follows [28]:

$$q(t) = aP(t) + bP_{rated} \quad (8)$$

Where a and b represent the fuel consumption coefficients, estimated at 0.246 and 0.08415 l/kWh respectively. P_{rated} is the rated power, and P(t) is the power output at a specified time.

III. Economic Analysis of Optimization Parameters

A. Cost of Energy

The cost of energy (COE) represents the average cost of the usable electricity produced by a hybrid system and can be determined by the following equation [31]:

$$COE = \frac{NPC}{\sum_{i=1}^{8760} P_{load}} \times CRF \quad (9)$$

where, P_{load} represents the power demand per hour, and CRF (Capital Recovery Factor) is defined as follows:

$$CRF = \frac{i \times (1+i)^n}{(1+i)^n - 1} \quad (10)$$

B. Loss of Power Supply Probability

Reliability is the basis for the operation of the entire system. In this article, the loss of power probability (LPSP) is presented as an indication of system reliability. LPSP measures the ability of power generation to meet load requirements.LPSP can be calculated from the total power outage duration divided by the total report duration [31].

$$LPSP = \frac{\sum_{i=1}^{8760}\left[P_{load}(t) - \left(P_{pv}(t) + P_{wt}(t) + P_{tid}(t) + P_{hyd}(t) + P_b(t)\right)\right]}{\sum_{i=1}^{8760} P_{load}(t)} \quad (11)$$

where $P_{load}(t)$ represents the power of load.

C. Renewable Factor

Renewable Factor (RF) determines the quantity of electricity produced by renewable resources about the non-renewable resources (diesel generator) used by the HRES and can be calculated in the following equation [31]:

$$RF(\%) = 1 - \left(\frac{\sum_{i=1}^{8760} P_{diesel}(t)}{\sum_{i=1}^{8760} P_{gen}(t)}\right) \times 100 \quad (12)$$

where P_{gen} is the total power of renewable energies. And, when RF is equal to 100%, this means an ideal system that relies solely on power generated from renewable energy resources. When it is at zero percent, it means that the power generated by the diesel generator is the same as the power produced by renewable energy resources.

IV. Formulation of the Optimization Problem

The HRES system, integrating renewable energy sources such as photovoltaic, wind,tidal, hydro, biomass, and batteries, is designed to supply electricity to a remote island in south-eastern Tunisia. It aims to guarantee system reliability, reduce energy costs, and minimize the probability of power loss. In this article, the cost of energy (COE) and the probability of power loss (LPSP) are used as optimization objectives.

A. Objective Function

To assess overall hybrid system performance, the probability of power loss (LPSP) and energy cost (COE) are suggested as the two objective functions, with the main goal being to minimize both functions to achieve high reliability and the minimum possible cost of the hybrid systems studied.

$$\min\{\mathrm{COE}, \mathrm{LPSP}\} \tag{13}$$

The various sizing optimization objectives depend on some restrictions deriving from each of the sources used in the system under study.

B. Constraints

Constraints are shown for achieving the required system design. For this HRES system, restrictions are defined in the following terms:

$$\begin{gathered}
\mathrm{N_{pvmin}} \le \mathrm{N_{pv}} \le \mathrm{N_{pvmax}} \\
\mathrm{N_{wtmin}} \le \mathrm{N_{wt}} \le \mathrm{N_{wtmax}} \\
\mathrm{N_{tidmin}} \le \mathrm{N_{tid}} \le \mathrm{N_{tidmax}} \\
\mathrm{N_{hydmin}} \le \mathrm{N_{hyd}} \le \mathrm{N_{hydmax}} \\
\mathrm{N_{bmin}} \le \mathrm{N_{b}} \le \mathrm{N_{bmax}} \\
\mathrm{LPSP} \le \mathrm{LPSP_{max}} \\
\mathrm{RF_{min}} \le \mathrm{RF} \\
\mathrm{A_d^{min}} \le \mathrm{A_d}
\end{gathered} \tag{14}$$

V. Optimization Algorithms

To meet the design challenges of our HRES system, we are investigating two different optimization approaches: MOPSO and SSO. These methods offer a flexible economic analysis platform and are based on natural principles, bringing new optimization perspectives. In this section, we present these methods in detail, describing their specific application to the sizing of hybrid energy systems to identify optimal and economically sustainable solutions.

A. Overview of the MOPSO Algorithm

A PSO algorithm was born out of the study of the predatory behavior of flocks. For PSO, a search for the birds within the population pool's empty zone is the solution to the optimization problem, i.e. "particles". All particles have a fitness value, as determined by the optimization function. Furthermore, each particle's direction and distance are defined by its velocity. All particles are traced to the optimal particles in the population, to find the optimum solution in the interval. The process of updating is as follows [30]:

$$\begin{gathered}
\mathrm{V_{i+1}} = \omega \mathrm{V_i} + \mathrm{C_1 rand()(pbest_i - X_i)} + \mathrm{C_2 rand()(gbest_i - X_i)} \\
\mathrm{X_{i+1}} = \mathrm{X_i} + \mathrm{V_{i+1}}
\end{gathered} \tag{15}$$

Where V_i represents the velocity and X_i the position of the particle; gbest represents the optimal location for all particles found in the entire population; rand() represents the random number between (0,1); X_i represents the particle's current position; c_1 and c_2 represent training factors. ω represents the particle swarm's dynamic weight value, whose value is:

$$\omega = \omega_{\mathrm{max}} - \omega_{\mathrm{min}} \times \frac{\mathrm{inter}}{\mathrm{inter_{max}}} \tag{16}$$

where ω_{max} is the initial weight of inertia; ω_{min} is the weight of inertia during iteration to maximum algebra; $inter_{max}$ is the maximum number of iterations; inter is the actual iteration number.

1) Description of the MOPSO algorithm: A criterion to classify a meta-heuristic algorithm for optimization problem solving consists of the number to be achieved: a single objective, a multi-objective problem, or a multiple-objective problem. The MOPSO (Multi-ObjectiveParticle Swarm Optimization) approach was developed to solve multi-objective optimization problems. MOPSO makes use of particles that represent possible solutions, which move in the search space following swarm-inspired rules. By updating the positions and velocities of these particles as the best solutions are identified, the system identifies non-dominated solutions forming the Pareto front. This makes it possible to determine optimal trade-offs among different objectives, offering a range of optimized options for making decisions in a highly complex environment [32].

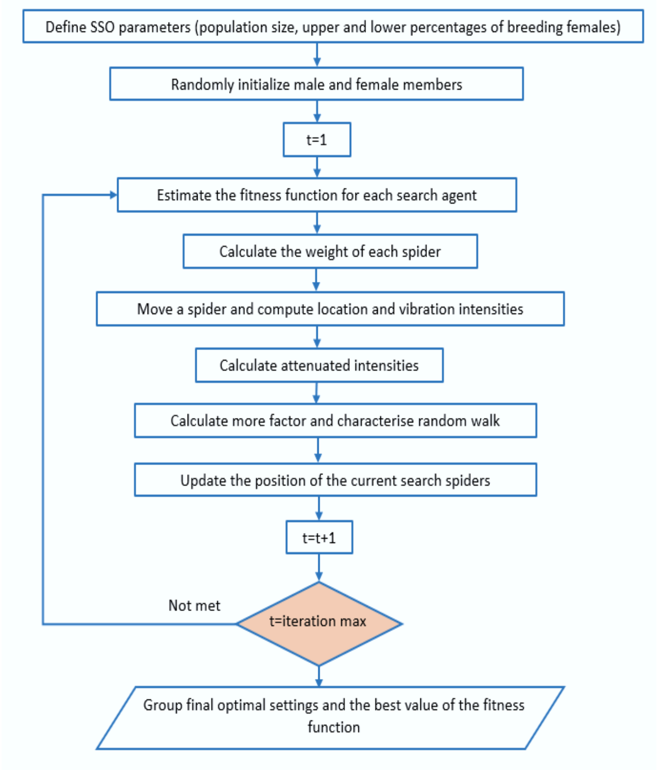
Algorithm 1: Pseudocode of MOPSO

```
Step 1
Input data includes meteorological, load demands, technical, economic, and constraint data.
Step 2
Set an upper bound and a lower bound for the source of HRES.
Step 3
C1 = 1.5, C2 = 1.5, inertia_weight = 0.9

Step 4
For each particle in particle_swarm:
particle.velocity = random_value()
particle.position = random_value()
particle.fitness = assess_fitness(particle.position)
Step 5
For each particle in particle_swarm:
Update $p_{best}$ and $g_{best}$ if necessary.
Step 6
For each particle in particle_swarm:
$\mathrm{particle.velocity} = \mathrm{inertia\_weight} \times \mathrm{particle.velocity}$
    $+\ \mathrm{C1}\ \ \mathrm{random\_value()}$
    $\times\ (\mathrm{particle.pbest\_position}$
    $-\ \mathrm{particle.position})\ +\ \mathrm{C2}\ \times \mathrm{random\_value()}$
    $\times\ (\mathrm{global.gbest\_position}$
    $-\ \mathrm{particle.position})\ \mathrm{particle.position}$
    $=\ \mathrm{particle.position}\ +\ \mathrm{particle.velocity}$
Step 7
Until max_iterations or non_dominated_sort_solution_found:
Repeat steps 5 and 6.
Return the best setting or optimal LPSP and COE values.
End
```

B. *Definition of Algorithm SSO*

The Social Spider Optimizer (SSO) represents an optimization algorithm inspired specifically by the social behavior of spiders. Using data from spider positions, social interactions, and the best historical solutions, it explores the found space. By encouraging spider cooperation and combining exploration and exploitation, the SSO can generate high-quality solutions for optimizing a particular objective function. Fig. 2 presents the general procedure of the SSO algorithm [29].



Define SSO parameters (population size, upper and lower percentages of breeding females)
Randomly initialize male and female members
t=1
Estimate the fitness function for each search agent
Calculate the weight of each spider
Move a spider and compute location and vibration intensities
Calculate attenuated intensities
Calculate more factor and characterise random walk
Update the position of the current search spiders
t=t+1
Not met
t=iteration max
Group final optimal settings and the best value of the fitness function

Fig. 2. Flow chart of the SSO process.

1) The proposed SSO-based solution methodology: The proposed methodology using the SSO algorithm for the optimal HRES system sizing is shown in Fig. 3. First, photovoltaic, wind, tidal, hydro, biomass, and battery requirements are defined, in addition to the load. Meteorological data from the installation site, including wind speed, solar radiation, ambient temperature, tidal speed, and water flow, are recorded.

The SSO process is performed for each possible solution, including N_{PV}, N_{WT}, N_{tid}, N_{hyd}, N_{b}, and N_{bat}. If LPSP converges to unity, this means that the load is not satisfied and that this solution is not reasonable, and these steps are then repeated on the next likely solution in the population. When the LPSP converges to zero, this indicates that the renewable energy sources (RES) realized are capable of satisfying the load. The steps continue until all solutions are satisfied, producing a reliable hybrid power system capable of satisfying the load throughout the systems lifetime.

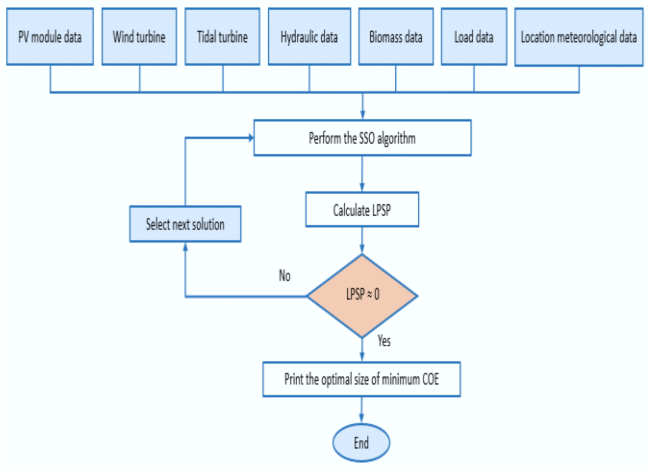


Fig. 3. Flowchart of the solution methodology with the SSO algorithm.

VI. Case Study

Our area of study is located on Djerba, a small island in southeastern Tunisia. Situated on the Gulf of Gabes, the island extends over a surface area of 514 km2. Its geographical coordinates stand at 33° 48′ N, 10° 51′ E. This site is therefore a convenient location for designing a hybrid energy system.

The metrological data for the system studied are presented in Table II with NASA application software, including the wind speed profile available at the chosen location, solar radiation profile, water flow rate, tidal speed, and the load profile for the entire month.

TABLE II. Monthly Energy Produced by HRES Components

Months	**Irradiation (kWh/m2/day)**	**Wind speed (m/s)**	**Tidal speed (m/s)**	**Water flow (l/min)**	**Load (kW)**
Jan	3.02	6.5	1	2.3	20.46
Feb	3.98	6.34	0.5	4.6	17.18
Mar	5.1	6.02	0.3	5	18.88

Dec	2.69	6.67	1.4	5	18.50

VII. Results

In this work, we have proposed the MOPSO algorithm for optimal sizing of PV, WT, hydro, hydro, biomass, and battery models. We compared the results obtained by this algorithm with those obtained by the SSO algorithm in order to validate the effectiveness of MOPSO in terms of reliability and cost reduction. We also studied the HRES system in four configurations:

- HRES 1: PV/WT/Tidal Turbine / Hydraulic/ Biomass/ Battery.
- HRES 2: PV/Tidal Turbine /Hydraulic /Biomass /Battery.
- HRES 3: PV/WT /Tidal Turbine /Hydraulic/Battery.
- HRES 4: WT /Tidal Turbine /Hydraulic/Battery.

Table III shows the parameters LCOE (levelized cost of energy), LPSP (loss of power supply probability), RF (renewable fraction), and N_{ad} for the two algorithms, MOPSO and SSO. The results indicate that the HRES 1 configuration offers the lowest energy cost, with an LCOE of 0.1$/kWh, while SSO gives an LCOE of 0.608$/kWh. The associated LPSP limit is 0.99%, and the RF is around 99%. The MOPSO algorithm achieves optimal results for all four configurations compared with the other optimization methods used.

Table IV also shows the component sizes for the four hybrid systems. It can be seen that the best configuration is HRES 1. The hybrid system sizing results obtained by the MOPSO and SSO algorithms offer distinct perspectives. The MOPSO algorithm demonstrated higher cost-effectiveness by increasing component size, while SSO adopted a more conservative approach.

The result obtained by MOPSO for the best configuration includes 181 photovoltaic panels, six wind turbines, one tidal turbine, eight hydraulic systems, three biomass systems, and 60 batteries. These results confirm the superiority of MOPSO for assessing the optimum size of hybrid power systems.

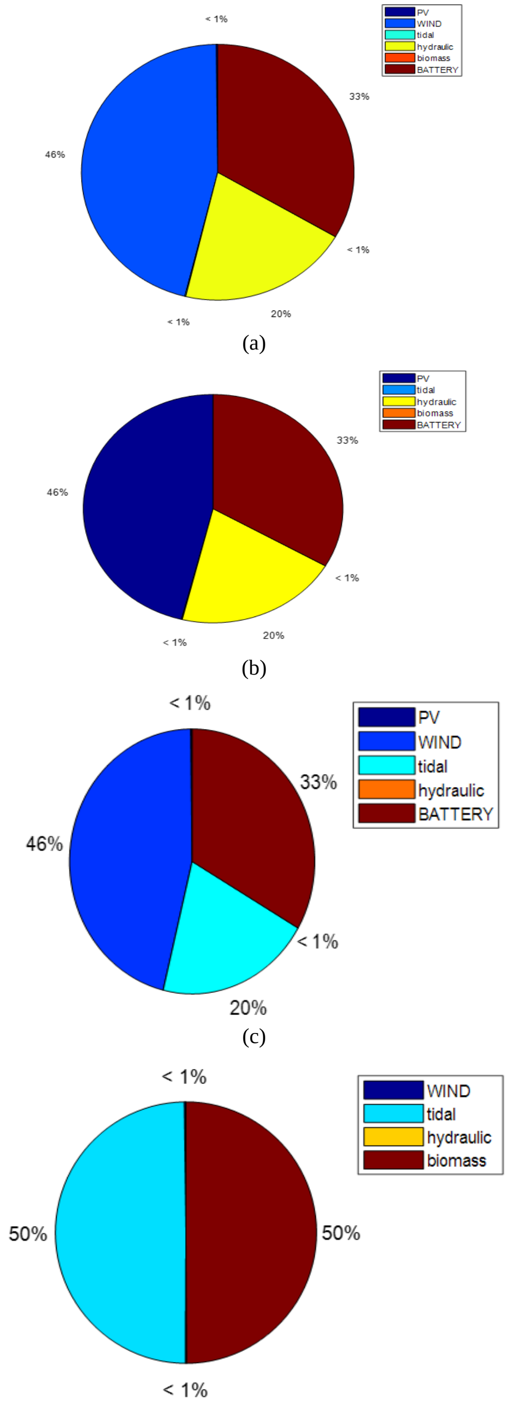
TABLE III. RESULTS BASED ON ECONOMIC AND TECHNICAL FACTORS IN ALL CONFIGURATIONS

Proposed HERS	Algorithm	COE ($/kWh)	LPSP (%)	RF (%)	N_{ad}
HRES 1	MOPSO	0.10	0.99	99.945	4
	SSO	0.608	0.489	0.015	22
HRES 2	MOPSO	0.55	0.183	0.426	5
	SSO	0.484	0.395	0.011	9
HRES 3	MOPSO	1.163	0.09	0.425	4
	SSO	0.496	0.391	0.014	17
HRES 4	MOPSO	0.562	0.18	0.305	1
	SSO	0.405	0.399	0.022	1

TABLE IV. OPTIMUM SIZING USING THE PROPOSED ALGORITHM FOR ALL CONFIGURATIONS

Proposed HERS	Algorithm	N_{PV}	N_{WT}		N_{tid}	N_{hyd}	N_b	N_{bat}
HRES 1	MOPSO	181	6		1	8	3	60
	SSO	7	1		2	3	2	42
HRES 2	MOPSO	50	--		1	3	2	50
	SSO	2	--		4	5	5	30
HRES 3	MOPSO	22	5		0	2	--	20
	SSO	5	4		3	4	--	44
HRES 4	MOPSO	--	11		1	4	3	12
	SSO	--	1		2	3	2	66

The percentage contribution of each energy source to annual load coverage, obtained by the proposed MOPSO for four hybrid system models, is shown in Fig. 4.



(a)

(b)

(c)

(d)

Fig. 4. Contribution of the HRES system based on the MOPSO algorithm: (a) HRES 1; (b) HRES 2 ; (c) HRES 3, (d) HRES 4.

Analysis of the MOPSO simulation results shows considerable variations in the contribution of energy sources. In some models, wind power dominated, accounting for up to 46% of overall production, while in others, photovoltaics also reached 46%. Batteries maintained a stable share of 33% in some models. Significant variations are observed, notably in a model where tidal power and biomass are the main sources, each accounting for 50% of production.

These results underline the importance of diversifying power sources to maintain the stability of energy systems.

VIII. Conclusion

This article presents a comparison between two optimization algorithms, MOPSO and SSO, to evaluate their respective performances. The main objective of this research was to determine the optimal size and the best economic configuration for a hybrid stand-alone power system (HRES) on the island of Djerba, Tunisia. The study focused on four different configurations, integrating renewable energy sources (RES) such as photovoltaics (PV), onshore wind (WT), tidal power, hydropower, and biomass, with battery storage systems.

Our results showed that the HRES 1 configuration was the most cost-effective, achieving a cost of energy (COE) of 0.1$/kWh. In addition, the optimal HRES configuration included 181 solar panels, six wind turbines, one tidal energy source, eight hydroelectric plants, three biomass plants, and 60 batteries.

The findings of this study are of crucial importance for decision-makers involved in the development of the renewable energy sector in the south-eastern region of Tunisia. The recommendations formulated can serve as a solid basis for strategic planning and policy development aimed at promoting the use of renewable energies and ensuring a sustainable energy transition in the region.

***Abstract*—User behaviour about an item is a choice predicated on their perception of the item in order to satisfy the intent of such a purchase pattern/choice as made. With virtual stores to improve consumer coverage, monetization and ease of product delivery, users' trust is lowered with the non-delivery of advertised products as items purchased are often replaced with new/similar products. To resolve the issues of lowered consumer trust and preference for products purchased via online shops – each transaction reflects a user buying behaviour. This, if harnessed – will aid businesses to reshape their inventory to handle various challenges arising from feature evolution, feature drift, product replacement, and concept evolution. Our study seeks to resolve these issues via a Bayesian network with trust, preference and intent as features of the virtual store to investigate their effectiveness in the design and usefulness to promote e-commerce in Nigeria. Data consists of 8,693 records collected via Google Play Scraper Library for Jumia as retrieved from over 586 respondents. Expert evaluation ranked the design choice in the use of the parameters as high.**

***Keywords*—Consumer preference; consumer trust; purchasing-pattern; purchase intentions; online virtual shops**

I. Introduction

Data is quantified (i.e. pre-processed to remove unwanted feats called noise), and analyzed to reveal patterns/trends) [1]. Data is anything we can manipulate [2], and safely exist in either of its (un)structured forms [3], [4]. With the great volume of data generated for a variety of purpose(s) [5] – processed data yields a transaction of mining tasks [6] that unveils hidden relations and underlying feats of interest in the dataset [7], [8]. Today, the Internet with its plethora of tools, transforms many businesses with platforms that brings together buyer and seller [3], [4], provisions a veritable, traceable payment mode, and allows for effective goods/services delivery [9], [10]. This integration is made imperative/critical, the use of web-contents in business operations and functioning [11], [12], and to provide control schemes that continually improve consumer experience, and ensure improved service quality and delivery [13], [14].

With the digital revolution, the global economy is become more info-based and dependent [15]. Businesses of various forms are springing forth; And Nigeria as the most populous black nation [16] – was in 2021, ranked the 38th largest e-commerce market with a revenue of US$7.6 Billion [17], ahead of Pakistan. Nigeria is expected to experience a global growth rate of over 12% from 2023–2025 [18], [19] with an Internet penetration that stands at 55.4 percent for the nation’s population with a total of 156million Internet users as of the January 2023 (Q1) [20], [21]. This survey by the Nigerian Bureau of Statistics holds for the use of e-commerce as consumers sell/purchase goods via electronic platform [22]. And in turn, has increased the sales volume of such e-commerce vendors to positively influence the growth of/in Small-Medium-Enterprise (SMEs). With e-commerce, SMEs can expand their distribution markets [23] via such a symbiotic relations and thus, increase monetization sales therein. Despite this plethora of positive effects, consumers still share doubts when transacting via online platforms. These can be attributed to fraudulent activities [24] from such online transaction(s) – as delivered items often differ from items ordered, identify theft, etc. [25]. Thus, issues of user trust in consumer preference and purchase intentions arise thus – in a vendor’s quest to meet the consumer purchase pattern and needs [26], [27].

Another issue with online (virtual) shopping is the adoption rate in the growth of e-commerce [28] – as there still persists the issue of doubts amongst consumer transactions. The effective use of online platforms is a direct impact from the consumer purchase intent and purpose, which must be met [29]. Thus, this study seeks to evaluate and determine features that can influence a consumer’s purchase intent and pattern by examining a known e-commerce (online) platform that is most frequently used by Nigerian consumers namely Jumia [30], [31].

II. Literature Review / Theoretical Framework

A. Literature Review: The Nigerian E-Commerce Market

Today, the nation Nigeria has a population of a little over 221,014,090 as of June 2023 based on the latest United Nations data from Worldometer. Nigeria has a Gross Domestic Product growth of US$506.6 Billion with an estimated growth of 2.41% [32], [33]. Her market is segmented thus: Beauty [34], Care [35], Consumer Electronics [36], Fashion [37], Drugs [38], Food and Beverages [38], Furniture/Homes (B2C and B2B) trends [39]. The market today, is driven and leverages on ICT-infrastructure, high internet penetration, and a growing number of card-based payment platforms – that hinges on the fact that her economy is fast embracing more cashless transactions with digital payment solutions adopted and adapted to suit the various needs of her citizens [40], [41]. With all her financial institutions adopting cashless, electronic transactions, there are a plethora of digital financial services platforms – to help consumer decisions and improve their purchasing pattern to satisfy their demands and needs therein [42], [43].

The Nigerian e-commerce market has contributed about 29 per cent globally – to e-commerce with a 30% increase in 2021, and penetration of digital payment solutions that encourage payment service providers onto the Nigerian e-commerce viable market [44]. The market is hampered in operation by the rise in phishing threats from fraudulent web acts [45], [46]. Excellent logistics can aid the effective creation of an e-market supply chain and management visibility, traceable goods/services delivery, and the overall consumer experience/satisfaction [47]. The restricted movement during the COVID-era lockdown [48], [49] witnessed many consumers shopping from home. This resulted in modified consumer behaviour, preference changes and a shift in the trust of product purchased and purchasing paradigm – and led to increased adoption in online (virtual) shops [50], [51].

B. Reviews on User Preference, Trust and Purchase Intents

A transaction often refers to the smallest, indivisible unit of data or information processing within a certain phenomenon or event [52]. Each transaction must either thus, succeed or fail as a complete unit. Transactions are basically processed using a transaction processing system (TPS) – which can also refer to a combination of hardware and software system that supports the processing of transactions. TPS also helps to sustain the smooth running of an organization or business by automating processes of managing large amounts of transactions handled on a daily basis [53]. This it does via accurately tracking of daily records, ensuring that transaction records, the require documents and its corresponding control procedures perform optimally [54], [55].

Transactional data are inherent in stream data, as grouping such data effectively yields a range of complications including: (a) the infinite length-size of data notes real-time data streams are continuous and transactions have no bounds, (b) concept drift is a common occurrence where a consumer shifts his/her decision to purchase a product, (c) concept evolution occurs if a new product acts as a close-substitute or replacement to a class of old products, and evolves the data stream, and (d) feature evolution is a recurrent process where various data-streams occur regularly during the text streams – wherever newer product features appear – with the corresponding increase in the data-streams [56]–[60].

Transactions are handled in real-time – making it tedious and difficult to manage. Items are purchased alone or as combination of itemset to form a basket. Virtual shops grants a consumer, the basket experience for which items are purchased directly in real-time via online platform [61], [62]. A consumer can also make a series of purchases – to yield an infinite number of changes in the buyer's preferences over time. This is referred to as concept drift in the consumer's purchasing pattern or behavior [63], [64].

C. Theories and Hypotheses for Consumer Purchase-Pattern

Resolving the issue(s) of preference, trust and intentions for purchasing pattern – we use association rules for transactions to generate the itemset(s); And thus, yield the purchasing pattern or behavior for a variety of customers. We adopt/adapt these theories using their corresponding (implied) relevance as thus:

- Theory of Reasoned Action emphasizes that behaviour very much depends on a consumer's attitude, choice and public perception. It posits that a consumer is influenced by their intentions, choices, and personal beliefs. These propagate as a shock to impact a consumer's decision; And align with [65]–[67] as in Fig. 1. Its relevance is that a consumer can buy items (online) with adequate confidence to use the tech due to its usage ease and hitch-free nature. This also impacts on intensity in use cum adoption of the system. When presented with expected results that are specific, a consumer can change his/her mind; And this impacts the action to be taken via such a decision, which yields an attitudinal and normative change in the user's trust and confidence in a product, and the overall experience with the product [68], [69]. Investigating if a consumer's action and attitude is tied to purchasing purpose/intention – seeks to ascertain if the consumer is rational when their choice is based on purpose, or if such action serves their best interest or their intentions and agrees with [70]–[72].
- Planned Behaviour Theory – states that attitude towards a behavior, subjective norms, and perceived control often shapes a consumer's behavioral intents and in turn, his/her actions. This theory improves the analytical capability of reasoned actions via the perceived control of behaviors. Since not all behavior is subject to a consumer's control – it is expedient we add perceived behavioral control which implies that irrespective of the action taken – a consumer's behavior is determined both by attitude, subjective norm, and perception/firm belief they are in control [73], [74].
- The Engel, Kollet, and Blackwell extend reasoned action by focusing on a consumer's mental state prior purchasing the product. It does so via planned set of behaviors as thus: (a) consumer absorbs item content via an advert, (b) s(he) processes the advertised content, and leans on experience to compare what-should-be versus what-is, and (c) s(he) then decides to either accept/reject the product purchase, a choice based on balanced insight via mental synthesis [75]. Manager must be equipped with appropriate data of the

product to drive consumers to keep buying, and will push sales up. Such information about the underlying feats can cause a purchase shift in behavior. If a consumer is not adequately informed, s(he) rejects (i.e does not buy) so as to balance their data with the online data available. Thus, external shocks (i.e friends and item review ratings, be it fake or not) may influence the consumer to decide to either accept/reject the product [76], [77].

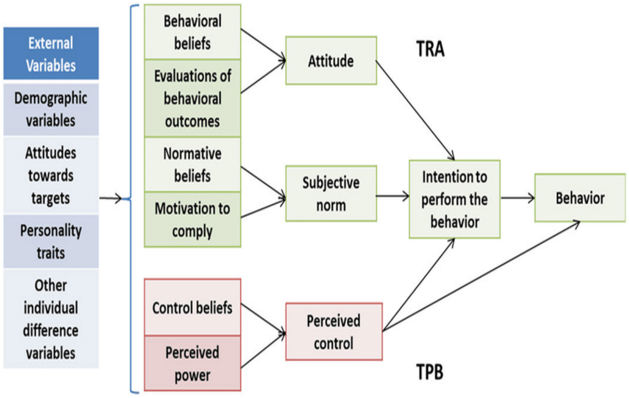

Fig. 1. The reasoned action theory (Source: [78], [79]).

D. Research Hypotheses

The hypothesis for the various features of interest include:

- Perceived Ease in Use is a degree in belief, confidence and trust a consumer places on the online platform vis-à-vis contents provided on the website. Thus, the consumer can easily navigate the platform with little or no challenge, to reflect the usage intensity and consumer interaction with the platform. And accounts for an overall satisfied consumer experience with access ease. It yields improved consumer-perceived usefulness and control [80]. Thus:

  H_1 = *Perceived use ease impacts on perceived usefulness.*

- Product Usefulness/Benefits is the degree/extent to which a platform improves a consumer's need to purchase as the more useful it is, the more transactions are performed, and the more benefits are harnessed. With faster transactions from their comfort [81] and usage easy – it yields user-satisfied and expected-content retrieval via the consumer-specific search [82] that improves overall experience to a user's benefit. This also impacts a user's purchase intents as the user also saves time with each transaction at lower cost, and greater access to a variety of product (types), and replacement products. The benefits experienced via online shops yield improved intentional buying and transactions, made by the consumer [83].

  H_2 = *Perceived usefulness impacts on benefit* → *and consumer benefits* → *impacts consumer intentions*

- Perceived Purchase Intentions – Product review are data points awarded to platforms by consumer in relation to a variety of items such as ease of use, product delivery, ability to find products with ease, etc. [84], [85]. These reviews are often poised to show a consumer's interaction with the online platform vis-à-vis a series of consumer satisfaction. These, help to improve confidence and trust, and also help to reduce a consumer's effort to learn navigation of the system. Their belief in the required ease to navigate the system is reflected in their intensity to use the system as well as their search for products whose results displays specific contents that are poised to satisfy the curiosity of the consumer. And thus, ensures the consumer's purchase intentions are met.

  H_3 = *Perceived ease impacts consumer purchase intention*

- Perceived Trust and Confidence – implies that the more a consumer interacts with an online platform, the more such a consumer concludes the great repute of such a store. This improves the perceived confidence and trust. Trust is quite critical in online purchasing patterns (since there is no face-to-face interaction). Trust guarantees that online stores will fulfill their obligation and care for the consumer(s). It is a vendor's responsibility to provide useful data, ensure consumer satisfaction for a complete transaction, and ensure the quality of products with safe delivery of products purchased. Thus, consumers attain usefulness from their trust in e-commerce platforms. And their confidence in the products delivered, in the vendor and online platforms, becomes imperative. Greater purchase intensity implies greater confidence and trust by the consumer in the online platform [86], [87].

- H_4 = *Consumer's confidence, trust and ease of use impact consumer's purchase intentions and pattern*

III. Methods and Materials

A. Data Collection and Gathering

Data were collected using Google Play Scraper Library for Python for the Jumia Online Shopping platform. A total of 8,693 records were collected in March 2023 – and retrieved from over 586 respondents. The scrapped records consist of personal data, user reviews, emails, posts, likes, shares, and replies – which is in agreement and as suggested by the study [88] in Table I.

TABLE I. DATASET DESCRIPTION, DATA TYPES, AND FORMAT

Features	Data_Type	Format
Order_ID	Long Int.	1234
Customer_ID	Short Int.	1234
Customer_Name	Object	ABCD
Payment_Number	Long Int.	1234
Payment_Amount	Float	123.45
Transaction Time	Time	M:H:S
Order_Date	Time	D:M:Y
Deliveray_Date	Int	1234

B. Proposed Bayesian Network

Bayesian net of conditional probabilities for random events, is a learning mode that represents data as probability relations of a variable-set under uncertainty as directed acyclic graph and conditional probability tables of a random variable [89], [90] – given occurrence of its parent nodes. In relation to the degree of belief – it measures plausibility of an event given incomplete data [91], [92]. It states that the probability of an event A and is conditional on another event B is given by P(A|B) – and differs from the probability of B conditional on A as P(B|A). Thus: (a) it is a relation between events P(A|B) and P(B|A), (b) it computes P(A|B) given data of P(B|A), and (c) its outcome uses new data to update the conditional probability of event. So when given a sample space *s*, with mutually exclusive events (A_1, A_2,…,A_n) – B can be any event from *s* with the probability P(B) > 0 [93], [94] and represented via the Eq. (1), which holds as:

$$P(\,A_k \mid B\,) = \frac{P(A_k)*P(\,B|A_k\,)}{P(A_1)*P(\,B|A_1\,)+..+P(A_n)*P(\,B|A_n\,)} \qquad (1)$$

Bayesian networks are trained to learn the underlying feats via probability distribution for each node. It uses two learning modes: (a) structured discovery, learns the network structure and its adopted parameters based on observed inputs using hill climbing/Tabu-Search; and (b) probability distribution learning is done with algorithms like Bayesian network [95]. The model uses relation analysis to emphasize consumer purchase-pattern. The issues of preference, trust and buyer intentions, arises from a vendor's quest to meet the consumer's purchase pattern and needs [96], [97]. These, in turn yields concept drift, and justifies our adoption of user behavior theories that directly explains their corresponding relevance to our various research problem. To derive meaningful data via these theories, we visualized the consumers' behavior using a Bayesian network as in Fig. 2 so as to help us resolve the issue of feature drift, concept drift and concept evolution. Thus, using the hypotheses, we design the Bayesian network as thus:

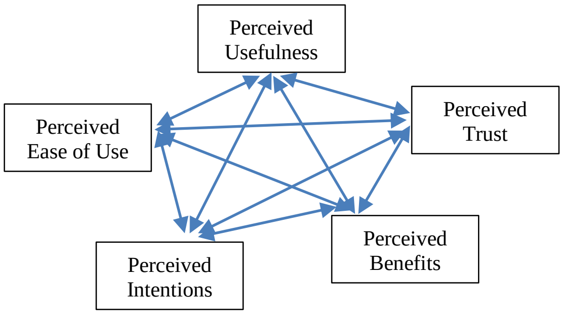

Fig. 2. Designing the model.

IV. RESULTS AND FINDINGS DISCUSSION

A. Performance Evaluation

System design in lieu of accountability, quality, and ethics for user-centric purchase-pattern to reflect various dimensions were re-purposed as [98] follows: (1) usefulness, (2) benefits, (3) purchase intents, (4) usage ease, (5) trust (as core features). With Eq. (1), we analyze the effectiveness E of the system as frequency of user's choice amongst its alternative(s) versus the total number of contents N. We further categorized into the following: (a) high is greater than 80%, (b) sufficient ranges between 71-80%, (c) moderate is between 55-60%, and (d) poor is below 55% [98], [99].

$$EP = [F/N] * 100 \qquad (2)$$

The ranges high and sufficient – implying design parameters were met and does not require revision. Moderate requires some form of revision and implies that the use of the parameters is not reflective in the proposed system; while the category poor implies a complete revision of the parameters of choice. Thus, evaluation for both experts and participants yield Table I and Table II respectively.

Table II shows high and sufficient categories ranging above 85% for all the evaluated variables by the various experts. The implication of which, is that these components do not require revisions of any kind.

TABLE II. EXPERTS' EVALUATION ON VARIABLES DESIGN

Parameters of Interest	1	2	3	4	5
Benefits	0.89	0.96	0.91	0.89	0.92
Usefulness	0.91	0.87	0.91	0.94	0.89
Usage Ease	0.75	0.89	0.79	0.89	0.91
Purchase Intentions/Purpose	0.92	0.92	0.86	0.85	0.90
User-Trust	0.91	0.90	0.93	0.98	0.89

Table III on participant evaluation shows the mean, standard deviation and dyadic interaction between the chosen variables, users and proposed system that leverages on the chosen feature of interest. Its mean values ranges implies that an effectiveness categorization interaction and use of the online platform ranges from over 90%. It also yields a dyadic interaction range that is above 95%.

TABLE III. PARTICIPANTS' EVALUATION OF DESIGN CHOICE

Parameters of Interest	σ	μ	+Di
Benefits	0.27	0.94	0.89
Usefulness	0.27	0.87	0.89
Usage Ease	0.23	0.82	0.73
Purchase Intentions/Purpose	0.33	0.90	0.95
User-Trust	0.28	0.81	0.78

B. Result Findings

Adapting the model capabilities in [100], [101] – we model the outer layer as a sine qua non-effect of the study's reliability and validation of the research variables (i.e. benefits, perceived ease of use, perceived usefulness, trust and perceived purchase intentions/purpose). We compute model fitness of all variables as a criterion size for the problem space, which is thus – a good reflective parameter/feature to aid quick convergence. If model converges on a validity value with a fitness of 0.7 and above – it implies that model has good correlation. These keys reflect each variable in Table I: B = benefits, PEU = perceived ease of use, PU = perceived usefulness, PI = perceived purchase intentions/purpose, and T = trust, as seen in Table IV.

TABLE IV. CONFIDENCE VALUES OF SIMULATED DATA (C_{tt})

	B	PEU	PU	T	PI
B	0.627	0.638	0.915	0.534	0.613
PEU	0706	0.773	0.909	0.664	0.787
PU	0745	0.625	0.736	0.931	0.639
T	0745	0.661	0.677	0.951	0.659
PI	0.628	0.642	0.944	0.629	0.758

In Table IV, shaded cells are the parameters of interest. Thus, our model converges with the fitness values and scores as above. Recall, that if the value converges at a fitness of 0.7 and above indicates that model has a good correlation. Thus, shows that cells PEU(PEU), PU(PU), T(T) and PI(PI) have correlates and convergences good. This implies that features PEU, PU, PI and T are of great significance to consumer overall satisfaction – in designing an online/virtual platform. Designers must ensure the system is useful (i.e. delivers on the consumer's request correct contents for the searched products), intentional (i.e. meets the purchase intention of the consumer), trustworthy (i.e. consumer can trust the sites from which contents were displayed), and ease of use (i.e. system must be flexible).

C. Discussion of Findings

From the Bayesian computation as in Table III – the model yields an overall probability distribution value that is greater than 1,860 with a significance level of 5%. It becomes quite clear and explicit that [102], [103]:

- Perceived usefulness (PU) is impacts significantly both on the perceived ease of use (PEU), purchase intention (PI) and trust, and this agrees with [104].
- Trust (T) also impacts significantly on perceived ease of use (PEU), purchase intention (PI) and perceived usefulness, and it agrees with [105].
- Purchase intention (PI) was found to impact significantly on perceived ease of use (PEU), perceived usefulness (PU) and trust (T), and this agrees with [106], [107].
- Perceived usefulness was found to impact significantly on perceived ease of use (PEU), purchase intention (PI) and trust (T) parameters [108], [109], respectively.

We posit that other parametric feat can be used to investigate similar relations to unveil other (un)reasoned actions in lieu of a consumer's purchasing-pattern. This study will help and act as pivot for business owners to effectively design virtual platform cum shops, and to adequately manage challenges of product placement, features cum concept drift [110], [111] in relation to consumer purchase and consumption pattern. They will bear in mind that certain parameters impact majorly in the design of their virtual shops namely ease of use, intention, usefulness of system and consumer trust of products acquired and delivered.

V. CONCLUSION

The study aimed to analyze the Jumia e-commerce in lieu of the consumer purchasing intentions, perceived usefulness of the Jumia platform, consumer trust for Jumia, its ease of use by consumers, and overall consumer benefits (and experience) for the Jumia online virtual shopping platform. The study was only limited to the use of the Jumia platform by consumers vis-à-vis the experts and participants as adopted for the study. However, study could not ascertain the relationship cum immediate impact between the consumer benefits and other features/parameters not described herewith or under-studied [112].

Research on the Path of Enhancing Employment and Entrepreneurship Ability of Deaf College Students Based on Knowledge Graph

Pengyu Liu*
Special Education College Changchun University, Changchun 130022, China

***Abstract*—Enhancing employment capabilities and selecting suitable career paths are crucial for deaf university students. The advancement of knowledge graph technology has opened up technical possibilities for career decision-making among these students. This paper calculates user preferences and introduces an exponential decay function integrated with a time factor to accurately reflect the dynamic changes in user interest preferences over time. Leveraging knowledge graphs for personalized recommendations, the study proposes recommending necessary skills to enhance employment and entrepreneurial capabilities among students. Additionally, it employs knowledge graphs to suggest more suitable career paths for deaf university students. Finally, through empirical validation, the paper demonstrates the effectiveness of the proposed hybrid clustering and interest-based collaborative filtering recommendation algorithm.**

***Keywords*—Knowledge graph; hearing impaired college students; employment and entrepreneurial ability; interest matching; feature extraction**

I. Introduction

Enhancing employability is crucial for hearing-impaired college students, who often face numerous challenges in the job market, such as difficulties in accessing information, limited communication abilities, and social prejudice. Improving their employability not only increases their competitiveness in the workplace but also promotes their social integration and self-fulfillment. This enhancement encompasses several aspects, including the acquisition of professional skills, the development of workplace soft skills, and the strengthening of adaptability and autonomous learning abilities. Achieving these improvements requires the collective effort of schools, governments, and various societal sectors through systematic education, training, and support measures to help hearing-impaired students better meet the demands of the job market [1]-[2].

Currently, the employment situation for hearing-impaired college students remains challenging. Despite the increase in employment opportunities due to the widespread availability of education and heightened social awareness, the overall employment rate is still relatively low. Many employers harbor misconceptions and biases about the abilities of hearing-impaired students, leading to discrimination and unfair treatment during the job search process [3]. Additionally, hearing-impaired students face significant limitations in career choices, as many high-skill, high-income professions remain inaccessible to them. Therefore, improving their employment situation requires a multi-faceted approach involving policy measures, corporate responsibility, and social support to foster a more inclusive and diverse employment environment [4].

A knowledge graph is a knowledge representation method based on graph structures, which expresses entities and their relationships through nodes and edges. The concept of the knowledge graph was introduced by Google in 2012, aiming to provide a semantically rich knowledge base through ontology standardization and information integration. Knowledge in knowledge graphs is represented and stored in the form of triples (e.g., <entity, relationship, entity> or <entity, attribute, attribute value>), enabling the structured management and querying of complex knowledge. Widely used in search engines, intelligent recommendations, and natural language processing, knowledge graphs offer users more accurate and relevant information services.

Knowledge graph technology holds significant potential to enhance the employment and entrepreneurship capabilities of hearing-impaired college students [5]-[6]. First, by constructing a knowledge graph related to these students, one can comprehensively understand their educational background, skill sets, and career interests, thus providing them with the most suitable career recommendations. For instance, a knowledge graph can integrate job requirement information from various industries and match it with the skills and interests of hearing-impaired students, offering personalized career advice.

Second, knowledge graph technology can be used to design personalized learning paths and skill training programs. Based on the career goals of hearing-impaired students, knowledge graphs can recommend relevant learning resources and courses, helping them systematically improve their professional skills and workplace soft skills. Additionally, knowledge graphs can track learning progress, provide real-time feedback and improvement suggestions, ensuring the effectiveness and relevance of the training.

Moreover, knowledge graph technology can support the entrepreneurial activities of hearing-impaired students. By analyzing market demands and industry trends, knowledge graphs can offer entrepreneurial guidance and resource support, helping students identify market opportunities and formulate scientific business plans. Knowledge graphs can also connect entrepreneurs with investors, mentors, and partners,

This work is supported by 2024 Jilin Provincial Department of Education Employment and Entrepreneurship and Student Management Special Project (number: JJKH20240769JY).

creating an ecosystem that supports the entrepreneurship of hearing-impaired students.

In summary, leveraging knowledge graph technology to recommend suitable career paths for hearing-impaired students and enhance their employment and entrepreneurship capabilities can significantly improve their integration into society and create more value for the community. Through scientific technological methods and systematic support measures, we can effectively improve the employment situation of hearing-impaired students, fostering their professional development and personal growth.

II. Literature Review

In this chapter, we introduce the development of knowledge spectrum and employability and summarize the research gaps by highlighting them.

A. Knowledge Graph

Numerous scholars abroad have made significant contributions to the development of knowledge graph technology. Hildrun Kretschmer, a renowned German scientometrician, has achieved notable results in the study of three-dimensional models of scientific collaboration, significantly advancing the field of knowledge graphs [7]-[8]. E.C. Noyons and colleagues at Leiden University in the Netherlands developed a set of mathematical methods for bibliometric mapping, further enhancing the development of knowledge graph technology.

Xiao et al. [9] provided a comprehensive review of knowledge graphs in manufacturing process planning. Analyzed the key technologies of process knowledge graph, including process knowledge representation, process knowledge extraction, process knowledge graph construction, process knowledge graph refinement, process knowledge graph validation, and process generation. Wang et al. [10] suggest using knowledge graphs for code or API recommendations, vulnerability mining, and localization to improve development and design efficiency and accuracy. Fettach et al. [11] use knowledge graphs to represent these data is useful for determining job market demand and establishing better evaluation methods.

The development of knowledge graph construction techniques has been rapid and increasingly sophisticated.

B. Employment and Entrepreneurship Level of Hearing-Impaired College Students

In the "Internet Plus" era, technology offers hearing-impaired college students opportunities to overcome barriers, allowing them to leverage information technology and choose home-based work through new media platforms [12]-[14]. This approach not only improves their employment prospects but also fosters innovation in employment models, aiding their adaptation to the workplace and societal environments. "Internet Plus" has revitalized the employment landscape in China, creating new opportunities. The employment models for hearing-impaired college students in the context of digitalization can be categorized into three types: direct employment, outsourced employment, and self-employment. However, these students face numerous challenges in employment and entrepreneurship due to limitations in educational attainment, knowledge reserves, and access to higher education, compounded by insufficient policy support and financial incentives for entrepreneurship.

Analyzing the opportunities and challenges for flexible employment of hearing-impaired college students through the Internet reveals that, on one hand, the development of the Internet has improved their employment quality and provided more job opportunities. On the other hand, the core human capital of hearing-impaired students in the market remains relatively low, necessitating continuous enhancement of their human capital. Scholars have proposed the concept of the "digital divide," indicating that hearing-impaired students cannot enjoy equal rights in acquiring and using relevant skills compared to other groups, leading to new issues of information inequality, which pose significant challenges to their employment [15].

Currently, the Internet facilitates employment by expanding the social networks of hearing-impaired students, thereby mitigating the spatial and temporal limitations caused by physical disabilities. Artificial intelligence (AI) technology, based on computer science, can significantly enhance the labor skills of hearing-impaired students, improving the quality of employment [16]-[17].

C. Research Gaps

In summary, the enhancement of employment and entrepreneurship capabilities for hearing-impaired college students involves addressing several critical issues:

1) Analyzing the Required Employment and Entrepreneurship Skills for Hearing-Impaired Students: It is essential to identify and understand the specific skills and competencies that hearing-impaired students need to succeed in the job market and entrepreneurial ventures. This involves assessing their educational backgrounds, existing skill sets, and the unique challenges they face.

2) Utilizing Knowledge Graphs to Recommend Relevant Skills: Knowledge graphs can play a pivotal role in guiding hearing-impaired students towards acquiring the necessary skills. By mapping out the relationships between various skills, job requirements, and educational resources, knowledge graphs can provide personalized recommendations for skill development, thereby enhancing their employability and entrepreneurial capabilities.

3) Leveraging Knowledge Graphs to Suggest Suitable Career and Entrepreneurship Paths: In addition to skill recommendations, knowledge graphs can be employed to suggest the most suitable career and entrepreneurial paths for hearing-impaired students. By integrating data on industry trends, job market demands, and individual preferences, knowledge graphs can help students identify and pursue opportunities that align with their strengths and interests.

The aforementioned points are crucial in improving the employment and entrepreneurship prospects of hearing-impaired college students. Given these challenges, this paper will further explore in subsequent sections how innovative technological approaches and methodologies can be utilized to help hearing-impaired students more effectively acquire the necessary skills and competencies. By addressing these issues, we aim to provide a comprehensive framework that supports their professional development and integration into the workforce.

III. Proposed Natural Language Processing Model

This chapter introduces our proposed methods for improving the employment and entrepreneurship level of hearing-impaired college students.

To analyze the employment and entrepreneurship capabilities of hearing-impaired students, we extracted data for the 2021 to 2023 cohorts from the academic administration system, including student registration records, academic transcripts, and course schedules. This data was then preprocessed using Python and office tools. Preprocessing was necessary for several reasons:

1) *Filtering irrelevant information:* The raw data contained numerous irrelevant entries that needed to be removed before importing into the Neo4j graph database.

2) *Data quality issues:* Many students had incomplete or poor-quality data due to multiple course failures, missed exams, or withdrawals. This data required cleaning and processing to be usable.

3) *Removing redundancy:* The integrated data had redundancies that needed to be eliminated to ensure consistency and accuracy without altering the original data.

We employed the Neo4j graph database for storing knowledge points. Unlike traditional relational databases, which store data in table fields, graph databases store data and the relationships between data on nodes and edges. In a graph database, these are known as "nodes" and "relationships." Each relationship consists of a start node, an end node, and an edge pointing from the start to the end node. All nodes in the database are interconnected by various relationships. Graph databases also support traditional database functionalities such as adding, deleting, modifying, and searching data.

We structured the student-related information knowledge graph into three main components: student information nodes, employment and entrepreneurship capability nodes, and course information nodes.

1) *Student information nodes:* The attributes of the "Student Information" node are defined as shown in Table I. The node is named 'S' with the label 'student.

2) *Employment and entrepreneurship information node:* The "employment and entrepreneurship information" node contains seven attributes. Table II shows the attribute name and description of the employment and entrepreneurship information node. The node name is T, the label is ability, and the node contains seven attributes.

3) *Course information node:* This paper contains seven attributes of the "Course Information" node. Table III shows the attribute name and description of the "Course information" node. This node is created after the relationship between the course line and student information is stripped.

TABLE I. Attribute Name and Attribute Description of the Student Information Node.

Attribute Name	Attribute Specification
Num	student number
Name	name
Sex	gender

TABLE II. Attributes of the Employment and Entrepreneurship Information Node

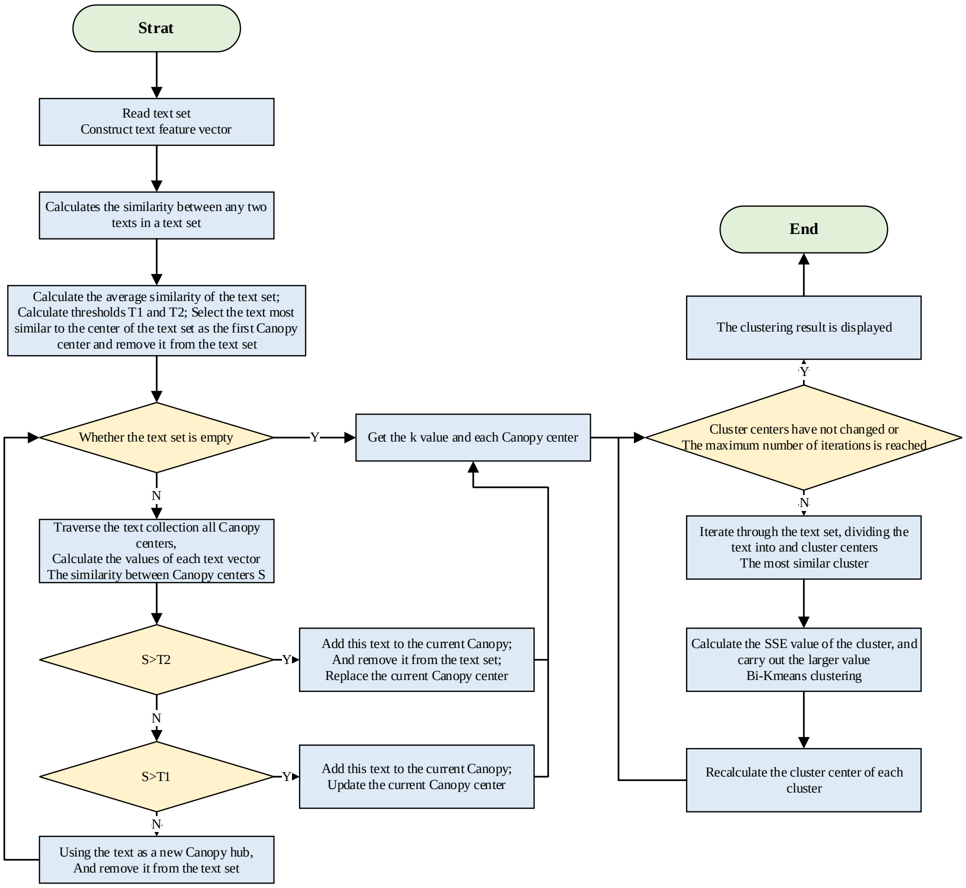
Attribute Name	Attribute Specification
prof	profession
Nature	Nature of company
city	city

TABLE III. Attribute Description of the Course Information Node

Attribute Name	Attribute Specification
kclb	Course category
kcbh	Course number
kcmc	Course title
xf	Credit hour
dkjs	Substitute teacher
ksxz	Nature of examination
ksfs	Examination method

By organizing the data in this manner, we aim to build a comprehensive and interconnected knowledge graph that facilitates a deeper understanding of the capabilities and needs of hearing-impaired students. This graph can then be used to develop personalized recommendations for skill development and career paths, ultimately enhancing their employment and entrepreneurship opportunities. Further sections of this paper will delve into the specifics of constructing this knowledge graph and the methodologies employed to leverage it for improving the career prospects of hearing-impaired students.

Building on the construction of the student information knowledge graph, we utilized student data to perform hybrid clustering on student users. Following this, we calculated the similarity between each student cluster's characteristics and the attributes defined for various employment and entrepreneurship directions. To enhance the clustering effectiveness, we employed a Canopy+Bi-Kmeans hybrid clustering model. This combination offers several advantages: it strengthens the robustness of individual clustering against noise and accelerates the similarity computation process. The flowchart of the Canopy+Bi-Kmeans algorithm is shown in Fig. 1.



Strat
Read text set
Construct text feature vector
Calculates the similarity between any two texts in a text set
Calculate the average similarity of the text set; Calculate thresholds T1 and T2; Select the text most similar to the center of the text set as the first Canopy center and remove it from the text set
Whether the text set is empty
Y
N
Get the k value and each Canopy center
Traverse the text collection all Canopy centers,
Calculate the values of each text vector
The similarity between Canopy centers S
S>T2
Y
Add this text to the current Canopy;
And remove it from the text set;
Replace the current Canopy center
N
S>T1
Y
Add this text to the current Canopy;
Update the current Canopy center
N
Using the text as a new Canopy hub,
And remove it from the text set

Y
Cluster centers have not changed or
The maximum number of iterations is reached
N
Iterate through the text set, dividing the text into and cluster centers
The most similar cluster
Calculate the SSE value of the cluster, and carry out the larger value
Bi-Kmeans clustering
Recalculate the cluster center of each cluster

Fig. 1. Flowchart of Canopy+Bi-Kmeans algorithm.

Expanding on the Canopy+Bi-Kmeans hybrid clustering model, the Canopy method serves as an initial, coarse-grained clustering step, which identifies the approximate clusters or "canopies" where points are grouped based on a loose distance threshold. This step reduces the search space for the subsequent, more precise clustering method, Bi-Kmeans. The Bi-Kmeans algorithm then refines these clusters by iteratively minimizing the within-cluster variance, resulting in more accurate and well-defined clusters.

The integration of these two methods leverages the strengths of each: Canopy's efficiency in handling large datasets and reducing computational complexity, and Bi-Kmeans' precision in fine-tuning the cluster boundaries. This hybrid approach not only improves the clustering quality but also significantly enhances computational efficiency, making it suitable for large-scale educational datasets.

By combining these methods, the Canopy+Bi-Kmeans hybrid model efficiently narrows down the data points into manageable clusters, which are then accurately refined. This approach is particularly beneficial in educational data mining, where large and diverse datasets are common.

Fig. 1 illustrates the flowchart of the Canopy+Bi-Kmeans algorithm, detailing the steps involved in the hybrid clustering process. Through this method, we aim to provide a robust framework for identifying and analyzing student clusters, thereby facilitating personalized recommendations for enhancing their employment and entrepreneurship skills.

Hearing-impaired college students can rate projects based on their personal interests. Tags play a crucial role in helping these students understand the content and attributes of the projects more deeply. By analyzing the number of tags, we can infer user preferences. However, this often leads to an overemphasis on current trendy tags, resulting in less accurate recommendations when users opt for less popular tags [18]. Consequently, this approach fails to fully capture and reflect users' interests and preferences.

To address this issue, we employ the Term Frequency-Inverse Document Frequency (TF-IDF) method to calculate user preferences. TF-IDF is a statistical measure used to evaluate the importance of a keyword within its dataset (as shown in Eq. (1)) [19]. This method helps balance the weight of popular and less popular tags, providing a more accurate reflection of user preferences.

By implementing the TF-IDF approach, we aim to improve the recommendation system's accuracy, ensuring that the preferences of hearing-impaired college students are adequately represented and that they receive more personalized and relevant project suggestions. This adjustment allows for a better alignment of user interests with the recommended content, enhancing the overall user experience.

The P_{ua} value is directly proportional to the degree of preference. Here, P_{ua} represents the preference value of user u for the project tag a. n denotes the total number of projects, and s denotes the total number of project tags. $\sum_{i=1}^{n} r_{ui}^{'} * f_{ia}$ indicates the number of times user u has tagged with tag a; $\sum_{i=1}^{n} \sum_{a=1}^{s} r_{ui}^{'} * f_{ia}$ represents the total number of times user u has tagged all projects; num_m represents the total number of users, num_{ua} represents the number of users who have tagged with tag a, $\sum_{i=1}^{n} \sum_{a=1}^{s} f_{ia}$ denotes the total number of tags, and $\sum_{i=1}^{n} f_{ia}$ denotes the total number of tag a.

Eq. (1) demonstrates that if a user's selected tag is infrequently chosen and comprises a smaller proportion of the entire tag set, it more accurately reflects the user's preferences, thus enhancing recommendation efficiency. For instance, when recommending employment directions in cloud computing and big data, we primarily analyze the courses closely related to this field and the student's grades in these courses. If a student’s performance in courses related to cloud computing and big data is significantly higher than in other courses, the likelihood of recommending cloud computing and big data as an employment or entrepreneurship direction increases.

$$P_{ua} = \frac{\sum_{i=1}^{n} r'_{ui} * f_{ia}}{\sum_{i=1}^{n} \sum_{a=1}^{s} r'_{ui} * f_{ia}} * \lg(\frac{num_m}{num_{ua}} * \frac{\sum_{i=1}^{n} \sum_{a=1}^{s} f_{ia}}{\sum_{i=1}^{n} f_{ia}}) \tag{1}$$

During the recommendation process for employment and entrepreneurship directions, if the student's interest includes "Network and Information Security," the recommendation degree for this direction will be elevated.

Traditional recommendation algorithms often use static tag identifiers for user preferences, typically represented by 0 and 1. This approach implies that the recommendation impact of these tags remains constant at all times, which is not effective for recommendations requiring temporal sensitivity. If user interest preferences are not considered dynamic over time, recommendations may not align with actual user preferences [20]. In reality, user interests are often dynamic and change over time [21]. To address this issue, at least two surveys should be conducted before making employment and entrepreneurship recommendations to capture changes in student interests. Recent user behavior is more relevant to recommendations than earlier behavior, so higher weight is assigned to recent tags to ensure timeliness and improve recommendation efficiency.

We introduce Eq. (2), which utilizes an exponential decay function incorporating a time factor to accurately reflect changes in user interest preferences over time. This approach ensures that recommendations remain relevant and aligned with the user’s current interests.

$$T_{ui} = \exp(-\frac{lbT_s * |\frac{t_{now} - t_{ui}}{T_s}|}{T_{att}}) \tag{2}$$

Among them, $T_{ui} \in (0,1)$ represents the time weight of user u for project i. T_s denotes the time window parameter, which signifies the duration of user preference interest. t_{now} is the time of the most recent survey collection on student interests, and t_{ui} is the time of the previous survey. T_{att} is the time decay parameter, representing the rate of interest preference decay. $\frac{t_{now} - t_{ui}}{T_s}$ is rounded up in the calculation, and $T_s * |\frac{t_{now} - t_{ui}}{T_s}|$ indicates the time segment in which the user's project evaluation occurred. If a user's interest remains unchanged over a year, with months as the statistical unit, then T_s =12. If recommendations are made within the same academic year after the user evaluates the project, i.e., $t_{now} - t_{ui} \leq 12$, the user's interest begins to decay after 12 months, with a decay period of 12 months, and the decay coefficient remains the same within the decay cycle.

When using the TF-IDF method to calculate user interest preferences, we integrate a time-weighted decay function (Eq. (3)) to derive user interest preferences and update the values in the user tag matrix accordingly. Finally, the normalized Euclidean distance gives the Eq. (4).

$$P_{ua} = \frac{\sum_{i=1}^{n} r'_{ui} * f_{ia} * T_{ui}}{\sum_{i=1}^{n} \sum_{a=1}^{s} r'_{ui} * f_{ia}} * \lg(\frac{num_m}{num_{ua}} * \frac{\sum_{i=1}^{n} \sum_{a=1}^{s} f_{ia}}{\sum_{i=1}^{n} f_{ia}}) \tag{3}$$

$$sim_1(u,v) = \frac{1}{1 + \sqrt{\sum_{i=1}^{n} (u_i - v_i)^2}} \tag{4}$$

Generally, when calculating similarity, personal attributes of users, such as gender, are not typically considered. Therefore, we have incorporated user attributes and integrated these fundamental user attributes into the similarity calculation.

The similarity of gender attributes is represented by Eq. (5).

$$sim_2(u,v) = \begin{cases} 0, X_u \neq X_v \\ 1, X_u = X_v \end{cases} \tag{5}$$

In Eq. (6), u and v represent different users, X_u and X_v denote the genders of users u and v respectively. By integrating user interest preferences and attributes, we derive a comprehensive similarity score, forming a novel similarity calculation model. Here, $\lambda \in [0,1]$ serves as a weighting coefficient. The value of $sim(u,v)$ is inversely proportional to the similarity between the two users.

$$sim(u,v) = \lambda sim_1(u,v) + (1-\lambda) sim_2(u,v) \tag{6}$$

Subsequently, predicting user ratings for items and making recommendations are expressed as shown in Eq. (7). Here, $\overline{r_u}$ represents the average rating given by user u for evaluated items, $\overline{r_v}$ denotes the average rating given by neighboring user v for evaluated items, N_u signifies the nearest neighbors of target user u, v denotes users in the neighbor set who have rated the item i, r_{vi} denotes the rating given by user v for item i, and $sim(u,v)$ represents the similarity between users u and v.

$$P_{ui} = \overline{r_u} + \frac{\sum_{v \in N_u} sim(u,v) * (r_{vi} - \overline{r_v})}{\sum_{v \in N_u} |sim(u,v)|} \tag{7}$$

IV. Experiment and Verification

In this section, we will verify the validity of the proposed method based on the experimental data set we collected.

A. *Experimental Environment*

The student employment and entrepreneurship direction recommendation system based on knowledge graph is implemented on B/S architecture. The specific system development environment is depicted in Table IV. We analyze collected data on course grades and corresponding behavioral data of hearing-impaired university students to construct a knowledge graph and generate student profiles. The system then provides recommendations for employment and entrepreneurship directions based on relevance, ranking the top three directions for recommendation. Additionally, the system recommends courses related to the user's interests in employment and entrepreneurship directions to enhance relevant skills.

Fig. 2 illustrates the verification process of the knowledge graph-based employment and entrepreneurship direction recommendation system. Initially, data integration from relevant business systems associated with student users and data obtained from the internet is stored in a data warehouse using ETL (Extract-Transform-Load) tools. Subsequently, data preprocessing and feature engineering are conducted to build persistent structures of personal user profiles for hearing-impaired university students. Finally, leveraging the knowledge graph, employment and entrepreneurship direction recommendations are applied based on student user profiles.

Fig. 2. NLL-test loss.

B. *Evaluation Parameter*

After several rounds of training, the scoring error is reduced and the optimal parameter recommendation model is obtained. The measure we use is the mean absolute error (MAE), shown by Eq. (8).

$$MAE = \frac{\sum_{u,v \in Test} |P_{ui} - r_{ui}|}{\sum_{u \in Test} |Test|} \tag{8}$$

Where r_{ui} denotes the true rating of user u for item i, and P_{ui} represents the predicted rating of user u for item i, the Mean Absolute Error (MAE) is calculated as the average absolute difference between P_{ui} and r_{ui} across the test set. A lower MAE score indicates better model performance and is evaluated using the formula:

C. *Test and Evaluation*

As shown in Table V, we determined the values of T_s, T_{att}, and λ through ablation experiments. The gray shading indicates the highest scores achieved. From the ablation experiments, it is evident that when $T_s = 5$，$T_{att} = 60$，$and\, \lambda = 0.4$, we achieve optimal performance.

Furthermore, as shown in Table VI, after setting the aforementioned parameters, we conducted ablation experiments to compare the impact of the k value in the algorithm and benchmarked it against other state-of-the-art (SOTA) algorithms. A smaller MAE value indicates better recommendation performance. It is evident from the results that our proposed algorithm achieves the highest accuracy compared to the other three algorithms tested. For instance, when the number of nearest neighbors is set to 25, the MAE reaches its minimum value across all tested algorithms. Our algorithm improves the performance by 5.25% compared to the second-ranked algorithm. The experiments demonstrate that our proposed method achieves lower scores, confirming its effectiveness.

TABLE V. ABLATION EXPERIMENT

T_s	T_{att}	λ	MAE
5	20	0.4	0.818
5	20	0.6	0.721
5	20	0.3	0.713
5	40	0.4	0.688
5	60	0.4	0.501
5	60	0.6	0.593
5	80	0.4	0.598
3	20	0.4	0.578
3	40	0.4	0.634
3	60	0.4	0.612
8	20	0.4	0.604
8	40	0.4	0.691
8	60	0.4	0.711

TABLE VI. MAE ABLATION EXPERIMENTS WITH DIFFERENT K VALUES

	5	**15**	**25**	**35**	**45**
UBCF	0.801	0.785	0.679	0.768	0.755
K means UBCF	0.734	0.699	0.645	0.759	0.765
Canopy+K means UBCF	0.736	0.731	0.622	0.659	0.713
OURS	0.631	0.612	0.591	0.601	0.622

To validate the reliability of our approach, as shown in Table VII, we collected feedback from recent deaf university graduates regarding their satisfaction with our recommendation method and their employment status. After implementing our method, they experienced a significant increase in employment rates and reported higher satisfaction with their job placements. This evidence supports the effectiveness and reliability of our approach.

TABLE VII. ALGORITHM EFFECT

	Employment satisfaction	**Employment rate**
Without our method	0.54	0.65
OURS	0.98	0.97

V. CONCLUSION

We integrated the course grades, interests, and employment and entrepreneurial directions of existing deaf university students. Utilizing knowledge graphs, we proposed a hybrid clustering and interest-based collaborative filtering recommendation algorithm. This approach establishes logical relationships between the interests, personal information, key courses, and career directions of deaf university students, thereby offering reliable and professional recommendations for employment and entrepreneurship, as well as related course information.

Furthermore, we conducted experimental comparisons to validate the effectiveness of our method and obtained approval from deaf university students. While our method demonstrated outstanding performance on the datasets we collected, showcasing excellent capabilities and results, its broader application requires more comprehensive validation. To ensure the accurate and sustained improvement of employment and entrepreneurial capabilities among deaf university students, we advocate for further empirical research on feasibility, effectiveness, security, and other aspects. This endeavor will help confirm the practical potential of our approach and guide its future dissemination and application in the educational domain.

***Abstract*—Numerous governmental entities, including hospitals and the Bureau of Statistics, as well as other functional units, have shown great interest in personalized privacy. Numerous models and techniques for data posting have been put forward, the majority of which concentrated on a single sensitive property. A few scholarly articles highlighted the need to protect the privacy of data which includes many sensitive qualities. Utilizing current techniques like the sanctity of privacy in data gets decreased if many sensitive values are published while maintaining k-anonymity and l-diversity simultaneously. Furthermore, customization hasn't been investigated in this context. We describe a publishing strategy in this research that handles customization when publishing material that has many sensitive features for analysis. The model makes use of a slicing strategy that is reinforced by fuzzy approaches for numerical sensitive characteristics based on variety, generalization of categorical sensitive attributes, and probabilistic anonymization of quasi-identifiers using differential privacy. We limit the confidence that an adversary may draw about a sensitive value in a publicly available data collection to the level of understanding as an inference drawn from known information. Both artificial datasets based on real-life healthcare data were used in the trials. The outcomes guarantee that the data value is maintained while securing individual's privacy**.

Keywords—Big data; privacy preservation; security; data publish; data privacy

I. Introduction

One of the largest technological breakthroughs in the near time, cloud computing, has developed quickly. These days, the market for cloud computing is well-established, leading many big businesses to construct effective cloud infrastructures. Cloud computing and data analytics go hand in hand, and the degree of data analytics available on cloud platforms is growing day by day.

Innovative advances in e-commerce, healthcare, and other fields are made possible by new approaches and platforms for big data analytics, which also open up a plethora of beneficial opportunities for companies [31]. But as fresh concerns about privacy are on the raise, the act of gathering and organizing data presents noteworthy privacy hazards, making information "security" and "privacy" a matter of concern. A trustworthy privacy model must be in place while processing to guard against external assaults and stop data leaks. Preventing potential security issues is necessary even during the storage phase. Several strategies are in practice to protect big data privacy. The primary methods in use may be categorized into three [1]: noise-based methods, data encryption, and anonymization techniques [12]-[14]. The first two aid in concealing the private details, but they can't guarantee privacy due to the prevalence of re-identification procedures [2]. Nonetheless, carrying out data analytics statistically employing noise-based methods is more beneficial and successful [3].

We have examined and used the noise-based privacy algorithm known as "Differential Privacy" on the Hadoop data analytics platform in this work. It claims to address the drawbacks of privacy solutions based on anonymization and encryption [17]-[19]. We refer to this privacy platform as "Data Sensitivity Preservation-Securing Value using Varied Differential Privacy Method (SP-SV Method)". It provides a solution in situations when the hazards related to privacy and the expenses for providing the required privacy of data are rising. A mathematical concept known as "differential privacy" describes the loss of one's privacy and measures the extent to which a particular privacy strategy, such as random noise insertion, would be effective in sustaining the privacy of specific information inside a dataset [4].

The noise or disturbance which has to be introduced to the attributes to gain the appropriate level of privacy depends on the security settings based on sensitivity of attributes. The degree to which the dataset's privacy-preserved outputs may be discriminated statistically is measured by the privacy-based approach [5]. As Hadoop can handle large-scale computing challenges, it is utilized for models of parallel data processing [6]. Still, there are shortcomings with this platform's privacy-related features. Actually, the privacy of a dataset is based upon if it is encrypted or anonymized [30]. The platform's privacy and security haven't changed in a while and many of Hadoop's sections have been developed independently [7] making privacy preservation more challenging.

The privacy preservation methods mostly concentrate on providing security and privacy to the data [22]. The data usability section is mostly slipping off the focus. The new "SP-SV Method" ensures the security of sensitive personal data in a dataset for data analysis through the implementation of a varied Differential Privacy algorithm in the Hadoop Map Reduce platform focusing on data usability. This ensures privacy with data usability for analytics. The SP-SV Method is an adaptable method since it doesn't need any extra knowledge to compute on the datasets providing secure and useful data.

II. Literature Survey

Cynthia Dwork et al., [15] laid out the mathematical foundations of differential privacy, which is a mathematical approach to safeguard individual privacy in big data analysis. It involves adding noise to data to protect individual information from being exposed. Using differential privacy concept, data can be allowed for analysis yet protecting the privacy of data.

Cynthia Dwork et al. [16], the paper discusses practical considerations and challenges in implementing differential privacy in real-world scenarios. It provides insights into deploying differential privacy techniques effectively.

HybrEx [20] is specifically a paradigm for cloud computing anonymity, security, and confidentiality that is intended for hybrid clouds. HybrEx has separated its data into sensitive and non-sensitive categories. Sensitive data is stored in a private cloud, while non-sensitive data is sent to public clouds. One of HybridEx's shortcomings is that it cannot manage generated values in Map stages in clouds that are private or public.

Machanavajjhala et al. [23], used Differential privacy nonetheless, to produce artificial datasets for statistical examination of patterns of commute in mapping applications. Handling datasets with broad domains was a problem because, despite the sparseness of the data, noise permeated the whole domain. The domain size was reduced by the use of exogenous data and procedures; nonetheless, the distribution of travel lengths was only appropriate for research involving very short journeys.

R. Agrawal et al. [24], reasoned that it is hard to estimate user privacy correctly when randomization is used since it disrupts the personal data of the user. They made an effort to respond to the query, "Is it still possible to construct sufficiently accurate predictive models with a large number of users who do this perturbation?"

S. R. Ganta et al. [25], subsequent research has shown that such criteria fall short of protecting an individual's privacy. The objective of the secure multi-party computing technique is to create a data mining model spanning many databases without disclosing the specific entries in each database.

Building a centralized warehouse may not be possible because of privacy concerns;

M. Kantarcioglu et al. [26], addressed issues with calculating association rules in such a setting. They assumed that all sites with homogenous databases had the same schema. On the other hand, every website has data on various entities. They intended to create universally applicable association guidelines while also restricting the amount of information that could be disclosed about individual sites.

Two general techniques for privacy-preserving data mining have been proposed: safe multi-party computing and randomization. While safe multi-party computing seeks to develop a method for mining data across many databases without disclosing specific information, randomization concentrates on protecting individual privacy. A platform for expanding data analysis called Privacy Integrated Queries (PINQ).

F. D. McSherry [27], performed calculations on private information while providing total privacy guarantees for each and every record in the underlying data sets. To prevent noise from affecting the computation's intermediate findings, PINQ employs a request/reply paradigm and stores the results on a reliable data server that is supplied by a system that is distributed.

I. Roy et al. [28], Airavat algorithm enforces restrictions on access and applies differential privacy to safeguard data. As far as safe computing and information privacy in MapReduce systems are concerned, this is the first technology that offers almost a required solution. To prevent unauthorized mappers from leaking information outside the group as well as granting mappers access to its contents and network, Airavat employs a required control scheme.
